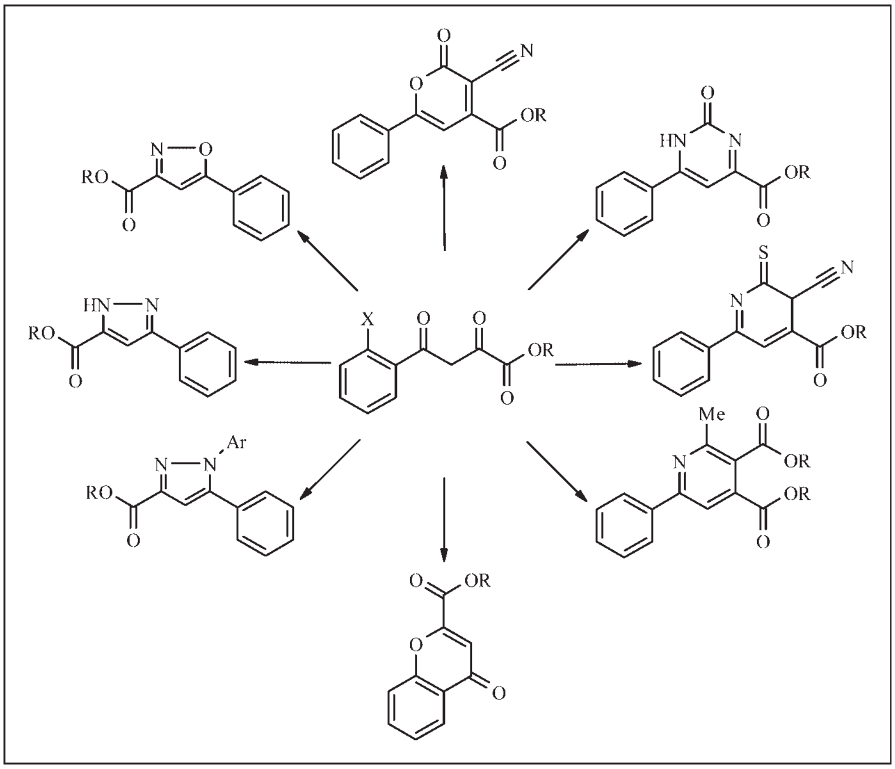
DOI 10.1002/jhet.15



The present review covers the utility of benzoylpyruvates as a vehicle for the preparation of highly functionalized heterocycles. Regio- and chemoselective features are discussed with reference to the application of different nucleophilic species. In this context, the preparation of such rings as pyrazoles, isoxazoles, primidines, and pyridines are presented. As the means to establish a distinct functional pattern, the rendered strategy can be seen as an alternative to cross-coupling protocols.

J. Heterocyclic Chem., **46**, 1 (2009).

INTRODUCTION

4-Aryl-2,4-dioxobutyrates are formally derivatives of pyruvic acid and are as such trivially referred to as benzoylpyruvates. Being endowed with multiple functionalities, they are important synthetic precursors, capable of interacting with both electrophilic as well as nucleophilic reagents. In particular, in the latter case they offer a versatile scaffold on which to mould annulated rings carrying distinct structural features. This versatility draws its impetus from the conspicuous qualitative differences between the three carbonyl functionalities, which makes regio- and chemoselective discrimination possible. Through a judicious matching of the applied nucleophilic species, the mode of annulation may be predicted, rendering a powerful tool for the construction of a variety of heterocyclic compounds. For example, the approach has found its use in the preparation of pyrazoles, isoxazoles, pyrimidines, and pyridines carrying a γ-aryl ester motif.

From a pharmaceutical point of view, the spatial arrangement of substituents conferred on heterocycles *via* benzoylpyruvate chemistry is highly interesting, since it can give rise to pronounced biological activity. Within the compound classes covered by pyrazoles, isoxazoles, pyrimidines, and pyridines, such diverse effects are observed as GPCR antagonism [1–4], ion-channel modulation [5] and kinase inhibition [6,7].

GENERAL CONSIDERATIONS

The ambivalent electrophilic nature of benzoylpyruvates resides on the presence of three interrelated

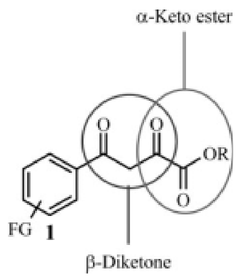


Figure 1. Dual nature of benzoylpyruvates.

carbonyl entities, capable of modulating and accentuating the individual electronic character through inductive and tautomeric effects. Embedded within the framework of the benzoylpyruvates are both the structural features of α-keto esters and β-diketones (Fig. 1). As a consequence, the chemistry of benzoylpyruvates may be expected to resonate this dual relationship.

In the case of α-keto esters **2**, the adjacent carboxyl moiety imparts the ketone with an enhanced electrophilic character due to its inductive withdrawal. However, this may be moderated by the presence of active protons due to keto/enol tautomerisation between **2** and **3** (Scheme 1).

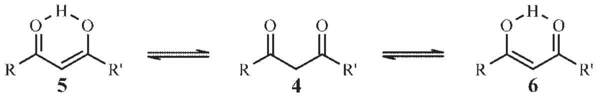
In the case of β-diketones **4**, sharing an active methylene group enables both carbonyl functionalities to undergo keto/enol tautomery between **4**, **5**, and **6**, effectively forming a Michael acceptor. To what extent the incipient groups are electronically distinguishable, *i.e.* the regiochemical preference leading to either **5** or **6**, depends on the peripheral substitution pattern (Scheme 2).

Combining the two features of the disseminated structure, yields a supposition on the reactivity of benzoylpyruvates, where the cooperative effect renders the position adjacent to the ester most susceptible to attack by nucleophiles (Scheme 3). Thus, in terms of regioselectivity, the outcome seems predictable.

If the applied nucleophile contains multiple activity, *i.e.* an ambident nucleophile like **10**, benzoylpyruvates can form rings *via* a formal cyclodehydration process. However, the annulation might either involve reaction on the ketone or on the ester, leading to **11** or **12**, thereby posing a chemoselective issue (Scheme 4). What is immediately evident is that the two reactive modes will result in different ring sizes and hence making allowance for kinetic versus thermodynamic control. In particular, the added stability originating from resonance energy, aromatization favors the formation of a γ-aryl ester motif **11**. Thus, the linker that joins the nucleophilic ‘‘warheads’’ and indeed the nature of the ‘‘warheads’’ themselves decide the direction of annulation.

Scheme 1. Keto/enol tautomery in α-keto esters.

Scheme 2. Keto/enol tautomery in β-diketones.



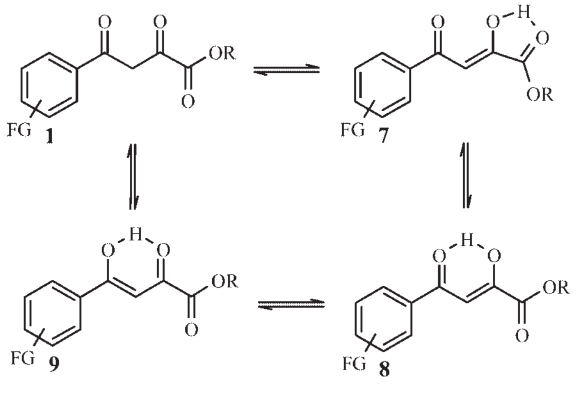
Because of the structural features exhibited by benzoylpyruvates, expectedly both acid and base catalysis may advance the cyclodehydration.

The benzoylpyruvates themselves are readily prepared by reacting enol ates of the corresponding acetophenone with a suitable oxalic diester [8–10]. In this respect, lithium enol ates offer a particular advantage by allowing the desired product to be isolated as a solid, shelf-stabile, 1:1 lithium complex. Generally, the protocol can be used to furnish benzoylpyruvates with an aryl moiety carrying either electron donating or electron withdrawing substituents [10]. Considering the number of commercially available acetophenones, benzoylpyruvates as a class do indeed constitute a diverse starting point for the preparation of heterocycles incorporating an aryl motif.

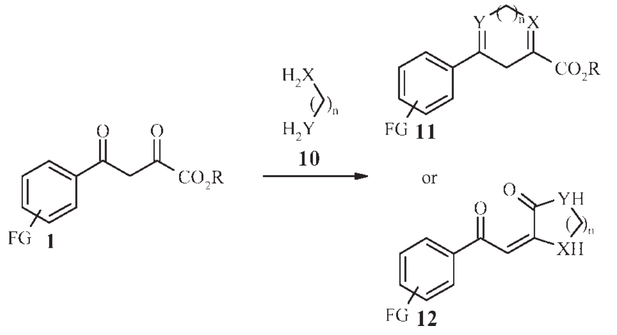
N,N′-DINUCLEOPHILES

Linked directly. Hydrazine **14** and its monosubstituted derivatives react smoothly with benzoylpyruvates in a highly chemoselective manner to afford 3,5-difunctionalized pyrazoles. In the simple case of hydrazine **14**

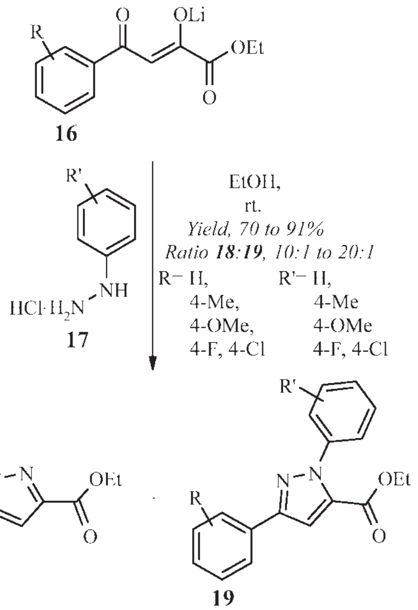
Scheme 3. Expected tautomeric contributions in benzoylpyruvates.



Scheme 4. Possible outcomes of reaction between benzoylpyruvates and dinucleophiles.



Scheme 6. Observed regioselectivity in reactions between benzoylpyruvates and arylhydrazines.



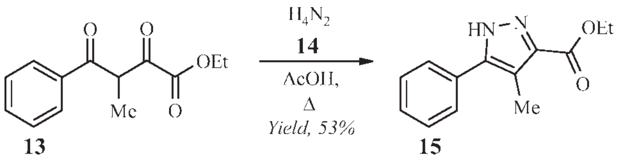
itself the regiochemical feature is void and the reaction proceeds to yield only one product [11–16]. As the starting benzoylpyruvate, exemplified by **13**, provides the carbon framework in its entirety, densely functionalized pyrazoles like **15** can be obtained in this manner (Scheme 5) [11,12,15,16].

On the other hand, attaching a substituent on hydrazine **14** could *a priori* be expected to give rise to regiochemical ambiguity. In practice, there is generally an accentuated preference, favoring formation of the 1-substituted pyrazole **18** over the 2-substituted pyrazole **19**, when arylhydrazines **17** are employed [17–19]. Nonetheless, the regioselectivity is subject to some extent of electronic modulation, both in terms of the substitution pattern on the benzoylpyruvate **16**, as well as on the arylhydrazine **17** (Scheme 6) [10]. Thus, with regard to matching the condensing partners, the regioselectivity is enhanced when an electron rich benzoylpyruvate **16** reacts with an electron poor arylhydrazine **17**.

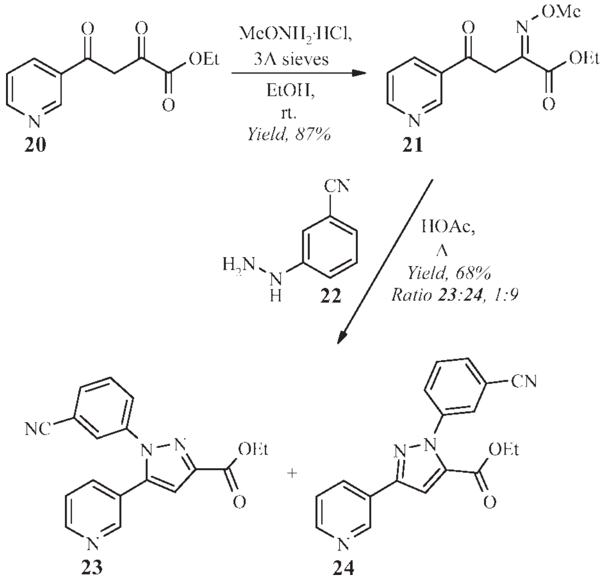
Taking advantage of the observed regiochemical preference, it is possible to invert the outcome of the reaction. Thus, transiently blocking the α-position in **20** as an oxime **21**, prior to performing the cyclodehydration step, allows the selective preparation of 2-substituted pyrazoles **24** (Scheme 7) [20].

Switching from an aryl to an alkyl substituent on hydrazine **14** may influence the regioisomeric distribution, for electronic reasons residing on the dinucleophile. On the other hand, interplay of steric factors can act as a counter to the erosion. Thus, in the case of bulky alkyl substituents, like cyclohexyl, the selectivity matches that which is observed for arylhydrazines **17** (*vide supra*) [21]. However, as expected when steric demand becomes smaller, reacting a benzoylpyruvate with a

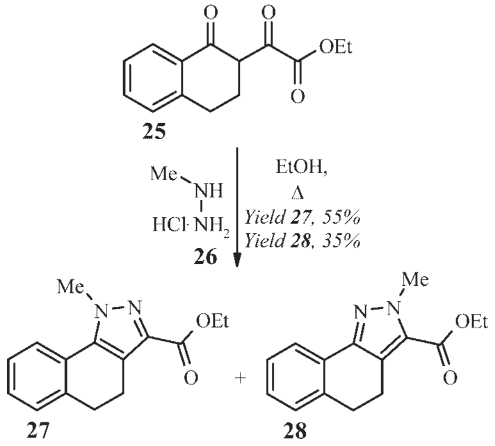
Scheme 5. Example on reaction between benzoylpyruvates and hydrazine.



Scheme 7. Example on path leading to inverted regioselectivity in reactions between benzoylpyruvates and arylhydrazines.



Scheme 8. Example on erosion of regioselectivity in the reaction with sterically nonencumbered alkylhydrazines.



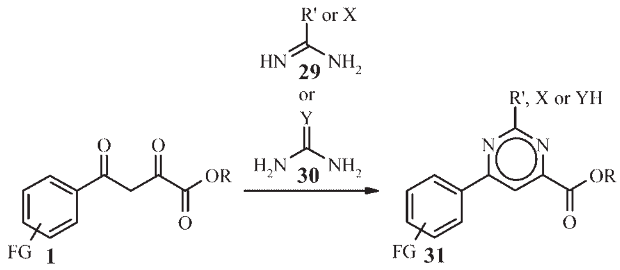
non-bulky alkylhydrazine **26** significantly increases the amount of 2-substituted pyrazole **28** (Scheme 8) [22,23].

Linked by one unit. The category of *N,N′*-dinucleophiles mutually appended to a central atom is generally restricted to compounds carrying a linker consisting of an sp^2-hybridized carbon. Thus, within that scope fall several interesting structural families, like amidines **29a** (R = H, alkyl or aryl), isoureas **29b** (R = O-alkyl or O-aryl), guanidines **29c** (R = NH_2, NH-alkyl, NH-aryl etc.) and ureas **30** (R = O or S). However, the majority of these dinucleophiles have as yet not seen any use in the chemistry of benzoylpyruvates, although having been applied to other β-diketones [24–27]. Resulting in the formation of an aromatic or latent aromatic system, the reaction should accordingly be highly favored, yielding 2,4,6-trifunctionalized pyrimidines **31** or derivatives thereof (Scheme 9).

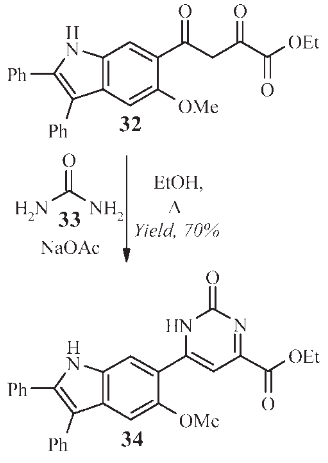
Amongst the examples following the delineated strategy, is the synthesis of pyrimidin-2-ones like **34**. Thus, the presence of base has been used to promote condensation between a benzoylpyruvate **32** and urea **33** (Scheme 10) [28].

In a similar fashion, condensation between a benzoylpyruvate **35** and guanidine **36** gives an entry to the imprinted 2-aminopyrimidine **37** (Scheme 11) [29].

Scheme 9. Strategy leading to 2,4,6-trisubstituted pyrimidines.



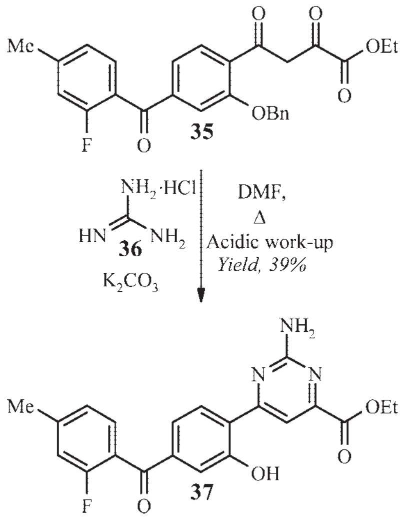
Scheme 10. Example on preparation of pyrimidin-2-ones.

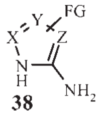


On the other hand, the *N,N′*-dinucleophile may be encased within a cyclic framework. Thus, the amidine and the guanidine make-up can be found as an integral part of heterocyclic amines, like in 2-aminopyrrole **38a** (X = H, Y = H, and Z = H,) and in 2-aminoimidazole **38b** (X = H, Y = H, and Z = N) (Fig. 2).

Reaction between benzoylpyruvates and five-membered aza-heterocyclic amines may offer an entry to a variety of [*a*]-fused pyrimidines, in consonance with the regiochemical supposition. An illustration of this strategy is cyclodehydration involving 3-aminopyrazole **40**, which affords only pyrazolo[1,5-*a*]pyrimidine **41** (Scheme 12) [30].

Scheme 11. Example on preparation of 2-aminopyrimidines.





38

Figure 2. Five-membered aza-heterocyclic amines as potential *N*,*N*′-dinucleophiles with a one-unit linker.

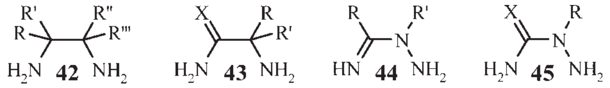


Figure 3. Selection of *N*,*N*′-dinucleophiles with a two-unit linker.

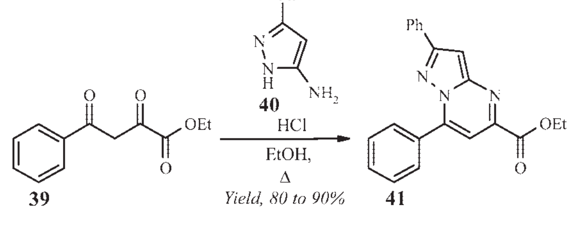
Linked by two units. The selection of potentially applicable *N*,*N*′-dinucleophiles carrying a two-unit linker is wide in terms of a cyclodehydration sequence on benzoylpyruvates. Considering the acyclic case, the linker may contain both carbon and heteroatom in combination, as well as varying in terms of hybridization, *i.e.* *C*-sp^3 versus *C*-sp^2. Accordingly, *N*,*N*′-dinucleophiles such as ethylene diamines **42**, α-amino amides **43** (X = O or S), aminoamidines **44**, semicarbazides **45a** (X = O or S), and aminoguanidines **45b** (X = NH) fall within this category (Fig. 3).

In contrast to the *N*,*N*′-dinucleophiles carrying shorter linkers, the product will not be aromatic when condensation involves the β-diketo moiety of the benzoylpyruvate. This mode of cyclisation will only lead to a labile seven-membered diimine. On the other hand, when condensation takes place across the α-keto ester moiety, the resulting annulet may or may not be aromatic. This mode of cyclisation leads however to a stabile six-membered ring containing a lactam function. As a consequence the observed chemoselectivity is altered relative to the previous examples (*vide supra*). Several of the dinucleophilic types listed in Figure 3 have been reacted with benzoylpyruvates and in all cases annulation involved the α-keto ester moiety [31–34]. Examples on these reactions are rendered in Scheme 13. Reactions involving ethylene diamines **49** or α-amino acrylamides **51** lead to piperazine-2-one derivatives like **50** and **52**. Similarly, reaction with semicarbazides **47** and aminoamidine **53** lead to 1,2,4-triazine-5-one derivatives like **48** and **53**. An important feature is the generation of a γ-related diketonoid motif that may be utilized in a second cyclodehydration step [34].

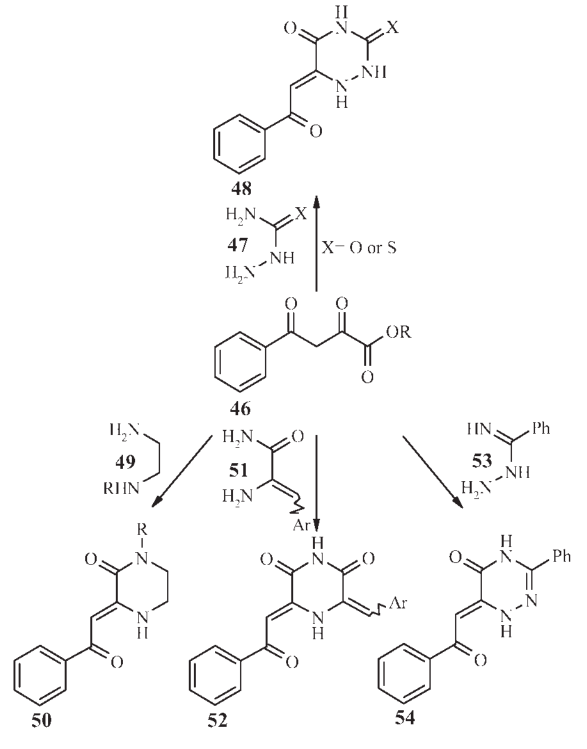
Scheme 12. Example on cyclodehydration involving cyclic *N*,*N*′-dinucleophiles with a one-unit linker.



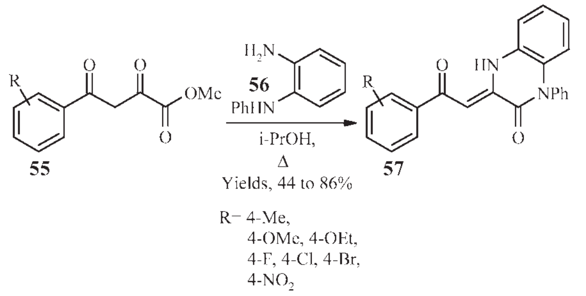
For the cyclic *N*,*N*′-dinucleophiles carrying a two-unit linker, the number of feasible candidates resonate the acyclic counterpart. In addition, the two amino groups may be joined through an ethene bridge, as is the case with aromatic systems containing vicinal amines. Accordingly, 3-functionalized 1H-quinoxaline-2-ones **57** can be made by reacting benzoylpyruvates **55** with a 1,2-aminobenzene **56** (Scheme 14) [35–39].

In some cases, the ethene bridged diamines need not an aromatic framework as support. For instance, benzoylpyruvates react with 5,6-diaminopyrimidine-2,4-dione derivatives **59**, yielding dihydropteridine-2,4,6-trione **60** and **61** (Scheme 15) [40]. It has been demonstrated that, depending on whether the reaction media is basic or acidic, it is possible to influence the

Scheme 13. Summary of examples on cyclodehydration involving acyclic *N*,*N*′-dinucleophiles with a two-unit linker.



Scheme 14. Example on cyclodehydration involving cyclic *N,N′*-dinucleophiles carrying a two-unit linker.

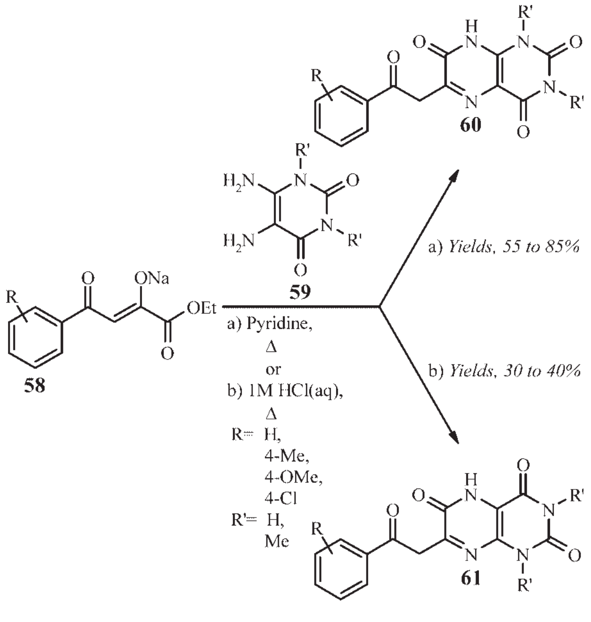


regioselectivity residing on the non-symmetrical nature of the *N,N′*-dinucleophile.

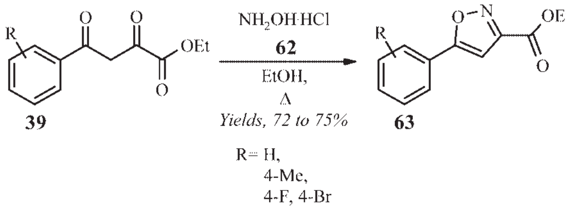
N,O-DINUCLEOPHILES

Linked directly. Because of the monovalent nature of oxygen, the category comprising directly linked *N,O*-dinucleophiles is limited to only one member, namely hydroxylamine **62**. However, the reaction between benzoylpyruvates and hydroxylamine **62** is facile, proceeding with both excellent regio- and chemoselectivity to afford the corresponding 5-arylisoxazole-3-carboxylic esters **63** (Scheme 16) [41–44]. Accordingly, the sequence of attack is therefore in adherence to what is expected of a Michael acceptor, where the softer amino group takes precedence over the hard oxygen.

Scheme 15. Example on regiochemical control involving cyclodehydration with *N,N′*-dinucleophiles carrying a two-unit linker.



Scheme 16. Example on cyclodehydration involving directly linked *N,O*-dinucleophiles.



Linked by one unit. Compounds filling the role as potential *N,O*-dinucleophiles appended with a one-unit linker are difficult to conceive. Thus, by analogy, when a β-diketone **64** is treated with ammonium carbamate **65**, the reaction results in quantitative formation of the corresponding α,β-unsaturated 1,3-aminoketone **66** [45]. Evidently, decomposition of either the prospect *N,O*-dinucleophile or any of the condensed intermediates preclude formation/isolation of a 1,3-oxazin-2-one, yielding instead β-enaminone **66** (Scheme 17).

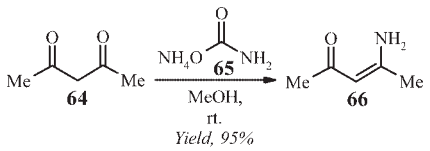
Linked by two units. As in the deliberations for the *N,N′*-dinucleophiles with a two-unit linker (*vide supra*), the same general considerations do apply for the *N,O*-dinucleophiles. In the acyclic case, one would therefore expect species like 2-aminoethanols and glycolamides to react with benzoylpyruvates following the hard/soft argument, affording dihydro-1,4-oxazine-2-ones and 1,4-oxazine-2,5-diones, respectively, via condensation across the α-keto ester moiety. However, apparently the literature does not contain any such examples.

Cyclic *N,O*-dinucleophiles appended by a two-unit linker are restricted to 2-aminophenols. Thus, when a benzoylpyruvate **55** reacts with 2-aminophenol **67** itself, the result is formation of the corresponding 1,4-benzoxazine-2-one **68** (Scheme 18) [46–48].

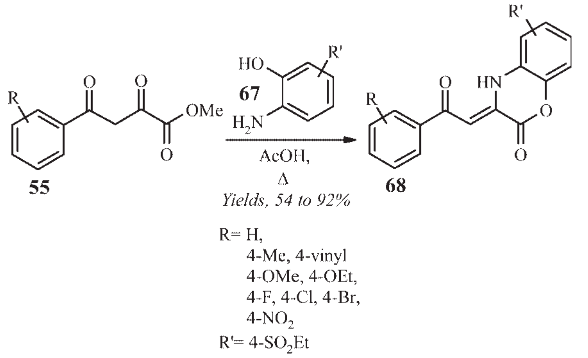
C,N-DINUCLEOPHILES

Linked directly. In the strict sense, directly linked *C,N*-dinucleophiles do not exist. However, some species might serve as surrogates to fulfill this purpose. One example is the radical anions, generated from imines or hydrazones in the presence of Ti(0), that react with β-

Scheme 17. Analogous example on reaction with a prospect *N,O*-dinucleophile.



Scheme 18. Example on cyclodehydration involving cyclic *N,O*-dinucleophiles carrying a two-unit linker.

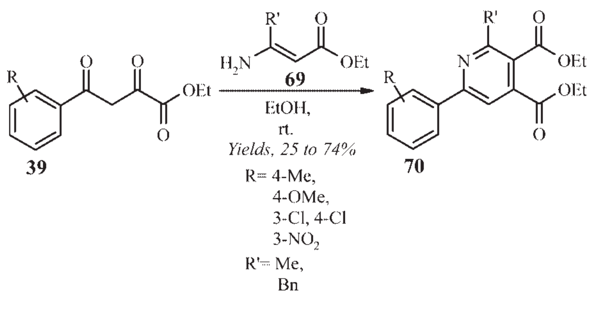


diketones to afford *N*-substituted pyrroles [49]. Another example is prodinucleophiles, such as 2-aminomethylpyridines, which are capable of reacting via an incipient active methylene, condensing with β-diketones to form 2-(2-pyridyl)pyrroles [50]. As yet, their extension to benzoylpyruvates has not been reported.

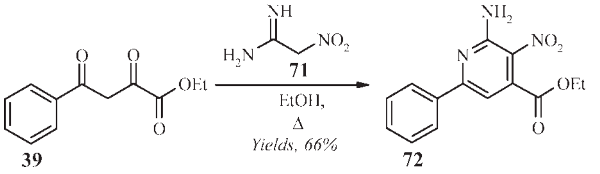
Linked by one unit. The *C,N*-dinucleophiles containing a one-unit linker are in principle diverse and the scope is wide, because it will afford substituted pyridines. In terms of regiochemistry, the directional preference of the cyclodehydration is perceivably unambiguous: The soft *C*-nucleophile is expected to attack at the benzoylpyruvate α-position, followed by annulation via the *N*-nucleophile on the γ-position. Thus, in the acyclic case, examples involving condensation with certain acetamide derivatives and enamines like **69** have appeared, resulting in the formation of pyridines **70** functionalized in the 2-,3-,4-, and 6-position (Scheme 19) [51–53]. This approach provides an expedient entry to densely ornamented pyridines.

Acetamidines carrying an electron withdrawing substituent may participate in a cyclodehydration sequence with β-diketones. This process is commonly referred to as Guareschi-Thorpe condensation [54]. An account of its application to benzoylpyruvates has been reported, involving reaction with nitroacetamidine **71** to afford pyridine **72** (Scheme 20) [55]. Subsequent elaboration via reduction of the nitro group can then be used to furnish fused pyridines.

Scheme 19. Example on cyclodehydration involving acyclic *C,N*-dinucleophiles carrying a one-unit linker.

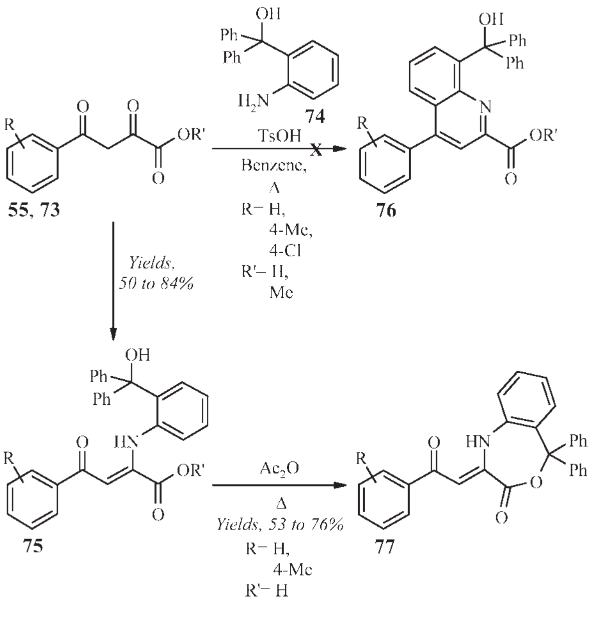


Scheme 20. Example on Guareschi-Thorpe condensation involving benzoylpyruvates.

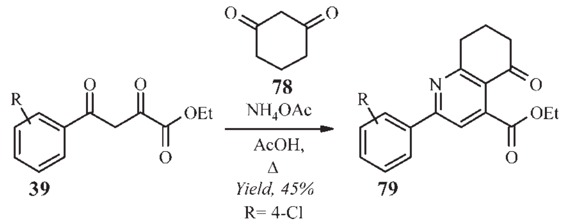


Applied to the cyclic case, in addition to performed enamines, aromatic amines could conceivably also serve as *C,N*-dinucleophiles. However, due to the relatively poor *C*-nucleophilicity, one would expect the amino group to take precedence. Formally, this type of cyclodehydration would be classified as a variation of the Skraup-Doebner-von Miller quinoline synthesis [56]. The major difference is the expected regiochemical outcome, since it is projected to occur with opposite sense of what is generally observed for the classical reaction. A route involving benzoylpyruvates would thus offer a complement in the preparation of substituted quinolines. Unfortunately, only the first step of the sequence leading to intermediate β-enaminone **75** has been demonstrated, emphasising that the critical point is the *C*-nucleophilicity (Scheme 21) [57]. Instead of yielding pyridine **76**, the overall sequence leads to annulation across the α-keto ester moiety, affording **77**. By analogy, the reaction between benzoylacetones and electron rich anilines is facile under acidic conditions [58].

Scheme 21. Reaction with a prospective cyclic *C,N*-dinucleophile carrying a one-unit linker.



Scheme 22. Example on cyclodehydration involving cyclic *C,N*-dinucleophiles carrying a one-unit linker.



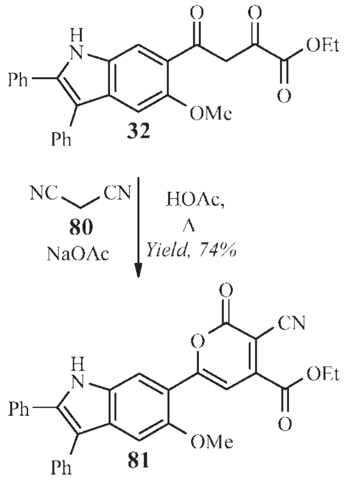
The reaction with performed cyclic enamines is nonetheless a facile process. In this case, the regiochemistry corresponds to that observed with acyclic enamines. Thus, when treating a benzoylpyruvate **39** with cyclohexane-1,3-dione **78** in the presence of an ammonia source, the reaction yields quinoline derivative **79** (Scheme 22) [59].

Linked by two units. Literature does not contain any example on the application of *C,N*-dinucleophiles with a two-unit linker, neither in relation to benzoylpyruvates nor β-diketones.

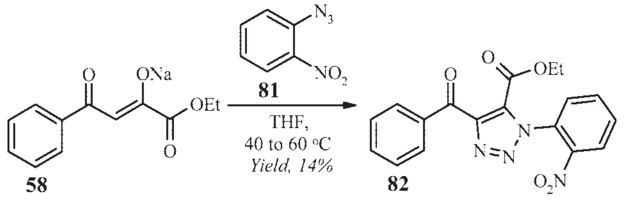
MISCELLANEOUS

The preparation of heterocyclic compounds from benzoylpyruvates needs not be limited to condensation entailing dinucleophilic species. An example is the reaction between malononitrile **80** and benzoylpyruvate **32** (Scheme 23) [28]. The incipient enol ate, formed by initial conjugate addition, attacks in turn one of the electrophilic nitriles to render a 3,4,6-functionalized pyran-2-one **81**. Therefore, within this context, reactants combining both nucleophilic and electrophilic features offer an alternative mode to form highly substituted rings.

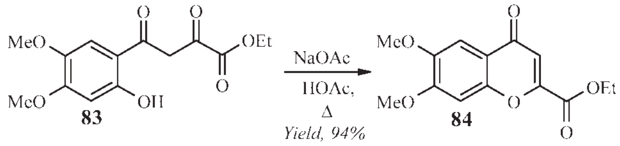
Scheme 23. Example on cyclodehydration via mixed mode.



Scheme 24. Example on 1,3-dipolar cycloaddition on benzoylpyruvates.



Scheme 25. Example on intramolecular cyclodehydration.



Another aspect related to the partially unsaturated nature bestowed on benzolpyruvates by the β-diketo moiety is a certain proclivity to engage with 1,3-dipoles. Thus, when treated with an organic azide, benzoylpyruvates may react to form cycloadducts, like 1,2,3-triazole **82** (Scheme 24) [60].

Benzoylpyruvates may themselves serve as cyclic precursors in the absence of external nucleophiles. With heteroatoms located at the 2-position of the aryl moiety, as in the case of **83**, it is possible to obtain fusion by intramolecular cyclodehydration across the α-keto group. This approach has been used to prepare chromone esters like **84** (Scheme 25) [61].

CONCLUSION

This review has highlighted the value of benzoylpyruvates as a synthetic template in the preparation of functionalized heterocycles. In particular, the value is evident when considering strategies towards biaryls, as an alternative to cross-coupling protocols.

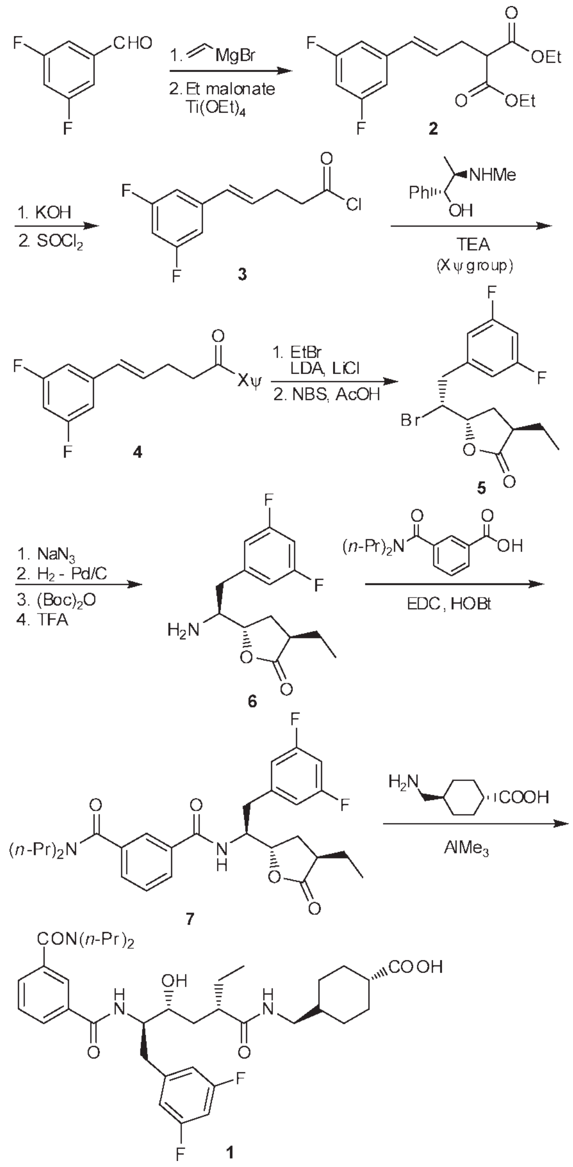
INTRODUCTION

Alzheimer's disease (AD), the neurodegenerative syndrome first described by Alois Alzheimer in 1906, affects more than 37 million people worldwide [1]. β-Amyloid cleaving enzyme-1 (BACE1) is an aspartyl protease isoform which is the principle neuronal protease responsible for the formation of Aβ fragments in the brain [2]. BACE1 is an excellent target for antiamyloid AD therapy and potent inhibitors of this enzyme have already been reported [3]. However, first generation inhibitors based on the peptidomimetic strategy showed problems related to the nature of their structure, such as blood-brain barrier crossing, poor oral bioavailability, and susceptibility to P-glycoprotein transport [4,5]. To overcome these difficulties, new nonpeptidomimetic β-secretase inhibitors were designed. After the discovery of the first nonpeptidomimetic inhibitors by Takeda Chemicals in 2001 [6], intensive efforts in research by both institutional and industrial laboratories resulted in the synthesis of hundreds of new generation inhibitors. We here review the synthesis of the most significant inhibitors, with particular emphasis on those developed by pharmaceutical companies.

ISOPHTHALAMIDE-BASED INHIBITORS

Elan Pharmaceuticals synthesized a variety of hydroxyethylene (HE) BACE1 inhibitors bearing the optimal isophthalamide *N*-terminus of the statin series and different C termini at the P1′ substituent. As an example, compound **1** inhibited BACE1 at 50 n*M* concentration [7]. Reaction of 3,5-difluorobenzaldehyde with vinylmagnesium bromide according to Orito [8] afforded 3-(3,5-difluorophenyl)-1-propen-3-ol which was treated with diethyl malonate in the presence of titanium tetraethoxide to give ethyl 4-(3,5-difluorophenyl)-3-butenoate **2**. Ester **2** underwent alkaline hydrolysis to the acid which was transformed into the corresponding acid chloride **3** with thionyl chloride. Coupling reaction of **3** with (1*R*,2*R*)-(-)-pseudoephedrine in the presence of triethylamine (TEA) and subsequent treatment of **4** with ethyl bromide in the presence of lithium diisopropylamide (LDA) and LiCl afforded a compound, which on treatment with *N*-bromosuccinimide (NBS) and AcOH at reflux underwent intramolecular lactonization to give **5**. The bromide was transformed to the corresponding azide by nucleophilic attack with sodium azide and concomitant inversion of the alpha chiral center. The azide was reduced with hydrogen in the presence of palladium as a catalyst and protected with bis-(*tert*-butoxycarbonyl)anhydride to give a compound, which then was treated with trifluoroacetic acid to afford **6**. *N*-Ethyl-*N*′-(3-dimethylaminopropyl)carbodiimide (EDC)/1-hydroxy-benzotriazole (HOBt) amide coupling to the isophthalamide furnished the lactone **7**. Finally, **7** was ring-opened using trimethylaluminum and the required amine to provide **1** (Scheme 1) [7,9].

Scheme 1



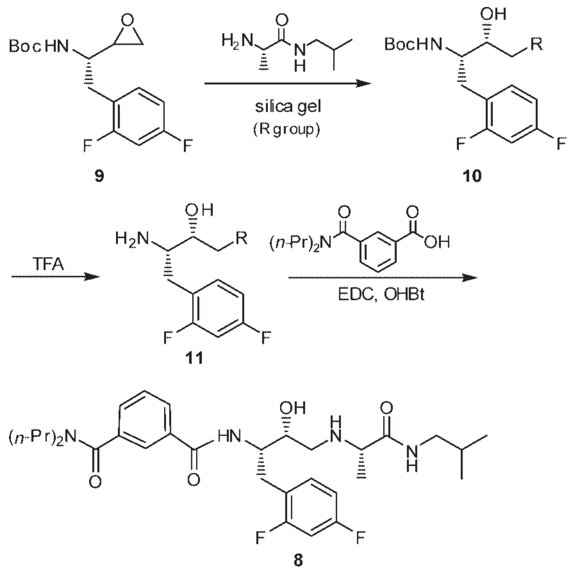
HE transition state-based inhibitor was replaced by an hydroxyethyl secondary amine (HEA) isosteric group in order to improve cell-to-enzyme potency. Compound **8** was a potent cellular inhibitor of Aβ production (more potent than the statin and the HE BACE inhibitors with comparable enzyme potency) [10]. The synthesis of **8** was accomplished starting from the erythro (*R*)-amino epoxide **9**, which was transformed into the Boc-protected amino alcohol **10**. Removal of the protecting group under TFA acidic conditions (**11**) and subsequent coupling reaction provided **8** (Scheme 2) [10].

Merck Research Laboratories synthesized HEA isosteres among potential HE motifs because of its lower molecular weight and one less amide bond. In addition, introduction of a sulfonamide group in a series of isophthalamides led to potent and selective BACE1 inhibitors [11–18].

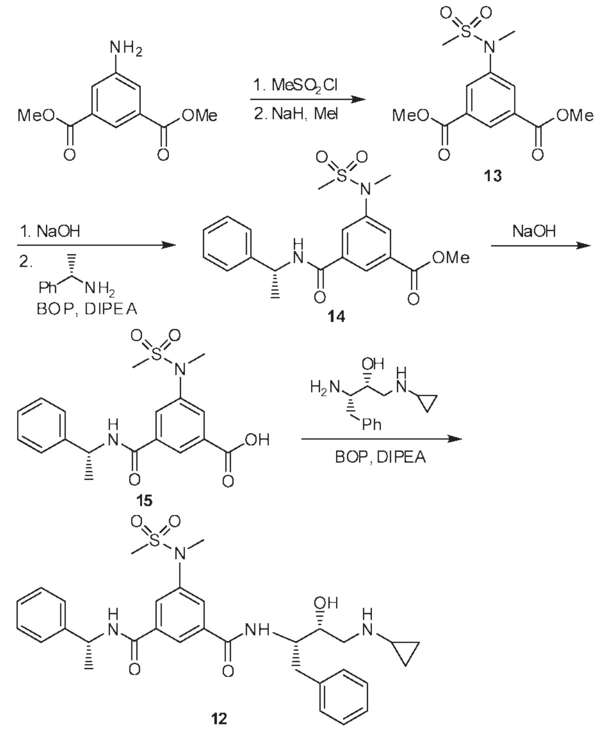
Compound **12** displayed excellent activity in both enzymatic ($IC_{50} = 15$ n*M*) and cell-based assays ($IC_{50} = 29$ n*M*), but showed moderate BACE1/BACE2 selectivity [12]. Isophthalamide **12** was prepared from 5-aminoisophthalic ester which was mesylated and then *N*-alkylated with methyl iodide to give **13**. Alkaline hydrolysis of **13** furnished the mono-ester which was coupled with (*R*)-α-methylbenzylamine in the presence of (benzotriazol-1-yloxy)tris(dimethylamino)phosphonium hexafluorophosphate (BOP)/*N*,*N*-diisopropylethylamine (DIPEA) to furnish **14**. Subsequent hydrolysis of the remaining ester, and amide coupling of **15** with 1-benzyl-3-cyclopropylamino-2-hydroxypropylamine gave **12** (Scheme 3) [12].

Analogues of **12** with both lower polar surface area and fewer H-bond donor/acceptor groups showed better pharmacodynamic and/or pharmacokinetic properties. Compound **16** was synthesized as S3-truncated analogue of **12**, and showed excellent binding activity [16]. An optimized synthesis of **16** is depicted in Scheme 4. Methyl 3-nitrobenzoate was treated with *N*-iodosuccinimide (NIS) in triflic acid (TfOH) to produce methyl 5-iodo-3-nitrobenzoate which was reduced to amine **17** with stannous chloride dihydrate. The aniline **17** was mesylated and then methylated with iodomethane in the presence of sodium hydride to give **18**. One-pot hydroindation/Suzuki coupling reaction furnished (*Z*)-methyl 3-(2-cyclopropylvinyl)-5-(*N*-methylmethylsulfonamido)-benzoate exclusively in 93% yield according to Oshima and coworkers [19]. The ester intermediate was then transformed into acid **19** by alkaline hydrolysis.

Scheme 2



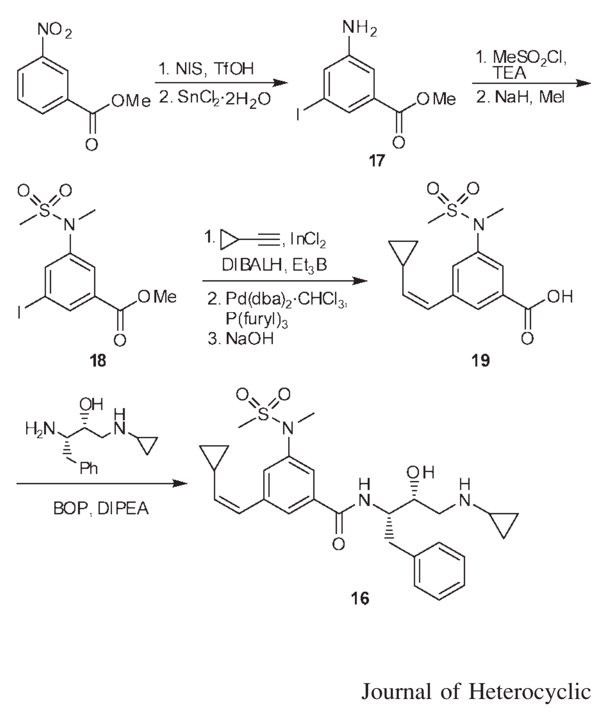
Scheme 3



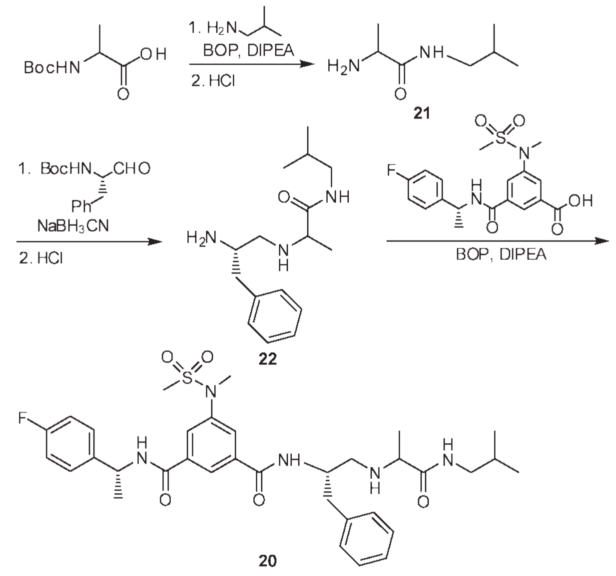
Reaction of **19** with the required amine in the presence of BOP and DIPEA afforded **16** [16].

Either small alkyl groups or longer hydrophilic substituents at the P1′ region produced compounds endowed with high BACE1 inhibitory potencies, and selectivity over BACE2 and human renin. Compound **20** was prepared by reaction of *iso*-butylamine with *N*-Boc-L-alanine and subsequent deprotection with gaseous HCl to afford *N*-*iso*-butylalaninamide (**21**). This compound was treated with *N*-Boc-L-phenylalanylaldheyde in the presence of sodium cyanoborohydride, and then deprotected with HCl to give **22**. Subsequent amide coupling of **22** with the appropriate benzoic acid in the presence of BOP and DIPEA afforded **20** (Scheme 5) [17].

Scheme 4



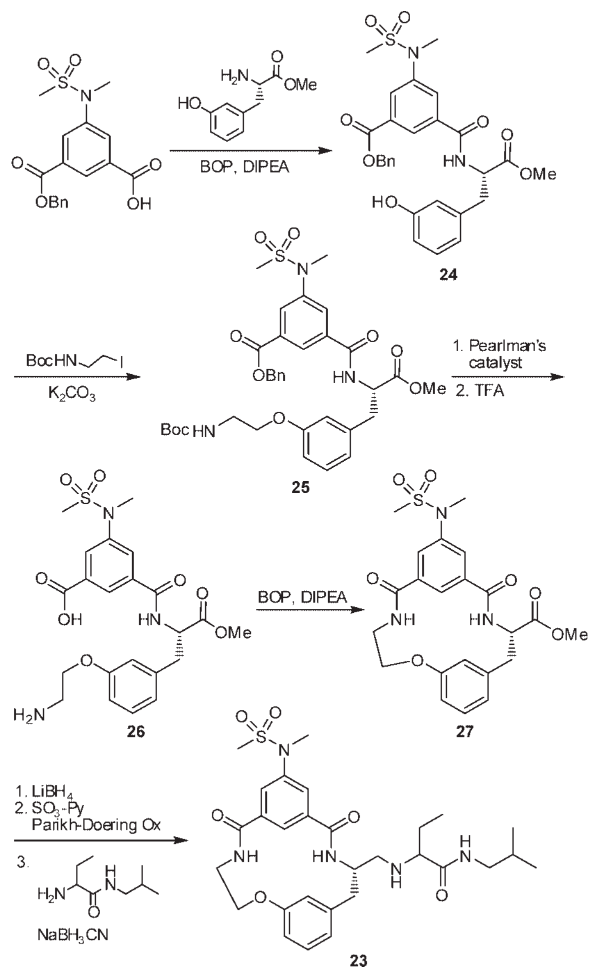
Scheme 5



X-ray crystallographic data of the **12**/BACE1 complex revealed the presence of space in proximity of the P1 and P3 groups. This observation prompted the design of macrocycles that would link these groups in an isophthalamide-based inhibitor. Macrocyclic **23**, which also incorporated a ψ[CH$_2$NH]-reduced amide bioisosteric group, exhibited high inhibitory potency (IC$_{50}$ = 32 n*M*, assayed as 1:1 diastereomeric mixture); however, in the cell-based assay **23** was significantly less potent (IC$_{50}$ = 5.4 μ*M*) [18]. Compound **23** was synthesized by reaction of 3-(*N*-methyl-methansulfonamido)-5-benzyloxycarbonylbenzoic acid with 3-tyrosine methyl ester in the presence of BOP and DIPEA to produce phenol **24** which was alkylated to **25** with *tert*-butyl (2-iodoethyl)carbamate. Deprotection of the benzyl ester using Pearlman's catalyst, followed by removal of the amino Boc protecting group afforded the corresponding *seco*-acid **26**. This acid underwent macrocyclization to **27** in the presence of BOP reagent and DIPEA. Subsequent two-steps transformation of **27** into the corresponding aldehyde and final reductive amination with (*S*)-2-amino-*N*-*iso*-butylbutanamide afforded **23** (Scheme 6) [18].

Efforts to improve potency culminated in the synthesis of macrocycle **28** as a single diastereomer. As BACE1 inhibitor, **28** (IC$_{50}$ = 4 n*M*) was 8-fold more potent than **23**, and showed significantly improved

Scheme 6

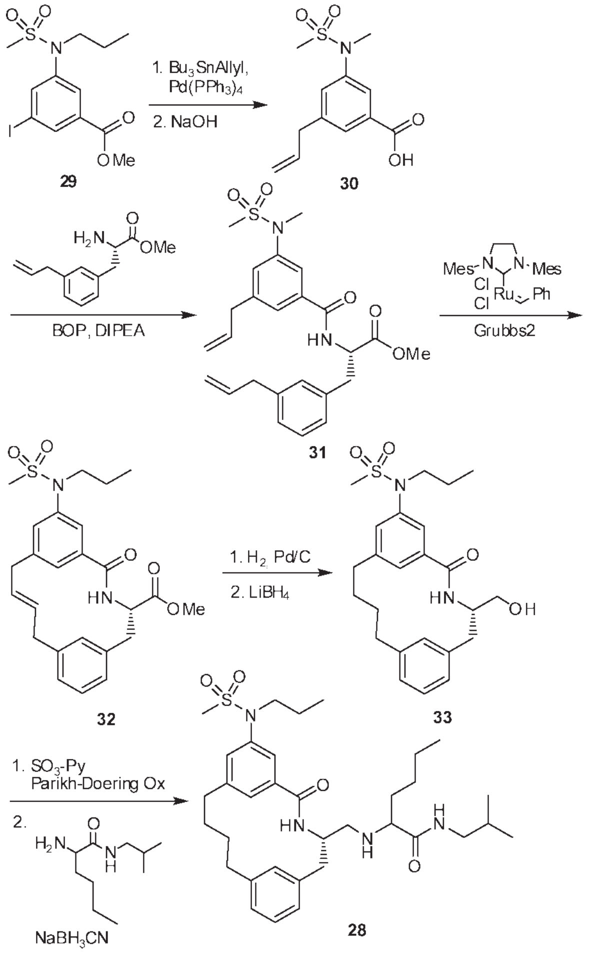


apparent permeability. An elegant synthesis of **28** is depicted in Scheme 7. Allylation of the iodoarene **29** under Stille conditions and subsequent hydrolysis of the methyl ester provided benzoic acid **30**. This acid was coupled with (*S*)-3-allyl phenylalanine to furnish the precursor **31**. Macrocyclization was accomplished through metathesis reaction using second-generation Grubbs catalyst. Hydrogenation of the *E*-olefin **32** and subsequent reduction of the ester using $LiBH_4$ provided alcohol **33**. The latter compound underwent Parikh-Doering oxidation, and finally reductive amination with *N*-isobutyl-L-norleucinamide to afford **28** [18].

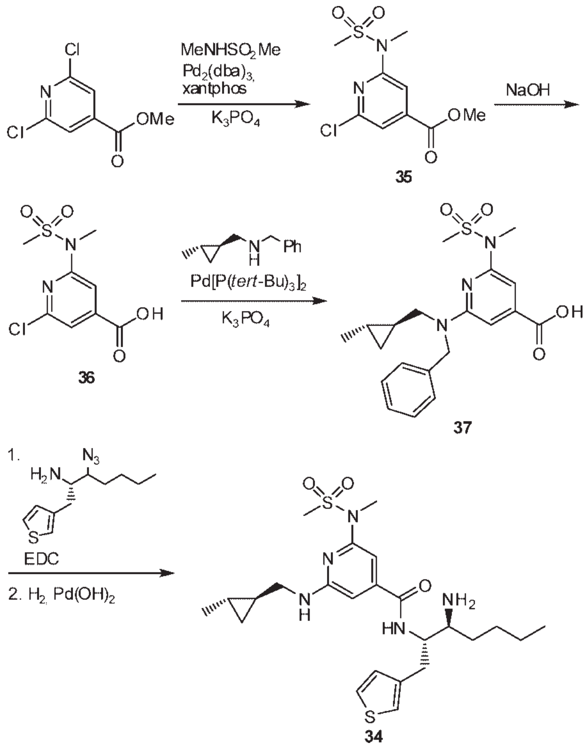
ISONICOTINAMIDES

In an effort to improve CNS penetration and pharmacokinetic stability of BACE1 inhibitors, Merck discovered a series of highly potent and selective isonicotinamides [20–22]. The improvement in potency was due to the incorporation of a *trans*-methyl-cyclopropane P3 that could be responsible for enhanced van der Waals contacts within the context of a 10s-loop down BACE1 conformation. Noncapped compound **34** displayed potent activity in both BACE1 (IC_{50} = 11 n*M*) and sAPP_NF cellular (IC_{50} = 38 n*M*) assays. Compound **34** was synthesized by reaction of methyl 2,6-dichloroisonicotinate with *N*-methyl methylsulfonamide in the presence of tris(dibenzylideneacetone)di-palladium(0) ($Pd_2(dba)_3$) and 9,9-dimethyl-4,5-bis (diphenylphosphino)xanthene (xantphos) to afford the intermediate arylsulfonamide **35**. Amide **35** underwent alkaline hydrolysis to afford the corresponding carboxylic acid **36**. Cross coupling reaction of **36** with *trans*-1-methyl-2-benzylaminomethylcyclopropane in the presence of palladium(0)tributyl-phosphine (Pd/P(*tert*-Bu)$_3$) gave **37**. Aminoacid **37** was coupled with the amino azide in the presence of *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide (EDC), and then hydrogenated with concomitant deprotection to provide **34** (Scheme 8) [20].

Scheme 7



Scheme 8



HETEROCYCLIC DERIVATIVES

Bristol-Myers Squibb synthesized heterocyclic derivatives, *i.e.*, pyrrolidine, pyrrolidinone, and azepinone compounds as β-secretase inhibitors [23–27]. Compound **38** inhibited BACE1 at concentration <0.1 μ*M* [26]. Compound **38** was obtained by treatment of the starting pyrrolidine derivative with rhodium tris(triphenylphosphine) chloride (Wilkinson's catalyst) to afford (2*R*,4*R*)-*tert*-butyl 2-((1*S*,2*S*)-2-benzyloxycarbonyl)-1-(*tert*-butyl dimethylsilyloxy)-3-phenylpropyl)-4-hydroxypyrrolidine -1-carboxylate (**39**). This compound was transformed into the corresponding mesylate by reaction with methanesulfonic acid in the presence of triphenylphosphine and diethyl azodicarboxylate, and then treated with sodium propanethiolate to give the 4-propylthiopyrrolidine derivative **41**. After oxidation of sulfur to sulfone with oxone (**42**), the Cbz protecting group was removed by catalytic reduction with hydrogen (Pd/C) to give **43**. Coupling the amino group of **43** with 3-dipropylaminocarbonyl-5-oxazol-2-yl-benzoic acid in the presence of *O*-(7-azabenzotriazol-1-yl)-*N*,*N*,*N*′,*N*′-tetramethyluronium hexafluorophosphate (HATU) and DIPEA gave a compound which was deprotected with 4*N* HCl to provide **38** (Scheme 9) [26].

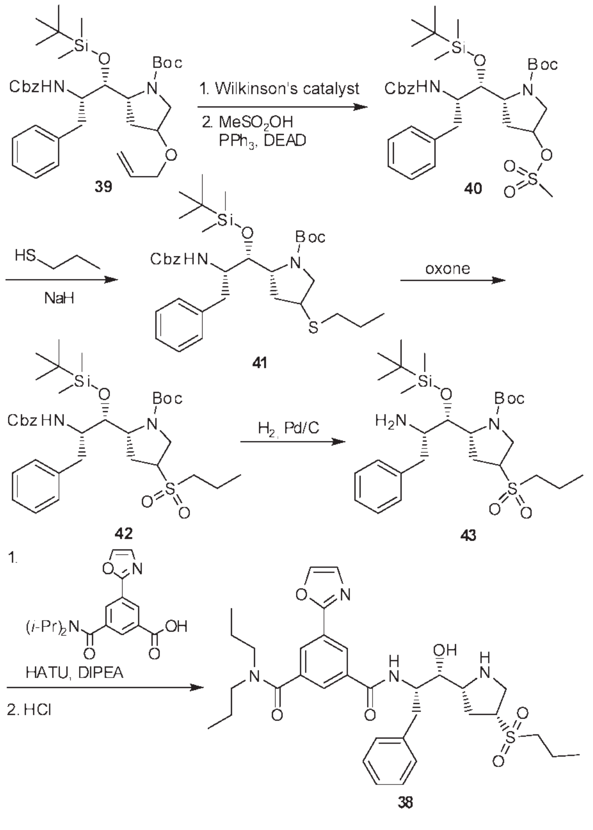
GUANIDINES

Guanidines were also reported as β-secretase inhibitors [28–38]; among these, indoleacetic acid acyl guanidine **44** inhibited BACE at <0.1 μ*M* concentration [38]. Compound **44** was obtained from 3,5-dichloro-4-aminobenzonitrile which was treated with sodium hexamethyldisilazane (NaHMDS) and acetyl chloride to form **45** which was reduced to benzylamine with lithium aluminum hydride. Amine **46** was treated with *N*-Boc-*S*-methylisothiourea in the presence of trifluoroacetic anhydride (TFAA) and DIPEA to give *tert*-butyl *N*-4-acetamido-3,5-dichlorobenzylcarbamidoyl-carbamate (**47**). This compound was coupled with 6-bromoindole-3-acetic acid in the presence of HATU and DIPEA to give **48**, which after deprotection with TFA afforded **44** (Scheme 10) [38].

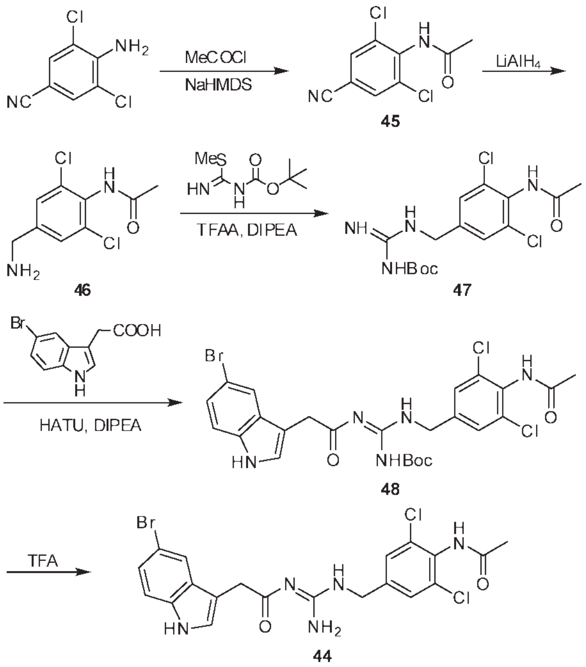
High-throughput screening (HTS) of Wyeth's compound library by means of a FRET assay identified acylguanidines as a new class of BACE1 inhibitors (*i.e.*, **49**: BACE1 IC_{50} = 3.7 μ*M*) [28]. Wyeth synthesized analogues **50–52** which were potent BACE1 inhibitors.

With the exception of **49**, these compounds were generally highly selective for BACE1 over cathepsin and

Scheme 9



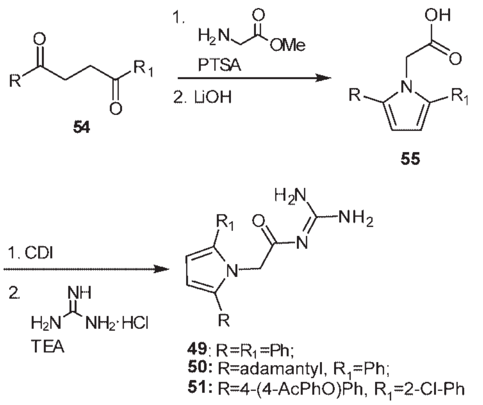
Scheme 10



pepsin ($IC_{50} > 50$ μ*M*). Compounds **49–53** were synthesized from the 1,4-diones **54** which were coupled with glycine methyl ester followed by alkaline hydrolysis to give different 2-(2,5-disubstituted-1*H*-pyrrol-1- yl)-acetic acids **55**. Activation of the acid with 1,1′-carbonyldiimidazole (CDI) and subsequent reaction with guanidine hydrochloride gave **49–51** (Scheme 11). The substituted acylguanidines **52** and **53** were prepared by reaction of the corresponding pyrroleacetic acid **55** with 1*H*-pyrazole-1-carboximidamide in the presence of CDI and subsequent displacement of the pyrazole leaving group of **56** with 3-amino-1-propanol (Scheme 12) [28].

Janssen Pharmaceuticals applied for 2-amino-3,4-dihydropyrido[3,4-*d*]pyrimidines which showed K_i values in the submicromolar range of concentration [37].

Scheme 11



49: R=R₁=Ph;
50: R=adamantyl, R₁=Ph;

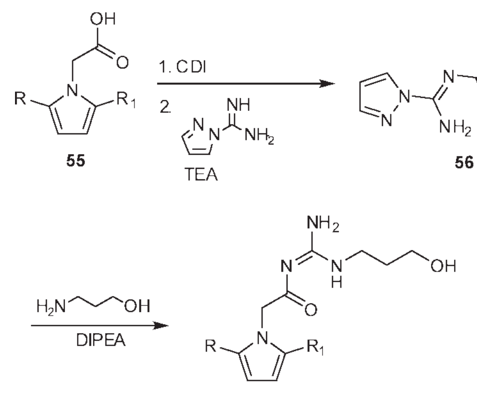
Scheme 12



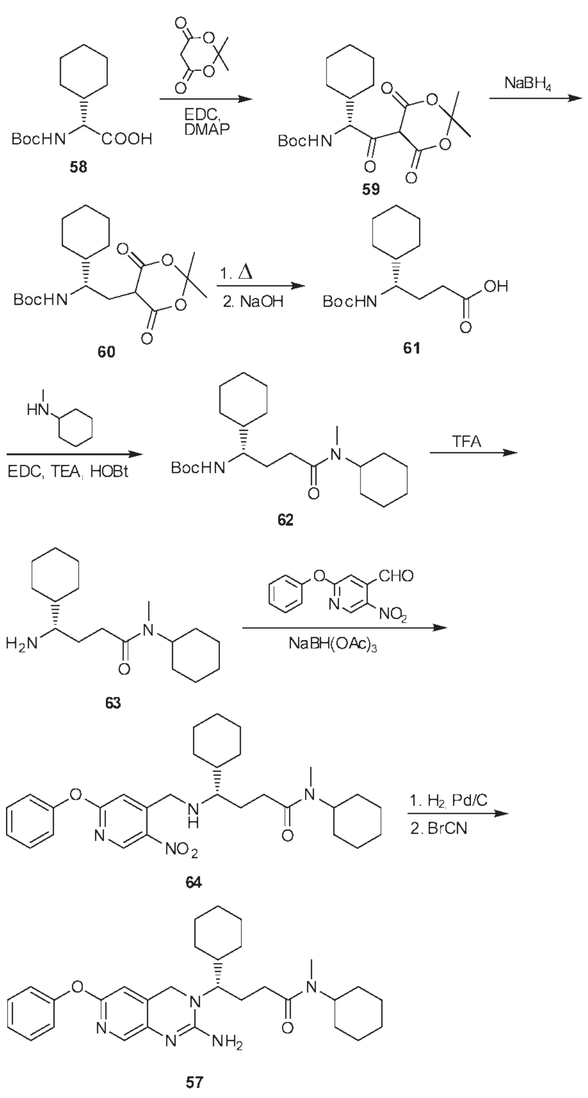
52: R=adamantyl, R₁=Ph;
53: R=4-*n*-PrOPh, R₁=2-Cl-Ph.

Johnson & Johnson Pharmaceuticals also focused SAR development on 2-amino-3,4-dihydroquinazoline [35]. The *S*-enantiomer **57** inhibited BACE1 with $K_i = 11$ n*M* (as racemate $K_i = 30$ n*M*). This compound exhibited excellent potency in a cellular assay, and additionally, lowered β-amyloid$_{1-40}$ in plasma by 40–70% in rats after per oral administration. Compound **57** was prepared from (*R*)-cyclohexylglycine **58** (>97% e.e.) which was treated with Meldrum's acid in the presence of EDC and 4-(dimethylamino)pyridine (DMAP) to afford **59**. $NaBH_4$ reduction of the ketone functionality provided **60** which underwent thermolysis in boiling toluene to give a lactam which was transformed into acid **61** by alkaline hydrolysis. Compound **61** was coupled with cyclohexylmethylamine in the presence of EDC, TEA, and HOBt to give amide **62**. After acidic cleavage of **62**, reaction of amine **63** with 2-phenoxy-5-nitropyridin-4-carboxaldehyde in the presence of sodium triacetoxyborohydride gave the nitroaminoalkyl intermediate **64** which was reduced to amine with hydrogen in the presence of palladium on carbon, and then cyclized to **57** with cyanogen bromide (Scheme 13) [35].

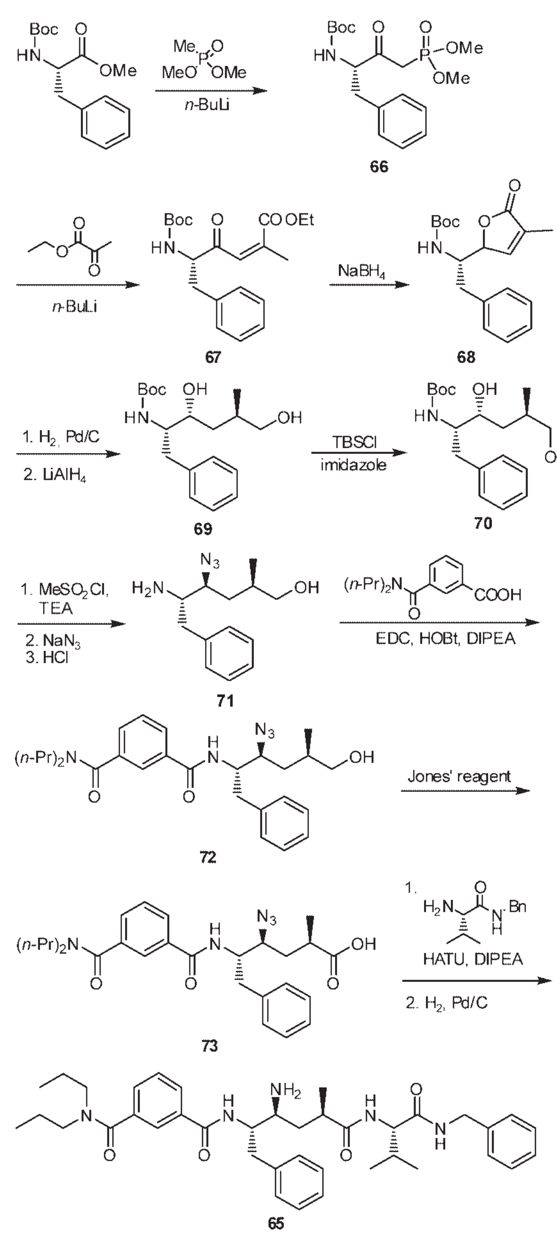
OTHER COMPOUNDS

Sunesis Pharmaceuticals considered the primary amine group as a possible bioisostere of the hydroxyl group present in HE-containing BACE1 inhibitors [39]. Replacement of the HE motif with the aminoethylene bioisostere afforded compounds endowed with slightly reduced enzymatic inhibitory activity but distinctly improved cell potency (the *S*-isomer was preferred for activity). Incorporation of a benzyl P_1 substituent (*i.e.*, **65**) resulted in a net increase in inhibitory potency relative to the isobutyl analogues. Compound **65** was synthesized from *N*-Boc-L-phenylalanine methyl ester which was treated with dimethyl methylphosphonate in the presence of *n*-butyl lithium to provide the corresponding phosphonate **66**. Reaction of crude **66** with ethyl pyruvate and *n*-butyl lithium gave ethyl (5*S*,2*Z*)-2-methyl-[5-(*tert*-butoxycarbonyl)amino]-4-oxo-6-phenyl-hex-2-enonate (**67**). Sodium borohydride reduction of **67** with concomitant intramolecular cyclization gave 2,5-dihydrofuran-2-one **68**. This compound was reduced to tetrahydrofuran-2-one with hydrogen in the presence of palladium over carbon, and then with lithium aluminum hydride to furnish (2*S*,3*R*,5*R*)-2-*tert*-butoxycarbonylamino-1-phenyl-5-methylhexan-3,6-diol (**69**). The diol was subsequently treated with *tert*-butyl-dimethylsilyl chloride (TBSCl) and imidazole (**70**), and then with methanesulfonyl chloride and triethylamine to furnish the corresponding methanesulfonate. Introduction of the azido group by displacing the methanesulfonate with sodium azide, and cleavage of both protecting groups with hydrochloric acid resulted in aminoalcohol **71** which was coupled with *N*,*N*-dipropyl isophthalamic acid in the presence of ECD, HOBt and DIPEA to form **72**. Oxidation of **72** to acid **73** with Jones' reagent (chromium trioxide and sulfuric acid) and further elaboration as above reported provided **65** (Scheme 14) [39].

Scheme 13



Scheme 14



CONCLUSION

Three-dimensional structural information for BACE1 in complex with a variety of inhibitors has led to great strides in the development of new effective agents for the treatment of AD. Both academia and pharmaceutical companies focused their efforts to develop new synthetic strategies for the synthesis of potent BACE1 inhibitors, such as isophthalamides, isonicotinamides, heterocycles and other derivatives, which showed improved drug properties when compared with first generation peptidic inhibitors. These synthetic routes may serve as useful tools for medicinal chemists in discovering new AD therapeutics.

N-Aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothiamides and *N*-aryl-4-hydroxycoumarin-3-carbothiamides were synthesized by the reaction of arylisothiocyanates with 4-hydroxy-6-methylpyran-2-one and 4-hydroxycoumarin, respectively. Novel products 3-[bis(arylamino)methylene]-6-methyl-2*H*,4*H*-pyran-2,4-diones and *N*,*N*′-diaryl-4-hydroxycoumarin-3-carboximidamides have also been obtained in the same reactions. Novel 4-acetoacetyl-3-phenylamino-4,5-dihydro-5*H*-pyrazol-5-ones were synthesized from the reaction of *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothiamides with an excess of hydrazine. The structure of all compounds was established by NMR and mass spectra.

J. Heterocyclic Chem., **46**, 18 (2009).

INTRODUCTION

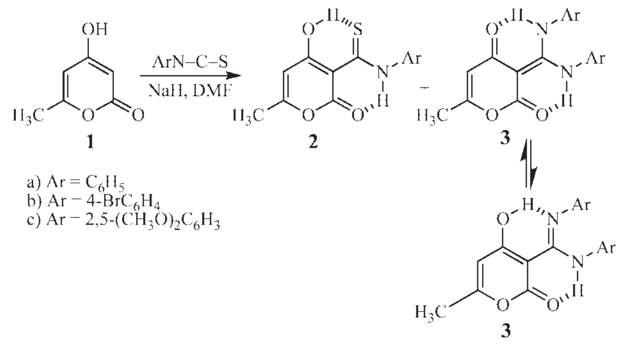
2-Pyrones and coumarins are an important class of heterocyclic compounds presenting important pharmaceutical properties. They have been found in a large number of natural products displaying significant biological activities, and certain synthetic derivatives are biologically active compounds (*e.g.*, potent HIV-1 protease and photosynthetic electron transport inhibitors; presenting sedative, anticonvulsive, anesthetic, and antifungal properties) [1–8]. These important potential applications led to the development of a plethora of synthetic procedures to synthesize pyrone derivatives either by traditional approaches or by transition metal-catalyzed procedures [9–21].

Taking into consideration the referred important biological activities of the 2-pyrones and coumarins and following our studies on the transformations of 4-hydroxy-6-methylpyran-2-one (triacetic acid lactone, TAL) **1** [22] and 4-hydroxycoumarin **4** [23–25], we developed a new synthetic method for *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothioamides **2** and *N*-aryl-4-hydroxycoumarin-3-carbothioamides **5**. In these transformations, novel products 3-[bis(arylamino)methylene]-6-methyl-2*H*,4*H*-pyran-2,4-diones **3** and *N*,*N*′-diaryl-4-hydroxycoumarin-3-carboximidamides **6** have also been obtained. In this communication, the synthesis of novel 4-acetoacetyl-3-arylamino-4,5-dihydro-5*H*-pyrazol-5-ones **10** were also established, by the reaction of *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothioamides **2** with hydrazine hydrate.

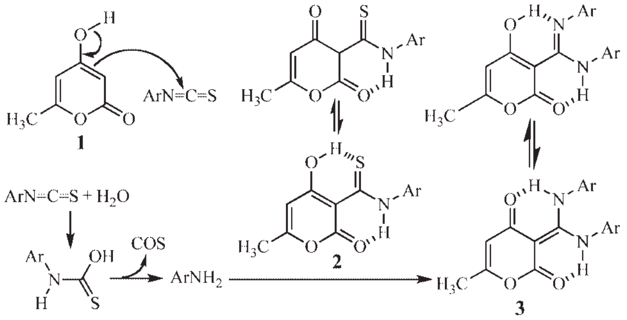
RESULTS AND DISCUSSION

Treatment of 4-hydroxy-6-methylpyran-2-one **1** with arylisothiocyanates in the presence of sodium hydride in DMF for 15 h led to the formation of a solid after the addition of water to the reaction mixture. The aqueous layer was acidified with hydrochloric acid (pH = 4–5), and after vigorous stirring at room temperature for 1.5 h, it led to the formation of a new solid. The elemental analysis and the mass spectra of the first solid indicated the absence of sulfur in the structure and that two molecules of arylisothiocyanates reacted with **1**. In the case of compound **3a**, apart from the molecular ion at *m*/*z* 320 ($C_{19}H_{16}N_2O_3$), its mass spectrum presents peaks corresponding to the loss of Ph—NH$_2$ and Ph—NH and intense peaks at *m*/*z* 85 and 65 corresponding to the characteristic fragments from cleavage of the 2-pyrone ring. These data suggest the formation of 3-(bis-phenylaminomethylene)-6-methyl-2*H*,4*H*-pyran-2,4-dione **3a**. This structure was also supported by its ^{1}H NMR spectrum, which presents four signals as singlets at δ 2.23, 5.73, 12.00, and 14.18 ppm because of the 6-Me, H-5, and two N*H* proton resonances, respectively. The ^{13}C NMR spectrum of **3a** presents two signals for the resonance of each carbon of the pyrandione moiety: C-3 (δ 85.2 and 104.4 ppm), C-5 (δ 105.8 and 108.4 ppm), C-6 (δ 140.3 and 163.4 ppm), C-4 (δ 178.8 ppm assigned to C—OH; δ 186.2 ppm assigned to C=O), and C-1′ [δ 168.9 ppm assigned to =C(NHAr)$_2$; δ 182.5 ppm

Scheme 1



Scheme 2



assigned to —C(NHAr)=NAr and the signals of the aromatic carbon. The appearance of this type of double ^{13}C NMR spectra is due to the presence of two tautomeric forms of compound **3a** (Scheme 1). All the spectroscopic features of **3b** and **3c** are similar to those described for **3a**, except for the resonances of the aromatic moieties and for the corresponding *m*/*z* values; confirming the generality of the reaction for other substituted arylisothiocyanates (Scheme 1).

The elemental analysis and the mass spectrum of the second solid are consistent with the structure of *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothiamides **2a–c**, bearing sulfur and nitrogen atoms in the structure. The ^{1}H NMR spectra of **2a–c** present four singlets at δ 2.29–2.30, 6.36–6.38, 12.70–12.92, and 14.90–15.89 ppm because of the resonance of 6-Me, H-5, NH, and OH, respectively. The ^{13}C NMR spectra of **2a–c** present signals characteristics of the carbothiamoyl group at δ 187.5–189.6 ppm. The mass spectra of **2a–c** present peaks corresponding to the molecular ion followed by the peaks corresponding to the loss of Ar—NH_2 and Ar—NH and intense peaks at *m*/*z* 85 and 65 corresponding to the characteristic fragments from cleavage of the 2-pyrone ring.

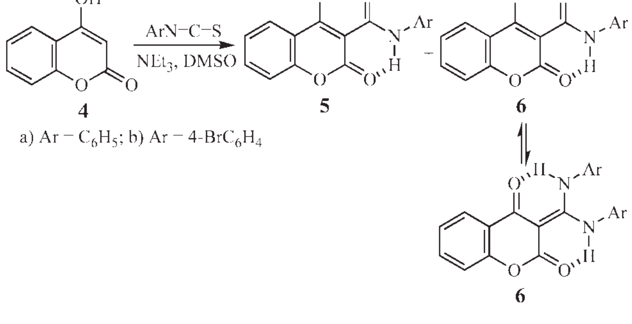
Surprisingly, to the best of our knowledge, 3-[bis(arylamino)methylene]-6-methyl-2*H*,4*H*-pyran-2,4-diones **3a–c** or related compounds have never been described in the literature; however, Bruno et al. have studied an analogous reaction of 5,6-dihydro-4-hydroxy-6-methyl-2*H*-pyran-2-one with arylisothiocyanates under the same experimental conditions and have isolated only 5,6-dihydro derivatives of compounds **2a–c** [26]. The formation of compounds **3a–c** would be explained through the formation of unstable intermediates thiocarbamic acid derivatives from arylisothiocyanates, which yields aniline derivatives after a decarboxylation-type reaction [27] that react with the already formed *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothioamides **2a–c** affording **3a–c** (Scheme 2). The yield of **3a** was considerably dependent on the amount of phenylisothiocyanate; using one molar equivalent 4-hydroxy-6-methyl-*N*-phenyl-2*H*-pyran-2-one-3-carbothioamide **2a** was the major product (75%), while using two molar equivalent led to the formation of 3-[bis(phenylamino)methylene]-6-methyl-2*H*,4*H*-pyran-2,4-dione **3a** as the major product (90%). This condensation was attempted in DMSO as solvent and in the presence of triethylamine giving rise to the expected products **2a** and **3a** in 45 and 55% yield, respectively.

To confirm the formation mechanism of **3a–c**, we have reacted **2a** with one equivalent of aniline in DMF for 2 h at room temperature and **3a** was obtained in good yield (90%).

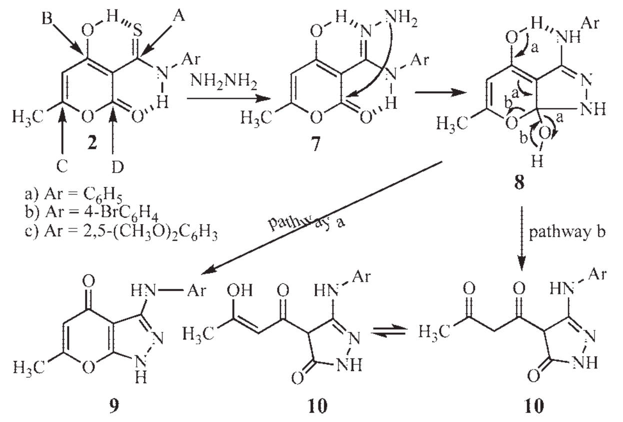
The condensation of 4-hydroxycoumarin **4** with arylisothiocyanates, using DMSO as solvent, gave the corresponding *N*-aryl-4-hydroxycoumarin-3-carbothioamides **5a,b** and also *N*,*N*′-diaryl-4-hydroxycoumarin-3-carboximidamides **6a,b** (Scheme 3). The ^{1}H NMR spectra of **5a,b** show two singlets at δ 13.34–13.35 and 17.45–17.60 ppm because of the resonance of NH and OH groups, whereas the ^{13}C NMR spectra show a characteristic carbothiamoyl signal at δ 188.4–189.1 ppm.

The IR spectrum of **6a** presented strong peaks at 1636–1617 and 3479–3407 cm^{-1}, which were attributed to the carbonyl (C=O) and —OH groups on the coumarin ring, respectively. The mass spectra of compounds **6a,b** indicated that the coumarin ring was conserved, with peaks being observed corresponding to the fragmentation of the coumarin ring at *m*/*z* 134, 143, and 117 [28,29]. From their ^{1}H NMR spectra, it is possible to observe the presence of signals corresponding to the resonances of two

Scheme 3



Scheme 4



exchangeable protons at δ 13.30–13.35 and 17.46–17.54 ppm, then assigned to the NH and OH groups, respectively. The ^{13}C NMR spectra showed that compound **6a,b** exist as a mixture of two tautomers (Scheme 3).

The next step of our work considered the reaction of compounds **2a–c** with hydrazine hydrate. These compounds **2a–c** have four (A, B, C, D) susceptible centers of nucleophilic attack, three of them into the pyrone ring, and a single molecule of hydrazine would therefore be liable to give a wide range of products (Scheme 4). Compounds **2a–c** reacted with hydrazine hydrate under reflux in a (1:1) mixture of ethanol/acetic acid and yielded only a single isolated solid as the reaction product. Elemental analysis and mass spectra showed that only one molecule of hydrazine had reacted, and the mass spectra also indicated the presence of fragments corresponding to an acetoacetyl group, with peaks at *m/z* 85, 56, and 43. This structure was also supported by the ^{1}H NMR spectra of **10a–c**, which present five singlets characteristics of a tautomeric equilibrium of acetoacetyl groups at δ 2.06–2.07, 2.32–2.33, 4.30–4.40, 6.11–6.13, and 16.30–16.70 ppm. These signals are assigned to the proton resonances of CH_3 (keto-enol form), CH_3 (β-diketone), CH_2 (β-diketone), CH, and OH (keto-enol form), respectively. We also observed two other singlets at δ 7.90–8.62 and 13.00–13.15 ppm, which were assigned to the NH-pyrazolone and NH—Ar groups, respectively. This condensation reaction allowed us to synthesize novel aminopyrazole derivatives in good yields (95–98%).

An explanation for the formation of pyrazole derivatives **10a–c** considered the hydrazine attack to the thioamide group (center A) of compounds **2a–c** leading to the carboximidamides **7a–c**. An intramolecular nucleophilic attack of the amine group from the amide moiety to the lactone carbonyl carbon (center D) gave rise to intermediates **8a–c**, which can follow two possible pathways (a and b). However, the isolation of pyrazole-type compounds **10a–c** led us to conclude that **8a–c** underwent the opening of the pyran ring by pathway b.

EXPERIMENTAL

Melting points were determined on a Stuart scientific SPM3 apparatus fitted with a microscope and are uncorrected. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ or DMSO-d_6 solutions on Bruker Avance 300 (300.13 MHz for ^{1}H and 75.47 MHz for ^{13}C) and Nujeol GSX 270 WB (270.00 MHz for ^{1}H and 67.5 MHz for ^{13}C) spectrometers. Chemical shifts are reported in ppm (δ) using TMS as internal reference and coupling constants (*J*) are given in Hz. ^{13}C assignments were made using DEPT-135, HSQC, and HMBC (delays for one bond and long-range *J* C/H couplings were optimized for 145 and 7 Hz, respectively) experiments. Mass spectra are obtained with ESI(+) and GC-MS. Positive-ion ESI mass spectra were acquired using a Q-TOF 2 instrument [diluting 1 μL of the sample chloroform solution ($\sim 10^{-5}$ *M*) in 200 μL of 0.1% trifluoroacetic acid/methanol solution. Nitrogen was used as nebulizer gas and argon as collision gas. The needle voltage was set at 3000 V, with the ion source at 80°C and desolvation temperature at 150°C. Cone voltage was 35 V].

General procedure for the synthesis of *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothioamides (2a–c) and 3-[bis(arylamino)methylene]-6-methyl-2*H*,4*H*-pyran-2,4-diones (3a–c). A solution of arylisothiocyanates (21 mmol) dissolved in 5 mL of DMF was added to a stirred solution of 2.52 g (20 mmol) of 4-hydroxy-6-methylpyran-2-one **1** and 0.576 g (24 mmol) of NaH 20% in mineral oil in 10 mL of DMF, under a nitrogen atmosphere. The reaction mixture was stirred at room temperature for 15 h. After this period, 50 mL of cold water was added to the reaction mixture, and the precipitate thus formed was collected by filtration and washed several times with a (1:1) mixture of diethyl ether:light petroleum. The solid was in each case recrystallized from isopropyl alcohol giving 3-[bis-(arylamino)methylene]-6-methyl-2*H*,4*H*-pyran-2,4-diones **3a–c**: **3a**, 1.92 g (30%); **3b**, 1.92 g (20%); **3c**, 3.08 (35%).

The aqueous layer was acidified with HCl 1*N* (pH = 4–5). After vigorous stirring at room temperature for 1.5 h, the precipitate thus formed was collected by filtration and washed several times with diethyl ether. The solid was in each case recrystallized from methanol giving *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothioamides **2a–c**: **2a**, 3.13 g (60%); **2b**, 5.10 g (75%); **2c**, 2.57 g (40%).

4-Hydroxy-6-methyl-N-phenyl-2H-pyran-2-one-3-carbothioamide (2a). This compound was obtained as yellow powder, mp 189–190°C; ^{1}H NMR ($CDCl_3$): δ 2.30 (s, 3H, C*H*$_3$), 6.37 (s, 1H, H-5), 7.31 (t, 1H, *J* = 7.5 Hz, ArH), 7.43 (t, 2H, *J* = 7.50 Hz, ArH), 7.53 (d, 2H, *J* = 7.5 Hz, ArH), 12.92 (s, 1H, N*H*), 15.89 (s, 1H, O*H*); ^{13}C NMR ($CDCl_3$): δ 19.1, 97.6, 102.6, 124.8, 127.0, 128.6, 137.1, 162.8, 165.3, 175.7, 187.5; ms (EI): *m/z* 263 (6, ^{34}S), 262 [28, $(M+H)^+$], 261 ($M^{+\cdot}$, 100, ^{32}S), 260 (77), 228 (87), 93 (42), 77 (40), 85 (32), 69 (12). *Anal.* Calcd. for $C_{13}H_{11}NO_3S$ (261.30): C, 59.76; H, 4.24; N, 5.36. Found: C, 60.07; H, 4.60; N, 5.59.

N-(4-Bromophenyl)-4-hydroxy-6-methyl-2H-pyran-2-one-3-carbothioamide (2b). This compound was obtained as yellow powder, mp 190–191°C; ^{1}H NMR (DMSO-d_6): δ 2.29 (s, 3H, C*H*$_3$), 6.38 (s, 1H, H-5), 7.58 (d, 2H, *J* = 8.0 Hz, ArH), 7.63 (d, 2H, *J* = 8.0 Hz, ArH), 12.70 (s, 1H, N*H*), 15.30 (s, 1H, O*H*); ^{13}C NMR (DMSO-d_6): δ 20.0, 99.7, 102.9, 120.0, 128.0, 132.7, 137.4, 163.2, 166.0, 174.8, 188.7; ms (ESI+): *m/z* 364 [7, $(M+Na)^+$, ^{81}Br, ^{32}S), 362 [9, $(M+Na)^+$, ^{79}Br, ^{32}S], 342

[80, (M+H)$^+$, ^{81}Br, ^{32}S], 340 [100, (M+H)$^+$, ^{79}Br, ^{32}S]. *Anal.* Calcd. for $C_{13}H_{10}BrNO_3S$ (340.19): C, 45.90; H, 2.96; N, 4.11. Found: C, 45.95; H, 3.01; N, 4.16.

N-(2,5-Dimethoxyphenyl)-4-hydroxy-6-methyl-2H-pyran-2-one-3-carbothioamide (2c). This compound was obtained as yellow powder, mp 169–170°C; ^{1}H NMR (DMSO-d_6): δ 2.28 (s, 3H C*H*$_3$), 3.80 (s, 3H, OC*H*$_3$), 3.90 (s, 3H, OC*H*$_3$), 6.36 (s, 1H, H-5), 7.60 (d, 1H, *J* = 7.3 Hz, ArH), 7.70 (d, 1H, *J* = 7.3 Hz, ArH), 8.10 (s, 1H, ArH), 12.70 (s, 1H, N*H*), 14.90 (s, 1H, O*H*); ^{13}C NMR (DMSO-d_6): δ 20.3, 58.0, 60.0, 100.9, 102.7, 125.8, 127.0, 129.6, 131.2, 131.5, 131.8, 162.9, 165.9, 174.0, 189.6; ms (EI): *m/z* 321 (M^{+-}, 45), 233 (100), 221 (5), 189 (8), 125 (8), 116 (10), 85 (20), 69 (55). *Anal.* Calcd. for $C_{15}H_{15}NO_5S$ (321.40): C, 56.06; H, 4.70; N, 4.36. Found: C, 55.95; H, 4.57; N, 4.36.

3-[Bis(phenylamino)methylene]-6-methyl-2H,4H-pyran-2,4-dione (3a). This compound was obtained as yellow powder, mp 147–148°C; ^{1}H NMR (CDCl$_3$): δ 2.23 (s, 3H, C*H*$_3$), 5.73 (s, 1H, H-5), 6.70–6.86 (m, 5H, ArH), 7.14–7.28 (m, 5H, ArH), 12.00 (s, 1H, N*H*) 14.18 (s, 1H, O*H*); ^{13}C NMR (CDCl$_3$): δ 19.1, 19.5, 85.2, 104.4, 105.8, 108.4, 117.4, 119.8, 123.4, 126.8, 128.2, 129.3, 140.3, 142.1, 144.8, 161.0, 163.4, 168.9, 178.8, 182.5, 186.2; IR: ν (cm^{-1}) 3478, 3209, 3031, 1636, 1550, 1448, 1342, 927, 759, 696; ms (EI): *m/z* 320 (M^{+-}, 18), 227 (14), 194 (38), 93 (100), 85 (4), 69 (17). *Anal.* Calcd. for $C_{19}H_{16}N_2O_3$ (320.34): C, 71.24; H, 5.03; N, 8.74. Found: C, 71.79; H, 5.13; N, 8.72.

3-[Bis(4-bromophenylamino)methylene]-6-methyl-2H,4H-pyran-2,4-dione (3b). This compound was obtained as yellow powder, mp 159–160°C; ^{1}H NMR (DMSO-d_6): δ 2.27 (s, 3H, C*H*$_3$), 5.93 (s, 1H, H-5), 7.43 (d, *J* = 8.0 Hz, 2H, ArH), 7.49 (d, *J* = 8.1 Hz, 2H, ArH), 7.55 (d, *J* = 8.1 Hz, 2H, ArH), 7.62 (d, J = 8.0 Hz, 2H, ArH), 13.20 (s, 1H, N*H*), 14.3 (s, 1H, O*H*); ^{13}C NMR (DMSO-d_6): δ 19.6, 20.0, 88.9, 103.3, 108.0, 117.1, 119.9, 126.1, 131.8, 132.3, 135.6, 137.6, 158.7, 162.3, 165.7, 166.3, 174.9, 182.9, 188.8; ms (ESI+): *m/z* 503 [5, (M+Na)$^+$, 2 × ^{81}Br], 501 [9, (M+Na)$^+$, ^{81}Br, ^{79}Br), 499 [4, (M+Na)$^+$, 2 × ^{79}Br], 481 [50, (M+H)$^+$, 2 × ^{81}Br], 479 [100, (M+H)$^+$, ^{81}Br, ^{79}Br], 477 [52, (M+H)$^+$, 2 × ^{79}Br]. *Anal.* Calcd. for $C_{19}H_{14}Br_2N_2O_3$ (478.13): C, 47.73; H, 2.95; N, 5.86. Found: C, 47.78; H, 2.96; N, 5.88.

3-[Bis(2,5-dimethoxyphenylamino)methylene]-6-methyl-2H,4H-pyran-2,4-dione (3c). This compound was obtained as white powder, mp 186–187°C; ^{1}H NMR (DMSO-d_6): δ 2.24 (s, 3H, C*H*$_3$), 3.80 (s, 3H, OC*H*$_3$), 3.90 (s, 3H, OC*H*$_3$), 6.25 (s, 1H, H-5), 7.40 (d, *J* = 7.2 Hz, 1H, ArH), 7.58 (d, *J* = 7.2 Hz, 1H, ArH), 7.60 (s, 1H, ArH), 7.67 (d, *J* = 8.2 Hz, 1H, ArH), 7.70 (d, *J* = 8.2 Hz, 1H, ArH), 8.12 (s, 1H, ArH), 13.20 (s, 1H, N*H*), 14.20 (s, 1H, O*H*); ^{13}C NMR (DMSO-d_6): δ 19.6, 19.9, 56.6, 88.9, 100.8, 103.3, 124.3, 125.5, 125.6, 126.5, 126.9, 130.8, 131.1, 131.3, 138.8, 139.8, 140.0, 147.0, 149.0, 162.9, 164.0, 165.0, 174.9, 180.0, 189.9; ms (EI): *m/z* 440 (20), 368 (14), 358 (29), 253 (9), 233 (69), 207 (100), 85 (12), 69 (20). *Anal.* Calcd. for $C_{23}H_{24}N_2O_7$ (440.45): C, 60.52; H, H 5.30; N, 6.14. Found: C, 61.07; H, 5.61; N, 6.39.

General procedure for the synthesis of *N*-aryl-4-hydroxycoumarin-3-carbothioamides (5a,b) and *N,N′*-diaryl-4-hydroxycoumarin-3-carboximidamides (6a,b). Aryliso-thiocyanates (15 mmol) was added to a stirred solution of 0.81 g (5 mmol) of 4-hydroxycoumarin **4** and 0.8 mL (5 mmol) of triethylamine dissolved in 10 mL of DMSO. The reaction mixture was stirred at room temperature for 15 h. After the addition of 50 mL of cold water, the precipitate thus formed was filtered and washed several times with a (1:1) mixture of diethyl ether:light petroleum. The solid was in each case recrystallized from isopropyl alcohol giving *N,N′*-diaryl-4-hydroxycoumarin-3-carboximidamides **6a,b**: **6a**, 979.0 mg (55%); **6b**, 1.15 g (45%).

The aqueous layer was acidified with HCl 1*N* (pH = 4–5). After vigorous stirring at room temperature for 1.5 h, the precipitate thus formed was collected by filtration and washed several times with diethyl ether. The solid was in each case recrystallized from isopropyl alcohol giving *N*-aryl-4-hydroxycoumarin-3-carbothioamides **5a,b**: **5a**, 445.5 mg (30%); **5b**, 659.8 mg (35%).

4-Hydroxy-N-phenylcoumarin-3-carbothioamide (5a). This compound was obtained as yellow powder, mp 145–146°C; ^{1}H NMR (CDCl$_3$): δ 6.88–7.54 (m, 5H, ArH), 7.68–8.17 (m, 4H, ArH), 13.35 (s, 1H, N*H*), 17.60 (s, 1H, O*H*); ^{13}C NMR (CDCl$_3$): δ 98.2, 117.0, 124.1, 125.4, 126.2, 128.1, 128.9, 129.5, 135.7, 137.7, 152.5, 163.6, 175.1 (C—OH), 189.1 (C=S), ms (ESI+): *m/z* 320 [100, (M+Na)$^+$], 298 [45, (M+H)$^+$]. *Anal.* Calcd. for $C_{16}H_{11}NO_3S$ (297.33): C, 64.63; H, 3.73; N, 4.71. Found: C, 64.68; H, 3.71; N, 4.71.

N-(4-Bromophenyl)-4-hydroxycoumarin-3-carbothioamide (5b). This compound was obtained as yellow powder, mp 270–271°C; ^{1}H NMR (CDCl$_3$): δ 6.75 (d, 2H, *J* = 9.8 Hz, ArH), 7.17 (d, 2H, *J* = 9.8 Hz, ArH), 7.31 (t, 1H, *J* = 9.0 Hz, ArH), 7.37 (d, 1H, *J* = 9.0 Hz, ArH), 7.69 (t, 1H, *J* = 9.0 Hz, ArH), 8.12 (d, 1H, *J* = 9.0 Hz, ArH), 13.34 (s, 1H, N*H*), 17.45 (s, 1H, O*H*); ^{13}C NMR (CDCl$_3$): δ 97.3, 116.0, 123.7, 125.3, 126.8, 131.2, 131.7, 134.7, 135.7, 136.0, 151.5, 162.7, 179.4 (C—OH), 188.4 (C=S); ms (ESI+): *m/z* 400 [26, (M+Na)$^+$, ^{81}Br], 398 [29, (M+Na)$^+$, ^{79}Br], 378 [96, (M+H)$^+$, ^{81}Br], 376 [100, (M+H)$^+$, ^{79}Br]. *Anal.* Calcd. for $C_{16}H_{10}BrNO_3S$ (376.23): C, 51.08; H, 2.68; N, 3.72. Found: C, 51.39; H, 3.04; N, 3.95.

4-Hydroxy-N,N′-diphenylcoumarin-3-carboximidamide (6a). This compound was obtained as white powder, mp 179–180°C; ^{1}H NMR (CDCl$_3$): δ 6.82–7.68 (m, 10 H, ArH), 8.05–8.10 (m, 4H, ArH), 13.30 (s, 1H, N*H*), 17.54 (s, 1H, O*H*); ^{13}C NMR (CDCl$_3$): δ 89.3, 97.7, 116.2, 116.5, 120.7, 123.6, 124.0, 124.9, 125.7, 125.8, 127.6, 128.4, 129.0, 135.2, 136.0, 137.2, 152.0, 152.6, 158.7, 163.0, 165.9, 174.6, 179.6, 188.6; IR: ν (cm^{-1}) 3479, 3407, 3235, 1617, 1381, 1048, 754; ms (ESI+): *m/z* 379 [80, (M+Na)$^+$], 357 [100, (M+H)$^+$]. *Anal.* Calcd. for $C_{22}H_{16}N_2O_3$ (356.34): C, 74.15; H, 4.53; N, 7.86. Found: C, 73.60; H, 4.52; N, 7.88.

N,N′-Di(4-bromophenyl)-4-hydroxycoumarin-3-carboximidamide (6b). This compound was obtained as white powder, mp 235–236°C; ^{1}H NMR (CDCl$_3$): δ 6.74 (d, 2H, *J* = 9.6 Hz, ArH), 7.17 (d, 2H, *J* = 8.7 Hz, ArH), 7.28 (d, 1H, *J* = 9.3 Hz, ArH), 7.31 (d, 2H, *J* = 8.7 Hz, ArH), 7.37 (t, 1H, *J* = 9.3 Hz, ArH), 7.55 (d, 2H, *J* = 9.6 Hz, ArH), 7.69 (t, 1H, *J* = 9.3 Hz, ArH), 8.12 (d, 1H, *J* = 9.3 Hz, ArH), 13.35 (s, 1H, N*H*), 17.46 (s, 1H, O*H*); ^{13}C NMR (CDCl$_3$): δ 89.4, 97.4, 116.1, 122.2, 123.8, 124.5, 124.7, 126.9, 131.3, 135.7, 149.2, 151.6, 158.7, 162.7, 166.0, 174.3, 180.2, 189.5; ms (EI): *m/z* 512 (40), 449 (9), 447 (10), 359 (18), 357 (20), 216 (15), 215 (100), 214 (15), 213 (99), 183 (3.9), 181 (4), 158 (2.5), 156 (3), 155 (25), 143 (2), 134 (50), 117 (2), 107 (9), 76 (8). *Anal.*

Calcd. for $C_{22}H_{14}Br_2N_2O_3$ (514.17): C, 51.39; H, 2.74; N, 5.45. Found: C, 51.64; H, 2.80; N, 5.51.

General procedure for the synthesis of 4-acetoacetyl-3-arylamino-4,5-dihydro-5*H*-pyrazol-5-ones (10a–c). Acetic acid (10 mL) and 5 mL ethanol were added to a mixture of *N*-aryl-4-hydroxy-6-methyl-2*H*-pyran-2-one-3-carbothioamides **2a–c** (10 mmol) and 5 mL (0.1 mol) of hydrazine hydrate. The reaction mixture was refluxed for 5 h and poured into crushed ice, and then the solid was collected by filtration, washed with water, and with a (1:1) mixture of water:ethanol. The solid was in each case recrystallized from A (1:1) mixture of ethanol:acetone giving 4-acetoacetyl-3-arylamino-4,5-dihydro-5*H*-pyrazol-5-ones **10a–c** (which are in equilibrium with the corresponding enolic form): **10a**, 2.47 g (95%); **10b**, 3.21 g (95%); **10c**, 3.13 g (98%).

4-Acetoacetyl-3-phenylamino-4,5-dihydro-5H-pyrazol-5-one (10a). This compound was obtained as green powder, mp 179–180°C; ^{1}H NMR ($CDCl_3$): δ 2.06 (s, CH_3-enol), 2.32 (s, CH_3-dione), 3.90 (s, 1H, H-4), 4.40 (s, CH_2-dione), 6.11 (s, C*H*-enol), 7.31–7.53 (m, 5H, ArH), 8.60 (s, 1H, N*H*), 13.15 (s, 1H, N*H*), 16.70 (s, 1H, O*H*); ^{13}C NMR ($CDCl_3$): δ 20.7, 64.0, 97.2, 104.0, 126.0, 127.6, 129.6, 137.3, 164.2, 164.5, 177.9, 188.3; ms (EI): *m/z* 260 [100, $(M+H)^+$], 228 (80), 217 (9), 203 (7), 175 (20), 93 (67), 77 (47), 85 (50), 56 (14), 43 (20). *Anal.* Calcd. for $C_{13}H_{13}N_3O_3$ (259.26): C, 60.23; H, 5.02; N, 16.22. Found: C, 60.73; H, 5.38; N, 16.45.

4-Acetoacetyl-3-(4-bromophenylamino)-4,5-dihydro-5H-pyrazol-5-one (10b). This compound was obtained as green powder, mp 200–202°C; ^{1}H NMR ($CDCl_3$): δ 2.07 (s, CH_3-enol), 2.32 (s, CH_3-dione), 3.91 (s, 1H, H-4), 4.40 (s, CH_2-dione), 6.11 (s, C*H*-enol), 7.40 (d, 2H, $J = 9.1$ Hz, ArH), 7.56 (d, 2H, $J = 9.1$ Hz, ArH), 8.62 (s, 1H, N*H*), 13.15 (s, 1H, N*H*), 16.50 (s, 1H, O*H*); ^{13}C NMR ($CDCl_3$): δ 20.1, 65.0, 97.3, 104.0, 121.0, 127.3, 132.2, 136.3, 164.1, 164.7, 178.0, 188.6; ms (ESI+): *m/z* 362 [96, $(M+Na)^+$, ^{81}Br], 360 [100, $(M+Na)^+$, ^{79}Br], 340 [45, $(M+H)^+$, ^{81}Br], 338 [50, $(M+H)^+$, ^{79}Br]. *Anal.* Calcd. for $C_{13}H_{12}BrN_3O_3$ (338.16): C, 46.29; H, 3.56; N, 12.46. Found: C, 45.74; H, 3.20; N, 12.23.

4-Acetoacetyl-3-(2,5-dimethoxyphenylamino)-4,5-dihydro-5H-pyrazol-5-one (10c). This compound was obtained as green powder, mp 186–187°C; ^{1}H NMR ($CDCl_3$): δ 2.07 (s, CH_3-enol), 2.33 (s, CH_3-dione), 3.86 (s, 1H, H-4), 3.93 (s, 3H, OCH_3), 3.95 (s, 3H, OCH_3), 4.30 (s, CH_2-dione), 6.13 (s, C*H*-enol), 7.37 (d, 1H, $J = 8.9$ Hz, ArH), 7.49 (d, 1H, $J = 8.9$ Hz, ArH), 7.70 (s, 1H, ArH), 7.90 (s, 1H, N*H*), 13.00 (s, 1H, N*H*), 16.40 (s, 1H, O*H*); ^{13}C NMR ($CDCl_3$): δ 20.1, 54.0, 58.0, 65.0, 104.0, 122.7, 125.2, 127.5, 131.3, 132.9, 136.6, 164.1, 164.9, 178.0, 188.0; ms (ESI+): *m/z* 342 [100, $(M+Na)^+$], 320 [33, $(M+H)^+$]. *Anal.* Calcd. for $C_{15}H_{17}N_3O_5$ (319.31): C, 56.43; H, 5.33; N, 13.16. Found: C, 56.98; H, 5.34; N, 13.70.

A facile synthesis of trisubstituted allyl thiols and allyl thiocarbamates has been accomplished from Baylis-Hillman adducts through bromination, thiocyanation, and acid-assisted hydrolysis reaction.

J. Heterocyclic Chem., **46**, 23 (2009).

INTRODUCTION

Thiols have attained significant importance as synthetic intermediates for valuable sulfur-containing compounds [1]. A number of reports have appeared on the potential applications of thiol functionality in various scientific disciplines such as pharmaceutical chemistry [2], self-assembled monolayers [3], nanoparticles [4], and conducting polymers [5]. Also, *S*-alkyl thiocarbamates are an important class of compounds that have received considerable attention [6,7] because of their numerous biological effects including anesthetic [8], fungicidal [9], bactericidal [9,10], pesticidal [11,12], and antiviral [13]. Despite the aforementioned reasons, thiocarbamates are most noted for their use as commercial herbicides [14].

Generally, thiols have been synthesized mainly from alkyl halides with thioacetate ion followed by deacetylation with base [15], disulfides *via* reduction [16], alkenes *via* anti-Markovnikov addition of thiolacetic acid, followed by deacetylation with strong base [17], alcohols *via* refluxing with hydrobromic acid and thiourea, followed by hydrolysis with strong base [18], thiocyanates *via* reduction [19], and thiocarbamates *via* hydrolysis [20]. The most widely used method for the preparation of thiocarbamates makes use of gaseous carbonyl sulfides and an amine, followed by subsequent treatment with base and alkyl halide [12,21], condensation of a thiol with an isocyanate [10], nucleophilic substitution of trichloroacetyl chloride with a thiol, followed by treatment of an amine [22], and the hydration of an organic thiocyanate [23,24]. In view of their significance in organic synthesis, it is still necessary to extend the scope of the allyl thiol and thiocarbamate families and develop new and convenient synthetic routes. Here the Baylis-Hillman (BH) chemistry [25] has been applied for the synthesis of these compounds.

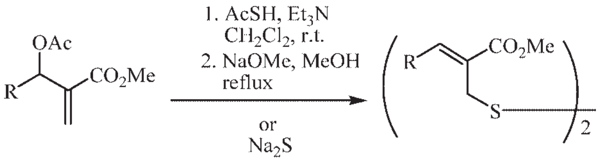
RESULTS AND DISCUSSION

The BH reaction is well known as a powerful carbon–carbon bond forming methods in organic synthesis [26]. Nucleophilic displacement of BH acetates or bromides is an important protocol for the synthesis of trisubstituted alkenes. Although there exist several methods for the nucleophilic displacement of BH acetates or bromides with various reagents [27], displacement with sulfur nucleophiles is limited [28].

Recently, we reported substitution reaction of BH acetates **1** with thiolacetic acid followed by deacetylation with base [29], and with sodium sulfide [30] to give the symmetric diallyl disulfides **2**, respectively, as shown in Scheme 1. No traces of the intended allyl thiols were produced. Although the literature has reported some interesting schemes to obtain allyl thiols, we felt that thiols can be obtained from allyl thiocyanates.

The known allyl thiocyanates **4** were obtained in high yields by displacement of 2-(bromomethyl)alkenoates with sodium thiocyanate [31], derived from BH adducts with *N*-bromosuccinimide-dimethyl sulfide [32]. Treatment of allyl thiocyanates **4** with 95% sulfuric acid–acetic acid (9:1, v/v) at −5 to 0°C produced allyl thiocarbamates **5** in 54–96% yields. On hydrolysis reaction of **5**

Scheme 1



1 2

with one equivalent of *p*-toluenesulfonic acid monohydrate (PTSA) in toluene and dichloromethane (9:1, v/v) reflux temperature, allyl thiols **6** were obtained in 75–94% yields (Scheme 2, Table 1). When using 0.1 equivalent of PTSA, the reaction was sluggish and the yield was low (Entries 1, 2, 7). Direct one-pot transformation of thiocyanate **4** to thiol **6** was unsuccessful with PTSA in refluxing toluene. All the products are unambiguously characterized using infrared spectra, ^{1}H and ^{13}C NMR data. In the ^{1}H NMR spectra, the characteristic chemical shift of the thiol protons of **6** were found at $\delta = 2.05$–2.12 as a triplet ($J = 7.6$–8.3 Hz), the methylene protons were observed at $\delta = 3.33$–3.60 as a doublet ($J = 7.6$–8.3 Hz), and the methine protons resonated at $\delta = 7.63$–7.92 as a singlet. Their infrared spectra showed absorption at 2557–2593 cm^{-1} for the thiol band.

CONCLUSION

In conclusion, a new method for the synthesis of trisubstituted allyl thiols from BH adducts has been developed through bromination, thiocyanation, and acid-assisted hydrolysis reaction.

EXPERIMENTAL

Silica gel 60 (70–230 mesh ASTM) used for column chromatography was supplied by E. Merck. Analytical thin-layer chromatography (TLC) was performed on Merck silica gel 60 F$_{254}$ TLC plates. Melting points were measured by an Electrothermal melting point apparatus and were uncorrected. Microanalysis was obtained using a Thermo Electron Corporation Flash EA 1112 element analyzer. Infrared spectra were recorded with a Nicolet Magna 550 FTIR spectrometer. The ^{1}H and ^{13}C NMR spectra were measured on a Gemini 300 spectrometer using deuteriochloroform. All chemical shifts are reported in parts per million relative to tetramethylsilane. The coupling constants (*J*) are expressed in Hertz.

The known methyl 3-aryl-2-(thiocyanatomethyl)propenoates **4** were prepared according to the literature procedure [31].

General procedure for the preparation of methyl (*Z*)-3-aryl-2-(carbamoylthiomethyl)propenoates 5. To an ice-cold mixture of 95% sulfuric acid (9 mL) and acetic acid (1 mL), allyl thiocyanate **4** (2 mmoles) was added in small portions for 15 min under stirring at −5 to 0°C. After dissolution of **4**, the mixture was stirred at room temperature for 0.5–2.5 h and then poured onto crushed ice. The white precipitate was collected by suction filtration, dried, and crystallized from dichloromethane and petroleum ether to give compound **5**.

The physical and spectral data of **5** prepared by this general method are as follows.

Methyl (Z)-2-carbamoylthiomethyl-3-phenylpropenoate (5a). Reaction time: 1 h; white solid; yield: 75%; mp: 99–100°C; ir (potassium bromide): 3419, 3327, 3182, 1707, 1675, 1597 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 3.85 (s, 3 H, OCH$_3$), 4.11 (s, 2 H, CH$_2$), 5.58 (s, 2 H, NH$_2$), 7.37–7.47 (m, 5 H, aromatic), 7.82 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 27.8, 52.4, 127.1, 128.7, 129.3, 129.5, 134.4, 142.5, 167.6, 168.4. *Anal.* Calcd. for $C_{12}H_{13}NO_3S$: C, 57.35; H, 5.21; N, 5.57; S, 12.76. Found: C, 57.20; H, 5.07; N, 5.39; S, 12.53.

Methyl (Z)-2-carbamoylthiomethyl-3-(4-chlorophenyl)propenoate (5b). Reaction time: 1 h; white solid; yield: 84%; mp: 108–109°C; ir (potassium bromide): 3396, 3298, 3202, 1707, 1655, 1619, 1592 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 3.85 (s, 3 H, OCH$_3$), 4.07 (s, 2 H, CH$_2$), 5.50 (s, 2 H, NH$_2$), 7.40 (s, 4 H, aromatic), 7.75 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 27.7, 52.4, 127.7, 129.0, 130.9, 132.8, 135.3, 141.0, 167.4, 168.2. *Anal.* Calcd. for $C_{12}H_{12}ClNO_3S$: C, 50.44; H, 4.23; N, 4.90; S, 11.22. Found: C, 50.19; H, 4.08; N, 5.20; S, 10.96.

[a] Values in parentheses indicate when 0.1 equivalent of PTSA was used.

Methyl (Z)-2-carbamoylthiomethyl-3-(2-chlorophenyl)propenoate (5c). Reaction time: 2.5 h; white solid; yield: 85%; mp: 102–103°C; ir (potassium bromide): 3419, 3326, 3308, 1698, 1662, 1607, 1438 cm^{-1}; ^1H NMR (deuteriochloroform): δ 3.87 (s, 3 H, OCH_3), 3.97 (s, 2 H, CH_2), 5.42 (s, 2 H, NH_2), 7.30–7.46 (m, 4 H, aromatic), 7.89 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 27.7, 52.5, 126.8, 129.5, 129.6, 130.1, 130.2, 133.2, 134.1, 139.3, 167.0, 168.1. *Anal.* Calcd. for $C_{12}H_{12}ClNO_3S$: C, 50.44; H, 4.23; N, 4.90; S, 11.22. Found: C, 50.22; H, 4.12; N, 4.76; S, 11.03.

Methyl (Z)-3-(2-bromophenyl)-2-(carbamoylthiomethyl)propenoate (5d). Reaction time: 2 h; white solid; yield: 86%; mp: 93–95°C; ir (potassium bromide): 3418, 3334, 1712, 1673, 1465, 1435 cm^{-1}; ^1H NMR (deuteriochloroform): δ 3.87 (s, 3 H, OCH_3), 3.94 (s, 2 H, CH_2), 5.47 (s, 2 H, NH_2), 7.20–7.39 (m, 3 H, aromatic), 7.62–7.64 (m, 1 H, aromatic), 7.82 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 27.6, 52.5, 124.0, 127.4, 129.3, 130.2, 130.3, 132.8, 135.1, 141.4, 167.0, 168.0. *Anal.* Calcd. for $C_{12}H_{12}BrNO_3S$: C, 43.65; H, 3.66; N, 4.24; S, 9.71. Found: C, 43.42; H, 3.40; N, 4.38; S, 9.52.

Methyl (Z)-2-(carbamoylthiomethyl)-3-(2-fluorophenyl)propenoate (5e). Reaction time: 1 h; white solid; yield: 87%; mp: 102–104°C; ir (potassium bromide): 3421, 3323, 3310, 3193, 1701, 1662, 1610, 1485, 1438 cm^{-1}; ^1H NMR (deuteriochloroform): δ 3.86 (s, 3 H, OCH_3), 4.04 (s, 2 H, CH_2), 5.42 (s, 2 H, NH_2), 7.09–7.49 (m, 4 H, aromatic), 7.85 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 27.8, 52.4, 115.6 (J = 22.0 Hz), 122.5 (J = 13.4 Hz), 124.2, 129.6, 130.2, 131.0, 134.7, 160.4 (J = 250 Hz), 167.0, 168.3. *Anal.* Calcd. for $C_{12}H_{12}FNO_3S$: C, 53.52; H, 4.49; N, 5.20; S, 11.91. Found: C, 53.70; H, 4.37; N, 5.02; S, 11.76.

Methyl (Z)-2-(carbamoylthiomethyl)-3-(4-nitrophenyl)propenoate (5f). Reaction time: 1 h; white solid; yield: 96%; mp: 144–145°C; ir (potassium bromide): 3401, 3324, 1717, 1633, 1592, 1517, 1345 cm^{-1}; ^1H NMR (dimethyl sulfoxide-d_6): δ 3.78 (s, 3 H, OCH_3), 3.90 (s, 2 H, CH_2), 7.66 (s, 2 H, NH_2), 7.73 (s, 1H, CH), 7.76 (d, 2 H, J = 8.8 Hz, aromatic), 8.27 (d, 2 H, J = 8.8 Hz, aromatic); ^{13}C NMR (dimethyl sulfoxide-d_6): δ 26.2, 52.4, 123.6, 130.6, 131.6, 137.9, 141.1, 147.2, 165.7, 166.6. *Anal.* Calcd. for $C_{12}H_{12}N_2O_5S$: C, 48.64; H, 4.08; N, 9.45; S, 10.82. Found: C, 48.39; H, 4.27; N, 9.28; S, 10.63.

Methyl (Z)-2-(carbamoylthiomethyl)-3-(2-nitrophenyl)propenoate (5g). Reaction time: 0.5 h; white solid; yield: 89%; mp: 113–114°C; ir (potassium bromide): 3436, 3335, 3175, 1712, 1680, 1606, 1522, 1437, 1344 cm^{-1}; ^1H NMR (deuteriochloroform): δ 3.79 (s, 2 H, CH_2), 3.87 (s, 3 H, OCH_3), 5.37 (s, 2 H, NH_2), 7.37–7.73 (m, 3 H, aromatic), 8.06 (s, 1 H, CH), 8.21–8.24 (m, 1 H, aromatic); ^{13}C NMR (deuteriochloroform): δ 27.3, 52.5, 124.9, 129.4, 129.5, 130.9, 131.2, 133.7, 139.2, 147.3, 166.7, 167.8. *Anal.* Calcd. for $C_{12}H_{12}N_2O_5S$: C, 48.64; H, 4.08; N, 9.45; S, 10.82. Found: C, 48.40; H, 3.88; N, 9.20; S, 10.59.

Methyl (Z)-2-(carbamoylthiomethyl)-3-(4-methylphenyl)propenoate (5h). Reaction time: 1 h; white solid; yield: 54%; mp: 119–120°C; ir (potassium bromide): 3376, 3298, 1699, 1678, 1616, 1436 cm^{-1}; ^1H NMR (deuteriochloroform): δ 2.38 (s, 3 H, CH_3), 3.84 (s, 3 H, OCH_3), 4.13 (s, 2 H, CH_2), 5.49 (s, 2 H, NH_2), 7.23 (d, 2 H, J = 7.9 Hz, aromatic), 7.37 (d, 2 H, J = 7.9 Hz, aromatic), 7.80 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.4, 28.0, 52.3, 126.0, 129.5, 129.7, 131.5, 139.6, 142.6, 167.8, 168.6. *Anal.* Calcd. for $C_{13}H_{15}NO_3S$: C, 58.85; H, 5.70; N, 5.28; S, 12.09. Found: C, 58.61; H, 5.43; N, 5.03; S, 12.31.

General procedure for the preparation of methyl (Z)-3-aryl-2-(mercaptomethyl)propenoates 6. A stirred solution of thiocarbamate **5** (1 mmole) and PTSA (0.19 g, 1 mmole) in a mixture of toluene (9 mL) and dichloromethane (1 mL) was heated at reflux temperature for 4–10 h. After cooling to room temperature, the mixture was diluted with saturated aqueous sodium bicarbonate solution (5 mL) and extracted with dichloromethane (3 × 10 mL). The combined organic layers were dried over anhydrous magnesium sulfate and the solvent was evaporated *in vacuo.* The resulting mixture was chromatographed on silica gel eluting with hexane/ethyl acetate (15:1) to produce **6**.

The physical and spectral data of **6** prepared by this general method are as follows.

Methyl (Z)-2-(mercaptomethyl)-3-phenylpropenoate (6a). Reaction time: 7 h; colorless oil; yield: 94%; ir (neat): 2571, 1712, 1628, 1493, 1447, 1434 cm^{-1}; ^1H NMR (deuteriochloroform): δ 2.06 (t, 1 H, J = 7.9 Hz, SH), 3.60 (d, 2 H, J = 7.9 Hz, CH_2), 3.87 (s, 3 H, OCH_3), 7.35–7.45 (m, 5 H, aromatic), 7.70 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.2, 52.2, 128.7, 129.0, 129.3, 131.8, 134.8, 139.7, 167.4. *Anal.* Calcd. for $C_{11}H_{12}O_2S$: C, 63.43; H, 5.81; S, 15.40. Found: C, 63.19; H, 5.75; S, 15.27.

Methyl (Z)-3-(4-chlorophenyl)-2-(mercaptomethyl)propenoate (6b). Reaction time: 4 h; colorless oil; yield: 89%; ir (neat): 2573, 1712, 1630, 1591, 1489, 1435 cm^{-1}; ^1H NMR (deuteriochloroform): δ 2.06 (t, 1 H, $J = 7.6$ Hz, SH), 3.55 (d, 2 H, $J = 7.6$ Hz, CH_2), 3.86 (s, 3 H, OCH_3), 7.36–7.41 (m, 4 H, aromatic), 7.63 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.1, 52.3, 129.0, 130.7, 132.3, 133.2, 135.0, 138.3, 167.1. *Anal*. Calcd. for $C_{11}H_{11}ClO_2S$: C, 54.43; H, 4.57; S, 13.21. Found: C, 54.22; H, 4.29; S, 12.90.

Methyl (Z)-3-(2-chlorophenyl)-2-(mercaptomethyl)propenoate (6c). Reaction time: 10 h; colorless oil; yield: 83%; ir (neat): 2582, 1714, 1633, 1468, 1436 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ2.08 (t, 1 H, $J = 8.3$ Hz, SH), 3.45 (d, 2 H, $J = 8.3$ Hz, CH_2), 3.88 (s, 3 H, OCH_3), 7.31–7.48 (m, 4 H, aromatic), 7.76 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.3, 52.4, 126.9, 129.7, 129.9, 130.0, 133.5, 133.6, 134.1, 136.5, 166.8. *Anal*. Calcd. for $C_{11}H_{11}ClO_2S$: C, 54.43; H, 4.57; S, 13.21. Found: C, 54.31; H, 4.40; S, 13.03.

Methyl (Z)-3-(2-bromophenyl)-2-(mercaptomethyl)propenoate (6d). Reaction time: 5 h; colorless oil; yield: 77%; ir (neat): 2574, 1714, 1633, 1464, 1434 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.07 (t, 1 H, $J = 8.0$ Hz, SH), 3.43 (d, 2 H, $J = 8.0$ Hz, CH_2), 3.89 (s, 3 H, OCH_3), 7.23–7.65 (m, 4 H, aromatic), 7.70 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.2, 52.4, 124.0, 127.5, 130.0, 130.2, 132.9, 133.3, 135.4, 138.7, 166.8. *Anal*. Calcd. for $C_{11}H_{11}BrO_2S$: C, 46.01; H, 3.86; S, 11.17. Found: C, 45.88; H, 3.60; S, 11.31.

Methyl (Z)-3-(2-fluorophenyl)-2-(mercaptomethyl)propenoate (6e). Reaction time: 5 h; white solid; yield: 78%; mp 32–34°C; ir (potassium bromide): 2557, 1708, 1632, 1608, 1482, 1461, 1434 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.08 (t, 1 H, $J = 7.9$ Hz, SH), 3.52 (d, 2 H, $J = 7.9$ Hz, CH_2), 3.87 (s, 3 H, OCH_3), 7.08–7.51 (m, 4 H, aromatic), 7.72 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.4, 52.3, 115.8 ($J =$ 22.0 Hz), 122.8 ($J = 13.4$ Hz), 130.1, 130.8, 130.9, 132.1, 133.8, 160.4 ($J = 250$ Hz), 166.8. *Anal*. Calcd. for $C_{11}H_{11}FO_2S$: C, 58.39; H, 4.90; S, 14.17. Found: C, 58.52; H, 4.72; S, 14.02.

Methyl (Z)-2-(mercaptomethyl)-3-(4-nitrophenyl)propenoate (6f). Reaction time: 6 h; yellowish solid; yield: 85%; mp 78–80°C; ir (potassium bromide): 2593, 1717, 1633, 1592, 1517, 1434, 1345 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.12 (t, 1 H, $J = 7.7$ Hz, SH), 3.53 (d, 2 H, $J = 7.7$ Hz, CH_2), 3.90 (s, 3 H, OCH_3), 7.60 (d, 2 H, $J = 8.3$ Hz, aromatic), 7.70 (s, 1 H, CH), 8.28 (d, 2 H, $J = 8.8$ Hz, aromatic); ^{13}C NMR (deuteriochloroform): δ 21.0, 52.6, 123.9, 130.0, 134.9, 136.8, 141.3, 147.6, 166.5. *Anal*. Calcd. for $C_{11}H_{11}NO_4S$: C, 52.16; H, 4.38; N, 5.53; S, 12.66. Found: C, 51.90; H, 4.02; N, 5.32; S, 12.37.

Methyl (Z)-2-(mercaptomethyl)-3-(2-nitrophenyl)propenoate (6g). Reaction time: 4 h; yellowish solid; yield: 94%; mp 48–49°C; ir (potassium bromide): 2569, 1721, 1635, 1605, 1569, 1513, 1429, 1337 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.08 (t, 1 H, $J = 8.2$ Hz, SH), 3.33 (d, 2 H, $J = 8.2$ Hz, CH_2), 3.89 (s, 3 H, OCH_3), 7.53–7.74 (m, 3 H, aromatic), 7.92 (s, 1 H, CH), 8.18–8.21 (m, 1 H, aromatic); ^{13}C NMR (deuteriochloroform): δ 21.2, 52.4, 125.1, 129.6, 130.8, 131.0, 133.1, 133.8, 136.4, 147.4, 166.4. *Anal*. Calcd. for $C_{11}H_{11}NO_4S$: C, 52.16; H, 4.38; N, 5.53; S, 12.66. Found: C, 52.03; H, 4.11; N, 5.42; S, 12.82.

Methyl (Z)-2-(mercaptomethyl)-3-(4-methylphenyl)-propenoate (6h). Reaction time: 7 h; colorless oil; yield: 75%; ir (neat): 2566, 1710, 1627, 1608, 1511, 1435 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.05 (t, 1 H, $J = 7.6$ Hz, SH), 2.38 (s, 3 H, CH_3), 3.60 (d, 2 H, $J = 7.6$ Hz, CH_2), 3.85 (s, 3H, OCH_3), 7.23 (d, 2 H, $J = 7.9$ Hz, aromatic), 7.35 (d, 2 H, $J =$ 7.9 Hz, aromatic), 7.67 (s, 1 H, CH); ^{13}C NMR (deuteriochloroform): δ 21.3, 21.4, 52.2, 129.4, 129.5, 130.9, 131.9, 139.3, 139.8, 167.5. *Anal*. Calcd. for $C_{12}H_{14}O_2S$: C, 64.83; H, 6.35; S, 14.42. Found: C, 64.61; H, 6.22; S, 14.28.

Condensation of 3-cyano-7-diethylamino-*N*-ethoxycarbonyl-iminocoumarin with various hydrazides as N-nucleophiles gave a new series of 2-oxo-2*H*-1-benzopyrano[2,3-*d*]pyrimidines bearing an acylhydrazino fragment in the 4-position. The structures of the products obtained were characterized using IR, ^{1}H NMR, ^{13}C NMR and elemental analysis. The optical properties were reported for three of these compounds.

J. Heterocyclic Chem., **46**, 28 (2009).

INTRODUCTION

Benzopyranopyrimidines have been increasingly investigated because of their important biological properties. They exhibit for example anticancer [1,2], analgesic [3], and antithrombotic [4] activities. In addition, benzopyranopyrimidines could also be of interest because their structure is close to that of rhodols, rhodamines, and fluoresceins [5], which constitute a well-known class of dyes. Different routes have been described in the literature for the synthesis of this class of condensed heterocycles [6–8]. As part of our investigations on the synthesis of benzopyranopyrimidines, we have reported previously [9], a new method based on the transformation of 3-cyano-iminocoumarins under the action of primary aliphatic and aromatic amines, on heating in methanol. We have shown that the reaction proceeded by an original mechanism that involves several consecutive steps including nucleophilic attack of the iminolactone ring, pyran ring opening, E/Z isomerization, and subsequent cyclization. As a continuation of our studies on the reactivity of 3-cyano-iminocoumarins with N-nucleophiles, we wish to report in this article on the condensation of 3-cyano-7-diethylamino-*N*-ethoxycarbonyl-iminocoumarin **1** with different hydrazides. The aim is to obtain a new series of benzopyranopyrimidines incorporating an acylhydrazino fragment in the 4-position, since the presence of this function could improve physiological activities. The optical properties of some benzopyranopyrimidines were also regarded.

RESULTS AND DISCUSSION

Iminocoumarin **1** was obtained by Knoevenagel condensation followed by *N*-ethoxycarbonylation as previously described in [9]. The condensation of this compound with various hydrazides (**2–11**, see Table 1) was studied, first focusing on a specific system, namely **1** and benzoic hydrazide **2** (Scheme 1), to determine the best conditions for synthesis. The progress of the reaction was followed by TLC analysis and by the changes in FTIR spectra of samples taken at regular intervals from the reaction medium. Thus, the FTIR spectra showed the progressive disappearance of the original peaks at 2214 and 1724 cm^{-1} arising from the C≡N and COOEt functions, respectively, as well as the appearance of characteristic peaks of the pyrimidine moiety at 1632 cm^{-1} (C=N), 1664 cm^{-1} (NH—NH—C=O) and 1644 cm^{-1} (C=0). The best result was obtained by refluxing the mixture of **1** and **2** in methanol during 2 h. 4-(2-Benzoylhydrazino)-8-diethylamino-2-oxo-2*H*-1-benzopyrano[*2,3-d*]pyrimidine (**11**) was thus obtained with a yield of 92% (Scheme 1). This product was isolated by simple filtration with high purity as confirmed by ^{1}H NMR, which showed the absence of resonance at 1.37 and 4.32 ppm arising from the original ethoxy fragment, and the presence of two peaks in the region of 10–11 ppm indicating the presence of the NH—NH—CO function.

When the reaction was carried out in acetic acid at room temperature the condensation of **1** with **2** did not

Table 1

Benzopyranopyrimidines obtained by condensation of iminocoumarin (**1**) with various hydrazides.

Hydrazide (RC(O)NH NH_2)	R	Benzopyranopyrimidine	Time (h)	Yield (%)
2		11	2	92
3		12	3	63
4		13	7	52
5		14	1	87
6		15	2	75
7		16	8	48
8		17	16	70
9	CH_3	18	1	45
10		19	3	85

Reaction time and yield according to the nature of substituent R.

take place and no benzopyranopyrimidine **11** was detected. It was found that **1** reacted intramolecularly in these conditions to produce the oxidized derivative **11a** (Scheme 1). This type of compound was reported by Blythin *et al.* [10] when carrying out the Knoevenagel reaction with salicylaldehydes and *N*-cyanoacety-lurethane.

On sight of these results, compound **1** was then condensed with hydrazides **3–10** at reflux in methanol and the progress of the reaction was monitored by TLC. The reagent specific structure induced changes in reactivity and the reaction time had to be modified (Table 1).

In each case, the reaction afforded the corresponding 4-acylhydrazinobenzopyranopyrimidine **12–19** as shown in Scheme 2 that summarizes the synthesis. The FTIR and NMR data relative to these compounds were in good agreement with their structure. It is interesting to note that the presence of both amine and hydrazide functions in hydrazide **6** could lead to the formation of two isomers (**15** and **15a**) resulting from the interaction of the imidic carbon with the two N-nucleophilic centers in the first step of the mechanism (Scheme 3). However, chromatographic and spectroscopic analyses showed that the iminocoumarin was selectively converted into **15** whereas **15a** was not detected, probably because the amine function is less nucleophilic than the hydrazide function. The structure of **15** was clearly confirmed by the ^1H NMR spectrum, which showed the presence of Ar—NH_2 (s, 2H, 5.71 ppm), NH—NH—CO (s, 1H, 10.16 ppm and s, 1H, 10.60 ppm) and the absence of peak around 4–5 ppm related to the NH_2 group of the hydrazidic fragment.

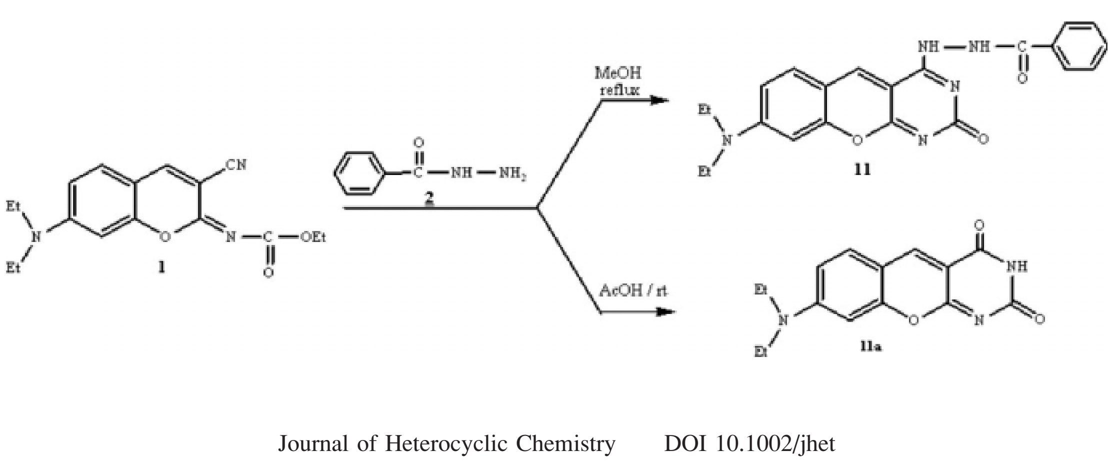
OPTICAL PROPERTIES

The electron conjugated system of benzopyranopyrimidines **11–19** is identical and should be poorly affected by the nature of the R substituent. It can therefore be expected that all these compounds share common spectroscopic behaviour. The optical properties were measured on three of them (namely compounds **12**, **13**, and **15**). The results are gathered in Table 2.

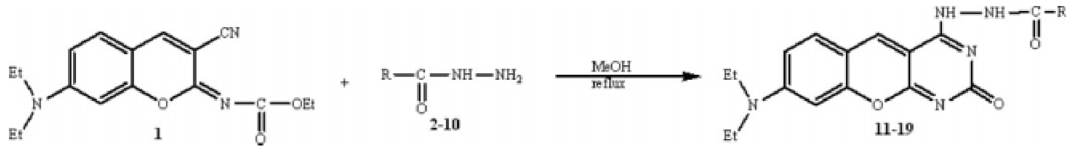
Compounds **12**, **13**, and **15** were poorly soluble in organic solvents. All were studied in dimethylsulfoxide, but only two of them could be dissolved in dichloromethane. The solutions were filtered on paper filter prior to spectroscopic study. However, for most of the samples, the absorption spectrum was particularly wide, with a markedly high baseline. This indicates that in spite of filtration, some particles were present in solution and scattered light.

For each sample, the excitation spectrum was much narrower than the absorption spectrum. For compound **13**, both spectra had almost the same maximum. For **15**

Scheme 1



Scheme 2. General scheme of the synthesis. Substitutent R as described in Table 1.



and **12**, the excitation spectra showed a considerable blue shift reaching 50 nm compared with the absorption spectra. Besides, the excitation spectra did not vary with the emission wavelength, and conversely, the emission spectra were independent of the excitation wavelength. This indicates the presence of only one fluorophore in each solution. The discrepancy between the absorption and excitation spectra could thus be attributed to the presence of nonfluorescent impurities. But, the TLC analyses of the three compounds gave a single spot, so the presence of impurities could be discarded. Consequently, it is most likely that these poorly soluble compounds form nonfluorescent aggregates in solution, these aggregates being particularly visible at long wavelengths on the absorption spectra.

The emission spectra did not show fine resolution. Their maximum was rather close for the three compounds, around 520 nm in DMSO and slightly above 500 nm in dichloromethane. A small solvent effect can thus be noted. The lifetimes were found to be monoexponential, above the nanosecond. The quantum yields were not calculated since the absorption spectra corresponded to two species at least, only one of which is fluorescent. Therefore, the quantum yields measured would have been lower than their actual value.

If comparing the properties of these benzopyranopyrimidines with those of parent compound **1** in the same solvents [11,12], it appears, as could be expected, that cyclization has led to a moderate shift of the absorption and emission wavelengths towards longer wavelengths. In contrast, the fluorescence lifetime is quite similar for the two types of compounds.

CONCLUSION

This article reported the facile synthesis of new 2-oxo-2*H*-1-benzopyrano[*2,3-d*]pyrimidines from the condensation of a 3-cyanoiminocoumarin with various hydrazides. The products were easily purified and obtained with a good yield. Their limited solubility in most of organic solvents could be a drawback for subsequent applications. However, it is possible that these compounds display interesting biological properties, which would deserve further investigations.

EXPERIMENTAL

7-Diethylamino-2-hydroxybenzaldehyde, malonitrile and hydrazides were commercially available from Aldrich. All melting points were determined on an Electrothermal 9100 apparatus. Infrared spectra were registered on a Jasco FT-IR 420 spectrophotometer apparatus using KBr pellets. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker WP 200 spectrometer at 300 MHz in DMSO-d$_6$ with TMS as internal standard (chemical shifts in ppm).

Scheme 3

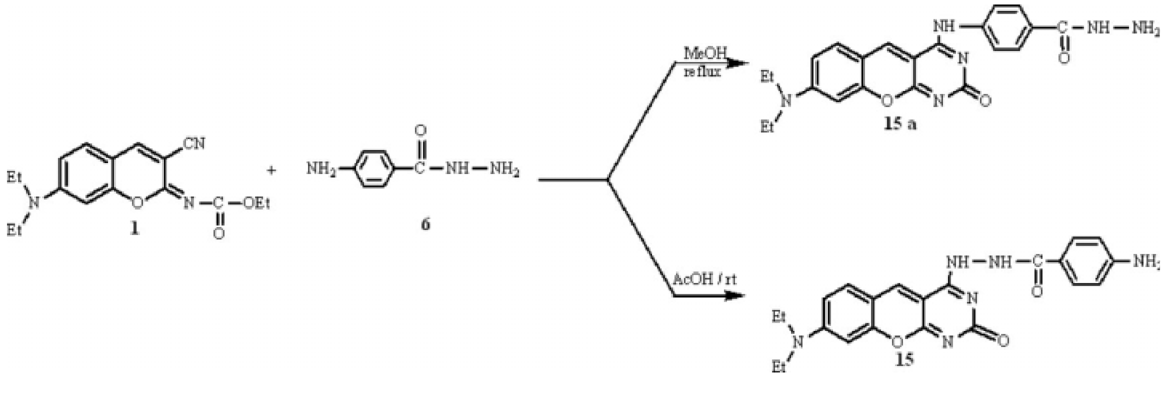


Table 2

Maximum absorption wavelength (λ_{abs}), maximum excitation wavelength (λ_{ex}), maximum emission wavelength (λ_{em}), and fluorescence lifetime (τ) for compounds 12, 13, and 15 in dimethylsulfoxide and dichloromethane.

Compound	λ_{abs} (nm)	λ_{ex} (nm)	λ_{em} (nm)	τ (ns)
12 (DMSO)	504	458	520	2.6 ± 0.3
13 (DMSO)	486	476	518	2.9 ± 0.2
13 (CH_2Cl_2)	484 (508 sh)	480	502	3.2 ± 0.2
15 (DMSO)	508	480	520	1.5 ± 0.2
15 (CH_2Cl_2)	502	451	507	1.9 ± 0.2

UV/vis absorption spectra were recorded on a Hewlett-Packard 8452A diode array spectrophotometer. Steady state fluorescence work was performed on a Photon Technology International (PTI) Quanta Master 1 spectrofluorometer. All excitation and emission spectra were corrected. Fluorescence decay was measured with the stroboscopic technique using a Strobe Master fluorescence lifetime spectrophotometer from PTI. The excitation source was a flash lamp filled with a mixture of nitrogen and helium (30/70). Data were collected over 200 channels with a time-base of 0.1 ns per channel. Analysis of fluorescence decay was performed using the multiexponential method software from PTI. All spectrophotometric measurements were conducted in a thermostated cell at 25°C.

3-Cyano-*N*-ethoxycarbonyl-7-diethylamino iminocoumarin 1. 3-Cyano-*N*-ethoxycarbonyl-7-diethylamino iminocoumarin **1** was prepared as previously described in [9].

General procedure for the synthesis of benzopyranopyrimidines 11–19. A solution of 3-cyano-*N*-ethoxycarbonyl-7-diethylamino iminocoumarin 1 (1.56 g, 5 mmol) and (5 mmol) of hydrazide in 30 mL of absolute methanol was refluxed during the time indicated in Table 1. After complete reaction, the benzopyranopyrimidine obtained was separated by filtration and washed with ethanol. For spectroscopic use, compound 12, 13, and 15 were purified on TLC plates using chloroform as the eluent.

A tandem inter- and intramolecular Pd-catalyzed amination protocol was studied on 4-chloro-3-iodoquinoline and 3-chloro-4-iodoquinoline with different aminohetarenes. Applying this method, ten novel quinoline derivatives and eight new heterocyclic ring systems were synthesized.

J. Heterocyclic Chem., **46**, 33 (2009).

INTRODUCTION

The quinoline-containing polycyclic compounds are expected to have interesting biological activity. Pyrazoloquinoline derivatives are active agents for the treatment of cancer and herpes virus infections [1,2]. Substituted indoloquinolines display biological properties such as antimalarial, antimuscarinic, antibacterial, antiviral, and cytotoxic activities *in vivo*, and significant antitumor properties *in vitro* [3–6].

The aim of this work was to prepare new heterocyclic ring systems, containing the quinoline skeleton. 4-Chloro-3-iodoquinoline (**1**) and 3-chloro-4-iodoquinoline (**2**) were reacted with aminohetarenes **3a-3e** to get hitherto unknown heterocyclic scaffolds.

RESULTS AND DISCUSSION

In 2004, Loones *et al*. described the first auto-tandem inter- and intramolecular Pd-catalyzed amination protocol on 2-chloro-3-iodopyridine with different amino (benzo)(di)azines [7]. A few years later, they extended their amination procedure on the benzo-analogue of 2-chloro-3-iodopyridine; 2-chloro-3-iodoquinoline [8]. To the best of our knowledge, there are no reports on the above-mentioned Pd-catalyzed amination of either 4-chloro-3-iodoquinoline (**1**) or 3-chloro-4-iodoquinoline (**2**).

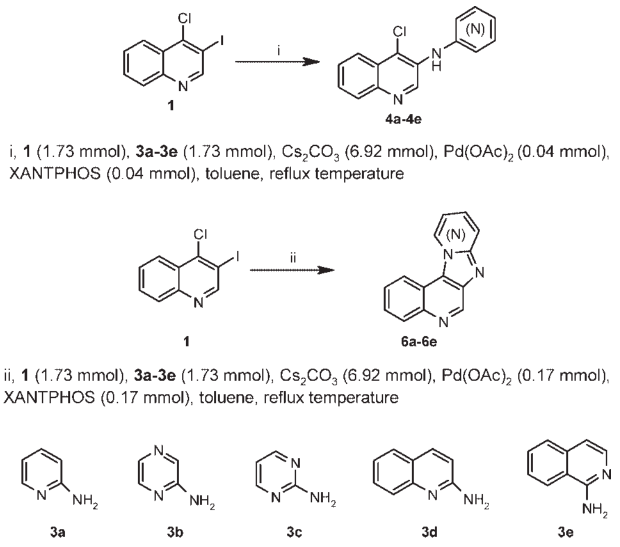
At the beginning of this work, we had some doubt whether this one-pot double amination reaction would work on our substrates **1-2**. To find the optimal conditions for the synthesis of **4-7,** some preliminary experiments were needed. The effects of solvent and ligand on the reaction rate were investigated for compound **1**.

In a first approach, we studied the effect of ligand on the auto-tandem Pd-catalyzed amination. *rac*-BINAP (2,2′-bis(diphenylphosphino)-1,1′-binaphthyl) [9] and XANTPHOS (4,5-bis(diphenylphosphino)-9,9-dimethylxanthene) [10] are commonly used ligands in the Buchwald-Hartwig aminations [11,12]. Concerning the amination of **1** with 2-aminopyridine (**3a**) under the same conditions ($Pd(OAc)_2$, Cs_2CO_3, toluene, reflux), XANTPHOS gave higher conversion for **6a** than *rac*-BINAP after the same reaction time (Scheme 1).

The effects of different solvents like toluene, DMF, and DME were studied keeping the other reaction conditions unchanged. The fastest reaction was observed in toluene.

On the basis of the small-scale experiments, different amino(benzo)(di)azines **3a-3e** were coupled with 4-

Scheme 1. Synthesis of **4a-4e** and **6a-6e**.



i, **1** (1.73 mmol), **3a-3e** (1.73 mmol), Cs_2CO_3 (6.92 mmol), $Pd(OAc)_2$ (0.04 mmol), XANTPHOS (0.04 mmol), toluene, reflux temperature

ii, **1** (1.73 mmol), **3a-3e** (1.73 mmol), Cs_2CO_3 (6.92 mmol), $Pd(OAc)_2$ (0.17 mmol), XANTPHOS (0.17 mmol), toluene, reflux temperature

chloro-3-iodoquinoline (**1**) in toluene in the presence of $Pd(OAc)_2$, XANTPHOS and Cs_2CO_3 at reflux temperature to get the unknown 3-amino-4-chloroquinoline derivatives **4a-4e** and the new polycyclic heterocycles **6a-6e**.

Table 1

Synthesis of **4a-4e.**

3	Time (h)	Yield (%)	4
3a	6	61	3b	3	61	3c	6 20	8 72	3d	5	78	3e	4	43	
Table 2

Synthesis of **6a-6e.**

3	Time (h)	Yield (%)	6
3a	21	32	3b	20	84	3c	21	Traces	3d	29	30	3e	22	51	
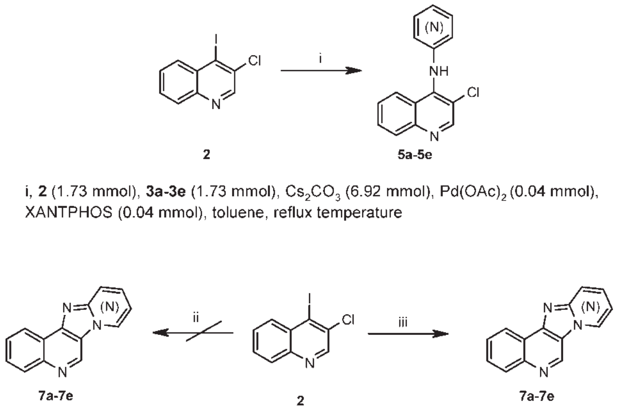
The desired intermediates **4a-4e** were obtained in moderate to good yields, 43–78%. The reaction time was different in every case but was comprised between 3 and 6 h. In the case of 4-chloro-3-(pyrimidin-2-yl)amino-quinoline (**4c**), only traces could be detected after 6 h; so the reaction was left longer (20 h) at reflux temperature resulting in a good yield of 72% being achieved. The results are reported in Table 1 and in the Experimental Section.

The new ring systems **6a, 6b, 6d, 6e** were obtained after 20–29 h, with varying yields (30–83%). 5,7,8,11a-Tetraazabenzo[*c*]fluorene (**6c**) was also formed, but only as a minor compound (Table 2).

We expanded our investigation to 3-chloro-4-iodoquinoline (**2**) as a substrate. The coupling reactions were carried out with the same aminohetarenes **3a-3e**. The monosubstituted intermediates **5a-5e** were prepared in the same way as when using 4-chloro-3-iodoquinoline (**1**) (Scheme 2).

A similar behavior was observed as in the case of **4a-4e**. The Pd-catalyzed intermolecular aminations afforded compounds **5a-5e** in moderate to good yields (50–78%). The reaction time was again the longest with 2-aminopyrimidine (**3c**), which resulted in 3-chloro-4-

Scheme 2. Synthesis of **5a-5e** and **7a-7e**.



i, **2** (1.73 mmol), **3a-3e** (1.73 mmol), Cs_2CO_3 (6.92 mmol), $Pd(OAc)_2$ (0.04 mmol), XANTPHOS (0.04 mmol), toluene, reflux temperature

ii, **2** (1.73 mmol), **3a-3e** (1.73 mmol), Cs_2CO_3 (6.92 mmol), $Pd(OAc)_2$ (0.17 mmol), XANTPHOS (0.17 mmol), toluene, reflux temperature
iii, **2** (1.73 mmol), **3a-3e** (1.73 mmol), Cs_2CO_3 (6.92 mmol), $Pd(OAc)_2$ (0.17 mmol), XANTPHOS (0.17 mmol), CuI (0.35 mmol), DME, reflux temperature

(pyrimidin-2-yl)aminoquinoline (**5c**). The results are reported in Table 3 and in the Experimental Section.

In contrast, the reaction conditions optimized for **6a-6e** did not work for the synthesis of **7a-7e**: in all cases, the reactions stopped at the stage of **5a-5e**. No intramolecular amination was observed, so we had to change our strategy. We wondered if it would be possible to prepare **7a-7e** in one-pot *via* orthogonal tandem catalysis (with simultaneously operating palladium and copper catalysts). Fortunately, by adding CuI (0.2 eq) to the reaction mixture (**2**, **3a-3e**, $Pd(OAc)_2$, XANTPHOS, Cs_2CO_3 and DME as solvent), the desired heterocycles **7a-7e** could be synthesized [8] (Scheme 2).

The formation of **7a-7e** directly from 3-chloro-4-iodoquinoline (**2**) and **3a-3e** gave varying results. Only traces of 5,6b,10,11-tetraazabenzo[*a*]fluorene (**7c**) were formed. Low yields were obtained in the reaction with 2-aminopyridine (**3a**) and 2-aminoquinoline (**3d**). In the coupling with **3b** and **3e,** moderate yields were achieved (Table 4).

In conclusion, the tandem inter- and intramolecular Pd-catalyzed amination protocol was applied on 4-chloro-3-iodoquinoline (**1**) and 3-chloro-4-iodoquinoline (**2**) with five different amidines **3a-3e**, affording novel heterocyclic systems. The reactions that were performed with compound **1** gave higher yields compared to the experiments with the other isomer **2**. Unfortunately in two cases—**1** and **2** with 2-aminopyrimidine (**3c**)—the reactions only gave traces of the desired products **6c**, **7c**.

In summary, we succeeded in preparing ten monosubstituted intermediates **4a-4e** and **5a-5e** and eight new heterocyclic scaffolds **6a**, **6b**, **6d**, **6e**, **7a**, **7b**, **7d**, **7e** whose biological activity warrants further investigation.

EXPERIMENTAL

All melting points were measured on a Büchi-545 apparatus and are uncorrected. Magnetic resonance spectra (^1H NMR) were recorded on a Varian 400 MHz spectrometer. Chemical shift values are reported in δ (ppm) relative to an internal standard (tetramethylsilane). All coupling constants are given in Hertz. Multiplicity is indicated using the following abbreviations: br, broad; d, doublet; t, triplet; m, multiplet; s, singlet. The mass spectra were measured on a FISONS TRIO 1000. Elemental analyses were carried out on an Elementar VARIO EL. Reactions were monitored by TLC on silica gel-protected aluminium sheets (Type 60 F 254, Merck), and the spots were detected by exposure to a UV-Lamp at 254 nm for a few seconds. Column chromatography was performed on silica gel. 4-Chloro-3-iodoquinoline (**1**) and 3-chloro-4-iodoquinoline (**2**) were synthesized using a modification of a known procedure described in literature [13,14]. All reagents were purchased from Aldrich except 2-aminopyrazine and 2-aminoquinoline, which were ordered from Fluka and Apollo, respectively. All the solvents were of the highest analitical grade.

General procedure for the preparation of 4a-4e and 5a-5e. A round-bottomed flask was charged with $Pd(OAc)_2$ (9 mg, 0.04 mmol, 0.02 eq), Xantphos (4,5-bis(diphenylphosphino)-9,9-dimethylxanthene) (24 mg, 0.04 mmol, 0.02 eq) and toluene (8 mL). The solution thus obtained was flushed with argon for 1 h under magnetic stirring at room temperature. Meanwhile, a three-necked round-bottomed flask was charged with 4-chloro-3-iodoquinoline (**1**) (0.50 g, 1.73 mmol, 1.00 eq) or 3-chloro-4-iodoquinoline (**2**) (0.50 g, 1.73 mmol, 1.00 eq), the corresponding amidine **3a-3e** (1.73 mmol, 1.00 eq), Cs_2CO_3 (2.25 g, 6.92 mmol, 4.00 eq) and toluene (15 mL). To this suspension, the preformed Pd-catalyst was added. The resulting mixture was flushed with argon again and heated for 3–21 h at reflux temperature. After cooling to room temperature, toluene was removed by evaporation, the residue was mixed with silica gel, and it was brought on top of a silica gel column and purified by flash chromatography.

4-Chloro-3-(pyridin-2-yl)aminoquinoline (4a). Purification by flash chromatography using hexane:EtOAc = 7:3 resulted in a white solid. Yield: 0.27 g, 1.05 mmol, 61%; mp. 213.4–213.5°C; ^1H NMR ($CDCl_3$) δ 6.86–6.88 (m, 3H, ArH, NH), 7.57–7.64 (m, 3H, ArH), 8.05–8.11 (m, 2H, ArH), 8.25–8.27 (m, 1H, ArH), 9.62 (s, 1H, ArH); MS: m/z = 255 ($M^{+\cdot}$); *Anal.* Calcd. for $C_{14}H_{10}ClN_3$ (255.71) C, 65.76; H, 3.94; N, 16.43. Found: C, 65.94; H, 3.93; N 16.38.

4-Chloro-3-(pyrazin-2-yl)aminoquinoline (4b). Purification by flash chromatography using toluene:MeOH = 95:5 resulted in a brownish solid, which was recrystallized from toluene to give a beige solid. Yield: 0.27 g, 1.05 mmol, 61%; mp. 176.2–176.3°C; ^1H NMR ($CDCl_3$) δ 6.98 (br, 1H, NH), 7.61–7.68 (2H, m, Ar), 8.08–8.18 (m, 4H, ArH), 8.32 (d, 1H, ArH, *J* = 1.2 Hz), 9.70 (s, 1H, ArH); MS: m/z = 256 ($M^{+\cdot}$); *Anal.* Calcd. for $C_{13}H_9ClN_4$ (256.70) C, 60.83; H, 3.53; N, 21.83. 3-Chloro-4-(isoquinolin-1-yl)aminoquinoline (5e). Purification by flash chromatography using hexane:EtOAc = 3:2, 1:1, 2:3 resulted in an orange solid. Yield: 0.41 g, 1.34 mmol, 78%; mp. >250°C; ^{1}H NMR ($CDCl_3$) (the mixture of two tautomers) δ 7.32–9.00 (m, 12 H, ArH, NH); MS: m/z = 305 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{18}H_{12}ClN_3$ (305.77) C, 70.71; H, 3.96; N, 13.74. Found: C, 70.85; H, 3.95; N, 13.70.

General procedure for the preparation of 6a-6e. A round-bottomed flask was charged with $Pd(OAc)_2$ (39 mg, 0.17 mmol, 0.10 eq), Xantphos (4,5-bis(diphenylphosphino)-9,9-dimethyl-xanthene) (0.10 g, 0.17 mmol, 0.10 eq) and toluene (8 mL). The solution thus obtained was flushed with argon for 1 h under magnetic stirring at room temperature. Meanwhile, a three-necked round-bottomed flask was charged with 4-chloro-3-iodoquinoline (1) (0.50 g, 1.73 mmol, 1.00 eq), the corresponding amidine 3a-3e (1.73 mmol, 1.00 eq), Cs_2CO_3 (2.25 g, 6.92 mmol, 4.00 eq) and toluene (15 mL). To this suspension, the preformed Pd-catalyst was added. The resulting mixture was flushed with argon again and heated for 20–29 h at reflux temperature. After cooling to room temperature, toluene was removed by evaporation, the residue was mixed with silica gel and it was brought on top of a silica gel column and purified by flash chromatography.

5,7,11a-Triazabenzo[c]fluorene (6a). Purification by flash chromatography using toluene:2-propanol = 4:1, 3:2, 2:3 resulted in a brownish solid which was recrystallized from toluene to give a beige solid. Yield: 0.12 g, 0.55 mmol, 32%; mp. 192.5-193.3°C; ^{1}H NMR ($CDCl_3$) δ 7.05–7.08 (m, 1H, ArH), 7.47–7.51 (m, 1H, ArH), 7.66–7.71 (m, 2H, ArH), 7.85 (d, 1H, ArH, *J* = 6.4 Hz), 8.32–8.34 (m, 2H, ArH), 8.96 (d, 1H, ArH, *J* = 4.8 Hz), 9.51 (s, 1H, ArH); MS: m/z = 219 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{14}H_9N_3$ (219.25) C, 76.70; H, 4.14. Found: C, 76.96; H, 4.13.

5,7,9,11a-Tetraazabenzo[c]fluorene (6b). Purification by flash chromatography using toluene:2-propanol = 9:1, 4:1, 3:2, 1:1 resulted in a light brownish solid. Yield: 0.32 g, 1.45 mmol, 84%; mp. >250°C; ^{1}H NMR (DMSO-d_6) δ 7.82–7.90 (m, 2H, ArH), 8.23 (d, 1H, ArH, *J* = 4.8 Hz), 8.30–8.32 (m, 1H, ArH), 8.88–8.91 (m, 1H, ArH), 9.52–9.57 (m, 3H, ArH); MS: m/z = 220 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{13}H_8N_4$ (220.24) C, 70.90; H, 3.66. Found: C, 70.75; H, 3.96.

5,7,13b-Triazadibenzo[c,g]fluorene (6d). Purification by flash chromatography using DCM:MeOH = 100:1, 100:2, 95:5 resulted in a yellowish solid. Yield: 0.14 g, 0.52 mmol, 30%; mp. 179.6–181.0°C; ^{1}H NMR ($CDCl_3$) δ 7.55–7.78 (m, 6H, ArH), 7.89 (d, 1H, ArH, *J* = 7.6 Hz), 8.36 (d, 1H, ArH, *J* = 8.0 Hz), 8.62 (d, 1H, ArH, *J* = 8.4 Hz), 9.53 (s, 1H, ArH); MS: m/z = 269 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{18}H_{11}N_3$ (269.31) C, 80.28; H, 4.12. Found: C, 80.55; H, 4.11.

6a,11,13-Triazadibenzo[a,g]fluorene (6e). Purification by flash chromatography using toluene:2-propanol = 4:1, 3:2, 2:3 resulted in a brownish solid which was recrystallized from EtOH to give a dark yellowish solid. Yield: 0.24 g, 0.89 mmol, 51%; mp. 229.7–229.8°C; ^{1}H NMR (DMSO-d_6) δ 7.57 (d, 1H, ArH, *J* = 7.6 Hz), 7.80–7.87 (m, 4H, ArH), 8.05–8.07 (m, 1H, ArH), 8.28–8.31 (m, 1H, ArH), 8.76–8.78 (m, 1H, ArH), 8.91–8.93 (m, 1H, ArH), 9.33 (d, 1H, ArH, *J* = 7.6 Hz), 9.52 (s, 1H, ArH); MS: m/z = 269 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{18}H_{11}N_3$ (269.31) C, 80.28; H, 4.12. Found: C, 80.07; H, 4.13.

General procedure for the preparation of 7a-7e. A round-bottomed flask was charged with $Pd(OAc)_2$ (39 mg, 0.17 mmol, 0.10 eq), Xantphos (4,5-bis(diphenylphosphino)-9,9-dimethyl-xanthene) (0.10 g, 0.17 mmol, 0.10 eq) and 1,2-dimethoxy-ethane (8 mL). The suspension thus obtained was flushed with argon for 1 h under magnetic stirring at room temperature. Meanwhile, a three-necked round-bottomed flask was charged with 3-chloro-4-iodoquinoline (2) (0.50 g, 1.73 mmol, 1.00 eq), the corresponding amidine (1.73 mmol, 1.0 eq), Cs_2CO_3 (2.255 g, 6.92 mmol, 4.0 eq), CuI (66 mg, 0.35 mmol, 0.20 eq) and 1,2-dimethoxyethane (10 mL). To this mixture, the preformed Pd-catalyst was added. The resulting mixture was flushed with argon again and heated for 19–28 h at reflux temperature. After cooling to room temperature, 1,2-dimethoxyethane was removed by evaporation, the residue was mixed with silica gel and it was placed on top of a silica gel column and purified by flash chromatography.

5,6b,11-Triazabenzo[a]fluorene (7a). Purification by flash chromatography using toluene:MeOH = 95:5 resulted in a yellowish solid which was recrystallized from EtOH to give a beige solid. Yield: 0.02 g, 0.09 mmol, 5%; mp. 244.7–244.8°C; ^{1}H NMR ($CDCl_3$) δ 7.08–7.11 (m, 1H, ArH), 7.58–7.62 (m, 1H, ArH), 7.70–7.81 (m, 2H, ArH), 7.91–7.92 (m, 1H, ArH), 8.26–8.28 (m, 1H, ArH), 8.73–8.75 (m, 2H, ArH), 9.50 (s, 1H, ArH); MS: m/z = 219 ($M^{+\cdot}$) *Anal*. Calcd. for $C_{14}H_9N_3$ (219.25) C, 76.70; H, 4.14. Found: C, 76.81; H, 4.13.

5,6b,9,11-Tetraazabenzo[a]fluorene (7b). Purification by flash chromatography using toluene:MeOH = 9:1, 4:1, 1:1 resulted in a brownish solid which was recrystallized from EtOH to give a light brownish solid. Yield: 0.25 g, 1.14 mmol, 66%; mp. >250°C; ^{1}H NMR (DMSO-d_6) δ 7.75–7.85 (m, 2H, ArH), 8.19–8.22 (m, 1H, ArH), 8.27 (d, 1H, ArH, *J* = 4.8 Hz), 8.61–8.63 (m, 1H, ArH), 9.41–9.42 (m, 1H, ArH), 9.49–9.50 (m, 1H, ArH), 9.91 (s, 1H, ArH); MS: m/z = 220 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{13}H_8N_4$ (220.24) C, 70.90; H, 3.66. Found: C, 70.79; H, 3.67.

5,6b,13-Triazadibenzo[a,g]fluorene (7d). Purification by flash chromatography using hexane:EtOAc = 3:2, 1:1, 2:3 resulted in a brownish solid which was recrystallized from EtOH to give a beige solid. Yield: 20 mg, 0.07 mmol, 4%; mp. >250°C; ^{1}H NMR ($CDCl_3$) δ 7.58–7.62 (m, 1H, ArH), 7.71–7.96 (m, 6H, ArH), 8.29 (d, 1H, ArH, *J* = 8 Hz), 8.67 (d, 1H, ArH, *J* = 8.4 Hz), 8.77–7.79 (m, 1H, ArH), 10.07 (s, 1H, ArH); MS: m/z = 269 ($M^{+\cdot}$); *Anal*. Calcd. for $C_{18}H_{11}N_3$ (269.31) C, 80.28; H, 4.12. Found: C, 80.05; H, 4.13.

5,6b,13-Triazadibenzo[a,i]fluorene (7e). Purification by flash chromatography using toluene:MeOH = 95:5, 1:1 resulted in a brownish solid which was recrystallized from EtOH to give a beige solid. Yield: 0.20 g, 0.74 mmol, 43%; mp. >250°C; ^{1}H NMR ($CDCl_3$) δ 7.28 (d, 1H, ArH, $J = 7.2$ Hz), 7.71–7.83 (m, 5H, ArH), 8.26–8.28 (m, 1H, ArH), 8.41 (d, 1H, ArH, $J = 7.2$ Hz), 8.81–8.83 (m, 1H, ArH), 8.95–8.98 (m, 1H, ArH), 9.46 (s, 1H, ArH); MS: m/z = 269 ($M^{+\cdot}$) *Anal.* Calcd. for $C_{18}H_{11}N_3$ (269.31) C, 80.28; H, 4.12. Found: C, 80.43; H, 4.11.

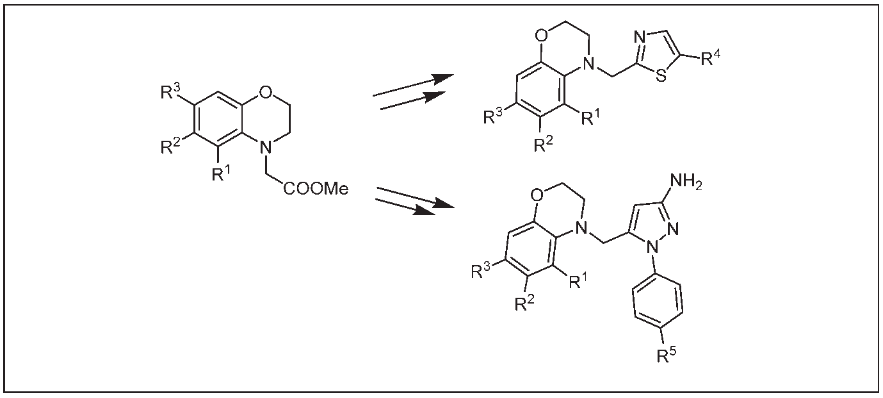
DOI 10.1002/jhet.10



Substituted 4-(5-alkyl-thiazol-2-ylmethyl)-3,4-dihydro-2*H*-1,4-benzoxazines and 5-(2,3-dihydro-1,4-benzoxazin-4-ylmethyl)-4-methyl-1-phenyl-1*H*-pyrazol-3-ylamines were prepared by the reaction of (2,3-dihydro-1,4-benzoxazin-4-yl)-acetic acid methyl ester and some common reagents to provide the product in satisfactory yields.

J. Heterocyclic Chem., **46**, 39 (2009).

INTRODUCTION

Benzoxazines have been used as intermediates in the synthesis of many heterocyclic structures of biological importance. These derivatives have been shown to be selective serotonin reuptake inhibitors. They have also shown activities toward 5-HT$_{1A}$ receptor while the 1,4-benzoxazine imidazole derivatives have shown *in vivo* activities against a murine experimental model of candidiasis. Some of the benzoxazines were most effective in promoting HUVEC apoptosis and inhibiting A549 cell proliferation [1–4]. Some of the *N*-substituted benzoxazines have been reported to cure thrombi-related diseases, for instance, platelet aggregation, thrombosis, myocardial infarction [5] *etc*. Derivatives of benzomorpholine have been incorporated to show hypotensive/antihypertensive effectiveness [6] as well as potential dopamine D$_3$ receptor ligands and inhibitions of cardiac phosphodiestrase (PDE) fraction *in vitro* and for positive inotropic activity *in vivo* [7]. They also tend to inhibit oxidative stress mediated neuronal degeneration in neuronal cell cultures [8,9].

The pyrazole and thiazole ring systems are common structural motifs in a number of biologically active molecules. Thiazole ring systems originate in nature as a consequence of peptide modification containing cysteine side chain residue and are the product of cyclodehydration and redox reactions. More recently, extensive studies have been focused on aryl pyrazoles for exhibiting cyclooxygenase-2 (COX-2) and non-nucleoside HIV-1 reverse transcriptase inhibitory properties. This structure has found applications in drug development for the treatment of allergies, hypertension, schizophrenia, inflammation, bacterial, and HIV7 infections. Aminothiazoles are known to be ligands of estrogen receptors as well as a novel class of adenosine receptor antagonists, whereas other analogues are used as fungicides, inhibiting *in vivo* growth of *Xanthomonas* and as an ingredient of herbicides or as schistosomicidal and antihelmintic drugs [10–15].

RESULTS AND DISCUSSION

As part of an ongoing program aimed at synthesizing benzoxazine derivatives of biological interest, we wanted to introduce different heterocyclic ring systems on the *N*-atom of the benzoxazines. Our literature survey revealed that benzoxazines-bearing pyrazole and thiazole rings on the *N*-atom have not been reported in spite of the fact that these two heterocyclic systems played an important role in drug development.

Earlier, we have reported [16] the synthesis of 3,4-dihydro-1,4-2*H*-benzoxazine from 2-aminophenols and

1,2-dibromoethane using K_2CO_3 in DMF, which was then subjected to N-substitution using alkyl bromide. Subsequent debenzylation and esterification yielded (2,3-dihydro-1,4-benzoxazin-4-yl)-acetic acid methyl ester **1**. Here, we report the synthesis of 4-(5-alkyl-thiazol-2-ylmethyl)-3,4-dihydro-2H-1,4-benzoxazines and 5-(2,3-dihydro-1,4-benzoxazin-4-ylmethyl)-4-methyl-1-phenyl-1H-pyrazol-3-ylamine starting from (2,3-dihydro-1,4-benzoxazin-4-yl)-acetic acid methyl ester.

The compounds **2a–j** (Table 1) were first prepared by converting the methyl ester derivatives to amide derivatives by passing NH_3 (g) through the solution of **3** at 0–5°C and then to the corresponding thioamides using Lawesson's reagent (Scheme 1). Further treatment with 1-bromo-alkan-2-one in ethanol gave the desired products in about 53–64% yields.

Compounds **3a–j** (Table 1) was prepared by first converting the methyl ester derivatives to the corresponding butyronitrile derivatives using NaH and acetonitrile. Further treatment with phenyl hydrazine yielded the desired products in 41–62% yields (Scheme 2). Catalytic amounts of KF increased the rate of the reaction and hence the yield.

EXPERIMENTAL

Carbon, hydrogen, and nitrogen analysis were performed with a Perkin-Elmer 2400 series II instrument. IR spectra were recorded on a BOMEM DA-8 FTIR spectrophotometer. The ^{1}H and ^{13}C NMR spectra were recorded on a Bruker AMX 400 spectrometer. Positive-ion and negative-ion electrospray ionization (ESI) mass spectra were measured on an ion trap analyzer Esquire 3000 (Bruker Daltonics).

Synthesis of Substituted 4-(5-alkyl-thiazol-2-ylmethyl)-3,4-dihydro-2*H*-1,4-benzoxazine. The methyl ester derivative (**1**) was first dissolved in methanol, the reaction mixture was cooled in ice, and NH_3 gas was passed through it for 10 min. The reaction mixture was stirred overnight at room temperature, resulting in separation of dirty white solids, which were separated by filtration to yield the amide derivative. The crude product was washed with hexane to yield the pure product. IR (KBr) ν cm^{-1} 3330 (m) and 3050 (m) ($CONH_2$) H^1 NMR (DMSO-d$_6$, 400 MHz) δ ppm 3.3 (t, 2H, *J* = 14.1 Hz), 4.07 (s, 2H,), 4.32 (t, 2H, *J* = 9.1 Hz), 6.24 (b, 2H), 6.46–6.5 (m, 4H). Calc. for $C_{10}H_{12}N_2O_2$ C, 62.49; H, 6.29; N, 14.57%; observed were C, 62.50; H, 6.28; N, 14.56%.

The amide derivative was then dissolved in Dry THF and treated with Lawesson's reagent (0.5 eq) and stirred overnight under N_2 atm. The reaction on completion was evaporated in vacuum and extracted with ethylacetate. The complete organic extract was dried over Na_2SO_4 and concentrated. The crude product was purified by column chromatography using ethyl acetate and hexane (1:10) as an eluent to yield the desired product. IR (KBr) ν cm^{-1} 1175. The 2-(2,3-dihydro-1,4-benzoxazin-4-yl)-thioacetamide was then refluxed with 1-bromo butan-2-one in ethanol, the reaction was monitored using TLC. The reaction on completion was evaporated in vacuum and extracted with DCM. The complete organic extract was dried over Na_2SO_4 and concentrated. The crude product was purified by column chromatography using ethyl acetate and hexane (1:20) as an eluent to yield the desired product (**2b**). Synthesis of 5-(2,3-dihydro-1,4-benzoxazin-4-ylmethyl)-4-methyl-1-phenyl-1*H*-pyrazol-3-ylamine. It involves the synthesis of butyronitrile derivative from the methyl ester(**1**) using acetonitrile (1.5 eq) and NaH (1.5 eq) in THF under N_2 atmosphere. The NaH was dissolved in THF, and acetonitrile was added drop wise at 0°C. The reaction mixture was allowed to stir at room temperature for ½ h and followed by drop wise addition of (**1**) solution in THF at 0°C. The reaction was then stirred at room temperature for 3 h. On completion of the reaction, the solvent was evaporated and work-up using ethyl acetate, the complete organic extracts were dried over Na_2SO_4 and evaporated to yield the crude product, which was purified by column chromatography using ethyl acetate and hexane (1:20). IR (KBr) ν cm^{-1} 2242 (CN stretching) H^1 NMR ($CDCl_3$, 400 MHz) δ ppm 3.61 (s, 2H), 3.82–3.86 (m, 2H), 4.24–4.26 (m, 2H), 4.56(s, 2H), 6.5–6.84 (m, 4H). Calc. for $C_{12}H_{12}N_2O_2$ C, 66.65; H, 5.59; N, 12.96%; observed were C, 66.64; H, 5.60; N, 12.94%. The butyronitrile derivative was then refluxed with substituted phenyl hydrazine (1.2 eq) for 4–5 h. The reaction on completion was evaporated under vacuum and worked-up using DCM. The complete organic was dried over Na_2SO_4 and evaporated to yield the crude product, which was purified by column chromatography using methanol and DCM (1:50) as an eluent.

A series of new imidazole derivatives containing 2(3*H*)-benzoxazolone or 2(3*H*)-benzothiazolone ring were synthesized as analogues of the antifungal drug bifonazole. All compounds were tested *in vitro* against *Candida albicans*, *Candida parapsilosis*, and *Candida krusli*.

J. Heterocyclic Chem., **46**, 44 (2009).

INTRODUCTION

As a result of the dramatic increase in fungal infections, in recent years serious attention has been directed toward the discovery and development of new antifungal drugs. Mostly caused by *Candida albicans*, these infections are often spread through the use of broad-spectrum antibiotics, immunosuppressive agents, anticancer, and anti-AIDS drugs [1]. The main problem in the treatment of fungal infections is the increasing prevalence of drug resistance especially in patients chronically subjected to antimycotic therapy such as persons infected with HIV [2].

Azoles (imidazole and triazole) are presented in many effective antifungal drugs widely used for the treatment of topical or inner mycoses, in particular AIDS-related mycotic pathologies [3]. Their main effect is to block fungal ergosterol biosynthesis by preventing the access of natural substrate lanosterol to the active site of the cytochrome P-450-dependent enzyme 14α-lanosterol demethylase [4,5]. Since the identification of clotrimazole in 1972 [6], a number of antifungal imidazole agents have been studied and now are used in clinical practice: miconazole, bifonazole, *etc* [7]. Fluconazole is one of the most important drugs in the triazole family (Fig. 1).

In searching for new compounds with potential antifungal activity, we synthesized a number of imidazole derivatives, containing 2(3*H*)-benzoxazolone or 2(3*H*)-benzothiazolone moiety. These compounds could be examined as heterocyclic analogues of bifonazole, in which the biphenyl moiety could be replaced with benzoxazole or benzothiazole ring. A chlorine atom was introduced at different position on benzene cycle.

In this article, we present the synthesis and the results of the initial biological investigations of series bifonazole-like imidazole derivatives.

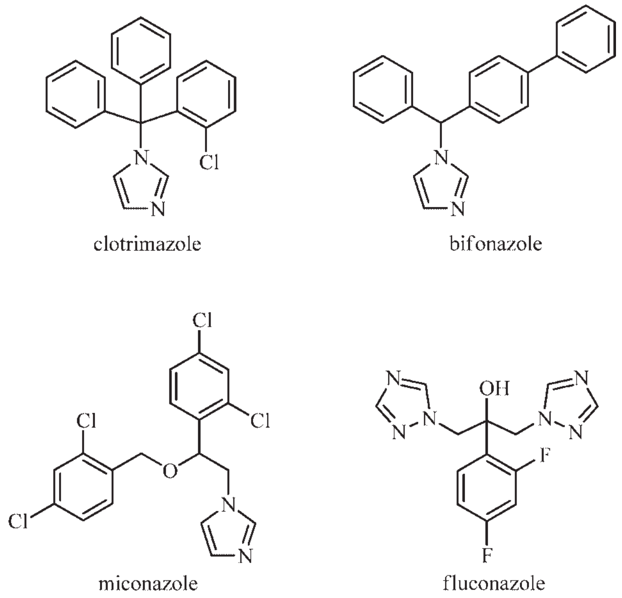

Figure 1. The structures of azole antifungal drugs used in clinical practice.

RESULTS AND DISCUSSION

A series of new imidazole derivatives **10a–o** with 2(3*H*)-benzoxazolone or 2(3*H*)-benzothiazolone moiety were prepared as potential antifungal agents as shown in Scheme 1.

The acylation of 3-methyl-2(3*H*)-benzoxazolone (**4**), 5-chloro-3-methyl-2(3*H*)-benzoxazolone (**5**), and 3-methyl-2(3*H*)-benzothiazolone (**6**) was carried out in polyphosphoric acid (PPA) with unsubstituted and various chloro-substituted benzoic acids and led to the corresponding 6-benzoyl derivatives **7a–o**.

The acylation of 2(3*H*)-benzoxazolone and 2(3*H*)-benzothiazolone was previously studied and was found to proceed with high regioselectivity [8–10]. The precise position of acylation was unequivocally assigned by X-ray single-crystal diffraction in the case of 6-benzoyl-2(3*H*)-benzoxazolone and 6-benzoyl-2(3*H*)-benzothiazolone [11,12].

Compounds **8a–o** were obtained in high yields and purity by a sodium borohydride reduction of the corresponding ketones **7a–o**. The reaction was carried out at room temperature in methanol and afforded the desired hydroxyl derivatives, which were the starting materials for the imidazole series.

Two general approaches can be used for the synthesis of imidazole derivatives **10a–o**: by reaction of carbinols **8a–o** with *N,N′*-carbonyldiimidazole (CDI) [13] or *N,N′*-sulfinyldiimidazole (SDI) [14] or by conversion of corresponding hydroxyl derivatives **8a–o** *via* their chlorides to the desired heterocycles **10a–o**. Our early experiments showed that the use of the first method of approach (CDI or SDI) brought low yields or in any case did not form the expect imidazole derivative. It may be possible, instead of the desired compounds **10a–o**, imidazole-*N*-carboxylic ester intermediates are formed [13]. Therefore, we followed the second approach: the compounds **8a–o** were converted to the corresponding chlorides **9a–o** by refluxing with thionyl chloride in toluene. This reaction afforded sufficiently pure chlorides **9a–o**, which were used without further purification. The condensation of crude chlorides **9a–o** with two equivalents of 1*H*-imidazole provided target imidazole derivatives **10a–o** and the formation of imidazole hydrochloride as a by-product. Compounds **10a–o** were isolated in good yields (Table 1) and purified by recrystallization.

The imidazole derivatives **10a–o** have one asymmetric carbon atom; however, we did not make any efforts for the separation of individual enantiomers in view of the fact that both enantiomers of bifonazole have been reported to possess the same antimycotic profile and potency [15].

The yields, melting points, and molecular formula of imidazole derivatives **10a–o** are listed in Table 1. All spectral data are in accordance with the assumed structures. In addition to the signals for aromatic protons, ^{1}H NMR spectra of the compounds **10a–o** reveal singlet at 3.39–3.47 ppm for the N-CH_3 protons from 2(3*H*)-benzoxazolone or 2(3*H*)-benzothiazolone ring. Furthermore, the spectra show singlet for methyne proton at the asymmetric carbon atom in range 6.53–6.92 ppm.

IR spectra of compounds **10a–o**, containing 2(3*H*)-benzoxazolone or 2(3*H*)-benzothiazolone ring showed carbonyl bands at 1750–1795 cm^{-1} and 1650–1680 cm^{-1}, respectively.

[a] Compound was isolated as a nitrate.

The new imidazole derivatives **10a–o** were evaluated *in vitro* against several pathogenic fungi responsible for human diseases using the twofold agar dilution method [16]. The results of this biological investigation did not report any significant activity against yeast. The most active compounds in the series showed weak antimicrobial activity against *Candida albicans*, *Candida parapsilosis*, and *Candida krusli* with MIC values 100–400 μM.

The results of the biological tests revealed that the replacement of the biphenyl portion of the bifonazole with 2(3*H*)-benzoxazolone or 2(3*H*)-benzothiazolone moiety afforded heterocyclic analogues, which are inactive as antimycotic agents toward *Candida* strains.

EXPERIMENTAL

Melting points were determined on a Boetius hot-stage microscope and are uncorrected. IR spectra (nujol) were recorded on a Specord 71 spectrophotometer. ^1H NMR spectra were obtained on a Bruker DRX 300 spectrometer operating at 300 MHz in $CDCl_3$. Chemical shifts were reported in δ units (ppm) relative to $(CH_3)_4Si$ as internal standard. Coupling constants (*J*) were reported in Hz. Elemental analyses (C, H, N, S) for final compounds were performed on a Vario III microanalyzer. Obtained results were within 0.4% of theoretical values. Thin layer chromatography (TLC) was carried out on Silica gel plates (Merck 60 F_{254}) using toluene–chloroform–ethyl acetate (3:1:1) and ethyl acetate–isopropanol (3:1) as eluent.

Ketones **7a–o** and corresponding alcohols **8a–o** were prepared according to the method described previously [17,18].

6-[(1*H*-Imidazol-1-yl)phenylmethyl]-3-methyl-2(3*H*)-benzoxazolone (10a). A solution of hydroxyl derivative **8a** (1.28 g, 5 mmol) in toluene (10 mL) and thionyl chloride (1 mL, 14 mmol) was refluxed for 30 min and then the excess of thionyl chloride was evaporated under reduced pressure. The obtained oil of **9a** was dissolved in toluene (15 mL) and imidazole (0.68 g, 10 mmol) was added. The mixture was refluxed for 6 h, until the chloride **9a** was no longer detectable (TLC). After cooling of the reaction mixture, 5% aqueous NaOH (10 mL) was added. The organic layer was washed with water and extracted with 10% HCl. The aqueous layer was neutralized with 10% NaOH, extracted with dichloromethane, dried ($MgSO_4$), and evaporated under reduced pressure. The obtained crude product **10a** crystallized slowly. Yield 1.22 g (80%), mp 144–145 °C (ethyl acetate); ir (nujol): 1765 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.41 (s, 3H, NCH_3), 6.56 (s, 1H, CH), 6.84–7.11 (m, 7H, ArH and ImH), 7.36–7.42 (m, 4H, ArH and ImH). Anal. Calcd. for $C_{18}H_{15}N_3O_2$: C 70.81; H 4.95; N 13.76. Found: C 70.56; H 4.98; N 13.46.

6-[(2-Chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10b). This compound was obtained according to the procedure for **10a**, using compound **8b** as a starting material. Yield: 1.36 g (82%), mp 143–144 °C (hexane–ethyl acetate 1:1); ir (nujol): 1780 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.43 (s, 3H, NCH_3), 6.79–6.85 (m, 2H, ArH and ImH), 6.92 (s, 1H, CH), 6.95–6.96 (m, 3H, ArH and ImH), 7.14 (s, 1H, ArH), 7.28 (dt, 1H, ArH, *J* = 1.8 Hz, *J* = 7.8 Hz), 7.35 (dt, 1H, ArH, *J* = 1.8 Hz, *J* = 7.8 Hz), 7.42 (s, 1H, ImH), 7.45 (dd, 1H, ArH, *J* = 1.8 Hz, *J* = 7.8 Hz). Anal. Calcd. for $C_{18}H_{14}ClN_3O_2$: C 63.63; H 4.15; N 12.37. Found: C 63.90; H 4.18; N 12.44.

6-[(3-Chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10c). This compound was obtained according to the procedure for **10a**, using compound **8c** as a starting material. Yield: 1.02 g (60%), mp 124–125 °C (hexane–ethyl acetate, 1:1); ir (nujol): 1780 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.43 (s, 3H, NCH_3), 6.54 (s, 1H, CH), 6.85 (s, 1H, ImH), 6.96–7.08 (m, 5H, ArH and ImH), 7.14 (s, 1H, ArH), 7.33–7.36 (m, 2H, ArH), 7.44 (s, 1H, ImH). Anal. Calcd. for $C_{18}H_{14}ClN_3O_2$: C 63.63; H 4.15; N 12.37. Found: C 63.86; H 4.18; N 12.45.

6-[(4-Chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10d). This compound was obtained according to the procedure for **10a**, using compound **8d** as a starting material. Yield: 1.16 g (68%), mp 108–110 °C (cyclohexane–ethyl acetate, 1:1); ir (nujol): 1760 (C=O) cm^{-1}; ^1H

NMR ($CDCl_3$): δ 3.43 (s, 3H, NCH_3), 6.55 (s, 1H, CH), 6.84 (s, 1H, ImH), 6.95–6.96 (m, 3H, ArH and ImH), 7.02 (d, 2H, ArH, *J* = 8.4 Hz), 7.14 (s, 1H, ArH), 7.34 (d, 2H, ArH, *J* = 8.4 Hz), 7.44 (s, 1H, ImH). Anal. Calcd. for $C_{18}H_{14}ClN_3O_2$: C 63.63; H 4.15; N 12.37. Found: C 63.96; H 4.10; N 12.56.

6-[(2,4-Dichlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10e). This compound was obtained according to the procedure for **10a**, using compound **8e** as a starting material. Yield: 0.94 g (50%), mp 167–168 °C (ethyl acetate); ir (nujol): 1750 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.43 (s, 3H, NCH_3), 6.7 (d, 1H, ArH, *J* = 7.4 Hz), 6.81 (s, 1H, ImH), 6.85 (s, 1H, CH), 6.93–6.98 (m, 3H, ArH and ImH), 7.15 (s, 1H, ArH), 7.27 (dd, 1H, ArH, *J* = 2.0 Hz, *J* = 7.4 Hz), 7.39 (s, 1H, ImH), 7.48 (d, 1H, ArH, *J* = 2.0 Hz). Anal. Calcd. for $C_{18}H_{13}Cl_2N_3O_2$: C 57.77; H 3.50; N 11.23. Found: C 57.68; H 3.62; N 11.07.

5-Chloro-6-[(1*H*-imidazol-1-yl)phenylmethyl]-3-methyl-2(3*H*)-benzoxazolone (10f). This compound was obtained according to the procedure for **10a**, using compound **8f** as a starting material. Yield: 1.17 g (69%), mp 195–196°C (ethyl acetate); ir (nujol): 1790 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.41 (s, 3H, NCH_3), 6.70 (s, 1H, CH), 6.81 (s, 1H, ImH), 6.91 (s, 1H, ArH), 7.05–7.07 (m, 3H, ArH and ImH), 7.13 (s, 1H, ArH), 7.34–7.40 (m, 4H, ArH and ImH). Anal. Calcd. for $C_{18}H_{14}ClN_3O_2$: C 63.63; H 4.15; N 12.37. Found: C 63.88; H 4.16; N 12.56.

5-Chloro-6-[(2-chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10g). This compound was obtained according to the procedure for **10a**, using compound **8g** as a starting material. Yield: 1.31 g (70%), mp 189–190 °C (ethyl acetate); ir (nujol): 1780 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.42 (s, 3H, NCH_3), 6.63 (s, 1H, CH), 6.76 (dd, 1H, ArH, *J* = 1.5 Hz, *J* = 7.5 Hz), 6.81 (s, 1H, ImH), 7.10 (s, 1H, ArH), 7.15 – 7.17 (m, 2H, ArH and ImH), 7.23 (dt, 1H, ArH, *J* = 1.5 Hz, *J* = 7.5 Hz), 7.33–7.39 (m, 2H, ArH and ImH), 7.46 (dd, 1H, ArH, *J* = 1.5 Hz, *J* = 7.5 Hz). Anal. Calcd. for $C_{18}H_{13}Cl_2N_3O_2$: C 57.77; H 3.50; N 11.23. Found: C 57.83; H 3.49; N 10.86.

5-Chloro-6-[(3-chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10h). This compound was obtained according to the procedure for **10a**, using compound **8h** as a starting material. Yield: 1.03 g (55%), mp 232–234 °C (toluene); ir (nujol): 1790 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.39 (s, 3H, NCH_3), 6.65 (s, 1H, CH), 6.81 (s, 1H, ImH), 6.89 (s, 1H, ArH), 6.93–6.96 (m, 1H, ArH), 7.04–7.15 (m, 3H, ArH and ImH), 7.31–7.41 (m, 3H, ArH and ImH). Anal. Calcd. for $C_{18}H_{13}Cl_2N_3O_2$: C 57.77; H 3.50; N 11.23. Found: C 57.93; H 3.41; N 11.36.

5-Chloro-6-[(4-chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10i). This compound was obtained according to the procedure for **10a**, using compound **8i** as a starting material. Yield: 0.97 g (52%), mp 119–121 °C (cyclohexane–ethyl acetate, 2:1); ir (nujol): 1795 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.42 (s, 3H, NCH_3), 6.67 (s, 1H, CH), 6.80 (s, 1H, ImH), 6.88 (s, 1H, ArH), 6.99 (d, 2H, ArH, *J* = 7.0 Hz), 7.07 (s, 1H, ArH), 7.14 (s, 1H, ImH), 7.35–7.39 (m, 3H, ArH and ImH). Anal. Calcd. for $C_{18}H_{13}Cl_2N_3O_2$: C 57.77; H 3.50; N 11.23. Found: C 58.09; H 3.72; N 11.27.

5-Chloro-6-[(2,4-dichlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzoxazolone (10j). This compound was obtained according to the procedure for **10a**, using compound **8j** as a starting material. Yield: 1.04 g (53%), mp 208–210 °C (toluene); ir (nujol): 1780 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.42 (s, 3H, NCH_3), 6.61 (s, 1H, CH), 6.69 (d, 1H, ArH, *J* = 8.4 Hz), 6.79 (s, 1H, ImH), 7.09–7.15 (m, 3H, ArH and ImH), 7.27 (dd, 1H, ArH, *J* = 2.1 Hz, *J* = 8.4 Hz), 7.37 (s, 1H, ImH), 7.49 (d, 1H, ArH, *J* = 2.1 Hz). Anal. Calcd. for $C_{18}H_{12}Cl_3N_3O_2$: C 52.90; H 2.96; N 10.28. Found: C 52.79; H 3.22; N 10.33.

6-[(1*H*-Imidazol-1-yl)phenylmethyl]-3-methyl-2(3*H*)-benzothiazolone (10k). This compound was obtained according to the procedure for **10a**, using compound **8k** as a starting material. Yield: 1.03 g (64%), mp 132–133 °C (ethyl acetate); ir (nujol): 1680 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.44 (s, 3H, NCH_3), 6.54 (s, 1H, CH), 6.84 (s, 1H, ImH), 6.99–7.13 (m, 6H, ArH and ImH), 7.35–7.43 (m, 4H, ArH and ImH). Anal. Calcd. for $C_{18}H_{15}N_3OS$: C 67.23; H 4.70; N 13.07. Found: C 67.09; H 4.55; N 13.43.

6-[(2-Chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzothiazolone (10l). This compound was obtained according to the procedure for **10a**, using compound **8l** as a starting material. Yield: 1.49 g (84%), mp 182–184 °C (cyclohexane–ethyl acetate, 1:1); ir (nujol): 1670 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.47 (s, 3H, NCH_3), 6.81–6.84 (m, 2H, ArH and ImH), 6.91 (s, 1H, CH), 7.02–7.13 (m, 4H, ArH and ImH), 7.29 (dt, 1H, ArH, *J* = 1.8 Hz, *J* = 7.8 Hz), 7.34 (dt, 1H, ArH, *J* = 1.8 Hz, *J* = 7.8 Hz), 7.39 (s, 1H, ImH), 7.45 (dd, 1H, ArH, *J* = 1.8 Hz, *J* = 7.8 Hz). Anal. Calcd. for $C_{18}H_{14}ClN_3OS$: C 60.76; H 3.97; N 11.81. Found: C 60.87; H 3.99; N 11.62.

6-[(3-Chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzothiazolone (10m). This compound was obtained according to the procedure for **10a**, using compound **8m** as a starting material. Yield: 1.39 g (78%), mp 149–150 °C (ethyl acetate); ir (nujol): 1670 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.47 (s, 3H, NCH_3), 6.53 (s, 1H, CH), 6.85 (s, 1H, ImH), 6.96–7.16 (m, 6H, ArH and ImH), 7.32–7.35 (m, 2H, ArH), 7.43 (s, 1H, ImH). Anal. Calcd. for $C_{18}H_{14}ClN_3OS$: C 60.76; H 3.97; N 11.81. Found: C 60.53; H 4.02; N 11.81.

6-[(4-Chlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzothiazolone nitrate (10n). This compound was obtained according to the procedure for **10a**, using compound **8n** as a starting material. The crude product **10n**, obtained as a viscous oily residue was dissolved in isopropanol and conc. HNO_3 was added. The obtained precipitate was collected by filtration and washed with cold isopropanol. Yield: 1.57 g (75%), mp 188–189 °C (isopropanol); ir (nujol): 2770–2250 (NH^+), 1660 (C=O) cm^{-1}. Anal. Calcd. for $C_{18}H_{14}ClN_3OS \times HNO_3$: C 51.62; H 3.61; N 13.38. Found: C 52.00; H 4.01; N 13.10.

6-[(2,4-Dichlorophenyl)(1*H*-imidazol-1-yl)methyl]-3-methyl-2(3*H*)-benzothiazolone (10o). This compound was obtained according to the procedure for **10a**, using compound **8o** as a starting material. Yield: 1.37 g (70%), mp 196–197 °C (ethyl acetate); ir (nujol): 1650 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.47 (s, 3H, NCH_3), 6.75 (d, 1H, ArH, *J* = 8.4 Hz), 6.81 (s, 1H, ImH), 6.85 (s, 1H, CH), 7.02–7.16 (m, 4H, ArH and ImH), 7.27 (dd, 1H, ArH, *J* = 1.8 Hz, *J* = 8.4 Hz), 7.38 (s, 1H, ImH), 7.48 (d, 1H, ArH, *J* = 1.8 Hz). Anal. Calcd. for $C_{18}H_{13}Cl_2N_3OS$: C 55.39; H 3.36; N 10.77. Found: C 55.78; H 3.46; N 10.55.

The solvent-free, microwave (MW)-assisted synthesis of a new series of 3′-(aryl/heteroaryl)-1-morpholinomethyl/piperidinomethylspiro[3*H*-indole-3,2′-thiazolidine]-2,4′(1*H*)-diones has been achieved in an open vessel. Isatins **1** undergo an easy condensation with various aryl/heteroaryl amines by MW using montmorillonite K10 clay as a solid support to afford Schiff bases **2**, which subsequently undergo smooth cyclization with TGA under neat MW conditions to afford the spiro thiazolidinones **3**. The spiro-compounds are made to react with morpholine/piperidine and formaldehyde to give the corresponding Mannich bases **4/5** in reasonably good yield.

J. Heterocyclic Chem., **46**, 49 (2009).

INTRODUCTION

Microwave-assisted organic synthesis (MAOS) has been recognized as one of the most fascinating areas of current research [1–3]. Coupling of microwave (MW) irradiation with the use of catalysts or mineral supported reactions, under solvent-free conditions, provides a clean chemical process with an advantageous merit of enhanced reaction rates, higher yields, greater selectivity, and ease of manipulation [4–7]. Isatin Mannich bases are found to have cytotoxicity against a panel of human cancer cells [8]. They also possess antibacterial, antifungal, antiviral, anti-HIV, anti-protozoal, and anthelmintic activities. Indole ring, when joined to the other aryl/heteroaryl systems through a spiro carbon atom at C-3, the resulting spiroindoles exhibit an

Physical and analytical data of compounds **2**.

Compound	R	R^1	Time (min)	Mp (°C)	Yield (%)	Molecular formula
2a	H	p-BrC_6H_4	3	242	94	$C_{14}H_9BrN_2O$
2b	H	Ph	3	183	97	$C_{14}H_{10}N_2O$
2c	Br	$CH_2C_6H_5$	3	105	90	$C_{15}H_{11}BrN_2O$
2d	Br	2-thiazolyl	2.5	120	63	$C_{11}H_6BrN_3OS$
2e	Br	2-pyridinyl	2	190	65	$C_{13}H_8BrN_3O$

increased spectrum of biological activities [9–11]. Further, spiro[indole-thiazolidine]-diones show a wide range of pharmacological properties as anticonvulsant, anti-inflammatory, antibacterial, and anti-fungal [12–14]. *N*-Piperidino-(or morpholino-) methylisatin-3-anils possess potential biological activity and have been prepared by the condensation of isatin with arylamines followed by the Mannich reaction with piperidine or morpholine [15]. Some new spiro[indoline-3,2′-thiazolidine]-2,4′-(1*H*)-diones and bis[spiro[indoline-3,2′-thiazolidine]-2,4′(1*H*)-diones] have been obtained thermally and under MW irradiation by the condensation of isatin, aromatic amines, and mercaptoacetate without isolating the imine intermediates [16]. 3′-Substituted phenylspiro[3*H*-indole-3,2′-thiazolidine]-2,4′-(1*H*)-diones are reported to have significant antimicrobial activity [17]. A convenient synthesis of spiro[3*H*-indole-3,2′thiazolidine]-2,4′(1*H*)-diones has also been carried out by the condensation and cyclization of isatin with various aromatic amines [18]. In view of the above and prompted by the solvent-free MAOS, we describe herein a MW-assisted regioselective synthesis of 3′-(aryl/heteroaryl)-1-morpholinomethyl/piperidinomethylspiro[3*H*-indole-3,2′-thiazolidine]-2,4′(1*H*)-diones under solvent-free conditions.

RESULTS AND DISCUSSION

The reaction sequence involves MW-induced preparation of Schiff bases **2a–e** (Table 1) from isatins **1a–b** and amines (R^2-NH_2) using montmorillonite K10 clay as a solid support, followed by the cyclocondensation of Schiff bases **2a–e** and mercaptoacetic acid under neat MW irradiation conditions to achieve the synthesis of spiro[indole-thiazolidine]-diones **3a–e** (Table 2). The resulting compounds **3a–e** are then allowed to react with either morpholine or piperidine and 37% formaldehyde, under solvent-free MW irradiation conditions, to afford the corresponding Mannich bases **4a–c** and **5a**,**b** (Table 3) in reasonably good yields (Scheme 1).

To optimize the yield of products, the effect of various parameters such as MW power, irradiation time, and molar proportions of the reactants were investigated in detail. The preparation of **2a** as reference compound was observed under three different sets of reaction conditions. In the first run, isatin was refluxed with *p*-bromoaniline in absolute ethanol for 2 h, yielding the product **2a** (83%). In the second run, the reactants were refluxed in triply distilled water containing a few drops of glacial acetic acid for 30 min affording **2a** (82%). Finally, the reaction was carried out under MW-assisted (800 W) solvent free conditions using K10 clay as a solid support, to afford **2a** (94%) in just 3 min. Because of the unambiguous merits, MW method was adopted for the preparation of the rest of the compounds (Table 1). It is worthwhile to mention that in the case of compounds **2d** and **2e** (*cf*. Table 1); a 500-mL Borosil beaker containing 200 mL of water was kept as a heat sink to avoid the burning of the compound. For compound **3a**, a higher MW power (420 W and 320 W) resulted in reasonably poor yield of product probably due to the loss of low boiling mercaptoacetic acid.

However, 160 W irradiation using equimolar quantities of **2a** and mercaptoacetic acid gave rise to an enhanced yield (65%) of the product **3a**. The yields of **3a–e** were considerably increased (72–86%) when the molar ratio of the reactants **2a** and mercaptoacetic acid were kept to be 1:2. A trace of acidic compound was also observed in this run. To achieve the optimum yield of Mannich bases **4**/**5**,

the reaction mixture was irradiated intermittently (30 s/cycle) to avoid the loss of low boiling reactants.

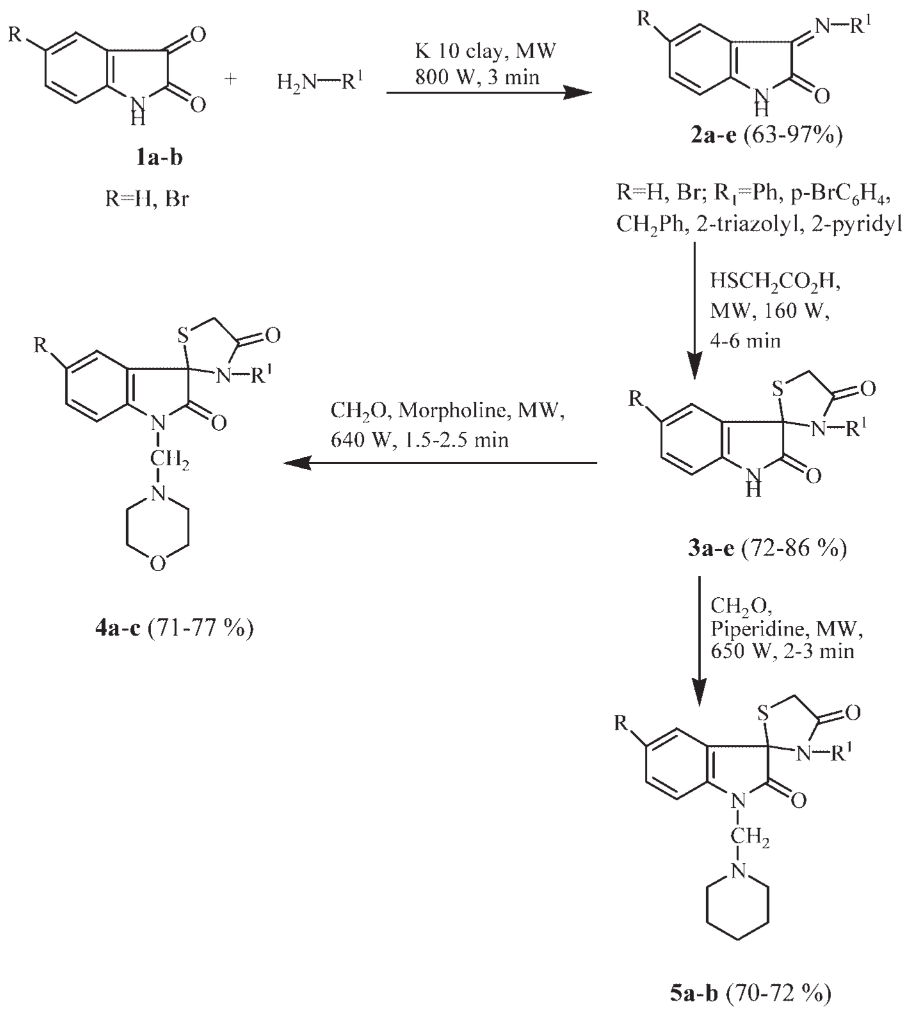
All the reactions were monitored by TLC and then worked up to afford the products, which exhibited physical and spectral data consistent with their structures.

EXPERIMENTAL

IR spectra were recorded on a JASCO FT/IR-5300 spectrophotometer, whereas NMR was run on a JEOL AL300 FTNMR spectrometer. The chemical shifts are given in δ ppm with respect to TMS as internal standard. The TLC spots were detected using iodine chamber. All commercially available chemicals were purchased from Aldrich and Merck.

General procedure for the synthesis of isatin Schiff bases (2). Equimolar quantities (1 mmole) of either isatin or 5-bromoisatin and corresponding amino reagent were blended with Montmorillonite K10 clay (20 mg) and heated for 2–3 min in a MW oven set (LG, Model MS-194W) for 900 W. Upon completion of the reaction, as checked by TLC, the product was extracted with CH_2Cl_2 (3 × 10 mL). After evaporation of

Scheme 1



the solvent under reduced pressure, the product was recrystallized from ethanol.

3-(p-Bromophenylimino)-isatin (2a). From *p*-bromoaniline, yellow crystals (94%), mp 242°C; ir (potassium bromide): NH 3236, C=O 1700, C=N 1619 cm^{-1}; ^1H NMR (DMSO-d_6): δ 9.2 (s, 1H, NH), 7.0–7.8 ppm (m, 8H, Ar—H); ^{13}C NMR (DMSO-d_6): 168 (C=O), 160 (C=N), 152 (C—N=C), 120–139 ppm (Ar—C's). Anal. Calcd. For $C_{14}H_9BrN_2O$: C, 55.84; H, 3.01; Br, 26.53; N, 9.30; O, 5.31. Found: C, 55.89; H, 3.06; Br, 26.48; N, 9.33; O, 5.28.

3-(Phenylimino)-isatin (2b). From aniline, yellow solid (97%), mp 183°C; ir (potassium bromide): NH 3260, C=O 1695, C=N 1612 cm^{-1}; ^1H NMR (DMSO-d_6): δ 9.3 (s, 1H, N—H,); 6.8–7.6 ppm (m, 9H, Ar—H); ^{13}C NMR (DMSO-d_6): 166 (C=O), 162 (C=N), 155 (C—N=C), 120–138 ppm (Ar—C's); Anal. Calcd. For $C_{14}H_{10}N_2O$: C, 75.66; H, 4.54; N, 12.60; O, 7.20. Found: C, 75.63; H, 4.55; N, 12.63; O, 7.18.

5-Bromo-3-(benzylimino)-isatin (2c). From benzyl amine, shiny light brown solid (90%), mp 105°C, ir (potassium bromide): NH 3350, C=O 1690, C=N 1610 cm^{-1}; ^1H NMR ($CDCl_3$): δ 9.1 (s, 1H, NH); 7.1–7.7 (m, 8H, Ar—H); 4.8 ppm (m, 2H, N—CH_2—C); ^{13}C NMR (DMSO-d_6): 168 (C=O), 161 (C=N), 152 (C—N=C), 118–137 (Ar—C's), 57 ppm (N—CH_2—C); Anal. Calcd. For $C_{15}H_{11}BrN_2O$: C, 57.16; H, 3.52; Br, 25.35; N, 8.89; O, 5.08. Found: C, 57.21; H, 3.57; Br, 25.27; N, 8.91; O, 4.91.

5-Bromo-3-(2-thiazolylimino)-isatin (2d). From 2-thiazolyl amine, dark brown solid (63%), mp 120°C; ir (potassium bromide): NH 3370, C=O 1692, C=N 1615 cm^{-1}; ^1H NMR ($CDCl_3$): δ 9.2 (s, 1H, NH); 7.4–7.8 (m, 3H, Ar—H); 7.3, 8.0 ppm (m, 2H, heteroAr—H); ^{13}C NMR (DMSO-d_6): 166 (C=O), 163 (C=N), 154 (C—N=C), 118–153 ppm (Ar and heteroAr C's); Anal. Calcd. For $C_{11}H_6BrN_3OS$: C, 42.87; H, 1.96; Br, 25.93; N, 13.64; O, 5.19; S, 10.41. Found: C, 42.79; H, 1.91; Br, 25.97; N, 13.60; O, 5.24; S, 10.50.

5-Bromo-3-(2-pyridinylimino)-isatin(2e). From 2-pyridinyl amine, yellow–orange solid (65%), mp 190°C; ir (potassium bromide): NH 3452, C=O 1685, C=N 1618 cm^{-1}; ^1H NMR ($CDCl_3$): δ 9.0 (s, 1H, NH); 7.4–7.8 (m, 3H, Ar—H); 7.2, 8.6 ppm (m, 2H, heteroAr—H); ^{13}C NMR (DMSO-d_6): 168 (C=O), 162 (C=N), 152 (C—N=C), 118–175 ppm (Ar and heteroAr C's); Anal. Calcd. For $C_{13}H_8BrN_3O$: C, 51.68; H, 2.67; Br, 26.45; N, 13.91; O, 5.30. Found: C, 51.61; H, 2.72; Br, 26.50; N, 13.85; O, 5.38.

General procedure for the synthesis of 3′-arylspiro[3*H*–indole-3,2′-thiazolidine]-2,4′(1*H*)-2,4-dione (3). A mixture of **2** (1 mmol) and mercaptoacetic acid (2 mmol) was heated for 4–6 min in a MW oven set for 160 W. The completion of the reaction was checked by TLC. The reaction content was then treated with 15 mL, 10% $NaHCO_3$ solution and stirred well. The resulting compound was filtered, washed with water, dried and recrystallized from ethanol to give the pure product.

3-(p-Bromophenyl)spiro[3H-indole-3,2′-thiazolidine]-2,4′(1H)-dione (3a). From **2a**, yellow solid (72%), mp 90°C; ir (potassium bromide): NH 3260, C=O 1720, 1690, C=N 1608 cm^{-1}; ^1H NMR ($CDCl_3$): δ 8.5 (s, 1H, NH), 6.8–7.5 ppm (m, 8H, Ar—H); ^{13}C NMR (DMSO-d_6): 77 (spiro C), 170,168 (2 C=O), 35 (S—CH_2—C), 118–141 ppm (Aromatic-C); Anal. Calcd. For $C_{16}H_{11}BrN_2O_2S$: C, 51.21; H, 2.95; Br, 21.29; N, 7.49; O, 8.53; S, 8.55. Found: C, 51.17; H, 3.09; Br, 21.37; N, 7.53; O, 8.44; S, 8.61.

3′-(Phenyl)spiro[3H-indole-3,2′-thiazolidine]-2,4′(1H)-dione (3b). From **2b**, dark brown solid (76%), mp 230°C; ir (potassium bromide): NH 3258, C=O 1730, 1695, C=N 1608 cm^{-1}; ^1H NMR ($CDCl_3$): δ 8.1 (s, 1H, NH), 6.8–7.5 (m, 9H, Ar—H), 3.5 ppm (S—CH_2—C); ^{13}C NMR (DMSO-d_6): 77 (spiro C), 170,168 (2 C=O), 35 (S—CH_2—C), 120–141 ppm (Aromatic-C); Anal. Calcd. For $C_{16}H_{12}N_2O_2S$: C, 64.85; H, 4.08; N, 9.45; O, 10.80; S, 10.82. Found: C, 64.91; H, 3.95; N, 9.52; O, 10.87; S, 10.90.

5-Bromo-3′-(benzyl)spiro[3H-indole-3,2′-thiazolidine]-2,4′(1H)-dione (3c). From **2c**, brown solid (75%), mp 125°C; ir (potassium bromide): NH 3345, C=O 1732, 1687 cm^{-1}; ^1H NMR ($CDCl_3$): δ 8.3 (s, 1H, NH), 7.1–7.4 (m, 8H, Ar—H), 3.4 (S—CH_2—C), 4.5 ppm (N—CH_2—C); ^{13}C NMR (DMSO-d_6): 74 (spiro C), 170,171 (2 C=O), 35 (S—CH_2—C), 47 (N—CH_2—C) 119–137 ppm (Aromatic-C), Anal. Calcd. For $C_{17}H_{13}BrN_2O_2S$: C, 52.45; H, 3.37; N, 7.20; O, 8.22; S, 8.24. Found: C, 52.39; H, 3.31; N, 7.14; O, 8.30; S, 8.38.

5-Bromo-3′-(2-thiazolyl)spiro[3H-indole-3,2′-thiazolidine]-2,4′(1H)-dione (3d). From **2d**, shiny blackish solid (78%), mp 135°C; ir (potassium bromide): NH 3360, C=O 1730, 1698 cm^{-1}; ^1H NMR ($CDCl_3$): δ 8.5 (s, 1H, NH), 7.2–7.4 (m, 3H, Ar—H), 3.5 (S—CH_2—C), 6.6–7.5 ppm (2H, thiazolyl), ^{13}C NMR (DMSO-d_6): 76 (spiro C), 170,168 (2 C=O), 35 (S—CH_2—C), 119–141 ppm (Aromatic-C), 108, 138, 172 (thiazolyl C), Anal. Calcd. For $C_{13}H_8BrN_3O_2S_2$: C, 40.85; H, 2.11; Br, 20.90; N, 10.99; O, 8.37; S, 16.78. Found: C, 40.91; H, 2.04; Br, 20.83; N, 11.03; O, 8.31; S, 16.84.

5-Bromo-3′-(2-piperidinyl)spiro[3H-indole-3,2′-thiazolidine]-2,4′(1H)-dione (3e). From **2e**, brown solid (87%), mp 120°C; ir (potassium bromide): NH 3450, C=O 1732, 1690 cm^{-1}; ^1H NMR ($CDCl_3$): δ 8.7 (s, 1H, NH), 7.2–7.4 (m, 3H, Ar—H), 7.1–8.5 (4H, pyridine), 3.5 ppm (S—CH_2—C), ^{13}C NMR (DMSO-d_6): 76 (spiro C), 170,168 (2 C=O), 35 (S—CH_2—C), 119–152 ppm (Aromatic-C and heteroAr-C), Anal. Calcd. for $C_{15}H_{10}BrN_3O_2S$: C, 47.89; H, 2.68; Br, 21.25; N, 11.17; O, 8.51; S, 8.52. Found: C, 47.95; H, 2.73; Br, 21.19; N, 11.11; O, 8.57; S, 8.46.

General procedure for the synthesis of 3′-aryl-1-morpholino/piperidinomethylspiro[3*H*-indole-thiazolidine]-2,4′(1*H*)-dione (4/5). An equimolar quantity of **3** (5 mmol) and morpholine/piperidine (5 mmol) was blended with 37 % formaldehyde (0.5 mL) and then irradiated in a MW oven at 640 W with 30 s/cycle for 2–3 min, as checked by TLC. After cooling, the product mixture was recrystallized from aqueous ethanol to afford product.

3′-(p-Bromophenyl)-1-morpholinomethylspiro[3H-indole-thiazolidine]-2,4′(1H)-dione (4a). From **3a**, yellow solid (71%), mp 114°C; ir (potassium bromide): C=O 1720, 1690 cm^{-1}; ^1H NMR ($CDCl_3$): δ 6.9–7.5 (m, 8H, Ar—H), 2.4–3.7 (m, 10H, 5 × CH_2), 4.6 ppm (s, N—CH_2—N); ^{13}C NMR (DMSO-d_6): 74 (spiro C), 170,168 (2 C=O), 35 (—CH_2—), 70 (N—CH_2—N), 54–71 (4 × CH_2), 118–142 ppm (Aromatic-C); Anal. Calcd. for $C_{21}H_{20}BrN_3O_3S$: C, 53.17; H, 4.25; Br, 16.84; N, 8.86; O, 10.12; S, 6.76. Found: C, 53.26; H, 4.18; Br, 16.76; N, 8.80; O, 10.21; S, 6.82

3′-(Phenyl)-1-morpholinomethylspiro[3H-indole-thiazolidine]-2,4′(1H)-dione (4b). From **3b**, yellow solid (77%), mp 101°C; ir. (potassium bromide): C=O 1730, 1695 cm^{-1}; ^1H NMR ($CDCl_3$): δ 6.9–7.3 (m, 9H, Ar—H), 2.4–3.4 (m, 10H, 5 × CH_2), 4.6 (s, N—CH_2—N), 3.4 ppm (S—CH_2—C), ^{13}C NMR

(DMSO-d_6): 74 (spiro C), 169,168 (2 C=O), 33 (—CH_2—), 71 (N—CH_2—N), 54–71 (4 × CH_2), 120–140 ppm (Aromatic-C), Anal. Calcd. for $C_{21}H_{21}N_3O_3S$: C, 63.78; H, 5.35; N, 10.63; O, 12.14; S, 8.11. Found: C, 63.85; H, 5.28 N, 10.60; O, 12.08; S, 8.28.

5-Bromo-3′-(2-piperidinyl)-1-morpholinomethylspiro [3H-indole-thiazolidine]-2,4′(1H)-dione (4c). From **3e**, brown solid (74%), mp 70°C; ir (potassium bromide): C=O 1740, 1700 cm^{-1}; ^1H NMR ($CDCl_3$): δ 6.9–7.3 (m, 3H, Ar—H), 2.3–3.7 (m, 8H, 4 × CH_2), 4.5 (s, N—CH_2—N), 3.3 (S—CH_2—C), 7.2–8.5 ppm (4H, pyridine), ^{13}C NMR (DMSO-d_6): 75 (spiro C), 170,168 (2 C=O), 33 (S—CH_2—C), 70 (N—CH_2—N), 54–71 (4 × CH_2), 119–142 (Aromatic-C), 115–153 ppm (pyridine C), Anal. Calcd. for $C_{20}H_{19}BrN_4O_3S$: C, 50.53; H, 4.03; Br, 16.81; N, 11.79; O, 10.10; S, 6.75. Found: C, 50.59; H, 4.11; Br, 16.77; N, 11.84; O, 10.17; S, 6.81.

5-Bromo-3′-(benzyl)-1-piperidinomethylspiro[3H-indole-thiazolidine]-2,4′(1H)-dione (5a). From **3c**, brown solid (70%), mp 85°C; ir (potassium bromide): C=O 1728, 1695 cm^{-1}; ^1H NMR ($CDCl_3$): δ 6.9–7.5 (m, 8H, Ar—H), 1.5–3.3 (m, 12H, 6 × CH_2), 4.6 (s, N—CH_2—N), 4.5 (N—CH_2—C), 3.3 ppm (S—CH_2—C), ^{13}C NMR (DMSO-d_6): 68 (spiro C), 171,168 (2 C=O), 35 (S—CH_2—C), 70 (N—CH_2—N), 54–71 (4 × CH_2), 125–141 ppm (Aromatic-C), Anal. Calcd. for $C_{23}H_{24}BrN_3O_3S$: C, 56.79; H, 4.97; Br, 16.43; N, 8.64; O, 6.58; S, 6.59. Found: C, 56.67; H, 5.08; Br, 16.49; N, 8.70; O, 6.49; S, 6.50.

5-Bromo-3′-(2-thiazolyl)-1-piperidinomethylspiro[3H-indole-thiazolidine]-2,4′(1H)-dione (5b). From **3d**, coffee colored shiny powder (72%), mp 120°C; ir (potassium bromide): C=O 1735, 1692 cm^{-1}; ^1H NMR ($CDCl_3$): δ 6.8–7.3 (m, 3H, Ar—H), 1.5–2.4 (m, 10H, 5 × CH_2), 4.5 (s, N—CH_2—N), 6.5,7.5 (2H, thiazole), 3.3 ppm (S—CH_2—C), ^{13}C NMR (DMSO-d_6): 74 (spiro C), 173,172 (2 C=O), 35 (S—CH_2—C), 70 (N—CH_2—N), 54–71 (5 × CH_2), 119–141 (Aromatic-C), 138,168,171 ppm (thiazole), Anal. Calcd. for $C_{19}H_{19}BrN_4O_2S_2$: C, 47.60; H, 3.49; Br, 16.67; N, 11.69; O, 6.67; S, 13.38. Found: C, 47.51; H, 3.56; Br, 16.71; N, 11.75; O, 6.59; S, 13.47

A simple facile one-step microwave-enhanced synthesis of methyl 4-substituted-6-amino-5-cyano-2-methylpyridine-3-carboxylate derivatives *via* a three-component reaction of aromatic aldehydes, malononitrile, and methyl 3-aminobut-2-enoate has been developed. It is an efficient and promising synthetic strategy to build the polyfunctional pyridine skeleton.

J. Heterocyclic Chem., **46**, 54 (2009).

INTRODUCTION

Multicomponent reactions (MCRs), an important class of organic reactions, are one-pot processes with at least three components to form a single product, which incorporates most or even all of the starting materials [1]. The huge interest for such multicomponent reactions during the last years has been oriented toward developing combinatorial chemistry procedures, because of their high efficiency and convenience of these reactions in comparison with multistage procedures. Hence, much scientific effort has been focused on the development of multicomponent procedures to prepare diverse heterocyclic compound libraries [2].

Pyridine and its derivatives have a vast range of biological activities. They have been used as herbicides [3], for enrichment of cereals [4], for regulation of arterial pressure [5], and cholesterol levels in blood [6]. In addition, some pyridines constitute an important class of antitumor compounds, which have been attracting significant attention [7,8]. Some polyfunctional pyridines are used as nonlinear optical materials [9], electrical materials [10], chelating agents in metal-ligand chemistry [11], and as fluorescent liquid crystals [12]. Therefore, development of efficient procedures toward functionalized pyridines is a quite important task in organic synthesis [13].

There is a great variety of methods described in the literature to synthesize similar skeleton [14]. Many precedent methods, however, have inevitable drawbacks: the aromatized polysubstituted pyridines were previously mostly synthesized through two steps: 1,4-DHPs were first prepared, which further proceeded to be oxidized to provide the corresponding aromatized compounds.

As part of an ongoing development of efficient protocols for the preparation of polysubstituted heterocycles from common intermediates [15], we recently discovered a simple and efficient method for the synthesis of polysubstituted pyridines (Scheme 1) *via* aldehydes, malononitrile, and methyl 3-aminobut-2-enoate under microwave (MW) irradiation.

RESULTS AND DISCUSSION

To optimize the reaction conditions, different organic solvents, such as ethanol, glycol, acetic acid, DMF, and mixed glycol-HOAc were tested in the synthesis of **4b** at 100°C. Table 1 show that the reactions in mixed glycol-HOAc (2:1, v/v) gave the best results (entry 6 of Table 1).

Moreover, to further optimize the reaction temperature, reactions using 4-chlorobenzaldehyde (**1b**, 1.0 mmol), malononitrile (**2**, 1.0 mmol), and methyl 3-aminobut-2-enoate (**3**, 1.0 mmol) were carried out in the range of 90–150°C in increments of 10°C each time in mixed glycol-HOAc (2:1, v/v) under microwave irradiation (initial power 100 W, maximum power 200 W). The results are shown in Table 2. When the temperature was increased from 90 to 120°C, the yield of product **4b** was improved. However, no significant increase in the

Table 2

Temperature optimization for the synthesis of **4b** under MW.

Entry	*T* (°C)	Time (min)	Yield (%)
1	90	9	70
2	100	9	76
3	110	9	83
4	120	7	88
5	130	7	85
6	140	7	83
7	150	7	80

yield of product **4b** was observed as the reaction temperature was raised from 130 to 150°C. Therefore, the temperature of 120°C was chosen for all further MW-assisted reactions.

The use of these optimal microwave experimental conditions [120°C, glycol-HOAc (2:1)] for the reactions of different aromatic aldehydes afforded good yields of polysubstituted pyridine derivatives. The results (Table 3, entries 1–10) indicated that aromatic aldehydes bearing either electron-donating (such as alkoxyl groups) or electron-withdrawing (such as nitro or halide groups) functional groups were all suitable for the reaction. Moreover, a heterocyclic aldehyde, thiophene-2-carbaldehyde (Table 3, entry 11), still showed high reactivity under these standard conditions.

Although the detailed mechanism of the above reaction remains to be fully clarified, the formation of **4** could be explained by a possible reaction sequence presented in Scheme 2. Compound **4** is expected to proceed *via* initial condensation of aromatic aldehydes with malononitrile to afford alkylidenemalononitrile **5**, which further undergoes *in situ* Michael addition with methyl 3-aminobut-2-enoate **3**, to yield intermediate **7**, which is then cyclized and subsequently dehydrogenated to afford the aromatized product **4**. This type of hydrogen loss was well precedented [16].

To test the mechanism described earlier, the reaction of intermediate product **5c** and methyl 3-aminobut-2-enoate **3** was carried out under microwave irradiation conditions. The target compound **4c** was obtained, in similar yields by the one-pot reaction. The results supported the proposed mechanism (Scheme 3).

In this study, all the products were characterized by IR and ^{1}H NMR spectral data as well as elemental analyses. Furthermore, the structure of **4a** [17] was established by X-ray crystallographic analysis. The molecular structure of **4a** was shown in Figure 1.

In conclusion, the microwave-assisted synthesis of polysubstituted pyridines in this paper is an efficient methodology allowing the facile preparation of these important polycyclic compounds. This procedure offers several advantages including operational simplicity, increased safety for small-scale high-speed synthesis that makes it a useful and attractive process for the synthesis of these compounds.

EXPERIMENTAL

Microwave irradiation was carried out with a microwave oven Emrys^{TM} Creator from Personal Chemistry, Uppsala,

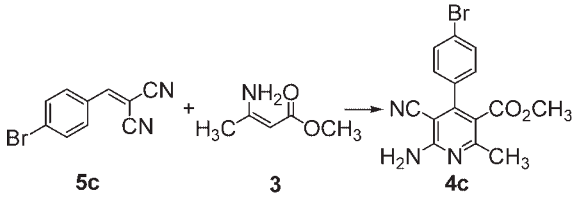
Sweden. Melting points were determined in the open capillaries and were uncorrected. IR spectra were taken on a FTIR-Tensor 27 spectrometer in KBr pellets and reported in cm^{-1}. ^1H NMR spectra were measured on a Bruker DPX 400 MHz spectrometer using TMS as an internal standard and DMSO-d_6 as solvent. Elemental analysis was determined by using a Perkin–Elmer 240c elemental analysis instrument. X-Ray crystallographic analysis was performed with a Siemens SMART CCD and a Siemens P4 diffractometer.

General procedure for the one-pot synthesis of compounds 4 under microwave irradiation conditions. Typically, in a 10-mL Emrys^{TM} reaction vial, aldehyde **1** (1 mmol), malononitrile **2** (1 mmol, 0.066 g), methyl 3-aminobut-2-enoate **3** (1 mmol, 0.115 g), glycol (1.0 mL), and HOAc (0.5 mL) were mixed and then capped. The mixture was irradiated for a given time at 120°C under microwave irradiation (initial power 100 W and maximum power 200 W). Upon completion, monitored by TLC, the reaction mixture was cooled to room temperature and then poured into cold water. The solid product was collected by Büchner filtration and was further purified by recrystallization from EtOH (95%) to give the pure product.

Methyl 6-amino-5-cyano-4-(4-fluorophenyl)-2-methyl-pyridine-3-carboxylate (4a). This compound was obtained according to the above general procedure; ir (potassium bromide): 3390, 3321, 3172, 3076, 2220, 1715, 1652, 1565, 1434, 1376, 1229, 1166, 1077, 958, 882, 665 cm^{-1}; ^1H NMR: 7.39–7.37 (m, 2H, 3′,5′-ArH), 7.36 (s, 2H, NH_2), 7.34–7.31 (m, 2H, 2′,4′-ArH), 3.43 (s, 3H, OCH_3), 2.38 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{12}FN_3O_2$: C, 63.15; H, 4.24; N, 14.73. Found: C, 63.12; H, 4.28; N, 14.75.

Methyl 6-amino-4-(4-chlorophenyl)-5-cyano-2-methyl-pyridine-3-carboxylate (4b). This compound was obtained according to the above general procedure, this compound is known (RN: 176689-71-7) [14d]; ir (potassium bromide): 3383, 3324, 3178, 3086, 2221, 1721, 1653, 1576, 1496, 1378, 1284, 1197, 1094, 960, 863, 661 cm^{-1}; ^1H NMR: 7.57 (d, 2H, J = 8.4 Hz, 2′,4′-ArH), 7.40 (s, 2H, NH_2), 7.34 (d, 2H, J = 8.4 Hz, 3′,5′-ArH), 3.44 (s, 3H, OCH_3), 2.39 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{12}ClN_3O_2$: C, 59.71; H, 4.01; N, 13.93. Found: C, 59.76; H, 4.05; N, 13.90.

Scheme 3



Methyl 6-amino-4-(4-bromophenyl)-5-cyano-2-methyl-pyridine-3-carboxylate (4c). This compound was obtained according to the above general procedure; ir (potassium bromide): 3405, 3313, 3161, 3069, 2217, 1718, 1651, 1557, 1437, 1376, 1283, 1104, 1012, 957, 882, 665 cm^{-1}; ^1H NMR: 7.71 (d, 2H, J = 8.4 Hz, 3′,5′-ArH), 7.40 (s, 2H, NH2), 7.27 (d, 2H, J = 8.4 Hz, 2′,4′-ArH), 3.45 (s, 3H, OCH_3), 2.39 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{12}BrN_3O_2$: C, 52.04; H, 3.49; N, 12.14. Found: C, 52.00; H, 3.45; N, 12.15.

Methyl 6-amino-5-cyano-2-methyl-4-(4-nitrophenyl)-pyridine-3-carboxylate (4d). This compound was obtained according to the above general procedure; ir (potassium bromide): 3383, 3331, 3151, 3061, 2222, 1720, 1661, 1562, 1433, 1382, 1282, 1107, 1017, 955, 888, 665 cm^{-1}; ^1H NMR: 8.35 (d, 2H, J = 8.8 Hz, 3′,5′-ArH), 7.62 (d, 2H, J = 8.4 Hz, 2′,4′-ArH), 7.53 (s, 2H, NH_2), 3.40 (s, 3H, OCH_3), 2.43 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{12}N_4O_4$: C, 57.69; H, 3.87; N, 17.94. Found: C, 57.70; H, 3.85; N, 17.95.

Methyl 6-amino-5-cyano-2-methyl-4-p-tolylpyridine-3-carboxylate (4e). This compound was obtained according to the above general procedure; ir (potassium bromide): 3338, 3321, 3173, 3048, 2219, 1712, 1652, 1560, 1434, 1376, 1286, 1110, 1077, 961, 882, 664 cm^{-1}; ^1H NMR: 7.30 (d, 2H, J = 7.6 Hz, 2′,4′-ArH), 7.19 (d, 2H, J = 8.0 Hz, 3′,5′-ArH), 7.11 (s, 2H, NH_2), 3.43 (s, 3H, OCH_3), 2.37 (s, 6H, CH_3). Anal. calcd for $C_{16}H_{15}N_3O_2$: C, 68.31; H, 5.37; N, 14.94. Found: C, 68.35; H, 5.39; N, 14.95.

Methyl 6-amino-4-(2-chlorophenyl)-5-cyano-2-methyl-pyridine-3-carboxylate (4f). This compound was obtained according to the above general procedure; ir (potassium bromide): 3385, 3325, 3177, 3052, 2222, 1717, 1654, 1594, 1431, 1378, 1283, 1168, 1035, 958, 802, 663 cm^{-1}; ^1H NMR: 7.61–7.59 (m, 1H, ArH), 7.49 (s, 2H, NH2), 7.47–7.42 (m, 2H, ArH), 7.29–7.27 (m, 1H, ArH), 3.37 (s, 3H, OCH_3), 2.45 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{12}ClN_3O_2$: C, 59.71; H, 4.01; N, 13.93. Found: C, 59.75; H, 4.04; N, 13.95.

Methyl 6-amino-5-cyano-2-methyl-4-phenylpyridine-3-carboxylate (4g). This compound was obtained according to the above general procedure, this compound is known (RN: 176689-69-3) [14d]; ir (potassium bromide): 3395, 3320, 3169, 3057, 2219, 1714, 1652, 1558, 1436, 1377, 1284, 1168, 1077, 960, 803, 662 cm^{-1}; ^1H NMR: 7.50–7.48 (m, 3H, ArH), 7.35 (s, 2H, NH_2), 7.31–7.29 (m, 2H, ArH), 3.39 (s, 3H, OCH_3), 2.39 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{13}N_3O_2$: C, 67.40; H, 4.90; N, 15.72; Found: C, 67.44; H, 4.95; N, 15.70.

Methyl 6-amino-4-(3,4-dichlorophenyl)-5-cyano-2-methylpyridine-3-carboxylate (4h). This compound was obtained according to the above general procedure; ir (potassium bromide): 3395, 3315, 3168, 3066, 2216, 1712, 1650, 1505, 1449, 1377, 1287, 1167, 1038, 926, 820, 775 cm^{-1}; ^1H NMR: 7.78 (d, 1H, $J = 8.4$ Hz, ArH), 7.68–7.67 (m, 1H, ArH), 7.47 (s, 2H, NH_2), 7.32 (dd, 1H, $J_1 = 8.0$ Hz, $J_2 = 2.4$ Hz, ArH), 3.47 (s, 3H, OCH_3), 2.41 (s, 3H, CH_3). Anal. calcd for $C_{15}H_{11}Cl_2N_3O_2$: C, 53.59; H, 3.30; N, 12.50. Found: C, 53.60; H, 3.33; N, 12.55.

Methyl 6-amino-5-cyano-4-(2,3-dimethoxyphenyl)-2-methylpyridine-3-carboxylate (4i). This compound was obtained according to the above general procedure; ir (potassium bromide): 3384, 3331, 3177, 3050, 2224, 1713, 1657, 1567, 1433, 1335, 1265, 1193, 1091, 818, 743 cm^{-1}; ^1H NMR: 7.31 (s, 2H, NH_2), 7.15–7.09 (m, 2H, ArH), 6.64 (dd, 1H, $J_1 = 8.0$ Hz, $J_2 = 2.4$ Hz, ArH), 3.86 (s, 3H, OCH_3), 3.61 (s, 3H, OCH_3), 3.41 (s, 3H, OCH_3), 2.40 (s, 3H, CH_3). Anal. calcd for $C_{17}H_{17}N_3O_4$: C, 62.38; H, 5.23; N, 12.84. Found: C, 62.36; H, 5.25; N, 12.80.

Methyl 6-amino-4-(benzo[d][1,3]dioxol-6-yl)-5-cyano-2-methylpyridine-3-carboxylate (4j). This compound was obtained according to the above general procedure; ir (potassium bromide): 3380, 3325, 3171, 3052, 2225, 1712, 1658, 1567, 1430, 1338, 1264, 1183, 1090, 810, 750 cm^{-1}; ^1H NMR: 7.27 (s, 2H, NH_2), 7.02 (d, 1H, $J = 8.0$ Hz, ArH), 6.92–6.91 (m, 1H, ArH), 6.75 (dd, 1H, $J_1 = 8.0$ Hz, $J_2 = 1.6$ Hz, ArH), 6.12 (s, 2H, CH_2), 3.48 (s, 3H, OCH_3), 2.35 (s, 3H, CH_3). Anal. calcd for $C_{16}H_{13}N_3O_4$: C, 61.73; H, 4.21; N, 13.50. Found: C, 61.76; H, 4.25; N, 13.54.

Methyl 6-amino-5-cyano-2-methyl-4-(thiophen-2-yl)pyridine-3-carboxylate (4k). This compound was obtained according to the above general procedure; ir (potassium bromide): 3390, 3320, 3163, 3060, 2219, 1713, 1654, 1560, 1434, 1330, 1261, 1168, 1041, 839, 736 cm^{-1}; ^1H NMR: 7.81 (dd, 1H, $J_1 = 8.0$ Hz, $J_2 = 1.2$ Hz, ArH), 7.35 (s, 2H, NH_2), 7.29–7.28 (m, 1H, ArH), 7.21–7.19 (m, 1H, ArH), 3.55 (s, 3H, OCH_3), 2.35 (s, 3H, CH_3). Anal. calcd for $C_{13}H_{11}N_3O_2S$: C, 57.13; H, 4.06; N, 15.37; S, 11.73. Found: C, 57.16; H, 4.05; N, 15.34; S, 11.75.

A group of acetylene regioisomers were designed such that a cyclooxygenase-2 (COX-2) SO_2Me pharmacophore was located at the ortho-, meta-, or para-position of the acetylene C-1 phenyl ring, and an iron-chelating 5-lipoxygenase (5-LOX) *N*-hydroxypyridin-2(1*H*)-one moiety was attached *via* its C-5 position to the C-2 position on an acetylene template (scaffold). These target linear acetylene regioisomers were synthesized *via* a palladium-catalyzed Sonogashira cross-coupling reaction. Structure-activity data acquired using *in vitro* cell-based inhibition assays indicated that this novel class of 1-(2-, 3-, or 4-methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene regioisomers did not inhibit the COX-2 or (5-LOX) enzymes, and that they are devoid of *in vivo* anti-inflammatory activities.

J. Heterocyclic Chem., **46**, 58 (2009).

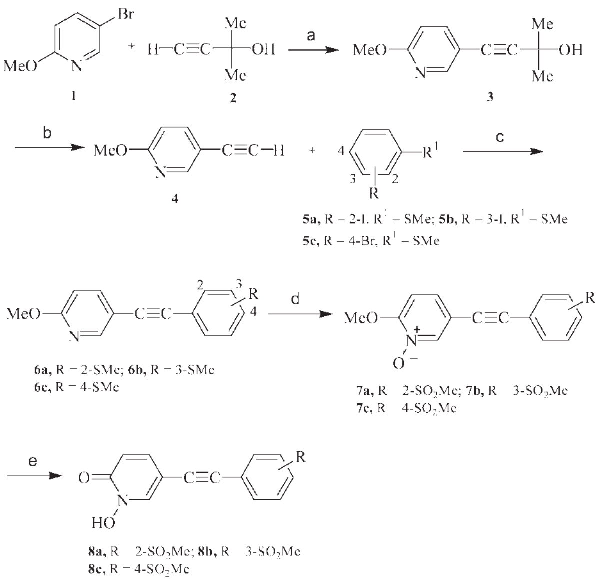
INTRODUCTION

Dual inhibitors of cyclooxygenase-2 (COX-2) and 5-lipoxygenase (5-LOX) represent an attractive safer alternative to selective COX-2 inhibitors. This view is based on a potentially greater anti-inflammatory efficacy because of their ability to synergistically block both metabolic pathways of the arachidonic acid (AA) cascade [1]. A group of 1-(2-, 3-, and 4-methanesulfonylphenyl)-2-(2-, 3-, and 4-pyridyl)acetylene regioisomers, which are effective COX-1/COX-2 inhibitors that exhibit *in vivo* anti-inflammatory activities, were recently reported [2]. The most successful effort to develop 5-LOX inhibitors has been in the area of hydroxamic acids and related *N*-hydroxyureas that likely chelate iron present in the 5-LOX enzyme [3]. The recently described 1-(methanesulfonlylphenyl)-2-(pyridyl)acetylene regioisomers possess a suitable scaffold (template) to design novel acyclic dual inhibitors of the COX and LOX enzymes [2]. It was anticipated that replacement of the pyridyl ring in these parent acetylenes by a *N*-hydroxypyridin-2(1*H*)one moiety, which has the potential to chelate iron, may provide a hitherto unknown class of dual COX/5-LOX inhibitory anti-inflammatory agents. Accordingly, we now describe the synthesis of a novel group of 1-(2-, 3-, or 4-methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene regioisomers (**8a–c**), to determine their potential utility as inhibitors of the COX-2 and 5-LOX enzymes.

RESULTS AND DISCUSSION

1-(Methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylenes (**6a–c**) were prepared in 28–72% yield using two consecutive palladium-catalyzed Sonogashira cross-coupling reactions [2,4–7]. The subsequent transformation of **6a–c** to the target 1-(2-, 3-, or 4-methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene regioisomers (**8a–c**) was carried out using the synthetic methodologies shown in Scheme 1. A modified procedure [8] was used to synthesize 5-ethynyl-2-methoxypyridine (**4**). Thus, Sonogashira coupling of 5-bromo-2-methoxypyridine (**1**) with 2-methylbut-3-yn-2-ol (**2**) in the presence of Et_3N, cuprous iodide (CuI), and dichloro-bis(triphenylphosphine)palladium(0) ([$PdCl_2(PPh_3)_2$]) catalyst afforded 4-(2-methoxypyridin-5-yl)-2-methyl-but-3-yn-2-ol (**3**) in 75% yield. Subsequent removal of the isopropanol moiety using sodium hydride furnished 5-ethynyl-2-methoxypyridine (**4**) in 82% yield.

Scheme 1. Reagents and conditions: (a) Et_3N, $Pd(PPh_3)_2Cl_2$, CuI, 70–75°C, 3 h; (b) benzene, NaH, 105–110°C, 1 h; (c) Et_3N, $Pd(PPh_3)_2Cl_2$, CuI, 90°C, 5 h; (d) *m*-chloroperoxybenzoic acid, CH_2Cl_2, 25°C, overnight; (e) (i) acetyl chloride, reflux, 1 h; (ii) MeOH, 25°C, overnight.



A second Sonogashira cross-coupling reaction of **4** with the halothioanisole (**5a–c**) regioisomers was carried out under an argon atmosphere in Et_3N using $[PdCl_2(PPh_3)_2]$/CuI as catalyst to furnish the respective 1-(methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylenes **6a–c** in 28–72% yield. Oxidation of **6a–c** with *meta*-chloroperbenzoic acid in dichloromethane [9] afforded the 1-(methanesulfonylphenyl)-2-(1-oxido-2-methoxypyrid-5-yl)acetylenes (**7a–c**) in 44–51% yield. Finally, reaction of the *N*-oxides **7a–c** with acetyl chloride at reflux, and then methanolysis in place of hydrolysis [9] furnished the target *N*-hydroxypyridin-2(1*H*)-ones (**8a–c**) in 69–91% yield.

Replacement of the carboxyl (CO_2H) in traditional arylacetic acid nonsteroidal anti-inflammatory drugs (NSAIDs) by a hydroxamic acid (CONHOH) moiety provided potent orally active 5-LOX inhibitory agents [10]. NSAIDs having a CONHOH or CON(Me)OH (pKa 9–11 range) in place of the CO_2H in traditional NSAIDs (pKa generally in the 4–5 range) are much less acidic, which decreases ulcerogenicity [11].

The rational for the design of the acyclic acetylenes **8a-c** was based on the expectations that (i) the phenyl ring bearing the SO_2Me pharmacophore will confer COX-2 inhibitory activity, and (ii) the *N*-hydroxypyridin-2(1*H*)one moiety will confer 5-LOX inhibitory activity. The CONOH part of the *N*-hydroxypyrid-2(1*H*)-one ring present in **8a–c** can be viewed as a cyclic hydroxamic acid mimetic. These *N*-hydroxypyridin-2(1*H*)-ones, like acyclic hydroxamic acids, are expected to serve as effective iron chelators to exhibit 5-LOX inhibitory activity. However, these cyclic *N*-hydroxypyridin-2(1*H*)-ones, unlike acyclic hydroxamic acids which undergo facile biotransformation to the carboxylic acids, are expected to be metabolically stable with improved oral efficacy.

In vitro cell-based inhibition assays were carried out to determine the biological effect of compounds **8a–c** on eicosanoid synthesis/release by measuring the amounts of cysteinyl leukotrienes (collectively referred to as a group of 5-LOX derived metabolites LTC_4, LTD_4, and LTE_4) and prostaglandin E_2 (PGE_2) secreted into the culture medium of human brain cancer cells. The assay to determine the ability of **8a–c** to inhibit *in vitro* cell-based 5-LOX activity showed that all three regioisomers failed to inhibit the 5-LOX enzyme ($IC_{50} > 50$ μM) relative to the reference drug nordihydroguaiaretic acid (NDGA, $IC_{50} = 35$ μM). Compounds **8a–c** were similarly inactive ($IC_{50} > 100$ μM) inhibitors of the COX-2 isozyme relative to the reference drug celecoxib ($IC_{50} = 2.5$ μM) in a cell-based assay.

The anti-inflammatory activities exhibited by the regioisomers **8a–c** were determined using a carrageenan-induced rat foot paw edema model at a 50 mg/kg oral dose. In this assay, compounds **8a–c** were all inactive anti-inflammatory (AI) agents compared with the reference drug celecoxib (79.9 ± 1.9% inhibition at 50 mg/kg po; $ID_{50} = 10.8$ mg/kg po).

The biological data acquired in this study indicate that the 1-(methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene structure is not a suitable template for the design of anti-inflammatory agents that act by inhibition of the 5-LOX and/or COX-2 enzymes.

EXPERIMENTAL

Melting points were determined on a Thomas-Hoover capillary apparatus and are uncorrected. Unless otherwise noted, infrared (IR) spectra were recorded as films on NaCl plates using a Nicolet 550 Series II Magna FTIR spectrometer. ^1H NMR spectra were measured on a Bruker AM-300 spectrometer in $CDCl_3$ or $CDCl_3$ + DMSO-d_6 with TMS as the internal standard. Microanalyses were performed for C, H, N (Micro-Analytical Service Laboratory, Department of Chemistry, University of Alberta) and were within ±0.4% of theoretical values. Silica gel column chromatography was performed using Merck silica gel 60 ASTM (70-230 mesh). 2-Iodothioanisole (**5a**) [12] and 3-iodothioanisole (**5b**) [13] were synthesized in 91% and 76% yields, respectively, starting from 2-(methylthio)aniline and 3-(methylthio)aniline using the procedure of Ullmann [14]. All other reagents, purchased from the Aldrich Chemical Company (Milwaukee, WI), were used without further purification.

4-(2-Methoxypyridin-5-yl)-2-methylbut-3-yn-2-ol (3). $PdCl_2(PPh_3)_2$ (63 mg, 0.09 mmoles) and CuI (19 mg, 0.10 mmoles) were added to a stirred solution of 5-bromo-2-methoxypyridine

(**1**) (2.75 mL, 21.39 mmoles) and 2-methylbut-3-yn-2-ol (**2**) (2.20 mL, 22.61 mmoles) in Et$_3$N (40 mL) under an argon atmosphere at 25°C, and the reaction was allowed to proceed at 70–75°C for 3 h. The reaction mixture was allowed to cool to 25°C, filtered, and excess Et$_3$N was removed from the filtrate *in vacuo*. The dark brown residue obtained was purified by silica gel column chromatography using hexane-EtOAc (3:1, v/v) as eluent to afford **3** in 75% yield; yellowish oil; IR (film): 3368 (OH), 2235 ($C{\equiv}C$) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 1.62 (s, 6H, C*Me*$_2$), 2.44 (br s, 1H, O*H*), 3.94 (s, 3H, O*Me*), 6.69 (d, *J* = 8.5 Hz, 1H, pyridyl H-3), 7.59 (dd, *J* = 8.5, 2.1 Hz, 1H, pyridyl H-4), 8.27 (d, *J* = 2.1 Hz, 1H, pyridyl H-6).

5-Ethynyl-2-methoxypyridine (4). Sodium hydride (26 mg, 1.08 mmoles) was added to a solution of 4-(2-methoxypyridin-5-yl)-2-methylbut-3-yn-2-ol (**3**) (1.52 g, 7.96 mmoles) in benzene (7 mL), and the reaction mixture was heated at 105–110°C for 1 h. Removal of the solvent *in vacuo* gave a dark brown oil, which was purified by silica gel column chromatography using hexane-EtOAc (3:1, v/v) as eluent to afford **4** in 82% yield; brown oil; IR (film): 2230 ($C{\equiv}C$) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 3.12 (s, 1H, $C{\equiv}CH$), 3.96 (s, 3H, O*Me*), 6.72 (d, *J* = 8.5 Hz, 1H, pyridyl H-3), 7.66 (dd, *J* = 8.5, 2.1 Hz, 1H, pyridyl H-4), 8.27 (d, *J* = 2.1 Hz, 1H, pyridyl H-6).

General procedure for the synthesis of 1-(methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylenes (6a–c). CuI (46 mg, 0.24 mmoles) was added with stirring to a solution containing PdCl$_2$(PPh$_3$)$_2$ (85 mg, 0.12 mmoles), 5-ethynyl-2-methoxypyridine (**4**) (6 mmoles), and a halothioanisole **5a**, **5b**, or **5c** (4 mmoles), in Et$_3$N (10 mL) under an argon atmosphere. The reaction mixture was heated at 90°C for 5 h, cooled to 25°C, and filtered to remove the inorganic salts. The solvent from the filtrate was removed *in vacuo*, and the residue obtained was purified by silica gel column chromatography using hexane-EtOAc (10:1, v/v) as eluent to furnish the respective product **6a–c**. Some physical and spectroscopic data for **6a–c** are listed below.

1-(2-Methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylene (6a). The product was obtained as a pale yellow oil using the Sonogashira coupling reaction of **4** with 2-iodothioanisole (**5a**) in 72% yield; IR (film): 2213 ($C{\equiv}C$), 1615, 1580, 1488 (Ar) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 2.52 (s, 3H, S*Me*), 4.00 (s, 3H, O*Me*), 6.77 (d, *J* = 8.5 Hz, 1H, pyridyl H-3), 7.12 (ddd, *J* = 7.6, 7.6, 1.2 Hz, 1H, phenyl H-5), 7.19 (dd, *J* = 7.6, 1.2 Hz, 1H, phenyl H-3), 7.31 (ddd, *J* = 7.6, 7.6, 1.2 Hz, 1H, phenyl H-4), 7.48 (d, *J* = 7.6, 1.2 Hz, 1H, phenyl H-6), 7.77 (dd, *J* = 8.5, 2.1 Hz, 1H, pyridyl H-4), 8.41 (d, *J* = 2.1 Hz, 1H, pyridyl H-6).

1-(3-Methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylene (6b). The product was obtained as a pale yellow oil using the Sonogashira coupling reaction of **4** with 3-iodothioanisole (**5b**) in 44% yield; IR (film): 2229 ($C{\equiv}C$), 1588, 1560, 1495 (Ar) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 2.51 (s, 3H, S*Me*), 3.99 (s, 3H, O*Me*), 6.77 (d, *J* = 8.9 Hz, 1H, pyridyl H-3), 7.20–7.31 (m, 3H, phenyl H-4, H-5, H-6), 7.39 (s, 1H, phenyl H-2), 7.72 (dd, *J* = 8.9, 2.1 Hz, 1H, pyridyl H-4), 8.36 (d, *J* = 2.1 Hz, 1H, pyridyl H-6).

1-(4-Methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylene (6c). The product was obtained as a pale yellow solid using the Sonogashira coupling reaction of **4** with 4-bromothioanisole (**5c**) in 28% yield; mp 85–87°C; IR (film): 2230 ($C{\equiv}C$), 1602, 1560, 1495 (Ar) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 2.51 (s, 3H, S*Me*), 4.00 (s, 3H, O*Me*), 6.77 (d, *J* = 8.5 Hz, 1H, pyridyl H-3), 7.21 (d, *J* = 8.5 Hz, 2H, phenyl H-3, H-5), 7.43 (d, *J* = 8.5 Hz, 2H, phenyl H-2, H-6), 7.72 (dd, *J* = 8.5, 2.1 Hz, 1H, pyridyl H-4), 8.36 (d, *J* = 2.1 Hz, 1H, pyridyl H-6).

General procedure for the synthesis of 1-(methanesulfonylphenyl)-2-(1-oxido-2-methoxypyrid-5-yl)acetylenes (7a-c). *m*-Chloroperoxybenzoic acid (77% max.) (12 mmoles) was added to a stirred solution of a 1-(methylthiophenyl)-2-(2-methoxypyrid-5-yl)acetylene (**6a**, **6b**, or **6c**, 2 mmoles) in dry CH$_2$Cl$_2$ (25 mL), and the reaction was allowed to proceed with stirring at 25°C overnight. The solvent CH$_2$Cl$_2$ was removed *in vacuo* to give a crude product, which was purified by silica gel column chromatography using methanol-EtOAc (2:3, v/v) as eluent to afford the respective product **7a–c**. Some physical and spectroscopic data for **7a–c** are listed below.

1-(2-Methanesulfonylphenyl)-2-(1-oxido-2-methoxypyrid-5-yl)acetylene (7a). Yield, 48%; pale yellow solid; mp 140–142°C; IR (film): 2220 ($C{\equiv}C$), 1669, 1602, 1521 (Ar), 1313, 1145 (SO$_2$) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 3.25 (s, 3H, SO$_2$*Me*), 4.16 (s, 3H, O*Me*), 6.98 (d, *J* = 8.5 Hz, 1H, pyridyl H-3), 7.52–7.70 (m, 3H, pyridyl H-4, phenyl H-4, H-5), 7.74 (dd, *J* = 7.6, 1.5 Hz, 1H, phenyl H-6), 8.15 (dd, *J* = 7.6, 1.5 Hz, 1H, phenyl H-3), 8.54 (d, *J* = 1.8 Hz, 1H, pyridyl H-6).

1-(3-Methanesulfonylphenyl)-2-(1-oxido-2-methoxypyrid-5-yl)acetylene (7b). Yield, 51%; pale yellow solid; mp 172–174°C; IR (film): 2227 ($C{\equiv}C$), 1609, 1528 (Ar), 1307, 1145 (SO$_2$) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 3.09 (s, 3H, SO$_2$*Me*), 4.14 (s, 3H, O*Me*), 6.93 (d, *J* = 8.5 Hz, 1H, pyridyl H-3), 7.47 (dd, *J* = 8.5, 1.8 Hz, 1H, pyridyl H-4), 7.61 (dd, *J* = 7.6, 7.6 Hz, 1H, phenyl H-5), 7.77 (ddd, *J* = 7.6, 1.5, 1.2 Hz, 1H, phenyl H-6), 7.95 (ddd, *J* = 7.6, 1.5, 1.2 Hz, 1H, phenyl H-4), 8.10 (dd, *J* = 1.5, 1.2 Hz, 1H, phenyl H-2), 8.45 (d, *J* = 1.8 Hz, 1H, pyridyl H-6).

1-(4-Methanesulfonylphenyl)-2-(1-oxido-2-methoxypyrid-5-yl)acetylene (7c). Yield, 44%; white solid; mp 175–177°C; IR (film): 2227 ($C{\equiv}C$), 1602, 1522 (Ar), 1300, 1146 (SO$_2$) cm^{-1}; ^{1}H NMR (CDCl$_3$) δ 3.08 (s, 3H, SO$_2$*Me*), 4.14 (s, 3H, O*Me*), 6.93 (d, *J* = 8.9 Hz, 1H, pyridyl H-3), 7.48 (d, *J* = 8.9, 1.8 Hz, 1H, pyridyl H-4), 7.71 (d, *J* = 8.5 Hz, 2H phenyl H-2, H-6), 7.95 (d, *J* = 8.5 Hz, 2H, phenyl H-3, H-5), 8.46 (d, *J* = 1.8 Hz, 1H, pyridyl H-6).

General procedure for the synthesis of 1-(methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylenes (**8a-c**). Acetyl chloride (6 mL) was added to a 1-(methanesulfonylphenyl)-2-(1-oxido-2-methoxypyrid-5-yl)acetylene (7a, 7b or 7c, 2 mmoles) and the reaction was allowed to proceed at reflux for 1 hour. The reaction mixture was cooled to 25°C, and excess acetyl chloride was removed *in vacuo*. The residue was dissolved in methanol prior to stirring at 25°C overnight. Methanol was removed *in vacuo* to give a solid product which was then mixed with Et$_2$O (10 mL) to form a slurry. Finally the product was filtered out and dried under vacuum to give the respective product (**8a-c**). The spectral and microanalytical data for compounds **8a-c** are listed below.

1-(2-Methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene (8a). Yield, 71%; brown solid; mp 198–200°C; IR (film): 2210 ($C{\equiv}C$), 1650 (CO), 1300, 1140 (SO$_2$) cm^{-1}; ^{1}H NMR (CDCl$_3$ + DMSO-d_6) δ 3.18 (s, 3H, SO$_2$*Me*), 6.54 (d, *J* = 9.2 Hz, 1H, pyridone H-3), 7.39 (dd, *J* = 9.2, 1.2 Hz, 1H, pyridone H-4), 7.46 (dd, *J* = 7.6, 7.6 Hz, 1H, phenyl H-

5), 7.55 (dd, $J = 7.6, 7.6$ Hz, 1H, phenyl H-4), 7.60 (d, $J = 7.6$ Hz, 1H, phenyl H-6), 7.93 (d, $J = 1.2$ Hz, 1H, pyridone H-6), 7.99 (d, $J = 7.6$ Hz, 1H, phenyl H-3). Anal. Calcd for $C_{14}H_{11}NO_4S{\cdot}1/2H_2O$: C, 56.32; H, 4.02; N, 4.69. Found: C, 56.30; H, 4.10; N, 4.83.

1-(3-Methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene (8b). Yield, 69%; brown solid; mp 205–207°C; IR (KBr): 2210 (C≡C), 1650 (CO), 1300, 1145 (SO_2) cm^{-1}; ^1H NMR ($CDCl_3$ + DMSO-d_6) δ 3.01 (s, 3H, SO_2Me), 6.54 (d, $J = 9.4$ Hz, 1H, pyridone H-3), 7.35 (dd, $J = 9.4, 2.4$ Hz, 1H, pyridone H-4), 7.50 (dd, $J = 7.6, 7.6$ Hz, 1H, phenyl H-5), 7.65 (ddd, $J = 7.6, 2.7, 1.5$ Hz, 1H, phenyl H-6), 7.80 (ddd, $J = 7.6, 2.7, 1.5$ Hz, 1H, phenyl H-4), 7.89 (d, $J = 2.4$ Hz, 1H, pyridone H-6), 7.93 (dd, $J = 1.5, 1.5$ Hz, 1H, phenyl H-2). Anal. Calcd for $C_{14}H_{11}NO_4S{\cdot}1/2H_2O$: C, 56.32; H, 4.02; N, 4.69. Found: C, 56.71; H, 3.80; N, 4.83.

1-(4-Methanesulfonylphenyl)-2-[5-(*N*-hydroxypyridin-2(1*H*)-one)]acetylene (8c). Yield, 91%; pale yellow solid; mp 234–236°C; IR (film): 2211 (C≡C), 1651 (CO), 1300, 1144 (SO_2) cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.20 (s, 3H, SO_2Me), 6.55 (d, $J = 9.5$ Hz, 1H, pyridone H-3), 7.50 (dd, $J = 9.5, 2.4$ Hz, 1H, pyridone H-4), 7.70 (d, $J = 8.5$ Hz, 2H phenyl H-2, H-6), 7.93 (d, $J = 8.5$ Hz, 2H, phenyl H-3, H-5), 8.33 (d, $J = 2.4$ Hz, 1H, pyridone H-6), 12.1 (br s, 1H, N-O*H*). Anal. Calcd for $C_{14}H_{11}NO_4S$: C, 58.12; H, 3.83; N, 4.84. Found: C, 57.80; H, 3.87; N, 4.95.

***In vitro* cell-based enzyme immunoassays for determination of prostaglandin E_2 (COX-2) and cysteinyl leukotrienes (5-LOX).** The biological effects of the test compounds **8a–c** on eicosanoid synthesis/release were determined by measuring the amounts of prostaglandin E_2 and cysteinyl leukotrienes (collectively referred to as a group of 5-LOX derived metabolites LTC_4, LTD_4, and LTE_4) secreted into the culture medium of human brain cancer cells. Primary culture of ED 273b-BT human glioblastoma cells derived from patient was established and characterized in our laboratory as previously described [15]. Cells were seeded in 12-well plates (2×10^5cells/well) and cultured in Dulbecco's modified Eagle's medium and F-12 nutrition mixture (Invitrogen, Grand Islands, NY) supplemented with 10% heat-inactivated fetal calf serum, 100 units/mL penicillin, and 100 units/mL streptomycin at 37°C in a humidified atmosphere of 5% CO_2. The cells were stimulated with the appropriate concentrations of the test compounds and the positive controls celecoxib (LKT Laboratories, St. Paul, MN) for COX-2 activity and NDGA (Cayman Chemical, Ann Arbor, MI) for 5-LOX activity. After a 24-h incubation, supernatants were harvested, centrifuged for 10 min at 2000 rpm and stored at −80°C until assayed. The concentrations of eicosanoids were determined using prostaglandin E_2 (catalog number 514010) and cysteinyl leukotriene (catalog number 520501) enzyme immunoassay kits (Cayman Chemical, Ann Arbor, MI) according to a previously reported method [16].

***In vivo* anti-inflammatory assay.** The test compounds **8a–c** and the reference drug celecoxib were evaluated using the in vivo carrageenan-induced foot paw edema model reported previously [17].

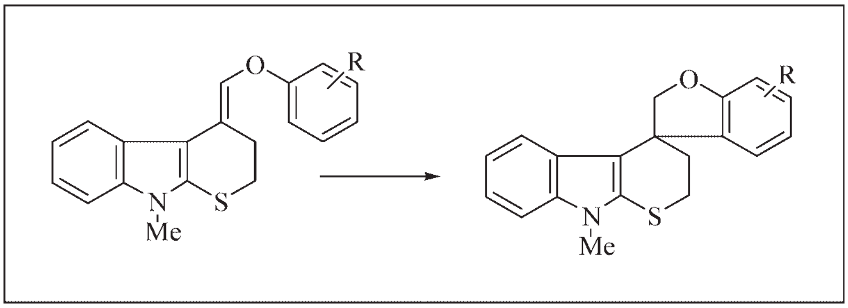
DOI 10.1002/jhet.31



Spirocyclic 4-{3′-benzo(2′,3′-dihydro)furo}-9-methyl-2,3,9-trihydrothiopyrano[2,3-*b*]indoles are regioselectively synthesized by treating suitable enol ethers, 4-aryloxymethylene-9-methyl-2,3,9-trihydrothiopyrano[2,3-*b*]indoles with H_2SO_4 in dichloromethane-methanol-water. The substrates for the aforesaid reaction are in turn synthesized by the *thio*-Claisen rearrangement of 2-(4′-aryloxybut-2′-ynylthio)-1-methylindoles.

J. Heterocyclic Chem., **46**, 62 (2009).

INTRODUCTION

Indoline-2-thiones are important starting materials in the synthesis of thiopyranoindole derivatives and have been applied for the synthesis of biologically active compounds [1]. There are many biologically active indole derivatives in the alkaloid family and indole derivatives are well known as medicinal compounds for their pharmaceutical and physiological activities [2]. Synthesis of oxygen-, nitrogen-, and sulfur-containing heterocyclic compounds [3] have received great attention in the field of synthetic organic chemistry and the synthesis of indole-annulated heterocyclic compounds are important as they are present in the wide range of natural products, many of which exhibit potent bioactivity [2,4]. The familiar bioactivity of various indole derivatives has drawn our interest to this area and we have tried to synthesize oxygen and sulfur containing indole derivatives. In this study after construction of a thiopyran ring fused with indole by means of *thio*-Claisen rearrangement [1,5] of the suitable sulfides we focused our attention to the synthesis of indole-annulated poly-heterocyclic compounds by acid catalyzed reaction of the enol ether [6–8]. Herein, we report the results of our investigation.

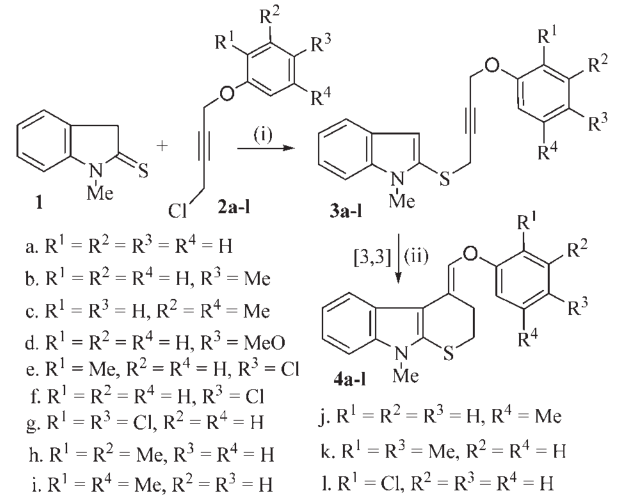
RESULTS AND DISCUSSION

The required precursors for our present study 4-(aryloxymethylene)-9-methyl-2,3,9-trihydrothiopyrano-[2,3-*b*]indoles (**4a-l**) were synthesized in 80–88% yield by the *thio*-Claisen rearrangement [5a] of 2-(4′-aryloxybut-2′-ynylthio)-1-methylindoles (**3a–l**) in refluxing chloro-benzene for 1 h. The compounds **3a–l** in turn were prepared in 90–94% yield by the reaction of 1-methyl-indoline-2-thione (**1**) and 1-aryloxy-4-chlorobut-2-yne (**2a–l**) under phase transfer catalysis (PTC) condition [5a,9] using benzyltriethyl ammonium chloride (BTEAC) as a phase transfer catalyst (Scheme 1).

A close examination of compounds **4** reveals that these are enol ethers and it is well known that enol ethers undergo hydrolysis in the presence of acid leading to the formation of corresponding aldehyde or ketone and alcohol or phenol [6–8]. With a view to hydrolyse the enol ether [8], compound **4a** was refluxed with conc. H_2SO_4 in dichloromethane-methanol-water mixture for 4 h. Three different products were obtained, a spiroheterocycle (**5a**, 11%), exocyclic double bond reduced product (**6a**, 42%) and a ketone (**7**, 8%) (Scheme 2).

The ^1H NMR spectrum of product **5a** showed two sets of one proton multiplets at δ 2.12–2.20 and 2.43–2.48 due to $—SCH_2C\mathbf{H}_2$ and another two sets of one proton multiplet at δ 3.11–3.15 and 3.19–3.23 due to $—SC\mathbf{H}_2$; two sets of one proton doublet at δ 4.40 (J = 9 Hz) and 4.65 (J = 9 Hz) due to $—OC\mathbf{H}_2$ (which are diastereotropic protons). ^{13}C NMR and DEPT-135 spectrum of **5a** indicates the presence of nineteen carbon atoms; among them one is CH_3, three are CH_2, eight are CH, and seven are

Scheme 1. Reagents and conditions: (i) 1% NaOH sol., DCM, BTEAC, stirring, 15 min., rt. (ii) Chlorobenzene, reflux, 1 h.



quaternary carbons. The ^{1}H NMR spectrum of product **6a** exhibited two sets of one proton multiplets at δ 2.09–2.20 and 2.60–2.67 due to —SCH$_2$C**H**$_2$, another two sets of one proton multiplets at δ 2.97–3.04 and 3.23–3.32 due to —SC**H**$_2$; one proton multiplet at δ 3.64–3.73 due to —CH$_2$C**H** at the asymmetric centre; one proton triplet at δ 3.86 ($J = 9.4$ Hz) and another one proton double of a doublet at δ 4.38 ($J = 9.4$, 3.9 Hz) due to —OC**H**$_2$ (diastereotropic protons). IR spectrum of compound **7** revealed a peak at 1719 cm^{-1} due to carbonyl group. ^{1}H NMR spectrum displayed to sets of two proton doublets at δ 6.93 ($J = 8.7$ Hz) and at δ 7.13 ($J = 8.7$ Hz) due to —SCH=C**H** and —SC**H**=CH, respectively.

The products **5a**, **6a**, and **7** were characterized from their elemental analyses and spectral data as 9′-methyl-2′,3′-dihydro-9′*H*-spiro{1-benzofuran-3,4′-thiopyrano[2,3-*b*]in-dole} (**5a**), 9-methyl-4-(phenyloxymethyl)-2,3,4,9-tetra-hydrothiopyrano[2,3-*b*]indole (**6a**) and 9-methyl-2,3,9-tri-hydrothiopyrano[2,3-*b*]indole-4-one (**7**). The product **5a** is the structural isomer of the spiroheterocyclic compound obtained by the aryl radical cyclization [5a] of the corresponding *o*-bromoenol ether.

To generalize the reaction all the substrates **4b–l** were similarly treated. The spiroheterocyclic products **5b-c, h–k** were obtained in 28–60% yield, the products **6b–l** were isolated in 18–48% yield along with the product **7** (4–8%) (Scheme 2).

Formation of products **5** to **7** from compounds **4** by acid catalysis may be explained by the initial protonation of the enol ether double bond of **4** to form a latent carbonium ion **9**. The protonation of vinyl ether normally occurs at the remote position relative to the oxygen function [6,7]. But, here the more basic nitrogen function of the diene unit is the controlling site of protonation [8]. The potential carbonium ion **9** may undergo nucleophilic attack by the aromatic double bond (pathway a, Scheme 3) to give a resonance-stabilized carbocation **10**, which may then lose a proton to give spiroheterocyclic compounds **5**.

Intermediate **9** may also undergo nucleophilic attack by water molecule (pathway b, Scheme 3) followed by deprotonation and elimination of anisole **8** to give **13** which may then undergo double group transfer reaction [8,10] with **4** to give compound **6** and compound **7** (Scheme 3). Removal of the anisole (**8**) was demonstrated by the GC analysis of the crude reaction mixture after usual workup of the reaction mixture of compound **4a** (Compared with a standard sample of anisole). RT (min) of the standard sample of anisole was 2.762 whereas; the reaction mixture gave a peak at 2.802.

The nucleophilic attack by the aromatic double bond to the latent carbonium ion **9** becomes facile when the phenyl ring becomes electron rich. The unsubstituted phenyl ring participate in nucleophilic attack leads to only 11% spiroheterocyclic product **5a** but the presence of electron donating methyl group in the phenyl ring increases the yield of the product **5**. The dimethyl substituted phenyl ring gives higher yield of the product **5** and the yield markedly increased when the methyl group is present at the *o*-, *p*- position with respect to the participating carbon atom of the phenyl ring, *e.g.* **5c** was obtained in 60% yield. Product **5** was not obtained for *p*-methoxy substituted phenyl ring. The presence of the electron withdrawing chlorine atom at the phenyl ring inhibits the nucleophilic attack by the phenyl ring to the latent carbonium ion **9** and the spiroheterocyclic product for those cases were not obtained. The double group transfer reaction is possible in all cases irrespective of the substitution in the

phenyl ring. Therefore, we obtained the products **6** and **7** in all the cases studied so far.

In conclusion the conditions under which the spiroheterocycles are formed is normally the usual ones for enol ether cleavage. From the experimental observation it is clear that the substituents on the phenyl ring seem to have a pronounced effect on the course of this reaction. We have developed an attractive strategy for the successful synthesis of spirocyclic indole annulated oxygen heterocyclic compounds having different connectivity between the furan and thiopyran ring with respect to the spirocyclic product obtained by the aryl radical cyclization [5a]. The methodology described here is synthetically useful and exhibits appreciable regioselectivity.

EXPERIMENTAL

Melting points were determined in open capillaries and are uncorrected. IR spectra were recorded on a Perkin-Elmer L 120-000A spectrometer (λ_{max} in cm^{-1}) on KBr disks. UV absorption spectra were recorded in EtOH on a Shimadzu UV-2401PC spectrophotometer (λ_{max} in nm). ^1H NMR (300 MHz, 500 MHz) and ^{13}C NMR spectra were recorded on a Bruker DPX-300 and Bruker DPX-500 spectrometer in $CDCl_3$ (chemical shift in δ) with TMS as an internal standard. Elemental analyses were recorded on a Leco 932 CHNS analyzer instrument; mass spectra were recorded on JEOL JMS-600 and Q-Tof micro instrument. ^1H NMR and ^{13}C NMR spectra were recorded at the Indian Institute of Chemical Biology, Kolkata and Bose Institute, Kolkata. GC analysis was performed at IICB, Kolkata on a Hewlett-Packard 6890 puls fitted with FID. Silica gel [(60–120 mesh), (230–400 mesh), Spectrochem, India] was used for chromatographic separation. Silica gel G [E-Merck (India)] was used for TLC. Petroleum ether refers to the fraction boiling between 60 and 80°C.

General procedure for the synthesis of compounds 3a–l. To a mixture of 1-methylindoline-2-thione (**1**, 0.49 g, 3 mmol) and 1-aryloxy-4-chlorobut-2-yne (**2a**, 0.58 g, 3 mmol) in dichloromethane (30 mL) was added a solution of benzyl triethyl ammonium chloride (BTEAC, 0.5 g, 1.8 mmol) in 1% aqueous NaOH (30 mL) and the mixture was magnetically stirred at room temperature for 15 minutes. The reaction mixture was then diluted with water (20 mL) and the dichloromethane layer was washed with 2*N* HCl (2 × 20 mL), water (2 × 20 mL), brine (20 mL), and dried (Na_2SO_4). Removal of dichloromethane at room temperature left an oily residue, which was subjected to column chromatography over silica gel (230–400 mesh). Elution of the column with petroleum ether-ethyl acetate (50:1) afforded compound **3a**. Compounds **3b–l** were prepared similarly.

Experimental data of compounds **3a–g** were published earlier [9].

1-Methyl-2-{4-(p-tolyloxy)but-2-ynylthio}-1H-indole (3h). Yield: 91%; Viscous liquid. IR (neat): ν_{max} = 1462, 2923 cm^{-1}. UV (EtOH): λ_{max} = 220, 290 nm. ^1H NMR (300 MHz, $CDCl_3$): δ_H = 2.16 (*s*, 3H, $ArCH_3$), 2.23 (*s*, 3H, $ArCH_3$), 3.44 (*s*, 2H, $-SCH_2$), 3.75 (*s*, 3H, $-NCH_3$), 4.59 (*s*, 2H, $-OCH_2$), 6.65–6.83 (*m*, 3H, ArH), 6.92 (s, 1H, =CH), 7.03–7.56 (*m*, 4H, ArH). MS: *m*/*z* = 335 (M^+). Anal. Calc. for $C_{21}H_{21}NOS$: C, 75.19; H, 6.31; N, 4.18%. Found: C, 75.35; H, 6.36; N, 4.07%.

2-{4-(3,5-Dimethylphenoxy)but-2-ynylthio}-1-methyl-1H-indole (3i). Yield: 94%; Viscous liquid. IR (neat): ν_{max} = 1466, 2931 cm^{-1}. UV (EtOH): λ_{max} = 224, 287 nm. ^1H NMR (300 MHz, $CDCl_3$): δ_H = 2.30 (*s*, 3H, $ArCH_3$), 2.31 (*s*, 3H, $ArCH_3$), 3.43 (*s*, 2H, $-SCH_2$), 3.72 (*s*, 3H, $-NCH_3$), 4.55 (*s*, 2H, $-OCH_2$), 6.51–6.58 (*m*, 3H, ArH), 6.75 (*s*, 1H, =CH), 7.04–7.54 (*m*, 4H, ArH). General procedure for the acid catalyzed reaction of compounds 4a-l. To the dichloromethane (8.4 mL) solution of compound **4a** (0.3 g, 1 mmol), water (3 mL), methanol (13.5 mL) and concentrated sulfuric acid (2.3 mL) were added. The reaction mixture was then refluxed on water bath for 4 h, allowed to cool and extracted with dichloromethane (2 × 10 mL). The combined extract was washed with sodium bicarbonate solution (3 × 15 mL), water (3 × 15 mL), brine (15 mL) and dried (Na_2SO_4). After removal of the solvent the crude mass was subjected to column chromatography. Elution of the column with petroleum ether-ethyl acetate (50:1) on silica gel (60–120 mesh) afforded the compounds **5a**, **6a**, and **7**. Compounds **4b–l** were also treated similarly.

9′-Methyl-3′,9′-dihydro-2*H*,2′*H*-spiro[benzofuran-3,4′-thiopyrano[2,3-*b*]indole] (5a). Yield: 11%; White solid; mp 156–158°C. IR (KBr): ν_{max} = 1479, 2898, 2918 cm^{-1}. UV (EtOH): λ_{max} = 233, 289, 297 nm. ^{1}H NMR (300 MHz, $CDCl_3$): δ_H = 2.12–2.20 (*m*, 1H, —$SCH_2C\mathbf{H}_2$), 2.43–2.48 (*m*, 1H, —$SCH_2C\mathbf{H}_2$), 3.11–3.15 (*m*, 1H, —$SC\mathbf{H}_2$), 3.19–3.23 (*m*, 1H, —$SC\mathbf{H}_2$), 3.64 (*s*, 3H, —NCH_3), 4.40 (d, 1H, *J* = 9 Hz, —OCH_2), 4.65 (d, 1H, *J* = 9 Hz, —OCH_2), 6.70–7.23 (*m*, 8H, Ar**H**). ^{13}C NMR and DEPT-135 (75 MHz, $CDCl_3$): δ_C = 25.49 (CH_2), 30.21 (CH_3), 38.03 (CH_2), 46.65 (C), 82.63 (CH_2), 107.80 (C), 108.60 (CH), 110.32(CH), 118.93 (CH), 119.60 (CH), 120.89 (CH), 121.46 (CH), 124.72 (CH), 126.71 (C), 128.99 (CH), 131.86 (C), 134.54 (C), 137.87 (C), 160.17 (C). 1,8-Diazabicyclo[5.4.0]undec-7-ene (DBU) efficiently catalyzes three-component one-pot condensations of aldehyde, malononitrile, and thiophenol to produce highly functionalized pyridines in excellent yield in aqueous ethanol.

J. Heterocyclic Chem., **46**, 69 (2009).

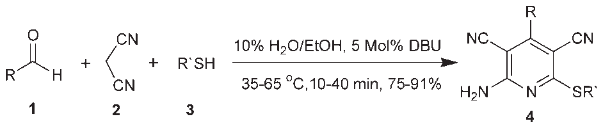
INTRODUCTION

The pyridine scaffold is a key constituent of a wide range of naturally occurring and synthetic bioactive compounds, pharmaceuticals, and functional materials [1–3]. Penta-substituted pyridines are known as medicinally privileged scaffold, inhibit MAPK-activated PK-2 [4] and modulate androgen receptor functions [5]. These compounds are also useful in the treatment of urinary incontinence [6], HBF infections [7], Creutzfeldt-Jacob disease [8], and Parkinson's disease, hypoxia/ischemia, asthma, kidney disease, epilepsy, cancer [9–11] and also exhibit antibacterial, anti-biofilm and anti-infective activities [12]. The importance of this class of compounds can be realized by the number of patents filed in the recent years [4–7,12]. Thus, synthesis of highly functionalized pyridine derivatives, with the aim to develop new drug molecules has been an active area of research [13–15]. Various synthetic protocols have been developed for the synthesis of pyridine-3,5-dicarbonitriles [16–25]. The most interesting synthetic methodology has been three-component condensation of aldehydes, malononitrile, and thiolphenols [17,26,27]. Various bases such as Et_3N, DABCO [17,26,27], and piperidine, morpholine, thiomorpholine, pyrrolidine, N,N-DIPEA, pyridine, 2,4,6-collidine, DMAP, aniline, *N*-methyl-aniline, *N*,*N*-dimethylaniline, and *N*,*N*-diethylaniline [27] have been used. However, the major drawback of these procedures is the formation of various side products [26], thus reducing the yield of the desired product to 20–48% [26,27]. It is important to mention here that Ranu *et al.* [28] have reported a better synthetic protocol for this reaction and immidazolium-based ionic liquid and ethanol have been used as reaction media. Although ionic liquids are considered to be green solvents as the risk of air pollution is significantly reduced due to their nonvolatile nature [29,30] but their toxicity, especially, immidazolium-based ionic liquids and cost has been a matter of concerns [31,32]. So, development of an improved synthetic protocol for the generation of pyridine-3,5-dicarbonitriles for lead optimization is of considerable interest. As a part of our ongoing effort towards the synthesis of biologically active compounds [33–35] and keeping the medicinal values of pyridine-3,5-dicarbonitriles in mind, we considered it necessary to develop an efficient high yielding synthetic protocol for the synthesis of this class of compounds.

RESULTS AND DISCUSSION

Careful literature analyses revealed that a variety of bases with pK_a ranges from 4 to 11 have been used for this multicomponent reaction. We speculated that use of neutral organic base that have high basicity, and can form a stable protonated species, may suppress the formation of enaminonitrile and other side products. 1,8-Diazabicyclo-[5.4.0]undec-7-ene (DBU) fulfills these requirements, and it has been used in many organic transformations in recent years. DBU is commercially available, cheap homogenous catalyst. It is a sterically hindered amidine base and especially useful where side reactions due to the inherent nucleophilicity of a basic nitrogen are a problem [36–40]. DBU is one of the strongest organic neutral base ($pK_a = 12$) and the +M effect of the adjacent nitrogen stabilizes the protonated species. Inspired with the catalytic potential of DBU, we examined the catalytic role of DBU in the synthesis of pyridine-3,5-dicarbonitriles *via* three component reaction of aldehydes, malononitriles, and thiols. The reaction of

Scheme 1



an aldehyde (**1**), malononitrile (**2**), and thiol (**3**) was carried out in the presence of catalytic amount of DBU (Scheme 1). We were pleased to observe that use of 5 mol % DBU as a catalyst in 10% aqueous ethanol significantly increases the rate of reaction and yield of the product at lower temperatures (Table 1). A wide range of substituted aromatic as well as heteroaromatic aldehydes underwent this three-component condensation with malononitrile and thiols to produce pyridine-3,5-dicarbonitriles (**4**) in high yield. The results are summarized in Table 1. All the utilized functionalities were found to be compatible under the reaction conditions.

For example, three-component reaction of benzaldehyde, malononitrile, and thiophenol lead to the formation of **4a** at 35°C in 15 min in 80% yield, while the same reaction takes 1.5 h to complete at reflux temperature in ethanol, and yield of the product was reported to be 35% when other bases were used [26]. Encouraged by this observation, a series of reactions were carried out under identical reaction conditions, and in all of the cases the product was isolated in very good yield (Table 1). However, reaction temperature was increased up to 65°C in some cases. A library of compounds was synthesized using 5 mol % DBU as base. The same reactions were also carried out in ethanol, but it was observed that the addition of 10% water in the reaction lead to increase in the yield to 8–10%. However, when ethanol-water (1:1) and water was used as a reaction media, no or very low yield was observed even at elevated temperature, due to the insolubility of the starting materials. We have also explored the possibility of using polyethylene glycol (PEG) as a reaction media, but no product formation was observed in PEG. This multicomponent reaction works well for unsubstituted (entry **4a**, **4q**, **4w**), electron poor (entry **4g**, **4h**), electron rich (entry **4b–4e**, **4i–4v**), and

Table 1

DBU catalyzed three-component synthesis of substituted pyridine-3,5-dicarbonitriles *via* Scheme 1.

heteroaromatic aldehydes (entry **4e**). However, aliphatic aldehydes either gave very poor yield or did not react.

According to the proposed mechanisms, the first step of this reaction is the formation of Knoevenagel product by the condensation of an aldehyde with malononitrile [26,27,41,42]. During this base-catalyzed three-component reaction, formation of many side products such as enaminonitrile, higher adducts, reduced products, and malononitrile self addition products have been noticed [26,41]. We believe that low reaction temperature, higher basicity, and stability of DBU-H^+ species generated in this reaction suppress the formation of these side products and, hence, yield of the product increases. It is important to mention here that use of DABCO has been shown to promote the reaction of hindered aldehydes, with marginal increase of yield of the product [26].

To assess the feasibility of the methodology on higher scale under identical reaction conditions, we carried out the reaction on a 50 gm scale (entry **4b**, **4g**) and it was observed that the reaction proceeded smoothly and the desired product was isolated in 87% and 85% yields, respectively. It is important to mention here that the reaction media can be reused for further reactions. For example, after completion of the reaction, the reaction mixture was cooled, and solid product was collected by filtration (entry 4b). To the filtrate, *p*-chlorobenzaldehyde, malononitrile, and thiophenol were added in the same molar ratio without additional load of DBU. The reaction mixture was stirred for specified time, marginal loss of the yield was observed in first three run (87%, 86%, and 83%), while in fourth and fifth run the yield dropped to 75% and 65%, respectively. Structures of all of the compounds were identified by their mp and spectral data.

CONCLUSION

In conclusion, we have developed a novel synthetic methodology for the synthesis of pyridine-3,5-dicarbonitriles using 5 mol % DBU as a catalyst and 10% aqueous ethanol as the reaction media through a three component condensation of aldehydes, malononitrile and thiols. The short reaction times, high yields, use of commercially inexpensive DBU as a catalyst, and reusability of the reaction media are the main advantages of this process.

EXPERIMENTAL

All of the chemicals used in the synthesis were purchased from Sigma-Aldrich and used as received. Thin-layer chromatography was used to monitor reaction progress. Compounds were purified either by crystallization or over silica gel column. Melting points were determined on a melting point apparatus and are uncorrected. IR (KBr) spectra were recorded using Perkin-Elmer FTIR spectrophotometer and the values are expressed as ν_{max} cm^{-1}. Mass spectral data were recorded on a waters micromass LCT Mass Spectrometer/Data system. The ^{1}H NMR and ^{13}C NMR spectra were recorded on Bruker Spectrospin spectrometer at 300 MHz and 75.5 MHz, respectively using TMS as an internal standard. The chemical shift values are recorded on δ scale and the coupling constants (*J*) are in Hz. Elemental analysis were performed on a Carlo Erba Model EA-1108 elemental analyzer and data of C, H, and N is within ±0.4% of calculated values.

General procedure for the synthesis of substituted pyridines. To a stirred solution of substituted benzaldehyde (4.71 mmol) in 10% aqueous ethanol (5 mL), DBU (5 mol %) was added followed by dropwise addition of malononitrile (9.43 mmol) at room temperature. To this stirred mixture substituted thiols (4.71 mmol) was added dropwise. The reaction mixture was stirred at 35–65°C as specified in Table 1; reaction progress was monitored by TLC. The crude product was collected by filtration and was purified by crystallization or by SiO_2 column chromatography. Spectral data of all unknown compounds is given later.

IR: 3437, 3327, 3217, 2219, 1626, 1552, 1462, 1377, 1270, 798, 776, 750, 721 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 7.53–7.62 (*m*, 5H), 7.66–7.68 (*m*, 5H), 7.91 (brs, 2H), 8.07–8.15 (*m*, 2H); HRMS calc. for $C_{23}H_{14}N_4S$: 378.0939, found: 378.0929; Anal. calc. for $C_{23}H_{14}N_4S$: C, 72.99; H, 3.73; N, 14.80; S, 8.47; found: C, 72.89; H, 3.66; N, 14.88; S, 8.42.

2-Amino-4-(3-nitrophenyl)-6-phenylsulphanylpyridine-3,5-dicarbonitrile (4g). IR: 3400, 3323, 3230, 2213, 1647, 1550, 1526, 1426, 1377, 1260, 1037, 805, 754 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 7.52–7.61 (*m*, 5H), 7.89–7.94 (*m*, 2H), 8.07 (*d*, *J* = 6 Hz, 1H), 8.45 (*d*, *J* = 6 Hz, 1H), 8.52 (brs, 2H); HRMS calc. for $C_{19}H_{11}N_5O_2S$: 373.0633, found: 373.0631; Anal. calc. for $C_{19}H_{11}N_5O_2S$: C, 61.12; H, 2.97; N, 18.76; S, 8.59; found: C, 61.18; H, 3.01; N, 18.69; S, 8.51.

2-Amino-4-(2-nitrophenyl)-6-(4-tolyl)sulphanylpyridine-3,5-dicarbonitrile (4h). IR: 3395, 3323, 3231, 2211, 1645, 1551, 1523, 1463, 1354, 1258, 1036, 813, 736 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 2.37 (s, 3H), 7.30 (*d*, *J* = 8 Hz, 2H), 7.50 (*d*, *J* = 8 Hz, 2H), 7.91–7.94 (*m*, 2H), 8.05 (*d*, *J* = 6 Hz, 1H), 8.43 (*d*, *J* = 6Hz, 1H), 8.52 (brs, 2H); ^{13}C NMR (75.5 MHz, DMSO-d_6): δ 87.15, 93.22, 114.78, 115.09, 123.36, 123.59, 125.13, 130.18, 130.65, 134.92, 135.21, 135.42, 139.66, 147.66, 156.26, 159.52, 166.64; HRMS calc. for $C_{20}H_{13}N_5O_2S$: 378.0790, found: 378.0799; Anal. calc. for $C_{20}H_{13}N_5O_2S$: C, 62.00; H, 3.38; N, 18.08; S, 8.28; found: C, 61.96; H, 3.42; N, 18.13; S, 8.20.

2-Amino-4-(2-naphthyl)-6-phenylsulphanylpyridine-3,5-dicarbonitrile (4j). IR: 3371, 2209, 1615, 1545, 1458, 1377, 1246, 815, 736 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 7.50–7.53 (*m*, 5H), 7.63–7.65 (*m*, 5H), 7.89 (brs, 2H), 8.06–8.18 (*m*, 2H); ^{13}C NMR (75.5 MHz, DMSO-d_6): δ 87.34, 93.63, 115.06, 115.38, 125.38, 127.03, 127.75, 128.41, 129.46, 129.67, 131.41, 132.25, 133.33, 134.82, 158.66, 159.68, 166.18; HRMS calc. for $C_{23}H_{14}N_4S$: 378.0939, found: 378.0935; Anal. calc. for $C_{23}H_{14}N_4S$: C, 72.99; H, 3.73; N, 14.80; S, 8.47; found: C, 72.93; H, 3.64; N, 14.85; S, 8.42.

2-Amino-4-(2-hydroxyphenyl)-6-phenylsulphanylpyridine-3,5-dicarbonitrile (4l). IR: 3422, 3338, 3208, 2183, 1639, 1614, 1579, 1545, 1460, 1404, 1377, 1263, 1193, 1046, 763, 749 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 6.95–7.15 (*m*, 6H), 7.33 (brs, 1H), 7.50–7.61 (*m*, 5H); HRMS calc. for $C_{19}H_{12}N_4OS$: 344.0732, found: 344.0738; Anal. calc. for $C_{19}H_{12}N_4OS$: C, 66.26; H, 3.51; N, 16.27; S, 9.31; found: C, 66.30; H, 3.55; N, 16.33; S, 9.40.

2-Amino-4-(4-bromophenyl)-6-phenylsulphanylpyridine-3,5-dicarbonitrile (4n). IR: 3441, 3336, 3220, 2219, 1629, 1555, 1529, 1459, 1378, 1312, 1257, 1022, 784, 758 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 7.52–7.60 (*m*, 5H), 7.80–7.82 (*m*, 4H), 7.88 (brs, 2H); Anal. calc. for $C_{19}H_{11}BrN_4S$: C, 56.03; H, 2.72; N, 13.76; S, 7.87; HRMS calc. for $C_{19}H_{11}BrN_4S$: 405.9888, found: 405.9885; found: C, 56.09; H, 2.78; N, 13.69; S, 7.81.

2-Amino-4-(3-tolyl)-6-(4-tolyl)sulphanylpyridine-3,5-dicarbonitrile (4o). IR: 3487, 3324, 3219, 2215, 1631, 1548, 1460, 1377, 1264, 1243, 1016, 801, 716 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 2.40 (*s*, 3H), 2.44 (*s*, 3H), 6.89 (brs, 2H), 7.25–7.30 (m, 4H), 7.33–7.36 (m, 1H), 7.40–7.45 (m, 3H); HRMS calc. for $C_{21}H_{16}N_4S$: 356.1096; found: 356.1099; Anal. calc. for $C_{21}H_{16}N_4S$: C, 70.76; H, 4.52; N, 15.72; S, 9.00; found: C, 70.80; H, 4.48; N, 15.77; S, 9.05.

2-Amino-4-(4-chlorophenyl)-6-(4-tolyl)sulphanylpyridine-3,5-dicarbonitrile (4p). IR: 3477, 3346, 3222, 2214, 1635, 1574, 1495, 1457, 1377, 1258, 1092, 836, 805, 795 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 2.37 (*s*, 3H), 7.30 (*d*, J = 8Hz, 2H), 7.48 (d, J = 8Hz, 2H), 7.58–7.68 (*m*, 4H), 7.83 (brs, 2H); HRMS calc. for $C_{20}H_{13}ClN_4S$: 376.0549, found: 376.0546; Anal. calc. for $C_{20}H_{13}ClN_4S$: C, 63.74; H, 3.48; N, 14.87; S, 8.51; found: C, 63.77; H, 3.51; N, 14.81; S, 8.4.

2-Amino-4-phenyl-6-(4-tolyl)sulphanylpyridine-3,5-dicarbonitrile (4q). IR: 3451, 3323, 3208, 2215, 1618, 1547, 1523, 1458, 1377, 1266, 1015, 897, 810, 755 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 2.37 (*s*, 3H), 7.30 (*d*, J = 8Hz, 2H), 7.47 (*d*, J = 8Hz, 2H), 7.54–7.56 (*m*, 5H), 7.80 (brs, 2H); HRMS calc. for $C_{20}H_{14}N_4S$: 342.0939; found: 342.0949; Anal. calc. for $C_{20}H_{14}N_4S$: C, 70.15; H, 4.12; N, 16.36; S, 9.36; found: C, 70.20; H, 4.08; N, 16.30; S, 9.30.

2-Amino-4-(4-hydroxyphenyl)-6-(2-aminophenyl)sulphanylpyridine-3,5-dicarbonitrile (4u). IR: 3317, 2197, 1638, 1610, 1542, 1508, 1456, 1410, 1247, 1170, 1023, 845, 760 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 5.50 (brs, 2H), 5.88 (brs, 1H), 6.40–6.46 (*m*, 2H), 6.79–6.86 (*m*, 4H), 7.28–7.31 (*m*, 2H), 7.69 (brs, 2H); HRMS calc. for $C_{19}H_{13}N_5OS$: 359.4056; found: 359.4146; Anal. calc. for $C_{19}H_{13}N_5OS$: C, 63.49; H, 3.65; N, 19.49; S, 8.92; found C, 63.51; H, 3.70; N, 19.41; S, 8.96.

2-Amino-4-(1-naphthyl)-6-(2-aminophenyl)sulphanylpy-ridine-3,5-dicarbonitrile (4v). IR: 3429, 3333, 3219, 2217, 1632, 1611, 1548, 1468, 1310, 1271, 1162, 1022, 996, 797 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 5.50 (brs, 2H), 6.58 (*t*, 1H), 6.81 (*d*, J = 8 Hz, 1H), 7.20 (*t*, 1H), 7.29 (*d*, J = 8 Hz, 1H), 7.55–7.69 (*m*, 4H), 7.77 (brs, 3H), 8.05–8.13 (*m*, 2H); HRMS calc. for $C_{23}H_{15}N_5S$: 393.4649; found: 393.4556; Anal. calc. for $C_{23}H_{15}N_5S$: C, 70.21; H, 3.84; N, 17.80; S, 8.15; found: C, 70.25; H, 3.88; N, 17.88; S, 8.11.

2-((Furan-2-yl)methylthio)-6-amino-4-phenylpyridine-3,5-dicaronitrile (4w). IR: 3470, 3325, 3215, 2210, 1625, 1540, 1419, 1243, 1150, 1010, 930, 780 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 4.59 (*s*, 2H), 6.40–6.56 (*m*, 2H), 7.54–7.60 (*m*, 6H), 8.16 (brs, 2H); HRMS calc. for $C_{18}H_{12}N_4OS$: 332.3802; found: 332.3781; Anal. calc. for $C_{18}H_{12}N_4OS$: C, 65.04; H, 3.64; N, 16.86; S, 9.65; found: C, 65.09; H, 3.57; N, 16.90; S, 9.69.

2-((Furan-2-yl)methylthio)-6-amino-4-(4-tolyl)pyridine-3,5-dicaronitrile (4x). IR: 3458, 3331, 3225, 2208, 1634, 1543, 1263, 1007, 769, 732 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 2.38 (*s*, 3H), 4.58 (*s*, 2H), 6.39–6.54 (*m*, 2H), 7.34–7.59 (*m*, 5H), 8.16 (brs, 2H); HRMS calc. for $C_{19}H_{14}N_4OS$: 346.4068; found: 346.4159; Anal. calc. for $C_{19}H_{14}N_4OS$: C, 65.88; H, 4.07; N, 16.17; S, 9.26; found: C, 65.82; H, 4.17; N, 16.21; S, 9.30.

2-((Furan-2-yl)methylthio)-6-amino-4-(4-bromophenyl)pyridine-3,5-dicaronitrile (4y). IR: 3407, 3337, 3245, 2216., 1629, 1573, 1527, 1487, 1373, 1294, 1133, 1090, 1016, 806, 743 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 4.11 (*s*, 2H), 7.29–7.33 (*m*, 3H), 7.50–7.65 (*m*, 4H), 7.99 (brs, 2H); HRMS calc. for $C_{18}H_{11}BrN_4OS$: 411.2763; found: 411.2753; Anal. calc. for $C_{18}H_{11}BrN_4OS$: C, 52.57; H, 2.70; N, 13.62; S, 7.80; found: C, 52.61; H, 2.71; N, 13.61; S, 7.89.

2-((Furan-2-yl)methylthio)-6-amino-4-(1-naphthyl)pyridine-3,5-dicaronitrile (4z). IR: 3475, 3328, 3220, 3053, 2993, 2214, 1630, 1547, 1503, 1419, 1269, 1245, 1211, 1155, 1040, 1010, 933, 825, 780, 733, 685 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 4.64 (*s*, 2H), 6.43–6.61 (*m*, 2H), 7.57–7.63 (*m*, 4H), 8.05–8.10 (*m*, 4H), 8.13 (brs, 2H); HRMS calc. for $C_{22}H_{14}N_4OS$: 382.4389; found: 382.4487; Anal. calc. for $C_{22}H_{14}N_4OS$: C, 69.09; H, 3.69; N, 14.65; S, 8.38; found: C, 69.10; H, 3.73; N, 14.61; S, 8.39.

2-((Furan-2-yl)methylthio)-6-amino-4-(2-naphthyl)pyridine-3,5-dicaronitrile (4aa). IR: 3475, 3328, 3220, 2214, 1630, 1547, 1461, 1419, 1269, 1245, 1211, 1155, 1040, 1010, 933, 860, 780, 733 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 4.60 (*s*, 2H), 6.40–6.56 (*m*, 2H), 7.61–7.63 (*m*, 4H), 8.00–8.09 (*m*, 4H), 8.12 (brs, 2H); Anal. calc. for $C_{22}H_{14}N_4OS$: C, 69.09; H, 3.69; N, 14.65; S, 8.38; found: C, 69.13; H, 3.79; N, 14.66; S, 8.32.

2-((Furan-2-yl)methylthio)-6-amino-4-(4-methoxyphenyl)-pyridine-3,5-dicaronitrile (4ab). IR: 3469, 3326, 3211, 2218, 1616, 1574, 1542, 1455, 1294, 1255, 1177, 1019, 839, 816, 749 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 3.83 (*s*, 3H), 4.58 (*s*, 2H), 6.40–6.55 (*m*, 2H), 7.09–7.11 (*m*, 2H), 7.48–7.60 (*m*, 3H), 8.12 (brs, 2H); HRMS calc. for $C_{19}H_{14}N_4O_2S$: 362.4062; found: 362.4162; Anal. calc. for $C_{19}H_{14}N_4O_2S$: C, 62.97; H, 3.89; N, 15.46; S, 8.85; found: C, 62.92; H, 3.93; N, 15.40; S, 8.79.

2-((Furan-2-yl)methylthio)-6-amino-4-(4-chlorophenyl)pyridine-3,5-dicaronitrile (4ac). IR: 3455, 3336, 3229, 2211, 1634, 1573, 1544, 1494, 1264, 1092, 929, 805, 742 cm^{-1}; ^{1}H NMR (300 MHz, DMSO-d_6): δ 4.58 (*s*, 2H), 6.39–6.55 (*m*, 2H), 7.56–7.66 (*m*, 5H), 8.20 (brs, 2H); HRMS calc. for $C_{18}H_{11}ClN_4OS$: 366.8250; found: 366.8151; Anal. calc. for $C_{18}H_{11}ClN_4OS$: C, 58.94; H, 3.02; N, 15.27; S, 8.74; found: C, 58.99; H, 3.03; N, 15.29; S, 8.78.

Acknowledgments. DSR is thankful to Department of Science and Technology (DST), New Delhi, University Grant Commissions, New Delhi, and University of Delhi, India for financial support. RS is grateful to DST for the DST-Young Scientist award.

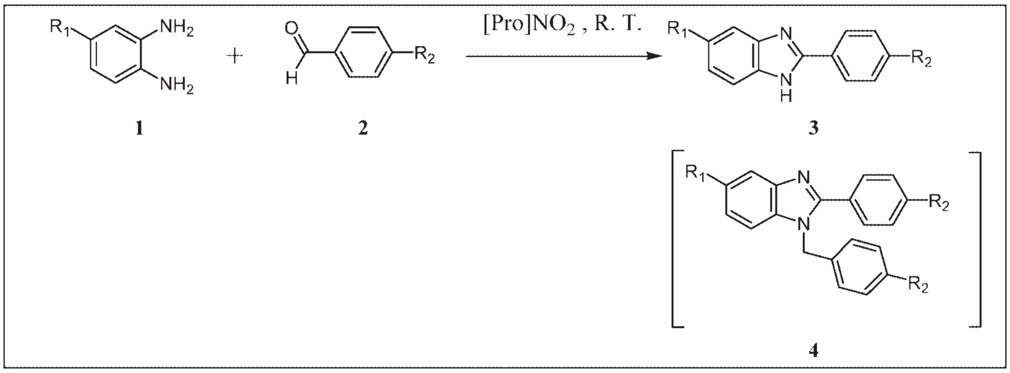
DOI 10.1002/jhet.35



A simple and eco-friendly protocol for the synthesis of substituted 2-arylbenzimidazoles is described. In this process, 2-arylbenzimidazoles were prepared in the presence of a newly introduced ionic liquid prolinium nitrate [Pro]NO$_3$ as catalyst, under solvent-free condition. This process was performed under mild condition without using any oxidant with good to excellent yields and remarkable chemoselectivity in the absence of any byproduct. The ionic liquid can be recovered easily and reused.

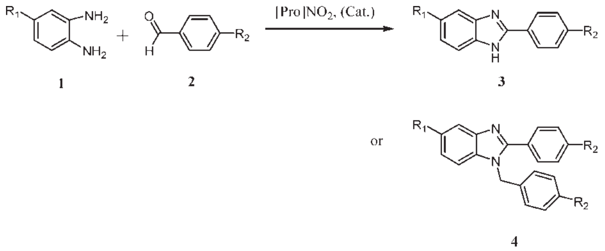
J. Heterocyclic Chem., **46**, 74 (2009).

INTRODUCTION

The benzimidazole ring system is an important pharmacophore in medicinal chemistry and modern drug discovery. Benzimidazole derivatives exhibit activities against several viruses such as influenza [1a], human cytomegalovirus [1b], and HIV [1c]. Benzimidazole and its derivatives have also been known to act as topoisomerase inhibitors [2], selective neuropeptide Y Y 1 receptor antagonists [3], potential antitumor [4] and antimicrobial agents [5], and factor Xa inhibitor [6]. The widespread interest in benzimidazole-containing structures has led to extensive studies toward their synthesis. The most important methodology toward synthesis of benzimidazoles is the oxidative cyclo-dehydrogenation of aniline Schiff bases, which are often generated *in situ* from the coupling reaction between *o*-phenylenediamines and aldehydes. Various oxidants have been examined for this two step process which we hereby refer to some of them such as nitrobenzene (high-boiling oxidant/solvent) [7], 1,4-benzoquinone [8] DDQ [9], tetracyanothylene [10], benzofuroxan [11], MnO$_2$ [12], Pb(OAc)$_4$ [13], oxone [14], and NaHSO$_3$ [15]. The availability of a vast number of aldehydes has certainly caused this two-step process to be extensively investigated by chemists. However, most of these procedures produce toxic or environmentally harmful byproducts, which often require laborious work-up to remove them from the reaction mixture, and/or suffer from low yields of isolation product. Molecular oxygen as oxidant has also been used but drawbacks such as prolonged reaction times and high temperature make it less useful [16]. In the case of I$_2$/KI/K$_2$CO$_3$/H$_2$O system, the yields for aldehydes with electron-donating groups were poor [17]. Very recently, iodobenzene diacetate (IBD) as oxidant in dioxane as solvent has led to significant results but the use of dioxane as a toxic solvent is the major limitation for this process from the environmental viewpoint [18]. In another report, application of L-proline in CHCl$_3$ as organocatalyst was presented but this route led to the formation of 1,2-di-substituted benzimidazoles exclusively not the 2-aryl derivatives [19].

The drive to environmentally sustainable, or so-called ‘‘green chemistry,’’ has provided one of the greatest challenges for the chemists of today [20a]. One of the major areas of research in this field is using ionic liquids (ILs) as both solvents and catalysts [20b]. There is only one report regarding formation of these compounds using an imidazolium IL (butylimidazolium tetrafluoroborate, ([Hbim]BF$_4$) as medium. In this process, the yields are good and the reaction times were short, and

Scheme 1



formation of byproducts had a negative effect on the yield [21].

ILs based on amino acids such as proline are one of the most important groups of recently developed ILs referred to as fully green ILs based on natural products. Their importance includes two different aspects. Bio-renewability and economical benefits are the major features of materials of this kind. Moreover, ILs of this type do not show defects such as air- or water-sensitivity of chloroaluminate ILs nor the potential HF releasing of hexafluorophosphate ILs. So, because of these advantages, attempts for the development and introduction of novel ILs based on natural products such as amino acids have been intensively investigated [22]. The main thrust of this work was to provide a new oxidant-free, selective and more sustainable protocol for the synthesis of 2-arylbenzimidazoles.

To the best of our knowledge, benzimidazole derivatives have rarely been synthesized with electron withdrawing substituents such as NO_2 and CO_2H on the fused benzo ring of benzimidazole. So, our other goal was to synthesize such derivatives using 4-nitro-1,2-phenyl-enediamine and 3,4-diaminobenzoic acid as reactant.

RESULTS AND DISCUSSION

During our investigation, at first, we chose *o*-phenylenediamine and 4-chlorobenzaldehyde as model reactants and examined the effect of the amount of prolinium nitrate ([Pro]NO_3) IL as catalyst in the absence of solvent under various temperatures (Scheme 1, Table 1).

Table 1

Prolinium nitrate ([Pro]NO_3) promoted preparation of 2-(4-chlorophenyl)benzimidazole (**3e**) under various conditions.

Entry	Amount of IL (mol %)	Temperature (°C)	Time (min)	Product (%)[a] 3	4
1	20	r.t.	20	89	–
2	20	60	20	89	Trace
4	40	r.t.	25	89	–
5	40	60	25	89	Trace
7	60	r.t.	25	85	Trace
8	60	60	25	70	20
10	100	r.t.	50	85	15
11	100	100	40	80	20

[a] Isolated yield.

To determine the optimum reaction conditions, three moles of phenylenediamines and three moles of 4-chlorobenzaldehyde together with a specified amount of IL were reacted under different temperatures. The results in Table 1 showed some interesting points. First of all, increasing amount of IL did not improve obviously the yield of **3e**. So, the optimum amount of IL was found to be 20% relative to reactants. The second important point which could be elicited evidently from these results is that raising the reaction temperature from r.t. to 60°C did not increase the yield and also did not improve the reaction rates. Moreover, the chemoselectivity decreased and formation of the byproduct **4** was observed in the process. These results indicates that the reaction is better to be carried out at r.t. using 20 mol % amount of IL without solvent to achieve the best results for the preparation of desired product **3** not product **4**.

Then, we continued our study to examine the reusability and recoverability of the catalyst as an additional important factor in the field of ILs. To achieve this, the model reaction of *o*-phenylenediamine (4 mmol) with 4-chlorobenzaldehyde (4 mmol) was carried out in the presence of IL (0.8 mmol). After completion of the reaction, the IL could be recovered as specified in Experimental section. The results of which are given in Table 2. These results showed a good recoverability and reusability for the synthesis of product **3e**. It can clearly be seen that even after four runs, the recovery percentage is high. However, the yield decreased significantly after four runs (Table 2, Run No. 4).

The decrease in the yields of the reaction after each use of IL could possibly be due to the fact that we could not manage to recover the catalyst quantitatively after each run. Consequently, we repeated the reaction with lower amounts of catalyst. To test this idea, we repeated the reaction by adding some fresh catalyst to the IL recovered after the first use and the result was the same as the first run (Table 2, No. 1). Moreover, we observed a slight change in appearance for the recovered IL,

Table 2

Results for reusability of IL [Pro]NO_3 in the process of 2-(4-chlorophenyl)benzimidazole (3e) synthesis.

Run no.	Recovery percent	Reaction time (min)	Yield (%)[a]
1	95	30	89
2	90	40	82
3	90	55	78
4	90	60	70

[a] Isolated yield.

which would be due to trace impurities from the reaction. These changes in appearance were observed more obviously after any recovery.

To evaluate the scope and limitations of this IL under solvent-free condition various benzaldehyde derivatives and different derivatives of *o*-phenylenediamines were examined (Table 3, entries 1–17). Among the various benzaldehydes tested, the best yields were achieved for benzaldehydes with electron-withdrawing substituents (Table 3, entries 4–7). While among *o*-phenylenediamine derivatives the yield of products obtained from 4-nitro-*o*-phenylenediamine were high and the rates of reactions were also remarkable (Table 3, entries 8–12). In all reactions, byproduct **4** was not observed by TLC. Only in the case of 4-methylbenzaldehyde as reactant (Table 3, entry 11), the reaction rate was relatively long and the yield was moderate not high. Repeating the reaction with 3,4-diaminobenzoic acid showed the best yield and reactivity for 4-nitrobenzaldehyde (Table 3, entry 17) and the other derivatives were also synthesized with interesting yield. These results demonstrate a great level of versatility and efficiency for the synthesis of 2-arylbenzimidazole derivatives.

To complete evaluation of chemoselectivity, our attempts were focused on performing the reaction with a new variation. At this stage, we carried out the model reaction of *o*-phenylenediamine derivatives (1 mmol) with 4-chlorobenzaldehyde (2 mmol) under optimal conditions (r.t. and 20% of IL relative to *o*-phenylenediamine derivatives). Surprisingly, even after 3 h, no byproduct **4** (**4e**, **4i**, and/or **4n**) were formed and TLC analysis showed only the presence of products **3** (**3e**, **3i**, and/or **3n**) with the excess amount of benzaldehydes used.

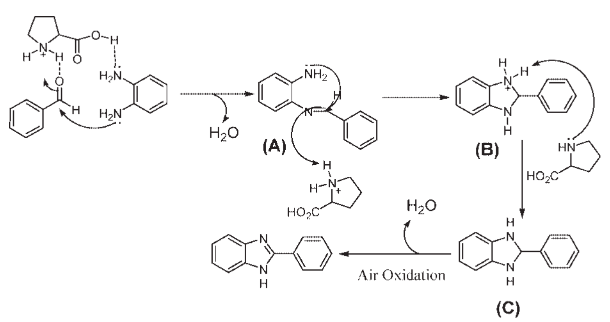
Scheme 2



According to these findings, a proposed reaction pathway for the synthesis of 2-arylbenzimidazoles is shown in Scheme 2. As can be seen, prolinium cation from IL first interacts with both reactants to form the Schiff base intermediate (A) which then undergoes cyclization *via* intramolecular attack by another amino moiety on Schiff base to form protonated benzimidazoline intermediate (B). Then, this intermediate would be deprotonated to 2,3-dihydrobenzimidazoline (C). Finally, the intermediate (C) would be aromatized by air oxidation under reaction vessel conditions.

In summary, we have developed an efficient, eco-friendly as well as solvent and oxidant-free protocol for the synthesis of 2-arylbenzimidazole derivatives starting from phenylenediamine derivatives and diverse benzaldehydes using fully "green" IL L-prolinium nitrate as catalyst. The yields of products are very good to excellent and use of toxic solvents is avoided. Synthesis of some novel 2-arylbenzimidazole derivatives under mild conditions is the most important aspect of this study. Simple work-up and high degree of IL reusability are other interesting points of the developed procedure.

EXPERIMENTAL

Melting points were recorded on a Buchi B-540 apparatus. IR spectra were recorded on an ABB Bomem Model FTLA200-100 instrument. ^1H and ^{13}C NMR spectra were measured with a Bruker DRX-300 Avance spectrometer at 300 and 75 MHz using TMS as an internal standard. Chemical shifts (δ) are reported relative to TMS, and coupling constants (J) are reported in Hertz (Hz). Mass spectra were recorded on a Shimadzu QP 1100 EX mass spectrometer with 70 eV ionization potential. Elemental analyses of new compounds were performed with a Vario EL III 0 Serial No. 11024054 instrument.

Typical experimental procedure for the preparation of substituted 2-arylbenzimidazoles using [Pro]NO_3 as catalyst. To a mixture of 4-chlorobenzaldehyde (3 mmol) and *o*-phenylenediamine (3 mmol) was added prolinium nitrate (prepared according to literature [22]) (0.6 mmol, 20% relative to reactants). The reaction mixture was stirred at 30°C and monitored by TLC (ethyl acetate:petroleum ether, 1:4). After completion of the reaction, water (10 mL) was added and the mixture was scratched and stirred for at least 30 min. The aqueous layer was filtered and the residues were purified by crystallization from EtOH:Water mixture. The product **3e** was obtained with 89% yield.

Aqueous layer containing IL was concentrated *in vacuo* to recycle and reuse the prolinium nitrate in another reaction.

Spectral and analytical data for substituted 2-arylbenzimidazoles.

2-Phenylbenzimidazole (3a). Light yellow solid; mp 283–285°C (Lit. [19] mp 289–291°C). IR (KBr): 1621 (C=N), 3447 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 13.31 (s, 1H), 8.27 (d, 2H, J = 3.0), 7.69 (m, 2H), 7.59 (s, 3H), 7.34 (m, 2H). ^{13}C NMR (75 MHz, DMSO-d_6): δ = 114.65, 123.62, 127.13, 127.35, 129.20, 131.23, 136.34, 150.16.

2-(4-Methylphenyl)benzimidazole (3b). Light yellow solid; mp 268–270°C (Lit. [24] mp 277°C). IR (KBr): 1617 (C=N), 3060, 3435 (NH) cm^{-1}. ^1H NMR (300 MHz, DMSO-d_6): δ 12.87 (s, 1H), 8.10 (d, 2H, J = 8.1 Hz), 7.61 (m, 2H), 7.33 (d, 2H, J = 8.1 Hz), 7.19 (m, 2H), 2.35 (s, 3H). ^{13}C NMR (75 MHz, DMSO-d_6): δ 20.96, 111.21, 118.72, 121.59, 126.42, 127.50, 129.52, 139.56, 151.45.

2-(4-Methoxyphenyl)benzimidazole (3c). Light yellow solid; mp 217–220°C (Lit. [19] mp 224–226°C). IR (KBr): 1612 (C=N), 3420 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 12.73 (s, 1H), 8.11 (d, 2H, J = 9.0 Hz), 7.54 (s, 2H), 7.16 (m, 2H), 7.11 (d, 2H, J = 9.0 Hz), 3.82 (s, 3H).

2-(4-Bromophenyl)benzimidazole (3d). Light yellow solid; mp 294–296°C (Lit. [19] mp 299–300°C). IR (KBr): 1597 (C=N), 3420 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 12.99 (s, 1H), 8.12 (d, 2H, J = 9.0 Hz), 7.75 (d, 2H, J = 9.0 Hz), 7.65 (m, 1H), 7.53 (m, 1H), 7.21 (m, 2H). ^{13}C NMR (75 MHz, DMSO-d_6): δ 111.43, 118.98, 121.86, 123.26, 128.35, 129.39, 131.98, 150.22.

2-(4-Chlorophenyl)benzimidazole (3e). Light yellow solid; mp 283–286°C (Lit. [19] mp 292–294°C). IR (KBr): 1597 (C=N), 3420 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 12.98 (s, 1H), 8.18 (d, 2H, J = 9.0 Hz), 7.62 (d, 3H, J = 9.0 Hz), 7.52 (d, 1H, J = 6.0 Hz), 7.21 (m, 2H).

2-(4-Fluorophenyl)benzimidazole (3f). Light yellow solid; mp 242–245°C (Lit. [19] mp 250–251°C). IR (KBr): 1602 (C=N), 3405 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 12.92 (s, 1H), 8.22 (m, 2H), 7.58 (m, 2H), 7.39 (t, 2H, J = 6.0 Hz), 7.19 (d, 2H, J = 6.0 Hz).

2-(4-Nitrophenyl)benzimidazole (3g). Light red solid; mp 307–309°C (Lit. [19] mp 316°C). IR (KBr): 1606 (C=N), 3409 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 13.28 (s, 1H), 8.40 (m, 4H), 7.65 (m, 2H), 7.26 (m, 2H).

2-(4-Bromophenyl)-5-nitrobenzimidazole (Mixture of tautomeric 3h and 4h). Yellow solid; mp 161–164°C. IR (KBr): 1608 (C=N), 3481 cm^{-1} (NH). ^1H NMR (300 MHz, DMSO-d_6): δ 13.64 (s, 1H), 8.11 (d, 1H, J = 8.4 Hz), 8.01 (d, 3H, J = 9 Hz), 7.91 (dd, 1H, J_1 = 9.0 Hz, J_2 = 2.4 Hz), 7.78 (d, 1H, J = 8.4 Hz), 7.70 (d, 3H, J = 9 Hz). ^{13}C NMR (75 MHz, DMSO-d_6): δ 108.05, 112.88, 113.13, 115.60, 124.55, 125.20, 128.24, 128.87, 131.00, 131.71, 132.20, 133.47, 133.96, 135.26, 135.90, 142.81, 143.36, 151.18, 158.54. A synthetic approach involving a solubilizing protecting group strategy is described to generate pyrido[2,3-*d*:6,5-*d*′]dipyrimidine-2,4,6,8-tetrones functionalized at positions 1 and 9 with alkylamine substitutents.

J. Heterocyclic Chem., **46**, 79 (2009).

INTRODUCTION

Pyrido[2,3-*d*:6,5-*d*′]dipyrimidine-2,4,6,8-tetrones (PDP) **4** illustrated in Scheme 1 are an interesting class of biannulated pyridine compounds. Derivatives of **4** have been shown to exhibit antibacterial and antiviral properties [1] as well as NAD-type redox catalytic activity [2]. Solid-state ribbons have also been described from the self-assembly of an amine derivative of **4**, which demonstrates the potential of these heterocyclic compounds in supramolecular synthesis applications [3].

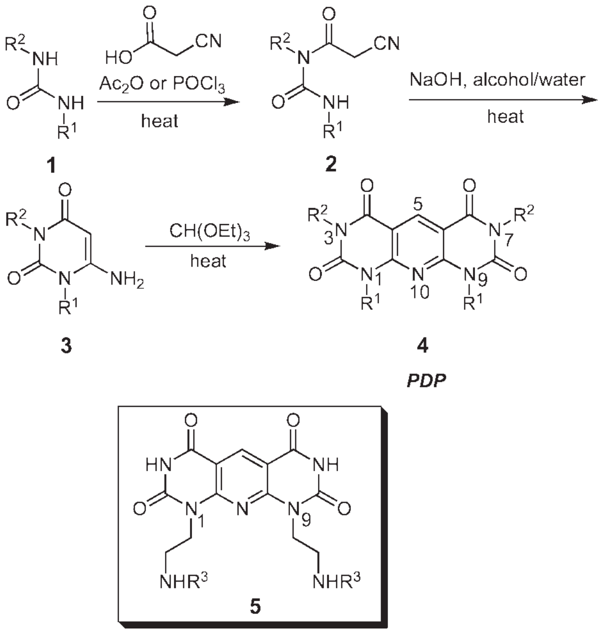
A typical synthetic scheme for these nitrogen-containing tricycles **4** is shown in Scheme 1 and begins with an often low-yielding condensation reaction of functionalized urea **1** with cyanoacetic acid under thermal conditions, followed by a base induced cyclization of **2** to generate 6-amino-uracil **3** [4]. A second condensation reaction between **3** and an electrophile such as triethyl orthoformate [3] (or an aromatic aldehyde [5a], or dimethyl sulfoxide [5b]), generates the target compound **4** (Scheme 1).

As part of our research program on the hierarchical self-assembly of a DNA-based G^C hybrid molecule into rosette nanotubes in aqueous media [6], we required PDP substrates **5** shown in Scheme 1, which were selectively functionalized at positions 1 and 9 with a variety of NHR^3 substituents such as L-Lysine. Given the harsh conditions required to construct the intermediate 6-aminouracil **3** and **4** (Scheme 1), we reasoned that it would be best to introduce these amine substituents (some of which would be incompatible with the acidic/basic conditions) after the PDP core **4** was constructed. A convergent strategy was therefore proposed as shown in Scheme 2, whereby the desired PDPs **5** would be derived from a common intermediate aldehyde **6** *via* a reductive amination reaction with the requisite amines. Aldehyde **6** would originate from an oxidative cleavage of di-alkene **7**, which in turn would be prepared from urea **8** containing a robust allyl group. Herein we describe the synthesis of **5** in detail, which required overcoming some challenging solubility constraints.

RESULTS AND DISCUSSION

The synthesis of **5** commenced according to Scheme 3, by treating commercially available *N*-allyl urea (**8**) with cyanoacetic acid and acetic anhydride at 85°C to provide the condensed adduct **9**. Cyclization of **9** in the presence of 10% sodium hydroxide in a 2:1 mixture of water and ethanol at 85°C generated uracil **10** with a moderate 57% yield [4c]. Finally, treatment of **10** with triethyl orthoformate in acetic acid under refluxing conditions for 2 h provided the desired allyl functionalized PDP adduct **7** in 80% yield [3]. Unfortunately, this adduct was found to be insoluble in many common organic solvents such as dichloromethane, ether, tetrahydrofuran, acetone, and methanol and could only be maintained in solution using dimethyl sulfoxide, refluxing *N*,*N*-dimethylformamide (DMF), or pyridine. This restricted our solvent choices for the subsequent two-step dihydroxylation/sodium periodate oxidative

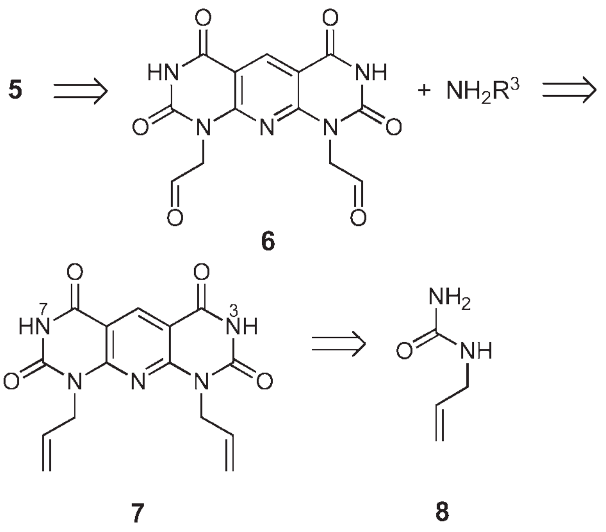
Scheme 1



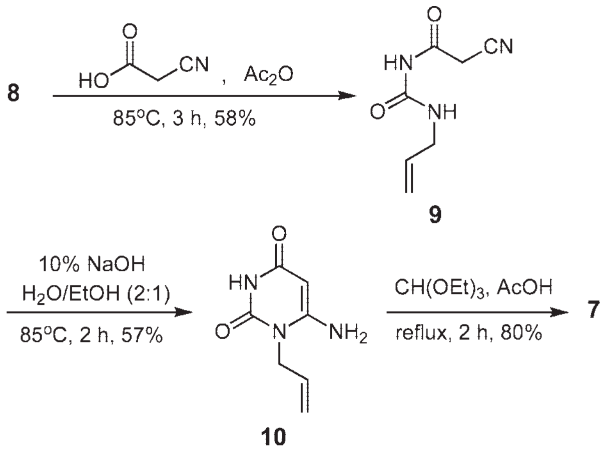
cleavage reaction for the preparation of **6**. Diol formation was therefore attempted using catalytic osmium tetroxide and an excess of 4-methyl-morpholine *N*-oxide (NMO) co-oxidant in a mixture of dimethyl sulfoxide and water, but only starting material was recovered.

To confer the required solubility to the PDP core **7**, various protecting groups (PGs) were installed on the nitrogen atoms at positions 3 and 7. The benzoyl (Bz) group was initially chosen and although it did afford the required solubility to conduct the oxidative cleavage reaction as illustrated in Scheme 4, the following reductive amination step of aldehyde **12** with protected lysine in the presence of sodium triacetoxyborohydride and *N*,*N*-diisopropylethylamine was very low yielding (5%). This was attributed to the removal of the Bz group(s) on **12** under the basic conditions, which caused the resulting material to precipitate out of the solution prior to undergoing the coupling reaction.

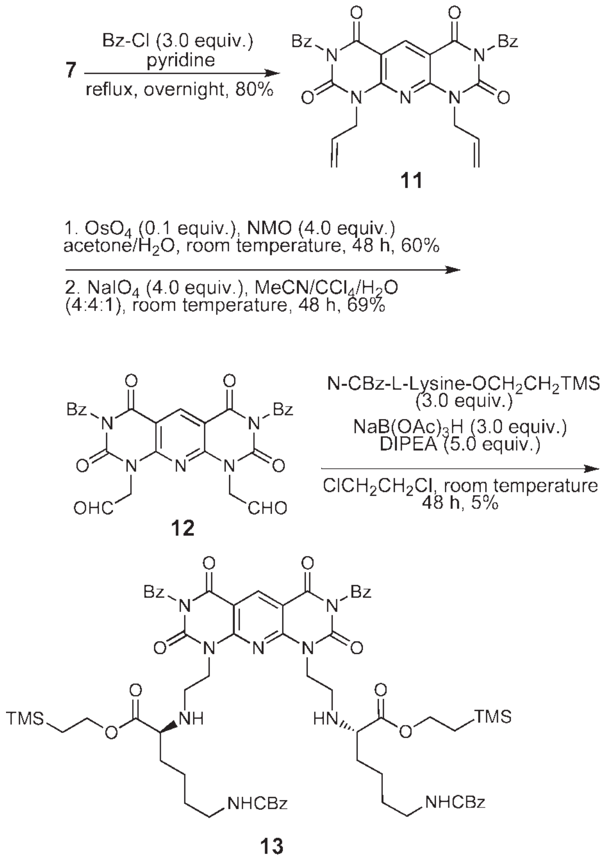
Scheme 2



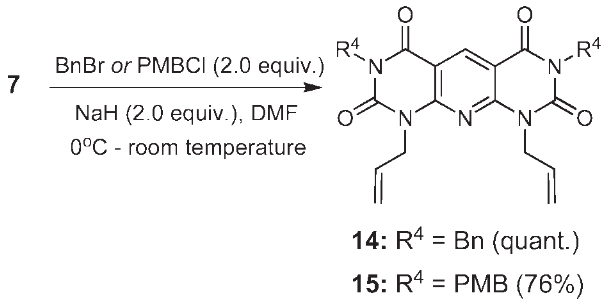
Scheme 3



Scheme 4



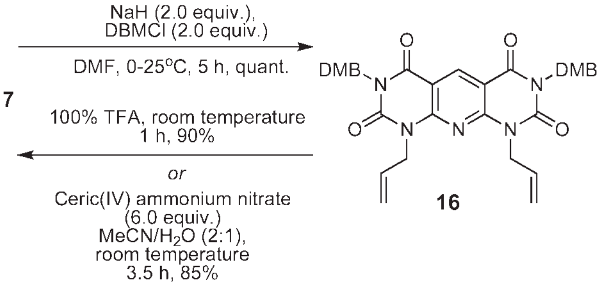
Scheme 5



Base-stable benzyl (Bn) and *p*-methoxy benzyl (PMB) PGs were subsequently installed on the PDP core **7** under standard conditions (Scheme 5). To ensure that these groups could also be easily removed, the deprotection of **14** and **15** was attempted under radical (2,3-dichloro-5,6-dicyano-*p*-benzoquinone, wet dichloromethane, room temperature, 1 day), acidic (98% trifluoroacetic acid (TFA), 2 days) and hydrogenation (H_2/Pd(C), acetic acid, 20 psi) conditions. Surprisingly, only starting material was recovered in all cases, except for the latter, in which the allyl group was reduced. Only in the presence of ceric (IV) ammonium nitrate in a 2:1 mixture of acetonitrile-water at room temperature for 14 h was the desired deprotected product **7** isolated, although in a mere 50% and 68% yield from **14** and **15**, respectively.

As a result of these unsatisfactory deprotection yields and limited conditions in which to remove the PMB/Bn groups, a fourth *N*-PG, DMB (di-(4-methoxyphenyl)-methyl) was also examined. Although it is less common than other *N*-PGs [7], examples of its applications can be found in amino acid [8a], allylic amine [8b], β-lactam [8c], and urethane/uridine [8d] synthesis to name a few. Gratifyingly, installation of DMB on compound **7** proceeded smoothly in the presence of sodium hydride and di-(4-methoxyphenyl)methyl chloride [9] in *N,N*-DMF to afford the bis-protected product **16** in quantitative yield (Scheme 6). Solubility tests also confirmed that **16** was soluble in a range of solvents such as acetone, dichloromethane, dimethylsulfoxide, *N,N*-DMF and ether with heating. Furthermore, the DMB group was easily removed under both acidic (100% TFA, room temperature, 1 h) and oxidative conditions (ceric (IV) ammonium nitrate, acetonitrile:water (2:1), room temperature, 3.5 h) in excellent yields of 90% and 85%, respectively (Scheme 6).

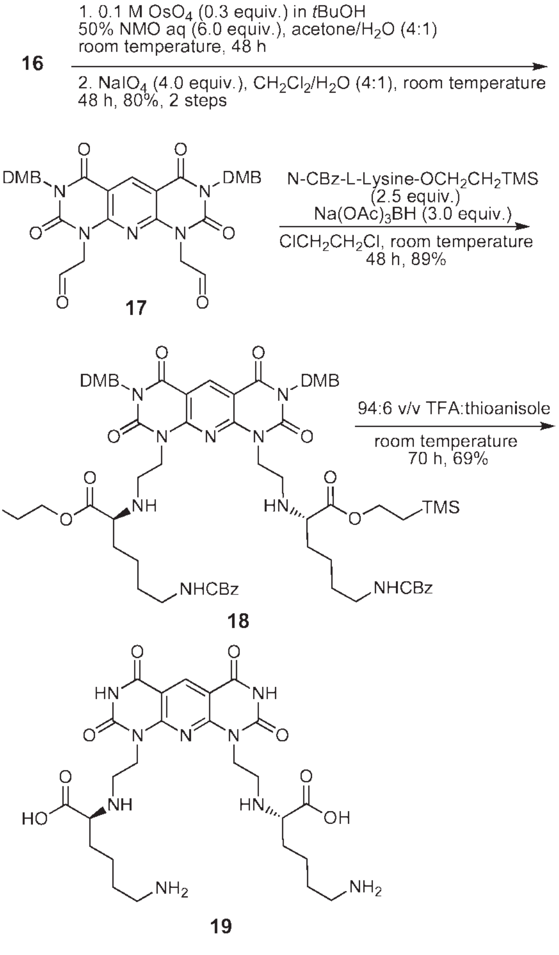
Scheme 6



With this PG strategy in hand, the synthesis was continued from compound **16**. Oxidative cleavage in the presence of catalytic osmium tetroxide and NMO followed by treatment with sodium periodate provided aldehyde **17** in 80% yield for the two steps. Double reductive amination of **17** with L-Lysine furnished the coupled adduct **18** in 89% yield. Finally, treatment of **18** with a 94:6 *v*/*v* TFA:thioanisole solution ensured complete removal of all six PGs (*i.e.*, benzyloxycarbonyl (Cbz), trimethylsilyl (TMS) and DMB) and the desired water-soluble PDP adduct **19** was obtained in 69% yield (~94% yield per PG).

In conclusion, a convergent synthetic strategy has been developed to access PDP substrates functionalized at positions 1 and 9 with amines such as L-lysine (*i.e.*,

Scheme 7



19) from the common intermediate aldehyde **17**. Central to this strategy is the protection of the nitrogen atoms at positions 3 and 7 on compound **7** with the base-stable DMB group. This PG provides the necessary solubility to the parent compound for the alkene cleavage and double reductive amination reactions and yet is sufficiently labile on the PDP core under both oxidative and acidic conditions for its eventual removal (Scheme 7).

EXPERIMENTAL

General. All commercial reagents and solvents were used without further purification except for dichloroethane which was purified on an MBraun solvent purification system. Reactions were monitored by TLC analysis using silica-coated TLC plates (Merck F 60254) and visualized under UV light. Flash chromatography was carried out using Merck 60 (0.040–0.063 mm) or Merck 60 (0.063–0.2 mm) silica. ^{1}H and ^{13}C NMR spectra were recorded on Varian Inova NMR spectrometers (300, 400, 500, or 600 MHz) with the solvent as the internal reference. The NMR data is presented as follows: chemical shift, multiplicity, coupling constant, integration. The mass spectra were performed at the Mass Spectrometry Laboratory at the Department of Chemistry, University of Alberta, or at the Analytical Laboratory of The National Institute for Nanotechnology, University of Alberta.

N-(Allylcarbamoyl)-2-cyanoacetamide (9). A mixture of allylurea (104.8 g, 1.046 mol), cyanoacetic acid (89.03 g, 1.046 mol) and acetic anhydride (197.4 mL, 2.092 mol) was heated for 3 h at 85°C. On cooling to room temperature, ether (530 mL) was added and the mixture was placed in an ice-bath for 2 h. The resulting solid was isolated, washed with ether and dried on the high vacuum to yield **9** as a white powder ($C_7H_9N_3O_2$, 98 g, 58%). $R_f = 0.6$ (SiO_2, 75% ethyl acetate/hexane); mp 140.1–141.9°C; ^{1}H NMR (300 MHz, DMSO-d_6) δ (ppm): 10.56 (brs, 1H), 8.03 (brs, 1H), 5.83 (ddt, J = 17.1, 10.2, 5.1 Hz, 1H), 5.16–5.05 (m, 2H), 3.90 (s, 2H), 3.78 (ddd, J = 5.1, 2.4, 1.5 Hz, 2H); ^{13}C NMR (125 MHz, DMSO-d_6) δ (ppm): 165.0, 152.2, 134.9, 115.2, 115.0, 41.3, 26.7; MS: *m/z* 168.40 (M$^+$ + 1). *Anal.* Calcd. for $C_7H_9N_3O_2$: C, 50.29; H, 5.43; N, 25.14. Found: C, 49.90, H, 5.35, N, 24.83.

1-Allyl-6-aminopyrimidine-2,4(1H,3H)-dione (10). A mixture of **9** (91 g, 0.54 mol) in water (248 mL) and ethanol (124 mL) was warmed to 85°C and slowly treated with 10% aqueous sodium hydroxide until a pH of 10 was obtained and the starting material was fully dissolved. After 10 min, the desired product **10** began to precipitate out of solution. The reaction mixture was stirred for an additional 2 h at 85°C and then treated with 1 *N* hydrochloric acid until the solution was slightly acidic. On cooling to room temperature, the resulting solid was isolated and dried on the high vaccum to furnish **10** as a white powder ($C_7H_9N_3O_2$, 51.5 g, 57%). $R_f = 0.6$ (SiO_2, 20% methanol/dichloromethane); mp 271.2–273.1°C; ^{1}H NMR (400 MHz, DMSO-d_6) δ (ppm): 10.38 (s, 1H), 6.71 (s, 2H), 5.79 (ddt, J = 17.2, 10.2, 4.5 Hz, 1H), 5.12–5.03 (m, 2H), 4.55 (s, 1H), 4.39–4.38 (m, 2H); ^{13}C NMR (125 MHz, DMSO-d_6) δ (ppm): 162.5, 155.7, 151.0, 132.4, 115.7, 75.2, 42.5; HRMS: *m/z* 167.0699 (M$^+$). *Anal.* Calcd. for $C_7H_9N_3O_2$: C, 50.29; H, 5.43; N, 25.14. Found: C, 50.40, H, 5.39, N, 25.15.

1,9-Diallylpyrido[2,3-d:6,5-d′]dipyrimidine-2,4,6,8 (1H, 3H,-7H,9H)-tetrone (7). A mixture of **10** (51.5 g, 0.308 mol), triethyl orthoformate (118 mL, 0.709 mol) and glacial acetic acid (1.2 L, 21 mol) was heated to reflux for 2 h. After cooling to room temperature, the precipitate was washed with glacial acetic acid, isolated by filtration and dried under high vacuum to provide **7** as a white solid ($C_{15}H_{13}N_5O_4$, 41.2 g, 80%). mp = 351.6–353.2°C (decomposes); ^{1}H NMR (500 MHz, DMSO-d_6) δ (ppm): 11.87 (s, 2H), 8.58 (s, 1H), 5.95–5.87 (m, 2H), 5.19–5.12 (m, 4H), 4.72–4.71 (m, 4H); ^{13}C NMR (125 MHz, DMSO-d_6) δ (ppm): 160.1, 154.0, 150.1, 137.6, 132.3, 116.9, 106.7, 43.8; HRMS: *m/z* 327.0971 (M$^+$). *Anal.* Calcd. for $C_{15}H_{13}N_5O_4$: C, 55.05; H, 4.00; N, 21.40. Found: C, 55.11, H, 4.03, N, 21.53.

1,9-Diallyl-3,7-(bis(4-methoxyphenyl)methyl)pyrido[2,3-d:6,5-d′] dipyrimidine-2,4,6,8(1H,3H,7H,9H)-tetrone (16). Compound **7** (1.3 g, 3.8 mmol) was slowly added to a mixture of NaH (183 mg, 7.63 mmol) in *N,N*-DMF (26 mL) at 0°C. After stirring for 1 h, di-(4-methoxyphenyl)methyl chloride (2.0 g, 7.6 mmol) was added and the reaction was slowly warmed to room temperature and stirred for 5 h. After re-cooling to 0°C, saturated aqueous ammonium chloride (50 mL) was added and the product was extracted with dichloromethane (3×). The combined organic phases were washed with water, dried over anhydrous sodium sulfate, filtered and concentrated *in vacuo* to provide **16** as a white foam ($C_{45}H_{41}N_5O_8$, 3.09 g, quantitative yield). $R_f = 0.8$ (50% ethyl acetate/hexane). ^{1}H NMR (600 MHz, CD_2Cl_2) δ (ppm): 9.06 (s, 1H), 7.36 (s, 2H), 7.33–7.30 (m, 8H), 6.87–6.86 (m, 8H), 5.95 (ddt, J = 22, 10.8, 5.4 Hz, 2H), 5.24–5.20 (m, 4H), 4.88 (d, J = 5.5 Hz, 4H), 3.80 (s, 12H); ^{13}C NMR (125 MHz, CD_2Cl_2) δ (ppm): 160.2, 159.3, 153.7, 150.6, 141.9, 132.0, 130.7, 130.3, 118.0, 113.7, 107.3, 59.9, 55.6, 45.7; MS: *m/z* 752.6 ((M$^+$ + 1)-C_2H_3). *Anal.* Calcd. for $C_{45}H_{41}N_5O_8$: C, 69.31; H, 5.30; N, 8.98. Found: C, 69.68, H, 5.53, N, 8.74.

1,9-Diacetaldehyde-3,7-(bis(4-methoxyphenyl)methyl)pyrido [2,3-d:6,5-d′]dipyrimidine-2,4,6,8(1H,3H,7H,9H)-tetrone (17). A solution of **16** (1 g, 1.3 mmol) in acetone/water (4:1, 50 mL) was treated with 50% aqueous *N*-methylmorpholine *N*-oxide (1.9 mL, 7.8 mmol) at room temperature. After stirring for 5 min, OsO_4 (4 mL, 0.1*M* solution in *t*-BuOH, 0.4 mmol) was added over a period of 5 min and the resulting solution was stirred at room temperature for 48 h. Sodium sulfite ($\sim$500 mg) was then added to quench the reaction and stirring was continued for an additional 1 h. The solvent was subsequently removed under reduced pressure, water was added and the product was extracted with dichloromethane (3×). The combined organic phases were washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated *in vacuo* to provide 1.1 g of crude tetrol. $R_f = 0.3$ (5% methanol/dichloromethane). A solution of the tetrol (1.1 g, 1.3 mmol) and sodium periodate (1.11 g, 5.2 mmol) in dichloromethane:water (4:1, 200 mL) was stirred at room temperature for 48 h. The organic layer was then separated, washed with water, dried over anhydrous sodium sulfate, filtered, and concentrated. Purification by flash chromatography on silica gel (0–2% methanol in dichloromethane) provided the desired product which was subsequently re-dissolved in dichloromethane and precipitated with hexane, filtered and dried under reduced pressure to provide **17** ($C_{43}H_{37}N_5O_{10}$, 812 mg, 80%) as a white solid. $R_f = 0.2$ (90% ethyl acetate/hexane); mp 172.8–173.9°C; ^{1}H NMR (500 MHz, acetone-d_6) δ (ppm): 9.63 (s, 2H), 8.94 (s, 1H), 7.33–7.30 (m, 10H), 6.87–6.85 (m, 8H), 5.11 (s, 4H), 3.77 (s, 12H); ^{13}C NMR (125 MHz, acetone-d_6) δ (ppm): 196.8, 161.1, 160.5, 154.8, 151.9, 142.3, 131.8, 131.4, 114.8, 108.6, 60.8, 56.1, 53.4; MS: *m*/*z* 784.6 ($M^+ + 1$). *Anal*. Calcd. for $C_{43}H_{37}N_5O_{10}$: C, 65.89; H, 4.76; N, 8.94. Found: C, 65.98, H, 4.93, N, 8.60.

1,9-Di((S)-2-(trimethylsilyl)ethyl-2-amino-6-(benzyloxy-carbonylamino)hexanoate)-3,7-(bis(4-methoxyphenyl)methyl)pyrido[2,3-d:6,5-d′]dipyrimidine-2,4,6,8(1H,3H,7H,9H)-tetrone (18). A solution of **17** (200 mg, 0.26 mmol) in dichloroethane (20 mL) was treated with *N*-Cbz-L-Lysine-OCH_2CH_2TMS (250 mg, 0.65 mmol) at room temperature. After stirring for 15 min, $Na(AcO)_3BH$ (165 mg, 0.78 mmol) was added and stirring was continued for an additional 48 h. The reaction was then quenched with water and the product was extracted with dichloromethane (2×). The combined organic layers were washed successively with 10% aqueous citric acid, water, 5% aqueous sodium bicarbonate and brine, dried over anhydrous sodium sulfate. Concentration under reduced pressure followed by purification by silica gel preparative thin layer chromatography (90% ethyl acetate/hexane) yielded compound **18** as white foam ($C_{81}H_{101}N_9O_{16}Si_2$, 346 mg, 89%). $R_f = 0.8$ (90% ethyl acetate/hexane); ^{1}H NMR (600 MHz, CD_2Cl_2) δ (ppm): 9.02 (s, 1H), 7.34–7.29 (m, 20H), 6.85–6.84 (m, 8H), 5.03 (s, 4H), 4.98 (s, 2H), 4.35 (dt, $J = 13.2$, 6.6 Hz, 4H), 4.16–4.13 (m, 4H), 3.77 (s, 12H), 3.15 (t, $J = 6.6$ Hz, 2H), 3.06 (dt, $J = 13.2$, 6.6 Hz, 4H), 2.97 (dt, $J = 13.0$, 6.0 Hz, 2H), 2.80–2.76 (m, 2H), 2.0 (broad s, 2H), 1.60–1.25 (m, 12H), 0.96–0.93 (m, 4H), 0.02 (s, 18H) ^{13}C NMR (150 MHz, CD_2Cl_2) δ (ppm): 175.8, 160.4, 159.6 , 156.8, 154.2, 151.4, 141.9, 137.7, 131.0, 130.9, 130.5, 128.9, 128.5, 113.9, 107.5, 66.8, 63.4, 61.7, 60.0, 55.8, 46.1, 43.6, 41.4, 33.6, 30.2, 23.6, 17.9, −1.2; MS: *m*/*z* 1512.8 ($M^+ + 1$). *Anal*. Calcd. for $C_{81}H_{101}N_9O_{16}Si_2$: C, 64.31; H, 6.73; N, 8.33. Found: C, 64.05, H, 6.78, N, 7.93.

1,9-Di((S)-2,6-diaminohexanoic acid)pyrido[2,3-d:6,5-d′]dipyrimidine-2,4,6,8 (1H,3H,7H,9H)-tetrone (19). A 94:6 *v*/*v* solution of TFA:thioanisole (10 mL) was added to **18** (70 mg, 0.046 mmol) at room temperature. After stirring for 70 h, ether (50 mL) was added and the resulting precipitate was filtered, washed with ether and dried under vacuum to provide **19** as a white solid (31 mg, 69%). ^{1}H NMR (500 MHz, D_2O) δ (ppm): 8.93 (s, 1H), 4.69–4.65 (m, 4H), 3.82 (t, $J = 6.5$ Hz, 2H), 3.58–3.44 (m, 4H), 3.01 (t, $J = 7.5$ Hz, 4H), 2.02–1.90 (m, 4H), 1.75–1.69 (m, 4H), 1.57–1.45 (m, 4H); ^{13}C NMR (150 MHz, D_2O) δ (ppm): 173.1, 162.1, 154.8, 152.1, 140.2, 108.0, 62.6, 44.5, 39.3, 39.0, 29.6, 26.7, 21.8; HRMS: *m*/*z* 592.2838 (M^+). *Anal*. Calcd. for $C_{25}H_{37}N_9O_8 \cdot 3.2CF_3$-$COOH \cdot 0.5H_2O$: C, 39.06; H, 4.30; N, 13.06. Found: C, 38.66, H, 4.69, N, 13.39.

A number of benzo[*c,d*]indolium derivatives have been synthesized.

J. Heterocyclic Chem., **46**, 84 (2009).

INTRODUCTION

Cationic indolium and benzo-fused indolium moieties are common heterocyclic end units in cyanine and other polymethine dyes. As a general rule, the dyes containing benzo[*c,d*]indolium systems are more stable and show a batochromic shift in their electronic spectra in comparison with indolium, benzo[*e*]indolium, and benzo[*g*]indolium counterparts [1,2]. Synthesis of several 1-substituted 2-methylbenzo[*c,d*]indolium salts and examples of their use in the preparation of visible and near-infrared dyes are described in this report. We have concentrated on the chemistry of a hydrophobic *N*-butyl derivative **4** (Schemes 1 and 2) and its water-soluble analog **13** (Scheme 3). The common precursor to these compounds is readily available 1,8-naphtholactam (**1**) [3,4].

RESULTS AND DISCUSSION

One of the synthetic routes to *N*-alkylbenzo[*c,d*]indolium salts starting with **1** involves the intermediary of a derivative **2** [5,6]. Following the well-established chemistry, compound **2** was alkylated with *n*-butyl bromide and the resultant *N*-butyl derivative **3** was transformed to the desired iodide salt **4** by treatment with a mixture of acetic acid, hydrochloric acid, and potassium iodide. We found that it is not necessary to purify the intermediate product **3** as the synthesis of **4** proceeds in high yield with crude substrate **3**. The 2-methyl group in **4** is activated toward a reaction with a base such as pyridine to generate an intermediate anhydrobase or an enamine by proton abstraction (not shown). This intermediate product is nucleophilic and, as such, can undergo a reaction with the electrophilic Vilsmeier reagent derived from *N,N*-dimethylformamide and phosphorus oxychloride (Scheme 1).

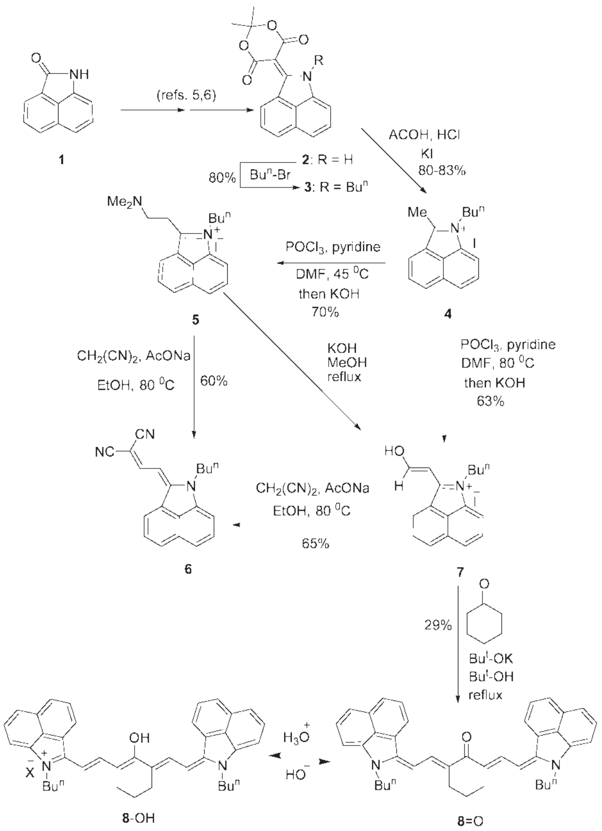
Interestingly, depending on conditions, two different products are formed, namely an enamine **5** or an unsaturated aldehyde **7**. The enamine **5** was independently transformed to the aldehyde **7** by treatment with potassium hydroxide in methanol under reflux conditions. Either compound **5** or **7**, can be efficiently condensed with malononitrile to give a visible dye **6**.

On the other hand, condensation of aldehyde **7** with cyclohexanone under basic conditions furnished a bis(aminodien)one **8=O** in low yield. This ketone is a visible dye (λ_{max} = 645 nm) in methanol under neutral or basic conditions. Under acidic conditions (pH < 2) dye **8=O** undergoes protonation at the carbonyl group with the formation of a hydroxy-substituted cyanine **8—OH** that absorbs in the near-infrared region (λ_{max} = 915 nm). The ketone/cyanine conversions are fully reversible, depending solely on pH conditions. Although the cyanine **8—OH** absorbs mainly in the invisible near-infrared region, it shows a residual absorption of low intensity in the visible region and is pink to the naked eye. The color change from deep dirty-green at basic or neutral pH to beautiful light-pink at low pH is quite dramatic. It should be noted that an attempted condensation of enamine **5** with cyclohexanone under conditions similar to those indicated above failed to produce dye **8=O**.

A different synthetic route to the dye system **8=O/8—OH** is presented in Scheme 2. We have previously used this approach for the synthesis of other pH-sensitive dyes [7].

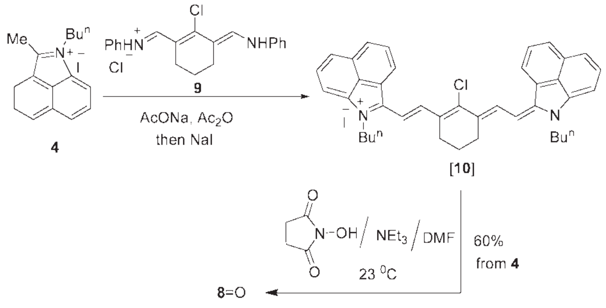
In this two-step preparation the substrate **4** was treated with the Vilsmeier-Haack reagent **9** [8] in acetic anhydride in the presence of sodium acetate as a base

Scheme 1

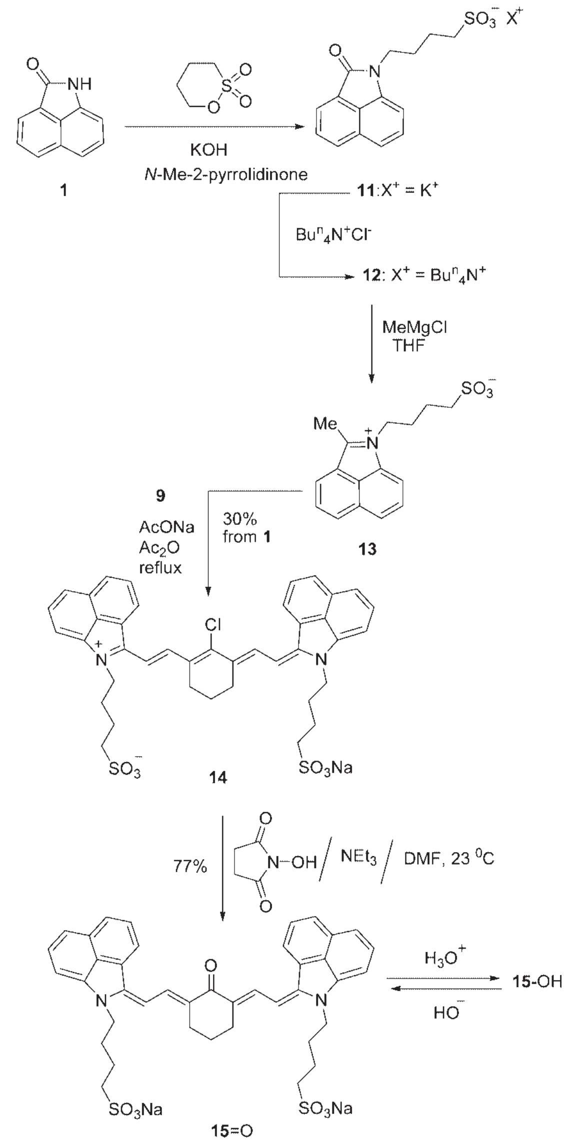


catalyst to furnish a chloro-substituted cyanine **10**, which then was transformed to **8=O** by the reaction with *N*-hydroxysuccinimide. The mechanism of this highly efficient transformation has been discussed previously [7]. This synthesis of **8=O** (Scheme 2) is more efficient and experimentally simpler than that shown in Scheme 1. Because of the high efficiency it was not necessary to purify the intermediate dye **10**. The final product **8=O** was obtained in an analytically pure form by using simple crystallization.

Scheme 2



Scheme 3



The synthesis of a water soluble pH-sensitive system **15=O/15—OH** is given in Scheme 3. The aqueous solubility is provided by the presence of sulfonate groups. As with other preparations discussed above, the starting material is 1,8-naphtholactam (**1**). Compound **1** was alkylated by the reaction with 1,4-butanesultone to give a sulfonatobutyl derivative **11**, the subsequent treatment of which with methylmagnesium chloride furnished the indolium product **13** [9]. The latter Grignard addition reaction gave compound **13** in low yield, which is due to low solubility of the potassium salt **11** in solvents suitable for organometallic reactions. This problem was overcome by transformation of the potassium salt **11** to a highly soluble tetrabutylammonium salt **12**. The reaction of **12** with methylmagnesium chloride in tetrahydrofuran furnished the desired product **13** in 85% yield. The subsequent construction of the dye system **15=O/15—OH** is similar to that of **8=O/8—OH**. The difference is in the use of a sulfonatobutyl derivative **13** (Scheme 3) rather than a butyl derivative **4** (Scheme 2) for the condensation reaction with the Vilsmeier-Haack reagent **9**.

Since compounds **8** and **15** share the same chromophore, they show virtually identical spectral properties that depend on pH conditions. The transition ketone/cyanine for both **8** and **15** is characterized by $pK_a = 2$, as obtained by spectrophotometric titrations.

EXPERIMENTAL

1-Butyl-2-methylbenzo[*c,d*]indolium iodide, 4. Conversion of the commercial substrate **1** to 2-(2,2-dimethyl-4,6-dioxo-1,3-dioxan-5-ylidene)1*H*-benzo[*c,d*]indole (**2**), alkylation of **2** with *n*-butyl bromide to give **3**, and then the treatment of crude product **3** with a mixture of acetic acid, hydrochloric acid and potassium iodide to give the desired salt **4** were conducted by using general procedures for the preparation of similar derivatives [5,6]. After crystallization from ethanol/water (1:5), compound **4** was obtained in a total yield of 40% starting from **1**, mp > 300°C; ^{1}H NMR (deuteriochloroform): δ 0.95 (t, $J = 7$ Hz, 3H), 1.45 (m, 2H), 1.78 (m, 2H), 3.20 (s, 3H), 4.17 (t, $J = 7$ Hz, 2H), 7.07 (d, $J = 8$ Hz, 1H), 7.47 (t, $J = 8$ Hz, 1H), 7.59 (d, $J = 8$ Hz, 1H), 7.87 (t, $J = 8$ Hz, 1H), 8.02 (d, $J = 8$ Hz, 1H), 9.10 (d, $J = 8$ Hz, 1H). *Anal.* Calcd. for $C_{16}H_{18}IN$: C, 54.71; H, 5.17; N, 3.99. Found: C, 54.80; H, 5.13; N, 4.06.

1-Butyl-2-(2-dimethylaminovinyl)benzo[*c,d*]indolium iodide, 5. *N,N*-Dimethylformamide (1.0 mL) was cooled to 0°C and treated dropwise with phosphorus oxychloride (0.21 mL, 2.3 mmol) and then with a solution of salt **4** (0.35 g, 1.0 mmol) and pyridine (0.2 mL) in *N,N*-dimethylformamide (2.0 mL). The mixture was heated to 65°C for 40 min, then treated with an aqueous solution of potassium hydroxide (60%, 1 mL) and heated to 45°C for an additional 30 min. Extraction with dichloromethane (4 × 10 mL) followed by concentration of the extract and silica gel chromatography of the residue eluting with dichloromethane/methanol (19:1) gave 0.28 g (70%) of **5**; mp 182–183°C; ^{1}H NMR (deuteriochloroform): δ 0.95 (t, $J = 8$ Hz, 3H), 1.45 (m, 2H), 1.78 (m, 2H), 3.47 (s, 3H), 3.86 (s, 3H), 4.17 (t, $J = 8$ Hz, 2H), 5.87 (d, $J = 12$ Hz, 1H), 7.07 (d, $J = 8$ Hz, 1H), 7.47 (t, $J = 8$ Hz, 1H), 7.59 (d, $J = 8$ Hz, 1H), 7.87 (t, $J = 8$ Hz, 1H), 8.02 (d, $J = 8$ Hz, 1H), 8.96 (d, $J = 12$ Hz, 1H), 9.10 (d, $J = 8$ Hz, 1H); ms (esi): *m/z* 279 (M^+). *Anal.* Calcd. for $C_{19}H_{23}IN_2$: C, 56.17; H, 5.71; N, 6.89. Found: C, 56,05; H, 5.72; N, 6.83.

[2-(1-Butyl-1,2-dihydrobenzo[*c,d*]indol-2-ylidene)ethylidene]malononitrile, 6. A solution of salt **5** (63 mg, 0.15 mmol), malononitrile (15 mg, 0.22 mmol) and sodium acetate (16 mg, 0.20 mmol) in anhydrous ethanol (15 mL) was heated under reflux for 1 h. Silica gel chromatography eluting with hexanes/dichloromethane (5:1) gave 27 mg (60%) of **6**; mp 180–181°C; ^{1}H NMR (deuteriochloroform): δ 1.00 (t, $J = 7$ Hz, 3H), 1.46 (m, 2H), 1.80 (m, 2H), 4.01 (t, $J = 7$ Hz, 2H), 6.25 (d, $J = 9$ Hz, 1H), 6.99 (m, 1H), 7.52 (m, 2H), 7.74 (t, $J = 8$ Hz, 1H), 8.00 (d, $J = 8$ Hz, 1H), 8.10 (d, $J = 8$ Hz, 1H), 8.32 (d, $J = 9$ Hz, 1H); ms (maldi) *m/z* 299 (M^+) and 300 ($M^+ + 1$); vis: λ_{max} in methanol, 519 nm and 556 nm. *Anal.* Calcd. For $C_{20}H_{17}N_3$: C, 80.24; H, 5.72; N, 14.04. Found: C, 80.22; H, 5.75; N, 13.91.

(1-Butyl-1,2-dihydrobenzo[*c,d*]indol-2-ylidene)acetaldehyde, 7. *N,N*-Dimethylformamide (1 mL) was stirred at 10°C and treated dropwise with phosphorus oxychloride (0.21 mL, 2.3 mmol) and then with a solution of **4** (1.9 g, 0.54 mmol) and pyridine (0.6 mL) in *N,N*-dimethylformamide (2 mL). The mixture was heated to 80°C for 40 min, then treated with an aqueous solution of potassium hydroxide (60%, 2.5 mL) and heated to 80°C for an additional 90 min. After cooling the mixture was extracted with dichloromethane (4 × 10 mL), the extracts were concentrated, and the residue was purified by silica gel chromatography eluting with dichloromethane/methanol (19:1) to furnish 1.6 g (65%) of **7**; mp 104–105°C; ^{1}H NMR (deuteriochloroform): δ 0.93 (t, $J = 7$ Hz, 3H), 1.39 (m, 2H), 1.66 (m, 2H), 4.00 (t, $J = 7$ Hz, 2H), 5.85 (d, $J = 8$ Hz, 1H), 7.12 (t, $J = 8$ Hz, 1H), 7.52 (m, 2H), 7.74 (t, $J = 8$ Hz, 1H), 8.07 (d, $J = 8$ Hz, 1H), 8.60 (d, $J = 8$ Hz, 1H), 10.33 (d, $J = 8$ Hz, 1H); ms (esi): *m/z* 252 (M^+). *Anal.* Calcd. for $C_{17}H_{18}NO$: C, 80.92; H, 7.19; N, 5.55. Found: C, 81.05; H, 6.88; N, 5.56.

2,6-Bis[(1-ethyl-1,2-dihydrobenzo[*c,d*]indol-2-ylidene)ethylidene]cyclohexanone, 8=O. A solution of potassium *tert*-butoxide (116 mg, 1 mmol) in *tert*-butanol (15 mL) was stirred under a nitrogen atmosphere and treated with the aldehyde **7** (150 mL, 0.67 mmol) and cyclohexanone (0.34 μL, 0.33 mmol). The mixture was heated under reflux for 12 h, then cooled and quenched with water (1.0 mL). The resultant precipitate was collected by filtration, washed with water and cold methanol, and dried under reduced pressure at 23°C; yield 54 mg (29%); mp 188–190°C; ^{1}H NMR (deuteriochloroform): δ 1.00 (m, 6H), 1.48 (m, 4H), 1.80 (m, 4H), 1.99 (m, 2H), 2.79 (m, 4H), 3.88 (m, 4H), 6.06 (d, $J = 13$ Hz, 2H), 6.68 (d, $J = 8$ Hz, 2H), 7.29 (d, $J = 8$ Hz, 2H), 7.40 (t, $J = 8$ Hz, 2H), 7.65 (t, $J = 8$ Hz, 2H), 7.77 (d, $J = 8$ Hz, 2H), 8.42 (d, $J = 8$ Hz, 2H), 8.77 (d, $J = 8$ Hz, 2H); vis: λ_{max} in methanol, 645 nm (ε 50800 M^{-1} cm^{-1}); nir: λ_{max} in methanol with one drop of concentrated hydrochloric acid (pH < 2, **8—OH**), 915 nm (ε 142000 M^{-1} cm^{-1}). *Anal.* Calcd. for $C_{40}H_{40}N_2O$: C, 85.06; H, 7.13; N, 4.96. Found: C, 85.33; H, 7.12; N, 4.95.

Alternative synthesis of 8=O. The Vilsmeier-Haack reagent **9** was obtained as reported previously [8]. Condensation of **9** with **4** was conducted in ethanol in the presence of sodium acetate by using a general procedure [10]. Crude product **10** was collected as a precipitate after treatment of the mixture with ether (nir: λ_{max} in methanol, 1025 nm) and used for the subsequent transformation to **8=O** without purification. Thus, crude dye **10**, obtained from 351 mg (1.0 mmol) of **4**, was dissolved in anhydrous *N,N*-dimethylformamide (15 mL), and this solution was treated with *N*-hydroxysuccinimide (0.33 g, 2.9 mmol) and triethylamine (0.5 mL) under a nitrogen atmosphere. The mixture was stirred at 23°C under nitrogen for 10 h and then diluted with ether (35 mL), which caused precipitation of **8=O**. The product was crystallized by dropwise dilution of a solution in methanol with *tert*-butyl methyl ether; yield 338 mg (60%) from **4**. The spectral characteristics of **8=O** thus obtained were virtually identical with those reported above.

1-(4-Sulfonatobutyl)-1,2-dihydrobenzo[*c,d*]indol-2-one, potassium salt, 11. This compound was obtained by the following modification of the published procedure [9] which did not include any characterization of the product. A mixture of **1** (1.69 g, 10 mmol), powdered potassium hydroxide (1.12 g, 20 mmol), and *N*-methyl-2-pyrrolidone (5 mL) was stirred at 23°C for 15 min and then treated with 1,4-butanesultone (1.49 g, 11 mmol). The mixture was stirred at 80°C for an additional 10 h, then cooled and treated dropwise with acetone (25 mL), which caused crystallization of product **11**; yield 3.26 g (95%); mp 235–240°C; ^{1}H NMR (deuterated dimethyl sulfoxide): δ 1.63 (t, $J = 7$ Hz, 2H), 1.78 (m, 2H), 2.45 (m, 2H), 3.90 (t, $J = 7$ Hz, 2H), 7.24 (d, $J = 7$ Hz, 1H), 7.56 (t, $J = 8$ Hz, 1H), 7.65 (d, $J = 8$ Hz, 1H), 7.82 (t, $J = 8$ Hz, 1H), 8.06 (d, $J = 8$Hz, 1H), 8.20 (d, $J = 8$ Hz, 1H). *High-resolution ms* (esi, negative ion mode): calcd. for $C_{15}H_{14}NO_4S$, *m*/*z* 304.0643 (M^-); found *m*/*z* 304.0655.

1-(4-Sulfonatobutyl)-1,2-dihydrobenzo[*c*,*d*]indol-2-one, tetrabutylammonium salt, 12. This compound was obtained by the following modification of the published procedure [9] which did not include any characterization of the product. A mixture of salt **11** (3.0 g, 10 mmol) and tetrabutylammonium chloride (3.1 g, 11 mmol) in acetic acid (10 mL) was stirred at 90°C, treated dropwise with ethyl acetate, cooled, and filtered from the precipitate of potassium chloride. The filtrate was concentrated on a rotary evaporator and the oily residue was dissolved in dry toluene (50 mL). The azeotropic removal of traces of water by concentration on a rotary evaporator gave salt **12** (5.0 g, 93%) as a viscous oil; ^{1}H NMR (deuterated dimethyl sulfoxide): δ 0.99 (t, $J = 8$ Hz, 12H), 1.43 (m, 8H), 1.65 (m, 8H), 1.95 (m, 4H), 2.90 (m, 2H), 3.27 (t, $J = 8$ Hz, 8H), 3.94 (t, $J = 7$ Hz), 6.98 (d, $J = 7$ Hz, 1H), 7.18 (d, $J = 7$ Hz, 1H), 7.25 (d, $J = 7$ Hz, 1H), 7.50 (m, 2H), 7.69 (t, $J = 7$ Hz, 1H), 8.02 (t, $J = 7$ Hz, 1H). *High-resolution ms* (esi, negative ion mode): calcd. for $C_{15}H_{14}NO_4S$ (M^-) , *m*/*z* 304.0643 ; found 304.0640.

1-(4-Sulfonatobutyl)-2-methylbenzo[*c*,*d*]indolium inner salt, 13. This compound was obtained by the following modification of the published procedure [9] which did not include any characterization of the product. Methylmagnesium chloride (3.0*M* solution in tetrahydrofuran, 15.0 mL, 45 mmol) was added dropwise to a stirred solution of salt **12** (5.46 g, 10 mmol) in anhydrous tetrahydrofuran under a nitrogen atmosphere. The mixture was stirred at 60°C for 1 h, then cooled, neutralized by dropwise addition of 3*M* hydrochloric acid, and consecutively diluted with ethanol (30 mL) and ether (30 mL). Cooling to 0°C for several hours resulted in crystallization of product **13**; yield 2.58 g (85%); mp 143–145°; ^{1}H NMR (deuterium oxide): δ 1.77 (t, $J = 8$ Hz, 2H), 2.03 (m, 2H), 2.84 (m, 2H), 3.01 (s, 3H), 4.50, (t, $J = 8$ Hz, 2H), 7.72 (t, $J = 8$ Hz, 1H), 7.84 (t, $J = 8$ Hz, 1H), 8.08 (m, 2H), 8.42 (d, $J = 8$ Hz, 1H), 8.50 (d, $J = 8$ Hz, 1H). *High-resolution ms* (maldi): calcd. for $C_{16}H_{18}NO_3S$ ($M^+ + 1$), *m*/*z* 304.1007; found *m*/*z* 304.1015.

Cyanine dye 14. A solution of inner salt **13** (303 mg, 1 mmol) Vilsmeier-Haack reagent **9** [8] (180 mg, 0.5 mmol), and sodium acetate (82 mg, 1 mmol) in acetic anhydride (20 mL) was heated under reflux for 8 h, then cooled and treated with ether (30 mL). The resultant precipitate of cyanine **14** was crystallized from methanol/ether; yield 115 mg (30%); mp > 300°C; ^{1}H NMR (deuterated dimethyl sulfoxide): δ 1.82 (m, 14H), 2.83 (t, $J = 7$ Hz, 4H), 4.01 (t, $J = 7$ Hz, 4H), 6.20 (d, $J = 13$ Hz, 2H), 6.88 (d, $J = 7$ Hz, 2H), 7.29 (d, $J = 7$ Hz, 2H), 7.42 (t, $J = 7$ Hz, 2H), 7.73 (t, $J = 7$ Hz, 2H), 7.84 (d, $J = 7$ Hz, 2H), 8.04 (d, $J = 7$ Hz, 2H), 8.37 (d, $J = 13$ Hz, 2H); nir: λ_{max} in methanol, 1013 nm. *High-resolution ms* (esi, negative ion mode): calcd. for $C_{40}H_{38}{}^{35}ClN_2O_6S_2$ (M^-), *m*/*z* 741.1860; found *m*/*z* 741.1871.

2,6-Bis[2-[1-(sodium4-sulfonatobutyl)-1,2-dihydrobenzo-[*c*,*d*]indol-2-ylidene)]ethylidene]cyclohexanone, 15=O. Cyanine **14** was allowed to react with *N*-hydroxy-succinimide in the presence of triethylamine in *N*,*N*-dimethylformamide as described above for a similar transformation of **10** to **8=O**. Product **15=O** was precipitated by addition of ether and crystallized from methanol/ether; yield 115 mg starting with 150 mg of **14** (77%); mp > 300°C; ^{1}H NMR (deuterated dimethyl sulfoxide): δ 1.86 (m, 14H), 2.85 (t, $J = 7$ Hz, 4H), 4.02 (t, $J = 7$ Hz, 4H), 6.20 (d, $J = 13$ Hz, 2H), 6.90 (d, $J = 7$ Hz, 2H), 7.32 (d, $J = 7$ Hz, 2H), 7.45 (t, $J = 7$ Hz, 2H), 7.75 (t, $J = 7$ Hz, 2H), 7.87 (d, $J = 7$ Hz, 2H), 8.06 (d, $J = 7$ Hz, 2H), 8.42 (d, $J = 7$ Hz, 2H); vis: λ_{max} in methanol, 645 nm (ε 50800 M^{-1} cm^{-1}); nir: λ_{max} in methanol with one drop of concentrated hydrochloric acid (pH < 2, **15—OH**), 914 nm (ε 142000 M^{-1} cm^{-1}). *High-resolution ms* (maldi, negative ion mode): calcd. for $C_{40}H_{39}N_2O_7S_2$ ($M^- + 1$), *m*/*z* 723.2199; found *m*/*z* 723.2234.

The reactivity of 3,4-diamino-1,2,5-oxadiazole (**2**) toward nucleophilic substitution of 3,6-bis(3,5-dimethylpyrazol-1yl)-1,2,4,5-tetrazine (**1**) was studied. A new class of high nitrogen heterocyclic systems was prepared. It was determined that 3,4-diamino-1,2,5-oxadiazole did not display the required nucleophilicity to be reactive. However, the anion of 3,4-diamino-1,2,5-oxadiazole, prepared by treatment with strong base, was sufficiently reactive to act as a nucleophile.

J. Heterocyclic Chem., **46**, 88 (2009).

INTRODUCTION

High nitrogen heterocyclic systems have seen increasing interest over the past decade due to their potential utility in numerous applications, such as propellants, explosives, and pyrotechnics [1–4]. We have primarily focused on the investigation of tetrazines [5–9] and 1,2,5-oxadiazoles [9] in the past, but had not combined the two heterocycles into a new heterocyclic system. Nucleophilic substitutions of tetrazines, in particular 3,6-bis(3,5-dimethylpyrazol-1yl)-1,2,4,5-tetrazine (**1**), have been studied extensively by us [10] and others [11,12]. Additionally, the nucleophilicity of 3,4-diamino-1,2,5-oxadiazole (**2**) has been studied as well [13], but there exist no literature examples describing the reactivity of **1** with **2** or any other tetrazine. We began our investigations by studying the substitution reaction of **1** with **2**. We wish to report here that we have been successful in identifying conditions that allow us to prepare the desired tetrazine-oxadiazole heterocyclic systems in good yield. We have also confirmed the structure through X-ray crystallography.

RESULTS AND DISCUSSION

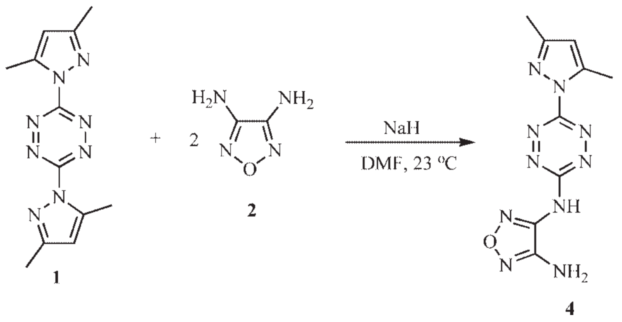
Our initial efforts toward the synthesis of **3** involved the reaction of **1** and **2** in refluxing acetonitrile (Scheme 1). Unfortunately, no reaction was observed even after 2 days. More polar solvents, such as dimethylformamide (DMF) were also investigated, but only trace amounts of product was observed by thin layer chromatography. Because of these setbacks, we focused on an approach we employed recently [5]. In this approach, we reported the synthesis of some new high nitrogen materials by reacting with the anion of nitroguanidine with **1** in methanol. The success of this chemistry led us to investigate whether similar conditions might be applicable with **1** and **2**.

As shown in Scheme 1, our strategy involved the deprotonation of **2** with sodium hydride in DMF. Our ultimate goal was to prepare **3** and as such, we employed two equivalents of **2**. When the reaction was performed at ambient temperature, we observed the complete conversion of **1** to a new product after a few hours as analyzed by thin layer chromatography. Isolation and analysis of the product showed that the material isolated was the mono-substituted product **4**.

It was believed that as the product **4** began to form, an acidic proton was generated, in the form of the oxadiazol-ylamino proton. This acidic proton serves to neutralize the anion of **2**, thus resulting in an unreactive form of **2**. We subsequently reasoned that the addition of more equivalents of the anion of **2** would allow for complete conversion of the intermediate **1** to **3**.

Indeed, when four equivalents of the anion of are generated in DMF by the reaction of sodium hydride and **2**, followed by the addition of **1** at ambient temperature, complete conversion of intermediate **4** to product **3**

Scheme 1



was observed. To isolate the product, the reaction was quenched by pouring into ice water and acidifying to pH = 1 (Scheme 2). Compound **3** was determined to be very thermally stable and doesn't begin to decompose until 280°C. An alternative approach that was equally successful was the use of two equivalents of **2** and four equivalents of sodium hydride.

X-ray quality crystals were grown from DMSO with slow diffusion of water. A crystal structure was determined for bis-substituted product **3** and is shown in Figure 1. The crystals obtained were a DMSO solvate containing two DMSO molecules and one molecule of **3**.

Interestingly, as shown in Scheme 3, a bis-tetrazine substituted 1,2,5 oxadiazole can be prepared by using two equivalents of **1** and only one equivalent of **2**. Although these new heterocycles contain a large percentage of nitrogen, they are not energetic materials. They are insensitive to impact, spark and friction. Each of these new heterocyclic molecules will now be investigated as potential starting materials for new high-nitrogen energetic materials.

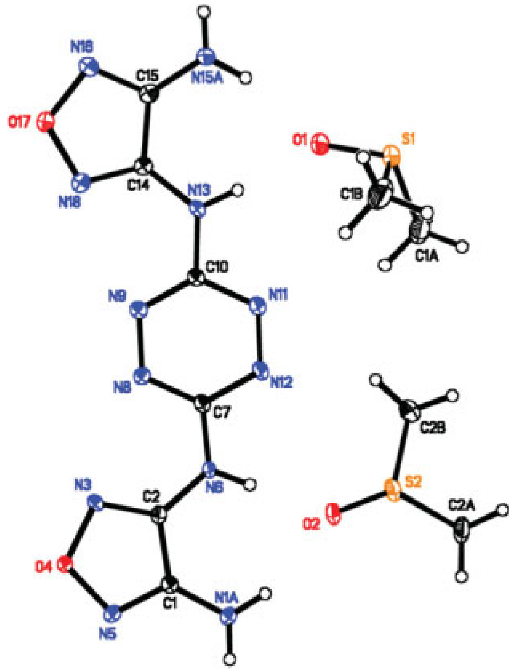


Figure 1. View of **3** showing the labeling of the nonhydrogen atoms. Thermal ellipsoids are shown at the 50% probability level. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

EXPERIMENTAL

3-(3,5-Dimethylpyrazol-1yl), 6-(3-amino-1,2,5-oxadiazol-4-ylamino)-1,2,4,5-tetrazine (4). To dimethylformamde (10 mL) was added 70 mg of NaH (60% dispersion in oil, 1.7 mmol), and 100 mg of 3,4-diamino-1,2,5-oxadiazole (1 mmol). The mixture was stirred at 23°C for 30 min. To the reaction mixture, 135 mg of **1** (0.5 mmol) was added. The reaction was then stirred at 23°C for 30 min. After this time **1** was completely consumed. The reaction mixture was then poured into ice water and acidified to pH = 1. The reaction was allowed to stand at 5°C for 16 h and a red precipitate formed. The material was collected by filtration, washed with water and air dried to provide 200 mg (73%), mp 87–89°C; IR (ν, cm^{-1}) 3477, 3354, 3227, 2925, 2851, 1646, 1609, 1581, 1558, 1527, 1450, 1417, 1323, 1262, 1082, 1049, 1025, 976, 955, 833, 800, 563. ^{1}H NMR (deuteriochloroform, ppm): δ 2.23 (s, 3H), 2.43 (s, 3H), 6.2 (s, 2H), 6.25 (s, 1H), 11.42 (s, 1H); ^{13}C NMR (deuteriodimethyl sulfoxide): δ 12.84, 13.37, 109.58,

142.01, 143.37, 151.13, 152.36, 157.88, 159.98. *Anal*. Calcd. for $C_9H_{10}N_{10}O$: C, 39.43; H, 3.68; N, 51.07. Found: C, 39.47; H, 3.65; N, 51.04.

3,4-Bis[6-(3,5-dimethylpyrazol-1yl)-1,2,4,5-tetrazin-6-ylamino]-1,2,5-oxadiazole (5). To a mixture of 540 mg of **1** (2.0 mmol) and 100 mg of 3,4-diamino-1,2,5-oxadiazole (1 mmol) in 5 mL of DMF was added 140 mg of NaH (60% dispersion in oil, 3.4 mmol) at 23°C. The reaction mixture was allowed to stir for 1 h. The reaction mixture was poured into 20 mL of water, acidified to pH = 1, the solid collected by filtration and washed with water to give a orange product 202 mg (45%), mp 196°C (dec); IR (ν, cm^{-1}) 3228, 3056, 2986, 2933, 1577, 1480, 1421, 1274, 1077, 1047, 1027, 971, 951, 801, 568. ^1H NMR (deuterioacetonitrile, ppm): δ 2.27 (s, 6H), 2.52 (s, 6H), 6.20 (s, 2H), 9.63 (bs, 2H). ^{13}C NMR (deuterioacetonitrile): δ 13.72, 13.74, 111.20, 143.97, 147.01, 153.69, 159.81, 161.06. *Anal*. 3,6-Bis(3-amino-1,2,5-oxadiazol-4-ylamino)-1,2,4,5-tetrazine (3). To a solution of 3.0 g (60% dispersion in oil, 75 mmol) of NaH in 50 mL of DMF was added 2.0 g (20 mmol) of **2**. The mixture was allowed to stir at 25°C for 30 min. A total of 1.35 g (5.0 mmol) of **1** was then added in one portion and the reaction allowed to stir at 25°C for 1 h. The reaction mixture was then poured into 200 mL of water and acidified to pH = 1. A red precipitate formed, the mixture was cooled in an ice bath, the solid collected by filtration and the orange-red solid was washed with water and air-dried to give 1.27 g (91%), mp 280°C (dec); IR (ν, cm^{-1}) 3391, 3329, 3260, 3080, 2953, 2921, 2851, 1642, 1634, 1511, 1446, 1421, 1307, 1262, 1074, 1008, 980, 861, 812. ^1H NMR (deuteriodimethylsulfoxide): δ 6.15 (bs, 4H), 10.8 (s, 2H); ^{13}C NMR (deuteriodimethylsulfoxide): δ 143.71, 151.76, 158.78. *Anal*. Calcd. for $C_6H_6N_{12}O_2$: C, 25.9; H, 2.17; N, 60.42. Found: C, 25.5; H, 2.19; N, 60.44.

Single-crystal X-ray diffraction analysis of 3. $C_{10}H_{18}N_{12}O_4S_2$, FW = 434.48, monoclinic, $P2_1/c$, $a = 10.1881(8)$ Å, $b = 19.4198(15)$ Å, $c = 9.9515(8)$ Å, $\alpha = 90°$, $\beta = 114.649(2)°$, $\gamma = 90°$, $V = 1789.5(2)$ Å^3, $Z = 4$, $\rho_{calc} = 1.613$ mg/m^3, $\mu = 0.186$ mm^{-1}, $F(000) = 904$, $R_1 = 0.0456$ for 3369 observed ($I > 2\sigma I$) reflections and 0.0545 for all 3680 reflections, Goodness-of-fit = 1.095, 253 parameters.

A thin red/orange plate of dimensions 0.56 mm × 0.21 mm × 0.007 mm was mounted on glass fiber using a small amount of Cargille immersion oil. Data were collected at the Advanced Photon Source in Argonne National Laboratory. A Bruker three-circle platform diffractometer equipped with a SMART 6000 CCD detector was used to collect the data. An Oxford Cryojet low temperature device was used to keep the crystals at a constant 103(2) K during data collection.

Data collection was performed and the unit cell was initially refined using *SMART* v5.625 [14]. Data reduction was performed using *SAINT* v6.36A [15] and *XPREP* v6.12 [16]. Corrections were applied for Lorentz, polarization, and absorption effects using *SADABS* v2.03 [17]. The structure was solved and refined with the aid of the programs in the *SHELXTL-plus* v6.10 system of programs [18]. The full-matrix least-squares refinement on F^2 included atomic coordinates and anisotropic thermal parameters for all non-H atoms. The H atoms were included using a riding model.

CCDC 685362 contains the supplementary crystallographic data for this article. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre *via* www.ccdc.cam.ac.uk/data_request/cif.

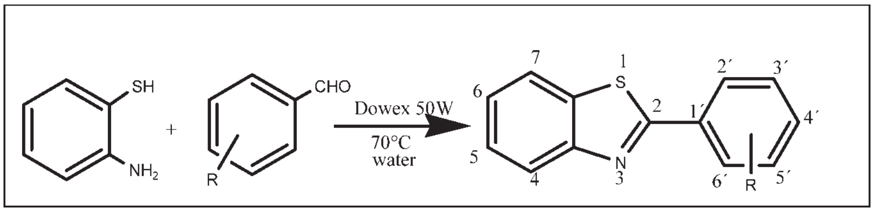
DOI 10.1002/jhet.9



2-Aminothiophenol and a variety of aryl aldehydes were allowed to react in one-pot operation to give 2-aryl-benzothiazoles in excellent yields in the presence of Dowex 50W in water. Very high yields coupled with the ease of work-up procedure, formation of no side products, employment of ''reusable'' catalyst, and ''green'' synthesis in aqueous medium without maintaining anhydrous reaction conditions are the most important aspects of this methodology.

J. Heterocyclic Chem., **46**, 91 (2009).

INTRODUCTION

The 2-substituted benzothiazole moiety is particularly very interesting in the area of medicinal and organic chemistry. The benzothiazolyl system possesses highly selective and potent antitumor activity. An example is that of substituted 2-(4-aminophenyl)-benzothiazoles, which show nanomolar inhibitory *in vitro* activity against a wide range of human breast, ovarian, colon, and renal cell lines [1]. Another such compound that shows potent and selective inhibitory activity against lung, colon, and breast cancer cell lines is 2-(3,4-dimethoxyphenyl)-5-fluorobenzothiazole [2]. Also, the 2-(4-dimethylaminophenyl)-benzothiazole is an integral component used for the treatment of Alzheimer's disease [3]. The presence of the benzothiazole nucleus is essential in the thermally stable rigid-rod polymers with high tensile strength and modulus [4]. Thus, the synthesis of this benzothiazole moiety is always a great challenge.

A number of synthetic routes are available for the construction of the benzothiazole nucleus. Among them, the most common ones being the condensation of 2-aminothiophenols with substituted carboxylic acids, acyl chlorides, aldehydes, and nitriles [5]. An alternate method includes potassium ferricyanide cyclization of thiobenzanilides (Jacobson's method [6]). Solvent-free synthesis of benzothiazoles under microwave irradiation in the presence of silica gel is also known [7a]. Very recently, the synthesis of this moiety under microwaves in absence of any catalyst has been reported by us [7b]. Most of these methods employ costly reagents and perfectly dry reaction conditions or the use of microwaves. Thus, a truly efficient diverse green synthetic scheme of such an important organic moiety in aqueous medium still needs to be explored.

RESULTS AND DISCUSSION

It has been recently reported from our laboratory [8] that Dowex 50W has proved to be a very effective and efficient catalyst for the construction of the 4-aryl-dihydropyrimidone nucleus. On the basis of such observation, we chose the sulfonic acid resin Dowex 50W in aqueous medium for the construction of the benzothiazole ring. Thus, a variety of aromatic aldehydes (**1**) were coupled with 2-aminothiophenol (**2**) in the presence of 10 mol % of Dowex 50W in water in a one-pot operation for the first time to synthesize the 2-substituted benzothiazoles (**3**) (Scheme 1, Table 1) in excellent yields. Water proved to be the best medium for this reaction. The yields of the products decreased on performing the reaction in water-methanol, water-ethanol, or water-tetrahydrofuran mixed solvents (all 50:50 by volume).

The advantages of using Dowex 50W are as follows: (a) it can be reused at least three times without

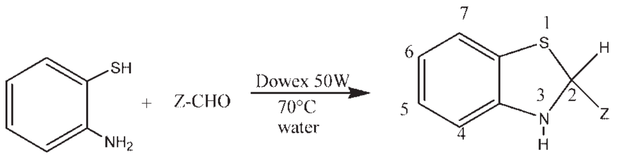
substantial loss of activity (b) dry conditions are not required (c) the reaction takes place very smoothly (d) no side products are obtained (e) the purification of the final product is very simple (f) no hazardous wastes from solvents or chemicals take place (g) the reaction conditions are very mild employing temperature of only 70°C, thus being able to sustain quite a large number of functional groups. Therefore, Dowex 50W is a ''green catalyst'' for the 2-aryl-benzothiazole formation in aqueous medium.

With salicaldehyde (**1s**), the reaction stopped at the benzothiazoline [**4**(**i**)(**s**)] stage (Scheme 2, Table 2, entry 1), and the stability of this intermediate by six-membered hydrogen bond (intramolecular) (Fig. 1) prevents it to react further to produce the benzothiazole. The isolation of this intermediate [**4**(**i**)(**s**)] confirms our earlier proposed mechanism [7b].

The fact that the reaction of salicaldehyde (**1s**) and 2-aminothiophenol (**2**) stops at the benzothiazoline stage is further proved by the work of Charles and Freiser [9]. The intermediate benzothiazoline [**4**(**i**)(**s**)] from salicaldehyde (**1s**) is converted to 2-hydroxyphenyl benzothiazole (**3s**) in good yield but under very drastic conditions (Scheme 3, Table 3, entry 1). The isolation of 2-hydroxyphenyl benzothiazoline [**4**(**i**)(**s**)] surely proves that the reaction passes through this intermediate. Following the same mechanistic pathway cited in our earlier reference [7b], benzothiazoles (**3**) are the final products for all the cases cited in Table 1.

Scheme 2



2 [Z=(R substituted aryl)(**1**) Z=alkyl] **4**(i) Z=R-substituted aryl (ii) Z=alkyl

The reaction therefore proceeds *via* the intermediate formation of benzothiazoline [7b]. This is further proved by the actual isolation of such intermediates from 2-chloro and 4-nitrobenzaldehydes by carrying out the reaction for a shorter time (entries 2 and 3, Table 2), which then proceed to completion (entries 2 and 3, Table 3). When the same reaction with Dowex 50W was carried out under argon atmosphere (in absence of oxygen) (carried out with 2-chloro, 4-nitro- and 2-hydroxy benzaldehydes), the reactions stopped at the benzothiazoline stage, which never proceeded to benzothiazoles. This surely proves that aerial oxygen is not essential for benzothiazoline formation, though it is absolutely essential for the oxidation step leading to the formation of benzothiazoles. The overall yield of the stepwise reaction was more or less the same as that of the one-step reaction, although the total time required for the stepwise reaction was slightly greater. It was not possible to isolate the intermediate benzothiazoline for all the other substrates as the next steps of oxidation and dehydration were very fast leading to the formation of benzothiazoles (the ultimate products in all cases). Stopping the reaction at various stages resulted in the formation of a mixture of benzothiazoline and benzothiazole of varied percentage compositions (done for 4-methoxy

benzaldehyde) [benzothiazoline: benzothiazole = 43:57 (obtained by the ^{1}H NMR integration of the methoxy peaks after 2 h and benzothiazoline: benzothiazole = 26:74 after 6 h].

Thus, Dowex 50W catalyses both the steps; the formation of the benzothiazoline ring and the formation of benzothiazole from benzothiazoline. Carrying out the reaction in argon (truly oxygen free) atmosphere, results in the isolation of benzothiazolines (for 2-chloro and 4-nitro benzaldehydes). Thus, the presence of the aerial oxygen is essential for the benzylic oxidation (C—H to C—OH) step, which is the penultimate one for benzothiazole formation. Without Dowex 50W, the reaction just initializes to 20% formation of the benzothiazoline along with unreacted aldehyde, which then never proceeds further. Thus, Dowex 50W has a definitive catalytic role toward benzothiazole formation. The reaction is widely applicable to a variety of substrates; nitro, methoxy, chloro, bromo, and hydroxy groups on the aryl nucleus perform smooth reactions (Table 1). With aliphatic aldehydes, the reaction stops at the benzothiazoline stage (done with *n*-propanal and *n*-butanal, Table 2), probably because of lower stability of the resultant benzothiazole (absence of conjugation with the aromatic ring).

CONCLUSIONS

This procedure of the synthesis of 2-aryl-benzothiazoles by Dowex 50W in aqueous medium in one-pot operation is a green, highly efficient, and cost effective method than the existing procedures. We hope that our method will be highly beneficial to both academic and industrial processes, being a highly general one with varied substituents in the aromatic aldehydes.

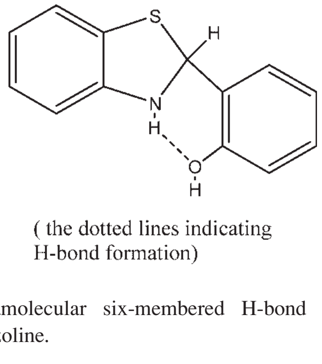

Figure 1. Intramolecular six-membered H-bond formation in 2-phenylbenzothiazoline.

EXPERIMENTAL

A typical experimental procedure is as follows: A mixture of 2-aminothiophenol (5 mmol), aromatic aldehyde (5 mmol), and Dowex 50W (10 mol %) were stirred in water (4 mL) at 70°C for the specified time period (Table 1), till the TLC showed the absence of the starting aldehyde. The reaction mixture was cooled, diluted with ethyl acetate (20 mL), filtered to remove Dowex 50W and extracted the aqueous part with ethyl acetate (2 × 20 mL). The combined organic layers were washed with brine, dried over Na_2SO_4, and concentrated *in vacuo*. The crude products were purified by crystallization from ethyl acetate and petroleum ether (60–80°C) to afford the 2-aryl-benzothiazoles (or 2-aryl-benzothiazolines) in excellent yields. All the products were characterized by their melting points, IR, ^{1}H NMR, and ^{13}C NMR spectral analyses. The data for a few selected compounds are given below:

2-(2′-Methoxyphenyl)-benzothiazole. (Table 1, entry 3): IR (KBr): 3435, 2932, 2372, 1586, 1458, 1427, 1286, 1246, 1013, and 754 cm^{-1}; ^{1}H NMR (CDCl$_3$, 300 MHz) δ: 8.51 (dd, *J* = 7.9 Hz and 1.7 Hz, 1H, C$_4$-H), 8.07 (dt, *J* = 7.8 Hz and 1.0 Hz, 1H, C$_7$-H), 7.89 (dt, *J* = 7.4 Hz and 0.6 Hz, 1H, C$_{6'}$-H), 7.48–7.38 (m, 2H, C$_5$-H and C$_6$-H), 7.33 (dt, *J* = 7.5 Hz and 1.1 Hz, 1H, C$_{4'}$-H), 7.10 (dt, *J* = 7.8 Hz and 1.1 Hz, 1H, C$_{5'}$-H), 7.02 (dd, *J* = 8.0 Hz and 0.7 Hz, 1H, C$_{3'}$-H), 4.00 (s, 3H, OMe); ^{13}C NMR (CDCl$_3$, 75 MHz), δ: 163.1, 157.2, 152.2, 136.1, 131.7, 129.5, 125.8, 124.5, 122.8, 122.3, 121.1, 121.1, 111.7, 55.7.

A series of substituted 5-acyl-4-hydroxy-2-(1*H*)-pyridinone derivatives has been prepared in a one-step procedure from condensation of (chlorocarbonyl)phenyl ketene with some enaminones which were prepared from 1,3-diketones, such as 2,4-pentanedione, 1-phenyl-1,3-butanedione, and ethyl acetoacetate in boiling toluene as a solvent. A mechanism is presented to account for the formation of the products. The overall sequence provides a simple and efficient route to prepare 3,4,5,6-tetrasubstituted 2-(1*H*)-pyridinone in good to excellent yields and in a short experimental time.

J. Heterocyclic Chem., **46**, 96 (2009).

INTRODUCTION

Heterocycles having a 2-pyridinone framework are an extensively studied class of compounds, owing partly to their diverse biological activities such as antibacterial [1] and antifungal [2] agents for free radical scavengers [3]. Ring fused 2-pyridinones have also attracted attention as lead compounds for the preparation of selective anticancer drugs [4,5], antiviral agents [6], angiotensin-converting enzyme (ACE) inhibitors [7], as well as inhibitors of A β-peptide aggregation [8], which is believed to play an important role in amyloid formation in Alzheimer's disease. In addition, dihydro and tetrahydro derivatives of 2-pyridinones have been applied as scaffolds for the construction of constrained amino acids [9,10]. With all these diverse properties in mind, medicinal chemists often incorporate these motifs in the design of novel biologically active molecules.

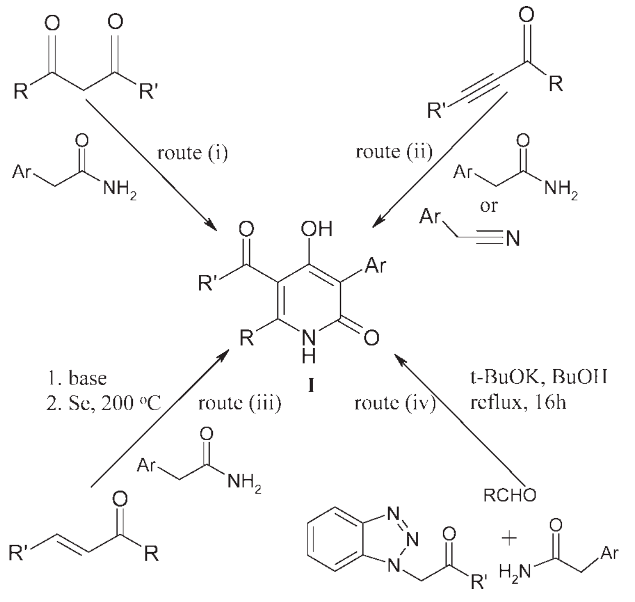
Ever since the first synthesis of 2-pyridinones was reported *via* a ferricyanide-mediated oxidation of pyridinium salts [11], many different methods for constructing these heterocycles in solution have appeared in the literature. Some of these reports include intramolecular Dieckmann like condensations [12], Michael additions [13,14], as well as cycloaddition [15] and cyclization procedures [16].

Fewer general methods exist for the preparation of 2-pyridinones substituted with aryl substituents and electron withdrawing groups such as CN, COR, COOR, and CONR2 at positions C3 and C5. Reported of 5-acyl-3-aryl-2-pyridinones usually include (Scheme 1) (i) reaction of 1,3-diketones with 2-arylacetamides (yields of **I** *ca*. 40%) [17]; (ii) Michael addition of arylacetamides or arylacetonitrile to 1,3-diaryl-2-propyne-1-ones affording products with limited diversity (3,4,6-triaryl substituted pyridinones in yields about 20%) [18]; (iii) Michael addition of 2-arylacetamides to 1,3-diaryl-2-propene-1-ones, is followed by cyclization subsequent oxidative aromatization of the intermediate dihydropyridinones with selenium at the high-temperature to yield 76–94% of the product I [19]; (iv) and finally synthesis *via* one-step [1 + 2 + 3] reactions of an aldehyde, α-benzotriazolyl ketone and arylacetamides [20].

RESULTS AND DISCUSSION

In continuing our interest in the synthesis of heterocyclic compounds by using chlorocarbonyl ketenes and

Scheme 1



1,3-binucleophiles such as 1,3-diketones [21], amides [22,23] and thioamides [24]; in this article we wish to report a one-pot synthesis of 5-acyl-4-hydroxy-2-(1*H*)-pyridinone derivatives which were prepared in a one-step procedure from readily available (chlorocarbonyl)-phenyl ketene and enaminones as 1,3-binucleophile. This method provides an easy route to prepare 2(1*H*)-pyridinones in good to excellent yields and short experimental time (Scheme 2).

Enaminones are versatile synthetic intermediatates that combine the ambident nucleophilicity of enamines with the ambident electrophilicity of enones [25]. There are many reports in the literature on the functionalization of enaminone by the introduction of different substituents on the nitrogen, the α-carbon and the β-carbonylic carbon atoms. These derivatives have been extensively used for the preparation of a variety of heterocyclic systems including some natural products and analogues [26]. Thomas Kappe *et al.* [27], have reported

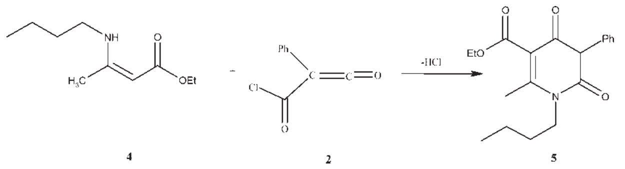
Scheme 3



the synthesis of 5-acyl-4-hydroxy-2-(1*H*)-pyridinone derivatives from the reaction of enaminones with dialkyl malonates under harsh experimental conditions [low yields (42–68%) and also long reaction times].

The chemical importance and diversity of pyridinones have made these compounds important synthetic goals and have stimulated new methods and reagents for the preparation of these heterocyclic compounds. In an effort to extend the scope and generality of the condensation reaction (Scheme 1) (chlorocarbonyl)phenyl ketene **2** was treated with enaminones **1**. The only product formed under these conditions was 5-acyl-4-hydroxy-3-phenyl-2-(1*H*)-pyridinones **3** in excellent yields in a short experimental time.

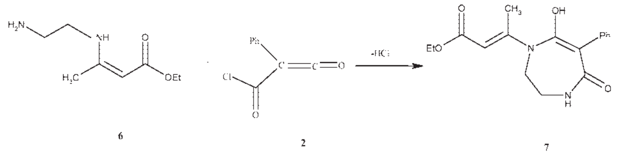
In this case, it was also found that the reaction of ethyl-3-(butylamino)-2-butenoate **4** with (chlorocarchloro-carbonyl)phenyl ketene **2** produce the corresponding pyridinone **5** (Scheme 3). It is pertinent to note that with the same experimental condition as the previous reaction different tautomer was formed.

The cycloaddition reaction of 4-[(2-aminoethyl) amino]-3-penten-2-one **6** with (chlorocarbonyl)phenyl ketene **2** resulted in the formation of ethyl (*E*)-3-(7-hydroxy-5-oxo-6-phenyl-2,3,4,5-tetrahydro-1*H*-1,4-diazepin-1-yl)-2-butanoate **7** as the only product (Scheme 4).

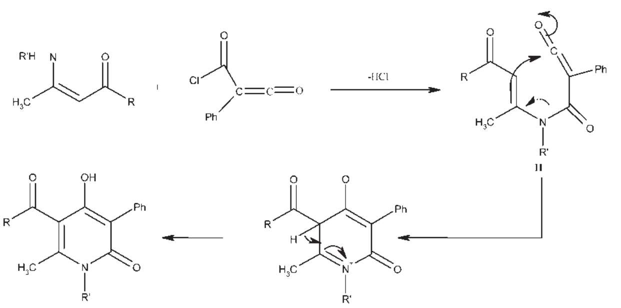
On the basis of this report, (chlorocarbonyl)aryl ketenes undergo a degenerate 1,3-shift of chlorine, as determined by ^{13}C NMR spectroscopy [28]. On the basis of our results, which was aforementioned, a plausible mechanism has been proposed for the reactions of (chlorocarbonyl)phenyl ketene with enaminones to yield 2-(1*H*)-pyridinone derivatives, as shown in Scheme 5. Initially, the NH group of enaminone as a good nucleophile will attack the acyl chloride of ketene, followed by ring closure of intermediate **2** to produce the product.

The structure of **3a-g** and compounds **5** and **7** were determined on the basis of their mass spectra, ^1H and

Scheme 4



Scheme 5



^{13}C NMR and IR spectroscopic data. The ^{1}H NMR and ^{13}C NMR spectra of 4-hydroxy-3,6-disubstituted-2(1*H*)-pyridinone derivatives **3a-d** exhibited only one tautomer.

The ^{1}H NMR spectrum of **3a** showed four kinds of proton signals. One signal quite downfield (δ 10.70 ppm) which is the proton of enol OH and a multiplet (δ = 7.62–7.10) for the aromatic protons (10 H) along with two signals at (δ = 2.33 and 2.17 ppm) which were identified as an acyl group in position 5 and the other methyl group in position 6. The ^{13}C NMR and mass spectra are also in accordance with the proposed structure.

We have shown that the condensation reaction of (chlorocarbonyl)phenyl ketene with enaminones occurs efficiently in boiling toluene as a solvent, providing a convenient and rapid synthesis of 4-hydroxy-3,4,6-tri substituted-2(1*H*)-pyridinone in high yield, by a simple procedure and short experimental time. Furthermore, the products are solid and precipitate out from the reaction mixture and their purifications are simple.

EXPERIMENTAL

(Chlorocarbonyl)phenyl ketene was prepared according to the literature procedure [29]. The enaminones are known and were prepared according to the general procedure reported in the literature [30].

Toluene, hexane, diethyl ether, and THF were dried over sodium and distilled prior to use. Melting points were measured on a calibrated Gallenkamp melting point apparatus. IR spectra were measured with a Mattson 1000 FT-IR spectrometer. ^{1}H and ^{13}C NMR spectra were measured with a BRUKER DRX-300 AVANCE spectrometer at 300.13 and 75.47 MHz, respectively. Mass spectra were recorded on a MS-QP2000A Shimadzu mass spectrometer operating at an ionization potential of 70 eV.

General procedure (3a-d). To a stirred solution of corresponding enaminone (2 mmol) in 20 mL dry boiling toluene, a mixture of 0.36 g (chlorocarbonyl)phenyl ketene (2 mmol) in 5 mL dry THF was added dropwise over 2 min. The product was formed immediately as a color precipitate. The reaction mixture was cooled and the solid product was collected and recrystallized from dry ethyl acetate hexane.

5-Acetyl-4-hydroxy-6-methyl-1,3-diphenyl-2(1*H*)-pyridinone (3a). The polymer-supported palladium(II) ethylenediamine [PS-en-Pd(II)] complex is a highly active catalyst for the heterocyclization that takes place during the Sonogashira reaction between an aryl iodide and 2-amino-1-(2-propynyl)pyridinium bromide. This heterogeneous palladium catalyst can readily be recovered from the reaction medium by simple filtration and reused without a significant loss in its activity.

J. Heterocyclic Chem., **46**, 100 (2009).

INTRODUCTION

Sonogashira reaction, the palladium-catalyzed cross-coupling reaction of terminal alkynes with aryl and vinyl halides, is one of the most important, powerful, and versatile tools in organic synthesis, and it has been widely applied to diverse areas such as natural product synthesis and material science [1]. The reaction generally proceeds in the presence of a homogeneous palladium catalyst, which makes the catalyst recovery a tedious operation and might result in unacceptable palladium contamination of the product. From the standpoint of green chemistry, the development of more environmentally benign conditions for the reaction, for example, the use of a heterogeneous palladium catalysts' would be desirable [2].

So far, cross-linked polystyrene or silica-supported palladium catalysts have been used for the Sonogashira reaction [3]. Unfortunately, they often result in lower catalytic activity compared with their soluble counterparts. To overcome this limitation, a novel methodology for creating insoluble and highly active catalysts is needed. Our approach was guided by three imperatives: (1) the support should be easily accessible; (2) starting with readily available and inexpensive reagents; and (3) the ligand anchored on the support should be air stable at room temperature, which should allow its storage in normal bottles with unlimited shelf life. To date, a few palladium complexes on functionalized polystyrene support have been prepared and successfully used in organic reactions [4]. However, to the best of our knowledge, there has been no examples involving arylation of imidazopyridine by [PS-en-Pd(II)] catalyzed (Sonogashira coupling) reactions described to date.

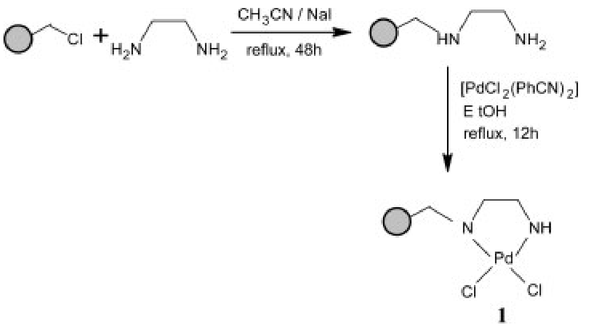
In continuation of our recent studies on the synthesis of fused heterocycles and the Pd-catalyzed reactions of acetylenes leading to heterocyclic compounds of biological significance [5], we became interested in developing a novel synthesis route to 2-substituted imidazo[1,2-*a*]pyridines. In this article, we wish to report the synthesis of the first polystyrene-supported palladium(II) ethylenediamine complex, abbreviated as PS-en-Pd(II), and its catalytic properties in the Sonogashira coupling reaction for the synthesis of imidazo[1,2-*a*]pyridines [6]. The supported catalyst could be reused several times without a significant degradation in its catalytic activity.

RESULTS AND DISCUSSION

We used the well-known chloromethylated polystyrene cross-linked with 2% divinylbenzene as support, because it is flexible enough and allows metallic atoms to be graft on *via* the ligands that are attached to the polymer beads. Reaction of the polystyrene resin with ethylenediamine in acetonitrile under reflux and the subsequent reaction of the aminated polystyrene with a solution of $[PdCl_2(C_6H_5CN)_2]$ in ethanol gave the polymer-supported palladium(II) complex catalyst **1** (Scheme 1).

Successful functionalization of the polymer was confirmed by elemental analysis. The *N* content of the resin was found to be 2.42% (0.82 mmol/g), which indicates

Scheme 1 Polystyrene-supported palladium(II) ethylenediamine complex **1**.



that only 58% of the total chlorines were substituted by amine. The metal loading of the polymer-supported palladium complex, which was determined by neutron activation analysis (NAA), was found to be 4.35% (0.41 mmol/g). In the IR spectrum of the polymer-bound ethylenediamine, the sharp C—Cl peak (due to the —CH_2Cl groups) at 1264 cm^{-1} in the starting polymer was practically omitted or was seen as a weak band after introduction of ethylenediamine and palladium on the polymer. The various IR frequencies for the catalyst were assigned as (Pd—N) $\approx$ 506 cm^{-1}, (C—N) $\approx$ 1100 cm^{-1}, and (N—H) $\approx$ 3400 cm^{-1}.

To evaluate the catalytic activity of the first polymer-supported PS-en-Pd(II) complex, the heterocyclization during Sonogashira coupling of 2-amino-1-(2-propynyl)-pyridinium bromide **3** with the aryl iodides **4a–i** was studied (Scheme 2). The reactions were performed under conditions similar to those used in the corresponding homogenous reactions. The influences of the bases, solvents, amounts of copper(I) iodide, and the catalyst on the catalytic property of the [PS-en-Pd(II)] complex were investigated using the coupling reaction of compound **3** with *o*-iodonitrobenzene. The results are tabulated in Table 1.

Among the bases tested, triethylamine proved to be the most efficient, and among the solvents used, dimethylformamide was the best choice. Increasing the amount of the palladium catalyst could shorten the reaction time, but does not increase the yield (entry 11). Low palladium concentration often prolonged the reaction time and decreased the yield (entries 12 and 13). We also found that with increase in the amount of copper(I) iodide, the reaction yield did not increase (entry 14). No product was obtained under copper-free conditions (entry 15). Copper(I) iodide was found to be an essential cocatalyst.

The reactions had to be carried out under an argon atmosphere, and we had to degas the mixture of DMF and triethylamine prior to use. The experimental results are summarized in Table 2. As it can be seen in this table, reaction of the aryl iodides with compound **3** proceeded smoothly under very mild conditions, giving the corresponding products in excellent yields.

The stability of [PS-en-Pd(II)] was studied in repeated Sonogashira coupling reactions. The coupling reaction of *o*-iodonitrobenzene with compound **3** was chosen as a model substrate to study the catalyst reuse and stability. The catalyst was separated from the reaction mixture after each experiment by filtration, washed with water and acetonitrile, and dried carefully before using it in the subsequent run. The reaction promoted by the fifth recycled catalyst gave **5a** in 75% yield (Table 3, entry 5).

The low yield could be due to the formation of byproducts. For instance, formation of a coupled intermediate without ring formation or ring closure without participation of the aryl group could be responsible for the low yield.

This reusability demonstrates the stability of the heterogeneous catalyst. Although no significant change in the activity of the catalyst was observed, we performed analysis of the catalyst after the fifth run in order to determine any change in the catalyst structure. The nature of the recovered catalyst was traced by IR spectroscopy. The results indicated that the catalyst showed no change in its IR spectrum after reuse for several times.

To determine the absolute amount of the palladium species leached into the solution, the crude reaction mixtures were evaporated to dryness and analyzed by NAA. It was shown that less than 0.5% of the total amount of the original palladium species was lost into the solution during the course of the reaction.

In conclusion, we developed a reusable heterogeneous catalyst [PS-en-Pd(II)] by first reacting the commercially available cross-linked chloromethylated polystyrene with ethylenediamine and the subsequent reaction of the product thus formed with dibenzonitrile palladium chloride. It efficiently catalyzed the heterogeneous Sonogashira coupling followed by cyclization reaction for the syntheses of various 2-substituted imidazopyridines. The

[a] All reactions were performed using 1.5 mmol of **3**, 1.0 mmol of *o*-iodonitrobenzene, 0.06 mmol of PPh_3, 3.0 mmol of base, and 5 mL of solvent at room temperature.

catalyst could be reused five times with reasonable catalytic activity on the fifth cycle. The advantages of our heterogeneous catalytic system over others are as follows: (1) the catalyst could be conveniently prepared from commercially available reagents; and (2) excellent performance and reusability of the catalyst.

EXPERIMENTAL

All the reagents used were of commercial reagent grade. Chloromethylated polystyrene (4–5% Cl and 2% cross-linked with divinylbenzene) was a Merck product. Scanning electron micrographs of the catalyst and polymer were taken on a SEM Philips XL 30. The IR spectra were obtained as potassium bromide pellets in the range 400–4000 cm^{-1} on a Shimadzo Model 460. The ^1H NMR and ^{13}C NMR spectra were recorded on a Bruker BRX 500 AVANCE spectrometer. The elemental analyses were obtained on a Thermo Finnigan Flash EA microanalyzer.

Preparation of polymer-bound ethylenediamine. To functionalize the polymer support with ethylenediamine, it was prepared by the following procedure: to a 250-mL round bottom flask equipped with a magnetic stir bar containing 120 mL acetonitrile, chloromethylated polystyrene (2 g, 2.5 mmol/Cl), and ethylenediamine (25 mmol), NaI (0.13 mmol) was added. The reaction mixture was refluxed for 48 h at which time the solid material and was collected by filtration and washed with 5 × 40 mL of CH_3CN, 5 × 40 mL of CH_3OH:K_2CO_3 (1 *M*) (1:1, v/v), 5×40 mL of CH_3OH:H_2O (1:1 v/v), and 3 × 40 mL of diethyl ether, and was subsequently dried in an oven.

Preparation of polystyrene-supported PS-en-Pd(II) complex (1). The functionalized polymer was kept in contact with 100 mL of ethanol for 30 min. An ethanolic solution of 0.25 g of $[PdCl_2(C_6H_5CN)_2]$ was added to it and heated to 50° for 6 h. The bright yellow colored polymer, impregnated with the metal complex, was collected by filtration, washed thoroughly with ethanol, and finally dried in vacuum at 70° for 24 h.

Synthesis of 2-amino-1-(2-propynyl) pyridinium bromide (3). A mixture of 2-amino pyridine (1.9 g, 20 mmol) and propargyl bromide (2 mL, 24 mmol) in ethanol (10 mL) was heated under reflux for 1 h. The precipitate formed was filtered off and recrystallized from ethanol to afford the title compound.

80% yield; m.p. 168–169°; ^1H NMR (DMSO-d_6): δ 3.85 (s, 1H, CH), 5.12 (s, 2H, CH_2), 6.85–8.23 (m, 4H, PyH), 8.72(s, 2H, NH_2); ^{13}C NMR (DMSO-d_6): δ 43.86, 76.04, 80.46, 114.00, 115.84, 139.83, 143.57, 154.52; ir (potassium bromide): 3300, 3200, 2100 cm^{-1}; Anal. Calcd. for $C_8H_9BrN_2$ (213.06): C, 45.09; H, 4.26; N, 13.15. Found: C, 45.50; H, 4.08; N, 13.51.

Synthesis of 2-substituted imidazo[2,1-b]pyridines (5a–i). A mixture of the aryl iodides (1.0 mmol), [(PS-en-Pd(II)] (60 mg, 0.03 mmol Pd), CuI (0.2 mmol), and triethylamine (3 mmol) was stirred in DMF (5 mL) at room temperature under an argon atmosphere. 2-Amino-1-(2-propynyl)pyridinium bromide (3) (1.50 mmol) was then added, and the mixture was stirred at room temperature for 12–16 h. After completion of the reaction, the resulting solution was concentrated *in vacuo*, and the crude product was subjected to column chromatography using $CHCl_3$:CH_3OH (95:5, v/v) as eluent to afford the pure product (Table 1).

2-(2-Nitrobenzyl)imidazo[1,2-a]pyridine (5a). This compound was obtained as a white solid. ^1H NMR (DMSO-d_6): δ 4.46(s, 2H, CH_2), 6.98–8.00 (m, 8H, PyH, ArH), 8.66 (s, 1H, imidazole proton); ^{13}C NMR (DMSO-d_6): δ 34.25, 114.60, 116.24, 122.85, 123.15, 129.10, 130.22, 130.95, 132.15, 134.27, 136.23, 139.12, 146.25, 148.33; ir (potassium bromide): 1510, 1340 cm^{-1}; Anal. Calcd. for $C_{14}H_{11}N_3O_2$ (253.25): C, 66.4; H, 4.38; N, 16.59. Found: C, 66.12; H, 4.11; N, 16.65.

2-(3-Nitrobenzyl)imidazo[1,2-a]pyridine (5b). This compound was obtained as a white solid. ^1H NMR (DMSO-d_6): δ

2-(4-Chloro-3-nitrobenzyl)imidazo[1,2-a]pyridine (5f). This compound was obtained as a white solid. ^{1}H NMR (DMSO-d_6): δ 4.25 (s, 2H, CH_2), 6.95–8.03 (m, 7H, PyH, ArH), 8.59 (s, 1H, imidazole proton); ^{13}C NMR (DMSO-d_6): δ 33.75, 114.37, 116.86, 123.80, 126.58, 127.72, 128.23, 130.85, 131.47, 132.36, 135.30, 137.65, 141.11, 148.15; ir (potassium bromide): 1510, 1345 cm^{-1}; Anal. Calcd. for $C_{14}H_{10}ClN_3O_2$ (287.70): C, 58.45; H, 3.50; N, 14.61. Found: C, 58.34; H, 3.38; N, 13.95.

2-(4-Cyanobenzyl)imidazo[1,2-a]pyridine (5g). This compound was obtained as a white solid. ^{1}H NMR (DMSO-d_6): δ 4.31 (s, 2H, CH_2), 6.99–8.32 (m, 8H, PyH, ArH), 8.59 (s, 1H, imidazole proton); ^{13}C NMR (DMSO-d_6): δ 34.26, 113.15, 114.86, 116.34, 120.06, 129.10, 130.55, 131.08, 131.67, 137.35, 140.22, 141.37, 148.24; ir (potassium bromide): 2200 cm^{-1}; Anal. Calcd. for $C_{15}H_{11}N_3$ (233.26): C, 77.23; H, 4.75; N, 18.01. Found: C, 77.52; H, 4.63; N, 18.08.

2-(4-Acetylbenzyl)imidazo[1,2-a]pyridine (5h). This compound was obtained as a white solid. ^{1}H NMR (DMSO-d_6): δ 2.51(s, 3H, CH_3), 4.22 (s, 2H, CH_2), 6.96–7.87 (m, 8H, PyH, ArH), 8.60(s, 1H, imidazole proton); ^{13}C NMR (DMSO-d_6): δ 27.49, 34.20, 114.33, 116.12, 127.51, 129.26, 130.09, 130.77, 133.27, 135.98, 137.35, 138.49, 145.30, 198.26; ir (potassium bromide): 1690 cm^{-1}; Anal. Calcd. for $C_{16}H_{14}N_2O$ (250.29): C, 76.78; H, 5.64; N, 11.19. Found: C, 76.60; H, 5.46; N, 11.25.

2-[4-(Methoxycarbonyl)benzyl]imidazo[1,2-a]pyridine (5i). This compound was obtained as a white solid. ^{1}H NMR (DMSO-d_6): δ 3.81 (s, 3H, CH_3), 4.24 (s, 2H, CH_2), 7.01–8.32(m, 8H, PyH, ArH), 8.64(s, 1H, imidazole proton); ^{13}C NMR (DMSO-d_6): δ 33.89, 51.76, 114.54, 116.28, 128.36, 129.15, 130.05, 130.68, 132.84, 136.98, 138.08, 139.31, 148.93, 167.35; ir (potassium bromide): 1710 cm^{-1}; Anal. Calcd. for $C_{16}H_{14}N_2O_2$ (266.29): C, 72.16; H, 5.30; N, 10.52. Found: C, 71.74; H, 5.45; N, 10.30.

The novel 1-(3,4-dimethoxyphenyl)-2-(2,3,4-trimethoxyphenyl)acrylonitrile was prepared from the condensation of the mixture of 2,3,4-trimethoxybenzaldehyde and 3,4-dimethoxyphenylacetonitrile in ethanol at 70°C with 20% aqueous sodium hydroxide solution. Cyclization and demethylation of the acrylacetonitrile was performed using pyridine hydrochloride. The obtained 7,8-dihydroxy-3-(3,4-dihydroxyphenyl)-2*H*-chromen-2-one was reacted with the poly(ethylene glycol) ditosylates in CH_3CN/alkali carbonate to afford bis-[12]crown-4, -[15]crown-5, and -[18]crown-6 chromenones. The chromatographically purified novel chromenone crown ethers were identified by IR, ^1H NMR, ^{13}C NMR, and MALDI-TOF mass spectrometry and elemental analysis.

J. Heterocyclic Chem., **46**, 105 (2009).

INTRODUCTION

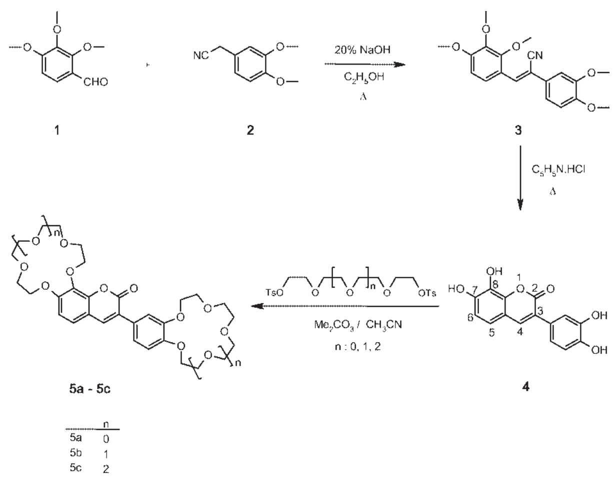
Macrocyclic molecules have attracted much attention because of their potential use in a variety of chemical processes, selective complexing agents for earth and alkaline metal ions, and photoinduced electron transfer [1]. Several macrocyclic ethers possessing oxygen dipoles have been synthesized to investigate their alkali and alkaline-earth cation membrane transport and binding properties by means of potentiometry, optical spectroscopy, as well as NMR spectroscopic methods [2,3]. The ionophores bearing suitable light sensitive moieties may undergo intermolecular changes at the electronic level upon cationic interactions of donor oxygen atoms [2]. Essentially, the fluorescence spectra of fluorogenic macrocycles is a reliable method to study cationic recognitions [2,4,5]. Crown ethers have also been used for chromatographic separations [6,7]. We have recently synthesized fluorogenic coumarin-[12]crown-4, -[15]crown-5, and -[18]crown-6 derivatives and examined cation binding effects using steady state fluorescence spectroscopy and reported their cationic interaction in acetonitrile [5,8–11]. However, the oxygen atom, which is contained in the phenyl moiety in coumarin arms potentially can participate along with the other oxygen atoms in the analog crown ether moiety formed 1:1 complex with a host ion [12–16].

We report here the synthesis of novel bis-[12]crown-4, -[15]crown-5, and -[18]crown-6 derivatives of 7,8-dihydroxy-3-(3,4-dihydroxyphenyl)-2*H*-chromen-2-one.

RESULTS AND DISCUSSION

The synthesis of the precursor compound, 1-(3,4-dimethoxyphenyl)-2-(2,3,4-trimethoxyphenyl)acrylonitrile (**3**) was accomplished using Knoevenagel condensation reaction [17]. Equal molar amounts of 2,3,4-trimethoxybenzaldehyde (**1**) and 3,4-dimethoxyphenylacetonitrile (**2**) in ethanol at 70°C (see Scheme 1) was reacted with 20% aqueous sodium hydroxide solution. The Knoevenagel reaction is stereoselective and resulted in the *E*-product. The precipitated acrylonitrile (**3**) was collected by filtration, washed with distilled water, and dried. The crude product was purified by crystallization from ethanol. Then, the ring closure of (**3**) was

Scheme 1



performed with freshly prepared pyridine hydrochloride at 180 °C. The compound, 7,8-dihydroxy-3-(3,4-dihydroxyphenyl)-2*H*-chromen-2-one, **(4)** was washed with water until neutral, dried, and recrystallized from acetic acid.

Compound **4** was reacted with poly(ethylene glycol) ditosylates in the presence of alkali carbonate in CH_3CN (Scheme 1) to give the 7,8-dihydroxy-3-(3,4-dihydroxyphenyl)-2*H*-chromen-2-one crown ethers (coumarino crown ether) **5a**, **5b**, **5c**, respectively.

The purification of crown ethers were done by column chromatography (silica gel-chloroform) to give pure coumarino crown ethers **(5a–5c)** in 12–23% yields. They were soluble in $CHCl_3$ or CH_2Cl_2. The novel compounds have been characterized by elemental analysis IR, ^1H NMR, ^{13}C NMR, and MALDI-TOF-MS.

The IR spectra of **3** showed absorption bands at 2840 and 2973 cm^{-1} for the C—H stretching. The characteristic band of the nitrile group (CN), benzene ring (C=C), and methoxy group (OCH_3) appeared at 2206, 1583–1403, 1350–1023 cm^{-1}, respectively. The IR spectrum of **4** showed a characteristic band for the hydroxyl group (OH), carbonyl group (C=O), benzene ring (C=C), and (C—O) 3560–3328, 1681, 1618–1535, 1311–1109 cm^{-1}, respectively.

The ^1H NMR spectra of **5a–5c** showed characteristic signals for etheral (—O—CH_2—CH_2—O—) protons at δ 3.85–4.48 ppm, each a triplet. In addition, the chemical shifts of the aromatic protons are observed at δ 6.86–7.81 ppm.

The ^{13}C NMR spectrum of **5a–5c** showed expected signals for aromatic, carbonyl, and etheral carbons at δ 109.83–140.63, 160.46–173.90, 69.06–75.17 ppm, respectively. Also the MALDI-TOF-MS and elemental analysis confirmed the formation of coumarino crown ether derivatives.

The obtained new coumarino crown ether compounds will next be examined for their cation binding properties using fluorescence spectroscopy.

EXPERIMENTAL

The starting chemicals were purchased from Aldrich or Merck unless otherwise cited. Melting points have been obtained on a Gallenkamp apparatus and are uncorrected. IR spectra were obtained from KBr pellets with a Schimadzu FTIR spectrometer, model 8300. Mass spectra have been obtained with a MALDI-TOF instrument, model Bruker Autoflex III. The ^1H NMR spectra have been obtained with a BRUKER spectrometer, model AVANCE-400 Cpx and TMS was used as the internal reference. Combustion analyses have been acquired with a LECO-932 CHN.

Synthesis of 1-(3,4-dimethoxyphenyl)-2-(2,3,4-trimethoxyphenyl)acrylonitrile (3). The typical procedure for synthesis of acrylonitrile **(3)** is performed according to the literature [18]. A mixture of 2,3,4-trimethoxybenzaldehyde **(1)** (4.82 g, 24.59 mmol) and 3,4-dimethoxyphenylacetonitrile **(2)** (4.34 g, 24.59 mmol) in ethanol (100 mL) was heated to 70°C; 20% aqueous sodium hydroxide solution was then added dropwise to the stirred solution until the onset of turbidity. The acrylonitrile **(3)** precipitated when the solution was cooled to room temperature. The precipitate was collected by filtration, washed with water, and dried. The crude product was purified by recrystallization from ethanol. 6.85 g (78%), mp 114–115 °C. ir (KBr): 2973–2840 (C—H), 2206 (CN), 1583–1403 (C=C), 1350–1023 (C—O) cm^{-1}; ^1H NMR (400 MHz/$CDCl_3$): δ 3.89 (s, 3H, OCH_3), 3.91 (s, 3H, OCH_3), 3.92 (s, 3H, OCH_3), 3.93 (s, 3H, OCH_3), 3.95 (s, 3H, OCH_3), 6.78 (d, J = 9.0 Hz, 1H), 6.91 (d, J = 8.2 Hz, 1H), 7.15 (d, J = 2.3 Hz, 1H,), 7.24 (dd, J = 8.2 Hz and 2.3 Hz, 1H), 7.72 (s, 1H), 7.96 (d, J = 9.0 Hz, 1H); ms: *m/z* 355.14 (M^+), 356.15 $(M+1)^+$, 357.15 $(M+2)^+$.

Synthesis of 7,8-dihydroxy-3-(3,4-dihydroxyphenyl)-2*H*-chromen-2-one (4). A mixture of the acrylonitrile **(3)** (6.85 g, 19.24 mmol) and freshly prepared pyridine hydrochloride (11.11 g, 96.20 mmol) was heated for 2 h at 180°C; the cooled solution was treated with water. The precipitated coumarin was washed with water until neutral, dried, and recrystallized from acetic acid. 4.6 g (83%), mp 295°C (lit: 297 °C [19]); ir (KBr): 3560–3328 (Ar—OH), 1681 (C=O), 1618–1535 (C=C), 1311–1109 (C—O) cm^{-1}; ^1H NMR (400 MHz/DMSO-d_6): δ 6.71 (d, J = 8.5 Hz, 1H), 6.85 (d, J = 8.5 Hz, 1H), 6.95 (dd, J = 8.5 Hz and 2.0 Hz 1H), 7.15 (d, J = 8.5 Hz, 1H), 7.22 (d, J = 2 Hz, 1H), 7.95 (s, 1H), 9.05 (br-s, 1H), 9.12 (br-s, 1H), 9.40 (br-s, 1H), 9.95 (br-s, 1H).

General procedure for the synthesis of 7,8-dihydroxy-3-(3,4-dihydroxyphenyl)-2*H*-chromen-2-one crown ethers (5a–5c). The typical procedure for the cyclization reaction leading to macrocyclic ethers **(5a–5c)** is as follows. A mixture of **4** (5 mmol), poly(ethylene glycol) ditosylate (10 mmol), and metal carbonate (20 mmol) was dissolved in 60 mL CH_3CN in a 100-mL reaction flask. The reaction mixture was heated for 35–40 h at 80–85°C. The solvent was distilled. Diluted HCl was added to the residue and the mixture was extracted with $CHCl_3$ (3 × 50 mL). The combined organic extracts were washed with water, dried over $CaCl_2$, and the

$CHCl_3$ solution evaporated *in vacuo*. Chromatography of the crude products (silica gel 60, Merck) with chloroform gave pure coumarino crown ethers (**5a–5c**).

14-(2,3,5,6,8,9-Hexahydrobenzo[b][1,4,7,10]tetraoxacyclododecin-12-yl)-5,6,8,9-tetrahydro-2H-[1,4,7,10]tetra-oxacyclododeca[2,3-h]chromen-15(3H)-one (5a; $C_{27}H_{30}O_{10}$). Compound **4** (1.5 g, 5.2 mmol), Na_2CO_3 (2.2 g, 21 mmol), tri(ethylene glycol) ditosylate (4.8 g, 10 mmol) in CH_3CN (60 mL) was reacted as described earlier to afford light yellow solid **5a**, 0.6 g (22%), mp 126–128°C; ^{1}H NMR (400 MHz/$CDCl_3$): δ 3.85 (t, J = 4Hz, 4H), 3.95 (t, J = 4Hz, 4H), 3.97 (t, J = 4Hz, 4H), 4.21 (t, J = 4Hz, 4H), 4.23 (t, J = 4Hz, 4H), 4.40 (t, 4Hz, 4H), 6.86 (d, J = 8.7 Hz, 1H, H-5′), 7.01 (d, J = 8.5 Hz, 1H, H-6), 7.19 (d, J = 8.7 Hz, 1H, H-5), 7.31 (dd, J = 8.5 Hz and 1.5 Hz, 1H, H-6′), 7.37 (d, J = 1.5 Hz, 1H, H-2′), 7.69 (s, 1H, H-4); ^{13}C NMR (100 MHz, $CDCl_3$/TMS): δ 69.75, 69.87, 70.31, 70.34, 70.51, 70.87, 71.18, 71.32, 71.66, 72.16, 72.23, 75.17, 111.06, 115.02, 117.74, 118.97, 123.17, 124.53, 126.25, 129.14, 136.26, 139.75, 147.72, 150.37, 151.25, 155.12, 160.46; ms: m/z 513.94 (M^+), 536.95 $(M+Na)^+$. Anal. Calc. for $C_{27}H_{30}O_{10}$: C, 63.03; H, 5.88. Found: C, 62.97; H, 5.68.

17-(2,3,5,6,8,9,11,12-Octahydrobenzo[b][1,4,7,10,13]pentaoxacyclopentadecin-15-yl)-5,6,8,9,11,12-hexahydro-2H-[1,4,7,10,13]pentaoxacyclopentadeca[2,3-h]chromen-18(3H)-one (5b; $C_{31}H_{38}O_{12}$). Compound 4 (1.0 g, 3.5 mmol), K_2CO_3 (1.93 g, 14 mmol), tetra(ethylene glycol) ditosylate (3.52 g, 7 mmol) in CH_3CN (60 mL) reacted as described earlier to afford light yellow solid 5b, 0.5 g (23%), mp: 136 °C; ^{1}H NMR (400 MHz/$CDCl_3$): δ 4.04 (t, J = 4Hz, 4H), 4.06 (t, J = 4Hz, 4H), 4.09 (t, J = 4Hz, 4H), 4.11 (t, J = 4Hz, 4H), 4.34 (t, J = 4Hz, 4H), 4.37 (t, 4Hz, 4H), 4.39 (t, 4Hz, 4H), 4.48 (t, 4Hz, 4H), 7.02 (d, J = 8 Hz, 1H, H-5′), 7.07 (d, J = 8 Hz, 1H, H-6), 7.25 (d, J = 8 Hz, 1H, H-5), 7.40 (dd, J = 8 Hz and 2 Hz, 1H, H-6′), 7.43 (d, J = 2 Hz, 1H, H-2′), 7.81 (s, 1H, H-4); ^{13}C NMR (100 MHz, $CDCl_3$/TMS): δ 69.08, 69.26, 69.45, 69.47, 69.75, 69.78, 70.42, 70.53, 70.61, 70.72, 70.77, 71.08, 71.16, 71.28, 71.30, 73.79, 109.83, 113.93, 114.92, 121.86, 122.87, 124.81, 128.43, 135.47, 139.30, 139.35, 147.73, 148.96, 149.83, 154.92, 160.58; ms: m/z 602.07 (M^+), 625.04 $(M+Na)^+$, 641.02 $(M+K)^+$. An efficient one-pot synthesis of 3,5-disubstitueted isoxazoles from β-diketones in room temperature ionic liquids (ILs) is described. Compared with the classical reaction conditions, this new synthetic method is environmentally friendly and has the advantages of recyclability of IL and very good to excellent yields.

J. Heterocyclic Chem., **46**, 108 (2009).

INTRODUCTION

Synthesis of substituted isoxazole derivatives is particularly important because a lot of compounds containing the isoxazole ring system are known to have a variety of biological activities in pharmaceutical and agricultural areas [1]. Their range of uses includes medicinal, herbicidal, fungicidal, pesticidal applications, dyes, insulating oils, and lubricants. Since Claisen's report in 1891 [2], many methods have been developed for the preparation of substituted isoxazoles which can generally be divided into two synthetic routes. The first involves the condensation reaction of a hydroxylamine with a carbonyl compound and provides easy access to 3,5-disubstituted isoxazoles [1]. The second route involves the 1,3-dipolar cycloaddition of a nitrile oxide with an alkyne. In this transformation, nitrile oxides react intermolecularly with monosubstituted alkynes to again give a preponderance of 3,5-disubstituted isoxazoles [3] and furoxan is a significant byproduct.

Room temperature ionic liquids (ILs) have been the subject of considerable interest as new, nonvolatile, and environmentally friendly alternatives to conventional organic solvents. They are salts of organic cations and a variety of anions [4–7]. ILs are compatible with several organic transformations [8–10], they readily immobilize several catalysts in their native form [11,12] or the supported catalysts [13]. They have been found to alter the outcome of chemical reactions in a dramatic fashion [14], thus forming a new paradigm in organic synthesis.

In continuation of our recent interest to use ILs, water or solventless systems as green reaction mediums [15], we report herein the synthesis of isoxazole derivatives in reusable imidazolium-based ILs using NaOH as base Scheme 1.

A typical reaction of dibenzoylmethane with hydroxyl-amine was carried out in the IL, [bmim]Br, at ambient conditions to form 3,5-diphenyl isoxazole. However, at room temperature, reaction does not proceed further to afford the product even in trace amounts. Consequently, the reaction was carried out at higher temperatures and optimum results were obtained at 65°C (75%).

For further optimization, several ILs based on butylmethylimidazolium salts [bmim]X with varying anions were screened for the typical reaction of dibenzoil-methane with hydroxylamine at 65°C for complete conversions as monitored by TLC to afford 3,5-diphenyl isoxazole. The results are recorded in Table 1. Evidently, [bmim]BF_4 was found to be superior in terms of yield (83%) and reaction time (5 h) when compared with other ILs.

Consequently, all further reactions with other β-diketones were conducted by using [bmim]BF_4 as the reaction medium Table 2. Acetylacetone and 2,4-hexanedione were mostly recovered unchanged. All the products were fully characterized by M.P., ^{13}C NMR, ^{1}H

NMR, and the values [16] were in agreement with those reported in literature.

Recycling of the IL was carried out for the reaction of β-diketone and hydroxylamine hydrochloride following an extremely straightforward protocol. After complete reaction and workup the residue containing IL was dissolved in EtOAc, filtered through a filter paper, dried over Na_2SO_4, and the solvent was removed on a rotary evaporator. The IL was further vacuum dried at 0.1 mmHg for 1 h and used for two more runs under identical conditions as for run 1. The results gained are shown in Table 3. It can be seen that a slight reduction in yield was observed in runs carried out using ''old'' IL, and furthermore the products obtained were of the same purity as in the first run.

In conclusion, a novel method for the one-pot synthesis of the biologically active isoxazoles has been developed by the reaction of β-diketone and hydroxylamine hydrochloride in the IL [bmim]Br in excellent isolated yields. The solvent IL was recovered almost entirely and recycled successfully. The moderate reaction conditions, easy workup procedure and recyclability of the nonvolatile IL make this an environment friendly method amenable for scaleup.

EXPERIMENTAL

All of the melting points are uncorrected and were determined with a Stuart scientific apparatus. Infrared spectra were recorded in KBr and were determined on a PerkinElmer FT-IR spectrometer. ^1H NMR spectra were recorded on a Bruker Avance 300 MHz spectrometer in $CDCl_3$ as solvent and TMS as internal standard. All solvents and chemicals were of research grade and were used as obtained from Merck. The imidazolium-based ILs investigated were prepared according to the procedure reported in the previous literature [17].

[16] General procedure for compounds (**1–7**): A mixture of β-diketone (1 mmol), hydroxylamine hydrochloride (1.1 mmol), and NaOH (1 mmol) was heated in 2 mL [bmim]BF_4 at 65°C for appropriate time (Table 1). The completion of reaction was monitored by TLC using (EtOAc/petroleum 1:8) as eluent. After completion of the reaction, the mixture was extracted with Et_2O (15 mL × 3). The Et_2O layers were collected and concentrated in vacuum. Then the crude mixture was purified by column chromatography using (HEX/EtOAc 9:1) on silica gel to afford corresponding isoxazoles. $C_{15}H_{11}NO$ (**1**): ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 7.65$ (d, 4H, Ph), 7.34 (m, 6H, Ph), 6.43 (s, 1H, CH); ^{13}C NMR (75 MHz, $CDCl_3$): $\delta = 156.9$, 147.1, 136.9, 127.9, 127.0, 126.1, 98.3; *Anal.* Calcd. for $C_{15}H_{11}NO$: C, 81.43; H, 5.01; N, 6.33; O, 7.23. The mild oxidation of sydnone-benzoylhydrazone hybrids with lead oxide in acetic acid/dichloromethane solution inducted their intramolecular cyclization to provide the corresponding 2,5-disubstituted-1,3,4-oxidiazole derivatives. The sydnone moiety has been efficient preserved for the future work in the mild oxidation.

J. Heterocyclic Chem., **46**, 111 (2009).

INTRODUCTION

Sydnones attract attention due to their wildly useful properties, including biological and pharmaceutical usage [1], synthetic application [2], photochromic properties [3], and preparation of electroluminescent materials [4]. Sydones, also considered as the masked hydrazines, can react with HCl for de-masking for the further formation of heterocycles [5].

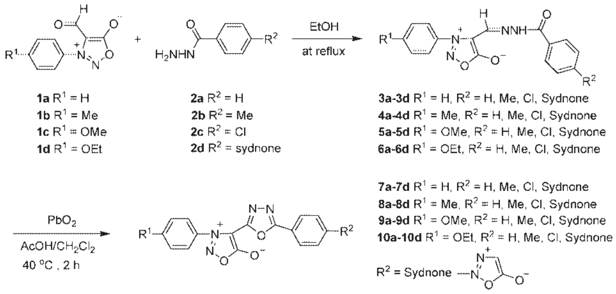
1,3,4-Oxadiazoles have been reported to be biologically versatile compounds displaying a variety of biological effects, which include anti-inflammatory [6], antifungal [7], antiparasitic [8], and antimicrobial activities [9]. In addition, they have been used as bioisosteres on the carboxamide moiety [10]. The most common synthetic approach to 1,3,4-oxidiazoles involves cyclodehydration of 1,2-diacylhydrazines. Typically, the reaction is carried out by using thionyl chloride [11], phosphorous oxychloride [12], phosphorous pentoxide [13], triphenylphosphine [14], or trifluoromethane–sulfonic anhydride as the dehydrating agent [15].

Another alternative route to 1,3,4-oxadiazoles by oxidative cyclization from the corresponding aldehyde *N*-acylhydrazones proceeds with lead tetraacetate [16], lead oxide [17], potassium permanganate [18], electrochemical methods [19], iodobenzene diacetate [20], or chloramine T [21]. The azines were used as oxidative cyclization precursors. Herein, we report the aldehyde *N*-acylhydrazone containing sydnone moiety with lead oxide reagent, at 40°C for 2 h to afford 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrids in 51–63%. In this mild oxidative cyclization, the sydnone moiety is able to be successful preserved without decomposition.

RESULTS AND DISCUSSION

The synthetic pathway of the 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrid derivatives (**7**–**10**) was depicted in Scheme 1. Following by the published procedure [2,22], the sydnone compounds were easily converted to the 3-aryl-4-formyl-sydnone derivatives **1a**–**1d** in a solution of $POCl_3$ and DMF by the Schmidt reaction. And benzoyl chloride reacted with hydrazine monohydrate to generate benzoylhydrazones **2a–2d**. Then various 3-aryl-4-formyl-sydnone derivatives **1a**–**1d** (p-R^1 = H, Me, OMe, and OEt) were mixed with benzoylhydrazones **2a–2d** (p-R^2 = H, Me, Cl, and sydnone) and stirred for 2.0–6.0 h in an EtOH solution to achieve the elimination and give the corresponding products **3–6** in good yields (74–86%, see Table 1) [23].

Scheme 1. The synthetical route of 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrid derivatives.



Aldehyde *N*-acylhydrazones **3–6** were performed the oxidative–cyclization by using fresh $KMnO_4$ in acetic acid/dichloromethane solution. The low isolable oxidative–cyclization products were provided because of the further oxidation formation and the damage of sydnone ring by $KMnO_4$. In the controllable and improvable experiment, the commercially available reagent lead oxide (PbO_2) was selected for the mild oxidative–cyclization agent [17,24]. When the aldehyde *N*-acylhydrazones **3–6** were oxidized with 2.5 equiv of lead oxide (PbO_2), the 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrid derivatives **7–10** were formed in 50–63% yields. The long range of the substitution effects on R^1 (H, Me, OMe, and OEt) and R^2 (H, Me, Cl, and sydnone) positions are not clearly a function of the isolated yield and the results are shown in Table 1.

The proposed oxidative–cyclization mechanism is shown in the Scheme 2. The aldehyde *N*-acylhydrazone **11** can be oxidized by lead oxide (PbO_2) to trap the hydrogen and afford the hydrazonyl radical **12** [17]. Because of the electron radical can be stabilized by the strong electronegativity of oxygen atom, the electron radical migrates from nitrogen to oxygen atom to form the radical intermediate **13**. The intermediate **13** undergoes the further oxidative cyclization to yield 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrid **14** [23].

Table 1

The yields of aldehyde *N*-acylhydrazones **3–6** and 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrid derivatives **7–10**.

Entry		Compounds	Yield	Compounds	Yield

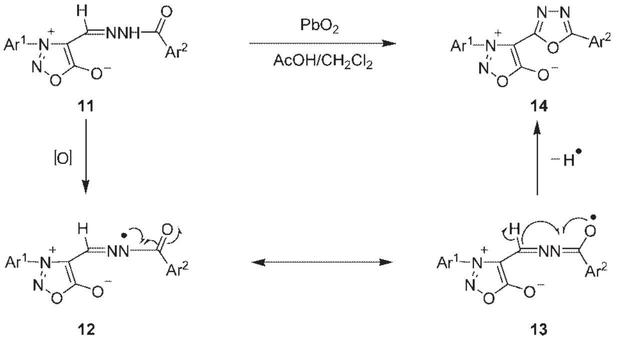
Scheme 2. The proposed mechanism of the oxidative cyclization.



In conclusion, we have developed a mild and efficient oxidative–cyclization method for the synthesis of 2,5-disubstituted-1,3,4-oxadiazole–sydnone hybrid derivatives. Using this mild radical cyclization, the sydnone ring was successfully preserved to provide 1,3,4-oxadiazole–sydnone hybrids in the core molecular.

EXPERIMENTAL

General procedure. Analytical thin-layer chromatography was performed on precoated plates (silica gel 60 F-254), purchased from Merck Inc. Purification by gravity column chromatography was carried out by use of Merck Reagents Silica Gel 60 (particle size 0.063–0.200 mm, 70–230 mesh ASTM). Infrared (IR) spectra were measured on a Bomem Michelson Series FT-IR spectrometer. The wave numbers reported are referenced to the polystyrene 1601 cm^{-1} absorption. Absorption intensities are recorded by the following abbreviations: s, strong; m, medium; w, weak. Proton NMR spectra were obtained on a Bruker-300 (400 MHz) spectrometer by use of $CDCl_3$ and d_6-DMSO as solvent. Carbon-13 NMR spectra were obtained on a Varian a Bruker-300 (100 MHz) spectrometer by used of $CDCl_3$ as solvent. Carbon-13 chemical shifts are referenced to the center of the $CDCl_3$ triplet (δ 77.0 ppm). Multiplicities are recorded by the following abbreviations: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; *J*, coupling constant (hertz). Elemental analyses were carried out on a Heraeus CHN–O RAPID element analyzer. Mass spectra were measured on a VG Platform II GC-MS Instruments. FAB mass and High-resolution mass spectra were obtained by means of a Finnigan/Thermo Quest MAT 95XL mass spectrometer.

Standard procedure for the substitution reaction. To a solution of 3-aryl-4-formyl-sydnone derivatives (**1a–1d**, 0.38 g, 2.00 mmol, 1.0 equiv) and benzoylhydrazones (**2a–2d**, 0.27 g, 2.00 mmol, 1.6 equiv) in EtOH (10 mL) was stirred and added one drop of aqueous H_2SO_4 solution.

The reaction mixture was stirred at room temperature for 2.0 h. After the reaction was completed, the resultant precipitate was filtrated, washed with cold EtOH (20 mL × 2), and dried in vacuum oven. The residue was purified by recrystallization from EtOAc to give pure aldehyde *N*-acylhydrazones **3–6** as white powder in 74–86% yields.

3-Phenyl-4-formylsydnone benzoylhydrazone (3a). Mp (recrystallized from EtOAc) 196–198°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 7.40–7.82 (m, 10 H), 8.11 (s, 1 H), 11.69 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 106.1, 125.9, 127.7, 128.7, 130.3, 132.1, 133.2, 133.4, 134.5, 142.1, 162.9, 164.3; IR (KBr) 3370 (s, NH), 1755 (m, C=O), 1695 m cm^{-1}; FABMS *m/z* (relative intensity) 309 (M + 1, 59), 308 (M$^+$, 15).

3-Phenyl-4-formylsydnone p-methylbenzoylhydrazone (3b). Mp (recrystallized from EtOAc) 197–199°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.21 (s, 3H, CH$_3$), 7.12–7.72 (m, 9 H), 8.03 (s, 1 H), 11.56 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.2, 106.2, 125.9, 127.5, 127.7, 129.2, 130.3, 132.8, 133.4, 134.3, 142.2, 162.8, 164.1; IR (KBr) 3338 (s, NH), 1754 (m, C=O), 1692 m cm^{-1}; FABMS *m/z* (relative intensity) 323 (M + 1, 74), 322 (M$^+$, 35).

3-Phenyl-4-formylsydnone p-chlorolbenzoylhydrazone (3c). Mp (recrystallized from EtOAc) 200–202°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 7.10–7.80 (m, 9 H), 7.86 (s, 1 H), 11.68 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 106.0, 125.3, 125.8, 127.1, 128.5, 130.2, 132.1, 133.2, 133.5, 142.3, 161.8, 163.9; IR (KBr) 3364 (s, NH), 1755 (m, C=O), 1689 m cm^{-1}.

3-Phenyl-4-formylsydnone 4-(sydnon-3-yl)benzoylhydrazone (3d). Mp (recrystallized from MeOH) 183–185°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 7.05–8.68 (m, 11 H, ArH + sydnone), 12.35 (s, 1 H, NH); IR (KBr) 3091 (s, NH), 1745 (m, C=O), 1681 m cm^{-1}; FABMS *m/z* (relative intensity) 393 (M + 1, 3), 392 (M$^+$, 24).

3-(p-Methylphenyl)-4-formylsydnone benzoylhydrazone (4a). Mp (recrystallized from EtOAc) 191–193°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.46 (s, 3H, CH$_3$), 7.25–7.75 (m, 9 H), 8.11 (s, 1 H), 11.66 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.1, 106.1, 125.7, 127.3, 127.7, 129.0, 129.3, 130.3, 131.1, 134.5, 143.2, 162.8, 164.7; IR (KBr) 3352 (s, NH), 1758 (m, C=O), 1692 m cm^{-1}.

3-(p-Methylphenyl)-4-formylsydnone p-methylbenzoylhydrazone (4b). Mp (recrystallized from EtOAc) 197–199°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.20 (s, 3H, CH$_3$), 2.46 (s, 3H, CH$_3$), 7.25–7.75 (m, 8 H), 8.16 (s, 1 H), 11.67 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.0, 21.2, 106.3, 126.2, 127.3, 127.9, 129.8, 130.4, 132.6,134.5, 142.6, 162.5, 164.0; IR (KBr) 3345 (s, NH), 1752 (m, C=O), 1695 m cm^{-1}.

3-(p-Methylphenyl)-4-formylsydnone p-chlorolbenzoylhydrazone (4c). Mp (recrystallized from EtOAc) 201–203°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.43 (s, 3H, CH$_3$), 7.28–7.90 (m, 8 H), 7.98 (s, 1 H), 11.63 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.0, 106.0, 125.1, 127.0, 127.4, 128.8, 129.1, 130.2, 130.9, 134.2, 143.1, 162.4, 164.1; IR (KBr) 3359 (s, NH), 1752 (m, C=O), 1695 m cm^{-1}.

3-(p-Methylphenyl)-4-formylsydnone 4-(sydnon-3-yl)benzoylhydrazone (4d). Mp (recrystallized from MeOH) 210–212°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.43 (s, 3H, CH$_3$), 7.39–8.15 (m, 10 H, ArH + sydnone), 11.93 (s, 1 H, NH); IR (KBr) 3095 (s, NH), 1751 (m, C=O), 1679 m cm^{-1}.

3-(p-Methoxyphenyl)-4-formylsydnone benzoyl-hydrazone (5a). Mp (recrystallized from EtOAc) 183–185°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 3.88 (s, 3H, OCH$_3$), 7.12–7.72 (m, 9 H), 8.03 (s, 1 H), 11.56 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 56.8, 106.2, 121.2, 121.7, 127.7, 129.3, 130.5, 130.6, 133.7, 134.8, 142.3, 162.8, 164.0; IR (KBr) 3334 (s, NH), 1755 (m, C=O), 1704 m cm^{-1}; FABMS *m/z* (relative intensity) 339 (M + 1, 68), 338 (M$^+$, 6).

3-(p-Methoxyphenyl)-4-formylsydnone p-methylbenzoylhydrazone (5b). Mp (recrystallized from EtOAc) 178–180°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.34 (s, 3H, CH$_3$), 3.88 (s, 3H, OCH$_3$), 7.25–7.79 (m, 8 H), 8.02 (s, 1 H), 11.66 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.1, 56.7, 106.4, 121.3, 121.8, 127.7, 129.1, 130.3, 131.8, 133.8, 134.5, 142.1, 162.7, 164.0; IR (KBr) 3332 (s, NH), 1748 (m, C=O), 1701 m cm^{-1}; FABMS *m/z* (relative intensity) 353 (M + 1, 21), 352 (M$^+$, 2).

3-(p-Methoxyphenyl)-4-formylsydnone p-chlorolbenzoylhydrazone (5c). Mp (recrystallized from EtOAc) 191–193°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 3.87 (s, 3H, OCH$_3$), 7.03–7.70 (m, 8 H), 7.90 (s, 1 H), 11.52 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 56.6, 106.1, 121.1, 121.2, 127.4, 129.2, 130.1, 130.5, 132.9, 134.5, 142.0, 161.7, 163.8; IR (KBr) 3361 (s, NH), 1755 (m, C=O), 1699 m cm^{-1}; FABMS *m/z* (relative intensity) 373 (M + 1, 62), 372 (M$^+$, 13).

3-(p-Methoxyphenyl)-4-formylsydnone 4-(sydnon-3-yl)benzoylhydrazone (5d). Mp (recrystallized from MeOH) 204–206°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 3.87 (s, 3H, OCH$_3$), 7.24–8.15 (m, 10 H, ArH + sydnone), 11.92 (s, 1 H, NH); IR (KBr) 3092 (s, NH), 1746 (m, C=O), 1683 m cm^{-1}; FABMS *m/z* (relative intensity) 423 (M + 1, 6), 422 (M$^+$, 1).

3-(p-Ethoxyphenyl)-4-formylsydnone benzoyl-hydrazone (6a). Mp (recrystallized from EtOAc) 192–194°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 1.37 (t, 3 H, J = 7.0 Hz, CH$_3$), 4.15 (q, 2 H, J = 7.0 Hz, CH$_2$), 7.20–7.83 (m, 9 H), 8.15 (s, 1 H), 11.70 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 14.7, 64.2, 106.2, 125.8, 127.5, 127.7, 128.7, 129.1, 132.2, 133.2, 134.9, 142.3, 161.5, 163.0; IR (KBr) 3352 (s, NH), 1749 (m, C=O), 1698 m cm^{-1}; FABMS *m/z* (relative intensity) 353 (M + 1, 21), 352 (M$^+$, 3).

3-(p-Ethoxyphenyl)-4-formylsydnone p-methylbenzoylhydrazone (6b). Mp (recrystallized from EtOAc) 189–191°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 1.33 (t, 3 H, J = 7.0 Hz, CH$_3$), 2.44 (s, 3H, CH$_3$), 4.13 (q, 2 H, J = 7.0 Hz, CH$_2$), 7.20–7.78 (m, 9 H), 8.15 (s, 1 H), 11.65 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 14.7, 21.2, 64.2, 106.1, 125.8, 127.4, 127.7, 128.7, 129.2, 130.2, 133.2, 134.6, 142.3, 164.0; IR (KBr) 3358 (s, NH), 1740 (m, C=O), 1695 m cm^{-1}; FABMS *m/z* (relative intensity) 367 (M + 1, 19), 366 (M$^+$, 4).

3-(p-Ethoxyphenyl)-4-formylsydnone p-chlorolbenzoylhydrazone (6c). Mp (recrystallized from EtOAc) 195–197°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 1.36 (t, 3 H, J = 7.0 Hz, CH$_3$), 4.13 (q, 2 H, J = 7.0 Hz, CH$_2$), 7.13–7.80 (m, 8 H), 7.91 (s, 1 H), 11.66 (s, 1 H, NH); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 14.6, 64.1, 105.8, 125.5, 127.2, 127.7, 128.8, 129.4, 132.2, 133.0, 134.6, 142.1, 160.8, 162.9; IR (KBr) 3350 (s, NH), 1745 (m, C=O), 1699 m cm^{-1}; FABMS *m/z* (relative intensity) 387 (M + 1, 51), 386 (M$^+$, 3).

3-(p-Ethoxyphenyl)-4-formylsydnone 4-(sydnon-3-yl)benzoylhydrazone (6d). Mp (recrystallized from MeOH) 178–180°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 1.37 (t, 3 H, J = 6.9 Hz, CH$_3$), 4.14 (q, 2 H, J = 6.9 Hz, CH$_2$), 7.21–8.16 (m, 10 H, ArH + sydnone), 11.93 (s, 1 H, NH); IR (KBr) 3094 (s, NH), 1749 (m, C=O), 1677 m cm^{-1}; FABMS *m/z* (relative intensity) 437 (M + 1, 6), 436 (M$^+$, 4).

Standard procedure for the oxidative–cyclization. Aldehyde *N*-acylhydrazones **3–6** (0.31 g, 1.00 mmol, 1.0 equiv) was dissolved in glacial acetic acid/dichloromethane (1/1, 15 mL). Lead oxide (PbO_2, 0.60 g, 2.50 mmol, 2.5 equiv) was added to the reaction mixture and stirred at 35–40°C for 1.5–6 h. After the reaction was completed, the reaction mixture was filtrated to remove the lead oxide residue and washed with cold dichloromethane (10 mL × 3). The filtrate was washed and extracted with saturated $NaHCO_3$ aqueous solution (20 mL × 2) to remove the residue glacial acetic acid. The combined organic layer was dried with $MgSO_{4\ (s)}$ and concentrated under reduced pressure. The residue was purified by recrystallization from dichloromethane to give pure 2,5-disubstituted-1,3,4-oxidiazole–sydnone hybrid derivatives **7–10** as a white powder in 50–63% yields.

3-Phenyl-4-(5-phenyl-1,3,4-oxadiazol-2-yl)sydnone (7a). Mp (recrystallized from CH_2Cl_2) 177–179°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 7.51–7.96 (m, 10 H); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 97.6, 120.6, 126.0, 126.5, 129.7, 129.9, 132.5, 133.0, 134.5, 154.1, 163.1, 163.9; IR (KBr) 1749 m cm^{-1}; FABMS *m*/*z* (relative intensity) 307 (M + 1, 77), 306 (M$^+$, 9); *Anal.* Calcd for $C_{16}H_{10}N_4O_3$: C, 62.74; H, 3.72; N, 18.30. Found: C, 62.51; H, 3.35; N, 18.04.

3-Phenyl-4-[5-(p-methylphenyl)-1,3,4-oxadiazol-2-yl]-sydnone (7b). Mp (recrystallized from CH_2Cl_2) 205–207°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.42 (s, 3H, CH_3), 7.34–7.94 (m, 9 H); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.2, 106.2, 125.9, 127.5, 127.7, 129.2, 130.3, 132.8, 133.4, 134.3, 142.2, 162.8, 164.1; IR (KBr) 1743 m cm^{-1}; FABMS *m*/*z* (relative intensity) 321 (M + 1, 48), 320 (M$^+$, 14); *Anal.* Calcd for $C_{17}H_{12}N_4O_3$: C, 63.75; H, 3.75; N, 17.50. Found: C, 63.91; H, 3.87; N, 17.81.

3-Phenyl-4-[5-(p-chlorophenyl)-1,3,4-oxadiazol-2-yl]sydnone (7c). Mp (recrystallized from CH_2Cl_2) 187–189°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 7.43–7.99 (m, 9 H); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 97.4, 121.3, 126.2,128.4, 129.5, 132.0, 133.1, 136.5, 154.5, 162.9, 164.0; IR (KBr) 1755 m cm^{-1}; *Anal.* Calcd for $C_{16}H_9N_4O_3Cl$: C, 56.38; H, 2.64; N, 16.45. Found: C, 56.63; H, 2.41; N, 16.64.

3-Phenyl-4-[5-(p-chlorophenyl)-1,3,4-oxadiazol-2-yl]-sydnone (7c). Mp (recrystallized from CH_2Cl_2) 187–189°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 7.43–7.99 (m, 9 H); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 97.4, 121.3, 126.2,128.4, 129.5, 132.0, 133.1, 136.5, 154.5, 162.9, 164.0; IR (KBr) 1755 m cm^{-1}; *Anal.* Calcd for $C_{16}H_9N_4O_3Cl$: C, 56.38; H, 2.64; N, 16.45. Found: C, 56.62; H, 2.41; N, 16.64.

3-p-Methylphenyl-4-(5-phenyl-1,3,4-oxadiazol-2-yl)sydnone (8a). Mp (recrystallized from CH_2Cl_2) 204–206°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.43 (s, 3H, CH_3), 7.41–7.78 (m, 9 H); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.2, 97.5, 122.6, 125.8, 126.7, 129.3, 129.9, 132.1, 133.5, 134.6, 154.5, 162.8, 163.6; IR (KBr) 1752 m cm^{-1}; FABMS *m*/*z* (relative intensity) 321 (M + 1, 45), 320 (M$^+$, 13); *Anal.* Calcd for $C_{17}H_{12}N_4O_3$: C, 63.75; H, 3.75; N, 17.50. Found: C, 63.68; H, 3.42; N, 17.86.

3-p-Methylphenyl-4-(5-phenyl-1,3,4-oxadiazol-2-yl)sydnone (8a). Mp (recrystallized from CH_2Cl_2) 204–206°C; ^{1}H NMR (DMSO-d_6, 300 MHz) δ 2.43 (s, 3H, CH_3), 7.41–7.78 (m, 9 H); ^{13}C NMR (DMSO-d_6, 75 MHz) δ 21.2, 97.5, 122.6, 125.8, 126.7, 129.3, 129.9, 132.1, 133.5, 134.6, 154.5, 162.8, 163.6; IR (KBr) 1752 m cm^{-1}; FABMS *m*/*z* (relative intensity) 321 (M + 1, 45), 320 (M$^+$, 13); *Anal.* Calcd for $C_{17}H_{12}N_4O_3$: C, 63.75; H, 3.75; N, 17.50. Found: C, 63.68; H, 3.42; N, 17.86.

3-(p-Methylphenyl)-4-[5-(p-chlorophenyl)-1,3,4-oxadiazol-2-yl]sydnone (8c). The synthesis of 2-acetyl-6-(1-naphthyl)-pyridine oxime ligand from 2,6-dibromopyridine and 1-bromo-naphthalene is described, and the new palladium(II) complex used as a Pd(0) precatalyst in the Suzuki cross-coupling reaction was studied. The results showed that the novel naphthalene pyridine oxime complex could serve as an efficient precatalyst.

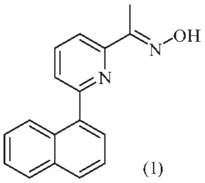
J. Heterocyclic Chem., **46**, 116 (2009).

INTRODUCTION

It is widely accepted that palladium-catalyzed cross-coupling reaction are one of the most important processes in synthesis chemistry, of which Suzuki–Miyaura cross-coupling reaction of aryl halides with organoboron reagents has become one of the most efficient and widely utilized methods for the formation of sp^2-sp^2 carbon-carbon bonds [1–4]. Traditional phosphane containing palladium catalysts have many disadvantages such as high cost, air- and thermo-sensitivity, low activity towards deactivated substrates, contamination of the products with the phosphane-based byproducts [5,6]. Therefore, many efforts have been made to find more active and stable palladium catalysts. In our lab, oxime containing molecule [7] was synthesized and its catalyst activity in cross-coupling reaction was examined. Poor enantioselectivity was observed. So, we want to improve the activity by substitution of naphthalene group to pyridine.

Some common conclusions concerning the influence of the electronic and steric properties of the ligands on the efficiency of the catalysts in Suzuki-Miyaura reaction were made based on the structure-activity analysis of these catalysts. Increasing the electronic density on palladium could enhance the catalytic activity particularly by promoting the aryl halide oxidative addition; while the bulkness of the ligand presumably could facilitate the reductive elimination step [6]. We introduced the 1-naphthalene group to the pyridine oxime to obtain more active catalyst, and here, we reported the synthesis and application of a novel naphthalene pyridine oxime ligand on the Suzuki reaction (1).



(1)

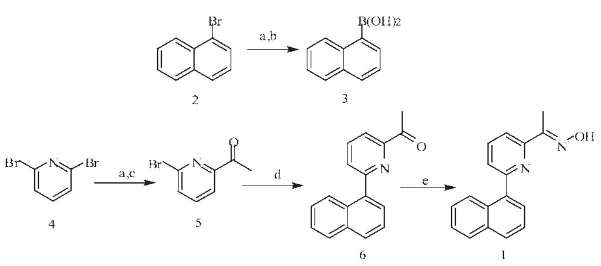
RESULTS AND DISCUSSION

Scheme 1 outlined the synthetic route employed in our lab for preparation of the substrate 1-[6-(1-naphthyl)-2-pyridyl]-1-ethanone oxime 1.

Our strategy for the synthesis of **6** was first based on the selective lithiation of 2,6-dibromopyridine [8–11] and then Suzuki cross coupling reaction [7]. After the synthesis of substrate of oxime, the precatalyst **7** was prepared by Scheme 2.

After the synthesis of (**7**), the application of naphthlene oxime ligand on Suzuki-cross coupling reaction was studied. At first, the optimal reaction time was investigated. The reaction was preceded very quickly at the first 60 min. Higher yield was not observed when the reaction time was longer as shown in Figure 1. So the optimal value for reaction time was 60 min.

Scheme 1



Conditions: a) ^{n}-BuLi, THF, -78 °C ; b) B(OBu)$_3$,-78 °C to r.t.; c) N,N-Dimethylacetamide,-78 °C to r.t.; d) Pd(PPh$_3$)$_2$Cl$_2$, 2M Na$_2$CO$_3$, Toluene, EtOH,reflux; e) NH$_2$OH HCl, EtOH,Pyridine,110 °C

The activity of the ligand was examined as shown in Table 1. The results demonstrated that the yield was influenced by the substitution of the aryl halides. The yield of bromo-benzene was the highest; the yield of *p*-bromo toluene was higher than that of *o*- and *m*-bromo toluene. 1-Methyl-4-nitrobenzene showed the lowest yield among all the reactions. This may be the reason that the substituents had the effect on reactivity of aryl halides. The nitro group was one of electron-withdrawing substituents decreasing the reactivity of the aryl halides, leading to the low yield in reaction. In addition, the effect of substituents on orientation was shown in Table 1. The methyl group was the weak electron-donating substituent. Therefore, the *ortho*/*para* bromo toluene was more active than the *meta* one because of a steric effect of the *ortho* methyl group behind the electron effection, the yield of *para* one was higher than that of *ortho* one. When water was added during the reaction, the yields become lower. When the 1-bromo-4-nitrobenzene was used as aryl halide in toluene with base of $CsCO_3$ for reflux 60 min, the yield was decreased to 33% (Run 8).

When the reaction of 1-(6-bromopyridin-2-yl)ethanone with naphthalen-1-ylboronic acid was carried out in toluene as solvent and Na_2CO_3 as base for refluxing 60 min and the yield was up to 85%, (Run 11), higher than the former reaction (Run 10).

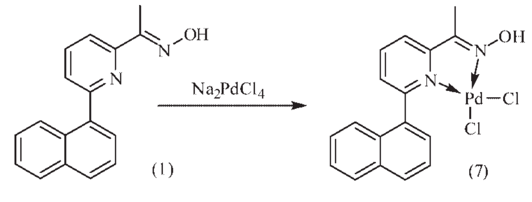
Further research related to higher activity based on the date is also underway.

EXPERIMENTAL

Deuterium NMR and CMR spectra were measured with a JNM-ECS400 NMR spectrometer at 400 MHz. Mass spectra (MS) were recorded on a JOEL JMS-AX505HA. The melting point was determined by MFB-595-030G digital thermometer apparatus.

1-Naphthylboronic acid(3). Dropwise addition of 7.95 mL (13.5 mmol) of a 1.7*M* solution of *t*-BuLi in pentane to a stirred solution of 1-bromonaphthaline (**2**) (2.67 g, 12.9 mmol) in 50 mL of THF at –78°C led to the formation of a white precipitate. After 45 min, 1.40 g (1.5 mL, 13.5 mmol) of $B(OMe)_3$ was added, and the resulting clear solution was maintained at –78°C for 1 h. The reaction mixture was allowed to warm to room temperature and stirring was continued for 3 h. A 10% solution of HCl (25 mL) and ethyl acetate (50 mL) were added. The aqueous layer was extracted with 4 × 20 mL of ethyl acetate. The combined organic layers were dried over Na_2SO_4 and the solvent was removed under reduced pressure. The off-white solid residue was suspended

Scheme 2



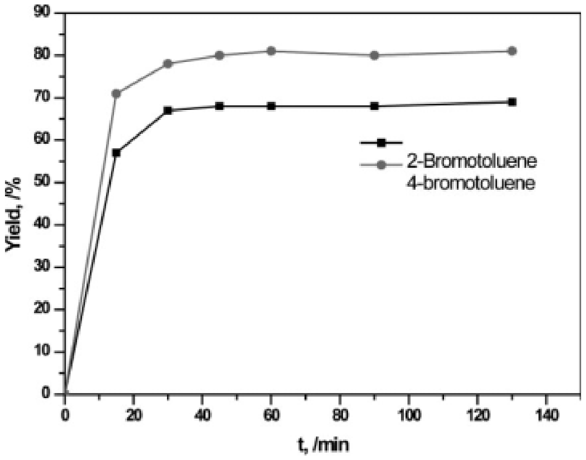


Figure 1. The yield-time relationship.

Table 1

Suzuki cross-coupling reaction.

Run	Ar-boronic acid	Br-Ar	Base	Water/ Toluene	Yield
1			Na_2CO_3	0:20	90
2			Na_2CO_3	0:20	73
3			Na_2CO_3	10:20	60
4			Na_2CO_3	0:20	60
5			Na_2CO_3	0:20	82
6			Na_2CO_3	10:20	55
7			Na_2CO_3	0:20	79
8			Ca_2CO_3	10:20	33
9			Na_2CO_3	0:20	94[a]
10			Na_2CO_3	10:20	80[b]
11			Na_2CO_3	10:20	85

Reagents and conditions: (2 mol%) Pd-catalyst, toluence, base, reflux, 60 min.

[a] Reactions time is 360 min.

[b] Catalyst is $Pd(PPh_3)_4$, reaction time is 12 h.

in 50 mL of petroleum ether and filtered to give **3** (2.13 g, yield 96%).

Mp 202–203°C; MS: *m/z* 172[M$^+$]; ^{1}H NMR (400 MHz, DMSO, δ, ppm); 7.50–8.10(*m*, 6H, Hnaph), 8.38(*s*, 2H, H_{OH}), 8.53(*d*, 1H, Hnaph, $J = 13.5$ Hz); IR(cm^{-1}) 3310 (—OH).

1-(6-Bromopyridin-2-yl)ethanone (5). A solution of 7.08 g (30 mmol) of 2,6-dibromopyridine (**4**) dissolved in 42 mL of dry THF was cooled to −78°C. The 2,6-dibromopyridine was lithiated by slowly adding 12 mL of a 2.6*M* solution of *n*-butyllithium in hexane. After the addition, the resulting dark yellow solution was stirred at −78° for 30 min. Then neat *N*,*N*-dimethylacetamide (4.2 mL, 54.3 mmol) was added over a period of 30 s. The reaction solution was stirred at −78 °C for 15 min, and then the solution was allowed to warm to room temperature. The resulting yellow solution was hydrolyzed with saturated NH_4Cl (40 mL). The mixture was stirred for additional 60 min, and the aqueous layer was separated and extracted with diethyl ether twice (100 mL and 60 mL, respectively). The combined organic layer was washed with brine 60 mL, dried (sodium sulfate) and evaporated to *ca.* 10 mL in volume and cooled to 0°C. After a few hours, a brown solid was isolated by filtration. The crude product was purified by chromatography on silica eluting with hexane/ethyl acetate (95:5) to afford white crystals, 5.1g (85%).

Mp 54–55°C; MS: *m/z* 199[M$^+$]; ^{1}H NMR (400 MHz, $CDCl_3$, δ, ppm) 2.69(*s*, 3H, CH_3),7.65–7.71(*m*, 2H, H_{Ar}), 7.97–7.99 (dd, $J = 7.25$, 1.36, 1H, CH_{Ar}); IR(KBr, cm^{-1}) 1696 (C=O); 593 (C—Br).

1-(6-Naphalen-1-yl)pyridin-2-yl]ethanone(6). To a solution of 3 (0.72 g, 3.60 mmol) and $Pd(OAc)_2$ (0.13 g) in 10 mL of deaerated toluene, 4 mL of a 4.4*M* aqueous solution of Na_2CO_3 were added, followed by a solution of 0.79 g (4.58 mmol) of 1-naphthylboronic acid in 10 mL of MeOH. The mixture was heated to 80–85°C under stirring for 30 h. The resulting solution was allowed to cool to room temperature and a solution of 8 mL of concentrated aqueous NH_3 in 20 mL of saturated aqueous Na_2CO_3 was added. The mixture was extracted with 3 × 50 mL of CH_2Cl_2. The combined organic layers were washed with 50 mL of water and 100 mL of brine and dried over Na_2SO_4. Removal of the solvent under reduced pressure gave 1.15 g of the crude product which was purified by flash chromatography [CC, SiO_2, i) petroleum ether/CH_2Cl_2 (4:1), $R_f = 0.1$, ii) CH_2Cl_2]. The desired product was obtained as an off-white solid in 80% yield (0.71 g).

MS: *m/z* 246[M − 1], 247 [M$^+$], 248[M + 1]; IR(cm^{-1}) 1698(C=O); ^{1}H NMR (400MHz, $CDCl_3$, δ, ppm) 2.76 (*s*, 3H, CH_3), 7.47–7.55 (*m*, 2H, H_{Ar}), 7.56–7.60 (*t*, $J = 7.30$, 7.70, 7.25, 1H, H_{Ar}), 7.64–7.66 (dd, $J = 7.02$, 0.91, 1.36, 1H, H_{Ar}), 7.76–7.78 (dd, $J = 7.70$, 0.91, 1H, H_{Ar}), 7.92–7.98(*m*, 3H, H_{Ar}),8.16-8.18(*d*, $J = 8.15$, 1H, H_{Ar})

1-(6-(Naphtgalene-1-yl)pyridin-2-yl)ethanone oxime (1). To a solution of $NH_2OH{\cdot}HCl$ (0.75 g, 10.8 mmol) in 10 mL of pyridine was added **6** (1.00 g, 5.22 mmol) and the mixture was stirred at 80°C for 4 h. After cooling to room temperature, the reaction mixture was poured into cold water and allowed to stay for 24 h. Precipitate thus formed was then collected by filtration, washed with water and dried in air to give 1.05 g (91%) of 3,5-diacetyl-2,6-dimethyl-pyridine dioxime.

Mp: 150–151°C; MS: *m/z* 262 [M$^+$]; ^{1}H NMR (400 MHz, DMSO, δ,ppm) 2.19(*s*, 3H, CH_3), 7.47–7.55(*m*, 2H, H_{Ar}), 7.57–7.61(*t*, $J = 7.25$, 1H, H_{Ar}), 7.61–7.63(dd, $J = 4.76$, 1.81, 1.36, 1H, H_{Ar}), 7.87–7.92(*t*, $J = 8.83$, 8.15, 9.51, 1H, H_{Ar}), 7.92–7.96(*t*, $J = 7.70$, 7.25, 8.15, 1H, H_{Ar}), 7.98–8.01(dd, $J = 7.16$, 1.36, 2H, H_{Ar}), 8.09–8.11(d, $J = 8.15$, 1H, H_{Ar}), 11.53(*s*, 1H, N-OH); ^{13}C NMR (400 MHz, DMSO, δ, ppm) 10.87, 118.67, 124.97, 125.90, 125.99, 126.53, 127.07, 128.06, 128.88, 129.33, 131.10, 134.06, 137.91, 138.39, 154.57, 157.96, 159.48. IR (KBr, cm^{-1}) 3300 (—OH).

Oxime-derived palladacycle (7) (preparation of precatalyst). To a stirred solution of sodium tetrachloropalladate(II) (147 mg, 0.5 mmol), which was obtained as well-formed crystals by treating $PdCl_2$ solutions with stoichiometric quantities of sodium chlorides and slowly evaporating the solutions in MeOH (2 mL), 2-acetyl-6-(1-naphthyl)-pyridine oxime (131 mg, 0.5 mmol) in MeOH (1 mL) was added dropwise. The precipitate was collected by filtration after stirring for 2 h and washed with MeOH and H_2O, then dried in vacuum over P_2O_5. Precatalyst **7** was obtained as a yellow-brownish powder (400 mg, 80%).

Mp > 300°C; IR(cm^{-1}): 1755, 1730, 1705 (C—O); MS: *m/z* 440[M + 1],880[M + M]; ^{1}H NMR (400 MHz, DMSO, δ, ppm) 2.19(*s*, 3H, CH_3), 7.47–7.64 (*m*, 5H, H_{Ar}), 7.87–8.00 (*m*, 4H, H_{Ar}), 11.53(*s*, 1H, N—OH); ^{13}C NMR (400 MHz, DMSO, δ, ppm) 10.87, 118.67, 124.96, 125.89, 125.98, 126.51, 127.06, 128.05, 128.87, 129.33, 131.09, 134.05, 137.91, 138.39, 154.57, 155.05, 157.96.

Acknowledgments. I thank Mr. Murakami for his technical assistance. This research was financially supported by the Sasakawa Scientific Research Grant from The Japan Science Society under grant number 19-314.

An efficient synthesis of benzoxazole-substituted 3,4-dihydropyrimidinones (DHPMs) using alumina supported trifluoromethane sulfonic acid as the catalyst for the first time from an aldehyde, β-keto ester, and benzoxazole-substituted urea and thiourea under solvent-free conditions is described. When compared with the classical Biginelli reaction conditions, this new method consistently has the advantage of excellent yields (80–93%) and short reaction time (30–120 minutes) at 120°C temperature.

J. Heterocyclic Chem., **46**, 119 (2009).

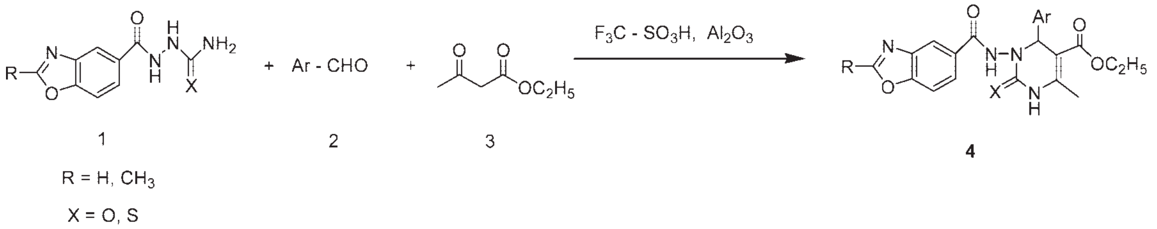
INTRODUCTION

The Biginelli (1893) reaction [1] is a simple one-pot condensation of an aldehyde, keto ester, and urea or thiourea in the presence of catalytic amount of acid to produce 3,4-dihydropyrimidin-2(1*H*)-ones. Dihydropyrimidinones (DHPMs) and their derivatives exhibit wide range of biological activities such as antibacterial, antiviral, antitumour, and anti-inflamatory actions [2]. Biginelli compounds exhibit pharmacological activities as calcium channel blockers, antihypertensive agents, α - 1a–antagonists, and neuro peptide Y(NPY) antagonists [3–6]. Biological activities of some marine alkaloids isolated were also found to contain the dihydropyrimidinone-5-carboxylate core [7]. Most notably among them are batezelladine alkaloids, which have been found to be potent HIV gp-120-CD4 inhibitors [8–10]. Consequently, syntheses of Biginelli compounds have gained importance, which often suffer from low yields practically in case of substituted aromatic and aliphatic aldehydes [11–13]. Even though, high yields could be achieved by following complex multistep procedures [14–17], these methods lack the simplicity of original one-pot Biginelli protocol. Therefore, Biginelli reaction continues to attract the attention of researchers for the discovery of a milder and efficient procedure for the synthesis of dihydropyrimidinones.

Similarly, benzoxazole nucleus can also be frequently recognized in the structure of numerous naturally occurring compounds with interesting biological and pharmacological properties. Benzaxazoles have been found to possess marked biological effects as anti inflammatory [18,19], anticancer [20] and antimicrobial [21,22] agents. In view of this benzoxazole-substituted urea and thiourea are used in the synthesis of 3,4-dihydropyrimidinones to get more biodynamic compounds.

In recent years, several synthetic procedures for preparing of DHPMs have been reported including classical conditions with microwave irradiation [23,24] and by using Lewis acids as well as protic acids as promoters such as [25–30] Conc. HCl, $BF_3.OEt_2$, PPE, KSF clay, $InCl_3$, $LaCl_3$, lanthanide triflate, H_2SO_4, ceric ammonium nitrate (CAN), $Mn(OAc)_3$, ion-exchange resin, 1*n*-butyl-3-methyl imidazolium tetra fluoroborate (BMImBF4), $BiCl_3$, $LiClO_4$, $InBr_3$, $FeCl_3$, $ZrCl_4$, $Cu(OTf)_2$, $Bi(OTf)_3$, LiBr, ytterbium triflates, NH_4Cl, $MgBr_2$, $SiO_2/NaHSO_4$, $CdCl_2$, and other reagents [31] have been found to be effective. Many of these methods involve expensive reagents, stochiometric amounts of catalysts, strongly acidic conditions, long reaction times, unsatisfactory yields, and incompatibility with other functional groups. Therefore, the development of a neutral alternative would extend the scope of the Biginelli reaction.

Scheme 1



Recently, the use of solid supported reagents [32] has received considerable importance in organic synthesis because of their ease of handling, enhanced reaction rates, greater selectivity, simple workup, and recoverability of catalysts. Among the various heterogeneous catalysts, particularly, alumina supported trifluoromethane sulfonic acid has advantages of low cost, ease of preparation, and catalyst recycling. As the reaction is heterogeneous in nature, the catalyst can conveniently be separated by simple filtration. In view of the recent surge in the use of heterogeneous catalysts [33–35], we wish to report a simple, convenient, and efficient method for the preparation of benzoxazole-substituted dihydropyrimidinone derivatives using alumina [36] supported trifluoromethane sulfonic acid, as an inexpensive and eco-friendly catalyst. This catalyst can act as eco-friendly for a variety of organic transformations because it is nonvolatile, recyclable, inexplosive, easy to handle, and thermally robust. In view of the emerging importance of heterogeneous catalysts, we wish to explore the use of alumina supported trifluoromethane sulfonic acid [37] as recyclable catalyst in the synthesis of DHPMs using substituted urea and thiourea.

RESULTS AND DISCUSSION

Initially, we have studied the Bignelli's one-pot condensation reaction of benzaldehyde (1.0 mmol) with benzoxazole-substituted urea (1.2 mmol) and ethyl acetoacetate (1.2 mmol) using 5 mol % of alumina-supported trifluoromethane sulfonic acid as catalyst under solvent free conditions (Scheme 1). The reaction is very fast and 90% conversion was observed in 1 h.

Encouraged by these results, we examined several aromatic and aliphatic aldehydes under optimized conditions (Table 1). Furthermore, the use of just 5 mol % alumina-supported trifluoromethane sulfonic acid as catalyst is sufficient to promote the reaction. There are no improvements in the reaction rates and yields by increasing the amount of the catalyst from 5 to 10 mol %. The best results were achieved when the reactions were carried out at 120°C temperature in an oil bath for 30–120 minutes in the presence of catalytic amount of alumina supported trifluoromethane sulfonic acid catalyst. The results are listed in Table 1. Another important feature of this procedure is the stability of a variety of functional groups such as ether, hydroxy, halides, nitro, *etc*., under these reaction conditions.

Benzoxazole-substituted urea and thiourea has been used with similar success to provide the corresponding dihydropyrimidinones and thiones in high yields, which are also of much interest with regard to biological activity. An acid sensitive aldehyde, worked well without formation of any side product. It is noteworthy which the survival of a variety of functional groups such as ether, hydroxy, halides, nitro, unsaturation, *etc*, under the reaction conditions.

The efficiency of the recovered catalyst was verified with the reaction of benzaldehyde, benzoxazole -substituted urea and ethyl acetoacetate (Entry 1). Using fresh catalyst, the yield of product (4**a**) was 90% while the recovered catalyst in the three subsequent recyclization the yields were 89, 87, and 86.

CONCLUSION

In summary, we have developed a new methodology for the synthesis of substituted DHPMs by using substituted urea and thiourea in the presence of a catalytic amount of alumina supported trifluoromethane sulfonic acid at 120°C temperature. Thus, alumina-supported trifluoromethane sulfonic acid mediated one-pot synthesis of DHPMs is, therefore, a simple, high yielding, time saving, and eco-friendly process. The catalyst can be prepared from available inexpensive reagents and can be easy recycled, which is heterogeneous and nonhazardous.

EXPERIMENTAL

All chemicals were A. R. grade obtained from Qualigens, India. All the solvents were purified by standard techniques. Column chromatographic separations were carried out on Silicagel 100–200 mesh size. I.R Spectra were scanned on a Perkin-Elmer, 1310 Spectrophotometer with sodium chloride optics. NMR spectra were recorded on a varian FT-200 MHz

(GEMINI) using tetramethyl silane (TMS) as the internal standard. Mass spectra were obtained on micro Mass VG70-70H spectrometer operating at 70 eV using a direct inlet system.

Preparation of the catalyst. The catalyst was prepared by mixing alumina (5 mmol) with a trifluoromethane sulfonic acid (5 mmol) in distilled water (10 mL). The resulting mixture was stirred for 30 minutes to absorb triflouromethane sulfonic acid on the surface of alumina. After removal of water in a rotary evaporator, the solid powder was dried at 120°C for 2–3 h under reduced pressure. The drying temperature was maintained below the decomposition temperatures of the salts.

General procedure for the synthesis of DHPMs. A solution of an appropriate β-keto ester (1.2 mmol), corresponding aldehyde (1.0 mmol), benzaxazole substituted urea or thiourea (1.2 mmol), and alumina-supported trifluoromethane sulfonic acid (5 mol %) under solvent-free conditions was heated at 120°C (completion of reaction was monitored by TLC). The reaction mixture was washed thoroughly with water, filtered and recrystallized from methanol to afford pure product. The spectral data of the compounds are given below.

A simple and highly efficient procedure has been described for the synthesis of 6-aryl-9-(4-phenoxphenyl)-1,2,4-triazolo [4,3-a] [1,8] napthyridines **(4)** by the oxidation of 4-phenoxybenzaldehyde 3-aryl-1,8-naphthyridin-2-ylhydrazones **(3)** with chloramines-T in methanol under microwave irradiation. The products were obtained in very good yields and excellent purities.

J. Heterocyclic Chem., **46**, 124 (2009).

INTRODUCTION

1,8-Naphthyridines constitute an important class of compounds possessing diverse biological activities [1–3]. Various 1,2,4-triazoles have been extensively explored for their applications in the field of biological and pharmacological activities [4–6]. Therefore, it was envisaged that chemical entities with both 1,8-naphthyridine and 1,2,4-triazole might result in compounds with interesting biological activity. Microwave-assisted organic synthesis has attracted considerable attention in recent years [7–10], due to enhanced reaction rates, high yields, improved selectivity, and cleaner products. Several methods have been developed for performing reactions with microwave irradiation in solution and under solvent-free conditions, but a homogeneous mixture is preferred to obtain uniform heating. The solvents with higher dielectric constants are superheated and the reactions take place rapidly. Chloramine-T (CAT) is a very versatile oxidizing agent and is of much importance in its synthetic utility [11,12]. In view of this and in continuation of our interest in microwave-assisted organic transformations on 1,8-napthyridine derivatives [13–17], we report herein, a convenient, practical and efficient method for the synthesis of 1,2,4-triazolo[4,3-*a*][1,8] naphthyridines using CAT in methanol under microwave irradiation.

e	4-ClC_6H_4		

RESULTS AND DISCUSSION

Condensation of 3-aryl-2-hydrazino-1,8-napthyridines (**1**) with 4-phenoxybenzaldehyde (**2**) in the presence of catalytic amount of DMF under microwave irradiation afforded the respective 4-phenoxybenzaldehyde 3-aryl-1,8-napthyridin-2-ylhydrazones (**3**) in excellent yields.

Oxidative cyclization of hydrazones **3** with CAT in methanol under microwave irradiation resulted in the formation of 6-aryl-9-(4-phenoxyphenyl)-1,2,4-triazolo-[4,3-*a*][1,8]naphthyridines (**4**). The oxidative transformation is clean and efficient. The experimental procedure is very simple. The high yield transformation did not form any undesirable by-products. Furthermore, the products were obtained with a higher degree of purity by this procedure and in most cases no further purification was needed. Interestingly, this oxidative reaction proceeds only to a minor extent (5–8% in 3.5–4.5 min) when conducted under conventional conditions in an oil-bath preheated to 110°C (temperature measured at the end of exposure during microwave experiment) which confirms the rate augmentation during microwave heating (Scheme 1).

The structural assignments of compounds **3** and **4** were based on their spectroscopic (IR and ^{1}H NMR; Table 1) and analytical data (Table 2).

The significant advantages of this procedure are operational simplicity, short reaction time, pure products, inexpensive, and nontoxicity of the reagent and high yields.

EXPERIMENTAL

Melting points were measured on a Cintex melting point apparatus and are uncorrected. The purity of the compounds was checked using precoated TLC plates (Merk, 60F-254). IR spectra (KBr) (ν_{max}: cm^{-1}) were recorded on a Perkin-Elmer BX series FTIR spectrophotometer. ^{1}H NMR spectra were recorded on a Varian Gemini 200 MHz spectrometer (Chemical shifts in δ, ppm) using TMS as internal standard. Microanalyses were performed on a Perkin-Elmer 240 CHN elemental analyzer. Microwave irradiation was carried out in a domestic microwave oven (LG MG 556p, 2450 MHz). The starting compounds **1** were prepared according to our reported

Table 1

IR and ^{1}H NMR spectral data of 4-phenoxybenzaldehyde 3-aryl-1,8-naphthyridin-2-ylhydrazones (**3**) and 6-aryl-9-(4-phenoxyphenyl)-1,2,4-triazolo-[4,3-*a*][1,8]naphthyridines (**4**).

procedures [16–20]. The 4-phenoxylbenzaldehyde (**2**) was purchased from Aldrich Chemical Company.

General procedure for the synthesis of 4-phenoxybenzaldehyde 3-aryl-1,8-naphthyridin-2-ylhydrazones (3). A mixture of 1 (20.0 mmol), 4-phenoxy-benzaldehyde (2, 20.0 mmol) and DMF (5 drops) was subjected to microwave irradiation at 400 watts intermittently at 30 s intervals for the specified time (Table 2). On completion of reaction, as monitored by TLC, the reaction mixture was cooled and treated with cold water. The resulting solid product was collected by filtration, washed with water and re-crystallized from ethanol to give **3** (Table 2).

General procedure for the synthesis of 6-aryl-9-(4-phenoxyphenyl)-1,2,4-triazolo[4,3-*a*][1,8]napthyridines (4). To a solution of appropriate hydrazone **4** (20.0 mmol) in methanol (15 mL), CAT (20.0 mmol) was added. The reaction mixture was exposed to microwaves at 400 watts intermittently at 30 s intervals for specified time (Table 2). After complete conversion as indicated by TLC, the reaction mixture was cooled and digested with cold water. The solid then obtained was collected by filtration, washed with water and re-crystallized from ethanol to afford **4** (Table 2).

Acknowledgments. The authors thank the Directors, IICT, Hyderabad and IITM, Chennai, India for providing spectral and analytical data.

Alumina-supported iodobenzene diacetate [PhI(OAc)$_2$-Al$_2$O$_3$] is a highly efficient reagent for the oxidative cyclization of [*o*-(1,8-naphthyridin-2-yl)phenoxy]acetic acid arylidene hydrazides **4** to 5-aryl-2-[*o*-(1,8-naphthyridin-2-yl)phenoxymethyl]-1,3,4-oxadiazoles **5** in solvent-free conditions under microwave irradiation. The products are obtained in good yields and in a state of high purity.

J. Heterocyclic Chem., **46**, 127 (2009).

INTRODUCTION

1,8-Naphthyridine derivatives acquired a special place in the heterocyclic field because of their diversified activities such as antibacterial [1], antitumor [2], antihypertensive [3], and anti-inflammatory [4]. 1,3,4-Oxadiazoles are biologically active [5,6], synthetically useful and important heterocyclic compounds. For these reasons the chemistry of 1,3,4-oxa-diazoles have been the subject of many investigations [7–10]. However, most of these investigations suffer from serious drawbacks which include the use of hazardous, highly toxic, long reaction times, low yields, drastic reaction conditions, and expensive or commercially unavailable reagents. In view of the rapidly increasing demands for green chemistry, an efficient and convenient method for the synthesis of 1,3,4-oxadiazoles is highly desirable.

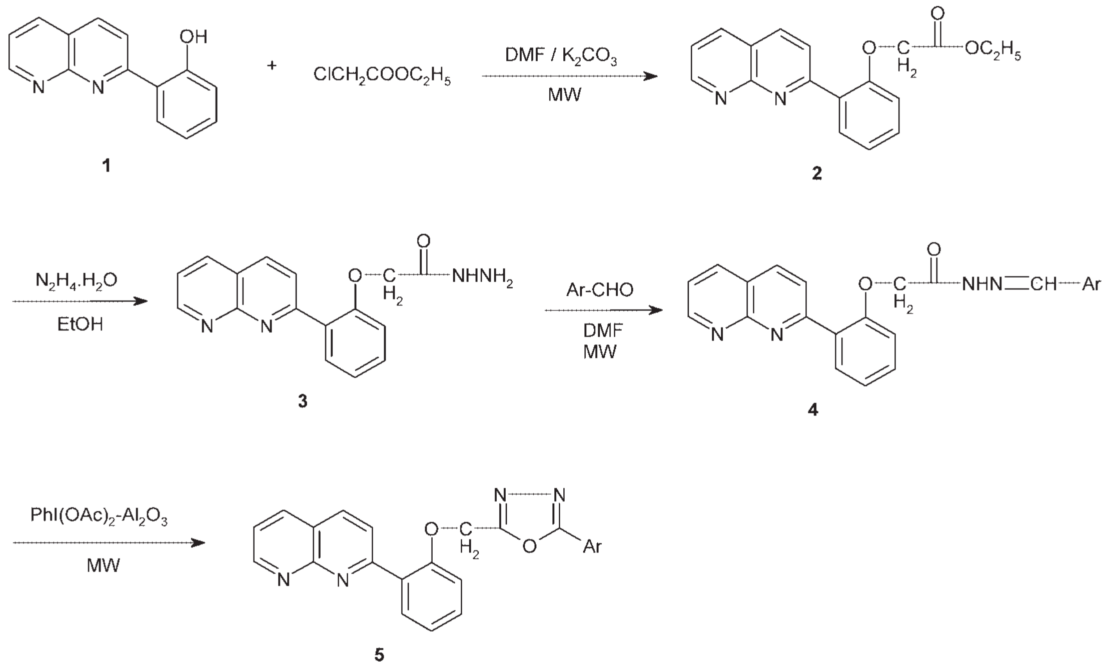
The versatile synthetic utility of organic hypervalent iodine reagents in general and iodobenzene diacetate (IBD) in particular is of current interest [11–13]. Microwave (MW) activation has become a very popular and useful technology in synthetic organic chemistry [14–16]. Recently, more interest has been focused on ''dry media'' synthesis using inorganic solid supports. The coupling of MW heating mode with the use of mineral solid support [17–19] such as alumina, silica, and clays have been used for the synthesis of several organic compounds with higher selectivity, yield and purity compared to traditional methods. In continuation of our interest in the MW assisted organic transformations of 1,8-naphthyrdines [20–23], we report herein, a practical and highly efficient method for the synthesis of 1,8-naphthyridinyl-1,3,4-oxadiazoles using alumina-supported IBD [PhI(OAc)$_2$-Al$_2$O$_3$] in solvent free conditions under MW irradiation.

RESULTS AND DISCUSSION

Alkylation of 2-(*o*-hydroxyphenyl)-1,8-naphthyridine **1** [24] with ethyl chloroacetate in DMF in the presence of anhydrous K$_2$CO$_3$ under MW irradiation resulted in the formation of ethyl [*o*-(1,8-naphthyridin-2-yl)phenoxy] acetate **2**, which on hydrazinolysis with refluxing hydrazine hydrate afforded [*o*-(1,8-naphthyridin-2-yl)phenoxy]acetic acid hydrazide **3**. Treatment of hydrazide **3** with aromatic aldehydes in the presence of catalytic amount of DMF under MW irradiation furnished the corresponding hydrazones, [*o*-(1,8-naphthyridin-2-yl)phenoxy]acetic acid arylidenehydrazides **4** in excellent yields.

The hydrazones **4** on oxidative cyclization with alumina-supported IBD [PhI(OAc)$_2$-Al$_2$O$_3$] [25] in the absence of solvent under MW irradiation resulted in the formation of 5-aryl-2-[*o*-(1,8-naphthyridin-2-yl)phenoxymethyl]-1,3,4-oxadiazoles **5** (Scheme 1). The reaction proceeds efficiently in good yields at ambient pressure within a few minutes. The transformation is very clean and rapid. The reaction conditions and work-up procedures are mild, simple and convenient. Furthermore, it is to be noted that highly pure products were obtained using this simple procedure and in most cases no further purification was needed. The recyclability of the alumina support makes this an environmentally friendly ''green'' protocol. On comparing the rate enhancement effect of MW irradiation on the investigated reaction, the oxidative

Scheme 1



cyclization of hydrazone **4a** was chosen as a model reaction. The reaction gave compound **5a** in 10% yield in 5.0 min, when conducted under conventional conditions in an oil-bath preheated to 120°C (temperature measured at the end of exposure during MW experiment).

The structural assignments to compounds **2–5** were based on their spectral (IR and ^{1}H NMR) and analytical data. To the best of our knowledge this is the first report of the rapid synthesis of 1,3,4-oxadiazoles using PhI(OAc)$_2$-Al$_2$O$_3$ under solvent-free MW irradiation conditions.

In conclusion, the present procedure with PhI(OAc)$_2$-Al$_2$O$_3$ provides a very efficient method for the synthesis of 1,3,4-oxadiazoles under solvent-free conditions using MW irradiation. The notable advantages of this method are: operational simplicity, ready availability of reagents and general applicability, mild reaction conditions, short reaction times, good yields, and environmentally benign procedure.

EXPERIMENTAL

Melting points were measured on a Cintex melting point apparatus and are uncorrected. The purity of the compounds was checked by TLC. IR spectra in KBr were recorded on a Perkin-Elmer BX series FTIR spectrophotometer. ^{1}H NMR spectra were recorded on a Varian Gemini 200 MHz spectrometer (chemical shifts in δ, ppm) using TMS as internal standard. Elemental analyses (CHN) were performed on a Perkin-Elmer 240 CHN analyzer. Irradiation was carried out in a domestic MW oven (LG MG-556P, 2450 MHz).

Ethyl [*o*-(1,8-naphthyridin-2-yl)phenoxy]-acetate 2. A mixture of 2-(*o*-hydroxyphenyl)-1,8-naphthyridine **1** (0.01 mol), ethyl chloroacetate (0.01 mol), anhydrous K$_2$CO$_3$ (0.01 mol), and DMF (10 mL) was exposed to MWs at 400 watts intermittently at 30 s intervals for 4.5 min. After completion of reaction, as indicated by TLC, the reaction was cooled and poured onto crushed ice. The precipitate thus obtained was collected by filtration, washed with water and re-crystallized from ethanol to give **2**, yield 96%, mp 130°C; IR: 1755, 1610 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 1.29 (t, J = 7.0 Hz, 3H, CH$_3$), 4.28 (q, J = 7.0 Hz, 2H, CH$_2$), 4.71 (s, 2H, O—CH$_2$), 8.28 (m, 3H, C$_3$—H, C$_4$—H, C$_5$—H), 7.98 (m, 1H, C$_6$—H), 9.13 (m, 1H, C$_7$—H), 6.90–7.59 (m, 4H, Ar—H); *Anal.* Calcd. for $C_{18}H_{16}N_2O_3$: C, 70.13; H, 5.19; N, 9.09. Found : C, 70.29; H, 5.24; N, 9.15%.

[*o*-(1,8-Naphthyridin-2-yl)-phenoxy]acetic acid hydrazide 3. A mixture of **2** (0.01 mol) and hydrazine hydrate (0.015 mol) in ethanol (20 mL) was refluxed on a water-bath for 6 h. The reaction mixture was cooled, the separated solid was collected by filtration and re-crystallized from ethanol to furnish **3**, yield 92%, mp 150°C; IR: 3450, 3275, 3082, 1675, 1605 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 1.92 (br, 2H, NH$_2$), 4.83 (s, 2H, CH$_2$), 8.22 (m, 3H, C$_3$—H, C$_4$—H, C$_5$—H), 7.95 (m, 1H, C$_6$—H), 9.12 (m, 1H, C$_7$—H), 6.97–7.54 (m, 4H, Ar—H), 9.56 (s, 1H, CONH); *Anal.* Calcd. for $C_{16}H_{14}N_4O_2$: C, 65.31; H, 4.76; N, 19.05. Found: C, 65.49; H, 4.80; N, 19.12%.

General procedure for the synthesis of [*o*-(1,8-naphthyridin-2-yl)phenoxy]acetic acid arylidene hydrazides 4. A mixture of **3** (0.01 mol), aromatic aldehyde (0.01 mol), and DMF (five drops) was subjected to MW irradiation at 400 watts intermittently at 30 s intervals for the specified time (Table 1). On completion of the reaction, as monitored by TLC, the reaction mixture was digested with cold water. The resulting solid

General procedure for the synthesis of 5-aryl-2-[*o*-(1,8-naphthyridin-2-yl)-phenoxymethyl]-1,3,4-oxadiazoles 5. Compound **4** (0.01 mol) and $PhI(OAc)_2$ (0.01 mol) doped on neutral alumina (1 g) are mixed thoroughly and exposed to MWs at 800 watts intermittently at 30 s intervals for the specific time (Table 1). After complete conversion as indicated by TLC, the reaction mixture was cooled and treated with methanol (30 mL). The methanol solution was poured into ice-cold water (50 mL), the precipitated solid was collected by filtration and re-crystallized from ethanol to furnish **5** (Table 1).

5a. IR: 1605 cm^{-1}; ^1H NMR ($CDCl_3$ + DMSO-d_6): δ 5.46 (s, 2H, CH_2), 8.20 (m, 3H, C_3—H, C_4—H, C_5—H), 8.00 (m, 1H, C_6—H), 9.15 (m, 1H, C_7—H), 7.04–7.60 (m, 9H, Ar—H).

A fast one-pot microwave-assisted solvent free synthesis of simple alkyl 1,2,3-triazole-4-carboxylate derivatives by 1,3-dipolar cycloaddition reactions with trimethylsilyl azide (Me_3Si-N_3) on the alkylpropiolates and DMAD in high yields is described.

J. Heterocyclic Chem., **46**, 131 (2009).

INTRODUCTION

The synthesis of important compounds with many applications in chemistry and medicinal area has been observed in the literature. Microwave-assisted synthesis has been utilized as a powerful and effective technique to promote a group of chemical reactions [1–9]. Since the first publications on the use of microwave irradiation in organic chemistry, the accelerated process described have been a lure for chemists to further apply new reactions to this technology [10]. Huisgen's 1,3-dipolar cycloaddition of alkynes and azides yielding triazoles is, undoubtedly, the premier example of click chemistry reactions [11–21]. This type of reaction is an effective and excellent reaction for preparation of 1,2,3-triazoles. 1,2,3-Triazoles are known to be relatively resilient to metabolic degradation and have known utility in several medicinal chemistry campaigns as isosteres for phenyl rings and carboxyl functionalities [19]. The triazoles may display a wide range of biological activity as anti-HIV and antimicrobial agents, as well as selective β_3 adrenergic receptor agonist and antiallergic agents [20–23]. Additionally, 1,2,3-triazoles are found in herbicides, fungicides, and dyes [14,24].

Because of these interesting activities, fast and new methods for the synthesis of these compounds should be significant. In general, 1,2,3-triazole formation requires harsh conditions, that is, high temperature and longer reaction times. In the original description, the explored examples showed that although these were relatively clean processes, they could take from 12 to 48 h at high temperatures (~110°C) [19]. Several examples of Cu(I)-catalyzed alkyne-azide 1,3-dipolar cycloaddition under milder conditions have been described. The mechanistic proposal of the Cu(I)-catalyzed alkyne-azide 1,3-dipolar cycloaddition was reported and found to involve polar transition states, favorable for microwave activation [25]. These Huisgen 1,3-dipolar cycloaddition of azides and alkynes resulting in 1,2,3-triazoles is one of the most powerful click reactions [14,24–26]. An example of microwave-assisted azide-alkyne cycloaddition was reported by Katritzky and Singh [11]. The reactions involved primary azides and acetylenic amide. Recently, the synthesis of simple alkyl 1,2,3-triazole-4-carboxylate derivatives was reported by reaction between N_3^- and alkylpropyolates [27–30]. The total reaction time was 48 h [29,30]. In another report, the reaction time for synthesis of **2**, **4**, and **6** was 90 h [30].

Here, was reported a fast one-pot microwave-assisted (60 W, 10 min) solvent free synthesis of simple alkyl 1,2,3-triazole-4-carboxylate (**2**, **4**, and **6**) derivatives by 1,3-dipolar cycloaddition reactions with trimethylsilyl azide **II** (Me_3Si-N_3) on the alkylpropyolates (**1**,**3**) and DMAD (**5**) in high yields.

RESULTS AND DISCUSSION

The results show that the trimethylsilyl (Me_3Si-) was removed at the final simple alkyl 1,2,3-triazole-4-carboxylate (**2**, **4**, and **6**) products. No details are given about the by-products and only the final products are considered.

The ^{13}C NMR results show 4, 5, and 3 C-atom types for **2**, **4**, and **6**, respectively. See results in the Experimental section. The [M^+] for **2**, **4**, and **6**, were 127, 141, and 185, respectively. The percentages of C, H, and N are explained in the Experimental section. In accordance with the results that were shown in the Experimental section the MS (and CI) spectrums and CHN analysis demonstrated that the trimethylsilyl (Me_3Si-) was removed from the products during the synthesis process.

EXPERIMENTAL

The simple imides that were synthesized (**2**, **4**, and **6**), are known compounds and those physical data, infrared and ^{1}H NMR spectra were essentially identical with those of authentic samples [27–30]. The FTIR spectra was recorded as KBr pellets on a Shimadzu FTIR 8000 spectrometer. ^{1}H NMR spectra was determined on a 300 MHz Brüker spectrometer. The solvent for NMR recording was DMSO. It should be noted that a limited amount of compounds is required for this experiment. Therefore some small quality of vapor is evolved during irradiation. The power generated by the microwave oven was measured before the experiments by the method described in the literature [31].

Caution: For safety reasons all of the experiments should be performed in an efficient hood in order to avoid contact with vapors, as some quantity of substances can be vaporized during irradiation.

Typical experimental procedure for synthesis of methyl-1*H*-1,2,3-triazole-4-carboxylate (2). A mixture of methyl-propiolate 1 (1 g, 1 mL, 0.012 mol) and trimethylsilyl azide (Me_3Si-N_3) II (1.2 g, 1.5 mL, 0.012 mol) was made in a dried heavy wall Pyrex tube. The tube was sealed and then exposed to microwave oven. After 10 min irradiation at 60 W power, the mixture was cooled to room temperature. The residue of compounds was evaporated under air and reduced pressure. An off-white solid was afforded. The product **2** can be re-crystallized from chloroform + acetone and petroleum ether. These stages afforded 0.049 g product (workup yield 82% and GC yield $\approx$100%).

The amounts of ethylpropiolate **3** and trimethylsilyl azide **II** (Me_3Si-N_3) for synthesis ethyl-1*H*-1,2,3-triazole-4-carboxylate (**4**) are: 0.965 g (1 mL, 0.010 mol) and 1.1 g (1.3 mL, 0.01 mol), respectively. The yield of **4** was 0.054 g, 83%. The amounts of DMAD **5** and Me_3Si-N_3 (**II**) for synthesis dimethyl-1*H*-1,2,3-triazole-4,5-carboxylate (**6**): are: 1.157 g (1 mL, 0.0082 mol) and 1 g (1.2 mL, 0.009 mol), respectively. The yield of **4** was 0.072 g, 77%.

Methyl-1*H*-1,2,3-triazole-4-carboxylate (2). White crystals, mp 127–128°C (lit. 126–128°C) [27–30]. FTIR (KBr): 3150 (N—H), 3138, 3005, 2937, 1708 (C=O), 1660, 1538, 1480, 1432, 1352, 1212, 1116, 1023, 843, 779 cm^{-1}. ^{1}H NMR δ_H (DMSO): 8.56 (s, 1H), 3.83 (s, 3H). ^{13}C NMR: 161, 138.8, 130.1, and 51.83. MS: *m/z* (relative intensity), $M_w = 127$; 127 (M^+, 8.8), 95 (70.6), 96 (100), 78 (17.6), and 63 (18.5). $C_4H_5N_3O_2$, CHN-analysis; calculated: C (37.80%), H (3.97%), and N (33.06%), experiment: C (37.73%), H (3.95%), and N (33.01%).

Ethyl-1*H*-1,2,3-triazole-4-carboxylate (4). White crystals, mp 102–104°C (lit. 102–104°C) [27–30]. FTIR (KBr): 3224 (N—H), 3167, 2986, 1723 (C=O), 1661, 1533, 1466, 1375, 1332, 1238, 1202, 1114, 1029, 843, 780 cm^{-1}. ^{1}H NMR δ_H (DMSO): 8.46 (s, 1H), 4.27–4.35 (q, 2H, 7.0 Hz) and 1.27–1.32 (t, 3H, 7.0 Hz). ^{13}C NMR: 160.4, 138.2, 131.4, 60.4, and 14.0. MS: *m/z* (relative intensity); $M_w = 141$; CI = 141 (6.82), 113 (47.73), 95 (100), 71, 68 (78.5), and 44 (34.1). $C_5H_7N_3O_2$, CHN-analysis; calculated: C (42.55%), H (5.00%), and N (29.77%), experiment: C (42.50%), H (5.03%), and N (29.74%).

Dimethyl-1*H*-1,2,3-triazole-4,5-carboxylate (6). White crystals, mp 116–118°C (lit. 117–118°C) [27–30]. FTIR (KBr): 3239 (N—H), 3100, 2996, 2861, 1742 (C=O), 1658, 1519, 1437, 1389, 1304, 1228, 1190, 1084, 990, 833, 767 cm^{-1}. ^{1}H NMR δ_H (DMSO): 3.87 (s). ^{13}C NMR: 160.2, 131.0, and 52.4. MS: *m/z* (relative intensity); $M_w = 185$; 187 ($M2H^+$, 38.2), 154 (67.65), 124 (58.8), 93, 58, and 43 (100). $C_6H_7N_3O_4$, CHN-analysis; calculated: C (38.92%), H (3.81%), and N (22.70%), experiment: C (38.98%), H (3.85%), and N (22.66%).

The simple one-pot microwave assisted solvent free synthesis of useful alkyl 1,2,3-triazole-4-carboxylate derivatives (**2**, **4**, and **6**) by Huisgen 1,3-dipolar cycloaddition reactions with trimethylsilyl azide (Me_3Si-N_3) on the alkylpropyolates **1**,**3** and DMAD (**5**), in high yields is described. Comparison of this procedure with the other methods confirms the facility and rapidity of this method for synthesis of the alkyl 1,2,3-triazole-4-carboxylate derivatives.

Acknowledgments. The authors gratefully acknowledge Professor Curt Wentrup and the colleagues in Chemistry Department of The University of Queensland-Australia, for their useful suggestions. The authors are grateful to the Research Council of Science and Research Campus and Arak branch of I.A. University for supporting this study.

Synthesis of novel isoxazolyl 1,3,5-benzoxadiazocines **5** has been accomplished by condensation of 3-amino-5-methylisoxazole **1** with salicylaldehydes, followed by reduction, treatment with arylisothiocyanates, and subsequent ring closure in the presence of formaldehyde. The methodology used in this synthesis is the first approach of its kind.

J. Heterocyclic Chem., **46**, 134 (2009).

INTRODUCTION

Benzoxadiazocines have been claimed to exhibit sedative, muscle relaxant and anticonvulsant effects [1]. Oxadiazocines are shown to act as bacteriocides, hypnotic agents [2], central nervous system stimulants [3], and are also known to possess pharmacological activity [4]. The biological importance and considerable therapeutic potential of these compounds generated interest in designing the synthesis of a number of derivatives [5], which might become potential drug candidates as inhibitors of HIV-1 reverse transcriptase [6]. Very recently, oxadiazocines are reported to have been used as immuno therapeutics, antimicrobial drugs, and vaccines [7]. Similarly isoxazole nucleus can be found frequently in the structure of numerous naturally occurring and synthetic compounds with interesting biological and pharmacological properties [8]. In spite of such a high potential significance for benzoxadiazocines and oxadiazocines, a survey of literature showed that little attention has been given toward the synthesis of this class of heterocyclic compounds. In view of this, and as a sequel to our work on the synthesis of a variety of heterocycles linked to the isoxazole moiety [9], we undertook the synthesis of isoxazolyl benzoxadiazocines to explore the pharmacological activity of these compounds. Herein, we present our results on the synthesis of isoxazolyl 1,3,5-benzoxadiazocines by adopting simple methodology.

RESULTS AND DISCUSSION

The reaction of 3-amino-5-methylisoxazole **1** with substituted salicylaldehydes in hot alcohol led to the formation of Schiff bases **2** in quantitative yields. The Schiff bases **2** on reduction with sodium borohydride produced 2-[(5-methyl-isoxazol-3-yl-amino)-methyl] phenols **3** in moderate to good yields. The nucleophilic addition of amino methyl phenols **3** with aryl isothiocyanates has been carried out in hot chloroform with stirring for 6 h. The resulting product has been identified as *N*-(5-methyl-isoxazol-3-yl)-*N*-(2-hydroxybenzyl)-*N*′-aryl thioureas **4**. The thioureas **4** on heating with formaldehyde in methanol solution underwent ring closure, involving an internal Mannich reaction, to give novel

4, 5f = R = OCH_3, Ar = C_6H_5

5-(5-methyl-isoxazol-3-yl)-3-aryl-3,4,5,6-tetrahydro-2*H*-1,3,5-benzoxadiazocine-4-thiones **5** in moderate to good yields (Scheme 1).

It can be concluded that a simple and efficient method to synthesize isoxazolyl benzoxadiazocines in good yields under mild conditions has been achieved. It is possible that these compounds may have applications as drugs; the activity data will be published elsewhere. This happens to be the first report on the synthesis of benzoxadiazocines linked to an isoxazole unit.

EXPERIMENTAL

All the melting points were determined on a Cintex melting point apparatus and are uncorrected. Analytical TLC was performed on Merck precoated 60 F_{254} silica gel plates. Visualization was done by exposing to Iodine vapor IR spectra (KBr pellet) were recorded on Perkin-Elmer BX series FTIR spectrophotometer. ^1H NMR spectra were recorded on a Varian Gemini 300 MHz spectrometer. Chemical shift values are given in ppm (δ) with tetramethylsilane as internal standard. Mass spectral measurements were carried out by EI method on a Jeol JMC-300 spectrometer at 70 eV. Elemental analyses were performed on a Carlo Erba 106 Perkin-Elmer model 240 analyzer.

General procedure for the preparation of 2-[(5-methyl-3-isoxazolyl)imino]methylphenols (2a–2e). 3-Amino-5-methyl-isoxazole **1** (0.01 mol) and salicylaldehyde (0.01 mol) were refluxed in ethanol (10 mL) for 2 h. The solution was cooled and the separated solid was collected by filtration and re-crystallized from pet ether.

2-[(5-Methyl-3-isoxazolyl)imino]methylphenol (2a). This compound was obtained as yellow crystals, yield 95%; mp 57–59°C, ^1H NMR (300 MHz, $CDCl_3$): $\delta = 2.38$ (s, 3H, CH_3), 5.95 (s, 1H, isoxazole-H), 6.82–7.55 (m, 4H, ArH), 8.82 (s, 1H, —N=CH—), 12.02 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m*/*z* 203 ($M + H^+$); IR (KBr): 3400 (O—H), 1607 (C=N), 1577, 1400 (C=C), 1282 cm^{-1} (C—O). *Anal.* Calcd. for $C_{11}H_{10}N_2O_2$ (202): C, 65.34; H, 4.95; N, 13.86. Found: C, 65.38; H, 5.10; N, 13.79.

4-Methyl-2-[(5-methyl-3-isoxazolyl)imino]methylphenol (2b). This compound was obtained as yellow crystals, yield 90%; mp 68–70°C, ^1H NMR (300 MHz, $CDCl_3$): $\delta = 2.41$ (s, 3H, CH_3), 2.50 (s, 3H, CH_3), 6.02 (s, 1H, isoxazole-H), 6.80–7.50 (m, 3H, ArH), 8.75 (s, 1H, —N=CH—), 12.85 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m*/*z* 217 ($M + H^+$); IR (KBr): 3390 (O—H), 1615 (C=N), 1580, 1450 (C=C), 1275 cm^{-1} (C—O). *Anal.* Calcd. for $C_{12}H_{12}N_2O_2$ (216): C, 66.66; H, 5.55; N, 12.96. Found: C, 66.60; H, 5.62; N, 12.90.

4-Methoxy-2-[(5-methyl-3-isoxazolyl) imino] methyl phenol (2c). This compound was obtained as yellow crystals, yield 90%; mp 80–82°C, ^1H NMR (300 MHz, $CDCl_3$): $\delta = 2.35$ (s, 3H, CH_3), 3.8 (s, 3H, OCH_3), 6.12 (s, 1H, isoxazole-H), 6.80–

7.10 (m, 3H, ArH), 8.80 (s, 1H, —N=CH—), 12.05 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 233 (M + H$^+$); IR (KBr): 3385 (O—H), 1620 (C=N), 1575, 1425 (C=C), 1280 cm^{-1} (C—O). *Anal.* Calcd. for $C_{12}H_{12}N_2O_3$ (232): C, 62.06; H, 5.17; N, 12.06. Found: C, 62.15; H, 5.13; N, 12.14.IR.

4-Chloro-2-[(5-methyl-3-isoxazolyl)imino]methylphenol (2d). This compound was obtained as yellow crystals, yield 88%; mp 93–95°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.41$ (s, 3H, CH_3), 5.90 (s, 1H, isoxazole-H), 7.50–8.02 (m, 3H, ArH), 8.85 (s, 1H, —N=CH—), 12.50 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 237 (M + H$^+$); IR (KBr): 3405 (O—H), 1615 (C=N), 1580, 1400 (C=C), 1275 cm^{-1} (C—O). *Anal.* Calcd. for $C_{11}H_9N_2O_2Cl$ (236): C, 55.93; H, 3.81; N, 11.86. Found: C, 56.05; H, 3.85; N, 11.88.

4-Bromo-2-[(5-methyl-3-isoxazolyl)imino]methylphenol (2e). This compound was obtained as yellow crystals, yield 95%; mp 110–112°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.35$ (s, 3H, CH_3), 6.02 (s, 1H, isoxazole-H), 7.70–8.02 (m, 3H, ArH), 8.90 (s, 1H, —N=CH—), 12.40 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 281 (M + H$^+$); IR (KBr): 3368 (O—H), 1612 (C=N), 1489 (C=C), 1275 cm^{-1} (C—O). *Anal.* Calcd. for $C_{11}H_9N_2O_2Br$ (280): C, 47.14; H, 3.21; N, 10.00. Found: C, 47.20; H, 3.29; N, 9.95.

General procedure for the preparation of 2-[(5-methyl-3-isoxazolyl)amino]methyl phenols (3a–3e). To an ethanolic solution (10 mL) of Schiff base **2** (0.01 mol) sodium borohydride (0.02 mol) was slowly added with stirring. The reaction was conducted at room temperature with stirring for 30 min. The solid that separated on pouring the reaction mixture into ice-cold water was collected filtration and re-crystallized from ethanol.

2-[(5-Methyl-3-isoxazolyl)amino]methylphenol (3a). This compound was obtained as brown crystals, yield 82%; mp 85–87°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.25$ (s, 3H, CH_3), 4.31 (s, 2H, —CH_2—), 5.20 (bs, 1H, NH, D_2O exchangeable), 5.66 (s, 1H, isoxazole-H), 6.80–7.25 (m, 4H, ArH), 9.45 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 205 (M + H$^+$); IR (KBr): 3640 (N—H), 3376 (O—H), 1631 (C=N), 1458 (C=C), 1210 cm^{-1} (C—O). *Anal.* Calcd. for $C_{11}H_{12}N_2O_2$ (204): C, 64.70; H, 5.88; N, 13.72. Found: C, 64.65; H, 5.82; N, 13.66.

4-Methyl-2-[(5-methyl-3-isoxazolyl)amino]methylphenol (3b). This compound was obtained as brown crystals, yield 85%; mp 79–81°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.30$ (s, 3H, CH_3), 2.50 (s, 3H, CH_3), 4.35 (s, 2H, —CH_2—), 5.50 (bs, 1H, NH, D_2O exchangeable), 5.70 (s, 1H, isoxazole-H), 7.00–7.50 (m, 3H, ArH), 10.05 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 219 (M + H$^+$); IR (KBr): 3500 (N—H), 3368 (O—H), 1605 (C=N), 1455 (C=C), 1065 cm^{-1} (C—O). *Anal.* Calcd. for $C_{12}H_{14}N_2O_2$ (218): C, 66.05; H, 6.42; N, 12.84. Found: C, 66.01; H, 5.98; N, 12.81.

4-Methoxy-2-[(5-methyl-3-isoxazolyl)amino]methylphenol (3c). This compound was obtained as brown crystals, yield 85%; mp 92–93°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.35$ (s, 3H, CH_3), 3.7 (s, 3H, CH_3), 4.00 (s, 2H, —CH_2—), 5.50 (bs, 1H, NH, D_2O exchangeable), 5.80 (s, 1H, isoxazole-H), 6.85–7.40 (m, 3H, ArH), 9.85 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 235 (M + H$^+$); IR (KBr): 3490 (N—H), 3350 (O—H), 1620 (C=N), 1460 (C=C), 1150 cm^{-1} (C—O). *Anal.* Calcd. for $C_{12}H_{14}N_2O_3$ (234): C, 61.53; H, 5.98; N, 11.96. Found: C, 61.88; H, 5.88; N, 11.85.

4-Chloro-2-[(5-methyl-3-isoxazolyl)amino]methylphenol (3d). This compound was obtained as brown crystals, yield 80%; mp 105–107°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.35$ (s, 3H, CH_3), 3.70 (s, 2H, —CH_2—), 4.50 (bs, 1H, NH, D_2O exchangeable), 6.02 (s, 1H, isoxazole-H), 7.00–7.50 (m, 3H, ArH), 10.02 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 239 (M + H$^+$); IR (KBr): 3550 (N—H), 3415 (O—H), 1630 (C=N), 1510 (C=C), 1205 cm^{-1} (C—O). *Anal.* Calcd. for $C_{11}H_{11}N_2O_2Cl$ (238): C, 55.46; H, 4.62; N, 11.76. Found: C, 55.50; H, 4.58; N, 11.80.

4-Bromo-2-[(5-methyl-3-isoxazolyl)amino]methylphenol (3e). This compound was obtained as brown crystals, yield 80%; mp 121–123°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.40$ (s, 3H, CH_3), 3.95 (s, 2H, —CH_2—), 5.00 (bs, 1H, NH, D_2O exchangeable), 5.95 (s, 1H, isoxazole-H), 7.20–7.80 (m, 3H, ArH), 9.80 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 283 (M + H$^+$); IR (KBr): 3500 (N—H), 3395 (O—H), 1615 (C=N), 1560 (C=C), 1180 cm^{-1} (C—O). *Anal.* Calcd. for $C_{11}H_{11}N_2O_2Br$ (282): C, 46.80; H, 3.90; N, 9.92. Found: C, 46.95; H, 4.01; N, 9.85.

General procedure for the preparation of *N*-(2-hydroxybenzyl)-*N*-(5-methyl-3-isoxazolyl)-*N*′-phenylthioureas (4a–4f). To chloroform solution (15 mL) of amino methylphenols 3 (0.01 mol) arylisothio cyanate (0.01 mol) was slowly added with stirring. The reaction mixture was stirred at 90°C for 6 h. The solvent was removed by distillation under reduced pressure and the crude product was re-crystallized from ethanol.

N-(2-Hydroxybenzyl)-N-(5-methyl-3-isoxazolyl)-N′-phenylthiourea (4a). This compound was obtained as brown crystals, yield 85%; mp 100–102°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta =$ 2.30 (s, 3H, CH_3), 4.60 (s, 2H, CH_2), 6.01 (s, 1H, isoxazole-H), 6.8–7.8 (m, 9H, ArH), 8.52 (bs, 1H, NH, D_2O exchangeable), 9.42 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 340 (M + H$^+$); IR (KBr): 3239 (N—H), 3180 (O—H), 1641 (C=N), 1582, 1515 (C=C), 1225 cm^{-1} (C=S). *Anal.* Calcd. for $C_{18}H_{17}N_3O_2S$ (339): C, 63.71; H, 5.01; N, 12.38.Found: C, 63.59; H, 4.95; N, 12.35.

N′-(4-Chlorophenyl)-N-(2-hydroxybenzyl)-N-(5-methyl-3-isoxazolyl) thiourea (4b). This compound was obtained as brown crystals, yield 88%; mp 124–126°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.35$ (s, 3H, CH_3), 4.94 (s, 2H, CH_2), 5.96 (s, 1H, isoxazole-H), 7.01–7.82 (m, 8H, ArH), 8.80 (bs, 1H, NH, D_2O exchangeable), 9.50 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 374 (M + H$^+$); IR (KBr): 3300 (N—H), 3225 (O—H), 1640 (C=N), 1575 (C=C), 1230 cm^{-1} (C=S). *Anal.* Calcd. for $C_{18}H_{16}N_3O_2SCl$ (373): C, 57.90; H, 4.28; N, 11.26. Found: C, 57.86; H, 4.25; N, 11.29.

N′-(4-Bromophenyl)-N-(2-hydroxybenzyl)-N-(5-methyl-3-isoxazolyl) thiourea (4c). This compound was obtained as brown crystals, yield 80% mp 133–135°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.38$ (s, 3H, CH_3), 4.85 (s, 2H, CH_2), 6.00 (s, 1H, isoxazole-H), 7.23–7.85 (m, 8H, ArH), 9.00 (bs, 1H, NH, D_2O exchangeable), 10.25 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 418 (M + H$^+$); *Anal.* Calcd. for $C_{18}H_{16}N_3O_2SBr$ (417): C, 51.79; H, 3.83; N, 10.07. Found: C, 51.82; H, 3.85; N, 9.98. IR (KBr): 3350 (N—H), 3200 (O—H), 1515 (C=C), 1225 cm^{-1} (C=S).

N-(2-Hydroxybenzyl)-N-(5-methyl-3-isoxazolyl)-N′-(4-methylphenyl) thiourea (4d). This was obtained as compound brown crystals, yield 85%; mp 120–122°C, ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 2.40$ (s, 3H, CH_3), 2.52 (s, 3H, CH_3), 4.75 (s, 2H, CH_2), 6.12 (s, 1H, isoxazole-H), 7.50–8.20 (m, 8H, ArH), 8.90 (bs, 1H, NH, D_2O exchangeable), 10.08 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 354 (M + H$^+$); IR

N-(2-Hydroxy-5-methylbenzyl)-N-(5-methyl-3-isoxazolyl)-N′-phenylthiourea (4e). This compound was obtained as brown crystals, yield 88%; mp 136–138°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.41 (s, 3H, CH_3), 2.50 (s, 3H, CH_3), 4.66 (s, 2H, CH_2), 5.98 (s, 1H, isoxazole-H), 7.20–8.00 (m, 8H, ArH), 9.00 (bs, 1H, NH, D_2O exchangeable), 10.05 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 354 (M + H$^+$); IR (KBr): 3380 (N—H), 3290 (O—H), 1565 (C=C), 1235 cm^{-1} (C=S). *Anal.* Calcd. for $C_{19}H_{19}N_3O_2S$ (353): C, 64.58; H, 5.38; N, 11.89. Found: C, 64.55; H, 5.35; N, 11.95.

N-(2-Hydroxy-5-methoxybenzyl)-N-(5-methyl-3-isoxazolyl)-N′-phenylthiourea (4f). This compound was obtained as brown crystals, yield 80%; mp 127–129°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.38 (s, 3H, CH_3), 3.80 (s, 3H, OCH_3), 4.70 (s, 2H, CH_2), 6.20 (s, 1H, isoxazole-H), 7.00–7.85 (m, 8H, ArH), 8.98 (bs, 1H, NH, D_2O exchangeable), 9.80 (bs, 1H, OH, D_2O exchangeable). EI-MS: *m/z* 370 (M + H$^+$); IR (KBr): 3375 (N—H), 3185 (O—H), 1560 (C=C), 1215 cm^{-1} (C=S). *Anal.* Calcd. for $C_{19}H_{19}N_3O_2S$ (369): C, 61.78; H, 5.14; N, 11.38. Found: C, 61.82; H, 5.08; N, 11.35.

General procedure for the preparation of 5-(5-methylisoxazol-3-yl)-3-aryl-3,4,5,6-tetrahydro-2*H*-1,3,5-benzoxadiazocine-4-thiones (5a–5f). To an ethanolic solution (15 mL) of thioureas 4 (0.01 mol), Formaldehyde (0.01 mol) was slowly added with stirring. The mixture was refluxed for 6–8 h (Monitored with TLC). The gummy product obtained, after the removal of solvent, was processed with pet ether. The product was purified by re-crystallization from ethanol.

5-(5-Methyl-3-isoxazolyl)-3-phenyl-3,4,5,6-tetrahydro-2H-1,3,5-benzoxadiazocine-4-thione (5a). This compound was obtained as pale brown crystals, yield 90%; mp 128–129°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.30 (s, 3H, CH_3), 4.55 (s, 2H, CH_2), 5.88 (s, 2H, CH_2), 6.02 (s, 1H, isoxazole-H), 7.02–7.65 (m, 9H, ArH). EI-MS: *m/z* 352 (M + H$^+$); IR (KBr): 1610 (C=N), 1220 cm^{-1} (C=S). *Anal.* Calcd. for $C_{19}H_{17}N_3O_2S$ (351): C, 64.95; H, 4.84; N, 11.96. Found: C, 65.01; H, 4.82; N, 11.92.

3-(4-Chlorophenyl)-5-(5-methyl-3-isoxazolyl)-3,4,5,6-tetrahydro-2H-1,3,5-benzoxadiazocine-4-thione (5b). This compound was obtained as pale brown crystals, yield 85%; mp 145–147°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.36 (s, 3H, CH_3), 4.62 (s, 2H, CH_2), 6.00 (s, 2H, CH_2), 6.20 (s, 1H, isoxazole-H), 7.23–7.85 (m, 8H, ArH). EI-MS: *m/z* 386 (M + H$^+$); IR (KBr): 1625 (C=N), 1210 cm^{-1} (C=S). *Anal.* Calcd. for $C_{19}H_{16}N_3O_2SCl$ (385): C, 59.22; H, 4.15; N, 10.90. Found: C, 59.17; H, 4.10; N, 11.00.

3-(4-Bromophenyl)-5-(5-methyl-3-isoxazolyl)-3,4,5,6-tetrahydro-2H-1,3,5-benzoxadiazocine-4-thione (5c). This compound was obtained as pale brown crystals, yield 85%; mp 160–162°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.40 (s, 3H, CH_3), 4.80 (s, 2H, CH_2), 6.05 (s, 2H, CH_2), 6.25 (s, 1H, isoxazole-H), 7.50–7.88 (m, 8H, ArH). EI-MS: *m/z* 430 (M + H$^+$); IR (KBr): 1600 (C=N), 1202 cm^{-1} (C=S). *Anal.* Calcd. for $C_{19}H_{16}N_3O_2SBr$ (429): C, 53.14; H, 3.72; N, 9.79. Found: C, 53.09; H, 3.70; N, 9.75.

5-(5-Methyl-3-isoxazolyl)-3-(4-methylphenyl)-3,4,5,6-tetrahydro-2H-1,3,5-benzoxadiazocine-4-thione (5d). This compound was obtained as pale brown crystals, yield 88%; mp 140–142°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.38 (s, 3H, CH_3), 2.48 (s, 3H, CH_3), 4.75 (s, 2H, CH_2), 5.85 (s, 2H, CH_2), 6.05 (s, 1H, isoxazole-H), 7.25–7.98 (m, 8H, ArH). EI-MS: *m/z* 366 (M + H$^+$); IR (KBr): 1618 (C=N), 1215 cm^{-1} (C=S). *Anal.* Calcd. for $C_{20}H_{19}N_3O_2S$ (365): C, 65.75; H, 5.20; N, 11.50. Found: C, 65.81; H, 5.15; N, 11.48.

8-Methyl-5-(5-methyl-3-isoxazolyl)-3-phenyl-3,4,5,6-tetrahydro-2H-1,3,5-benzoxadiazocine-4-thione (5e). This compound was obtained as pale brown crystals, yield 80%; mp 155–157°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.42 (s, 3H, CH_3), 2.52 (s, 3H, CH_3), 4.60 (s, 2H, CH_2), 5.80 (s, 2H, CH_2), 6.02 (s, 1H, isoxazole-H), 7.00–7.65 (m, 8H, ArH). EI-MS: *m/z* 366 (M + H$^+$); IR (KBr): 1610 (C=N), 1225 cm^{-1} (C=S). *Anal.* Calcd. for $C_{20}H_{19}N_3O_2S$ (365): C, 65.75; H, 5.20; N, 11.50. Found: C, 65.70; H, 5.22; N, 11.47.

8-Methoxy-5-(5-methyl-3-isoxazolyl)-3-phenyl-3,4,5,6-tetrahydro-2H-1,3,5-benzoxadiazocine-4-thione (5f). This compound was obtained as pale brown crystals, yield 80%; mp 165–167°C, ^{1}H NMR (300 MHz, $CDCl_3$): δ = 2.38 (s, 3H, CH_3), 3.80 (s, 3H, OCH_3), 4.80 (s, 2H, CH_2), 6.00 (s, 2H, CH_2), 6.15 (s, 1H, isoxazole-H), 7.00–7.50 (m, 8H, ArH). EI-MS: *m/z* 382 (M + H$^+$); IR (KBr): 1625 (C=N), 1235 cm^{-1} (C=S). *Anal.* Calcd. for $C_{20}H_{19}N_3O_3S$ (381): C, 62.99; H, 4.98; N, 11.02. Found: C, 63.05; H, 5.01; N, 11.00.

5a~v **6a~v**

The three-component condensation of 3-amino-5-alkylthio-1,2,4-triazoles with aromatic aldehydes and β-ketoester was studied to develop a regioselective Biginelli-like reaction. The results indicated that the reaction solvent and the properties of the β-ketoester component displayed great influence on the regioselectivity. This is the first report about the regioselectivity of the aminotriazole-based Biginelli-like reaction.

J. Heterocyclic Chem., **46**, 139 (2009).

INTRODUCTION

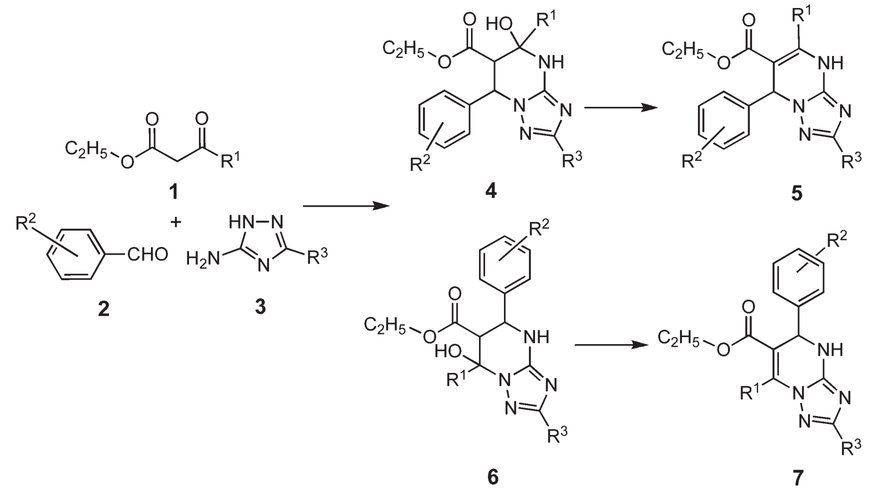
In the last decades, dihydropyrimidinones (DHPMs) and their sulfur analogs have attracted much attention because of their wide range of biological activities. For example, many DHPMs were reported to be calcium or/and potassium channel blockers and openers [1], antihypertensive agents [2], α-adrenergic antagonists [3], neuropeptide Y (NPY) antagonists [4], and HIV gp-120-CD4 inhibitors [5]. The most important and direct method for the synthesis of DHPMs is based on the Biginelli reaction reported first in 1893 [6]. The classical Biginelli reaction of an aldehyde, a β-ketoester, and urea or thiourea requires strongly acidic conditions. Recently, the Biginelli reaction was extended to the synthesis of dihydrotriazolo-pyrimidine by replacing the urea component with 5-amino-1,2,4-triazole [7–12]. Because the β-ketoester and 5-amino-1,2,4-triazole are asymmetric, four possible products (**4**, **5**, **6**, and **7**) could be obtained theoretically (Scheme 1) according to the mechanism of the traditional Biginelli reaction. However, so far no attention has been paid to the regioselectivity of the aminoazole-based Biginelli reaction.

The existing results about the aminoazole-based Biginelli-like reaction indicated that only product **5** was obtained or only product **4** was obtained at first, which then suffered subsequent dehydration to afford product **5** [7–12]. No reports about the formation of products **6** or **7** could be found in the existing literature. As a continuation of our systematic research work on the synthesis and biological activity of triazolopyrimidines [13–16], we report herein the first example of regioselective Biginelli-like reactions based on 3-alkylthio-5-amino-1,2,4-triazole, in which products **5** and **6** could be produced by regioselectivity depending on the reaction conditions.

RESULTS AND DISCUSSION

First, the reaction of ethyl acetoacetate, 4-methoxybenzaldehyde, and 3-methylthio-5-amino-1,2,4-triazole was selected as a model reaction. Some reported catalysts or additives, such as H_3BO_3 [17], *p*-toluene sulfonic acid (TSA) [18], $FeCl_3$ [19], $InCl_3$ [20], and HCl [21], and solvents, such as C_2H_5OH, DMF, H_2O, THF, HOAc, CH_2Cl_2, and $CHCl_3$, were screened. As shown in Table 1, the TSA/H_2O system was found to give almost equivalent amounts of products **5a** and **6a** with a moderate overall yield (**5a** and **6a**, 69%). Then, this system was extended to other substrates, and the results are listed in Table 2. As shown in Table 2, when ethyl acetoacetate and ethyl chloroacetoacetate acted as β-ketoester components, two isomers were isolated in all cases. Interestingly, only one isomer was isolated for the reaction of ethyl trifluoroacetoacetate and 4-substituted benzaldehyde. For example, the reactions of 4-methoxybenzaldehyde (Table 2, entry 15), 4-chlorobenzaldehyde (Table 2, entry 16), 4-chlorobenzaldehyde (Table 2, entry 17), 3,4-dichlorobenzaldehyde (Table 2, entry 18), and 4-nitrobenzaldehyde (Table 2, entry 19) afforded isomers **5o–s** in isolated yields of 40, 48, 49, 51, and 55%, respectively. However, the reactions of benzaldehyde (Table 2, entry 21) and 4-methylbenzaldehyde (Table 2, entry 22) afforded product **6u-v** in isolated yields of 80% and 60%, respectively. However, the reactions of 2-fluorobenzaldehyde (Table 2, entry 20) also

Scheme 1



afforded product **6t**. From these results, we can conclude that the electronic property and the position of the R^1 group has the most important effect on the regioselectivity of the aminotriazole-based Biginelli reaction in H_2O solution. Additionally, the effect of R^2 group on the regioselectivity is complex, whereas the R^3 group seems to have no obvious effect on the regioselectivity.

In addition, as shown in Table 1, the reaction under the system of HCl/C_2H_5OH afforded regioselectivity isomer **5a** in a yield of 32%, a little higher than that in DMF solution. Then, we studied the extension of this reaction system to other substrates, and the results are listed in Table 3. Additionally, microwave irradiation has been proven to be a powerful technique for promoting a variety of chemical reactions [22–25]. The main benefits of performing reactions under microwave irradiation conditions are significant rate enhancements and higher yields. Recently, the technique of microwave irradiation was also applied to improve the yields and shorten the reaction time of Biginelli reactions [26–28]. So, the results in C_2H_5OH solution under microwave irradiation were compared with those under conventional heating as listed in Table 3, which indicated that the yields under microwave irradiation were improved as

Table 1

[a] Detected by HPLC, but unable to be isolated.

expected by 3–10%, and the reaction time was also shortened from 18 h to 30 min.

The structures of compounds **4–7** correspond to the direction of the interaction established earlier in the reactions between 3-amino-5-alkylthio-1,2,4-triazoles and arylidenacetoacetates (**8**) (Scheme 2). Formation of the pyrimidine ring with the participation of the arylidene derivatives (**8**) occurs *via* interaction of the β-carbon atom of the acetoacetate with the carbonyl group of the aldehydes. For example, in H_2O solution with TSA as catalyst, the reaction proceeded first with the participation of $N_{(2)}$ or $3\text{-}NH_2$ of the 3-amino-5-alkylthio-1,2,4-triazoles to afford regioselectivity ethyl 7-aryl-2-alkylthio-4,7-dihydro-1,2,4-triazolo-[1,5-*a*]pyrimidine-6-carboxylate (**5**) or ethyl-7-hydroxy-7-alkyl-5-aryl-2-alkylthio-4,5,6,7-tetrahydro-1,2,4-triazolo[1,5-*a*]pyrimidine-6-carboxylate (**6**) depending on the property of the aromatic aldehydes when ethyl trifluoroacetoacetate was used as the β-ketoester component. When ethyl acetoacetate and ethyl chloroacetoacetate acted as β-ketoester components, the reaction always produced two isomers **5** and **6**. However, the reactions in C_2H_5OH solution always proceeded first with the participation of $N_{(2)}$ to produce regioselectivity of the isomer **5**.

Recently, Chebanov *et al.* reported the three-component condensation of 3-amino-5-alkylthio-1,2,4-triazoles with aromatic aldehydes and acetoacetamides in C_2H_5OH solution under microwave irradiation without any catalyst [12]. Prompted by these results, we also examined the microwave-assisted aminoazole-based Biginelli-like reaction in C_2H_5OH solution without any catalyst. The results shown in Table 3 indicated that the yields were improved significantly compared with those in the presence of HCl as catalyst. Further, it should be noted that different from the situation in H_2O solution using TSA as catalyst, only isomer **5** was formed using C_2H_5OH as reaction solvent no matter what β-ketoester component was used. Additionally, the properties of the R^1 and R^2 group displayed great effects on the yields of product **5**. Ethyl trifluoroacetoacetate always gave higher yields than ethyl acetoacetate and ethyl chloroacetoacetate. Benzaldehydes with electron-withdrawing group

[a] Yields of the reactions without any catalyst under conventional heating.

[b] Yields of the reactions without any catalyst under microwave irradiation.

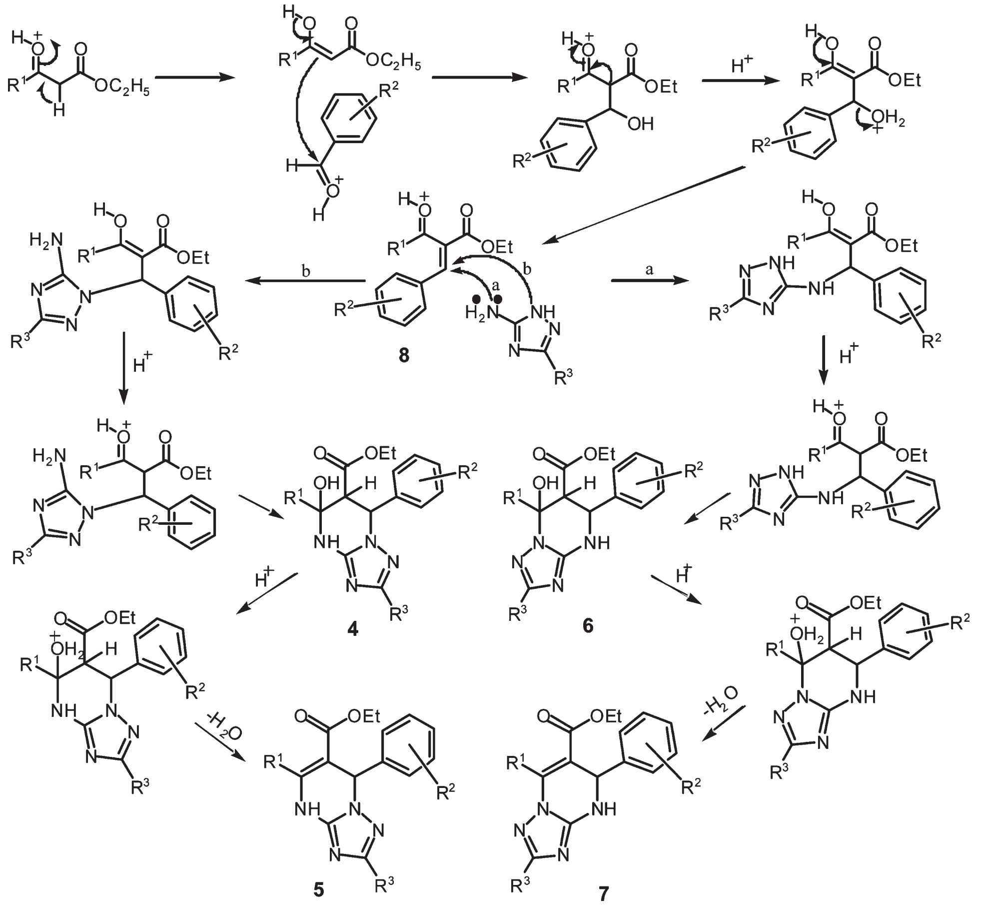
always afforded higher yields of products than benzaldehydes with electron-donating groups. For example, the reaction of 4-pyridylaldehyde (entry 5, Table 3) gave the highest yield (80% in the presence of HCl, 82% without any catalyst) among eight aromatic aldehydes used in this study.

Structure determination. As shown in Scheme 1, four possible products could be obtained theoretically, but only two isomers, compounds **5** and **6**, were identified in this study. The structures of **5** and **6** were assigned by ^1H NMR, ^{13}C NMR, MS, and X-ray diffraction analysis to be ethyl 7-aryl-2-alkylthio-4,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine-6-carboxylate and ethyl 7-hydroxy-7-alkyl-5-aryl-2-alkylthio-4,5,6,7-tetrahydro-1,2,4-triazolo[1,5-*a*]pyrimidine-6-carboxylate, respectively. For example, compound **5d** displayed two single peaks at 6.77 and 10.90 ppm for 7-CH and 4-NH, respectively, whereas an obvious AB system at 3.44 and 5.62 ppm for 5-CH and 6-CH was observed in the ^1H NMR spectrum of compound **6d**. The peak for the 4-NH of compound **6d** appeared at 6.88 ppm. Ultimately, the structures of **5d** and **6d** were established on the basis of a X-ray analysis as shown in Figure 1.

CONCLUSIONS

In summary, the three-component condensation of 3-amino-5-alkylthio-1,2,4-triazoles with aromatic aldehydes and β-ketoester was studied. The obtained results showed that the reaction solvent and the properties of the β-ketoester components had a great influence on the regioselect. In H_2O solution with TSA as catalyst, the reaction proceeded first with the participation of $N_{(2)}$ or $3\text{-}NH_2$ of the 3-amino-5-alkylthio-1,2,4-triazoles to afford regioselectivity ethyl 7-aryl-2-alkylthio-4,7-

Scheme 2. The hypothetic mechanism of reaction.



dihydro-1,2,4-triazolo-[1,5-*a*]pyrimidine-6-carboxylate (**5**) or ethyl-7-hydroxy-7-alkyl-5-aryl-2-alkylthio-4,5,6,7-tetrahydro-1,2,4-triazolo[1,5-*a*]pyrimidine-6-carboxylate (**6**) depending on the property of the aromatic aldehydes when ethyl trifluoroacetoacetate was used as the β-ketoester component. When ethyl acetoacetate and ethyl chloroacetoacetate acted as β-ketoester components, the reaction always produced two isomers **5** and **6**. However, the reactions in C_2H_5OH solution always proceeded first with the participation of $N_{(2)}$ to produce regioselectivity isomer **5**. The yields of the reaction in C_2H_5OH solution in the absence of any catalyst were improved significantly when compared with those in the presence of HCl as catalyst. Additionally, compared with the conventional heating, microwave irradiation improved the yields of the reaction in C_2H_5OH solution and shortened the reaction time to a great extent. To our knowledge, this is the first report about the regioselectivity of aminotriazole-based Biginelli-like reactions.

EXPERIMENTAL

Melting points are uncorrected. Mass spectra were measured on a Finnigan Trace MS spectrometer. NMR spectra were recorded in $CDCl_3$ on a Varian Mercury 400 spectrometer, and resonances are given in ppm (δ) relative to TMS. HPLC analyses were performed on an Agilent 1100 MWD instrument. Microwave irradiation reactions were carried out on a Smith-synthesizer^{TM} instrument.

General procedure for the three-component reaction in H_2O solution. A solution of β-ketoester (1 mmol), aromatic aldehyde (1 mmol), and 3-amino-5-alkylthio-1,2,4-triazoles (1 mmol) in H_2O (3 mL) containing a catalytic amount of TSA was heated under 80°C for 10 h. The resulting mixture was extracted with CH_2Cl_2 (10 mL × 3), and then the extract was dried over sodium sulfate and filtered. The filtrate was condensed under reduced pressure, and the residue was purified by chromatography on SiO_2 ($V_{\text{acetone}}/V_{\text{petroleum ether}} = 1/10$) to afford products **5** and **6**.

General procedure for the three-component reaction in C_2H_5OH solution using HCl as catalyst. A solution of β-ketoester (1 mmol), aromatic aldehyde (1 mmol), and 3-amino-5-alkylthio-1,2,4-triazoles (1 mmol) in EtOH (3 mL)

Compound 5m. White solid, mp 293–294; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.17 (t, 3H, *J* = 6.8 Hz), 3.80 (s, 3H), 4.11 (q, 2H, *J* = 6.8 Hz), 4.16 (d, 1H, *J* = 12.8 Hz), 4.28 (d, 1H, $J = 12.8$ Hz), 4.90 (d, 1H, $J = 12.0$ Hz), 5.07 (d, 1H, $J = 12.0$ Hz), 6.35 (s, 1H), 6.84–7.24 (m, 9H), 10.99 (s, 1H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.95, 36.67, 39.83, 55.25, 59.56, 60.77, 101.29, 113.91, 127.26, 128.36, 128.64, 128.97, 132.71, 137.22, 143.25, 147.61, 157.84, 159.64, 164.44; EI-MS (70Ev, *m/z*) (relative intensity %): 472 (10), 470 (M^+, 40), 462 (7), 434 (70), 401 (16), 373 (10), 355 (12), 327 (12), 313 (21), 283 (24), 267 (23), 241 (22), 228 (25), 197 (20), 185 (20), 172 (14), 158 (12), 123 (28), 115 (10), 91 (100); Elemental *Anal.* Calcd. for $C_{23}H_{23}ClN_4O_3S$: C, 58.65; H, 4.92; N, 11.90; Found: C, 58.88; H, 5.12; N, 12.05.

Compound 5n. White solid, mp > 300; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.16 (t, 3H, $J = 7.2$ Hz), 4.11 (q, 2H, $J = 7.2$ Hz), 4.15 (d, 1H, $J = 13.6$ Hz), 4.27 (d, 1H, $J = 13.6$ Hz), 4.92 (d, 1H, $J = 12.0$ Hz), 5.07 (d, 1H, $J = 12.0$ Hz), 6.36 (s, 1H), 7.17–7.32 (m, 9H), 10.92 (s, 1H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.95, 36.54, 39.80, 59.52, 60.95, 100.63, 127.34, 128.37, 128.81, 128.86, 128.92, 134.46, 137.12, 138.87, 143.75, 147.59, 158.28, 164.18; EI-MS (70Ev, *m/z*) (relative intensity %): 478 (14), 476 (54), 474 (M^+, 73), 438 (57), 405 (31), 391 (23), 377 (10), 362 (17), 327 (9), 288 (10), 258 (13), 246 (14), 228 (9), 162 (7), 149 (8), 133 (34), 105 (22), 91 (100); Elemental *Anal.* Calcd. for $C_{22}H_{20}Cl_2N_4O_2S$: C, 55.58; H, 4.24; N, 11.79; Found: C, 55.41; H, 4.51; N, 11.63.

Compound 5o. White solid, mp 154–155; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.16 (t, 3H, $J = 7.2$ Hz), 2.46 (s, 3H), 3.79 (s, 3H), 4.12 (m, 2H), 6.38 (s, 1H), 6.86–7.26 (m, 4H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.60, 14.16, 55.21, 60.11, 61.66, 106.45, 114.11, 115.73, 118.48, 121.22, 123.97, 128.78, 130.15, 130.52, 130.87, 147.11, 159.98, 160.76, 163.17; EI-MS (70Ev, *m/z*) (relative intensity %): 416 (5), 414 (M^+, 100), 385 (25), 367 (78), 341 (44), 325 (12), 294 (10), 279 (16), 233 (6), 213 (9), 170 (4), 85 (4); Elemental *Anal.* Calcd. for $C_{17}H_{17}F_3N_4O_3S$: C, 49.27; H, 4.13; N, 13.52; Found: C, 49.42; H, 4.36; N, 13.69.

Compound 5p. White solid, mp 188–189; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.17 (t, 3H, $J = 7.2$ Hz), 2.45 (s, 3H), 4.13 (m, 2H), 6.40 (s, 1H), 7.25–7.35 (m, 4H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.60, 14.12, 60.02, 61.87, 92.29, 105.74, 115.60, 118.36, 121.11, 123.86, 128.87, 129.09, 130.83, 131.20, 131.57, 135.05, 136.76, 147.06, 161.17, 162.92; EI-MS (70Ev, *m/z*) (relative intensity %): 420 (29), 418 (M^+, 100), 389 (32), 371 (62), 349 (32), 307 (21), 279 (17), 263 (3), 233 (8), 217 (5), 182 (3), 111 (5); Elemental *Anal.* Calcd. for $C_{16}H_{14}ClF_3N_4O_2S$: C, 45.88; H, 3.37; N, 13.38; Found: C, 45.62; H, 3.47; N, 13.11.

Compound 5q. White solid, mp 160–161; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.16 (t, 3H, $J = 7.2$ Hz), 4.12 (m, 2H), 4.12 (d, 1H, $J = 13.2$ Hz), 4.24 (d, 1H, $J = 13.2$ Hz), 6.39 (s, 1H), 7.18–7.34 (m, 9H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.59, 35.77, 59.99, 61.84, 105.47, 115.57, 118.32, 121.07, 123.82, 127.22, 128.27, 128.90, 129.07, 129.82, 130.94, 131.31, 131.68, 132.04, 135.01, 136.77, 146.96, 159.64, 162.94; EI-MS (70Ev, *m/z*) (relative intensity %): 496 (32), 494 (M^+, 100), 461 (65), 449 (4), 415 (12), 403 (6), 390 (4), 217 (3), 172 (4), 121 (7), 91 (99); Elemental *Anal.* Calcd. for $C_{22}H_{18}ClF_3N_4O_2S$: C, 53.39; H, 3.67; N, 11.32; Found: C, 53.62; H, 3.84; N, 11.08.

Compound 5r. White solid, mp 188–189; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.20 (t, 3H, $J = 7.2$ Hz), 2.47 (s, 3H), 4.16 (m, 2H), 6.39 (s, 1H), 7.14–7.45 (m, 3H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.60, 14.11, 59.58, 61.92, 104.87, 114.19, 115.54, 118.33, 121.08, 123.79, 126.80, 129.61, 130.93, 131.37, 131.82, 132.22, 132.51, 133.03, 133.42, 138.44, 147.06, 161.54, 162.80; EI-MS (70Ev, *m/z*) (relative intensity %): 454 (100), 452 (M^+, 88), 423 (32), 405 (84), 383 (43), 359 (10), 307 (39), 279 (26), 251 (6), 233 (10), 201 (5), 165 (7), 109 (6); Elemental *Anal.* Calcd. for $C_{16}H_{13}Cl_2F_3N_4O_2S$: C, 42.40; H, 2.89; N, 12.36; Found: C, 42.50; H, 3.05; N, 12.05.

Compound 5s. Yellow solid, mp 209–210; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.19 (t, 3H, $J = 7.2$ Hz), 2.45 (s, 3H), 4.15 (m, 2H), 6.54 (s, 1H), 7.51–8.25 (m, 4H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.60, 14.02, 59.83, 62.14, 104.58, 115.49, 118.30, 120.87, 124.13, 128.61, 131.88, 132.22, 132.60, 132.93, 144.79, 147.20, 148.14, 161.73, 162.68; EI-MS (70Ev, *m/z*) (relative intensity %): 244 (3), 227 (2), 199 (2), 138 (20), 107 (33), 77 (100); Elemental *Anal.* Calcd. for $C_{16}H_{14}F_3N_5O_4S$: C, 44.76; H, 3.29; N, 16.31; Found: C, 45.02; H, 3.38; N, 16.05.

Compound 5t. White solid, mp 155–156; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.15 (t, 3H, $J = 7.2$ Hz), 2.45 (s, 3H), 4.04 (m, 2H), 6.65 (s, 1H), 7.03–7.35 (m, 4H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.54, 14.10, 55.83, 61.68, 104.53, 115.56, 115.89, 116.22, 118.40, 121.13, 123.83, 124.44, 125.46, 125.60, 129.82, 130.87, 131.61, 131.92, 132.27, 132.58; EI-MS (70Ev, *m/z*) (relative intensity %): 402 (M^+, 53), 373 (13), 353 (27), 333 (22), 307 (12), 279 (9), 266 (10), 249 (22), 198 (14), 168 (99), 139 (100), 124 (92), 106 (32); Elemental *Anal.* Calcd. for $C_{16}H_{14}F_4N_4O_2S$: C, 47.76; H, 3.51; N, 13.92; Found: C, 48.02; H, 3.76; N, 14.15.

Compound 5u. White solid, mp 179–180; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.14 (t, 3H, $J = 7.2$ Hz), 2.46 (s, 3H), 4.04 (m, 2H), 6.43 (s, 1H), 7.30–7.38 (m, 3H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.60, 14.11, 60.58, 60.72, 61.74, 106.19, 115.68, 118.48, 121.19, 123.90, 127.43, 128.83, 129.04, 130.51, 130.79, 131.20, 131.57, 138.33, 147.29, 160.81, 163.10; EI-MS (70Ev, *m/z*) (relative intensity %): 385 (19), 384 (M^+, 100), 355 (20), 337 (50), 315 (19), 307 (25), 279 (19), 133 (8); Elemental *Anal.* Calcd. for $C_{16}H_{15}F_3N_4O_2S$: C, 50.00; H, 3.93; N, 14.58; Found: C, 50.08; H, 4.00; N, 14.30.

Compound 5v. White solid, mp 156–157; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 1.16 (t, 3H, $J = 7.2$ Hz), 2.33 (s, 3H), 2.46 (s, 3H), 4.12 (m, 2H), 6.38 (s, 1H), 7.15 (dd, 2H, $J = 8.4$ Hz), 7.19 (dd, 2H, $J = 8.0$ Hz); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.60, 14.12, 21.17, 60.39, 61.57, 106.44, 115.73, 118.54, 121.16, 123.92, 127.33, 129.48, 130.41, 130.72, 131.14, 131.50, 135.45, 138.93, 147.23, 160.83, 163.12; EI-MS (70Ev, *m/z*) (relative intensity %): 400 (5), 398 (M^+, 100), 369 (25), 351 (81), 329 (28), 307 (30), 278 (31), 233 (8), 197 (4), 165 (3), 115 (7); Elemental *Anal.* Calcd. for $C_{17}H_{16}F_4N_4O_2S$: C, 49.04; H, 3.87; N, 13.46; Found: C, 49.25; H, 3.67; N, 13.19.

Compound 6a. White solid, mp 154–155; ^{1}H NMR ($CDCl_3$, 400 MHz) δ (ppm): 0.96 (t, 3H, $J = 7.2$ Hz), 1.89 (s, 3H), 2.43 (s, 3H), 3.04 (d, 1H, $J = 11.2$ Hz), 3.81 (s, 3H), 3.95 (m, 2H), 4.95 (d, 1H, $J = 11.2$ Hz), 5.93 (s, 1H), 6.87–7.34 (m, 4H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ (ppm): 13.71, 14.30, 25.69, 53.84, 55.33, 57.10, 61, 50, 81.83, 114.12, 129.08, 129.74, 153.14, 159.09, 160.10, 169.87; EI-MS (70Ev, *m/z*) (relative intensity %): 379 (8), 378 (M$^+$, 32), 360 (12), 335 (7), 313 (9), 289 (8), 247 (100), 233 (41), 200 (38), 174 (24), 161 (64), 146 (61), 129 (64), 115 (23); Elemental *Anal.* Calcd. for $C_{17}H_{22}N_4O_4S$: C, 53.95; H, 5.86; N, 14.80; Found: C, 53.76; H, 6.04; N, 14.92.

Compound 6d. White solid, mp 151–152; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.97 (t, 3H, *J* = 7.2 Hz), 1.86 (s, 3H), 2.43 (s, 3H), 3.44 (d, 1H, *J* = 11.2 Hz), 4.01 (m, 2H), 5.62 (d, 1H, *J* = 11.2 Hz), 6.88 (s, 1H), 7.25–7.50 (m, 3H); ^{13} C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.69, 14.30, 24.38, 49.63, 52.14, 61.88, 82.10, 127.61, 129.67, 133.89, 139.11, 153.69, 159.52, 169.83; EI-MS (70Ev, *m/z*) (relative intensity %): 418 (4), 416 (M$^+$, 7), 373 (5), 327 (9), 287 (23), 251 (100), 223 (21),199 (15), 170 (8), 13 0 (28), 114 (8); Elemental *Anal.* Calcd. for $C_{16}H_{18}Cl_2N_4O_3S$: C, 46.05; H, 4.35; N, 13.43; Found: C, 46.33; H, 4.08; N, 13.80.

Compound 6f. White solid, mp 140–141; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.96 (t, 3H, *J* = 7.2 Hz), 1.80 (s, 3H), 2.31 (s, 3H), 3.05 (d, 1H, *J* = 11.2 Hz), 3.92 (m, 2H), 4.20 (d, 1H, *J* = 13.2 Hz), 4.27 (d, 1H, *J* = 13.2 Hz), 4.94 (d, 1H, *J* = 11.2 Hz), 5.86 (s, 1H), 7.13–7.37 (m, 9H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.60, 21.11, 25.69, 36.13, 54.33, 56.74, 61.48, 81.87, 127.21, 127.72, 128.44, 129.13, 129.49, 134.52, 137.47, 138.86, 152.90, 157.88, 170.12; EI-MS (70Ev, *m/z*) (relative intensity %): 438 (M$^+$, 5), 369 (2), 308 (50), 275 (30), 231 (27), 217 (72), 206 (65), 187 (21), 173 (24), 143 (28), 115 (51), 102 (16), 90 (100); Elemental *Anal.* Calcd. for $C_{23}H_{26}N_4O_3S$: C, 62.99; H, 5.98; N, 12.78; Found: C, 62.77; H, 6.17; N, 12.94.

Compound 6h. White solid, mp 152–153; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.96 (t, 3H, *J* = 7.2 Hz), 1.78 (s, 3H), 3.01 (d, 1H, *J* = 11.2 Hz), 3.92 (m, 2H), 4.12 (d, 1H, *J* = 13.2 Hz), 4.20 (d, 1H, *J* = 13.2 Hz), 4.96 (d, 1H, *J* = 11.6 Hz), 6.63 (s, 1H), 7.23–7.35 (m, 9H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.70, 25.61, 35.92, 53.68, 56.84, 61.73, 81.85, 127.20, 128.44, 128.91, 129.04, 129.29, 134.77, 136.32, 137.28, 152.91, 157.83, 169.64; EI-MS (70Ev, *m/z*) (relative intensity %): 458 (M$^+$, 2), 328 (64), 295 (48), 251 (49), 237 (36), 217 (42), 206 (100), 189 (9), 173 (46), 165 (37), 141 (11), 115 (11), 101 (18); Elemental *Anal.* Calcd. for $C_{22}H_{23}ClN_4O_3S$: C, 57.57; H, 5.05; N, 12.21; Found: C, 57.82; H, 5.30; N, 12.09.

Compound 6i. White solid, mp 147–148; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.93 (t, 3H, *J* = 7.2 Hz), 2.36 (s, 3H), 2.39 (s, 3H), 3.55 (d, 1H, *J* = 11.6 Hz), 3.88 (d, 1H, *J* = 12.0 Hz), 3.94 (m, 2H), 4.36 (d, 1H, *J* = 11.6 Hz), 4.93 (d, 1H, *J* = 11.2 Hz), 5.82 (s, 1H), 7.17–7.34 (m, 4H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.52, 14.20, 21.24, 46.08, 51.73, 54.14, 61.88, 83.63, 127.81, 129.50, 134.08, 139.22, 153.91, 159.79, 169.90; EI-MS (70Ev, *m/z*) (relative intensity %): 396 (M$^+$, 6), 360 (2), 273 (3), 266 (6), 251 (6), 231 (100), 217 (53), 185 (5), 164 (4), 145 (13), 130 (36), 115 (47), 103 (9); Elemental *Anal.* Calcd. for $C_{17}H_{21}ClN_4O_3S$: C, 51.45; H, 5.33; N, 14.12; Found: C, 51.57; H, 5.05; N, 14.34.

Compound 6m. White solid, mp 147–148; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.94 (t, 3H, *J* = 7.2 Hz), 3.52 (d, 1H, *J* = 11.6 Hz), 3.76 (s, 3H), 3.87 (d, 1H, *J* = 12.0 Hz), 3.96 (m, 2H), 4.02 (d, 1H, *J* = 12.8 Hz), 4.16 (d, 1H, *J* = 12.8 Hz), 4.34 (d, 1H, *J* = 11.6 Hz), 4.91 (d, 1H, *J* = 11.6 Hz), 6.33 (s, 1H), 6.85–7.36 (m, 9H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.60, 35.82, 46.19, 51.89, 53.04, 55.22, 61.73, 83.61, 113.88, 127.11, 128.26, 128.86, 129.37, 137.24, 154.13, 158.30, 160.04, 169.11; EI-MS (70Ev, *m/z*) (relative intensity %): 324 (16), 291 (8), 282 (17), 233 (89), 206 (38), 189 (9), 173 (24), 161 (22), 137 (19), 115 (50), 91 (100); Elemental *Anal.* Calcd. for $C_{23}H_{25}ClN_4O_4S$: C, 56.49; H, 5.15; N, 11.46; Found: C, 56.78; H, 5.06; N, 11.57.

Compound 6n. White solid, mp 150–151; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.97 (t, 3H, *J* = 7.2 Hz), 3.51 (d, 1H, *J* = 11.2 Hz), 3.87 (d, 1H, *J* = 11.2 Hz), 3.94 (m, 2H), 4.03 (d, 1H, *J* = 13.2 Hz), 4.15 (d, 1H, *J* = 13.2 Hz), 4.34 (d, 1H, *J* = 11.2 Hz), 4.93 (d, 1H, *J* = 11.2 Hz), 6.78 (s, 1H), 7.23–7.39 (m, 9H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.60, 35.91, 45.86, 51.69, 53.40, 61.87, 83.73, 127.32, 128.45, 128.86, 129.02, 129.64, 135.03, 135.87, 137.11, 154.10, 158.50, 169.14; EI-MS (70Ev, *m/z*) (relative intensity %): 493 (M$^+$, 1), 419 (1), 366 (2), 328 (61), 295 (43), 286 (21), 251 (4), 237 (99), 206 (100), 190 (10), 173 (45), 165 (33), 136 (23), 115 (29), 101 (25); Elemental *Anal.* Calcd. for $C_{22}H_{22}Cl_2N_4O_3S$: C, 53.55; H, 4.49; N, 11.36; Found: C, 53.78; H, 4.72; N, 11.70.

Compound 6t. White solid, mp 158–159; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.88 (t, 3H, *J* = 7.2 Hz), 2.33 (s, 3H), 3.78 (d, 1H, *J* = 4.0 Hz), 3.84 (m, 2H), 5.44 (d, 1H, *J* = 4.0 Hz), 7.12–7.46 (m, 4H); ^{13}C NMR (DMSO, 100 MHz) δ (ppm): 13.54, 47.03, 48.10, 60.43, 60.61, 81.23, 81.46, 115.25, 115.44, 121.42, 123.74, 123.79, 124.23, 124.67, 127.88, 130.50, 153.93, 155.62, 157.67, 158.33, 159.40, 160.77, 164.65, 165.52; EI-MS (70Ev, *m/z*) (relative intensity %): 422 (6), 420 (M$^+$, 100), 401 (20), 373 (7), 353 (12), 277 (14), 235 (72), 217 (83), 184 (5), 149 (25), 134 (27), 115 (22); Elemental *Anal.* Calcd. for $C_{16}H_{16}F_4N_4O_3S$: C, 45.71; H, 3.84; N, 13.33; Found: C, 45.54; H, 4.05; N, 13.56.

Compound 6u. White solid, mp 143–144; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.88 (t, 3H, *J* = 7.2 Hz), 2.26 (s, 3H), 3.59 (d, 1H, *J* = 4.0 Hz), 3.85 (m, 2H), 5.10 (d, 1H, *J* = 4.4 Hz), 7.32–7.40 (m, 5H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.60, 14.22, 49.89, 54,14, 61.12, 81.87, 82.32, 121.24, 124.13, 126.65, 126.91, 136.14, 155.10, 160.83, 165.44; EI-MS (70Ev, *m/z*) (relative intensity %): 402 (M$^+$, 8), 369 (4), 272 (3), 230 (4), 217 (100), 203 (5), 184 (9), 171 (6), 139 (15), 115 (22); Elemental *Anal.* Calcd. for $C_{16}H_{17}F_3N_4O_3S$: C, 47.76; H, 4.26; N, 13.92; Found: C, 48.04; H, 4.02; N, 14.15.

Compound 6v. White solid, mp 153–154; ^{1}H NMR (CDCl$_3$, 400 MHz) δ (ppm): 0.92 (t, 3H, *J* = 7.2 Hz), 2.29 (s, 3H), 2.34 (s, 3H), 3.56 (d, 1H, *J* = 4.0 Hz), 3.87 (q, 2H, *J* = 7.2 Hz), 5.06 (d, 1H, *J* = 4.0 Hz), 7.07–7.24 (m, 4H); ^{13}C NMR (CDCl$_3$, 100 MHz) δ (ppm): 13.22, 13.58, 14.20, 49.87, 53.90, 61.23, 81.91, 82.19, 118.22, 121.14, 123.88, 126.55, 127.64, 129.61, 132.88, 138.83, 139.74, 155.13, 160.89, 165.54; EI-MS (70Ev, *m/z*) (relative intensity %): 416 (M$^+$, 6), 286 (2), 271 (3), 231 (100), 217 (8), 184 (5), 139 (9), 130 (14), 115 (19); Elemental *Anal.* Calcd. for $C_{17}H_{19}F_3N_4O_3S$: C, 49.03; H, 4.60; N, 13.45; Found: C, 49.37; H, 4.63; N, 13.13.

Acknowledgments. This work was supported by the National NSFC grants (Nos. 20572030, 20432010, 20528201, and 20702018), the Cultivation Fund of the Key Scientific and Technical Innovation Project, Ministry of Education of China (No.705039), and Program for Excellent Research Group of Hubei Province (No. 2004ABC002).

A simple and efficient three component process for the synthesis of 2-amino-2-chromenes utilizing the reaction of aryl aldehydes **1a–1h** with active methylenes **2a,b** and 1-naphthol **3** in refluxing ethanol/piperidine under microwave-heating is described.

J. Heterocyclic Chem., **46**, 149 (2009).

INTRODUCTION

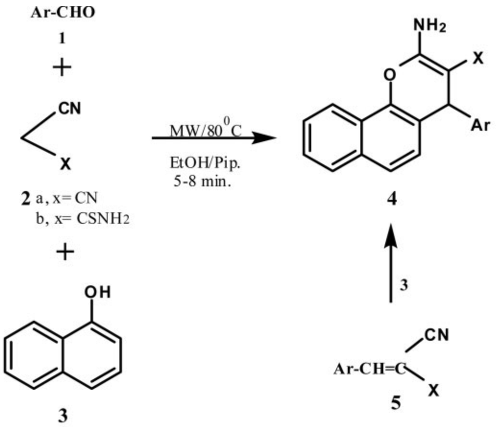
Substituted 2-amino-2-chromenes have received considerable attention due to their importance as pigments, cosmetics, potential agrochemicals, and being the main constituents of many natural products [1–5]. Accordingly, their synthesis has received much attention from organic chemists. These compounds are generally prepared by multicomponent condensation of aromatic aldehyde **1**, active methylene derivatives **2** and activated phenol or naphthol **3** in the presence of piperidine using acetonitrile or ethanol as a solvent under conventional heating for periods ranging from 2–3 h in moderate yields [6–9]. Also, relatively benign reagents such as cetyltrimethylammonium chloride (CTACl) and basic alumina in water have been used [10]. Thus, substituted 2-amino-2-chromenes **4** will be produced in moderate to good yields by heating a mixture of **1**, **2**, and **3** in water in the presence of a catalytic amount of CTACl for 6 h under reflux. It is obvious that, most of these require prolonged reaction time, reagents in stoichiometric amounts and provide moderate yields of the product. Recently [11], a three component condensation in MeOH in the presence of nanosized magnesium oxide as a catalyst at room temperature has been reported. Although, this process is efficient and convenient, the usage of MeOH as a solvent for the reaction and work-up is not recommended due to the toxicity.

In recent years, there has been extensive effort to adapt green technologies in synthetic organic chemistry, so as to minimize waste production, material and energy consumption, and the use of hazardous compounds. Microwave-assisted reactions have received great interest because of their simplicity in operation, enhanced reaction rates, products with high purity, and better yields compared to those conducted by conventional heating [12–14]. Also, a three-component one step reaction is of great interest for cost savings due to raw materials consumption, energy use, and time. We do believe that combining microwave heating technique with a three-component one step reaction will be beneficial and interesting. In continuation to our interest for the synthesis of azoles, azines, and fused rings [15–17], we report herein the synthesis of 2-amino-2-chromenes *via* three-component synthesis by using microwave technique.

RESULTS AND DISCUSSION

The synthesis of 2-amino-2-chromenes under conventional heating technique requires prolonged reaction time and affords moderate yields of products. Conducting a three-component synthesis of these target molecules under microwave irradiation and, to the best of our knowledge, has never been published before. Thus, when a mixture of benzaldehyde **1a**, malononitrile **2a** and α-naphthol **3** in 10 mL of ethanol and in the presence of piperidine as a catalyst was refluxed in a microwave labstation for 5 min at 80°C, the corresponding 2-amino-2-chromene derivative **4a** was obtained in almost quantitative yield (Scheme 1). The structure of the formed product was established by spectral and analytical data and also by comparison with authentic sample synthesized by reaction of benzylidene malononitrile **5** with α-naphthol under conventional heating [18]. Thus,

Scheme 1



1,4, 5	Ar	X	Time (min.)	Yield (%)
a	C_6H_5	CN	5	93
b	4-OCH_3-C_6H_4	CN	5	94
c	4-Cl-C_6H_4	CN	5	88
d	4-NO_2-C_6H_4	CN	10	85
e	3-pyridyl	CN	5	95
f	4-pyridyl	CN	5	89

Three component synthesis of 2-amino-2-chromenes.

IR spectrum for compound **4a** revealed both amino and cyano groups at ν_{max} 3400 and 2200 cm^{-1}, respectively. ^{1}H NMR spectrum of this product revealed signals that are in accord with the proposed structure. It reveals signals at $\delta = 4.77$ (s, 1H, 4H-pyran); 6.8 (br, s, 2H, NH_2), 6.93 (d, $J = 8$ Hz, 1H, H-5), 7.08–7.23 (m, 5H, Ar—H); 7.33–7.43 (m, 3H, Ar—H), 7.52 (d, $J = 8$ Hz, 1H, H-7), 8.10 (d, $J = 8$ Hz, 1H, H-10). ^{13}C NMR revealed signals at $\delta = 40.92$, 61.06, 108.50, 116.6, 120.80, 123.20, 124.80, 125.90, 126.80, 126.92, 127.80, 129.10, 129.50, 133.22, 133.40, 142.90, 143.30, 158.60. To examine the aromatic aldehyde substrate effect on the rate and overall yield, various aldehydes **1b–1d** were used under the aforementioned reaction conditions. From the results, we can see that all reactions proceeded smoothly to afford the corresponding 2-amino-2-chromene derivatives **4b–4d** in high yield. Slightly diminished yields were observed when the substituent is an electron withdrawing group.

To examine the scope of such techniques, heteroaryl and aliphatic aldehydes **1e–1h** were also used and the corresponding 2-amino-2-chromene derivatives **4e–4h** were obtained in high yields. The structure assigned for the reaction products were established based on analytical and spectral data (*cf*. Experimental part for details). Cyanothioacetamide (**2b**) was also examined as an active methylene compound and the corresponding 2-amino-2-chromen **4h** was obtained.

In conclusion, in green chemistry it is generally recognized that the best reaction requires no solvent. In our procedure we used a little amount of ethanol compared to the quantities of starting materials. Refluxing under microwave technique in the presence of this little amount of solvent perform a homogenous heating, which prevents charring of neat samples and offers a simple and high yield process for the synthesis of 2-amino-2-chromene derivatives.

EXPERIMENTAL

All melting points were determined on a Gallenkamp melting point apparatus and are uncorrected. The reactions were conducted in milestone START-Labstation for microwave enhanced chemistry provided with a sensor for adjusting the temperature and a refluxing condenser. IR spectra (KBr) were measured with a Schimadzu Model 470 spectrophotometer.

^{1}H NMR (300 MHz) and ^{13}C NMR (100 MHz) spectra were measured on a Varian spectrometer using DMSO-d_6 as solvent and TMS as internal Standard, chemical shifts are expressed as δ ppm. Analytical data were determined on the Microanalytical Data Unit at Cairo University. Compounds **4g,4h** were found identical with authentic samples [18].

General procedure for the synthesis of 2-amino-2-chromenes (4a–4g). A solution of the appropriate aldehyde **1**, α-naphthol (**2**) and active methylene **3** (0.01 mol) in ethanol (10 mL), and catalytic amount of piperidine (2 drops) was heated under reflux in a milestone labstation at 80°C for a period of 5–8 min. Upon standing at room temperature a solid product was formed which was collected by filtration to afford compounds **4a–4g**. An additional amount of products were obtained *via* evaporation of the solvent under reduced pressure.

2-Amino-3-cyano-4-phenyl-4H-benzo[h]chromene (4a). Compound **4a** (93%) was obtained as colorless crystals (ethanol). M.P. 179–180°C. *Anal.* Calcd. for $C_{20}H_{14}N_2O$ (298.35): C, 80.52; H, 4.73; N, 9.40. Found: C, 80.40; H, 4.63; N, 9.50. IR (KBr): 3420 (NH_2); 2200 (CN) cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ = 4.77 (s, 1H, 4H-pyran); 6.8 (br, s, 2H, NH_2), 6.93 (d, J = 8 Hz, 1H, H-5), 7.08–7.23 (m, 5H, Ar—H); 7.33–7.43 (m, 3H, Ar—H), 7.52 (d, J = 8 Hz, 1H, H-7), 8.10 (d, J = 8 Hz, 1H, H-10).

2-Amino-3-cyano-4-(4-methoxyphenyl)-4H-benzo[h]chromene (4b). Compound **4b** (94%) was obtained as yellow crystals (ethanol). M.P. 188–189°C. *Anal.* Calcd. for $C_{21}H_{16}N_2O_2$ (328.36): C, 76.80; H, 4.91; N, 8.53. Found: C, 76.70; H, 4.80; N, 8.33. IR (KBr): 3430 (NH_2); 2200 (CN) cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ = 3.90 (s, 3H, OCH_3), 4.54 (s, 1H, 4H-pyran), 6.82 (br, s, 2H, NH_2), 7.0 (d, J = 8 Hz, 1H, H-5), 7.10–7.22 (m, 4H, Ar—H), 7.39–7.40 (m, 3H, Ar—H), 7.53 (d, J = 8 Hz, 1H, H-7), 8.12 (d, J = 8 Hz, 1H, H-10).

2-Amino-3-cyano-4-(4-chlorophenyl)-4H-benzo[h]chromene (4c). Compound **4c** (94%) was obtained as yellow crystals (ethanol). M.P. 232–234°C. *Anal.* Calcd. for $C_{20}H_{13}ClN_2O$ (332.78): C, 72.18; H, 3.94; Cl, 10.65; N, 8.42. Found: C, 72.10; H, 3.70; Cl, 10.50; N, 8.20. IR (KBr): 3450 (NH_2); 2200 (CN) cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ = 4.55 (s, 1H, 4H-pyran), 6.70 (br, s, 2H, NH_2), 7.1 (d, J = 8 Hz, 1H, H-5), 7.21–7.33 (m, 4H, Ar—H), 7.40–7.45 (m, 3H, Ar—H), 7.56 (d, J = 8 Hz, 1H, H-7), 8.15 (d, J = 8 Hz, 1H, H-10).

2-Amino-3-cyano-4-(4-nitrophenyl)-4H-benzo[h]chromene (4d). Compound **4d** (85%) was obtained as yellow crystals (ethanol). M.P. 240–241°C. *Anal.* Calcd. for $C_{20}H_{13}N_3O_3$ (343.34): C, 69.96; H, 3.82; N, 12.24. Found: C, 69.80; H, 3.92; N, 12.13. IR (KBr): 3440 (NH_2), 2220 (CN) cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ = 4.58 (s, 1H, 4H-pyran), 6.79 (br, s, 2H, NH_2), 7.18 (d, J = 8 Hz, 1H, H-5), 7.25–7.41 (m, 4H, Ar—H), 7.46–7. 51 (m, 3H, Ar—H), 7.61 (d, J = 8 Hz, 1H, H-7), 8.21 (d, J = 8 Hz, 1H, H-10).

2-Amino-3-cyano-4-(3-pyridyl)-4H-benzo[h]chromene (4e). Compound **4e** (95%) was obtained as yellow crystals (ethanol). M.P. 240–241°C. *Anal.* Calcd. for $C_{19}H_{13}N_3O$ (299.33): C, 76.24; H, 4.38; N, 14.04. Found: C, 76.10; H, 4.50; N, 14.00. IR (KBr): 4310 (NH_2); 2220 (CN) cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ = 4.90 (s, 1H, 4H-pyran); 7.11 (d, J = 8 Hz, 1H, H-5 or H-6), 7.22 (s, 2H, NH_2); 7.33 (dd, J = 8 Hz and 4.5 Hz, pyridine H-5); 7.50–7.70 (m, 4H, H-6 or H-5, H-7, H-8, and pyridine H-6), 7.89 (d, J = 8 Hz, 1H, H-7 or H-10); 8.24 (d, J = 8 Hz,1H, H-7 or H-10), 8.46 (d, J = 4.5 Hz, 1H, pyridine H-4), 8.55 (s, 1H, pyridine H-2).

2-Amino-3-cyano-4-(4-pyridyl)-4H-benzo[h]chromene (4f). Compound **4f** (93%) was obtained as yellow crystals (ethanol). M.P. 200–202°C. *Anal.* Calcd. for $C_{19}H_{13}N_3O$ (299.33): C, 76.24; H, 4.38; N, 14.04. Found: C, 76.13; H, 4.34; N, 14.24. IR (KBr): 3354 (NH_2); 2220 (CN) cm^{-1}. ^{1}H NMR (300 MHz, DMSO-d_6): δ = 4.97 (s, 1H, 4H-pyran), 7.14 (d, J = 8 Hz, 1H, H-5 or H-6), 7.27 (m, 4H, pyridine H-3, pyridine H-5 and NH_2), 7.56–7.73 (m, 2H, H-8 or H-9), 7.66 (d, J = 8 Hz, 1H, H-6 or H-5), 7.80 (d, J = 8 Hz, 1H, H-7 or H-10), 8.22 (d, J = 8 Hz, 1H, H-7, or H-10), 8.52 (d, 2H, J = 5 Hz, pyridine H-2 and H-6).

Acknowledgment. K. U. Sadek is grateful to the *AvH* Foundation for donation of milestone microwave labstation, which is of great help in finishing this work.

An efficient and convenient method for the preparation of pyrimidine and quinazoline derivatives by the one-pot reaction of aromatic aldehydes, cyclic ketones and guanidine carbonate, in the presence of sodium hydroxide under solvent-free condition was reported. This method has the advantages of excellent yields, mild reaction conditions, easy work-up, and being environmentally friendly over the existing procedures.

J. Heterocyclic Chem., **46**, 152 (2009).

INTRODUCTION

Pyrimidine and its derivatives, as the nitrogen-containing heterocycles, are extremely important compounds with high biological activities [1]. The quinazoline nucleus is also a very attractive and useful scaffold in medicinal chemistry: it can be found as a pharmacophore in a wide variety of biologically active compounds, such as antitumorals [2], antibacterials [3], antivirals [4], and many other therapeutic agents [5].

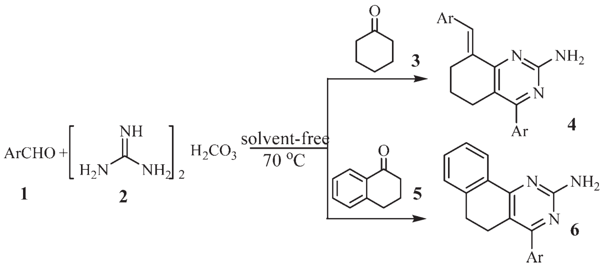
In recent years, because of increasing environmental concerns and the regulatory constraints faced in the chemical and pharmaceutical industries, the development of environmentally friendly organic synthesis has become a crucial and demanding area in modern organic chemical research [6]. In order to avoid using organic solvents, solvent-free organic reactions [7], a ''green'' organic chemistry method, have been of great interest. These have many advantages such as high efficiency and selectivity, easy separation and purification, mild reaction conditions, and reduction in waste produced. Many organic reactions have been carried out just by heating [8].

In continuation to our current studies on the application of solvent-free conditions for the synthesis of organic compounds [9], herein, we would like to report a practical and simple method to prepare pyrimidine and quinazoline derivatives by heating the starting materials under dry conditions.

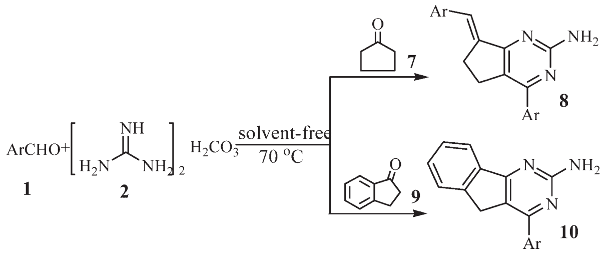
RESULTS AND DISCUSSION

At first, cyclohexanone (2 mmol), aromatic aldehyde (4 mmol), guanidine carbonate (1 mmol) and NaOH (0.2 g) were chosen to react together under solvent-free conditions at 70°C, and the reaction proceeded smoothly in short time (about 15 min) and the corresponding compounds 4-aryl-8-arylidene)-5,6,7,8-tetrahydroquinaz-olin-2-amine (**4a–4h**) could be gained with high yields (Scheme 1). Then, the reagent of 3,4-dihydronaphthalen-1(2*H*)-one (2 mmol) was chosen to replace cyclohexanone to react with aromatic aldehyde (2 mmol), guanidine carbonate (1 mmol) under the same conditions, and the corresponding fused-ring quinazoline derivatives: *viz*. 4-(4-bromophenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (**6a–6h**), were obgained with excellent yields. The results of reactions were listed in Table 1. As shown in Table 1, all the reactions proceeded smoothly with high yields. We also observed that electron-

Scheme 1



Scheme 2



withdrawing substituents (—Cl, —Br), and electron-donating substituents (—CH_3, —OCH_3) had no effect on the reaction.

In order to apply this reaction to a library synthesis, cyclopentanone and indan-1-one were chosen to react with aromatic aldehyde, and guanidine carbonate under same reaction conditions (Scheme 2). To our delight, all reactions could be completed successfully, and (*E*)-7-arylidene)-4-aryl-6,7-dihydro-5*H*-cyclopenta[*d*] pyrimidin-2-amine (**8a–8f**) and 4-aryl-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (**10a–10g**) could be gained with good yields. The reaction results are summarized in Table 2. The structures of **4**, **6**, **8,** and **10** were confirmed by ir, ^{1}H NMR and elemental analysis, furthermore, the reported products were identified by comparison of melting point with those described in the literatures [10].

Although similar compounds have been reported in the literature and the disadvantages of reported methods were obvious, such as long reaction time, lower product yields and harsh conditions, furthermore, the excess of organic solvent was requisite.

In conclusion, an efficient method for the synthesis of pyrimidine and quinazoline derivatives by condensation of cyclic ketone, aromatic aldehydes, and guanidine carbonate was successfully established under solvent-free condition catalyzed by NaOH. The advantages of this procedure are high yields, mild reaction conditions, easy work-up, and environmentally friendly procedure.

EXPERIMENTAL

Melting points were determined on XT-5 microscopic melting-point apparatus and were uncorrected. IR spectra were recorded on a FT Bruker Tensor 27 spectrometer. ^{1}H NMR spectra were obtained from solution in DMSO-d_6 with Me_4Si as internal standard using a Bruker-400 spectrometer. Microanalyses were carried out using a Perkin-Elmer 2400 II analyzer.

General procedure for the synthesis of pyrimidine and quinazoline derivatives. The mixture of ketones **3** and **7**, or **5** and **9** (2 mmol), aromatic aldehydes **2** (4 mmol or 2 mmol), guanidine carbonate **3** (1 mmol) and NaOH (0.2 g) was put in a reaction flask and heated at 70°C for about 15 min. After completing the reaction, the reaction mixture was poured into water, and then washed with water thoroughly. The product was filtered, dried, and recrystallized from 95% ethanol.

Anal. Calcd. For $\mathrm{C_{23}H_{23}N_3}$: C 80.90, H 6.79, N 12.31. Found: C 80.72, H 6.73, N 12.25.

(*E*)-8-(4-Methoxybenzylidene)-4-(4-methoxyphenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4b). This compound was obtained as yellow crystals, mp 230–232°C, Lit. [10d] 245–247°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3482, 3377, 3202, 2934, 1606, 1579, 1538, 1509, 1447, 1406, 1356, 1333, 1298, 1247; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 7.98 (1H, s, ArCH=), 7.53 (2H, d, J = 8.4 Hz, ArH), 7.42 (2H, d, J = 8.4 Hz, ArH), 7.01 (4H, dd, J = 6.0 Hz, J = 6.0 Hz, ArH), 6.28 (2H, s, $\mathrm{NH_2}$), 3.81 (3H, s, $\mathrm{OCH_3}$), 2.80 (3H, s, $\mathrm{OCH_3}$), 2.79 (2H, t, J = 5.6 Hz, $\mathrm{CH_2}$), 2.64 (2H, t, J = 5.6 Hz, $\mathrm{CH_2}$), 1.62 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{23}H_{23}N_3O_2}$: C 73.97, H 6.21, N 11.25. Found: C 73.78, H 6.27, N 11.31.

(*E*)-8-(3,4-Dimethylbenzylidene)-4-(3,4-dimethylphenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4c). This compound was obtained as yellow crystals, mp 191–193°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3494, 3284, 3155, 2921, 1625, 1540, 1503, 1459, 1359, 1335, 1221; 1H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 7.98 (1H, s, ArCH=), 7.33 (1H, s, ArH), 7.25 (3H,m, ArH), 7.19 (2H, t, J = 8.8 Hz, ArH), 6.30 (2H, s, $\mathrm{NH_2}$), 2.80 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$), 2.61 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$), 2.28 (6H, s, 2$\mathrm{CH_3}$), 2.27 (3H, s, $\mathrm{CH_3}$), 2.25 (3H, s, $\mathrm{CH_3}$),1.61 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{25}H_{27}N_3}$: C 81.26, H 7.37, N 11.37. Found: C 81.51, H 7.35, N 11.40.

(*E*)-8-(3,4-Dimethoxybenzylidene)-4-(3,4-dimethoxyphenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4d). This compound was obtained as yellow crystals, mp 249–251°C, Lit. [10d] 231–233°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3484, 3280, 3154, 3074, 2936, 1619, 1541, 1459, 1260, 1234; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 7.99 (1H, s, ArCH=), 7.11–7.15 (2H, m, ArH), 7.03 (4H, dd, J = 8.0 Hz, J = 8.0 Hz, ArH), 6.28 (2H, s, $\mathrm{NH_2}$), 3.81 (3H, s, $\mathrm{OCH_3}$), 3.80 (3H, s, $\mathrm{OCH_3}$), 3.79 (3H, s, $\mathrm{OCH_3}$), 3.77 (3H, s, $\mathrm{OCH_3}$), 2.84 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$), 2.65 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$), 1.63 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{25}H_{27}N_3O_4}$: C 69.27, H 6.28, N 9.69. Found: C 69.08, H 6.35, N 9.61.

(*E*)-8-(4-Bromobenzylidene)-4-(4-bromophenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4e). This compound was obtained as yellow crystals, mp 211–213°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3488, 3287, 3157, 2934, 1625, 1591, 1540, 1486, 1456, 1332, 1231; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 7.98 (1H, s, ArCH=), 7.67 (2H, d, J = 8.4 Hz, ArH), 7.62 (2H, d, J = 8.4 Hz, ArH), 7.52 (2H, d, J = 8.4 Hz, ArH), 7.41 (2H, d, J = 8.4 Hz, ArH), 6.45 (2H, s, $\mathrm{NH_2}$), 2.77 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$), 2.60 (2H, t, J = 6.0 Hz, $\mathrm{CH_2}$), 1.63 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{21}H_{17}Br_2N_3}$: C 53.53, H 3.64, N 8.92. Found: C 53.33, H 3.62, N 8.96.

(*E*)-8-(4-Chlorobenzylidene)-4-(4-chlorophenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4f). This compound was obtained as yellow crystals, mp 195–197°C, Lit. [10d] 224–226°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3497, 3319, 3202, 2939, 1631, 1606, 1543, 1507, 1464, 1417, 1357, 1333, 1317, 1224; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 8.01 (1H, s, ArCH=), 7.61 (2H, dd, J = 6.0 Hz, J = 6.0 Hz, ArH), 7.51 (2H, dd, J = 6.0 Hz, J = 6.0 Hz, ArH), 7.28 (4H, q, J = 8.8 Hz, J = 6.4 Hz, ArH), 6.41 (2H, s, $\mathrm{NH_2}$), 2.78 (2H, br, $\mathrm{CH_2}$), 2.60 (2H, t, J = 5.2 Hz, J = 5.2 Hz, $\mathrm{CH_2}$), 1.63 (2H, t, J = 5.2 Hz, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{21}H_{17}Cl_2N_3}$: C 65.98, H 4.48, N 10.99. Found: C 65.72, H 4.55, N 10.68.

(*E*)-8-(3-Chlorobenzylidene)-4-(3-chlorophenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4g). This compound was obtained as yellow crystals, mp 237–238°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3484, 3285, 3157, 3078, 2932, 1624, 1592, 1543, 1461, 1436, 1411, 1351, 1334, 1268, 1219; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 7.98 (1H, s, ArCH=), 7.60 (1H, s, ArH), 7.38-7.54 (7H, m, ArH), 6.48 (2H, s, $\mathrm{NH_2}$), 2.78 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$), 2.61 (2H, t, J = 6.0 Hz, $\mathrm{CH_2}$), 1.63 (2H, t, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{21}H_{17}Cl_2N_3}$: C 65.98, H 4.48, N 10.99. Found: C 65.80, H 4.50, N 10.95.

(*E*)-8-(3,4-Dichlorobenzylidene)-4-(3,4-dichlorophenyl)-5,6,7,8-tetrahydroquinazolin-2-amine (4h). This compound was obtained as yellow crystals, mp 200–202°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3479, 3296, 3184, 1625, 1541, 1472, 1415, 1389, 1351, 1331, 1215; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 7.95 (1H, s, ArCH=), 7.82 (1H, s, ArH), 7.74 (1H, J = 8.4 Hz, ArH), 7.68 (2H, J = 8.4 Hz, ArH), 7.57 (1H, J = 8.4 Hz, ArH), 7.44 (1H, J = 8.4 Hz, ArH) 6.53 (2H, s, $\mathrm{NH_2}$), 2.77 (2H, t, J = 5.2 Hz, J = 5.2 Hz, $\mathrm{CH_2}$), 2.61 (2H, t, J = 6.0 Hz, J = 6.0 Hz, $\mathrm{CH_2}$), 1.63 (2H, t, J = 5.2 Hz, J = 5.2 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{21}H_{15}Cl_4N_3}$: C 55.90, H 3.35, N 9.31. Found: C 55.78, H 3.34, N 9.34.

4-*p*-Tolyl-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6a). This compound was obtained as yellow crystals, mp 192–194°C, Lit. [10g] 193–194°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3472, 3394, 3296, 2940, 1613, 1586, 1545, 1445, 1373, 1322, 1210; ^{1}H NMR (400MHz, DMSO-d6) (δ, ppm): 8.18 (1H, dd, J = 1.2 Hz, J = 1.6 Hz, ArH), 7.48 (2H, d, J = 8.0 Hz, ArH), 7.39 (2H, q, J = 6.8 Hz, J = 7.2 Hz, ArH), 7.29 (3H, d, J = 7.6 Hz, ArH), 6.48 (2H, s, $\mathrm{NH_2}$), 2.77 (4H, s, 2$\mathrm{CH_2}$), 2.38 (3H, s, $\mathrm{CH_3}$). Anal. Calcd. For $\mathrm{C_{19}H_{17}N_3}$: C 79.41, H 5.96, N 14.62. Found: C 79.60, H 5.89, N 14.70.

4-(4-Methoxyphenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6b). This compound was obtained as yellow crystals, mp 186–187°C, Lit. [10g] 182–183°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3467, 3287, 3178, 2940, 2830, 1609, 1578, 1547, 1510, 1453, 1405, 1374, 1322, 1302, 1277, 1251, 1214; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 8.18 (1H, dd, J = 1.2 Hz, J = 1.6 Hz, ArH), 7.56 (2H, d, J = 8.4 Hz, ArH), 7.39 (2H, q, J = 6.0 Hz, J = 7.2 Hz, ArH), 7.32 (1H, d, J = 6.0 Hz, ArH), 7.04 (2H, d, J = 8.4 Hz, ArH), 6.47 (2H, s, $\mathrm{NH_2}$), 3.82 (3H, s, $\mathrm{CH_3O}$), 2.78 (4H, d, J = 3.2 Hz, 2$\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{19}H_{17}N_3O}$: C 75.23, H 5.65, N 13.85. Found: C 75.42, H 5.69, N 13.79.

4-(3,4-Dimethoxyphenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6c). This compound was obtained as yellow crystals, mp 198–200°C, Lit. [10c] 203–204°C; ir (KBr, ν, $\mathrm{cm^{-1}}$): 3437, 3341, 3221, 2996, 2957, 1625, 1603, 1583, 1543, 1511, 1451, 1420, 1388, 1370, 1329, 1209; ^{1}H NMR (400MHz, DMSO-d$_6$) (δ, ppm): 8.17 (1H, dd, J = 1.2 Hz, J = 1.6 Hz, ArH), 7.39 (2H, q, J = 6.4 Hz, J = 7.2 Hz, ArH), 7.29 (1H, d, J = 6.4 Hz, ArH), 7.18 (1H, s, ArH), 7.14 (1H, d, J = 8.0 Hz, ArH), 7.05 (1H, d, J = 8.0 Hz, ArH), 6.48 (2H, s, $\mathrm{NH_2}$), 3.82 (3H, s, $\mathrm{CH_3O}$), 3.79 (3H, s, $\mathrm{CH_3O}$), 2.82 (2H, t, J = 1.6 Hz, J = 4.0 Hz, $\mathrm{CH_2}$), 2.78 (2H, t, J = 1.6 Hz, J = 4.0 Hz, $\mathrm{CH_2}$). Anal. Calcd. For $\mathrm{C_{20}H_{19}N_3O_2}$: C 72.05, H 5.74, N 12.60. Found: C 72.21, H 5.69, N 12.71.

4-(4-Fluorophenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6d). This compound was obtained as yellow crystals, mp 194–196°C; ir (KBr, ν, cm^{-1}): 3489, 3302, 3175, 2946, 1627, 1604, 1553, 1499, 1452, 1413, 1398, 1373, 1321, 1297, 1222; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.18 (1H, dd, *J* = 1.2 Hz, *J* = 1.6 Hz, ArH), 7.64 (2H, dd, *J* = 5.6 Hz, *J* = 5.6 Hz, ArH), 7.40 (2H, q, *J* = 7.2 Hz, *J* = 8.0 Hz, ArH), 7.30 (3H, dd, *J* = 5.6 Hz, *J* = 8.0 Hz, ArH), 6.53 (2H, s, NH_2), 2.77 (4H, s, $2CH_2$). Anal. Calcd. For $C_{18}H_{14}FN_3$: C 74.21, H 4.84, N 14.42. Found: C 74.35, H 4.82, N 14.46.

4-(4-Bromophenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6e). This compound was obtained as yellow crystals, mp 228–230°C; ir (KBr, ν, cm^{-1}): 3385, 3319, 3216, 2942, 1634, 1589, 1569, 1541, 1487, 1450, 1413, 1390, 1371, 1322, 1211; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.18 (1H, dd, *J* = 1.2 Hz, *J* = 1.6 Hz, ArH), 7.69 (2H, d, *J* = 8.4 Hz, ArH), 7.55 (2H, d, *J* = 8.4 Hz, ArH), 7.40 (2H, q, *J* = 6.8 Hz, *J* = 8.4 Hz, ArH), 7.30 (1H, d, *J* = 6.8 Hz, ArH), 6.56 (2H, s, NH_2), 2.77 (4H, s, $2CH_2$). Anal. Calcd. For $C_{18}H_{14}BrN_3$: C 61.38, H 4.01, N 11.93. Found: C 61.50, H 4.03, N 11.90.

4-(4-Chlorophenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6f). This compound was obtained as yellow crystals, mp 216–218°C, Lit. [10g] 222–223°C; ir (KBr, ν, cm^{-1}): 3391, 3327, 3221, 2942, 1638, 1597, 1586, 1572, 1543, 1492, 1458, 1412, 1394, 1372, 1323, 1212; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.18 (1H, dd, *J* = 1.2 Hz, *J* = 1.6 Hz, ArH), 7.62 (2H, d, *J* = 8.4 Hz, ArH), 7.55 (2H, d, *J* = 8.4 Hz, ArH), 7.40 (2H, q, *J* = 6.0 Hz, *J* = 8.4 Hz, ArH), 7.30 (1H, d, *J* = 6.4 Hz, ArH), 6.56 (2H, s, NH_2), 2.77 (4H, s, $2CH_2$). Anal. Calcd. For $C_{18}H_{14}ClN_3$: C 70.24, H 4.58, N 13.65. Found: C 70.43, H 4.50, N 13.58.

4-(3,4-Dichlorophenyl)-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6g). This compound was obtained as yellow crystals, mp 210–212°C, Lit. [10c] 221–223°C; ir (KBr, ν, cm^{-1}): 3485, 3297, 3183, 2934, 1622, 1564, 1544, 1492, 1470, 1450, 1410, 1386, 1365, 1350, 1317, 1298, 1247, 1212; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.18 (1H, d, *J* = 7.2 Hz, ArH), 7.84 (1H, d, *J* = 2.0 Hz, ArH), 7.56 (1H, d, *J* = 8.4 Hz, ArH), 7.58 (1H, dd, *J* = 2.0 Hz, *J* = 2.0 Hz, ArH), 7.40 (2H, q, *J* = 7.2 Hz, *J* = 8.0 Hz, ArH), 7.30 (1H, d, *J* = 7.2 Hz, ArH), 6.63 (2H, s, NH_2), 2.78 (4H, s, CH_2). Anal. Calcd. For $C_{18}H_{13}Cl_2N_3$: C 63.17, H 3.83, N 12.28. Found: C 63.40, H 3.76, N 12.21.

4-Phenyl-5,6-dihydrobenzo[*h*]quinazolin-2-amine (6h). This compound was obtained as yellow crystals, mp 164–165°C, Lit. [10h] 174–175°C; ir (KBr, ν, cm^{-1}): 3387, 3321, 3214, 2936, 1634, 1606, 1585, 1544, 1495, 1451, 1440, 1411, 1373, 1384, 1322, 1208; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.18 (1H, dd, *J* = 1.2 Hz, *J* = 1.6 Hz, ArH), 7.57 (2H, dd, *J* = 1.6 Hz, *J* = 2.0 Hz, ArH), 7.47-7.52 (3H, m, ArH), 7.40 (2H, q, *J* = 5.6 Hz, *J* = 7.6 Hz, ArH), 7.30 (1H, d, *J* = 7.6 Hz, ArH), 6.51 (2H, s, NH_2), 2.77 (4H, s, CH_2). Anal. Calcd. For $C_{18}H_{15}N_3$: C 79.10, H 5.53, N 15.37. Found: C 79.33, H 5.48, N 15.25.

(*E*)-7-(4-Methylbenzylidene)-4-p-tolyl-6,7-dihydro-5*H*-cyclopenta[*d*]pyrimidin-2-amine (8a). This compound was obtained as yellow crystals, mp 229–230°C; ir (KBr, ν, cm^{-1}): 3474, 3313, 3184, 2916, 1624, 1549, 1510, 1455, 1413, 1361, 1224, 1202; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 7.84 (2H, d, *J* = 8.0 Hz, ArH), 7.45 (2H, d, *J* = 8.0 Hz, ArH), 7.41 (1H, s, ArCH=), 7.31 (2H, d, *J* = 8.0 Hz, ArH), 7.24 (2H, *J* = 8.0 Hz, ArH), 6.51 (2H, s, NH_2), 3.12 (2H, d, *J* = 7.2 Hz, CH_2), 3.04 (2H, d, *J* = 4.0 Hz, CH_2), 2.37 (3H, s, CH_3), 2.33 (3H, s, CH_3). Anal. Calcd. For $C_{22}H_{21}N_3$: C 80.70, H 6.46, N 12.83. Found: C 80.86, H 6.48, N 12.80.

(*E*)-7-(4-Methoxybenzylidene)-4-(4-methoxyphenyl)-6,7-dihydro-5*H*-cyclopenta[*d*]pyrimidin-2-amine (8b). This compound was obtained as yellow crystals, mp 256–258°C; ir (KBr, ν, cm^{-1}): 3475, 3370, 3217, 2934, 1624, 1606, 1582, 1542, 1510, 1460, 1440, 1399, 1366, 1308, 1248, 1220; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 7.94 (2H, d, *J* = 8.8 Hz, ArH), 7.53 (2H, d, *J* = 8.8 Hz, ArH), 7.39 (1H, s, ArCH=), 7.07 (2H, d, *J* = 8.8 Hz, ArH), 7.02 (2H, d, *J* = 8.8 Hz, ArH), 6.42 (2H, s, NH_2), 3.83 (3H, s, CH_3O), 3.80 (3H, s, CH_3O), 3.17 (2H, t, *J* = 6.4 Hz, CH_2), 3.06 (2H, t, *J* = 6.4 Hz, CH_2). Anal. Calcd. For $C_{22}H_{21}N_3O_2$: C 73.52, H 5.89, N 11.69. Found: C 73.38, H 5.91, N 11.73.

(*E*)-7-(4-fluorobenzylidene)-4-(4-fluorophenyl)-6,7-dihydro-5*H*-cyclopenta[*d*]pyrimidin-2-amine (8c). This compound was obtained as yellow crystals, mp 187–189°C; ir (KBr, ν, cm^{-1}): 3485, 3337, 3239, 3064, 2934, 1624, 1615, 1582, 1542, 1509, 1459, 1440, 1316, 1248, 1227; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.01(2H, dd, *J* = 5.6 Hz, *J* = 5.6 Hz, ArH), 7.63 (2H, dd, *J* = 5.6 Hz, *J* = 5.6 Hz, ArH), 7.43 (1H, s, ArCH=), 7.35 (2H, t, *J* = 8.8 Hz, ArH), 7.27 (2H, t, *J* = 8.8 Hz, ArH), 6.57 (2H, s, NH_2), 3.15 (2H, d, *J* = 7.2 Hz, CH_2), 3.08 (2H, t, *J* = 4.4 Hz, *J* = 4.4 Hz, CH_2). Anal. Calcd. For $C_{20}H_{15}F_2N_3$: C 71.63, H 4.51, N 12.53. Found: C 71.47, H 4.53, N 12.48.

(*E*)-7-(4-Chlorobenzylidene)-4-(4-chlorophenyl)-6,7-dihydro-5*H*-cyclopenta[*d*]pyrimidin-2-amine (8d). This compound was obtained as yellow crystals, mp 165–167°C; ir (KBr, ν, cm^{-1}): 3483, 3323, 3192, 2928, 1672, 1623, 1594, 1544, 1492, 1460, 1407, 1361, 1295, 1225; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 7.97 (2H, d, *J* = 8.8 Hz, ArH), 7.62 (2H, d, *J* = 8.8 Hz, ArH), 7.58 (1H, s, ArCH=), 7.50 (2H, d, *J* = 8.8 Hz, ArH), 7.42 (2H, t, *J* = 8.8 Hz, ArH), 6.63 (2H, s, NH_2), 3.16 (2H, d, *J* = 6.8 Hz, CH_2), 3.09 (2H, t, *J* = 6.8 Hz, CH_2). Anal. Calcd. For $C_{20}H_{15}Cl_2N_3$: C 65.23, H 4.11, N 11.41. Found: C 65.48, H 4.13, N 11.37.

(*E*)-7-(3-Chlorobenzylidene)-4-(3-chlorophenyl)-6,7-dihydro-5*H*-cyclopenta[*d*]pyrimidin-2-amine (8e). This compound was obtained as yellow crystals, mp 135–137°C; ir (KBr, ν, cm^{-1}): 3469, 3298, 3174, 2913, 1689, 1621, 1590, 1561, 1541, 1476, 1459, 1421, 1351, 1279, 1250, 1228, 1205; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.01 (2H, d, *J* = 7.6 Hz, ArH), 7.68 (2H, d, *J* = 6.8 Hz, ArH), 7.61 (1H, s, ArCH=), 7.54 (2H, d, *J* = 6.8 Hz, ArH), 7.40 (2H, d, *J* = 7.6 Hz, ArH), 6.67 (2H, s, NH_2), 3.18 (2H, t, *J* = 5.6 Hz, CH_2), 3.03 (2H, t, *J* = 5.6 Hz, CH_2). Anal. Calcd. For $C_{20}H_{15}Cl_2N_3$: C 65.23, H 4.11, N 11.41. Found: C 65.48, H 4.13, N 11.37.

(*E*)-7-(4-Bromobenzylidene)-4-(4-bromophenyl)-6,7-dihydro-5*H*-cyclopenta[*d*]pyrimidin-2-amine (8f). This compound was obtained as yellow crystals, mp 180–182°C; ir (KBr, ν, cm^{-1}): 3454, 3293, 3170, 2956, 1672, 1620, 1588, 1488, 1459, 1403, 1351, 1176; ^{1}H NMR (400MHz, DMSO-d_6) (δ, ppm): 7.95 (2H, d, *J* = 8.8 Hz, ArH), 7.70 (2H, d, *J* = 8.8 Hz, ArH), 7.66 (1H, s, ArCH=), 7.59 (2H, d, *J* = 8.8 Hz, ArH), 7.42 (2H, d, *J* = 8.8 Hz, ArH), 6.98 (2H, s, NH_2), 3.09 (2H, t, *J* = 5.6 Hz, CH_2), 2.88 (2H, t, *J* = 5.6 Hz, CH_2). Anal. Calcd. For $C_{20}H_{15}Br_2N_3$: C 52.54, H 3.31, N 9.19. Found: C 52.67, H 3.34, N 9.15.

4-*p*-Tolyl-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10a). This compound was obtained as yellow crystals, mp 199–200°C; ir (KBr, ν, cm^{-1}): 3480, 3305, 3177, 2898, 1625, 1586, 1561, 1509, 1483, 1465, 1452, 1413, 1398, 1369, 1308, 1251; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.02 (2H, d, J = 8.0 Hz, ArH), 7.91 (1H, d, J = 7.6 Hz, ArH), 7.68 (1H, d, J = 7.2 Hz, ArH), 7.54 (1H, t, J = 7.2 Hz, ArH), 7.48 (1H, t, J = 7.2 Hz, ArH), 7.36 (2H, J = 8.0 Hz, ArH), 6.64 (2H, s, NH_2), 4.12 (2H, s, CH_2), 2.40 (3H, s, CH_3). Anal. Calcd. For $C_{18}H_{15}N_3$: C 79.10, H 5.53, N 15.37. Found: C 79.35, H 5.51, N 15.31.

4-(4-Methoxyphenyl)-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10b). This compound was obtained as yellow crystals, mp 206–208°C, Lit. [10f] 240–241°C; ir (KBr, ν, cm^{-1}): 3312, 3178, 2887, 1643, 1608, 1591, 1567, 1533, 1510, 1481, 1466, 1438, 1422, 1395, 1370, 1301, 1255, 1209; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.11 (2H, d, J = 8.8 Hz, ArH), 7.94 (1H, d, J = 7.6 Hz, ArH), 7.68 (1H, d, J = 7.2 Hz, ArH), 7.54 (1H, t, J = 7.2 Hz, ArH), 7.48 (1H, t, J = 7.2 Hz, ArH), 7.11 (2H, J = 8.0 Hz, ArH), 6.60 (2H, s, NH_2), 4.12 (2H, s, CH_2), 3.85 (3H, s, CH_3O). Anal. Calcd. For $C_{18}H_{15}N_3O$: C 74.72, H 5.23, N 14.52. Found: C 74.58, H 5.30, N 14.61.

4-(3,4-Dimethoxyphenyl)-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10c). This compound was obtained as yellow crystals, mp 271–273°C; ir (KBr, ν, cm^{-1}): 3405, 3310, 3189, 2962, 2935, 1640, 1604, 1542, 1511, 1484, 1463, 1449, 1423, 1401, 1378, 1326, 1250, 1235, 1211; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 7.91 (1H, d, J = 7.6 Hz, ArH), 7.68–7.72 (3H, m, ArH), 7.49–7.54 (2H, m, ArH), 7.12 (1H, d, J = 8.0 Hz, ArH), 6.60 (2H, s, NH_2), 4.15 (2H, s, CH_2), 3.88 (3H, s, CH_3O), 3.85 (3H, s, CH_3O). Anal. Calcd. For $C_{19}H_{17}N_3O_2$: C 71.46, H 5.37, N 13.16. Found: C 71.70, H 5.35, N 13.22.

4-(4-Fluorophenyl)-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10d). This compound was obtained as yellow crystals, mp 225–227°C; ir (KBr, ν, cm^{-1}): 3482, 3306, 3176, 2890, 1632, 1588, 1566, 1509, 1488, 1463, 1449, 1419, 1394, 1372, 1300, 1279, 1253, 1222; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.17 (2H, dd, J = 5.6 Hz, J = 5.6 Hz, ArH), 7.92 (1H, d, J = 7.2 Hz, ArH), 7.68 (1H, d, J = 7.2 Hz, ArH), 7.54 (1H, t, J = 7.2 Hz, ArH), 7.49 (1H, t, J = 7.2 Hz, ArH), 7.38 (2H, t, J = 8.8 Hz, ArH), 6.70 (2H, s, NH_2), 4.13 (2H, s, CH_2). Anal. Calcd. For $C_{17}H_{12}FN_3$: C 73.63, H 4.36, N 15.15. Found: C 73.78, H 4.34, N 15.18.

4-(4-Chlorophenyl)-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10e). This compound was obtained as yellow crystals, mp 237–238°C, Lit. [10f] 245–246°C; ir (KBr, ν, cm^{-1}): 3454, 3302, 3181, 1635, 1592, 1581, 1565, 1545, 1485, 1468, 1453, 1413, 1391, 1369, 1301, 1250, 1212; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.14 (2H, d, J = 8.8 Hz, ArH), 7.92 (1H, d, J = 7.2 Hz, ArH), 7.69 (1H, d, J = 7.2 Hz, ArH), 7.62 (2H, d, J = 8.4 Hz, ArH), 7.56 (1H, t, J = 7.2 Hz, ArH), 7.49 (1H, t, J = 7.2 Hz, ArH), 6.72 (2H, s, NH_2), 4.13 (2H, s, CH_2). Anal. Calcd. For $C_{17}H_{12}ClN_3$: C 69.51, H 4.12, N 14.30. Found: C 69.69, H 4.20, N 14.21.

4-(4-Bromophenyl)-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10f). This compound was obtained as yellow crystals, mp 233–234°C, Lit. [10f] 218–219°C; ir (KBr, ν, cm^{-1}): 3455, 3302, 3182, 1634, 1591, 1579, 1562, 1547, 1486, 1468, 1452, 1409, 1388, 1366, 1300, 1251, 1212; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.07 (2H, d, J = 8.0 Hz, ArH), 7.92 (1H, d, J = 7.6 Hz, ArH), 7.76 (2H, d, J = 8.4 Hz, ArH), 7.69 (1H, d, J = 7.6 Hz, ArH), 7.56 (1H, t, J = 7.2 Hz, J = 7.2 Hz, ArH), 7.50 (1H, t, J = 7.2 Hz, J = 7.2 Hz, ArH), 6.73 (2H, s, NH_2), 4.13 (2H, s, CH_2). Anal. Calcd. For $C_{17}H_{12}BrN_3$: C 60.37, H 3.58, N 12.42. Found: C 60.49, H 3.51, N 12.33.

4-(3,4-Dichlorophenyl)-5*H*-indeno[1,2-*d*]pyrimidin-2-amine (10g). This compound was obtained as yellow crystals, mp 232–233°C; ir (KBr, ν, cm^{-1}): 3481, 3316, 3185, 2903, 1646, 1613, 1592, 1558, 1487, 1469, 1408, 1375, 1361, 1286, 1260, 1245, 1203; ^1H NMR (400MHz, DMSO-d_6) (δ, ppm): 8.33 (1H, d, J = 1.6 Hz, ArH), 8.09 (1H, dd, J = 1.6 Hz, J = 2.0 Hz, ArH), 7.93 (1H, d, J = 7.6 Hz, ArH), 7.81 (1H, d, J = 7.6 Hz, ArH), 7.70 (1H, d, J = 7.6 Hz, ArH), 7.56 (1H, t, J = 7.6 Hz, ArH), 7.52 (1H, t, J = 7.6 Hz, ArH), 6.80 (2H, s, NH_2), 4.16 (2H, s, CH_2). Anal. Calcd. For $C_{17}H_{11}Cl_2N_3$: C 62.21, H 3.38, N 12.80. Found: C 62.35, H 3.36, N 12.77.

This article describes the methodology that allows the simultaneous introduction of a trifluoromethyl group and a 7-, 8-, and 10-membered cycloalkane ring fused to heterocyclic derivatives. A series of 10 geminated polymethylene trifluoromethyl substituted isoxazolines, pyrazoles, pyrimidinones, and a pyrazolyl-quinoline were obtained in moderate to good yields from the reaction of three 2-trifluoroacetyl-1-methoxycycloalkenes derived from cycloheptanone, cyclooctanone, and cyclododecanone with hydroxylamine hydrochloride, hydrazine hydrochloride, urea, and 7-chloro-4-hydrazinoquinoline.

J. Heterocyclic Chem., **46**, 158 (2009).

INTRODUCTION

Among some classes of compounds that show biological activity, heterocycles [1] such as isoxazolines, pyrazoles, and pyrimidinones have been shown to be of great importance. These compounds present a wide range of biological applications [2–9] both in the pharmaceutical area and the agrochemical industry, including as CNS depressants and analgesics, as well as for their antitumor, antibacterial, and anti-HIV activity, and antifungal, antiviral, antiparasitic, antitubercular, and insecticidal properties.

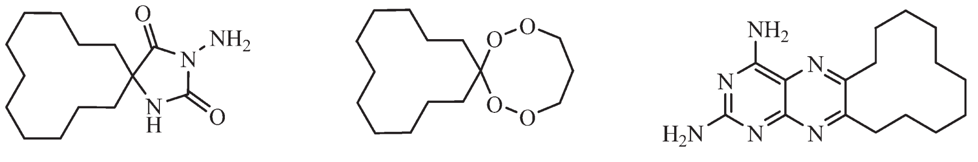
A review of the literature has shown that the synthesis of heterocyclic compounds derived from cycloalkane has been relatively unexplored. In many cases, it has been observed that enlargement of the cycloalkane ring-size influences the biological effect, where cyclododecane derivatives present an advantageous position (Fig. 1) [10–12]. Moreover, some cycloalkanespiro-5-hydantoins have a modest anticonvulsive effect.

However, a study of structure-activity relationships of various 3-aminocycloalkanespiro-hydantoins showed that (**I**) [10] and similar compounds, in contrast to hydantoins, exerted well pronounced atropinsensitive and contractile effects on guinea-pig ileum longitudinal muscle preparations.

In 2001, Kim *et al.* [11] prepared tetraoxacycloalkanes and the subsequent evaluation of antimalarial activity of the cyclic peroxides *in vitro* and *in vivo* revealed cyclododecane (**II**) derivatives to be a promising potent antimalarial drug.

Taylor *et al.* [12] synthesized cycloalka[*g*]pteridines (**III**) and studied their biological activity as dihydrofolate reductase inhibitors against *Lactobacillus casei* and *Trypanosoma cruzi*. Activity was found to depend upon ring size, with the greatest activity exhibited by the cyclododecane derivative, which was ~1000 times more active than the cyclohexane derivative.

In addition, fluorine-containing heterocyclic compounds are of significant interest because of their biological properties [13]. The introduction of a trifluoromethyl and its higher homologue groups into a heterocycle frequently results in more potent activity than that of the parent compound, a fact, which is probably related to the high lipophilicity of perfluoroalkyl substituents [14,15]. As a consequence, in recent years much attention has been devoted to the synthesis of



I II III

Figure 1. Cycloalkane derivatives of biological relevance.

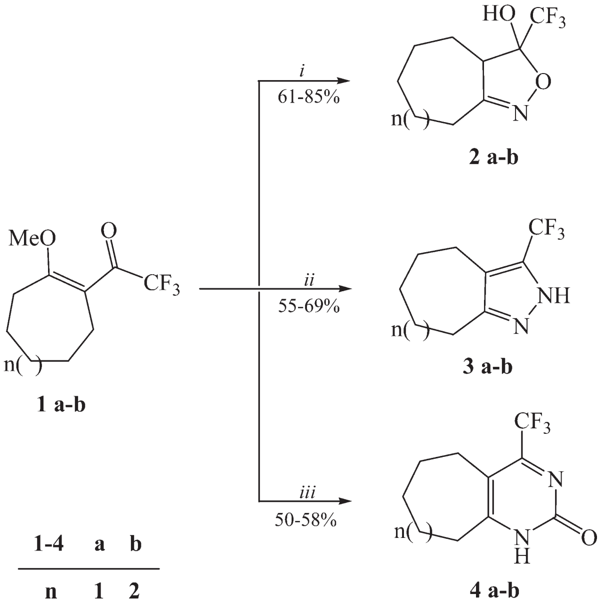
trifluorinated compounds and many have proven to be of important therapeutic value [16,17].

The preparation of trifluoromethylated heterocyclic compounds from cyclocondensation reactions of β-alkoxyvinyl trihalomethyl ketones with 1,2 and 1,3 dinucleophilic compounds has been developed by our research group [18–23]. Recently, the synthesis [24] and ^{17}O NMR spectroscopy of 2-trifluoroacetyl-1-methoxycycloalkenes [25] derived from cyclopentanone, cyclohexanone, cycloheptanone, cyclooctanone, and cyclododecanone [26] were reported. However, there is no publication in the literature with the objective of carrying out a regiospecific and simultaneous introduction of a trifluoromethyl group and a fused 7-, 8-, and 10-membered cycloalkane ring fused to heterocyclic derivatives starting from b-alkoxyvinyl trifluoromethyl ketones and hydroxylamine, hydrazines or urea.

Although many methods for the synthesis of isoxazolines, pyrazoles, and pyrimidinones and functionalized derivatives have been published, attempts at the synthesis of trifluoromethyl substituted and geminated cycloalka-heterocycles have not yet been successful. A search of the literature showed that by a conventional procedure, only 3-trifluoromethyl-1,4,5,6,7,8-hexahydrocyclohepta[*c*]pyrazole has been obtained from a direct reaction of trifluoroacetylcycloheptanone and hydrazine hydrochloride [27].

Considering the biological importance of trifluoromethyl substituted heterocyclic compounds derived from cycloalkanes, we reported our new results on the reaction of 2-trifluoroacetyl-1-methoxycycloalkenes derived from cycloheptanone and cyclooctanone in the synthesis and isolation of novel cycloalka -isoxazolines, -pyrazoles, and -pyrimidinones containing a fused 7-, 8-membered ring (Scheme 1). Because of the fact that heterocycles derived from cyclododecanone have shown greater activity in relation to derivatives of cyclohexanone, we also reported the synthesis and isolation of novel heterocyclic compounds fused to a cyclododecane ring (Scheme 2).

Scheme 1. Reagents and conditions: (i) $NH_2OH.HCl$, Pyridine, H_2O, 45°C, 24 h; (ii) $NH_2NH_2.HCl$, Pyridine, EtOH, reflux, 8 h; (iii) $NH_2CONH_2/BF_3.OEt_2$, *i*-PrOH, reflux, 20 h.

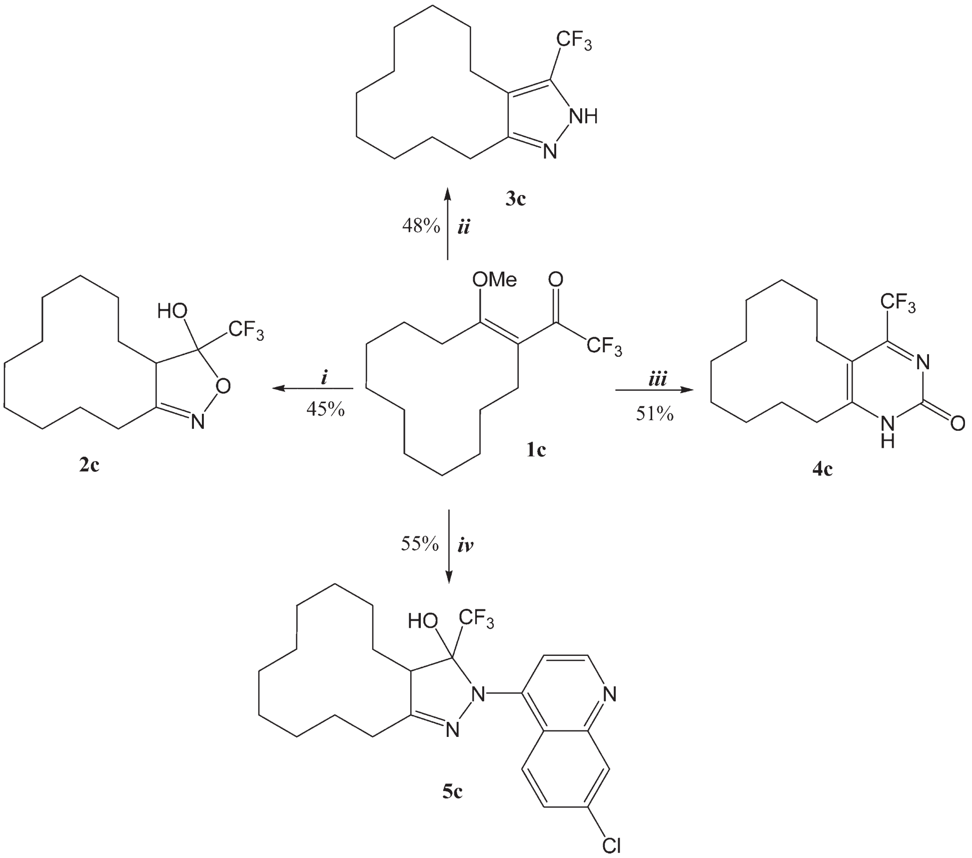


RESULTS AND DISCUSSION

2-Trifluoroacetyl-1-methoxycycloalkenes **1a–c** were obtained by a direct acylation reaction of the 1,1-dimethoxycycloalkanes derived from the respective cycloalkanones with trifluoracetic anhydride in the presence of pyridine, as described in the literature [20,28–30]. Subsequently, we reacted pure 2-trifluoroacetyl-1-methoxycycloalkenes **1a–c** with hydroxylamine, hydrazines, and urea, regiospecifically obtaining, in an one-step reaction, 3-hydroxy-3-trifluoromethyl-3,4-dihydro-cycloalka[*c*]isoxazoles **2a–c** (45–85%), 3-trifluoromethyl-3,4-dihydrocycloalka[*c*]pyrazoles **3a–c** (48–69%), 4-trifluoromethylcycloalka[*d*]-2(1*H*)pyrimidinones **4a–c** (50–58%) and 4-(3-hydroxy-3-trifluoromethyl-cyclododeca[*c*]pyrazol-2-yl)-7-chloroquinoline (**5c**) (55%).

Presumably, the reactions start with the Michael addition of the amino groups of the dinucleophiles at the β-carbon atom of the enones **1a–c** furnishing addition products. The aminoether function is unstable in pyridine/water or in alcohol (reaction solvents) and the methoxy group is eliminated as methanol. Subsequently,

Scheme 2. Reagents and conditions: (i) $NH_2OH.HCl$, Pyridine, H_2O, 45°C, 24 h; (ii) $NH_2NH_2.HCl$, Pyridine, EtOH, reflux, 8 h; (iii) NH_2CONH_2/$BF_3.OEt_2$, *i*-PrOH, reflux, 20 h; (iv) 7-chloro-4-hydrazino-quinoline, MeOH, reflux, 6 h.



the intramolecular cyclization reaction occurs and involves the carbonyl function of the not isolated β-enaminone and the second heteroatom of the dinucleophile reagent. In addition, the elimination of a water molecule is not likely to occur in the isoxazole structures (**2a–c**) because of the electron-withdrawing effect of the oxygen and the basic reaction condition employed (pyridine/water) or because of the electronic effect of cloro-quinoline substituent (**5c**).

The reactions of 2-trifluoroacetyl-1-methoxycycloalkenes **1a–c** with hydroxylamine hydrochloride using pyridine/H_2O as solvent were carried out under mild conditions at 45°C for 24 h. After 24 h, the isoxazolines **2a–c** were isolated by a simple extraction with diethyl ether.

Cycloalka[*c*]pyrazoles **3a–c**, were obtained from the reaction of 2-trifluoroacetyl-1-methoxycycloalkenes **1a–c**, with hydrazine hydrochloride in the presence of pyridine. The reactions to obtain **3a–b, 7** were carried out at a molar ratio of 1:1 in methanol as solvent at 80°C for 8 h.

Cycloalka[*d*]-2(1*H*)pyrimidinones **4a–c**, were prepared from the cyclocondensation reaction of 2-trifluoroacetyl-1-methoxycycloalkenes **1a–c**, with urea, carried out at a 1:1.5 molar ratio in anhydrous propan-2-ol as solvent. The most satisfactory results were obtained when the reactions were performed under mild conditions by stirring the reagents for 20 h at 80–85°C, using a Lewis acid as catalyst ($BF_3.OEt_2$). After 20 h, the reactions were refrigerated and the solids were isolated by filtration.

Subsequently, 2-trifluoroacetyl-1-methoxycyclododecene (**1c**) was used to prepare cyclododeca[*c*]pyrazoles (**5c**) derived from 7-chloro-4-hydrazinoquinoline. The objective of synthesizing compound **5c** was to build a molecule that would serve as the foundation for a family of new antimalarials. The reaction was carried out in methanol for 6 h at 65°C, similar to the methodology systematized by Bonacorso *et al.* [31] to obtain pyrazolylquinolines. Compound **5c** was obtained in satisfactory yield (55%), after recrystallization from methanol.

The unambiguous ^1H and ^{13}C NMR chemical shift assignments of cycloalka -isoxazolines (**2a–c**), -pyrazoles (**3a–c**), -pyrimidinones (**4a–c**), and -pyrazoline (**5c**), were made with the help of homo- and hetero- nuclear COSY, HMQC, and HMBC 2D NMR experiments and by comparison with NMR data of the literature [27] and from other 2-pyrazolines previously synthesized in our laboratory [26,31(a)].

In conclusion, we consider the one-step and regiospecific reaction reported here to be a useful, simple, new, and convenient method, which employs commercially available reagents and mild conventional conditions to obtain novel interesting trifluoromethylated heterocycles fused to a cycloalkane ring.

EXPERIMENTAL

Unless otherwise indicated all common reagents and solvents were used as obtained from commercial suppliers without further purification. All melting points were determined on a Reichert Thermovar apparatus and are uncorrected. Mass spectra were registered in a HP 5973 MSD connected to a HP 6890 GC and interfaced by a Pentium PC. The GC was equipped with a split–splitless injector, auto sampler, cross-linked HP-5 capillary column (30 m, 0.32 mm internal diameter), and helium was used as the carrier gas. ^{1}H and ^{13}C NMR spectra were acquired on a Bruker DPX 200 or Bruker DPX 400 spectrometer (^{1}H at 20.13 MHz or 40.13 MHz and ^{13}C at 50.32 MHz or 100.62 MHz, respectively), 5 mm sample tubes, 298 K digital resolution ± 0.01 ppm, in methyl sulfoxide-d_6 using tetramethylsilane as internal reference. The CHN elemental analyses were performed on a Perkin–Elemer 2400 CHN elemental analyzer (São Paulo University, USP/Brazil).

Synthetic procedures. ***General procedure for the preparation of 3-hydroxy-3-trifluoromethyl-3,4-dihydro-cycloalka[c]isoxazoles (2a–c).*** To a stirred solution of 2-trifluoroacetyl-1-methoxycycloalkenes (**1a**–**c**) (5 mmol) in pyridine (0.4 g; 5 mmol), was added a solution of hydroxylamine hydrochloride (0.35 g; 5 mmol) in H_2O (2 mL). The mixture was stirred at 45°C for 24 h. After 24 h, water (50 mL) was added and extracted with diethyl ether (3 × 15 mL), dried with Na_2CO_3 and evaporated. The solids were recrystallized from methanol or diethyl ether.

3-Hydroxy-3-trifluoromethyl-3H-3a,4,5,6,7,8-hexahydro-cyclohepta[c]isoxazole (2a). This compound was obtained as white crystals (85% yield), Mp. 128–130°C.^{1}H NMR (DMSO-d_6): δ 8.02 (s, 1H, OH), 3.52 (m, 1H, CH), 2.63–2.42 (m, 2H, CH_2), 1.74–1.48 (m, 8H, CH_2).^{13}C NMR (DMSO)-d_6): δ 163.7 (C-8a), 122.8 (q, CF_3, ^1J = 285.4), 102.7 (q, C-3, ^2J = 31.8) 54.3 (C-3a), 30.4 (CH_2), 27.5 (CH_2), 26.6 (CH_2), 25.2 (CH_2), 23.8 (CH_2). General procedure for the preparation of 3-trifluoromethyl-cycloalka[c]1H-pyrazole (3a–c). To a solution of hydrazine hydrochloride (0.35 g; 5 mmol) in the presence of pyridine (0.4 g; 5 mmol), was added 2-trifluoroacetyl-1-methoxycycloalkenes (5 mmol) (**1a**–**c**) in ethanol (10 mL) and the mixture was stirred in ice bath. The mixture was then stirred at room temperature for 30 min and under reflux for another 8 h. After 8 h, the solution was concentrated and cooled (<10°C). The crystalline solids were isolated by filtration and washed with cold ethanol.

3-Trifluoromethyl-1,4,5,6,7,8-hexahydrocyclohepta[c]pyrazole (3a). This compound was obtained as white crystals [27] (69% yield), Mp. 132–134°C. (Lit. [27], Mp. 154.1°C). ^{1}H NMR (DMSO-d_6): δ 13.09 (s, 1H, NH), 2.76–2.74 (m, 2H, CH_2), 2.61–2.58 (m, 2H, CH_2), 1.80–1.61 (m, 6H, CH_2). ^{13}C NMR (DMSO)-d_6): δ 144.63 (C-8a), 138.46 (q, C-3, ^2J = 34.6), 122.51 (q, CF_3, ^1J = 269.15), 117.17 (C-3a), 30.96 (CH_2), 27.93 (CH_2), 26.43 (CH_2), 25.75 (CH_2), 23.19 (CH_2). The reactions of 1,3-diphenyltetrazol-5-ylidene, a rare example of mesoionic carbenes, with electron-deficient unsaturated compounds were studied. The carbene reacted with dimethyl 1,2,4,5-tetrazine-3,6-dicarboxylate to give a 5-tetrazoliomethylide, together with hydrazine derivatives. The reaction with tetracyanoethylene gave another methylide in low yield. On the contrary, the reactions with weaker electrophiles, such as 3,6-diphenyl-1,2,4,5-tetrazine, fumalonitrile, *N*-phenylmaleimide, and dimethyl acetylenedicarboxylate, did not give any coupling products, but gave phenylated products and/or Michael addition products *via* the degradation of the 1,3-diphenyltetrazole ring. Novel mesoionic mono- and bis(carbene)-rhodium(I) complexes were synthesized and the structures were characterized by X-ray crystallography. Their catalytic activities for the decarbonylative addition reaction of benzoyl chloride to ethynylbenzene were investigated.

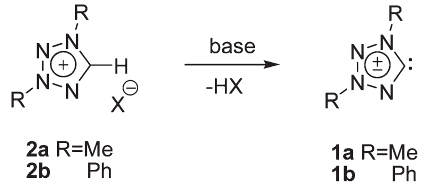
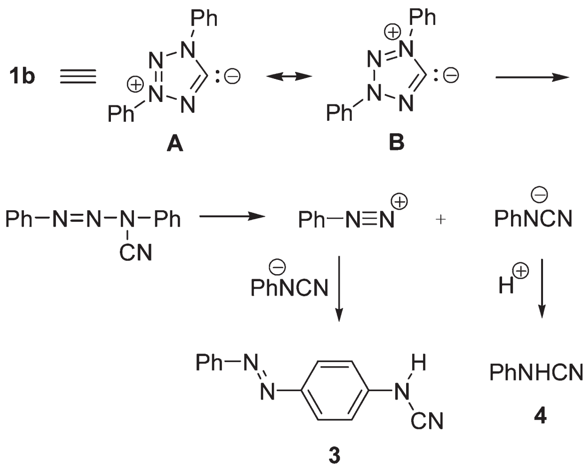
J. Heterocyclic Chem., **46**, 164 (2009).

INTRODUCTION

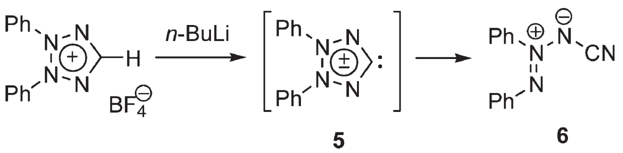
Since the Arduengo's pioneering work on stable heterocyclic carbenes, various heterocyclic carbenes, including *N*-heterocyclic carbenes (NHCs) such as imidazol-2-ylidene and 1,2,4-triazol-3-ylidene, have hitherto been prepared and their physical and chemical properties have intensively been investigated [1]. Mesoionic compounds are the unique family of heterocycles owing to their interesting electronic nature; *i.e.*, they cannot be formulated satisfactorily by a single covalent or polar structure, but expressed as a resonance hybrid of a series of dipolar canonical structures [2]. Mesoionic carbenes, which are derived formally from mesoionic compounds by a removal of the exo-cyclic atom(s), are also resonance hybrids of several canonical structures. Contrary to the extensive study on NHCs, mesoionic carbenes are scarcely studied. 1,3-Dimethyl- (**1a**) and 1,3-diphenyltetrazol-5-ylidene (**1b**) are rare examples of such mesoionic carbenes. These carbenes are easily prepared by deprotonation of the corresponding 1,3-disubstituted tetrazolium salts **2a**,**b** with a base at low temperature [3,4]. Alternatively, **1b** can also be generated by the reaction of 5-azido-1,3-diphenyltetrazolium salt with sodium azide [5]. Carbene **1** is thermally labile; upon warming to room temperature, **1** undergoes a ring-opening to give 3-cyanotriazene. In the case of **1b**, further degradation and recombination reactions occur spontaneously to give 4-(phenylazo)phenylcyanamide (**3**) and phenylcyanamide (**4**) (Scheme 1) [6]. As an isomeric carbene of **1**, 2,3-diphenyltetrazol-5-ylidene (**5**) is also known, which is generated similarly by deprotonation of 2,3-diphenyltetrazolium salts [7]. This mesoionic carbene is also unstable to give cyanoazimine **6** (Scheme 2). Although various stable NHCs have recently been attracting increasing interest, only these two examples **1** and **5** of mesoionic carbenes are thus far synthesized.



Scheme 1



Scheme 2



Our previous work demonstrated that carbene **1b** has a nucleophilic nature and hence is best expressed by the singlet structures **A** and **B**. For example, although the attempted reactions with alkyl halides or carbonyl compounds were unsuccessful, **1b** reacts readily with nitrogen electrophiles such as benzenediazonium and azidotetrazolium salts [4,5]. Here, we report further reactions of **1b** with electron-deficient tetrazine and alkene electrophiles. Furthermore, the synthesis and characterization of stable rhodium(I) complexes of **1b** are disclosed as examples of transition-metal complexes of mesoionic carbenes.

RESULTS AND DISCUSSION

A. Reaction with 1,2,4,5-tetrazines. It is reported that 1,2,4-triazol-3-ylidene reacts with 3,6-diphenyl-1,2,4,5-tetrazine to give a [4+1] cycloaddition product [8]. We attempted the reaction of **1b** with 3,6-diphenyl-1,2,4,5-tetrazine. However, no reaction occurred and only the degradation products **3** and **4** were obtained. Next, dimethyl 1,2,4,5-tetrazine-3,6-dicarboxylate **8**, a more electron-poor tetrazine bearing the electron-withdrawing substituents, was employed. The carbene **1b** was generated *in situ* from the tetrazolium salt **2b** and reacted with **8** under different reaction conditions, by changing the solvent and the reaction temperature. These results are summarized in Table 1.

Three products **9**, **10**, and **11** have been isolated from the reaction mixtures in varying yields, together with small amounts of olate **7** and **4** (Scheme 3). Olate **7** is considered to be formed by the reaction of **1b** with atmospheric oxygen [4]. The compound **9** has been revealed to be a 1:1 adduct of **1b** and **8** on the basis of the MS and elemental analyses. A characteristic signal at 78.7 ppm in the ^{13}C NMR spectrum suggests that this compound is a 5-tetrazoliomethylide derivative [9]. The structure was finally comfirmed by X-ray chrystallography (Fig. 1). The exo-cyclic methylide C—C—N plane and the tetrazolium ring share almost the same plane. The phenyl ring at N^3 lies in this plane; on the contrary, the phenyl ring at N^1 as well as the tetrazole ring attached to the methylide carbon tilt considerably. The pivotal carbon—carbon bond length is 1.406(3) Å, indicating a mixed nature of single and double bonds. Compound **10** has a molecular formula $C_{19}H_{16}N_6O_4$, which corresponds to a loss of N_2 from the sum of **1b** and **8**. ^{1}H and ^{13}C NMR data show that **10** has a *p*-substituted benzene ring and two inequivalent CO_2Me groups. The structure was eventually deduced to be 4-(*p*-phenylazo) phenylhydrazone of a pyrazolone derivative. Compound **11** has a structure similar to **10**, bearing an unsubstituted phenylhydrazone moiety. An attempted reaction of **11** with benzene-diazonium salt did not give **10**. This fact suggests that **10** might be formed *via* an intramolecular migration of the phenylazo group. The most plausible mechanism for the formation of compounds **9**, **10**, and **11** is shown in Scheme 4.

A nucleophilic attack of **1b** to the electron-deficient carbon of tetrazine **8** followed by a ring-contraction

Table 1

The reaction of mesoionic carbene **1b** with **8**.

Entry	Temperature	Solvent	*t* (h)	Yield (%)

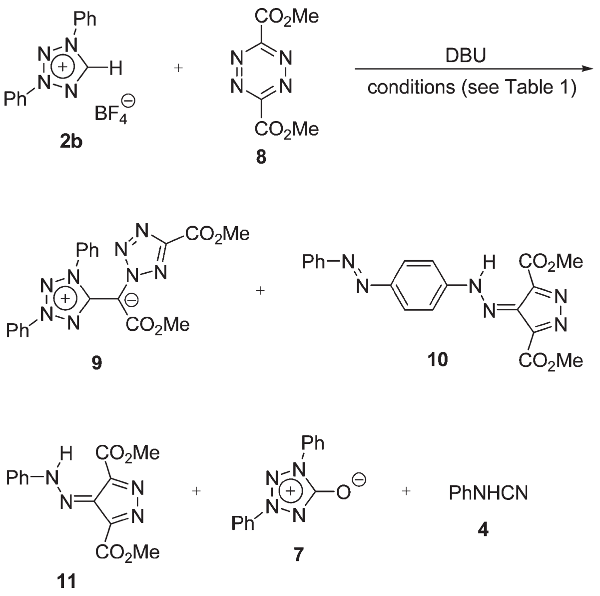
Scheme 3



furnishes **9**. Compounds **10** and **11** are considered to be formed *via* the spiro intermediate **C** which is akin to the product of the reaction of 1,2,4-triazol-3-ylidene and diphenyltetrazine [8]. The cleavage of the tetrazole ring of **C** followed by an intramolecular migration of the phenylazo group (aza para-Claisen rearrangement) gives **10**, whereas a loss of the phenylazo group furnishes **11**. Now it has been found that carbene **1b** reacts readily with the electron-deficient unsaturated compound. Then, the reactions of **1b** with alkenes with electron-withdrawing groups were next undertaken.

B. Reaction with tetracyanoethylene. A mixture of the tetrazolium salt **2b** and tetracyanoethylene was treated with DBU at –60°C, and the mixture was warmed to room temperature. The reaction gave a complex mixture of products, from which only cyanomethylide **12** was isolated as stable yellow crystals in low yield (9%) after column chromatography. The formation of **12** is rationalized by Scheme 5. The initially formed Michael adduct is considered to undergo a cyano group migration to furnish the fully conjugated methylide **12**.

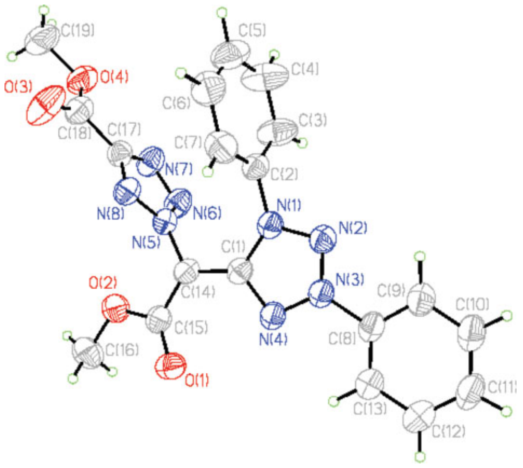


Figure 1. Molecular structure of methylide **9**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

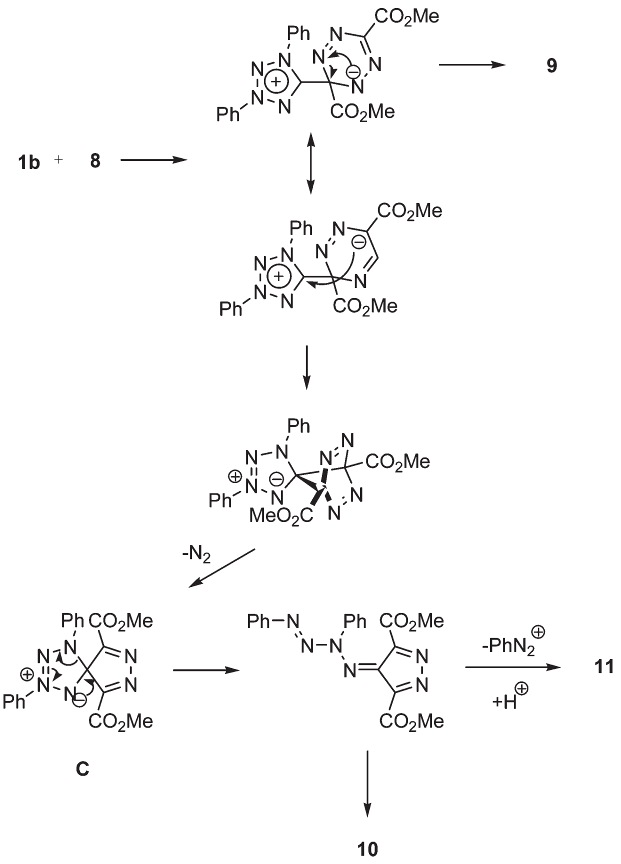
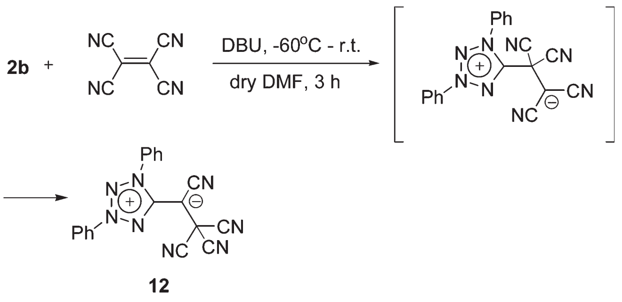
Scheme 4

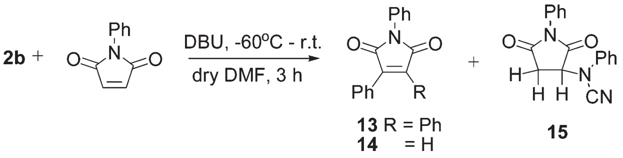


C. Reaction with *N*-phenylmaleimide, fumalonitrile, and dimethyl acetylenedicarboxylate. The reaction of mesoionic carbene **1b** with *N*-phenylmaleimide at –60°C to room temperature gave phenylated maleimides **13** and **14** together with cyanamide **15** (Scheme 6). To determine the origin of the phenyl group of **13** and **14**,

Scheme 5



Scheme 6

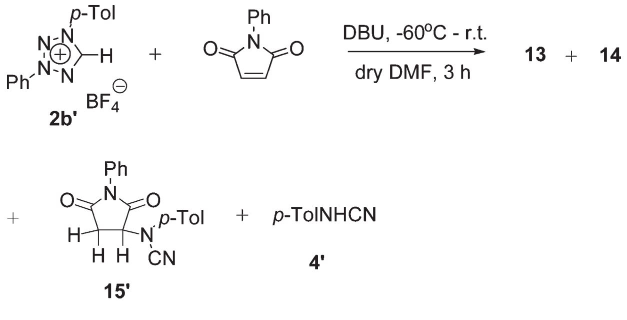


1-(*p*-tolyl)-3-phenyltetrazolium **2b′** was employed in place of **2b**. The reaction gave **13** and **14**, and the *p*-tolylcyanamide adduct **15′**. *p*-Tolylcyanamide **4′** itself was also isolated (Scheme 7). On the basis of these results, a plausible reaction mechanism is illustrated in Scheme 8. Carbene **1b** decomposes thermally to give benzendiazonium cation and phenylcyanamide anion; the former is considered to give phenyl radical [10] which reacts with *N*-phenylmaleimide to furnish the phenylated compounds **13** and **14**. The phenylcyanamide anion gives the adduct **15** *via* the Michael addition to *N*-phenylmaleimide.

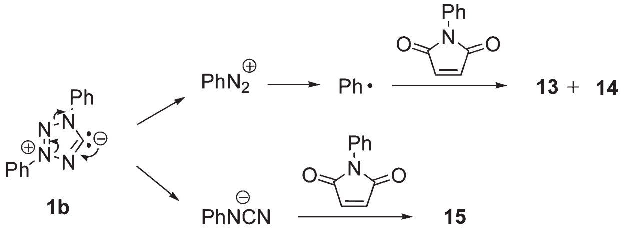
The reaction of **1b** with fumalonitrile also gave the phenylation products **16**, **17**, and **18** in low yields, together with the degradation products **3** and **4**. The reaction with dimethyl acetylenedicarboxylate gave the addition product **19** in 29% yield *via* a similar mechanism to the *N*-phenylmaleimide case (Scheme 9).

D. Preparation and characterization of rhodium(I) complexes of 1,3-diphenyltetrazol-5-ylidene. It is well known that carbenes can be stabilized by complexation with metals. Indeed, a large number of main group metal as well as transition metal complexes of NHCs have hitherto been prepared and characterized. Of such NHCs, imidazol-2-ylidene [11] and 1,2,4-triazol-3-ylidene [12] are most extensively studied, and some imidazol-2-ylidene-metal complexes have been used as effective catalysts in organic syntheses [13]. On the other hand, very few examples of mesoionic carbene-metal complexes, such as mercury(II) and palladium(II) complexes, have been synthesized by us [4]. Here, we describe the preparation and characterization of rhodium(I) complexes of **1b** as a new entry of mesoionic carbene-metal complexes.

Scheme 7



Scheme 8

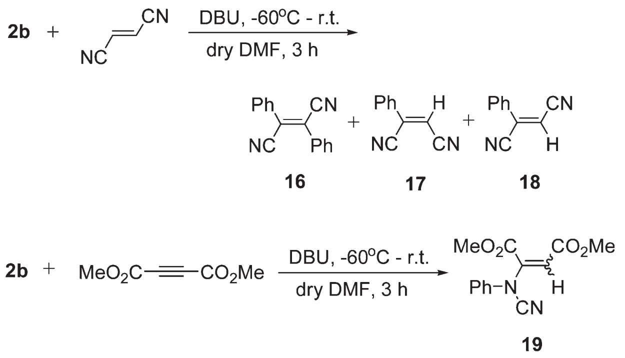


The reactions of tetrazolium salt **2b** with bis(1,5-cyclooctadiene)-μ,μ′-dichlorodirhodium (**20**) in DMF mediated by DBU were performed under various conditions. Two products, namely, mono- **21** and bis(tetrazol-5-ylidene)rhodium(I) complexes **22**, were isolated as stable crystalline solids (Scheme 10, Table 2). When an excess tetrazolium salt **2b** was used **22** was formed exclusively. Obviously, the cationic bis-carbene complex **22** is formed *via* the neutral mono-carbene complex **21**. Indeed, the reaction of **21** with **2b**/DBU gave **22**.

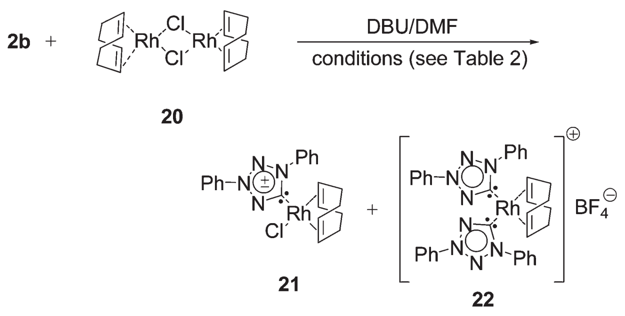
The molecular structures of the rhodium(I) complexes **21** and **22** were analyzed by X-ray crystallography (Figs. 2 and 3). In the square planner complex **21**, the tetrazol-5-ylidene ring is twisted relative to the coordination plane. The bond angle C(carbene)-Rh-Cl is 90.59(8)°. The C(carbene)-Rh length [2.017(3) Å] is almost coincident to that of (imidazol-2-ylidene)rhodium complex [11] [2.023(2) Å] and somewhat longer than that of (1,2,4-triazol-3-ylidene)rhodium complex [12(a)] [2.004 (7) Å]. The cationic bis(tetrazol-5-ylidene) complex **22** is also square planner. The bond angle C(carbene)-Rh-C(carbene) is 90.47(13)°. The C(carbene)-Rh lengths [2.039(3) and 2.031(3) Å] are longer than that of **21**, whereas they are shorter than the averaged length (2.047 Å) of the corresponding (imidazol-2-ylidene)rhodium complex [11].

To evaluate the catalytic activities, the complexes **21** and **22** were subjected to the decarbonylative addition reaction of benzoyl chloride to ethynylbenzene. The reaction is known to give (*Z*)-1-chloro-1,2-diphenylethene (**23**) by the catalysis of the $(cod)_2Rh_2Cl_2$ (**20**)

Scheme 9



Scheme 10



[14]. The mono(tetrazol-5-ylidene)Rh complex **21** (10 mol%) was found to be as effective as **20** to give **23** in 61% yield (Scheme 11). On the contrary, the bis (tetrazol-5-ylidene) complex **22** is less reactive to give lower yield (22%) of **23**, probably owing to the steric crowding around the rhodium atom.

CONCLUSION

The nucleophilic nature of 1,3-diphenyltetrazol-5-ylidene **1b** was demonstrated in the reactions with the electron-deficient tetrazine and alkene to yield the new 5-tetrazoliomethylide compounds **9** and **12**. In the cases of weak electrophiles, the degradation of the tetrazole ring took place and the phenylated products were obtained. Two (tetrazol-5-ylidene)rhodium(I) complexes **21** and **22** were synthesized *via* a nucleophilic displacement of the chlorine atoms of **20** with **1b**. Catalytic activities of **21** and **22** were investigated for the chloroarylation of ethynylbenzene. Further catalytic properties of these new rhodium complexes are now under way.

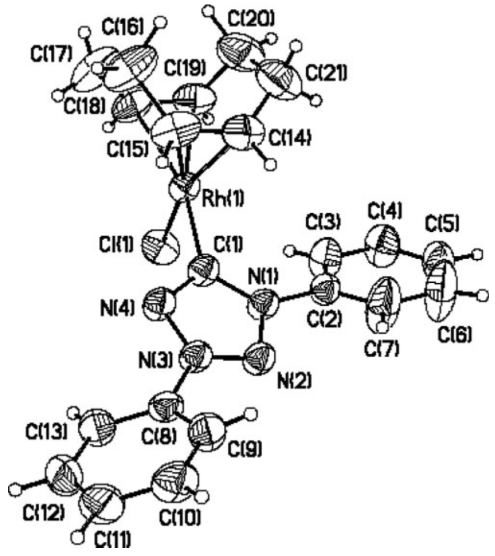

Figure 2. Molecular structure of the (tetrazol-5-ylidene)rhodium complex **21**.

Melting points were measured with a hot-stage apparatus and are uncorrected. Elemental analyses were carried with a Perkin–Elmer 2400 II CHNS/O. IR spectra were taken as KBr discs on a JASCO A-102 spectrometer. Electronic spectra were measured on a U-3500 spectrophotometer. ^1H NMR spectra were obtained using a Varian Gemini 200 (200 MHz) or a Varian Gemini 300 (300 MHz), and ^{13}C NMR spectra were obtained using a Varian Gemini-200 (50 MHz). Chemical shifts are recorded in ppm downfield from tetramethylsilane. *J* values are given in Hz. Mass spectra were taken with a Hitachi M-2000 spectrometer (EI, 70 eV). For TLC, Merck Silica gel 60 F_{254} Plate and Fuji Silysia Chemical Ltd. NH TLC Plate were used. For column chromatography, Merck Silica gel 60 (0.063–0.200 mm) and Fuji Silysia Chemical Ltd. Chromatorex NH Chromatography Silica Gel (100–200 mesh) were used.

Although no problems were hitherto encountered, it should be noted that polyaza compounds may in general be explosive and should be handled with due care.

Reaction with dimethyl 1,2,4,5-tetrazine-3,6-dicarboxylate (8).

Typical procedure. To a solution of **2b** (1.6 g, 5.0 mmol) and **8** (0.99 g, 5.0 mmol) in dry DMF (20 mL), DBU (0.75 mL, 5.0 mmol) was added at −60°C, and the mixture was warmed gradually to room temperature during a period of 4 h (Table 1, entry 3). Water was added and the precipitated

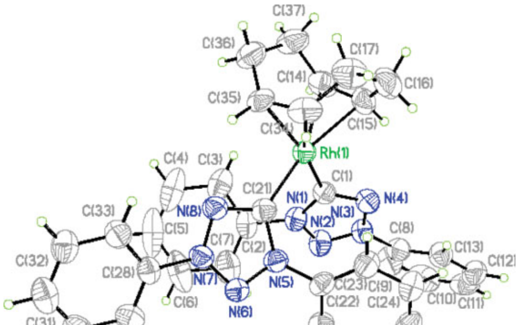

Figure 3. Molecular structure of the bis(tetrazol-5-ylidene)rhodium complex **22**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

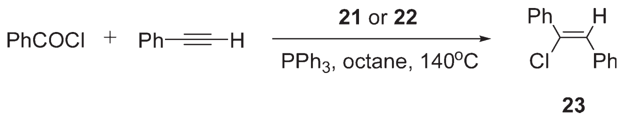
Scheme 11



solid was filtered off. The products were extracted from the filtrate with dichloro-methane. The extracts were dried over anhydrous Na_2SO_4 and the solvent was removed under reduced pressure. The residue (reddish brown solid, 1.0 g) was chromatographed (SiO_2/CH_2Cl_2:EtOAc gradient and MeOH) to give **4** (49 mg, 8%), **7** (26 mg, 2%), and a mixture of **9**, **10**, and **11** (0.72 g). On the basis of the ^1H NMR analysis, the yields were estimated to be **9** (15%), **10** (4%), and **11** (22%). Pure samples of **9**, **10**, and **11** were obtained after repeated column chromatography. The entries 1 and 2 were similarly carried out by changing the solvent and the reaction temperature. The results are summarized in Table 1.

Found C, 57.36; H, 4.04; N, 20.65.

Dimethyl 4-(phenylhydrazono)-4H-pyrazole-3,5-dicarboxylate (11). Blass crystals; Mp. 159.5–162°C (MeOH); ir (KBr): 3280–2800, 1740, 1698, 1618, 1578, 1528, 1496, 1450, 1366, 1338, 1292, 1230, 1208, 1178, 1076, 1034, 962, 850–820, 772, 740, 730, 698/cm; ^1H NMR (200 MHz, deuteriochloroform): δ 4.07 (s, 3H, Me), 4.13 (s, 3H, Me), 7.20–7.27 (m, 1H, *p*-Ph), 7.40–7.48 (m, 2H, *m*-Ph), 7.77–7.81 (m, 2H *o*-Ph), 10.47 (bs, 1H, NH); ^{13}C NMR (50 MHz, deuteriochloroform): δ 53.5 (Me), 53.8 (Me), 121.6 (*o*-Ph), 125.7 (*p*-Ph), 129.2 (*m*-Ph), 135.8, 136.1 (*i*-Ph, C=N), 152.1, 155.6, 162.7, 165.7 ($CO_2Me \times 2$, C—$CO_2Me \times 2$); uv/vis (MeCN): λ_{max} (log ε) = 362.0 (3.44), 292.0 (4.21), 261 (3.96), 228 nm (3.97); ms (EI, 70 eV): *m/z* 289 (M^++1, 18), 288 (M^+, 100), 229 (41), 170 (77), 144 (82), 117 (72), 77 (73). *Anal.* Calcd. for $C_{13}H_{12}N_4O_4$ (288.3): C, 54.16; H, 4.20; N, 19.44. Found C, 54.00; H, 4.13; N, 19.01.

Reaction with tetracyanoethylene. DBU (0.15 mL, 1.0 mmol) was added to a mixture of **2b** (0.31 g, 1.0 mmol) and tetracyanoethylene (0.13 g, 1.0 mmol) in DMF (3.0 mL) at –60°C. The mixture was gradually warmed to room temperature and allowed to stand at room temperature for 3 h. Water was added and the black solid deposited was collected by filtration (0.33 g). The solid was chromatographed (SiO_2/CH_2Cl_2-MeCN gradient and MeOH) to give 12 (32 mg, 9%), 7 (59 mg, 25%), together with two unknown compounds. ^1H NMR and ^{13}C NMR spectra of the unknown compounds are very similar to those of 2. However, the structures of these products could not be determined.

(Cyano)(tricyanomethyl)-α-(1,3-diphenyl-5-tetrazolio)-methylide (12). Yellow crystals, Mp. 153–157°C (acetone/hexane); ir (KBr): 2940, 2180, 1592, 1560, 1486, 1466, 1456, 1364, 1342, 1292, 1268, 1176, 1072, 998, 842, 760, 720, 710, 688/cm; ^1H NMR (200 MHz, deuteriochloroform): δ 7.64–7.73 (m, 8H, Ph), 8.18 (dd, 2H, $J_1 = 8.0$ Hz, $J_2 = 1.5$ Hz, Ph). ^{13}C NMR (50 MHz, deuteriochloroform): δ 30.5 [—$C(CN)_3$], 38.6 (C^-), 107.4 (CN × 3), 115.9 (CN), 120.6 (*o*-Ph), 126.4 (*o*-Ph), 129.8 (*m*-Ph), 130.4 (*m*-Ph), 131.2 (*i*-Ph), 132.6 (*p*-Ph), 133.2 (*p*-Ph), 134.7 (*i*-Ph), 157.2 (C^+); uv/vis (MeCN): λ_{max} (log ε) = 379.0 (3.68), 276.0 nm (4.31); ms (EI, 70 eV): *m/z* 351 (M^++1, 3), 350 (M^+, 10), 324 (9), 270 (10), 245 (3), 194 (60), 179 (40), 152 (23), 128 (100), 118 (67), 103 (32). *Anal.* Calcd. for $C_{19}H_{10}N_8$ (350.35): C, 65.13; H, 2.88; N, 31.99. Found C, 64.94; H, 2.99; N, 32.18.

Reaction with *N*-phenylmaleimide. To a mixture of 2b (0.31 g, 1.0 mmol) and *N*-phenylmaleimide (0.17 g, 1.0 mmol) in DMF (3.0 mL) was added DBU (0.15 mL, 1.0 mmol) at –60°C, and the mixture was gradually warmed to room temperature in a period of 1.5 h, and then further stirred at room temperature for 1.5 h. Water was added and the products were extracted with dichloromethane. The extracts were dried over anhydrous Na_2SO_4 and the solvent was removed under reduced pressure. The residue (0.32 g) was chromatographed (SiO_2/CH_2Cl_2:hexane =1:1 to MeOH) to give 13 (37 mg, 11%), 14 (22 mg, 9%), 15 (57 mg, 20%) and 7 (4 mg, 2%).

1,3,4-Triphenyl-1H-pyrrole-2,5-dione (13). Yellow crystals, Mp. 174–176°C (EtOH) (lit Mp. 175°C) [15].

1,3-Diphenyl-1H-pyrrole-2,5-dione (14). Pale yellow crystals, Mp. 115–120°C (EtOH) (lit Mp. 117°C) [16].

(2,5-Dioxo-1-phenylpyrrolidin-3-yl)phenylcyanamide (15). Colourless crystals; Mp. 138.5–140.5°C (acetone/hexane); ir (KBr): 2220, 1720, 1596, 1498, 1396, 1380, 1370, 1250, 1186, 748, 700, 684/cm; ^1H NMR (200 MHz, deuteriochloroform): δ 3.25 (dd, $J = 18.4$ Hz, $J = 6.3$ Hz, 1H, trans-CH_2), 3.46 (dd, $J = 18.4$ Hz, $J = 9.1$ Hz, 1H, cis-CH_2), 4.92 (dd, J=9.1 Hz, $J = 6.3$ Hz, 1H, CH), 7.21–7.55 (m, 10H, Ph); ^{13}C NMR (50 MHz, deuteriochloroform): δ 35.6 (CH_2), 59.1 (CH), 112.7 (CN), 120.0 (*o*-Ph), 127.4 (*p*-Ph), 127.9 (*o*-Ph), 130.8 (*p*-Ph), 130.9 (*m*-Ph), 131.7 (*m*-Ph), 132.6 (*i*-NPh), 140.9 (*i*-NCNPh), 172.9, 173.2 (C=O); ms (EI, 70 eV): *m/z* 292 (M^++1, 21), 291 (M^+, 100), 173 (63), 144 (90), 129, (17), 118 (56), 104

(70), 91 (65), 77 (81). *Anal.* Calcd. for $C_{17}H_{13}N_3O_2$ (291.304): C, 70.09; H, 4.50; N, 14.43. Found C, 70.12; H, 4.51; N, 14.47.

The reaction of 3-phenyl-1-*p*-tolyltetrazolium salt **2b**′ and *N*-phenylmaleimide was similarly conducted as above to yield **13** (54 mg, 17%), **14** (26 mg, 10%), **15**′ (70 mg, 23%), and **4**′ (29 mg, 22%).

(2,5-Dioxo-1-phenylpyrrolidin-3-yl)-*p*-tolylcyanamide (15′). Colourless crystals, Mp. 140–142°C (acetone/hexane); ir (KBr): 3075, 2935, 2855, 2210, 1716, 1512, 1398, 1370, 1250, 1176, 818, 810, 740, 700/cm; ^{1}H NMR (200 MHz, deuteriochloroform): δ 2.36 (s, 3H, Me), 3.22 (dd, *J* = 18.5 Hz, *J* = 6.4 Hz, 1H, trans-CH_2), 3.43 (dd, *J* = 18.5 Hz, *J* = 9.2 Hz, 1H, cis-CH_2), 4.86 (dd, *J* = 9.2 Hz, *J* = 6.4 Hz, 1H, CH), 7.21–7.35 (m, 6H, Ph), 7.44–7.51 (m, 3H, Ph); ^{13}C NMR (50 MHz, deuteriochloroform): δ 20.7 (Me), 33.8 (CH_2), 57.9 (CH), 111.6 (CN), 118.9 (Ph), 126.2 (Ph), 129.0 (*p*-Ph), 129.2 (Ph), 130.5 (Ph), 130.9 (*i*-NPh), 135.9, 136.6 (*i*-NCNPh, *C*—Me), 171.3, 171.6 (C=O); ms (EI, 70 eV): *m*/*z* 306 (M^++1, 12), 305 (M^+, 55), 173 (100), 158 (42), 132 (9), 131 (90), 91 (78). *Anal.* Calcd. for $C_{18}H_{15}N_3O_2$ (305.33): C, 70.80; H, 4.95; N, 13.77. Found C, 70.46; H, 4.78; N, 13.64.

***p*-Tolylcyanamide (4′).** Oil; ir (KBr): 3175–2900, 2215, 1704, 1614, 1594, 1514, 1398, 1310, 1282, 1248, 804/cm; ^{1}H NMR (200 MHz, deuteriochloroform): δ 2.31 (s, 3H, Me), 6.31 (bs, 1H, NH), 6.91 (d, *J* = 8.5 Hz, 2H, Ph), 7.13 (d, *J* = 8.5 Hz, 2H, Ph) [17].

Reaction with fumaronitrile. To a mixture of **2b** (0.31 g, 1.0 mmol) and fumaronitrile (0.78 g, 1.0 mmol) in DMF (3.0 mL) was added DBU (0.15 mL, 1.0 mmol) at –60°C, and the mixture was gradually warmed to room temperature in a period of 1.5 h, and then further stirred at room temperature for 1.5 h. Water was added and the products were extracted with dichloromethane. The extracts were dried over anhydrous Na_2SO_4 and the solvent was removed under reduced pressure. The residue (0.23 g) was chromatographed (SiO_2/CH_2Cl_2: hexane = 2:3→MeOH) to give **16** (21 mg, 9%), **17** (5 mg, 3%), **18** (11 mg, 7%) and **7** (18 mg, 8%). A mixture of **3** and **4** (42 mg, 3:4 = 31:69) was also obtained.

2,3-Diphenylfumalonitrile (16). Colourless crystals, Mp. 157–159°C (hexane) (lit Mp. 160–161°C) [18].

2-Phenylmaleonitrile (17). Colourless crystals, Mp. 37–43°C (lit Mp. 40.5–41°C) [18].

2-Phenylfumalonitrile (18). Colourless crystals, Mp. 86–91°C (hexane) (lit Mp. 87.5–88°C) [18].

Reaction with dimethyl acetylenedicarboxylate. To a mixture of **2b** (0.31 g, 1.0 mmol) and dimethyl acetylene-dicarboxylate (DMAD) (0.25 mL, 2.0 mmol) in DMF (2.0 mL) was added DBU (0.15 mL, 1.0 mmol) at –60°C, and the mixture was gradually warmed to room temperature in a period of 1.5 h, and then further stirred at room temperature for 1.5 h. Water was added and the products were extracted with dichloromethane. The extracts were dried over anhydrous Na_2SO_4 and the solvent was removed under reduced pressure. The residue (0.57 g) was chromatographed (SiO_2/CH_2Cl_2-EtOAc gradient and MeOH) to give **19** (75 mg, 29% yield, *E*/*Z* mixture = 3:1) and **7** (18 mg, 8% yield). DMAD was recovered (53 mg, recovery 19%).

Dimethyl 2-(phenylcyanamido)-2-butenedicarboxylate (19). Pale yellow crystals; Mp. 77–85.5°C (CH_2Cl_2/hexane); ir (KBr, *E*/*Z* mixture): 2230, 1736, 1722, 1640, 1594, 1492, 1436, 1270, 1222, 1066, 1014, 894, 774, 760, 692/cm; ^{1}H NMR (200 MHz, deuteriochloroform, *E* isomer): δ 3.77 (s, 3H, Me), 3.81 (s, 3H, Me), 7.00 (s, 1H, =C*H*CO_2Me), 7.06–7.11 (m, 2H, *o*-Ph), 7.16–7.23 (m, 1H, *p*-Ph), 7.34–7.42 (m, 2H, *m*-Ph); ^{13}C NMR (50 MHz, $CDCl_3$, *E* isomer): δ 52.7 (Me), 53.6 (Me), 117.4 (*o*-Ph), 125.5, 126.1 (C=*C*HCO_2Me, *p*-Ph), 129.7 (*m*-Ph), 136.3, 139.0 (*C*=CH, *i*-Ph), 162.2 (*C*O_2Me), 162.5 (*C*O_2Me); uv/vis (MeCN, *E* isomer): λ_{max} (log ε) = 317.0 (3.37), 227 nm (4.23); ms (EI, 70 eV, *E*/*Z* mixture): *m*/*z* (%): 261 (M^++1, 18), 260 (M^+, 100), 245 (25), 229 (37), 201 (61), 200 (33), 169 (27), 157 (52), 142 (28), 115 (30). *Anal.* Calcd. for $C_{13}H_{12}N_2O_4$ (288.27): C, 59.99; H, 4.65; N, 10.77. Found C, 60.30; H, 4.70; N, 10.88.

Reaction of tetrazolium salt 2b with bis(1,5-cyclooctadiene)-μ,μ′-dichlorodirhodium (20). Typical procedure (Table 2, entry 1): A mixture of **2b** (0.16 g, 0.50 mmol) and bis (1,5-cyclooctadiene)-μ,μ′-dichlorodirhodium (**20**) (0.13 g, 0.25 mmol) in dry DMF (10 mL) was cooled to –60°C. DBU (75 μL, 0.5 mmol) was added and the mixture was stirred at −60°C for 3 h. Cold water was added and the precipitated solid (0.13 g) was filtered. The filtrate was extracted with CH_2Cl_2, washed with water, and dried (Na_2SO_4). The solvent was evaporated and the residue (90 mg) was chromatographed (SiO_2/CH_2Cl_2→ MeOH) to give bis(1,5-cyclooctadiene)-μ,μ′-dichlorodirhodium (16 mg, 12% recovery), **21** (29 mg, 12%), and **22** (16 mg). The precipitated solid was purified by column chromatography (SiO_2/CH_2Cl_2→MeOH) to give **22** (43 mg). The total yield of **22** is 59 mg (31%). Other reactions were conducted similarly, and the results are summarized in Table 2.

Complex 21. Yellow crystals, Mp. 165°C (EtOH); ir (KBr): 2940, 2860, 1488, 1362, 1230, 1140, 1014, 762, 680/cm; ^{1}H NMR (200 MHz, deuteriochloroform): δ 1.86–1.95 (m, 4H, cod-CH_2), 2.32–2.37 (m, 4H, cod-CH_2), 3.35 (s, 2H, cod-CH), 5.17 (s, 2H, cod-CH), 7.59–7.67 (m, 6H, Ph), 8.21–8.26 (m, 2H, Ph), 8.74–8.78 (m, 2H, Ph); ^{13}C NMR (50 MHz, deuteriochloroform): δ 29.0, 32.7 (cod-CH_2), 69.7 (d, *J* (^{103}Rh-^{13}C) = 14.3 Hz, cod-CH), 98.7 (d, *J* (^{103}Rh-^{13}C) = 7.2 Hz, cod-CH), 120.6, 123.9 (*o*-Ph), 128.9, 129.7 (*m*-Ph), 130.2, 131.6 (*p*-Ph), 135.0, 135.9 (*i*-Ph), 187.7 (d, *J* (^{103}Rh-^{13}C) = 51.6 Hz, Rh-C); uv/vis (MeCN): λ_{max} (log ε) = 280.5 (3.20), 384.0 nm (2.23). *Anal.* Calcd. for $C_{21}H_{22}ClN_4Rh$ (468.77): C 53.80, H 4.69, N 11.95; found C 53.70, H 4.60, N 11.90.

Complex 22. Yellow crystals, Mp. 152–154°C (EtOH); ir (KBr): 1590, 1492, 1468, 1358, 1310, 1230, 1124, 1096, 1038, 1010, 766, 684/cm; ^{1}H NMR (200 MHz, deuteriochloroform): δ 2.22–2.44 (m, 8H, cod-CH_2), 4.65 (s, 4H, cod-CH), 7.51–7.63 (m, 12H, Ph), 7.96–8.01 (m, 4H, Ph), 8.40–8.45 (m, 4H, Ph). ^{13}C NMR (50 MHz, deuteriochloroform): δ 31.1 (cod-CH_2), 90.7 (d, *J* (^{103}Rh-^{13}C) = 8.0 Hz, cod-CH), 120.6, 123.6 (*o*-Ph), 129.3, 129.9 (*m*-Ph), 130.8, 132.0 (*p*-Ph), 134.7, 135.2 (*i*-Ph), 185.3 (d, *J* (^{103}Rh-^{13}C) = 54.8 Hz, Rh-C); uv/vis (MeCN): λ_{max} (log ε) = 282.0 (3.37), 409.5 nm (2.21). *Anal.* Calcd. for $C_{34}H_{32}BF_4N_8Rh$ (742.01): C, 55.03; H, 4.31; N, 15.09. Found C, 54.86; H, 4.26; N, 14.96.

Reaction of tetrazolium salt 2b with complex 21. A mixture of **2b** (22 mg, 0.070 mmol) and **21** (33 mg, 0.070 mmol) in dry DMF (1 mL) was cooled to –60°C. DBU (11 μL, 0.07 mmol) was added and the mixture was stirred at –60°C for 4 h. Cold water was added and the precipitated solid (0.16 g) was filtered. The product was purified by column chromatography (SiO_2/CH_2Cl_2) to give **22** (23 mg, 44%). A small amount of complex **21** was recovered (11 mg, 33%).

Reaction of ethynylbenzene and benzoyl chloride catalyzed by 21 or 22. A mixture of ethynylbenzene (0.33 mL, 3.0 mmol), benzoyl chloride (0.23 mL, 2.0 mmol), triphenylphosphine (5.2 mg, 0.020 mmol), and **21** (9.4 mg, 0.020 mmol) in octane (5 mL) was heated overnight at 140°C. 2-Methylnaphthalene (20 mg) was added as an internal standard, and the reaction mixture was analyzed by glc. The yield of the product (**23**) was estimated to be 61%. The mixture was chromatographed (SiO_2/hexane) and **23** was isolated (0.18 g, 43%). The reaction with **22** was similarly carried out and the yield of **23** was 22% (glc).

X-ray crystallography. X-ray analysis of **9** was performed on a sample recrystallized from CH_2Cl_2/hexane. Complex **21** was recrystallized from ethanol, and **22** from a mixture of CH_2Cl_2:EtOAc:hexane = 1:9:1.

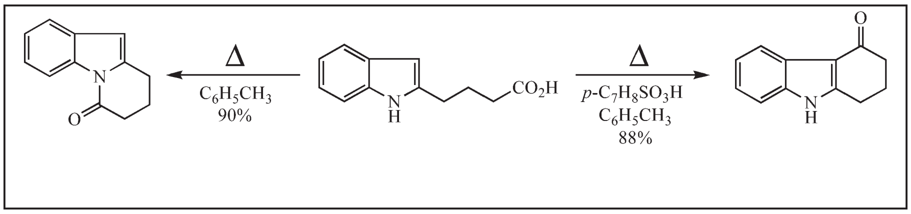
DOI 10.1002/jhet.22



Efficient syntheses of the title ring systems have been developed from 1*H*-indole-2-butanoic acid, which was easily prepared from 2-fluoro-1-nitrobenzene in four steps. Heating 1*H*-indole-2-butanoic acid in toluene containing *p*-toluenesulfonic acid at 110°C furnished 1,2,3,9-tetrahydro-4*H*-carbazol-4-one in 88% yield. Heating this same acid in toluene with no added acid gave 8,9-dihydropyrido[1,2-*a*]-indol-6(7*H*)-one in 90% yield. The tetrahydro-4*H*-carbazol-4-one was also prepared directly in 92% yield from methyl 6-(2-nitrophenyl)-5-oxohexanoate by a tandem reduction—cycloaromatization—acylation reaction with iron in concentrated hydrochloric acid at 110°C. Application of this approach to the closure of five- and seven-membered rings was also successful.

J. Heterocyclic Chem., **46**, 172 (2009).

INTRODUCTION

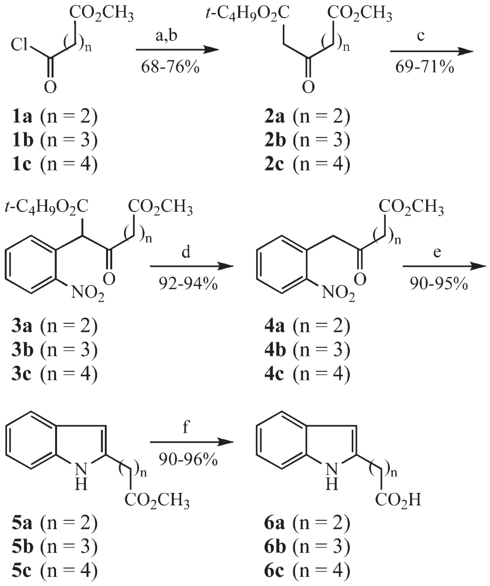
Earlier studies from this laboratory [1] and by others [2] described the synthesis of substituted indoles from 2-nitrobenzyl ketones based on a tandem reduction—cycloaromatization reaction. Our recent work has sought to assemble more complex structures using this strategy. In this study, we have developed a route to synthesize 1,2,3,9-tetrahydro-4*H*-carbazol-4-one and 8,9-dihydropyrido[1,2-*a*]indol-6(7*H*)-one from 1*H*-indole-2-butanoic acid. In the course of this study, we also discovered that the tetrahydro-4*H*-carbazol-4-one could be prepared from methyl 6-(2-nitrophenyl)-5-oxohexanoate in one step by a tandem reduction—cycloaromatization—acylation sequence. Tetrahydro-4*H*-carbazol-4-one is an important building block for the synthesis of alkaloids [3] as well as the core ring structure in current drugs used for the treatment of cancer [4], HIV [5], congestive heart failure [6], and emesis resulting from chemotherapy [7]; 8,9-dihydropyrido[1,2-*a*]indol-6(7*H*)-ones have been studied for the treatment of ischemic disorders [8] and vomiting caused by cancer treatment [9].

Several other approaches have been reported for the tetrahydro-4*H*-carbazol-4-one system. The Fischer indole synthesis between phenylhydrazine and 1,3-cyclohexanedione is the simplest, but only provides a 50% yield [10]. Other routes include C4 oxidation of tetrahydrocarbazole [11]; base-promoted cyclization of 2-(2-trifluoroacetamidophenyl)-2-cyclohexen-1-one [12]; copper(I)-mediated [13] or photochemical [14] arylation of *N*-substituted enaminones; and a number of palladium-catalyzed coupling reactions [15]. Our synthesis requires several steps, but permits the preparation of two pharmacologically valuable compounds without excessively hazardous reagents or expensive catalysts. We have also found that other saturated ring homologues of the title compounds are available using this strategy.

RESULTS AND DISCUSSION

Our cyclization studies required access to a series of 1*H*-indole-2-alkanecarboxylic acids. To this end, a synthesis of these precursors was devised and carried out from Meldrum's acid [16] and commercially available (ω-chlorocarbonyl)alkanoic esters **1a–c** (Scheme 1). Acylation of Meldrum's acid with **1a–c** in the presence of pyridine followed by refluxing in *tert*-butyl alcohol gave the *tert*-butyl methyl 3-oxoalkanedicarboxylic esters **2a-c** in 68–76% yields [17]. Deprotonation of **2a–c** with sodium hydride in anhydrous *N*,*N*-dimethylformamide and reaction with 2-fluoro-1-nitrobenzene at 55–60°C afforded the nucleophilic aromatic substitution products **3a–c** in yields ranging from 69 to 71% [1,2]. Subsequent exposure of **3a–c** to trifluoroacetic acid in the presence of triethylsilane [18] resulted in *tert*-butyl ester cleavage and decarboxylation to provide nitro ketoesters **4a–c** in 92–94% yields. Treatment of **4a-c** with iron powder in acetic acid then initiated a tandem reduction—cycloaromatization reaction to furnish 1*H*-indole-2-alkanecarboxylic esters **5a–c** in 90–95% yields [1]. Finally, basic hydrolysis of **5a–c** provided acids **6a–c** in 90–96% yields.

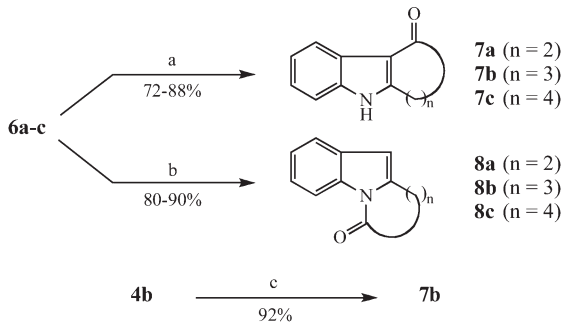
Scheme 1 [a]



[a] Key: (a) Meldrum's acid, pyridine, CH_2Cl_2, 0–22°C; (b) t-C_4H_9OH, reflux; (c) NaH, dimethylformamide; 2-fluoro-1-nitrobenzene, 55–60 °C, 48 h; (d) CF_3CO_2H, $(C_2H_5)_3SiH$, CH_2Cl_2, 22°C, 1 h; (e) Fe (>100 mesh), CH_3CO_2H, 115°C, 30 min; (f) 1*M* aqueous NaOH, dioxane, 22°C, 1 h.

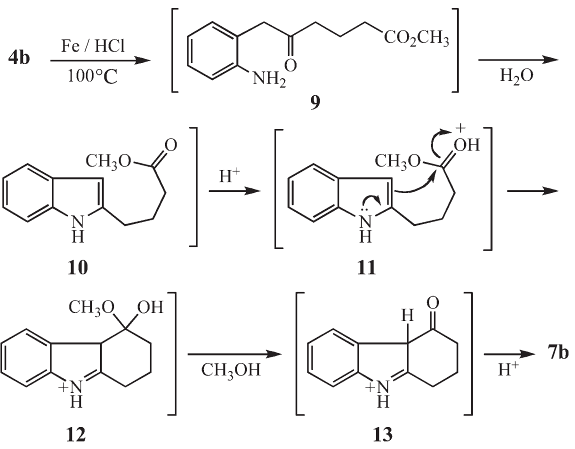
The results of our cyclization studies are summarized in Scheme 2. Treatment of **6a–c** with 2.0–6.0 equivalents of *p*-toluenesulfonic acid in refluxing toluene resulted in a Friedel-Crafts-like ring closure of the acid to C3 of the indole moiety to yield **7a–c** in 72–88% yields. Refluxing **6b** in toluene without the added *p*-toluenesulfonic acid resulted in closure to lactam **8b** (90%); acids **6a** and **6c** did not cyclize under these conditions reflecting stereoelectronic problems in closing the five- and seven-membered rings. Lactamization of **6a** and **6c** was possible in ≥80% yields, however, using *N*-(3-dimethylaminopropyl)-*N*′-ethylcarbodiimide hydrochloride [19] in the presence of 1.6 equivalents of 4-(dimethylamino)pyridine [20]. Numerous other ring-closing regimes [21] failed to give the desired lactams. This seems to be the first report describing the use of *N*-(3-dimethylaminopropyl)-*N*′-ethylcarbodiimide with 4-(dimethylamino)pyridine for lactam closures. The function of the base in this reaction is two-fold, neutralizing the hydrochloride salt of the carbodiimide and scavenging a proton from the cyclized amide.

Scheme 2 [a]



[a] Key: (a) p-$C_7H_8SO_3H$, $PhCH_3$, 110°C; (b) for **6a** and **6c**, *N*-(3-dimethylaminopropyl)-*N*'-ethylcarbodiimide hydrochloride, 4-(dimethylamino)pyridine, CH_2Cl_2, 22°C; for **6b**, $PhCH_3$, 110°C; (c) Fe (>100 mesh), concentrated HCl, 110°C, 20 min.

Scheme 3



Remarkably, it was found that treatment of **4b** with iron in concentrated hydrochloric acid yielded **7b** in 92% yield by a tandem process involving a reduction—cycloaromatization—acylation sequence. Attempts to cyclize **6a** and **6c** under the same conditions afforded significantly lower yields and the product mixtures were more complex. The one-step conversion of **4b** to **7b** represents a new tandem reaction sequence.

Mechanistically, reduction of the aromatic nitro group is followed by cycloaromatization to the indole system as previously observed [1,2]. Under strong acid conditions, however, the methyl ester is cyclized onto the C3 position of indole. This most likely occurs by protonation of the ester carbonyl, addition of the electron-rich indole double bond to the carbonyl carbon, loss of methanol and rearomatization (Scheme 3). The closure of acids **6a** and **6c**–**7a** and **7c** should be analogous to the conversion of **10** to **7b** with loss of water in the penultimate step. Finally, the lactamization reactions proceed *via* the expected cyclocondensation mechanisms, with and without added carbodiimide.

CONCLUSION

We have developed a new approach to the synthesis of the title compounds using 1*H*-indole-2-butanoic acid (**6b**) as a common intermediate. Heating this acid in refluxing toluene containing *p*-toluenesulfonic acid affords 1,2,3,9-tetrahydro-4*H*-carbazol-4-one (**7b**), while heating in toluene with no added acid yields 8,9-dihydropyrido[1,2-*a*]indol-6(7*H*)-one (**8b**). A high yield of **7b** can also be achieved directly from **4b** *via* a tandem reduction—cycloaromatization—acylation reaction promoted by iron in concentrated hydrochloric acid. Homologues **7a** and **7c** can also be prepared by heating **6a** and **6c** in toluene with *p*-toluenesulfonic acid, but direct conversion from **4a** and **4c** with iron in concentrated hydrochloric acid was unsuccessful. Lactamization of **6a** and **6c** requires treatment with *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide hydrochloride in the presence of excess 4-(dimethylamino)pyridine. The synthesis requires several steps, but provides a number of pharmacologically useful compounds in high yield without excessively hazardous or expensive reagents.

EXPERIMENTAL

The commercial acid chlorides were used as received. *N*,*N*-Dimethylformamide, from a freshly opened bottle, was dried over 4 Å molecular sieves under nitrogen and transferred by syringe into reactions where it was used. The hydrochloric acid (1*M*, 2*M*, and 6*M*), sodium hydroxide (1*M*), ammonium chloride (saturated), sodium bicarbonate (saturated), and sodium chloride (saturated) employed in various procedures refer to aqueous solutions. All reactions were run under N_2 in oven-dried glassware. Reactions were monitored by thin layer chromatography on silica gel GF plates (Analtech 21521). Preparative separations were performed using flash column chromatography [22] on silica gel (grade 62, 60–200 mesh) mixed with ultraviolet-active phosphor (Sorbent Technologies UV-5) or thin layer chromatography on 20 cm x 20 cm silica gel GF plates (Analtech 02015). Band elution, for both methods, was monitored using a hand-held ultraviolet lamp. Hexanes used in chromatography had a boiling range of 65–70°C. Melting points were uncorrected. Infrared spectra were run as thin films on sodium chloride disks and were referenced to polystyrene. Unless otherwise indicated, ^{1}H and ^{13}C nuclear magnetic resonance spectra were measured in chloroform-d_1 at 300 MHz and 75 MHz, respectively, and were referenced to internal tetramethylsilane; coupling constants (*J*) are reported in Hertz. Low-resolution mass spectra (electron impact/direct probe) were run at 70 electron volts.

Representative procedure for the preparation of *tert*-butyl methyl 3-oxoalkanedicarboxylic esters: *tert*-butyl methyl 3-oxohexanedioate (2a). The procedure of Yonemitsu and coworkers was used [18]. To a stirred solution of 7.00 g (48.6 mmoles) of Meldrum's acid and 7.68 g (97.2 mmoles) of pyridine in 50 mL of dichloromethane at 0°C was added a solution of 7.68 g (51.0 mmoles) of **1a** in 10 mL of dichloromethane. Stirring was continued at 0°C for 30 min and at 22°C for 1 h. The crude reaction mixture was washed with 2*M* hydrochloric acid (three times) to remove the excess pyridine and the solution was dried (magnesium sulfate) and concentrated under vacuum. The resulting oil was dissolved in 50 mL of *tert*-butyl alcohol and refluxed for 3 h. The crude reaction mixture was cooled, concentrated under vacuum and distilled under high vacuum to give 8.20 g (73%) of keto diester **2a** containing some enol as a colorless oil, bp 85–110°C (0.5 mmHg). IR: 1737, 1717 cm^{-1}; ^{1}H NMR: δ 3.68 (s, 3H), 3.41 (s, 2H), 2.87 (t, 2H, *J* = 6.6), 2.62 (t, 2H, *J* = 6.6), 1.47 (s, 9H); ^{13}C NMR: δ 201.4, 172.8, 166.2, 81.9, 51.7, 50.4, 37.2, 27.8 (3C), 27.5.

***tert*-Butyl methyl 3-oxoheptanedioate (2b).** This compound (9.00 g, 76% containing some enol) was isolated as a colorless oil, bp 110–130°C (0.5 mmHg). IR: 1738, 1716 cm^{-1}; ^{1}H NMR: δ 3.67 (s, 3H), 3.35 (s, 2H), 2.62 (t, 2H, *J* = 7.0), 2.36 (t, 2H, *J* = 7.2), 1.92 (quintet, 2H, *J* = 7.1), 1.47 (s, 9H); ^{13}C NMR: δ 202.5, 173.5, 166.4, 82.0, 51.5, 50.5, 41.6, 32.7, 27.9 (3C), 18.5.

***tert*-Butyl methyl 3-oxooctanedioate (2c).** This compound (8.50 g, 68% containing some enol) was isolated as a colorless oil, bp 125–140°C (0.5 mmHg). IR: 1735, 1716 cm^{-1}; ^{1}H NMR: δ 3.67 (s, 3H), 3.35 (s, 2H), 2.56 (distorted t, 2H, *J* = 6.7), 2.33 (distorted t, 2H, *J* = 6.7), 1.63 (m, 4H), 1.47 (s, 9H); ^{13}C NMR: δ 202.8, 173.7, 166.4, 81.9, 51.5, 50.5, 42.3, 33.7, 27.9 (3C), 24.2, 22.7.

Representative procedure for nucleophilic aromatic substitution: *tert*-butyl methyl 2-(2-nitrophenyl)-3-oxohexanedioate (3a). A modification of the procedure described by Bunce *et al.* was used [1]. To a suspension of 1.36 g (56.7 mmoles) of oil-free sodium hydride in 20 mL of dry *N*,*N*-dimethylformamide was added 4.00 g (28.4 mmoles) of 2-fluoro-1-nitrobenzene in 25 mL of dimethylformamide. Stirring was initiated and a solution of 6.35 g (29.7 mmoles) of **2a** in 5 mL of dimethylformamide was added. The reaction mixture was heated to 55–60°C and stirred for 48 h, then cooled, added to 50 mL of saturated ammonium chloride and extracted with ether (three times). The combined organic extracts were washed with saturated sodium chloride (one time), dried (magnesium sulfate) and concentrated under vacuum. The crude product was purified by flash chromatography on a 50 cm × 2 cm silica gel column using 10% ether in hexanes to give 6.65 g (69%) of keto diester **3a** containing some enol as a yellow oil. IR: 1736, 1640, 1613, 1520, 1351 cm^{-1}; ^{1}H NMR: δ 7.98 (dd, 1H, *J* = 8.0, 1.2), 7.58 (td, 1H, *J* = 7.6, 1.4), 7.46 (td, 1H, *J* = 7.9, 1.6), 7.33 (dd, 1H, *J* = 7.6, 1.4), 5.28 (s, 1H), 3.64 (s, 3H), 2.50 (m, 4H), 1.32 (s, 9H); ^{13}C NMR: δ 200.4, 172.7, 170.6, 149.7, 133.7, 132.6, 130.1, 128.3, 124.5, 82.6, 61.3, 51.7, 37.4, 29.8, 27.8 (3C).

***tert*-Butyl methyl 2-(2-nitrophenyl)-3-oxoheptanedioate (3b).** This compound (6.00 g, 69% containing some enol) was isolated as a yellow oil. IR: 1738, 1645, 1526, 1394, 1352 cm^{-1}; ^{1}H NMR: δ 7.98 (dd, 1H, *J* = 8.0, 1.2), 7.57 (td, 1H, *J* = 7.6, 1.4), 7.45 (td, 1H, *J* = 7.9, 1.4), 7.25 (dd, 1H, *J* = 7.6, 1.4), 5.25 (s, 1H), 3.57 (s, 3H), 2.25 (m, 4H), 1.88 (m, 2H), 1.33 (s, 9H); ^{13}C NMR: δ 200.8, 172.7, 170.7, 149.7, 133.7, 132.8, 130.1, 128.4, 124.3, 82.6, 61.3, 51.8, 37.4, 29.9, 28.0, 27.8 (3C).

***tert*-Butyl methyl 2-(2-nitrophenyl)-3-oxooctanedioate (3c).** This compound (4.20 g, 71% containing some enol) was isolated as a yellow oil. IR: 1735, 1643, 1615, 1524, 1352 cm^{-1}; ^{1}H NMR: δ 7.98 (dd, 1H, *J* = 8.0, 1.3), 7.56 (td, 1H, *J* = 7.5, 1.4), 7.45 (td, 1H, *J* = 7.9, 1.6). 7.25 (dd, 1H, *J* = 7.7. 1.4), 5.26 (s, 1H), 3.63 (s, 3H), 2.21 (m, 2H), 2,12 (m, 2H), 1.57 (m, 4H), 1.24 (s, 9H); ^{13}C NMR: δ 201.8, 173.7, 170.7, 149.7, 133.7, 132.5, 130.5, 128.8, 124.3, 82.4, 61.0, 51.5, 33.6, 32.5, 27.8 (3C), 25.7, 24.3.

Representative procedure for *tert*-butyl ester cleavage and decarboxylation: methyl 5-(2-nitrophenyl)-4-oxopentanoate (4a). The procedure of Mehta *et al.* [17] was used. To a solution of 5.20 g (14.8 mmoles) of **3a** in 50 mL of dichloromethane were added 27.6 g (18.0 mL, 242 mmoles) of trifluoroacetic acid and 4.88 g (6.70 mL, 42.0 mmoles) of triethylsilane. The mixture was stirred at 22°C for 1 h and then concentrated under vacuum to give 3.50 g (94%) of **4a** as a light yellow oil, which was used without further purification. IR: 1735, 1722, 1525, 1351 cm^{-1}; ^{1}H NMR: δ 8.11 (dd, 1H, *J* = 8.0, 1.1), 7.60 (td, 1H, *J* = 7.7, 1.3), 7.46 (td, 1H, *J* = 7.9, 1.5), 7.31 (dd, 1H, *J* = 7.7, 1.1), 4.16 (s, 2H), 3.67 (s, 3H), 2.93 (t, 2H, *J* = 6.5), 2.65 (t, 2H, *J* = 6.5); ^{13}C NMR: δ 204.0, 173.1, 148.5, 133.7, 133.6, 130.1, 128.5, 125.2, 51.8, 47.8, 37.1, 27.8; ms: *m/z* 251 (M^{+}). *Anal.* Calcd. for $C_{12}H_{13}NO_5$: C, 57.37; H, 5.18; N, 5.58. Found: C, 57.41; H, 5.21; N, 5.53.

Methyl 6-(2-nitrophenyl)-5-oxohexanoate (4b). This compound (3.46 g, 92%) was isolated as a light yellow oil and used without further purification. IR: 1729, 1525, 1346 cm^{-1}; ^{1}H NMR: δ 8.11 (dd, 1H, *J* = 8.0, 1.1), 7.59 (td, 1H, *J* = 7.7, 1.5), 7.46 (td, 1H, *J* = 7.9, 1.5), 7.28 (dd, 1H, *J* = 7.7, 1.1), 4.09 (s, 2H), 3.68 (s, 3H), 2.70 (t, 2H, *J* = 7.1), 2.38 (t, 2H, *J* = 7.1), 1.96 (quintet, 2H, *J* = 7.1); ^{13}C NMR: δ 204.9, 173.6, 148.6, 133.6 (2C), 130.2, 128.4, 125.2, 51.6, 47.9, 41.4, 32.9, 18.7; ms: *m/z* 265 (M^{+}). *Anal.* Calcd. for $C_{13}H_{15}NO_5$: C, 58.87; H, 5.66; N, 5.28. Found: C, 59.00: H, 5.58; N, 5.23.

Methyl 7-(2-nitrophenyl)-6-oxoheptanoate (4c). This compound (1.45 g, 92%) was isolated as a light yellow oil and used without further purification. IR: 1727, 1528, 1352 cm^{-1}; ^{1}H NMR: δ 8.10 (dd, 1H, *J* = 8.2, 1.3), 7.59 (td, 1H, *J* = 7.5, 1.3), 7.46 (td, 1H, *J* = 8.1, 1.5), 7.27 (dd, 1H, *J* = 7.6, 1.1), 4.10 (s, 2H), 3.67 (s, 3H), 2.62 (distorted t, 2H, *J* = 6.8), 2.34 (distorted t, 2H, *J* = 6.8), 1.67 (m, 4H); ^{13}C NMR: δ 205.2, 173.8, 148.6, 133.5 (2C), 130.3, 128.3, 125.2, 51.5, 47.8, 42.2, 33.7, 24.3, 22.9; ms: *m/z* 279 (M^{+}). *Anal.* Calcd. for $C_{14}H_{17}NO_5$: C, 60.22; H, 6.09; N, 5.02. Found: C, 60.24; H, 6.10; N, 4.98.

Representative procedure for reductive cyclization to the 1*H*-indoles: methyl 1*H*-indole-2-propanoate (5a). The procedure of Bunce *et al*. [1] was used. A mixture of 1.50 g (5.98 mmoles) of **4a**, 25 mL of acetic acid and 2.00 g (35.9 mmoles, 6.0 eq) of iron powder (>100 mesh) was heated with stirring at 115°C (oil bath) until thin layer chromatography indicated complete consumption of starting material (*ca* 30 min). The crude reaction was cooled, transferred to a separatory funnel containing 50 mL of water and extracted with ether (three times). The combined ether layers were washed with water (one time), saturated sodium bicarbonate (three times), saturated sodium chloride (one time), then dried (magnesium sulfate) and concentrated under vacuum to give a brown solid. Recrystallization from hexanes gave 1.10 g (91%) of **5a** as a tan solid, mp 97–98°C (lit [23] mp 97–98°C, hexane). IR: 3357, 1720 cm^{-1}; ^{1}H NMR: δ 8.47 (br s, 1H), 7.52 (dd, 1H, *J* = 7.9, 0.6), 7.31 (dq, 1H, *J* = 8.0, 0.9), 7.12 (td, 1H, *J* = 7.9, 1.3), 7.06 (td, 1H, *J* = 7.9, 1.1), 6.24 (dd, 1H, *J* = 2.0, 0.9), 3.72 (s, 3H), 3.08 (t, 2H, *J* = 6.7), 2.73 (t, 2H, *J* = 6.7); ^{13}C NMR: δ 174.3, 138.1, 136.0, 128.4, 121.3, 119.9, 119.6, 110.5, 99.8, 51.9, 33.9, 23.1; ms: *m/z* 203 (M^{+}). *Anal.* Calcd. for $C_{12}H_{13}NO_2$: C, 70.94; H, 6.40; N, 6.90. Found: C, 70.92; H, 6.39; N, 6.92.

Methyl 1*H*-indole-2-butanoate (5b). This compound (1.15 g, 95%) was isolated as a tan solid, mp 69–71°C. IR: 3392, 1718 cm^{-1}; ^{1}H NMR: 8.06 (br s, 1H), 7.52 (d, 1H, *J* = 7.6 Hz), 7.30 (d, 1H, *J* = 6.0 Hz), 7.08 (m, 2H), 6.25 (s, 1H), 3.66 (s, 3H), 2.81 (t, 2H, *J* = 7.2 Hz), 2.40 (t, 2H, *J* = 7.2 Hz), 2.04 (m, 2H); ^{13}C NMR: δ 173.9, 138.4, 128.8, 121.1, 119.8, 119.6, 110.3, 100.0, 51.6, 33.1, 30.0, 27.3, 24.5; ms: *m/z* 217 (M^{+}). *Anal.* Calcd. for $C_{13}H_{15}NO_2$: C, 71.89; H, 6.91; N, 6.45. Found: C, 71.85; H, 6.92; N, 6.43.

Methyl 1*H*-indole-2-pentanoate (5c). This compound (1.10 g, 90%) was isolated as a tan solid, mp 121–124°C. IR: 3353, 1719 cm^{-1}; ^{1}H NMR: δ 7.98 (br s, 1H), 7.52 (d, 1H, *J* = 6.8 Hz), 7.28 (d, 1H, *J* = 8.0 Hz), 7.08 (m, 2H), 6.24 (s, 1H), 3.67 (s, 3H), 2.76 (t, 2H, *J* = 7.2 Hz), 2.37 (t, 2H, *J* = 3.6 Hz), 1.76 (m, 4H); ^{13}C NMR: δ 174.2, 139.3, 136.0, 128.9, 121.2, 119.6, 119.8, 110.5, 99.8, 51.7, 33.9, 28.7, 28.0, 24.6; ms: *m/z* 231 (M^{+}). *Anal.* Calcd. for $C_{14}H_{17}NO_2$: C, 72.73; H, 7.36; N, 6.06. Found: C, 72.70; H, 7.33; N, 6.10.

Representative procedure for the ester hydrolysis: 1*H*-indole-2-propanoic acid (6a). A mixture of 1.00 g (4.93 mmoles) of **5a** in 20 mL of dioxane and 15 mL of 1*M* sodium hydroxide was stirred at 22°C for 1 h. The solution was concentrated to one-half volume under vacuum, acidified with 3*M* hydrochloric acid and extracted with ether (three times). The combined ether layers were washed with saturated sodium chloride (one time), then dried (magnesium sulfate) and concentrated under vacuum. The crude product was purified by flash chromatography on a 15 cm × 2 cm silica gel column using 50% ether in hexanes to give 0.85 g (91%) of **6a** as a white solid, mp 165–167°C (lit [24] mp 167°C). IR: 3462–2300, 3392, 1701 cm^{-1}; ^{1}H NMR: δ 9.87 (br s, 1H), 8.26 (br s, 1H), 7.52 (dd, 1H, *J* = 7.7, 0.7), 7.30 (dd, 1H, *J* = 8.0, 0.9), 7.13 (td, 1H, *J* = 7.7, 1.3), 7.07 (td, 1H, *J* = 7.9, 1.1), 6.26 (dd, 1H, *J* = 1.9, 0.8), 3.08 (t, 2H, *J* = 6.8), 2.81 (t, 2H, *J* = 6.8); ^{13}C NMR: δ 178.4, 137.6, 135.5, 128.4, 121.4, 119.9, 119.7, 110.5, 99.9, 33.6, 22.9; ms: *m/z* 189 (M^{+}). *Anal.* Calcd. for $C_{11}H_{11}NO_2$: C, 69.84; H, 5.82; N, 7.41. Found: C, 69.88; H, 5.85; N, 7.37.

1*H*-Indole-2-butanoic acid (6b). This compound (0.33 g, 90%) was isolated as a white solid, mp 114–115°C. IR: 3252–2348, 3386, 1700 cm^{-1}; ^{1}H NMR: 10.85 (br s, 1H), 7.95 (br s, 1H), 7.52 (dd, 1H, *J* = 7.7, 0.7), 7.29 (dd, 1H, *J* = 8.0, 0.9), 7.12 (td, 1H, 7.9, 1.3), 7.07 (td, 1H, *J* = 7.7, 1.1), 6.27 (dd, 1H, *J* = 2.0, 0.8), 2.83 (t, 2H, *J* = 7.3), 2.45 (t, 2H, *J* = 7.3), 2.06 (quintet, 2H, *J* = 7.3); ^{13}C NMR: δ 179.2, 138.1, 135.9, 128.7, 121.2, 119.9, 119.7, 110.4, 100.1, 33.0, 27.3, 24.2; ms: *m/z* 203 (M^{+}). *Anal.* Calcd. for $C_{12}H_{13}NO_2$: C, 70.94; H, 6.40; N, 6.90. Found: C, 70.98; H, 6.41; N, 6.85.

1*H*-Indole-2-pentanoic acid (6c).. This compound (0.90 g, 96%) was isolated as a white solid, mp 145–147°C. IR: 3425–2350, 3384, 1700 cm^{-1}; ^{1}H NMR: δ 10.50 (s, 1H), 7.92 (br s, 1H), 7.52 (d, 1H, *J* = 6.8 Hz), 7.30 (d, 1H, *J* = 8.0 Hz), 7.10 (m, 2H), 6.24 (s, 1H), 2.80 (t, 2H, *J* = 6.8 Hz), 2.42 (t, 2H, *J* = 7.2 Hz), 1.76 (m, 4H); ^{13}C NMR: δ 178.4, 138.9, 135.7, 128.7, 121.0, 119.7, 119.6, 110.2, 99.7, 33.4, 28.4, 27.8, 24.1; ms: *m/z* 217 (M^{+}). *Anal.* Calcd. for $C_{13}H_{15}NO_2$: C, 71.89; H, 6.91; N, 6.45. Found: C, 71.88; H, 6.86; N, 6.47.

Representative procedure for indole acylation: 3,4-dihydrocyclopent[*b*]indol-1(2*H*)-one (7a). A solution of 200 mg (1.06 mmoles) of **6a** in 10 mL of toluene was heated to reflux and 200 mg of *p*-toluenesulfonic acid monohydrate was slowly added through the top of the condenser. After 1 h at reflux, a second 200-mg portion of *p*-toluenesulfonic acid (total 400 mg, 2.10 mmoles, 2.0 eq) was added and refluxing was continued for a total of 12 h. The resulting solution was cooled, added to water and extracted with ether. The ether layer was washed with saturated sodium bicarbonate (three times) and saturated sodium chloride (one time), then dried (magnesium sulfate) and concentrated under vacuum. The crude product was purified by flash chromatography on a 20 cm × 2 cm silica gel column using increasing concentrations of ether in hexanes to give 136 mg (75%) of **7a** as an off-white solid, mp 250–252°C (lit [11] mp 252–253°C). IR: 3371, 1648 cm^{-1}; ^{1}H NMR (dimethyl sulfoxide-d_6): δ 12.0 (br s, 1H), 7.67 (d, 1H, *J* = 7.5), 7.45 (d, 1H, *J* = 8.0), 7.22 (td, 1H, *J* = 7.7, 1.3), 7.16 (td, 1H, *J* = 7.7, 1.3), 3.08 (m, 2H), 2.82 (m, 2H); ^{13}C NMR (dimethyl sulfoxide-d_6): δ 194.7, 167.7, 142.2, 129.8, 127.6, 122.9, 121.5, 119.4, 112.6, 40.6, 21.0; ms: *m*/*z* 171 (M$^+$). *Anal.* Calcd. for $C_{11}H_9NO$: C, 77.19; H, 5.26; N, 8.19. Found: C, 76.94; H, 5.20; N, 8.23.

1,2,3,9-Tetrahydro-4H-carbazol-4-one (7b). This compound was prepared from 150 mg (0.74 mmoles) of **6b** using a modified procedure. In this case, 844 mg (4.44 mmoles, 6.0 eq) of *p*-toluenesulfonic acid monohydrate was required and this was added in 2.0-eq portions at 1-h intervals during the first 3 h of the 12-h reflux period. Product **7b** (120 mg, 88%) was isolated as an off-white solid, mp 225–228°C (dec) (lit [11] mp 219–221°C). IR: 3368, 1588, 1566 cm^{-1}; ^{1}H NMR (dimethyl sulfoxide-d_6): δ 11.7 (br s, 1H), 7.99 (d, 1H, *J* = 7.5), 7.46 (dd, 1H, *J* = 7.8, 1.1), 7.25 (td, 1H, *J* = 7.7, 1.2), 7.19 (td, 1H, *J* = 7.7, 1.2), 2.99 (t, 2H, *J* = 6.3), 2.42 (t, 2H, *J* = 6.4), 2.13 (quintet, 2H, *J* = 6.4); ^{13}C NMR (dimethyl sulfoxide-d_6): δ 192.1, 148.4, 134.1, 122.7, 122.2, 120.5, 120.2, 108.8, 106.5, 37.7, 22.9, 20.4; ms: *m*/*z* 185 (M$^+$). *Anal.* Calcd. for $C_{12}H_{11}NO$: C, 77.84; H, 5.95; N, 7.57. Found: C, 77.78; H, 5.94; N, 7.60.

6,7,8,9-Tetrahydrocyclohept[b]indol-10(5H)-one (7c). This compound was prepared as described for **7b** using 203 mg (0.93 mmoles) of **6c** to give 133 mg (72%) of **7c** as a tan solid, mp 217–218 °C (lit [11] mp 220–221°C). IR: 3365, 1718 cm^{-1}; ^{1}H NMR (dimethyl sulfoxide-d_6): δ 11.7 (br s, 1H), 8.14 (dd, 1H, *J* = 7.4, 1.4), 7.34 (dd, 1H, *J* = 7.9, 1.3), 7.12 (m, 2H), 3.10 (t, 2H, *J* = 6.3), 2.64 (m, 2H), 1.93 (quintet, 2H, *J* = 6.4), 1.83 (m, 2H); ^{13}C NMR (dimethyl sulfoxide-d_6): δ 196.4, 149.0, 135.0, 127.3, 122.2, 121.2, 120.9, 113.7, 110.9, 42.7, 27.0, 24.3, 21.8; ms: *m*/*z* 199 (M$^+$). *Anal.* Calcd. for $C_{13}H_{13}NO$: C, 78.39; H, 6.53; N, 7.04. Found: C, 78.19; H, 6.48; N, 7.05.

Direct preparation of 7b from 4b. A 100-mL single-necked round-bottomed flask equipped with a reflux condenser (N_2 inlet) and a magnetic stir bar was charged with 200 mg (0.75 mmoles) of **4b** and 8 mL of concentrated hydrochloric acid. The mixture was heated to 80°C (oil bath) and 126 mg (2.25 mmoles, 3.0 eq) of iron powder (>100 mesh) was added (*Caution!* This addition is sufficiently exothermic to boil the mixture). The reaction is contained by using a large flask and immediately replacing the condenser after adding the iron). The reaction was refluxed at 110°C until thin layer chromatography indicated complete consumption of starting material (*ca* 20 min), then cooled, added to 15 mL of water and extracted with ether (three times). The combined ether layers were washed with saturated sodium chloride (one time), dried (magnesium sulfate) and concentrated under vacuum. The resulting solid was flash chromatographed on a 20 cm × 2 cm silica gel column eluted with increasing concentrations of ether in hexanes to give 128 mg (92%) of **7b**. The physical properties and spectral data matched those reported above.

Representative procedures for lactam formation: 1,2-dihydro-3*H*-pyrrolo[1,2-*a*]indol-3-one (8a). To a suspension of 100 mg (0.53 mmoles) of **6a** in 5 mL of dichloromethane was added 103 mg (0.85 mmoles, 1.6 eq) of 4-(dimethylamino)pyridine. The mixture was stirred for 10 min to give a clear light brown solution. To this solution was added 101 mg (0.53 mmoles) of *N*-(3-dimethylaminopropyl-*N*′-ethylcarbodiimide hydrochloride and the reaction mixture was stirred at 22°C for 24 h. The crude reaction mixture was washed with water, 1*M* hydrochloric acid, saturated sodium bicarbonate and saturated sodium chloride, then dried (magnesium sulfate) and concentrated under vacuum. The resulting oil was purified by preparative thin layer chromatography using 60% ether in hexanes to give 72 mg (80%) of the lactam as a white solid, mp 149–151°C (lit [25] mp 151–153°C). IR: 1731 cm^{-1}; ^{1}H NMR: δ 8.07 (m, 1H), 7.48 (m, 1H), 7.25 (m, 2H), 6.27 (s, 1H), 3.14 (A of ABm, 2H), 3.08 (B of ABm, 2H); ^{13}C NMR: δ 171.6, 143.6, 135.3, 130.4, 124.0, 123.2, 120.5, 113.5, 100.3, 34.9, 19.6; ms: *m*/*z* 171 (M$^+$). *Anal.* Calcd. for $C_{11}H_9NO$: C, 77.19; H, 5.26; N, 8.19. Found: C, 77.14; H, 5.24; N, 8.21.

8,9-Dihydropyrido[1,2-a]indol-6(7H)-one (8b). This compound was prepared by dissolving 100 mg (0.49 mmoles) of **6b** in 15 mL of dry toluene and refluxing for 36 h. The reaction mixture was cooled and the solvent was evaporated to dryness under vacuum. The crude product was purified by preparative thin layer chromatography using 50% ether in hexanes to give 82 mg (90%) of **8b** as a white solid, mp 78–79°C (lit [25] mp 79–81°C). IR: 1690, cm^{-1}; ^{1}H NMR: δ 8.44 (dd, 1H, *J* = 8.1, 0.9), 7.45 (dd, 1H, *J* = 6.8, 1.6), 7.25 (m, 2H), 6.31 (s, 1H), 2.97 (td, 2H, *J* = 6.8, 1.2), 2.78 (t, 2H, *J* = 6.4), 2.07 (quintet, 2H, *J* = 6.4); ^{13}C NMR: δ 169.4, 138.1, 134.8, 129.7, 124.0, 123.9, 119.6, 116.3, 104.8, 34.4, 23.8, 21.4; ms: *m*/*z* 185 (M$^+$). *Anal.* Calcd. for $C_{12}H_{11}NO$: C, 77.84; H, 5.95; N, 7.57. Found: C, 77.76; H, 5.93; N, 7.59.

7,8,9,10-Tetrahydro-6H-azepino[1,2-a]indol-6-one (8c). This compound was prepared as described for **8a** on an 80 mg (0.37 mmole) scale to give 60 mg (81%) of the lactam as a white solid, mp 172–175°C. IR: 1692 cm^{-1}; ^{1}H NMR: δ 8.42 (dm, 1H, *J* = 7.9), 7.46 (dm, 1H, *J* = 7.3), 7.32–7.20 (complex, 2H), 6.36 (s, 1H), 3.06 (t, 2H, *J* = 5.9), 2.94 (distorted t, 2H, *J* = 5.8), 1.94 (m, 4H); ^{13}C NMR: δ 173.8, 139.5, 136.9, 129.6, 124.1, 123.5, 119.5, 116.3, 107.9, 35.9, 25.8, 23.7, 20.8; ms: *m*/*z* 199 (M$^+$). *Anal.* Calcd. for $C_{13}H_{13}NO$: C, 78.39; H, 6.53; N, 7.04. Found: C, 78.35; H, 6.54; N, 7.06.

Acknowledgment. B. N. thanks the Department of Chemistry at Oklahoma State University for a teaching assistantship. Funding for the 300 MHz NMR spectrometer of the Oklahoma Statewide Shared NMR Facility was provided by NSF (BIR-9512269), the Oklahoma State Regents for Higher Education, the W. M. Keck Foundation, and Conoco, Inc. Finally, the authors wish to thank the OSU College of Arts and Sciences for funds to upgrade our departmental FTIR and GC-MS instruments.

A rapid microwave-assisted green chemical synthesis of condensed 2-substituted-pyrimidin-4(3*H*)-ones **3, 4,** and **5** involving the condensation of a variety of nitriles with *o*-aminoesters of thiophene **2a–e**, benzene **2f**, dimethoxybenzene **2g** and quinazolinone **2h** in the presence of catalytic amount of HCl alone or with the Lewis acid $AlCl_3$ under solvent-free conditions, is described for the first time. This novel and clean one-pot methodology, which is characterized by very short reaction times and easy workup procedures, can be exploited to generate a diverse library of condensed pyrimidine heterocycles.

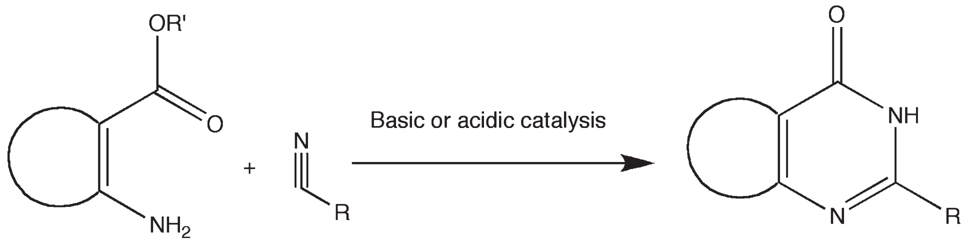
J. Heterocyclic Chem., **46**, 178 (2009).

INTRODUCTION

Pyrimidines and condensed pyrimidines have a long and distinguished history of their numerous biological and medicinal applications [1]. The synthesis and biological evaluation [2] of potentially bioactive condensed pyrimidines, appropriately functionalized, especially at the 2- and 4-positions have attracted considerable attention of medicinal chemists worldwide. Therefore, the synthesis of condensed pyrimidines has been a very important process, subject to improvement, from time to time. The regularly employed synthetic methodologies involve annelation of the pyrimidine ring on an appropriately substituted carbocycle or heterocycle [3].

Of these the most popularly used synthetic methodology is the ‘‘Principal Pyrimidine Synthesis’’, which involves mainly the cyclocondensation of *o*-aminocarbonyl substrates with reagents like amidines, ureas, thiourea or imidates [3]. Alternatively use of nitriles as reagents for cyclocondensation with *o*-aminocarbonyl substrates is relatively less exploited and is reported under basic [4,5] as well as

Scheme 1



acidic [6,7] conditions. The direct use of nitriles in these cyclocondensations is attractive as it offers more flexibility and generates a variety of 2-substituents in the resultant condensed pyrimidines. Nitriles often being the precursors for amidines are also more economical than the amidines (Scheme 1).

It would be very interesting to adopt this reaction for high throughput synthesis in order to generate diverse libraries of condensed pyrimidines of type **1** with four diverse points for further functionalization.

The direct use of the electrophilic properties of nitriles in such syntheses, though previously reported [8], has received only scant attention. Shishoo and coworkers [6,7,9–15] have exploited the reactions of a variety of nitriles with a host of *o*-aminocarbonyl substrates, under the influence of dry HCl gas under conventional conditions to obtain a wide range of 2-substituted-4-oxo/4-amino/4-chloro and 4-aryl condensed pyrimidines (Scheme 2). These reactions are known to proceed *via* the imidoyl halide intermediate, whose carbon is highly electrophilic. The cyclocondensation proceeds *via* the transient amidine intermediate. This interesting reaction has been developed as a synthetic method of general applicability to obtain a variety of condensed 2-substituted-4-functionalized pyrimidines. The reaction generally takes 8–12 h for completion and typically involves bubbling of dry HCl gas through the reaction mixture in dioxane (Scheme 2).

c: Under microwave irradiation; 350W, 10-40 min (66-95%).

Reactions that are adaptable for high speed throughput syntheses have become an important component of the modern medicinal chemist's armory, as a great number of compounds can be produced through such rapid parallel synthetic programs [16]. Synthetic methods that enable the rapid production of an array of heterocycles, useful for the identification of new lead structures are of critical importance from the point of new drug discovery. Moreover, quinazolines, thienopyrimidines and other condensed pyrimidine scaffolds are important heterocyclic building blocks and have been shown to possess significant pharmacological activity against a variety of molecular targets [17].

Our encouraging results in the MWI-based syntheses of thiophene *o*-aminoesters involving Gewald reaction [18], as well as, thienopyrimidine bioisosteres of gefitinib [19] under microwave irradiation conditions, motivated us to assess whether the use of MWI could be extended to the single pot cyclocondensation of the nitriles with various *o*-aminoester substrates under solvent-free conditions for generating compound libraries of condensed pyrimidines of type **1**.

Herein, we report for the first time a rapid microwave-assisted green synthesis of condensed 2-substitutedpyrimidin-4(3*H*)-ones, **3**, **4**, and **5** involving the condensation of a variety of nitriles with *o*-aminoesters of thiophene **2a–e**, benzene **2f**, dimethoxybenzene **2g** and quinazolinone **2h** in the presence of catalytic amount of HCl alone or with the Lewis acid, $AlCl_3$ under solvent-free conditions (Scheme 3).

RESULTS AND DISCUSSION

We started the experiments using different nitriles such as acetonitrile, chloroacetonitrile and acrylonitrile. The conventional methods for the synthesis of the target condensed 2-substitutedpyrimidin-4(3*H*)-ones are through the cyclization of appropriate *o*-amino esters **2** with these nitriles under acidic conditions in the solvent, 1,4-dioxane at 0–5°C. This particular reaction requires

bubbling of dry HCl gas in the reaction mixture for 8–12 h, which is the time taken to complete the reaction depending upon the nature of nitrile used. Interestingly, these same reactions under microwave irradiation at 350 W were accomplished by using catalytic amount of concentrated HCl (33% w/v, 5.0 mL) in very short time periods. The physical data for the 2-substituted-thieno[2,3-*d*]pyrimidin-4(3*H*)-ones **3a–e**, **4a–e**, **5a–e** synthesized under MWI is presented in Table 1 and that for the 2-substitutedquinazolines **3f–h**, **4f,** and **5f–h** is recorded in Table 2. The reaction time varied depending upon the type of nitrile used. The reactions with acetonitrile were completed in 40–75 min to obtain the condensed 2-methylpyrimidin-4(3*H*)-ones **3a–h** with isolated yields ranging from 68–94%. The reactions with acrylonitrile were completed in 20–50 min and afforded the condensed 2-chloroethylpyrimidin-4(3*H*)-ones **4a-f** in 85–96% yields (Scheme 3).

Interestingly, when the reactive nitrile, chloroacetonitrile was used, the reaction went to completion in just 10–40 min and afforded the corresponding 2-chloromethylpyrimidin-4(3*H*)-ones **5a–h** in generally excellent isolated yields (>90%). Thus, in all the aforementioned cases, there is considerable reduction in the reaction times, when conventional heating is replaced by microwave-assisted heating, *i.e*., from 6–12 h to 10–75 min, respectively. Considerable improvement in yields was also observed.

A very important and noteworthy fact is that all the reactions depicted in Scheme 3 failed to proceed in the absence of HCl. This indicates that these reactions under MWI, may also be involving the imidoyl chloride intermediates [22,23]. Further, in a few typical cases, only catalytic amount of HCl failed to bring about the completion of the reaction. This was observed in the reaction of **2a** and **2c** with acrylonitrile to prepare

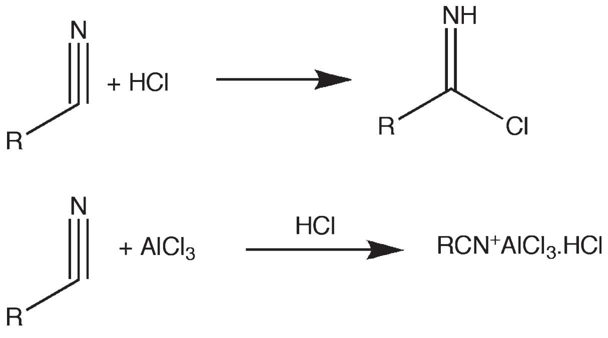
compounds **4a** and **4c,** respectively. However, addition of catalytic amount of a Lewis acid, anhydrous $AlCl_3$ along with conc. HCl, accomplished the successful completion of the aforementioned reactions to afford the target condensed 2-substitutedpyrimidin-4(3*H*)-ones **4a** and **4c** in excellent isolated yields (Table 1). Thus, the Lewis acid $AlCl_3$, has forwarded the reactions, probably by way of forming the electrophilic nitrile-metal halide, hydrohalide complex as shown below (Scheme 4) [24].

CONCLUSION

A novel microwave-assisted green synthesis of the condensed 2-substitutedpyrimidin-4(3*H*)-ones **3**, **4**, and **5** under solvent-free conditions has been reported for the first time. The unusually rapid synthetic methodology involves the cyclocondensation of a variety of nitriles with *o*-aminoesters of thiophene **2a-e**, benzene **2f**, dimethoxybenzene **2g** and quinazolinone **2h** in the presence of catalytic amount of conc. HCl alone or with the Lewis acid, $AlCl_3$. This novel synthesis involving nitriles as the building blocks, under microwave irradiation for these condensed 2-substitutedpyrimidin-4(3*H*)-ones requires only 10–75 min as compared to the conventional heating protocols requiring 6–12 h, thereby showing a significant acceleration in reaction rates (Tables 1 and 2). The reaction proceeds through the same activated electrophilic nitrile derivatives, the imidoyl halide intermediate and affords the products in yields superior to that by the conventional protocols. Coupled with simple workup procedures and superior yields the methodology is eminently suitable for the generation of diverse libraries of condensed 2-substituted-pyrimidin-4(3*H*)-ones employing parallel synthesis procedures.

Scheme 4



EXPERIMENTAL

Microwave synthesizer (Questron Technologies, Canada; model: Q-Pro M) having monomode open-vessel was used for the synthesis. All the chemicals used in the synthesis were of laboratory grade. The melting points were determined in open capillary on Veego (VMP-D) electronic apparatus and are uncorrected. The IR spectra of synthesized compounds were recorded on Perkin Elmer BX_2 FT-IR Spectrophotometer in KBr and reported in cm^{-1}. ^1H NMR spectra were measured on a Varian Mercury YH-300 FT NMR spectrometer in DMSO-d_6 with chemical shifts (δ) given in ppm relative to TMS as internal standard. Thin layer chromatography was performed on precoated silica plates (Merck Silicagel F_{254}) using hexane-ethyl acetate-glacial acetic acid (4.5 mL:0.5 mL:2drops), chloroform-methanol (4.5 mL:0.5 mL) as the solvent systems and the spots were visualized by exposure to iodine vapors or under ultra violet (UV) light. The HCl used was 33% w/v aqueous and was of LR grade.

General procedure A.

Reaction of 2-amino-3-carbethoxysubstrates 2 with nitriles (in presence of only conc. HCl). A mixture of the appropriate 2-amino-3-carbethoxy substrate **2** (0.02 moles), nitrile (0.022 moles) and catalytic amount of HCl (33% w/v, 5.0 mL) was irradiated at 350 W for 10–75 min in a microwave synthesizer. The progress of reaction was monitored (using TLC) after 5-min intervals. The reaction mixture was allowed to cool to room temperature, and after completion of the reaction poured into ice-water. The resulting precipitated solid was collected by filtration, washed with chilled water and dried. The crude product on recrystallization from methanol-chloroform mixture yielded the appropriate condensed 2-substitutedpyrimidin-4-(3*H*)-ones **3a–h, 4b, 4d–f,** and **5a–h.**

2-Methyl-5,6,7,8-tetrahydro-3H-benzo[4,5]thieno[2,3-d]pyrimidin-4-one (3a). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1659 cm^{-1}; ^1H NMR: δ 1.77 (s, 4H, 6- and 7-CH_2), 2.30 (s, 3H, 2-CH_3), 2.70 (s, 2H, 5-CH_2), 2.83 (s, 2H, 8-CH_2). Anal. Calcd. for $C_{11}H_{12}N_2OS$: C, 59.90; H, 5.47. Found: C, 59.66; H, 5.38.

2,5,6-Trimethylthieno[2,3-d]pyrimidin-4(3H)-one (3b). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1665 cm^{-1}; ^1H NMR: δ 2.37 (s, 3H, 2-CH_3), 2.46 (s, 3H, 5-CH_3), 2.51 (s, 3H, 6-CH_3), 12.04 (s, br, 1H, 3-NH). Anal. Calcd. for $C_9H_{10}N_2OS$: C, 55.64; H, 5.15. Found: C, 55.81; H, 5.52.

2-Methyl-5-(4-methylphenyl)thieno[2,3-d]pyrimidin-4(3H)-one (3c). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1670 cm^{-1}; ^1H NMR: δ 2.39 (s, 3H, 2-CH_3), 2.47 (s, 3H, Ar—CH_3), 7.04 (s, 1H, 6-H), 7.16–7.48 (m, 4H, phenyl protons), 11.90 (s, 1H, 3-NH). Anal. Calcd. for $C_{14}H_{14}N_2OS$: C, 65.66; H, 4.73. Found: C, 65.76; H, 4.52.

Ethyl 3,4-dihydro-2,5-dimethyl-4-oxothieno[2,3-d]pyrimidin 6-carboxylate (3d). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1718, 1667 cm^{-1}; ^1H NMR: δ 1.40 (t, 3H, 6-$COOCH_2$*CH_3*, *J* = 7.3 Hz), 2.55 (s, 3H, 2-CH_3), 2.94 (s, 3H, 5-CH_3), 4.36(q, 2H, 6-COO*CH_2*CH_3, *J* = 7.1 Hz,); 10.95 (1H, s, 3-NH). Anal. Calcd. for $C_{10}H_{11}N_2O_2S$: C, 52.37; H, 4.74. Found: C, 52.56; H, 4.97.

2-Methyl-5-phenylthieno[2,3-d]pyrimidin-4(3H)-one (3e). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1671 cm^{-1}; ^1H NMR: δ 3.36 (s, 3H, 2-CH_3), 7.31–7.50 (m, 5H, phenyl protons and 6-H), 12.28(s, 1H, 3-NH). Anal. Calcd. for $C_{13}H_{10}N_2OS$: C, 64.46; H, 4.12. Found: C, 64.15; H, 4.46.

2-Methylquinazolin-4(3H)-one (3f). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1666 cm^{-1}; ^1H NMR: δ 2.50 (s, 2H, 2-CH_3), 7.38–7.74 (m, 4H, phenyl protons), 12.13 (s, br, 1H, 3-NH). Anal. Calcd. for $C_9H_8N_2O$: C, 67.44; H, 5.02. Found: C, 67.63; H, 5.42.

6,7-Dimethoxy-2-methylquinazolin-4(3H)-one (3g). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1669 cm^{-1}; ^1H NMR: δ 2.55 (s, 3H, 2-CH_3), 3.99 (s, 6H, 6- and 7-OCH_3), 7.02–7.55 (m, 2H, phenyl protons), 10.87 (s, 1H, 3-NH). Anal. Calcd. for $C_{11}H_{12}N_2O_3$: C, 59.90; H, 5.41. Found: C, 58.99; H, 5.72.

2-Methyl-3H-[1,2,4]triazino[6,1-b]quinazolin-4,10-dione (3h). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1680 cm^{-1}; ^1H NMR: δ 2.37 (s, 3H, 2-CH_3), 7.72–8.22 (m, 4H, phenyl protons). Anal. Calcd. for $C_{11}H_8N_4O_2$: C, 57.90; H, 3.51. Found: C, 57.69; H, 3.71.

2-(2-Chloroethyl)-5,6-dimethylthieno[2,3-d]pyrimidin-4(3H)-one (4b). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1669 cm^{-1}; ^1H NMR: δ 2.38 (s, 3H, 5-CH_3), 2.47 (s, 3H, 6-CH_3), 3.19 (t, 2H, 2-CH_2CH_2Cl, *J* = 7.5 Hz), 3.97 (t, 2H, 2-CH_2CH_2Cl , *J* = 7.2 Hz), 12.34 (s, br, 1H, 3-NH). Anal. Calcd. for $C_{10}H_{11}ClN_2OS$: C, 49.40; H, 4.53. Found: C, 49.14; H, 4.35.

Ethyl 2-(2-chloroethyl)-3,4-dihydro-5-methyl-4-oxothieno [2,3-d]pyrimidin 6-carb-oxylate (4d). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1719, 1670 cm^{-1}; ^1H NMR: δ 1.41 (t, 3H, 6-$COOCH_2$*CH_3*, *J* = 7.3 Hz), 2.9 (s, 3H, 5-CH_3), 3.24 (t, 2H, 2-*CH_2*CH_2Cl, *J* = 6.7 Hz), 4.29 (t, 2H, 2-CH_2*CH_2*Cl, *J* = 7.3 Hz CH_2), 4.3 (q, 2H, 6-COO*CH_2*CH_3, *J* = 7.1 Hz), 12.30 (s, 1H, 3-NH). Anal. Calcd. for $C_{11}H_{13}ClN_2O_2S$: C, 47.93; H, 4.35. Found: C, 47.97; H, 4.42.

2-(2-Chloroethyl)-5-phenylthieno[2,3-d]pyrimidin-4(3H)-one (4e). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1685cm^{-1}; ^1H NMR: δ 3.19 (t, 2H, 2-*CH_2*CH_2Cl, *J* = 7.2 Hz), 4.02 (t, 2H, 2-*CH_2*CH_2Cl, *J* = 7.5 Hz), 7.30–7.50 (m, 6H, phenyl protons and 6-H), 12.40 (s, br, 1H, 3-NH). Anal. Calcd. for $C_{14}H_{11}ClN_2OS$: C, 57.83; H, 3.81. Found: C, 57.74; H, 3.89.

2-(2-Chloroethyl)quinazolin-4(3H)-one (4f). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1678 cm^{-1}; ^1H NMR: δ 3.18 (t, 2H, 2-*CH_2*CH_2Cl, *J* = 6.3, 7.2 Hz), 4.06 (t, 2H, 2-*CH_2*CH_2Cl, *J* = 6.3, 7.2 Hz), 7.44–8.07 (m, 4H, phenyl protons), 10.25 (s, 1H, 3-NH). Anal. Calcd. for $C_{10}H_9ClN_2O$: C, 57.55; H, 4.37. Found: C, 57.49; H, 4.80.

2-Chloromethyl-5,6,7,8-tetrahydro-3H-benzo[4,5]thieno[2,3-d]pyrimidin-4-one (5a). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1663 cm^{-1}; ^1H NMR: δ 1.86 (s, 4H, 6- and 7-CH_2), 2.79 (s, 2H, 5-CH_2), 3.02 (s, 2H, 8-CH_2), 4.55 (s, 2H, 2-*CH_2*Cl), 10.65 (s, br, 1H, 3-NH). Anal. Calcd. for $C_{11}H_{11}ClN_2OS$: C, 51.87; H, 4.30. Found: C, 57.69; H, 4.25.

2-Chloromethyl-5,6-dimethylthieno[2,3-d]pyrimidin-4(3H)-one (5b). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1662 cm^{-1}; ^1H NMR: δ 2.39 (s, 3H, 5-CH_3), 2.47 (s, 3H, 6-CH_3), 4.51 (s, 2H, 2-*CH_2*Cl), 10.03(s, br, 1H, 3-N*H*). Anal. Calcd. for $C_9H_9ClN_2OS$: C, 47.20; H, 3.95. Found: C, 47.30; H, 3.40.

2-Chloromethyl-5-(4-methylphenyl)thieno[2,3-d]pyrimidin-4(3H)-one (5c). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1651 cm^{-1}; ^{1}H NMR: δ 2.39 (s, 3H, Ar-CH_3), 4.53 (s, 2H, 2-*CH*$_2$Cl), 7.13 (s, 1H, 6-H), 7.19–7.46 (m, 4H, phenyl protons), 10.43 (s, 1H, 3-NH). Anal. Calcd. for $C_{14}H_{13}ClN_2OS$: C, 57.89; H, 3.80. Found: C, 57.79; H, 3.87.

Ethyl 2-chloromethyl-3,4-dihydro-5-methyl-4-oxothieno [2,3-d]pyrimidine 6-carboxylate (5d). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1725, 1670 cm^{-1}; ^{1}H NMR: δ 1.41 (t, 3H, 6-COOCH$_2$*CH*$_3$ $J = 7.0$ Hz,), 2.95 (s, 3H, 5-CH_3), 4.38 (q, 2H, 6-COO*CH*$_2$CH$_3$, $J = 7.0$ Hz), 4.57 (s, 2H, 2-*CH*$_2$Cl), 10.62 (s, 1H, 3-NH). Anal. Calcd. for $C_{10}H_{11}ClN_2O_2S$: C, 46.04; H, 3.86. Found: C, 46.10; H, 3.92.

2-Chloromethyl-5-phenylthieno[2,3-d]pyrimidin-4(3H)-one (5e). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1663 cm^{-1}; ^{1}H NMR: δ 4.58 (s, 2H, 2-*CH*$_2$Cl), 7.31–7.52 (m, 5H, aryl protons and 6-H), 12.69 (s, br, 1H, 3-NH). Anal. Calcd. for $C_{13}H_9ClN_2OS$: C, 56.49; H, 3.23. Found: C, 56.62; H, 3.33.

2-Chloromethylquinazolin-4(3H)-one (5f). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1697 cm^{-1}; ^{1}H NMR: δ 4.53 (s, 2H, 2-*CH*$_2$Cl), 7.49–7.82 (m, 4H, aryl protons), 12.56 (s, br, 1H, 3-NH). Anal. Calcd. for $C_9H_7ClN_2O$: C, 55.50; H, 3.64. Found: C, 55.62; H, 3.24.

2-Chloromethyl-6,7-dimethoxyquinazolin-4(3H)-one (5g). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1668 cm^{-1}; ^{1}H NMR: δ 4.0 (s, 6H, 6- and 7-OCH_3), 4.57 (s, 2H, 2-*CH*$_2$Cl), 7.01–7.59 (m, 2H, aryl protons) 9.75 (s, 1H, 3-NH). Anal. Calcd. for $C_{11}H_{11}ClN_2O_3$: C, 51.85; H, 4.36. Found: C, 51.66; H, 4.20.

2-Chloromethyl-3H-[1,2,4]triazino[6,1-b]quinazoline-4,10-dione (5h). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1690 cm^{-1}; ^{1}H NMR: δ 4.59 (s, 2H, 2-*CH*$_2$Cl), 7.53–7.79 (m, 4H, aryl protons), 9.48 (s, br, 1H, 3-NH). Anal. Calcd. for $C_{11}H_7ClN_4O_2$: C, 50.35; H, 2.66. Found: C, 50.29; H, 2.81.

General procedure B.

Reaction of 2-amino-3-carbethoxythiophenes 2a and 2c with acrylonitrile (in presence of conc. HCl and AlCl$_3$). A mixture of appropriate 2-amino-3-carbethoxythiophene **2a** or **2c** (0.02 moles), acrylonitrile (0.022 moles), aq. HCl (33% w/v, 5.0 mL) and anhydrous $AlCl_3$ (0.1–0.25 g) was irradiated at 350 W for 35–45 min in a microwave synthesizer. After completion of reaction, the reaction mixture was allowed to cool to room temperature then was poured into ice-water. The resulting precipitated solid was collected by filtration, washed with chilled water and dried. The crude product on recrystallization from methanol–chloroform mixture yielded the appropriate condensed 2-chloroethylthieno[2,3-*d*]pyrimidin-4-(3*H*)-ones **4a** or **4c**.

2-(2-Chloroethyl)-5,6,7,8-tetrahydro-3H-benzo[b]thieno[2,3-d]pyrimidin-4-one (4a). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1665 cm^{-1}; ^{1}H NMR: δ 1.90 (4H, s, 6- and 7-CH_2), 2.81 (s, 2H, 5-CH_2), 3.02 (s, 2H, 8-CH_2), 3.23 (t, 2H, 2-*CH*$_2$CH$_2$Cl, $J = 7.0$ Hz), 4.02 (t, 2H, 2-*CH*$_2$CH$_2$Cl, $J = 6.2$ Hz), 11.90 (s, 1H, br, 3-NH); Anal. Calcd. for $C_{11}H_7ClN_4O_2$: C, 53.66; H, 4.83. Found: C, 53.44; H, 4.60.

2-(2-Chloroethyl)-5-(4-methylphenyl)thieno[2,3-d]pyrimidin-4(3H)-one (4c). This compound was obtained according to the aforementioned general procedure; IR (potassium bromide): CO 1672 cm^{-1}; ^{1}H NMR: δ 2.40 (3H, s, Ar-CH_3), 3.06 (2H, t, 2-*CH*$_2$CH$_2$Cl, $J = 7.0$ Hz,), 3.87 (t, 2H, 2-CH$_2$*CH*$_2$Cl, $J = 7.0$ Hz, 7.06 (s, 1H, 6-H), 7.15–7.45 (m, 4H, aryl protons), 12.99 (s, 1H, 3-NH). Anal. Calcd. for $C_{15}H_{15}ClN_2OS$: C, 59.10; H, 4.33; Found: C, 59.25; H, 4.20.

General procedure C: Conventional method. A stream of dry hydrogen chloride gas was bubbled through an ice-cold mixture of the appropriate 2-amino-3-carbethoxysubstrate, **2a–h** (0.06 mole) and appropriate nitrile (0.09 mole) in dry dioxane (60 mL) for 8–12 h while maintaining the temperature below 10°C. The reaction mixture was allowed to stand thereafter at room temperature for 12 h. The reaction was then heated on a water bath for 2–3 h, cooled to room temperature and poured onto ice-water mixture (150–200 mL) and neutralized with strong ammonium hydroxide solution (50%v/v). The solid that separated was collected by filtration, washed with water, dried and recrystallized from appropriate solvent.

Acknowledgments. The authors are thankful to the Indian Council of Medical Research (ICMR) for providing financial assistance to Mr. Jitender B. Bariwal and Mr. M. K. Kathiravan to carry out this work. They are also grateful to Sinhgad Technical Education Society, Pune for providing facilities to carry out this work.

Novel functionalized 1,3-dialkylimidazolinium salts (LHCl) as NHC precursors have been prepared and successfully applied in palladium-catalyzed arylation of benzaldehydes. The ortho position of aromatic aldehydes was directly and selectively arylated with aryl chlorides in the presence of a catalytic system prepared *in situ* from $Pd(OAc)_2$, 1,3-dialkylimidazolinium chlorides (**2a–c**), and Cs_2CO_3.

J. Heterocyclic Chem., **46**, 186 (2009).

INTRODUCTION

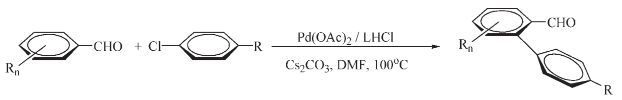
The functionalization of aryl compounds is of major importance in the field of modern arene chemistry because of the ubiquity of aromatic and heteroaromatic units in fine chemical intermediates, pharmaceutical, agrochemicals, polymers, liquid crystals, new materials [1], and ligands for homogeneous transition metal catalysts [1]. Among the different aromatic functionalization reactions, palladium-catalyzed coupling processes such as the Heck [2], Suzuki [3], Kumada [4], Sonogashira [5], Buchwald-Hartwig amination [6], and other C—C and C—O bond forming reactions offer elegant possibilities for the synthesis of substituted arenas. The main advantages of the coupling processes are based on the ready availability of starting materials, the simplicity and generality of the methods, and the broad tolerance of palladium catalysts toward various functional groups. Therefore, the ability to couple an aryl halide directly at the unreactive C—H position of an arene without the need for a sacrificial electrophilic boron or tin fragment would be highly desirable [7]. The selective functionalization of C—H bonds has attracted substantial interest due to potential shortening of synthetic sequences [8]. At present, development of methods for sp^2 C—H bond functionalization in directing-group containing arenas and electron-rich heterocycles has received the most attention. For a number directing group containing substances, the conversion of aromatic *ortho*-C—H bonds to C—C bonds has been demonstrated. Compounds containing amide, pyridine, oxazoline, imine, ketone, and phenol directing groups have been ortho-arylated or alkylated under palladium, ruthenium, or rhodium catalysis [9]. However, aryl chlorides were rarely used, despite the fact that chlorinated arenes are cheaper to manufacture and therefore play a vital role as intermediates in the chemical industry. Presumably, this is due to the fact that the chlorides were generally found to be unreactive under the conditions employed to couple bromides, iodides, and triflates.

Recently, it has been shown that palladium complexes of *N*-heterocyclic carbene [NHC] ligands offer distinct advantages as possible alternatives for Pd/phosphine systems in C—C coupling reactions [10]. Thus, some highly active palladium systems with monodentate carbene ligands have been developed for the activation of aryl chlorides [11].

We have previously reported the use of an *in situ* formed imidazolidin-2-ylidene, tetrahydropyrimidin-2-ylidene and tetrahydrodiazepin-2-ylidene, benzimidazol-2-ylidene palladium(II) systems that exhibit high activity for various coupling reactions of aryl bromides and aryl chlorides [12]. Recently, we report that the *in situ* generation of catalysts, from $[RuCl_2(p\text{-cymene})]_2$ and pyrimidinium or benzimidazolium salt in the presence of Cs_2CO_3, selectively promote the diarylation of 2-pyridylbenzene with aryl bromides [13].

The nature of the NHC ligand has a tremendous influence on the rate of catalyzed reactions. To find more efficient palladium catalysts, we have prepared a series of new bulky or functional 1,3-dialkylimidazolinium (**2a–c**), containing imidazoline ring. Herein, we report a Miaura coupling of aryl chlorides (Scheme 1) using a

Scheme 1



mild practical *in situ* generated catalytic system composed of commercially available and stable reagents, $Pd(OAc)_2$ as the palladium source, 1,3-dialkylimidazolinium chloride (**2a–c**) as a carbene precursor, and Cs_2CO_3 as a base.

RESULTS AND DISCUSSION

1,3-Dialkylimidazolinium chlorides (**2a–c**) are conventional NHC precursors. The functionalized or bulky imidazolinium salts, **2a–c**, were synthesized by consecutive alkylation of 1-benzhydrylimidazoline (**1**) with alkyl halides (Scheme 2).

According to Scheme 2, the salts (**2a–c**) were obtained in almost quantitative yield by quarternization of 1-benzhydrylimidazoline [1] in DMF with alkyl halides [14,15]. The salts are air- and moisture-stable both in the solid state and in solution. The structures of **2a–c** were determined by their characteristic spectroscopic data and elemental analyses. ^{13}C NMR chemical shifts are consistent with the proposed structure; the imino carbon resonance appeared as a typical singlet in the ^1H-decoupled mode at 157.8, 158.6, and 157.7 ppm, respectively, for imidazolinium chlorides **2a–c**. The ^1H NMR spectra of the imidazolinium salts further supported the assigned structures; the resonances for C[2]-H were observed as sharp singlets in the 8.75, 8.58, and 8.31 ppm, respectively, for **2a–c**. The IR data for imidazolinium salts **2a–c** clearly indicate the presence of the —C=N— group with a ν(C=N) vibration at 1636, 1650, and 1645 cm^{-1}, respectively, for **2a–c**. The NMR values are similar to those found for other 1,3-dialkylimidazolinium salts [15].

It is worth noting that *in situ* formation of the NHC complex by deprotonation of the imidazolinium salt led to significantly better results than the use of the preformed complex. The success of these processes as well as the recent reports by Miura and coworkers [16–19] prompted us to examine whether *in situ* generated NHC complexes could be used for the direct arylation of the arene rings of aromatic aldehydes. Formyl groups are synthetically very useful because they can be converted to many other functional groups. Herein, we report a mild, practical, Pd-catalyzed arylation of benzaldehydes using air-stable $Pd(OAc)_2$ as the catalyst, 1,3-dialkylimidazolinium chlorides (LHCl, **2a–c**, Scheme 2) as the NHC ligand precursors, Cs_2CO_3 as the base, and DMF as the solvent. Our initial exploration of the reaction conditions for the palladium-catalyzed arylation of aldehydes focused on the coupling of benzaldehyde and 4-chloroacetophenone [Table 1, entries 1–3]. The best results for mono ortho-arylation of benzaldehydes using 4-chloroacetophenone were obtained at 100°C in DMF using Cs_2CO_3 as base, and a catalyst system generated *in situ* from 1% mmol of $Pd(OAc)_2$ and 2% mmol of LHCl (**2a–c**).

Table 1 summarizes representative results from screening the three imidazolinium salts (LHCl), for a variety of substrates that undergo ortho-arylation. Several trends are readily apparent: The use of NHC ligand precursors **2a–c** allowed lower reaction temperatures (100°C), and shorter reaction times. The procedure is simple and does not require induction periods. All complexes led to good conversions (79 to 95%) at low catalyst concentration (1.0 mmol%). Although not dramatic, consistent differences in yields were observed in the reactions according to the ligand precursors **2a–c**. Presumably, the bulkier ligands derived from **2a–c** are more effective in stabilizing the palladium complex. This new method was compatible with the presence of both electron-withdrawing and electron-donating groups in the para position of the halobenzene. Table 1 also shows that a diverse group of aromatic aldehydes can be coupled. Control experiments showed that in the absence of either $Pd(OAc)_2$ or LHCl, no reaction was observed. It is worth noting that, in contrast to our

Scheme 2. Synthesis of 1,3-dialkylimidazolinium chlorides (LHCl).

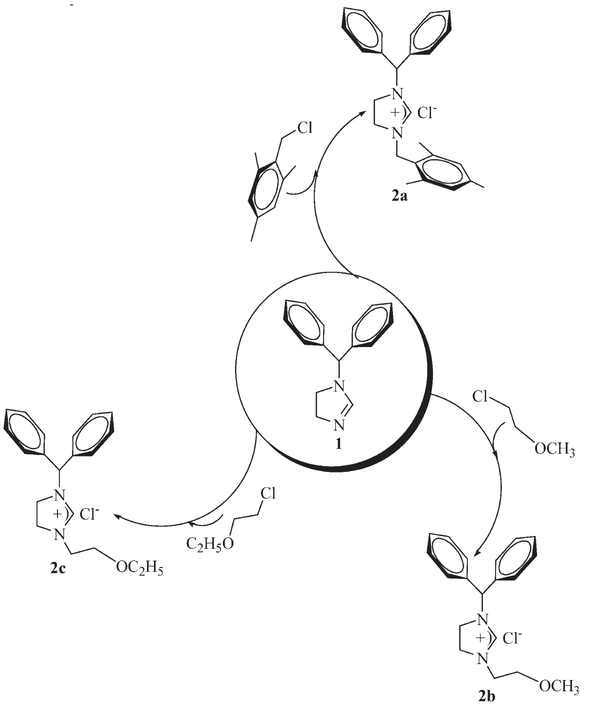


Table 1

[a] Reactions conditions: 1.0 mmol of R-C_6H_4Cl-*p*, 1.0 mmol of aldehyde, 2 mmol Cs_2CO_3, 1.0 mmol% $Pd(OAc)_2$, 2 mmol% 1,3-dialkylimidazolinium salt, DMF (3 mL), 100°C, 15 h.

[b] Yield determined by NMR and GC, purity of compounds was checked by NMR and yields are based on the aldehyde.

findings, arylation of benzaldehyde with 4-bromoanisole in the presence of $\mathrm{Ni(dppe)Br_2/Zn}$ has been reported to give diaryl carbinols [20].

The palladium-catalyzed arylation of carbonyl compounds or phenols, reported by Miura is considered to proceed *via* coordination between the phenolate or enolate oxygen of the substrates and the arylpalladium intermediate [16]. Consequently, one may expect that oxygen from the aldehyde may function as a phenolate oxygen.

EXPERIMENTAL

All reactions for the preparation of 1,3-dialkylimidazolinium salts [2a–c] were carried out under argon using standard Schlenk-type flasks. All reagents were purchased from Aldrich Chemical (Istanbul). The solvents, $\mathrm{Et_2O}$ over Na, DMF over BaO, EtOH over Mg were distilled before use. All ^{1}H and ^{13}C NMR experiments were performed in $\mathrm{CDCl_3}$. ^{1}H NMR and ^{13}C NMR spectra were recorded using a Bruker AC300P FT spectrometer operating at 300.13 MHz (^{1}H), 75.47 MHz (^{13}C). Chemical shifts (δ) are given in ppm relative to TMS, coupling constants (J) in Hz. Melting points were measures in open capillary tubes with an Electrothermal-9200 melting point apparatus and are uncorrected. Elemental analyses were performed by TUBITAK (Ankara, Turkey) Microlab.

Preparation of 1-benzhydryl-3-(2,4,6-trimethylbenzyl)-imidazolinium chloride (2a). To a solution of 1-(benzhydryl) imidazolin (2.0 g, 9.6 mmol) in DMF (3 mL), 2,4,6-tri-methylbenzylchloride (1.78 g, 10.5 mmol) was added; the resulting solution was stirred for 1 h at room temperature and heated for 12 h at 80°C. $\mathrm{Et_2O}$ (10 mL) was added to the reaction mixture. A white solid precipitated during this period. The precipitate was then crystallized from $\mathrm{EtOH/Et_2O}$ (1:2). Yield: 3.12 g (86%), mp 209–210°C; ir: 1636 $\mathrm{cm^{-1}}$ (C=N). ^{1}H NMR (δ, $\mathrm{CDCl_3}$): 2.19 (3H, $\mathrm{CH_2C_6H_2(C}H_3)_3$-4), 2.26 (s, 6H, $\mathrm{CH_2C_6H_2(C}H_3)_3$-2,6), 3.88 (s, 4H, $\mathrm{NC}H_2\mathrm{C}H_2\mathrm{N}$), 5.79 (s, 2H, $\mathrm{C}H_2\mathrm{—(C_6H_2)—(CH_3)_3}$-2,4,6), 6.80 (s, 2H, $\mathrm{CH_2—(C_6}H_2)\mathrm{—(CH_3)_3}$), 6.45 (s, 1H, $\mathrm{C}H\mathrm{(C_6H_5)_2}$), 7.26–7.37 (m, 10H, Ar), 8.75 (s,1H, 2—CH). ^{13}C NMR (δ, $\mathrm{CDCl_3}$): 21.1 ($\mathrm{CH_2C_6H_2(}C\mathrm{H_3)_3}$-4), 20.3 ($\mathrm{CH_2C_6H_2(}C\mathrm{H_3)_3}$-2,6), 47.1 ($C\mathrm{H_2—(C_6H_2)—(CH_3)_3}$-2,4,6), 48.0 and 48.7 ($\mathrm{N}C\mathrm{H_2}C\mathrm{H_2N}$), 65.9 ($C\mathrm{H(C_6H_5)_2}$), 125.5, 128.6, 129.1, 129.5, 139.9, 135.9, 139.0, and 139.3 (Ar), 157.8 (2—CH). Anal. Calcd. for $\mathrm{C_{26}H_{29}N_2Cl}$: C, 72.54; H, 7.23; N, 6.59. Found: C, 72.56; H, 7.28; N, 6.55.

Preparation of 1-benzhydryl-3-(methoxyethyl)-imidazolinium chloride (2b). This compound was prepared from 1-(benzhydryl)imidazolin (2 g, 9.6 mmol) and 2-methoxyethyl chloride (1.0 g, 10.5 mmol) in DMF (3 mL). Yield:2.65 g (91%), mp 144–145°C; ir: 1650 $\mathrm{cm^{-1}}$ (C=N). ^{1}H NMR (δ, $\mathrm{CDCl_3}$): 3.25 (s, 3H, $\mathrm{OC}H_3$), 3.57 (t, 2H, J = 4.4 Hz, $\mathrm{NCH_2C}H_2\mathrm{O}$), 3.78 (t, 2H, J = 4.4 Hz, $\mathrm{NC}H_2\mathrm{CH_2O}$), 3.89 and 4.13 (m, 4H, $\mathrm{NC}H_2\mathrm{C}H_2\mathrm{N}$), 6.37 (s, 1H, $\mathrm{C}H\mathrm{(C_6H_5)_2}$), 7.32 (m, 10H, Ar); 8.58 (s, 1H, 2—CH). ^{13}C NMR (δ, $\mathrm{CDCl_3}$): 48.3 and 48.8 ($\mathrm{N}C\mathrm{H_2}C\mathrm{H_2N}$), 59.3 ($\mathrm{O}C\mathrm{H_3}$), 66.1 ($\mathrm{NCH_2}C\mathrm{H_2O}$), 50.3 ($\mathrm{N}C\mathrm{H_2CH_2O}$), 69.0 ($C\mathrm{H(C_6H_5)_2}$), 128.9, 129.3, 129.7, and 136.1 (Ar), 158.6 (2—CH). Anal. Calcd. for $\mathrm{C_{19}H_{23}N_2OCl}$: C, 68.97; H, 7.01; N, 8.47. Found: C, 68.93; H, 6.98; N, 8.50.

Preparation of 1-benzhydryl-3-(ethoxyethyl)imidazolinium chloride (2c). This compound was prepared from 1-(benzhydryl)imidazolin (2 g, 9.6 mmol) and 2-ethoxyethyl chloride (1.15 g, 10.5 mmol) in DMF (3 mL). Yield: 2.70 g (89%), ir: 1645 $\mathrm{cm^{-1}}$ (C=N). ^{1}H NMR (δ, $\mathrm{CDCl_3}$): 0.89 (t, 3H, J = 5.7 Hz, $\mathrm{OCH_2C}H_3$), 3.31 (q, 2H, J = 5.7 Hz, $\mathrm{OC}H_2\mathrm{CH_3}$), 3.46 (t, 2H, J = 4.2 Hz, $\mathrm{NCH_2C}H_2\mathrm{O}$), 3.58 (t, 2H, J = 3.9 Hz, $\mathrm{C}H_2\mathrm{CH_2O}$), 3.73 and 4.04 (m, 4H, $\mathrm{NC}H_2\mathrm{C}H_2\mathrm{N}$), 6.26 (s, 1H, $\mathrm{C}H\mathrm{(C_6H_5)_2}$), 6.96–7.59 (m, 10H, Ar), 8.31 (s, 1H, 2—CH). ^{13}C NMR (δ, $\mathrm{CDCl_3}$): 14.9 ($\mathrm{OCH_2}C\mathrm{H_3}$), 47.8 ($\mathrm{O}C\mathrm{H_2CH_3}$), 65.5 ($\mathrm{NCH_2}C\mathrm{H_2O}$), 66.2 ($\mathrm{N}C\mathrm{H_2CH_2O}$), 48.3 and 49.9 ($\mathrm{N}C\mathrm{H_2}C\mathrm{H_2N}$); 66.4 ($C\mathrm{H(C_6H_5)_2}$); 128.3, 128.8, 129.2, and 135.7 (Ar), 157.8 (2—CH). Anal. Calcd. for $\mathrm{C_{20}H_{25}N_2OCl}$: C, 69.65; H, 7.31; N, 8.12. Found: C, 69.66; H, 7.29; N, 8.11.

General procedure for arylation of benzaldehyde derivatives. A dried Schlenk flask equipped with a magnetic stirring bar was charged with the aldehyde (1.0 mmol), aryl chloride (1.0 mmol), $\mathrm{Pd(OAc)_2}$ (0.01 mmol), imidazolinium chloride (0.02 mmol), $\mathrm{Cs_2CO_3}$ (2.0 mmol), and DMF (3 mL). After stirring at 100°C for 15 h, the mixture was cooled to room temperature and then quenched by addition of aqueous 1*N* HCl and extracted with diethyl ether. The isolated organic layer was dried over $\mathrm{MgSO_4}$, filtered, concentrated *in vacuo*, and purified by column chromatography on silica gel eluting with ethyl acetate/hexane (1:5). Analysis of the reaction product was carried out by NMR and GC-MS.

P23

Synthesis of a number of 7,8-disubstituted theophyllines including enantiomers of the hypotensive agent **P23** is described.

J. Heterocyclic Chem., **46**, 191 (2009).

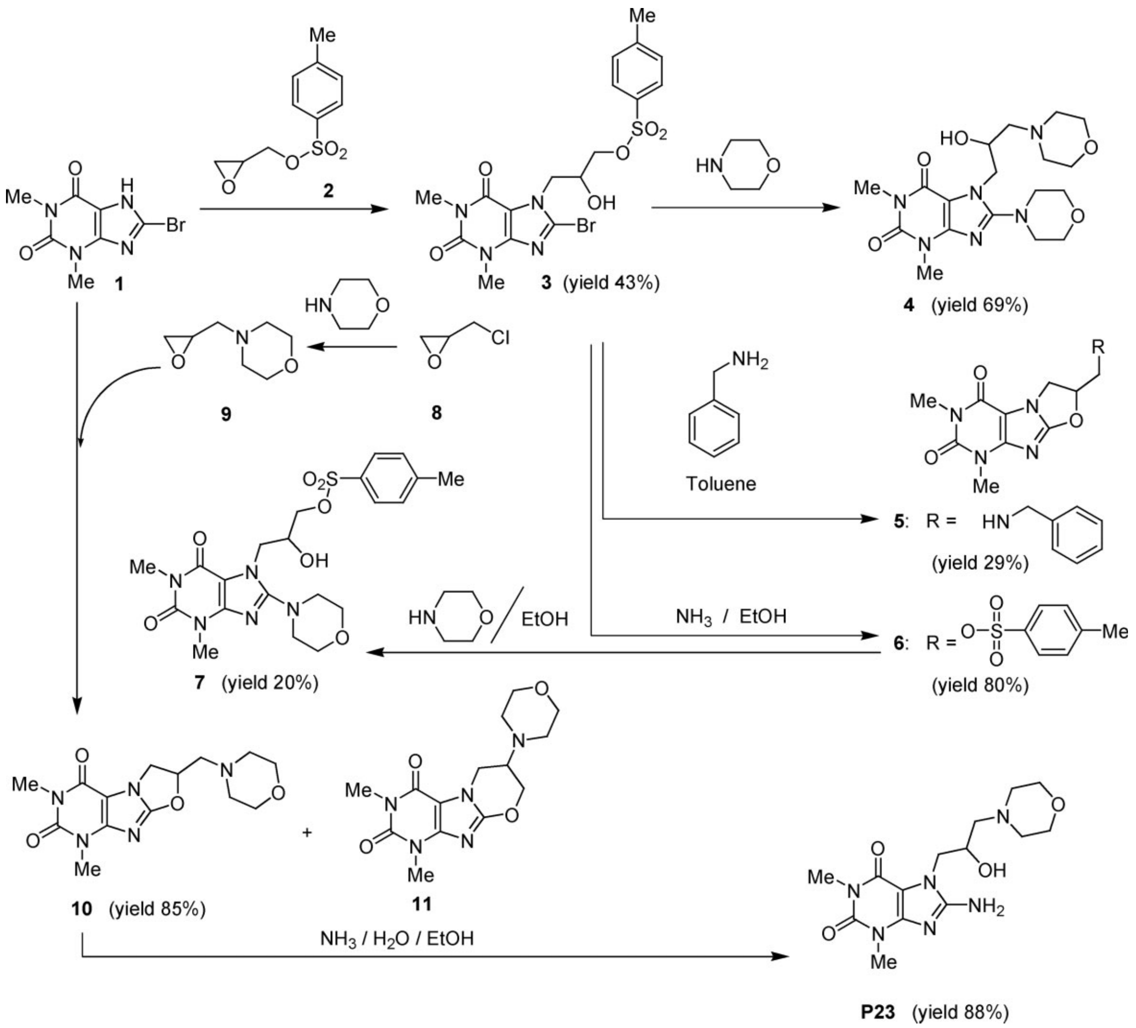
INTRODUCTION

N-Methyl derivatives of xanthine including caffeine, theobromine, and theophylline show diverse biological activities. An additional substitution of these compounds results in modulation of their biological responses. In particular, a 7,8-disubstituted theophylline **P23** (structure in Scheme 1) was synthesized two decades ago and protected by patents as a potent hypotensive agent that acts on the cardiovascular system [1]. The original synthesis of **P23** was based on a reaction of theophylline with racemic epichlorohydrin to give the racemic intermediate and final products. No attempts were made to synthesize enantiomers of **P23**, which is a requirement of the current drug development process. More specifically, two enantiomers of a chiral drug candidate must be biologically assayed. Since the patent protection of the chemistry leading to the racemate of **P23** has recently expired, the patented information is in the public domain. Therefore, it was of interest to review the previously published chemistry in an attempt to synthesize enantiomers of **P23**. Unfortunately, we have found that the use of enantiomerically pure epichlorohydrin instead of a racemic substrate in the reaction with 8-bromotheophylline (**1**) results in an extensive racemization of the intermediate adduct. Additional methodologies are illustrated in Scheme 1.

To test the feasibility of the designed synthetic routes, the first experiments involved the reaction of **1** with racemic reagents, namely 2,3-epoxypropyl 4-toluenesulfonate (**2**) and 2,3-epoxypropylmorpholine (**9**).

Compound **2** [2] and the reagent **9** [3] were synthesized by using the published procedures. Treatment of **1** with **2** gave the expected adduct **3** in 43% yield. It was believed that a selective nucleophilic displacement of the tosylate function in **3** by the reaction with morpholine followed by the addition of ammonia to the C=N—Br moiety of the resultant intermediate product and then elimination of bromide anion would produce the desired product **P23**. Unfortunately, the treatment of **3** with morpholine resulted in the displacement and addition reactions simultaneously to give a dimorpholino derivative **4**. On the other hand, it was thought that the addition reaction of less sterically hindered benzylamine with the C=N—Br moiety of **3** would be a selective process. The benzyl group could be removed later by hydrogenation. To our surprise a tricyclic product **5** was formed instead, showing that the third ring system is formed by the benzylamine-aided ionization of the hydroxyl function in the side chain followed by addition of the alkoxide anion to the C=N—Br moiety and a subsequent elimination of bromide. The treatment of **3** with ammonia also resulted in cyclization, however, without nucleophilic displacement of the tosylsulfonyl group, to give **6** as the final product. Another surprising result was obtained upon an attempted nucleophilic displacement of the tosylsulfonyl group in **6** by treatment with morpholine. Thus, the tosylsulfonyl group was retained in the bicyclic product **7**. The loss of the third ring can be explained in terms of the addition reaction

Scheme 1



of morpholine to the C=N function of **6** followed by elimination of alkoxide anion from the resultant adduct.

The successful preparation of **P23** that is also amendable to the synthesis of individual enantiomers is based on the reaction of 8-bromotheophylline (**1**) with *N*-(2,3-epoxypropyl)morpholine (**9**). Reagent **9** is not a commercial product and was obtained by the reaction of morpholine with epichlorohydrin (**8**) which is available in the form of a racemate or individual enantiomers. It has been suggested previously that the reaction of morpholine with an optically active substrate (*S*)-(+)-**8** is accompanied by extensive racemization of the epoxyamino product (*S*)-(−)-**9** [3-5]. We have shown that the racemization can be minimized by using mild conditions. As can be seen from the experimental part, the absolute values of the optical rotations for the enantiomers of **9** obtained by us are virtually identical. The greater optical purity of our sample of (−)-**9** is indicated by the absolute rotation, $[\alpha]_D = -25.4^\circ$ (c = 10% in toluene), as opposed to the value published previously, $[\alpha]_D = -20.2^\circ$, and measured under similar conditions [3]. The optical rotation of the (+)-**9** enantiomer has not been reported previously.

We have published recently that the treatment of 8-bromotheophylline (**1**) with the reagent **9** yields the oxazoline derivative **10** and, depending on conditions, varying amounts of the rearrangement product **11**. Relatively short reaction time and temperature favour the formation of **10** which can be obtained in an 85% yield. Conversely, heating the mixture at an elevated temperature for a prolonged period of time results in an efficient rearrangement of the initially formed compound **10** to the oxazine derivative **11** [6].

The racemic compound **10** was treated with ammonia in aqueous ethanol to give racemic product **P23**.

After optimization of the conditions a similar treatment of the enantiomers of **10** furnished optically active samples of **P23**. Their enantiomeric excess (defined as the percent excess of the enantiomer over the racemate) was calculated by analysis of the ^{1}H NMR spectra of diastereomeric esters of the samples of **P23** with (*S*)-(+)-α-methoxyphenylacetic acid. The procedure has been published previously [7], and the relative intensity of the singlets for the methine protons MeOC**H**(Ph)COO (δ 4.70-4.80) is the most informative. The obtained values of the enantiomeric excess for the samples containing (+)-**P23** and (−)-**P23** as the major enantiomers were 54% and 58%, respectively. These values correspond to the enantiomerically enriched samples containing 77% and 79% of the major enantiomer, respectively. The partial racemization observed for the synthesis of **P23** may be related to the partial racemization of **9**, as already mentioned [3]. Nevertheless, on the basis of the stereospecific chemistry involved, it can be safely assumed that the absolute configuration of the major enantiomer in the samples, (*R*)-(−)-**P23** and (*S*)-(+)-**P23**, are as shown. More specifically, the chemical transformations **8** → **9** → **10** → **P23** do not involve stereocenters in these compounds and, as a result, the absolute configurations, *R* or *S*, are retained in the intermediate and final products.

EXPERIMENTAL

Melting points (Pyrex capillary) are uncorrected. Electron-impact mass spectra (ei-ms) were recorded at 70 eV. High resolution time-of-flight mass spectra were recorded using electron-spray ionization (*high resolution ms*) with 0.5% ammonia in methanol for the negative ion mode and 0.1% formic acid in methanol for the positive ion mode. ^{1}H NMR spectra were obtained at 300 MHz in deuteriochloroform solution with the solvent used as an internal standard. All commercial reagents were purchased from Aldrich or Fluka and used without purification.

8-Bromo-7-[2-hydroxy-3-(4-tolylsulfonyloxy)propyl]theophylline [(±)-3]. A solution of (±)-2,3-epoxypropyl 4-toluenesulfonate (**2**, 0.27 g, 1.2 mmol), 8-bromotheophylline (**1**, 0.21 g, 0.8 mmol), and a catalytic amount of pyridine (0.02 g, 0.2 mmol) in *n*-propanol (2.5 mL) was heated under reflux for 1 hour. After cooling the mixture was concentrated on a rotary evaporator, and the residue was subjected to silica gel chromatography eluting with dichloromethane/methanol (49:1). Product (±)-**3** was obtained in a 43% yield, mp 78–79°C; ^{1}H NMR: δ 2.46 (s, 3H), 3.38 (s, 3H), 3.56 (s, 3H), 3.80 (br s, 1H), 4.12–4.18 (m, 3H), 4.48 (d, *J* = 1.4 Hz, 2H), 7.38 (d, *J* = 8.5 Hz, 2H), 7.85 (d, *J* = 8.5 Hz, 2H). *High resolution ms.* Calcd for $C_{17}H_{20}{}^{79}BrN_4O_6{}^{32}S$ ($M^+ + 1$): m/z 487.0287. Found: m/z 487.0290.

7-(2-Hydroxy-3-morpholinopropyl)-8-morpholinotheophylline [(±)-4]. A solution of (±)-**3** (0.05 g, 0.10 mmol) and morpholine (0.02 g, 0.21 mmol) in toluene (5 mL) was heated under reflux for 1.5 hours. The mixture was concentrated on a rotary evaporator, and the residue was subjected to silica gel chromatography eluting with dichloromethane/methanol (49:1). Compound **4** was obtained in a 69% yield, mp 175–176°C; ^{1}H NMR: δ 2.46 (m, 4H), 2.63 (m, 2H), 3.22 (m, 2H), 3.46 (m, 2H), 3.37 (s, 3H), 3.54 (s, 3H), 3.70 (m, 4H), 3.83 (m, 4H), 4.04 (m, 2H), 4.18 (m, 1H), 4.30 (m, 1H); ei-ms: m/z 408 (M^+, 10), 308 (50), 265 (10), 126 (50), 100 (100). *High resolution ms.* Calcd. for $C_{18}H_{27}N_6O_5$ ($M^- - 1$): m/z 407.2043. Found: m/z 407.2055.

7-[(Benzylamino)methyl]-1,3-dimethyl-6,7-dihydro-oxazolo[2,3-*f*]purine-1*H*,3*H*-2,4-dione [(±)-5]. A solution of **2** (0.05 g, 0.10 mmol) and benzylamine (0.02 g, 0.20 mmol) in toluene (5 mL) was heated under reflux. The reaction was completed after 1.5 hours, as judged by TLC analysis on silica gel eluting with chloroform/methanol (9:1). The resultant precipitate of benzylammonium 4-toluenosulfonate was filtered off and the solution was concentrated on a rotary evaporator. Product **5** was isolated by chromatography on silica gel eluting with chloroform/methanol (9:1), yield 29%, mp 252–253°C; ^{1}H NMR: δ 3.30 (s, 3H), 3.35 (s, 2H), 3.49 (s, 3H), 3.80 (s, 1H), 4.40 (m, 2H), 4.47 (m, 1H), 4.80 (m, 2H), 7.30 (m, 5H); ei-ms: m/z 341 (M^+, 100), 250 (25), 91 (40). *High resolution ms.* Calcd. for $C_{17}H_{20}N_5O_3$ ($M^+ + 1$): m/z 342.1566. Found: m/z 342.1570.

7-[(4-Tolylsulfonyloxy)methyl]-1,3-dimethyl-6,7-dihydro-oxazolo[2,3-*f*]purine-1*H*,3*H*-2,4-dione [(±)-6]. Gaseous ammonia was slowly bubbled at 0° through a solution of **3** (0.27 g, 0.6 mmol) in anhydrous ethanol. After 3 hours the resultant precipitate of **6** was collected by filtration and dried at 25°; yield 80%, mp 215–220°C; ^{1}H NMR: δ 2.50 (s, 3H), 3.42 (s, 3H), 3.55 (s, 3H), 4.40 (m, 4H), 5.68 (m, 1H), 7.42 (d, *J* = 8.5 Hz, 2H), 7.80 (d, *J* = 8.5 Hz, 2H); ei-ms: m/z 406 (M^+, 100), 234 (25), 91 (30). *High resolution ms.* Calcd. for $C_{17}H_{17}N_4O_6{}^{32}S$ ($M^- - 1$): m/z 405.0869. Found: m/z 405.0883.

7-[2-Hydroxy-3-(4-tolylsulfonyloxy)propyl]-8-morpholinotheophylline (±)-7]. A mixture of (±)-**6** (0.03 g, 0.08 mmol), morpholine (0.015 g, 0.16 mmol), and ethanol (2 mL) was stirred at 25°C for 24 h. Concentration of the mixture on a rotary evaporator followed by chromatography of the residue on silica gel eluting with dichloromethane/methanol (49:1) gave product 7 in a 20% yield, mp 163–164°C; ^{1}H NMR: δ 2.50 (s, 3H), 3.31 (m, 4H), 3.40 (s, 3H), 3.57 (s, 3H), 3.88 (m, 4H), 3.94 (m, 1H), 4.25 (m, 4H), 5.52 (br s, 1H), 7.42 (d, *J* = 8.2 Hz, 2H), 7.82 (d, *J* = 8.2 Hz, 2H). *High resolution ms.* Calcd. for $C_{21}H_{28}N_5O_7{}^{32}S$ ($M^+ + 1$): m/z 494.1709. Found: m/z 494.1685.

(±)-*N*-(2,3-Epoxypropyl)morpholine [(±)-9]. A mixture of morpholine (8.5 g, 0.1 mol) and water (0.5 mL) was treated dropwise with (±)epichlorohydrin (**8**, 9.25 g, 0.1 mol) in such a way that the temperature did not exceed 35 °C (exothermic reaction). After the addition was completed (1.5 h), the mixture was treated with an aqueous solution of sodium hydroxide (38%, 12.5 g) and then stirred for an additional 1 hour. The precipitate of sodium chloride was filtered off, and the filter and the flask was washed with ether (3 × 30 mL). The ether solution was dried (anhydrous K_2CO_3), then concentrated on a rotary evaporator, and the oily residue was distilled under reduced pressure (45–48°C/20 mmHg). Racemic product **9** was obtained in a 40% yield and its ^{1}H NMR spectrum was virtually identical with that reported [3] for the compound obtained by using a different synthetic route.

(2*R*)-(+)-*N*-(2,3-Epoxypropyl)morpholine [(2*R*)-(+)-9]. The reaction with (2*R*)-(−)-epichlorohydrin with morpholine and workup were conducted as described above; $[\alpha]_D = +24.1°$ (c = 10% in toluene).

(2*S*)-(-)-*N*-(2,3-Epoxypropyl)morpholine [(2*S*)-(−)-9]. The reaction with (2*S*)-(+)-epichlorohydrin with morpholine and workup were conducted as described above; $[\alpha]_D = -25.4°$ (c = 10% in toluene); reported $[\alpha]_D = -20.2°$ in toluene [3].

1,3-Dimethyl-7-morpholinomethyl-6,7-dihydrooxazolo-[2,3-*f*]-purine-1*H*,3*H*-2,4-dione [(±)-10, (7*S*)-(−)-10 and (7*R*)-(+)-10]. A mixture of 8-bromotheophylline (**1**, 0.39 g, 1.5 mmol), racemic compound **9** (0.31 g, 2 mmol), and pyridine (0.08 g, 1 mmol) in ethanol (5 mL) was stirred at room temperature for up to 10 days until TLC analysis (silica gel, chloroform/triethylamine, 9:1) showed the absence of **1** and/or the presence of a small amount of a byproduct **11**. Then the mixture containing precipitate of **10** was cooled to 0°C for an additional 24 h and filtered. Product (±)-**10** was obtained in an analytically pure form by chromatography on silica gel eluting with chloroform/methanol (9:1): yield 85%, mp 230–231°C. A similar treatment of **1** with (R)-(+)-**9** gave (R)-(+)-**10**, mp 176–178°C, $[\alpha]_D = +55.3°$ (c = 3% in dichloromethane/metanol, 49:1). A similar treatment of **1** with (*S*)-(−)-**9** gave (*S*)-(−)-**10**, mp 180–182°C, $[\alpha]_D = -49.7°$ (c = 3% in dichloromethane/methanol, 49:1). The ^{1}H NMR spectra of these three products were virtually identical with that reported previously for (±)-**10** [6]; ei-ms (identical in all cases): m/z 321 (M^+, 30), 234 (40), 126 (55), 113 (20), 100 (100). Anal. Calcd. for $C_{14}H_{19}N_5O_4$ [(±)-**10**]: C, 52.33; H, 5.95; N, 21.79. Found: C, 52.06; H, 5.93; N, 21.53.

8-Amino-7-(2-hydroxy-3-morpholinopropyl)theophylline [(±)-P23, (*S*)-(+)-P23, and (*R*)-(−)-P23]. A mixture of (±)-**10** (0.32 g, 1.0 mmol), aqueous ammonia (25%, 10 mL), and ethanol (15 mL) was heated in a pressure vessel to 110°C for 6 hours. After cooling the mixture was concentrated on a rotary evaporator and subjected to silica gel chromatography eluting with chloroform/methanol (49:1), yield 88%, mp 221–222°C (reported [1] mp 226–228°C for the racemic product); ^{1}H NMR: δ 2.44 (m, 2H), 2.66 (m, 4H), 3.37 (s, 3H), 3.50 (s, 3H), 3.66 (m, 4H), 4.18 (m, 1H), 4.40 (m, 2H), 4.50 (br s, 1H), 5.74 (br s, 2H); ei-ms: m/z 338 (20), 238 (45), 126 (50), 100 (100). The treatment of (7S)-(−)-**10** with ammonia gave (*S*)-(+)-**P23**, $[\alpha]_D = +5.3°$ (c = 2.2% in dichloromethane/methanol, 49:1). The treatment of (7*R*)-(+)-**10** with ammonia gave (*R*)-(−)-**P23**, $[\alpha]_D = -8.0°$ (c = 2.2% in dichloromethane/methanol, 49:1). The mp, NMR and ms data reported above are identical for all three products. Anal. Calcd. for $C_{14}H_{22}N_6O_4$ [(+)-**P23**]: C, 49.72; H, 6.55; N, 24.84. Found: C, 49.49; H, 6.90; N, 24.51.

Derivatization of P23 for analysis of the enantiomeric excess by ^{1}H NMR. Esterification of the secondary alcohol function of **P23** with (*S*)-(+)-α-methoxyphenylacetic acid was conducted by using a published procedure [7]. The ester was purified by chromatography on silica gel eluting with chloroform/methanol (49:1). The ^{1}H NMR spectra of the diastereomeric derivatives were taken in deuteriochloroform, and the ratio of the signals of the methine protons MeOCH(Ph)COO (δ 4.70–4.80) were analyzed [7].

Novel analogs of trifenagrel were synthesized by using inexpensive and reusable phosphotungstic acid, $H_3[PW_{12}O_{40}]$ (3 mol %) catalyst under classical heating. Two of the newly synthesized triaryl imidazoles exhibited moderate antibacterial activity.

J. Heterocyclic Chem., **46**, 195 (2009).

INTRODUCTION

In 1858, Debus [1] reported the reaction between glyoxal and ammonia and this reaction pioneered a novel synthetic route to imidazole. Subsequently imidazoles have received significant attention because of their synthesis, reactions, and biochemical properties [2]. The prevalence of imidazoles in natural products and pharmacologically active compounds has instituted a diverse array of synthetic approaches to these heterocycles. Even today, research in imidazole chemistry continues unabated because compounds containing an imidazole moiety have biological and pharmaceutical importance.

Synthesizing analogs of biologically active molecules is part of the drug discovery process and is a basic application of synthetic organic chemistry. One such pharmacologically potent 2,4,5-triaryl imidazole is trifenagrel (**1**) (Fig. 1) that inhibits both arachidonate and collagen induced aggregation of platelets with equal or greater potency (5–12 fold) than indomethacin and aspirin, without exhibiting the gastric damage associated with these typical cyclogenase inhibitors [3]. The potential of trifenagrel (as an antithrombic compound) rekindled an interest in us to synthesize its analogs for detailed structural activity relationship studies, efficient lead structure identification, and optimization in a drug discovery program.

Trifenagrel was first synthesized by Phillips *et al.* [4], by reaction of 2-(2-dimethylaminoethoxy) benzaldehyde, benzil, and ammonium acetate using glacial acetic acid as solvent under reflux condition. Later Wolkenberg *et al.* [5] reported the same reaction under microwave irradiation. The synthetic methods proposed for trifenagrel have limitations of harsh reaction conditions and use of polar solvent (acetic acid) leading to complex isolation and recovery procedures. Therefore, there is merit in using a nonsophisticated, recoverable, and reusable catalyst for the synthesis of analogs of trifenagrel.

In recent years, heteropoly acids (HPAs) have proved to be good catalysts in one-pot multicomponent construction of heterocyclic compounds. HPAs have a very strong Bronsted acidity and are efficient oxidants, exhibiting fast reversible multielectron redox transformations under mild conditions. HPAs are useful as catalysts because of the following unique characteristics: (a) catalytic performance, (b) chemical and physical properties, (c) molecular and bulk composition, and (d) method of synthesis of the catalyst [6]. One such mild HPA is phosphotungstic acid (PTA), $H_3[PW_{12}O_{40}]$ which has emerged as a powerful catalyst in recent years due to economic and environmental considerations. Recently, Heravi *et al.* [7] reported synthesis of tetrasubstituted imidazoles using HPAs as green and reusable catalysts. Therefore, we decided to investigate its catalytic activity for synthesis of novel triaryl imidazoles. In continuation of our work [8,9] in exploring applications of HPAs in fine organic chemistry, we have developed a method for solvent free synthesis of novel analogs of trifenagrel by using inexpensive and reusable PTA, $H_3[PW_{12}O_{40}]$ (3.0 mol %) catalyst under classical heating in a highly efficient manner.

RESULTS AND DISCUSSION

As a starting point of our study, we have selected 3-hydroxybenzaldehyde (**2**) and allowed it to react with 1,2-dibromoethane in the presence of 6*N* NaOH to give 3-(2-bromoethoxy) benzaldehyde (**3**) with 62% yield (Scheme 1). The formation of compound (**3**) was evident from the ^1H NMR by the appearance of aliphatic protons at δ 3.58 and δ 4.24 as triplets. Compound (**3**) was then treated with dimethylamine in the presence of methanol to afford compound (**4a**) in 90% yield. In the ^1H NMR spectrum of compound (**4a**) characteristic methyl protons appeared as a singlet at δ 2.90.

Similarly two more amine derivatives (**4b, 4c**) were prepared from compound (**3**). 3-(2-Piperidinoethoxy) benzaldehyde (**4a**) was obtained in 66% yield by the reaction of piperidine with compound (**3**). In the ^1H NMR spectrum of compound (**4b**), the aliphatic protons of piperidine appeared at δ 1.45 as multiplet and at δ 3.48 as triplet, respectively. In an identical manner, compound (**4c**) was prepared in 73% yield and ^1H NMR spectrum of this compound showed two triplets at δ 2.45 and δ 3.68.

The three-component condensation of benzil (**5**), aldehydes (**4a–c**), and ammonium acetate in the presence of 3 mol % of PTA gave trisubstituted imidazoles (**6a–c**) (Scheme 1). The compound (**6a**) was characterized from mass spectrum (ESI) by the appearance of $[M + H]^+$ peak at *m/z* 384 and from ^1H NMR by the appearance of increased aromatic protons at δ 7.22–7.60 and the absence of CHO proton at δ 10.01. Similarly the compounds (**6b, 6c**) were synthesized and their spectroscopic features fully supported the assigned structures.

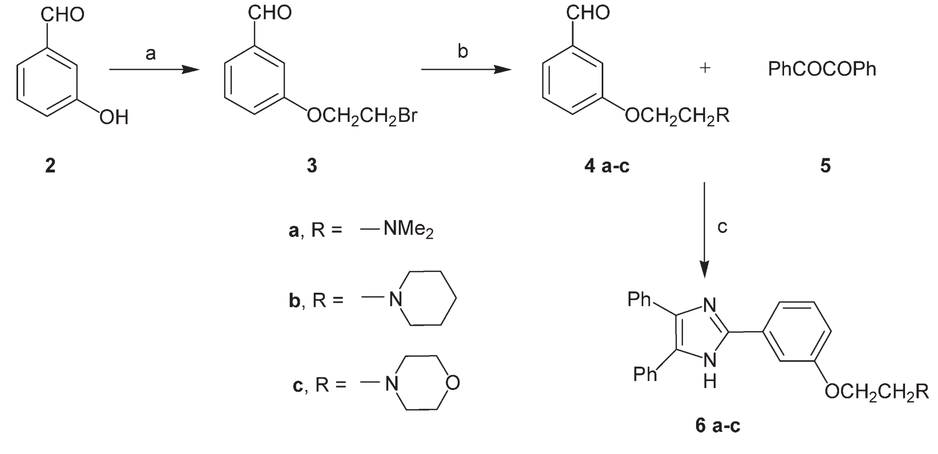
The scope of the reaction was further extended for the preparation of 4-hydroxybenzaldehyde (**7**) and vanillin (**8**) derived analogs of trifenagrel. Thus, compounds (**7** and **8**) on reaction with 1,2-dibromoethane in the presence of 6*N* NaOH provided the compounds (**9** and **10**), respectively. The formation of compounds (**9** and **10**) was evident from the appearance of $[M + H]^+$ peak at *m/z* 230 and 250 in mass spectrum (ESI) respectively, $-C{=}O$ stretching of aldehyde at 1684 and 1680 cm^{-1} respectively in IR and the appearance of methylene protons as triplets at δ 3.66 and δ 4.36 respectively in ^1H NMR of both the compounds (**9** and **10**).

Compounds (**9** and **10**) were then treated with dimethylamine in the presence of methanol to afford compounds (**11a** and **11b**) as liquids in excellent yield (Scheme 2). The formation of the compound (**11a** and **11b**) was evident by the appearance of $[M + H]^+$ peak at *m/z* 193 and 224 respectively in the mass spectrum (ESI), $-C{=}O$ stretching of aldehyde at 1690 and 1682 cm^{-1} in IR and by the appearance of a singlet at δ 2.33 and δ 2.32 respectively in ^1H NMR spectra corresponding to methyl protons of amine.

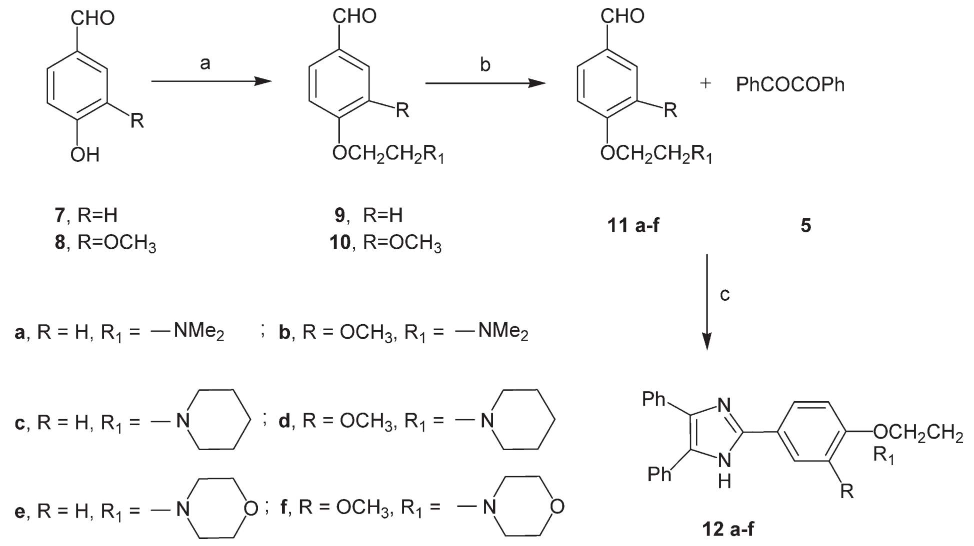
In a similar way two more derivatives for each (**11c, 11d, 11e,** and **11f**) were synthesized and their spectroscopic features fully supported its assigned structure.

The three-component condensation of benzil (**5**), aldehydes (**11a–f**), and ammonium acetate in the presence of 3 mol % of PTA gave trisubstituted imidazoles (**12a–f**) (Scheme 2). The compound (**12a**) was characterized

Scheme 1. Reagents and conditions: (a) $BrCH_2CH_2Br$, 6N NaOH (b) amine, MeOH (c) PTA (3.0 mol %), NH_4OAc, 2h.



Scheme 2. Reagents and conditions: (a) $BrCH_2CH_2Br$, 6N NaOH (b) amine, MeOH (c) PTA (3 mol %), NH_4OAc, 2h.



from mass spectrum (ESI) by the appearance of $[M + H]^+$ peak at *m/z* 384, IR by the appearance of —NH band at 3058 cm^{-1} and from ^1H NMR by the appearance of increased aromatic protons at δ 7.30–7.90 and the absence of CHO proton at δ 9.93. Similarly the compounds **(11b-f)** were synthesized and their spectroscopic data are in agreement with the assigned structures.

All the newly synthesized compounds **6a–c** and **12a–f** were screened for antibacterial and antifungal activities [10]. All the compounds were active against Gram-negative and Gram-positive bacteria. Among the screened compounds, **12a** showed good activity against Gram-negative and Gram-positive bacteria. Compounds **12a** and **12b** exhibited moderate activity against *Bacillus subtilis* (Table 1).

All the compounds were screened for antifungal activity against *Sacchromyces cerevisiae*, *Aspergillus niger*, *Rhizopus oryzae,* and *Candida albicans* by agar cup diffusion method [11] using Amphotericin-B as standard. All the compounds showed mild antifungal activity.

In summary, novel analogs of trifenagrel were synthesized by using inexpensive and reusable PTA, $H_3[PW_{12}O_{40}]$ catalyst under classical heating and screened for antibacterial and antifungal activities. Compounds **12a** and **12b** showed moderate antibacterial activity.

EXPERIMENTAL

Melting points were measured with Fiescher-Johns melting point apparatus. ^1H NMR spectra were recorded with an AVANCE 300 Bruker (at 300 MHz) and Gemini 200 MHz

spectrometers in $CDCl_3$. Chemical shifts relative to TMS as internal standard are given as δ values in ppm. ^{13}C NMR was recorded in $CDCl_3$ on a Varian (75 Hz) spectrometer. IR spectra were taken with a Perkin-Elmer 1725A FT-IR spectrophotometer. EI-MS mass spectra were measured at 70 eV (EI).

3-(2-Bromoethoxy)-benzaldehyde (3). A mixture of 3-hydroxybenzaldehyde (6.20 g, 50.8 mmol), 1,2-dibromoethane (38.14 g, 203 mmol), and methanol (50 mL) were heated to reflux. Then, 6*N* NaOH (10 mL) was added in 1.0 mL portions with 30 min intervals. After 18 h of stirring at reflux, the methanol was removed on rotary evaporator. Water (25 mL) was added to the residue and the mixture was extracted into ether (2 × 25 mL). The ethereal extracts were combined and washed with 6*N* NaOH (2 × 10 mL). Again ether layer was separated, dried over Na_2SO_4, concentrated to obtain crude product as brown syrup which was chromatographed over silica gel (60–120 mesh) using hexane:ethyl acetate (8:2) as eluent to obtain titled compound (7.21 g, 62%) (**3**) as brown liquid. IR (Neat): ν 3448, 1695, 1258 cm^{-1}, ^1H NMR (300 MHz, $CDCl_3$): δ 3.58 (t, 2H, $-CH_2$), 4.24 (t, 2H, $-CH_2$), 7.03–7.15 (m, 1H, Ar-H), 7.26 (m, 1H, Ar-H), 7.32–7.43 (m, 2H, Ar-H), 9.89 (s, 1H, $-CHO$), ^{13}C NMR (75 MHz, $CDCl_3$): δ 28.77, 67.78, 112.81, 121.65, 123.73, 129.97, 137.54, 158.39, 191.61. EI-MS: *m*/*z* 229 $[M]^+$. Anal.Cacld. for: $C_9H_9O_2Br$: C, 47.19; H, 3.95. Found: C, 47.02; H, 3.98.

3-(2-Dimethylaminoethoxy)benzaldehyde (4a). A mixture of 3-(2-bromoethoxy)-benzaldehyde (1.00 g, 4.36 mmol), 40% dimethylamine solution (10 mL, 81.6 mmol), and methanol (20 mL) was stirred at room temperature for 60 h. After completion of the reaction, methanol was removed on rotary evaporator to obtain the titled compound (**4a**) (0.75 g, 90%) as pale yellow solid. mp: 175–177°C, IR (KBr): ν 3423, 2958, 1679 cm^{-1}, ^1H NMR (200 MHz, DMSO-d_6): δ 2.90 (s, 6H, 2 × CH_3), 3.58 (t, 2H, $-CH_2$), 4.44 (t, 2H, $-CH_2$), 7.30–7.40 (m, 1H, Ar-H), 7.48–7.53 (m, 1H, Ar-H), 7.60–7.63 (m, 2H, Ar-H), 10.01 (s, 1H, $-CHO$), ^{13}C NMR (75 MHz, DMSO-d_6): δ 42.68, 55.17, 62.31, 113.61, 121.44, 123.30, 130.39, 137.49, 157.91, 192.76. EI-MS: *m*/*z* 193 $[M]^+$. Anal. Cacld. for: $C_{11}H_{15}NO_2$: C, 68.37; H, 7.82. Found: C, 68.33; H, 7.89.

2-(3-[2-Dimethylaminoethoxy) phenyl]-4,5-diphenylimidazole (6a). A mixture of benzil (0.42 g, 2.0 mmol), 3-(2-dimethylaminoethoxy) benzaldehyde (0.42 g, 2.0 mmol), ammonium acetate (0.54 g, 7.0 mmol), and PTA (0.1 g, 3 mol %) was heated at 140°C for 2 h. After completion of the reaction, the reaction mixture was cooled to room temperature and diluted with acetone (20 mL). Reaction mixture was filtered to remove catalyst and the filtrate was concentrated on rotary evaporator to syrup. Basification (of the syrup) with ammonium hydroxide (4 mL) resulted in separation of solid, which was collected by filtration *in vacuo* to obtain the titled compound (0.66 g, 86%) (**6a**) as white solid. mp: 182–183°C, IR (KBr): ν 3423, 2928, 1594, 1461 cm^{-1}, ^1H NMR (200 MHz, DMSO-d_6): δ 2.38 (s, 6H, 2 × CH_3), 2.80 (t, 2H, $-CH_2$), 4.17 (t, 2H, $-CH_2$), 6.72–6.81 (m, 1H, Ar-H), 7.22–7.40 (m, 7H, Ar-H), 7.55–7.60 (m, 4H, Ar-H), 7.65–7.72 (m, 2H, Ar-H), ^{13}C NMR (75 MHz, DMSO-d_6): δ 45.26, 57.45, 65.57, 110.95, 114.57, 117.71, 125.21, 127.10, 127.65, 128.37, 129.76, 131.61, 135.11, 145.33, 158.69. ESI-MS: *m*/*z* 384 $[M + H]^+$. Anal. Cacld. for: $C_{25}H_{25}N_30$: C, 78.30; H, 6.57. Found: C, 78.36; H, 6.51.

3-(2-Piperidinoethoxy)benzaldehyde (4b). A mixture of 3-(2-bromoethoxy)-benzaldehyde (1.50 g, 6.55 mmol), piperidine (1.55 g, 18.2 mmol), and methanol (15 mL) was refluxed for 3 h. After completion of the reaction, methanol was removed on rotary evaporator and to the resulting residue 4*N* NaOH (10 mL) was added and stirred for 10 min. Then reaction mixture was extracted into ether (3 × 25 mL) and the combined ethereal phases were extracted into 4*N* HCl (2 × 10 mL) and water (2 × 10 mL). The combined HCl and water extracts were basified with 8*N* NaOH (20 mL) and extracted into ether (2 × 25 mL). The ethereal extracts were washed with water (2 × 50 mL). Organic phase was separated, dried over Na_2SO_4, concentrated to obtain the titled compound (**4b**) (1.0 g, 66%) as brown syrup. IR (Neat): ν 3422, 2932, 1697, 1262 cm^{-1}, ^1H NMR (300 MHz, $CDCl_3$): δ 1.42–1.63 (m, 6H, 3 × $-CH_2$), 2.48 (t, 4H, 2 × $-CH_2$), 2.74 (t, 2H, $-CH_2$), 4.14 (t, 2H, $-CH_2$), 6.95–6.98 (m, 1H, Ar-H), 7.77–7.81 (m, 3H, Ar-H), 9.85 (s, 1H, $-CHO$). ESI-MS: *m*/*z* 234 $[M + H]^+$. Anal. Cacld. for: $C_{14}H_{19}NO_2$: C, 72.07; H, 8.20. Found: C, 72.02; H, 8.01.

2-(3-[2-(Piperidino)ethoxy)phenyl]-4,5-diphenylimidazole (6b). Prepared following the procedure described for (**6a**) using benzil (0.42 g, 2.0 mmol), 3-(2-piperidinoethoxy) benzaldehyde (0.51 g, 2.1 mmol), ammonium acetate (0.54 g, 7.0 mmol), and PTA (0.1 g, 3 mol %) to obtain the titled compound (**6b**) (0.70 g, 83%) as brown solid. mp: 142–145°C, IR (Neat): ν 3421, 2923, 1026 cm^{-1}, ^1H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 1.47–1.53 (m, 2H, $-CH_2$), 1.66–1.71 (m, 4H, 2 × $-CH_2$), 2.63–2.72 (m, 2H, $-CH_2$), 2.90 (t, 2H, $-CH_2$), 4.27 (t, 2H, $-CH_2$), 6.78 (d, 2H, Ar-H), 7.18–7.30 (m, 5H, Ar-H), 7.53–7.56 (d, J = 6.98 Hz, 4H, Ar-H), 7.64–7.67 (m, 2H, Ar-H), 7.84 (m, 1H, Ar-H), ^{13}C NMR (75 MHz, DMSO-d_6): δ 125.73, 125.95, 126.58, 127.40, 127.68, 127.79, 128.10, 128.25, 128.37, 130.01,135.93, 144.91, 145.43, 159.26. ESI-MS: *m*/*z* 424 $[M + H]^+$. Anal. Cacld. for: $C_{28}H_{29}N_3O$: C, 79.40; H, 6.89. Found: C, 79.48; H, 6.94.

3-(2-Morpholinoethoxy)-benzaldehyde (4c). Prepared following the procedure described for (**4b**) using 3-(2-bromoethoxy)-benzaldehyde (2.50 g, 10.9 mmol), morpholine (2.62 g, 30.1 mmol), and methanol (25 mL) to obtain the titled compound (**4c**) (1.88 g, 73%) as brown syrup. IR (Neat): ν 3446, 1696,1263 cm^{-1}, ^1H NMR (300 MHz, $CDCl_3$): δ 2.54 (t, 4H, 2 × $-CH_2$), 2.78 (t, 2H, $-CH_2$), 3.68 (t, 4H, 2 × $-CH_2$), 4.14 (t, 2H, $-CH_2$), 7.12–7.17 (m, 1H, Ar-H), 7.26 (m, 1H, Ar-H), 7.40–7.43 (m, 2H, Ar-H), 9.94 (s, 1H, $-CHO$). ESI-MS: *m*/*z* 236 $[M + H]^+$. Anal. Cacld. for: $C_{13}H_{17}NO_3$: C, 66.36; H, 7.28. Found: C, 66.31; H, 7.30.

2-(3-[2-(Morpholino)ethoxy)phenyl]-4,5-diphenylimidazole (6c). Prepared following the procedure described for (**6a**) using benzil (0.42 g, 2.0 mmol), 3-(2-morpholinoethoxy) benzaldehyde (0.51 g, 2.1 mmol), ammonium acetate (0.54 g, 7.0 mmol), and PTA (0.1 g, 3 mol %) to obtain the titled compound (**6c**) (0.68 g, 81%) as pale brown solid. mp: 218–219°C, IR (Neat): ν 3422, 1654, 1026 cm^{-1}, ^1H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 2.58 (t, 4H, 2 × $-CH_2$), 2.79 (t, 2H, $-CH_2$), 3.68 (t, 4H, 2 × $-CH_2$), 4.18 (t, 2H, $-CH_2$), 6.81–6.86 (m, 1H, Ar-H), 7.15–7.70 (m, 13H, Ar-H), 12.26 (brs, 1H, $-NH$), ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 52.62, 56.16, 65.29, 76.99, 109.80, 113.45, 116.65, 126.94, 128.25, 136.49, 144.56, 157.58. ESI-MS: *m*/*z* 426 $[M + H]^+$.

Anal. Cacld. for: $C_{27}H_{27}N_3O_2$: C, 76.28; H, 6.31. Found: C, 76.28; H, 6.31.

4-(2-Bromoethoxy) benzaldehyde (9). Prepared following the procedure described for (**3**) using 4-hydroxybenzaldehyde (6.20 g, 50.8 mmol), 1,2-dibromoethane (38.14 g, 203 mmol), and methanol (50 mL) to obtain the titled compound (7.55 g, 65%) (**9**) as white solid. mp: 55–58°C, IR (KBr): ν 3349, 2927, 1601 cm^{-1}. ^{1}H NMR (300 MHz, $CDCl_3$): δ 3.64 (t, 2H, —CH_2), 4.36 (t, 2H, —CH_2), 7.00 (d, J = 9.06 Hz, 2H, Ar-H), 7.81 (d, J = 8.30 Hz, 2H, Ar-H), 9.82 (s, 1H, —CHO), ^{13}C NMR (75 MHz, $CDCl_3$): δ 28.59, 29.66, 67.98, 76.72, 77.14, 77.57, 114.90, 130.47, 131.98, 163.00, 190.63. EI-MS: *m/z* 229 [M]$^+$. Anal. Cacld. for: $C_9H_9O_2Br$: C, 47.19; H, 3.95. Found: C, 47.10; H, 4.01.

4-(2-Dimethylaminoethoxy)benzaldehyde (11a). Prepared following the procedure described for (**4a**) using 4-(2-bromoethoxy)-benzaldehyde (1.00 g, 4.36 mmol), 40% dimethylamine solution (10 mL, 81.6 mmol), and methanol (20 mL) to obtain the title compound (0.77 g, 92%) (**11a**) as brown liquid. IR (Neat): υ 3437, 1690, 1600 cm^{-1}, ^{1}H NMR (300 MHz, $CDCl_3$): δ 2.33 (s, 6H, 2 × CH_3), 2.78 (t, 2H, —CH_2), 4.16 (t, 2H, —CH_2), 6.99–6.94 (m, 2H, Ar-H), 7.36–7.39 (m, 2H, Ar-H), 9.80 (s, 1H, —CHO). EI-MS: *m/z* 193 [M]$^+$. Anal. Cacld. for: $C_{11}H_{15}NO_2$: C, 68.37; H, 7.82. Found: C, 68.41; H, 7.80.

2-(4-[2-Dimethylaminoethoxy)phenyl]-4,5-diphenylimidazole (12a). Prepared following the procedure described for (**6a**) using benzil (0.14 g, 0.67 mmol), 4-(2-dimethylaminoethoxy) benzaldehyde (0.15 g, 0.77 mmol), ammonium acetate (0.18 g, 2.30 mmol), catalyst PTA (0.1 g, 3 mol %) to obtain the titled compound (0.22 g, 89%) (**12a**) as brown solid. mp: 120–125°C, IR (Neat): ν 3058, 2928, 1494, 1245 cm^{-1}, ^{1}H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 2.32 (s, 6H, 2 × CH_3), 2.72 (t, 2H, —CH_2), 4.08 (t, 2H, —CH_2), 6.90 (d, J = 6.86 Hz, 3H, Ar-H), 7.24–7.28 (m, 5H, Ar-H), 7.54 (d, J = 7.55 Hz, 4H, Ar-H), 7.98 (d, J = 10.98 Hz, 2H, Ar-H), ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 21.81, 44.77, 64.77, 122.85, 125.64, 113.93, 126.46, 127.61, 127.37, 127.92, 128.04,129.77, 132.71, 145.73, 158.11. ESI-MS: *m/z* 384 [M + H]$^+$. Anal. Cacld. for: $C_{25}H_{25}N_3O$: C, 78.30; H, 6.57. Found: C, 78.36; H, 6.51.

4-(2-Piperidinoethoxy) benzaldehyde (11c). Prepared following the procedure described for (**4b**) using 4-(2-bromoethoxy)-benzaldehyde (0.85 g, 3.71 mmol), piperidine (0.80 g, 9.41 mmol), and methanol (15 mL) to obtain the titled compound (**11c**) (0.83 g, 95%) as brown syrup. IR (Neat): υ 2934, 1692, 1601 cm^{-1}, ^{1}H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 1.42–1.64 (m, 6H, 3 × CH_2), 2.47 (t, 4H, 2 × —CH_2), 2.74 (t, 2H, —CH_2), 4.11 (t, 2H, —CH_2), 7.09–7.15 (m, 2H, Ar-H), 7.34–7.45 (m, 2H, Ar-H), 9.93 (s, 1H, —CHO). ESI-MS: *m/z* 234 [M + H]$^+$. Anal. Cacld. for: $C_{14}H_{19}NO_2$: C, 72.07; H, 8.20. Found: C, 72.02; H, 8.01.

2-(4-[2-(Piperidino)ethoxy)phenyl]-4,5-diphenylimidazole (12c). Prepared following the procedure described for (**7a**) using benzil (0.42 g, 2.0 mmol), 4-(2-piperidinoethoxy)-benzaldehyde (0.51 g, 2.1 mmol), ammonium acetate (0.54 g, 7.0 mmol), catalyst PTA (0.1 g, 3 mol %) to obtain the titled compound (0.74 g, 88%) (**12c**) as pale brown solid. mp: 188–190°C, IR (Neat): ν 3419, 1651, 1025 cm^{-1}, ^{1}H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 1.38 (m, 6H, 3 × CH_2), 2.50 (t, 4H, 2 × —CH_2), 2.74 (t, 2H, —CH_2), 4.11 (t, 2H, —CH_2), 6.90–6.94 (d, J = 8.86 Hz, 2H, Ar-H), 7.21–7.33 (m, 6H, Ar-H), 7.53–7.56 (d, J = 7.55 Hz, 4H, Ar-H), 7.97–8.02 (m, 2H, Ar-H), ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 19.71, 21.69, 66.60, 108.53, 112.11, 113.14, 120.12, 121.91, 125.49, 126.42, 126.79, 127.61, 128.86, 129.68, 132.04, 133.50, 136.23, 150.13, 157.10, 190.60. ESI-MS: *m/z* 424 [M + H]$^+$. Anal. Cacld. for: $C_{28}H_{29}N_3O$: C, 79.40; H, 6.89. Found: C, 79.48; H, 6.94.

4-(2-Morpholino)ethoxy)benzaldehyde (11e). Prepared following the procedure described for **(5b)** using 4-(2-bromoethoxy)-benzaldehyde (1.00 g, 4.3 mmol), morpholine (1.06 g, 12.18 mmol), and methanol (12.5 mL) to obtain the titled compound (**11e**) (0.97 g, 97%) as brown syrup. IR (Neat): ν 2953, 1689, 1600 cm^{-1}, ^{1}H NMR (300 MHz, $CDCl_3$): δ 2.54 (t, 4H, 2 × —CH_2), 2.79 (t, 2H, —CH_2), 3.68 (t, 4H, 2 × —CH_2), 4.15 (t, 2H, —CH_2), 6.95–7.00 (d, J = 9.06 Hz, 2H, Ar-H), 7.79 (d, J = 8.30 Hz, 2H, Ar-H), 9.85 (s, 1H, —CHO). ESI-MS: *m/z* 236 [M + H]$^+$. Anal. Cacld. for: $C_{13}H_{17}NO_3$: C, 66.36; H, 7.28. Found: C, 66.31; H, 7.30.

2-(4-[2-(Morpholino)ethoxy)phenyl]-4,5-diphenylimidazol (12e). Prepared following the procedure described for (**7a**) using benzil (0.42 g, 2.0 mmol), 4-(2-morpholinoethoxy) benzaldehyde (0.51 g, 2.1 mmol), ammoniumacetate (0.54 g, 7.0 mmol), catalyst phosphotungsticacid (0.1 g, 3 mol %) to obtain the titled compound (**11e**) (0.65 g, 70%) as brown semisolid. IR (Neat): ν 3059, 1603, 1247 cm^{-1}, ^{1}H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 2.55 (t, 4H, 2 × —CH_2), 2.78 (t, 2H, —CH_2), 3.68 (t, 4H, 2 × —CH_2), 4.13 (t, 2H, —CH_2), 6.90 (d, J = 8.86 Hz, 2H, Ar-H), 7.20–7.57 (m, 10H, Ar-H), 8.00 (m, 2H, Ar-H), ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 23.57, 53.42, 56.85, 65.22, 66.07, 100.85, 113.96, 122.97, 125.67, 125.88, 126.40, 127.33, 127.67, 128.31, 129.59,132.01, 129.95, 145.58, 158.23, 163.30. ESI-MS: *m/z* 426 [M + H]$^+$. Anal. Cacld. for: $C_{27}H_{27}N_3O_2$: C, 76.28; H, 6.31. Found: C, 76.28; H, 6.31.

4-(2-Bromoethoxy)-3-methoxybenzaldehyde (10). Prepared following the procedure described for (**3**) using 4-(3-methoxy) hydroxybenzaldehyde (8.00 g, 52.2 mmol), 1,2-dibromoethane (39.19 g, 208.6 mmol), and methanol (50 mL) to obtain the titled compound (**10**) (9.30 g, 68%) as white crystalline solid. mp: 62–65°C, IR (KBr): ν 3342, 1680, 1270 cm^{-1}, ^{1}H NMR (300 MHz, $CDCl_3$): δ 3.66 (t, 2H, —CH_2), 3.92 (s, 3H, —OCH_3), 4.37 (t, 2H, —CH_2), 6.94 (d, J = 8.30 Hz, 2H, Ar-H), 7.36–7.40 (m, 2H, Ar-H), 9.82 (s, 1H, —CHO), ^{13}C NMR (75 MHz, $CDCl_3$): δ 28.09, 56.03, 68.67, 109.77, 112.34, 126.30, 130.75, 149.92, 152.80, 190.75. ESI-MS: *m/z* 261 [M + H]$^+$. Anal. Cacld. for: $C_{10}H_{11}O_3Br$: C, 46.35; H, 4.27. Found: C, 46.30; H, 4.30.

4-(2-Dimethylaminoethoxy)-3-methoxybenzaldehyde (11b). Prepared following the procedure described for (**5a**) using 4-(2-bromoethoxy)-3-methoxybenzaldehyde (1.00 g, 3.84 mmol), 40% dimethylamine solution (10 mL, 81.6 mmol), and methanol (20 mL) to obtain the title compound (**11b**) (0.77 g, 89%) as yellow syrup. IR (Neat): ν 2941,1682, 1270 cm^{-1}, ^{1}H NMR (300 MHz, $CDCl_3$): δ 2.32 (s, 6H, 2 × CH_3), 2.77 (t, 2H, —CH_2), 3.91 (s, 3H, —OCH_3), 4.15 (t, 2H, —CH_2), 6.93 (d, 1H, Ar-H), 7.36 (d, 2H, Ar-H), 9.81 (s, 1H, —CHO), ^{13}C NMR (75 MHz, $CDCl_3$): δ 45.60, 55.76, 57.58, 66.66, 109.06, 111.28, 126.58, 129.96, 149.59, 153.60, 190.74. EI-MS: *m/z* 224 [M]$^+$. Anal. Cacld. for: $C_{12}H_{17}NO_3$: C, 64.55; H, 7.67. Found: C, 64.49; H, 7.73.

2-(4-[2-Dimethylaminoethoxy)-3-methoxyphenyl]-4,5-diphenylimidazole (12b). Prepared following the procedure described for (**7a**) using benzil (0.42 g, 2.0 mmol), 4-(2-

dimethylaminoethoxy)-3-methoxybenzaldehyde (0.49 g, 2.23 mmol), ammonium acetate (0.54 g, 7.0 mmol), catalyst PTA (0.1 g, 3 mol %) to obtain the titled compound (**12b**) (0.70 g, 85%) as gray solid. mp: 188–190°C, IR (KBr): ν 3386, 1506, 1264 cm^{-1}, ^{1}H NMR (200 MHz, DMSO-d_6): δ 2.29 (s, 6H, 2 × CH_3), 2.69 (t, 2H, —CH_2), 3.91 (s, 3H, —OCH_3), 4.09 (t, 2H, —CH_2), 6.98 (d, J = 6.86 Hz, 1H, Ar-H), 7.21–7.39 (m, 5H, Ar-H), 7.52–7.71 (m, 7H, Ar-H), ^{13}C NMR (75 MHz, DMSO-d_6): δ 44.97, 55.60, 57.19, 65.79, 108.95, 113.38, 117.87, 123.57, 128.35, 145.59, 147.90, 148.99. ESI-MS: *m/z* 414 [M + H]$^+$. Anal. Cacld. for: $C_{26}H_{27}N_3O_2$: C, 75.48; H, 6.51. Found: C, 75.40; H, 6.59.

4-(2-Piperidino)ethoxy)-3-methoxybenzaldehyde (11d). Prepared following the procedure described for (**5b**) using 4-(2-bromoethoxy)-3-methoxybenzaldehyde (1.00 g, 3.84 mmol), piperidine (0.81 g, 9.41 mmol), and methanol (15 mL) to obtain the titled compound (**11d**) (0.84 g, 83%) as brown syrup. IR (Neat): ν 2934, 1683, 1269 cm^{-1}, ^{1}H NMR (300 MHz, $CDCl_3$): δ 1.41–1.48 (m, 2H, —CH_2), 1.59–1.64 (m, 4H, 2 × —CH_2), 2.49 (t, 4H, 2 × —CH_2), 2.80 (t, 2H, —CH_2), 3.92 (s, 3H, —OCH_3), 4.18 (t, 2H, —CH_2), 6.93 (d, J = 7.55 Hz, 1H, Ar-H), 7.36–7.39 (m, 2H, Ar-H), 9.81 (s, 1H, —CHO), ESI-MS: *m/z* 264 [M + H]$^+$. Anal. cacld. for: $C_{15}H_{21}NO_3$: C, 68.39; H, 8.04. Found: C, 68.43; H, 8.01.

2-(4-[2-(Piperidino)ethoxy)-3-methoxyphenyl]-4,5-diphenylimidazole (12d). Prepared following the procedure described for (**7a**) using benzil (0.42 g, 2.0 mmol), 4-(2-piperidinoethoxy)-3-methoxybenzaldehyde (0.58 g, 2.2 mmol), ammonium acetate (0.64 g, 8.3 mmol), catalyst PTA (0.10 g, 3 mol %) to obtain the titled compound (**12d**) (0.72 g, 80%) as yellow solid. mp: 100–102°C, IR (Neat): ν 3422, 1647, 1025 cm^{-1}, ^{1}H NMR (200 MHz, $CDCl_3$ + DMSO-d_6): δ 1.45–1.61 (m, 6H, 3 × CH_2), 2.52 (t, 4H, 2 × —CH_2), 2.79 (t, 2H, —CH_2), 3.92 (s, 3H, —OCH_3), 4.14 (t, 2H, —CH_2), 5.05 (brs, 1H, —NH), 6.88 (d, J = 8.86 Hz, 1H, Ar-H), 7.20–7.33 (m, 6H, Ar-H), 7.53–7.67 (m, 6H, Ar-H), ^{13}C NMR (75 MHz, $CDCl_3$ + DMSO-d_6): δ 21.39, 22.05, 23.27, 24.66, 53.97, 55.55, 56.77, 65.23, 109.04, 112.53, 117.96, 123.54, 126.58, 127.63, 127.88, 132.92, 145.91, 147.76, 148.76, 172.88, 173.86. ESI-MS: *m/z* 454 [M + H]$^+$. Anal. Cacld. for: $C_{29}H_{31}N_3O_2$: C, 76.79; H, 6.88. Found: C, 76.87; H, 6.80.

4-(2-Morpholino)ethoxy)-3-methoxybenzaldehyde (11f). Prepared following the procedure described for (**5b**) using, 4-(2-bromoethoxy)-3-methoxybenzaldehyde (1.00 g, 3.84 mmol), morpholine (0.93 g, 10.7 mmol), and methanol (15 mL) to obtain the titled compound (**11f**) (0.99 g, 97%) as brown syrup. IR (Neat): υ 2924, 1681, 1269 cm^{-1}, ^{1}H NMR (300 MHz, $CDCl_3$): δ 2.57 (t, 4H, 2 × —CH_2), 2.84 (t, 2H, —CH_2), 3.67 (t, 4H, 2 × —CH_2), 3.91 (s, 3H, —OCH_3), 4.18 (t, 2H, —CH_2), 6.92 (d, J = 9.06 Hz, 1H, Ar-H), 7.37 (d, J = 8.30 Hz, 2H, Ar-H), 9.81 (s, 1H, —CHO). ESI-MS: *m/z* 266 [M + H]$^+$. Anal. Cacld. for: $C_{14}H_{19}NO_4$: C, 63.38; H, 7.21. Found: C, 63.32; H, 7.28.

2-(4-[2-(Morpholino)ethoxy)-3-methoxyphenyl]-4,5-di-phenylimidazole (12f). Prepared following the procedure described for (**7a**) using, benzil (0.42 g, 2.0 mmol), 4-(2-morpholinoethoxy)-3-methoxybenzaldehyde (0.58 g, 2.1 mmol), ammonium acetate (0.64 g, 8.3 mmol), catalyst PTA (0.1 g, 3 mol %) to obtain the titled compound (**12f**) (0.78 g, 86%) as pale brown solid. mp: 198–200°C, IR (Neat): ν 3061, 2939, 1500 cm^{-1}, ^{1}H NMR (200 MHz, DMSO-d_6): δ 2.51–2.56 (m, 4H, 2 × —CH_2), 2.76 (t, 2H, —CH_2), 3.61 (t, 4H, 2 × —CH_2), 3.89 (s, 3H, —OCH_3), 4.12 (t, 2H, —CH_2), 6.95–7.65 (m, 13H, Ar-H), 12.34 (brs, 1H, —NH), ^{13}C NMR (75 MHz, DMSO-d_6): δ 53.13, 55.67, 56.48, 65.20, 65.36, 113.71, 117.94, 127.06, 127.69, 128.38, 145.53, 147.87, 149.07. ESI-MS: *m/z* 456 [M + H]$^+$. Anal. Cacld. for: $C_{28}H_{29}N_3O_3$: C, 73.82; H, 6.41. Found: C, 73.74; H, 6.49.

Acknowledgments. The authors thank Head, Organic Chemistry Division-II, and Director, IICT for their support. They also thank CSIR, New Delhi, for financial assistance.

New multiarm aromatic chalcone derivatives **2a-d** were prepared through cross-aldol condensation reaction between multiarm aromatic ketones **1a-d** and 4-(dimethyl amino)benzaldehyde in basic medium. The multiarm aromatic chalcones **2a** and **2c** were able to undergo cyclization reactions when treated with hydrazine or any of it's derivatives to yield the corresponding pyrazolines **3a** and **3c** that were reacted with 2,3-dichloro-5,6-dicyano-1,4-benzoquenone in benzene to yield the aromatic pyrazoles **4a** and **4c**, respectively.

J. Heterocyclic Chem., **46**, 201 (2009).

INTRODUCTION

Heterocyclic chemistry is one of the most interesting and rapidly growing areas of chemical research. Heterocyclic components are found in many natural molecules, such as enzymes, vitamins, hormones, antibiotics and alkaloids, as well as pharmaceuticals, herbicides and dyes [1].

Chemically, chalcones consist of open-chain flavonoids in which the two aromatic rings are joined by a three carbon α,β-unsaturated carbonyl system. Chalcones can undergo many reactions to produce desirable products with desirable applications. They are precursors of flavonoids and isoflavonoids which are abundant in plants [2,3]. Chalcone derivatives have shown good physicochemical and biological activity, including antibacterial, antifungal, and anti-inflammatory [4]. Oxygenated chalcones serve as potential antimalarial agents [5], as antiplasmodial [6], as antiprotozoal, anti-HIV and antimicrobial and they also have an inhibitory effect on the proliferation of human leukemia cells [7]. Chalcones are also a class of anticancer agents, displaying promising therapeutic efficacy for the treatment of human cancers. For example, a chalcone derivative isolated from Chinese licorice root, has been associated with a wide variety of anticancer activity such as Licochalcone-A [8]. Chalcones have also found potential applications as artificial sweeteners, drugs, and agrochemicals [9]. The importance of this class of compounds is not only due to their biological activities but also due to their colors; they give yellow to orange colors in flowers. So, they are attractive to insects in such a way that they contribute to the flower's pollination [10]. Also they are part of some biological macromolecules and microenvironment in micelles [11]. Polymers that have pendent chalcone group become more photoconductive and photosensitive. Such polymers act as negative photo resist material [12]. Recently, the inhibitive action of chalcone derivatives on the corrosion of steel in hydrochloric acid and sulfuric acid solution was studied by Benkaddour and coworkers [13]. In addition, chalcones were widely used for various optical applications including second harmonic generation materials in nonlinear optics [14], liquid crystal display [15], photorefractive polymers, holographic recording materials, and fluorescent probes for sensing of metal ions. As a result, the photophysical properties of chalcones containing alkylamino groups as electron donors have been studied by numerous researchers [16,17].

Various heterocyclic systems can be obtained using chalcone as starting material. These derivatives have different applications. For example, pyrimidine is used as analgesic, antitumor, antifungal and antibacterial agent. Pyrazoles are used as ultraviolet stabilizer, anticancer, muscle relaxant, anti-inflammatory, antipyretic, antiarrhythmic, tranquilizing, anticonvulsant, hypotensive, monoamino oxidase inhibitor, antidiabetic and antibacterial agent [18–23]. Pyrazolines are used to produce photoconductive polymers [24], also used as scintillation solutes [25], as cytotoxic agent [26], they have also broad biological activities; such as psychoanaleptic, anticonvulsant, and antidepressant [27]. Thiazol derivatives have been reported to possess tuberculostatic, antibacterial, and antifungal activities [28].

Therefore, due to the wide application of chalcones and their heterocyclic derivatives, we have synthesized new compounds containing the benzene ring as a nucleus that is substituted with two, three, four or five-arm chalcone moieties. These multiarm chalcones were used for the synthesis of the corresponding heterocyclic compounds containing more than one pyrazoline or pyrazole rings.

RESULTS AND DISCUSSION

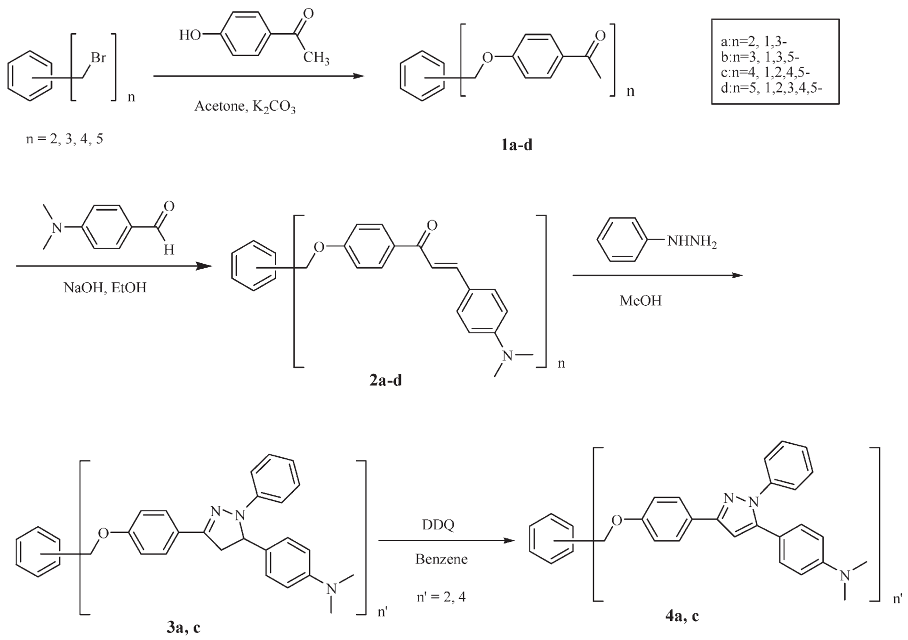
New heterocyclic five-membered ring compounds containing two, four pyrazolines **3a, c** and pyrazoles **4a, c** rings respectively were synthesized and characterized. The synthesis of the compounds **3a, c** and **4a, c** was carried out in a multistep procedure starting from cross-aldol condensation reaction between multiarm aromatic ketones **1a-d** and 4-(dimethylamino)benzaldehyde in basic medium to form the corresponding multiarm aromatic chalcones **2a-d**. We have already described the synthesis of the multiarm aromatic ketones **1b** and **1c** in previous work [29]. The ketones **1a** and **1d** are prepared by a similar procedure through nucleophilic substitution reaction between the corresponding 1,3-bis(bromomethyl)benzene and 1,2,3,4,5-pentakis(bromomethyl)-benzene with 4-hydroxyacetophenone respectively in the presence of potassium carbonate in refluxing dry acetone. The IR spectra of the chalcones **2a-d** showed characteristic bands in the range 1661–1679 for the carbonyl group, 1227–1261 cm^{-1} for the ether linkage and 1595–1599 cm^{-1} for the conjugated double bond. The ^{1}H NMR spectra of the chalcones **2a-d** showed characteristic singlet peak in the range 4.65–5.28 ppm for methylene protons ($-CH_2O-$), another singlet peak at 3.02–3.04 ppm for methyl protons on the nitrogen atom [$-N(CH_3)_2$] and appearance of new peaks at 7.47–7.66 ppm and 7.73–7.96 ppm for the protons of the conjugated double bond ($-CH=CH-$). The coupling constant value ($^3J_{-CH=CH-} = 16$ Hz) of the protons substituted on the double bond, showed that they are in the *trans* orientation relative to each other and thus the multiarm aromatic chalcones have *E*-configuration. The ^{13}C NMR spectra of the chalcones **2a-d** exhibit characteristic peaks at 66.7–69.9 ppm for the methylene carbon ($-CH_2O-$), at 40.0–40.2 ppm for the methyl carbons on the nitrogen atom [$-N(CH_3)_2$] and appearance of new peaks at 121.0–124.2 ppm and 143.0–145.2 ppm for the carbons of the double bond ($-CH=CH-$). The cyclization reaction of the chalcones **2a, c** was carried by treatment with phenylhydrazine in methanol at 0°C to yield the corresponding pyrazolines **3a, c** (**3a**: 63%, **3c**: 55%), which are nonaromatic. Aromatization of the pyrazolines **3a, c** was carried out through reacting them with 2,3-dichloro-5,6-dicyano-1,4-benzoquenone (DDQ) in boiling benzene to yield the aromatic pyrazoles **4a, c** in 75 and 43% yields, respectively.

The IR spectra of the pyrazolines **3a, c** and pyrazoles **4a, c** exhibited absorption bands at 1599–1601 cm^{-1} for the (C=N) bond, at 1340–1382 cm^{-1} for the (C−N) bond in pyrazoline and at 1669–1672 cm^{-1} for the (C=C) double bond in pyrazole. The ^{1}H NMR spectra of the pyrazolines **3a, c** showed characteristic doublet of doublet peaks in the range 4.12–5.04 ppm for the protons ($-CH-N-$) and two doublet of doublets at 3.07–3.76 ppm for the protons of the methylene group ($-CH_2-$) of the pyrazoline. However, a singlet peak at 6.68–7.09 ppm for the pyrazole aromatic proton was observed. The ^{13}C NMR spectra of the pyrazolines **3a, c** showed characteristic signals at 40–42 ppm for the carbon of the ($-CH_2-$) and another signal at 52–53 ppm for the carbon of the ($-CH-N-$) of the pyrazoline. In case of the pyrazole, the characteristic signals were observed at 105–106 ppm for the ($-CH=C-N-$) carbon bearing a proton and at 142–145 ppm for the ($-C-N-$) carbon of the pyrazole ring.

Since compounds **3a, c** and **4a, c** are solid, it was found that the melting point of the compound increases by increasing the number of the carbon atoms present. Also, it was found that the melting point of the pyrazoline derivatives is higher than that for the corresponding aromatic pyrazole derivatives.

The cytotoxicity and the biological activity of the chalcones **2a-d**, their pyrazoline and pyrazole

Scheme 1



derivatives will be studied in the near future (Scheme 1, Table 1).

EXPERIMENTAL

The melting points (mp) of all compounds were determined on an electrothermal digital melting point apparatus. Infrared (IR) spectra of the prepared compounds were recorded using a NICOLET 410 FTIR spectrometer (ν in cm^{-1}). The IR spectra of pure substances were measured as KBr-pellets. The ^1H and ^{13}C NMR spectra were recorded on Bruker AM400 and AC200 ultra shield spectrometers in deuterochloroform or dimethyl sulfoxide-d_6 with tetramethylsilane as an internal standard. The spectral data were reported in delta (δ) units relative to the tetramethylsilane reference line. Mass spectra were acquired using a MAT95 instrument of the Finnigan Company (FD: 5 kV Ionizing energy, field desorption) instruments. The signals were given as *m/z* with the relative intensity between brackets. Elemental analyses were performed in the analytical laboratory of the Institute of Organic Chemistry of the University of Mainz, Mainz, Germany. Analytical thin layer chromatography (TLC) was carried out using TLC-silica plates 60F254 (0.2 mm) of the Merck Company. The detection was followed by UV-lamp or through coloring with iodine. Chromatographic separation was carried out using Merck silica gel (60–230 mesh). The ratios of the solvents and mixed mobile phase were given in volume ratio.

M-xylene, mesitylene, tetra- and penta-methylbenzene were obtained from Aldrich. 4-Hydroxyacetophenone, *N*-bromosuccinimide, 4-(dimethyl amino)benzaldhyde, 2,3-dichloro-5,6-dicyano-1,4-benzo-quenone were obtained from ACROS. These chemicals were used without further purification.

General Procedure for the Preparation of Ketones (1a-d). Ketones **1b**, **c** were prepared from the corresponding bromomethylbenzene derivatives which were prepared from the corresponding methylbenzene derivatives and characterized as described in ref. 29. Whereas the new ketones **1a** and **1d** were prepared following the same procedure but using a mixture of 4-hydroxyacetophenone (1.36 g, 10.0 mmol) and (1.19 g, 4.5 mmol) of 1,3-bis(bromomethyl)benzene or (0.74 g, 1.4 mmol) of 1,2,3,4,5-pentakis(bromomethyl)benzene, respectively, potassium carbonate (1.38 g, 10.0 mmol) and the same equivalent amount of potassium iodide as the bromo compound in dry acetone (100 mL) were refluxed for 48–72 h. The reaction was followed up by TLC (20% chloroform:40% hexane:40% ethyl acetate) until completion. After cooling, the reaction mixture was diluted with water (50 mL) and extracted with dichloromethane (3 × 40 mL). The combined organic layers were dried over magnesium sulphate. The solvent was evaporated under vacuum and the residual solid was washed with diethyl ether. When necessary, a recrystalization from acetone or chloroform was performed.

1,1′-[1,3-Benzenediylbis(methyleneoxy-4,1-phenylene)]bisethanone (1a). This compound was obtained as colorless crystals (1.43 g, 85%)(acetone), mp 139–141°C; IR (potassium bromide): 2936, 1674, 1597, 1242, 1505, 831 cm^{-1}; ^1H NMR (deuteriochloroform): δ 2.55 (s, 6H, CH_3), 5.15 (s, 4H, $2xOCH_2$), 6.98 (d, J = 7.4 Hz, 4H, Ph-H), 7.40 (m, 3H, central-Ph-H), 7.49 (s, 1H, central-Ph-H), 7.91 (d, J = 7.4 Hz, 4H, Ph-H); ^{13}C NMR (deuteriochloroform): δ 26.31 (2C, CH_3), 69.87 (2C, 2 × OCH_2), 114.53 (4C, Ph-C), 126.39 (2C, Ph-C), 127.24 (2C, central-Ph-C), 129.10 (2C, central-Ph-C), 130.13 (1C, central-Ph-C), 130.63 (4C, Ph-C), 136.83 (1C, central-Ph-C), 162.48 (2C, Ph-C), 196.78 (2C, 2 × C=O); ms: (5 kV, fd) *m/z* (%) 374 (100). *Anal.* Calcd. for $C_{24}H_{22}O_4$: C, 76.99; H, 5.92. Found: C, 76.78; H, 5.81.

Table 1

Chemical percentage yield of the compounds (**1a**, **1d**, **2a-d**, **3a**, **3c** and **4a**, **4c**).

[Cpd*] is compound.

1,1′,1″,1‴,1⁗,1′′′′′-[1,2,3,4,5-Benzenepentaylpentakis(methyleneoxy-4,1-phenylene)]pentakisethanone (1d). This compound was obtained as pale yellow powder (1.13 g, 87%), mp 234–235°C; IR (potassium bromide): 2932, 1674, 1598, 1575, 1505, 1241, 1171, 831 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 2.50 (s, 15H, CH_3), 5.10 (s, 10H, 5 × OCH_2), 6.99 (d, *J* = 7.4 Hz, 10H, Ph-H), 7.46 (s, 1H, central-Ph-H), 7.93 (d, *J* = 7.4 Hz, 10H, Ph-H); ^{13}C NMR (deuteriochloroform): δ 26.35 (5C, CH_3), 63.57 (5C, 5 × OCH_2), 114.41 (10C, Ph-C), 126.39 (5C, Ph-C), 130.61 (10C, Ph-C), 130.50–131.18 (5C, central-Ph-C), 137.64 (1C, central-Ph-C), 161.83 (5C, Ph-C), 196.54 (5C, 5 × C=O); ms: (5 kV, fd) *m*/*z* (%) 818 (100). *Anal*. Calcd. for $C_{51}H_{46}O_{10}$: C, 74.80; H, 5.66. Found: C, 74.79; H, 5.56.

General procedure for the preparation of multi arm Chalcones (2a-d). A mixture of 4-(dimethylamino)benzaldhyde (1.49 g, 10.0 mmol) and (1.50 g, 4.0 mmol) of ketone **1a**, or (1.41 g, 2.7 mmol) of ketone **1b**, or (1.27 g, 1.9 mmol) of ketone **1c**, or (0.98 g, 1.2 mmol) of ketone **1d**, respectively, was prepared by dissolving the ketone in dry and warm ethanol (25 mL) at 50°C. A second solution of equivalent amount of sodium hydroxide was dissolved in dry ethanol (20 mL) and was added very slowly to the first solution with stirring at 50°C until completion. The mixture was left stirring for 2–5 days. The reaction progress was followed by TLC with different ratio of mobile phase (hexane:ethyl acetate) for each compound until completion. The solvent was evaporated under vacuum and the residual solid was purified by Column chromatography using different ratio of eluants (hexane:ethyl acetate) for each compound.

(2E,2′E)-1,1′-[1,3-Benzenediylbis(methyleneoxy-4,1-phenylene)] bis{3-[4-(dimethylamino)phenyl]-2-propen-1-one} (2a). This compound was obtained as pale-yellow powder (1.46 g, 85%), mp 130°C (decomposition); IR (potassium bromide): 1672, 1598, 1254, 1227, 981, 811 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 3.02 (s, 12H, CH_3), 5.15 (s, 4H, 2 × OCH_2), 7.02 (d, 4H, Ph-H), 7.46 (m, 3H, central-Ph-H), 7.05 (s, 1H, central-Ph-H), 7.92 (d, 4H, Ph-H), 7.54 (d, 2H, $^3J_{11-12}$ = 16 Hz, Ph-H), 7.94 (d, 2H, Ph-H), 6.99 (d, 4H, Ph-H), 6.86 (d, 4H, Ph-H); ^{13}C NMR (deuteriochloroform): δ 40.18 (4C, CH_3), 69.90 (2C, 2 × OCH_2), 111.29 (4C, Ph-C), 130.26 (2C, Ph-C), 127.14 (2C, central-Ph-C), 128.90 (2C, central-Ph-C), 130.28 (1C, central-Ph-C), 130.30 (4C, Ph-C), 142.03 (1C, central-Ph-C), 163.04 (2C, Ph-C), 121.21 (2C, Ph-C), 145.11 (2C, Ph-C), 121.69 (2C, Ph-C), 114.55 (4C, Ph-C), 127.36 (4C, Ph-C), 142.19 (2C, Ph-C), 188.67 (2C, 2 × C=O); ms: (5 kV, fd) *m*/*z* (%) 637 (100). *Anal*. General procedure for the preparation of Multi arm pyrazolines (3a, c) and pyrazoles (4a, c). Phenylhydrazine (0.43 g, 4 mmol) in methanol (1.0 mL) was added dropwise at 0°C under nitrogen atmosphere to a solution of (0.31 g, 0.50 mmol) enone 2a or (0.30, 0.25 mmol) enone 2c respectively in dry methanol (20 mL). The addition was completed within 5 h after which the mixture was left stirring for about 30 h. The reaction was followed by TLC in (40% toluene:60% ethyl acetate) until completion. The solvent was evaporated under vacuum and the residual solid was purified by column chromatography using (40% toluene:60% ethyl acetate) as eluant to yield the pyrazolines 3a, c which already contains some autoxidation product of pyrazoles 4a, c. The regular oxidation of pyrazolines 3a, c to the corresponding pyrazoles 4a, c was achieved by evaporating methanol and dissolving the residual solid in boiling benzene (3.0 mL) then (0.09 g, 0.4 mmol) 2,3-dichloro-5,6-dicyano-1,4-benzoquenone was added slowly with stirring. After 1–2 h, the products were purified by column chromatography using (50% toluene:50% ethyl acetate) as the eluant for the compounds.

3,3′-[1,3-Benzenediylbis(methyleneoxy-4,1-phenylene)]bis{4,5-dihydro-5-[4-(dimethylamino)phenyl]-1-phenylpyrazol-3-yl} (3a). This compound was obtained as orange solid (0.25 g, 63%), mp 172–174°C; IR (potassium bromide): 1601, 1455, 1382, 1219, 1076, 792 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 3.10 (s, 12H, CH3), 5.26 (s, 4H, 2 × OCH_2), 7.09 (d, 4H, Ph-H), 7.76 (m, 3H, central-Ph-H), 7.55 (s, 1H, central-Ph-H), 7.76 (d, 4H, Ph-H), 2.07 (dd, 4H, —CH_2—), 4.12 (m, 2H, —CH—), 6.70 (d, 4H, Ph-H), 6.99 (d, 4H, Ph-H), 7.10 (m, 10H, Phen-H); ^{13}C NMR (deuteriochloroform): δ 40.23 (4C, CH_3), 67.78 (2C, 5 × OCH_2), 111.86 (4C, Ph-C), 125.09 (2C, Ph-C), 140.48 (2C, central-Ph-C), 128.90 (2C, central-Ph-C), 130.14 (1C, central-Ph-C), 130.67 (4C, Ph-C), 128.35 (1C, central-Ph-C), 162.09 (2C, Ph-C), 152.02 (2C, Ph-C), 40.23 (2C, —CH_2—), 53.29 (2C, —CH—), 121.06 (2C, Ph-C), 114.40 (4C, Ph-C), 128.35 (4C, Ph-C), 143.52 (2C, Ph-C), 135.12 (2C, Ph-C), 113.57, 130.42, 132.08 (10C, Ph-C); ms: (5 kV, fd) m/z (%) 817 (100). *Anal*. Calcd. For $C_{54}H_{52}N_6O_2$: C, 79.38; H, 6.42; N, 10.29. Found: C, 79.23; H, 6.29; N, 10.21.

3,3′,3″,3‴-[1,2,4,5-Benzenetetrayltetrakis(methyleneoxy-4,1-phenylene)]pentakis{4,5-dihydro-5-[4-(dimethylamino)phenyl]-1-phenylpyrazol-3-yl} (3c). This compound was obtained as brown solid (0.21 g, 55%), mp 106°C (decomposition); IR (potassium bromide): 1648, 1599, 1340, 1255, 1164, 812 cm^{-1}; ^{1}H NMR (deuteriodimethylsulfoxide-d_6): δ 2.89 (s, 24H, CH_3), 5.02 (s, 8H, 4 × OCH_2), 6.84 (d, 8H, Ph-H), 7.34 (s, 2H, central-Ph-H), 7.40 (d, 8H, Ph-H), 3.69 (dd, 8H, —CH_2—), 5.04 (m, 4H, —CH—), 7.01 (d, 8H, Ph-H), 6.71 (d, 8H, Ph-H), 6.92 (m, 20H, Ph-H); ^{13}C NMR (deuteriodimethylsulfoxide-d_6): δ 40.99 (8C, CH_3), 69.10 (4C, 4 × OCH_2), 112.90 (8C, Ph-C), 125.67 (4C, Ph-C), 114.12 (2C, central-Ph-C), 129.09 (4C, central-Ph-C), 130.63 (8C, Ph-C), 164.12 (4C, Ph-C), 152.29 (4C, Ph-C), 42.28 (4C, —CH_2—), 52.29 (4C, —CH—), 124.84 (4C, Ph-C), 114.40 (8C, Ph-C), 128.79 (8C, Ph-C), 139.74 (4C, Ph-C), 136.73 (4C, Ph-C), 113.60, 130.63, 130.84 (20C, Ph-C); ms: (5 kV, fd) *m/z* (%) 1556 (100). *Anal*. A simple synthesis of several 2*H*-benzo[*g*]chromene-5,10-diones *via* the ring closing metathesis reaction of prerequisite bisolefins, prepared from the α-vinylnaphthoquinones, is described.

J. Heterocyclic Chem., **46**, 207 (2009).

INTRODUCTION

Heterocyclic compounds sharing quinonoid constituents are wide spread in nature and exhibit a broad range of biological activities [1]. Among them, pyranonaphthoquinones with some famous examples such as α-lapachone [2], β-lapachone [3], pentalongin [4], and pyranokunthone A and B [5] have attracted considerable synthetic attention because of their interesting pharmacological actions (Fig. 1) [6]. Specifically, lapachone derivatives and lapachol-type naphthoquinone compounds obtained from the bark of the lapacho tree (*Tabebuia avellanedae*) from Central and South America [2a] are known to display antitumor [7], anti-inflammatory [8], antifungal [9], antimalarial [10], and antibacterial [11] properties. Owing to the remarkable biological activities of lapachones, there has been much interest in the development of easy and simple methodologies to synthesize lapachone derivatives. Pyranonaphthoquinones including lapachone derivatives are most typically produced through the alkylation of 2-hydroxy-1,4-naphthoquinone followed by cyclization [12]. Recently, Lee and coworkers reported one-pot synthesis of pyranonaphthoquinone derivatives starting from 2-hydroxy-1,4-naphthoquinone with a variety of α,β-unsaturated aldehydes by a tandem Knoevenagel-electrocyclic reaction [6b].

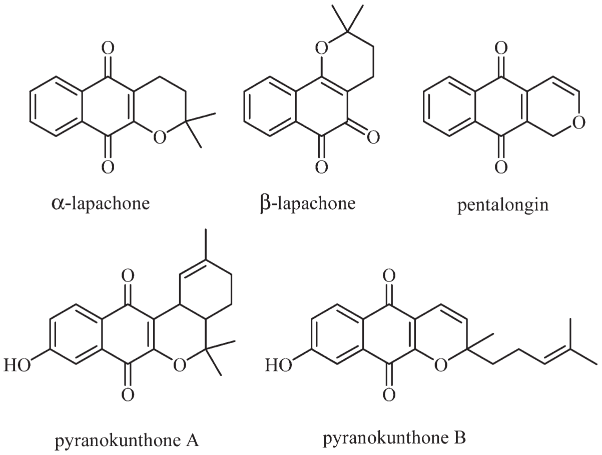

Figure 1. Naturally occuring pyranonaphthoquinones.

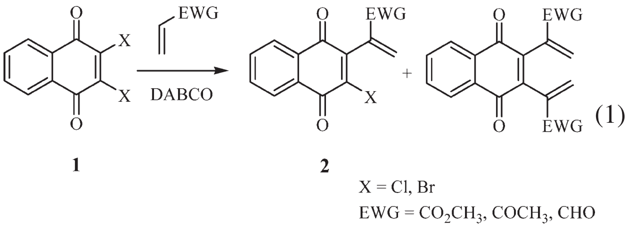
The Morita–Baylis–Hillman (MBH) reaction has been one of the most intensively studied carbon–carbon bond-forming reactions in organic synthesis [13]. Many efforts have been focused on the extension of useful electrophiles in the MBH reaction [14] besides aldehydes, which are the traditional source of electrophiles. In our earlier articles [15], we have demonstrated that 1,4-diazabicyclo[2,2,2]octane (DABCO)-assisted enolate anions of several activated olefins were useful in substitution reactions of 2,3-dihalo-1,4-naphthoquinones, leading to the formation of α-vinylnaphthoquinones and divinylnaphthoquinones under MBH reaction conditions [eq. (1)]. We also reported that these α-vinylated products were useful substrates for the synthesis of 4-chloro-5-hydroxy-1*H*-benzo[*g*]indoles in the presence of primary amines *via* the Nenitzescu indole synthetic route [15b].

As a continuation of our interest in the syntheses of heterocyclic compounds with possible biological activities using MBH chemistry [16], we now report a new synthetic pathway to 2*H*-benzo[*g*]chromenes from α-vinylnaphthoquinones using Grubbs second generation catalyst for the ring closing step [4b,17]. Although various 2*H*-benzo[*g*]chromenes were prepared earlier [6], to our knowledge, no synthetic example of 4-acyl-2*H*-benzo[*g*]chromene derivatives has been previously reported.



RESULTS AND DISCUSSION

We hypothesized that a pyran ring might be obtained from the ring closing metathesis (RCM) reaction of an appropriate bisolefin precursor **3** as shown in Scheme 1. The bisolefin **3** would result from the nucleophilic substitution reaction of a halogen atom on the known α-vinylnaphthoquinone **2** into allyl alkoxide. Accordingly, the known α-vinylnaphthoquinone **2a** was first synthesized as the stating material under MBH reaction condition [15a]. Treatment of **2a** with a suspension of 1.2 equivalent of allyl alcohol and sodium hydride in *N*,*N*-dimethylformamide at room temperature afforded disubstituted naphthoquinone **3a** in a moderate yield (47%) (Scheme 2). With this precursor **3a** in hand, we undertook the RCM reaction using 1 mol % of Grubbs second generation catalyst in refluxing dichloromethane (0.01*M*) under nitrogen atmosphere. Unfortunately, the reaction did not proceed at all and no trace of ring closed product was detected on thin layer chromatography (TLC). However, to our delight, an increased amount of catalyst (5 mol %) allowed the formation of the desired RCM product **5a** in a moderate yield (56%) after 2 h, without dimerized compounds. Moreover, the yield improved to 74% and the reaction time was shortened to 30 min with increased amount of catalyst (10 mol %).

We then aimed to extend the utility of this RCM reaction; therefore, we investigated further reactions of other types of bisolefins with various allyl alcohols. At first, bisolefins **3b** and **3c**, which have more steric hinderance at the allylic position than **3a**, were prepared in 78 and 54% yields, respectively, and RCM reactions of **3b** and **3c** furnished cyclized products **5b** (63%) and **5c** (80%) in good yields after 2 h with 10 mol % of catalyst. In these cases, we observed that the steric effect of allyl alcohol moiety required greater loading of catalyst and more reaction time to complete the RCM reaction [18].

We next examined the reactivity of other electron-deficient olefin systems such as acetyl and formyl groups. The bisolefins **3d-f** were prepared under similar reaction conditions from **2b** [15a] in 56–69% yields. Generally, the RCM reactions of **3d-f** required more catalyst and longer reaction times as shown in Table 1. In the case of **3d**, 5 mol % loading of catalyst was not sufficient to obtain the desired product **5d**. The bisolefin **3d** was transformed into the desired 2*H*-benzo[*g*]chromene **5d** in an excellent yield (91%) using 10 mol % of catalyst in refluxing dichloromethane (0.01*M*) after 40 min. Also, addition of 15 mol % catalyst led to successful formation of **5e** and **5f** in acceptable yields (41 and 66%) from the bisolefin **3e** and **3f**, respectively [19]. Additionally, the reactions of **2c** [15a] with 3-buten-2-ol and 1-penten-3-ol afforded the corresponding bisolefin **3g** and **3h** in low yields (21 and 31%), respectively. These relatively poor yields may arise from the high reactivity of *O*-nucleophiles toward the aldehyde group. On exposure of these bisolefins to RCM reaction conditions (15 mol % of catalyst), the RCM products **5g** [20] and **5h** were obtained in 40 and 42% yields, respectively. Efforts to obtain more steric secondary and tertiary alcohols such as α-vinylbenzyl alcohol, 1,4-pentadien-3-ol, and 2-methyl-3-buten-2-ol from the substitution reaction of **2a** were unsuccessful under various reaction conditions.

The mechanism for the formation of **5** is proposed in Scheme 2. The ruthenium carbene complex adds to one of the olefins as a [2 + 2] cycloaddition to give a four-membered ring **4a** with the metal atom in the ring. In this instance, the same reaction happens in reverse, either to give the starting materials or, by cleavage of the other two bonds, a new carbene complex **4b** and

styrene. Next, an intramolecular [2 + 2] cycloaddition joins up the six-member ring and produces a second metalla cyclobutane **4c**, which decomposes in the same way as the first one to give a third carbene complex and the product **5**.

The structure of **5** was established on the basis of spectroscopic data. The ^1H NMR spectra of both **5a** and **5d** showed disappearance of terminal alkenic protons. In the ^1H NMR of **5a**, the signal from the two C2 methylene protons appeared at δ 5.03 as a doublet ($J = 4.1$ Hz), and C3 vinylic proton appeared at δ 6.34 as a triplet ($J = 4.1$ Hz). In the case of **5d**, the signal corresponding to the two C2 methylene protons was observed at δ 5.05 as a doublet ($J = 4.0$ Hz), and C3 vinylic proton appeared at δ 6.10 as a triplet ($J = 4.0$ Hz). The ^{13}C NMR spectra of **5a** and **5d** each exhibited fifteen absorption peaks, including a signal at δ 166.3 for the ester carbonyl group of **5a** and a signal at δ 199.2 for the acetyl carbonyl group of **5d**.

CONCLUSION

In summary, we have synthesized several 2*H*-benzo[*g*]chromene derivatives with electron-withdrawing substituents at C4 position *via* RCM reaction from the easily accessible α-vinylnaphthoquinones. However, couplings

between α-vinylnaphthoquinones and some steric allyl alcohols to produce bisolefin precursors remain limited.

EXPERIMENTAL

Silica gel 60 (70-230 mesh ASTM) used for column chromatography was supplied by E. Merck. Analytical TLC was performed on Merck silica gel 60 F_{254} TLC plates. Melting points were measured by an Electrothermal melting point apparatus and were uncorrected. Microanalysis was obtained using a Thermo Electron Corporation Flash EA 1112 element analyzer. Infrared spectra were recorded with a Nicolet Magna 550 FTIR spectrometer. Electron impact (EI) mass and high resolution mass spectra were obtained using a Jeol SX 102 mass spectrometer. The ^{1}H NMR and ^{13}C NMR spectra were measured on a Gemini 300 spectrometer using deuteriochloroform. All chemical shifts are reported in parts per million relative to tetramethylsilane. The coupling constants (*J*) are expressed in Hertz.

Allyl alcohol, 3-buten-2-ol, 1-penten-3-ol, 1,4-pentadien-3-ol, 2-methyl-3-buten-2-ol, α-vinylbenzyl alcohol, and Grubbs second-generation catalyst were obtained from Aldrich and used without further purification. The known α-vinylnaphthoquinones **2a**, **2b**, and **2c** were prepared according to the published procedures [15a].

Methyl 2-[3-(allyloxy)-1,4-dihydro-1,4-dioxonaphthalen-2-yl]acrylate (3a). To a stirred suspension of ally alcohol (0.16 mL, 2.4 mmol) and sodium hydride (58 mg, 2.4 mmol) in *N*,*N*-dimethylformamide (5 mL) was added **2a** (642 mg, 2 mmol) at room temperature. After stirring for 2 h, the reaction mixture was diluted with water (40 mL) and extracted with dichloromethane (3 × 30 mL). The combined organic layers were dried over anhydrous magnesium sulfate and the solvent was evaporated *in vacuo*. The resulting mixture was chromatographed on silica gel eluting with hexane/ethyl acetate (6:1) to produce **3a** (280 mg, 47%) as an oil; IR (neat): 1727, 1673, 1657, 1595, 1576, 1335 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 3.77 (s, 3H), 4.91 (d, *J* = 5.5 Hz, 1H), 5.24 (d, *J* = 10.4 Hz, 1H), 5.35 (d, *J* = 17.1 Hz, 1H), 5.88 (s, 1H), 5.97 (ddd, *J* = 17.1, 10.4 and 5.5 Hz, 1H), 6.69 (s, 1H), 7.72–7.75 (m, 2H), 8.08–8.11 (m, 2H). ^{13}C NMR (deuteriochloroform): δ 52.3, 74.3, 118.7, 126.3, 126.5, 129.2, 131.3, 131.5, 131.6, 131.7, 132.9, 133.5, 134.2, 156.6, 166.1, 181.6, 183.7; *Anal*. Calcd. for $C_{17}H_{14}O_5$: C, 68.45; H, 4.73. Found: C, 68.27; H, 4.82.

Methyl 2-[3-(but-3-en-2-yloxy)-1,4-dihydro-1,4-dioxonaphthalen-2-yl]acrylate (3b). A mixture of 3-buten-2-ol (0.21 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol), and **2a** (642 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 2 h. The work-up procedure was the same as described earlier to produce **3b** (487 mg, 78%) as an oil; IR (neat): 1728, 1673, 1657, 1596, 1576, 1437 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.41 (d, *J* = 6.4 Hz, 3H), 3.76 (s, 3H), 5.10 (d, *J* = 10.1 Hz, 1H), 5.19 (d, *J* = 17.4 Hz, 1H), 5.48 (qd, *J* = 7.0 and 6.4 Hz, 1H), 5.82 (ddd, *J* = 17.4, 10.1, and 7.0 Hz, 1H), 5.87 (s, 1H), 6.67 (s, 1H), 7.71–7.74 (m, 2H), 8.06–8.10 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 21.4, 52.2, 80.8, 117.5, 126.3, 126.5, 128.9, 130.9, 131.5, 131.7, 131.8, 133.4, 134.1, 138.3, 156.3, 166.2, 181.9, 183.8; *Anal*. Calcd. for $C_{18}H_{16}O_5$: C, 69.22; H, 5.16. Found: C, 69.44; H, 5.23.

Methyl 2-[1,4-dihydro-1,4-dioxo-3-(pent-1-en-3-yloxy)-naphthalene-2-yl]acrylate (3c). A mixture of 1-penten-3-ol (0.25 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol) and **2a** (642 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 2 h. The work-up procedure was the same as described earlier to produce **3c** (352 mg, 54%) as an oil; IR (neat): 1728, 1672, 1656, 1595, 1575, 1436 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 0.94 (t, *J* = 7.6 Hz, 3H), 1.59–1.73 (m, 1H), 1.76–1.87 (m, 1H), 3.76 (s, 3H), 5.15 (d, *J* = 10.1 Hz, 1H), 5.17 (d, *J* = 17.1 Hz, 1H), 5.31 (td, *J* = 7.9 and 7.3 Hz, 1H), 5.72 (ddd, *J* = 17.1, 10.1, and 7.9 Hz, 1H), 5.87 (s, 1H), 6.68 (s, 1H), 7.69–7.76 (m, 2H), 8.05–8.09 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 9.3, 28.4, 52.2, 85.8, 119.0, 126.3, 126.5, 127.8, 130.7, 131.5, 131.7, 131.8, 133.4, 134.0, 136.8, 156.5, 166.2, 181.9, 183.8; *Anal*. Calcd. for $C_{19}H_{18}O_5$: C, 69.93; H, 5.56. Found: C, 69.69; H, 5.44.

3-(Allyloxy)-2-(but-3-en-2-one-3-yl)naphthalene-1,4-dione (3d). A mixture of allyl alcohol (0.16 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol), and **2b** (610 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 2 h. The work-up procedure was the same as described earlier to produce **3d** (288 mg, 51%) as an oil; IR (neat): 1673, 1654, 1594, 1576, 1364, 1333 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.45 (s, 3H), 4.86 (d, *J* = 5.8 Hz, 1H), 5.23 (d, *J* = 10.4 Hz, 1H), 5.33 (d, *J* = 17.1 Hz, 1H), 5.94 (ddd, *J* = 17.1, 10.4 and 5.8 Hz, 1H), 6.00 (s, 1H), 6.48 (s, 1H), 7.70–7.76 (m, 2H), 8.05–8.09 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 26.1, 74.3, 118.8, 126.3, 126.5, 129.7, 130.3, 131.4, 131.7, 132.9, 133.5, 134.1, 140.5, 156.9, 181.5, 183.8, 197.8; *Anal*. Calcd. for $C_{17}H_{14}O_4$: C, 72.33; H, 5.00. Found: C, 72.48; H, 5.23.

3-(But-3-en-2-yloxy)-2-(but-3-en-2-one-3-yl)naphthalene-1,4-dione (3e). A mixture of 3-buten-2-ol (0.21 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol) and **2b** (610 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 2 h. The work-up procedure was the same as described earlier to produce **3e** (397 mg, 67%) as an oil; IR (neat): 1673, 1652, 1595, 1334, 1254 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.39 (d, *J* = 6.4 Hz, 3H), 2.44 (s, 1H), 5.11 (d, *J* = 10.4 Hz, 1H), 5.18 (d, *J* = 17.4 Hz, 1H), 5.45 (qd, *J* = 7.0 and 6.4 Hz, 1H), 5.80 (ddd, *J* = 17.4, 10.4, and 7.0 Hz, 1H), 5.97 (s, 1H), 6.45 (s, 1H), 7.69–7.75 (m, 2H), 8.04–8.08 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 21.3, 26.3, 80.8, 117.6, 126.3, 126.5, 129.5, 131.4, 131.7, 132.1, 133.4, 134.0, 138.3, 140.6, 156.5, 181.8, 183.9, 197.9; *Anal*. Calcd. for $C_{18}H_{16}O_4$: C, 72.96; H, 5.44. Found: C, 72.72; H, 5.28.

2-(But-3-en-2-one-3-yl)-3-(pent-1-en-3-yloxy)naphthalene-1,4-dione (3f). A mixture of 1-penten-3-ol (0.25 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol), and **2b** (610 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 2 h. The work-up procedure was the same as described earlier to produce **3f** (428 mg, 69%) as an oil; IR (neat): 1673, 1656, 1595, 1573, 1334, 1293 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 0.93 (t, *J* = 7.3 Hz, 3H), 1.40–1.71 (m, 1H), 1.73–1.85 (m, 1H), 2.43 (s, 3H), 5.15 (d, *J* = 10.4 Hz, 1H), 5.17 (d, *J* = 17.1 Hz, 1H), 5.31 (td, *J* = 7.9 and 7.0 Hz, 1H), 5.7 (ddd, *J* = 17.1, 10.4, and 7.9 Hz, 1H), 5.96 (s, 1H), 6.45 (s, 1H), 7.68–7.74 (m, 2H), 8.03–8.07 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 9.3, 26.3, 28.4, 85.8, 119.1, 126.3, 126.4, 129.4, 131.5, 131.7, 131.8, 133.4, 134.0, 136.8, 140.7, 156.7, 181.8, 183.9, 197.9; *Anal*. Calcd. for $C_{19}H_{18}O_4$: C, 73.53; H, 5.85. Found: C, 73.40; H, 5.66.

2-[3-(But-3-en-2-yloxy)-1,4-dihydro-1,4-dioxonaphthalen-2-yl]acrylaldehyde (3g). A mixture of 3-buten-2-ol (0.21 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol), and **2c** (582 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 1 h. The work-up procedure was the same as described earlier to produce **3g** (119 mg, 21%) as an oil; IR (neat): 1697, 1673, 1654, 1595, 1575, 1331 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.38 (d, J = 6.1 Hz, 3H), 5.11 (d, J = 10.4 Hz, 1H), 5.17 (d, J = 17.4 Hz, 1H), 5.53 (qd, J = 7.3 and 6.1 Hz, 1H), 5.80 (ddd, J = 17.4, 10.4, and 7.3 Hz, 1H), 6.48 (s, 1H), 6.58 (s, 1H), 7.69–7.77 (m, 2H), 8.05–8.09 (m, 2H), 9.64 (s, 1H); ^{13}C NMR (deuteriochloroform): δ 21.4, 80.8, 117.7, 126.4, 126.5, 128.7, 131.4, 131.7, 133.5, 134.1, 138.1, 138.2, 140.9, 157.0, 181.6, 183.3, 191.1; *Anal.* Calcd. for $C_{17}H_{14}O_4$: C, 72.33; H, 5.00. Found: C, 72.08; H, 5.29.

2-[1,4-Dihydro-1,4-dioxo-3-(pent-1-en-3-yloxy)-naphthalene-2-yl]acrylaldehyde (3h). A mixture of 1-penten-3-ol (0.25 mL, 2.4 mmol), sodium hydride (58 mg, 2.4 mmol), and **2c** (582 mg, 2 mmol) in *N*,*N*-dimethylformamide (5 mL) was stirred at room temperature for 1 h. The work-up procedure was the same as described earlier to produce **3h** (184 mg, 31%) as an oil; IR (neat): 1697, 1674, 1655, 1595, 1575, 1331 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 0.92 (t, J = 7.3 Hz, 3H), 1.56–1.70 (m, 1H), 1.72–1.86 (m, 1H), 5.15 (d, J = 9.8 Hz, 1H), 5.18 (d, J = 17.7 Hz, 1H), 5.35 (td, J = 7.9 and 7.0 Hz, 1H), 5.70 (ddd, J = 17.7, 9.8, and 7.9 Hz, 1H), 6.48 (s, 1H), 6.60 (s, 1H), 7.67–7.75 (m, 2H), 8.04–8.08 (m, 2H), 9.64 (s, 1H); ^{13}C NMR (deuteriochloroform): δ 9.3, 28.4, 85.9, 119.3, 126.4, 126.5, 127.9, 131.5, 131.7, 133.5, 134.1, 136.7, 138.1, 140.9, 157.3, 181.7, 183.3, 191.1; *Anal.* Calcd. for $C_{18}H_{16}O_4$: C, 72.96; H, 5.44. Found: C, 72.63; H, 5.28.

Preparation of 2*H*-benzo[*g*]chromenes 5a-h: General Procedure. Bisolefin **3a-h** (0.5 mmol) was dissolved in 50 mL (0.01*M*) of dichloromethane. Then Grubbs II catalyst was added (10–15 mol %) and the solution was refluxed for 0.5–2.5 h under nitrogen atmosphere. The mixture was concentrated *in vacuo*. Purification on silica gel (hexane/ethyl acetate, 2:1) afforded **5a-h** as a solid.

The physical and spectral data of **5a**-**h** prepared by this general method are listed in the following paragraphs.

Methyl 5,10-dihydro-5,10-dioxo-2H-benzo[g]chromene-4-carboxylate (5a). Yellow solid; yield 74%; mp 182–183°C; IR (potassium bromide): 1724, 1676, 1650, 1631, 1591, 1571, 1455 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 3.86 (s, 3H), 5.03 (d, J = 4.1 Hz, 2H), 6.34 (t, J = 4.1 Hz, 1H), 7.70–7.79 (m, 2H), 8.08–8.13 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 52.6, 66.3, 119.8, 126.0, 126.4, 126.6, 127.2, 130.8, 131.5, 133.5, 134.5, 154.9, 166.3, 178.8, 180.3; ms: m/z (%) = 270 (28) [M$^+$], 238 (15), 210 (16), 183 (42), 127 (64), 115 (26), 104 (100); hrms (EI): m/z Calcd. for $C_{15}H_{10}O_5$: 270.0528; Found: 270.0518; *Anal.* Calcd. for $C_{15}H_{10}O_5$: C, 66.67; H, 3.73. Found: C, 66.52; H, 3.59.

Methyl 5,10-dihydro-2-methyl-5,10-dioxo-2H-beno[g]chromene-4-carboxylate (5b). Yellow solid; yield 63%; mp 148–149°C; IR (potassium bromide): 1732, 1677, 1651, 1632, 1591, 1571, 1438 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.61 (d, J = 6.7 Hz, 3H), 3.86 (s, 3H), 5.24 (qd, J = 6.7 and 3.7 Hz, 1H), 6.21 (d, J = 3.7 Hz, 1H), 7.69–7.77 (m, 2H), 8.08–8.13 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 19.9, 52.6, 73.7, 118.9, 126.3, 126.4, 126.6, 130.2, 131.0, 131.6, 133.4, 134.4, 154.1, 166.6, 179.0, 180.4; ms: m/z (%) = 284 (73) [M$^+$], 269 (100), 252 (99), 241 (66), 224 (64), 197 (80), 196 (72), 163 (30), 139 (34), 115 (39), 104 (37). hrms (EI): m/z Calcd. for $C_{16}H_{12}O_5$: 284.0685; Found: 284.0683; *Anal.* Calcd. for $C_{16}H_{12}O_5$: C, 67.60; H, 4.25. Found: C, 61.45; H, 4.43.

Methyl 2-ethyl-5,10-dihydro-5,10-dioxo-2H-benzo[g]-chromene-4-carboxylate (5c). Yellow solid; yield 80%; mp 94–95°C; IR (potassium bromide): 1729, 1676, 1652, 1634, 1590, 1570, 1456, 1435 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.09 (t, J = 7.4 Hz, 3H), 1.86–2.03 (m, 2H), 3.86 (s, 1H), 5.05 (td, J = 6.3 and 3.9 Hz, 1H), 6.23 (d, J = 3.9 Hz, 1H), 7.68–7.78 (m, 2H), 8.07–8.13 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 8.8, 27.0, 52.5, 78.4, 119.0, 126.3, 126.5, 126.7, 129.2, 131.0, 131.6, 133.4, 134.3, 154.3, 166.7, 178.9, 180.4; ms: m/z (%) = 298 (31) [M$^+$], 270 (96), 269 (100), 241 (100), 239 (47), 210 (31), 181 (29), 153 (30), 104 (52); hrms (EI): m/z Calcd. for $C_{17}H_{14}O_5$: 298.0841; Found: 298.0839; *Anal.* Calcd. for $C_{17}H_{14}O_5$: C, 68.45; H, 4.73. Found: C, 68.20; H, 4.55.

4-Acetyl-2H-benzo[g]chromene-5,10-dione (5d). Red solid; yield 91%; mp 173–174°C; IR (potassium bromide): 1702, 1678, 1650, 1591, 1571, 1404 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 2.37 (s, 3H), 5.05 (d, J = 4.0 Hz, 2H), 6.10 (t, J = 4.0 Hz, 1H), 7.71–7.79 (m, 2H), 8.07–8.13 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 29.0, 66.4, 120.3, 122.8, 126.4, 126.6, 130.8, 131.3, 133.7, 134.5, 135.6, 155.2, 178.8, 180.9, 199.2; ms: m/z (%) = 254 (45) [M$^+$], 212 (19), 183 (77), 155 (28), 139 (12), 128 (100), 127 (100), 104 (66); hrms (EI): m/z Calcd. for $C_{15}H_{10}O_4$: 254.0579; Found: 254.0580; *Anal.* Calcd. for $C_{15}H_{10}O_4$: C, 70.86; H, 3.96. Found: C, 70.59; H, 4.21.

4-Acetyl-2-methyl-2H-benzo[g]chromene-5,10-dione (5e). Red solid; yield 41%; mp 137–138°C; IR (potassium bromide): 1695, 1675, 1646, 1592, 1569, 1394 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.61 (d, J = 6.7 Hz, 3H), 2.36 (s, 3H), 5.25 (qd, J = 6.7 and 3.7 Hz, 1H), 5.95 (d, J = 3.7 Hz, 1H), 7.71–7.78 (m, 2H), 8.07–8.13 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 20.2, 29.2, 73.8, 119.4, 126.4, 126.6, 127.0, 131.0, 131.3, 133.6, 134.4, 134.7, 154.4, 179.1, 181.0, 199.6; ms: m/z (%) = 268 (100) [M$^+$], 253 (27), 225 (47), 197 (56), 183 (30), 141 (22), 115 (28), 105 (18); hrms (EI): m/z Calcd. for $C_{16}H_{12}O_4$: 268.0736; Found: 268.0733; *Anal.* Calcd. for $C_{16}H_{12}O_4$: C, 71.64; H, 4.51. Found: C, 71.51; H, 4.42.

4-Acetyl-2-ethyl-2H-benzo[g]chromene-5,10-dione (5f). Yellow solid; yield 66%; mp 85–86°C; IR (potassium bromide): 1700, 1676, 1652, 1593, 1569, 1394 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.09 (t, J = 7.3 Hz, 3H), 1.86–2.05 (m, 2H), 2.36 (s, 3H), 5.07 (td, J = 6.1 and 3.7 Hz, 1H), 5.97 (d, J = 3.7 Hz, 1H), 7.70–7.78 (m, 2H), 8.06–8.13 (m, 2H); ^{13}C NMR (deuteriochloroform): δ 8.8, 27.4, 29.2, 78.6, 119.4, 125.9, 126.4, 126.6, 131.0, 131.4, 133.6, 134.4, 135.1, 154.6, 179.0, 181.0, 199.8; ms: m/z (%) = 282 (57) [M$^+$], 253 (100), 239 (28), 225 (100), 211 (29), 197 (39), 183 (33), 165 (31), 105 (33); hrms (EI): m/z Calcd. for $C_{17}H_{14}O_4$: 282.0892; Found: 282.0892; *Anal.* Calcd. for $C_{17}H_{14}O_4$: C, 72.33; H, 5.00. Found: C, 72.11; H, 4.85.

5,10-Dihydro-2-methyl-5,10-dioxo-2H-benzo[g]chromene-4-carbaldehyde (5g). Orange solid; yield 40% [20]; ^{1}H NMR (deuteriochloroform): δ 1.62 (d, J = 7.0 Hz, 3H), 5.35 (qd, J = 4.0 and 7.0 Hz, 1H), 6.49 (d, J = 4.0 Hz, 1H), 7.74–7.81 (m, 2H), 8.12–8.14 (m, 2H), 10.16 (s, 1H).

2-Ethyl-5,10-dihydro-5,10-dioxo-2H-benzo[g]chromene-4-carbaldehyde (5h). Orange solid; yield 42%; mp 109–110°C; IR (potassium bromide): 1719, 1676, 1647, 1612, 1592, 1561, 1458, 1346 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.10 (t, J = 7.4 Hz, 3H), 1.93–1.99 (m, 2H), 5.17 (td, J = 6.1 and 4.1 Hz, 1H), 6.52 (d, J = 4.1 Hz, 1H), 7.72–7.80 (m, 2H), 8.11–8.13 (m, 2H), 10.16 (s, 1H); ^{13}C NMR (deuteriochloroform): δ

8.7, 27.4, 78.8, 118.0, 126.4, 126.6, 131.0, 131.4, 131.6, 131.7, 133.7, 134.5, 154.7, 178.9, 182.0, 189.0; ms: *m/z* (%) = 268 (69) [M^+], 240 (100), 222 (56), 197 (37), 165 (36), 135 (21), 105 (14); *Anal*. Calcd. for $C_{16}H_{12}O_4$: C, 71.64; H, 4.51. Found: C, 71.90; H, 4.38.

2-Trideuteriopyridine-4,6-d_2 (**1-4,6-d_2**), 3-methylpyridine-2,6-d_2 (**2-2,6-d_2**), 3-methylpyridine-2,4,6-d_3 (**2-2,4,6-d_3**), and 4-trideuteriopyridine-2,6-d_2 (**3-2,6-d_2**) were synthesized from the appropriate 2-, 3-, or 4-methylpyridine N-oxides. These deuterated products were characterized by their ^{1}H NMR and ^{13}C NMR spectra.

J. Heterocyclic Chem., **46**, 213 (2009).

INTRODUCTION

Work in our laboratory has shown that irradiation of pyridine [1,2], cyanopyridines [3], and methylpyridines [3] in the vapor phase results in deep-seated rearrangements in which the ring atoms, along with the attached substituents, change their relative positions. To map the transpositions of these atoms within the heteroaromatic ring, the photo-rearrangements of a variety of deuterated pyridine derivatives were studied. The deuterium atoms served as positional labels and allowed determination of where a particular ring atom in the photoproduct originated in the reactant.

The synthesis and characterization of the six isomeric dideuteriopyridines and the three isomeric trideuteriopyridines [4] and three isomeric dideuteriocyanopyridines [5] have already been reported. To complete our work in this area, we now report the synthesis and characterization of the three dideuterio and one trideuteriomethylpyridines shown in Scheme 1.

RESULTS AND DISCUSSION

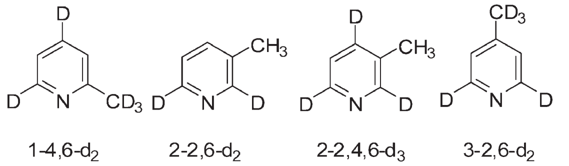
In the case of 3- and 4-methylpyridines, both open positions α to the ring nitrogen were deuterated by two successive base catalyzed H/D exchanges [6] in the commercially available 3- and 4-methylpyridine N-oxides, **4-a,b**, followed by reduction using phosphorous trichloride in dichloromethane [7] as shown in Scheme 2.

The structures of **2-2,6-d_2** and **3-2,6-d_2** were confirmed by the spectroscopic data shown in Tables 1 and 2. Deuteration at ring positions 2 and 6 of each compound was confirmed by ^{1}H NMR and ^{13}C NMR spectra. In particular, in the case of **2-2,6-d_2**, the ^{1}H NMR spectrum exhibited a pair of doublets ($J = 7.6$ Hz) at δ 7.18 and 7.40 where H4 and H5 are known to absorb, but only very low intensity signals at δ 8.37 and 8.38 due to residual protons at ring positions 2 and 6. Similarly, the complete proton decoupled ^{13}C NMR spectrum exhibited singlets at δ 123.4, 133.3, and 136.8 due to C5, C3, and C4 respectively and triplets at δ 146.9 ($J =$ 28.3 Hz) and 150.2 ($J = 28.4$ Hz) due to C6 and C2 confirming that these ring carbon atoms are bonded to deuterium.

As expected, the ^{1}H NMR spectrum of the more symmetrical **3-2,6-d_2** exhibited an intense singlet at δ 7.06, where H3 and H5 are known to absorb, but only a very small signal at δ 8.40, where H2 and H6 are known to absorb. In addition, the ^{13}C NMR spectrum exhibited singlets at 124.9 and 147.3 due to C3,5 and C4 respectively, and a triplet ($J = 28.4$ Hz) confirming that the equivalent C2,6 carbon atoms are both bonded to deuterium. These results confirm that in both compounds, deuteration has taken place exclusively at ring positions 2 and 6.

As shown in Scheme 3, **4a-2,6-d_2** is also a suitable precursor for the trideuterated methylpyridine **2-2,4,6-d_3**. As shown, the conversion involved electrophilic nitration at C4 [7], replacement of the nitro group with chloro [7], reduction of the N-oxide [6], and finally, replacement of the C4 chloro with deuterium using palladium on charcoal in a deuterium atmosphere [8]. The spectral data in Tables 1 and 2 confirm that the three-deuterium atoms are exclusively at ring positions 2, 4, and 6. In particular, the ^{1}H NMR spectrum exhibits an

Scheme 1



intense singlet at δ 7.10 indicating that the ring contains a single proton at the C5 position. Furthermore, the ^{13}C NMR spectrum shows triplets at δ 136.7 (J = 24.3 Hz), 146.9 (J = 27.3 Hz), and 150.3 Hz (J = 26.7 Hz) for C4, C6, and C2, respectively, whereas the signals at δ 123.5 and 136.7 due to C5 and C3 appeared as sharp singlets.

In the case of the 2-methylpyridine isomer, which has only one open position α to the ring nitrogen, the synthetic approach outlined in Scheme 4 was followed. Thus, commercially available 2-methylpyridine N-oxide (**8**) was first monodeuterated at ring position 6, α to the ring nitrogen, using two successive base catalyzed H/D exchanges [6]. Introduction of deuterium into ring position 4 was then accomplished by nitration [7], replacement of nitro with chloro [7], reduction of the N-oxide [6], and finally replacement of chlorine for deuterium using D$_2$ and Pd/C [8].

The spectral data in Tables 1 and 2 confirm that the two deuterium atoms are exclusively at ring positions 4 and 6. Accordingly, the ^{1}H NMR spectrum exhibited singlets at δ 7.06 and 7.13 where protons at ring positions 5 and 3 are known to absorb but signals of very low intensity at δ 7.55 and 8.40 indicating only residual protons at ring positions 4 and 6. In addition, the ^{13}C NMR spectrum exhibited a singlet for a quaternary carbon at δ 159.4 due to the C2 ring carbon and sharp singlets at δ 124.0 and 121.6 where the C3 and C5 ring carbons are known to absorb. In contrast, the signals due to the C6 and C4 carbon atoms appeared as triplets at δ 149.9 (J = 27.6 Hz) and 136.9 (J = 28.3 Hz) due to coupling of these carbon atoms with deuterium.

CONCLUSION

The synthetic procedures described allow the synthesis of the four deuterated-methylpyridines shown in Scheme 1. The positions of the deuterium atoms in the pyridine ring were unambiguously confirmed by the ^{1}H NMR and ^{13}C NMR data shown in Tables 1 and 2.

EXPERIMENTAL

Melting points were determined using a MEL-TEMP apparatus and are uncorrected. ^{1}H NMR and ^{13}C spectra were recorded at 400.1 and 100.6 MHz in acetone-d$_6$ on a Brucker FT-NMR system. ^{1}H NMR and ^{13}C chemical shifts were measured relative to internal tetramethylsilane and chloroform, respectively. All ^{13}C NMR spectra are proton-decoupled. Mass spectra were recorded with an HP 5970B mass selective detector interfaced to an HP 588 capillary gas chromatograph.

2-Trideuteriomethylpyridine N-oxide-6-d, (8-6-d$_1$), 3-methylpyridine N-oxide-2,6-d$_2$ (4a-2,6-d$_2$), and 4-trideuteromethylpyridine-2,6-d$_2$ (4b-2,6-d$_2$). The open positions α to nitrogen were deuterated by dissolving 3-methylpyridine N-oxide (4a) (1.0g, 9.0 mmol), 4-methylpyridine N-oxide (4b) (1.0g, 9.0 mmol), or 2-methylpyridine N-oxide (8) (3.4g, 36.5 mmol) in a solution of sodium carbonate (2.0 g) in deuterium oxide (20 mL). The mixture was heated in an oil bath at 110°C for 12 h. The resulting solution was allowed to cool and extracted with dichloromethane (5 × 30 mL). The combined dichloromethane extracts were dried (sodium sulfate) and concentrated to give partially deuterated product which was subjected to a second hydrogen-deuterium exchange as mentioned earlier to provide the final products, which were purified by Kugelrohr distillation (water aspirator).

Compound **4a-2,6-d$_2$** was obtained as a colorless liquid in a yield of 0.8 g (7.2 mmol, 80%); ^{1}H NMR (deuterium oxide) δ 2.3 (s, 3H), 7.26 (d, 1H, J = 8.1 Hz) 7.42 (d, 1H, J = 8.1 Hz); ^{13}C NMR (deuterium oxide) δ 18.4, 125.4, 127.8, 136.3 (t, J = 27.6 Hz), 136.6, 139.3 (t, J = 26.8 Hz).

Compound **4b-2,6-d$_2$** was obtained as a colorless liquid in a yield of 0.7 g (6.0 mmol, 79%); ^{1}H NMR (deuterium oxide) δ 2.1 (residual methyl protons), 7.28 (s, 2H); ^{13}C NMR (deuterium oxide) δ 19.8 (m), 128.4, 138.5 (t, J = 29.1 Hz), 146.2.

Compound **8-6-d$_1$**, was obtained as a colorless liquid in a yield of 3.0 g (27.3 mmol, 84.5%); ^{1}H NMR (deuterium oxide) δ 2.6 (residual methyl protons), 7.06–7.22 (m, 3H); ^{13}C NMR (deuterium oxide) δ 17.5 (m), 123.9, 126.3, 139.2 (t, J = 28.4 Hz), 149.4.

3-Methylpyridine-2,6-d$_2$ (2-2,6-d$_2$) and 4-trideuteriomethylpyridine-2,6-d$_2$ (3-2,6-d$_2$). 3-Methylpyridine N-oxide-2-6-d$_2$ (4a-2,6-d$_2$) (0.80 g, 7.2 mmol) or 4-trideuteriomethylpyridine N-oxide-2,6-d$_2$ (4b-2,6-d$_2$) (0.70 g, 6.0 mmol) dissolved in dichloromethane (40 mL) was added dropwise to phosphorous trichloride (2.4 mL) at 0°. The resulting mixture was heated at reflux for 1 h, cooled to room temperature and poured onto ice (15 g). The resulting mixture was made basic with aqueous sodium hydroxide (10%) and extracted with

^{a} These signals are due to residual protons in the methyl group.

dichloromethane (5 × 5 mL). The combined extract was dried (sodium sulfate) and concentrated.

3-Methylpyridine-2,6-d$_2$ (**2-2,6-d$_2$**) was obtained as a colorless oil (0.50 g, 5.3 mmol, 73%); MS *m/z* (%) 95 (100), 68 (36), 67 (39). The NMR data are given in Tables 1 and 2.

4-Trideuteriomethylpyridine-2,6-d$_2$ (**3-2,6-d$_2$**) was obtained as a colorless oil (0.45 g, 4.5 mmol, 75%); MS *m/z* (%) 98 (100), 80 (5), 70 (43). The NMR data are given in Tables 1 and 2.

2-Trideuteriomethylpyridine-4,6-d$_2$(1-4,6-d$_2$)

4-Nitro-2-trideuteriomethylpyridine N-oxide-6d (9-6-d$_1$). 2-Trideuteriomethylpyridine N-oxide-6d$_1$(**8-6-d$_1$**) (2.5 g, 22.1 mmol) was added dropwise to a cold mixture of concentrated sulfuric acid (5.0 mL) and concentrated nitric acid (5.0 mL) while keeping the temperature below 50°C. The resulting clear solution was allowed to stir at room temperature for 10 min and then heated at 110°C for 5 h. The resulting solution was allowed to cool to room temperature and neutralized with saturated aqueous sodium bicarbonate. The neutralized solution was extracted with dichloromethane (3 × 50 mL). The extract was dried (sodium sulfate) and concentrated to give crude 4-nitro-2-trideuteriomethylpyridine N-oxide-6d$_1$ (**9-6-d$_1$**) as a yellow solid (1.7 g). Recrystallization from acetone gave **9-6-d$_1$** as yellow crystals; mp 153–155°C; ^{1}H NMR (deuteriochloroform) δ 2.3 (residual methyl protons), 7.90 (s, 1H), 8.10 (s, 1H); ^{13}C NMR (deuteriochloroform) δ 1.71 (m), 117.5, 120.2, 139.3 (t, J = 28.4 Hz), 141.2, 150.1.

4-Chloro-2-trideuteriomethylpyridine N-oxide-6d$_1$ (10-6-d$_1$). 4-Nitro-2-trideuterio-methylpyridine N-oxide-6d$_1$ (**9-6-d$_1$**) (1.5 g, 9.5 mmol) was dissolved in concentrated hydrochloric acid (20 mL) and heated in an oil bath at 135°C for 18 h. The reaction mixture was allowed to cool to room temperature and extracted with chloroform (5 × 20 mL). The combined chloroform extracts were dried (sodium sulfate) and concentrated to give a yellow solid (1.0g) which was subjected to column chromatography (silica gel). Elution with ethyl acetate provided unreacted starting material. Elution with methanol provided 4-chloro-2-trideuteriopyridine N-oxide-6d$_1$ (**10-6-d$_1$**) as a yellow viscous liquid (0.60 g, 4.1 mmol, 43%); ^{1}H NMR (deuteriochloroform) δ 2.3 (residual methyl protons), 7.0 (s, 1H) 7.2 (s, 1H); ^{13}C NMR (deuteriochloroform) δ 17.7 (m), 124.2, 126.8, 131.7, 140.1 (t, J = 29.1 Hz), 150.5; MS *m/z* (%), 149 (22), 147 (70), 146 (45), 129 (100), 128 (45), 92 (40).

4-Chloro-2-trideuteriomethylpyridine-6d$_1$ (11-6-d$_1$). 4-Chloro-2-trideuteriomethyl-pyridine N-oxide-6d$_1$ (**10-6-d$_1$**) (0.80 g, 5.4 mmol) dissolved in dichloromethane (40 mL) was added to phosphorous trichloride (3.0 mL) at 0°C. The resulting mixture was heated at reflux for 1 h, cooled to room temperature, and poured onto ice (20 g). The resulting mixture was made basic with aqueous sodium hydroxide (10%) and extracted with dichloromethane (5 × 30 mL). The combined extract was dried (sodium sulfate) and concentrated to give **11-6-d$_1$** as a brown viscous liquid (0.50 g, 3.7 mmol, 69%); ^{1}H NMR (deuteriochloroform) δ 2.3 (residual methyl protons), 6.9 (s, 1H), 7.0 (s, 1H); ^{13}C NMR (deuteriochloroform) δ 23.9 (m), 121.1, 123.5, 144.1, 149.7 (t, J = 27.6 Hz), 159.9; MS *m/z* (%) 133 (30), 131 (100), 130 (62), 95 (33), 94 (13).

2-Trideuteriomethylpyridine-4,6-d$_2$ (1-4,6-d$_2$). 4-Chloro-2-trideuteriomethylpyridine-6-d$_1$) (**11-6-d$_1$**) (0.50 g, 3.8 mmol) dissolved in diethyl ether (20 mL) was placed in a Büchner

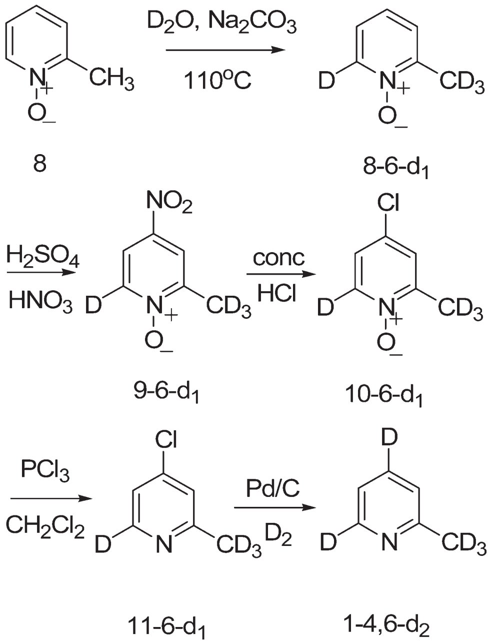
flask containing potassium carbonate (1.5 g), Pd-C (10%, 0.030g), and a magnetic stirring bar. The flask was sealed with a septum and equipped with a balloon at the side arm. A side-arm test tube containing sodium metal (1.2 g) was sealed with a septum and the side-arm was connected to the Büchner flask. The entire system was purged with nitrogen for 10 min. Deuterium oxide (3.0 mL) was then added through the septum to the sodium in the side-arm test tube. The deuterium gas generated filled the system and caused the balloon to expand. The reaction mixture in the Büchner flask was stirred in the deuterium atmosphere for 4 h. The Pd-C was removed by filtration and washed with dichloromethane. The combined ether and dichloromethane was concentrated by distillation through a Vigreux column to give a brown liquid residue (0.30 g) which was purified by Kugelrohr distillation (atm. pressure, oven temperature 130°C). **1-4,6-d$_2$** was collected as a clear liquid (0.13 g, 1.3 mmol, 34%); MS *m/z* (%), 98 (100), 70 (42), 69 (12). See Tables 1 and 2 for NMR data.

Scheme 4



3-Methylpyridine-2,4,6-d$_3$ (2-2,4,6-d$_3$)

3-Methyl-4-nitropyridine N-oxide-2,6-d$_2$ (5a-2,6-d$_2$). 3-Methylpyridine N-oxide-2,6-d$_2$ (4a-2,6-d$_2$) (1.9 g, 17.2 mol) was treated as for the nitration of 8-6-d$_1$ presented earlier to give 5a-2,6-d$_2$ as yellow crystals (1.3 g, 8.3 mmol, 48%, mp 154–157°C); ^{1}H NMR (deuteriochloroform), δ 2.60 (s, 3H), 8.00 (s, 1H); ^{13}C NMR (deuteriochloroform) δ 18.5, 122.5, 133.2, 137.9 (t, J = 28.4 Hz); 141.8 (t, J = 26.8 Hz), 143.4; MS *m/z* (%) 156 (100), 140 (7), 139 (13), 84 (30).

4-Chloro-3-methylpyridine N-oxide-2,6-d$_2$ (6a-2,6-d$_2$). 3-Methyl-4-nitropyridine N-oxide-2,6-d$_2$ (**5a-2,6-d$_2$**) (1.3 g, 8.3 mmol) was treated as for the conversion of **9-6-d$_1$** to **10-6-d$_1$** presented earlier to give **6a-2,6-d$_2$** as a yellow viscous liquid (0.5 g, 3.5 mmol, 42%); ^{1}H NMR (deuteriochloroform) δ 2.2 (s, 3H), 7.2 (s, 1H); ^{13}C NMR (deuteriochloroform) δ 16.8, 124.3, 132.3, 144.4, 148.2 (t, J = 28.4 Hz), 151.5 (t, J = 28.4 Hz); MS *m/z* (%) 145 (100), 129 (63), 94 (42), 54 (47).

4-Chloro-3-methylpyridine-2,6-d$_2$ (7-2,6-d$_2$). **6a-2,6-d$_2$** (0.5 g, 3.5 mmol) was treated as for the conversion of **10-6-d$_1$** to **11-6-d$_1$**, presented earlier to give **7a-2,6-d$_2$** as a brown viscous liquid (0.3 g, 2.3 mmol, 66%); ^{1}H NMR (deuteriochloroform) δ 2.3 (s, 3H), 6.9 (s, 1H), 7.2 (s, 1H); ^{13}C NMR (deuteriochloroform) δ 16.8, 124.2, 132.5, 148.2 (t, J = 28.4 Hz), 151.6 (t, J = 28.4 Hz); MS *m/z* (%) 131 (35), 129 (100), 94 (87), 66 (74).

3-Methylpyridine-2,4-6-d$_3$ (2-2,4,6-d$_3$). **7a-2,6-d$_2$** (0.25 g, 1.9 mmol) in methanol (10 mL) was treated as for the conversion of **11-6-d$_1$** to **1-4,6-d$_2$**. Kugelrohr distillation of the crude product (atmospheric pressure, oven temperature 130° C) gave **2-2,4,6-d$_3$** as a clear liquid (0.1 g, 1.0 mmol, 53%): MS *m/z* (%) 96 (100), 29 (37), 68 (46), 67 (31). See Tables 1 and 2 for NMR data.

A series of propargylic alcohol was synthesized by the addition of phenylacetylene to isatin and its N-substituted derivatives for the first time. This reaction involves activation of zinc reagent *via* coordination with carbonyl substrates that behave ''ligand like.'' The bioactivities on protective effect on the apoptosis of PC12 cells induced by H_2O_2 and cytotoxicity against lung cancer A549 and P388 cell line of these compounds were investigated, and several compounds showed potent activities.

J. Heterocyclic Chem., **46**, 217 (2009).

INTRODUCTION

The reactions, which lead to carbon–carbon bond formation by addition of nucleophiles to carbonyl group electrophiles, are of great importance in the continuing development of efficient processes for synthesis. Addition of acetylides to carbonyl substrates has attracted the attention of organic chemists and is still a very active field of organic reactions. The reaction gives access to preparation of propargylic alcohols, which are well known as versatile building blocks in the synthesis of complex natural products [1,2] and can be transformed into other functional groups, such as chalcones [3], and oxasilacyclopentene [4,5]. The addition of alkynes to ketones is also a very useful practical strategy to create tertiary alcohols with a new stereogenic center [6–8].

Some natural products with the structure of propargylic alcohol showed potent bioactivities, such as panaxyno1 (PNN), which performs potent activities on neuro-protection [9] and antitumor [10]. Isatin has been found in many natural products, with the function of modulating biochemical processes [11–13]. The advances in the use of isatin for organic synthesis and a survey of its biological activities are continuously reported [14–16]. In 1963, Ried reported the synthesis of 3-hydroxy-3-(phenyl-ethynyl)indol-2-one for the first time, with a low yield of 28% [17]. But in the following years, there was no further attention paid to the synthesis and its bioactivity.

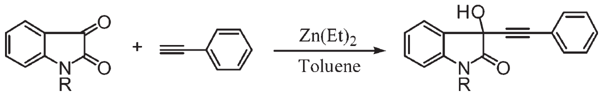
In this article, we describe the addition of phenyl-acetylene to isatin and (*N*-substituted) isatins promoted by Et_2Zn without employing specific ligands to form 3-hydroxy-3-(phenylethynyl)indol-2-one analogues (Scheme 1). Furthermore, the bioactivity on neuroprotection and antitumor of these isatin derivatives was evaluated for the first time.

RESULTS AND DISCUSSION

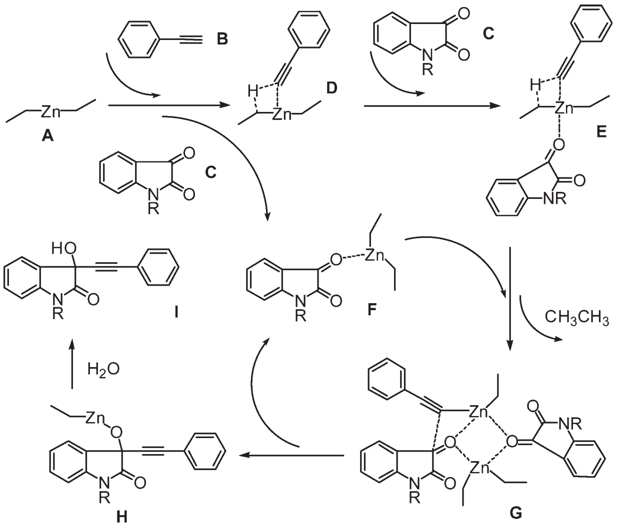
Chemistry. The *in situ* generated $ZnMe_2$-acetylides from Me_2Zn and acetylides have been used in a direct addition process with aldehydes and ketones without the employment of specific ligands [18]. In our preliminary studies, the reaction was carried out at room temperature. Unfortunately, the outcome was found very complex (by TLC), and the desired product was in a low yield after purification by flash chromatography. Higher yields were obtained at lower temperatures. Also, a variety of substrates were examined at 0°C, and the results are summarized in Table 1.

It can be found from Table 1 that the temperature deeply effects the reaction of the addition of phenyl-acetylene to (*N*-methyl) isatin. The reaction at relatively higher temperature (rt) gave poor yield, and the yields increased as the temperature is decreased, and the yield

Scheme 1



Scheme 2



was highest at 0°C. Significantly, lower temperatures such as −10°C did not improve the yield.

In consideration of the accepted mechanism for ligand-assisted addition of Et_2Zn to aldehydes, Pier *et al.* [18] investigated the possibility that a zinc-ketone complex acts as a bifunctional catalyst, bringing together an additional 1 equiv of ketone and zinc reagent in a bicyclic transition state (TS). On the basis of the proposed mechanism, we assumed that this reaction involves activation of the zinc reagent *via* coordination with isatins. The activated TS are shown in Scheme 2. In the TS (G), two molecules of (*N*-substituted) isatin behaved in a ''ligand like'' fashion to activate a phenylacetylene by two oxygen atoms coordinating with two Zn as bridged-atoms. The addition of activated phenylacetylene to a neighbor carbonyl formed H, and F was released into another cycle. The desired product (I) is provided through hydrolysis in the final step of the reaction.

Because the substrates have more than one coordinative and reactive point, the TS might be more complex, which lead to several side reactions, the addition of ethyl to isatins can be considered as an example. We could find the yields were very low in entries 7 and 11 because of the more reactive substrates. (*N*-Acyl) isatins (entries 12 and 13) were also introduced into this reaction, but the product was too complex to determine whether there was a desired product.

Biological activity. Compounds 2–9 were screened for their biological activities on protective effect on the apoptosis of PC12 cells induced by H_2O_2 and cytotoxicity against A549 and P388 cell line at various concentrations by the reported methods [19,20]. The neuroprotection and cytotoxicity in *vitro* screening results are shown in Table 2.

From the table, we find that compounds **4**, **5**, and **6** showed potent activity, which were more effective than VE ((±) α-Tocophreol), with the percentage of 46.62, 65.93, and 35.89% at 2 μg/mL respectively, as compound **5** was not cytotoxic against PC12 cell under the concentration of 2–200 μg/mL, whereas compounds **4** and **6** showed some cytotoxicity. Other compounds were either inactive or cytotoxic against PC12 cell. The results of in *vitro* cytotoxicity of compounds 2–9 against A549 and P388 cell line were given in Table 3.

From the results, it was found that almost all compounds could inhibit both cancer cells effectively at the concentration of 100 μ*M*. Compounds **6** and **8** showed

potent activity, with the inhibition percentage of 97.2, 95.3 and 97.9, 85.9, only compound **5** was inactive against P388.

EXPERIMENTAL

In an oven-dried flask connected to a nitrogen/vacuum line was placed phenylacetylene (1.6 mmol) followed by the slow addition of Et_2Zn 1*M* solution in toluene (1.5 mmol, 1.5 mL) (2.5 mmol Et_2Zn for isatin). The resulting solution was stirred at room temperature for 1 h and then cooled to 0°C with an ice-water bath. The (*N*-substituted) isatin (1 mmol) was added to the reaction mixture. The resulting solution was stirred at 0°C for 12 h, and then warmed to room temperature. The reaction was quenched with water (10 mL). The mixture was stirred for 10 min and then filtered over Celite. The mixture evaporated under reduced pressure and was purified by flash chromatography (silica gel, petroleum ether/ethyl acetate = 10: 1–4: 1).

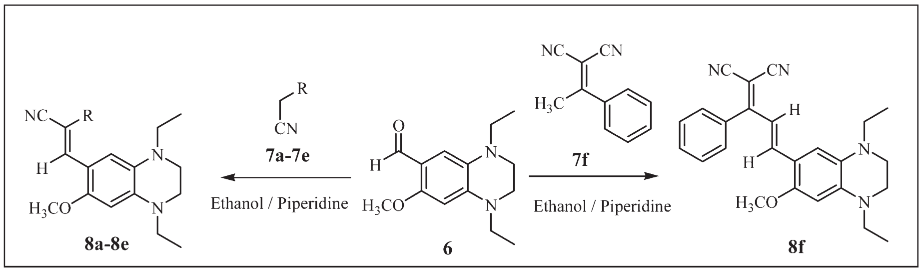
DOI 10.1002/jhet.64



The novel 1,4-diethyl-1,2,3,4-tetrahydro-7-methoxyquinoxalin-6-carboxaldehyde was synthesized, characterized, and condensed with suitably substituted active methylene compounds by classical Knoevenagel condensation reaction to obtain novel monostyryl dyes **8a-8e** and a bis-styryl dye **8f**. These novel styryl dyes have hue varying from orange to violet. The dyes were applied to polyester fibers. The spectral and thermal characteristics of the dyes and fastness properties of the dyed polyester fabric were investigated.

J. Heterocyclic Chem., **46**, 221 (2009).

INTRODUCTION

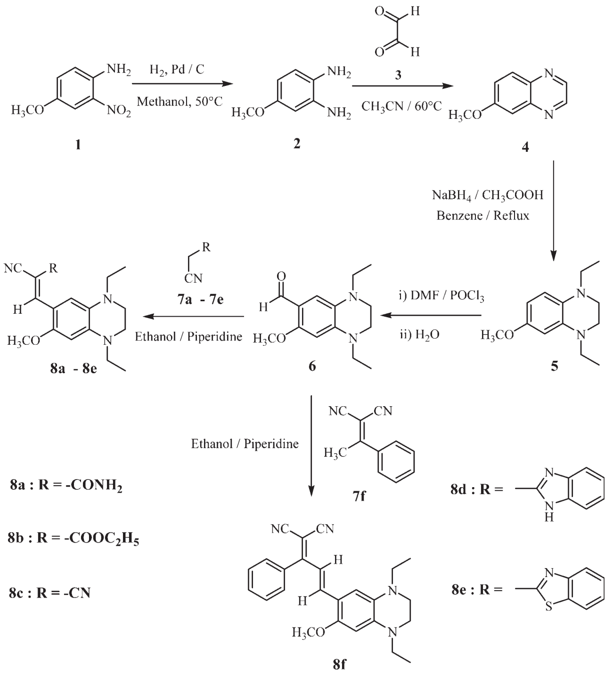
Heterocyclic compounds are of interest as functional materials in the emitters of electroluminescence devices and in molecular probes used for biochemical research, as well as in the traditional textile and polymer fields [1–3]. Heterocyclic chromophores are useful materials in the search for new biologically active compounds and diagnostic methods [4]. They are generally known to have planar and rigid π-conjugation system, and many of them are based on rigid ring systems such as coumarin, naphthalimide, perylene, pyrromethene, and rhodamine. Our research group has been interested in the chemistry of nitrogen containing heterocyclic molecules for many years. Various heterocyclic chromophores based on quinoxaline nucleus have been studied in our laboratory. Fluorescent compounds based on 2-methylthiazolo[4,5-*b*]quinoxaline [5,6], 2-methyl-(1,3)-dithiolium[4,5-*b*]quinoxaline [7] have been reported. In this contribution, we want to report synthesis and application of some new 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline derivatives with different electron donating abilities.

Quinoxalines are, in general, comparatively easy to prepare and numerous derivatives thereof have been designed and synthesized for potential use as biologically active molecules. The classical synthesis of quinoxalines involves condensation of aromatic 1,2-diamines with 1,2-dicarbonyl compounds. The reaction is facile and is the most widely used synthetic method for both quinoxaline itself and its derivatives. They can be easily reduced to 1,2,3,4-tetrahydroquinoxalines by reducing agents such as lithium aluminum hydride [8] and sodium borohydride [9] in excellent yields. Sequential reduction and alkylation of N-heterocycles such as indole to N-alkylated indoline and quinoline to N-alkylated-1,2,3,4-tetrahydroquinoline by sodium borohydride and trifluoroacetic acid is well known [10–13]. Quinoxalines can also be sequentially reduced and dialkylated using sodium borohydride and carboxylic acids. 6-Nitroquinoxaline has been subjected to reductive alkylation using sodium borohydride and glacial acetic acid to obtain 1,4-diethyl-1,2,3,4-tetrahydro-6-nitroquinoxaline [14]. These results led us to explore the utility of substituted tetrahydroquinoxalines to prepare novel styryl dyes.

In this study, 6-methoxyquinoxaline was subjected to alkylative reduction to afford 1,4-diethyl-1,2,3,4-tetrahydro-6-methoxyquinoxaline. This key intermediate was then used to prepare novel red to violet styryl dyes by convenient method of synthesis. We have varied the electron accepting groups to study the influence of the nature of substituents on spectral characteristics of the dyes. To increase the bathochromicity further and study the effect of incorporation of another styryl group, 1,4-diethyl-7-methoxy-1,2,3,4-tetrahydroquinoxalin-6-carboxaldehyde was condensed with

Scheme 1

Synthetic pathway of the dyes **8a-8f**



1,1-dicyano-2-methyl-2-phenylethene. The extended styryl dye thus obtained showed violet hue and displayed absorption maxima at 585 nm. The spectral properties of these novel heterocycles in various solvents differing considerably in polarity and their application as disperse dyes for polyester fabric are reported latter. The thermogravimetric analysis was also carried out to study thermal stability of the dyes.

RESULTS AND DISCUSSION

Synthesis of styryl dyes. The novel styryl dyes were prepared by classical Knoevenagel condensation of 1,4-diethyl-7-methoxy-1,2,3,4-tetrahydroquinoxalin-6-carboxaldehyde **6** and various active methylene compounds **7a-7f** as shown in Scheme 1. In the first stage, 4-methoxy-2-nitroaniline **1** was hydrogenated over palladium charcoal catalyst in methanol to obtain 4-methoxy-1,2-phenylenediamine **2**, which was subsequently condensed with glyoxal **3** in acetonitrile to afford 6-methoxyquinoxaline **4** in excellent yield. Reductive alkylation of 6-methoxyquinoxaline with sodium borohydride and glacial acetic acid in dry benzene yielded 1,4-diethyl-6-methoxy-1,2,3,4-tetrahydroquinoxaline **5**. The electron rich 1,2,3,4-tetrahydroquinoxaline derivative **5** was subjected to Vilsmeier–Haack reaction to yield 1,4-diethyl-7-methoxy-1,2,3,4-tetrahydroquinoxalin-6-carboxaldehyde **6**. To obtain styryl dyes **8a-8f**, a mixture of this aldehyde **6** and the corresponding active methylene compound was refluxed in absolute ethanol and catalytic amount of piperidine. The structures of the dyes were confirmed by IR, ^{1}H NMR, and elemental analysis. The results are summarized in experimental section.

Spectral characteristics of the dyes. Basic absorption characteristics of the compounds such as the absorption maxima (λ_{max}), extinction coefficient (ε) were measured in different solvents and are presented in Table 1. The electronic absorption spectra of the dyes **8a-8f** in methanol displayed absorption maxima in the visible region from 480 to 585 nm, which underwent bathochromic shift depending on the extent of conjugation as well as electron withdrawing nature of the acceptor group. The values of molar extinction coefficients were in the range from 12,477 L/mol cm to 31,899 L/mol cm. In the case of monostyryl dyes, introduction of heterocyclic ring as electron acceptor caused a strong bathochromic shift. Especially, dye containing benzothiazole ring showed remarkable shift towards longer wavelength with ε_{max} value of 25,514. This is due to high electronegativity of sulphur atom in the ring and increase in π-delocalization conjugation in the dye. The bis-styryl dye **8f** showed well pronounced maxima at 585 nm, longest among the reported dyes in this communication. This further increase in bathochromicity was attributed to incorporation of another styryl group which produced dye based on 1,1-dicyano-2,4-

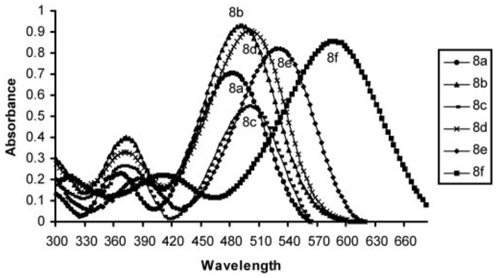

Figure 1. Absorption maxima of the dyes **8a-8f** in methanol.

diarylbutadiene system. The ε_{max} value of the dye was 24,306. The dye exhibited intense violet hue, which is usually difficult to obtain with small styryl structures.

To investigate the influence of solvents on the absorption maxima of the dyes, their absorption spectra were measured in different solvents such as dimethyl formamide, acetonitrile, methanol, and acetone. The solvents differ considerably in polarity and ability to form H-bonding. The electronic absorption spectra of the styryl dyes showed absorption maxima in the visible region at 475–583 nm in acetone, 484–586 nm in acetonitrile, and 478–598 nm in dimethyl formamide (DMF). From the presented values in Table 1, it is evident that practically no solvent effect was observed. Only in case of DMF slight bathochromicity was noticed. The dyes reported in this study exhibit no fluorescence in solvents; however, very weak fluorescence was observed when dissolved in DMF. Figure 1 displays absorption maxima of the dyes **8a-8f** in methanol.

Thermal properties of the dyes. The dyes were subjected to the thermogravimetric analysis to investigate their thermal stability. The change in weight of the dye was measured as a function of temperature. Figures 2 and 3 display thermograph of the representative dyes **8b** and **8f**, respectively. The thermogravimetric curve for the monostyryl dye **8b** (Fig. 2) shows a clear plateau followed by a sharp decomposition curve. The loss in weight of the dye is rapid when heated above 266°C. These results indicate that the dye is stable up to 266°C after which it decomposes rapidly and decomposition completes above 466°C. Almost similar pattern of thermogravimetric curve was obtained for the bis-styryl dye **8f** (Fig. 3) which is stable up to 274°C then starts decomposing slowly and completely decomposes above 502°C. It is clear from the presented data that both monostyryl and bis-styryl dyes have good thermal stability.

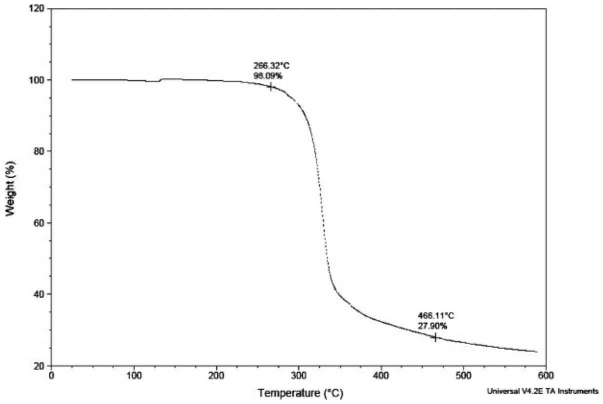

Figure 2. Thermogravimetric curve for the monostyryl dye **8b**.

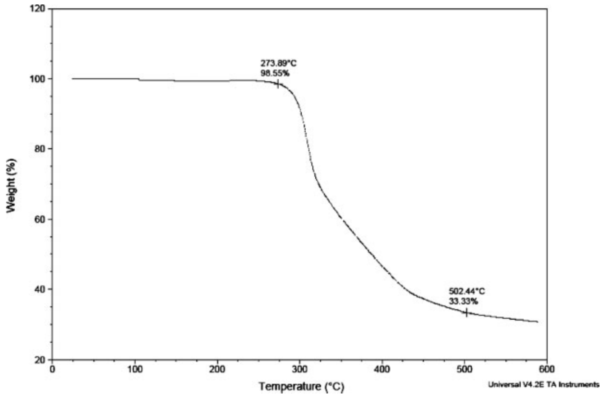

Figure 3. Thermogravimetric curve for the bis-styryl dye **8f**.

Fastness properties of the dyes. Fastness properties of the dyes under study were determined from the standpoint of their application as disperse dyes for polyester fabrics. The dyes **8a-8f** were applied to polyester fiber at 2% shade by high temperature-pressure technique and generally gave bright intense hue ranging from orange to violet. The fastness properties of the dyed fabric such as wash fastness, light fastness, and sublimation fastness were evaluated and assessed on 1 (poor) to 7 (outstanding) rating. The light fastness, wash fastness, and sublimation fastness properties were evaluated as per AATCC standard test methods [15–17]. Table 2 presents values of the fastness properties of dyed polyester fabric. For sublimation fastness determinations, the dyed

Table 2

Fastness properties of the dyes **8a–8f** on polyester fabric.

Dye No.	Light fastness (1–7)	Wash fastness (1–5)	Sublimation fastness (1–5)
8a	4	4	3
8b	3	5	2
8c	3	3	4
8d	5	4	4
8e	6	5	3
8f	4	5	3

1, Poor; 2, Fair; 3, Fairly good; 4, Good; 5, Very good; 6, Excellent; 7, Outstanding.

polyester fabrics were stitched between two pieces of undyed polyester fabrics (stain cloths) and treated at 200°C for 1 min. Any staining on the undyed piece, change in tone, or loss in depth was assessed on a 1 (poor) to 5 (very good) rating.

All the dyes built up well on polyester to give strong, bright colors. The light fastness of the dyes was of generally good order and varied from 3 to 6, dye **8e** exhibited excellent light fastness. The sublimation fastness of the dyes was in the range of 2–4, thus showed good sublimation fastness properties on polyester fabric. The dyes showed good wash fastness, as it is usual with disperse dyes.

EXPERIMENTAL

All melting points were uncorrected and in degree Celsius (°C). IR spectra were recorded on a Bomem Hartmann and Braun MB-Series FIIR spectrometer (KBr). ^{1}H NMR spectra were recorded on Varian 300 MHz mercury plus spectrometer, and chemical shifts are expressed in δ ppm using TMS as an internal standard. Microanalysis for C, H, and N were performed on Thermofignnin Elemental analyzer. Electronic spectra were recorded on Spectronic spectrophotometer from dye solutions in DMF, methanol, acetone, and acetonitrile. Thermogravimetric analysis was carried out on SDT Q600 v8.2 Build 100 model of TA instruments.

Synthesis of 6-methoxyquinoxaline (4). 4-Methoxy-2-nitroaniline (16.8 g, 0.1 mol) was dissolved in methanol (200 mL) and hydrogenated in Parr hydrogenator using 10% Pd/C catalyst at 60°C for 6 h (reaction monitored on TLC). After cooling, the reaction mass was filtered to separate catalyst and concentrated in roto-evaporator. Residue obtained was dissolved in dry acetonitrile (350 mL) and to this solution was added glyoxal (40%, 32.0 mL, 2.6 mol). Reaction mixture was then stirred at 60°C for 6 h and cooled. Solvent was removed in roto-evaporator and the dark brown sticky solid obtained was passed over silica gel column to remove base impurities (Eluent: 70% ethyl acetate in hexane). 6-Methoxyquinoxaline was obtained as white solid in excellent yield, 13.6 g (85%), mp 58–60°C (Lit mp 60°C [18]).

Synthesis of 1,4-diethyl-6-methoxy-1,2,3,4-tetrahydroquinoxaline (5). 6-Methoxyquinoxaline (5.5 g, 0.034 mol) was dissolved in dry benzene (350 mL) and cooled to 5°C. To this cold solution was added sodium borohydride (13.2 g, 0.35 mol) over a period of 15 min. Pale yellow slurry thus obtained was stirred for 10 min. Glacial acetic acid (57.3 mL, 60 g, 1.0 mol) was added to it drop wise over a period of 1 h maintaining the temperature 5–10°C. The brownish slurry that formed was stirred for another 1 h at 10°C and allowed to attain room temperature. It was then heated to gentle reflux for 5 h (reaction monitored on TLC). On cooling, thick red resinous mass was obtained to which water (250 mL) was added. The benzene layer formed was separated and the aqueous layer was extracted with ethyl acetate (3 × 100 mL). Combined extracts and benzene layer were washed repeatedly with dilute sodium carbonate solution and water, dried over anhydrous sodium sulfate, filtered and vacuum evaporated. The dark brown oil obtained was purified by vacuum distillation to afford golden yellow oil, 6.35 g (84%), bp 142–144°C at 2 mm.

Synthesis of 1,4-diethyl-7-methoxy-1,2,3,4-tetrahydro-6-quinoxalinecarboxaldehyde (6). Phosphorous oxychloride (8.0 mL, 0.09 mol) was added to dimethyl formamide (10.1 mL, 0.13 mol) at 5°C under stirring. After 15 min, 1,4-diethyl-6-methoxy-1,2,3,4-tetrahydroquinoxaline (11.0 g, 0.05 mol) was added to the cooled reagent under stirring. The mixture was then heated at 70–80°C for 4 h and poured on ice water. The clear solution was neutralized by adding cold sodium hydroxide solution (15%) maintaining the temperature at 10–15°C. The sticky mass obtained was extracted in ethyl acetate (4 × 100 mL). Ethyl acetate extracts were combined, dried over anhydrous sodium sulfate, and vacuum evaporated. Brown sticky solid showing dark yellow spot on TLC was purified by column chromatography using neutral activated aluminum oxide (Eluent: 40% ethyl acetate in hexane), 8.43 g (68%), bp 146–148°C, IR: CO 1712 cm^{-1}, ^{1}H NMR: δ 1.16 (t, 6.9Hz, 3H, CH_3), δ 1.23 (t, 6.9Hz, 3H, CH_3), δ 3.13–3.18 (m, 2H), δ 3.31 (q, 6.9Hz, 2H, CH_2), δ 3.41 (q, 6.9Hz, 2H, CH_2), δ 3.49–3.54 (m, 2H), δ 3.93 (s, 3H, OCH_3), δ 6.0 (s, 1H, phenyl proton), δ 7.0 (s, 1H, phenyl proton), δ 10.20 (s, 1H, aldehydic proton), *Anal.* Calcd for $C_{14}H_{20}N_2O_2$: C, 67.71; H, 8.12; N, 11.28. Found: C, 67.81; H, 8.14; N, 11.34.

Synthesis of styryl dyes (8a–8f).

Synthesis of 2-cyano-3-(1,4-diethyl-7-methoxy-1,2,3,4-tetrahydroquinoxalin-6-yl)-2-propenoic acid ethylester (8b). 1,4-Diethyl-7-methoxy-1,2,3,4-tetrahydro-6-quinoxalinecarboxaldehyde (2.48 g, 0.01 mol) and ethyl cyanoacetate 1.13 g (0.01 mol) were dissolved in dry ethanol. Piperidine (0.1 mL) was added to it and reaction mixture was refluxed for 2 h. Ethanol was removed by distillation and reddish crystals were washed with water and dried. Dye **(8b)** thus obtained was further purified by column chromatography using neutral activated aluminum oxide (Eluent: 30% ethyl acetate in hexane), 2.7 g, 78%, mp 128–132°C, IR: CO 1755, CN 2210 cm^{-1}, ^{1}H NMR: δ 1.21 (t, 6.9Hz, 3H, CH_3), δ 1.26 (t, 6.9Hz, 3H, CH_3), δ 1.36 (t, 6.9Hz, 3H, CH_3), δ 3.16–3.22 (m, 2H), δ 3.34 (q, 6.9Hz, 2H, CH_2), δ 3.44 (q, 6.9Hz, 2H, CH_2), δ 3.53–3.59 (m, 2H), δ 3.92 (s, 3H, OCH_3), δ 4.44 (q, 6.9Hz, 2H, CH_2), δ 6.0 (s, 1H, phenyl proton), δ 7.7 (s, 1H, phenyl proton), δ 8.6 (s, 1H, olefinic proton), *Anal.* Calcd for $C_{19}H_{25}N_3O_3$: C, 66.45; H, 7.34; N, 12.24. Found: C, 66.56; H, 7.35; N, 12.31.

Synthesis of 2-cyano-3-(1,4-diethyl-7-methoxy-1,2,3,4-tetrahydroquinoxalin-6-yl)-2-propenamide (8a). 2.54 g (81%), mp 172–175°C, IR: CO 1685, CN 2218 cm^{-1}, ^{1}H NMR: δ 1.20 (t, 7.1Hz, 3H, CH_3), δ 1.25 (t, 7.1Hz, 3H, CH_3), δ 3.18–3.23 (m, 2H), δ 3.35 (q, 6.9Hz, 2H, CH_2), δ 3.44 (q, 6.9Hz, 2H, CH_2), δ 3.54–3.59 (m, 2H), δ 3.90 (s, 3H, OCH_3), δ 5.3 (s, 2H, $CONH_2$ proton), δ 6.0 (s, 1H, phenyl proton), δ 7.6 (s, 1H, phenyl proton), δ 8.5 (s, 1H, olefinic proton), *Anal.* Calcd for $C_{17}H_{22}N_4O_2$: C, 64.95; H, 7.05; N, 17.82. The reaction of vinyl ethers with *o*-hydroxybenzyl alcohols under different reaction conditions was investigated. The aim of this attempt was to find out whether the protection reactions or the hetero Diels–Alder reaction of quinone methide *in situ* generated from *o*-hydroxybenzyl alcohol is more likely to occur. *o*-hydroxybenzyl alcohols can give hetero Diels–Alder reactions with dihydro-2*H*-pyran at high temperatures but only when used with acid catalysts. At room temperature, even in the presence of acid catalyst, reactions yielded regular protection products. However, butyl vinyl ether and 4-methoxy-3-butenone could not give intermolecular cycloaddition reactions under the acidic conditions, because both decomposed to the new products with acids. Hetero-Diels–Alder products obtained only under thermal conditions but in low yields.

J. Heterocyclic Chem., **46**, 226 (2009).

INTRODUCTION

Protective groups play important roles in modern multistep synthetic organic chemistry and numerous publications on the selection of more suitable protecting groups for hydroxyl functions have appeared in recent years.

In our previous study, we reported selective *o*-benzylation of primary hydroxyl groups of di-and tri-hydroxyl compounds by using bis(acetylacetonato) copper as a catalyst [1].

Another well-known method for the protection of hydroxy groups is forming tetrahydropyranyl ether by reaction with 3,4-dihydro-2*H*-pyran (DHP). By using this method, diols, in which two hydroxyl groups are far away from each other can be protected in good yields. Hence, the main products are monotetrahydropyranyl ethers [2]. In these reactions, the reason for the low yield of the diprotection products is not well understood.

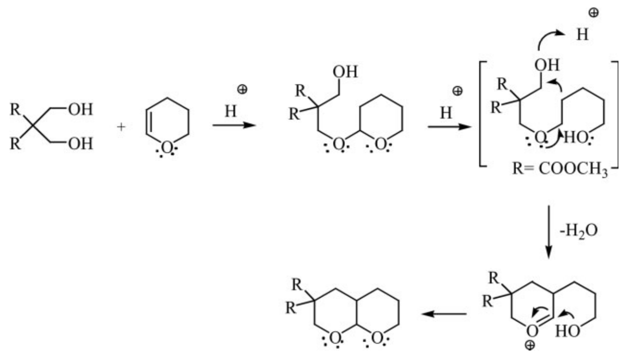
However, we have recently demonstrated that bicyclic acetals can readily be obtained with high diastereoselectivity from the reaction of 1,2- and 1,3-diols and DHP [3] (Scheme 1). In reactions carried out at 25°C using pyridine-*p*-toluene sulfonic acid (PPTS) as the catalyst, the first step is acetal formation by the addition of one of the hydroxyl groups of the diol to DHP in the usual way, the second step is ring opening of the DHP moiety and the generation of an enol ether, and the third step is water elimination and recyclization to the oxonium ion.

In particular, fused pyranobenzoxepine (**I**) was obtained from the *o*-hydroxymethylbenzyl alcohol (Fig. 1).

Formation of bicyclic acetals under catalytic conditions from aliphatic dihydroxy compounds leads us to investigate the reactions of aromatic dihydroxy compounds with DHP. We have chosen *o*-hydroxybenzyl alcohol as the diol because it has either two types of OH groups for protection reactions or it is the precursor of the quinone methide intermediate [4–6].

The aim of this study is to compare whether the protection reactions are more likely, or the hetero

Scheme 1



Diels–Alder reaction of quinone methide *in situ* generated from *o*-hydroxybenzyl alcohol is more likely to occur.

RESULTS AND DISCUSSION

Quinone methides are generally produced under thermal, photolytic, or catalytic conditions. In past years, *o*-hydroxybenzaldehydes have been preferred for generation of quinone methides under catalytic conditions [7–9]. Treatment of salicylaldehydes with 3,4-DHP in the presence of metal triflates resulted in pyrano[2,3-*b*]benzopyrans. For the reactions carried out under thermal conditions different precursors were used; while Ohwada and coworkers [10] used 4*H*-1,2-benzoxazines as precursor, Baldwin and coworkers [11] proposed a new method for *o*-quinone methide generation from *o*-methyleneacetoxy-phenols. They investigated the reactions of *o*-acetyloxymethyl phenol (2-hydroxybenzyl acetate) with dienophiles (including DHP) under thermal conditions (Scheme 2). Bray reported the generation and hetero-Diels–Alder reaction of an *o*-quinone methide using ^{i}PrMgCl under mild, anionic conditions [11]. Reactions of another precursor *o*-hydroxybenzyl alcohol and open-chain enol ethers under thermal conditions was investigated by Pochini and coworkers [12].

Under photolytic conditions *o*-hydroxybenzyl alcohol and DHP also produced benzopyranopyran derivatives [13] (Scheme 2).

However, there are no reports on the reaction of *o*-hydroxybenzyl alcohol with DHP under both catalytic and thermal conditions. Therefore, in this study, we have investigated the reaction products of DHP and *o*-hydroxybenzyl alcohol, both with acid catalysts and under thermal conditions.

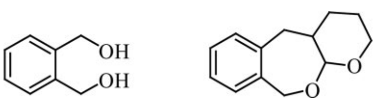


Figure 1. Reaction product of DHP and *o*-hydroxymethylbenzyl alcohol.

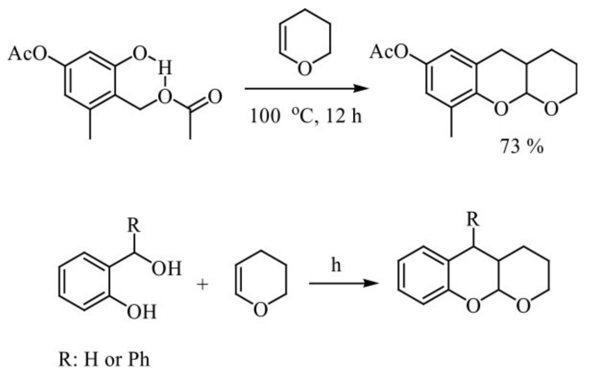
Scheme 2



On the basis of the concept mentioned earlier, we reacted *o*-hydroxybenzyl alcohol with DHP in the presence of PPTS at the reflux temperature of toluene. The reaction produced *cis*-fused pyrano[2,3-*b*]benzopyran (**III**) and self-reaction products of DHP (**IX**) (Scheme 3). However, the yield was lower than that of Baldwin's method. The regular mono protection product (**V**) was also obtained in low yield. Diprotection products were not detected.

The structure and the stereochemistry of compound (**III**) was elucidated by spectroscopic and chromatographic data and the results were compared with former results [7–9]. Spectroscopic data showed that the reaction was highly diastereoselective, and the coupling constant, $J = 2.6$ Hz for the bridgehead protons proved the formation of the *cis*-fused bicyclic structure.

However, when the reaction was performed in toluene without catalyst, a desired pyranobenzopyran formed in very low yield, in contrast to Baldwin's result. Mono protection product **V** was observed as main product and

[a] Not isolated.

[b] Reaction was performed with Dean–Stark apparatus.

[c] Yields are from GC analysis.

the rest of the reaction mixture was mainly unreacted *o*-hydroxybenzyl alcohol.

Furthermore, the reaction of 3-bromo-2-hydroxymethyl phenol with DHP under similar reaction conditions resulted in the corresponding pyranobenzopyran (**IV**).

To investigate the effect of reaction conditions on product types and their distribution, reactions were repeated at different temperatures, using different solvents and catalysts. Results of these studies are tabulated in Table 1.

The catalysts are PPTS and the strong acidic ion exchange resin Amberlyst-15. The reason for choosing Amberlyst-15 was to investigate the influence of acid structure on diastereoselectivity, but no change on stereoselectivity was observed. Increasing the reaction time did not effect the reaction yield or type of products. At room temperature, the expected protection products were obtained. As the reaction temperature was increased to 62°C self-reaction products of DHP began to form.

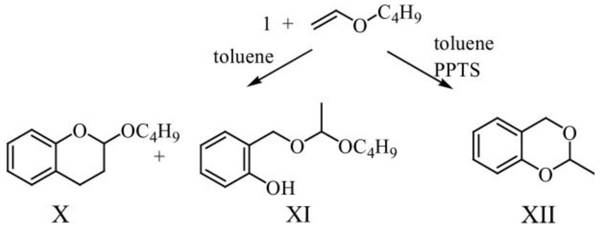
After determination of the appropriate reaction conditions for the formation of quinone methides, we worked on similar reactions of open-chain enol ethers. In this attempt, the aim was to compare the type of products with the products produced before. Butyl vinyl ether was chosen as open-chain enol ether. The reaction of butyl vinyl ether with *o*-hydroxybenzyl alcohol in toluene without catalyst resulted, mainly in two products; a corresponding 2-butoxychroman **X** (10%) and a usual addition compound **XI** (50%) (Scheme 4). The ratio of two products was determined by GC analysis of the crude product. 2-Butoxychroman has been recently produced by Ohwada and coworkers [10] under thermal conditions from 4*H*-1,2-benzoxazines, and also by Bray [11] from *o*-hydroxybenzyl acetate.

When this reaction was carried out with catalyst, none of the corresponding acetalic structures were found in the reaction mixture, instead the sole product (90%) was compound **XII** which resulted from the reaction of *o*-hydroxybenzyl alcohol and acetaldehyde produced from the decomposition of butyl vinyl ether in acidic medium. Compound **XII** was synthesized [14] before, from *o*-hydroxybenzyl alcohol and acetaldehyde dimethylacetal with 42% yield. There are several studies on the decomposition of vinyl ethers yielding acetaldehyde [15,16]. As seen in Scheme 4, similar to DHP, vinyl butyl ether afforded the desired acetalic structure with yield lower than that of the regular protection product.

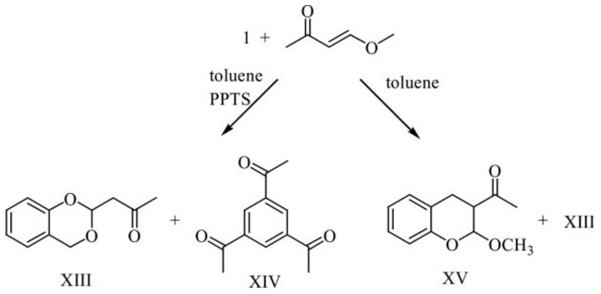
The reaction of 4-methoxy-3-butenone with *o*-hydroxybenzyl alcohol was also performed with and without catalyst. In the presence of catalyst mainly two products were obtained; compounds **XIII** (80%) and **XIV** (10%). Compound **XIII** resulted from *o*-hydroxybenzyl alcohol and 3-oxo-butanal formed *in situ* from the transformation of 4-methoxy-3-butenone [17] (Scheme 5).

Formation of compound **XIV** can be explained with the cyclization reaction of 4-methoxy-3-butenone in acidic medium as described previously [18]. When the reaction was performed without catalyst, the main product was again compound **XIII** (50%). However,

Scheme 4



Scheme 5



compound **XV** was also detected from GC-MS and ^{1}H NMR analysis with a yield of 20%. This compound is formed through the [4 + 2] cycloaddition reaction of quinone methide to 4-methoxy-3-butenone. Desktop molecular modeling calculations indicated that substituents existing in diaxial positions are more favorable structures for compound **XV**. NMR studies also supports the MM$_2$ calculations, because the coupling constant for acetalic and methine protons is $J = 2.8$.

These results indicated that *o*-hydroxybenzyl alcohols can give hetero Diels–Alder reactions with DHP at high temperatures but only when used with acid catalysts. At room temperature, even in the presence of acid catalyst, reactions yielded regular protection products. However, butyl vinyl ether and 4-methoxy-3-butenone could not give intermolecular cycloaddition reactions under the acidic conditions, because both decomposed to the new products with acids. Hetero-Diels–Alder products were obtained only under thermal conditions but in low yields.

EXPERIMENTAL

All general chemicals and starting materials purchased from commercial sources, except PPTS. IR spectra were recorded on a Jasco FTIR 5300 spectrometer using neat compounds as films between NaCl cells. ^{1}H and ^{13}C NMR spectra were run with Bruker 250 MHz spectrometer and reported as ppm relative to TMS. GC-MS spectra were obtained on Thermo Finnigan Trace DSQ instrument using ZB-5MS capillary column. The products were purified by column chromatography on neutral silicagel 60 (0.040–0.063 mm) from Merck, Darmstadt. Purity of compounds was proved by GC analysis (column: HP-1, 30m, 5′ 100°C, 20°C/min to 290°C, 5′ 290°C).

Preparation of PPTS. 0.15 mol of pyridine was added to 0.003 mol of *p*-toluenesulfonic acid and the mixture was stirred at room temperature for 20 min. After evaporation of pyridine, the product was crystallized from acetone.

General procedure A (with catalyst). Vinyl ether compound (2 mmol) was added dropwise to a stirred solution of I or III (1 mmol) and PPTS (0.1 mmol) in toluene (30 mL). The mixture was stirred at reflux temperature for 24 h in a Dean Stark apparatus. Then the solution was washed with half-saturated brine to remove the catalyst. After the evaporation of solvent, the crude products were purified by column chromatography using ethyl acetate/hexane as the eluent.

General procedure B (without catalyst). Vinyl ether compound (2 mmol) was added dropwise to the solution of I (1 mmol) in toluene (30 mL) and the solution was stirred for 24 h under reflux conditions. Then the solvent was evaporated and the crude product was purified by column chromatography using ethyl acetate/hexane as the eluent.

A variety of substituted spiro(benzoisothiazole-pyrazoles) have been prepared by the condensation of dilithiated *C*(α),*N*-carboalkoxyhydrazones with lithiated methyl 2-(aminosulfonyl)benzoate followed by the cyclization of intermediates with acetic anhydride, which also resulted in spiro *N*-acetylated products when carbomethoxyhydrazones or carboethoxyhydrazones were used, and spiro *NH* products when carbo-*tert*-butoxyhydrazones were used.

J. Heterocyclic Chem., **46**, 231 (2009).

INTRODUCTION

Pyrazoles [1] and benzoisothiazole dioxides [2] have been prepared and studied because of their biological potential, serving as intermediate compounds in other syntheses, spectral studies, theoretical studies, and other uses. Various spiro pyrazoles have been investigated [3], and spiro benzoisothiazoles dioxides (BIDs) have received limited study [4]. There are no reports concerning the preparation of spiro(benzoisothiazole-pyrazole) dioxides.

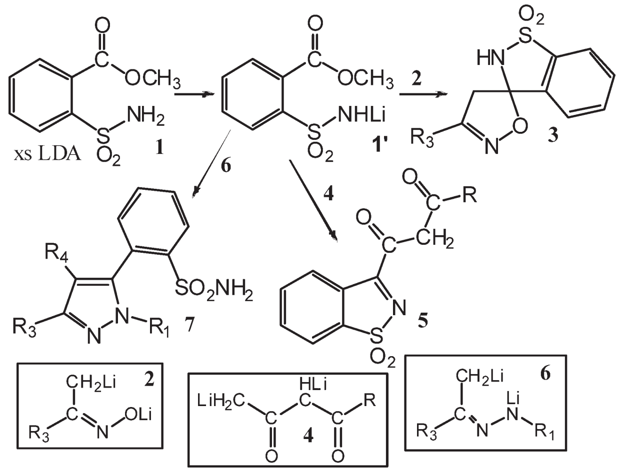
In this laboratory, BIDs and pyrazoles have been synthesized by the condensation-cyclization of polylithiated intermediates, prepared in excess lithium diisopropylamide (LDA), with methyl 2-(aminosulfonyl)benzoate **1**, Scheme 1. Specifically, anionic electrophile **1′** has been condensed-cyclized with dilithiated oximes **2** to afford spiro(BID-isoxazoles) **3** [5]; with dilithiated β-ketoesters **4** (R = OMe or OEt) to afford BID-β-ketoesters **5** (R = OMe or OEt); with dilithiated β-diketones **4** (R = Ar) to afford BID-β-diketones **5** (R = Ar); or with trilithiated β-ketoamides **4** (R = $NLiC_6H_5$) resulting in BID β-ketoamides **5** (R = NHC_6H_5) [6].

N-Phenyl-, or *NH*- pyrazolebenzenesulfonamides **7** resulted [7,8] when dilithiated phenylhydrazones (R_1 = Ph) or dilithiated carbo-*tert*-butoxyhydrazones (R_1 = *t*-Bu) were condensed-cyclized (also hydrolysis-decarboxylation for **7**, *NH*-) with **1′** (from **1**).

RESULTS AND DISCUSSION

During the current investigation dilithiated carboalkoxyhydrazones **6a–l** (**6f**, trilithiated) or **9a–c** were

Scheme 1. Condensation-cyclization syntheses with methyl 2-(aminosulfonyl)benzoate.



condensed-cyclized with lithiated methyl 2-(aminosulfonyl)benzoate **1′** (from **1**) to afford spiro(BID-pyrazoles) **8a–l** or **10a–c** and not pyrazole-benzenesulfon-amides **7** Scheme 2.

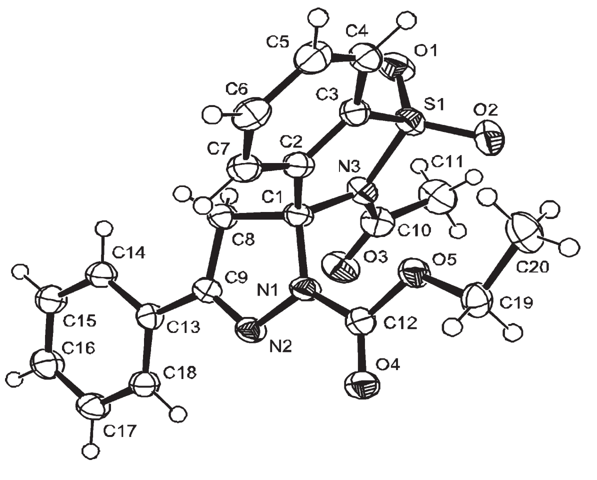

Figure 1. ORTEP diagram (50% ellipsoids for non-hydrogen atoms), $C_{20}H_{19}N_3O_5S$ **8a** [9].

Specifically, **6a–l** or **9a–c** underwent an anion-anion condensation with **1′** to form intermediate compounds that were isolated but not characterized followed by cyclization and *N*-acetylation with acetic anhydride to afford *N*-acetyl spiro(BID-pyrazoles) **8a–f, 10a,** and **10b**. Trilithiated 2′-hydroxyacetophenone carbomethoxyhydrazone **6f** (R_3 = 2-LiOC_6H_4) was condensed with **1′**, and intermediates were cyclized to afford *O*-acetylation and *N*-acetylation spiro product **8f**. The *N*-acetylation process did not occur when dilithiated carbo-*tert*-butoxyhydrazone intermediates were used instead, and only *NH* spiro(BID-pyrazoles) **8g–l** and **10c** were isolated.

N-Acetylated spiro(BID-pyrazoles) **8a–f** were not originally anticipated, and an X-ray single crystal analysis was determined for spiro product **8a** resulting from the condensation-cyclization of **6a** (R_1 = Et, R_3 = C_6H_5) with **1′**.

The molecular structure of **8a** is shown in Figure 1 (atoms assigned numbers), and selected bond distances and angles are listed in Table 1. The bond lengths agree with the assignment of the double bond shown between C9 and N2. Because the unit cell of each compound is centrosymmetric, both enantiomorphic structures about the C1 chiral center are present.

The least squares best planes representing the fused rings are nearly coplanar with angles of 1.52° between

them. The two five-member rings in each molecule are nearly perpendicular with an angle of 89.54°. The rings connected by C9 and C13 are nearly coplanar with angles of 9.19°, which allows for extended pi bonding between these rings and possibly with the atoms in the C12 carboxylate group.

In addition to single crystal X-ray analysis leading to results illustrated in the ORTEP diagram, Figure 1, other representative characterization parameters supported the spiro structure, such as DEPT clearly identifying CH_2 or CH in appropriate products. The ^{1}H-NMR CH_2 absorption for **8a–l** were noted as a pair of doublets δ 3.54–3.66 and δ 3.97–4.04 ppm, $J = 18.0$–18.7 Hz; *N*-acetyl singlet proton absorptions were displayed at δ 2.52–2.64, usually 2.63 or 2.64 ppm in products **8a–f**, **10a** and **10b** and absent in products **8g–l** and **10c**. The ^{13}C NMR for all products displayed the spiro carbon absorption from δ 80.4–84.0 ppm. Combustion analysis indicated incorporation of water (methanol in **8k**) [10] in the analytical crystalline products **8a, 8c, 8d, 8j,** and **8l**. LCMS for most of the products contained the expected $(M + H)^+$; for **8i** and **8j** it was not detected. Base ions for each of these products may be explained by loss of a carbo-*tert*-butoxy fragment.

Mechanistic details, Scheme 3, to explain the formation of products may involve dilithiated carboalkoxyhydrazone and monolithiated ester-sulfonamide **1′**, leading to intermediates **11** and/or **12** (*e.g.,* from acetophenones), with each having potential for difficulty in cyclodehydration. Attempts to isolate saccharin from treatment of **1** (to **1′**) with LDA under the same reaction conditions were unsuccessful.

Products **8g–l** and **10c** were only formed from cyclization and not accompanied by *N*-acetylation, which may be attributed to the larger size of the *tert*-butoxy group hindering further reaction at the BIDs nitrogen with acetic anhydride, and its success was dependant on the strong cyclization ability of acetic anhydride/pyridine.

EXPERIMENTAL

Melting points were obtained with a Mel-Temp II melting point apparatus in open capillary tubes and are uncorrected. Entry compounds, *C*(α),*N*-carboalkoxy-hydrazones were prepared from *C*(α),*O*-ketones in a 1:1 condensation with methyl, ethyl, or *tert*-butyl carbazate [11]. The tetrahydrofuran (THF) was distilled from sodium (benzophenone ketyl as an indicator of dryness) prior to use, and organic chemicals were obtained from Aldrich Chemical Co. Infrared spectra were obtained with a Nicolet Impact 410 FT-IR. Proton and ^{13}C NMR spectra were obtained with a Varian Associates Mercury Oxford 300 MHz nuclear magnetic resonance spectrometer, and chemical shifts were recorded in δ ppm downfield from an internal tetramethylsilane standard. Combustion analyses were performed by Quantitative Technologies, Inc., P.O. Box 470, Whitehouse, NJ 08888. LCMS analyses were measured on a Thermo-Finnigan LCQ Advantage system with the Surveyor autosampler, Surveyor pump, and LCQ Advantage Max mass spectral detector using electrospray ionization; 2 mg samples were prepared in 2 mL/L of acetonitrile; 10 μL injections were pumped at 1.00 mL/min isocratically with 70% acetonitrile and 30% water, each buffered with 0.1% formic acid by volume; 15 min runs were reproduced in both the positive and negative (when needed) MS modes. Data were collected at full scan from 100 to 650 amu.

2*H*-spiro[Benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylates (8a–l) and (10a–c). LDA (0.0788 mol or 0.0945 mol for **8f**) was prepared by the addition of 49 mL (or 59 mL for **8f**) of 1.6*M* *n*-butyllithium in hexanes to a three-neck round-bottomed flask (*e.g.*, 500 mL), equipped with a nitrogen inlet tube, a side-arm addition funnel (*e.g.*, 125 mL), and a magnetic stir bar. The flask was cooled in an ice water bath and 8.02 g or 9.54 g for **8f** (0.0788 mol or 0.0945 mol for **8f**) of diisopropylamine, dissolved in 25–30 mL of dry THF, was added from the addition funnel at a fast dropwise rate during a 5 min period (0°C, nitrogen). The solution was stirred for an additional 15–20 min, and then 0.0150 mol of the carboalkoxyhydrazone dissolved in 50 mL of THF was added at a fast dropwise rate during 5–10 min. After 1 hr (2 h for **8f**), 3.39 g (0.0158 mol) of methyl 2-(aminosulfonyl)benzoate **1**, dissolved in 25-35 mL of THF was added, during 5 min, to the polylithiated intermediate, and the solution was stirred and condensed for 1 h. Finally, 100 mL of 3*M* hydrochloric acid was added quickly followed by 100 mL of solvent grade ether, then stirring the two-phase mixture for 5 min, followed by careful neutralization with solid sodium bicarbonate, and the two liquid phases or solid materials separated. If a solid appeared at this point, the biphasic mixture could be filtered. The aqueous layer was extracted with ether or THF (2 × 75 mL), and the organic fractions were combined, filtered, evaporated, and the solid organic materials were air-dried.

The twofold cyclization and acetylation required 6 mL of acetic anhydride and 4 mL of pyridine for each 1 g of dry intermediate(s) compound(s) [12]. Each gram of solid intermediate(s) was dissolved in pyridine followed by the dropwise addition of acetic anhydride. The solution was stirred at room temperature for 1 h. The addition of *ca.* 80 g of ice usually resulted in a precipitate, which was collected by filtration, washed with water and recrystallized from methanol or ethanol.

Ethyl2-acetyl-5′-phenyl-2*H*-spiro[benzo-[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8a). Compound **8a** was obtained in 69% yield, mp 179–182°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated acetophenone carboethoxyhydrazone and **1′**. IR: 1709 and 1727 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 1.67 (m, 3H), 2.64 (s, 3H, CH_3), 3.68–4.06 (m, 4H) [13], and 7.41–7.68, 7.71–7.91 (m, 9H, ArH). ^{13}C NMR (deuteriochloroform): δ 14.8, 23.7, 49.5 (DEPT CH_2), 53.6, 81.2, 121.2, 122.9, 127.6, 128.9, 129.2, 131.3, 132.5, 133.5, 135.3, 137.1, 147.7, 151.0 and 166.9. LCMS, exact mass, 413.10: $(M + H)^+$, 414.04. *Anal.* Calcd for $C_{20}H_{19}N_3O_5S \cdot 1/4\ H_2O$: C, 57.47; H, 4.70; N, 10.05. Found: C, 57.47; H, 4.63; N, 10.08.

Single crystal X-ray structure determination. Yellow crystals of $C_{20}H_{19}N_3O_5S$ **8a** were recrystallized from ethanol in order to give satisfactory crystals for X-ray determination. Crystal data for X-ray studies were collected at −120°C on a Mercury CCD area detector coupled with a Rigaku AFC8 diffractometer with graphite monochromated Mo-K radiation. Data were collected in 0.50° oscillations in ω with 20 s exposures. A sweep of data was done using ω oscillations from −40.0° to 90.0° at $\chi = 45.0°$ and $\varphi = 0.0°$; a second sweep was performed using ω oscillations from −30.0° to 80.0° at $\chi = 45.0°$ and $\varphi = 90.0°$. The crystal-to-detector distances were 27.7147 mm. Details of the data collection is reported in Table 2. Data were collected, processed, and corrected for Lorentz polarization and for absorption using CrystalClear (Rigaku) [15].

Max and min transmission	0.9408, 0.9317
Data, restraints, parameters	3544, 0, 264
Final *R* indices $I > 2\sigma(I)$	$R_1 = 0.0515$ $wR_2 = 0.1243$
R indices all data	$R_1 = 0.0585$ $wR_2 = 0.1305$
Goodness of fit on F^2	1.098
Largest diff peak and hole (e Å^{-3})	0.245, −0.373

The non-hydrogen atoms were refined anisotropically. Ideal hydrogen atom coordinates were calculated and the hydrogen atoms were allowed to ride on their respective carbon atoms. The temperature factors of all hydrogen atoms were varied isotropically. Structure solution, refinement, and the calculation of derived results were performed using the *SHELX-97* [16] package of computer programs. Neutral atom scattering factors were those of Cromer and Waber [16], and the real and imaginary anomalous dispersion corrections were those of Cromer [17].

Methyl 2-acetyl-5′-(4-chlorophenyl)-2*H*-spiro-[benzo[*d*] isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8b). Compound **8b** was obtained in 74% yield, mp 181°C dec (benzene/hexanes), from the two-step procedure for the condensation-cyclization of dilithiated 4′-chloroacetophenone carbomethoxyhydrazone and **1′**. IR: 1705 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 2.64 (s, 3H, CH_3), 3.67(d, 1H, *J* = 18.7 Hz), 3.74 (s, 3H, CH_3O), and 3.99 (d, 1H) and 7.39–7.50, 7.68–7.82 (m, 7H, ArH) and 7.90 (d, 1H, *J* = 7.5 Hz). ^{13}C NMR (deuteriochloroform): δ 24.0, 49.0 (DEPT CH_2), 53.9, 81.6, 121.5, 123.1, 128.2, 129.3, 131.6, 132.7, 135.6, 136.9, 151.1. LCMS, exact mass, 433.05: $(M + H)^+$, 433.99; $(M - H)^-$, 432.10. *Anal.* Calcd for $C_{19}H_{16}\ Cl\ N_3O_5S$: C, 52.60; H, 3.72; N, 9.69. Found: C, 52.75; H, 3.64; N, 9.70.

Methyl 2-acetyl-5′-(2-furanyl)-2*H*-spiro-[benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8c). Compound **8c** was obtained in 44% yield, mp 177–178°C (benzene/hexanes), from the two-step procedure for the condensation-cyclization of dilithiated 2-acetylfuran carbomethoxyhydrazone and **1′**. IR: 1709 and 1728 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 2.64 (s, 3H, CH_3), 3.66 (d, 1H, *J* = 18.6 Hz), 3.74 (s, 3H, CH_3O), 3.97 (d, 1H, *J* = 18.6 Hz), 6.51–6.53 (m, 1H), 6.87 (s br, 1H), 7.47–7.54 (m, 1H), 7.69–7.83 (m, 3H, ArH) and 7.89 (d, 1H, *J* = 7.5 Hz). ^{13} C NMR (deuteriochloroform): δ 23.9, 48.6 (DEPT CH_2), 53.7, 80.9, 112.2, 112.7, 121.4, 123.0, 131.5, 132.6, 135.5, 137.2, 144.0, 144.9, 145.8, 151.2, and 167.0. LCMS exact mass, 389.07: $(M + H)^+$, 389.94. *Anal.* Calcd for $C_{17}H_{15}N_3O_6S \cdot 1/2\ H_2O$: C, 51.25; H, 4.05; N, 10.55. Found: C, 51.30; H, 3.91; N, 10.33.

Ethyl 2-acetyl-5′-(2-furanyl)-2*H*-spiro-[benzo[*d*]-isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8d). Compound **8d** was obtained in 40% yield, mp 145–147 °C (ethanol), from the two-step procedure for the condensation-cyclization of dilithiated 2-acetylfuran carboethoxyhydrazone and **1′**. IR: 1712 cm^{-1}. ^{1}H NMR (DMSO-d_6): δ 1.06 (t, 3H), 2.50 (s, 3H), 3.43–3.46 (m, 1H), 3.88–3.96 (m, 3H), 6.67–6.69 (m, 1H), 6.94 (d, 1H, *J* = 3.6 Hz), 7.76–7.92 (m, 5H), and 8.14 (d, 1H, *J* = 7.8 Hz). ^{13}C NMR (DMSO-d_6): δ 23.4, 48.1, 61.7, 80.8, 112.2, 113.6, 121.0, 123.9, 131.6, 135.8, 143.9, 145.6, and 166.1. LCMS, exact mass, 403.08: $(M + H)^+$, 403.95; $(M - H)^-$, 402.11. *Anal.* Calcd for $C_{18}H_{17}N_3O_6S \cdot 7/8\ H_2O$: C, 51.58; H, 4.51; N, 10.02. Found: C, 51.48; H, 3.38; N, 9.95.

Methyl 2-acetyl-5′-(4-methylphenyl)-2*H*-spiro-[benzo[*d*]-isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8e). Compound **8e** was obtained in 40% yield, mp 166–168°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 4′-methylacetophenone carbomethoxyhydrazone and **1′**. IR: 1709 and 1728 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 2.39 (s, 3H), 2.63 (s, 3H), 3.65–4.03 (m, 5H) [13], 7.21–7.28, 7.46–7.48, and 7.63–7.90 (m, 8H). ^{13}C NMR (DMSO-d$_6$): δ 21.7, 24.1, 48.9 (DEPT CH$_2$), 53.4, 82.0, 121.4, 124.5, 127.4, 128.5, 130.0, 132.2, 136.4, 137.5, 140.1, 151.2, 153.1, and 166.7. LCMS, exact mass, 413.10: (M + H)$^+$, 414.08. *Anal.* Calcd for $C_{20}H_{19}N_3O_5S$: C, 58.10; H, 4.63; N, 10.16. Found: C, 58.06; H, 4.70; N, 9.97.

Methyl 2-acetyl-5′-(2-acetoxyphenyl)-2*H*-spiro-[benzo[*d*]-isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8f). Compound **8f** was obtained in 58% yield, mp 218–220°C (benzene/hexanes) from the two-step procedure for the condensation-cyclization of trilithiated 2′-hydroxyacetophenone carbomethoxyhydrazone and **1′**. IR: 1703 and 1728 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 2.39 (s, 3H), 2.63(s, 3H), 3.65–3.71 (m, 4H), 4.02 (d, 1H, *J* = 18.3 Hz), 7.18 (d, 1H, *J* = 7.8 Hz), 7.26–7.31 (m, 1H), 7.42–7.49 (m, 2H), 7.69–7.80 (m, 3H), and 7.87 (d, 1H, *J* = 7.8 Hz). ^{13}C NMR (deuteriochloroform): δ 22.3, 23.8, 50.2, 53.4 (DEPT CH$_2$), 80.6, 121.2, 123.0, 123.3, 124.9, 126.3, 129.5, 131.4, 132.5, 135.5, 137.2, 148.8, 149.0, 151.1, 166.9, and 170.1. LCMS, exact mass, 457.09: (M + H)$^+$, 457.93. *Anal.* Calcd for $C_{21}H_{19}N_3O_7S$: C, 58.10; H, 4.63; N, 10.16. Found: C, 58.06; H, 4.70; N, 9.97.

1,1-Dimethylethyl 5′-(4-methoxyphenyl)-2*H*-spiro-[benzo-[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8g). Compound **8g** was obtained in 92% yield, mp 190–191°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 4′-methoxyacetophenone carbo-*t*-butoxyhydrazone and **1′**. IR: 1696 and 3128 cm^{-1}. ^{1}H NMR (DMSO-d$_6$): δ 1.03 (s, 9H, CH$_3$), 3.68–3.91 (m, 2H, CH$_2$), 3.82 (s, 3H, OCH$_3$), 7.04 (d, 2H, *J* = 9.0 Hz), 7.63–7.88 (m, 6H), and 9.18 (s, NH). ^{13}C NMR (DMSO-d$_6$): δ 27.2, 49.3 (DEPT CH$_2$), 55.4, 80.6, 80.9, 114.2, 120.6, 123.5, 123.9, 128.2, 130.3, 133.6, 135.5, 139.8, 149.9, 151.3, and 160.8. LCMS, exact mass, 429.14: (M + H)$^+$, 429.67. *Anal.* Calcd for $C_{21}H_{23}N_3O_5S$: C, 58.73; H, 5.40; N, 9.78. Found: C, 58.41; H, 5.49; N, 9.65.

1,1-Dimethylethyl 5′-(3,4-dimethoxyphenyl)-2*H*-spiro-[benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8h). Compound **8h** was obtained in 38% yield, mp 200–203°C (ethanol), from the two-step procedure for the condensation-cyclization of dilithiated 3′,4′-dimethoxyacetophenone carbo-*t*-butoxyhydrazone and **1′**. IR: 1727 and 3231 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 1.17 (s, 9H, CH$_3$), 3.65 (d, 1H, *J* = 15.0 Hz), 3.90 (s, 3H, OCH$_3$), 3.91 (s, 3H, OCH$_3$), 3.95 (d, 1H, *J* = 18.3 Hz), 6.81 (d, 1H, *J* = 8.4 Hz), 7.01 (dd, 1H, *J* = 8.1 Hz), 7.39 (d, 1H, *J* = 2.1 Hz), 7.51 (d, 1H, *J* = 7.8 Hz), 7.61–7.74 (m, 2H), and (7.81 and 7.83 singlets broad, 1H). ^{13}C NMR (deuteriochloroform): δ 27.8, 50.5 (DEPT CH$_2$), 81.3, 83.4, 108.6, 110.6, 120.7, 121.3, 123.9, 123.3, 130.5, 133.9, 136.1, 141.3, 149.1, 150.3, 151.3, and 151.6. LCMS, exact mass, 459.15: (M + H)$^+$, 459.64. *Anal.* Calcd for $C_{22}H_{25}N_3O_6S$: C, 57.50; H, 5.48; N, 9.14. Found: C, 57.26; H, 5.55; N, 9.03.

1,1-Dimethylethyl 5′-phenyl-2*H*-spiro-[benzo[*d*]-isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8i). Compound **8i** was obtained in 59% yield, mp 193–197°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated acetophenone carbo-*t*-butoxyhydrazone and **1′**. IR: 1701, 1728, and 3195 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.25 (s, 9H, CH$_3$), 3.66 (d, 1H, *J* =18.3 Hz), 4.04 (d, 1Hz, *J* = 18.3 Hz), 5.78 (s, 1H), and 7.39–7.41, 7.61–7.82 (m, 9H). ^{13}C NMR (deuteriochloroform): δ 27.7, 50.5 (DEPT CH$_2$), 81.4, 83.6, 121.1, 122.8, 126.8, 128.3, 128.8, 130.2, 130.4, 130.7, 133.8, 136.2, and 151.9. LCMS, exact mass, 399.13: LCMS, (M + H)$^+$ not detected, base peak 299.07. *Anal.* Calcd for $C_{20}H_{21}N_3O_4S$: C, 60.13; H, 5.30; N, 10.52. Found: C, 59.98; H, 5.37; N, 10.50.

1,1-Dimethylethyl 5′-(4-methylphenyl)-2*H*-spiro-[benzo-[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8j). Compound **8j** was obtained in 33% yield, mp 181.5–182°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 4′-methylacetophenone carbo-*t*-butoxyhydrazone and **1′**. IR: 1697 and ~3100 broad cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 1.17 (s, 9H, CH$_3$), 2.37 (s, 3H, CH$_3$), 3.62 (d, 1H, *J* = 18.0 Hz), 3.99 (d, 1H, CH$_3$, *J* = 18.0 Hz), 5.84 (s), 7.20 (d, 1H, *J* = 8.0 Hz), 7.47 (d, 1H, *J* = 7.8 Hz), 7.59–7.72 (m, 5H), and 7.81 (d, 1H, *J* = 7.8 Hz). ^{13}C NMR (deuteriochloroform): δ 21.7, 27.8, 50.7, 81.5, 83.6, 121.3, 123.0, 127.0, 127.4, 127.6, 129.7, 130.5, 133.8, 136.3, 141.4, 141.7, 150.3, and 152.1. LCMS, exact mass, 413.14: (M + H)$^+$ not detected, base peak 314.00. *Anal.* Calcd for $C_{21}H_{23}N_3O_5S\cdot \frac{1}{4} H_2O$: C, 60.34; H, 5.67; N, 10.05. Found: C, 60.28; H, 5.70; N, 10.05.

1,1-Dimethylethyl 5′-(4-chlorophenyl)-2*H*-spiro-[benzo-[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (8k). Compound **8k** was obtained in 35% yield, mp 152–155°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 4′-chloroacetophenone carbo-*t*-butoxyhydrazone and **1′**. IR: 1693 and 3438 broad cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 1.15 (s, 9H), 3.54 (d, 1H, *J* = 18.0 Hz), 4.00 (d, 1H, *J* = 18.3 Hz), 7.38 (d, 2H, *J* = 8.7 Hz), 7.49 (d, 1H, *J* = 7.5 Hz), 7.63–7.70 (m, 4H), and 7.79 (d, 1H, *J* = 6.9 Hz). ^{13}C NMR (deuteriochloroform): δ 27.9, 50.6, 51.0, 81.7, 83.9, 121.5, 123.1, 128.3, 129.1, 129.4, 130.7, 134.1, 136.3, 137.0, 141.3, 150.4, and 151.1. LCMS, exact mass, 433.09: (M + H)$^+$, 433.75. *Anal.* Calcd for $C_{20}H_{20}\,Cl\,N_3O_4S\cdot 5/4\,CH_3OH$ [10]: C, 53.74; H, 5.52; N, 8.85. Found: C, 53.88; H, 5.19; N, 8.94.

1,1-Dimethylethyl 5′-(3,4-dimethylphenyl)-2*H*-spiro-[benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-car-boxylate (8l). Compound **8l** was obtained in 31% yield, mp 197–201°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 3′,4′-dimethylacetophenone carbo-*t*-butoxyhydrazone and **1′**. IR: 1712 and 3415 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 1.18 (s, 9H, CH$_3$), 2.28 (s, 3H, CH$_3$), 2.30 (s, 3H, CH$_3$), 3.64 (d, 1H, *J* = 18.3 Hz), 4.01(d, 1H, CH$_3$, *J* = 18.0 Hz), 5.7 (s), 7.17 (d, 1H, *J* = 8.1 Hz), 7.42–7.59 (m, 2H), 7.60–7.73 (m, 4H), and 7.81 (d, 2H, *J* = 7.8 Hz). ^{13}C NMR (deuteriochloroform): δ 19.7, 19.9, 27.7, 50.7 (DEPT CH$_2$), 81.3, 83.4, 107.4, 121.1, 122.8, 124.4, 127.7, 127.9, 130.0, 130.3, 133.8, 136.2, 137.2, 140.0, and 152.2. LCMS, exact mass, 427.16: (M + H)$^+$, 427.70. *Anal.* Calcd for $C_{22}H_{25}N_3O_4S\cdot 1H_2O$: C, 59.31; H, 6.11; N, 9.43. Found: C, 59.69: H, 6.26; N, 9.07.

Ethyl 2-acetyl-3′-(4,5-dihydrobenz[*g*]indazinyl)-2*H*-spiro-[benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (10a). Compound **10a** was obtained in 60% yield, mp 257–259°C dec (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 1-tetralone carboethoxyhydrazone and **1′**. IR: 1703 and 1739 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 0.91 (m, 1H), 1.27 (m, 3H), 1.80–1.84 (m, 1H), 2.03–2.05 (m, 1H), 2.52 (s, 3H, CH$_3$), 3.70–3.91 (m, 3H, OCH$_3$), 7.16–7.18 (m, 1H), 7.29–7.37 (m, 3H), 7.61–7.90 (m, 4H), and 8.22–8.24 (m, 1H). ^{13}C NMR (deuteriochloroform): δ 14.3, 22.1 (DEPT CH$_2$), 24.1 (CH$_3$ DEPT), 29.5 (CH$_2$ DEPT), 59.1 (DEPT CH), 62.9, 84.0, 121.4, 123.4, 125.9, 126.4, 127.2, 129.2, 131.0, 131.3, 132.6, 135.3, 138.9, 152.9, and 167.6. LCMS, exact mass, 439.12: (M + H)$^+$, 439.99. *Anal*. Calcd for C$_{22}$H$_{21}$N$_3$O$_5$S: C, 60.12; H, 4.82; N, 9.56. Found: C, 59.82; H, 4.54; N, 9.95.

Methyl 2-acetyl-3′-(4,5-dihydrobenz[*g*]indazinyl)-2*H*-spiro[benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-di-oxide-2′(4′*H*)-carboxylate (10b). Compound **10b** was obtained in 71% yield, mp 209°C dec (ethanol), from the two-step procedure for the condensation-cyclization of dilithiated 1-tetralone carbomethoxyhydrazone and **1′**. IR: 1701 cm^{-1}. ^{1}H NMR (deuteriochloroform): δ 1.80–1.85 (m, 1H), 2.03–2.06 (m, 1H), 2.63 (s, 3H, CH$_3$), 2.75–2.98 (m, 2H), 3.60–3.82 (m, 4H, CH and OCH$_3$), 7.16–7.39, 7.57–7.90 (m, 7H), and 8.21 (d, 1H, J = 6.6 Hz). ^{13}C NMR (deuteriochloroform): δ 22.1, 24.1, 29.5, 53.9 (DEPT CH$_2$), 59.2, 84.0, 121.5, 123.3, 125.8, 127.3, 129.2, 131.1, 131.4, 131.7, 132.7, 135.4, 139.1, 152.0, 153.2, and 167.8. LCMS, exact mass, 425.10: (M + H)$^+$, 426.05. *Anal*. Calcd for C$_{21}$H$_{19}$N$_3$O$_5$S: C, 59.28; H, 4.50; N, 9.88. Found: C, 58.94; H, 4.63; N, 9.60.

1,1-Dimethylethyl 3′-(4,5-dihydrobenz[*g*]indazinyl)-2*H*-spiro[benzo[*d*]isothiazole-3,3′-pyrazole]-1,1-dioxide-2′(4′*H*)-carboxylate (10c). Compound **10c** was obtained in 39 % yield, mp 187–188°C (methanol), from the two-step procedure for the condensation-cyclization of dilithiated 1-tetralone carbo-*t*-butoxyhydrazone and **1′**. IR: 1689 and 3183 broad cm^{-1}. ^{1}H NMR (DMSO-d$_6$): δ 1.05 (s, 9H, CH$_3$), 1.70–1.74 (m, 1H of CH$_2$), 1.91–1.99 (m, 1H of CH$_2$), 2.69–3.00 (m, 2H, CH$_2$), 3.85 (dd, 1H, CH, J = 4.4, 13.2 Hz), 7.29–7.42 (m, 3H), and 7.67–7.92 (m, 4H), 7.93 (d, 1H, J = 7.2 Hz), and 9.27 (s, NH). ^{13} C NMR (DMSO-d$_6$): δ 21.9, 27.8, 28.9, 56.3 (DEPT CH), 81.3, 83.9, 121.2, 124.5, 124.7, 127.47, 127.52, 129.9, 139.9, 131.1, 133.9, 136.3, 139.9, 140.2, 150.9, and 153.0. LCMS, exact mass, 425.14: (M + H)$^+$, 425.74. *Anal*. Calcd for C$_{22}$H$_{23}$N$_3$O$_4$S: C, 62.10; H, 5.45; N, 9.88. Found: C, 62.14; H, 5.52; N, 9.78.

A series of pyrimido[4,5-*b*]quinoline derivatives was synthesized by three-component reaction of 6-aminopyrimidine, aromatic aldehydes and 1,3-cyclohexanedione or 5,5-dimethyl-1,3-cyclohexanedione in aqueous media in the presence of triethylbenzylammonium chloride. This protocol has the advantages of higher yields, lower lost, easy work-up, and environmentally friendly procedure.

J. Heterocyclic Chem., **46**, 237 (2009).

INTRODUCTION

The importance of uracil and its annelated derivatives is well recognized by synthetic [1] as well as biological [2] chemists. With the development of clinically useful anticancer and antiviral drugs [3], there has recently been remarkable interest in the synthetic manipulations of uracils [4]. Uracil derivatives have been reported in the literature to be versatile building blocks for the synthesis of a wide range of heterocyclic motifs, including pyridopyrimidines [5] and pyrazolopyrimidines [6]. Pyrido[2,3-*d*]pyrimidines have received considerable attention over the past years because of their wide range of biological activities, such as antitumor [7], antibacterial [8], anti-inflammatory [9], antifungal [10], antileishmaniasis [11], and also act as cyclin-dependent kinase 4 inhibitors [12]. Recently, Tu *et al.* [13] reported the synthesis of pyrimido[4,5-*b*]quinoline-4,6-dione through one-pot condensation of 2,6-diaminopyrimidine-4-one, aldehyde and cyclic a 1,3-dicarbonyl compound in glycol under microwave irradiation without catalyst. However, they were reacted in organic solvent and needed a special reaction instrument.

Multicomponent reactions (MCRs), in which multiple reactions are combined into one synthetic operation, have been used extensively to form carbon–carbon and carbon-heteroatom bonds in synthetic chemistry [14]. Such reactions offer a wide range of possibilities for the efficient construction of highly complex molecules in a single procedural step, thus avoid complicated purification operations and allow savings of both solvents and reagents. The need to reduce the amount of toxic waste and by-product arising from chemical process requires increasing emphasis on the use of less toxic and environmentally compatible materials in the design of new synthetic methods. One of the most promising approaches is using water as reaction media. Breslow *et al.* [15], who showed that hydrophobic effects could strongly enhance the rate of several organic reactions, rediscovered the use of water as a solvent in organic chemistry in the 1980s. There has been growing recognition that water is an attractive medium for many organic reactions [16]. Many MCRs in aqueous medium have been reported [17]. As part of our current studies on the development of new routes to heterocyclic systems [18], we now report an efficient and clean synthetic route to pyrimido[4,5-*b*]quinoline derivatives in aqueous media.

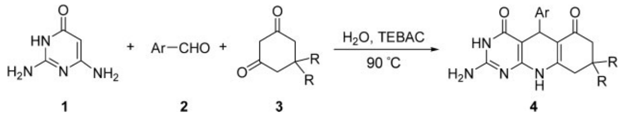
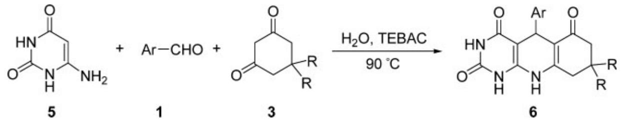


Scheme 2



RESULTS AND DISCUSSION

When the three-component reaction of 2,6-diaminopyrimidine-4-one **1**, aromatic aldehyde **2**, and 1,3-cyclohexanedione or 5,5-dimethyl-1,3-cyclohexanedione **3** was performed in water in the presence of TEBAC at 90°C, 2-amino-5-aryl-8,9-dihydropyrimidino[4,5-*b*]quinoline-4,6 (1*H*,3*H*,5*H*,10*H*)-dione **4** were obtained in high yields (Scheme 1). The results are summarized in Table 1.

As expected, when the 2,6-diaminopyrimidine-4-one **1** was replaced by 6-aminopyrimdine-1,3-dione **5**, another series of 5-aryl-8,9-dihydropyrimido[4,5-*b*]quinoline-2,4,6(1*H*,3*H*,5*H*,10*H*)-trione **6** were obtained under the same reaction conditions (Scheme 2). The results are summarized in Table 2.

As shown in Tables 1 and 2, this protocol can be applied not only to aromatic aldehydes with either electron-withdrawing groups (such as nitro- or halide-groups) or electron-donating groups (such as alkoxy or alkyl groups), but also to heterocyclic aldehydes with excellent yields under same conditions. Therefore, we concluded that the electronic nature of the substituents has no significant effect on these reactions.

In this study, all the products were characterized by mp, IR, and ^{1}H NMR spectral data as well as elemental analyses.

A reasonable mechanism for the formation of the product **4** is outlined in Scheme 3. The reaction occurs *via* an initial formation of α,β-unsaturated ketone, from the Knoevenagel condensation of aldehyde and 1,3-dicarbonyl compounds, which suffers nucleophilic attack to give the Michael adduct **7**. The intermediate product **7** then cyclizes and subsequently dehydrates to afford the product **4**.

Table 1

The synthesis of pyrimido[4,5-*b*]quinoline derivatives **4** in aqueous media.

Entry	R	Ar	Reaction time (h)	Isolated yield (%)
4a	H	4-FC_6H_4	12	95
4b	H	4-HOC_6H_4	16	93
4c	H	3-$NO_2C_6H_4$	18	94
4d	H	4-$NO_2C_6H_4$	16	90
4e	H	4-ClC_6H_4	20	92
4f	H	4-BrC_6H_4	20	86
4g	CH_3	4-ClC_6H_4	18	95
4h	CH_3	4-HOC_6H_4	20	86
4i	CH_3	4-$NO_2C_6H_4$	16	86
4j	CH_3	3,4-$(CH_3O)_2C_6H_3$	17	92
4k	CH_3	3,4-$Cl_2C_6H_3$	20	96
4l	CH_3	3-$NO_2C_6H_4$	13	94
4m	CH_3	4-BrC_6H_4	12	94
4n	CH_3	3,4-$OCH_2OC_6H_3$	21	92
4o	CH_3	Pyridine-3-yl	14	88

In summary, a series of pyrimido[4,5-*b*]quinoline derivatives were synthesized *via* three-component reaction of aldehydes, 6-amminopyrimidine and 1,3-cyclohexanedione or 5,5-dimethyl-1,3-cyclohexanedione in water in the presence of TEBAC. Compared with other methods, this new method has the advantages of high yields, mild reaction conditions, easy work-up, inexpensive reagents, and environmentally friendly procedure.

EXPERIMENTAL

Melting points were determined with a TX-5 microscopic melting-point apparatus and were uncorrected. IR spectra were recorded on a Tensor 27 spectrometer in KBr. ^{1}H NMR spectra were measured on a Bruker DPX-400 MHz spectrometer using TMS standard and DMSO-d_6 as solvent. Elemental analyses were performed on Perkin-Elmer 2400II elemental analyzer.

General Procedure for the Synthesis of Pyrimido[4,5-*b*]quinoline Derivatives. A suspension of a mixture of 6-aminopyrimidine **1** or **5** (2 mmol), aldehyde **2** (2 mmol), 1,3-cyclohexanedione or 5,5-dimethyl-1,3-cyclohexanedione **3** (2 mmol) and TEBAC (0.15 g, 0.66 mmol) was stirred in water (10 mL) at 90°C for several hours. After completion monitored by TLC, the reaction mixture was allowed to cool to room temperature. The crystalline powder formed recrystallized from DMF to give pure **4** or **6**.

2-Amino-5-(4-fluorophenyl)-8,9-dihydropyrimido[4,5-b]-quinoline-4,6(3H,5H,7H,10H)-dione (4a). This compound was obtained as white needles with mp > 300°C; IR (potassium

Found: C, 52.94; H, 3.86; N, 14.63.

2-Amino-5-(4-chlorophenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4g). This compound was obtained as yellow needles with mp > 300°C (Lit. [13] > 300°C); IR (potassium bromide): 3397, 3169, 2965, 1679, 1647, 1621, 1515, 1478, 1446, 1363, 1303, 1279, 1246, 1217, 1198, 1155, 1140, 1090, 1014, 860, 805, 778, 690 cm^{-1}; ^{1}H NMR (DMSO-d_6): 0.89 (s, 3H, CH$_3$), 1.00 (s, 3H, CH$_3$), 1.98 (d, J = 16.0 Hz, 1H, CH), 2.17 (d, J = 16.0 Hz, 1H, CH), 2.38 (d, J = 17.2 Hz, 1H, CH), 2.45 (d, J = 17.2 Hz, 1H, CH), 4.79 (s, 1H, CH), 6.34 (br. s, 2H, NH$_2$), 7.17 (d, J = 8.4 Hz, 2H, ArH), 7.21 (d, J = 8.4 Hz, 2H, ArH), 9.35 (br. s, 1H, NH), 10.41 (br. s, 1H, NH). *Anal.* Calcd. for $C_{19}H_{19}ClN_4O_2$: C, 61.54; H, 5.16; N, 15.11. Found: C, 61.76; H, 5.09; N, 15.28.

2-Amino-5-(4-hydroxyphenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4h). This compound was obtained as pale yellow prisms with mp > 300°C; IR (potassium bromide): 3440, 3330, 2955, 1675, 1647, 1615, 1514, 1455, 1372, 1284, 1250, 1226, 1202, 1173, 1168, 1139, 1105, 1057, 1028, 975, 854, 808, 769 cm^{-1}; ^{1}H NMR (DMSO-d_6): 0.90 (s, 3H, CH$_3$), 1.00 (s, 3H, CH$_3$), 1.98 (d, J = 16.0 Hz, 1H, CH), 2.15 (d, J = 16.0 Hz, 1H, CH), 2.36 (d, J = 17.2 Hz, 1H, CH), 2.43 (d, J = 17.2 Hz, 1H, CH), 4.71 (s, 1H, CH), 6.25 (br. s, 2H, NH$_2$), 6.53 (d, J = 8.0 Hz, 2H, ArH), 6.95 (d, J = 8.0 Hz, 2H, ArH), 8.95 (br. s, 1H, OH), 9.23 (br. s, 1H, NH), 10.31 (br. s, 1H, NH). *Anal.* Calcd. for $C_{19}H_{20}N_4O_3$: C, 64.76; H, 5.72; N, 15.90. Found: C, 64.83; H, 5.84; N, 15.78.

2-Amino-5-(4-nitrophenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4i). This compound was obtained as yellow needles with mp > 300°C (Lit. [13] > 300°C); IR (potassium bromide): 3470, 3335, 3256, 3179, 3069, 2958, 1661, 1618, 1594, 1516, 1453, 1419, 1366, 1352, 1285, 1245, 1227, 1204, 1188, 1157, 881, 830, 805, 785, 739, 684 cm^{-1}; ^1H NMR (DMSO-d_6): 0.89 (s, 3H, CH_3), 1.01 (s, 3H, CH_3), 1.98 (d, $J = 16.0$ Hz, 1H, CH), 2.18 (d, $J = 16.0$ Hz, 1H, CH), 2.41 (d, $J = 17.2$ Hz, 1H, CH), 2.48 (d, $J = 17.2$ Hz, 1H, CH), 4.91 (s, 1H, CH), 6.38 (br. s, 2H, NH_2), 7.43 (dd, $J_1 = 6.8$ Hz, $J_2 = 6.0$ Hz, 2H, ArH), 8.08 (dd, $J_1 = 6.8$ Hz, $J_2 = 6.0$ Hz 2H, ArH), 9.46 (br. s, 1H, NH), 10.43 (br. s, 1H, NH). *Anal.* Calcd. for $C_{19}H_{19}N_5O_4$: C, 59.84; H, 5.02; N, 18.36. Found: C, 60.05; H, 4.97; N, 18.54.

2-Amino-5-(3,4-dimethoxyphenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4j). This compound was obtained as yellow prisms with mp > 300°C (Lit. [13] > 300°C); IR (potassium bromide): 3432, 3263, 3184, 2956, 1669, 1625, 1588, 1513, 1451, 1369, 1283, 1266, 1246, 1224, 1199, 1139, 1025, 803, 766 cm^{-1}; ^1H NMR (DMSO-d_6): 0.94 (s, 3H, CH_3), 1.02 (s, 3H, CH_3), 2.00 (d, $J = 15.6$ Hz, 1H, CH), 2.18 (d, $J = 15.6$ Hz, 1H, CH), 2.38 (d, $J = 17.2$ Hz, 1H, CH), 2.45 (d, $J = 17.2$ Hz, 1H, CH), 3.65 (s, 3H, CH_3O), 3.67 (s, 3H, CH_3O), 4.77 (s, 1H, CH), 6.28 (br. s, 2H, NH_2), 6.64 (d, $J = 8.0$ Hz, 1H, ArH), 6.74 (d, $J = 8.0$ Hz, 1H, ArH), 6.83 (s, 1H, ArH), 9.24 (br. s, 1H, NH), 10.33 (br. s, 1H, NH). *Anal.* Calcd. for $C_{21}H_{24}N_4O_4$: C, 63.62; H, 6.10; N, 14.13. Found: C, 63.74; H, 6.02; N, 14.26.

2-Amino-5-(3,4-dichlorophenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4k). This compound was obtained as white needles with mp > 300°C; IR (potassium bromide): 3462, 3252, 3059, 2957, 1677, 1603, 1519, 1461, 1372, 1307, 1284, 1228, 1191, 1173, 1140, 1097, 1028, 878, 842, 818, 791, 748, 703 cm^{-1}; ^1H NMR (DMSO-d_6): 0.90 (s, 3H, CH_3), 1.01 (s, 3H, CH_3), 2.00 (d, $J = 16.0$ Hz, 1H, CH), 2.18 (d, $J = 16.0$ Hz, 1H, CH), 2.40 (d, $J = 17.2$ Hz, 1H, CH), 2.46 (d, $J = 17.2$ Hz, 1H, CH), 4.78 (s, 1H, CH), 6.39 (br. s, 2H, NH_2), 7.12 (dd, $J_1 = 2.0$ Hz, $J_2 = 8.0$ Hz, 1H, ArH), 7.33 (d, $J = 2.0$ Hz, 1H, ArH), 7.44 (d, $J = 8.0$ Hz, 1H, ArH), 9.42 (br. s, 1H, NH), 10.44 (br. s, 1H, NH). *Anal.* Calcd. for $C_{19}H_{18}Cl_2N_4O_2$: C, 56.31; H, 4.48; N, 13.82. Found: C, 56.48; H, 4.33; N, 13.97.

2-Amino-5-(3-nitrophenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4l). This compound was obtained as yellow needles with mp > 300°C (Lit. [13] > 300°C); IR (potassium bromide): 3470, 3350, 3257, 3194, 2958, 1664, 1649, 1509, 1443, 1417, 1364, 1308, 1285, 1242, 1226, 1202, 1188, 1157, 1098, 1025, 881, 830, 806, 785, 738 cm^{-1}; ^1H NMR (DMSO-d_6): 0.90 (s, 3H, CH_3), 1.02 (s, 3H, CH_3), 1.99 (d, $J = 16.0$ Hz, 1H, CH), 2.19 (d, $J = 16.0$ Hz, 1H, CH), 2.42 (d, $J = 17.6$ Hz, 1H, CH), 2.49 (d, $J = 17.6$ Hz, 1H, CH), 4.92 (s, 1H, CH), 6.39 (br. s, 2H, NH_2), 7.50 (t, $J = 8.0$ Hz, 1H, 1H, ArH), 7.64 (d, $J = 7.6$ Hz, 1H, ArH), 7.95 (d, $J = 7.6$ Hz, 1H, ArH), 7.99 (s, 1H, ArH), 9.45 (br. s, 1H, NH), 10.42 (br. s, 1H, NH). *Anal.* Calcd. for $C_{19}H_{19}N_5O_4$: C, 59.84; H, 5.02; N, 18.36. Found: C, 59.98; H, 5.14; N, 18.19.

2-Amino-5-(4-bromophenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4m). This compound was obtained as yellow needles with mp > 300°C; IR (potassium bromide): 3471, 3323, 3250, 3186, 1659, 1621, 1515, 1486, 1451, 1370, 1284, 1238, 1227, 1204, 1155, 1070, 1011, 842, 809, 782 cm^{-1}; ^1H NMR (DMSO-d_6): 0.89 (s, 3H, CH_3), 1.01 (s, 3H, CH_3), 1.98 (d, $J = 16.0$ Hz, 1H, CH), 2.17 (d, $J = 16.0$ Hz, 1H, CH), 2.38 (d, $J = 17.2$ Hz, 1H, CH), 2.45 (d, $J = 17.2$ Hz, 1H, CH), 4.77 (s, 1H, CH), 6.32 (br. s, 2H, NH_2), 7.12 (d, $J = 8.4$ Hz, 2H, ArH), 7.35 (d, $J =8.4$ Hz, 2H, ArH), 9.34 (br. s, 1H, NH), 10.38 (br. s, 1H, NH). *Anal.* Calcd. for $C_{19}H_{19}BrN_4O_2$: C, 54.95; H, 4.61; N, 13.49. Found: C, 55.06; H, 4.53; N, 13.41.

2-Amino-5-(3,4-dimethylenedioxyphenyl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4n). This compound was obtained as yellow needles with mp > 300°C (Lit. [13] > 300°C); IR (potassium bromide): 3216, 3188, 2958, 2902, 1622, 1558, 1540, 1508, 1488, 1455, 1372, 1283, 1232, 1200, 1041, 1029, 931, 882, 784 cm^{-1}; ^1H NMR (DMSO-d_6): 0.91 (s, 3H, CH_3), 1.00 (s, 3H, CH_3), 2.00 (d, $J = 16.0$ Hz, 1H, CH), 2.16 (d, $J = 16.0$ Hz, 1H, CH), 2.38 (d, $J = 17.2$ Hz, 1H, CH), 2.44 (d, $J = 17.2$ Hz, 1H, CH), 4.73 (s, 1H, CH), 5.89 (s, 2H, OCH_2O), 6.35 (br. s, 2H, NH_2), 6.60 (d, $J = 8.0$ Hz, 1H, ArH), 6.66–6.72 (m, 2H, ArH), 9.32 (br. s, 1H, NH), 10.46 (br. s, 1H, NH). *Anal.* Calcd. for $C_{20}H_{20}N_4O_4$: C, 63.15; H, 5.30; N, 14.73. Found: C, 63.07; H, 5.42; N, 14.86.

2-Amino-5-(pyridin-3-yl)-8,8-dimethyl-8,9-dihydropyrimido[4,5-b]quinoline-4,6(3H,5H,7H,10H)-dione (4o). This compound was obtained as yellow needles with mp > 300°C; IR (potassium bromide): 3417, 3373, 3263, 3194, 2960, 1660, 1625, 1544, 1513, 1470, 1453, 1400, 1370, 1277, 1242, 1227, 1197, 1154, 1140, 1044, 843, 804, 783, 752, 711 cm^{-1}; ^1H NMR (DMSO-d_6): 0.89 (s, 3H, CH_3), 1.01 (s, 3H, CH_3), 1.99 (d, $J = 16.0$ Hz, 1H, CH), 2.18 (d, $J = 16.0$ Hz, 1H, CH), 2.41 (d, $J = 16.8$ Hz, 1H, CH), 2.47 (d, $J = 16.8$ Hz, 1H, CH), 4.79 (s, 1H, CH), 6.36 (br. s, 2H, NH_2), 7.20 (dd, $J_1 = 4.8$ Hz, $J_2 = 8.0$ Hz, 1H, ArH), 7.49 (dd, $J_1 = 2.0$ Hz, $J_2 = 4.8$ Hz, 1H, ArH), 8.25 (dd, $J_1 = 2.0$ Hz, $J_2 = 4.8$ Hz, 1H, ArH), 8.39 (d, $J = 2.0$ Hz, 1H, ArH), 9.41 (br. s, 1H, NH), 10.42 (br. s, 1H, NH). *Anal.* Calcd. for $C_{18}H_{19}N_5O_2$: C, 64.08; H, 5.68; N, 20.76. Found: C, 64.32; H, 5.54; N, 20.92.

5-(3,4-Dichlorophenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,7H,10H)-trione (6a). This compound was obtained as white prisms with mp > 300°C; IR (potassium bromide): 3247, 3207, 3078, 2949, 1714, 1682, 1629, 1609, 1522, 1476, 1439, 1378, 1330, 1303, 1252, 1228, 1182, 1143, 1112, 1029, 994, 955, 901, 820, 778 cm^{-1}; ^1H NMR (DMSO-d_6): 1.71–1.96 (m, 2H, CH_2), 2.10–2.30 (m, 2H, CH_2), 2.54–2.66 (m, 2H, CH_2), 4.76 (s, 1H, CH), 7.16 (dd, $J_1 = 2.0$ Hz, $J_2 = 8.4$ Hz, 1H, ArH), 7.38 (d, $J = 2.0$ Hz, 1H, ArH), 7.47 (d, $J = 8.4$ Hz, 1H, ArH), 9.00 (br. s, 1H, NH), 10.29 (br. s, 1H, NH), 10.80 (br. s, 1H, NH). *Anal.* Calcd. for $C_{17}H_{13}Cl_2N_3O_3$: C, 53.99; H, 3.46; N, 11.11. Found: C, 54.08; H, 3.56; N, 11.04.

5-(3-Nitrophenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,7H,10H)-trione (6b). This compound was obtained as pale yellow prisms with mp > 300°C; IR (potassium bromide): 3279, 3221, 3074, 2970, 1720, 1684, 1632, 1597, 1528, 1470, 1447, 1382, 1358, 1258, 1207, 1186, 1147, 1128, 1089, 994, 914, 845, 822, 772, 740 cm^{-1}; ^1H NMR (DMSO-d_6): 1.75–1.99 (m, 2H, CH_2), 2.18–2.30 (m, 2H, CH_2), 2.53–2.69 (m, 2H, CH_2), 4.91 (s, 1H, CH), 7.52 (t, $J = 8.0$ Hz, 1H, ArH), 7.66 (d, $J = 6.0$ Hz, 1H, ArH), 7.98 (t, $J = 8.0$ Hz, 1H, ArH), 8.03 (s, 1H, ArH), 9.05 (br. s, 1H, NH), 10.32 (br. s, 1H, NH), 10.81 (br. s, 1H, NH). *Anal.* Calcd. for $C_{17}H_{14}N_4O_5$: C, 57.63; H, 3.98; N, 15.81. Found: C, 57.81; H, 4.02; N, 15.69.

5-(2,4-Dichlorophenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,10H)-trione (6c). This compound was obtained as white prisms with mp > 300°C; IR (potassium bromide): 3248, 3207, 3079, 2952, 1723, 1670, 1629, 1603, 1537, 1483, 1426, 1418, 1382, 1341, 1267, 1187, 1149, 1110, 1036, 994, 904, 862, 815, 760, 705 cm^{-1}; ^{1}H NMR (DMSO-d_6): 1.70–1.95 (m, 2H, CH_2), 2.10–2.27 (m, 2H, CH_2), 2.51–2.60 (m, 2H, CH_2), 5.03 (s, 1H, CH), 7.26 (dd, J_1 = 2.0 Hz, J_2 = 8.4 Hz, 1H, ArH), 7.31 (d, J = 8.4 Hz, 1H, ArH), 7.34 (d, J = 2.0 Hz, 1H, ArH), 8.97 (br. s, 1H, NH), 10.21 (br. s, 1H, NH), 10.67 (br. s, 1H, NH). *Anal.* Calcd. for $C_{17}H_{13}Cl_2N_3O_3$: C, 53.99; H, 3.46; N, 11.11. Found: C, 54.07; H, 3.28; N, 11.25.

5-(2-Nitrophenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,7H,10H)-trione (6d). This compound was obtained as red prisms with mp > 300°C; IR (potassium bromide): 3298, 3246, 3010, 2962, 2829, 1734, 1664, 1644, 1531, 1485, 1429, 1378, 1359, 1304, 1261, 1227, 1188, 1143, 1000, 893, 867, 755, 706, 689 cm^{-1}; ^{1}H NMR (DMSO-d_6): 1.74–1.96 (m, 2H, CH_2), 2.10–2.28 (m, 2H, CH_2), 2.51–2.62 (m, 2H, CH_2), 5.61 (s, 1H, CH), 7.29–7.34 (m, 1H, ArH), 7.41 (dd, J_1 = 1.2 Hz, J_2 = 7.6 Hz, 1H, ArH), 7.51–7.57 (m, 1H, ArH), 7.71 (dd, J_1 = 1.2 Hz, J_2 = 8.0 Hz, 1H, ArH), 8.92 (br. s, 1H, NH), 10.18 (br. s, 1H, NH), 10.68 (br. s, 1H, NH). *Anal.* Calcd. for $C_{17}H_{14}N_4O_5$: C, 57.63; H, 3.98; N, 15.81. Found: C, 57.82; H, 4.06; N, 15.96.

5-(4-Nitrophenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,7H,10H)-trione (6e). This compound was obtained as yellow needles with mp > 300°C; IR (potassium bromide): 3360, 3272, 3194, 3052, 2947, 1713, 1669, 1522, 1483, 1438, 1411, 1380, 1348, 1265, 1207, 1188, 1148, 1109, 998, 869, 824, 765, 697 cm^{-1}; ^{1}H NMR (DMSO-d_6): 1.73–1.98 (m, 2H, CH_2), 2.15–2.30 (m, 2H, CH_2), 2.55–2.70 (m, 2H, CH_2), 4.90 (s, 1H, CH), 7.48 (d, J = 8.8 Hz, 2H, ArH), 8.08 (d, J = 8.8 Hz, 2H, ArH), 9.04 (br. s, 1H, NH), 10.30 (br. s, 1H, NH), 10.80 (br. s, 1H, NH). *Anal.* Calcd. for $C_{17}H_{14}N_4O_5$: C, 57.63; H, 3.98; N, 15.81. Found: C, 57.88; H, 4.09; N, 15.74.

5-(3,4-Dimethoxyphenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,7H,10H)-trione (6f). This compound was obtained as pale yellow needles with mp > 300°C; IR (potassium bromide): 3598, 3179, 2954, 1723, 1653, 1595, 1536, 1470, 1417, 1377, 1335, 1266, 1231, 1202, 1169, 1141, 1087, 1025, 974, 930, 864, 797, 762 cm^{-1}; ^{1}H NMR (DMSO-d_6): 0.89 (s, 3H, CH_3), 1.03 (s, 3H, CH_3), 2.04 (d, J = 16.0 Hz, 1H, CH), 2.22 (d, J = 16.0 Hz, 1H, CH), 2.42 (d, J = 17.2 Hz, 1H, CH), 2.49 (d, J = 17.6 Hz, 1H, CH), 3.67 (s, 6H, 2 × CH_3O), 4.71 (s, 1H, CH), 6.66 (dd, J_1 = 1.6 Hz, J_2 = 8.0 Hz, 1H, ArH), 6.77 (d, J = 8.0 Hz, 1H, ArH), 6.81 (d, J = 1.6 Hz, 1H, ArH), 8.73 (br. s, 1H, NH), 10.21 (br. s, 1H, NH), 10.71 (br. s, 1H, NH). *Anal.* Calcd. for $C_{21}H_{23}N_3O_5$: C, 63.46; H, 5.83; N, 10.57. Found: C, 63.72; H, 5.69; N, 10.75.

5-(4-Hydroxyphenyl)-8,9-dihydropyrimido[4,5-b]quinoline-2,4,6(1H,3H,5H,7H,10H)-trione (6g). This compound was obtained as pale yellow needles with mp > 300°C; IR (potassium bromide): 3328, 3201, 3021, 2954, 2933, 2874, 1707, 1679, 1614, 1542, 1512, 1480, 1416, 1376, 1329, 1296, 1252, 1227, 1206, 1177, 1164, 1146, 1050, 1003, 861, 851, 830, 797, 786, 764 cm^{-1}; ^{1}H NMR (DMSO-d_6): 0.89 (s, 3H, CH_3), 1.02 (s, 3H, CH_3), 2.01 (d, J = 16.0 Hz, 1H, CH), 2.19 (d, J = 16.0 Hz, 1H, CH), 2.40 (d, J = 16.8 Hz, 1H, CH), 2.47 (d, J = 16.8 Hz, 1H, CH), 4.64 (s, 1H, CH), 6.56 (d, J = 8.0 Hz, 2H, ArH), 6.96 (d, J = 8.0 Hz, 2H, ArH), 8.70 (br. s, 1H, OH), 9.09 (br. s, 1H, NH), 10.18 (br. s, 1H, NH), 10.72 (br. s, 1H, NH). *Anal.* Calcd. F or $C_{19}H_{19}N_3O_4$: C, 64.58; H, 5.42; N, 11.89. Found: C, 64.63; H, 5.36; N, 11.97.

Symmetrically-armed molecules based on a 2,6-diamidopyridine core, 2,6-bis[*N*-(1′-piperidinylethyl)-carbamyl]pyridine (**1**), 2,6-bis[*N*-(1′-piperazinylethyl)carbamyl]pyridine (**2**), 2,6-bis[*N*-2′-(5″-nitropyridine)-1′-azapropyl)carbamyl]pyridine (**3**), 2,6-bis[*N*-(3′-hydroxypropyl)carbamyl]pyridine (**4**), 2,6-bis[*N*-(5′-hydroxy-3′-azapentyl)carbamyl]pyridine (**5**), 2,6-bis[*N*-2′-oxo-2′,3′-dihydropyrimidin-4′-yl)carbamyl]-pyridine (**6**) as well as the thioamide analogue 2,6-bis[(S-2′-pyridinyl)carbothiyl]pyridine (**7**) have been prepared and characterized. An X-ray crystal structure of **1** confirms its formation. These molecules are potentially multidentate ligands for metal ions, and complexation has been probed through spectroscopic characterization, particularly by electrospray ionization mass spectrometry, and isolation of some first-row transition metal complexes. The ligands, with potentially coordinating arms extending from each amide, dominantly form simple 1:1 M:L complexes. They show no tendency toward polynuclear helicate formation.

J. Heterocyclic Chem., **46**, 243 (2009).

INTRODUCTION

Development of molecules that contain pyridine-2-carboxamido functionality within larger frameworks have been vigorously pursued in recent years [1–7]. Molecules with a —HN—OC—pyridine—CO—NH— core have found wide application, ranging from use in electroluminescent devices to oxidation catalysts. Recently, systems based on a 2,6-diamidopyridine core that support helicate metal complex formation have been developed [3,6,8], and represent a novel extension of this chemistry. This type of structure appears to arise in systems with aromatic nitrogen heterocycles terminating the two pendant arms, where favorable π-π stacking interactions support oligomer self-assembly. It is therefore of interest to develop and examine examples of symmetrical molecules with different potentially chelating arms, here 2,6-bis[*N*-(1′-piperidinylethyl)carbamyl]-pyridine (**1**), 2,6-bis[*N*-(1′-piperazinylethyl)carbamyl]-pyridine (**2**), 2,6-bis[*N*-(2′-(5″-nitropyridine)-1′-azapropyl)carbamyl]pyridine (**3**), 2,6-bi[*N*-(3′-hydroxypropyl) carbamyl]pyridine (**4**), and 2,6-bis[*N*-(5′-hydroxy-3′-azapentyl)carbamyl]pyridine (**5**). To extend the examination further, we have prepared two examples without methylene linkages in the arms, 2,6-bis[*N*-(2′-oxo-2′,3′-dihydropyrimidin-4′-yl)carbamyl]pyridine (**6**) and the thioamide analogue 2,6-bis[*S*-(2′-pyridyl)carbothiyl]pyridine (**7**).

7

While 2,6-bis[*N*-(2′-pyridylmethyl)carbamyl]pyridine (**8**) has a strong tendency to form helical species on metal ion complexation [8], the longer-chain analogue **9** shows no tendency toward helicate formation [9], suggesting that forces that control helicate formation are subtle. Further, although **8** displays no chirality as a free ligand [10], adopting the *syn*, *syn* conformation resulting from intramolecular hydrogen bonding, a bisoxazoline analogue adopts a helical superstructure in the crystal even when a metal is absent [11]. Combining strands containing heteroatoms with a core subunit containing a heteroatom such as **10** or **11** can lead in a very simple way to structures where a helical conformation is stabilized by a network of intramolecular hydrogen bonds [12]. Whether this capacity for helicate formation, either as free or complexed species, also extends to systems with aliphatic side chains reported here was one factor driving this study. Complexation of the new molecules reported here is explored in part with a view to probing stoichometry and to explore the thesis that terminating saturated amine and alcohol groups, although capable of strong hydrogen bonding interactions, do not tend to support the formation of helicates because they have no π-π stacking ability.

RESULTS AND DISCUSSION

Synthesis of diamides. The new symmetrically armed compounds have been prepared using as the core reagent 2,6-bis(methoxy-carbonyl)pyridine, reacting with an amine. Conventional reflux in an organic solvent was not always successful, and a microwave reactor was used in some cases to drive the reaction to completion. For example, the synthesis of **2** was not achieved by refluxing in toluene, even for extended periods; the product obtained after 3 days reflux was assigned as a mixture of the diester precursor and the one-armed monoamide, from spectroscopy. However, solvent-free reaction conducted in a microwave proved successful. Possibly, reaction with an acid chloride rather than an ester may have been more successful conventionally, but the microwave technology supplied the answer to low reactivity without the need to change the key reagent; yields of up to 90% were achieved. Only with the synthesis of the thioamide 7, where a thiol rather than an amine is involved in the reaction, was the acid chloride approach necessarily adopted.

Compounds isolated were all microanalytically pure and readily characterized spectroscopically. For example, with diamide **1**, the NMR spectra are fully consistent with the structure assigned. The proton-decoupled ^{13}C spectrum displays nine peaks (five methylene, three aromatic and one amide carbon resonances), as expected for the symmetric diamide. The methylenes on the piperidine ring can be assigned unambiguously, with large signals at δ 54.1 and 25.0 ppm associated with the equivalent pairs of —***C***H$_2$—N— and adjacent —C—***C***H$_2$—C, respectively, and the remaining single central methylene found at 23.5 ppm. The two remaining methylenes of the aminoethyl chain are at 35.5 (—***C***H$_2$—N$_{sec}$) and 58.4 (—***C***H$_2$—NHCO—) ppm. By analogy to the spectra of the known diamide **8** and the diester precursor, the aromatic resonances can be assigned to the single ***C***H opposite the N group (138.0), the adjacent equivalent pair of ***C***H groups (124.0) and the equivalent pair of tertiary ***C*** (148.3), with the amide resonance at 163.4 ppm. Assignment in the ^{1}H NMR spectrum is facile from comparison with known analogues. Three resonances in the aromatic region display a ratio of 2:2:1, with the —NH—CO— resonance (a broadened triplet) at δ 9.17 ppm. Other resonances at 7.98 and 8.30 ppm are assigned to the protons of the single CH opposite the N group and the adjacent equivalent pair of CH groups, respectively. A set of resonances between δ 1.5 and 4.2 ppm arise from the 14 methylene protons, all of which are coupled, yielding a complex pattern that is not fully resolved. The set of methylenes in **1** give rise to strong resonances in the IR spectrum between 2760 and 2930 cm^{-1}. A strong —CO— resonance also occurs at 1658 cm^{-1}, with other —NHCO— bands at 1538 and 1444 cm^{-1}. The most characteristic pyridine resonances are those at 753 and 644 cm^{-1}. In the electrospray ionization mass spectrometry (ESI-MS), the species $\mathbf{1}\cdot H^{+}$ is observed at *m*/*z* 388 (calc. 388), with a minor peak due to the dihydrate at *m*/*z* 424. Details for other compounds prepared appear in summary form in the Experimental section.

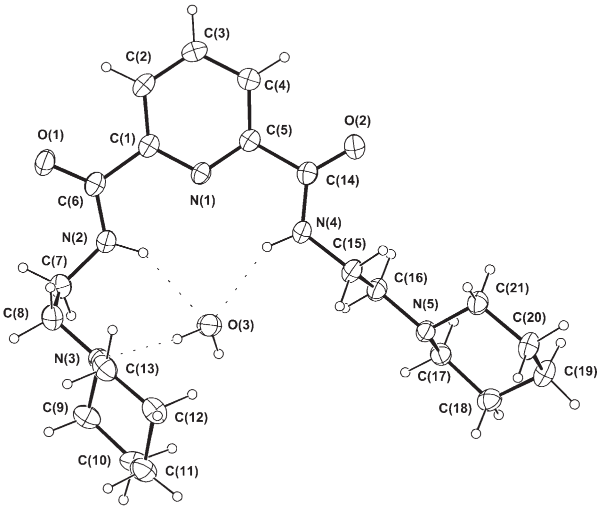

Figure 1. An ORTEP view of **1**, with 50% displacement ellipsoids.

An X-ray crystal structure analysis of **1** confirms the proposed connectivity in this molecule (Fig. 1), with distances and angle that are typical of these types of systems. The C—N distances to pyridine N (av. 1.339 Å), amide N (av. 1.335 Å to CO, av. 1.451 Å to CH_2), and tertiary amine (av. 1.469 Å) are consistent with the character of these groups. The pyridine ring is essentially planar, with the piperidine rings in chair conformations. The water molecule (O(3)) is structurally important, being strongly hydrogen-bonded to amide protons (HN(2) and HN(4)) and to the piperidine nitrogen (N(3)) of one of the two pendant arms. The N(2)H…O(3) and N(4)H…(O(3) distances are 1.331 and 1.450 Å, with the O(3)H….N(3) distance 1.473 Å. This water molecule is not only intramolecularly bonded to **1** but is also connected intermolecularly to an adjacent molecule, building a chain parallel to the *c*-axis. The arm that is not hydrogen-bonded (which includes N(5)) is displaced well away from the water molecule, with C—N_{tert} distances slightly longer (~10 pm) for the hydrogen-bonded compared with the nonbonded arm. Helicity seen in some aromatic-rich examples is not evident here.

The product **2** is anticipated to be spectroscopically somewhat similar to **1**, because the sole difference is the replacement of the methylene opposite the tertiary amine in the six-membered ring by an —NH— group, reducing the number of inequivalent carbons from nine to eight. Aromatic resonances occur at δ 124.4 (124.0 in **1**), 139.3 (138.0 in **1**), and 147.4 (C_{tert}, 148.3 in **1**), with the amide C at 164.9 ppm (163.4 in **1**). Methylenes in the aliphatic ring are unambiguously defined by their intensity, and occur at 43.3 and 51.5 ppm. Notably, the equivalent methylenes occur at 25.0 and 54.1 ppm in **1**, with the significant shift of one methylene here arising from transition for one equivalent pair from a —C—***C***H_2—C— to a —C—***C***H_2—N— environment, as required in the structure. Other methylenes in the chain linking to the amide have resonances at 35.5 and 56.1 ppm. Notable in the ^1H NMR is the absence of any resonance above 2.2 ppm, fully consistent with there being no —C—CH_2—C— entities. A complex pattern of peaks occur from 2.3 to 3.6 ppm for the methylene groups, with the two types of pyridine protons found at 7.95 and 8.08 ppm. In the ESI-MS, the species **2**·H^+ is dominant at *m*/*z* 390.

The synthesis of **3** is of interest because it has pyridine groups terminating the chains and thus provides an extension of the series from a compound with a one atom chain, **8**, and a two atom chain, **9**, to now a three atom chain, joining each terminal pyridine group to the amide. Other differences resulting from the commercial precursor used here are the 5-nitro group on the pyridine ring, characterized clearly by IR resonances at 1540 and 1334 cm^{-1}, and an aza group in the propyl chain. Strong amine bands occur at 3280, 3230, and 1590 cm^{-1} in the IR spectrum. The amide group is defined by resonances in the NMR spectra at 161.4 ppm (^{13}C), and 8.84 ppm (^1H), analogous to positions in other molecules synthesized. The presence of two magnetically distinctly types of pyridine ring is clear in the ^{13}C NMR, with a complex set of resonances, some overlapping, between 146.6 and 108.4 ppm. Methylene resonances occur at 43.0 and 48.5 ppm. The ^1H NMR spectrum displays aliphatic resonances between 2.5 and 3.1 ppm, and aromatic resonances between 6.5 and 8.2 ppm, with protons adjacent to the nitro group being shifted to higher field. In the ESI-MS, the dominant species is **3**·H^+ (*m*/*z* 496).

The aminoalcohol-based ligands **4** and **5** were prepared in good yield by conventional methods. Their spectroscopy has characteristics consistent with their formation. For **4**, the ^{13}C resonances of the aliphatic chains shows the three expected signals at 30.5 (central C—CH_2—C), 36.2 (—CH_2—N—) and 59.0 (—CH_2—OH) ppm, with three resonances from the single pyridine (124.3, 139.3, 147.6 (pyC_{tert}) ppm) and a single carbonyl resonance (165.3 ppm) as required for a symmetrically armed ligand. The alcohol has a characteristic strong IR resonance at 3425 cm^{-1}, apart from the compound showing typical amide bands. The analogue **5** is also spectroscopically consistent with the structure assigned.

The ligand **6**, based on cytosine, forms readily under microwave conditions despite there being possibly greater steric demands as a result of the reacting amine being attached directly to an aromatic ring. Two carbonyl resonances are found in the ^{13}C NMR near 160 ppm, due to the amide and pendant ring carbonyl groups, as well as a set of six aromatic resonances due to the carbons in the cytosine and pyridine rings.

The final example, **7** is a thioamide; as such, it was appropriate to prepare it by reaction of an acid chloride rather than a diester, due to the different reactivity of the thiol group. This is a very rapid and clean reaction, with the product isolated in high yield. The —CO—S— functionality leads to a shift in the carbonyl resonance in the ^{13}C NMR to near 190 ppm; the presence of aromatic resonances, five from the pendant pyridine and three from the core pyridine, is consistent with the presence of two equivalent chains.

Transition metal complexes. Complexation behavior was probed spectroscopically (particularly by ESI-MS), with only selected examples prepared and isolated as solids. The type of complexes formed by the 2,6-diamidopyridines is influenced by the type of pendant chains present, and the donor groups therein. With Cu(II), all of **1–6** apparently form only simple 1:1 complexes in solution from ESI-MS, with several examples isolated as blue-purple solids. For **1–5**, the relatively long chains from the amide to the terminal donors suggest sufficient flexibility that would allow the donor groups terminating these arms to bind in addition to the planar —$^{-}$N—OC—pyridine—CO—N^{-}— unit; the two pendant arms donors may thus promote the favored five-coordination. Others symmetric N_5-diamide compounds such as **12** and **13** have been described [13], prepared by a different route. The copper(II) complex of **12** reportedly binds copper(II) ion as a 1:1 M:L species to form a pentadentate mononuclear copper(II) ion. This complex is one of a number of mononuclear copper(II) complexes that contain dicarboxamido ligation in CuN_5 chromophores [9,14], and support the assignment of similar geometries for the present complexes. Unfortunately, crystals suitable for X-ray structure have not been obtained. However, ESI-MS clearly supports simple ML structures and not higher order polymetallic systems. For example, **2** in the presence of $Cu(OAc)_2$ exhibits no peaks that can be assigned to polymetallic species, but a signal at *m*/*z* 479, 481 arises from $[Cu(\mathbf{2})(OAc)]^+$. The ligands **1** and **2** not only have flexible two-carbon chains linking the amide groups to the terminal group, but the terminal group in each case is an aliphatic amine in a nonaromatic ring, unable to stabilize polynuclear assemblies through π-stacking of terminal groups, and are not expected to form helicates.

The way the pendant chains can influence coordination outcomes has been illustrated with **8** and **9**; whereas **8** shows a strong tendency toward helicate formation on complexation, the analogue with a longer methylene chain, **9**, is not known to form helicates [8]. It is not surprising, therefore, that the even longer chain analogue **3** studied here also does not form helicates, from spectroscopic and ESI-MS evidence. For **4** and **5**, with pendant chains terminated by alcohol groups, we also observe no evidence of helicates despite the potential for alcohol groups to be involved in strong hydrogen bonding interactions that could stabilize more complex assemblies. The general observation of only simple 1:1 complexes forming with aliphatic amines or alcohols as arms indirectly supports a key role for π-stacking in helicate assembly.

For **6** and **7**, where no methylene spacer groups separate the amide groups from the pendant rings, there is again no evidence for oligomeric complexes forming. For the copper(II) complex of **6**, binding of at least the central pyridine N and the two amido N is expected, but this has not been explored in any detail at this stage. For **7**, there is limited evidence that complexation was achieved, consistent with the thioamide being a poor donor, disrupting binding by other groups. However, an apparent Zn(II) complex precipitated readily, suggesting that complexation is possible. Although the nature of this species is uncertain, the limited studies show no real evidence for other than simple 1:1 speciation, and hence further examination was not pursued.

Complexation of diamides with nickel(II) usually yield species that are light brown and thus presumably low-spin square-planar d^8 species, also assigned as simple 1:1 monomers from ESI-MS. There is no clear evidence of helicate formation with these ligands and this metal; in solution, ESI-MS shows no peaks assignable to polynuclear species. For example, spectra of mixtures of **1** or **2** with nickel(II) acetate are dominated by peaks due to $Ni(L\text{-}H)^+$ (*m*/*z* 445 and 447 for **1** and **2**, respectively). With **4**, where alone an N_3O_2 donor set is offered, an orange diamagnetic solid was isolated, its magnetic and spectroscopic properties confirming it as a monomeric square-planar species, presumably with one pendant arm unbound. Cobalt(III) complexes of **1** and **3** were prepared to probe the mode of binding of these systems to an inert metal ion strongly favoring octahedral coordination. Simple 1:1 complexes with ligand bound symmetrically to the metal ion are supported, from spectroscopic characterization and comparison with analogues [15], with either *mer*-CoN_3X_3 geometry with pendant amines or as a CoN_5X complex involving binding of all five nitrogen donors found. Complexation of inert octahedral Co(III) by these ligand systems is fully consistent with expected behavior, and the chemistry does not warrant further extension.

CONCLUSION

Synthesis of symmetrically armed diamides based on the 2,6-diamidopyridine core with a range of new pendants has been established, with microwave synthesis promoting formation of desired products. Consistent with earlier studies, 2,6-diamidopyridines with pendant chains including at least two methylene groups do not undergo helicate formation irrespective of the type of donor group terminating the chains. For aliphatic-terminated molecules like **1** and **2**, loss of the ability of the pendants to participate in π-stacking, found to stabilize helicates with **8**, further restricts the likelihood of helicate formation. It is notable that all known polynuclear helicates of this class of ligand have high levels of aromaticity, and the failure of saturated ligand systems examined here to helicate indirectly supports a role for aromatic groups as structure makers. A more extensive examination of the coordination of these new ligand systems is not warranted, as complexation has been defined adequately here as dominated by simple 1:1 M:L species. Because none of the variety of diamide ligand systems prepared here, irrespective of the type of pendant groups involved, showed a propensity toward helicate formation, the view that stabilization of helicates is not routinely promoted simply because of the presence of the —NHCO—py—CONH— core is supported; this means that the character of the pendant groups is particularly important, as otherwise conventional coordination chemistry results.

EXPERIMENTAL

NMR spectra were recorded on solutions of ligand and complexes, usually in $CDCl_3$ or D_2O, using a Bruker DPX300 spectrometer, whereas FTIR spectra were recorded on a Bio-Rad Win-IR spectrometer with compounds dispersed in KBr disks. UV–Vis spectra were recorded using a Hitachi 150-20 UV–Vis spectrophotometer. ESI-MS were recorded for aqueous or methanolic 10^{-4} *M* solutions, using a Micromass VG Platform II single quadrupole mass spectrometer; experimental peak values are identified by the *m/z* ratio of the most abundant peak. Microanalysis was performed by the Microanalytical Unit, A.N.U., Canberra. 2,6-Bis(methoxycarbonyl)pyridine was made as reported in [8].

Diamide syntheses. ***2,6-Bis[N-(1′-piperidinylethyl)carbamyl]pyridine (1).*** 2,6-Bis(methoxycarbonyl)pyridine (5 g, 25.5 mmol) was suspended in toluene (300 mL) and a solution of the 1-(2′-aminoethyl)-piperidine (7.5 g, 58.5 mmol) was added slowly to the stirring solution. The solution was stirred and heated (~100°C) for 30 min, then refluxed for 24 h. The heat source was removed, the condenser replaced by a $CaCl_2$ drying tube, and stirring continued for another 2 days. Evaporation of solvent yielded a brown oily product. This was twice taken up with diethyl ether and re-evaporated, resulting in a brown sticky solid, which was washed well with water three times and crystallized on standing (1.8 g, 20%). ^{13}C NMR ($CDCl_3$): δ 23.5, 25.1 (—C—CH$_2$—C), 35.7, 54.0, 58.0 (—CH$_2$—N), 123.9, 137.9 (pyCH), 148.4 (pyC$_{tert}$), 163.3 (CO) ppm; ^{1}H NMR ($CDCl_3$): δ 1.5–4.2 (m, 28H, —CH$_2$—), 7.98 (t, 1H, pyH), 8.30 (d, 2H, pyH), 9.17 (t, 2H, —NHCO—); IR: 3470 (OH_2), 3317, 1657, 1538, 1444 (NHCO), 1119, 753, 682 (py) cm^{-1}; ESI-MS (H_2O): *m/z* 388 (**1**) H$^+$). *Anal.* Calcd for $C_{21}H_{33}N_5O_2{\cdot}H_2O$: C, 62.2; H, 8.7; N, 17.5. Found: C, 62.1; H, 8.7; N, 17.2.

2,6-Bis[N-(1′-piperazinylethyl)carbamyl]pyridine (2). Reaction as for **1** was unsuccessful, but using a microwave reactor (Panasonic Dimension 4, Genius NN-C 2000W) proved successful. The diester (1 g, 5.1 mmol) and 1-(2′-aminoethyl)-piperazine (1.44 g, 11.1 mmol) were mixed in a small flask fitted with a microcondenser. The mixture was placed in the microwave for 180 s on high power, and a brown oily product resulted. After standing at room temperature overnight, diethyl ether (20 mL) was added. Further standing for ~24 h resulted in an oily solid, which was washed with water (50 mL) three times, yielding a light brown solid on drying (1.04 g, 80%). ^{13}C NMR ($CDCl_3$): δ 35.5, 43.3, 51.4, 56.1 (—CH$_2$—N), 124.4, 139.3 (pyCH), 147.4 (pyC$_{tert}$), 164.9 (—NHCO—) ppm; ^{1}H NMR ($CDCl_3$): δ 2.3–3.6 (m, 24H, —CH$_2$—), 4.6 (br m, 2H, —NH—), 7.95 (t, 1H, pyH), 8.08 (d, 2H, pyH), 9.12 (br t, 2H, —NHCO—) ppm; IR: 3475 (OH_2), 3290, 1627 (—NH—), 1608, 1540, 1444 (NHCO), 1080, 763, 690 (py) cm^{-1}; ESI-MS (H_2O): *m/z* 390 (**2**·H$^+$). *Anal.* Calcd for $C_{20}H_{34}N_7O_2 \cdot 1.25H_2O$: C, 56.2; H, 8.8, N, 22.9. Found: C, 55.9; H, 8.8; N, 22.9.

2,6-Bis[N-2′-(5″-nitropyridine)-1′-azapropyl)carbamyl]pyridine (3). 2-(3′-Amino-1′-azapropyl)-5-nitropyridine (2.04 g, 16 mmol) and 2,6-bis(methoxycarbonyl)pyridine (2.0 g, 8 mmol) were mixed in a small flask fitted with a condenser and microwaved for 25 min at medium power. The resulted brown oil was left at room temperature overnight after diethyl ether (30 mL) was added, and the pale yellow solid that formed was washed with water (3 × 50 mL), collected, washed with small amounts of ethanol then diethyl ether in turn, and dried in a desiccator (3.7 g, 74%). ^{13}C NMR ($CDCl_3$): δ 43.0, 48.5 (—CH$_2$—), 108.4, 124.2, 131.8, 134.2, 134.4 (pyC), 139.4, 146.6, (pyC$_{tert}$), 161.3 (CO) ppm; ^{1}H NMR ($CDCl_3$): δ 2.5–3.1 (m, 8H, —CH$_2$), 6.5–8.1 (m, 9H, overlapping pyH), 8.83 (br t, 2H, —NHCO—) ppm; IR: 3470 (OH_2), 1608, 1458 (—NHCO), 1545, 1333 (—NO$_2$), 1108, 1037, 823, 763, 688 (py) cm^{-1}; ESI-MS (H_2O): *m/z* 496 (**3**·H$^+$). *Anal.* Calcd for $C_{21}H_{21}N_9O_6{\cdot}2H_2O$: C, 47.5; H, 4.8; N, 23.7. Found: C, 47.5; H, 5.1; N, 23.5.

2,6-Bis[N-(3′-hydroxypropyl)carbamyl]pyridine (4). A solution of 2,6-bis(methoxycarbonyl)pyridine (0.975 g, 5 mmol) in toluene (30 mL) was stirred and heated (60°C), and a solution of 3-amino-1-propanol (0.976 g, 13 mmol) in toluene (11 mL) was added slowly. The mixture was heated to ~100°C using an oil bath and stirred for 1 h, then refluxed for 22 h; some white solid commenced forming after refluxing ~6 h. Heating was discontinued and slow cooling allowed as the mixture was stirred for a further 24 h at room temperature. During this time, white solid continued to form; this was collected, washed in turn with diethyl ether (3 × 5 mL) and a little chloroform, and air dried (1.36 g, 98%). ^{13}C NMR (D_2O): δ 30.5 (—C—CH$_2$—C), 36.2 (—CH$_2$—N), 59.0 (—CH$_2$—O), 124.3, 139.3 (pyCH), 147.7 (pyC$_{tert}$), 165.3 (CO) ppm; ^{1}H NMR (D_2O): δ 1.89 (m, 4H, —C—CH$_2$—C), 3.50 (t, 4H, —CH$_2$—O), 3.69 (t, 4H, —CH$_2$—N), 8.12 (m, 3H, overlapped pyH); IR: 3425 (OH), 3286, 1659, 1543 (NHCO), 1110, 1072, 1034, 941, 848, 748, 679 (py) cm^{-1}. *Anal.* Calcd for $C_{13}H_{19}N_3O_4{\cdot}{}^1/_4H_2O$: C, 54.6; H, 6.7; N, 14.7. Found: C, 54.6; H, 6.2; N, 14.7.

2,6-Bis[N-(5′-hydroxy-3′-azapentyl)carbamyl]pyridine (5). A solution of 2,6-bis(methoxycarbonyl)pyridine (1.953 g, 10 mmol) in toluene (15 mL) was stirred and heated (85°C), and a solution of 2-(2′-aminoethylamino)ethan-1-ol (2.185 g, 21 mmol) in toluene (5 mL) was added slowly. The mixture was heated to ~100°C and stirred for 0.5 h, then refluxed for 24 h; a yellow oily product commenced forming after ~1 h. The heat was turned off and slow cooling allowed as the mixture was stirred for a further 24 h at room temperature. During this time more product formed; this was collected, washed with a little diethyl ether, redissolved in chloroform (20 mL) and extracted with water (3 ×15 mL). The aqueous phase was collected, and the water was removed by rotary evaporation, resulting in a light yellow oily product (2.4 g, 71 %). ^{13}C NMR (D_2O): δ 39.2, 47.7, 50.2 (—CH_2—N), 60.6 (—CH_2—O), 125.1, 139.9 (pyCH), 148.0 (pyC$_{tert}$), 165.8 (CO) ppm; ^{1}H NMR (D_2O): δ 2.88 (t, 4H, —CH_2—N), 2.94 (t, 4H, —CH_2—N), 3.61 (t, 4H, —CH_2—N), 3.78 (t, 4H, —CH_2—O), 8.10 (m, 3H, overlapped pyH) ppm; IR: 3480 (OH_2), 3325 (OH), 1651, 1543 (NHCO), 1126, 1057, 918, 849, 748, 671 (py) cm^{-1}. *Anal.* Calcd for $C_{15}H_{25}N_5O_4\cdot 2H_2O$: C, 47.9; H, 7.8; N, 18.7. Found: C, 47.5; H, 7.8; N, 19.1.

2,6-Bis[N-(2′-oxo-2′,3′-dihydropyrimidin-4′-yl)carbamyl]-pyridine (6). Cytosine (1.14 g, 8 mmol) and 2,6-bis(methoxycarbonyl)pyridine (1.0 g, 4 mmol) were mixed in a small flask fitted with a condenser and microwaved for 20 min at low power. On cooling to room temperature, a glistening white precipitate formed and was collected. Spectroscopy identified this as a mixture of the desired product and some unreacted cytosine. Selective dissolution of the product in hot acetone (~100 mL) and filtration effected separation. The solution was taken to dryness, the product collected, washed with small amounts of diethyl ether, and dried in a desiccator (0.9 g, 65%). ^{13}C NMR (D_2O): δ 93.6, 128.7, 142.6, 144.9 (pyC, pyrimC), 146.0, 148.4 (pyC$_{tert}$, pyrimC$_{tert}$), 159.7, 164.6 (CO) ppm; ^{1}H NMR (D_2O): δ 6.20 (m, 4H, pyrimH), 7.76 (m, 3H, overlapped pyH), 8.50 (br m, 2H, —NHCO—) ppm; IR: 1670 (C=N), 1653, 1455 (NHCO), 1110, 1037, 825, 765 (py) cm^{-1}; ESI-MS (MeOH): *m/z* 363 (**6**·H$^+$). *Anal.* Calcd for $C_{15}H_{11}N_7O_4$: C, 51.0; H, 3.2; N, 27.7. Found: C, 50.8; H, 3.3; N, 27.5.

2,6-Bis[S-(2′-pyridyl)carbothiyl]pyridine (7). A mixture of pyridine-2-thiol (2.18 g, 19.6 mmol) and triethylamine (1.98 g, 19.6 mmol) dissolved in dichloromethane (50 mL) was added dropwise over ~10 min to a solution of 2,6-bis(chlorocarbonyl)-pyridine (2.0 g, 9.8 mmol) in dichloromethane (50 mL) stirring in an icebath. The reaction was rapid and was halted after 20 min, when the insoluble white hydrochloride salt of triethylamine was removed *via* gravity filtration. The resultant filtrate was taken to dryness under reduced pressure to yield a crude orange solid. This was mixed with ethyl acetate (40 mL) and the suspended product collected by vacuum filtration. Washing the solid with several fractions of diethyl ether gave a pale orange solid on drying (3.0 g, 86%). ^{13}C NMR ($CDCl_3$): δ 123.7, 124.6, 130.6, 137.2, 139.2, 146.4 (pyC), 150.6, 152.1 (pyC$_{tert}$), 190.9 (CO) ppm; ^{1}H NMR ($CDCl_3$): δ 7.3–8.1 (m, 9H, overlapped pyH), 8.65 (m, 2H, NpyH) ppm; IR: 3490 (OH_2), 1607, 1459 (CO), 1109, 1041, 822, 765 (py) cm^{-1}; ESI-MS (MeOH): *m/z* 353 (**7**·H$^+$) *Anal.* Calcd for $C_{17}H_{11}N_3O_2S_2\cdot\frac{1}{3}H_2O$: C, 56.8; H, 3.3; N, 11.7. Found: C, 56.9; H, 3.6; N, 11.4.

Metal complex syntheses. ***Aqua(hydrogen 2,6-bis[N-(1′-piperidinylethyl)carbamido]pyridine)dichlorocobalt(III), [Co((1)-H)Cl₂(OH₂)].*** To a solution of **1** (1.63 g, 4 mmol) in methanol (50 mL) was added a solution of $CoCl_2\cdot 6H_2O$ (0.95 g, 4.2 mmol) in water (50 mL). The resulted dark brown solution was stirred and heated (60°C) for 4 h. After stirring at room temperature overnight, HCl (10*M*, 1 mL) was added to the solution, and stirring was continued for ~24 h. The solution was diluted to 1 L with water and sorbed onto a column of Dowex 50W × 2 cation exchange resin. The column was washed with 1*M* HCl to remove any unreacted Co(II)$_{aq}$. The major product was removed by elution with 5*M* HCl, and was rotary evaporated to a small volume then set aside for crystallization. After a few weeks standing, anation yielded a neutral green powder (brown-yellow in aqueous solution) that was collected, washed with ethanol, ether, and dried in a desiccator (1.1 g, 56%). ^{13}C NMR (D_2O): δ 20.4, 22.1 (C—CH_2—C), 33.7, 53.1, 55.2 (—CH_2—N), 124.8, 139.5, 147.1 (pyC), 166.0 (NCO) ppm; ^{1}H NMR (D_2O): δ 1.7–3.8 (m, 28H, —CH_2—), 7.9 (br t, 1H, pyH), 8.18 (br d, 2H, pyH) ppm; IR: 3450 (OH_2), 1675, 1648 (CO), 1541, 1455, 1418 (NCO), 1120, 755, 676 (py) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 518 nm (61 M^{-1} cm^{-1}), 332 (807). *Anal.* Calcd for $C_{21}H_{34}N_5O_3Cl_2Co$: C, 47.1; H, 6.6; N, 13.1%. Found: C, 47.0; H, 7.1; N, 13.0.

Aqua(2,6-bis[N-(2′-(5″-nitropyridine)-1′-azapropyl)carbamido]pyridine)cobalt(III) chloride, [Co((3)-2H)(OH₂)]Cl. A solution of **3** (0.5 g, 4 mmol) in methanol (100 mL) was mixed with $CoCl_2\cdot 6H_2O$ (0.95 g, 4 mmol) in water (100 mL) and pH adjusted to ~7. The brown solution was stirred overnight, and then 10*M* hydrochloric acid (1 mL) was added to the solution, which was stirred at room temperature for ~24 h, then diluted to 1 L with water and sorbed onto a column of Dowex 50W × 2 cation exchange resin. The column was washed with water, then eluted with 1*M* HCl to remove any unreacted Co(II)$_{aq}$. The product was removed with 3*M* HCl and concentrated on a rotary evaporator to a small volume, then set aside for crystallization. After a few weeks, red-brown microcrystals were collected, washed with a small amount of absolute ethanol then diethyl ether in turn, and dried in a desiccator (1.7 g, 71%). IR: 1604 (NH), 1475, 1420, 1365 (NCO), 1505, 1373 (—NO_2), 1154, 1077, 822, 766 (py) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 584 nm (48 M^{-1} cm^{-1}); (1*M* HCl) 508 nm (ε 28), 348 (118); ESI-MS: *m/z* 588 ([ML(OH_2)]$^+$·OH_2). *Anal.* Calcd for $C_{21}H_{19}N_9ClCoO_7\cdot 1\frac{3}{4}H_2O$: C, 39.8; H, 3.6; N, 19.8. Found: C, 40.0; H, 3.7; N, 19.7.

(2,6-Bis[N-(2′-(5′-nitropyridine)-1′-azapropyl)carbamido]-pyridine)copper(II), [Cu((3)-2H)]. Solutions of **3** (0.05 g, 0.09 mmol) in methanol (50 mL) and copper chloride (0.01 g, 0.09 mmol) in water (5 mL) were mixed in a flask, pH adjusted (~7) and then warmed (60°C) for 2 h with stirring, giving a clear blue solution. This was rotary evaporated dry, redissolved in methanol (25 mL), filtered, and stood in a flask (lightly stoppered with cotton wool) in a fume cupboard. After a week some blue crystals were collected by filtration, washed with a small amount of ethanol then diethyl ether in turn, and air dried (0.025 g, 41%). IR: 1590, 1417 (NCO), 1546, 1375 (NO_2), 1151, 1033, 820, 767 (py) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 687 nm (131 M^{-1} cm^{-1}). *Anal.* Calcd for $C_{21}H_{19}CuN_9O_6\cdot 2\frac{1}{2}H_2O$: C, 41.9, H, 4.1, N, 20.9. Found: C, 41.9, H, 4.3, N, 20.8.

(2,6-Bis[N-(3′-hydroxypropyl)carbamido]pyridine)copper(II), [Cu((4)-2H)]. To a stirring solution of **4** (0.143 g, 0.5 mmol) and NaOH (0.052 g, 1.3 mmol) in methanol (10 mL) was slowly added a solution of $Cu(ClO_4)_2\cdot 6H_2O$ (0.185 g, 0.5 mmol) in methanol (2 mL). The immediately formed purple solution was stirred at room temperature for 30 min, and then stood in a sealed jar in a diethyl ether atmosphere. Purple microcrystals formed after several days, and were collected and air dried; these were a sesqui(hydrate hydrogen perchlorate) salt (0.153 g, 59%). IR: 3379 (OH), 1651 (CO), 1574 (NCO), 1142, 1088, 987, 841, 756, 687 (py), 1119, 632 (ClO_4^-) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 576 nm (142 M^{-1} cm^{-1}). *Anal.* Calcd for $C_{13}H_{17}CuN_3O_4 \cdot 1\frac{1}{2}H_2O \cdot 1\frac{1}{2}HClO_4$: C, 30.0; H, 4.2; N, 8.0. Found: C, 29.9; H, 4.5; N, 7.8.

(2,6-Bis[N-(3′-hydroxypropyl)carbamido]pyridine)nickel(II), [Ni(4-2H)]. To a stirring solution of **4** (0.428 g, 1.5 mmol) and NaOH (0.120 g, 3 mmol) in methanol (25 mL) was slowly added a solution of $Ni(ClO_4)_2 \cdot 6H_2O$ (0.549 g, 1.5 mmol) in methanol (5 mL), and the pH was raised to ∼10 with methanolic NaOH solution. The resulting orange-red solution was heated for 2 h at 60°C, and then allowed to cool and filtered to remove some green solid. The orange-red filtrate was rotary evaporated to dryness, washed with diethyl ether (2 × 20 mL), then was redissolved in a small volume of methanol (∼10 mL) and crystals grown in a diethyl ether atmosphere. Some orange crystals formed after several days, and were collected, washed with a little diethyl ether and air dried; they crystallized as a diamagnetic monohydrogen perchlorate salt (0.34 g, 68%). ^{1}H NMR (D_2O): δ 1.92 (m, 4H, CH_2), 3.53 (t, 4H, CH_2), 3.73 (t, 4H, CH_2), 8.14 (m, 3H, pyH); ^{13}C NMR (D_2O): δ 30.5 (CH_2), 36.2 ($-CH_2-N$), 59.0 ($-CH_2-O$), 124.2, 139.2 (pyCH), 147.4 (pyC$_{tert}$), 165.0 (CO) ppm; IR: 3333 (OH), 1651, 1543 (NCO), 1149, 1088, 995, 849, 748, 687 (py) 1119, 630 (ClO_4^-) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 365 nm (72 M^{-1} cm^{-1}). *Anal.* Calcd for $C_{13}H_{17}NiN_3O_4 \cdot HClO_4$: C, 35.6; H, 4.2; N, 9.6. Found: C, 35.9; H, 4.6; N, 9.2.

(2,6-Bis[N-(5′-hydroxy-3′-azapentyl)carbamido]pyridine)-copper(II), [Cu((5)-2H)]. To a stirring solution of **5** (0.190 g, 0.5 mmol) and NaOH (0.050 g, 1.25 mmol) in methanol (10 mL) was slowly added a solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.185 g, 0.5 mmol) in methanol (2 mL). The immediately formed blue solution was stirred at room temperature for 30 min, and then stood in a sealed jar in a diethyl ether bath. Blue solid formed after several days, and was collected and air dried; it crystallized as a sesqui(hydrate hydrogen perchlorate) salt (0.155 g, 52%). IR: 3425 (OH), 1651, 1574 (NCO), 1142, 1119, 1088, 841, 764, 687 (py), 1068, 633 (ClO_4^-) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 598 nm (113 M^{-1} cm^{-1}). *Anal.* Calcd for $C_{15}H_{23}CuN_5O_4 \cdot 1\frac{1}{2}H_2O\ 1\frac{1}{2}HClO_4$: C, 31.2; H, 4.8; N, 12.1. Found: C, 31.3; H, 4.5; N, 11.8.

(2,6-Bis[N-(2′-oxo-2′,3′-dihydropyrimidin-4′-yl)carbamido]-pyridine)copper(II), [Cu((6)-2H)]. A solution of **6** (0.35 g, 1 mmol) in water was stirred at room temperature. A solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (0.37 g, 1 mmol) was added. The resulting blue solution was allowed to evaporate slowly over the course of several weeks, yielding light blue crystals that were collected *via* filtration and air dried; it crystallized as a hydrogen perchlorate trihydrate salt (0.28 g, 55%). IR: 1670 (C=N), 1610, 1540, 1445 (NCO), 1110, 825, 765, 690 (py), 1070, 630 (ClO_4^-) cm^{-1}; UV–Vis (OH_2): λ_{max} (ε_{max}) 570 nm (120 M^{-1} cm^{-1}). *Anal.* Calcd for $C_{15}H_9N_7O_4Cu \cdot 3H_2O \cdot HClO_4$: C, 31.5; H, 3.0; N, 17.1. Found: C, 31.7; H, 2.85; N, 16.8.

(2,6-Bis[S-(2′-pyridyl)carbothiyl]pyridine)zinc(II) acetate monohydrate, [Zn(7)](CH$_3$COO)$_2$·H$_2$O. To a stirred ethanolic solution of **7** (0.2 g, 0.57 mmol) was added dropwise an aqueous solution containing zinc acetate monohydrate (0.11 g, 0.57 mmol). During the addition, a thick white precipitate formed, and this was collected by vacuum filtration, washed in turn with water and ethanol portions, and air dried (0.20 g, 83%). ^{13}C NMR (d_6-DMSO): δ 34.4 (CH_3), 115.3, 119.1, 128.0 131.3, 137.3, 138.8 (pyC), 144.3, 147.9 (pyC$_{tert}$), 169.2 (COO), 188.0 (CO) ppm; ^{1}H NMR (d_6-DMSO): δ 2.35 (s, 3H, CH_3), 6.83 (t, 2H, pyH), 7.07 (t, 2H, pyH), 7.24 (d, 2H, pyH), 7.42 (t, 1H, pyH), 7.62 (br s, 2H, pyH), 7.85 (m, 2H, pyH); IR: 1612, 1540, 1451 (CO), 1595 (COO^-), 1060, 820, 765, 680 (py) cm^{-1}. *Anal.* Calcd for $C_{21}H_{17}N_3O_6S_2Zn \cdot H_2O$: C, 56.3; H, 3.4; N, 11.6. Found: C, 56.9; H, 3.6; N, 11.4.

X-ray crystallography. A pale yellow prismatic crystal of **1**, crystallized by diethyl ether diffusion into a methanol solution in a sealed vessel, was mounted and quenched in a cold nitrogen gas stream from an Oxford Cryosystems Cryostream. A Bruker SMART 1000 CCD diffractometer using graphite monochromated MoKα radiation was used for data collection. Cell constants were obtained from a least squares refinement against 1014 reflections located between 5 and 56° 2θ. Data were collected at 150(2) Kelvin with ω scans to 57° 2θ. The data integration and reduction were undertaken with SAINT and XPREP [16], and subsequent computations were carried out with the teXsan [17], WinGX [18], and XTAL [19] graphical user interfaces. The intensities of 161 standard reflections recollected at the end of the experiment did not change significantly during the data collection. A Gaussian absorption correction [16,20] was applied to the data.

The structure was solved in the space group *C*2/c(#15) by direct methods with SIR97 [21], and extended and refined with SHELXL-97 [22]. The nonhydrogen atoms were modeled with anisotropic displacement parameters and a general riding atom model was used for H atoms. Amine and water sites were located and modeled with isotropic displacement parameters. The crystallographic data (excluding structure factors) for the structure are available from the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC671132. Copies may be obtained from CCDC, Union Road, Cambridge CB2 1EZ, UK (deposit@ccdc.cam.ac.uk).

Crystal data. Microwave assisted synthesis, metallation, and β-formylation of porphyrins is described. All synthetic reactions were carried out on inorganic polymer solid support using microwave energy. It is the first documented application of the Duff reaction in the field of porphyrins and metalloporphyrins. The overall process is simple, easy, and environment friendly. FTIR, UV–visible, elemental analysis, ^{1}H NMR, and mass spectrometry were used to characterize the compounds.

J. Heterocyclic Chem., **46**, 251 (2009).

INTRODUCTION

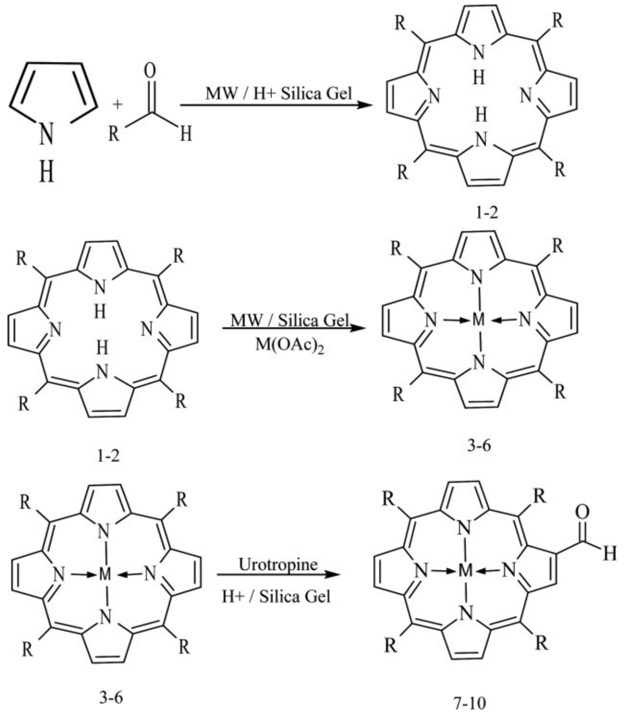
The solid-state synthetic methods have attracted much attention and are widely used for the synthesis of a variety of compounds [1–3]. Microwave assisted organic synthesis has became an increasingly popular technique in academic and industrial laboratories because of certain advantages particularly shorter reaction times, minimum solvent requirement, and ease of purification [4–6]. Application of microwave power in synthesis, metallation, and substitution reactions of porphyrins is not a new concept [7–9]. In the past few years, porphyrin chemistry under microwave heating has been under intense study with significant benefits. Microwave assisted reactions are believed to facilitate the polarization of the substrate thereby increasing the rate of the reactions [10–12]. Herein, we wish to report the use of inorganic polymer solid support for synthesis, metallation, and formylation of porphyrins.

Porphyrins are tetrapyrrolic molecules, the electronic properties of which can be tailored by the variation of peripheral substitution or by central atom [13]. A single porphyrin molecule offers twelve peripheral substitution positions; four meso and eight β-positions. As a result peripheral substitution reactions of porphyrin with different functional groups are highly important reactions. Known functionalization reactions of porphyrins include sulfonation, nitration, halogenation, and Vilsmeier formylation [14,15]. One functional group that allows asymmetric modification and is widely used in porphyrin chemistry is the formyl group [16,17]. Formyl porphyrins are not only prepared synthetically but also occur naturally [18]. Formyl porphyrins are important precursors for the synthesis of multiporphyrin systems [19]. Many methods are available in the literature to formylate the porphyrins at meso and β-positions [20–22]. Both synthetic and natural porphyrins have been formylated by different methods but the most popular is the Vilsmeier reaction [23]. According to the best of our knowledge, there has not been a single example to formylate the porphyrins by Duff reaction over inorganic solid support under microwave radiations.

RESULTS AND DISCUSSION

The classical porphyrin synthesis popularized by Alder, Longo, and Lindsey makes use of toxic and corrosive solvents [24–26]. However, with the advent of microwave radiation as source of energy for chemical reactions, it has been possible to synthesize the porphyrins and metalloporphyrins under solventless conditions

Scheme 1



[27]. The first report of solid-state synthesis of porphyrins under microwave radiations used silica gel, alumina, clay, and montmonillonite. According to that report, the yields were poor and not more than 10% [28].

The experimental technique applied for the organic synthesis described below is based on microwave power. The aim of this work was to investigate the solid phase synthesis, metallation, and formylation of porphyrins. The overall process for the synthesis of formyl porphyrins is rapid, efficient, and eco-friendly (Scheme 1).

Two reaction techniques were used namely (i) Solventless heating with controlled temperature, and (ii) Dry media procedure with controlled temperature. Initially, we used microwave radiation under solventless conditions for the synthesis of Porphyrin **1** and **2** without using any solid support (Table 1). In another experiment, the mixtures of aldehyde and pyrrole were supported on dry neutral silica gel and irradiated with microwave radiation to get Porphyrin **1** and **2** but the yields were not greater than 10%. Alternatively, silica gel was first acidified with propanoic acid, dried in an oven at 50°C for 12 h. This silica gel was used to support the mixtures of reacting aldehyde and pyrrole. Upon microwave irradiation, Porphyrin **1** and **2** were obtained in good yields (Table 2).

Table 1

Solventless synthesis of porphyrins.

Mixture	Porphyrin	% Age yield
Pyrrole and Cuminaldehyde	Porphyrin [1]	22
Pyrrole and 3,5-di-*tert*-butyl benzaldehyde	Porphyrin [2]	20

W = 200 Watts; Time = 6 min; Temperature = 100°C.

Table 2

Solid phase supported porphyrin synthesis.

Mixture over H^+/silica gel	Porphyrin	% Age yield
Pyrrole and Cuminaldehyde	Porphyrin [1]	37
Pyrrole and 3,5-di-*tert*-butyl benzaldehyde	Porphyrin [2]	32

W = 200 Watts; Time = 10 min; Temperature = 100°C.

Metallation of Porphyrin **1** and **2** was achieved when mixture of Porphyrin **1** and **2** and metal acetate adsorbed on neutral silica gel were irradiated under microwave radiation (Table 3). In another experiment, propanoic acid/silica gel containing synthesized crude Porphyrin **1** and **2** were washed thoroughly with the saturated solution of metal acetate in methanol. After drying, silica gel was irradiated with microwave radiation to get Metallo-porphyrin **3**, **4**, **5**, and **6** (Table 3). Hence, after the synthesis of Porphyrin **1** and **2** on acidic silica gel one may use the same silica gel for the synthesis of Metalloporphyrin **3**, **4**, **5**, and **6** without any purification step. One pot synthesis of Metalloporphyrin **3**, **4**, **5**, and **6** was also investigated when mixture of reacting aldehyde, pyrrole, and metal acetate were simultaneously heated under microwave radiations over neutral silica gel. The results were not more than 6% probably because of poor synthesis of Porphyrin **1** and **2** over neutral silica gel. On the other hand, when acidic silica gel was used for one pot synthesis of Metalloporphyrin **3**, **4**, **5**, and **6**, under microwave radiations, metallation failed because of the acidic environment.

Table 3

Metalloporphyrins.

Mixture over silica gel	Metalloporphyrin	% Age yield
$Ni(OAc)_2$ and Porphyrin [1]	Metalloporphyrin [3]	90
$Ni(OAc)_2$ and Porphyrin [2]	Metalloporphyrin [4]	92
$Cu(OAc)_2$ and Porphyrin [1]	Metalloporphyrin [5]	94
$Cu(OAc)_2$ and Porphyrin [2]	Metalloporphyrin [6]	93

W = 250 Watts; Time = 15 min; Temperature = 111°C.

Table 4

Formylporphyrins.

Mixture on H^+/ silica gel	Product	% Age yield
Urotropine and porphyrin [3]	Formyl porphyrin [7]	54
Urotropine and porphyrin [4]	Formyl porphyrin [8]	50
Urotropine and porphyrin [5]	Formyl porphyrin [9]	54
Urotropine and porphyrin [6]	Formyl porphyrin [10]	51

W = 200 Watts; Time = 18 min; Temperature = 111°C.

After successful synthesis (Table 2) and metallation of Porphyrin **1** and **2** (Table 3), we applied the standard Vilsmeier method for the introduction of formyl group onto Metalloporphyrin **3**, **4**, **5**, or **6**. Dry neutral silica gel containing Metalloporphyrin **3**, **4**, **5**, or **6** was mixed with the Vilsmeier salt adsorbed on silica gel. On microwave irradiation, demetallattion was exclusively observed. When all attempts to formylate the Metalloporphyrin **3**, **4**, **5**, and **6** over silica gel solid support under microwave radiations were failed, we applied Duff reaction. Duff reaction require strongly acidic conditions whereas under such conditions metalloporphyrins demetallate [29]. To overcome this problem, we used acidified silica gel instead of acid itself under solventless conditions to get formyl porphyrin **7**, **8**, **9**, and **10** (Table 4).

UV–visible spectra of Porphyrin **1** and **2** showed characteristic Soret and Q bands. On metallation, two visible bands appeared along with a Soret band. ^{1}H NMR spectra of free-base Porphyrin **1** and **2** showed a singlet in the high field region for imino-protons that disappeared on metallation. Formyl porphyrin **7**, **8**, **9**, and **10** showed two clear singlets at downfield region; one for formyl proton and second for β-pyrrolic proton immediately next to formyl group. FTIR of formyl porphyrin **7**, **8**, **9**, and **10** showed clear sharp peak around 1660 cm^{-1} for C=O group.

EXPERIMENTAL

Melting points were determined on a Kofler micromelting point apparatus without correction. IR spectra were recorded on a Nicolet Impact-410 FTIR spectrophotometer in KBr. ^{1}H NMR spectra were measured in $CDCl_3$ using TMS as internal standard with a Bruker 500 MHz spectrometer. MS spectra were taken on a KRATOS-AEI-MS50 spectrometer. Elemental analyses were performed on a PE-2400 CHN elemental analyzer. UV/Vis measurements were performed with a Shimadzu Multispec-1501. All the reactions were performed in the commercial microwave oven having maximum output power 500 Watts. Reagents from Merck and Aldrich Chemical were used. Anhydrous Silica gel 60–100 (0.063–0.2 mm) was used as solid support after dehydration under microwave irradiation for 4 min.

General procedures

(i) Solventless heating with controlled temperature. The reagents were mixed together in a low boiling point solvent at room temperature. Solvent was removed under vacuum. The reaction mixture was heated under microwave radiation in a quartz flask having an outer solvent circulating jacket for the control of temperature. The sample was cooled in an ice bath. TLC was used to monitor the reaction progress. The reaction product was extracted with solvent; the extract was filtered, dried over anhydrous sodium sulfate, and then the solvent was removed. The product was purified by column chromatography.

(ii) Dry media procedure with controlled temperature. The reagents were dissolved in a low boiling point solvent at room temperature; anhydrous microwave transparent inorganic solid support (silica gel) was added and the solvent was removed under vacuum. The adsorbed reaction mixture was introduced in an open quartz flask having an outer solvent circulating jacket for the control of temperature. It was subjected to microwave irradiation. The reaction mixture was cooled in an ice bath. TLC was used to monitor the reaction progress. The reaction product was purified by column chromatography. For column chromatography, the reaction mixture was applied as such onto silica column and eluted with mixture of solvents. Solvents were removed under vacuum to get product.

Preparation of propanoic acid/silica. Silica gel (15 g, Merck, 60–100 mesh size) was mixed well with 5 g of propanoic acid in a mortar. The resultant mixture was dried in an oven at 60°C for 12 h. Acidic silica gel was obtained as white powder.

Preparation of H_2SO_4/silica gel. H_2SO_4 (5 g, 95%) and silica gel (15 g, Merck, 60–100 mesh size) were mixed in a mortar. The resultant mixture was dried in an oven at 90°C for 12 h. Acidic silica gel was obtained as white powder.

Porphyrin [1] (1A). A mixture of pyrrole (0.04 mole, 2.68 g) and cuminaldehyde (0.04 mole, 5.93 g) was subjected to microwave irradiation according to solventless heating with controlled temperature method (i) (Table 1). After cooling, the reaction mixture was applied onto silica column and eluted with chloroform: *n*-hexane (1:2). The fast moving band was collected and the solvent was evaporated to get Porphyrin [1] (22%). mp > 350°C; Anal. Calcd. for $C_{56}H_{54}N_4$: C, 85.89; H, 6.96; N, 7.16. MS (*m*/*z*, %) 1118 (M^+, 100%), 57 (84%).

Metalloporphyrin [4] (3D). Silica gel obtained directly from Experiment-2B having adsorbed crude Porphyrin [2] was thoroughly washed with 50 mL of saturated solution of nickel acetate in methanol. Silica gel was dried and heated under microwave according dry media procedure (ii) (Table 3). After cooling, the reaction mixture was applied as such onto silica column and eluted with chloroform: petroleum ether; b.p 60–90°C (1:3). The fast moving band was collected, and the solvent was evaporated to get Metalloporphyrin [4] (92%).

Metalloporphyrin [5] (3E). Experiment-3A procedure was repeated with copper acetate (1 mmole, 181.63 mg) to get Metalloporphyrin [5] (Table 3) (94%). mp > 350°C; Anal. Calcd. for $C_{56}H_{52}CuN_4$: C, 79.62; H, 6.21; N, 6.63. Found: C, 79.50; H, 6.23; N, 6.65. IR(KBr):ν_{max} 2922, 1670, 1460, 1342, 1000, 802, 722 cm^{-1}; UV($CHCl_3$) λ_{max} 415, 540 nm. MS (*m*/*z*, %): 844.6 (M^+, 15.85%), 842.6 (72%), 837.6 (100%).

Metalloporphyrin [5] (3F). Silica gel obtained directly from experiment 1-B having crude synthesized Porphyrin 1 was washed thoroughly with 50 mL of a saturated solution of copper acetate in methanol. After drying, silica gel was irradiated with microwave (Table 3). Pure Metalloporphyrin [5] was obtained by column chromatography using chloroform: petroleum ether; b.p 60–90°C (1:3) as mobile phase. The fast moving band was collected and the solvent was evaporated to get pure Metalloporphyrin [5] (94%).

Metalloporphyrin [6] (3G). Experiment-3C procedure was repeated with copper acetate (1 mmole, 181.63 mg) to get Metalloporphyrin [6] (Table 3) (93%). mp > 350°C; Anal. Calcd. for $C_{76}H_{92}CuN_4$: C, 81.13; H, 8.24; N, 4.98. Found: C, 81.20; H, 8.22; N, 5.0. IR.(KBr)ν_{max} 3060, 2980, 2940, 2860, 1600, 1520, 1480, 1440, 1400 cm^{-1}; UV($CHCl_3$) λ_{max} 420, 540 nm. MS (*m*/*z*, %) 1123 (M^+, 23%), 57 (34%).

Metalloporphyrin [6] (3H). Silica gel obtained directly from the experiment 2-B having crude synthesized Porphyrin 2 was washed thoroughly with 50 mL of a saturated solution of copper acetate in methanol. After drying, silica gel was irradiated with microwave (Table 3). Purification was done by column chromatography using chloroform: petroleum ether; b.p 60–90°C (1:3) as mobile phase. The fast moving band was collected, and the solvent was evaporated to get pure Metalloporphyrin [6] (93%).

Formyl porphyrin [7] (4A). Urotropine (1 mmole, 140.19 mg) and Metalloporphyrin [3] (0.04 mmole, 33.59 mg) were powder together in an agate mortar. These were doped on H_2SO_4/silica gel (15 g) and heated under microwave according to dry media procedure (ii) (Table 4). After cooling, 50 mL of water was added and reaction mixture was stirred at room temperature for 30 min. Water was removed by filtration and residue was dried in vacuum desiccator. It was applied onto silica column and eluted with chloroform: petroleum ether; b.p 60–90°C (2:1). The fast moving band was collected and the solvent was evaporated to get 2-formyl-5,10,15,20-tetrakis(4′-isopropylphenyl)porphyrinatonickel(II) [7] (54%). mp > 350°C; Anal.Calcd. for $C_{57}H_{52}N_4NiO$: C, 78.90; H, 6.04; N, 6.46. Found: C, 78.80; H, 6.03; N, 6.50. IR(KBr)ν_{max} 2956, 2923, 1669 (C=O), 1545, 1507, 1459, 1351, 1056, 1001, 937, 813, 797, 719 cm^{-1}; UV($CHCl_3$)λ_{max} 435, 545, 585 nm. ^1H NMR($CDCl_3$): δ 1.48 (d, *J* = 6.7 Hz, $8CH_3$), 3.18 (sep, *J* = 6.7 Hz, 4CH), 7.52 (d, *J* = 6.9 Hz, 4m-Ph2H), 7.89 (d, *J* = 6.9 Hz, 4o-Ph2H), 8.72 (m, β-pyrrolic H 7, 8, 12, 13, 17, 18), 9.20 (s, CH 3), 9.34 (s, CHO). MS (*m*/*z*, %), 867 (M^+, 1%), 413 (100%), 277 (24%).

Formyl porphyrin [8] (4B). Urotropine (1 mmole, 140.19 mg) and Metalloporphyrin [4] (0.04 mmole, 44.81 mg) were treated according to the procedure describe in experiment (4A) to get 2-formyl-5,10,15,20-tetrakis(3′,5′-di-*tert*-butylphenyl)porphyrinatonickel(II) [8] (50%). mp > 350°C; Anal.Calcd. for $C_{77}H_{92}N_4NiO$: C, 80.54; H, 8.08; N, 4.88. Found: C, 80.45; H, 8.09; N, 4.89. IR(KBr)ν_{max} 3080, 2970, 2920, 2880, 1680 (C=O), 1600, 1480, 1440, 1400, 1370, 1360 cm^{-1}; UV ($CHCl_3$)λ_{max} 435, 545, 585 nm. ^1H NMR($CDCl_3$): δ 1.45 (m, 8t-Bu), 7.71 (m, C_5 p-PhH, C_{10} p-PhH, C_{15} p-PhH); 7.74 (t, J = 1.8 Hz, C_{20} p-PhH), 7.79 (d, J = 1.8 Hz, C_5 o-Ph2H, 6H), 7.82 (d, J = 1.8 Hz, C_{10} o-Ph2H), 7.82 (d, J = 1.8 Hz, C_{15} o-Ph2H), 7.88 (d, J = 1.8 Hz, C_{20} o-Ph2H), 8.77 (m, β-pyrrolic H 7, 8, 12, 13, 17, 18), 9.03 (s, CH 3), 9.34 (s, CHO). MS (*m*/*z*, %) 1147 (M^+, 1%), 235 (23%), 193 (18%), 189 (25%), 57 (100%).

Formyl porphyrin [9] (4C). Experiment (4A) procedure was repeated by using Metalloporphyrin [5] (0.04 mmole) to get 2-formyl-5, 10, 15, 20-tetrakis(4′-isopropylphenyl)porphyrinatocopper(II) [9] (54%) (Table 4). mp > 350°C; Anal.-Calcd. for $C_{57}H_{52}CuN_4O$: C, 78.46; H, 6.01; N, 6.42. Found: C, 78.51; H, 6.03; N, 6.44. IR (KBr) ν_{max} 2957, 2923, 1670 (C=O), 1559, 1540, 1507, 1458, 1342, 1055, 1000, 798, 721 cm^{-1};UV($CHCl_3$)λ_{max} 430, 550, 595 nm. MS (*m*/*z*, %) 872 (M^+, 3%), 349 (100%), 236 (71%).

Formyl porphyrin [10] (4D). Experiment (4B) procedure was repeated by using Metalloporphyrin [6] to get 2-formyl-5,10,15,20-tetrakis(3′,5′-di-*tert*-butylphenyl)porphyrinatocopper (II) [10] (51%) (Table 4). mp > 350°C; Anal.Calcd. for $C_{77}H_{92}CuN_4O$: C, 80.20; H, 8.04; N, 4.86. Found: C, 80.18; H, 8.04; N, 4.85. IR(KBr)ν_{max} 2961, 1671 (C=O), 1591, 1560, 1540, 1362, 1345, 1288 cm^{-1}. UV($CHCl_3$) λ_{max} 430, 550, 595 nm. MS (*m*/*z*, %) 1154 (M^+, 3%), 349 (100%), 236 (71%), 189 (24%).

A novel approach to regioselective synthesis of new 5-amino-6-arylamino-1*H*-pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-one **5** derivatives *via* a tandem aza-wittig and annulation reaction of iminophosphorance **2**, aromatic isocyanates and hydrazine in 69.6–94.7% isolated yields is reported. The compound **5** reacted with triethyl orthoformate to give compound **6** in good yield (65.8–82.8%). Their structure was clearly confirmed by spectroscopy data (IR, ^{1}H NMR, MS, elemental analysis) and the results of preliminary bioassay indicated that compounds **5** and **6** possess high antifungal activity against *Botrytis cinerea Pers* and *Sclerotinia sclerotiorum*, and compound **5h** showed 100, 96.4, and 90.2% inhibitory rate to *Botrytis cinerea Pers*, *Pyricularia oryzae,* and *Sclerotinia sclerotiorum* at the concentration of 50 mg/L. The antifungal activities of compound **6** were generally higher than those of compound **5**.

J. Heterocyclic Chem., **46**, 256 (2009).

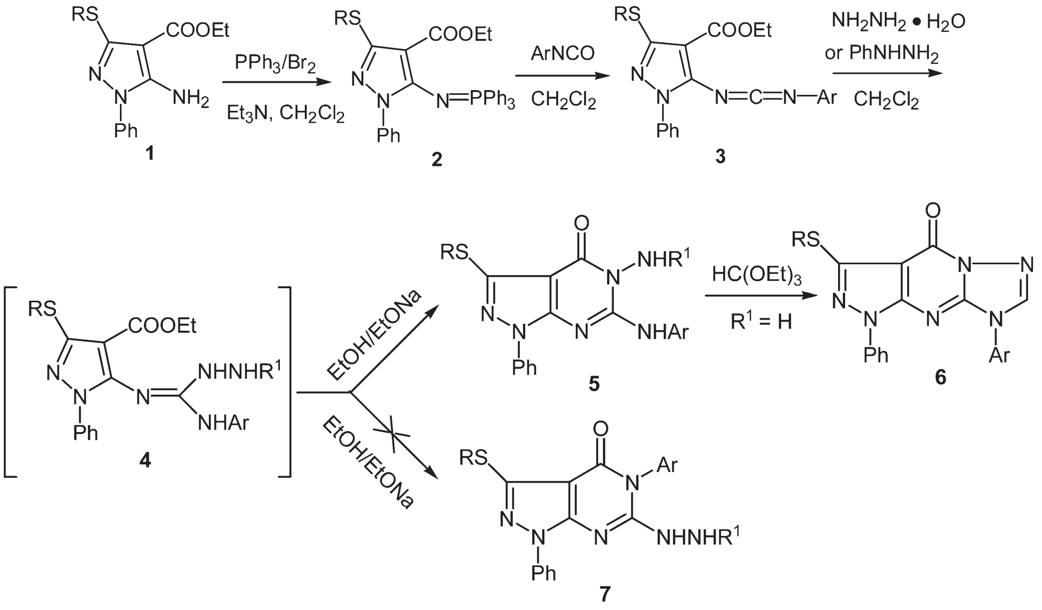
INTRODUCTION

Pyrazolopyrimidines and related fused heterocycles have been the focus of great interest over many years due to the fact that many compounds containing a fused pyrimidinone ring have remarkable biological and chemotherapeutic properties [1]. Pyrazolo[3,4-*d*]-pyrimidines are often employed as mGluR1 antagonists [2], antimicrobial and antifungal or antitumor agents [3], various animal enzyme inhibitors [4], and agrochemicals [5]. Moreover, triazole and its fused heterocycles form part of an extensive investigation of biologically active compounds, such as substituted triazole derivatives [6], triazolo[1,5-*a*]pyrimidine derivatives [7], and their derivatives [8]. In our previous research [5a–d], we reported a reaction of ethyl 3-alkylthio-1-phenyl-5-triphenylphosphoranoimino-1*H*-pyrazole-4-carboxylate (abbreviation iminophosphorane) **2** with isocycanates and alkylamine to give 6-alkylamino-5-aryl-pyrazolo[3,4-*d*]pyrimidin-4-one derivatives, the nitrogen atom of which were from isocyanates. Those compounds showed satisfactory antifungicidal activities. Inspired by the manifold biological activities of pyrazolo[3,4-*d*]pyrimidines and pyrazolotriazolopyrimidine derivatives, we set out to utilize hydrazine to produce new compounds of potential biochemical interest. However, we obtained 5-amino-6-arylamino-1*H*-pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-ones **5** instead of 6-hydrazino-5-aryl-pyrazolo[3,4-*d*]pyrimidin-4-one **7** derivatives. Here, we report a novel facile regioselective synthesis of a new series of 5-amino-6-arylamino-1*H*-pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-ones **5**, having nitrogen atoms from hydrazine, and 2*H*-pyrazolo[3,4-*d*][1,2,4]triazolo[1,5-*a*] pyrimidin-4-one derivatives **6** and their results of preliminary bioassay against *Botrytis cinerea Pers*, *Pyricularia oryzae*, *Gibberella zeae*, and *Sclerotinia sclerotiorum.*

RESULTS AND DISCUSSION

Iminophosphoranes **2** [5a–c] reacted with isocyanates to give the key intermediates carbodiimide **3**. Treatment of **3** with hydrazines at room temperature gave the intermediate guanidines **4** [5a], which, in the presence of NaOEt, reacted to give the crude target compound **5**. After evaporation of part of the solvent, the crude products were collected by filtration. After recrystallization from DMF/petroleum ether or column chromatography on a silica gel, white crystals were obtained in 69.6–94.7% yields (Scheme 1, Table 1). The spectra data

Scheme 1



identified the white crystal as 3-alkylthio-5-amino-6-arylamino-1-phenyl-1*H*-pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-ones **5** instead of the isomer 3-alkylthio-6-hydrazine-5-aryl-1-phenyl-1*H*-pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-ones **7**. In this reaction, a variety of substituents can be tolerated in Ar group, such as electron-donating group (*e.g*., Me), or electron-withdrawing group (*e.g*., F, Cl). R^1 also could be C_6H_5 or H. In the absence of sodium ethoxide, the compound **5** would be obtained with very low yields if the quantity of hydrazine was equal to iminophosphoranes **2**. In contrast, in the presence of a large excess of hydrazine the reaction took place smoothly and the compound **5** was obtained in satisfactory yields even in the absence of NaOEt. On refluxing Compound **5** with triethyl orthoformate, compound **6** was obtained in 65.8–82.8% yields in the present *p*-TsOH.

The structures of compounds **5** and **6** were deduced from their spectra data (^{1}H NMR, IR, EI-MS, and elementary analysis). ^{1}H NMR spectra of compound **5** showed the signal of NH_2 at δ 5.55–5.74 as singlet and compound **6** showed the signal of triazole at δ 9.23–9.34 as singlet [8b]. A combination of chemical shift and couplings allowed the complete and unambiguous assignment of all signals and demonstrated that the major products correspond to structure. The IR spectra of **5** exhibited N—H, C=O, and C=N absorptions. The EI-MS spectra of **5** and **6** showed the molecular ion peak. All the fragmentation ions were consistent with their structures and could be clearly assigned. In addition, the structures of compound **6** further verified the proposed structure of compound **5**. The results of the elementary analysis are within the acceptable range.

Table 1

Yields of compounds **5** and **6**.

Compounds	R	R_1	Ar	Yield of **5** (%)	Yield of **6** (%)
5a, 6a	Me	H	C_6H_5	75.8	71.6
5b, 6b	Me	H	*p*-MeC_6H_4	84.6	73.2
5c, 6c	Me	H	*o*-ClC_6H_4	69.6	82.8

Biological activities. The fungi were obtained from the College of Plant Protect, Central China Agriculture University, China. The antifungal activities of all compounds **5**, **6**, and 2-(4′-thiazoly)-benzimidazole (commercial name: thiabendazole), a commercially available fungicide, were evaluated *in vitro* according to the reported method [9], as shown in Table 2 by contrasting to distilled water. The results showed that all compounds **5** and **6** possessed good inhibition effects against *Sclerotinia sclerotiorum* (inhibition rates 60.7–97.1% and 81.0–100%). Comparing compounds **5** with **6**, it showed that the antifungal activities of compound **6** were generally higher than those of compound **5**. Some of the compounds **5** and **6** exhibited good inhibitory rates against *Botrytis cinerea Pers* and *Pyricularia oryzae*. For example, the inhibitory rates of compounds **6a**, **5b**, **6b**, **5d**, **5f**, and **6f** were 91.8, 94.7, 82.2, 93.0, 89.5, and 91.8% to *Botrytis cinerea Pers* and that of **5f** was 85.7% to *Pyricularia oryzae* at 50 mg/L. It was also interesting to note that compound **5h** showed high antifungal activities to all of *Botrytis cinerea Pers*, *Pyricularia oryzae*, *Gibberella zeae*, and *Sclerotinia sclerotiorum.*

EXPERIMENTAL

Melting points were determined using a WRS-1B Digital melting point apparatus. MS was measured on a Finnigan Trace Mass 2000 Spectrometer at 70 eV. IR was recorded on an Avatar 360 Spectrometer as KBr pellets with absorption given in cm^{-1}. ^{1}H NMR spectra were obtained using a Varian Mercury 400 (or 300) Spectrometer with TMS as the internal reference and DMSO-d_6 or $CDCl_3$ as the solvent. Elementary analysis was taken on a Vario EL III elementary analysis instrument. All of the solvents and materials were of reagent grade and purified as required. Ethyl 5-amino-3-alkylthio-1-phenyl-1*H*-pyrazole-4-carboxylate **1** [10], iminophosphoranes **2** [5a–c] were prepared according to literature.

General procedure for the preparation of 3-alkylthio-5-amino-6-arylamino-1-phenyl-1*H*-pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-ones (5). To a solution of iminophosphorane **2** (2 mmol) in dry methylene dichloride (20 mL) aryl isocyanate (2 mmol) was added under nitrogen atmosphere at room temperature. After the reaction mixture was stirred for 1.5 h, 0.118 g (2.0 mmol, 85%) of hydrazine hydrate or 0.227 g (2.0 mmol) phenylhydrazine was added, and the resulting mixture was stirred for an additional 30 min. Then the solvent was removed under reduced pressure, and 25 mL anhydrous ethanol and 1.5 mL of sodium ethoxide (3 mol/L) in ethanol were added to the mixture. After 3 h of stirring at room temperature, the solution was concentrated under reduced pressure and successively cooled. The crude product was collected by filtration. After recrystallization from DMF/petroleum ether or column chromatography on silica gel, white crystal was obtained.

5-Amino-3-methylthio-1-phenyl-6-phenylamino-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5a). White crystals, mp 236.2–238.1°C; IR (KBr) ν (cm^{-1}): 3336, 3267, 1692, 1596, 1554, 909, 770, 743, 688; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.60 (s, 3H, SCH_3), 5.57 (br s, 2H, NH_2), 7.11 (t, 1H, $J = 7.2$ Hz, Ph), 7.25 (t, 1H, $J = 7.2$ Hz, Ph), 7.36 (t, 2H, $J = 7.6$ Hz, Ph), 7.46 (d, 2H, $J = 7.6$ Hz, Ph), 7.73 (d, 2H, $J = 7.5$ Hz, Ph), 8.03 (d, 2H, $J = 7.8$ Hz, Ph), 9.67 (s, 1H, *NH*Ph); EI-MS (70 eV, *m*/*z*, rel. int.) 365 (M + 1, 49), 364 (M^+, 81); *Anal.* Calcd. for $C_{18}H_{16}N_6OS$: C, 59.32; H, 4.43; N, 23.06; Found: C, 59.1; H, 4.37; N, 22.96.

5-Amino-3-methylthio-1-phenyl-6-tolylamino-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5b). White crystals, mp 235.3–238.6°C; IR (KBr) ν (cm^{-1}): 3333, 3261, 1691, 1597, 1555, 751, 690; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.30 (s, 3H, *p*-$CH_3C_6H_4$), 2.60 (s, 3H, SCH_3), 5.55 (s, 2H, NH_2), 6.85–7.68 (m, 7H, Ar), 8.03 (d, 2H, $J = 7.5$ Hz, Ar), 9.57 (s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 379 (M + 1, 31), 378 (M^+,100); *Anal.* Calcd. for $C_{19}H_{18}N_6OS$: C, 60.30; H, 4.79; N, 22.21; Found: C, 59.99; H, 4.61; N, 22.45.

5-Amino-3-methylthio-1-phenyl-6-(o-chlorophenylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5c). White crystals, mp 248.1–248.8°C; IR (KBr) ν (cm^{-1}): 3328, 3189, 1688, 1598, 1582, 1562, 1543, 1398, 752, 682; ^{1}H NMR (DMSO-d_6, 400 MHz): δ 2.61 (s, 3H, SCH_3), 5.74 (s, 2H, NH_2), 7.20 (t, 1H, *J* = 7.6 Hz, Ar), 7.30 (t, 1H, *J* = 7.6 Hz, Ar), 7.43–7.50 (m, 3H, Ar), 7.58 (d, 1H, *J* = 8.0 Hz, Ar), 8.00 (d, 2H, *J* = 7.6 Hz, Ar), 8.30 (d, 1H, *J* = 8.0 Hz, Ar), 9.85 (br s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 399 (M + 1, 41), 398 (M^+, 66); *Anal.* Calcd. for $C_{18}H_{15}ClN_6OS$: C, 54.20; H, 3.79; N, 21.07; Found: C, 54.32; H, 3.76; N, 21.22.

5-Amino-3-methylthio-1-phenyl-6-(o-fluorophenylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5d). White crystal, mp 238–239°C; IR (KBr) ν (cm^{-1}): 3352, 3314, 3266, 1721, 1621, 1600, 1542 (Ar), 1455, 922, 768; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.61(s, 3H, SCH_3), 5.65 (s, 2H, NH_2), 7.25–7.46 (m, 6H, Ar), 7.98 (d, 3H, *J* = 8.4 Hz, Ar), 9.61(s, 1H, *o*-FC_6H_4*NH*); EI-MS (70 eV, *m*/*z*, rel. int.): 384 (M + 2, 13), 383 (M + 1, 49), 382 (M^+, 89); *Anal.* Calcd. for $C_{18}H_{15}FN_6OS$: C, 56.53; H, 3.95; N, 21.98; Found: C, 56.39; H, 3.92; N, 22.03.

5-Amino-3-benzylthio-1-phenyl-6-phenylamino-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5e). White crystals, mp 226.0–227.8°C, IR (KBr) ν (cm^{-1}): 3319, 1684, 1596, 1554, 927, 759, 689,501; ^{1}H NMR ($CDCl_3$, 300 MHz) δ 4.47 (s, 2H, *CH_2*Ph), 5.58 (s, 2H, NH_2), 7.12 (t, 1H, *J* = 7.2 Hz, Ph), 7.20–7.50 (m, 10H, Ph), 7.73 (d, 2H, *J* = 8.1 Hz), 8.04 (d, 2H, *J* = 8.4 Hz), 9.69 (s, 1H, Ph*NH*); EI-MS (70 eV, *m*/*z*, rel. int.): 442 (M + 2, 2), 441 (M^+, 7); *Anal.* Calcd. for $C_{24}H_{20}N_6OS$: C, 65.44; H, 4.58; N, 19.08; Found: C, 65.52; H, 4.43; N, 19.07.

5-Amino-3-benzylthio-1-phenyl-6-(p-tolylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5f). White crystals, mp 250.0–250.6°C; IR (KBr) ν (cm^{-1}): 3314, 3255, 1689, 1596, 1556, 770, 692; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.29 (s, 3H, CH_3), 4.46 (s, 2H, $PhCH_2$), 5.56 (s, 2H, NH_2), 6.83–6.91 (m, 1H, Ar), 7.16 (d, 2H, *J* = 7.5 Hz, Ar) 7.14–7.49 (m, 7H, Ar), 7.59 (d, 2H, *J* = 7.8 Hz, Ar), 8.04 (d, 2H, *J* = 8.1 Hz, Ar), 9.54 (br s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 454 (M^+, 26); *Anal.* Calcd. for $C_{25}H_{22}N_6OS$: C, 66.06; H, 4.88; N, 18.49; Found: C, 66.25; H, 4.89; N, 18.36.

5-Amino-3-benzylthio-1-phenyl-6-(o-chlorophenylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5g). White crystals, mp 219.6–220.3°C; IR (KBr) ν (cm^{-1}): 3333, 3257, 3192, 1677, 1598, 1585, 1545, 1215, 754, 687; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 4.48 (s, 2H, Ph*CH_2*), 5.74 (br s, 2H, NH_2), 7.22–7.52 (m, 10H, Ar), 7.59 (d, 1H, *J* = 7.6 Hz, Ar), 7.99 (d, 2H, *J* = 7.6 Hz, Ar), 8.30 (d, 1H, *J* = 8.0 Hz, Ar), 9.83 (br s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 474 (M^+, 13); *Anal.* Calcd. for $C_{24}H_{19}ClN_6OS$: C, 60.69; H, 4.03; N, 17.69; Found: C, 60.58; H, 4.09; N, 17.82.

5-Amino-3-methylthio-1-phenyl-6-(p-chlorophenylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5h). White crystals, mp 245.2–247.5°C; IR (KBr) ν (cm^{-1}): 3380, 3311, 3125, 1718, 1601, 1562, 1543, 925, 768; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.60 (s, 3H, SCH_3), 5.57 (s, 2H, NH_2), 7.28 (t, 1H, *J* = 7.2 Hz, Ar), 7.40 (d, 2H, *J* = 8.7 Hz, Ar), 7.49 (t, 2H, *J* = 7.9 Hz, Ar), 7.78 (d, 2H, *J* = 8.7 Hz, Ar), 8.00 (d, 2H, *J* = 7.8 Hz, Ar), 9.81 (s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 399 (M + 1, 41), 398 (M^+, 78); *Anal.* Calcd. for $C_{18}H_{15}ClN_6OS$: C, 54.20; H, 3.79; N, 21.07; Found: C, 54.07; H, 3.71; N, 21.30.

3-Methylthio-1-phenyl-5-phenylamino-6-(p-tolylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5i). White crystals, mp 222.4–222.8°C; IR (KBr) ν (cm^{-1}): 3369, 3252, 1690, 1598, 1546, 949, 761, 689; ^{1}H NMR ($CDCl_3$, 400 MHz) δ 2.34 (s, 3H, C_6H_4*CH_3*), 2.58 (s, 3H, SCH_3), 6.86 (d, 2H, *J* = 7.5 Hz, Ar), 6.91 (t, 1H, *J* = 7.2 Hz, Ar), 7.06 (br s, 1H, Ph*NH*N), 7.13 (d, 2H, *J* = 8.1 Hz, Ar), 7.24–7.27 (m, 3H, Ar), 7.41 (t, 2H, *J* = 8.0 Hz, Ar), 7.50 (d, 2H, *J* = 8.1 Hz, Ar), 8.06 (d, 2H, *J* = 8.1 Hz, Ar), 8.35 (s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 455 (M + 1, 46), 454 (M^+, 81); *Anal.* Calcd. for $C_{25}H_{22}N_6OS$: C, 66.06; H, 4.88; N, 18.49; Found: C, 65.80; H, 4.85; N, 18.57.

3-Methylthio-1-phenyl-5-phenylamino-6-(m-chlorophenylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5j). White crystals, mp 208.5–210.5°C; IR (KBr) ν (cm^{-1}): 3342, 3261, 1695, 1599, 1545, 951, 759, 683; ^{1}H NMR ($CDCl_3$, 300 MHz) δ 2.54 (s, 3H, SCH_3), 6.84 (d, 2H, *J* = 7.5 Hz, Ar), 7.01 (t, 2H, *J* = 7.2 Hz), 7.08–7.29 (m, 5H, Ar and Ph*NH*N), 7.45 (t, 2H, *J* = 7.8 Hz, Ar), 8.01 (d, 2H, *J* = 7.8 Hz, Ar), 8.14 (s, 1H, *m*-ClC_6H_4), 8.51 (s, 1H, Ar*NH*); EI-MS (70 eV, *m*/*z*, rel. int.) 475 (M + 1, 35), 474 (M^+, 69); *Anal.* Calcd. for $C_{24}H_{19}ClN_6OS$: C, 60.69; H, 4.03; N, 17.69; Found: C, 60.39; H, 4.00; N, 17.72.

3-Benzylthio-1-phenyl-5-phenylamino-6-(p-tolylamino)-1H-pyrazolo[3,4-d]pyrimidin-4(5H)-one (5k). White crystals, mp 198.6–198.8°C; IR (KBr) ν (cm^{-1}): 3317, 3271, 1701, 1592, 1547, 772, 688; ^{1}H NMR ($CDCl_3$, 400 MHz) δ 2.34 (s, 3H, C_6H_4*CH_3*), 4.42 (s, 2H, Ph*CH_2*), 6.86 (d, 2H, *J* = 7.5 Hz, Ar), 7.01 (t, 2H, *J* = 6.9 Hz, Ar), 7.12–7.28 (m, 8H, Ar and Ph*NH*N), 7.39–7.43 (m, 4H, Ar), 7.48 (t, 2H, *J* = 6.4 Hz, Ar), 8.07 (d, 2H, *J* = 7.8 Hz, Ar), 8.33 (s, 1H, NH); EI-MS (70 eV, *m*/*z*, rel. int.) 531 (M + 1, 26), 530 (M^+, 50); *Anal.* Calcd. for $C_{31}H_{26}N_6OS$: C, 70.17; H, 4.94; N, 15.84; Found: C, 69.89; H, 5.00; N, 15.63.

General Procedure for the preparation of 3-alkylthio-8-aryl-phenyl-1,8-dihydropyrazolo[3,4-*d*][1,2,4]triazolo[1,5-*a*] pyrimidin-4-one (6). To a suspension of the appropriate 5-amino-3-alkylthio-6-arylamino-1-phenyl-1*H*- pyrazolo[3,4-*d*]pyrimidin-4(5*H*)-one **5** (1.5 mmol) in 25 mL of triethyl orthoformate *p*-toluenesulfonic acid (*p*-TsOH) (0.4 g, 2.25 mmol) was added. The reaction mixture was refluxed for 15 h under stirring. After cooling to room temperature, a yellowish substance precipitated. The crude product was collected by filtration and washed with water. After recrystallization from dimethylformamide, the products were obtained as colorless crystal.

3-Methylthio-1,8-diphenyl-1,8-2H-pyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6a). White crystals, mp 253–255°C, IR (KBr) ν (cm^{-1}): 3144, 3081, 2925, 1718, 1605, 1578, 1560, 1527, 1388, 1265, 1165, 902, 768; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.65 (s, 3H, SCH_3), 7.31 (t, 1H, *J* = 6.8 Hz, Ph), 7.49–7.57 (m, 3H, Ph), 7.67 (t, 2H, *J* = 8.2 Hz, Ph), 7.93 (d, 2H, *J* = 8.0 Hz, Ph), 8.08 (d, 2H, *J* = 8.4 Hz, Ph), 9.34 (s, 1H, triazole-H); EI-MS (70 eV, *m*/*z*, rel. int.) 375 (M + 1, 13), 374 (M^+, 36); *Anal.* Calcd. for $C_{19}H_{14}N_6OS$: C, 60.95; H, 3.77; N, 22.45; Found: C, 61.02; H, 3.75; N, 22.53.

3-Methylthio-1-phenyl-8-(p-methylphenyl)-1,8-2H-pyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6b). White crystals, mp 253–256°C, IR(KBr) ν (cm^{-1}): 3133, 3076, 2919, 1721, 1596, 1574, 1398, 1169, 900, 767, 673; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.41 (s, 3H, *p*-*CH_3*Ph), 2.67 (s, 3H, SCH_3), 7.31 (t, 1H, *J* = 7.6 Hz, Ar), 7.45–7.53 (m, 4H, Ar), 7.80 (d, 2H, *J* = 8.0 Hz, Ar), 8.07 (d, 2H, *J* = 8.0 Hz, Ar), 9.29 (s, 1H, triazole-H); EI-MS (70 eV, *m/z*, rel. int.) 389 (M + 1, 22), 388 (M^+, 62); *Anal.* Calcd. for $C_{20}H_{16}N_6OS$: C, 61.84; H, 4.15; N, 21.63; Found: C, 61.90; H, 4.13; N, 21.65.

3-Methylthio-1-phenyl-8-(o-chlorophenyl)-1,8-dihydropyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6c). White crystals, mp 216–218°C, IR (KBr) ν (cm^{-1}): 3139, 3069, 1722, 1609, 1585, 1525, 1398, 1229, 1124, 902, 766, 687; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.64 (s, 3H, SCH_3), 7.27 (t, 1H, $J = 7.6$ Hz, Ar), 7.44 (t, 2H, $J = 7.8$ Hz, Ar), 7.66–7.70 (m, 2H, Ar), 7.83–7.90 (m, 2H, Ar), 7.94 (d, 2H, $J = 8.0$ Hz, Ph), 9.23 (s, 1H, triazole-H); EI-MS (70 eV, *m/z*, rel. int.): 409 (M + 1, 32), 408 (M^+, 57); *Anal.* Calcd. for $C_{19}H_{13}ClN_6OS$: C, 55.81; H, 3.20; N, 20.55; Found: C, 55.85; H, 3.22; N, 20.51.

3-Methylthio-1-phenyl-8-(o-fluorophenyl)-1,8-dihydropyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6d). White crystal, mp 224–225°C; IR (KBr) ν (cm^{-1}): 3146, 1712, 1607, 1585, 1525, 1509, 1398, 1234, 904, 769, 752; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.65 (s, 3H, SCH_3), 7.29 (t, 1H, $J = 7.4$ Hz, Ar), 7.44–7.69 (m, 5H, Ar), 7.92 (t, 1H, $J = 7.6$ Hz, Ar), 8.00 (d, 2H, $J = 8.0$ Hz, Ar), 9.23 (s, 1H, triazole-H); EI-MS (70 eV, *m/z*, rel. int.): 393 (M + 1, 31), 392 (M^+, 63); *Anal.* Calcd. for $C_{19}H_{13}FN_6OS$: C, 58.15; H, 3.34; N, 21.42; Found: C, 58.13; H, 3.32; N, 21.48.

3-Benzylthio-1,8-diphenyl-1,8-dihydropyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6e). White crystals, mp 224–226°C; IR (KBr) ν (cm^{-1}): 3118, 3064, 1718, 1608, 1580, 1528, 1389, 1163, 757, 685; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 4.51 (s, 2H, PhCH_2), 7.26 (t, 1H, $J = 7.2$ Hz, Ph), 7.34 (t, 3H, $J = 7.4$ Hz, Ph), 7.50–7.67 (m, 7H, Ph), 7.92 (d, 2H, $J = 7.6$ Hz, Ph), 8.08 (d, 2H, $J = 7.6$ Hz, Ph), 9.34 (s, 1H, triazole-H); EI-MS (70 eV, *m/z*, rel. int.) 450 (M^+, 8); *Anal.* Calcd. for $C_{25}H_{18}N_6OS$: C, 66.65; H, 4.03; N, 18.65; Found: C, 66.70; H, 4.02; N, 18.70.

3-Benzylthio-8-(p-tolyl)-1-phenyl-1,8-dihydropyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6f). White crystals, mp 257–259°C; IR (KBr) ν (cm^{-1}): 3137, 2923, 1718, 1601, 1580, 1527, 1390, 1165, 978, 769, 702; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 2.41 (s, 3H, *p*-CH_3Ph), 4.52 (s, 2H, PhCH_2), 7.32–7.53 (m, 10H, Ar), 7.79 (d, 2H, $J = 8.0$ Hz, Ar), 8.08 (d, 2H, $J = 8.0$ Hz, Ar), 9.29 (s, 1H, triazole-H); EI-MS (70 eV, *m/z*, rel. int.): 464 (M^+, 6); *Anal.* Calcd. for $C_{26}H_{20}N_6OS$: C, 67.22; H, 4.34; N, 18.09; Found: C, 67.26; H, 4.37; N, 18.12.

3-Benzylthio-8-(o-chlorophenyl)-1-phenyl-1,8-dihydropyrazolo[3,4-d][1,2,4]triazolo[1,5-a]pyrimidin-4-one (6g). White crystals, mp 221–223°C; IR (KBr) ν (cm^{-1}): 3144, 1718, 1704, 1605, 1561, 1399, 1122, 1065, 905, 770, 687; ^{1}H NMR (DMSO-d_6, 400 MHz) δ 4.52 (s, 2H, PhCH_2), 7.26–7.89 (m, 12H, Ar), 7.94 (d, 2H, $J = 8.4$ Hz, Ar), 9.23 (s, 1H, triazole-H); EI-MS (70 eV, *m/z*, rel. int.): 393 (M + 1, 9), 392 (M^+, 6); *Anal.* Calcd. for $C_{15}H_{17}ClN_6OS$: C, 61.92; H, 3.53; N, 17.33; Found: C, 62.00; H, 3.58; N, 17.32.

Acknowledgments. This work was supported by the Hunan Provincial Natural Science Foundation of China (No. 05JJ30022) and Scientific Research Fund of the Hunan Provincial Education Department (No. 06B081).

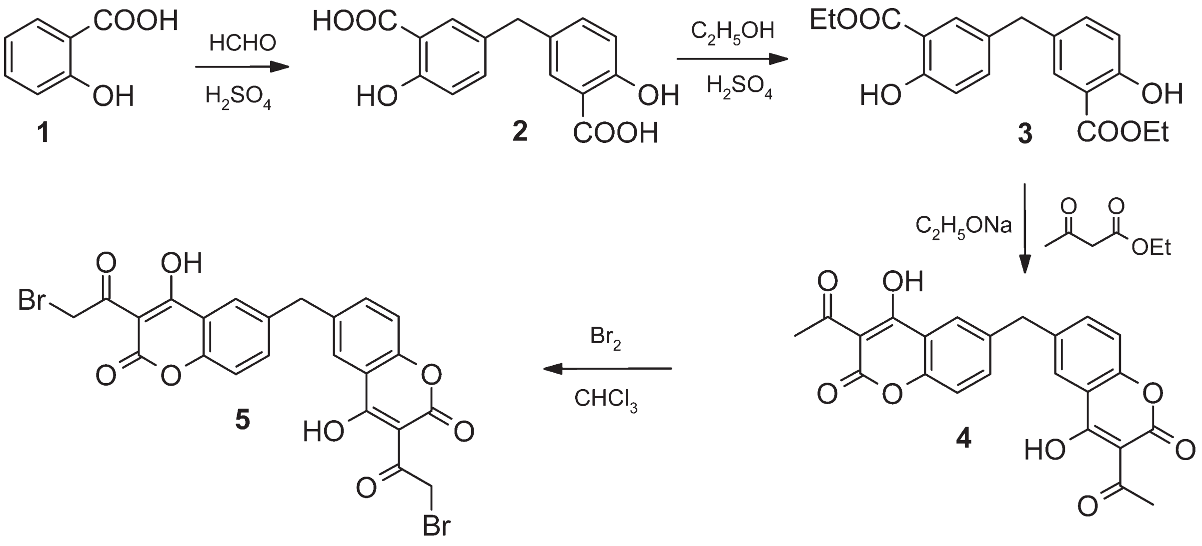
A series of novel bis-[3-(2-arylmethylidenimino-1,3-thiazol-4-yl)-4-hydroxy-*2H*-chromen-2-one-6-yl]methane **7a-f** and bis-[3-(2-arylidenhydrazo-1,3-thiazol-4-yl)-4-hydroxy-*2H*-chromen-2-one-6-yl]-methane **8a-f** were synthesized in good yields from bis-[3-(2-bromoacetyl-4-hydroxy-*2H*-chromen-2-one-6-yl]methane **5**. The chemical structures of the newly synthesized compounds were elucidated by their IR, ^{1}H NMR, MS, and elemental analyses. Further, all the compounds were screened for their antimicrobial activity against Gram-positive, Gram-negative bacteria, and fungi. Among the synthesized compounds, **7c**, **7e,** and **8c** were found to be the most active against almost all the test bacteria. The compound **8c** displayed notable antibacterial activity against *Bacillus subtilis* (ATCC 6633), *Staphylococcus aureus* (ATCC6538p), *Micrococcus luteus* (IFC 12708), *Proteus vulgaris* (ATCC 3851) and *Salmonella typhimurium* (ATCC 14028), equal to that of ampicillin. Similarly these compounds also showed potent antifungal effect against *Candida albicans* (ATCC 10231), *Aspergillus fumigatus* (HIC 6094), *Trichophyton rubrum* (IFO 9185), and *Trichophyton mentagrophytes* (IFO 40996).

J. Heterocyclic Chem., **46**, 261 (2009).

INTRODUCTION

The treatment of infectious diseases still remains an important and challenging problem because of a combination of factors including emerging infectious diseases and the increasing number of multidrug resistant microbial pathogens. Despite a large number of antibiotics and chemotherapeutics available for medical use, at the same time the emergence of old and new antibiotic resistance created in the last decades revealed a substantial medical need for new classes of antimicrobial agents. There is a real perceived need for the discovery of new compounds endowed with antimicrobial activity, possibly acting through mechanism of action, which are distinct from those of well-known classes of antibacterial agents to which many clinically relevant pathogens are now resistant. Similarly in the recent decades, an increased incidence of fungal infections has been observed as a consequence of the growing number of immunocompromised patients and the frequent use of antibacterial and cytotoxic drugs. For many fungal

Scheme 1



infections, polyenes, such as amphotericin B, represent the standard therapy. Polyenes bind to membrane sterols, leading to membrane permeability, leakage, and cell death. However, the clinical use of amphotericin B is limited by a high frequency of renal toxicity, and several adverse effects [1]. Although the various molecules were designed and synthesized for the above aim and to reduce the adverse effects, it was demonstrated that azoles and thiazoles, such as fluconazole, which act on ergosterol biosynthesis, offer several advantages in terms of decreased toxicity after oral or intravenous [2] administration and are often employed in the treatment of fungal infections, therefore the thiazoles, azoles, and their derivatives could be considered as possible antimicrobial agents [3].

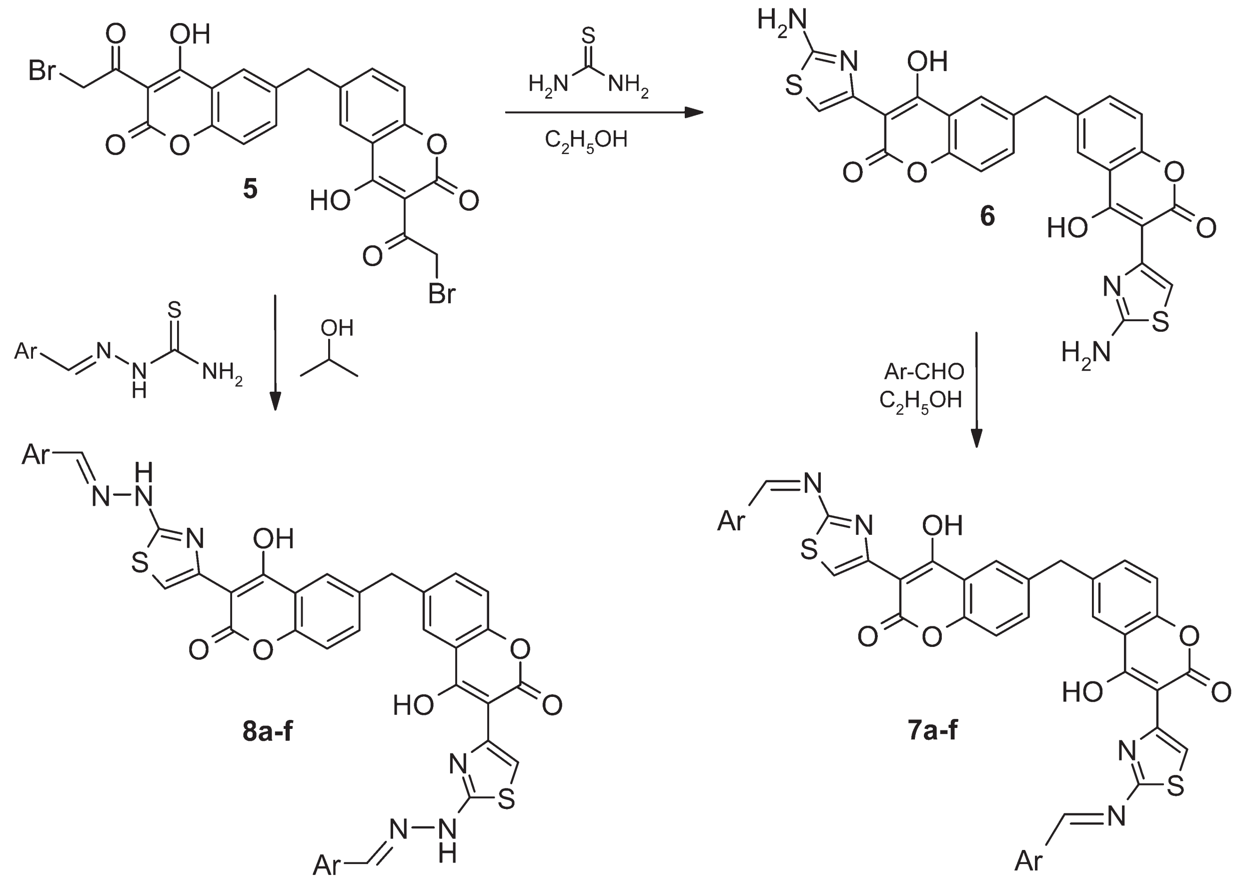
The thiazole nucleus also appears frequently in the structure of various natural products and biologically active compounds, notably thiamine (vitamin-B), antibiotics such as penicillin, micrococcin [4], troglitazone [5], and many metabolic products of fungi and primitive marine animals, including 2-(aminoalkyl)thiazole-4-carboxylic acids [6]. Similarly coumarins are a class of compounds with biological activity [7], such as analgesics [8], anticoagulant [9], specific inhibitors of α-chymotripsin [10], human leukocyte elastase [11], diuretics [12], platelet aggregation [13], anticancer [14], inhibitor of HIV-1 protease [15], and antibacterial agents [16]. Following the successful introduction of antimicrobial agents, inspired by the biological profile of thiazole and coumarin and their increasing importance in pharmaceutical and biological fields, and in continuation of our research on biologically active heterocycles [17] considering the scope to introduce thiazolyl moiety into the coumarin ring, it was thought worthwhile to undertake the synthesis of the title compounds with the view to obtain certain new chemical entities with both active pharmacophores in a single molecular frame work for the potential intensified biological activities.

In this article, we wish to report the synthesis of novel bis-[3-(2-arylmethylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane **7** in good yields, from bis-[3-(2-amino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane **6**, which in tern is synthesized by the reaction of bis-[3-(2-bromoacetyl-4-hydroxy-2*H*-chromen-2-one-6-yl]methane **5** with thiourea, and also the synthesis of novel bis-[3-(2-arylidenhydrazo-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane **8** in good yields, from compound **5** and arylthiosemicarbazone (Schemes 1 and 2). The antibacterial and antifungal activities of the compounds **7a-f** and **8a-f** have also been evaluated.

RESULTS AND DISCUSSION

The key intermediate **5**, required for the synthesis of the title compounds was prepared according to the procedure outlined in the Scheme 1. Condensation of the salicylic acid **1** and formaldehyde in the presence of sulfuric acid gave bis-(4-hydroxy-3-carboxyphenyl)methane **2** in good yield [18]. Compound **2** was then reacted with ethyl alcohol in presence of catalytic amount of sulfuric acid to afford bis-(4-hydroxy-3-carbethoxyphenyl)methane **3** in good yield [17b], subsequently cyclocondensation of compound **3** with ethylacetoacetate in presence of sodium ethoxide gave bis-(3-acetyl-4-hydroxy-2*H*-chromen-2-one-6-yl)methane **4** [17b]. α-Bromination of compound **4** with bromine in chloroform

Scheme 2



7/8: Ar = **a**) C_6H_5; **b**) 4-NO_2-C_6H_4; **c**) 4-Br-C_6H_4; **d**) 4-MeO-C_6H_4; **e**) 3,4-(O-CH_2-O)C_6H_3; **f**) 2-furyl

at low temperature afforded bis-[3-(2-bromoacetyl-4-hydroxy-2*H*-chromen-2-one-6-yl] methane **5** in 85% yield. The cyclocondensation of compound **5** with thiourea in refluxing ethanol gave bis-[3-(2-amino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane **6** in 78% yield. Subsequently condensation of compound **6** with various aromatic aldehydes in refluxing ethanol gave the title compound bis-[3-(2-arylmethylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane **7a-f** in good to excellent yields (Scheme 2).

Further, the intermediate **5** was treated with the various arylthiosemicarbazone (prepared by the reaction of aromatic aldehydes with thiosemicarbazide in presence of sodium acetate in acetic acid) in refluxing isopropyl alcohol to give the other title compound bis-[3-(2-arylidenhydrazo-1,3-thiazol-4-yl)-4-hydroxy-*2H*-chromen-2-one-6-yl]methane **8a-f** in good yields (Scheme 2). The structures of all the synthesized compounds were confirmed by their IR, ^{1}H NMR, MS, and elemental analyses and further screened for their antibacterial and antifungal activities.

Antibacterial activity. The *in vitro* antibacterial activity of the newly prepared compounds was screened against three representative gram-positive bacteria *viz. Bacillus subtilis* (ATCC 6633), *Staphylococcus aureus* (ATCC 6538p), and *Micrococcus luteus* (IFC 12708), three Gram-negative bacteria *viz. Proteus vulgaris* (ATCC 3851), *Salmonella typhimurium* (ATCC 14028), and *Escherichia coli* (ATCC 25922) by the broth dilution method, recommended by National Committee for Clinical Laboratory Standards (NCCLS) [19]. Bacteria were grown over night in Luria Bertani (LB) broth at 37°C, harvested by centrifugation, and then washed twice with sterile distilled water. Stock solutions of the series of compounds were prepared in DMSO. Each stock solution was diluted with standard method broth (Difco) to prepare serial two-fold dilutions in the range of 50–0.8 μg/mL. Ten microtiters of the broth containing about 10^5 colony forming units (cfu)/mL of test bacteria was added to each well of 96-well microtiter plate. Culture plates were incubated for 24 h at 37°C, and the growth was monitored visually and

Table 1

Antibacterial activity of compounds **7a-f** and **8a-f**.

	Minimum inhibitory concentration (MIC, μg/mL)					
Compound	*B. subtilis*	*S. aureus*	*M. luteus*	*P. vulgaris*	*S. typhimurium*	*E. coli*
7a	25.0	25.0	—	—	25.0	—
7b	12.5	12.5	12.5	12.5	12.5	25.0
7c	3.12	6.25	1.56	1.56	3.12	6.25
7d	12.5	12.5	6.25	—	12.5	25.0
7e	6.25	6.25	3.12	12.5	12.5	12.5
7f	25.0	12.5	3.12	12.5	6.25	25.0
8a	25.0	25.0	50.0	—	50.0	—
8b	6.25	12.5	12.5	25.0	12.5	25.0
8c	1.56	1.56	1.56	1.56	1.56	12.5
8d	12.5	12.5	12.5	12.5	12.5	—
8e	3.12	3.12	3.12	6.25	3.12	6.25
8f	12.5	12.5	6.25	6.25	12.5	12.5
Ampicillin	1.56	1.56	1.56	3.12	3.12	12.5

—Indicates bacteria are resistant to the compound >50 μg/mL concentration. Standard deviation 0.05.

spectrophotometrically. Amphicillin was used as a standard drug, the lowest concentration (highest dilution) required to arrest the growth of bacteria was regarded as minimum inhibitory concentration (MIC, μg/mL), was determined for all the compounds and compared with the control. The MIC values of the compounds screened are given in Table 1.

The investigation of antibacterial screening data revealed that all the tested compounds exhibited interesting biological activity however, with a degree of variation. Compound **8c** is highly active against all the microorganisms employed, except *E. coli*, at 1.56 μg/mL concentration, it is almost equal to the standard. Compound **7c** is also highly active but only against *M.luteus* and *P. vulgaris* at the same concentration as **8c**. The compound **8e** also showed good antibacterial activity against *B.subtilis*, *S. aureus*, *M. Luteus*, and *S. typhimurium*.

Compound **7a** is almost inactive towards *M. luteus*, *P. vulgaris*, and *E. coli*. The remaining compounds showed moderate to good activity.

Antifungal activity. The newly prepared compounds were screened for their antifungal activity against four fungal organism *viz*. *Candida albicans* (ATCC 10231), *Aspergillus fumigatus* (HIC 6094), *Trichophyton rubrum* (IFO 9185), and *Trichophyton mentagrophytes* (IFO 40996). *C. albicans* was grown for 48 h at 28°C in YPD broth (1% yeast extract, 2% peptone, and 2% dextrose), harvested by centrifugation and then washed twice with sterile distilled water. *A. fumigatus*, *T. rubrum*, and *T. mentagrophytes* were plated in potato dextrose agar (PDA) (Difco) and incubated at 28°C for two weeks. Spores were washed three times with sterile distilled water and resuspended in distilled water to obtain an initial inoculum size of 10^5 spores/mL. Each test compound was dissolved in DMSO and diluted with potato dextrose broth (Difco) to prepare serial two-fold dilutions in the range of 100 to 0.8 μg/mL. Ten microtiters of the broth containing about 10^3 (for yeast) and 10^4 (for filamentous fungi) cells/mL of test fungi was added to each well of a 96-well microtiter plate. Culture plates were incubated for 48 ~ 72 h at 28°C. The fungal activity of each compound was compared with standard drug Amphotericin B. Minimum inhibitory concentration (MIC, μg/mL) were measured and compared with controls; the MIC values of the compounds screened are given in Table 2.

The antifungal screening data showed only moderate activity of the test compounds. Among the screened compounds, compound **7c** is highly active against *T. rubrum*, *T. mentagrophytes*, compound **7e** is also active against only *C. albicans* and compound **8c** is highly active against *C. albicans*, *T. mentagrophytes*, the activity of these compounds are almost equal to the standard, it is interesting to note that compounds **7e** and **8c** showed good antifungal activity toward *C. albicans* at the concentration of 3.12 μg/mL, it is less than the concentration of standard.

In conclusion, a series of novel bis-[3-(2-arylmethyllidenimino-1,3-thiazol-4-yl)-4-hydroxy-*2H*-chromen-2-one-6-yl]methane **7** and novel bis-[3-(2-arylidenhydrazo-1,3-thiazol-4-yl)-4-hydroxy-*2H*-chromen-2-one-6-yl]methane **8** has been designed and synthesized. The antimicrobial activity of these compounds was evaluated against various Gram-positive, Gram-negative bacteria and fungi. Among the synthesized compounds, **7c**, **7e,** and **8c** showed good activity against bacteria and fungi

Table 2

Antifungal activity of compounds **7a-f** and **8a-f**.

and emerged as potential molecules for further development.

EXPERIMENTAL

Research chemicals were purchased from either Aldrich Company or Fluka and used without further purification, or were prepared according to the procedure described in the literature. Reactions were monitored by thin layer chromatography (TLC) on silica gel plates (60 F_{254}; Merck) visualizing with ultraviolet light or iodine vapors. The yields of the products reported here are unoptimized. Melting points were determined on a Fisher-Johns apparatus and are uncorrected. IR spectra were recorded on a Perkin-Elmer FTIR 5000 spectrometer, using KBr pellets. ^{1}H NMR spectra were recorded on a Varian Gemini spectrometer, operating at 300 MHz. Chemical shifts (δ) are reported in parts per million down field from tetramethylsilane. Mass spectra were obtained on a VG micro mass 7070H spectrometer operating at 70 eV. Elemental analyses were performed on a Perkin-Elmer 240 CHN elemental analyzer.

Synthesis of bis-[3-(2-bromoacetyl-4-hydroxy-2*H*-chromen- 2-one-6-yl] methane (5). To a stirred solution of **4** (1 mmol) in chloroform (20 mL), was added drop wise a solution of bromine (3 mmol) dissolved in chloroform (20 mL) at 0–5°C. The mixture was further stirred for 4 h. After completion of the reaction, monitored by TLC, the mixture was then poured into ice cold water. Crude product was collected by filtration, washed with water, dried, and recrystallized from ethanol to give pure compound **5** in 85% of yield as red solid, mp 208–210°C; IR (KBr): ν 3480, 1728, 1680, 1587, 1180, 586 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 15.07 (2H, s, OH), 7.50 (2H, s, ArH), 7.18 (2H, d, J = 8.62 Hz, ArH), 7.14 (2H, d, J = 8.62 Hz, ArH), 4.21 (4H, s, CH_2Br), 3.98 (2H, s, CH_2); MS: m/z 578 (M^+). Anal. calcd for $C_{23}H_{14}Br_2O_8$: C, 47.78; H, 2.44. Found: C, 47.72; H, 2.46.

Synthesis of bis-[3-(2-amino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (6). To a stirred solution of thiourea (3 mmol) in 1-propanol (20 mL), was added drop wise a solution of **5** (1 mmol) in 1-propanol (20 mL) over a period of 30 min. The mixture was refluxed for 3 h, and then pyridine (5 mL) was added and continued reflux for 5 h. After completion of the reaction, monitored by TLC, the solvent was removed *in vacuo*. The crude product was dried and crystallized from ethanol to give compound **6** in 78% of yield as brown solid, mp 224-26°C; IR (KBr): ν 3480-3275, 1720, 1614, 1582, 758, 638 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 7.78 (2H, s, ArH), 7.63 (2H, s, ArH), 7.40 (4H, bs, NH_2), 7.32 (2H, s, OH), 7.23 (2H, d, J = 8.72 Hz, ArH), 7.14 (2H, d, J = 8.72 Hz, ArH), 3.98 (2H, s, CH_2); MS: m/z 532 (M^+). Anal. calcd for $C_{25}H_{16}N_4O_6S_2$: C, 56.39; H, 3.03; N, 1052. Found: C, 55.82; H, 3.09; N, 10.44.

Synthesis of bis-[3-(2-arylmethylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (7a-f). A mixture of aromatic aldehyde (2 mmol) and compound **6** (1 mmol) in ethanol (20 mL) was refluxed for 1 h. After completion of the reaction (monitored by TLC), the mixture was cooled and the solvent evaporated. The formed crude product was washed with cold aq. ethanol and then the product was purified by recrystallization from ethanol to afford pure compound **7**.

Bis-[3-(2-phenylmethylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (7a). This compound was obtained as yellow solid; Yield 81%; Mp 254-56°C; IR (KBr): ν 3410, 3062, 1720, 1615, 1580, 1471, 1180, 638 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 11.07 (2H, s, OH), 8.47 (2H, s, ArH), 8.26 (2H, s, CH), 7.62 (2H, s, ArH), 7.38 (4H, d J = 7.2 Hz, ArH), 7.30 (4H, d, J = 7.2 Hz, ArH), 7.19 (2H, d, J = 8.72 Hz, ArH), 7.17 (4H, s, ArH), 3.99 (2H, s CH_2); MS: m/z 532 (M^+). Anal. calcd. for $C_{39}H_{24}N_4O_6S_2$: C, 66.09; H, 3.41; N, 7.90. Found: C, 66.00; H, 3.36; N, 7.92.

Bis-[3-(2-(4-nitrophenyl)methylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (7b). This compound was obtained as brown solid; Yield 76%; Mp 247-49°C;

IR (KBr): ν 3410, 3065, 1728, 1612, 1580, 1472, 1345, 1180, 638 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 11.72 (2H, s, OH), 8.46 (2H, s, ArH), 8.28 (2H, s, CH), 8.24 (4H, d, J = 8.5 Hz, ArH), 7.72 (4H, d, J = 8.5 Hz, ArH), 7.62 (2H, s, ArH), 7.20 (2H, d, J = 8.72 Hz, ArH), 7.17 (2H, d, J = 8.7 Hz, ArH), 4.00 (2H, s CH$_2$); MS: m/z 799 (M$^+$ +1). Anal. calcd. for $C_{39}H_{22}N_6O_{10}S_2$: C, 58.65; H, 2.78; N, 10.52. Found: C, 58.60; H, 2.80; N, 10.46.

Bis-[3-(2-(4-bromophenyl)methylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (7c). This compound was obtained as yellow solid; Yield 75%; Mp 223-25°C; IR (KBr): ν 3410, 3065, 1720, 1616, 1582, 1474, 1180, 638, 586 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 11.72 (2H, s, OH), 8.46 (2H, s, ArH), 8.28 (2H, s, CH), 7.62 (2H, s, ArH), 7.49 (4H, d, J = 8.5 Hz, ArH), 7.38 (4H, d, J = 8.3 Hz, ArH), 7.20 (2H, d, J = 8.72 Hz, ArH), 7.17 (2H, d, J = 8.7 Hz, ArH), 4.00 (2H, s CH$_2$); MS: m/z 866 (M$^+$). Anal. calcd. for $C_{39}H_{22}Br_2N_4O_6S_2$: C, 54.06; H, 2.56; N, 6.47. Found: C, 54.00; H, 2.51; N, 6.50.

Bis-[3-(2-(4-methoxyphenylmethylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (7d). This compound was obtained as red solid; Yield 74%; Mp 252-54°C; IR (KBr): ν 3410, 3065, 1728, 1615, 1584, 1472, 1250, 1180, 638 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 11.42 (2H, s, OH), 8.49 (2H, s, ArH), 8.34 (2H, s, CH), 7.62 (2H, s, ArH), 7.21 (2H, d, J = 8.52 Hz, ArH), 7.14 (2H, d, J = 8.52 Hz, ArH), 7.09 (4H, d, J = 8.51 Hz, ArH), 6.72 (4H, d, J = 8.51 Hz, ArH), 4.00 (2H, s CH$_2$), 3.79 (6H, s, OCH$_3$); MS: m/z 768 (M$^+$). Anal. calcd. for $C_{41}H_{28}N_4O_8S_2$: C, 64.05; H, 3.67; N, 7.29. Found: C, 64.09; H, 3.64; N, 7.22.

Bis-[3-(2-(3,4-methylendioxyphenyl)methylidenimino-1,3-thiazol-4-yl)-4-hydroxy-2*H*-chromen-2-one-6-yl]methane (7e). This compound was obtained as black solid; Yield 76%; Mp 262-64°C; IR (KBr): ν 3415, 3062, 1728, 1615, 1584, 638 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 11.59 (2H, s, OH), 8.52 (2H, s, ArH), 8.30 (2H, s, CH), 7.62 (2H, s, ArH), 7.20-7.18 (2H, m, ArH), 7.12 (2H, d, J = 8.52 Hz, ArH), 6.87 (2H, d, J = 7.56 Hz, ArH), 6.80 (2H, d, J = 7.56 Hz, ArH), 5.81 (4H, s, CH$_2$), 4.00 (2H, s, CH$_2$); MS: m/z 796 (M$^+$). Hexaminium salts of 4-pyrones **3a, b** were synthesized by treatment of 2-(4-bromomethylphenyl)-6-methyl-4*H*-pyran-4-one **2a** and 2-(4-bromomethylphenyl)-6-phenyl-4*H*-pyran-4-one **2b** with hexamethylenetetramine in chloroform in 71 and 84% yields respectively. Hydrolysis of **3a** and **3b** in EtOH:H_2O produced the corresponding aldehydes **4a** and **4b** in 43 and 58% yields respectively. The reaction of bromopyrones **2b** and **2c** with dimethylsulfide in MeOH: CH_2Cl_2 afforded the corresponding sulfonium salts **5b** and **5c** in 66 and 65% yields respectively. Treatment of **5b** and **5c** with arene carbaldehydes such as (Ar = *p*-ClC_6H_4, *o*-ClC_6H_4, *p*-$NO_2C_6H_4$, *o*-$NO_2C_6H_4$, *p*-FC_6H_4, 2-naphthyl, *p*-$MeOC_6H_4$, C_6H_5CH=CH, *p*-MeC_6H_4, C_6H_5 and 4-(4-oxo-6-phenyl-4*H*-pyran-2-yl)-benzaldehyde **4b**) in the presence of sodium hydroxide in CH_3CN:H_2O afforded eleven *trans*-epoxides in 61–93% yields.

J. Heterocyclic Chem., **46**, 268 (2009).

INTRODUCTION

For many years, 4-pyrones have been extensively studied due to a wide range of applications. They are biologically active and synthetically useful compounds [1–9]. Among their various biological properties anti-HIV [10,11] and anti-cancer effects have aroused considerable attention [12,13]. Furthermore epoxides are useful and important synthetic precursors and have found divers applications in organic synthesis [14,15]. There are many reports on the synthesis of epoxides possessing various heterocyclic moieties [16–18]. However synthesis and reactions of pyrone sulfonium salts and corresponding ylides with arene carbaldehydes have not been reported as yet. Thus, we became interested in the synthesis, characterization and evaluation of this category of compounds.

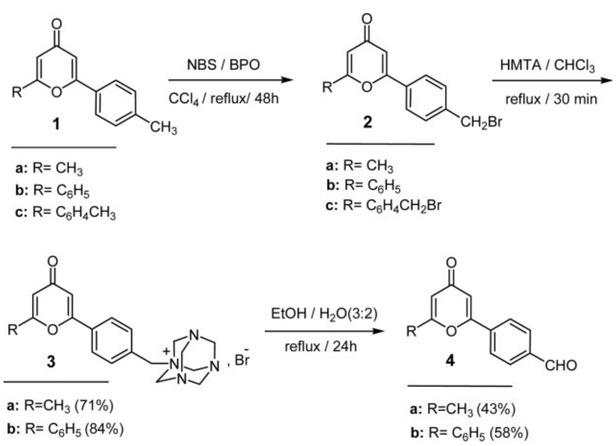
RESULTS AND DISCUSSION

We are interested in synthesis and developing the chemistry of pyrone derivatives [19–21]. In continuation of our investigations we have synthesized pyrone sulfonium ylides, arene carbaldehydes **4a**, **b** and corresponding *trans*-epoxides.Arylpyrones **1a** and **1b** were prepared according to the literature in two steps [22]. Bromination of pyrones **1(a–c)** with *N*-bromosuccinimide (NBS) produced the corresponding bromopyrones **2(a–c)** in 55–70% yields respectively [23]. The hexaminium salts **3a, b** were synthesized by reaction of bromopyrones **2a, b** with hexamethylenetetramine (HMTA) in dry chloroform in 71 and 84% yields respectively. Treatment of **3a** and **3b** with EtOH:H_2O under reflux afforded the corresponding aldehydes **4a** and **4b** in 43 and 58% yields respectively (Scheme 1).

The structures of all new compounds **3a, b** and **4a, b** were established on the basis of the FT-IR, ^{1}H NMR, ^{13}C NMR, mass spectral data and elemental analysis.

The sulfonium salts **5b** and **5c** were synthesized by reaction of bromopyrones **2b** and **2c** with dimethylsulfide in MeOH:CH_2Cl_2 in 66 and 65% yields respectively

Scheme 1



(Scheme 2). It can be seen from the experimental section that all spectroscopic data (FT-IR, ^{1}H NMR, ^{13}C NMR) and elemental analysis are in full agreement with proposed structures.

Synthesis of epoxides was the final step of this investigation. Thus treatment of 2,6-bis-sulfonium salt **5c** with eight arene carbaldehydes produced the bis-epoxides in 30–73% yields. Solubility of bis-epoxides in various solvents was very low; consequently purification and evaluation of these compounds was very difficult, time consuming and materials intensive. For these reasons we focused our attention on the synthesis of mono-epoxides. Thus treatment of mono-sulfonium salt of pyrone **5b** with various arene carbaldehydes resulted in the formation of mono-epoxides **6(b$_1$-b$_{10}$)** and **7** in 61–93% yields (Scheme 3).

The structures of the epoxides were established on the basis of FT-IR, ^{1}H NMR, ^{13}C NMR [24], mass spectral data and elemental analysis and by comparison with literature ^{1}H NMR data for epoxide protons [25,26]. In a similar manner the reaction of sulfonium salt **5b** with aldehyde **4b** resulted in the formation of epoxide **7** in 61% yield (Scheme 4).

CONCLUSION

In this study, hexaminium salts of 4-pyrones have been synthesized by reaction of bromomethylpyrones with hexamethylenetetramine. Aldehyes **4a, b** were synthesized by hydrolysis of hexaminium salts. Mono-epoxide derivatives of 4-pyrone have been synthesized by reaction of arene carbaldehydes with 4-pyrone sulfonium ylide. Ring opening reactions of epoxides are under investigation.

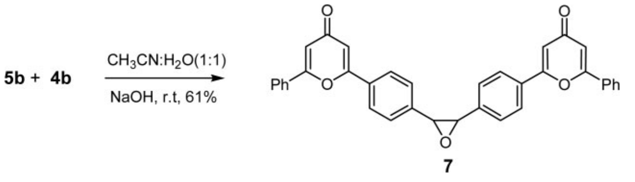
EXPERIMENTAL

^{1}H NMR and ^{13}C NMR spectra were recorded with a FT-NMR-Bruker spectrometer at 400 and 100 MHz respectively. FT-IR spectra were obtained using KBr pellets on tensor 27-Bruker. Mass spectra were recorded on Finnigan-Mat 8400, 70ev mass spectrometer. Elemental analyses were carried out on a Heareus CHN-Rapid, and were found to agree favorably with the calculated values. Thin layer chromatography was performed using silica gel 60 HF$_{254}$. Melting points were recorded on Mel-TEMP 1202D apparatus and are uncorrected.

2-(4-Bromomethylphenyl)-6-methyl-4*H*-pyran-4-one (2a). A mixture of 2-methyl-6-(4-methylphenyl)-4*H*-pyran-4-one 1a (1g, 5 mmol), NBS (0.91g, 5.12 mmol) and catalytic amount of benzoyl peroxide in CCl$_4$ (20 mL) was heated at reflux for 48 h. The reaction mixture was cooled to room temperature and the precipitate was collected by filtration. The solid was dissolved in CH$_2$Cl$_2$ (40 mL), washed with saturated aqueous NaHCO$_3$ solution (3 × 10 mL) and water (2 × 10 mL) then dried over MgSO$_4$. The crude product was purified by preparative layer chromatography (PLC) on silica gel using *n*-hexane:acetone (2:1) as eluent to produce the title compound. White solid, 0.77g (55%), mp 170–172°C; FT-IR(KBr): 3041, 2973, 1660 (pyrone C=O), 1596, 1507, 1389, 1233, 917, 841cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 2.36 (s, 3H, CH$_3$), 4.50 (s, 2H, CH$_2$), 6.17 (d, 1H, J = 1.1 Hz, vinyl-H), 6.68 (d, 1H, J = 2 Hz, vinyl-H), 7.49 (d, 2H, J = 8 Hz, Ar-H), 7.72 (d, 2H, J = 8 Hz, Ar-H) ppm; ^{13}C NMR (CDCl$_3$): δ 18.81, 31.14, 109.97, 113.40, 125.13, 128.59, 130.20, 139.94, 161.72, 164.35, 178.98 ppm; ms: m/z (%): 280 and 278 (M^{+}, 6 and 6), 199 (40), 171 (100), 115 (56). Anal. Calcd. for C$_{13}$H$_{11}$BrO$_2$: C, 55.95; H, 3.94. Found: C, 55.59; H, 3.90.

Scheme 4



General procedure for synthesis of hexaminium salts (3a and 3b). 2-(4-Bromomethylphenyl)-6-methyl-4*H*-pyran-4-one 2a and 2-(4-bromomethylphenyl)-6-phenyl-4*H*-pyran-4-one 2b (5.86 mmol) were dissolved in dry $CHCl_3$ (20 mL). Then a solution of hexamethylenetetramine (5.86 mmol) in $CHCl_3$ (20 mL) was added dropwise to the flask. The mixture was refluxed for 30 min to complete precipitation. The precipitate collected by was filtered, and washed with chloroform and dried *in vacuo* to give hexaminium salts.

Hexaminium salt (3a). White solid, 2.12 g (71%), FT-IR (KBr): 3046, 2967, 2899, 1656 (pyrone C=O), 1600, 1511, 1390, 1036, 931, 821 cm^{-1}; ^1H NMR (D_2O): δ 2.37 (s, 3H, CH_3), 4.18 (s, 2H, CH_2), 4.59 and 4.62 (AB system, J_{AB} = 12 Hz, 3 × CH_2), 5.15 (s, 6H, 3 × CH_2), 6.19 (d, 1H, *J* = 1.5 Hz, vinyl-H), 6.69 (d, 1H, *J* = 2 Hz, vinyl-H), 7.58 (d, 2H, *J* = 8 Hz, Ar-H), 7.91 (d, 2H, *J* = 8 Hz, Ar-H) ppm; ^{13}C NMR (D_2O): δ 18.02, 59.08, 68.87, 77.12, 108.77, 111.94, 125.71, 126.69, 131.26, 131.97, 162.78, 168.32, 181.59 ppm. Anal. Calcd. for $C_{19}H_{23}O_2N_4Br$: C, 54.45; H, 5.40; N, 13.36. Found: C, 54.16; H, 5.50; N, 13.30.

Hexaminium salt (3b). White solid, 2.30g (84%), FT-IR (KBr): 3056, 2949, 2893, 1646 (pyrone C=O), 1601, 1500, 1457, 1437, 1005, 775 cm^{-1}; ^1H NMR (D_2O): δ 4.04 (s, 2H, CH_2), 4.60 and 4.62 (AB system, J_{AB} = 16 Hz, 3 × CH_2), 5.11 (s, 6H, 3 × CH_2), 6.32 (d, 1H, *J* = 2 Hz, vinyl-H), 6.42 (d, 1H, *J* = 2 Hz, vinyl-H), 7.26 (d, 2H, *J* = 8 Hz, Ar-H), 7.38-7.44 (m, 5H, Ar-H), 7.63 (d, 2H, *J* = 8 Hz, Ar-H) ppm; ^{13}C NMR (DMSO-d_6): δ 58.38, 69.77, 77.73, 110.98, 111.59, 126.01, 126.57, 128.92, 129.21, 130.77, 131.58, 132.47, 133.25, 161.50, 162.41, 178.87 ppm. Anal. Calcd. for $C_{24}H_{25}O_2N_4Br$: C, 59.91; H, 5.14; N, 11.63. Found: C, 59.60; H, 5.20; N, 11.25.

4-(6-Methyl-4-oxo-4*H*-pyran-2-yl)benzaldehyde (4a). A solution of hexaminium salt 3a (0.1g, 0.24 mmol) in 10 mL of EtOH:H_2O (3:2) was refluxed for 24 h. The reaction mixture was cooled and solvent was removed under reduced pressure and then water was added (5 mL). The reaction mixture was extracted by ethyl acetate (3 × 10 mL) and dried over $MgSO_4$. The solvent was removed under reduced pressure and crude product was purified by PLC on silica gel using *n*-hexane:acetone (2:1) as eluent. White solid, 0.022 g (43%), mp 183–85°C. FT-IR (KBr): 3055, 2960, 2857, 2769, 1698 (aldehyde C=O), 1662 (pyrone C=O), 1607, 1391, 1171, 956, 825 cm^{-1}; ^1H NMR ($CDCl_3$): δ 2.41 (s, 3H, CH_3), 6.23 (s, 1H, vinyl-H), 6.80 (d, 1H, *J* = 2 Hz, vinyl-H), 7.93 (d, 2H, *J* = 8.4 Hz, Ar-H), 8.0 (d, 2H, *J* = 8.4 Hz, Ar-H), 10.09 (s, 1H, aldehyde-H) ppm; ^{13}C NMR ($CDCl_3$): δ 20.31, 112.86, 115.14, 126.76, 130.53, 136.99, 138.30, 162.25, 166.13, 180.13, 191.64 ppm; ms: m/z (%); 214 (M^+, 28), 186 (94), 129 (100), 77 (38). Anal. Calcd. for $C_{13}H_{10}O_3$: C, 72.92; H, 4.67. Found: C, 72.80; H, 4.80.

4-(4-Oxo-6-phenyl-4*H*-pyran-2-yl)-benzaldehyde (4b). A solution of hexaminium salt 3b (2g, 14.16 mmol) in 50 mL of EtOH: H_2O (3:2) was refluxed for 24 h. The mixture was cooled and diluted with water. The precipitate was collected by filtration, washed with water and dried *in vacuo*. The crude product was purified by column chromatography on silica gel using *n*-hexane:acetone (2:1) as eluent to give the title compound. White solid, 0.66 g (58%), mp 185–187°C. FT-IR (KBr): 3062, 2830, 2738, 1697 (aldehyde C=O), 1646 (pyrone C=O), 1384, 890 cm^{-1}; ^1H NMR ($CDCl_3$): δ 6.85 (d, 1H, *J* = 2 Hz, vinyl-H), 6.90 (d, 1H, *J* = 2 Hz, vinyl-H), 7.55-7.56 (m, 3H, Ar-H), 7.85-7.87 (m, 2H, Ar-H), 8.04 (s, 4H, Ar-H), 10.11 (s, 1H, aldehyde-H) ppm; ^{13}C NMR ($CDCl_3$): δ 110.76, 112.08, 124.98, 125.52, 128.25, 129.26, 130.19, 130.68, 135.74, 136.99, 160.70, 162.69, 178.77, 190.14 ppm; ms: m/z (%): 276 (M^+, 85), 247 (100), 220 (48), 189 (44), 165 (35), 129 (23), 105 (17), 102 (29), 77 (25). Anal. Calcd. for $C_{18}H_{12}O_3$: C, 78.31; H, 4.34. Found: C, 77.95; H, 4.50.

General procedure for the synthesis of sulfonium salts (5b and 5c). To a stirred solution of 2-(4-bromomethylphenyl)-6-phenyl-4*H*-pyran-4-one 2b (2 g, 5.865 mmol) in dry MeOH:CH_2Cl_2 (2:1) was added dimethylsulfide (1.7 mL, 23.46 mmol) in one portion at 35°C under argon and the mixture was stirred for 72 h. The crude product was purified by concentration, precipitation in cold acetone (0°C), filtration followed by vacuum drying to give 5b.

In a similar manner, sulfonium salt 5c was prepared by reaction of 2,6-bis (4-bromomethylphenyl)-4*H*-pyran-4-one 2c (1g, 30 mmol) and dimethylsulfide (1.4 mL, 18.43 mmol).

Dimethyl[4-(4-oxo-6-phenyl-4*H*-pyran-2-yl)benzyl] sulfoniumbromide (5b). White powder, 1.56 g (66%), FT-IR (KBr): 3096, 2988, 2923, 2823, 1644 (pyrone C=O), 1428, 1388, 1016, 850 cm^{-1}; ^1H NMR (DMSO-d_6): δ 2.87 (s, 6H, 2 × CH_3), 4.82 (s, 2H, CH_2), 7.04 (d, 1H, *J* = 2 Hz, Vinyl-H), 7.08 (d, 1H, *J* = 2 Hz, Vinyl-H), 7.56-7.61 (m, 3H, Ph-H), 7.68 (d, 2H, *J* = 8 Hz, Ar-H), 8.17 (d, 2H, *J* = 8 Hz, Ar-H) ppm; ^{13}C NMR (DMSO-d_6): δ 23.88, 44.95, 110.98, 111.49, 126.07, 126.86, 129.23, 130.81, 131.49, 131.60, 131.77, 131.97, 161.55, 162.45, 178.92 ppm. Anal. Calcd. for $C_{20}H_{19}$ BrO_2S: C, 59.59; H, 4.71; S, 7.93. Found: C, 59.30; H, 4.70; S, 7.71.

2,6-Bis[dimethyl(4-methyphenyl)sulfoniumbromide]-4*H*-pyran-4-one (5c). Yellow solid, 0.83 g (65%), FT-IR (KBr): 3046, 2996, 2907, 2826, 1643 (pyrone C=O), 1599, 1505, 1420, 1383, 847cm^{-1}; ^1H NMR (D_2O): δ 2.85 (s, 12H, 4 × CH_3), 4.62 (s, 4H, 2 × CH_2), 6.52 (s, 2H, vinyl-H), 7.48 (d, 4H, *J* = 8 Hz, Ar-H), 7.69 (d, 4H, *J* = 8 Hz, Ar-H) ppm; ^{13}C NMR (D_2O): δ 24.35, 46.38, 110.65, 127.25, 131.30, 131.41, 131.87, 163.46, 182.15 ppm. Anal. Calcd. for $C_{23}H_{26}Br_2O_2S_2$: C, 49.49; H, 4.65; S, 11.48. Found: C, 49.47; H, 4.69; S, 11.49.

General procedure for the synthesis of epoxides 6(b_1-b_{10}) and 7. To a solution of sulfonium salt 5b (0.248 mmol) and aromatic aldehyde or pyronecarbaldehyde 4b (0.248 mmol) in acetonitrile:water (1:1) was added NaOH powder (0.248 mmol) at r.t and was stirred for 1 h to complete reaction. The resulting precipitates were filtered off and washed with water to remove remaining sulfonium salt, then dried in vacuum to give the epoxide.

2-{4-[3-(4-Chlorophenyl)oxiranyl]phenyl}-6-phenyl-4*H*-pyran-4-one ($6b_1$). White solid, 0.08g (81%), mp 208–210°C, FT-IR (KBr): 3059, 2990, 1645 (pyrone C=O), 1601, 1394, 1085, 832 cm^{-1}; ^1H NMR ($CDCl_3$): δ 3.86 (d, 1H, *J* = 1.6 Hz, epoxide-H), 3.90 (d, 1H, *J* = 1.6 Hz, epoxide-H), 6.83 (s, 2H, vinyl-H), 7.26-7.31 (m, 2H, Ar-H), 7.36-7.39 (m, 2H, Ar-H), 7.49-7.56 (m, 5H, Ar-H), 7.85-7.89 (m, 4H, Ar-H) ppm; ^{13}C NMR ($CDCl_3$): δ 61.21, 61.42, 110.50, 110.55, 124.94, 125.22, 125.23, 125.84, 127.87, 128.17, 130.42, 130.47, 130.55, 133.42, 134.07, 139.37, 161.79, 162.39, 179.08 ppm; ms: m/z (%): 402 and 400 (M^+, 13 and 40), 371 (46), 365 (30), 275 (15), 191 (13), 147 (23), 133 (36), 105 (59), 102 (92), 89 (100), 77 (30), 69 (14). Anal. Calcd. for $C_{25}H_{17}ClO_3$: C, 74.95; H, 4.24. Found: C, 74.62; H, 4.30.

2-{4-[3-(2-Chlorophenyl)oxiranyl]phenyl}-6-phenyl-4*H*-pyran-4-one (6b$_2$). White solid, 0.039 g (78%), mp 195–196°C, FT-IR (KBr): 3039, 2987, 1646 (pyrone C=O), 1604, 1391, 1032, 764 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.83 (d, 1H, $J = 1.2$ Hz, epoxide-H), 4.23 (d, 1H, $J = 1.2$ Hz, epoxide-H), 6.85 (s, 2H, vinyl-H), 7.26-7.40 (m, 4H, Ar-H), 7.54-7.56 (m, 5H, Ar-H), 7.86-7.91 (m, 4H, Ar-H) ppm; ^{13}C NMR (CDCl$_3$): δ 59.35, 60.52, 110.43, 110.48, 124.78, 124.97, 125.27, 125.39, 126.16, 128.19, 128.30, 130.38, 130.51, 132.20, 133.61, 139.43, 161.99, 162.49, 179.15 ppm; ms: m/z (%): 402 and 400 (M$^+$, 5 and 14), 371 (7), 105 (73), 102 (100), 89 (97), 77 (39). Anal. Calcd. for $C_{25}H_{17}ClO_3$: C, 74.95; H, 4.24. Found: C, 74.70; H, 4.30.

2-{4-[3-(4-Nitrophenyl)oxiranyl]phenyl}-6-phenyl-4*H*-pyran-4-one (6b$_3$). White solid, 0.09 g (89%), mp 228–230°C, FT-IR (KBr): 3060, 2985, 1645 (pyrone C=O), 1597, 1514 (N=O), 1442, 1393, 1339 (N=O), 846 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.94 (d, 1H, $J = 1.2$ Hz, epoxide-H), 4.00 (d, 1H, $J = 1.2$ Hz, epoxide-H), 6.82 (s, 2H, vinyl-H), 7.50-7.55 (m, 7H, Ar-H), 7.85-7.91 (m, 4H, Ar-H), 8.26 (d, 2H, $J = 8$ Hz, Ar-H) ppm; ^{13}C NMR (CDCl$_3$): 60.87, 61.62, 110.49, 110.63, 122.96, 124.95, 125.31, 128.20, 130.34, 130.55, 130.86, 138.65, 142.75, 147.02, 161.69, 162.49, 179.03 ppm. Anal. Calcd. for $C_{25}H_{17}NO_5$: C, 73.05; H, 4.16; N, 3.40. Found: C, 72.80; H, 4.00; N, 3.40.

2-{4-[3-(2-Nitrophenyl)oxiranyl]phenyl}-6-phenyl-4*H*-pyran-4-one (6b$_4$). White solid, 0.094 g (93%), mp 240–241°C, FT-IR (KBr): 3068, 2855, 1643 (pyrone C=O), 1591, 1520 (N=O), 1399, 1340 (N=O), 852 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.87 (d, 1H, $J = 2$ Hz, epoxide-H), 4.49 (d, 1H, $J = 2$ Hz, epoxide-H), 6.81-6.82 (m, 2H, vinyl-H), 7.51-7.57 (m, 6H, Ar-H), 7.73-7.74 (m, 2H, Ar-H), 7.84-7.90 (m, 4H, Ar-H), 8.19 (d, 1H, $J = 8$ Hz, Ar-H) ppm; ^{13}C NMR (CDCl$_3$): δ 59.40, 60.37, 110.44, 110.55, 123.77, 124.92, 125.25, 125.53, 126.04, 127.92, 128.14, 130.38, 130.43, 130.66, 132.42, 133.44, 138.87, 146.47, 161.86, 162.35, 179.10 ppm. Anal. Calcd. for $C_{25}H_{17}NO_5$: C, 73.05; H, 4.13; N, 3.40. Found: C, 72.65; H, 4.00; N 3.40.

2-{4-[3-(4-Fluorophenyl)oxiranyl]-phenyl}-6-phenyl-4*H*-pyran-4-one(6b$_5$). White solid, 0.083g (88%), mp 186–187°C, FT-IR (KBr): 3058, 2984, 1645 (pyrone C=O), 1601, 1507, 1447, 1392, 1230, 831 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.87 (d, 1H, $J = 1.6$ Hz, epoxide-H), 3.91 (d, 1H, $J = 1.6$ Hz, epoxide-H), 6.83 (s, 2H, vinyl-H), 7.07-7.11 (m, 2H, Ar-H), 7.32-7.35 (m, 2H, Ar-H), 7.49-7.55 (m, 5H, Ph-H), 7.85-7.89 (m, 4H, Ar-H) ppm; ^{13}C NMR (CDCl$_3$): δ 61.18, 61.53, 110.54, 114.59, 114.80, 124.96, 125.23, 126.19, 126.27, 128.19, 130.43, 130.50, 131.28, 131.31, 139.52, 160.69, 161.84, 162.40, 163.15, 179.13 ppm; ms: m/z (%): 384 (M$^+$, 16), 355 (17), 147 (13), 108 (85), 105 (67), 102 (100), 77 (36), 69 (18). Anal. Calcd. for $C_{25}H_{17}FO_3$: C, 78.16; H, 4.42. Found: C, 77.77; H, 4.40.

2-[4-(3-Naphthalen-2-yl-oxiranyl)-phenyl]-6-phenyl-4*H*-4-one (6b$_6$). White solid, 0.086g (84%), mp 187–189°C, FT-IR (KBr): 3051, 2976, 1642 (pyrone C=O), 1600, 1503, 1390, 824 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 4.05 (d, 1H, $J = 1.6$, epoxide-H), 4.06 (d, 1H, $J = 1.6$, epoxide-H), 6.83 (s, 2H, vinyl-H), 7.42-7.57 (m, 8H, Ar-H), 7.48-7.57 (m, 7H, Ar-H), 7.84-7.90 (m, 8H, Ar-H) ppm; ^{13}C NMR (CDCl$_3$): δ 61.21, 62.30, 110.41, 110.42, 121.56, 124.15, 124.86, 125.12, 125.20, 125.26, 125.48, 126.75, 126.77, 127.51, 128.10, 130.35, 130.39, 132.07, 132.38, 132.91, 139.70, 161.74, 162.24, 178.99 ppm; ms: m/z (%): 416 (M$^+$, 3), 387 (8), 155 (21), 40 (68), 139 (100), 105 (55), 102 (38), 91 (79), 77 (52), 69 (8). 2,6-Bis(1*H*-indole-6-yl)-4*H*-pyran-4-one **4** was synthesized *via* Leimgruber–Batcho methodology starting from 2,6-bis(4-methyl-3-nitrophenyl)-4*H*-pyran-4-one **2**. Enamine intermediate in this reaction, **3**, reacts with aroyl chlorides in the presence of 1,4-diazabicyclo[2.2.2]octane in dioxane to give the substituted enamines **8(a-c)**. Enamines **8a,b** undergo reductive cyclization with Fe/AcOH to the corresponding 3-aroylindoles **10a,b**.

J. Heterocyclic Chem., **46**, 273 (2009).

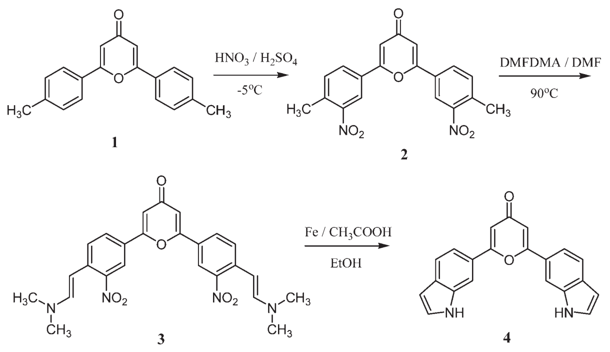
INTRODUCTION

The indole ring system is one of the most ubiquitous heterocycles in nature and an important structural component in many pharmaceutical agents [1]. Therefore synthesis and functionalization of indoles has been a major area of focus for synthetic organic chemists, and numerous methods for the preparation of indoles have been developed [2]. One powerful procedure is the Leimgruber–Batcho indole synthesis [3]. The classical sequence of this reaction that has been used for the preparation of 2,3-unsubstituted indoles, involves the condensation of methyl group positioned adjacent to an aromatic nitro group (as 2, Scheme 1) with *N*,*N*-dimethyl formamide-dimethyl acetal (DMFDMA) to give the enamine intermediate such as **3**. Subsequent reduction of the nitro group leads to spontaneous cyclization and formation of the corresponding indole derivative (as **4**). Modifications of Leimgruber–Batcho procedure to accelerate products formation [4] or to the production of *N*-substituted indoles [5] have also been described.

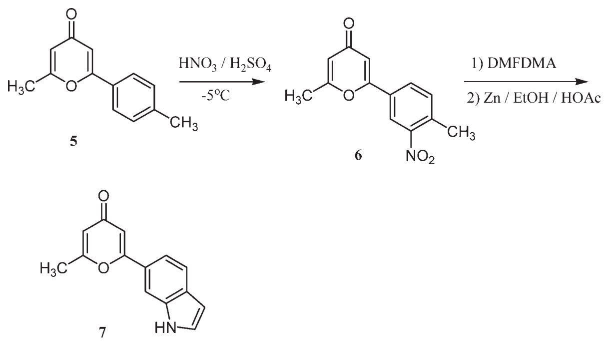
Synthesis of 3-substituted indoles has also received continued attention. 3-Acylindoles are precursors to a variety of biologically important alkaloids [6]. 3-Aroylindoles represent significant biological activities, for example, some of these have potential as promising anticancer agents [7]. For the synthesis of 3-aroylindoles, electrophilic substitution at C-3 position of indole ring through reaction of indoles with aroyl chlorides in the presence of Grignard reagents as base and/or metal chlorides as Lewis acid is well known [7]. Another appropriate method for synthesis of 3-substituted indoles, which include functionalization of enamine intermediates in Leimgruber–Batcho procedure, has rarely been reported [8]. This modification, in which reaction of the enamine intermediate with aroyl chlorides carried out in the presence of a tertiary amine, can be considerable for its potential regiochemical control in the synthesis of 3-substituted indoles.

Polycyclic aryl and heteroaryl substituted 4-pyrones have also been found in a variety of natural and synthetic biologically active compounds [9]. They have been shown to be anticoagulant [10a], anti-HIV [10b], and antitumor [10c] agents. Through our attempts to prepare various azaaryl substituted 4-pyrones, we turned

Scheme 1



Scheme 2



our attention to the 4-pyrone derivatives that would allow for the construction of the indole moiety. Herein, we report synthesis of two (1*H*-indole-6-yl)-4-pyrones *via* the Leimgruber–Batcho methodology and then reaction of enamine intermediate **3** with aroylchlorides in the presence of 1,4-diazabicyclo[2.2.2]octane (DABCO) as tertiary amine and the results of reductive cyclization of obtained enaminones for synthesis of 3-aroyl substituted indole derivatives.

RESULTS AND DISCUSSION

Scheme 1 shows the synthetic sequences for preparation of product **4**. The starting compound **1** was synthesized through cyclization of related 1,3,5-triketone derivative under acidic conditions, which is an important method for the synthesis of a variety of 4-pyrone structures [11]. Nitration of **1** with HNO_3/H_2SO_4 at −5°C for 0.5 h afforded the dinitro **2** in quantitative yield. These nitration conditions were different from those reported for nitration of diphenyl-4-pyrones [12]. Treatment of **2** with 8 equiv. of DMFDMA at 90°C for 24 h gave stable dienamine **3** in 86% yield. Reductive cyclization of **3** was carried out using Fe or Zn in EtOH/HOAc at 80°C, that provided the 2,6-bis(1*H*-indole-6-yl)-4*H*-pyran-4-one **4** after 5 and 24 h, respectively. Therefore the conditions using Fe/EtOH/AcOH were optimal resulting in a faster and also a cleaner reaction.

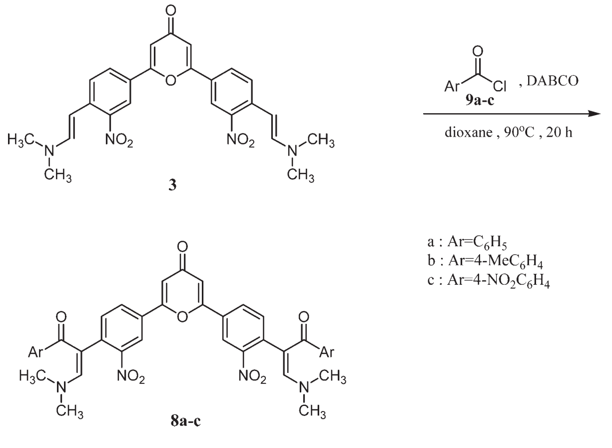
We also used 2-(4-methylphenyl)-6-methyl-4*H*-pyran-4-one **5** in the same synthetic sequence. This compound was synthesized according to reported procedure [13]. Nitration of **5** gave the *ortho*-nitrotolyl derivative **6**. Treatment of **6** with DMFDMA at 80°C and subsequent reduction of nitro group resulted the indole **7** in 33% yield. The enamine intermediate in this reaction that was not isolated was readily converted to indole **7**, by stirring with the Zn/EtOH/AcOH mixture at room temperature for 4 h. This result indicated that oxidation of the methyl ortho- to nitro-group in compound **6** has predominantly been achieved (Scheme 2).

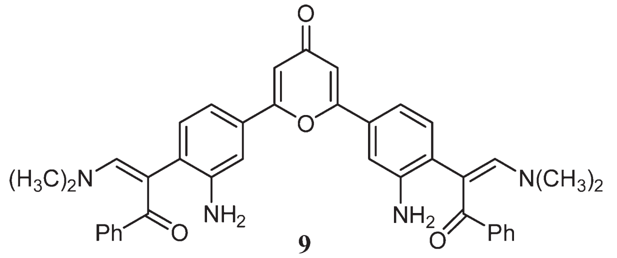
We then examined the incorporation of aroyl substituents onto the enamine intermediate **3**. The reactivity of enamine **3** toward aroyl chlorides such as benzoylchloride, 4-methylbenzoylchloride, and 4-nitrobenzoylchloride was explored initially using triethylamine in dry dioxane at 90°C. Under these conditions no reactivity was observed. Then, we used 2 equiv. of DABCO instead of triethylamine, and the substitution was successfully achieved as shown in Scheme 3. The structures of products **8a-c** were characterized by spectroscopic data and elemental analysis.

In the final step, a few reagents and conditions were evaluated to optimize the reductive cyclization of enaminones **8a-c** to form the 3-aroyl substituted indole derivatives. When the compound **8a** was treated with Zn or Fe in 1:1 mixture of EtOH–AcOH at 90–100°C for 24 h, the major product that was formed and separated, showed a singlet at 3.0 ppm for 12 protons in ^1H NMR spectrum (in DMSO-d_6), which indicated the presence of $-N(CH_3)_2$ groups in molecule and established that the cyclization has not been accomplished. Spectroscopic data confirmed the symmetrical structure of **9**, which was obtained in 32% yield under these conditions (Fig. 1).

Treatment of enaminones **8a** and **8b** with Fe/AcOH at 100°C for 24 h, gave the desired bis(indole) derivatives

Scheme 3





9

Figure 1. Structure of compound **9** obtained from reduction of the enaminone **8a** with Zn in EtOH–AcOH (1:1).

10a and **10b** as major products, respectively (Scheme 4). These compounds were separated and characterized by spectroscopic methods. The Fe/AcOH system has been described previously for reduction-cyclization of nitro group for construction of a variety of indole structures [14].

We also found that using Fe in 1*M* aqueous HCl solution/MeOH with heating resulted in a complex mixture with unidentified residues.

In conclusion, we have reported the synthesis of two (1*H*-indole-6-yl)-4-pyrones *via* Leimgruber–Batcho indole synthesis, starting from the corresponding *ortho*-methylnitrophenyl derivatives. Aroyl substituents at C-3 of the bis(indole) derivative were installed *via* reaction of the enamine intermediate with aroylchlorides before the final reductive cyclization. Among the different conditions and reagents that were examined for reductive cyclization of enaminoketones, the Fe/AcOH at 100°C was the appropriate method for this purpose. This modified Leimgruber–Batcho procedure is attractive because of the regioselectivity of substitution, which may be observed less in the direct C-3 aroylation of indole nucleus.

EXPERIMENTAL

Melting points were determined on a 1202D model Electrothermal MEL-TEMP apparatus and are uncorrected. FTIR spectra were obtained with a Bruker Tensor 27 spectrometer. ^1H NMR and ^{13}C NMR spectra were recorded with a Bruker Spectrospin Avance 400 spectrometer operating at 400 and 100 MHz, respectively; chemical shifts are given in parts per million (ppm, δ) relative to solvent peaks as internal standards (δ: $CDCl_3$: 7.26 ppm (^1H), 76 ppm (^{13}C); DMSO-d_6: 2.50 ppm (^1H), 39.5 ppm (^{13}C)). Mass spectra (MS) were measured by a Shimadzo (70 ev) spectrometer and elemental analyses were measured by Vario EL III apparatus (Elementar Co.). Column chromatography was done using silica gel (Merk Kieselgel 60, no. 9385, 230-400 mesh ASTM). Thin-layer chromatography was done with prepared glass-backed plates (20 × 20 cm^2, 500 μ) using silica gel (Merk Kieselgel 60 HF_{254}, no. 7739).

2,6-Bis(4-methyl-3-nitrophenyl)-4*H*-pyran-4-one (2). A stirred solution of 3.66 g (0.013 mol) of 2,6-bis(4-methylphenyl)-4*H*-pyran-4-one (**1**) in 11.5 mL of concentrated sulfuric acid (95–98%) cooled to −5°C using ice-salt bath. To this solution, 7 mL of fuming nitric acid was added dropwise over 15 min. The reaction mixture was stirred at −5°C for a further 0.5 h and then poured to 100 g ice. The produced precipitate was collected by filtration and washed with water and dried *in vacuo* to give **2** (4.7 g, 98% yield) as a white solid, mp 254°C; FTIR (KBr): ν 3065, 2977, 1663 (pyrone C=O), 1614, 1528, 1444, 1355 cm^{-1}; ^1H NMR($CDCl_3$): δ 2.703 (s, 6H, CH_3), 6.861 (s, 2H, pyrone H-3), 7.564 (d, 2H, J = 8.1 Hz, phenyl H-5), 7.948 (dd, 2H, J = 8.0, 1.9 Hz, phenyl H-6), 8.438 (d, 2H, J = 1.9 Hz, phenyl H-2) ppm; ^{13}C NMR ($CDCl_3$): δ 19.5 (CH_3), 111.4, 121.1, 128.6, 129.3, 133.0, 136.1, 148.7, 160.0, 178.0 (pyrone CO) ppm. MS (*m/z*, %): 366 (M^+, 30), 338 (100). *Anal.* Calcd. for $C_{19}H_{14}N_2O_6$: C, 62.32; H, 3.82; N, 7.65. Found: C, 61.94; H, 3.89; N, 7.39.

2,6-Bis{4-[*trans*-2-(*N,N*-dimethylamino)ethenyl]-3-nitrophenyl}-4*H*-pyran-4-one (3). A mixture of (**2**) (4.70 g, 0.013 mol) and DMFDMA(12.4 g, 0.104 mol) in 100 mL DMF was heated at 90°C under Ar for 24 h. After cooling, the precipitated product was filtered, washed several times with H_2O, and dried *in vacuo* to provide 5.3 g (86.5 %) of **3** as a deep red solid, mp 250°C; FTIR(KBr): ν 3075, 2900, 2802, 1640 (pyrone C=O), 1591, 1516, 1375, 1209, 1098 cm^{-1}; ^1H NMR (DMSO-d_6): δ 2.975 (s, 12H, $-N(CH_3)_2$), 5.713 (d, 2H, J = 13.2 Hz, PhCH=), 6.961 (s, 2H, pyrone H-3), 7.777 (d, 2H, J = 13.2 Hz, $=CH-N(Me)_2$), 7.859 (d, 2H, J = 8.9 Hz, phenyl H-5), 7.935 (dd, 2H, J = 8.8, 1.9 Hz, phenyl H-6), 8.364 (d, 2H, J = 2.0 Hz, phenyl H-2) ppm; ^{13}C NMR ($CDCl_3$): δ 39.9 (CH_3-N), 89.5, 109.2, 122.4, 123.0, 123.2, 127.6, 137.8, 143.2, 145.7, 160.4, 178.6 (pyrone CO) ppm; MS (*m/z*, %): 476 (M^+, 65), 459 (40), 386 (50), 42 (100); *Anal.* Calcd. for $C_{25}H_{24}N_4O_6$: C, 63.02; H, 5.04; N, 11.76. Found: C, 62.86; H, 5.27; N, 11.90.

2,6-Bis(1*H*-indole-6-yl)-4*H*-pyran-4-one (4). A suspension of (**3**) (0.476 g, 1 mmol), AcOH (6 mL), EtOH (6 mL), and Fe (2.24 g, 40 mmol) was heated with stirring at 80°C. After 5 h, the dark color of the reaction mixture disappeared and a brown suspension was obtained, indicating the completion of reaction. The reaction mixture was cooled, concentrated by rotary evaporator to remove EtOH, neutralized by saturated $NaHCO_3$ solution, and then extracted by EtOAc. The extract was dried over anhydrous Na_2SO_4, concentrated and purified by thin-layer chromatography (silica gel, 1:1 acetone:*n*-hexane) to give 0.114 g (35% yield) of **4**, mp 280°C (decomp.); FTIR (KBr): ν 3367 (NH), 3161, 2918, 1637 (pyrone C=O), 1575, 1554, 1456, 1395, 1181 cm^{-1}; ^1H NMR (DMSO-d_6): δ 6.557 (t, br., 2H, J = 1.8 Hz, indole H-3), 6.891 (s, 2H, pyrone H-3), 7.568 (t, 2H, J = 2.7 Hz, indole H-2), 7.674 (dd, 2H, J = 8.4, 1.5 Hz, indole H-5), 7.739 (d, 2H, J = 8.4 Hz, indole H-4), 8.091 (s, 2H, indole H-7), 11.506 (s, 2H, NH) ppm; ^{13}C NMR (DMSO-d_6): δ 101.6, 109.4,

2-(4-Methyl-3-nitrophenyl)-6-methyl-4*H*-pyran-4-one (6). A stirred solution of 0.4 g (2 mmol) of 2-(4-methylphenyl)-6-methyl-4*H*-pyran-4-one (**5**) in 1 mL of concentrated sulfuric acid (95–98 %) cooled to −5°C using ice-salt bath. To this solution, 0.6 mL of fuming nitric acid was added dropwise over 15 min. The reaction mixture was stirred at −5°C for a further 0.5 h and then poured to 100 g ice. The precipitate was collected by filtration, washed with water, and dried *in vacuo* to give **6** (0.45 g, 92% yield) as a white solid, mp 160°C; FTIR (KBr): ν 3066, 2970, 1660 (pyrone C=O), 1612, 1531, 1402, 1350, 1168, 920, 796 cm^{-1}; ^1H NMR ($CDCl_3$): δ 2.378 (s, 3H, CH_3), 2.627 (s, 3H, CH_3), 6.172 (d, 1H, J = 1.1 Hz, pyrone H-5), 6.695 (d, 1H, J = 1.9 Hz, pyrone H-3), 7.457 (d, 1H, J = 8.1 Hz, phenyl H-5), 7.828 (dd, 1H, J = 8.4, 1.7 Hz, phenyl H-6), 8.324 (d, 1H, J = 1.6 Hz, phenyl H-2) ppm; ^{13}C NMR ($CDCl_3$): δ 18.8, 19.3, 110.3, 113.5, 120.7, 128.3, 129.4, 132.6, 135.4, 148.4, 159.7, 164.5, 178.4 (pyrone CO) ppm; MS (*m/z*, %): 245 (M^+, 89), 228 (42), 217 (32), 172 (100), 89 (46); *Anal*. Calcd. for $C_{13}H_{11}NO_4$; C, 63.67; H, 4.49; N, 5.71. Found: C, 63.30; H, 4.52; N, 5.47.

2-(1*H*-indole-6-yl)-6-methyl-4*H*-pyran-4-one (7). A mixture of (**6**) (0.4 g, 1.63 mmol) and DMFDMA (0.78 g, 6.53 mmol) in 1 mL DMF was heated at 80°C under Ar for 24 h. After cooling, 30 mL H_2O was added to the reaction mixture and the precipitated product was filtered, washed with H_2O, and dried *in vacuo*. The red solid was mixed with Zn (2.12 g, 32.6 mmol), EtOH (4 mL), and AcOH (4 mL). The mixture was stirred at r.t. for 4 h and then concentrated by rotary evaporator. The residue was neutralized by saturated $NaHCO_3$ solution and the precipitate was filtered. This solid was purified by thin-layer chromatography (silica gel, 1:1 acetone:*n*-hexane) to give **7** (0.12 g, 33% yield). mp 228°C; FTIR (KBr): ν 3331(NH), 3002, 2976, 1650 (pyrone C=O), 1590, 1406, 1324, 1159, 916, 676 cm^{-1}; ^1H NMR ($CDCl_3$): δ 2.393 (s, 3H, CH_3), 6.185 (d, 1H, J = 1.0 Hz, pyrone H-5), 6.608 (s, 1H, pyrone H-3), 6.768 (d, 1H, J = 2.2 Hz, indole H-3), 7.380 (t, 1H, J = 2.8 Hz, indole H-2), 7.516 (dd, 1H, J = 8.4, 1.5 Hz, indole H-5), 7.710 (d, 1H, J = 8.4 Hz, indole H-4), 7.869 (s, 1H, indole H-7), 8.896 (s, 1H, NH) ppm; ^{13}C NMR ($CDCl_3$): δ 18.9 (CH_3), 102.0, 108.1, 108.7, 113.1, 116.4, 120.1, 123.8, 126.2, 129.4, 134.6, 164.1, 164.2, 179.5 (pyrone CO) ppm; MS (*m/z*, %): 225 (M^+, 28); *Anal*. Calcd. for $C_{14}H_{11}NO_2$: C, 74.67; H, 4.89; N, 6.22. Found: C, 74.29; H, 5.00; N, 6.51.

General procedure for the synthesis of enaminoketones (8a-c). A mixture of enamine (**3**) (0.952 g, 2 mmol), DABCO (0.448 g, 4 mmol), and aroylchlorides (**9a-c**) (12 mmol) in 20 mL dioxane (dry) was heated at 90°C for 20 h. The resulting suspension was cooled to r.t. and water (120 mL) was added. The resulting mixture was stirred for 5 min and then extracted with chloroform (4 × 50 mL). The combined chloroform extract was washed with 150 mL of H_2O, dried over Na_2SO_4, and concentrated to dryness. The residue was purified by column chromatography (silica gel, 6:4 acetone:*n*-hexane) to give the products **9a-c**.

2,6-Bis{4-[(Z)-1-benzoyl-2-(N,N-dimethylamino) ethenyl]-3-nitrophenyl}-4H-pyran-4-one (8a). This compound was obtained as a red solid in 67% yield, mp 160–162°C; FTIR (KBr): ν 3062, 2921, 1702 (benzoyl C=O), 1649 (pyrone C=O), 1579, 1534, 1382, 1312 cm^{-1}; ^1H NMR ($CDCl_3$): δ 2.832 (s, 12H, —$N(CH_3)_2$), 6.887 (s, 2H, pyrone H-3), 7.262 (d, 2H, J = 1.9 Hz, =CH—$N(Me)_2$), 7.470–7.362 (m, 10H, benzoyl-H), 7.519 (d, 2H, J = 6.9 Hz, phenyl H-5), 8.006 (d, 2H, J = 6.5 Hz, phenyl H-6), 8.392 (s, 2H, phenyl H-2) ppm; ^{13}C NMR ($CDCl_3$): δ 42.8 (CH_3-N), 106.5, 111.4, 120.5, 127.0, 127.4, 127.6, 129.0, 129.5, 134.2, 134.7, 139.6, 149.8, 154.3, 160.1, 178.2 (pyrone CO), 192.3 (benzoyl CO) ppm; *Anal*. Calcd. for $C_{39}H_{32}N_4O_8$: C, 68.35; H, 4.67; N, 8.18. Found: C, 68.63; H, 5.00; N, 8.05.

2,6-Bis{4-[(Z)-2-(N,N-dimethylamino)-1-(4-methylbenzoyl) ethenyl]-3-nitrophenyl}-4H-pyran-4-one (8b). This compound was obtained as a red solid in 65% yield, mp 165–168°C; FTIR (KBr): ν 3021, 2918, 1702 (aroyl C=O), 1649 (pyrone C=O), 1579, 1531, 1382, 1308, 1096 cm^{-1}; ^1H NMR ($CDCl_3$): δ 2.383 (s, 6H, *p*-CH_3-benzoyl), 2.844 (s, 12H, $N(CH_3)_2$), 6.911 (s, 2H, pyrone H-3), 7.187 (d, 4H, J = 7.8 Hz, aroyl H-3), 7.298 (s, 2H, =CH—$N(Me)_2$), 7.439 (d, 4H, J = 7.9 Hz, aroyl H-2), 7.476 (s, 2H, phenyl H-5), 8.005 (s, br, 2H, phenyl H-6), 8.391 (s, 2H, phenyl H-2) ppm; ^{13}C NMR ($CDCl_3$): 28.2 (*p*-CH_3-benzoyl), 42.9 (CH_3-N), 106.5, 111.5, 120.6, 127.0, 127.5, 127.6, 129.0, 129.6, 134.2, 134.7, 139.6, 149.8, 154.2, 160.1, 178.1 (pyrone CO), 192.3 (aroyl CO) ppm; *Anal*. Calcd. for $C_{41}H_{36}N_4O_8$: C, 69.03; H, 5.05; N, 7.85. Found: C, 68.98; H, 5.09; N, 7.78.

2,6-Bis{4-[(Z)-2-(N,N-dimethylamino)-1-(4-nitrobenzoyl)-ethenyl]-3–nitrophenyl}-4H-pyran-4-one (8c). This compound was obtained as an orange solid in 54% yield, mp 172–174°C; FTIR (KBr): ν 3070, 2921, 1711 (aroyl C=O), 1648 (pyrone C=O), 1571, 1524, 1389, 1347, 1313, 1097 cm^{-1}; ^1H NMR ($CDCl_3$): δ 2.881 (s, 12H, $N(CH_3)_2$), 6.920 (s, 2H, pyrone H-3), 7.184 (s, 2H, =CH—$N(Me)_2$), 7.490 (d, 2H, J = 8.0 Hz, phenyl H-5), 7.666 (d, 4H, J = 8.5 Hz, aroyl H-3), 8.028 (d, 2H, J = 7.8 Hz, phenyl H-6), 8.252 (d, 4H, J = 8.5 Hz, aroyl H-2), 8.429 (d, 2H, J = 1.4 Hz, phenyl H-2) ppm; ^{13}C NMR ($CDCl_3$): δ 45.9 (CH_3-N), 111.7, 120.8, 122.4, 122.5, 127.7, 128.1, 130.1, 133.7, 134.2, 145.6, 147.4, 149.8, 154.3, 178.1 (pyrone CO), 189.9 (aroyl CO) ppm; *Anal*. Calcd. for $C_{39}H_{30}N_6O_{12}$: C, 60.41; H, 3.87; N, 10.84. Found: C, 60.09; H, 4.13, N, 10.71.

2,6-Bis{3-amino-4-[(*Z*)-1-benzoyl-2-(*N*,*N*-dimethylamino)ethenyl]phenyl}-4*H*-pyran-4-one (9). A suspension of **8a** (0.342 g, 0.5 mmol), AcOH (3 mL), EtOH (3 mL), and Zn (1.30 g, 20 mmol) was heated with stirring at 90°C for 24 h. The hot reaction mixture was then filtered and washed with an appropriate amount of warm methanol. The combined filtrate was then concentrated by rotary evaporator to remove the alcohols (EtOH, MeOH), neutralized by saturated $NaHCO_3$ solution and extracted by EtOAc. The extract was dried over anhydrous Na_2SO_4, concentrated, and purified by thin-layer chromatography (silica gel, 1:1 acetone:chloroform) to give 0.099 g (32% yield) of **9** as brown solid, mp 300°C (decomp.), FTIR (KBr): ν 3383, 3217 (NH_2), 3067, 2920, 1737 (benzoyl C=O), 1635 (pyrone C=O), 1562, 1460, 1406 cm^{-1}; ^1H NMR (DMSO-d_6): δ 3.024 (s, 12H, —$N(CH_3)_2$), 6.713 (s, 2H, pyrone H-3), 6.777 (d, 2H, J = 8.5 Hz, phenyl H-5), 7.419 (dd, 2H, J = 8.5, 1.5 Hz, phenyl H-6), 7.493–7.530 (m, 6H: 2H, =CH—$N(Me)_2$, 4H, benzoyl H-3), 7.586 (t, 2H, J = 7.3 Hz, benzoyl H-4), 7.670 (d, 4H, J = 7.6 Hz, benzoyl H-2), 7.957 (d, 2H, J = 1.2 Hz, phenyl H-2), 11.686 (br., NH_2) ppm; ^{13}C

NMR (DMSO-d_6): δ 41.7 (CH_3-N), 97.3, 107.3, 108.0, 117.5, 118.3, 121.6, 128.4, 128.5, 131.2, 131.9, 133.1, 141.9, 155.5, 163.0, 178.9 (pyrone CO), 188.2 (benzoyl CO) ppm; *Anal.* Calcd. for $C_{39}H_{36}N_4O_4$: C, 75.00; H, 5.77; N, 8.97. Found C, 74.88; H, 5.59; N, 9.16.

General procedure for the synthesis of 3-aroylindoles (10a-b). A mixture of the enaminone **8a** or **8b** (0.3 mmol), iron powder (0.5 g), and glacial HOAc (4 mL) was refluxed at 100°C. After 24 h, the dark color of the reaction mixture disappeared and a brown suspension was obtained. The reaction mixture was cooled, neutralized by saturated $NaHCO_3$ solution, and then extracted by EtOAc. The extract was dried over anhydrous Na_2SO_4, concentrated and purified by thin-layer chromatography (silica gel, EtOAc) to give the products **10a** or **10b** in 25 and 22% yield, respectively.

2,6-Bis(3-benzoyl-1H-indole-6-yl)-4H-pyran-4-one (10a). This compound was obtained as a pale-yellow solid in 25% yield, mp 270°C (decomp.); FTIR (KBr): ν 3416 (NH), 3122, 2923, 1736 (benzoyl C=O), 1637 (pyrone C=O), 1576, 1502, 1451 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 7.011 (s, 2H, pyrone H-3), 7.550–7.586 (m, 4H, benzoyl H-3), 7.639 (t, 2H, $J = 7.0$ Hz, benzoyl H-4), 7.828 (d, 4H, $J = 7.1$ Hz, benzoyl H-2), 7.954 (d, 2H, $J = 8.0$ Hz, indole H-4), 8.140 (s, 2H, indole H-7), 8.234 (s, 2H, indole H-2), 8.404 (d, 2H, $J = 8.5$ Hz, indole H-5), 8.879 (s, 2H, NH, deuterium oxide-exchangeable) ppm; ^{13}C NMR (DMSO-d_6): δ 110.3, 110.6, 115.2, 119.8, 122.1, 125.9, 128.5, 128.6, 128.7, 131.5, 136.8, 138.2, 140.1, 163.4, 179.1 (pyrone CO), 190.0 (benzoyl CO) ppm; *Anal.* Calcd. for $C_{35}H_{22}N_2O_4$: C, 78.65; H, 4.12; N, 5.24. Found: C, 78.60; H, 4.23; N, 5.01.

2,6-Bis[1H-indole-3-(4-methylbenzoyl)-6-yl]-4H-pyran-4-one (10b). This compound was obtained as a pale-yellow solid, mp 240°C (decomp.); FTIR (KBr): ν 3398 (NH), 3100, 2925, 1737 (aroyl C=O), 1641 (pyrone C=O), 1600, 1517, 1452, 1423, 1383 cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 2.422 (s, 6H, CH_3), 7.011 (s, 2H, pyrone H-3), 7.376 (d, 4H, $J = 7.9$ Hz, aroyl H-3), 7.751 (d, 4H, $J = 7.9$ Hz, aroyl H-2), 7.946 (d, 2H, $J = 8.6$ Hz, indole H-4), 8.147 (s, 2H, indole H-7), 8.225 (s, 2H, indole H-2), 8.302 (s, 2H, NH, deuterium oxide-exchangeable) 8.389 (d, 2H, $J = 8.5$ Hz, indole H-5) ppm; ^{13}C NMR (DMSO-d_6): δ 28.4, 109.6, 110.8, 115.3, 119.3, 121.9, 125.3, 128.7, 128.9, 129.1, 131.2, 137.6, 138.2, 141.4, 162.9, 179.0 (pyrone CO), 189.6 (aroyl CO) ppm; *Anal.* Calcd. for $C_{37}H_{26}N_2O_4$: C, 79.00; H, 4.62; N, 4.98. Found: C, 78.77; H, 4.45; N, 4.77.

The microwave assisted, solvent free, parallel syntheses of title compounds is described in this protocol. Twelve new tetraaryl imidazoles, which are incorporated with the chemotherapeutic pharmacophores, have been synthesized by adopting one pot multicomponent reaction. Attempt has been made to investigate the mechanism behind the formation of tetraaryl imidazoles by product identification method. The synthesized compounds were analyzed by physical and analytical data. The synthesized compounds were evaluated for their antibacterial, antitubercular, and short-term anticancer activity. Compound **13** was found to be the candidate compound to investigate further for its potential anticancer activity.

J. Heterocyclic Chem., **46**, 278 (2009).

INTRODUCTION

Syntheses of heterocyclic compounds from readily available reagents by simple and efficient methods are the major requirements of heterocyclic chemistry. A survey of the pertinent literature reveals that, tetraaryl imidazoles possess diverse biological activities apart from their synthetic interests [1–3]. They are reported to exhibit pharmacological activities such as antirheumatoid arthritis [4], antituberculosis [5], antiHIV [6], antiepileptic [7], and anticancer activity [8,9]. Some of the best-selling therapies today contain this versatile heterocycle in their core structures. Therefore, it would be difficult to underestimate the importance of imidazoles in the pharmaceutical industry. Structurally, imidazole shows all the typical properties of an aromatic ring system.

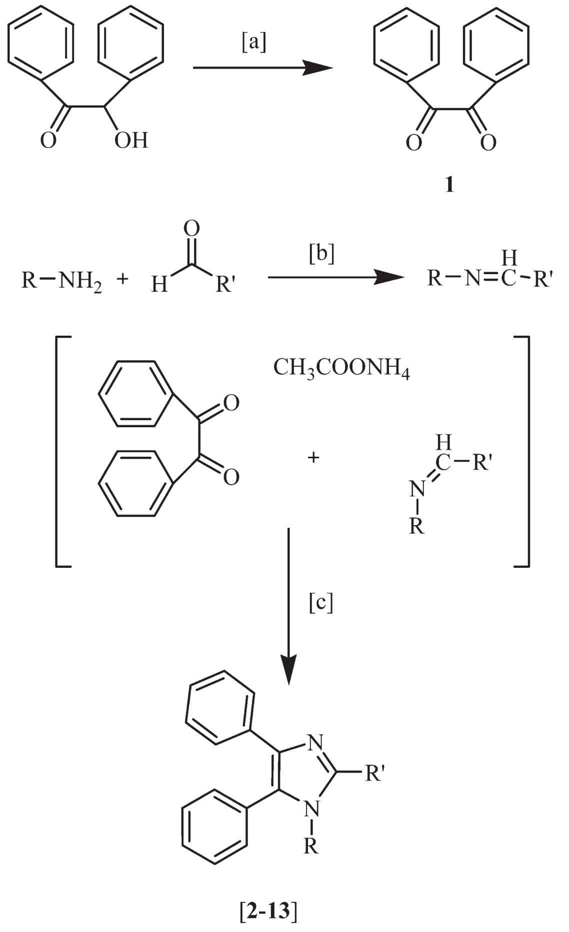
In 1858, Debus reported the reaction between glyoxal and ammonia, ever since this reaction became a novel route to the syntheses of imidazoles [10]. Later, a number of articles have described the syntheses of various imidazoles [11–19].

On the basis of the above observations, we have sought to synthesize novel tetraaryl imidazoles which are incorporated with the chemotherapeutic pharmacophores such as sulphanilamide, its bioisoster PABA (*p*-aminobenzoic acid) and INH (isoniazid) as possible antibacterial, antitubercular, or anticancer agents.

RESULTS AND DISCUSSION

Benzoin on oxidation gave Benzil **1** (Scheme 1). In an attempt to search for oxidizing agent to oxidize a mono ketone to diketone, we tried using oxidizing agents such as aluminium nitrate, cerric ammonium sulphate, ferric ammonium sulphate, potassium nitrate, and sodium nitrite. Among these oxidizing agents, only sodium nitrite was able to oxidize mono ketone to

Scheme 1. Preparation of tetraaryl imidazoles. (a) $NaNO_2$, AcOH, reflux for 50 min. (b) Conv; AcOH, Reflux 5-6 h. MW; Activated silica gel, 1000 W, 8 min. (c) Conv; Ammonium acetate, Reflux 12-15 h. MW; Ammonium acetate, 1000 W, 14–23 min.



diketone efficiently in the presence of glacial acetic acid as a solvent. In the literature [20], nitric acid and lead nitrate were used to oxidize benzoin to benzil taking 1.5 h for completing reaction, involving a nasty brown nitrogenous gas evolution. The same reaction using sodium nitrite just takes 50 min for completion. The yield of benzil was better when compared with the existing oxidizing agents and the brown nitrogenous gas evolution was also been reduced.

The primary aromatic or heteroarylamine was condensed with aryl or heteroaryl aldehydes to afford the corresponding Schiff's base. Schiff's base was further treated with ammonium acetate and benzil in the presence of glacial acetic acid as a solvent, gave the corresponding tetraaryl imidazoles (**2-13**) according to Scheme 1. The microwave assisted parallel syntheses were performed under solvent-free conditions using activated silica gel at the full power of 1000 W. Schiff's base formation was completed after 8 min of microwave irradiation, whereas tetraaryl imidazoles formed after 14–23 min of microwave irradiation.

We have an opinion that, the acidic nature of silica gel would have enhanced this reaction particularly during dehydration steps. All the synthesized compounds were analyzed by TLC, mp, IR, ^1H NMR, MASS, and elemental analysis. The ^1H NMR showed a characteristic peak for NH between 8.77 and 8.86 δ ppm for compounds containing INH (**2-4**). A characteristic peak for NH_2 was observed between 6.57 and 6.82 δ ppm for compounds containing sulphanilamide (**5-9**). A characteristic peak for COOH was observed between 12.94 and 13.04 δ ppm for compounds containing PABA (**10-13**).

Initially, we tried to synthesize the tetraaryl imidazoles by adopting a one-pot single-step multicomponent reaction by both conventional and microwave method [21–23], involving primary aromatic amine, aldehyde, benzyl, and ammonium acetate as shown in Scheme 2.

However, the above reaction gave triaryl imidazole in addition to the tetraaryl imidazole with incorporated aryl amine in a yield ratio of 3:1, respectively. This result indicated that, the formation of triaryl imidazole is relatively easy when compared with tetraaryl imidazole. To improve the yield of tetraaryl imidazoles and to synthesize them selectively, we have modified the procedure according to the Scheme 1. Hence, for this reason we prepared the Schiff's bases first and then taken further to the cyclization step involving equivalent amount of diketone and excess of ammonium acetate. The list of synthesized compounds and the comparative yield statement between microwave and conventional method is as shown in Table 1.

[b] Microwave irradiation (Whirlpool™ domestic microwave oven).

[c] The cytotoxic concentration (which inhibited 50% growth of total cells).

To understand the reaction mechanism, we performed a couple of experiments to find out the possible intermediates formed during the formation of tetraaryl imidazoles [24]. The experiments were designed to identify the intermediates under similar reaction conditions as follows,

1. Benzil with ammonium acetate
2. Benzil with PABA
3. PABA with anisaldehyde
4. Ammonium acetate with anisaldehyde
5. Product of experiment 3 with benzil and excess of ammonium acetate.

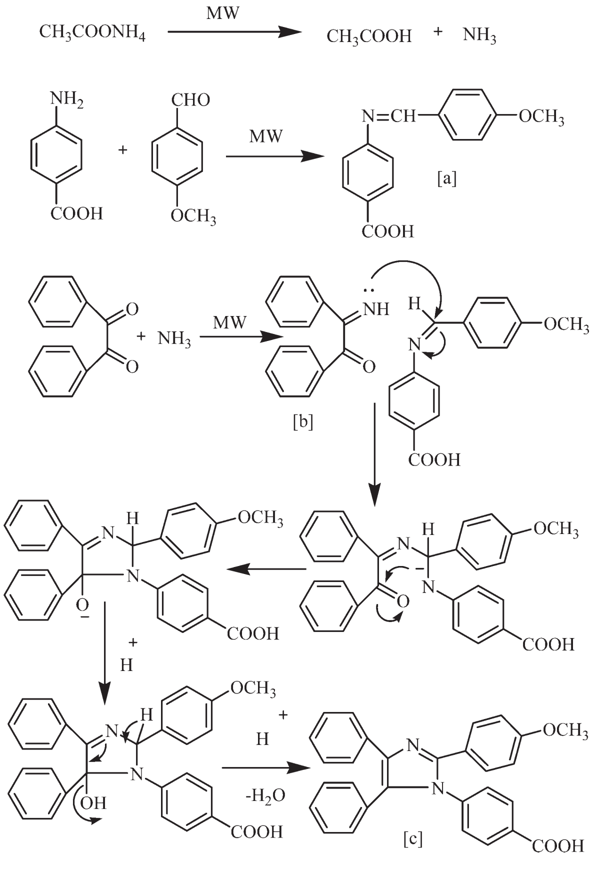
The reaction mixtures were irradiated with microwaves for 8 min and directly fed to the mass spectrometry to find out the intermediates formed under APCI (atmospheric pressure chemical ionization) technique. The reaction mixture of experiment 1 showed a molecular ion peak at 209.0 confirming the formation of mono imine and another molecular ion peak at 208.0 for a di imine. TLC also showed one spot each for mono imine and di imine. Further, isolated yield ratio was found to be 7:1 for the mono imine and di imine, respectively. This experiment indicated that, mono imine formation is favored over the di imine. The reaction mixture of experiment 2 showed the molecular ion peak at 329.1. However, the isolated yield was found to be just 4%. This result indicates that the formation of Schiffs base from diketone is quite difficult in this reaction. Probably, the steric crowding around the diketone (benzil) and less reactivity of aromatic amine may not have favored the formation of Schiff's base. The reaction mixture of experiment 3 showed a molecular ion peak at 255.0 confirming the formation of Schiff's base between aldehyde and aromatic amine, the TLC showed a clear single spot. The isolated yield was found to be about 98%. The reaction mixture of experiment 4 showed a molecular ion peak at 135.0 indicating formation of imine. But, we could not isolate the product, which may be because of its instability or its being formed in very low quantities. The reaction mixture of experiment 5 showed a molecular ion peak at 444.95 confirming the formation of tetraaryl imidazole and no peak was observed for triaryl imidazole. The TLC showed single spot for the formation of tetraaryl imidazole and isolated yield was found to be 99%. The experiment 5 clearly indicates that the Schiffs base formation between aldehyde and aromatic amine is more likely during the formation of tetraaryl imidazole. In contrast to this, the experiment 2 results reveal that possibility of Schiffs bases formation between aryl amine and diketone is less likely under this set of reactants and provided reaction conditions. All the above experiments were conducted by both conventional and microwave method. Acetic acid was used as a solvent in conventional method, whereas activated silica gel was used in the microwave method. By the conventional method all the above reaction mixtures were refluxed for 10 h. The observations were found to be same under both the methods.

In addition to the above experiments, we stopped the reaction between benzil, anisaldehyde, PABA, and ammonium acetate at the half way stage under both microwave and conventional methods. The reaction mixtures were directly fed to the mass spectromet. Presence of triaryl imidazole, tetraaryl imidazole, and product of experiment 1 and 3 was observed.

All the above experimental results revealed the possible intermediates formed during the formation of title compounds. The possible motive or driving force for this reaction would be the formation of relatively more stable imidazole ring system. On the basis of these facts the possible mechanism may be postulated as shown in the Scheme 3.

Even though, protocol and postulated mechanism for the formation of triaryl imidazoles is reported by

Scheme 3. (a) Schiff's base, (b) Imine, (c) Tetraaryl imidazole.



Siddiqui [25] recently in the year 2005. The present protocol and postulated mechanism for the formation of tetraaryl imidazoles attempts to give the better insight based on the experimental facts. We differ from their postulated mechanism by saying; imine formation will be favored between diketone and ammonia, rather between aldehyde and ammonia. The reason for this as already explained in the results of experiment 4. However, further studies are required to come to any hard core conclusion.

All the synthesized tetraaryl imidazoles incorporated with chemotherapeutic pharmacophores were evaluated for their *in vitro* antibacterial activity against two-gram positive bacteriae such as *B. subtilis* and *S. aureus* and two gram negative bacteriae *E. coli* and *K. pneumoniae*. Only compound no **13** exhibited a moderate activity with minimum inhibitory concentration (MIC) of 250 μg against *S. aureus*. Surprisingly, no other compound exhibited an antibacterial activity.

All the synthesized compounds were evaluated for their possible antimycobacterial activity toward a strain of *M. tuberculosis* $H_{37}Rv$ sensitive to isoniazid. Middlebrook (MB) 7H10 agar medium was used for testing antitubercular activity. The MIC determination was performed from 1 to 50 μg/mL concentrations. But, no compound exhibited MIC below 50 μg/mL concentration including the tetraaryl imidazoles containing isoniazid moiety (**2**, **3**, and **4**).

Anticancer activity of the synthesized compounds was evaluated by determining the percentage growth inhibition of DLA (Dalton's lymphoma ascites) cells by tryphan blue dye exclusion technique. Compounds **2**, **9**, and **13** showed good anticancer activity with CTC_{50} (cytotoxic concentration) at 190.26, 438.50, and 94.63 μg/mL, respectively. The synthesized tetraaryl imidazoles and their CTC_{50} values are as shown in Table 1.

In conclusion, we have developed a microwave assisted, convenient, efficient, and environmentally benign protocol for the syntheses of biologically active tetraaryl imidazoles. The present microwave method was found to be better than conventional method in terms of reaction time, yield, and relatively simple method to perform parallel syntheses. Thus, this methodology becomes an efficient strategy for the rapid syntheses of tetraaryl imidazoles, selectively. From the point of biological interest, compound **13** was found to be the candidate compound to investigate further for its anticancer activity.

EXPERIMENTAL

The laboratory grade chemicals and reagents were used to synthesize all the reported compounds. The melting points were determined in open capillaries. Temperatures are expressed in °C and are uncorrected. The IR spectra of compounds were recorded on Perkin-Elmer infrared–283 FTIR spectrometer by KBr pellet technique and are expressed in cm^{-1}. ^1H NMR spectra were recorded on Bruker DRX-300 (300 MHZ, FT-NMR) spectrophotometer using TMS as an internal standard, $CDCl_3$, or DMSO-d_6 as a solvent. The chemical shifts are expressed in δ ppm and following abbreviations are used: s, singlet; d, doublet; t, triplet; q, quartlet; and m, multiplet. Mass spectrum was obtained using LC-MS (Schimadzu-2010AT) under atmospheric pressure chemical ionization technique (APCI) and elemental analysis was performed using Elemental Vario EL III, Carlo-Erba 1108. TLC was performed to monitor the reactions and to determine the purity of the products on precoated aluminum plates using 10% methanol in chloroform or 20% ethyl acetate in pet ether as a mobile phase.

Procedure for the preparation of benzil (1). Crude benzoin (10 g, 0.048 mole) and 15 g of sodium nitrite were transferred to a 250-mL round bottom flask containing 40 mL of glacial acetic acid. The reaction mixture was refluxed using an air condenser for about 50 min (till the evolution of white gaseous vapors ceases). Then the reaction mixture was cooled and poured into a beaker containing 100 mL of ice-cold water. The mixture was stirred well until the oil separates completely as a yellow solid. The crude benzil was collected by filtration, washed thoroughly with water, and recrystallized from ethanol. The reaction was monitored through TLC. Yellow crystals (97%); mp 95°C, IR (cm^{-1}, KBr): 3047 (Ar C—H), 1707 (C=O), 1601 (C=C).

General procedure for the preparation of Schiff's bases

Conventional method. Equimolar amounts (0.01 mole) of aromatic amine and aromatic aldehyde were transferred to a 250-mL flat bottom flask containing 15 mL of glacial acetic acid to serve as a solvent, then refluxed with stirring for about 6 h. After completion of the reaction, the reaction mixture was allowed to cool to give a corresponding product. The reactions were monitored through TLC. The completed reactions were taken directly for the preparation tetraaryl imidazoles.

Microwave method. This reaction was carried out in a parallel synthetic way as shown in Scheme 1. Equimolar amounts (0.01 mole) of aromatic amine and aromatic aldehyde were transferred to a clean and dry mortar containing 2 g of activated silica gel, triturate to become a uniform mixture. The reaction mixture was then transferred to a 100 mL beaker. Like this all other beakers containing different reaction mixtures were kept inside the microwave oven in a circle and then microwave irradiation was carried out at 1000 W power for about 8 min. Intermittent cooling was done after every 60 s of microwave irradiation. During intermittent cooling, the reaction mixtures were thoroughly mixed using a glass rod. The reactions were monitored through TLC. The completed reactions were taken directly for the preparation of tetraaryl imidazoles without any work up.

General procedures for the preparation of tetraaryl imidazoles (2-13)

Conventional method. Benzil (0.01 mole) was transferred along with excess of ammonium acetate (0.1 mole) into a flask containing the Schiff's base (0.01 mole) obtained in the previous conventional procedure. The reaction mixture was stirred and refluxed on heating plate with magnetic stirrer for about 12–15 h. The reaction was monitored through TLC. When complete, the reaction mixture was poured into 250 mL of water to remove ammonium acetate and acetic acid and the product was collected by filtration dried in a hot air oven. The crude product was washed with 2 × 10 mL of toluene to remove traces of any unreacted benzil; further purification by was by recrystallized using ethyl acetate.

Microwave method. This reaction was carried out in a parallel synthetic way as shown in Scheme 1. Benzil (0.01 mole) was transferred along with excess of ammonium acetate (0.1 mole) into a dry mortar containing the Schiff's base (0.01 mole) obtained in the previous microwave procedure. Triturate to become a uniform mixture. The reaction mixture was then transferred to 100 mL beaker. Likewise, all other beakers containing different reaction mixtures were kept inside the microwave oven in a circle and then microwave irradiation was carried out at 1000 W power for about 14–23 min. Intermittent cooling was done after every 60 s of microwave irradiation. During intermittent cooling, the reaction mixtures were thoroughly mixed. The reactions were monitored through TLC. The reaction mixtures were withdrawn from microwave oven soon after the reactions were completed. The completed and cooled reaction mixture was poured in to 250 mL of water to remove ammonium acetate and acetic acid, filtered, and dried it in hot air oven. The crude product along with silica gel was washed with 2 × 10 mL of toluene to remove traces of any unreacted benzil, further extracted with ethyl acetate. The ethyl acetate was heated, filtered in hot condition, and allowed to cool. The solid crystals formed were collected by filtration and dried under vacuum.

The physical, analytical, and spectral data of final compounds are given in the following text.

N*-[2-(3-Nitrophenyl)-4,5-diphenylimidazol-1-yl]-pyridamide (2).* Pale yellow crystals; mp 45°C; IR (cm^{-1}, KBr): 3250 (NH), 3032 (Ar C-H), 1654 (C=O), 1621 (C=C), 1595 (C=N), 1528 (NO), 1368 (NO), 1275 (C—N); ^{1}H NMR (δ ppm): 7.25-7.82 (m, 17H, ArH), 8.5 (s, 1H, ArH), 8.82 (bs, 1H, NH); MS (m/z): found 461.80, calcd 462 (M+H)$^+$. 311.05, 326.9, 342.0, 385.10. Anal. Calcd for $C_{28}H_{20}N_2O_3$: C, 77.76; H, 4.66; N, 6.48 Found: C, 77.45; H, 4.36; N, 6.16.

Antibacterial activity screening procedure. All the synthesized compounds were screened for their antibacterial activity against two-gram positive bacteria such as *B. subtilis* and *S. aureus* and two gram negative bacteria *E. coli* and *K. pneumoniae* according to the standard procedure [26,27]. The primary screen was carried out using the agar disc-diffusion method using Muller-Hinton agar medium. Sterile filter paper discs (8 mm diameter) were moistened with test compound solution in DMSO of specific concentration 500 μg/disc were carefully placed on agar culture plates that had been previously inoculated separately with bacteria. The plates were incubated at 37°C and inhibition of growth was measured after 24 h. The minimal inhibitory concentration (MIC) for the compound 13 against *S. aureus* was carried out using the microdilution susceptibility method in Muller-Hinton Broth by two-fold dilution method and it was found to be 250 μg/mL. Streptomycin was used as a standard drug (MIC $<$ 18 μg against all the bacteria).

Antimycobacterial activity screening procedure. Middlebrook (MB) 7H10 agar medium was used for testing of antitubercular activity of the compounds. Culture of *M. tuberculosis* $H_{37}Rv$ grown on Lowenstein-Jensen (L-J) was harvested in saline containing 0.05% Tween-80 and used according to the standard procedure [28]. The minimum concentration of the drug or compounds that completely inhibited the growth of different mycobacterium was recorded as minimum inhibitory concentration (MIC) with respect to the used inoculum. The MIC for test compounds was performed up to 50 μg/mL concentrations. Isoniazid (INH) was used as a standard drug (MIC, 21 μg/mL).

Anticancer activity screening procedure. Anticancer activities [29–33] of the synthesized compounds were assessed by determining the percentage inhibition of DLA (Dalton's lymphoma ascite) cells by tryphan blue dye exclusion technique according to the standard procedure [33]. We checked anticancer activity of all the synthesized compounds at the concentration of 500, 250, 125, 62.5, 31.25 μg/mL. The percentage growth inhibition was calculated by using the following formula: % Growth inhibition = [(Total cells – Live cells) × 100]/Total cells.

The CTC_{50} values were calculated by plotting the graph between concentration versus percentage growth inhibition and by bisecting concentration at the 50% growth inhibition. The synthesized tetraaryl imidazoles and their CTC_{50} values are as shown in Table 1. Cyclophospamide was used as standard drug (CTC_{50}, 12 μg/mL).

Acknowledgment. We thank Dr. A. K. Goel, assistant director, CDRI, Lucknow, for providing elemental analysis and antitubercular activity data.

The reaction of 3-amino-1,2,4-triazole (**1**) with arylidene-5-acetyl barbituric acid (**2b,c**) or dehydroacetic acid (**2a**) by refluxing in butanol leads to the formation of dihydro-1,2,4-triazolo[1,5-*a*]pyrimidines **3a–c**.

J. Heterocyclic Chem., **46**, 285 (2009).

INTRODUCTION

Azolopyrimidines are analogs of many naturally occurring compounds, such as purines, and therefore they have been excellent objects for the search of new physiologically active compounds for quite a long time [1–3]. The entrance of a pharmacofore into the molecule of azolopyrimidine can lead to compounds with interesting biological properties.

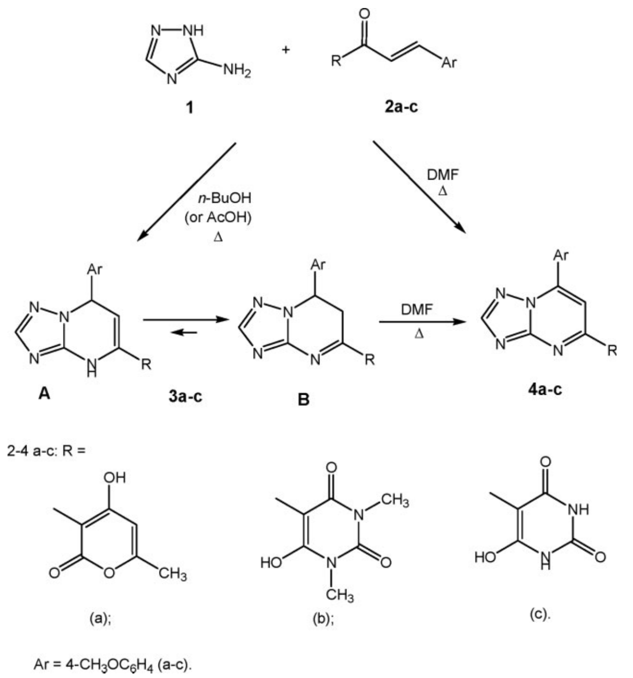
From the other side, it was shown [4] that partially hydrogenated azoloazines with a nodal nitrogen are useful for studying a wide set of theoretical problems, for example, imine-enamine tautomerization. Therefore, the important aim of this work was a continuation of our previous research about tautomerization processes in dihydroazolopyrimidines [5,6], especially synthesis of dihydro-1,2,4-triazolo[1,5-*a*]pyrimidines with a proton-acceptor substituent which could lead to the intramolecular hydrogen bond between a substituent and the NH group of pyrimidine ring, and investigation of the tautomeric equilibrium in such compounds. In our opinion, one of the possible solutions for both problems would be synthesis of dihydro-1,2,4-triazolo[1,5-*a*]pyrimidines that contained 6-hydroxypyrimidine-2,4-dion-5-yl or 4-hydroxy-6-methylpyran-2-on-3-yl substituents.

It is known [4] that the most convenient preparative method for synthesis of dihydroazolopyrimidines with nodal nitrogen atom is the reaction of aromatic α,β-unsaturated ketones or their synthetic precursors with aminoazoles which contain an amidine fragment. This synthetic way allowed obtaining a large number of dihydroazolopyrimidine derivatives that have different electronic properties of azole ring and contain various alkyl or aryl substituents in pyrimidine ring causing a wide set of electronic and solvation properties.

RESULTS AND DISCUSSION

We established that 3-amino-1,2,4-triazole (**1**) can react with arylidene derivatives of dehydroacetic acid (3-acetyl-4-hydroxy-6-methyl-2*H*-pyran-2-one**, 2a**), 5-acetyl-1,3-dimethylbarbituric (**2b**) and 5-acetylbarbituric (**2a**) acids by heating their equimolar amounts in

Scheme 1



n-buthanol or acetic acid, which leads to 6,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidines (**3a–c**) that contain a 4-hydroxy-6-methyl-2*H*-pyrane-2-one-3-yl (**3a**), 6-hydroxy-1,3-dimethylpyrimidine-2,4-dione-5-yl (**3b**), and 6-hydroxy-1*H*-pyrimidine-2,4-dione-5-yl (**3c**), respectively, on the C-5 of triazolopyrimidine system.

Performing the reaction between amine **1** and compounds **2a–c** by heating in dimethylformamide led to the formation of heteroaromatic azolopyrimidines (**4a–c**). The same compounds were obtained by heating **3a–c** in DMF.

The structure of **3a–c** was established by their NMR data. ^{1}H NMR spectra of **3a–c** (in DMSO-d_6) contained signals corresponding to an AMX system, multiplet of aromatic ring, singlet of triazole proton, and signals of heterocyclic substituent. Thus, the NMR data showed the existence of **3a–c** in the tautomeric 6,7-dihydro form exclusively (*i.e.*, ‘‘**B**’’ form on the Scheme 1). Additionally, ^{13}C NMR spectra of **3a** and **3c** confirmed their structure. The mass spectra of **3a–c** showed molecular ion peaks.

Concerning the tautomerism of considered dihydroazolopyrimidines, it is necessary to mention that, according to our previous research, 4,7-diphenyldihydro-1,2,4-triazolo-[1,5-*a*]pyrimidine (**5**) exists exclusively in the 1,4-dihydro form (*i.e.*, ‘‘**A**’’ form on the Scheme 2) in the solid state and in solutions [6], whereas 2-hydroxyaryl derivative (**6**) is a mixture of two tautomeric forms ‘‘**A**’’ and ‘‘**B**’’ in DMSO-d_6 with relative ratio of ‘‘**A**’’ form 75–85% [5].

Further, it was shown [7] that the ‘‘**B**’’ form can be partially stabilized by entrance of electron-donating aryl, *e.g., p*-dimethylaminophenyl, on C-5 of the corresponding dihydroazolopyrimidine (according to [7] azolopyrimidine **7** leads to mixture of imine and enamine forms in ratio ~55:45).

The relative stabilization of the ‘‘**B**’’ form in **3a–c** should be explained, in our opinion, by the influence of two effects, especially electron-donating properties of substituent on C-5 on the one hand and hydrogen bond formation on the other hand.

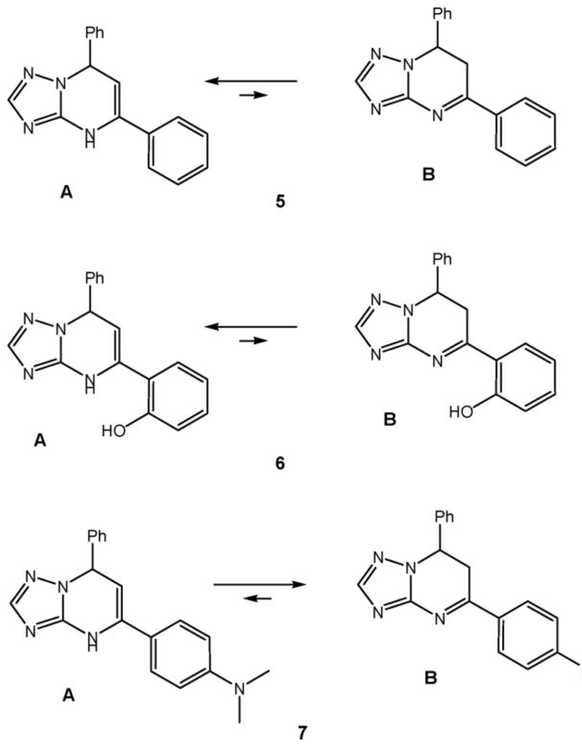
The ^{1}H NMR spectra of **4a–c** contained multiplets of 4-methoxyphenyl substituent in the aromatic area, singlets of pyrimidine and triazole ring in the low-field area, signals corresponding to the substituents at C-5 of triazolopyrimidine, and a broad singlet corresponding to the hydroxy group at 16–18 ppm, which is totally consistent with proposed structure of **4a–c**.

EXPERIMENTAL

Starting 3-amino-1,2,4-triazole, dehydroacetic acid, 5-acetylbarbituric, and 5-acetyl-1,3-dimethylbarbituric acid are commercially available. The compounds **2a,c** were prepared according to [8] (**2a**), [9] (**2c**). Compound **2b** was prepared similar to **2c** [9].

Each reaction was monitored by TLC on Silufol UV-254 plates with ethyl acetate/chloroform (1:1). Melting points were

Scheme 2



determined with a Kofler apparatus. The ^{1}H and ^{13}C NMR spectra were recorded in DMSO-d_6 at 200 MHz (50 MHz for ^{13}C) on a Varian Mercury VX-200 spectrometer and analyzed with ADVASP$^{\mathrm{TM}}$ Analyzer program (Umatek International Inc.). Chemical shifts are reported in ppm (δ−scale), coupling constants (*J*) in Hz, internal standard was $Si(CH_3)_4$. The EI mass spectra were obtained on Varian 1200L with electron energy 70 eV.

6-Hydroxy-5-[3-(4-methoxyphenyl)-propenon-1-yl]-1,3-dimethyl-pyrimidine-2,4-dione (2b). The mixture of 3.96 g (0.02 mol) 5-acetyl-1,3-dimethylbarbituric acid, 2.72 g (0.02 mol) of 4-methoxybenzaldehyde and 0.8 g (0.02 mol) of sodium hydroxide in 20 mL of methanol was refluxed for 12 h. The reaction mixture was cooled to room temperature and neutralized with concentrated HCl. The precipitate formed was filtered off. Yield 4.0 g (63%), mp 190–191°C (from methanol); ^{1}H NMR: δ 3.19 (s, 6H, 2*CH_3); 3.81 (s, 3H, CH_3O); 7.03 (m, 2H, *m*-ArH); 7.68 (m, 2H, *o*-ArH); 7.94 (d, 1H, J = 15.8 Hz (α-H)); 8.34 (d, 1H, (β-H)); 17.0 (br. s, 1H, (OH)). Anal. Calcd. for $C_{16}H_{16}N_2O_5$: C, 60.75; H, 5.10; N, 8.86. Found C, 60.45; H, 4.95; N, 8.77.

5-(4-Hydroxy-6-methylpyran-2-on-3-yl)-7-(4-methoxy-phenyl)-6,7-dihydro-1,2,4-triazolo[1,5-*a*]pyrimidine (3a). ***Method A.*** The mixture of 3-(4-hydroxy-6-methyl-2-oxo-2*H*-3-pyranyl)-1-(4-methoxyphenyl)-2-propen-1-one (**2a** [8], 2.86 g, 0.01 mol) and 3-amino-1,2,4-triazole (**1,** 0.92 g, 0.011 mol) in 15 mL of *n*-buthanol was refluxed for 1 h. The reaction mixture was cooled to room temperature, the precipitate that formed was filtered off. The yield was 2.53 g (72%), mp 181–183°C (from ethanol).

Method B. The 2.86 g (0.01 mol) of **2a** and 0.92 g (0.011 mol) of **1** in 5 mL glacial acetic acid were refluxed for 2 h. The mixture was cooled and diluted with 10 mL of acetone. The precipitate that formed was filtered off. Yield was 1.96 g (56%), mp 181–183°C (from ethanol).

Sulfamic acid has been found to be an efficient catalyst for the one-pot synthesis of novel 2,5-diaryl-1,3,4-oxadiazoles by condensation of different coumarinoyl hydrazides with various coumarinoyl or quinolinoyl chlorides under microwave irradiation and conventional heating. Some of the advantages of this method are low reaction times, operational simplicity, and high yields.

J. Heterocyclic Chem., **46**, 289 (2009).

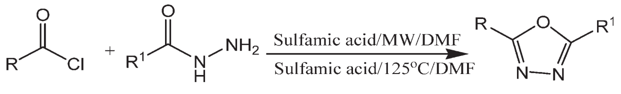
INTRODUCTION

1,3,4-Oxadiazoles and their derivatives have a wide range of biological and therapeutic properties such as antimicrobial [1], antifungal [2], and anti-inflammatory action [3]. Also, vinblastine-like [4] oxadiazole molecules that incorporate a coumarin moiety have been reported as potent antitumor and antibacterial agents [5,6]. Because of these important findings, the synthesis of these kinds of molecules has attracted significant interest. The general synthesis of oxadiazoles can be classified into four main synthetic strategies as follows: (i) cyclization of diacylhydrazines [7–11], (ii) oxidation of acyl hydrazones [12,13], (iii) acid-catalyzed condensation of acyl hydrazides with orthoesters [14–18], and (iv) solid-state synthesis and other methods [19–27]. However, these methods suffer from harsh reaction conditions and long reaction times. Therefore, it was deemed necessary to develop efficient and simple procedures for the synthesis of these biologically important oxadiazole derivatives.

RESULTS AND DISCUSSION

Sulfamic acid (SA) has emerged as an excellent solid acid catalyst for acid-catalyzed reactions such as functional group protection and deprotection [28], and is used in some important organic transformations such as the synthesis of xanthenes [29], Beckmann rearrangement reactions [30], Pechmann [31] and Biginelli [32] condensations. SA is a recyclable and very stable crystalline solid [33], because of its immiscible nature with common organic solvents and its ease in handling. Microwave irradiation accelerated synthesis is emerging as a powerful tool in organic synthesis [34], since this technique affords short reaction times, increased yields, and high purities of reaction products, as well as ease in manipulation. These observations prompted us to investigate an efficient SA-catalyzed one-pot synthesis of novel 2,5-diaryl-1,3,4-oxadiazoles from aryl acid chlorides and aryl hydrazides in dimethylformamide (DMF) utilizing both microwave irradiation and conventional heating (Scheme 1). In the microwave irradiation procedure for the synthesis of 2,5-diaryl-1,3,4-oxadiazoles, the reaction mass containing the aryl acid chloride and the aryl hydrazide was irradiated in a domestic microwave oven at a 300 watt power level over 30 s intervals in an open vessel for 4–5 min. The oxadiazoles were also conventionally prepared at 125°C over 4–5 h. The structures of all newly synthesized 2,5-diaryl-1,3,4-

Scheme 1. Sulfamic acid catalyzed synthesis of 2,5-diaryl-1,3,4-oxadiazoles.



1 2 3

oxadiazoles were confirmed by IR, ^{1}H NMR and mass spectral data.

To study the efficiency of a number of acidic catalysts compared with SA in the synthesis of the 2,5-diaryl-1,3,4-oxadiazoles, we conducted a model reaction between 3-coumarinoyl chloride and 3-coumarinoyl hydrazide in the presence of either SA, silica sulfuric acid, *p*-toluenesulfonic acid, or sulfuric acid (all at 4 mol %) under both microwave irradiation (Method A) and conventional heating (Method B) conditions (Table 1). In this study it was found that, compared with the other acid catalysts utilized, SA was a more effective catalyst with respect to reaction time and yield of the resulting 1,3,4-oxadiazole (Table 1).

A variety of symmetrical and unsymmetrical 2,5-diaryl-1,3,4-oxadiazoles were also synthesized *via* the above microwave procedure, all of which were obtained in good yields (Table 2), illustrating the versatility of the method.

CONCLUSION

In conclusion, an efficient, facile and flexible one-pot synthesis of 2,5-diaryl-1,3,4-oxadiazoles *via* SA-catalyzed microwave irradiation has been developed. We consider this methodology to be superior to existing methodologies for the synthesis of 2,5-disubstituted-1,3,4-oxadiazoles.

EXPERIMENTAL

All the melting points were determined in open capillary in liquid paraffin bath and are uncorrected. The purity of the compounds was checked by TLC. IR spectra (KBr) were recorded on Shimadzu FTIR model 8010 spectrometer and the ^{1}H NMR spectra on Varian Gemini 200 MHz Spectrometer using TMS as an internal standard. The C, H, and N analysis of the compounds was done on a Carlo Erba model EA1108. Mass spectra were obtained on a Jeol JMS D-300 Spectrometer. For the microwave irradiation experiments (BPL 800T) domestic microwave oven was used.

General procedure for the synthesis of 2,5-diaryl-1,3,4-oxadiazoles (3a-m) *via* methods A and B.

Method A. The coumarinoyl or quinolinoyl chloride (1.1 mmol), coumarinoyl hydrazide (1.5 mmol), and SA (0.04 mmol) were added to DMF (2 mL). The reaction mass was irradiated in a microwave oven (BPL, 800 model) at a power level of 300 W over 30 s intervals in an open vessel for 4–5 min (Table 2). Completion of the reaction was determined by TLC monitoring. The reaction mass was cooled to room temperature, poured over crushed ice, and stirred for 15 min at 0–5°C. The precipitated product was collected by filtration, washed with cold water and air-dried. Pure product was obtained by recrystallization from ethanol.

Method B. The coumarinoyl or quinolinoyl chloride (1.1 mmol), coumarinoyl hydrazide (1.5 mmol), and SA (0.04 mmol) were added to DMF (3 mL). The reaction mixture was stirred at 125°C for 4–5 h (Table 2). The progress of the reaction was monitored by TLC. After completion of the reaction, the contents were cooled to room temperature, poured over crushed ice and stirred for 15 min at 0–5°C. The precipitated product was collected by filtration, washed with cold water and air-dried. Pure product was obtained by recrystallization from ethanol.

Synthesis of 10-(halophenyl)-9-(4-methoxyphenyl)-3,4,6,7,9,10-hexahydroacridine-1,8-(2H,5H)-dione derivates have been prepared and their absorption, emission, and laser properties have been evaluated. The structures of all the synthesized compounds were characterized by spectroscopic methods IR, ^{1}H NMR, ^{13}C-APT, MS, and elemental analysis.

J. Heterocyclic Chem., **46**, 294 (2009).

INTRODUCTION

Many organic compounds demonstrated laser activity in the 310–1100 nm region [1]. These laser dyes have been classified as xanthene dyes, cyanine or polymethine dyes, linear and condensed polybenzoid compounds, and heterocyclic compounds. In the heterocyclic series, rhodamine, coumarin, and acridinedione have been known as efficient laser dyes. So far, the acridinedione ring system reported possesses laser activity in the 475–500 nm region [2–5]. The effectiveness of lasing can be controlled by substituents at the 9- and 10-positions of the acridine chromophore [6]. Therefore, acridinediones with substituents at 9- or 10-positions have already been synthesized by using different methods [7–13]. Photochemical properties of some acridinedione dyes were reported in literature [14–16]. In this study, we reported the synthesis of novel halogen substitute acridinediones. In addition to UV, fluorescence spectra and laser activity of the acridinedione dyes were examined (Table 1).

RESULTS AND DISCUSSION

The tetraketones were formed by the condensation of cyclohexane-1,3-dione or 5,5-dimethyl-1,3-cyclohexanedione with 4-methoxybenzaldehyde furnishing compounds **I** and **II**. Then, tetraketones were refluxed together various halo-anilines with acetic acid-ammonium acetate system in toluene for the syntheses of acridinediones (Scheme 1). Acridinediones were obtained with high yield (from 75 to 92%) and short reaction time 2 h data for all compounds. Physical and analytical data of compounds were given in Table 1.

The purity of the compounds was checked by using TLC. All of the products were characterized by IR, ^{1}H NMR, ^{13}C-APT, mass spectrometry, and elemental analyses.

All spectral data are in accordance with assigned structures. In IR spectra, aromatic C—H, aliphatic C—H, and C=O stretching bands were observed at expected values. In the ^{1}H NMR spectra, methyl protons were seen at ~0.85–1.10 ppm as two singlet peaks. Aromatic, methylene, methane, and OCH$_3$ protons were seen at expected values. The ^{13}C-APT spectra of the compounds displayed the number of resonance that fit exactly with the number of expected carbon resonances. Mass spectra of the compounds were taken using the chemical ionization (CI) technique. In general molecular ion peaks were seen in spectra and the base peaks were found by cleavage of the aryl ring from the parent molecule. The structure of compounds IX was further confirmed by an X-ray crystallographic analysis [17]. In summary, all compounds show good florescence and laser activity in chloroform ($1 \times 10^{-4}M$). Table 1 gives the absorption, emission, and laser activity of the dyes that have high

lasing efficiencies using chloroform as solvent. The tuning range for the dyes lies between 530 and 558 nm (Fig. 1).

EXPERIMENTAL

Melting points were measured on an Electrothermal 9100 apparatus. Absorption spectra were performed on an ATI Unicam UV-100 spectrophotometer. Infrared absorption spectra were recorded from a Mattson 1000-FTIR spectrometer, using KBr pellets. ^1H NMR (300 MHz) and ^{13}C-APT (75 MHz) spectra were obtained with a Bruker DPX-300 FT-NMR instrument with $CDCl_3$ as solvent. Mass spectra with CI were recorded on a AGILENT 1100 MSD instrument. The elemental analyses (C, H, N) were conducted using the Elemental Analyser LECO CHNS-932. Fluorescence spectra were obtained with Varian CARY Eclipse Fluorescence Spectrophotometer. The dye solutions (in a 2 cm × 2 cm quartz cell) were excited by using Ar ion laser; its wavelength was 488 nm and the pulse duration 6 ns and were detected by a diode. All measurements were performed in the presence of air at room temperature.

General procedure. The syntheses of compounds **I** and **II** were achieved according to the procedure described in the literature [20]. For that purpose, 4-methoxybenzaldehyde (3.40 g, 25 mmol) was added to the solution of cyclohexane-l,3-dione (5.60 g, 50 mmol) in aq. methanol (20 mL) and warmed until the solution became cloudy. The tetraketone started to separate out. Then, the reaction mixture was diluted with water to 250 mL and allowed to stand overnight; the tetraketone was collected by filtration and dried and recrystallized from methanol (**I:** yield 92%, mp 196°C; lit. mp for **I:** 196°C [20] and **II:** yield 90%, mp 142–143°C; lit. mp for **II:** 142–143°C [21], 125.5–126.5°C [21]).

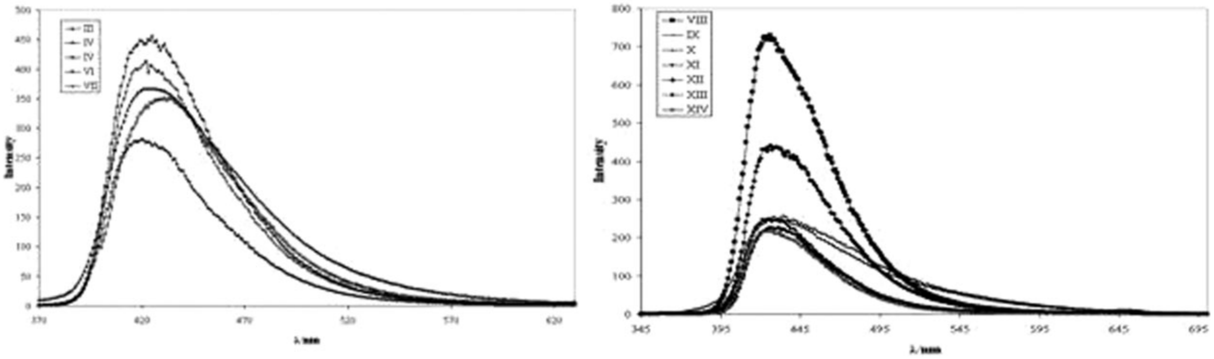

Figure 1. Fluorescence spectra of the dyes **III–XIV**.

10-(4-Fluorophenyl)-9-(4-methoxyphenyl)-3,4,6,7-hexadroacridine-1,8-(2*H*,5*H*-dione (III). The solution of 2,2'-((4-methoxyphenyl)methylene) dicyclohexane-1,3-dione **(I)** (1.03 g, 3 mmol), 4-fluorobenzenamine (0.34 g, 3.0 mmol), and excess amount of ammonium acetate were prepared with 20 mL toluene-acetic acid mixture (1:1). The formed solution was refluxed for 2 h by using a Dean-Stark apparatus. Then, the reaction mixture was poured into 100 mL water. Afterwards, last mixture was taken to a separation flask and 25 mL $CHCl_3$ was added. The organic phase was separated and evaporated. Halo-acridinedione **(III)** was separated from residue by thin layer chromatography and dried and then recrystallized from $CHCl_3$–MeOH (9:1). This compound was obtained as yellow solid, mp 265–266°C; IR: 3063 (Ar-H), 2954 (C—H), 1631 (C=O), 1585 (C=C) cm^{-1}. ^1H NMR: δ 1.73–1.97 (m, 4H, 2 × CH_2), 2.03–2.47 (m, 8H, 4 × CH_2), 3.77 (s, 3H, OCH_3), 5.32 (s, 1H, CH), 6.82 (d, 2H, J = 8.5 Hz, ArH), 7.18–7.36 (m, 6H, ArH). ^{13}C-APT: δ 21.10 (CH_2), 28.33 (CH_2), 31.18 (CH), 36.65 (CH_2), 55.18 (OCH_3), 113.63 (CH), 116.04 (C), 116.98 (CH), 129.33 (CH), 131.67 (CH), 135.07 (C), 138.79 (C), 151.30 (C), 160.90 (C), 164.23 (C), 196.14 (C). Condensation of thiourea derivatives with 1,4-dibromobutane gave 1,3-thiazepine derivatives (**1a**, **b**, **c** – **3a**, **b**, **c**). Elementary analysis, MS and ^{1}H NMR spectra confirmed the identity of the products. The molecular structure of **2b** was determined by an X-ray analysis.

INTRODUCTION

Derivatives of 1,3-thiazepine rings are important because of their biological activity [1–4]. The 1,3-thiazepine rings is present in Omipatrilat, which is currently in the phase IV of clinical trials. By inhibiting the activity of the angiotensin converting enzyme (ACE), that causes blood vessels to constrict, Omapatrilat lowers blood pressure. Another advantage of this drug is inhibition of the enzyme known as neutral endopeptidase (NEP), which causes blood vessels to relax [5,6].

The noncondensed 1,3-thiazepine rings can be prepared by using various methods. They can be divided into two main groups.

The first synthetic route is based on the cyclocondensation of thiourea derivatives resulting in 1,3-thiazepine ring systems. Following this way, diethyl allylmalonate reacted with thiourea in an unique manner giving an excellent yield of ethyl 2-amino-7-methyl-4-oxo-4,5,6,7-tetrahydro-1,3-thiazepine-5-carboxylate [7,8]. By this method, 2-amino derivatives of 7-methyl-4-oxo-4,5,6,7-tetrahydro-1,3-thiazepine-5-carboxylic acid ester in reaction of 1-alkyl-3-pent-4-enoyl-thiourea with Br_2 were obtained [9,10]. Furthermore, 4-bromo-butyryl chloride was also used as a cyclizing agent of *N*,*N*'-diphenylthiourea [11]. Condensation reaction of 4-amino-butan-1-ol with isothiocyanate leads to thiourea derivatives. Cyclization reaction of these thiourea derivatives in acidic solution resulted in 4-substituted (methyl, benzyl and propyl) imino-4,5,6,7-tetrahydro-1,3-thiazepine [12–15].

The second method for preparation of noncondensed 1,3-thiazepine ring systems is cyclization of compounds possessing N and S atoms in their chains. In this case, amines, aldehydes and halogen derivatives are utilized as highly effective cyclization reagents. Following this way, the reaction of 4-bromobutyl isothiocyanate with aromatic amines served as general preparative method for homologous 2-arylimino-1,3-thiazepines [16]. Further-more, hexahydro-1,3-thiazepin-4-ones were obtained *via* cyclocondensation of 4-mercapto-butyric acid alkyl ester with alkyl or aryl-aldehydes [17]. Moreover, 2*H*-hexa-hydro-1,3-thiazepine derivatives substituted by a nitro-methylene group in the second position were obtained in reaction of 1-methylo-thiolo-propylamine with 2,2,2-tri-halo-1-nitroethane [18]. 1,3-Thiazepine ring system was also synthesized by the alkilation of *N*-[1-mercapto-1-alkylamino-methylidene]-benzenesulfonamide sodium salt with dihaloalkanes [19].

In the present paper the 1,3-thiazepine system was obtained by the condensation reaction of thiourea derivatives with 1,4-dibromobutane.

RESULTS AND DISCUSSION

The preparation of nine new 1,3-thiazepine derivatives of 10-isopropyl-8-methyl-4-azatricyclo [5.2.2.0^{2,6}] undec-8-ene-3,5-dione, 1-isopropyl-7-methyl-4-azatricyclo-[5.2.2.0^{2,6}]undec-8-ene-3,5-dione and 1,7,8,9,10-

Scheme 1

1a, b, c - 3a, b, c

penta-methyl-4-azatricyclo[5.2.1.$0^{2,6}$]dec-8-ene-3,5-dione (Scheme 1) is described.

Anhydrides and imides obtained in Diels-Alder reaction were used as starting materials. Anhydride or imide **1** was obtained in the reaction of enantiomeric (*R*)-(-)-α-phellandrene with furan-2,5-dione or pyrrole-2,5-dione [20,21]. The reaction of α-terpinene with furan-2,5-dione or pyrrole-2,5-dione gave compound **2** [21–23] while compound **3** was obtained in reaction of 1,2,3,4,5-penta-methylcyclopentadiene with furan-2,5-dione or pyrrole-2,5-dione [24,25].

Obtained tricyclic anhydrides or imides were subjected to the reaction of hydrazine (80 % aqueous solution) as described previously [26,27].

In order to obtain the corresponding thiourea derivatives of above compounds they were subjected to the reaction with phenyl-, 4-methoxyphenyl-, cyclohexyl-isothiocyanate [27].

Products were transformed into 1,3-thiazepine derivatives by condensation with 1,4-dibromobutane. This method of synthesis of 1,3-thiazepine noncondensed rings has not been described in literature so far. The general synthetic pathway is given in Scheme 1. Formula of the investigated compounds is given in Table 1.

Obtained compounds were purified by flash chromatography. Elementary analysis, MS and ^{1}H NMR spectra confirmed the identity of the products. The molecular structure of **2b** was determined by an X-ray analysis.

Compounds investigated using EI MS show distinct signals of molecular ions at the expected m/z values, *i.e.* for **1a**, **2a**, and **3a** the value 437 was noted, and for **2b** the corresponding value was 467.

In the spectrum of **3a** an intense (100%) signal due to the ion $[M\text{-}135]^{+\bullet}$ has been observed, apparently due to the elimination of phenylisothiocyanate (PhNCS). Analogous splitting was noted for **2a** and **1a**, whereas in case of **2b**, consequently, 4-methoxyphenylisothiocyanate (CH_3O-PhNCS) was severed. However, the intensities of these signals for **2a**, **1a,** and **2b** were only 6, 20 and 2 %, respectively.

Furthermore, in the fragmentation patterns of **1a**, **2a,** and **2b** the most intense (100%) signal appeared at m/z 70. This value matches with the composition C_5H_{10} for which the isopentene cation-radical structure $[(CH_3)_2CHCH = CH_2]^{+\bullet}$ could be proposed, resulting from the sequential cleavage of the parent molecule. It might be assumed that above fragmentation path corresponds to the presence of the isopropyl substituent in the parent compounds **1a**, **2a**, and **2b**, which is absent in **3a**. Formation of the isopentene moiety from **2a** and **2b** requires a rearrangement of isopropyl substituent, whereas in **1a** the isopentane moiety already occurs as a part of condensed rings, serving as precursor for isopentene. The weak signal in the spectrum of **3a** at m/z 70 (13) occurs in close sequence of other signals showing similar intensity and was not referred to above fragmentation. Proposed fragmentation paths are shown in the Figure 1.

Above results concerning the m/z values of molecular ions and also the fragmentation patterns confirm the expected composition of investigated compounds.

The structure of 1,3-thiazepine and the exocyclic imino form of thiourea fragment were confirmed by the X-ray crystallography of **2b**. In its crystal structure two conformations of thiazepine ring are stabilized. The disorder of S1 and C4 atoms results in twist chair (TC) and deformed boat (B) conformers which are energetically nearly equivalent [28]. The major component (TC)

EXPERIMENTAL

Melting points were determined in a Kofler's apparatus and are uncorrected. The ^1H NMR spectra were recorded on a Bruker AVANCE DMX400 spectrometer, operating at 400 MHz. The chemical shift values are expressed in ppm relative to TMS as an internal standard. Elemental analyses were recorded with a CHN 2400 Perkin-Elmer model. Mass spectra of **1a**, **2a**, **3a,** and **2b** were recorded on an AMD-604 double focusing spectrometer with BE geometry (AMD Intectra, Germany). EI low resolution spectra were obtained with electron energy 70 eV, acceleration voltage 8 kV and ion source temperature 220°C. Samples were introduced using a direct insertion probe heated, when required, in the range 30–120°C. Mass spectral ESI measurements for **1b**, **3b**, **1c**, **2c**, **3c** were carried out on Waters ZQ Micromass instruments with quadrupol mass analyzer. The spectra were performed in the positive ion mode at a declustering potential of 40–60 V. The sample was previously separated on a UPLC column (C18) using UPLC ACQUITY^{TM} system by Waters connected with DPA detector.

Diffraction data for **2b** were measured at 292 K on a KM4 diffractometer using variable scan speed in the $\omega/2\theta$ scan mode and graphite monochromated Cu K_α radiation (λ = 1.54178 Å). A single crystal of dimensions 0.46 × 0.43 × 0.43 mm^3 was used for the data collection.

Flash chromatography was performed on Merck silica gel 60 (200-400 mesh) using chloroform as eluant. Analytical TLC was carried out on silica gel F_{254} (Merck) plates (0.25 mm thickness).

1,3-THIAZEPINE DERIVATIVES (1a,b,c–3a,b,c)

General procedure. Sodium hydride dispersion (60%) in mineral oil (0.44 g, ~10 mmol) was added in a single portion to a stirred solution of thiourea derivative (10 mmol) in anhydrous *N,N*-dimethylformamide at room temperature. After hydrogen evolution ceased, 1,4-dibromobutane (15 mmol) was added to the reaction mixture, after 5 and 15 min. respectively. The mixture was stirred for 6 h. Evaporation in vacuum gave a residue which was then purified by column chromatography (chloroform was used as eluant). The compound was crystallized from ethanol.

Crystal data for **2b**: monoclinic, space group $P2_1/c$, a = 14.407(3), b = 11.586(2), c = 14.851(3) Å, β = 92.92(3)°, V = 2475.7(8) Å^3, Z = 4, d_{calc} = 1.255 g/cm^3, μ(Cu K_α) = 1.415 mm^{-1}. In the θ range 3.07–73.51°, 4971 reflections were collected of which 4793 were unique (R_{int} = 0.0264). The structure was solved by direct methods using SHELXS-97 program [29] and refined by full-matrix least-squares on F^2 using SHELXL-97 program [29]. The non-H atoms were refined with anisotropic displacement parameters, except of S1A and C4A atoms. The two atoms of thiazepine ring are disordered over two positions with sof's of 0.877(4) and 0.123(4) for S1, C4, and S1A, C4A, respectively. H-atom positions were calculated from the geometry. H-atoms were given isotropic factors of 1.2 or 1.5 Ueq of the bonded C-atoms; the C–H bond 'riding' model was used in the refinement.

Crystallographic data have been deposited with the Cambridge Crystallographic Data Centre as CCDC No. 684835. Copies of the data can be obtained on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: +44 1223 336 033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk).

A new series of bis-1,5-[2′*H*,3′*H*-dihydro-4′(substituted phenyl)-1′,5′-benzothiazipin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene 3 and bis-1,5-[-2′,3′,4′,5′-teterahydro-2′-(substitutedphenyl)-4′-oxo-thiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene 4 have been synthesized by reacting 1,3-bis-[substituted cinnamate]-3,3-dimethyl-1,4-cyclohexadiene 2 with 2-aminothiophenol and thiogylcolic acid, respectively, through an environmentally benign procedure. The title compounds have been evaluated for their antimicrobial activities. Reaction under ultrasound irradiation resulted in enhancement of yields and reaction rates. Structures of the synthesized compounds have been elucidated on the basis of the elemental analysis and spectral data.

J. Heterocyclic Chem., **46**, 303 (2009).

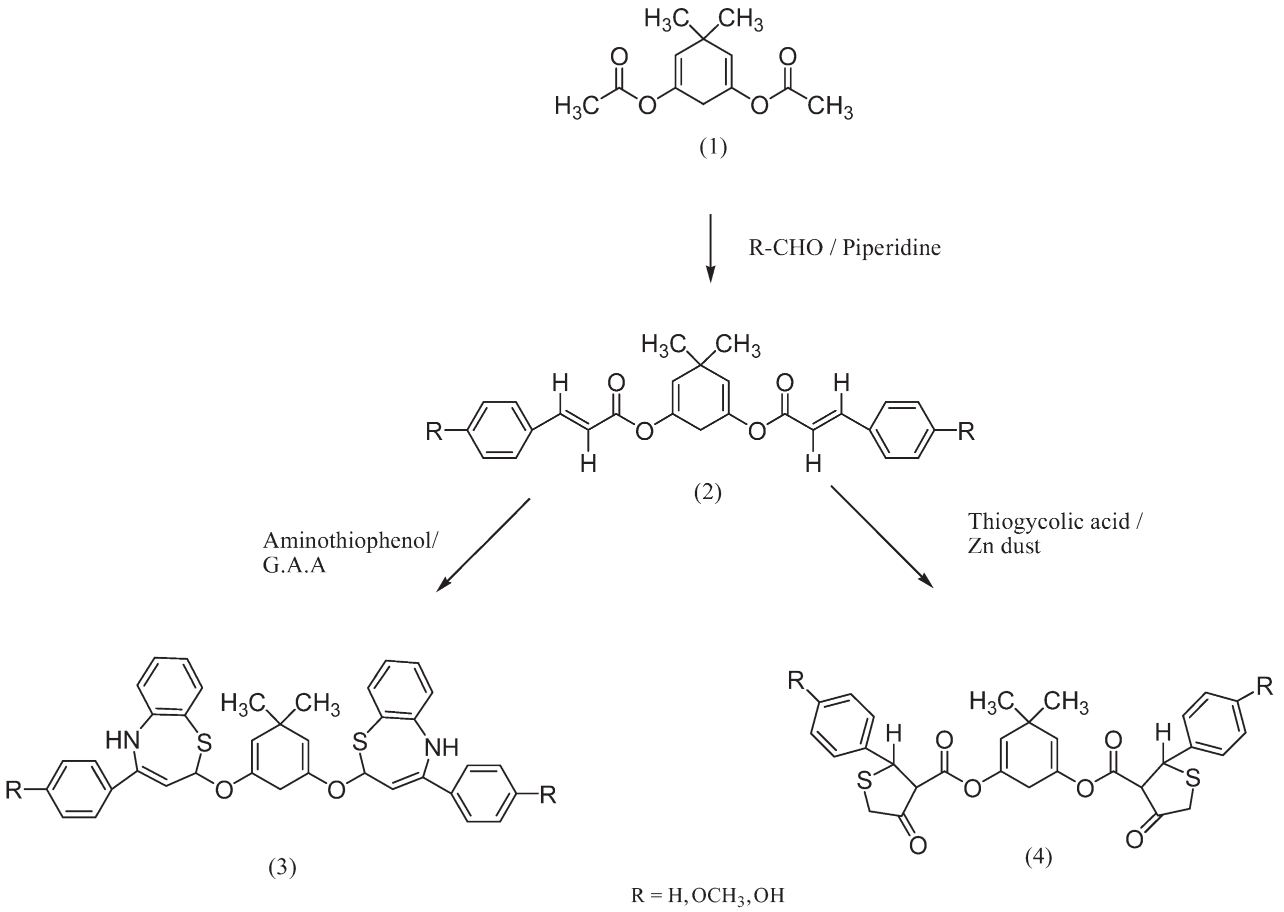
INTRODUCTION

The use of ultrasound irradiation for activating various reactions is well documented in the literature such as synthesis of azoles and diazenes [1], Reformatsky reaction [2], oxidation of substrates like hydroquinones [3], conversion of nitro compounds to carbamates [4], pinacol coupling [5], Ullmann condensation [6] *etc*.

The advantages of ultrasound-assisted chemical reactions include higher yields, shorter reaction times, and milder reaction conditions when compared with classical methods [7–11]. The effect of ultrasound has mostly been shown by increasing the yields of reactions and in some cases, changing the ratio of products formed. The most important effects of ultrasound arise from acoustic cavitation; formation, growth, and implosive collapse of bubbles in the liquid by passing ultrasonic waves through this medium [12,13]. The implosive collapse of the bubble generates localized hot spots through adiabatic compression or shock wave formation within the gas phase of the collapsing bubble. These bubbles create pressures of hundreds of atmospheres and temperature of thousands of degrees within the cavities during their collapse [14,15]. In all of these reactions, it was found that ultrasound accelerates the reactions [16–22].

Benzothiazepine derivatives possess potential anti-ulcer [23], analgesic [24], vaso-depressant [25], anti hypertensive [26], antidementia [27], antibacterial, and anti-fungal activities [28–30]. The biodynamic nature of benzothiazepines derivatives led to the current synthesis of 1,5-benzothiazepines having various substituents, which may prove to be of medical significance. Similarly, thiophenes derivatives are also well known for diverse biological activities and play a key role as anti-inflammatory [31,32], anti-protozoa [33], antitumor agents [34], and alternate substrate inhibitors of cholesterol eastrase [35]. In recent years, attention has been increasingly paid to the synthesis of bis-heterocyclic compounds, which exhibit various biological activities [36–45]. The wide range of therapeutic value of the above ring system prompted us to synthesize several new bis-1,5-[substituted cinnamate]-3,3-dimethyl-1,4-cyclohexadiene **2** and its utility as a building block in the synthesis of several new bis-1,5-[2′H,3′H-dihydro-4′(substituted phenyl)-1′,5′-benzothiazepin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene **3** and bis-1,5-[-2′,3′,4′,5′-teterahydro-2′-(substitutedphenyl)-4′-oxothiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene **4** compounds (Scheme 1). The structures of the products were confirmed by elemental analysis, IR, ^{1}H, ^{13}C NMR, and MS spectral analysis. The antimicrobial activities of the newly synthesized compounds were also investigated.

Scheme 1



RESULTS AND DISCUSSION

The reaction sequences leading to the different bis-heterocyclic ring is outlined in Scheme 1. The reaction of 3,3-dimethyl-1,5-dihydroxy-1,4-cyclohexadiene with acetic anhydride yielded bis-1,5-[acetoxy]-3,3-dimethyl-1,4-cyclohexadiene which was converted into bis-1,5-[substituted cinnamate]-3,3-dimethyl-1,4-cyclohexadiene **2**, on treatment with substituted aromatic aldehydes. Formation of compound **2** was evidenced by the appearance of a signal at 7.8 ppm (α,β unsaturated carbonyl) in the ^{1}H NMR spectra and in IR spectra band because of carbonyl at 1634 cm^{-1}. In the ^{13}C NMR spectra, the signal 188.24 ppm was observed due to O=C< in compound **2**. The reaction of 2-aminothiophenol with compounds having α,β unsaturated in conjugation with carbonyl system in acidic media afforded bis-1,5-[2′*H*,3′*H*-dihydro-4′(substitutedphenyl)-1′,5′-benzothiazipin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene **3**. In ^{1}H NMR spectra of compound **3**, the signal at 3.74 was observed due to —NH—, 6.0 due to C—H and at 7.35 due to C—H and in the IR spectra of bis-benzothiazepine **3**, the band at 3070 (—N—H—) and 1432 cm^{-1} (—C—S—) also confirmed. In ^{13}C NMR spectra, the signal at 65 ppm was observed because of >CH—S— and 70 (>C—S—benzothiazepine ring).

Similarly, the bis-1,5-[substituted cinnamate]-3,3-dimethyl-1,4-cyclohexadiene **2** on treatment with thioglycolic acid underwent cyclization to the bis-1,5-[2′,3′,4′,5′-teterahydro-2′-(substitutedphenyl)-4′-oxothiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene **4** (Scheme 1). The spectral data are in agreement with the proposed structures. The IR spectrum of **4** showed C—S stretching bands at 1340–1350 cm^{-1} and its ^{1}H NMR spectrum the chemical shifts due to CH_2 of ring was observed at 3.42 ppm. Appearance of two C=O at 196.66 and 199.23 ppm in ^{13}C NMR confirmed the formation of **4**. Keeping in view the advantages of ultrasound irradiation technique, the reaction was also carried out under sonication condition. The formation of compounds **2, 3,** and **4** was completed in 15 to 25 min under sonication condition when compared with conventional method, which took 4 to 5 h. The compounds obtained by both the routes were found identical as they showed same melting point and similar spectral data.

The comparative data of the compounds have been listed in Table 1.

Antibacterial activity. All the newly synthesized compounds were initially screened for their *in vitro* antibacterial activities against the gram-positive *S aureus, C diphtheriae*, and *S cerevisiae,* the gram-negative *E coli* and *P aeruginosa* by disc diffusion method [46].The compounds were tested at a concentration of 100 μg/mL. The zone of inhibition was measured in mm and was compared with the reference standard antibiotics namely ampicillin trihydrates drugs 50 μg/mL. Compounds displayed good activity toward the gram-positive bacteria S *aureus, C diphtheriae*, and *S cerevisiae*, but the compounds showed less activity toward gram-negative bacteria *E coli* and *P aeruginosa*. The results of antibacterial screening studies are reported in Table 2.

CONCLUSIONS

In conclusion, the ultrasound irradiation for synthesis of the title compound offers significant reduction in the reaction time, operation simplicity, cleaner reaction, easy work-up, and improved yields. The procedure clearly highlights the advantages of ultrasound. The synthesized compounds also displayed noteworthy convincing antibacterial activity against gram-positive bacteria *S aureus, C diphtheriae*, *and S cerevisiae*.

[a] Diameter of the hole was 6 mm.

EXPERIMENTAL

Melting points of all synthesized compounds were determined in open capillary tubes on an electrothermal apparatus and are uncorrected. The purity of the compounds was monitored by TLC on silica gel coated aluminium plates (Merck) as adsorbent and UV light as visualizing agent; IR spectra (potassium bromide in cm^{-1}) were recorded on a Perkin-Elmer spectrophotometer in the range of 4000–400 cm^{-1}. ^{1}H NMR spectra were recorded on Varian 500 MHz NMR spectrophotometer using deuteriochloroform as solvent and trimethylsilane as an internal standard (chemical shifts in δ ppm) and MS spectra were taken on a Jeol sx-102/PA-6000 (EI) spectrometer. C, H, N estimation was recorded on Carlo Erba 1108 (CHN) Elemental Analyzer. Experiment under ultrasound irradiation is carried out in probe sonicator manufactured by Dakshin.

General preparation of bis-1,5-[substituted cinnamate]-3,3-dimethyl-1,4-cyclohexadiene (2a-c)

Method A (ultrasound method). A mixture of (0.02 mol) substituted aromatic aldehyde, (0.01 mol) 1, 2 mL (0.02 mol) of piperidine in 15 mL of ethanol were exposed to ultrasound irradiation for 15 min. On completion of the reaction (monitoring on TLC), the mixture was poured on crushed ice. The product that precipitated out was collected by filtration, washed with water, and recrystallized from ethanol.

Method B (conventional method). A solution of (0.02 mol) substitute aromatic aldehydes, (0.01 mol) 1, 2 mL (0.02 mol) piperidine in 15 mL of ethanol were refluxed on water bath for 4 h. The reaction was monitored by TLC, and after completion of the reaction, the contents were poured on crushed ice. The solid obtained was collected by filtration, washed with water, and recrystallized from ethanol to obtain compound 2(a-c).

Bis-1,5-[cinnamate]-3,3-dimethyl-1,4-cyclohexadiene (2a). This compound was obtained as white crystal, mp 200–202°C; IR (potassium bromide): CO 1645, C=C 1625 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 0.96 (s, 6-H, 2xCH_3), 2.44 (s, 2-H, CH_2), 4.69 (s, 2-H, CH), 7.82 (s, 4H, α, β unsaturated carbonyl), 6.98–8.02 (m, 10-H, aromatic protons). ^{13}C NMR: 27.28 $(CH_3)_2$, 37.33 (CH_2), 73.08 (tetrahedral carbon) and 108.21–115.32 (4xC=C), 125.69–131.56 (Ar—C), 188.42 (C=O), MS: *m/z* 402 (m^{+2}). *Anal.* Calcd. for $C_{26}H_{24}O_4$: C, 78.21; H, 6.01. Found: C, 77.87; H, 5.91.

Bis-1,5-[4″-methoxycinnamate]-3,3-dimethyl-1,4-cyclohexadiene (2b). This compound was obtained as light green crystal, mp 215–217°C; IR (potassium bromide): CO 1652, C=C 1620 cm^{-1}; ^{1}H NMR (deuteriochloroform): δ 1.07 (s, 6-H, 2xCH_3), 2.25 (s, 2-H, CH_2), 3.73 (s, 6-H, OCH_3), 4.75 (s, 2-H, CH), 7.89 (s, 4-H, α, β unsaturated carbonyl), 6.88–7.89 (m, 8-H, aromatic proton). ^{13}C NMR: 26.32 $(CH_3)_2$, 37.89 (CH_2), 41.21 (OCH_3), 73.87 (tetrahedral carbon) and 111.32–114.45 (4xC=C), 126.34–132.43 (Ar—C), 189.09 (C=O), MS: *m/z* 462 (m^{+2}). *Anal.* Calcd. for $C_{28}H_{28}O_6$: C, 73.04; H, 6.08. Found: C, 72.84; H, 5.85.

Bis-1,5-[4″-hydroxycinnamate]-3,3-dimethyl-1,4-cyclohexadiene (2c). This compound was obtained as yellow crystal, mp 198–199°C; IR (potassium bromide): OH 3421, CO 1631, C=C 1610 cm^{-1}, ^{1}H NMR (deuteriochloroform): δ 0.98 (s, 6-H, 2xCH_3), 2.34 (s, 2-H, CH_2), 4.56 (s, H, OH), 4.67 (s, 2-H, CH), 7.76 (s, 4-H, α, β unsaturated carbonyl), 6.95–7.79 (m, 8-H, aromatic proton). ^{13}C NMR: 26.86 $(CH_3)_2$, 37.64 (CH_2), 40.76 (OCH_3), 72.89 (tetrahedral carbon) and 113–115.35 (4xC=C), 125.89–131.83 (Ar—C), 189.98 (C=O), MS: *m/z* 432 (m^{+2}). *Anal.* Calcd. for $C_{26}H_{24}O_6$: C, 72.22; H, 5.67. Found: C, 72.14; H, 5.63.

General preparation of bis-1,5-[2′H,3′H-dihydro-4′(substitutedphenyl)-1′,5′-benzothiazipin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene (3a-c)

Method A (ultrasound method). A mixture of (0.01 mol) 2, 2.14 mL (0.02 mol) 2-aminothiophenol and 1 mL acetic acid in 10 mL of ethanol was subjected to ultrasound irradiation for 24 min. The reaction mixture was poured on crushed ice. The solid separated, filtered, washed with water, and recrystallized from ethanol.

Method B (conventional method). A solution of (0.01 mol) 2, 2.14 mL (0.02 mol) 2-aminothiophenol and 1 mL acetic acid in 10 mL of ethanol was reflux on water bath for 3 h then poured on to ice, the product was isolated in a similar manner as described in the above method.

Bis-1,5-[2′H,3′H-dihydro-4′phenyl-1′,5′-benzothiazipin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene (3a). This compound was obtained as light yellow crystal, mp 70–72°C; IR (potassium bromide): C=C 1632, C—S—C 1456 cm^{-1}, ^{1}H NMR (deuterio-chloroform): δ 0.96 (s, 6-H, 2xCH_3), 2.44 (s, 2-H, CH_2), 3.62 (s, 2-H, NH), 4.25 (s, 2-H, CH), 6.56 (d, 2-H, C_2—H), 7.24 (d, 2-H, C_3—H), 6.56–8.06 (m, 18-H, Aromatic protons). ^{13}C NMR: 27.24 (2xCH_3), 32.45 (CH_2), 65.45 (C_2—H), 72.21 (C_3—H), 73.54 (tetrahedral carbon) and 108.15–136.748 (C=C and Ar—C), MS: *m/z* 616 (m^{+2}). *Anal.* Calcd. for $C_{38}H_{34}N_2O_2S_2$: C, 73.22; H, 5.76; N,4.74; S, 10.84 Found: C, 73.08;H, 5.47; N, 4.59; S, 10.68.

Bis-1,5-[2′H,3′H-dihydro-4′(4″-methoxyphenyl)-1′,5′-benzothiazipin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene (3b). This compound was obtained as greenish yellow crystal, mp 73–76°C; IR (potassium bromide): C=C 1625, C—S—C 1443 cm^{-1}, ^{1}H NMR (deuteriochloroform): δ 0.99 (s, 6-H, 2xCH_3), 2.44 (s, 2-H, CH_2), 3.55 (s, 2-H, NH), 3.85 (s, 6-H, OCH_3), 4.32 (s, 2-H, CH), 6.43 (d, 2-H, C_2—H), 7.37 (d, 2-H, C_3—H), 6.96–8.03 (m, 16-H, Aromatic protrons). ^{13}C NMR: 26.31 (2xCH_3), 32.89 (CH_2), 39.32 (OCH_3), 65.52 (C_2—H), 72.63 (C_3—H), 73.76 (tetrahedral carbon), 108–136.31 (C=C and Ar—C), MS: *m/z* 676 (m^{+2}). *Anal.* Calcd. for $C_{40}H_{38}N_2O_4S_2$: C, 70.15; H, 5.84; N,4.30; S, 9.84. Found: C, 69.41; H, 5.68; N, 4.12; S, 9.73.

Bis-1,5-[2′H,3′H-dihydro-4′(4″-hydroxyphenyl)-1′,5′-benzothiazipin-2′-oxy]-3,3-dimethyl-1,4-cyclohexadiene (3c). This compound was obtained as colorless crystal, mp 95–97°C; IR (potassium bromide): OH 3448, C=C 1636, C—S—C 1421 cm^{-1}, ^{1}H NMR (deuteriochloroform): δ 1.02 (s, 6-H, 2xCH_3), 2.34 (s, 2-H, CH_2), 3.57 (s, 2-H, NH), 4.32 (s, 2-H, CH), 4.73 (s, 1-H, OH), 6.38 (d, 2-H, C_2—H), 7.63 (d, 2-H, C_3—H), 6.73–7.83 (m, 16-H, Aromatic proton). ^{13}C NMR: 27.45 (2xCH_3), 31.67 (CH_2), 65.68 (C_2—H), 73.54 (C_3—H), 73.76 (tetrahedral carbon), 105.45–137.76 (C=C and Ar—C), MS: m/z 648 (m^{+2}). *Anal.* Calcd. for $C_{38}H_{34}N_2O_4S_2$: C, 69.45; H, 5.49; N,4.50; S, 10.28. Found: C, 69.32; H, 5.34; N, 4.38; S, 10.11.

General preparation of bis-1,5-[-2′,3′,4′,5′-teterahydro-2′-(substitutedphenyl)-4′-oxo-thiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene (4a-c).

Method A (ultrasound method). A mixture of (0.01 mol) 2, 1.38 mL (0.02 mol) thiogylcolic acid, 1 g zinc dust in 10 mL of dioxane were subjected to ultrasound irradiation for 20 min.

After completion of the reaction, as monitored by TLC, the mixture was poured into ice-cold water. The solid obtained was collected by filtration and recrystallized from alcohol. The characteristic data of the compound are given in Table 2.

Method B (conventional method). A mixture of (0.01 mol) 2, 1.38 mL (0.02 mol) thiogylcolic acid and 1 g zinc dust in 10 mL of ethanol were heated under mild condition for 4.5 h. The product was isolated in a similar manner as described above.

Bis-1,5-[-2′,3′,4′,5′-teterahydro-2′-(phenyl)-4′-oxo-thiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene (4a). This compound was obtained as light cream crystal, mp 165–167°C; IR (potassium bromide): CO 1628, C—S—C 1408 cm^{-1}. ^1H NMR (deuteriochloroform): δ 0.97 (s, 6-H, $2xCH_3$), 2.44 (s, 2-H, CH_2), 3.21 (s, 2-H, C'_2—H), 3.46 (s, 4-H,$2XCH_2$), 3.90 (s, 2-H, C'_3—H), 4.69 (s, 2-H, CH), 7.19–8.02 (m, 10-H, Aromatic proton). ^{13}C NMR: 27.29 ($2xCH_3$), 29.28 (C'_2), 32.18 (CH_2), 42.21 (C'_3), 50.71(CH_2—C'_5), 73.21 (tetrahedral carbon), 109.10–115.5 (2xC=C), 128.21–131.56 (Ar—C), 196.44 (C=O), 210.21 (C=O). MS: *m/z* 520 (m^{+2}). *Anal*. Calcd. for $C_{30}H_{28}O_6S_2$: C, 69.49; H, 5.40; S, 12.35. Found: C, 69.21; H, 5.23; S, 12.21.

Bis-1,5-[-2′,3′,4′,5′-teterahydro-2′-(4″-methoxyphenyl)-4′-oxothiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene (4b). This compound was obtained as dark green crystal, mp 148–149°C; IR (potassium bromide): CO 1610, C—S—C 1443 cm^{-1}. ^1H NMR (deuteriochloroform): δ 0.96 (s, 6-H, $2xCH_3$), 2.36 (s, 2-H, CH_2), 3.21 (s, 2-H, C'_2—H), 3.46 (s, 4-H, $2xCH_2$), 3.83 (s, 2-H, C'_3—H), 3.94 (s, 6-H, OCH_3), 4.43 (s, 2-H, CH), 6.81–7.83 (m, 8-H, Aromatic proton). ^{13}C NMR: 27.32 ($2xCH_3$), 29.43 (C'_2), 31.67 (CH_2), 39.34 (OCH_3), 41.54 (C'_3), 52.56 (CH_2—C'_5), 73.02 (tetrahedral carbon), 110.98–116.12 (2xC=C), 116.32–133.34 (Ar—C), 198.07 (C=O), 209.87 (C=O). MS: *m/z* 610 (m^{+2}). *Anal*. Calcd. for $C_{32}H_{32}O_6S_2$: C, 63.15; H, 5.26; S, 10.58. Found: C, 62.94; H, 5.11; S, 10.32.

Bis-1,5-[-2′,3′,4′,5′-teterahydro-2′-(4″-hydroxyphenyl)-4′-oxo-thiophen-3′-carboxylate]-3,3-dimethyl-1,4-cyclohexadiene (4c). This compound was obtained as colorless crystal, mp 158–160°C; IR (potassium bromide): CO 1615, C—S—C 1448 cm^{-1}. ^1H NMR (deuteriochloroform): δ 9.86 (s, 6-H, $2xCH_3$), 2.21 (s, 2-H, CH_2), 3.28 (s, 2-H, C'_2—H), 3.38 (s, 4-H, $2xCH_2$), 3.97 (s, 2-H, C'_3—H), 4.51 (s, 2-H, CH), 4.75 (s, 2-H, OH), 7.08–8.16 (m, 8-H, Aromatic proton). ^{13}C NMR: 27.12 ($2xCH_3$), 29.87 (C'_2), 32.54 (CH_2), 41.84 (C'_3), 52.93 (CH_2—C'_5), 73.12 (tetrahedral carbon), 109.12–116.23 (2xC=C), 116.34–136.65 (Ar—C), 196.78 (C=O), 204.45 (C=O). MS: *m/z* 552 (m^{+2}). *Anal*. Calcd. for $C_{30}H_{28}O_8S_2$: C, 65.45; H, 5.09; S, 11.63. Found: C, 65.23; H, 4.96; S, 11.32.

Acknowledgments. The authors are grateful to the Principal Ms. Manju J. Nichani and Management of K.C. College, Mumbai for providing necessary facilities and to the Head, Department of Microbiology for antimicrobial studies. Authors are also thankful to the Director, Institute of Science, Mumbai (India) for providing spectral analyses.

INTRODUCTION

Non steroidal anti-inflammatory drugs (NSAIDs) are of huge therapeutic benefit in the treatment of rheumatoid arthritis and anti-inflammatory, analgesic, and antipyretic activities and are widely used to treat acute and chronic inflammatory disorders [1,2]. NSAIDs are not only useful in the treatment of inflammatory diseases but they can also reduce the risk of Alzheimer's disease [3,4]. Although NSAIDs are the most widely used drugs, their long-term clinical employment is associated with significant side effects and the steady use determines the onset of gastrointestinal lesions, bleeding, and nephrotoxicity [5,6]. Therefore, the discovery of new safer anti-inflammatory drugs represents a challenging goal for such a research area. Functionalized tetrahydropyridine (THP) ring systems are widely found in biologically active natural products and pharmaceuticals [7–12]. The anti-inflammatory activities of compounds consisting of reduced pyridine systems have been investigated [13–18]. The chemistry of substituted 1,3,4-oxadiazoles and their derivatives received considerable attention during the last decade as potential antimicrobial, antifungal, anti-inflammatory, analgesic, CNS-stimulating, anticonvulsive, anti-cancer, diuretic, and antihypertensive agents [19–30]. The electrophilic cyclization of iminium ions (Mannich cyclization) to generate unsaturated azacyclic systems [31] and the synthesis of tetrahydropyridine derivatives by partial reduction of *N*-ylides constitute some of the most important methods for preparing tetrahydropyridines. From our previous research, Redda and coworkers reported the synthesis and anti-inflammatory activity profiles of a few 1,2,3,6-terahydropyrines [32]. The results showed the pharmacological activites of the derivatives of THP depended on the nature of the substituents on the THP ring system (Fig. 1). This investigation is a continuation of synthesis of 1,2,3,6-tetrahydropyridine designed to modify the tetrahydropyridine ring and phenyl moieties by introducing groups with various electronic properties. Incorporation of the 1,3,4-oxadiazole moiety might enhance biological activity of the tetrahydropyridine derivatives. Hence, it was thought worthwhile to synthesize 1,3,4-oxadizol-2-yl tetrahydropyridines and study their anti-inflammatory and anti-cancer activities.

In the current investigation, we have synthesized many analogs maintaining the 1,3,4-oxadiazole-2-yl-1,2,3,6-tetrahydropyridine ring and having modifications on the oxadiazole, phenyl ring, and interchanging the sulfonyl/carbonyl groups at position X to compare their biological activities. We expect that these structural modifications would affect the compounds electron density, lipophilicity, and the compounds steric configurations.

Chemistry. The starting compound was 4-(5-methyl/phenyl-1,3,4-oxadiazol-2-yl)pyridine (**3**) obtained by the

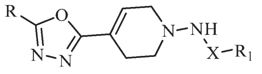

Figure 1. General structure of the target compounds. R = —CH_3, C_6H_5; R_1 = C_6H_5, 4-OCH_3—C_6H_4, 4-F—C_6H_4, 4-Br—C_6H_4, 4-*tert*-butyl-C_6H_4, X = CO, SO_2.

reaction of isonicotinic acid hydrazide and triethyl orthoacetate/triethylorthobenzoate, which was heated under reflux for 24 h [33] as outlined in Scheme 1. Substituted *N*-[4(5-methyl/phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2*H*)-yl]benzamide/benzenesulfonamides (**11a–n**) were prepared *via* partial reduction of *N*-ylides with a mild reducing agent, as outlined in Scheme 2. The ylides were prepared by coupling *N*-aminopyridinum salt (**8**) with appropriate acyl chlorides or sulfonyl chlorides. *O*-mesitylene sulfonyl hydroxylamine (MSH) (**7**) was used to prepare the *N*-amino salt as an aminating agent [34]. Reaction of *N*-aminopyridinium derivatives with substituted acylating agents like acyl chlorides and sulfonyl chlorides, followed by treatment with a base afforded *N*-ylides (**10**) as stable crystalline solids. Sodium borohyride reduction of (**10a–n**) in absolute ethanol furnished the target compounds substituted *N*-[4(5-methyl/phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2*H*)-yl] benzamide/benzene sulfonamides (**11a–n**).

RESULTS AND DISCUSSION

The results of synthesis of the pyridinium ylides (**10a–n**) and corresponding tetrahydropyridines (**11a–n**) are summarized in Table 1 and Table 2. The tetrahydropyridines are thermally stable and soluble in chloroform, dichloromethane, and other polar solvents. Analytical data of these compounds **10a–n** and **11a–n** are presented in Tables 3 and 4. The pharmacological evaluations of the compounds for anti-inflammatory and anti cancer activities are underway.

EXPERIMENTAL

The structures of the products described were confirmed by IR, ^{1}H NMR, and elemental analysis data. ^{1}H NMR spectra were determined on a Varian Gemini HX 300 MHz spectrometer using $CDCl_3$ as solvent unless otherwise specified. Chemical shifts (δ) are reported in parts per million (ppm) downfield from TMS as an internal standard. Infrared spectra were run with KBr pellets on a Perkin–Elmer 1430 FT spectrometer. Elemental analyses were performed by Galbraith Laboratories (Knoxville, TN). Melting points were determined on a Mel-Temp 3.0 melting point apparatus and were uncorrected. Chemicals and solvents were purchased from Sigma-Aldrich Chemical Company (Milwaukee, WI), Fisher Scientific Company (Suwannee, GA). Separations on column chromatography were performed on silica gel (200–425 mesh). All reactions and purification procedures were monitored by TLC on Whatman AL SIL g/UV, 250 μm layer flexible plates, with visualization under UV light.

General procedure-1

Synthesis of 4-(5-methyl-1,3,4-oxadiazol-2-yl)pyridine (3). To a solution of isonicotinic acid hydrazide 25 g (182.3 mmol) in triethyl orthoacetate (135 mL) was added and refluxed for 24 h. The excess triethyl orthoacetate was distilled under reduced pressure, and the residue was washed with cold ethanol. The residue was recrystallized from ethanol and obtained as brown crystals, yield 24 g (81.7%); Mp 148–150°C; ^{1}H NMR ($CDCl_3$): δ 2.66 (s, 3H, —CH_3); 7.88 (dd, *J* = 1.8, 1.5 Hz, 2H, C_3, C_5—H); 8.81 (dd, *J* = 1.8, 1.5 Hz; 2 H, C_2, C_6—H).

Synthesis of 4-(5-phenyl-1,3,4-oxadiazol-2-yl)pyridine (3). To a solution of isonicotinic acid hydrazide 20 g (145.6 mmol) in triethyl orthobenzoate (135 mL) was added and refluxed for 24 h. The excess triethyl orthobenzoate was distilled under reduced pressure, and the residue was washed with cold ethanol. The residue was recrystallized from ethanol and obtained as light yellow color solid, yield 29.17 g (89.8%); Mp 160–161°C. ^{1}H NMR ($CDCl_3$): δ 7.51–7.61 (m. 3H, $C_{3'}$, $C_{4'}C_{5'}$—H); 7.98 (d, *J* = 5.1 Hz, 2H, $C_{2'}$, $C_{6'}$—H); 8.12 (dd, *J* = 1.8, 1.5 Hz; 2 H, C_3, C_5—H), 8.84 (d, *J* = 6.9 Hz, 2H, C_2, C_6—H).

General procedure-2

Synthesis of 1-(benzoylimino)-4-(5-methyl-1,3,4-oxadiazol-2yl) pyridinium ylide (10a). To an ice cooled solution of 4-(5-methyl-1,3,4-oxadiazol-2yl)pyridine (4.35 g, 26.99 mmol) in 15 mL of dry methylene chloride was added dropwise *O*-mesitylenesulfonylhydroxylamine (5.81 g, 26.99 mmol) in 10 mL of dry methylene chloride over 5 min with stirring. The reaction stirred at 0°C for 3 h at which time 60 mL of ether was added and the suspension filtered. The precipitate was recrystallized from ethyl acetate-methanol (5:1 v/v) to give 1-amino-4-(5-methyl-1,3,4,-oxadiazol-2-yl)pyridinium mesitylene sulfonate (**7**) in 57.5% yield. The *N*-aminopyridinium salt (2.0 g, 5.096 mmol) in 30 mL of anhydrous tetrahydrofuran (THF) containing triethylamine at 70°C was stirred for 5 min before benzoyl chloride (1.43 g, 10.19 mmol) was added. The mixture was allowed to proceed for 12 h at which time 70 mL of saturated sodium bicarbonate ($NaHCO_3$) was used to arrest the reaction. The product 1-[(benzoylimino)-4-(5-methyl-1,3,4-oxadiazol-2yl)]pyridinium ylide (**10a**) was extracted with (2 × 100 mL) of chloroform and dried over anhydrous sodium sulfate. The solvent was removed *in vacuo* to give crude product, which was purified by column chromatography (2.5 × 22 cm) on silica gel (200–425 mesh) using ethyl acetate: methanol (9:1 v/v) as eluent. The resultant product (**10a**) was off-white solid obtained in 34.4% yield, Mp 273–275°C; IR (KBr): ν 1593 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.71 (s, 3H, —CH_3 of oxadiazol ring), 7.43 (m, 3H, $C_{3'}$, $C_{4'}$ and $C_{5'}$—H), 8.18 (m,

Synthesis of 1-[(4-methoxy benzoyl)imino]-4-(5-methyl-1,3,4-oxadiazol-2-yl) pyridinium ylide (10b). The compound **10b** was obtained following general procedure 2 as yellow crystalline solid obtained in 50.6% yield, Mp 253–254°C; IR (KBr) ν 1605 (C=O)/cm ; ^{1}H NMR ($CDCl_3$): δ 2.70 (s, 3H, —CH_3 of oxadiazol ring), 3.86 (s, 3H, —OCH_3 group), 6.94 (d, *J* = 9.0 Hz, 2H, $C_{3'}$,$C_{5'}$—H), 8.16 (dd, *J* = 7.2, 8.7 Hz, 4H, C_3,C_5, and $C_{2'}$,$C_{6'}$—H), 9.18 (d, *J* = 7.5 Hz, 2H, C_2, C_6—H).

Synthesis of 1-[(4-fluorobenzoyl)imino]-4-(5-methyl-1,3,4-oxadiazol-2-yl) pyridinium ylide (10c). The compound **10c** was obtained following general procedure 2 as white solid obtained in 51.3% yield, Mp 283–284°C; IR (KBr): ν 1604 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.71 (s, 3H, —CH_3 of oxadiazol ring), 7.09 (t, 2H, *J* = 9.0 Hz, $C_{3'}$, $C_{5'}$—H), 8.16 (d, 2H, *J* = 6.0 Hz, $C_{2'}$, $C_{6'}$—H), 8.21 (d, 2H, *J* = 7.2 Hz, C_3, C_5—H), 9.16 (d, 2H, *J* = 6.6 Hz, C_2, C_6—H).

Synthesis of 1-[(4-bromobenzoyl)imino]-4-(5-methyl-1,3,4-oxadiazol-2-yl) pyridinium ylide (10d). The compound **10d** was obtained following general procedure 2 as yellow color solid obtained in 61.9% yield, Mp 290–291°C; IR (KBr): ν 1601 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.69 (s, 3H, —CH_3 of oxadiazol ring), 7.53 (d, 2H *J* = 8.4 Hz, $C_{3'}$, $C_{5'}$—H), 8.03 (d, 2H, *J* = 8.4 Hz, $C_{2'}$, $C_{6'}$—H), 8.20 (d, 2H, *J* = 7.2 Hz, C_3, C_5—H), 9.15 (d, 2H, *J* = 7.2 Hz, C_2, C_6—H).

Synthesis of 1-[(4-tert-butylbenzoyl)imino]-4-(5-methyl-1,3,4-oxadiazol-2-yl) pyridinium ylide (10e). The compound **10e** was obtained following general procedure 2 as yellow crystalline solid obtained in 24.6% yield, Mp 246–248°C; IR (KBr): ν 1604 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 1.35 (s 9H, *tert*-butyl group), 2.70 (s, 3H, —CH_3 of oxadiazol ring), 7.44 (d, 2H, *J* = 8.4 Hz, $C_{3'}$, $C_{5'}$—H), 8.09 (d, 2H, *J* = 8.1 Hz, $C_{2'}$, $C_{6'}$—H), 8.18 (d, 2H, *J* = 6.9 Hz, C_3, C_5—H), 9.18 (d, 2H, *J* = 7.2 Hz, C_2, C_6—H).

Synthesis of 4-(5-methyl-1,3,4-oxadiazol-2-yl)-1-[(phenylsulfonyl)amino]pyridinium ylide (10f). The compound **10f** was obtained following general procedure 2 as brown crystalline solid obtained in 47.8% yield, Mp 268–269°C; IR (KBr): ν 1332, 1205 (SO_2)/cm; ^{1}H NMR ($CDCl_3$): δ 2.69 (s, 3H, —CH_3 of oxadiazol ring), 7.37–7.45 (m, 3H, $C_{3'}$, $C_{4'}$ and $C_{5'}$—H), 8.16 (ddd, 4H, *J* = 7.2, 1.7, and 2.3 Hz, C_3, C_5 and $C_{2'}$, $C_{6'}$—H), 9.16 (d, 2H, *J* = 7.2 Hz, C_2, C_6—H).

Synthesis of 1-{[(4-methoxyphenyl)sulfonyl]imino}-4-(5-methyl-1,3,4-oxadiazol-2-yl) pyridinium ylide (10g). The compound **10g** was obtained following general procedure 2 as brown crystalline solid obtained in 56.2% yield, Mp 218–220°C; IR (KBr): ν 1280, 1137 (SO_2)/cm; ^{1}H NMR ($CDCl_3$): δ 2.66 (s, 3H, —CH_3 of oxadiazol ring), 3.81 (s, 3H, —OCH_3 group), 6.87 (d, 2H, *J* = 8.8 Hz, $C_{3'}$, $C_{5'}$—H), 7.74(dd, 2H, *J* = 1.9, 5.0 Hz, $C_{2'}$, $C_{6'}$—H), 8.06 (d, 2H, *J* = 7.1 Hz, C_3, C_5—H), 8.63 (d, 2H, *J* = 7.1 Hz, C_2, C_6—H).

Synthesis of 1-(benzoylimino)-4-(5-phenyl-1,3,4-oxadiazol-2yl) pyridinium ylide (10h). The compound **10h** was obtained following general procedure 2 as white crystalline solid obtained in 39.6% yield, Mp 262–263°C; IR (KBr): ν 1548 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 7.38–7.62 (complex multiplet, 6H, phenyl protons), 8.16 (ddd, 4H, *J* = 4.2, 1.5, 1.5 Hz,

obtained in 43.6% yield, Mp 211–213°C; IR (KBr): ν 1282, 1150 (SO_2)/cm; ^{1}H NMR ($CDCl_3$): δ 7.37–7.64 (complex multiplet, 6H, phenyl protons), 7.80 (d, 2H, J = 6.9 Hz, $C_{2'}$, $C_{6'}$—H), 8.12 (d, 2H, J = 6.9 Hz, $C_{2''}$, $C_{6''}$—H), 8.20 (d, 2H, J = 6.3 Hz, C_3, C_5—H), 8.67 (d, 2H, J = 6.6 Hz, C_2, C_6—H).

Synthesis of 1-{[(4-methoxyphenyl)sulfonyl]imino}-4-(5-phenyl-1,3,4-oxadiazol-2-yl)-pyridinium Ylide (10m). The compound **10m** was obtained following general procedure 2 as yellow solid obtained in 37.5% yield, Mp 259–261°C; IR (KBr): ν 1280, 1134 (SO_2)/cm; ^{1}H NMR ($CDCl_3$): δ 3.81 (s, —OCH_3), 6.88 (d, 2H, J = 8.7 Hz, $C_{3''}$, $C_{5''}$—H), 7.54–7.65 (m, 3H, $C_{3'}$, $C_{4'}$, $C_{5'}$—H), 7.76 (d, 2H, J = 8.7 Hz, $C_{2'}$, $C_{6'}$—H), 8.12 (d, 2H, J = 6.9 Hz, $C_{2''}$, $C_{6''}$—H), 8.19 (d, 2H, J = 6.6 Hz, C_3, C_5—H), 8.70 (d, 2H, J = 6.3 Hz, C_2, C_6—H).

Synthesis of 1-{[(4-tert-butylphenyl)sulfonyl]imino}-4-(5-phenyl-1,3,4-oxadiazol-2-yl) pyridinium ylide (10n). The compound **10n** was obtained following general procedure 2 as yellow solid obtained in 74.2% yield, Mp 242–244°C; IR (KBr): ν 1296, 1136 (SO_2)/cm; ^{1}H NMR ($CDCl_3$): δ 1.28 (s, 9H, *t*-butyl group), 7.41 (d, 2H, J = 8.4 Hz, $C_{3''}$, $C_{5''}$—H), 7.52–7.64 (m, 3H, $C_{3'}$, $C_{4'}$, $C_{5'}$—H), 7.74 (d, 2H, J = 8.4 Hz, $C_{2'}$, $C_{6'}$—H), 8.11 (dd, 2H, J = 1.5, 6.9 Hz, $C_{2''}$, $C_{6''}$—H), 8.19 (d, 2H, J = 6.6 Hz, C_3, C_5—H), 8.70 (d, 2H, J = 6.3 Hz, C_2, C_6—H).

General procedure-3

N-[4[(5-Methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl] benzamide (11a). A solution of 1-(Benzoylimino)-4-(5-methyl-1,3,4-oxadiazol-2yl) pyridinium ylide **10a** (0.25 g, 0.79 mmol) in dichloromethane: ethanol (1:1 v/v, 40 mL) was added dropwise to a stirred suspension of sodium borohydride (0.12 g, 3.16 mmol) in 10 mL of absolute ethanol over a period or 30 min. The resulting solution was stirred for 4 h at 0°C and then overnight for a total of 24 h. The excess sodium borohyride was treated with 50 mL distilled water. It was then extracted with dichloromethane (200 mL) and dried over anhydrous sodium sulfate. The dichloromethane filtrate was evaporated *in vacuo* and the product chromatographed on a column of silica gel using ethyl acetate: methanol (9:1 v/v) as an eluent. The solid obtained was further crystallized from dichlormethane: ethylacetate (3:2 v/v) and furnished **11a** as a white flakes (61.0% yield), Mp 208–210°C; IR (KBr): ν 3213 (NH), 1638 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.54 (s, 3H, —CH_3 of oxadiazol ring), 2.86 (m, 2H, C_3—H), 3.34 (t, J = 5.7 Hz, 2H, C_2—H), 3.84 (m, 2H, C_6—H), 6.65 (m, 1H, C_5—H olefinic proton), 7.17 (brs, 1H, —NH D_2O exchange), 7.48 (m, 3H, $C_{3'}$,$C_{4'}$ and $C_{5'}$—H), 7.74 (d, J = 7.5 Hz, 2H, $C_{2'}$,$C_{6'}$—H).

4-Methoxy-N-[4-(5-methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzamide (11b). The compound **11b** was

obtained following general procedure 3 as off-white solid 54.3% yield, Mp 238–240°C; IR (KBr): ν 3183 (NH), 1625 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.54 (s, 3H, CH_3), 2.85 (m, 2H, C_3—H), 3.32 (t, 2H, J = 6.0 Hz, C_2—H), 3.82 (brs, 2H, C_6—H), 3.84 (s, —OCH_3 group), 6.64 (m, C_5—H, olefinic), 6.92 (d, 2H, J = 8.7 Hz, $C_{3'}$,$C_{5'}$—H), 7.14 (brs, —NH, D_2O exchange), 7.72 (d, 2H, J = 8.4 Hz, $C_{2'}$, $C_{6'}$—H).

4-Fluoro-**N*****-[4-(5-methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzamide (11c).*** The compound **11c** was obtained following general procedure 3 as white granules 68.7% yield, Mp 215–217°C; IR (KBr): ν 3190 (NH), 1636 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.52 (s, 3H, CH_3 of oxadiazol ring), 2.84 (m, 2H, C_3—H), 3.30 (t, 2H, J = 6.2 Hz, C_2—H), 3.81 (brs, 2H, C_6—H), 6.62 (m, 1H, C_5—H, olefinic proton), 7.71 (t, 2H, J = 8.6 Hz, $C_{3'}$, $C_{5'}$—H), 7.15 (brs, 1H, NH proton, D_2O exchange), 7.75 (d, 2H, J = 8.4 Hz, $C_{2'}$, $C_{6'}$—H).

4-Bromo-**N*****-[4-(5-methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydro pyridin-1(2H)-yl]-benzamide (11d).*** The compound **11d** was obtained following general procedure 3 as yellow solid 33.8% yield, Mp 216–217°C; IR (KBr): ν 3185 (NH), 1635 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 2.53 (s, 3H, CH_3 of oxadiazol ring), 2.85 (m, 2H, C_3—H), 3.31 (t, 2H, J = 6.2 Hz, C_2—H), 3.81 (brs, 2H, C_6—H), 6.64 (m, 1H, C_5—H, olefinic proton), 7.72 (t, 2H, J = 8.6 Hz, $C_{3'}$, $C_{5'}$—H), 7.13 (brs, NH proton, D_2O exchange), 7.75 (d, 2H, J = 8.4 Hz, $C_{2'}$, $C_{6'}$—H).

4-tert-Butyl--**N*****-[4-(5-methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzamide (11e).*** The compound **11e** was obtained following general procedure 3 as off-white solid 65.4% yield, Mp 211–213°C; IR (KBr): ν 3274 (NH), 1643 (C=O)/cm; ^{1}H NMR ($CDCl_3$): δ 1.31 (s 9H, *tert*-butyl group), 2.52 (s, 3H, —CH_3 of oxadiazol ring), 2.84 (m, 2H, C_3—H), 3.30 (t, 2H, J = 5.4 Hz, C_2—H), 3.81 (brs, 2H, C_6—H), 6.62 (m, 1H, C_5—H, olefinic proton), 7.14 (brs, 1H, —NH proton, D_2O exchange), 7.43 (d, 2H, J = 8.3 Hz, $C_{3'}$, $C_{5'}$,—H), 7.66 (d, 2H, J = 8.1 Hz, $C_{2'}$, $C_{6'}$—H).

N***-[4-(5-Methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzene sulfonamide (11f).*** The compound **11f** was obtained following general procedure 3 as white solid 48.2% yield, Mp 208–210°C; IR (KBr): ν 3069 (NH), and 1332, 1164 (SO_2)/cm; ^{1}H NMR ($CDCl_3$): δ 2.53 (s, 3H, —CH_3 of oxadiazol ring), 2.85 (m, 2H, C_3—H), 3.31 (t, 2H, J = 5.8 Hz, C_2—H), 3.82 (brs, 2H, C_6—H), 6.63 (m, 1H, C_5—H, olefinic proton), 7.16 (brs, —NH, D_2O exchange), 7.40–7.54 (m 3H, $C_{3'}$, $C_{4'}$, $C_{5'}$—H), 7.73 (d, 2H, J = 7.3 Hz, $C_{2'}$, $C_{6'}$—H).

4-Methoxy-**N*****-[4-(5-methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzene sulfonamide (11g).*** The compound **11g** was obtained following general procedure 3 as white granules 54.4% yield, Mp 150–152°C; IR (KBr): ν 3078 (NH), and 1331, 1163 (SO$_2$)/cm; ^{1}H NMR (CDCl$_3$): δ 2.50 (s, 3H, —CH$_3$ of oxadiazol ring), 2.49 (m, 2H, C$_3$—H), 2.77 (t, 2H, J = 5.4 Hz, C$_2$—H), 3.45 (d, 2H, J = 3 Hz, C$_6$—H), 3.86 (s, 3H, —OCH$_3$), 5.47 (s, 1H, —NH, D$_2$O exchange), 6.46 (m, 1H, C$_5$—H olefinic proton), 6.96 (d, 2H, J = 9.0 Hz, C$_{3'}$, C$_{5'}$—H), 7.86 (dd, 2H, J = 3.0, 6.9 Hz, C$_{2'}$,C$_{6'}$—H).

N***-[4-(5-Phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]benzamide (11h).*** The compound **11h** was obtained following general procedure 3 as white granules 30.4% yield, Mp 203–204°C; IR (KBr): ν 3189 (NH), 1635 (C=O)/cm; ^{1}H NMR (CDCl$_3$): δ 2.93 (m, 2H, C$_3$—H), 3.36 (t, 2H, J = Hz, C$_2$—H), 3.88 (brs, 2H, C$_6$—H), 6.79 (m, 1H, C$_5$—H, olefinic proton), 7.21 (brs, 1H, —NH, D$_2$O exchange), 7.40–7.53 (complex m, 6H, C$_{3'}$, C$_{4'}$, C$_{5'}$ and C$_{3''}$, C$_{4''}$, C$_{5''}$—H), 7.74 (d, 2H, J = 7.2 Hz, C$_{2'}$, C$_{6'}$—H), 8.05 (dd, 2H, J = 1.2, 6.0 Hz C$_{2''}$, C$_{6''}$—H,).

4-Methoxy-**N*****-[4-(5-phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzamide (11i).*** The compound **11i** was obtained following general procedure 3 as white solid 44.8% yield, Mp 217–218°C; IR (KBr): ν 3221 (NH), 1638 (C=O)/cm; ^{1}H NMR (CDCl$_3$): δ 2.91 (m, 2H, C$_3$—H), 3.34 (t, 2H, J = 5.7 Hz, C$_2$—H), 3.83 (s, 3H, —OCH$_3$), 3.86 (brs, 2H, C$_6$—H), 6.78 (m, 1H, C$_5$—H, olefinic proton), 6.90 (d, 2H, J = 8.7 Hz, C$_{3''}$, C$_{5''}$—H), 7.15 (brs, 1H, —NH, D$_2$O exchange), 7.45–7.54 (m, 3H, C$_{3'}$, C$_{4'}$, C$_{5'}$—H), 7.71 (d, 2H, J = 7.8 Hz, C$_{2''}$, C$_{6''}$—H), 8.05 (dd, 2H, J = 1.5, 6.0 Hz, C$_{2'}$, C$_{6'}$—H).

4-Fluoro-**N*****-[4-(5-phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzamide (11j).*** The compound **11j** was obtained following general procedure 3 as white solid 51.4% yield, Mp 213–215°C; IR (KBr): ν 3185 (NH), 1637 (C=O)/cm; ^{1}H NMR (CDCl$_3$): δ 2.92 (m, 2H, C$_3$—H), 3.34 (t, 2H, J = 5.8 Hz, C$_2$—H), 3.86 (brs, 2H, C$_6$—H), 6.78 (m, 1H, C$_5$—H, olefinic proton), 7.10 (t, 2H, J = 8.7 Hz, C$_{3''}$, C$_{5''}$—H), 7.25 (brs, 1H, —NH, D$_2$O exchange), 7.45–7.55 (m, 3H, C$_{3'}$, C$_{4'}$, C$_{5'}$—H), 7.71 (d, 2H, J = 7.8 Hz, C$_{2'}$, C$_{6'}$—H), 8.05 (dd, 2H, J = 0.9, 6.3 Hz, C$_{2''}$, C$_{6''}$—H).

4-tert-Butyl-**N*****-[4-(5-methyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]benzamide (11k).*** The compound **11k** was obtained following general procedure 3 as white solid 32.5% yield, Mp 209–211°C; IR (KBr): ν 3211 (NH), 1638 (C=O)/cm; ^{1}H NMR (CDCl$_3$): δ 1.31 (s, 9H, *t*-butyl group), 2.94 (m, 2H, C$_3$—H), 3.40 (t, 2H, J = 5.7 Hz, C$_2$—H), 3.92 (d, 2H, J = 2.4 Hz, C$_6$—H), 6.78 (m, 1H, C$_5$—H, olefinic proton), 7.39 (brs, 1H, —NH, D$_2$O exchange), 7.43–7.53 (m, 5H, phenyl protons), 7.69 (d, 2H, J = 8.1 Hz, C$_{3''}$, C$_{5''}$—H), 8.05 (d, 2H, J = 8.1 Hz, C$_{2''}$, C$_{6''}$—H).

N***-[4-(5-Phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzene sulfonamide (11l).*** The compound **11l** was obtained following general procedure 3 as white granules 33.6% yield, Mp 162–163°C; IR (KBr): ν 3106 (NH), 13323, 1168 (SO$_2$)/cm; ^{1}H NMR (CDCl$_3$): δ 2.65 (m, 2H, C$_3$—H), 2.81 (t, 2H, J = 5.7 Hz, C$_2$—H), 3.03 (brs, 2H, C$_6$—H), 5.72 (brs, 1H, —NH, D$_2$O exchange), 6.62 (m, 1H, C$_5$—H, olefinic proton), 7.44—7.64 (complex m, 6H, C$_{3'}$, C$_{4'}$, C$_{5'}$ and C$_{3''}$, C$_{4''}$, C$_{5''}$—H), 7.96 (dd, 2H, J = 1.2 and 7.2 Hz, C$_{2'}$, C$_{6'}$—H), 8.01 (dd, 2H, J = 1.5, 6.0 Hz, C$_{2''}$, C$_{6''}$ —H).

4-Methoxy-**N*****-[4-(5-phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]-benzene-sulfonamide (11m).*** The compound **11m** was obtained following general procedure 3 as white solid 42.5% yield, Mp 135–136°C; IR (KBr): ν 3089 (NH), 1330, 1154 (SO$_2$)/cm; ^{1}H NMR (CDCl$_3$): δ 2.67 (m, 2H, C$_3$—H), 2.81 (t, 2H, J = 5.4 Hz, C$_2$—H), 3.51 (d, 2H, J = 3.0 Hz, C$_6$—H), 3.87 (s, 3H, —OCH$_3$), 5.45 (s, 1H, —NH, D$_2$O exchange), 6.63 (m, 1H, C$_5$—H, olefinic proton), 6.98 (d, 2H, J = 9.0 Hz, C$_{3''}$, C$_{5''}$—H), 7.45–7.54 (m, 3H, C3′, C4′, C$_{5'}$—H), 7.88 (d, 2H, J = 9.0 Hz, C$_{2'}$, C$_{6'}$—H), 8.02 (dd, 2H, J = 1.2, 6.6 Hz, C$_{2''}$, C$_{6''}$—H).

4-tert-butyl-**N*****-[4-(5-phenyl-1,3,4-oxadiazol-2-yl)-3,6-dihydropyridin-1(2H)-yl]benzene sulfonamide (11n).*** The compound **11n** was obtained following general procedure 3 as white solid 48.5% yield, Mp 163–134°C; IR (KBr): ν 3088 (NH), 1335, 1152 (SO$_2$)/cm; ^{1}H NMR (CDCl$_3$): δ 1.33 (s, 9H, t-butyl group), 2.67 (m, 2H, C$_3$—H), 2.81 (t, 2H, J = 5.4 Hz, C$_2$—H), 3.52 (d, 2H, J = 2.4 Hz, C$_6$—H), 5.55 (brs, 1H, —NH, D$_2$O exchange), 6.64 (m, 1H, C$_5$—H, olefinic proton), 6.98 (d, 2H, J = 9.0 Hz, C$_{3''}$, C$_{5''}$—H), 7.45–7.54 (m, 3H, C$_{3'}$, C$_{4'}$, C$_{5'}$—H), 7.88 (d, 2H, J = 9.0 Hz, C$_{2'}$, C$_{6'}$—H), 8.02 (dd, 2H, J = 1.2, 6.6 Hz, C$_{2''}$, C$_{6''}$—H).

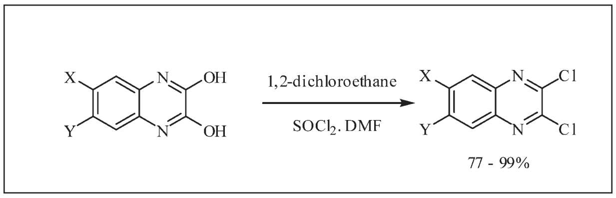
DOI 10.1002/jhet.56



A convenient and high-yielding synthesis of 2,3-dichloroquinoxalines from the corresponding 2,3-dihydroxyquinoxalines has been developed. Treatment of a slurry of the 2,3-dihydroxyquinoxaline **1a–j** with *N*,*N*-dimethylformamide in the presence of excess thionylchloride in 1,2-dichloroethane results in the rapid and high-yielding formation of the 2,3-dichloroquinoxaline derivatives **2a–j**. Simplified workup and purification procedures for these compounds are also described.

J. Heterocyclic Chem., **46**, 317 (2009).

INTRODUCTION

The chemistry of 2,3-dichloroquinoxalines has received considerable attention in the past [1]. This class of compounds has previously been shown to exhibit a broad range of biological activity. For example, various derivatives of 2,3-dichloroquinoxalines have been shown to exhibit fungicidal and bactericidal activity [2]. They have also shown utility in industrial applications such as use as reactive dyes for fibers [3].

These dichloroquinoxaline compounds have traditionally been prepared by chlorination of the corresponding quinoxaline 2,3-diones (2,3-dihydroxyquinoxalines) with phosphorous-based chlorinating reagents. Phosphorus oxychloride ($POCl_3$) is the most common agent used, usually in the presence of an initiator such as *N*,*N*-dimethylaniline [4], or phosphorus pentachloride (PCl_5). However, the hazards of handling phosphorus oxychloride or phosphorus pentachloride are not to be taken lightly. Moreover, phosphorus containing waste streams is becoming increasingly difficult to dispose of in industrial settings.

Recently, Zimcik and coworkers [5] reported the synthesis of 2,3-dichloro-6,7-dicyanoquinoxaline from 2,3-dihy-droxy-6,7-dicyanoquinoxaline, using thionyl chloride in the presence of small amounts of *N*,*N*-dimethylformamide (DMF). Similarly, Tanaka and coworkers [6] has reported the synthesis of 2,3-dichloro-6-trifluoromethylquinoxaline from 2,3-dihydroxy-6-trifluoromethylquinoxaline with an excess of thionyl chloride ($SOCl_2$) in *N*,*N*-DMF as the solvent. In both of these cases, the actual chlorinating reagent is undoubtedly the Vilsmeier reagent, generated *in situ* from the reaction of *N*,*N*-DMF with thionyl chloride.

We have recently synthesized a series of 2,3-dichloroquinoxalines using a similar approach of generating the Vilsmeier reagent *in situ* by the addition of catalytic amounts of *N*,*N*-DMF to a slurry of 2,3-dihydroxyquinoxalines and thionyl chloride in 1,2-dichloroethane. Inspired by these earlier reports, we herein report the general utility of this reaction protocol and give experimental details for simplified workup and purification procedures for the synthesis of 2,3-dichloroquinoxalines *via* chlorination of 2,3-dihydroxyquinoxalines with the Vilsmeier reagent.

RESULTS AND DISCUSSION

2,3-Dichloroquinoxalines, **2** (Scheme 1), can be readily prepared by chlorination of 2,3-dihydroxyquinoxalines, **1**, which in turn can be prepared by the

Scheme 1

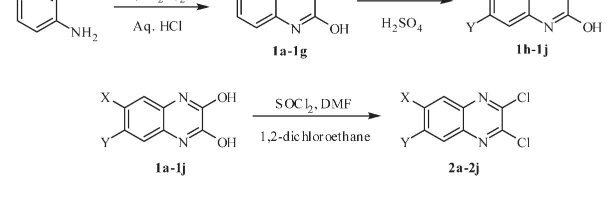


Table 1

Physical and analytical data of compounds **2a–j**.

Compound	X	Y	Time (h)	Mp (°C)	Yield (%)
2a	H	H	2	100–102[a]	95
2b	NO_2	H	4	152–153[a]	99
2c	Cl	H	4	144[a]	99
2d	CH_3	H	2	113–114[a]	93
2e	F	H	2	143–145[b]	98
2f	CN	H	2	239–240[b]	77
2g	CF_3	H	2	91–93[b]	81
2h	CH_3	NO_2	2	134–136[b]	95
2i	Cl	NO_2	0.5	135–137[b]	93
2j	NO_2	NO_2	0.5	210–212[b]	92

[a] Recrystallized from CH_3CN/H_2O.

[b] Filtered through SiO_2 with CH_2Cl_2.

condensation of commercially available 1,2-phenylenediamines with oxalic acid in aqueous hydrochloric acid (HCl) [1]. Mono and dinitroquinoxalines **1b** and **1h–1j** were prepared by nitration of the parent dihydroxyquinoxaline with one or two equivalents of potassium nitrate (KNO_3) in sulfuric acid (H_2SO_4) [7].

We have found that 2,3-dichloroquinoxalines **2a–2j** are readily formed by the drop wise addition of catalytic amounts of *N*,*N*-DMF (10 mol %) to slurry of the corresponding 2,3-dihydroxyquinoxalines **1a–1j** in 1,2-dichloroethene and an excess (2.5–3.0 molar equivalents) of thionyl chloride (Table 1).

In all cases, the desired 2,3-dichloroquinoxaline was rapidly formed by bringing the reaction mixture to reflux. After complete conversion, the reaction mixture was cooled to ambient temperature, followed by concentration to dryness. Purification of the desired product can then be readily accomplished by recrystallization of the crude product from acetonitrile/water, giving the desired 2,3-dichloroquinoxaline in high yield and purity. Alternatively, and particularly convenient for larger scale reactions, the residual material obtained after evaporation of the excess thionyl chloride and 1,2-dichloroethane can be purified by slurrying the initially isolated residue in water, followed by filtration and re-dissolving the crude product into methylene chloride (CH_2Cl_2) and filtering through a plug of silica gel.

There are several advantages to this method over those previously reported. First is that $SOCl_2$/DMF is considerably less expensive and less hazardous than using $POCl_3$/*N*,*N*-dimethylaniline. Also, in general, the reaction requires much shorter reaction times. For example, in our experiments, chlorination of **1c** with $POCl_3$/*N*,*N*-dimethylaniline required refluxing for 6 days for complete conversion and **2c** was obtained in 76% yield. In contrast, chlorination of **1c** with $SOCl_2$/DMF in 1,2-dichloroethane led to complete reaction within 4 h, giving a near quantitative yield of **2c**.

EXPERIMENTAL

General experimental procedures. All solvents and reagents were reagent grade and were used without further purification. ^1H and ^{13}C NMR spectra were obtained on a Varian XM-300 NMR. All yields reported are those of isolated material judged homogeneous by ^1H NMR.

General procedure for the synthesis of 2,3-dihydroxyquinoxalines 1a–j. ***2,3-Dihydroxyquinoxline (1a).*** A solution of oxalic acid (27.1 g, 0.215 mol) in 4*N* aqueous HCl (50 mL) was added to a solution of 1,2-diaminobenzene (20.9 g, 0.193 mol) in 4*N* HCl (150 mL), and the resulting solution was heated to reflux for 2 h. The reaction mixture was cooled to ambient temperature, and the resulting precipitate was isolated by filtration, washed with water, and dried, giving 30.5 g (98%) of **1a** as an off white powder, mp >300°C: ^1H NMR (DMSO-d_6): δ 11.90 (s, 2H), 7.13–7.04 (m, 4H); ^{13}C NMR (DMSO-d_6): δ 155.12, 125.52, 122.91, 115.06.

General procedure for the nitration of 2,3-dihydroxyquinoxalines 1h–j. ***2,3-Dihydroxy-6-nitro-7-methylquinoxaline (1h).*** To a solution of 2,3-dihydroxy-6-methylquinoxaline (10.0 g, 0.0574 mol) in H_2SO_4 (124 mL) at 0°C was added, in several portions, KNO_3 (6.39 g, 0.0632 mol), and the resulting solution was allowed to warm to ambient temperature and stirred overnight. The reaction mixture was carefully poured into 500 mL of ice/water, stirred 30 min, filtered, washed with water and dried, giving 12.2 g (96%) of **1h** as a pale yellow solid, mp >300°C. ^1H NMR (DMSO-d_6): δ 12.20 (s, 1H), 12.02 (s, 1H), 7.72 (s, 1H), 6.95 (s, 1H), 2.47 (s, 3H); ^{13}C NMR (DMSO-d_6): δ 155.10, 154.47, 142.21, 130.10, 128.69, 124.05, 117.70, 111.60, 20.31.

General procedure for the chlorination of dihydroxyquinoxalines. ***2,3-Dichloroquinoxaline (2a).*** *N*,*N*-Dimethylformamide (0.045 g, 0.00062 mol, 0.1 eq) was added dropwise to a slurry of 2,3-dihydroxyquinoxaline (2.0 g, 0.012 mol) and thionyl chloride (3.7 g, 0.031 mol) in 1,2-dichloroethane (20 mL). The resulting reaction mixture was heated to reflux for 2 h then concentrated to dryness. The residue was dissolved in 1,2-dichloroethane (25 mL) and concentrated to dryness. The resulting solid was recrystallized from CH_3CN/H_2O, giving 2.3 g (95%) of **2a** as fine, off white needles, mp 100–102°C; ^1H NMR ($CDCl_3$): δ 8.10–8.06 (m, 2H), 7.98–7.93 (m, 2H); ^{13}C NMR ($CDCl_3$) 144.50, 139.92, 131.67, 127.81. *Anal.* Calcd. for $C_8H_4Cl_2N_2$: C, 48.28; H, 2.03; N, 14.07. Found: C, 47.87; H, 2.1; N, 14.00.

2,3-Dichloro-6-nitroquinoxaline (2b). This compound was prepared from *N*,*N*-DMF (0.11 g, 0.0014 mol), 2,3-dihydroxy-6-nitroquinoxaline (3.0 g, 0.0145 mol) and thionylchloride (4.31 g, 0.035 mol) in 1,2-dichloroethane (30 mL) as previously described, to give 3.52 g (99%) of **2b** after recrystallization (CH_3CN/H_2O) as a tan powder, mp 152–153°C; ^1H NMR (DMSO-d_6) (d, J = 2.4 Hz, 1H), 8.57 (dd, J = 9.2, 2,5 Hz, 1H), 8.28 (d, J = 9.2 Hz, 1H); ^{13}C NMR (DMSO-d_6) 148.18, 148.07, 147.28, 142.3, 138.83, 129.68, 124.74, 123.67. *Anal.* Calcd. for $C_8H_3Cl_2N_3O_2$: C, 39.37; H, 1.24; N, 17.22. Found: C, 39.11; H, 1.03; N, 16.99.

2,3,6-Trichloroquinoxaline (2c). This compound was prepared from *N*,*N*-DMF (0.074 g, 0.001 mol), 6-chloro-2,3-dihydroxyquinoxaline (2.0 g, 0.0102 mol), and thionylchloride (3.02 g, 0.025 mol) in 1,2-dichloroethane (10 mL) after 4 h reflux to give 3.52 g (99%) of **2c** after recrystallization from

CH_3CN/H_2O as yellow needles, mp 144°C; ^1H NMR (DMSO-d_6) 8.23 (d, $J = 2.2$ Hz, 1H), 8.12 (d, $J = 8.9$ Hz, 1H), 7.98 (dd, $J = 9.0$, 2.3 Hz, 1H); ^{13}C NMR (DMSO-d_6) 145.87, 145.05, 140.28, 138.67, 135.91, 132.10, 129.57, 126.72, 126.72. *Anal.* Calcd. for $C_8H_3Cl_3N_2$: C, 41.15; H, 1.30; N, 12.00. Found: C, 40.83; H, 1.22; N, 12.20.

2,3-Dichloro-6-methylquinoxaline (2d). This compound was prepared from *N,N*-DMF (0.083 g, 0.0011 mol), 2,3-dihydroxy-6-methylquinoxaline (2.0 g, 0.012 mol) and thionylchloride (3.38 g, 0.028 mol) in 1,2-dichloroethane (20 mL) after 2 h at reflux. Recrystallized from CH_3CN/H_2O to give 2.25 g (93%) of **2d** as fine, light tan colored needles, mp 113–114°C; ^1H NMR (DMSO-d_6): δ 7.94 (d, $J = 8.3$ Hz, 1H), 7.82 (s, 1H), 7.77 (d, $J = 8.4$ Hz, 1H), 3.38 (s, 3H); ^{13}C NMR (DMSO-d_6) δ 144.27, 143.39, 142.33, 139.97, 138.34, 133.72, 127.30, 126.54, 21.30. *Anal.* Calcd. for $C_9H_6Cl_2N_2$: C, 50.73; H, 2.84; N, 13.15. Found: C, 50.37; H, 2.88; N, 13.22.

2,3-Dichloro-6-fluoroquinoxaline (2e). This compound was prepared from *N,N*-DMF (0.41 g, 0.0056 mol), 6-fluoro-3-dihydroxyquinoxaline (10.0 g, 0.0555 mol) and thionyl chloride (16.5 g, 0.139 mol) in 1,2-dichloroethane (50 mL), and the resulting reaction mixture was heated at reflux for 2 h. The resulting solution was cooled to room temperature and concentrated to dryness. The resulting solid was slurried in water (150 mL) for 30 min, then filtered and dried. The residue was taken up in a minimum of CH_2Cl_2 and filtered through a short column of silica gel, eluting with CH_2Cl_2. Concentration then gave 11.75 g (98%) of **2e** as a pale yellow solid, mp 143–145°C; ^1H NMR (DMSO-d_6): δ 8.18 (dd, $J = 9.2$, 5.6 Hz, 1H), 7.95 (dd, $J = 9.2$, 2.7 Hz, 1H), 7.88 (dd, $J = 8.4$, 2.7 Hz, 1H). *Anal.* Calcd. for $C_8H_3Cl_2FN_2$: C, 44.27; H, 1.39; N, 12.91. Found: C, 44.03; H, 1.33; N, 12.88.

2,3-Dichloro-6-cyanoquinoxaline (2f). *N,N*-dimethylformamide (0.039 g, 0.0005 mol) was added dropwise to a slurry of 6-cyano-2,3-dihydroxyquinoxaline (1.0 g, 0.0054 mol) and thionyl chloride (1.6 g, 0.013 mol) in 1,2-dichloroethane (5 mL), and the resulting solution was heated at reflux for 2 h. The solution was cooled and concentrated. The residue was slurried in water (50 mL) for 30 min, then filtered and dried. The residue was taken up in a minimum of CH_2Cl_2 and filtered through a short column of silica gel, eluting with CH_2Cl_2. Concentration gave 0.92 g (77%) of **2f** as a light gray powder, mp 239–240°C; ^1H NMR ($CDCl_3$): δ 8.40 (d, $J = 1.8$ Hz, 1H), 8.15 (d, $J = 8.7$ Hz, 1H); 7.97 (dd, $J = 8.7$, 1.8 Hz, 1H); ^{13}C NMR ($CDCl_3$) δ 147.58, 146.71, 141.42, 139.03, 133.74, 132.49, 129.35, 117.47, 113.51. *Anal.* Calcd. for $C_9H_3Cl_2N_3$: C, 48.25; H, 1.35; N, 18.76. Found: C, 48.22; H, 1.15; N, 18.57.

2,3-Dichloro-6-trifluoromethylquinoxaline (2g). This compound was prepared from *N,N*-DMF (0.19 g, 0.0026 mol), 2,3-dihydroxy-6-trifluoromethylquinoxaline (6.0 g, 0.026 mol) and thionyl chloride (7.8 g, 0.065 mol) in 1,2-dichloroethane (50 mL) after 2 h reflux to give 5.62 g (81%) of **2g** after filtration through a short column of silica gel, eluting with CH_2Cl_2, mp 91–93°C; ^1H NMR (DMSO-d_6): δ 8.50 (bs, 1H), 8.30 (d, $J = 8.8$ Hz, 1H), 8.20 (dd, $J = 8.8$, 2.0 Hz, 1H). *Anal.* Calcd. for $C_9H_3Cl_2F_3N_2$: C, 40.48; H, 1.13; N, 10.49. Found: C, 40.20; H, 1.15; N, 10.50.

2,3-Dichloro-7-methyl-6-nitroquinoxaline (2h). This compound was prepared from *N,N*-DMF (0.072 g, 0.00090 mol), 2,3-dihydroxy-6-nitro-7-methylquinoxaline (2.0 g, 0.00090 mol) and thionyl chloride (2.69 g, 0.023 mol) in 1,2-dichloroethane (5 mL) after 2 h at reflux to give 5.62 g (81%) of **2h** after filtration through a short column of silica gel, eluting with CH_2Cl_2, mp 134–136°C; ^1H NMR (DMSO-d_6): δ 8.66 (s, 1H), 8.18 (s, 1H), 2.67 (s, 3H). ^{13}C NMR (DMSO-d_6) δ 150.56, 147.81, 146.48, 140.94, 137.57, 134.57, 130.88, 123.65, 19.00. *Anal.* Calcd. for $C_9H_5Cl_2N_3O_2$: C, 41.89; H, 1.95; N, 16.28. Found: C, 41.93; H, 1.22; N, 16.50.

2,3,6-Trichloro-7-nitroquinoxaline (2i). This compound was prepared from *N,N*-DMF (0.364 g, 0.0050 mol), 2,3-dihydroxy-6-chloro-7-nitroquinoxaline (12.0 g, 0.0498 mol) and thionyl chloride (14.8 g, 0.124 mol) in 1,2-dichloroethane (50 mL) after 30 min at reflux to give 12.8 g (93%) of **2i** as a golden yellow powder after filtration through short column of silica gel, eluting with CH_2Cl_2, mp 135–137°C; ^1H NMR (DMSO-d_6): δ 8.89 (s, 1H), 8.58 (s, 1H). ^{13}C NMR (DMSO-d_6) δ 148.72, 148.58, 147.62, 140.88, 138.01, 130.35, 126.02, 124.72. *Anal.* Calcd. for $C_8H_2Cl_3N_3O_2$: C, 34.50; H, 0.72; N, 15.09. Found: C, 34.52; H, 0.81; N, 15.11.

Novel microbiocides 2-(hydroxymethyl)benzo[*d*]isothiazol-3(2*H*)-one (**7**) and (3-oxobenzo[*d*]isothiazol-2(3*H*)-yl)methyl benzencarboxylates (**11a-c**) were synthesized in good yields, and their structures were characterized by means of ^{1}H NMR, MS, and elemental analysis. The new compounds were tested preliminarily in laboratory assays against the aquicolous bacteria including *Escherichia coli, Staphyloccus aurueus, Vibrio alginolyticus, Aeromonas hydrophila*, and *Bacillus subtilis*. The results show all the synthesized compounds have good antimicrobial activity. The antimicrobial activity of all the tested compounds against all test bacteria is >96.6% at the concentration of 10^{-2} mg mL^{-1}. These compounds can be further developed for effective microbiocides in the future.

J. Heterocyclic Chem., **46**, 320 (2009).

INTRODUCTION

Marine biological fouling, usually termed marine biofouling, can be defined as the undesirable accumulation of microorganisms, plants, and animals on artificial surfaces immersed in sea water. The first phase of the fouling is the attachment of microorganisms. So it is important to inhibit the microorganism for antifouling. After the definitive ban on tin-based antifouling substances, the most important issue for paint manufacturers is to develop an alternative antifouling paint that achieves the same performance as the organic tin-based antifouling paints without significant cost increase.

As a class of antimicrobial agents against bacteria and fungi isothiazole derivatives have many advantages such as highly efficient, low poisonous; they are environmentally friendly [1]. Isothiazole-3(2*H*)-ones and heterocyclic bioisomeric derivatives such as **1-10** shown in Figure 1 are potent industrial and medicinal microbiocides with antifungal and antibacterial activities [2–4]. Okachi *et al*. synthesized 2-(hydroxymethyl)benzo[*d*]isothiazol-3(2*H*)-one **7** and its derivatives (**8** and **9**) and tested for their *in vitro* antibacterial activity against *Mycobacterium tuberculosis* H37Rv including resistant strains against streptomycin, kanamycin, or isonicotinic acid hydrazide. All the compounds showed good antibacterial activity and no crossresistance between the current antitubercular agents [5]. Vicini *et al*. described a series of 2-aminobenzo[*d*]isothiazol-3(2*H*)-one derivatives **10**, which were synthesized and screened *in vitro* for inhibition of platelet aggregation and for their spasmolytic activity, with the awareness that the development of antiplatelet agents with additional vasodilation activity could be beneficial in the treatment of various vaso-occlusive disorders. The tested compounds show a powerful antiplatelet activity and various modifications resulted in molecules possessing antiaggregating effects as well as spasmolytic actions [6].

According to the earlier-mentioned facts and the principle of combination of bioactive substructure, we herein designed and synthesized benzisothiazolone derivatives 2-(hydroxymethyl)benzo[*d*]isothiazol-3(2*H*)-one (**7**) and (3-oxobenzo[*d*]isothiazol-2(3*H*)-yl)methyl benzencarboxylates (**11a-c**) in good yields, and their structures as shown in Scheme 1. The structures of **11** were confirmed by means of ^{1}H NMR, MS, and

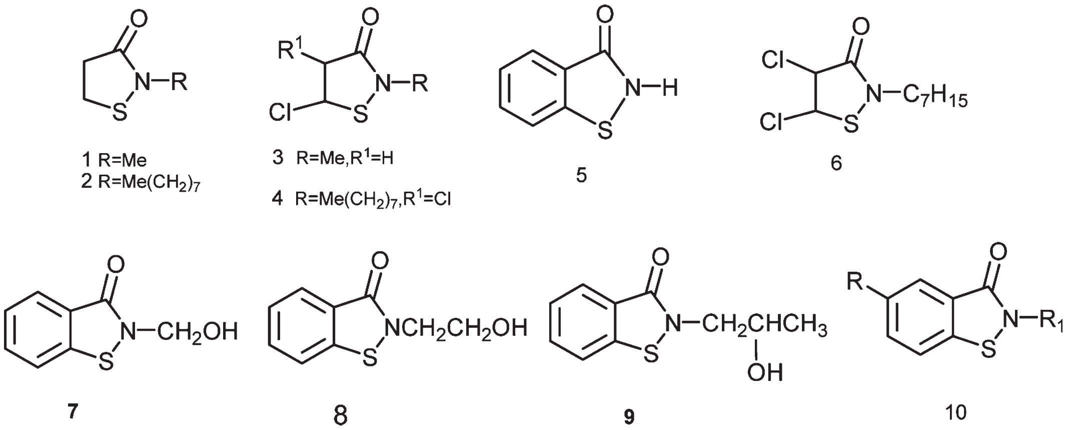

Figure 1. Previously reported bioactive compounds **1-10**.

elemental analysis. Their bioactivities were also tested preliminarily.

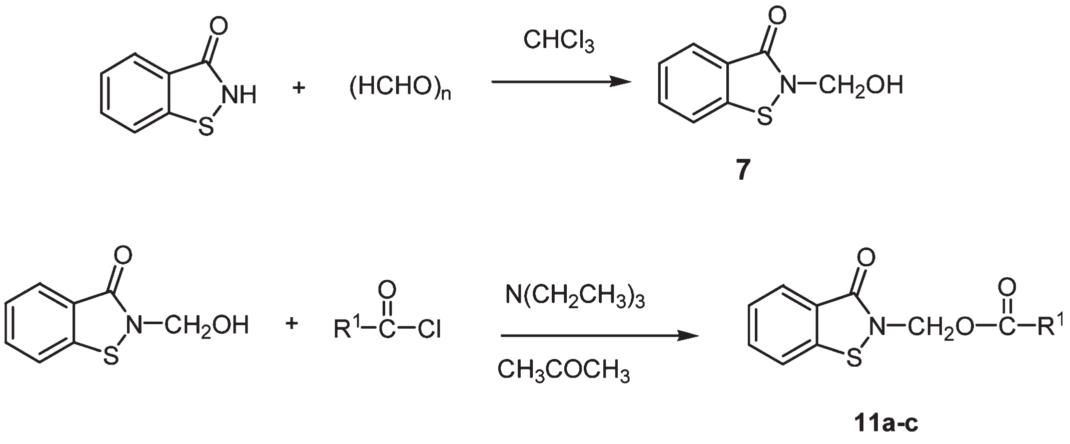
RESULTS AND DISCUSSION

We synthesized novel compounds (3-oxobenzo[*d*]isothiazol-2(3*H*)-yl)methyl benzencarboxylates (**11a-c**) by the reaction of 2-(hydroxymethyl)benzo[*d*]isothiazol-3(2*H*)-one (**7**) and benzoyl chloride derivatives (see Scheme 1) in good yield (66–72%). Their structures were characterized by means of ^{1}H NMR, MS, and elemental analysis.

The compounds **7** and **11a-c** were preliminarily tested in laboratory *in vitro* to evaluate their antimicrobial effect. The five bacterium used here include *Escherichia coli, Staphyloccus aurueus, Vibrio alginolyticus, Aeromonas hydrophila*, and *Bacillus subtilis*. We tested the antimicrobial activity using the viable cells plate count method as described in the literature [7,8].

Plate cultures were prepared as follows (g L^{-1}): 3 g beef, 5 g peptone, 5 g sodium chloride, 1 g yeast extract, and 18 g agar. The medium was dissolved completely and the pH value of the culture medium was adjusted to 7.2 with NaOH. And then the medium was autoclaved at 121°C and 20 psi for 15 min. The compounds synthesized in this article were dissolved in DMSO concentration in different concentration and then absolutely mixed with cultures (same as plate cultures except agar) containing bacteria. The mixture was homogenized in a laboratory homogenizer (IKA, MS2, minishaker, China) and serial dilutions were prepared, then 0.1 mL of each dilution was spread with a bent sterile glass rod on duplicate prepoured plates. After

Scheme 1. Synthesis route to the title compounds **7** and **11**.



11a, R^1=C_6H_5, **11b**, R^1= 4-FC_6H_4, **11c**, R^1= 3,5-$Me_2C_6H_3$

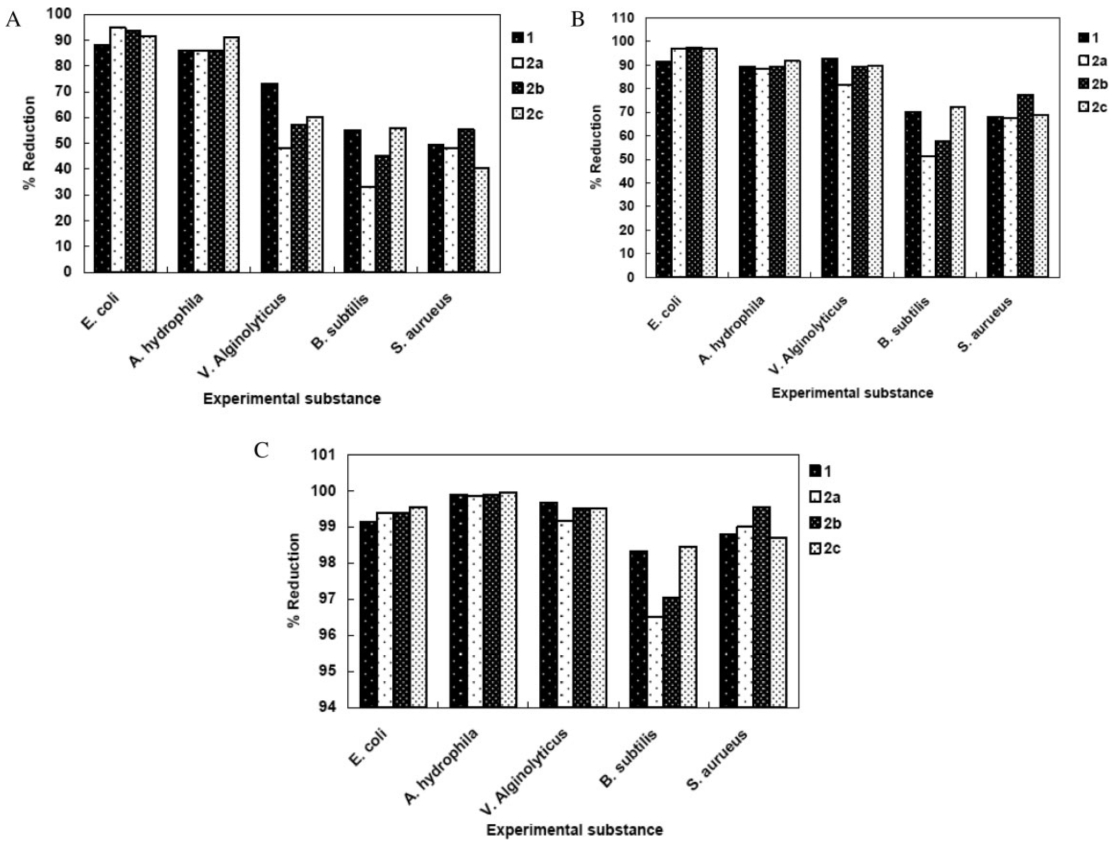


Figure 2. Microbial activity data of compounds **7** and **11a-c** in different concentration: 10^{-4} mg mL^{-1} (A), 10^{-3} mg mL^{-1} (B), 10^{-2} mg mL^{-1} (C), expressed as percent viable counting reduction.

24 h incubation at 28°C, colonies were counted. Pure DMSO (17 μL, 8.5% *v*/*v*) was used as negative control. The antimicrobial activity of the tested compounds (**11a-c**) was compared with compound **7** under similar culture conditions and has proved to be a good antimicrobial compound. Percent viable counting reduction was calculated using the following formula [9]:

$$100\% - \frac{\text{Experimental viable count}}{\text{DMSO viable count}} \times 100\% \qquad (1)$$

The antimicrobial activity of the synthesized compounds is shown in Figure 2. All the synthesized compounds showed certain antimicrobial activities against the tested bacterium. It is shown in Figure 2 that the microbial activity increased obviously with the increasing of the concentration of the compounds. When the concentration of the compounds is 10^{-4} mg mL^{-1} [Fig. 2(A)], the compounds showed good microbial activity against *Escherichia coli* and *Aeromonas hydrophila* with the viable cell reduction about 90%. When the compounds concentration reached 10^{-2} mg mL^{-1} [Fig. 2(C)], all the tested compounds showed excellent microbial activity against all the tested bacterium with the viable cell reduction >96.6%. Compared with compound **7** under similar culture conditions, the tested compounds (**11a-c**) showed equivalent or better antimicrobial activity. So the novel synthesized compounds should be potential microbial inhibitors.

CONCLUSION

In conclusion, we have achieved a short total synthesis of (3-oxobenzo[*d*]isothiazol-2(3*H*)-yl)methyl benzencarboxylates (**11a-c**) in good yield and their microbial activities were evaluated against the aquicolous bacteria *Escherichia coli, Staphyloccus aurueus, Vibrio alginolyticus, Aeromonas hydrophila*, and *Bacillus subtilis*. The synthesized **11a-c** exhibited high-antimicrobial activity. These results will allow us to investigate the structure-activity relationships in more detail by using more various derivatives of 2-(hydroxymethyl)benzo[*d*]isothiazol-3(2*H*)-one (**7**) in the future.

EXPERIMENTAL

Melting points were determined with an Electrothermal-XT4-100 digital melting point apparatus. The ^{1}H NMR spectra were recorded on a Bruker AV-400 FT NMR spectrometer using

TMS as internal standard and DMSO-d_6 as solvent. The elemental analyses were performed with a Bruker DALTONICS analyzer. The MS spectra were taken on a HP-5988A spectrometer.

Procedure for preparation of 7. A mixture of benzoisothiazolone (3.02 g, 0.02 mol commercial from National Medicine Corporation, Shanghai of China), polyoxymethylene (5.28 g, 0.022 mol) in 10 mL of chloroform was refluxed for 5 h at 60°C under stirring. Compound **7** (3.13 g, 87%) was obtained by the usual work-up of the reaction mixture. The physical and spectral data of compound **7** were in accordance with the data reported by Morley *et al.* [4].

General procedure for the synthesis of (3-oxobenzo[*d*]isothiazol-2(3*H*)-yl)methyl benzencarboxylates 11a-c. To the stirred and cooled solution of compound **7** (1.81 g, 10 mmol), triethylamine (1.22 g, 11 mmol) in 20 mL of acetone (dried before used) with ice-water bath, benzoyl chloride (1.41 g, 10 mmol) was added dropwise. The colorless precipitates were obtained as soon as by addition of benzoyl chloride. When benzoyl chloride was added completely, the ice-water bath was removed and the resulting mixture was continuously refluxed for 2 h with stirring. After the reaction quenched, the reaction mixture was concentrated under reduced pressure, and purified by column chromatography on silica gel (petroleum ether:ethyl acetate = 3:1) to gave pure crystals of **11a**, mp 114–116°C; ^{1}H NMR (DMSO-d_6, 400 MHz) δ: 6.15 (s, 2H, CH_2), 7.27~7.87 (m, 9H, Ar-H); GC-MS (ESI) *m*/*z*: 285 (M^+), 256, 164, 136, 105, 77; *Anal.* Calcd. for $C_{15}H_{11}NO_3S$: C, 63.14; H, 3.89; N, 4.91; Found: C, 62.87; H, 3.46; N 4.88.

(3-Oxobenzo[d]isothiazol-2(3H)-yl)methyl 4-fluorobenzencarboxylate (11b). This compound (2.18 g, 72%) was obtained as crystals, mp 95–96°C; ^{1}H NMR (DMSO-d_6, 400 MHz) δ: 6.14 (s, 2H, CH_2), 7.07~7.85 (m, 9H, Ar-H); MS (ESI) *m*/*z*: 303.3(M^+); *Anal.* Calcd. for $C_{15}H_{10}FNO_3S$: C, 59.40; H, 3.32; N, 4.62; Found: C, 59.10; H, 3.39; N, 4.57.

(3-Oxobenzo[d]isothiazol-2(3H)-yl)methyl 3,5-dimethylbenzencarboxylate (11c). This compound (2.16 g, 69%) was obtained as crystals, mp 109–111°C; ^{1}H NMR (DMSO-d_6, 400 MHz) δ: 1.27 (m, 6H, $2CH_3$), 6.10 (s, 2H, CH_2), 7.07~7.79 (m, 7H, Ar-H); MS (ESI) *m*/*z*: 313.4 (M^+); *Anal.* Calcd. for $C_{17}H_{15}NO_3S$: C, 65.16; H, 4.82; N, 4.47; Found: C, 64.96; H, 4.45; N 4.41.

Here we report Pd catalyzed synthesis of *N,N*-dimethyl[1,8]naphthyridine-2-amines by facile incorporation of N(Me)$_2$ group from DMF in moderate to good yield.

J. Heterocyclic Chem., **46**, 324 (2009).

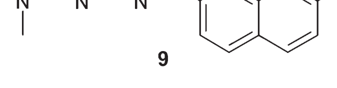
INTRODUCTION

Naphthyridine system is of great importance because of their broad applications in medicine. 1,8-Naphthyridine or naphthyridone systems are potentially useful as antihypertensives, antitumor agents, immunostimulants, and herbicide safeners. Also, *N,N*-dimethyl amino substituted 1,8-naphthyridines act as diuretic agents [1]. *N,N*-Dimethylamino group is present in methylene blue, crystal violet, 4-*N,N*-dimethylaminopyridine *etc*. (which are both biologically and chemically important compounds) [2]. In addition to palladium catalyzed C—C homo and hetero coupling reactions of aryl halides [3], it has been emerging as a powerful approach for the C—N coupling reactions [4,5]. Hawes *et al*. [1d] were able to incorporate the *N,N*-dimethylamino group in 1,8-napthyridines by treatment with gaseous dimethylamine. Palladium catalyzed aminocarbonylation using formamides as the amine source is also reported [5c]. With this information, we became interested to explore the reactions capable of introducing *N,N*-dimethylamino group in halo[1,8]naphthyridine systems.

RESULTS AND DISCUSSION

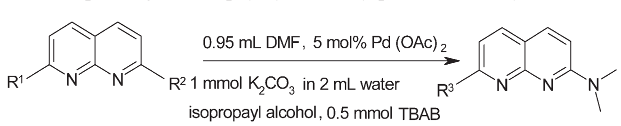
In our attempt to synthesize *N,N*-dimethylamino substituted 1,8-naphthyridines, we have carried out the reaction at room temperature with *N,N*-dimethylamine for direct replacement of halides but it does not work. Even under refluxing condition, the reaction does not proceed. The reaction is then carried out in the presence of Pd(OAc)$_2$ at room temperature and then it is also refluxed but the reaction fails. We then intended to change to *N,N*-dimethylformamide to see whether it may be a possible source of *N,N*-dimethylamino group by use of palladium catalysis. By several attempts, the reaction of one mmol of halo-napthyridine using DMF (0.95 mL), aqueous K$_2$CO$_3$ (1 mmol in 0.35 mL of water), TBAB (0.5 mmol), and Pd(OAc)$_2$ (0.05 mmol) at room temperature does not proceed but under reflux at 115°C, the reaction is successful with moderate to high yield (Table 1). The reaction rate and the yields are increased by the addition of isopropyl alcohol due to acceleration in the generation of Pd (0) [3g]. Although this method is similar to carbon-carbon homo-coupling reaction as reported by Lamaire, [3g] we are able to isolate only in one case the carbon-carbon homo-coupled yellow crystalline product *N,N,N′,N′*-tetramethyl-3,3′-bi-[1,8]-naphthyridin-7,7′-diamine **9** from (7-chloro-[1,8]-napthyridin-2-yl)-dimethylamine **2**.

Although various types of palladium catalyzed amination reactions are known [4], the incorporation of *N,N*-dimethylamino group is not hitherto reported from DMF in the [1,8]-naphthyridine system. So we report for the first time the incorporation of *N,N*-dimethylamino group from DMF under this reaction condition in the variously substituted [1,8]-napthyridines (Table 1). In the other aryl halides including pyridine halides homocoupled products result as reported in the literature [3g].



9

Scheme 1. Synthesis of *N*,*N*-dimethyl-1,8-naphthyridin-2-amines from the corresponding halo-naphythyridines by palladium catalysis.



In Table 1, entry 8, 7-bromo-1*H*-[1,8]naphthyridine-2-one **8** is represented as the enol-form for convenience but it is actually present in the lactam form.

The yield of the products increases as the number of chlorine atoms decreases from **5** to **7** which may be due to the C—Cl bond strength. In case of 2,7-dichloro-1,8-naphthyridine **5**, after 4 h reflux, mono- and disubstituted products **2** and **2a** are, respectively, formed with the same ratio but after 8 h no mono substituted product **2** is found. For mixed bromo chloro napthyridine **7**, the same result is observed where bromo group is always substituted but not chloro, which may be due to the lower bond strength of C—Br bond than C—Cl bond. The starting chloro and bromo derivatives are made according to the literature procedure [6,7].

EXPERIMENTAL

Representative experimental procedure for *N*-(7-dimethyl amino[1,8]naphthyridin-2-yl)acetamide 4a. In a round-bottomed flask, a mixture of *N*-(7-chloro-[1,8]naphthyridin-2-yl)-acetamide **4** (170 mg, 0.813 mmol), $Pd(OAc)_2$ (11.3 mg, 0.05 mmol), K_2CO_3 (112 mg, 0.813 mmol), TBAB (130.1 mg, 0.4065 mmol), water (0.8 mL), DMF (1.5 mL), and 2 mL of isopropyl alcohol is taken and refluxed for 7.5 h under nitrogen atmosphere. The whole solution is then passed through a celite bed (2 cm), washed well with isopropyl alcohol, the filtrate is then evaporated under reduced pressure and washed well with brine followed by water. The organic layer is then dried with Na_2SO_4 (anhydrous) and evaporated under reduced pressure followed by column chromatography using 2% methanol in CH_2Cl_2 offering the corresponding *N*,*N*-dimethylamino derivative, *N*-(7-dimethylamino-[1,8]naphthyridin-2-yl)-acetamide **4a** as yellow crystals. mp. 214–216°C; IR (KBr): 3219, 3062, 1692, 1609, 1326, 1151, 834, 796.45 cm^{-1}; ^1H NMR ($CDCl_3$, 400 MHz): δ 8.349 (bs, 1H), 8.094 (d, 1H, J = 8.5 Hz), 7.914(d, 1H, J = 8.5 Hz), 7.786 (d, 1H, J = 9.0Hz), 6.827 (d, 1H, J = 9.0Hz), 3.266 (s, 6H), 2.215 (s, 3H); ms (ESI) *m*/*z* 244.97 (M^++H+Na, 100), 497.97 (2M+H+Na, 80). [a] In this case dehydro halogenated product is obtained in 20% yield. All reactions are carried out at 115°C, $Pd(OAc)_2$ (0.05 mmol), K_2CO_3 (1 mmol in 0.35 mL of water), TBAB (0.5 mmol), and 2 mL of isopropyl alcohol with respect to 1 mmol of the naphthyridine halide.

[b] Also C—C coupled product *N*,*N*,*N*′,*N*′-tetramethyl-3,3′-bi-[1,8]-naphthyridine-7,7′-diamine **9** is isolated in 15% yield.

for $C_{20}H_{20}N_6$: C, 69.75; H, 5.85; N, 24.40. Found: C, 69.78; H, 5.80; N, 24.44.

Preparation of 2-bromo-7-methyl[1,8]naphthyridine 1. In a round-bottomed flask, hydrobromic acid (0.624 mL 48%, 5.65 mmol) is taken. The flask is cooled to 0°C by ice-salt bath and then 7-methyl-[1,8]-napthyridin-2-yl-amine (200 mg, 1.257 mmol) is added to it over a period of 10 min. Then bromine [0.194 mL (0.464 mg), 3.77 mmol] is added dropwise carefully maintaining the temperature at 0°C. After addition of bromine, $NaNO_2$ (216.66 mg, 3.14 mmol) in water (0.31 mL) is added for a period of 1.5 h. Here, the temperature of the reaction should be maintained at 0°C to −5°C. After addition is complete, it is stirred for 30 min. The precipitate obtained is filtered and finally washed well with water to make it acid-free and the mother liquor is collected and neutralized with NaOH adding crushed ice and then it is extracted with CH_2Cl_2 (4 × 25 mL) and is dried with anhydrous Na_2SO_4. The solvent is removed by evaporation under reduced pressure. This crude product is pure enough to be crystallized to afford white microcrystals of the title compound **1**, 215 mg (77%). mp. 202–205°C, IR (KBr): 2931, 1277, 1150, 545 cm^{-1}; ^1H NMR ($CDCl_3$, 300 MHz): δ 8.07 (d, 1H, $J = 9.33$ Hz), 7.97 (d, 1H, $J = 8.4$ Hz), 7.58 (d, 1H, $J = 8.1$ Hz), 7.41 (d, 1H, $J = 8.1$ Hz), 2.80 (s, 3H), ms (ESI): m/z 244.96 (M^++Na, 100), 246.97 (M^++Na+2, 98). Vilsmeier–Haack formylation of acetonitrile using dimethylformamide and phosphorus oxychloride leading to a novel intermediate, *N*-((*E*)-3-(dimethylamino)-2-formylacryloyl)formamidine **2** and its utility in the synthesis of pyrimidine-fused heterocycles such as pyrazolo[1,5-*a*]pyrimidines and triazolo[1,5-*a*]pyrimidine is reported.

J. Heterocyclic Chem., **46**, 327 (2009).

INTRODUCTION

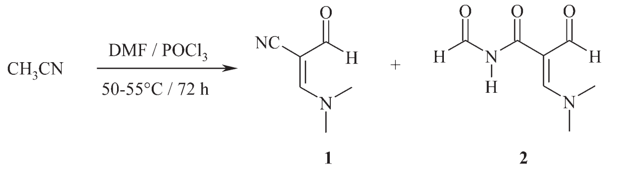
The synthesis of pyrazolo[1,5-*a*]pyrimidines is a promising avenue of research owing to various bioactivities displayed by this class of compounds. They have been established as selective inhibitors of adenosine cyclic mono phosphate (cAMP) phosphodiesterase *in vitro* [1,2]. In addition to this some of these compounds showed antischistosomal activity [3]. Another class of compounds, [1,2,4]triazolo[1,5-*a*]pyrimidine derivatives are promising inhibitors against trypanosomatid parasites [4], displaying inhibition percentages far higher than those reached with traditional drugs used against *T. cruzi* and *L. donovani*, such as ketoconazole [5], pentavalent antimonials [6], nitroimidazole, and itraconazole [7].

Vilsmeier–Haack formylation has emerged as a powerful tool for the formylation of various organic compounds. In 1970, Reichardt and Kermer [8] demonstrated the synthesis of 3-dimethylamino-2-formyl acrylonitrile **1** *via* the Vilsmeier–Haack formylation of acetonitrile. However, after intensive investigation of the same reaction we have achieved two products, *i.e.*, 3-dimethylamino-2-formyl acrylonitrile **1** and an unusual product *N*-((*E*)-3-(dimethylamino)-2-formylacryloyl)formamidine **2** (Scheme 1). From literature, it was noted that the related synthons have been used for the synthesis of pyrimidines and condensed pyrimidines [9–12]. Previously, we have used compound **1** for the synthesis of different annulated heterocycles [13,14]. Considering the synthetic utility of Compound **1** [15–17] and our interest in this area [18–20] prompted us to perform various condensation reactions of **2** with 5(3)amino heterocycles. We herein report the synthesis of an unexpected compound, *N*-((*E*)-3-(dimethylamino)-2-formylacryloyl) formamidine **2** and its utility in the synthesis of pyrimidine-fused heterocycles such as pyrazolo[1,5-*a*]pyrimidines and triazolo[1,5-*a*]pyrimidine.

RESULTS AND DISCUSSION

The Vilsmeier–Haack formylation of acetonitrile was carried out by Reichardt and Kermer by refluxing the reaction mixture of acetonitrile, DMF, and phosphorus oxychloride (1:0.6:0.6 mol) to furnish 3-dimethylamino-2-formyl acrylonitrile **1** in 10–12% yield. The same reaction carried out by us resulted in the formation of two products **1** and **2**. Encouraged by these results, we optimized the reaction conditions using different molar ratios of DMF and phosphorus oxychloride with respect to acetonitrile (Table 1). The ratio of molar equivalents played an important role in the formation of compounds **1** and **2**. Thus, the best results were obtained when a mixture of acetonitrile, DMF, and phosphorus oxychloride (1:3:3 mol) was heated to 50–55°C for 72 h. The reaction mixture was then poured into ice and neutralized with sodium hydrogencarbonate. The resultant

Scheme 1. Vilsmeier–Haack formylation of acetonitrile leading to a novel intermediate **2**.



suspension was extracted with dichloromethane. The organic layer was dried and concentrated under vacuum to give crude product, which was then recrystallized from ethanol to afford a pale yellow solid, *i.e.*, compound **2** in 25% yield. The aqueous layer was concentrated under vacuum to a semisolid, which on recrystallization with ethanol furnished compound **1** in 20% yield. Compound **1** gave satisfactory spectral and physical data and was identical with that of reported earlier [8].

The structure of compound **2** was deduced from its ^{1}H and ^{13}C NMR spectra. The mass spectrum of **2** displayed the molecular ion (M^{+}) peak at 170 *m*/*z,* which is consistent with the molecular weight of **2**. The ^{1}H NMR spectrum of **2** showed singlet at δ 8.03 representing olefinic proton, doublet at δ 9.10 corresponding to aldehyde proton neighboring to —NH of amide. The singlet at δ 9.31 represented another aldehyde proton. The other signals appeared at δ 3.20 (s, 3H, NCH_3) and 3.40 (s, 3H, NCH_3). The —NH proton appeared at δ 11.43 as abroad singlet.

We observed that Vilsmeier–Haack formylation of acetonitrile with the optimized reaction conditions furnished two compounds with different yields. The structure of compound **2** was also supported by further nucleophilic substitution reaction with 5(3)-amino heterocycles. Thus condensation of compound **2** with 5(3)-amino pyrazoles **3a-c** furnished pyrazolo[1,5-*a*]pyrimidines **4a-c** in (Scheme 2, Table 2) 75–80% yield. During condensation of **2** with **3a-c** it was observed that the *N*-formyl group in **2** undergoes hydrolysis to amido function in **4a-c**. The condensation of **2** with pyrimidine-2-carboxamidine **5** furnished 2-(pyrimidine-2-yl)pyrimidine-5-carboxamide **6** (Scheme 3) in 80% yield. Similarly, 1,2,4 triazolo[1,5-*a*]pyrimidine-6-carboxamide **8** (Scheme 4) was synthesized in 82% yield from the reaction of 5(3)-amino[1,2,4]triazole **7** with **2**. The structure of the compounds **4**, **6**, and **8** were determined from spectroscopic data. Several attempts to cyclize **2** with 2-amino heterocycles **9a-e** did not lead to the desired product (**11a-e**). However, compound **2** on condensation with 2-aminopyridines or 2-aminopyrimidine in ethanol at reflux temperature furnished open chain compounds **10a-e** in 75–80% yield (Scheme 5, Table 3). It was interesting to observe that, the condensation of **2** with *o*-phenylenediamine **12** under similar reaction conditions furnished open chain compound **13** with the *N*-formyl group remaining intact (Scheme 6). Attempts to cyclize compound **12–14** were unsuccessful.

To conclude the Vilsmeier–Haack formylation of acetonitrile with optimized reaction conditions leads to a highly stable synthone *N*-((*E*)-3-(dimethylamino)-2-formyl acryloyl)formamide **2** which can further be used for the synthesis of various new heterocycles. Herein, we have reported the synthesis of some pyrazolopyrimidines and triazolopyrimidines. These heterocycles can exhibit a number of bioactivities specifically inhibitory action against cAMP phosphodiesterase. Biological investigations are in progress in our laboratory and shall be reported in a due course.

EXPERIMENTAL

Melting points were determined on a Buchi melting point apparatus, Mod. B-545 and are uncorrected. The ^{1}H (300 MHz) and ^{13}C (75 MHz) NMR spectra were recorded on a Varian XL-300 spectrometer. Chemical shifts are reported in parts per million (ppm) relative to tetramethylsilane, and multiplicities are given as s (singlet), d (doublet), t (triplet), q (quartet), or m (multiplate). The solvent for NMR spectra was DMSO-d_6 unless otherwise stated. Infrared spectra were taken on Thermo Electron Corporation NICOLET 380 FTIR

instrument in potassium bromide pellets unless otherwise stated. Mass spectrum was recorded on Shimadzu GC-MS QP 2010A mass spectrometer with an ionization potential of 70 eV. Elemental analysis was performed on a Hosli CH-Analyzer and was within ±0.4 of the theoretical percentage. All reactions were monitored by thin layer chromatography, carried out on 0.2-mm silica gel 60 F-254 (Merck) plates using UV light (254 and 366 nm) for detection. Common reagent grade chemicals are either commercially available and were used without further purification or prepared by standard literature procedures.

***N*-((E)-3-(Dimethylamino)-2-formylacryloyl) formamidine (2).** To a stirred solution of acetonitrile (41.05 g, 1000 mmol) and DMF (219.30 g, 3000 mmol) at 0–5°C was added dropwise over 1.5 h phosphorus oxychloride (459.99 g, 3000 mmol). The mixture was stirred at 50–55°C for 72 h. It was then quenched in ice, neutralized with sodium hydrogencarbonate. The resultant suspension was extracted with dichloromethane (9 × 500 mL). The combined organic extractions were washed with saturated aqueous NaCl and dried. The solvent was evaporated under reduced pressure, and the solid residue was recrystallized from ethanol affording compound 2 as a pale yellow solid, 42.5 g (25%) (Table 1, Entry 6); m.p 145–147°C, IR (KBr): 3049, 2920, 1700, 1653, 1578, 1273, 1176, 840 cm^{-1}. ^{1}H NMR (300 MHz, DMSO): δ 11.43 (d, J = 6.9 Hz,1H, NH), 9.31 (s, 1H, CHO), 9.10 (d, J = 9.9 Hz,1H, NH—CHO), 8.03 (s, 1H, CH), 3.41 (s, 3H, N—CH$_3$), 3.21 (s, 3H, N—CH$_3$). ^{13}C NMR (75 MHz, DMSO): δ 186.8, 164.3, 163.5, 162.7, 101.7, 48.6, 43.3. *Anal*. Unexpected quinoxalines (**3**) have been obtained from a one-pot reaction of 2-[(2-oxo-2-arylethyl)anilino]-1-aryl-1-ethanones (**1**) with *o*-phenylenediamine (**2**) in the presence of a catalytic amount of *p*-toluene sulfonic acid. The reaction presumably involves a tandem carbonyl addition—eliminative cyclization—air oxidation sequence.

J. Heterocyclic Chem., **46**, 332 (2009).

INTRODUCTION

Solvent-free approach using microwave irradiation opens numerous possibilities for conducting rapid heterocyclic synthesis *via* cyclocondensation reactions using a variety of supported reagents [1]. Generally, cyclocondensation reactions, where light polar molecules as water and alcohol are eliminated, constitute good candidates for microwaves. Furthermore, there are advantages of these solvent-free protocols with reduced reaction time and generally improved yields.

Nitrogen-containing heterocyclic compounds are indispensable structural units for both the chemist and the biochemist. In continuation of our work [2] on the chemistry of bis(aroylmethyl)anilines, which is relatively unexplored [3], herein, we report the condensation reaction of bis(aroylmethyl)anilines with 1,2-diaminobenzene. The reaction of diphenacyl aniline with 2-aminophenol and 2-aminothiophenol has led to diazine-fused benzheteroazole derivatives [4] (Fig. 1). In the same angle, the reaction of diphenacyl aniline with *o*-phenylenediamine is expected to give a related product. But unexpected quinoxaline is obtained as the major product in this reaction and the details are presented in this article.

RESULTS AND DISCUSSION

Hinsberg [5] reported that 2-bromoacetophenone gave directly 2-arylquinoxalines when reacted with *o*-phenylenediamine or *m*-tolylenediamine in boiling alcohol. He suggested that dihydroquinoxaline was an intermediate product which was readily oxidized by air to the corresponding quinoxaline. Buu-Hoi and Khoi [6] reported quantitative yields of 2-arylquinoxalines directly from the reaction of 2-bromo-3′-nitroacetophenone and 2-bromo-4′-nitroacetophenone with *o*-phenylenediamine in the presence of sodium acetate.

Quinoxalines constitute the basis of many insecticides, fungicides, herbicides, and anthelmintics, as well as being important in human health and as receptor antagonists [7]. There are numerous methods of preparing quinoxalines, but the double condensation of a 1,2-dicarbonyl compound and a 1,2-diaminoaromatic is commonly used [8]. This article describes the first report

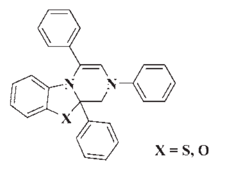

Figure 1. Benzheteroazoles.

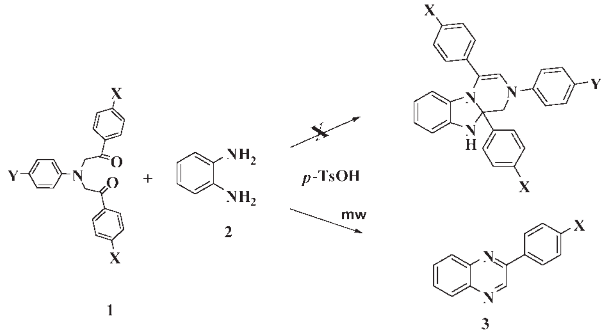
of the formation of quinoxalines from 3-aza-1,5-diketones.

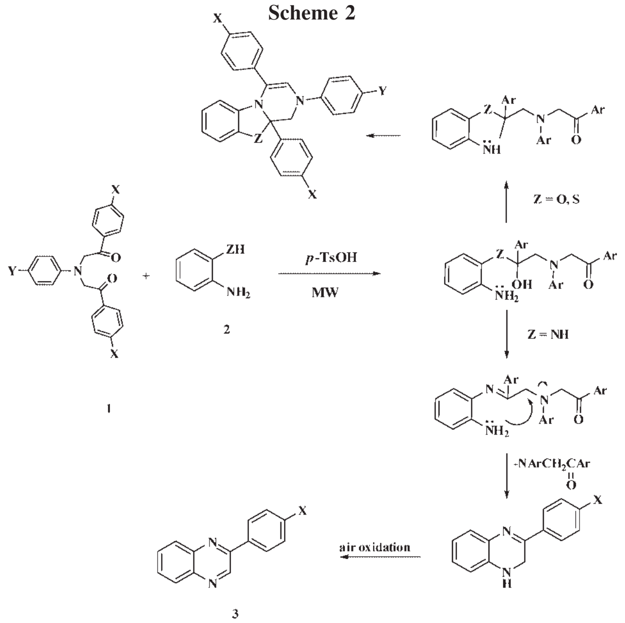
A mixture of *o*-phenylenediamine **2** with appropriately substituted diphenacyl aniline **1** was taken in a 1:1 molar ratio along with a catalytic amount of *p*-toluene sulfonic acid and ground well to ensure thorough mixing with no solvent. This mixture was placed in an open glass tube over a silica bath in a domestic microwave oven and irradiated for 10 min at 540 W. The major product **3** (Scheme 1) was isolated from the remaining mass of the reaction mixture by column chromatography and the product eluted first. Compound **3** was obtained in considerable yield and all the compounds were characterized by their NMR spectral data. The ^{1}H NMR spectrum of a representative compound, 2-(4-methylphenyl)quinoxaline (3, X = Me) showed the presence of one singlet at 2.38 ppm accounting for three hydrogen atoms. A two proton doublet is visible at 7.30 ppm (J = 8.4 Hz) and a six proton multiplet appears in the region 7.65–8.18 ppm. There is a singlet appearing downfield, 9.24 ppm. The ^{13}C NMR spectrum of this compound has signals at 20.4, 126.4, 128.0, 128.2, 128.5, 128.8, 129.2, 133.0, 139.5, 140.4, 141.3, 142.3, and 150.8 ppm. The data are very much consistence with 2-arylquinoxaline. Thus the major compound **3** formed in the reaction is unexpected 2-arylquinoxalines, which has been confirmed by comparing with an authentic sample of 2-phenylquinoxaline.

Scheme 1



Starting compound	X	Y	Percentage Yield of **3**
1a	H	H	68
1b	Cl	H	73
1c	Me	H	65
1d	Cl	Me	70
1e	Me	Me	75
1f	Me	OMe	70

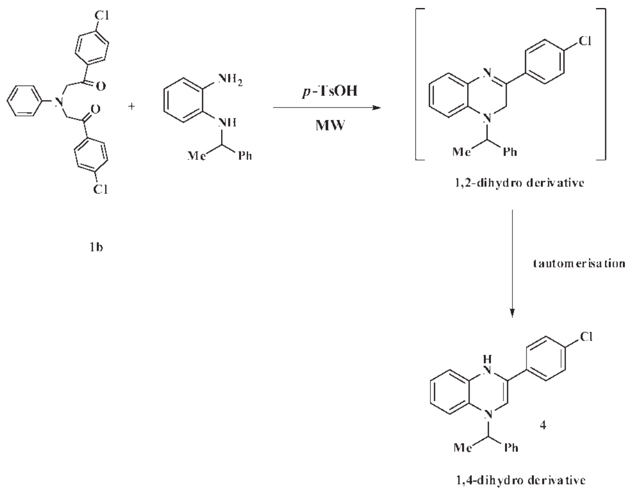
Scheme 2



The quinoxalines **3** presumably arise from a tandem sequence of reactions and the mechanism (Scheme 2) envisages an acid catalyzed imine formation followed by the attack of amino group on the methylene carbon—not on the imino carbon—displacing $NPhCH_2COPh$ group. This is contrary to the case of the reaction **1** with 2-aminophenol and 2-aminothiophenol. There the initial attack by the nucleophilic center SH or OH on the electrophilic carbonyl gives a tertiary alcohol and the nitrogen of the amino group attacks this carbon center, displacing hydroxyl group (probably *via* the initially formed carbocation with the help of *p*-toluene sulphonic acid). But in the present case, the initially formed tertiary alcohol undergoes 1,2-elimination forming an imine. Now the second nitrogen of the amino group does not attack this imino carbon rather attacks the methylene carbon displacing $NPhCH_2COPh$ group (again aided by *p*-toluene sulphonic acid through protonation of the leaving group, thus increasing its leaving group ability).

With the successful optimization results in hand, we investigated the scope of this process to another substituted diamine, *N*-(1-phenylethyl)-1,2-diaminobenzene.

Scheme 3



When the reaction is carried out with substituted 1,2-diaminobenzene, *N*-(1-phenylethyl)-1,2-diaminobenzene, prepared from 2-chloronitrobenzene and dl-phenylethylamine, the final oxidation step shown in Scheme 2 is not possible and the 1,2-dihydroquonoxaline can be expected. Hence, the proposed reaction of **1b** with *N*-(1-phenylethyl)-1,2-diaminobenzene was carried out under identical condition as depicted in Scheme 2. The reaction proceeds smoothly giving a product **4** (Scheme 3). The ^{1}H NMR spectrum has a three hydrogen doublet and one hydrogen multiplet at 1.85 ppm and 4.63 ppm, respectively. In the aromatic/olefinic region, there are 14 hydrogen resonances. In the ^{13}C NMR spectrum, there are signals at 22.2 and 43.9 ppm apart from 16 signals in the olefinic/aromatic region. There is no methylenic carbon or hydrogen. Thus the ^{1}H NMR and ^{13}C NMR spectra of the compound **4** clearly suggest the structure to be a 1,4-dihydroquinoxazine and not a 1,2-dihydroquinoxazine. It is surprising that the 1,2-dihydro system obtained has rearranged to a 1,4-dihydro system.

Even in the case of **3**, it is probable that if the air oxidation is prevented, then the 1,2-dihydro system would have not been isolated and the 1,4-dihydro system would have been obtained.

EXPERIMENTAL

All chemicals were of reagent grade quality and used without further purification. All melting points were recorded in open capillaries and are uncorrected. The ^{1}H NMR and ^{13}C NMR spectra were recorded on a Bruker 300 MHz spectrometer at 300 and 75 MHz respectively in CDCl$_3$ using TMS as internal standard. The related 2D NMR spectra also recorded on the same instrument. Chemical shifts are given in parts per million (δ-scale) and coupling constants are given in hertz.

General procedure for the preparation of 2-arylquinoxaline (3). A mixture of 2-[(2-oxo-2-arylethyl)anilino]-1-aryl-1-ethanone **1** (0.0015 mol), 1,2-benzenediamine (0.2 g, 0.0015 mol) and catalytic amount of *p*-toluenesulfonic acid was irradiated in an open glass tube over a silica bath in a domestic microwave oven and irradiated for 10 min at power level 5 (540 W). The reaction mixture was treated with water and then extracted with dichloromethane. The organic layer was washed with water repeatedly and dried over anhydrous calcium chloride and evaporated to give the crude product. Purification of the product was performed by column chromatography on silica gel using petroleum ether-ethyl acetate [97:3 (*v*/*v*)] mixture as eluent. The signal due to NH hydrogen is so broad that it is not visible in these compounds. However, when exchanged with D$_2$O, the HOD peak appears confirming the presence of NH signal.

2-Phenylquinoxaline (3, X = H). This compound was obtained as colorless solid, mp, 79°C (Lit. m.p. 76–77°C [9]); ^{1}H NMR (300 MHz, CDCl$_3$): 7.51–7.56 (m, 3H), 7.73–7.82 (m, 2H), 8.11–8.22 (m, 4H), 9.3 (s, 1H); ^{13}C NMR (75 MHz, CDCl$_3$): 127.5 (d), 129.0 (d), 129.1 (d), 129.5 (d), 129.6 (d), 130.1 (d), 130.3 (d), 136.7 (s), 141.5 (s), 142.2 (s), 143.3 (d), 151.8 (s).

2-(4-Chlorophenyl)quinoxaline (3, X = Cl). This compound was obtained as colorless solid, mp, 128°C (Lit. m.p. 137°C [10]); ^{1}H NMR (300 MHz, CDCl$_3$): 7.53–7.56 (m, 2H), 7.78–7.83 (m, 2H), 8.15–8.18 (m, 4H), 9.3 (s, 1H); ^{13}C NMR (75 MHz, CDCl$_3$): 129.2 (d), 129.5 (d), 129.8 (d), 129.9 (d), 130.2 (d), 130.8 (d), 135.5 (s), 137.0 (s), 142.0 (s), 142.6 (s), 143.3 (d), 151.0 (s).

2-(4-Methylphenyl)quinoxaline (3, X = Me). This compound was obtained as colorless solid, mp, 92°C (Lit. m.p. 94°C [10]); ^{1}H NMR (300 MHz, CDCl$_3$): 2.38 (s, 3H); 7.30(d, 2H, J = 8.4 Hz); 7.65–7.73 (m, 2H); 8.02–8.08 (m, 4H); 9.24 (s, 1H); ^{13}C NMR (75 MHz, CDCl$_3$): 20.4 (q), 126.4 (d), 128.0 (d), 128.2 (d), 128.5 (d), 128.8 (d), 129.2 (d), 133.0 (s), 139.5 (s), 140.4 (s), 141.3 (s), 142.3 (d), 150.8 (d).

3-(4-Chlorophenyl)-1-(1-phenylethyl)-1,4-dihydroquinoxaline (4). This compound was obtained as yellow solid, yield 68%, mp, 146°C; ^{1}H NMR (300 MHz, CDCl$_3$): 1.85 (d, J = 6.9 Hz, 3H); 4.63 (q, J = 6.9 Hz, 1H); 7.14–8.31 (m, 14H); ^{13}C NMR (75 MHz, CDCl$_3$): 22.2 (q), 43.9 (d), 126.4 (d), 127.8 (d), 128.4 (d), 128.5 (d), 129.0 (d), 129.1 (d), 129.6 (d), 129.8 (d), 130.3 (d), 135.0 (d), 137.4 (s), 140.4 (s), 141.5 (s), 144.2 (s), 154.2 (s), 157.3 (s); *Anal.* Calcd. for $C_{22}H_{19}ClN_2$: C, 76.18; H, 5.52; N, 8.08%. Found: C, 76.25, H, 5. 54; N, 8.03%.

6 Compounds

A solventless parallel synthesis of some novel, *N*-substituted dihydropyridines by the application of microwaves is reported. The synthetic methodology adopted to synthesize the titled compounds and their antioxidant activity is described.

J. Heterocyclic Chem., **46**, 336 (2009).

INTRODUCTION

Heterocyclic synthesis plays an important role in medicinal chemistry by virtue of its application in the production of large number of medicinal compounds. Among many utility of heterocyclic syntheses one such important use is in the production of drugs, either currently on the market or those yet to be released.

Dihydropyridine (DHP) chemistry began in 1882, when Hantzsch for the first time published the syntheses of DHPs by multicomponent reaction, which now bears his name [1–3]. 1,4-DHPs such as nifedipine and nitrendipine are used even today as antihypertensive agents [4–6].

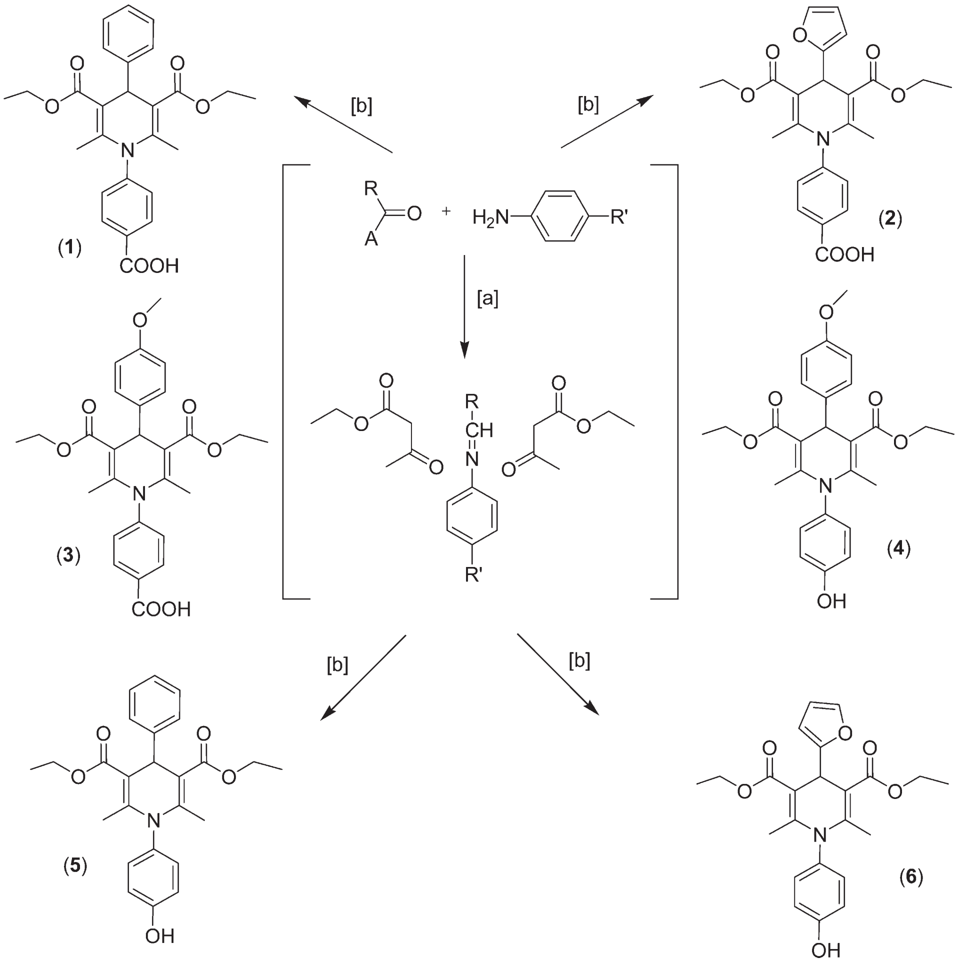
1,4-DHPs are known to possess various biological activities such as multidrug reversal (MDR) in tumor cells [7], potential immunomodulating [8], as well as antitubercular activities [9]. The 3D QSAR results show the minimum structure requirement for DHPs to exhibit antitubercular activity [10]. A further study of *N*-substitution at the labile hydrogen of DHPs skeleton proved to be important for MDR reversal in tumor cells apart from analytical and synthetic interest [11]. These observations provoked us to work on *N*-substituted DHPs for their possible antioxidant activity by incorporating phenolic and carboxyl groups [12].

Industrial chemistry in this millennium is widely adopting the concept of green chemistry to meet the fundamental scientific challenges of protecting the human health and environment while maintaining commercial viability. The emerging area of green chemistry envisages minimum hazard as the performance criteria while designing new chemical process. One of the thirst areas for achieving this target is to explore alternative reaction conditions and reaction media to accomplish the desired chemical transformations with minimized by-products or waste as well as eliminating the use of conventional organic solvents, if possible. Microwaves (MWs) as an alternative energy source has become an attractive tool in organic synthesis [13,14], resulting in a significant decrease in reaction times, especially for endothermic reactions.

RESULTS AND DISCUSSION

Because of biological interest, we have synthesized *N*-substituted 1,4-DHPs by parallel syntheses using *p*-toluenesulphonic acid (PTSA) as a catalyst under MW irradiation conditions as per Scheme 1. The PTSA was found to be a better catalyst than $AlCl_3$ and HCl in

Scheme 1. Microwave-assisted parallel syntheses of *N*-substituted-1,4-dihydropyridines; (a) Silica gel, MW, 700 W, 8 min; (b) PTSA, MW, 700 W, 12–15 min.

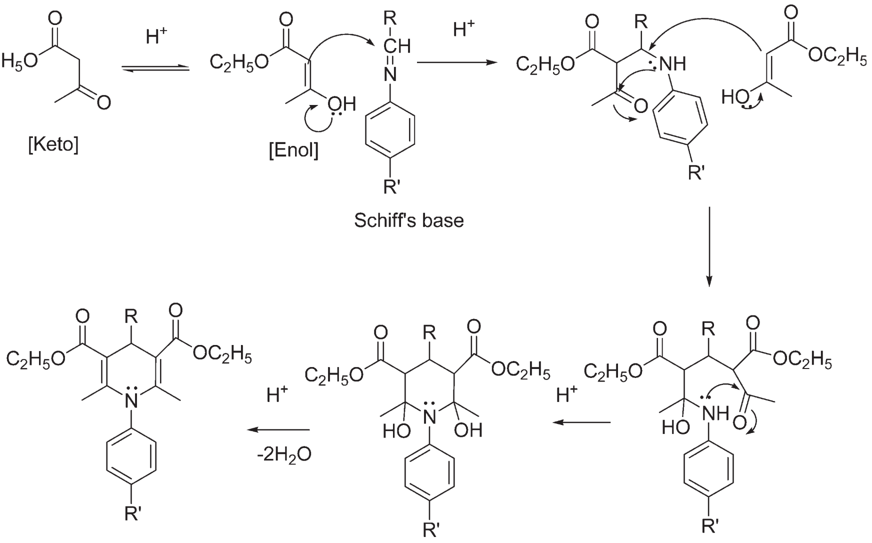


terms of yields. Also, it was convenient to perform the parallel synthesis under solvent free conditions using PTSA as a cyclizing agent and silica gel as adsorbent.

Initially, we made an attempt to synthesize *N*-aryl-1,4-DHPs through conventional and MW methods. In both the methods there was a formation of Schiff's base, but by the conventional method, we could not prepare *N*-substituted 1,4-DHPs, successfully. We repeated the experiment several times under conventional heating. In each case, the thin layer chromatography (TLC) was unclear and showed multiple spots. PTSA was developed as an efficient catalyst for the formation of final products under MWs when compared with the other reported catalysts such as HCl, $AlCl_3$, *etc.* [2].

We had also made an attempt to prepare the titled compounds by adopting one pot, one step, multicomponent reaction involving equivalent amounts of aryl amine, aryl aldehyde with two equivalent amount of ethyl acetoacetate under similar MW irradiation conditions. However, only 10–20% yields of the final compounds were obtained. In addition, the products were found to be impure with many by-products. One of the major reason why the single step syntheses was not successful was found to be the formation of acetoacetanilide because of a reaction between arylamine and ethyl acetoacetate. This was conformed by subjecting the crude reaction mixture to high-resolution mass spectrometry (HRMS). The syntheses of the titled compounds through the Schiff's base preparation escaped from the formation of acetoacetanilide. Another reason for the success of the reaction was due to the possibility of the correct steric alignment of the Schiff's base with a β-keto ester to react during its reaction mechanism as shown in Scheme 2.

Scheme 2. The possible reaction mechanism for the formation of *N*-substituted1,4-dihydropyridines.



Final compounds were first analyzed by TLC and melting point determination. Then, the synthesized compounds were subjected to spectral analysis such as IR, NMR, and MASS spectrometry to confirm the structures. All the analytical details showed satisfactory results. For all compounds, a characteristic singlet peak for symmetric CH was observed between 5.0 and 5.5 ppm in the ^{1}H NMR spectrum.

The synthesized compounds were tested for *in vitro* antioxidant activity using standard nitric oxide assay method [15]. Among all the synthesized compounds, compounds **4** and **6** exhibited potential antioxidant activity with IC_{50} value at 11 and 28 μg concentrations, respectively. The *in vitro* antioxidant results reveal that there is need for further investigation. Hence, the work in this direction is in progress and it will be reported in our next publication.

In conclusion, a simple protocol for the syntheses of *N*-aryl-1,4-DHPs was developed under environmentally benign, MW irradiation conditions using PTSA as a catalyst. It was found that the MW method is selective and efficient when compared with the conventional method.

EXPERIMENTAL

The IR was recorded on Perkin Elmer Infrared-283 FTIR by KBr pellet technique. NMR was taken on Bruker ACF-300 MHz spectrometer apparatus using TMS as internal standard and $CDCl_3$ or DMSO-d_6 as a solvent. The chemical shifts are expressed in δ ppm and following abbreviations are used: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet. HRMS analysis was done on Perkin-Elmer Sciex API-150-EX by ESI ionization technique. Elemental analysis was carried out for carbon, hydrogen, and nitrogen using an Elementar Vario (EL III Carlo Erba11080). MW irradiation was done using, Whirl Pool domestic MW oven as well as MW Synthesizer (2450 MHz, Catalyst Systems, India). All the reactions were monitored using thin layer chromatogram. TLC was performed using 4% methanol in chloroform as mobile phase on aluminum plates that are precoated with silica gel GF.

General procedure for the preparation of Schiff's bases. Equimolar amounts (0.01*M*) of aromatic amine and aromatic aldehyde were transferred to a clean and dry mortar, triturate to become a uniform mixture. The reaction mixture was then transferred to a 100 mL beaker containing 2 g of activated silica gel. Similarly, all other beakers containing different reaction mixtures were kept inside the MW oven in a circle and then MW irradiation was carried out at 700 W power for about 8 min. Intermittent cooling was done after every 60 s of MW irradiation. During intermittent cooling, the reaction mixtures were thoroughly mixed. The reactions were monitored through TLC. The completed reactions were taken directly for the preparation *N*-substituted DHPs without any work up, immediately.

General procedure for the preparation of *N*-substituted-1,4-DHPs (1-6). This reaction was carried out in a parallel synthetic way as shown in Scheme 1. Ethyl acetoacetate (0.02*M*) was transferred in to a dry mortar containing the Schiff's base (~0.01*M*) obtained in the previous MW procedure. Add a catalytic amount or pinch of PTSA and triturate to become a uniform mixture. The reaction mixture was then transferred to 100 mL beaker. Similarly, all other beakers containing different reaction mixtures were kept inside the MW oven in a circle and then MW irradiation was carried out at 700 W power for about 12–15 min. Intermittent cooling was done after every 60 s of MW irradiation. During intermittent cooling, the reaction mixtures were thoroughly mixed. The reactions were monitored through TLC. The reaction mixtures were withdrawn from MW oven soon after the reaction is completed based on TLC data at regular intervals. The reaction mixtures were poured in to the beaker containing water and extracted with ethyl acetate. The ethyl acetate layer was dried over sodium sulfate and evaporated under vacuum to get crude products. The obtained crude products were further purified by recrystallization using ethyl acetate-hexane mixture (1:1) or by column chromatography using 5% EtOAc in pet ether as a mobile phase over silica gel.

4-(3,5-Di(ethoxycarbonyl)-2,6-dimethyl-4-phenylpyridin-1(4H)-yl)benzoic acid (1). Pale yellow colored solid, Yield 61%, mp 135–137°C; IR (KBr, cm^{-1}): 3471 (O—H), 3081 (Ar C—H), 2919 (Ali C—H), 1721 (C=O), 1713 (C=O), 1626 (C=C). ^1H NMR (δ ppm, $CDCl_3$): 1.19 (t, 6H, $2CH_3$), 2.10 (s, 6H, $2CH_3$), 4.04 (q, 4H, $2CH_2$), 5.31 (s, 1H, CH), 6.94–7.59 (m, 9H, ArH), 12.98 (s, 1H, OH). 4-(3,5-Di(ethoxycarbonyl)-4-(4-methoxyphenyl)-2,6-dimethylpyridin-1(4H)-yl)benzoic acid (3). Pale yellow solid, Yield 75 %, mp 99–101°C; IR (KBr, cm^{-1}): 3446 (O—H), 3053 (Ar C—H), 2939 (Ali C—H), 1717 (C=O), 1709 (C=O), 1623 (C=C). ^1H NMR (δ ppm, $CDCl_3$): 1.21 (t, 6H, $2CH_3$), 2.19 (s, 6H, $2CH_3$), 3.71 (s, 3H, OCH_3), 4.07 (q, 4H, $2CH_2$), 5.07 (s, 1H, CH), 6.91–7.53 (m, 8H, ArH), 12.48 (s, 1H, OH). MS (*m/z*): calcd. 479, found 479.11 (M^+). MS 464, 387, 301, 142. *Anal.* Calcd. for $C_{27} H_{29}NO_7$: C, 67.63; H, 6.10; N, 2.92. Found: C, 67.78; H, 5.89; N, 2.77.

Diethyl-1,4-dihydro-1-(4-hydroxyphenyl)-4-(4-methoxyphenyl)-2,6-dimethylpyridine-3,5-dicarboxylate (4). Yellowish brown solid, Yield 81 %, mp 88–90°C; IR (KBr, cm^{-1}): 3436 (O—H), 3048 (Ar C—H), 2927 (Ali C—H), 1719 (C=O), 1638 (C=C). ^1H NMR (δ ppm, $CDCl_3$): 1.26 (t, 6H, $2CH_3$), 2.22 (s, 6H, $2CH_3$), 3.81 (s, 3H, OCH_3), 4.02 (q, 4H, $2CH_2$), 5.19 (s, 1H, CH), 6.90–7.40 (m, 8H, ArH), 9.41 (s, 1H, OH). MS (*m/z*): calcd. 451, found 451.48 (M^+). MS: 436, 398, 312, 151. *Anal.* Calcd. for $C_{26} H_{29}NO_6$: C, 69.16; H, 6.47; N, 3.10. Found: C, 69.35; H, 6.39; N, 2.89.

Diethyl-1,4-dihydro-1-(4-hydroxyphenyl)-2,6-dimethyl-4-phenylpyridine-3,5-dicarboxylate(5). Yellow crystals, Yield 78 %, mp 89–91°C; IR (KBr, cm^{-1}): 3448 (O—H), 3078 (Ar C—H), 2912 (Ali C—H), 1719 (C=O), 1712 (C=O), 1611 (C=C). ^1H NMR (δ ppm, $CDCl_3$): 1.23 (t, 6H, $2CH_3$), 2.21 (s, 6H, $2CH_3$), 4.10 (q, 4H, $2CH_2$), 5.23 (s, 1H, CH), 6.84–7.47 (m, 9H, ArH), 9.90 (s, 1H, OH). MS (*m/z*): calcd. 421, found 421.17 (M^+). MS: 406, 353, 331, 262, 121. *Anal.* Calcd. for $C_{25} H_{27}NO_5$: C, 71.24; H, 6.46; N, 3.32. Found: C, 70.87; H, 6.33; N, 3.41.

Diethyl-4-(furan-2-yl)-1,4-dihydro-1-(4-hydroxyphenyl)-2,6-dimethylpyridine-3,5-dicarboxylate (6). Light brown colored solid, Yield 72%, mp 67–69°C; IR (KBr, cm^{-1}): 3410 (O—H), 3054 (Ar C—H), 2967 (Ali C—H), 1715 (C=O). ^1H NMR (δ ppm, $CDCl_3$): 1.20 (t, 6H, $2CH_3$), 1.91 (s, 6H, $2CH_3$), 4.1 (q, 4H, $2CH_2$), 5.25 (s, 1H, CH), 5.9 (d, 1H, CH Fur), 6.1 (t, 1H, CH Fur), 6.8 (d, 2H, ArH), 6.9 (d, 2H, ArH), 7.2 (d, 1H, CH Fur), 9.83 (s, 1H, OH). MS (*m/z*): calcd. 411, found 411.32 (M^+). MS: 397, 346, 251, 220, 121. *Anal.* Calcd. for $C_{23}H_{25}NO_6$: C, 67.14; H, 6.12; N, 3.40. Found: C, 67.49; H, 5.85; N, 3.32.

Antioxidant activity screening by nitric oxide radical inhibition assay. The reaction mixture (6 mL) containing sodium nitroprusside (10 m*M*, 4 mL), phosphate buffer saline (1 mL), and compound (1–64 μg/mL) was incubated at 25°C for 150 min. After incubation, 0.5 mL of the reaction mixture was removed, 1 mL of sulfanilic acid reagent (0.33% in 20% glacial acetic acid) was mixed and allowed to stand for 5 min for completion of diazotization reaction, and 1 mL of naphthyl ethylene diamine dihydrochloride was added, mixed, and allowed to stand for 30 min in diffused light. The absorbance was measured at 540 nm against the blank in a 96-well microtitre plate using an ELISA reader.

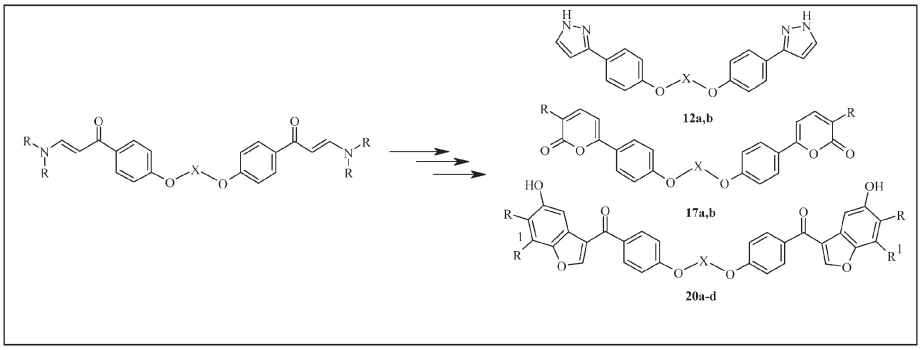
DOI 10.1002/jhet.40



New bis(enaminone) derivatives, **5a,b** and **9a,b**, were prepared in good yields. Their synthetic utilities as key intermediates for the synthesis of novel bis(pyrazole) **12a,b**, bis(pyrane) **17a,b**, and bis(benzo[*b*]-furan) **20a–d** derivatives were also investigated.

J. Heterocyclic Chem., **46**, 340 (2009).

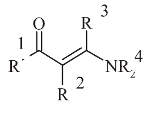
INTRODUCTION

There has been continuous interest in the synthesis of new heterocyclic systems containing pyrazole, pyrane, and benzofuran moieties because of their wide applications in different areas. Various series of pyrazole and their annelated derivatives are reported to have diverse biological activities as antifungal [2], antitumor [3], anti-inflammatory [4], and antinociceptive activities [4,5]. In addition, some pyrazole derivatives have been reported to be useful as inhibitor for cyclooxygenase-2, lipoxygenase [6], elastase [7], and factor Xa (fXa) [8]. Moreover, some of bis(pyrazole) palladium complexes are used as phenylacetylene polymerization catalyst [9]. On the other hand, pyrane and its related fused heterocycles are of interest as potential bioactive molecules. They are known to be used as anticancer [10], antibacterial [11], and anti-inflammatory agents [12] and to inhibit the amidolytic activity of human thrombin [13]. In addition, benzofuran derivatives constitute a structural unit of a number of natural products and biologically active compounds [14–17]. Furthermore, bis(compounds) have received great attention as being model compounds for main chain polymers [18–22]. It is also reported that many biologically active natural and synthetic products have molecular symmetry [23].

Keeping the above facts in mind and in continuation of our interest in the synthesis of bis(hetrocycles) [24–27], we describe herein a simple and efficient route for the synthesis of novel bis(enaminones) and studied their synthetic utilities as key intermediates for the synthesis of novel bis(pyrazolylphenoxy), bis(pyranylphenoxy), and bis(benzo[*b*]furanylphenoxy)alkanes.

RESULTS AND DISCUSSION

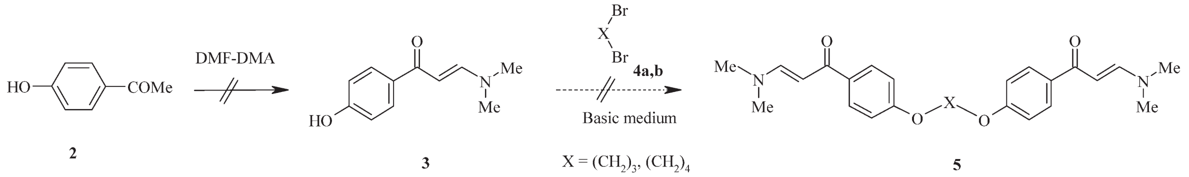
Recently, enaminones **1** were prepared by different synthetic approaches and their use as key intermediates for the synthesis of a wide variety of heterocycles have been investigated [28].



1

In continuation of these studies, we report here on the synthesis of the novel α,ω-bis(enaminones) and investigated its synthetic utility as building blocks for new symmetrical bis(heterocycles). Two strategies were studied for the synthesis of the target enaminones **5**. In the

Scheme 1



first one, we planed to prepare compound **5** starting from 4-hydroxyacetophenone (**2**) by reaction with dimethylformamide-dimethylacetal (DMF-DMA) to give the corresponding enaminone **3** followed by bis-alkylation with the appropriate dibromoalkanes **4a,b** as shown in Scheme 1.

Unfortunately, reaction of **2** with DMF-DMA afforded oily residue that cannot be handled and could not be characterized.

In the second strategy, we investigated the synthesis of **5** using α,ω-bis(4-acetylphenoxy)alkanes **7a,b** as starting materials. Compounds **7a,b** could be obtained by the reaction of the potassium salt **6** (obtained upon treatment of 4-hydroxyacetophenone (**2**) with ethanolic potassium hydroxide) with the appropriate dibromoalkanes **4a,b** in boiling DMF. Solventless heating of compounds **7a,b** with DMF-DMA furnished the corresponding bis(enaminone) derivatives **5a,b** in moderate yields. The ^{1}H NMR spectra of the isolated products revealed, in each case, one singlet near δ 3.0 due to the *N*,*N*-dimethylamino protons and two doublets near δ 5.7 and 7.8 characteristic for the olefinic–C*H*=C*H*—N protons with the same coupling constant value $J = 12$ Hz (typical for trans-configuration) [29], in addition to the other signals characteristic for the alkane and the aromatic moieties. The mass spectra of **5a,b** showed their correct molecular ion peaks at *m*/*z* 422 and 436, respectively.

Treatment of the bis(enaminone) derivatives **5a,b** with piperidine in refluxing ethanol afforded the new bis(enaminones) **9a,b** in 65 and 64% yields, respectively. Furthermore, treatment of the bis(enaminone) **5a,b** with morpholine under similar reaction conditions gave the bis(enaminones) **9c,d** in 60% yields, respectively. The formation of the bis(enaminones) **9a–d** from **5a,b** is suggested to proceed through the formation of the intermediate **8a–d** followed by elimination of two molecules of dimethylamine as outlined in Scheme 2.

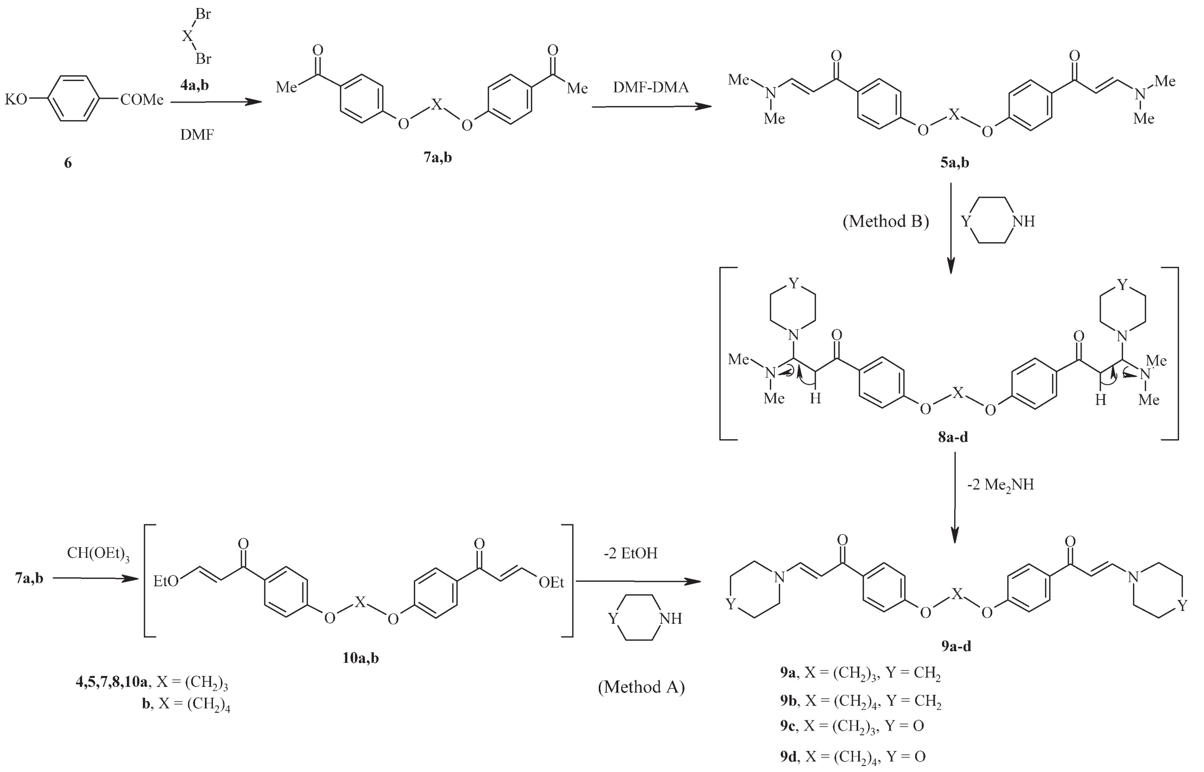
In view of the low yield of the above synthetic methodology, compounds **9a–d** could be obtained by alternative procedures through heating a mixture of the α,ω-bis(acetyl) derivatives **7a,b**, and triethylorthoformate with piperidine or morpholine to afford the corresponding bis(enaminone) derivatives **9a–d** in 71–82% yields. It is proposed that triethylorthoformate reacts with the bis(acetyl) **7a,b** to give the nonisolable bis(vinyl) ethers **10a,b**. Reaction of **10a,b** with piperidine or morpholine *via* Michael-type addition followed by ethanol elimination to give compounds **9a–d**. Elemental analyses and spectral data (IR, MS, ^{1}H NMR, and ^{13}C NMR) of the reaction products confirmed the assigned structures **9a–d**. The ^{1}H NMR spectrum of **9a**, for example, showed two multiplets at δ 1.57 and 3.38 integrated for 12 and 8 protons, respectively, for the piperidyl-CH_2's, a quintet at δ 2.19 and a triplet at δ 4.19 ($J = 5.7$ Hz) due to the propane-2-CH_2 and 1,3-CH_2O-, respectively, in addition to two doublet at δ 5.96 and 7.60 corresponding to the olefinic–C*H*=C*H*—N protons ($J = 12.3$ Hz, typical for trans-configuration) and two doublets at δ 6.96 and 7.87 due to the 1,4-disubstituted phenyl protons ($J = 7.2$ Hz). Its mass spectrum also showed the correct molecular ion peak at *m*/*z* 502.

Having now available the new bis(enaminones) **5a,b** and **9a,b** prompted us to study their synthetic utilities as key intermediates for novel bis(5- and 6-membered) heterocycles. Thus, heating the 1,3-bis(enaminone) **5a**, as a representative example, with hydrazine hydrate in glacial acetic acid resulted in the formation of the 1,3-bis(1*H*-3-pyrazolylphenoxy)propane (**12a**) in 66% yield as depicted in Scheme 3. The structure of compound **12a** was substantiated from its elemental and spectral analyses. Its IR spectrum showed the absence of an absorption band characteristic for C=O as well as the presence of pyrazole-NH absorption at 3199 cm^{-1}. The ^{1}H NMR spectrum of **12a** showed three singlet signals at δ 3.47, 6.56, and 7.62 due to the pyrazole 1-NH, 4-CH, and 5-CH protons, respectively. Similarly, treatment of bis(enaminone) **5b** with hydrazine in acetic acid gave the corresponding 1,4–bis(1*H*-3-pyrazolylphenoxy) butane **12b** in 70% yield (Scheme 3).

It is noteworthy to mention that the bis(pyrazolylphenoxy)alkanes **12a,b** could also be prepared from the appropriate bis(enaminones) **9a,b** in 48 and 55% yields, respectively, using the above synthetic methodology (Scheme 3).

The formation of the bis(pyrazoles) **12a,b** from **5a,b** or **9a,b** is supposed to proceed through the formation of the nonisolable intermediates **11a,b** followed by the elimination of two molecules of the appropriate secondary amines as depicted in Scheme 3.

Scheme 2

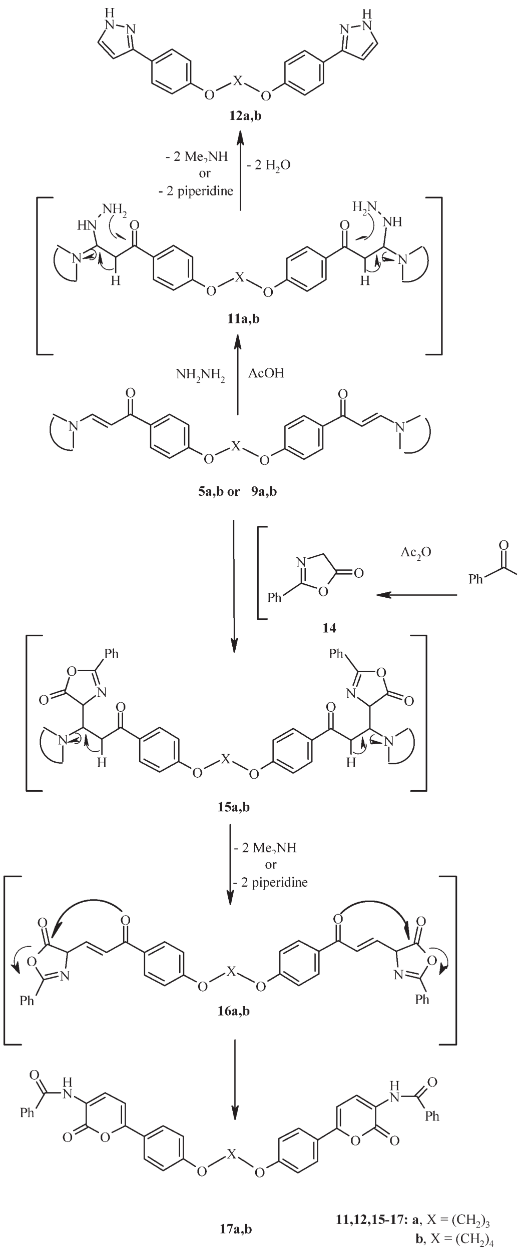


Our study is now extended to include the synthesis of new bis(pyran) derivatives **17a**,**b**. Thus, the bis(enaminone) **5a** was allowed to react with *N*-benzoylglycine **13** in refluxing acetic anhydride to give a single product as examined by TLC. Elemental analyses and mass spectrum of the isolated product were completely in agreement with the molecular formula $C_{39}H_{30}N_2O_8$. The structure of the product is assumed to be **17a** according to the rationale outlined in Scheme 3, which is also similar to analogous reported results [30,31]. Firstly, the nonisolable oxazolone **14** was supposed to be formed from *N*-benzoylglycine **13** upon reaction with acetic anhydride. The latter compound reacts with the enaminone **5a** to form the intermediates **15a**, which eliminate two molecules of dimethylamine or piperidine to give **16a**. The latter then undergoes intramolecular cyclization accompanied with ring opening to give compound **17a** in 74% yield. The ^{1}H NMR of compound **17a** was free of any aliphatic protons except that of the 1,3-dioxypropane moiety and exhibited two characteristic doublets at δ 7.03 and 8.16 each integrated for 2H with J = 7.2 Hz (for 5-H and 4-H protons of the pyranone moiety). In addition, two doublets at δ 7.8 and 7.94 each one integrated for four protons with J = 7.8 Hz (for the two 1,4-disubstituted phenyl moieties) besides the aromatic multiplet for two phenyl groups. Furthermore, the appearance of NH absorption at 3405 cm^{-1} in the IR spectrum as well as its appearance as a broad singlet at δ 9.50 in the ^{1}H NMR spectrum strongly supported this assignment. Similarly, reaction of compound **5b** or **9a,b** with *N*-benzoylglycine **13** under the same reaction conditions gave the corresponding bis(pyranylphenoxy) alkane derivatives **17b** in 77% or **17a,b** in 45 and 52% yields, respectively, as depicted in Scheme 3.

Next, we have also described the synthesis of the new bis(benzofuran) derivatives **20a–d** in 61–79% by the reaction of the appropriate bis(enaminone) derivatives **5a,b** or **9a,b** with the corresponding quinones **18a,b**. Thus, reaction of **5a,b** or **9a,b** with 4-benzoquinone (**18a**) in refluxing acetic acid afforded the corresponding 1,3-bis(benzofuran) derivatives **20a,b** in 43–79% yields. Similarly, reaction of **5a,b** or **9a,b** with 1,4-naphthoquinone (**18b**) under the same reaction conditions gave the target bis(naphthofuran) **20c,d** in 31–74% yields as outlined in Scheme 4. It is assumed that quinines **18a,b** are initially added to the enaminones **5a,b** or **9a,b** to give the nonisolable intermediate **19a–d**. Subsequent intermolecular cyclization *via* dimethylamine or piperidine elimination gave the target compounds **20a–d**. The structures of compounds **20a–d** were inferred from different spectroscopic and analytical data.

It is noteworthy to mention here that the bis(heterocycles) **12a,b**, **17a,b**, and **20a–d** were also prepared from the corresponding enaminones **9c,d** but in very

Scheme 3



low yields compared with those obtained from **5a,b** and **9a,b**.

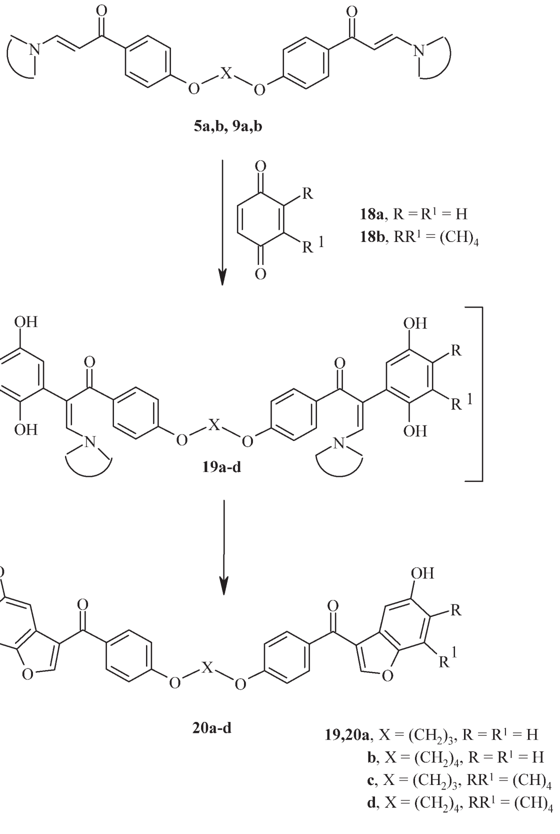
In conclusion, the present investigation describes an efficient method for access toward bis(enaminones) as well as novel bis(heterocycles) containing two biologically active moieties. We believe that these new series of symmetrical bis(hetrocycles) may exhibit potentially diverse useful applications in the field of medicinal chemistry. Also, development of the above synthetic methodology should lead to synthesis of a large number of symmetrical bis(hetrocycles) with a wide variety of substituents as well as different bridges. Moreover, our synthetic methodology offers the advantage of their easy use on a large scale in a simple procedure from inexpensive starting materials.

EXPERIMENTAL

Melting points were measured with a Gallenkamp apparatus. IR spectra were recorded on Shimadzu FT-IR 8101 PC infrared spectrophotometer. The ^{1}H NMR spectra were determined in CDCl$_3$ or DMSO-d_6 at 300 MHz on a Varian Mercury VX 300 NMR spectrometer using TMS as an internal standard. Mass spectra were measured on a GCMS-QP1000 EX spectrometer at 70 eV. Elemental analyses were carried out at the Microanalytical center of Cairo University. 1,3-Dibromopropane, 1,4-dibromobutane, 1,4-benzoquinone (**18a**), and 1,4-naphthoquinone (**18b**) were used as purchased from Aldrich.

Synthesis of α,ω-bis(4-acetylphenoxy)alkanes 7a,b. 4-Hydroxyacetophenone (**2**) (20 mmol) was dissolved in hot ethanolic KOH solution [prepared by dissolving 1.12 g (20 mmol) of KOH in 20 mL of absolute ethanol], and the solvent was then removed *in vacuo*. The remaining material was dissolved in DMF (15 mL) and the appropriate dibromides **4a,b** (10 mmol) was added. The reaction mixture was refluxed for 5 min during which KCl was separated. The solvent was then removed *in vacuo* and the remaining material was poured over crushed ice. The solid obtained was recrystallized from ethanol to give colorless crystals of compound **7a**, mp 125–127°C (ref. [32] mp 126°C) and compound **7b** mp 146–148°C (ref. [33] mp 149°C).

Scheme 4



Synthesis of bis(enaminones) 5a,b. A mixture of bis(acetyl) derivatives 7**a,b** (10 mmol) and dimethylformamide-dimethylacetal (DMF-DMA) (5.4 g, 45 mmol) was refluxed for 10 h. The reaction mixture was left to cool to room temperature and the resulting yellow solid products were collected by filtration, washed with ethanol, dried, and finally recrystallized from ethanol to afford the corresponding bis(enaminone) derivatives **5a,b**, as pale yellow crystals respectively.

1,3-Bis{4-[(*E*)-3-(*N,N*-dimethylamino)prop-2-enoyl]phenoxy}propane (5a). Yield 2.62 g (62%); mp 170–172°C; IR (KBr) ν_{max}/cm^{-1} 1642 (C=O), 1599 (C=C); ^{1}H NMR (CDCl$_3$) δ 2.29 (quintet, *J* = 6 Hz, 2H, OCH$_2$*CH*$_2$CH$_2$O), 3.01 (brs, 12H, 4 NCH$_3$), 4.21 (t, *J* = 6 Hz, 4H, O*CH*$_2$CH$_2$*CH*$_2$O), 5.69 (d, *J* = 12 Hz, 2H, 2 N—CH=*CH*—CO), 6.91 (d, *J* = 9 Hz, 4H, ArH), 7.77 (d, *J* = 12 Hz, 2H, 2 N—*CH*=CH—CO), 7.88 (d, *J* = 9 Hz, 4H, ArH); MS: *m/z* (%) 422 (M$^+$, 5), 403 (15.4), 307 (6.8), 213 (5.4), 160 (12.1), 121 (25.8), 107 (19.3), 98 (100), 70 (75.5). Anal. for $C_{25}H_{30}N_2O_4$ Calcd: C, 71.07; H, 7.16; N, 6.63. Found: C, 70.84; H, 7.22; N, 6.48%.

1,4-Bis{4-[(*E*)-3-(*N,N*-dimethylamino)prop-2-enoyl]phenoxy}butane (5b). Yield 2.49 g (57%); mp 200–202°C; IR (KBr) ν_{max}/cm^{-1} 1640 (C=O), 1600 (C=C); ^{1}H NMR (CDCl$_3$) δ 2.0 (brs, 4H, OCH$_2$*CH*$_2$*CH*$_2$CH$_2$O), 3.02 (brs, 12H, 4 NCH$_3$), 4.1 (brs, 4H, O*CH*$_2$CH$_2$CH$_2$*CH*$_2$O), 5.71 (d, *J* = 12 Hz, 2H, 2 N—CH=*CH*—CO), 6.90 (d, *J* = 9 Hz, 4H, ArH), 7.78 (d, *J* = 12 Hz, 2H, 2 N—*CH*=CH—CO), 7.89 (d, *J* = 9 Hz, 4H, ArH); MS: *m/z* (%) 436 (M$^+$,7.6), 418 (18.7), 363 (7.0), 245 (14.7), 227 (12.6), 161 (15.1), 120 (36.8), 97 (100), 70 (90.2). Anal. for $C_{26}H_{32}N_2O_4$ Calcd: C, 71.53; H, 7.39; N, 6.42. Found: C, 71.80; H, 7.22; N, 6.18%.

Synthesis of bis(piperidyl) and bis(morpholinyl) enaminones 9a–d ***Method A: General procedure.*** A mixture of the bis(acetyl) derivatives **7a,b** (5 mmol), triethylorthoformate (4.5 g, 15 mmol), and the appropriate cyclic amine (piperidine or morpholine) (20 mmol) was heated at refluxing temperature for 6 h. The reaction mixture was then allowed to cool and the resulting precipitate was collected by filtration, washed with ethanol, and dried. Recrystallization from EtOH/DMF afforded the corresponding bis(cyclic) amine derivatives 9**a–d** in 70–82% yield.

Method B: General procedure. A mixture of the bis(enaminone) derivative **5a,b** (5 mmol) and the appropriate cyclic amine (piperidine or morpholine) (20 mmol) in ethanol (30 mL) was refluxed for 8 h. After cooling, the precipitated product was collected by filtration, washed with ethanol, and dried. Recrystallization from the EtOH/DMF afforded compounds identical in all respects with 9**a–d** obtained above but in slightly lower yields 60–65%.

1,3-Bis{4-[(*E*)-3-(*N*-piperidyl)prop-2-enoyl]phenoxy}propane (9a). Yield: method A/method B (80/65%); yellow powder; mp 160–162°C (EtOH); IR (KBr) ν_{max}/cm^{-1} 1638 (C=O), 1600 (C=C); ^{1}H NMR (DMSO-*d*$_6$) δ 1.57 (brs, 12H, 6 piperidyl-*CH*$_2$), 2.20 (quintet, *J* = 5.7 Hz, 2H, OCH$_2$*CH*$_2$CH$_2$O), 3.38 (brs, 8H, 4 piperidyl-N*CH*$_2$), 4.19 (t, *J* = 5.7 Hz, 4H, O*CH*$_2$CH$_2$*CH*$_2$O), 5.96 (d, *J* = 12.3 Hz, 2H, 2 N—CH=*CH*—CO), 6.96 (d, *J* = 7.2 Hz, 4H, ArH), 7.60 (d, *J* = 12.3 Hz, 2H, 2 N—*CH*=CH—CO) 7.87 (d, *J* = 7.2 Hz, 4H, ArH); MS: *m/z* (%) 502 (M$^+$, 2), 485 (5.7), 420 (10.2), 347 (6.4), 160 (6.8), 137 (8.7), 120 (24.5), 109 (100), 83 (29.3), 54 (39.3). Anal. for $C_{31}H_{38}N_2O_4$ Calcd: C, 74.07; H, 7.62; N, 5.57. Found: C, 74.15; H, 7.41; N, 5.69%.

1,4-Bis{4-[(*E*)-3-(*N*-piperidyl)prop-2-enoyl]phenoxy}butane (9b). Yield: method A/method B (71/64%); yellow powder; mp 250–252°C (EtOH/DMF); IR (KBr) ν_{max}/cm^{-1} 1674 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 1.58 (brs, 12H, 6 piperidyl-*CH*$_2$), 1.89 (brs, 4H, OCH$_2$*CH*$_2$*CH*$_2$CH$_2$O), 3.39 (brs, 8H, 4 piperidyl-N*CH*$_2$), 4.10 (brs, 4H, O*CH*$_2$CH$_2$CH$_2$*CH*$_2$O), 5.97 (d, *J* = 12 Hz, 2H, 2 N—CH=*CH*—CO), 6.95 (d, *J* = 9 Hz, 4H, ArH), 7.60 (d, *J* = 12 Hz, 2H, 2 N—*CH*=CH—CO) 7.87 (d, *J* = 9 Hz, 4H, ArH); MS: *m/z* (%) 517 (M+1, 15.4), 498 (40.1), 434 (36.8), 110 (100), 95 (24.4). Anal. for $C_{32}H_{40}N_2O_4$ Calcd: C, 74.39; H, 7.80; N, 5.42. Found: C, 74.52; H, 7.98; N, 5.50%.

1,3-Bis{4-[(*E*)-3-(*N*-morpholinyl)prop-2-enoyl]phenoxy}propane (9c). Yield: method A/method B (82/60%); yellow crystals; mp 205–207°C (EtOH); IR (KBr) ν_{max}/cm^{-1} 1664 (C=O); ^{1}H NMR (CDCl$_3$) δ 2.30 (quintet, *J* = 6 Hz, 2H, OCH$_2$*CH*$_2$CH$_2$O), 3.38 (t, *J* = 5.1 Hz, 8H, 4 N*CH*$_2$CH$_2$O), 3.76 (t, *J* = 5.1 Hz, 8H, 4 O*CH*$_2$CH$_2$N), 4.22 (t, *J* = 6 Hz, 4H, O*CH*$_2$CH$_2$*CH*$_2$O), 5.87 (d, *J* = 12.6 Hz, 2H, 2 N—CH=*CH*—CO), 6.93 (d, *J* = 7.2 Hz, 4H, ArH), 7.70 (d, *J* = 12.6 Hz, 2H, 2 N—*CH*=CH—CO) 7.88 (d, *J* = 7.2 Hz, 4H, ArH); MS: *m/z* (%) 506 (M$^+$, 43.3), 423 (100), 310 (38.5), 256 (26.9), 218 (34.6), 186 (34.6), 149 (25.0), 133 (49.0), 121 (53.8), 91 (23.1), 81 (60.6), 68 (36.5). 1,4-Bis{4-[(*E*)-3-(*N*-morpholinyl)prop-2-enoyl]phenoxy}butane (9c). Yield: method A/method B (74/60%); yellow crystals; mp 211–213°C (EtOH/DMF); IR (KBr) ν_{max}/cm^{-1} 1671 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 1.86 (brs, 4H, OCH$_2$*CH*$_2$*CH*$_2$CH$_2$O), 3.46 (m, 8H, 4 N*CH*$_2$CH$_2$O), 3.62 (brs, 8H, 4 O*CH*$_2$CH$_2$N), 4.06 (brs, 4H, O*CH*$_2$CH$_2$CH$_2$*CH*$_2$O), 6.04 (d, *J* = 12.6 Hz, 2H, 2 N—CH=*CH*—CO), 6.95 (d, *J* = 8.4 Hz, 4H, ArH), 7.63 (d, *J* = 12.6 Hz, 2H, 2 N—*CH*=CH—CO) 7.89 (d, *J* = 8.4 Hz, 4H, ArH); ^{13}C NMR (DMSO-*d*$_6$) δ 25.2, 46.0, 65.6, 67.2, 113.7, 129.1, 130.3, 132.4, 152.1, 160.9, 185.3; MS: *m/z* (%) 520 (M$^+$, 17.3), 437 (31.3), 407 (92.7), 272 (22.9), 191 (64.1), 149 (65.1), 112 (72.4), 82 (95.8), 55 (100). Anal. for $C_{30}H_{36}N_2O_6$ Calcd: C, 69.21; H, 6.97; N, 5.38. Found: C, 69.58; H, 7.11; N, 5.45%.

Synthesis of the bis(pyrazole) Derivatives 12a,b. ***Method A: General procedure.*** A mixture of the bis(enaminone) derivatives **5a,b** (2 mmol) and hydrazine hydrate (1 mL, 99%) in glacial acetic acid (20 mL) was left to stir at room temperature overnight. The precipitated product was collected by filtration, washed with ethanol, and dried. Recrystallization from ethanol furnished the corresponding pyrazole derivatives **12a** and **12b** in 66 and 70% yields, respectively.

Method B: General procedure. The reactions were carried out under the same conditions in method A by replacing the enaminones **5a,b** with piperidyl ones **9a,b**. The yields of this method were lower than that of method A (**12a**: 48% and **12b**: 55%).

1,3-Bis[4-(1*H*-pyrazol-3-yl)phenoxy]propane (12a). Colorless powder, mp 182–184°C; IR (KBr) ν_{max}/cm^{-1} 3199 (NH), 1602 (C=N); ^{1}H NMR (DMSO-*d*$_6$) δ 2.25 (m, 2H, OCH$_2$*CH*$_2$CH$_2$O), 3.47 (brs, 2H, 2 NH, D$_2$O-exchangeable), 4.18 (m, 4H, O*CH*$_2$CH$_2$*CH*$_2$O), 6.56 (s, 2H, 2 pyrazole-4-CH), 7.62 (s, 2H, 2 pyrazole-5-CH), 7.69 (d, *J* = 8.1 Hz, 4H, ArH), 7.84 (d, *J* = 8.1 Hz, 4H, ArH); MS *m/z* (%) 360 (M$^+$, 57.8), 201 (100), 159 (68.8), 131 (72.5), 116 (48.6), 89 (41.3). Anal. for

$C_{21}H_{20}N_4O_2$ Calcd: C, 69.98; H, 5.59; N, 15.54. Found: C, 69.62; H, 5.74; N, 15.30%.

1,4-Bis[4-(1*H*-pyrazol-3-yl)phenoxy]butane (12b). Colorless powder, mp 227–229°C; IR (KBr) ν_{max}/cm^{-1} 3186 (NH), 1612 (C=N); ^{1}H NMR (DMSO-*d*$_6$) δ 1.91 (s, 4H, OCH$_2$*CH$_2$CH$_2$*CH$_2$O), 3.3 (brs, 2H, 2 NH, D$_2$O-exchangeable), 4.07 (s, 4H, O*CH$_2$*CH$_2$CH$_2$*CH$_2$*O), 6.59 (d, J = 2.1 Hz, 2H, 2 pyrazole-4-CH), 6.98 (d, J = 8.4 Hz, 4H, ArH), 7.64 (d, J = 1.8 Hz, 2H, 2 pyrazole-5-CH), 7.70 (d, J = 8.4 Hz, 4H, ArH); MS: *m*/*z* (%) 374 (M$^+$, 17.7), 215 (100), 173 (55.5), 160 (31.2), 131 (27.1), 77 (22.2), 55 (28.3). Anal. for $C_{22}H_{22}N_4O_2$ Calcd: C, 70.57; H, 5.92; N, 14.96. Found: C, 70.94; H, 5.78; N, 14.86%.

Synthesis of the bis(pyran-2-one) derivatives 17a,b ***Method A: General procedure.*** A solution of the bis(enaminones) **5a,b** (1 mmol) and *N*-benzoylglycine (**13**) (0.36 g, 2 mmol) in acetic anhydride (20 mL) was heated under reflux for 1 h then left to cool to room temperature. The solid product that formed upon cooling was collected by filtration and recrystallized from DMF/water to give the bis(pyran-2-one) derivatives **17a,b**, in 74 and 77% yields, respectively.

Method B: General procedure. The reactions were carried out under the same experimental conditions mentioned in method A earlier using the piperidyl derivatives **9a,b** instead of the enaminones **5a,b** to afford the bis(pyran-2-one) derivatives **17a,b** in 45 and 52% yields, respectively.

1,3-Bis[4-(3-benzoylamino-2-oxo-2*H*-pyran-6-yl)phenoxy]-propane (17a). Orange-colored powder, mp 250–252°C; IR (KBr) ν_{max}/cm^{-1} 3405 (NH), 1705, 1671 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 2.24 (m, 2H, OCH$_2$*CH$_2$*CH$_2$O), 4.25 (m, 4H, O*CH$_2$*CH$_2$*CH$_2$*O), 7.03 (d, J = 7.2 Hz, 2H, 2 pyranone-5-CH), 7.1–7.96 (m, 18H, ArH), 8.16 (d, J = 7.2 Hz, 2H, 2 pyranone-4-CH), 9.50 (brs, 2H, 2 NH, D$_2$O-exchangeable); MS: *m*/*z* (%) 654 (M$^+$, 48.5), 105 (100), 77 (23.1), 50 (16.4). Anal. for $C_{39}H_{30}N_2O_8$ Calcd: C, 71.55; H, 4.62; N, 4.28. Found: C, 71.86; H, 4.43; N, 4.21%.

1,4-Bis[4-(3-benzoylamino-2-oxo-2H-pyran-6-yl)phenoxy]-butane (17b). Orange-colored powder, mp > 300°C; IR (KBr) ν_{max}/cm^{-1} 3403 (NH), 1698, 1637 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 1.91 (m, 4H, OCH$_2$*CH$_2$CH$_2$*CH$_2$O), 4.14 (m, 4H, O*CH$_2$*CH$_2$CH$_2$*CH$_2$*O), 7.03–7.13 (m, 20H, ArH, 2 pyranone-5-CH), 8.16 (d, J = 7.5 Hz, 2H, 2 pyranone-4-CH), 9.56 (brs, 2H, 2 NH, D$_2$O-exchangeable); Anal. for $C_{40}H_{32}N_2O_8$ Calcd: C, 71.85; H, 4.82; N, 4.19. Found: C, 72.11; H, 4.65; N, 4.38%.

Synthesis of the bis(benzofurans) 20a,b and bis(naphthofurans) 20c,d ***Method A: General procedure.*** To a stirred solution of the bis(enaminones) **5a,b** (2 mmol) in acetic acid (20 mL), *p*-benzoquinone (**18a**) or 1,4-naphthoquinone (**18b**) (4 mmol) was added and the reaction mixture was stirred overnight at room temperature. The solid product formed was collected by filtration, washed with water and ethanol, dried, and finally recrystallized from EtOH/DMF to give the corresponding bis(benzofurans) **20a,b** and bis(naphthofurans) **20c,d**, respectively.

Method B: General procedure. This method is similar to method A except that the enaminone derivatives **9a,b** were used instead of **5a,b** to afford the corresponding bis(benzofurans) **20a,b** and bis(naphthofuran) derivatives **20c,d** but in lower yields compared to that obtained in method A.

1,3-Bis[4-(5-hydroxybenzo[*b*]furan-3-ylcarbonyl)phenoxy]propane (20a). Yield: method A/method B (66/43%); pale yellow powder, mp 190–192°C; IR (KBr) ν_{max}/cm^{-1} 3258 (OH), 1658 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 2.25 (m, 2H, OCH$_2$*CH$_2$*CH$_2$O), 4.28 (m, 4H, O*CH$_2$*CH$_2$*CH$_2$*O), 6.83–6.88 (m, 2H, ArH), 7.05–7.15 (m, 5H, ArH), 7.45–7.52 (m, 2H, ArH), 7.87–7.94 (m, 5H, ArH), 8.54 (s, 2H, 2 furan-2-CH), 9.44 (brs, 2H, 2 OH, D$_2$O-exchangeable); ^{13}C NMR (DMSO-*d*$_6$): δ 28.4, 64.6, 106.5, 111.9, 114.3, 114.5, 119.9, 125.9, 130.4, 131.02, 148.9, 153.4, 154.6, 162.03, 187.9; MS: *m*/*z* (%) 548 (M$^+$, 50), 161 (100), 121 (26.8), 105 (36.2), 93 (26.1), 76 (25.4), 51 (24.6). Anal. for $C_{33}H_{24}O_8$ Calcd: C, 72.26; H, 4.41. Found: C, 72.63; H, 4.27%.

1,4-Bis[4-(5-hydroxybenzo[*b*]furan-3-ylcarbonyl)phenoxy]butane (20b). Yield: method A/method B (79/47%); pale yellow powder, mp 283–285°C; IR (KBr) ν_{max}/cm^{-1} 3277 (OH), 1662 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 1.94 (m, 4H, OCH$_2$*CH$_2$CH$_2$*CH$_2$O), 4.15 (m, 4H, O*CH$_2$*CH$_2$CH$_2$*CH$_2$*O), 6.84–7.09 (m, 6H, ArH), 7.45–7.52 (m, 4H, ArH), 7.85–7.92 (m, 4H, ArH), 8.53 (s, 2H, 2 furan-2-CH), 9.38 (brs, 2H, 2 OH, D$_2$O-exchangeable); MS: *m*/*z* (%) 562 (M$^+$, 35.2), 428 (60.2), 309 (25), 254 (25.8), 161 (100), 121 (64.8), 76 (32), 55 (65.6). Anal. for $C_{34}H_{26}O_8$ Calcd: C, 72.59; H, 4.66. Found: C, 72.44; H, 4.84%.

1,3-Bis[4-(5-hydroxynaphtho[1,2-*b*]furan-3-ylcarbonyl)-phenoxy]propane (20c). Yield: method A/method B (61/31%); pale yellow powder, mp 258–260°C; IR (KBr) ν_{max}/cm^{-1} 3224 (OH), 1672 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 2.24 (m, 2H, OCH$_2$*CH$_2$*CH$_2$O), 4.26 (m, 4H, O*CH$_2$*CH$_2$*CH$_2$*O), 7.04–7.16 (m, 6H, ArH), 7.55–7.95 (m, 10H, ArH), 8.18–8.28 (m, 2H, ArH), 8.62 (s, 2H, 2 furan-2-CH), 10.17 (s, 2H, 2 OH, D$_2$O-exchangeable); ^{13}C NMR (DMSO-*d*$_6$): δ 28.4, 64.6, 114.3, 114.5, 119.3, 120.8, 121.1, 121.5, 123.3, 123.5, 124.9, 127.4, 130.5, 131.2, 144.5, 150.8, 151.7, 162.3, 188.2. Anal. for $C_{41}H_{28}O_8$ Calcd: C, 75.92; H, 4.35. Found: C, 76.22; H, 4.29%.

1,4-Bis[4-(5-hydroxynaphtho[1,2-*b*]furan-3-ylcarbonyl)-phenoxy]butane (20d). Yield: method A/method B (74/40%); pale yellow powder, mp > 300°C; IR (KBr) ν_{max}/cm^{-1} 3213 (OH), 1706 (C=O); ^{1}H NMR (DMSO-*d*$_6$) δ 1.93 (m, 4H, OCH$_2$*CH$_2$CH$_2$*CH$_2$O), 4.12 (m, 4H, O*CH$_2$*CH$_2$CH$_2$*CH$_2$*O—), 7.09–7.13 (m, 6H, ArH), 7.54–7.96 (m, 10H, ArH), 8.18–8.28 (m, 2H, ArH), 8.64 (s, 2H, 2 furan-2-CH), 10.25 (brs, 2H, 2 OH, D$_2$O-exchangeable); ^{13}C NMR (DMSO-*d*$_6$): δ 25.3, 67.6, 114.0, 114.3, 119.3, 120.7, 121, 121.4, 123.3, 123.5, 124.9, 127.3, 129.1, 131.1, 144.5, 150.7, 151.5, 162.3, 188.2. Anal. for $C_{42}H_{30}O_8$ Calcd: C, 76.12; H, 4.56. Found: C, 76.00; H, 4.44%.

The reaction of oxiranes with carbon disulfide for preparation of cyclic dithiocarbonates was carried out in water under catalytic amount of an organic base such as dimethylaminopyridine or triethylamine. The reaction conditions are simple and give high yields of desired products.

J. Heterocyclic Chem., **46**, 347 (2009).

INTRODUCTION

Because it was reported that Diels–Alder reactions could be greatly accelerated by using water as a solvent instead of organic solvents [1], considerable attention has been directed toward the development of organic reactions in water. Besides Diels–Alder reaction, water was used in almost all of the useful organic reactions, even reactions involving water sensitive materials [2]. It is obvious that water is the most inexpensive and environmentally benign solvent. Thus, development of novel reactivity as well as selectivity that cannot be attained in conventional organic solvents is one of the challenging goals of aqueous chemistry [1].

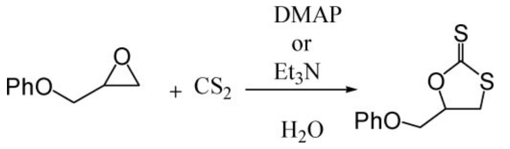
Tertiary amines- and pyridine-based organo catalysts were introduced to synthetic chemistry as a powerful nucleophilic group-transfer catalyst since more than 3 decades ago [3], because of their ability to catalyze important reactions such as acylation [4], esterification [5], macrolactonization [6], Baylis-Hillman [7], and silylation reactions [8]. Also, because of high potential of these compounds for developing of chiral acylating catalyst [9], several research groups are interested in this field of chemistry. 4-(Dimethylamino) pyridine (DMAP) is one of the standard catalysts for nucleophilic group-transfer reactions.

There are many reports on the reaction of epoxide with carbon disulfide [10]. Usually, high pressure and elevated temperature as well as long reaction times have been used for the synthesis of cyclic dithiocarbonates. Harsh reaction conditions have been reported for the synthesis and purification of five-membered cyclic dithiocarbonates, its regioisomers, and trithiocarbonates depending on the catalyst, temperature, and pressure. Shi and his coworkers studied the reaction between epoxy propane and carbon disulfide in the presence of DMAP and *p*-methoxyphenol as a catalyst at high temperature to afford the cyclic dithiocarbonate in 45% yield [11]. Recently, Maggi *et. al* reported a very interesting method for the synthesis of cyclic dithiocarbonates in the presence of hydrotalcite catalyst with good yields [12]. But there is no report for the preparation of cyclic dithiocarbonates in water therefore availability of a facile and green procedure to cover these drawbacks is interesting.

RESULTS AND DISCUSSION

Encouraged by our good experience to open the epoxide ring by nucleophiles such as amines [13] and dithiocarbamate anion [14] in water and in continuation of our previous work for the synthesis of dithiocarbamates in water and solvent-free conditions [15], we were interested to investigate the reaction of epoxides with CS_2 in the presence of Lewis bases in aqueous medium (Scheme 1). For this purpose, different Lewis bases such as Et_3N, DMAP, DABCO, and DBU were examined, and we have found that DMAP and Et_3N (10 mol %) gave the best results for the preparation of cyclic

Scheme 1. Synthesis of cyclic dithiocarbonate in water.



dithiocarbonates. We also tried the halide salts such as LiCl in water as catalyst, but we did not obtain good results (Table 1, entry 12). Also solvent effect was examined for the reaction of 2,3-epoxypropyl phenyl ether and CS_2 by using different organic solvents, but we did not obtain any desired products, except for ethanol, which gave only 10% yield (*ca.* Table 1).

After optimizing the reaction conditions, we tried to expand our results to other epoxides and the results are reported in Table 2. As shown in Table 2, 1,2-epoxides gave moderate to good yields but for cyclic epoxides such as cyclohexane epoxide, we obtained the product in low yield. For epichlorohydrin, 91% isolated yield was obtained. Only for styrene epoxide two regioisomers were obtained in 2:1 ratio and total yields of 52%. The ratio was determined by ^{1}H NMR with using the area of the peak of benzylic hydrogen in the two regioisomers (Entry 7, Table 2).

A plausible mechanism for this reaction is shown in Scheme 2. It is possible that the ability of water to give hydrogen bond with epoxides makes this transformation very efficient. We supposed that DMAP activates the CS_2 to dithiocarbamate anion **1**, which attacks to the water-activated epoxide to give compound **2**. In the next step, the epoxide's oxygen attacks the thiocarbonyl to remove DMAP and to form the cyclic dithiocarbonate 3.

CONCLUSIONS

In conclusion, we showed a very mild, facile, economical, and friendly method for the synthesis of cyclic dithiocarbonates in the presence of catalytic amount of DMAP. Also in large scale synthesis, extraction of products does not need to any organic solvent and only separation of organic phase from aqueous phase gives the crude products. Trying to do this reaction under asymmetrical conditions with chiral Lewis bases is undertaken in our laboratory.

EXPERIMENTAL

General. All chemicals were purchased and used without any further purification. NMR spectra were recorded at 500 MHz for proton and at 125 MHz for carbon nuclei in $CDCl_3$. The products were purified by column chromatography carried out on silica gel using ethyl acetate/petroleum ether mixtures. All compounds were characterized by their spectroscopic data (IR, ^{1}H NMR, and ^{13}C NMR) by comparison with those reported in the literature. Reactions were carried out at room temperature. Carbon disulfide, DMAP, and all epoxides are commercially available and used without further purification.

General procedure for the synthesis of the cyclic dithiocarbonates in water. In a round-bottomed flask equipped with magnet stirrer, epoxide (5 mmol), carbon disulfide (10 mmol) and water (20 mL) were added. To this mixture, DMAD or Et_3N (0.5 mmol) was added and stirred for 20 h. The progress of the reaction was checked by TLC. After completion of the reaction, the product was extracted with ethyl acetate and washed with water to remove the catalyst. The crude products were purified with column chromatography using silica gel as stationary phase and mixture of hexane and ethyl acetate (7:3) as an eluent to give the pure products with the yields shown in Table 2. Unreacted epoxides were recovered with column chromatography. Selected spectroscopic data for compounds are given in Table 2.

Compound (3a). Yellow crystal; mp 55–57°C. ^{1}H NMR (500 MHz, $CDCl_3$): δ 3.78–3.85 (m, 2H, CH_2), 4.35 (m, 2H, CH_2), 5.48 (m, 1H, CH), 6.96 (d, $J = 7.9$ Hz, 2H, $2CH_{ar}$), 7.06 (t, $J = 7.4$, 1H, CH_{ar}), 7.36 (m, 2H, $2CH_{ar}$) ppm. ^{13}C NMR (125.7 MHz, $CDCl_3$): δ 36.8, 66.7, 88.2, 114.9, 122.4, 130.2, 158.1, 211.9 ppm; IR (KBr): 1595, 1498, 1199, 1059 cm^{-1}.

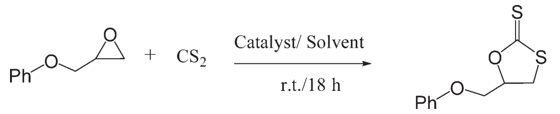
Compound (3b). Yellow oil; ^{1}H NMR (500 MHz, $CDCl_3$): δ 1.15 (d, $J = 7.5$ Hz, 6H, $2CH_3$), 3.60–3.65 (m, 3H, CH_2 and CH), 3.70 (m, 2H, CH_2), 5.16 (m, 1H, CH) ppm. ^{13}C NMR (125.7 MHz, $CDCl_3$): δ 22.4, 36.6, 67.1, 73.2, 89.7, 211.8 (C=S) ppm. IR (KBr): 1703, 1452, 1417, 1372, 1332 cm^{-1}.

Compound (3c). Yellow oil; ^{1}H NMR (500 MHz, $CDCl_3$): δ 3.73–3.78(m, 2H, CH_2), 3.9 (m, 2H, CH_2), 5.3 (m, 1H, CH) ppm. ^{13}C NMR (125.7 MHz, $CDCl_3$): δ 31.2, 37.3, 42.9, 88.4, 209.9 (C=S) ppm. IR (KBr): 1706, 1430, 1425, 1377, 1141, 1072 cm^{-1}.

Compound (3d). Yellow oil; ^{1}H NMR (500 MHz, $CDCl_3$): δ 3.60–3.70 (m, 2H, CH_2), 3.73–3.83 (m, 2H, CH_2), 4.07 (d, $J = 5.7$ Hz, 2H, CH_2), 5.2–5.3 (m, 3H, CH and CH_2), 5.88 (m, 1H, CH) ppm. ^{13}C NMR (125.7 MHz, $CDCl_3$): δ 36.5, 68.9, 72.9, 89.5, 118.3, 134.2, 211.2 (C=S) ppm. IR (KBr): 1702, 1638, 1423, 1419, 1354 cm^{-1}.

Table 1

Solvent and catalyst effects on the syntheis of cyclic dithiocarbonates.



Entry	Solvent	Catalyst (mol %)	Yield (%)
1	H_2O	DMAP (50%)	84
2	H_2O	DMAP (10%)	76
3	H_2O	Et_3N (10%)	72
4	C_2H_5OH	DMAP (10%)	10
5	CH_2Cl_2	DMAP (10%)	0
6	$ClCH_2CH_2Cl$	DMAP (10%)	0
7	CH_3CN	DMAP (10%)	0
8	THF	DMAP (10%)	0
9	Toluene	DMAP (10%)	0
10	Acetone	DMAP (10%)	0
11	Solvent free	DMAP (10%)	50
12	H_2O	LiCl (10%)	0

Compound (3e). Yellow oil ^{1}H NMR (500 MHz, $CDCl_3$): δ 1.08 (t, J = 7.5 Hz, 3H, CH_3), 1.85 (m, 1H, one proton of CH_2), 2.00 (m, 1H, one proton of CH_2), 3.39 (dd, J = 11.7, 7.2 Hz, 1H, one proton of CH_2), 3.61 (dd, J = 11.7, 5.4 Hz, 1H, one proton of CH_2), 5.05 (m, 1H, CH) ppm. ^{13}C NMR (125.7 MHz, $CDCl_3$): δ 10.2, 27.2, 39.4, 93.2, 212.1 (C=S) ppm. IR (KBr): 1714, 1619, 1511, 1426, 1332, 1268 cm^{-1}.

A simple and efficient synthesis of 1(2*H*)-phthalazinone derivatives was achieved *via* reaction of phthalaldehydic acid and various phenyl hydrazines in acetonitrile using $HClO_4$-SiO_2 as a catalyst in very good yields.

J. Heterocyclic Chem., **46**, 351 (2009).

INTRODUCTION

Heterocyclic compounds occur very widely in nature and are essential to life. Nitrogen-containing heterocyclic molecules constitute the largest portion of chemical entities, which are part of many natural products, fine chemicals, and biologically active pharmaceuticals vital for enhancing the quality of life [1]. Phthalazine scaffold have shown its potential as a privileged structure for the generation of drug-like libraries in drug-discovery process [2]. 2*H*-Phthalazin-1-ones are of considerable interest due to their antidiabatic [3] and antiallergic activities [4], and its bioactivity has been researched extensively [5–8]. They are also useful intermediates for the synthesis of inhibitors of the VEGF (vascular endothelial growth factor) receptor tyrosine kinases for the treatment of cancer [9]. However, phthalazinone derivatives have attracted considerable attention in the development of novel antiasthmatic agents with dual activities of thromboxane A_2 (TXA_2) synthetase inhibition and bronchodialation [10]. Consequently, there is a need to develop new methods to synthesis of these compounds.

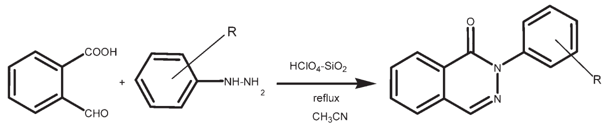
Solid-supported reagents are unique catalysts that have become popular over the last 2 decades [11]. The high catalytic activity, low toxicity, moisture, and air tolerance, their recyclability and particularly low price make the use of solid supported reagents attractive alternatives to conventional Lewis acids and triflates [12]. Although the catalytic applications of solid supported reagents for organic synthesis have been well established, relatively few examples are reported on the use of $HClO_4$-SiO_2 [13]. We have recently used $HClO_4$–SiO_2 for the synthesis of 14-aryl or alkyl-14-H-dibenzoxanthenes [14]. As part of our program aimed at developing new selective and environmental friendly methodologies for the preparation of fine chemicals [15–18], herein we report an efficient and convenient procedure for the synthesis of 1(2*H*)-phthalazinones using $HClO_4$-SiO_2 as a reusable and heterogeneous catalyst in good yields (Scheme 1).

RESULTS AND DISCUSSION

1(2*H*)-Phthalazinone were obtained by phthalaldehydic acid and various phenyl hydrazines in CH_3CN using $HClO_4$-SiO_2 as a reusable catalyst (Scheme 1) in good yields (Table 1). It has been proven recently that $HClO_4$-SiO_2 is a mild, worthwhile heterogeneous catalyst, which efficiently and selectively catalyzes various organic transformations and synthesis. The effect of temperature was studied by carrying out the reactions at different temperature (25°C), 50°C and under refluxing temperature (82°C). As it shown in Table 1, the yields of reactions increased as the reaction temperature was raised. These results showed that refluxing temperature would be the temperature of choice for all reactions. The reaction proceeded very cleanly under reflux condition and were free of side products.

Influences of solvents are the important parameter for the determination of yield of the products. The reaction was conducted in various solvents on the synthesis of 3a using $HClO_4$-SiO_2 as a reusable catalyst.

Scheme 1



As shown in Table 2, the performance of various solvents are in the following order: acetonitrile > ethyl acetate > THF > toluene > dichloromethane.

Acetonitrile shows better yields, when compared with other solvents. In addition, the time required for

Table 1

Synthesis of 2,4,5-triaryl-imidazoles using various heteropolyacids under refluxing condition.

Entry	Substrate	Product	Time (h)	*M*p (°C)		Yield (%)[a]

1		 3a	1	104	104–105 [19]	50	85	95
2		 3b	1.5	206	204–206 [20]	43	76	92
3		 3c	2	176	175–177 [21]	40	63	80
4		 3d	2	170	168–169 [22]	45	70	81
5		 3e	1.5	121	120.5–121.5 [19]	50	79	90
6		 3f	1.5	136	135 [23]	50	75	90
7		 3g	2	127	126–127 [24]	43	70	80

[a] Yields were analyzed by GC.

Table 2

Synthesis of 3a with $HClO_4$-SiO_2 in the presence of different solvents.

Entry	Solvent	Temperature	Time (min)	Yield (%)[a]
1	Acetonitrile	reflux	1	95
2	Ethyl acetate	reflux	1	92
3	THF	reflux	1.20	90
4	Toluene	reflux	2	90
5	Dichloromethane	reflux	2	89

[a] Yields were analyzed by GC.

completion of the reaction was found to be less in acetonitrile. This is due to higher solvent polarity of acetonitrile when compared with that of other solvents. We expect that the solvent removes products from the active surface of the catalyst. Therefore, more polar solvents may remove the product better and thus regenerate the catalyst active sites allowing continuation of the catalytic reaction.

The reactions proceeded efficiently at mild conditions and are completed within 1–2 h, in contrast to conventional methods that require long reaction times. This method not only affords the products in good yields but also avoids the problems associated with catalyst cost, handling, safety, and pollution. This catalyst is eco-friendly for a variety of organic transformations. It is nonvolatile, nonexplosive, easy to handle, and thermally robust. The time required for completion of the reaction was found to be less for phenyl hydrazine when compared with substrates bearing electron withdrawing groups (Table 1, entries 2–7). Moreover, the steric hindrance seems to have significant effects on reaction times and yields (Table 2, entries 3, 4, 7).

In conclusion, we are reporting an efficient process for the synthesis of biologically interesting functionalized 1(2*H*)-phthalazinone derivatives starting from readily available and inexpensive reagents. It can be concluded that $HClO_4$-SiO_2 is an efficient and excellent catalyst for the synthesis of these compounds in high yields and mild conditions in short reaction times. This method offers some advantages in terms of simplicity of performance. The low cost of the catalyst, low toxicity of the catalyst, fast reaction times, recyclability of the catalyst, and high yields of the products are the other advantages for this synthesis. We believe our procedure will find important applications in the synthesis of 1(2*H*)-phthalazinones. The method is also relatively environmentally benign.

EXPERIMENTAL

All products are known compounds and were characterized by mp, IR, ^1H NMR, and GC/MS. Melting points were measured by using the capillary tube method with an electro thermal 9200 apparatus. ^1H NMR spectra were recorded on a Bruker AQS AVANCE-300 MHz spectrometer using TMS as an internal standard ($CDCl_3$ solution). IR spectra were recorded from KBr disk on the FTIR Bruker Tensor 27. GC/MS spectra were recorded on an Agilent Technologies 6890 network GC system and an Agilent 5973 network Mass selective detector. Thin layer chromatography (TLC) on commercial aluminum-backed plates of silica gel, 60 F254 was used to monitor the progress of reactions. All products were characterized by spectra and physical data.

Preparation of 2-phenyl-2*H*-phthalazin-1-one (3a): A typical procedure. To a mixture of phthalaldehydic acid (1 mmol, 15 g) and phenylhydrazine (1 mmole, 1 mL) in acetonitrile (5 mL), a catalytic amount of $HClO_4$–SiO_2 (0.01 mmol) was added and refluxing was continued for 1 h. The reaction progress was monitored by TLC. After completion of the reaction, the mixture was then filtrated (in order to separation of catalyst from the mixture). The filtrate was then diluted with 5% $NaHCO_3$ (5 mL) and the product was extracted with diethyl ether (2 × 5 mL) and dried over $MgSO_4$. The solvent was evaporated under reduced pressure and the crude product was obtained. The resulting solid product was recrystallized from ethanol to give the pure product.

3a: mp. 104°C; IR: 1620 (C=N), 1670 (C=O) cm^{-1}; ^1H NMR:δ 7.59–8.27 (m, 9H, Ar—H), 8.8 (s, 1H); ms: *m*/*z* 222 (M^+).

3c: mp. 176°C; IR: 1633 (C=N), 1674 (C=O) cm^{-1}; ^1H NMR:δ 7.61–8.43 (m, 7H, Ar—H); ms: *m*/*z* 301 (M^+).

Preparation of the $HClO_4$–SiO_2 catalyst [13]. $HClO_4$ (1.8 g, 12.5 mmol, as a 70% aq. solution) was added to a suspension of SiO_2 (230–400 mesh, 23.7 g) in Et_2O (70.0 mL). The mixture was concentrated and the residue was heated at 100°C for 72 h under vacuum to furnish $HClO_4$–SiO_2 (0.5 mmol/g) as a free flowing powder (50 mg = 0.025 mmol of $HClO_4$).

Caution. Although no explosions were reported under these conditions, extreme care has to be taken for large scale reactions. The preparation of the catalyst should be performed with special care and in a safe environment.

Reusability of catalyst. Next, we investigated the reusability of $HClO_4$–SiO_2. When the reaction was completed, the catalyst was separated by simple filtration and recovered with $CHCl_3$ (2 × 5 mL) and subsequently dried at 80°C in order to be. $HClO_4$–SiO_2 can be reused in subsequent reactions without significant decrease in activity even after five runs (Table 3).

Table 3

Reuse of the $HClO_4$-SiO_2 for synthesis of 2-phenyl-2*H*-phthalazin-l-one (3a).

The review surveys the chemistry of diaza-, triaza-, and tetraazaphenothiazines and their benzo and dibenzo derivatives consisting of over 30 different heterocyclic systems.

J. Heterocyclic Chem., **46**, 355 (2009).

INTRODUCTION

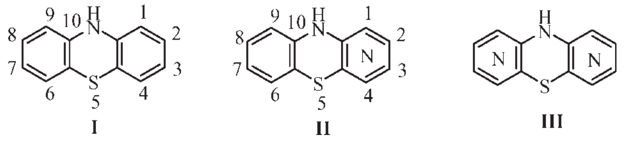
Phenothiazine (10*H*-dibenzo-1,4-thiazine, **I**) was obtained for the first time by Bernthsen in 1883 in the thionation of diphenylamine [1]. Since this moment over 5000 phenothiazine derivatives have been obtained and this class of organic compounds became very important because of their varied biological and chemical properties. Phenothiazines (mainly substituted at positions 2 and 10) exhibit valuable activities such as neuroleptic, antiemetic, antihistaminic, antipuritic, analgesic, and antihelmintic. At least 100 phenothiazines were used in therapy. Recent reports deal with anticancer, antiplasmid, and antibacterial activities, reversal of multidrug resistance and potential treatment in Alzheimer's and Creutzfeldt-Jakob diseases [2–6].

Modifications of the parent phenothiazine structure have been carried out by:

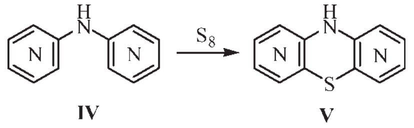
1. an introduction of a substituent at the thiazine nitrogen atom (at position 10),
2. an introduction of a substituent at the benzene ring (at positions 1–4 and 6–9, most often at position 2),
3. an oxidation of the sulfide function into sulfoxide and sulfone ones,
4. a substitution of one or two benzene rings with homoaromatic and heteroaromatic rings (most often azine rings).

Substitution with one or two azine rings led to new type of fused heterocyclic compounds being azinobenzo-1,4-thiazines II and diazino-1,4-thiazines III. Depending on the structure of an azine ring (pyridine, pyridazine, pyrimidine, pyrazine, quinoline, quinoxaline, and 1,2,4-triazine) they can form tri-, tetra-, and pentacyclic heterocycles. There has been known over 30 types of such heterocyclic systems. Okafor, Castle, and Wise synthesized a significant portion of these systems. As the azine rings contain one or more nitrogen atoms, these compounds are named as azaphenothiazines (monoaza-, di-, tri-, and tetraazaphenothiazines) (Scheme 1).

Scheme 1



Scheme 2



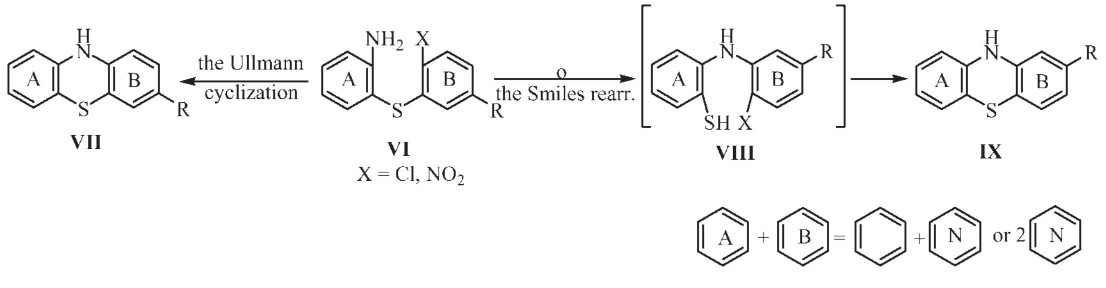
Synthesis of azaphenothiazines has been achieved by the following methods (generally outlined in Schemes 2–6):

1. thionation of diazinyl amines with elemental sulfur as a hydrogen atom substitution.
2. cyclization of phenyl azinyl sulfides or diazinyl sulfides proceeding directly as the Ullmann cyclization or with the Smiles rearrangement (the S→N type, phenyl or azinyl part migrates from sulfur atom to the nitrogen atom giving amine, not isolated) depending on the reaction conditions. The amino group might be attached to the phenyl ring and a leaving group X to an azinyl ring or inversely. Sometimes, it is impossible to state if a reaction goes with or without the rearrangement because the Ullmann's and Smiles's products are the same. The rearrangement proceeds under basic (most often) but also under acidic and neutral conditions.
3. cyclization of phenyl azinyl amines or diazinyl amines possessing a mercapto and good leaving groups (chlorine, nitro).
4. reactions of pairs of *ortho*-aminobenzenethiols or *ortho*-aminoazinethiols (or tautomers) with *ortho*-disubstituted azines, proceeding through formation of sulfides or amines which were not isolated during synthesis.
5. building of an azine ring to the benzo-1,4-thiazine moiety.

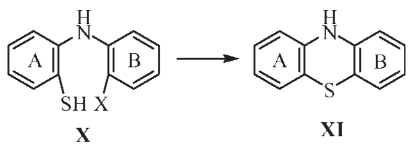
Phenothiazines were reviewed in the 50s and 70s [7–10] and exhaustively in a monograph edited by Gupta in the 80s [11]. Recently, a retrosynthetic approach to the synthesis of phenothiazines was described [12]. Syntheses and properties of monoazaphenothiazines were reviewed in 1990 in Polish based on 78 references [13]. Monoaza-, diaza-, triaza-, and tetraazaphenothiazines have already been reviewed by Okafor in the 70s in two articles [14,15], but those reviews were incomplete. Synthesis of azaphenothiazines from diazinyl sulfides was also a part in a chapter of the monograph [16]. Reading the chemical literature on the azaphenothiazines, we found misunderstanding chemical names and ring numbering, not to mention some incorrect names. As in the 60s and 70s, there were three nomenclature systems of azaphenothiazines, two based on the azaphenothiazine name (x-azaphenothiazine, x,y-diazaphenothiazine, x,y,z-triazaphenothiazine, and x,y,z,w-tetraazaphenothiazine) but with different numbering of the tricyclic ring system (British and American system **A**, German system **B**) and one based on heterocylic ring system **C** (Scheme 7) as the azino[...]benzo [1,4]thiazine, diazino[...][1,4]thiazine, or azino[...]azino[...][1,4]thiazine names (in the last two examples, the two azine rings are the same or different) but with another numbering system. The last system was not always used properly with determination of a place of the ring fusion in square brackets. All those systems were used in Chemical Abstracts after original articles. All of it led to confusion: 1,2-diazaphenothiazines in German articles and patents were in fact 3,4-diazaphenothiazines in American and British articles and patents, 1,3-diazaphenothiazines in fact 2,4-diazaphenothiazines, 2,7-diazaphenothiazines in fact 3,7-diazaphenothiazines. The wrong system numbering causes some misunderstandings, for example: 2,3,6,9-tetraazaphenothiazine should be named as 1,4,7,8-tetraazaphenothiazine. Unfortunately, we found that this confusion is still valid.

It is worth noting that not all azaphenothiazines structures were unequivocally determined, some structures were deduced from chemical properties or spectroscopic

Scheme 3



Scheme 4



data and only a few structures were based on X-ray analysis.

We think that the chemistry of diaza-, triaza-, and tetraazaphenothiazines which consists of over 30 different heterocyclic systems and is published in over 100 articles and patents requires to be reviewed.

The aim of this review is:

1. to arrange and to clarify the chemistry (synthesis and properties) of diazaphenothiazines, triazaphenothiazines, and tetraazaphenothiazines,
2. to discuss the articles and patents of this field up to 2008 and
3. to correct some azaphenothiazine names.

This material has been divided into tricyclic, tetracyclic, and pentacyclic azaphenothiazines with increasing numbers of nitrogen atoms in the systems:

1. diazaphenothiazines (1,2-, 1,3-, 1,4-, 1,6-, 1,9-, 2,3-, 2,4-, 2,7-, 3,4-, 3,6-, and 3,7-),
2. triazaphenothiazines (1,3,4-, 1,3,6-, 1,3,9-, 1,4,6-, 1,4,9-, and 2,3,6-),
3. tetraazaphenothiazines (1,2,6,7-, 1,2,7,8-, 1,3,6,8-, 1,3,6,9-, 1,4,7,8-, 2,3,6,7-, 2,3,6,8-, 2,3,7,8-, 2,4,6,8-, and 3,4,6,7-) and
4. their benzo, dibenzo, and naphtho derivatives.

For this review, to compare the structures of all azaphenothiazines and to clarify discussion, the structures were drawn as the phenothiazine derivatives (the structure **A** in Scheme 7).

Tricyclic diazaphenothiazines. ***1,2-Diazaphenothiazines (pyridazino[4,3-b][1,4]benzothiazines).*** 1,2-Diazaphenothiazines accompanied by 2,3- and 3,4-diazaphenothiazines were achieved in synthesis of the pyridazine derivatives. The first synthesis was carried out by Druey using *o*-aminophenyl 3,6-dichloro-4-pyridazinyl sulfide **1** (obtained from *o*-aminobenzenethiol and 3,4,6-trichloropyridazine) which in acidic medium led to 3-chloro-1,2-diazaphenothiazine **2** (no experimental data included). The same result was obtained when acetylated sulfide **3** was used [17]. Later this first synthesis was repeated giving in concentrated hydrochloric acid expected 3-chloro-1,2-diazaphenothiazine **2** (through postulated its hydrochloride **4**, not isolated) but in diluted hydrochloric acid or acetic acid giving isomeric compound, 2-chloro-3,4-diazaphenothiazine **6** (no yields given), as a product of the Smiles rearrangement to amine **5**. The same product **6** was obtained even from sulfide **7** (Scheme 8) [18,19].

Similar mixtures of isomeric products, 4-chloro-1,2-diazaphenothiazine **10** and 1-chloro-2,3-diazaphenothiazine **11**, were obtained in 51 and 17% yields directly from *o*-aminobenzenethiol **8** and 3,4,5-trichloropyridazine **9** in ethanol in the presence of potassium hydroxide at room temperature. When this reaction of trichloropyridazine **9** was carried out at 30–60°C or with two equivalents of *o*-aminobenzenethiol **8**, the only product was 4-(*o*-aminophenylthio)-1,2-diazaphenothiazine **13**. As 4-chloro-1,2-diazaphenothiazine **10** did not react with aminobenzenethiol **8** in ethanolic potassium hydroxide, the authors postulated the formation of bis-sulfide **12** as an intermediate product (Scheme 9) [20].

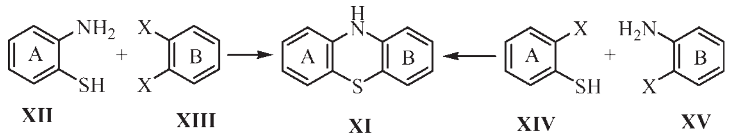
Reaction of 3,4,5-trichloropyridazine **9** with *N*-methylated *o*-aminobenzenethiol **14** (obtained by hydrolysis of 3-methyl-2(3*H*)-benzothiazolinone) in ethanolic potassium hydroxide at 0°C led unexpectedly to 4-chloro-10-methyl-2,3-diazaphenothiazine **15** as the sole product. The same reaction in methanolic potassium hydroxide at room temperature led to expected 4-(*o*-methylaminophenylthio)-1,2-diazaphenothiazine **16** (Scheme 10) [20].

The *N*-methyl analogous of sulfide **1**, sulfide **17**, heated in ethanol (with diluted hydrochloric acid) gave the rearrangement product, 10-methyl-2-chloro-3,4-diazaphenothiazine **18**, but in concentrated hydrochloric acid 10-methyl-3-chloro-1,2-diazaphenothiazine **19** (Scheme 11) [19].

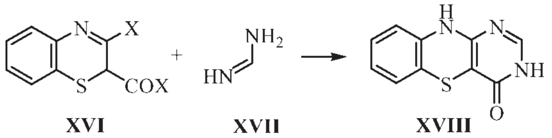
3-Chloro- and 4-chloro-1,2-diazaphenothiazines **10** and **2** were dechlorinated over palladium charcoal to unsubstituted 1,2-diazaphenothiazine **20** what proved the chloro compound structures (Scheme 12) [19,20].

10*H*-3-Chloro-1,2-diazaphenothiazine **2** was alkylated with methyl iodide and diethylaminoethyl chloride in liquid ammonia (with sodium amide) to 10-substituted 1,2-diazaphenothiazines **21** and **22**. The chlorine atom in 3-chloro-1,2-diazaphenothiazines **2** and **21** was

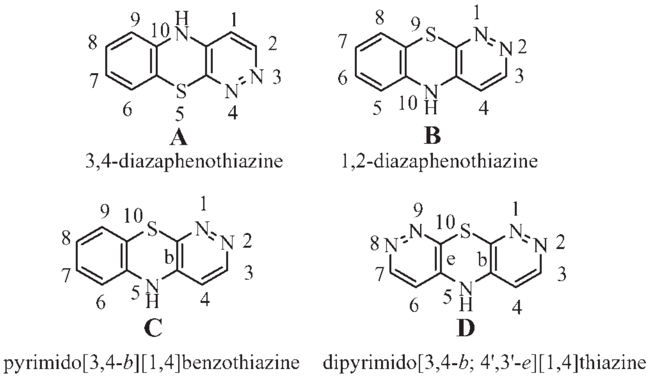
Scheme 5



Scheme 6



Scheme 7



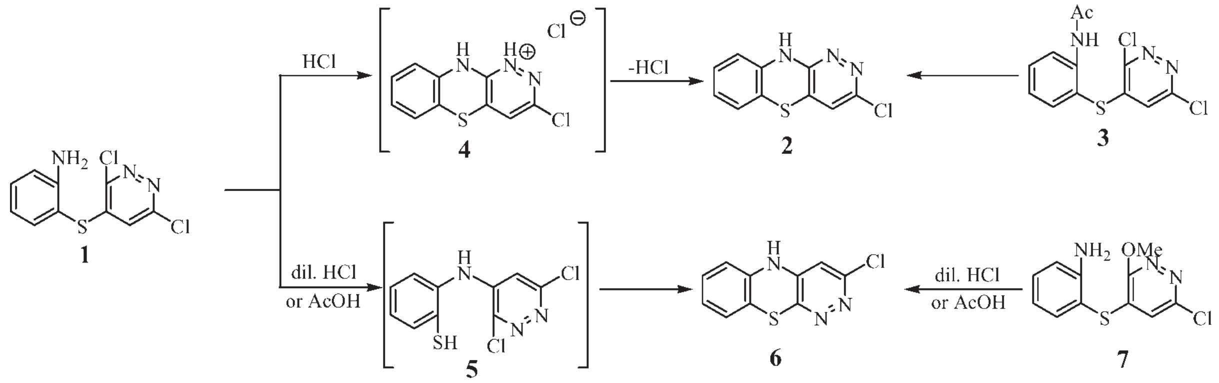
substituted in the reactions of with sodium methoxide and diethylaminoethylamine to give 3-substituted diazaphenothiazines **22** and **23**. Diazaphenothiazine **2** was oxidized with hydrogen peroxide to compound **24**, possessing *S,S*-dioxide and *N*-oxide functions (Scheme 13) [17,18].

Similarly, the chlorine atom in 10*H*-4-chloro-1,2-diazaphenothiazine **10** was substituted with the alkoxy group in the reactions with methanol and ethanol in the presence of sodium, and with dimethylamine in a sealed tube at 160°C to give 4-substituted 1,2-diazaphenothiazines **25** (Scheme 14) [20].

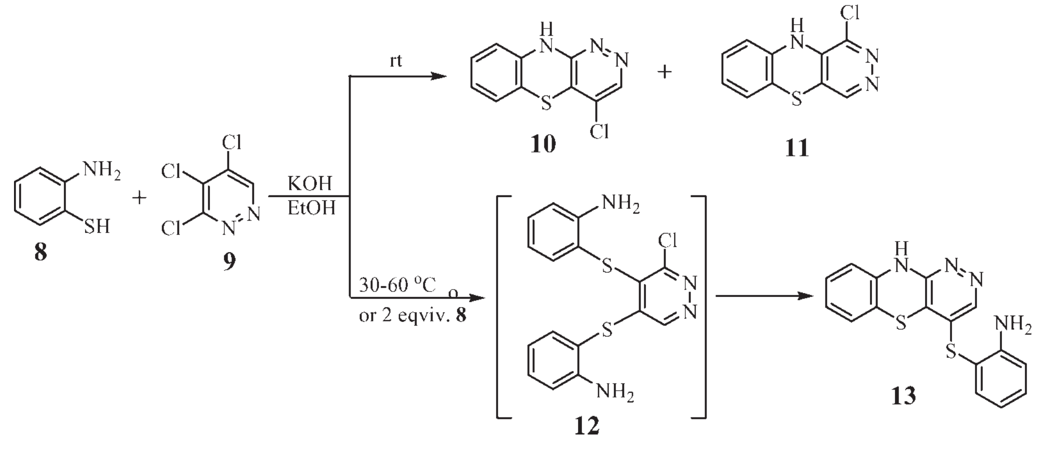
The reactions discussed earlier were later patented [21–24]. Diazaphenothiazine **22** (R_1 = OMe, R = $CH_2CH_2NEt_2$) showed antihistaminic activity [17].

1,3-Diazaphenothiazines (pyrimido[5,4-b][1,4]benzothiazines). 1,3-Diazaphenothiazines were obtained with the use of pyrimidine compounds in reactions which also produced 2,4-diazaphenothiazines. The first synthesis of this azaphenothiazine was carried out by Westermann and coworkers in 1958 who underwent a cyclization of *o*-aminophenyl 4-pyrimidinyl sulfide **25** in DMF (with potassium carbonate) under nitrogen atmosphere

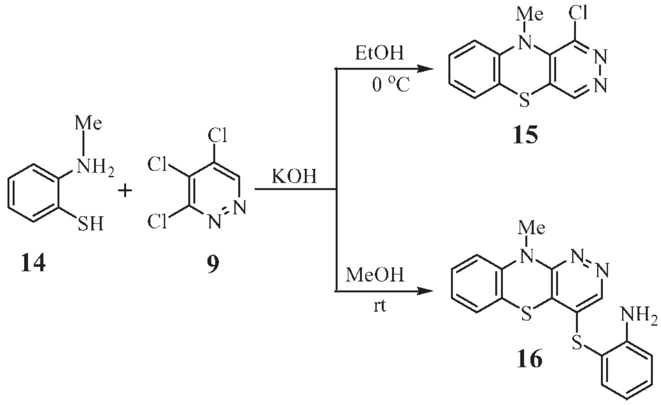
Scheme 8



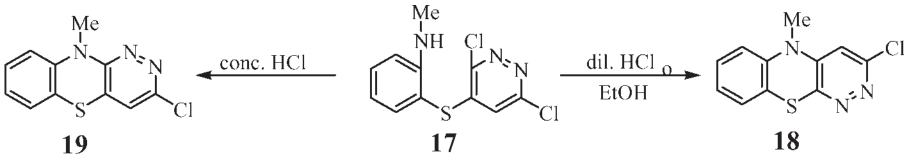
Scheme 9



Scheme 10



Scheme 11

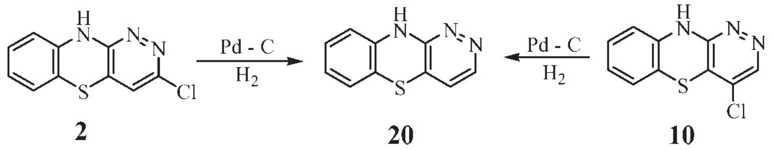


to isomeric 1,3-diazaphenothiazine **26** and 2,4-diazaphenothiazine **27** in very low yield. The discrimination of the isomers was arbitrary. One of the products, diazaphenothiazine **26**, was a result of the Smiles rearrangement occurring during the reaction course (Scheme 15) [25].

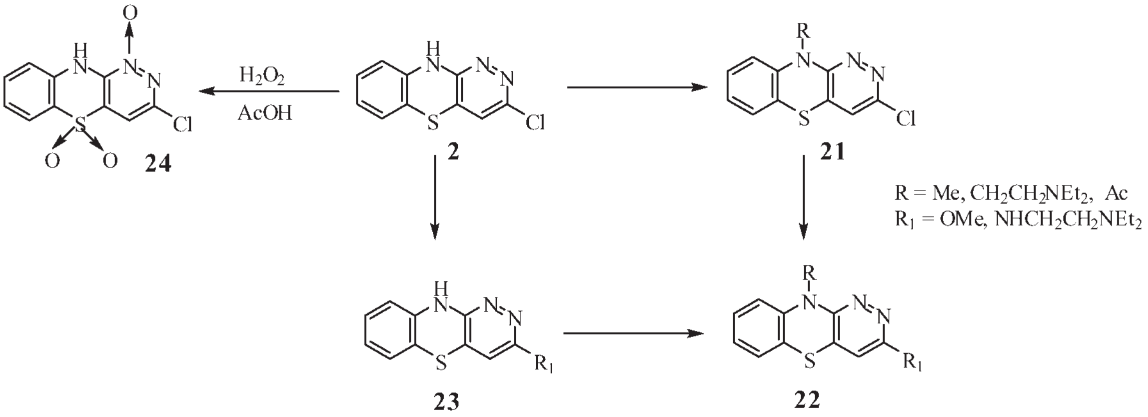
Further cyclizations of substituted sulfides **28** in DMF (with potassium carbonate and copper powder) led to only one product, namely substituted 1,3-diazaphenothiazines **29** in 15–71% yields, through the Smiles rearrangement to the appropriate amines, which, however, were not isolated. Such *o*-mercaptophenyl pyrimidinyl amines **30** (obtained separately) under the same reaction conditions gave 1,3-diazaphenothiazines **29** in moderate yields (42–58%) (Scheme 16) [25].

Later Roth and Phillips with coworkers independently developed a synthesis of 1,3-diazaphenothiazines. Reaction of 4-bromo-5-chloropyrimidine **31** with aminobenzenethiol **8** under basic conditions (ethanol,

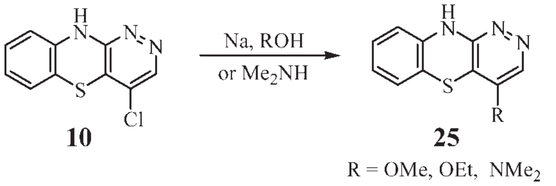
Scheme 12



Scheme 13



Scheme 14



triethylamine) led to aminophenyl 4-pyrimidinyl sulfide **32** which in ethanol and ethanolic hydrogen chloride underwent rearrangement to amine **33** (not isolated) and subsequent acid catalyzed cyclization to 2,4-diamino-1,3-diazaphenothiazine **34** in high yield (95%). The same product was obtained (in 90% yield) directly from compounds **8** and **31** in diluted hydrochloric acid through postulated amine **33** (Scheme 17) [26–28].

Substituted *o*-aminophenyl 4-hydroxy-5-pyrimidinyl sulfides **35** (obtained from substituted 5-bromoisocytosine or 5-bromouracil and substituted aminobenzenethiols) reacted in a different manner under similar acidic conditions (hydrochloric acid or sulfuric acid in 85% ethanol) to produce various substituted 1,3-diazaphenothiazines **37** without the Smiles rearrangement [29]. Later the authors (Roth and Bunnett) [30] proposed another structure of starting materials, the keto tautomers, *o*-aminophenyl 4-oxo-3,4-dihydro-5-pyrimidinyl sulfides **36** which explains well the attack of the amino group at the carbonyl carbon (at position 4, instead of position 5) and the resulting formation of the thiazine ring. Cyclization of various sulfides **36** led to substituted 1,3-diazaphenothiazines **37**, possessing substituents in positions 2 (mainly), 4, 7, and 8 (Scheme 18). 2-Hydroxy-1,3-diazaphenothiazines **37** (R_1 = OH) were transformed into the chloro derivatives **37** (R_1 = Cl) in the reaction with phosphoryl chloride and further *via* dichloro substitution to other derivatives **37** (R_1 = OMe, OCH_2CH_2OMe, SH, $NHNH_2$, $NHCH_2CH_2NMe_2$, $NHCH_2CH_2CH_2NMe_2$, *etc*). 2-Hydrazino-1,3-diazaphenothiazine **37** (R_1 = NH_2NH_2, R_2 and X = H) was transformed to parent 1,3-diazaphenothiazine **26** in the action of hydrochloric acid and copper sulfate [29].

Many various multisubstituted 1,3-diazaphenothiazines were obtained using these methods and were patented [30–35]. When alkylamino compounds **38** were

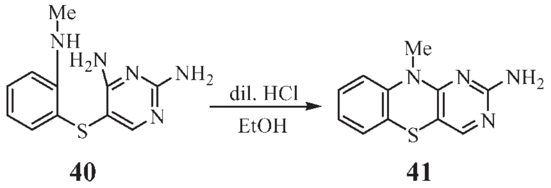
Scheme 19

R = Me, Bu

Scheme 20



used in ethylene glycol (with potassium carbonate) under nitrogen, the reaction led to 10-alkyl-1,3-diazaphenothiazines **39** (Scheme 19) [36].

The very interesting sulfide **40** possessing three amino groups, reacted by intramolecular substitution of the amino group with the methylamino group in ethanol containing hydrochloric acid, giving 10-methyl-1,3-diazaphenothiazine **41** (Scheme 20) [36].

Reactions of *N*-substituted phenyl uracilyl sulfides **42** (obtained from substituted aminobenzenethiols and bromochlorouracils) in ethanol or DMF underwent the Smiles rearrangement and cyclization to 10-substituted 1,3-diazaphenothiazine-2,4(1*H*,3*H*)-diones **43** in excellent yield (75–93%) [37]. On the contrary, phenyl uracilyl sulfide **44** in acetic acid or in alcohol with hydrochloric acid underwent cyclization without the rearrangement (Scheme 21) [38,39].

Reactions of substituted aminobenzenethiols **45** with 5-bromo- and 5-bromo-5-nitrobarbituric acids **46** and **47** led to 10*H*- and 10*H*-4a-nitro-1,3-diazaphenothiazine derivatives **48** and **49** (Scheme 22) [40].

Reaction of aminobenzenethiol **8** with *N*-substituted chloronitrouracil **50** in benzene (with triethylamine) proceeded *via* the Smiles rearrangement to give 10*H*-1,3-diazaphenothiazine-2,4(1*H*,3*H*)-dione **51** (Scheme 23) [41].

Very interesting transformations were described in Pfizer's patents [42,43]. Substituted anilinouracils **52** underwent cyclization with thionyl chloride in chloroform under nitrogen atmosphere to 4a-chloro derivatives of 1,3-diazaphenothiazine **53**. The chloro derivatives **53** with reducing agents (hydrazines, zinc, or reducing cations and anions) in methylene chloride gave stable radicals **54** or (with excess of agents) 1,3-diazaphenothiazine-2,4(1*H*,-3*H*)-diones **55**. The chloro derivatives **53** were transformed into 4a-substituted derivatives **56** by substitution of the reactive chlorine atom (Scheme 24).

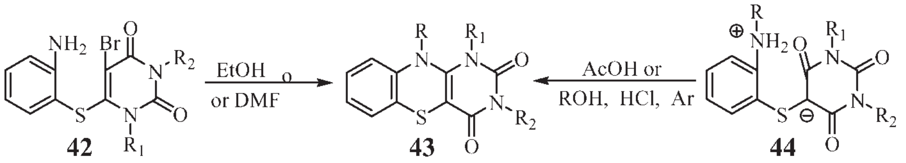
Reaction of *N*-tetraacetylribityl derivative of anilinouracil **57** with sulfur chloride in chloroform led to 10-tetraacetylribityl-1,3-diazaphenothiazinedione **58** which was deacetylated with ammonia in moderate yield (Scheme 25) [44].

Pyrimidobenzothiazepines **60** in the reaction with iodine in morpholine underwent a ring contraction to give 10*H*-1,3-diazaphenothiazinedione **51** but with iodine or *N*-halogenosuccinimide in other solvents gave 4a-substituted derivatives **61** (Scheme 26) [45].

An unusual synthesis was described by Granik and Luszkov who built the 1,3-diazine ring in benzothiazine **62** in reactions with substituted amidines **63** giving 1,3-diazaphenothiazines **64** or **65** (Scheme 27) [46].

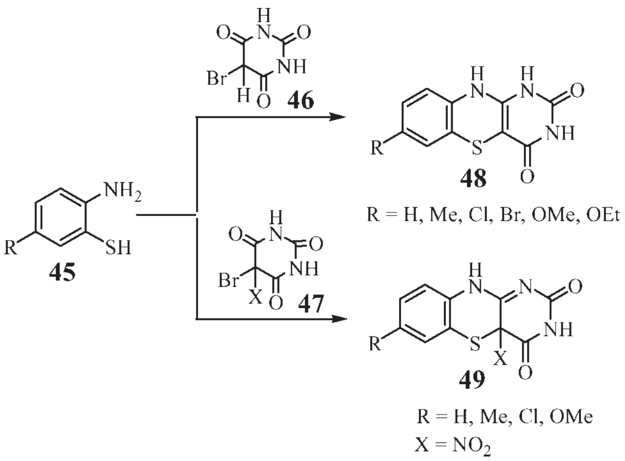
10*H*-1,3-Diazaphenothiazines **37** were transformed into 10-substituted 1,3-diazaphenothiazines **66** in the

Scheme 21



R = H, Me, $CH_2CH_2CH_2NMe_2$
R_1, R_2 = H, Me

Scheme 22



reaction with alkyl and aminoalkyl chlorides in DMF or xylene (with sodium amide or sodium hydride) (Scheme 28) [36,47].

Much more complicated was the alkylation of 1,3-diazaphenothiazine-2,4(1*H*,3*H*)-diones which led to *N*-, *O*-, *C*-, and *N*-alkylated products. The alkylation of 1,3-dialkyl compound **67** with alkyl halides or sulfates in DMF (with sodium hydride) led unexpectedly to the *S*-alkyl ylide **68** alone or with 4a-alkyl derivatives **69** [42,48]. When only allyl iodide was used, 4a-allyl derivative **69** was obtained (Scheme 29) [48]. In contrast to the alkylation of 10*H*-1,3-diazaphenothiazine, the alkylation of 10*H*-1,3-diazaphenothiazinediones **67** (R = H) did not proceed at the nitrogen atom in position 10.

Alkylation of 1,3-unsubstituted 1,3-diazaphenothiazines **70** in DMF (with potassium carbonate) yielded the *N*-, *O*-, and *C*-alkylated products **71-73** (Scheme 30) [39].

When 3,10-dimethyl-1,3-diazaphenothiazinedione **74** was alkylated in chloroform in the presence of diisopropylethylamine, the *S*-alkyl ylide of another type **75** was obtained in 100% yield (Scheme 31). Alkylation in DMF gave different products depending on the alkyl halide nature [39].

An X-ray analysis of selected sulfonium ylide (provided by Pfizer Co.) confirmed the structure as the *S*-alkyl compound and the major canonical structure was proposed as **76** (Scheme 32) [49].

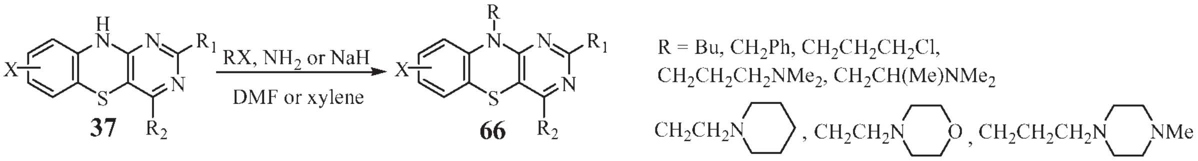
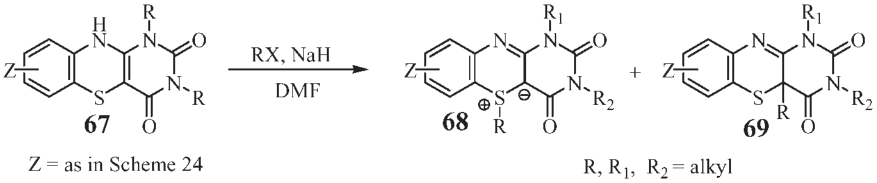
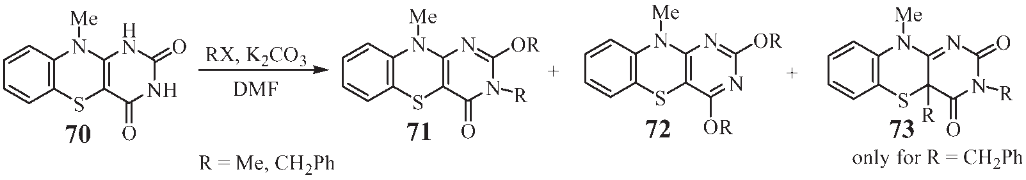


Scheme 29



Scheme 30



Although alkylation of 10*H*-1,3-dialkyl-1,3-diazaphenothiazinediones **77** proceeded mainly to *S*-ylides, heating those compounds induced thermal rearrangement (the S→N type) to 10-alkyl derivatives **78**. Ultraviolet irradiation induced a ring expansion to pyrimidobenzothiazepines **79** (Scheme 33) [48].

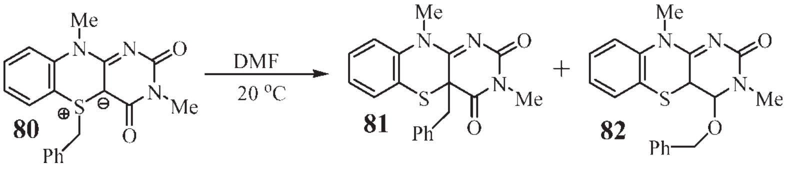
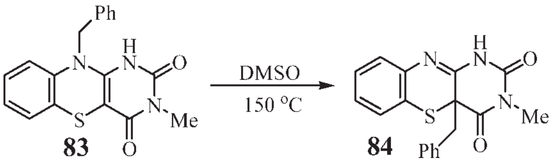
R = H, Ph

Scheme 34



Scheme 35



On the other hand, *S*-ylide **80** in DMF underwent the S→C and S→O benzyl group migration to give 4a-benzyl and *O*-benzyl derivatives **81** and **82** (Scheme 34) [49].

The benzyl group in compound **83** during heating in DMSO underwent the N→C migration to give derivative **84** (Scheme 35) [49].

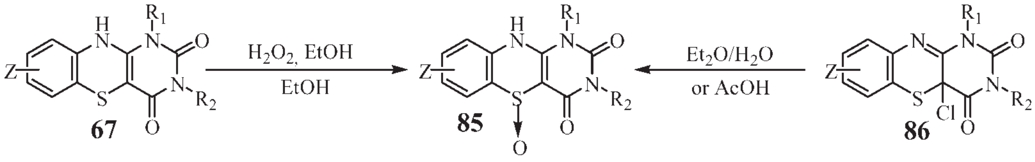
10*H*-1,3-Diazaphenothiazinediones **67** were oxidized with hydrogen peroxide in ethanol giving *S*-oxide derivatives **85**. The same compounds were obtained from 4a-chloro compound **86** in ether/water or acetic acid (Scheme 36) [42].

Both 4a-chloro derivatives **53** and *S*-oxide **85** heated in aqueous acetone or glacial acetic acid on a steam bath underwent degradation to imidazolylbenzothiazole derivatives **87** (Scheme 37) [43].

1,3-Diazaphenothiazine-2,4-diones with sulfuric acid and diacetyl gave a radical cation and a radical, respectively [50]. Several alkyl, amino, and aminoalkyl 1,3-diazaphenothiazines exhibited antibacterial activity against *Streptococcus fecalis, Escherichia coli, Staphylococcus aureus, Proteus vulgaris*, and *Pseudomonas aeruginosa* [31–36], and analgesic and anti-inflammatory activity [37].

1,4-Diazaphenothiazines (pyrazino[2,3-b][1,4]benzothiazines). The first synthesis of 1,4-diazaphenothiazine was described by Gulbenk and coworkers in their patents in 1972–1974 [51–53]. Reaction of

Scheme 36



R_1, R_2, Z as in Scheme 24

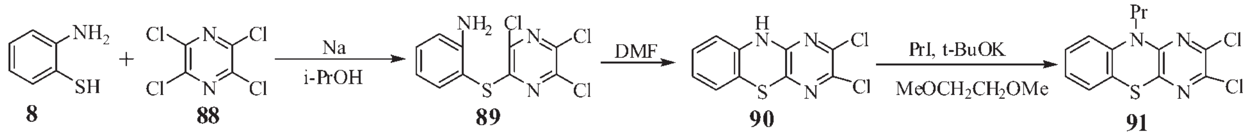
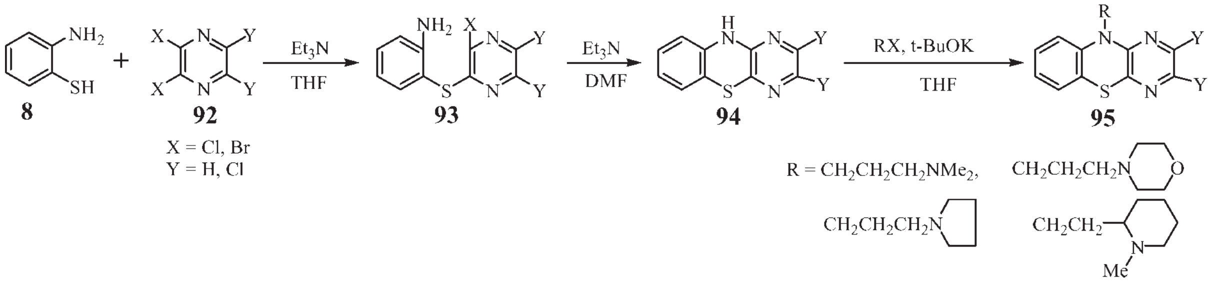
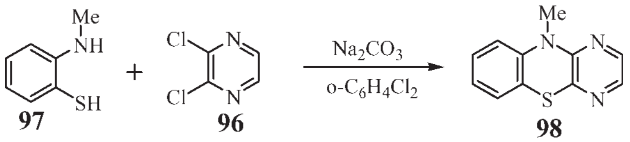
Scheme 38



Scheme 39



Scheme 40



tetrachloropyrazine **88** with aminobenzenethiol **8** in isopropyl alcohol (in the presence of sodium) led to aminophenyl pyrazinyl sulfide **89** which further in DMF cyclized to 2,3-dichloro-1,4-diazaphenothiazine **90**. *N*-Alkylation of compound **90** with propyl iodide in dimethoxyethane (with potassium *t*-butoxide) gave 10-propyl derivative **91** (Scheme 38).

During the same time period, Tong in his patent [54] described reactions of aminobenzenethiol **8** not only with tetrachloropyrazine **88** but also with dichloro- and dibromopyrazine **92** in THF in the presence of triethylamine. The obtained aminophenyl pyrazinyl sulfides **93** underwent cyclization in DMF to yield 1,4-diazaphenothiazines **94** (in 70% yield for unsubstituted product). The last compounds were transformed into the 10-aminoalkyl derivatives **95** in the aminoalkylation with aminoalkyl chlorides in THF (with potassium *t*-butoxide, Scheme 39).

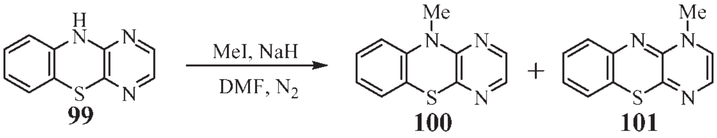
Later other authors [55,56], unaware of those patents, carried out the reaction of 2,3-dichloropyrazine **96** with aminobenzenethiol **8** in *o*-dichlorobenzene (with sodium carbonate) to give 10*H*-1,4-diazaphenothiazine **94** (Y = H) in 62% yield. Excellent yield (94%) of diazaphenothiazine **94** was achieved when this reaction was carried out in DMF (with sodium hydroxide) [57]. When *o*-methylaminobenzenethiol **97** was used instead of compound **8**, 10-methyl-1,4-diazaphenothiazine **98** was obtained in 63% yield (Scheme 40) [55].

Methylation of 10*H*-1,4-diazaphenothiazine **99** with methyl iodide in DMF (in the presence of sodium hydride) under nitrogen atmosphere gave the expected 10-methyl derivative **100** in 75% yield and the unexpected side product **101** (1-methyl derivative) in 1.2% yield (Scheme 41) [55].

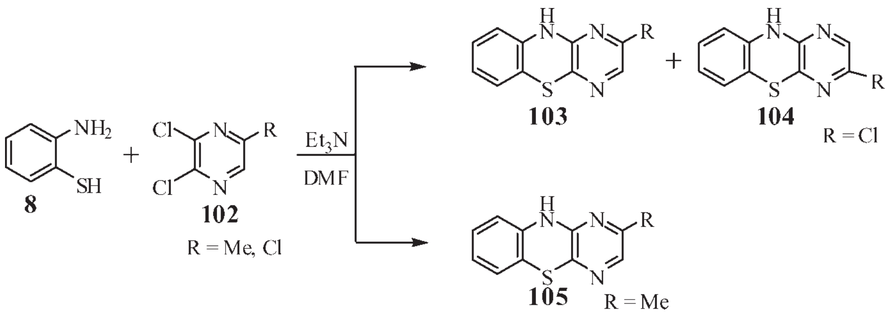
When unsymmetrical pyrazine derivatives, 2,3,5-trichloropyrazine and 2,3-dichloro-5-methylpyrazine **102** were used, one or two diazaphenothiazines were formed because of possibility of accompanying Smiles rearrangement. Reaction of compound **102** (R = Cl) with aminobenzenethiol **8** in DMF led to 2-chloro- and 3-chloro-10*H*-diazaphenothiazines **103** and **104** in 26 and 15% yields. The isomers were discriminated on the basis of NMR long range ^{13}C-^{1}H couplings and confirmed by X-ray analysis of isomer **103**. Reaction with compound **102** (R = Me) led only to one product, 2-methyl derivative **105**, in 66% yield (Scheme 42) [58].

In the reaction of dichloropyrazine **96** with 4-chloro-2-aminobenzenethiol **106** the sulfide **107** was isolated in 57% yield which further heated without solvent at 220°C underwent cyclization to 8-chloro-1,4-diazaphenothiazine **108** in 47% yield (Scheme 43) [58].

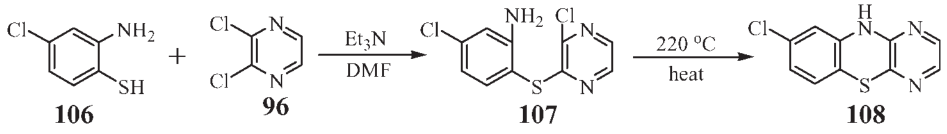
Scheme 41



Scheme 42



Scheme 43

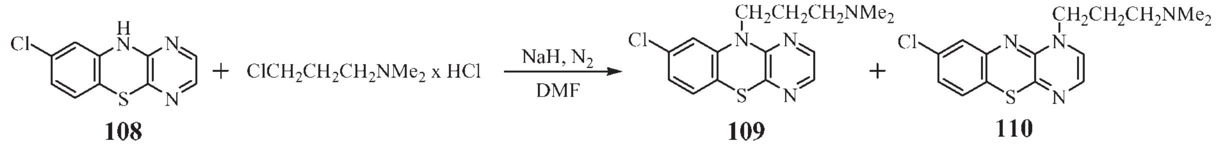


Alkylation of substituted 10*H*-1,4-diazaphenothiazines with aminoalkyl chlorides or their hydrochlorides in DMF (with sodium hydride) in nitrogen atmosphere gave 10-aminoalkyl derivatives which were transformed further into hydrochlorides. Only when 8-chloro-1,4-diazaphenothiazine **108** was alkylated with dimethylaminopropyl chloride hydrochloride two products, 10- and 1-dimethylaminopropyl-1,4-diazaphenothiazine **109** and **110**, were isolated as hydrochlorides in 47 and 17% yields (Scheme 44) [58].

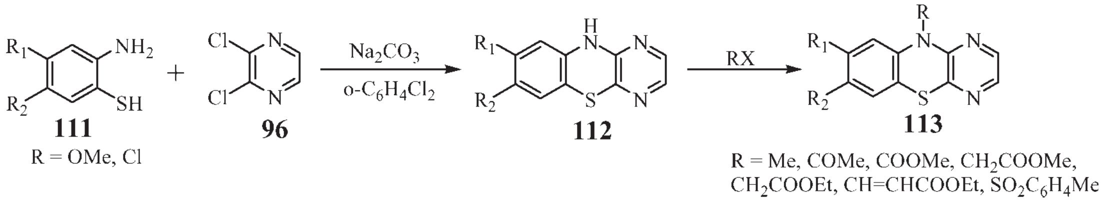
10*H*-1,4-Diazaphenothiazine **99** was once more obtained from sulfide **93** (X = Cl, Y = H) but this time with DBU in pyridine. Using substituted *o*-aminobenzenethiols **111** and 2,3-dichloropyrazine **96** in *o*-dichlorobenzene (with sodium carbonate), 1,4-diazaphenothiazines **112** were obtained, which were further *N*-alkylated, acylated, and sulfonylated to give various derivatives **113** (Scheme 45) [59].

Very recently Kaneko et al. [60–62] synthesized 8-methoxycarbonyl-10*H*-1,4-diazaphenothiazine **115** from 2-amino-4-methoxycarbonylbenzenethiol **114** and 2,3-dichloropyrazine **96** in DMF. The obtained 8-methoxycarbonyl compound was reduced with lithium aluminum hydride to 8-hydroxymethyl derivative **116**. Because of low stability of aminobenzenethiol **114**, a second route was elaborated from phenyl pyrazinyl sulfide **117** (obtained from 3-nitro-4-mercaptobenzyl alcohol and 2,3-dichlo-ropyrazine **96** followed by reduction of the nitro group). Sulfide **117** cyclized in methanol containing hydrochloric acid to give 8-hydroxymethyl derivative **116** in high yield of 99%. This compound was transformed into the chloromethyl derivative **118** by chlorination with methanesulfonyl chloride in DMF/pyridine under nitrogen atmosphere. Reactions of chloromethyl compound **118** with secondary monocyclic and bicyclic amines gave about 60 of 2-aminomethyl

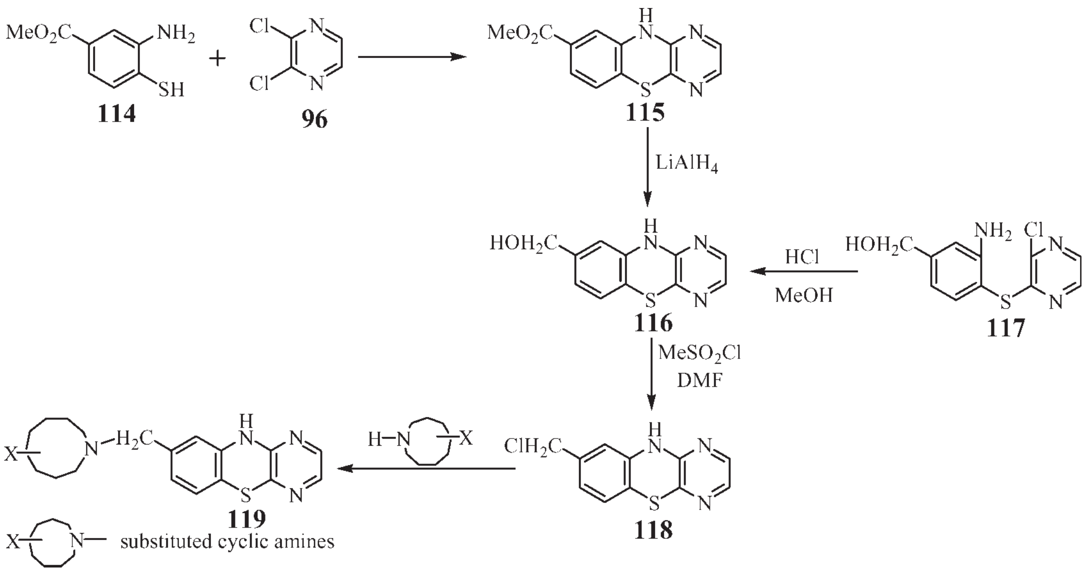
Scheme 44



Scheme 45



Scheme 46



derivatives **119** of biological activity (Scheme 46) [60–62].

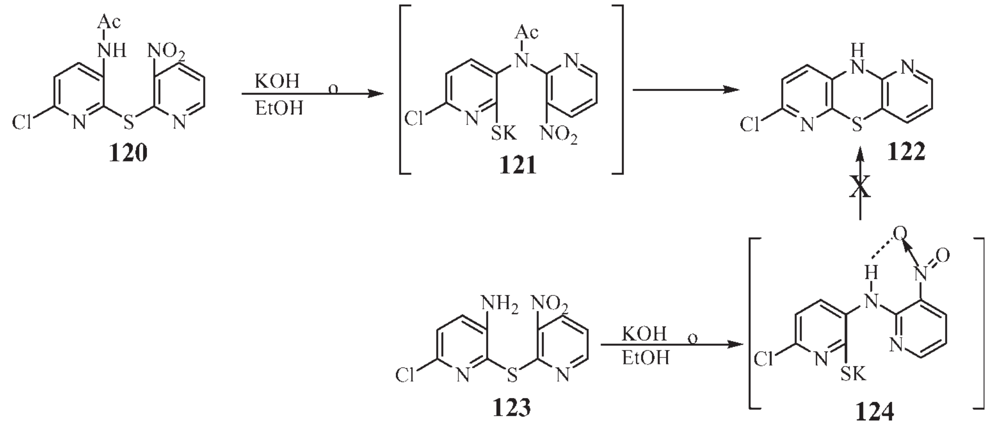
1,4-Diazaphenothiazines were transformed into other derivatives: by oxidation with hydrogen peroxide or potassium permanganate to *S*-oxides and *S,S*-dioxides [55,56,59,63], by nitration to the nitro compounds [55,56] or by reaction with iodobenzene to benzothiazole compound [55]. Most of 1,4-diazaphenothiazines exhibited very interesting biological activities: bactericidal, fungicidal, herbicidal [51–54,63], insecticidal [51–54], helminthicidal, pesticidal [51–53], neuroleptic [58], and are inhibitors of the 5-lipoxygenase enzyme system [59] and promising candidates for the treatment of autoimmune inflammatory diseases [61,62].

1,6-Diazaphenothiazines (dipyrido[2,3-b;2′,3′-e][1,4] thiazines). The first synthesis of 1,6-diazaphenothiazines was described by Maki [64]. Reaction of 3-acetylamino-6-chloro-3′-nitro-2,2′-dipyridinyl sulfide **120** (obtained from 3-amino-6-chloro-2(1*H*)-pyridinethione and 2-chloro-3-nitropyridine followed by acetylation) in ethanol (with sodium hydroxide) underwent cyclization to 7-chloro-10*H*-1,6-diazaphenothiazine **122** in 68% yield through the Smiles rearrangement to dipyridinyl amine **121**. During cyclization the acetyl group was hydrolyzed. It is interesting that the nonacetylated sulfide **123** did not undergo cyclization due to a conformation **124** produced by the hydrogen bondings between the amino and nitro groups (Scheme 47).

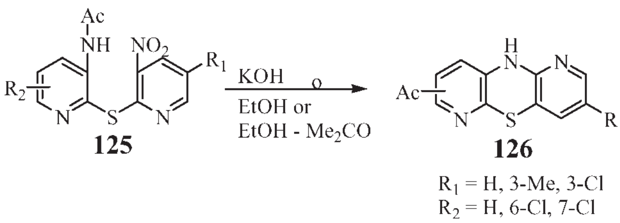
Similar procedures were used to obtain unsubstituted, 3-methyl-, 3,6-dichloro-, and 3,7-dichloro-1,6-diazapheno-thiazines **126** from appropriate dipyridinyl sulfides **125** with acetylamino groups (Scheme 48) [65–67].

Nonacetylated amines **127** (obtained directly from appropriate aminopyridinethiones and chloronitropyridines or from 3-amino-3′-nitro-2,2′-dipyridinyl sulfides *via* the Smiles rearrangement in basic or acidic media)

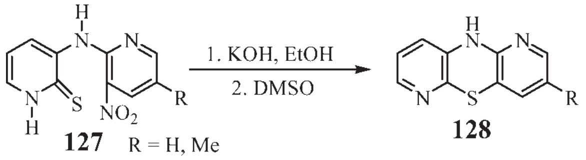
Scheme 47



Scheme 48



Scheme 49



[67,68] were able to undergo cyclization to 1,6-diazaphenothiazines **128** in DMSO (potassium hydroxide and ethanol were used to obtain potassium pyridinethiolate) (Scheme 49) [67].

Very interesting was the reaction of dipyridinyl amine **129** with 2-chloro-3-nitropyridine **130** to give compound **131**, possessing three pyridine units, which cyclized in DMSO through the Smiles rearrangement to 10-(3′-nitro-2′-pyridinyl)-1,6-diazaphenothiazine **132** (in 78% yield, Scheme 50) [67].

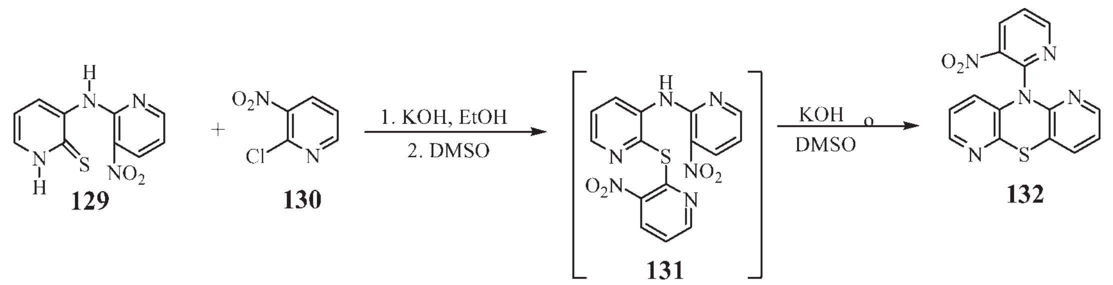
10-Substituted 1,6-diazaphenothiazines **133** and **134** were obtained from unsubstituted compound **126** in the reaction with acrylonitrile and dimethylaminopropyl chlorides (Scheme 51) [65,67].

3-Dimethylaminopropyl derivatives turned out to be more toxic than chlorpromazine and produced CNS depression) [65,67].

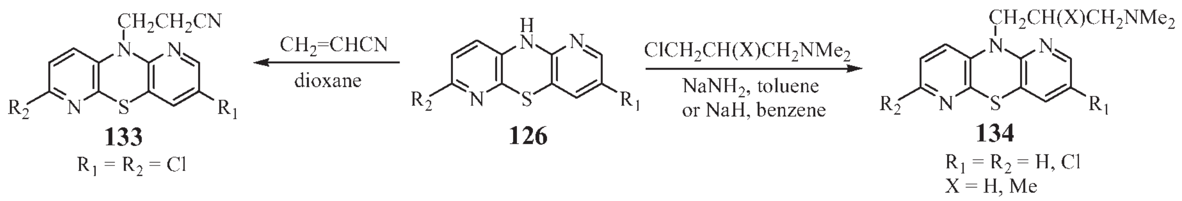
1,9-Diazaphenothiazines (dipyrido[3,2-b;2′,3′-e][1,4] thiazines). 10*H*-1,9-Diazaphenothiazine **136** was obtained by Rath in the sulfurization of 2,2′-dipyridinyl amine **135** with elemental sulfur at higher temperature (no details) and was converted into dimethylaminopropyl derivative **137** using dimethylaminopropyl chloride in xylene (with sodium amide) (Scheme 52) [69].

2,3-Diazaphenothiazines (pyridazino[4,5-b][1,4] benzothiazines). 1-Chloro-2,3-diazaphenothiazine **11** was obtained beside 4-chloro-1,2-diazaphenothiazine **10** in the reaction of aminobenzenethiol **8** with trichloropyridazine **9** as was already mentioned (Scheme 9) [20]. The first synthesis of 2,3-diazaphenothiazine was carried out in 1962 by heating aminophenyl pyridazinyl sulfide **138** in acetic anhydride to give 10-acetyl-2,3-diazaphenothiazin-1(2*H*)-one **139** which was deacetylated to 10*H*-derivative **140** in methanolic potassium hydroxide (Scheme 53) [70].

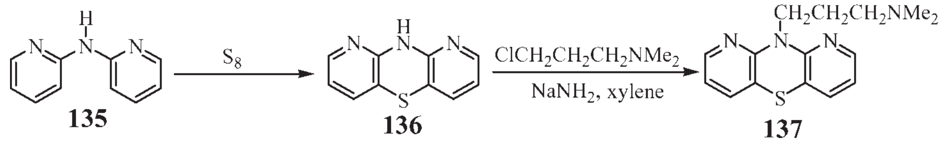
Scheme 50



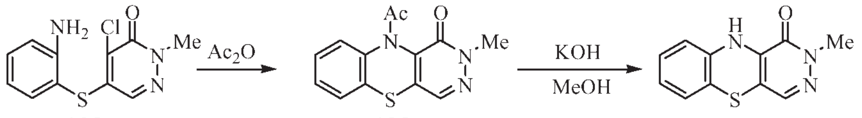
Scheme 51



Scheme 52

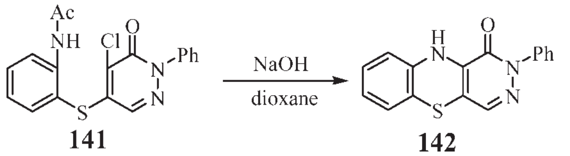


Scheme 53



138 **139** **140**

Scheme 54



141 **142**

Similarly, *N*-acetylaminophenyl pyridazinyl sulfide **141** heated in dioxane (with sodium hydroxide) gave at once 10*H*-2,3-diazaphenothiazinone **142** (Scheme 54) [70].

Later, Yoneda, Nitta, and Ohtaka published and patented reactions of aminophenyl pyrazinyl sulfides **143** which underwent cyclization with or without the Smiles rearrangement to isomeric 10*H*-2,3-diazaphenothiazinones **144** or **145** depending on the reaction conditions (basic or acidic, Scheme 55) [20,71–74].

In the same time Scapini, Duro, and Pappalardo carried out cyclization of sulfide **146** under basic conditions (acetone, potassium hydroxide) to obtain 10*H*-2,3-diazaphenothiazinon-4(3*H*)-ones **147** *via* the Smiles rearrangement (Scheme 56) [75].

Later, two teams (Pappalardo, Duro, and Maki with coworkers) independently carried out a similar cyclization of sulfide **141** under basic conditions to give phenyl derivatives of 10*H*-2,3-diazaphenothiazinon-4(3*H*)-one **148** *via* the Smiles rearrangement [76,77]. Sulfide **141** in acidic medium gave isomeric 10*H*-2,3-diazaphenothiazinon-1(2*H*)-one **142** (Scheme 57) [76].

The same product **142** was obtained in the cyclization of sulfide **149** under acidic conditions. The structure of the product was supported by unequivocal synthesis using amine **150** (Scheme 58) [76].

The 2,3-diazaphenothiazine chemistry was later widely explored mainly by Duro and Pappalardo with coworkers. They used various substituted aminophenyl pyridazinyl sulfides **151** which under basic conditions cyclized *via* the Smiles rearrangement, but under acidic conditions without the rearrangement, to give isomeric substituted 2,3-diazaphenothiazinones **152** and **153**, respectively. Whereas the acetyl group was deacetylated in the acidic medium during the synthesis (to form 10*H*-2,3-diazaphenothiazinones **153**, R = H), in basic medium was most often stable (Scheme 59) [78–84].

A very unusual synthesis was carried out using bis-sulfide **154** which underwent cyclization under basic conditions to 10*H*-2,3-diazaphenothiazin-4-one **155**. The *N*-acetylaminobenzenethiolate group turned out to be a quite good leaving group (Scheme 60) [75].

Similarly, bis-sulfide **156** gave 10*H*- and 10-acetyl-2,3-diazaphenothiazine-1,4-diones **157** (Scheme 61) [85].

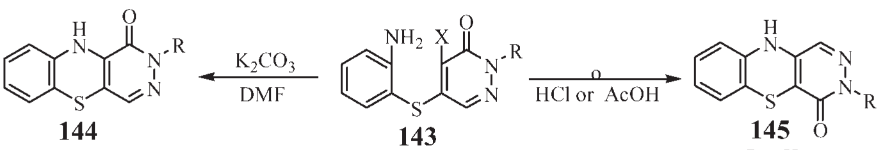
When *N*-methylaminophenyl pyridazinyl sulfide **158** was used in acidic medium, the product was identified as 3,10-dimethylphenothiazinium perchlorate **159** (Scheme 62) [79].

The direct synthesis of 2,3-diazaphenothiazinones with the use of aminobenzenethiols and pyridazine derivatives was less explored. Reactions of *N,S*-diacetyl derivatives of aminobenzenethiol **160** with dibromopyridazinones **161** under basic conditions led to 10*H*-2,3-diazaphenothiazinon-4(3*H*)-ones **147** (Scheme 63) [75].

On the other hand, aminobenzenethiol and its acetyl derivatives **162** reacted with dihalogenopyridazinones **163** in the presence of equimolar amount of sodium hydroxide (in methanol) to form 10*H*-2,3-diazaphenothiazin-1(2*H*)-one **164**. The same product **164** was obtained when potassium carbonate in DMF was used. When two equivalents of sodium hydroxide or equimolar amount of potassium hydroxide were used, isomeric 10*H*-2,3-diazaphenothiazinon-4(3*H*)-ones **165** were formed (Scheme 64) [72,86].

Similarly, reaction of *N*-methylaminobenzenethiol **97** with dibromopyridazinedione **166** led to two 2,3-diazaphenothiazine-1,4-diones **167** and **168** depending on the amount of sodium hydroxide (Scheme 65) [82].

Scheme 55



144

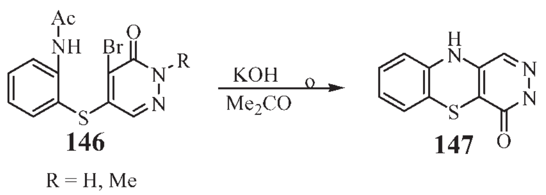
143
X = Cl, Br

145
R = H

Scheme 56



When potassium hydroxide was used in the reaction of *N*-acetylaminobenzenethiol **14** with dibromopyridazinedione **169** only one 2,3-diazaphenothiazine-1,4-dione **170** was obtained (Scheme 66) [83].

Reaction of *N,S*-diacetyl derivative of aminobenzenethiol **160** with dibromopyridazinediones **171** under basic conditions led to 10*H*- or 10-acetyl-2,3-diazaphenothiazine-1,4-diones **172** (Scheme 67) [85,87].

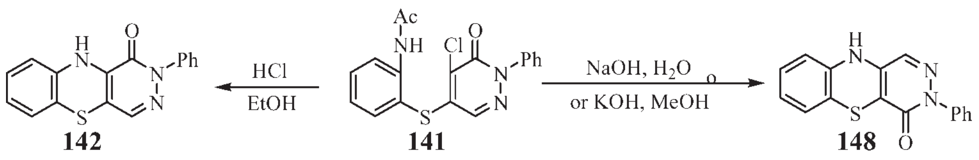
A very rare method of synthesis of an azine ring in the multiazaphenothiazine chemistry was applied by Pappalardo and coworkers. 2,3-Di(ethoxycarbonyl)-1,4-benzothiazine **173** in the annulation reaction with hydrazines led to 10*H*-2,3-diazaphenothiazine-1,4-diones **174** by building of the pyridazinedione ring (Scheme 68) [85,87].

The chemistry of 2,3-diazaphenothiazines involves alkylation, the transformation of the oxo functions, substitution of the chlorine atoms, building an azole ring, nitration and oxidation. Alkylation of 10*H*-2,3-diazaphenothiazine **175** with methyl iodide or sulfate in methanol (with addition of perchloric acid) proceeded smoothly in the pyridazine ring to give a mixture of 2- and 3-methyl-10*H*-2,3-diazaphenothiazinium perchlorates **159** and **176** (Scheme 69) [79].

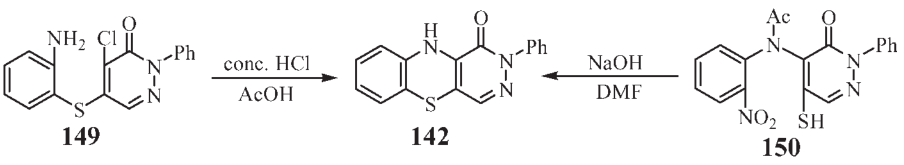
Chloro-2,3-diazaphenothiazines **177** gave only one methylation product with the methyl group farther from the chlorine atom (Scheme 70) [79].

The alkylation of 10*H*-2,3-diazaphenothiazinones **180** and **181** with methyl iodide or aminoalkyl chlorides

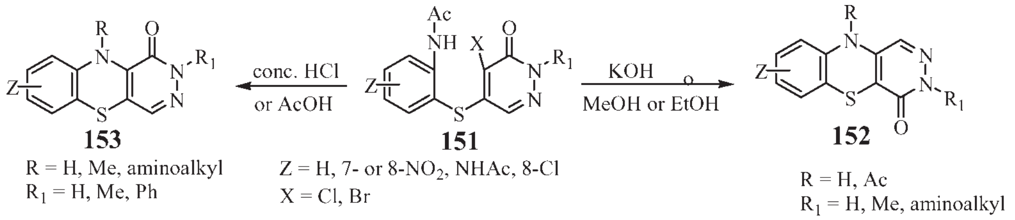
Scheme 57



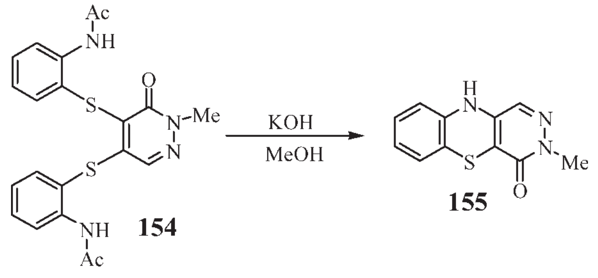
Scheme 58



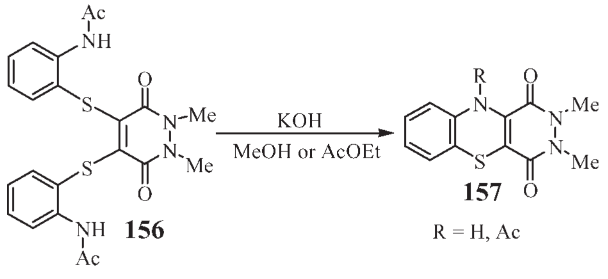
Scheme 59



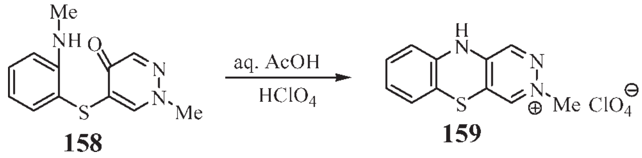
Scheme 60



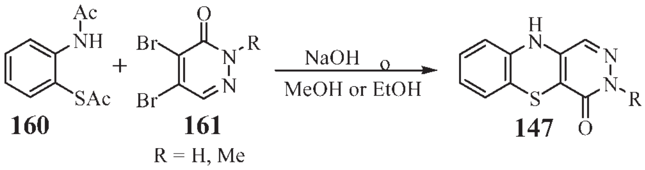
Scheme 61



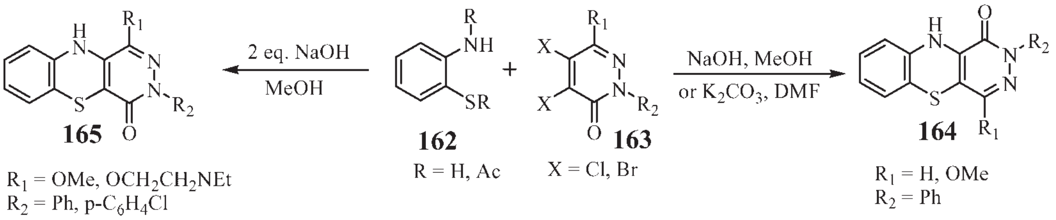
Scheme 62



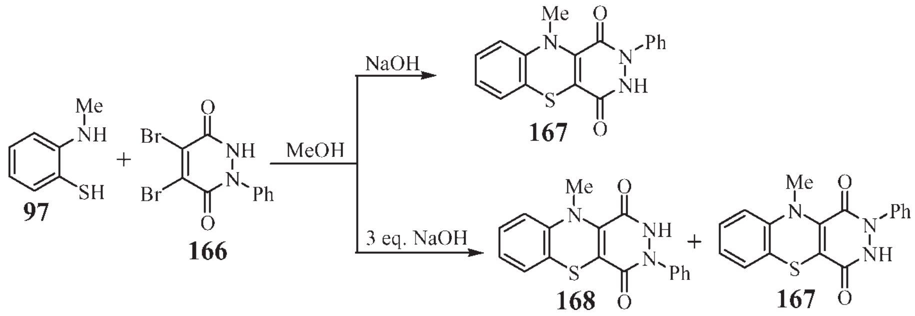
Scheme 63



Scheme 64



Scheme 65

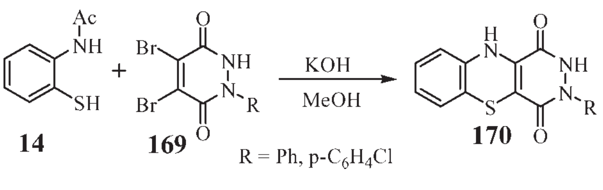


under basic conditions proceeded in the pyridazinone ring to give appropriate 2- and 3-alkyl derivatives **182** and **183** (Scheme 71) [20,71,73,83,84,88,89]. Much more complicated was the alkylation of 10*H*- and 10-methyl-2,3-diazaphenothiazine-1,4-diones giving not only expected *N*-methyl but also *O*-methyl derivatives [77,86].

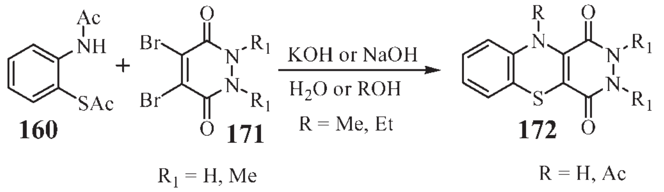
A very interesting distinction of isomeric phenyl derivatives of 10*H*-2,3-phenothiazinones **142** and **148** was carried out by action of sodium ethoxide. Whereas isomer **142** gave the product of a ring contraction **184**, isomer **148** gave sodium salt of diazaphenothiazine **185** which was further methylated to form 10-methyl derivative **186** and dimer **187** (Scheme 72) [76].

Isomeric diazaphenothiazinones **188** and **189** were converted to chloro compounds **11** and **190** which were further transformed to the hydrazine and amine derivatives **191** and **192**. The hydrazine compounds were oxidized with cupric ions to the same parent 10*H*-2,3-diazaphenothiazine **175**. On the other hand, the hydrazine

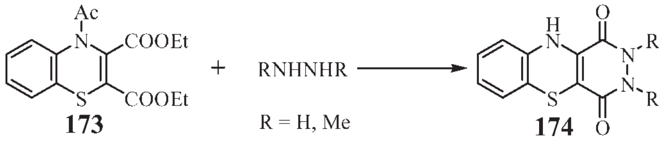
Scheme 66



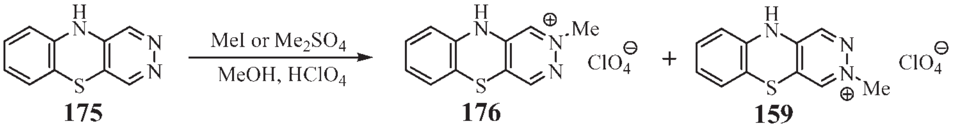
Scheme 67



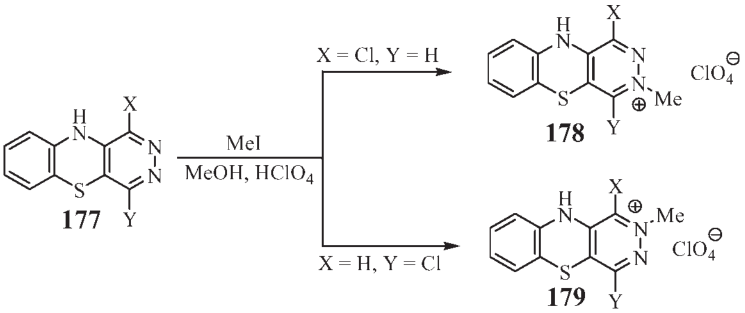
Scheme 68



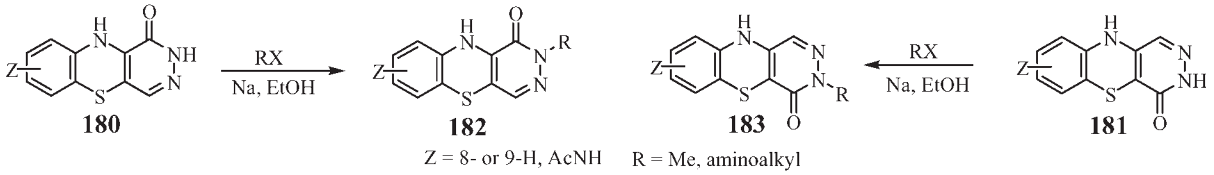
Scheme 69



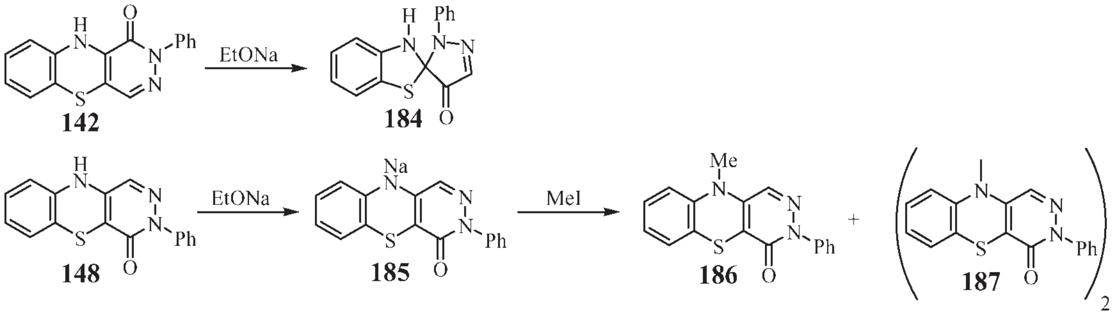
Scheme 70



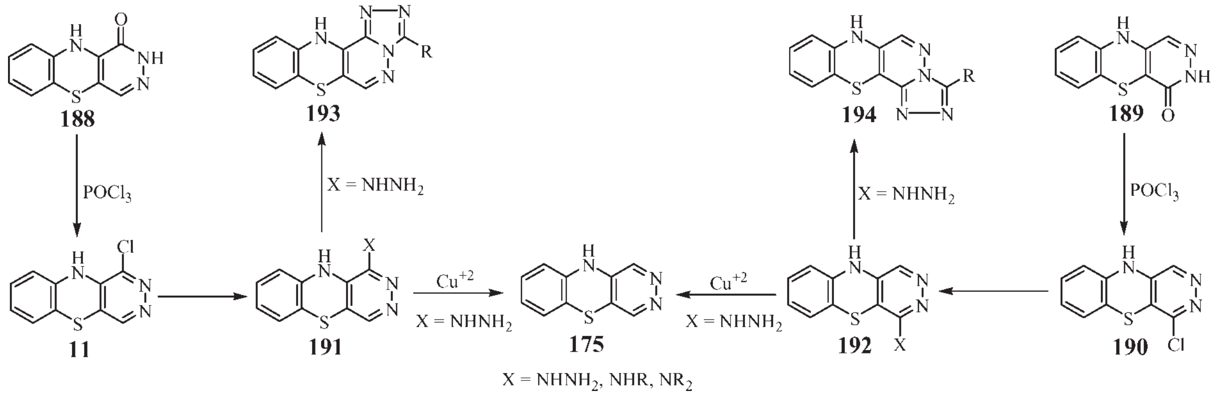
Scheme 71



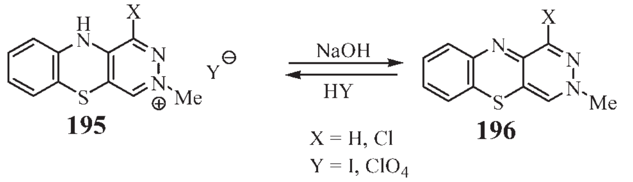
Scheme 72



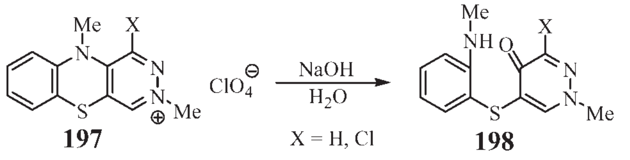
Scheme 73



Scheme 74



Scheme 75



compounds with acetic acid gave tetracyclic triazolodiazaphenothiazines **193** and **194** (R = Me, Scheme 73) [90]. Similar triazolo compounds (R = alkyl, *S*-alkyl, *S*-aminoalkyl) were obtained from the same or other hydrazine substrates [78,80,91].

2,3-Diazaphenothiazinium salts exhibited different properties under basic conditions. Whereas the 10*H*-2-alkyl salt was unreactive, the 10*H*-3-alkyl salt **195** gave 3-methyl-2,3-diazaphenothiazine **196**. This product can be converted back to the thiazinium salt **195** by action of acid (perchloric or hydroiodic, Scheme 74) [79,90].

When position 10 was methylated as in 3,10-dimethyl-2,3-diazaphenothiazinium perchlorate **197**, action of alkali led unexpectedly to opening of the 1,4-thiazine ring to give sulfide **198** (Scheme 75) [79].

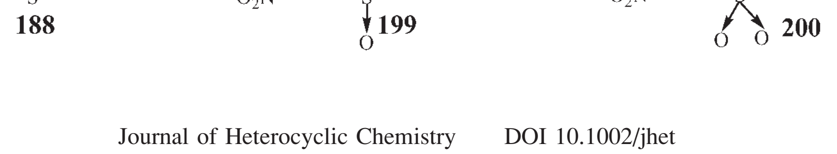
Nitration of 10*H*-diazaphenothiazin-1-one **188** with fuming nitric acid led to 7-nitro-2,3-diazaphenothiazin-1-one *S*-oxide **199**, which can be further converted to *S,S*-dioxide **200** by action of hydrogen peroxide in acetic acid (Scheme 76) [81]. Other transformations of 2,3-diazaphenothiazines were connected with the chlorine atom substitution, reduction of the nitro group and acetylation of the 10*H* position [75–78,82–85,90].

The postulated structures of 2,3-diazaphenothiazines and their salts were based on chemical transformations to known compounds (*e.g.*, 2,3-diazaphenothiazin-1(2*H*)-ones and 2,3-diazaphenothiazin-4(3*H*)-ones to chloro-2,3-diazaphenothiazines), on the ^{1}H NMR spectra (a shift of the H-1 proton [92], shielding of the H-1 and H-4 protons in salts [79], long range coupling between the H-4 and H-10 protons [80,90]) and UV spectra (distinction of 1,2-, 2,3-, and 3,4-diazaphenothiazines [20], distinction of 3- and 10-substituted 2,3-diazaphenothiazines [80]). Unquestionable structure evidences came from X-ray analysis of the selected compounds: 10-methyl-2,3-azaphenothiazine, 1-chloro-10-methyl-2,3-azaphenothiazine, 10*H*-2,3-azaphenothiazin-1(2*H*)-one, and 10*H*-2,3-azaphenothiazin-4(3*H*)-one [93–95].

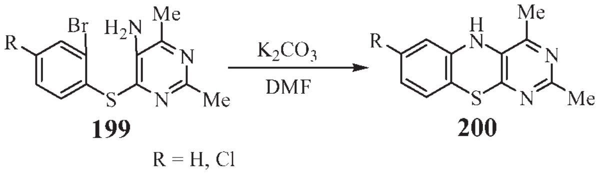
Some 2,3-diazaphenothiazines exhibited wide spectrum of biological activities: anti-inflammatory [88,89,91], analgesic [88,89,91,96], sedative [73,74,89], antiallergic [80], antiparasitic [96], antihistaminic [74,96], and antiarrhythmic [80].

2,4-Diazaphenothiazines (pyrimidino[4,5-b][1,4] benzothiazines). As was shown in Scheme 15, 10*H*-2,4-diazaphenothiazine **27** was the minor product of cyclization of amino-phenyl 4-pyrimidinyl sulfide **25** in DMF

Scheme 76



Scheme 77



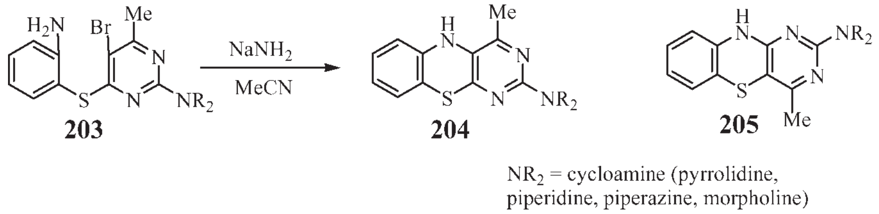
(with potassium carbonate) [25]. Reactions of *o*-bromophenyl 4-pyrimidinyl sulfides **201** in DMF (with potassium carbonate and copper powder), according to the authors, proceeded without the Smiles rearrangement to substituted 10*H*-2,4-diazaphenothiazines **202** (Scheme 77) [25,47].

Very recently an interesting cyclization of substituted *o*-aminophenyl 4-pyrimidinyl sulfides **203** in acetonitrile (with sodium amide) was published. According to the authors, the products were identified on the spectral (^{1}H NMR, IR, and MS) and microanalytical data as 3-substituted 2,4-diazaphenothiazines **204**. As the reaction conditions seem to favor the Smiles rearrangement, the obtained products are rather 1,3-diazaphenothiazines **205** (Scheme 78) [97].

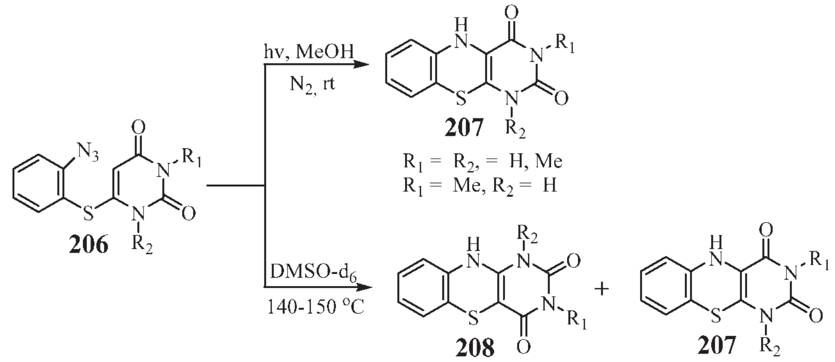
Although an irradiation of 6-(2-azidophenylthio)uracil **206** in methanol with a mercury lamp under nitrogen atmosphere resulted in exclusive formation of 2,4-diazaphenothiazine-1,3-diones **207**, thermolysis in DMSO-*d*$_6$ led to 1,3-diazaphenothiazine-2,4-diones **208** and 2,4-diazaphenothiazine-1,3-diones **207** in ratio of 2:1 (Scheme 79) [98].

Japanese groups [99–101] carried out reactions of the uracil compounds **209** with *N*-bromosuccinimide in ethanol followed by reaction with aminobenzenethiol **8** to obtain 2,4-diazaphenothiazinones **210**. It was found that those reactions proceeded through formation of 6-bromouracils which further formed with ethanol the diethoxy derivatives. The isolated diethoxy compound **211** reacted with aminobenzenethiol **8** to give 2,4-diazaphenothiazinedione **210** (R$_1$, R$_2$ = H, X = O, Scheme 80) [99].

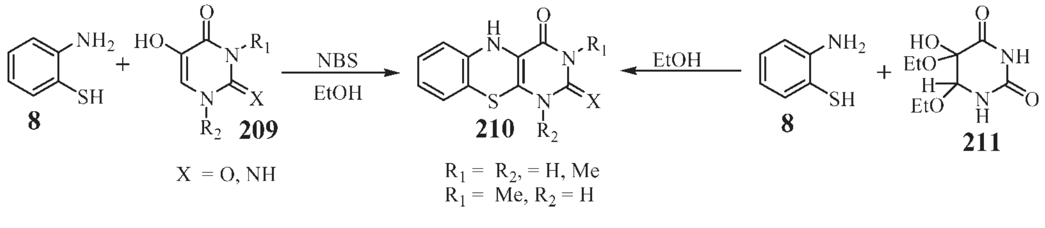
Scheme 78



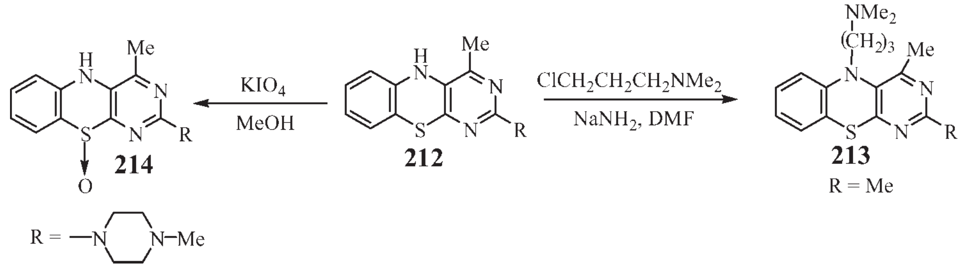
Scheme 79



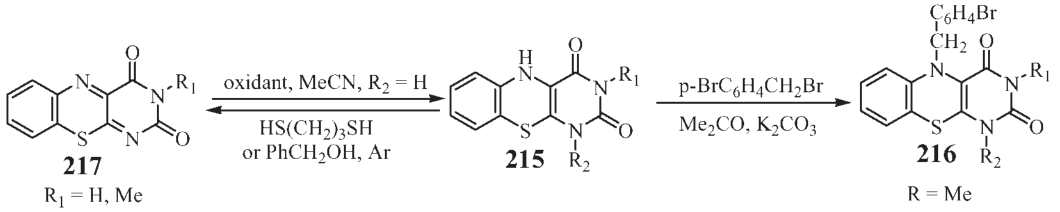
Scheme 80



Scheme 81



Scheme 82



1,3-Disubstituted 10*H*-2,4-diazaphenothiazine **212** was alkylated with dimethylaminopropyl chloride to give 10-aminoalkyl derivative **213** [25] and oxidized with potassium metaperiodate to give the 2,4-diazaphenothiazine *S*-oxide **214** (Scheme 81) [97].

Similarly, 1,3-disubstituted 10*H*-2,4-diazaphenothiazine-1,3-dione **215** was alkylated in acetone with *p*-bromobenzyl bromide to form 10-bromobenzyl derivative **216** [101]. Reaction with an oxidant (*e.g.*, 1,4-benzoquinone) in acetonitrile led to 2,4-diazaphenothiazine-1,3(2*H*)-diones **217** (called also as 10-thiaisoalloxazines). Reduction with propanedithiol or benzyl alcohol gave substrate **215** back (Scheme 82) [98,101]. Compound **217** underwent a smooth ring contraction on reaction with amines [102].

Some 2,4-diazaphenothiazines showed anti-inflammatory, antibacterial, antifungal, and analgesic activities [25–47] and some 2,4-diazaphenothiazine-1,3-diones inhibiting activity to lipoxygenases [97,100].

2,7-Diazaphenothiazines (dipyrido[3,4-b;3′,4′-e][1,4] thiazines). Reactions of 4-chloro-3-nitropyridine **218** with sodium sulfide in DMF led unexpectedly to 10*H*- and 10-(3′-nitro-4′-pyridinyl)-2,7-diazaphenothiazines **219** and **220** as major products (in modest yields) and to isomeric 2,7- and 2,8-diazathianthrenes **221** and **222** as minor products (Scheme 83, the last compounds were only products in DMSO) [103].

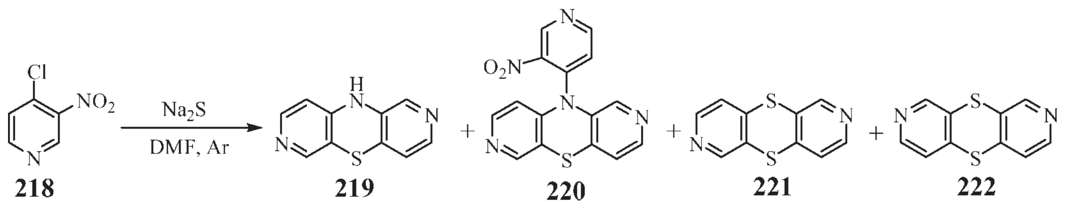
It is worth noting that the unexpected products **219** and **220** were results of single and double Smiles rearrangements of sulfides **224** and **226** and reductive properties of DMF (Scheme 84).

Later the synthesis was improved using sodium 3-nitro-4-pyridinethiolate **223**, or pairs of disubstituted pyridines **218** and **227–229**, or dipyridinyl sulfide **224**. 2,7-Diazaphenothiazine **219** was further transformed into 10-substituted derivatives **230** in reactions with appropriate halogenocompounds in DMF (with sodium hydride) or dioxane (with sodium hydroxide, Scheme 85) [104].

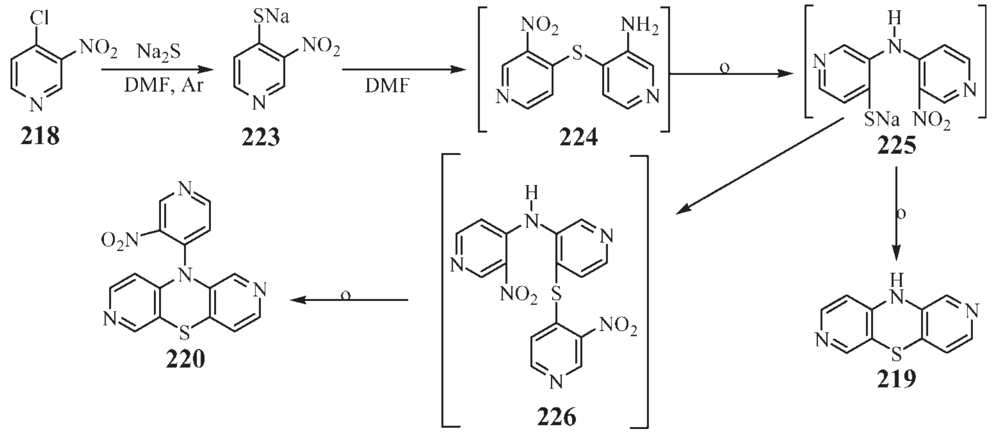
The structures of 2,7-diazaphenothiazines **219**, **220**, and **230** were determined on the basis of spectroscopic analyses (^{1}H NMR, ^{1}H-^{1}H COSY, and NOE) and confirmed by X-ray analysis of compound **220** [103,104]. For selected compounds lipophilic character and promising anti-cancer activities against lung, colon, renal cancers, and leukemia were determined [105,106].

3,4-Diazaphenothiazines (pyridazino[3,4-b][1,4] benzothiazines). The first synthesis of 3,4-diazaphenothiazine was achieved when *o*-aminophenyl 4-pyridazinyl sulfides **1** and **7** were heated in diluted

Scheme 83



Scheme 84



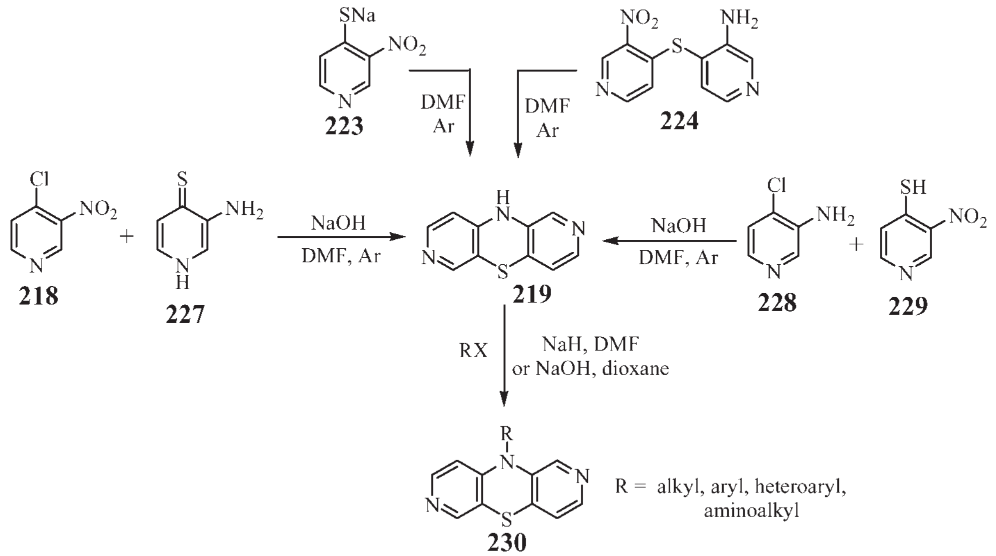
hydrochloric acid or acetic acid to give 2-chloro-3,4-diazaphenothiazine **6** through the Smiles rearrangement as is shown in Scheme 8. It worth noting that sulfide **1** in methanolic potassium hydroxide did not lead to 3,4-diazaphenothiazine **6** but to sulfide **7** which under acidic conditions underwent rearrangement and cyclization. The 10-methyl derivative **18** was obtained under the same conditions when the *N*-methylated sulfide **17** was used as depicted in Scheme 11 [18,19].

Attempts to obtain the parent 10*H*-3,4-diazaphenothiazine **232** from chloro compound **6** with catalytic hydrogenation over palladium charcoal was unsuccessful [19]. Only when aminophenyl 4-cyano-3-pyridazinyl sulfide **231** was stirred in DMSO (with sodium hydride) at room temperature 3,4-diazaphenothiazine **232** was obtained (in 85% yield). Reaction proceeded without the rearrangement (Scheme 86) [107].

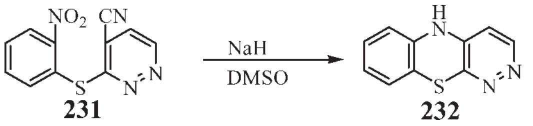
10-Substituted 3,4-diazaphenothiazines **237** were obtained when N-substituted *o*-aminobenzenethiols **233** (obtained from 3-substituted benzothiazolinone by alkaline decomposition) reacted with 3,4,6-trichloropyridazine **234** in ethanol (with potassium hydroxide) to give aminophenyl 4-pyridazinyl sulfide **235** (not always isolated) whose treatment in ethanol (with diluted hydrochloride acid) yielded 10-substituted 3,4-diazaphenothiazine **237** through rearrangement to amine **236** (Scheme 87) [108].

In a German patent [109], 10-substituted 3,4-diazaphenothiazines were described as the products of the reactions of 10*H*-3,4-diazaphenothiazine with dialkylaminoalkyl chlorides but lack of appropriate structures questioned the used 3,4-diazaphenothiazine (rather 1,2-diazaphenothiazine). 2-Chloro-3,4-diazaphenothiazines **6** underwent acetylation with acetic anhydride to

Scheme 85



Scheme 86



derivative **238**, the chlorine atom substitution with methoxy and dimethylamino groups to derivatives **239** and oxidation to *S,S*-dioxide *N*-oxide derivative **240** (Scheme 88) [18,19,108]. 2-Methoxy derivatives were also obtained for 10-substituted diazaphenothiazines (**237**, R = benzyl, dimethylaminoethyl) [19,108].

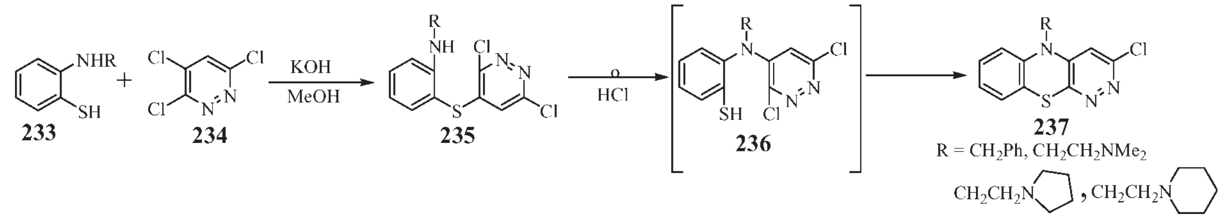
10-Pyrrolidinylethyl and dimethylaminoethyl derivatives **237** exhibited antihistaminic activity [107].

3,6-Diazaphenothiazines (dipyrido[2,3-b;4′,3′-e][1,4] thiazines). The first synthesis was described by Okafor [110] who carried out reactions of 3-amino-2(1*H*)-pyridinethione **241** with 3,5-dinitro-4-chloropyridine **242** in methanolic potassium hydroxide. The reaction proceeds through a formation of dipyridinyl sulfide **243** which undergoes rearrangement to dipyridinyl amine **244** to give 3,6-diazaphenothiazine **245**. The product structure was determined on the basis of strong hydrogen bonding between the NH and NO_2 groups (Scheme 89) [110].

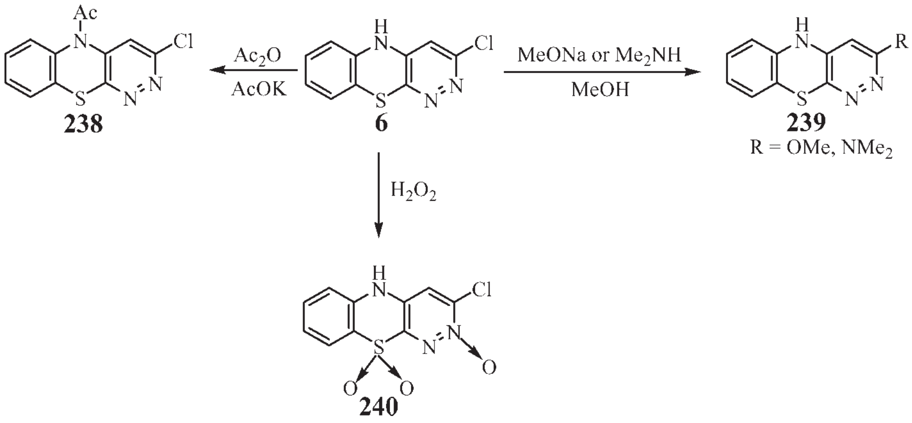
3,6-Diazaphenothiazines **245** were oxidized by sulfuric and nitric acids to *S*-oxide derivatives [111].

3,7-Diazaphenothiazines (dipyrido[3,4-b;4′,3′-e][1,4] thiazines). 10*H*-3,7-Diazaphenothiazine **247** was obtained in very low yield (9 and 6%, respectively) from sulfurization of 4,4′-dipyridinyl amine **246** with elemental sulfur at very high temperature (280–290°C) in the presence of iodine or with disodium tetrasulfide (at 260°C) [112,113]. When the cylization was carried out in *o*-dichlorobenzene with sulfur dichloride or when 3,7-diazaphenothiazine **247** was heated under those conditions, X,X′-dichloro-10*H*-3,7-diazaphenothiazine was formed (where X, X′ are most likely 4 and 4′) [114]. *N*-Alkylation with diethylaminoethyl and

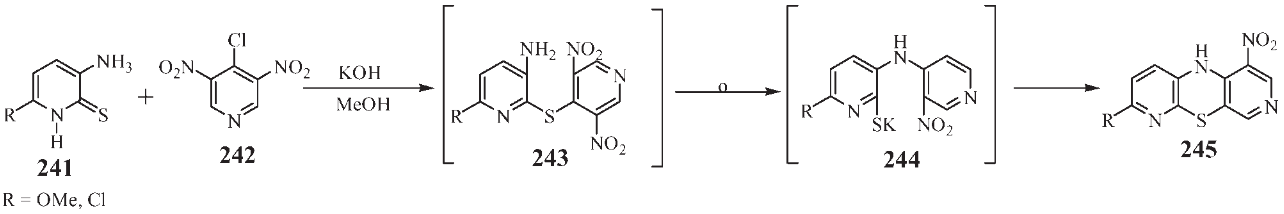
Scheme 87



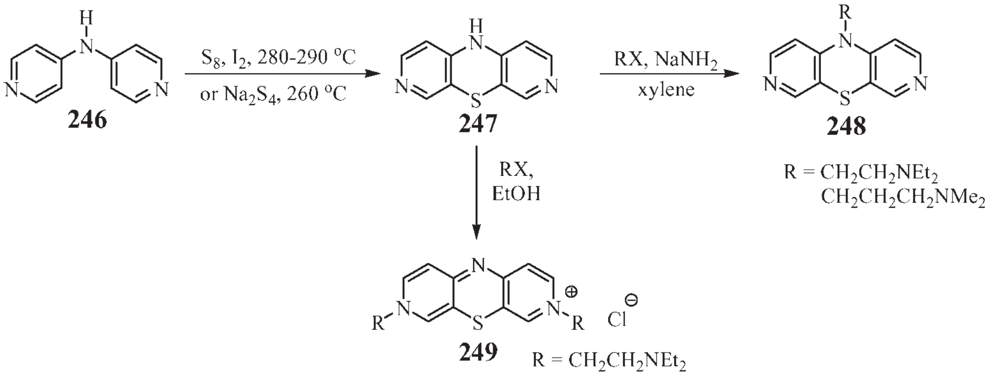
Scheme 88



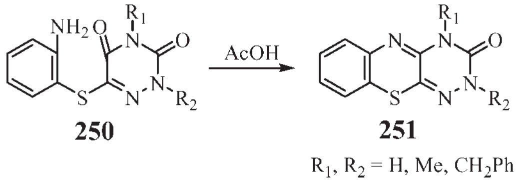
Scheme 89



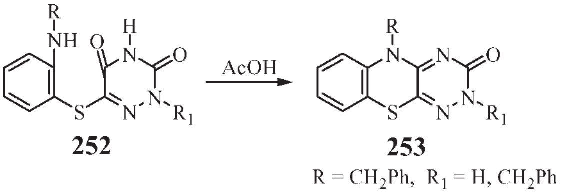
Scheme 90



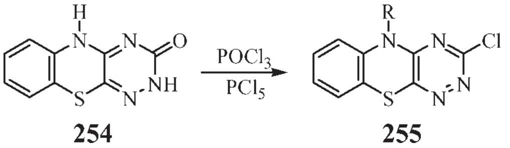
Scheme 91



Scheme 92



Scheme 93



dimethylaminopropyl chlorides proceeded at the thiazine or pyridine nitrogen atoms depending on the reaction conditions (xylene with sodium amide or only ethanol) to give 10-dialkylaminoalkyl derivatives **248** or the ammonium compound **249** (Scheme 90) [115].

3,7-Diazaphenothiazines **248** exhibited antihistaminic activity [115].

Tricyclic triazaphenothiazines. ***1,3,4-Triazaphenothiazines (benzo[1,2,4]triazino-[5,6-e][1,4]thiazines).*** Kaji et al. heated aminophenyl 1,2,4-triazinyl sulfides **250** in acetic acid to give 1*H*-1,3,4-triazaphenothiazin-2(1*H*)-one **251** without the rearrangement (Scheme 91) [116].

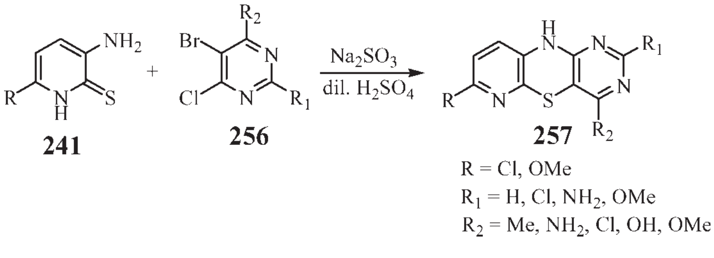
When *N*-benzyl derivative of aminophenyl triazinyl sulfide (with 4*H* function) **252** was used, appropriate 10-benzyl-1,3,4-triazaphenothiazin-2(1*H*)one **253** was obtained in low yield (20%, Scheme 92) [117].

The oxo group was substituted by the chlorine atom in 10*H*-1,3,4-triazaphenothiazinone **254** in the reaction with phosphoryl chloride giving 2-chloro derivative **255** (Scheme 93) [118].

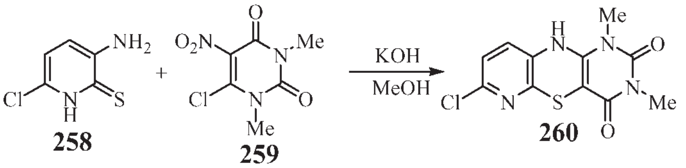
1,3,6-Triazaphenothiazine (pyrido[2,3-b]pyrimido-[4,5-e][1,4]thiazines). Reactions of substituted 3-aminopyridine-2(1*H*)-thiones **241** with chlorobromopyrimidines **256** in highly diluted sulfuric acid (100:1) (with sodium sulfite) led without rearrangement directly to 1,3,6-triazaphenothiazines **257** in low to excellent yields (11–95%, Scheme 94). The structure of the product as 1,3,6-triaza compounds (but not the 2,4,6-triaza isomers) was based on the lack of formation of the 1,10-diazole ring during diazotization of the amino derivative [119,120].

A similar reaction of aminopyridinethione **258** with 1,3-dimethyl-5-nitro-6-chlorouracil **259** in methanol (in the presence of base) led to 1,3,6-triazaphenothiazine-2,4-(1*H*,3*H*)-dione **260** in 66% yield (Scheme 95) [121,122].

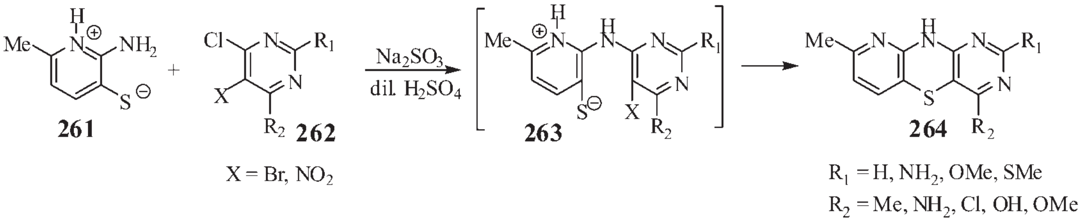
Scheme 94



Scheme 95



Scheme 96



1,3,6-Triazaphenothiazines **257** exhibited appreciable CNS-depressant activities [120].

1,3,9-Triazaphenothiazine (pyrido[3,2-b]pyrimido-[4,5-e][1,4]thiazines). The reaction of the betaine **261** with chlorobromopyrimidines or chloronitropyrimidines **262** in diluted sulfuric acid (with sodium sulfite) led directly to 1,3,9-triazaphenothiazines **264** (Scheme 96) [120,123–125]. The same reaction under basic conditions gave no products. The authors postulated that the reaction proceeded *via* formation of diazinyl amine **263**, which underwent cyclization smoothly, as they isolated compound **263** ($X = H$, $R_1 = R_2 =$ OMe) from the reaction of compound **261** with 4-chloropyrimidine **262** (without the 5-bromo function, $X = H$). The structure of the resulting product **264** was reported as the 1,3,9-triaza compound (but not the 2,4,9-triaza isomer) based on the lack of formation of the 1,10-diazole ring during diazotization of the amino derivative [124].

1,3,9-Triazaphenothiazines **264** exhibited appreciable CNS-depressant activities [120].

1,4,6-Triazaphenothiazine (pyrido[2,3-b]pyrimido[2′,3′-e][1,4]thiazines). Reaction of substituted 3-aminopyridine-2(1*H*)-thiones **241** with 2,3-dichloropyrazine **96** in aqueous propylene glycol (with sodium hydroxide) led to 7-substituted 1,4,6-triazaphenothiazines **265** in 67–89% yield (Scheme 97).

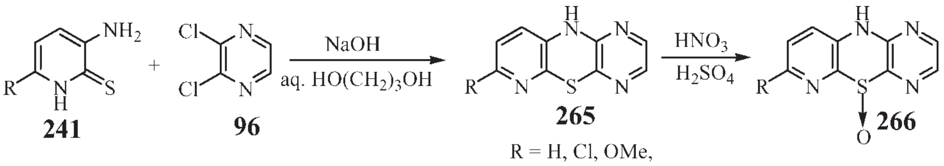
Triazaphenothiazines **265** were converted to their *S*-oxide derivatives **266** by the action of mixed concentrated nitric and sulfuric acids [125].

1,4,9-Triazaphenothiazines (pyrido[3,2-b]pyrazino[2′,3′-e][1,4]thiazines). The reaction of the betaine **261** with trichloropyrazine **267** in DMA (with sodium hydroxide) aimed at obtaining triazaphenothiazines **268** or **269** gave unexpectedly the bis-sulfide **270** in 82% yield. The formation of the second sulfide function proceeded more smoothly than the thiazine ring closure (Scheme 98) [126].

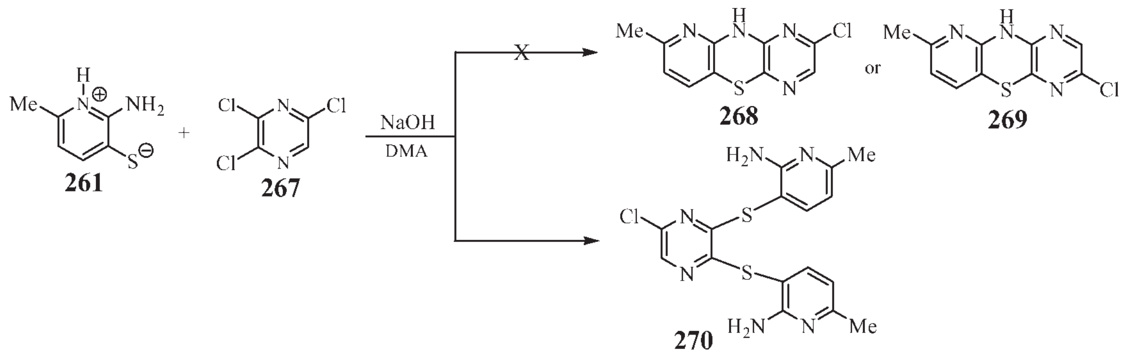
2,3,6-Triazaphenothiazine (pyrido[2,3-b]pyridazino-[4′,5′-e][1,4]thiazines). Reaction of 6-methoxy-3-aminopyridine-2(1*H*)-thione **271** with 4,5-dichloropyridazin-3(2*H*)-one **272** in aqueous DMSO (with sodium hydroxide) gave the pyridinyl pyridazinyl sulfide **273** which further in concentrated hydrochloric acid underwent cyclization to 2,3,6-triazaphenothiazin-1(2*H*)-one **274** in 82% yield. Direct reaction of compounds **271** and **272** in aqueous DMSO (for prolonged periods of time) gave the same triazaphenothiazinone **274** in 41% yield and the sulfide **275** (in 26% yield). Sulfide **273**, when heated in acetic acid, underwent the Smiles rearrangement and cyclization to isomeric 2,3,6-triazaphenothiazin-4(3*H*)-one **276** in 89% yield (Scheme 99). The structure of isomeric triazaphenothiazinones was established on the basis of a very broad signal for 10-H proton of isomer **274** (1-one) because of strong NHO hydrogen bonding [127].

Reaction of 3-aminopyridine-2(1*H*)-thione **277** with 4,5-dichloropyridazine **278** in ethanol (with potassium hydroxide) under nitrogen atmosphere led to 2,3,6-triazaphenothiazine **279** in 63% yield (Scheme 100) [126].

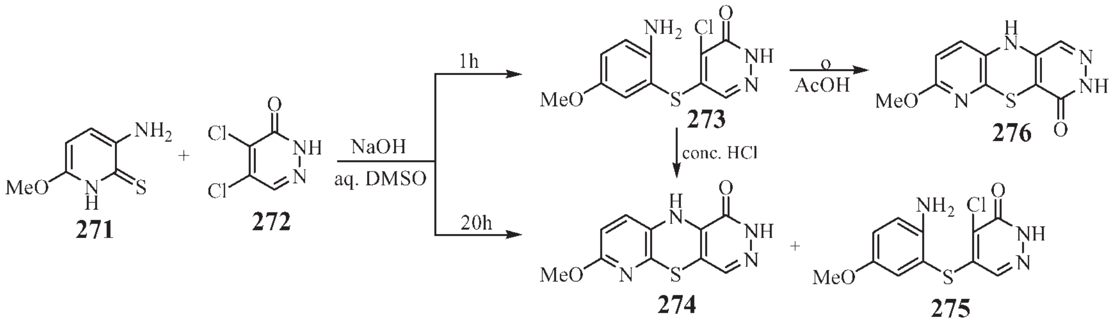
Scheme 97



Scheme 98



Scheme 99

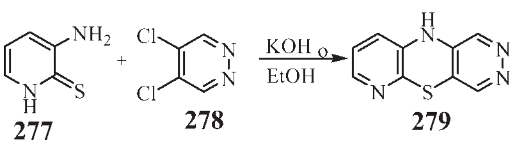


Later, Baltrop and Owen repeated this reaction and questioned the previous result. The obtained product was also identified as 2,3,6-triazaphenothiazine **279** [128] but possessed a different melting point, ^{1}H NMR, UV spectra, and elemental analysis only was similar.

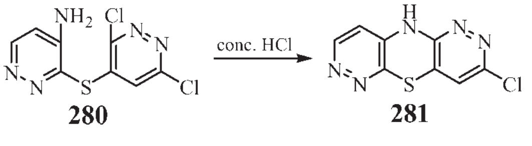
Tricyclic tetraazaphenothiazines. ***1,2,6,7-Tetraazaphenothiazine (dipyridazino[3,4-b;3′,4′-e][1,4]thiazines).*** Heating dipyridazinyl sulfide **280** in concentrated hydrochloric acid led to 1,2,6,7-tetraazaphenothiazine **281** in 61% yield (Scheme 101) [129].

1,2,7,8-Tetraazaphenothiazine (dipyridazino[4,3-b;4′,5′-e][1,4]thiazines). Cyclization of dipyridazinyl sulfide **282** in concentrated hydrochloric acid gave 1,2,7,8-tetraazaphenothiazine **283** in 63% yield (Scheme 102) [129].

Scheme 100



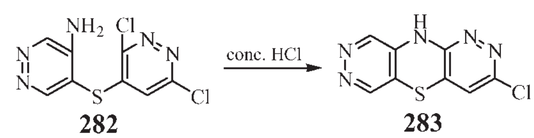
Scheme 101



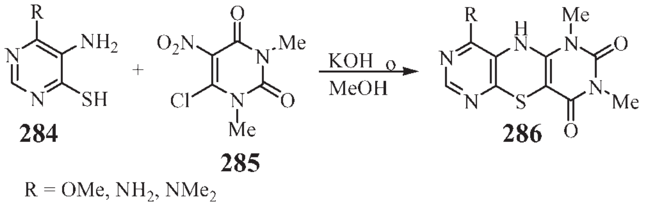
1,3,6,8-Tetraazaphenothiazine (dipyrimido[4,5-b;4′,5′-e][1,4]thiazines). Reactions of substituted 5-aminopyrimidine-4-thiols **284** with 1,3-dimethyl-5-nitro-6-chlorouracil **285** in ethanol (with potassium hydroxide) led to 1,3,6,8-tetraazaphenothiazine-2,4(1*H*,3*H*)-diones **286** in 54–78% yield *via* the Smiles rearrangement (Scheme 103).

When 1,3-dimethyl-5-amino-6-mercaptouracil **287** was used in the reaction, 1,3,6,8-tetraazaphenothiazine-2,4,7,-9(1*H*,3*H*,6*H*,8*H*)-tetraone **288** was obtained in 58% yield (Scheme 104) [121,122].

Scheme 102

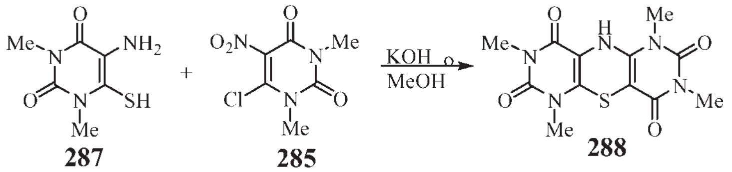


Scheme 103

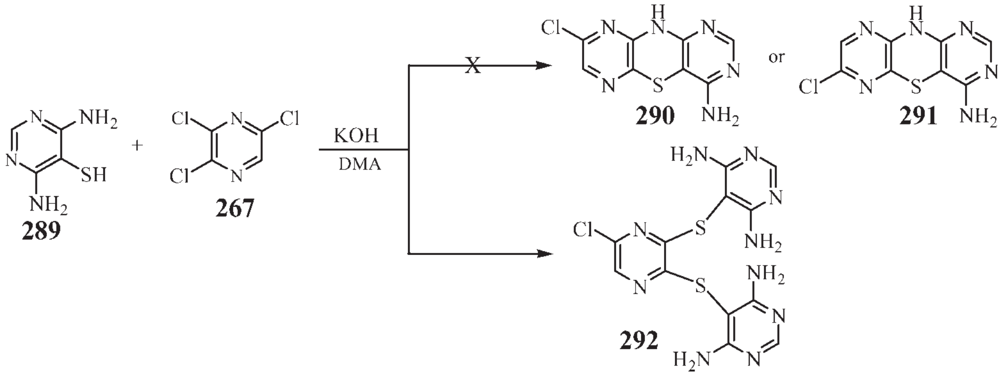


R = OMe, NH_2, NMe_2

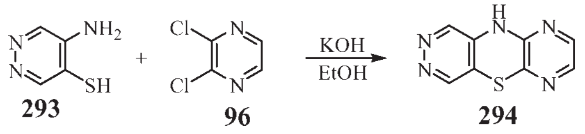
Scheme 104



Scheme 105



Scheme 106



1,3,6,9-Tetraazaphenothiazine (pyrazino[2,3-b]pyrimido[4′,5′-e][1,4]thiazines). Reaction of 4,6-diaminopyrimidine-5-thiol **289** with trichloropyrazine **267** in DMA did not lead to tetraazaphenothiazine **290** or **291** but unexpectedly to the bis-sulfide **292** in high yield (93%, Scheme 105) [126].

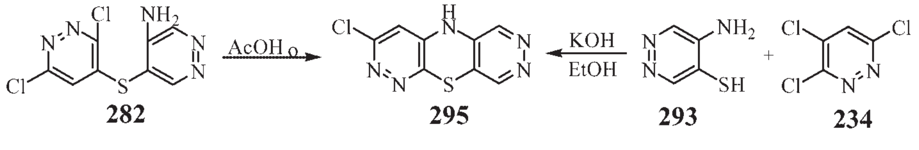
1,4,7,8-Tetraazaphenothiazine (pyrazino[2,3-b]pyridazino[4′,5′-e][1,4]thiazines). Reaction of 4-aminopyridazine-5-thiol **293** with dichloropyrazine **96** (with potassium hydroxide) led to 1,4,7,8-tetraazaphenothiazine **294** in low yield (30%, Scheme 106) [126].

2,3,6,7-Tetraazaphenothiazine (dipyridazino[3,4-b;4′,5′-e][1,4]thiazines). Dipyridazinyl sulfide **282** in acetic acid underwent the Smiles rearrangement and cyclization to give 8-chloro-2,3,6,7-tetraazaphenothiazine **295** in 82% yield. The same product was obtained in the reaction of aminopyridazinethiol **293** with trichloropyridazine **234** in ethanol (with potassium hydroxide) in 88% yield (Scheme 107).

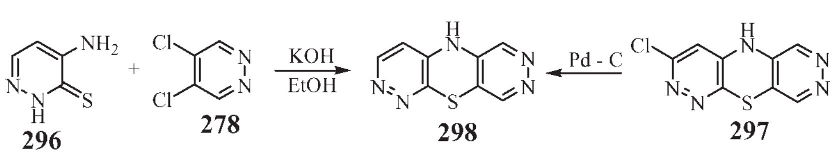
The parent 2,3,6,7-tetraazaphenothiazine **298** was obtained in the reaction of 4-aminopyridazine-3-thione **296** with dichloropyrazine **278** in ethanol (with a base) in 57% yield or by dechlorination of chlorotetraazaphenothiazine **297** in 55% yield with a use of palladium charcoal (Scheme 108).

Alkylation of tetraazaphenothiazine **297** with aminoalkyl chlorides in liquid ammonia (with sodium amide) yielded aminoalkyl derivatives **298** in 43–55% yield (Scheme 109) [129].

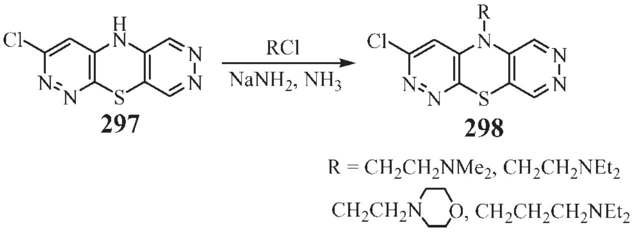
Scheme 107



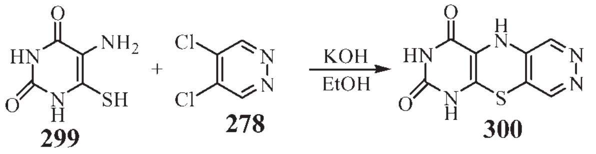
Scheme 108



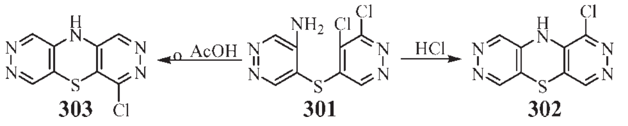
Scheme 109



Scheme 110



Scheme 111



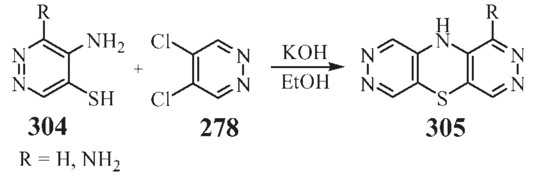
2,3,6,8-Tetraazaphenothiazine (pyridazino[4,5-b]pyrimido[5′,4′-e][1,4]thiazines). Reaction of 5-aminouracil-6-thiol **299** with dichloropyridazine **278** in ethanol (with potassium hydroxide) led to 2,3,6,8-tetraazaphenothiazine-7,9(6*H*,8*H*)-dione **300** in 50% yield (Scheme 110) [126].

2,3,7,8-Tetraazaphenothiazine (dipyridazino[4,5-b;4′,5′-e][1,4]thiazines). Whereas dipyridazinyl sulfide **301** in hydrochloric acid underwent cyclization to 1-chloro-2,3,7,8-tetraazapheno-thiazine **302** in 58% yield, in acetic acid it underwent the Smiles rearrangement and cyclization to isomeric 4-chloro-2,3,7,8-tetraazaphenothiazine **303** in 57% yield (Scheme 111).

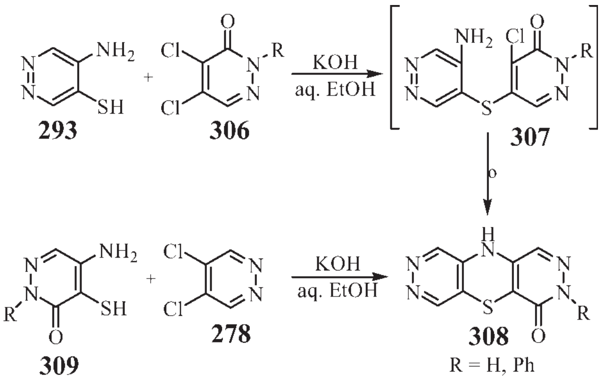
The parent tetraazaphenothiazine and the amino derivative **305** were obtained in the reaction of 4-amino-3-pyridazinethiols **304** with dichloropyridazine **278** in ethanol (with potassium hydroxide) in 66 and 72% yield (Scheme 112).

With dichloropyridazinones **306** in aqueous ethanol (in the presence of a base) the aminopyridazinethiol **293** underwent the Smiles rearrangement and cyclization to 2,3,7,8-tetraazaphenothiazin-4-ones **308**. Crude dipyridazinyl sulfide **307** (R = H) underwent the rearrangement and cyclization during crystallization from ethanol. The structures of the products **308** were established by independent synthesis using 5-amino-4-mercaptopyridazin-3(2*H*)-one **309** and dichloropyridazine **278** under the same conditions (Scheme 113).

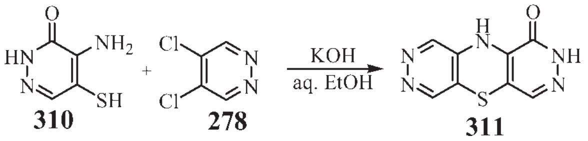
Scheme 112



Scheme 113



Scheme 114

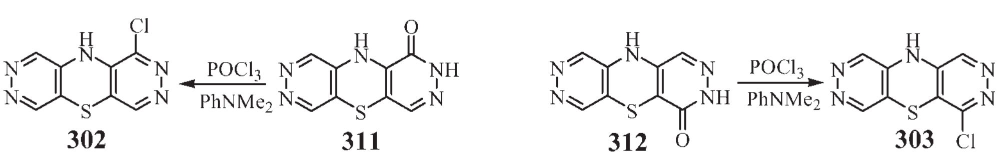


When 5-amino-4-mercaptopyridazin-6(1*H*)-one **310** was used in the reaction with dichloropyridazine **278**, isomeric 2,3,7,8-tetraazaphenothiazin-1-one **311** was obtained in 75% yield (Scheme 114).

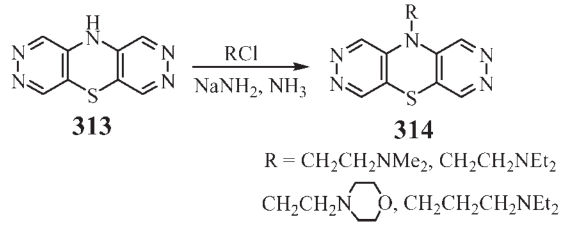
Both tetraazaphenothiazinones **311** and **312** were converted into the chloro derivatives **302** and **303** in low yield (27 and 40%) by the action of phosphoryl chloride with *N*,*N*-dimethylaniline (Scheme 115).

The parent 10*H*-tetraazaphenothiazine **313** was transformed into aminoalkyl derivatives **314** in 39–51% yield by *N*-alkylation with aminoalkyl chlorides in liquid ammonia (in the presence of sodium amide, Scheme 116) [129].

Scheme 115



Scheme 116



2,4,6,8-Tetraazaphenothiazine (dipyrimido[4,5-b;5′,4′-e][1,4]thiazines). Reaction of 5,6-diamino-1,3-dimethyluracil **315** with liquid hydrogen sulfide in pyridine in a sealed tube led unexpectedly to 2,4,6,8-tetraazaphenothiazine-1,3,7,9(2*H*,4*H*,6*H*,8*H*)-tetraone **316** in 55% yield. To establish the correct structure of the product, an independent synthesis (in 58% yield) was carried out using aminomercaptouracil **287** and 5-hydroxy-1,3-dimethyluracil **317** in the presence of N-bromosuccinimide in ethanol (Scheme 117).

N-Alkylation of tetraazaphenothiazine **316** with benzyl and *p*-bromobenzyl bromides in DMF or acetone (with bases) led not only to the expected benzyl derivatives **317** (in 29 and 14% yield) but also to the unexpected benzyl derivatives of the ring contraction product, dipyrimidopyrroles **318** (in 7 and 46% yield, respectively, Scheme 118) [101].

3,4,6,7-Tetraazaphenothiazine (dipyridazino[3,4-b;4′,3′-e][1,4]thiazines). Whereas dipyridazinyl sulfide **280** gave in concentrated hydrochloric acid 1,2,6,7-tetraazaphenothiazine **281** (Scheme 101), in acetic acid gave 2-chloro-3,4,6,7-tetraazaphenothiazine **319** (in 47% yield) as a result of the Smiles rearrangement (Scheme 119).

Reaction of aminopyridazinethione **296** with dichloropyridazine **320** in ethanol (in the presence of potassium hydroxide) led to parent 3,4,6,7-tetraazaphenothiazine **321** in 60% yield (Scheme 120) [129].

Tetracyclic phenothiazines (benzo derivatives of phenothiazines).

Benzo derivatives of 1,4-diazaphenothiazines (quinoxalino[2,3-b]benzo[1,4]thiazines). The first synthesis was carried out by Walter and co-workers as early as 1933 using aminobenzenethiol **8** and 2,3-dichloroquinoxaline **322** (no details). The product structure was postulated as 12*H*-benzo-1,4-diazaphenothiazine **323** (Scheme 121) [130].

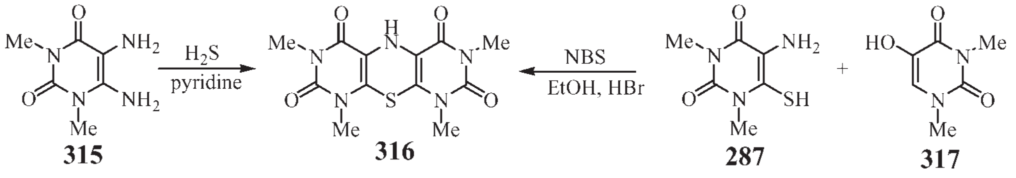
Almost 30 years later Schindler and Peterili (1961) repeated this synthesis using 5-chloro-2-aminobenzenethiol **324** and substituted 2,3-dichloroquinoxalines **325** to obtain substituted 12*H*-8-chlorobenzo-1,4-diazaphenothiazines **326** (Scheme 122) [131].

In the same time Riedel and Deuschel [132] and later Carter with Cheeseman [55] and Okafor [57] carried out the same reaction of aminobenzenethiol **8** with 2,3-dichloroquinoxalines **325** in *o*-dichlorobenzene or DMF (with bases) to obtain postulated 11*H*-benzo-1,4-diazaphenothiazines **327** (Scheme 123). When R ≠ H, the product was assigned as the 2-chloro compound **327** (X = Cl [57]) or was not determined at all (X = Me, Cl, OMe [132]).

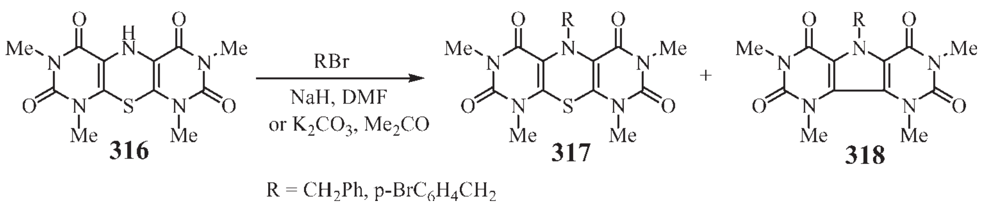
When *N*-substituted aminobenzenethiols **328** and substituted 2,3-dichloroquinoxalines **325** or quinoxaline-2,3-(1*H*,4*H*)-diones **329** were used, the obtained products were assigned as 11-substituted benzo-1,4-diazaphenothiazines **330** (Scheme 124) [55,132].

Whereas 11*H*- or 12*H*-benzo-1,4-diazaphenothiazines **323** or **331** (according to the authors), when methylated with methyl iodide in DMF (with sodium hydride), gave two compounds: the expected 11-methyl derivative as the main product **332** (in 45% yield) and the 12-methyl derivative **333** as the minor product (in 25% yield) [55], alkylated with aminoalkyl chlorides gave only one product: 11- or 12-substituted compound (**334** or **335**, not

Scheme 117

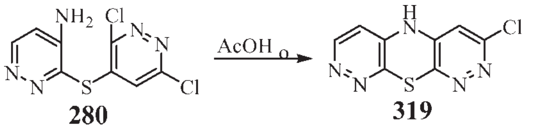


Scheme 118

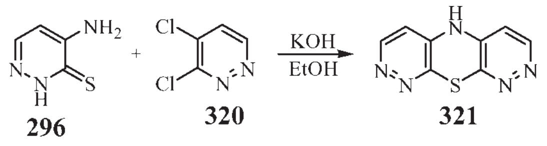


R = CH_2Ph, p-$BrC_6H_4CH_2$

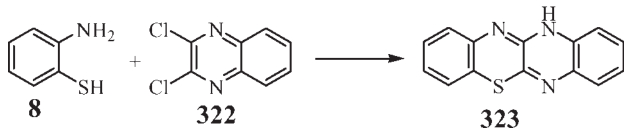
Scheme 119



Scheme 120



Scheme 121



determined) [131]. Acetylation with acetic anhydride gave only one product assigned as the 11-acetyl derivative **336** (Scheme 125) [55].

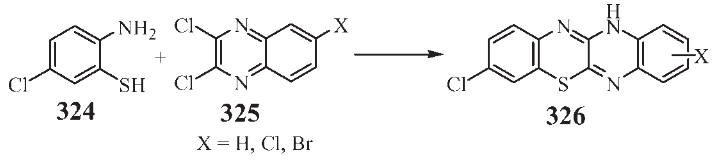
Oxidation of the 11-methyl derivative **332** with iodobenzene dichloride led to *S*-oxide derivative **337**, but with potassium permanganate to *S*,*S*-dioxide **338** (Scheme 126) [55].

Nitration of benzo-1,4-diazaphenothiazines **339** gave products depending on the nitrating agents. Nitration with sodium nitrate led to the mononitro derivative **340** but with mixed nitric and sulfuric acid to the nitration and oxidation product, the dinitro and *S*-oxide derivative **341** (Scheme 127) [55,57]. The last nitration was carried out to determine the correct structure of chlorobenzo-1,4-diazaphenothiazine (the position of the chlorine atom) **339** (X = Cl) by analysis of the directive influence of the functional groups [57].

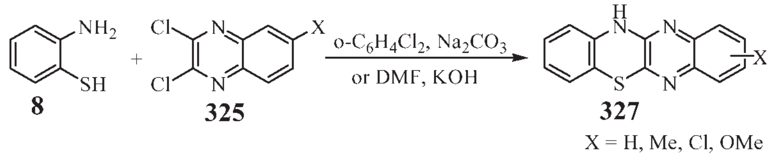
Some benzo-1,4-diazaphenothiazines exhibited antiallergic, anticonvulsive, sedative, adrenolytic, and serotonin-antagonistic activities [131] and yellow pigment dye properties [132].

Benzo derivatives of 3,6-diazaphenothiazines (pyrido[2,3-b]quino[4′,3′-e][1,4]-thiazines). Reactions of 5,12-dialkylthioquinanthrenediinium dichlorides **342** with 3-aminopyridine in pyridine proceeded *via* the 1,4-dithiin ring opening to give 1-alkyl-4-(3-pyridinylamino)-quinolinium-3-thiolate **343** in 63–70% yield or 5-alkyl-12*H*-benzodiazaphenothiazinium chlorides **344** in 60–66% yield, depending on the presence of atmospheric oxygen in the reaction mixture. Quinolinium thiolate **343** in the presence of aniline hydrochloride and air was converted

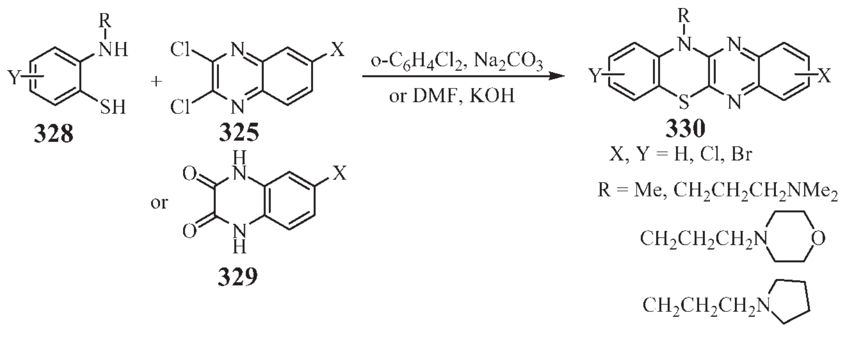
Scheme 122



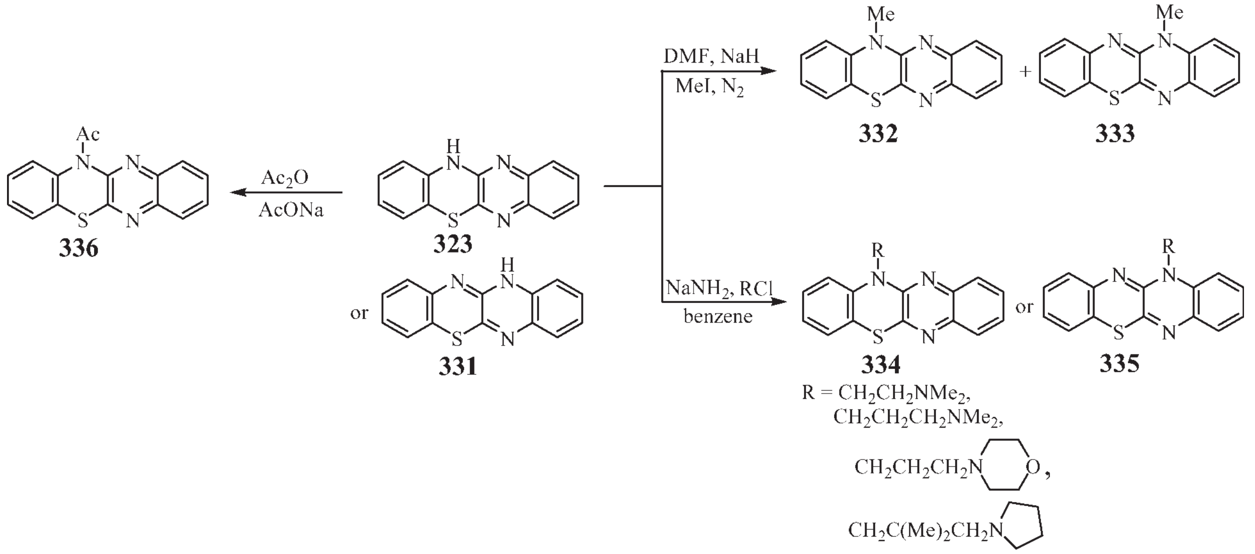
Scheme 123



Scheme 124



Scheme 125



336 **323** **331** **332** **333** **334** **335**

to benzodiazaphenothiazinium salt **344** in 67–69% yield which was further transformed into 5-alkylbenzodiazaphenothiazines **345** in quantitative yield (Scheme 128).

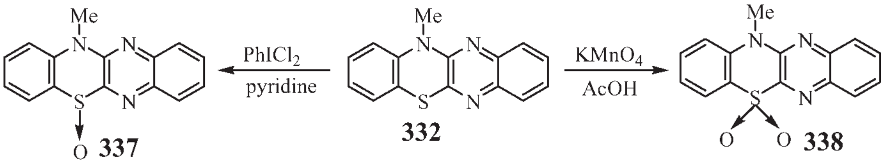
The structure of phenothiazinium salts was determined based on coupling constants analysis and was confirmed by X-ray analysis of the ethyl derivative **344** (R = Et) [133].

Benzo derivatives of 1,4,9-triazaphenothiazines (pyrido[3,2-b]quinoxalino[2′,3′-e][1,4]thiazines). Reaction of 2-amino-6-methylpyridine-3-thiol **261** with dichloro- and trichloroquinoxalines **325** in DMF (with sodium hydroxide) did not lead to tetracyclic azaphenothiazines **346** or **347** but unexpectedly to the bis-sulfide **348** in 77 and 71% yield, respectively (Scheme 129) [127].

Benzo derivative of 1,3,6,9-tetraazaphenothiazines (pyrimido[5,4-b]quinoxalino[2′,3′,-e][1,4]thiazines. Reactions of substituted 4-aminopyridazine-5-thiols **349** with 2,3-dichloroquinoxalines **325** in aqueous propylene glycol (with potassium hydroxide) led to benzo derivatives of 1,3,6,9-tetraazaphenothiazines **350** in 84–95% yield *via* the Smiles rearrangement. The structures of the products were established on the basis of further nitration under mild conditions and the discussion of the directive influence of the NH group. The products were identified as substituted 8-nitrotetraazabenzophenothiazine-*S*-oxides **351** (Scheme 130) [134].

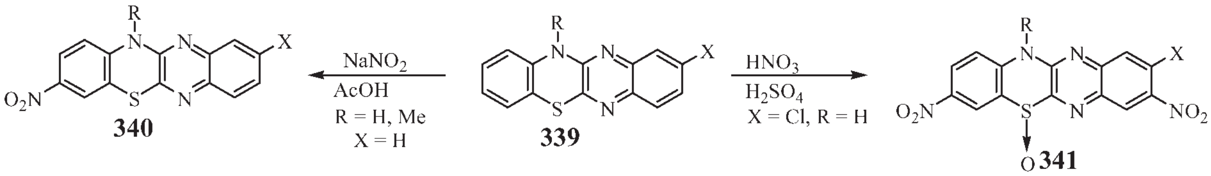
Benzo derivatives of 1,4,6,8-tetraazaphenothiazines (pyrimido[4,5-b]quinoxalino[2′,3′-e][1,4]thiazines). Reactions of 4,5-diaminopyrimidine-6(1*H*)-thione **352** with 2,3-dichloroquinoxalines **325** in aqueous DMF (with sodium hydroxide) proceeded *via* the Smiles rearrangement to give benzo derivatives of 1,4,6,8-tetraazaphenothiazines **353** in high yield (92 and 85% yield, respectively). The structure of the chloro product was based on further nitration under mild conditions and the discussion of the directive influence of the functional groups. The product

Scheme 126



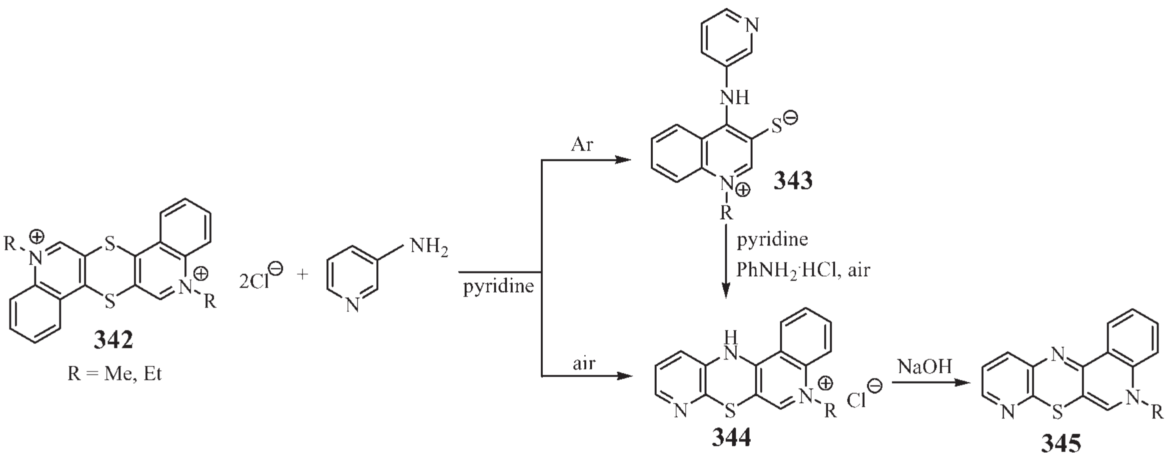
337 **332** **338**

Scheme 127



340 **339** **341**

Scheme 128



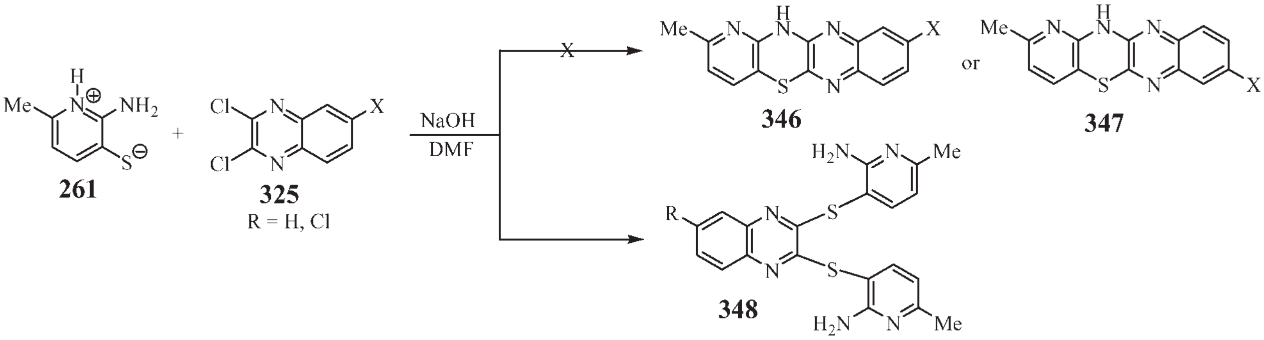
was identified as 10-amino-2-chloro-3-nitrotetraazabenzo[*b*]phenothiazine *S*-oxide **354** (Scheme 131).

To confirm the presence of the proton at the thiazine nitrogen atom compound **353** (R = H) was diazotized and heated to give triazolobenzotetraazaphenothiazine **355** in 81% yield (Scheme 132) [135].

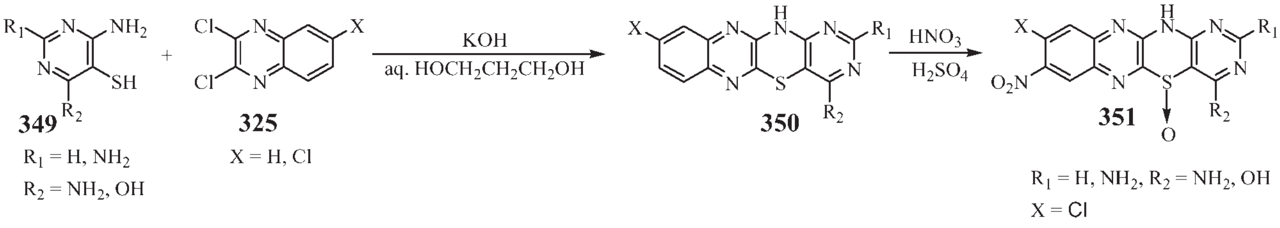
Pentacyclic phenothiazines (dibenzo derivatives of phenothiazines).

Dibenzo derivatives of 1,9-diazaphenothiazines (diquino[3,2-b;2′,3′-e]thiazines). Reaction of dihydroquinolin-2(1*H*)-one **356** with thionyl chloride in DMF led unexpectedly to the diquinothiazine **357** (in 21%

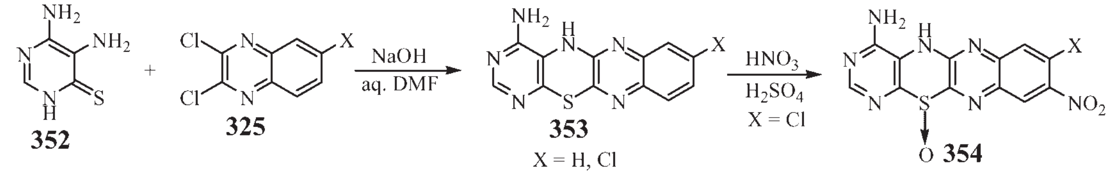
Scheme 129



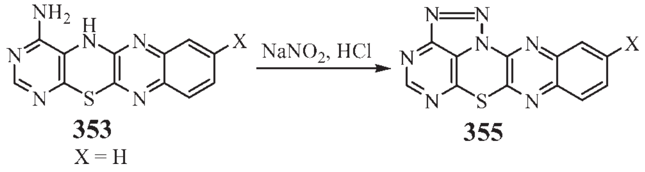
Scheme 130



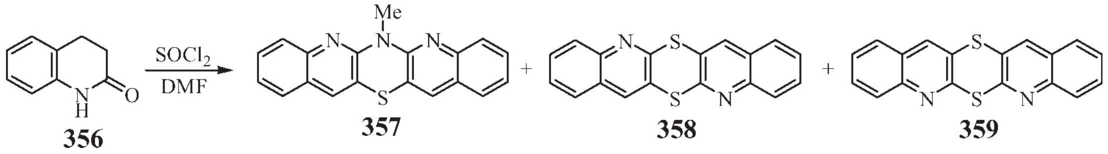
Scheme 131



Scheme 132



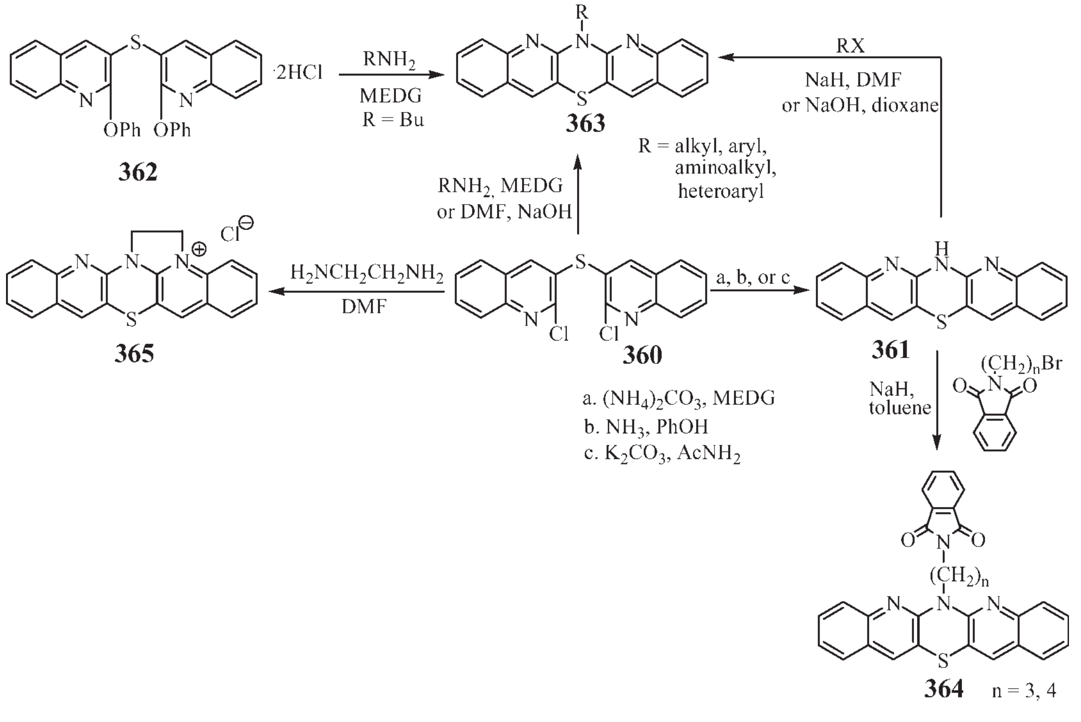
Scheme 133



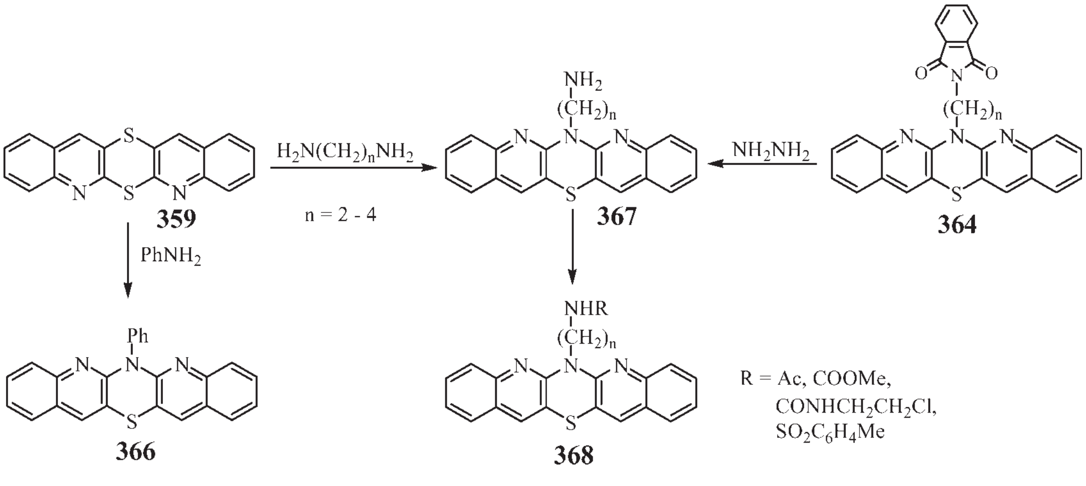
yield) and the isomeric diquinodithiins **358** and **359** (Scheme 133) [136].

Annulation reactions of 2,2′-dichloro-3,3′-diquinolinyl sulfide **360** with ammonium carbonate in MEDG (mono-methyl ether of diethylene glycol) or with gaseous ammonia in phenol or with acetamide (in the presence of potassium carbonate) led to 6*H*-diquinothiazine **361** (the dibenzo derivative of 1,9-diazaphenothiazine) in 10%, 13 and 57% yield, respectively. Further annulation reactions of sulfide **360** with primary aliphatic, aromatic, and heteroaromatic amines in MEDG or with DMF (in the presence of sodium hydroxide) and dihydrochloride of 2,2′-diphenoxy-3,3′-diquinolinyl sulfide **362** (the main product in the reaction of sulfide **360** with ammonia in phenol) with butylamine in MEDG gave various alkyl-, aminoalkyl-, aryl-, and heteroaryldiquinothiazines **363** in low to good yields. The alkyl derivatives were also obtained by alkylation of 6*H*-diquinothiazine **361** with alkyl and aminoalkyl halides in DMF (with sodium hydride) or in dioxane (with sodium hydroxide). Alkylation with phthalimidoalkyl bromides in toluene (with sodium hydride) gave phthalimidoalkyl derivatives **364** in good yields. When 2-chloroethylamine was used, the reaction proceeded through the formation of 2-chloroethyldiquinothiazine which underwent very smoothly intramolecular alkylation to give hexacyclic compound,

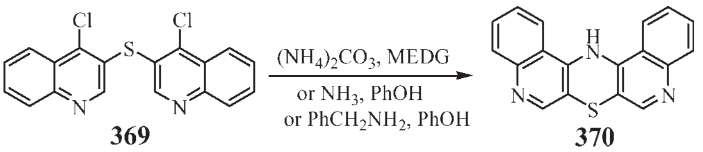
Scheme 134



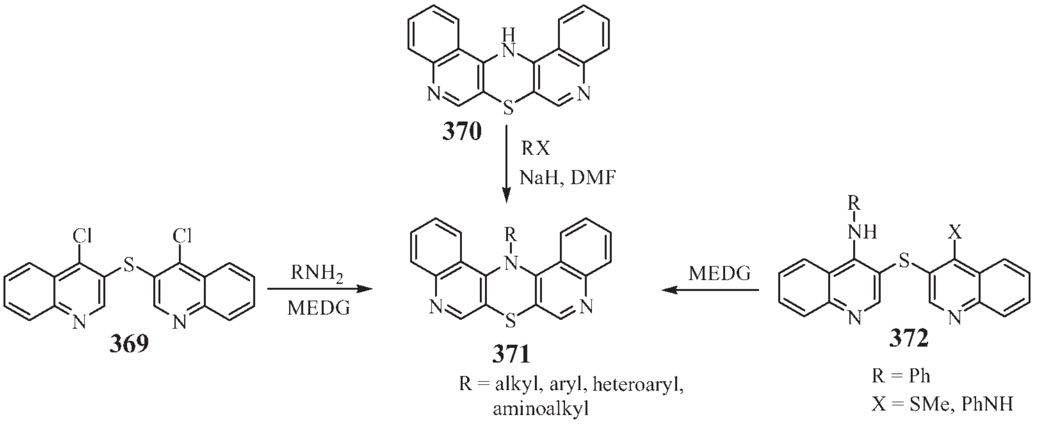
Scheme 135



Scheme 136



Scheme 137



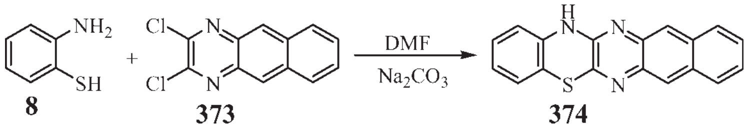
5,6-ethylenediquinothiazinium chloride **365** in 53% yield (Scheme 134) [136–138].

Diquinodithiin **359** turned out to be good substrate in the reaction with aniline and diaminoalkanes to give phenyl and aminoalkyl derivatives **366** and **367** in good yields. The last compounds were also obtained from phthalimidoalkyl derivatives **364** by action of hydrazine. The aminoalkyldiquinothiazines **367** were converted into acyl, sulfonyl, and half-mustard derivatives **368** in 68–90% yield (Scheme 135) [138].

The structures of diquinothiazines were established on the basis of ^{1}H NMR (^{1}H-^{1}H COSY and NOE) spectra and were confirmed by X-ray analysis of the phenyl and 4-nitrophenyl derivatives [137,139]. The diquinothiazine system turned out to be very lipophilic [140,141]. Some selected diquinothiazines exhibited significant anticancer activities against lung, colon, breast, renal and CNS cancers, melanoma and leukemia [138].

Dibenzo derivatives of 3,7-diazaphenothiazines (diquino [3,4-b;4′,3′-e]thiazines). Annulation reactions of 4,4′-dichloro-3,3′-diquinolinyl sulfide **369** with ammonium carbonate in MEDG or with gaseous ammonia in phenol led to 14*H*-diquinothiazine **370** (the dibenzo derivative of 3,7-diazaphenothiazine) in 27 and 65% yield. The same product was formed in 86% yield when benzylamine was used (Scheme 136).

Scheme 138



Further annulation reactions with primary aliphatic, aromatic and heteroaromatic amines in MEDG led to various 14-substituted dibenzodiazaphenothiazines **371**. 14-Alkyl derivatives were also obtained by *N*-alkylation of unsubstituted diquinothiazine **370** with alkyl halides in DMF (with sodium hydride). The phenyl derivative was also formed in cyclization of diquinolinyl sulfides **372** in MEDG (Scheme 137) [142–144].

The structure of dibenzodiazaphenothiazines **371** was based on ^{1}H NMR (^{1}H-^{1}H COSY, NOE) spectra and was confirmed by X-ray analyses of the methyl and phenyl derivatives [145,146].

Naphtho derivative of 1,4-diazaphenothiazine (benzo-[g]quinoxalinobenzo[1,4]thiazine). Reaction of aminobenzenethiol **8** with 2,3-dichlorobenzoquinoxaline **373** led to the pentacyclic naphtho-1,4-diazaphenothiazine **374**, an orange pigment dye (Scheme 138) [132].

CONCLUDING REMARKS

Modification of the phenothiazine structures by substitution of the benzene ring with an azine ring brought over 30 different azaphenothiazine systems. The authors hope that this review will provide the arranged knowledge of the diaza-, triaza-, and tetraazaphenothiazine chemistry and will clarify their nomenclature. The reader should take into account that not all the cited authors were aware of the Smiles rearrangement step and not all the azaphenothiazines were identified unequivocally. Re-emergence of classical phenothiazines in the treatment of various diseases perhaps will pay attention to the synthesis and structure of monoaza-, diaza-, triaza-, and tetraazaphenothiazines as potential biological phenothiazine derivatives.

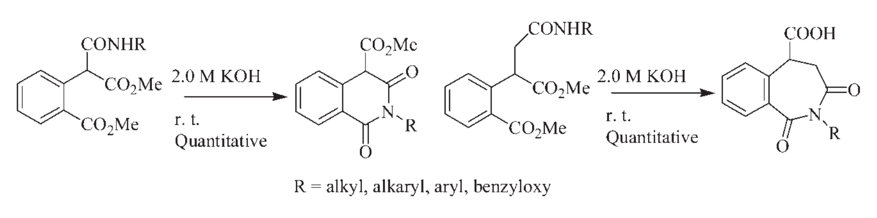
Received September 9, 2008
DOI 10.1002/jhet.52



A series of 4-methoxycarbonylisoquinoline-1,3-diones was obtained from homophthalic acid in four steps. The key step was the quantitative and rapid alkaline cyclization of 2-methoxycarbonyl-2-(2-methoxycarbonylphenyl) acetamides. Homologation easily afforded in the same conditions 5-carboxy-2-benzazepine-1,3-dione.

J. Heterocyclic Chem., **46**, 392 (2009).

INTRODUCTION

4-Substituted isoquinoline-1,3-dione framework may serve as the backbone for the production of several series of biologically active compounds, mainly in the field of diabetes (aldose reductase inhibitors) [1], inflammation [2] (cycloxygenase [3] and lipoxygenase [4] inhibitors), herbicides, and plant growth regulators [5]. Our current research program is devoted to the evaluation of 2-hydroxyisoquinoline-1,3-diones as potential HIV-1 integrase and/or ribonuclease H inhibitors. For that purpose, we needed to develop a facile and efficient route to 4-alkoxycarbonyl-2-benzyloxyquinoline-1,3-diones as precursor of the lead compounds.

Two routes were possible (Scheme 1). The first one consists in synthesizing the 4-unsubstituted isoquinoline-1,3-dione by reaction of a primary amine with homophthalic anhydride, acid or diester (Scheme 1; route a) [1,3,5]. Then functionalization at position 4 is usually performed by reacting the isoquinoline-1,3-dione with a cyanoformate [1], a chloroformate [5], an acylchloride [3], or a sulfonylchloride [3] in presence of a base (pyridine, $LiN(SiMe_3)_2$, NaH or DBU) [1,3,5]. In our hands, the reaction of 2-benzyloxyisoquinoline-1,3-dione with methyl chloroformate in presence of a base (LDA or NaH) allowed us to isolate the desired product only in poor yields, because of a low reactivity and a degradation of the quinoline ring. Alternatively, ortho-halogenated benzoic acids can be converted to a dimethylmalonate derivative by the Hurtley reaction and the treatment with the appropriate amine gives 4-alkoxycarbonyl-isoquinoline-1,3-diones after activation with thionyl chloride (Scheme 1; route b) [1,6,7].

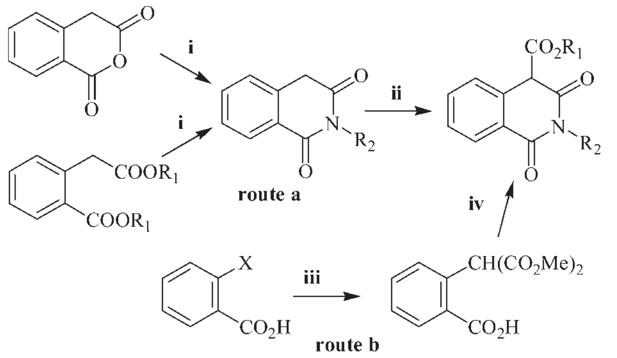
Once again, we could not obtain satisfactorily the cyclized product by this method. We also noticed a third possibility, which consists in treating quinone monoacetals with diethylmalonate in presence of KOtBu. However, to date, only one example using this method has been reported [8].

These failures led us to modify route b by activating a carboxylic acid function of the malonate derivative instead of activating the benzoic acid function. We report herein synthetic studies on this novel four step procedure (Scheme 2). A series of 4-methoxycarbonylisoquinoline-1,3-diones variously substituted at the nitrogen atom was obtained (Table 1).

RESULTS AND DISCUSSION

Homophthalic acid **1** was quantitatively esterified with methylic alcohol. The anion of the homophthalic diester **2** obtained by treatment with LDA reacted with carbon dioxide according to Lazer *et al.* [9] to yield the methyl 2-(2-methoxycarbonylphenyl) malonate monoester **3** in 62% yield. Using activation with the BOP reagent [10], the corresponding amides **4a-h** were synthesized with

Scheme 1. Reagents and conditions: (i) R_2NH_2, DMF, or xylenes; (ii) $ClCOOR_1$, pyridine, or $CNCOOR_1$, $LiN(SiMe_3)_2$, THF; (iii) NaH, CuBr, $CH_2(COOMe)_2$; (iv) $SOCl_2$ then R_2NH_2, THF.



several alkyl, alkylaryl, aryl, benzyloxy amines, and glycine in satisfactory yields (52–85%). The cyclization was easily achieved using 2.5*M* potassium hydroxide in aqueous methanol at room temperature for 5 min. This reaction was quantitative and the 2-substituted-4-methoxycarbonylisoquinoline-1,3-diones **5a-h** were isolated as variable mixtures of keto (0–50%) and enol (50–100%) forms. When the nitrogen atom was substituted by an ethoxycarbonylmethyl group (**4f**, Table 1), hydrolysis of this ethyl ester function occurred during the cyclization process whereas the residual methyl ester of the malonate derivative was conserved. Thus compound **5f** is substituted at position 2 by a carboxymethyl group, which could be variously functionalized (by a peptidic structure for example). Conversely, the carbon-chlorine bond in compound **4g** (Table 1) was found to be resistant to the basic conditions of cyclization.

This easy alkaline cyclization process led us to investigate the possible synthesis of homologous derivatives. For this purpose, homophthalic dimethyl ester **2** was first alkylated with allyl bromide in the presence of LDA (Scheme 3) to give **6**. The allylic oxidation with potassium periodate and potassium permanganate afforded methyl 2-(carboxymethyl)-2-(2-methoxycarbonylphenyl) ethanoate **7** in 63% yield. Using benzyloxyamine as a model, we synthesized the corresponding amide **8** in 42% yield. Cyclization of **8** was of particular interest since it may give either a five-membered ring (1-benzyloxy-3-arylsuccinimide **9**) or a seven-membered ring (a 2-benzazepine-1,3-dione **11**) depending on the reactivity of the two methyl ester functions (Fig. 1). With a 5 min reaction time, a mixture of **10** (80%) and **11** (20%) was obtained. Prolonging the reaction time (15 min) gave only quantitatively the 1,3-dioxo-2-benzazepine-5-carboxylic acid **10**.

To determine the structure of **10**, it was quantitatively converted into **11** using classical esterification

Scheme 2

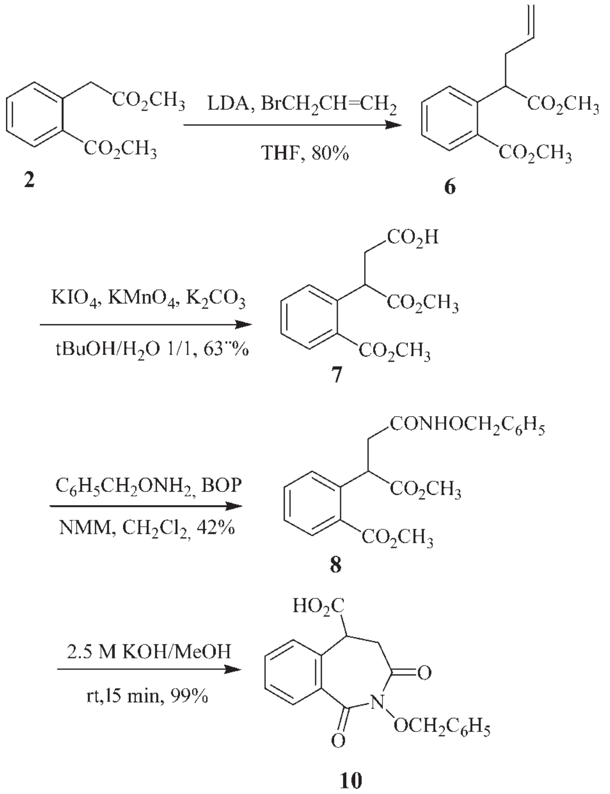
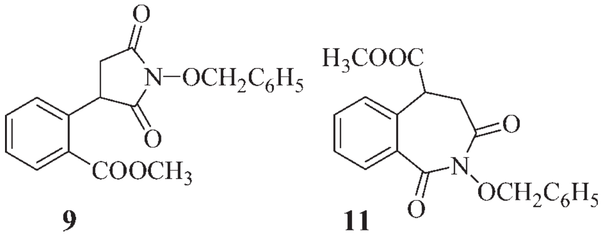
Scheme 3





9 **11**

Figure 1. Possible products from the cyclization of **8**.

conditions. The benzazepine structure of **11** was established on the basis of ^{1}H-^{13}C correlation experiments. Briefly, the CO signal of the ester function (170.6 ppm) can be easily identified *via* the methyl group (3.57 ppm). This CO signal correlated with H-5 (4.23 ppm) which also gave a correlation with carbon 3 (168.5 ppm). On the other side, carbon 1 (161.1 ppm) gave correlations with H-9 and H-8 (8.27 and 7.30 ppm, respectively). The isolation of **10** as a single cyclized product clearly shows that the benzoic ester function of **8** was more reactive than the aliphatic one.

In conclusion, eight 2-substituted-4-methoxycarbonylisoquinoline-1,3-diones (substituents: alkyl, alkylaryl, aryl, benzyloxy, carboxymethylene) have been synthesized in a four-step procedure in overall yields ranging between 29 and 53%. Other alkoxycarbonyl groups may be introduced at position 4 (data not shown). This novel synthetic scheme employs four steps. In terms of yield, the introduction of the carboxylic acid function and the subsequent coupling with an amine are the two limiting steps whereas the two remaining ones are quantitative. In terms of cumulative reaction time, this novel route is undoubtedly more advantageous than route a (Scheme 1) starting from homophtalic acid derivatives, which requires much longer reaction times (4–72 h for the amine condensation and 3–24 h for the subsequent substitution) [1,3,5].

We compared our synthetic scheme to route b. Malamas *et al.* [1] reported the synthesis of **5** (R = CH$_2$-C$_6$H$_4$-oF-pBr) in 78% overall yield. Other analogues were also briefly described without any experimental information about the final cyclization step using variously substituted benzylamines and alkylamines. We compared the two routes for the synthesis of **5a**, **5d**, **5e**, and **5h**. Compounds **5a** and **5d** were synthesized by both methods with similar overall yields around 40%. In contrast our method was better than route b for the synthesis of **5e** and **5h**, which were obtained with 54 and 44% overall yields, respectively while route b failed to give these compounds. Crude residues contained mixtures of byproducts without any trace of the desired cyclized compound. So the two methods are comparable when the R substituent at position 2 is an alkyl or a benzyl group. When this substituent is an aryl or a benzyloxy group, our method is largely superior to route b. But the main advantage of our route over routes a and b lies in the clean, efficient and rapid last cyclization step, which is quantitatively performed within only 5 min reaction time. The homologation showed the better reactivity of the benzoate ester versus the malonate one and led also efficiently to the formation of a 5-carboxy-2-benzazepine-1,3-dione derivative. This route could also be employed and modified to synthesize variously substituted 2-benzazepine-1,3-diones since the elaboration of such compounds have been scarcely investigated. To the best of our knowledge, only diphenimides [11] and a few examples of 2- and 4-substituted derivatives have been so far reported [12,13].

EXPERIMENTAL

Silica gel, 200–400 mesh (Merck) was used for column chromatography. Melting points were obtained on a Reichert Thermopan melting point apparatus, equipped with a microscope. NMR spectra were obtained on an AC 300 Bruker spectrometer in the appropriate solvent with TMS as internal reference. J values are given in Hz. Elemental analyses were performed by CNRS laboratories (Vernaison) and were within 0.4% of the theoretical values.

Methyl 2-(2-methoxy-2-oxoethyl)benzoate (2). Homophtalic acid **1** (5 g, 28.0 mmol) was dissolved in MeOH (100 mL) and thionyl chloride (5.5 mL, 62.0 mmol) was added dropwise. The solution was heated under reflux for 2 h and concentrated *in vacuo*. The residue was dissolved in AcOEt and washed several times with 10% NaHCO$_3$. After drying over Na$_2$SO$_4$, the solvent was evaporated *in vacuo* to yield **2** as a yellow oil (99%). ^{1}H NMR (300 MHz, DMSO-d_6): δ = 3.60 (s, 3H, OCH$_3$), 3.78 (s, 3H, OCH$_3$), 4.00 (s, 2H, CH$_2$), 7.36 (m, 3H, H$_{Ar}$), 7.92 (dd, ^3J = 8.2 Hz, ^4J = 2.0 Hz, 1H, H$_{Ar}$); ^{13}C NMR (75 MHz, DMSO-d_6): δ = 36.7 (CH$_2$), 51.4 (OCH$_3$), 51.8 (OCH$_3$), 127.4 (CH), 129.5 (C), 130.3 (CH), 132.4 (CH), 132.6 (CH), 135.9 (C), 166.9 (CO), 172.4 (CO).

3-Methoxy-2-[2-(methoxycarbonyl)phenyl]-3-oxopropanoic acid (3). A solution of freshly distilled diisopropylamine (0.75 mL, 5.35 mmol) in 10.0 mL of dry THF under an argon atmosphere was cooled to –78°C and 3.34 mL of 1.6*M* *n*-butyllithium (5.35 mmol) was added. After 30 min reaction at –78°C, a solution of **2** (0.79 g, 3.8 mmol) in 10.0 mL of THF was added dropwise. After stirring the solution for 30 min, the temperature had risen to –5°C and the argon inlet was removed. CO$_2$ formed from addition of sulfuric acid on anhydrous barium carbonate was bubbled through the reaction mixture for 20 min. The mixture was acidified with 2.0*M* HCl and then extracted with CHCl$_3$. The combined organic extracts were extracted with 10% Na$_2$CO$_3$. The basic extracts were made acidic by the careful addition of 2.0*M* HCl and the product was extracted into CHCl$_3$ (3 × 100 mL). The combined CHCl$_3$ extracts were dried over Na$_2$SO$_4$. The solvent was removed under reduced pressure to give an oily residue, which crystallized on cooling. Orange solid (0.49 g; 62%); mp 100°C; ^{1}H NMR (300 MHz, CDCl$_3$): δ = 3.75 (s, 3H, OCH$_3$), 3.87 (s, 3H, OCH_3), 5.16 (s, 1H, CH), 7.38 (dd, $^{3}J = 7.7$ Hz, $^{4}J = 1.2$ Hz, 1H, H_{Ar}), 7.44 (td, $^{3}J = 7.7$ Hz, $^{4}J = 1.2$ Hz, 1H, H_{Ar}), 7.57 (td, $^{3}J = 7.7$ Hz, $^{4}J = 1.2$ Hz, 1H, H_{Ar}), 8.07 (dd, $^{3}J = 7.7$ Hz, $^{4}J = 1.2$ Hz, 1H, H_{Ar}), 11.22 (br s, 1H, COOH); ^{13}C NMR (75 MHz, $CDCl_3$): $\delta = 52.5$ (OCH_3), 53.3 (OCH_3), 55.5 (CH), 128.5 (CH), 128.6 (C), 131.3 (CH), 132.3 (CH), 132.9 (CH), 134.4 (C), 167.7 (CO), 170.6 (CO), 170.8 (CO).

Methyl 2-{1-[(4-fluorobenzyl)amino]-3-methoxy-1,3-dioxopropan-2-yl}benzoate (4a). BOP (1.69 g, 4.0 mmol) was added to an ice-cooled solution of **3** (1.00 g, 4.0 mmol), 4-fluorobenzylamine (0.50 g, 4.0 mmol) and 4-methylmorpholine (2.2 mL, 20.0 mmol) in a minimum of CH_2Cl_2. After 30 min stirring at 0°C and 3 h at room temperature, the mixture was washed with 1.0*M* HCl, 1.0*M* $NaHCO_3$ solutions and brine. The organic layer was dried over Na_2SO_4 and concentrated *in vacuo*. After column chromatography of the residue (eluent: petroleum ether/AcOEt, 70/30 then 50/50), the product was obtained as beige crystals (52%); mp 127°C; ^{1}H NMR (300 MHz, $CDCl_3$): $\delta = 3.59$ (s, 3H, OCH_3), 3.72 (s, 3H, OCH_3), 4.25 (dd, $^{2}J = 14.9$ Hz, $^{3}J = 6.0$ Hz, 1H, CH_2), 4.32 (dd, $^{2}J = 14.9$ Hz, $^{3}J = 6.0$ Hz, 1H, CH_2), 5.20 (s, 1H, CH), 6.85 (t, $^{3}J = 8.4$ Hz, 2H, H_{Ar}), 7.08 (dd, $^{3}J = 8.8$ Hz, $^{4}J = 5.4$ Hz, 2H, H_{Ar}), 7.29 (td, $^{3}J = 7.5$ Hz, $^{4}J = 2.0$ Hz, 1H, H_{Ar}), 7.40–7.50 (m, 2H, H_{Ar}), 7.64 (t, $^{3}J = 5.3$ Hz, 1H, NH), 7.87 (dd, $^{3}J = 7.6$ Hz, $^{4}J = 1.2$ Hz, 1H, H_{Ar}); ^{13}C NMR (75 MHz, $CDCl_3$): $\delta = 42.7$ (CH_2), 52.2 (OCH_3), 52.5 (OCH_3), 55.1 (CH), 115.1 (d, $^{2}J = 21.4$ Hz, 2CH), 127.8 (CH), 128.8 (C), 129.0 (d, $^{3}J = 8.3$ Hz, 2CH), 130.6 (CH), 131.6 (CH), 132.5 (CH), 133.9 (d, $^{4}J = 3.3$ Hz, C), 135.5 (C), 161.8 (d, $^{1}J = 243.3$ Hz, C), 167.3 (CO), 168.0 (CO), 170.1 (CO); *Anal.* Calc for $C_{19}H_{18}FNO_5$: C, 63.50; H, 5.05; O, 22.26. Methyl 2-(1-methoxy-1-oxopent-4-en-2-yl)benzoate (6). A solution of freshly distilled diisopropylamine (0.75 mL, 5.35 mmol) in 10.0 mL of dry THF under an argon atmosphere was cooled to –78°C and 3.34 mL of 1.6*M* *n*-butyllithium (5.35 mmol) in THF was added. After 20 min reaction at –78°C, a solution of **2** (0.79 g, 3.8 mmol) in 10.0 mL of THF was added dropwise. After stirring the solution for 30 min at –78°C, allyl bromide (0.66 mL, 7.6 mmol) was added dropwise. Stirring was pursued 1 h at –78°C and then 1 h at room temperature. The reaction was quenched with NH$_4$Cl and the solution was extracted several times with ether. The combined organic layers were dried over Na$_2$SO$_4$ and concentrated *in vacuo*. The residue was purified by column chromatography (eluent: petroleum ether/AcOEt, 80/20) to give **6** as an orange oil (80%); ^{1}H NMR (300 MHz, CDCl$_3$): $\delta = 2.39$ (m, 1H, CH$_2$), 2.71 (m, 1H, CH$_2$), 3.45 (s, 3H, OCH$_3$), 3.70 (s, 3H, OCH$_3$), 4.60 (t, $^3J = 7.6$ Hz, 1H, CH), 4.81 (dd, $^3J = 10.8$ Hz, $^2J = 2.0$ Hz, 1H, CH), 4.88 (dd, $^3J = 17.5$ Hz, $^2J = 2.0$ Hz, 1H, CH), 5.54–5.74 (m, 1H, CH), 7.12 (td, $^3J = 7.8$ Hz, $^4J = 1.5$ Hz, 1H, H$_{Ar}$), 7.28 (m, 2H, H$_{Ar}$), 7.75 (dd, $^3J = 7.7$ Hz, $^4J = 1.2$ Hz, 1H, H$_{Ar}$); ^{13}C NMR (75 MHz, CDCl$_3$): $\delta = 37.2$ (CH$_2$), 46.5 (CH), 51.4 (OCH$_3$), 51.6 (OCH$_3$), 116.4 (=*C*H$_2$), 126.6 (CH), 128.4 (CH), 129.3 (C), 130.3 (CH), 131.8 (CH), 135.1 (C), 139.6 (C), 167.2 (CO), 173.3 (CO); *Anal.* Calc for $C_{14}H_{16}O_4$: C, 67.73; H, 6.50; O, 25.78. Found: C, 67.95; H, 6.28; O, 25.59.

4-Methoxy-3-[2-(methoxycarbonyl)phenyl]-4-oxobutanoic acid (7). To **6** (1.6 g, 6.0 mmol) in *t*-BuOH (10.0 mL) was added a solution of K$_2$CO$_3$ (2.49 g, 18.0 mmol) in H$_2$O (20 mL). To the resulting mixture were added KIO$_4$ (4.14 g, 18.0 mmol) and KMnO$_4$ (0.66 g, 4.2 mmol). After stirring for 1 h at room temperature, the mixture was extracted with AcOEt and this organic layer was discarded. The aqueous layer was acidified with concentrated HCl solution and again exhaustively extracted with AcOEt. The combined organic layers were dried over Na$_2$SO$_4$ and evaporation of the solvent *in vacuo* gave an oil which crystallized on standing. The obtained beige crystals were carefully rinsed with ether (63%); mp 144°C; ^{1}H NMR (300 MHz, CDCl$_3$): $\delta = 2.80$ (dd, $^2J = 17.4$ Hz, $^3J = 5.0$ Hz, 1H, CH$_2$), 3.25 (dd, $^2J = 17.3$ Hz, $^3J = 9.2$ Hz, 1H, CH$_2$), 3.69 (s, 3H, OCH$_3$), 3.91 (s, 3H, OCH$_3$), 4.99 (dd, $^3J = 9.2$ Hz, $^3J = 5.0$ Hz, 1H, CH), 7.28–7.39 (m, 2H, H$_{Ar}$), 7.50 (td, $^3J = 7.5$ Hz, $^4J = 1.3$ Hz, 1H, H$_{Ar}$), 7.97 (dd, $^3J = 7.9$ Hz, $^4J = 1.5$ Hz, 1H, H$_{Ar}$), 9.58 (br s, 1H, OH); ^{13}C NMR (75 MHz, CDCl$_3$): $\delta = 37.6$ (CH$_2$), 44.1 (CH), 52.3 (OCH$_3$), 52.4 (OCH$_3$), 127.6 (CH), 129.1 (CH), 129.2 (C), 131.2 (CH), 132.7 (CH), 139.0 (C), 167.6 (CO), 173.4 (CO), 177.7 (CO); *Anal.* Calc for $C_{13}H_{14}O_6$: C, 58.64; H, 5.30; O, 36.06. Found: C, 58.87; H, 5.18; O, 36.25.

Methyl 2-{4-[(benzyloxy)amino]-1-methoxy-1,4-dioxobutan-2-yl}benzoate (8). Same method as for the preparation of **4a**. Yellow oil (42%). ^{1}H NMR (300 MHz, CDCl$_3$): $\delta = 2.48$

(dd, ^2J = 15.1 Hz, ^3J = 5.9 Hz, 1H, CH_2), 2.94 (dd, ^2J = 15.1 Hz, ^3J = 7.8 Hz, 1H, CH_2), 3.53 (s, 3H, OCH_3), 3.77 (s, 3H, OCH_3), 4.69 (d, ^2J = 11.1 Hz, 1H, OCH_2), 4.76 (d, ^2J = 11.1 Hz, 1H, OCH_2), 4.99 (t, ^3J = 6.9 Hz, 1H, CH), 7.20–7.30 (m, 7H, H_{Ar}), 7.39 (td, ^3J = 7.5 Hz, ^4J = 1.3 Hz, 1H, H_{Ar}), 7.86 (dd, ^3J = 7.9 Hz, ^4J = 1.5 Hz, 1H, H_{Ar}), 9.47 (s, 1H, NH); ^{13}C NMR (75 MHz, $CDCl_3$): δ = 35.9 (CH_2), 44.5 (CH), 51.7 (OCH_3), 51.8 (OCH_3), 77.5 (OCH_2), 127.0 (CH), 127.9 (2CH), 128.0 (CH), 128.8 (2CH), 128.8 (C), 129.7 (CH), 130.7 (CH), 132.1 (CH), 135.1 (C), 138.9 (C), 167.3 (CO), 168.3 (CO), 173.0 (CO); *Anal.* Calc for $C_{20}H_{21}NO_6$: C, 64.68; H, 5.70; O, 25.85. DOI 10.1002/jhet.25

Racemic thioflavanone (thio)acylhydrazones undergo transformation into *racemic* 3-acetylspiro[1,3,4-oxa(thia)-diazoline-2,4′-thioflavans] with *trans* O(1) or S(1) and Ph(2′eq) under acetylating conditions. Conjugation between the ethylenic bond and sp^2 C(4) in thioflavones encumber both the formation of (thio)acylhydrazones and their subsequent spirocyclization. On the other hand, subsequent dehydrogenation of the thiopyran moiety of spiro compounds results in formation of sp^2 C(4) and simultaneous degradation of the spirodiazoline ring.

J. Heterocyclic Chem., **46**, 399 (2009).

INTRODUCTION

A great variety of natural benzopyrans, *e.g.*, chrom(an)ones, flav(an)ones, exhibit biological activity and have beneficial effects as free radical scavengers, antioxidants, CNS active agents, aldose reductase inhibitors [1], aromatase inhibitors [2], *etc*. Some synthetic (halogenated, nitro) derivatives have significant anxiolytic properties [3]. Carbonyl condensation products, *e.g.*, oximes [4], imines [5], acyl hydrazones, thiosemicarbazones [6] have been reported to display antimicrobial and estrogen receptor activities, respectively. Also flavone-related, naturally occurring 2-arylquinolines [7] and antimitotic 2-phenylquinolones [8] are known.

Recently, also the chemistry and the biological properties of the bioisosteric thioflavonoid compounds [9], including (spiro)heterocyclic derivatives [10], excite increasing interest. Thiochrom(an)ones and thioflav(an)ones as well as their 1-oxides and 1,1-dioxides have been reported to have antimicrobial [11], antiviral [12], and antitumor [8,9c,13] properties. The synthesis and herbicidal properties of benzothiopyran-4-one hydrazones [14a] and related cyclic *O*-*O*-acetals spiro[benzothiopyran-4,2′-dioxolanes] [14b] have been described, as well.

Formerly, we have observed that under physiological conditions the potentially biological active cyclic *N*,*O*- and *N*,*S*-acetals 3-acetyl-1,3,4-oxa(thia)diazolines undergo deacetylation and transform into (thio)acylhydrazones [15]. Therefore, in consideration of the aforementioned literature findings, as an extension of our examinations for the synthesis of 2-phenyltetrahydroquinoline (**5j**) [16] and flavanone-spiro-oxa(thia)diazolines (**5k**, **l**) [17a], respectively, we aimed at the synthesis of their bioisosteric spiro-thioflavonoid analogs [17b].

RESULTS AND DISCUSSION

As potential substrates for cyclization into oxa(thia)-diazolines **5a–i** under acetylating conditions, hydrazone derivatives **3** and **4** of thioflav(an)ones **1** and **2** were prepared from the corresponding carbonyl parent compounds **1** and **2**, respectively, by known methods (see Table 3 and Experimental section).

In comparison with aryl aralkyl ketones due to electronic (*e.g.*, conjugative) effects aryl vinyl ketones exhibit a diminished reactivity toward carbonyl condensation agents. This is markedly valid for the cyclic analogs (thio)flavones [18], capable of resonance between contributing (thio)benzopyrylium dipole structures. Moreover also the oxidation state of sulfur in these unsaturated compounds (*e.g.*, **2a–c**) affects reactivity [19]. Nevertheless, analogously to the synthesis of flavone (acyl)hydrazones [18a,b] thioflavone hydrazone (**4a**) has been successfully produced [19b,c] by condensing hydrazine with thioflaven-4-thione [20] or its derivative 4-methylthioflavylium iodide [19b], instead of thioflavone (**2a**).

As to the conjugation between the sp^2 C(4) and the C═C bond of the thioflaven ring, similarly to that previously found [17a] for the flavone analogs, this encumbered not only the formation of (thio)acylhydrazones but also their subsequent cyclization into spiro(thia)oxadiazolines. On the other hand, devoid of a chance for conjugation, dehydrogenation of the thiopyran ring of the spiroheterocycles **5** became difficult in comparison with that of the thioflavanone parent compound (**1a**) [21], nevertheless when eventually performed, it led to the cleavage of the diazoline rings with transformation of the spiro-C into the sp^2 hybrid state (C(4)═O,N). Therefore, the mutual action of the hybrid electron orbital states of C(4) and C(2), C(3) carbons was studied experimentally in detail with the (trans)formation of spirocompounds **5** and their precursors (acyl)hydrazones **3**, **4**, and related compounds as well.

Spirocyclization of *racemic* thioflavanone (thio)acylhydrazones **3** into spiro(thia)oxadiazolines **5a–e** was accomplished (see Table 4) in good yields by using acetylating agents Ac_2O/py or $Ac_2O/ZnCl_2$ previously successfully applied [16,17,21] for (spiro)cyclization of various ketone (thio)acylhydrazones. As a result of the heterocyclization, C(4) of the thiopyran ring became sp^3 hybridized and asymmetric, thus theoretically enabling the formation of *racemic* 2,4-diastereomers. Newly spirothiadiazolines **5c**,**d**,**e** with trans S(1) and Ph($2'_{eq}$) structures were stated to form HPLC separable isomers in solution due to a hindered rotation of the endocyclic N(3)Ac group [17b] (Scheme 1). Recently, the stereostructure of 3-acetylspiro[1,3,4-oxadiazoline-2,4′-thioflavan] (**5a**) and 3-acetylspiro[1,3,4-thiadiazoline-2,4′-thioflavans] (**5c**,**d**,**e**), prepared likewise under acetylating conditions, has been stated by ^{1}H- and ^{13}C NMR, as well as X-ray analytical methods and MOPAC QM calculations to have *trans* O(1) or S(1) and Ph($2'_{eq}$) [17b]. The "anomalous" ^{1}H NMR spectra (remarkable downfield shift of signals H($3'_{ax}$), attributed to the anisotropy

effect of the near *N*(3)Ac C=O group) are observed also in the present work (Tables 1 and 2) confirming the analogous stereostructure of spiro products **5a**,**b**,**f–i**. Treatment of semicarbazone **3d** with $Ac_2O/ZnCl_2$ at room temperature for **3d** afforded oxadiazoline **5a** (Scheme 2) but with Ac_2O/py at 100°C for 3 h **5a** and diacetylhydrazone **3c**. Similarly, on treatment with Ac_2O/py at 145°C (bath) for 45 min phenylthiosemicarbazone **3f** underwent transformation to give thiadiazoline **5e** (mp 192–194°C, from EtOAc) and oxadiazoline **5a** (mp 210.5–212°C, from $CHCl_3$/EtOAc), after purification by column chromatography, in 60 and 6% yields, respectively [17b]. The degradation of semicarbazones [23] and thiosemicarbazones [17a,23a,c] under acylating conditions is well documented. By treatment with Ac_2O/$ZnCl_2$ at room temperature, thioflavanone acetylhydrazone (**3b**) was transformed into spiro-oxadiazoline **5a** (see Scheme 2 and Table 4). Under similar conditions, however, semicarbazone 1,1-dioxide **3h** resisted cyclization and also degradation to the corresponding acetylhydrazone, instead acetylsemicarbazone **3i** was formed (Scheme 3), 200 MHz ^1H NMR(DMSO-d_6, δ, ppm): 11.53 and 10.75, 2 brs, 2H, 2NH; 2.14, s, 3H, Ac. Attempted syntheses of **5h** and **5j** by treating **3h** and **3g**, respectively, with Ac_2O/pyridine at 100°C for 3 h resulted in the formation of multicomponent mixtures.

Thus, the tendency for spiro-cyclization seems to be diminished or even ceased by the presence of strong electron-withdrawing components at position 1. Therefore, the synthesis of spiro-oxadiazoline 1′-oxides and 1′,1′-dioxides was attempted by oxidation of the corresponding spirothioflavans. Hot $NaIO_4$/aq. 2-PrOH (substrate/oxidant ratio, 1:4) has been reported [24] to transform thioflavanone (**1a**) into thioflavone 1,1-dioxide (**2c**). Presumably due to the absence of a sp^2 hybridization at position 4, under similar conditions (mole ratio 1:8) spiro-oxadiazoline **5a** was transformed, without dehydrogenation, into a mixture of the corresponding 1′-oxide **5f** and 1′,1′-dioxide **5h**. The selective syntheses of sulfoxides **5a**→**5f** and **5b**→**5g** were accomplished by treatment with $NaIO_4$/aq. 2-PrOH or with dimethyldioxirane generated *in situ* by potassium peroxymonosulfate ($2\ KHSO_5 \cdot KHSO_4 \cdot K_2SO_4$) in aq. Me_2CO. Potassium permanganate oxidation of spiro-oxadiazoline **5a**,**b** afforded the corresponding sulfones **5h**,**i** in very good yields (see Scheme 4 and Experimental section).

The effect of a C(2)=C(3) unsaturation and also that of the oxidation state of sulfur in the benzo heterocycle

Table 2

200 MHz ^1H NMR($CDCl_3$) data of 5-substituted 3-acetylspiro[1,3,4-oxadiazoline-2,4′-thioflavans] as well as 1′- and 1′,1′-oxides **5a,b,f–i**.

[a] The $H(3'_{ax})$ signals of spiro compounds are downfield shifted in comparison with those of hydrazones **3** (cf. Table 1). This can be attributed to the carbonyl neighbouring anisotropy effect of Ac(3) [17b].

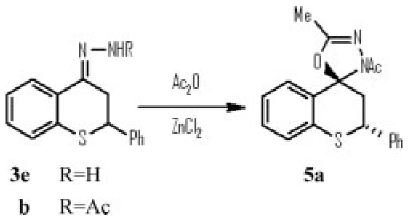
Scheme 2



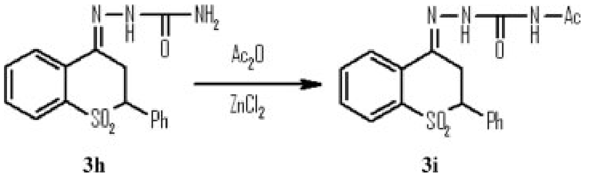
could be well demonstrated. Thus, though treatment with Ac_2O/py at 100°C has been reported [17a] to transform flavone thiosemicarbazone into the corresponding diacetylhydrazone, a similar treatment of thioflavone thiosemicarbazone (**4d**) afforded (see Experimental section) spirothiadiazoline **6** and diacetylhydrazone **4c** in 56 and 18% yields, respectively. However, on treatment with Ac_2O/py even under milder conditions (see Experimental section), thioflavone 1,1-dioxide thiosemicarbazone (**4e**) was degraded to acetylhydrazone **4f** in 69% yield and no 3-acetyl-5-acetylaminospiro[1,3,4-thiadiazoline-2,4′-thioflaven] 1′,1′-dioxide could be isolated (Scheme 5).

As an alternative rout for preparing spiro[oxa(thia)-diazoline-2,4′-thioflavens] the dehydrogenation of the corresponding thioflavan analogs **5** was investigated. The powerful one-electron acceptor oxidant CAN is known [24,25] to dehydrogenate thioflavanone (**1a**) to thioflavone (**2a**) readily at room temperature. However, for transforming spirothioflavans **5** into the corresponding thioflaven analogs, CAN turned out to be unsuitable as this agent transformed **5b** into thioflavone (**2a**) with simultaneous degradation of the spiro-oxadiazoline moiety (see Scheme 6 and Experimental section). This early experience prompted us to investigate the dehydrogenation of thiopyran [21,24,22] and that of the *N*,*S*-acetal 1,3,4-thiadiazoline [26] or *N*,*O*-acetal 1,3,4-oxadiazoline [27] systems separately, by using various types of oxidants and dehydrogenating agents of diverse mechanisms of action. Also the attempts for dehydrogenating the thiopyran ring of spirocompound **5** by iodobenzene 1,1-diacetate (IBDA, (diacetoxyiodo)-benzene) or 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) produced unsatisfactory results. After treating spiro-oxadiazoline **5a** with IBDA for preserving the diazoline moiety at room temperature in AcOH for 7 d or in MeOH for 14 d the substrate could be recovered in *ca.* 60% yield. Moreover, reaction of spiro-oxadiazoline **5b** with hot DDQ/dioxane/TsOH led to the formation of a mixture comprising substrate **5b** and degradation product thioflavone **2a**.

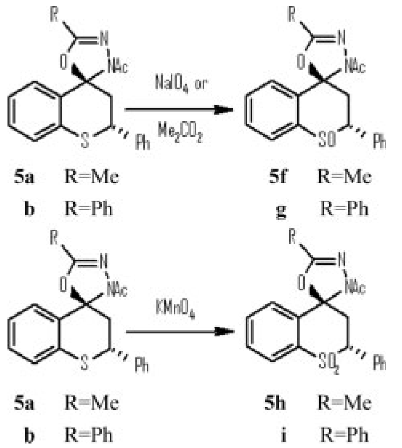
For dehydrogenation of the benzoheterocycle, in comparison with flavanones, as an additional reaction rout is known the transformation of thiochromanone 1-oxides (*e.g.* **1b**) into thiochromones (*e.g.* **2a**) in alkaline solution [28,19b] or under Pummerer-type reaction conditions [29,19b,25b]. Thus, treatments with Ac_2O/TsOH or Ac_2O/dimethylaminopyridine (DMAP) have been reported [22b] to transform **1b** into **2a**, but with the Ac_2O/Et_3N couple *via* cleavage of the thiopyran ring, into disulfide **7** (Scheme 6).

On the basis of these findings, the dehydrogenation of spirocompounds **5** (X = S) to the corresponding spirothioflavens *via* transformation of the spirothioflavan 1-oxides (X = SO) under acetylating conditions in the presence of acid or base (nucleophilic) catalysts, hence under circumstances successfully applied just for the

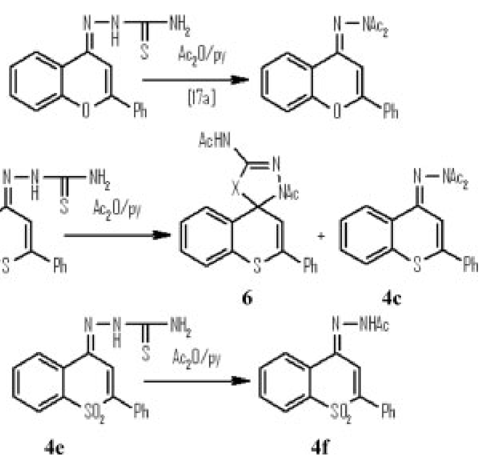
Scheme 3



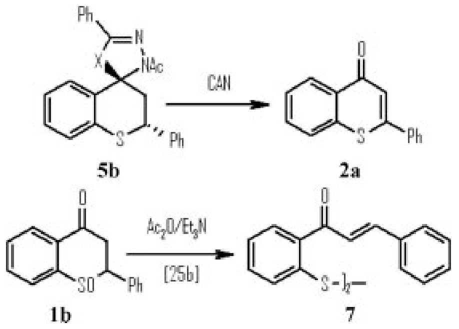
Scheme 4



Scheme 5



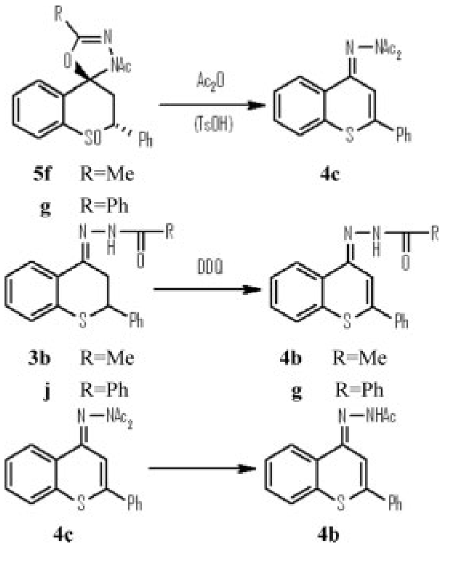
Scheme 6



spirocyclization, seemed to be feasible. However, presumably due to the lack of a sp^2 C(4) moiety similar treatments of sulfoxide **5f** with Ac_2O/Et_3N at room temperature for 48 h and that of **5g** with the Ac_2O/DMAP couple at room temperature for 72 h or with Ac_2O/py at 100°C for 22 h were found to be ineffective and the unchanged substrates could be recovered in 78, 90, and 67% yields, respectively. Treatment with Ac_2O/(TsOH) transformed spirothioflavan 1′-oxides, both **5f** and **5g**, into thioflavone diacetylhydrazone (**4c**) with cleavage of the oxadiazoline ring and a subsequent transacetylation, respectively (see Experimental section); thus, 2,3-dehydrogenation of the benzothiopyran ring was accompanied by a sp^3→sp^2 change at C(4) (Scheme 7).

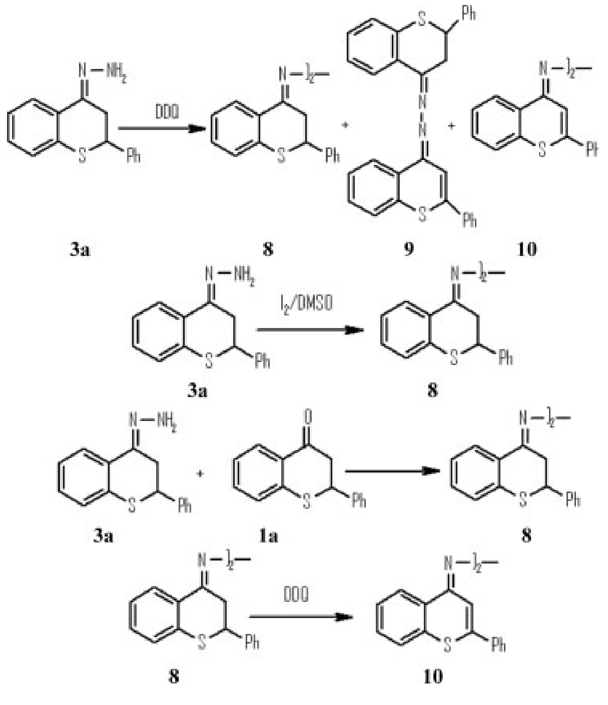
Owing to the unsatisfactory results with the dehydrogenation of spirocompounds **5**, also similar transformation of their nitrogen-containing precursors thioflavanone (acyl)hydrazones (**3**) with sp^2 C(4) was investigated. Treatment with DDQ dehydrogenated acylhydrazones **3b**,**j** to acetylhydrazone **4b** (prepared also by partial deacetylation of diacetylhydrazone **4c**, see Experimental section) and benzoylhydrazone **4g**, respectively, in very good yields, but it converted thiosemicarbazone **3e** in dioxane solution to give a multicomponent mixture. Reaction with DDQ transformed hydrazone **3a** into the corresponding azine **8** as well as its partially and fully dehydrogenated derivatives **9** and **10**, respectively. Azine **8** was obtained also by treating hydrazone **3a** with I_2/DMSO or by condensing hydrazone **3a** with thioflavanone (**1a**). DDQ dehydrogenation of azine **8** afforded azine **10** in 80% yield (see Scheme 8 and Experimental section). Attempts for dehydrogenating azine **8–10** by treatment with hot $NaIO_4$/aq. dioxane or hot IBDA/MeOH (or dioxane) were unsuccessful as in these cases very complex mixtures of products were formed. Hypervalent iodine oxidation of hydrazine [30] to the reductive, instable diimide and that of aromatic hydrazones to azines [31] have been reported already.

Scheme 7

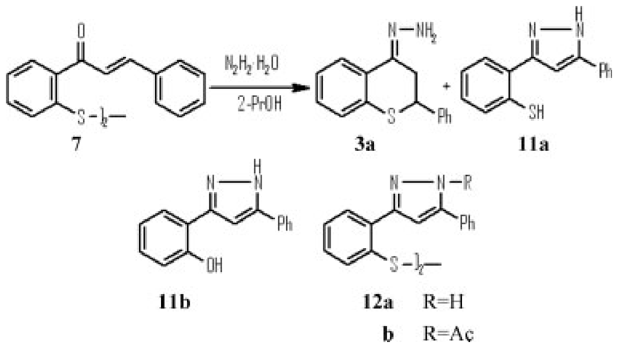


The synthesis of thioflavanone hydrazones [19b] (*e.g.*, by boiling thioflavanone **1a** with $N_2H_4 \cdot H_2O$/EtOH to give the corresponding hydrazone **3a**) is a clear-cut reaction. Because of a reversible flavanone (**1d**) ⇌ 2′-hydroxychalcone (2-cinnamoyl-phenol, 2-hydroxyphenyl styryl ketone) transformation, on treatment with hydrazine flavanone undergoes reaction, depending on the reaction conditions, to give the corresponding hydrazone and 3-(2-hydroxyphenyl)-5-phenyl-4,5-dihydropyrazole, respectively [32a,b,18e]. An analogous treatment of flavone (**2d**) with hydrazine or the thermal rearrangement of flavone hydrazone has been reported to afford the

Scheme 8



Scheme 9



corresponding pyrazole derivative **11b** [32b,18e]. As a result of the special electron shell structure the more pronounced nucleophilicity and the conjugative interaction of sulfur [19] within the heterocycle may appear in some characteristic properties of the molecule, thus extending our synthetic works with (thio)flavonoids [16,17a,21,24,22a] we (re)examined the reaction between thioflavone and hydrazine. Recently we have found [33] that the treatment of thioflavone (**2a**) with $N_2H_4 \cdot H_2O$ in hot 2-PrOH leads to the formation of 3-(2-mercaptophenyl)-5-phenylpyrazole (**11a**) which by a subsequent spontaneous oxidation in a $CHCl_3$ solution affords disulfide **12a**. (It is well known that the oxidation of alkyl- and arylthiols by molecular oxygen to disulfides may be catalyzed by aliphatic amines or alkali hydroxides [34].) As due to the possibility for a prototropic change, the structure of pyrazoles [35] with aromatic substituents cannot be unequivocally elucidated by IR and NMR spectrometry, this has been carried out [33] eventually by a MALDI-TOF mass spectrometric study of the acetyl derivative **12b**.

In connection with our previous findings [22b] that heterolysis of disulfide **7** leads to the formation of thioflavanone (**1a**) and 2-benzylidenebenzo[*b*]thiophen-3(2*H*)-one (thioaurone) we attempted the transformation of disulfide **7** with $N_2H_4 \cdot H_2O$/2-PrOH to obtain the 4,5-dihydro analogs of **11a** or **12a**. However, this reaction afforded thioflavanone hydrazone (**3a**) and pyrazole **11a** which was isolated as disulfide **12a** (see Scheme 9 and Experimental section).

CONCLUSION

Thioflavanone (thio)acylhydrazones transform into 3-acetylspiro[1,3,4-(thia)oxadiazoline-2,4′-thioflavans] with trans S(l) or O(l) and Ph($2'_{eq}$) under acetylating conditions. The presence of 2,3-unsaturation or oxidation of sulfur of thioflav(an)one render more difficult both the synthesis of (thio)acylhydrazones and the subsequent spirocyclization. Additional 2′,3′-dehydrogenation of the spirocompounds with various dehydrogenating agents had no result or was accompanied by degradation of the spirodiazoline ring with a simultaneous $sp^3 \rightarrow sp^2$ change at C(4).

EXPERIMENTAL

Melting points (uncorrected): Kofler block. Solutions were concentrated under reduced pressure in a rotary evaporator (<50°C, bath), TLC: Kieselgel 60 F_{254} (Merck, Alurolle). IR (KBr disks): Perkin-Elmer 16 PC-FT spectrometer. 200 MHz ^{1}H- and 50 MHz ^{13}C NMR: Bruker WP 200 SY, 360 MHz ^{1}H- and 90 MHz ^{13}C NMR: Bruker AM 360 spectrometer; for recording the ^{13}C spectra, *J*-echo techniques were used.

General operations of processing the reaction mixtures (see Tables 3 and 4). (**A**) The product was collected by filtration in the cold. (**B**) The cold mixture was poured into ice-water. (**C**) A solution of the product in $CHCl_3$ was treated with fuller's earth and charcoal and then concentrated. (**D**) For decomposing the excess of BzCl, drop-by-drop water (1.25 mL) was added with cooling and stirring and the mixture was kept at room temperature for 1 h. (**E**) The mixture was concentrated. (**F**) The residue was triturated with MeOH in the cold. (**G**) The residue was triturated with water in the cold.

Dehydrogenation of thioflavanone (1a) by $PhI(OAc)_2$ to 2a. A solution of **1a** (0.120 g, 0.5 mmol) and $PhI(OAc)_2$ (0.247 g, 0.75 mmol) in MeOH (5 mL) was kept at room temperature for 12 d and then concentrated (finally at *ca.* 1 Torr). A solution of the residue in MeOH (0.5 mL) deposited on seeding TLC homogeneous and with an authentic compound identical thioflavone (**2a**, 0.082 g, 68.6%; when reacted at boiling for 2 d, in a sixfold scale, a 86.2% yield has been observed [21]), mp 125.5°C.

Thioflavone acetylhydrazone (4b). (**a**) A mixture of thioflavanone acetylhydrazone (**3b**, 0.371 g, 1.25 mmol), DDQ (0.307 g, 1.32 mmol, 98%), anhydrous dioxane (12 mL), and a catalytic amount of *p*-toluenesulphonic acid (TsOH) was boiled with stirring for 24 h, then cooled to give a solid (0.597 g, a mixture of **4b** and $DDQH_2$), which when stirred with aq. $NaHCO_3$ in excess, in the presence of some 2-PrOH as a humidifier, afforded undissolved title acetyl-hydrazone **4b** (0.250 g, 68%), mp 256–257°C.

(**b**) A mixture of diacetylhydrazone **4c** (0.168 g, 0.5 mmol), MeOH (10 mL) and pyridine (2 drops) was boiled with stirring for 6 h to give, on cooling, acetylhydrazone **4b** (0.131 g, 89%), mp 257.5°C. A similar partial deacetylation was observed during purification of **4c** by CC [Kieselge1 60, Merck; $CHCl_3$/EtOAc (95:5)], when **4b**, mp 258°C was isolated. IR(KBr, ν, cm^{-1}): 1666 (s, Amide-I). ^{1}H NMR(200 MHz, DMSO-d_6, δ, ppm): 11.17 (s, 0.7 H, NH) and 10.79 (s, 0.3 H, NH) presumably due to an *E*/*Z* isomerism, 8.33–8.25 (m, 1 H, H(5)), 7.90–7.78 (m, 2 H, H—Ar), 7.61 (s, 1 H, H(3)), 7.58–7.43 (m, 6 H, H—Ar), 2,29 (s, 2.1 H, 0.7 Ac) and 2.07 (s, 0.9 H, 0.3 Ac). *Anal.* Calcd. for $C_{17}H_{14}N_2OS$ C, 69,4; H, 4.8; N, 9.5; S, 10.9. Found: C, 69.3; H, 4.8; N, 9.6; S, 11.0.

Thioflavone thiosemicarbazone (4d). A mixture of thioflavone (**2a**, 10.008 g, 42 mmol), powdered thiosemicarbazide (6.000 g, 65.8 mmol), MeOH (100 mL), and conc. HCl (1 mL, 11.7 mmol) was boiled with stirring for 65 h and then cooled.

[a] The C, H, N, and S analyses date for the products are agreeing with the theoretical values within ± 0.3–0.4% limit.

[b] Bath if not bp.

[c] For general operations of processing the reaction mixtures see Experimental.

[d] Without workup of the mother liquors if not stated otherwise.

[e] To a solution of **3a** in pyridine was added Ac_2O dropwise with cooling and stirring during 10 min.

[f] Anhydrous.

[g] TLC homogeneous.

[h] Mp 242°C.

[i] The mixture was stirred at least until the dissolution was complete.

[j] To give spiro compound isomer **5a** see also Table 4. The $CHCl_3$ mother liquor was concentrated and the residue stirred with PhH at room temperature to extract **3c**, IR (KBr, v, cm^{-1}); 1725 (s), 1689 (s), 1652 (m), 1610 (s).

[k] TLC ($CHCl_3$/MeOH(9:1)) homogeneous; mp 253–254°C, ref. [19b] 245–247°C (EtOH); the sample was a generous gift of J Bálint Ph.D and prepared [19b] by boiling a mixture of thioflavanone 1,1-dioxide (**1c**), semicarbazide hydrochloride (in 10% excess), and EtOH containing a catalytic amount of concd. HCl for ca. 4 h.

[l] Dropwise addition of BzCl to a solution of **3a** in anhydrous pyridine with ice cooling and stirring.

[m] TLC almost homogeneous, 234–236°C.

[n] IR (KBr, v, cm^{-1}): 1642 (s).

The solid was collected by filtration and washed several times with water and then with hexane to give crude product **4d** (10.877 g, 83%), mp 208–210°C (ref. [19b] 204–207°C (from EtOH)). The mother liquor was concentrated and the residue triturated with water to give a second crop (1.624 g, 12%) of **4d**. $C_{16}H_{13}N_3S_2$.

Thioflavone thiosemicarbazone 1,1-dioxide(4e). A mixture of powdered sulfone **2c** (0.270 g, 1 mmol), powdered

Table 4

Preparation and properties of 3-acetylspiro[1,3,4-thiadiazoline-2,4′-thioflavans] **5a,b**.[a]

[a] For preparation of analogous spiro 1,3,4-thiadiazolines (**5c,d,e**) see ref. [17b].

[b] Bath, if not bp.

[c] For general operations of processing the reaction mixtures see Experimental.

[d] Without workup of mother liquors if not stated otherwise.

[e] The C,H,N, and S analyses data for the products are agreeing with the theoretical values within ± 0.3-0.4% limit.

[f] To a solution of anhydrous $ZnCl_2$ in Ac_2O was added the substrate.

[g] The reaction mixture was stirred at least until the dissolution was complete.

[h] To give a crude product.

[i] TLC homogeneous product.

[j] Mp 206-208 °C.

[k] From the mother liquor TLC homogeneous diacetythydrazone **3c**,(6.7%), mp 137°C (from PhH/hexane) could be isolated, cf. Table 3.

[l] Pyridine, anhydrous.

thiosemicarbazide (0.100 g, 1.1 mmol), MeOH (4.7 mL), and MeOH/HCl (0.3 mL *ca*. 0.35 mmol HCl; prepared by mixing 4.5 mL MeOH and 0.5 mL conc. HCl) was boiled with stirring for 9 h to give crude thiosemicarbazone **4e** (0.318 g, 92.5), mp 234–236°C, identical with an authentic [19b] compound (found mp 233–236°C, reported [19b] 192°C (from EtOH)). $C_{16}H_{13}N_3O_2S_2$. The crude product was pure enough for subsequent transformations.

Degradation of thioflavone thiosemicarbazone 1,1-dioxide (4e) to acetylhydrazone 4f. A mixture of thiosemicarbazone **4e** (1.030 g, 3 mmol), Ac_2O (4.5 mL, 48 mmol) and anhydrous pyridine (3 mL, 37 mmol) was stirred at 51°C bath for 5 h and kept at room temperature for 16 h. The crystalline solid was collected by filtration, washed with Ac_2O and hexane, dried over KOH and silica gel in vacuum desiccator to give TLC [$CHCl_3$/EtOAc (8:2), $CHCl_3/Et_2O$ (8:2), or $CHCl_3$/MeOH (95:5)] homogeneous crude product (0.678 g, 69.2%), mp 275–276°C (the hot melt resolidified and melted finally at 281–282°C) or when recrystallized from $CHCl_3$/EtOH, mp 275°C. The Ac_2O/py mother liquor was concentrated, the solid residue was triturated with anhydrous EtOH (1 mL) in the cold to give a second crop of **4f** (0.079 g, 8.1%), mp 278°C and then 284°C. IR(KBr, ν, cm^{-1}): 1678 (s), 1638 (m), 1562 (m). ^1H NMR(200 MHz, DMSO-d_6, δ, ppm); 8.36–8.31 and 8.08–8.03 (both m and 1 H, 2 H-Ar), 7.97 (s, 1 H, H(3)) 7.90–7.86 and 7.84–7.72 (both m and 2 H, 4 H—Ar), 7.63–7.58 (m, 3 H, H—Ar), 2.34 (s, 3 H, Ac). *Anal*. Calcd. for $C_{17}H_{14}N_2O_3S$ C, 62.6; H, 4.3; N, 8.6; S 9.8. Found C, 63.0; H, 4.4; N, 8.4; S, 10.0.

Thioflavone benzoylhydrazone (4g). A mixture of thioflavanone benzoylhydrazone (**3j**, 0.166 g, 0.462 mmol), DDQ (0.112 g, 0.485 mmol, 98%), anhydrous dioxane (4 mL), and a catalytic amount of TsOH was boiled with stirring tor 14 h, then cooled and concentrated. For the removal of $DDQH_2$, the residue was stirred with aq. $NaHCO_3$ in the presence of some drops of 2-PrOH as a humidifier to leave undissolved crude product **4g** (0.152 g, 92%). A solution of the crude product in $CHCl_3$ was treated with charcoal and concentrated. Crystallization of the residue from 2-PrOH (7 mL) afforded pure **4g** (0.121 g, 73%), mp 240°C. ^1H NMR(360 MHz, DMSO-d_6,δ, ppm): 11.28 (bs, 1 H, NH), 8.47 (bs shaped m, 1 H, H(5)), 7.90–7.83 (m, 4 H, H(6,7,8) and H(3)), 7.61–7.51 (m, 10 H, 2 Ph). *Anal*. Calcd. for $C_{22}H_{16}N_2OS$ C, 74.1; H, 4.5; N, 7.9. Found C, 74.3; H, 4.6; N, 7.9.

Attempted dehydrogenation of spirothioflavan 5a by $PhI(OAc)_2$. A mixture of finely powdered **5a** (0.169 g, 0.5 mmol), $PhI(OAc)_2$ (0.247 g, 0.75 mmol) and MeOH (5 mL) was stirred at room temperature for 14 d. The solid was collected by filtration to give TLC homogeneous starting **5a** (0.104 g, 62%), mp 215–216°C.

For a transformation of thioflavanone (**1a**) to **2a**, under similar conditions, see Experimental section.

CAN degradation of spiro-oxadiazoline 5b to thioflavone (2a). According to the literature method [25] for the CAN dehydrogenation of thioflavanone (**1a**), to a solution of finely powdered spirocompound **5b** (0.401 g, 1 mmol) in MeCN (30 mL), placed in a separatory funnel, was added a solution of CAN (3.838 g, 7 mmol) in water (10 mL). The mixture was shaken carefully and when the effervescence ceased, diluted with water (50 mL) and extracted with Et_2O (6 × 12 mL). The Et_2O solution was washed with aq. $NaHCO_3$ and water, dried ($MgSO_4$), and concentrated. Separation of the multicomponent residue by CC (Silica Woelm 100–200 μm, $CHCl_3/Et_2O$ (95:5)] afforded thioflavone (**2a**, 0.096 g, 40%), mp 124°C [ref. [25] 124.5–125.5°C (from anhydrous EtOH), ref. [36] 122–123°C (from MeOH)]. ^1H NMR(200 MHz, $CDCl_3$, δ, ppm): 8.58–8.53 (m, 1 H, H(5)), 7.73–7.50 (m, 8 H, H—Ar), 7.25 [s, 1 H, H(3) (for $CHCl_3$ was δ 7.26); ref. [37] 7.27 (s, 1 H, H(3) ($CDCl_3$); Bruker 300 spectrometer), ref. [36] 7.35 ($CDCl_3$; Varian T-60 and/or EM-390 instruments)]. The product was identical in all respects [inclusive also TLC and IR(KBr)] with an authentic compound.

Attempted dehydrogenation of spirothioflavan 5b by DDQ. A mixture of **5b** (0.200 g, 0.5 mmol), DDQ (0.243 g, 0.525 mmol, 98%), anhydrous dioxane (6 mL), and anhydrous 4-toluenesulfonic acid (a catalytic amount) was stirred at room temperature for 5 h and at 93°C (bath) for 17 h, then concentrated. For the removal of TsOH and $DDQH_2$, the doughy residue was partitioned between aq. $NaHCO_3$ and $CHCl_3$. The organic layer washed with water and dried ($MgSO_4$) contained [TLC, $CHCl_3$/EtOAc (95:5)] *ca*. equal amounts of unchanged **5b** and thioflavone (**2a**) as the major components besides traces of four minor ones.

3-Acetyl-5-methylspiro[1,3,4-oxadiazoline-2,4′-thioflavan] 1′-oxide (5f). (**a**) To a solution of $NaIO_4$ (0.428 g, 2 mmol) in water (10 mL) were added **5a** (0.169 g, 0.5 mmol) and 2-PrOH (10 mL). The mixture was boiled with stirring for 5 h, cooled and then concentrated. The residue was diluted with water up to *ca*. 30 mL to give **5f** (0.103 g, 85%), mp 209–212°C.

(**b**) To a suspension of powdered **5a** (3.384 g, 10 mmol) in Me_2CO (300 mL) were added, both in small portions, powdered OXONE (2 $KHSO_5 \cdot KHSO_4 \cdot K_2SO_4$, 3.60 g, 5.85 mmol) and water (35 mL) with stirring at 4–8°C (bath temperature) during 6 h. The mixture was stirred with cooling for 4 h and at room temperature for 14 h, and then filtered. The filtrate was concentrated and the residue crystallized from EtOAc to give crude **5f** (3.395 g, 96%), mp 200–202°C, contaminated (TLC) with a small amount of **5a**. Purification of the crude product by CC [silica gel 60; $CHCl_3$/EtOAc (9:1)] and subsequent crystallization from EtOAc afforded TLC homogeneous **5f** (2.381 g, 67%), mp 208–209°C. IR(KBr, ν, cm^{-1}): 1046 (s, S=O); ^{13}C NMR(50 MHz, $CDCl_3$, δ, ppm): 166.19 (*C*=O), 153.89 (C(5)), 143.39, 134.50 and 132.88 (3 quat. aromatic C), 131.18, 130.92, 129.07, 128.99 (2 C), 128.48 (2 C), 127.22, and 126.29 (9 aromatic =CH), 97.65 (spiro C(2,4′)), 62.99 (C(2′)), 34.08 (C(3′)), 22.02 (*C*H_3—CO), 11.36 (CH_3(5)). *Anal*. Calcd. for $C_{19}H_{18}N_2O_3S$ C, 64.4; H, 5.1; N 7.9; S, 9.05. Found: C, 64.1; H, 5.1; N, 7.8; S, 9.1.

3-Acetyl-5-phenylspiro[1,3,4-oxadiazoline-2,4′-thioflavan] 1′-oxide (5g). (**a**) To a solution of **5b** (3.604 g, 9 mmol) in hot 2-PrOH (290 mL) was added a solution of $NaIO_4$ (3.850 g, 18 mmol) in warm water (100 mL). The mixture was boiled for 2 h and then diluted with water up to *ca*. 600 mL to give crude **5g** (2.917 g, 78%) contaminated with a small amount of sulfone **5i**. Purification by CC [Silica Woelm 100–200 μm, $CHCl_3$/EtOAc (95:5)] afforded TLC homogeneous product **5g** (1.929 g, 51.5%) mp 216–218°C (from $CHCl_3$/EtOAc). IR(KBr, ν, cm^{-1}): 1044 (s, S=O). *Anal*. Calcd. for $C_{24}H_{20}N_2O_3S$ C, 69.2; H, 4.8; N 6.7; S 7.7. Found: C 69.4; H 4.9; N, 6.6; S, 7.6.

(**b**) To a suspension of powdered **5b** (4.005 g, 10 mmol) in Me_2CO (300 mL) were added, both in small portions, powdered OXONE (potassium peroxymonosulfate, 3.70 g, 6 mmol) and water (35 mL) with stirring at 4–8°C (bath temperature) during 4 h. The mixture was stirred on with cooling for 7 h and at room temperature for 12 h and then filtered; the solid was washed with water to leave undissolved crude **5g** (2.071 g, 50%). The aq. Me_2CO mother liquor was concentrated, the residue triturated with water to give a second crop of **5g** (1.967 g 47%). A solution of the crude products in $CHCl_3$ was treated with charcoal and concentrated. The residue was crystallized from EtOAc to give pure title compound **5g** (3.666 g 88%), mp 208–210°C, TLC identical with the product described in (**a**).

Transformation of spiro[oxadiazoline-2,4′-thioflavan] 1′-oxides 5f and 5g into thioflavone diacetylhydrazone (4c). (**a**) A mixture of 5-methyl spirocompound **5f** (3.544 g, 10 mmol), Ac_2O (50 mL, 530 mmol) and TsOH (like a pea) was heated at 98°C (bath) with stirring for 16 h, then cooled and concentrated. The cold residue was triturated with ice/water for 1 h, and then extracted with $CHCl_3$. The $CHCl_3$ solution was washed with aq. $NaHCO_3$ and water, dried ($MgSO_4$), and concentrated. Recrystallization of the residue two times from EtOAc afforded pale yellow crystals of **4c** (1,534 g, 46%), mp 175°C. IR(KBr, ν, cm^{-1}): 1720(s), 1706(s), 1690(s), 1682(s), 1648(w), 1592(s). ^1H NMR(360 MHz, $CDCl_3$, δ, ppm): 8.77–8.75 (m, 1 H, H(5)), 7,58–7.43 (m, 8 H, H—Ar), 6.80 (s, 1 H, H(3), 2.47 (s, 6 H, 2 Ac). ^{13}C NMR(90 MHz, $CDCl_3$, δ, ppm): 170.28 (2 C, 2 *C*=O), 162.56, 148.81, 136.98, and 134.45 (quat. aromatic C), 130.62 (2 C), 129.15 (2 C), 127.82, 127.02 (3 C), and 126.34 (aromatic CH), 111.99 (C(3)), 25.90 (2 C, *C*H_3—C=O). *Anal.* Calcd. for $C_{19}H_{16}N_2O_2S$ C, 67.8; H, 4.8; N, 8.3; S, 9.5. Found: C, 67.8; H, 4.8; N, 8.4; S, 9.6.

(**b**) A mixture of 5-pheny1 spirocompound **5g** (0.833 g, 2 mmol), Ac_2O (10 mL, 106 mmol) and TsOH (like a pepper) was heated at 100°C (bath) with stirring for 18 h, then cooled and concentrated. The cold residue was triturated with MeOH (2 mL) for 2.5 h and then water (*ca.* 7 mL) was added in portions to give a solid (0.707 g). A solution of the product in $CHCl_3$ was treated with charcoal and concentrated. The residue was crystallized from EtOAc to give **4c** (0.292 g, 43%), mp 174.5–175°C, identical (TLC, IR) with the product obtained from the 5-methyl spirocompound **5f** aforementioned in (**a**).

3-Acetyl-5-methylspiro[1,3,4-oxadiazoline-2,4′-thioflavan] 1′,1′-dioxide (5h). To a suspension of powdered spirothioflavan **5a** (1.692 g, 5 mmol) in 96% AcOH (50 mL) were added, both in small portions, powdered $KMnO_4$ (1.613 g, 10.2 mmol) and water (10 mL) at room temperature with cooling and stirring during 45 min. The mixture was stirred further for 1.5 h and then under cooling 30% H_2O_2 (*ca.* 1.2 mL) was added drop-by-drop until discoloration. The mixture was diluted with water up to *ca.* 200 mL, kept at 4°C for 1.5 h to give crystalline crude 1′,1′-dioxide **5h** (1.449 g, 78%), mp 224–225°C. Recrystallization from PhMe afforded pure **5h** (1.313 g 71%), mp 227°C. IR(KBr, ν, cm^{-1}): 1314 (s), 1154 (s), 1138 (s) (SO_2). *Anal.* Calcd. for $C_{19}H_{18}N_2O_4S$ C, 61.6; H, 4.9; N, 7.6; S, 8.7. Found: C, 61.8; H, 4.9; N, 7.5; S, 8.6.

3-Acetyl-5-phenylspiro[1,3,4-oxadiazoline-2,4′-thioflavan] 1′,1′-dioxide (5i). To a solution of spirothioflavan **5b** (0.401 g, 1 mmol) in 96% AcOH (16 mL) was added powdered $KMnO_4$ (0.395 g, 2.5 mmol) in small portions with stirring at room temperature during 20 min. The mixture was stirred further for 2 h, and then for dissolving the oxidant, water (12 mL) was added in portions during 1.5 h. After an additional stirring for 1 h the precipitated solid was collected by filtration, washed with water to give TLC homogeneous crude **5i** (0.389 g, 90%), mp 227–228°C. A solution of the crude product in $CHCl_3$ was treated with charcoal and concentrated. The residue was boiled in 2-PrOH (3 mL) to give analytically pure **5i** (0.378 g, 87%), mp 228°C. IR(KBr, ν, cm^{-1}): 1312 (s), 1156 (s) and 1136 (s) (SO_2). *Anal.* Calcd. for $C_{24}H_{20}N_2O_4S$ C, 66.6; H, 4.7; N, 6.5; S, 7.4. Found: C, 66.5; H, 4.7; N, 6.4; S, 7.4.

5-Acetamido-3-acetylspiro[1,3,4-thiadiazoline-2,4′-thioflaven] (6). A mixture of thíosemicarbazone **4d** (1.869 g, 6 mmol), Ac_2O (15 mL, 159 mmol) and pyridine (3 mL, 37 mmol) was kept at 100°C for 3 h and then at 4°C for 18 h to give yellow crystals of crude diacetylhydrazone **4c** (0.367 g, 18%), mp 170–171°C, TLC [$CHCl_3$/MeOH (9:1)] identical with an authentic compound. The mother liquor was concentrated and the residue triturated with anhydrous EtOH under cooling, and for increasing the separation of crystals, gradually hexane (16 mL) was added then kept at room temperature for *ca.* 16 h to give a crystalline second crop of product (1.090 g). The mother liquor of the second crop was concentrated and the residue triturated with water to give a solid (0.874 g). The second and third crops of crude products contained the same compound as the major component [TLC, $CHCl_3$/MeOH (9:1)]. Purification of the third crop by CC [silica gel 60; $CHCl_3/Et_2O$ (8:2)] and when combined with the second crop, subsequent crystallization from Et_2O with addition of hexane afforded pure **6** (1.328 g, 56%), mp 248–249°C. IR(KBr, ν, cm^{-1}): 1674 (s), 1646 (s), 1614 (s). ^1H NMR(200 MHz,$CDCl_3$, δ, ppm): 9.20 (s, 1 H, N*H*Ac), 7.59–7.54 (m, 2 H, H—Ar), 7.39–7.22 (m, 7 H, H—Ar), 6.50 (s, 1 H, H(3′)), 2.43 (s, 3 H, Ac), 1.91(s, 3 H, Ac). ^{13}C NMR(50 MHz, $CDCl_3$, δ, ppm): 169.74 and 169.47 (2 C=O), 145.02 (C(5)), 136.74, 133.42, 132.96, and 129.70 (3 quat. aromatic C, and C(2′)), 129.27, 128.72 (2 C), 128.01, 127.48, 126.75 (2 C), 126.33, and 125.16 (9 aromatic =CH), 120.08 (C(3′)), 79.92 (spiro C(2,4′)), 23.69 and 22.30 (2 *C*H_3—C=O). *Anal.* Calcd. for $C_{20}H_{17}N_3O_2S_2$ C, 60.7; H, 4.3; N, 10.6; S, 16.2. Found C, 60.8; H, 4.4; N, 10.6; S, 16.3.

Thioflavanone azine (8). (**a**) To a solution of hydrazone **3a** (0.509 g, 2 mmol) in DMSO (3 mL) at *ca.* 60°C was added 0.1*M* I_2/DMSO (3 mL, 0.3 mmol). The mixture was kept at 100°C for 45 min and then gradually water (*ca.* 25 mL) was added to give crude **8** (0.471 g, 99%, mp 267°C) containing some unchanged **3a**. Heating the crude product in MeOH (5 mL) left undissolved pure **8** (0.358 g, 75%), mp 270–271°C (ref. [19b] 270°C (PhH), prepared by condensing thioflavanone **1a** with hydrazine hydrate).

(**b**) A mixture of thioflavanone (**1a**, 1.502 g, 6.25 mmol), hydrazone **3a** (1.272 g, 5 mmol), 2-PrOH (25 mL), and a catalytic amount of TsOH was boiled with stirring for 10 h to give crude (1.697 g, 71%; mp 269–270°C) or recrystallized **8** (1.495 g, 63%), mp 270°C (from Diglyme or PhH), TLC identical with the product described in (**a**). $C_{30}H_{24}N_2S_2$.

Dehydrogenation of thioflavanone azine (8) to azine 10. A mixture of azine **8** (0.119 g, 0.25 mmol), DDQ (0.122 g, 0.525 mmol, 98%), anhydrous dioxane (10 mL), and a catalytic amount of TsOH was boiled with stirring for 18 h then concentrated. The residue was washed with $CHCl_3$ and the solid stirred with aq. $NaHCO_3$ in the presence of some drops of 2-PrOH as a humidifier to give **10** (0.095 g, 80%), purplish crystals of a metallic lustre, mp 283–286°C (ref. [19b] 280–285°C (from EtOH), prepared by treatment of 4-methylthio-thioflavylium iodide or thioflaven-4-thione with $N_2H_4{\cdot}H_2O$). $C_{30}H_{20}N_2S_2$.

Reaction of thioflavanone hydrazone (3a) with DDQ, formation of azines 8 and 9. A mixture of hydrazone **3a** (1.017 g 4 mmol), DDQ (0.973 g, 4.2 mmol, 98%) and anhydrous dioxane (20 mL) was stirred at room temperature for some minutes, whilst the deep green color of the solution, produced by a transiently formed charge-transfer complex, became brownish-red and under significant effervescence the mixture thickened. Hereupon, the mixture was boiled for 4 h with stirring, and then concentrated. For removing $DDQH_2$ the residue was stirred with aq. $NaHCO_3$ at room temperature to leave undissolved a brownish solid (0.967 g, mp 213–220°C) consisting of two major components (TLC, $CHCl_3$). Purification by CC (silica gel 60, $CHCl_3$) afforded azine **8** (0.387 g, 41%, mp 270°C (from PhMe) and orange-red crystals of **9** (0.104 g, 11%), mp 255–256°C (from $CHCl_3$/EtOAc). ^1H NMR(200 MHz, $CDCl_3$, δ, ppm): 8.59–8.56 (m, 1 H, H(5)), 8.48–8.45 (m, 1 H H(5)), 7.81 (s, 1 H, =CH(3)), 7.71–7.66 (m, 2 H, H—Ar), 7.50–7.16 (m, 14 H, H—Ar), 4.48 (dd, 1 H, $J_{2,3e} = 3$ Hz, $J_{2,3a} = 13$ Hz, H(2)), 4.19 (q, 1 H, $J_{2,3e} = 3$ Hz, $J_{3e3a} = 17.5$ Hz, $H_e(3)$), 3.13 (q, 1 H, $J_{2,3a} = 13$ Hz, $J_{3e,3a} = 17.5$ Hz, $H_a(3)$). *Anal.* Calcd. for $C_{30}H_{22}N_2S_2$ C, 75.9; H, 4.7; N, 5.9. Found: C, 75.8; H, 4,6; N, 5,9.

Transformation of 2-cinnamoylphenyl disulfide (7) into thioflavanone hydrazone (3a) and pyrazole 11a. A mixture of 98% $N_2H_4{\cdot}H_2O$ (9 mL, ~180 mmol), 2-PrOH (25 mL) and **7** [22b] (4.307 g, 9 mmol, 18 mmol of chalcone moiety) was stirred at room temperature for 5 h and then the clear solution formed was kept at 100°C for 16 h. The solution was cooled and deep freezed at *ca.* −20°C for 2.5 d to give crude (2.093 g, 91.4%, yield calculated for 9 mmol, mp 116–117°C) or recrystallized **3a**, mp 120–121°C (from MeOH), identical [mp, TLC: $CHCl_3$/EtOAc (95:5), IR] with an authentic compound prepared from **1a** (see ref. [17b]). The mother liquor of the crude product was concentrated, the residue dissolved in Me_2CO (3 mL) and for transforming **11a** into the more easily isolable disulfide **12a**, kept at 4°C for 4 d. The deposited crystals were collected by filtration and washed with Me_2CO/hexane (1:1) to give crude (0.190 g, 4.2%, mp 226–227°C) or recrystallized **12a**, mp 230°C (from 2-methoxyethyl ether with addition of water). The product is identical [mp, TLC: $CHCl_3$/MeOH (9:1), IR] with that obtained by treating thioflavone with hydrazine hydrate [33]. *Anal.* Calcd. for $C_{30}H_{22}N_4S_2$ C, 71.7; H, 4.4; N, 11.1. Found: C, 71.8; H, 4.5; N, 11.1.

Acknowledgments. The author thanks Mrs. Katalin Tréfás for the microanalyses and for recording the IR spectra, Mme Sára Balla and Mrs. Éva Józsa for recording the 200 and 360 MHz ^1H- as well as 50 and 90 MHz ^{13}C NMR spectra. Thanks are due, with particular deference, to the late János Bálint, Ph.D. (BIOGAL Pharmaceutical Works, Debrecen, Hungary) for the generous gift of authentic samples of **3a**,**d**,**h** and **4a**,**d**,**e** for identification. Financial support from the Hungarian Scientific Research Fund (OTKA Grant numbers: T025016 and T037201) for this work is gratefully acknowledged.

The regiochemistry was investigated for the reaction of 2-chloromethyl-4,5-dichloropyridazin-3(2*H*)-one (**1**) with some phenols **2** in the presence of a base in organic solvents. Seven diphenoxy derivatives **5** were synthesized selectively from **1** and phenols **2** under two optimized conditions. The product distributions of these reactions are dependent on the base, the solvent, and/or the substitutes of phenols.

J. Heterocyclic Chem., **46**, 410 (2009).

INTRODUCTION

Chloromethyl-4,5-dichloropyridazin-3(2*H*)-one (**1**) is a key intermediate for the synthesis of their derivatives, fluorescence molecules containing pyridazinone ring [1,2], and also biologically active compounds [3–7]. Because of involving four electrophilic carbons such as $ClCH_2N$-, C-3, C-4, and C-5, however, the reaction of compound **1** with a nucleophile such as phenol affords two or three products [8,9]. Also, the retro-ene reaction of compound **1** under basic condition was reported [9]. Based upon the atomic charges of compound **1** [10], the reactivity of the C-5 position about the nucleophile is more active than the α-C and C-4 positions (Fig. 1). Therefore, the selective synthesis of 5-phenoxy-2-phenoxymethyl-, 5-phenoxy-, or 2-phenoxymethyl derivative under basic condition is difficult.

In connection with the SAR study and the evaluation of biological activity such as cardiovascular activity or immunosuppressive activity, we need some 2-(phenoxymethyl)-5-phenoxylpyridazin-3(2*H*)-ones. Thus, we attempted to study on the regiochemistry in the reaction of compound **1** with phenols under basic condition (Scheme 1). In this article, we report the results for the title reactions.

RESULTS AND DISCUSSION

First, we examined the effect of the bases in the reaction of **1** with *o*-vaniline (**2a**) in acetonitrile. Reaction of compound **1** with two equivalents *o*-vaniline (**2a**) in the presence of base in refluxing acetonitrile gave products **3a**, **4a**, and **5a**. The distribution of the products for these reactions is shown in Table 1.

When K_2CO_3, Cs_2CO_3, and Na_2CO_3 as the base were used, compound **5a** was the main product. However, the reaction did not progress using NaH, Et_3N, and *N*,*N*-dimethylaminopyridine as base in refluxing acetonitrile. We selected potassium carbonate as the suitable base for this reaction.

On the other hand, we examined the effect of the solvents for the same reaction under different conditions such as at reflux temperature or under microwave irradiation.

Although two products were detected, the reaction of **1** with **2a** in acetonitrile, ethyl acetate, tetrahydrofuran, or acetone under the same conditions gave **5a** as the main product (entries 1, 2, 5, 6, 7, 8, 9, and 10, in Table 2). Compound **1** was reacted with **2a** in the presence of potassium carbonate in refluxing methanol or under microwave irradiation to afford selectively **5a** in

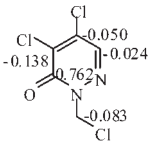

Figure 1. Atomic charge of carbons at the MP2/6-311+G** for compound **1**.

excellent yield, respectively (entries 3 and 4 in Table 2). Compound **4a** was the main product when refluxing toluene was used, whereas the reaction did not occur in toluene under microwave irradiation. Even though the conversion ratio of **1** was low, **4a** was the main product in the reaction in methylene chloride and diethyl ether under microwave irradiation (entries 14 and 16 in Table 2). We did not find significant differences for the distribution of the products between the classical heating system and microwave irradiation system. According to TLC analysis, the product **5a** yielded *via* the 2-phenoxymethyl compound **4a** in the reaction of **1** with **2a**, whereas the 5-phenoxy derivative **3a** did not convert to **5a** under the same condition. Based upon the selectivity and the practical reaction conditions, therefore, we selected the optimized conditions, that is, (i) refluxing acetonitrile/potassium carbonate system and (ii) refluxing methanol/potassium carbonate system. Using the two optimized system, we investigated the effect of the substitutes of phenols. Most interestingly, reaction of **1** with 2**b** (2 equiv.) or **2e** (2 equiv.) under two optimized conditions gave selectively the corresponding 5-phenoxy derivatives **3b** or **3e** in excellent yields (entries 1, 2, 7, and 8 in Table 3). Treatment of **1** with **2j** under our two conditions also afforded selectively α-phenoxy derivative **4j** in excellent yield (entries 17 and 18 in Table 3).

Although compound **1** was reacted with **2c** in refluxing acetonitrile to afford **4c** (48%) and **5c** (46%), the same reaction was carried out in refluxing methanol to give selectively **5c** in 94% yield (entries 3 and 4 in Table 3). On the other hand, compound **1** was reacted with **2d** or **2f–2i** under the same conditions to afford selectively α-diphenoxy derivatives **5d** or **5f–5i** in good to excellent yields, respectively (entries 5–6 and 9–16 in Table 3). The chemical structures of the all products were characterized by IR spectroscopy, NMR spectroscopy, and the elemental analysis.

CONCLUSIONS

In conclusion, the regiochemistry was investigated for the reaction of compound **1** with some phenols **2** in the presence of a base in organic solvents. Although diphenoxy derivatives **5** were synthesized selectively under two optimized conditions, we did not find any regularity. Although significant differences for the distribution of the products did not show under the classical heating system and microwave irradiation, the regiochemistry in

the reaction is effected by the base, the solvent, and/or the substitutes of phenols. Further work including the theoretical study on the regiochemistry and the biological activity are under way in our laboratory.

EXPERIMENTAL

Melting points were determined with a capillary apparatus and uncorrected. ^{1}H and ^{13}C NMR spectra were recorded on a 300 MHz spectrophotometer with chemical shift values reported in δ units (ppm) relative to an internal standard (TMS). IR spectra were obtained on an IR spectrophotometer. Elemental analyses were performed with a CHNS-932 (Leco). 2-Chloromethyl-4,5-dichloropyridazin-3(*2H*)-one was synthesized by the literature method [2]. Microwave reaction was carried out by using a CEM, Discover microwave apparatus.

General procedure for the reaction of 2-chloromethyl-4,5-dichloropyridazin-3(2*H*)-one (1) with phenols (2).

Method 1. A solution of 2-hydroxy-3-methoxybenzaldehyde (2.8 g, 2 equiv.) and base (2 equiv.), 2-chloromethyl-4,5-dichloro-pyridazin-3(*2H*)-one (**2**) (2 g, 1 equiv.), and solvent (30 mL) was refluxed until **2** disappeared by TLC monitoring. After cooling the mixture to room temperature, the mixture was filtered and concentrated. The distribution of products was analyzed by ^{1}H NMR quantitative analysis. The products 3, 4, and 5 were also isolated by column chromatography on silica gel (2.5 × 8 cm) with *n*-hexane/EtOAc (2:1, v/v).

Method 2. 2-Chloromethyl-4,5-dichloropyridazin-3(2*H*)-one (**2**) (0.1 g, 1 equiv.) was dissolved in solvent (7 mL) in a 10 mL microwave vessel. 2-Hydroxy-3-methoxybenzaldehyde (0.14 g, 2 equiv.) and base (2 equiv.) were added. The vessel was closed and placed into a microwave apparatus. The mixture was irradiated per 10 min at 120°C with a set power of 300 W. After cooling, the mixture was filtered on a glass filter under vacuum. The distribution of products was analyzed by ^{1}H NMR quantitative analysis.

2-(5-Chloro-l-chloromethyl-6-oxo-l,6-dihydropyridazin-4-yloxy)-3-methoxybenzaldehyde (3a). Prepared by the Method 1 and 2. mp; 145°C. IR (KBr) 3081, 3045, 2935, 2878, 1663, 1581, 1479, 1452, 1387, 1254, 1213 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.87 (s, 3H), 5.86 (s, 2H, N-CH$_2$), 7.35 (d, 1H, J = 6 Hz), 7.42 (s, 1H), 7.46 (t, 1H, J = 6 Hz), 7.58 (d, 1H, J = 6 Hz), 10.30 ppm (s, CHO 1H); ^{13}C NMR (CDCl$_3$): δ 56.55, 58.29, 118.31, 121.12, 127.71, 129.26, 130.17, 142.79, 151.25, 153.83, 157.77, 187.75 ppm; Elemental analysis calcd. for $C_{13}H_{10}Cl_2N_2O_4$: C,47.44; H,3.06; N, 8.51; Found: C, 47.50; H, 3.10; N, 8.57.

4-Chloro-2-(chloromethyl)-5-phenoxypyridazin-3-(*2H*)-one (3b). Prepared by the Method 1. mp 78°C. IR (KBr) 3067, 3011, 1660, 1609, 1585, 1487, 1393, 1311, 1278, 1216, 1155 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 5.85 (s, 2H), 7.11 (d, 2H, J = 7.64 Hz), 7.32 (m, 1H), 7.48 (m, 2H), 7.53 ppm (s, 1H); ^{13}C NMR (CDCl$_3$): δ 58.29, 115.99, 119.79, 126.42, 130.55, 130.62, 131.23, 153.31, 153.72 ppm; Elemental analysis calcd. for $C_{11}H_8Cl_2N_2O_2$: C, 48.73; H, 2.97; N, 10.33. Found: C, 48.80; H, 3.00; N, 10.37.

4-Chloro-2-chloromethyl-5-[(2,6-dichloro-4-nitrophenoxy) methyl]pyridazin-3(*2H*)-one (3e). Prepared by the Method 1. mp 152°C. IR(KBr) 3086, 3054, 1678, 1588, 1523, 1506, 1349, 1293, 1249, 1215, 973, 956 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 6.11 (s, 2H), 7.77 (s, 1H), 8.21 ppm (s. 2H); ^{13}C NMR (CDCl$_3$): δ 81.58, 124.51, 129.94, 134.90, 136.66, 137.53, 144.20, 155.33, 156.82 ppm; Elemental analysis calcd. for $C_{12}H_7Cl_4N_3O_4$: C, 36.12; H, 1.77; N, 10.53. Found: C, 36.17; H, 1.79; N, 10.57.

2-[(4,5-Dichloro-6-oxopyridazin-l(*6H*)-yl)methoxy]-3-methoxybenzaldehyde (4a). Prepared by the Method 1 and 2. mp 143°C. IR (KBr) 3077, 3011, 2993, 2885, 2846, 1695, 1666, 1615, 1581, 1481, 1460, 1392, 1278, 1250,1217 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.91 (s, 3H), 6.09 (s, 2H, N-CH$_2$), 7.16 (d, 2H, J = 3 Hz), 7.34 (t, 1H, J = 5.1 Hz), 7.72 (s, 1H), 10.16 ppm (s, 1H); ^{13}C NMR (CDCl$_3$): δ 56.21, 81.44, 117.99, 119.41, 125.34, 129.93, 134.87, 136.33, 137.20, 148.32, 152.35, 156.58, 189.73 ppm; Elemental analysis calcd. for $C_{13}H_{10}Cl_2N_2O_4$: C,47.44; H,3.06; N, 8.51; Found: C, 47.49; H, 3.11; N, 8.58.

4,5-Dichloro-2-[(2,6-dichlorophenoxy)methyl]pyridazin-3(*2H*)-one (4c). Prepared by the Method 1. mp 142°C. IR (KBr) 3093, 3053, 1676, 1663, 1584, 1456, 1440, 1402, 1297, 1242, 1224, 1003, 990, 962 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 6.03 (s, 2H), 7.05 (t, 1H, J = 8.15 Hz), 7.29 (m, 2H), 7.72 ppm (s, 1H); ^{13}C NMR (CDCl$_3$): δ 81.46, 126.17, 129.07, 129.14, 134.84, 136.12, 137.17, 149.68, 156.80 ppm; Elemental analysis calcd. for $C_{11}H_6Cl_4N_2O_2$: C, 38.86; H, 1.78; N, 8.24. Found: C, 38.90; H, 1.82; N, 8.27.

4,5-Dichloro-2-((2,4-dinitrophenoxy)methyl)pyridazin-3(*2H*)-one (4j). Prepared by the Method 1. mp 147–149°C. IR (KBr) 3095, 3062, 1681, 1607, 1586, 1525, 1349, 1273, 1249, 987, 964 cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 6.24 (s, 2H), 7.75 (d, 1H, J = 9.24 Hz), 7.90 (s, 1H), 8.47 (dd, 1H, J = 2.77, 6.45 Hz), 8.70 ppm (d, 1H, J = 2.74 Hz); ^{13}C NMR (CDCl$_3$): δ 79.10, 117.90, 121.72, 128.99, 135.14, 137.46, 137.85, 140.17, 141.90, 154.30, 156.62 ppm; Elemental analysis calcd. for $C_{11}H_6Cl_2N_4O_6$: C, 36.59; H, 1.67; N, 15.52. Found: C, 36.63; H, 1.70; N, 15.58.

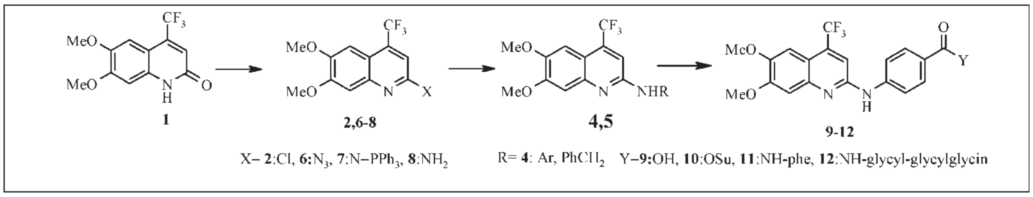
DOI 10.1002/jhet.109



2-Amino-substituted 6,7-dimethoxy-4-trifluoromethyl-quinolines were synthesized from the 2-oxo compound **1** *via* 2-chloroquinoline **2** and aminated with anilines or benzylamine to give highly fluorescent molecules **4**, 5. 2-Aminoquinoline **8** was obtained *via* azidation of **2**–**6**, reaction to the phosphazene **7**, and hydrolysis. 4-Ethoxycarbonyl derivative **4b** is suitable for linking appropriate biomolecules. The construction of a linking group was achieved by conversion of **4b** *via* carboxylic acid **9** to the reactive *O*-succinimide ester **10**, which reacts easily with amino acids or peptides to amides **11** and **12**. The fluorescent properties were investigated and are comparable with derivatives of **1**.

J. Heterocyclic Chem., **46**, 415 (2009).

INTRODUCTION

Coumarins and carbostyrils with push-pull systems are studied extensively as fluorescent dyes [1]. However, many carbostyrils (2-quinolones) show disadvantages in luminescence properties compared with coumarins because of shorter absorption and emission wavelengths [2]. Recently, we reported a series of studies about the fluorescence properties of differently substituted carbostyrils [3] with suitable structure elements which shifted the wavelengths up to 440 nm absorption and 540 nm emission maxima. These structure elements were electron donating substituents such as amino or methoxy groups in both positions 6 and 7 and an electron deficient substituent in position 4. Such properties make this compound class also interesting for the use in sensor and electroluminescence devices [4,5]. The advantage of 3,4-dimethoxycarbostyril derivatives was shown recently in their use as fluorescence resonance energy transfer systems [6], in the study of luminescence resonance transfer techniques [7a] and incorporated in a time resolved pH sensor as covalently attached europium complex [7b].

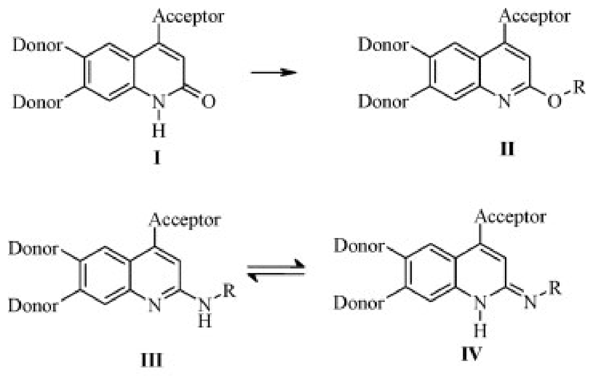
In our earlier articles [3a–f], we described the synthesis of highly fluorescent push-pull substituted carbostyrils (type **I**) with donor substituents at positions 6 and 7 and acceptor substituents at position 4 having widely pH independent properties, large Stokes shifts and medium to high-quantum yields. The functionalization to *O*-succinimidyl (OSu) esters at N-1 and 6-O and labelling of biopolymers such as peptides and carbohydrates was carried out without any blue-shift, resulting in absorbing close to the visible range and emitting in aqueous solution at 430–450 nm, suitable for biochemistry and medicine.

After the variation of substituents at positions 4, 6, and 7, we report in this article about the investigation on the synthesis and properties of 2-aminoquinolines **III**[3g]. In contrast to type **II** structures [3b], 2-aminoquinolines **III** have a possible tautomeric 2-imino structure **IV** as potential fluorescent compounds (Scheme 1).

RESULTS AND DISCUSSION

For our study, we selected 6,7-dimethoxy-4-trifluoromethyl-2-quinolone **1** as the starting compound, with methoxy groups as the donor and a trifluoromethyl group as the acceptor substituents. The synthesis of the carbostyril ring system was achieved by cyclocondensation of 3,4-dimethoxyaniline with trifluoro-methyl-acetoacetate as described recently [3b,c]. The conversion of the 2-oxo group to the reactive 2-chloro moiety in compound **2** was achieved with phosphoryl chloride. Conventional heating required a reaction time of 12 h and produced many by-products. The application of

Scheme 1



Acceptor substituents: e.g. CF_3, CN
Donor substituents: e.g. MeO, RNH

microwave heating allowed the isolation of chloroquinoline **2** after 30 min with similar yields but better purity (Scheme 2).

The conversion of the 2-chloro group in **2** to a free 2-amino group was achieved in a three step reaction by exchange of the 2-chloro substituent against the 2-azido group in dimethylformamide at 80°C using Kryptofix-5 as catalyst, to give 2-azidoquinoline **6**. According to IR spectra the azide **6A** exists predominantly in its tautomeric tetrazolo structure **6T** similar as shown in many investigations [8]. The Staudinger reaction with triphenylphosphane gave the corresponding phosphazene **7**, which is hydrolyzed by acid catalysis with hydrochloric acid in water/methanol to give the free 2-aminoquinoline **8** in an overall yield of about 67%. The aminoquinoline **8**, however, did not show sufficient fluorescent properties for further applications, probably caused by the predominant tautomeric amino-structure of type **III**, so this way was not continued.

On the other hand, 2-arylamino and 2-benzyl-aminoquinolines **4a-c** and **5**, which were obtained from the 2-chloro derivative with the appropriate anilines **3a-c** or benzylamine in a one step reaction in 62–66% yield, showed good fluorescence properties (possibly deriving from the formation of a tautomeric imino structure in the state of fluorescence excitation); see Table 1. Surprisingly, the benzylamino derivative **5** showed similar fluorescence properties as the arylamino derivatives **4**, which means, that the influence of the aryl group attached to the 2-amino group (forming an azomethine-type structure as imino tautomer) has no remarkable influence on luminescence properties. However, products with substituted benzylamines were not stable enough for further investigation (Scheme 3).

Spectral assignment of **4** and **5** to an amino- or imino-structure was not possible, because differences caused by solvent influences are strong and the ^{1}H NMR signals of NH ranged between 5.2 and 10.9 ppm with chloroform as the solvent.

Using suitable substituted derivatives such as 4-(2-quinolinylamino)benzoate **4b** (R^2 = COOEt) allowed the introduction of linker groups attached at the phenyl ring at the amino/imino-position 2. For the construction of linker groups to aminogroups of natural products, a reactive *O*-succinimide ester (OSu-ester) was planned because OSu-esters attached to heterocycles are known to be easily available, stable, and useful to link to biological samples. The synthesis was achieved by saponification of the ethyl ester group of **4b** to the free carboxylic acid **9** in ethanolic sodium hydroxide solution, and re-esterification with *N*-hydroxysuccinimide in the presence of carbodiimide, which gave the active OSu ester **10** in good yields.

The OSu ester **10** reacted smoothly under biological conditions in buffered aqueous DMSO solution below 50°C with biomolecules such as aminoacids and peptides. We synthesized two fluorescence marked

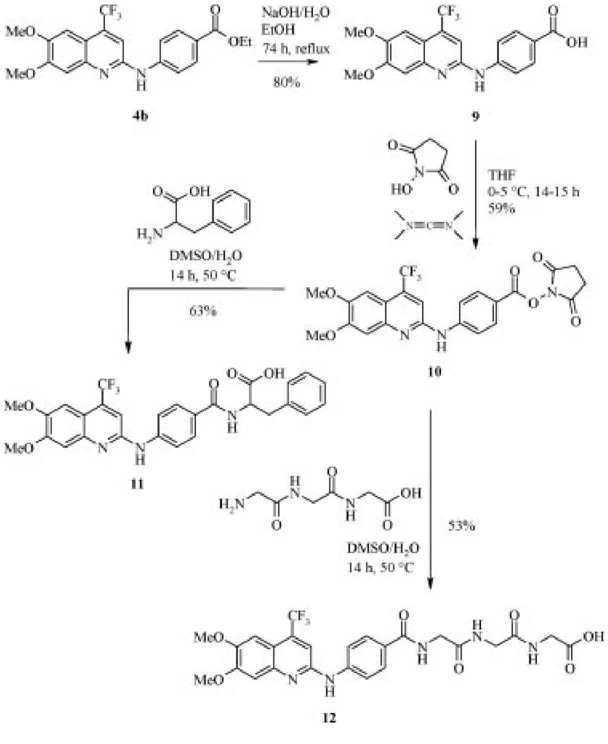
examples, the phenylalanine derivative **11** and the glycyl-glycyl-glycin **12** linked at the amino group of the amino acid with the linker molecule.

Electronic spectra. Absorption spectra of recently synthesized 4-(trifluoromethyl)carbostyrils [3b,c] were rather similar with $\lambda_{max} \sim$ 350–380 nm in DMSO or water; there was also no great difference between NH- and N-alkyl derivatives, which means, that in all cases the tautomeric amide group (N1-C2) of structure **I** is predominant. In the 2-amino/imino series (structures **III**/**IV**) comparable absorption wavelengths were obtained (Table 1): The UV wavelengths are slightly higher (375–398 nm), the Stokes' shifts are in the region 50–70 nm. However, the fluorescence quantum yields, which were high for any N1-alkylated analyte of type **I** [3b,c], decreased from $\Phi_F = 0.1$ in the ester **4b** to $\Phi_F = 0.03$–0.06 in linked 2-amino analogues **11**,**12**. Ester **4c** shows a higher ε value because of the asymmetric structure, which causes changes in dipole properties.

Scheme 3



CONCLUSION

We could show that the conversion of the carbostyril **1** to its 2-aza analogues **4** and **5** can be achieved in good yields to obtain subsequently OSu ester **10** with comparable fluorescence spectral properties, however, with too low-quantum yield values for the use in analytical tasks. From the 6,7-dimethoxy-4-(trifluoro-methyl)-carbostyril series until now investigated, only N1-alkylated carbostyrils of structure type **I** [3c] gave quantum yields high enough for this purpose.

EXPERIMENTAL

Melting points were determined using a Stuart SMP3 Melting Point Apparatus in open capillary tubes. ^{1}H NMR and ^{13}C NMR spectra were recorded on a Bruker AMX 360 instrument (360 or 90 MHz) or on a Bruker Avance DRX 500 instrument (500 or 125 MHz). Chemical shifts are given in ppm (δ) from the internal TMS standard. IR spectra were recorded using a Mattson Galaxy Series FTIR 7020 instrument with potassium bromide discs. Elemental analyses were performed at the Microanalytical Laboratory of the University of Vienna, Austria. Mass spectra were obtained from a HP 1100 LC/MSD mass spectral instrument (positive or negative APCI ion source, 50–200 V, nitrogen). UV/Vis spectra were recorded on a Shimadzu UV/Vis scanning spectrophotometer UV-2101 PC; concentration: 0.01 mg/mL. Excitation and emission spectra were recorded using a Shimadzu RF-5001 PC spectrofluorometer, concentration: 0.001 mg/mL. Determination of quantum yields: emission signals were set in relation to the known signal of quinine sulfate at pH 1. Analytical HPLC was performed on a Shimadzu LC 20 system equipped with a diode array detector (215 and 254 nm) on a Pathfinder AS reversed phase (4.6150 mm, 5 μm) column, running an acetonitrile/water gradient (30–100% acetonitrile).

Microwave-assisted syntheses were carried out in an Emrys Synthesizer at 2450 MHz (Biotage AB, Uppsala). All reactions were monitored by thin layer chromatography (TLC) on 0.2-mm silica gel F-254 (Merck) plates using UV light (254 and 366 nm) for detection. Common reagent-grade chemicals are either commercially available and were used without further purification or prepared by standard literature procedures. All optical measurements were performed using analytical grade solvents.

2-Chloro-6,7-dimethoxy-4-(trifluoromethyl)quinoline (2)

Method A. A mixture of 6,7-dimethoxy-4-(trifluoromethyl)-quinolone (**1**) [3c] (2.73 g, 10 mmol) and phosphoryl chloride (7.60 g, 50 mmol) was heated under reflux for 12 h. The reaction mixture was cooled to room temperature and poured onto crushed ice (250 g) and kept for 30 min. The solid obtained was filtered by suction, washed with excess of water to afford 2.65 g (91% yield) of colorless needles.

Method B. A mixture of 6,7-dimethoxy-4-(trifluoromethyl)-quinolone (**1**) (0.273 g, 1 mmol) and phosphoryl chloride (3.0 g, 20 mmol) was heated at 120°C for 30 min by microwave irradiation in a sealed tube. After cooling to room temperature, the reaction mixture was worked up as described in method A. The yield was 0.260 g (90%), colorless needles, m.p. 134–136°C (ethanol); IR: 3468 m, 2978 w, 1619 m, 1593 m cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 4.05 (2 s, 6H, 2 OMe), 7.29 (s, 1H, 3-H), 7.43 and 7.56 (2 s, 2H, ArH); *Anal.* Calcd. for $C_{12}H_9ClF_3NO_2$ (291.66): C, 49.42; H, 3.11; N, 4.80; Found C, 49.21; H, 2.90; N, 4.58.

6,7-Dimethoxy-*N*-phenyl-4-(trifluoromethyl)quinolin-2-amine (4a). A mixture of 2-chloroquinoline **2** (0.291 g, 1 mmol) and aniline (**4a**) (0.186 g, 2 mmol) was heated for 3 h to 130°C. The reaction mixture was cooled to room temperature, the formed solid filtered and digested with diethylether (100 mL). The ether solution was taken to dryness under reduced pressure and the oily residue purified by dry flash column chromatography [9] using toluene as the eluent. The yield was 0.230 g (66%), pale yellow needles, m.p. 147–148°C (ethanol); IR: 3438 m, 3385 s, 1630 m, 1618 m, 1599 m cm^{-1}, ^{1}H NMR (CDCl$_3$): δ 4.00 and 4.03 (2 s, 6H, 2 OMe), 6.92 (s, b, 1H, 2-NH), 7.11–7.17 (m, 2H, ArH), 7.21–7.27 (m, 2H, ArH), 7.38 (t, *J* = 7.5 Hz, 2H, ArH), 7.54 and 7.57 (2 s, 2H, ArH);*Anal.* Calcd. for $C_{18}H_{15}F_3N_2O_2$ (348.33): C, 62.07; H, 4.34; N, 8.07; Found C, 62.02; H, 4.16; N, 7.95.

Ethyl 4-{[6,7-dimethoxy-4-(trifluoromethyl)quinolin-2-yl]amino}benzoate (4b). A mixture of 2-chloroquinoline **2** (2.91 g, 10 mmol) and ethyl 4-aminobenzoate (**3b**) (3.30 g, 20 mmol) was heated for 3 h to 130°C. The reaction mixture was cooled to room temperature, the formed solid filtered by suction, washed with ethanol (100 mL), and dried. The yield was 2.85 g (65%), yellow needles, m.p. 210–211°C (ethanol); IR: 3357 s, 3215 m, 2926 m, 1682 s, 1619 m, 1602 s cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 1.39 (t, *J* = 7.5 Hz, 3H, Me), 4.02 and 4.07 (2 s, 6H, 2 OMe), 4.35 (q, *J* = 7.1 Hz, 2H, CH$_2$), 6.96 (s, 1H, NH), 7.16 (s, 1H, ArH), 7.24 (s, 1H, ArH), 7.29 (s, 1H, ArH), 7.73 (d, *J* = 7.5 Hz, 2H, ArH), 8.07 (d, *J* = 7.5 Hz, 2H, ArH); MS: *m*/*z* (%) = 421 (21, M + 1), 420 (100, M$^+$);*Anal.* Calcd. for $C_{21}H_{19}F_3N_2O_4$ (420.39): C, 60.00; H, 4.56; N, 6.66; Found C, 59.92; H, 4.28; N, 6.65.

Methyl 2-{[6,7-dimethoxy-4-(trifluoromethyl)quinolin-2-yl]amino}benzoate (4c). A mixture of 2-chloroquinoline **2** (0.291 g, 1 mmol) and methyl anthranilate (0.302 g, 2 mmol) was heated for 3 h to 130°C. The mixture was cooled, the formed solid filtered by suction, washed with ethanol (100 mL), and dried. The yield was 0.252 g (62%), yellow needles, m.p. 188–189°C (ethanol); IR: 3266 m, 1684 s, 1601 m, 1570 w, 1536 m cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.97, 4.02, and 4.07 (3 s, 9H, 3 OMe), 6.98 (t, *J* = 8.3 Hz, 1H, ArH), 7.17 (s, 1H, ArH), 7.24 (s, 1H, ArH), 7.33 (s, 1H, ArH), 7.60 (t, *J* = 8.1 Hz, 1H, ArH), 8.07 (d, *J* = 8.3 Hz, 1H, ArH), 9.19 (d, *J* = 8.6 Hz, 1H, ArH), 10.96 (s, 1H, NH); MS: *m*/*z* (%) = 407 (20, M + 1), 406 (100, M), 375 (15), 374 (33); *Anal.* Calcd. for $C_{20}H_{17}F_3N_2O_4$ (406.36): C, 59.12; H, 4.22; N, 6.89; Found C, 58.83; H, 4.56; N, 6.54.

***N*-Benzyl-6,7-dimethoxy-4-(trifluoromethyl)quinolin-2-amine (5).** A mixture of 2-chloroquinoline **2** (0.291g, 1 mmol) and benzylamine (0.214 g, 2 mmol) was heated for 3 h to 130°C. The reaction mixture was cooled to room temperature, the formed solid filtered, dissolved in water (100 mL), and brought to pH 13 with conc. aq. sodium hydroxide solution. The aqueous solution was extracted with diethylether (3 × 30 mL), the ether solution taken to dryness under reduced pressure and the oily product purified by dry flash column chromatography [9] using toluene as eluent. The yield was 0.224 g (62%), pale yellow needles, m.p. 98–99°C (ethanol); IR: 3435 s, 3253 m, 1632 s, 1514 m cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.98 and 4.02 (2 s, 6H, 2 OMe), 4.71 (d, *J* = 5.8 Hz, 2H, CH$_2$), 5.04 (s, 1H, NH), 6.84 (s, 1H, ArH), 7.18 (s, 2H, ArH), 7.31–7.43 (m, 5H, PhH); MS: *m*/*z* (%) = 363 (25, M + 1), 362 (100, M), 361 (12, M − 1), 272 (8); *Anal.* Calcd. for $C_{19}H_{17}F_3N_2O_2$ (362.35): C, 62.98; H, 4.73; N, 7.73; Found C, 62.79; H, 4.57; N, 7.72.

7,8-Dimethoxy-5-(trifluoromethyl)tetrazolo[1,5-a]quinoline (6). A suspension of 2-chloroquinoline **2** (0.291 g, 1 mmol), sodium azide (0.260 g, 4 mmol), and Kryptofix-5 (0.01 g) in dimethylformamide (7 mL) was heated under TLC monitoring for about 80 h to 75–80°C. Then the mixture was cooled to room temperature and poured into ice/water (100 mL), the formed solid filtered by suction and washed with cold water (100 mL). The yield was 0.240 g (80%), brownish needles, m.p. 237–239°C (ethanol); IR: 1617 w, 1528 m, 1505 w cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 4.08 and 4.18 (2 s, 6H, OMe), 7.51 (s, 1H, ArH), 8.18 (s, 1H, ArH), 8.23 (s, 1H, ArH); MS: *m*/*z* (%) = 299 (14, M + 1), 298 (100, M), 272 (13); *Anal.* Calcd. for $C_{12}H_9F_3N_4O_2$ (298.23): C, 48.33; H, 3.04; N, 18.79; Found: C, 48.08; H, 3.01; N, 18.48.

6,7-Dimethoxy-4-(trifluoromethyl)-*N*-(triphenylphosphoranylidene)quinolin-2-amine (7). A mixture of tetrazolo[1,5-a]quinoline **6** (0.298 g, 1 mmol), and triphenylphosphane (0.524 g, 2 mmol) in toluene (8 mL) was heated under TLC monitoring for about 22 h under reflux. The solvent was removed under reduced pressure and the oily residue triturated with cyclohexane. The formed solid was filtered by suction, and washed with cyclohexane until the excess of triphenylphosphane was removed. The yield was 0.260 g (87%), brownish prisms, m.p. 183–184°C (methanol); IR: 1606 m, 1509 m cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.88 and 3.93 (2 s, 6H, 2 OMe), 6.67 (s, 1H, ArH), 7.14 (s, 1H, ArH), 7.37 (s, 1H, ArH), 7.44–7.48 (m, 6H, ArH), 7.52–7.56 (m, 3H, ArH), 7.86–7.92 (m, 6H, ArH); *Anal.* Calcd. for $C_{30}H_{24}F_3N_2O_2P$ (532.51): C, 67.67; H, 4.54; N, 5.26; Found: C, 67.94; H, 4.65; N, 5.06.

6,7-Dimethoxy-4-(trifluoromethyl)quinolin-2-amine (8). A mixture of *N*-(triphenylphosphoranylidene)quinolin-2-amine **7**

(0.532 g, 1 mmol) and conc. hydrochloric acid (7 mL) in methanol (8 mL) was heated under TLC monitoring for 5 h under reflux. The reaction mixture was cooled to room temperature, the formed solid filtered by suction and washed with excess of water until pH of 7 was reached. The yield was 0.262 g (96%), yellowish green crystals, m.p. 283–284°C (ethanol); IR: 3345 s, 3090 s, 1680 s, 1647 m, 1618 w, 1520 m cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 3.87 and 3.94 (2 s, 6H, OMe), 7.09 (s, 1H, ArH), 7.32 (s, 1H, ArH), 7.38 (s, 1H, ArH), 8.62 (s, b, 2H, NH$_2$); *Anal.* Calcd. for $C_{12}H_{11}F_3N_2O_2$ (272.23): C, 52.95; H, 4.07; N, 10.29; Found: C, 52.65; H, 3.78; N, 10.02.

4-{[6,7-Dimethoxy-4-(trifluoromethyl)quinolin-2-yl]amino}benzoic acid (9). A mixture of 4-(quinolin-2-yl)aminobenzoate **4b** (0.420 g, 1 mmol) and 1*M* aq. sodium hydroxide solution (2 mL) in ethanol (20 mL) was heated for 7 h under reflux, then the solvent was removed under reduced pressure and the residue dissolved in water (10 mL) under cooling. The mixture was acidified with conc. hydrochloric acid to pH = 1–2, the resulting precipitate filtered by suction and washed with excess of water. The yield was 0.310 g (80%), yellow prisms, m.p. 275–276° C (ethyl acetate); IR: 3457 s, 2940 w, 1677 s, 1624 w, 1600 s, 1526 s cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 3.87 and 3.96 (2 s, 6H, 2 OMe), 7.10 (s, 1H, ArH), 7.36 (s, 1H, ArH), 7.38 (s, 1H, ArH), 7.91 (d, *J* = 8.6 Hz, 2H, ArH), 8.04 (d, *J* = 8.6 Hz, 2H, ArH), 9.95 (s, 1H, NH), 12.54 (s, 1H, OH); MS: *m*/*z* (%) = 393 (18, M + 1), 392 (100, M), 377 (12); *Anal.* Calcd. for $C_{19}H_{15}F_3N_2O_4$ (392.34): C, 58.17; H, 3.85; N, 7.14; Found: C, 57.82; H, 3.76; N, 7.00.

1[(4-{[6,7-Dimethoxy-4-(trifluoromethyl)quinolin-2-yl]amino}benzoyl)oxy]pyrrolidine-2,5-dione (OSu-ester) (10). *N*-Hydroxysuccinimide (0.115 g, 1 mmol) was added slowly with stirring at 0°C to a solution of 4-(quinolin-2-yl)amino-benzoic acid **9** (0.392 g, 1 mmol) in dry tetrahydrofuran (20 mL). Then *N*,*N*-diisopropylcarbodiimide (0.125 g, 1 mmol) was added dropwise with stirring at 0–5°C which formed a yellowish-white precipitate. This mixture was stirred further at 0–5°C for 14–15 h. The solvent was removed under reduced pressure and the solid residue obtained was digested in dry tetrahydrofuran (10 mL), filtered and washed well with dry tetrahydrofuran. Then the solid was stirred in dry ethanol (50 mL) at room temperature for 30 min to remove *N*,*N*-diisopropylurea formed during the reaction. Suction filtration afforded 0.288 g (59%) of OSu-ester, pale yellow prisms, m.p. 268–269°C (ethanol); IR: 3435 s, 3340 s, 3212 m, 1765 s, 1723 s, 1618 w, 1598 s, 1578 w cm^{-1};^{1}H NMR (CDCl$_3$): δ 2.93 (s, 4H, 2 CH$_2$), 4.03 and 4.09 (2 s, 6H, 2 OMe), 7.22 (s, 1H, ArH), 7.25 (s, 1H, ArH), 7.33 (s, 1H, ArH), 7.77 (d, *J* = 8.4, 2H, ArH), 8.16 (d, *J* = 8.6, 2H, ArH); MS: *m*/*z* (%) = 490 (25, M + 1), 489 (100, M), 392 (10); *Anal.* Calcd. for $C_{23}H_{18}F_3N_3O_6$ (489.41): C, 56.45; H, 3.71; N, 8.59; Found: C, 56.44; H, 3.89; N, 8.30.

***N*-(4-{[6,7-Dimethoxy-4-(trifluoromethyl)quinolin-2-yl]amino}benzoyl)phenylalanine (11).** To a solution of (D,L)phenylalanine (38 mg, 0.2 mmol) in dimethyl-sulfoxide/water (9:1, 2.5 mL), a solution of OSu-ester **10** (98 mg, 0.2 mmol) in dimethylsulfoxide/water (9:1, 2.5 mL) was added dropwise at room temperature. Then aq. pH 7 buffer (0.75 mL) was added, the mixture stirred for 14 h at 50°C, poured into water (25 mL) and then acidified with conc. hydrochloric acid to pH = 1–2. A solid separated, which was filtered by suction and washed with excess of water to afford 85 mg (63%) of yellow prisms, m.p. 272–273°C (acetone); IR: 3366 w, 2933 m, 1647 w, 1625 w, 1603 s, 1575 w cm^{-1}; ^{1}H NMR (CDCl$_3$): δ 3.33 and 3.41 (2 dd, *J* = 5.7 and 13.9 Hz, 2H, CH$_2$), 3.99 and 4.05 (2 s, 6H, 2 OMe), 5.09 (dd, 5.8 and 6.7 Hz, 1H, CH), 6.87 (d, *J* = 5.9 Hz, 1H, amide-NH), 7.18–7.24 (m, 6H, ArH), 7.30 and 7.33, (2 s, 2H, ArH), 7.37 (d, *J* = 8.2 Hz, 2H, ArH), 7.75 (d, *J* = 8.3 Hz, 2H, ArH), 10.20 (s, 1H, 2-NH); MS: *m*/*z* (%) = 541 (11, M + 2), 540 (47, M + 1), 539 (100, M), 538 (35, M − 1), 391 (14); *Anal.* Calcd. for $C_{28}H_{24}F_3N_3O_5$ (539.52): C, 62.34; H, 4.48; N, 7.79; Found C, 61.91; H, 4.37; N, 7.63.

***N*-(4-{[6,7-Dimethoxy-4-(trifluoromethyl)quinolin-2-yl]amino}benzoyl)glycylglycylglycine (12).** To a solution of glycylglycyl-glycine (38 mg, 0.2 mmol) in dimethyl-sulfoxide/water (9:1, 2.5 mL), a solution of OSu-ester **10** (98 mg, 0.2 mmol) in dimethylsulfoxide/water (9:1, 2.5 mL) was added dropwise at room temperature. Then aq. pH 7 buffer (0.75 mL) was added, the mixture stirred for 14 h at 50°C, poured into water (25 mL), and then acidified with conc. hydrochloric acid to pH = 1–2. A solid separated, which was filtered by suction and washed with excess of water to afford 75 mg (53%) of yellow prisms, m.p. 238–239°C (acetone); IR: 3338 s, 3306 s, 3117 m, 3088 m, 2961 w, 2925 m, 1721 s, 1662 s, 1625 w, 1605 s, 1568 w, 1531 s cm^{-1}; ^{1}H NMR (DMSO-d_6): δ 3.76–3.78 (m, 4H, 2 CH$_2$), 3.87 (s, 3H, OMe), 3.90 (d, *J* = 5.4 Hz, 2H, CH$_2$), 3.97 (s, 3H, OMe), 7.11 (s, 1H, ArH), 7.35 and 7.39 (2 s, 2H, ArH), 7.88 (d, *J* = 8.6 Hz, 2H, ArH), 8.01 (d, *J* = 8.3 Hz, 2H, ArH), 8.17–8.24 (m, 2H, amide-NH), 8.64 (t, *J* = 5.3 Hz, 1H, amide-NH), 9.91 (s, 1H, 2-NH); MS: *m*/*z* (%) = 564 (14, M + 1), 563 (42, M), 507 (17), 450 (25), 449 (100), 392(85); *Anal.* Calcd. for $C_{25}H_{24}F_3N_5O_7$ (563.49): Calcd. 3-Imino-2-amino-isatines were obtained by a one-pot reaction of an excess of aniline (or its derivatives) with 1,2-bis(dimethylamino)-1,2-dichloro-ethene (prepared *in situ* from DMF). Subsequent hydrolysis yielded the corresponding isatine derivatives in reasonable to high yields. DFT calculations with regard to the mechanisms of this reaction sequence are presented.

J. Heterocyclic Chem., **46**, 421 (2009).

INTRODUCTION

Isatine **4** and its derivatives play an important role in the pharmaceutical and dye industry. Drugs containing isatine units cure diseases such as epilepsy [1], tuberculosis [2], and bulimia [3]. Isatin derivatives are furthermore employed as antibacterial [4] or antifugal [5] compounds or to treat inflammations [6].

Because of its importance, various synthetic routes to isatine and its derivatives have been developed. Although the large-scale synthesis of unsubstituted isatine is accomplished by oxidation of indigo [7], several methods are known for the preparation of isatine derivatives on the laboratory or pharmaceutical scale. Among these are the classical methods by Sandmeyer [8] and Gassman and von Bergen [9] as well as a more recent methodology developed by Meth-Cohn and Goon [10], the latter of which is restricted, however, to *N*-methyl isatines. Yet, most of these methods involve harsh conditions, expensive chemicals, and require multiple steps, including the isolation of several intermediates.

In the course of our investigations of nucleophilic substitution reactions on 1,2-bis(dimethylamino)-1,2-bisonio-ethenes [11], we have developed a new versatile one-pot synthesis of N-unsubstituted isatine derivatives, starting from the common solvent DMF and involving mostly customary chemicals, as described in more detail below.

RESULTS AND DISCUSSION

In the early 1980s, Boehme and Sutoyo [12] reported on the dimerization of deprotonated chlorochlorides deriving from DMF (and other formamides), yielding 1,2-bis(dimethylamino)-1,2-dichloro-ethene **1** (Scheme 1).

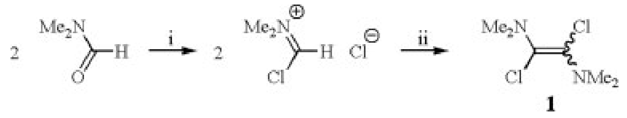
We found that treatment of a solution of **1** in THF with an excess of aniline did not result in the formation of the anticipated tetraaminoethene **2** (Scheme 2). Instead the known [13] isatine derivative **3** was isolated after stirring the reaction mixture for 24 h at room temperature and subsequent exposure to aerial oxygen. Apart from spectroscopic data, the structure of **3** was further confirmed by single-crystal X-ray crystallography, which was in perfect agreement with the already published structural analysis of **3** [14].

Indole derivative **3** could be isolated in 65% yield over all steps (*i.e*., based on the amount of DMF used) by simple recrystallization from ethanol. Hydrolysis of **3** to isatine **4** could be achieved by treating **3** with conc. HCl in glacial acetic acid (yield: 71 %) [15]. Thus, a novel synthetic route to isatine **4** from DMF could be developed, which requires only the isolation of intermediate **3** *via* recrystallization (as ethene **1** can be prepared from DMF in a one-pot reaction and can be treated *in situ* with aniline to give the isatine precursor **3**).

To examine the range of application of our method, we reacted several aromatic amines of different electronic nature with ethene **1**. Results are shown in Table 1.

In all cases, the corresponding N-unsubstituted isatines **4a–g** could be obtained by recrystallization from ethanol. Although reaction conditions were not specifically optimized for the different aniline derivatives, reasonable overall yields (based on the amount of DMF) could be achieved in most cases. Still higher yields

Scheme 1. Synthesis of **1** by deprotonation of a chlorochloride derived from DMF; (i) $C_2O_2Cl_2$, 0 °C and (ii) Hünig's base ($NEt\mathit{i}Pr_2$).



should be within reach by further optimization of the reaction procedure. Based on these (few) orientating experiments, no definitive statement can be made concerning the influence of the various substituents X, Y, and Z on the overall yield. It seems, though, that the presence of electron-withdrawing groups leads to a lower yield of the corresponding intermediate of type **3**. This would be in accordance with the reaction mechanism proposed below. Yet, in our experiments we also observed that addition of the bromo- and fluoro-substituted aniline derivatives to a solution of ethene **1** resulted in a stronger increase of temperature and a faster optical change of the solution (compared with the other derivatives).

In contrast, when adding *N*-methyl aniline to a solution of **1**, no indications of such a cyclization reaction could be observed. Instead, the corresponding bis(dimethylamino)-bis(methyl-phenylamino)-ethene was detected by mass spectrometry (as well as its bis-oxidized form). Obviously, both chloro-substituents had been substituted by *N*-methyl aniline. Thus, only primary anilines are applicable for the synthesis of isatine derivatives according to our new method. A possible reason for this limitation is given below. In the case of secondary aniline derivatives, it should in principle be possible to isolate the corresponding tetraamino-ethenes (*cf.* Scheme 2).

Table 1

Synthesis of isatine derivatives **3a–g** and isatines **4a–g**.

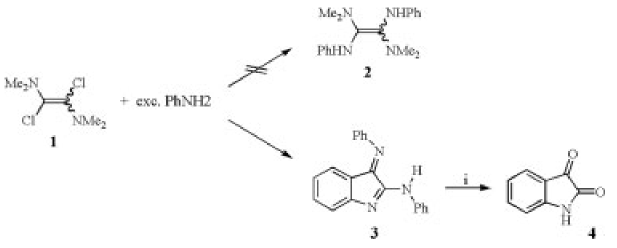
	X	Y	Z	**3** (%)[a]	**4** (%)[b]
a	H	H	H	65	71
b	CH_3	H	H	25	68
c	OCH_3	H	H	65	66
d	H	Br	H	18	93
e	F	H	H	28	85
f	$COOCH_3$	H	H	–	10
g	H			–	31

[a] Yields for **3a–g** are based on the amount of DMF.

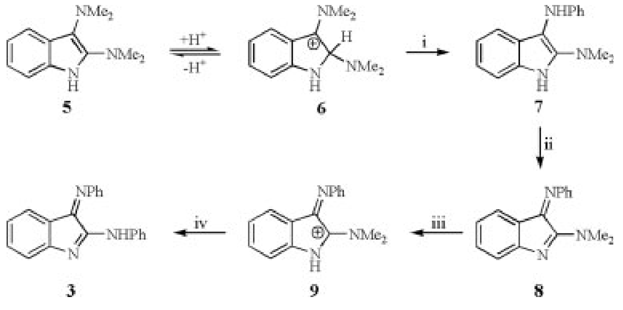
[b] Yields for **4a–e** are based on the amount of **3a–e** and for **4f,g** on the amount of DMF, as intermediates **3f,g** were not isolated.

During the course of our investigations, some intermediates could be detected, which shed some light on the mechanism of the formation of **3** from ethene **1**. It was observed that a clear, red solution of **3** in THF was only obtained after exposure of the reaction mixture to aerial oxygen. Under inert gas conditions, addition of aniline to ethene **1** resulted in an orange suspension. Although the solid compound could be isolated, it proved to be very sensitive to oxygen and could not be characterized by NMR spectroscopy. Its mass spectrum, however, showed a peak at $m/z = 252$, in accord with structure **7** (Scheme 3). When the colorless solid was dissolved in CH_2Cl_2 and stirred on air, the solution turned red rapidly. Apparently, oxidation to **8** had taken place, as evidenced by a mass peak at $m/z = 250$ (substitution at position C2 of the heterocycle can be ruled out due to the fact that its oxidation would produce an anti-aromatic intermediate). Compound **8** could be isolated and characterized by NMR spectroscopy. As expected, its methyl groups show a coalescence phenomenon at about −10°C. Incidentally, analogous compounds could also be detected during the preparation of

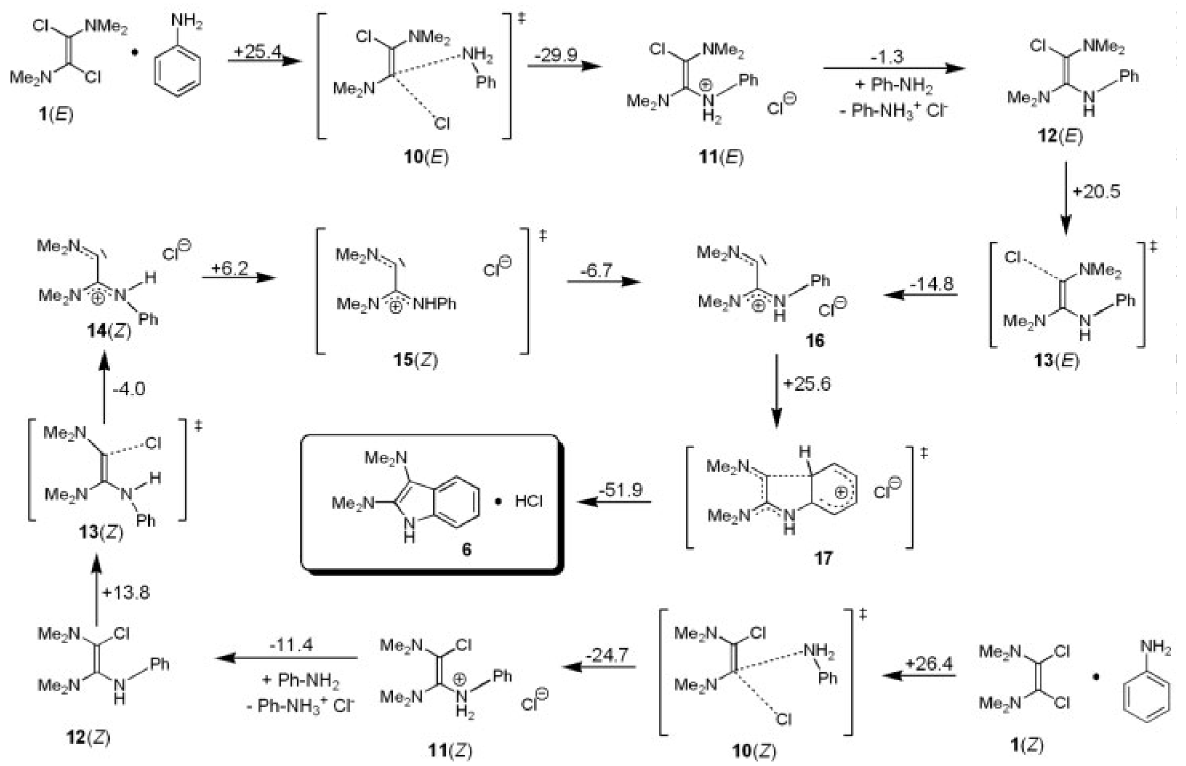
Scheme 2. Reaction of **1** with an excess of aniline; (i) conc. HCl in glacial CH_3COOH.



Scheme 3. Proposed mechanism of the formation of 3 (starting after cyclization to 5) according to experimental hints; (i) + $PhNH_2$, -$HNMe_2$, (ii) oxidation by air, (iii) + H^+, and (iv) + $PhNH_2$, -$HNMe_2$.



Scheme 4



compounds **3d–f**. In the case of compound **3d**, a heterocyclic intermediate containing two dimethylamino groups (analogous to **5** in Scheme 3) could also be detected in the reaction mixture *via* mass spectrometry.

Thus, it seems plausible that the primary product of the ring closure reaction leading to **3**(**a**) is intermediate **5**. After subsequent substitution of the dimethylamino group at C2 by aniline, oxidation by aerial oxygen leads to the (experimentally isolated) compound **8**. Further substitution of the second NMe$_2$ group by aniline finally yields isatine derivate **3**. This mechanism is shown in Scheme 3.

When *N*-methyl aniline instead of aniline is used in the reaction with ethene **1**, the corresponding *N*-methylated intermediate **7** cannot be oxidized *via* formal H$_2$ abstraction, and thus only primary amines are applicable as reactants.

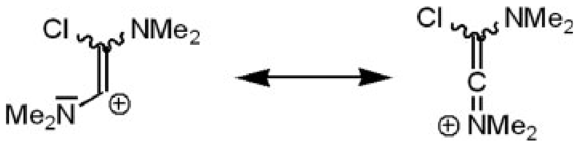
No experimental data could be obtained regarding the mechanisms of the ring closure, ultimately leading to compound **5**. Therefore, DFT calculations were carried out to gain some insight into the first steps of the formation of the isatine derivative from ethene **1**.

Computational section. The reaction sequence starting from ethylene derivative **1** and aniline to yield the isatine derivative **5** includes several mechanistic key steps. To analyze and characterize those steps, DFT-computations were performed using the Gaussian 98W suite of programs (for further details see Supporting Information). Scheme 4 shows the complete reaction path.

The first key step of the reaction sequence is the substitution of chloride in **1** by aniline. In principle such substitutions at vinyl-like carbon centres can proceed in two different ways: (a) *via* an addition/elimination mechanism under formation of an intermediate in analogy to the S$_N$Ar mechanism (subsequently called **A**) or (b) *via* an elimination/addition mechanism in analogy to the S$_N$1 mechanism (subsequently called **B**) [16,17]. Reactions according to **A** were found for ethylene derivatives carrying strong electron withdrawing substituents. In contrast, ethylene derivatives with electron donating substituents show reactions according to **B**. Ethylene derivative **1** has two –I-acceptor substituents (chlorine) and two donor substituents (NMe$_2$). Hence, in principle both alternative mechanisms are to be considered. Because **1** is synthesized *in situ*, a mixture of the *E*- and *Z*-isomer enters the reaction sequence (this problem will be addressed later). Both forms need to be analyzed computationally.

Because of the gas phase conditions in the computations, the formation of ions (as in **B**) will not be favored. Hence, the corresponding reaction barriers should be overestimated in comparison to the real

Scheme 5. Partial formation of ketene-iminium structure in the transition state.



substitution conditions in polar solvents. Even with this handicap, the reaction barrier in **B** was found to be 26.4 kcal/mol for the *Z*-form and 25.4 kcal/mol for the *E*-isomer. A reaction according to **A**, or alternatively *via* a S_N2-in-plane mechanism, could not be determined computationally, but the corresponding reaction barrier was found to be at least 50 kcal/mol for both isomers. NBO analyses of the corresponding transition structures clearly explain this result. The cation in **10**, formed by elimination of chloride from **1**, is stabilized by partial formation of a ketene-iminium structure (*cf.* Scheme 5). The electron distribution of the N—C—π-bond [18] indicates the partial bond formation, whereas the C—C—π-bond is not influenced at all. N—C—C angles are 176° (*Z*-form) and 156° (*E*-form).

The bond lengths between the formally cationic carbon centre and both the chloride ion (351 and 315 pm) and the aniline (355 and 261 pm) indicate the formation of a nearly uncoordinated ketene-iminium-system.

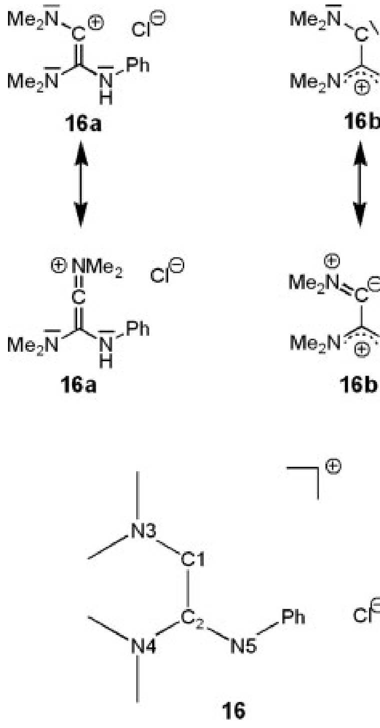
The second key step of the reaction sequence is the substitution of the second chlorine substituent in **12** under formation of the five-ring system **5**. Since **12** carries three donor substituents and only one chlorine substituent, the exchange reaction should proceed *via* the same mechanism as for derivative **1**, or even *via* formation of a ketene-iminium species as an intermediate, and not as a transition structure. Both isomers of **12** can be transformed into the same salt-like structure **16** (*via* transition state **13** (*E*-form) or two transition states **13** and **15**, with one connecting, energetically not favored intermediate **14** (*Z*-form)). This result simplifies the problem of the *E*- and *Z*-isomers because the question of *E* or *Z* does not occur in **16**. The (highest) reaction barrier for this transformation is 21 kcal/mol and the salt **16** is energetically not favored in comparison to **12** (6 kcal/mol for the *E*-isomer, 9 kcal/mol for the *Z*-isomer, respectively). But it should always be taken into account that these energies will be much lower for the experimental reaction due to solvent effects. Those will make structures **12** and **16** energetically at least comparable or even favor the salt **16**. The chloride ion in **16** is stabilized *via* several hydrogen bonds in the gas phase.

Nevertheless, this result brings up another interesting question: What is the electronic nature of **16**? Is this intermediate a cation stabilized *via* a ketene-iminium contribution (**16a**) or must it be seen as a donor–acceptor substituted carbene **16b** (*cf.* Scheme 6) Analysis of bond lengths, bond angles, and tetrahedral angles in context with NBO analysis answers this question (Scheme 6).

The representative bond lengths clearly show that **16** is not a ketene-iminium species. Additionally, NBO analysis identifies a lone pair located at C1 with a hybridization of $sp^{1.65}$ and partial formation of a double bond between C1 and N3 with a density distribution of 26% (C1) and 74% (N3). Hence, the best representation of the nature of **16** is that of a donor–acceptor substituted carbene **16b**, which is stabilized by partial formation of an iminium structure as is shown in Scheme 6.

Because of this electronic nature the subsequent ring formation could occur *via* nucleophilic attack of the carbenes lone pair toward the aniline's π* system or alternatively *via* nucleophilic attack of the aniline's π systems toward to unoccupied orbital of the carbene. The calculated barrier for the ring closure is 25.6 kcal/mol (B3LYP/6-311+G**). NBO analysis of the corresponding transition state **17** shows that the unoccupied orbital at the carbene centre is nucleophilically attacked by the aniline's π system. In the transition state **17**, the new C—C—σ bond starts to form (density distribution: 33% on C1 and 67% on the aromatic centre) and the

Scheme 6. Electronic nature of 16 and geometry at B3LYP/6-311+G**. Selected bond lengths [pm] and angles [°]: C1-C2=146; C1-N3=129; C2-N4=134; C2-N5=135; C2-C1-N3=118; C1-C2-N4=119; C1-C2-N5=122; N4-C2-N5=119; C1-C2-N4-N5=176; N3-C1-C2-N4=107; N3-C1-C2-N5=78.



ethylene's C—C—π bond is ''rebuilt'' (density distribution: 46% on C1 and 54% on C2). The C1-N3 double bond, responsible for the partial ''iminium character'' of **16**, is reduced to a distribution of 18% on C1 and 82% on N3. Figure 1 gives representative geometry parameters for **17**.

Retrosynthetical analysis.. Examined from a retrosynthetical point of view, formation of isatine **4** is achieved by the reaction of aniline with C_2O_2 (in combination with an oxidation reaction), which is unstable under normal reaction conditions [19] (Scheme 7). Thus, ethene **1** acts as a synthetic equivalent of C_2O_2.

By substitution of both chloro-substituents of ethene **1**, followed by subsequent oxidation and hydrolysis, the synthesis of further, structurally different diketones appears to be feasible.

CONCLUSIONS

A new synthetic route to *N*-unsubstituted isatines has been presented, which is based on the reaction of ethene **1** with aniline derivatives. The isatine precursors **3a–g** are obtained under mild reaction conditions in a one-pot reaction starting from DMF. Apart from the respective substituted aniline, only standard chemicals such as oxalyl chloride or Hünig's base are employed as reactants, and isolation of the isatine precursors is accomplished by simple recrystallization. In general, reasonable overall yields could be achieved (especially for anilines with electron-donating substituents). Taking all that into account, the method presented in this article shares most of its advantages with the introduced method by Meth-Cohn and Goon [10] but in addition offers the possibility to synthesize N-unsubstituted isatine derivatives. Our method thus seems to have all prerequisites to evolve as a versatile isatine synthesis, especially for small or medium scale amounts.

EXPERIMENTAL

General. All operations in THF were carried out under a dry inert nitrogen atmosphere using standard Schlenk techniques. THF was distilled under nitrogen from sodium-benzophenone. ^{1}H NMR, ^{13}C NMR, and ^{19}F NMR spectra were recorded on a Bruker Avance spectrometer. The IR-spectra were taken on Bruker spectrophotometer in KBr pellets. Mass spectra were determined using a Micromass ZabSpec spectrometer. The elemental analyses were obtained on a EA 1110 CHNS analyzer.

General procedure for the preparation of 3a–e. A solution of 0.92 mL (12 mmol) DMF in 25 mL THF was cooled to 0°C, and under inert gas conditions, 1.03 mL (12 mmol) oxalyl chloride was added. After stirring for 2 h at room temperature, the suspension was again cooled to 0°C and a solution of 2.1 mL (12 mmol) Hünig's base (NEt*i*Pr$_2$) was added dropwise. After stirring for 1 h at 0°C and 2 h at room temperature, the precipitate was filtered off, and then 25 mmol of the corresponding aniline was added to the filtrate. After stirring for 16 h at room temperature, aerial oxygen was passed through the solution for several hours. The solvent was evaporated, the residue dissolved in 150 mL CH_2Cl_2 and washed twice with 50 mL H_2O. The organic phase was evaporated to dryness and the residue recrystallized from boiling ethanol.

2-Phenylamino-3-phenylimino-3H-indole 3a. Red solid; ^{1}H NMR ($CDCl_3$): δ = 6.64 (m, 2H, Phen), 7.05 (dd, J = 7.70 Hz, 1.1, 2H, Phen), 7.09 (t, J = 7.70 Hz, 1H, Phen), 7.23 (m, 3H, Phen), 7.42 (m, 4H, Phen), 7.85 (d, J = 7.70 Hz, 2H, Phen), 7.91 (s, 1H, NH); ^{13}C NMR ($CDCl_3$): δ = 118.9 (CH Phen), 119.3 (CH Phen), 119.6 (C q), 122.8 (CH, Phen), 123.6 (CH, Phen), 125.8 (CH, Phen), 129.4 (CH, Phen), 129.6 (CH, Phen), 134.7 (CH, Phen), 138.5 (C q), 149.0 (C q), 158.3 (C q), 160.4 (C q), 162.9 (C q); IR (KBr): 3337, 164, 1629, 1597, 1574, 1545, 1481, 1440, 1320, 1300, 1244, 1226, 1192, 1146, 902, 785, 755, 715, 690, 582, 532, 509, 494 cm^{-1}; MS (FAB$^+$): *m/z*: 298[M$^+$+1]; elemental analysis calcd for $C_{20}H_{15}N_3$: C 80.78, H 5.08, N 14.13; found C 79.12, H 5.38, N 14.05.

Deep Red solid; ^{1}H NMR ($CDCl_3$): δ = 2.06 (s, 3H, CH_3), 2.32 (s, 3H, CH_3), 2.41 (s, 3H, CH_3), 6.61 (s, 1H, Phen), 6.97 (d, J = 8.17 Hz, 2H, Phen), 7.05 (q, J = 7.81 Hz, 2H, Phen), 7.17 (d, J = 8.17 Hz, 2H, Phen), 7.23 (d, J = 8.05 Hz, 2H, Phen), 7.71 (d, J = 8.42 Hz, 2H, Phen), 7.83 (s, 1H, NH); ^{13}C NMR ($CDCl_3$): δ = 20.6 (CH_3), 20.8 (CH_3), 118.7 (CH, Phen), 119.1 (CH, Phen), 119.2 (CH, Phen), 119.8 (C q, Phen), 126.2 (CH, Phen), 129.8 (CH, Phen), 130.0 (CH, Phen), 132.0 (C q, Phen), 132.9 (C q, Phen), 134.9 (CH, Phen), 135.6 (C q, Phen),136.2 (C q, Phen), 146.3 (C q, Phen), 158.0 (C q), 160.7 (C q); IR (KBr): 3202, 3025, 2918, 1657, 1602, 1569, 1542, 1511, 1500, 1469, 1449, 1333, 1305, 1248, 1197, 1172, 1101, 1035, 939, 860, 840, 820, 735, 718, 578, 510cm^{-1}; MS (FAB$^+$): m/z: 340[M$^+$+1]; elemental analysis calcd for $C_{23}H_{21}N_3$: C 81.38, H 6.24, N 12.38; found C 80.86, H 6.24, N 12.33.

3-(4-Methoxyphenylimino)-5-methoxy-N-(4-methoxyphenyl)-3H-indol-2-amine 3c. Violet solid; ^{1}H NMR ($CDCl_3$): δ = 3.57 (s, 3H, CH_3), 3.79 (s, 3H, CH_3), 3.84 (s, 3H, CH_3), 6.54 (d, J = 2.45 Hz, 1H, Phen), 6.76 (dd, J = 8.43, 2.54 Hz, 1H, Phen), 6.94 (m, 4H, Phen), 7.06 (d, J = 8.95 Hz, 3H, Phen), 7.74 (m, 3H, Phen, NH); ^{13}C NMR ($CDCl_3$): δ = 55.5 (CH_3), 55.6 (CH_3), 112.4 (CH, Phen), 114.4 (CH, Phen), 114.5 (CH, Phen), 118.1 (CH, Phen), 118.8 (CH, Phen), 120.2 (C q, Phen), 120.3 (CH, Phen), 121.0 (CH, Phen), 132.0 (C q, Phen), 141.3 (C q, Phen), 155.2 (C q, Phen), 155.6 (C q, Phen), 156.1 (C q, Phen), 157.5 (C q, Phen), 158.0 (C q), 159.6 (C q); IR (KBr): 3338, 3000, 2946, 2829, 1632, 1608, 1579, 1542, 1506, 1468, 1435, 1299, 1285, 1238, 1212, 1184, 1172, 1132, 1106, 1038, 1024, 879, 852, 823, 801, 771, 739, 636, 589, 503 cm^{-1}; MS (FAB$^+$): m/z: 388[M$^+$+1]; elemental analysis calcd for $C_{23}H_{21}N_3O_3$: C 71.30, H 5.46, N 10.85; found C 70.68, H 5.45, N 10.57.

3-(3-Bromophenylimino)-6-bromo-N-(3-bromophenyl)-3H-indol-2-amine 3d. Red solid; ^{1}H NMR ($CDCl_3$): δ = 6.51 (d, J = 8.24 Hz, 1H, Phen), 6.83 (dd, J = 8.24, 1.65 Hz, 1H, Phen), 6.96 (m, 1H, Phen), 7.22 (m, 4H, Phen), 7.41 (m, 1H, Phen), 7.68 (m, 1H, Phen), 8.06 (s, 1H, NH); ^{13}C NMR ($CDCl_3$): δ = 117.4 (CH, Phen), 117.7 (C q, Phen), 117.9 (CH, Phen), 121.8 (CH, Phen), 122.2 (CH, Phen), 122.7 (CH, Phen), 122.9 (C q, Phen), 123.1 (C q, Phen), 126.0 (CH, Phen), 126.3 (CH, Phen), 126.9 (CH, Phen), 128.8 (CH, Phen), 129.6 (C q, Phen), 130.5 (CH, Phen), 130.5 (C q, Phen), 130.8 (CH, Phen), 139.3 (C q, Phen), 149.5 (C q, Phen), 157.9 (C q), 159.3 (C q); IR (KBr): 3316, 1672, 1625, 1594, 1564, 1543, 1478, 1466, 1439, 1409, 1308, 1262, 1229, 1187, 1088, 1051, 1022, 994, 921, 872, 853, 808, 767, 738, 677, 657, 596, 424 cm^{-1}; MS (FAB$^+$): m/z: 532[M$^+$-2], 534[M$^+$], 536[M$^+$+2]; elemental analysis calcd for $C_{23}H_{21}Br_3N_3$: C 44.98, H 2.26, N 7.87; found C 44.30, H 2.77, N 7.48.

3-(4-Fluorophenylimino)-5-fluoro-N-(4-fluorophenyl)-3H-indol-2-amine 3e. Red solid; ^{1}H NMR ($CDCl_3$): δ = 6.44 (m, 1H, Phen), 6.83 (m, 2H, Phen), 7.01 (m, 5H, Phen), 7.15 (m, 2H, Phen), 7.78 (m, 2H, Phen); ^{13}C NMR ($CDCl_3$): δ = 112.6, 112.9 (CH, Phen), 115.5, 115.7 (C q, Phen), 115.8, 116.0 (CH, Phen), 116.2, 116.2 (C q, Phen), 116.3, 116.6 (CH, Phen), 119.4 (C q, Phen), 119.6, 119.7 (C q, Phen), 120.5 (CH, Phen), 120.6 (CH, Phen), 120.6 (CH, Phen), 120.7 (CH, Phen), 143.9 (C q), 157.3, 157.7 (C q, Phen), 159.7, 160.1 (C q, Phen), 162.1 (C q); IR (KBr): 3199, 1656, 1629, 1578, 1544, 1500, 1460, 1302, 1270, 1232, 1206, 1184, 1153, 1124, 890, 847, 826, 741, 581, 516, 498, 464 cm^{-1}; MS (FAB$^+$): m/z: 352[M$^+$+1]; elemental analysis calcd for $C_{23}H_{21}F_3N_3$x0.5 H_2O: C 66.66, H 3.64, N 11.66; found C 65.58, H 3.59, N 11.53.

General procedure for the preparation of 4a–e. A solution of 2.3 mmol of the isatin derivatives **3a–e**, 30 mL glacial acetic acid, 4 mL conc. HCl and 4 mL H_2O was refluxed for 20 min. After cooling to RT the solvent was evaporated to dryness *in vacuo*. The orange residue was then taken up in water, filtrated, washed with water and dried under vacuum.

Isatine 4a. Orange solid; ^{1}H NMR (Aceton-d_6): δ = 7.02 (d, J = 7.92 Hz, 1H, H4), 7.11 (t, J = 7.5 Hz, 1H, H5), 7.52 (d, J = 7.23 Hz, 1H, H7), 7.62 (t, J = 7.71 Hz, 1H, H6), 10.00 (s, 1H, NH); ^{13}C NMR (Aceton-d_6): δ = 113.3 (C7), 119.3 (C3a), 124.2 (C5), 125.7 (C4), 139.6 (C6), 151.8 (C7a), 160.2 (C2), 185.3 (C3); IR (KBr): 3192, 1730, 1618, 1461, 1332, 1202, 1144, 1096, 947, 771, 661, 638, 480, 456 cm^{-1}; MS (FAB$^+$): m/z: 148 [M$^+$+1]; elemental analysis calcd for $C_8H_5NO_2 \times 0.25\ H_2O$: C 63.37, H 3.66, N 9.24; found C 63.54, H 3.63, N 8.92.

5-Methylisatine 4b. Orange/red solid; ^{1}H NMR (Aceton-d_6): δ = 2.29 (s, 3H, CH_3), 6.89 (d, J = 7.98 Hz, 1H, H7), 7.31 (s, 1H, H4), 7.41 (d, J = 8.01 Hz, 1H, H6), 9.87 (s, 1H, NH); ^{13}C NMR (Aceton-d_6): δ = 20.4 (CH_3), 113.2 (C7), 119.3 (C3a), 125.8 (C4), 133.9 (C5), 140.0 (C6), 149.7 (C7a), 160.4 (C2), 185.5 (C3); IR (KBr): 3286, 1743, 1626, 1491, 1438, 1399, 1304, 1195, 1127, 825, 738, 659, 552, 456 cm^{-1}; MS (FAB$^+$): m/z 161[M$^+$]; elemental analysis calcd for $C_9H_7NO_2$: C 67.08, H 4.38, N 8.69; found C 67.00, H 4.22, N 8.77.

5-Methoxyisatine 4c. Orange solid; ^{1}H NMR (DMSO-d_6): δ = 3.73 (s, 3H, OCH_3), 6.83 (d, J = 8.52 Hz, 1H, H7), 7.05 (d, J = 2.63 Hz, 1H, H4), 7.17 (dd, J = 8.52, 2.72 Hz, 1H, H6), 10.83 (s, 1H, NH); ^{13}C NMR (DMSO-d_6): δ = 55.7 (OCH_3), 108.7 (C4), 113.3 (C6), 118.0 (C3a), 124.8 (C7), 144.6 (C7a), 155.3 (C5), 159.5 (C2), 184.6 (C3); IR (KBr): 3156, 3101, 1748, 1732, 1637, 1607, 1492, 1446, 1408, 1309, 1284, 1265, 1242, 1201, 1154, 1035, 982, 903, 825, 773, 740, 703, 657, 603, 459 cm^{-1}; MS (FAB$^+$): m/z 178 [M$^+$+H]; elemental analysis calcd for $C_9H_7NO_3$: C 61.02, H 3.98, N 7.90; found C 60.38, H 4.06, N 7.80.

6-Bromoisatine 4d. Yellow/orange solid; ^{1}H NMR (DMSO-d_6): δ = 7.07 (d, J = 1.47 Hz, 1H, H7), 7.25 (dd, J = 7.99, 1.57 Hz, 1H, H5), 7.43 (d, J = 7.97 Hz, 1H, H4), 11.16 (s, 1H, NH); ^{13}C NMR (DMSO-d_6): δ = 114.9 (C7), 117.0 (C3a), 125.6 (C5), 126.2 (C3), 131.6 (C6), 151.5 (C7a), 159.3 (C2), 183.2 (C3); IR (KBr): 3172, 1744, 1716, 1609, 1443, 1327, 1262, 1246, 1206, 1100, 1053, 953, 907, 892, 789, 742, 663, 589, 511, 471 cm^{-1}; MS-EI: m/z 224 [M$^+$, ^{79}Br], 226 [M$^+$, ^{81}Br]; elemental analysis calcd for $C_8H_4NO_2Br$: C 42.51, H 1.78, N 6.20; found C 41.80, H 2.15, N 5.78.

5-Fluoroisatine 4e. Orange/red solid; ^{1}H NMR (DMSO-d_6): δ = 6.89 (dd, J = 8.8, 3.85, 1H, H7), 7.35 (dd, J = 7.14, 2.74 Hz, 1H, H4), 7.42 (m, 1H, H6), 11.03 (s, 1H, NH); ^{13}C NMR (DMSO-d_6): δ = 111.30, 111.53 (C4), 113.46, 113.53 (C7), 118.47, 118.54 (C3a), 124.47, 124.71 (C6), 146.8 (C7a), 156.9 (C2), 159.35, 159.53 (C5), 183.9 (C3); ^{19}F NMR (DMSO-d_6): δ = 121.0 (m, C5F); IR (KBr): 3213, 1738, 1619, 1489, 1389, 1290, 1262, 1141, 1105, 912, 890, 847, 792, 739, 655, 604, 459 cm^{-1}; MS (FAB$^+$): m/z 166 [M$^+$+1]; elemental analysis calcd for $C_8H_4NO_2F \times 0.5\ H_2O$: C 55.18, H 2.89, N 8.04; found C 54.29, H 3.09, N 7.29.

General procedure for the preparation of 4f,g. A solution of 0.92 mL (12 mmol) DMF in 25 mL THF was cooled to 0°C and under inert gas conditions 1.03 mL (12 mmol) oxalyl chloride were added. After stirring for 2 h at room temperature, the suspension was again cooled to 0°C and a solution of 2.1 mL (12 mmol) Hünig's base (NEt*i*Pr_2) was added dropwise. After stirring for 1 h at 0°C and 2 h at room temperature, the precipitate was filtered off, and then to the filtrate, 25 mmol of the corresponding aniline was added. After stirring for 16 h at room temperature, aerial oxygen was passed through the solution for several hours. The solvent was evaporated the residue was taken up in 36 mL glacial acetic acid, 5 mL conc. HCl and 5 mL H_2O. This solution was refluxed for 20 minutes. After cooling to RT the solvent was evaporated to dryness *in vacuo*. The orange residue was then taken up in water, filtrated, washed with water and dried under vacuum.

5-Methyl-carboxylate-isatine 4f. Yellow/orange solid; ^{1}H NMR (DMSO-d_6): $\delta = 3.82$ (s, 3H, $COOCH_3$), 7.62 (d, $J =$ 8.67 Hz, 1H, H7), 7.91 (s, 1H, H4), 8.14 (dd, $J = 8.25, 1.68$, 1H, H6), 11.41 (s, 1H, NH); ^{13}C NMR (DMSO-d_6): $\delta = 52.3$ (CH_3), 112.2 (C7), 118.0 (C3a), 123.8 (C5), 124.9 (C4), 138.9 (C6), 154.1 (C7a), 159.7 (COOMe), 165.2 (C2), 183.3 (C3); IR (KBr): 3255, 1763, 1731, 1703, 1618, 1493, 1431, 1393, 1250, 1199, 1133, 1086, 998, 948, 867, 818, 773, 747, 723, 679, 534, 465 cm^{-1}; MS (FAB$^+$): *m/z* 206 [M$^+$+1]; elemental analysis calcd for $C_{10}H_7NO_4 \times 0.5\ H_2O$: C 56.08, H 3.76, N 6.54; found C 56.63, H 3.62, N 6.87.

5-Hydrazinoquinoline and 8-hydrazinoquinoline were converted *via* Fischer syntheses with 3-methylbutan-2-one into pyrido-indolenines 2,3,3-trimethyl-3*H*-pyrrolo[2,3-*f*]quinoline **7** and 2,3,3-trimethyl-3*H*-pyrrolo[3,2-*h*]quinoline **11**, respectively. Exposure of the indolenines to the Vilsmeier reagent produced aminomethylene-malondialdehydes **8** and **12**, which reacted with hydrazine or arylhydrazines to give 4-(3*H*-pyrrolo[2,3-*f*]quinolin-2-yl)- and 4-(3*H*-pyrrolo[3,2-*h*]quinolin-2-yl)-pyrazoles, **9** and **13**.

J. Heterocyclic Chem., **46**, 428 (2009).

INTRODUCTION

We recently described the reaction of 2,3,3-trimethylindolenines (3*H*-indoles) **1** with the Vilsmeier reagent formed from dimethylformamide and phosphorus oxychloride to produce aminomethylene malondi-aldehydes **2** [1,2]. Additionally, we showed that these intriguing polyfunctional compounds reacted well with hydrazine or arylhydrazines to produce 4-(3,3-dimethyl-3*H*-indol-2-yl)-substituted pyrazoles, **3**, with migration of the double bond into the dihydropyrrole ring thus restoring the indolenine structure from which the sequence started [2] (Scheme 1). We have now been able to show that the principles embodied in these transformations can be incorporated into more complex heterocyclic systems and thus have prepared several 4-(3,3-dimethyl-3*H*-pyrrolo[2,3-*f*]quinolin-2-yl)pyrazoles and 4-(3,3-dimethyl-3*H*-pyrrolo[3,3-*h*]quinolin-2-yl)pyrazoles.

For the mechanism of formation of the aminomethylene malondialdehydes, we suggested that a small equilibrium concentration of an enamine tautomer **4** is successively *C*-substituted and thus, before hydrolysis during work-up, species **5** is present (Scheme 2). We suggest that a comparable mechanism operates in the work described herein.

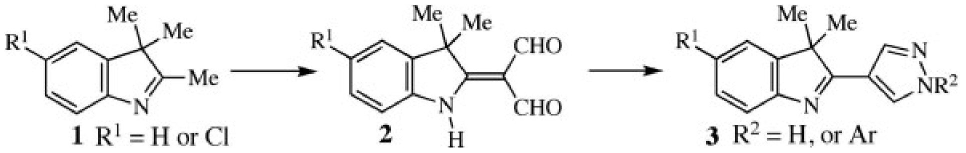
RESULTS AND DISCUSSION

Reduction of 5-nitroquinoline [3] with hydrazine and iron(III) chloride gave 5-aminoquinoline, diazotization of which, then reduction of the diazonium salt with tin(II) chloride, produced the corresponding 5-hydrazino-quinoline **6** [4] dihydrochloride. Reaction of compound **6** with isopropyl methyl ketone in a Fischer reaction [5] produced the pyrido-indolenine (2,3,3-trimethyl-3*H*-pyrrolo[2,3-*f*]quinoline) **7** in acceptable yield (Scheme 3). Similarly, 8-hydrazinoquinoline, prepared by prolonged heating of 8-hydroxyquinoline with hydrazine hydrate [6], reacted with isopropyl methyl ketone in hot acetic acid to give the isomeric pyrido-indolenine (2,3,3-trimethyl-3*H*-pyrrolo[3,2-*h*]quinoline [7]) **11** in 60% yield (Scheme 4). The structures of the two key pyrido-indolenines were evident from their molecular formulae, the six-hydrogen singlets for the geminal methyl groups, at δ 1.35 and 1.37 ppm for **7** and **11**, and singlet signals for the imine-methyl groups, resonating at δ 2.38 and 2.41 ppm, respectively. Each compound had an AB system for the *ortho*-related benzene ring protons, in addition to the three pyridine ring signals in normal positions. Each of the pyrido-indolenines was now reacted with the Vilsmeier reagent and, in yields of 94% and 81%, respectively, aminomethylene malondialdehydes **8** and **12** were obtained (Schemes 3 and 4).

The structures of the aminomethylene malon-dialdehydes rests on the observation of two one-hydrogen singlets at δ 9.83 and δ 9.86 for **8** and δ 9.82 and δ 9.90 for **12** corresponding to aldehyde protons. Absorptions at 3164 cm^{-1} and 3160 cm^{-1} for **8** and **12**, respectively, were evidence for the presence of N—H bonds, further confirmed by ^1H NMR one-hydrogen signals for the *N*-hydrogens appearing at δ 14.03 (**8**) and δ 14.45 (**12**), respectively.

As in our previous work [2], the aminomethylene malondialdehydes reacted smoothly with hydrazine and various arylhydrazines to give pyrazoles, with migration

Scheme 1



of the double bond to reform the imine unit (Schemes 3 and 4). For pyrazoles **9a–g**, the newly formed five-membered heterocyclic ring protons resonated in the range δ 8.30–9.70 and for the isomers, **13a–e**, in the range δ 8.30–9.10.

EXPERIMENTAL

Melting points were recorded on a Philip Harris C4954718 apparatus and are uncorrected. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker Avance AQS 300 MHz spectrometer, at 300 MHz and 75 MHz, respectively. Chemical shifts δ are in parts per million (ppm) measured in $CDCl_3$ as solvent and relative to TMS as the internal standard. Infrared spectra were recorded on a Thermonicolet-Nexus 670 FTIR instrument and elemental analyses were carried out on an Exeter analytical model CE440 C, H and N elemental analyzer. High resolution mass spectra were recorded on an Agilent Technology (HP), MS Model: 5973 Network Mass, selective detector ion source: electron impact (EI) 70 eV, ion source temperature: 230 °C, Analyzer: quadrupole, analyzer temperature: 150 °C, and relative abundances of fragments are quoted in parentheses after the *m*/*z* values.

5-Aminoquinoline. A mixture of 5-nitroquinoline (2.65 g, 15.2 mmol), activated carbon (600 mg), ferric chloride hexahydrate (250 mg), and methanol (50 mL) was refluxed for 10 min with stirring. Hydrazine hydrate (3.75 g, 80%) was added over 30 min to the boiling solution. The mixture was stirred under reflux for an additional 12 h, cooled, and evaporated. The resulting slurry was dissolved in dichloromethane (50 mL), washed with water (2 × 20 mL), and dried ($MgSO_4$). Evaporation of the solvent yielded a yellow solid, which was identified as 5-aminoquinoline. Yield 85%; mp: 108–110 °C (lit. 110 °C); IR: 3196, 1585, 1365, 792 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 4.22 (bs, 2H), 6.77 (dd, 1H, J = 8.4, 1.2 Hz), 7.26 (dd, 1H, J = 8.4, 4.2 Hz), 7.47 (t, 1H, J = 8.4 Hz), 7.56 (d, 1H, J = 8.4 Hz), 8.14 (dd, 1H, J = 8.4, 1.8 Hz), 8.84 (dd, 1H, J = 4.2, 1.8 Hz); ^{13}C NMR ($CDCl_3$): δ 109.95, 118.69, 119.55, 119.97, 129.60, 130.05, 142.42, 149.10, 150.21.

General procedure for the synthesis of (7) and (11). A mixture of quinolinylhydrazine dihydrochloride (5 g, 21 mmol) and isopropyl methyl ketone (1.85 g, 21 mmol) was refluxed in acetic acid (100 mL) for 3–5 h and then cooled, diluted with water (100 mL), and neutralized with NaOH 2 *M*, then extracted with ethyl acetate (4 × 100 mL). The organic layer was dried over Na_2SO_4. The solvent was evaporated and the resulting viscous oil recrystallized from EtOH to give the quinolinyl-indolenines identified as (**7**) or (**11**).

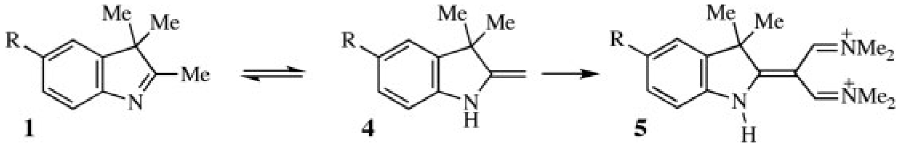
2,3,3-Trimethyl-3H-pyrrolo[2,3-f]quinoline (7). 65% Yield; mp 115–118 °C; IR: 2964, 2928, 1561, 1366 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 1.35 (s, 6H), 2.38 (s, 3H), 7.44 (dd, 1H, J = 8.4, 4.2 Hz), 7.64 (d, 1H, J = 8.4 Hz), 7.98 (d, 1H, J = 8.4 Hz), 8.84 (dd, 1H, J = 8.4, 1.8 Hz), 8.90 (dd, 1H, J = 4.2, 1.8 Hz); ^{13}C NMR ($CDCl_3$): δ 15.57, 22.50, 54.77, 121.11, 121.87, 122.54, 126.47, 131.80, 142.28, 148.21, 148.67, 149.90, 189.72; *m*/*z*: 210 $[M]^+$, 195 (100), 181, 169, 154, 129, 84. Found: M^+ 210.1158, $C_{14}H_{14}N_2$ requires M^+ 210.1157.

2,3,3-Trimethyl-3H-pyrrolo[3,2-h]quinoline (11). 80% Yield; mp 114–116 °C; IR: 2966, 1686, 1515, 1359 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 1.37 (s, 6H), 2.41 (s, 3H), 7.38 (dd, 1H, J = 8.4, 4.2 Hz), 7.50 (d, 1H, J = 8.1 Hz), 7.70 (d, 1H, J = 8.1 Hz), 8.17 (dd, 1H, J = 8.4, 1.8 Hz), 9.00 (dd, 1H, J = 4.2, 1.8 Hz); ^{13}C NMR ($CDCl_3$): δ 15.58, 22.43, 55.45, 120.37, 120.97, 125.37, 128.36, 136.59, 140.40, 146.03, 148.64, 150.58, 189.87; *m*/*z*: 210 M^+, 195 (100), 181, 169, 154, 129, 84. Found: M^+ 210.1157, $C_{14}H_{14}N_2$ requires M^+ 210.1157.

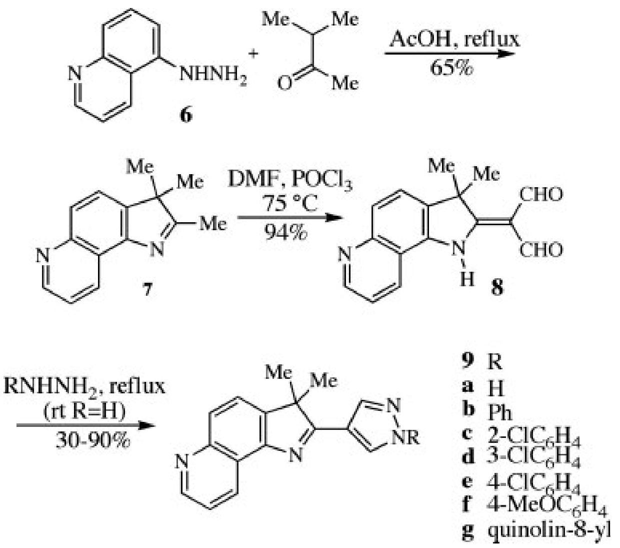
General procedure for the synthesis of (8) and (12). To *N*,*N*-dimethylformamide (10 mL) cooled in an ice bath was added dropwise phosphorus oxychloride (7 mL, 75 mmol) with stirring at below 10 °C. After this addition, a solution of (**7**) or (**11**) (25 mmol, 5.25 g) in DMF (10 mL) was added dropwise. The cooling bath was removed and the reaction mixture was stirred at 75 °C for 4–6 h. The resulting solution was added to ice-cooled water and made alkaline with NaOH(aq.) solution. The resulting precipitate was collected by filtration, dried in air, recrystallized from ethanol, and identified as (**8**) or (**12**).

(3,3-Dimethyl-3H-pyrrolo[2,3-f]quinolin-2-ylidene)malondialdehyde (8). 94% Yield; mp 180–183 °C; IR: NH 3164, 2965, 2763, 1679, 1601, 1518, 1363, 1166, 814, 771 cm^{-1}; ^{1}H NMR

Scheme 2



Scheme 3



($CDCl_3$): δ 1.86 (s, 6H), 7.55 (dd, 1H, *J* = 8.4, 4.2 Hz), 7.72 (d, 1H, *J* = 8.70 Hz), 8.06 (d, 1H, *J* = 8.70 Hz), 8.34 (dd, 1H, *J* = 8.4, 1.8 Hz), 9.02 (dd, 1H, *J* = 4.2, 1.8 Hz), 9.83 (s, 1H), 9.86 (s, 1H,), 14.03 (bs, 1H); ^{13}C NMR ($CDCl_3$): δ 22.84, 52.43, 110.17, 115.82, 121.79, 122.74, 127.55, 129.20, 134.34, 137.27, 148.08, 150.98, 180.33, 187.62, 192.68. Found: % C 72.02; H 5.38; N 10.63. $C_{16}H_{14}N_2O_2$ requires % C 72.16; H 5.30; N 10.52.

(3,3-Dimethyl-3H-pyrrolo[3,2-h]quinolin-2-ylidene)malondialdehyde (12). 81% Yield; mp 166–168 °C; IR: NH 3160, 2966, 2763,1673, 1602, 1504, 1325, 1161, 816, 768 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 1.87 (s, 6H), 7.50 (dd, 1H, *J* = 8.4, 4.2 Hz), 7.54 (d, 1H, *J* = 8.1 Hz), 7.73 (d, 1H, *J* = 8.1 Hz), 8.23 (dd, 1H, *J* = 8.4, 1.5 Hz), 8.97 (dd, 1H, *J* = 4.2, 1.5 Hz), 9.82 (s, 1H), 9.90 (s, 1H), 14.45 (bs, 1H); ^{13}C NMR ($CDCl_3$): δ 22.75, 53.05, 110.03, 120.02, 121.87, 125.34, 128.26, 135.85, 136.08, 139.95, 150.94, 150.95, 179.05, 187.99, 192.21. Found: % C 71.98; H; 5.31; N 10.44. $C_{16}H_{14}N_2O_2$ requires % C 72.16; H 5.30; N 10.52.

General procedure for the synthesis of (9a) and (13a). A mixture of the malondialdehyde (**8**) or (**12**) (0.5 mmol) and hydrazine monohydrate (0.05 g, 1 mmol) in absolute ethanol (1 mL) was stirred at room temperature for 24 h (R = H). After concentrating the solution, the resulting crystals were collected by filtration and recrystallized from EtOH to give the (**9a**) and (**13a**).

4-(3,3-Dimethyl-3H-pyrrolo[2,3-f]quinolin-2-yl)pyrazole (9a). 60% Yield; mp 130–132 °C; IR: 3137, 2969, 2926, 1570, 1486, 1330, 1062, 924, 832, 822 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 1.60 (s, 6H), 3.50 (bs, 1H, NH), 7.51 (dd, 1H, *J* = 8.4, 4.3 Hz), 7.74 (d, 1H, *J* = 8.4 Hz), 8.04 (d, 1H, *J* = 8.4 Hz), 8.35 (s, 2H), 8.95–9.01 (m, 2H); ^{13}C NMR ($CDCl_3$): δ 24.28, 54.34, 116.24, 119.55, 121.07, 122.15, 122.28, 126.47, 132.12, 134.22, 142.77, 148.45, 150.12, 179.96. General procedure for the synthesis of (9b–g) and (13b–g). A mixture of the malondialdehyde (**8**) or (**12**) (0.5 mmol) and the arylhydrazine (0.55 mmol) in absolute ethanol (15 mL) was heated with stirring at reflux for 2–3 h. After cooling and concentrating the solution, the resulting crystals were collected by filtration and recrystallized from EtOH to give the corresponding pyrazoles.

1-Phenyl-4-(3,3-dimethyl-3H-pyrrolo[2,3-f]quinolin-2-yl)-pyrazole (9b). 70% Yield; mp 168–170 °C; IR: 3059, 2968, 2928, 2576, 1572, 1561, 1497, 1377, 950 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 1.61 (s, 6H), 7.34 (dd, 1H, *J* = 8.4, 4.5 Hz), 7.43–7.51 (m, 3H), 7.70 (d, 1H, *J* = 8.4 Hz), 7.77 (m, 2H), 8.07 (d, 1H, *J* = 8.4 Hz), 8.38 (s, 1H), 8.68 (s, 1H), 8.94 (dd, 1H, *J* = 4.5, 1.8 Hz), 9.00 (dt, 1H, *J* = 8.4, 0.9 Hz); ^{13}C NMR ($CDCl_3$): δ 24.18, 54.36, 118.06, 119.52, 121.15, 122.18, 122.74, 125.56, 127.22, 127.43, 129.48, 129.61, 133.06, 139.42, 140.75, 143.14, 147.25, 149.35, 179.77. Found: % C 78.29; H 5.26; N 16.41. $C_{22}H_{18}N_4$ requires % C 78.08; H 5.36; N 16.56.

1-(2-Chlorophenyl)-4-(3,3-dimethyl-3H-pyrrolo[2,3-f]quinolin-2-yl)pyrazole (9c). 90% Yield; mp 100–103 °C; IR: 2958, 2927, 1580, 1559, 1491, 1451, 1365, 940, 816, 755 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ 1.58 (s, 6H), 7.36–7.41 (m, 2H), 7.53–7.58 (m, 2H), 7.65 (dd, 1H, *J* = 7.5, 1.8 Hz), 7.76 (d, 1H, *J* = 8.4 Hz), 8.14 (d, 1H, *J* = 8.4 Hz), 8.45 (s, 1H), 8.59 (s, 1H), 8.95 (dd, 1H, *J* = 4.2, 1.5 Hz), 9.10 (d, 1H, *J* = 8.4 Hz); ^{13}C NMR ($CDCl_3$): δ 24.21, 54.48, 117.25, 121.04,122.27, 123.28, 124.90, 127.66, 127.92, 128.24, 129.78, 130.81, 131.81, 134.12, 137.43, 140.77, 143.47, 146.27, 148.67, 149.26, 179.90. A series of isatin oximes was alkylated with alkyl halides and under Mitsunobu conditions to generate *O*-alkylated oxime ether and *N*-alkylated nitrone products. Alkylation of the sodium salts of oximes **5a** and **5b** with alkyl iodides produced predominantly the *N*-alkylated nitrones (*E*)-**7** while alkylation of **5a** and **5b** with the harder electrophiles alkyl bromides and alkyl chlorides, gave mostly the *O*-alkylated products, oxime ethers (*E*)-**6**. Interestingly, alkylation of oxime **5b** under Mitsunobu conditions with isopropyl alcohol produced the *N*-alkylated nitrone (*E*)-**7bd** as the major product. However, alkylation of oxime **5c**, which incorporates a sterically bulky bromine substituent at the C-4 position of the isatin heterocycle, with 2-bromo- and 2-iodo-propane or with isopropyl alcohol under Mitsunobu conditions gave exclusively the *O*-alkylated product, oxime ether (*Z*)-**6cd**. The oxime ether and nitrone products **6** and **7**, respectively, were characterized by LC/MS, ^{1}H NMR, and ^{13}C NMR. In addition, the structures of oxime ether (*E*)-**6bd** and nitrone (*E*)-**7ad** were determined by X-ray crystallography.

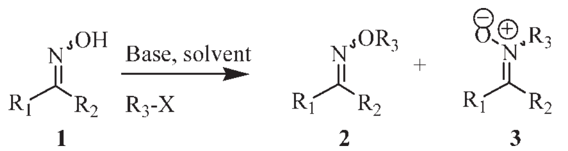
J. Heterocyclic Chem., **46**, 432 (2009).

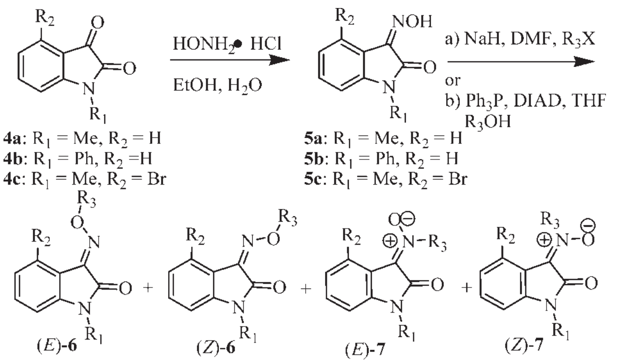
INTRODUCTION

Oximes (**1**) are important synthetic intermediates in organic synthesis that have also found application in a medicinal chemistry setting. As a synthetically useful functionality, oximes can be used to protect carbonyl groups, reduced to an amine or, in the case of oximes derived from aldehydes, undergo dehydration to a nitrile [1]. During the course of our survey of small molecule inhibitors of respiratory syncytial virus (RSV) fusion, we were interested in probing the potential of isatin-derived oximes as bioisosteres of the benzimidazol-2-one template that has provided a series of potent antiviral agents [2]. Isatin derivatives have found wide application as scaffolds in medicinal chemistry, including a series of Schiff bases and hydrazones evaluated as potential anticonvulsants [3] and cyclin-dependent kinase-2 inhibitors [4]. In addition, a number of isatin and oxindole derivatives demonstrate antiviral properties, exemplified by inhibitors of poxvirus [5], ectromelia [6], rhinovirus [7], HIV-1 [8], and the coronavirus responsible for severe acute respiratory syndrome (SARS) [9]. Oximes have been examined as useful pharmacophores in a range of therapeutic agents that encompass multiple disease areas. For example, oxime derivatives have been evaluated as dual agonists of peroxisome proliferator-activated receptors (PPARs) α and γ for the treatment of type II diabetes [10], vascular endothelial growth factor (VEGF)-2 kinase inhibitors as antiproliferative agents [11], *N*-methyl-D-aspartate (NMDA) [12] and AMPA/kainite [13] receptor antagonists, and γ-aminobutyric acid (GABA) uptake inhibitors as potential anticonvulsants [14]. A particularly prominent oxime ether derivative

Scheme 1. Alkylation of oximes of general structure **1**.



Scheme 2. Alkylation of isatin oximes.



that has been evaluated in clinical trials as an antiviral agent for the treatment of HIV infection is SCH 351125, an orally bioavailable CCR5 receptor antagonist [15].

To establish the potential of isatin-derived oxime ethers as RSV fusion inhibitors, a parallel synthesis approach was envisioned as a means of rapidly generating a series of isatin oxime ethers **6** from oximes **5** by a simple alkylation procedure. However, it is well established that the alkylation of oximes of general structure **1** can produce *O*-alkyloxime-ethers **2** and *N*-alkylated nitrones **3**, as shown in Scheme 1, depending upon the site at which alkylation occurs [16,17]. The ratio of *O*- to *N*-alkylated products can be influenced by several factors, including the geometry of the oxime salts derived from **1**. For example, alkylation of an *(E)*-aldoxime sodium salt with alkyl halides produced mainly the *O*-alkylated oximes but alkylation of the (*Z*)-aldoxime sodium salt with the same series of electrophiles produced similar amounts of the *N*- and *O*-alkylated products [17]. Whilst there are many reports in the literature of oxime alkylation procedures, there has not been a systematic study of the alkylation of isatin oximes **5** and structural characterization of the possible products, the oxime ethers **6** and nitrones **7**. The alkylation of oxime **5** is potentially a complex process since four products can be formed: *(E)*- and (*Z*)-oximes **6** and *(E)*- and (*Z*)-nitrones **7**, and it was anticipated that product distribution would show some dependence on the reagents, the reaction conditions, and the substitution patterns of the aryl ring. In this article, we report the results of studies of the alkylation of a series of isatin oximes **5** and characterization of the products by LC/MS, ^1H NMR, ^{13}C NMR and, for select examples, X-ray crystallography.

RESULTS AND DISCUSSION

The procedures for the preparation and alkylation of isatin oximes **5** are summarized in Scheme 2. Isatin oximes **5a-c** were readily obtained from isatins **4a–c** by treatment with $NH_2OH{\cdot}HCl$ in aqueous EtOH. Isatins **4a** and **4b** were available from commercial sources and *N*-methyl-4-bromo isatin (**4c**) was obtained by alkylation of commercially available 4-bromoisatin with methyl iodide in the presence of K_2CO_3 as the base. Alkylation of **5a** and **5b** by deprotonation with NaH in DMF and exposure to alkyl halides gave mixtures of isatin *O*-alkyloxime ethers *(E)*-**6** and nitrones *(E)*-**7**, with the distribution of the products for each reaction summarized in Tables 1 and 2. DMF was chosen as the solvent to

[a] Alkylation of oxime **5b** with alkyl halides in the presence of NaH and under Mitsunobu reaction conditions with isopropyl alcohol for entries 1–3 and entry 4, respectively.

[b] Isomeric product ratios were determined by weight after purification by flash column chromatography. Ratios in parentheses were determined by integration of HPLC peaks.

[c] Yield based on 6% recovered starting material.

ensure high solubility of the isatin oximes **5a** and **5b** and their sodium salts during the course of the reaction, since heterogeneous reaction conditions caused by the precipitation of oxime salts from solvents such as acetone or toluene have been reported to influence the ratio of products formed [16]. The effect of the counter ion on product distribution was also examined, with lithium, potassium, and tetramethylammonium salts evaluated in addition to sodium [16]. Furthermore, the application of the Mitsunobu reaction to this process was also studied. Several *O*-alkylated isatin oxime ethers were also obtained by combining isatins **4a–c** with *O*-alkylated hydroxylamine hydrochloride salts in aqueous EtOH for the purpose of comparison with the products obtained from the alkylation reactions.

The results of these studies, compiled in Table 1, reveal that the reaction yields are generally excellent, ranging from 64 to 97% and that product distribution between the *O*- and *N*-alkylated products is dependent on the nature of the electrophile. When soft electrophiles such as alkyl iodides were employed, the *N*-alkylated products, isatin nitrones *(E)*-**7**, were favored slightly over the *O*-alkylated oxime ethers **6**, with the ratio ranging from just over 1:1 to 2:1 (Table 1, Entries 1–4 and 7). 2-Iodocyclopentane provided an exception, producing a 58:42 ratio of oxime to nitrone, respectively (Table 1, Entry 6). However, with harder electrophiles, such as alkyl bromides (Table 1, Entries 5 and 9) and alkyl chlorides (Table 1, Entry 8), this trend was largely reversed with the *O*-alkylated products predominating, in the range of 3:2 to 9:1.

The effect of the nature of the alkyl halide on the ratio of *O*- and *N*-alkylated products formed in base-catalyzed processes was observed earlier with both benzophenone oxime [16] and aldoxime [17] systems. In those studies, the *O*-alkylated products predominated by three to ninefold, with alkyl chlorides providing the highest preference for *O*-alkylation. However, the studies were not conducted in a systematic fashion and correlation of the effect of hard and soft electrophiles on product distribution could not be fully appreciated. In addition, the study of aldoxime alkylation was complicated by the geometry of the aldoxime sodium salt which exerted a profound effect on the product ratio [17]. The *(E)*-aldoxime sodium salt was found to give the oxime ether by a preference of three to ninefold over the nitrone products, whereas the (*Z*)-aldoxime sodium salt showed little preference for *O*- *versus N*-alkylation, presumably a consequence of the reduced steric encumbrance around the nitrogen atom in this conformation.

To more closely evaluate the effect of the leaving group on the ratio of *O*- and *N*-alkylated product formation in the isatin oxime system, additional alkylation experiments were conducted with **5b** using 2-iodo-, 2-bromo-, and 2-chloro-propane, which afforded a mixture of *O*-alkyloxime ether *(E)*-**6bd** and the nitrone *(E)*-**7bd**. In addition, since the pKa of many oximes is similar to that of a phenol [18], alkylation of **5b** with isopropyl alcohol under the mild conditions associated with the Mitsunobu reaction was examined [19]. The results of this survey are compiled in Table 2 where the yields of products were generally high, 83–86%, except in the case of 2-chloropropane (Entry 3, 61% yield). The alkylation of **5b** with 2-chloropropane was a sluggish process, and the reaction was worked up after an extended, 76 h time interval. The data in Table 2 reveal a slight preference toward the *N*-alkylated nitrone *(E)*-**7bd** when the soft electrophile 2-iodopropane was employed. However, the *O*-alkylated product, ether *(E)*-**6bd**, predominated slightly when 2-bromopropane was used as the electrophile, and the ratio further amplified in the reaction of **5b** with 2-chloropropane. Interestingly, under Mitsunobu conditions, the oxime **5b** reacted with isopropyl alcohol to afford predominantly the *N*-alkylated nitrone *(E)*-**7bd** in a ratio of 88:12 over the *O*-alkylated oxime ether *(E)*-**6bd** (Table 2, Entry 4). To the best of our knowledge, this experiment represents the first example of oxime alkylation under Mitsunobu conditions affording a nitrone product.

Table 3

Key spectroscopic data for isatin oximes **6** and nitrones **7**.

	Oxime **6**/Nitrone **7**	^{1}H NMR of oxime and nitrone in CDCl$_3$		Chemical shift differences between oximes and nitrones

	(*E*)-**7bd**	8.47	6.30–6.39		

The structures of the alkylated isatin oximes were determined by a combination of spectroscopic methods. The oxime ethers **6** could readily be distinguished from the nitrones **7** by examination of the infra red spectra. An earlier report identified unique N-O absorbances for the nitrone and oxime between 1170–1280 and 920–1005 cm^{-1}, respectively [16]. The IR spectrum of the oxime ether *(E)*-**6ad** exhibits the characteristic N-O band at 971 cm^{-1}, which is absent in the IR spectrum of the isomeric nitrone *(E)*-**7ad** (Table 1, Entry 4). Conversely, a unique nitrone N-O band appeared at 1241 cm^{-1} in the IR spectrum of nitrone *(E)*-**7ad** that is not exhibited by the oxime ether *(E)*-**6ad**.

The ^{1}H NMR spectra of oxime ethers **6** and nitrones **7** are generally quite similar with the exception of the chemical shifts for the C-4 aryl hydrogen atom and the protons on the carbon atoms attached to the oxime oxygen or nitrone nitrogen atoms. The ^{1}H NMR chemical shifts for the isatin C-4 aryl hydrogen, and the protons on the carbon atom attached to the oxime oxygen and nitrone nitrogen atoms are presented in Table 3. In the ^{1}H NMR, the C-4 aryl hydrogen of isatin nitrones **7** consistently resonates between 0.28 and 0.48 ppm downfield of the chemical shift of the same proton in the corresponding isatin oxime ethers **6**, attributed to a deshielding effect induced by the nitrone moiety. Similarly, the ^{1}H NMR chemical shifts for the protons on the carbon atom attached to the nitrone nitrogen atom in **7** resonate downfield of the protons on the carbon atom bound to the oxygen atom in the oxime ethers **6**. For the series of nitrones **7ab**, **7ac**, **7ah**, and **7ai** and their corresponding oxime ether isomers **6ab**, **6ac**, **6ah**, and **6ai**, compounds all prepared from primary alkyl halides, the ^{1}H NMR chemical shifts of the methylene protons differ by 0.27 to 0.52 ppm (Table 3, Entries 1, 2, 7, and 8). For nitrones **7ad**, **7ae**, **7af**, **7ag**, and **7bd** and oxime ethers **6ad**, **6ae**, **6af**, **6ag**, and **6bd**, derived from secondary alkyl halides, the differences in ^{1}H NMR chemical shifts of the methine protons are more pronounced, with a difference of 1.41 to 1.69 ppm (Table 3, Entries 3–6 and 9).

To provide further support for the structural assignments, a single crystal X-ray structure was obtained for the nitrone *(E)*-**7ad**, which indicates that this compound possesses an *(E)*-geometric configuration, as depicted in Figure 1. Attempts to recrystallize the corresponding oxime ether *(E)*-**6ad** for X-ray crystallographic structure determination to allow a direct comparison with *(E)*-**7ad** were unsuccessful. However, the solid state structure was determined for the close analogue, oxime ether *(E)*-**6bd** in which the isatin *N* substituent is phenyl rather than methyl and, as depicted in Figure 2, this compound also possesses the *(E)*-geometric configuration. In the *(E)*-configuration, the oxygen atoms of the oxime *(E)*-**6bd** and nitrone *(E)*-**7ad** project away from the carbonyl oxygen of the isatin amide moiety, presumably to optimize dipole interactions and minimize the lone pair-lone pair repulsion that would exist in the (*Z*)-oxime and lone pair-negative charge repulsions that would occur in the isomeric (*Z*)-nitrone (*vide infra*). In addition, the

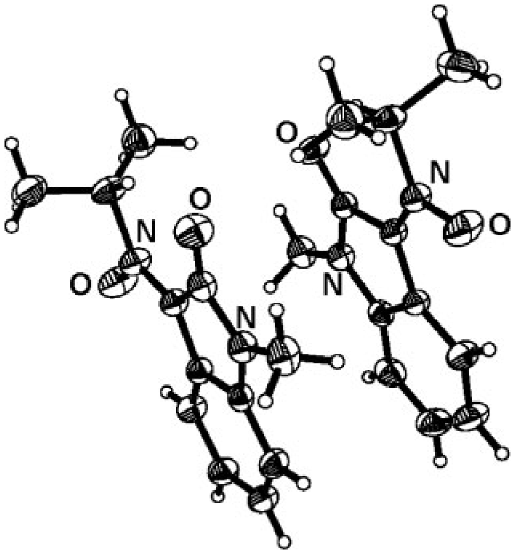

Figure 1. X-ray crystallographic structure of nitrone *(E)*-**7ad**.

crystallographic structures indicate that the oxygen atom of both the oxime ether *(E)*-**6bd** and nitrone *(E)*-**7ad** are situated within hydrogen bonding distance of the C-4-aryl hydrogen, measured at 2.527 Å for *(E)*-**6bd** and 2.446 Å for *(E)*-**7ad**, respectively.

The X-ray crystallographic data for oxime ether *(E)*-**6bd** and nitrone *(E)*-**7ad** indicate without ambiguity that both are *(E)*-isomers. On the basis of the additional studies and *ab initio* calculations described below, we conclude that all of the oxime ethers and nitrones presented in Tables 1 and 2 most likely possess the *(E)*-geometric configuration.

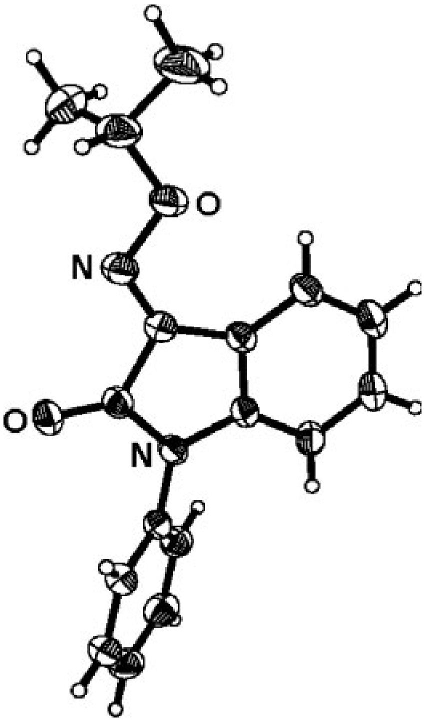

Figure 2. X-ray crystallographic structure of oxime ether*(E)*-**6bd**.

The (*Z*)-isomers of either an oxime ether or nitrone analog were not isolated from any of the alkylation procedures, consistent with an earlier report that indicated that the nitrone (*Z*)-**7aa** could only be produced briefly when nitrone *(E)*-**7aa** was irradiated at a temperature maintained between 6 and 10°C [20,21]. However, warming to room temperature resulted in isomerization of (*Z*)-**7aa** to *(E)*-**7aa**. HPLC analysis of the products produced in the alkylation reaction that afforded oxime *(E)*-**6bd** and nitrone *(E)*-**7bd** indicated a trace of an additional peak with a retention time close to oxime *(E)*-**6bd** that may be the isomeric oxime, (*Z*)-**6bd**; however, this compound could not be isolated. In an attempt to increase the production of the (*Z*)-oxime isomer, direct oxime ether formation from isatin **4b** was examined. Condensation of **4b** with 1.2 equivalents of *O*-isopropylhydroxylamine hydrochloride in EtOH/H_2O gave a 96% yield of oxime product that was an 89:11 mixture of *(E)*-**6bd** and (*Z*)-**6bd** as determined by HPLC (Table 4, Entry 1). Oxime ethers *(E)*-**6bd** and *(Z)*-**6bd** were prepared in 95% yield under the same conditions but with an equimolar quantity of pyridine included to neutralize the HCl present in the reaction mixture in an attempt to reduce interconversion between the (*Z*) to *(E)* isomers (Table 4, Entry 2). Under these conditions, the

Table 4

Condensation of **4b** and **4c** with *O*-isopropyl hydroxylamine to give *(E)*- and (*Z*)-oxime ether **6**.

No.	(*E*)-Oxime	(*Z*)-Oxime	R_1	R_2	Ratio of isomer E:Z-oxime[a] (%)	Total yield (%)[d]

Table 5

Ab initio calculations for nitrone and oxime ether geometric isomers.

Calculation Method	Nitrone:Δ[(*E*)-**7ad**—(*Z*)-**7ad**] (kcal/mol)	Oxime: Δ[(*E*)-**6ad**—(*Z*)-**6ad**] (kcal/mol)	Oxime:Δ[(*E*)-**6cd**—(*Z*)-**6cd**] (kcal/mol)
B3LYP/6-31G* (solvent: H_2O)	−6.9	−3.2	2.1
B3LYP-31G*// B3LYP-6-31+G* (solvent: H_2O)	−6.1	−3.5	2.3
B3LYP-31G*// B3LYP-aug-cc- pvdz (solvent: H_2O)	−5.6	−3.4	2.3

ratio of oxime ether *(E)*-**6bd** and (*Z*)-**6bd** was 93:7 by analytical HPLC, indicating that (*Z*) to *(E)* product isomerization was not a significant issue when the reaction was conducted under slightly acidic conditions. To further favor the formation of a (*Z*)-oxime isomer, a sterically bulky bromine substituent was introduced at the C-4 position of the isatin heterocycle. Condensation of *N*-methyl-4-bromoisatin (**4c**) with *O*-isopropylhydroxylamine hydrochloride in EtOH/H_2O produced two oxime ether products **6cd**, which were separable by silica gel column chromatography to give products in a ratio of 57:43. The ^{1}H NMR, ^{13}C NMR and LC/MS spectra of the two products were very similar but could be differentiated by close inspection of the data. In the ^{1}H NMR, the methine proton on the carbon atom attached to the oxygen atom of the oxime ether appears as a septet. For the minor oxime ether isomer, this methine proton resonance is centered at 4.77 ppm, which is slightly downfield of the methine proton for the major oxime ether isomer, centered at 4.74 ppm. The isatin *N*-Me protons resonate as singlets at 3.22 ppm for the minor isomer and 3.20 ppm for the major isomer, whereas the signal for the two methyl protons of the isopropyl group appear as doublets at 1.45 ppm for the minor isomer and 1.47 ppm for the major isomer. The minor product completely isomerized to the major oxime ether within an hour as a solution in $CDCl_3$ in an NMR tube. Although the minor isomer was readily recrystallized from a mixture of ether and hexanes at 4°C, the small rod crystals that resulted failed to diffract satisfactorily to allow a structure determination. An attempt to prepare oxime ether *(E)*-**6ad** from the bromo isatin oxime **6cd** by subjecting each one separately to a lithium-halogen exchange reaction followed by protonation to allow correlation with *(E)*-**6ad** was unsuccessful.

In an effort to illuminate further the issue of *(E)* and (*Z*) ratios, *ab initio* studies were conducted. Comparative analysis of *(E)*- and (*Z*)-oximes **6ad** and **6cd** and *(E)*- and (*Z*)-nitrones **7ad** were performed through geometry optimization and relative energy evaluation. The geometries were optimized using DFT at the B3LYP/6-31G* level of theory and basis set. The derived geometries were then used to perform corrections using B3LYP/6-31+G* and Dunning's aug-cc-PVDZ basis sets [22]. Both geometry optimizations and single point energy evaluations were performed in the presence of solvent (water) using the PCM method available in G03 [23]. The relative energies for nitrones *(E)*- and (*Z*)-**7ad**, and oximes *(E)*- and (*Z*)-**6ad**, and *(E)*- and (*Z*)-**6cd** are presented in Table 5. The conformational analysis calculation results presented in Table 5 reveal that the nitrone **7ad** with the *(E)*-geometric configuration is stabilized by 5.9–6.9 kcal/mole when compared to its (*Z*)-isomer due to an unfavorable dipole–dipole interaction between the negatively charged oxygen of the nitrone and the lone pair of electrons on the isatin carbonyl moiety in the (*Z*)-isomer. The experimentally measured dipole moments of a structurally similar pair of nitrone isomers that incorporate an α-carbonyl moiety are reported to differ by four units [21]. For example, the dipole moments for *(E)-N*-(2,2,5,5-tetramethyl-4-oxodihydrofuran-3(2H)-ylidene)methanamine oxide and its (*Z*)-isomer were determined in dioxane to be 1.09 ± 0.13 and 5.31 ± 0.11, respectively [21]. The significant energy difference between the *(E)*- and (*Z*)-nitrones **7ad** is consistent with earlier studies of the isomerization of nitrone *(E)*-**7aa** to (*Z*)-**7aa** upon irradiation and explains the difficulties encountered in isolating the nitrone (*Z*)-**7ad** due to its facile isomerization to *(E)*-**7ad** at room temperature [21]. For the oxime derivatives, repulsion between the lone pairs of electrons on the oxime oxygen atom and the isatin carbonyl moiety leads to *(E)*-**6ad** being the more stable isomer by 3.2–3.5 kcal/mole based on the three molecular calculation methods when compared with (*Z*)-**6ad**. However, in oxime (*Z*)-**6cd** where R_2 = Br, steric hindrance overrides the stereo electronic effects that dominate the geometry of oxime ether (*Z*)-**6ad**. Thus, the oxime ether (*Z*)-**6cd** is more stable by 2.1–2.3 kcal/mole over the *(E)*-isomer. The results of these calculations led us to assign the major product as oxime ether (*Z*)-**6cd** and the minor product as the *trans*-isomer, *(E)*-**6cd** (Table 4, Entry 3).

The insights associated with the effect of a Br substituent at C-4 of the heterocycle on oxime geometry prompted an examination of the effect of this substitution pattern on the outcome of oxime alkylation. Thus,

Table 6

Alkylation of isatin oxime **5c** with *iso*-propyl halides under basic conditions and isopropyl alcohol under Mitsunobu conditions to give *O*-alkylated (*Z*)-oxime ethers.

Entry No.	Reagent used	Oxime (*Z*)-**6cd** (%)	Total yield (%)[a]	Reaction time (h)
1	iPrI	100	90	18
2	iPrBr	100	91	18
3	iPrOH	100	85	18

[a] Isolated yield after silica gel chromatography purification.

N-methyl-4-bromoisatin oxime **5c** was alkylated with *iso*-propyl bromide and *iso*-propyl iodide under basic conditions and also reacted with isopropyl alcohol under Mitsunobu conditions with the result that the *O*-alkylated product (*Z*)-**6cd** was formed exclusively in high yield in all cases. These data are presented in Table 6 and the oxime ether (*Z*)-**6cd** prepared in these reactions was spectroscopically and chromatographically identical to the major oxime ether product (*Z*)-**6cd** prepared by condensing *N*-methyl-4-bromoisatin with *O*-isopropylhydroxylamine hydrochloride (Table 4, Entry 3). This result presumably reflects the development of unfavorable steric interactions between the nitrone *N* substituents and the C-4 bromine atom in the transition state and dominates the previously observed propensity for softer electrophiles to react at the oxime *N* atom.

In summary, alkylation of the sodium salts of a series of isatin oximes **5a** and **5b** with soft electrophiles such as iodoalkanes leads to a slight preference for the *N*-alkylated nitrone products, while harder electrophiles, such as bromo- and chloro-alkanes, preferentially produce *O*-alkylated oxime ether products. Under Mitsunobu conditions, isatin oximes **5b** underwent alkylation preferentially on nitrogen leading to a predominance of the nitrone products. The installation of a bromine atom at C-4 of the heteroaryl ring of oxime **5c** led to the exclusive formation of the (*Z*)-oxime ether, the steric interactions provided by the bromine atom overriding the inherent stereo electronic control exerted by the interaction between the oxime oxygen atom and the α-carbonyl moiety.

EXPERIMENTAL

General directions. ^{1}H- and ^{13}C NMR spectra were obtained at 500 MHz and 126 MHz NMR, respectively. The chemical shifts (δ) are recorded in parts per million (ppm) downfield from TMS. Unless otherwise noted, all NMR samples were prepared in $CDCl_3$. IR spectra were recorded on Perkin Elmer System 2000 FT-IR. Drying of the organic layer during work-up was carried out over anhydrous $MgSO_4$, followed by filtration. Column chromatography was carried out on silica gel (SiO_2) according to Still's flash chromatography technique [24]. Melting points are uncorrected.

Preparative procedures. ***3-(Hydroxyimino)-1-methylindolin-2-one (5a).*** To a slurry of 1-methylisatin (**4a**) (5.28 g, 31.77 mmol) in EtOH (50 mL) was added a solution of $NH_2OH{\cdot}HCl$ (3.31 g, 47.66 mmol) in H_2O (6 mL) and the resulting brown reaction mixture stirred at rt. After 3 h, the solvent was removed *in vacuo* to afford a greenish-yellow paste that was triturated with H_2O (50 mL), filtered, and washed with H_2O (50 mL). The greenish-yellow solid product was dried in a vacuum oven overnight to give **5a** (5.49 g, 98% yield), which was used without further purification, m.p. 193.0–195.5°C (lit. m.p. 193–197°C) [25]; ^{1}H NMR δ 3.25 (s, 3 H), 6.83 (d, J = 7.63 Hz, 1H), 7.08 (t, J = 7.48 Hz, 1H), 7.40 (t, J = 7.78 Hz, 1H), 8.06 (d, J = 7.32 Hz, 1H), 9.57 (s, 1 H); ^{13}C NMR δ 26.2, 108.5, 115.6, 117.6, 123.3, 128.4, 132.7, 144.6, 163.8; LC-MS, MS m/z 177 (M+H).

General alkylation procedure. To a solution of isatin oxime **5** in DMF (0.25*M*) was added 1.2 equivalents of NaH (60% dispersion in oil) followed after 10 min by 1.2 equivalents of an alkyl halide. The progress of the reaction was followed by TLC and LC/MS. When the reaction was complete, the mixture was diluted with EtOAc and washed with dilute aqueous HCl. The reaction of oximes **5** with 2-iodopropane and 2-bromopropane as electrophiles were typically complete after 0.5 and 2.5 h, respectively, as indicated by TLC and LC/MS. The color of the reaction mixture changed during the course of the reaction from an initial dark red, presumably due to the isatin oxime alkoxy anion, to a brown reaction mixture after the oxime alkoxy anion was consumed. However, both reaction mixtures were allowed to stir at room temperature for 15 h before work up. HPLC determination of the ratio of products of the reaction using 2-iodopropane after 0.5 and 15 h showed no change in the product ratio; thus, there was no interconversion of products under the reaction conditions up to 15 h.

(E)-N-(1-methyl-2-oxoindolin-3-ylidene)ethanamine oxide ((E)-7ab). This compound was obtained as orange solid, m.p. 103.0–104.5°C; ^{1}H NMR δ 1.52 (t, J = 7.32 Hz, 3 H), 3.27 (s, 3 H), 4.81 (q, J = 7.32 Hz, 2 H), 6.82 (d, J = 7.63 Hz, 1 H), 7.09 (t, J = 7.63 Hz, 1 H), 7.36 (t, J = 7.63 Hz, 1 H), 8.33 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 13.4, 26.2, 42.5, 58.2, 107.8, 118.3, 123.2, 124.9, 131.4, 133.5, 141.1, 160.5; LC-MS, MS m/z 205 (M+H); *Anal.* Calcd for $C_{11}H_{12}N_2O_2$: C, 64.69; H, 5.92; N, 13.71. Found: C, 64.75; H, 5.83; N, 13.60.

(E)-3-(ethoxyimino)-1-methylindolin-2-one ((E)-6ab). This compound was obtained as yellow solid, m.p. 76.0–77.0°C; ^{1}H NMR δ 1.44 (t, J = 7.17 Hz, 3 H), 3.23 (s, 3 H), 4.54 (q, J = 7.12 Hz, 2 H), 6.81 (d, J = 7.63 Hz, 1 H), 7.05 (t, J = 7.63 Hz, 1 H), 7.37 (dt, J = 7.78, 0.92 Hz, 1 H), 7.95 (d, J = 7.32 Hz, 1 H); ^{13}C NMR δ 14.8, 26.1, 73.0, 108.3, 116.0, 123.0, 127.8, 132.3, 143.6, 144.5, 163.8; LC-MS, MS m/z 205 (M+H); *Anal.* Calcd for $C_{11}H_{12}N_2O_2$: C, 64.69; H, 5.92; N, 13.71. Found: C, 64.55; H, 5.67; N, 13.66.

(E)-N-(1-methyl-2-oxoindolin-3-ylidene)propan-1-amine oxide ((E)-7ac). This compound was obtained as orange solid, m.p. 76.5–78.0°C; ^{1}H NMR δ 1.01 (t, J = 7.48 Hz, 3 H), 1.95–2.03 (m, 2 H), 3.27 (s, 3 H), 4.76 (t, J = 7.32 Hz, 2 H), 6.82 (d, J = 7.63 Hz, 1 H), 7.09 (t, J = 7.63 Hz, 1 H), 7.37 (dt, J = 7.78, 1.22 Hz, 1 H), 8.35 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 11.0, 22.0, 26.2, 64.3, 107.7, 118.2, 123.1, 124.9, 131.4, 134.1, 141.0, 160.6; LC-MS, MS m/z 219 (M+H); *Anal.* Calcd for $C_{12}H_{14}N_2O_2$: C, 66.03; H, 6.46; N, 12.83. Found: C, 66.03; H, 6.24; N, 12.79.

(E)-1-methyl-3-(propoxyimino)indolin-2-one ((E)-6ac). This compound was obtained as yellow solid, m.p. 53.0–54.5°C; ^{1}H NMR δ 1.01 (t, J = 7.32 Hz, 3 H), 1.81–1.89 (m, 2 H) 3.23 (s, 3 H), 4.45 (t, J = 6.56 Hz, 2 H), 6.81 (d, J = 7.93 Hz, 1 H), 7.06 (t, J = 7.48 Hz, 1 H), 7.38 (t, J = 7.78 Hz, 1 H), 7.95 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 10.3, 22.6, 26.1, 79.0, 108.4, 116.0, 123.0, 127.7, 132.3, 143.6, 144.5, 163.8; LC-MS, MS m/z 219 (M+H); *Anal.* Calcd for $C_{12}H_{14}N_2O_2$: C, 66.03; H, 6.46; N, 12.83. Found: C, 65.97; H, 6.46; N, 12.74.

(E)-3-(Isopropoxyimino)-1-methylindolin-2-one ((E)-6ad) and (E)-N-(1-methyl-2-oxoindolin-3-ylidene)propan-2-amine oxide ((E)-7ad). To a solution of isatin oxime 5a (1.01 g, 5.73 mmol) in DMF (23 mL, 0.25*M*) was added NaH (60% 0.275 g of a dispersion in oil, 6.88 mmol) followed after 10 min by 2-iodopropane (1.18 g, 6.88 mmol). After stirring the brown reaction mixture at rt for 15 h, the DMF was removed *in vacuo*, the residue dissolved in EtOAc (150 mL), and then washed with 1*N* HCl (2 × 50 mL). The aqueous layer was extracted with EtOAc (50 mL), and the combined organic layers washed with brine, dried, and concentrated to afford viscous brown oil. Chromatography on a column of silica gel using a 3:1 mixture of hexane and EtOAc as eluant gave nitrone *(E)*-**7ad** (0.675 g, 54% yield) as an orange solid followed by oxime ether *(E)*-**6ad** (0.441 g, 45% yield) as a viscous yellow oil which solidified upon standing at rt.

***(E)*-7ad**: m.p. 113.0–114.5°C; IR (neat) νmax 3055, 2982, 1701, 1610, 1551, 1466, 1241, 737 cm^{-1}; ^{1}H NMR δ 1.45 (dd, J = 6.56, 1.37 Hz, 6H), 3.27 (d, J = 1.22 Hz, 3 H), 6.28–6.37 (m, 1H), 6.82 (d, J = 7.93 Hz, 1H), 7.07–7.12 (m, 1H), 8.37 (d, J = 7.63 Hz, 2H); ^{13}C NMR δ 20.5, 26.2, 61.9, 107.7, 118.5, 123.2, 124.8, 131.2, 133.1, 140.9, 160.6. (E)-N-(1-methyl-2-oxoindolin-3-ylidene)pentan-3-amine oxide ((E)-7ae). This compound was obtained as orange solid, m.p. 82.5–84.0°C; ^{1}H NMR δ 0.89 (t, J = 7.48 Hz, 6 H), 1.64–1.77 (m, 2 H), 1.92–2.05 (m, 2 H), 3.28 (s, 3 H), 6.06–6.14 (m, 1 H), 6.83 (d, J = 7.93 Hz, 1 H), 7.10 (dt, J = 7.63, 0.92 Hz, 1 H), 7.37 (dt, J = 7.78, 1.22 Hz, 1 H), 8.42 (d, J = 6.71 Hz, 1 H); ^{13}C NMR δ 10.4, 26.2, 26.6, 73.0, 107.7, 118.2, 123.2, 124.9, 131.4, 135.4, 140.8, 160.8; LC-MS, MS m/z 247 (M+H); *Anal.* Calcd for $C_{14}H_{18}N_2O_2$: C, 68.27; H, 7.36; N, 11.37. Found: C, 68.18; H, 7.13; N, 11.38.

(E)-1-methyl-3-(pentan-3-yloxyimino)indolin-2-one ((E)-6ae). This compound was obtained as yellow viscous oil, ^{1}H NMR δ 0.96 (t, J = 7.32 Hz, 6 H), 1.69–1.85 (m, 4 H), 3.23 (s, 3 H), 4.38–4.45 (m, 1 H), 6.81 (d, J = 7.93 Hz, 1 H), 7.05 (dt, J = 7.48, 0.92 Hz, 1 H), 7.36 (dt, J = 7.78, 1.22 Hz, 1 H), 7.94 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 9.6, 26.2, 89.8, 108.3, 116.1, 123.0, 127.6, 132.1, 143.4, 144.3, 163.9; LC-MS, MS m/z 247 (M+H).

(E)-N-(1-methyl-2-oxoindolin-3-ylidene)cyclopentanamine oxide ((E)-7af). This compound was obtained as orange solid, m.p. 98.0–100.0°C; ^{1}H NMR δ 1.64–1.73 (m, 2 H) 1.88–1.98 (m, 2 H), 2.02–2.09 (m, 2 H), 2.10–2.19 (m, 2 H), 3.27 (s, 3 H), 6.45–6.53 (m, 1 H), 6.81 (d, J = 7.93 Hz, 1 H), 7.08 (dt, J = 7.63, 0.92 Hz, 1 H), 7.35 (dt, J = 7.78, 1.22 Hz, 1 H), 8.35 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 26.1, 26.1, 31.8, 70.7, 107.7, 118.5, 123.2, 124.8, 131.2, 133.8, 140.8, 160.7; LC-MS, MS m/z 245 (M+H); *Anal.* Calcd for $C_{14}H_{16}N_2O_2$: C, 68.83; H, 6.60; N, 11.46. Found: C, 68.95; H, 6.56; N, 11.44.

(E)-3-(cyclopentyloxyimino)-1-methylindolin-2-one ((E)-6af). This compound was obtained as yellow solid, m.p. 54.0–55.5°C; ^{1}H NMR δ 1.59–1.68 (m, 2 H), 1.70–1.81 (m, 2 H), 1.87–1.96 (m, 2 H), 1.97–2.05 (m, 2 H), 3.21 (s, 3 H), 5.06–5.12 (m, 1 H), 6.79 (d, J = 7.93 Hz, 1 H), 7.03 (dt, J = 7.55, 0.76 Hz, 1 H), 7.35 (dt, J = 7.78, 1.22 Hz, 1 H), 7.88 (d, J = 7.32 Hz, 1 H); ^{13}C NMR δ 23.9, 25.9, 32.6, 89.2, 108.4, 116.0, 123.0, 127.5, 132.3, 143.6, 144.4, 163.8; LC-MS, MS m/z 245 (M+H); *Anal.* Calcd for $C_{14}H_{16}N_2O_2$: C, 68.83; H, 6.60; N, 11.46. Found: C, 69.01; H, 6.52; N, 11.47.

(E)-N-(1-methyl-2-oxoindolin-3-ylidene)cyclohexanamine oxide ((E)-7ag). This compound was obtained as orange solid, m.p. 109.5–110.5°C; ^{1}H NMR δ 1.19–1.30 (m, 1 H), 1.40–1.54 (m, 2 H), 1.68–1.75 (m, 1 H), 1.86–1.98 (m, 6 H), 3.27 (s, 3 H), 5.94–6.02 (m, 1 H), 6.81 (d, J = 7.63 Hz, 1 H), 7.08 (dt, J = 7.63, 0.92 Hz, 1 H), 7.35 (dt, J = 7.71, 1.37 Hz, 1 H), 8.36 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 25.1, 25.2, 26.1, 30.8, 69.6, 107.7, 118.5, 123.2, 124.8, 131.2, 133.2, 140.8, 160.6; LC-MS, MS m/z 249 (M+H); *Anal.* Calcd for $C_{15}H_{18}N_2O_2$: C, 69.74; H, 7.02; N, 10.84. Found: C, 69.77; H, 7.00; N, 10.82.

(E)-3-(cyclohexyloxyimino)-1-methylindolin-2-one ((E)-6ag). This compound was obtained as yellow solid, m.p. 57.0–60.0°C; ^{1}H NMR δ 1.30–1.46 (m, 3 H), 1.53–1.59 (m, 1 H), 1.61–1.70 (m, 2 H), 1.72–1.82 (m, 2 H), 2.03–2.11 (m, 2 H), 3.23 (s, 3 H), 4.48–4.57 (m, 1 H), 6.80 (d, J = 7.63 Hz, 1 H), 7.03–7.07 (m, 1 H), 7.36 (dt, J = 7.78, 1.22 Hz, 1 H), 7.95 (d, J = 7.32 Hz, 1 H); ^{13}C NMR δ 23.6, 25.6, 26.2, 31.7, 84.4, 108.3, 116.1, 123.0, 127.7, 132.2, 143.5, 144.4, 163.9; LC-MS, MS m/z 249 (M+H); *Anal.* Calcd for $C_{15}H_{18}N_2O_2$: C, 69.74; H, 7.02; N, 10.84. Found: C, 69.75; H, 6.96; N, 10.79.

(E)-1-(4-methoxyphenyl)-N-(1-methyl-2-oxoindolin-3-ylidene)methanamine oxide ((E)-7ah). This compound was obtained as orange solid, m.p. 126.0–133.0°C; ^{1}H NMR δ 3.29 (s, 3 H), 3.78 (s, 3 H), 5.88 (s, 2 H), 6.80 (d, J = 7.63 Hz, 1 H), 6.87 (d, J = 8.85 Hz, 2 H), 7.06 (t, J = 7.78 Hz, 1 H), 7.35 (dt, J = 7.71, 1.07 Hz, 1 H), 7.55 (d, J = 8.55 Hz, 2 H), 8.30 (d, J = 7.63 Hz, 1 H); ^{13}C NMR δ 26.3, 55.4, 65.3, 107.8, 114.2, 118.3, 123.2, 125.0, 126.3, 131.2, 131.5, 133.4, 141.1, 160.2, 160.8; LC-MS, MS m/z 297 (M+H); *Anal.* Calcd for $C_{17}H_{16}N_2O_3$: C, 68.90; H, 5.44; N, 9.45. Found: C, 68.69; H, 5.42; N, 9.24.

(E)-3-(4-methoxybenzyloxyimino)-1-methylindolin-2-one ((E)-6ah). This compound was obtained as orange solid, m.p. 96.5–101.0°C; ^{1}H NMR δ 3.23 (s, 3 H), 3.81 (s, 3 H), 5.44 (s, 2 H), 6.80 (d, J = 7.94 Hz, 1 H), 6.91 (d, J = 8.55 Hz, 2 H), 7.00 (t, J = 7.63 Hz, 1 H), 7.35 (dt, J = 7.86, 1.07 Hz, 1 H), 7.39 (d, J = 8.54 Hz, 2 H), 7.88 (d, J = 7.32 Hz, 1 H); ^{13}C NMR δ 26.2, 55.4, 79.2, 108.3, 114.1, 116.0, 123.0, 128.0, 128.5, 130.3, 132.5, 144.0, 144.6, 160.0, 163.7; LC-MS, MS m/z 297 (M+H)); *Anal*. Calcd for $C_{17}H_{16}N_2O_3$: C, 68.90; H, 5.44; N, 9.45. Found: C, 68.63; H, 5.31; N, 9.18.

(E)-2-tert-butoxy-N-(1-methyl-2-oxoindolin-3-ylidene)-2-oxoethanamine oxide ((E)-7ai). This compound was obtained as orange solid, m.p. 132.0–142.0°C; ^{1}H NMR δ 1.50 (s, 9 H), 3.25 (s, 3 H), 5.45 (s, 2 H), 6.83 (d, *J* = 7.93 Hz, 1 H), 7.10 (t, *J* = 7.63 Hz, 1 H), 7.39 (dt, *J* = 7.78, 1.22 Hz, 1 H), 8.34 (d, *J* = 7.63 Hz, 1 H); ^{13}C NMR δ 26.2, 28.1, 65.4, 83.7, 107.9, 117.8, 123.3, 125.3, 132.0, 134.9, 141.6, 160.7, 164.3; LC-MS, MS m/z 313 (M+Na); *Anal*. Calcd for $C_{15}H_{18}N_2O_4$: C, 62.05; H, 6.24; N, 9.65. Found: C, 61.72; H, 6.50; N, 9.28.

(E)-tert-butyl-2-(1-methyl-2-oxoindolin-3-ylideneaminooxy) acetate ((E)-6ai). This compound was obtained as yellow solid, m.p. 120.5–122.0°C; ^{1}H NMR δ 1.48 (s, 9 H), 3.22 (s, 3 H), 4.90 (s, 2 H), 6.81 (d, *J* = 7.63 Hz, 1 H), 7.06 (dt, *J* = 7.63, 0.92 Hz, 1 H), 7.39 (dt, *J* = 7.78, 1.22 Hz, 1 H), 8.05 (d, *J* = 7.63 Hz, 1 H); ^{13}C NMR δ 26.2, 28.3, 73.3, 82.5, 108.5, 115.7, 123.3, 128.7, 133.0, 144.8, 145.1, 163.5, 167.7; LC-MS, MS m/z 313 (M+Na); *Anal*. Calcd for $C_{15}H_{18}N_2O_4$: C, 62.05; H, 6.24; N, 9.65. Found: C, 61.87; H, 6.525; N, 9.56.

(E)-3-(Isopropoxyimino)-1-methylindolin-2-one ((E)-6ad). To a slurry of **4a** (5.02 g, 6.14 mmol) in EtOH (12 mL) was added a brown cloudy solution of 2-(ammoniooxy)propane chloride (0.822 g, 7.37 mmol) in H_2O (4 mL). The resulting brown reaction mixture was stirred at rt for 3 h, the solvent was removed *in vacuo* to leave a greenish-yellow oil which was redissolved in EtOAc (50 mL), and washed with 1*N* aqueous HCl (2 × 10 mL). The aqueous layers were extracted with EtOAc (50 mL), and the organic layers combined and washed with 10% aqueous Na_2CO_3 (10 mL) and brine before being dried and concentrated to afford a viscous yellow oil. ^{1}H NMR δ 1.42 (d, *J* = 6.10 Hz, 6H), 3.23 (s, 3H), 4.73–4.81 (m, 1H), 6.81 (d, *J* = 7.93 Hz, 1H), 7.05 (t, *J* = 7.63 Hz, 1H), 7.37 (t, *J* = 7.32 Hz, 1H), 7.95 (d, *J* = 7.63 Hz, 1H); ^{13}C NMR δ 21.8, 26.1, 79.6, 108.3, 116.1, 122.9, 127.7, 131.7, 143.3, 144.4, 163.9; LC-MS, MS m/z 219 (M+H).

3-(Hydroxyimino)-1-phenylindolin-2-one (5b). 3-(Hy-droxyimino)-1-phenylindolin-2-one (**5b**) was prepared in quantitative yield from 1-phenylisatin (**4b**) according to the procedure described for the preparation of **5a**. This compound was obtained as orange solid, m.p. 219.0–221.0°C (lit. m.p. 221°C) [26]; ^{1}H NMR δ 6.79 (d, *J* = 7.9 Hz, 1 H), 7.14 (dt, *J* = 7.6, 0.6 Hz, 1 H), 7.35 (dt, *J* = 7.8, 1.2 Hz, 1 H), 7.41–7.44 (m, 2 H), 7.46 (t, *J* = 7.6 Hz, 1 H), 7.57 (t, *J* = 7.6 Hz, 2 H), 8.15 (d, *J* = 7.6 Hz, 1 H); ^{13}C NMR δ 109.8, 116.2, 123.7, 127.0, 127.8, 128.7, 129.8, 132.1, 134.2, 144.0, 144.3, 164.5; *Anal*. Calcd for $C_{14}H_{10}N_2O_2$: C, 70.58; H, 4.23; N, 11.75; found: C, 70.45; H, 4.14; N, 11.49.

(E)-3-(Isopropoxyimino)-1-phenylindolin-2-one ((E)-6bd) and (E)-N-(2-oxo-1-phenylindolin-3-ylidene)propan-2-amine oxide ((E)-7bd). Compounds ***(E)*-6bd** and ***(E)*-7bd** were prepared from **5b** in 36% and 47% yield, respectively, following the alkylation procedure used for the preparation of *(E)*-**6ad** and *(E)*-**7ad**.

(*E*)-7bd: This compound was obtained as orange solid, m.p. 83.0–89.0°C; ^{1}H NMR δ 1.47 (d, *J* = 6.4 Hz, 6 H), 6.30–6.39 (m, 1 H), 6.79 (d, *J* = 7.9 Hz, 1 H), 7.11 (t, *J* = 7.5 Hz, 1 H), 7.27 (t, *J* = 7.8 Hz, 1 H), 7.42 (d, *J* = 7.0 Hz, 3 H), 7.52 (t, *J* = 7.5 Hz, 2 H), 8.47 (d, *J* = 7.3 Hz, 1 H); ^{13}C NMR δ 20.5, 62.2, 109.1, 118.7, 123.6, 124.9, 127.0, 128.4, 129.7, 131.2, 132.8, 134.1, 140.8, 160.0; LC-MS, MS m/z 281 (M+H); *Anal*. Calcd for $C_{17}H_{16}N_2O_2$: C, 72.83; H, 5.75; N, 9.99. Found: C, 72.72; H, 5.65; N, 9.92.

(*E*)-6bd: This compound was obtained as yellow solid, m.p. 125.5–127.0°C; ^{1}H NMR δ 1.47 (d, *J* = 6.1 Hz, 6 H), 4.78–4.87 (m, 1 H), 6.81 (d, *J* = 7.9 Hz, 1 H), 7.10 (t, *J* = 7.5 Hz, 1 H), 7.30 (dt, *J* = 7.9, 1.2 Hz, 1 H), 7.41 (d, *J* = 7.0 Hz, 3 H), 7.52 (t, *J* = 7.5 Hz, 2 H), 8.05 (d, *J* = 6.4 Hz, 1 H); ^{13}C NMR δ 21.9, 79.9, 109.7, 116.2, 123.4, 126.8, 127.9, 128.3, 129.8, 132.1, 134.0, 143.1, 144.4, 163.0; LC-MS, MS m/z 281 (M+H); *Anal*. Calcd for $C_{17}H_{16}N_2O_2$: C, 72.83; H, 5.75; N, 9.99. Found: C, 72.77; H, 5.72; N, 9.93.

(E)-3-(Isopropoxyimino)-1-phenylindolin-2-one ((E)-6bd) and (E)-N-(2-oxo-1-phenylindolin-3-ylidene)propan-2-amine oxide ((E)-7bd). To a solution of **5b** (104 mg, 0.437 mmol), 2-propanol (67.4 μL, 0.875 mmol) and triphenylphosphine (229 mg, 0.875 mmol) in THF (1.8 mL) maintained at 0°C was added diisopropyl azodicarboxylate (172 μL, 0.875 mmol). The resulting greenish-yellow solution was stirred at rt for 18 h, diluted with EtOAc (25 mL) and washed with aqueous 10% Na_2CO_3. The aqueous layer was extracted with EtOAc (25 mL), and the combined organic layers washed with 0.1*N* HCl (5 mL) and brine, dried and concentrated to afford a light orange viscous oil. Chromatography on a column of silica gel using a 4:1 mixture of hexane and EtOAc as eluant gave nitrone ***(E)*-7bd** (91 mg, 74% yield) as an orange solid followed by oxime ether ***(E)*-6bd** (12.3 mg, 10% yield) as a yellow viscous oil which solidified upon standing at rt.

(*E*)-7bd: ^{1}H NMR δ 1.48 (d, *J* = 6.4 Hz, 6 H), 6.30–6.39 (m, 1 H), 6.80 (d, *J* = 7.9 Hz, 1 H), 7.13 (t, *J* = 7.6 Hz, 1 H), 7.29 (dt, *J* = 7.8, 0.9 Hz, 1 H), 7.41–7.46 (m, 3 H), 7.54 (t, *J* = 7.5 Hz, 2 H), 8.48 (d, *J* = 7.3 Hz, 1 H).

(*E*)-6bd: ^{1}H NMR δ 1.46 (d, *J* = 6.4 Hz, 6 H), 4.78–4.87 (m, 1 H), 6.81 (d, *J* = 7.9 Hz, 1 H), 7.10 (t, *J* = 7.6 Hz, 1 H), 7.30 (t, *J* = 7.8 Hz, 1 H), 7.39–7.43 (m, 3 H), 7.52 (t, *J* = 7.5 Hz, 2 H), 8.05 (d, *J* = 7.6 Hz, 1 H).

4-Bromo-1-methylindoline-2,3-dione (4c). K_2CO_3 (4.95 g, 35.84 mmol) and CH_3I (10.17 g, 71.67 mmol) were added to a solution of 4-bromoisatin (5.4 g, 23.89 mmol) in DMF (50 mL) and the mixture heated at 80°C for 30 min. After cooling to rt, the mixture was diluted with H_2O (50 mL) and the precipitated red solid collected by filtration and washed with H_2O (2 × 25 mL). The product was dried in a vacuum oven to give **4c** (5.20 g) as a red solid that was used further without purification, m.p.199.5–200.5°C; ^{1}H NMR δ 3.25 (s, 3 H), 6.84 (d, *J* = 7.9 Hz, 1 H), 7.26 (d, *J* = 3.4 Hz, 1 H), 7.41 (t, *J* = 8.1 Hz, 1 H); ^{13}C NMR δ 26.4, 108.7, 116.4, 121.7, 128.6, 138.4, 153.1, 157.4, 180.7; *Anal*. Calcd for $C_9H_6BrNO_2$: C, 45.03; H, 2.51; N, 5.83; Br, 33.28. Found: C, 44.84; H, 2.48; N, 5.83; Br, 33.02.

4-Bromo-3-(hydroxyimino)-1-methylindolin-2-one (5c). Compound **5c** was prepared from **4c** using the procedure described for the preparation of **5a** with the exception that the reaction was heated at 55°C overnight. This compound was obtained as orange solid, m.p. 186.0–188.5°C; ^{1}H NMR δ 3.25 (s, 3 H), 6.84 (d, *J* = 7.9 Hz, 1 H), 7.25 (d, *J* = 7.2 Hz, 1 H), 7.41 (t, *J* = 7.9 Hz, 1 H); ^{13}C NMR δ 26.4, 108.7, 116.4, 121.7, 128.6, 138.4, 153.1, 157.4, 180.7; *Anal*. Calcd for $C_9H_7BrN_2O_2$: C, 42.38; H, 2.76; N, 10.98; Br, 31.32. Found: C, 42.14; H, 2.73; N, 10.74; Br, 30.95.

(Z)-4-Bromo-3-(isopropoxyimino)-1-methylindolin-2-one ((Z)-6cd) and (E)-4-bromo-3-(isopropoxyimino)-1-methylindolin-2-one ((E)-6cd). To a slurry of **4c** (1.03 g, 4.29 mmol) in EtOH (12 mL) was added a brown cloudy solution of 2-(ammoniooxy)propane chloride (0.527 g, 4.72 mmol) in H_2O (4 mL). The brown mixture was stirred at 52°C for 3.5 h, the solvent removed in *vacuo* and the residue dissolved in EtOAc (50 mL) and washed with H_2O (50 mL). The aqueous layer was extracted with EtOAc (50 mL), and the combined organic layers were washed with brine, dried, and concentrated to leave a light orange viscous oil. Chromatography on a column of silica gel using a mixture of hexane and EtOAc (3:1 then 2:1) as eluant afforded oxime ether (*Z*)-**6cd** (0.706 g, 56% yield) followed by oxime ether *(E)*-**6cd** (0.448 g, 35% yield) both isolated as yellow solids.

(Z)-6cd: m.p. 67.0–68.5°C; ^{1}H NMR δ 1.46 (d, J = 6.41 Hz, 6H), 3.20 (s, 3H), 4.70–4.78 (m, 1H), 6.74 (d, J = 7.93 Hz, 1H), 7.15 (t, J = 7.93 Hz, 1H), 7.22 (d, J = 8.24 Hz, 1H); ^{13}C NMR δ 21.4, 25.8, 80.1, 107.0, 116.7, 118.5, 127.6, 131.0, 141.1, 144.9, 156.6; LC-MS, MS m/z 297 (M+H); *Anal*. Calcd for $C_{12}H_{13}BrN_2O_2$: C, 48.50; H, 4.41; N, 9.42; Br, 26.89. Found: C, 48.74; H, 4.28; N, 9.32; Br, 27.00.

***(E)*-6cd**: m.p. 78.0–79.5°C; ^{1}H NMR δ 1.44 (d, J = 6.10 Hz, 6H), 3.22 (s, 3H), 4.76–4.85 (m, 1H), 6.74 (d, J = 7.93 Hz, 1H), 7.16 (t, J = 8.09 Hz, 1H), 7.28 (dd, J = 8.24, 0.92 Hz, 1H); ^{13}C NMR δ 21.8, 26.4, 81.0, 107.4, 117.6, 119.8, 129.3, 132.6, 139.7, 147.1, 163.5; LC-MS, MS m/z 297 (M+H).

(*Z*)-**6cd** was also prepared exclusively by alkylation of **5c** with 2-iodopropane or 2-bromopropane under the same conditions used to prepare *(E)*-**6ad**, m.p. 66.5–68.0°C; ^{1}H NMR δ 1.46 (d, J = 6.4 Hz, 6H), 3.20 (s, 3H), 4.69–4.78 (m, 1H), 6.74 (dd, J = 7.6, 0.6 Hz, 1H), 7.16 (t, J = 7.9 Hz, 1H), 7.23 (dd, J = 8.2, 0.6 Hz, 1H); LC-MS, MS m/z 297 (M+H).

(*Z*)-**6cd** was also prepared exclusively in 85% yield from **5c** and isopropyl alcohol under the Mitsunobu conditions described for the preparation of *(E)*-**6bd** and *(E)*-**7bd** above. This compound was obtained as yellow solid, m.p. 66.0–67.5°C; ^{1}H NMR δ 1.47 (d, J = 6.4 Hz, 6H), 3.21 (s, 3H), 4.70–4.79 (m, 1H), 6.75 (d, J = 7.6 Hz, 1H), 7.16 (t, J = 7.9 Hz, 1H), 7.24 (d, J = 8.2 Hz, 1H); LC-MS, MS m/z 297 (M+H).

X-ray crystallographic data for compounds *(E)*-**6bd** and *(E)*-**7ad** have also been deposited with the Cambridge Crystallographic Data Center as CCDC 661142 and CCDC 661143, respectively.

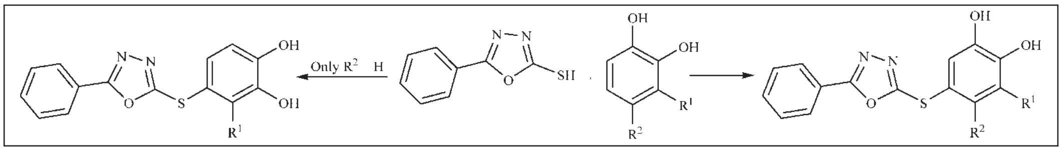
Received March 11, 2008
DOI 10.1002/jhet.86



Electrochemical oxidation of catechols to corresponding *o*-quinones was successfully performed in aqueous solution by electrolysis at the controlled potentials. Quinones derived from catechols, participate in Michael addition reactions with 5-phenyl-1,3,4-oxadiazole-2-thiol and *via* EC mechanism, converted to corresponding 5-phenyl-1,3,4-oxadiazol-2-ylthio-benzene-1,2-diol derivatives (**4** and **4′**). The products have been characterized using IR, ^{1}H NMR, ^{13}C NMR, X-ray, and mass spectral data.

J. Heterocyclic Chem., **46**, 443 (2009).

INTRODUCTION

Derivatives of 1,3,4-oxadiazole constitute an important family of heterocyclic compounds. Some material applications of 1,3,4-oxadiazole derivatives lie in the field of liquid crystals [1]. 1,3,4-Oxadiazole derivatives are also among the most widely used electron-conducting and hole-blocking materials in organic light-emitting diodes [2]. Substituted 1,3,4-oxadiazoles are associated with many types of biological properties [3–5]. The 2-aryl-5-(substituted)-1,3,4-oxadiazoles have been reported to show antibacterial [6,7], antifungal [8], anti-inflammatory [9,10], and hypoglycemic [7] activity. Catechols can be oxidized electrochemically to *o*-quinones. *O*-quinones derived from catechols are quite reactive and can be attacked by nucleophiles [11–15]. Regarding the importance of 1,3,4-oxadiazole derivatives in biological systems and following our previous works [16–19], we have reported the simple electrochemical method for the synthesis of some novel 1,3,4-oxadiazole derivatives from catechols and 5-phenyl-1,3,4-oxadiazole-2-thiol in this work.

RESULTS AND DISCUSSION

The electrochemical oxidation of catechols (**1a–d**) in the presence of 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**) undergoes a smooth 1:1 addition reaction in water medium at an ambient temperature to produce 5-phenyl-1,3,4-oxadiazol-2-ylthio-benzene-1,2-diol (**4** and **4′**). Cyclic voltammetry (CV) of 1 m*M* 4-methylcatechol (**1a**) in water/acetonitrile (95/5) solution containing 0.15*M* phosphate buffer (pH 7.2) shows one anodic (A_1) and corresponding cathodic peak (C_1), which is related to the transformation of 4-methylcatechol (**1a**) to *o*-benzoquinone (**2a**) and *vice versa* through a quasi-reversible two-electron process (Fig. 1, curve I).

A peak current ratio (I_P^{C1}/I_P^{A1}) of nearly one, particularly during the repetitive recycling of potential, can be considered as a criterion for the stability of *o*-benzoquinone produced at the surface of electrode under the experimental conditions. In other words, any hydroxylation [20] or dimerization [21] reactions are too slow to be observed on the time scale of the CV. Then, the electrochemical oxidation of catechols (**1**) was studied in the presence of 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**) as a nucleophile. Figure 1 (curve II) shows the cyclic voltammogram obtained for a 1 m*M* 4-methylcatechol (**1a**) in the presence of 1 m*M* 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**). The cyclic voltammogram of 1 m*M* 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**) is shown in Figure 1, curve III, for comparison.

The multicyclic voltammograms of **1a** in the presence of **3** are shown in Figure 2. The voltammograms exhibit a relatively intense decrease in anodic peak (A_1) together with some potential shift in a positive direction. The positive shift of the A_1 peak in the presence of **3** is due to the formation of thin film of product at the surface of the electrode in the experimental condition [22].

Characteristics of the products are shown in Table 1. It can be observed that when methyl and methoxy groups are presented in C-3 position, two products are formed. This could be due to nucleophilic attack at either the C-4 or C-5 position. Further investigations

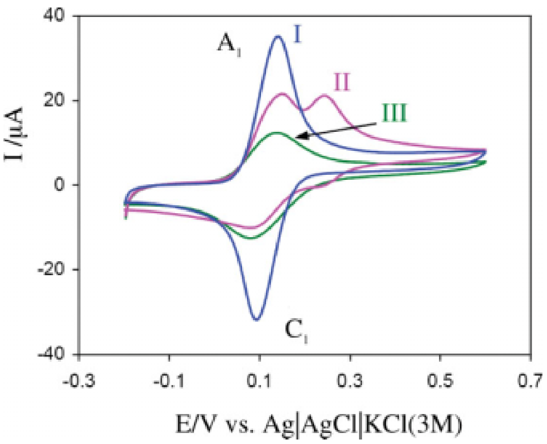


Figure 1. Cyclic voltammograms of 1 m*M* 4-methylcatechol (**1a**) in the absence (I) and in the presence (II) of 1 m*M* 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**) and 1 m*M* 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**) in the absence of 4-methylcatechol (III) at a glassy carbon electrode (1.8 mm diameter), in phosphate buffer (pH 7.2, $C = 0.15M$); scan rate: 100 mV s^{-1}; room temperature. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

confirmed the suggestion using ^1H NMR results and single crystal X-ray diffraction analysis (Fig. 3).

The percentage of each isomer was calculated from the ^1H NMR spectrum according to the intensity of peaks that are observed in both aliphatic and aromatic regions.

These voltammetry and spectral results allowed us to propose an EC mechanism [23] for the electrooxidation of catechols in the presence of 5-phenyl-1,3,4-oxadiazole-2-thiol (Scheme 1).

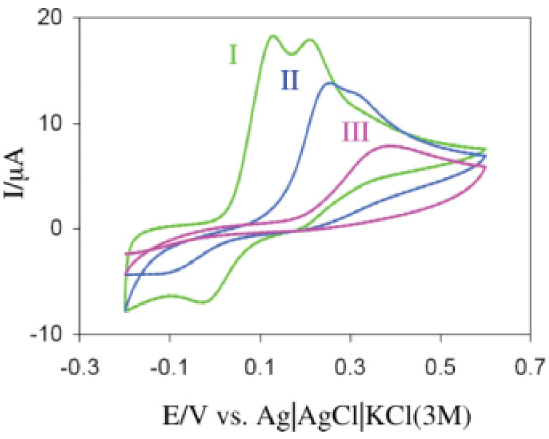

Figure 2. Multicycle voltammograms of 1 m*M* 4-methylcatechol (**1a**) in the presence of 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**), at glassy carbon electrode (1.8 mm diameter) in water/acetonitrile (95/5) containing of phosphates (KH_2PO_4/K_2HPO_4) as the buffer and supporting electrolyte (pH 7.2, $C = 0.15M$), scan rate: 100 mV s^{-1}; room temperature. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

EXPERIMENTAL

Apparatus and reagents. Cyclic voltammetry was performed using µAutolab potentiostat/galvanostat type III. Preparative analysis was carried out using an EG&G PAR A Model 174 A potentiostat/galvanostat. The working electrode (WE) used in the voltammetry experiment was a glassy carbon disc (1.8 mm diameter), and the platinum wire was used as the counter electrode (CE). The WE used in macroscale electrolysis was an assembly of three carbon rods (8 mm diameter and 4 cm length) and a large platinum gauze (3 × 3 cm^2) constituted the CE. The WE potentials were measured *versus* the Ag|AgCl|KCl (3*M*) as a reference electrode (all electrodes were obtained from Azar electrode, Urmia, I. R. Iran). NMR spectra were recorded on a Bruker DRx-300 Avance Instruments. IR spectra were recorded on a Bruker IFS-66 FTIR Spectrophotometer. Mass spectra were obtained using a QP-1100EX Shimadzu GC-MS (EI at 70 eV). Melting points of the products were obtained using an electrothermal melting point model 9200.

Chemicals (catechol, 3-methoxycatechol, 4-methylcatechol, and 5-phenyl-1,3,4-oxadiazole-2-thiol) were reagent-grade, and phosphate salts were of pro-analysis grade from E. Merck and

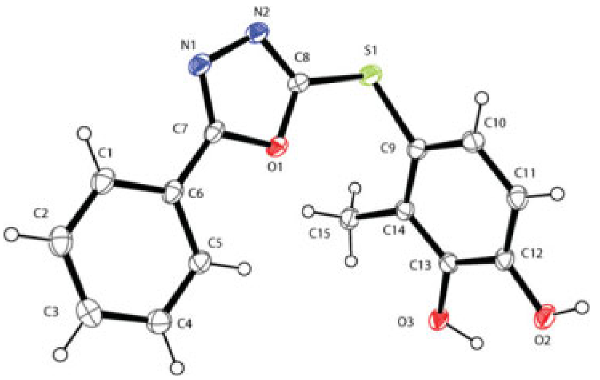

Figure 3. ORTEP structure of **4′d**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

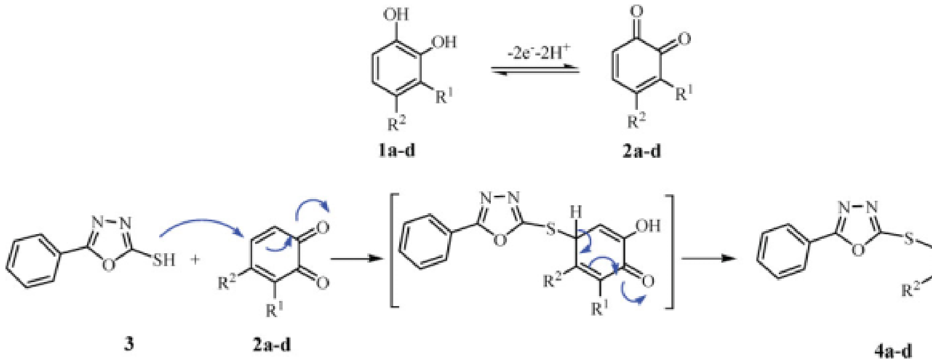
Scheme 1. Proposed mechanism for the electrooxidation of catechols in the presence of 5-phenyl-1,3,4-oxadiazole-2-thiol (**3**). [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]



3-methylcatechol was reagent-grade from Acros. These chemicals were used without further purification. All experiments were carried out at room temperature.

Electroorganic synthesis of products. In a typical procedure, 100 mL mixture of water/acetonitrile (95/5) containing phosphates (KH_2PO_4/K_2HPO_4) as the buffer and supporting electrolyte (pH 7.2, $C = 0.15M$) was preelectrolyzed at the potential mentioned in Table 2 in an undivided cell. Subsequently, 2 mmol of catechols (**1a**–**d**) and 2 mmol of nucleophile (**3**) were added to the cell. Finally, the electrolysis was performed at the same potential.

The electrolysis was terminated when the decay of the current became more than 95%. The process was interrupted several times during the electrolysis and the carbon anode was washed in acetone to reactivate it. At the end of electrolysis, the cell was placed in a refrigerator overnight. The precipitated solid was collected by filtration and then was washed several times with distilled water. After purification, products were characterized using IR, ^{1}H NMR, ^{13}C NMR, X-ray, and Mass spectral data.

Characteristics of the products. ***4-(5-Phenyl-1,3,4-oxadiazol-2-ylthio)-5-methylbenzene-1,2-diol (4a).*** m.p. 205–207°C. MS (70 eV) *m/z* (relative intensity): 300 (22), 178 (38), 124 (42), 77 (100), 39 (43).

Crystal data for (4′d) $C_{15}H_{12}N_2O_3S_1$, $M_w = 300.34$: space group monoclinic, $P2_1/a$, $a = 8.3924(6)$ Å, $b = 18.4381(15)$ Å, $c = 9.7245(6)$ Å, $\beta = 111.713(5)°$, $V = 1398.00(17)$ Å^{-3}:

Table 2

Applied potentials for the synthesis of products.

Conversion	Applied potential (*V*) *vs.* Ag|AgCl|KCl (3*M*)
1a → **4a**	0.15
1b → **4b**	0.2
1c → (**4c**:**4′c**)	0.10
1d → (**4d**:**4′d**)	0.15

$Z = 4$, $D_c = 1.427$ mg/m^3: $F(000) = 624$, crystal size = 0.20 mm × 0.16 mm × 0.12 mm, radiation Mo Kα ($\lambda = 0.71073$ Å), theta range for data collection 2.21°–29.28°. Intensity data were collected at 298 K with a STOE IDPS II two-circle diffractometer and using ω-scanning technique, in the range of $-11 \leq h \leq 10$, $-25 \leq k \leq 24$, $-13 \leq l \leq 13$. The structure was solved by direct methods [24] and refined an F^2 by full-matrix least squares using the X-STEP32 program package [25] giving a final $R_1 = 0.0684$, $wR_2 = 0.1520$ for $I > 2\sigma(I)$ reflections.
