2-Aryl-4-quinolones are versatile synthetic intermediates and several articles continue to appear in literature describing their synthesis, chemical transformation, structural properties, and biological activities. Their versatility as synthetic intermediates is a consequence of 4-quinolone moiety, which contains several reactive centers (positions 1, 3, and 4) for possible functionalization and can also enable different degree of unsaturation. In this review, we describe methods developed to-date for the synthesis of 2-arylquinolin-4(1*H*)-ones and their *N*-alkylated and *O*-alkylated derivatives.

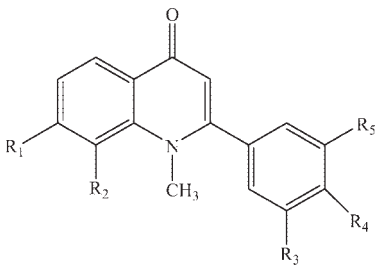
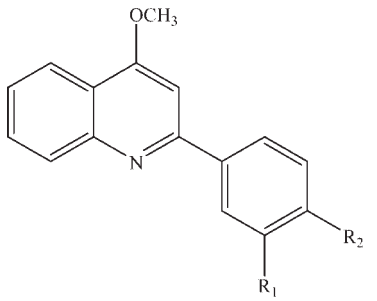
## 1. INTRODUCTION

2-Aryl-4-quinolone moiety constitutes important chemical unit in a large variety of naturally occurring compounds and it plays an extremely important role in synthetic and medicinal chemistry. Most of the 2-aryl-4-quinolones and their 2-arylquinoline derivatives are widely distributed in the plant family *Rutaceae*. Eduleine or 7-methoxy-1-methyl-2-phenylquinolin-4(1*H*)-one (**I**) ($R_1$ = $OCH_3$; $R_2$, $R_3$, $R_4$, $R_5$ = H), for example, was first isolated from the bark of the Mexican tree *Casimiroa edulis* [1] and the bark of *Lunasia quercifolia* (Warb) [2]. Eduleine and its 4-methoxy-1-methyl-2-(3,4-methylenedioxyphenyl)quinolin-4(1*H*)-one analogue (**II**) ($R_1$ = $OCH_3$; $R_2$, $R_5$ = H; $R_3$+$R_4$ = —$OCH_2O$—) were also isolated from the leaves of *Lunasia amara* Blanco of the Philippine origin [2]. Graveoline (**III**) ($R_1$, $R_2$, $R_5$ = H; $R_3$+$R_4$ = —$OCH_2O$—), on the other hand, was first isolated from *Ruta graveolens* and its substituted derivatives methoxygraveoline (**IV**) ($R_1$, $R_2$, $R_5$ = $OCH_3$; $R_3$+$R_4$ = —$OCH_2O$—) and 3,8-dimethoxygraveoline (**V**) (R = R′ = OMe) were isolated from the roots of the Brazilian plant *Esenbeckia grandiflora* [3]. The isomeric 4-methoxy-2-phenylquinoline (**VI**) ($R_1$, $R_2$ = H) and its 4-methoxy-2-(3,4-methylenedioxyphenyl)quinoline analogue (**VII**) ($R_1$+$R_2$ = —$OCH_2O$—) were also isolated from the leaves of *Lunasia amara* Blanco [2].



(**I**) $R_1 = OCH_3$; $R_2, R_3, R_4, R_5 = H$
(**II**) $R_1 = OCH_3$; $R_2, R_5 = H$; $R_3+R_4 = OCH_2O$—
(**III**) $R_1$, $R_2$, $R_5$ = H; $R_3+R_4$ = —$OCH_2O$—
(**IV**) $R_1$, $R_2$, $R_5$ = $OCH_3$; $R_3+R_4$ = —$OCH_2O$—
(**V**) $R_1 = H$; $R_2, R_5 = OCH_3$; $R_3+R_4 = $—$OCH_2O$—



(**VI**) $R_1$, $R_2$ = H
(**VII**) $R_1+R_2$ = —$OCH_2O$—

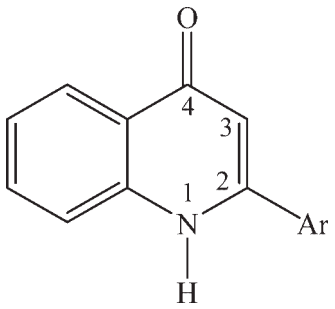


**Figure 1.** Generalized structure of 2-arylquinolin-4(1*H*)-one.

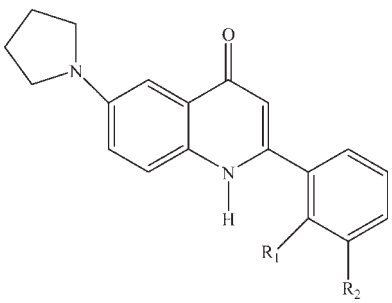
Over the last years, the interest in 2-arylquinolin-4(1*H*)-ones and their analogues have been the subject of extensive study as potential anti-tumor, anti-mitotic, and cytotoxic agents [4–8] as well as anti-platelet agents [9,10]. 2-(3-Methoxyphenyl)-6-(1-pyrrolinyl)quinolin-4(1*H*)-one (**VIII**) ($R_1$ = H, $R_2$ = $OCH_3$) and 2-(2-fluorophenyl)-6-(1-pyrrolinyl)quinolin-4(1*H*)-one analogue (**IX**) ($R_1$ = F, $R_2$ = H), for example, are potent inhibitors of tubulin polymerization ($IC_{50}$ = 0.44 μ*M* (**I**); 0.46 μM (**IX**)) and exhibit anti-mitotic anti-tumor activity at low concentrations having effects comparable to those of colchicine, podophyllotoxin, and combretastatin A-4 [4,5]. The 4-substituted quinoline moiety constitutes the framework for several nitrogen-containing heterocycles known to exhibit cytotoxic [11], anti-leishmanial [12], anti-malarial [13], and anti-bacterial properties [14]. Aryl substituted quinolines have also been reported to serve as estrogen receptor modulators [15] and also as potent inhibitors of tyrosine kinase PDGF-RTK [16]. The naturally occurring 4-methoxy-2-phenylquinoline (**VI**) and its 4-methoxy-2-(3,4-methylenedioxyphenyl)quinoline analogue (**VII**) [8] have recently been found to exhibit inhibitory activity against *Mycobacterium tuberculosis* $H_{37}Rv$ [17].



(**VIII**) $R_1$ = H, $R_2$ = $OCH_3$
(**IX**) $R_1$ = F, $R_2$ = H

The 2-aryl-4-quinolones are also versatile synthetic intermediates and several articles continue to appear in literature describing their synthesis, chemical transformation, structural properties, and biological activities. Their versatility as synthetic intermediates is a consequence of 4-quinolone moiety (Fig. 1), which contains

**Scheme 1. Reagents**: (i) $(C_6H_5)_2O$, 140°C, 30 min or EtOH, heat, 2–4 h; (ii) $(C_6H_5)_2O$, 250–260°C.

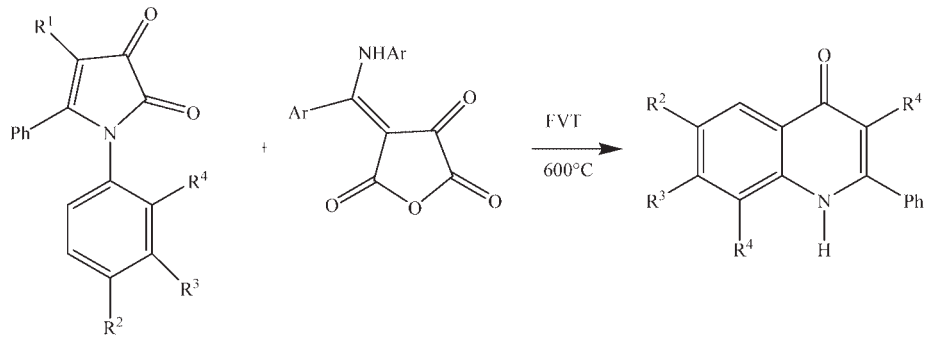
several reactive centers (positions 1, 3, and 4) for possible functionalization and can also enable different degree of unsaturation. They are known to undergo electrophilic substitution with alkyl derivatives to afford *N*- or *O*-alkylated derivatives or a mixture of the two isomers depending on the nature of the electrophile used and steric effect on the quinolone moiety. Aromatization of the 4-quinolone moiety with phosphorus oxychloride occurs with ease to afford 4-chloroquinolines which are important intermediates in the synthesis of 2-arylquinolines bearing a heteroatom group in the 4-position. Their α,β-unsaturated framework allows C-3 halogenation to yield 3-halogeno derivatives, which have been shown to undergo metal-catalyzed C—C formation to yield polysubstituted and polynuclear derivatives.

Although the popularity of variously substituted 2-arylquinolin-4(1*H*)-ones has been increasing over the years, their synthesis and transformation into *N*-alkylated or *O*-alkylated derivatives have never been reviewed. We wish to address this need by reviewing various methods developed to-date for the synthesis of 2-arylquinolin-4(1*H*)-ones and their transformation to *N*-alkylated and *O*-alkylated derivatives.

## 2. SYNTHESIS OF 2-ARYLQUINOLIN-4 (1*H*)-ONES

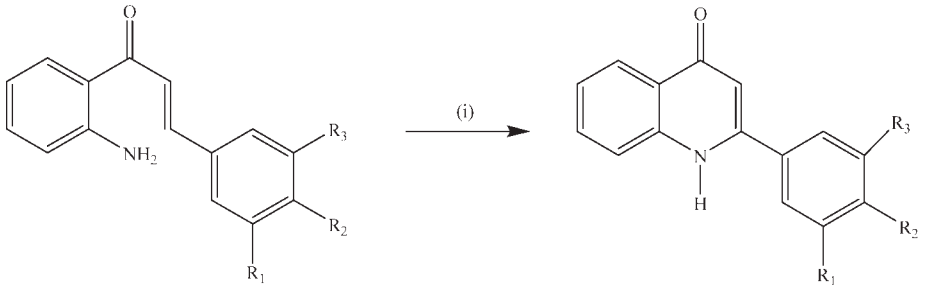
**2.1. From arylamines and carbonyl derivatives.** Several articles continue to appear in literature describing novel methods for the synthesis of 2-arylquinolin-4(1*H*)-ones. In one of the earliest methods, anthranilic acid or its ester derivative was heated with the acetal of an alkyl aryl ketone to yield the corresponding 2-arylquinolin-4(1*H*)-one [18]. Arylamines were also condensed with an ethyl benzoylacetate derivative in the presence of polyphosphoric acid (PPA) to afford 2-arylquinolin-4(1*H*)-ones [6,9,19]. Both these pathways are, however, not suitable for the synthesis of 2-arylquinolin-4(1*H*)-ones with multiple substituents. Anilinoarylidenemalonates derived from β-chloroarylidenemalonates and sodium diethyl malonate were previously cyclized at 250°C to afford 2-aryl-3(ethoxycarbonyl)-4-quinolones

**Scheme 2**



**5** **6** **7**

**Scheme 3. Reagents**: (i) $Pd(PPh_3)_2Cl_2$, THF, heat, 2 h.



**8** **9**

[20]. Lai and coworkers also subjected anilinoarylidenemalonates derived from carboxymidoyl chlorides to thermolysis at 170°C to afford 2-aryl-3(ethoxycarbonyl)-4-quinolones [8]. Thermolysis of the mono-ethoxycarbonyl vinyl derivatives, which are formed in comparable yields along with the anilinoarylidenemalonates afforded the 2-aryl-4-quinolones. In another development, 2,2-dimethyl-5-methylthioalkylidene-1,3-dioxane-4,6-diones **1** (R = Me, Et, Pr, Ph), which are easily prepared from Meldrum's acid (2,2-dimethyl[1,3]dioxane-4,6-dione) were condensed with substituted arylamines **2** (X = H, Me, $NO_2$, Br, Cl) in refluxing diphenyl ether or ethanol with (isolated yields: 54–57%) or without isolating the resulting intermediate **3** to afford 2-alkyl- and 2-arylquinolin-4(1*H*)-ones **4** (60–96%) upon cyclization in $Ph_2O$ at very high temperature (Scheme 1) [21].

2-Arylquinolin-4(1*H*)-ones were also prepared by condensing ethyl benzoylacetate with aniline in ethanol at 50°C followed by heating the resulting intermediate at 240–250°C in diphenyl ether [22,23]. A series of substituted 2-aryl-4-quinolones **7** has been synthesized in good yields (16–88%) from 1-aryl-5-phenylpyrrole-2,3-diones **5** substituted at the 4-position with cyano ($R^1$ = CN) or methoxycarbonyl group ($R^1$ = $CO_2Me$) and **6** *via* flash thermolysis (FVT) at 600°C (Scheme 2) [24].

**2.2. From 2-aminochalcones or 2-aryl-1,2,3,4,-tetrahydroquinol-4-ones.** 2′-Amonichalcones and their isomeric 2-aryl-1,2,3,4-tetrahydro-4-quinolone derivatives have also been used as substrates for the synthesis of 2-arylquinolin-4(1*H*)-ones. The 2′-amonichalcones **8**, which are readily accessible *via* Murphy-Watanism's aldol condensation of 2-aminoacetophenone with benzaldehyde derivative [25,26], have been found to undergo intramolecular cyclization in THF in the presence of dichloro-bis(triphenylphosphine)palladium(II) to afford the corresponding 2-arylquinolin-4(1*H*)-ones **9** in good yields (55–85%) (Scheme 3) [27]. The main disadvantage of this reaction is the use of stoichiometric amounts of the organometallic reagent and column chromatographic separation of the NH-4-oxo derivatives that are almost insoluble in many organic solvents.

Thallium(III) *p*-tolylsulfonate (TTS) in dimethoxyethane (DME) [28] or iodobenzene diacetate in methanolic KOH [29,30] were used before to dehydrogenate 2-aryl-1,2,3,4-tetrahydro-4-quinolones **10** to 2-aryl-4-quinolones **9** (Scheme 4). The 2-aryl-1,2,3,4-tetrahydro-4-quinolones are themselves easily obtainable through acid-catalyzed cyclization of the isomeric 2-amonichalcones **8** [25,26]. Lee and Youn, recently used zinc chloride in acetonitrile to cyclize series of 2-amonichalcones to afford the corresponding isomeric 2-aryl-1,2,3,4-tetrahydro-4-quinolone derivatives in high yields (>85%) [30]. The 2-aryl-1,2,3,4-tetrahydro-4-quinolones bearing substituents on the fused benzo ring can also be prepared through direct one-pot acid-catalyzed condensation of substituted

$R_1$ = H, OH, $OCH_3$

$R_2$ = H, OH, $OCH_3$

aniline derivatives with ethyl benzoylacetate in refluxing toluene [22,23].

The other approach to 2-arylquinolones makes use of flavylium salts **12** derived from the condensation of 2-hydroxyacetophenones **11** with aryldehydes in ethyl orthoformate in the presence of potentially explosive perchloric acid (Scheme 5) [31]. The resulting flavylium salt is then treated with aqueous ammonia to release the corresponding 2-aryl-4-quinolone **13**. A modification of this procedure employs trifluoroacetic acid or trifluoromethanesulfonic acid in ethyl orthoformate or dichloromethane to afford flavylium salts in high yields, however, the expected 2-aryquinolones are isolated in relatively low yields (18–59%) [32].

**2.3. Synthesis from 2-aminoacetophenone and aroylchlorides.** The most convenient and high yielding method usually used for the synthesis of 2-arylquinolin-4(1*H*)-ones involves the use of 2-aminoacetophenones **14** and substituted benzoyl chlorides **15** as starting material [5,7,33,34]. The resulting *N*-benzoyl-2-aminoacetophenone **16** is cyclized under reflux using t-BuOK in t-BuOH to afford the corresponding 2-arylquinolin-4(1*H*)-one **17** in high yield (60–80%) and purity (Scheme 6).

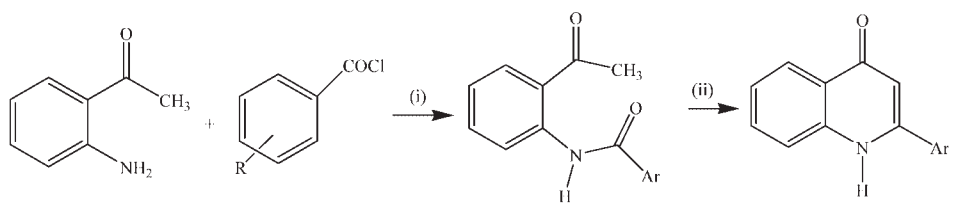
The reaction has also been carried out under microwave conditions involving irradiation of acylated 2′-aminoacetophenone in the presence of sodium hydroxide to afford 2-aryl-4-quinolones [35].

**2.4. Methods involving organometallic reagents.** Less traditional syntheses of 2-arylquinolin-4(1*H*)-ones, which make use of transitional metals have been developed. Palladium-catalyzed carbonylation of 2-haloaniline **18** in the presence of terminal acetylenes **19** under proper conditions (20 kg/cm$^2$ of CO at 120°C) afforded a variety of 2-substituted quinolin-4(1*H*)-ones **20** (Scheme 7) [36]. Carbonylation of series of *o*-iodoanilines and terminal alkynes in the presence of palladium catalyst [$PdCl_2$(dppf)] afforded 2-aryl-4-quinolones in good yields (62–83%) [37]. The reaction was found to proceed well in both secondary (diethylamine) and tertiary amines (triethylamine) and in benzene containing 4 equivalent of diethylamine.

Variously substituted 2-arylquinolin-4(1*H*)-ones **23** can also be obtained in appreciable yields (72–97%) *via* sequential Cu-catalyzed amidation of halophenones **21** followed by a base-promoted Camps cyclization of the resulting *N*-(2-ketoaryl)amides **22** (Scheme 8) [38].

A mild and high yielding (>85%) one-pot synthesis of 2-arylquinolin-4(1*H*)-ones **26** *via* sequential palladium-catalyzed amidation of 2′-bromoacetophenone derivatives **24** followed by base-promoted intramolecular cyclization of **25** has been recently developed (Scheme 9) [39].

**Scheme 6. Reagents:** (i) $NEt_3$, THF, 0°C to r.t. 2 h; (ii) t-BuOK, t-BuOH, heat, 20 h.



**14** **15** **16** **17**

**18** (X = Br, I) **19** **20**

R, R' = H (90%)

R = H, R' = -OMe (95%)

R = H, R' = -$CO_2$Et (85%)

R, R' = -$OCH_2O$- (88%)

These novel methods that make use of organometallic reagents are high yielding and allow synthesis of variously substituted potentially tautomeric 2-arylquinolin-4(1*H*)-ones [40].

## 3. REACTIONS OF 2-ARYLQUINOLIN-4(1*H*)-ONES

New findings on the biological properties of 2-aryl-4-quiolones reveal a need to increase the diversity of substituents around the 4-quinolone framework. This moiety contains several reactive centers for possible functionalization to yield novel systems, which can themselves serve as substrates for further chemical transformation. The 2-arylquinolin-4(1*H*)-ones have been found to undergo C-3 halogenation, *N*- or *O*-alkylation, and oxidative aromatization.

**3.1. C-3 Halogenation.** Halogenated heterocyclic systems continue to attract considerable attention because of the profound effect a halogen atom can have on the physical, chemical, and biological properties of such substances. Iodine–$Na_2CO_3$ mixture in THF at room temperature was previously used to effect C-3 iodination of 2-arylquinolin-4(1*H*)-ones **27** to afford the corresponding 2-aryl-3-iodoquinolin-4(1*H*)-ones **28** (X = I) in high yield and purity (Scheme 10) [41]. The NH-4-oxo derivatives can also be iodinated using iodine–ammonium cerium nitrate (CAN) mixture in acetonitrile at 70–80°C to afford 2-aryl-3-iodoquinolin-4(1*H*)-ones [42]. On the other hand, the analogous 2-aryl-3-bromoquinolin-4(1*H*)-ones **28** (X = Br) were prepared in high yield and purity from the corresponding 2-arylquinolin-4(1*H*)-ones using pyridinium tribromide in acetic acid at room temperature (Scheme 10) [41].

**3.2. Alkylation of 2-arylquinolin-4(1H)-ones and their derivatives.** The synthetic versatility of the potentially tautomeric 4-quinolone framework enables interconversion between the NH-4-oxo precursors and their *O*- or *N*-methylated derivatives. Comparison of spectroscopic data (IR, NMR, and ms) of these fixed derivatives (*O*- or *N*-alkylated) with those of the corresponding precursors (NH-4-oxo) has been used to resolve uncertainties on the 2-substituted 4-quinolone *versus* 2-substituted 4-quinolinol tautomeric equilibrium [40]. The naturally occurring 4-methoxy-2-phenylquinoline **29**

**Scheme 8. Reagents:** (i) Amide, CuI, ligand, toluene, heat; (ii) NaOH, 1,4-dioxane, heat.

**24** **25** **26**

was previously treated with HCl in methanol under reflux to yield the 2-phenylquinol-4-one **30**, which was in turn converted to the NMe-4-oxo derivative **31** using dimethyl sulfate under basic conditions [43]. On the other hand, when heated with MeI, the 4-methoxyquinoline **29** yielded the dimethylated salt **32**, which upon treatment with a base afforded the isomeric 1-methyl-2-phenylquinoline **31** (Scheme 11).

The most classical method used for alkylation of 2-arylquinolin-4(1*H*)-ones involves subjecting the NH-4-oxo derivative to a base followed by quenching with the corresponding alkyl halide. Methylation of the 2-substituted-4(1*H*)-quinolones **33** using MeI-$K_2CO_3$ mixture in DMF was reported to afford a mixture of the *O*-methylated **34** and *N*-methylated derivatives **35** (Scheme 12) [44] while on the other hand, NaH and MeI in DMF afforded the *O*-methylquinoline derivatives, exclusively [45]. It was, however, discovered by Kuo and coworkers that the product mixture comprised of *N*- and *O*-methylated derivatives in the ratio 2:3 [46]. Alkylation of 2-phenylquinolin-4(1*H*)-one with methyl iodide or various primary alkyl, allyl, and benzyl halides in DMF in the presence of NaH, on the other hand, afforded the corresponding *N*-alkylated derivatives as sole products [47]. Enol ethers were also isolated as sole products when 2-(2-fluorophenyl)-6,7-methylenedioxyquinolin-4(1*H*)-one was treated with NaH in DMF followed by alkylation with ethyl chloroacetate or ethyl 4-chlorobutyrate [5]. Alkylation of 2-arylquinolin-4(1*H*)-ones with various alkyl halides also afforded the corresponding *O*-alkylated derivatives, exclusively [10]. Methylation was, however, found not to be regioselective under these conditions affording mixtures of *O*-methylated and *N*-methylated isomers.

It was also observed that the presence of substituent at C-5 or C-3 position has significant effect on the regioselectivity of alkylation of the quinolone derivatives. Treatment of 5,7-dimethoxy-2-phenylquinolin-4(1*H*)-one **36** (R, R′ = OMe) with MeI-$K_2CO_3$ mixture in DMF afforded *O*-methylated derivative **37** as the sole product (Scheme 13) [48]. On the other hand, under similar reaction conditions, 5-hydroxy-7-methoxy-2-phenyl-4-quinolone **36** (R = OH, R′ = OMe) afforded both *O*- **37** and *N*-methylated derivatives **38** [46] with *N*-methylated derivative as major product (ratio 9:1 *N*-alkylated *vs*. *O*-alkylated) [49]. Hadjeri *et al*. attributed the observed non-regioselectivity to the tautomeric equilibrium between the NH-4-oxo and its quinolinol isomer which is favored by chelation effect of the 5-OH group [48]. Treatment of the analogous 5-ethyl-2-phenylquinolin-4(1*H*)-one **36** (R = Et, R′ = H) with NaH-MeI mixture in THF afforded both *O*-methylated **37** (R″ = Me) and *N*-methylated isomers **38** (R″ = Me) in the ratio 1:5.4 [10]. On the other hand, under similar reaction conditions ethyl iodide and various ethoxycarbonylalkyl halides afforded only the corresponding *O*-alkylated products **37** (R = Et, R′ = H; R″ = Et, $CH_2CO_2Et$, $CH_2CO_2H$) [10].

The 3-halogenated NH-4-oxo derivatives **39** (R′ = Br, I) were treated with NaH in THF to afford the *N*-methylated derivatives **40** as the only products (Scheme 14) [41,50,51]. The observed regioselectivity was attributed to the preponderance of these derivatives as the NH-4-oxo tautomers in polar medium and solid state [40,51]. 2-Aryl-3-bromo-1-methylquinolin-4(1*H*)-ones **40** (X = Br) were also prepared directly from the corresponding 2-aryl-1-methylquinolin-4(1*H*)-one precursors in high yields (77–93%) using pyridinium tribromide in acetic acid at room temperature [41].

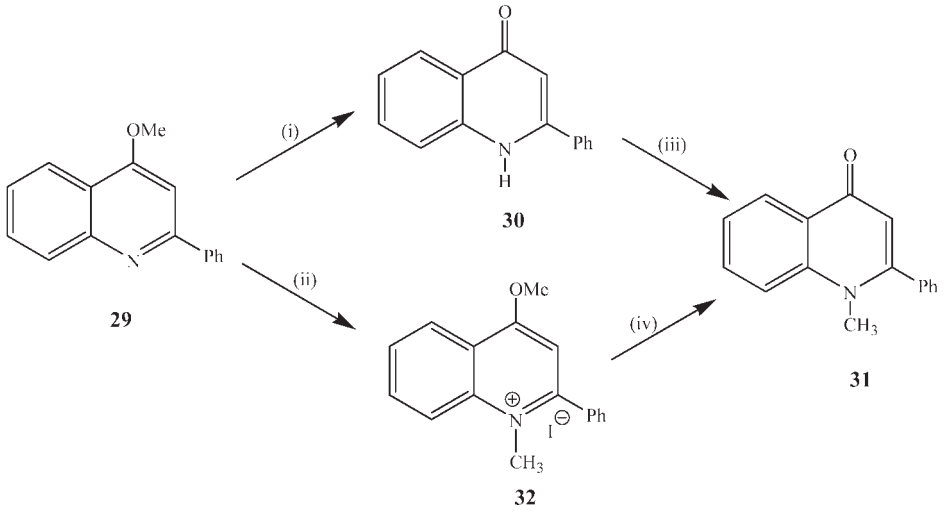
**Scheme 11. Reagents**: (i) HCl, MeOH, heat; (ii) MeI, heat; (iii) $Me_2SO_4$, NaOH; (iv) NaOH.



In another development, series of pharmaceutically important *N*-methylated 2-aryl-4-quinolone alkaloids **44** were prepared by methylation of 2-arylquinolines **43** with methyl trifluoromethanesulfonate followed by oxidation with potassium ferricyanate $[K_3Fe(CN)_6]$ (Scheme 15) [52]. 2-Arylquinoline **43** used as substrate in this investigation were, in turn, synthesized by Diels–Alder reaction of substituted 1,2,3-benzotriazine **41** prepared by oxidation of 1-amino-1*H*-indazole with lead tetraacetate, and pyrrolidine enamine of substituted acetophenone **42** in dry chloroform in the presence of zinc bromide under reflux [52].

Although primary alkyl halides and benzyl halides afforded the *O*-alkylated derivatives exclusively, the problem of non-regioselectivity with methylation necessitates the development of sure-fire methods for the direct and regioselective synthesis of either *N*- or *O*-methylated isomers. Very few methods have been developed to-date for the direct synthesis of *N*-alkyl 2-arylquinolin-4(1*H*)-ones.

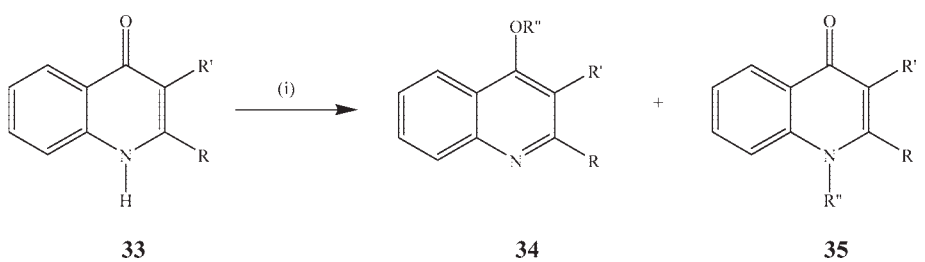
***3.2.1. Direct synthesis of N-alkylated 2-arylquino-linones.*** The shortest route (one-step synthesis) reported to-date for the synthesis of 2-aryl-1-methyl-4-quinolones **47** in appreciable yields involves the condensation of lithium enolates of acetophenone derivatives **46** with substituted *N*-methylisatoic anhydrides **45** (Scheme 16) [46,53]. Although the reaction is high yielding, each reaction when using different substrates has its unique temperature requirements for completion.

Several *N*-methylated 2-aryl-4-quinolinones were prepared in moderate yields by treatment of resin bound flavylium salts with methylamine following a similar procedure outlined in Scheme 5 [32]. In another development involving synthesis of *N*-alkylated 2-arylquinolone derivatives, 2-aminoacetophenone **48** was first condensed with various aldehydes followed by selective reduction using $NaBH_3CN$ to yield **49** (Scheme 17). The alkylated derivatives **49** were, in turn, acylated using various benzoyl chlorides and the resulting amides **50** were cyclized using t-BuOK in refluxing t-BuOH to afford 1-benzyl-2-arylquinolin-4(1*H*)-ones **51** [54].

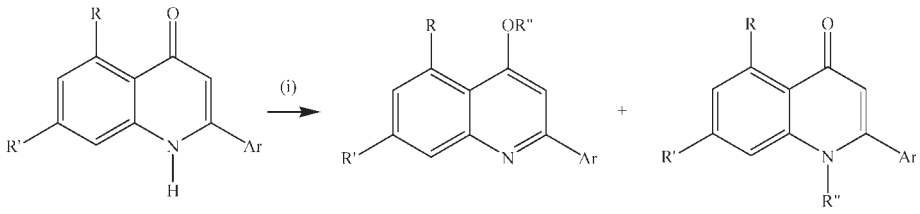
Palladium-catalyzed carbonylation of *N*-ethyl-2-iodoaniline **52** with phenylacetylene **53** in diethylamine afforded a mixture of enamine **54** (52%) and 2-phenylquinoline **55** (20%) (Scheme 18). Further heating of the enamine in THF in the presence of NaH effected smooth cyclization leading to quantitative yield of the quinolone [36].

A direct one-pot synthesis of 2-aryl-1-methylquinolin-4(1*H*)-ones **58**, which involves treatment of *N*-arylamidoacetophenone derivatives **56** with MeI in presence of

**Scheme 12. Reagents**: (i) MeI, NaH in THF or DMF; MeI, $K_2CO_3$ in DMF or Acetone.



**Scheme 13. Reagents**: (i) $K_2CO_3$, R″X, DMF or NaH, R″X, THF.



**36** **37** **38**

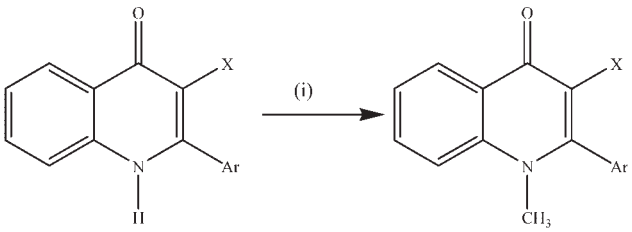
NaH in THF was recently described (Scheme 19) [40]. The corresponding *N*-methylated arylamidoacetophenone derivatives **57** were isolated in trace amounts (>5%).

Friedel-Crafts acylation of **59** using stannic chloride ($SnCl_4$) as catalyst afforded **60,** which upon cyclization with t-BuOK in t-BuOH yielded the corresponding 2-aryl-1-methylquinolin-4(1*H*)-ones **61** (Scheme 20) [55]. This cyclization previously worked well for the synthesis of 2-aryl-3,5,7-trimethoxy-4-quinolones from *N*-phenylamido methoxyacetophenones prepared, in turn, *via* stannic chloride-catalyzed Friedel-Crafts acylation of 3,5-dimethoxyphenyl-*N*-phenylamide with methoxyacetyl chloride in 1,2-dichloroethane [56].

Iodocyclization of the dimethylamino systems **62** using iodine in dichloromethane proved highly selective for the 6-endo-digonal pathway to afford 2-substituted 3-iodo-1-methylquinolin-4(1*H*)-ones **63** in high yield (94%, R = 4-MeO) (Scheme 21) [57].

***3.2.2. Direct synthesis of* O*-alkylated 2-arylquinolines.*** An alkoxide-mediated cyclization of Schiff bases **64** derived from the reaction of trifluoromethylaniline with alkyl or heterophenyl ketones is reported to afford 2-aryl-4-alkoxyquinoline **65**, exclusively [58,59]. In this reaction, the Schiff base is treated with t-KOBu in THF under reflux to afford the alkoxyquinoline derivative (OR = t-BuO) in high yield (83%) (Scheme 22) [58]. On the other hand, under similar reaction conditions, use of sodium or potassium ethoxide afforded the corresponding 4-ethoxy-2-phenylquinoline (R = Et) in lower yield (25%). The 2,3,4-trisubstituted quinoline (R′ = $CH_3$; R″ = t-Bu) was prepared in 52% yield following similar procedure [58].

**Scheme 14. Reagents**: (i) NaH, MeI, THF, r.t. 18 h.



**39** (X = Br, I) **40**

One of the recent developments in the synthesis of 4-alkoxyquinolines involved direct synthesis of the naturally occurring 4-alkoxy-2-arylquinoline derivatives from the corresponding 2-aryl-1,2,3,4-tetrahydro-4-quinolones using oxidative reagents (Scheme 23). Oxidation of 2-aryl-1,2,3,4-tetrahydro-4-quinolones **66** to 2-aryl-4-methoxyquinolines **67** was effected with either thallium(III) nitrate [60] or [hydroxyl(tosyloxy)iodo]benzene [61] in trimethyl orthoformate in the presence of catalytic amount of perchloric acid. Molecular iodine in refluxing methanol was also found to effect oxidative aromatization of 2-aryl-1,2,3,4-tetrahydro-4-quinolones **66** to 2-aryl-4-methoxyquinolines **67** [62]. Recently, Kumar and coworkers used $FeCl_3{\cdot}6H_2O$ in methanol to effect oxidative aromatization of series of 2-aryl-1,2,3,4-tetrahydroquinolin-4-ones to afford 2-aryl-4-methoxyquinolines in 70–85% yields [63]. $FeCl_3{\cdot}6H_2O$ in methanol was later used by these authors to effect direct one-pot synthesis of series of 2-aryl- and 2-heteroaryl-4-methoxyquinolines (55–72%) and their flavones derivatives from the corresponding 2-azachalcones and 2-hydroxychalcones, respectively [64].

Series of 2,4-disubstituted quinolines **69** (X = Br, I, SEt, SPh) including 4-alkoxy-2-arylquinolines (X = OEt, OMe, OAr) were prepared in moderate to high yields (33–98%) from the corresponding β-(2-aminophenyl)-α,β-ynones **68** using various nucleophiles (Scheme 24) [65].

The 4-alkoxy-2-arylquinolines **72** (R′ = Me, Et, i-Pr) were recently prepared in low to moderate yields (10–81%) from 2-(2-(trimethylsilyl)ethynyl)anilines **70** and aryldehydes **71** in the presence of sulfuric acid in alcohols (Scheme 25) [66].

Although simple and efficient, the above reagents used for direct oxidative aromatization of 2-aryl-1,2,3,4-tetrahydro-4-quinolones cannot be used for the synthesis of 2,3-disubstituted 4-alkoxyquinoline derivatives. On the other hand, the Skraup, Döbner-Miller, Friedländer and Combes reactions, which are well known classical methods for the synthesis of polysubstituted quinolines, cannot be adapted for the synthesis of quinoline derivatives bearing 4-alkoxy group [67]. Consequently, indirect methods remain the method of choice for the

yield the expected 4-phenoxy- or 4-alkoxyquinoline derivatives **75** (Scheme 26) [69,70]. This approach, which takes advantage of the ease of displacement of 4-chlorine atom by nucleophiles has recently been used for the synthesis of 2,3-disubstituted 4-alkoxyquinoline derivatives (R′ = Me) that cannot be easily prepared otherwise. Series of 2-aryl-3-bromo/iodo-4-methoxyquinolines were prepared this way from the corresponding 2-aryl-4-chloro-3-halogenoquinolines [50,51,70].

This indirect approach has also been adapted to involve the use of organometalic reagents in the synthesis of 2,3-disubstituted 4-alkoxyquinolines. The synthesis of 3-aryl-2-(ethyl/phenyl)-4-phenoxyquinolines **78**, involved initial C-2 coupling of 3-aryl-2,4-dichloroquinolines **76** with alkyl- or aryl-zinc reagents ($R_2Zn$; R = Et, Ph) followed by displacement of the 4-chlorine atom from **77** with bromophenol derivative (Scheme 27) [71].

The results of sequential functionalization of 2-aryl-4-chloro-3-iodoquinolines **73** (X = I) *via* palladium-catalyzed cross-coupling with phenylboronic acid followed by displacement of the 4-chloro atom from the resulting 2,3-diaryl-4-chloroquinolines **78** with methoxide ion to yield 2,3-diaryl-4-methoxyquinolines **79** have recently been described (Scheme 28). Compounds **79** were also

prepared *via* Suzuki–Miyaura cross-coupling of 2-aryl-3-iodo-4-methoxyquinolines **74** (R′ = Me, X = I) with phenylboronic acid [70]. Demethylation of the methoxy compounds **79** with $BBr_3$ in $CH_2Cl_2$ gave the 2,3-diaryl-4(1*H*)-quinolinones **80**.

This demethylation represents a convenient synthetic strategy for the construction of 2,3-diarylquinolin-4(1*H*)-ones of potential biological interest that can be obtainable only with difficulty otherwise.

## 4. CONCLUSIONS

Overall, the methods described in this review present another example showing the potential of 2-arylquinolin-4(1*H*)-ones in the synthesis of 2,3-substituted NH-4-oxo derivatives and their transformation into *N*-alkylated and *O*-alkylated derivatives. Interestingly, *O*-alkylated and *N*-alkylated quinolone derivatives do not feature at all in a recent review on quinolines by Kouznetsov *et al.* [72]. Despite the establishment of structural requirements and optimum reaction conditions suitable for the synthesis of *N*-alkylated quinolone derivatives, there is still a growing need for development of generalized methods for the synthesis of polysubstituted derivatives. On the other hand, indirect methods, which make use of 4-chloroquinolines and take advantage of the ease of displacement of the 4-chloro atom remain the best option for the synthesis of polysubstituted 4-alkoxyquinolines.

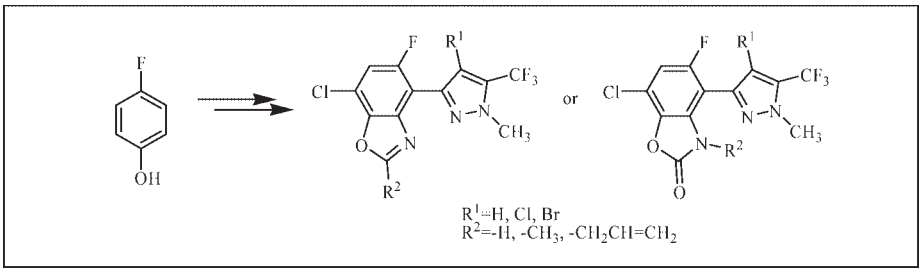
Published online 21 December 2009 in Wiley InterScience (www.interscience.wiley.com).



In recent years, protoporphyrinogen oxidase (Protox) inhibitor herbicides are developed rapidly, because of this type of herbicides shows high herbicidal activity and low toxicity. In this paper, we prepared a series of new substituted pyrazolyl benzoxazole derivative, which were synthesized from 4-fluorophenol, via a serial of reactions included chlorination, acylation, condensation, ring closure, methylation, nitration, and so on. All the structures are confirmed by $^1$H NMR, MS and element analysis. Preliminary bioassay shows that most substituted pyrazolyl benzoxazole derivatives exhibit high herbicidal activity to the tested gramineous weeds and latifoliate weeds.

*J. Heterocyclic Chem.,* **47**, 15 (2010).

## INTRODUCTION

Herbicides play an important role in agricultural practices. In recent 30 years, herbicides targeting the enzyme protoporphyrinogen IX oxidase (Protox), which have been used commercially to control annual grasses and weeds in soybean, peanut, cotton, rice, and other crops, are developed rapidly [1–3], because this type of herbicides shows high bioactivity and low toxicity. Diphenyl ether (DPE) herbicides are the first widely used family of Protox inhibitor herbicides. Nitrofen was the leading compound of this kind [4].

The bicyclic nature of diphenyl ethers is similar to the structure of half of protoporphyrinogen IX, which allows competitive inhibition of Protox located in the plastid by occupying the binding site for protoporphyrinogen IX [5–7]. Besides, many other chemical structures belong to this family are reported, such as phenyl heterocycle (Heterocycle including triazolinone, oxazolidone, pyrazole, phthalamide, etc.) and benzoheterocycle. Many of them are commercial and of high bioactivity [8–11]. Some samples of commercial Protox inhibitors are shown in Figure 1.

As the development of Protox inhibitor, many benzoheterocyclic compounds have shown good herbicidal activity, which are effective at controlling grass and broadleaf weeds at low dose [12–14]. In recent years, benzoxazole derivatives were found to be high bioactivities [15–19]. Earlier work at our laboratory involved some pyrazole [20] and isoxazole [21] derivatives with high herbicidal activity. In this article, we described the syntheses and herbicidal activity of pyrazolyl benzoxazole derivatives. Preliminary bioassay showed that most of them had good herbicidal activity.

## RESULTS AND DISCUSSION

The syntheses of the compounds are described in the Schemes 1 and 2, and the yields were not optimized. The intermediates **10a–10c** and **11a–11c** were synthesized from 4-fluorophenol, via a serial of reactions included chlorination, acylation, condensation, ring closure, methylation, nitration, and so on (Scheme 1). The title compounds can be obtained through the different ring-close and alkyl reactions from compounds **10a–10c** or **11a–11c** (Scheme 2).

The synthesis of **11** is the key step, which involves reducing nitro group to amino group in the phenyl ring. At the beginning, we used sodium sulfide to reduce nitro group, the yield was only 10%. We also used the method of catalytic hydrogenation with Pt/C, but the selectivity was not good. Finally, we found reduction of **10** with iron and saturated ammonium chloride has the higher yield (86%) and selectivity. For the product **11** is sensitive to air, reaction should be carried out under

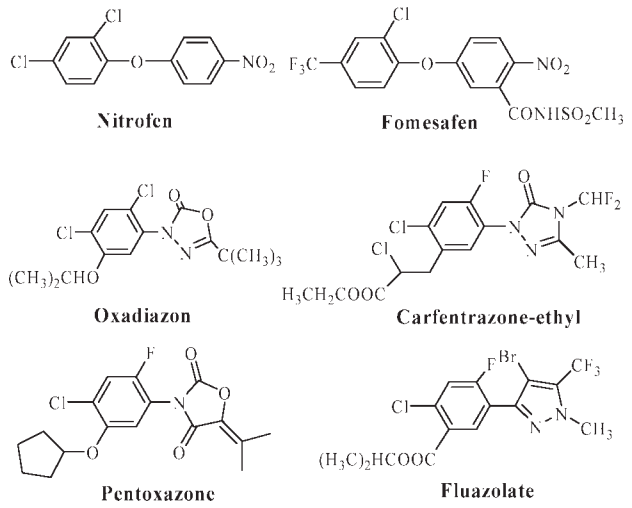


**Figure 1.** Samples of commercial protox inhibitors.

nitrogen, and the crude product is used directly in the next reaction without further purification.

**13** can be synthesized by stirring the mixture of compounds **11** and acetyl chloride or acetic anhydride at room temperature, but the selectivity was not satisfied. So we changed to another pathway. At first, **10** was acetylation to form **12**, then **12** was reduced with iron and subjected to ring-closed in acetic acid. By that way **13** was made in good yield.

**15** and **16** are isomers. The different reacting conditions lead to different products. When using base such as anhydrous potassium carbonate as the catalyst, and acetone as solvent, alkyl was attached to atom N. But when silver (I) oxide and methylene chloride were employed, alkyl was attached to atom O. The distinguishing of **15** and **16** can be determined by the shift of $^1$H NMR. For example, **15a:** δ: 3.18 (s, 3H, NC$H_3$); **16a:** δ: 4.31 (s, 3H, OC$H_3$).

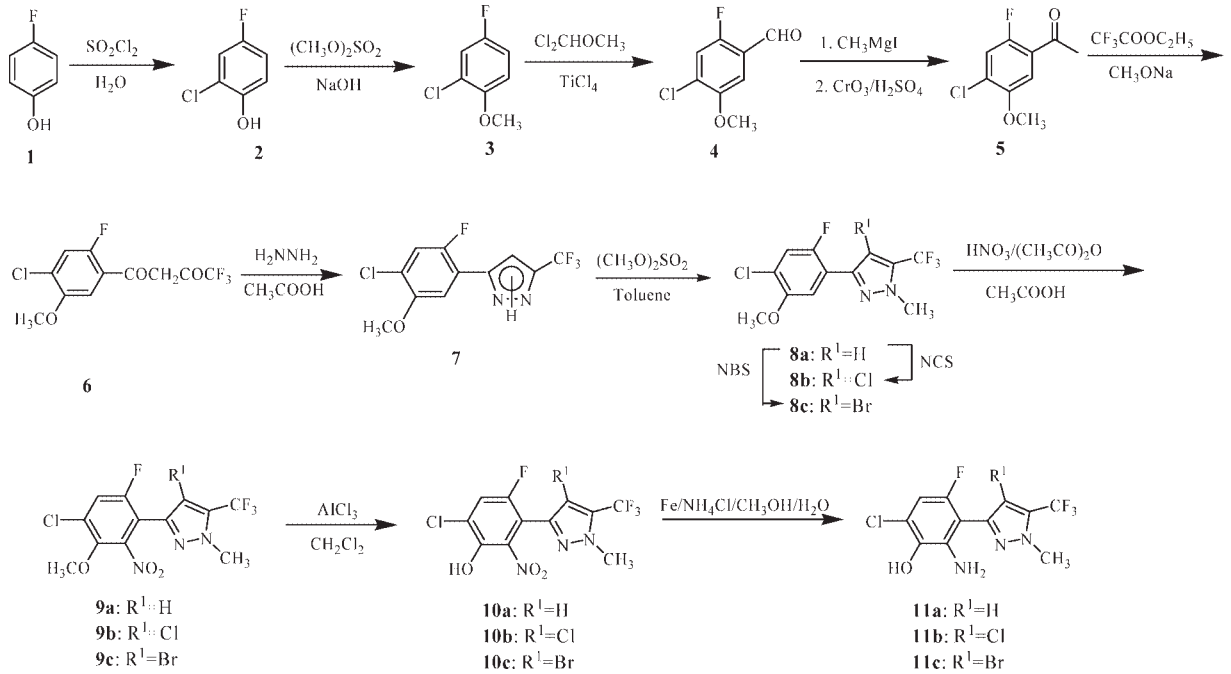
The herbicidal activity of the compounds were tested against *Setaria viridis, Ditaria sanguinalis* (monocot crops) and *Abutilon theophrasti* (dicot crops) using Fomesafen and Fluazolate for comparison. The results shown in Table 1 were the effect visual measurement treat after 10 days.

From Table 1 we can conclude that most of them had good herbicidal activity. When no substituent on pyrazole position 4, there is no herbicidal activity or low activity (**13a, 14a, 15a, 16a, 17a**), but when halogen (such as chlorine or bromine) is on pyrazole, most of them show good herbicidal efficacy. Similar results have been reported by Meazza *et al*. [22]. Their study on pyrroles showed that the halopyrrole nucleus is important for biological activity; if there is only hydrogen on pyrrole the compounds are virtually inactive.

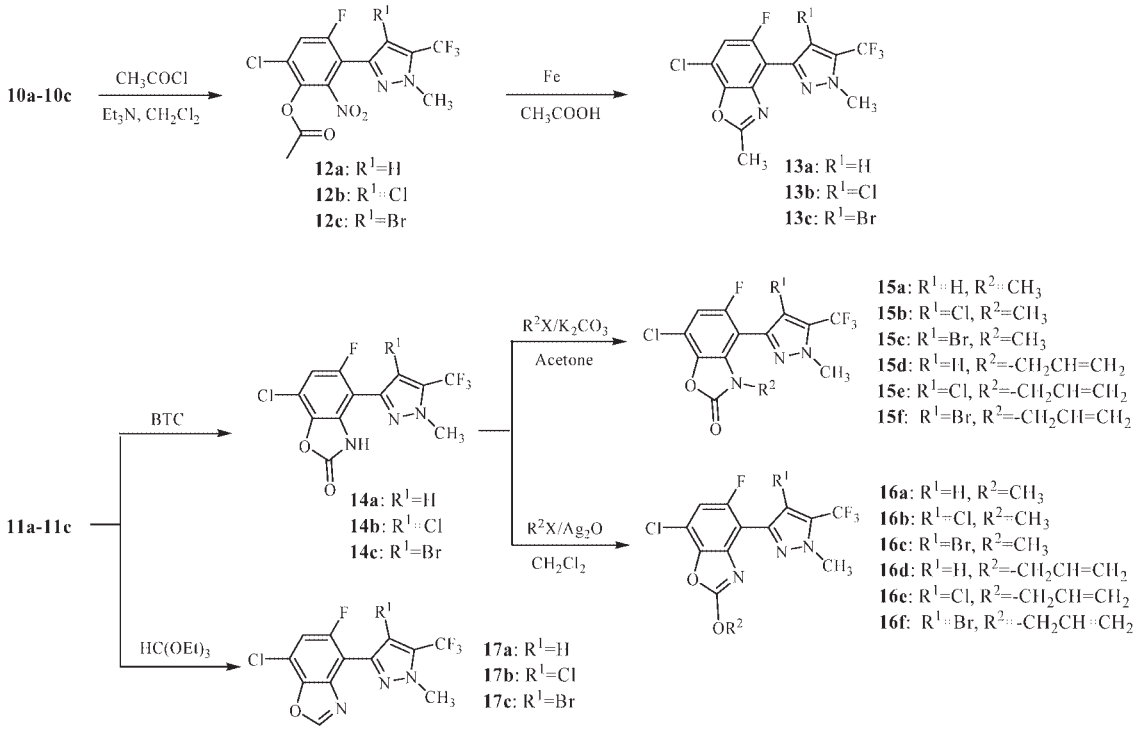
The herbicidal activity of compound **14** is not high, mainly because of its poor lipophilicity. When its lipophilicity is increased by introducing methyl or allyl to N or O atom, which form **15** or **16**, the activity is much increased.

Compared with corresponding compounds **15** (**b, c, e, f**) and **16** (**b, c, e, f**) , we can find that the herbicidal

**Scheme 1.** Syntheses of the intermediates.



**Scheme 2.** Syntheses of the aimed compounds.



activities of the compounds alkyl attached to atom O is higher than that of alkyl attached to atom N. And the activity of **16b** is all 100% even at the usage dose of 37.5 g/hm$^2$, so it is a valuable compound that fit for dicot crops and monocot crops. **15b** and **15e** are good for dicot crops, reached more than 80% at the usage

[a] 0 = no activity and 10 = total kill.
[b] The usage dose of compounds (g a.i./ hm$^2$).

dose of 37.5 g/hm$^2$, but for monocot crops, the activity not very high. The activity of **17c** is higher than **17b** for monocot crops, but for dicot crops, they are the same.

The activity of compounds **16b, 16c, 16f,** and **17c** is obviously higher than Fomesafen, **16b** and **16c** is even a little higher than Fluazolate.

## EXPERIMENTAL

Melting points were taken on a Micro melting point apparatus (X-6, Beijing Tech Instrument Co. Ltd.) and were uncorrected. $^1$H NMR spectra were measured in deuterochloroform on a Varian VA400 MHz spectrometer with TMS as an internal standard. Elemental analyses were performed on a Vario EL III (Elementar, German) elemental analysis instrumentation. MS were obtained with a HP1100 high Performance Liquid Chromatography/Mass Selective Detector.

**8** were synthesized from 4-Fluorophenol according to the existing methods [23,24].

**General procedure for 9a–9c.** ***3-(4-Chloro-6-fluoro-3-methoxy-2-nitrophenyl)-1-methyl-5-trifluoromethyl-1H-pyrazole (9a)*** A mixed acid (27 mL, V(acetic anhydride): V(fuming nitric acid)= 2:1) was added dropwise to a solution of **8a** ( 8 g, 0.026 mol) in acetic acid (25 mL) while maintaining the reaction solution at 0°C, and the resulting mixture was stirred at 0°C for 2 h. The reaction solution was poured into water, filtrated, and washed with water. The crude product was recrystallized with ethanol. **9a** was obtained in 83% yield as a faint yellow solid; m.p. 94.0–96.0°C; MS (API-ES, positive), *m*/*z*: 354 ([M+H]$^+$); **$^1$H NMR**, δ: 7.37 (d, 1H, $J$ = 9.6 Hz, Ph-*H*), 6.94 (d, 1H, $J$ = 3.2 Hz, Pyr-*H*), 4.02 (s, 3H, Pyr-C$H_3$), 3.98 (s, 3H, OC$H_3$). Anal. Calcd. for $C_{12}H_8ClF_4N_3O_3$ (353.7): C, 40.75; H, 2.28; N, 11.88. Found: C, 40.87; H, 2. 35; N, 11.67.

***4-Chloro-3-(4-chloro-6-fluoro-3-methoxy-2-nitrophenyl)-1-methyl-5-trifluoromethyl-1H-pyrazole (9b).*** The compound was orange pasty matter and was used directly in the next reaction without purification; MS (API-ES, positive), *m*/*z*: 388 ([M+H]$^+$); **$^1$H NMR**, δ: 7.42 (d, 1H, $J$ = 7.6 Hz, Ph-*H*), 4.02 (s, 3H, Pyr-C$H_3$), 4.01 (s, 3H, OC$H_3$). Anal. Calcd. for $C_{12}H_7Cl_2F_4N_3O_3$ (388.1): C, 37.14; H, 1.82; N, 10.83. Found: C, 36.87; H, 1.63; N, 10.67.

***4-Bromo-3-(4-chloro-6-fluoro-3-methoxy-2-nitrophenyl)-1-methyl-5-trifluoromethyl-1H-pyrazole (9c).*** The compound was orange pasty matter and was used directly in the next reaction without purification; MS (API-ES, positive), *m*/*z*: 432 ([M+H]$^+$); **$^1$H NMR**, δ: 7.42 (d, 1H, $J$ = 7.6 Hz, Ph-*H*), 4.03 (s, 3H, Pyr-C$H_3$), 4.01 (s, 3H, OC$H_3$). Anal. Calcd. for $C_{12}H_7BrClF_4N_3O_3$ (432.6): C, 33.32; H, 1.63; N, 9.71. Found: C, 32.99; H, 1.60; N, 9.62.

**General procedure for 10a-10c.** ***6-Chloro-4-fluoro-3-(1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-2-nitrophenol (10a).*** A mixture of **9a** (3.9 g, 11 mmol), anhydrous aluminium chloride (3.7 g, 27.7 mmol) and dichloromethane (70 mL) were stirred at room temperature for 2 h. The reaction solution was poured into icy hydrochloric acid and extracted with dichloromethane (20 mL × 3). The combined organic layer was washed with water, dried over anhydrous magnesium sulfate and concentrated under vacuum. **10a** was obtained in 100% yield as a yellow powder and was used directly in the next reaction without purification. A sample suiting for analysis was obtained by recrystallization with a mixture of petroleum ether and ethyl acetate (3:1); m.p. 94.0–97.0°C; MS (API-ES, negative), *m*/*z*: 338 ([M-H]$^-$); $^1$H NMR, δ: 7.53 (d, 1H, $J$ = 9.6 Hz, Ph-*H*), 6.95 (d, 1H, $J$ = 3.2 Hz, Pyr-*H*), 4.01 (s, 3H, Pyr-C$H_3$). Anal. Calcd. for $C_{11}H_6ClF_4N_3O_3$ (339.6): C, 38.90; H, 1.78; N, 12.37. Found: C, 38.84; H, 1.71; N, 12.42.

***6-Chloro-3-(4-chloro-1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-4-fluoro-2-nitrophenol (10b).*** The compound was a light yellow powder and was used directly in the next reaction without purification. The yield of two steps was 82%. A sample suiting for analysis was obtained by recrystallization with a mixture of petroleum ether and ethyl acetate (3:1); m.p. 85.2–87.1°C; MS (API-ES, negative), *m*/*z*: 372 ([M-H]$^-$); **$^1$H NMR**, δ: 7.58 (d, 1H, $J$ = 8.4 Hz, Ph-*H*), 4.03 (s, 3H, Pyr-C$H_3$). Anal. Calcd. for $C_{11}H_5Cl_2F_4N_3O_3$ (374.1): C, 35.32; H, 1.35; N, 11.23. Found: C, 35.64; H, 1.43; N, 11.42.

***3-(4-Bromo-1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-6-chloro-4-fluoro-2-nitrophenol (10c).*** The compound was a yellow powder and was used directly in the next reaction without purification. The yield of two steps was 83%. A sample suiting for analysis was obtained by recrystallization with a mixture of petroleum ether and ethyl acetate (3:1); m.p. 86.3–88.6°C; MS (API-ES, negative), *m*/*z*: 416 ([M-H]$^-$); **$^1$H NMR**, δ: 7.58 (d, 1H, $J$ = 8.4 Hz, Ph-*H*), 4.04 (s, 3H, Pyr-C$H_3$). Anal. Calcd. for $C_{11}H_5BrClF_4N_3O_3$ (418.5): C, 31.57; H, 1.20; N, 10.04. Found: C, 31.69; H, 1.23; N, 10.25.

**General procedure for 11a–11c.** ***2-Amino-6-chloro-4-fluoro-3-(1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)phenol (11a).*** Under nitrogen a mixture of **10a** (3.7 g, 10.9 mmol), iron (3.8 g, 0.068 mol), a solution of saturated ammonium chloride (120 mL) and methanol (80 mL) were stirred at 55°C for 6 h. Then methanol was removed under vacuum. The reaction solution was filtrated and the filtrate was extracted with ethyl acetate (40 mL × 3). The combined organic layer was washed with water, dried over anhydrous magnesium sulfate and concentrated under vacuum. **11a** was obtained in 86% yield as a brown solid and was used directly in the next reaction without purification.

***2-Amino-6-chloro-3-(4-chloro-1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-4-fluorophenol (11b).*** The crude product was obtained as brown paste and was used directly in the next reaction without purification. The yield of crude product was 95%.

***2-Amino-3-(4-bromo-1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-6-chloro-4-fluorophenol (11c).*** The crude product was obtained as brown paste and was used directly in the next reaction without purification. The yield of crude product was 90%.

**General procedure for 12a–12c.** ***6-Chloro-4-fluoro-3-(1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-2-nitrophenyl acetate (12a).*** A mixture of **10a** (650 mg, 1.91 mmol), acetyl chloride (0.2 mL, 2.96 mmol), triethylamine (0.3 mL, 2.16 mmol) and methylene chloride (25 mL) was stirred at 40°C for 1 h. The reaction solution was poured into water. The organic layer was washed with a solution of 5% sodium bicarbonate and water, dried over anhydrous magnesium sulfate and concentrated under vacuum. The crude product was recrystallized with ethanol. **12a** was obtained in 85% yield as a white powder; m.p. 137.5–139.2°C; MS (API-ES, positive), *m*/*z*: 382 ([M+H]$^+$), 404 ([M+Na]$^+$); **$^1$H NMR** δ: 7.45 (d, $J$ = 9.6 Hz, 1H, Ph-*H*),

6.95 (d, $J$ = 3.2 Hz, 1H, Pyr-*H*), 4.00 (s, 3H, Pyr-C$H_3$), 2.36 (s, 3H, COC$H_3$). Anal. Calcd. for $C_{13}H_8ClF_4N_3O_4$ (381.7): C, 40.91; H, 2.11; N, 11.01. Found: C, 40.62; H, 2.20; N, 11.25.

***6-Chloro-3-(4-chloro-1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-4-fluoro-2-nitrophenyl acetate (12b).*** The compound was obtained in 75% yield as a light brown powder; m.p. 103.8–105.3°C; MS (API-ES, positive), *m*/*z*: 416 ([M+H]$^+$), 438 ([M+Na]$^+$); **$^1$H NMR** δ: 7.51 (d, $J$ = 8.4 Hz, 1H, Ph-*H*), 4.02 (s, 3H, Pyr-C$H_3$), 2.37 (s, 3H, COC$H_3$). Anal. Calcd. for $C_{13}H_7Cl_2F_4N_3O_4$ (416.1): C, 37.52; H, 1.70; N, 10.10. Found: C, 37.69; H, 1.73; N, 10.27.

***3-(4-Bromo-1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-6-chloro-4-fluoro-2-nitrophenyl acetate (12c).*** The compound was obtained in 72% yield as a brown powder; m.p. 107.9–109.0°C; MS (API-ES, positive), *m*/*z*: 460 ([M+H]$^+$); **$^1$H NMR** δ: 7.51 (d, $J$ = 8.0 Hz, 1H, Ph-*H*), 4.04 (s, 3H, Pyr-C$H_3$), 2.37 (s, 3H, COC$H_3$). Anal. Calcd. for $C_{13}H_7BrClF_4N_3O_4$ (460.6): C, 33.90; H, 1.53; N, 9.12. Found: C, 34.02; H, 1.68; N, 8.91.

**General procedure for 13a–13c.** ***7-chloro-5-fluoro-2-methyl-4-(1-methyl-5-trifluoromethyl-1H-pyrazol-3-yl)-benzoxazole (13a).*** Under nitrogen a mixture of **12a** (680 mg, 1.78 mmol), iron (1.0 g, 0.017 mol), and acetic acid (35 mL) were stirred at 80°C for 3 h. The reaction solution was filtrated and the filtrate was poured into water, filtrated, and washed with water, recrystallized with ethanol. **13a** was obtained in 74% yield as a white solid; m.p. 124.9–126.9°C; MS (API-ES, positive), *m*/*z*: 334 ([M+H]$^+$), 356 ([M+Na]$^+$); **$^1$H NMR** δ: 7.27 (s, 1H, Pyr-*H*), 7.21 (d, $J$ = 10.8 Hz, 1H, Ph-*H*), 4.14 (s, 3H, Pyr-C$H_3$), 2.73 (s, 3H, Oxa-C$H_3$). A series of 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s were synthesized via three-component reactions of aromatic aldehydes, 4-hydroxy-6-methyl-2*H*-pyran-2-one, and ammonium acetate in water under microwave irradiation. This method has the advantages of environmental friendliness, short reaction time, high yields, and easy operation. This efficient synthesis not only offers an economical and green synthetic strategy to this class of significant compounds but also enriches the investigations on microwave-assisted synthesis in water.

*J. Heterocyclic Chem.*, **47**, 22 (2010).

## INTRODUCTION

The pyridinone ring is one of the most well-known systems among the naturally occurring heterocycles. Many members of this class of heterocycles have antibacterial [1], antifungal [2], cardiotonic [3], antineoplastic [4], antiinflammatory and analgesic [5], and other significant bioactivities [6]. Therefore, pyridinone derivatives, especially bispyridinone derivatives, which contain two skeletons of pyridinone in one molecular structure, are of great importance in medicinal and organic chemistry.

However, survey of the literature only reveals two typical methods on synthesizing 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s. One method is the condensation of 4-hydroxy-6-methyl-2-pyridone with aromatic aldehydes catalyzed by triethylamine in ethanol under traditional heating condition [7]. Unfortunately, this method suffers from low yield (14–45%), long reaction time (8–10 h), and use of toxic organic catalyst and solvent.

Another method is the multicomponent reaction of triacetic acid lactone, aromatic aldehydes, and ammonium acetate in ethanol under traditional heating conditions [8]. However, this approach still has disadvantages of lower yield (11–45%), longer reaction time (26 h), and being less environmental-unfriendly because ethanol, a volatile and flammable organic solvent, is used. As a result, developing a green and efficient approach to the synthesis of 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s is of great significance.

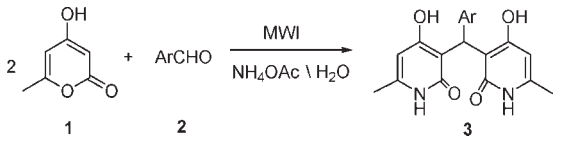
In recent years, microwave-assisted synthesis in water as solvent has become a hotspot of investigation, because it combines the two prominent green chemistry principles of ''safer solvents'' and ''energy efficiency'' [9]. In addition to the general advantages of water as solvent [10], several benefits for the reaction are expected when using water as reaction medium for microwave-superheated protocols [11].

As a continuation of our efforts on synthesizing heterocycles possessing significant bioactivities with green and efficient method [12], we herein report the synthesis of 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s through three-component reactions of 4-hydroxy-6-methyl-2*H*-pyran-2-one **1**, aromatic aldehydes **2**, and ammonium acetate in water under microwave irradiation (MWI) (Scheme 1). This efficient synthesis not only offers a green synthetic strategy to this class of significant compounds but also enriches the investigations on microwave-assisted synthesis in water.

## RESULTS AND DISCUSSION

Initially, to demonstrate the superiority of water as solvent, despite its natural property of being harmless to environment, we compared the synthesis of **3c** in water with other organic solvents including glycol, DMF,

**Scheme 1**



glacial acetic acid, and ethanol. The mixture of 4-hydroxy-6-methyl-2*H*-pyran-2-one **1** (2 mmol), 4-bromophenyl aldehyde **2c** (1 mmol), ammonium acetate (2 mmol), and corresponding solvent (2 mL) was irradiated under MWI at 100°C and 150 W for a given time, then the crude product was purified by recrystallization from EtOH.

The results (Table 1) reveal that compared with the solvents of glycol, DMF, and EtOH, water can not only improve the yield but also shorten the time of this reaction. Although the yield of the reaction in acetic acid is a little higher than that in water, considering environmental friendliness and avoidance of using toxic organic reagents, water was preferred as solvent for all further microwave-assisted reactions.

Moreover, the same reaction of **1** (2 mmol), **2c** (1 mmol), and ammonium acetate (2 mmol) in water (2 mL) under MWI (150 W) was used to optimize the reaction temperature, and the results are shown in Table 2. It is obvious that 90°C is the most suitable reaction temperature.

Under these optimized reaction conditions, a series of 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s **3** were synthesized, and the results are given in Table 3. As shown in Table 3, this protocol can be applied not only to aromatic aldehydes with electron-withdrawing groups but also to those with electron-donating groups under the same conditions. Therefore, the electronic nature of the substrate has no significant effect on this reaction.

Although the detailed mechanism of the above reaction remains to be fully clarified, the formation of 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s **3** could be explained by a reaction sequence presented in Scheme 2.

First, the condensation of aldehyde **2** and 4-hydroxy-6-methyl-2*H*-pyran-2-one **1** gave intermediate **4**, which was then attacked by **1** to generate another intermediate **5**. Finally, the ammonolysis, intermolecular cyclization and dehydration of **5** gave rise to target product **3**.

**Table 1**

Solvent optimization for the synthesis of **3c**.

| Entry | Solvent | Time (min) | Yield (%) |
|---|---|---|---|
| 1 | glycol | 12 | 76 |
| 2 | water | 8 | 81 |
| 3 | AcOH | 6 | 83 |
| 4 | DMF | 16 | 73 |
| 5 | EtOH | 10 | 78 |

**Table 2**

Temperature optimization for the synthesis of **3c**.

| Entry | T (°C) | Time (min) | Yield (%) |
|---|---|---|---|
| 1 | 60 | 15 | 44 |
| 2 | 70 | 12 | 65 |
| 3 | 80 | 10 | 74 |
| 4 | 90 | 8 | 83 |
| 5 | 100 | 8 | 81 |
| 6 | 110 | 8 | 80 |

All the products were characterized by IR, $^1$H NMR, and elemental analyses.

In conclusion, we have developed a green and efficient approach to the synthesis of 3,3′-arylidenebis[4-hydroxy-6-methyl-2(1*H*)-3-pyridinone]s in water under MWI. This method has the notable advantages over the existing ones owing to its features of environmental friendliness, short reaction time, high yield, low cost, and easy operation. On the other hand, this reaction supplies a good example of efficient microwave-assisted synthesis in water as solvent.

## EXPERIMENTAL

MWI was carried out in a monomodal Emrys Creator from Personal Chemistry, Uppsala, Sweden. Melting points were determined in XT5 apparatus and are uncorrected. IR spectra were recorded on a FT-IR-Tensor 27 spectrometer. $^1$H NMR spectra were measured on a DPX 400 spectrometer operating at 400 MHz, using DMSO-$d_6$ as solvent and TMS as internal standard. Elemental analysis was determined by using a Perkin-Elmer 240c elemental analysis instrument.

**General procedure for the syntheses of compounds 3 with MWI.** Typically, in a 10-mL Emrys reaction vial, 4-hydroxy-6-methyl-2*H*-pyran-2-one **1** (2 mmol), aldehyde **2** (1 mmol), ammonium acetate (2 mmol), and water (2 mL) were

A green and simple synthesis of 4-ayrl-3,4-dihydro-1*H*-pyrimido[1,2-*a*]benzimidazole derivatives was accomplished in excellent yields via the reaction of aryl aldehyde, 1,3-dicarbonyl compounds and 1*H*-benzo[*d*]imidazol-2-amine in ionic liquid of [bmim$^+$][$BF_4^-$]. This protocol has the advantages of easier work-up, mild reaction conditions, high yields, and an environmentally benign procedure compared with the reported methods.

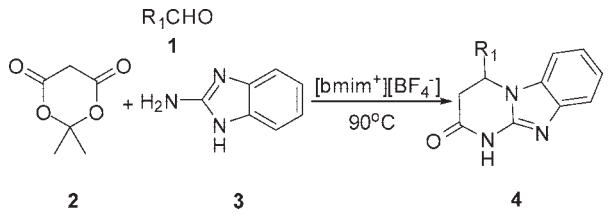
## INTRODUCTION

The small organic molecules, such as, the fused nitrogen-containing heterocycles receive a large amount of attention in the literature due to their exciting biological properties and their roles as pharmacophores of considerable historical importance. For example, the derivatives of pyrimido[1,2-*a*]benzimidazol-2-one can be used as inhibitor of cell proliferation [1], lymphocyte specific kinase [2], DNA-topoisomerase I [3], and protein kinase [4]. Hence, the preparation of this important heterocyclic core unit has gained much importance. However, only one method reported to synthesize these compounds was via the reaction of α, β-unsaturated esters, which could be prepared via the condensation reaction, with 1*H*-benzo [*d*]imidazol-2-amine in the presence of organic solvents or under solvent-free conditions at high temperature [5–9]. Furthermore, most of the synthetic protocols in literature so far have many drawbacks, including prolonged reaction time, drastic reaction conditions, the use of some toxic organic solvents, such as, nitrobenzene, and low yields. Therefore, the development of simple, convenient, and environmentally benign approaches for the synthesis of these compounds is still desirable.

A multicomponent reaction (MCR) can create highly complex molecules from readily available starting materials without the complicated purification operations; thus, MCRs are resource- and time-effective and economically favorable processes in diversity generation [10–13]. Recently, there have been tremendous development in three- and four-component reactions and great efforts continue to be made to develop new MCRs [14–19]. Besides, the ionic liquids have been widely used as environmentally benign reaction media in organic synthesis because of their unique properties of nonvolatility, nonflammability, and recyclability. Many organic reactions, including MCRs, were carried out efficiently in ionic liquids [20–28]. To continue our work on the synthesis of heterocyclic compounds via MCR in ionic liquids [29–31], we report herein the three-component synthesis of 4-aryl-3,4-dihydro-1*H*-pyrimido[1,2-*a*]benzimidazol-2-one in ionic liquid (Scheme 1).

**Scheme 1**



## RESULTS AND DISCUSSION

The effect of solvent on the reaction was initially examined by reacting phenyl aldehyde (1 mmol), 2,2-dimethyl-1,3-dioxane-4,6-dione (1 mmol), and 1*H*-benzo[*d*]imidazol-2-amine (1 mmol) at room temperature. The results in Table 1 show that only in ionic liquids the expected product **4a** was given with moderate yield (60–75%) by the three-component reaction. Furthermore, the reaction accomplished in [bmim$^+$][BF$_4^-$] exhibited higher yield (75%) than other counterparts. Therefore, we carried out the three-component reaction in [bmim$^+$][BF$_4^-$] to synthesize the desired products.

To find the optimal reaction temperature, the synthesis of (**4a**) was studied at different temperatures. The results are summarized in Table 2. As shown in Table 2, the reaction at 90°C proceeded in highest yield among the six reaction temperatures tested. Therefore, 90°C was chosen for this reaction.

Based on the optimized reaction conditions, a series of 4-aryl-3,4-dihydro-1*H*-pyrimido[1,2-*a*]benzimidazol-2-one were synthesized. The results, summarized in Table 3, show that the three-component reaction in [bmim$^+$][BF$_4^-$] gave the corresponding products in moderate to good yields. This methodology can be applied to aromatic aldehydes either with electron-withdrawing groups (such as, a nitro group, halogen) or electron-donating groups (such as, a methoxy) with excellent yields under the same conditions. Therefore, we conclude that the electronic nature of substituents of the aromatic aldehyde had no significant effect on the reaction. Even the heterocyclic aldehyde could be used in this reaction (**4h**). However, when the aliphatic aldehyde was applied to this reaction, no expected product was obtained.

All of the compounds were characterized by HRMS(ESI), FTIR, and $^1$H NMR. To further elucidate the structure of products, a single crystal of compound **4a** was prepared and its structure was determined by X-ray diffraction (Fig. 1).

The recovery and reuse of solvent and/or catalyst are highly preferable in terms of green synthetic process. Therefore, with the success of the above reactions, we continued our research by studying the reuse of the solvent. It turned out that the recovery and reuse of [bmim$^+$][BF$_4^-$] is not only convenient but also efficient. Thus, at completion monitored by TLC, the reaction mixture was cooled to room temperature and poured into water. The solid product was collected by filtration and recrystallized from ethanol to give the pure product. The filtrate was washed with acetic ester, concentrated under reduced pressure, and dried *in vacuo* at 100°C for several hours to give the reusable solvent. Studies by using phenyl aldehyde, 2,2-dimethyl-1,3-dioxane-4,6-dione and 1*H*-benzo[*d*]imidazol-2-amine as model substrates shows that the recovered solvent could be successively recycled in subsequent reactions without almost

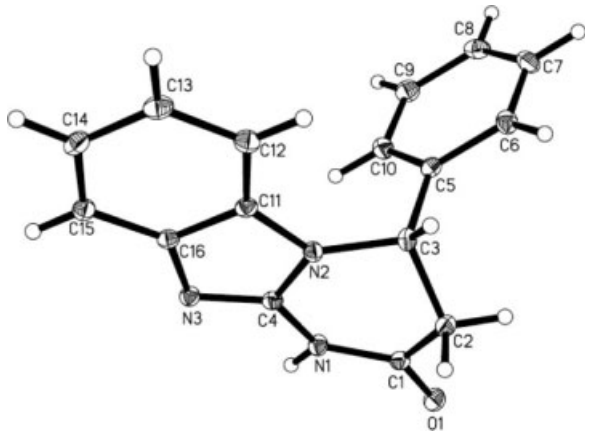

**Figure 1.** The crystal structure of **4a**.

any decrease in its efficiency. The results of the reuse of the ionic liquid are summarized in Table 4. Even in the fourth round, the yield of the product **4a** is fairly high.

A plausible mechanism of the reaction was presented in Scheme 2. Product **4** may be synthesized via sequential Knoevenagel condensation, Michael addition, cyclization, and elimination mechanism (Scheme 2). The condensation between aldehyde and Meldrum's acid gave 5-arylidene substituted Meldrum's acid **5**. Michael addition between **5** and 1*H*-benzo[*d*]imidazol-2-amine **3** then furnished the intermediate **6**, which isomerized to **7**. After that, intramolecular cyclization of **7** gave **8**, which finally afforded **4** by loosing acetone and carbon dioxide.

To test the proposed reaction pathway, compound **5a** was synthesized in [bmim$^+$][BF$_4^-$] and it could react with **3** smoothly and gave product **4a** with yield similar to the three-component reaction in ionic liquid. The fact supported the supposed reaction mechanism.

To extend the scope of this protocol for the synthesis of the derivatives of pyrimido[1,2-*a*]benzimidazole, other cyclic 1,3-dicarbonyl compounds (Scheme 3) and acyclic 1,3-dicarbonyl compounds (Scheme 4) were applied in the three-component synthesis as the surrogates of 2,2-dimethyl-1,3-dioxane-4,6-dione. The results, listed in Tables 5 and 6, show that these three-component reactions in ionic liquid gave the desired products, **10** and **12**, successfully.

In summary, we have developed an efficient, economical, safe, and environmentally benign procedure for

**Table 4**

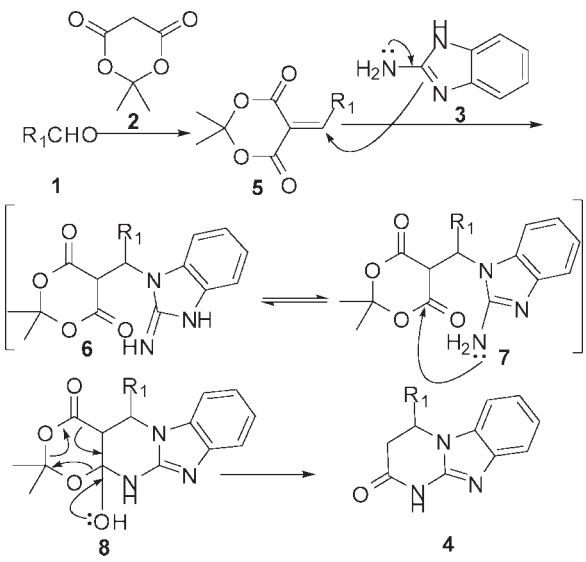
**Scheme 2**



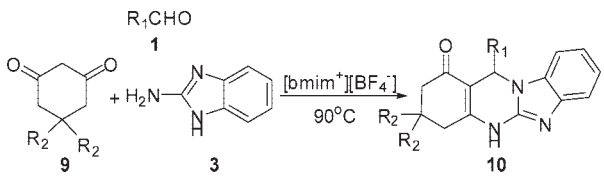
synthesizing 4-aryl-1*H*-pyrimido[1,2-*a*]benzimidazole derivatives in ionic liquid medium [bmim$^+$][BF$_4^-$]. Meanwhile, the ionic liquid was chosen as a kind of green solvent, which could be reused for several rounds without significant loss of activity.

## EXPERIMENTAL

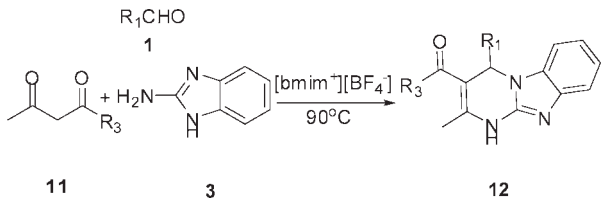
Common reagents and materials were purchased from commercial sources and purified by recrystallization or distillation. NMR spectra were recorded on a Bruker DPX 400; data for $^1$H are reported as follows: chemical shift (ppm), integration, multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; and br, broad), coupling constant (Hz), and number. Infrared (IR) spectra were recorded on a TENSOR 27 spectrophotometer in KBr pellet and are reported in terms of frequency of absorption (cm$^{-1}$). HRMS (ESI) were determined by using micrOTOF-QIIHRMS/MS instrument (BRUKER). Melting points were determined in open capillaries and are uncorrected. The single crystal diffraction data were gathered on a Rigaku Saturn diffractometer.

**General procedure for the synthesis of 4-Aryl-1*H*-pyrimido[1,2-*a*]benzimidazol derivatives.** Aryl aldehyde **1** (1.0 mmol), 2,2-dimethyl-1,3-dioxane-4,6-dione **2** (0.14 g, 1.0 mmol), and 1*H*-benzo[*d*]imidazol-2-amine **3** (0.13 g, 1.0 mmol) were mixed in 3 mL [bmim$^+$][BF$_4^-$]. Then, the mixture was stirred for a certain time (monitored by TLC) at 90°C. The result mixture was cooled to room temperature and poured into 20 mL of water. The solid product was collected by

**Scheme 3**



**Scheme 4**



filtration and recrystallized from ethanol to give the pure compound **4**. The filtrate was washed with acetic ester for several times, concentrated under reduced pressure, and dried *in vacuo* at 100°C for several hours to give the reusable solvent. A similar procedure was used in preparing the following compounds **10** and **12**.

***4-Phenyl-3,4-dihydro-1H-benzo[4,5]imidazo[1,2-a]pyrimidin-2-one (4a).*** IR (potassium bromide): 3059, 3034, 2912, 1730, 1649, 1590, 1458, 1363, 1323, 1287, 1245, 1168, 926, 890, 766, 743, 700 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δδ11.66 (s, 1H, NH), 7.83 (d, $J$ = 8.0 Hz, 1H, ArH), 7.46–7.40 (m, 2H, ArH), 7.35–7.32 (m, 3H, ArH), 7.08–7.03 (m, 3H, ArH), 5.94 (q, $J$ = 4.0 Hz, 1H, CH), 3.52 (dd, $J_1$ = 8.0 Hz, $J_2$ = 16.0 Hz, 1H, $CH_2$), 2.94 (dd, $J_1$ = 3.2 Hz, $J_2$ = 16.4 Hz, 1H, $CH_2$). Published online 21 December 2009 in Wiley InterScience (www.interscience.wiley.com).

New series of 4-(substituted biphenyl-4-yl)-6-methyl-2-oxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester and 4-(substituted biphenyl-4-yl)-6-methyl-2-thioxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester has been synthesized and the structures of the new compounds were established on the basis of $^1$H NMR, Mass (ES/MS), elemental analysis, and melting point. *In-vitro* antibacterial activity (MIC activity) was evaluated and compared with standard drugs ciprofloxacin, sparfloxacin, and trovafloxacin. Most of the compounds in this new series have shown moderate antibacterial activity against both Gram-positive and Gram-negative organisms.

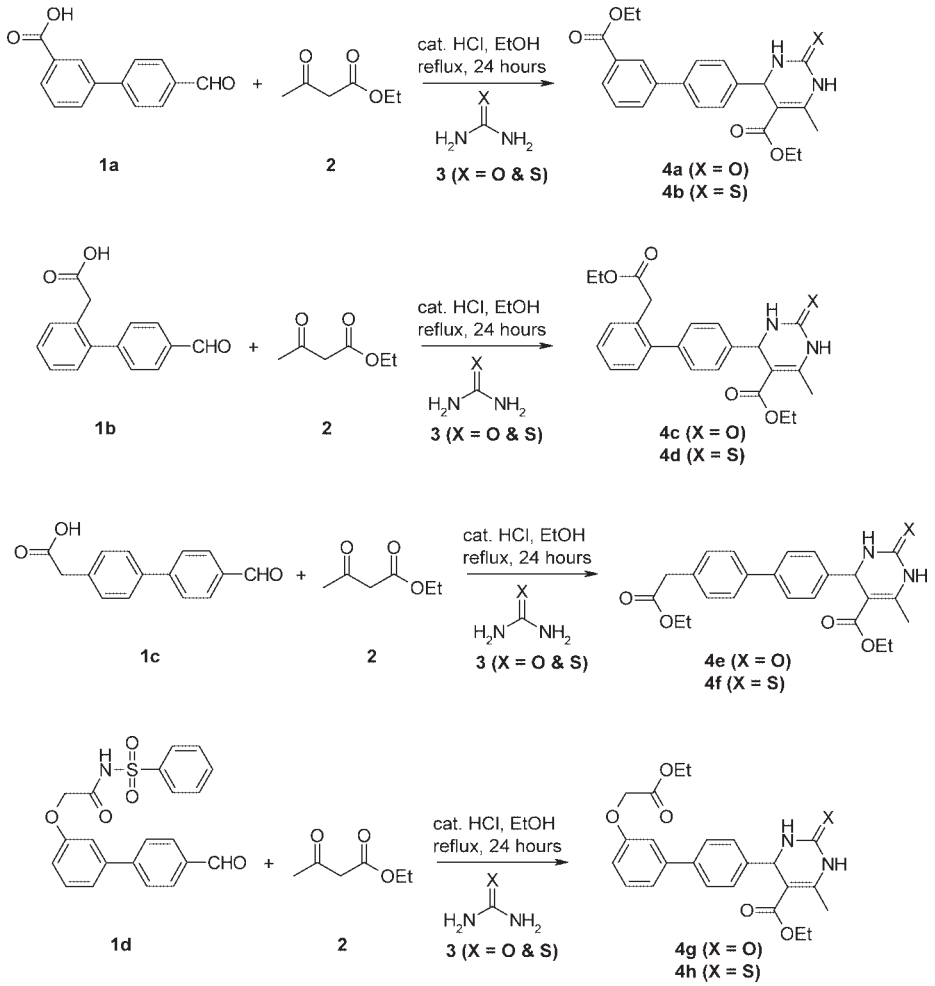
## INTRODUCTION

Numerous antibiotics have been prescribed and found to be effective on various infectious disorders. However, the appearance of multidrug-resistant Gram-positive bacteria, in particular, methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant Enterococci (VRE) is causing a serious menace. Moreover, the emergence of vancomycin-resistant MRSA can be anticipated in foreseeable future. For the treatment of these intractable infections, a new anti-infectious agent is needed. The synthetic antibiotics include the sulphonamide drugs, nitrofuran derivative, pyridine- carboxylic acid analogues, fluoroquinolones, and oxazolidinones. The semi-synthetic antibiotics include the penicillins, cephalosporins, tetracyclines, and macrolides. Among them, the sulphonamide drugs, nitrofuran derivatives, penicillins, and tetracyclines are scarcely used in clinical therapy. Quinolone antibiotics are widely prescribed drugs because of their safety, good tolerance, broad antibacterial spectrum, and less resistance [1–4]. Macrolide antibiotics, including Erythromycin and related compounds, continue to be an important therapeutic class against Gram-positive organisms, with second generation macrolides such as Clarithromycin and Azithromycin being widely prescribed due to their efficacy, safety, and lack of serious side effects [5]. Oxazolidinone antibacterial agents [6] are newer class of synthetic antibacterial agents with activity against Gram-positive bacteria. Linezolid [7] is well known as first promising candidate of oxazolidinone and works effectively against numerous serious Gram-positive human pathogens caused by MRSA and VRE. Quinolines and naphthyridines are also emerging as a new class of synthetic antibacterial agents.

- Dihydropyrimidones and their thione analogues have been reported to exhibit wide range of biological activities such as antiviral, antitumor agents, anti-carcinogenic, anti-inflammatory, analgesic, and most important anti-hypertensive activity. Dihydropyrimidinones (DHPMS) have now been recognized as vital drugs in the antihypertensive treatment as well as calcium channel blockers, $\alpha$-1$\alpha$-antagonists, and neuropeptide Y (NPY) antagonists [8]. Some of them are batzeladine alkaloids, which have been found to be potent HIV gp 120-CD4 inhibitors [9]. DHPMS and their sulfur analogues are pharmacologically important because of their antibacterial, antitumor, and anti-inflammatory properties [10]. The biological activity of some recently isolated alkaloids has also been attributed to the presence of dihydropyrimidinone moiety in the corresponding molecule [11]. Since dihydropyrimidones and thiones have been reported to exhibit wide range of biological activity and so far none of

**Scheme 1**

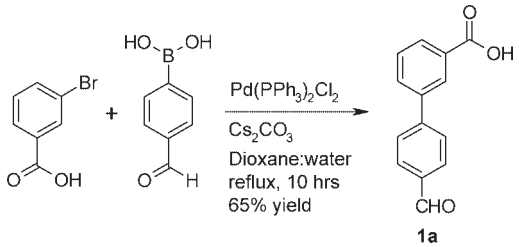


them have been evaluated for anti-bacterial activity, we decided to synthesise new series of dihydropyrimidones and thiones and evaluate them for anti-bacterial activity.

- In 1893, Biginelli [12] reported the first synthesis of DHPMS by a simple one-pot condensation reaction of ethyl acetoacetate, benzaldehyde, and urea. In the following decades, the original cyclocondensation reaction had been extended widely to include variation in all three components, allowing access to a large number of multifunctionalized DHPMS derivatives. However, it suffers from low yields of the product particularly in the case of substituted aromatic and aliphatic aldehydes. Recently, several methods have been reported for preparing dihydropyrimidines using different lewis acid such as $BF_3.OEt_2$, $LaCl_3$, $La(OTf)_3$, $Yb(OTf)_3$ $ZnCl_2$, $ZnBr_2$, $ZrCl_4$, $BiCl_3$, $Bi(OTf)_3$, LiBr, $LiClO_4$, $Mn(OAc)_3$, CAN, $FeCl_3.6H_2O$, $NiCl_2.6H_2O$, *etc*.[13] as well as protic acids such as $H_2SO_4$, HOAc, conc. HCl [14] as promoters.
- Oxazolidinones, a new class of antibacterial agent has many promising candidates with biaryl moiety [15]. The excellent *in vitro* antibacterial activity (MIC activity) has been attributed because of biaryl part and accordingly new series of biaryl dihydropyrimidones and thiones has been synthesized.

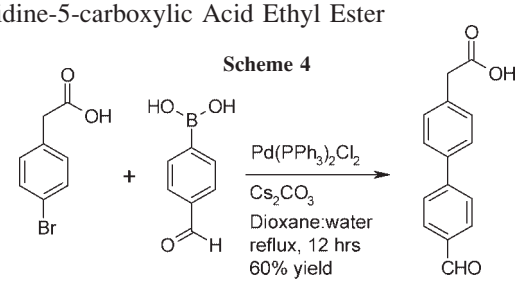
Herein, we describe the synthesis, characterization, and biological evaluation of new series of 4-(substituted biphenyl-4-yl)-6-methyl-2-oxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester and 4-(substituted biphenyl-4-yl)-6-methyl-2-thioxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester as potential antibacterials along with their *in vitro* biological activity (MIC activity). The synthesis of [4-(substituted biphenyl-4-yl)-6-methyl-2-oxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester and 4-(substituted biphenyl-4-yl)-6-methyl-2-thioxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester is outlined in Scheme 1.

**Scheme 2**



**1a**

**Scheme 4**



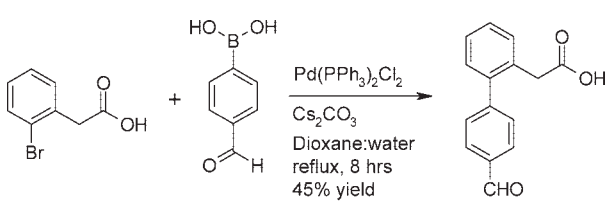
**1c**

The synthesis is achieved in two parts: first part involves the synthesis of differentially substituted biaryl aldehydes and the second part involves Biginelli condensation of these biaryl aldehydes with ethylacetoacetate and urea or thiourea to afford the desired compounds. The biaryl aldehydes **1a** (4′-formyl-biphenyl-3-carboxylic acid), **1b** (4′-formyl-biphenyl-2-yl-acetic acid), and **1c** (4′-formyl-biphenyl-4-yl-acetic acid) have been synthesized by Suzuki coupling of 4-formylphenylboronic acid with respective aryl bromide using bis(triphenylphosphine) palladium(II) chloride as a catalyst and cesium carbonate as a base in dioxane: water as solvent at reflux temperature (Schemes 2–4).

**N-[2-(4′-Formyl-biphenyl-2-yloxy)-acetyl]-benzenesulfonamide (1d).** The synthesis starts with alkylation of 3-bromo phenol (**i**) with chloroacetic acid in water using sodium hydroxide as base to afford (2-bromo-phenoxy)-acetic acid (**ii,** CAS#1798-99-8). Second step involves reaction of compound **ii** (acid chloride) with benzene sulphonamide in DCM using triethylamine as a base to afford *N*-[2-(2-bromo-phenoxy)-acetyl]-benzenesulfonamide (**iii**). Third step involves Suzuki coupling of compound **iii** with 4-formylphenylboronic acid using bis(triphenyl-phosphine)palladium(II) chloride as a catalyst and cesium carbonate as a base in dioxane: water at reflux temperature to afford the desired biaryl aldehyde **1d** (Scheme 5).

Second part of synthesis involves Biginelli condensation of these biaryl aldehydes (**1a, 1b, 1c,** and **1d**) with ethylacetoacetate (**2**) and urea/thiourea (**3**) in ethanol using catalytic HCl to afford the desired dihydropyrimidones and thiones (**4a–4h,** Scheme 1). Since the reaction is carried out with catalytic HCl in ethanol, all the final compounds are isolated as respective ethyl esters (**4a–4h,** Scheme 1). The benzenesulphonamido side chain was incorporated in biaryl aldehyde since sulphonamides have been reported to exhibit good antibacterial activity. However, during the reaction, the benzenesulphonamido portion of biaryl aldehyde was hydrolysed to acid and finally isolated as ethyl ester (**4g, 4h,** Scheme 1). The Biginelli condensation of biaryl aldehyde, ethylacetoacetate, and urea is clean and high yielding (60–70% yield) when compared with thiourea, where the yields are between 45 and 60%.

**Scheme 3**



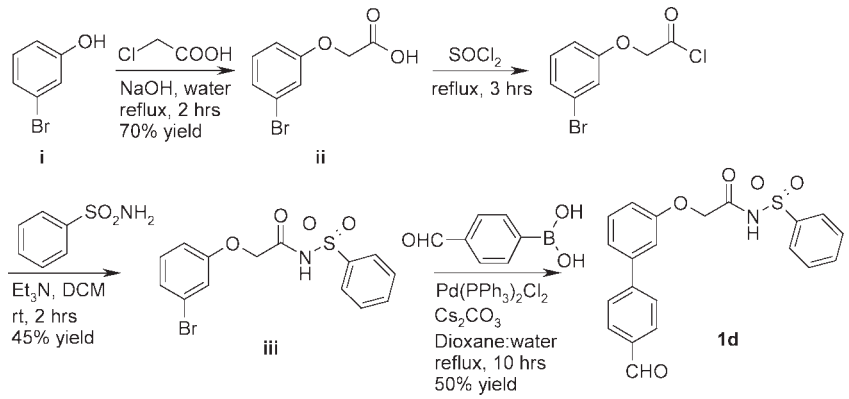
**1b**

The new 4-(substituted-biphenyl-4-yl)-6-methyl-2-oxo/thioxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl esters prepared above were tested *in vitro versus* a panel of Gram-positive and Gram-negative clinical isolates. Minimum inhibitory concentration (MIC) was determined by standard agar dilution method as per NCCLS guidelines and the values are shown in Table 1. The data of ciprofloxacin, sparfloxacin, and trovafloxacin were used as reference standards.

**Results of biological evaluation.** Most of the compounds in the series have shown moderate antibacterial activity against both Gram-positive and Gram-negative strains, except for *Pseudomonas aeruginosa* and *E. faecium*, where all the tested compounds were inactive (MIC $>$ 32 μg/ml) in comparison with ciprofloxacin, sparfloxacin, and trovafloxacin as reference standards. In all the cases, the thioxo analogues have shown one-fold better activity with respect to their oxo counterparts.

In summary, the synthesis of new 4-(substituted-biphenyl-4-yl)-6-methyl-2-oxo/thioxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl esters has been described. Most of the compounds in the series have shown moderate antibacterial activity against *S. aureus*, *S. epidermis*, *E. coli*, and *Klebsiella species* as compared to ciprofloxacin, sparfloxacin, and trovafloxacin. Since the preliminary series of novel dihydropyrimidones and thiones have shown moderate antibacterial activity, the possibility remains that more structural variation might change/ improve the activity profile. In connection with this notion, we point out for the first time dihydropyrimidones and their thione analogues as potential antibacterial agents and suggest that the further study is warranted.

**Scheme 5**



## EXPERIMENTAL

Melting points were determined on Quality Precise apparatus and are uncorrected. $^1$H NMR spectra were recorded on Bruker 400-MHz spectrometer. Chemical shifts are reported in δ units (ppm) relative to TMS as internal standard. Electron spray ionization mass spectra (ES-MS) were recorded on Water-Micromass Quattro-II spectrometer. All the solvents and reagents used were of AR grade and were used without further purification.

**4′-Formyl-biphenyl-3-carboxylic acid (1a).** To a stirred solution of 3-bromobenzoic acid (1 g, 4.98 mmol) in dioxane: water (20 mL, 4:1) was added cesium carbonate (4.85 g, 14.92 mmol) followed by addition of 4-formylphenylboronic acid (0.90 g, 5.96 mmol) and the resulting solution was stirred and degassed under nitrogen for 15 min. Bis(triphenylphosphine) palladium(II) chloride (0.17 g, 0.24 mmol) was added and the reaction mixture was stirred at reflux temperature for 10 h. After completion (monitored by TLC, 1:9 MeOH: CHCl3 as

mobile phase), solvent was removed under reduced pressure and diluted with water. The aqueous phase was acidified upto pH 4 by dilute HCl and then extracted with ethyl acetate (3 × 25 mL). The combined organic layers were dried ($Na_2SO_4$) and concentrated under reduced pressure. The crude compound was purified by column chromatography (60–120 mesh silica gel) eluting with methanol: chloroform (2:98) to afford the title compound **1a** as light yellow solid (0.70 g, 65% yield). $^1$H NMR (400 MHz, DMSO-$d_6$) δ 7.65 (t, 1H), 7.95–7.97 (d, $J$ = 8.08 Hz, 2H), 8.00–8.03 (m, 4H), 8.26 (s, 1H), 10.07 (s, 1H), 13.20 (s, 1H, COOH); Mass ($m/z$): 228 (M + H, 100%).

**(4′-Formyl-biphenyl-2-yl)-acetic acid (1b).** To a stirred solution of 2-bromophenylacetic acid (1 g, 4.65 mmol) in dioxane: water (20 mL, 4:1) was added cesium carbonate (4.53 g, 13.95 mmol) followed by addition of 4-formylphenylboronic acid (0.84 g, 5.58 mmol) and the resulting solution was stirred and degassed under nitrogen for 15 min. Bis(triphenyl-phosphine)palladium(II) chloride (0.16 g, 0.23 mmol) was added and the reaction mixture was stirred at reflux temperature for 8 h. After completion (monitored by TLC, 1:9 MeOH: CHCl3 as mobile phase), solvent was removed under reduced pressure and diluted with water. The aqueous phase was acidified upto pH 4 by dilute HCl and then extracted with ethyl acetate (3 × 25 mL). The combined organic layers were dried ($Na_2SO_4$) and concentrated under reduced pressure. The crude compound was purified by column chromatography (60–120 mesh silica gel) eluting with methanol: chloroform (2:98) to afford the title compound 1b as yellow solid (0.49 g, 45% yield). M.p. 171–173°C; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 3.54 (s, 2H), 7.35–7.40 (m, 2H), 7.53 (d, $J$ = 8.16 Hz, 2H), 7.89–7.92 (m, 2H), 7.96–8.02 (m, 2H), 10.07 (s, 1H), 12.31 (bs, 1H, COOH); Mass ($m/z$): 241 (M + H, 100%).

**(4′-Formyl-biphenyl-4-yl)-acetic acid (1c).** To a stirred solution of 4-bromophenylacetic acid (1 g, 4.65 mmol) in dioxane: water (20 mL, 4:1) was added cesium carbonate (4.53 g, 13.95 mmol) followed by addition of 4-formylphenylboronic acid (0.84 g, 5.58 mmol) and the resulting solution was stirred and degassed under nitrogen for 15 min. Bis(triphenyl-phosphine)palladium(II) chloride (0.16 g, 0.23 mmol) was added and the reaction mixture was stirred at reflux temperature for 12 h. After completion (monitored by TLC, 1:9 MeOH: CHCl3 as mobile phase), solvent was removed under reduced pressure and diluted with water. The aqueous phase was acidified upto pH 4 by dilute HCl and then extracted with ethyl acetate (3 × 25 mL). The combined organic layers were dried ($Na_2SO_4$) and concentrated under reduced pressure. The crude compound was purified by column chromatography (60–120 mesh silica gel) eluting with methanol: chloroform (2:98) to afford the title compound 1c as yellow solid (0.65 g, 60% yield). $^1$H NMR (400 MHz, DMSO-$d_6$) δ 3.64 (s, 2H), 7.40 (d, $J$ = 8 Hz, 2H), 7.72 (d, $J$ = 7.96 Hz, 2H), 7.91 (d, $J$ = 8.08 Hz, 2H), 7.99 (d, $J$ = 7.96 Hz, 2H), 10.05 (s, 1H), 12.41 (s, 1H, COOH); Mass ($m/z$): 241 (M + H, 100%).

**(3-Bromo-phenoxy)-acetic acid (ii).** To a stirred solution of 3-bromo phenol (i) (5 g, 28 mmol) in water (50 mL) was added NaOH (1.34 g, 33.6 mmol) followed by addition of chloroacetic acid (2.89 g, 30.8 mmol) and the resulting solution was refluxed for 2 h. After completion, the reaction mixture was acidified upto pH 4 by 6*N* HCl and the resulting mixture was extracted ethyl acetate (3 × 50 mL). The combined organic layers were dried ($Na_2SO_4$) and concentrated under reduced pressure to afford the title compound ii as yellow solid (4.67 g, 70% yield). $^1$H NMR (400 MHz, DMSO-$d_6$) δ 4.72 (s, 2H), 6.92–6.95 (m, 1H), 7.12–7.15 (m, 2H), 7.24 (t, $J$ = 7.84, 1.96 Hz, 1H), 13.09 (s, 1H, COOH); Mass ($m/z$): 232 (M + H, 100%).

***N*-[2-(3-Bromo-phenoxy)-acetyl]-benzenesulfonamide (iii).** A stirred solution of compound ii (2.5 g, 10.82 mmol) in $SOCl_2$ (15 mL) was refluxed under nitrogen atmosphere for 3 h. After completion, solvent was removed completely under reduced pressure to afford the acid chloride. To this acid chloride solution dissolved in DCM (25 mL) was added triethylamine (3 mL, 21.64 mmol) followed by addition of benzenesulphonamide (2.03 g, 12.98 mmol) under cooling. After addition, the reaction mixture was stirred at room temperature for additional 2 h. After completion, the reaction mixture was quenched with water (25 mL) and the organic phase was separated, dried ($Na_2SO_4$), and concentrated under reduced pressure. The crude compound was purified by column chromatography (60–120 mesh silica gel) eluting with 1:1 ethyl acetate: hexane to afford the title compound iii (1.80 g, 45% yield). M.p. 207–210°C; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 4.70 (s, 2H), 6.81–6.84 (dd, $J$ = 2.32, 1.84 Hz, 1H), 7.02 (t, $J$ = 2.2, 1.96 Hz, 1H), 7.12 (d, $J$ = 8.08 Hz, 1H), 7.19 (m, 1H), 7.63 (m, 2H), 7.72 (m, 1H), 7.92 (m, 2H), 12.49 (bs, 1H, COOH); Mass ($m/z$): 371 (M + H, 100%).

***N*-[2-(4′-Formyl-biphenyl-3-yloxy)-acetyl]-benzenesulfonamide (1d).** To a stirred solution of *N*-[2-(3-bromo-phenoxy)-acetyl]-benzenesulfonamide (**iii**) (1 g, 2.70 mmol) in dioxane: water (20 mL, 4:1) was added cesium carbonate (2.63 g, 8.10 mmol) followed by addition of 4-formylphenylboronic acid (0.49 g, 3.24 mmol) and the resulting solution was stirred and degassed under nitrogen for 15 min. Bis(triphenylphosphine)palladium(II) chloride (0.094 g, 0.13 mmol) was added and the reaction mixture was stirred at reflux temperature for 10 h. After completion (monitored by TLC, 1:9 MeOH: CHCl3 as mobile phase), solvent was removed under reduced pressure and diluted with water. The aqueous phase was acidified upto pH 4 by dilute HCl and then extracted with ethyl acetate (3 × 25 mL). The combined organic layers were dried ($Na_2SO_4$) and concentrated under reduced pressure. The crude compound was purified by column chromatography (60–120 mesh silica gel) eluting with methanol: chloroform (1:99) to afford the title compound **1d** as yellow solid (0.53 g, 50% yield). M.p. 143–145°C; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 4.77 (s, 2H), 6.88 (d, $J$ = 7.84 Hz, 1H), 7.13 (s, 1H), 7.32–7.39 (m, 2H), 7.55–7.59 (m, 2H), 7.61–7.65 (m, 1H), 7.81 (d, $J$ = 8.08 Hz, 2H), 7.92 (d, $J$ = 7.80 Hz, 2H), 7.99 (d, $J$ = 8.12 Hz, 1H), 10.06 (s, 1H), 12.52 (bs, 1H, COOH); Mass ($m/z$): 396 (M + H, 100%).

**General procedure for synthesis of compounds 4a to 4h.** To a stirred solution of ethyl acetoacetate (**2**) (2 mmol) in ethanol was added biaryl aldehyde (**1a-1d**) (2 mmol), urea/thiourea (**3**) (3 mmol) followed by addition of 0.5 mL of 6*N* HCl. The resulting solution was stirred at reflux for 16 h. After completion, solvent was removed under reduced pressure and the residue obtained was extracted with ethyl acetate. The combined organic layers were dried ($Na_2SO_4$) and concentrated under reduced pressure. The crude compound was purified by column chromatography (60–120 mesh silica gel) eluting with ethyl acetate: hexane (1:1) to afford the title compounds **4a–4h** as solid.

**4-(3′-Ethoxycarbonyl-biphenyl-4-yl)-6-methyl-2-oxo-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid ethyl ester (4a).** Light yellow solid; 65% yield; M.p. 128–130°C; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 1.12 (t, $J$ = 7.08, 7.08 Hz, 3H), 1.33 (t, $J$ = 7.12, 7.08 Hz, 3H), 2.26 (s, 3H), 3.98–4.03 (q, $J$ = 7.08, 7.16 Hz, 2H), 4.31–4.37 (q, $J$ = 7.04, 7.16 Hz, 2H), 5.20 (d, $J$ = 2.96 Hz, 1H), 7.35 (d, $J$ = 8.24 Hz, 2H), 7.59–7.63 (m, 2H), 7.66 (d, $J$ = 8.28 Hz, 2H), 7.91–7.95 (m, 2H), 8.15 (bs, 1H, NH), 9.25 (s, 1H, NH); Mass (*m/z*): 409 (M + H, 100%); Anal. **MIC determination.** ***Bacterial isolates.*** The strains were collected from major hospitals of India during the period 2003–2006 and were identified by standard laboratory procedures.

MIC was determined by standard agar dilution method as per CLSI (formerly, NCCLS) guidelines (Approved Standard M7-A6, vol. 23, 2003) on Mueller-Hinton agar containing serial two-fold dilutions of the compounds. Strains were grown in Tryptic Soya Broth (TSB, HiMedia, India) for 18–24 h. The overnight grown cultures were diluted appropriately so that the final density is approximately $10^7$ CFU/mL. A portion of this diluted broth was transferred to seed block of a multipoint inoculator (Applied Quality Services, United Kingdom). The inoculating pins were standardized to inoculate 1–2 μL of this broth, so that the final CFU was $1 \times 10^4$–$5 \times 10^4$ CFU/ spot. The inoculated plates were allowed to stand until the moisture in the inoculum spot has been absorbed in the media.

The inoculated plates were inverted and incubated for 18–24 h at 35°C in an ambient air incubator (Newtronic, India). After the completion of incubation period, the plates were read visually.

MIC was defined as the lowest concentration that inhibited the growth of strain completely. Drug free plates were used to ensure the growth of strains. *Staphylococcus aureus* ATCC 25923, *Escherichia coli* ATCC 25922 and *Pseudomonas aeruginosa* ATCC 27853 were used as quality control strains for each run of MIC determination.

Electrochemical oxidations of catechols have been studied in the presence of 6-amino pyrimidine derivatives as nucleophiles in aqueous solution using cyclic voltammetry. The efficient electro-organic synthesis of products has been successfully performed at carbon rod electrodes in an undivided cell under controlled potential conditions in good yield and purity.

## INTRODUCTION

Pyrimidine and its derivatives are attracting the attention of an increasing number of synthetic organic chemists because of their broad range of biological activity and medicinal importance [1,2]. Numerous reports delineate the antitumor [3], antiviral [4], antioxidant [5], antifungal [6], and hepatoprotective [7], activities of these compounds. Therefore, large efforts for the preparation of these molecules have been directed toward the synthetic manipulation of uracils [8]. The importance of pyrimidine derivatives prompted us to synthesis a number of these compounds from catechols and thiouracils. We have investigated the electrochemical oxidation of catechols (**1a**–**1c**) in the presence of 6-amino pyrimidine derivatives (**3a**, **3b**) as nucleophiles. This work has led to the development of a facile and environmentally friendly electrochemical method for synthesis of pyrimidine derivatives (**5a**–**5c**) and uracil derivatives (**8d**–**8f**).

## RESULTS AND DISCUSSION

Cyclic voltammetry of 2 m*M* solution of catechol (**1a**) in 0.2*M* sodium acetate solution containing 10% acetonitrile as supporting electrolyte shows an anodic ($A_1$) and a corresponding cathodic peak ($C_1$), which correspond to the transformation of (**1a**) to *o*-quinone (**2a**) and *vice versa* within a quasi-reversible two electrons reaction (Fig. 1, curve a). A peak current ratio ($I_P^{C1}/I_P^{A1}$) of nearly unity can be considered as a criterion for the stability of *o*-quinones (**2a**) produced at the surface of the electrode under the experimental conditions [9,10]. In other words, any hydroxylation [11,12], dimerization

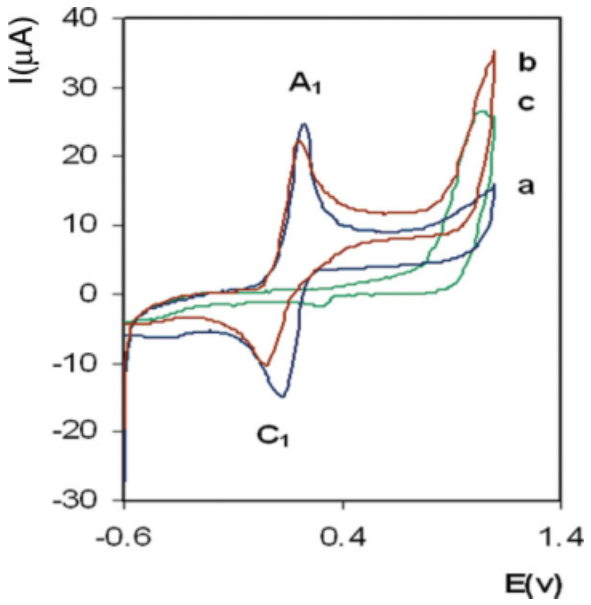

**Figure 1.** Cyclic voltammogram of 2 m*M* catechol (**1a**): (a) in absence of 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one (**3a**), (b) in the presence of 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one, (c) cyclic voltammogram of 2 m*M* 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one (**3a**) in the absence of catechol, at glassy carbon electrode, in 0.2*M* sodium acetate solution containing 10% acetonitrile. Scan rate: 100 $mVs^{-1}$, $T$ = ambient temperature. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

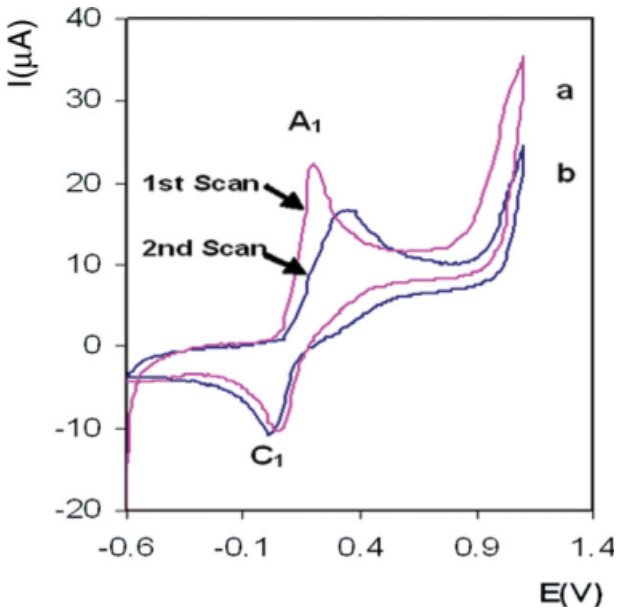

**Figure 2.** Cyclic voltammogram of 2 m*M* catechol: (a) in the presence of 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one (first cycle), (b) in the presence of 2 m*M* 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one (second cycle), at glassy carbon electrode, in 0.2*M* sodium acetate solution containing 10% acetonitrile. Scan rate: 100 mV $s^{-1}$, $T$ = ambient temperature. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

[13,14], or radical cations formation [15–18] are too slow to be observed on the time scale of cyclic voltammetry.

To get further support on the electrochemical oxidation of catechol (**1a**), it was studied in the presence of **3a** as a nucleophile. Curve b in Figure 1 shows the cyclic voltammogram obtained for a 2.0 m*M* solution of **1a** in the presence of 2.0 m*M* **3a**. The voltammogram exhibits decreasing in cathodic counterpart ($C_1$) of anodic peak ($A_1$). This is due to the reactivity of **1a** with **3a**. The cyclic voltammogram of 2.0 m*M* of **3a** is shown in Figure 1 curve c, for comparison.

The multicyclic voltammogram of **1a** in the presence of 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one (**3a**) are shown in Figure 2. In this figure, the second scan exhibits a relatively intense decrease in anodic peak current $A_1$ together with a potential shift in a positive direction. The decrease in $A_1$ peak current and positive shift of this peak are probably due to the formation of a thin film of product at the surface of the electrode inhibiting to a certain extent the performance of electrode process [19,20].

Furthermore, it was observed that the height of the $C_1$ peak increased proportional to augmentation of potential scan rate (Fig. 3, curve a–f). This confirms the reactivity of **2a** toward **3a**. A similar situation was observed when **3a**/**1a** concentration ratio is decreases. Moreover, the current function for $A_1$ peak ($I_P^{A1}/v^{1/2}$) decreases slightly with increasing scan rate (Fig. 3, curve g).

Controlled-potential coulometry was performed in an aqueous solution containing 0.5 mmol of **1a** and 0.5 mmol of **3a** at the potential of $A_1$ peak. At the end of coulometry, it was specified that charge consumption per molecules of **1a** becomes about $2e^-$.

The coulometry and voltammetry results allow us to propose an EC mechanism[16,17] for the electro-oxidation of **1a** in the presence of **3a** (Scheme 1). According to our results, the Michael addition reaction of **3a** to *o*-quinone (**2a**) [eq. (2)] seems to occur much faster than other side reactions, which leads to the product **5a**. The overoxidation of **5a** was circumvented during the preparative reaction because of the almost insolubility of the product in acetate buffer solution medium.

The electro-organic synthesis of **5b** and **5c** has been performed using oxidation of **1b** and **1c** in the presence of **3a** as described for **5a** (Table 1).

The electro-oxidation of catechol (**1a**) in the presence of 6-amino-2,3-dihydro-2-thioxopyrimidin-4(1*H*)-one (**3b**) as a nucleophile was studied by cyclic voltammetry and controlled-potential coulometry in 0.2*M* sodium acetate solution containing 10% acetonitrile too. Figure 4, curve b, shows the cyclic voltammogram obtained for a 2.0 m*M*

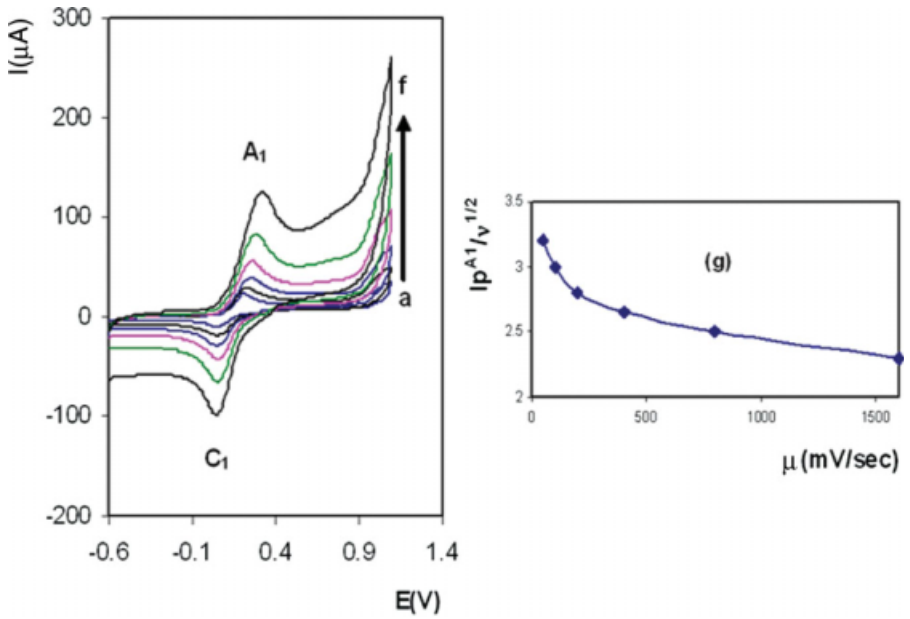

**Figure 3.** Typical cyclic voltammogram of 2 m*M* catechol (**1a**) in the presence of 2 m*M* 6-amino-1-methyl-2-(methyl)2-(methylthio)pyrimidin-4(1*H*)-one (**3a**) in 0.2*M* sodium acetate solution containing 10% acetonitrile at a glassy carbon electrode (1.8-mm diameter) at various scan rate. Scan rate from (a) to (f) are 50, 100, 200, 400, 800, and 1600 mV $s^{-1}$, respectively. (g) Variation of peak current ratio ($I_P^{A1}/v^{1/2}$) *versus* scan rate, $T$ = ambient temperature. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

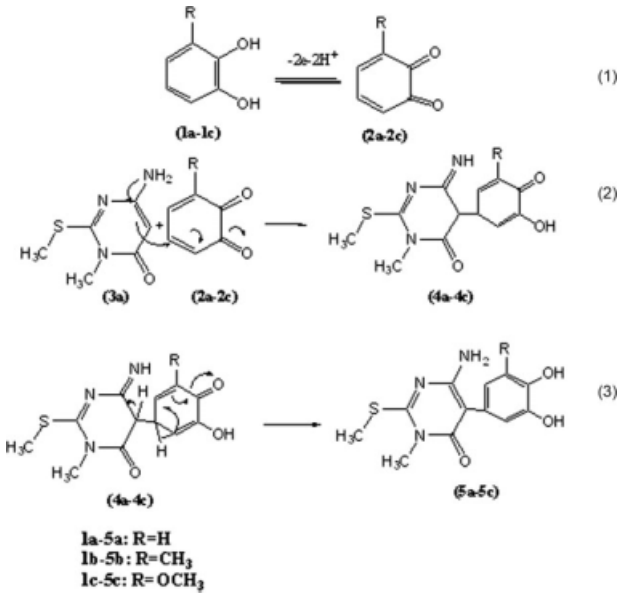
solution of **1a** in the presence of 2.0 m*M* **3b**. The voltammogram clearly exhibits an increase in anodic peak $A_1$ and a decrease in the cathodic peak $C_1$. This is due to the reactivity of **2a** with **3b**. For comparison, the cyclic voltammogram of 2.0 m*M* solutions of catechol (**1a**) and **3b** are shown in Figure 4, curves a and c, respectively.

The possible reason for the observed large increase in the $\mathbf{A_1}$ peak current could be the oxidation of

**Scheme 1**



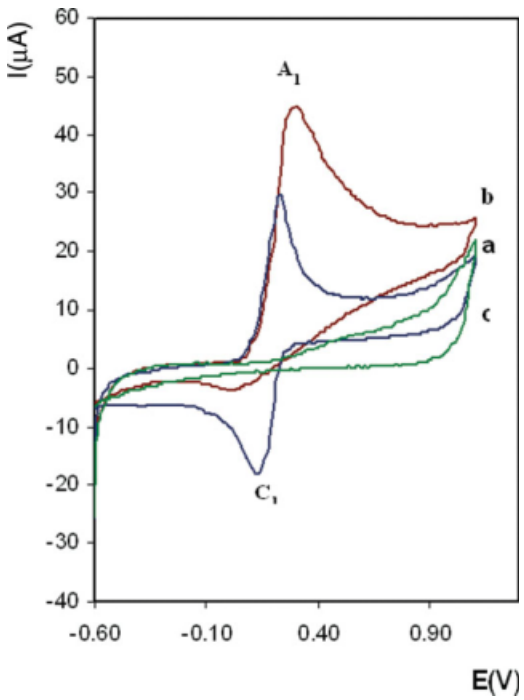


**Figure 4.** Cyclic voltammogram of 2 m*M* catechol (**1a**): (a) in the absence of 6-amino-2,3-dihydro-2-thioxopyrimidin-4(1*H*)-one (**3b**), (b) in the presence of **3b**, (c) cyclic voltammogram of 2 m*M* 6-amino-2,3-dihydro-2-thioxopyrimidin-4(1H)-one (**3b**) in the absence of catechol, at glassy carbon electrode, in 0.2*M* sodium acetate solution containing 10% acetonitrile. Scan rate: 100 mV $s^{-1}$, $T$ = ambient temperature. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

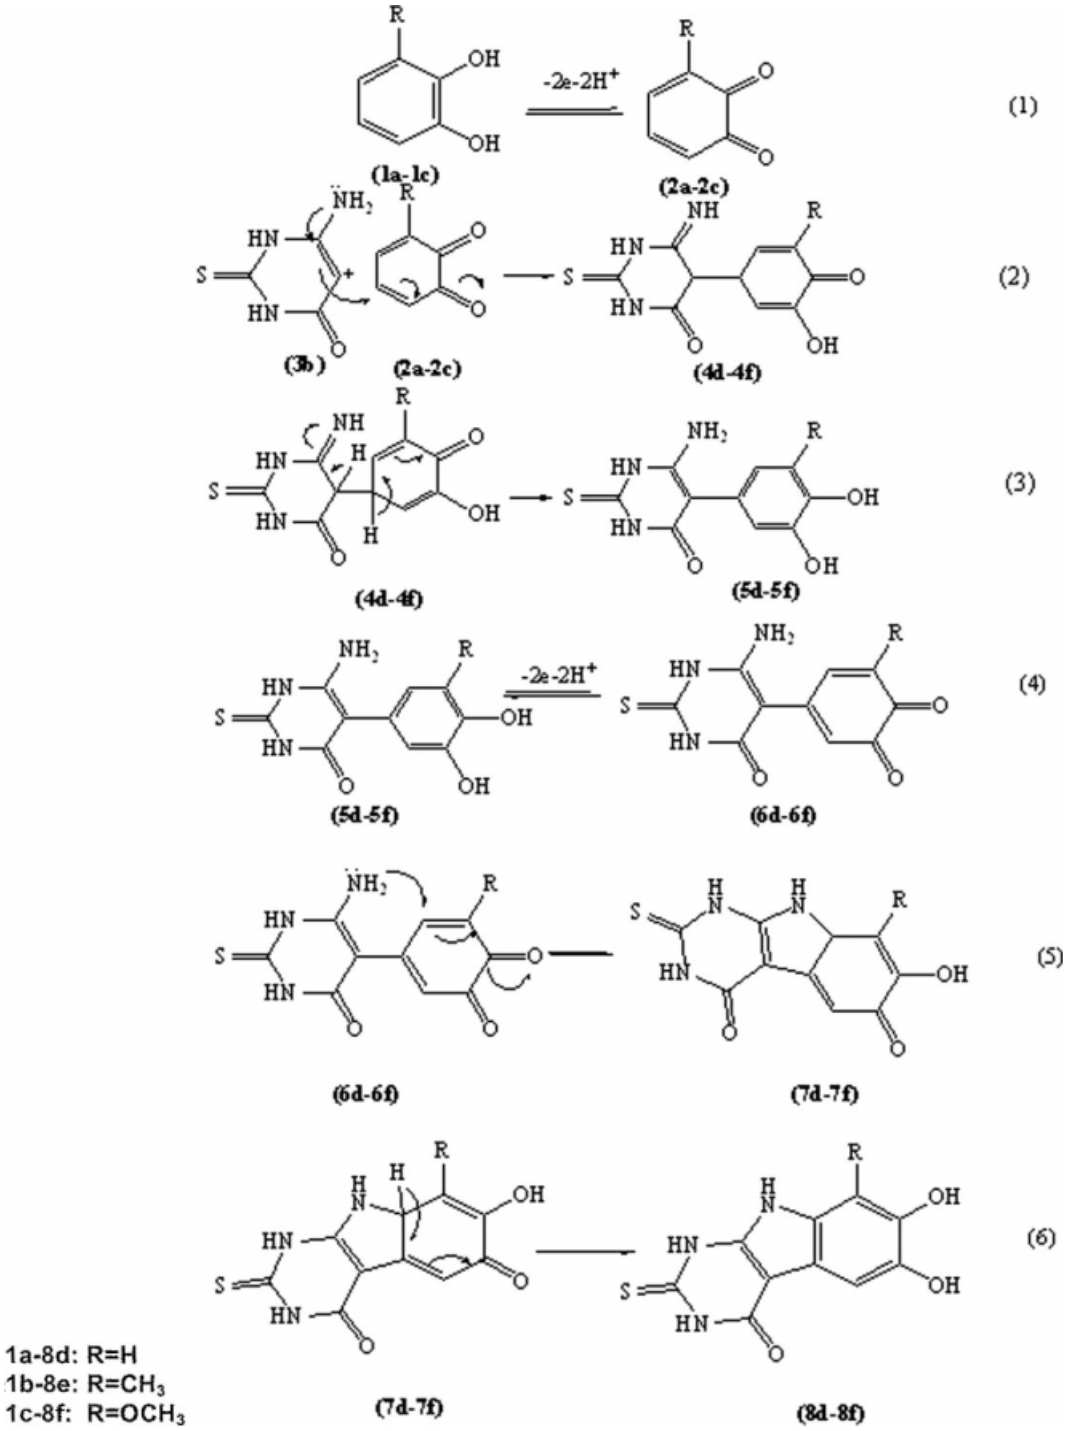
**Scheme 2**



intermediate **5c** at a potential close to that of the starting catechol. This oxidation is due to solubility of the **5c** in the reaction medium. The most important differences between this and previous cases are the large increase in the $A_1$ peak current (Fig. 4, curve b) and the number of transferred electrons during controlled-potential coulometry.

The results demonstrate that contrary to the previous cases, the consumed charge is about $4e^-$ per molecule of catechol (**1a**). This is related to two two-electron transfer processes [eqs. (1) and (4) in Scheme 2]. The coulometry, voltammetry, and NMR results allow us to propose an ECEC mechanism [21–24], indicated in

Scheme 2 for the electro-oxidation of catechol (**1a**) in the presence of **3b**.

## CONCLUSIONS

In conclusion, the results of this work show that catechols (**1a–1c**) are oxidized to their respective *o*-benzoquinone (**2a–2c**). The formed *o*-benzoquinones are attacked by nucleophiles **3a** and **3b** to form final products **5a–5c** and **8d–8f**. We observed an interesting diversity in the electro-oxidation mechanism and products of catechols (**1a–1c**) in the presence of (**3a**, **3b**). In the cases of **1a–1c** in the presence of **3a**, the final products **5a–5c** are pyrimidine derivatives that were obtained after consumption of $2e^-$ per molecule **1a**, **1b**, and **1c**. In the case of **1a–1c** in the presence of **3b**, the final products **8d–8f** are uracil derivatives that were obtained after consumption of $4e^-$ per molecule **1a–1c**, *via* intermolecular and intramolecular Michael addition reactions. The overall mechanism for anodic oxidation of catechols (**1a–1c**) in the presence of **3a** and **3b** are presented in Schemes 1 and 2. These mechanisms show a good diversity in anodic oxidation of **1a–1c** in the presence of **3a** and **3b**.

## EXPERIMENTAL

**Chemical and solutions.** Catechol derivatives were reagent-grade materials, sodium acetate, and other solvents were of proanalysis grade (all from E. Merck). These chemicals were used without further purification. The stock solution of catechols was prepared daily.

**Electrode and electrochemical instrument.** A cyclic voltammetry was performed using a micro-Autolab type III potentiostat/galvanostat and millimole scale electrolysis was performed using a pp-200 Zahrner potentiostat/galvanostat. The working electrode used in voltammetry experiments was a glassy carbon disc (2.7 $mm^2$ area) and a platinum wire was used as the counter electrode. The working electrode used in controlled-potential coulometry and millimole scale electrolysis was assembly of three carbon rods (27 $cm^2$ area) and large platinum gauze constituted the counter electrode. The working electrode potentials were measured *versus* 3*M* Ag/AgCl reference electrode (carbon rods from Azar electrode and other electrodes from Metrohm).

Bruker IFS-66 FTIR spectrometer, Shimadzu QP 1100-EX mass spectrometer operating at an ionization potential of 70 eV, and Bruker DRX-300 AVANCE NMR spectrometer were used for recording different spectra.

**Electrochemical synthesis of 5a–c and 8d–f.** In a typical procedure, 100 mL of 0.2*M* sodium acetate solution containing 10% acetonitrile was pre-electrolyzed at mentioned potential (Table 1) *versus* 3*M* Ag/AgCl in an undivided cell. Then 2 mmol of catechols (**1a–1c**) and 2 mmol of nucleophiles (**3a**, **3b**) were added to the cell. Initially, the current density was ~2 $mA/cm^2$ and the electrolysis was terminated when the decay of the current became more than 95%. The process was interrupted during the electrolysis and the graphite anode was washed in acetone to reactivate it. At the end of electrolysis, a few drops of acetic acid were added to the solution and the cell was placed in a refrigerator overnight. The precipitated solid was collected by filtration and purified by washing with hot water (Table 1).

**Table 1**

Electro-analytical and preparative data.

An environmentally benign three-component reaction in aqueous media has been reported for the synthesis of spiro[indole-3,8′-phenaleno[1,2-*b*]pyran]-9′-carbonitriles and spiro[indole-3,4′-pyrano[4,3-*b*]pyran]-3′-carbonitriles.

## INTRODUCTION

Modern synthetic design demands high efficiency in terms of minimization of synthetic steps together with maximization of complexity [1]. One of the best methods to fulfill these goals is the development and use of multicomponent reactions (MCRs), which consist of several simultaneous bond-forming reactions and allow the high efficient synthesis of complex molecules starting from simple substrates in a one-pot manner [2]. MCRs are economically and environmentally very advantageous because multistep syntheses produce considerable amounts of waste mainly due to complex isolation procedures often involving expensive, toxic, and hazardous solvents after each step.

Indole and indoline fragments are important moieties of a large number of a variety of natural products and medicinal agents [3], and some of indolines, spiro-annulated with heterocycles in the third position, have shown high biological activity [4–6]. The spirooxindole system is the core structure of many pharmacological agents and natural alkaloids [7–9]. Therefore, a number of methods have been reported for the preparation of spirooxindole fused heterocycles [10].

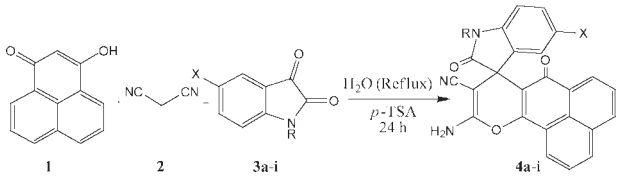
Chromene derivatives are an important group of compounds, widely exist in plants, including edible vegetables and fruits [11]. Synthetic analogues were developed over the years, some of them displaying remarkable effects as pharmaceuticals [12–14], including antifungal [15] and antimicrobial activity [16]. Similarly, substituted 2-amino-pyrans take a significant place among the six-membered oxygen-containing heterocycles. Some of them possess anticancer and antimicrobial activity [17]. Serotonin receptor modulators (pteropodine and its stereoisomers), natural alkaloids, containing both spiroindole and pyran cycles, were isolated from stem bark of *Uncaria tomentosa* [7]. Several spiroheterocycles, containing both indole and pyran heterocycles possess anticonvulsant and analgetic [18], herbicidal [19], and antibacterial activities [20].

As part of our program aimed at developing new selective and environmentally friendly methodologies for the preparation of heterocyclic compounds [21], we performed the preparation of some new spirooxindole containing chromene or pyran ring fragments via a three-component condensation reaction using water as the reaction medium. Organic transformations in water without using toxic organic solvents are one of the current focuses today, especially in our environmentally conscious society [22].

## RESULTS AND DISCUSSION

The one-pot, three-component condensation reaction of 3-hydroxy-1*H*-phenalen-1-one 1, malononitrile 2, and

**Scheme 1**



isatins 3a–i in the presence of *p*-toluenesulfonic acid (*p*-TSA) as an inexpensive and available catalyst proceeded rapidly in refluxing water and were complete after 24 h to afford 10′-amino-1,2-dihydro-2,7′-dioxospiro[3*H*-indole-3,8′(7*H*,8*H*)-phenaleno[1,2-*b*]pyran]-9′-carbonitrile derivatives 4a–i in good yields (Scheme 1). $^{1}$H and $^{13}$C NMR spectra of the crude products clearly indicated the formation of fused indoline phenalenopyran 4.

The optimized results are summarized in Table 1. The results were excellent in terms of yields and product purity using isatin derivatives in the presence of *p*-TSA, whereas without it the yields of products were low (<30%) even after 48 h. To the best of our knowledge, this new procedure provides the first example of an efficient and three-component method for the synthesis of spiro[indole-3,8′-phenaleno[1,2-*b*]pyran]-9′-carbonitriles **4**. However, when this reaction was carried out with ethyl cyanoacetate, the TLC and $^{1}$H NMR spectra of the reaction mixture showed a combination of starting materials and numerous products; the expected product was obtained in only trace amount.

A possible mechanism for the formation of **4** is proposed in Scheme 2. It is reasonable to assume that **4** results from initial formation of intermediate isatylidene malononitriles **5** by standard Knoevenagel condensation of the malonitrile **2** and isatin **3**. Then, the subsequent Michael-type addition of the 3-hydroxy-1*H*-phenalen-1-one (**1**) to the intermediate **5**, followed by cyclization and tautomerization affords the corresponding products **4** (Scheme 2).

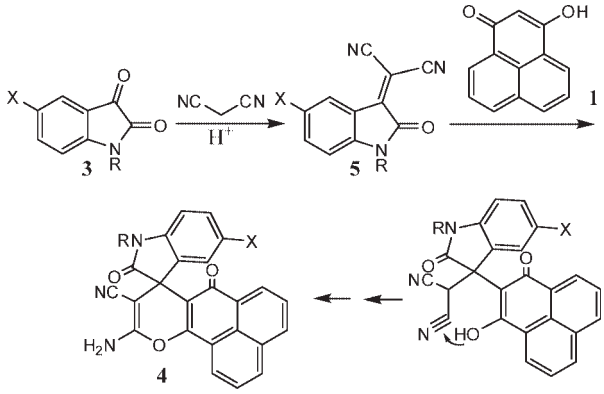
The nature of these compounds as 1:1:1 adducts was apparent from their mass spectra, which displayed, in each case, the molecular ion peak at appropriate *m*/*z* values. Compounds **4** are stable solids whose structures are fully supported by IR, $^{1}$H and $^{13}$C NMR spectroscopy, mass spectrometry, and elemental analysis.

**Table 1**

Synthesis of Spiro[indole-3,8′-phenalenopyran]-9′-carbonitriles **4**.

| Products **4** | R | X | Yield (%) |
|---|---|---|---|
| **a** | H | H | 93 |
| **b** | Me | H | 75 |
| **c** | Et | H | 83 |
| **d** | H | $NO_2$ | 90 |
| **e** | Me | $NO_2$ | 73 |
| **f** | Et | $NO_2$ | 88 |
| **g** | H | Br | 94 |
| **h** | Me | Br | 91 |
| **i** | Et | Br | 89 |

**Scheme 2**



As expected, when the 3-hydroxy-1*H*-phenalen-1-one **1** was replaced by 4-hydroxy-6-methyl-2*H*-pyran-2-one **6**, another series of spiro[indole-3,4′-pyrano[4,3-*b*]pyran]-3′-carbonitriles **7** were obtained under the same reaction conditions (Scheme 3).

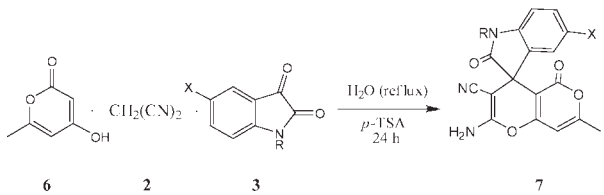
Finally, when we extended this reaction to 1*H*-inden-1,2,3-trion (**8**), product of 2′-amino-1,3-dihydro-7′-methyl-1,3,5′-trioxospiro[2*H*-indene-2,4′(4*H*,5*H*)-pyrano[4,3-*b*]pyran]-3′-carbonitrile **9** was generated in 65% yield after 24 h (Scheme 4).

In conclusion, we have developed an efficient, clean, one-pot and three-component synthesis of new spiro[indole-3,8′-phenaleno[1,2-*b*]pyran]-9′-carbonitriles, spiro[indole-3,4′-pyrano[4,3-*b*]pyran]-3′-carbonitriles and spiro[2*H*-indene-2,4′(4*H*,5*H*)-pyrano[4,3-*b*]pyran]-3′-carbonitrile in aqueous media. Prominent among the advantages of this new method are operational simplicity, good yields, and easy work-up procedures used.

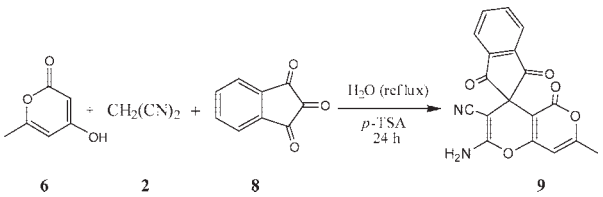
## EXPERIMENTAL

Melting points were measured on an Electrothermal 9100 apparatus and are uncorrected. Mass spectra were recorded on a FINNIGAN-MAT 8430 mass spectrometer operating at an ionization potential of 70 eV. $^{1}$H and $^{13}$C NMR spectra were recorded on a BRUKER DRX-300 AVANCE spectrometer at 300.13 MHz and 75.47 MHz, respectively. IR spectra were

**Scheme 3**



**Scheme 4**



6 2 8 9

recorded using an FTIR apparatus. Elemental analyses were performed using a Heracus CHN-O-Rapid analyzer.

**Typical procedure for the preparation of spirooxindoles 4a–i, 7a–c, and 9.** A mixture of malononitrile (1 mmol), isatins (1 mmol), 3-hydroxy-1*H*-phenalen-1-one or 4-hydroxy-6-methyl-2*H*-pyran-2-one (1 mmol), *p*-TSA (0.1 g) was refluxed in water (5 mL) for 24 h (TLC). After completion of reaction, the reaction mixture was filtered and the precipitate washed with ethanol to afford the pure product.

Using L-tyrosine as a chiral starting material, we developed an efficient synthetic route to (–)-MY 336a. A key step in the sequence is a highly regio- and diastereoselective intermolecular Pictet-Spengler cyclization reaction between amino alcohol and benzyloxyacetaldehyde.

*J. Heterocyclic Chem.*, **47**, 50 (2010).

## INTRODUCTION

MY 336a was isolated in 1986 from the culture broth of *Streptomyces gabonae* KY2234 (ATCC 15282) and was characterized as a β-adrenergic receptor antagonist with high affinities toward $\beta_1$- and $\beta_2$-adrenergic receptors [1] (Fig. 1). Although the relative stereochemistry of MY 336a was determined by an X-ray study of its tetra-acetyl derivative, there has been no report on the elucidation of its absolute stereochemistry so far [2]. Kaufman reported the total synthesis of the racemic MY 336a and its epimer, which used Jackson's isoquinoline synthesis as the key reaction [3]. To date, there has been no report on the total synthesis of its optically pure isomer except an attempt to an enantioselective synthesis of MY336a [4].

In the course of our study of the total synthesis of (–)-Renieramycin G and (–)-Lemonomycin, we take (–)-MY 336a as a key precursor for the construction of the AB ring system of (–)-Renieramycin G and (–)-Lemonomycin. Our group had previously reported the construction of the AB ring system of ecteinascidin-saframycin alkaloids by the Pictect-Spengler cyclization between the L-DOPA derivatives and benzyloxyacetaldehyde in which the 1,3-*cis*-diastereoisomer was the main product [5]. Herein, we report an efficient total synthesis of (–)-MY 336a on the basis of this methodology.

## RESULTS AND DISCUSSION

Various methods to synthesize the highly functionalized L-tyrosine derivatives have been reported [6], and we followed an existing procedure under modified conditions to prepare compound **7** (Scheme 1) [7]. Compound **4** was conveniently prepared from L-tyrosine in four steps [7a]: Reduction of compound **4** by catalytic hydrogenation to give compound **5**; Formylation of **5** with $MeOCHCl_2$ in $CH_2Cl_2$ at room temperature in the presence of $TiCl_4$ to afford aldehyde **6**; Baeyer-Villiger oxidation of **6** using MCPBA in chloroform at room temperature and the subsequent hydrolysis of the resulting formate to give phenol **7**. Next, compound **7** was reduced to the corresponding alcohol **8** by $LiBH_4$ in 91% yield. The *N*-acetyl group was removed with 6*N* aq HCl in $CH_3OH$ to give the amino alcohol **9** in 87% yield. The highly regio- and diastereoselective Pictet-Spengler cyclization reaction between amino alcohol **9** and benzyloxyacetaldehyde at 0°C provided the 1,3-*cis*-tetrahydroisoquinoline **10** in 64% yield and **11** in 20% yield, respectively [8]. Initially, we removed the *N*-acetyl group of compoud **7** to get a phenylalanine methyl ester. However, the Pictet-Spengler cyclization reaction between phenylalanine methyl ester and benzyloxyacetaldehyde to construct the tetrahydrosioquinoline fragment met with low yield and poor diastereoselectivity and was ultimately abandoned [5,8a]. Finally, the *O*-benzyl group of tetrahydroisoquinoline **10** was removed by catalytic hydrogenation to give the expected product (–)-MY 336a in 86% yield.

The stereochemistry of compound **1** was verified on the basis of its NOE spectroscopy. Obvious NOE enhancement was observed between 1-H and 3-H; thus a *cis*-1,3-diaxial relationship was confirmed. The ortho-relationship between 5-H and 6-Me was confirmed by the observed NOE enhancement between them.

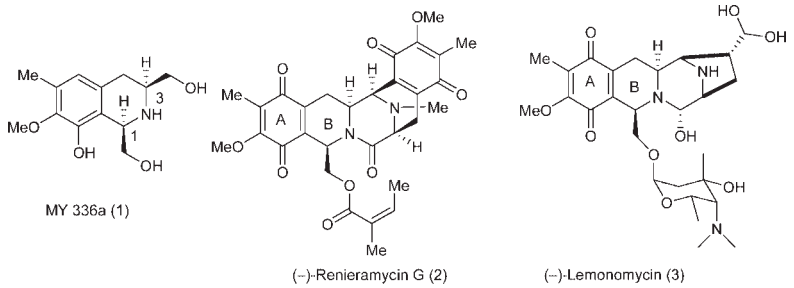

**Figure 1.** Structures of (–)-MY 336a and related tetrahydroisoquinoline alkaloids.

In summary, we have developed a new efficient route to synthesize (–)-MY 336a using L-tyrosine as a chiral starting material, which can be used to elucidate the absolute stereochemistry of natural MY 336a. Further study on the synthesis of Renieramycin G and Lemonomycin based on the methodology is ongoing in our laboratory.

## EXPERIMENTAL

**General.** $^1$H NMR spectra were recorded at 600 MHz or 300 MHz spectrometer at 24 °C in the indicated solvent and are reported in ppm relative to tetramethylsilane and referenced internally to the residually protonated solvent. $^{13}$C NMR spectra were recorded at 150 or 75 MHz spectrometer at 24°C in the solvent indicated and are reported in ppm relative to tetramethylsilane and referenced internally to the residually protonated solvent. HRMS were carried out by Agilent LC/MSD TOF. Optical rotations were measured on a PerkinElmer Polarimeter 341LC using 10 cm cells and the sodium D line (589 nm) at 20°C and concentration indicated. All reagents were obtained from commercial suppliers unless otherwise stated.

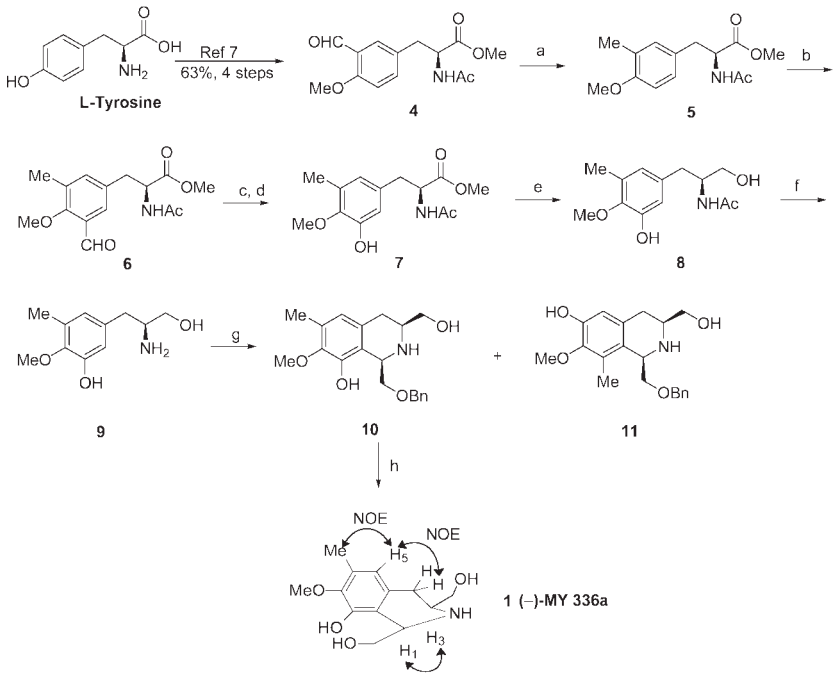
**(*S*)-Methyl-2-acetamido-3-(4-methoxy-3-methylphenyl)propanoate (5).** To a solution of compound **4** (48 g, 0. 17 mol) in MeOH (750 mL) at room temperature was added 1*N* aq. HCl (40 mL) and 10% Pd-C (moist, 30 g), and the mixture was hydrogenated in a Parr apparatus (50 psi $H_2$) for 4 h. The reaction mixture was filtered through celite, washed with MeOH, and concentrated under vacuum. The residue was dissolved in EtOAc (500 mL) and was then washed with saturated aq. $NaHCO_3$. The phases were separated, and the aqueous phase was extracted with EtOAc (200 mL 2×). The combined organic phase was washed with brine, dried over $Na_2SO_4$, and concentrated under reduced pressure. The residue was purified by column chromatography ($CHCl_3$) to afford compound **5** (38 g, 83%) as a clear oil. $[\alpha]_D^{20}$: +103.6 (c 1.0, $CHCl_3$). HRMS calcd. for $C_{14}H_{20}NO_4(M+H^+)$ 266.1392, found 266.1390. $^1$H NMR (300 MHz, $CDCl_3$): δ 6.89 (m, 2 H), 6.74 (d, $J$ = 8.1 Hz, 1 H), 6.00 (d, $J$ = 7.5 Hz, 1 H), 4.85 (m, 1 H), 3.79 (s, 3 H), 3.72 (s, 3 H), 3.08 (m, 2 H), 2.17 (s, 3 H), 1.98 (s, 3 H). $^{13}$C NMR (75 MHz, $CDCl_3$): δ 172.2, 169.5, 156.8, 131.4, 127.3, 127.1, 126.6, 109.8, 55.1, 53.2, 52.1, 36.8, 23.0, 16.1.

**(*S*)-Methyl-2-acetamido-3-(3-formyl-4-methoxy-5-methylphenyl)propanoate(6).** Titanium chloride (58 mL, 0.42 mol, 3 equiv) in $CH_2Cl_2$ (150 mL ) was added dropwise over 1 h to a solution of compound **5** (37 g, 0.14 mol) and α,α-dichloromethyl methyl ether (16 mL, 0.18 mol, 1.3 equiv) in $CH_2Cl_2$ (250 ml) with stirring under 0°C. The cooling bath was removed, and the mixture was stirred for a further 3 h, and then poured into ice-water (400 mL). The phases were separated, and the aqueous phase was extracted with $CH_2Cl_2$ (200 mL 2×). The combined organic phase was washed with brine, dried over $Na_2SO_4$, and concentrated by rotary evaporation. The residue was purified by column chromatography (25% *n*-hexane in EtOAc) to provide compound **6** (37.7 g, 92%) as a white solid. $[\alpha]_D^{20}$: +102.5 (c 1.0, $CHCl_3$). HRMS calcd. for $C_{15}H_{20}NO_5(M+H^+)$ 294.1341, found 294.1339. $^1$H NMR (300 MHz, $CDCl_3$): δ 10.33 (s, 1 H), 7.41 (d, $J$ = 2.1 Hz, 1 H), 7.22 (d, $J$ = 2.1 Hz, 1 H), 6.09 (d, $J$ = 7.5 Hz, 1 H), 4.88 (m, 1 H), 3.88 (s, 3 H), 3.75 (s, 3 H), 3.17 (dd, $J$ = 13.8, 5.4 Hz, 1 H), 3.06 (dd, $J$ = 13.8, 6.0 Hz, 1 H), 2.31 (s, 3 H), 1.99 (s, 3 H). $^{13}$C NMR (75 MHz, $CDCl_3$): δ 190.0, 171.8, 169.4, 160.8, 138.3, 132.5, 132.1, 128.9, 126.6, 63.1, 53.0, 52.4, 37.0, 23.0, 15.5.

**(*S*)-methyl-2-acetamido-3-(3-hydroxy-4-me-thoxy-5-methylphenyl)propanoate (7).** To an ice cold solution of compound **6** (15.0 g, 51.2 mmol) in $CHCl_3$ (300 mL) was added MCPBA (26.5 g, 153.6 mmol). The mixture was stirred vigorously at room temperature for 6 h and then washed sequentially with 10% $Na_2S_2O_3$, saturated aqueous $NaHCO_3$, brine, and dried over $Na_2SO_4$. The solution was concentrated, and the residue was dissolved in MeOH (150 mL). Then concentrated HCl (12 N, 1.28 mL, 15.3 mmol, 0.3 equiv) was added at 0°C. The solution was then stirred for 10 h at room temperature and then concentrated by rotary evaporation. The residue was purified by column chromatography (2% $CH_3OH$ in $CHCl_3$) to provide compound **7** (13.2 g, 91%) as a yellow oil. $[\alpha]_D^{20}$: +91.5 (c 0.5, $CHCl_3$). HRMS calcd. for $C_{14}H_{20}NO_5(M+H^+)$ 282.1345, found 282.1341.$^1$H NMR (300 MHz, $CDCl_3$): δ 6.54 (d, $J$ = 1.5 Hz, 1 H), 6.42 (d, $J$ = 1.2 Hz, 1 H), 6.14 (d, $J$ = 7.5 Hz, 1 H), 4.83 (dd, $J$ = 12.9, 5.7 Hz, 1 H), 3.77 (s, 3 H), 3.75 (s, 3 H), 2.97 (m, 2 H), 2.24 (s, 3 H), 2.00 (s, 3 H). $^{13}$C NMR (75 MHz, $CDCl_3$): δ 172.1, 170.0, 148.9, 144.5, 131.9, 130.9, 122.9, 114.2, 60.3, 53.1, 52.2, 37.1, 22.9, 15.7.

**(*S*)-5-(2-Amino-3-hydroxypropyl)-2-meth-oxy-3-methylphenol (9).** To a solution of compound **7** (5.0 g, 13.9 mmol) in THF (25 mL) was added $LiBH_4$ (0.39 g, 18.1 mmol, 1.3 equiv) in portions at 0°C. Then, the mixture was stirred for 18 h at room temperature and quenched slowly with saturated aqueous $NH_4Cl$ (60 mL) and extracted with EtOAc (80 mL 3×). The organic layer was washed with brine (100 mL), dried over $Na_2SO_4$, and concentrated by rotary evaporation. The residue was purified by column chromatography (EtOAc) to provide **8** (4.2 g, 91%) as a white solid.

**Scheme 1.** Reagents and conditions: (a) $H_2$ (50 psi), 10% Pd-C, 1*N* aq. HCl, $CH_3OH$, 4 h, 83%; (b) $MeOCHCl_2$, $TiCl_4$, $CH_2Cl_2$, r.t., 4 h, 92%; (c) MCPBA, $CHCl_3$, r.t., 6 h; (d) 12*N* HCl, $CH_3OH$, 10 h, 91% for two steps; (e) $LiBH_4$, THF, r.t., 24 h, 91%; (f) 6*N* aq. HCl, $CH_3OH$, reflux, 10 h, 87% ; (g) $BnOCH_2CHO$, 4 Å molecular sieves, $CH_2Cl_2/CF_3CH_2OH$=7:1, 0°C, 8 h, compound **10** in 64% yield, compound **11** in 20% yield; (h) $H_2$(50 psi), $Pd(OH)_2$, $CH_3OH$, 12 h, 86%.



To a solution of **8** (3.4 g, 10.2 mmol) in $CH_3OH$ (60 mL) was added 6 *N* aq. HCl (11 mL), and then, the mixture was refluxed in an oil bath (80°C) for 6 h. The reaction solution was removed by rotary evaporation, and the residue was dissolved in $CH_3OH$. The solution was basified with $NEt_3$ and purified directly by column chromatography ($SiO_2$ treated with $NEt_3$, 5% $CH_3OH$ in $CHCl_3$; then 10% $CH_3OH$ in $CHCl_3$) to provide **9** (2.6 g, 87%) as a white solid. $[\alpha]_D^{20}$: −7.4 (c 0.5, $CH_3OH$). HRMS calcd. for $C_{11}H_{18}NO_3(M+H^+)$ 212.1281, found 212.1313. $^1$H NMR (300 MHz, $CD_3COD$): δ 6.78 (d, *J* = 2.1 Hz, 1H), 6.73 (d, *J* = 1.8 Hz, 1H), 3.90 (s, 3 H), 3.85 (dd, *J* = 11.7 Hz, 3.9 Hz, 1H), 3.67 (dd, *J* = 11.7 Hz, 6.6Hz, 1H), 3.52 (m, 1H), 2.92 (m, 2 H), 2.40 (s, 3 H). $^{13}$C NMR (75MHz, $CD_3COD$): δ 151.4, 146.5, 133.1, 133.0, 123.4, 116.0, 61.9, 60.4, 55.8, 36.3, 15.9.

**(1R,3*S*)-1-(Benzyloxymethyl)-3-(hydroxyl-methyl)-7-methoxy-6-methyl-1,2,3,4-tetra-hydroisoquinolin-8-ol (10) and (1R,3S)1-(benzyloxymethyl)-3-(hydroxyl-methyl)-7-methoxy-8-methyl-1,2,3,4-tetra-hydroisoquinolin-6-ol (11).** To a solution of **9** (0.60 g, 2.84 mmol), acetic acid (0.43 g, 0.42 mL, 7.5 mmol, 2.5 equiv) and the 4 Å molecular sieves (0.5 g) in dichloromethane and 2,2,2-trifluoroethanol (7:1, v/v, 12 mL), a solution of benzyloxyacetaldehyde (0.47 g, 3.1 mmol, 1.1 equiv) in dichloromethane was added slowly *via* syringe over 1 h at 0°C. After being stirred at 0°C for 8 h, the reaction mixture was diluted with dichloromethane and filtered. The filtrate was concentrated under reduced pressure, and the residue was purified by flash column chromatography (2% MeOH in chloroform) to afford **10** (0.63 g, 64%) and **11** (0.19 g, 20%) as white solid. Compound 10: $[\alpha]_D^{20}$: −115.2 (c 0.5, $CH_3OH$). HRMS calcd. for $C_{20}H_{26}NO_4(M+H^+)$ 344.1856, found 344.1885. $^1$H NMR (300 MHz, DMSO-$d_6$): δ 8.65 (s, 1 H), 7.32 (m, 5 H ), 6.37 (s, 1 H), 4.71(t, *J* = 5.1 Hz, 1 H), 4.52 (d, *J* = 12.0 Hz, 1 H), 4.46 (d, *J* = 12.0 Hz, 1 H), 4.31 (brd, *J* = 6.0 Hz, 1 H), 4.13 (dd, *J* = 8.7, 2.7 Hz,1 H), 3.59 (s, 3 H), 3.46 (m, 1 H), 3.43 (d, *J* = 8.7 Hz, 1 H ), 3.34 (m, 1 H), 3.33 (s, 1H), 2.68(m, 1 H), 2.42 (dd, *J* = 14.7, 2.4 Hz, 1 H), 2.28(dd, *J* = 14.7, 10.8 Hz, 1 H), 2.14(s, 3 H). $^{13}$C NMR (75 MHz, DMSO-$d_6$): δ 146.7, 143.8, 138.7, 132.6, 128.1, 128.0, 127.3, 127.2, 120.9, 73.8, 72.0, 65.2, 59.9, 53.9, 53.0, 33.0, 15.3. Compound **11**: $^1$H NMR (300 MHz, DMSO-*d*6): δ 8.94 (s, 1 H), 7.35 (m, 5 H ), 6.40 (s, 1 H), 4.77(t, *J* = 2.4 Hz, 1 H), 4.59 (d, *J* = 12.3 Hz, 1 H), 4.53 (d, *J* = 12.3 Hz, 1 H), 4.09 (dd, *J* = 9.9, 2.7 Hz, 1 H), 3.60 (s, 3 H), 3.50 (d, *J* = 9.9, 5.4 Hz, 1 H), 3.47(d, *J* = 12.9 Hz, 1 H), 3.28(dd, *J* = 8.4, 2.7 Hz, 1 H), 3.22(m, 1 H), 3.10 (m, 1 H), 2.74(s, 1 H), 2.44 (dd, *J* = 15.9, 3.9 Hz, 1 H), 2.17(dd, *J* = 15.9, 10.8 Hz, 1 H), 2.03(s, 3 H). $^{13}$C NMR (75 MHz, DMSO-*d*6): δ 148.1, 143.9, 138.6, 130.4, 128.2, 127.8, 127.5, 127.3, 125.8, 124.4, 114.2, 71.9, 68.8, 65.7, 59.3, 53.0, 47.5, 31.3, 11.2.

**(–)-MY 336a (1).** To a solution of compound **10** (230 mg, 0.67 mmol ) in MeOH (4 mL) at room temperature was added $Pd(OH)_2$ (moist, Pd content 20%, 50 mg), and the mixture was hydrogenated in a Parr apparatus (50 psi $H_2$) for 10 h. The reaction mixture was filtered through celite, washed with MeOH, and concentrated under vacuum. The pale yellow residue was purified by column chromatograph ($SiO_2$ treated with triethylamine, 5% MeOH in $CHCl_3$) to afford compound **1** (147 mg, 86%) as a yellow solid. $[\alpha]_D^{20}$: −97.3 (c 0.5, $CH_3OH$). HRMS calcd. for $C_{13}H_{20}NO_4(M+H^+)$ 254.1387, found 254.1421 $^1$H NMR (600 MHz, DMSO- $d_6$): δ 8.65 (s, 1 H), 6.34 (s, 1 H), 4.66 (s, 1 H), 4.10 (t, *J* = 4.2 Hz, 1 H), 3.90 (dd, *J* = 10.2, 4.2 Hz, 1 H, 1-$CH_2OH$,), 3.59(s, 3 H, 7-OMe), 3.43 (dd, *J* = 10.8, 4.8

Hz, 1H, 3-$CH_2OH$), 3.36 (dd, $J = 10.2$, 6.6 Hz, 1H, 1-$CH_2OH$), 3.32 (dd, $J = 10.8$, 6.6 Hz, 1 H, 3-$CH_2OH$), 2.68 (m, 1 H, 3-H), 2.41 (dd, $J = 15.0$, 2.4 Hz, 1 H, 4-$H_{eq}$), 2.24 (dd, $J = 14.4$, 11.4 Hz, 1 H, 4-$H_{ax}$), 2.11(s, 3 H, 6-Me). $^{13}C$ NMR (75MHz, DMSO-$d_6$): δ 146.8, 143.9, 132.4, 127.8, 121.9, 120.9, 65.3, 64.8, 59.7, 54.9, 53.9, 33.0, 15.3.

*N*-substituted donepezil-related isoquinolines have been prepared as potential acetylcholinesterase inhibitors (AChEIs). Microwave assisted procedures and solution-phase parallel synthesis were chosen to optimize the synthetic approach and improve the yields. All synthesized compounds were tested for their AChE inhibitory activity by colorimetric Ellman method and some of them (**10**, **13**, and **28**) displayed low inhibitory effects at μ*M* concentrations.

## INTRODUCTION

Alzheimer's disease (AD), the most common cause of senile dementia, is a neurodegenerative disorder characterized by loss of cognitive ability and severe behavioral abnormalities, which become increasingly serious with disease progression [1].

AD is mainly characterized by a pronounced degeneration of the cholinergic system and by the alteration of other neurotransmitter systems such as the glutamatergic system. Cholinergic abnormalities are associated with (a) the accumulation of protein deposits as β-amyloid peptide (Aβ), the main component of the senile plaques and derived from amyloid precursor protein (APP); (b) the abnormal phosphorylation of τ protein resulting in the formation of neurofibrillary tangles (NFT).

As the cause of the disease has yet to be identified, despite the numerous drugs have been studied as potential anti-AD agents, its treatment has been confined to limiting the progression of the disease. Until now, drug development has focused on (i) symptomatic treatments for restoring deficient neurotransmitters and (ii) etiologically based treatments for slowing or halting the rate of progression [2,3].

Current strategies in the search for new therapeutic approaches are based on different morphological and biochemical characteristics of AD and focus on the following directions: (i) agents compensating the cholinergic system hypofunction; (ii) agents interfering with the metabolism of Aβ; (iii) agents affecting the process of τ protein iperphosphorylation and formation of NFT; (iv) agents protecting neurons from toxic metabolites formed in neurodegenerative processes; and (v) agents activating other neurotransmitter systems to indirectly compensate the cholinergic function deficit.

Currently, only a few therapeutic drugs are available for the treatment of AD; their pharmacological effect is the enhancement of the central cholinergic function, by increasing brain acetylcholine (ACh) level [2,4–6].

Cholinergic therapy for Alzheimer's disease is mainly concentrated on the inhibition of acetylcholinesterase (AChE, EC 3.1.1.7), the main enzyme involved in the breakdown of acetylcholine in the normal brain [7,8]. Tacrine (**1**, Cognex®), donepezil (**2**, Aricept®), rivastigmine (**3**, Exelon®), and galantamine (**4**, Reminyl®) (Fig. 1) are the most widely used acetylcholinesterase inhibitors (AChEIs) [9]. The main effect of AChEIs on neurotransmission is thought to be associated with the increase of both the duration of action and the concentration of the neurotransmitter in the synaptic cleft, resulting in an improvement of the activation of the cholinergic receptors [10].

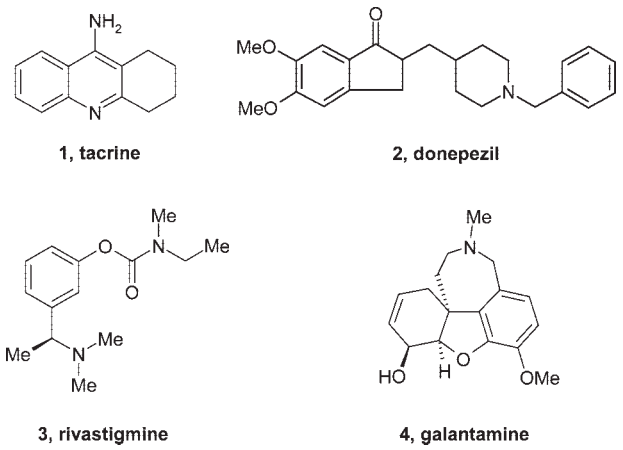

**Figure 1.** AChE inhibitors used for the treatment of AD.

Recently, it has been pointed out that AChE exerts secondary noncholinergic functions and it is also responsible for the pro-aggregating activity toward Aβ, thus suggesting that AChE plays a key role in the development of the senile plaques. In particular, the peripheral anionic binding site (PAS) of AChE is responsible for the AChE–Aβ interaction promoting amyloid fibril formation [11,12]. For these reasons AChEIs able to interact with both catalytic and peripheral binding sites (i.e., dual binding site inhibitors) represent a new therapeutic approach to counteract hypofunction of the cholinergic system and to avoid Aβ aggregation [13]. On the basis of this evidence several classes of dual binding site AChE inhibitors have been developed. Recently, different classes of such compounds have been designed from donepezil (**2**) [14–18]. As demonstrated by the crystal structure of their complex with *Torpedo californica* AChE (*Tc*AChE), **2** is able to occupy the entire length of the enzyme active-site gorge forming various interactions with specific residues, such as aromatic residues, stacking interactions between the benzyl and indanone moieties and the indole ring of Trp84 and Trp279 at the catalytic and peripheral sites, respectively, and the cation–π interaction between the piperidine nitrogen and the phenyl ring of Phe330 residue.

However, now it also seems that the role of butyrylcholinesterase (BChE, EC 3.1.1.8) in hydrolysing acetylcholine may be relevant in brain degenerative conditions. In fact, as Alzheimer disease progresses, AChE activity decreases in some brain regions, while BChE activity increases. This is probably related to a relative increase in the numbers of BChE-positive neurons, likely as compensation for AChE decrease. For these reasons, one of the most innovative approaches is the development of cholinesterase inhibitors (ChEIs), able to inhibit AChE and BChE [6].

We herein report the design, the synthesis and the cholinesterase (AChE and BChE) inhibitory activity of a new series of *N*-substituted 6,7-dimethoxyisoquinoline derivatives (**5–30**, Fig. 2) containing in their structures some moieties considered able to inhibit enzyme activity. The 6,7-dimethoxyisoquinoline nucleus and the benzyl substituent were chosen considering the donepezil chemical structure; furthermore, the linker was modified with the aim of evaluating the effect on the inhibitory potency of the distance between (i) the two aromatic rings that could be involved in stacking interactions with the indole ring of Trp84 and Trp279; (ii) the aromatic ring and the positive ionisable nitrogen atom of benzyl-piperidine or -piperazine moiety. Moreover, we inserted into the linker the carbonyl group that characterizes a useful interaction point for the donepezil-like derivatives.

All synthesized compounds were tested for their ability to inhibit AChE and some compounds were also evaluated against BChE.

## RESULTS AND DISCUSSION

As shown in Scheme 1, the synthesis of designed compounds was performed starting from the commercially available 6,7-dimethoxy-1,2,3,4-tetrahydroisoquinoline (**31**) that was functionalized to give the different *N*-substituted derivatives **5–29**.

Compounds **5–7** were easily prepared by reaction of derivative **31** with a suitable arylbromide under basic conditions. The reaction of isoquinoline **31** and ethyl oxalylchloride in the presence of triethylamine gave ethyl ester intermediate which was converted into derivative **32** by hydrolysis under basic conditions and then treatment with 6*N* HCl. Thus, 1-(4-benzylpiperidin-1-yl)-2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl) ethane-1,2-dione (**8**) was easily achieved by HBTU-mediated coupling of intermediate **32** with benzylpiperidine.

Also compounds **9–29** were prepared in two steps. In the first step, **31** was combined with 2-chloroacetyl chloride to give the key intermediate **33**, which in the second step was reacted with benzylpiperidine or 4-arylmethylpiperazine derivatives to provide compounds **9–29**. These reactions were carried out following a solution phase parallel

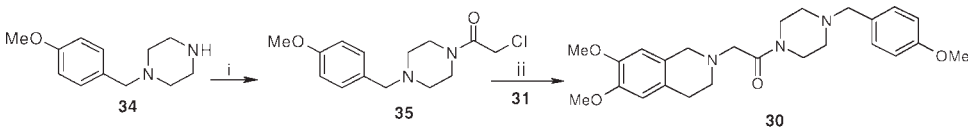
**Reagents and conditions:** i) $R_1C_6H_4CH_2Br$, TEA, DCM r.t., 24 h or NaH, DMF, r.t., 3 h; iia) ClCOCOOEt, TEA, DCM, 25°C, 5 min., 280 Watt; iib) KOH, EtOH/$H_2O$, HCl 6N; iii) HBTU, TEA, benzylpiperidine, DMF, 40 min, 25°C, 250 Watt; iv) $ClCOCH_2Cl$, TEA, DCM, 0°C, 1h; v) cycloalkylamine, TEA, DCM, Δ, 24h.

synthetic (SPPS) approach, using a Buchi Syncore reactor, which allowed us to prepare a small library of analogs.

As shown in Scheme 2, the synthesis of 2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl)-1-[4-(4-methoxybenzyl)piperazin-1-yl]ethanone (**30**) was realized by using an alternative procedure. Compound **35** was prepared by the same method employed for compound **33** but starting from the 4-(4-methoxyphenyl)methyl-piperazine **34**. Then, the reactive intermediate **35** was combined with **31** to give **30** under basic conditions.

To evaluate the inhibitory activity, all compounds were prepared as hydrochloride derivatives (except compound **8**) and tested on human recombinant AChE according to Ellman [19], using tacrine (**1**) as reference compound. Unfortunately, only derivatives **10**, **13**, and **28** showed inhibitory effects at μ*M* concentrations. The $IC_{50}$ values were 176 μ*M* (**10**), 102 μ*M* (**13**), and 148 μ*M* (**28**), respectively. These results showed that our compounds exhibited lower potency than **1** ($IC_{50}$ = 424 n*M*) and **2** ($IC_{50}$ = 23.1 n*M*) [20].

**Scheme 2**



**Reagents and conditions:** i) $ClCOCH_2Cl$, TEA, DCM, rt, 1h; ii) NaH, dry DMF, $N_2$, r.t., 20h.

Moreover, to explore the dual inhibitor effects of the most active compounds (**10**, **13**, and **28**), we performed the assay against the BChE enzyme at different concentrations (25–800 μ*M*). The results obtained suggest that these compounds did not significantly inhibit BChE; only compound **13** showed 82% of inhibitory activity at the highest tested dose (800 μ*M*).

In conclusion, microwave-assisted procedures and solution-phase parallel synthesis were set up to prepare new isoquinoline derivatives (**5–30**) as potential donepezil-like AChE inhibitors. These approaches allowed us to successfully obtain a small library of compounds that were tested as cholinesterase inhibitors. Some of the synthesized compounds showed inhibitory activity at μ*M* concentrations. However, these results are not useful to make structure-activity relationships for this new series of isoquinolines.

## EXPERIMENTAL

**Chemistry.** All microwave-assisted reactions were carried out in a CEM Focused Microwave Synthesis System, Model Discover working at the potency necessary for refluxing under atmospheric conditions (i.e., 250–300 W). Melting points were determined on a BUCHI Melting Point B-545 apparatus and are uncorrected. Elemental analyses were carried out by University of Messina (C, H, N) using a Carlo Erba Model 1106 Elemental Analyzer and by Redox S.n.c. (Monza, Italy) (C, H, N, Cl). The obtained results are within ± 0.4% of the theoretical values. Merck silica gel 60 $F_{254}$ plates were used for analytical TLC; column chromatography was performed on Merck silica gel 60 (230–400 mesh) and Flash Chromatography (FC) on a Biotage SP4 EXP. $^1$H NMR spectra were recorded in deuterochloroform ($CDCl_3$) with TMS as internal standard or hexa-deutero-dimethylsulfoxide (DMSO-$d_6$) on a Varian Gemini-300 spectrometer. Chemical shifts were expressed in δ (ppm) and coupling constants (*J*) in Hz.

**General procedure for the synthesis of 2-benzyl-1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline derivatives (5–7).** 1, 2,3,4-Tetrahydro-6,7-dimethoxyisoquinoline hydrochloride (229.70 mg, 1 mmol) was dissolved in water (10 mL) and alkalinized with a saturated aqueous solution of NaOH until pH = 10–11. The resulting mixture was extracted with ethyl acetate, dried over sodium sulfate ($Na_2SO_4$) and concentrated in vacuo to give the corresponding free-base **31**. Then 1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline (**31**) (193.25 mg, 1 mmol) was dissolved in dichloromethane (DCM) (10 mL) and triethylamine (TEA) (102.20 mg, 1 mmol) was added. The mixture was treated with the suitable benzyl bromide (1 mmol) and stirred for 24 h at room temperature. The reaction was quenched with water (10 mL), extracted with ethyl acetate (3 × 10 mL) and dried over $Na_2SO_4$. After removal of the solvent under reduced pressure, the residue was powdered by treatment with diethyl ether and crystallized from ethanol to give derivatives **5–7**. Compounds **5–7** were also obtained in higher yields using a catalytic amount of sodium hydride (NaH) in dimethylformamide (DMF) (2 mL). In this case, the reaction mixture was stirred at room temperature for 3 h and then a saturated aqueous $NaHCO_3$ solution was added. After the extraction with ethyl acetate (3 × 10 mL) the organic phase was reduced under vacuo, the residue powdered by treatment with diethyl ether and crystallized from ethanol to give the desired derivatives **5–7**.

**2-Benzyl-1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline (5).** Mp 85–87°C, yield 77%; $^1$H NMR (δ in $CDCl_3$) : 2.72–2.83 (m, 4H, $CH_2$), 3.55 (s, 2H, $CH_2$), 3.68 (s, 2H, $CH_2$), 3.81 (s, 3H, $CH_3O$), 3.84 (s, 3H, $CH_3O$), 6.48 (s, 1H, ArH), 6.60 (s, 1H, ArH), 7.28–7.41 (m, 5H, ArH). Anal. Calcd for $C_{18}H_{21}NO_2$: C, 76.42; H, 7.50; N, 4.79. Found: C, 76.30; H, 7.47; N, 4.94.

**2-(4-Chlorobenzyl)-1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline (6).** Mp 95–97°C, yield 52%; $^1$H NMR (δ in $CDCl_3$) : 2.70–2.84 (m, 4H, $CH_2$), 3.53 (s, 2H, $CH_2$), 3.64 (s, 2H, $CH_2$), 3.81 (s, 3H, $CH_3O$), 3.84 (s, 3H, $CH_3O$), 6.48 (s, 1H, ArH), 6.60 (s, 1H, ArH), 7.30 (d, 2H, $J$ = 8.8, ArH), 7.34 (d, 2H, $J$ = 8.8, ArH). Anal. Calcd for $C_{18}H_{20}ClNO_2$: C, 68.23; H, 6.20; N, 4.32. Found: C, 68.03; H, 6.34; N, 4.41.

**2-(4-Fluorobenzyl)-1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline (7).** Mp 96–98°C, yield 43%; $^1$H NMR (δ in $CDCl_3$) : 2.77–2.87 (m, 4H, $CH_2$), 3.58 (s, 2H, $CH_2$), 3.69 (s, 2H, $CH_2$), 3.86 (s, 3H, $CH_3O$), 3.89 (s, 3H, $CH_3O$), 6.53 (s, 1H, ArH), 6.65 (s, 1H, ArH), 7.07–7.41 (m, 4H, ArH). Anal. Calcd for $C_{18}H_{20}FNO_2$: C, 71.87; H, 6.60; N, 4.51. Found: C, 71.74; H, 6.69; N, 4.65.

**Synthesis of 1-(4-benzylpiperidin-1-yl)-2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl)ethane-1,2-dione (8).** A mixture of 1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline (**31**) (193.25 mg, 1 mmol) in DCM (3 mL), ethyl oxalylchloride (166.50 mg, 1.22 mmol) and TEA (173.70 mg, 1.72 mmol) was placed in a cylindrical quartz tube (Ø 2 cm), then stirred and irradiated in a microwave oven (280 Watt, 5 min, 25°C). The resulting mixture was diluted with DCM (15 mL), washed with a saturated $NaHCO_3$ aqueous solution (2 × 10 mL) and with water (2 × 10 mL) and then extracted with ethyl acetate. The combined organic phases were dried over $Na_2SO_4$ and evaporated under reduced pressure to give the ester intermediate as a yellow oil which was dissolved in 50% EtOH/water (5 mL), basified with KOH and stirred at room temperature for 5 min. Successively the mixture was acidified by the addition of HCl (6.0*N*) and the resulting solution was extracted with chloroform (3 × 10 mL), dried over $Na_2SO_4$ and the solvent removed under reduced pressure to afford the corresponding

acid **32**. To a solution in DMF (5 mL) of crude material obtained in previous step (265 mg, 1 mmol) and O-benzotriazole-*N*,*N*,*N*′,*N*′-tetramethyl-uronium-hexafluoro-phosphate (HBTU) (379 mg, 1 mmol) 4-benzylpiperidine (352 mg, 2 mmol) was added; the reaction mixture was placed in a cylindrical quartz tube (Ø 2 cm), stirred and irradiated in a microwave oven for two subsequent periods in the same conditions (250 Watt, 20 min, 25°C). The cooled organic layer was diluted with water (10 mL), extracted with ethyl acetate (3 × 10 mL) and dried over $Na_2SO_4$. The solvent was removed until dryness under reduced pressure and the resultant crude purified by silica gel column chromatography (chloroform/methanol; 99:1) to give compound **8** as a white solid.

**1-(4-Benzylpiperidin-1-yl)-2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl)ethane-1,2-dione (8).** Mp 115–117°C, yield 66%. $^1$H NMR (δ, ppm, in $CDCl_3$): 1.24–1.43 (m, 4H, $CH_2$), 1.62–1.74 (m, 3H, CH and $CH_2$), 2.53–3.04 (m, 6H, $CH_2$), 3.62–3.66 (m, 2H, $CH_2$), 3.86 (s, 6H, $CH_3O$), 4.69 (s, 2H, $CH_2$), 6.55 (s, 1H, ArH), 6.63 (s, 1H, ArH), 7.08–7.29 (m, 5H, ArH). Anal. Calcd for $C_{25}H_{30}N_2O_4$: C, 71.15; H, 7.04; N, 6.46. Found: C, 71.07; H, 7.16; N, 6.63.

**Synthesis of 2-(4-benzylpiperidin-1-yl)-2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1H)-yl)ethanone (9).** 1,2,3,4-Tetrahydro-6,7-dimethoxyisoquinoline (**31**) (193.25 mg, 1 mmol) was dissolved in DCM (10 mL) and TEA (102.20 mg, 1 mmol) was added. After the addition dropwise at 0°C of 2-chloroacetyl chloride (56 mg, 0.5 mmol), the reaction mixture was stirred at rt for 1 h. The solution was washed with water (3 × 10 mL), dried over $Na_2SO_4$ and concentrated in vacuo. The resulting residue was powdered by treatment with diethyl ether to provide intermediate **33**. To a solution of 2-chloro-1-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl)ethanone (**33**) (270 mg, 1 mmol) in DCM (10 mL), 4-benzylpiperidine (175.28 mg, 1 mmol) and TEA (102.20 mg, 1 mmol) were added. The mixture was heated under reflux, stirred for 24 h, cooled to r.t., washed with water (3 × 10 mL) and dried over $Na_2SO_4$. After removal of the solvent under reduced pressure, the residue was powdered by treatment with diethyl ether and crystallized from ethanol to give compound **9**.

**2-Chloro-1-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl) ethanone (33).** Mp 198–200°C, yield 75%. $^1$H NMR (δ, ppm, in DMSO-$d_6$): 2.68–2.78 (m, 2H, $CH_2$), 3.62–3.66 (m, 2H, $CH_2$), 3.70 (s, 6H, $CH_3O$), 4.44 (s, 2H, $CH_2$), 4.51 (s, 2H, $CH_2$), 6.74 (s, 1H, ArH), 6.79 (s, 1H, ArH). Anal. Calcd for $C_{13}H_{16}ClNO_3$: C, 57.89; H, 5.98; N, 5.19. Found: C, 57.97; H, 5.76; N, 5.23.

**2-(4-Benzylpiperidin-1-yl)-2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1H)-yl)ethanone (9).** Mp110–111°C, yield 45%. $^1$H NMR (δ, ppm, in $CDCl_3$): 1.25–1.32 (m, 4H, $CH_2$), 1.65–1.98 (m, 1H, CH), 2.01 (t, 4H, $J$ = 10.4, $CH_2N$), 2.53 (d, 2H, $J$ = 7.1, $CH_2$), 2.76–2.83 (m, 2H, $CH_2$), 3.21 (s, 2H, $CH_2N$), 3.77–3.81 (m, 2H, $CH_2$), 3.85 (s, 3H, $CH_3O$), 3.87 (s, 3H, $CH_3O$), 4.64 (s, 2H, $CH_2$), 6.61 (s, 1H, ArH), 6.63 (s, 1H, ArH), 7.12–7.25 (m, 5H, ArH). Anal. Calcd for $C_{25}H_{32}N_2O_3$: C, 73.44; H, 7.75; N, 6.91. Found: C, 73.50; H, 7.90; N, 6.86.

**General procedure for the synthesis of 2-(4-arylpiperazin-1-yl)-1-[3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl] ethanone derivatives (10-27).** To a solution of the intermediate **33** (270 mg, 1 mmol) in DCM (10 mL) suitable arylpiperazine (1 mmol) and TEA (101 mg, 1 mmol) were added in the Buchi Syncore reactor. The mixture was heated under reflux and stirred for 24 h, cooled to room temperature, washed with water (10 mL × 3) and dried over $Na_2SO_4$. After removal of the solvent under reduced pressure, the residue was powdered by treatment with diethyl ether and crystallized from ethanol or, in some cases, purified by flash chromatography (FC) eluting with chloroform/ethyl acetate (90:10) as eluent to give the pure derivatives (**10**–**27**).

In order to prepare compound **10** the 4-benzylpiperazine was prepared by the following procedure: mono Boc-protected piperazine (1 mmol) was dissolved in DMF (10 mL) and treated with benzylbromide (171.04 mg, 1 mmol). The mixture was cooled at 0°C and NaH (24 mg, 1 mmol) was cautiously added. The reaction was stirred in ice-bath for 1 hour and then washed with a solution of water/diethyl ether (1:2) (3 × 8 mL). The organic phase was dried over $Na_2SO_4$ and concentrated in vacuo. The resulting residue was powdered by treatment with diethyl ether to provide 4-benzyl-piperazine-1-carboxylic acid tert-butyl ester intermediate which was used for the next step without further purification. Deprotection was achieved by dissolving Boc-intermediate in trifluoroacetic acid. The mixture was stirred at 0°C for 30 min and then concentrated under reduced pressure. The residue was basified with saturated $NaHCO_3$ aqueous solution until pH = 9 and extracted with chloroform (3 × 10 mL). The combined organic phases were dried over $Na_2SO_4$, evaporated under reduced pressure and the residue powdered by treatment with diethyl ether to give the desired 4-benzylpiperazine.

**2-(4-Benzylpiperazin-1-yl)-1-[3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl]ethanone (10).** Mp 102°C dec, yield 70%. $^1$H NMR (δ, ppm, in $CDCl_3$): 2.49–2.54 (m, 8H, $CH_2$), 2.82–2.86 (m, 2H, $CH_2$), 3.26 (s, 2H, $CH_2$), 3.48–3.51 (m, 2H, $CH_2$), 3.76–3.81 (m, 2H, $CH_2$), 3.85 (s, 3H, $CH_3O$), 3.86 (s, 3H, $CH_3O$), 4.64–4.68 (m, 2H, $CH_2$), 6.61 (s, 1H, ArH), 6.63 (s, 1H, ArH), 7.24–7.32 (m, 5H, ArH). Anal. Calcd for $C_{24}H_{31}N_3O_3$: C, 70.39; H, 7.63; N, 10.26. Found: C, 70.53; H, 7.43; N, 10.45.

**2-[4-(4-Bromobenzyl)piperazin-1-yl]-1-[3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl]ethanone (11).** Mp 137–139°C, yield 51%. $^1$H NMR (δ, ppm, in DMSO-$d_6$): 2.42–2.49 (m, 8H, $CH_2$), 2.64–2.76 (m, 2H, $CH_2$), 3.20 (s, 2H, $CH_2$), 3.31–3.62 (m, 4H, $CH_2$), 3.69 (s, 3H, $CH_3O$) 3.70 (s, 3H, $CH_3O$), 4.48–4.61 (m, 2H, $CH_2$), 6.71 (s, 1H, ArH), 6.75 (s, 1H, ArH), 7.20–7.53 (m, 4H, ArH). **Synthesis of 1-[3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl]-2-[4-((1,3-dioxolan-2-yl)methyl)piperazin-1-yl] ethanone (29).** Derivative **29** was obtained with the same procedure of compounds **10–27** by treatment of intermediate **33** (270 mg, 1 mmol) with 1-[(1,3-dioxolan-2-yl)methyl]piperazine (172 mg, 1 mmol). Mp 113–115°C, yield 89%. $^1$H nmr (δ, ppm, in $CDCl_3$): 2.58–2.60 (m, 12H, $CH_2$), 2.75–2.86 (m, 2H, $CH_2$), 3.26 (s, 2H, $CH_2$), 3.76–3.80 (m, 2H, $CH_2$), 3.85 (s, 3H, $CH_3O$), 3.87 (s, 3H, $CH_3O$), 3.88–3.99 (m, 2H, $CH_2$), 4.65–4.69 (m, 2H, $CH_2$), 4.99–5.00 (m, 1H, CH), 6.58–6.63 (m, 2H, ArH). Anal. Calcd for $C_{21}H_{31}N_3O_5$: C, 62.20; H, 7.71; N, 10.36. Found: C, 62.41; H, 7.59; N, 10.14.

**Synthesis of 2-(3,4-dihydro-6,7-dimethoxyisoquinolin-2(1*H*)-yl)-1-[4-(4-methoxybenzyl)piperazin-1-yl]ethanone (30).** 1-(4-Methoxybenzyl)piperazine (**34**) (206 mg, 1 mmol) was dissolved in DCM (10ml) and TEA (101 mg, 1 mmol) was added. 2-Chloroacetyl chloride (113 mg, 1 mmol) was added dropwise at 0°C and the solution stirred at room temperature for 1 h. The reaction mixture was washed with water (3 × 10 mL), dried over $Na_2SO_4$ and concentrated to give intermediate **35** as an oily residue, which was used in the next step without further purification. To a suspension of **35** (369 mg, 1 mmol) and NaH (120 mg, 5 mmol) in dry DMF (2 mL) **31** was added and the reaction was stirred at r.t. under $N_2$ atmosphere for 20 h. Then it was quenched with a saturated $NaHCO_3$ aqueous solution (10 mL) and extracted with ethyl acetate (3 × 10 mL). The organic phase was washed with water, dried over $Na_2SO_4$ and concentrated under reduced pressure. The resulting residue was crystallized upon trituration with diethyl ether and ethyl acetate and the solid was recrystallized from ethanol to provide compound **30**. Mp 132–133°C, yield 46%. $^1$H NMR (δ, ppm, in DMSO-$d_6$): 2.25–2.29 (m, 4H, $CH_2$), 2.62–2.67 (m, 4H, $CH_2$), 3.26 (s, 2H, $CH_2$), 3.37 (s, 2H, $CH_2$), 3.43–3.52 (m, 4H, $CH_2$), 3.48 (s, 2H, $CH_2$), 3.67 (s, 3H, $CH_3O$), 3.69 (s, 3H, $CH_3O$), 3.71 (s, 3H, $CH_3O$), 6.59–7.18 (m, 6H, ArH). Anal. Calcd for $C_{25}H_{33}N_3O_4$: C, 68.31; H, 7.57; N, 9.56. Found: C, 68.51; H, 7.72; N, 9.39.

For the biological evaluation, the hydrochloride salts of compounds **5–7** and **9–30** were prepared as follows: the free bases were dissolved in DCM and HCl (g) was bubbled over a period of 1 h. The solvent was removed under reduced pressure to give the corresponding hydrochloride derivatives which were crystallized by diethyl ether. The obtained compounds were characterized by elemental analysis and the melting points are reported later.

**2-Benzyl-1,2,3,4-tetrahydro-6,7-dimethoxyisoquinoline hydrochloride (5·HCl).** Mp 243–245°C. Anal. Calcd for $C_{18}H_{21}NO_2$·HCl: C, 67.60; H, 6.93; N, 4.38; Cl 11.08. Found: C, 67.72; H, 6.69; N, 4.52; Cl 11.23.

## INHIBITION OF AChE AND BChE

The cholinesterase assays were performed using colorimetric method reported by Ellman [19]. The assay solution consisted of a 0.1*M* phosphate buffer pH 8.0, with the addition of 0.01*M* 5,5′-dithio-bis(2-nitrobenzoic acid), 0.044 Unit/mL human recombinant AChE or BChE derived from human serum and 0.037*M* of substrate (acetylthiocholine iodide or butyrylthiocholine iodide, respectively). All the reagents were purchased from Sigma Chemical Company. AChE and BChE were dissolved in 0.1*M* phosphate buffer pH 8.0 containing Triton X-100 0.1%. The enzymes were diluted before use in order to reach an activity ranging between 0.250 and 0.100 AU $min^{-1}$ in the final assay conditions. Stock solutions of the tested compounds were prepared in water. Different concentrations of each test compound (analyzed in triplicate) were used to obtain inhibition of ACh- and BChE activity ranging between 20 and 80%. Following a 20 min pre-incubation at 37°C with inhibitor and enzyme, the reaction was started by the addition of substrate. Initial rates were determined at 37°C by measuring the absorbance at 412 nm every 1 min during 5 min with a Beckman DU 800 spectrophotometer. The reaction rates were compared and the percent inhibition due to the presence of test compounds was calculated. Blanks containing all components except enzyme were run in order to account for nonenzymatic reactions. Tacrine (0.5 μ*M*), a reversible, non selective inhibitor of AChE and an ever stronger inhibitor of BChE was used to test assay efficiency (–65% and –93%, respectively). The percent inhibition of the enzyme activity due to the presence of increasing test compound concentration was calculated by the following expression: $100 - (v_i/v_0 \times 100)$, where $v_i$ is the initial rate calculated in the presence of inhibitor and $v_0$ is the enzyme activity. The concentration producing 50% inhibition ($IC_{50}$) was calculated using a computer programme (SAS/STAT) of the method of Litchfield and Wilcoxon.

Some halogen-free acyclic task-specific ionic liquids (TSILs) were synthesized as novel and recyclable catalysts for the synthesis of 5-oxo-5,6,7,8-tetrahydro-4H-benzo[b]pyrans by one-pot three-component condensation of aromatic aldehyde, malononitrile (or ethyl cyanoacetate), and dimedone (or 1,3-cyclohexanedione) in water. The condensation accomplished successfully with good yields ranged from 86 to 94%. After the reaction, the products could simply be separated from the catalyst/water, and the catalyst could be reused at least 10 times without noticeably decreasing the catalytic activity.

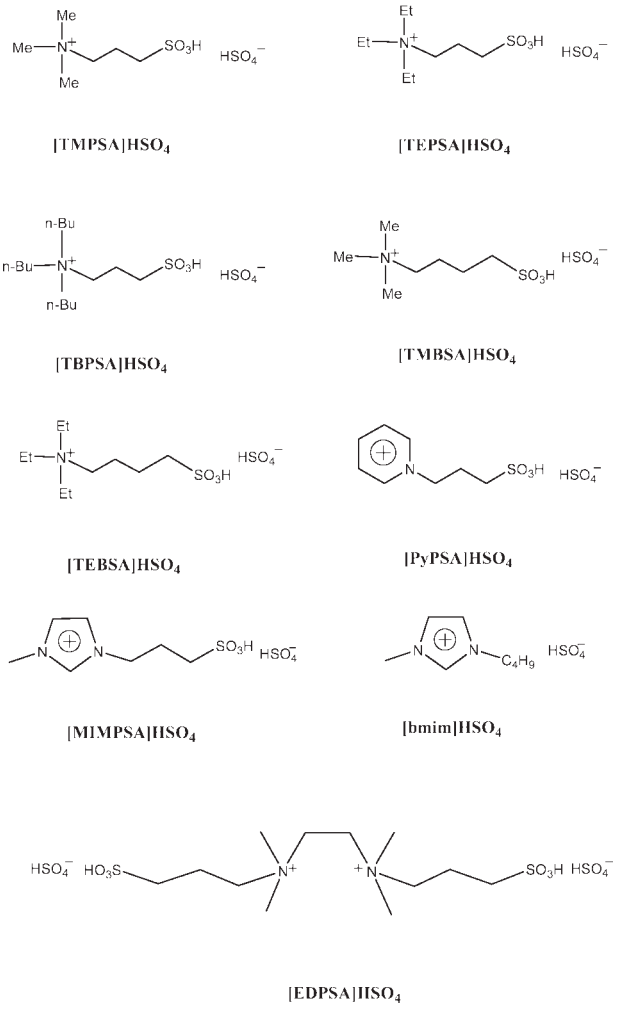
## INTRODUCTION

4*H*-Benzopyrans have attracted considerable attention because of their useful biological and pharmacological properties [1]. The synthesis of 5-oxo-5,6,7,8-tetrahydro-4*H*-benzo[b]pyrans usually involves a condensation of appropriate active methylene carbonyl compounds, aromatic aldehydes, and malononitrile (or cyanoacetates) catalyzed mainly by organic and mineral acids in organic solvents, which often suffer from the drawbacks of low yield, high reaction temperature, toxicity and difficulty in product separation. Recently, many synthetic methods for preparing these compounds have been reported by the condensation of aromatic aldehydes and active methylene carbonyl compounds in the presence of phase transfer catalyst [2], rare earth perfluorooctanoates [3], KF-Alumina [4], sodium selenate [5], and proline [6] as catalysts, as well as with the assistance of microwave [7] or ultrasound irradiation [8]. However, the search for the new readily available and green catalysts is still being actively pursued these years.

Ionic liquids have attracted wide interest as environmental benign catalysts or excellent alternatives to organic solvents these years because of their favorable properties such as negligible volatility, high thermal stability [9]. Brønsted acidic or basic task-specific ionic liquids (TSILs) are designed to replace traditional acids or bases in organic synthetic procedure. In view of both the advantages and disadvantages of homogeneous and heterogeneous catalytic reactions, the use of TSILs as reaction medium/catalytic system may offer a convenient solution to both the solvent emission and catalytic recycling problem. Some researchers have already used ionic liquids as solvents/catalysts in condensation reactions [10–12]. Recently, Luo and coworkers [13] reported a new temperature-dependent biphasic system comprising PEG-1000-based acidic ionic liquid/toluene, and it is used in preparation of benzopyrans. Chen *et al*. [14] used *N*,*N*-dimethylamino-functionalized basic ionic liquid to catalyze one-pot multicomponent reaction for the synthesis of benzopyrans. In fact, the use of Brønsted-acidic or basic TSILs as catalysts is an area of ongoing activity; however, the development and exploration of TSILs are currently in the preliminary stage. On the other hand, reactions in aqueous media may offer many advantages such as simple operation and high efficiency in many organic reactions. Thus, it is necessary to carry out this condensation using TSILs as catalysts in aqueous media.

In our previous work, some novel and cheap $SO_3H$-functional halogen-free acidic ionic liquids that bear an

**Scheme 1**



alkane sulfonic acid group in an acyclic trialkylammonium cation have been synthesized to catalyze some organic reactions [15]. In continuation of our work in studying acid-catalyzed reactions in ionic liquids, we report here the synthesis of 5-oxo-5,6,7,8-tetrahydro-4*H*-benzo[b] pyrans by condensation of aromatic aldehyde, malononitrile (or ethyl cyanoacetate), and dimedone (or 1,3-cyclohexanedione) in water catalyzed by acidic ionic liquids.

## RESULTS AND DISCUSSION

The preparation of $SO_3H$-functionalized halogen-free acidic ionic liquids (Scheme 1) was made up of two-step atom economic reaction. The chemical yields for both the zwitterions formation and acidification steps were essentially quantitative since neither reaction produced byproducts. The preparation of [bmim]$HSO_4$ was accomplished by anion metathesis with $NaHSO_4$ in good yield of 96%.

The fresh new TSILs with $HSO_4^-$ anion are somewhat viscous colorless or pale brown liquids at room temperature. All produced TSILs are entirely miscible with water and soluble or partly soluble in organic solvents.

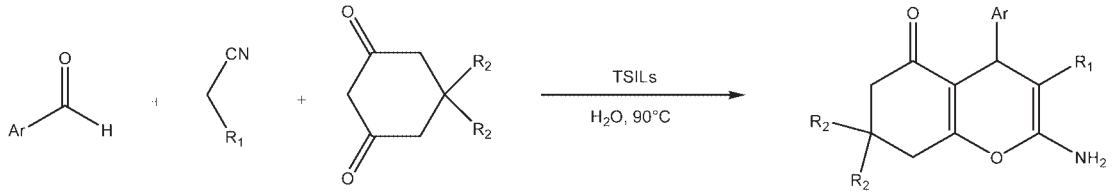
To optimize the reaction conditions (Scheme 2), for the beginning of this study, benzaldehyde, malononitrile, and dimedone were used as the model reactants at 90°C in TSILs/water for a length of time to compare the catalytic performance of the TSILs in aqueous medium. As shown in Table 1, no desirable product could be detected when a mixture of model reactants was heated at 90°C for 8 h in the absence of ionic liquid (Table 1, entry 1), which indicated that the catalysts should be absolutely necessary for this condensation. All the nine TSILs proved to be very active, leading to 82–90% yield of 5-oxo-5,6,7,8-tetrahydro-4*H*-benzo[b]pyrans in the presence of 10% TSILs (entries 5, 10–17). In addition, ionic liquids containing the longer length of alkyl chain are relatively efficient; however, the better immiscibility of the resulted product with the shorter length of alkyl chain ionic liquids should facilitate the separation in work-up procedure. Hence, [TEBSA]$HSO_4$ should be the best catalyst for this condensation among these ionic liquids and the optimized reaction conditions went to entry 5 in Table 1.

Condensation reaction in [TEBSA]$HSO_4$/$H_2O$ gave a yield of 89%, which was nearly the same as that in organic solvents. The chemical industry is under considerable pressure to replace many of the volatile organic compounds (VOCs) that are currently used as solvents in organic synthesis. As a clean and cheap solvent, it is of great importance to carry out this reaction in water for the environmental and economic reasons.

While optimizing the reaction condition, the recycling performance of [TEBSA]$HSO_4$ was investigated using the above-mentioned model reaction. After the separation of the products **4**, the catalyst-containing filtrate was reused in the next run without further purification. The data listed in Table 2 showed that the [TEBSA]$HSO_4$ could be reused at least 10 times without obviously decreasing of the catalytic activity. Compared with the traditional solvents and catalysts, the easy and efficient recycling performance is also an attractive property of the ionic liquids for the environmental protection and economic reasons.

Then, the condensation reaction of various aromatic aldehyde, malononitrile (or ethyl cyanoacetate), and dimedone (or 1,3-cyclohexanedione) in the presence of [TEBSA]·$HSO_4$ as an environmentally benign ionic liquid was explored under the optimized reaction conditions described earlier, and the results are presented in Table 3. It can easily be seen that in all cases the reactions gave the products in good yields ranged from 86 to 94%. Aromatic aldehydes carrying either electron-donation or electron-withdrawing substituents afforded good yields of 5-oxo-5,6,7,8-tetrahydro-4*H*-benzo[b] pyrans in high purity. However, the product obtained is

**Scheme 2**



racemic, which indicated that the reaction was accomplished with no regioselectivity in this procedure.

In conclusion, some acyclic TSILs such as [TEBSA]·$HSO_4$, [TBPSA]·$HSO_4$, [EDPSA]·$HSO_4$, and so on were synthesized in an atom-economic procedure. These ionic liquids were found to be efficient catalysts for the synthesis of 5-oxo-5,6,7,8-tetrahydro-4*H*-benzo[b] pyrans in aqueous media, offering the practical convenience in the product separation from the ionic liquid/water system. The merit of this methodology is that it is simple, mild, and efficient, and the raw materials are cheaper than TSILs with imidazole or triphenylphosphine as the cation. Therefore, we believe that the work reported here would have potential application in green chemistry.

## EXPERIMENTAL

Melting points were determined on X-6 microscope melting apparatus. The IR spectra were run on a Nicolete spectrometer and expressed in $cm^{-1}$ (KBr). $^1H$ NMR spectra were recorded on Bruker DRX300 (300 MHz) and $^{13}C$ NMR spectra on Bruker DRX300 (75.5 MHz) spectrometer. Elemental analyses were recorded on Perkin–Elmer C spectrometer. Mass spectra were obtained with automated FININIGAN Trace Ultra-Trace DSQ GC/MS spectrometer. All chemicals (AR grade) were commercially available and used without further purification.

**Synthesis of halogen-free $SO_3$-functional acidic ionic liquids (TSILs).** All acyclic $SO_3H$-functionalized halogen-free acidic ionic liquids, such as [TEBSA]$HSO_4$, [TBPSA]$HSO_4$, were synthesized according to our previous methods [15d], and the pyridine, imidazole-based acidic ionic liquids for comparison were synthesized according to reported methods [15c]. Their structures were analyzed by $^1H$ NMR, $^{13}C$ NMR, and MS spectral data. The selected spectral data for acidic halogen-free TSILs.

## INTRODUCTION

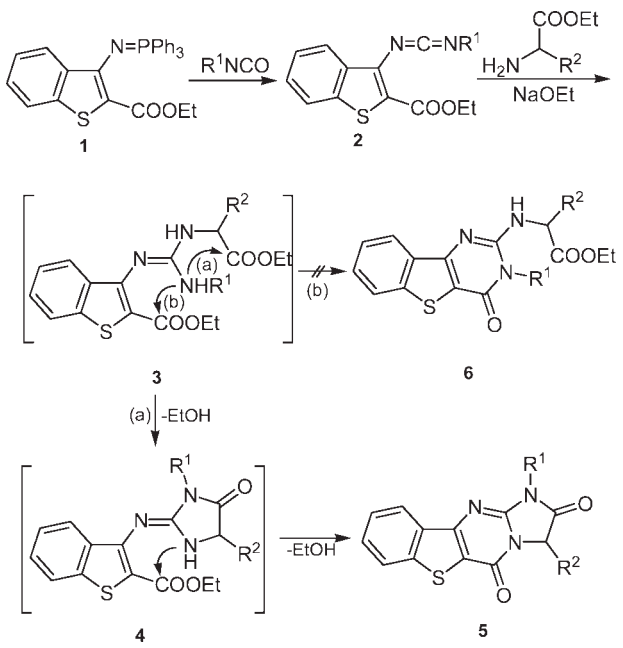
Thienopyrimidines are of great importance because of their significant antifungal and antibacterial activities, as well as their good anticonvulsant and angiotensin or $H_1$ receptor antagonistic activities [1,2]. Although some derivatives of benzothienopyrimidines have shown good antithrombotic, cardiotonic, and α adrenergic antagonistical activities [3,4], there are few reports on synthesis of benzothieno[3,2-*d*]pyrimidin-4(3*H*)-ones, which are of considerable interest as potential biological active compounds or pharmaceuticals. On the other hand, heterocycles containing imidazolones nucleus also exhibit various biological activities. Several of them have shown good antibacterial, antifungal activities or being used as leukotriene $B_4$ receptor antagonist and potassium channel openers [5,6]. The introduction of an imidazolone ring to the benzothieno[3,2-*d*]pyrimidin-4(3*H*)-one system is expected to influence the biological activities significantly. However, this tetracyclic system has been much less investigated and there is no report on synthesis of benzothieno[3,2-d]-imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones, probably due to the fact that the tetracyclic system is not easily accessible by routine synthetic methods.

The aza-Wittig reactions of iminophosphoranes have received increased attention in view of their utility in the synthesis of nitrogen heterocyclic compounds [7–23]. Annelation of ring systems with N-heterocycles by means of an aza-Wittig reaction has been widely utilized because of the availability of functionalized iminophosphoranes. Recently, we have been interested in the synthesis of pyrimidinones and imidazolones *via* aza-Wittig reaction, with the aim of evaluating their fungicidal activities [24–32]. We also reported an efficient synthesis of benzothieno[3,2-*d*]pyrimidin-4(3*H*)-ones *via* aza-Wittig reaction of β ethoxycarbonyl iminophosphorane **1** with isocyanate and subsequent reaction with various nucleophiles under mild conditions [29]. However, the reaction of α-amino ester with β ethoxycarbonyl carbodiimde was not investigated. Here, we wish to report further a selective synthesis of the previously unreported benzothieno[3,2-d]imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones *via* a tandem aza-Wittig/heterocumulene-mediated annulation.

## RESULTS AND DISCUSSION

Iminophosphorane **1** reacted with isocyanates to give carbodiimides **2**, which were allowed to react with α-amino ester at room temperature in the presence of catalytic amount of sodium ethoxide to give benzothieno[3,2-d]imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones **5** selectively (Scheme 1). A variety of α-amino ester and isocyanate could be used for this synthetic strategy and the products **5** were obtained in good yields (Table 1). Presumably, the reaction of carbodiimides **2** with α-amino ester should afford primarily guanidine intermediates of type **3**. From these intermediates **3**, the formation of two cyclized products imidazolone **4** (*via* path a), benzothieno[3,2-d]pyrimidin-4(3*H*)-one **6** (*via* path b) could in principle take place. The formation of **5** might probably due to a tandem cyclization of **3** to

**Scheme 1**



imidazolone intermediate **4** and further base catalytic cyclization between the imidazolone ring's NH and ethoxylate. An imidazolone intermediate **4d** had been successfully isolated before the reaction mixture was treated with sodium ethoxide. Further treatment of **4d** with sodium ethoxide also gave the cyclized product **5d**. The result illustrated that the imidazolone **4** is more easily produced from intermediate **3** than benzothieno[3,2-d]pyrimidin-4(3*H*)-one **6**, and the cyclization of **4** to product **5** should be carried out in strong basic condition.

When chiral α-amino ester was used, recemization of the product **5** took place completely under the reaction condition. This is probably due to the easy recemization of C-3 of the benzothieno[3,2-d]imidazo[1,2-a] pyrimidine-2,5-(1*H*, 3*H*)-dione ring under the strong basic condition.

The structure of benzothieno[3,2-d]imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones **5** was confirmed by their spectrum data. For example, the $^1$H NMR spectrum of **5b** shows two singlets at 4.98 ppm as quarterlets and 1.95 ppm as doublet due to the CH and $CH_3$, respectively. The signals attributable to the Ar—Hs are found at 8.12 ppm–7.44 ppm as mutiplets. The IR spectra of **5b** revealed two C=O absorption bands at 1761 and 1683 $cm^{-1}$ due to the imidazolone and pyrimidinone carbonyl group, respectively. The MS spectrum of **5b** shows strong molecular ion peak at m/z 347 with 100% abundance. Furthermore, a single crystal of **5b** was obtained from a $CH_2Cl_2$ solution of **5b**. X-ray structure analysis verified again the proposed structure (Fig. 1). The pyrimidine ring has a flattened-boat conformation and a pseudo-mirror plane running through the bridgehead N atom and the opposite C atom. The dihedral angles between the planar fused benzene (*A*), thienyl (*B*), imidazole (*D*), and substituent phenyl (*E*) rings are

In summary, we have developed an efficient synthesis of benzothieno [3,2-d]imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones *via* a cascade aza-Wittig/heterocumulene-mediated annulation. This method utilizes easily accessible starting material and allows mild reaction conditions, straightforward product isolation and good yields.

## EXPERIMENTAL

Melting points were determined using a X-4 model apparatus and were uncorrected. MS were measured on a Finnigan Trace MS spectrometer. NMR spectra were recorded in $CDCl_3$ on a Varian Mercury Plus 400 (400 Hz) spectrometer and chemical shifts (δ) were given in ppm using $(CH_3)_4Si$ as an internal reference (δ = 0). IR was recorded on a PE-983 infrared spectrometer as KBr pellets with absorption in $cm^{-1}$. Elementary analyses were taken on a Vario EL III elementary analysis instrument. The X-ray diffraction data were collected on a Bruker SMART AXS CCD diffractometer.

**General procedure for the preparation of benzothieno [3,2-d]imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones (5).** To a solution of iminophosphorane **1** (0.96 g, 2 mmol) in dry methylene dichloride (15 mL) was added aromatic isocyanate (2 mmol) under nitrogen at room temperature. After the reaction mixture was stood for 6–8 h at 0–5°C, the solvent was removed off under reduced pressure and ether/petroleum ether (1:2, 20 mL) was added to precipitate triphenylphosphine oxide. Filtered, the solvent was removed to give carbodiimide **2**, which was directly used without further purification. A mixture of α-amino acid ester hydrochloride (2 mmol) and triethylamine (0.61 g, 4 mmol) in acetonitrile (10 mL) was stirred for 10 min and filtered. Then, the filtrate was added to the solution of carbodiimide **2** prepared above in dry methylene dichloride (10 mL) at room temperature. After stirring for 0.5 h, the solution was concentrated and anhydrous EtOH (10 mL) with several drops of EtONa in EtOH was added. The mixture was stirred for 4–6 h at room temperature The solution was concentrated under reduced pressure and the residual was recrystallized from methylene dichloride/petroleum ether to give benzothieno [3,2-d]-imidazo[1,2-a]pyrimidine-2,5-(1*H*, 3*H*)-diones **5**.

*O*-phenylene-diamine derivative containing colorimetric dinitroquinoxaline has been synthesized. Its UV-vis spectroscopy and $^1$H NMR investigation reveal that the receptor shows the strong binding ability for $AcO^-$, $F^-$, and $H_2PO_4^-$, moderate binding abilities for $OH^-$ and almost no binding abilities for $Cl^-$, $Br^-$, and $I^-$. The interaction of the receptor with studied anions achieving the recognition of anions is proposed to come from the N—H. . .F and potential C—H. . .F hydrogen bonding in its neutral form. The results indicate that it is well suitable for the anion complexation, which is presumably contributed to its ring topology possessing a rigidity conjugation system. Moreover, the molecular orbital level of this receptor and its tautomer were further determined by means of theoretical investigations.

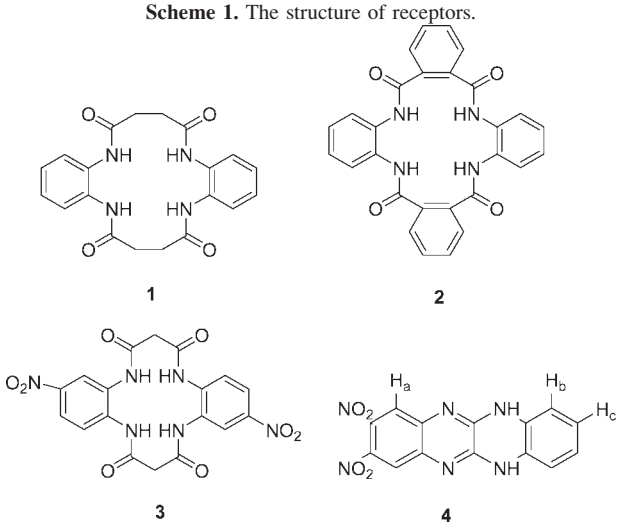
## INTRODUCTION

Host-guest systems for recognition of anionic guest species play an important role in the development of supramolecular chemistry [1]. The molecular recognition of anionic guests by synthetic hosts is an area of ever increasing research activity [2]. Study of anion receptors has special potential applications in the synthesis of anion sensors [3], membrane transmit carriers [4], and mimic enzyme catalysts, etc. [5,6]. Particularly there is a current interest in the synthesis of colorimetric neutral chemosensors for detection of anions. Synthetic nitrogen-based receptors designed for the selective binding of anions are usually either the positively charged ammonium salts, i.e., protonated polyamines and/or quaternary ammonium salts, or some of the neutral species, such as, amides, sulfonamides, pyrroles, ureas, and thioureas [7–9]. For example, in 1968, Park and Simmons [10] synthesized a series of dicyclopolyamines compounds and the results indicated that it is the protonated polyamines that interacted with anions. Lehn and coworkers [11–16] reported that during the interaction of polyamines with anions, the polyamines were in the form of protonated polyamines too. However, the neutral amine receptors which can interact with various anions have not yet been reported, and even more for achieving the possibility of the naked-eye detection about the bonding of anions. In the previous work, we studied the recognition property of 16-membered or 14-membered amide macrocycle (Scheme 1, **1**–**3**) with various anions [17,18]. In this article, we synthesized and studied the anion binding abilities of six-membered cycle, a neutral diamine receptor containing dinitroquinoxaline (Scheme 1, **4**) in order to find the difference of anion binding ability between macro and microcycle. The anion recognition properties of receptor **4** with different anions ($F^-$, $Cl^-$, $Br^-$, $I^-$, $AcO^-$, $H_2PO_4^-$, and $OH^-$) has been studied by UV-vis and $^1$H NMR experiment and the results indicate that the receptor shows higher binding abilities for $AcO^-$, $F^-$, and $H_2PO_4^-$ and the interaction of receptor **4** with various anions is in the form of a neutral diamine. This work is one of the progressive steps in pushing the development of an anion recognition method based upon the neutral amine recognition sites.

**Scheme 1.** The structure of receptors.



## RESULTS AND DISCUSSION

The interaction of receptor **4** with anions was investigated through the spectrophotometric titration by the addition of a standard dimethyl sulfoxide (DMSO) solution of the tetrabutyl ammonium salt (TBA) of the investigated anion to a DMSO solution of **4**.

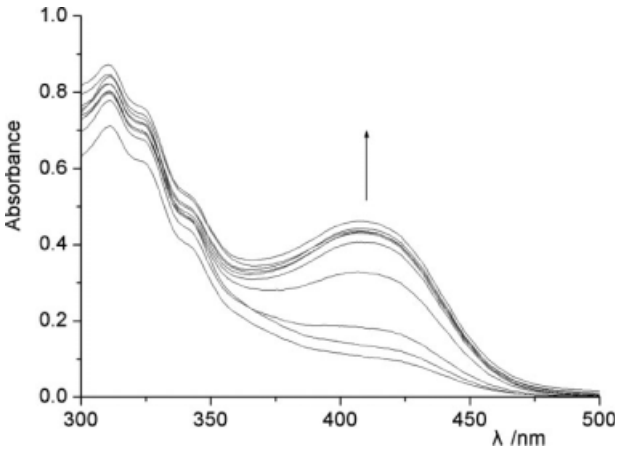


**Figure 1.** UV-vis spectrum of receptor **4** changes upon the addition of fluoride anion; [**4**] = $4.0 \times 10^{-5}$ mol/L, [$F^-$] = 0–$160 \times 10^{-5}$ mol/L. Arrows indicate the direction of increasing anion concentration.

Figure 1 shows the changes in the absorption spectrum of receptor **4** observed upon the addition of fluoride anion. In the absence of anion, the spectrum of receptor **4** is characterized by the presence of one peak at 315 nm. The addition of fluoride anion results in the development of a new band at 409 nm, changing the

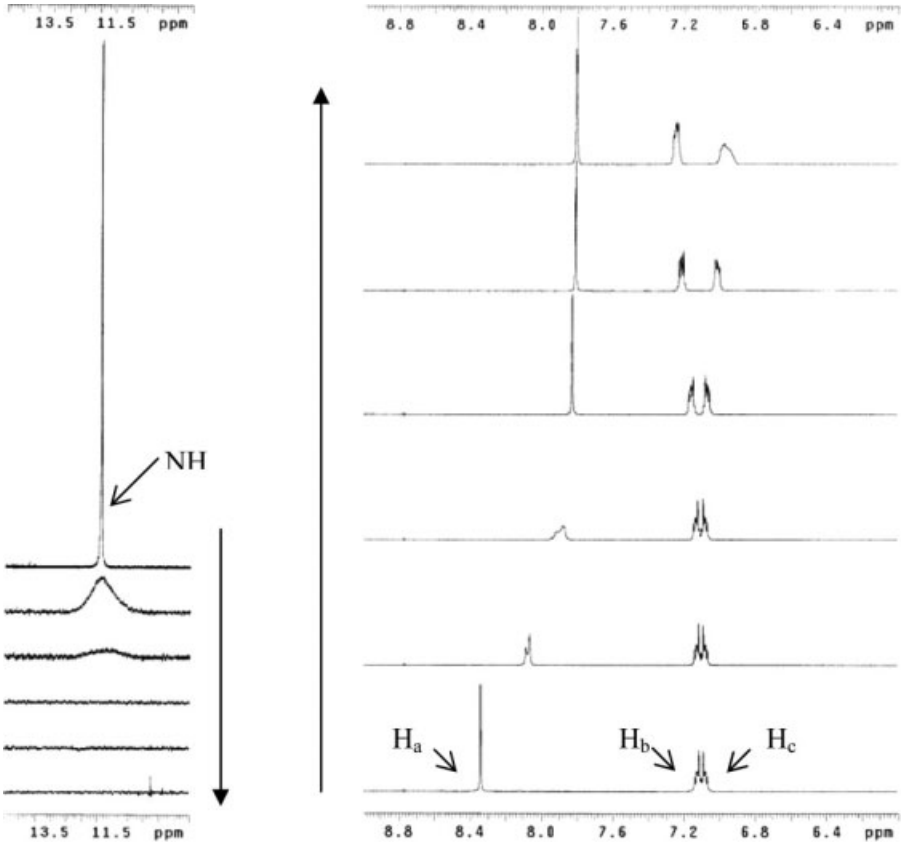

**Figure 2.** Plots of $^1$H NMR spectra of receptor **4** in DMSO-$d_6$ upon the addition of various quantities of $Bu_4NF$. The arrows' direction represent the additions of $Bu_4NF$ are 0, 0.5, 1, 2, 5, 10 equiv., respectively.

**Table 1**

Affinity constants of receptor **4** with various anions.

| Anion | $K_s$ ($M^{-1}$) |
|---|---|
| $AcO^-$ | $(3.20 \pm 0.35) \times 10^4$ |
| $F^-$ | $(1.32 \pm 0.33) \times 10^4$ |
| $H_2PO_4^-$ | $(1.12 \pm 0.12) \times 10^4$ |
| $OH^-$ | $(2.99 \pm 0.41) \times 10^3$ |

color of the solution from colorless to pale-yellow. The addition of $AcO^-$, $H_2PO_4^-$, and $OH^-$, respectively, induces a similar color change. On the other hand, exposure to $Cl^-$, $Br^-$ or $I^-$, i.e., species that do not bind to receptor **4** appreciably, do not lead to any noticeable change in the solution color. This phenomenon makes this system an effective anion sensor under these solution conditions.

Very recently, a number of fluorogenic and/or chromogenic anion sensors comprising recognition moieties, such as, urea, thiourea, or amide have been reported to undergo an anion-induced deprotonation [19–21]. According to these reports, there appears one new triplet resonance at 16.1 ppm, the characteristic resonance of bifluoride (F—H—F) and the chemical shifts of noninteracted sites' proton signals occur up-field. To look into the anion binding properties of receptor for fluoride on anion recognition, $^1H$ NMR titration experiments in DMSO-$d_6$ were performed (Fig. 2). From Figure 2, different patterns are observed in the titration ranges of 0–1 and 1–2 equiv. ranges. The NH signal (11.9 ppm) becomes broadened and the chemical shift of the phenyl signal $H_a$ upfield after the addition of 1 quantities of TBAF. During this process, the chemical shifts of $H_b$ and $H_c$ do not change. After the addition of 2 equiv of TBAF, the NH signal completely disappears and the shift of $H_a$ is stopped, only peak-shape change occur (from broad to sharp). The state of affairs can be accounted by hypothesizing that the first added fluoride anion establishes H-bonding interaction with the NH of receptor **4**. Due to the strong electron-withdrawing effect of $NO_2$, the shielding effect induced by H-bonding is more sensitive to $H_a$ than $H_b$ and $H_c$. Therefore, the signal of $H_a$ upfield and the signal of $H_b$, $H_c$ almost occurs no changes. On addition of 2 equiv. fluoride anion, detailed analysis reveals the significant upfield shifts of $H_c$, except $H_b$, which exhibits a downfield shift from 7.1 to 7.3 ppm, indicating the formation of potential C—H. . .F H-bonding during the titration [22].

Job plots for receptor **4** at 298 K with anions as guest in DMSO solution show the maxima at a mole fraction of 0.5, which signifies that the host binds the anionic guest in a 1:1 ratio. Affinity constants of receptor **4** for anionic species are calculated according to the eq. (1), 1:1 host-guest complexation [23–25].

$$X = X_0 + 0.5\Delta\varepsilon\{c_H + c_G + 1/K_s - [(c_H + c_G + 1/K_s)^2 - 4c_H c_G]^{1/2}\} \quad (1)$$

where $c_G$ and $c_H$ are the concentration of guest and host, respectively. $X$ is the intensity of absorbance at certain concentration of host and guest. $X_0$ is the intensity of absorbance of host when the anion is not added. $K_s$ is the affinity constant of host-guest complexation. $\Delta\varepsilon$ is the change in molar extinction coefficient.

Affinity constants of receptor **4** for anionic species are summarized in Table 1. The affinity constants of receptor with $Cl^-$, $Br^-$, and $I^-$ cannot be determined because the anions almost have no binding abilities with receptor. From Table 1, the anion affinity of receptor **4** is decreased in the order of $AcO^- > F^- > H_2PO_4^- > OH^- >> Cl^-$, $Br^-$, and $I^-$. Among the anions investigated, the highest affinity is observed with acetate. The reason may be that only the acetate matches perfectly with receptor **4** geometrically and thus has the highest affinity with receptor **4**.

As is well-known, neutral amines almost have no binding ability with anions. However, receptor **4** we synthesized has high affinity with some anions. We speculate that the electron density of diamine moieties is decreased due to the very strong electron-withdrawing effect of $NO_2$. Theoretical investigation on molecular orbital level using density functional theory at B3LYP/3-21G level with Gaussion03 program [26] can prove this (Fig. 3). In receptor **4**, the charges of the nitrogen atoms interacted with anion (N11, N12) are −0.569624 and −0.569623, respectively. The charges of N11 and N12 interacted with anions in non-containing $NO_2$

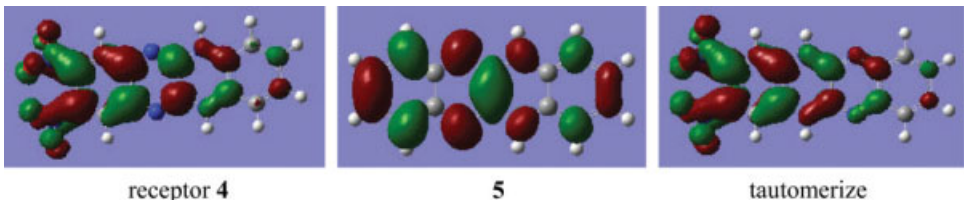

**Figure 3.** Molecular orbital level of receptor **4**, its tautomer and compound **5**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

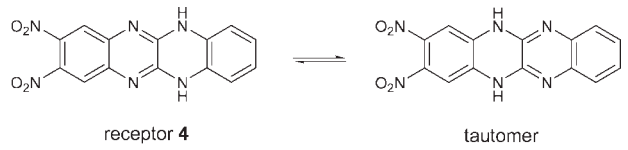

**Figure 4.** The structure of receptor **4** and tautomer.

compound (**5**) are both −0.581427. The stronger the binding ability, the smaller the charge of N11 and N12. Thus, the ability of forming the hydrogen bond between diamine and anion is appeared in receptor **4**. In addition, receptor **4** exists as tautomer (Fig. 4). Whether does receptor **4** or its tautomer interact with various anions? The molecular orbital level of its tautomer was optimized (Fig. 3). The charges of N11 and N12 in tautomer are both −0.655013. Therefore, receptor **4** may interact with anions rather than its tautomer.

These results enable us to assume that the binding of anion with diamine moieties will induce a spectral change in the complex (Fig. 5). From Figure 5, the difference in spacer units are responsible for the anion selectivity. Fluoride anion, a spherical ion, interacts with diamines through the H-bonding. Both of the two oxygen atoms of acetate anion, forming a ''Y'' configuration, probably interact with diamines through two H-bonding. The affinity constant of acetate anion is higher than that of fluoride anion due to the ''Y'' configuration, acetate anion, is better matched with receptor than spherical configuration, fluoride anion in space. Therefore, the affinity constant is related on the matched degree between receptor and anion. Here, it should be pointed out that the proposed binding mode in Figure 5 as drown is planar structure and does not present its geometry. According to optimized results, the geometry of receptor **4** is planar. It may change under the inducement of anions, especially the NH ring may distort [27].

However, the selectivity between $AcO^-$ and $F^-$ is unfortunately not large enough for any practical application purpose. The selectivity is probably also influenced by the size complementarity between anions and cavity.

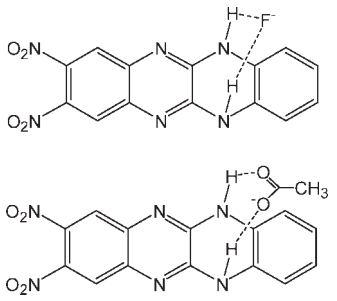

**Figure 5.** A proposed hydrogen bond configuration formed between receptor **4** and anions.

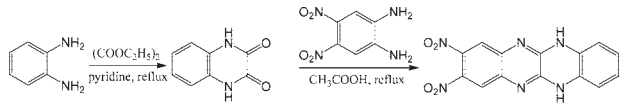
**Scheme 2.** The synthesis route of **4**.



In previous papers, 16-membered and 14-membered amide macrocycle (receptor **1**-**3**) show high selectivity for certain anion. So, we may be further modify the receptor by tuning the size of the ring in receptor **4** (for example, altered to a 16-membered or a 18-membered ring, etc.) in order to find a receptor containing amine recognition site that fits well for $AcO^-$, $F^-$, or other anions geometrically.

## CONCLUSION

In summary, we have synthesized a neutral cyclic diamine containing phenyl ring and colorimetric dinitroquinoxaline. The UV-vis titration and $^1$H NMR experiments indicate that receptor **4** shows the strong affinity for $AcO^-$, $F^-$, and $H_2PO_4^-$, moderate affinities for $OH^-$, and almost no affinities for $Cl^-$, $Br^-$, and $I^-$. Moreover, the interaction of the synthetic receptor with $F^-$, $AcO^-$, $H_2PO_4^-$, and $OH^-$ results in a visible change of color, and the receptor can thus be used as a colorimetric sensor. Receptor **4** interacts with various anions in the form of a neutral diamine, not protonated polyamines. In addition, we found that the selectivity of six-membered amine cycle (**4**) is not better than that of 16- or 14-membered amide cycle (**1**–**3**). In addition, theoretical investigations show that receptor **4** may interact with anions rather than its tautomer.

This work is one of the progressive steps in pushing the development of an anion recognition method based upon the neutral amine recognition site. Further studies on this line are in progress.

## EXPERIMENTAL

Most of the starting materials were obtained commercially and all reagents and solvents used were of analytical grade. All anions, in the form of TBAs, were purchased from Sigma-Aldrich Chemical Co., stored in a desiccator under vacuum containing self-indicating silica, and used without any further purification. DMSO was distilled *in vacuo* after dried with $CaH_2$. Tetra-*n*-butylammonium salts (such as $(n\text{-}C_4H_9)_4NF$, $(n\text{-}C_4H_9)_4NCl$, $(n\text{-}C_4H_9)_4NBr$, $(n\text{-}C_4H_9)_4NI$, $(n\text{-}C_4H_9)_4NAcO$, $(n\text{-}C_4H_9)_4NH_2PO_4$, and $(n\text{-}C_4H_9)_4NOH$) were dried for 24 h in vacuum with $P_2O_5$ at 333 K before use. C, H, and N elemental analyses were made on Vanio-EL. $^1$H NMR spectra were recorded on a Varian UNITY Plus-400 MHz Spectrometer. FAB-MS was made on VG ZAB-HS. UV-vis spectroscopy titrations were made on Shimadzu UV2450 spectrophotometer.

*N*,*N*′-(*o*-phenylene)-6,7-dinitro-2,3-diamino-quinoxaline (**4**) was synthesized according to the route shown in Scheme 2.

**1,4-Quinoxaline-2,3-dione [28].** *o*-diaminebenzene (10.8 g, 0.1 mol), diethyl oxalate (13.5 mL, 0.1 mol), and pyridine (200 mL) were added in 250 mL three-neck. The mixture refluxed with $N_2$ for 72 h. After cooled, the mixture was filtrated and we obtained colorless solid. The solid was washed with ethanol, ether, and dried in vacuum. Yield 61.3%. $^1$H NMR (400 MHz DMSO-$d_6$) δ 11.9 (s, 2H), 7.1 (m, 4H). Anal. Calcd. for $C_8H_6N_2O_2$: C, 59.26; H, 3.73; N, 17.28; Found: C, 59.73; H 3.58; N, 17.67. FAB-MS (*m*/*z*): 163 $(M + H)^+$.

***N*,*N*′-(*o*-Phenylene)-6,7-dinitro-2,3-diamino-quinoxaline (4).** 1,4-quinoxaline-2,3-dione (2.5 mmol, 0.81 g), 4,5-dinitro-*o*-diaminebenzene (2.5 mmol, 0.49 g), and acetic acid (100 mL) were refluxed for 12 h. After cooled, the mixture was filtrated and we obtained brown solid. The solid was washed with water, ethanol, and recrystallized, respectively, from acetic acid and dried in vacuum. Yield 84.8%. $^1$H NMR (400 MHz DMSO-$d_6$) δ 11.9 (s, 2H), 8.3 (s, 2H), 7.1 (m, 4H). Anal. Calcd. for $C_{28}H_{16}N_{12}O_8 \cdot 2CH_3COOH$: C, 50.01; H, 3.15; N, 21.87; Found: C, 49.73; H, 3.58; N, 21.77.

**Acknowledgments.** This work was supported by 20371028 and 20671052 project from the National Natural Science Foundation of China.

A series of 5-arylidene derivatives **3a-k**, as potential antifungal agents, were synthesized in good to high yields by the reaction of 2-benzimidazolylimino-4-thiazolidinone and corresponding aromatic aldehyde in a buffered medium. These compounds were evaluated for their antifungal activities against four agricultural fungi, *Botrytis elliptica*, *Fusarium graminearum, Phytophthora nicotianae*, and *Rhizoctonia solani*. Thereby, it was found that the compound **1** exhibits an antifungal effect against *P. nicotianae* and *B. elliptica*, comparable with carbendazim as a standard antifungal. Our results may provide some guidance for development of some novel benzimidazole-based antifungal lead structures.

## INTRODUCTION

Thiazolidin-4-ones constitute an important class of heterocyclic compounds because of their broad range of biological activities [1–5]. It is also well known that thiazolidin-4-ones have antifungal activity [6–9] and are used as a new class of potent anti-HIV-1 agents with marked reverse transcriptase (RT) inhibitory effects [10,11].

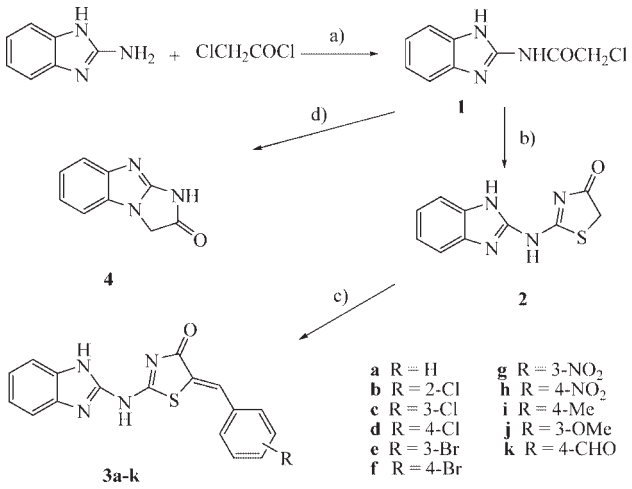
Benzimidazole derivatives are also of wide interest because of their diverse biological activities, such as anticancer, antiproliferative, antiviral, and platelet-anti-aggregating agents [12–16]. Benzimidazoles containing a subunit group, especially a methyl carbamate group on position C(2) (Carbendazim), are found as potential antifungal agent for plants [17]. Because of the aforementioned findings and also because of the incessant interest in the chemistry and antimicrobial activity of benzimidazoles, substantial attention should be paid to the synthesis of novel benzimidazole derivatives especially benzimidazolyl substituted 2-iminiothiazolidin-4-ones. In view of these reports, we extended our research for the synthesis of a novel class of benzimidazole substituted 2-iminiothiazolidin-4-ones resulting from the reaction of 2-(1H-benzimidazol-2-ylamino)-1,3-thiazol-4(5H)-one **2** with various aromatic aldehydes. The antifungal activity of these compounds was investigated against some agricultural fungi.

## RESULTS AND DISCUSSION

Compound **1**, N-(1*H*-benzimidazol-2-yl)-2-chloroactamide, was synthesized from 2-amino benzimidazole using a variation of the reported procedure [9]. The compound **1** on heterocyclization in the presence of ammonium thiocyanate in refluxing ethanol (96%) efficiently produced compound **2** without any further purification [5]. Compounds **3a–k** were obtained by refluxing **2** with corresponding aromatic aldehydes in buffered glacial acetic acid (Scheme 1). Compound **3k** was selectively obtained by the reaction of **2** with an aromatic dialdehyde. The presence of an aldehyde group in the phenyl ring of the product was evidently confirmed by $^1$H NMR, Ms, and infrared (IR) data. Finally, compound **4** was synthesized by refluxing **1** in the presence of $K_2CO_3$ in acetone. All new compounds were characterized using spectroscopy data (IR, $^1$H, and $^{13}$C NMR).

Compounds **2** and **3a–k** exist as lactam forms on the basis of the mechanism suggested by Vicini *et al.* [18]. This mechanism is more reasonable than that one led to

**Scheme 1.** Conditions: (a) Acetone, 2 h, reflux. (b) $NH_4SCN$, 96% EtOH, 8 h, reflux. (c) AcOH, AcONa, 3–10 h, reflux. (d) Acetone, $K_2CO_3$, 4 h, reflux.



the formation of an imine structure **5** as shown in Scheme 2 [9]. In $^1$H NMR spectra of compounds **2** and **3a–k**, the resonance of two NH protons at 12.13 and 12.37–12.85 ppm are in support of the lactam form, because an imine proton appears at much higher field (about 9.70) [19,20]. The $^1$H NMR and IR spectroscopy data (the absence signal of an OH group) is in agreement with a γ-lactam, confirm the $\mathbf{2}_a$ and $\mathbf{2}_b$ tautomeric forms in the solid and liquid states (Scheme 2).

Compounds (**1, 2, 3a–k, 4**) were tested for fungicidal activity against four agricultural fungi. The results (Table 1) show that the compounds **1** and **2** have higher antifungal activity than others and are comparable with carbendazim. The more interesting result could be observed in the treatment of compound **1**, which could completely inhibit the growth of *Phytophthora nicotianae* and *Botrytis elliptica* isolates. Compounds **3b** and **3f** also completely inhibit the growth of *B. elliptica*. Although, all of the compounds have the inhibiting effect against *B. elliptical*, no *Rhizoctonia solani* have. The other results are briefly mentioned in Table 1. It may also be noticed that introduction of benzylidene group at C-5 decreased the fungicidal activity.

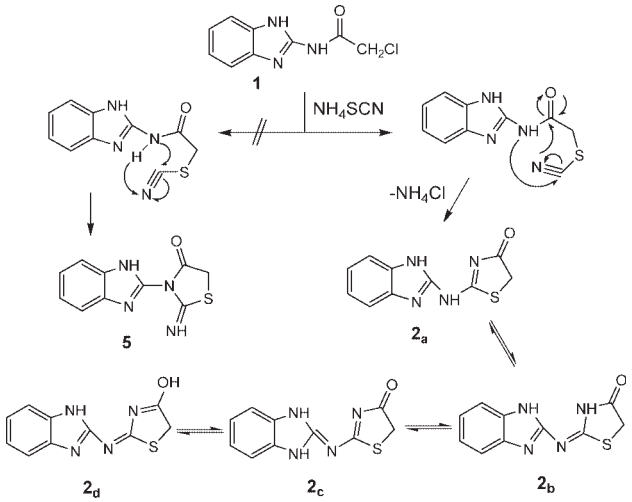
In conclusion, we have described the synthesis of 2-benzimidazolylimino-5-arylidene-4-thiazolidinones, **3a–k** by the reaction of 2-benzimidazolylimino-4-thiazolidinone, **2** and corresponding aromatic aldehydes in a buffered medium with good to high yields. We also evaluated their antifungal activities against four agricultural fungi.

**Scheme 2**



## EXPERIMENTAL

All used chemicals were prepared from Merck or Fluka Company. Melting points were determined using an electro thermal digital apparatus and are uncorrected. IR spectra were performed on a Galaxy series FT IR 5000 spectrometer using KBr discs. NMR spectra were recorded on a Bruker (300 MHz) spectrometer. Chemical shifts (ppm) were referenced to the internal standards tetramethylsilane. Elemental analyses were performed on a Vario EL III elemental analyzer. Reactions were monitored by thin layer chromatography (TLC).

**Synthesis of N-(1H-benzimidazol-2-yl)-2-chloroactamide (1).** A solution of 2-amino benzimidazole (4.0 g, 0.03 mole) in dry acetone (40 mL) was cooled to 0–5°C. A solution of chloroacetyl chloride (4.78 mL, 0.06 mole) in dry acetone (15 mL) was slowly added to it with vigorous stirring. The reaction mixture was refluxed for 2 h, and the solvent was removed under reduced pressure. The residue was washed with sodium bicarbonate (5%) and subsequently with water. The crude product was air dried and crystallized from ethanol to give the colorless crystals **1**, 4.1 g (65%), mp 219–222°C; $R_f$ (ethyl

acetate/hexane 3:1) 0.65; IR (KBr): 3333 (NH), 3055 (CH), 2966 (CH$_2$), 1685 (C=O), 1633, 1583 (C=N), 1456 (C=C) cm$^{-1}$; $^1$H NMR (DMSO-d$_6$, 300 MHz): δ 4.37 (s, 2H, CH$_2$), 7.09–7.13 (m, 2H, H-Ar), 7.43–7.46 (q, 2H, H-Ar), 12.08 (s, 2H, NH); $^{13}$C NMR (DMSO-d$_6$, 75 MHz): δ 43.9 (CH$_2$), 114.3, 121.9, 135.7, 147.4 (C=N), 167.7 (C=O). Anal. Calcd. for $C_9H_8ClN_3O$: C, 51.56; H, 3.85; N, 20.04. Found: C, 51.45; H, 3.82; N, 20.14.

**Synthesis of 2-(1H-benzimidazol-2-ylamino)-1,3-thiazol-4(5H)-one (2).** A solution of compound **1** (3.0 g, 0.01 mole) and ammonium thiocyanate (1.96 g, 0.02 mole) in 50 mL of ethanol (96%) was refluxed for 8 h and allowed to stand for 2 h. The precipitate was filtered, washed with aqueous ethanol, and recrystallized from dioxane/water to give light yellow crystals **2** to yield 2.7 g (81%), mp 284°C; $R_f$ (ethylacetate/hexane 3:1) 0.5; IR (KBr): 3138 (NH), 3065 (CH-Ar), 2926 (CH), 1697 (C=O), 1620, 1581 (C=N), 1352 (C=C) cm$^{-1}$; $^1$H NMR (DMSO-d$_6$, 300 MHz): δ 3.96 (s, 2H, CH$_2$), 7.12–7.49 (m, 4H, H-Ar), 12.13 (br., 2H, NH); the NH protons disappeared on D$_2$O addition; $^{13}$C NMR (DMSO-d$_6$, 75 MHz): δ 35.2 (CH$_2$), 112.7, 121.8, 142.6, 152.2 (C=N), 164.6 (C=N), 174.7 (C=O). Anal. Calcd. for $C_{10}H_8N_4OS$: C, 51.71; H, 3.47; N, 24.12; S, 13.81. Found: C, 51.58; H, 3.51; N, 24.22; S, 13.80.

**General procedure for the synthesis of compounds (3).** A well-stirred solution of compound **2** (0.2 g, 0.86 mmole) in 4–6 mL of acetic acid was buffered with sodium acetate (0.2 g, 2.58 mmole) and added the appropriate arylaldehyde (1.7 mmole). The solution was refluxed for desired time. The completion of the reaction was monitored by TLC (toluene/dioxane/acetic acid 18:2:1). The reaction mixture was then cooled to room temperature to produce the precipitate. The precipitate was filtered, abundantly washed with water, and then recrystallized from dioxane or dioxane/water to give the pure crystals (**3a**–**k**).

***2-(1H-Benzimidazol-2-ylamino)-5-benzylidene-1,3-thiazol-4(5H)-one (3a).*** This compound was obtained by refluxing for 7 h to yield 0.26 g (96%), mp 326–327°C; IR (KBr): 3138 (NH), 3067 (CH-Ar), 1697 (C=O), 1618, 1581 (C=N), 1454, 1352, 1253 (C=C) cm$^{-1}$; $^1$H NMR (DMSO-d$_6$, 300 MHz): δ 7.14–7.71 (m, 10H, H-Ar and C=CH-Ph), 12.38 (s, 1H, NH), 12.75 (s, 1H, NH); $^{13}$C NMR (DMSO-d$_6$, 75 MHz): δ 112.9, 121.8, 124.1, 129.1, 129.6, 129.9, 130.5, 133.8, 134.1, 150.3 (C=N), 179.3 (C=N), 181.2 (C=O). Anal. Calcd. for $C_{17}H_{12}N_4OS$: C, 63.73; H, 3.78; N, 17.49; S, 10.01. Found: C, 64.01; H, 3.81; N, 17.39; S, 10.00.

***2-(1H-Benzimidazol-2-ylamino)-5-(2-chlorobenzylidene)-1,3-thiazol-4(5H)-one (3b).*** This compound was obtained by refluxing for 6 h to yield 0.16 g (52%), mp 304°C; IR (KBr): 3151 (NH), 3063 (CH-Ar), 1695 (C=O), 1622, 1589 (C=N), 1471, 1352, 1255 (C=C) cm$^{-1}$; $^1$H NMR (DMSO-d$_6$, 300 MHz): δ 7.15–7.68 (m, 8H, H-Ar), 7.87 (s, 1H, C=CH-Ar), 12.42 (s, 1H, NH), 12.92 (br., s, 1H, NH); $^{13}$C-NMR (DMSO-d$_6$ (CD$_3$)$_2$SO, 75 MHz): 112.9, 123.8, 124.2, 128.4, 129.0, 129.7, 130.6, 131.1, 131.9, 132.9, 134.6, 150.1 (C=N), 179.3 (C=N), 180.7 (C=O). **Antifungal assays.** Fungicidal activity of compounds (**1**, **2**, **3a–k**, and **4**) were tested against four phytopathogenic fungal isolates, including *B. elliptica*, *Fusarium graminearum*, *P. nicotianae*, and *R. solani,* provided by Department of Plant diseases of Iranian Plant Protection Research Institute *in vitro*. Two negative controls: one with DMSO, the solvent of all tested compounds (no antifungal activity has been noted) and the other as untreated potato dextrose agar petri dishes used using the agar growth medium poison technique [8]. The medium was potato dextrose agar, and the concentration of the tested compounds was 50 ppm. After 5 days incubation at 25°C, the growth diameter of treatments was measured, and the percentage inhibition of growth for each compound was determined based on the negative control growth of each fungal species under the same incubation conditions. Carbendazim as a reference was included to compare with compounds (**1**, **2**, **3a–k**, and **4**). All tests were performed in triplicate and the average results, as a percentage (%) inhibition of growth, are shown in Table 1.

**Acknowledgment.** We thank the Chemistry Department of Arak University for providing of financial supports and the Department of Plant Diseases of Iranian Plant Protection Research Institute for the evaluating of biological activities.

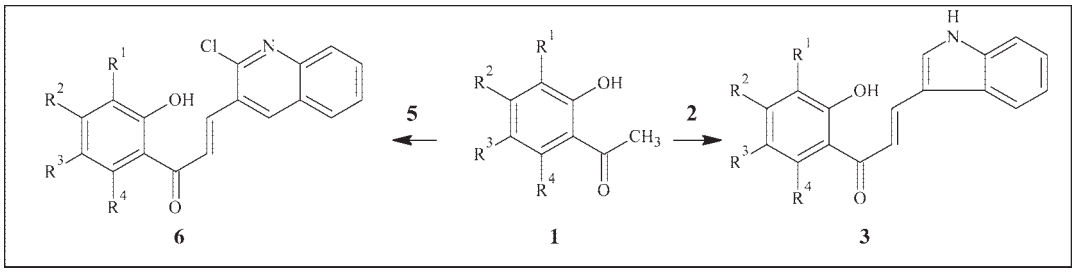
Published online 29 December 2009 in Wiley InterScience (www.interscience.wiley.com).



The chalcones 1-(2′-hydroxy-aryl)-3-(1-indol-3-yl)-prop-2-en-1-one **(3)** and 1-(2′-hydroxy-aryl)-3-(2-chloroquinolin-3-yl)-prop-2-en-1-one **(6)** were synthesised by piperidine mediated condensation of an ethanolic solution of an *o*-hydroxyacetophenone **(1)** with corresponding heteroaryl-3-carboxaldehyde. The structures have been established on the basis of elemental (C, H, N) analysis, UV, IR, $^1$H NMR spectral data. The compounds **3** and **6** were screened for antimicrobial activities against a variety of bacterial agents.

*J. Heterocyclic Chem.*, **47**, 81 (2010).

## INTRODUCTION

Chalcones are well known naturally occurring pigments which serve as valuable intermediate in organic synthesis of flavonoid compounds [1]. It has found significant role in pharmaceutical effects [2] including antioncogenic, antiinflammatory, antiulcerative, analgesic, antiviral, antimalarial and antibacterial activities. Chloroquinoline [3] and indole [4] compounds are known to exhibit variety of antimicrobial activity. Also, it has been reported that chalcone having quinoline moiety is an intermediate for the synthesis of chloroquinoline cyanopyridines and cyanopyrans derivatives [5].

In the Claisen-Schemidt condensation of Chalcone synthesis, 2′-hydroxy functional group may cyclise to the corresponding flavanones under higher concentration of alkali. Also, side reactions such as multiple condensations, polymerizations, and rearrangements are common. These undesirable side reaction decreases the yields of the target adduct and render their purification difficult [6]. So, it was planned to use a weaker base like piperidine instead of using strong base to enhance the better yields.

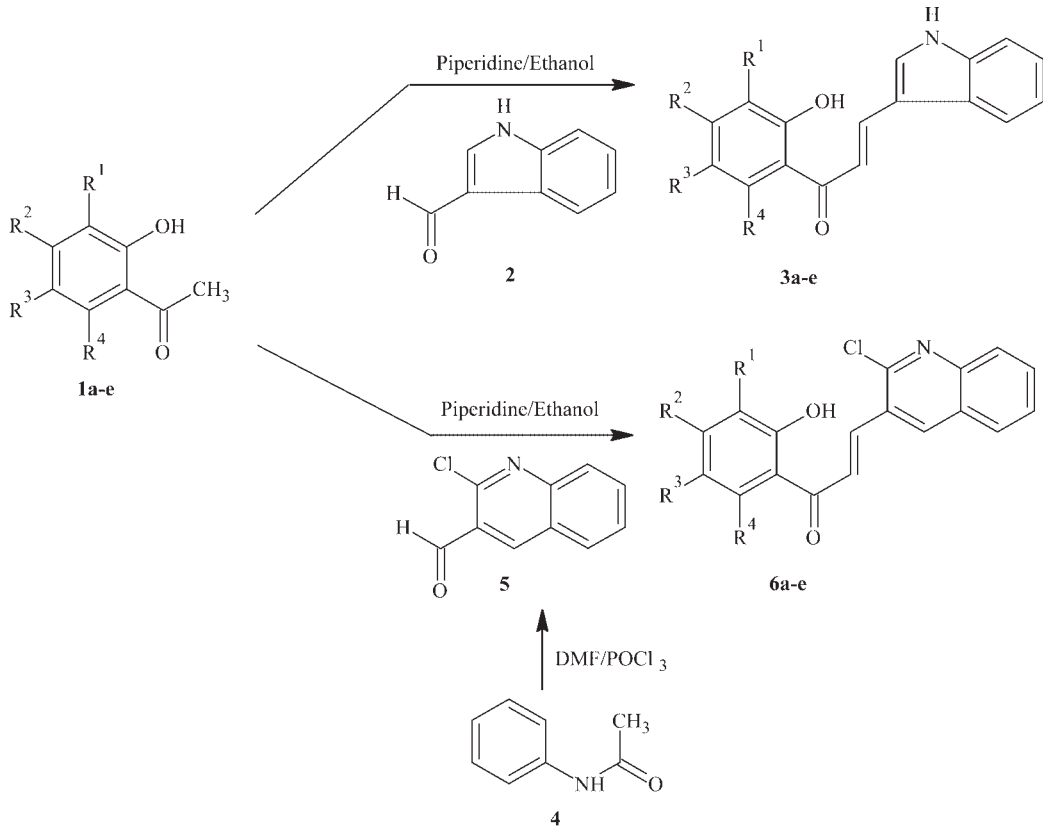
In present communication, we report piperidine mediated synthesis of N-heterocyclic chalcones **3** and **6** from indole-3-carboxaldehyde and 2-chloroquinoline-3-carboxaldehyde respectively. The structures of the compound **3** and **6** have been established on the basis of elemental (C, H, N) analysis, UV, IR, $^1$H NMR spectral data and they were screened for antibacterial activities.

## RESULTS AND DISCUSSION

The syntheses of 1-(2′-hydroxy-aryl)-3-(1-indol-3-yl)-prop-2-en-1-one **(3)** and 1-(2′-hydroxyaryl)-3-(2-chloroquinolin-3-yl)-prop-2-en-1-one **(6)** was carried out by condensation of an ethanolic solution of an *o*-hydroxyacetophenone **(1)** in the presence of piperidine with indole-3-carboxaldehyde **(2)** and with 2-chloroquinolin-3-carboxaldehyde **(5)** as shown in Scheme 1.

The compounds **3** and **6** gave violet colouration with alcoholic $FeCl_3$ test indicating the presence of chelated hydroxyl group in it. Also, gave positive test for presence of elements such as N and Cl in corresponding chalcone by sodium fusion extraction test. When using $AlCl_3$-HCl as shift reagents, bathochromic shift about 40 nm at band-I was observed in UV spectral studies of products **3** and **6** due to presence of chelated hydroxyl group. IR spectra of compounds **3** revealed the presence of —NH absorption bands in the region of 3228–3098 cm$^{-1}$, in addition to two characteristic signals about 1630 cm$^{-1}$ for the unsaturated keto group and 3043–3444 cm$^{-1}$ for hydroxyl groups. Similarly, IR spectrum of compounds **6** showed absorption at 3436–3431 cm$^{-1}$, 1654–1621 cm$^{-1}$, 1446–1432 cm$^{-1}$ and 744–756 cm$^{-1}$ for presence of —OH, —C=O, —C=N—, —Cl groups, respectively. The $^1$H NMR spectra gave two doublet centred about δ 7.6 and δ 8.2 with coupling constant about $J = 15$ Hz were assigned to the trans olefinic proton at $C_\alpha$ and $C_\beta$ position. The entire $^1$H NMR spectral data were given in the experimental part and the values were in accordance with the title compounds **3** and **6**.

**Scheme 1**



**Antibacterial activities.** The antibacterial activity of the compounds **3** and **6** have been evaluated using filter paper disc diffusion method [7] at a concentration of 100 μg/disc against human pathogenic bacteria such as *Staphylococcus aureus* ($G^+$), *Shigella dysenteriae* ($G^-$) and *Salmonella typhi* ($G^-$). Kanamycin (30 μg/disc) was used as standard for comparing the activity. Each sample was used in triplicates for the determination of antibacterial activity. The diameter of observed inhibition zone of **3** and **6** were measured (in mm) and they are given in Table 1.

By visualizing the antibacterial data, it could be observed that most of the compound shows significant activity. The compound **3e**, **6a**, **6e** showed excellent activity for all the three test microorganisms. However, compounds **3d, 6c** are inactive against *S. aureus* and compounds **3d, 6b** are inactive for *S. dysenteriae*. Similarly compounds **3b, 6d** are inactive against *S. typhi*. The preliminary result confirms the importance of chloroquinone nucleus and indole nucleus with respect to antibacterial activity.

## EXPERIMENTAL

Melting point determinations were made in open capillaries and were uncorrected. TLC was carried out using Merck brand Silica Gel-G and spotting was done using iodine or UV light. UV spectra were taken in Perkin-Elmer 402 UV-Vis spectrophotometer. IR spectra were recorded in Perkin-Elmer 577 IR spectrophotometer. $^1$H NMR spectra were conducted on Bruker (300 MHz) spectrometer in $CDCl_3$ with tetramethylsilane as the internal standard. The chemical shifts are reported in ppm scale. The compound **(2)** was obtained from SISCO research laboratories and used as such. The compound **(5)** was prepared adopting the published procedure with the same melting point at 150°C [8].

**General procedure for synthesis of 1-(2′-hydroxy-aryl)-3-(1-indol-3-yl)-prop-2-en-1-one (3).** To a mixture of *o*-hydroxyacetophenone (0.01 mol) and indole-3-carboxaldehyde (0.01 mol) in ethanol (50 mL), piperidine (1 mL) was added and refluxed. After the completion of reaction, which was monitored by TLC, ethanol was distilled off and residue was poured on ice water (100 mL). It was kept overnight in the refrigerator. The resulting solid was collected by filtration, washed with distilled water and crystallized from methanol to give corresponding chalcone **3**.

***Synthesis of 1-(2′-hydroxy-4′-methoxyphenyl)-3-(1-indol-3-yl)-prop-2-en-1-one (3a).*** Yellow solid (0.75 g, 25.6%); mp. 196°C; $\lambda_{max}$ ($CHCl_3$, nm): 274, 396; ir (KBr, $cm^{-1}$): 3374($\nu_{OH}$), 3225($\nu_{>NH}$), 1625($\nu_{C=O}$); $^1$H NMR (300 MHz, $CDCl_3$): δ 13.90 (s, 1H, 2′-OH), 6.54 (d, 1H, 3′-H), 3.87 (s, 3H, 4′-$OCH_3$), 6.44 (d, 1H, 5′-H), 7.96 (d, 1H, 6′-H), 7.81 (d, 1H, $C_\alpha$H, $J$ = 15.3 Hz), 8.18 (d, 1H, $C_\beta$H, $J$ = 15.3 Hz), 8.61 (s, 1H, > NH), 7.66 (d, 1H, 2-H), 8.04 (d, 1H, 4-H), 7.33 (m, 2H, 5- and 6-H), 7.46 (m, 1H, 7-H); *Anal*. **Antibacterial activities.** The antibacterial activity of the compounds **3** and **6** have been evaluated using filter paper disc diffusion method [7] at a concentration of 100 μg/disc against human pathogenic bacteria such as *Staphylococcus aureus* ($G^+$), *Shigella dysenteriae* ($G^-$), and *Salmonella typhi* ($G^-$). Kanamycin (30 μg/disc) was used as standard for comparing the activity. Each sample was prepared with dimethyl sulfoxide (DMSO) to the concentration of 100 μg/mL. Dried and sterilized filter paper discs (6 mm in diameter) were impregnated with test solution using micropipette and the residual solvents were completely evaporated. Discs containing the test materials were placed on nutrient agar medium uniformly seeded with the test microorganisms. Standard disc of kanamycin (30 μg/disc) and blank discs were used as positive and negative control, respectively. These plates were then kept at low temperature (4°C) for 24 h to allow maximum diffusion of test materials and kanamycin. The plates were then incubated at 37°C for 18 h to allow maximum growth of the organisms. Then, the antimicrobial activity of the test agents was determined by measuring the diameter of zone of inhibition expressed in mm. The experiment was carried out in triplicate.

**Acknowledgment.** The authors thank Dr. R.Gandhidasan (Professor in Chemistry, Madurai Kamaraj University) for providing the lab facilities to carry out this research work.

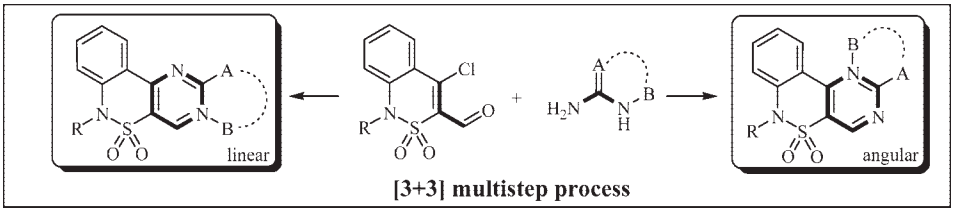
Published online 29 December 2009 in Wiley InterScience (www.interscience.wiley.com).



The method of pyrimidine ring fusion at the [*c*] side of benzothiazines based on the reaction of their chloroaldehyde derivatives with amidines is described. Formation of the structural isomers of reaction products was investigated, and regioselectivity of heterocyclization reactions was shown. A number of novel pyrimidobenzothiazines were synthesized.

*J. Heterocyclic Chem.*, **47**, 85 (2010).

## INTRODUCTION

Among benzothiazine derivatives, there are a number of compounds known to show biological activity [1]. In particular, heterocyclic ring fusion on a side [*c*] of benzothiazine leads to the condensed systems some representatives of which are known as drugs. Thus, 5-methyl-3-(2-pyridyl)-2H,5H-1,3-oxazino[5,6c][1,2]benzo thiazin-2, 4-(3H)-dione-6,6-dioxide **1** [2] is a well-known anti-inflammatory agent (trade name ''Droxicam''), and (4-methoxy-3,5-dimethyl-phenyl)-(9-methyl-9H-10-thia-2,4,9-triaza-phenantren-3-yl)-amine **2** is a protein tyrosine kinase inhibitor [3] (Fig. 1). However, condensed benzothiazines currently used in medicine have a number of adverse effects [4].

## RESULTS AND DISCUSSION

In our previous paper [5], we have reported the synthesis of some novel benzo[*e*][2,1]thiazine derivatives—chloroaldehydes **3a–e** (Fig. 2), and their chemistry was shown to be quite diverse. Compounds **3** contain labile chlorine atom at C-4 and carbonyl group at C-3 position of the ring. We assumed that the studies of chloroaldehyde fragment reactivity could provide a way to obtain new condensed benzothiazines devoid of side effects or less toxic.

In this article, we describe the method of pyrimidine ring fusion at the [*c*] side of benzothiazines. The route developed by our group involves the interaction of chloroaldehydes **3a–e** with bis-nucleophilic agents **4a–i** containing N-C-N fragment (Table 1). When amidines **4a–c** are used as nucleophiles, the formation of pyrimidobenzothiazines as only products is expected. In case of asymmetric bis-nucleophiles **4d–i**, structural isomers of the reaction product can be formed. Depending on which electrophilic center is attacked by nucleophile at the first stage of heterocyclization process, linear- or angular-type fused compound is obtained.

Pyrazoles **4d–f** and benzoimidazole **4h** both contain two N-nucleophilic centers, thus in reactions with chloroaldehydes **3** two different isomeric pyrazolobenzothiazine products are possible (Scheme 1). Triazole **4g** and quinazalone **4i** contain three N-nucleophilic centers each, which causes four possible isomeric products in reaction with **3** (Scheme 2). One of current research goals was to establish exactly which isomer is formed in every case.

The interaction of chloroaldehydes **3a,b** with amidines **4a–c** (Scheme 3) led to pyrimidobenzothiazines **5a–f**. Reactions proceeded under mild conditions, and no first-stage intermediates were observed in the reaction mixtures.

The next step of this work was to investigate the reactions of compounds **3** with aminopyrazoles **4d–f**. The heating of **3** with **4d–f** resulted in crystalline products **6** (Scheme 4). We have expected the formation of angular products, and $^1$H NMR spectra of compounds **6a–l** did not contradict angular structures, as H-1 phenylene proton doublet was observed to undergo low-field shift. However, X-ray analysis proved the structure of compounds **6a–l** to be linear (Fig. 3). It seems that the signal of phenylene proton in compound **6** can shift to 8.5 ppm due to the effect of nitrogen atom of pyrimidine ring.

We have not found in the literature any example of the reaction of β-halogenvinylcarbonyl compounds with

**Figure 2.** 4-Chloro-benzo[c][1,2]thiazine-3-carbaldehydes **3a–e**.

amidine nucleophiles proceeding *via* nucleophilic substitution of halogen atom at the first stage of the reaction followed by nucleophilic addition to carbonyl group resulting in the products of linear type. All reactions of analogous nature described until now proceed by Schiff base formation at first stage, then displacement of chlorine. What we observe is opposite to that route. Aldehyde group in compounds **3** is more sterically available than C-4 carbon atom; therefore, its reactions have to proceed under kinetic control, whereas the substitution of chlorine is rather thermodynamically controlled process. We assume the nucleophilic substitution of chlorine atom to be the ''push–pull'' process, with addition of exocyclic amino function of **4d–f** to C-4 carbon followed by halogen cleavage with C3–C4 double bond restoration.

The interaction of **3b,c** with 2-aminobenzoimidazole **4h** proceeds in a similar way (Scheme 5). Upon mild heating (30–35°C) of the reaction solution in DMF, the mixture of the Schiff base **8a,b** and the heterocyclization product **9a,b** is formed in the equimolar ratio ($^1$H NMR data). Subsequent temperature increase (50–70°C) acts in favor of the cyclic derivative **9a,b** (1:2 ratio). Heating the mixture to 100°C results in the formation of **9a,b** only. The interaction between the protons with chemical shifts 7.51 and 8.45 ppm (Scheme 5) observed during 1D-NOESY experiment proved angular structure of products **9**. Analysis of 3D molecular models led to the conclusion that compounds **9** most probably adopt helical-type structure.

When 3-aminotriazole **4g** was used as a nucleophile, the reaction with **3a–c** proceeded in more common manner: the initial condensation of exocyclic amino function with carbonyl group is followed by the displacement of chlorine atom (Scheme 6). Depending on which nitrogen atom (N-2 or N-4) attacks the C-4 position at the second stage of the heterocyclization, formation of structural isomers of the reaction products **7** can occur. 1D-NOESY experiment revealed strong interaction between the protons with chemical shifts 8.82 and 9.58 ppm (Scheme 6) that proved N-4 (but not N-2) nitrogen atom of 3-aminotriazole to participate in the ring formation.

The reactions of chloroaldehydes **3** with 2-aminoquinazolin-4-one **4i** give angular compounds **10a–c** (Scheme 7).

To determine the structure of the product isolated from the reaction mixture, $^1$H and $^{13}$C NMR spectroscopy was used. The investigation of 3D models of the product showed that in the structure **10** the doublet of H-1 proton should be shifted to low field due to the neighboring carbonyl oxygen effect.

In experimental NMR spectrum, we observe a pronounced shift of the doublet that due to homonuclear (COSY) and heteronuclear ($^1$H-$^{13}$C HMBC, HMQC) correlation experiments originated from the H-5 proton of starting benzothiazine **3**. Thus, the reaction proceeds regioselectively; the ''amide'' nitrogen of the starting quinazoline **4i** participates in cyclization.

Structures of all aforementioned compounds were established on the basis of their $^1$H NMR, $^{13}$C NMR, Mass spectrometry data, and elemental microanalyses.

In summary, we disclose the synthesis of novel benzo [*e*][2,1]thiazine derivatives, in particular substituted pyrimidobenzothiazines and pyrazolo-, imidazo-, triazolopyrimidobenzothiazines. These compounds were obtained in high yields (∼70–80%) *via* convenient protocols involving heterocyclization reactions of chloroaldehydes **3a–e** with N-C-N bisnucleophiles **4a–i**.

## EXPERIMENTAL

The NMR spectra were measured on a Varian 400 spectrometer at 25°C using DMSO-$d_6$. All chemical shifts are reported in ppm relative to TMS.

Starting materials used were obtained from Makrochim and used without further purification. Dry solvents were prepared according to the standard methods.

**6-Alkyl-6H-pyrimido[5,4-c][2,1]benzothiazine-5,5-dioxides (5a–f); general procedure.** The mixture of β-chloroaldehyde **3** (1 mmol) with the corresponding amidine **4a–c** (1.2 mmol) was dissolved in 2 mL of dry DMF. Triethylamine (2 mL) was added and the reaction mixture was heated for 6 h at 80°C. The mixture was cooled to room temperature, quenched with water (20 mL), solid product was filtered off, and then washed with ethanol. The pure product was obtained by crystallization from DMF (64–86%).

4-Bromomethylcoumarins (**1**) reacted with sodium azide in aqueous acetone to give 4-azidomethylcoumarins (**2**), which underwent 1,3-dipolar cycloaddition with acetylenic dipolarophiles to give triazoles (**3**). These triazoles (**3**) have been found to exhibit interesting variations in the chemical shifts of $C_3$—H and $C_4$-methylene protons. Protonation studies indicate that the shielding effect of the $C_3$—H of coumarin is due to π-electrons of the triazole ring, further supported by diffraction and computational studies.

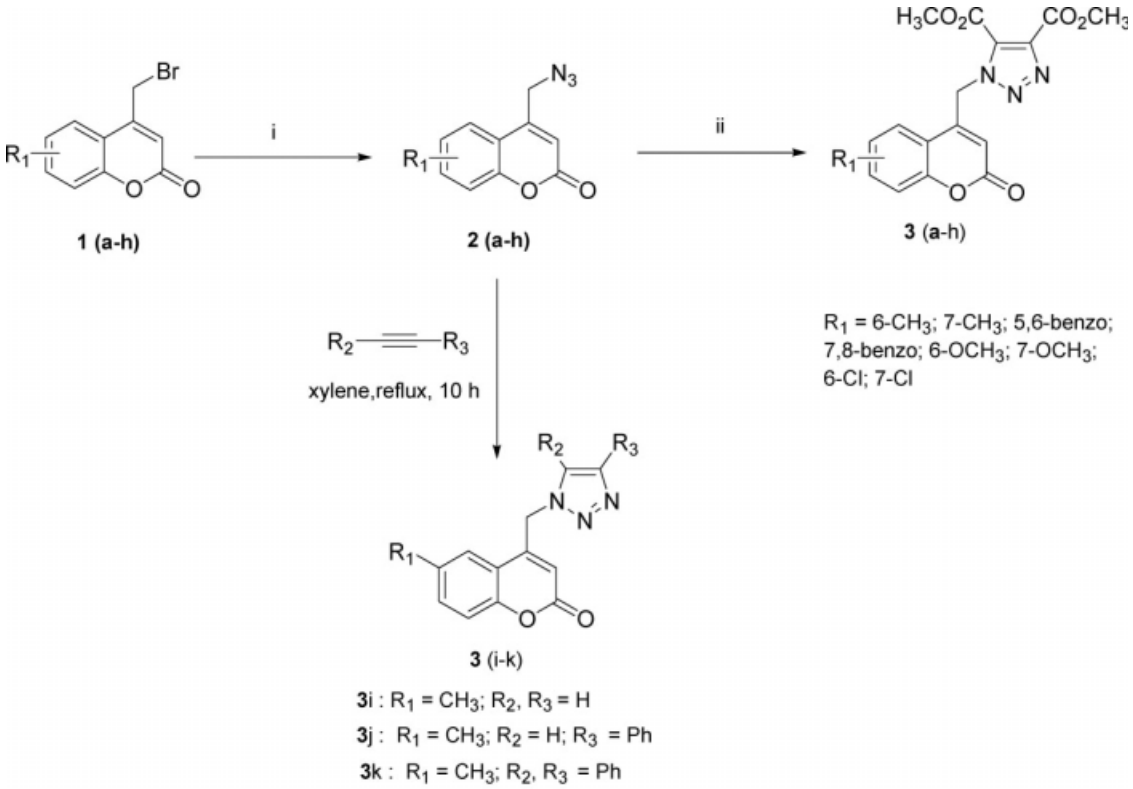
## INTRODUCTION

Organic azides are an important class of 1,3-dipoles, which have been recently recognized as crucial functional groups in click chemistry [1]. The exergonic reaction of azides with acetylenic dipolarophiles has resulted in one of the best synthetic routes to 1,2,3-triazoles [2]. This single-step transformation has been investigated for its regioselectivity in aqueous systems [3], in ionic liquids [4], in copper (I) catalysis [5], and by the solid-phase approach [6]. In view of the wide range of biological activities of 1,2,3-triazoles [7,8] and in continuation of our study on biologically active and fluorescent 4-substituted coumarins [9,10], it was thought of substantial intellectual appeal to link the 1,2,3-triazole moiety at the allylic position with respect to the biogenetically important $C_3$—$C_4$ double bond of coumarin. There are very few reports on pyranone-substituted 1,3 dipoles except for the reactions of coumarin 4-nitrile oxides [11].

## RESULTS AND DISCUSSION

The required dipolar azide intermediates (**2**) were synthesized by the reaction of sodium azide with various 4-bromomethylcoumarins (**1**) [12] in aqueous acetone at room temperature and were quite stable even above 100°C. The first acetylenic dipolarophile used in this investigation was dimethylacetylenedicarboxylate (DMAD), giving rise to triazolomethylcoumarins (**3**) in refluxing xylene (Scheme 1). In the $^1$H NMR spectrum of the azide, (**2a**, $R_1$ = 6-$CH_3$) as expected, the $C_4$—$CH_2$ protons linked to the azido group were observed at 4.57 ppm and the $C_3$—H of coumarin, appeared as a singlet at 6.52 ppm. The $^1$H NMR of DMAD adduct **3a** showed two interesting features such as (i) $C_4$—$CH_2$ protons showed a downfield shift and were observed at 6.05 ppm when compared with 4.56 ppm observed in the case of 4-anilinomethylcoumarins or 5.20 ppm observed in the case of 4-phenoxymethylcoumarins. (ii) The $C_3$—H of coumarin in the DMAD

**Scheme 1.** Synthesis of triazolomethylcoumarins from click chemistry.



adduct experienced an upfield shift and was observed as a singlet at 5.60 ppm, as against 6.60–6.70 ppm in the case of both 4-anilinomethyl or 4-phenoxymethyl coumarins [13,14]. To the best of our knowledge, there is only one report in the literature on this type of shielding effect of coumarin $C_3$—H in 7-methoxy-4-platinomethylcoumarin complex coordinated with 1,10-phenanthroline [15]. This rare type of shielding effect of coumarin $C_3$—H and simultaneous pronounced deshielding of the $C_4$-methylene protons were due to the triazole on the $C_4$—$CH_2$ group, which has been consistently observed in all the cycloaddition adducts of the azides and DMAD (Table 1). It is interesting to note that benzylic azides have also been reported to undergo similar dipolar cycloaddition reaction [16], but no effects on the chemical shifts of the *ortho* protons have been observed. The chemical shift for the methylene protons in *p*-hydroxybenzyl azide and DMAD adduct is around 5.60 ppm, whereas the aromatic *ortho* protons were found to resonate at 7.11 ppm [17].

| **g** | 6-Cl | 4.55 | 6.01 | 6.58 | 5.77 |
| **h** | 7-Cl | 4.54 | 6.06 | 6.56 | 5.81 |

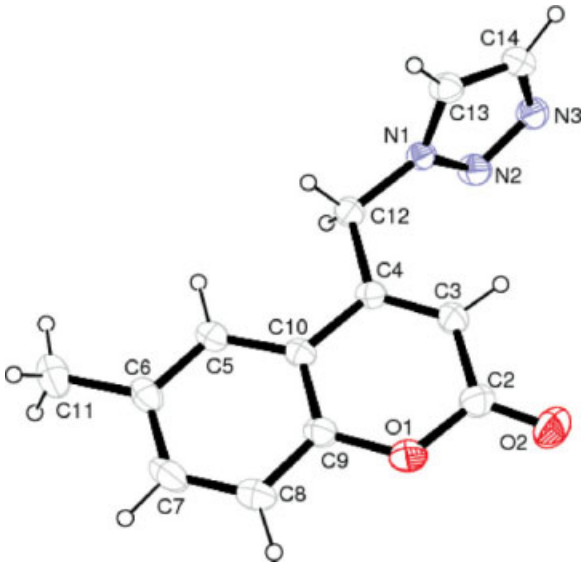

**Figure 1.** ORTEP diagram of triazole adduct **3i**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

**Effect of substituents.** The possible role played by the two ester groups in this observation was verified by using other dipolarophiles such as acetylene, phenylacetylene, and diphenylacetylene in this reaction with azide **2a** (Fig. 1). This led to the formation of adducts **3i**, **3j**, and **3k**, respectively (Scheme 1). In all these cases, similar trend has been observed. Hence, the origin of this effect lies in the triazole ring rather than the substituents.

**Temperature effect.** To understand the nature of this phenomenon, we recorded the temperature-dependent NMR for one of the DMAD adducts (**3a)** at various temperatures. Up to a temperature of 393 K, there was a regular decrease in the chemical shift values of $C_4$-methylene protons from 6.1790 to 6.1090 δ ppm. The $C_3$—H protons showed a slight increase from 5.638 to 5.790 ppm (Table 2). This behavior indicated the absence of any intramolecular hydrogen bonding between $C_3$—H and triazole nitrogen *via* a six-membered ring.

**Table 2**

Temperature dependence of chemical shifts of C4—$CH_2$ and C3—H of (**3a**) in DMSO-$d_6$.

| | Chemical shifts (δ ppm) | |
|---|---|---|
| Temperature (K) | $C_4$—$CH_2$ | $C_3$—H |
| 303.1 | 6.1790 | 5.638 |
| 313.1 | 6.1710 | 5.654 |
| 323.1 | 6.1645 | 5.670 |
| 333.1 | 6.1565 | 5.689 |
| 343.1 | 6.1475 | 5.706 |
| 353.1 | 6.1405 | 5.725 |
| 373.1 | 6.1245 | 5.758 |
| 393.1 | 6.1090 | 5.790 |

**Protonation behavior.** Qualitative protonation studies were performed by adding two drops of trifluoroacetic acid ($CF_3CO_2H$) in $CDCl_3$, which resulted in significant changes in the chemical shifts of $C_3$—H and $C_4$—$CH_2$ protons. In the case of **3a,** the $C_3$—H proton was further shifted downfield to 6.01 ppm from 5.60 ppm and $C_4$—$CH_2$ protons were also deshielded to 6.30 ppm from 6.05 ppm. This trend was observed for all the substituted cycloadducts (**3**) (Table 3). In the case of acetylene adduct **3i**, the trend was also similar, whereas the $C_4$—$CH_2$ protons showed downfield shift from 5.77 to 6.16 ppm and the $C_3$—H from 5.94 to 6.41 ppm. Probable structures of the protonated species **5** and **6** (Scheme 2) indicate that $N_1$ of the triazole ring can be quaternized and inductively withdraw the electron density at $C_4$—$CH_2$, which would cause deshielding effect.

However, the simultaneous deshielding effect of $C_3$—H under this condition strongly supports an argument that the $C_3$—H proton falls in the shielding zone of the triazole moiety, which is perturbed due to protonation. Further, the higher deshielding of the methylene protons was observed, which can also be explained in

**Table 3**

Chemical shifts of C4—$CH_2$ and C3—H upon protonation ($CDCl_3$ + TFA) in DMAD adducts (**3a–3h**).

| | | $C_4$—$CH_2$ | | $C_3$—H | |
|---|---|---|---|---|---|
| Compound | R | $CDCl_3$ | $CDCl_3$ + TFA | $CDCl_3$ | $CDCl_3$ + TFA |

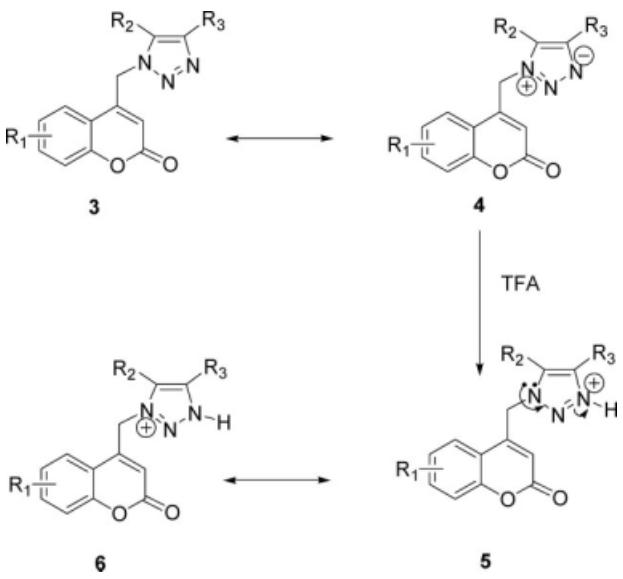
**Scheme 2.** Schematic representation of protonation behavior.



terms of enhanced contribution of the dipolar form **4** to the ground-state resonance of compound **3**.

**Diffraction studies.** We have performed a single crystal analysis of the acetylene adduct **3i**. The ORTEP diagram (Fig. 1) clearly shows that the planar triazole ring is oriented at an angle of 78.88° with respect to the coumarin ring. This supports our argument that the shielding of the $C_3$—H is due to the triazole ring and not because of any substituents.

**Computational support.** We have also performed the geometry optimization of the triazoles **3a** and **3k** molecules, which are shown in the Figure 2 using the Gaussian 03 program [18]. The minimization was performed according to the density functional theory at the B3LYP method with standard Gaussian split-valence 6-31G (d,p) basis set. The two structures clearly revealed the relative orientations of the triazole ring with respect to the $C_3$ proton of the coumarin (Fig. 2). The anisotropic effect observed on the $C_3$—H of coumarin is due to the angularly oriented triazole ring, the π-electron cloud of which will have a shielding effect.

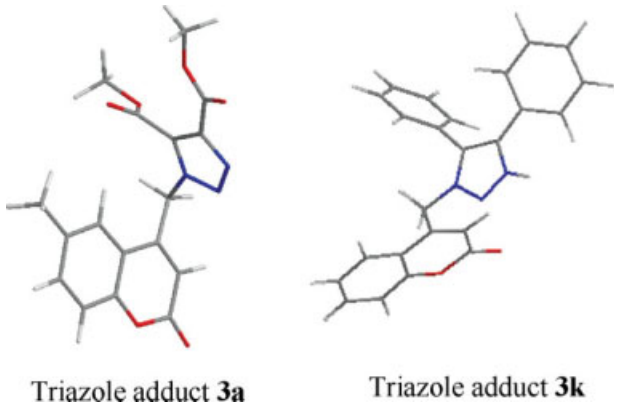


**Figure 2.** Optimized geometries of compounds **3a** and **3k**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

## CONCLUSIONS

The unusual anisotropic effects observed in the 4-triazolomethyl coumarins synthesized from 4-azidomethyl-coumarins **2** and a variety of acetylenic dipolarophiles are due to the angularly oriented triazole, which has been shown by NMR, X-ray diffraction, and computational studies.

**Table 4**

Synthesis of 4-azidomethyl-chromen-2-ones **(2a–2h)**and 1-(2-oxo-*2H*-chromen-4-ylmethyl)-*1H*-[1,2,3]triazoles **(3a–3k).**

| Entry | Product | $R_1$ | $R_2$ | $R_3$ | Melting point (°C) | Yield (%) |

## EXPERIMENTAL

Melting points were determined by open capillary method and are uncorrected. The elemental analysis was performed using Heraus CHN rapid analyzer. Analytical TLC was performed on Merck precoated 60 $F_{254}$ silica gel plates. IR spectra (KBr disc) were recorded on a Nicolet-5700 FTIR spectrophotometer. $^1H$ and $^{13}C$ NMR spectra were recorded on Bruker 300 MHz spectrometer using $CDCl_3$ as a solvent and tetramethylsilane as an internal standard. The chemical shifts are expressed in δ ppm scale down field from tetramethylsilane and proton signals are indicated as s = singlet, d = doublet, t = triplet and m = multiplet. EI 70 EV and AUTOSPEC electron impact mass spectrometer was used to record mass spectra.

**Preparation of substituted 4-bromomethylcoumarins (1a–1h).** The required substituted 4-bromomethylcoumarins **1** [14] have been synthesized by the Pechmann cyclization of various phenols with 4-bromoethylacetoacetate.

**General procedure for the preparation of 4-azidomethylchromen-2-ones (2a–2h).** 4-Bromo-methylcoumarin **1** (0.01 mol) was taken in acetone (20 mL) in a round bottom flask. To this, sodium azide (0.012 mol) in 3 mL of water was added dropwise with stirring. The stirring was continued for 10 h (reaction was monitored by TLC). Then, the reaction mixture was poured to ice cold water. The separated solid was filtered and recrystallized using suitable solvent (Table 4).

***4-Azidomethyl-6-methyl-chromen-2-one (2a).*** Colorless solid (ethanol), mp. 110°C, yield 63%; IR (KBr, ν in $cm^{-1}$): 1722 (lactone C=O), 2109 ($N_3$); $^1H$ NMR (300 MHz, $CDCl_3$): δ 2.44 (s, 3H, C6—$CH_3$), 4.57 (s, 2H, CH2—$N_3$), 6.52 (s, 1H, C3—H), 7.30 (s, 1H, C5—H), 7.32 (d, 1H, C7—H, $J$ = 7.9 Hz), 7.40 (d, 1H, C8—H, $J$ = 8.3 Hz); LCMS *m/z*: 216 [M + 1]. ## INTRODUCTION

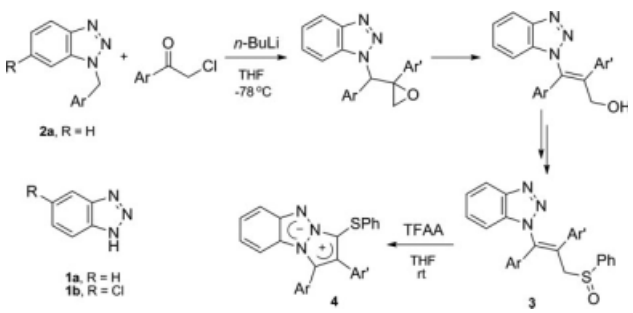
Benzotriazole has received a great amount of attention over the last three decades owing to the potential utility as a synthetic auxiliary for the synthesis of a diverse class of organic compounds [1]. Recently, we reported the reactions of 3-(benzotriazol-1-yl)-2,3-disubstituted propenyl phenyl sulfoxides **3** [2], prepared from 1-(arylmethyl)-1*H*-benzotriazoles **2a** and 1-aryl-2-chloroethanone in five steps, with trifluoroacetic anhydride (TFAA) yielding triazapentalenes **4** *via* a Pummerer-type intramolecular nucleophilic attack of N-2 of the benzotriazole moiety [2a] (Scheme 1).

In connection with the exploration of the synthetic utility of **1**, the introduction of an alkyl group at the benzylic position of 1-(2-azidoarylmethyl)-1*H*-benzotriazoles **6** ($R^2$ = 2-$N_3$) was attempted simply because the azido group may be utilized as a precursor for generation of nitrene [3]. Nitrene is known as a useful reactive species for the synthesis of nitrogen-containing heterocyclic compounds *via* insertion or addition reactions. One can envisage the reaction of a benzylic carbanion, generated from compounds **6** by a strong base, with alkyl halides. However, a problem to be encountered with this methodology is to overcome the possible reaction of the azido group with the strong base. A search through the literature showed that simple alkyl azides reacted with both Grignard reagents in diethyl ether at 0°C or alkyllithiums in *n*-pentane to give alkyltriazenes [4]. The latter reactions in ether did not occur. The reaction leading to triazenes was sensitive to the solvents. Furthermore, to the best of our knowledge, there has been no report on the reactions of aryl azides with both Grignard reagents and alkyllithiums. Compounds **6** are insoluble in *n*-pentane at room temperature. Consequently, it was necessary to obtain information on the reactivity of aryl azides including **6** toward various bases. The results obtained from our examination are described herein.

## RESULTS AND DISCUSSION

2-Azidobenzyl bromides **5** ($R^2$ = 2-$N_3$, X = Br), precursors of 1-(2-azidoarylmethyl)-1*H*-benzotriazoles **6a-b**, **6d-e**, and **6g**, were prepared by diazotization of *o*-toluidine derivatives, followed by bromination of the methyl group using NBS in the presence of benzoyl peroxide [5b]. On the other hand, 2-azidobenzyl chloride **5** ($R^2$ = 2-$N_3$, X = Cl), precursors of compounds **6c** and **6f**, were prepared by diazotization of 2-aminobenzyl alcohols, followed by chlorination using $SOCl_2$ in $CH_2Cl_2$. Treatment of **5** with benzotriazoles **1a-b** in the presence of NaOEt in absolute ethanol [6] gave a mixture of **6** and 2-(2-azidoarylmethyl)-2*H*-benzotriazoles **7** which were separated by chromatography (Scheme 2).

**Scheme 1**



Yields of compounds **6** and **7** are summarized in Table 1.

Treatment of **6a** with *n*-BuLi (1.1 equiv.) in THF at −78°C, followed by addition of allyl bromide (1.1 equiv.) with stirring for 1 h did not reveal any new spots except for those of the starting materials on TLC. However, after being stirred at room temperature for 2 h, TLC of the reaction mixture showed four spots including that corresponding to **6a** ($R_f$ = 0.71, EtOAc:*n*-hexane = 1:4). Chromatography of the reaction mixture (silica gel, 70–230 mesh) gave two 2*H*-indazole derivatives **8a** (R = $R^1$ = H) (25%), **9a** (R = $R^1$ = H) (21%), 2-[(benzotriazol-1-yl)methyl]phenylamine (**10a**) (R = $R^1$ = H) (25%) and 2-[1-(benzotriazol-1-yl)-3-butenyl]phenylamine (**11a**) (R = $R^1$ = H) (0%) together with unreacted **6a** (24%) containing a minute amount of 1-[(2-azidophenyl)(allyl)methyl]-1*H*-benzotriazole (**12a**) (Scheme 3). The yield of each product was variable depending on the concentrations of *n*-BuLi and allyl bromide. The results are summarized in Table 2.

Table 2 shows that compounds **9a** and **10a** were formed without allyl bromide and a considerable amount of **6a** (40%) remained unreacted when 1.0 molar equiv. of *n*-BuLi was employed (entry 1). The result is inconsistent with the formation of dialkyltriazenes from analogous reactions involving simple alkyl azides and alkyllithiums in *n*-pentane [4a]. However, the reaction of **6a** with MeMgBr in THF for 1 h at 0°C, and subsequently at room temperature for 2 h, gave methyltriazene **13** (91%) as expected. The $^1$H NMR (300 MHz, $CDCl_3$) spectrum showed a singlet at 3.24 ppm, corresponding to the structure of **13**.

**13**

On addition of allyl bromide (1.1 equiv.), compound **8a** was obtained in 20% yield at the expense of **6a** and **10a** (entry 2). The amounts of recovered **6a** as well as **8a** were decreased somewhat by two-fold increase of the concentration of *n*-BuLi only (entry 3). When the concentrations of *n*-BuLi and allyl bromide were increased two-fold, respectively (entry 4), the yield of **8a** increased to 38% at the expense of **9a** and **6a**. However, further increase in the concentration of *n*-BuLi (4.0 equiv.) while maintaining the same concentration of

allyl bromide (2.2 equiv.), did not affect the yields of **8a** and **9a** but only reduced the amount of unreacted **6a** by 5% (entry 5). Finally, the amount of unreacted **6a** decreased with increase in the concentration of *n*-BuLi and yet the yield of **8a** did not exceed 39%. In addition, the yields of **9a** were not much affected by altering the concentrations of either *n*-BuLi or allyl bromide.

Since the yields of compound **11a** increased with the concentrations of *n*-BuLi and allyl bromide (entries 4 and 5) and the sum of the yields of **10a** and **11a** appeared nearly constant, **10a**, prepared independently from **6a** and $NaBH_4$ [7], was treated with allyl bromide (2.5 and 3.0 equiv.) in the presence of *n*-BuLi (2.5 and 3.0 equiv.) in THF for 1 h at 0°C, and subsequently at room temperature for 2 h to observe if compound **11a** is formed *via* compound **10a**. From the reactions were obtained **11a** (0 and 3%), allyl[2-{(benzotriazol-1-yl)methyl}phenyl]amine (**14**) (38 and 16%), diallyl[2-{(benzotriazol-1-yl)methyl}phenyl]amine (**15**) (33 and 41%), and allyl[2-{1-(benzotriazol-1-yl)-3-butenyl}phenyl]-amine (**16**) (5 and 17%), respectively (Scheme 4). Compounds **14**–**16** were not detected in the reaction of **6a** under similar conditions but compound **11a** was observed (Scheme 4).

The result indicates that a small portion of compound **11a** may be formed *via* **10a**. For optimization of the reaction conditions, the reactions of **6a** (1.25 mmol) with allyl bromide were carried out in the presence of various bases under the same foregoing conditions. The results are summarized in Table 3.

Table 3 showed that not only a considerable amount of **6a** was used up to give unidentifiable mixtures but also a large quantity of unreacted **6a** was recovered. Consequently, *n*-BuLi was employed as a base for reactions of other compounds **6**. Yields of **8**–**11** and unreacted **6** are summarized in Table 4.

The structure of **8** was determined on the basis of the X-ray crystal structure of **8g** (Fig. 1).

The structures of **9** were determined on the basis of spectroscopic and analytical data. In particular, the HMBC spectrum of **9a** shows that the N2-H proton correlates with C3a and C7a carbon atoms, which clearly indicates that the compound is 2*H*-indazole derivative [8] rather than 1*H*-indazole derivative.

To obtain mechanistic information, **6h** was subjected to the same foregoing conditions (Scheme 5). From the reaction were obtained allylated compound **19** (4%) and amino compound **20** (45%) together with unreacted **6h** (28%). The result indicated that reduction of the azido group yielding amino group occurs readily compared with allylation at the benzylic position.

Although there exist plentiful examples of the direct conversion of an azido group to an amino group [9], *n*-BuLi-mediated the same type of conversion has seldom appeared in the literature [10]. We have found that treatment of simple aryl azides with *n*-BuLi (2.0 equiv.) under the same foregoing conditions gave arylamine as

major compounds (Scheme 6). Product yields are summarized in Table 5.

The formation of **19** coupled with **12c** as minor product indicates that alkylation at the benzylic position occurs under the conditions where the azido group is intact. Of course, compounds analogous to **8** and **9** cannot be formed from the reaction of **6h**. Interestingly, the reaction of **6a** with a mixture of an equal

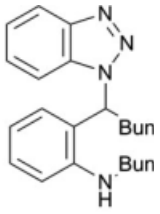
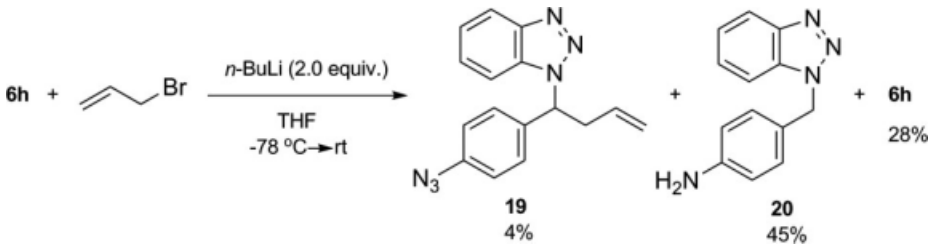
**17**



**18**

**Scheme 5**



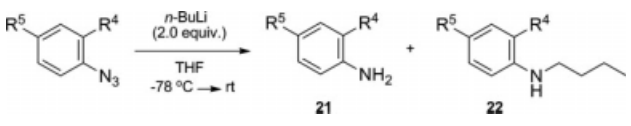
molar amount of allyl bromide (1.2 equiv.) and benzyl bromide (1.2 equiv.) under the same foregoing conditions showed four spots on TLC (silica gel, EtOAc:*n*-hexane = 1:4), corresponding to **8d** ($R_f = 0.79$), a mixture of **8a** and **23** ($R_f = 0.70$), **9a** ($R_f = 0.42$), and **10a** ($R_f = 0.27$) along with a weak spot having a long tail (Scheme 7).

An attempt at separation of the mixture of **8a** and **23** was unsuccessful. However, FAB MS shows mass number (*m*/*z*) 331 ($M^+ + 1$) and 381 ($M^+ + 1$), corresponding to the molecular weight of **8a** and **23** plus one, respectively. The formation of **23** suggests that the $R^3$ of compounds **8** is introduced in a stepwise manner.

The formation of compound **8a** may be initiated by deprotonation of benzylic hydrogen to give a carbanion **24**, followed by an intramolecular nucleophilic attack of the carbanion on the tetravalent nitrogen atom of an azido group, leading to a five-membered intermediate **25** with a negative charge on each nitrogen atom (Scheme 8).

Monoalkylation of **25** gives 1,3-dipolar intermediate **26a**, which is stabilized by a resonance form **26b**. Subsequent allylation, followed by deprotonation would give **8a**. In the meantime, a nucleophilic attack of *n*-butyl carbanion on an azido group gives 1-*n*-butyl-3-phenyltriazene **27a** [4], which may be stabilized by a resonance form **27b**. Intramolecular proton transfer of **27a** would generate a carbanion **28**. Protonation of **28**, followed by decomposition would give **10a** or **17** [11]. Alternatively, compounds **10a** and **17** can be formed from intermediate **27** *via* the same protonation and decomposition processes. In contrast, intramolecular nucleophilic attack of the benzylic carbanion **29**, a tautomer of **28**, on the trivalent nitrogen concomitant with displacing the *n*-butylamide ion would lead to **30**, a tautomer of **9a** and **31**. However, we obtained **9a** as a single compound. It has been reported that 1*H*-indazoles are thermodynamically more stable than 2*H*-indazoles [12] and that the equilibrium position between tautomers is dependent on the solvent polarity. However, molecular mechanics calculations show that **8g** ($E = 35.75$ kcal/mol) is more stable than its 1*H*-isomer ($E = 38.54$ kcal/mol) by 2.79 kcal/mol [13]. Similarly, 2*H*-indazole **9a** ($E = 29.75$ kcal/mol) is more stable than its 1*H*-indazole isomer ($E = 33.70$ kcal/mol) by 3.95 kcal/mol. This tendency is consistent with the experimental results. Further study is necessary to delineate why 2*H*-**8** and 2*H*-**9** are more stable than 1*H*-**8** and 1*H*-**9**, respectively. A nucleophilic attack of the carbanion **24** on allyl bromide would give **12a**, analogous to **19**. A similar reaction of **12a** as shown in the formation of **10a** from **27a** would give **11a**.

**Scheme 6**



## CONCLUSION

In summary, when 1-(2-azidoarylmethyl)-1*H*-benzotriazoles (**6**) was treated with *n*-BuLi in THF at −78°C, followed by an addition of alkyl halides, *i.e.*, allyl, benzyl, ethyl bromides, TLC did not exhibit any new spots. On the other hand, four new spots corresponding to 2*H*-indazole derivatives **8** and **9**, which to the best of our knowledge had not been previously reported in the reactions of azido compounds, together with some weak spots, were observed at room temperature. Compounds **8** are envisaged to be formed by a nucleophilic attack of benzylic carbanion on the azido group, followed by displacement of halides twice in stepwise manner by the $S_N2$ mechanism. Compounds **9** would be formed by a nucleophilic attack of benzylic carbanion on triazenes. The formation of compounds **10** and **11** may be

## EXPERIMENTAL

The $^1$H NMR spectra was recorded at 300 MHz, unless otherwise stated in $CDCl_3$ solution containing tetramethylsilane as internal standard: *J* values are given in hertz (Hz). The $^{13}$C NMR spectra were recorded at 75 MHz, unless otherwise stated in $CDCl_3$ solution. IR spectra were recorded in KBr or thin-film samples on KBr plates. Mass spectra were obtained by electron impact at 70 eV. Elemental analyses were determined by the National Center for Inter-University Research Facilities, Seoul National University. Column chromatography was performed using silica gel (Merck, 70-230 mesh ASTM). Mps were determined on a Fisher–Johns melting-point apparatus and are uncorrected.

**General procedure for the synthesis of 2-azidoarylmethyl halides 5**

***2-Azidoarylmethyl bromides 5a-b, 5d-e, and 5g-h.*** To a stirred solution of arylamine (32.80 mmol) in concentrated $H_2SO_4$ (6 mL) was added $NaNO_2$ (39.36 mmol) at 0°C. The mixture was stirred for 30 min, followed by addition of $NaN_3$ (55.76 mmol), which was additionally stirred for 24 h. Work-up according to the literature procedure [5a] gave substituted 2-azidotoluenes. A mixture of 2-azidotoluene, *N*-bromosuccinimide (NBS) (1.05 equiv.) and benzoyl peroxide (0.05 equiv.) in benzene (60 mL) was heated at reflux for 24 h [5b]. Usual work-up of the reaction mixture gave **5a-b** (73, 87%), **5d-e** (79, 64%), and **5g** (89%), respectively. Similarly, 4-azidobenzyl bromide (**5h**) was prepared from 4-azidotoluene in 90% yield.

***2-Azidoarylmethyl chlorides 5c and 5f.*** To a stirred solution of substituted 2-aminoarylmethyl alcohols (32.80 mmol) in concentrated $H_2SO_4$ (6 mL) was added $NaNO_2$ (39.36 mmol) at 0°C for 30 min, followed by addition of $NaN_3$ (55.76 mmol). The mixture was additionally stirred for 24 h, followed by usual work-up gave substituted 2-azidoarylmethyl alcohol. Treatment of 2-azidoarylmethyl alcohols with thionyl chloride [5c] (1.2 equiv.) at 0°C for 3 h gave **5c** (63%) and **5f** (62%).

**General procedure for the synthesis of 1-(2-azidoarylmethyl)-1*H*-benzotriazoles 6 and 2-(2-azidoarylmethyl)-2*H*-benzotriazoles 7.** To a stirred solution of sodium (5.65–8.82 mmol) in absolute ethanol (20 mL) was added a solution of benzotriazole (**1a**) (5.38–8.40 mmol) in absolute ethanol (30 mL). The mixture was stirred for 20 min, followed by addition of **5** (5.65–8.82 mmol), which was heated for 3.5 h at reflux. Work-up according to the literature procedure [6] gave compounds **6** and **7**. Yields are listed in Table 1.

**Reaction of 5-chlorobenzotriazole (1b) with 2-azidobenzyl bromide (5a).** In accordance with the aforementioned general procedure, **5a** (1770 mg, 8.34 mmol) was added to a mixture of **1b** (1220 mg, 7.94 mmol) and Na (183 mg, 8.34 mmol) in absolute ethanol (50 mL). The mixture was stirred for 12 h at room temperature. After removal of the solvent *in vacuo*, the residue was chromatographed on a silica gel (3.0 × 15 cm$^2$) using a mixture of EtOAc and *n*-hexane (1:5) to give 2-(2-azidophenylmethyl)-2*H*-(5-chlorobenzotriazole) (**7i**) (407 mg, 18%), a mixture of 1-(2-azidophenylmethyl)-6-chloro-1*H*-benzotriazole (**6i**) and 1-(2-azidophenylmethyl)-5-chloro-1*H*-benzotriazole (**6i′**) (995 mg, 44%) and unreacted **1b**. The mixture of **6i** and **6i′** (1:1 based on the $^1$H NMR signal of $CH_2$) was separated by the repeated recrystallization using a mixture of EtOAc and *n*-hexane (1:15) to give **6i** and **6i′** as solids.

Calc. for $C_{13}H_{11}ClN_4$: C, 60.35; H, 4.3; N, 21.7%); $\nu_{max}$ (KBr)/cm$^{-1}$ 3348, 3231, 3042, 2950, 2856, 1601, 1580, 1441, 1281, 1154, 1072, 906, 742, and 521; $^1$H NMR δ 4.29 (2H, s, $NH_2$), 5.77 (2H, s, $CH_2$), 7.10–7.19 (2H, m, ArH), 7.28 (1H, d, *J* 8.0, ArH), 7.31 (1H, d, *J* 8.7, ArH), 7.42–7.52 (2H, m, ArH), and 8.17 (1H, d, *J* 8.8, ArH); $^{13}$C NMR δ 50.6, 110.1, 118.8, 121.4, 125.6, 125.7, 125.8, 130.4, 130.6, 133.9, 134.3, 138.4, and 145.1.

**Reaction of 6a with a mixture of allyl bromide and benzyl bromide.** In accordance with the aforementioned general procedure, a mixture of **6a** (330 mg, 1.32 mmol), allyl bromide (191 mg, 1.58 mmol), benzyl bromide (270 mg, 1.58 mmol), and *n*-BuLi (3.30 mmol) in THF was stirred for 1 h at −78°C to room temperature for 2 h. TLC (silica gel, EtOAc: *n*-hexane = 1:4) showed four major spots ($R_f$ = 0.79, 0.70, 0.42, and 0.27). The mixture was chromatographed on a silica gel (2.5 × 13 cm$^2$). Elution with EtOAc and *n*-hexane (1:6) gave **8a** (40 mg, 7%), a mixture of compounds (114 mg), **9a** (37 mg, 12 %), and **10a** (29 mg, 10%). Separation of the mixture has been unsuccessful. However, the $^1$H NMR spectrum of the mixture indicated that the mixture consisted of **8a** (39 mg, 9%) and 2-(*N*-allyl-*N*-benzylamino)-3-(benzotriazol-1-yl)-2*H*-indazole (**23**) (75 mg, 15%). FAB MS showed mass

number (*m*/*z*) 331 and 381, which corresponding to the molecular weights of **8a** plus 1 and **23** plus 1, respectively.

***23.*** Viscous liquid (mixed with **8a**); $\nu_{max}$ (KBr)/cm$^{-1}$ 3056, 2924, 2840, 1628, 1600, 1554, 1523, 1444, 1370, 1226, 1160, 990, 942, 830, 740, and 520; $^1$H NMR δ 3.97 (1H, d, *J* 4.6, C*H*$_2$CH=CH$_2$), 4.09 (2H, s, C*H*$_2$Ph), 5.06 (1H, d, *J* 16.9, =CH$_2$), 5.14 (1H, d, *J* 17.2, =CH$_2$), 5.71–5.87 (1H, m, =CH), 6.77–6.97 (4H, m, ArH), 7.01–7.25 (3H, m, ArH), 7.30–7.51 (4H, m, ArH), 7.85 (1H, d, *J* 8.7, ArH), and 8.21 (1H, d, *J* 8.3, ArH); $^{13}$C NMR δ 61.1, 61.6, 110.4, 118.7, 120.5, 124.2, 124.8, 127.5, 128.1, 128.6, 128.7, 128.9, 129.5, 129.6, 132.8, 134.7, 135.9, 145.4, and 145.5.

**Reaction of 6a with allyl bromide in the presence of various bases.** In accordance with the aforementioned general procedure, **6a** (200 mg, 1.25 mmol) was treated with bases such as *tert*-BuLi (1.88 mmol), $NaNH_2$ (1.88 mmol), $KN(SiMe_3)_2$ (1.88 mmol), LDA (1.88 mmol) followed by TMEDA (145 mg, 1.25 mmol), and *n*-BuLi (1.88 mmol) followed by *tert*-BuOK (140mg, 1.25 mmol) in THF (25 mL) for 1 h at −78°C and then 2 h at room temperature. The only exception was the reaction with NaH (1.88 mmol) for 5 h at room temperature. The reaction was quenched by addition of water (30 mL). The mixture was extracted with $CH_2Cl_2$ (20 mL × 3). The combined extract was dried over $MgSO_4$. Chromatography (2.5 × 10 cm$^2$, EtOAc:*n*-hexane = 1:5) of the residue gave unreacted **6a** and **8a**-**10a**, depending on the bases. The results are summarized in Table 3.

**General procedure for the reactions of simple aryl azides with *n*-BuLi.** To a stirred solution of aryl azides (4.88 mmol) in THF (25 mL) for 1 h at −78°C was added *n*-BuLi (9.76 mmol). The mixture was stirred for 2 h at room temperature and worked up as usual. Chromatography of the residue using a mixture of EtOAc and *n*-hexane (1:10) gave alkyl aryl amines **22**, aryl amines **22**, and unreacted aryl azides.

**Reaction with *p*-azidotoluene.** In accordance with the aforementioned general procedure, *p*-azidotoluene (540 mg, 4.06 mmol) was treated with *n*-BuLi (8.12 mmol) to give *p*-toluidine (**21a**) (300 mg, 69%), *N*-butyl-*p*-toluidine [14] (**22a**) (53 mg, 8%) and unreacted *o*-azidotoluene (5 mg, 1%).

**Reaction with *o*-azidotoluene.** In accordance with the aforementioned general procedure, *o*-azidotoluene (650 mg, 4.88 mmol) was treated with *n*-BuLi (9.76 mmol) to give *o*-toluidine (**21b**) (397 mg, 76%), *N*-butyl-*o*-toluidine [14] (**22b**) (48 mg, 6%) and unreacted *o*-azidotoluene (13 mg, 2%).

**Reaction with *o*-azidoethylbenzene.** In accordance with the aforementioned general procedure, *o*-azidoethylbenzene (520 mg, 3.53 mmol) was treated with *n*-BuLi (7.06 mmol) to give *o*-ethylamine (**21c**) (295 mg, 69%) and *N*-butyl-2-ethylphenyl amine [15] (**22c**) (50 mg, 8%).

**Reaction with 2-azidodiphenylmethane.** In accordance with the aforementioned general procedure, 2-azidodiphenylmethane (500 mg, 2.39 mmol) was treated with *n*-BuLi (4.78 mmol) to give *o*-(*n*-butylamino)diphenylmethane [16] (**22d**) (40 mg, 7%) and 2-benzylaniline [17] (**21d**) (315 mg, 72%).

**Reaction of 6a with methylmagnesium bromide.** To a solution of methylmagnesium bromide (250 mg, 2.10 mmol) in THF (15 mL) at 0°C was added **6a** (350 mg, 1.40 mmol). The mixture was stirred for 1 h at 0°C and then at room temperature for 2 h. The mixture was worked up as usual and chromatographed on a silica gel (2.5 × 5 cm$^2$) using a mixture of EtOAc and *n*-hexane (1:1) to give 2-[(benzotriazol-1-yl)methyl]phenyl methyltriazene (**13**) (338 mg, 91%). Mp 133–135°C (from $CH_2Cl_2$–*n*-hexane) (Found: C, 63.0; H, 5.3; N, 31.65. Calc. for $C_{14}H_{14}N_6$: C, 63.1; H, 5.3; N, 31.6%); $\nu_{max}$ (KBr)/cm$^{-1}$ 3263, 3066, 3003, 2954, 1431, 1371, 1220, 1077, 943, 746, 718, and 531; $^1$H NMR δ 3.24 (3H, s, $CH_3$), 6.16 (2H, s, $CH_2$), 7.07–7.07 (2H, m, ArH), 7.25–7.38 (3H, m, ArH), 7.42–7.51 (2H, m, ArH), 8.05 (1H, d, *J* 7.1, ArH), and 8.36 (1H, s, NH); $^{13}$C NMR δ 48.4, 110.7, 120.2, 124.2, 126.7, 127.5, 129.4, 129.6, 133.4, and 146.6.

**Preparation of 1-(2-aminophenylmethyl)benzotriazole 10a.** In accordance with the literature procedure [7], a solution of 1-(2-azidophenylmethyl)benzotriazole (**6a**) (250 mg, 1.00 mmol) in a mixture of THF (30 mL) and MeOH (0.3 mL) was treated with $NaBH_4$ (12 mg, 0.30 mmol). The mixture was heated at reflux for 2 h. Work-up gave **10a** (202 mg, 90%).

**Reaction of 10a with allyl bromide in the presence of *n*-BuLi.** To a stirred solution of **10a** (202 mg, 0.90 mmol) in THF (25 mL) at −78°C was added *n*-BuLi (2.25 mmol) and allyl bromide (272 mg, 2.25 mmol). After being stirred for 2 h at room temperature, the mixture was worked up as usual. Chromatography (2.5 × 13 cm$^2$) using a mixture of EtOAc and *n*-hexane (1:4) as an eluent gave allyl[2-{1-(benzotriazol-1-yl)-3-butenyl}-phenyl]amine (**16**) (14 mg, 5%), diallyl[2-{(benzotriazol-1-yl)methyl}phenyl]amine (**15**) (89 mg, 33%), allyl[2-{(benzotriazol-1-yl)methyl}phenyl]amine (**14**) (90 mg, 38%).

A study on the acid catalyzed halogen dance (ACHD) on deactivated bromopyrroles is reported. A different behavior is observed when considering singly deactivated pyrrole alkylcarboxamides, or doubly deactivated pyrroleketo-lactams (aldisines). Although less electron deficient pyrrole alkylcarboxamides suffer from ACHD, the double deactivation on keto-lactams disfavors pyrrole ring protonation thus preventing halogen scrambling. The mechanism involved in the rearrangement is hypothesized.

## INTRODUCTION

The first example of the well-known Halogen Dance (HD, also named halogen scrambling, halogen migration, halogen isomerization, halogen shift) reaction dates back to 1951, when Vaitiekunas isolated tetrabromothiophene instead of 2-ethynylthiophene by treating 2-bromothiophene with sodium acetylide in liquid ammonia [1]. The reaction was induced by the presence of the base and since then it has been largely investigated. Currently, the base catalyzed halogen dance (BCHD) is considered a useful tool for the introduction of halogen on aromatic and heteroaromatic substrates in positions that could be hardly reached with other methods. A recently published review thoroughly describes BCHD with elucidations of the mechanism and description of the factors that influence the reaction [2]. Among all the heteroaromatic substrates, no examples on pyrrole have been reported.

What is known in the literature referring to pyrroles solely deals with the effect of acids on substituents in the 2 position of the ring. In this context, acyl [3] and sulfinyl [4] moieties as well as halogens (bromine and chlorine) [5] have been considered. Rearrangement of 2-acylpyrroles aimed at the synthesis of 3-acyl isomers has been studied in the presence of strong acids (PPA, TFA). A [1,2]-acyl shift was hypothesized to rationalize the formation of the products [3(b)], as it was previously postulated for the isomerization of 2-acetylindoles [6]. Rearrangement as side-reaction, on the contrary, was observed in the sulfinylation of pyrroles with sulfinylchlorides: 2-sulfinylpyrroles were contaminated by 3-sulfinyl isomers, likely coming from an acid-catalyzed migration of the substituent in 2-position due to HCl released during the reaction [4]. Moreover, PPA-mediated cyclization of 3-(2-pyrrolyl)propionic acids afforded the expected products along with undesired regioisomers arising from both alkyl and acyl migration [3(a)]. Complex reaction mixtures were also obtained when pyrrole was treated with molecular bromine: beside the expected 2-bromopyrrole, products deriving from both isomerization and disproportionation of the brominated substrate were detected [5(a)]. The mechanism of bromine isomerization and disproportionation of *N*-benzyl-2-bromopyrrole in the presence of TFA has been recently investigated by Park *et al*., who suggested a 1,3-bromine shift to explain rearrangement on the corresponding *N*-benzyl-2-bromo-5-deuterio pyrrole [5(c)].

Thus, if on one hand halogen dance may be useful for the insertion of groups in specific positions of aromatic and heteroaromatic substrates, on the other hand it could represent a parasitic reaction when the shift of the halogen is unwanted. This is the case, for instance, of 2-bromoaldisine **1** (common name of 2-Bromo-6,7-

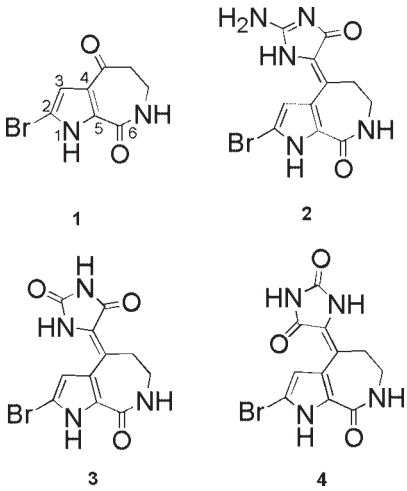

**Figure 1.** Bromopyrrole alkaloids derived from 2-bromoaldisine **1**.

dihydro-1H,5H-pyrrolo[2,3-c]azepine-4,8-dione), envisaged as the key-intermediate for the synthesis of some bromopyrrole alkaloids, such as (*Z*)-hymenialdisine **2** [7], (*Z*)-axinohydantoin **3,** and (*E*)-axinohydantoin **4** [8] (Fig. 1).

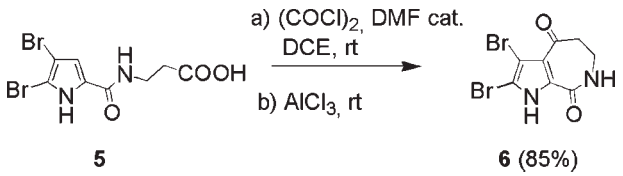
The synthesis of **1** was reported for the first time by Annoura by means of a $PPA/P_2O_5$-mediated cyclization of the corresponding 2-bromopyrrole propionic acid [7(a)]. The reaction suffered from bromine scrambling, delivering a 1:1 mixture of hardly separable bromoaldisine regioisomers. Interestingly, this was the first example of acid catalyzed halogen dance (ACHD) on deactivated pyrroles.

This side-reaction was later efficiently avoided by exploiting a Friedel-Craft-type cyclization on the acyl chloride intermediate in the presence of $AlCl_3$, affording **1** as the sole product in 69% optimized yield [8]. The same synthetic protocol allowed the preparation of 2,3-dibromoaldisine **6** [9] from the corresponding dibromoacid **5** [10] in 85% yield without any bromine rearrangement, differently from what previously reported in the presence of $PPA/P_2O_5$ [10] (Scheme 1).

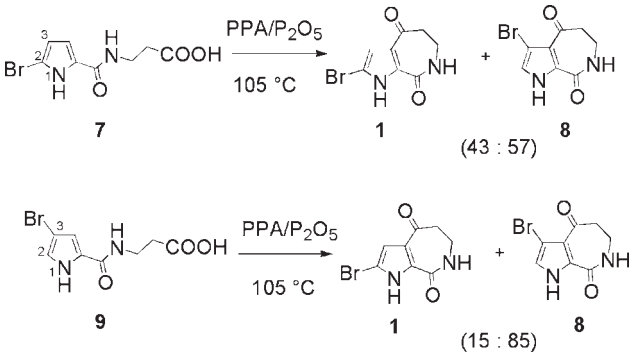
## RESULTS AND DISCUSSION

The different reaction outcomes that a protic acid ($PPA/P_2O_5$) *versus* a Lewis acid ($AlCl_3$) displayed while performing the synthesis of bromoaldisines **1** and **6**, prompted us to study in more detail the ACHD on variously deactivated bromopyrroles in a strong acidic environment.

**Scheme 1.** Lewis acid-mediated synthesis of **6.**



**Scheme 2.** ACHD on bromopyrrolecarboxamides **7** and **9.**



To this purpose we decided, at first, to confirm the observations previously published for the synthesis of 2-bromo (**1**) and 3-bromoaldisine (**8**), by using the same reaction conditions (reagents, temperature, and reaction time) in the cyclization of **7** and **9** [11] (Scheme 2). As described, treatment of **7** with $PPA/P_2O_5$ at 105°C for 1 h produced a mixture of **1** and **8** in a 43:57 ratio (measured by $^1H$ NMR). On the contrary, in our hands regioisomer **9** [12] gave rise to a 15:85 mixture of **1** and **8** under the same conditions, in contrast with the literature (1:1 ratio as for **7**) [7(a)].

In these examples, $PPA/P_2O_5$ mediates both cyclization and scrambling of bromine atom. With the aim of trying to understand whether halogen dance (HD) took place before or after cyclization, the same acidic treatment was performed directly on brominated aldisines **1** and **8**. 2-Bromoaldisine **1** was synthesized as already described [8], while 3-bromoaldisine **8** was successfully isolated from the enriched mixture (15:85) deriving from **9** (see Scheme 2) by means of preparative HPLC. The two substrates have then been subjected to $PPA/P_2O_5$ treatment. The results highlighted minor differences, namely 2-bromoaldisine **1** was not prone at all to

rearrangement, while 3-bromoaldisine **8** produced a small percentage (2%) of 2-bromoisomer **1** (Scheme 3). This means that these keto-lactams hardly undergo halogen scrambling and HD occurs before cyclization.

The observations of ACHD on these substrates are summarized in Table 1.

Intrigued by these outcomes, we decided to evaluate the effect of PPA/$P_2O_5$ on bromopyrroles that: (a) were singly deactivated, like pyrrole alkylcarboxamides **7** and **9**, and (b) could not undergo cyclization, differently from **7** and **9**. Bromopyrrole methylcarboxamides **11** and **13** [11] have been chosen as the suitable substrates to the purpose, having the same EWG as **7** and **9**. Their synthesis is reported in Scheme 4: treatment of 2-trichloroacetylpyrrole with methylamine and subsequent bromination of **10** with NBS in THF/MeOH (2:1) afforded **11** (60% yield over two steps). The direct bromination of the same starting material with $Br_2$ in $CHCl_3$ and subsequent reaction of intermediate **12** with methylamine yielded **13** [13] (70% yield over two steps).

Both bromopyrroles **11** and **13** underwent rearrangement in different ratios, along with disproportionation that generated des-bromo derivative **10** and 4,5-di-bromomethylamide **14** (Scheme 5, Table 2).

As previously mentioned, the amount of the products has been determined by integrating isolated pyrrole CH signals in the $^1$H NMR spectra of the reaction mixtures [Fig. 2(a,b)].

These results allowed us to make some considerations about the kinetics/thermodynamics of the ACHD on deactivated pyrroles compared to cyclization and to hypothesize a possible mechanism. First, it is evident that pyrrole alkylcarboxamides (*i.e.*, **7**, **9**, **11**, and **13**) are more prone to halogen rearrangement (Table 1, Entries 3 and 4; Table 2) than aldisines (Table 1, Entries 1 and 2). Second, scrambling of the halogen is faster when involving a shift from 2- to 3-position at the pyrrole ring (Table 1, Entry 3; Table 2, Entry 1) than vice versa (Table 1, Entry 4; Table 2, Entry 2). The ratio of 2-bromo and 3-bromoaldisine generated from **7** and the distribution of 2- and 3-regioisomers deriving from **11** (Table 1, Entry 3; Table 2, Entry 1) are the same. This means that the two mixtures reach the equilibrium during the reaction (thermodynamic conditions). Moreover, considering that aldisines are insensitive to ACHD, it is fair to assert that, for **7**, $V_{2S} > V_{2C}$, where $V_{2S}$ represents the velocity of scrambling, and $V_{2C}$ the velocity of cyclization (Scheme 6).

On the contrary, the same treatment on **9** and **13** did not spring out analogous results. The ratios of the two aldisines (products of **9**) and of 2- and 3-regioisomers arising from **13** measured in the experiments are different, meaning that these reaction mixtures are under kinetic conditions. It is possible to postulate that, for **9**, $V_{3C} \geq V_{3S}$, meaning that the velocity of cyclization and of scrambling are competitive (see Table 1, Entry 4). Furthermore, rearrangement from 2-position of **7** and **11** is faster than from carbon 3 of **9** and **13**, that explains the higher velocity with which **11** and **7** reach the equilibrium ($V_{2S} > V_{3S}$, see Table 1, Entries 3 and 4, and Table 2). Finally, disproportionation on **7** and **9** and on aldisines **1** and **6** has never been observed, while for **11** and **13** only to a less extent, meaning that this side-reaction is the slowest ($V_D << V_S$ and $V_C$, being $V_D$ = velocity of disproportionation).

**Table 2**

Results of ACHD on **11** and **13** (105°C, 1 h).

| Entry | Substrate | **11** (%)[a] | **13** (%)[a] | **10** (%)[a] | **14** (%)[a] |
|---|---|---|---|---|---|
| 1 | **11** | 32 (46)[b] | 38 (54)[b] | 15 | 15 |
| 2 | **13** | 25 (34)[b] | 49 (66)[b] | 13 | 13 |

[a] Measured by integrating isolated pyrrole CH signals in $^1$H NMR spectrum.
[b] In brackets the relative percentage of **11** and **13** is reported.

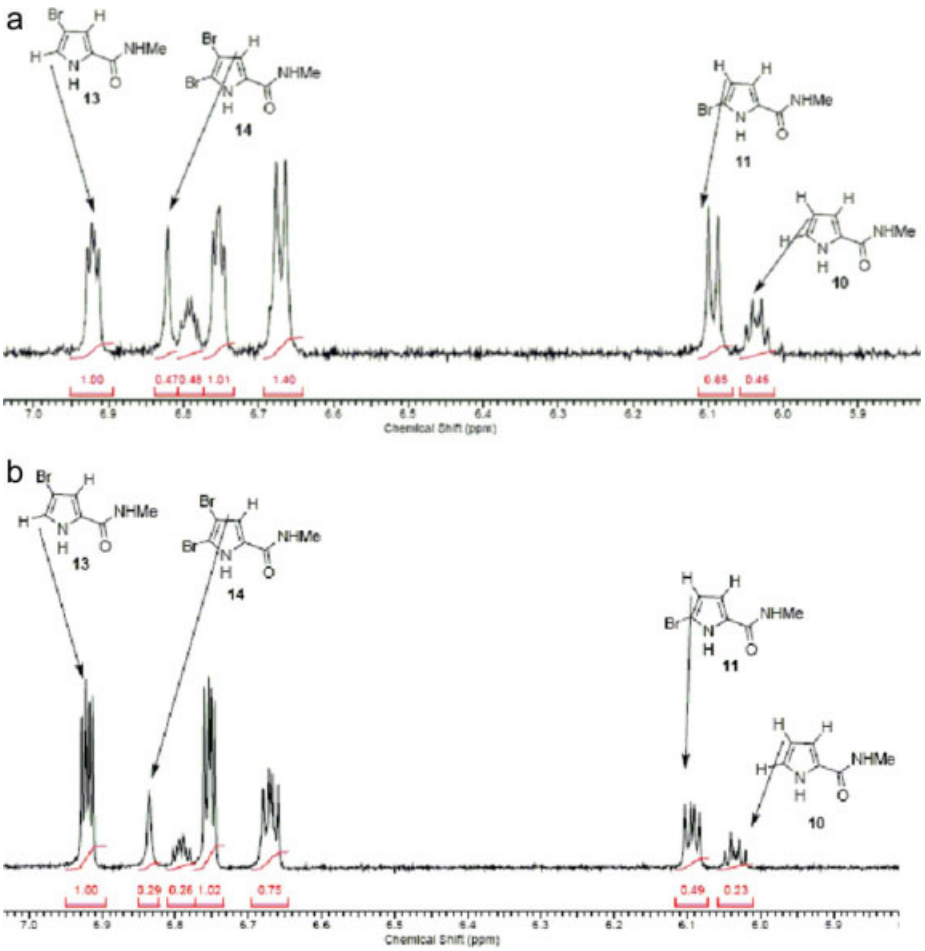

**Figure 2.** $^{1}$H NMR analysis of ACHD on **11** (**2a**: top) and **13** (**2b**: bottom). [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

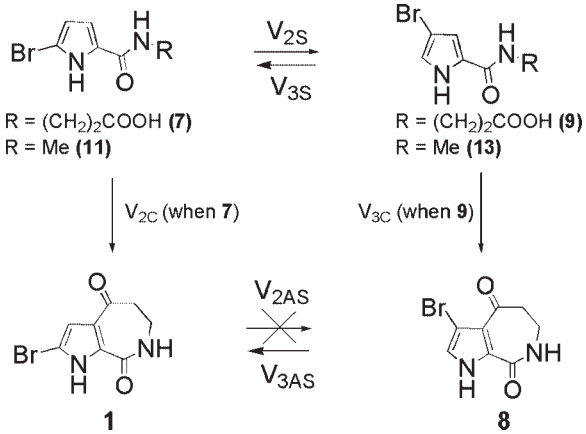
A rearrangement mechanism was postulated to explain ACHD (Scheme 7). In strong acid media, **7** and **11** are subjected to protonation at the 2-position of the pyrrole affording **7a** and **11a**, respectively, which undergo a 1,2-bromine shift toward **9a** and **13a**, passing through transient cyclic bromonium intermediate **15**. The same mechanism can be invoked for **9** and **13**, that are protonated at 3-position generating **9a** and **13a**, respectively. A cyclic bromonium intermediate has been hypothesized instead of free $Br^{+}$ cation because statistically this would have generated a higher amount of dibrominated pyrrole from **11** and **13** (see Table 2) and the presence of dibromo/desbromo aldisines from **7** and **9** (see Table 1).

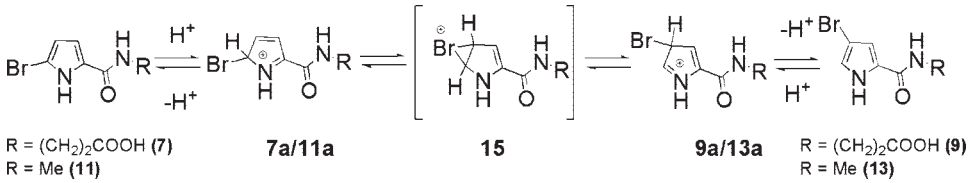
## EXPERIMENTAL

**General.** Melting points were determined in open glass capillaries with a Buchi 535 melting point apparatus, and are uncorrected. NMR spectra (1D $^{1}$H and 2D H-C hetero correlated) were recorded at 25°C in DMSO-$d_6$ on a Varian Inova 500 spectrometer equipped with a 5 mm $^{1}$H{$^{13}$C,$^{15}$N} z-axis-PFG indirect detection cold probe or at 28°C on a Varian Mercury 300 spectrometer equipped with a 5 mm switchable probe $^{15}$N-$^{31}$P{$^{1}$H,$^{19}$F}. Residual solvent signal was used as

**Scheme 6.** Velocity of cyclization *versus* scrambling.



**Scheme 7.** ACHD mechanism hypothesized.



reference; chemical shifts and coupling constants are reported, respectively, in δ (ppm) and Hz. ESI(+) high-resolution mass spectra (HRMS) were obtained on a Waters Q-Tof Ultima directly connected with micro HPLC 1100 Agilent [14].

## CONCLUSION

In conclusion, a study on the ACHD on deactivated bromopyrroles has been reported and an hypothetical mechanism has been suggested. A different behavior was observed when considering singly deactivated pyrrole alkylcarboxamides, or doubly deactivated pyrrole-keto-lactams (aldisines). While less electron deficient pyrrole alkylcarboxamides suffered from ACHD, the double deactivation on keto-lactams disfavored protonation thus preventing halogen scrambling. Moreover, in the carboxamides series, scrambling was faster when bromine atom was in the 2-position rather than on 3-carbon. In addition, during the conversion of pyrrole alkylcarboxamides **7** and **9** into aldisines, cyclization occurred, respectively, after scrambling and at a competitive velocity.

## EXPERIMENTAL

**General procedure for ACHD.** $P_2O_5$ (2 eq) and PPA (28 eq) were mechanically stirred and heated at 120°C for 50 min, to obtain a clear solution. The substrate was then added and the mixture was heated at 105°C for 1 h. The mixture was poured into ice water and stirred for 1 h. The solid was filtered off, washed with water, and dried. A second aliquot of reaction mixture was recovered from the aqueous phase as follow: the water solution was cooled, neutralized with concentrated sodium hydroxide, and extracted with $CH_2Cl_2$. The organic phase was dried over anhydrous $Na_2SO_4$, concentrated, and combined with the solid.

**2,3-Dibromo-6,7-dihydro-1H,5H-pyrrolo[2,3-c]azepine-4,8-dione (6).** To a suspension of **5** (414 mg, 1.21 mmol) in dry $CH_2Cl_2$ (15 mL) oxalyl chloride (0.21 mL, 2.43 mmol) and $DMF_{cat}$ (0.015 mL) were added. The mixture was stirred under nitrogen until completion of gas evolution. The solvent was removed under reduced pressure and the crude was dissolved in 1,2-dichloroethane (40 mL). 4-Å molecular sieves and aluminium trichloride (0.65 g, 4.87 mmol) were subsequently added. The red solution was stirred at room temperature overnight. After removal of the solvent under reduced pressure, the residue was dissolved in water, made alkaline by addition of 2*N* sodium hydroxide and then acidified to pH 2 with conc. HCl. The precipitate was filtered, washed with water, and dried under vacuum. **6** was isolated as white solid (334 mg, 85%). mp: 270–272°C. $^1$H NMR (400 MHz, DMSO-$d_6$) δ ppm 2.76 (m, 2 H) 3.34 (m, 2 H) 8.47 (br. s., 1 H) 13.46 (br. s., 1 H). $^{13}$C NMR (125.7 and 75.4 MHz, DMSO-$d_6$) δ 36.0, 44.3, 99.0, 110.3, 120.5, 130.6, 161.5, 192.6. HRMS calcd for $C_8H_7Br_2N_2O_2$ [M+H$^+$] 320.8869 found 320.8853.

**3-Bromo-6,7-dihydro-1H,5H-pyrrolo[2,3-c]azepine-4,8-dione (8).** The general procedure for ACHD was performed on **9** (170 mg, 0.65 mmol). One hundred thirty milligram of crude were purified by prep-HPLC (eluant 0,05% $NH_3$ in $H_2O$/Acetonitrile 95:5 as a mobile phase A and Acetonitrile as mobile phase B), affording **8** (102 mg, 64%) as a white solid. The separation was achieved using a rapid gradient increasing 0–25% B in 15 min followed by a hold at 100% B for 2 min at a flow rate of 20 mL/min. mp: 248–250°C. $^1$H NMR (400 MHz, DMSO-$d_6$) δ ppm 2.76 (m, 2 H, $CH_2CO$) 3.35 (m, 2 H, C*H*$_2$NH) 7.20 (s, 1 H, C*H*NH) 8.45 (t, $J$ = 5.12 Hz, 1 H, N*H*CH$_2$) 12.52 (br. s., 1 H, NH). $^{13}$C NMR (125.7 MHz, DMSO-$d_6$) δ 35.6, 44.6, 96.7, 118.9, 124.0, 128.8, 161.5, 193.8, HRMS calcd for $C_8H_8BrN_2O_2$ [M+H$^+$] 242.9764 found 242.9759.

**1H-Pyrrole-2-carboxylic acid methyl amide (10).** To a solution of 2-trichloroacetylpyrrole (2.12 g, 9.98 mmol) in 40 mL of dry $CH_3CN$, a 2*M* solution of $MeNH_2$ in THF was added (12.5 mL, 25 mmol). The mixture was stirred under nitrogen, at room temperature for 48 h, until HPLC revealed the disappearance of the starting material. The solvent was removed under reduced pressure to give **10** as white solid. mp: 151–152°C. $^1$H NMR (400 MHz, DMSO-$d_6$) δ ppm 2.72–2.74 (d, 3 H, $J$ = 5 Hz, $CH_3$) 6.06 (dt, $J$ = 3.63, 2.40 Hz, 1 H, CHC*H*CH) 6.70 (ddd, $J$ = 3.69, 2.41, 1.46 Hz, 1 H, CHC*H*C) 6.82 (td, $J$ = 2.69, 1.46 Hz, 1 H, CHC*H*N) 7.89 (br. s., 1 H, N*H*CH$_3$) 11.37 (br. s., 1 H, NH).

**5-Bromo-1H-pyrrole-2-carboxylic acid methylamide (11).** To a stirred solution of **10** (500 mg, 4.03 mmol) in dry MeOH (84 mL) and dry THF (168 mL) at 0°C, *N*-bromosuccinimide (NBS) (323 mg, 1.81 mmol) was added. The cold bath was removed and the reaction mixture was allowed to warm to room temperature under stirring. After 3 h, a HPLC control revealed a 50% conversion of **10–11**. The mixture was recooled to 0°C and more NBS (323 mg, 1.81 mmol) was added. The ice bath was removed and the reactants were stirred for further 2 h at room temperature. The solvent was then removed under vacuum and the residue was purified by flash chromatography (eluant $Et_2O$/Hexane 2:1) to give **11** in mixture with **14** as side product. **11** was isolated as white solid by reverse-phase chromatography (eluant 0.1% trifluoroacetic

acid in $H_2O$/acetonitrile 95/5 as mobile phase A and Acetonitrile as mobile phase B) (490 mg, 60%). mp: 173–175°C. $^1$H NMR (400 MHz, DMSO-$d_6$) δ ppm 2.71 (d, $J$ = 4.64 Hz, 3 H, $CH_3$) 6.11 (dd, $J$ = 3.72, 2.38 Hz, 1 H, CHC*H*CBr) 6.69 (dd, $J$ = 3.78, 2.69 Hz, 1 H, CHC*H*C) 7.93 (q, $J$ = 3.99 Hz, 1 H, N*H*$CH_3$) 12.15 (br. s., 1 H, NH). $^{13}$C NMR (125.7 MHz, DMSO-$d_6$) δ 25.0, 102.1, 110.5, 111.2, 128.8, 160.5. HRMS calcd for $C_6H_8BrN_2O$ [M+H$^+$] 202.9815 found 202.9821.

**4-Bromo-2-(trichloroacetyl)pyrrole (12).** 2-(Trichloroacetyl)pyrrole (10 g, 0.05 mol) in $CHCl_3$ (50 mL) was treated with $Br_2$ (9.5 g, 0.06 mol) in $CHCl_3$ (3 mL) at 5°C. The ice bath was removed and the reactants were stirred for 1 h at room temperature. The mixture was diluted with $CH_2Cl_2$ and washed with $H_2O$, $NaHCO_3$, and brine. The organic layer was dried (over $Na_2SO_4$) and concentrated under vacuum. The crude was then crystallized from hexane-$CH_2Cl_2$ affording **12** (11.3 g, 70%). $^1$H NMR (400 MHz, DMSO-$d_6$) δ ppm 7.34 (dd, $J$ = 2.68, 1.46 Hz, 1 H, CC*H*C) 7.56 (dd, $J$ = 3.29, 1.46 Hz, 1 H, C*H*N) 12.85 (br. s., 1 H).

**4-Bromo-1H-pyrrole-2-carboxylic acid methylamide (13).** Compound **12** (575 mg, 1.98 mmol) was treated with a 2*M* solution of $MeNH_2$ in THF (2.45 mL, 4.95 mmol) delivering **13** (400 mg, quantitative) as white solid after removal of the solvent. mp: 178–180°C. $^1$H NMR (300 MHz, DMSO-$d_6$) δ ppm 2.70 (d, $J$ = 4.69 Hz, 3 H, $CH_3$) 6.75 (dd, $J$ = 2.64, 1.47 Hz, 1 H, CHCBr) 6.92 (dd, $J$ = 2.93, 1.47 Hz, 1 H, CHN) 8.01 (q, 1 H, N*H*$CH_3$) 11.75 (br. s., 1 H, NH).

**Acknowledgments.** The authors acknowledge Dr. Maurizio Pulici and Dr. Sergio Mantegani for helpful suggestions and enlightening discussions, Dr. Daniela Borghi for NMR consulting.

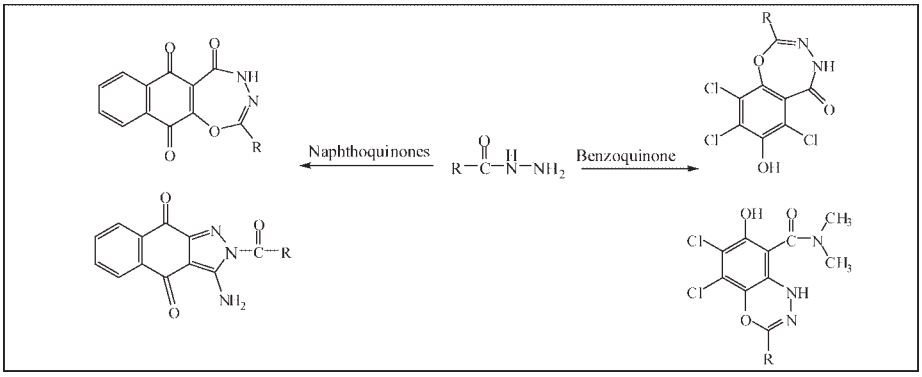
Published online 5 January 2010 in Wiley InterScience (www.interscience.wiley.com).



Nucleophilic attack by substituted hydrazides on C-2, C-3 of 2,3,5,6-tetrachloro-1,4-benzoquinone and 2,3-dichloro-1,4-naphthoquinone initiates the formation of benzo[e][1,3,4]oxadiazine and benzo- as well as naphthoxadiazepine derivatives. On the other hand, substituted hydrazides attack 1,4-naphthoquinone-2,3-dicarbonitrile to form benzo[f]indazole-4,9-dione derivatives. A rationale for the conversions observed is presented.

*J. Heterocyclic Chem.,* **47**, 118 (2010).

## INTRODUCTION

2,3,5,6-Tetrachloro-1,4-benzoquinone (**2**) and 2,3-dichloro-1,4-naphthoquinone (**3**) undergo nucleophilic substitution of one or two chlorine atoms by primary amines [1,2], amino acids [3,4], and aziridines [5]. Up to four nitrogen residues are introduced into **2** and **3** in their reaction with pyrazole [6], imidazole [7,8], and 1,2,4-triazole [7,9]. Amides and thioamides were added to **3** to produce two related heterocyclic diones series in excellent yields [10–14]. The reaction of **2** and **3** with $N^1$, $N^2$-diarylamidines to give benzimidazole and indole derivatives has been reported [15,16]. Heterocyclization of substituted thiosemicarbazides and dithiobiureas during the reaction with benzoquinones and naphthoquinones, different successful approach for the synthesis of oxathiadiazole [17], thiadiazine [17,18], imidazoxadiazole [19], imidazothiadiazole [20], and indazole [21] derivatives. A large variety of quinones, including many fused heterocyclic rings, have been used as synthetic intermediates in medicinal [22–25] and dye chemistry [26–29].

## RESULTS AND DISCUSSION

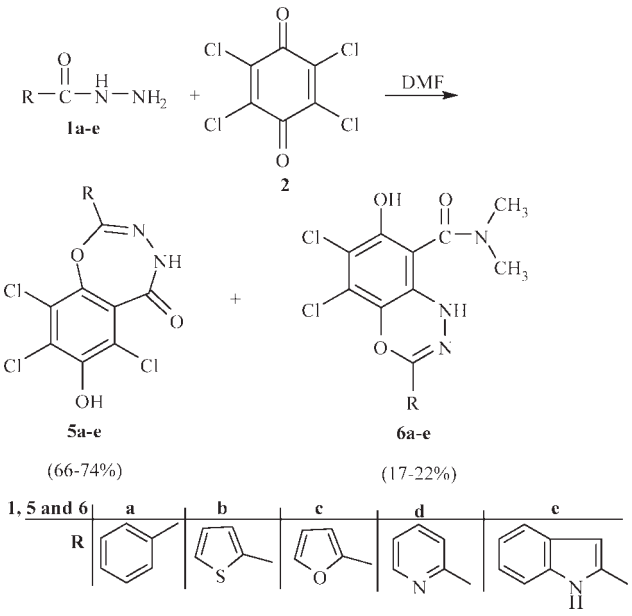
We report herein the results of our recent investigation on the reactions of substituted hydrazides **1a-e** with 2,3,5,6-tetrachloro-1,4-benzoquinone (**2**), 2,3-dichloro-1,4-naphthoquinone (**3**) and 1,4-naphthoquinone-2,3-dicarbonitrile (**4**).

Equimolar solutions of **1a-e** and **2** in DMF upon standing for 48 hours at room temperature formed the derivatives of benzoxadiazepine **5a-e** as major product (66–74%) and benzoxadiazine **6a-e** as minor product (17–22%) (Scheme 1).

The structural assignment of 6,8,9-trichloro-7-hydroxy-2-(substituted)benzo[*f*][1,3,4]oxadiazepine-5(*H*)-one **5a-e** are based on the following spectral data: The IR spectrum showed a broad bands at $\nu_{max}$ 3455–3480 and 3280–3335 because of OH and NH, sharp band at 1700–1710 for carbonyl group and 1620–1630 $cm^{-1}$ for C=N.

The $^1H$ NMR displayed two broad singlets, one at $\delta$ = 7.79–7.86 ppm and the other at $\delta$ = 9.57–9.62 ppm because of oxadiazepine-NH and phenolic-OH, respectively. The $^{13}C$ NMR spectrum showed a signal at $\delta$ = 152.46–152.75 ppm for aromatic quaternary carbon atom bearing a hydroxyl group [30], the presence of one carbonyl group at $\delta$ = 169.73–169.84 ppm and oxadiazepinone-C-2 at $\delta$ = 156.66–156.86 ppm. In the $^{13}C$ NMR the absence of characteristic resonance signals of the carbonyl carbon atoms of chloranil **2** around 182–184 [31] ppm support the structure **5a-e**. The formation of **5b** was further confirmed by mass spectrometry.

**Scheme 1**



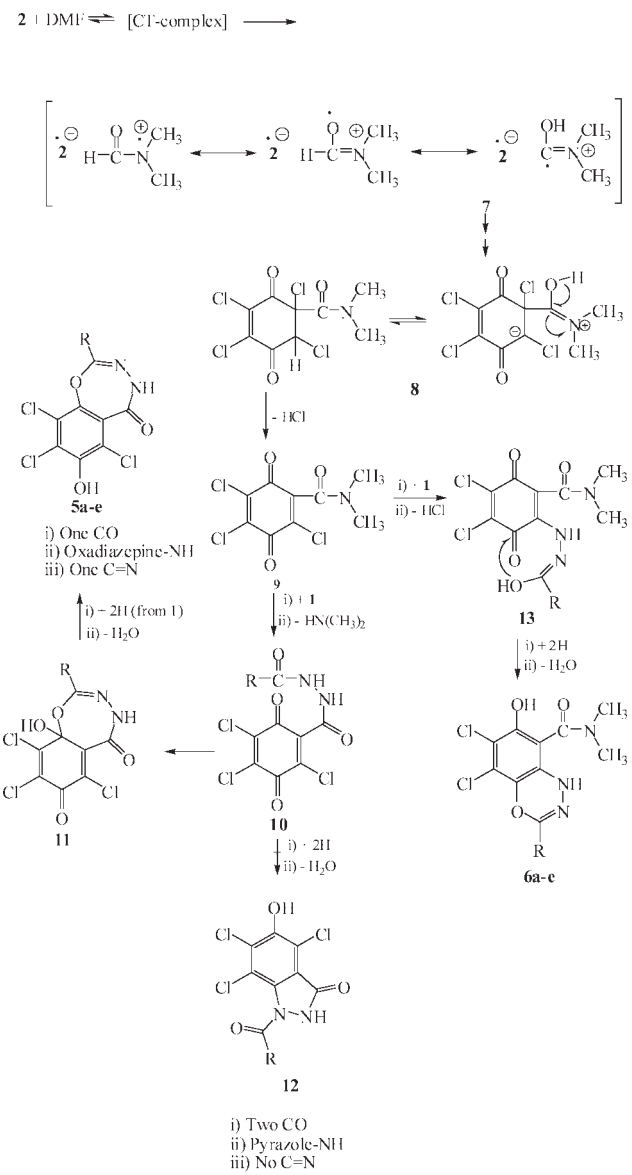
Besides the molecular ion at 362/368, the characteristic fragment ion patterns of trichloro compounds were observed. The EI mass spectrum of **5b** is characterized by loss of 111 a.m.u (most likely thiophene carbonyl group) followed by loss of 28 a.m.u (dinitrogen or carbonyl group). The *a priori* possible isomeric structure **12a-e** (Scheme 2) was ruled out on the basis of IR and $^{13}C$ NMR spectral data.

The structural assignment of **6a-e** was supported by the following spectral data: In its $^{13}C$ NMR spectrum, the characteristic absorption signal of two carbonyl carbon atoms of chloranil are replaced by signals at $\delta$ = 140.87–141.12 and $\delta$=152.46–153.04 ppm, which are characteristic of aromatic quaternary carbon bearing oxygen [30]. In addition Ph—C—Cl appears at 121.94–122.32 and 123.14–123.46 [31] ppm. The carbonyl group attached to $N(CH_3)_2$ resonates at $\delta$ = 171.23–171.42 [31] ppm. The IR spectrum of **6a-e** showed bands at 3470–3490 and 3290–3315 due to OH and NH, and strong absorption at 1680–1690 due to carbonyl group. The $^1H$ NMR spectrum of **6a-e** showed signals at 3.36–344, 7.69–7.81, and 9.61–9.74 due to $N(CH_3)_2$, oxadiazine–NH and hydroxyl group, respectively. It is worthy to note that the mass spectra of compounds **6a-e** show the loss of O=C—$N(CH_3)_2$, $N_2$ or CO, as well as RCO from the molecular ions.

Scheme 2 summarizes the reactions responsible for the formation of compounds **5** and **6**. It shows the interaction of **1a-e** with chloranil (**2**) in DMF as a solvent proceeded in an interesting manner because of the participation of DMF in the course of the reaction, as reported in our earlier publications on the reactions of hydrazino-1,2,4-triazinoindole [32], amino- and diamino-1,2,4-triazole derivatives [9] and 3,5-diaminopyrazoles [6] with chloronated benzoquinones and naphthoquinones.

Unstable charge-transfer complexes may be formed during the reaction between chlorinated quinone and DMF, followed by the formation of anionic cationic radicals **7**. Recombination of the radicals afforded the adduct **8**, which gradually split off a molecule of hydrogen chloride to form **9**. The latter interacted with the hydrazide **1** with elimination a molecule of dimethylamine and another of water in presence of hydrogen protons (possibly from **1**) to afford benzoxadiazepine derivatives **5a-e**. On the other hand compound **9** reacted with **1** to give **6a-e** as illustrated in Scheme 2.

**Scheme 2**



2,3-Dichloro-1,4-naphthoquinone **3** was chosen to compare its reactivity toward the hydrazides **1a-e** with chloranil (**2**).

It has been described in the literature that **3** resembles **2** in most of its substitution reactions, especially with compounds containing nucleophilic nitrogen (amines, amino acids, pyrazoles, imidazoles, etc) [1–7,9]. From this point of view one might expect that **1a-e** should react with **2** similarly like **3**. Earlier, it had been reported that **1a** reacted with **3**, ultimately giving 2,3-di(benzoyl-hydrazinyl)naphthalene-1,4-dione (**14**) (Scheme 3). We report here the results of recent investigations on the reaction of **1a-e** with **3**.

Mixing equimolar amounts of **1a-e** and **3** in DMF for 72 hours led to the formation of 2-substituted naphtho[2,3-*f*][1,3,4]oxadiazepine-5,6,11-(4*H*)-triones **16a-e** (Scheme 3). The IR spectra of **16a-e** (in KBr) showed NH absorption at 3230–3245 $cm^{-1}$, carbonyl groups at 1705–1725 and 1680–1690, as well as bands characteristic of C—O—C and C=N at 1090 and 1620–1630, respectively. The $^1H$ NMR spectra of **16a-e** clearly show one broad signal at 7.78–7.84 ppm due to oxadiazepine-NH.

Signals around 169.58–169–84 (C-5), 187.39–187.78 (C–6) [31] and 187.33–187.80 (C-11) [31] and 156.78–156.86 (C-2), in $^{13}C$ NMR spectra lend further support to the structure assigned to **16a-e**. The EI-mass spectra need a brief comment for **16a-e**, m/z = 213 represent the derivative of benzindazolyl fragment formed by release of corresponding RCO from the molecular ion, which undergo loss of 28 a.m.u (dinitrogen or CO group).

The present investigation also dealt with the study of the chemical behavior of hydrazides **1a-e** toward 1,4-naphthoquinone-2,3-dicarbonitrile (**4**). Substituted benzo[*f*]indazolediones **17a-e** and diacylhydrazines **18a-e** were obtained from the reaction of **1a-e** with (**4**) (Scheme 4).

Compounds **17a-e** exhibited IR absorptions at 3330–3345 ($NH_2$), 1685–1690 and 1660–1665 (CO). The $^1H$ NMR spectra of **17a-e** clearly showed one broad signal at 6.67–6.73 ppm because of $NH_2$, besides the aromatic protons. Signals at 153.29–153.48 (C-3), 100.89–101.46 (C-3a), 139.81–140.11 (C9a), 188.54–188.74 (C-4), 187.75–187.89 (C-9), 165.46–165.73 (CO), 137.86 (indole-C-2) and 99.74 (indole-C-5) in the $^{13}C$ NMR spectra of **17a-e** lend further supported the structure assigned to **17a-e**. The structure of **17e** was evidently confirmed by mass spectrometrically, besides the molecular ion at m/z = 356 (39%), the characteristic fragment ion pattern of indole-2-carbonyl at 144 (86), $C_6H_4CO^+$ group at 104 (77), benzoyl cation at 91 (89) and 77 (100) as a base peak. A possible reaction process is depicted in Scheme 5.

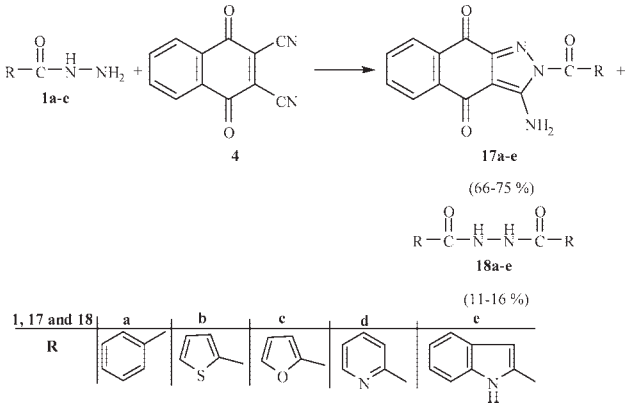
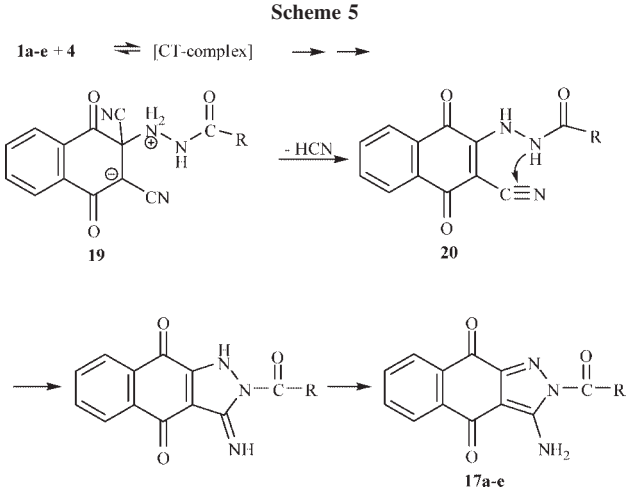


**Scheme 5**



## CONCLUSIONS

In a fairly complex and multistep process, benzo[e][1,3,4]oxadiazine, benzo[f]indazole-4,9-dione and benzoxadiazepine as well as naphthoxadiazepine derivatives are formed from **1a-e** and (**2-4**) during the nucleophilic attack by substituted hydrazides on C-2, C-3 of 2,3,5,6-tetrachloro-1,4-benzoquinone and 2,3-dichloro-1,4-naphthoquinone. On the other hand, 1,4-naphthoquinone-2,3-dicarbonitrile (**4**) may act as either as a mediator or as a building block in heterocyclization of substituted hydrazides. The results reported here supplement the rich of substituted hydrazides **1a-e**.

## EXPERIMENTAL

Mp's were determined using open glass capillaries on a Gallenkamp melting point apparatus and are uncorrected. The IR spectra were recorded with a Shimadzu 408 instrument using potassium bromide pellets. The $^1$H NMR (400.13 MHz) and $^{13}$C NMR (100.6 MHz) spectra were measured in DMSO-$d_6$ using a Bruker AM400 with TMS as an internal standard. Chemical shifts are expressed as δ [ppm], s = singlet, m = multiplet and b = broad. Assignments of carbon resonances have been supported by DEPT experiments. Mass spectra have been obtained with Varian MAT CH-7 instrument using electron impact ionization (70 eV). Elemental analyses have been determined by the Microanalytical Center, Cairo University, Egypt. For preparative layer chromatography (plc) 1.0 mm thick air-dried layers of slurry applied silica gel, Merck $Pf_{254}$ on 48 cm wide and 20 cm high glass plates were used, zones were detected by their color and indicator fluorescence quenching upon exposure to 254 nm light and extracted with acetone.

**Starting materials.** Substituted hydrazides **1a-e** were prepared according to published procedures, as were 2-thiophene carbohydrazide (**1b**), mp 135–137°C (ref. [33] 134–136°C); furan-2-carbohydrazide (**1c**), mp 77–79 (ref. [34] 78°C); 2-pyridine carbohydrazide (**1d**), mp 136–138°C (ref. [35] 137°C); indole-2-carbohydrazide (**1e**), mp 243–245°C (ref. [36,37] 246°C) and phenyl carbohydrazide (**1a**) (Aldrich), 2,3,5,6-tetrachloro-1,4-benzoquinone (**2**) (Aldrich) and 2,3-dichloro-1,4-naphthoquinone (**3**) (Aldrich) were used as received. 1,4-Naphthoquinone-2,3-dicarbonitrile (**4**) was prepared from 2,3-dichloro-1,4-naphthoquinone (**3**) according to Budni et al [38].

**Reaction of substituted hydrazides 1a-e with (2).** To a solution of **2** (246 mg, 1 mmol) in dry DMF (15 mL) a solution of **1a-e** (1.0 mmol each) in 5 mL of DMF was added dropwise over 5 min. at room temperature with stirring and admission of air. The stirring was continued for 48 h with admission of air to complete the reaction. The reaction mixture was concentrated to drynes. The residue was taken up several times with cold ethanol (10 mL) and slurry was concentrated again to remove any residual DMF. The residue was dissolved in acetone (5 mL). This solution in each case was applied to 5 plc-plates and developed with toluene/ethyl acetate (5:1) for the run with **1a**, toluene/ethyl acetate (4:1) for the runs with **1b-d** and toluene/ethyl acetate (3:1) for the run with **1e** to give numerous colored zones. The two intense of which were removed and extracted. The fastest migrating one contained substituted benzo[1,3,4]oxadiazepine **5a-e**, the slowest migrating zone contained substituted benzo-[1,3,4]oxadiazinecarboxamide **6a-e**. Extraction of zones with acetone and recrystallized.

**6,8,9-Trichloro-7-hydroxy-2-phenylbenzo[*f*][1,3,4]-oxadiazepin-5-(4*H*)-one (5a).** Compound **5a** was obtained as reddish brown crystals (0.264 g, 74%), mp 216–217°C (acetonitrile), IR: 3460 (OH), 3310 (NH), 1705 (CO), 1625 (C=N), 1596 (Ar—C=C), 1085 (C—O—C). $^1$H NMR: δ 7.18–7.53 (m, 5H, Ar—H), 7.84 (br, 1H, oxadiazepine—NH), 9.56 (br, 1H, OH); $^{13}$C NMR: δ 120.71 (C-5a), 122.53, 123.74, 124.17 (C-6, 8 and 9), 126.51, 128.26, 130.14 (Ar—CH), 134.72 (Ar—C), 147.38 (C-9a), 152.56 (C-7), 156.86 (C-2), 169.84 (CO); ms m/z: 356/362 ($M^+$, 42), 322 (26), 286 (34), 250 (21), 194 (26), 158 (11), 105 (67), 77 (100), 65 (49); Anal. Calcd. for $C_{14}H_7Cl_3N_2O_3$ (357.58): C, 47.02; H, 1.97; Cl, 29.74; N, 7.83. Found: C, 46.81; H, 2.11; Cl, 29.51; N, 7.64.

**6,8,9-Trichloro-7-hydroxy-2-(thiophen-2-yl)benzo[*f*][1,3,4]-oxadiazepin-5-(4*H*)-one (5b).** Compound **5b** was obtained as reddish brown crystals (0.258g, 71%), mp 257–259°C (acetonitrile). IR: 3470 (OH), 3295 (NH), 1700 (CO), 1630 (C=N), 1585 (Ar—C=C), 1090 (C—O—C). $^1$H NMR: δ 7.05–7.38 (m, 3H, thiophene-H), 7.79 (br, 1H, oxadiazepine-NH), 9.62 (br, 1H, OH); $^{13}$C NMR: δ 120.59 (C-5a), 122.42, 123.55, 123.96 (C-6, 8 and 9), 126.27, 127.69, 127.94 (thiophene-CH), 130.16 (thiophene-C), 148.06 (C-9a), 152.61 (C-7), 156.79 (C-2), 169.76 (CO); ms m/z: 362/368 ($M^+$, 34), 328 (18), 292 (27), 218 (41), 111 (100), 107 (53), 82 (46); Anal. Calcd. for $C_{12}H_5Cl_3N_2O_3S$ (363.60): C, 39.64; H, 1.39; Cl, 29.25; N, 7.70. Found C, 39.41; H, 1.51; Cl, 29.47; N, 7.54.

**6,8,9-Trichloro-7-hydroxy-2-(furan-2-yl)benzo[*f*][1,3,4]-oxadiazepin-5-(4*H*)-one (5c).** Compound **5c** was obtained as reddish brown crystals (0.229 g, 66%), mp 207–208°C (acetonitrile). IR: 3455 (OH), 3335 (NH), 1710 (CO), 1625 (C=N), 1085 (C—O—C); $^1$H NMR: δ 7.11–7.46 (m, 3H, furan-H), 7.82 (br, 1H, oxadiazepine-NH), 9.57 (br, 1H, OH); $^{13}$C NMR: δ 120.71 (C-5a), 122.19, 123.64, 123.92 (C-6, 8 and 9), 125.98, 126.11 (furan-CH), 141.57, 142.11 (furan-C-2, C-5), 147.96 (C-9a), 152.75 (C-7), 156.68 (C-2), 169.81 (CO); ms m/z: 346/352 ($M^+$, 38), 312 (25), 276 (16), 220 (31), 184 (27), 95 (100), 67 (71); Anal. Calcd. For $C_{12}H_5Cl_3N_2O_4$ (347.54): C, 41.47; H, 1.45; Cl, 30.60; N, 8.06. Found C, 41.66; H, 1.56; Cl, 30.38; N, 7.87.

**6,8,9-Trichloro-7-hydroxy-2-(pyridin-2-yl)benzo[*f*][1,3,4]-oxadiazepin-5-(4*H*)-one (5d).** Compound **5d** was obtained as reddish brown crystals (0.247g, 69%), mp 226–228°C (ethanol). IR: 3480 (OH), 3315 (NH), 1705 (CO), 1620 (C=N), 1590 (Ar—C=C), 1080 (C—O—C); $^1$H NMR: δ 7.48–8.41 (m, 5H, pyridine-H and oxadiazepine-NH), 9.57 (br, 1H, OH); $^{13}$C NMR: δ 121.07 (C-5a), 122.31, 123.62, 123.89 (C-6, 8 and 9), 127.89, 128.75, 130.14 (pyridine-CH), 146.35, 147.11 (pyridine C-2, C-6), 148.22 (C-9a), 152.57 (C-7), 156.85 (C-2), 169.73 (CO); ms m/z: 357/363 ($M^+$, 21), 323 (18), 287 (34), 195 (47), 106 (83), 78 (100); Anal. Calcd. for $C_{13}H_6Cl_3N_3O_3$ (358.56): C, 43.55; H, 1.69; Cl, 29.66; N, 11.72. Found C, 43.33; H, 1.78; Cl, 29.43; N, 11.87.

**2-(1*H*-Indole-2-yl)-6,8,9-trichloro-7-hydroxy-benzo[*f*][1,3,4]-oxadiazepin-5-(4*H*)-one (5e).** Compound **5e** was obtained as reddish brown crystals (0.265g, 67%), mp 271–273°C (methanol). IR: 3475–3280 (OH, NH's), 1710 (CO), 1630 (C=N), 1595 (Ar—C=C), 1090 (C—O—C); $^1$H NMR: δ 6.64 (s, 1H,

indole-CH), 7.12–7.68 (m, 4H, Ar—H), 7.86 (br, 1H, oxadiazepine-NH), 9.58 (br, 1H, OH), 11.62 (br, 1H, indole-NH); $^{13}$C NMR: δ 99.71(indole-CH), 121.98 (C-5a), 121.87, 123.35, 123.92 (C-6, 8 and 9), 127.14, 127.96 (Ar—CH), 130.55 (indole-C3a), 134.66, 137.12 (indole C-2 and C-7a), 152.46 (C-7), 156.81 (C-2), 169.80 (CO); MS m/z: 395/361 ($M^+$, 29), 331 (26), 295 (38), 242 (21), 186 (12), 144 (62), 116 (76), 92 (100), 77 (83), 65 (41); Anal. Calcd. for $C_{16}H_8Cl_3N_3O_3$ (396.61): C, 48.45; H, 2.03; Cl, 26.82; N, 10.59. Found C, 48.64; H, 1.91; Cl, 27.03; N, 10.77.

**5,6-Dichloro-7-hydroxy-*N,N′*-dimethyl-3-phenyl-1*H*-benzo[*e*][1,3,4]oxadiazine-8-carboxamide (6a).** Compound **6a** was obtained as deep red brown crystals (0.062g, 17%), mp 248–250°C (acetonitrile). IR: 3485 (OH), 3290 (NH), 1690 (CO), 1625 (C=N), 1585 (Ar—C=C), 1080 (C—O—C); $^1$H NMR: δ 3.44 (s, 6H, $N(CH_3)_2$), 7.24–7.79 (m, 6H, Ar—H and oxadiazine-NH), 9.67 (br, 1H, OH); $^{13}$C: δ 36.29 ($CH_3$), 106.83 (C-8), 122.27, 123.14 (C-5 and C-6), 127.21, 128.54, 130.16 (Ar-CH), 134.27 (Ar-C), 138.44 (C-8a), 141.11 (C-4a), 152.51 (C-7), 156.76 (C-3), 171.41 (CO); MS m/z: 365/369 ($M^+$, 41), 329 (18), 257 (44), 193 (29), 105 (81), 77 (100), 65 (74); Anal. Calcd. for $C_{16}H_{13}Cl_2N_3O_3$ (366.20): C, 52.48; H, 3.58; Cl, 19.36; N, 11.47. Found C, 52.66; H, 3.45; Cl, 19.59; N, 11.65.

**5,6-Dichloro-7-hydroxy-*N,N′*-dimethyl-3-(thio-phen-2-yl-1*H*-benzo[*e*][1,3,4]oxadiazine-8-carbox-amide (6b).** Compound **6b** was obtained as reddish brown crystals (0.067g, 18%), mp 276–278°C (ethanol). IR: 3470 (OH), 3310 (NH), 1685 (CO), 1630 (C=N), 1590 (Ar—C=C), 1085 (C—O—C); $^1$H NMR: δ 3.36 (s, 6H, $N(CH_3)_2$), 7.11–7.39 (m, 3H, thiophene-H), 7.71 (br, 1H, oxadiazine-NH), 9.70 (br, 1H, OH); $^{13}$C: δ 36.41 ($CH_3$), 107.12 (C-8), 121.94, 123.32 (C-5 and C-6), 126.22, 127.56, 127.84 (thiophene-CH), 130.12 (thiophene-C), 138.51 (C-8a), 140.97 (C-4a), 152.46 (C-7), 156.81 (C-3), 171.23 (CO); ms m/z: 371/375 ($M^+$, 26), 336 (29), 300 (12), 264 (21), 153 (8), 111 (100), 83 (76); Anal. Calcd. for $C_{14}H_{11}Cl_2N_3O_3S$ (372.23): C, 45.17; H, 2.98; Cl, 19.05; N, 11.29; S, 8.61. Found C, 44.94; H, 3.10; Cl, 18.88; N, 11.41; S, 8.83.

**5,6-Dichloro-7-hydroxy-*N,N′*-dimethyl-3-(thio-phen-2-yl-1*H*-benzo[*e*][1,3,4]oxadiazine-8-carbox-amide (6c).** Compound **6c** was obtained as brown crystals (0.078g, 22%), mp 235–237°C (ethanol). IR: 3480 (OH), 3300 (NH), 1680 (CO), 1625 (C=N), 1590 (Ar—C=C), 1085 (C—O—C); $^1$Hnmr: δ 3.40 (s, 6H, $N(CH_3)_2$), 6.95–7.35 (m, 3H, furan-H), 7.69 (br, 1H, oxadiazine-NH), 9.67 (br, 1H, OH); $^{13}$C: δ 36.38 ($CH_3$), 106.91 (C-8), 122.18, 123.27 (C-5 and C-6), 125.96, 126.47 (furan-CH), 138.36 (C-8a), 141.12 (C-4a), 142.76, 143.63 (furan-C-2 and C-5), 152.64 (C-7), 156.77 (C-3), 171.34 (CO); MS m/z: 355/359 ($M^+$, 27), 320 (42), 284 (18), 212 (37), 117 (52), 95 (100), 67 (68); Anal. Calcd. for $C_{14}H_{11}Cl_2N_3O_4$ (356.16): C, 47.21; H, 3.11; Cl, 19.91; N, 11.80. Found C, 47.44; H, 2.98; Cl, 20.08; N, 12.02.

**5,6-Dichloro-7-hydroxy-*N,N′*-dimethyl-3-(pyridin-2-yl-1*H*-benzo[*e*][1,3,4]oxadiazine-8-carboxamide (6d).** Compound **6d** was obtained as brown crystals (0.062g, 17%), mp 261–263°C (acetonitrile). IR: 3490 (OH), 3315 (NH), 1690 (CO), 1630 (C=N), 1585 (Ar—C=C), 1080 (C—O—C); $^1$H: δ 3.38 (s, 6H, $N(CH_3)_2$), 7.36—8.48 (m, 5H, pyridine-H and oxadiazine-NH), 9.74 (br, 1H, OH); $^{13}$C: δ 36.44 ($CH_3$), 107.09 (C-8), 122.28, 123.46 (C-5 and C-6), 127.16, 128.91, 130.28 (pyridine-CH), 138.42 (C-8a), 140.87 (C-4a), 146.42, 147.83 (pyridine-C-2 and C-6), 152.71 (C-7), 156.84 (C-3), 171.42 (CO); MS m/z: 366/370 ($M^+$, 35), 332 (19), 296 (27), 224 (41), 196 (23), 106 (74), 78 (100); Anal. Calcd. for $C_{15}H_{12}Cl_2N_4O_3$ (367.19): C, 49.07; H, 3.29; Cl, 19.31; N, 15.26. Found C, 48.84; H, 3.41; Cl, 19.07; N, 15.43.

**5,6-Dichloro-7-hydroxy-*N,N′*-dimethyl-3-(pyridin-2-yl-1*H*-benzo[*e*][1,3,4]oxadiazine-8-carboxamide (6e).** Compound **6e** was obtained as brown crystals (0.073g, 18%), mp 301–303°C (methanol). IR: 3485 (OH), 3340-3295 (NH's), 1690 (CO), 1630 (C=N), 1600 (Ar-C=C), 1085 (C—O—C); $^1$H NMR: δ 3.41 (s, 6H, $N(CH_3)_2$), 6.64 (s, 1H, indole-CH), 7.26–7.81 (m, 5H, Ar—H and oxadiazine-NH), 9.62 (br, 1H, OH), 11.71 (br, 1H, indole-NH); $^{13}$C NMR: δ 36.45 ($CH_3$), 98.95 (indole-CH), 106.88 (C-8), 122.32, 123.41 (C-5 and C-6), 126.37, 127.74 (Ar-CH), 130.71 (indole-C-3a), 135.07, 137.36 (indole-C-2 and C-7a), 138.53 (C-8a), 141.07 (C-4a), 153.04 (C-7), 156.91 (C-3), 171.26 (CO); MS m/z: 404/408 ($M^+$, 25), 370 (32), 334 (12), 262 (46), 234 (19), 144 (56), 91 (76), 77 (100), 65 (85); Anal. Calcd. for $C_{18}H_{14}Cl_2N_4O_3$ (405.23): C, 53.35; H, 3.48; Cl, 17.50; N, 13.83. Found C, 53.17; H, 3.61; Cl, 17.72; N, 14.05.

**Reaction of substituted hydrazides 1a-e with (3).** A solution of **1a-e** (1.0 mmol) in 15 mL of dry DMF was added dropwise with stirring to a solution of **3** (1.0 mmol) in 10 mL of dry DMF. The reaction mixture was stirring for 72 h, during which time it turned from faint orange into deep red. The precipitate of substituted naphtho[2,3-*f*][1,3,4]oxadiazepine-5,6,11-(4*H*)-trione **16** was filtered and washed several times with cold ethanol, and crystallized from suitable solvent.

**2-Phenylnaphtho[2,3-*f*][1,3,4]oxadiazepine-5,6,11-(4*H*)-trione (16a).** Compound **16a** was obtained as reddish brown crystals (0.280g, 88%), mp 289–291°C (acetonitrile). IR: 3230 (NH), 1710, 1685 (CO), 1620 (C=N), 1585 (Ar—C=C), 1090 (C—O—C); $^1$H NMR: δ 7.14–7.76 (m, 5H, Ar—H), 7.84 (br, 1H, oxadiazepine-NH), 8.04–8.21 (m, 4H, Ar—H); $^{13}$C NMR: δ 126.49, 128.84, 129.12, 134.61, 136.66 (Ar—CH), 131.45, 132.45, 132.17, 141.36 (Ar—C), 156.86 (C-2), 169.64 (oxadiazepine-CO), 187.44, 187.78 (C-6 and C-11); ms m/z: 318 ($M^+$, 46), 213 (26), 185 (61), 105 (81), 104 (76), 77 (100), 65 (67); Anal. Calcd. for $C_{18}H_{10}N_2O_4$ (318.28): C, 67.92; H, 3.17; N, 8.80. Found C, 68.14; H, 3.06; N, 9.04.

**2-(Thiophen-2-yl)naphtho[2,3-*f*][1,3,4]oxadiaz-epine-5,6,11-(4*H*)-trione (16b).** Compound **16b** was obtained as brown crystals (0.272 g, 84%), mp 307–309°C (ethanol). IR: 3245 (NH), 1715, 1680 (CO), 1625 (C=N), 1585 (Ar-C=C), 1080 (C-O-C); $^1$H NMR: δ 7.08–7.46 (m, 3H, thiophene-H), 7.80 (br, 1H, oxadiazepine-NH), 8.05–8.19 (m, 4H, Ar—H); $^{13}$C NMR: δ 126.23, 127.76, 128.33, (thiophene-CH), 129.36, 136.94 (Ar-CH), 131.64, 131.16, 141.19 (Ar—C), 156.80 (C-2), 169.58 (oxadiazepine-CO), 187.39, 187.68 (C-6 and C-11); ms m/z: 324 ($M^+$, 23), 213 (34), 185 (48), 111 (100), 104 (56), 77 (86), 65 (61); Anal. Calcd. for $C_{16}H_8N_2O_4S$ (324.31): C, 59.26; H, 2.49; N, 8.64; S, 9.89. Found C, 59.09; H, 2.61; N, 8.43; S, 10.04.

**2-(Furan-2-yl)naphtho[2,3-*f*][1,3,4]oxadiazepine-5,6,11-(4*H*)-trione (16c).** Compound **16c** was obtained as brown crystals (0.253 g, 82%), mp 274–276°C (ethanol). IR: 3235 (NH), 1710, 1690 (CO), 1620 (C=N), 1590 (Ar—C=C), 1085 (C—O—C); $^1$H: δ 6.97–7.38 (m, 3H, furan-H), 7.78 (br, 1H, oxadiazepine-NH), 8.00–8.22 (m, 4H, Ar—H); $^{13}$C NMR: δ

126.08, 126.26 (furan-CH), 129.54, 136.89 (Ar—CH), 131.55, 131.96, 140.87 (Ar—C), 141.62, 142.26 (furan-C-2 and C-5), 156.85 (C-2), 169.84 (oxadiazepine-CO), 187.46, 187.72 (C-6 and C-11); ms m/z: 308 ($M^+$, 32), 213 (28), 185 (57), 157 (21), 104 (71), 95 (63), 77 (100), 65 (84); Anal. Calcd. for $C_{16}H_8N_2O_5$ (308.25): C, 62.34; H, 2.62; N, 9.09. Found C, 62.51; H, 2.77; N, 8.83.

**2-(Pyridin-2-yl)naphtho[2,3-*f*][1,3,4]oxadiazepine-5,6,11-(4*H*)-trione (16d).** Compound **16d** was obtained as brown crystals (0.255 g, 80%), mp 297-299°C (acetonitrile). IR: 3245 (NH), 1705, 1690 (CO), 1625 (C=N), 1585 (Ar—C=C), 1090 (C—O—C); $^1$H NMR: δ 7.36–8.49 (m, 9H, Ar—H, pyridine-H and oxadiazepine-NH); $^{13}$C NMR: δ 126.54, 128.73 (pyridine-CH), 129.49, 130.37, 136.94 (Ar-CH and pyridine-CH), 131.57 (Ar-C), 146.39, 147.81 (pyridine-C-2 and C-6), 156.82 (C-2), 169.64 (oxadiazepine-CO), 187.51, 187.80 (C-6 and C-11); ms m/z: 319 ($M^+$, 28), 213 (41), 185 (64), 157 (22), 106 (88), 104 (73), 77 (100), 65 (56); Anal. Calcd. for $C_{17}H_9N_3O_4$ (319.27): C, 63.95; H, 2.84; N, 13.16. Found C, 64.16; H, 2.71; N, 12.98.

**2-(1*H*-Indol-2-yl)naphtho[2,3-*f*][1,3,4]oxadiaz-epine-5,6,11-(4*H*)-trione (16e).** Compound **16e** was obtained as reddish brown crystals (0.282 g, 79%), mp 331–333°C (methanol). IR: 3330-3240 (NH's), 1710, 1685 (CO), 1630 (C=N), 1600 (Ar—C=C), 1085 (C—O—C); $^1$H NMR: δ 6.61 (s, 1H, indole-CH), 7.16–7.64 (m, 4H, Ar—H), 7.82 (br, 1H, oxadiazepine-NH), 8.05–8.27 (m, 4H, Ar—H), 11.71 (br, 1H, indole-NH); $^{13}$C NMR: δ 99.63 (indole-CH), 127.26, 129.41, 136.22, 137.38 (Ar—CH), 130.26, 131.66, 134.27, 139.26 (Ar—C and indole-C-2), 156.78 (C-2), 169.75 (oxadiazepine-CO), 187.48, 187.73 (C-6 and C-11); ms m/z: 357 ($M^+$, 34), 213 (26), 185 (54), 144 (62), 104 (57), 91 (74), 77 (100), 65 (63); Anal. Calcd. for $C_{20}H_{11}N_3O_4$ (357.32): C, 67.23; H, 3.10; N, 11.76. Found C, 67.06; H, 2.97; N, 11.89.

**Reactions of substituted hydrazides 1a-e with (4).** A solution of **1a-e** (1.0 mmol) in 15 mL of dry DMF was added dropwise with stirring to a solution of 1,4-naphthoquinone-2,3-dicarbonitrile (**4**) (208 mg, 1.0 mmol) in 10 mL of dry DMF. The reaction colour changed gradually from green to purple and latter turns into brown colour. The stirring was continued for 72 h with admission of air to complete the reaction. The reaction mixture was concentrated and the residue was then separated by plc using toluene/ethyl acetate (5:1) for the runs with (**1a-d**) and toluene/ethyl acetate (3:1) for the run with (**1e**) to give numerous zones, two intense of which were removed and extracted. The fastest migrating one which quenched all indicator fluorescence upon exposure to 254nm UV-light contained diacylhydrazines **18a-e**. The slowest migrating zone (which is always characterized by deep yellow colour) contained substituted benzo[*f*]- indazolediones **17a-e**.

**3-Amino-2-benzoyl-2*H*-benzo[*f*]indazole-4,9-dione (17a).** Compound **17a** was obtained as deep yellow crystals (0.222 g, 70 %), mp 271–273°C (ethanol). IR: 3345 ($NH_2$), 1685, 1660 (CO), 1620 (C=N), 1585 (Ar-C=C); $^1$H NMR: δ 6.71 (br, 2H, $NH_2$), 7.28–7.77 (m, 5H, Ar—H), 8.06–8.22 (m, 4H, Ar—H); $^{13}$C NMR: δ 101.16 (C-3a), 126.52, 128.32, 129.26, 133.12, 136.51 (Ar—CH), 130.76, 131.44 (Ar-C), 139.86 (C-9a), 153.46 (C-3), 165.55 (CO), 187.82 (C-9), 188.68 (C-4); ms m/z: 317 ($M^+$, 52), 212 (41), 184 (26), 105 (100), 104 (76), 77 (81), 65 (72); Anal. Calcd. for $C_{18}H_{11}N_3O_3$ (317.30): C, 68.14; H, 3.49; N, 13.24. Found C, 67.88; H, 3.61; N, 13.40.

**3-Amino-2-(thiophen-2-carbonyl)-2*H*-benzo[*f*]-indazole-4,9-dione (17b).** Compound **17b** was obtained as yellow crystals (0.242 g, 75%), mp 295–297°C (acetonitrile). IR: 3335 ($NH_2$), 1690, 1660 (CO), 1625 (C=N), 1590 (Ar-C=C); $^1$H NMR: δ 6.67 (br, 2H, $NH_2$), 7.14–7.52 (m, 3H, thiophene-H), 8.05–8.19 (m, 4H, Ar—H); $^{13}$C NMR: δ 100.89 (C-3a), 126.72, 129.33, 129.78, 130.12, 136.44 (Ar—CH and thiophene-CH), 131.58, 132.29 (Ar—C and thiophene-C), 140.08 (C-9a), 153.36 (C-3), 165.46 (CO), 187.76 (C-9), 188.54 (C-4); ms m/z: 323 ($M^+$, 41), 212 (56), 184 (44), 111 (100), 104 (62), 77 (83), 65 (74); Anal. Calcd. for $C_{16}H_9N_3O_3S$ (323.33): C, 59.44; H, 2.81; N, 13.00; S, 9.92. Found C, 59.26; H, 2.94; N, 12.82; S, 10. 13.

**3-Amino-2-(furan-2-carbonyl)-2*H*-benzo[*f*]-indazole-4,9-dione (17c).** Compound **17c** was obtained as yellow crystals (0.209 g, 68%), mp 259–261°C (ethanol). IR: 3330 ($NH_2$), 1685, 1665 (CO), 1620 (C=N), 1590 (Ar—C=C), 1080 (C-O-C); $^1$H NMR: δ 6.69 (br, 2H, $NH_2$), 7.08–7.46 (m, 3H, furan-H), 8.08-8.24 (m, 4H, Ar—H); $^{13}$C NMR: δ 101.14 (C-3a), 126.13, 126.76, 129.41, 136.28 (Ar—CH and furan-CH), 131.64 (Ar—C), 139.90 (C-9a), 147.42, 148.51 (furan-C-2 and C-5), 153.29 (C-3), 165.65 (CO), 187.89 (C-9), 188.74 (C-4). ms m/z: 307 ($M^+$, 59), 212 (38), 184 (61), 104 (72), 95 (86), 77 (100), 65 (76); Anal. Calcd. for $C_{16}H_9N_3O_4$ (307.26): C, 62.54; H, 2.95; N, 13.68. Found C, 62.37; H, 3.10; N, 13.87.

**3-Amino-2-picolinoyl-2*H*-benzo[*f*]indazole-4,9-dione (17d).** Compound **17d** was obtained as yellow crystals (0.229 g, 72%), mp 276-278°C (acetonitrile). IR: 3335 ($NH_2$), 1685, 1660 (CO), 1620 (C=N), 1585 (Ar—C=C). $^1$H NMR: δ 6.68 (br, 2H, $NH_2$), 7.56–8.48 (m, 8H, Ar—H and pyridine-H). $^{13}$C NMR: δ 100.96 (C-3a), 126.43, 128.51, 129.55, 130.12, 136.34 (Ar—CH and pyridine-CH), 131.59 (Ar—C), 139.81 (C-9a), 147.86, 148.62 (pyridine-C-2, C-6), 153.37 (C-3), 165.55 (CO), 187.75 (C-9), 188.64 (C-4). ms m/z: 318 ($M^+$, 62), 212 (53), 184 (67), 106 (100), 104 (76), 77 (83), 65 (64). $C_{17}H_{10}N_4O_3$ (318.29): C, 64.15; H, 3.17; N, 17.60. Found C, 63.96; H, 3.28; N, 17.76.

**3-Amino-2-(1*H*-indole-2-carbonyl)-2*H*-benzo[*f*]-indazole-4,9-dione (17e).** Compound **17e** was obtained as yellowish brown crystals (0.235 g, 66%), mp 324–326°C (acetonitrile). IR: 3340, 3270 ($NH_2$, NH), 1690, 1665 (CO), 1625 (C=N), 1590 (Ar-C=C); $^1$H NMR: δ 6.59 (s, 1H, indole-CH), 6.73 (br, 2H, $NH_2$), 7.28–7.83 (m, 4H, Ar—H), 8.05–8.26 (m, 4H, Ar—H), 11.69 (br, 1H, indole-NH); $^{13}$C NMR: δ 99.74 (indole-C-3), 101.46 (C-3a), 126.46, 127.29, 129.41, 130.29, 136.36 (Ar—CH), 130.52, 131.64 (Ar—C), 137.86 (indole-C-2), 138.68 (indole-C-7a), 140.11 (C-9a), 153.48 (C-3), 165.73 (CO), 187.75 (C-9), 188.65 (C-4); ms m/z: 356 ($M^+$, 39), 212 (26), 184 (55), 144 (86), 104 (77), 91 (89), 77 (100), 65 (62); Anal. Calcd. for $C_{20}H_{12}N_4O_3$ (356.33): C, 67.41; H, 3.39; N, 15.72. Found C, 67.22; H, 3.27; N, 15.89.

***N*′-Benzoylbenzohydrazide (18a).** Yield (0.038g, 16%), mp 239–241°C (ref. [39,40] 237–238°C). $^1$H NMR: δ 7.26–7.40 (m, 3H, Ar—H), 7.44–7.64 (m, 4H, Ar—H), 7.78–7.83 (m, 3H, Ar—H), 10.68 (br, 2H, NH).

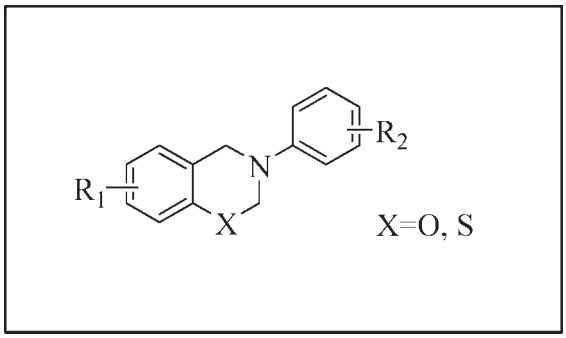
Published online 5 January 2010 in Wiley InterScience (www.interscience.wiley.com).



A simple and efficient synthesis of substituted benzo [1,3] oxazine and benzo [1,3] thiazine derivatives under conventional heating, as well as microwave irradiation is reported. The compounds were obtained by the reaction of electron rich phenols, formaldehyde, and aromatic amines in methanol. Reactions which take 12–16 hr under conventional heating were successfully completed within a few minutes under microwave irradiation (solventless) with moderate to excellent yields.

## INTRODUCTION

Development of novel synthetic methods for the construction of new analogs of bioactive heterocyclic compounds represents a major challenge in synthetic organic and medicinal chemistry. The importance of [1,3]-oxazines and [1,3]-thiazines in biological systems has attracted great interest because of their medicinal and pharmacological characteristics [1]. Many compounds containing [1,3]-oxazine moiety have found wide biological activities such as being anticancer [2], analgesic [3], antifungal [3], antitubercular [4], antihypertensive [5], antithromobotic [6], antiulcer [7], anticonvulsant, and antibacterial [8]. Moreover, certain kinds of [1,3]-oxazines are of interest as photochromic compounds [9].

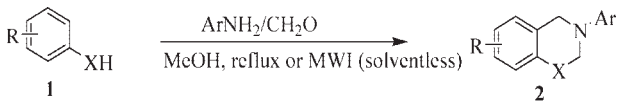
It is well known that the presence of a thiol function in many enzymes ('–SH enzymes') is essential for their enzyme activity. Likewise, incorporation of a thiol function in heterocycles, nucleosides or nucleotides has led to a number of analogues possessing interesting biological and therapeutic properties [10–17]. The [1,3]-thiazine nucleus is the active core of cephalosporins, which are among the most widely used β-lactam antibiotics. Owing to their chemical and biological interest, synthesis of various unsubstituted and substituted 1,3-oxazine and 1,3-thiazine derivatives is reported as they appear to be attractive scaffolds for exploiting chemical diversity. Previously, napth-1, 3-oxazine derivatives have been reported using 2-napthol and various substituted aryl and heteroaryl aldehydes in the presence of dry methanolic ammonia [18–20]. In view of the importance of substituted [1,3]-oxazines and [1,3]-thiazines, we have initiated a programme for the development of simpler and more convenient methods for preparing heterocyclic systems with high efficacy.

## RESULTS AND DISCUSSION

Our present study mainly focuses on the synthesis of various substituted [1,3]-oxazines and [1,3]-thiazines (Scheme 1) and their relative comparison with microwave assisted synthesis. $^{1}H$ and $^{13}C$ NMR spectra show that the products were obtained in good purity. The substituents on benzyl ring did not have significant influence on the reaction time and yields. All reactions which take many hours under conventional heating were completed in 3–8 min under microwave irradiation with enhanced yields. The results are presented in Table 1.

For these one-pot reactions of phenol, formaldehyde, and aromatic amines, it is noteworthy that simultaneous mixing resulted in poor yields [21]; however good

**Scheme 1**



yields were obtained by the pretreatment of formaldehyde with the aromatic amines to form Schiff bases, which upon treatment with phenol yielded the required 1,3-oxazines. Also it has been found that this reaction worked well with formaldehyde but failed with other aldehydes. Here we presume that steric hindrance stops

the reaction at the open-chain Schiff bases without proceeding further to the cyclocondensation products. Reactions with other aromatic aldehydes gave same results [18,22]. Mcdonagh and Smith [23] reported the ring-chain tautomerism of the condensation products of o-hydroxybenzylamine with a number of aldehydes where aliphatic aldehydes tend to give predominantly or exclusively 1, 3-oxazines whereas aromatic aldehydes tend to give predominantly open chain structures (Schiff bases). Hence, it suggests that the Schiff bases formed are quite stable and do not react further even with increasing reaction time as well as temperature. In course of our study, it has been found that electron donating substituents on the alcohol, as well as the aromatic primary amines favour the reactions to give the desired products. All the observations in both conventional as well as microwave synthesis are similar except in the reaction time and yield. This clearly indicates the advantages of microwave chemistry which is fast developing as a convenient and ecofriendly mode of synthesis.

In summary, the aforementioned protocol reports the conventional and microwave synthesis of 1, 3-oxazines, as well as a few numbers of 1, 3-thiazines from simple and easily available starting materials in which microwave synthesis is preferred as an alternative mode of reactions. This microwave induced procedure offers several advantages including operational simplicity, high yields, simple work up and reactions are completed within short time.

## EXPERIMENTAL SECTION

Microwave reactions were carried out in a CEM Discover Benchmate microwave digester. Melting points were determined in open capillary tubes with a Thomas-Hoover apparatus and are uncorrected. Infrared spectra were recorded on a BOMEM DA-8 FTIR instrument and the frequencies are expressed in $cm^{-1}$. $^1H$ and $^{13}C$ NMR (400 MHz) spectra were recorded on a Bruker Avance II-400 spectrometer using $CDCl_3$ as the solvent. Chemical shifts are reported in ppm downfield from internal tetramethylsilane and are given on the δ scale. Mass spectral data were obtained with a JEOL D-300 (EI) mass spectrometer. Elemental analyses were carried out on a Heraeus CHN-O-Rapid analyzer. All compounds give satisfactory elemental analyses within ± 0.4% of the theoretical values. All reactions were monitored by TLC using precoated aluminum sheets (silica gel 60 F 254 0.2 mm thickness) and developed in an iodine chamber or under UVGL-15 mineral light 254 lamp. Column chromatographic separations were carried out using ACME silica gel (60–120 mesh).

**General procedure for conventional synthesis.** To a well stirred solution of the amine (1 mmol) in 5 mL of methanol, formaldehyde (2 mmol) was added dropwise upon which a thick white precipitate was formed. After stirring at room temperature for about 15–20 min, phenol (1 mmol) dissolved in methanol was added dropwise. The reaction mixture was then refluxed at 70°C for 14–16 hr. After the reaction was completed (monitored by TLC), the solvent was evaporated under reduced pressure and the resultant mixture was purified by column chromatography to afford the pure compound.

**General procedure for microwave assisted synthesis.** A mixture of the amine (1 mmol), formaldehyde (2 mmol) and phenol (1 mmol) was irradiated in a microwave digester at 5–10 bar, 80–120 W, 180–250 seconds without the use of solvent. After the reaction was completed (monitored by TLC) the resultant mixture was purified by column chromatography to afford the pure compound.

The physical and spectral data of the products are as follows:

**3,4-Dihydro-3-phenyl-2*H*-benzo[e][1,3]oxazine (2a).** mp 48°C, IR (KBr): 3036 (Ar—C—H), 1597 (C=C), 1227 (Ar—C—O), 1087 (—$CH_2$—O), 1370 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 4.61 (s, 2H, $CH_2$), 5.34 (s, 2H, $CH_2$), 6.77–7.02 (m, 9H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 49.9, 79.0, 115.4, 116.1, 117.9, 120.3, 125.4, 127.4, 128.8, 128.9, 128.9, 129.4, 147.9, 153.9. MS: m/z =211 ($M^+$). *Anal. Calcd*. For $C_{14}H_{13}NO$: C, 79.59; H, 6.20; N, 6.63%. Found: C, 79.63; H, 6.18; N, 6.67%.

**3,4-Dihydro-3-o-tolyl-2*H*-benzo[e][1,3]oxazine (2b).** mp 52°C, IR (KBr): 3037 (Ar—C—H), 1596 (C=C), 1227 (Ar—C—O), 1084 (—$CH_2$—O), 1372 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.24 (s, 3H, $CH_3$), 4.55 (s, 2H, $CH_2$), 5.33 (s, 2H, $CH_2$), 6.65–7.11 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 18.7, 58.3, 79.6, 115.1, 115.9, 118.5, 121.3, 122.7, 127.4, 127.9, 128.6, 129.8, 130.6, 148.0, 157.6. MS: m/z =225 ($M^+$). *Anal. Calcd*. For $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22%. Found: C, 79.99; H, 6.75; N, 6.18%.

**3,4-Dihydro-3-m-tolyl-2*H*-benzo[e][1,3]oxazine (2c).** mp 55°C, IR (KBr): 3035 (Ar—C—H), 1597 (C=C), 1226 (Ar—C—O), 1079 (—$CH_2$—O), 1373 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 3H, $CH_3$), 4.60 (s, 2H, $CH_2$), 5.41 (s, 2H, $CH_2$), 6.39–7.02 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 18.4, 55.1, 78.9, 110.7, 115.2, 115.8, 118.4, 120.7, 123.0, 127.8, 129.8, 130.2, 138.8, 147.9, 157.4. MS: m/z =225 ($M^+$). *Anal. Calcd*. For $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22%. Found: C, 79.98; H, 6.74; N, 6.19%.

**3,4-Dihydro-3-p-tolyl-2*H*-benzo[e][1,3]oxazine (2d).** mp 66°C, IR (KBr): 3037 (Ar—C—H), 1597 (C=C), 1228 (Ar—C—O), 1088 (—$CH_2$—O), 1371 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.35 (s, 3H, $CH_3$), 4.55 (s, 2H, $CH_2$), 5.40 (s, 2H, $CH_2$), 6.47–7.10 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 23.2, 55.7, 79.2, 113.7, 114.6, 114.8, 120.4, 123.7, 126.0, 128.4, 129.6, 130.7, 132.8, 145.9, 155.4. MS: m/z =225 ($M^+$). *Anal. Calcd*. For $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22%. Found: C, 80.01; H, 6.67; N, 6.26%.

**3-(4-ethylphenyl)-3,4-dihydro-2*H*-benzo[e][1,3]oxazine (2e).** mp 69°C, IR (KBr): 3036 (Ar—C—H), 1596 (C=C), 1225 (Ar—C—O), 1087 (—$CH_2$—O), 1368 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 1.26 (s, 3H, $CH_3$), 2.63 (q, 2H, $CH_2$), 4.60 (s, 2H, $CH_2$), 5.42 (s, 2H, $CH_2$), 6.54–7.02 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 16.1, 35.2, 54.3, 88.9, 113.8, 114.2, 114.6, 120.5, 123.3, 127.1, 127.9, 128.7, 129.2, 129.7, 147.4, 156.8. MS: m/z =239 ($M^+$). *Anal. Calcd*. For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.34; H, 7.14; N, 5.88%.

**3,4-Dihydro-8-methyl-3-phenyl-2*H*-benzo[e][1,3]oxazine (2f).** mp 42°C, IR (KBr): 3024 (Ar—C—H), 1609 (C=C), 1223 (Ar—C—O), 1085 (—$CH_2$—O), 1336 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.33 (s, 3H, $CH_3$), 4.58 (s, 2H, $CH_2$), 5.34 (s, 2H, $CH_2$), 6.56–7.13 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 15.3, 56.3, 79.9, 114.2, 114.6, 118.5, 121.3, 122.1, 124.9, 126.7, 128.2, 129.1, 129.7, 148.4, 157.6. MS: m/z =225 ($M^+$). *Anal. Calcd*. For $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22%. Found: C, 80.00; H, 6.68; N, 6.24%.

**3,4-Dihydro-8-methyl-3-o-tolyl-2*H*-benzo[e][1,3]oxazine (2g).** mp 54°C, IR (KBr): 3025 (Ar—C—H), 1583 (C=C), 1227 (Ar—C—O), 1085 (—$CH_2$—O), 1367 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 6H, $CH_3$), 4.62 (s, 2H, $CH_2$), 5.35 (s, 2H, $CH_2$), 6.47–7.02 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 15.3, 16.4, 58.3, 79.7, 114.7, 118.5, 120.5, 124.5, 126.3, 126.5, 127.4, 128.9, 126.7, 128.2, 146.6, 156.6. MS: m/z =239 ($M^+$). *Anal. Calcd*. For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.33; H, 7.13; N, 5.81%.

**3,4-Dihydro-8-methyl-3-m-tolyl-2*H*-benzo[e][1,3]oxazine (2h).** mp 57°C, IR (KBr): 3027 (Ar—C—H), 1590 (C=C), 1223 (Ar—C—O), 1087 (—$CH_2$—O), 1375 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.36 (s, 6H, $CH_3$), 4.62 (s, 2H, $CH_2$), 5.41 (s, 2H, $CH_2$), 6.39–7.11 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 15.7, 23.7, 58.3, 79.3, 111.4, 114.4, 118.7, 120.2, 121.4, 123.5, 126.6, 128.3, 129.4, 138.9, 148.6, 156.8. MS: m/

z = 239 ($M^+$). *Anal. Calcd.* For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.34; H, 7.12; N, 5.82%.

**3,4-Dihydro-8-methyl-3-p-tolyl-2*H*-benzo[e][1,3]oxazine (2i).** mp 68°C, IR (KBr): 3027 (Ar—C—H), 1581 (C=C), 1220 (Ar—C—O), 1085 (—$CH_2$—O), 1360 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.32 (s, 6H, $CH_3$), 4.58 (s, 2H, $CH_2$), 5.40 (s, 2H, $CH_2$), 6.47–7.10 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 14.7, 25.7, 58.2, 78.9, 115.4, 115.4, 120.6, 122.4, 124.5, 126.7, 127.7, 128.6, 129.4, 130.8, 147.6, 155.8. MS: m/z = 239 ($M^+$). *Anal. Calcd.* For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.34; H, 7.13; N, 5.87%.

**3-(4-ethylphenyl-3,4-dihydro-8-methyl-2*H*-benzo[e][1,3] oxazine (2j).** mp 67°C, IR (KBr): 3024 (Ar—C—H), 1582 (C=C), 1266 (Ar—C—O), 1087 (—$CH_2$—O), 1362 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 1.26 (s, 3H, $CH_3$), 2.33 (s, 3H, $CH_3$), 2.60 (q, 2H, $CH_2$), 4.60 (s, 2H, $CH_2$), 5.37 (s, 2H, $CH_2$), 6.74–7.18 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 14.1, 15.2, 33.7, 56.9, 78.6, 114.5, 114.6, 120.5, 123.3, 126.1, 127.9, 129.7, 129.7, 130.1, 132.9, 147.4, 157.8. MS: m/z =253 ($M^+$). *Anal. Calcd.* For $C_{17}H_{19}NO$: C, 80.60; H, 7.56; N, 5.53%. Found: C, 80.64; H, 7.57; N, 5.51%.

**3,4-Dihydro-7-methyl-3-phenyl-2*H*-benzo[e][1,3]oxazine (2k).** mp 54°C, IR (KBr): 3027 (Ar—C—H), 1601 (C=C), 1227 (Ar—C—O), 1084 (—$CH_2$—O), 1327 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.64 (s, 3H, $CH_3$), 4.59 (s, 2H, $CH_2$), 5.34 (s, 2H, $CH_2$), 6.62–7.09 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 21.1, 50.2, 79.4, 114.6, 117.2, 117.7, 118.1, 118.2, 121.3, 126.0, 129.2, 129.2, 137.8, 148.4, 154.1. MS: m/z =225 ($M^+$). *Anal. Calcd.* For $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22%. Found: C, 79.99; H, 6.75; N, 6.18%.

**3,4-Dihydro-7-methyl-3-o-tolyl-2*H*-benzo[e][1,3]oxazine (2l).** mp 63°C, IR (KBr): 3026 (Ar—C—H), 1589 (C=C), 1223 (Ar—C—O), 1087 (—$CH_2$—O), 1351 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 6H, $CH_3$), 4.35 (s, 2H, $CH_2$), 5.32 (s, 2H, $CH_2$), 6.77–7.01 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 15.6, 25.1, 56.2, 79.4, 112.6, 114.2, 117.7, 119.1, 126.2, 127.3, 128.5, 129.2, 136.2, 137.8, 148.4, 154.1. MS: m/z =239 ($M^+$). *Anal. Calcd.* For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.33; H, 7.13; N, 5.82%.

**3,4-Dihydro-7-methyl-3-m-tolyl-2*H*-benzo[e][1,3]oxazine (2m).** mp 75°C, IR (KBr): 3023 (Ar—C—H), 1576 (C=C), 1225 (Ar—C—O), 1084 (—$CH_2$—O), 1327 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 6H, $CH_3$), 4.45 (s, 2H, $CH_2$), 5.33 (s, 2H, $CH_2$), 6.65–7.00 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 24.6, 25.1, 56.2, 79.2, 111.6, 112.2, 114.7, 119.1, 119.2, 121.3, 128.5, 129.2, 136.9, 139.8, 148.5, 156.1. MS: m/z =239 ($M^+$). *Anal. Calcd.* For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.34; H, 7.14; N, 5.81%.

**3,4-Dihydro-7-methyl-3-p-tolyl-2*H*-benzo[e][1,3]oxazine (2n).** mp 78°C, IR (KBr): 3036 (Ar—C—H), 1597 (C=C), 1229 (Ar—C—O), 1082 (—$CH_2$—O), 1370 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 6H, $CH_3$), 4.52 (s, 2H, $CH_2$), 5.34 (s, 2H, $CH_2$), 6.67–7.10 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 24.6, 24.1, 56.2, 79.2, 112.2, 113.6, 114.7, 119.3, 121.2, 127.3, 128.5, 129.2, 130.2, 137.8, 146.4, 157.2. MS: m/z =239 ($M^+$). *Anal. Calcd.* For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.32; H, 7.15; N, 5.81%.

**3-(4-ethylphenyl)-3,4-dihydro-7-methyl-2*H*-benzo[e][1,3] oxazine (2o).** mp 72°C, IR (KBr): 3041 (Ar—C—H), 1604 (C=C), 1231 (Ar—C—O), 1085 (—$CH_2$—O), 1365 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 1.25 (s, 3H, $CH_3$), 2.60 (q, 2H, $CH_2$), 4.62 (s, 2H, $CH_2$), 5.38 (s, 2H, $CH_2$), 6.54–7.02 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 14.1, 25.2, 32.6, 53.3, 78.9, 113.8, 114.2, 114.7, 120.5, 121.3, 127.1, 128.5, 128.7, 129.1, 137.7, 147.4, 156.8. MS: m/z =253 ($M^+$). *Anal. Calcd.* For $C_{17}H_{19}NO$: C, 80.60; H, 7.56; N, 5.53%. Found: C, 80.64; H, 7.52; N, 5.55%.

**3,4-Dihydro-6-methyl-3-phenyl-2*H*-benzo[e][1,3]oxazine (2p).** mp 40°C, IR (KBr): 3110 (Ar—C—H), 1585 (C=C), 1230 (Ar—C—O), 1085 (—$CH_2$—O), 1366 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 3H, $CH_3$), 4.59 (s, 2H, $CH_2$), 5.34 (s, 2H, $CH_2$), 6.62–7.11 (m, 8H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 24.1, 53.2, 79.7, 114.6, 114.2, 115.7, 118.1, 122.2, 128.3, 129.0, 129.2, 129.8, 130.2, 148.5, 154.2. MS: m/z =225 ($M^+$). *Anal. Calcd.* For $C_{15}H_{15}NO$: C, 79.97; H, 6.71; N, 6.22%. Found: C, 79.99; H, 6.75; N, 6.18%.

**3,4-Dihydro-6-methyl-3-o-tolyl-2*H*-benzo[e][1,3]oxazine (2q).** mp 62°C, IR (KBr): 3037 (Ar—C—H), 1598 (C=C), 1228 (Ar—C—O), 1087 (—$CH_2$—O), 1370 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 6H, $CH_3$), 4.41 (s, 2H, $CH_2$), 5.32 (s, 2H, $CH_2$), 6.71–7.10 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 15.6, 24.1, 56.2, 79.2, 114.7, 114.9, 118.7, 122.4, 126.6, 127.3, 128.0, 129.2, 130.9, 130.8, 146.5, 155.1. *Anal.* MS: m/z =239 ($M^+$). *Calcd.* For $C_{16}H_{17}NO$: C, 80.30; H, 7.16; N, 5.85%. Found: C, 80.34; H, 7.13; N, 5.81%.

**3,4-Dihydro-6-methyl-3-m-tolyl-2*H*-benzo[e][1,3]oxazine (2r).** mp 68°C, IR (KBr): 3041 (Ar—C—H), 1600 (C=C), 1237 (Ar—C—O), 1081 (—$CH_2$—O), 1372 (Ar—C—N) $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ 2.34 (s, 6H, $CH_3$), 4.51 (s, 2H, $CH_2$), 5.33 (s, 2H, $CH_2$), 6.68–7.10 (m, 7H, ArH). $^{13}C$ NMR ($CDCl_3$): δ 24.1, 24.1, 56.2, 79.6, 111.7, 114.7, 114.9, 118.4, 122.6, 128.5, 129.5, 130.3, 130.8, 139.0, 148.4, 155.1. ## INTRODUCTION

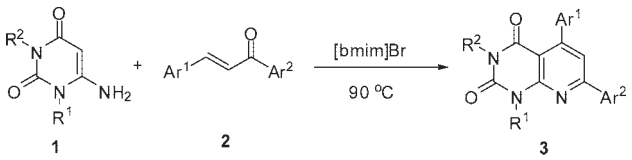
The importance of uracil and its annulated derivatives is well recognized by synthetic [1] as well as biological [2] chemists. With the development of clinically useful anticancer and antiviral drugs [3], there has recently been remarkable interest in the synthetic manipulations of uracils [4]. Pyrido[2,3-*d*]pyrimidines have received considerable attention over the past years because of their wide range of biological activities, which include antitumor [5], antibacterial [6], anti-inflammatory [7], antifungal [8], and antileishmaniasis [9] properties, and also act as cyclin-dependent kinase 4 inhibitors [10]. Therefore, for the preparation of these complex molecules large efforts have been directed towards the synthetic manipulation of uracils. Broom *et al*. [11] synthesized pyrido[2,3-*d*]pyrimidines from the reaction of DMAD and 6-aminouracile in protic solvent but obtained uncyclized condensed acetylenic adduct when the reaction was carried in DMF [12]. Wawzonek reported the synthesis of pyrido[2,3-*d*]pyrimidine-2,4-diones by the acid- and base-catalyzed condensation of 6-amino-1,3-dimethyluracil with α,β-unsaturated carbonyl compounds [13]. Bhuyan *et al*. [14] reported the synthesis of pyrido[2,3-*d*]pyrimidines from the reaction of arylidenemalononitrile with 6-aminouracil in refluxing 1-propanol, but in this reaction, benzylmalononitrile was obtained as by-product and the amount of arylidenemalononitrile needed was in excess. Quiroga *et al* [15] reported the synthesis of prrido[2,3-*d*]pyrimidines by the reaction of 6-amino-2,3-dihydro-2-thioxo-4(1*H*)-pyrimidinone and α,β-unsaturated ketones in boiling DMF. Recently, Bagley *et al*. [16] reported a new method for the synthesis of pyrido[2,3-*d*]pyrimidines by the reaction of 2,6-diaminopyrimidin-4-one and butynones in a range of different solvents at room temperature or 60°C. Quiroga *et al*. [17] reported the synthesis of pyrido[2,3-d]pyrimidines *via* a selective cyclocondensation reaction between 6-aminopyrimidines and the Mannich bases, propiophenone hydrochlorides. Devi *et al*. [18] reported a novel three-component one-pot synthesis of pyrido[2,3-*d*]pyrimidines using microwave heating. These methods usually require harsh conditions, using organic solvents, long reaction times and complex synthetic pathways.

The ionic liquids have been the subject of considerable current interest as environmentally benign reaction media in organic synthesis because of their unique properties of nonvolatility, nonflammability, and recyclability, among others [19]. Numerous chemical reaction, such as polymerization [20], hydrogenation [21], regioselective alkylation [22], Friedel-Crafts reactions [23], dimerization of alkenes [24], Diels-Alder reactions [25], Michael reactions [26], Cross-coupling reactions [27], and some enzymic reactions [28] can be carried out in ionic liquid. As part of our current studies on the development of new routes to heterocyclic systems [29], we herein describe a facile synthesis of pyrido[2,3-

**Scheme 1**



1 2 3

*d*]pyrimidine derivatives by the reaction of 6-aminopyrimidine-2,4-dione and α,β-unsaturated ketones in ionic liquid without using any catalyst (Scheme 1).

## RESULTS AND DISCUSSION

Choosing an appropriate solvent is of crucial importance for the successful organic synthesis. To search for the optimal solvent, the reaction of 6-amino-1,3-dimethylpyrimidine-2,4(1*H*,3*H*)-dione **1a** and 1-(4-chlorophenyl)-3-(4-methylphenyl)prop-2-en-1-one **2a** was examined using ionic liquid such as [bmim]Br, [bmim]$BF_4$, [bmim]$PF_6$, acetone, acetonitrile, ethanol, chloroform, and DMF as solvent, respectively, at different temperature for the synthesis of **3a**. The results are summarized in Table 1.

It can be seen from Table 1 that the reactions using ionic liquids (Table 1, entries 6–8) as the solvents resulted in higher yields and shorter reaction times than those using organic solvents (Table 1, entries 1–5). On the basis of the obtained results, [bmim]Br was found to be superior in terms of cheap and yield. To optimize the reaction temperature, the reactions were carried out at different temperature ranging from room temperature to 90°C. We found that the yield of the product **3a** was improved and the reaction time was shortened, as the temperature was increased to 90°C (Table 1, entries 8–12). Therefore, the most suitable reaction temperature is to 90°C. Under these optimized reaction conditions, a series of pyrido[2,3-*d*]pyrimidine derivatives **3** were synthesized. The results are summarized in Table 2.

As shown in Table 2, this protocol can be applied not only to the aromatic rings of α,β-unsaturated ketones with electron-withdrawing groups (such as halide and nitro groups), but also to α,β-unsaturated ketones with electron-donating groups (such as alkyl and alkoxyl groups). Therefore, we concluded that the electronic nature of the substituents of aromatic rings of α,β-unsaturated ketones has no significant effect on this reaction.

In this study, all the products **3** were characterized by mp, IR, and $^1$H NMR spectral data as well as HRMS analysis.

Although the detailed mechanism of above reaction remains not to be fully clarified, the formation of compounds **3** could be explained by a reaction sequence presented in Scheme 2. We proposed that the reaction proceeded *via* a reaction sequence of Michael addition, cyclization, dehydration and aromatization. First, the Michael addition reaction of 6-aminopyrimidine- 2,4-dione **1** to α,β-unsaturated ketones **2** give the intermediate product **4**, which on intermolecular cyclization and dehydration gave rise to **5**. In the last step, the intermediate product **5** aromatized to product **3**.

In conclusion, we have developed an efficient synthesis of 5,7-diarylpyrido[2,3-*d*]pyrimidine-2,4(1*H*,3*H*)-diones *via* the reaction of 6-aminopyrimidine-2,4-dione and α,β-unsaturated ketones in ionic liquid without any catalyst. This protocol has the advantages of easier work-up, milder reaction conditions, high yields, and environmentally benign procedure over traditional methods.

## EXPERIMENTAL

Commercial solvents and reagents were used as received. Melting points were uncorrected. IR spectra were recorded on Varian F-1000 spectrometer in KBr with absorptions in $cm^{-1}$. $^1$H NMR was determined on Varian-400 MHz spectrometer in DMSO-$d_6$ or $CDCl_3$ solution. *J* values are in Hz. Chemical shifts are expressed in ppm downfield from internal standard TMS. HRMS data were obtained using TOF-MS instrument.

**General procedure for the synthesis of pyrido[2,3-*d*]pyrimidines derivatives 3.** A dry 50 mL flask was charged with 6-aminopyrimidine-2,4-dione 1 (1 mmol), α,β-unsaturated ketones 2 (1 mmol), and ionic liquid [bmim]Br (2 mL). The mixture was stirred at 90°C for 5–7.5 h to complete the reaction (monitored by TLC), then 50 mL $H_2O$ was added. The solid was filtered off and washed with water. The crude product was purified by recrystallization from ethanol to give 3.

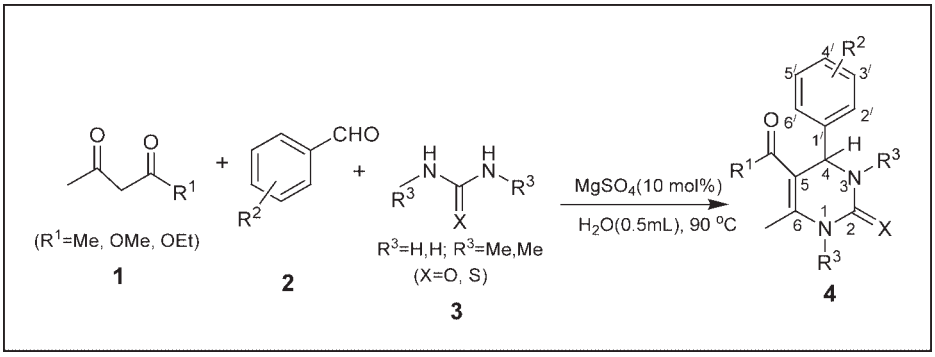
Published online 5 January 2010 in Wiley InterScience (www.interscience.wiley.com).



Different alkaline metal (II) sulfates were used as catalysts for the *N*,*N*′-dimethyl substituted as well as unsubstituted 4-aryl-3,4-dihydropyrimidones (thiones) and their corresponding bis-analogues in aqueous medium. Among the various salts, $MgSO_4 \cdot 7H_2O$ (Epsom salt) proved to be the best catalyst giving the desired products in good to excellent yields. This catalyst enables the construction of a series of compound libraries particularly for *N*,*N*′-dimethyl substituted DHPM's whose synthesis is very rare in the literature. The reaction on a wide variety substrates was evaluated by the application of green chemistry metrics and a very good correlation was obtained.

*J. Heterocyclic Chem.*, **47**, 136 (2010).

## INTRODUCTION

The actual driving force for the development of new catalysts for the structural motif-*N*,*N*′-disubstituted(unsubstituted)-4-aryl-3,4-dihydropyrimidones being a heterocyclic moiety of remarkable pharmacological importance [1] is to prepare compound libraries for screening in drug discoveries. The appropriately functionalized dihydropyrimidones (DHPMs) are very prominent as mitotic kinesin inhibitors, $\alpha_1$-adrenergic antagonists and potent hypertensive agents [1]. The importance of the *N*,*N*′-disubstituted DHPMs lies in the fact that *N*,*N*′-disubstitution promotes lipophilicity and advances chemozymatic synthesis of enantiopure DHPMs in organic solvents [2]. When three component coupling (3CC) involving an aldehyde, alkyl acetoacetate, and *N*,*N*′-dimethylurea is performed, the synthesis of the desired dihydropyrimidones often fail or produces the desired products in very low yields due to the formation of multiple side products. Solvent-free conditions also fail to produce them [3]. Till date, the synthesis of *N*,*N*′-disubstituted DHPMs remains a great challenge for organic chemists.

Green Chemistry is a rapidly developing new field that provides a proactive avenue for the sustainable development of future science and technology [4]. Nowadays many reactions are being carried out in water for environmental protection. From this view point, it is desirable, instead of organic solvents, to use water as a reaction medium as, water is safe, easy handling, abundant and an environmentally benign solvent. Therefore, we aimed at the synthesis of the *N*,*N*′-disubstituted and *N*,*N*′-unsubstituted DHPMs in aqueous medium.

## RESULTS AND DISCUSSION

Dihydropyrimidones (DHPMs) possess immense biological activity [5] and therefore the synthesis of this nucleus has received much attention. It must be mentioned that the synthesis of the *N*,*N*′-dimethyl substituted DHPMs is rather difficult and there are only few references in the literature. The simple DHPMs, first synthesized by Biginelli [6], have already been prepared by a number of methods. In spite of this, very few reports of the synthesis of this ring system exist in water [7–9]. Thus, exploration for catalysts leading to the synthesis of this extremely important ring system in aqueous medium is still needed. In continuation of our sincere

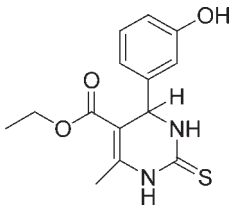


**Figure 1.** Monastrol.

efforts in carrying out reactions in aqueous medium [10–12], we envisaged the construction of a wide variety of *N*,*N*′-unsubstituted and dimethyl substituted dihydropyrimidones and also bis-dihydropyrimidones in water with variations in all the three components. This catalyst has been efficiently utilized for the synthesis of the mitotic kinesin EG 5 inhibitor Monastrol [13] (Fig. 1) in excellent yield.

For the initial exploration, the condensation of ethylacetoacetate, 4-chlorobenzaldehyde and urea with $MgSO_4$ (10 mol %) was studied in different solvents to optimize the reaction condition and to establish the feasibility of our catalyst (Table 1).

From Table 1, we find that the synthesis of the dihydropyrimidone produced from 4-chlorobenzaldehyde, EAA and urea proceeds best in water at 90°C in water (entry 12). Almost no reaction took place in aqueous medium at lower temperatures (entries 9–11). Use of higher temperature did not increase the yield further (entry 13). The yields were much lower when carried out in organic solvents (entries 1–8). Therefore, water has a definite role for the green reaction medium as it has an unique property of inducing hydrophobic interactions between the substrate and the catalyst.

Our next task was the choice of the catalyst for the model reaction with EAA, urea, and 4-chlorobenzaldehyde with 0.5 mL of water at 90°C and the results are summarized in Table 2.

We tried Group IIA metal sulfates as the catalyst for the dihydropyrimidone formation in water at 90°C. It was observed that $MgSO_4 \cdot 7H_2O$ (Epsom salt) produced the desired product in maximum yield. It was also observed that the solubility of the Group IIA metal sulfate decreases down the group in accordance with Fajan's rules, which states that solubility decreases with increasing cationic radius. Therefore, the yield with Epsom salt was maximum probably due to an optimum correlation between its solubility and ionic character. The partial covalent character of $Mg^{+2}$ ion helps to form strong metal-oxygen bonds (similarly as in ref. [5]) thereby increasing the electrophilicity of the carbonyl carbons of the β-keto esters or β-diketones.

Once the optimum reaction conditions were finalized, the catalyst was effectively utilized for the synthesis of a wide variety of *N*,*N*′-unsubstituted-3,4-dihydropyrimidin-2(1H)-ones and thiones (Scheme 1, $R^3 = H$) and the results are summarized in Table 3.

**Table 2**

Choice of catalyst for the reaction of EAA, urea, and 4-chlorobenzaldehyde with 0.5 mL water at 90°C.

| Entry | Catalyst (10 mol%) (with water of hydration) | Time (h) | Yield % (isolated w. r. t. starting aldehyde) |
|---|---|---|---|
| 1 | – | 10 | 5 |
| 2 | $MgSO_4$ | 4 | 90 |
| 3 | $CaSO_4$ | 6 | 60 |
| 4 | $SrSO_4$ | 7 | 47 |
| 5 | $BaSO_4$ | 10 | 20 |

Our next target was the application of our catalyst for the synthesis of the dimethyl substituted DHPM's and hence to synthesize ''drug-like'' molecules. This is because the synthesis of these *N*,*N*′-dimethyl DHPMs are rather difficult and thus references for their synthesis are very rare. To establish the scope and utility of our catalyst, a number of reactions (Table 4) were conducted and the products isolated. It was noted that on scaling up the reaction, the amount of $MgSO_4$ need not be increased proportionately. After lyophilization of the water extract obtained from the filtration of the product, the recovered catalyst could be reused to a maximum of three successive preparations of the DHPMs with almost the same yield of the reaction. The water extract responded to positive tests for both $Mg^{+2}$ and $SO_4^{2-}$ ions indicating that the catalyst remains intact after the reaction. The role of the catalyst is therefore to increase the electrophilicity of the aldehyde carbonyl which is very obvious as with other metal salts and also to coordinate with the carbonyl oxygen of the β-keto ester and the β-diketone.

On analysis of Tables 3 and 4, we find that our catalyst produced the *N*,*N*′-unsubstituted-3,4-dihydropyrimidin-2(1*H*)-ones in excellent yields and the *N*,*N*′-dimethyl DHPMs in good yields. The reaction also accommodated a wide variety of substrates in the aldehyde part, both electron-donating and electron-withdrawing acting equally well. Ethylacetoacetate, methylacetoacetate, and acetylacetone were varied as the β-keto esters or the β-diketone. Again, urea and thiourea were equally effective in carrying out the reaction. Table 3, entry 4 depicts the synthesis of Monastrol (Fig. 1). In all the cases, the pure product was isolated by simple filtration. Recrystallization from aqueous ethanol produced the pure 3, 4-dihydropyrimidin-2(1*H*)-ones. Thus, the products were obtained in pure form without any column chromatography or any cumbersome work-up techniques. In all the cases, 100% conversion was observed as no starting materials were present in thin layer chromatography (TLC) or in $^1$H NMR (crude) after the reaction. With aliphatic aldehydes, only 10% conversion (by TLC) was observed and the final products cannot be isolated from the reaction mixture. The reaction was also 100% selective as a single product was obtained for all cases for aromatic aldehydes. This is possibly due to the higher stability of the acyl imines (with increasing conjugation) for aromatic aldehydes than with aliphatic ones. This methodology in aqueous medium is obviously a green one as no toxic chemicals or reagents were used and no side products were obtained.

Encouraged by the aforementioned results, we turned our attention toward the utilization of our catalyst toward the construction of the bis-3,4-dihydropyrimidin-2(1*H*)-ones (thiones). We found that the reactions proceeded smoothly in aqueous medium with $MgSO_4$ (10 mol %) to produce the *N*,*N*′-unsubstituted bis-compounds in excellent yields (Scheme 2, Table 5). The reaction generated two new chiral centers at $C_4$ and $C_4'$-positions, the relative stereochemistry of which could be either RR or RS. X-ray crystallography of these compounds was not possible due to their amorphous nature. With dimethyl urea and thiourea, the formation of these bis-compounds did not go to completion. These bis-compounds are otherwise quite difficult to achieve and therefore the application of our catalyst provides an easy access to the construction of these compounds.

The mechanism of the dihydropyrimidone formation is similar as proposed by Folkers and Johnson [15]. The

initial formation of the acylimine intermediate takes place which reacts subsequently with the β-diketone or β-ketoester effectively. The partial covalent character of $Mg^{+2}$ helps in forming a strong metal oxygen bond which helps in increasing the electrophilicity of the β-diketone or β-ketoester in the same manner as mentioned in ref. [5]. Finally, a favorable cyclization and dehydration path follows to produce the dihydropyrimidone system.

In a nutshell, our methodology has the following distinct advantages over the earlier reported procedures [6.9]: (a) the reactions are investigated in water and hence avoids the hassles of organic solvents, (b) the catalyst is rather simple and cheap, (c) anhydrous reaction conditions need not be maintained, (d) additional proton sources are not required, (e) the products are obtained by simple filtration without the need for column chromatography, (f) this methodology is particularly useful for the synthesis of the dimethyl dihydropyrimidones and bis-dihydropyrimidones which are otherwise quite rare in the literature, and (g) it is a totally green methodology.

**Green metric calculations.** The green metrics were calculated using the procedures reported in the literature.[4] Their definitions are given as follows:

*Mass Intensity (MI)* = Total mass used in a process or process step (g)/mass of product (g)

*Reaction mass efficiency (RME)* = (Σ mass of products/Σ mass of reactants) × 100

*Carbon efficiency (CE)* = [(No. of moles of product × No. of carbons in product)/Σ (No. of moles of reactant × No. of carbons in reactant)] × 100

*Atom economy (AE)* = [molecular weight of product/Σ molecular weight of reactant] ×100

[a] Isolated.

Mass intensity (MI), reaction mass efficiency (RME), carbon efficiency (CE), and atom economy (AE) have been considered as a measure of environmental sustainability in minimizing the amount of theoretical waste. MI considers the yield stoichiometry, the solvent and the RME is the natural measure of greenness that takes into account the yield, excess or catalytic amount of reactants used but it does not account for any solvent use. CE is the percentage of carbon gain or loss, that is, whether all the carbon atoms of the reactant are present in the product. It is a very important parameter in our reaction as our reaction involves carbon atoms. Finally, the AE is a theoretical calculation of the chemical and environmental efficiency of the reaction which allows

for the effect on stoichiometric equation, not considering any solvent, excess of reagents and formation of intermediate or any other side product, etc. So from this aforementioned point, the ideal situation is MI $\approx$ 1, % RME $\approx$ 100, % CE $\approx$ 100, % AE $\approx$ 100.

We have shown the green metrics calculations for some selected compounds using urea, thiourea, or dimethyl urea (Table 6). The results reveal that our reactions have excellent MI values for almost all the compounds (Table 6). MI values of the reactions are very much dependent on solvent. Use of lesser amount of solvent in the reaction will lead to the ideal situation. We use only 0.5 mL of water in our reactions which is the optimum value. Use of lower amount of solvent (water) in the reaction will lead to increase in MI, but lower yield, as the catalyst will not react in lesser amount of solvent used. Thus, the MI values obtained were highly acceptable. Our reactions have excellent CE (for reactions with urea and thiourea) and quite good CE (for reactions with dimethyl counterparts), which in these cases is equal to the yield because all the carbon atoms of the reactant are present in the

product. In the same direction, the excellent yields with the catalyst produced good values of RME while moderate yield produced moderate RME values. Table 6 shows that all our reactions possess excellent AE values mostly being 89–90%. Thus all the reactions carried out using our methodology have very good green metrics correlations.

## CONCLUSION

It can be concluded that $MgSO_4 \cdot 7H_2O$ (10 mol %) in 0.5 mL water proves to be the best catalyst amongst all the alkaline Group II metals for dihydropyrimidone, bis-dihydropyrimidone and particularly, *N*,*N*′-dimethyl dihydropyrimidone formation. Since only 10 mol % of the catalyst and 0.5 mL of water are used, the reaction condition meets several green chemistry principles. The isolation of the reaction products is very simple and does not require column chromatography for most cases.

## EXPERIMENTAL

**General.** Ethanol was distilled before use. All the chemicals were purchased from Aldrich Chemical Company and Spectrochem (Mumbai, India). Silica Gel G with binder from Spectrochem was used for thin layer chromatography. $MgSO_4 \cdot 7H_2O$ was purchased from Spectrochem was used as such. $^1H$ and $^{13}C$ NMR spectra were obtained on Bruker 300 MHz instrument at 300 and 75 MHz, respectively. $CDCl_3$ and DMSO-$d_6$ were purchased from Aldrich Chemical Company. Melting points were determined on an electrical melting point apparatus with an open capillary and are uncorrected. IR spectra were recorded on a Perkin-Elmer spectrophotometer RX/FTIR system.

**General experimental procedure for dihydropyrimidone/bis-dihydropyrimidone formation.** A mixture of aromatic aldehyde (1 mmol), β-keto ester or β-diketone (1.3 mmol/2.6 mmol), urea/thiourea/*N*,*N*′-dimethyl urea/*N*,*N*′-dimethyl thiourea (1.5 mmol/3.0 mmol) and $MgSO_4 \cdot 7H_2O$ (10 mol %) and 0.5 mL water were mixed thoroughly and then taken in a 5 mL conical flask. It was next placed in water bath at 90°C and heated for the specified time as mentioned in Tables 3–5. The reactions were monitored by TLC for the absence of the starting aldehyde. After completion of the reaction, the crude mass was cooled, poured into crushed ice, and stirred for further 10 min, when the dihydropyrimidones (solids) precipitated out. They were directly filtered and crystallized from hot aqueous ethanol to obtain the finally pure products. The liquid DHPMs products were extracted with (2 × 5) mL ethyl acetate, washed with brine, solvent removed to obtain the crude products. The pure products (liquids) were obtained by column chromatography with silica gel (100–200 mesh) and elution with ethyl acetate/petroleum ether (60–80°C). All the products were characterized by their spectral and analytical data.

The data for all the previously unknown compounds are given later:

Acetoacetanilide was trilithiated with excess lithium diisopropylamide to form a reactive trianion-type intermediate. This was followed by a regioselective Claisen-type condensation of the trilithiated intermediate with a variety of aromatic esters to afford new *C*-acylated intermediates, 3,5-diketopentane-carboxanilides, that were not isolated but immediately condensed-cyclized with hydrazine to afford the *NH*-pyrazoleacetanilides, 5-aryl-1*H*-pyrazole-3-acetanilides, before these *C*-acylated intermediates had an opportunity to rearrange to anilino-pyranones, 4-anilino-6-aryl-2*H*-pyran-2-ones.

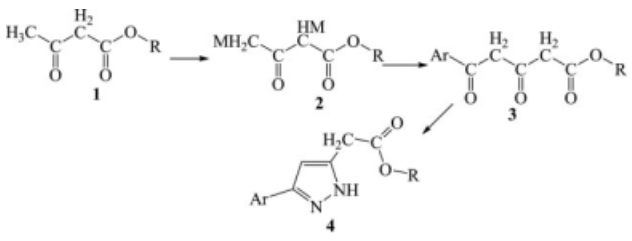
## INTRODUCTION

Pyrazoles of all substitution types continue to be prepared and studied, either as stand alone molecular systems, or as part of a fused-ring group of compounds, such as, indazoles and dihydrobenzindazoles [1]. *NH*-Pyrazole-3-acetic acids and their derivatives have received limited investigation [2], with a single recent citation dealing with the preparation of *NH*-pyrazole-3-acetanilides [3], and a single report for *NH*-pyrazole-3-acetic acid hydrazides [4]. Of the possible pyrazole substitution types, the *NH*-pyrazoles continue to receive increasing interest, especially in ligand investigations [5] (Scheme 1).

Claisen type strong base studies with β-ketoesters dianions **2** resulting from deprotonation of **1** with alkali metal amides (M = Li, Na, or K), lithium diisopropylamide (LDA), and other strong bases [6] was followed by condensation with carboxy electrophiles, usually an ester, and sometimes *N*-acylaziridines [7]. This afforded *C*-acylated products **3**, diketoesters, that could be isolated and transformed by condensation-cyclization with hydrazine into additional products, *NH*-pyrazoles **4**.

**Scheme 1.** Syntheses with dimetalated β-ketoesters.

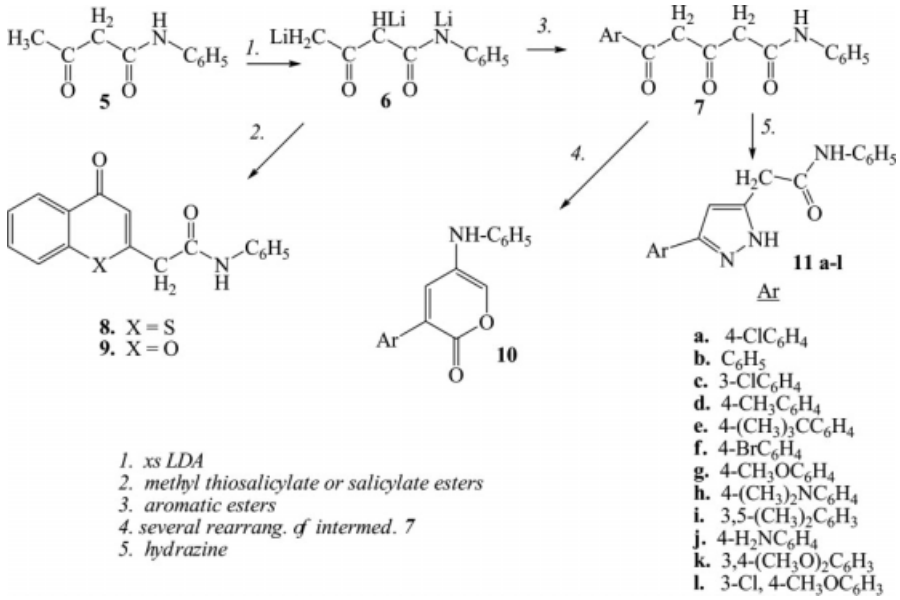


Some of the dianion-type β-ketoester systems **2** have been expanded to trianion-type β-ketoamide intermediates **6** that could be used in additional syntheses (Scheme 2). Recently, acetoacetanilide **5** has been trilithiated with excess LDA, and these intermediates **6** were regioselectively condensed at the terminal carbon atom with lithiated methyl thiosalicylate or a variety of lithiated methyl salicylates to afford *C*-acylation products **7** that were acid cyclized to 4*H*-1-benzothiopyran-4-ones (thiochromone-acetanilides) **8** [8] or 4*H*-1-benzopyran-4-ones (chromone-acetanilides) **9** [9], respectively. When the trilithiated intermediates **6** were condensed with other substituted benzoate esters, such as, methyl 4-methoxybenzoate, rearrangement products usually resulted and were identified as substituted 2-pyranones, 4-anilino-6-aryl-2*H*-pyran-2-ones **10** [10].

## RESULTS AND DISCUSSION

During this investigation, 2-[3-(phenyl or substituted phenyl)-1*H*-pyrazol-5-yl]-*N*-phenylacetamides, *NH*-pyrazole

**Scheme 2.** Syntheses with trilithiated acetoacetanilide including 5-aryl-1*H*-pyrazole-3-acetanilides **11a–l.**



acetanilides, **11a–l** were prepared by the immediate condensation-cyclization of 5-(phenyl or substituted phenyl)-3,5-dioxo-*N*-phenylpentamides, diketopentanilides **7**, (from **5** and **6**) intermediate compounds with hydrazine. Intermediate diketopentanilides **7** were prepared by modification and extension of some strong-base multiple anion procedures where trianion **6** resulted from treatment of acetoacetanilide **5** with excess LDA to **6**, and then condensed with a variety of substituted benzoate esters, that did not contain an ortho-substituted nucleophilic functional group (e.g., thiophenol).

The purification of these diketopentanilide intermediates **7** presented a good possibility of rearrangements to anilino-pyranones **10**; consequently, they were treated with excess hydrazine which resulted in the preferential condensation of a hydrazine nitrogen with one of the two carbonyl carbons of diketopentanilide intermediates **7** followed by cyclodehydration to the targeted pyrazoleacetic acid anilides **11a–l**. Anilino-pyranones **10** were not found.

The pyrazole acetanilides **11a–l** can be represented as a molecular system with numerous tautomeric forms (**I–VI**), including the keto-enol and annular tautomers with the pyrazole *N*—*H* hydrogen bonded to either of the adjacent nitrogen atoms (annular tautomers). IR carbonyl absorptions from crystalline products were noted at 1651–1676 $cm^{-1}$. Proton magnetic spectra indicated predominantly or exclusively keto tautomer, with the methylene absorptions appearing as a singlet at δ 3.44–3.78 ppm. The $C_4$—H absorptions of the pyrazole ring were noted at δ 6.31−6.69 ppm. Carbon-13 NMR spectra were indicative of structure but they were inconclusive. Even after extensive scans, the projected number of carbon absorptions were usually not obtained [3]. The C4 (CH carbon) resonance absorptions of the pyrazole ring in all cases were noted δ 101–107 ppm, which is in accord with estimates and recent experimental data reported by others [3,4]. DEPT taken after 5000 C-13 NMR scans on **11b** followed by HMQC indicated the presence of the methylene carbon absorptions at δ 35.8 ppm, which was matched with H-1 NMR methylene protons absorption at δ 3.72 ppm; the C-13 NMR absorption at δ 102.5 ppm was matched with H-1 NMR $C_4$—H of the pyrazole ring absorption at δ 6.61 ppm. Other C-13 NMR absorptions were noted for the methylene carbons from δ 32.9 to 40.2 ppm. LC-MS for all compounds, $(M+H)^+$, were also satisfactory and combustion analysis for the compounds were supportive. The single crystal X-ray analysis obtained for product **11c** indicated that a single tautomer in the keto form (**I**, Fig. 1) with a hydrogen bonded to the nitrogen adjacent to the pyrazole carbon also bonded to the methylene (C3 in the ORTEP diagram illustrated in Fig. 2) and that the pyrazole ring is nearly planar [12].

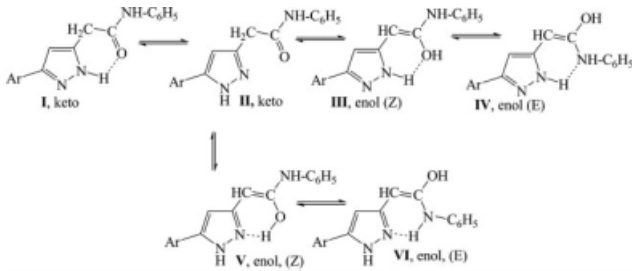


**Figure 1.** 5-Aryl-1*H*-pyrazole-3-acetanilide tautomers **I–VI**.

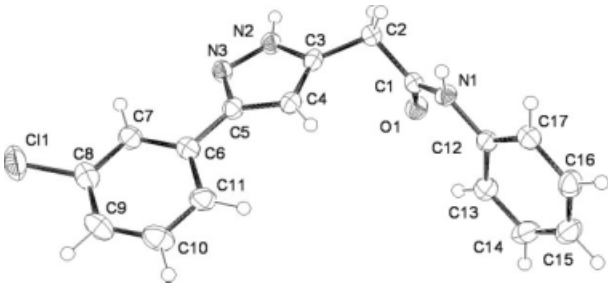

**Figure 2.** ORTEP diagram (50% ellipsoids for nonhydrogen atoms), $C_{17}H_{14}ClN_3O$ **11c** [11].

The molecular structure of **11c** is shown in Figure 2 and selected bond distances and angles are listed in Table 1. The bond lengths agree with the assignment of the double bond shown between C1 and O1 for the keto form (see ORTEP diagram for numbering of atoms).

The least squares best planes representing the rings containing C6 and C5 are nearly coplanar with an angle of 18.3° between them. There is likely some extended pi bonding between these rings. Each molecule is hydrogen bonded to four molecules: N3 to the H atom on N1, H on N2 to O1, O1 to the H atom on N2, and H on N1 to N3.

The overall yields for the two-step synthesis may not be optimal for an individual product, with the strong base reactions usually having the greatest variance. A practical side to the synthesis is the availability of starting materials, the use of less toxic acylating reagents (aromatic esters vs. acyl aziridines), a procedure that is reproducible by someone not necessarily familiar with strong base synthesis methods, and that the procedure is conducive to making targeted products which can be prepared in gram quantities after recrystallization from common solvents. Although not investigated extensively, tetramethylethylenediamine (TMEDA) did not markedly increase the overall yield, on occasion ~5% [6g]. In addition to all products targeted and prepared being new, they have the potential for use in agriculture and medicine, applications in other syntheses, and for spectral and theoretical studies.

## EXPERIMENTAL

Melting points were obtained with a Mel-Temp II melting point apparatus in open capillary tubes and are uncorrected. Fourier transform infrared spectra were obtained with a Mattson Genesis II FTIR with Specac Golden Gate Accessory. Proton and C-13 nuclear magnetic resonance spectra were obtained with a Varian Associates Mercury Oxford (300 MHz for H-1 and 75 MHz for C-13) nuclear magnetic resonance spectrometer, and chemical shifts are recorded in δ ppm downfield from an internal tetramethylsilane (TMS) standard. Combustion analyses were performed by Quantitative Technologies, Inc., P.O. Box 470, Whitehouse, NJ 08888. LCMS analyses were measured on a Thermo-Finnigan LCQ Advantage system with the Surveyor autosampler, Surveyor pump, and LCQ Advantage Max mass spectral detector using electrospray ionization; 2 mg samples were prepared in 2 mL $min^{-1}$ of acetonitrile; 10 μL injections were pumped at 1.00 mL $min^{-1}$ isocratically with 70% acetonitrile and 30% water, each buffered with 0.1% formic acid by volume; 15 min runs were reproduced in positive MS modes. Data were collected at full scan from 100 to 650 amu.

**General procedure for the preparation of 5-aryl-1*H*-pyrazole-3-acetic acid anilides (11a–l). Ratio of reagents—Acetoacetanilide:LDA:ester, 1:4:1 for 11a–g, and 1:5:1 for 11h and 11j.** In a typical reaction sequence, LDA was prepared in a round bottomed flask by the addition of 39–40 mL (50 mL for **11h** and **11j**) of 1.60*M* *n*-butyllithium (0.0630 mol/0.0788 mol for **11h** and **11j**) in hexanes (e.g., 500 mL), equipped with a nitrogen inlet tube, and a side-arm addition funnel (recommended). The flask was cooled in an ice water bath, and 6.41 g (0.0630 mol) or 8.01 g (0.0788 mol for **11h** and **11j**) of diisopropylamine (99.5%, Aldrich Chemical Co.), dissolved in 25–35 mL of dry THF was added from the addition funnel at a fast drop wise rate during a 5 min period. The solution was stirred for an additional 15–20 min, and then treated during 5 min with acetoacetanilide **6** (99.5%, Aldrich Chemical Co.),

2.65 g (0.015 mol) dissolved in 40–60 mL of THF. After 3 h, a solution of 0.0158 mol (5% molar excess) of substituted benzoate ester dissolved in 25–35 mL of THF, was added, during 5 min, to the trilithiated intermediate **7**, and the solution was stirred overnight ($N_2$) at room temperature. Finally, 100 mL of 3*M* hydrochloric acid was added all at once, followed by an additional 100 mL of reagent grade ether, and the two-phase mixture was separated, followed by extraction of the aqueous layer with ether (2 × 50 mL). The combined organic fractions were extracted with 25 mL of 5% sodium bicarbonate solution, then 25 mL water. The resulting solution was dried ($MgSO_4$), decanted, and evaporated (if rotoevap. used, temperature of water bath ~40°C). An oil usually resulted, which was taken up in 50–75 mL of methanol followed by 6 mL of hydrazine hydrate, 1 mL of acetic acid, and the solution heated under reflux for 2–4 h. The resulting solution was allowed to evaporate, and the resulting solid was recrystallized, usually from common solvents to afford products **11a–l**.

***2-[3-(4-Chlorophenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11a).*** Compound **11a** was obtained in 34% yield, mp 234–235°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-chlorobenzoate. IR: 1651, 3217, and 3332 cm$^{-1}$. $^1$H NMR (DMSO-$d_6$): δ 3.78 (s, 2H, $CH_2$), 6.63 (s, 1H, $C_4$—H, pyrazole), 7.05 (t, 1H, ArH, $J$ = 7.5 Hz), 7.31 (t, 2H, ArH, $J$ = 7.8 Hz), 7.45 (m, 2H, ArH), 7.63 (d, 2H, ArH, $J$ = 7.8 Hz), 7.79 (m, 2H, ArH), 10.22 (s, 1H, NH), and 12.86 (s, 1H, NH). $^{13}$C NMR (DMSO-$d_6$): 31.37, 102.78 (C4, pyrazole), 119.8, 124.0, 127.4, 129.4, 139.8, 147.3, 174.1, 178.5. LCMS, theor. exact mass, 311.08: exp. $(M+H)^+$ 312.0. Anal. Calcd for $C_{17}H_{14}ClN_3O \cdot 1/8\ H_2O$ [13]: C, 65.02; H, 4.57; N, 13.38. Found: C, 64.97; H, 4.28; N, 12.98.

***2-[3-Phenyl-1H-pyrazol-5-yl]-N-phenylacetamide (11b).*** Compound **11b** was obtained in 31% yield, mp 222–224°C (methanol/benzene), from the two-step procedure for the condensation-cyclization of **6** and methyl benzoate. IR: 1668, 3195 cm$^{-1}$. $^1$H NMR (DMSO-$d_6$): δ 3.72 (s, 2H, $CH_2$), 6.61 (s, 1H, $C_4$—H, pyrazole), 7.04 (t, 1H, ArH, $J$ = 7.5 Hz), 7.31–7.43 (m, 5H, ArH), 7.64 (d, 2H, ArH, $J$ = 7.5 Hz), 7.76 (d, 2H, ArH, $J$ = 7.5 Hz), and 10.23 (NH). $^{13}$C NMR (DMSO-$d_6$): 35.8, 102.6 (C4, pyrazole), 119.8, 124.0, 125.7, 128.2, 129.5, 132.6, 139.9, 168.4. LCMS, theor. exact mass, 277.12: exp. $(M+H)^+$, 278.04. Anal. Calcd for $C_{17}H_{15}N_3O$: C, 73.63; H, 5.45; N, 15.04. Found: C, 73.22; H, 5.47; N, 15.04.

***2-[3-(3-Chlorophenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11c).*** Compound **11c** was obtained in 49% yield, mp 191–194°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 3-chlorobenzoate. IR: 753, 1655, 3132, and 3194 cm$^{-1}$. $^1$H NMR (DMSO-$d_6$): δ 3.78 (s, 2H, $CH_2$), 6.69 (s, 1H, $C_4$—H, pyrazole), 7.06 (t, 1H, ArH, $J$ = 7.8 Hz), 7.29–7.44 (m, 4H, ArH), 7.63 (d, 2H, ArH, $J$ = 7.5 Hz), 7.76 (d, 2H, ArH, $J$ = 7.5 Hz), and 10.23 (s, 1H, NH). $^{13}$C NMR (DMSO-$d_6$): 34.59, 103.5 (C4, pyrazole), 119.5, 124.7, 125.7, 127.8, 129.1, 131.7, 134.5, 139.9. LCMS, theor. exact mass, 311.08: exp. $(M+H)^+$, 312.01. Anal. Calcd for $C_{17}H_{14}\ ClN_3O \cdot 1/3\ H_2O$ [13]: C, 64.25; H, 4.65; N, 13.22. Found: C, 64.34; H, 4.84; N, 13.04.

***Single crystal X-ray structure determination.*** Yellow crystals of $C_{17}H_{14}ClN_3O$ **11c** were recrystallized from an ethanol-water solution in order to give satisfactory crystals for X-ray

determination. Crystal data for X-ray studies were collected at 20°C on a Mercury CCD area detector coupled with a Rigaku AFC8 diffractometer with graphite monochromated Mo-K radiation. Data were collected in 0.5° oscillations in ω with 40 s exposures. A sweep of data was done using ω oscillations from −40.0° to 90.0° at $\chi = 45°$ and $\phi = 0.0°$; a second sweep was performed using ω oscillations from −30.0° to 80.0° at $\chi = 45°$ and $\phi = 90.0°$. The crystal-to-detector distance was 27.7789 mm. Details of the data collection are reported in Table 2. Data were collected, processed, and corrected for Lorentz polarization and for absorption using CrystalClear (Rigaku) [15].

The nonhydrogen atoms were refined anistropically. Ideal hydrogen atom coordinates for the rings containing C6 and C12 (see numbering of atoms in ORTEP diagram, Fig. 2) were calculated and the hydrogen atoms were allowed to ride on their respective carbon atoms. The hydrogen atoms on N1, N2, C2, and C4 were located by difference and then ideal coordinates were calculated and these hydrogen atoms were allowed to ride on their respective atoms. The temperature factors of all hydrogen atoms were varied isotropically. Structure solution, refinement, and the calculation of derived results were performed using the SHELX-97 [16] package of computer programs. Neutral atom scattering factors were those of Cromer and Waber [16], and the real and imaginary anomalous dispersion corrections were those of Cromer [17].

***2-[3-(4-Methylphenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11d).*** Compound **11d** was obtained in 40% yield, mp 196–198°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-methylbenzoate. IR: 1338, 1660 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 2.51 (s, 2H, $CH_3$), 3.72 (s, 2H, $CH_2$), 6.56 (s, 1H, $C_4$—H, pyrazole), 7.05 (t, 1H, ArH, $J = 7.5$ Hz), 7.20–7.34 (m, 4H, ArH), 7.62–7.66 (m, 4H, ArH), 10.22 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): δ 25.79, 26.23, 39.51, 54.04, 106.98 (C4, pyrazole), 124.6, 128.7, 130.4, 134.2, 134.4, 134.8, 142.3, 144.6, 173.3. LCMS, theor. exact mass 291.14: exp. $(M+H)^+$, 292.08. Anal. Calcd for $C_{18}H_{17}N_3O \cdot 1/2\ H_2O$ [13]: C, 71.90; H, 6.04; N, 13.99. Found: C, 72.01; H, 6.26; N, 14.38.

***2-[3-(4-(1,1-Dimethylethyl)phenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11e).*** Compound **11e** was obtained in 37% yield, mp 262–265°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-(1,1-dimethylethyl)benzoate. IR: 1676, 3128 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 1.26 (s, 9H, $CH_3$), 3.44 (s, 2H, $CH_2$), 6.55 (s, 1H, $C_4$—H, pyrazole), 7.03 (t, 1H, ArH, $J = 7.5$ Hz), 7.29 (t, 2H, ArH, $J = 8.1$ Hz), 7.40 (d, 2H, ArH, $J = 8.4$ Hz), 10.20 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): 26.6, 31.8, 35.0, 102.3 (C4, pyrazole), 113.1, 119.9, 123.9, 125.5, 125.2, 126.2, 129.4, 139.9. LCMS, theor. exact mass 333.18: exp. $(M+H)^+$, 334.10. Anal. Calcd for $C_{20}H_{23}N_3O$: C, 75.65; H, 6.95; N, 12.60. Found: C, 75.28; H, 7.01; N, 12.54.

***2-[3-(4-Bromophenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11f).*** Compound **11f** was obtained in 19% yield, mp 246–249°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-bromobenzoate. IR: 1651, 3209 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 3.44 (s, 2H, $CH_2$), 6.54 (s, 1H, $C_4$—H, pyrazole), 7.03 (d, 1H, ArH, $J = 8.3$ Hz), 7.31 (t, 2H, ArH, $J = 5.4$ Hz), and 7.57–7.62 (m, 4H, ArH) and 10.20 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): δ 34.3, 102.6 (C4, pyrazole), 119.8, 124.0, 127.7, 129.4, 132.2, 139.0, 139.8, 142.2, 149.9, 172.2. LCMS, theor. exact mass 355.03: exp. $(M+H)^+$, 355.98. Anal. Calcd for $C_{17}H_{14}\ BrN_3O$: C, 57.32; H, 3.96; N, 11.85. Found: C, 56.94; H, 3.89; N, 11.83.

***2-[3-(4-Methoxyphenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11g).*** Compound **11g** was obtained in 40% yield, mp 201–203°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-methoxybenzoate. IR: 1660, 3283 $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ $^1H$ NMR (DMSO-$d_6$): δ 3.66 (s, 2H, $CH_2$), 3.75 (s, 3H, $OCH_3$), 6.47 (s, 1H, $C_4$—H, pyrazole), 6.94–7.05 (m, 3H, ArH), 7.24–7.31 (m, 2H, ArH), 7.58–7.67 (m, 4H, ArH) and 10.16 (s, NH). $^{13}C$ NMR (DMSO-$d_6$): 36.01, 54.86, 78.36, 100.94 (C4, pyrazole), 113.8, 119.2, 123.1, 126.3, 128.4, 129.4, 138.9, 158.8, 167.8. LCMS, theor. exact mass, 307.13: exp. $(M+H)^+$, 308.06. Anal. Calcd for $C_{18}H_{17}N_3O_2$: C, 70.34; H, 5.58; N, 13.67. Found: C, 70.11; H, 5.55; N, 13.51.

***2-[3-[4-(Dimethylamino)phenyl]-1H-pyrazol-5-yl]-N-phenylacetamide (11h).*** Compound **11h** was obtained in a 19% yield, mp 272–275°C (DMF), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-dimethylaminobenzoate. IR: 1610, 1670, 3184 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 2.92 (s, 6H, $CH_3$), 3.67(s, 2H, $CH_2$), 6.38 (s, 1H, $C_4$—H, pyrazole), 6.72 (d, 2H, ArH, $J = 9.0$ Hz), 7.02 (t, 1H, ArH, $J = 7.2$ Hz), 7.27 (t, 2H, $J = 7.8$ Hz, ArH), 7.55 (d, 2H, ArH, $J = 8.7$ Hz), 7.62 (d, 2H, ArH, $J = 7.5$ Hz), 8.17 (d, 2H, ArH), 10.09 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): 36.5, 44.0, 87.6, 101.0 (C4, pyrazole), 113.0, 119.8, 123.9, 126.6, 129.4, 139.2, 149.7, 139.9, 150.5. LCMS, theor. exact mass, 320.38: exp. $(M+H)^+$, 321.09. Anal. Calcd for $C_{19}H_{20}N_4O \cdot 1/4\ H_2O$ [13]: C, 70.24; H, 6.36; N, 17.34. Found: C, 70.30; H, 6.40; N, 17.49.

***2-[3-(3,5-Dimethylphenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11i).*** Compound **11i** was obtained in a 40% yield, 222–224°C (ethanol/benzene), from the two-step procedure for the condensation-cyclization of **6** and methyl 3,5-dimethylbenzoate. IR: 1660, 3238 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 2.29 (s, 6H, $CH_3$), 3.38 (s, 2H, $CH_2$), 6.55 (s, 1H, $C_4$—H, pyrazole), 6.92 (s, 1H, ArH), 7.05 (t, 1H, ArH, $J = 7.5$ Hz), 7.31 (t, 2H, ArH, $J = 7.5$ Hz), 7.37 (s, 1H, ArH), 7.61 (s, 2H, ArH), 7.64 (d, 2H, ArH, $J = 1.2$ Hz), 10.19 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): 21.7, 37.6, 102.5 (C4, pyrazole), 107.0, 112.7, 119.8, 123.5, 123.9, 129.4, 130.0, 138.6, 139.9, 160.8. LCMS, theor. exact mass, 305.15: exp. $(M+H)^+$, 306.17. Anal. Calcd for $C_{19}H_{19}N_3O$: C, 74.73; H, 6.27; N, 13.76. Found: C, 74.34; H, 6.34; N, 13.66.

***2-[3-(4-Aminophenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11j).*** Compound **11j** was obtained in a 32% yield, 178–180°C (ethanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 4-aminobenzoate. IR: 1662, 2777, 3322 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 3.62 (s, 2H, $CH_2$), 5.32 (s, 1H, NH), 6.32 (s, 1H, $C_4$—H, pyrazole), 6.53 (s, 2H, NH), 6.58 (d, 2H, ArH, $J = 7.2$ Hz), 7.02 (t, 1H, ArH, $J = 7.5$ Hz), 7.28 (t, 2H, ArH), 7.36 (d, 2H, ArH, $J = 8.7$ Hz), 7.61 (d, 2H, ArH, $J = 7.5$ Hz), 10.18 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): 39.5, 100.8 (C4, pyrazole), 113.2, 115.1, 119.8, 120.8, 121.7, 123.9, 125.9, 126.7, 129.4, 130.1, 139.9, 168.9. LCMS, theor. exact mass, 292.34: exp. $(M+H)^+$ 293.04. Anal. Calcd for $C_{17}H_{16}N_4O \cdot 1/4\ H_2O$ [13]: C, 68.79; H, 5.60; N, 18.87. Found: C, 68.85; H, 5.49; N, 18.26.

***2-[3-(3,4-Dimethoxyphenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11k).*** Compound **11k** was obtained in a 19% yield, 198–

200°C (methanol), from the two-step procedure for the condensation-cyclization of **6** and methyl 3,4-dimethoxybenzoate. IR: 1655, 2931, 3193 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 3.68 (s, 2H, $CH_2$), 3.78 (s, 3H, $OCH_3$), 3.80 (s, 3H, $OCH_3$), 5.28 (s, 1H, NH), 6.35 (s, 1H, $C_4$—H, pyrazole), 6.54–6.76 (m, 3H, ArH) 6.94–7.18 (m, 3H, ArH), 7.49–7.57 (m, 3H, ArH), and 9.22 (s, 1H, NH); $^{13}C$ NMR (DMSO-$d_6$): 37.9, 56.2, 87.5, 102.1 (C4, pyrazole), 109.4, 112.6, 118.1, 119.8, 123.9, 129.4, 139.9, 147.9, 149.6, 168.0. LCMS, theor. exact mass, 337.37: exp. $(M+H)^+$ 338.08. Anal. Calcd for $C_{19}H_{19}N_3O_3 \cdot 1/4\ H_2O$ [13]: C, 66.75; H, 5.75; N, 12.29. Found: C, 67.11; H, 5.62; N, 12.23.

***2-[3-(3-Chloro-4-methoxyphenyl)-1H-pyrazol-5-yl]-N-phenylacetamide (11l).*** Compound **11l** was obtained in a 30% yield, 215–218°C (ethanol) from the two-step procedure for the condensation-cyclization of **6** and methyl 3-chloro-4-methoxybenzoate. IR: 1502, 1600, 1667, 2839, 3263 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 3.77 (s, 2H, $CH_2$), 3.85 (s, 3H, $CH_3O$), 5.41 (s, 1H, NH) 6.56 (s, 1H, $C_4$—H, pyrazole), 7.03 (t, 1H, ArH, $J$ = 7.2 Hz), 7.14 (d, 1H, ArH, $J$ = 8.4 Hz), 7.31 (t, 2H, ArH, $J$ = 7.5 Hz), 7.60 (d, 1H, ArH, $J$ = 1.8 Hz), 7.69 (d, 2H, ArH, $J$ = 1.8 Hz), 7.80 (s, 1H, ArH), 12.74 (s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$): 26.2, 40.2, 56.8, 103.3 (C4, pyrazole), 113.7, 119.8, 122.0, 124.0, 125.6, 126.9, 129.4, 139.8, 154.5, 167.9. LCMS, theor. exact mass, 341.09: exp. $(M+H)^+$, 342.01. Anal. Calcd for $C_{18}H_{16}ClN_3O_2$: C, 63.25; H, 4.72; N, 12.29. Found: C, 62.91; H, 4.79; N, 12.19.

Copper triflate has been found to be an efficient catalyst for the synthesis of benzimidazoles from *o*-phenylenediamine and aldehydes at reflux temperature under acetonitrile solvent. This new method consistently has the advantage of excellent yields (74–95%) at reflux temperature.

*J. Heterocyclic Chem.,* **47**, 153 (2010).

## INTRODUCTION

Benzimidazoles are highly biologically active compounds and exhibit antiviral, antinulcer, antihypertension, and anticancer properties [1]. Because of wide biological significance, the synthesis of these compounds has received a great deal of attention. The synthesis of benzimidazoles involves treatment of 1,2-phenylenediamines with carboxylic acids or various derivatives under strongly acidic conditions or with aldehydes followed by oxidation [2,3] for which various oxidative reagents have been used [4,5]. Many of these processes suffer from one or more limitations, such as long reaction times, occurrence of several side reactions, drastic reaction conditions, low yields, and tedious work-up procedure. Therefore, the search continues for a better catalyst for the synthesis of benzimidazoles in terms of mild reaction conditions.

Recently, the use of copper triflate catalyst [6,7] has received considerable importance in organic synthesis because of their ease of handling, enhanced reaction rates, greater selectivity, simple workup. Among the various catalysts, particularly, copper triflate has advantages of low cost and ease of preparation. In view of this, we have used copper triflate as an efficient catalyst for the benzimidazole synthesis in our laboratory.

## RESULTS AND DISCUSSION

Initially, we have studied the condensation reaction of aldehyde (1.0 mmol) with 1,2-phenylenediamine (1.2 mmol) using copper triflate (1.0 mmol) under reflux temperature under acetonitrile solvent (Scheme 1). Copper triflate catalyst is acting as Lewis acid and the formation of benzimidazole may be through the following mechanism. (Scheme 2).

Encouraged by these results, we examined several aromatic aldehydes under the optimized conditions. This condensation proceeded smoothly in refluxing acetonitrile and also complete with in 5 h of reaction time. Several aldehydes (aromatic, heteroaromatic, and aliphatic) underwent the above conversion to form a series of benzimidazoles (Table 1). Aromatic aldehydes containing both electron-donating and electron-withdrawing groups worked well. The method is suitable for the preparation of benzimidazoles from an acid sensitive aldehyde such as furfuraldehyde (**3k**) and the sterically

**Scheme 1**

| **3k** |  |  | 5.0 | 75 |
| **3l** |  |  | 5.0 | 74 |

hindered aldehyde 2-naphthaldehyde (**3l**). Substituted aldehydes have been used with similar success to provide the corresponding benzimidazoles in high yields, which are also of much interest with regard to biological activity. The reaction conditions are mild and the experimental procedure is simple. The products were formed in high yields (74–95%). The structures of the products were determined from their spectral ($^1$H NMR, IR, and MS) data. Several examples illustrating this novel and general method for the synthesis of benzimidazoles are summarized in Table 1.

## CONCLUSIONS

In summary, we have developed a new methodology for the synthesis of various benzimidazoles by using 1,2-phenylenediamines and substituted aldehydes in the presence of copper triflate catalyst at reflux temperature. Thus, this method is a simple, high yielding, time saving, and the utility of copper triflate catalyst for synthesis of benzimidazoles would be precious addition to available methods.

## EXPERIMENTAL

**General procedure for the synthesis of benzimidazoles.** To a mixture of an aldehyde (0.5 mmol) and 1,2-phenylenediamine (0.6 mmol) in acetonitrile (5 mL) under a nitrogen atmosphere, coppertriflate (0.5 mmol) was added. The mixture was stirred at reflux temperature, and the reaction was monitored by TLC. After completion, the solvent was evaporated and the mixture was extracted with EtOAc (3 × 10 mL). The extract was concentrated, and the crude product was purified by silica gel column chromatography using ethyl acetate–*n*-hexane (1:9) as eluent to afford the desired product **3**. The residue was subjected to column chromatography (silica gel, hexane–EtOAc) to obtain the pure benzimidazole. The spectral ($^1$H NMR, IR, and MS) data of some representative benzimidazoles are given below.

Triazole skeleton is ubiquitous in pharmaceutically important compounds. A novel series of indoline-containing triazole with different amides are described, which exhibit antibacterial and antifungal activities. The chemical synthesis strategies used, the complete characterization of the compounds, their *in vitro* screening, and the promising activity as reflected in the MIC values are reported.

*J. Heterocyclic Chem.,* **47**, 156 (2010).

## INTRODUCTION

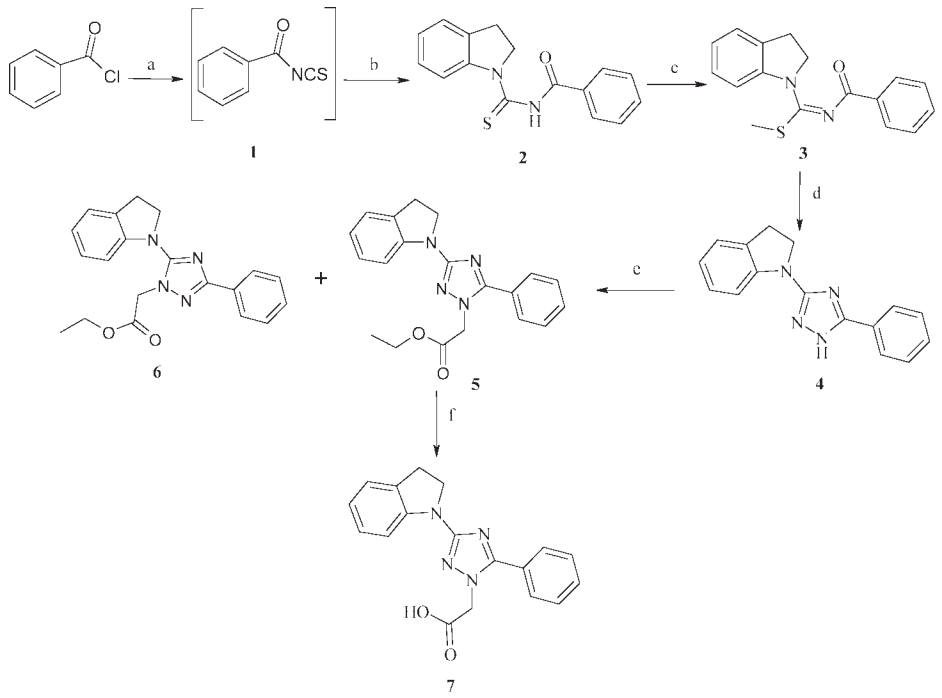
Developing new antimicrobial agents (antibacterial and antifungal) continues to attract attention and is an area of rigorous research. Although a large number of antibiotics and chemotherapeutics are available for medical use, the antimicrobial resistance created a substantial need of new class of antimicrobial agents in the last decades [1–3].

Triazole and its derivatives have distinct status as pharmaceutical agents. They have been found to have high therapeutic value as antifungal [4–6], anti-inflammatory [7], antimalarial [8], antiviral [9], antihypertensive [10], analgesic [11], antihyperuricemic [12], and anticancer agents [13,14]. Recently, synthesis of trisubstituted 1,2,4-triazole derivatives reported as a modulator of nicotinic receptor agonist [15] and antitumor and antiviral agents [16], in addition triazole derivatives revealing promising antimicrobial activities [17–23]. In continued quest of new antimicrobial agents, we designed and synthesized novel 1,2,4-triazole derivatives containing indoline ring. Structures of the products were characterized by IR, $^1$H-NMR, mass spectrometry, and elemental analysis. Results of biological activities indicate that some compounds possess potential antimicrobial activity.

## RESULTS AND DISCUSSION

**Chemistry.** The synthetic strategy involved in the synthesis of intermediate and target compounds is outlined in Schemes 1 and 2. The key intermediate [3-(2,3-dihydroindol-1-yl)-5-phenyl[1,2,4] triazol-1-yl]acetic acid **7** was prepared as outlined in Scheme 1 [24,25]. Benzoyl chloride reacted with ammonium thiocyanate to obtain benzoyl thiocyanate **1**, which was treated *in situ* with indoline to provide the addition product *N*-benzoyl thiourea **2** [26]. The addition product **2** was methylated by methyl iodide to produce *N*-benzoyl-S-methylisothiourea **3**, which was further cyclized with hydrazine hydrated in refluxing ethanol to give the triazole **4**. The triazole **4** was alkylated by ethyl bromoacetate in the presence of sodium hydride in dry THF to afford two regioisomers **5** and **6**. The isomer **5** was hydrolyzed in the presence of aqueous LiOH to give the corresponding

**Scheme 1.** Reagents and conditions: (a) ammonium thiocyanate, acetone, 56°C, 30 min; (b) indoline, acetone, 56°C, 1 h; (c) methyl iodide, $K_2CO_3$, DMF, rt, 1 h; (d) hydrazine hydrate, ethanol, reflux, 5 h; (e) ethyl bromoacetate, NaH, THF, rt, 4 h; (f) aq. $LiOH.H_2O$, THF-methanol, rt, 5 h.



acid derivative **7**, which was used as a key intermediate for the synthesis of target compounds.

The two regioisomers **5** and **6** were separated by chromatography on silica gel, and the resulting regioisomer ethyl [3-(2,3-dihydroindol-1-yl)-5-phenyl[1,2,4] triazol-1-yl]acetate **5** was the major product. The structures of these two regioisomers **5** and **6** were assigned based on NMR analysis and confirmed by NOE NMR experiments [24,27] (Fig. 1).

The synthesis of target compounds **8a–e** and **9a–e** is outlined in Scheme 2. The amide coupling of [3-(2,3-dihydroindol-1-yl)-5-phenyl[1,2,4] triazol-1-yl]acetic acid **7** was carried out with different amines, in the presence of EDCI in THF at room temperature, with excellent yield.

The structures of all the intermediates and final compounds **8a–e** and **9a–e** were found on the basis of elemental analysis and spectrographic (IR, $^1$H-NMR, and Mass) data. The physical characterization data are listed in Table 1.

**Biological activities.** The newly synthesized derivatives were evaluated for their *in vitro* antibacterial activity against gram-negative *E. coli*, *P. aeruginosa*, gram-positive *S. aureus*, *S. pyogenes*, and antifungal activity against *C. albicans* and *A. niger* by microbroth dilution methods [28–30]. The standard strains used for screening of antibacterial and antifungal activities were procured from the Institute of Microbial Technology (IMTECH), Chandigarh, India. The MIC values are given in Table 2. The standard drug used for antibacterial activity was ciprofloxacin and nystatin for antifungal activity. Mueller Hinton broth was used as nutrient medium for bacteria and Sabouraud dextrose broth for fungal to grow. Inoculum size for test strain was adjusted to 108 CFU/mL by comparing the turbidity. Serial dilutions were prepared for primary and secondary screening. The target compounds and standard drugs were dissolved in DMSO water at a concentration of 2.0 mg/mL. In primary screening, 500, 250, and 125 μg/mL

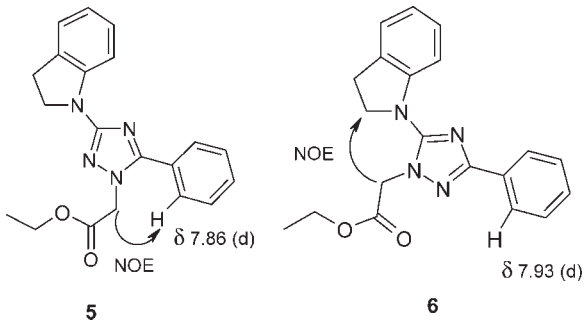


**Figure 1.** NOE was observed between 1-methylene and ortho-proton of phenyl group of compound **5** and between 1-methylene and *N*-methylene group of compound **6**. Chemical shift of ortho-hydrogen of phenyl in compound **6** was more downfield because of extra deshielding effect from the triazole ring.

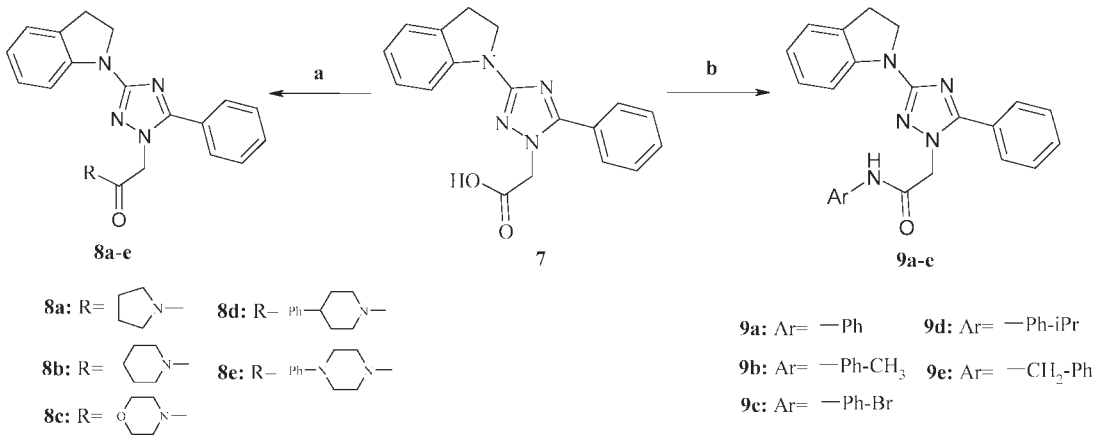
**Scheme 2.** Reagents and conditions: (a) corresponding secondary cyclic amine, EDCI, DIPEA, THF, rt, 5–10 h and (b) corresponding aromatic amine, EDCI, DIPEA, THF, rt, 5–8 h.



concentrations of the synthesized drugs were taken. Data were not taken for the initial solution, because of the high DMSO concentration (10%). The active synthesized drugs found in this primary screening were further tested in a second set of dilution against all microorganisms. In secondary screening, the drugs found active in primary screening were similarly diluted to obtain 100, 50, 25, 12.5, and 6.250 μg/mL concentrations. The inoculated wells were incubated overnight at 37°C in a humid atmosphere. The highest dilution showing at least 99% inhibition zone is taken as MIC.

Results of antibacterial and antifungal activities of screened compounds indicate that some compounds possess comparable antibacterial activity with respect to reference drug ciprofloxacin. Compounds **8a–e** with secondary amide functionality exhibited moderate to excellent activity against all the tested bacterial strains, but not showed satisfactory activity against fungal strains. Compound **8a** exhibited excellent activity against *E. coli*, whereas moderate activity against *P. aeruginosa* and *S. aureus*. Compound **8b** showed very good active against *P. aeruginosa* only, whereas compound **8c** exhibited moderate activity against all the tested bacteria except *S. pyogenes*. Compound **8e** showed excellent activity against *S. aureus* and moderate activity against all the other tested bacteria. While the other series with aromatic amide functionality, compounds **9a–e**, did not show comparable inhibition with any tested bacterial and fungal organisms.

## EXPERIMENTAL

Melting points were determined with a Buchi B-545 melting point apparatus and are uncorrected. IR spectra were recorded on a Perkin-Elmer PE-1600 FTIR spectrometer in KBr disc. $^1$H-NMR spectra were recorded on a Varian 400 spectrometer in DMSO-$d_6$ as a solvent and TMS as an internal standard. Peak values are shown in δ ppm. EI-MS spectra were measured on a Waters mass spectrometer. Progress of the reaction was checked by thin layer chromatography (TLC) on silica gel-coated aluminum sheets (silica gel 60 F254) using a mixture of ethyl acetate and hexane (5:5 v/v). All of the solvents and materials were reagent grade and purified as required.

***N*-(2,3-Dihydroindole-1-carbothioyl)benzamide (2).** Benzoyl chloride was added to a stirred solution of $NH_4SCN$ (3.51 g, 0.046 mol) in acetone (30 mL), and the resultant suspension was refluxed for 30 min and then cooled to room temperature. A solution of indoline (5.0 g, 0.042 mol) in acetone (30 mL)

***N*-[1-(2,3-Dihydroindol-1-yl)-1-methylsulfanyl-methylidene] benzamide (3).** Methyl iodide (2.38 mL, 0.038 mol) was added to a stirred suspension of compound **2** (9.0 g, 0.031 mol) and anhydrous $K_2CO_3$ (6.4 g, 0.046 mol) in DMF (50 mL) and stirred for 1 h at room temperature. Reaction mixture was poured in water (200 mL) and stirred for 15 min. The resulting off-white solid was filtered, washed with water, and dried *in vacuo*. Solid was crystallized from rectified spirit to give compound **3** as off-white solid. Yield 7.33 g (78.0%), m.p. 87–89°C; $^1$H-NMR (DMSO-$d_6$): δ 2.234 (s, 3H, $CH_3$); 3.17–3.25 (t, 2H, $CH_2$, $J$ = 8.5 Hz), 4.17–4.25 (t, 2H, $CH_2$, $J$ = 8.5 Hz), 7.02–7.20 (m, 2H, ArH), 7.28–7.32 (d, 1H, ArH), 7.43–7.58 (m, 3H, ArH), 8.02–8.09 (m, 3H, ArH); ms: *m/z* 297 (M+1). Anal. Calcd. for $C_{17}H_{16}N_2OS$: C, 68.89; H, 5.44; N, 9.45; Found: C, 68.77; H, 5.58; N, 9.33.

**1-(5-Phenyl-1*H*-[1,2,4]triazol-3-yl)-2,3-dihydro-1*H*-indole (4).** A solution of compound **3** (7.0 g, 0.023 mol) and hydrazine hydrate (1.78 mL, 0.035 mol) in ethanol (50 mL) was refluxed for 5 h, cooled, and poured into water (100 mL), and the mixture was stirred at room temperature. The resulting white solid was collected by filtration and washed with water to give a crude compound **3**. The solid was recrystallized in ethanol to give a pure compound **4** as white solid. Yield 4.64 g (75%), m.p. 131–133°C; $^1$H-NMR (DMSO-$d_6$): δ 3.16–3.25 (t, 2H, $CH_2$, $J$ = 8.2 Hz), 3.92–4.01 (t, 2H, $CH_2$, $J$ = 8.2 Hz), 6.72–6.81 (t, 1H, ArH), 7.13–7.21 (m, 2H, ArH), 7.49–7.53 (m, 3H, ArH), 7.69–7.73 (m, 2H, ArH), 7.81–7.86 (m, 1H, ArH), 12.9 (s, 1H, NH); ms: *m/z* 263 (M+1). Anal. Calcd. for $C_{16}H_{14}N_4$: C, 73.26; H, 5.38; N, 21.36; Found: C, 73.12; H, 5.51; N, 21.48.

**Ethyl[3-(2,3-dihydroindol-1-yl)-5-phenyl[1,2,4]triazol-1-yl] acetate (5) and ethyl[5-(2,3-dihydroindol-1-yl)-3-phenyl[1, 2,4]triazol-1-yl]acetate (6).** A solution of compound **4** (4.5 g, 0.017 mol) in dry THF was treated with NaH (1.0 g, 0.025 mol) at room temperature for 20 min, followed by ethyl bromoacetate (2.0 mL, 0.018 mol). The reaction mixture was stirred for 4 h at room temperature, and TLC indicated two products. The mixture was evaporated and the product was separated by chromatography on silica gel (20% EtOAc/hexane) to afford **5** and **6**.

***5*.** The major product, white solid. Yield 3.76 g (63%), m.p. 160–162°C; $^1$H-NMR (DMSO-$d_6$): δ 1.28–1.30 (t, 3H, $CH_3$, $J$ = 7.10 Hz), 3.17–3.20 (t, 2H, $CH_2$, $J$ = 8.30 Hz), 4.02–4.06 (t, 2H, $CH_2$, $J$ = 8.30 Hz), 4.11–4.13 (q, 2H, $CH_2$, $J$ = 7.11 Hz), 4.99 (s, 2H, $CH_2$), 6.77–6.81 (t, 1H, ArH), 7.11–7.15 (t, 1H, ArH), 7.17–7.19 (d, 1H, ArH), 7.55–7.57 (m, 3H, ArH), 7.70–7.73 (m, 2H, ArH), 7.84–7.86 (d, 1H, ArH); ms: *m/z* 349 (M+1). Anal. Calcd. for $C_{20}H_{20}N_4O_2$: C, 68.95; H, 5.79; N, 16.08; Found: C, 68.73; H, 5.93; N, 15.90.

***6*.** The minor product, white solid. Yield 0.59 g (10%), m.p. 171–163°C; $^1$H-NMR (DMSO-$d_6$): δ 1.27–1.29 (t, 3H, $CH_3$, $J$ = 7.10 Hz), 3.14–3.16 (t, 2H, $CH_2$, $J$ = 8.25 Hz), 3.28–3.34 (m, 2H, $CH_2$), 4.10–4.12 (q, 2H, $CH_2$, $J$ = 7.10 Hz), 5.05 (s, 2H, $CH_2$), 6.85–6.89 (t, 1H, ArH), 7.17–7.19 (t, 1H, ArH), 7.22–7.24 (t, 1H, ArH), 7.57–7.60 (m, 3H, ArH), 7.77–7.79 (m, 2H, ArH), 7.91–7.93 (dd, 1H, ArH); ms: *m/z* 349 (M+1). **[3-(2,3-Dihydro-indol-1-yl)-5-phenyl[1,2,4]triazol-1-yl]acetic acid (7).** A solution of compound **6** (3.70 g, 0.010 mol) in THF-MeOH (20:20 mL) was treated with LiOH.$H_2$0 (0.89 g, 0.021 mol) at room temperature for 5 h, and the mixture was evaporated *in vacuo*. Water (50 mL) was added to the residue and washed with ethyl acetate (20 mL). Aqueous layer was acidified to pH 4 by adding dil. HCl, and the resulting precipitate was filtered, washed with water, and dried *in vacuo* to give compound **7** as white solid. Yield 2.75 g (81%), m.p. 200–202°C; $^1$H-NMR (DMSO-$d_6$): δ 3.13–3.21 (t, 2H, $CH_2$, $J$ = 8.31 Hz), 4.00–4.08 (t, 2H, $CH_2$, $J$ = 8.31 Hz), 4.99 (s, 2H, $CH_2$), 6.75–6.83 (t, 1H, ArH), 7.10–7.20 (m, 2H, ArH), 7.54–7.57 (m, 3H, ArH), 7.70–7.74 (m, 2H, ArH), 7.84–7.88 (d, 1H,

ArH), 13.51 (s, 1H, COOH); ms: *m/z* 319 (M-1). Anal. Calcd. for $C_{18}H_{16}N_4O_2$: C, 67.49; H, 5.03; N, 17.49; Found: C, 67.57; H, 5.16; N, 17.31.

**General procedure for the synthesis of compounds 8a–e and 9a–e.** A stirred solution of compound **6** (0.625 mmol), corresponding amino derivative (0.687 mmol), and diisopropylethylamine (1.25 mmol) in anhydrous THF (10 mL) was cooled to 0°C. EDCI (0.750 mmol) was added to the above mixture, and the resulting solution was stirred at room temperature for 5–7 h. The reaction mixture was evaporated *in vacuo*, and water (50 mL) was added to the residue and acidified to pH 4 by adding dil. HCl. The solid separated was collected by filtration, washed with water, and dried. Compound was recrystallized from 95% ethanol to give pure compounds **8a–e** and **9a–e**. The yield, the reaction time, and the physical properties are reported in Table 1.

A series of novel 1,2,4-triazolo[1,5-a]pyrimidine derivatives containing an α-amino phosphonate moiety **5** were designed and synthesized by the multi-step reactions. Their structures were clearly confirmed by spectroscopic data (IR, $^{1}$H NMR, $^{31}$P NMR, MS) and elemental analysis, compound **5b** was further determined by X-ray diffraction crystallography. The results of preliminary bioassay indicated that some of the title compounds **5** possessed moderate herbicidal activities against dicotyledonous plants (*Brassica campestris L*) at the concentration of 100 mg/L. For example, compound **5i** possessed 92.0% inhibitory activity against *B. campestris L* and showed better activity than that of the commercialized herbicide Bispyribac-sodium; however, compounds **5** displayed weak herbicidal activity at the concentration of 10 mg/L.

## INTRODUCTION

α-Amino phosphonic acid and their ester derivatives, as bioisosteres of natural amino acids, are receiving an increasing attention in medicinal chemistry and pesticide science due to their wide biological activities, such as enzyme inhibition, antibiotics, and haptens of catalytic antibodies, fungicides, herbicides, plant regulators and plant virucides [1–7]. Recently, 1,2,4-Triazolopyrimidine derivatives exhibited wide biological activities and were used as herbicides in plant protection [8–12]. A lot of triazolopyrimidine sulfonamide herbicides, such as Cloransulam-methyl, Flumetsulam, Diclosulam, Penoxsulam and Metosulam (Fig. 1), were commercialized, these herbicides acted as acetolactate synthase (ALS) inhibitors, which have been identified as a very fruitful acting target for herbicides in the last decades [13]. To find novel potent and selective herbicide lead compounds, we have designed a series of novel 1,2,4-triazolo[1, 5-a]pyrimidine derivatives containing an α-amino phosphonate moiety **5**. The target compounds **5** were evaluated for herbicidal activities in this paper. The synthetic route is listed in Scheme 1, the molecular structure of compound **5b** is shown in Figure 2. Crystallographic data (excluding structure factors) for the structure have been deposited with the Cambridge Crystallographic Data Center as supplementary publication CCDC No. 734888 (available free of charge at http://www.ccdc.cam.ac.uk/conts/retrieving/html or from the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK).

## RESULTS AND DISCUSSION

**Synthesis and structure determination of title compounds 5.** 5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-methylsulfone **1** were prepared using 3-amino-1,2,4-triazole-5-thiol and acetyl acetone as the starting materials, followed by S-alkylation and oxidation by $H_2O_2$ and $NaWO_4$ in good yield. 2-(5,7-Dimethyl-[1,2,4] triazolo[1,5-a]pyrimidin-2-yloxy)benzoic acid **3** was prepared by the reaction of **1** and methyl 2-hydroxybenzoate in the presence of sodium hydroxide in refluxing toluene, followed by the saponification in the presence

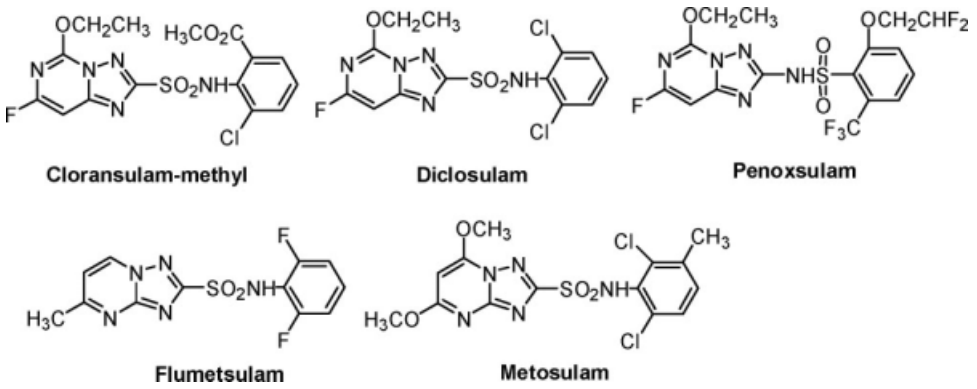

**Figure 1.** Structures of some commercial triazolopyrimidine-2-sulfonamide herbicides.

of aqueous sodium hydroxide. **3** reacted with α-amino-phosphonates **4** to generate the target compounds **5** in good yields in mild condition using dicyclohexylcarbodiimide (DCC) as the dehydration agent. The structures of target compounds **5** were characterized from their spectral data (IR, $^{1}$H NMR, $^{31}$P NMR, EI-MS) and elemental analysis, compound **5b** was further determined by single crystal X-ray diffraction analysis (see Fig. 2). In the $^{1}$H NMR spectra of **5**, the CH proton linking with the phosphonyl group displayed doublet of doublet due to coupling with P atom and NH proton with the coupling constant of 21 and 9.0 Hz, respectively. While the NH and pyrimidine protons appeared as a singlet with chemical shift atδ 6.8 and 8.0, respectively. The IR spectra of compounds **5** showed normal stretching absorption bands indicating the existence of the NH (∼3240 $cm^{-1}$), C═O (∼1660 $cm^{-1}$), P═O (∼1225 $cm^{-1}$), P─O─C (∼1025 $cm^{-1}$) moieties. The ESI-MS of compounds **5** revealed the existence of their molecular ion peaks, which were in accordance with the given structures of products **5**.

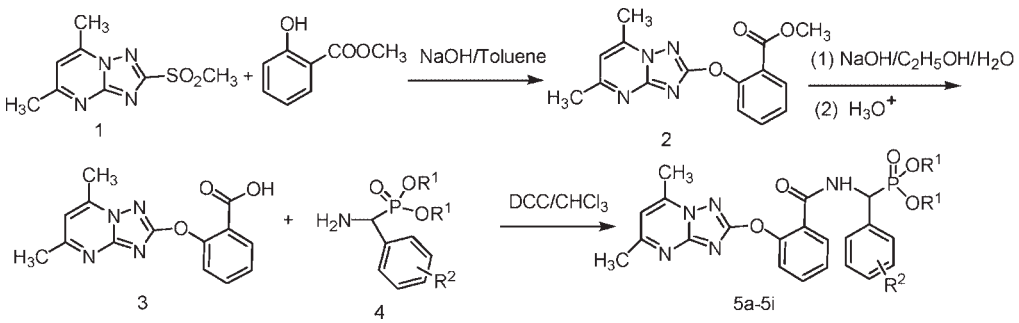
**Herbicidal activities.** The herbicidal activity values of the title compounds **5** against *Brassica campestris L* (rape) and *Echinochloa crus-galli* (barnyard grass) has been investigated at the dosages of 100 and 10 mg/L compared with the commercially available herbicide, Bispyribac-sodium according to the method described in the experimental section. The results of preliminary bioassy indicated that some of the title compounds **5** possessed moderate herbicidal activities against dicotyledonous plants (*B. campestris L*) at the concentration of 100 mg/L. For example, compound **5i** possessed 92.0% inhibitory activity against *B. campestris L* and showed better herbicidal activity than that of the commercialized herbicide Bispyribac-sodium. Futhermore, most of compounds **5** showed stronger inhibitory activity against dicotyledonous plants (*B. campestris L*) than that of monocotyledonous plants (*Radix E. crus-galli*). However, compounds **5** displayed weak herbicidal activity at the concentration of 10 mg/L. Further herbicidal evaluation (*in vivo*) and the structure–activity relationships are under investigation.

**Conclusion.** In summary, we have designed and synthesized one series of novel 1,2,4-triazolo[1,5-a]pyrimidine derivatives containing an α-amino phosphonate moiety **5**. The results of preliminary bioassy indicated that some of the title compounds **5** possessed moderate herbicidal activities against dicotyledonous plants (*B. campestris L*) at the concerntration of 100 mg/L.

## EXPERIMENTAL

The melting points of the products were determined on an XT-4 binocular microscope (Beijing Tech Instrument, Beijing,

**Scheme 1.** Synthesis of the title compounds **5**.



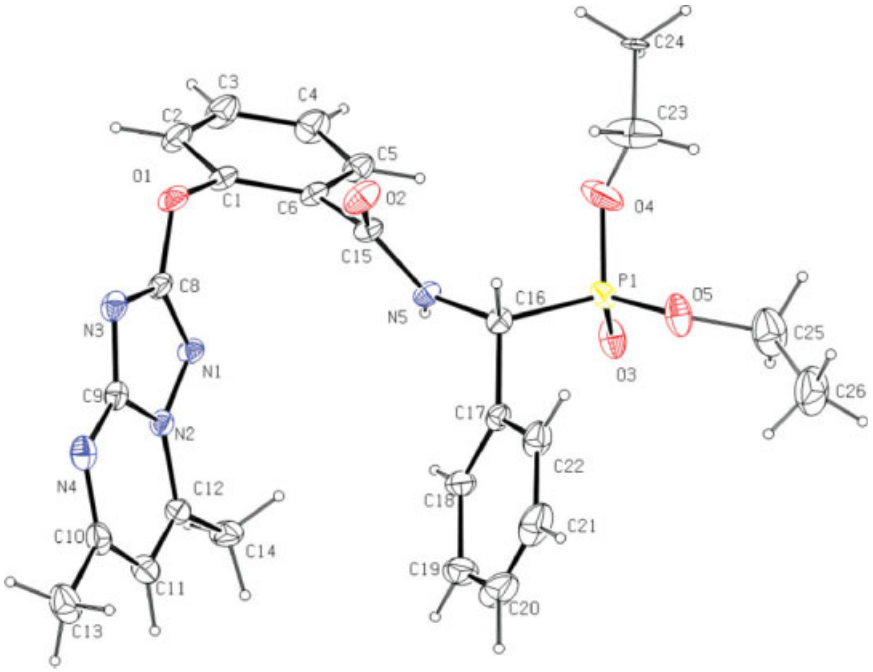


**Figure 2.** Molecular structure of compound **5b**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

China) and were uncorrected. The IR spectra were recorded on a Nicolet NEXUS470 spectrometer as KBr pellets with absorption given in $cm^{-1}$. $^1H$ and $^{31}P$ NMR spectra were performed on a Varian Mercury-PLUS400 (400 MHz) or Varian Mercury Plus-600 (600 MHz) spectrometer at room temperature in $CDCl_3$ with TMS and 85% $H_3PO_4$ as the internal and external standards, respectively. Mass spectra was measured on an Applied Biosystems API 2000 LC/MS/MS (ESI-MS) spectrometer. Elemental analysis was taken on a Elementar Vario EL III elemental analysis instrument. X-ray diffraction was carried out on a Bruker Smart 1000 CCD diffractometer (Germany). Analytical thin layer chromatography (TLC) was performed on silica gel GF254. Column chromatographic purification was carried out using silica gel. Unless otherwise noted, all materials were commercially available and were used directly without further purification. All solvents were dried and redistilled before use. 5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-methylsulfone **1** were prepared by the annulation reaction of 3-amino-1,2,4-triazole-5-thiol with acetyl acetone, followed by S-alkylation and oxidation by $H_2O_2$ and $NaWO_4$ according to the reported procedure [14], yield 82%, m.p. 187–188°C. Dialkyl α-amino phosphonates **4** were prepared from aromatic aldehyde, ammonium hydroxide and dialkyl phosphites in moderate yields according to the reported synthetic protocols [15,16].

**Synthesis of methyl 2-(5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-yloxy)benzoate 2.** Methyl 2-hydroxy-benzoate (0.91 g, 6 mmol), sodium hydroxide (0.24 g, 6 mmol) and anhydrous toluene (60 mL) were stirred under reflux for 3h, while the water was removed away during the reaction time. 5,7-Dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-methylsulfone **1** (2.26 g, 10 mmol) was added and stirred under reflux for 10 h till the reaction completed (monitored by TLC). The solid was filtered off, and the solvent was removed under a reduced pressure, the residue was purified by column chromatography on silica gel using petroleum ether/acetone (1:1 *v*/*v*) as the eluent, giving a white solid, yield: 68%, mp: 141–142°C. Anal. Cacld for $C_{15}H_{14}N_3O_3$: C, 60.40; H, 4.73; N, 18.78. Found: C, 60.17; H, 4.91; N, 18.55.

**Synthesis of 2-(5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-yloxy)benzoic acid 3.** Methyl 2-(5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-loxy)benzoate **2** (1.19 g, 4 mmol), sodium hydroxide (0.32 g, 8 mmol), water (10 mL) and ethanol (10 mL) were stirred at 80–90°C for 1–2 h. The solution was acidified by dilute hydrochloride, The crude product was collected by filtration, washed by ethyl ether, the product was obtained as a yellow solid, yield: 80%, mp: 103–104°C. Anal. Cacld for $C_{14}H_{12}N_4O_3$: C, 59.15; H, 4.25; N, 19.71. Found: C, 59.30; H, 4.19; N, 19.47.

**General synthetic procedure for *O,O*-dialkyl *N*-[2-(5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-yloxy)benzoxyl]-1-amino-1-substitutedbenzyl phosphonate 5.** 2-(5,7-dimethyl-[1,2,4]triazolo[1,5-a]pyrimidin-2-yloxy)benzoic acid **3** (0.284 g, 1.0 mmol), *O,O′*-diethyl α-amino (substituted phenyl) methylphosphonate **4** (1.0 mmol) and anhydrous chloroform (5 mL) were added to a 50 mL three-necked flask at 273 K, DCC (0.225 g, 1.1 mmol) in anhydrous chloroform (5 mL) was added dropwise slowly. The mixture was allowed to be stirred at room temperature overnight. After the solvent was removed under a reduced pressure, the residue was purified by column chromatography on silica gel using petroleum ether/acetone (1:2 *v*/*v*) as the eluent, giving the target compounds as a light yellow solid or liquid.

**Herbicidal activity (*in vitro*).** The herbicidal evaluation of compounds **5** were carried out in the laboratory of biological activities test, Nankai University, China. Compounds **5** were determined with *B. campestris L.* and *Radix E. crus-galli* as samples of annual dicotyledonous and monocotyledonous plants, respectively, using a previously reported procedure [17]. For all of the bioassay tests, each treatment was repeated two times.

***Treatment.*** The emulsions of purified compounds were prepared by dissolving them in 100 μL of *N*,*N*-dimethylformamide with the addition of 2 μL of Tween 20. The mixture of the same amount of water, *N*,*N*-dimethylformamide, and Tween 20 was used as control. The commercially available herbicide, Bispyribac-sodium was used as a compared sample to evaluate the herbicidal activity of the target compounds **5**.

**Inhibition of the root-growth of rape (*B. campestris* L.).** Rape seeds were soaked in distilled water for 4 h before being placed on a filter paper in a 6 cm Petri plate, to which 2 mL of inhibitor solution had been added in advance. Usually, 10 seeds were used on each plate. The plate was placed in a dark room and allowed to germinate for 72 h at 28 ± 1°C. The lengths of 10 rape roots selected from each plate were measured, and the means were calculated. The percentage inhibition was used to describe the control efficiency of the compounds. The herbicidal activity was listed in Table 1.

**Inhibition of the seedling growth of barnyard grass [*Radix Echinochloa crus-galli*].** Ten *Radix E. crus-galli* seeds were placed into a 50 mL cup covered with a layer of glass beads and a piece of filter paper at the bottom, to which 6 mL of inhibitor solution had been added in advance. The cup was placed in a bright room, and the seeds were allowed to germinate for 72 h at 28 ± 1°C. The heights of the above-ground parts of the seedlings in each cup were measured, and the mean values were calculated. The percentage inhibition was used to describe the control efficiency of the compounds. The herbicidal activity is also listed in Table 1.

**Acknowledgments.** The authors are grateful to the Natural Science Foundation of China (Grant No. 20872046), and the Natural Science Foundation of Hubei Province (Grant No. 2008CDB086) for the financial support.

Syntheses of new formyl ester- and cyano ester-substituted bithiophenes, bifurans, and furanothiophenes in good yield are described. The key synthetic step uses Stille coupling of appropriately substituted bromo 5-ring heterocycles with stannyl-substituted 5-ring heterocycles.

## INTRODUCTION

Compounds containing 2,2′-bithiophene, 2,2′-bifuran, and 2,2′-furanothiophene cores play important roles in material sciences [1], pharmaceutical [2], and agrochemical [3] fields. The various optical properties of these bichalcophenes have lead to their extensive use in nonlinear optical devices [4], sensors [5], solar cells [6], and other advanced materials. These bichalcophene units appear in important medicinal chemical applications including antibacterial [7] and anticancer studies [8]. Bichalcophene diamidines of the type I and II from our laboratory have been shown to recognize G-quadruplex DNA [9]. Formyl and ester bichalcophene analogs can undergo a variety of condensation reactions to prepare more complex molecules of importance to material science as well as for the generation of useful bioactive molecules. Cyano derivatives are key intermediates for the preparation of amidine molecules, which are important molecules in such diverse fields as medicinal chemistry [9] and catalyst development [10]. In view of our interest in molecules that recognize G-quadruplex DNA [9] and other ones, which can potentially function as diagnostics [11] for parasites and as an expansion of our previous bichalcophene work [12(a)]. We report here the synthesis of new bichalcophenes with formyl, ester, and cyano substituents that can serve as versatile building blocks for the preparation of more complex molecules (Fig. 1).

## RESULTS AND DISCUSSION

Scheme 1 outlines our approach to the synthesis of both the bichalcophene formyl and cyano esters. We chose to use the Stille approach for the coupling to form the bichalcophene units because this methodology is known to be quite robust and can be performed under neutral conditions [1(b),2,12(b)]. For ease of preparation of the Stille reagent, we chose to use the acetal-protected formyl furan **2a** and thiophene **2b**. The commercially available aldehydes **1a**, **b** were converted into the previously unreported acetals **2a**, **b** in high yields (>95%) using NBS as a catalyst, under mild conditions [13].The new tri-*n*-butylstannyl reagents were prepared in good yields (>80%) by a conventional *n*-butyllithium debromination of **2a**, **b** at −78°C followed by reaction with tri-*n*-butyltin chloride. The Stille coupling reaction between **3a**, **b** and commercially available **4a**, **b** in the presence of a 5 mol % of Pd $(PPh_3)_4$ using 1,4-dioxane as solvent at 100°C for 24 h followed by deprotection of the acetal product by stirring with conc. HCl solution for 6 h gave the desired new formyl analogs **5a–d** in good yields (>73%). The formyl esters were converted into the cyano esters (**6a–d**) using a conventional two-step process of conversion of the aldehydes into the corresponding oximes followed by acetic anhydride-facilitated dehydration to provide the new nitriles in good isolated yields (>75%).

In conclusion, we have reported a concise synthesis, in good yields, of new cyano and formyl ester-substituted bichalcophenes, which can be used for the

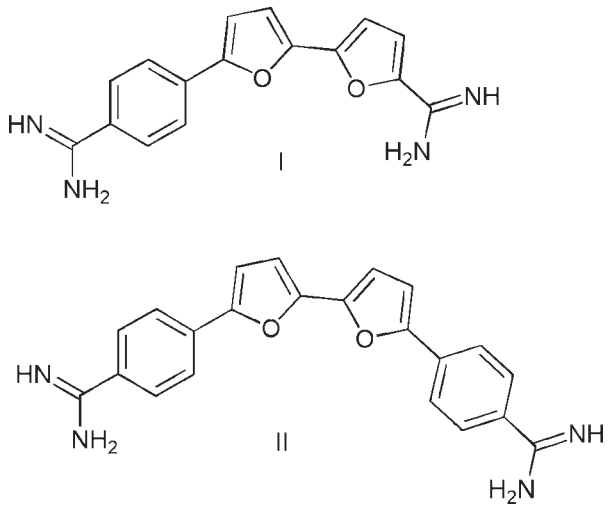

**Figure 1.** Bichalcophenes which recognize G-quadruplex DNA.

preparation of more complex molecules for multiple applications.

## EXPERIMENTAL

All commercial reagents were used without purification. Melting points were determined on a Mel-Temp 3.0 melting point apparatus and are uncorrected. TLC analysis was carried out on silica gel 60 F254 precoated aluminum sheets using UV light for detection. $^1$H- and $^{13}$C-NMR spectra were recorded on a Bruker 400 MHz spectrometer using the indicated solvents. Mass spectra were obtained from the Georgia State University Mass Spectrometry Laboratory, Atlanta, GA. Elemental analysis were performed by Atlantic Microlab, Norcross, GA.

**General procedure for the synthesis of 2a, b.** A 1.06 g NBS (6 mmol) was added in portions to a stirred mixture of **1a**, **b** (130 mmol) and 19.55 mL trimethyl orthoformate (190 mmol) in 150 mL anhydrous $CH_2Cl_2$ and 15 mL anhydrous $CH_3OH$ at 0°–5°. After the addition was completed, the resulting mixture was stirred overnight at room temperature, quenched with water, and the organic layer was separated, washed with water again, dried (sodium sulfate), and evaporated. The resulting oil was purified by distillation.

***2-Bromo-5-(dimethoxymethyl) furan (2a).*** Colorless liquid, yield 95%; bp 45°C (0.35 mmHg); $^1$H-NMR (400 MHz, $CDCl_3$): $\delta = 6.91$ (d, $J = 2.8$ Hz, 1 H), 6.85 (d, $J = 2.8$ Hz, 1 H), 5.38 (s, 1 H), 3.36 (s, 6 H); $^{13}$C-NMR ($CDCl_3$): $\delta = 52.3$, 99.6, 112.7, 125.7, 130.4, 143.1; ESI-MS: *m/z* calculated for $C_7H_9BrO_3$: 221.05, Found: 222.1 ($M^+ + 1$), 223.1 ($M^+ + 2$); Anal. Calcd. for $C_7H_9BrO_3$: C, 38.03; H, 4.10; Found: C, 37.81; H, 4.25.

***2-Bromo-5-(dimethoxymethyl) thiophene (2b).*** Colorless liquid, yield 97%; bp 69°C (0.25 mm Hg). $^1$H-NMR (400 MHz, $CDCl_3$): $\delta = 6.96$ (d, $J = 4$ Hz, 1 H), 6.83 (dd, $J = 1.2$, 4 Hz, 1 H), 5.54 (d, $J = 1.2$, 1 H), 3.33 (s, 6 H); $^{13}$C-NMR ($CDCl_3$): $\delta = 52.5$, 99.7, 112.5, 125.9, 131.1, 142.8; ESI-MS: *m/z* calculated for $C_7H_9BrO_2S$: 237.11, Found: 238.3 ($M^+ + 1$), 239.3 ($M^+ + 2$); Anal. Calcd. for $C_7H_9BrO_2S$: C, 35.46; H, 3.83; Found: C, 35.22; H, 4.15.

**General procedure for the synthesis of 3a, b.** A 101 mL 1.6*M* *n*-butyllithium solution in hexane (150 mmol) was added slowly to a stirred solution of **2a**, **b** (130 mmol) in 150 mL anhydrous THF under nitrogen atmosphere at –78°C. After the addition was completed, the mixture was stirred for 4 h and then 40.6 mL tri-*n*-butyltin chloride (150 mmol) was added slowly at –78°C. After stirring overnight, the solution was quenched with 50 mL water and solvents were removed under reduced pressure. The residue was extracted with 200 mL ether, the organic layer was washed with 30 mL 10% NaF solution and 100 mL water, dried (sodium sulfate), and concentrated. The resulting oil was purified by distillation.

***5-(Dimethoxymethyl)furan-2-yl-tri-n-butylstannane (3a).*** Yellow oil, yield 84%; bp 145°C (0.6 mm Hg); $^1$H-NMR (400 MHz, $CDCl_3$): $\delta = 6.53$ (d, $J = 2.8$ Hz, 1 H), 6.44 (d, $J = 2.8$ Hz, 1 H), 5.50 (s, 1 H), 3.39 (s, 6 H). 1.64 (m, 6 H), 1.53 (m, 6 H), 1.25 (m, 6 H), 1.09 (m, 9 H); $^{13}$C-NMR ($CDCl_3$): $\delta = 12.5$, 15.5, 26.9, 28.9, 52.4, 100.4, 126.4, 134.8, 135.1, 146.9; ESI-MS: *m/z* calculated for $C_{19}H_{36}O_3Sn$: 431.20, Found: 432.3 ($M^+ + 1$); Anal. Calcd. for $C_{19}H_{36}O_3Sn$: C, 52.92; H, 8.42; Found: C, 52.71; H, 8.55.

***5-(Dimethoxymethyl)thiophen-2-yl-tri-n-butylstannane (3b).*** Yellow oil, yield 81%; bp 185°C (0.7 mm Hg); $^1$H-NMR (400 MHz, $CDCl_3$): $\delta = 7.28$ (d, $J = 2.8$ Hz, 1 H), 7.15 (d, $J = 2.8$ Hz, 1 H), 5.69 (s, 1 H), 3.48 (s, 6 H), 1.78 (m, 6 H), 1.60 (m, 6 H), 1.48 (m, 6 H), 1.17 (m, 9 H); $^{13}$C-NMR ($CDCl_3$): $\delta = 13.2$, 17.3, 27.4, 28.5, 52.7, 101.1, 126.9, 134.2, 135.7, 146.3; ESI-MS: *m/z* calculated for $C_{19}H_{36}O_2SSn$: 447.26, Found: 448.2 ($M^+ + 1$); Anal. Calcd. for $C_{19}H_{36}O_2SSn$: C, 51.02; H, 8.11; Found: C, 51.17; H, 7.99.

**General procedure for the synthesis of 5a–d.** A 1.15 g tetrakis-triphenyl-phosphine palladium (1 mmol) was added to a stirred mixture of **3a**, **b** (20 mmol) and **4a**, **b** (20 mmol) in deaerated dry 40 mL dioxane under nitrogen atmosphere. The vigorously stirred mixture was warmed to 90–100°C for 24 h. The solvent was removed under reduced pressure; the residue was dissolved in 150 mL dichloromethane containing 5 mL of concentrated ammonia, then washed with water, and passed through celite. The solution was mixed with conc. 5 mL HCl, stirred for 6 h, separated and washed with water, dried (sodium sulfate), and evaporated. The product was purified by column chromatography on silica gel, using dichloromethane as eluent.

***Methyl 5′-formyl-2,2′-bifuran-5-carboxylate (5a).*** Yellow solid, yield (two steps) 79%; mp 129–130°C; $^1$H-NMR (400 MHz, $CDCl_3$): $\delta = 9.65$ (s, 1 H), 7.69 (d, $J = 3.6$ Hz, 1 H), 7.49 (d, $J = 3.6$ Hz, 1 H), 7.24 (brs, 1 H), 7.25 (brs, 1 H), 3.86 (s, 3 H); $^{13}$C-NMR ($CDCl_3$): $\delta = 53.1$, 111.2, 125.6, 127.6, 133.8, 135.2, 137.4, 152.3, 152.7, 161.9, 178.5; ESI-MS: *m/z* calculated for $C_{11}H_8O_5$: 220.18, Found: 221 ($M^+ + 1$); Anal. Calcd. for $C_{11}H_8O_5$: C, 60.00; H, 3.66; Found: C, 60.28; H, 3.79.

***Methyl 5-(5-formylfuran-2-yl) thiophene-2-carboxylate (5b).*** Yellowish white solid, yield (two steps) 85%; mp 143–143.5°C. $^1$H-NMR (400 MHz, $CDCl_3$): $\delta = 9.62$ (s, 1 H), 7.85 (d, $J = 4$ Hz, 1 H), 7.79 (d, $J = 4$ Hz, 1 H), 7.68 (d, $J = 4$ Hz, 1 H), 7.34 (d, $J = 4$, 1 H), 3.91 (s, 3 H); $^{13}$C-NMR ($CDCl_3$): $\delta = 53.1$, 111.3, 125.7, 127.8, 133.8, 135.1, 137.9, 152.3, 152.9, 162.1, 177.3; ESI-MS: *m/z* calculated for $C_{11}H_8O_4S$: 236.24, Found: 237 ($M^+ + 1$); Anal. Calcd. for $C_{11}H_8O_4S$: C, 55.92; H, 3.41; Found: C, 56.21; H, 3.48.

**General procedure for the synthesis of 6a–d.** A 10 mL aqueous solution of 0.7 g hydroxylamine hydrochloride (10 mmol) and 1.06 g sodium carbonate (10 mmol) was added to a stirred solution of **5a–d** (10 mmol) in 25 mL methanol and heated at reflux for 24 h. Evaporation of the solvent under reduced pressure to yield a precipitate that was partitioned between water and 100 mL ethyl acetate, and the organic layer was dried (sodium sulfate) and then concentrated to dryness under reduced pressure. The crude oxime was allowed to reflux in 20 mL acetic anhydride for 24 h, and the solvent was evaporated under reduced pressure. The product was purified by column chromatography on silica gel, using hexanes/ethyl acetate (80/20, v/v) as eluent.

Ketene *N*,*S*-acetals reacted with β-ketoesters in the presence of $Zn(NO_3)_2 \cdot 6H_2O$ as catalyst, in ethanol solvent, giving 6-alkylsulfanylpyridines **4** in good yields without complicated purification procedures. Oxidization of compounds **4** with aqueous hydrogen peroxide in the presence of catalytic sodium wolframate led to the formation of 6-alkylsulfonylpyridine derivatives **5**, which could be further derivatized in the 6-position by nucleophilic reactions with phenols or amines to give multisubstituted pyridine compounds **8**. Bioassays indicated that some of the compounds of the type **8** have good herbicidal activity at a dose of 100 mg/L on the roots of oil rape and barnyard grass.

*J. Heterocyclic Chem.,* **47**, 171 (2010).

## INTRODUCTION

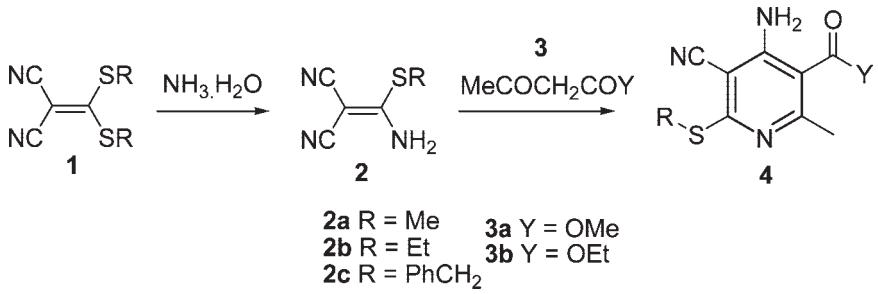
Muti-substituted pyridine derivatives occupy a central position in modern heterocyclic chemistry particularly in the pharmaceutical and agrochemical fields [1–4]. Therefore, new and improved synthetic studies about the preparation of this important heterocyclic ring system are of contemporary interest. The Hantzsch reaction has been proved to be a versatile method for the preparation of a large range of pyridines and dihydropyridines with symmetrical substitution patterns [5,6]. But the synthesis of multi-substituted pyridines with unsymmetrical substitution patterns is often difficult and involves multistep sequences, so there is still a great need to develop new approaches to pyridines of this type.

Our interests in the preparation of new heterocyclic compounds prompted us to elaborate novel methods for the synthesis of unsymmetrical multi-substituted pyridines and the evaluation of their biological activities. In this context, we report here an improved and convenient synthesis of the unsymmetrical multisubstituted pyridines **4** from easily accessible staring materials ketene *N*,*S*-acetals **2** and β-ketoesters **3**, as well as the preparation of various functional derivatives **5** and **8** resulting from a oxidization sequence and nucleophilic reactions. A preliminary *in vitro* bioassay indicated that some of the compounds of the type **8** have good herbicidal activity.

## RESULTS AND DISCUSSION

The intermediates 1 and **2** can be prepared according to a published method [7]. It was reported that 4-aminopyridine **4** (Scheme 1) was prepared in moderate yield (48%) by using anhydrous stannic chloride as catalyst [8,9]. However, we found that there were some drawbacks with this method which need to be addressed. First, this method requires anhydrous conditions because tin (IV) chloride is readily hydrolyzed in water. Furthermore, the poor solubility of the reactants and the $SnCl_4$ catalyst in toluene, used as the solvent for the reaction, often leads to a low yield and prolonged reaction time. And finally, the complex and cockamamie workup procedure involves a dilution of the reaction mixture with a saturated aqueous solution of sodium carbonate and an extraction of the reactant mixture with ethyl acetate

**Scheme 1.** Synthesis of 6-alkylsulfanyl substituted pyridines **4**.



before the title compound can be isolated and purified by a flash chromatography on silica gel.

In this study, various catalysts, different solvents as well as the reaction times and the molar ratios of reactants were tested to optimize the reaction conditions. The survey of reaction conditions and results are summarized in Table 1. The initial study was performed on the reaction of 2-(amino-methylthio-methylene)-malononitrile with ethyl acetoacetate in the presence of anhydrous $SnCl_4$ (2 equiv.) in refluxing toluene, which gave a yield of 38% of **4b** (entry 1). Corresponding reactions carried out in polar solvents such as ethanol led to none of the required product being observed (entry 2).

It was found that catalysts and solvents have a dramatic influence on the efficiency of the reaction. A variety of catalysts, such as $ZnCl_2$ (entries 3–4), $Zn(OAc)_2 \cdot 2H_2O$ (entry 6), $Zn(NO_3)_2 \cdot 6H_2O$ (entries 7–9), catalyze the reactions more efficiently than $SnCl_4$ (entries 1–2). And when ethanol was used as the solvent, $Zn(NO_3)_2 \cdot 6H_2O$ provided the best catalytic efficiency. We also found that the higher concentration of β-ketoesters (2 equiv.) slightly increased the yield (entry 7 *vs*. entry 8).

When using $Zn(NO_3)_2 \cdot 6H_2O$ as catalyst, we found that there was almost no change on the reaction yields when the reaction time changed from 12 h to 6 h whereas other variables were kept constant (entry 8 *vs*. entry 9). However, when a catalytic amount of triethylbenzylammonium chloride (TEBA) was added to the reaction, a maximum amount of the title compound **4b** was obtained (entry 10).

To investigate the scope of this reaction and to establish its tolerance of different substrates under the optimized conditions, a range of different β-ketoesters **3** and ketene *N,S*-acetals **2** were heated at reflux in ethanol in the presence of stoichiometric amounts of zinc(II) nitrate and a catalytic amount of TEBA. In all the cases investigated (Table 2), the expected pyridine **4** was isolated in good to excellent yield (86–95%), and no regioisomeric products were detected.

Bearing in mind the fact that the alkylsulfanyl group of compound **4** can be oxidized into alkylsulfonyl group, we became interested in identifying new ways to synthesize pyridines in which the methylsulfonyl group could serve as a leaving group to facilitate C—C bond-forming in the reactions. 6-Alkylsulfanyl pyridine derivatives **4** was treated with aqueous hydrogen peroxide in the presence of sodium wolframate as catalyst to give 6-alkylsulfonyl pyridine derivatives **5**. Acetic acid was a solvent of choice for the reaction stated in the literature [10]. In our case, however, acetic acid was not the best candidate as the reaction proceed in acetic acid at room

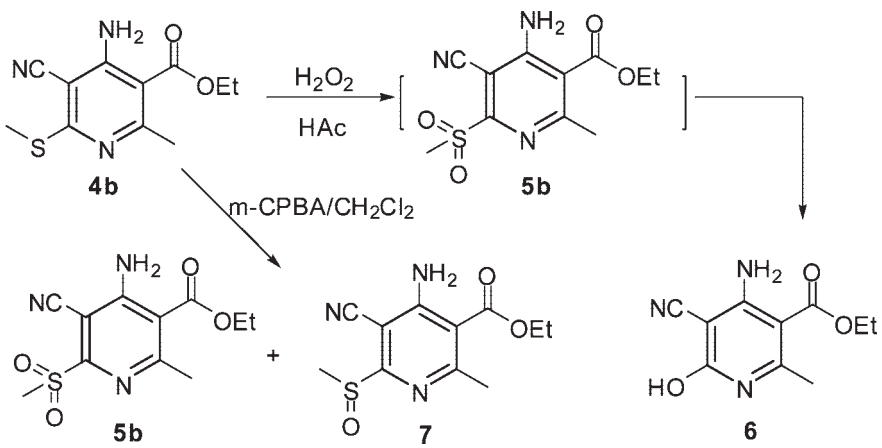
temperature or refluxing temperature gave mainly the byproduct of 4-amino-5-cyano-6-hydroxy-2-methyl-3-ethyloxycarbonyl pyridine **6** (Scheme 2). It may be due in part to the instability of 6-methylsulfonyl pyridine **5b** which could be hydrolyzed under the strong polar conditions.

On the other hand, when the reaction was performed in a less polar solvent of dichloromethane with *m*-chloroperbenzoic acid (*m*-CPBA) as oxidizing reagent, a mixture of 6-methylsulfonyl pyridine **5b** and 6-methylsulfinyl pyridine **7** were obtained (Scheme 2). In addition to these observations, we also attempted to use other solvents such as ethanol, methanol, acetonitrile, or even mixtures of these solvents coupled with different oxidizing reagents. Finally, $H_2O_2$-DMF was identified as the best oxidizing reagent-solvent combination in terms of both operational simplicity and yield. Under the optimized conditions, compound **4** was easily transformated into compound **5** with a high yield after refluxing for 2 h in DMF with aqueous hydrogen peroxide in the presence of sodium wolframate as catalyst (Scheme 3). The workup and purification of the reaction products were easy and efficient.

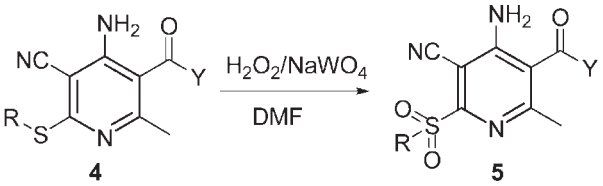
With robust synthesis procedure of 6-methylsulfonyl pyridine **5** in hand, a series of studies on compound **5** were performed to access other 6-substitued pyridine derivatives. The direct reaction of compound **5** with phenols failed to produce 6-aryloxy substituted pyridine **8a–j**. However, when performed in the presence of catalytic potassium carbonate in acetonitrile, the reaction took place and offered **8a–j** in good yield (Scheme 4). Irrespective of the fact whether the substituents on the phenols were electron-withdrawing or electron-releasing groups, the reaction was completed smoothly at refluxing temperature for 1–3 h. On the other hand, when the reaction was performed with NaH as the catalyst, no title product was separated out. This suggested that the compound **5** was unstable and the $SO_2R$ group can be replaced by hydride ion of NaH firstly, which led to the next nucleophilic attack of phenoxides to methylsulfonyl group not occurring.

Conversion of compound **5** into 6-alkylamino substituted pyridine **8k–p** (Scheme 4) was effectively carried out by treatment of acetonitrile solutions of the 6-methylsulfonyl substituted pyridine **5** with 2 equivalent of amines at ambient temperature overnight followed by straight-forward purification of recrystallization. It was noteworthy that the isolated yield of **8k–p** was good despite that the amine is alkylamino or bulkyl heterocycle amino group (Table 3).

**Scheme 2.** Oxidization of **4b** using HAc and $CH_2Cl_2$ as solvent.



**Scheme 3.** Synthesis of 6-alkylsulfonyl pyridines **5**.



The compounds obtained were characterized fully by using spectroscopic methods (IR, $^1$H NMR and EI-MS) and elemental analysis. For example, the IR spectra of **8a** revealed CN and C=O absorption bands at 2225 and 1689 cm$^{-1}$ respectively, the signals attributable to the $NH_2$ are found at 3450 and 3346 cm$^{-1}$. The $^1$H NMR spectrum of **8a** also shows the signals of $NH_2$ at 6.66 ppm as a broad absorption. The MS spectrum of **8a** shows strong molecular ion peak at *m/z* 331 with 100% abundance. In the case of **8h** [11], the structure was additionally confirmed by single-crystal X-ray diffraction (Fig. 1).

The preliminary herbicidal activity of compounds **8** series was evaluated comparable to a commercial herbicide 2,4-D, against two representative targets, oil rape and barnyard grass, at concentrations of 100 mg/L and 10 mg/L, according to a literature method [12]. The results are listed in Table 3 and show that these compounds have moderate to good herbicidal activity against the roots of these two species at the rate of 100 mg/L, especially against the root of oil rape. Compound with substituted phenoxy moiety in position 6 of the pyridine ring showed much better activity than 6-amino-substituted compounds. Switching the substituent Y from methoxy to ethoxy has no obvious effect on the inhibition rates.

In summary, we have developed an improved and convenient synthetic method for the preparation of multisubstituted pyridine derivatives with unsymmetrical substitution patterns. Some multisubstituted pyridines-containing compounds could be synthesized from simple precursors which are assembled in a modular fashion from readily available and inexpensive starting materials. The biological evaluation showed that some compounds have good herbicidal activities and we feel that this method will further facilitate exploration of this increasingly important pharmacophore.

## EXPERIMENTAL

Melting points were measured on an electrothermal melting point apparatus and are uncorrected. Mass spectra were measured on a Finnigan Trace MS 2000 spectrometer. IR spectra were recorded on a PE-983 infrared spectrometer as KBr pellets with absorption in cm$^{-1}$. $^1$H NMR spectra were recorded in $CDCl_3$ or DMSO on a Varian Mercury 400 spectrometer and resonances were given in ppm (δ) relative to TMS (δ 0.00 ppm). $^{13}$C NMR spectra were recorded using $CDCl_3$ as the solvent on a Varian Mercury 600 spectrometer and resonances are given in ppm (δ) relative to $CDCl_3$ (δ 77.00 ppm). The elementary analysis was performed on a Vario EL III elementary analysis instrument. All of the solvents and materials were reagent grade and purified as required.

**General procedure for the preparation of compounds (4a–f).** A mixture of 2-(alkylsulfanyl-amino-methylene)-malononitrile **2** (10 mmol) and $Zn(NO_2)_2 \cdot 6H_2O$ (20 mmol) and a catalytic amount of TEBA (0.2 mmol) were added to a stirred solution of β-ketoesters **3** (20 mmol) in ethanol (30 mL). The solution was heated in an oil bath and refluxed for 6–8 h, and then cooled to room temperature. The crude precipitated product was collected by filtration. Further purification was accomplished by recrystallization from ethanol to give pure products **4a–f**.

**General procedure for the preparation of compounds (5a–d, 6,7).** A mixture of 4-amino-5-cyano-2-methyl-6-alkylsulfanyl-nicotinic acid alkyl esters **4a–d** (10 mmol) and the catalysis sodium wolframate (0.1 mmol) were added to DMF (30 mL) and heated to 40°C. A solution of aqueous hydrogen peroxide (12 mmol) in ethanol (5 mL) was added at a rate of 1d/s to keep the internal temperature below 50°C. The mixture stirred at 60°C for 3 h and then cooled. The reaction mixture poured into 300 mL of water and the solution was stirred for 4–6 h at room temperature and the precipitate was collected by filtration. The products were air dried and recrystallized from ethanol to give pure product 4-amino-5-cyano-6-alkylsulfonyl- 2-methyl-nicotinic acid alkyl esters **5a–d.**

When this reaction was performed in a solvent of acetic acid, the product **6** was obtained in 50% yield. And when the same reaction was carried out in presence of m-chloroperbenzoic acid (m-CPBA), as oxidizing reagent in $CH_2Cl_2$, a mixture of 6-methylsulfonyl pyridine **5b** and 6-methylsulfinyl pyridine **7** were obtained. The purification procedure was carried out by flash silica gel chromatography using petroleum ether/ethyl acetate (3:1, v/v) as eluent to give product **7** in 67% yield and **5b** in 25% yield.

***4-Amino-5-cyano-6-methylsulfonyl-2-methyl-nicotinic acid methyl ester (5a).*** This compound was obtained as white solid, mp 172.0–174.0°C, yield 85%; IR: 3409, 3298, 2928, 2223(CN), 1697(C=O), 1613, 1554, 1307, 1255, 1138 $cm^{-1}$; $^1H$ NMR ($CDCl_3$): δ2.76 (s, 3H, Py-$CH_3$), 3.32 (s, 3H, $SO_2CH_3$), 3.99 (s, 3H, $OCH_3$), 7.05 ppm (s, 2H, $NH_2$); ms: *m/z* 269 ($M^+$, 7), 237 (5), 218 (9), 205 (51), 190 (14), 175 (52), 158 (21), 129 (28); *Anal.* Calcd for $C_{10}H_{11}N_3O_4S$: C, 44.60; H, 4.12; N, 15.60; S, 11.91. **General procedure for the preparation of compounds (8k–p).** A mixture of 4-amino-5-cyano-6-methylsulfonyl-2-methyl-nicotinic acid alkyl ester **5a** or **5b** (5 mmol),

alkylamines or heterocycleamines (10 mmol), and 20 mL of acetonitrile was stirred for 4–5 h at room temperature. The color of the reaction mixture was changed into yellow. The reaction mixture was poured into 100 mL of water and this solution was stirred for 2 h. The crude product that precipitated was collected by filtration. The filtrate was recrystallized from dichloromethane/petroleum ether to give pure 4-amino-5-cyano-2-methyl-6-alkylamino-nicotinic acid alkyl esters **8 k–p.**

***4-Amino-5-cyano-2-methyl-6-ethylamino-nicotinic acid ethyl ester (8k).*** This compound was obtained as white solid, mp 151.0–154.0°C, yield 90%; $^1$H NMR ($CDCl_3$): δ 1.24(t, 3H, $NHCH_2\underline{CH_3}$, $J$ = 7.2 Hz), 1.38(t, 3H, $OCH_2\underline{CH_3}$, $J$ = 7.2 Hz), 2.60 (s, 3H, Py-$CH_3$), 3.55–3.61(m, 2H, $\underline{NHCH_2}CH_3$), 4.33(q, 2H, $O\underline{CH_2}CH_3$, $J$ = 6.8 Hz), 5.08(s, 1H, $\underline{NH}$), 6.68 ppm (s, 2H, $\underline{NH_2}$); ms: $m/z$ 248 ($M^+$, 100), 233(88.0), 219 (84.8), 205(64.9), 187 (46.8), 174 (98.7), 159 (38.0), 117 (6.0), 44 (7.9); *Anal*. The exploration of potential utilization of microwaves as an energy source for heterocyclic synthesis was herein investigated using condensation of 3-acetylcoumarin (**1**) with aromatic and heteroaromatic aldehydes to afford the corresponding aromatic chalcones (**2a–j**) and heteroaromatic chalcones (**3a–e** and **4a–e**), respectively, in good to excellent yield within 1–3 min. The chemical structures were confirmed by analytical and spectral data. All the synthesized compounds were screened for their antibacterial activity and 3-{3-(4-dimethylaminophenyl)acryloyl}-2*H*-chromen-2-one (**2i**) was discovered to be the most active at minimum inhibitory concentration (MIC) value of 7.8 μg/mL.

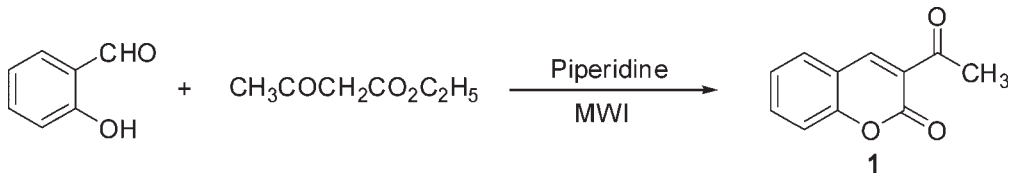
## INTRODUCTION

Over the years, coumarins have been established as well-known naturally occurring oxygen-heterocyclic compounds isolated from various plants [1–4]. They are the family of lactones containing benzopyrone skeletal framework that have enjoyed isolation from plant as well as total synthesis in the laboratory. The plant extracts containing coumarin-related heterocycles are employed as herbal remedies in traditional systems of medicine. The synthesis of coumarin (2-oxo-2*H*-chromene) derivatives has attracted considerable attention of organic and medicinal chemists due to its wide usage in food additives [5], fragrances, pharmaceuticals, and agrochemicals [6]. Furthermore, the pharmacological and biochemical properties as well as therapeutic applications of coumarins depend upon the pattern of substitution [7]. In view of this, coumarins have attracted intense interest in recent years because of their diverse pharmacological properties. Hence, coumarins have been reported to possess, among others, anticoagulant [8,9], antitubercular [10], antileucemic [11], antimicrobial [12,13], anti-inflammatory [14,15], anti-HIV [16], analgesic [17,18], anticancer [19], antitumoral [20], anticonvulsant [21,22], antiplatelet [23], antifungal [24,25] antiviral [26,27], antibacterial [28–31], and antimalarial [32] activities.

Some coumarin derivatives can be utilized beneficially for the synthesis of valuable heterocyclic ring systems. In like fashion, chalcones are essential building blocks [33] and valuable reactive intermediates for the synthesis of various heterocyclic compounds [34–36] as well as metal complexes [37–39] of high-biological relevance. Many techniques have been employed in the synthesis of coumarin frameworks [40,41] and chalcone moieties [42,43]. However, microwave-assisted approach toward the synthesis of coumarin chalcones has not been extensively explored.

The continuing drive to develop more economical and environmentally friendly chemical processes has spurred synthetic chemists to seek more versatile methods such as microwave method, for running reactions with less waste and short reaction time [44,45]. On the basis of the experimental data from various studies, chemists

**Scheme 1.** Microwave assisted synthesis of 3-acetylcoumarin, **1**.



have found that microwave-enhanced chemical reaction rates can be faster than those of conventional heating methods by as much as a 1000-fold [46].

In view of our current trust in the microwave-assisted organic synthesis [47] and various findings mentioned earlier, there is merit in developing a facile route for the formation of coumarins incorporated with chalcone templates *via* microwave synthetic approach to investigate the antimicrobial properties of such targeted library.

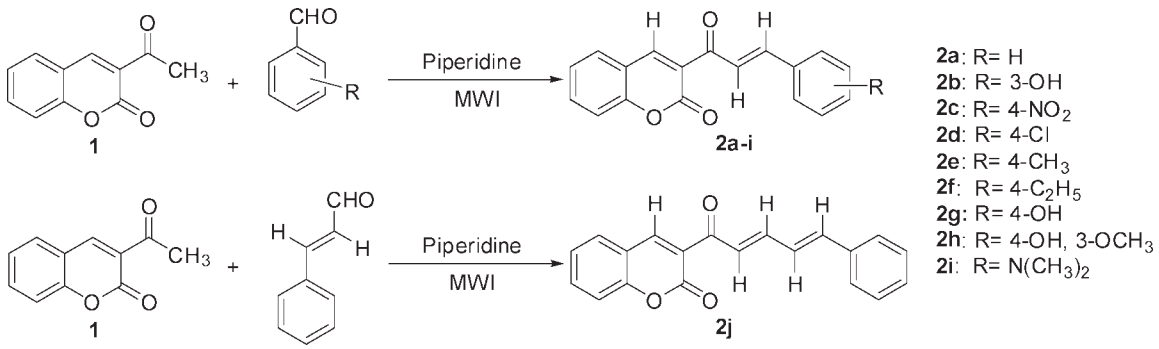
## RESULTS AND DISCUSSION

**Chemistry.** In a continuing effort to obtain new antimicrobial drug candidates, the synthesis of s-phenyl- and s-furan-2-ylcoumarin derivatives were attempted in the presence of catalytic amount of piperidine in a solvent less medium. 3-Acetylcoumarin, **1**, used as the essential precursor in this study, was synthesized by the reaction of salisaldehyde with ethyl acetoacetate in the presence of catalytic amount of piperidine (Scheme 1). Furthermore, 3-acetylcoumarin, **1** was made to undergo condensation reaction with substituted benzaldehdye to afford chalcones 3-{3-(s-aryl)acryloyl)}-2*H*-chromen-2-one, **2a–i**, whereas the replacement of benzaldehyde with cinnamaldehyde resulted in the formation of chalcone 3-(5-phenylpenta-2,4-dienoyl)-2*H*-chromen-2-one **2j** under microwave irradiation (Scheme 2). The reaction of **1** with heteroaromatic aldehyde; furfural and pyrrole-2-carbaladehyde furnished chalcones 3-{3-(s-heteroaromatic) acryloyl)}-2*H*-chromen-2-one **3a–e** and **4a–e**, respectively (Scheme 3) in moderate yields.

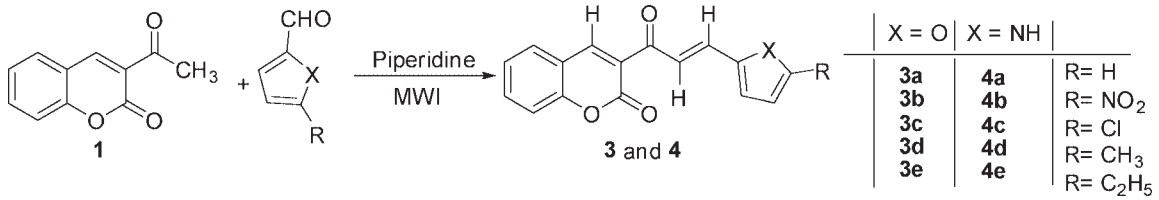
Preliminary optimization of reaction conditions was done by comparing the synthesis of **2a** in the presence of two solvents and solvent-free media (Table 1). It was observed that the solvent free medium gave the most suitable condition for the synthesis of **2a**, and therefore, it was used in all subsequent experiments. The effect of temperature was studied by carrying out the synthesis of **2a** at different temperatures; 50, 100, and 140°C (Table 2) using neat reaction condition in solvent free media. It was discovered that yield is a function of temperature, since the yield increased as the reaction temperature was raised. In fact, **2a** had the highest yield (97%) at 140°C. The results show that neat preparation of **2a** in solvent free medium at 140°C provides an efficient way to access diverse, highly functionalized coumarin containing chalcones. Hence, these optimum conditions were applied for the synthesis of a series of 3-{3-(s-aryl and (s-heteroaryl)acryloyl}-2*H*-chromen-2-one derivatives **2a–j**, **3a–e**, and **4a–e**, respectively. The melting points of the compounds varied between 119 and 289°C for all the compounds except **3c** and **4e** which did not melt even at 300°C. The progress of the reaction was monitored by TLC spotting with $R_f$ values ranging between 0.44 and 0.85 in acetone/methanol (3:1, v/v) solvent system.

The structures of newly synthesized compounds were elucidated by IR, UV, NMR, mass spectral studies, and elemental analysis. The IR spectrum, of **2a**, for instance, exhibited the absorption band at 1740 $cm^{-1}$ due to the presence of C=O (ester) which was confirmed by the presence of C—O of lactone at 1363 $cm^{-1}$. The band at 1673 $cm^{-1}$ and 1606 $cm^{-1}$ depicted the presence of C=O (conjugated ketone) and C=C (aromatic), respectively. The UV–visible spectrum of **2a** gave rise to wavelength ($\lambda_{max}$) at 224 nm and 348 nm with log ε

**Scheme 2.** Microwave assisted synthesis of various s-arylchalcones, **2a–j**.



**Scheme 3.** Microwave assisted synthesis of various s-heteroaromatic chalcones, **3a–e** and **4a–e**.



values of 3.99 and 3.47, respectively, whereas a shoulder was observed at 375 nm. The wavelength at 224 nm was as a result of $\pi \rightarrow \pi^*$ transition of phenyl ring, whereas 348 nm was as a result of $n \rightarrow \pi^*$ transition of the enone attached to coumarin moiety at 3-position, whereas a bathochromic shift observed as a shoulder at 375 nm was due to the presence of extensive conjugation of the π-electron systems. In $^1$H-NMR spectrum ($CD_3OD$) of **2a**, a doublet at δ 7.03 (1H, $J$ = 8.5 Hz, CO—CH=C); a multiplet at δ 7.33–7.84 (9H, which was made up of four protons of benzofused coumarin and five phenyl protons); a doublet at δ 7.82 (1H, $J$ = 8.5 Hz, CO—C=CH) and a singlet at δ 8.57 (1H, Coumarin-H) were all observed down field of TMS scale. The $^{13}$C-NMR spectrum showed peaks at δ 183.7 ppm due to C=O (conjugated ketone), whereas the peak at δ 159.4 ppm was due to the presence of C=O (ester). Other peaks which were observed between δ 153.0 and 116.1 ppm were due to sixteen $sp^2$ hybridized carbon atoms. The mass spectrum of **2a** showed the molecular ion peak at m/z 276 corresponding to its molecular weight. The base peak was observed at 173, whereas other daughter fragment noticed at m/z 199 was due to loss of phenyl free radical. The result of elemental analysis (Table 3) did not only correlate well with the molecular masses of the compounds but also showed a consistent minimum difference of not more than ±0.40 between % calculated and % found for the carbon, hydrogen, and nitrogen of the prepared compounds.

**Antibacterial activities.** The antibacterial activity of 21 synthesized compounds, **1**–**4e**, was determined *in vitro* by agar well diffusion technique [48]. The media were inoculated with test organisms and a solution of the tested compound in DMSO solvent. The zones of inhibition were measured after 24 h of incubation. The *in vitro* general sensitivity testing of the prepared compounds, **1**–**4e** was carried out against five gram positive bacteria [*Bacillus anthracis* (LIO), *Bacillus stearothermophilus* (NCIB 8222), *Bacillus subtilis* (NCIB 3610), *Bacillus cereus* (NCIB 6349), *Staphylococcus aureus* (NCIB 8588)] and five gram negative bacteria [*Escherichia coli* (NCIB 86), *Klebsiella pneumonia* (NCIB 418), *Pseudomonas aeruginosa* (NCIB 950), *Pseudomonas fluorescence* (NCIB 3756), *Shigella dysenteriae* (LIO)] as well as the standard drug streptomycin (Table 4). It was observed that the zones of inhibition of **1**, **2a**, **2d**, **2f**, **2g** on growth of various bacteria varied between 10 mm and 23 mm, whereas that of **2b**, **2c**, **2j**, **3a**, **4c** was between 10 mm and 21 mm. Others include **3b**, **3d**, **4d**, **4e** with zones of inhibition of 11–23 mm and **2e**, **2i**, **3c**, **4a** with inhibition zones of 15–31 mm.

In like fashion, the zones of inhibition of **2h** on the bacteria growth ranged between 14 mm and 18 mm, whereas that of **3e** ranged between 14 mm and 22 mm. Furthermore, streptomycin standard was active on all bacteria with the zones of inhibition ranging from 17 mm to 28 mm, except on *E. coli*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* where resistance was noticed. Compared with streptomycin, compounds **2e**, **2i**, and **4a** revealed larger zones of inhibition against *Bacillus stearothermophilus* (*i.e.*, >23 mm) and *Bacillus subtilis* (*i.e.*, >27 mm), whereas **2d** and **4e** showed the same zones of inhibition as streptomycin upon *Bacillus cereus* (23 mm).

However, high degree of resistance as well as small zones of inhibition were observed upon the screening of synthesized compounds against *Bacillus cereus*, *Staphylococcus aureus, Pseudomonas aeruginosa*, *Pseudomonas fluorescence*, and *Shigella dysenteriae*. In view of these, minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) tests were selectively carried out on the remaining five

– Indicates bacteria are resistant to the compounds >100 μg/mL.
MIC, minimum inhibitory concentration, i.e. the lowest concentration to completely inhibit bacterial growth; MBC, minimum bactericidal concentration, i.e. the lowest concentration to completely kill bacteria.

microorganisms comprising three gram +ve (*Bacillus anthracis, Bacillus subtilis*, and *Bacillus stearothermophilus*) and two gram –ve (*Escherichia coli* and *Klebsiella pneumonia*e) bacterial strains (Table 5). MIC is defined as the lowest concentration of the compounds that completely inhibit the growth of microorganism, whereas MBC is the lowest concentration at which 99.9% of the inoculum was killed. The MIC values of the compounds varied between 7.8 and 31.2 μg/mL, whereas that of streptomycin was between 7.8 and 15.6 μg/mL. The MBC of few compounds was found to be the same as MIC but in most of the compounds, it was twofold or threefold or fourfold higher than their corresponding MIC values. In the long run, **2i** emerged as the most active antibacterial agent at 7.8 μg/mL.

## CONCLUSIONS

It was discovered that microwave-assisted approach is highly efficient procedure for the preparation of various coumarin chalcones, especially in the solvent-free media. By visualizing the antimicrobial data, the results revealed that the compounds exhibited high potency as antibacterial agents. The most active compound was 3-{(3-(4-dimethylamino phenyl)acryloyl}-2*H*-chromen-2-one (**2i**) with an MIC value of 7.8 μg/mL. Thus, 3-(substituted aryl and substituted heteroaromatic)acryloyl)-2*H*-chromen-2-one derivatives synthesized as well as the starting material may seem promising for further activity optimization studies.

## EXPERIMENTAL

**General condition (chemical synthesis).** Melting points were determined with open capillary tube on a Gallenkamp (variable heater) melting point apparatus and were uncorrected. Infra red spectra were recorded as KBr disc using a Shimadzu IR-740 Spectrophotometer, whereas UV–visible spectra were recorded on a Heλiosεα v2.02 Unicam Spectrophotometer using methanol solvent. $^{1}$H- and $^{13}$C-NMR were run on a Jeol EX 400 Spectrometer using deuteriated methanol with tetramethylsilane as the internal standard and δ values recorded in ppm. Mass spectra were run on Finnigan MAT 312 machine. All compounds were routinely checked by TLC on silica gel G plates using $CH_3COCH_3$:$CH_3OH$ (3:1, v/v) solvent system and the developed plates were visualized under UV light. The elemental analysis (C, H, N) of compounds were performed using a Carlo Erba-1108 elemental analyzer. The microwave-assisted syntheses were carried out in a CEM Discover monomode oven using sealed tube, with magnetic stirring, and the temperature control was fixed at 140°C. All reagents used

were obtained from Sigma-Aldrich Chemicals, except piperidine and furfural derivatives which were obtained from BDH Chemical Limited. Solvents used were of analytical grade and, when necessary, were purified and dried by standard method.

**3-Acetylcoumarin (1).** To a mixture of salicyaldehyde (0.86 mL, 81.89 mmoles) and ethyl acetoacetate (11.5mL, 90.13 mmoles) was added catalytic amount of piperidine (0.2 mL, 1.64 mmoles) and swirled thoroughly. The mixture was irradiated in microwave oven at 400 W for 1 min. The solid product was filtered, dried, and recrystallized from methanol to afford pure 3-acetyl coumarin **1** in appropriate yield (Table 3). $\lambda_{max}$ (Log ε): 216 (5.29), 236 (4.65), 288 (4.57), 327 (4.57), 348 (4.49), 355 (4.24), 369 (4.01). IR (KBr): 2925 (CH aliphatic), 1746 (C=O ester), 1685 (C=O), 1606 (C=C), 1369 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 2.27 (s, 3H, $CH_3$), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 198.7 (C=O), 159.4 (C=O), 153.0, 137.4, 131.2, 128.3, 127.9, 125.4, 118.1, 116.1, 29.6 ($CH_3$) ppm. MS: m/z 188 ($M^+$, 80%), 145 (100%), 94 (50%).

**General procedure for synthesis of (2a–j).** To an equimolar mixture of 3-acetylcoumarin, **1** (1 g, 5.3 mmoles) and substituted benzaldehyde (5.3 mmoles) was added piperidine (0.2 mL, 1.64 mmoles) drop wisely with continuous stirring until homogeneity was achieved. The mixture was irradiated in microwave oven at 400 W for 1–3 min. The crude product was filtered, dried, and recrystallized from appropriate solvent to afford **2a–j** in varied yields (Table 3).

***3-Cinnamoyl-2H-chromen-2-one (2a).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), benzaldehyde (0.5 mL, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 3 min, 140°C. Purification: recrystallization (ethanol). $\lambda_{max}$ (Log ε): 224 (3.99), 348 (3.47), 375 (3.01s). IR (KBr): 1740, 1673, 1606, 1363 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.33–7.84 (m, 9H, Benzofused coumarin-4H and Ar-5H), 7.82 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7 (C=O), 159.4 (C=O), 153.0, 147.2, 142.2, 135.2, 134.2, 128.6, 128.6, 128.5, 128.5, 128.3, 127.9, 127.9, 125.4, 125.4, 118.1, 116.1 ppm. MS: m/z 276 ($M^+$, 75%), 199 (60%), 173 (100%).

***3-(3-(3-Hydroxyphenyl)acryloyl)-2H-chromen-2-one (2b).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), *m*-hydroxybenzaldehyde (0.65 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 2 min, 140°C. Purification: recrystallization (methanol). $\lambda_{max}$ (Log ε): 208 (3.82), 280 (3.32), 348 (3.46), 361 (3.46), 369 (3.45). IR (KBr): 3302, 1703, 1648, 1600, 1375 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 5.35 (s, 1H, OH, $D_2O$ exchangeable), 6.70 (s, 1H, Ar-H), 6.83 (d, 1H, Ar-H), 7.03 (d, 1H, $J$ = 8.8 Hz, CO—CH=C), 7.16 (d, 1H, Ar-H), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 7.53 (t, 1H, Ar-H), 7.96 (d, 1H, $J$ = 8.8 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7 (C=O), 159.4 (C=O), 158.4, 153.0, 147.2, 142.2, 135.4, 134.2, 130.0, 128.3, 127.9, 125.4, 125.4, 121.1, 118.1, 117.6, 116.1, 115.1 ppm. MS: m/z 292 ($M^+$, 30%), 275 (50%), 199 (25%), 145 (100%).

***3-(3-(4-Nitrophenyl)acryloyl)-2H-chromen-2-one (2c).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), *p*-nitrobenzaldehyde (0.80 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 1 min, 140°C. Purification: recrystallization (methylated spirit). $\lambda_{max}$ (Log ε): 220 (4.22), 328 (3.76), 368 (3.87). IR (KBr): 1740, 1673, 1606, 1364, 738 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 7.32 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.96 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 8.03 (d, 2H, Ar-H), 8.21 (d, 2H, Ar-H), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7 (C=O), 159.4 (C=O), 153.0, 147.2, 147.1, 142.2, 141.3, 134.2, 129.0, 129.0, 128.3, 127.9, 125.4, 125.4, 123.8, 123.8, 118.1, 116.1 ppm. MS: m/z 321 ($M^+$, 70%), 275 (47%), 145 (100%).

***3-(3-(4-Chlorophenyl)acryloyl)-2H-chromen-2-one (2d).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), *p*-chlorobenzaldehyde (0.74 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 1.5 min, 140°C. Purification: recrystallization (methanol). $^1$H-NMR ($CD_3OD$, 400 Hz): δ 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.82 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 7.44 (d, 2H, Ar-H), 7.68 (d, 2H, Ar-H), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7, 159.4, 153.0, 147.2, 142.2, 134.2, 133.5, 133.3, 129.0, 129.0, 128.7, 128.7, 128.3, 127.9, 125.4, 125.4, 118.1, 116.1 ppm. MS: m/z 310.5 ($M^+$, 80%), 275 (40%).

***3-(3-(3-p-Tolylacryloyl)-2H-chromen-2-one (2e).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), *p*-methylbenzaldehyde (0.65 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 2 min, 140°C. Purification: recrystallization (methanol). $^1$H-NMR ($CD_3OD$, 400 Hz): δ 2.34 (s, 3H, $CH_3$), 7.18 (d, 2H, Ar-H), 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 7.59 (d, 2H, Ar-H), 7.82 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7, 159.4, 153.0, 147.2, 142.2, 137.6, 134.2, 132.2, 128.9, 128.9, 128.5, 128.5, 128.3, 127.9, 125.4, 125.4, 118.1, 116.1, 21.3 ($CH_3$) ppm. MS: m/z 290 ($M^+$, 50%), 199 (100%).

***3-(3-(4-Ethylphenyl)acryloyl)-2H-chromen-2-one (2f).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), *p*-ethylbenzaldehyde (0.72 mL, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 2 min, 140°C. Purification: recrystallization (methanol). $^1$H-NMR ($CD_3OD$, 400 Hz): δ 1.25 (t, 3H, $J$ = 7.0 Hz, $CH_3$), 2.60 (q, 2H, $J$ = 7.0 Hz, $CH_2$), 6.77 (d, 2H, Ar-H), 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.42–7.84 (m, 6H, Benzofused coumarin-4H and Ar-2H), 7.82(d, 1H, $J$ = 8.5 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7, 159.4, 153.0, 142.2, 143.5, 142.2, 134.2, 132.4, 128.5, 128.5, 128.3, 127.9, 127.6, 127.6, 125.4, 125.4, 118.1, 116.1, 28.2 ($CH_2$), 14.5 ($CH_3$). MS: m/z 304 ($M^+$, 80%), 285 (35%), 145 (100%).

***3-(3-(4-Hydroxyphenyl)acryloyl)-2H-chromen-2-one (2g).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), *p*-hydroxybenzaldehyde (0.65 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 3 min, 140°C. Purification: recrystallization (ethanol). $\lambda_{max}$ (Log ε): 211 (3.52), 336 (3.41), 368 (3.56). IR (KBr): 3241, 1734, 1685, 1612, 1375 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 5.35 (s, 1H, OH, $D_2O$ exchangeable), 6.65 (d, 2H, Ar-H), 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 7.56 (d, 2H, Ar-H), 7.82 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7, 159.4, 157.7 (C—OH), 153.0, 147.2, 142.2, 134.2, 130.6, 130.6, 128.3, 127.9, 127.8, 125.4, 125.4, 118.1, 116.1, 115.8 ppm. MS: m/z 292 ($M^+$, 40%), 275 (75%), 199 (50%), 145 (100%).

***3-(3-(4-Hydroxy-3-methoxyphenyl)acryloyl)-2H-chromen-2-one (2h).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), vanillin

(0.81 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 1 min, 140°C. Purification: recrystallization (ethanol). $\lambda_{max}$ (Log ε): 208 (4.03), 244 (3.91), 352 (3.42). IR (KBr): 1740, 1685, 1600, 1338 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 3.83 (s, 3H, $OCH_3$), 5.35 (s, 1H, OH, $D_2O$ exchangeable), 6.79 (d, 1H, Ar-H), 6.99 (d, 1H, Ar-H), 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.16 (s, 1H, Ar-H), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 7.82 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7 (C=O), 159.4 (C=O), 153.0, 149.1 (*C*—$OCH_3$), 147.9 (C—OH), 147.2, 142.2, 134.2, 128.3, 127.9, 127.6, 125.4, 125.4, 122.9, 118.1, 116.8, 116.1, 111.9, 56.1 ($OCH_3$) ppm. MS: m/z 323 ($M^+$, 68%), 275 (60%), 199 (50%).

***3-(3-(4-Dimethylaminophenyl)acryloyl)-2H-chromen-2-one (2i).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), 4-(*N*,*N*-dimethylamino)benzaldehyde (1.27 g, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 2.5 min, 140°C. Purification: recrystallization (ethanol). $\lambda_{max}$ (Log ε): 208 (4.00), 327 (3.90s), 344 (3.97), 448 (3.84). IR (KBr): 1746, 1685, 1594, 1375 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 3.06 (s, 6H, 2×$CH_3$), 6.71 (d, 2H, Ar-H), 7.03 (d, 1H, $J$ = 8.5 Hz, CO—CH=C), 7.72 (d, 2H, Ar-H), 7.42–7.84 (m, 4H, Ar-H), 7.82 (d, 1H, $J$ = 8.5 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7 (C=O), 159.4 (C=O), 153.0, 150.3, 147.2, 142.2, 134.2, 129.7, 129.7, 128.3, 127.9, 125.4, 125.4, 124.7, 118.1, 116.1, 111.7, 111.7, 41.3 (2×$CH_3$) ppm. MS: m/z 319 ($M^+$, 70%), 199 (100%).

***3-(5-Phenylpenta-2,4-dienoyl)-2H-chromen-2-one (2j).*** Reagents: Compound **1** (1.0 g, 5.3 mmoles), cinnamaldehyde (0.67 mL, 5.3 mmoles), piperidine (0.2 mL). Conditions: MWI for 1 min, 140°C. Purification: recrystallization (ethanol). $\lambda_{max}$ (Log ε): 212 (3.72), 300 (3.49), 330 (3.49), 347 (3.53), 360 (3.53), 366 (3.53), 369 (4.01). IR (KBr): 3241, 1746, 1740, 1650, 1594, 1375 $cm^{-1}$. $^1$H-NMR ($CD_3OD$, 400 Hz): δ 1.24 (t, 3H, $J$ = 7.2 Hz, $CH_3$), 3.11 (q, 2H, $J$ = 7.2 Hz, $CH_2$), 5.0 (s, 1H, NH; $D_2O$ exchangeable), 6.07 (d, 1H, $J$ = 11.5 Hz, Pyrrolo-H), 6.35 (d, 1H, $J$ = 11.5 Hz, Pyrrolo-H), 7.03 (d, 1H, $J$ = 8.2 Hz, CO—CH=C), 7.42–7.84 (m, 4H, Benzofused coumarin-H), 7.66 (d, 1H, $J$ = 8.2 Hz, CO—C=CH), 8.57 (s, 1H, Coumarin-H). $^{13}$C-NMR ($CD_3OD$, 400 Hz): δ 183.7 (C=O), 159.4 (C=O), 153.0, 147.2, 143.4, 136.1, 134.2, 129.5, 129.3, 128.3, 127.9, 125.4, 118.1, 116.1, 112.0, 107.7, 21.4 ($CH_2$), 13.7 ($CH_3$).

**Antibacterial activity assays.** Most of the organisms used were standard bacteria of National Collection for Industrial Bacteria (NCIB), whereas few others were Locally Isolated Organisms (LIO). The organisms were *Bacillus cereus* (NCIB 6349), *Bacillus stearothermophilus* (NCIB 8222), *Bacillus subtilis* (NCIB 3610), *Bacillus anthracis* (LIO), *Bacillus polymyxa* (LIO), *Corynebacterium pyogenes* (LIO), *Streptococcus faecalis* (NCIB775), *Staphylococcus aureus* (NCIB 8588), *Clostridium sporogenes* (LIO), *Escherichia coli* (NCIB 86), *Pseudomonas fluorescence* (NCIB 3756), *Klebsiella pneumonia* (NCIB 418), *Shigella dysenteriae* (LIO), *Pseudomonas aeruginosa* (NCIB 950), and *Candida albican* (LIO).

**Antibacterial sensitivity testing of compounds, 1–4e.** All the synthesized compounds (**1–4e**) and streptomycin were screened for antibacterial activity on nine gram positive and five gram negative bacterial strains using agar well diffusion method [48]. The medium employed was diagnostic sensitivity test agar (Biotech Ltd.). With the aid of a sterile 1 mL pipette, about 0.2 mL of the broth culture of test organism was added to 18 mL sterile molten diagnostic sensitivity test agar (Biotech Ltd.) which had already cooled down to 45°C. This was well mixed and poured into previously sterilized Petri dishes, which had been properly labeled according to the test organisms. The medium was then allowed to set. With the aid of a sterile cork borer, the required numbers of holes were bored into the medium. The wells were made of about 5 mm to the edge of the plate. The wells were then filled up aseptically with the solution of the compound in DMSO using Pasteur pipettes. Streptomycin was used as the standard antibacterial agent at a concentration of 1000 μg/mL. The plates were allowed to stand for about 1 h on the bench for proper diffusion of the antibacterial agents into the medium and then incubated uprightly at 37°C for 24 h. Care was taken not to stockpile the plates. Clear zones of inhibition in millimetres indicated the relative susceptibility of the bacteria to the compounds (**1–4e**) and streptomycin standard.

**Determination of MIC and MBC.** The minimum inhibitory concentration (MIC) was done using the method of Russell and Furr [48]. Based on the level of resistance of some organisms and large zones of inhibition experienced in others, minimum inhibitory concentration (MIC) was selectively done for five gram positive and five gram negative bacterial strains. Different concentrations (7.8 and 100.0 μg/mL) of the compounds and standard were prepared using a twofold dilution which was prepared in a sterile plate with the aid of sterile pipette and then mixed with 18 mL of molten nutrient agar. This was then allowed to set. The surface of the nutrient agar plate was allowed to dry before streaking with overnight broth cultures of the bacterial strains. The plates were then labeled accordingly and incubated at 37°C for up to 72 h. They were subsequently examined for the presence or absence of growth.

The lowest concentration preventing the growth of bacteria was taken as the minimum inhibitory concentration of the compounds. This procedure was likewise repeated for the streptomycin (standard).

To obtain minimum bactericidal concentration (MBC), 0.1 mL volume was taken from each tube and spread on agar plates. The number of c.f.u was counted after 18–24 h of incubation at 35°C.

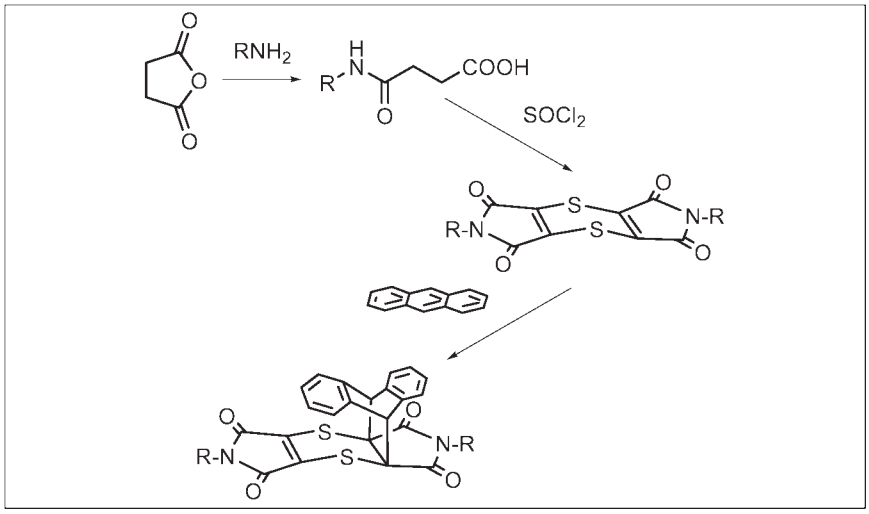
DOI 10.1002/jhet.305
Published online 8 January 2010 in Wiley InterScience (www.interscience.wiley.com).



A simple and facile access to new solvatochromic maleimide-fused *N*-allyl- and *N*-alkyl-substituted 1,4-dithiines from the corresponding *N*-substituted succinamic acid derivatives in one-pot with oxidation by thionyl chloride is described. The Diels–Alder reaction of these 1,4-dithiines with anthracene has been investigated. The 1,4-dithiine derivatives react smoothly with anthracene *via* charge-transfer complexes to form the Diels–Alder adducts in excellent yields.

*J. Heterocyclic Chem.,* **47**, 188 (2010).

## INTRODUCTION

Sulfur-containing heterocyclic compounds have held the focus of researchers along decades of historical development of organic synthesis. Their biological activities and unique structures allow several applications in different parts of pharmaceutical and agrochemical research or in material science [1].

The synthesis of 1,4-dithiines has recevied much attention because of their biological activity, particularly as fungicides and antibacterials [2], their application in synthetic organic and medicinal chemistry, their structural and electronic properties, their ability to act as electron donors [3], and the wide variety of synthetic transformation they undergo [3]. Some derivatives of 1,4-dithiines show activities as nonpeptide antagonists of the human Galanin hGAL-1 receptors [4], and some 1,4-dithiine-2,3,5,6-tetracarboxydiimides have been used as anthelmintics [5]. Detailed research of 1,4-dithiines has been limited by a lack of suitable synthetic approaches. Some 1,4-dithiines have been known for more than 100 years, although the correct stuctures were assigned recently [1,6,7]. Many polycyclic 1,4-dithiine derivatives are useful as pigments and functional materials for electrooptical applications [7].

For 80 years, the Diels–Alder reaction has remained as one of the best and most powerful methods of synthesis of six-membered rings and bicyclic molecules [8]. Many factors, such as its versatility, its high regio- and stereoselectivity, and its ability to rapidly give polyfunctionality have contributed to the popularity of this reaction in organic syntheses.

Anthracene and its derivatives are among the most useful polycyclic aromatic compounds and efficient photochromic systems. In view of their fluorescent properties, they are of practical interest as sensors and markers in biological or supramolecular systems [9]. Anthracenes are well-known as fairly reactive dienes that easily undergo both thermal and photochemical Diels–Alder cycloadditions with a variety of dienophiles [10]. In the thermal [4+2] cycloaddition reaction mechanism, new

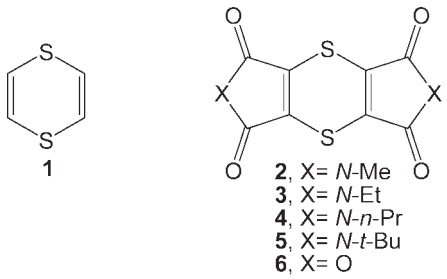


**Figure 1.** 1,4-Dithiine and its derivatives.

sigma bonds are formed simultaneously, either by direct addition or *via* intermediate charge-transfer (CT) complex (electron donor-acceptor molecular complex). Many studies have indicated the observation of transient color that disappears as the thermal Diels–Alder reaction proceeds. This has been shown to be due to the formation of a CT complex during the course of the reaction [11].

Very few articles deal with the synthesis, characterization, reactions, and properties of maleimide-fused 1,4-dithiines [7,12–15]. Hayakawa *et al*. [12] and Kim *et al*. [13] have reported the preparation of the methyl, ethyl, propyl, and *t*-butyl derivatives of maleimide-fused 1,4-dithiine with short experimental details. The mechanistic pathway was not suggested in these reports. Valla *et al*. [14] and Zentz *et al*. [15] have reported the preparation of the propyl, isopropyl, butyl, and benzyl derivatives of maleimide-fused 1,4-dithiine with experimental details and investigated the mechanistic pathway by using a Pummerer rearrangement-like reaction. 1,4-Dithiines **2, 3, 4,** and **5** were used as a dienophile for Diels–Alder reactions by Hayakawa *et al*. [12] and Kim *et al*. [13] (Fig. 1).

1,4-Dithiine **1** and its derivatives undergo thermal elimination of sulfur to produce corresponding thiophene derivatives [16]. Nevertheless, thermal stability of *N*,*N*′-dimethyl-dipyrrole-fused dithiine **2** and the dianhydride **6** was observed by Draber [17], along with the formation of cycloadducts with anthracene (Fig. 1).

Draber [17] has suggested the planar structure of **2** and **6** based on strong ultraviolet absorptions at long wavelenghts, thermal stability, and the ability to form CT complexes. Indeed, various molecular orbital calculations have indicated **2** and **6** to be nearly planar [12]. 1,4-Ditihiine **3** exhibits a planar structure that makes easy the formation of CT crystals with anthracene in alternate donor-acceptor stacks [13].

## RESULTS AND DISCUSSION

This study describes synthesis of new solvatochromic maleimide-fused *N*-allyl- and *N*-alkyl-substituted 1,4-dithiines (**9a–d**) from succinamic acid derivatives (**8a–d**) in one-pot with oxidation by thionyl chloride and their subsequent Diels–Alder cycloaddition reactions with anthracene.

**Maleimide-fused *N*-allyl- and *N*-alkyl-substituted 1,4-dithiines.** The initial study began with the reaction between succinic anhydride **7** and the appropriate amines to give *N*-substituted succinamic acid derivatives. Maleimide-fused *N*-allyl [18] and *N*-alkyl 1,4-dithiines were prepared in high yields from corresponding *N*-substituted succinamic acid derivatives using $SOCl_2$ according to the earlier reported procedure (Table 1) by Michaïlidis *et al*. [19], who reported without experimental details. 1,4-Dithiines **9a–d** are green and deep green crystals, but their solutions in various solvents (diethyl ether, ethanol, chloroform, acetone, and benzene) are coloured yellow (**9a** in diethyl ether, ethanol, and acetone; **9c** in ethanol), green (**9a** in benzene; **9c** in acetone; **9d** in ethanol), deep geen (**9a** in chloroform; **9c** in diethyl ether and chloroform), deep blue (**9c** in benzene; **9d** in diethyl ether), purple (**9b** in acetone), deep blue-green (**9d** in benzene and chloroform), deep blue-purple (**9b** in benzene and chloroform; **9d** in acetone); thus, products **9a–d** are higly solvatochromic. Maleimide-fused *N*-allyl 1,4-dithiine **9a** is partly soluble in diethyl ether and ethanol, whereas **9b** is insoluble in diethyl ether and ethanol.

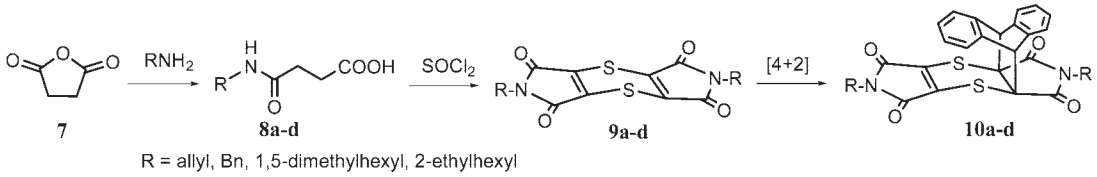
The conjugation of double bond with carbonyl groups in 1,4-dithiines **9a–d** leads to both the $n \rightarrow \pi^*$ and the $\pi \rightarrow \pi^*$ transitions being shifted to longer wavelengths. The absorptions are found between 300 and 310 nm for $\pi \rightarrow \pi^*$ transition and between 378 and 389 nm for $n \rightarrow \pi^*$ transition in **9a–d**. The $n \rightarrow \pi^*$ transitions are much less intense ($\epsilon$ = 1271–1803) than $\pi \rightarrow \pi^*$ transition ($\epsilon$ = 1657–2439).

The reaction is straightforward and requires simple and inexpensive starting materials. We have, thus, introduced a highly efficient methodology for the synthesis of maleimide-fused *N*-allyl- and *N*-alkyl-substituted 1,4-dithiines. It may be widely applicable for the preparation of a variety of 1,4-dithiines.

**Diels–Alder cycloaddition reactions.** When anthracene was allowed to react with 1,4-dithiines **9a–d** in refluxing benzene, the characteristic green, deep blue, deep blue-green, and deep blue-purple colors of **9a–d** disappeared, and the corresponding Diels–Alder cycloadducts **10a–d** were obtained in 95, 89, 94, and 90% yields, respectively (Table 1). Much longer reaction times were needed for **9c** and **9d** than for the reaction of **9a** and **9b**, probably, because of the increased steric bulk. Anthracene and **9a–b** in $CHCl_3$ underwent a slow reaction at room temperature in the dark in 2 weeks, giving the Diels–Alder cycloadducts **10a** and **10b** in 99 and 94% yield, respectively. The same reaction was

**Table 1**

Formation of 1,4-dithiines and the Diels-Alder cycloadducts.



| Entry | 1,4-Dithiine | Yield (%) | Diels-Alder cycloadduct | Time | Yield (%) |
|---|---|---|---|---|---|
| 1 |  **9a** | 63 |  **10a** | 24 h<br>2 weeks | 95[a]<br>99[b] |
| 2 |  **9b** | 60 |  **10b** | 22 h<br>2 weeks | 89[a]<br>94[b] |
| 3 |  **9c** | 88 |  **10c** | 5 days<br>4 weeks | 94[a]<br>74[b] |
| 4 |  **9d** | 87 |  **10d** | 3 days<br>4 weeks | 90[a]<br>79[b] |

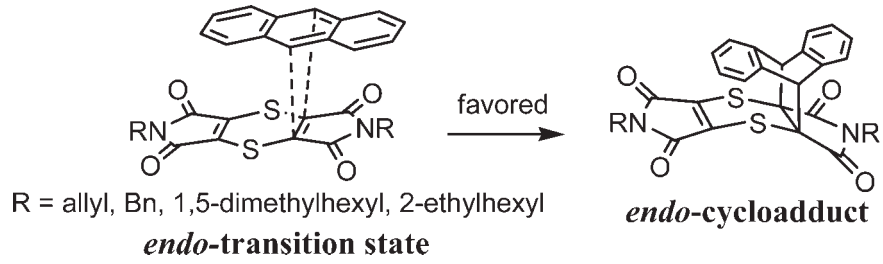
The Diels–Alder reaction conditions: [a]: benzene, reflux; [b]: $CHCl_3$, rt, in the dark.

carried out using **9c** and **9d** under the same reaction conditions but over a time of 4 weeks, giving **10c** and **10d** in 74 and 79% yield, respectively (Table 1). The Diels–Alder cycloadducts **10a–d** were bright yellow crystals, which were reasonably soluble in dichloromethane, chloroform, and ethanol. Only *endo*-cycloadducts **10a** and **10b** were obtained, while the Diels–Alder cycloadducts **10c** and **10d** were shown to be a mixture of two diastereoisomers in a 1:1 ratio as shown by integration of signals in the $^1$H NMR spectrum. The structure of these adducts **10a–d** were determined on the basis of $^1$H and $^{13}$C NMR spectroscopy, mass spectroscopy, and elemental analysis.

When anthracene and 1,4-dithiine approach each other in the Diels–Alder reaction, the best overlap is achieved when the reactants lie directly on top of one another, a geometry that leads to *endo*- rather than *exo*-product. The kinetically favorable *endo*-Diels–Alder cycloadduct is formed faster (lowest activation energy), even though the thermodynamically favorable *exo*-product is more stable. Secondary orbital overlap in the transition state between the orbitals on the carbonyl groups in the 1,4-dithiine and the orbitals in the anthracene not directly involved in bonding. These interactions do not lead to bond formation, but they do lower the energy of the transition state (Scheme 1).

The IR spectra exhibited characteristic imide bands at 1771 and 1707 $cm^{-1}$ for **10a**, at 1776 and 1708 $cm^{-1}$ for **10b**, at 1773 and 1706 $cm^{-1}$ for **10c**, and at 1767 and 1703 $cm^{-1}$ for **10d**. $^1$H NMR spectra showed two *N*-allyl or *N*-alkyl proton signals for one isomer, one of them being shifted upfield as a result of shielding effect

**Scheme 1.** Formation of the *endo*-Diels–Alder cycloadduct.



of the anthracene ring. Characteristic absorptions of anthracene have disappeared, indicating destruction of the anthracene conjugated system by the Diels–Alder cycloadditon. The UV–vis spectroscopic analysis of the Diels–Alder cycloadducts **10a–d** revealed the appearance of new absorption bands at 405, 412, 410, and 411 nm, respectively.

In accordance with the reported early experimental results [13], there are two pathways for the formation of the Diels–Alder cycloadducts of 1,4-dithiines **9a–d** and anthracene (Fig. 2). The choice of these reaction pathways only depends on the electronic properties of dienophile (1,4-dithiine) and diene (anthracene). Electron-rich dienes (anthracene, 9-methylanthracene, 9,10-dimethylanthracene) give a cycloadduct *via* pathway I, modestly electron-deficient diene (9-anthracenecarboxaldehyde) give a cycloadduct *via* pathway II, and no reaction occurs to the strongly electron-deficient diene (9-nitroanthracene) [12]. 1,4-Dithiine derivatives 9a–d act as strong acceptors in CT complex formation and possess high reactivity as planar electron-rich dienes.

According to the preliminary investigation by Draber [17], the reaction of 1,4-dithiines **9a–d** with the electron-rich anthracene occurred *via* CT complexes, as evidenced by unusual color change during the reaction.

We, herein, report new 1,4-dithiine derivatives and their Diels–Alder cycloadducts. The oxidation reaction by thionyl chloride was succesfully applied to **8a–d**, which gave the corresponding ring-closed 1,4-dithiines **9a–d** in good yields. To the best of our knowledge, three of the synthesized 1,4-dithiines, **9a, 9c,** and **9d,** and all Diels–Alder cycloadducts **10a–d** are new compounds. To the best of our knowledge, this method is the first example of a one-step synthesis of maleimide-fused *N*-allyl- and sterically-bulky *N*-alkyl-substituted 1,4-dithiines directly from succinamic acid derivatives by thionyl chloride oxidation. This one-pot reaction converts various succinamic acid derivatives to solvatochromic 1,4-dithiines, which underwent the Diels–Alder reactions with anthracene in excellent yields.

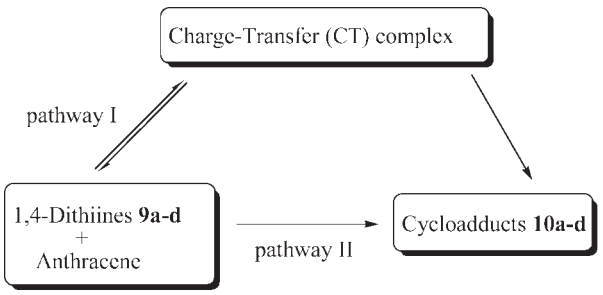


**Figure 2.** Pathway I: The cycloaddition *via* CT complex, pathway II: Direct cycloaddition.

## EXPERIMENTAL

The melting points were measured on an Electrothermal 9100 melting point apparatus and are uncorrected. The UV–vis absorption spectra were determined with a Perkin Elmer Lamda 25 spectrophotometer in chloroform solutions using 10-mm quartz cells. The IR spectra were recorded on a One FTIR ATR Perkin Elmer spectrometer. The $^{1}H$ and $^{13}C$ NMR spectra were taken with a Varian NMR Gemini 300 and Bruker 400 Ultra Shield spectrometers and chemical shifts were recorded as ppm downfield from internal tetramethylsilane. The mass spectra were taken on a Waters ZQ Micromass LC/MS spectrometer. Elemental analyses were performed on a Leco 932 CHNS instrument. All chemicals were purchased from commercial suppliers and used directly without any further purification. Organic solvents were dried by standard methods and were distilled before use. All the reactions were performed under a nitrogen atmosphere. Reaction progress was monitored by TLC on precoated aluminum-backed plates (Merck SIL G/$UV_{254}$), and chromophoric compounds were visualised by UV light and subsequent staining with alkaline potassium permanganate solution or iodine. Petroleum ether refers to light petroleum (bp 40–60°C).

**General procedure for the preparation of *N*-substituted succinamic acids (8a–d).** Reaction of succinic anhydride **7** (16 mmol) with the appropriate amine (20 mmol) in the presence of the dry appropriate solvent (10 mL, THF, MeCN, acetone, or 1,4-dioxane) at room temperature with stirring for a few hours generated the corresponding *N*-substituted succinamic acids **8a–d**. After the reaction was completed, the solvent was removed under reduced pressure and recrystallized from the appropriate solvent ($Et_2O$, 1,4-dioxane, or water).

Glycine, a novel heterogeneous organocatalyst, is found to be highly effective for the synthesis of polyhydroquinoline derivatives in a one-pot multicomponent reaction *via* Hantzsch condensation under controlled microwave (MW) irradiation. The combination of glycine and MW has promising features for the reaction response, such as the shortest reaction time, excellent product yields, and simple work-up of the products.

## INTRODUCTION

Microwave (MW) irradiation has evolved as a powerful method to perform organic synthesis with great success, particularly in the light of the current paradigm shift to ''green chemistry.'' It provides chemical processes with special attributes, such as enhanced reaction rates, higher yields of pure products, better selectivity, improved ease of manipulation, rapid optimization of reactions, and several eco-friendly advantages [1]. An important way to improve synthetic efficiency and to give access to a multitude of diversified molecules from simple building blocks is the development of multicomponent synthesis. Multicomponent reactions (MCRs) have recently taken a new dimension in organic synthesis, as they comply well with the requirements for ideal organic syntheses [2,3]. According to the current synthetic and environmental requirements, MCRs using MW methodology are of great interest.

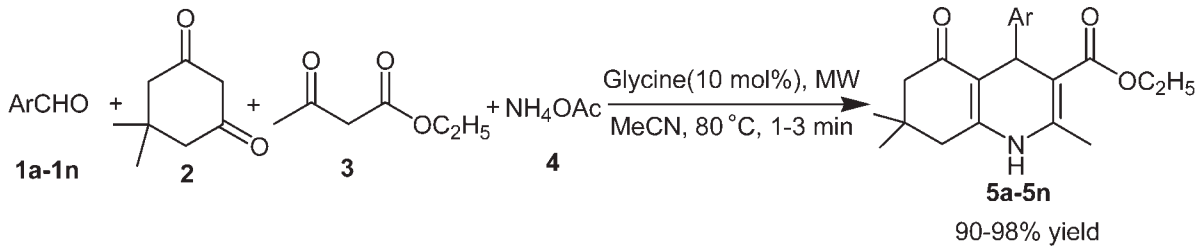
Polyhydroquinoline derivatives have a great deal of importance because of their diverse medicinal applications, which include calcium channel activity, vasodilators, bronchodilators, antiatherosclerotics, hepatoprotective, antidiabetic, antihypertensive, neuroprotectant, platelet antiaggregatory activity, cerebral antischemic activity, and chemosensitizer activity [4–10]. Owing to the remarkable potential of these compounds as a source of valuable drugs, various methods have been reported using conditions such as conventional heating [11], solar thermal energy [12], ionic liquid [13], TMSCl-NaI [14], metal triflates [15], grinding [16], Hy-Zeolite [17], montmorillonite K-10 [18], cerium(IV) ammonium nitrate [19], iron(III) trifluoroacetate [20], $HClO_4$-$SiO_2$ [21], heteropoly acid [22], molecular iodine [23], PTSA [24], L-proline and derivatives [25], nickel [26], polymers [27], and Baker's yeast [28]. Most of these processes, however, suffer from one or other drawbacks such as longer reaction time, lower product yield, harsh conditions, high costs, and use of hazardous catalysts. As a result, an eco-safe and efficient alternative method for the preparation of polyhydroquinoline is highly desirable. As there is no report on the use of glycine as an organocatalyst in the Hantzsch condensation, we wish to demonstrate the catalytic activity of this organocatalyst in the synthesis of polyhydroquinolines.

## RESULTS AND DISCUSSION

We report herein a benign, rapid, and efficient four-component, one-pot synthesis of polyhydroquinolines in excellent yields using aromatic aldehydes, dimedone, ethyl acetoacetate, and ammonium acetate in the presence of catalytic amount of glycine (10 mol %) in acetonitrile under monomode MW irradiation (Scheme 1).

To optimize the synthesis, a typical four-component reaction of benzaldehyde **1a**, dimedone **2**, ethyl acetoacetate **3**, and ammonium acetate **4** was undertaken using

**Scheme 1**



a catalytic amount of different amino acids such as L-alanine, L-valine, and glycine in different solvents such as acetonitrile, ethanol, and water under varying reaction conditions to obtain the corresponding polyhydroquinoline derivative **5a** (Table 1). Consistent with Table 1, the optimum yield (95%) of product **5a** was obtained in the presence of catalytic amount of glycine (10 mol %) in solvent acetonitrile (entry 6) in 1 min under single-mode MW heating (180 W, 80°C). Decreasing the catalyst levels, MW power or temperature reduced the product yield considerably (Table 1; Entries 13, 16, and 17). An increase in the molar proportion of catalyst, MW power, and temperature did not bring about any further increase in the product yield, rather, a bit diminution was observed (Table 1; entries 14, 15, 18, and 19). It is assumed that the acidic hydrogen of carboxylic function and the small size of glycine play a key role in the catalysis of the reaction. Under the optimized set of reaction conditions (entry 6), a number of aromatic aldehydes **1** were allowed to undergo MCR with **2**, **3**, and **4** in a molar ratio of 1:1:1:1.2 in the presence of glycine (10 mol %) in acetonitrile under MW (180 W, 80°C) heating. The results are given in Table 2. All the electron-rich and electron-deficient aldehydes worked well leading to excellent yields of products.

After completion of the reaction, the resulting precipitate was filtered and recrystallized from methanol to yield pure substituted polyhydroquinolines **5a–5n**. All the products were crystalline and fully characterized on the basis of their melting points, elemental analyses, and spectral data (IR, $^1$H-NMR, and $^{13}$C-NMR).

## CONCLUSIONS

In conclusion, the present MW irradiation procedure provides an easy and efficient access to polyhydroquinolines *via* Hantzsch condensation using glycine as an organocatalyst. The mildness of the conversion, experimental simplicity, compatibility with various functional groups, excellent product yield, shorter reaction time, and the easy work-up procedure make this approach more attractive in synthesizing a variety of such derivatives.

## EXPERIMENTAL

All the chemicals were procured from Aldrich, USA and E. Merck, Germany and were purified before use. IR spectra were recorded on a JASCO FT/IR-5300 spectrophotometer. NMR spectra were run on a JEOL AL300 FTNMR spectrometer; chemical shifts are given in δ ppm, relative to TMS as an internal standard. Elemental microanalysis was performed on Exeter Analytical Model CE-440 CHN analyzer. Melting points were measured in open capillaries and are uncorrected. The MW irradiation was effected using the CEM's Discover Bench Mate (magnetron frequency 2455 MHz) single-mode MW synthesis system using safe pressure regulation 10-mL pressurized vials with ''snap-on'' cap.

**General procedure for the synthesis of polyhydroquinolines 5.** A mixture of aldehyde **1** (1 mmol), dimedone **2** (1 mmol), ethyl acetoacetate **3** (1 mmol), ammonium acetate **4** (1.2 mmol), glycine (10 mol %), and acetonitrile (1 mL) was placed in a sealed pressure regulation 10-mL pressurized vial with ''snap-on'' cap and was irradiated in the single-mode MW synthesis system at 180 W power and 80°C temperature for 1–3 min. After completion of reaction (TLC), the mixture was cooled and the resulting product was washed with cold water to remove any unreacted ammonium acetate. The crude product was finally recrystallized from methanol to afford the pure products **5a–5n**.

## INTRODUCTION

The organic compounds having fluorophores that are sensitive to environment are of great importance [1–5] in chemistry and biology. The fluorescence emission spectra of some heterocyclic compounds such as benzo [de]benzo[4,5]imidazo[2,1-a]isoquinoline (Fig. 1) are sensitive to environment [6–8], and some of such heterocyclic compounds are used as organic photoconductive materials [9]. Therefore, the functionalization of such heterocyclic compounds is expected to form derivatives that may possess interesting optical properties [10]. Heterocyclic compounds having more numbers of delocalized aromatic rings in conjugation to each other would lead to better as well as novel optical properties [9]. With an interest to identify and characterize and also to understand optical properties of compounds bearing fluorophores that are sensitive to environment, we have synthesized few heterocyclic compounds as shown in Figure 1. We have studied fluorescence emission of these compounds and compared with some of their derivatives.

## RESULTS AND DISCUSSION

**Synthesis of the heterocycles.** The compounds **2** and **4** were prepared by the reactions as depicted in Schemes 1 and 2. The condensation of 1,8-naphthalic anhydride with 4-nitro 1,2-diaminobenzene in acetic acid gave 11-nitro-benzo[de] benzo[4,5] imidazo[2,1-a] isoquinolin-7-one (**1**). Although this reaction is expected to give two isomeric products, we obtained a single isomeric product. This is due to the fact that such cyclization process passes through imide intermediates. It is recently shown that only one imide isomer is formed in this reaction before cyclization. This was shown by trapping the intermediate imide derivative in dimethylformamide (DMF) as a solvent. The formation of specific imide in this reaction, between the two possible isomers, may be attributed to the ease of attack of the less sterically crowded [11] amino group at *p*-position to the nitro group of 4-nitro 1,2-diaminobenzene. The reduction of the nitro group of the compound **1** resulted in the formation of the corresponding amine **2**. Acetic acid is found

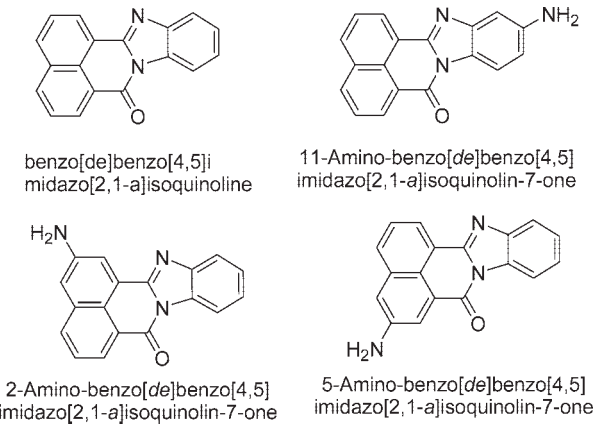

**Figure 1.** Structure of the heterocycles.

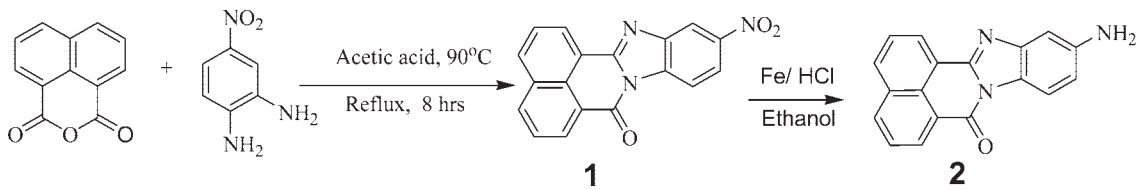
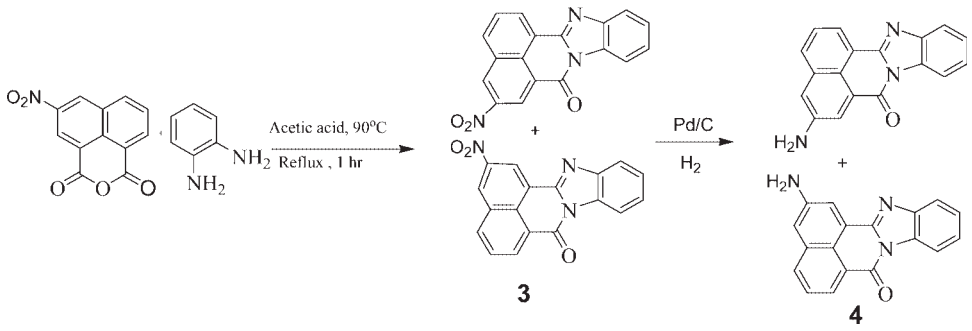
to be appropriate solvent for the synthesis of **2**. Recently, we have discussed about the role of solvent in the formation of similar heterocycles [11] and also mentioned about the usefulness of acetic acid in the synthesis of such heterocycles. Similarly, the condensation reaction of 3-nitro-1,8-naphthalic anhydride with 1,2-diaminobenzene gave a mixture of isomeric products, namely 2-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]one-methane and 5-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one (**3**). We could not separate the two isomers by conventional chromatographic techniques such as preparative thin layer (TLC) or column chromatography. The $^1$H-NMR chemical shift and the integration values of the mixture of isomers suggest formation of almost an equimolar mixture of the two isomers. In an earlier report, it was suggested that similar reaction under microwave irradiation in the presence of alumina resulted only one isomer [12], but in our case we have failed to obtain pure isomer through the reaction condition described herein, and the isomeric product separation of **3** was not successful. However, the condensation reaction of 3-nitro-1,8-naphthalic anhydride with 1,2-diaminobenzene under solvothermal condition in acetic acid at 150°C in an autoclave gave only one isomer. The $^1$H-NMR spectra of this isomer obtained from this reaction is given as Supporting Information. It has eight peaks in aromatic region and tallies the structure of 2-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]one methane. The assignment of the $^1$H-NMR of this compound is on the assumption that the simulated $^1$H-NMR of other isomer namely 5-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one shows proton signals at relatively high chemical shift than the 2-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]one methane. As the optical properties of these two isomers and derivatives are indistinguishable, we proceeded to take the mixture of isomers for optical study described in the Experimental section. The reduction of the nitro groups of these isomers (**3**) was carried out by hydrogen gas with a catalytic amount of palladized carbon to prepare two isomeric amine derivatives **4** (Scheme 2). In the case of **1**, we have obtained only one isomer because of the presence of nitro-group on diamino benzene ring, which could differentiate the two amino groups on the ring in terms of reactivity. The nitro group on the compound **1** was reduced to amino group, and the amino group was further functionalized to various derivatives **5–8** as illustrated in Scheme 3. Methyl and acyl derivatives (**9–12**) of compound **4** were also synthesized by similar procedure (Scheme 4).

**Optical properties.** The compounds **2** and **4** show solvatochromic properties, and the absorption features of **2** and **4** differ in different solvents, which are listed in Table 1. The compounds **2** and **4** are derived from a planar aromatic ring system, which is derived from 1,8-naphthalic anhydride [6]. The imides derived from naphthalic anhydride are useful as fluorescence probes, and their applications are decided by the presence of tether connecting two similar or dissimilar molecules [12]. The compounds **2** and **4** have reasonable fluorescence emission properties on excitation at appropriate wavelengths. The UV–visible absorption spectra as well as fluorescence emission spectra of several derivatives of 11-amino benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one (**2**) are recorded and listed in Table 2. Among the nitro and amino group (compounds **1** and **2**), the later shifts the fluorescence emission towards higher wavelength. In the case of substituted amines, it is observed that the substituent attached on nitrogen also leads to emission to higher wavelength. Among the *N*-substituent compounds **5–8**, the highest shift is observed in *N*-benzoylated derivative (**7**). It is attributed to the fact that benzoate group participates in delocalization of electrons with the aromatic ring of the heterocycle. The fluorescence emission of **2** in dichloromethane solution is

**Scheme 1**



**Scheme 2**



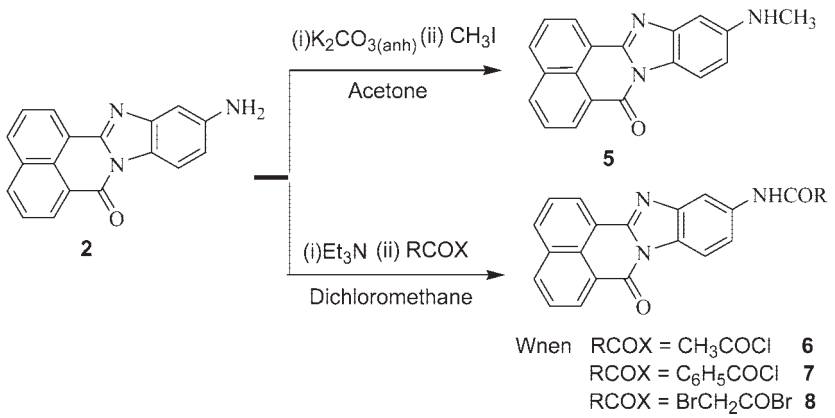
observed at 508 nm upon excitation at 410 nm. The compound **2** is found to be fluorescence inactive in methanol. Accordingly, the fluorescence emission of the **2** observed from dichloromethane solution also gets quenched on addition of methanol (Fig. 2). The fluorescence emission spectra of various derivatives of 11-amino-benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one (**2**) and mixture of 2-amino-benzo[de]benzo[4,5]-imidazo[2,1-a]isoquinolin-7-one and 5-amino-benzo[de]-benzo[4,5]imidazo[2,1-a]isoquinolin-7-one (**4**) were also recorded, and the emission wavelengths and quantum yields are listed in Table 2. Although the compound **4** is a mixture of two isomers, in none of the cases, we could obtain any distinguishable fluorescence emission features of the two isomers. The wavelength shifts and intensity changes in various derivatives of **2** and **4** predominantly occur from the electronic effect caused to the overall electronic environment by the presence of the substituents. It is important to note that the emission spectra of naphthalimide fluorophores having amine groups are proton responsive [13], and such compounds have relevance in recognition of anions [14].

In the case of compound **2**, the protonation causes shift in the fluorescence emission to a lower wavelength from the parent compound. For example, the parent compound **2** in dichloromethane on excitation at 410 nm emits at 514 nm, and the shifts to 508 and 498 nm, respectively, on addition of 1 and 2 equiv of hydrochloric acid (HCl).

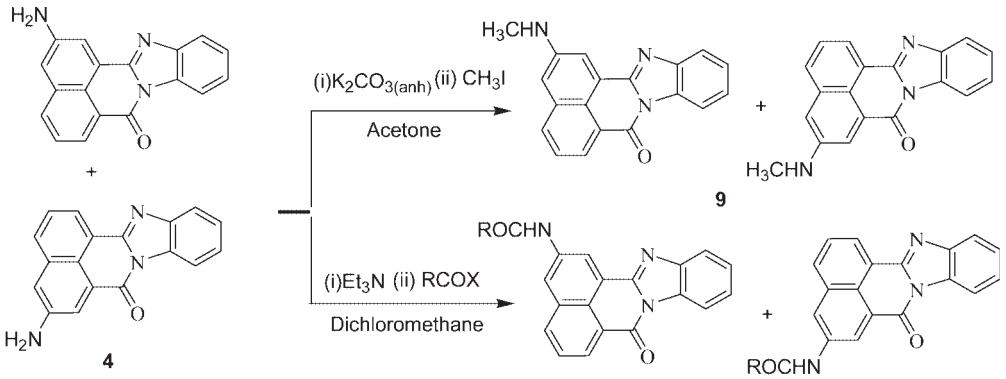
The emission spectra of **4** are highly solvent dependent. A solution of **4** on excitation at 410 nm in dichloromethane, acetonitrile, and methanol shows fluorescence emission at 491 ($\Phi = 0.458$), 527, and 562 nm, respectively [Fig. 3(a)]. Such large characteristic shifts in emission spectra make it possible to distinguish these three solvents. From Table 1, it is clear that the compound **4** shows very small solvatochromicity in visible spectra, whereas it shows a large shift in emission spectra on change of solvents. This suggests that a polar excited state capable of forming exciplex with different solvents is involved in the fluorescence emission.

Addition of methanol to dichloromethane solution of **4** changes its fluorescence emission; initially, the emission occurring due to excitation at 410 nm decreases, but the emission shifts to a higher wavelength and on gradual addition of methanol it once again increases and reaches the emission wavelength that corresponds to the observed emission wavelength from a methanolic solution of **4** [Fig. 3(b)]. Similarly, the addition of methanol to an acetonitrile solution of **4** shifts the fluorescence emission to higher wavelength [Fig. 3(c)]. The compound **4** also shows proton responsive fluorescence

**Scheme 3**



**Scheme 4**



emission, which is dependent on the hydrogen ion concentrations. For example, treatment of a solution of **4** with HCl (1 equiv) causes a change of fluorescence emission from 491 to 501 nm, and on addition of 2 equiv of the acid, the emission occurs at 510 nm [Fig. 3(d)]. These results suggest that the protonation effects the delocalization of electrons of the amino group, which in turn contributes to the changes in the emission spectra of these compounds. The solvato-emissive properties can be attributed to the stabilization of polar exited state by polar solvent, whereas the proton responsive nature is attributed to the hydrogen bonding by protic solvent and protonation by mineral acid. Similar properties are seen in receptors of carboxylic acids [15].

## CONCLUSIONS

A large shift in fluorescence emission wavelength is observed on introduction of amino group at different positions of benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one. Different organic solvents such as dichloromethane, acetonitrile, and methanol can be distinguished from the emission wavelengths of the **4** in these solvents. Depending on the position of an amino group on the rings and protonation of the amino groups at different positions, the fluorescence emissions shifts to higher or lower wavelength.

**Table 1**

Effect of solvent on the visible spectra of **2** and **4**.

|  | Solvent | $\lambda_{max}$ (nm) | ε ($M^{-1}$ $cm^{-1}$) |
|---|---|---|---|
| R = $NH_2$, $R_1$, $R_2$ = H (**2**) | Dichloromethane | 430 | 12,727 |
| R = $NH_2$, $R_1$, $R_2$ = H (**2**) | Methanol | 437 | 10,227 |
| R = $NH_2$, $R_1$, $R_2$ = H (**2**) | Acetonitrile | 444 | 9545 |
| R = H, $R_1$, $R_2$ = H/$NH_2$ (**4**) | Dichloromethane | 427 | 11,212 |

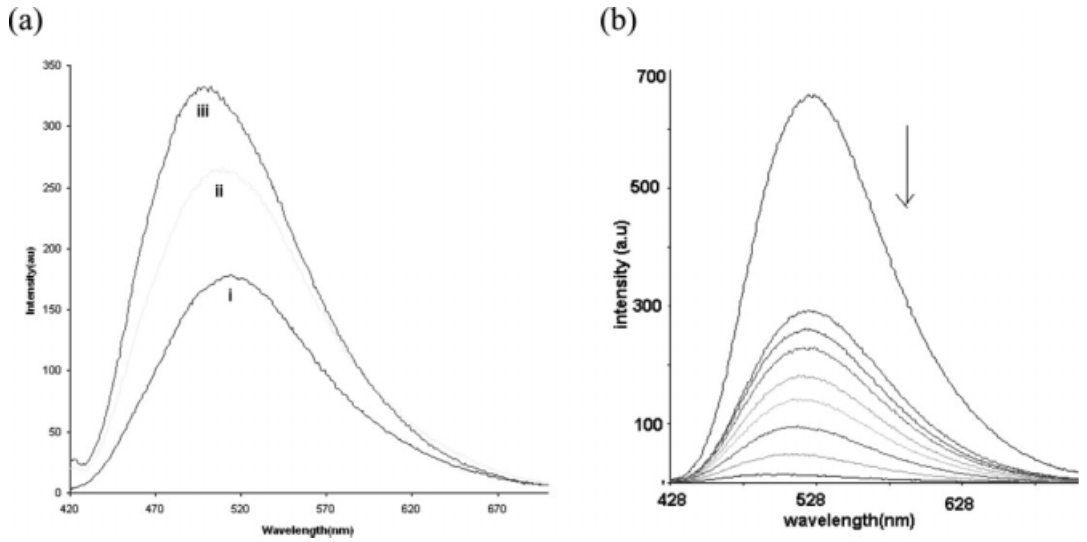

**Figure 2.** (a) Fluorescence emission ($\lambda_{ex}$ = 410 nm) spectra of (i) **2** in dichloromethane: (ii) on addition of 1 mol equiv of HCl and (iii) on addition of 2 mol equiv of HCl (in each cases 3 mL of 1.1 × $10^{-5}M$ solution). (b) Effect of the addition of methanol (100 μL aliquots) to a solution of **2** in dichloromethane.

The NMR spectra were recorded on a 400 MHz Varian FT-NMR instrument with TMS as an internal standard. Mass spectra were recorded in a Water LC-MS. The melting points of the compounds were determined in a Buchi B-540 melting point apparatus. All the optical measurements were carried out by dissolving calculated amount of the compounds in spectroscopic grade solvents. The fluorescence titrations were carried out in quartz cuvette by adding different aliquots of titrant/s by micropipette to a parent solution (3 mL).

**Determination of fluorescence quantum yield.** Fluorescence quantum yields were determined by calibrating with perylene (Φ = 0.94) by fluorescence excitation at 410 nm as standard. The fluorescence quantum yield was calculated by using the following formula [16]:

$$\frac{(\text{Quantum yield})_{\text{sample}}}{(\text{Quantum yield})_{\text{standard}}} = \frac{\text{Absorption of standard}\,(\text{Area under the graph of emission spectra})_{\text{Sample}}}{\text{Absorption of sample}\,(\text{Area under the graph of emissio spectra})_{\text{Standard}}}.$$

For calculation of the quantum yield of the other samples, the identical procedures were used.

**Synthesis and characterization of various compounds.**

***Compound 1.*** A mixture of 1,8-naphthalic anhydride (0.99 g, 5 mmol) and 4-nitro 1,2 diaminobenzene (0.77 g, 5 mmol) was refluxed in acetic acid (10 mL) for 4 h. The reaction mixture was cooled and water (20 mL ) was added to the reaction mixture and stirred for 20 min. The precipitate was filtered and washed several times with water to remove acetic acid. The product was air dried to obtain 11-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one in 77% yield. Elemental Anal. Calcd. for $C_{19}H_9N_3O_3$; C, 68.57; H, 2.88; Found C, 68.60, H, 2.86. $^1$H-NMR (400 MHz, $CDCl_3$): 9.17 (d, 1H, $J$ = 2.4), 8.75 (m, 4H), 8.51 (dm, 1H, $J$ = 7.2), 8.19 (s, 1H), 7.87 (m, 2H). IR (KBr, $cm^{-1}$): 1699 (s), 1517 (s), 1335 (s). ESI-MS: 316.1757 ($M + H^+$) m.p. 415°C.

***Compound 2.*** To a solution of 11-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one (0.32 g, 1 mmol) in ethanol/water (2:1, 20 mL), iron powder (35 mmol) and aqueous HCl (10%, 5 mL) were added. The mixture was kept at 90°C for 2 h. The reaction mixture was brought to room temperature and then water (10 mL) was added to the reaction mixture and filtered. The solid product obtained was washed with water and the product was purified by preparative TLC. Yield: 55%. Elemental Anal Calcd. for $C_{18}H_{11}N_3O$; C, 75.78; H, 3.89; Found C, 75.80, H, 3.90. $^1$H-NMR (400 MHz, $CDCl_3$) 8.76 (m, 2H), 8.26 (d, 1H, $J$ = 8.4 Hz), 8.1 (d, 1H, $J$ = 8 Hz), 7.9 (d,1H, $J$ = 2.4 Hz), 7.8 (m, 2H), 7.66 (d, 1H, $J$ = 8.4 Hz), 6.85 (d, 1H, $J$ = 8.4 Hz), 5.0 (s, 2H).$^{13}$C-NMR ($CDCl_3$): 158.9, 145.8, 137.4, 134.3, 134.2, 131.6, 130.8, 129.7, 129.5, 129.3, 127.4, 125.9, 125.7, 123.1, 120.2, 120.1, 118.5, 115.3. IR (KBr, $cm^{-1}$): 3232 (w), 3363 (s), 1589 (m), 1621 (s), 1697 (s). ESI-MS = 286.1864 ($M + H^+$). m.p. 406°C.

***Compound 3.*** A mixture of 3-nitro-1,8-naphthalic anhydride (1.22 g, 5 mmol) and 1,2 diaminobenzene (0.54 g, 5 mmol) was refluxed in acetic acid (20 mL) at 90°C for 4 h. The reaction mixture was cooled and then water (20 mL) was added to the reaction mixture and stirred for 20 min. The precipitate was filtered and washed several times with water to remove acetic acid, and the product was air dried to obtain a mixture of 2-nitro-benzo[de]benzo[4,5]imidazo[2,1-a]onemethane and 5-nitro-benzo[de]benzo[4,5]imidazo [2,1-a]isoquinolin-7-one in

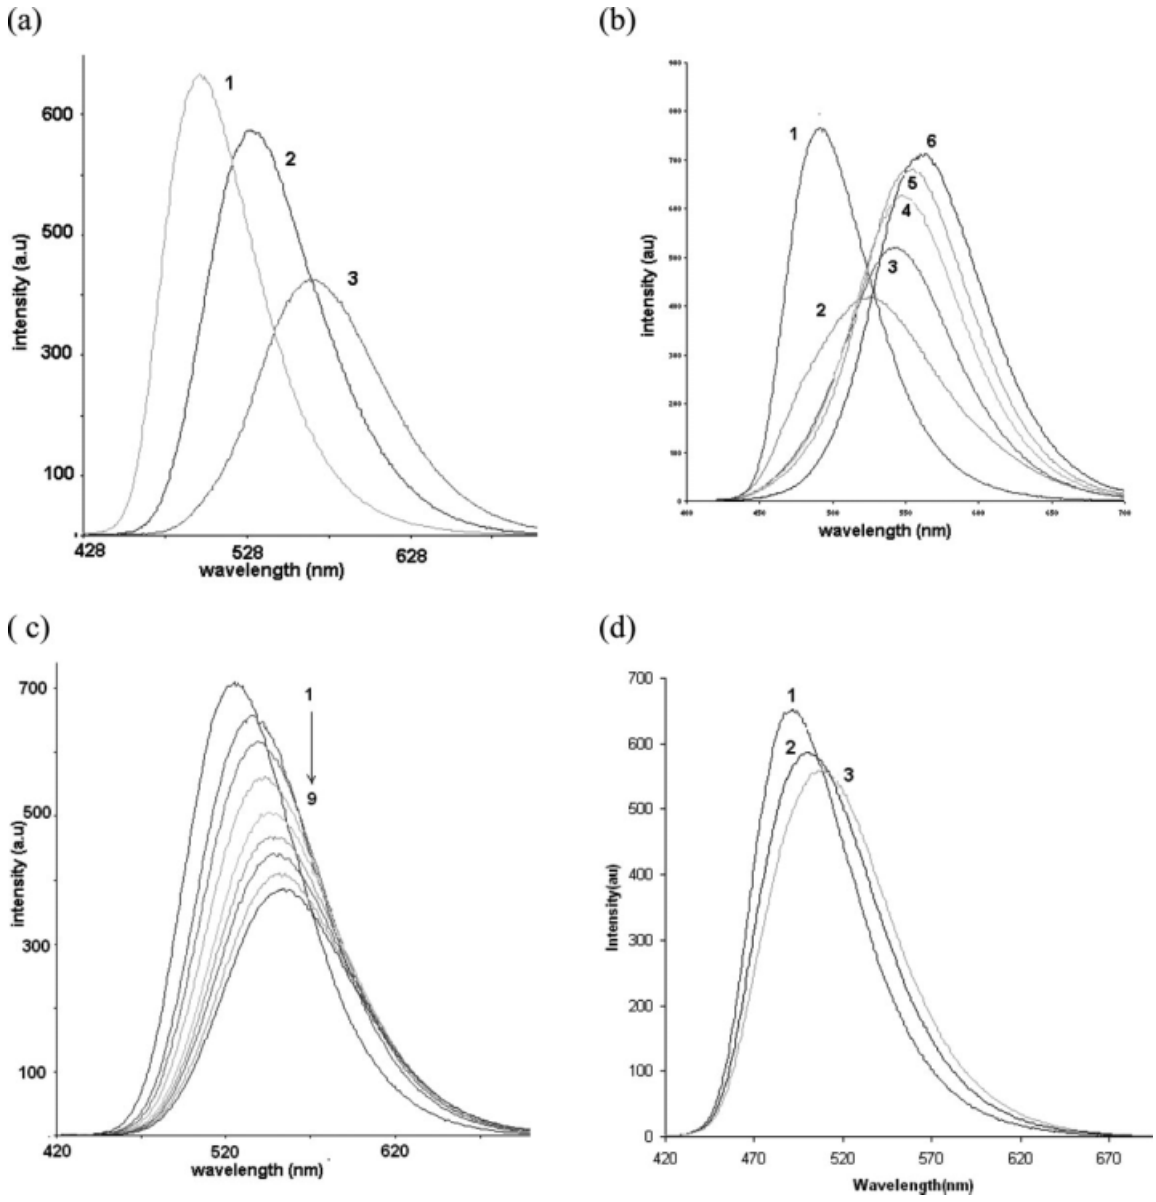

**Figure 3.** The fluorescence emission of ($\lambda_{ex}$ = 410 nm): (a) **4** in (i) dichloromethane, (ii) acetonitrile, and (iii) methanol (in each cases 3 mL of $1.1 \times 10^{-5}M$ solution **4**); (b) **4** on addition of different aliquots of methanol (50 μL each from 2–6) to a dichloromethane solution of **4**; (c) **4** on addition of different aliquots of methanol (50 μL each from 2–6) to an acetonitrile solution of **4**; (d) **4** (1) in dichloromethane and on addition of (2) 1 equiv of HCl or (3) 2 equiv of HCl.

86% yield. $^1$H-NMR (400 MHz, $CDCl_3$): 9.55 (d, $J$ = 4 Hz, 1H) 9.48 (d, $J$ = 4 Hz, 1H), 9.18 (d, $J$ = 4 Hz, 1H), 9.0 (d, $J$ = 4 Hz, 1H), 8.98 (d, 1H, $J$ = 8 Hz), 8.95 (d, 1H, $J$ = 8 Hz), 8.54 (m, 2H), 8.48 (d, 1H, $J$ = 8 Hz), 8.35 (d, $J$ = 8 Hz, 1H), 7.99 (t, $J$ = 8 Hz, 2H), 7.91–7.94 (m, 2H), 7.50–7.53 (m, 4H). IR (KBr, cm$^{-1}$): 3444 (m), 3067 (m), 1696 (s), 1596 (m), 1531 (m), 1443 (w), 1343 (s), 1234 (m), 1152 (w), 1039 (w), 751 (m), 557 (w). ESI-MS: 316.1814 ($M + H^+$). m.p. 410°C.

***Compound 4.*** To a solution of mixture of 2-nitro-benzo[de]-benzo[4,5]imidazo[2,1-a]onemethane and 5-nitro-benzo[de]-benzo[4,5]imidazo [2,1-a]isoquinolin-7-one (1.58 g, 5 mmol) in tetrahydrofuran (20 mL), palladized carbon (10%, 0.1 g) was added. The mixture was stirred under hydrogen atmosphere (50 psi) for 24 h, filtered, and the solvent was removed from filtrate under reduced pressure to get the desired product. The yield after purification was 85%. $^1$H-NMR (400 MHz, $CDCl_3$): 8.48–8.56 (m, 4H), 8.25 (d, $J$ = 3 Hz, 1H), 8.18 (d, 1H, $J$ = 3 Hz), 7.96 (d, $J$ = 8 Hz, 1H), 7.83–7.85 (m, 2H), 7.62–7.67 (m, 2H), 7.43–7.48 (m, 4H), 7.35 (d, $J$ = 3 Hz, 1H) 4.2 (broad s, 2H). $^{13}$C-NMR ($CDCl_3$): 158.1, 145.4, 134.2,

133.3, 130.0, 128.2, 127.8, 127.4, 125.9, 125.6, 125.4, 123.9, 122.4, 120.1, 118.0, 116.1, 115.7, 112.5. IR (KBr, $cm^{-1}$): 3448 (w), 3362 (s), 2924 (m), 2851 (m), 1690 (s), 1627 (s), 1550 (w), 1448 (w), 1352 (s), 1330 (s), 1166 (w), 1050 (w), 872 (w), 764 (w). ESI-MS: 286.1957 ($M + H^+$). m.p. 405°C.

***Compounds 5–8.*** The 11-amino-benzo[de]benzo[4,5]imidazo[2,1-a]isoquinolin-7-one (**2**) was converted to corresponding *N*-methyl (**5**), *N*-acetyl (**6**), *N*-benzoyl (**7**), and *N*-bromoacetyl derivatives (**8**) by reactions with suitable reagents as follows:

***Compound 5.*** A mixture of compound **1** (0.1 g, 0.35 mmol) and anhydrous potassium carbonate was refluxed in dry acetone with methyl iodide (0.08 g, 0.53 mmol) for 24 h. The reaction mixture was evaporated, water (15 mL) and dichloromethane (15 mL) were added, the organic layer was separated, and the product was extracted from the dichloromethane by evaporation. The compound was further purified by TLC. Yield: 25 %. $^1$H-NMR (400 MHz, DMSO-$d_6$): 8.65 (d, 1H, $J = 7.2$ Hz), 8.16 (d, 1H, $J = 8.4$ Hz), 7.98 (d, 1H, $J = 8.4$ Hz), 7.82 (d, 1H, $J = 2.8$ Hz), 7.7 (m, 4H), 6.86 (dd, 1H, $J = 2.8$ Hz), 3.0 (s, 3H). IR (KBr, $cm^{-1}$): 3390 (s), 2924 (s), 2853 (m), 1693 (s), 1621 (s), 1502 (s), 1318 (m). ESI-MS: 300.1132 ($M + H^+$). m.p. 386°C.

***Compounds 6–8.*** The compound **2** (0.06 g, 0.2 mmol) was mixed with RCOX (for **6**, **7** R = $CH_3$, Ph and X = Cl, respectively, whereas for **8** R = $BrCH_2CO$- and X = Br) and triethylamine (0.4 mL) in dry dichloromethane (10 mL). The mixture was stirred overnight at room temperature. On adding 40 mL water to the reaction mixture, the solid products in pure form were obtained from dichloromethane in quantitative yield.

***Compound 6.*** $^1$H-NMR (400 MHz, DMSO-$d_6$): 10.26 (s,1H), 8.9 (s,1H), 8.72 (d, 2H, $J = 8$ Hz ), 8.54 (d, 1H, $J = 8.4$ Hz), 8.38 (d, 1H, $J = 8.4$ Hz), 7.94 (m, 2H), 7.8 (d, 1H, $J = 8.8$ Hz ), 7.64 (d, 1H, $J = 8.4$ Hz), 2.1 (s, 3H). $^{13}$C-NMR (100 MHz, DMSO-$d_6$): 168.4, 159.8, 149.9, 143.7, 139.2, 137.2, 135.5, 132.1, 131.7, 131.1, 127.4, 127.1, 126.7, 122.5, 119.92, 117.5, 116.9, 115.0, 109.6, 105.9, 24.1. IR (KBr, $cm^{-1}$): 3302 (s), 2923 (s), 2852 (m), 1702 (s), 1662 (s), 1597 (m). ESI-MS: 328.1220 ($M + H^+$). m.p. 395°C.

***Compound 7.*** $^1$H-NMR (400 MHz, DMSO-$d_6$) 10.57 (s, 1H), 8.7 (d, 1H, $J = 3.6$ Hz), 8.52 (d, 1H, $J = 7.6$ Hz), 8.36 (d, 1H, $J = 7.2$ Hz), 8.15 (d,1H, $J = 4.8$ Hz), 8.04 (d,1H, $J = 4.8$ Hz), 7.94 (d, 2H, $J = 4.8$ Hz), 7.9 (s, 1H), 7.83 (d, 1H, $J = 7.2$ Hz), 7.63 (d, 2H, $J = 4.8$ Hz), 7.57 (s, 1H), 7.51 (d, 2H, $J = 4.8$ Hz). $^{13}$C-NMR (100 MHz, DMSO-$d_6$): 165.5, 160.0, 148.63, 139.5, 136.7, 135.3, 135.0, 131.7, 131.4, 131.0, 129.3, 128.4, 127.8, 127.3, 127.0, 126.1, 122.5, 120.0, 119.2, 118.7, 115.0, 111.1, 107.2. IR (KBr, $cm^{-1}$): 3301 (m), 3071 (m), 1703 (s), 1601 (m), 1699 (s). ESI-MS: 390.1217 ($M + H^+$). m.p. 385°C.

***Compound 8.*** $^1$H-NMR (400 MHz, DMSO-$d_6$): 10.72 (s, 1H), 8.90 (s, 1H), 8.70 (d, 2H, $J = 8.4$ Hz), 8.53 (d, 1H, $J = 8.4$ Hz), 8.37 (d, 1H, $J = 8.4$ Hz), 7.9 (m, 2H), 7.8 (m, 1H), 7.65 (d, 1H, $J = 8.4$ Hz), 4.1 (s, 2H). $^{13}$C-NMR (100 MHz, DMSO-$d_6$): 170.9, 160.0, 148.5, 136.5, 136.1, 135.5, 132.4, 131.8, 131.3, 127.4, 127.1, 126.2, 122.5, 119.8, 119.47, 119.2, 118.3, 117.6, 106.5, 62.0. IR (KBr, $cm^{-1}$): 3253 (s), 2959 (s), 1698 (m), 1654 (s), 1737 (s), 1591 (m), 1233 (m). ESI-MS: 405.9840 and 407.9832 ($M + H^+$). m.p. 378°C.

***Compounds 9–12.*** The compounds **9**, **10**, **11**, and **12** were synthesized from compound **4** by identical procedure that is described for **5**, **6**, **7**, and **8**, respectively.

***Compound 9.*** Yield: 28%. $^1$H-NMR (400 MHz, $CDCl_3$): 8.53 (m,4H), 8.43 (d, 1H, $J = 6.4$ Hz), 8.39 (d, 1H, $J = 2.8$ Hz), 8.32 (d, 1H, $J = 2.8$ Hz), 8.00 (d, 1H, $J = 8.0$ Hz), 7.85 (m, 4H), 7.62 (m, 2H), 7.45 (m, 4H), 7.21 (d, 1H, $J = 2.4$ Hz), 7.10 (d, 1H, $J = 2.4$ Hz), 3.07 (d, 6H, $J = 6.8$ Hz). IR (KBr, $cm^{-1}$): 3445 (s), 2924 (m), 2852 (w), 2357 (w), 1622 (s), 1430 (m), 1327 (s), 1231 (m), 1159 (w), 927 (w), 842 (w), 763 (m). ESI-MS: 300.1147 ($M + H^+$). m.p. 367°C.

Pyrolysis of 1,7-di-[(*E*)-1-morpholinomethylidene]- and 1,7-di-[(*E*)-1-piperidino-methylidene]-4,6,10,12-tetramethylamino-2,8-dioxo-1,7-diaza-3,5,9,11-cyclododecatetraene-3,9-dicarbonitrile **6a,b** afforded pyridone **10** in addition to cyanamides **11a,b**. On the other hand, pyrolysis of 1-[*E*-(4-(*E*-3-cyano-4,6-dimethyl-2-oxopyridin-1(*2H*)-ylimino) methylpiperazin-1-yl] methylenamino-4,6-dimethyl-2-oxo-1,2-dihydropyridine-3-carbonitrile **8** gave 1-amino-4,6-dimethyl-2-oxo-1,2-dihydropyridine-3-carbonitrile **13** as well as piperazine. The mechanism of pyrolysis and the effect of stereochemistry of pyrolyzed substrates on the nature of the pyrolysates are discussed.

*J. Heterocyclic Chem.*, **47**, 207 (2010).

## INTRODUCTION

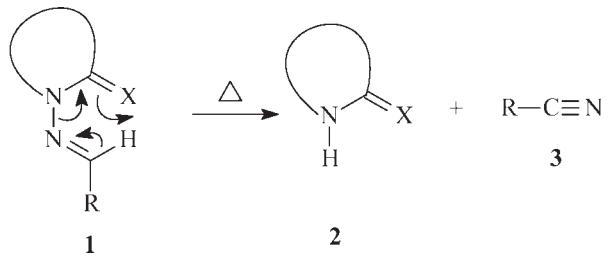
*N*-Aminoheteroaromatics are readily obtainable precursors [1–5]. The amino function could then be condensed with aromatic aldehydes into **1**. The gas-phase pyrolysis of this derivative produces pyridones **2** and nitriles **3** [6,7]. This approach offers an ideal and environmentally friendly methodology for synthesis of nitriles and related compounds, as no reagents, solvents, or catalysts are used in these thermal gas-phase reactions [8]. It seemed to us quite feasible that simple alternation in the structure of starting substrates could also be adopted as a strategy to synthesize cyanamides as well as organic cyanates (Scheme 1).

## RESULTS AND DISCUSSION

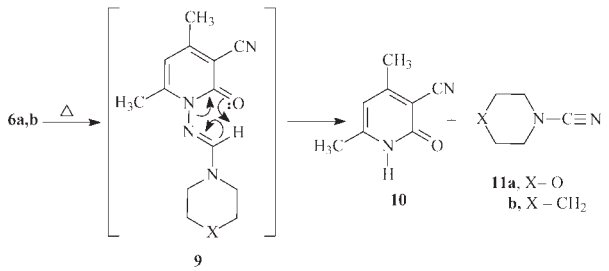
In the present article, we report synthesis of different substituted 1,7-diaza-3,5,9,11-cyclododecatetraene derivatives **4** as well as the results of their pyrolysis in the gas phase. In a recent investigation, we established that the reaction of acetylacetone with 2-cyanoacetohydrazide in the presence of diethylamine gave a dimeric product **4** of $m/z = 327$ ($M^{+\cdot} + 1$) [7]. Here, the reaction of the dimeric product **4** with triethylorthoformate afforded the diiminoformate **5,** which is then converted into **6a,b** and **8** through reaction with secondary amines, namely, morpholine, piperidine, and piperazine. Compound **5** could as well be generated *in situ* in a one-pot synthesis by mixing the three products under reflux in *N*,*N*-dimethylformamide. The reaction is facile, clean, and efficient, and is free from by-products. The structural assignments of compounds **5–8** were inferred from their mass spectra and other analytical data. Formation of **8** is believed to occur via initial conversion of diiminoformate **5** to the intermediate iminoformate **7** and subsequent condensation of two molecules of **7** with one molecule of piperazine (Scheme 2).

Pyrolysing **6a,b** in the gas phase gave the expected 1,2-dihydropyridine-3-carbonitrile derivative **10** and cyanamide **11a,b** via the methyleneamino-1,2-dihydropyridine-3-carbonitrile derivative **9** (Scheme 3). Formation of these products was confirmed by LCMS and by TLC, as well as $^1$H NMR of products of pyrolysis against

**Scheme 1**



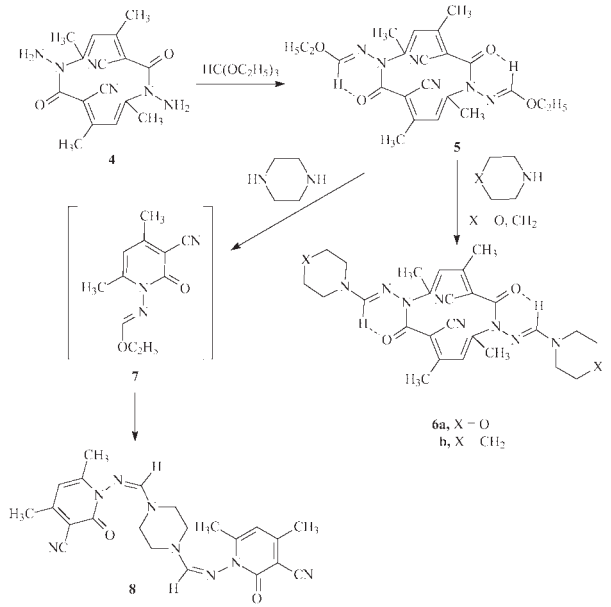
**Scheme 3**



authentic specimens of pyridone **10**. On the other hand, pyrolysis of **8** afforded **13** without formation of **12** (Scheme 4).

The difference in the pyrolytic behavior of **6a,b** and **8** is most likely a result of their stereochemistry. Thus, the pyrolyzed compounds **6a,b** exist in the (*E*) form, while **8** exists in the (*Z*) form. If one assumes that the pyrolysis of **8** (***E***) occurred via the H-bonded intermediate (Scheme 3), one would obtain pyridine **10** and dicyanamide **12** as pyrolytic products. As the *N*-aminopyridone **13** was the pyrolytic product obtained from **8** and no trace of the dicyanamide **12** was detected, it can thus be expected that **8** exists in the non-H-bonded (*Z*) form. In fact here, hydrolysis of **8** under the pyrolytic reaction conditions took place. To our knowledge such a hydrolysis has not been reported earlier. In conclusion, we could determine structures of pyrolysis products of **6a,b** and **8**. In addition, a new and safe route for synthesis of cyanamide **11a,b** is reported. Although **11a,b** could be obtained by treating cyanogen bromide with Mannich bases [9] and with morpholine compounds [10,11], this route required the use of hazardous and explosive cyanogen bromide reagents.

**Scheme 2**



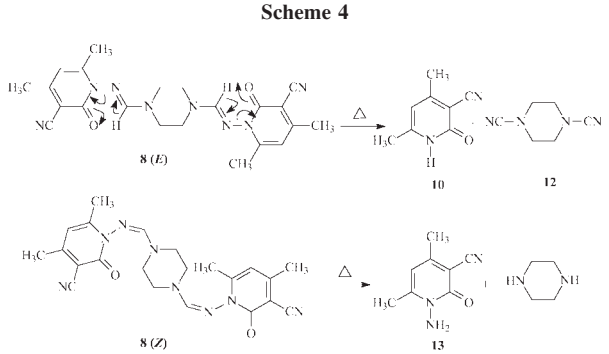
## EXPERIMENTAL

Melting points were determined on a Shimadzu-Gallenkamp apparatus and are uncorrected. Elemental analysis was by means of a LECO CHNS-932 Elemental Analyzer. NMR spectra were measured using a Bruker DPX 400 MHz superconducting spectrometer, and FT-IR measurements were from a Perkin Elmer 2000 FT-IR system. Mass spectrometric analysis was carried out on a VG-Autospec-Q high performance tri-sector GC/MS/MS, and the instrument for HPLC was an Agilent 1100 series LC/MSD with an API-ES/APCI ionization mode.

**1,7-Diamino-4,6,10,12-tetramethyl-2,8-dioxo-1,7-diazacyclododeca-3,5,9,11-tetraene-3,9-dicarbonitrile 4.** This compound was prepared following published procedure. It was obtained as white crystals from ethanol (yield 94%); m.p. 171–172°C, Lit. mp. 174°C [7]; IR (KBr): λ max/cm$^{-1}$: 3420, 3332 ($NH_2$), and 2216 (CN); MS: $m/z$ = 327 ($M^{+\cdot}$+1). $^1$H NMR (DMSO): δ = 2.31 (s, 6H, $2CH_3$), 2.42 (s, 6H, $2CH_3$), 6.15 (br s, 4H, $2NH_2$ $D_2O$ exchangeable), 6.33 (s, 2H). Anal. Calcd. for $C_{16}H_{18}N_6O_2$ (326.36): C 58.89, H 5.56, N 25.75. Found C 59.00, H 5.49, N 25.89.

**4,6,10,12-Tetramethyl-1,7-(diethoxy-dimethylene-amino)-2,8-dioxo-1,7-diaza-3,5,9,11-cyclododeca-tetraene-3,9-dicarbonitrile 5.** To a stirred mixture of compound **4** (0.01 mol, 3.26g) in 10 mL of *N*,*N*-dimethylformamide was added triethyl orthoformate (0.01 mol, 1.48 g). The resulted mixture was refluxed for 15 min. The solvent was removed and resulting solid was recrystallized from ethanol. Yield 86% (3.77g); m.p. 150°C; IR (KBr): λ max/cm$^{-1}$: 2218 (CN), 1658 (C=O); MS: $m/z$ = 439 ($M^{+\cdot}$+ 1); $^1$H NMR (DMSO): δ = 1.35 (t, 6H, $J$ = 7.04 Hz $2CH_3$), 2.28 (s, 6H, $2CH_3$), 2.33 (s, 6H, $2CH_3$), 4.35

**Scheme 4**



(q, 4H, $J$ = 7.04 Hz $2CH_2$), 6.37 (s, 2H, cycloalkene-H), 8.36 (s, 2H, amidine-H). Anal. Calcd. for $C_{22}H_{26}N_6O_4$ (438.49): C 60.26, H 5.98, N 19.17. Found C 60.06, H 5.94, N 19.25.

**General procedure for the preparation of compounds 6a,b and 8.** To a stirred mixture of compound **5** (0.01 mol, 4.38 g) in 20 mL of DMF was added the appropriate amine (0.01 mol). The mixture thus obtained was heated under reflux for 20 hours. The solvent was removed and the resulting solid was recrystallized from DMF.

**4,6,10,12-Tetramethyl-1,7-di-[(*E*)-1-morpholino-methylidene] amino-2,8-dioxo-1,7-diaza-3,5,9,11-cyclododecatetraene-3,9-dicarbonitrile 6a.** Yield 85% (4.42 g); m.p. 190°C, brown crystals from DMF; IR (KBr): ν/cm$^{-1}$: 2216 (CN), 1647 (C=O); MS: $m/z$ = 521 ($M^{+\cdot}$ + 1); $^1$H NMR (DMSO-$d_6$): δ (ppm) = 2.26 (s, 6H, $2CH_3$), 2.30 (s, 6H, $2CH_3$), 3.50–3.54 (m, 8H, morpholino-H), 3.62–3.65 (m, 8H, morpholino-H), 6.30 (s, 2H, cycloalkene-H), 7.93 (s, 2H, amidine-H). Anal. Calcd. for $C_{26}H_{32}N_8O_4$ (520.59): C 59.99, H 6.20, N 21.52. Found C 60.06, H 6.26, N 21.58.

**4,6,10,12-Tetramethyl-2,8-dioxo-1,7-di-[(*E*)-1-piperidinomethylidene]amino-1,7-diaza-3,5,9,11-cyclododecatetraene-3,9-dicarbonitrile 6b.** Yield 92% (4.75 g); m.p. 115°C, brownish crystals from ethanol; IR (KBr): ν/cm$^{-1}$: 2213 (CN), 1652 (C=O); MS: $m/z$ = 517 ($M^{+\cdot}$+1); $^1$H NMR (DMSO-$d_6$): δ (ppm) = 1.50–1.57 (m, 8H, piperidinyl-H), 1.63–1.66 (m, 4H, piperidinyl-H), 2.25 (s, 6H, $2CH_3$), 2.29 (s, 6H, $2CH_3$), 3.29–3.31(m, 4H, piperidinyl-H), 3.48–3.52 (m, 4H, piperidinyl-H), 6.26 (s, 2H, cycloalkene-H), 7.81 (s, 2H, amidine-H). Anal. Calcd. for $C_{28}H_{36}N_8O_2$ (516.65): C 65.09, H 7.02, N 21.69. Found C 64.67, H 6.71, N 21.57.

**1,1'-{Piperazine-1,4-diylbis[(*Z*)-methylylidenenitrilo]} bis (4,6-dimethyl-2-oxo-1,2-dihydropyridine-3-carbonitrile 8.** Yield 62% (2.67 g); m.p. >300 °C, buff crystals from DMF; IR (KBr): ν/cm$^{-1}$: 2217 (CN), 1642 (C=O); MS: $m/z$ = 433 ($M^{+\cdot}$+1); $^1$H NMR (DMSO-$d_6$): δ (ppm) = 2.29 (s, 6H, $2CH_3$), 2.31 (s, 6H, $CH_3$), 3.44–3.48 (m, 4H, piperidinyl-H), 3.57–3.64 (m, 4H, piperidinyl-H), 6.30 (s, 2H, pyridyl H-5), 8.00 (s, 2H, amidine-H). **General Procedure for Pyrolysis of 6a,b and 8.** Each of compounds **6a–c** and **8** was introduced in the reaction tube (1.5 × 12 cm$^2$ Pyrex), cooled in liquid nitrogen, sealed under vacuum (0.06 mbar) and placed in the pyrolyser for 900 s at a temperature of complete pyrolysis. The pyrolysate was then separated into its constituents by preparative TLC (MERCK, 12 PSC-Platten 20 × 20 cm$^2$, Silica gel 60 $F_{254}$ 2 mm) using chloroform: petroleum ether (bp 40:60) in 80:20 ratio as eluent, and each constituent was collected, analyzed and characterized. The techniques used include $^1$H NMR and GC/MS.

**Morpholine-4-carbonitrile 11a.** MS: $m/z$ = 112 ($M^{+\cdot}$) for $C_5H_8N_2O$ (112.13). IR = 2220 cm$^{-1}$ (CN). $^1$H NMR ($CDCl_3$): δ (ppm) = 3.05–3.08 (m, 2H, morpholinyl-H), 3.21–3.23 (m, 2H, morpholinyl-H), 3.43–3.49 (m, 2H, morpholinyl-H), 3.59–3.68 (m, 2H, morpholinyl-H). [Lit $^1$H NMR 90 MHz ($CDCl_3$) [12]: δ (ppm) = 3.2–3.3 (m, 4H), 3.6–3.7 (m, 4H)].

**Piperidine-1-carbonitrile 11b.** MS: $m/z$ = 110 ($M^{+\cdot}$) for $C_6H_{10}N_2$ (110.16). $^1$H NMR ($CDCl_3$): δ (ppm) = 1.41–1.52 (m, 6H, piperidinyl-H), 3.56–3.78 (m, 4H, piperidinyl-H). Lit $^1$H NMR 90 MHz ($CDCl_3$) [13]: δ (ppm) = 1.45–1.68 (m, 6H), 3.2–3.5 (m, 4H)].

**4,6-Dimethyl-2-oxo-1,2-dihydropyridine-3-carbonitrile 10.** MS: $m/z$ = 163 ($M^{+\cdot}$) for $C_8H_8N_2O$ (148.16). $^1$H NMR ($CDCl_3$): δ (ppm) = 2.33 (s, 3H, $CH_3$), 2.40 (s, 2H, $CH_3$), 3.60 (br s, 1H, NH $D_2O$ exchangeable), 6.21 (s, 1H, pyridyl H-5). [Lit $^1$H NMR 200 MHz (DMSO/$CDCl_3$ 2:1 [14]): δ (ppm) = 2.23 (s, 3H), 2.32 (s, 3H), 3.40 (br s, 1H), 6.07 (s, 1H)].

**1-Amino-4,6-dimethyl-2-oxo-1,2-dihydropyridine-3-carbonitrile 13.** MS: $m/z$ = 163 ($M^{+\cdot}$) for $C_8H_9N_3O$ (163.18). $^1$H NMR ($CDCl_3$): δ (ppm) = 2.33 (s, 3H, $CH_3$), 2.38 (s, 2H, $CH_3$), 6.15 (br s, 4H, $2NH_2$ $D_2O$ exchangeable), 6.31 (s, 1H, pyridyl H-5).

**Acknowledgment.** The support of the University of Kuwait received through research grant (SC02/03) and the facilities of Analab/SAF (GS02/01, GS03/01) are gratefully acknowledged.

The first quinolyl substituted 1,2,4-triazole, 3,5-bis(2-quinolyl)-1,2,4-triazole (**4**), was synthesized from 2-cyanoquinoline (**1**) through an intermediate 2-quinolylhydrazidine (**2**) with 60.4% yield in a simple way. In the synthetic process of **4**, another new intermediate, 1,4-diamino-1,4-bis(2-quinolyl)-2,3-diaza-1,3-butadiene (**3**) was obtained in a yield of 81.5%. Additionally, the absolute configurations of both **3** and **4** were determined by X-ray crystallography.

## INTRODUCTION

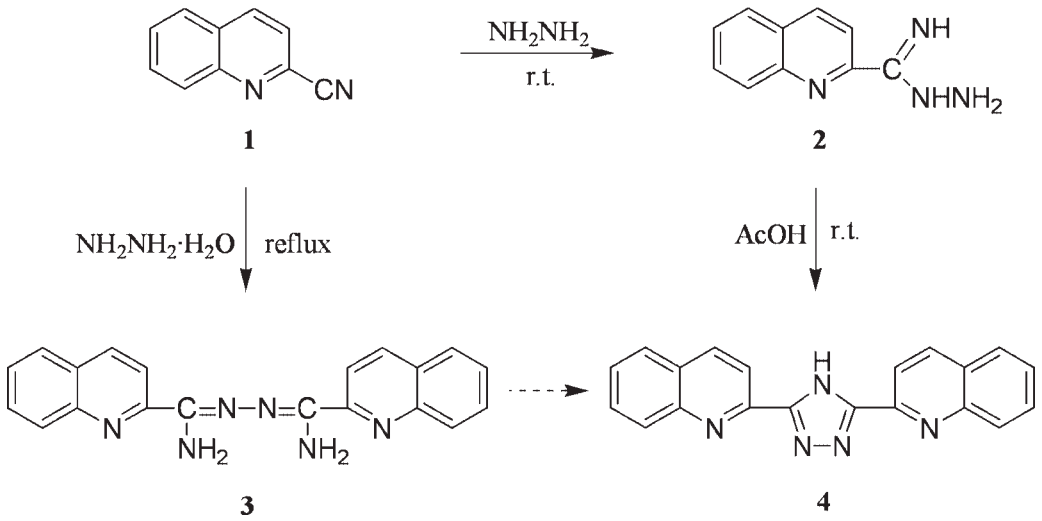
Over recent years, heterocyclic compounds containing 1,2,4-triazole rings have attracted widespread attention because of their broad applications as antifungus, antitumor, fungicide, weedicide, and so on [1]. Moreover, substituted 1,2,4-triazoles are very useful ligands in coordination chemistry [2–4]. This is mainly because of that they can act as bridging ligands between transition metal ions thus providing rich and versatile coordination modes. More interestingly, their ligand strength is in the right region to give iron(II) spin-crossover complexes, which could be used as molecular-based memory devices, displays and switching materials [5,6].

Although a lot of 1,2,4-triazole compounds with substituted alkyl, phenyl or pyridyl groups [3,7] have been synthesized successfully, substituted 1,2,4-triazoles with quinolyl group, an important alkaloid with stronger conjugated system, have never been reported so far. Recently, we have prepared some new triaryltriazole compounds [8,9] and their complexes [10–16]. As a continuation of our investigation on the substituted 1,2,4-triazoles, herein, we present the first synthesis of 3,5-bis(2-quinolyl)-1,2,4-triazole (**4**) through the nucleophilic addition of hydrazine to 2-cyanoquinoline (**1**) (Scheme 1). The product **4** was characterized by UV, FTIR, $^1$H NMR, TOF-MS spectra, elemental analysis and single crystal X-ray diffraction. In addition, another new intermediate, 1,4-diamino-1,4-bis(2-quinolyl)-2,3-diaza-1,3-butadiene (**3**), has also been obtained and its crystal structure was described [17].

## RESULTS AND DISCUSSION

Several methods have been reported for the syntheses of 3,5-diaryl-substituted 1,2,4-triazoles [18–24]. However, following the method (Scheme 2) reported by Geldard and Lions [23] using 2-cyanoquinoline (**1**) instead of 2-cyanopyridine as starting material for the synthesis

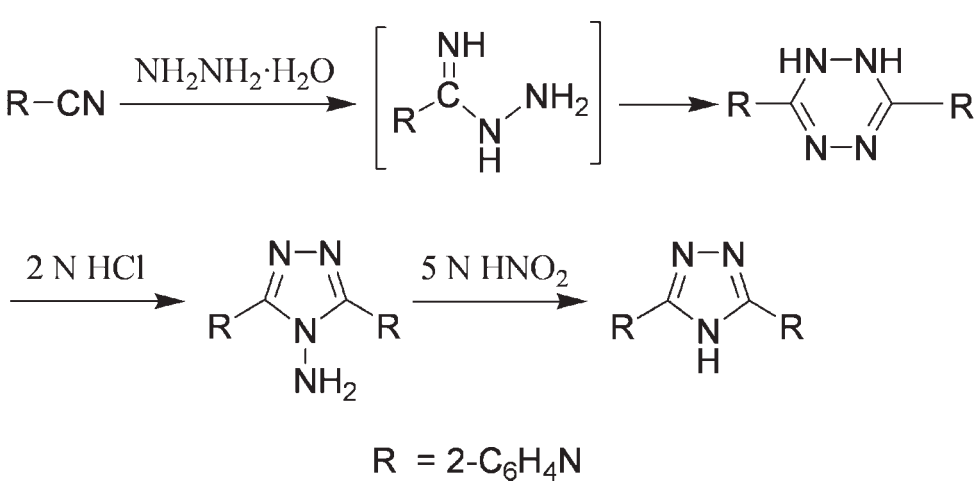
**Scheme 1**



of **4**, we did not obtain the corresponding 1,2,4,5-tetrazine. The corresponding 1,2,4,5-tetrazine was also not obtained, though we changed the reaction conditions such as the molar ratios of the 2-cyanoquinoline and hydrazine hydrate, reaction temperature, and replacing hydrazine hydrate with anhydrous hydrazine. Instead, two different intermediates were identified. One is 1,4-diamino-1,4-bis(2-quinolyl)-2,3-diaza-1,3-butadiene (**3**) with 81.5% yield after refluxing **1** and hydrazine hydrate (molar ratios 1:2) for 2 h at 110°C [24]. The other is 2-quinolylhydrazidine (**2**) in a yield of 94.6% by stirring **1** and anhydrous hydrazine (molar ratios 1:33) in anhydrous ethanol for 3 h at room temperature [25]. The structure of **3** has been determined by X-ray crystallography (Fig. 1). When **3** was heated to 200°C in argon atmosphere, only trace amounts of compound **4** was formed. In contrast, when **2** was mixed in acetic acid at room temperature, **4** was obtained in a yield of 60.4% [26]. To our knowledge, this is the first report to synthesize 3,5-diaryl-substituted 1,2,4-triazoles without involving the corresponding 1,2,4,5-tetrazine and 1,2,4-triazoline intermediates compared with the other methods [23,24].

The molecular structure of **4** was also confirmed by X-ray crystallography. Single crystals of **4** were obtained by slow evaporation of its ethanol solution at ambient temperature. A structural view with atom-numbering scheme is shown in Figure 2 and selected bond lengths and bond angles are listed in Table 1. The X-ray structure analysis indicates that **4** consists of two quinolyl rings and one triazole ring. These rings do not share a common plane. The quinolyl ring with N1 atom makes a dihedral angle of 10.1(4)° with the triazole ring, whereas the quinolyl ring with N5 atom makes a dihedral angle of 35.5(4)° with respect to the triazole plane. The dihedral angle between two quinolyl groups is

**Scheme 2**



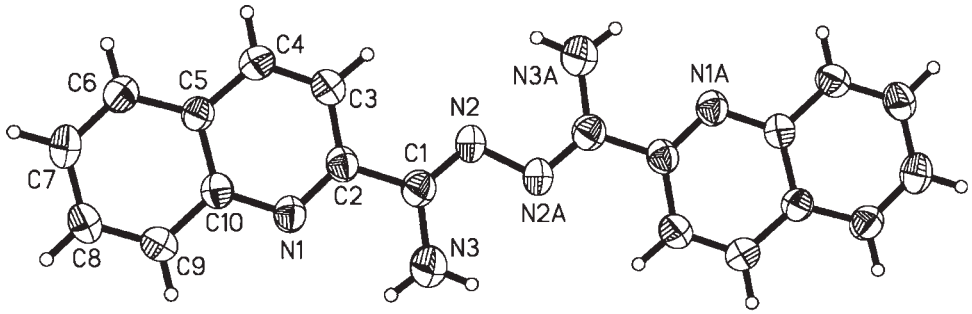


**Figure 1.** A view of **3** showing the atom-numbering scheme. Thermal ellipsoids are shown at the 50% probability level.

37.7(4)°. The bond lengths and bond angles in the structure of **4** are in the usual ranges. In the crystal, the possibility of N—H···N hydrogen bonds is reduced due to the presence of the bulky quinolyl groups. However, the molecules of **4** are further stabilized by C—H···π interactions involving C19-H19 and the phenyl ring at (−1/2 + *x*, 1/2−y, 1/2 + z) [C19···π = 3.588(5) Å and C19-H19···π = 136.6(4)°] [8].

## EXPERIMENTAL

Melting points were determined with an X-4 digital microscope melting-point apparatus (Beijing) and are uncorrected. UV-vis spectra were recorded on a Perkin-Elmer Lambda 35 spectrophotometer at room temperature. FT-IR spectra were recorded on a Nicolet 380 FT-IR instrument using KBr disks. $^1$H NMR spectra were measured on a Bruker AM 500 MHz spectrometer. Chemical shifts are reported in parts per million (ppm) downfield from tetramethylsilane (TMS). Mass spectra were recorded on an Autoflex II TOF/TOF. Elemental analyses of compounds were performed with an Elementer Varian EL III instrument. Commercial reagents were used without further purification unless otherwise stated. 2-Cyanoquinoline (**1**) was synthesized according to literature method [27].

**2-Quinolylhydrazidine (2).** A mixture of **1** (1.54 g, 10 mmol) and anhydrous hydrazine (10.2 mL, 321 mmol) was stirred in anhydrous ethanol (6.3 mL) at ambient temperature for 2 h. The solid was collected and washed with cold water. Then the crude product was recrystallized from anhydrous ethanol to give yellow needles 1.76 g (94.6%), mp 191–192°C (lit. mp 191–192°C [25]); IR (ν, cm$^{-1}$): 3436, 3290, 3178, 3061, 3012, 1636, 1599, 1561, 1507, 831, 747, 625, 477. $^1$H NMR ($CDCl_3$, ppm): δ 4.74 (s, 2H, NH), 5.38 (s, 2H, $NH_2$), 7.51–7.54 (t, 1H, ArH), 7.68–7.71 (t, 1H, ArH), 7.79–7.81 (d, 1H, ArH), 8.05–8.07 (d, 1H, ArH), 8.10–8.15 (m, 2H, ArH).

**1,4-Diamino-1,4-bis(2-quinolyl)-2,3-diaza-1,3-butadiene (3).** A mixture of **1** (1.2 g, 7.8 mmol) and hydrazine hydrate (1.2 mL) was stirred at 110°C for 2 h. Upon cooling to ambient temperature, the solid was collected and recrystallized from ethyl acetate to give yellow needles 1.08 g (81.5%), mp 178–180°C; UV (EtOH, nm): 209 (1.32), 240 (1.70), 296 (0.53), 308 (0.51), 332 (0.47, sh). IR (ν, cm$^{-1}$): 3436, 3289, 3180, 3058, 1637, 1598, 1561, 1507, 831, 747, 625, 477. $^1$H NMR ($CDCl_3$, ppm): δ 5.47 (s, 2H, $NH_2$), 7.54–7.58 (t, 1H, ArH), 7.62–7.76 (t, 1H, ArH), 7.82–7.85 (d, 1H, ArH), 8.07–8.10 (d, 1H, ArH), 8.16–8.17 (t, 2H, ArH). Anal. Calcd. for $C_{20}H_{16}N_6$: C, 70.57; H, 4.74; N, 24.69. Found: C, 70.68; H, 4.99; N, 24.54.

**3,5-Bis(2-quinolyl)-1,2,4-triazole (4).** At 0°C, **2** (2.44 g, 13.1 mmol) was mixed with glacial acetic acid (7.5 mL, 131 mmol) and then stirred for 3 h at room temperature. After the removal of unreacted acid under vacuum, the crude product was recrystallized from anhydrous ethanol to yield colorless crystals 1.28 g (60.4%), mp 226–227°C; UV (EtOH, nm): 213 (2.04), 248 (2.27), 306 (0.71), 320 (0.83), 335 (1.00). IR (ν, cm$^{-1}$): 3174, 3056, 1698, 1615, 1598, 1567, 1502, 836, 769, 615, 476. $^1$H NMR ($CDCl_3$, ppm): δ 7.66 (s, 1H, ArH), 7.84 (s, 1H, ArH), 7.93 (s, 1H, ArH), 8.36 (s, 1H, ArH), 8.43 (s, 1H, ArH), 8.56 (s, 1H, ArH). MS: m/z 324.1 ($M^+ + 1$), 323.1 ($M^+$), 295.1 ($M^+ + 1 - N_2$), 294.1 ($M^+ - N_2$). Anal. Calcd. for $C_{20}H_{13}N_5$: C, 74.28; H, 4.05; N, 21.66. Found: C, 74.42; H, 4.18; N, 21.52.

**Single-crystal X-ray diffraction analysis of 4.** $C_{20}H_{13}N_5$, $M_r = 323.35$, monoclinic, $P2_1/c$, $a = 14.306(3)$ Å, $b = 7.0990(14)$ Å, $c = 15.372(3)$ Å, $\beta = 95.85(3)°$, $V = 1553.0(5)$ Å$^3$, $Z = 4$, $\rho = 1.383$ mg/m$^3$, $\mu = 0.087$ mm$^{-1}$, $F(000) = 672$, $R_1 = 0.0775$ for 1248 observed ($I > 2\sigma(I)$) reflections and 0.1822 for all 2939 reflections, Goodness-of-fit = 1.003, 226 parameters.

A colorless block crystal of **4** with dimensions 0.06 × 0.10 × 0.10 mm$^3$ was selected for lattice parameter determination and collection of intensity data at 293 K on a FR590 CAD4 four-circle diffractometer with monochromated Mo $K_\alpha$ radiation ($\lambda = 0.71073$ Å) using a $\theta/2\theta$ scan mode. The data was corrected for Lorenz and polarization effects during data reduction. An empirical absorption correction based on $\psi$ scans was applied. The structure was solved by the direct methods and refined on $F^2$ by full-matrix least-squares methods using the SHELXL version 5.10 [28]. All nonhydrogen atoms were refined anisotropically. Hydrogen atoms for C—H and N—H were placed in calculated positions (0.96 Å), assigned fixed isotropic thermal parameters at 1.2 times the equivalent isotropic $U$ of the atoms to which they are attached, and allowed to ride on their respective parent atoms.

CCDC 736135 contains the supplementary crystallographic data for this article. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre *via* www.ccdc.cam.ac.uk/data_request/cif.

N-substituted furylmethylimines are prepared by condensing 6-aminocoumarins with furfural, these on sodium borohydride reduction afford *N*-[coumarin-6′-yl]-2-furylamines. Intramolecular [4+2] cycloaddition of these amines with maleic anhydride results into 3-[*N*-coumarin-6′-yl]-4-oxo-10-oxa-3-azatricyclo[5.2.1.0$^{1,5}$]dec-8-ene-6-carboxylic acids **4a–c**. The [4+2] cycloadducts on *p*-toluene sulphonic acid treatment followed by esterification yield the titled compounds. Compound **5a–c** was also reduced to isoindolone alcohol **7a–c** by sodium borohydride in the presence of a base. All the compounds have been tested *in vitro* for their antimicrobial activity against gram-positive bacteria *Bacillus subtilis, Staphylococcus aureus*, one gram-negative bacteria, *Escherichia coli*, and one fungal strain *Candida albicans* at 100 μg/mL concentration.

## INTRODUCTION

A variety of heterocyclic compounds bearing isoindolone skeleton reported to possess wide range of biological activities, such as antipsychotic [1], antihypertensive [2], antiviral [3], and antileukemic [4]. Furthermore, isoindolones have been widely used as building blocks for the synthesis of various drugs and natural products. Likewise, coumarins have also gained considerable synthetic and pharmacological interest for a long time because of their various biological activities [5–9]. In continuation of our work [10–15], keeping the biological profile of the two class of compounds in view, it appeared of interest to synthesize a molecular entity displaying the structural features of both the class of compounds.

Intramolecular Diels-Alder reaction of furan (IMDAF) methodology offers a facile way of constructing isoindolone moiety on a pre-existing 2-furylmethyl amine system [16]. In this article, we wish to report the synthesis of methyl-3-oxo-2,3-dihydro-1*H*-isoindolone-5-carboxylates using the IMDAF approach.

## RESULTS AND DISCUSSION

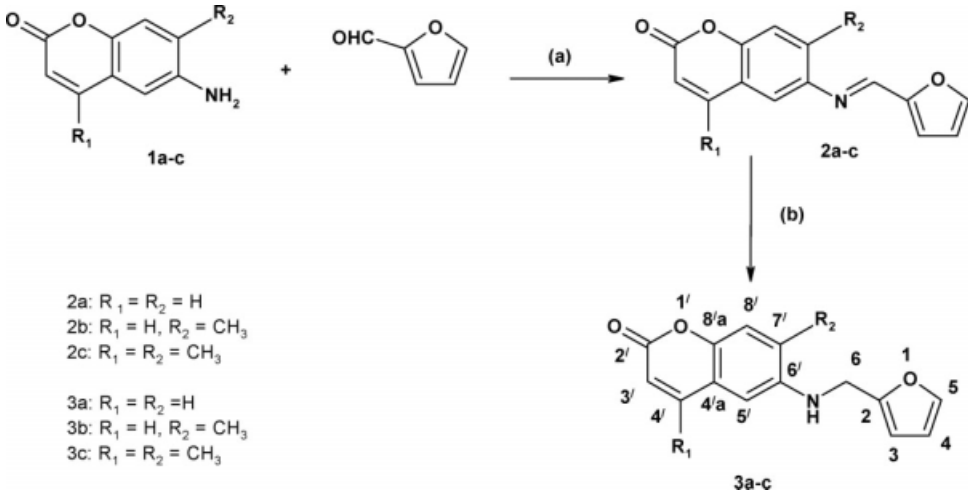
The required N-substituted 2-furylmethyl-amine **3a–c** was obtained by sodium borohydride reduction of the N-substituted 2-furylmethimines (**2a–c**) derived from 6-amino coumarin (**1a–c**) and furfural (Scheme 1). Capitalizing on the reactivity of the furan nucleus to words dienophiles in the Diels-Alder reaction, these furylmethyl amine were subsequently treated with maleic anhydride to afford compound **4a–c**.

The formation of stereochemically defined exo-tricyclic cycloadduct proceeds smoothly *via* initial N-acylation followed by intramolecular Diels-Alder reaction (one-pot reaction) [17–19] Scheme 2.

In the next step, ring opening followed by aromatization of the epoxy isoindolones was accomplished by subjecting the cycloadduct (**4a–c**) to *p*-toluene sulphonic acid (pTSA) in refluxing toluene [16]. The resultant product was characterized as 2-[*N*-coumarin-6′-yl]-3-oxo-2,3-dihydro-1*H*-isoindolone-5-carboxylic acid (**5a–c**). The presence of carboxy function was confirmed by converting (**5a–c**) to their corresponding methyl esters (**6a–c**) and isoindolone alcohol (**7a–c**) Scheme 3.

**Spectral characterization.** Formation of furfural amines **3a–c** was confirmed by the IR spectra, which showed characteristic —NH stretching at 3438 cm$^{-1}$. In its $^1$H NMR in $CDCl_3$, it showed a singlet at δ 4.34 ppm integrating for two methylene protons. The formation of cycloadduct was confirmed by the absence of —NH stretching in IR spectra and the presence of characteristic bands for the vibrations of the amide and carboxylic group in the regions of 1620–1690 and 1710–

**Scheme 1.** Reagents and conditions:(a) toluene, reflux, 5 h and (b) $NaBH_4$, MeOH, 0°C, 3 h.



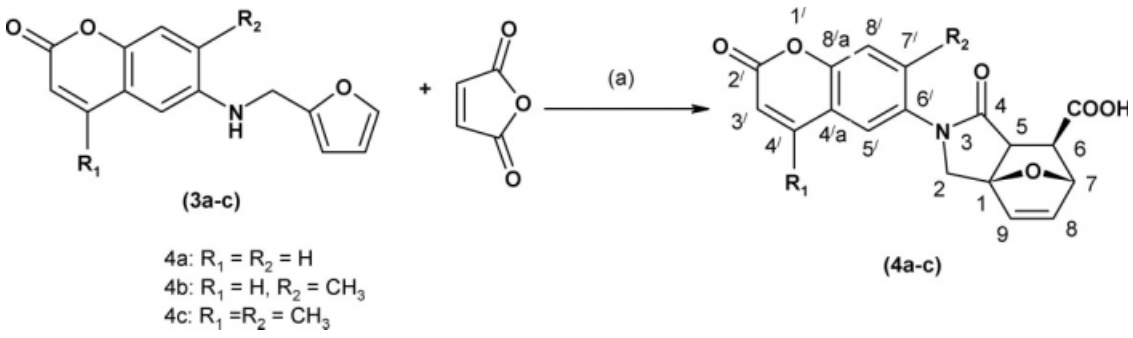
1726 $cm^{-1}$, respectively. The $^1H$ NMR spectra of compound **4c** contain three characteristic signals for mutually interacting protons 7-H, 8-H, and 9-H with chemical shifts of 5.07, 6.50, and 6.65 ppm, respectively, and coupling constants $J_{7,8} = 1.8$ Hz and $J_{8,9} = 5.7$ Hz, respectively. The absence of the $J_{6,7}$ spin–spin coupling constant indicates the endo arrangement of the 5-H and 6-H protons ($J_{5,6} = 9$ Hz) and the exo arrangement of the carboxyl and amide constituents. The C-2 protons of $CH_2$ are magnetically nonequivalent and are observed as an AB quartet at 4.57 and 3.84 ppm ($J_{AB} = 11.4$ Hz), respectively. Compound **5c** shows a singlet at δ 5.13 for the $CH_2$ protons along with other signals. Compounds **5a–c** were independently confirmed by converting them into their corresponding methyl-esters, showing stretching vibration between 1730 and 1735 $cm^{-1}$ for carbonyl group of methyl ester. The $^1H$ NMR of compound **6c** shows an additional singlet at δ 3.83 ppm for three protons of methyl ester. 5-Hydroxymethyl-2-[*N*-coumarin-6′-yl]-3-oxo-2,3-dihydro-1*H*-isoindolone **7a–c** shows singlet at δ 4.68 for $CH_2$—OH protons along with the other signals.

*In vitro* antimicrobial evaluation of newly synthesized compounds was done against three bacterial and one fungal strain by agar-well diffusion method [20] at 100 μg/mL concentration. Antibacterial activity of the test compounds was evaluated against two gram-positive bacteria, *Bacillus subtilis* and *Staphylococcus aureus,* and one gram-negative bacteria, *Escherichia coli*, using ampicillin as standard drug. Antifungal activity was screened against one fungal strain, *Candida albicans*, using clotrimazole as standard drug. The results are given in Table 1.

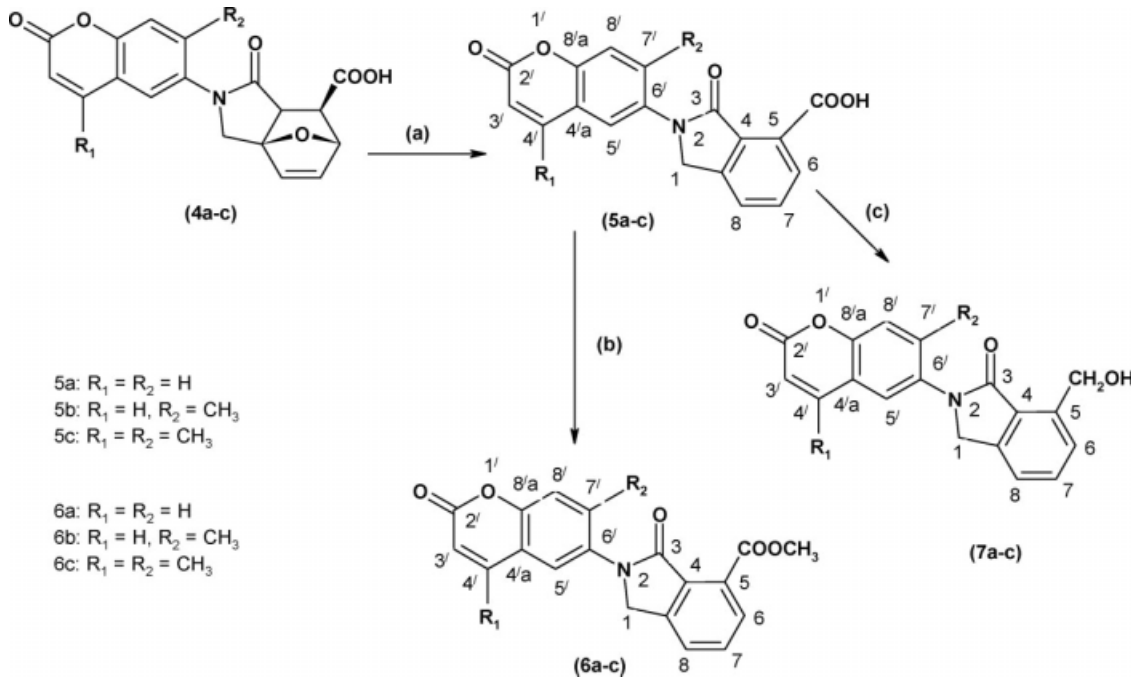
## CONCLUSIONS

In conclusion, a series of novel 2-[*N*-coumarin-6′-yl]-3-oxo-2,3-dihydro-1*H*-isoindolone-5-carboxylic acid (**5a–c**), methyl-2-[*N*-coumarin-6′-yl]-3-oxo-2,3-dihydro-1*H*-isoindolone-5-carboxylate (**6a–c**), and 5-hydroxymethyl-2-[*N*-coumarin-6′-yl]-3-oxo-2,3-dihydro-1*H*-isoindolone (**7a–c**) were synthesized by IMDAF, and their antimicrobial activities have been evaluated.

**Scheme 2.** Reagents and conditions: (a) maleic anhydride, benzene.



**Scheme 3.** Reagents and conditions: (a) pTSA, toluene, reflux, (b) MeOH, Conc. $H_2SO_4$, reflux, 8 h, and (c) THF, ethylchloroformate, TEA/$NaBH_4$/MeOH, r.t, 24 h.



Among the tested compounds, compounds **5c**, **6c,** and **7c** with methyl substitution on fourth and seventh positions of benzopyran ring have showed significant activities.

## EXPERIMENTAL

Melting points were taken in open capillaries and are uncorrected. FTIR spectra ($V_{max}$ in $cm^{-1}$) were recorded on a Perkin Elmer 400 spectrometer using KBr. NMR spectra were recorded on JEOL NMR AL300 (300 MHz) using TMS as standard and mass spectra on a Shimadzu GC-MS QP-2010. Elemental analyses were carried out in IIT, Mumbai. The reactions are followed up and purity of the products is carried out on precoated TLC plates (Silica gel 60 F254, Merck), visualizing the spots in ultraviolet light. All the new compounds gave satisfactory elemental analyses.

**Synthesis of *N*-[coumarin-6′-yl]-2-furylmethinimine (2a–c).** Imines (**2a–c**) were prepared by refluxing a mixture of freshly distilled furfuraldehyde and appropriate 6-amino coumarin in toluene using Dean-Stark apparatus, refluxing was continued for 5 h. Toluene was distilled off on a rotary evaporator and the crude imine was used in the next step without purification.

**Synthesis of *N*-[coumarin-6′-yl]-2-furylmethylamine (3a–c).** Sodiumborohydride was added in small portions to a solution of imine (**2a–c**) in methanol at 0°C for 30 min and there after at room temp for 3 h, and then acidified with 10% HCl to pH 1. The resulting mixture was adjusted to pH 11 with aq $NH_3$ solution and extracted with ethyl acetate. The combined organic layer was washed with brine, dried ($Na_2SO_4$), and concentrated *in vacuo* to give off white solid.

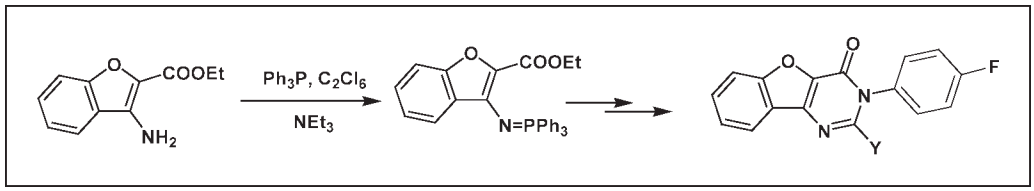
Published online 5 January 2010 in Wiley InterScience (www.interscience.wiley.com).



Carbodiimide, obtained from aza-Wittig reaction of iminophosphorane with 4-fluorophenyl isocyanate, reacted with various nucleophiles under mild conditions to give a series of 2-substituted-3-(4-fluorophenyl)-benzofuro [3,2-d] pyrimidin-4(3H)-ones in satisfactory yield. Their structures were confirmed using NMR, EI-Ms, IR, and elementary analysis, and compound **7b** was further analyzed by single-crystal. The preliminary bioassays indicated that these compounds showed moderate fungicidal activities against six kinds of fungi at a concentration of 50 mg/L.

## INTRODUCTION

Benzofuropyrimidinones are important heterocycles bearing remarkable biological activities. Some of them have shown good analgesic, anti-inflammatory, and antimicrobial activities [1–3], whereas others exhibited good anticoccidial and blood sugar-lowering activities [4,5]. On the other hand, many examples have been demonstrated that incorporation of fluorine atom in molecular structure of heterocyclic compounds often resulted in the improvement of pharmacological properties of the compounds as compared to their non-fluorine analogs [6,7]. The introduction of a fluorine atom to the benzofuropyrimidinone system is expected to influence the biological activities significantly. However, there is no report of a generally useful synthesis of 2-substituted-3-(4-fluorophenyl)-benzofuro [3,2-d] pyrimidin-4(3H)-ones.

The aza-Wittig reactions of functionalized iminophosphoranes with isocyanates have been applied to produce carbodiimides, functional groups consisting of the formula N=C=N, able to undergo a plethora of heterocyclization reactions [8,9]. Here, in continuation of our earlier work [10,11], we wish to report a new method of the previously unreported incorporation of fluorine atom in molecular structure of benzofuropyrimidinones *via* the aza-Wittig reactions of functionalized iminophosphorane with 4-fluorophenyl isocyanate under mild condition, which synthesized 2-substituted-(4-fluorophenyl)-benzofuro [3,2-d] pyrimidin-4(3H)-ones.

## RESULT AND DISCUSSION

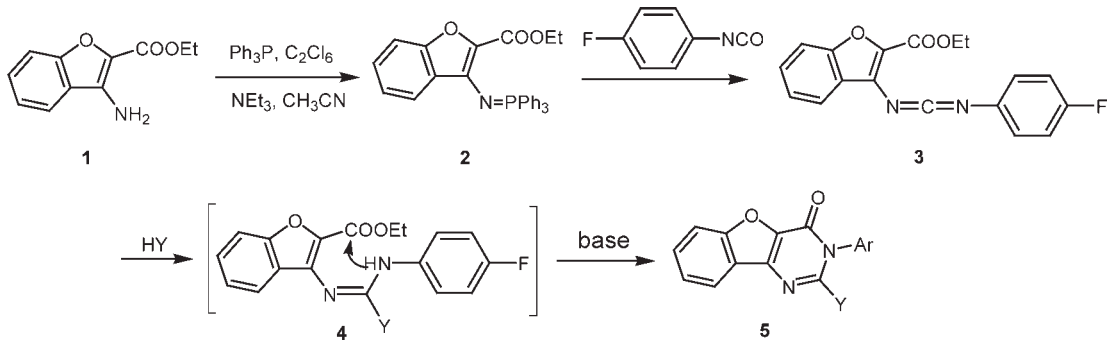
**Synthesis.** The iminophosphorane 2 reacted with *p*-fluorophenyl isocyanate to give carbodiimide 3, which were allowed to react with secondary amines to provide guanidine intermediates 4 ($Y=R_2N$). In the presence of catalytic amount of sodium ethoxide, 4 were converted easily to 2-dialkylamino-3-*p*-fluorophenyl-benzofuro [3,2-d] pyrimidin-4(3H)-ones 5 in satisfactory yields at room temperature (Scheme 1).

The reaction of carbodiimide 3 with phenols produced 2-aryloxy-3-*p*-fluorophenyl-benzofuro [3,2-d] pyrimidin-4(3H)-ones 5 (Y = ArO) in the presence of catalytic amount of potassium carbonate in good yields. The direct reaction of carbodiimide 3 with primary alcohol (ROH) gave 2-alkoxy-3-*p*-fluorophenyl-benzofuro [3,2-d] pyrimidin-4(3H)-ones 5 (Y = RO) in excellent yields in the presence of catalytic amount of $RO^-Na^+$. The results are listed in Table 1.

The reaction of carbodiimide 3 with primary amine $RNH_2$ in the presence of $EtO^-Na^+$ produced only 2-alkylamino-3-*p*-fluorophenyl-benzofuro [3,2-d] pyrimidin-4(3H)-ones 7, and the other isomer 8 was not found (Scheme 2). The same selectivity was also observed in similar cases [11]. The results are also listed in Table 1.

The structures of all products were confirmed using NMR, IR, elemental analysis, and MS. The structure of **7** was deduced from its $^1$H NMR data. Among the possible regioisomers, we obtained only **7** from the reaction mixture after recrystallization; the other isomer **8** was

**Scheme 1**



not found by $^1$H NMR analysis of the reaction mixture. Furthermore, a single crystal of **7b** was obtained from a $CH_2Cl_2$ solution of **7b**. X-ray structure analysis verified again the proposed structure [12] (Fig. 1), which showed that all ring atoms in the benzofuro [3,2-d] pyrimidinone system are essentially coplanar; the C15-C20 phenyl ring is twisted with respect to it, with a dihedral angle of 87.35(3)°. Intermolecular C---H. . .O and N---H. . .O hydrogen bonds link the molecules, helping to stabilize the crystal structure. Further stability the crystal structure is provided by offset π–π stacking interactions involving the fused benzofuro [3,2-d] pyrimidin system moieties.

**Fungicidal activity.** The fungicidal activities of compounds **5** and **7** were screened against six kinds of fungi, *Fusarium oxysporum, Rhizoctonia solani, Botrytis cinerea, Gibberella zeae, Dothiorella gregaria,* and *Colletotrichum gossypii* at a concentration of 50 mg/L according to the reported method [13] and the results are also listed in Table 2. It was found that the compounds showed moderate fungicidal activities when fluorine atom was introduced. As a result, fluorine containing compounds **5i** (79%) displayed better fungicidal activities than non-substituted phenyl compounds **5j** (42%) to *B. cinerea*.

In conclusion, we have developed an efficient synthesis of 2-substituted-3-(4-fluorophenyl)-benzofuro [3,2-d] pyrimidin-4(3H)-ones *via* the aza-Wittig reactions of functionalized iminophosphorane with 4-fluorophenyl isocyanate. Because of the mild reaction condition, good yields, easily accessible starting material, and straightforward product isolation, we think that the versatile synthetic approach discussed here in many cases compares favorably with other existing methods. The preliminary bioassay indicated that all compounds showed moderate fungicidal activities against six kinds of fungi, *F. oxysporum, R. solani, B. cinerea, G. zeae, D. gregaria,* and *C. gossypii* at a concentration of 50 mg/L.

ured on a Finnigan Trace MS spectrometer. Elemental analyses were taken on a Vario EL III elementary analysis instrument. The melting points were determined on X4 microscopic melting apparatus (uncorrected). All the solvents and materials were reagent grade and purified as required.

**General procedure for the preparation of 2-dialkylamino-3-(4-fluorophenyl)-benzofuro [3,2-d] pyrimidin-4(3H)-ones 5a–5d.** To a solution of iminophosphorane **2** (0.93 g, 2 mmol) in dry methylene chloride (15 mL) was added *p*-Fluorophenyl isocyanate (2 mmol) under nitrogen at room temperature. After the reaction mixture was stood for 8–12 h at 0–5°C, the solvent was removed off under reduced pressure and ether/petroleum ether (1:2, 20 mL) was added to precipitate triphenylphosphine oxide. After filtration, the solvent was removed to give carbodiimide **3**, which was used directly without further purification. To the solution of **3** prepared above in methylene chloride (15 mL) was added dialkylamine (2 mmol). After the reaction mixture was allowed to stand for 0.5–4 h, the solution was condensed and anhydrous ethanol (10 mL) with several drops of $EtO^-Na^+$ in EtOH was added. The mixture was stirred for 1–4 h at room temperature. The solution was concentrated under reduced pressure and the residual was recrystallized from ethanol and dichloromethane (v/v = 1:1) at room temperature to give 2-substituted-benzofuro [3,2-d] pyrimidin-4(3H)-ones **5a–5d.**

**Fungicidal testing.** *F. oxysporium, R. solani, B. cinereapers, G. zeae, D. gregaria,* and *C. gossypii* were provided through the courtesy of the Center for bioassay, Central China Normal University. The tested samples were dissolved in 0.5 mL of DMF, added to a drop of emulsifying agent (Tween 80) and sterile water at a concentration of 500 mg/L. The solutions (1 mL) were mixed rapidly with thawed potato glucose agar culture medium (9 mL) under 50°C. The mixtures were poured into Petri dishes. After the dishes were cooled, the solidified plates were incubated with 4 mm mycelium disk, inverted, and incubated at 28°C for 48 h. The mixed medium without

sample was used as the blank control. Three replicates of each test were carried out. The mycelial elongation radius (mm) of fungi settlements was measured after 48 h of culture. The growth inhibition rates were calculated with the following equation: $I = [(C-T)/C] \times 100\%$. Here, $I$ is the growth inhibition rate (%), $C$ is the control settlement radius (mm), and $T$ is the treatment group fungi settlement radius (mm).

**Crystal structure determination.** Single crystal X-ray diffraction data for **7b** at 292 K on a Bruker Smart Apex Area CCD equipped with Mo Ka radiation ($\lambda = 0.71073$ A°). Crystallographic data (excluding structure factors) for the structures in this article have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC 671114. Copies of the data can be obtained, free of charge, on application to CCDC, 12 Union Road, Cambridge CB2 1EZ.

The derivatives of 5-substituted-2,4-thiazolidinedione have a broad spectrum of biological activities. In this article, new 5-(arylidene)-3-(4-methylbenzoyl)thiayolidine-2,4-diones **3a–k,** with arylidene groups such as 4-phenylbenzylidene **3a,** 3,4-dimethoxybenzylidene **3b,** 2-hydroxybenzylidene **3c,** 4-ethoxybenzylidene **3d,** 5-methyl-2-furfurylidene **3e**, 4-dimethylaminobenzylidene **3f,** 1-naphthylidene **3g,** 3,4-methylenedioxybenzylidene **3h,** 4-benzyloxybenzylidene **3i**, benzylidene **3j**, and 4-methoxybenzylidene **3k,** were synthesized by direct acylation of alkali metal salts of 5-arylidene-2,4-thiazolidinediones with 4-methylbenzoylchloride. Their structures were confirmed by elemental analysis, IR, $^1$H NMR and MS spectroscopy. In addition, crystal structure of the compound **3d** was determined using single-crystal X-ray diffraction data.

## INTRODUCTION

Thiazolidinone derivates are reported to show variety of biological activities. Depending on the substituents, especially thiazolidinediones can produce different pharmacological activities such as antibacterial, antifungal [1], anticonvulsant [2], antidiabetic [3], cyclooxygenase and lipogenase inhibitory [4], antioxidant [5], and antiproliferative [6] activity. Moreover, the importance of 5-substituted-2,4-thiazolidinedione and their derivatives is due to their biological activities including antimicrobial [1] and fungicidal activity [7], as well as their utilization in a variety of therapeutic areas [8–14].

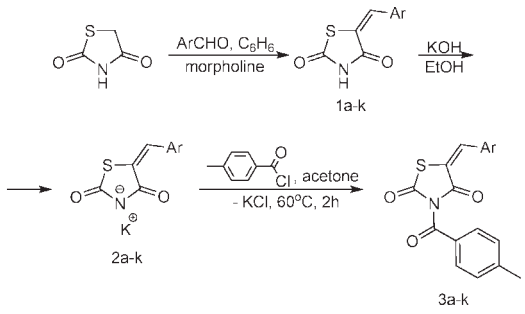
In some heterocyclylbenzenes [15,16] and substituted pyrazoles [17], which have herbicidal and defoliant characteristic, there is a 3-methylbenzoyl substructure. This study is focused on the link of 5-arylidene-2,4-thiazolidinediones and bioactive structural unit, 3-methylbenzoyl group, in order to find novel potential herbicides and defoliants. Crystal structure of the selected compound **3d** was also determined using single-crystal X-ray diffraction data.

## RESULTS AND DISCUSSION

The reactive methylene group of the 2,4-thiazolidinedione has previously been successfully condensed with aldehydes, forming respectively 5-arylidene-2,4-thiazolidinediones **1a–k** [18]. These compounds were later transformed in their potassium salts **2a–k** [19]. By direct acylation of solid alkali metal salts of 5-arylidene-2,4-thiazolidinediones with 4-methylbenzoylchloride in refluxing dry acetone the corresponding 5-(arylidene)-3-(4-methylbenzoyl)thiazolidine-2,4-diones **3a–k** were prepared. The obtained compounds **3a–k** were synthesized as yellow crystals in high yields (56.2–99.4%). The synthesis route is shown in Scheme 1.

All the newly synthesized compounds were characterized by elemental analysis, IR, $^1$H NMR, and MS (see

**Scheme 1**



Ar = $C_{12}H_9$ (a); 3,4-$(MeO)_2C_6H_3$ (b); 2-$OHC_6H_4$ (c); 4-$EtOC_6H_4$ (d); 5-$MeC_4H_2O$ (e); 4-$Me_2NC_6H_4$ (f); 1-$C_{10}H_7$ (g); 3,4-$OCH_2OC_6H_3$ (h); 4-$PhCH_2OC_6H_4$ (i); $C_6H_5$ (j); 4-$MeOC_6H_4$ (k)

''Experimental'' section). The elemental analysis and MS of 5-(arylidene)-3-(4-methylbenzoyl)thiazolidine-2,4-diones **3a–k**, agreed with the molecular formula of these compounds. The structure of synthesized compounds was confirmed by $^1$H NMR and IR spectroscopy. $^1$H NMR spectra 5-(arylidene)-3-(4-methylbenzoyl)thiazolidine-2,4-diones **3a–k,** clearly showed presence of benzoyl protons ($\delta \sim 7.3$ and 7.8 ppm) and methyl protons ($\delta \sim 2.45$ ppm) in comparison with spectra of 5-arylidene-2,4-thiazolidinediones **1a–k** [18]. IR spectra of all newly synthesized compounds **3a–k,** contain characteristic bands attributed to the methyl-benzoyl (C═O, about 1760 $cm^{-1}$) and benzoyl (about 1450 and 1600 $cm^{-1}$) vibrations that are used in the structural characterization of this type of compounds.

**Crystal structure of the compound 3d.** The molecular structure of compound **3d** is shown in Figure 1, and selected bond lengths and bond angles are listed in Table 1. Bond lengths and angles are in well agreement with some parent and similar compounds [20–22]. The main part of molecule, including the side ethoxy group, is almost planar with dihedral angle between benzylidene and thiazolidine-2,4-dione rings of only 5.8°. This is as expected, since practically the same angles (5.4°–5.9°) are found in some similar compounds [20,21]. The slight deviation from planarity can be attributed to the short repulsive S···H14–C14 contact with S···C14 distance of only 3.260(2) Å. On the other hand, dihedral angle between planes of thiazolidine-2,4-dione and methylbenzylidene rings is 67.1°.

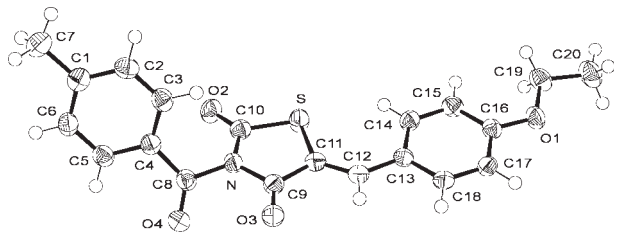


**Figure 1.** The molecular structure of compound **3d.**

The characteristic feature in crystal packing is the stacking of molecules in columns running along *b*-axis (Fig. 2). These columns further make a regular grid parallel to the planes (1 0 1) and (1 0 0) [Fig. 2(a)]. Within the columns there are stacking π−π interactions, which alternatively involve two benzylidene rings or pairs of both benzylidene and thiazolidine-2,4-dione rings [Fig. 2(b)]. As, for example, distances between planes of two benzylidene rings are only 3.32 and 3.33 Å the stacking π–π interactions can be described as very strong. In addition to van der Waals contacts, between the neighboring columns there are several C—H···O interactions involving mainly C atoms from terminal $CH_3$ groups, as well as few C atoms from 4-methylbenzoyl and benzylidene rings. In this way, the columns are only loosely connected to each other.

On the basis of presented crystal structure of **3d** compound it can be assumed that: (a) in all compounds (**3a–k**) the main part of molecule, including benzylidene and thiazolidine-2,4-dione rings, is almost planar; (b) π–π interactions between aromatic rings have a predominant role in molecular packing; (c) in all derivatives the C11—C12 bond is longer than double (C═C) bond, while the C12—C13 bond is shorter than the expected value for a single bond, probably because of delocalization of π-electrons through the whole substructure (C11═CH—$C_{arom}$). This delocalization is a reason why the attempts to carry out some addition reactions, which are inherent for the double bond, were unsuccessful.

## EXPERIMENTAL

**Materials and methods.** The solvent and all reagents used in this study were purchased from commercial suppliers and were used as received. The melting points were obtained with

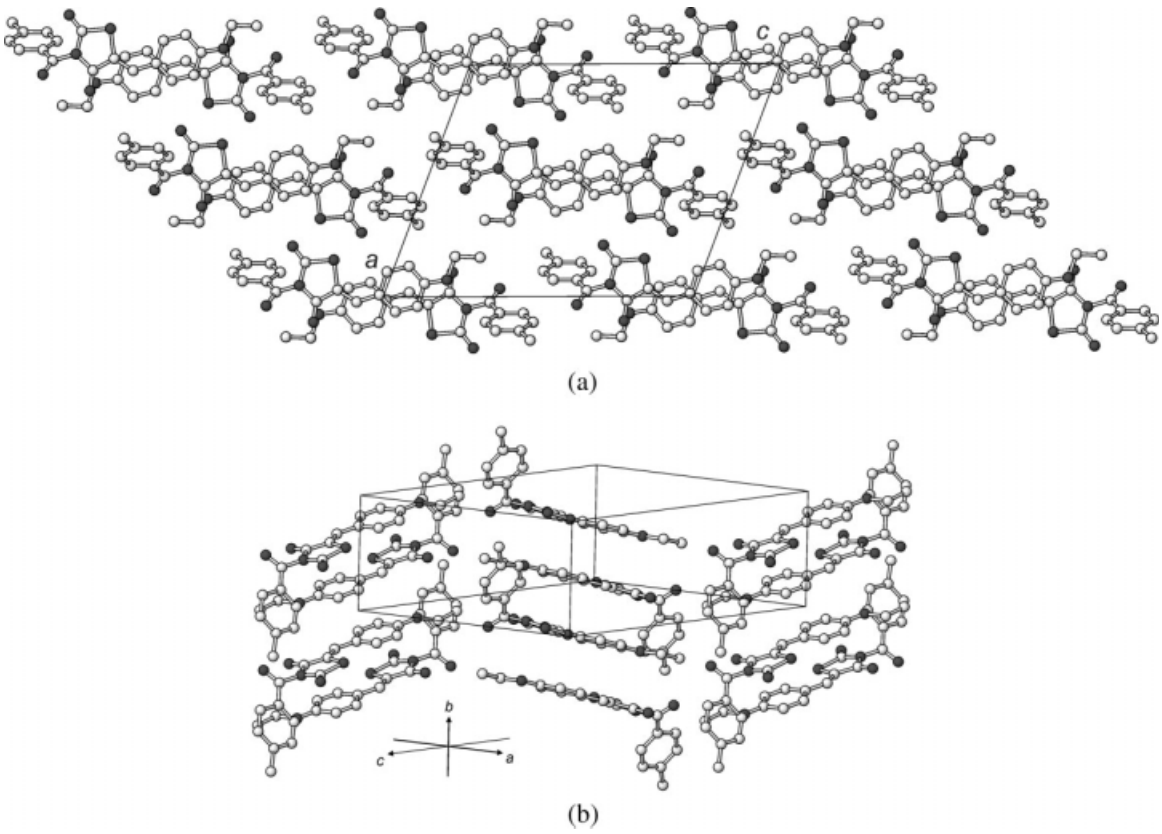

**Figure 2.** The packing of molecules **3d** (heteroatoms are dark, hydrogen atoms are omitted for clarity): (a) projection onto *ac*-plane and (b) projection approximately parallel to the (101) plane.

STUART SMP 10 melting point apparatus. Infrared spectra (ν in $cm^{-1}$) were recorded on a Perkin Elmer FTIR 1725 X spectrophotometer using KBr disks. The $^1H$ NMR spectra were recorded on a Varian Gemini 200 (200 MHz) instrument; chemical shifts (δ) are given relative to tetramethylsilane (TMS). The mass spectra were obtained on Finnigan MAT–8230 BE spectrometer with EI–CI source at 200°C, EI: 70 eV, 0.5 mA; CI: 1 m Torr of isobutane, 150 eV, 0.2 mA.

Single-crystals of the compound **3d** were obtained by recrystallization from EtOH. X-ray diffraction data were collected at 150 K on a Nonius Kappa CCD diffractometer using Mo Kα radiation. The structure was solved by direct methods and refined by a full-matrix least-squares procedure based on $F^2$ using the programs from WinGX suite [23]. All nonhydrogen atoms were refined anisotropically, while the hydrogen atoms were found in Δ$F$ maps and were refined isotropically with no constraints. Selected crystal data and refinement results are listed in Table 2.

**Syntheses.** ***General procedure for the preparation of the 5-(arylidene)-3-(4-methylbenzoyl)thiazolidine-2,4-diones 3a–k.*** 5-Arylidene-2,4-thiazolidinedione potassium salts (1 mmol) were suspended in dry acetone (20 mL) and 4-methylbenzoylchloride (1 mmol) was added at room temperature. The reaction mixtures were stirred at 60°C for 2 h and cooled to room temperature. Finally, the reaction mixtures were filtered and acetone was removed to give the crystalline products. The products were recrystallized from absolute EtOH.

**Table 2**

Crystal data and refinement details for **3d**.

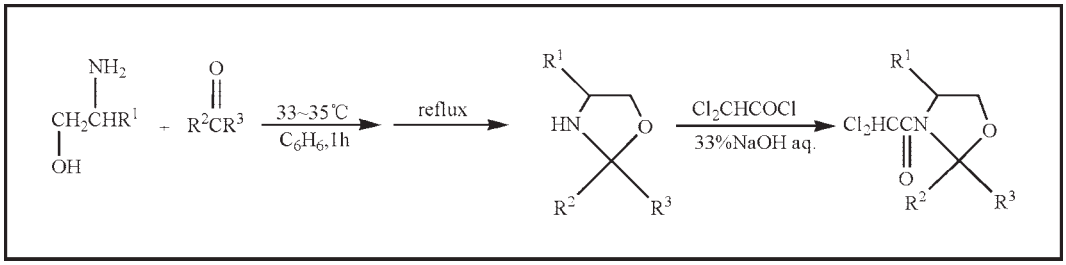
Published online 8 January 2010 in Wiley InterScience (www.interscience.wiley.com).



A short and efficient route of synthesis and structural characterization of a series of novel *N*-dichloroacetyl-1,3-oxazolidine derivatives has been developed. These new compounds characterized of the disubstitution at position 2 by alkyl, cycloalkane, and phenyl were synthesized in good yields via a sequential procedure involving condensation and acylation. All the compounds are characterized by IR, $^1$H NMR, $^{13}$C NMR, and element analysis.

## INTRODUCTION

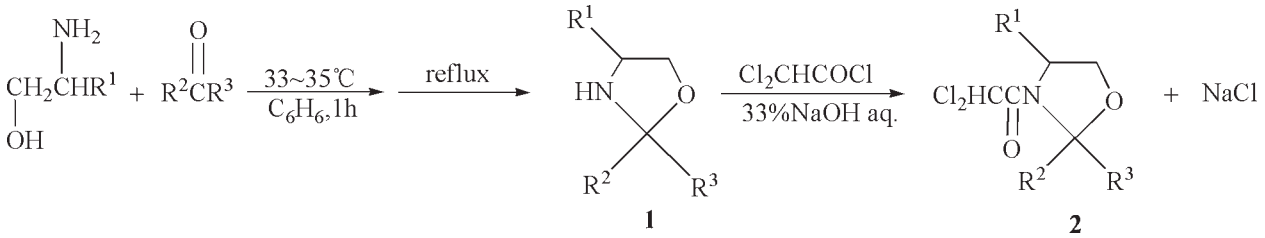
The herbicide safeners are chemicals that increase the tolerance of crop plants to herbicides without affecting the weed control efficacy [1]. Some reports indicate promising results for the development of safeners for postemergence herbicides in many kinds of crops. The discovery of *N*-dichloroacetyl compounds acted as herbicide safener by the mechanism of increasing the activities of glutathione-S-transferase (GST) and some herbicidal target enzyme has drawn widespread attention in agricultural biochemistry [2]. Now many *N*-dichloroacetyl compounds have been commercialized as herbicide safeners, such as benoxacor, dichlormid, furilazole, and so on. *N*-dichloroacetyl oxazolidines are becoming increasingly important for the development of excellent biologically active compounds [3]. According to the theory of structure and activity relationship (SAR), the substituent structure of the oxazolidines will influence the bioactivities. To investigate the relationship between the substituent structure and bioactivity, we designed and synthesized a series of *N*-dichloroacetyl oxazolidines with different substituents on 2 and 4 positions.

Oxazolidines are usually prepared from β-hydroxy amines by a [4+1] ring synthesis [4], and a few examples are reported from the [3+2] cycloaddition of azomethine ylides and carbonyl compounds (mostly benzaldehyde) [5], and in other ways [6]. The acylation of oxazolidines and dichloroacetyl chloride was achieved by using triethylamine as the attaching acid agent and benzene as the reaction medium [7]. Among the commonly used methods, we wished to find a novel and efficient method for the preparation of series of *N*-dichloroacetyl oxazolidine derivatives with different substituents with NaOH aq.acted as the attaching acid agent (Scheme 1). The structure of compounds were listed in Table 1.

## RESULTS AND DISCUSSION

We improved the synthetic route reported in the literatures [6,7] by using different attaching acid agent and reaction temperature without any catalyst. A possible mechanism for the reaction was depicted in Scheme 2. Reaction of an aldehyde or a ketone with β-amino alcohol yielded an open-chain imine, which existed in equilibrium with oxazolidine [8]. As oxazolidine can easily become an imine in the presence of alkaline over 18°C [9], we chose sodium hydroxide solution rather than triethylamine as the attaching acid agent. Triethylamine is soluble in the organic layer and rendered the organic phase where oxazolidine was present as strong alkaline. Under the alkaline condition, oxazolidine quickly became the imine, and hence oxazolidine could not be attained or were hard to be separated. In contrast,

**Scheme 1.** Route for the synthesis N-dichloroacetyl oxazolidines.



sodium hydroxide was insoluble in organic phase, and it not only kept the organic phase weak alkaline, but also reacted quickly with side product HCl. The by-product NaCl could be easily removed from the organic phase. The yields were higher when NaOH aq. acted as attaching acid agent (Table 2).

Another factor controlling the yield was temperature. Under the alkaline condition and with a temperature above 18°C, oxazolidine easily decomposed to imine (Scheme 2). Furthermore, the reaction of oxazolidine with dichloroacetyl chloride was exothermic. Therefore, logically we should employ a low reaction temperature. However, a suboptimal temperature would prolong the time required to add dichloroacetyl chloride and result in superfluous by-products. The reaction temperature was optimized at −5 to 0°C.

We also probed the effect of stirring time on yields. The result showed that the yields were higher when ethanolamine as the reaction agent than that of 2-amino-1-butanol. From the structure of **2h** we found that the ethyl steric hindrance effect hindered the reaction of dichloroacetyl chloride with oxazolidine. Furthermore, the electron donor inductive effect of ethyl (+I) of 2-amine-1-butanol decreased the protonation of amino and hydroxy, which makes it difficult for 2-amine-1-butanol to react with aldehyde or a ketone.

Finally, the single crystal of **2h** was obtained by dissolving it in the solvent of ethyl acetate and light petroleum, followed by slow evaporation. The colorless crystal with a dimension of 0.26 × 0.20 × 0.18 $mm^3$ was selected for X-ray diffraction analysis. The bond lengths and bone angles of the oxazolidine ring were both normal with the average bond length being 1.466 Å (Table 3). The average bond length of cyclopentyl was 1.501 Å, similar to C—C bond length (1.541 Å). The bond lengths of C4—N1 and C4—O1 being close to the typical C—N and C—O bond lengths, respectively (Fig. 1). The C5—O2 bond length of 1.222(3) Å was indicative of a double bond C=O (1.21–1.23 Å). The *p*-π conjunction between N1 and C5—O2 resulted in shorter bond length of C5—N1 [1.336(3) Å] than the typical C—N bond length (1.472 Å; Fig. 1).

In conclusion, we have developed a novel efficient one-pot synthesis of *N*-dichloroacetyl-1,3-oxazolidine derivatives via ring closure and acylation. The advantages of our approach are mild reaction conditions, short reaction time, easy work-up and high yields of products.

## EXPERIMENTAL

**Chemistry.** The infrared (IR) spectra were taken on a KJ-IN-27G infrared spectrophotometer (KBr). The $^1$H NMR spectra and $^{13}$C NMR spectra were recorded on a Bruker AVANVE 300 MHz nuclear magnetic resonance spectrometer with $CDCl_3$ as the solvent and TMS as the internal standard. The elemental analysis was performed on FLASH EA1112 elemental analyzer. The melting points were determined on Beijng Taike melting point apparatus (X-4) and uncorrected. All the reagents were of analytical reagents grade.

A total of 0.067 mol ethanolamine (or 2-amino-1-butanol) and 0.067 mol of aldehyde or ketone were mixed with 25 mL of benzene. The reaction mixture was stirred for 1 h at 33–35°C. Then the mixture was heated to reflux and water was stripped off, followed by cooling to 0°C and addition of 7.5 mL of 33% sodium hydroxide solution was added. 7.4 mL (0.08 mol) of dichloroacetyl chloride was added dropwise with stirring and cooling in an ice bath. Then stirring was continued for 2 h. The mixture was rinsed with water until pH = 7. The organic phase was dried over anhydrous magnesium sulfate and the benzene was removed under vacuum. **2d-h** was separated by column chromatography on silica gel. The crude products **2a-c** were recrystallized with ethyl acetate and light petroleum, white crystal was obtained.

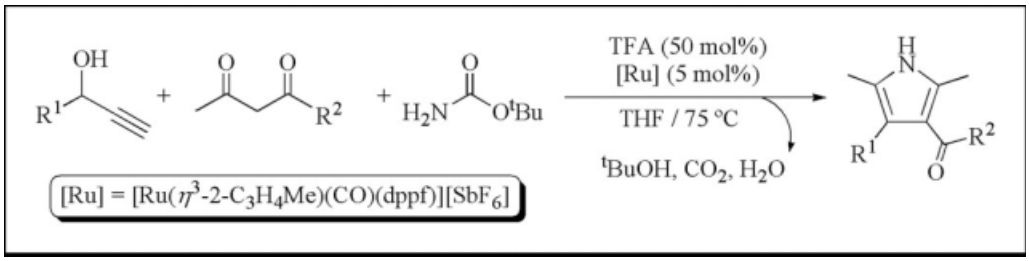
Published online 8 January 2010 in Wiley InterScience (www.interscience.wiley.com).



Several tetrasubstituted N—H pyrroles, functionalized with ester or ketone groups at C-3 position, were prepared by one-pot coupling of secondary propargylic alcohols with 1,3-dicarbonyl compounds and *tert*-butyl carbamate, *via in situ* deprotection of the corresponding pentasubstituted N-Boc pyrroles. The three-component coupling process was promoted by the combined use of the 16-electron ruthenium(II) catalyst [Ru($\eta^3$-2-$C_3H_4$Me)(CO)(dppf)][$SbF_6$] (dppf = 1,1′-bis(diphenylphosphino)ferrocene) and trifluoroacetic acid (TFA).

*J. Heterocyclic Chem.*, **47**, 233 (2010).

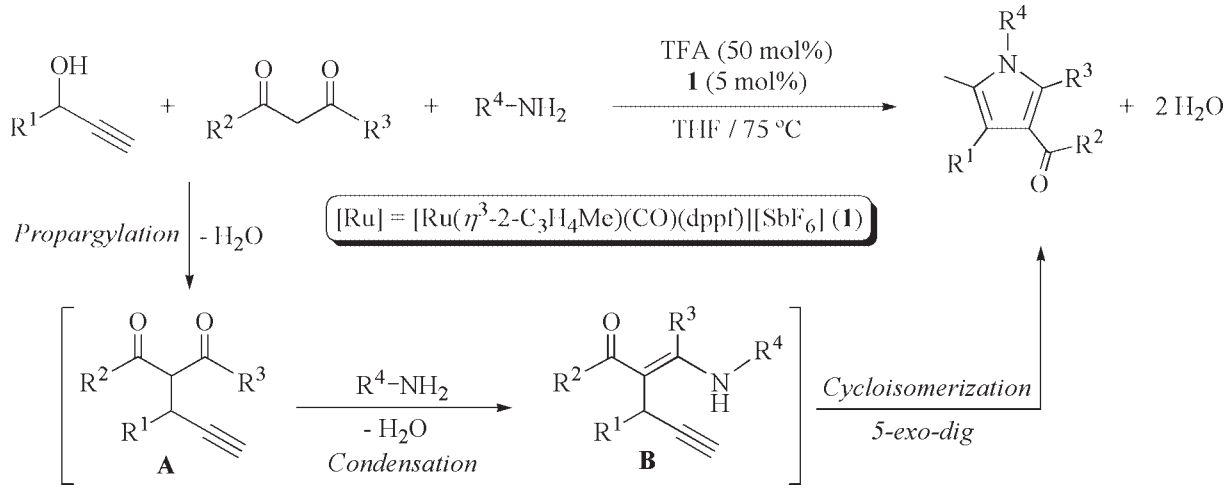
## INTRODUCTION

Pyrroles are one of the most prominent heterocyclic compounds, being present as key structural motifs in several natural products (for reviews, see [1]), conducting organic materials (for reviews, see [2]), and bioactive molecules (for reviews, see [3]). Consequently, a large number of general methods have been developed to construct these five-membered heterocycles, including the well-known Knorr, Paal-Knorr, and Hantzch syntheses, 1,3-dipolar cycloaddition reactions, reductive couplings, and aza-Wittig reactions (see, for example, [4]). However, it is still challenging to prepare polysubstituted pyrroles directly from inexpensive and readily available starting materials. In this sense, important efforts have been made during the last years in the design of multicomponent strategies (for reviews and highlights on pyrrole syntheses through multicomponent reactions, see [5] and for recent examples of multicomponent syntheses of pyrroles, see [6]). Multicomponent reactions (MCR), in which multiple reactants are combined into a single product, offer significant advantages over classical linear syntheses since molecular diversity can be reached from simple precursors in an efficient, economic, and environmentally friendly manner (see, for example, [7]).

In this context, we have recently described an efficient one-pot three-component coupling reaction for the synthesis of fully substituted pyrroles from secondary propargylic alcohols, 1,3-dicarbonyl compounds (β-diketones or β-keto esters), and primary amines (Scheme 1) [8]. The process, which is catalyzed by the 16-electron allyl-ruthenium(II) complex [Ru($\eta^3$-2-$C_3H_4$Me)(CO)(dppf)][$SbF_6$] (**1**; dppf = 1,1′-bis(diphenylphosphino)ferrocene) and trifluoroacetic acid (TFA), involves the initial propargylation of the 1,3-dicarbonyl compound promoted by TFA, subsequent condensation between the resulting γ-keto alkyne **A** and the primary amine to afford a β-enamino ester or ketone **B**, which undergoes a ruthenium-catalyzed 5-*exo-dig* annulation to give the final pyrrole (indium(III) chloride is also able to promote efficiently these propargylation/condensation/cycloisomerization tandem reactions [9]; we note that involvement of propargylic alcohols in multicomponent syntheses of pyrroles is scarcely documented [10]).

Following this route, which allows the direct introduction of carbonyl functionalities onto the pyrrolic skeleton and tolerates the presence of a wide variety of functional groups in the starting materials, a large number of pentasubstituted pyrroles could be synthesized in good to excellent yields [8]. As an extension of these studies, herein, we report on the applicability of this one-pot

**Scheme 1**



three-component reaction for the synthesis of tetrasubstituted N—H pyrroles.

## RESULTS AND DISCUSSION

In our first report, we already attempted the preparation of N—H pyrroles by coupling secondary propargylic alcohols with 1,3-dicarbonyl compounds in the presence of simple ammonia sources such as $NH_4OH$ or $NH_4Cl$. Unfortunately, the desired products were not formed using these inexpensive reagents, the reactions leading instead to the major formation of tetrasubtituted furans as the result of the known 5-*exo-dig* annulation of γ-keto alkyne intermediates **A** [11]. Only the use of propargylamine allowed us the preparation of this type of molecules (one example), *via* TFA-promoted scission of the C—N bond on the initially formed pentasubstituted *N*-propargyl pyrrole [8]. However, an extremely long reaction time (4 days) was required reducing considerably the synthetic interest of the process. This fact prompted us to search for a more appropriate NH source compatible with the propargylation/condensation/cycloisomerization sequence outlined in Scheme 1. Thus, our attention turned firstly to ammonium carbamate since it was successfully employed by Zhan and coworkers in related reactions using $InCl_3$ as promoter [9]. However, the reactions, which were performed in the presence of variable amounts of this reagent (1–10 equiv.), led again to the major formation of furans with only traces of the desired NH pyrroles being detected by GC/MS in the crude reaction mixtures. Neither the use of primary silylamines, such as $NH_2SiPh_3$, gave to the desired results. Finally, we were pleased to find that commercially available *tert*-butyl carbamate is compatible with our one-pot three-component reaction. Thus, as shown in Scheme 2, treatment of THF solutions of propargylic alcohols **2a–e** with ethyl acetoacetate and *tert*-butyl carbamate (1:1:1 molar ratio) in the presence of 50 mol % of TFA and 5 mol % of complex **1** led, after 24 h of heating (75°C), to the selective formation of pyrroles **3a–e**, which were isolated in 60–82% yield after appropriate chromatographic workup.

Characterization of **3a–e** was straightforward by following their analytical and spectroscopic data. In particular, the presence of the N—H unit was unambiguously confirmed by the appearance of: (i) an intense absorption band at about 3300 $cm^{-1}$ in their IR spectra, and (ii) a singlet signal at about 8 ppm in their $^1$H-NMR spectra. Pyrroles **3a–e** result from the TFA-mediated hydrolysis of the *tert*-butyl ester (Boc) group in the initially formed pentasubstituted pyrroles **C** (detected monitoring the reactions by GC/MS) and subsequent decarboxylation of the resulting intermediates **D** (The Boc group is a versatile and commonly used protecting group for the pyrrole nitrogen atom, being easily removable in acidic media. See, for example, [12]).

Following the same approach, NH-pyrroles **4a–d** and **5a–b** (Fig. 1) could also be synthesized in 64–79% yield employing methyl acetoacetate and 2,4-pentanedione as the 1,3-dicarbonyl compound, respectively, thus confirming the generality of this transformation.

In summary, an efficient MCR reaction for the preparation of tetrasubstituted N—H pyrroles, functionalized with carbonyl groups at C-3 position, has been developed using the catalytic system [Ru(η$^3$-2-$C_3H_4$Me)(CO)(dppf)][$SbF_6$]/TFA. The results reported herein represent a new example of the utility of the allyl-ruthenium(II) complex **1** in synthetic organic chemistry (for an account on the applications of complex **1** in synthesis, see [13]).

## EXPERIMENTAL

Infrared spectra were recorded on a Perkin-Elmer 1720-XFT spectrometer. NMR spectra were recorded on a Bruker DPX-300 instrument at 300 MHz ($^1$H) or 75 MHz ($^{13}$C). The chemical shift values (δ) are given in parts per million and are referred to the residual peak of the deuterated solvent used ($CDCl_3$). DEPT experiments have been carried out for all the compounds reported. GC/MS measurements were performed on a Agilent 6890N equipment coupled to a 5973 mass detector (70 eV electron impact ionization) using a HP-1MS column. Elemental analyses were acquired with a Perkin-Elmer 2400 microanalyzer. Flash chromatography was performed using Merck silica gel 60 (230–400 mesh). All reagents were obtained from commercial suppliers and used without any further purification, with the exception of complex **1** [14] and propargylic alcohols **2b–e** [15] which were prepared by following the methods reported in the literature.

**General procedure for the catalytic reactions.** The appropriate propargylic alcohol **2a–e** (1 mmol), 1,3-dicarbonyl compound (1 mmol), and *tert*-butyl carbamate (1 mmol) were introduced into a sealed tube under a nitrogen atmosphere. THF (0.5 mL), complex **1** (0.049 g, 0.05 mmol), and TFA (37 μL, 0.5 mmol) were then added at room temperature, and the resulting solution was heated at 75°C for 24 h. After elimination of the solvent under reduced pressure, the crude reaction mixture was purified by column chromatography over silica gel using an ethyl acetate/hexane mixture (1:10 v/v) as eluent. $^1$H and $^{13}$C{$^1$H} NMR spectra, as well as melting points, obtained for compounds **3a** [9], **3b** [16], **3d** [8], **3e** [9], **4a** [16], **4c** [16], **5a** [17], and **5b** [18] were in complete accord with those described in the literature. Characterization data for the novel pyrroles **3c** and **4b**,**d** are as follows:

***4-(3-Methoxyphenyl)-2,5-dimethyl-1H-pyrrole-3-carboxylic acid ethyl ester (3c)*** Orange solid; Yield: 0.169 g (62%); mp: 144°C; IR (Nujol): 3311 (N—H), 1683 (C=O) cm$^{-1}$; $^1$H-NMR (300 MHz, $CDCl_3$): δ 1.08 (t, $J$ = 7.1 Hz, 3H), 2.10, 2.49, and 3.80 (s, 3H each), 4.09 (q, $J$ = 7.1 Hz, 2H), 6.78–6.86 (m, 3H), 7.24 (m, 1H), 8.21 (s, 1H) ppm; $^{13}$C{$^1$H} NMR (75 MHz, $CDCl_3$): δ 11.1, 13.5, 14.0, 55.1, 59.0, 110.5, 111.3, 116.0, 122.1, 123.0, 123.5, 128.1, 133.5, 137.6, 158.7, 165.7 ppm; GC-MS (EI, 70 eV): *m*/*z* 273 (100%, M$^+$), 244 (60), 227 (55), 198 (18), 184 (25), 168 (20), 156 (15), 115 (15); Anal. Poly(ethylene glycol) (PEG-400) has been used as sustainable, nonvolatile, and environmental friendly reaction solvent for the synthesis of title compounds. Various diaryl pyrido[3,2-c]coumarins have been synthesized in one step by reacting 4-hydroxy-7-methyl-coumarin with α,β-unsaturated ketones in the presence of ammonium acetate. Further, *in vitro* antimicrobial (antibacterial and antifungal) activities of the compounds were screened against different pathogens. The results revealed that most of them showed potent activity.

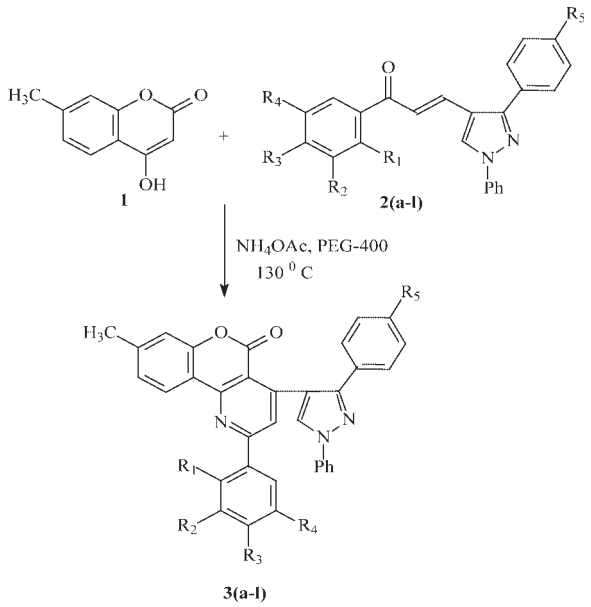
*J. Heterocyclic Chem.*, **47**, 237 (2010).

## INTRODUCTION

Coumarins are well-known natural products and may exhibit high level of biological activity [1]. Coumarins are also used as food additives, in cosmetics [2], as optical brightening agents [3], dispersed fluorescent and laser dyes [4]. For instance, coumarin nucleus is present in promising drug candidates as nonpeptidic HIV protease inhibitors [5], topoisomerase II [6], and tyrosine kinase [7] inhibitors. Coumarins fused with pyridines have also been reported to posses antiallergic [8], anticoagulant [9], antidiabetic [10], and analgesic [11] properties, being characterized by a phenanthrene like structure as found in tetrahydrocannabinol. Pyrido[3,2-c]coumarin, the back bone of naturally occurring alkaloid, santiagonamine [12] isolated from Berberis Dawinii (Barberidaca). This alkaloid has interesting wound healing properties [13]. Owing to such interesting properties, synthesis of pyrido-coumarins has remained an active subject of interest. However, a survey of these literatures quotes reveals that the most of the methods are multistep or difficult starting materials. Hence, it

**Scheme 1**



was thought worthwhile to envisage a synthesis of pyrido-fused coumarins.

## RESULTS AND DISCUSSION

In view of the current emphasis on green chemistry [14], our approach is to reduce the use of solvents that are volatile organic compounds (VOCs), which are potentially toxic and hazardous [15]. Recently, liquid polymers or low-melting polymers have emerged as alternative green reaction media with unique properties such as thermal stability, commercial availability, nonvolatility, immiscibility with a number of organic solvents, and recyclability. Poly(ethylene glycols) (PEGs) are preferred over other polymers because they are inexpensive, completely nonhalogenated, easily degradable, and of low toxicity [16]. Many organic reactions have been carried out using PEGs as solvent or cosolvent such as Heck reaction [17], asymmetric dihydroxylation [18], Suzuki crosscoupling reaction [19], oxydehydrogenation of alcohols and cyclic dienes, oxidation of sulfides and the Wacker reaction [20], and partial reduction reaction of alkynes [21]. The use of PEG as a recyclable solvent system for the metal mediated radical polymerization of methyl methacrylate and styrene has also been reported [22].

As quoted by Kroehnke [23], reaction of α,β-unsaturated ketones with the active methylene function of phenacyl bromide pyridinium salt of ammonium acetate and acetic acid yields pyridine. This methodology has been successfully utilized by us for the synthesis of variety of pyridyl substituted coumarins. In this article, here, we wish to report the expeditious synthesis of novel pyrido-fused coumarin derivatives (**3a–l**) under benign reaction solvent.

The starting 4-hydroxy-7-methyl-coumarin (**1**) was prepared by the literature procedure using an appropriately *m*-cresol and malonic acid, a Lewis acid ($ZnCl_2$) and as condensing agent phosphorous oxychloride ($POCl_3$), whereas the α,β-unsaturated carbonyl compounds (**2a–l**) were already reported [24]. Thus, various 2,4-diaryl pyrido[3,2-c]coumarins **3**(**a–l**) have been synthesized by reacting 4-hydroxy-7-methyl-coumarin **1** with α,β-unsaturated ketones **2**(**a–l**) in the presence of ammonium acetate in PEG-400 (Scheme 1).

**Mechanism of pyrido-coumarin formation.** The formation of products **3**(**a–l**) involves the Kroehnke's mechanism. Mannich bases provide the required α,β-unsaturated ketones *in situ* during the course of reaction, to which the Micheal addition of coumarioyl methyl pyridinium salts takes place resulting in a 1,5-dionyl pyridinium (not isolated) derivative, which subsequently cyclization in the presence of ammonium acetate afford the 2,4-diaryl pyrido[3,2-c]coumarins (Scheme 2). The

[b] Pure isolated yields of products.

presence of IR absorption bands in the region 1660–1690 $cm^{-1}$ clearly indicates that >C=O group of chalcone has been transformed into coumarin (lactone). $^1H$ NMR revealed that singlet of methyl proton at δ 2.30–2.50 ppm. The multiplet at δ 7.00–8.20 is due to aromatic protons. A singlet of phenolic proton appeared at δ 11.00–12.50 ppm ($D_2O$ exchangeable).

In summary, we have demonstrated an efficient, one-pot method toward the expeditious synthesis of 2,4-diaryl pyrido[3,2-c]coumarins using PEG-400 as an alternative reaction solvent. The advantages of the present protocol are the simplicity of operation, the high yields of products, the recyclability of PEG-400 and preclusion of the usage of volatile organic solvents. Antimicrobial and antifungal activities of the all synthesized compounds were summarized in Table 2. The compounds **3b**, **3d**, **3e**, **3f, 3h**, **3j**, and **3l** showed good antibacterial activity against one or more bacteria. Compounds **3a**, **3c**, **3d**, **3i**, and **3k** were found to be active against *Escherichia coli*. On the other hand, the compounds **3i**, **3k** was found to be active against *Salmonella typhi*. The compounds **3i**, **3j**, and **3k** were also found to be active against *Bacillus subtilis*. Most of the compounds showed inhibitory effect against fungi. The compounds **3a**, **3c**, **3d**, **3g**, **3j**, and **3l** showed most potent activity against all pathogens than other tested compounds. The substitution of hydroxyl group in position 2 and presence of halo groups in 3 and 5 positions of aryl nucleus, which may enhance the antimicrobial activity of the products against various pathogens.

## EXPERIMENTAL

Melting points were determined by open capillary method and were uncorrected. IR spectra were recorded (in KBr pallets) on Shimadzu spectrophotometer. $^1H$ NMR spectra were recorded (in DMSO-$d_6$) on Avance-300 MHz spectrometer using TMS as an internal standard. The mass were recorded on EI-Shimazdu-GC-MS spectrometer. Elemental analyses were performed on a Carlo Erba 106 Perkin-Elmer model 240 analyzer.

### Chemistry

***General procedure for the synthesis of α,β-unsaturated carbonyl compounds (2a–l)[24].*** A mixture of substituted 2-hydroxy acetophenone (5 mmol), 1-phenyl-3-(4-sustituted phenyl) pyrazol-4-carboxaldehyde (5 mmol), KOH (1 mmol), and PEG-400 (20 mL) was stirred at 40°C for 1 h. After completion of the reaction (monitored by TLC), the crude mixture was worked up in ice cold water (100 mL). Separated product was filtered out. The PEG-400 was recovered from water and utilized to synthesize further chalcones.

***Typical procedure for the synthesis of 2,4-diaryl pyrido[3,2-c]coumarins (3a–l).*** To a well-stirred solution of 4-hydroxy-7-methyl-coumarin **1** (0.528 g; 6 mmol) in PEG-400 (20 mL) was added ammonium acetate (6.0 g) followed by chalcone **2a** (2.514 g; 6 mmol) in PEG-400 (10 mL). The reaction mixture was stirred at room temperature for 30 min and then refluxed gently on oil-bath at 130°C for the period as shown in Table 1. After completion of the reaction (checked by TLC), the reaction mixture was allowed to reach room temperature and was poured into ice cold water (100 mL). The resultant solid was filtered, washed with 2 × 5 mL ice cold water and recrystallized by chloroform to give pure product **3a**.

To check the reusability of the solvent, the filtrate was evaporated to remove water leaving PEG behind in the container and subjected for second run by charging the same substrates. The results of the first and second experiments were almost consistent in yield.

**Biology.** All the synthesized compounds **3(a-l)** were screened for their *in vitro* antimicrobial activity by agar well diffusion method [25]. Antibacterial activity was checked against bacteria *Escherichia coli*, *Salmonella typhi*, *Staphylococcus aureus*, and *Bacillus subtilis*. The culture strains of bacteria maintained on nutrient agar slant at 37 ± 2°C temperature for 24–48 h. Antifungal activity was studied against *Aspergillus niger*, *Aspergillus flavus*, *Penicillium chrysogenum*, and *Fusarium moniliforme*. The results were compared with *Penicillin* and *Nystatin*, respectively. All the culture strains of fungi maintained on potato dextrose agar (PDA) slant at 27 ± 2°C temperature for 24–28 h, till sporulation. Spore of strains were transferred in 5 mL of sterile water containing 1% Tween-80 (to suspend the spore properly). The spores were counted by Hemocytometer ($10^6$ CFU/mL). Sterile plate PDA was prepared containing 2% agar 0.1 mL of each fungal spore suspension was spread on each plate and incubated at 27 ± 2°C temperature for 12 h. After incubation well prepared using sterile cork borer and each agar well was filled with 0.1 mL pyrido coumarin solution of concentration 50, 100, and 250 μg/mL for screening minimum inhibitory concentration (MIC). Dimethyl sulfoxide (DMSO) was used as control without compound.

The plates were kept in refrigerator for 20 min for diffusion and then incubated at 27 ± 2°C temperature for 24–28 h in incubator. After incubation, zone of inhibition of compounds was measured in millimeters, along with control and standard. MIC value of pyrido coumarins was obtained 100 μg/mL for both antibacterial and antifungal activity. Results of the study are shown in Table 2.

**Acknowledgments.** The authors gratefully thank the Principal, Yeshwant Mahavidyalaya, Nanded, for providing laboratory facilities. We also thank the Director, IICT, Hyderabad, for providing necessary instrumental facilities.

This review summarizes the methods for preparing 1*H*-benzimidazole-2-acetonitriles and their reactions in the past years, some of which have been applied to the synthesis of biologically active molecules. The main reactions are divided into several groups according to some types of the fused benzimidazoles.

*J. Heterocyclic Chem.,* **47**, 243 (2010).

**Contents** **Page**

## 1. INTRODUCTION

1*H*-Benzimidazole-2-acetonitriles are convenient precursors which have been extensively utilized in heterocyclic synthesis. Many reactions were developed in the last decades for which the reactivity of 1*H*-benzimidazole-2-acetonitriles towards diverse reagents was utilized for the synthesis of nitrogen bridged heterocycles. From the point of view for biological activities, benzimidazole derivatives are useful intermediates and subunits for the development of molecules having pharmaceutical or biological interests [1,2]. Also, substituted benzimidazole derivatives have found applications in diverse therapeutic areas such as antiulcer drugs, anticancer drugs, antiviral drugs, and antiprotozoan species [3–6]. The main purpose of this review is to present a survey of the literature on the synthesis and reactions of 1*H*-benzimidazole-2-acetonitriles during the last decades.

**1**

## 2. METHODS FOR SYNTHESIS OF 1*H*-BENZIMIDAZOLE-2-ACETONITRILES

Two major approaches have been developed for the synthesis of 1*H*-benzimidazole-2-acetonitriles. The first approach involves the construction of the 1*H*-benzimidazole-2-acetonitriles by cyclization of *o*-phenylenediamine derivatives with reagents such as cyanoacetic acid ester, ethyl 2-cyanoacetimidate, and cyanoacetamide. The second method entails ring transformation of benzodiazepine-3-carbonitrile.

**2.1. From *o*-phenylenediamine derivatives.** 1*H*-Benzimidazole-2-acetonitriles **1** were synthesized by fusion of *o*-phenylenediamines and cyanoacetate at high temperature (Scheme 1) [7–15].

Katsuyama and Kubo have been reported the synthesis of 5-hydroxymethyl-1*H*-benzimidazole-2-acetonitrile **2** starting from 3,4-diaminobenzoic acid (Scheme 2) [16].

Ethyl 2-cyanoacetimidate hydrochloride was converted into 1*H*-benzimidazole-2-acetonitrile **3** by fusion with 1,2-phenylenediamine (Scheme 3) [17].

Compound **3** was prepared by condensation of 1,2-phenylenediamine with cyanoacetamide in an inert organic solvent (Scheme 4) [18].

Cyclocondensation of enaminonitriles (R = $CO_2Et$, Bz) with *o*-pheylenediamine gave 1*H*-benzimidazole-2-acetonitrile **4** (Scheme 5) [19].

**2.2. Ring transformation of benzodiazepine-3-carbonitrile.** Treatment of benzodiazepine-3-carbonitrile **5** with methoxyamine hydrochloride resulted in the ring transformation of oxime **6** whose hydrolysis and neutralization gave the target molecule (Scheme 6) [20,21].

Ring cleavage of benzodiazepines **7** (R = Me, Et) with methylamine provided dihydropyrimidines **8**, which underwent ring transformations and hydrolysis to furnish 2-(1*H*-benzo[*d*]imidazol-2-yl)-3-(methylamino)acrylonitrile **9** (Scheme 7) [22].

## 3. SYNTHESIS OF FUSED BENZIMIDAZOLES

**3.1. Pyrrolobenzimidazoles.** Elwan has reported the synthesis of pyrrolo[1,2-*a*]benzimidazoles **12**. The reaction of 1*H*-benzimidazole-2-acetonitrile **3** with hydrazonoyl halides (**10a**, X = Cl; $R_1$ = Me; $R_2$ = H, Cl, Me; **10b**, X = Br; $R_1$ = Ph; $R_2$ = H, $NO_2$, Me) in the presence of triethylamine led to the formation of pyrrolo[1,2-*a*]benzimidazoles **12**. It has been suggested that the reaction starts from the nucleophilic substitution of the halogen with the benzimidazole carbanion to provide intermediate **11**, which upon dehydration gives the pyrrolobenzimidazoles **12** (Scheme 8) [23].

Awadallah *et al*. revised the structure of **12** into the 3-arylazo-2-methylpyrrolo[1,2-*a*]benzimidazoles (**13**, Ar = 4-Cl-$C_6H_4$, 4-Br-$C_6H_4$) by the X-ray crystallography (Scheme 9) [24].

On the other hand, the reaction of hydrazonoyl chlorides (**14** X = Cl; $R_1$ = Et; $R_2$ = H, Cl, Me, $NO_2$; $R_2$ = H; $R_1$ = Me; $R_2$ = Cl) with 1*H*-benzimidazole-2-acetonitrile **3** in the presence of sodium ethoxide yielded the pyrazolopyrrolobenzimidazole **16** *via* the intermediates **15** (Scheme 10) [23,25].

Condensation of the benzimidazoline **17** with the 2-aminothiophene-3-carboxylates **18** [$R_1$ = Ph, $R_2$ = H (**18a**); $R_1R_2 = (CH_2)_4$ (**18b**)] in DMF at 100°C provided the tetrahydropyrrolothienopyrimidinediones **19** in 42–67% yields. The reaction of compound **17** with triethylamine produced pyrrolobenzimidazole **20**. This reactivity was explained in terms of steric factors of **17** in which the substituent shields the heterocyclic nitrogen atom and hinders intramolecular alkylation (Scheme 11) [26].

Reaction of dichloromaleimide with 1*H*-benzimidazole-2-acetonitriles followed by intramolecular cyclization of **21** furnished 1,3-dioxo-1,3-dihydropyrrolo [3′,4′:4,5]pyrrolo[1,2-*a*]benzimidazoles **22** (R = H, Me) [27] (Scheme 12).

The pyrrolo[1,2-*a*]benzimidazole-3-carbonitrile **24** was prepared by reaction of compound **3** with oxalic acid bis(*p*-tolylimidoyl) chloride **23** in the presence of triethylamine (Scheme 13) [28].

Treatment of 1-alkyl-4,5-dichloro-3-nitropyridazin-6-one (**25**, $R_1$ = Et, Me) with ambident nucleophiles (*i.e*., 1*H*-benzimidazole-2-acetonitriles) in the presence of potassium carbonate led to selective substitution of a chorine

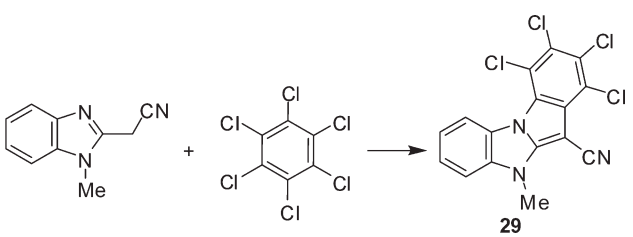
atom by the quaternary carbon atom of the carbanion formed from a substituted acetonitrile **26** (Scheme 14) [29].

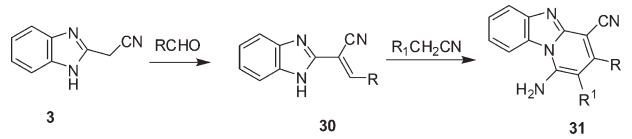
Reaction of 2,3-dichloro-5,6-dicyanopyrazine with **3** led to α-(3-chloro-5,6-dicyanopyrazin-2-yl)-α-(2-azaheteroaryl)acetonitriles **27**. Subsequent heating in pyridine causes an intramolecular cyclization to yield condensed pyrrolo[*b*]pyrazine **28** (Scheme 15) [30].

The nucleophilic substitution reaction of hexachlorobenzene with 1-methyl-1*H*-benzimidazole-2-acetonitrile yielded the condensed indole **29** (Scheme 16) [31].

**Scheme 16**



**Scheme 17**



**3.2. Pyridobenzimidazoles.** Condensation of the pyridine ring with benzimidazole, that is, the passage to pyridobenzimidazoles, extended the spectrum of biological activity [32,33]. The main methods for preparation of pyridobenzimidazoles starting from 2-cyanomethylbenzimidazoles can be occurred *via* Knoevenagel reaction followed by cyclocondensation, Michael addition, reaction with enaminones, and cyclocondensation with β-dicarbonyl compounds.

***3.2.1. Knoevenagel reaction.*** Cyclization of **30** with malononitrile or ethyl cyanoacetate (R = aromatic subs.; $R_1$ = CN, $CO_2Et$) in ethanol in the presence of piperidine produced pyridobenzimidazoles **31**(Scheme 17) [34].

Highly fluorescent 7-(diethylamino)benzimidazo[1,2-*a*]quinoline-3-carbonitrile **33** was prepared by cyclization of 4-(diethylamino)-2-methoxybenzaldehyde **32** with **3** (Scheme 18) [35].

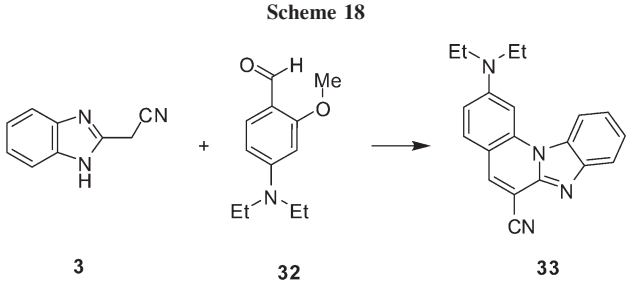
Reaction of the **3** with 2,6-dihalobenzaldehydes (**34**, X = F, Cl, Br) in dioxane led to cinnamonitriles **35** and intramolecular cyclization in DMF benzo[4,5]imidazo[1,2-*a*]quinoline-6-carbonitriles **36** which was obtained directly by refluxing in DMF containing triethylamine (Scheme 19) [36,37].

1-Aryl-3-chloro-4-isoquinolinecarbaldehydes (**37**; R = 4-chlorophenyl, 2,3-dichlorophenyl, 3- and 4-nitrophenyl) were condensed with **3** in DMF to produce diheteroarylpropenenitriles (**38**, same R), which cyclized to yield **39** (same R) [38] (Scheme 20).

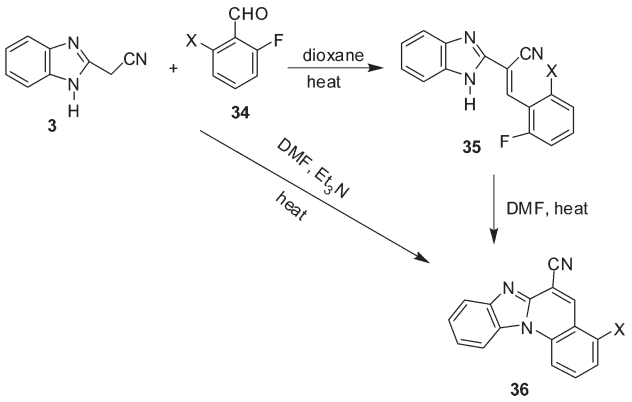
The condensation of 1-phenylpyrazole-4-carboaldehydes (**40**, R = Me, Ph) with benzimidazole-2-acetonitrile **3** led to the formation of fluorescent 3-methyl-1-phenyl-1*H*-pyrazolo[4.3:5,6]pyrido[1,2-*a*]benzimidazole-5-carbonitrile **41**. Similar condensation of 2-chloro-7-methylquinoline-3-carbaldehyde **42** furnished the corresponding 1,2-fused benzimidazo heterocycle **43** (Scheme 21) [39,40].

Chromenes (**44**, R = H, Cl, Br, Me, Et) reacted with **3** in ethylene glycol to yield pyridobenzimidazoles **45** in 65–80% yields (Scheme 22) [41].

**Scheme 18**



**Scheme 19**



Ring transformations of pentose glycals (**46**, $R_1$ = H, $R_2$ = BnO; $R_1$ = BnO, $R_2$ = H) with **3** furnished the pyridiobenzimidazoles **47** (Scheme 23) [42,43].

Vilsmeier-Haack reaction of 3-β-acetoxyandrostan-17-one **48** with phosphorus oxychloride and DMF produced 3-β-acetoxy-17-chloro-16-formyl-5α-androst-16-ene **49**. Reaction of **49** with 1*H*-benzimidazole-2-acetonitrile **3** in refluxing ethanolic solution furnished benzimidazolopyridoandrostane **51** in 82% yield, However, the intermediate **50** was yielded in 70% in the presence of piperidine (Scheme 24) [44].

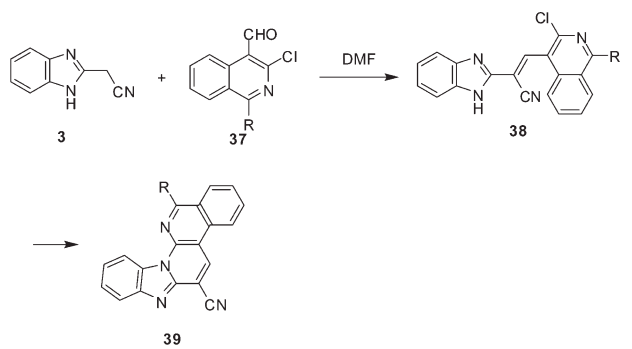
***3.2.2. Michael addition.*** Michael addition of **3** to chalcone in ethanol having a catalytic amount of piperidine led to the formation of pyridobenzimidazole **52** (Scheme 25) [45,46].

Addition of 1*H*-benzimidazole-2-acetonitrile **3** to arylidenemalononitrile **53** produced 1-amino-3-aryl pyrido[1,2-*a*]benzomidazole-2,4-dicarbonitrile **54** (R = aryl). Compounds **54** reacted with formamide yielding 4-amino-5-arylpyrimido[5′,4′:5,6]pyrido[1,2-*a*]benzimidazole-6-carbonitrile **55** (R = aryl) [47,48] (Scheme 26).

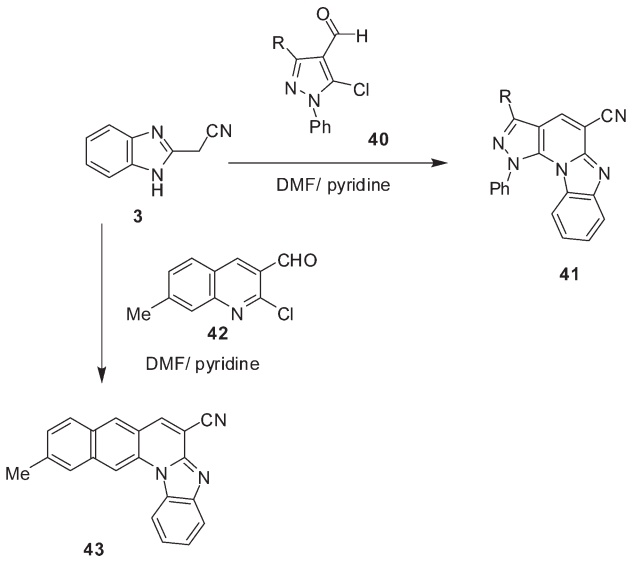
Reaction of arylidene-1*H*-benzimidazol-2-ylacetonitriles **56** with 1*H*-benzimidazole-2-acetonitrile **3** furnished pyrido[1,2-*a*]benzimidazole **57** (Scheme 27) [49].

The formation of pyridobenzimidazole **61** can be achieved by addition of active methylene component **3**

**Scheme 20**



**Scheme 21**



to 4-ethoxymethylene-2-phenyl-5-oxazolone **58** to form the intermediate **59**, which underwent intramolecular acylation at the nitrogen atom of benzimidazole nucleus with cleavage of oxazolone ring to form intermediate **60**. Finally, elimination of ethanol furnished pyridobenzimidazole **61** (Scheme 28) [50].

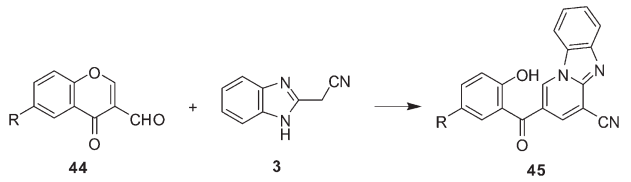
Ethyl 2-cyano-3-(5-chloro-1,3-diphenylpyrazol-4-yl)acrylate **62** underwent Michael addition with **3** to produce pyrido[1,2-*a*]benzimidazole **63** (Scheme 29) [51].

Cyclocondensation of 3-aryl-2-(2-benzimidazolyl)acrylonitrile **64** (R = 1-naphthyl, Ph, 4-$MeOC_6H_4$, 4-$ClC_6H_4$) with ethyl acetoacetate and cyanoacetohydrazide gave pyridobenzimidazolones **65**, and aminopyridobenzimidazoles **66**, respectively (Scheme 30) [52].

Treatment of 1-(methyl 2-*O*-benzyl-4,6-*O*-benzylidene-3-deoxy-α,α-*D*-altropyranosid-3-yl)-4-phenyl-but-3-yn-2-one **67** with **3** produced benz[4,5]imidazo[1,2-*a*]pyridine-4-carbonitrile derivative **68** (Scheme 31) [53].

***3.2.3. Reaction with enaminones.*** Enaminone derivatives are highly reactive intermediates and are extensively used for the synthesis of heterocyclic compounds. Dawood *et al*., have reported the synthesis of pyrido[1,2-*a*]benzimidazole derivative **70** by reaction of 1-(benzo[d]thiazol-2-yl)-3-(dimethylamino)prop-2-en-1-one **69** with **3** in ethanol in the presence of piperidine (Scheme 32) [54].

**Scheme 22**



The reaction of enaminonitrile **71** with **3** was also conducted in refluxing ethanol in the presence of a catalytic amount of piperidine to afford 3-amino-2-(benzothiazol-2-yl)carbonylpyrido[1,2-*a*]-benzimidazole-4-carbonitrile **72** (Scheme 33) [55].

Also, treatment of enaminonitrile [2-(benzothiazol-2-yl)-3-(*N*,*N*-dimethylamino)-prop-2-enenitrile] **73** with **3** in refluxing ethanol in the presence of catalytic amount of piperidine afforded 3-amino-2-(benzothiazol-2-yl)pyrido[1,2-*a*]benzimidazol-4-carbonitrile **74** (Scheme 34) [56].

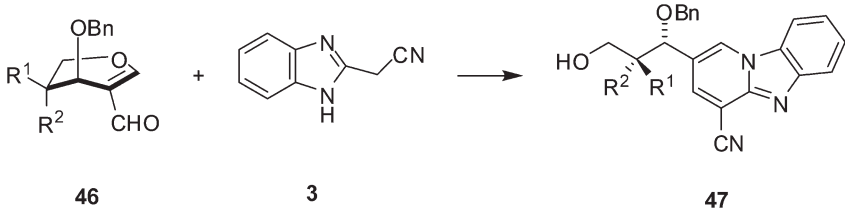
Pyrido[1,2-*a*]benzimidazoles **76** were synthesized by reacting 3-aryl-2-(*N*,*N*-dimethylamino)methylene-3-oxopropanenitriles **75** with **3** [31,55,57]. Elmaati *et al*. in 2002 have been reported the synthesis of pyridobenzimidazole **78**. Reaction of enaminone of acetoacetanilide **77** with **3** yielded the target compound **78** (Scheme 35) [57].

Hassanien in 2005, reported the reaction of methyl 2-benzoyl-3-dimethylaminopropenoate **79** with 2-(1*H*-benzo[*d*]imidazol-2-yl)acetonitrile **3** in refluxing acetic acid in the presence of ammonium acetate to produce methyl 4-cyano-3-phenylbenzimidazo[1,2-*a*]pyridine-2-carboxylate **80**, but not **81** (Scheme 36) [58].

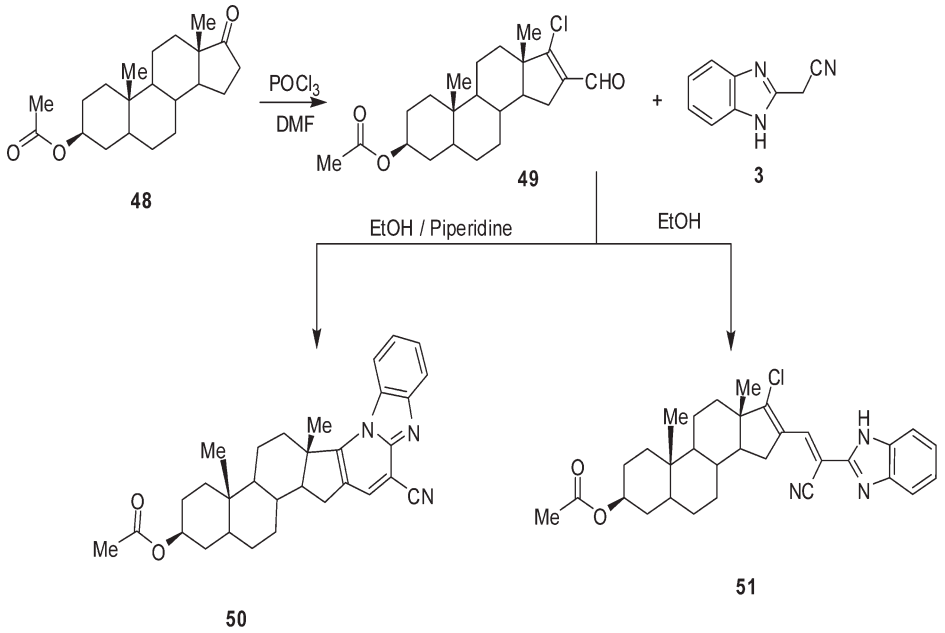
Microwave irradiation of dimedone **82**, dimethylformamidedimethyl acetal and **3** in iso-propanol and a catalytic amount of piperidine led to the formation of tetrahydrobenzo[4,5]imidazo[1,2-*a*]quinolin-6-yl cyanide **83** (Scheme 37) [59].

The enaminone 2-dimethylaminomethylene-1,3-indandione **84** reacted with **3** to produce indenofluorene **85** [33], while its reaction with 2-dimethylaminomethylene-3-(phenylhydrazono)indan-1-one **86** furnished diazaindenofluorene derivative **87** (Scheme 38) [60].

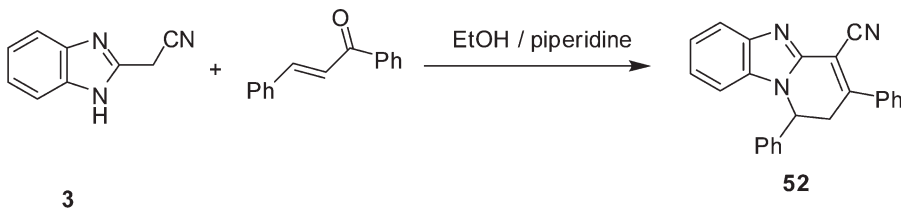
**Scheme 23**



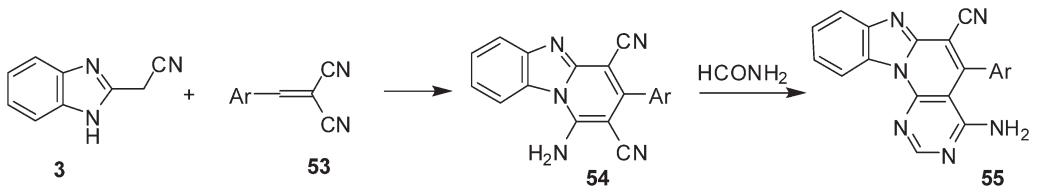
**Scheme 24**



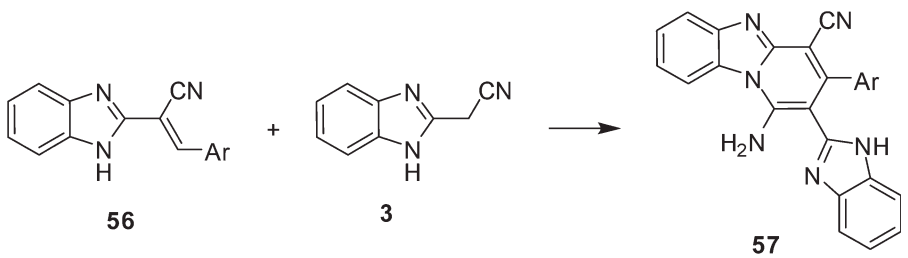
**Scheme 25**



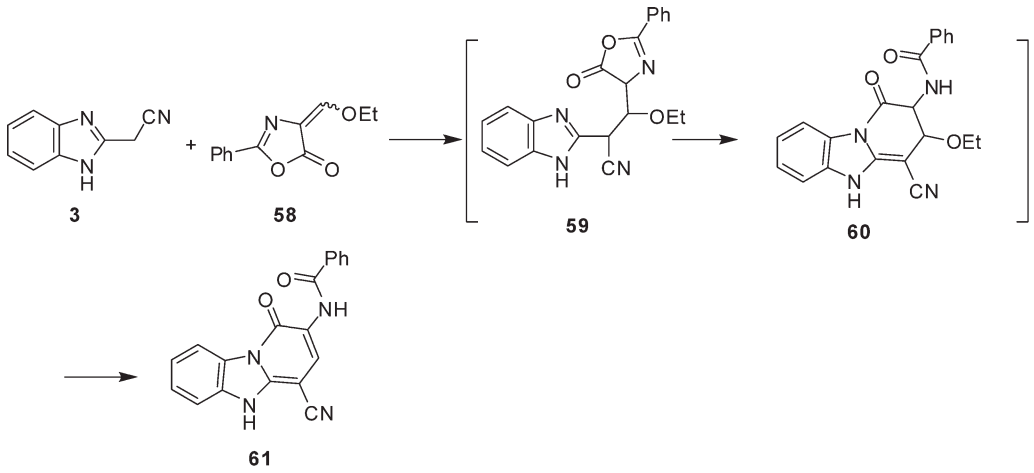
**Scheme 26**



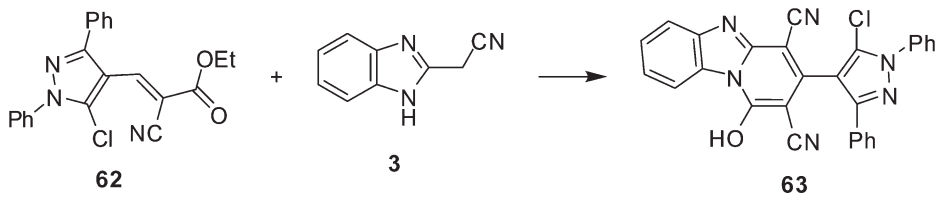
**Scheme 27**



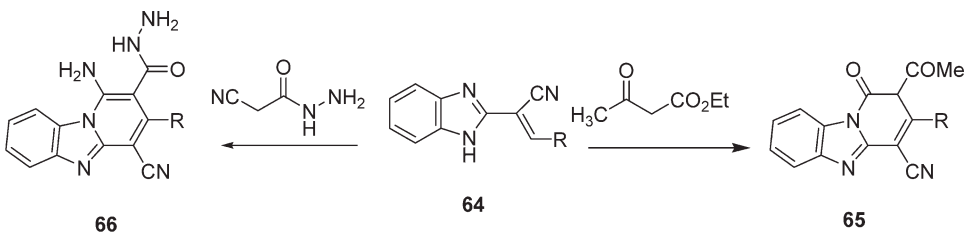
**Scheme 28**



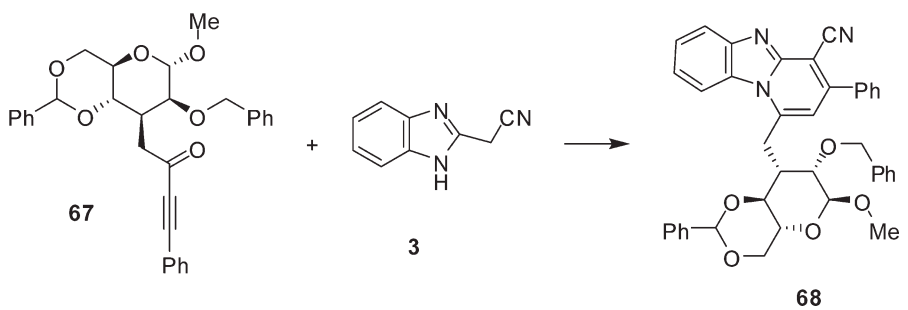
**Scheme 29**



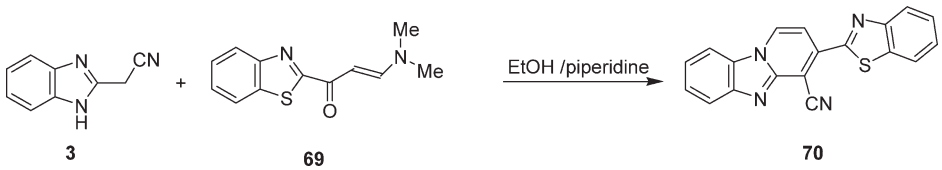
**Scheme 30**



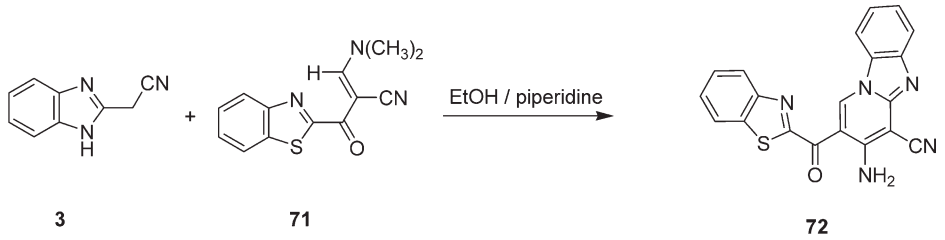
**Scheme 31**



**Scheme 32**

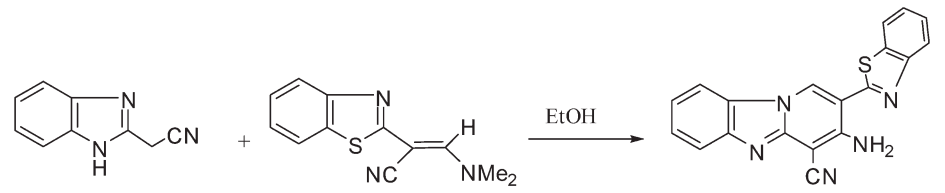


**Scheme 33**



**3** **71** **72**

**Scheme 34**



**3** **73** **74**

Benzo[4,5]imidazo[1,2-*a*]pyridine-2,4-dicarbonitrile **89** was obtained *via* treatment of enaminone **88** with 1*H*-benzimidazole-2-acetonitrile **3** in ethanol and has a catalytic amount of piperidine (Scheme 39) [61,62].

***3.2.4. Reaction with β-dicarbonyl compounds.*** 3-Methylpyrido[1,2-*a*]benzimidazole-4-carbonitrile **90** (prepared by the condensation of **3** and ethyl acetoacetate) is formylated with DMF-$POCl_3$ to 2-formyl-3-methylpyrido[1,2-*a*]benzimidazol-4-carbonitrile **91**(Scheme 40) [63].

1-Oxo-*1H,5H*-pyrido[1,2-*a*]benzimidazole-4-carbonitriles **94** by fusing **3** with some ethyl acetoacetate **92** in the presence of ammonium acetate or with ethyl β-aminocrotonate **93** (R = H, $R_1$ = Me) [64] (Scheme 41).

Pyrido[1,2-*a*]benzimidazole-4-carboxylic acid **95** was prepared in excellent yield by condensation of **3** with acetyl acetone followed by hydrolysis of the nitrile group by sulfuric acid (Scheme 42) [65,66].

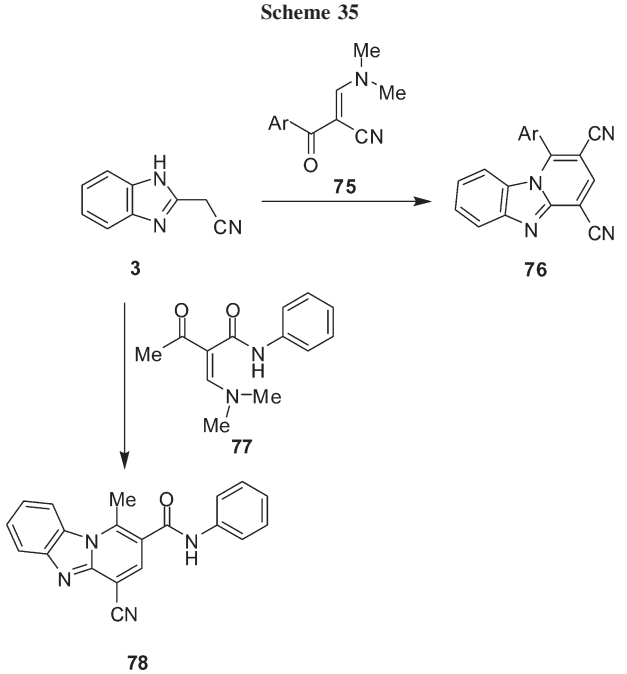
Pyrrolo[3′,4′:3,4]pyrido[1,2-*a*]benzimidazoles **97** [R = Bu, Bn, $MeOCH_2CH_2$, $O(CH_2CH_2)_2NCH_2CH_2$, 2-furyl-$CH_2$, 4-$MeC_6H_4$, 2-$MeC_6H_4$] were prepared in two steps. The condensation of **3** with ethyl 4-chloro-3-oxobutanoate led to the formation of 3-chloromethyl-1,5-dihydro-1-oxopyrido[1,2-*a*]benzimidazole-4-carbonitrile **96**. Amination of **96** with primary amines yielded **97** (Scheme 43) [67].

Condensation of benzimidazole **98** with ethoxymethylenemalonic acid esters (**99**, R = Et, Me) and acetoacetic ester gave the corresponding pyrido[1,2-*a*]benzimidazoles **100**, **101** (Scheme 44) [7].

Cycloalkylpyrido[1,2-*a*]benzimidazoles **102–104** were prepared by reaction of **3** with dimethyl 2-oxocyclopentane-1,3-dicarboxylate, dimethyl 3-oxocyclopentane-1,2-dicarboxylate, or methyl 2-oxocyclohexanecarboxylate in the presence of two equivalent of ammonium acetate at 140°C, these compounds exhibited a good *in vitro* antineoplastic activity especially against most of the leukemia cell lines (Scheme 45) [68–70].

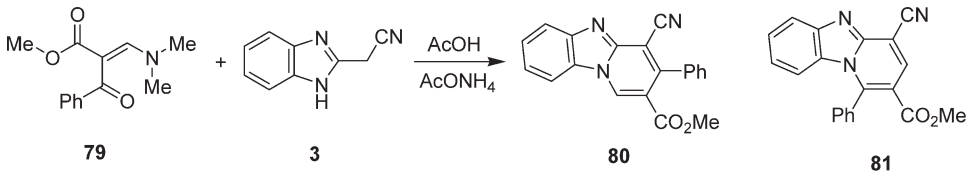
***3.2.5. C-acylation.*** 2-Chloronicotinoyl chloride reacted with 1-methyl-benzimidazole-2-acetonitriles, to give 97% conjugated nitrile **105** which cyclized on heating to give the corresponding 1,8-naphthyridine **106** in high yield (Scheme 46) [71].

**Scheme 35**



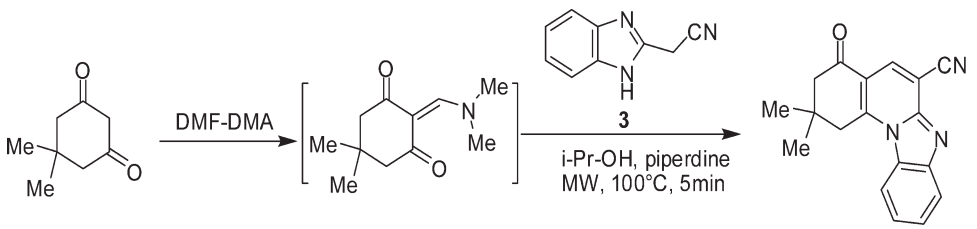
**3** **76** **78**

**Scheme 36**



79 3 80 81

**Scheme 37**



82 83

1-Methyl-benzimidazole-2-acetonitriles condensed with 2-haloaromatic esters (**107**, X = Cl, F; R = H, $O_2N$; $R_1$ = Me, Et) in refluxing acetonitrile containing potassium or cesium carbonate to give condensed isoquinolones **108** (Scheme 47) [72–74].

3-Hydroxy-*1H,5H*-pyrido[1,2-*a*]benzimidazol-1-ones (**110**, R = Et, Bu, $PhCH_2$, Ph) were prepared by cyclization of 1*H*-benzimidazole-2-acetonitrile with the dicarboxylate **109** (Scheme 48) [75,76].

Condensed azine **112** was prepared by cyclization of the corresponding benzothiophene **111** in refluxing ether (Scheme 49) [77].

***3.2.6. Miscellaneous methods.*** A one-step synthesis of benzimidazolo[1,5-*a*]pyridine **114** was reported. The reaction of 2-(2-phenylhydrazono)malononitrile **113** with **3** in refluxing ethanol yielded the target molecule **114** (Scheme 50) [78].

2-Imino-*N*′-*p*-arylpropanehydrazonoyl cyanide (**115**, R = Me, OMe, $NO_2$) were condensed with **3** in acetic acid to give the corresponding 3-methylpyrido[1,2-*a*]benzimidazoles **116** which then oxidized with cuprous acetate in DMF to triazolo[4,5-*b*]pyrido[1′,2′-*a*]benzimidazoles **117** (Scheme 51) [79].

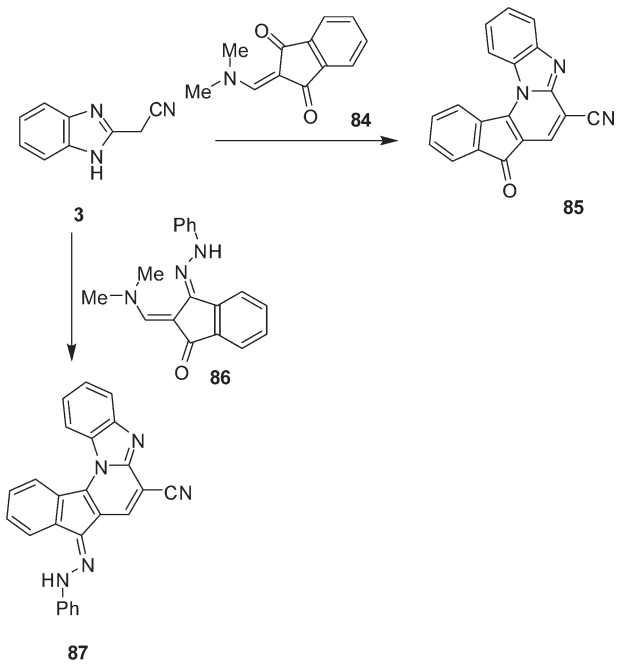
Reaction of **3** with 3-aminobut-2-enenitrile **118** afforded 1-amino-3-methylpyrido[1,2-*a*]benzimidazole-4-carbonitrile **119** (Scheme 52) [80].

Compound **3** reacted with sodium salts of 3-hydroxymethylene-2-alkanones (**120**, R = H, Me, $R_1$ = Me, aryl) in piperidine acetate and aqueous ethanol to yield two isomeric structures **121** and **122**. The X-ray analysis confirmed the presence of **121** in the solid state (Scheme 53) [81].

The cycloannulation of dianion **123** derived from **3** with the acyclic ketene dithioacetals (**124**, R = Ph, Me) produced 4-cyano-1-phenyl (or 1-methyl)-3-(methylthio)-pyrido[1,2-*a*]benzimidazoles **125** in good yields *via* the intermediate **124** (Scheme 54) [82].

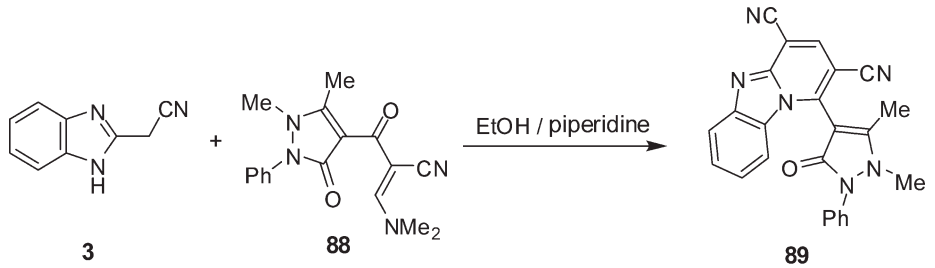
Benzimidazole-2-acetonitriles (R = H, Me) were treated with carbon disulphide and dimethyl sulfate to furnish thioesters **126**. Reactions of (**126**, R = H, Me) with methyl 2-cyano-3,3-bis(methylthio)acrylate (**127a**, X = $CO_2Me$), 2-[bis(methylthio)methylene]malononitrile (**127b**, X = CN), and 2-(ethoxymethylene)malononitrile gave pyridobenzimidazoles (**128**, $R_1$ = SMe, Z = O, NH; $R_1$ = H, Z = NH) (Scheme 55) [83].

**Scheme 38**

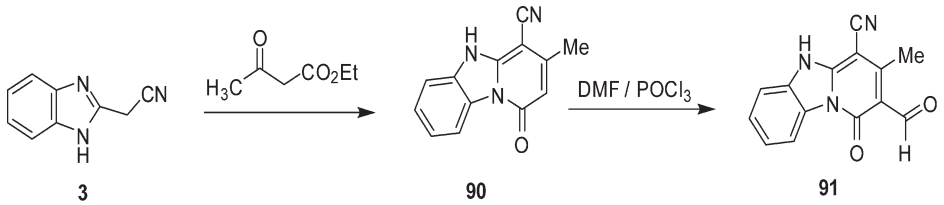


85

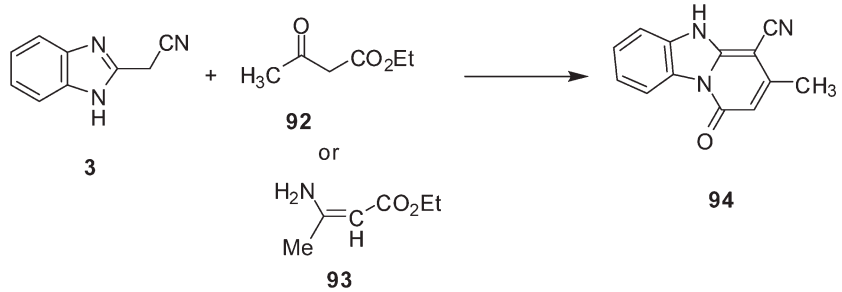
**Scheme 39**



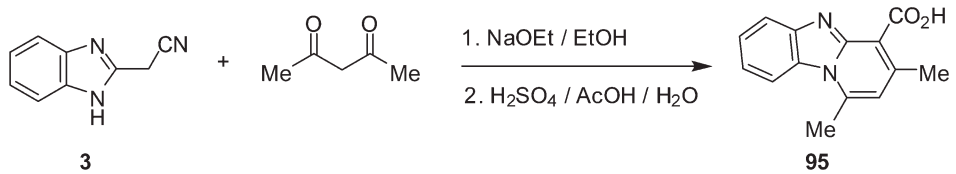
**Scheme 40**



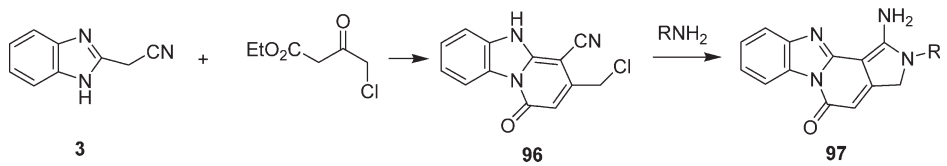
**Scheme 41**



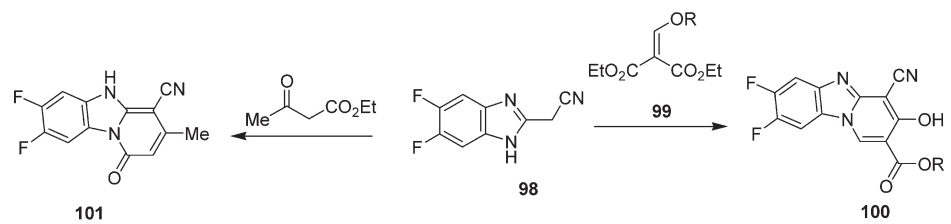
**Scheme 42**



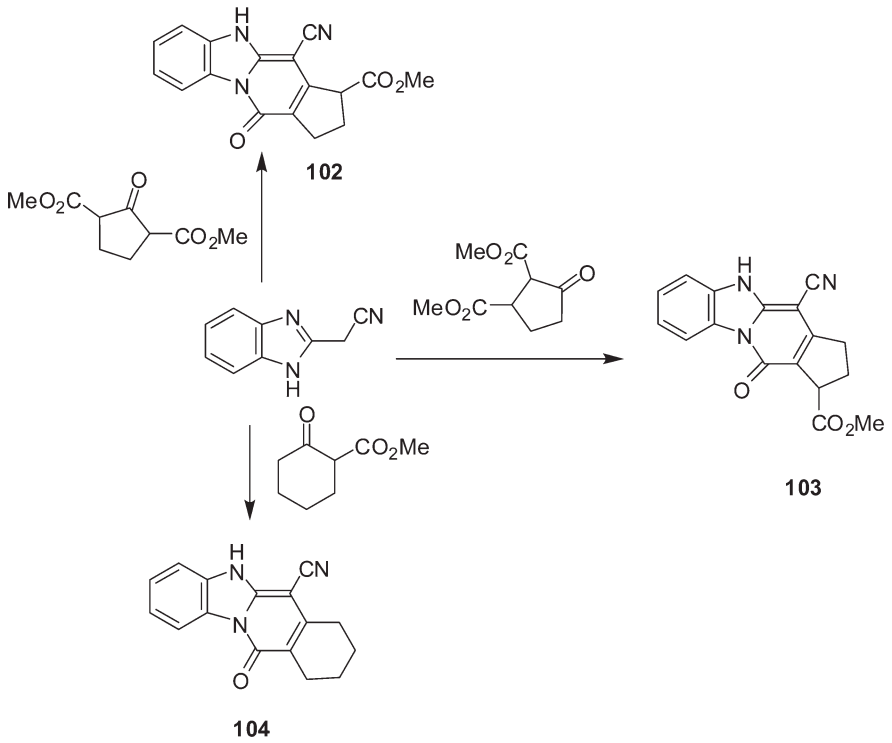
**Scheme 43**



**Scheme 44**



**Scheme 45**



The reaction of **3** with triethyl orthoformate and hippuric acid derivatives in refluxing acetic anhydride afforded pyrido[1,2-*a*]benzimidazole derivatives **131** *via* the intermediates **129** then **130**. The latter cyclizes *via* water elimination to yield pyrido[1,2-*a*]benzimidazole derivatives **131** (Scheme 56) [84].

Thermal condensation of **3** with diethyl ethoxymethylenemalonate in diphenyl ether at 240–250°C gave 75% yield ethyl 4-cyano-3-hydroxypyrido[1,2-*a*]benzimidazole-2-carboxylate **132** (Scheme 57) [33].

Base-catalyzed condensation-cyclization of **3** with 4-(methylthio)-2-oxo-6-aryl-2*H*-pyran-3-carbonitriles (**133**, Ar = aryl, 3-pyridyl, 4-pyridyl) led to the formation of pyrido[1,2-*a*]benzimidazoles **134** as a major product and pyrano[4,3-*d*]pyrido[1,2-*a*]benzimidazoles **135** as a minor one (Scheme 58) [85].

Reactions of 2-chlorobenzonitriles (**136**, R = H, $NO_2$) and 2-chloro-3-quinolinecarbonitrile with 1*H*-benzimidazole-2-acetonitriles ($R_1$ = H, Me, Et) gave condensed isoquinolinimines (**137**; R = H, $NO_2$; X = NH, NMe, NEt) and condensed 1,8-naphthyridinimines (**138**; X = NMe) [86] (Scheme 59).

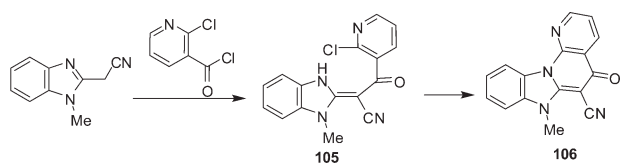
2-(2-Hydroxyethyl)-1-oxo-pyrido[l,2-*a*]benzimidazole-4-carbonitrile **139** was prepared by reacting **3** with 2-acetylbutyrolactone in the presence of ammonium acetate, whereas the 2-benzamido compound **140** was obtained by reacting **3** with 4-ethoxymethylene-2-phenyloxazolin-5-one (Scheme 60) [87].

Cyanamide in the presence of methanol, s-triazine and **3** gave primary product cyanoethene **141** which was stabilized *via* intermediate **142** to give pyridobenzimidazole **143** (Scheme 61) [88].

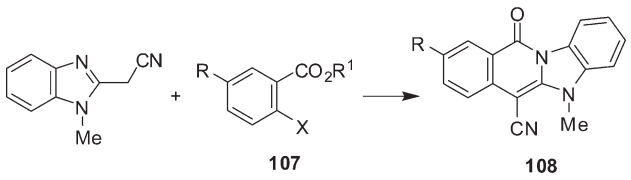
The reaction of 3-methylthio-4-phenyl-1,2-dithiolium perchlorate **144** with **3** in a mixture of acetonitrile/dioxane in the presence of triethylamine gave two products. The major product was cyanopyridobenzimidazole **145** formed by initial reaction of acetonitrile at the unsubstituted 5-position of the dithiole ring, followed by ring opening and recyclization. The other product was dithiole **146** (Scheme 62) [89].

Reactions of **3** with diketene in acetic acid at room temperature gave *C*-acetoacetyl derivative **147** which easily cyclized to give 4-cyano-3-methylpyrido[1,2-*a*]benzimidazole-1(5*H*)-one **148** (Scheme 63) [90].

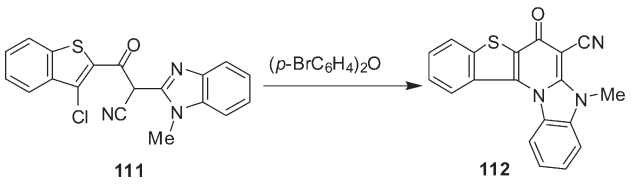
**Scheme 46**



**Scheme 47**



**Scheme 49**



The nucleophilic attack of carbanion of 1*H*-benzimidazole-2-acetonitriles (R = H, Me) at C-4 of pyrimidine ring in **149** led to the formation of the non-isolated intermediate **150**, which underwent intramolecular cyclization through acylation at the nitrogen atom of benzimidazole leading to pyridopyrimidine **151** (Scheme 64) [91].

**3.3. Pyrimidobenzimidazoles.** A one-step synthesis of azolo[5″,1″:3′,4′][1,2,4]triazino[5′,6′:4,5]pyrimido[1,6-*a*]benzimidazoles (**155**, Z = N, CH) has been achieved by the reaction of ethyl 2-cyanomethyl-1*H*-benzimidazole-1-carboxylate **152** with heterocyclic diazonium salts **153** through the formation of the intermediate **154** (Scheme 65) [92].

Acylation of 2-(1*H*-imidazol-2-yl)acetonitriles (R = H, Me) by haloalkyl isocyanates (**156**, Ar = Ph, 4-tolyl, 4-anisyl) followed by heterocyclization of **157** afforded 1,2,3,5-tetrahydrobenzo[4,5]imidazo[1,2-*c*]pyrimidines **158** (Scheme 66) [93].

Compound **3** reacted with ethyl chloroformate in the presence of triethylamine to give *N*- and *C*-acyl derivatives **152** and **159** respectively, which separated by fractional crystallization from dioxane. Reaction of C-acyl derivative **159** with guanidine sulfate in dry pyridine and sodium methoxide gave 1-amino-3-hydroxy-4-cyanopyrimidino[1,6-*a*]benzimidazole **160** (Scheme 67) [94].

Abdelhamid *et al*. have reported the synthesis of benzimidazo[1,2-*c*]pyrimidine-4-carbonitriles **162**. Treatment of 2-(1-ethoxycarbonyl)benzimidazoylacetonitrile **152** with isothiocyanates (R = Me, Ph) in the presence of potassium hydroxide gave the target compounds **162** in good yield *via* the formation of thioanilide intermediate **161** (Scheme 68) [95,96].

The reaction of **3** with sulfur, arylisothiocyanates, and carbon disulfide has been reported by Ivachtchenko *et al*. [97] and Badawy *et al*. [98] to give **163** which underwent methylation to give **164** (Scheme 69).

The mechanism of the reaction has described as follows (Scheme 70):

Five-component condensation of isothiocyanates ($R_1$ = 4-EtO, 3-MeO), sulfur, 1*H*-benzimidazole-2-acetonitrile **3**, triethylamine, and carbon disulfide furnished triethylammonium 3-aryl-[1,3]thiazolo[4′,5′:4,5]pyrimido[1,6-*a*]benzimidazole-2(3*H*)-thioxo-5-thiolates **166**, the alkylation of **166** led to 3-aryl-5-R-thio-[1,3]thiazolo[4′,5′:4,5]pyrimidino[1,6-*a*]benzimidazole-2(3*H*)-thiones **167** ($R_2$ = Me, 2-(methyl)-1,3-dioxolane, $CH_2CO_2Et$) [97] (Scheme 71).

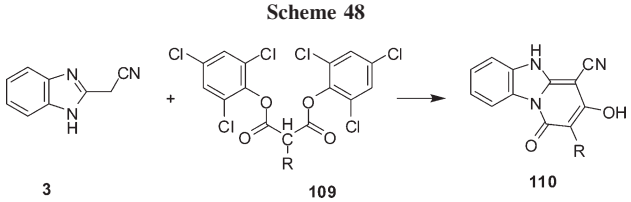
A buffered solution of 1,2,4-triazole-5-diazoium salt **168** was coupled with 1-methylbenzimidazole-2-yl-acetonitrile **3** to yield the corresponding hydrazones **169**, intramolecular cyclization of the latter compound gave triazolo[5,1-*c*]-1,2,4-triazine **170**. Similarly, indazole-3-diazonium chloride **171** also coupled readily with **3** to yield hydrazone **172** which cyclized in refluxing pyridine to produce 1,2,4-triazino[3,4-*b*]indazole **173** in to two tautomeric forms [99] (Scheme 72).

Compound **3** reacted with a variety of *N*-acyl imidates (**174**, $R_1$ = Me, Et; $R_2$ = Me, Et, Ph) under microwave irradiation in open vessels to give the corresponding pyrimido[1,6-*a*]benzimidazoles **175** [100] (Scheme 73).

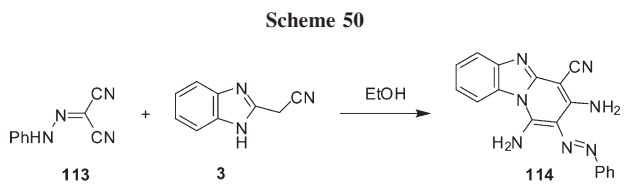
Compound **3** condensed with aminoesters (**176**, $R_1$ = Ph, 4-$EtOC_6H_4$, 2- and 4-$ClC_6H_4$, 2,5-$Cl_2C_6H_3$, 2-naphthyl, PhNMe; $R_2$ = alkyl) to give 60–75% cyanoketones **177**, which underwent acid-catalyzed intramolecular cycloaddition to give 78–87% title compounds (**178**, $R_1$ = Ph, 4-$EtOC_6H_4$, 2-$ClC_6H_4$, PhNMe). Refluxing (**178**, $R_1$ = Ph) with anhydrides or acid chlorides gave 72–98% tetracyclic cyclocondensation products (**179**, $R_3$ = Me, Et, 2-$XC_6H_4$; X = H, F, Cl, Br, iodo) [101] (Scheme 74).

Badawey *et al*. [102] reported that **3** (R = H, Me) was allowed to react with ethoxycarbonylisocyanate at

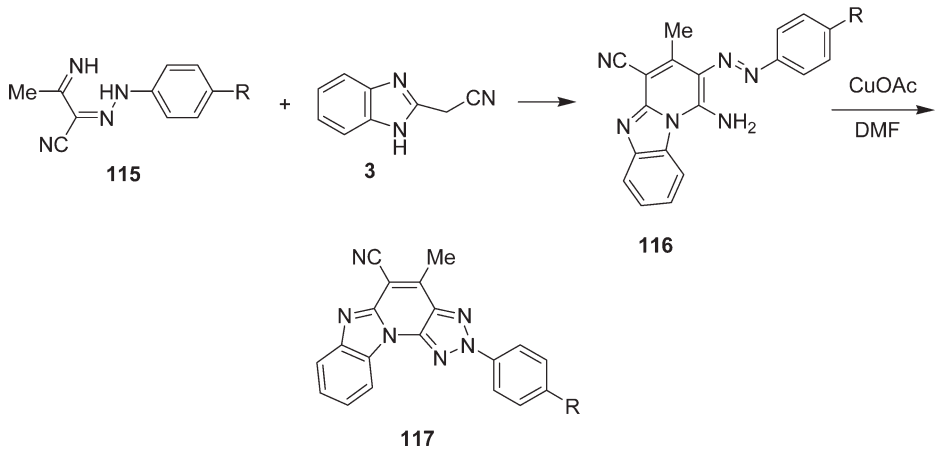
**Scheme 48**



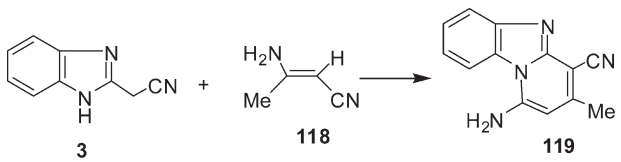
**Scheme 50**



**Scheme 51**



**Scheme 52**

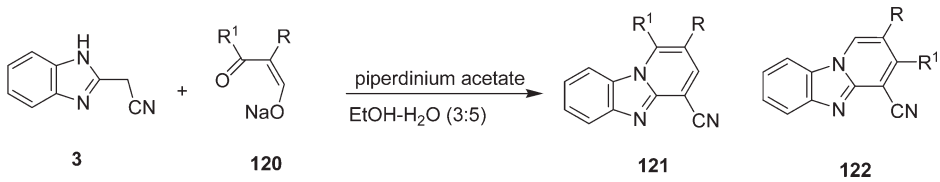


room temperature to afford the intermediate **180**, which was readily cyclized in boiling bromobenzene to the corresponding 7,8-disubstituted-1,3-dioxo-*2H*,*5H*-pyrimido[1,6-*a*]benzimidazole-4-carbonitrile **181** in excellent yield (Scheme 75).

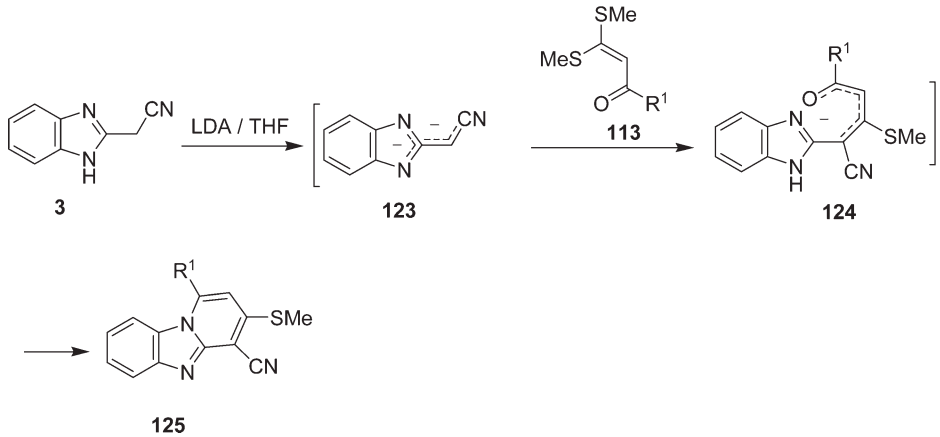
Reaction of **3** with cyanoamide (**182**, R = SMe, $SCH_2Ph$, 4-phenylpiperazino, Me, 4-$MeC_6H_4$, 4-$ClC_6H_4$, 2-furyl, 2-thienyl; $R_1$ = SMe, $SCH_2Ph$, OMe) and β-diketones (**183**, $R_2$ = Me, Ph) gave the pyrimido[1,6-*a*]benzimidazole-4-carbonitrile **184**(Scheme 76) [103].

Compound **3** and 2-(2,2,2-trifluoro-*N*-methylacetamido)benzoyl chloride **185** gave the 1-acylbenzimidazole **186**, which was cyclized with sodium *t*-butoxide in pyridine to give quinolone **187**, which was cyclized with

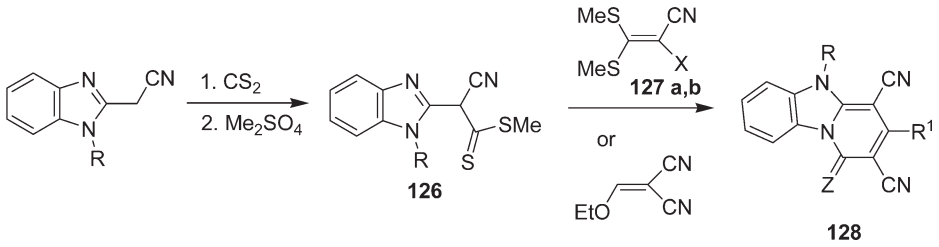
**Scheme 53**



**Scheme 54**



**Scheme 55**



acid chlorides, anhydrides, or triethylorthoformate to give **188** (Scheme 77) [104].

Pyrimido[1,6-*a*]benzimidazole **189** was prepared by heating of **3** with trichloroacetonitrile followed by cyclocondensation with triethylorthoformate (Scheme 78) [105].

2-Amino-3-(benzimidazol-2-yl)-1,8-naphthyridine **190** was obtained by condensation of 2-aminonicotinaldehyde with **3**. 7-Arylbenzimidazo[1′,2′:1,6]pyrimido[4,5-*b*][1,8]naphthyridines (**192**, R = Ph, 4-$MeC_6H_4$, 2-thienyl, *etc*.) were prepared by oxidation of the 6,7-dihydro derivatives **191**, which were obtained by condensation of benzaldehydes with 2-amino-3-(2-benzimidazolyl)-1,8-naphthyridine **190** (Scheme 79) [106].

Pyrroloquinoline **194** was prepared in good yield by treating 1*H*-benzimidazole-2-acetonitrile **3** with quinoline derivative **193** in refluxing pyridine containing sodium *t*-butoxide. Cyclization of **194** by refluxing acetic anhydride gave 85% **195** (Scheme 80) [107].

Benzimidazolylchromones (**198**, X = O, S) were prepared in high yields by cyclocondensation of hydroxy aromatic carboxylic acid methyl esters or 2-mercaptomethylbenzoate **197** with **3**. Acylation of **198** with acid chlorides (R = Me, Ph, Pr) gave benzimidazolobenzothiopyranopyrimidine **199** (Scheme 81) [108–110].

Cyclocondensation of **3** with hydrazones (**200**, $R_1$ = H, 2-, 3-, 4-Me, 4-Br) gave 90–99% **201** which were cyclized by acyl chlorides or anhydrides to give 80–94% **202** [$R_1$ as above, $R_2$ = H, Me, Et, Ph, 3,4,5-$(MeO)_3C_6H_2$] [110,111] (Scheme 82).

Treatment of 2,3,5-trimethyl-1,4-benzoquinone with **3** (R = H, Me) gave 2-amino-3-(benzimidazol-2-yl)benzo[*b*]furans **203** in high yield, respectively. Compound **203** were converted to 87–98% **204** ($R_1$ = $R_2$ = H; $R_1$ = Me, $R_2$ = Ac; $R_1$ = Et, $R_2$ = COEt; $R_1$ = Pr, $R_2$ =

COPr; $R_1$ = Ph, $R_2$ = Bz) by treatment with anhydrides trialkylorthoformate or acid chlorides (Scheme 83) [112].

Reaction of dimethyl *N*-cyanodithioiminocarbonate with **3** can be utilized for the synthesis of 2-amino-5-cyano-4-(methylthio)pyrimidino[1,6-*a*]benzimidazole **206**, by reaction in dioxane containing a catalytic amount of potassium hydroxide at room temperature (Scheme 84) [113].

The Lewis acid catalyzed synthesis and chromatographic purification of isatoic anhydride-derived 2-(2′-anilinyl)-1,3-benzoxazole (**2**) can result in the co-isolation of **2** and a light pink colored impurity (<5%). This latter species has been identified (NMR, single crystal X-ray diffraction, mp) as 2′-hydroxy-2-aminobenzanilide (**3**), which represents a predictable intermediate in the formation of **2**. Compound **3** crystallizes in an orthorhombic crystal system of space group $P2_12_12_1$ with four molecules in the unit cell ($\alpha = \beta = \gamma = 90°$; $a = 6.715$ (2) Å, $b = 12.100$ (4) Å, $c = 13.321$ (4) Å; $V = 1082.2$ (6) Å$^3$). Pure **2** is characterized as a colorless, high-melting solid; unlike the dark colored oil that is isolated if **2** contains traces of **3**.

## INTRODUCTION

Oxazoles, 2-oxazolines (*i.e.*, 4,5-dihydro-1,3-oxazoles) and 1,3-benzoxazoles represent an important group of organic heterocyclic compounds. These materials have found widespread applications as ligands in transition metal and main group coordination chemistry and as important monomers in polymer science. In addition, these heterocycles are used in medicinal chemistry and in regio-selective and enantio-selective synthesis [3–12]. Our own interests lie in the design and application of novel oxazoles for metal-mediated catalysis and in fundamental studies of inorganic structural chemistry [13–18]. Several years ago, Gajare *et al*. demonstrated that isatoic anhydride (*i.e.*, 2*H*-3,1-benzoxazine-2,4(1*H*) dione: **1**; Scheme 1) [19–21] can be used as a useful synthon for the production of *o*-anilinyl-oxazolines, -oxazines, and -benzoxazoles [22]. Their coupling strategy involved the application of kaolinitic clay as a Lewis acid promoter of decarboxylative coupling and subsequent dehydrative ring formation reactions between **1** and ω-aminoalcohols (Scheme 1; E = —$(CRR')_n$— ($n$ = 2 or 3), *o*—$C_6H_4$). Our independent study of this reaction using $ZnCl_2$ [23] or $ZnBr_2$ [24,25] as catalyst had revealed that the desired product of the above reaction between **1** and *o*-aminophenol, *viz*. 2-(1,3-benzoxazol-2-yl)aniline (**2**: *i.e.*, 2-[*o*-anilinyl]-1,3-benzoxazole: Scheme 1), can be problematic to isolate in pure form by these reaction protocols [22,23]. Details of this investigation are reported herein.

## RESULTS AND DISCUSSION

We were perplexed by the earlier disclosure (and indeed in our own synthesis and purification by similar means) [23,24] that compound **2**, following chromatographic isolation, often takes the form of a dark colored analytically pure oil. Compared with the variety of other structurally analogous materials that we had made, it seemed unusual that this compound should exist as a liquid under ambient conditions. A thorough search of the literature reveals that compound **2** has in fact been previously reported by several different synthetic

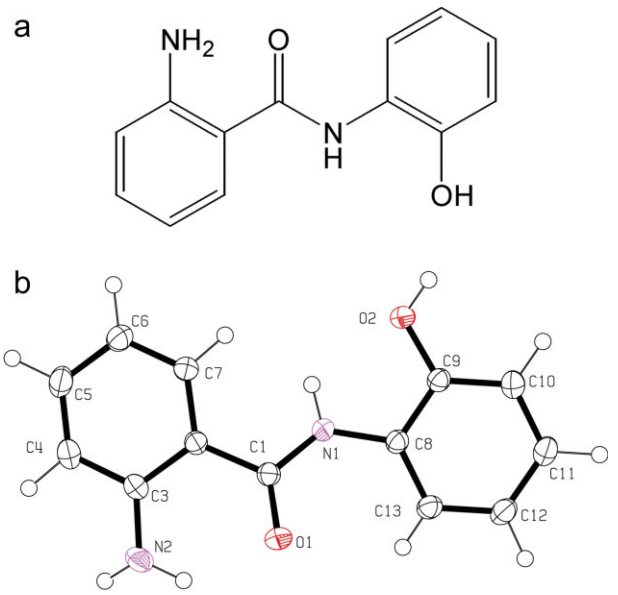

**Figure 1.** (a) A molecular representation of **3**. (b) An ORTEP diagram of a molecule of **3** found in the unit cell. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

methodologies and in all cases reported as a colorless solid. However, there is considerable discrepancy as to the exact mp of **2** (reported mps: 126°C [26]; 113–115°C [27]; 105–105.5°C [28]; 105°C [29]). On one occasion in our own laboratories, we also obtained the said material as an off-white solid with a mp of 103–105°C (which we likewise reported in 2003 [23]), a property consistent with that reported independently by both Culbertson et al. [29] and Igeta and coworkers [28]. These conflicting observations promoted us to re-examine both **2** and the ''oil'' material more closely, and we have thus found that flash chromatographic isolation of **2** using EtOAc/hexanes (v/v: 50/50 or 25/75) mixtures often leads [22,23] to the contamination of **2** with a small amount of a second light pink-colored compound (**3**). When this impurity is present, impure **2** does indeed take the form of a viscous tar-like oil which is typically dark in color. This material is usually isolated when the accompanying solvent is removed expeditiously by, for example, rotary evaporation. An interesting facet of this oil is the acceptable level of analytical purity (calculated for $C_{13}H_{10}N_2O$: C 74.28, H 4.76, N 13.33; found [22]: C 74.48, H 4.26, N 13.61%). We have succeeded in isolating **2** that is free of **3** by careful fractional crystallization of the resulting mixture dissolved in EtOAc/hexanes. Slow solvent removal by evaporation under ambient conditions (in open test tubes) leads to the gradual precipitation of a white material in the form of needles (identified as **2**) and a second crystalline light pink-colored solid (**3**), which is present in quite small amounts relative to that of **2**. Investigation of this latter material isolated in this way *via* $^1$H NMR spectroscopy and mp measurements (mp: 136–136.5°C) reveals very similar properties to those reported [30] some 40 years ago for 2′-hydroxy-2-aminobenzanilide (lit. mp: 139–140°C: Fig. 1). This compound is an obvious and predictable intermediate [19–21,23] in the synthesis of **2** from **1**. To obtain unequivocal evidence on the nature of **3**, a single crystal X-ray diffraction study was carried out. Compound **3**, 2′-hydroxy-2-aminobenzanilide (Fig. 1), crystallizes in the $P2_12_12_1$ space group with four molecules in the unit cell (see Table 1). The molecules contain virtually co-planar aromatic groupings and intra-molecular *H*-bonding between the amide oxygen atom (O1) and the $NH_2$ group (O1···H—N2 = 2.024 Å) and the amide *H*-atom and the *O*-atom of the phenolic —OH functionality (O2···H1—N1 = 2.132 Å). In addition, a close inter-molecular contact is found between the *H* of this —OH group (*i.e.*, H2C) and O1 (O1···H2C = 1.773 Å). An ORTEP representation of a molecule of **3** from the unit cell is shown in Figure 1.

**Table 1**

Selected bond distances (Å), bond angles (deg), and dihedral angles (deg) for compound **3** with estimated standard deviations in parentheses (see Fig. 1).

| | |
|---|---|
| Bond distances | |

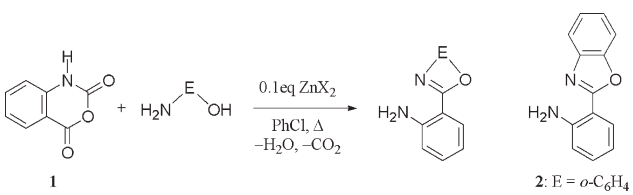
| O2–C9 | 1.364 (2) |
| N1–C1 | 1.349 (2) |
| N1–C8 | 1.410 (2) |
| N2–C3 | 1.371 (2) |
| Bond angles | |
| C8–N1–C1 | 129.68 (11) |
| O1–C1–N1 | 121.86 (11) |
| Dihedral angle | |
| C8–N1–C1–C2 | 173.11 (11) |

**Scheme 1**



The off-white needle form of **2** (mp: 103–105°C) isolated above was subjected to recrystallization from boiling pet. spirit (60–80°C bp range) to yield initially a cream colored material in the form of very thin needles (mp: 106–108°C). This crop was subsequently recrystallized a second time from the same solvent to give colorless needles (mp: 109–111°C). The variability in mp behavior of **2** may be due to its sensitivity to gradual yellowing (presumably oxidation) under ambient

conditions. We have been unable to recrystallize **2** from hydrocarbon media to a point in which the measured mp mimics that disclosed by Padmaja *et al*. (126°C: to our knowledge the highest mp reported for **2**) [26]. Their method used glacial acetic acid for recrystallization. Using this solvent gave white material of mp 113–114°C. It should also be noted that the analytical purity of **2**, as described in [22], could contain traces of **3**. For example, the contamination of a sample of **2** by 1% by weight of **3** (corresponding to 9.3 molecules of **3** per 100 that of **2**) gives a calculated elemental analysis (calc.: C 74.16; H 4.79; N 13.38%) consistent with **2** (*vide supra*) and this concentration of impurity makes it unlikely that **3** would be easily spotted by NMR spectroscopy. Despite these facts, it does appear as if all these levels of purity of **2** are still of sufficient quality for the use of this material in subsequent syntheses [23,31,32].

## EXPERIMENTAL

**Isolation of 2-(1,3-benzoxazol-2-yl)aniline (2) and 2′-hydroxy-2-aminobenzanilide (3).** The synthesis of compounds **2** and **3** was carried out as described in reference [23]. Purification of the reaction mixture *via* flash chromatography (1/1 v/v hexanes/EtOAc) using ~50 g of silica on a column of 2 cm diameter yielded ~40 fractions (~15 mL each in test tubes). These extractions were left to evaporate in open air (fumehood) of which the first 15 contained solid pure (NMR) **2** (yield 36% [23]); fractions 16–18, which were slightly pink in color, yielded about 50 mg of **3** (0.4%) and a small amount of **2**. Compounds **2** and **3** were then separated manually from these fractions. The latter fractions contained species which could not be unequivocally identified (NMR). Properties of **2**: mp 113–114°C (AcOH; lit.: see text); pmr (δ, 400 MHz, deuterochloroform): data was consistent to within experimental error to that reported (lit. [28]). Properties of **3**: mp: 136–136.5°C (1/1 v/v hexanes/EtOAc; lit. [30] 139–140°C); pmr (δ, 600 MHz, deuterochloroform containing ~10% hexadeutero-dmso), 9.11 (s, br, 1H, N*H*), 8.75 (s, br, 1H, O*H*), 7.71 (dd, 1H, $J$ = 1.7, 7.8, Ar*H*), 7.34 (dd, 1H, $J$ = 1.5, 7.9, Ar*H*), 7.00 (td, 1H, $J$ = 1.2, 7.2, Ar*H*), 6.75 (m, 1H, Ar*H*), 6.72 (dd, 1H, $J$ = 1.8, 7.8, Ar*H*), 6.63 (m, 2H, Ar*H*), 6.52 (dd, 1H, $J$ = 1.2, 7.8, Ar*H*), 6.46 (td, 1H, $J$ = 1.2, 7.2, Ar*H*), 2.60 (s, v. br, N$H_2$); cmr (δ, 150 MHz, deuterochloroform containing ~10% hexadeutero-dmso), 167.5 (*C*=O), 148.7, 147.1, 132.1, 127.6, 126.3, 124.4, 121.0, 119.3, 117.0, 116.0, 115.9, 115.5.

**Crystal data for 3.** The structure of complex **3** was solved using previously described methods [33]. Formula $C_{13}H_{12}N_2O_2$, MW: 229.24, orthorhombic, space group $P2_12_12_1$, $a$ = 6.715 (2) Å, $b$ = 12.100 (4) Å, $c$ = 13.320 (4) Å, α = β = γ = 90°, $V$ = 1082.2 (6) Å$^3$, $D_c$ = 1.401 g/cm$^3$, $Z$ = 4. Crystal size: 0.80 × 0.71 × 0.56 mm$^3$, light pink. Temperature = 173 (2) K, λ(MoKα) = 0.71073 Å, Absolute coefficient = 0.097 mm$^{-1}$, $F$(000) = 480, θ range for data collection: 2.27–32.46°, *hkl* range: –4 to 10, –17 to 18, –20 to 18. Reflexions collected: 16,294, Independent reflexions: 3893 [$R$(int) = 0.0581], Completeness to θ = 32.46°: 99.9%, Absorption corr.: numerical, max. and min. transmission: 0.9479, 0.9265, refinement method: full-matrix least-squares on $F^2$, data/restraints/parameters: 3893/0/202, GOF on $F^2$: 1.042, final $R$ indices [$I > 2\sigma(I)$] $R1$ = 0.0446, w$R2$ = 0.1126, $R$ indices (all data): $R1$ = 0.0544, w$R2$ = 0.1193, absolute structure parameter: 0.7 (10), largest diff. peak and hole: 0.241–0.272 eÅ$^{-3}$. The molecular representation found in Figure 1 was drawn using ORTEP-III for Windows [34]. CCDC #747662 contains the supplementary crystallographic data for this article. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre *via* www.ccdc.cam.ac.uk/data_request/cif.

## CONCLUSIONS

This investigation has demonstrated that compound **2** (*i.e*., 2-[1,3-benzoxazol-2-yl]aniline) can be problematic to isolate in very pure form under the reaction conditions described independently by us and Gajare *et al*. Contamination of **2** by its ring opened precursor (2′-hydroxy-2-aminobenzanilide: **3**) can lead to the isolation of analytically ''pure'' material in an oil-like form. Caution is likewise advised as to the measurement of the purity of solid **2** by mp determination although lower melting point material appears to be of sufficient purity for later synthetic applications. Material with the most pronounced mp behavior is that which has been recrystallized from glacial acetic acid as described previously [26]. The contaminant of **2**, *viz*. **3**, has been fully characterized (mp, NMR, X-ray diffraction).

**Acknowledgments.** This work has been funded by a generous donation from Research Corporation. The authors are also indebted to the support of both Acadia and Ryerson Universities and NSERC (Canada) in the form of a Discovery Grant (RAG) and *via* an NSERC USRA™. Prof. K. J. Haller (Suranaree University of Technology) is also thanked for his preliminary examination of compound **3**. Mr. Shawn McFadden (RUAC) and Dr. D. W. Hughes (MAX Facility) are also thanked for their contributions to this research.

Amidoalkyl naphthol derivatives have been synthesized in good yields in a one-pot condensation of β-naphthol, aromatic aldehydes and urea in presence of TMSCl/NaI at room temperature. Ring closure of amidoalkyl naphthol derivatives occurred at 140°C to afford 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazin-3-one derivatives.

*J. Heterocyclic Chem.*, **47**, 272 (2010).

## INTRODUCTION

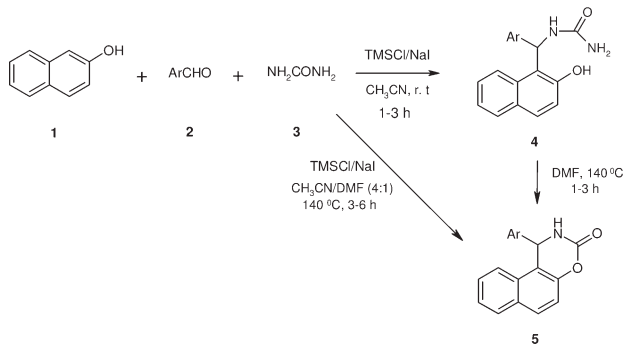
Multicomponent reactions have emerged as powerful strategies with the emphasis on the search for atom-efficient transformations of easily available starting materials into complex organic molecules, which provide maximum diversity are encouraging on economy and environmental grounds [1]. One such example is the reaction of β-naphthol and aldehydes with urea to produce amidoalkyl naphthols or oxazinone derivatives. Benzoxazin-4-one derivatives are an important class of heterocyclic compounds [2–5], which exibit many industrial, research, and clinical applications. Naphthalene condensed oxazinone derivatives are known to possess interesting pharmacological and reported as antibacterial agents [6]. These compounds have also been used in the preparation of chiral amino phosphine ligands for asymmetric catalysis [7]. Even though a large number of methods [8–15] were reported for the preparation of intermediate compounds (amidoalkyl naphthols), ring closure reactions to give naphthalene condensed oxazinone derivatives have not been thoroughly investigated [16–19]. This has stimulated significant interest and there is always considerable demand in exploring more milder, convenient, practical, and efficient reagents for their synthesis using multicomponent reactions. Therefore, the development of simple, convenient, and practical procedures for the synthesis of naphtho[1,2-e][1,3]oxazin-3-one derivatives continue to be a challenging endeavor in synthetic organic chemistry.

## RESULTS AND DISCUSSION

TMSCl/NaI combination has been explored in various organic transformations [19]. In continuation of our efforts to explore the synthetic utility of TMSCl/NaI combination [20], herein we report a three-component approach for the one-pot synthesis of a series of amidoalkyl naphthols and naphthoxazinones under different reaction conditions using TMSCl/NaI (Scheme 1).

Initially, we examined the reaction of naphthol (**1**), benzaldehyde (**2**), and urea (**3**) in the presence of TMSCl/NaI in $CH_3CN$ at room temperature and found to give the corresponding intermediate amidoalkyl naphthol derivative **4a** in 81% yield. The structure of the product was confirmed by spectral data and compared with the authentic sample. Similarly, other aromatic aldehydes were also reacted to give the intermediate compounds in good yields at room temperature (Scheme 2) and the results are presented in Table 1. Under present conditions, formation of side products, such as, dibenzoxanthenes was not observed. When an intermediate amidoalkyl naphthol derivative **4a** was heated in DMF at 140°C for 1.2 h cyclization occurred to produce the naphthoxazinone **5a**. Encouraged by this result, the reaction of β-naphthol (**1**), benzaldehyde (**2**), and urea (**3**) in the presence of TMSCl/NaI in $CH_3CN$/DMF (4:1) was directly heated at 140°C and found to give the cyclized product, naphthoxazinone **5a** exclusively within 1 h, without isolating the intermediate **4a**. To find out the scope and generality of this reaction, we turned our attention to various substituted aldehydes.

**Scheme 1**



The aromatic aldehydes containing both electron-donating and electron-withdrawing groups afforded the desired products. All the reactions were clean at 140°C and the corresponding cyclized products **5b–m** were obtained in good yields without isolating intermediate compounds **4**. The results are summarized in Table 2. The products were characterized by spectral data and known compounds were compared with the authentic samples data.

In summary, we have demonstrated an efficient protocol for the synthesis of amidoalkyl naphthols and naphthoxazinone derivatives using TMSCl/NaI as promoter. The notable features of this method are mild reaction conditions, greater selectivity, simplicity in operation, which make it an attractive and very useful process for the synthesis of amidoalkyl naphthol and naphthoxazinone derivatives of biological importance.

## EXPERIMENTAL

Melting points were recorded on Buchi R-535 apparatus and are uncorrected. IR spectra were recorded on a PerkinElmer FTIR 240-c spectrophotometer using KBr optics. $^1$H NMR spectra were recorded onVarian-unity 300 spectrometer in CDCl3 using TMS as internal standard. Mass spectra were recorded on a Finnigan MAT 1020 mass spectrometer operating at 70 eV.

**General procedure for the synthesis of amidoalkyl naphthol derivatives 4 and naphthoxazinones 5.** To a mixture of 1 equiv. of β-naphthol, 1 equiv. of aromatic aldehyde and 1.5 equiv. of urea in acetonitrile (10 mL) was added 1.5 equiv. of TMSCl and 1.5 equiv. of NaI at 0°C and stirred at room temperature (see Table 1). After completion, followed by TLC, acetonitrile was removed and ethyl acetate was added to the residue. Ethyl acetate was washed with water, sodium thiosulfate, and brine solution, dried, and concentrated. The crude residue was purified by column chromatography (EtOAc/hexane, 1:3) to afford the pure product **4**.

**Scheme 2**

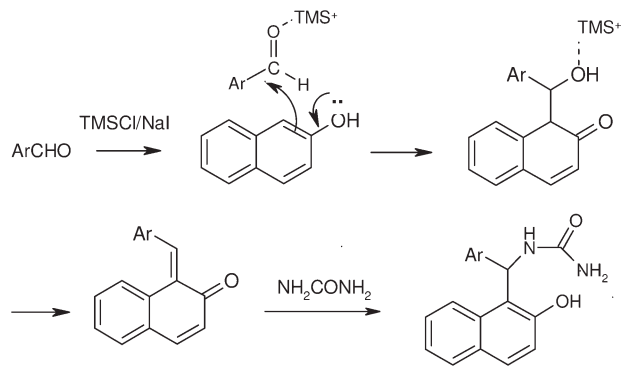


**Table 1**

TMSCl/NaI catalyzed synthesis of amidoalkyl naphthols (**4**).[a,b]

| Entry | Aldehyde | Time (h) | Yield (%) | mp (°C) |
|---|---|---|---|---|
| **4a** |  | 1.5 | 81 | 212 |
| **4b** |  | 1.8 | 79 | 208 |
| **4c** |  | 1.2 | 78 | 193 |
| **4d** |  | 3 | 78 | 198 |
| **4e** |  | 2.3 | 81 | 179 |

[a] All products were confirmed by their spectral data and compared with authentic samples.
[b] Isolated yields after purification.

A mixture of intermediate amidoalkyl naphthol derivative **4** in DMF was heated at 140°C for 1–3 h. After completion of cyclization reaction, followed by TLC, water was added and extracted with ether. The organic layer was washed with water and brine solution, dried, and concentrated. The crude residue was purified by column chromatography (EtOAc/hexane, 1:3) to afford naphthoxazinone product **5**.

**General procedure for the one-pot synthesis of naphthoxazinones 5.** To a mixture of 1 equiv. of β-naphthol, 1 equiv. of aromatic aldehyde and 1.5 equiv. of urea in acetonitrile/dimethyl formamide (6 mL:1.5 mL; 4:1) was added 1.5 equiv. of TMSCl and 1.5 equiv. of NaI at 0°C and stirred at 140°C (see Table 2). After completion, followed by TLC, solvent mixture was removed by rotary evaporation and ethyl acetate was added to the residue. Ethyl acetate was washed with water, sodium thiosulfate, and brine solution, dried, and concentrated. The crude residue was purified by column chromatography (EtOAc/hexane, 1:3) to afford the pure product **5**.

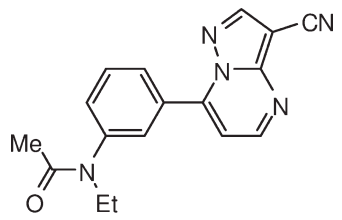
Synthesis of several potential impurities and/or degradation products of zaleplon is identified. All the prepared compounds were unambiguously identified by NMR techniques. Spectral characteristics (IR, UV, MS) of these compounds are also given.

*J. Heterocyclic Chem.*, **47**, 276 (2010).

## INTRODUCTION

Zaleplon (**1**) is a nonbenzodiazepine hypnotic belonging with zolpidem and zopiclon to the so-called Z-hypnotic class [1,2]. Clinical results have shown that zaleplon is efficacious in the treatment of insomnia where difficulty in falling asleep is the primary problem. Zaleplon unlike many other hypnotic drugs does not interfere with sleep architecture and can be administered for up to 5 weeks without the risk of dependence or rebound insomnia upon discontinuation [3].



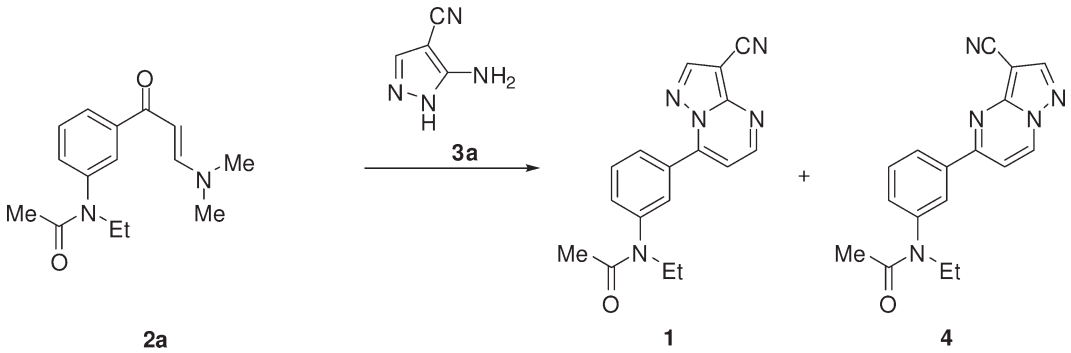
**zaleplon (1)**

Most of the described methods [4–7] of preparation of zaleplon are based on reaction of *N*-[3-[(2*E*)-3-(dimethylamino)prop-2-enoyl]phenyl]-*N*-ethylacetamide (**2a**) with 5-amino-1*H*-pyrazol-4-carbonitrile (**3a**) under acidic conditions. The original patent [4] describes the reaction in anhydrous acetic acid, but under these conditions considerable amounts of the corresponding isomer **4** is formed. Much better results are achieved using aqueous acetic [5] or formic [6] acids. Probably the best results regarding purity and yields are obtained when the reaction is done in aqueous alcohols in the presence of hydrochloric acid [7,8] (Scheme 1).

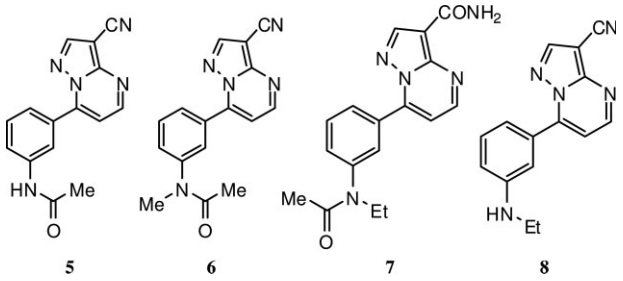
One of the principal parts of documentation of any active pharmaceutical ingredient (API) is description of impurities and/or degradation products which can be present. Identified impurities should be included in the specification when they are present at a level higher than the identification threshold, which is usually 0.10%. These impurities must be not only identified but also either isolated or independently synthesized.

Several impurities of zaleplon, including regioisomer **4** and compounds **5–8**, have recently been isolated and identified [9]. We have recently reported synthesis of zaleplon regioisomer **4** based on the Suzuki-Miyaura coupling [10]. To the best of our knowledge, no report on the synthesis of compounds **5–8** has been published

**Scheme 1.** Formation of zaleplon (**1**) and its regioisomer **4**.



and therefore we decided to synthesize these and other potential impurities as standards.

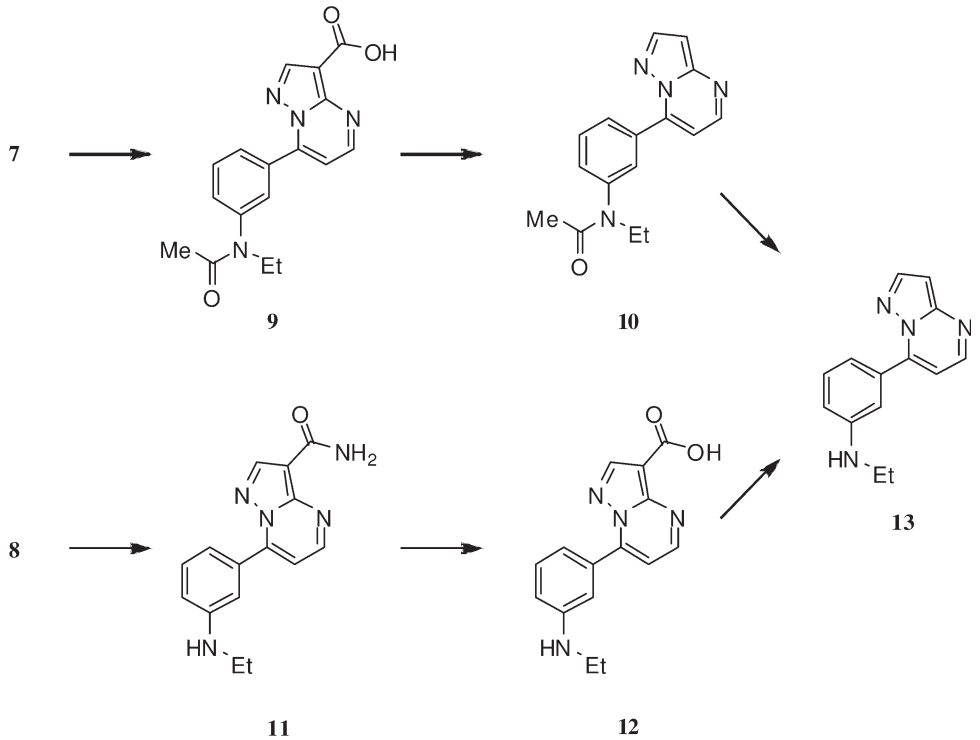


From the structures, it is evident that compounds **5** and **6** are process-related impurities formed by reaction of the corresponding impurities in **2** with **3a**. On the other hand, compounds **7** and **8** are products of hydrolysis of zaleplon leading to the nitrile group hydrolysis and anilide group hydrolysis, respectively. Our initial stress tests of zaleplon envisaged also formation of other similar impurities, as shown in Scheme 2, and therefore we decided to synthesise them.

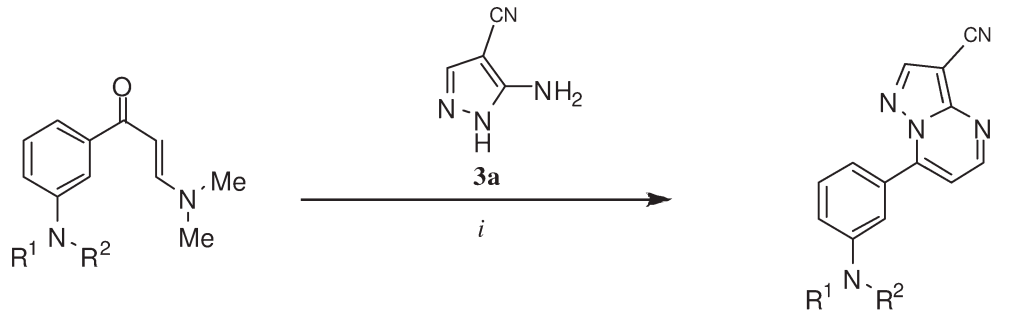
## RESULTS AND DISCUSSION

During our development of generic zaleplon, we decided to prepare compounds **5–13** as standards. Compounds **5** and **6** were prepared analogously as zaleplon starting from commercially available compound **2b** and compound **2c**, respectively. Compound **2c** was prepared

**Scheme 2.** Possible degradation pathways of zaleplon under stress tests conditions.



**Scheme 3.** Preparation of process-related impurities **5** and **6** and impurity **8**.



**2b** $R^1$ = Ac, $R^2$ = H
**2c** $R^1$ = Ac, $R^2$ = Me
**2d** $R^1$ = CHO, $R^2$ = H
**2e** $R^1$ = CHO, $R^2$ = Et

*i;* HCl, EtOH, reflux

**5** $R^1$ = Ac, $R^2$ = H
**6** $R^1$ = Ac, $R^2$ = Me
**8** $R^1$ = H, $R^2$ = Et
**14** $R^1$ = CHO, $R^2$ = Et

from **2b** using sodium hydride/iodomethane. For the synthesis of compounds **8**, **11**–**13**, we decided to start from **2d** ($R^1$ = CHO, $R^2$ = H), which was easily obtained from 3-aminoacetophenone by subsequent formylation, folowed by treatment with DMFDMA. Compound **2d** then provided **2e** using NaH/DMF and EtI.

$^1$H NMR spectra of all of the compounds **2** showed that the methyl groups are nonequivalent as a result of the hindered rotation of dimethylamino group.

Compounds **2b** and **2c** heated with pyrazole **3a** in EtOH or MeOH and small amounts of concentrated hydrochloric acid provided good yields of the corresponding products **5** and **6**. Formyl derivative **2e** under the same conditions, was completely deprotected to give compound **8**. When the reaction was done with anhydrous solution of HCl in EtOH or in formic acid, the corresponding formyl derivative **14** was obtained (Scheme 3).

We intended to prepare amide impurity **7** by aminolysis of the corresponding ethyl ester and we also hoped that hydrolysis of this ester can provide acid **9**. For this purpose we prepared pyrazolecarboxylate **3b** using a modification of the literature procedure [11]. Similarly, also the corresponding benzyl ester **3c** was prepared [12]. Using general procedure described above, starting from compounds **2a** and **2e**, esters **15-18** were prepared (Scheme 4).

Aminolysis of both esters **15** and **16** to the corresponding amides **19** and **20** was very sluggish even using saturated ethanolic ammonia at 100°C under pressure; the mixtures after five days still contain about 10% of the starting compounds. Compound **19** was also

**20** $R^1$ = H

*i;* $NH_3$, EtOH, 100 °C, 5 d; *ii,* $NH_3$, EtOH, $MgBr_2$, 100 °C, 1 d

obtained using catalysis [13] with $MgBr_2$, which shortened the reaction time but the crude mixture contained several impurities not present in case the reaction was done without the catalyst (Scheme 5).

Our initial attempts to synthesize acid **9** by hydrolysis of the corresponding ester **15** led under all conditions used to complex mixtures. Therefore the benzyl esters **17** and **18** were prepared and their hydrogenolytic debenzylation provided the corresponding acids **9** and **12** (Scheme 6). However, prolongation of the reaction time led to partial overreduction providing compounds having molecular weight higher by 4H (LC-MS).

Initially we tried to avoid direct condensation of compounds **2a** and **2e** with 3-amino-4-pyrazol carboxylic acid (**3d**) and its amide (**3e**) since we expected partial hydrolysis and decarboxylation during the reaction. When we tried to do the reaction of **2a** with **3d** in a mixture of ethanol and hydrochloric acid, a mixture of the required acid **9** and its ethyl ester **15** was formed. However, we found that at 50°C in acetic acid the reaction is clean to give the required product **9** in good yield. Similarly, using formic acid and the following hydrolysis with aqueous hydrochloric acid, unsubstituted compound **12** was obtained (Scheme 7).

## EXPERIMENTAL

Reagents used in the synthesis were purchased from Sigma-Aldrich and were used without purification.

Melting points were measured on a Kofler block and are uncorrected. The IR spectra were measured on a Nicolet Nexus FTIR instrument (Thermo) by accumulation of 64 scans with 4 $cm^{-1}$ resolution using the ATR technique (ZnSe crystal); wavenumbers are given in $cm^{-1}$. The UV spectra were recorded on a Hewlett-Packard 8452A spectrophotometer (ethanol) in the range 190–400 nm. NMR experiments were carried out on a Bruker Avance 250. The Mass spectra [MS/MS; ionization mode APCI(+)] were measured on an API 3000 PE machine (Sciex Instruments, Applied Biosystems).

UV $\lambda_{max}$ (log ε): 206 (4.49), 234 (4.51), 350 (3.82). $^1H$ NMR (DMSO): δ 1.06 (t, 3H, $J$ = 7.2, $NCH_2C\mathbf{H}_3$), 1.85 (s, 3H, $C\mathbf{H}_3CO$), 3.72 (q, 2H, $J$ = 7.2, $CH_2$), 7.54-8.20 (m, 7H, 5 × Ar—H, 1 × $CONH_2$), 8.61 (s, 1H, H-2), 8.86 (d, 1H, $J$ = 4.5, H-5). $^{13}C$ NMR (DMSO): 12.91, 22.67, 43.37, 105.49, 109.32, 128.81, 129.43, 129.75, 130.11, 131.12, 142.63, 145.73, 146.09, 147.53, 151.86, 162.54, 169.70. UV $\lambda_{max}$ (log ε): 206 (4.49), 234 (4.51), 350 (3.82). Anal. Calcd. for $C_{17}H_{17}N_5O_2$: C 63.15; H 5.30; N 21.66. Found: C 63.38; H 5.48; N 21.99. HRMS Calcd. for $C_{17}H_{18}N_5O_2$ $(M+H)^+$ 324.14605. Found: 324.14551.

***Method B.*** The procedure is similar as Method (A), only 0.2 g of $MgBr_2$ was added and the mixture was heated for 1 day to provide after chromatography 38% of **19**.

***Method C.*** A mixture of **2a** (0.2 g, 0.8 mmol), 3-amino-4-pyrazol carboxamide (**3e**; 0.1 g, 0.8 mmol), and ethanol (3.8 mL) with concentrated HCl (0. 1 mL) was heated in a vial at 50°C for 24 hrs. A solid precipitated during the heating. The mixture was cooled down, the precipitate was filtered off to give 0.17 g of yellow crystals (66%); mp 233–237°C.

**7-[3-(Ethylamino)phenyl]pyrazolo[1,5-*a*]pyrimidin-3-carboxamide (20).** Using Method A described for the preparation of 7-[3-[acetyl(ethyl)amino]phenyl]pyrazolo[1,5-*a*]pyrimidin-3-carboxamide (**19**), compound **20** was obtained in 60% yield; mp 193–203°C. IR: NH 3366, 3305, 3116, CH 2950, C=O 1666, C=C + C=N 1626, 1543, 1513, 1472 $cm^{-1}$. UV $\lambda_{max}$ (log ε): 206 (4.07), 246 (4.15), 350 (3.81). $^1H$ NMR (DMSO): δ 1.20 (t, 3H, $J$ = 7.1, $CH_3$), 3.10 (q, 2H, $J$ = 7.1, $CH_2$), 5.90 (t, 1H, $J$ = 5.3, NH), 6.80-7.38 (m, 5H, Ar—H), 7.50 (s, 1H, $CONH_2$), 7.63 (s, 1H, $CONH_2$), 8.59 (s, 1H, H-2), 8.81 (d, 1H, $J$ = 4.5, H-5). $^{13}C$ NMR (DMSO): 14.21, 37.22, 105.17, 108.77, 112.55, 114.79, 116.61, 129.06, 130.45, 145.60, 146.80, 148.18, 148.88, 151.77, 162.64. Anal. Calcd. for $C_{15}H_{15}N_5O$: C 64.04; H 5.37; N 24.90. Found: C 63.87; H 5.22; N 25.34. HRMS Calcd. for $C_{15}H_{16}N_5O$ $(M+H)^+$ 282.13549. Found: 282.13510.

**7-(3-(*N*-Ethylacetamido)phenyl)pyrazolo[1,5-*a*]pyrimidine-3-carboxylic acid (9).** A mixture of *N*-[(2*E*)-3-[3-(dimethylamino)prop-2-enoyl]phenyl]-*N*-ethylacetamide (**2a**, 1 g, 4 mmol), 3-amino-4-pyrazolecarboxylic acid (**3d**; 0.5 g, 4 mmol), acetic acid (20 mL) was stirred at 50°C for 24 hrs. The mixture was evaporated, the residue was dissolved in $CH_2Cl_2$ and extracted with 10% solution of $Na_2CO_3$ (5 × 8 mL). Insoluble particles were filtered off from the collected aqueous portions and the clear solution was acidified with acetic acid. Then the solution was extracted with $CH_2Cl_2$ (10 × 15 mL) and the extract was dried with $MgSO_4$. The residue after evaporation was triturated with water and the insoluble portion was filtered off to give 0.3 g (48%); mp 195–200°C (decomp.). IR: NH 3293, CH 2973, 2934, C=O 1652, 1575, 1544, C=C + C=N 1402, CO 1299 $cm^{-1}$. UV $\lambda_{max}$ (log ε): 206 (4.11), 236 (4.33), 352 (3.56). $^1H$ NMR (250 MHz, DMSO): 1.05 (t, 3H, $J$ = 7.1, $NCH_2C\mathbf{H}_3$), 2.08 (s, 3H, $COCH_3$), 3.72 (q, 2H, $J$ = 7.1, $CH_2$), 7.31 (d, 1H, $J$ = 4.4, H-6), 7.54 (d, 1H, $J$ = 7.6, H-4′ or H-6′), 7.67 (d, 1H, $J$ = 7.6, H-5′), 8.01 (m, 1H, H-2′), 8.11 (d, 1H, $J$ = 7.6, H-4′ or H-6′), 8.34 (s, 1H, H-2), 8.65 (d, 1H, $J$ = 4.4, H-5). $^{13}C$ NMR (DMSO): 12.93, 22.65, 43.55, 107.78, 111.84, 128.59, 129.17, 129.67, 130.67, 131.81, 142.60, 145.00, 146.92, 147.06, 150.34, 165.72, 174.69. HRMS Calcd. for $C_{17}H_{17}N_4O_3$ $(M+H)^+$ 325.13007. Found: 325.129469.

**7-(3-(*N*-Ethylamino)phenyl)pyrazolo[1,5-*a*]pyrimidine-3-carboxylic acid (12).** A mixture of *N*-[(2*E*)-3-[3-(dimethylamino)prop-2-enoyl]phenyl]-*N*-ethylformamide (**2a**) (**2e,** 0.25 g, 1 mmol), 3-amino-4-pyrazolecarboxylic acid (**3d**; 0.13 g, 1 mmol), formic acid (4 mL) was stirred at 75°C for 16 hrs. The mixture was evaporated and the residue was stirred with concentrated hydrochloric acid (3 mL) at 50°C for 15 min. The residue after evaporation was dissolved in water (10 mL), alkalized with 10% NaOH and extracted with diethyl ether (2 × 5 mL). The extract was dried with $MgSO_4$ and the residue after evaporation containing according to TLC pure product of decarboxylation **13** (50 mg, 21%). The aqueous layer was neutralized with acetic acid and extracted with dichloromethane (3 × 10 mL). The extract was washed with water and dried with $MgSO_4$. The residue after evaporation was triturated with water and the insoluble

portion was filtered off to provide 0.19 g (64%) of yellowish crystals; mp 198–206°C (decomp.). IR: CH 2981, 2941, C=O 1667, 1652, NH 1538, CO 1231 $cm^{-1}$. UV $\lambda_{max}$ (log ε): 204 (4.35), 236 (4.43), 352 (3.40). $^1$H NMR (250 MHz, DMSO): 1.18 (t, 3H, $J = 7.2$, $NCH_2C\mathbf{H}_3$), 3.07 (q, 2H, $J = 7.2$, $CH_2$), 6.78 (d, 1H, $J = 4.4$, H-6), 7.14-7.35 (m, 4H, arom. H), 8.57 (s, 1H, H-2), 8.78 (d, 1H, $J = 4.4$, H-5). $^{13}$C NMR (DMSO): 14.23, 37.99, 109.22, 112.57, 114.69, 114.97, 116.62, 129.02, 130.17, 130.61, 147.01, 147.97, 152.40, 163.23, 173.05. HRMS Calcd. for $C_{15}H_{14}N_4O_3$ $(M+H)^+$ 298.106590. Found: 298.11893.

A simple and highly efficient procedure for the Biginelli condensation reaction of aldehydes, β-ketoesters, urea, or thiourea catalyzed by Ceric ammonium nitrate (CAN) as a Lewis-acid at ambient temperature is described. The procedure proved to be simple and of high yield.

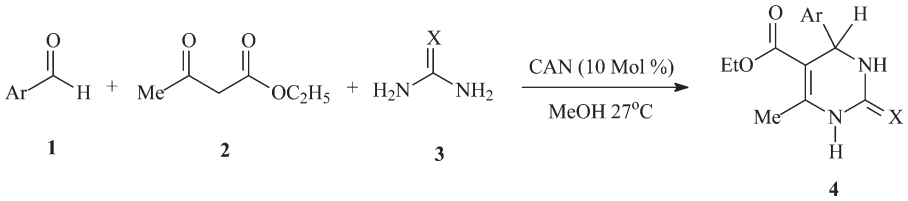
## INTRODUCTION

Dihydropyrimidines (DHPMs) and their derivatives are class of heterocycles that posses a wide range of biological and therapeutic properties. They act as calcium channel blockers, antihypertensive agents, and α-la-antagonists and neuropeptide Y (NPY) antagonists [1–3]. Furthermore, several bioactive isolated marine alkaloids, in particular, the batzelladine alkaloids were found to contain 2-amino-1,4-dihydropyrimidine carboxylate core that have been found to be potent HIV gp-120-CD4 inhibitors [4–6]. They also have known to posses antibacterial, antiviral, antitumor and anti-inflammatory activities [7,8]. Thus, a synthesis of these heterocyclic molecules has been of much importance in current years.

The most simple and direct method for their synthesis was first reported by Biginelli [9] since more than 100 years ago; it involves a three one-pot condensation of benzaldehyde, ethyl acetoacetate, and urea under strong acidic conditions with a low yield. In the past 10 years, several one-pot methodologies for the synthesis of DHPM derivatives were developed. This involves the use of several catalysts such as lanthanide triflates [10], $ZrCl_4$ [11], $VCl_3$ [12], $PPh_3$ [13], $InBr_3$ [14], $GaX_3$ [15], $H_3BO_3$ [16], $KAl(SO_4)_2{\cdot}12H_2O$ supported on silica [17], $Y(NO_3)_3{\cdot}6H_2O$ [18], $Ce(NO_3)_3{\cdot}6H_2O$ [19], $CeCl_3$ and InCl3 [20], Nafion-H [21]. Microwave heating [22], ultrasound irradiation [23], and ionic liquids [24] were also performed as green techniques for their synthesis. Very recently, an efficient synthesis of DHPMs utilizing $CaF_2$ in refluxing EtOH [25], $Cu(NH_2SO_3)_2$ in refluxing acetic acid [26] and the use of etidronic acid catalyst [27] were reported. However, many drawbacks were associated with such synthesis such as the use of expensive reagents, strong acidic conditions, long reaction times, and low to moderate yields. Consequently, there is a need to develop a new efficient and simple method using inexpensive and environmentally benign catalyst. Ceric ammonium nitrate (CAN) was tested as an alternative catalyst. It is worth mentioning that the $CeCl_3{\cdot}7H_2O$ or $Ce(NO_3)_3{\cdot}6H_2O$ catalyzed synthesis of DHMPs suffers from some drawbacks such as the use of fairly high amounts of catalysts (100–20 mol %) or heating at 80°C.

Ceric ammonium nitrate (CAN) is a convenient and widely used reagent for affecting a broad spectrum of synthetic transformations due to its many advantages such as solubility in water and various organic solvents, inexpensiveness, ecofriendly nature, uncomplicated handling, fast conversions, and convenient work-up procedure which make CAN a potent catalyst in organic synthesis. Although DHMPs has been previously synthesized utilizing CAN as one electron oxidant [28] under ultrasound irradiation, we found that there is no need for sonification as the reaction proceeds smoothly at ambient temperature. Also, we do believe that CAN acts as a Lewis acid catalyst because of the applicability of our protocol for the synthesis of DHMP thiones. The use of CAN as a Lewis-acid catalyst in C—N bond formation

**Scheme 1**



in heterocyclic chemistry is somehow limited [29]. Thus, in continuation to our efforts in the synthesis of azoles and azines [30,31] *via* simple and high-yielding protocol, we report herein and for the first time a novel three component one-pot synthesis of Biginelli 3,4-dihydropyrimidine-2(1H)-ones and 2-(1H)-thiones in high yields *via* the reaction of aromatic aldehydes, ethyl acetoacetate, urea, or thiourea using CAN as catalyst at ambient temperature.

## RESULTS AND DISCUSSION

When aryl aldehydes **1** was treated with ethyl acetoacetate **2** and urea or thiourea **3** in MeOH (10 mL) in the presence of CAN (10 mol %) at ambient temperature (27°C), and the reaction mixture was left overnight, the dihydropyrimidinones/thiones **4** were obtained in a high yield (cf. Scheme 1). The optimization of the reaction was investigated. For this goal, we explored the effect of catalyst molar ratio and solvent effect on the overall yield. Our investigation clearly revealed that addition of (10 mol %) of CAN to the reaction mixture containing 1:1:1.2 molar ratio of 1:2:3 at ambient temperature was optimal for the formation of the condensation products. In addition, MeOH was found to be the best solvent among those tested ($H_2O$, EtOH, THF).

To study the scope of the procedure, a variety of aromatic, heteroaromatic, and α,β-unsaturated aldehydes were utilized. In all cases, the reaction proceeds smoothly in a high yield with a slight decrease in the yield when the aryl substituent involves a strong electron donating group. However, attempts to apply this to simple aliphatic aldehydes were unsuccessful (Table 1).

A proposed mechanism to account for the formation of 4 is demonstrated in Scheme 2.

**Table 1**

CAN catalyzed one-pot synthesis of Biginelli 3,4-dihydropyridin-2(1*H*)-ones and their corresponding 2-(1*H*)-thiones.

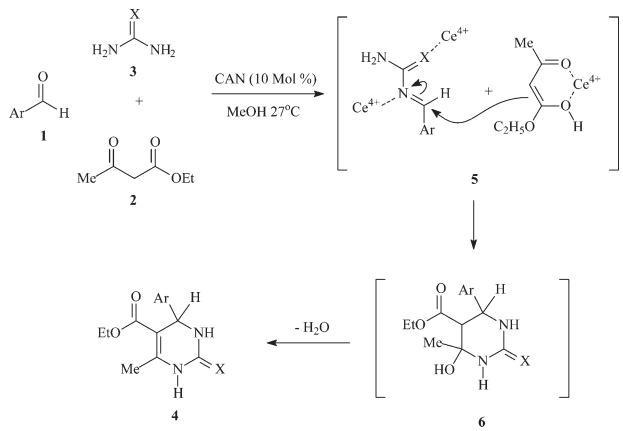
## CONCLUSIONS

In conclusion, a catalytic amount of ceric ammonium nitrate (CAN) efficiently catalyzes the three component one-pot synthesis of Biginelli condensation product in MeOH at ambient temperature. The procedure proved to be simple, highly efficient, produces excellent yields which make it a useful and important addition to the well-known Biginelli reaction.

## EXPERIMENTAL

Melting points were determined on a Shimadzu-Gallenkamp apparatus and are uncorrected. Elemental analyses were obtained on a LECO CHNS-932 Elemental Analyzer. Infrared spectra were recorded in KBr on a Perkin-Elmer 2000 FTIR system. $^1$H-NMR and $^{13}$C-NMR (DMSO-$d_6$) spectra were determined on a Bruker DPX spectrometer operating at 400 MHz for $^1$H-NMR and 100 MHz for $^{13}$C-NMR in DMSO-$d_6$ as solvents and TMS as internal standard; chemical shifts are reported in δ (ppm). Mass spectra were measured on VG Autospec Q MS 30 and MS 9 (AEI) spectrometers, with EI 70 eV.

**Scheme 2**



**General procedure for the synthesis of compounds 4a–j.** To a mixture of each of aldehyde 2a–i (10 mmol), ethylacetoacetate (10 mmol), urea or thiourea (12 mmol) dissolved in MeOH (20 mL), was added cerium IV ammonium nitrate (10 mol %). The reaction mixture was stirred at room temperature (27°C) overnight. Brine solution was then added to the mixture and the salt formed was collected by filtration and recrystallized from EtOH to afford pure samples of compounds **4a–j**.

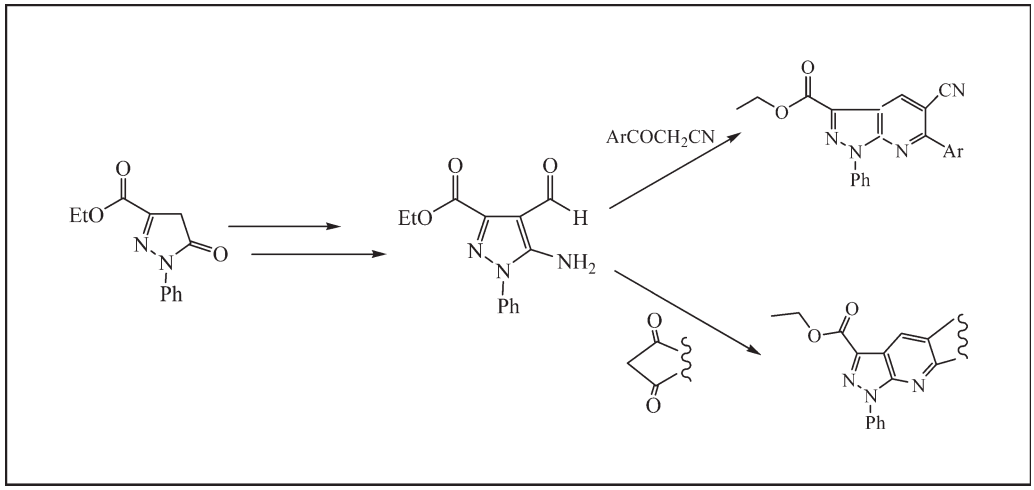
Published online 22 February 2010 in Wiley InterScience (www.interscience.wiley.com).



A series of 1,3,6-trisubstituted and 1,3,5,6-tetrasubstituted pyrazolo [3,4-*b*] pyridines **5** have been synthesized by series of reactions on 1-phenyl-3-carboxylate pyrazolone to obtain *o*-aminoaldehyde, which undergo facile condensation with various α-methylene ketones, nitriles, and esters, furnish fused pyridine derivative in good yield.

*J. Heterocyclic Chem.,* **47**, 287 (2010).

## INTRODUCTION

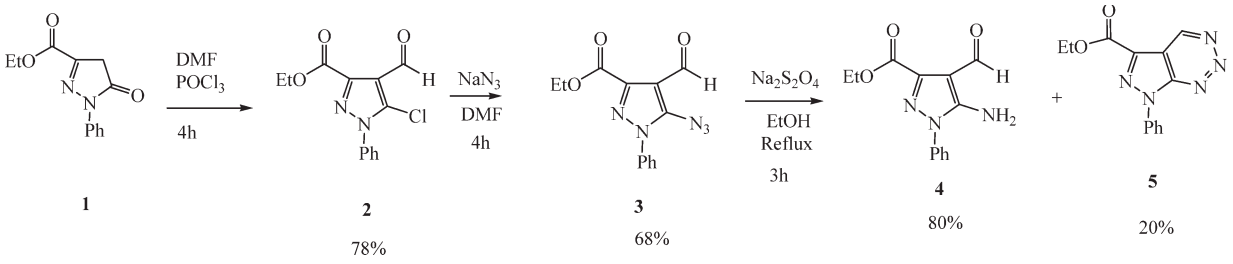
Pyrazolo[3,4-*b*]pyridines as aza-analogues of indazoles are attractive targets in organic synthesis because of their significant biological activities, such as hypoglycemic [1], psychotropic [2], cytotoxic [3], antiviral [4], fungicidal [5], antiasthmatic [6], antiallergic [7], antitumor [8], and antibacterial [9]. These compounds were also used in coronary of neurodegenerative diseases [10,11]. A number of pyrazolo[3,4-*b*]pyridines display interesting anxiolytic activity (*e.g.*, tracazolate), which are potentially biologically active compounds as new inhibitors of xantine oxidases [12]. They have proved to be active against gram-positive and gram-negative bacteria [13] and also as compounds for inhibition of cholesterol formation [14].

*o*-Aminoaldehydes are the key intermediates for the synthesis of various biologically active heterocycles, *e.g.*, [15,16]. The Friedlander condensation of *o*-aminoaldehyde with ketones furnished required tri/tetra cyclic pyrazolo[3,4-*b*]pyridine. The required starting compound *i.e.*, ethyl 4,5-dihydro-5-oxo-1-phenyl-1*H*-carboxylate **1** is prepared by esterification of ethyl 4,5-dihydro-5-oxo-1-phenyl-1*H*-carboxylicacid [17].

*o*-Aminoaldehyde **4,** the key starting compound, was obtained by series of reactions including Vilsmeir-Haack formylation of **1** to furnish *o*-chloroaldehyde **2**, which on $S_N2$ displacement of chloride ($Cl^-$) by azide ($-N_3$) yield **3** in 68% yield. Compound **3** on reductions with sodium dithionate $Na_2S_2O_4$ yields two products *o*-aminoaldehyde **4** in 80% and triazine-5-carboxylate **5** in 20%. The formation of compound **5** can be rationalized by condensation of carbonyl with electronegative nitrogen of azide.

Compounds **4** and **5** were separated on column and were characterized by spectroscopic and analytical methods (Scheme 1), *e.g.*, IR spectra of **4** and **5** both showed ester carbonyl stretching at 1760 $cm^{-1}$, whereas only **4** showed doublet at 3451 and 3347 $cm^{-1}$ for $NH_2$ and 2712 and 1716 $cm^{-1}$for CHO groups. The peaks due to $NH_2$ and CHO are absent in IR spectra of **5**. The $^1$H-NMR of **4** and **5** also help lot to distinguish between **4** and **5**. The $NH_2$ and CHO protons were observed at δ 5.91 and 10.26 in compound **4** and both of these signals

**Scheme 1**

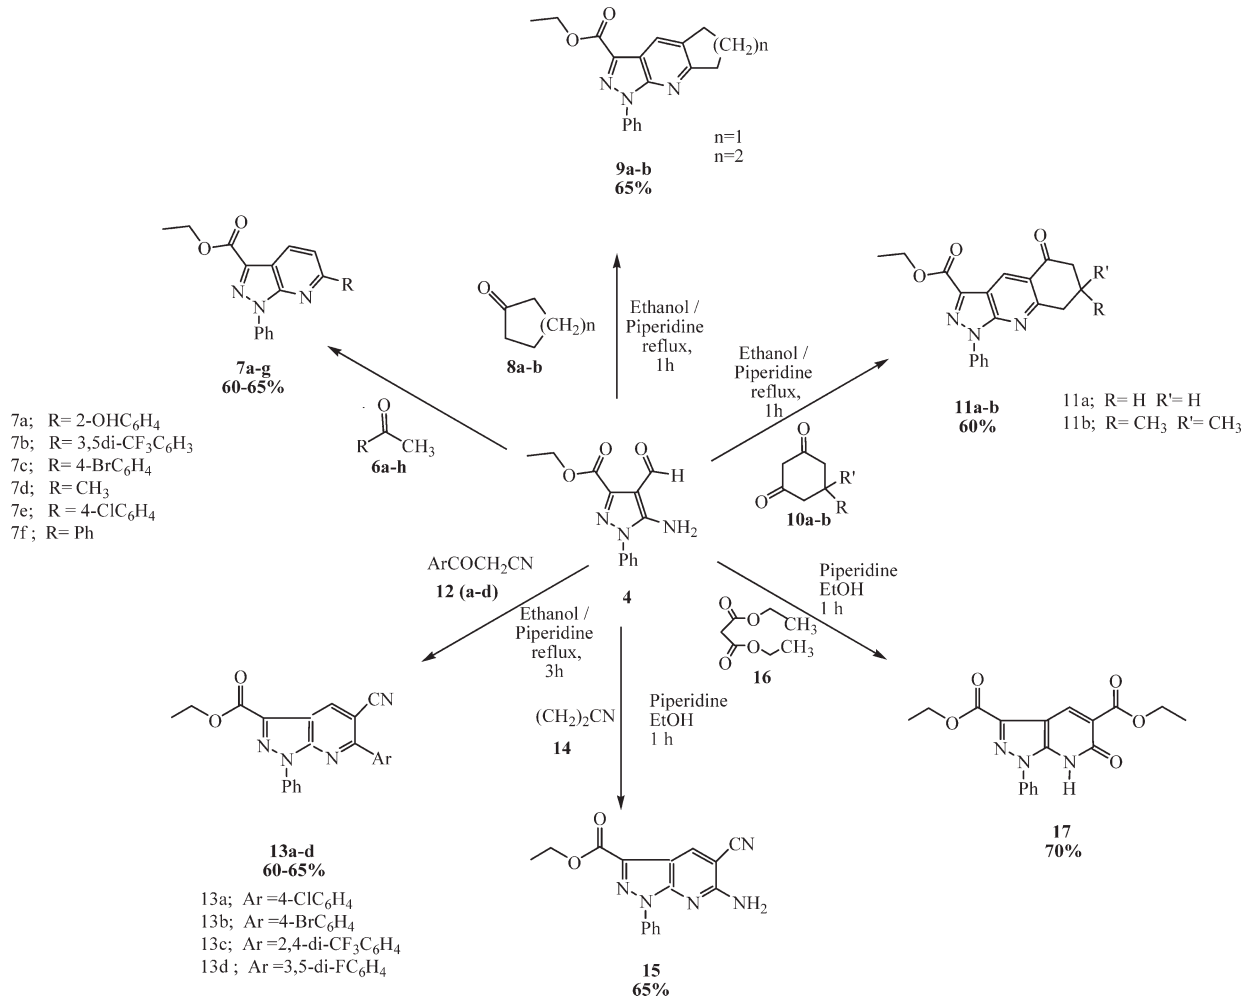


are absent in **5**. While compound **5** showed a sharp singlet at δ 8.31 for $C_4H$. The elemental analyses were also in agreement with the proposed structures of **4** and **5**.

The novel Friedlander condensation of *o*-aminoaldehyde **4** with α-methylene ketones, nitriles, and esters containing active methylene groups was carried out in the presence of piperidine offered fused pyridines in good yields. Thus, the condensation of aromatic methyl ketones **6** and **4** under ethanol reflux furnishes **7** in 60–65% yields. The cyclic ketones **8** on condensation with **4** yield tricyclic pyridines **9** in 60–65% yield.

Similarly, *o*-aminoaldehyde **4** on condensation with dimedone or cyclohexane 1,2-dione **10** offered **11** in 60% yield. Compound **11** is α-methylene ketones functionality, which has potential to generate new heterocycles (Scheme 2). All the obtained compounds were well characterized by IR, $^1$H-, $^{13}$C-NMR, and mass

**Scheme 2**



spectroscopy given in the Experimental section. In all above reaction, the ester group remains intact in the product. The reactions reported here provide a versatile method for synthesis of various substituted 3-ethycarboxy pyrazolo[3,4-*b*]pyridines. We have extended Friedlander condensation using nitriles and esters having reactive methylene group to generate libraries of new heterocycles having multifunctional groups. Reactions with reactive methylene such as aroylacetonitrile **12** and malanonitrile **14** with **4** furnished 6-aryl 5-cyanopyrazloyridines **13** and 6-amino-5-cyanopyrazloyridines **15** in 60–65% yield. Another multifunctional heterocycle **17** was obtained by condensation of diethylmalonate with *o*-aminopyrazole **4** (Scheme 2). The IR, $^1$H-NMR, $^{13}$C-NMR, Mass, and elemental analysis confirm all structures of these synthesized compounds.

## EXPERIMENTAL

Melting points were determined on a Gallenkamp melting point apparatus and are uncorrected. IR spectra were recorded as KBr pellets on a Schimadzu FFTIR-408 spectrophotometer. $^1$H, $^{13}$C-NMR spectra were recorded on a Varian XL-300 (300 MHz, 75 MHz) spectrometer in DMSO-$d_6$ or $CDCl_3$ using TMS as an internal standard, and chemical shifts are expressed in δ (ppm) unit. Elemental analyses were carried out on Hosli CH-Analyzer and are within ±0.3 of the theoretical percentages. All reactions were monitored by thin-layer chromatography carried out on 0.2-mm silica gel (sd Fine Chemicals, 60–120 mesh powder). Common reagent grade chemicals are either commercially available and were used without further purification or prepared by standard literature procedures.

**Ethyl-5-chloro-4-formyl-4,5-dihydro-1*H*-pyrazole-3-carboxylate (2).** To a solution of ethyl-4,5 dihydro-5-oxo-1-phenyl-1*H*-pyrazole-3-carboxylate **1** (0.1 mol, 23.2 g) in dimethyl formamide (0.5 mol, 37 mL) was added phosphorous oxychloride (0.3 mol, 46 mL) in small portions at 10–15°C with stirring. The reaction mixture was stirred at 65–70°C for 4 h and poured into ice-cold water (900 mL). The precipitated product was filtered by suction, washed with water, and recrystallized. Colorless prism (ethanol), mp. 135–136°C, yield 24.5 g (78%), IR: 3417m, 2720, 1739s, 1671m, 1597w cm$^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.34 (t, 3H, $J$ = 6.8 Hz, $CH_3$), 4.41 (q, 2H, $J$ = 6.8 Hz, $OCH_2$), 7.54–7.61 (m, 5H, Ar-H), 10.31 (S, 1H, CHO). Anal. Calcd. for $C_{13}H_{11}Cl\ N_2O_3$: C, 56.03; H, 3.98; N, 10.05. Found: C, 56.25; H, 3.70; N, 10.23.

**Ethyl-5-azido-4-formyl-4,5-dihydro-1-phenyl-1*H*-pyrazole-3-carboxylate (3).** To the solution of ethyl-5-chloro-4-formyl-4,5-dihydro-1*H*-pyrazole-3-carboxylate **2** (27.869 g, 0.1 mol) in dimethylformamide (150 mL), sodium azide (7.15 g, 0.109 mol) was slowly added for 30 min. The reaction mixture was stirred for 4 h (TLC check, toluene/acetone 8:2) and poured in ice-cold water (1000 mL). The precipitated solid was filtered on suction pump and dried to give colorless prism (ethanol), mp. 75–76°C. Yield 19.38 g (68%), IR: 3419m, 3390m, 2164m, 1720s, 1668m, 1597w cm$^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.33 (t, $J$ = 6.8 Hz, 3H, $CH_3$); 4.46 (q, $J$ = 6.8 Hz, 2H, —$OCH_2$); 7.50–7.60 (m, 5H, Ar-H), 10.26 (s, 1H CHO). Anal. Cacld. for $C_{13}H_{11}N_5O_3$: C, 54.74; H, 3.89; N, 24.55. Found: C, 54.67; H, 3.78; N, 24.38. *m*/*z* (70 eV): 285.

**General procedure for the synthesis of ethyl-5-amino-4-formyl-4,5-dihydro-1-phenyl-1*H*-pyrazole-3-carboxylate (4) and ethyl-7-phenyl-7*H*-pyrazolo[3,4-d][1,2,3]triazene-5-carboxylate (5).** A mixture of ethyl-5-azido-4-formyl-4,5-dihydro-1-phenyl-1*H*-pyrazole-3-carboxylate (25 g, 0.089 mol) and sodium dithionate (0.1 mol, 17.4 g) in ethanol (275 mL) was refluxed for 3 h (TLC check, toluene/acetone, 8:2). The mixture was then poured into ice-cold water (800 mL). The precipitated solid was filtered by suction, washed with water, and dried. The obtained solid was separated by column chromatography using silica 60–120 mesh powder and eluting with toluene/acetone as 9:1. mp. 183–184°C, yield 18.44 g (80%), pale-yellow-color needles (ethanol) IR: 3451m, 3347m, 2712s, 1716m, 1677s, 1597w cm$^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.41 (t, $J$ = 7.2 Hz, 3H, $CH_3$), 4.49 (q, $J$ = 7.2 Hz, 2H, $OCH_2$), 5.91 (bs, 2H, exchange with $D_2O$, $NH_2$), 7.47–7.48 (m, 5H, Ar-H), 10.26 (s, 1H, CHO). $^{13}$C-NMR (75 MHz DMSO-$d_6$) 15.0, 61.9, 105.6, 125.5, 129.7 (2C'S), 130.6 (2C'S), 137.4, 143.0, 151.4, 162.2, 186.3. Anal. Calcd. for $C_{13}H_{13}N_3O_3$: C, 60.22; H, 5.05; N,16.21. Found: C, 60.34; H, 5.23; N, 16.46.

**Ethyl-7-phenyl-7*H*-pyrazolo[3,4-d][1,2,3]triazene-5-carboxylate (5).** Yellow needle (ethanol) mp. 216–217°C, yield 4.61 g (20%), IR: 2980m, 1760s, 1710s, 1610m, 1510s cm$^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.44 (t, $J$ = 6.2 Hz, 3H, $CH_3$), 4.45 (q, $J$ = 6.2 Hz, 2H, —$OCH_2$), 7.43–7.48 (m, 5H, Ar-H), 8.31 (s, 1H, CH). Anal. Calcd. for $C_{13}H_{11}N_5O_2$: C, 57.99; H, 4.12; N, 26.01. Found: C, 57.82; H, 4.20; N, 26.18.

**General procedure for the synthesis of 1-phenyl-1*H*-pyrazolo-[3,4-*b*]pyridine-3-carboxylate (7a–g).** A mixture of 4 (0.2 g, 7.0 mmol) and substituted acetophenone 6 (0.12 g, 8.0 mmol) in ethanol (15–20 mL) with catalytic amount of piperedine (0.5 mL) was refluxed for 3 h (TLC check. toluene/acetone, 8:2). The reaction mixture was then cooled to room temperature, and the obtained solid was collected by suction filtration, washed with ethanol, and recrystallized.

**Ethyl-6-(2-hydroxyphenyl)-1-phenyl-1*H*-pyrazolo-[3,4-b]pyridine-3-carboxylate (7a).** Colorless prism (methanol) mp. 140–141°C, yield 1.5 g (60%), IR: 3450m, 1835s, 1730s, 1668m cm$^{-1}$. $^1$H-NMR (DMSO-$d_6$): δ 1.43 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.45 (q, $J$ = 6.8 Hz, 2H, $OCH_2$), 7.0 (t, $J$ = 7.1 Hz, 2H Ar-H), 7.2 (t, $J$ = 7.1 Hz, 2H, Ar-H), 7.6 (d, 1H, $J$ = 6.8 Hz, Ar-H), 8.0–8.1 (m, 5H, Ar-H), 8.3 (d, $J$ = 6.8 Hz,1H, Ar-H), 11.90 (bs, 1H —OH). $^{13}$C-NMR (75 MHz, DMSO-$d_6$) 15.1, 62.0, 115.2, 118.4, 119.6, 120.4, 122.2, 123.6 (2C), 128.9, 130.3, 130.5 (2C), 132.8, 133.1, 136.3, 138.7, 149.4, 157.9, 158.6, 162.0. Anal. Calcd. for $C_{21}H_{17}N_3O_3$: C, 70.18; H, 4.77; N,11.69. Found: C, 70.24; H, 4.58; N,11.87. *m*/*z* (70 eV): 359 [M + 1].

**Ethyl-6-(3,5-bis(trifluoromethyl)phenyl)-1-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-3-carboxylate (7b).** Colorless needle (ethanol/water, 8:2), mp. 168–170°C, yield 1.94 g (58%), IR: 3280m, 1710s, 1640w cm$^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.42 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.46 (q, 2H, $J$ = 6.8 Hz, —$OCH_2$), 7.45 (d, $J$ = 8.1 Hz, 2H, Ar-H), 7.56 (d, $J$ = 8.1 Hz, 2H, Ar-H), 8.14 (s, 1H, Ar-H), 8.25 (d, $J$ = 7.6 Hz, 2H, Ar-H), 8.48 (d, $J$ = 7.6 Hz, 2H, Ar-H), 8.70 (s, 1H, Ar-H). Anal. Calcd. for $C_{23}H_{15}F_6N_3O_2$: C, 57.63; H, 3.15; N, 8.77. Found: C, 57.48; H, 3.29; N, 8.84; *m*/*z* (70 eV) = 482 [M + 1, 90%], 481 [M + 1, 60%], 480, 439, 338, 254.

**Ethyl-6-(4-bromophenyl)-1-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-3-carboxylate (7c).** Colourless needles (ethanol/water, 8:2), mp. 170–172°C, yield 1.76 g (60%), IR: 1760w, 1620m, 1091w $cm^{-1}$. $^1$H-NMR (300 MHz, $CDCl_3$): δ 1.50 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.60 (q, $J$ = 6.8 Hz, 2H, $OCH_2$), 8.31 (dd, $J$ = 8.2 and 2.3 Hz 2H, Ar-H), 7.92 (dd, $J$ = 8.2 and 2.3 Hz, 2H, Ar-H), 7.23–7.7 (m, 5H, Ar-H), 9.01 (d, 1H, $J$ = 8.60 Hz, Ar-H); 9.21 (d, 1H, $J$ = 8.60 Hz Ar-H). Anal. Calcd. for $C_{21}H_{16}BrN_3O_2$: C, 59.73; H, 3.82; N, 9.95. Found C, 59.68; H, 3.79; N, 9.90.

**Ethyl-6-methyl-1-phenyl-1*H*-pyrazolo [3,4-*b*]pyridine-3-carboxylate (7d).** Colorless needles (ethanol/water, 8:2) mp. 136–137°C, yield 1.21 g (62%), IR: 2350s, 1668m, 1610s, 1540w, 1410w $cm^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.41 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.40 (q, $J$ = 6.8 Hz, 2H, $CH_2$), 2.67 (s, $J$ = 6.6 Hz, 3H, $CH_3$), 7.22 (t, $J$ = 6.3 Hz, 2H, Ar-H), 7.61 (t, $J$ = 6.3 Hz, 1H, Ar-H), 8.0–8.1 (m, 2H, Ar-H), 8.32 (d, $J$ = 7.3 Hz, 1H, Ar-H), 8.60 (d, $J$ = 7.2 Hz, 1H, Ar-H). Anal. Calcd. for: $C_{16}H_{15}N_3O_2$ Calcd: C, 68.34, H, 5.37, N,14.94. Found: C, 68.33, H, 5.36, N, 14.90.

**Ethyl-6-(4-chlorophenyl)-1-phenyl-1*H*-pyrazolo[3,4-b]pyridine-3-carboxylate (7e).** Colorless needles (ethanol: water, 8:2) mp. 186–187°C, yield 1.45 g (55%). IR: 2339m, 1668s, 1630w, 1576s $cm^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.70 (t, $J$ = 6.4 Hz, 3H, $CH_3$), 4.41 (q, $J$ = 6.4 Hz, 2H, $OCH_2$), 7.23–7.70 (m, 5H, Ar-H), 7.75 (d, $J$ = 8.2 Hz, 2H, Ar-H), 7.99 (d, $J$ = 8.2 Hz, 2H Ar-H), 8.11 (d, $J$ = 8.2 Hz, 1H, Ar-H), 8.32 (d, $J$ = 8.3 Hz, 1H, Ar-H). Anal. Calcd. for $C_{21}H_{16}ClN_3O_2$: C, 66.76; H, 4.27; N, 11.12. Found: C, 59.54; H, 3.98; N, 11.32.

**Ethyl-1,6 diphenyl-1*H*-pyrazolo [3,4-*b*] pyridine-3-carboxylate (7f).** Colorless needles (ethylacetate), mp.176–177°C, yield 1.44 g (60%). IR: 2339m, 1587w $cm^{-1}$ $^1$H-NMR ($CDCl_3$): δ 1.70 (t, $J$ = 6.4 Hz, 3H, $CH_3$), 4.45 (q, $J$ = 6.4 Hz, 2H, $OCH_2$), 7.23–7.70 (m, 10H, Ar-H), 7.75 (d, $J$ = 8.1 Hz, 1H, Ar-H), 8.11 (d, $J$ = 8.1 Hz, 1H, Ar-H). Anal. Calcd. for: $C_{21}H_{17}N_3O_2$: C, 73.45; H, 4.99; N, 12.24. Found: C, 73.26; H, 4.75; N, 12.42.

**General procedure for the synthesis of pyrazolo-[4,3-*e*]pyridine-3-carboxylate (9a, b).** The mixture of 4 (0.2 g, 7.0 mmol) and aromatic ketones 8 (7.0 mmol) with catalytic amount of piperedine (0.2 mL) was dissolved in ethanol (15 mL). The reaction mixture was then refluxed for 4 h (TLC check, toluene/acetone, 8:2). The reaction mixture was then cooled to room temperature, and the obtained solid was collected by suction filtration, washed with ethanol, and recrystallized to furnish compound 9.

**Ethyl-1-phenyl-1,5,6,7-tetrahydrocyclopenta[*b*]pyrazolo [4,3-*e*]pyridine-3-carboxylate (9a).** Colorless needles (ethanol/DMF, 5:1), mp.160–161°C, yield 1.39 g (65%). IR: 1740m, 1605s, 1510 w $cm^{-1}$. $^1$H-NMR (DMSO-$d_6$): δ 1.43 (t, 3H, $J$ = 6.8 Hz, $CH_3$), 2.21 (t, 2H, $J$ = 6.4 Hz, $CH_2$), 3.21 (t, $J$ = 6.4 Hz, $CH_2$), 3.45 (t, 2H, $J$ = 6.4 Hz, $CH_2$), 4.51 (q, 2H, $J$ = 6.8 Hz, $OCH_2$), 7.17–8.32 (m, 5H, Ar-H), 8.44 (s, 1H, $C_4$H). $m/z$ (70 eV): 307 (M + 1, 90%). $^{13}$C-NMR (75 MHz, DMSO-$d_6$). 144.2, 160.4, 60.9, 14.1, 110.3,147.8, 134.0, 33.1, 135.5, 165.1, 34.9, 25.3, 139.7, 120.2, 129.4, 126.3, 129.4, 120.2. Anal. Cacld. for $C_{18}H_{16}N_3O_2$: C, 70.34; H, 5.58; N, 13.67. Found: C, 70.30; H, 5.62; N, 13.60.

**Ethyl-1-phenyl-5,6,7,8-tetrahydro-1*H*-pyrazolo-[3,4-b] quinoline-3-carboxylate (9b).** Colorless needles (ethanol/DMF, 5:1), mp. 163–164°C, yield 1.33 g (62%), IR: 1742w, 1605s, 1510 w $cm^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.52 (t, $J$ = 6.4 Hz, 3H, $CH_3$), 2.10 (t, $J$ = 6.4 Hz, 4H, 2 ($CH_2$), 2.90 (t, $J$ = 6.4 Hz, 2H, $CH_2$), 3.01 (t, 2H, $J$ = 6.4 Hz, $CH_2$), 4.60 (q, $J$ = 7.1 Hz, 2H, $OCH_3$), 7.5–8.10 (m, 5H, Ar-H), 8.20 (s, 1H. $C_4$—H). Anal. Calcd. for $C_{18}H_{17}N_3O_2$: C, 71.01; H, 5.96; N, 13.08. Found: C, 71.11; H, 5.98; N, 13.11.

**General procedure for the synthesis of pyrazolo [3,4-b]quinoline-3-carboxylate (11a, b).** The mixture of 4 (0.2 g, 7.0 mmol) and dimedone 10 (7.0 mmol) with catalytic amount of piperedine (0.2 mL) was refluxed in ethanol (15 mL) for 4 h (TLC check). The reaction mixture was then cooled to room temperature, and the obtained solid was collected by suction filtration, washed with ethanol, and recrystallized to afford compound 11.

**Ethyl-5,6,7,8-tetrahydro-5-oxo-1-phenyl-1*H*-pyrazolo [3,4-*b*]quinoline-3-carboxylate (11a).** Colorless needles (ethanol/DMF, 8:2), mp. 201–202°C, yield 1.31 g (56%). IR: 2990w, 1740s, 1640s, 1620s, 1590w, 1410w $cm^{-1}$. $^1$H-NMR ($CDCl_3$): 1.40 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 2.10 (t, 4H, $J$ = 6.3 Hz, $2CH_2$), 2.72 (t, 2H, $J$ = 6.8 Hz, $CH_2$), 3.24 (t, $J$ = 6.3 Hz, 2H, $CH_2$), 4.51 (q, 2H, $J$ = 6.8 Hz, $CH_2$), 7.5–8.20 (m, 5H, Ar-H), 8.90 (s, 1H, Ar-H). $m/z$ (70 eV): 335 (M + 1, 80%). Anal. Calcd. for: $C_{19}H_{17}N_3O_3$: C, 68.05; H, 5.11; N, 12.53. Found: C, 68.11; H, 5.06; N, 12.48.

**Ethyl-5,6,7,8-tetrahydro-7,7-dimemehtyl-5-oxo-1-phenyl-1*H*-pyrazolo[3,4-*b*]quinoline-3-carboxylate (11b).** Colorless needles (ethanol/DMF, 8:2), mp. 204–206°C, yield 1.40 g (60%), IR: 2980m, 1750m, 1700, 1640, 1410 $cm^{-1}$. $^1$H-NMR (DMSO-$d_6$): δ 1.42 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 2.47 (s, 2H, $CH_2$), 2.62 (s, 3H, $CH_3$), 3.20 (s, 3H, $CH_3$), 3.28 (s, 2H, $OCH_2$), 7.45 (t, 1H, Ar-H), 7.62 (t, $J$ = 7.1 Hz, 2H, Ar-H), 8.21 (d, $J$= 7.1 Hz 1H, Ar-H), 8.90 (s,1H, $C_4$—H). $m/z$ (70 eV): 363[M + 1]. $^{13}$C-NMR(75 MHz, DMSO-$d_6$), 144.2, 160.4, 60.9, 14.2, 110.3, 147.8, 135.9, 133.1, 168.1, 52.3, 33.2, 53.2, 196.9,26.7, 26.7, 139.7, 120.2, 129.4, 126.3, 129.3, 120.2. Anal. Calcd. for $C_{21}H_{21}N_3O_3$: C, 69.41; H, 5.82; N, 11.56. Found: C, 69.43; H, 5.78; N, 11.52.

**General procedure for the synthesis of pyrazolo-[3,4-b]pyridine-3-carboxylate (13a–d).** The mixture of **4** (0.2 g, 7.0 mmol), benzoylacetonitrile **12** (7.0 mmol), and catalytic amount of piperedine (0.5 mL) were dissolved in ethanol (15 mL). The reaction mixture was then refluxed for 4 h (TLC check, toluene/acetone, 8:2). The mixture was then cooled to room temperature, and the obtained solid was collected by suction filtration, washed with ethanol, and recrystallized to afford compound **13**.

**Ethyl-6-(4-chlorophenyl)-5-cyano-1-phenyl-1*H*-pyrazolo-[3,4-*b*]pyridine-3-carboxylate (13a).** Colorless solid (ethanol/DMF, 8:2), mp. 246–247°C, yield 1.74 g (62%), IR: 3000w, 2240w, 1740m, 1680m, 1620s, 1510, 1420w $cm^{-1}$. $^1$H-NMR (DMSO-$d_6$): δ 1.62 (t, 3H, $J$ = 6.8 Hz, $CH_3$), 4.70 (q, $J$ = 6.8 Hz, 2H, —$OCH_2$), 7.1–7.82 (m, 5H, ArH), 7.92 (d, $J$ = 6.8 Hz, 2H, $CH_2$), 8.15 (d, $J$ = 8 Hz, 2H, $CH_2$), 9.01 (s, 1H, $C_4$H). $^{13}$C-NMR (75 MHz, DMSO-$d_6$), 110.3, 147.8, 163.9, 108.7, 141.3, 134.4, 144.2, 160.4, 60.9, 14.1, 129.0, 129.4, 132.9, 129.4, 129.0, 139.7, 120.2, 129.4, 126.3, 129.4, 120.2, 117.0. Anal. Calcd. for $C_{22}H_{15}ClN_4O_2$: C, 65.59; H, 3.75; N, 13.91. Found: C, 65.59; H, 3.75; N, 13.91.

**Ethyl-6-(4-bromophenyl)-5-cyano-1-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-3-carboxylate (13b).** Pale-yellow-color solid (ethanol/DMF, 8:2), mp. 261–262°C, yield 1.87 g (55–58%), IR: 2240s, 1780s, 1680w, 1620s, 1510w, 1420w $cm^{-1}$. $^1$H-

NMR ($CDCl_3$): δ 1.60 (t, $J$ = 6.74 Hz, 3H, $CH_3$), 4.70 (q, $J$ = 6.74 Hz, 2H, $OCH_2$), 7.20–7.80 (m, 5H, Ar-H), 7.92 (d, $J$= 8.2 Hz, 2H, $CH_2$), 8.18 (d, $J$ = 8.2 Hz, 2H, $CH_2$), 9.03 (s, 1H, Ar-H). Anal. Calcd. for $C_{22}H_{15}BrN_4O_2$: C, 59.08; H, 3.38; N,12.53. Found: C, 59.13; H, 3.35; N, 12.48.

**Ethyl-6-(2,4-bis(trifluoromethyl)phenyl)-5-cyano-1-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-3-carboxylate (13c).** Pale-yellow-color solid (ethanol/DMF, 8:2), mp. 190–192°C, yield 2.10 g (60%), IR: 3100s, 2250s, 1710m, 1610m, 1540w, 1410w $cm^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.51 (t, 3H, $J$ = 6.8 Hz, $CH_3$), 4.60 (q, 2H, $J$ = 6.8 Hz, $CH_2$), 7.58–7.61 (m, 5H, Ar-H), 8.08 (s, 1H, Ar-H), 8.82 (s, 1H, Ar-H), 8.46 (s, 1H, Ar-H), 9.11 (s, 1H, $C_4H$). Anal. Calcd. for $C_{24}H_{14}F_6N_4O_2$: C, 57.15; H, 2.80; N, 11.11. Found: C, 57.10; H, 2.83; N, 11.08.

**Ethyl-5-cyano-6-(3,5-difluorophenyl)-1-phenyl-1*H*-pyrazolo [3,4-*b*] pyridine-3-carboxylate (13d).** Colorless needles (ethanol/DMF, 8:2), mp. 204–206°C. Yield 1.64 g (58–60%), IR: 3080w, 2240s, 1745m, 1620s, 1540m, 1420w $cm^{-1}$. $^1$H-NMR ($CDCl_3$): δ 1.55 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.60 (q, $J$ = 6.8 Hz, 2H, —$OCH_2$), 7.10 (dd, $J$ = 8.3 and 2.3 Hz, 1H, Ar-H), 7.40 (d, $J$ = 8 Hz, 1H, Ar-H), 7.50 (d, $J$ = 2.3 Hz, 1H, Ar-H), 7.55–7.85 (m, 5H, Ar-H), 9.10 (s, 1H, Ar-H). Anal. Calcd. for $C_{22}H_{14}F_2N_4O_2$: C, 65.35; H, 3.49; N, 13.86. Found: C, 65.31; H, 3.46; N, 13.84.

**Ethyl-6-amino-5-cyano-1-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-3-carboxylate (15).** To the reaction mixture of **4** (0.2 g, 7.0 mmol) and malononitrile **14** (0.05 g, 8.0 mmol) in ethanol (15 mL), catalytic amount of piperedine (0.5 mL) was added. The reaction mixture was refluxed for 4 h (TLC check, toluene/acetone, 8:2) and then cooled to room temperature. The separated solid was filtered by suction to afford colorless needles (ethanol/DMF, 8:2), mp. 206–207°C, yield 1.40 g (65%), IR: 3476w, 2240s, 1610s, 1590w, 1554w $cm^{-1}$. $^1$H-NMR (DMSO-$d_6$): δ 1.55 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.60 (q, $J$ = 6.8 Hz, 2H, $OCH_2$), 5.40 (bs, 2H, $NH_2$, $D_2O$ exchange), 7.20–8.10 (m, 5H, Ar-H), 8.6 (s, 1H, Ar-H). $^{13}$C-NMR (75 MHz, DMSO-$d_6$): δ 15.0 (2C), 62.1 (2C), 91.9, 108.6, 117.5, 122.8, 128.2, 130.1, 139.1, 140.0, 152.4, 159.8,161.7. Anal. Calcd. for $C_{16}H_{13}N_5O_2$: C, 62.51; H, 4.26; N, 22.79. Found: C, 62.53; H, 4.23; N, 22.75.

**Diethyl 6,7-dihydro-6-oxo-1-phenyl-1*H*-pyrazolo [3,4-*b*]pyridine-3,5-dicarboxylate (17).** A mixture of **4** (0.2 g, 7.0 mmol) and diethylmalonate **16** (0.14 g, 9.0 mmol) in ethanol (15 mL) with catalytic amount of piperedine (0.5 mL) was refluxed for 4 h (TLC check, toluene/acetone, 8:2). The reaction mixture was cooled at room temperature. The separated solid was filtered by suction to afford pale-yellow solid (ethanol/DMF, 8:2), mp. 142–143°C, yield 1.73 g (70%), IR: 3450w, 1710s, 1674s, 1610s, 1595w $cm^{-1}$. $^1$H-NMR (DMSO-$d_6$): δ 1.20 (t, $J$ = 6.4 Hz, 3H, $CH_3$), 1.42 (t, $J$ = 6.8 Hz, 3H, $CH_3$), 4.11 (q, $J$ = 6.3 Hz, 2H, $OCH_2$), 4.39 (q, $J$ = 6.3 Hz, 2H, —$OCH_2$); 7.25–8.30 (m, 5H, Ar-H), 8.40 (s, 1H, $C_4H$); 12.60 (bs, 1H, NH). $m/z$ (70 eV): 354 [M − 1]. $^{13}$C-NMR (75 MHz, DMSO-$d_6$): δ 14.1 (2C), 61.0 (2C), 139.7, 120.2, 129.4, 126.3, 129.4, 120.2, 143.4, 97.0, 136.6, 161.2, 120.9, 135.8, 165.0, 160.4. Anal. Calcd. for $C_{18}H_{17}N_3O_5$: C, 60.84; H, 4.82; N, 11.83. Found: C, 60.83; H, 4.85; N, 11.80.

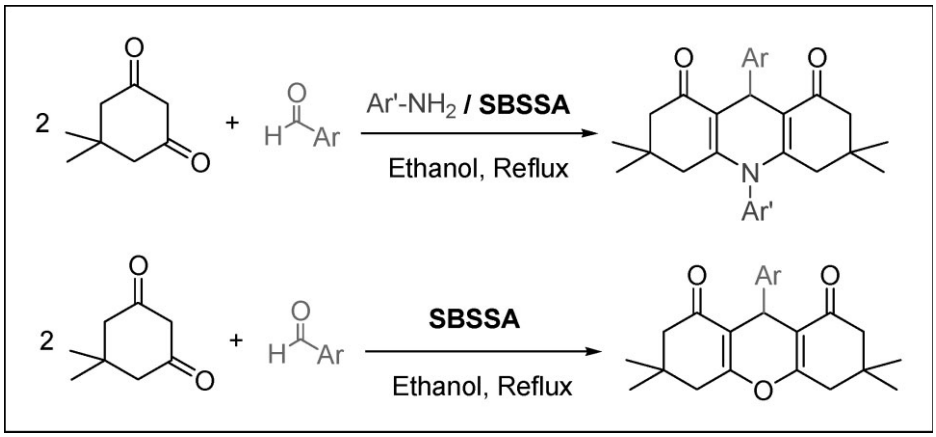
Published online 23 February 2010 in Wiley InterScience (www.interscience.wiley.com).



Silica-bonded *S*-sulfonic acid (SBSSA) has been found to be an efficient catalyst for the synthesis of 1,8-dioxo-decahydroacridines and 1,8-dioxo-octahydroxanthenes in excellent yields. The former have been synthesized from aromatic aldehydes, amines, and 5,5-dimethyl-1,3-cyclohexanedione, whereas the latter from this mixture without amines. The method is an easy access to functionalized acridine and xanthene derivatives. The catalyst can be reused.

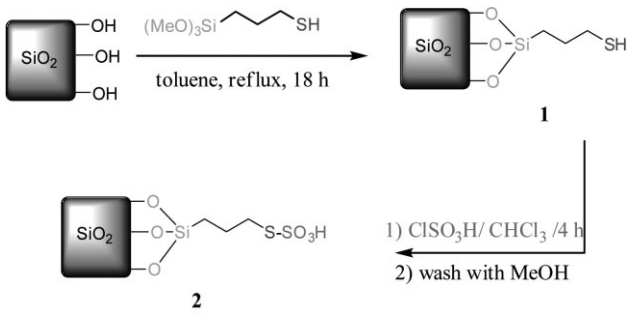
*J. Heterocyclic Chem.,* **47**, 292 (2010).

## INTRODUCTION

The development of heterogeneous catalysts for fine chemical synthesis has become a major area of research. The potential advantages of these materials over homogeneous systems (simplified recovery and reusability, the potential for incorporation in continuous reactors and micro reactors) can lead to novel and environmentally benign chemical procedures for academia and industry [1]. From this viewpoint, catalytic reactions lead to valuable processes, because the use of stoichiometric reagents that are often toxic poses inherent limitations from both an economical and an environmental viewpoint and in specific relation to product purification and waste management [2]. It is clear that green chemistry not only requires the use of environmentally benign reagents and solvents but also it is very crucial to recover and reuse the catalyst. One way to overcome the problem of recyclability of the traditional acid catalyst is to chemically anchor their reactive center onto a large surface area inorganic solid carrier to create new organic–inorganic hybrid catalyst [3]. In these types of solids, the reactive centers are highly mobile similar to homogeneous catalysts and at the same time these species have the advantage of being recyclable in the same fashion as heterogeneous catalysts. In view of this, several types of solid sulfonic acid functionalized silica (both amorphous and ordered) have been synthesized and applied as an alternative to traditional sulfonic acid resins and homogeneous acids in catalyzing chemical transformations [4,5]. Application of solid acids in organic transformation has an important role, because these species have many advantages, such as, simplicity in handling, decreased reactor and plant corrosion problems, and more environmentally safe disposal [4–10].

1,8-Dioxo-9-aryl-10-aryl-decahydroacridines and their derivatives are polyfunctionalized 1,4-dihydropyridine derivatives. In recent years, 1,4-dihydropyridines and their derivatives have attracted strong interest for the treatment of cardiovascular diseases, such as, angina pectoris [11] and hypertension [12]. Acridine derivatives have been used to synthesize labeled conjugates with medicinals, peptides, proteins, and nucleic acids [13–15] that exhibit antitumor and DNA-binding properties. Multicomponent reactions (MCRs) constitute, an

**Scheme 1.** Preparation of silica bonded *S*-sulfonic acid.



especially attractive synthetic strategy, for rapid and efficient library generation because the products are formed in a single step and diversity can be achieved simply by varying the reaction components [16]. Thus, new routes utilizing a MCR protocol for the synthesis of these molecules can attract considerable attention in the search for rapid-entry methods to these heterocycles.

Reportedly, the conventional synthesis of acridines and their derivatives has been performed in an organic acid, such as, HOAc [17]. Recently, few methodologies have been reported in the literature for the synthesis of decahydroacridines [18]. Each of these methods has limitations, such as, poor yields, cumbersome work up procedure, and generation of polluting effluents [17].

Xanthenes are an important class of organic compounds that find use as dyes, fluorescent material for visualization of biomolecules, and in laser technologies due to their useful spectroscopic properties [19]. Xanthenes have also received significant attention from many pharmaceutical and organic chemists essentially because of the broad spectrum of their biological and pharmaceutical properties, such as, antiviral [20], antibacterial [21], antinociceptive activities [22] as well as efficiency in photodynamic therapy [23] and anti-inflammatory activities [24]. There are several reports in the literature for the synthesis of 1,8-dioxooctahydroxanthene derivatives using aromatic aldehydes and 5,5-dimethyl-1,3-cyclohexanedione, these include $InCl_3{\cdot}4H_2O$ in ionic liquid [25], solid-state condensation by grinding at room temperature [26], diammonium hydrogen phosphate [27], *p*-dodecylbenzenesulfonic acid in water [28], $Fe^{3+}$-montmorilonite [29], $NaHSO_4$-$SiO_2$ or silica chloride [30], amberlyst-15 [18d], silica sulfuric acid [31], tetrabutylammonium hydrogen sulfate [32], trimethylsilylchloride [33], 1-butyl-3-methylimidazolium hydrogen sulfate [34], montmorillonite K-10-supported [35], and covalently anchored sulfonic acid on silica gel [36]. Each of these methods have their own advantages but also some of them often suffer from one or more disadvantages, such as, prolonged reaction time, tedious work-up processes, low yield [37], expensive reagents [18d,25], and hazardous organic solvents [37]. Consequently, there is scope for further innovation of methods with milder reaction conditions, short reaction times, increase in variation of the substituents in the components, and better yields in the synthesis of 1,8-dioxodecahydroacridines and 1,8-dioxo-octahydroxanthenes, which can be possibly achieved by choosing silica-bonded *S*-sulfonic acid (SBSSA) as a catalyst for this MCR.

## RESULTS AND DISCUSSION

Recently, we have reported the preparation of SBSSA and its application as catalyst for the synthesis of 1,1-diacetates [5a], quinoxaline [5b], and coumarin derivatives [5c] (Scheme 1).

In our continued interest in the development of a highly expedient methodology for the synthesis of fine chemicals and heterocyclic compounds of biological importance [38], we report here the synthesis of 1,8-dioxo-9-aryl-10-aryl-decahydroacridines and 1,8-dioxo-octahydroxanthenes in the presence of SBSSA as a heterogeneous solid acid (Scheme 2).

To determine the scope of the designed protocol, a number of commercially available aromatic aldehydes have condensed with dimedone and aryl amines under optimized reaction conditions, and the results are summarized in Table 1. We investigated further the electronic effect of different substituents present on the aldehyde component. It was observed that a wide range of aldehydes having both electron-donating and electron-withdrawing groups were equally facile for the reaction, resulting in the formation of decahydroacridine derivatives in very good yields. We also observed that various aniline derivatives reacted smoothly under the reaction conditions.

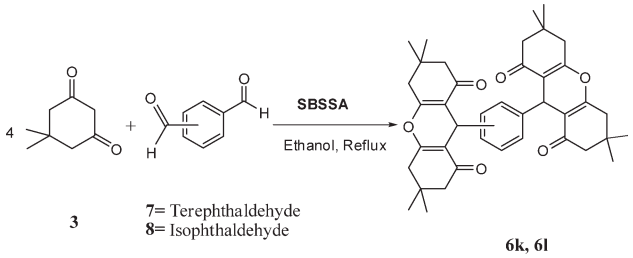
[a] Reaction conditions: Dimedone (2 mmol), aldehyde (1 mmol), catalyst (0.03 g) in refluxing ethanol.
[b] Isolated yield.

Encouraged by these results, we carried out reaction of 5,5-dimethyl-1,3-cyclohexanedione (**3**) and aromatic aldehydes (**4**) in the presence of SBSSA (0.03 g) in refluxing ethanol, which afforded 1,8-dioxo-octahydroxanthene derivatives **6a–n** in excellent yields within a short period of time (Scheme 2, Table 2). Here also the aromatic aldehydes containing both electron-donating and electron-withdrawing groups afforded the products in high yields.

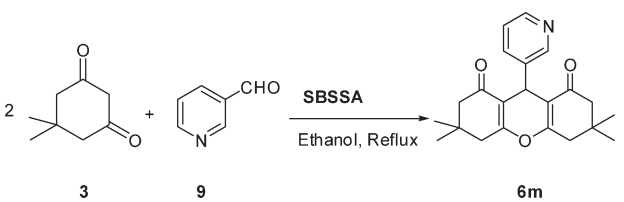
The practical synthetic efficiency of this reaction was highlighted by the reaction of terephthaldehyde (**7**) and isophthaldehyde (**8**) with dimedone (**3**) to give structurally complex xanthenone derivatives (**6k** and **6l**), Scheme 3.

An important feature of this method is that the heterocyclic functionality present in the molecule remains

**Scheme 3.** Synthesis of bis(1,8-dioxo-octahydroxanthenes).



**Scheme 4.** Synthesis of 9-(pyridine-3-yl)-1,8-dioxo-octahydroxanthene.



unaffected. This fact was amply demonstrated by the reaction of pyridine-3-caboxaldehyde (**9**) with dimedone (**3**), which gave 9-(pyridine-3-yl)-1,8-dioxo-octahydroxanthene (**6m**) in excellent yield (Scheme 4).

The possibility of recycling the catalyst was examined using the condensation reaction of 5,5-dimethyl-1,3-cyclohexanedione and 4-chlorobenzaldehyde in ethanol under the optimized conditions. When the reaction was complete, the mixture was filtered and the remaining was washed with warm ethanol, and the catalyst reused in the next reaction. The recycled catalyst could be reused four times without any additional treatment. No observation of any appreciable loss in the catalytic activity of SBSSA was observed (Table 2, entry 2).

In conclusion, we have developed an efficient method for the synthesis of 1,8-dioxo-9-aryl-10-aryl-decahydroacridines and 1,8-dioxo-octahydroxanthenes in high yields using SBSSA as a catalyst. The catalyst was recovered and reused without any noticeable loss of reactivity. The mild reaction conditions and simplicity of the procedure offers improvements over many existing methods.

## EXPERIMENTAL

**General.** Chemicals were purchased from Fluka, Merck, and Aldrich Chemical Companies. All of the products are known, except **5c**–**5h**, and characterized by comparison of their spectral (IR, $^1$H NMR) and physical data with those reported in literature. SBSSA was prepared according to our previous reported procedure [5].

**General procedure for the synthesis of 1,8-dioxo-9-aryl-10-aryl-decahydroacridines derivatives.** To a solution of an aromatic aldehyde (1 mmol), 5,5-dimethyl-1,3-cyclohexanedione (2 mmol) and aryl amine (1 mmol) in ethanol (2 mL) in a round-bottom flask, SBSSA (0.03 g) was added. The mixture was heated under reflux conditions and the reaction was monitored by TLC. After completion of the reaction, the mixture was filtered and the remaining was washed with warm ethanol in order to separate catalyst. Then, water (20 mL) was added to the filtrate and was allowed to stand at room temperature for 1 h. During this time, crystals of the pure product were formed, which were collected by filtration and dried. For further purification, if needed, the products were recrystalized from hot ethanol. The spectral data are given below.

**General procedure for the synthesis of 1,8-dioxo-octahydroxanthene derivatives.** To a solution of an aromatic aldehyde (1 mmol) and 5,5-dimethyl-1,3-cyclohexanedione (2 mmol) in ethanol (2 mL) in a round-bottom flask, SBSSA (0.03 g) was added. The mixture was heated under reflux conditions and the reaction was monitored by TLC. After completion of the reaction, the mixture was filtered and the remaining was washed with warm ethanol in order to separate catalyst. Then, water (20 mL) was added to the filtrate and was allowed to stand at room temperature for 1 h. During this time, crystals of the pure product were formed, which were collected by filtration and dried. For further purification if needed, the products recrystalized from hot ethanol. The NMR data are given below.

An efficient microwave-assisted synthesis of 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles from the cyclocondensation reaction between enones [$CF_3C(O)C(R^2) = C(R^1)(OR)$, where $R^2$ = H, Me; $R^1$ = H, Me, Et, Pr, *i*-Pr, *t*-Bu, *i*-Bu, Ph, 4-$NO_2$-Ph, 4-Cl-Ph, 4-Br-Ph, 4-F-Ph and R = Me, Et] and methyl hydrazinocarboxylate under solvent-free conditions is reported. This process is an efficient alternative to the traditional thermal heating and furnishes the heterocyclic compounds in good to excellent yields in a short reaction time. To show the versatility of 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles, dehydration reactions of these compounds are also demonstrated.

## INTRODUCTION

In recent years, the progress in the field of solvent-free reactions has gained significance because of the high efficiency, operational simplicity and environmentally benign processes. The use of microwave energy to heat chemical reactions on a laboratory scale is growing at a rapid rate. In many instances, controlled microwave heating under sealed vessel conditions has been shown to dramatically reduce reaction times, increase product yields, and enhance product purities by reducing unwanted side reactions when compared to conventional synthetic methods [1,2]. The advantages of this useful technology have more recently also been exploited in the context of multistep total synthesis [3] and medicinal chemistry/drug discovery [4] and have additionally penetrated other important fields [5–8]. The use of microwave irradiation in chemistry has thus become such a popular technique in the scientific community that it might be assumed that, in a few years, most chemists will probably use microwave energy to heat chemical reactions on a laboratory scale [9]. In this context, the use of microwave-assisted organic synthesis (MAOS) has emerged as an alternative and efficient tool, especially in heterocyclic synthesis [10]. 4,5-Dihydropyrazoles are important nitrogen-containing five-membered heterocyclic compounds, with an extensive application in the agrochemical [11] and pharmaceutical fields [12–15]. 4,5-Dihydropyrazoles are quite stable, and have inspired chemists to utilize this fragment in bioactive moieties to synthesize new compounds possessing biological activities. In addition, the presence of fluorine at strategic positions in the molecules can alter the course of the reaction as well as the biological properties of the product [16]. Several 4,5-dihydropyrazoles have played a crucial role in the development of theoretical studies in heterocyclic chemistry and are also extensively used building blocks in organic chemistry [11]. The introduction of halogens and halogenated groups into organic molecules often confers significant and useful changes in their chemical and physical properties.

Therefore, methods for the synthesis of halogenated compounds have received considerable interest in recent years, in particular, fluorinated compounds [17a,b]. The presence of a trifluoromethyl group into cyclic compounds especially at a strategic position of drug molecules has become an important aspect of pharmaceutical research owing to the unique physical and biological properties of fluorine [17c]. The steric requirement of the fluorine atom resembles that of hydrogen (Van der Waals radii: $CF_3$ = 1.35 Å versus $CH_3$ = 1.29 Å). Thus substitution of a methyl by a trifluoromethyl group in a drug candidate usually allows the trifluoromethylated analog to be comparable in size and follow similar drug-protein interactions of parent methyl compound. However, the strong covalent bonding of C—F bond (116 kcal $mol^{-1}$) versus that of the C—H bond (100 kcal $mol^{-1}$) [17d] can often avoid unwanted metabolic transformations. The high electronegativity of fluorine enables a trifluoromethyl group to decrease the electron density and the basicity or enhance the electrophilicity of the neighboring functional groups within a molecule. In many systems, the substitution of the methyl group by a trifluoromethyl group results in added lipophilicity ($\pi_{CF3}$ = 1.07 versus $\pi_{CH3}$ = 0.50) [17e], which may lead to easier absorption and transportation of the molecules within biological systems and thereby improve the overall pharmacokinetic properties of drug candidates.

General methods for the preparation of these compounds involve reactions of hydrazine derivatives with trifluoromethylated precursors such as 1-trifluoromethylated 1,3-diketones [18], β-alkoxyvinyl trifluoromethyl ketones [19], β-trifluoromethyl enaminones [20], and others [21–25]. 1,3-Dipolar cycloaddition reactions of diazoalkanes or nitrilimines with olefins or alkynes have also been carried out, but this procedure has been little used in pyrazole synthesis because 1,3-dipoles are often difficult to prepare and are potentially explosive [26]. In recent years, we have developed a general synthesis of 1,1,1-trihalo-4-methoxy-3-alken-2-ones [27], important halogen-containing building blocks, and shown their usefulness in heterocyclic preparations, such as isoxazoles, pyrazoles, pyrrolidinones, pyrimidines, pyridines, thiazines, and diazepines [27]. Our research group is continuously interested in a more environmentally benign synthesis, which can be demonstrated by our recent articles that focus on solvent-free synthesis [28] and the use of ionic liquids as reaction media [29], associated to efficient techniques such as microwave [30] and ultrasound irradiation [31]. In our sustained interest on the study of heterocyclic synthesis, herein, we wish to report a mild and efficient microwave-assisted method for the preparation of 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles and their derivatives, 5-trifluoromethylpyrazoles, under solvent-free conditions.

## RESULTS AND DISCUSSION

The enones **1a–m** were obtained from the acylation reaction of enol ether or acetal with trifluoroacetic anhydride in accordance with the methodology developed in our laboratory [27]. Methyl hydrazinocarboxylate **2** was obtained commercially.

The synthesis of 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles **3a–m** was performed in a microwave equipment specially designed for organic synthesis. The reaction was carried out under solvent-free conditions by the mixture of enones **1a–m** with methyl hydrazinocarboxylate **2**, in a molar ratio of 1:1.25, respectively, under solvent-free conditions in a range of time between 6 and 8 min and at temperatures indicated in Scheme 1. Under these reaction conditions, the products 4,5-dihydro-1*H*-pyrazoles **3a–m** were obtained in good to high yields and in short reaction times (Scheme 1).

The scope of this microwave-assisted method developed for 4,5-dihydropyrazoles was demonstrated by using enones with various substituents ($R^1$). The results obtained show that the presence of a substituent $R^1$ in the 4-position of the enone **1** influenced the reaction conditions. Enones containing 4-alkyl and 4-aryl substituents were more reactive and presented shorter reaction times, while the non-substituted enone **1a** ($R^1$ = H) required a longer reaction time. This behavior can be explained by the inductive and hyperconjugative/mesomeric effects of the alkyl and aryl substituents, which make the C-β of the enone more

reactive. It is also possible to note that aryl substituted enones (**1h–l**) furnished the products at lower temperatures.

Although the 4,5-dihydropyrazoles **3b,m** have been reported in the literature, their synthesis and spectral characterization have not yet been reported. 4,5-Dihydropyrazoles **3** showed sets of $^{1}H$ and $^{13}C$ NMR data that correspond to the proposed structures. Compounds **3** showed $^{1}H$ NMR chemical shifts of the diastereotopic methylene protons (H-4a and H-4b) as a characteristic AB-system and as a doublet at the range of 3.10–3.74 ppm, respectively, with a geminal coupling constant at the range of $^{2}J$ 18–20 Hz. Previous studies have demonstrated that the doublet in the low field is correspondent to the hydrogen ''cis'' in relation to the hydroxyl group [32]. The same compounds showed $^{13}C$ NMR spectra with typical chemical shifts of 4,5-dihydropyrazole rings at the ranges of 144.3–153.9 (C-3), 38.5–45.6 (C-4), 89.3–92.0 (C-5), 122.5–124.3 ($CF_3$).

The efficiency of this synthetic route was more apparent when the same reaction was performed using conventional thermal heating. Under these conditions of heating, the addition of a solvent was necessary. Ethanol was the solvent chosen due to its polarity and environmental properties that make it a good solvent for cyclocondensation reactions. The reaction of enone **1m** with methyl hydrazinocarboxylate **2** was performed in a molar ratio of 1:1.25, respectively. After 20 h, at room temperature the product **3m** was isolated in moderate yield (70%).

Many studies have shown that the presence of the trifluoromethyl group in 4,5-dihydro-1*H*-pyrazoles is one of the important factors involved in their stability [27]. Thus, it is extremely important to investigate the possibility of dehydrating 4,5-dihydropyrazoles to obtain the aromatic 1-carboxymethyl-pyrazoles. In a strategy to obtain the dehydrated products using microwave irradiation, the reaction of enones **1** with methyl hydrazinocarboxylate **2** was carried out in a molar ratio of 1:1.2 under solvent-free conditions at 200°C. However, the 1-carboxy-5-trifluoromethylpyrazole was not obtained, and the formation of 5-dehydropyrazoles **4a,b,h** was observed, as a result of dehydration with simultaneous loss of the carboxylate group (Scheme 2). Product **4h** was obtained after only 12 min of irradiation at 200°C, demonstrating that the dehydration reaction under MW conditions was sensitive to the substituent effect, and that the phenyl substituent stabilized the products 1-carboxy-5-trifluoromethyl-4,5-dihydro-1*H*-pyrazoles.

[b] Yield of isolated products.

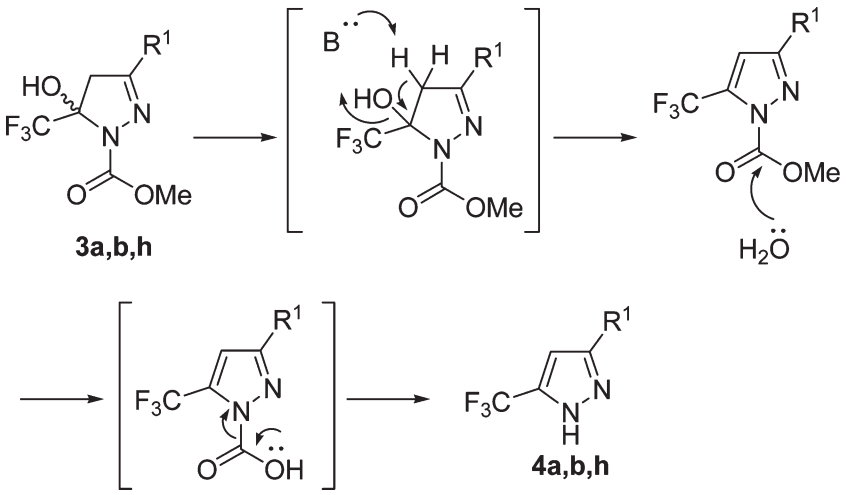
This failure to obtain dehydrated 5-trifluoromethyl-1*H*-pyrazole was a surprise, considering that in previous studies [33], we obtained similar trihalomethylated 4,5-dihydropyrazoles containing a strong electron-withdrawing group attached to the N1-atom, where it was possible to eliminate a water molecule and to obtain the aromatic pyrazole without the loss of the N1-group, by stirring the reaction mixture in ethanol, for 24 hours, at 45°C, followed by reflux in the presence of sulfuric acid for 4 hours. However, we also observed that some 4,5-dihydropyrazoles with an electron-withdrawing group attached to the N1-atom underwent dehydration when heated, with the simultaneous loss of the methyl carboxylate group leading to the formation of 5-trifluoromethylpyrazole [34]. Scheme 3 shows the mechanistic pathway for the formation of products **4a,b,h** [35]. Firstly, the base removes the acid hydrogen leading to water elimination. Then, ester hydrolysis occurs by nucleophilic attack of water on the carboxyl carbon of the ester and subsequent decarboxylation, leading to NH-pyrazole formation.

In summary, we have developed a simple and fast microwave-assisted and solvent-free method to obtain both 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles and their 5-dehydropyrazoles derivatives. This method furnished the products in high to excellent yields through the employment of an environmentally benign approach.

## EXPERIMENTAL

Unless otherwise indicated, all common reactants and solvents were used as obtained from commercial suppliers without further purifications. Reactions were performed using a CEM Discover (300 W) microwave mono Mode for Synthesis controlled by Synergis Version 3.5.9 software. The irradiation power was established at a maximum level of 200 W, the internal vessel pressure at a maximum level of 250 psi. The exact power and pressure was different for each reaction and depended on the reaction temperature, as shown in Figures 1 and 2. The reaction temperatures were constant and recorded by an infrared probe provided by the instrument manufacturer for direct monitoring of the internal temperature, as shown in Figures 1 and 2. Reactions to obtain **3a–m** were performed in simultaneous cooling mode (Power On) and with maximum stirring, while the reactions to obtain **4a,b,h** were performed in Power Off mode.

**Scheme 3**



$^1$H and $^{13}$C NMR spectra were recorded on a Bruker DPX 400 ($^1$H at 400.13 MHz and $^{13}$C at 100.62 MHz) in 5 ppm sample tubes at 298 K (digital resolution ± 0.01 ppm) in $CDCl_3$/TMS solutions. Mass spectra were registered in a HP 5973 MSD connected to a HP 6890 GC and interfaced by a Pentium PC. The GC was equipped with a split-splitless injector, autosampler, cross-linked to a HP-5 capillary column (30 m 0.32 mm of internal diameter), and helium was used as the carrier gas. All melting points were determined on a Reichert Thermovar apparatus.

**Conventional method typical procedure for the synthesis of 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles (3m).** Enones **1m** (1 mmol), methyl hydrazinocarboxylate **2** (1.2 mmol) and ethanol (3 mL) were placed into a round-bottom flask equipped with a stir bar. The mixture was stirred at room temperature during 20 h. After the completion of the reaction, ethanol was removed, dichloromethane (10 mL) was added and the solution was washed with water (3 × 10 mL). The organic layer was dried with $Na_2SO_4$ and the solvent was removed under reduced pressure. The product **3m** was obtained in their pure form without further purification.

**Microwave irradiation typical procedure for the synthesis of 1-carboxymethyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles (3a–m).** Enones **1a–m** (1 mmol) and methyl hydrazinocarboxylate **2** (1.25 mmol) were placed into a 10 mL reaction vessel equipped with a stir bar. The mixture was irradiated at 50 or 100°C (Scheme 1), the power irradiated during the reaction was in the range of 45–80 W, where the internal pressure was of 31–34 psi. The reaction was performed in simultaneous cooling mode (Power On) with high magnetic stirring, during the times and temperatures described in Scheme 1. After completion of the reaction, dichloromethane (10 mL) was added and the solution was washed with water (3 × 10 mL). The organic layer was dried with $Na_2SO_4$ and the solvent was removed under reduced pressure. The products **3a-m** were obtained in their pure form without further purification.

**Typical procedure for the synthesis of 5-trifluoromethyl-1*H*-pyrazoles (4a,b,h).** Enones **1a,b,h** (1 mmol) and methyl hydrazinocarboxylate **2** (1.2 mmol) were placed into a 10 mL reaction vessel equipped with a stir bar. The mixture was irradiated at 200°C, the power irradiated during the reaction was in the range of 25–200 W, where the internal pressure was of 54–86 psi. The reaction was performed without simultaneous cooling (Power Off) at high magnetic stirring, during the times and temperatures described in Scheme 2. After the completion of the reaction, dichloromethane (10 mL) was added and the solution was washed with water (3 × 10 mL). The organic layer was dried with $Na_2SO_4$ and the solvent was removed under reduced pressure. The products **4a,b,h** were obtained in their pure form without further purification.

**1-Carboxymethyl-5-trifluoromethyl-5-hydroxy-3-(2-methylpropyl)-4,5-dihydro-1*H*-pyrazole (3g).** M.p. 41–43°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 0.99 (2s, 6H, $2CH_3$, H11), 1.94 (q, 1H, CH, H10), 2.30 (t, 2H, $CH_2$, H9), 3.12 (d, 1H, $^2J$ = 19 Hz, H4b), 3.28 (d, 1H, $^2J$ = 19 Hz, H4a), 3.91 (s, 3H, $OCH_3$); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 13.1 ($CH_3$), 29.0 ($CH_2$), 28.0 ($CH_2$), 21.8 ($CH_2$), 45.06 (C4), 57.38 (OMe), 90.8 (q, $^2J$ = 34 Hz, C5), 122.7 (q,$^1J$ = 286 Hz, $CF_3$), 153.17 (C3), 157.35 (C=O); GC/MS (m/z, %) 268 ($M^+$, 33), 251 (4.5), 199 (100), 167 (40).

**1-Carboxymethyl-3-phenyl-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole (3h).** M.p. 153–155°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 3.55 (d, 1H, $^2J$ = 18 Hz, H4a), 3.69 (d, 1H, $^2J$ = 18 Hz, H4b), 3.94 (s, 3H, $OCH_3$), 7.43–7.45 (m, 3H, H-Ar), 7.69–7.73 (m, 2H, H-Ar); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 43.3 (C4), 53.8 (OMe), 91.6 (q, $^2J$ = 34 Hz, C5), 123.5 (q, $^1J$ = 286 Hz, $CF_3$), 130.9, 129.7, 128.7, 126.6 (C-Ar), 152.9 (C3), 158.2 (C=O); GC/MS (m/z, %) 288 ($M^+$, 85), 257 (2), 229 (2), 219 (100).

**1-Carboxymethyl-3-(4-nitrophenyl)-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole (3i).** M.p. 180–182°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 3.59 (d, 1H, $^2J$ = 18 Hz, H4b), 3.74 (d, 1H, $^2J$ = 18 Hz, H4a), 3.97 (s, 3H, $OCH_3$), 8.20–8.31 (m, 4H, H-Ar); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 43.1 (C4), 54.1 (OMe), 92.0 (q, $^2J$ = 34 Hz, C5), 122.85 (q, $^1J$ = 286 Hz, $CF_3$), 150.5, 135.7, 127.5, 124.0 (C-

Ar), 148.9 (C3), 153.7 (C=O); GC/MS (m/z, %) 333 ($M^+$, 28), 316 (1), 274 (1), 264 (100).

**1-Carboxymethyl-3-(4-chlorophenyl)-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole (3j).** M.p. 107–109°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 3.61 (d, 1H, $^2J$ = 19 Hz, H4a), 3.66 (d, 1H, $^2J$ = 19 Hz, H4b), 3.94 (s, 3H, $OCH_3$), 7.40 (d, 2H, H-Ar), 7.69 (d, 2H, H-Ar); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 43.2 (C4), 55.9 (OMe), 91.4 (q, $^2J$ = 34 Hz, C5), 124.3 (q, $^1J$ = 286 Hz, $CF_3$), 137.1, 129.1, 128.4, 127.6 (C-Ar), 151.8 (C3), 153.9 (C=O); GC/MS (m/z, %) 323 ($M^+ + H^+$, 30), 322 (90), 253 (100), 209 (70), 137 (60).

**1-Carboxymethyl-3-(4-bromophenyl)-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole (3k).** M.p. 148–151°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 3.51 (d, 1H, $^2J$ = 18 Hz, H4a), 3.65 (d, 1H, $^2J$ = 18 Hz, H4b), 3.94 (s, 3H, $OCH_3$), 7.56 (s, 4H, H-Ar); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 43.1 (C4), 53.8 (OMe), 90.4 (q, $^2J$ = 32 Hz, C5), 122.9 (q, $^1J$ = 287 Hz, $CF_3$), 132.1, 128.8, 128.1, 125.5 (C-Ar), 151.8 (C3), 153.8 (C=O); GC/MS (m/z, %) 367 ($M^+$, 82), 297 (100), 280 (1).

**1-Carboxymethyl-3-(4-fluorophenyl)-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole (3l).** M.p. 145–147°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 3.52 (d, 1H, $^2J$ = 18 Hz, H4a), 3.66 (d, 1H, $^2J$ = 18 Hz, H4b), 3.94 (s, 3H, $OCH_3$), 7.11 (d, 2H, H-Ar), 7.72 (d, 2H, H-Ar); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 43.3 (C4), 53.8 ($OCH_3$), 91.3 (q, $^2J$ = 34 Hz, C5), 122.5 (q,$^1J$ = 286 Hz, $CF_3$), 165.6, 163.1, 128.8, 115.9 (C-Ar), 151.8 (C3), 153.9 (C=O); GC/MS (m/z, %) 306 ($M^+$, 75), 237 (100), 218 (6).

**1-Carboxymethyl-5-trifluoromethyl-5-hydroxy-4-methyl-4,5-dihydro-1*H*-pyrazole (3m).** M.p. 68–71°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 1.27 (d, 1H, $CH_3$), 1.43 (q, 1H, CH), 3.92 (s, 3H, $OCH_3$), 6.87 (s, 1H, CH); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 9.9 ($CH_3$), 47.7 (C4), 53.7 (OMe), 89.4 (q, $^2J$ = 34 Hz, C5), 123.2 (q, $^1J$ = 286 Hz, $CF_3$), 149.7 (C3), 154.1 (C=O); GC/MS (m/z, %) 227 ($M^+ + H^+$, 13), 209 (27), 157 (100), 113 (24).

**5-Trifluoromethyl-1*H*-pyrazole (4a).** Oil; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 6.60 (d, 1H, $^3J$ = 2.0 Hz, H4), 7.86 (d, 1H, $^3J$ = 2.0 Hz, H3), 13.57 (s, 1H, NH). $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 141.3 (q, $^2J$ = 36.7 Hz, C5), 130.5 (C3), 122.1 (q, $^1J$ = 267.7 Hz, $CF_3$), 103.2 (C4). GC/MS (m/z, %) 136 ($M^+$, 100), 117 (49), 69 (65).

**5-Trifluoromethyl-3-methyl-1*H*-pyrazole (4b).** M.p. 89–90°C; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 2.33 (s, 3H, Me), 6.30 (s, 1H, H4), 12.89 (s, 1H, NH); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 10.3 (Me), 102.8 (C4), 121.5 (q, $^1J$ = 287 Hz, $CF_3$), 141.4 (C3), 142.8 (q, $^2J$ = 34 Hz, C5); GC/MS (m/z, %) 150 ($M^+$, 100), 131 (45), 101 (40), 81 (40), 51 (22).

**5-Trifluoromethyl-3-phenyl-1*H*-pyrazole (4h).** Oil; $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm) 6.80 (s, 1H, H4), 7.26–7.59 (m, 5H, H-Ar). $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm) 145.1 (C3), 143.5 (q, $^2J$ = 38.1 Hz, C5), 121.1 (q, $^1J$ = 268.6 Hz, $CF_3$), 100.9 (C4), 125.6, 127.9, 129.1, 129.3 (C-Ar). GC/MS (m/z, %) 212 ($M^+$, 100), 193 (9), 143 (25), 77 (27).

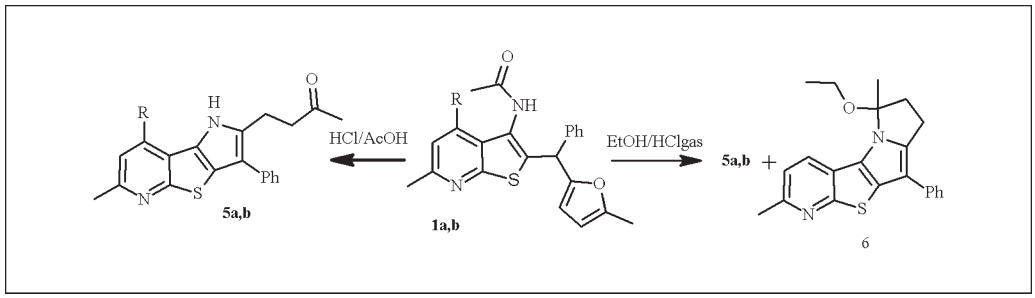
Published online 2 March 2010 in Wiley InterScience (www.interscience.wiley.com).



The preparation of new 3-amino-2-furfurylthieno[2,3-*b*]pyridines (**1a,b**, 69–80%) is described. Subsequent acidic rearrangement of **1a,b** afforded two new annulated heterocyclic products, **5a,b**, pyrrolothieno[2,3-*b*]pyridines (45–74%), and **6**, pyridothieno[2,3-*b*]pyrrolizine (22%), depending on reaction conditions.

*J. Heterocyclic Chem.,* **47**, 309 (2010).

## INTRODUCTION

Thieno[2,3-*b*]pyridine derivatives are well known to possess varied biological and pharmacological activities, and hence, their synthesis has been of interest to chemists [1–7]. We have successively used different thieno[2,3-*b*]pyridine derivatives as intermediates for synthesis of some interesting conjugated and annulated heterocyclic systems [8–11].

Thus, continuing our investigation along this line, we herein wish to report the synthesis and acid catalyzed transformations of *N*-{2-[(5-methyl-2-furyl)(phenyl)methyl]thieno[2,3-*b*]pyridin-3-yl}acetamides.

## RESULTS AND DISCUSSION

The preparation and transformations of 3-amino-2-furfurylthieno[2,3-*b*]pyridines (e.g. 1, Scheme 1) under acid conditions have attracted our attention because these substances could be considered as heteroanalogues of *ortho*-aminobenzylfurans, which were converted into indole derivatives *via* the furan ring recyclization under acid conditions [12–14] (Scheme 1).

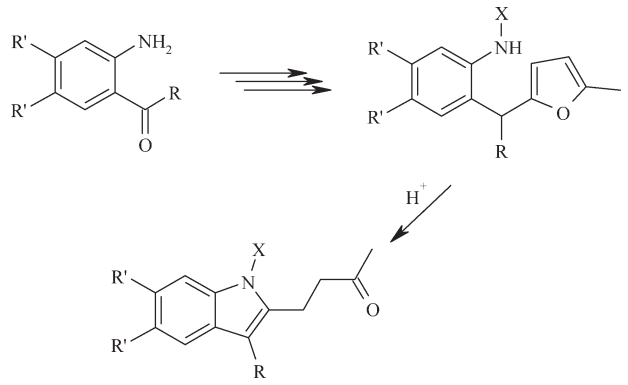
The 3-amino-2-furfurylthieno[2,3-*b*]pyridines **1** were prepared easily from 3-amino-2-benzoylthieno[2,3-*b*]pyridines **2** according to Scheme 2. This approach included an acetylation of aminoketones **2** with acetyl chloride followed by reduction of carbonyl group and alkylation of 2-methylfuran with the alcohols obtained. A mixture of 70% $HClO_4$, acetic anhydride, and acetic acid ($HClO_4$:$Ac_2O$:AcOH = 5.6:3.3:5.2 mmoles) was used as a catalyst for the last stage. The application of the catalyst allowed to decrease undesired side-transformations of alcohols **4a,b** and 2-methylfuran during the reaction [15].

A new heterocyclic system—pyridothienopyrrole **5**—was made from **1** by successive treatment with concentrated HCl in acetic acid under heating (Scheme 3). A cleavage of the protective acetyl group was observed during the reaction.

An attempt to recyclize **1** on heating in ethanolic HCl solution gave the unusual results: if **1b** (R = Me) was smoothly converted into the corresponding pyridothienopyrrole **5b** (64%), **1a** (R = H) gave two substances. We found that in addition to the expected **5a** (45%) another product—a compound **6** (22%)—was isolated from the reaction mixture (Scheme 3).

The structure of **6** is assigned by X-ray analysis [Fig.(1)] [16]. The crystal was grown from $CH_2Cl_2$-petroleum ether mixture. Pyrrolidine moiety of the molecule is practically planar: the angle between planes C(7)-N(2)-C(10)-C(6) and C(7)-C(8)-C(9) is 176.1°. H(8b)-C(8)-C(7)-C(19), H(8a)-C(8)-C(7)-H(9a), H(9b)-C(9)-C(8)-H(8b), and H(9a)-C(9)-C(8)-H(8a) torsion

**Scheme 1**

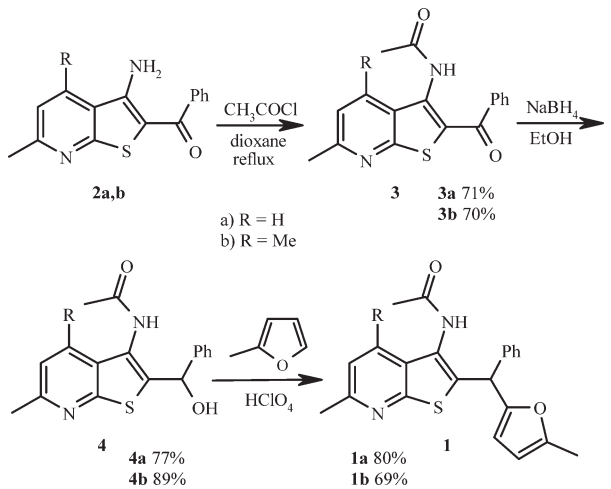


angles equals 4.6, 2.4, 2.1, and 4.7°, correspondingly. Phenyl substituent is located in a plane forming an angle of 3.4° with the heterocyclic core.

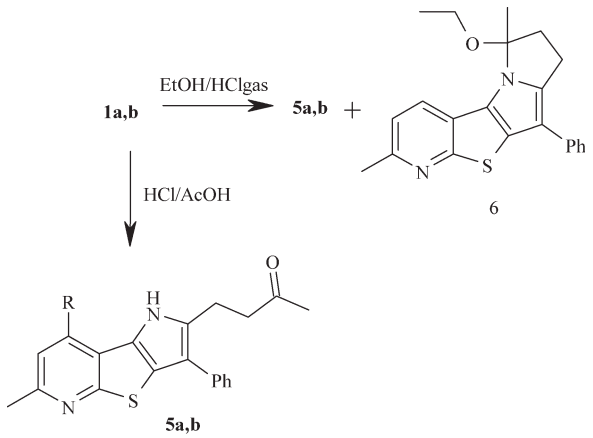
We suppose that the formation of **5a** and **6** proceeds as follows: the furan ring opening leads to a diketone, which in turn reacts with amino group to afford **A** (Scheme 4). The aromatization of **A** leads to pyrrole ring formation as observed earlier for benzylfurans [11–13] to give compound **5a** (Path ***a***). Another route—pyrrolizine **6** formation—is a concurrent process. Probably, compound **6** is provided by ring closure of dihydropyrrolothienopyridine **A** with side chain carbonyl group to produce a cyclic semiaminal **B** (Path ***b***). The interaction between the semiaminal **B** and EtOH molecule allows fixing the pyrrolizine ring as ethoxy derivative which then converts into **6**.

We found that all efforts to furnish the pyrrolizine **6** by heating of the ketone **5a** under identical conditions failed. In our opinion, this result confirms the proposed mechanism: the alkylation occurs before the aromatization of the pyrrole ring. On treating **1a,b** with HCl/

**Scheme 2**



**Scheme 3**



AcOH mixture only **5a,b** (74%, 61%) were formed. In this case the Path ***a*** is predominant because of the equilibrium between cyclic seminal **B** and **A**.

As to the recyclization of **1b**, we suppose that the Me-substituent in position 4 of the pyridine ring prevents the pyrrolidine ring closure, probably, due to steric factors. So in this case, the Path ***a*** is the only possible way for the reaction.

In conclusion, acid-catalyzed transformations of 2-furfurylthieno[2,3-*b*]pyridines have been studied, and the unusual intramolecular N-alkylation of pyrrole ring under acid condition has been disclosed. Possible mechanism of the reaction has been proposed.

## EXPERIMENTAL

Melting points are uncorrected. $^1$H-NMR spectra were measured in DMSO-$d_6$ on Bruker AM 300 spectrometer using TMS as an internal standard. Coupling constant ($J$) values are given in Hz. Mass spectra were recorded on a Kratos MS-30 instrument with 70 eV impact ionization. IR spectra were recorded

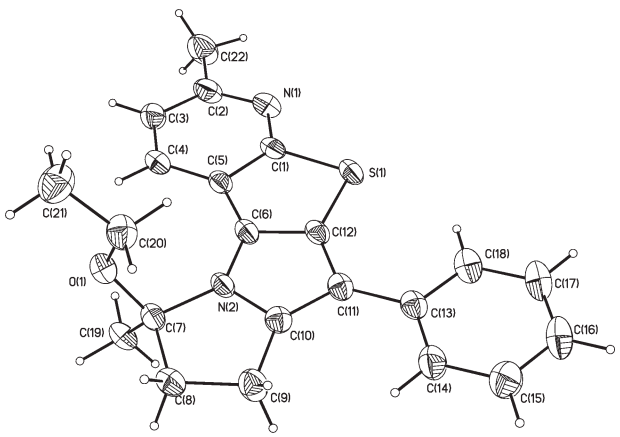


**Figure 1.** ORTEP of the molecular structure of compound **6.**

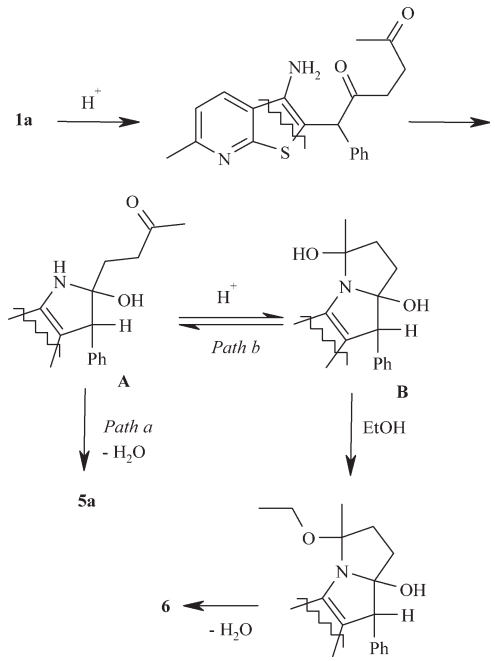
**Scheme 4**



on an InfraLUM FT-02 spectrometer, and absorptions are given in wavenumbers ($cm^{-1}$). Column chromatography was carried out using KSK silica gel (5–40 μm) manufactured by Sorbpolymer Ltd.

**General procedure for acetylation of amines 2a,b.** A mixture of amine (**2a,b**) (10 mmoles) and AcCl (20 mmoles) in 1,4-dioxane (60 mL) was refluxed until the complete conversion of the compounds **2** (TLC). To the cooled stirred mixture, water (10–15 mL) was added drop by drop, and the resulted mixture was left at RT for crystallization of a product. The precipitate thus obtained was separated with suction, washed with aq solution of sodium hydrocarbonate, water, and air-dried. Recrystallization of the solid from DMF yielded compounds **3a,b** as colorless crystals.

***N-(2-Benzoyl-4,6-dimethylthieno[2,3-b]pyridin-3-yl)acetamide (3a).*** This compound was obtained as colorless crystals in 71% yield, mp 161–162°C; IR: NH 3245, CO 1662, CO 1645 $cm^{-1}$; $^1$H-NMR (DMSO-$d_6$): δ 1.50 (s, 3H, $COCH_3$), 2.57 (s, 3H, 4-$CH_3$), 2.62 (s, 3H, 6-$CH_3$), 7.19 (s, 1H, H-5), 7.52 (t, 2H, $H_{Ph}$, $J$ = 7.3 Hz), 7.62–7.74 (m, 3H, phenyl protons), 9.76 ppm (s, 1H, NH), ms: *m/z* 324 (29), 281 (100), 121 (11), 105 (13), 59 (25), 43 (49). Anal. Calcd for $C_{18}H_{16}N_2O_2S$: C, 66.65; H, 4.97; N, 8.64. Found: C, 66.80; H, 5.09; N, 8.70.

***N-(2-Benzoyl-6-methylthieno[2,3-b]pyridin-3-yl)acetamide (3b).*** This compound was obtained as colorless crystals in 70% yield, mp 187–188°C; IR: NH 3213, 3192, CO 1705, CO 1635 $cm^{-1}$; $^1$H-NMR (DMSO-$d_6$): δ 1.65 (s, 3H, $COCH_3$), 2.65 (s, 3H, 6-$CH_3$), 7.42–7.55 (m, 3H, phenyl protons), 7.60–7.67 (m, 2H, phenyl protons), 7.72 (d, 1H, $J$ = 7.3 Hz, H-5), 8.33 (d, 1H, $J$ = 8.1 Hz, H-4), 10.51 ppm (s, 1H, NH); ms: *m/z* 310 (21), 269 (12), 268 (82), 267 (94), 105 (17), 101 (13), 77 (100), 69 (12), 59 (35), 57 (17), 55 (14), 51 (18), 45 (22). Anal. Calcd for $C_{17}H_{14}N_2O_2S$: C, 65.79; H, 4.55; N, 9.03. Found: C, 65.91; H, 4.68; N, 8.91.

**General procedure for the reduction of acylaminoketones 3a,b.** To a vigorously stirred suspension of acylaminoketone (**3a,b**) (5 mmoles) in ethanol (40 mL), $NaBH_4$ (0.23 g, 6 mmoles) was added portion wise, and the mixture was kept at 50–60°C for 2 h. After that the mixture was diluted with water (200 mL) and a precipitate formed was separated by filtration. The solid was recrystallized from ethanol yielding alcohols **4a,b**.

***N-{2-[Hydroxy(phenyl)methyl]-4,6-dimethylthieno[2,3-b]pyridin-3-yl}acetamide (4a).*** This compound was obtained as white powder in 77% yield, mp 178–179 °C; IR: OH 3280, NH 3225, 3120, CO 1652 $cm^{-1}$; $^1$H-NMR (DMSO-$d_6$): δ 2.03 (s, 3H, $COCH_3$), 3.35 (s, 6H, 4-,6-$CH_3$), 5.98 (d, 1H, *CH*—OH, $J$ = 3.7 Hz), 6.36 (d, 1H, CH—*OH*, $J$ = 3.7 Hz), 7.00 (s, 1H, H-5), 7.20–7.41 (m, 5H, phenyl protons), 9.51 ppm (s, 1H, NH), ms: *m/z* 326 (0.7), 308 (20), 293 (40), 267 (100), 265 (98), 251 (12), 105 (21), 101 (10), 80 (38), 76 (17), 59 (24), 43 (59). Anal. Calcd for $C_{18}H_{18}N_2O_2S$: C, 66.23; H, 5.56; N, 8.58. Found: C, 66.32; H, 5.60; N, 8.69.

***N-{2-[Hydroxy(phenyl)methyl]-6-methylthieno[2,3-b]pyridin-3-yl}acetamide (4b).*** This compound was obtained as white powder in 89% yield, mp 197–198°C; IR: OH 3259, NH 3230, 3158, CO 1656 $cm^{-1}$; $^1$H-NMR (DMSO-$d_6$): δ 2.06 (s, 3H, $COCH_3$), 2.50 (c, 3H, 6-$CH_3$), 6.12 (d, 1H, *CH*—OH, $J$ = 4.4 Hz), 6.37 (d, 1H, CH—*OH*, $J$ = 4.4 Hz), 7.19–7.43 (m, 6H, phenyl protons, H-5), 7.75 (d, 1H, H-4, $J$ = 8.8 Hz), 9.67 ppm (s, 1H, NH); ms: *m/z* 253 (32), 252 (20), 251 (100), 134 (26), 105 (30), 91 (15), 90 (19), 77 (41), 65 (12), 63 (11), 59 (15), 43 (28). Anal. Calcd for $C_{17}H_{16}N_2O_2S$: C, 65.36; H, 5.16; N, 8.97. Found: C, 65.46; H, 5.24; N, 8.89.

***Preparation of N-{2-[(5-methyl-2-furyl)(phenyl)methyl]thieno[2,3-b]pyridin-3-yl}acetamide (1a,b).*** To a solution of **4a,b** (8.3 mmoles) in 1,4-dioxane (20 mL), 2-methylfuran (1.12 mL, 12.5 mmoles) and a catalyst (0.4 mL), which was a mixture of 70% $HClO_4$ (2 mL), $Ac_2O$ (5.3 mL) and AcOH (3 mL), was added [15]. The mixture was refluxed for 5 h until no initial compound remained (TLC control), then it was poured into of cold water (100 mL), neutralized with sodium hydrocarbonate to pH ∼ 6–7. The crude product was filtered with suction and recrystallized from ethanol with charcoal.

***N-{6-Methyl-2-[(5-methyl-2-furyl)(phenyl)methyl]thieno[2,3-b]pyridin-3-yl}acetamide (1a).*** This compound was obtained as white powder in 80% yield, mp 186–187°C; IR: NH 3247, CO 1659 $cm^{-1}$; $^1$H-NMR (DMSO-$d_6$): δ 2.05 (s, 3H, $COCH_3$), 2.22 (s, 3H, $CH_3$), 2.55 (s, 3H, $CH_3$), 5.90 (s, 1H, CH), 6.00 (d, 1H, $H_{Fur}$, $J$ = 3.2 Hz), 6.08 (d, 1H, $H_{Fur}$, $J$ = 3.2 Hz), 7.26 (s, 5H, phenyl protons), 7.77 (s, 2H, H-5, H-4), 9.68 ppm (s, 1H, NH). Published online 2 March 2010 in Wiley InterScience (www.interscience.wiley.com).

An efficient green protocol for the preparation of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones employing a three-component one-pot condensation reaction of β-naphthol, aromatic aldehyde, urea or thiourea in the presence of montmorillonite K10 clay under solvent free conditions has been described. The present procedure offers advantages such as shorter reaction time (<90 min), simple workup, excellent yields, recovery and reusability of catalyst.

*J. Heterocyclic Chem.*, **47**, 313 (2010).

## INTRODUCTION

Recently, benzoxazinone derivatisation has attained considerable significance in potential antiviral target compounds [1]. The prime driving force in this area is the fight against HIV by developing more efficacious drugs than Efavirenz (Sustiva), a benzoxazinone derivative which is presently in clinical use for the treatment of AIDS.

The construction of new analogs of bioactive heterocyclic compounds represents a major challenge in synthetic organic and medicinal chemistry. Due to their broad spectrum of biological activities naphthalene-condensed 1,3-oxazin-3-ones have been reported to act as antibacterial agents [2]. Heterogeneous organic reactions have proven useful to chemists both in academia and in industry. Clay-catalyzed organic transformations have generated considerable interest because of their inexpensive nature and special catalytic attributes under heterogeneous reaction conditions [3].

In this context, a recent report [4] and related publications [5] on one pot three component synthesis of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones by the condensation of aldehydes, urea or thiourea with β-naphthol in the presence of acid *p*-TSA attracted our attention. This method suffers from the drawbacks of green chemistry such as prolonged reaction times, recovery and reusability of catalyst. The demand for environmentally benign procedure with reusable catalyst necessitated us to develop an alternate method for the synthesis of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones. In continuation of our work on the use of heterogeneous solid acid catalysts [6], we describe in this report a general and efficient green protocol for the preparation of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones, employing a one-pot three-component condensation of β-naphthol, aromatic aldehydes urea or thiourea in the presence of montmorillonite K10 clay under solvent free conditions. This method is superior to the reported methods in all aspects such as short reaction times and excellent yields.

## RESULTS AND DISCUSSION

Initially to determine the most appropriate reaction conditions and to evaluate the catalytic activity of Lewis/protic acid catalysts, a model study was carried out on the synthesis of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3] oxazine-3-one **4a** (Table 1) by the condensation of benzaldehyde **1a** with β-naphthol **2** and urea **3a** in different sets of reaction conditions. Among all the tested catalysts such as Silica sulfuric acid, *p*-TSA, AcOH, LiCl, $CuCl_2$, $HClO_4$-$SiO_2$, Amberlist-15, and IR-120 under solvent free conditions we found that the best results were obtained with the condensation in the presence of montmorillonite K10 catalyst (Table 1, entry **1**).

The condensation of mixture of benzaldehyde **1a** (1 mmol) with β-naphthol **2** (1 mmol) and urea **3a** (1.5 mmol) in the presence of montmorillonite K10 (0. 3 mmol) was carried out at 160°C for 0.5 h under solvent free conditions (Scheme 1). The reaction proceeded

**Table 1**

Synthesis of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine -3-one 4a using different catalysts under solvent free conditions.

[a] Benzaldehyde (1 mmol), urea (1.5 mmol), β-napthol (1 mmol), catalyst (0.3 mmol).
[b] Isolated yields.

smoothly and gave the corresponding 1,2-dihydro-1-aryl naphtho[1,2-e][1,3]oxazine-3-one **4a** as the sole product in 89% isolated yield. Ethyl acetate was added to the reaction mixture and simply filtering the mixture and evaporating the solvent from the filtrate gave the crude product, which was purified by crystallization in ethyl acetate: hexane (1:3) to obtain **4a** as white solid.

To evaluate the generality of the process, several examples illustrating the present method for the synthesis of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones **4** was studied (Table 2). The reaction of β-naphthol **2** with various aromatic aldehydes bearing electron withdrawing groups (such as nitro, halide), electron releasing groups (such as methoxy, methyl or hydroxyl groups), and urea or thiourea was carried out in the presence of Montmorillonite K 10 as a catalyst.

The heterocyclic aldehydes such as furfural (entry m, Table 2) and 2-Chloroquinoline-3-aldehyde (entry n, Table 2) on reaction with β-naphthol **2** and urea **3** in the presence of montmorillonite K10 clay under solvent free conditions was sluggish and the corresponding products were isolated only in 10–15% yields. The poor reaction of heterocyclic aldehydes (entry m & n Table 2) with β-naphthol **2** can be explained by considering the possibility of binding of basic hetero atom (m & n) on the surface of Montmorillonite K10 clay. The results obtained in the current method are illustrated in Table 2. All products obtained were fully characterized by spectroscopic methods such as IR, $^1$H NMR, $^{13}$C NMR and mass spectroscopy and also by comparison with the reported spectral data [4].

On the basis of all our experimental results, together with the literature reports [4], we have proposed the plausible mechanism for the formation of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones **4** in the presence of Montmorillonite K10 clay (Scheme 2). The reaction is believed to proceed through the formation of an *N*-acylimine intermediate **5** formed *in situ* by the reaction of aldehyde **1** with urea or thiourea **3**. The subsequent addition of the β-naphthol to the *N*-acylimine, followed by cyclization affords the corresponding products **4**(a-p) and ammonia.

The simplicity, together with the use of inexpensive, non-toxic, and environmentally benign catalyst under solvent free condition is other remarkable features of the procedure. The catalyst was recovered by filtration, washed several times with methanol, dried at 120°C for 72 h and reused with out significant loss of catalyst activity.

In conclusion, we have reported herein a novel and ecofriendly method for the synthesis of 1,2-dihydro-1-aryl naphtho[1,2-e][1,3]oxazine-3-ones using Montmorillonite K10 clay under solvent free conditions. The advantages of the present protocol are mild heterogeneous reaction conditions, shorter reaction times, and easy work up. The inexpensive, ready availability, recyclablity of the catalyst make the procedure an attractive alternative to the existing methods for the synthesis of 1,2-dihydro-1-arylnaphtho[1,2-e][1,3]oxazine-3-ones.

## EXPERIMENTAL

**General procedure.** A mixture of β-naphthol (1 mmol), aldehyde (1 mmol), urea or thiourea (1.5 mmol) and Montmorillonite K10 clay (0.3 mmol) was rapidly stirred and heated at 160°C for the specified time (Table 2). After TLC indicates the disappearance of starting material, reaction was cooled to room temperature, ethyl acetate (25 mL) was added and the insoluble material was filtered to separate the catalyst. The filtrate was concentrated under vacuum and the crude residue was purified by crystallization in ethyl acetate: hexane (1:3) to afford pure product **4** in excellent yields as specified in Table 2. The catalyst filtered was washed with methanol (3 × 10 mL), dried at 120°C for 72 h and reused. The isolated product yields after each cycle is 78%. All products obtained were fully characterized by spectroscopic methods such as IR, $^1$H NMR, $^{13}$C NMR and mass spectroscopy and have been identified by the comparison of the spectral data with those reported.

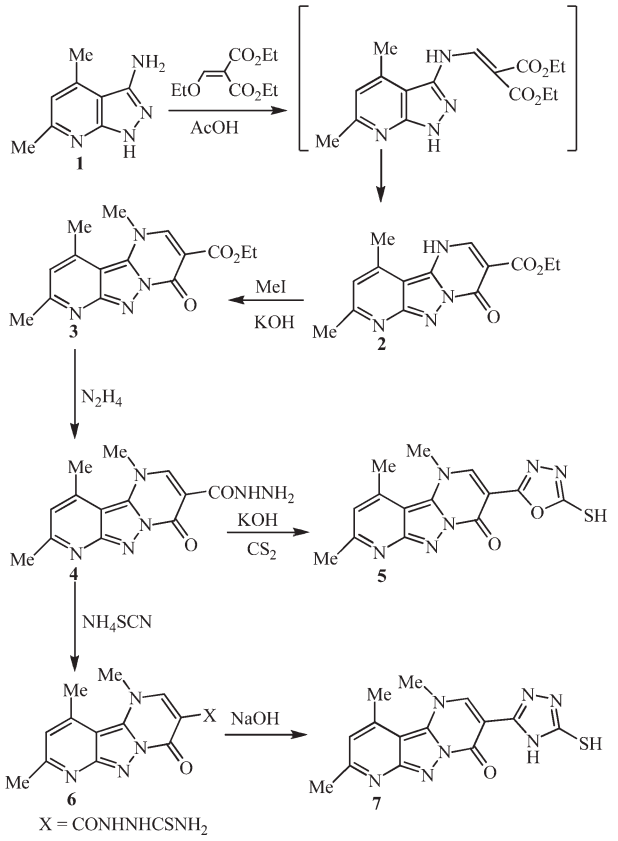
## INTRODUCTION

1*H*-Pyrazolo[3,4-*b*]pyridines comprise a very interesting class of compounds because of their significant and versatile biological and pharmacological activities, such as antimalarial [1], antiproliferative [2], antimicrobial [3–5] inhibition of cyclin-dependent kinases [6] and cardiovascular [7–9] antiviral [10–12] and antileishmanial [13] activities. In general, the pyrazolopyridines are found to be active antitubercular agents [14,15] active against gram positive and negative bacteria [16]. As well as pyrazolopyrimidines [17,18] are selective inhibitors of cyclic 3′,5′-adenosine mono-phosphat (cAMP) phosphodiesterases *in vitro*, and some of them possess anxiolytic properties comparable to those of benzodiazepines.[19]. Moreover, pyridopyrazolopyrimidines revaled antiproliferative activity [20] and are used as potent kinase inhibitors [21]. To enhance the activity of pyrazolopyridines and pyrazolopyrimidines, several approaches were followed to construct another ring over those ring systems described in the literature [22–26] are available on preparation of pyridopyrazolopyrimidines which left much scope for further study. Furthermore, it has been reported that certain compounds bearing 1,3,4-oxa-, thiadiazole, and 1,2,4-triazole nucleus possess significant anti-inflammatory activity [27–37]. In view of these reports, we reported herein the synthesis of some newer heterocyclic systems containing pyridopyrazolopyrimidine system isolated with 1,2,4-triazoles, 1,3,4-oxa-, and thiadiazoles, and fused with pyrazoles derivative.

## RESULTS AND DISCUSSION

4,6-Dimethyl-1*H*-pyrazolo[3,4-*b*]pyridine-3-amine was prepared according to the reported method [38,39] which undergo the cyclocondensation reaction with diethyl ethoxymethylenemalonate yielded directly the 8,10-dimethyl-4-oxo-1,4-dihydropyrido[2′,3′:3,4]pyrazolo [1,5-*a*]pyrimidine-3-carboxylate (**2**) without the isolation of the enamine intermediate [40], the structure of **2** was confirmed by the correctly positioned and coupled $^1$H NMR spectrum, which presents signals as triplet at δ 1.29, quartet at 4.32 ppm because of the ester group and as singlet at δ 8.68, 12.24 ppm due to the H-2 and NH protons, respectively. The $^{13}$C NMR spectrum of **2** showed a characteristic signals, for the ester group, at δ 24.2, 62.0 ($CH_2CH_3$), 166.0 (*C*OOEt), and 154.5 (C-4) ppm. The latter compound **2** was alkylated, by its reaction with methyl iodide in presence of KOH to afford 1,8,10-trimethyl-4-oxo-1,4-dihydropyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidine-3-carboxylate (**3**), to increase its solubility during its reactions, which was elucidated by the appearance of the new signals in the $^1$H NMR spectrum as singlet at δ 3.96 ppm due to N—$CH_3$. The alkylated derivative **3** was subjected to react with hydrazine hydrate to give the corresponding carbohydrazide derivative **4** which was confirmed by its IR spectrum showed a characteristic C=O absorptions at 1640 and 1677 cm$^{-1}$, and its $^1$H NMR spectrum agree with the structure which showed a characteristic a broad singlet band for CONHN$H_2$ at δ 4.78 ppm. Hydrazide derivative (**4**) is versatile synthetic intermediate for the

**Scheme 1**

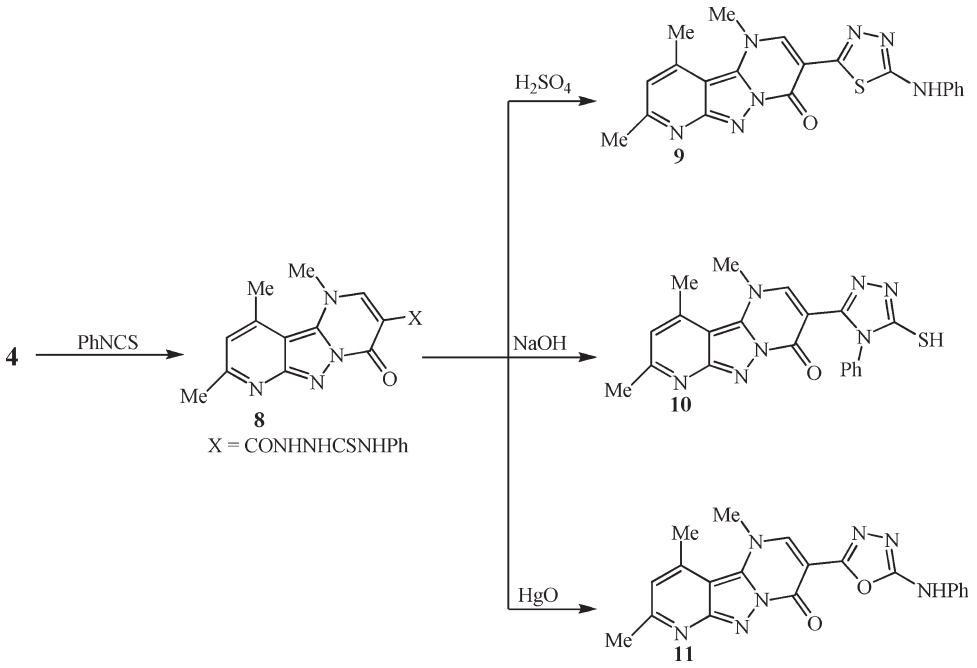


preparation of many heterocyclic moieties. In view of this report, we report herein some reactions of this hydrazide **4** to obtain new heterocyclic rings attached and/or fused to the pyridopyrazolopyridine moiety. Reaction of hydrazide **4** with $CS_2$ in alc. KOH at reflux temperature afforded the corresponding 1,8,10-trimethyl-3-(5-sulfanyl-1,3,4-oxadiazol-2-yl)pyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidin-4(1*H*)-one (**5**) which was elucidated, besides the elemental analysis, $^1$H NMR spectrum represented the presence of the characteristic broad singlet due to the SH group at δ 13.12 ppm and its mass spectrum revealed the molecular ion peak at *m*/*z* 328 indicated the molecular weight of **5**. The $^{13}$C NMR spectrum showed a characteristic isooxazole signals at δ 162.0 and 171.3 ppm. Also the reaction of **4** with ammonium thiocyanate in absolute ethanol gave the corresponding thiosemicarbazide **6** which undergo the cyclization reaction through its treatment with sodium hydroxide giving 1,8,10-trimethyl-3-(5-sulfanyl-4*H*-1,2,4-triazol-3-yl)pyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidin-4(1*H*)-one (**7**) which was confirmed by $^1$H NMR spectrum which showed the presence of signals as a broad bands at δ 10.92 and 12.55 ppm due to the NH and SH groups, respectively, its mass spectrum presents peaks corresponding to peaks at *m*/*z* 327 and 328 corresponding to $M^+$ and $M^+$+1, respectively (Scheme 1).

On treatment of the hydrazide **4** with phenylisothiocyanate, in the way like its reaction with ammonium thiocyanate, afforded the corresponding the thiosemicarbazide **8** which was considered the key intermediate to prepare the 1,8,10-trimethyl-3-[5-(phenylamino)-1,3,4-thiadiazol-2-yl]pyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidin-4(1*H*)-one (**9**), 1,8,10-trimethyl-3-(4-phenyl-5-sulfanyl-4*H*-1,2,4-triazol-3-yl)pyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidin-4(1*H*)-one (**10**), and 1,8,10-trimethyl-3-[5-(phenylamino)-1,3,4-oxadiazol-2-yl]pyrido[2′,3′:3,4]pyrazolo [1,5-*a*]pyrimidin-4(1*H*)-one (**11**), in about 66–74% yields, after its treatment with sulfuric acid, 2*N* sodium hydroxide, and mercuric oxide, respectively. The preferred formation of the 1,3,4-thiadiazole derivative **9** under such acidic conditions can be due to the loss of nucleophilicity of *N*-4 as a result of its protonation leading to an increase in the nucleophilicity of the sulfur atom toward the attack of the carbonyl carbon. On the other hand, the cyclization of **4** was carried out under alkaline conditions, the nucleophilicity of N-4 is enhanced and leads to cyclization with carbonyl carbon atom to afford the 1,2,4-triazole derivative **10**. 1,3,4-Oxadiazole derivative **11** was performed by mercuric oxide, the mode of cyclization includes desulfurization, which introduces the oxygen atom in the cyclization process. The structure assignment of these derivatives were based on the $^1$H NMR spectra showed signals due to the N*H*Ph present in **9** and **11** at δ 9.86, 9.46 ppm, as a broad singlet, but in derivative **10** showed the broad singlet at δ 13.06 ppm due to the SH group. All the other aromatic and aliphatic protons were observed at the expected regions. Mass spectra of these derivatives showed a [$M^+$+1] peak, in agreement with their molecular formula, also the elemental analysis are consistent with the structure of these derivatives **9**, **10**, and **11** (Scheme 2).

The starting material, pyridopyrazolopyrimidine carboxylate **2** was transformed into ethyl 4-chloro-8,10-dimethylpyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidine-3-carboxylate by phosphorous oxychloride at boiling temperature thus providing intermediate precursor **12** for all four new final compounds. They furnished fused tetracyclic compounds **13a–d** by reaction with various purchased hydrazines in boiling xylene. The previously reported method, consisting of a nucleophylic substitution of the chlorine atom with the hydrazine derivative followed by cyclization [41], again showed itself to be useful and profitable for the aims proposed. 6,8-dimethyl-2,3-dihydro-3*H*-pyrazolo[3,2-*d*]pyrido[2′,3′:3,4]pyrazolo[1,5-*a*]pyrimidine-3-one derivatives **13a–d** were elucidated by the IR spectra which presented strong peaks at 1640–1620, 3466–3409,

**Scheme 2**



and 2210 $cm^{-1}$ which were attributed to the carbonyl (C═O) and ─NH groups on the pyrazole and pyrimidine, respectively. The mass spectra of these compounds **13a–d** indicated that the molecular ion peaks were observed as $M^+$ and $M^+$+H. From their $^1H$ NMR spectra, it is possible to observe the presence of signals corresponding to the NH of pyrimidine at the range δ 10.99–11.15 ppm, the absence of the ester group and presence the new signals in aliphatic region such as in compound **13a** at δ 4.18 ppm due to the N─$CH_3$ and the increase of signals in the aromatic part because the presence of phenyl derivatives in compounds **13b–d**. In addition, the elemental analysis is consistent with the structure of theses compounds **13a–d** (Scheme 3).

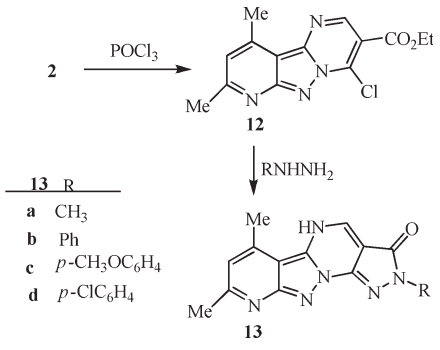
## EXPERIMENTAL

Melting points were determined using Kofter block instrument. The progresses of reactions were monitored by TLC (analytical silica gel plates 60 $F_{254}$). NMR spectra were recorded on a Bruker AC 250 FT NMR spectrometer at 300 MHz for $^1H$ NMR and at 75.5 MHz for $^{13}C$ NMR with TMS as an internal standard, chemical shifts are reported in ppm (δ) and coupling constants (*J*) are given in Hz. IR spectra were recorded on Perkin-Elmer 1430 sectrpphotometer using KBr disc technique. Mass spectra were measured on a Kratos 50 tc spectrometers. Elemental analyses were performed at the Chemistry Institute, Copenhagen University.

**Ethyl 8,10-dimethyl-4-oxo-1,4-dihydropyrido[2′,3′:3,4] pyrazolo[1,5-a]pyrimidine-3-carboxylate (2).** A mixture of 1.94 g of aminopyrazolopyridine **1** (12 mmol) and 2.59 g of diethyl ethoxymethylenemalonate (12 mmol) was dissolved in 20-mL glacial acetic acid and the reaction mixture was refluxed for 10 h cooling to room temperature and poured into ice/water. The solid product was collected by filtration, washed with water, dried, and recerystalization from methanol to afford the yellow crystals of **2**, 3.12 g (91%), mp 222–223°C; $^1H$ NMR (DMSO-$d_6$): δ 1.29 (t, 3H, $J$ = 7 Hz, $CH_3CH_2$), 2.66 (s, 3H, $CH_3$), 2.91 (s, 3H, $CH_3$), 4.32 (q, 2H, $J$ = 7.0 Hz $CH_3CH_2$), 7.03 (s, 1H, ArH), 8.68 (s, 1H, ArH), 12.24 (bs, 1H, NH); $^{13}C$ NMR (DMSO-$d_6$): δ 14.3, 19.2, 24.2, 62.0, 91.2, 116.8, 122.2, 145.8, 148.2, 151.2, 153.6, 154.5, 158.3, 166.0; ms (EI): *m/z* 287 ($M^+$+1, 5), 286 ($M^+$, 26), 241 (23), 240 (100). Anal. Cacld. for $C_{14}H_{14}N_4O_3$ (286.29): C, 58.73; H, 4.93, N, 19.57. Found: C, 58.60; H, 4.75; N, 19.35.

**1,8,10-Trimethyl-4-oxo-1,4-dihydropyrido[2′,3′:3,4]pyrazolo [1,5-a]pyrimidine-3-carboxylate (3).** A solution of 1.77 g (6.2 mmol) of **2** in 20 mL of acetone, cooled by immersion in a water/ice bath, was added to 1.74 g (31.0 mmol) of powdered KOH. On vigorous stirring, 1.76 g of methyl iodide (12.4 mmol) was added and the mixture was stirred for 30 min at room temperature. After the addition of 90 mL of toluene, a precipitate of inorganic salt had formed, which was filtered

**Scheme 3**



off. The organic mixture was treated with 20 mL of saturated NaCl solution, dried with anhydrous $Na_2SO_4$, and evaporated under reduced pressure. The residue was triturated with ethanol and the solid product was collected by filtration, and recrystalization from ethanol to afford the white powder of **3**, 1.52 g (82%); mp 150–152°C; IR (KBr) ν $cm^{-1}$ 1745 ($CO_2Et$), 1633 (CO); $^1H$ NMR ($CDCl_3$): δ 1.26 (t, 3H, $J = 7$ Hz, $CH_3CH_2$), 2.56 (s, 3H, $CH_3$), 2.83 (s, 3H, $CH_3$), 3.96 (s, 3H, N—$CH_3$), 4.29 (q, 2H, $J = 7$ Hz, $CH_3CH_2$), 7.00 (s, 1H, ArH), 8.68 (s, 1H, ArH); (EI): *m/z* 301 ($M^+$+1, 20), 300 ($M^+$, 100),, 255 (25), 227 (30), 184 (8), 131 (60), 115 (16). Anal. Cacld. for $C_{15}H_{16}N_4O_3$ (300.31): C, 59.99; H, 5.37, N, 18.66. Found: C, 59.76; H, 5.25; N, 18.45.

**1,8,10-Trimethyl-4-oxo-1,4-dihydropyrido[2′,3′:3,4] pyrazolo [1,5-a]pyrimidine-3-carbohydrazide (4).** A mixture of 3.0 g of **3** (10 mmol) and 1.25 g of hydrazine hydrate (25 mmol) in 30 mL ethanol was heated under reflux for 4 h. The excess of ethanol was removed under reduced pressure and the resulting precipitate was filtered off, washed with ethanol, and recrystallized from methanol to give colorless of **4**, 2.51 g (88%); mp 266–267°C; IR (KBr) ν $cm^{-1}$: 3310–3212 ($NHNH_2$), 1640, 1677 (2 CO); $^1H$ NMR (DMSO-$d_6$): δ 2.54 (s, 3H, $CH_3$), 2.81 (s, 3H, $CH_3$), 3.86 (s, 3H, N—$CH_3$), 4.78 (bs, 2H, $NH_2$), 7.22 (s, 1H, ArH), 8.78 (s, 1H, ArH), 9.45 (bs, 1H, NH); ms (EI): *m/z* 287 ($M^+$+1, 55), 286 ($M^+$, 20), 257 (15), 228 (100), 199 (23), 175 (12), 147 (36). Anal. Cacld. for $C_{13}H_{14}N_6O_2$ (286.29): C, 54.54; H, 4.93, N, 29.35. Found: C, 54.33; H, 4.65; N, 29.15.

**1,8,10-Trimethyl-3-(5-sulfanyl-1,3,4-oxadiazol-2-yl)pyrido [2′,3′:3,4]pyrazolo[1,5-a]pyrimidin-4(1H)-one (5).** A mixture of 2.86 g of hydrazide **4** (10 mmol) and 0.6 mL of carbon disulfide (10 mmol) was added to a solution of 0.56 g KOH (10 mmol) in 50 mL water and 50 mL ethanol. The reaction mixture was refluxed for 4 h. After evaporating it to dryness under reduced pressure, a solid product was obtained. This was dissolved in 50 mL water and acidified with conc. HCl. The precipitate was filtered off, washed with water, and recrystallized from ethanol to afford the whit crystals of **5**, 2.25 g (69%); mp 210–212°C; $^1H$ NMR (DMSO-$d_6$): δ 2.55 (s, 3H, $CH_3$), 2.86 (s, 3H, $CH_3$), 3.88 (s, 3H, N—$CH_3$), 7.32 (s, 1H, ArH), 8.95 (s, 1H, ArH), 13.12 (bs, 1H, SH); $^{13}C$ NMR (DMSO-$d_6$): δ 14.3, 19.2, 24.2, 90.2, 116.7, 121.6, 145.5, 148.4, 151.1, 152.4, 155.3, 157.5, 162.0, 171.3; ms (EI): *m/z* 329 ($M^+$+1, 10), 328 ($M^+$, 65), 294 (100), 239 (20), 201 (23), 151 (12), 77 (11). Condensation of cyclohexane-1,3-dione/barbituric acid, thiourea/urea, and aromatic aldehyde in the mole ratio of 1:1:3 in solventless reaction in presence of $NiCl_2$/KI afforded 1,5-diaryl-3-thioxo-2,4-diazaspiro[5.5]undecane-7,11-dione/1,5-diaryl-2,4-diazaspiro[5.5]undecane-3,7,11-trione analogues and 7,11-diaryl-9-thioxo-2,4,8,10-tetraazaspiro[5.5]undecane-1,3,5,-trione/7,11-diaryl-2,4,8,10-tetraazaspiro[5.5] undecane-1,3,5,9-tetraone analogues, respectively. The similar condensation of cyclohexane-1,3-dione/ cyclohexanone, thiourea/urea, and aromatic aldehyde/heteroaromatic aldehyde in the mole ratio of 1:1:1 in refluxing methanol afforded 4-aryl/heteroaryl-2-thioxo-1,2,3,4,5,6,7,8-octahydroquinazolin-5-one, 4-aryl/heteroaryl-1,2,3,4,5,6,7,8-octahydroquinazoline-2,5-dione analogues and 4-aryl/heteroaryl-1,2,3,4,5, 6,7,8-octahydroquinazoline-2-thione, 4-aryl/heteroaryl-1,2,3,4,5,6,7,8-octahydroquinazolin-2-one analogues, respectively. Condensation of heterocyclic active methylene compound, barbituric acid, thiourea/ urea, and aromatic aldehydes under similar set of conditions in 1:1:1 mole ratio was carried which afforded 5-aryl-7-thioxo-1,2,3,4,5,6,7,8-octahydropyrimido[4,5-d]pyrimidine-2,4-dione/5-aryl-1,2,3,4,5, 6,7,8-octahydropyrimido[4,5-d]pyrimidine-2,4,7-trione analogues. Similar condensation of an active methine compound, 2-acetylcyclohexanone, thiourea/urea, and aromatic aldehydes in the mole ratio of 1:1:1 produced 5-aryl-1-methyl-3-thioxo-2,4-diazaspiro[5.5]undec-1-en-7-one/5-aryl-1-methyl-2, 4-diazaspiro[5.5]undec-1-ene-3, 7-dione analogues, the spiro compounds of entirely different kind. All these identifications and characterizations have been based on the elemental analysis and spectral data.

*J. Heterocyclic Chem.*, **47**, 324 (2010).

## INTRODUCTION

The synthesis of spiro compounds has been a subject of great interest to research workers. Spiro derivatives based on heteropolycyclics have antibacterial, anticonvulsant, antitumor, and anticancer activities. Similarly, condensed heterocyclics containing quinazoline moiety are ranked among the most versatile biologically active compounds possessing pharmacological properties like being anticonvulsant [1, 2], anticoagulant [3], antifibrillatory [4], cardiac stimulant [5], diuretic [6], antibacterial [7], antiviral [8], antifungal [9], antiasthematic, antiallergic [10], and antitubercular [11a]. In addition to its diverse biological activity, the quinazoline nucleus is also a key component in a relatively varied range of colored products [11b]. Compounds possessing pyrimidopyrimidine nucleus show potent biological activities including inhibition of angiogenesis, tumor inhibition [12], and tyrosine kinase inhibitors [13]. Some of the pyrimidopyrimidine derivatives, particularly 3-(2-methylphenyl)-10-phenyl-2-thioxothiazolo[4,5-d]pyrimido[2,1-

b]pyrimidine [14] have been screened for antifungal activity against *Aspergillus niger* and *Penicillium citrinum*. These promising biological activities encouraged us to prepare some new heterocyclic derivatives.

In the past decade, dihydropyrimidinones and their derivatives have attracted considerable interest because they exhibit promising activities as calcium channel blockers, antihypertensive agents, α-1a-antagonists [15], and neuropeptide Y (NPY) antagonists. Moreover, several alkaloids containing the dihydropyrimidine core unit have been isolated from marine sources, which also exhibit interesting biological properties [16], most notably among these are the batzellandine alkaloids, which were found to be potent HIV group-120-CD4 inhibitors [17]. The synthesis of the core heterocyclic nucleus of dihydropyrimidinones, tetrahydropyrimidinones, partially reduced quinazolines, and their thio analogues is of much current importance. The most simple and straightforward procedure, first reported by Biginelli in 1893, involves three-component, one pot condensation of a ethyl acetoacetate with an aldehyde and urea under strongly acidic conditions [18]. This procedure is known as the Biginelli reaction. The major drawback associated with this protocol is the low yield, particularly for substituted aromatic and aliphatic aldehydes [19]. Recently, many synthetic methods for preparing dihydropyrimidinones have been reported including classical conditions, with microwave and ultrasound irradiation and by using Lewis acids as well as protic acid promoters such as; $H_2SO_4$ [20], $BF_3$ $Et_2O$/CuCl [21], $InCl_3$ [22], $BiCl_3$ [23], $LiClO_4$ [24], $Ag_3PW_{12}O_{40}$ [25], and $FeCl_3$ $6H_2O$/HCl [26]. Acidic ionic liquids as effective catalysts for this transformation were also utilized [27]. However, some of the reported methods also suffer from drawbacks such as nonrecyclability, harsh reaction conditions, long reaction times, the need of an additive, tedious work-up, and environmental pollution. Moreover, some of the methods are only practical for aromatic aldehydes especially the unsubstituted ones. Therefore, a need still exists for versatile, simple and environment-friendly processes wehereby DHPMs as single ring compounds, as a component in condensed heterocycles and as moieties in spiro heterocyclic systems can be formed under milder and practical conditions. In recent years, multicomponent coupling reactions [28] for the synthesis of the title and closely related compounds have received considerable attention. It is a major attraction to chemists because two or more steps in the synthetic sequence can be carried out without the isolation of intermediates. Thus, the synthesis of compounds containing heterocyclic nucleus is of current interest under this strategy. We, herein, report three component coupling reaction (Biginelli type of reaction), which provides an easy access to spiro and condensed/fused heterocycles in fairly good yield. It is worthwhile to mention here, that we proposed a new one pot method for synthesizing novel spiro pyrimidinethiones/spiro pyrimidinones; varied substituted and reduced quinazolinethiones/quinazolinones and condensed pyrimidopyrimidines. In this work, we describe a general and practical route for the Biginelli type cyclocondensation reactions using $NiCl_2$ + KI as the catalyst. This can serve as a general method which provides an easy access to spiro and condensed systems in excellent yield.

## RESULTS AND DISCUSSION

A facile and one pot combination that not only preserves the simplicity of Biginelli's one pot reaction but also consistently produces excellent yields of the spiro

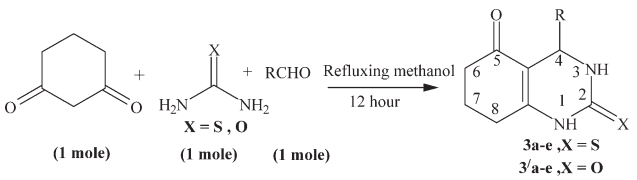
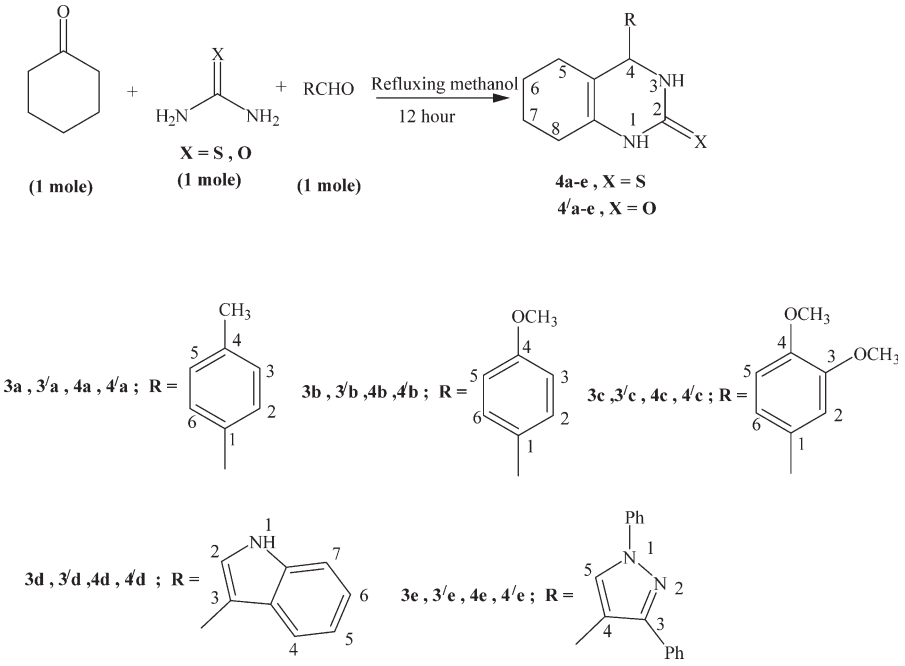
pyrimidinethiones/spiro pyrimidinones (**1a-f/1′a-f**) has been developed as shown in Scheme 1. In a typical general experimental procedure by using highly exceptional conditions, a melt of the mixture of 1,3-dicarbonyl compound (cyclohexane-1,3-dione or barbituric acid), thiourea/urea, an aromatic aldehyde in the mole ratio of 1:1:3 was stirred without using any solvent at 70–80°C in the presence of catalytic amount of $NiCl_2$ + KI for a certain period of time required to complete the reaction (TLC), resulting in the formation of spiro pyrimidinethiones/spiro pyrimidinones. To study the generality of this process, many transformations illustrating this novel and general method for the synthesis of spiro pyrimidinethiones/spiro pyrimidinones were studied and the physical data including elemental analysis of the products is summarized in experimental section. A variety of substituted aromatic aldehydes and the cyclic dicarbonyl compounds afforded high yields of products in high purity. These reactions leading to the formation of spiro pyrimidinethiones/spiro pyrimidinones were confounded from the green perspectives, by the requirements for extractive isolation followed by recrystallization to afford material of a suitable quality. The solvent free approach afforded good yields of products examined during the course of this study. In majority of instances, solvent free approach generated pyrimidinethiones/pyrimidinones of exceptionally good purity. For comparison, condensation of an active methine compound, 2-acetylcyclohexanone (a cyclic β -diketone), thiourea/urea, and aromatic aldehyde in the mole ratio of 1:1:1 produced altogether an unexpected and a novel spiro compound instead of a normal condensed product (a quinazoline analogue), which was characterized as 5-aryl-1-methyl-3-thioxo-2,4-diazaspiro[5.5]undec-1-en-7-one/5-aryl-1-methyl-2,4-diazaspiro[5.5]undec-1-ene-3,7-dione analogue (**2a-e/2′a-e**) as shown in Scheme 2. In another general experimental procedure, condensation of cyclohexane-1,3-dione, thiourea/urea, and aromatic aldehyde/heteroaromatic aldehyde in the mole ratio of 1:1:1 in refluxing methanol for 10–12 h resulted in the formation of 4-aryl/heteroaryl-2-thioxo-1,2,3,4,5,6,7,8-octahydroquinazolin-5-one/4-aryl/heteroaryl-1, 2,3,4,5,6,7,8-octahydro quinazoline-2,5-dione derivatives (**3a-e/3′a-e**) as shown in Scheme 3. Similarly, condensation of cyclohexanone, thiourea/urea, and aromatic or heteroaromatic aldehydes produces 4-aryl/heteroaryl-1,2,3,4,5,6,7,8-octahydroquinazoline-2-thione/4-aryl/heteroaryl-1,2,3,4,5,6,7,8 octahydroquinazolin-2-one analogues (**4a-e/4′a-e**) as shown in Scheme 4. Condensation of active methylene heterocyclic compound, barbituric acid, thiourea/urea, and aromatic aldehyde under similar set of conditions afforded 5-aryl-7-thioxo-1,2,3,4,5,6,7,8-pyrimidine-2,4,7-trione derivatives (**5a-d/5′a-d**) as shown in Scheme 5. The physical data of the products of all these reactions has been included in the experimental section. In conclusion, three-component condensation provides an efficient and improved method for the synthesis of spiro and condensed heterocycles. Moreover, this method offers

**Scheme 3**



**Scheme 4**



several advantages including high yield, simple work-up procedure and is free from pollution. The structures of all these compounds were established by elemental analysis and spectral studies (IR, $^1$H NMR, and $^{13}$C NMR spectra of some compounds).

A characteristic multiplet at δ 2.0–2.35 due to six protons of the trimethylene chain of the cyclohexane component of the spiro system; a sharp singlet signal due to two similar benzylic methyl protons corresponding to six protons at δ 2.40 and a downfield singlet around δ 5.0 due to two identical protons at positions 1 and 5 of the spiro system along with the usual appearance of aromatic protons in the $^1$H NMR spectrum speaks unequivocally of the characterized 1,5-bis(*p*-methylphenyl)-3-thioxo-2,4-diazaspiro[5.5]undecane-7,11-dione structure of the thioxo compound **1a**. The prominent absence of appearance of methylene chain protons, presence of two closely located sharp singlet signals of three protons of each of the two methoxyl groups, one at δ 3.68 and the other at δ 3.72 and more downfield appearance of a signal of two protons due to H-7 and H-11 of the spiro system at δ 5.25 in the $^1$H NMR spectra of **1f** not only confirmed but distinguished this tetrazaspiro system from the diazaspiro system. Disappearance of a triplet signal due to methine proton of 2-acetylcyclohexanone and appearance of a slightly upfield singlet at δ 1.22 due to methyl group as compared with that of 2-acetylcyclohexanone (δ 2.68); a multiplet due to eight protons of tetramethylene chain at δ 1.79–2.25; a signal at δ 3.70 due to methoxyl protons and a highly downfield singlet at δ 5.18 due to one proton, H-5 in $^1$H NMR spectrum of **2c** confirmed the generation of a substituted and functionalized cyclohexanespiropyrimidine system, characterized for this compound. The only characteristic difference in the $^1$H NMR spectra of quinazoline compounds **3** and **4** is that in former we have a slightly downfield multiplet due to six protons of the trimethylene chain and in the latter a slightly up field multiplet due to eight protons of the tetramethylene chain. In compounds **5**, where in the $^1$H NMR spectra there is a dearth of protons on the carbon atoms of the heterocyclic system, the only prominent singlet characterizing the system is due to a single proton at δ 4.70, supplemented by the elemental analysis data and characteristic IR peaks data as detailed in the experimental part of individual compounds.

In products **1a-f** and **1′a-f**, besides the stereochemistry involved due to spiro system of the 2 six-membered heterocyclic and carbocyclic ring, there are two similar chiral centers on one of the rings of the spiro system. So,

**Scheme 5**

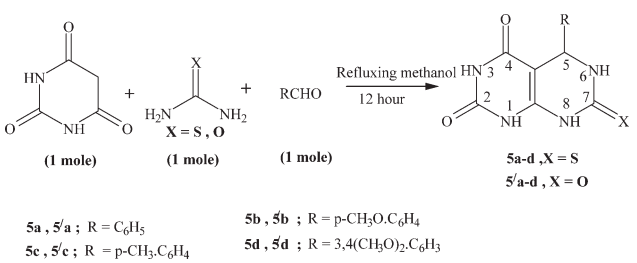


**Table 1**

Antimicrobial activity of 1,5-diaryl-3-thioxo-2,4-diazaspiro[5.5]undecane-7,11-dione/1,5-diaryl-2,4-diazaspiro[5.5]undecane-3,7,11-trione (**1a-c/1′a-c**) and 7,11-diaryl-9-thioxo-2,4,8,10-tetrazaspiro[5.5]undecane-1,3,5-trione/7,11-diaryl-2,4,8,10-tetrazaspiro[5.5]undecane-1,3,5,9 tetraone (**1d-e/1′d-e**).

Standard norfloxacin: *Escherichia coli* 28, *Bacillus subtills* 26, *Bacillus cereus* 28; standard fluconazol: *Aspergillus niger* 32, *Penicillium* species 25, *Cladosporium* species 23.

theoretically three distereoisomers (not four distereoisomers and a pair of racemates) should exist including a pair of enantiomers and a meso (optically inactive) stereomer for all these compounds. In this study, it could not be established whether entirely the meso stereomer is formed or one of the optically active enantiomers or a mixture of all the stereomers is formed. However, from the almost zero specific optical rotation values observed for these compounds, it could be summarized that either the only meso stereoisomer or almost a 50:50 racemic mixture is formed. The resolution into enantiomers in this study could not be carried on successfully and is under active study presently. The compounds **2a-e**, **2′a-e**, **3a-e**, **3′a-e**, **4a-e**, **4′a-e**, **5a-d**, and **5′a-d** were all obtained also as racemates.

**Antimicrobial activity.** Some of the compounds were screened for their antibacterial activity against *Escherichia coli*, *Bacillus sublitis*, and *Bacillus cereus* at concentration of 1000 μg and for antifungal activity against *Aspergillus niger*, Penicillium *species*, and *Cladosporium species* at the same concentration by well diffusion technique [16,17,29–33]. Standard antibacterial norfloxacin and antifungal fluconazole were also screened under similar conditions for a comparison. The zones of inhibition formed were measured [34] in millimeters and are shown in Table 1.

Antimicrobial activity of 1,5-diaryl-3-thioxo-2,4-diazaspiro[5.5]undecane-7,11-dione/1,5-diaryl-2,4-diazaspiro[5.5]undecane-3,7,11-trione (**1a-c/1′a-c)** and 7,11-diaryl-9-thioxo-2,4,8,10-tetrazaspiro[5.5]undecane-1,3, 5-trione/7,11-diaryl-2,4,8,10-tetrazaspiro[5.5]undecane-1,3,5,9 tetraone (**1d-e/1′d-e)**.

It was interesting to observe summarily that all the compounds **1a-f** and **1′a-f** were highly effective against *E. coli* for antibacterial and *Cladosporium* species for antifungal activity and noneffective against other species.

## EXPERIMENTAL

**General.** Melting points were measured in open capillaries on perfit melting point apparatus and are incorrect. IR spectra on KBr were recorded on Brucker-4800 infrared spectrometer. NMR and EIMS/HRMS spectra were recorded on Brucker AC-400 (400 MHz and 100 MHz) and JEOL D-300 mass spectrometer, respectively. Elemental analysis was carried out on simple CHNS analyzer (CHNS-932, LECO Corporation, USA). $^{1}H$ and $^{13}C$ chemical shifts are reported in parts per million (ppm) from tetramethylsilane (TMS) as internal standard. All experiments were performed in oven dried glass apparatus. SISCO silica was used as adsorbent for TLC (0.5 mm thick plates) and TLC plates were eluted with 1:9 ratios of ethyl acetate and *n*-hexane. The column chromatography was performed over silica gel (60–120 mesh) with graded solvent systems of ethyl acetate-pet. ether (60–80).

**General procedure for the synthesis of 1,5-diaryl-3-thioxo-2,4-diazaspiro[5.5]undecane-7,11-dione/1,5-diaryl-2,4-diazaspiro[5.5]undecane-3,7,11-trione (1a-f/1′a-f).** To a magnetically stirred melt of aromatic aldehyde (3 moles) and cyclic active methylene compound (cyclohexane-1,3-dione or barbituric acid) (1 mole) at (70–80°C); thiourea/urea (1 mole) and $NiCl_2$ + KI (0.1 mole) were added at this temperature. The mixture was stirred at 110°C for 6–8 h. After the completion of the reaction as monitored by TLC, the reaction mixture was cooled at room temperature and poured onto crushed ice and again stirred for 10–20 min. The solid thus separated was filtered, washed with cold water and crystallized from ethanol to get **1a-f/1′a-f.**

**General procedure for the synthesis of reduced 4-aryl/heteroaryl-2-thioxo-quinazolin-5-one, 4-aryl/heteroaryl-quinazoline-2,5-dione (3a-e/3′a-e), 4-aryl/heteroaryl quinazoline-2-thione/4-aryl/heteroaryl-quinazolin-2-one (4a-e/4′a-e), and 5-aryl-7-thioxo pyrimidopyrimidine-2,4-dione/5-aryl-pyrimidopyrimidine-2,4,7-trione (5a–d/5′a-d).** A highly grinded and finally powdered homogeneous trinary mixture of appropriate aromatic/hetero aromatic aldehyde (1 mole), thiourea/urea (1 mole), and cyclohexane-1,3-dione/cyclohexanone/barbituric acid (1 mole) in 70–80 mL of methanol was refluxed for 10–12 h. After the completion of reaction as monitored by TLC, the reaction mixture was concentrated to one-third of its volume and was then poured onto ice cold water. The precipitate separated out, filtered, washed, dried, and further recrystallized from ethanol to get the required product.

# Facile and One Pot Synthetic Routes for Various Novel, Differently Fused and Promising Heteropolycycles

Shallu Gupta, Poonam Gupta, Anand Sachar, and R. L. Sharma*

Department of Chemistry, University of Jammu, Jammu 180006, India

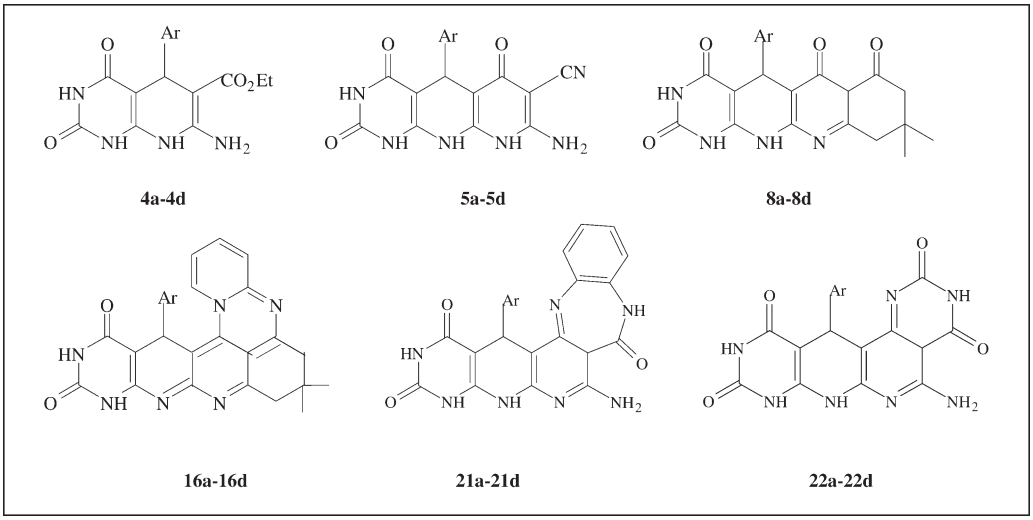
Published online 2 March 2010 in Wiley InterScience (www.interscience.wiley.com).



Four-component one pot cyclocondensation of aromatic aldehydes 1, ethyl cyanoacetate 2, barbituric acid 3 and ammonium acetate in methanol gave substituted and functionalised pyrido[2,3-d]pyrimidine derivatives 4 and 4′ after initial Knoevenagel, subsequent Micheal and final heterocyclization reactions. Compounds 4 on reaction with different active methylene compounds resulted in the formation of again functionalized and diversly substituted pyrimidonaphthyridines 5-7, 9 and benzo[b] pyrimidonaphthyridines 8. The various compounds of systems 7 and 8 on further condensation with the reactive and mostly the bifunctional moieties like urea/thiourea, and 2-aminopyridine generated the novel and differently fused dipyrimidonaphthyridines 10/11 and pyrimidonaphthyridinoquinazolines 13/14, and pyrido-pyrimido- pyrimido[1,8]naphthyridines 15 and pyrimidonaphthyridino- pyridoquinazolines 16, respectively, hitherto unknown in literature. Compounds 7 on condensation with *o*-phenylenediamine produced novel pyrimidonaphthyridinobenzodiazepines 12. Other novel systems like pyrido[2,3-d;6,5-d′]dipyrimidines 17, dipyrimido[4,5-b:5′,4′-g][1,8]naphthyridines 18, 1,3,4,6,7,8,9,11-octazabenzo[de]-naphthacenes 19, dipyrimido[4,5-b:5′,4′-g][1,8]naphthyridines 20, pyrimido[5′,4′:6,7][1,8]naphthyridino[4,3-b][1,5]benzodiazepines 21, dipyrimido[4,5-b:4′,5′-f][1,8]naphthyridines 22 and dipyrimido [4,5-b:5′,4′-g][1,8] naphthyridines 23 have also been generated in this study.

## INTRODUCTION

The benzodiazepines are a class of drugs with hypnotic [1], anxiolytic, anticonvulsant, amnestic, and muscle relaxant properties. They serve as cholecystokinin A and B antagonists [2], opioid receptor ligands [3], platelet-activating factor antagonists [4], HIV inhibitors [5], and farnesyltransferase inhibitors [6]. Benzodiazepines [7] can be used in anxiety disorders, insomnia, involuntary movement disorders, and in detoxification from alcohol and other substances. The pyridopyrimidines are very popularly and widely known compounds as a consequence of their activity against a variety of pathogenic bacteria and have potential activity such as antipyretic, diuretic, bacteriostatic, sedative, and coronary dilating agents [8]. The chemical transformations of the pyridopyrimidine ring system by the introduction and assemblage of different substituents and heterocyclic rings in fused form have allowed expansion of the research to the structure activity relationship to afford new insight into the molecular interactions at the receptor level. Many heterocyclic compounds having pyrido-pyrimidine nucleus are also known to have a wide range of biological activities [9]. Condensed system having 1,8-naphthyridine and a pyrimidine nucleus constitutes a

**d;** Ar = 3,4-OCH $_2$O-$C_6H_3$

group of important compounds because of their vital pharmacological properties. Members of this family have wide applications in medicinal chemistry, being used to have antibacterial [10], antithrombic [11], and anticonvulsant behavior [12]. The quinazoline ring system is a commonly encountered structural core in a number of natural and synthetic molecules with a wide range of biological activities [13]. Many of the quinazoline derivatives are known to exhibit anti-inflammatory [14], anthelmentic [15], analgesic [16], CNS-depressant [17], and anticonvulsive activities [18]. Metolazone and quinethazone are two quinazoline-based drugs that are used currently as diuretics in medicines [19]. Vasicine and related naturally occurring quinazoline alkaloids, and other quinazoline bearing natural metabolites including a number of tryptoquivalines are the famous broncodilators [20], oxytocics, and antifungals being used since time immemorial. The bacterial and bacteriolytic activities have not been extensively studied in pyrimidine, quinazoline, naphthyridine, and benzo[b]diazepine systems in both isolation and in fused assemblages. Literature survey reveals that a fair amount of work has been published in the condensation reactions of barbituric acid, dimedone, and other active methylene carbocyclic and heterocyclic compounds. Because of long standing interest in our laboratory in the condensation reactions of active methylene compounds [21–23] and generation of new fused (''ortho'' and ''ortho and peri''), bridged [23], spiro [24], ring assembly and cyclophane [25] heterocyclic compounds, we have extended our synthetic activity along these lines to include the synthesis of some pyridopyrimidine, pyrimidonaphthyridine, benzo[b]pyrimidonaphthyridine, dipyrimidonaphthyridine, pyrimidonaphthyridinoquinazoline, pyrimidonaphthyridinobenzodiazepine, pyridopyrimido- pyrimido- naphthyridine, pyrimidonaphthyridino-pyridoquinazoline, and 1,3,4,6,7,8,9,11-octazabenzo[de]naphthacene systems.

It was interesting to study these di- and tri- and unknown and unreported tetra-, penta-, and hexa- cyclic heterocyclic systems containing various vital nitrogen heterocyclic moieties, expectedly enriched with potential antimicrobial, antifungal, and other important biological activities. To prepare these novel classes of compounds, we synthesized and used ethyl 7-amino-2,4-diketo-5-aryl-1,2,3,4,5,8-hexahydropyrido[2,3-d]pyrimidine-6-carboxylate **4** as the key intermediate synthon.

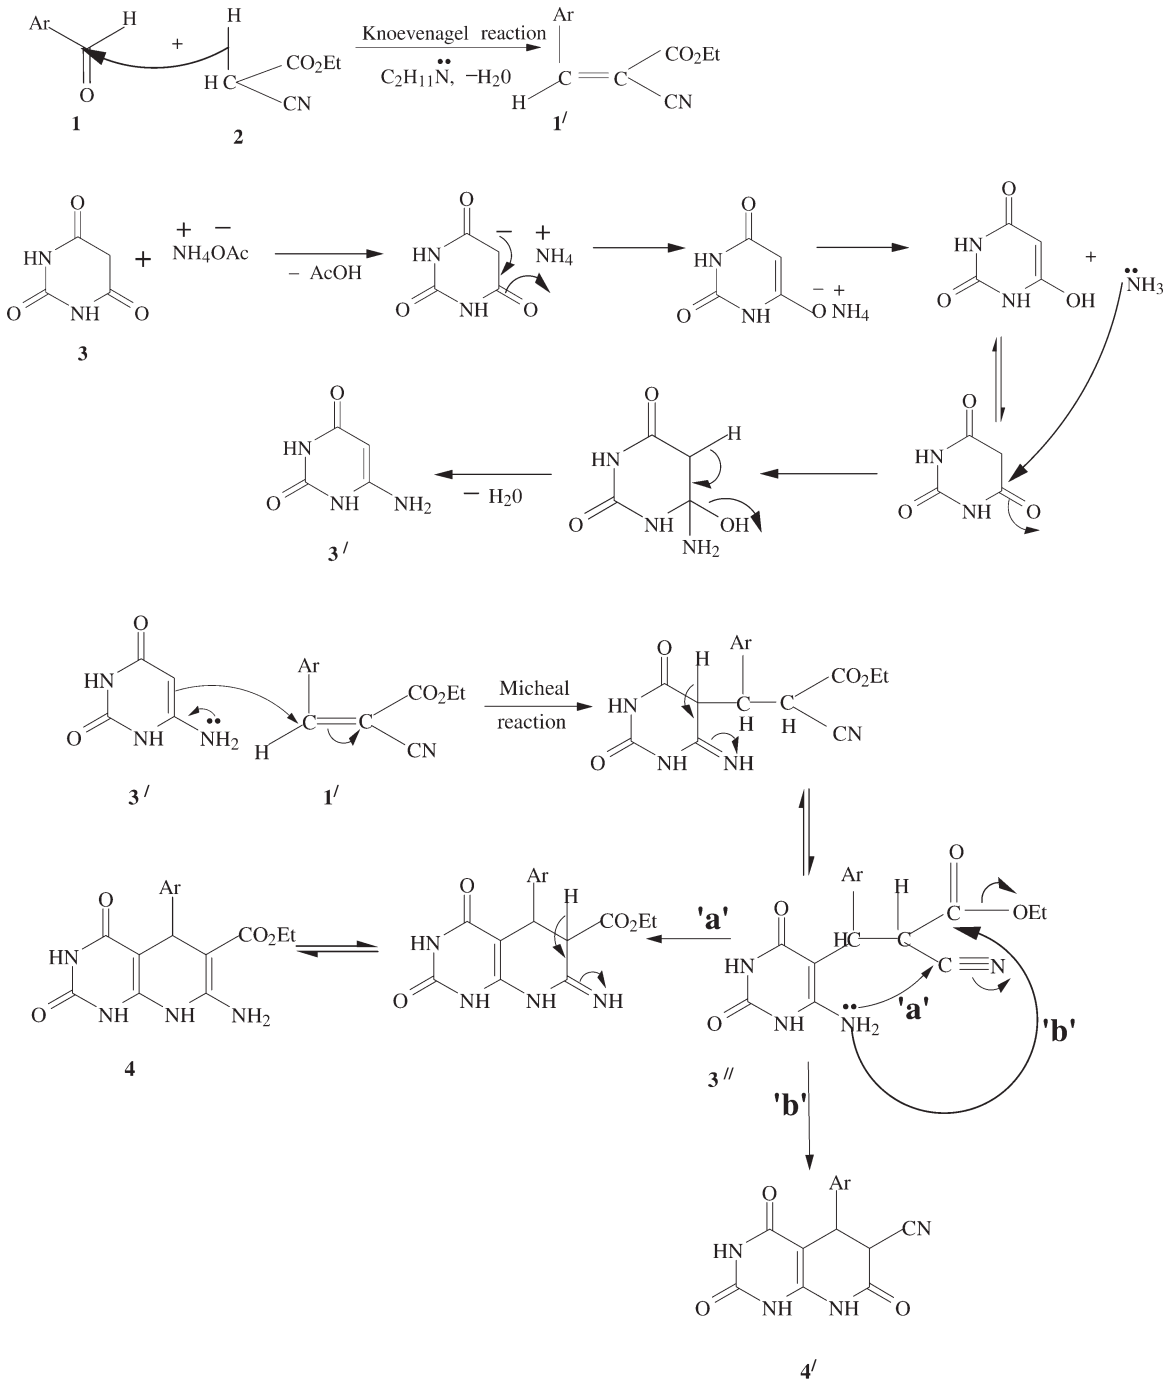
## RESULTS AND DISCUSSION

The key intermediates **4a–4d** used as starting materials [26] have been prepared in better yields by refluxing the aromatic aldehydes **1**, ethyl cyanoacetate **2**, barbituric acid, **3** and excess of ammonium acetate in methanol though some traces of compound **4′** in each case were formed. The main product **4** was separated by fractional crystallization and from the mother liquor a pale yellow colored side product **4′** was isolated in each case that was characterized as 6-cyano-5-aryl-1,2,3,4,5,6,7,8-octahydropyrido[2,3-d]pyrimidine-2,4,7-trione. The formation of these key intermediates **4** and mechanism of their formation have been exhibited (Scheme 1 and 2 respectively).

The reaction sequence in the formation of **4** may be proceeding via initial formation of ethyl arylidenecyanoacetate **1′** by reaction of aromatic aldehyde **1** and ethyl cyanoacetate **2** through typical Knoevenagel condensation. Subsequently, the intermediate **1′** reacts with 6-amino uracil **3′** obtained through the aminodehydration of barbituric acid **3** to produce another intermediate **3″** which on cyclocondensation results in the formation of **4** and **4′** (Scheme 2).

The structure of **4a** was established on the basis of elemental analysis, IR and $^1$H NMR spectral data. The IR spectrum of compound **4a** showed strong absorption bands at υ 3333 and 3423 cm$^{-1}$ for amino group and at υ 1675, 1682, 1690 cm$^{-1}$ for (C=O) group. Its $^1$H NMR spectrum showed as usual a quartet and a triplet

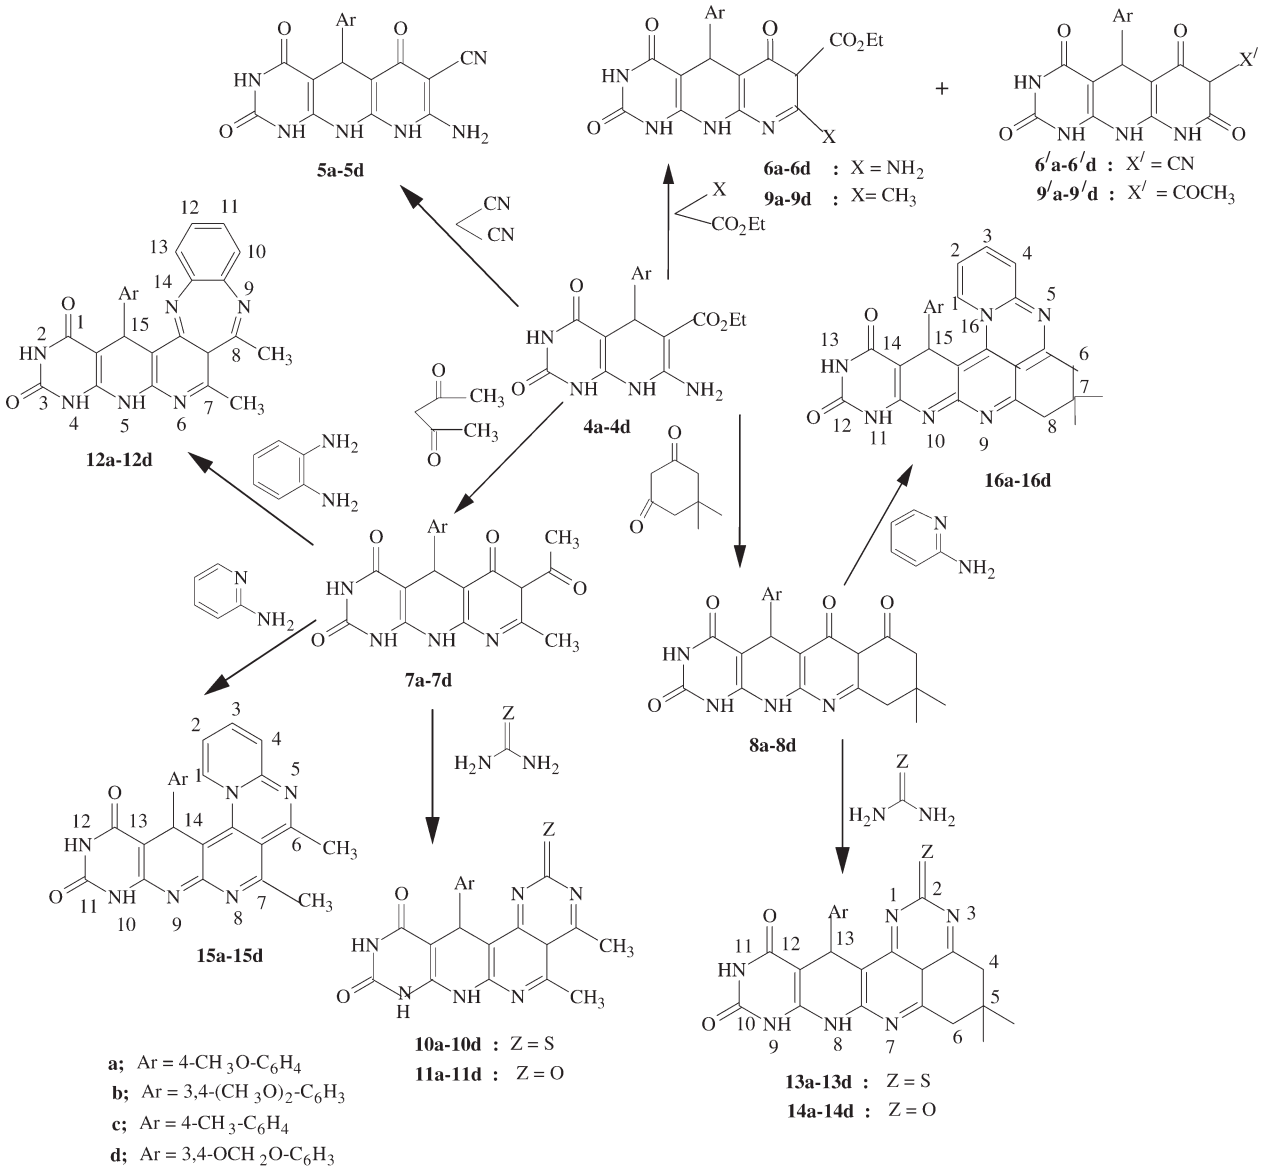
**Scheme 2**



due to $CH_2$ and $CH_3$ protons respectively of the ethyl ester functionality besides other protons including a multiplet of aromatic proton, a singlet of chiral proton, a singlet at δ 3.75 due to $OCH_3$ group and $D_2O$ exchangeable protons. Treatment of compounds **4a–4d** with malononitrile under refluxing in DMF in the presence of catalytic amount of piperidine gave products identified as 8-amino-7-cyano-5-aryl-1,2,3,4,5,6,9,10-octahydropyrimido[4,5-b][1,8]naphthyridine-2,4,6-triones **5a–5d** (Scheme 3). The structures of these products were established on the basis of their analytical and spectral data.

Condensation of compounds **4a–4d** with ethyl cyanoacetate under similar conditions gave major products identified as 8-amino-7-ethoxycarbonyl-5-aryl-1,2,3,4,5,6, 7,10-octahydro-pyrimido[4,5-b][1,8]naphthyridine-2,4,6-triones

**Scheme 3**



**6a–6d** and minor products identified as 7-cyano-5-aryl-1,2,3,4,5,6,7,8,9,10-decahydropyrimido[4,5-b][1,8]naphthyridine-2,4,6,8-tetraones **6′a–6′d**. Their structures were established as usual on the basis of elemental and spectral data. Similar condensation of compounds **4a–4d** with acetylacetone [27] under refluxing in DMSO in the presence of catalytic amount of $P_2O_5$ gave the enamine ketones in good yields. The enamine ketones were then cyclized in presence of $K_2CO_3$ and copper powder in refluxing dry acetone giving substituted pyrimidonaphthyridine derivatives **7a–7d**. Condensation of compounds **4a–4d** with other active methylene compounds like dimedone and ethyl acetoacetate resulted in the formation of substituted benzo[b] pyrimidonaphthyridine **8a–8d** and substituted pyrimidonaphthyridine compounds **9a–9d** and **9′a–9′d**, respectively. The structures of all these compounds were established as usual by elemental analysis and spectral studies, details of which are given in the experimental section. Cyclocondensation of compounds **7a–7d** with urea/thiourea separately resulted in the formation of substituted dipyrimidonaphthyridines **10a–10d** and **11a–11d** and similar treatment of **8a–8d** resulting in the formation of pyrimidonaphthyridinoquinazoline derivatives **13a–13d** and **14a–14d**. On condensation with *o*-phenylenediamine, compounds **7a–7d** resulted in the formation of substituted pyrimidonaphthyridinobenzodiazepine compounds **12a–12d**. The $^1$H NMR data of compound **12b** showed two singlets at δ 3.73 and 3.78 indicating the presence of two methoxyl groups, a singlet at δ 4.74 indicating the presence of chiral CH proton, peaks at δ 8.79, 8.95 and 9.74 due to three $D_2O$

exchangeable (NH) protons. The three aromatic protons of 3,4-dimethoxyphenyl group appeared at δ 6.64–6.95 as a multiplet and another multiplet was located at δ 7.13–7.32 due to four aromatic protons of the benzodiazepine moiety. A singlet at δ 2.47 due to methyl group attached to diazepine ring and another very highly downfield singlet at δ 2.83 revealed the presence of methyl group attached to pyridine ring. These assignments richly characterized the compound **12b** as 7,8-dimethyl-15-(3,4-dimethoxy phenyl)-2,3,4,5,7a,15-hexahydro-1*H*-pyrimido[5′,4′:6,7][1,8]naphthyridino[4,3-b][1,5]benzo- diazepine-1,3-dione. Further, compounds **7a–7d** and **8a–8d** on similar cyclocondensations with 2-aminopyridine were attributed to generate substituted pyrido[2′,1′:2,3]pyrimido[4,5-f] pyrimido[4,5-b][1,8]naphthyridine-11,13-diones **15a–15d** and substituted pyrimido [5′,4′:6,7] [1,8]naphthyridino[4,3,2-de] pyrido[2,1-b]quinazolines **16a–16d**, respectively, on the grounds that the $^1$H NMR data of compound **15c** revealed the presence of two $D_2O$ exchangeable (NH) protons at δ 8.96 and 9.74, a singlet at δ 2.22 due to methyl group of *p*-methylphenyl ring, a singlet at δ 4.74 indicating the presence of chiral CH proton, a double doublet at δ 6.80–6.95 and 6.65–6.67 with ortho coupling indicating the presence of *p*-methylphenyl ring, a multiplet at δ 6.39–6.62 showing the presence of another set of four aromatic protons and two sharp singlets at δ 2.29 and 2.72 due to other two methyl groups in the compound; and $^1$H NMR data of compound **16d** showing peaks due to two $D_2O$ exchangeable (NH) protons at δ 8.97 and 9.79, two singlet at δ 1.88 and 2.12 due to two methylene groups, a singlet at δ 1.11 due to six protons of two gem dimethyl groups, a singlet at δ 4.74 due to chiral CH proton, a multiplet at δ 6.49–6.62 showing the presence of four protons of Nitrogen bridged pyrimidine ring, a sharp singlet at δ 5.87 due to two methylenedioxy protons and a multiplet at δ 6.47–6.89 due to three aromatic protons of the methylenedioxyphenyl group.

Compounds **4, 5** and **6** on condensation with formamide could close the recurring generation of the COOR/CN group at adjacent position to $NH_2$ group in the same ring resulting in the production of pyrido[2,3-d;6,5-d′]dipyrimidines **17**, dipyrimido[4,5-b:5′,4′-g][1,8]naphthyridines **18** which subsequently generated 1,3,4,6,7,8,9,11-octaza benzo[de]naphthacenes **19** with more of formamide and dipyrimido[4,5-b:5′,4′-g][1,8]naphthyridines **20**, respectively. In addition, compound **6** on treatment with *o*-phenylenediamine produced a novel pentacyclic heterocyclic system, pyrimido [5′,4′:6,7] [1,8]naphthyridino[4,3-b][1,5]benzodiazepines **21**, and on heating with thiourea, it produced dipyrimido[4,5-b:4′,5′-f][1,8]naphthyridine **22** and dipyrimido[4,5-b:5′,4′-g][1,8]naphthyridine **23** the two differently fused systems (Scheme 4). The compounds **22** and **23** have been distinguished on the basis of analytical and spectral data. In the $^1$H NMR spectra, the singlet at δ 2.26 ppm due to the proton on the fused tertiary carbon atom (C-4a) of the structure **22** (experimental data given for **22b**) does not appear as downfield as the singlet at δ 3.92 ppm due to the proton on the fused tertiary carbon atom (C-6a) of the structure **23** (experimental details given for **23a**), latter is flanked on either side by C═O groups. There is a marked $D_2O$ exchangeable singlet at δ 3.85 ppm for **22b** due to $NH_2$ group in the $^1$H NMR spectrum. Such chemical shift value is absent in $^1$H NMR spectrum of **23a**. Analytical data of **22a** and **23a** (with same aryl substituents) have revealed their molecular formulae to be $C_{19}H_{15}N_7O_4S$ and $C_{19}H_{14}N_6O_5S$, respectively, which are same as calculated for their proposed structures. So, structure **22** is a $H_{15}N_7O_4$ compound without aryl groups, whereas structure **23** is a $H_{14}N_6O_5$ compound without aryl groups. The observed % of Nitrogen in former is 22.54 and in latter 19.19. Same is true for the other pairs, i.e., **22b** and **23b**, **22c** and **23c**, and **22d** and **23d**. The m/z for the parent peak ($M^+$) could also speak for different molecular masses of the two structures **22** and **23**.

In compound **23a**, the pure ketonic group on Carbon-6 shows C═O stretching frequency 1715 $cm^{-1}$, higher than the other carbonyl stretching frequencies (1660–1680$cm^{-1}$) of lactam and thiolactam rings present in structures **22** and **23**. This higher valued carbonyl stretching frequency is absent in the IR spectrum of structure **22b**. The free amino group on the unsaturated carbon atom shows marked N—H stretching frequency (3200–3500$cm^{-1}$) in structures **22** and this is lacking in IR spectrum of structure **23a**.

The preliminary tests of the keto compound like formation of 2,4-dinitrophenyl hydrazone, phenylhydrazone, semicarbazone, and oxime could be confirmed only for structure **23** (keto group at C-6). Structure **22** could not respond to these tests as it contains carbonyl groups only in the form of lactam and thiolactam functionalities. Similarly, Structures **22** give all the preliminary tests of free amino group.

All the other products were similarly characterized by $^1$H NMR and $^{13}$C NMR data, and their elemental analysis data was also in complete agreement with the assigned structures. The structural formulae, m.ps, yield, molecular formulae, and elemental analysis for these compounds are shown in tabular form (Table 1).

The novel fused heterocyclic systems belonging to compounds **8a–8d**, **10a–10d**, **12a–12d**, **13a–13d**, **15a–15d**, **16a–16d**, **18a–18d**, and **19a–19d** are highly fascinating and interesting and are being reported for the first time in literature especially as regards their generation. The heterocyclic compounds **8** and **18** with linear, ''ortho'' fused structures; **10, 12**, and **15** with angular ''ortho'' fused structures; and compounds **13, 16**, and **19**

**Scheme 4**

**d;** Ar = 3,4-$OCH_2O$-$C_6H_3$

with ''ortho'' and ''ortho and peri'' fused structures contain various component heterocyclic moieties like pyrimidine, pyridine, quinazoline, quinoline, [1,8]naphthyridine, and benzodiazepine present in different modes of combinations and all known for their remarkable, varied, and highly useful physiological activities.

From the study of the key reactions discussed in the present exposition for transformation of an active methylene cyclic compound into a polycyclic ring system containing one six-membered ring more than the substrate, it can be summarily concluded that a reaction of an active methylene compound like malononitrile, ethyl cyanoacetate, and ethyl acetoacetate with a cyclic system having $NH_2$ and groups like CN/COOH/COOR in adjacent position to each other can serve as a recurring contributor for the transformation of a linear system into another linear system having one more ring till the reaction gets stopped due to very high cyclicity (7,8,9. . .membered) and molecular weight or availability of very small amount of substrates to proceed further

due to large number of steps having occurred till then or the reaction is terminated intentionally according to desirability of the required cyclicity by closing the reaction by condensation of the product with formamide and finally generating another terminal pyrimidine ring (Scheme 4).

All the compounds under various heterocyclic systems discussed herein were obtained either as a racemic mixture of a pair of enantiomers or as a mixture of two racemates or as only enantiomer or a diastereomer of unknown stereochemistry. The resolution of the racemic mixtures into the chiral enantiomers could not be carried in this study, and the compounds were used and characterized as obtained.

**Pharmacology.** One compound each from the systems synthesized in this study was subjected to bactericidal and bacteriolytic activity against *Escherichia coli*. The clinical syndromes associated with human beings are urinary track infections, neonatal meningitis, and gastroenteritis.

**The bactericidal and bacteriolytic activity.** The compounds under study (20mg) were dissolved in 500 IL of DMSO. Five microlitres (0.2 mg approx) of the stock solution was taken and 95 IL bacterial suspension in Tris buffer saline (0.8 OD at 580 nm) was added to it. The mixture was incubated at 14°C for 14 h. After incubation, it was subjected to plating in TCBS agar (Thiosulphate, Citric, Bile salt, Sucrose agar). After 12 h, the culture plate was observed for bacterial growth.

For bacteriolytic activity, bacterial suspension in TBS was prepared with an optical density of 0.8 OD at 580 nm (double beam UV spectrometer). TBS (Tris buffer saline) served as the blank. The test compound (10mg) was dissolved in 150 L of DMSO and 2850 IL of bacterial suspension in TBS was added to it. The initial OD of the sample was recorded. The mixture was incubated for 90 min at 23°C. Final OD of the mixture was recorded. The initial OD minus the final OD gives the bacteriolytic activity. The —NH— group and the —O— group on the given moieties may bind with the negatively charged phosphate group on phospholipids present on the wall of bacteria. This causes inhibition of the activities of lysosomal phospholipases because of the neutralization of the negative charges of phospholipid bilayer, leading to potential antibacterial activity.

**Observations.** The active compounds exhibited a range between mild to strong bactericidal activity against gram-negative bacteria *Escherichia coli* (Table 2). The compounds were also subjected to bacteriolytic activity against *E. coli*. The compounds **4d**, **5d**, **6d**, **8d**, **11d**, **18d**, **20d**, **21d**, and **22d** showed mild bacteriolytic activity; compounds **9d**, **10d**, **13d**, **14d**, **15d**, **17d**, **19d**, and **23d** exhibited moderate bacteriolytic activity; and compounds **7d**, **12d**, and **16d** showed strong bacteriolytic activity against *E. coli* (Table 3). Ciprofloxacin was used as standard antibiotic in this study.

## EXPERIMENTAL

**General.** The melting points were determined in open capillary tubes in Perfit melting point apparatus and are uncorrected. The purity of the products was checked on TLC plates coated with silica gel-G and detected by iodine vapors. The IR spectra were recorded on Perkin Elmer Infrared model S99-B and on Shimdzu IR-435 spectrophotometer ($\upsilon_{max}$ in $cm^{-1}$). $^1H$ NMR and $^{13}C$ NMR spectra were recorded on a varian unity 200 MHz NMR spectrophotometer using ppm on δ scale). Elemental analysis was performed on a simple CHNS analyzer (model: CHNS-932, LECO Corporation, USA; IR Technology Services).

**General procedure for the synthesis of ethyl 7-amino-2,4-diketo-5-aryl-1,2,3,4,5,8-hexahydropyrido[2,3-d]pyrimidine-6-carboxylates 4a–4d and 6-cyano-5-aryl-1,2,3,4,5, 6,7, 8-octahydropyrido[2,3-d]pyrimidine-2,4,7-trione 4′a–4′d.** A mixture of equimolar amounts (0.01 moles) of aromatic aldehydes **1**, ethyl cyanoacetate **2**, and barbituric acid **3** along with

Bacterial activity: B.A.
Concentration is 2 mg/mL.
(+): mild bacterial activity was observed.
(++): moderate bacterial activity was observed.
(+++): strong bacterial activity was observed.

excess of ammonium acetate in methanol was refluxed on water bath for 8–10 h. After the reaction is over as monitored on TLC, the reaction mixture was concentrated and cooled at room temperature. The solid products **4** was separated by fractional crystallization as a major product and from the mother liquor a pale yellow colored solid product **4′** was isolated on prolonged cooling as a minor product. The spectral data along with IUPAC names of the products and names of the starting materials for some of the compounds is mentioned below:

***Ethyl 7-amino-2,4-diketo-5-(3,4-dimethoxyphenyl)-1,2,3,4,5,8-hexahydropyrido[2,3-d] pyrimidine-6-carboxylate (4b).*** It was obtained using veratraldehyde. IR(KBr,υ,$cm^{-1}$): 1605 (C=C), 1675, 1682, 1695 (C=O), 3254 ($NH_2$), 3334–3410 (3NH) $cm^{-1}$; $^1$H NMR ($CDCl_3$): δ 1.37 (t, 3H, $CH_3$), 2.94 (q, 2H, $OCH_2$), 3.73 (s, 3H, $OCH_3$), 3.76 (s, 3H, $OCH_3$), 4.72 (s, 1H, 5-CH), 5.58 (s, 2H, $NH_2$), 6.74–6.96 (m, 3H, ArH's), 8.76–9.86 (br.s, 3H, NH).

***Ethyl 7-amino-2,4-diketo-5-(3,4-methylenedioxyphenyl)-1,2,3,4,5,8-hexahydropyrido [2,3-d]pyrimidine-6-carboxylate (4d).*** It was obtained using piperonal. IR(KBr,υ,$cm^{-1}$): 1605 (C=C), 1675, 1680, 1695 (C=O), 3256 ($NH_2$), 3334–3412 (3NH) $cm^{-1}$; $^1$H NMR ($CDCl_3$): δ 1.37 (t, 3H, $CH_3$), 2.94 (q, 2H, $OCH_2$), 4.72 (s, 1H, 5-CH), 5.58 (s, 2H, $NH_2$), 5.79 (s, 2H, $O_2CH_2$), 6.57–6.67 (m, 3H, ArH's), 8.78–9.89 (br.s, 3H, NH).

***6-Cyano-5-(4-methoxyphenyl)-1,2,3,4,5,6,7,8-octahydropyrido [2,3-d]pyrimidine-2,4,7-trione (4′a).*** It was obtained using anisaldehyde as a minor product along with **4a** as major product. IR(KBr,υ,$cm^{-1}$): 1605 (C=C), 1670, 1680, 1692 (C=O), 2195 (C=N), 3333–3405 (NH) $cm^{-1}$; $^1$H NMR ($CDCl_3$) : δ 3.74 (s, 3H, $OCH_3$), 4.25 (s, 1H, CH), 4.42 (s, 1H, 5-CH), 6.83–6.95 (d, 2H, ArH's), 6.64–6.69 (d, 2H, ArH's), 8.75–9.85 (br.s, 3H, NH, $D_2O$ exchangeable).

***6-Cyano-5-(3,4-dimethoxyphenyl)-1,2,3,4,5,6,7,8-octahydropyrido[2,3-d]pyrimidine-2,4,7-trione (4′b).*** It was obtained using veratraldehyde as a minor product along with **4b** as major product. IR(KBr,υ,$cm^{-1}$): 1605 (C=C) 1670, 1682, 1690 (C=O), 2194 (C=N), 3333–3405 (3NH) $cm^{-1}$; $^1$H NMR ($CDCl_3$) : δ 3.73 (s, 3H, $OCH_3$), 3.78 (s, 3H, $OCH_3$), 4.25 (s, 1H, CH), 4.52 (s, 1H, 5-CH), 6.46–6.54 (m, 3H, ArH's), 8.71–9.83 (br.s, 3H, NH).

**General procedure for the synthesis of 8-amino-7-cyano-5-aryl-1,2,3,4,5,6,9,10-octahydropyrimido[4,5-b][1,8]naphthyridine-2,4,6-triones 5a–5d.** A mixture of **4** (10 mmoles) and malononitrile (10 mmoles) in DMF (20 mL) containing piperidine (0.1 mL) was refluxed for 5–6 h. The reaction was left to cool at room temperature and then poured into ice-cold water with stirring. The solid product **5** so formed was collected by filtration and crystallized from acetic acid as brown crystals.

***8-Amino-7-cyano-5-(3,4-dimethoxyphenyl)-1,2,3,4,5,6,9,10-octahydropyrimido[4,5-b][1,8] naphthyridine-2,4,6-trione (5b).*** It was obtained from **4b**. IR(KBr,υ,$cm^{-1}$): 1605 (C=C), 1610, 1635, 1674 (C=O), 2223 (C=N), 3430 ($NH_2$), 3445–3538 (4NH),$cm^{-1}$; $^1$H NMR($CDCl_3$): δ 3.73 (s, 3H, $OCH_3$), 3.78 (s, 3H, $OCH_3$), 4.74 (s, 1H, 5-CH), 6.78–6.95 (m, 3H, ArH's), 7.98 (s, 2H, $NH_2$), 8.82–9.89 (br.s, 4H, NH).

***8-Amino-7-cyano-5-(3,4-methylenedioxyphenyl)-1,2,3,4,5,6,9,10-octahydropyrimido[4,5-b][1,8]naphthyridine-2,4,6-trione (5d).*** It was obtained from **4d**. IR(KBr,υ,$cm^{-1}$): 1605 (C=C), 1612, 1625, 1674 (C=O), 2198 (C=N), 3423 ($NH_2$), 3425–3536 (4NH) $cm^{-1}$; $^1$H NMR ($CDCl_3$): δ 4.74 (s, 1H, 5-CH), 5.86 (s, 2H, $O_2CH_2$), 6.54–6.68 (m, 3H, ArH's), 7.95 (s, 2H, $NH_2$), 8.83–9.87 (br.s, 4H, NH).

**General procedure for the synthesis of substituted pyrimido[4,5-b][1,8]naphthyridines 6a–6d, 6′a–6′d, 9a–9d, and 9′a–9′d.** A mixture of **4** (10 mmoles) and ethyl cyanoacetate/ethyl acetoacetate (10 mmoles) in DMF (20 mL) containing piperidine (0.1 mL) was refluxed for 6–8 h yielding **6, 6′** and **9, 9′**, respectively. The reaction was left to cool at room temperature and then poured on to ice-cold water. The solid product so formed was collected by filtration and crystallized from acetic acid. Using ethyl cyanoacetate, the main product **6** separated out first and from the mother liquor another minor product **6′** separated on keeping in refrigerator. Similarly, **9** and **9′** were separated as major and minor products, respectively, while using ethyl acetoacetate.

***8-Amino-7-ethoxycarbonyl-5-(4-methoxyphenyl)-1,2,3,4,5,6,7,10-octahydropyrimido[4,5-b][1,8]naphthyridine-2,4,6-trione (6a).*** It was obtained from **4a** as a major product. IR(KBr,υ,$cm^{-1}$): 1076 (C—O—C), 1528 (C⋯⋯C of aromatic ring), 1645, 1658, 1672, 1695 (C=O), 2926 (C—H, aliphatic), 3047 (C—H, aromatic ), 3336–3486 (3NH), 3428 ($NH_2$) $cm^{-1}$; $^1$H NMR($CDCl_3$): δ 1.37 (t, 3H, $CH_3$), 2.92 (q, 2H, $OCH_2$), 3.73 (s, 3H, $OCH_3$), 4.21 (s, 1H, CH), 4.42 (s, 1H, 5-CH), 6.65–6.67 (d, 2H, ArH's), 6.70–6.93 (d, 2H, ArH's), 7.89 (s, 2H, $NH_2$), 8.80–9.86 (br.s, 3H, NH).

***8-Amino-7-ethoxycarbonyl-5-(3,4-dimethoxyphenyl)-1,2,3,4,5,6,7,10-octahydropyrimido [4,5-b][1,8]naphthyridine-2,4,6-trione (6b).*** It was obtained from **4b** as a major product. IR(KBr,υ,$cm^{-1}$): 1078 (C—O—C), 1527 (C⋯⋯C of aromatic ring), 1647, 1662, 1680, 1690 (C=O), 2928 (C—H, aliphatic), 3048 (C—H, aromatic ), 3425 ($NH_2$), 3436–3538 (3NH)$cm^{-1}$; $^1$H NMR ($CDCl_3$): δ 1.35 (t, 3H, $CH_3$), 2.92 (q, 2H, $OCH_2$),

A series of 1-arylmethyl-4,5-dihydro-2-aryl-1H-imidazoles were synthesized expeditiously in good yields from 1,2-diaminoethane and aromatic aldehydes in the presence of zeolite under microwave irradiation in the absence of solvent. The resulting substituted imidazoles are characterized by $^{1}H$ and $^{13}C$ NMR, elemental analysis, and mass spectral data.

## INTRODUCTION

The use of microwave (MW) irradiation as a non-conventional energy source has become of considerable interest in organic chemistry. This novel method has proved to be very efficient in various reactions, especially in organic synthesis [1–5], which has several advantages over classical thermal conditions in providing increased reaction rates, simplicity, and improved yields. The development of one-pot reaction has been of great interest in organic synthesis because this methodology provides easy access to highly complex molecules from relatively simple reagents under economically favorable reaction conditions. Thus, the combination of the one-pot strategy with the use of eco-friendly zeolite catalysts becomes a powerful means of preparation for specific target compounds to minimize pollutants and to reduce production cost [6–9]. MW irradiation has been used to effect organic reactions, such as cyclization [10], aromatic substitution [11], oxidation [12], alkylation [13], decarboxylation [14], radical reactions [15], condensation [16], peptide synthesis [17], etc.

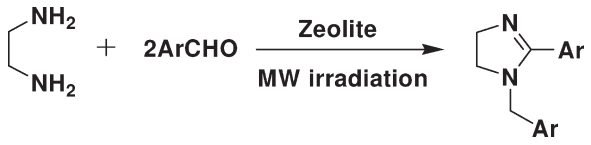
Imidazole chemistry currently attracts considerable attention, where the imidazole derivatives are extensively applied as *N*-ligands coordinating transition metals [18,19]. The application of imidazoles in medicinal chemistry [20], chemistry of natural products/alkaloids [21], and 1,3-disubstituted imidazole salts as ionic liquids [22] are well known. Several methods are reported in the literature for the synthesis of imidazoles, such as: (a) synthesis *via* hetero-Cope rearrangement [23]; (b) four-component condensation of arylglyoxals, primary amines, carboxylic acids, and iso-cyanides on Wang resin [24,25]; (c) reaction of *N*-(2-oxo)-amides with ammonium trifluoroacetate [26]. Compounds with an imidazole ring system have many pharmacological properties and play important roles in biochemical processes [27]. Organic chemists have been making extensive efforts to produce heterocyclic compounds by developing new and efficient synthetic transformations [28]. Recently, palladium and copper-catalyzed strategies have been successfully applied to the assembly of various heterocyclic compounds *via* one-pot synthesis [29].

Many of the synthetic protocols for imidazoles reported so far suffer from one or more disadvantages, such as harsh reaction conditions, poor yields, prolonged time period, use of hazardous, and often expensive acid catalysts. We have employed to achieve simple and environmentally compatible synthetic methodology for the synthesis of substituted imidazoles in the presence of zeolite under MW irradiation.

## RESULTS AND DISCUSSION

Reactions were carried out simply by mixing 1,2-diaminoethane with different substituted aromatic aldehydes in the presence of zeolite under solvent-free condition

**Scheme 1.** MW assisted synthesis of substituted imidazoles.



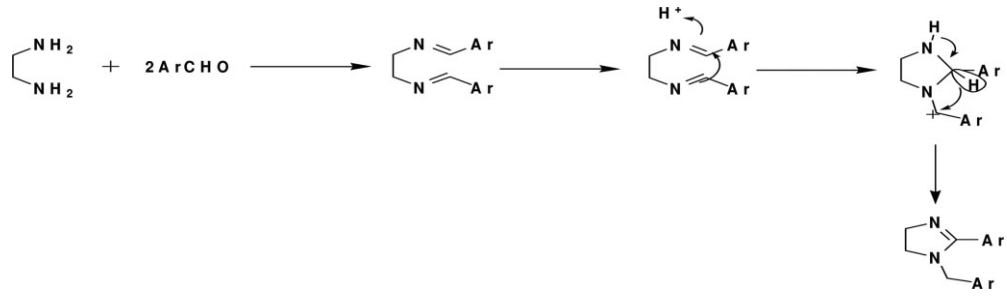
(Scheme 1). All the 1-arylmethyl-4,5-dihydro-2-aryl-1H-imidazoles derivatives were obtained in excellent yields.

This study describes a successful approach for the synthesis of substituted imidazoles using a laboratory MW reactor. This MW technology does not require linking-cleaving chemistry and afford the products immediately. In a solvent-free cyclization reaction of imidazoles is developed, which requires MW irradiation of 1,2-diaminoethane and aromatic aldehydes in the presence of zeolite. This support allows for easy separation of the solid catalyst and product by simple filtration, and in optimal conditions the supported catalyst can be reused multiple times. The readily and exclusive formation of cyclized imidazoles occurs in good yields.

The same reaction under thermal conditions (Scheme 2) affords lower yields (Table 1). Hence, it is clear from the yield comparison plot (Fig. 1) of classical and MW assisted synthesis of the substituted imidazoles that MW irradiation has been found to be easier, convenient, eco-friendly, and yield of all the products are more than good as compared with the classical method. In general, synthesis of substituted imidazole under thermal conditions may occur in two steps, formation of Schiff base and its cyclization.

The reaction may tentatively be visualized to occur *via* a tandem sequence of reactions depicted in reaction mechanism (Mechanism 1) involving (i) formation of *N*,*N*′–bis(aryl)ethylenediimine, (ii) protonation of the *N*,*N*′–bis(aryl)ethylenediimine by zeolite and ring closure leading to a five membered ring in either a sequential or a concerted manner, (iii) 1,3-hydride transfer, and (iv) deprotonation. While the aryl groups/nitrogen atom could stabilize the positively charged intermediates involved in the intermediate steps, the aromatic stabilization of the resulting imidazoles could provide the impetus for the transformation. The reaction under MW condition goes to completion in 6 min. Physical properties of the substituted imidazoles are given in Table 2.

**Mechanism 1:** The possible reaction mechanism.



## EXPERIMENTAL

**General.** All the chemicals and solvents were obtained from Merck (AR grade) and were used without further purification. Melting points were taken in an open capillary tube. The MW assisted synthesis of titled compounds were carried out in a CEM – 908010, bench mate model, 300 watts laboratory MW reactor. Elemental analyses were carried out using a Perkin-Elmer, CHN elemental analyzer model 2400. $^{1}$H NMR and $^{13}$C NMR spectra of the imidazoles were recorded on a Bruker-Avance (300 MHz), Varian-Gemini (200 MHz) spectrophotometer using DMSO solvent and TMS as the internal standard. EI-MS spectra were determined on a LCQ ion trap mass spectrometer (Thermo Fisher, San Jose, CA, USA), equipped with an EI source.

**Synthesis of 1-arylmethyl-4,5-dihydro-2-aryl-1H-imidazoles.** 1,2-diaminoethane (0.108 g, 1 mmol), benzaldehyde (0.212 g, 2 mmol), and zeolite (montmorillonite K-10) (0.1 g) was thoroughly mixed. The reaction mixture was irradiated for 6 min with 100 W MWs at 110°C in MW oven in the temperature control mode. The completion of the reaction was monitored by TLC. After the irradiation was over, the reaction mixture was cooled and added into water and extracted with diethyl

**Scheme 2.** Synthesis of substituted imidazole under thermal condition.

ether. After filtering the zeolite particles, the ethereal layer was washed with water, dried with anhydrous sodium sulphate, and the solvent removed. The crude product was recrystallized from methanol.

**Synthesis of 1-arylmethyl-4,5-dihydro-2-aryl-1H-imidazoles by classical method.** A mixture of Schiff base (0.7 mmol), catalytic amount of $H_2SO_4$ and ethanol (50 mL) were refluxed for ~4 h. The completion of the reaction was monitored by TLC. After completion of the reaction, the reaction mixture was set on one side to cool. Solid deposit was collected by the filtration. The crude product was recrystallized from methanol.

## CONCLUSIONS

In this study, we reported a highly efficient MW assisted rapid and solvent-free synthesis of substituted 1H imidazoles in the presence of zeolite. MW chemistry is a green chemical method that improves reaction conditions and product yields, while reducing solvent amounts and reaction times. The one-pot nature of the present procedure makes it an acceptable alternative to multistep approaches. It also simplifies the laborious procedures and offers considerable advantages, such as: elimination of solvents, use of substances without any modification or activation, high yields, short reaction times, employment of reusable solid catalysts, and environmentally friendly character over the existing methodologies.

**Acknowledgments.** We greatly acknowledge to Head of the Chemistry Department RTM Nagpur University, for laboratory facilities.

A facile microwave-assisted synthesis of imidazol-5(4*H*)-one derivatives is accomplished *via* reactions of 4-arylmethylene-2-phenyloxazol-5(4*H*)-ones with urea (or ammonium acetate) in ethylene glycol. The cascade reaction is simple to perform and occurs under mild conditions with broad scope of applicability.

## INTRODUCTION

Green fluorescent protein (GFP) including imidazolidinone skeleton (Fig. 1) [1], is an autofluorescent protein of 238 amino acid residues that is derived from the Pacific Northwest jellyfish, *Aequorea victoria* [2]. The GFP chromophore exhibits promising applications in molecular and cell biology due to its intrinsic visible fluorescence, which is easily detectable by fluorescence spectroscopy [3–5]. Therefore, much interest has been geared toward the engineering of novel color variants [6,7] of the GFP in light of its wide applicability in the life sciences.

In addition, the imidazolone core represents an attractive pharmacophore that displays extensively pharmacological and medicinal activities [8,9]. In particular, imidazol-5(4*H*)-one and its derivatives have possessed an unique role in drug discovery and crop protection [10,11], serving as combinatorial chemistry groups. In general routes, the imidazolone ring is formed by condensing glycine ester of acetimidic or phenylacetimidic acid in the solvents, such as benzene, dioxane, and acetone [12–14]. All these methods [12–17] have one or more limitations such as inaccessibility of precursors, narrow substrate scope, and operational complexity. Recently, a microwave-improved synthesis of imidazolones using graphite as support has been reported [15]. In the light of current studies, the development of a practically simple, economical, and high-yielding route to a wide variety of imidazol-5(4*H*)-one derivative (Fig. 2) is strongly desired. Herein, we like to report a cascade reaction of 4-arylmethylene-2-phenyloxazol-5(4*H*)-ones **1** (Compounds **1** were conveniently prepared following a literature procedure: [18]) with urea **2** (or ammonium acetate) for synthesis of imidazol-5(4*H*)-ones under microwave irradiation (MWI) at 150°C in ethylene glycol (Scheme 1).

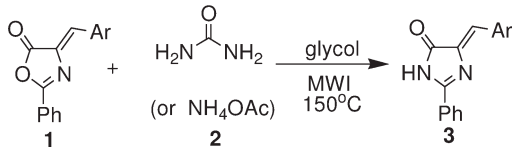
## RESULTS AND DISCUSSION

To choose the most appropriate solvents, the MW-assisted reaction (Scheme 2) of 4-(4-chlorobenzylidene)-2-phenyloxazol-5(4*H*)-one (**1c**, 1 mmol) and urea (**2**, 1.5 mmol) was examined using glacial acetic acid (HOAc), ethylene glycol, ethanol (EtOH), *N*,*N*-dimethyl

**Scheme 1**



formamide (DMF), water as the solvent (2.0 mL) at 150°C, respectively. All the reactions were carried out at the maximum power of 300 W. As shown in Table 1, we could see the reaction in glycol gave the best results (Table 1, entry 2).

To further optimize reaction conditions, the same reaction was performed in ethylene glycol and 300 W at the temperatures ranging from 110 to 180°C in increments of 10°C each time. The yield of product **3c** was improved from 23 to 93%, when the temperature was raised from 110 to 150°C (Table 2, entries 1–5). However, no significant increase in the yield of product **3c** was observed as the reaction temperature was raised from 150 to 180°C (Table 2, entries 5–8). Therefore, 150°C phenyloxazol-5(4*H*)-ones were performed, which leads to the corresponding 4-arylmethylene-2-phenyl-1*H*-imidazol-5(4*H*)-ones with good yields.

Under the optimal conditions [glycol, 150°C, 300 W (maximum power)], reactions of different 4-arylmethylene-2-phenyloxazol-5(4*H*)-ones were performed, which leads to the corresponding 4-arylmethylene-2-phenyl-1*H*-imidazol-5(4*H*)-ones with good yields. The electronic effect of the aryl group in 4-arylmethylene-2-phenyloxazol-5(4*H*)-ones was investigated. As shown in Table 3, both electron-withdrawing (such as nitro) and electron-donating (such as alkoxy) groups readily provided compounds 3 in good yields. Moreover, the heterocyclic phenyloxazol-5(4*H*)-ones such as 2-phenyl-4-((thiophen-2-yl)methylene) oxazol-5(4*H*)-one (Table 3, entry 9) still displayed a high reactivity under this standard condition.

We envisaged that ammonia, obtained by urea (or ammonium acetate), attacks on carbonyl group in 4-arylmethylene-2-phenyloxazol-5(4*H*)-ones **1** as a nucleophile. Bond formation should lead directly to intermediate **7** *via* ring opening, which then poised to attack adjacent reactive carbonyl group. Finally, an intramolecular condensation occurred and 4-arylmethylene-2-phenyl-1*H*-imidazol-5(4*H*)-ones **3** were obtained (Scheme 3).

**Scheme 2**

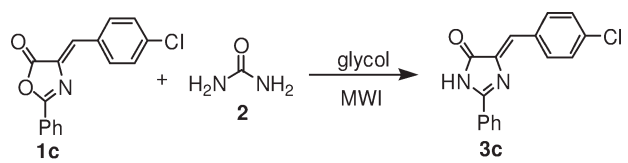


**Table 1**

Solvent optimization for the synthesis of **3c** under MWI.

| Entry | Solvent | Temp (°C) | Time (min) | Yield (%) |
|---|---|---|---|---|
| 1 | HOAc | 150 | 5 | trace |
| 2 | Glycol | 150 | 5 | 93 |
| 3 | EtOH | 150 | 5 | 63 |
| 4 | DMF | 150 | 5 | 79 |
| 5 | Water | 150 | 5 | 32 |

In a further study, aromatic amine **4** was employed instead of urea **2** in this case. The reactions proceeded smoothly too. However, the desired products **3** were not detected. Instead, a series of open-chain products **5** were obtained in high yields (Scheme 4). The reason may be attributed to the nucleophilicity of amine. When R is a phenyl group, the resulting *N*-phenylformamide derivative decreases the nucleophilicity of amine, which is difficult to form closed-ring products **3**. The synthesis of these compounds has reported in our previous study (Compounds **5** were conveniently prepared following a literature procedure: [19]).

In summary, we demonstrated a simple method, using readily available starting materials and simple experimental procedures, for the efficient synthesis of imidazol-5(4*H*)-one derivative and related compounds. Particularly, valuable features of this cascade reaction included operational simplicity, high yields, increased safety for small-scale high-speed synthesis, and broader substrate scope.

## EXPERIMENTAL

All reactions were performed in a monomodal Emrys™ Creator from Personal Chemistry, Uppsala, Sweden. Melting points were determined in open capillaries and are uncorrected. IR spectra were recorded on a FTIR-tensor 27 spectrometer in KBr. $^1$H NMR spectra were measured on a DPX 400 MHz spectrometer using TMS as an internal standard and DMSO-$d_6$ as solvent. Elemental analysis was determined by using a Perkin-Elmer 240c elemental analysis instrument.

***4-Arylmethylene-2-phenyl-1H-imidazol-5(4H)-one (3).*** In a 10 mL Emrys™ reaction vial, 4-arylmethylene-2-phenyloxazol-5(4*H*)-ones (1 mmol) with urea (1.5 mmol), ammonium acetate (1.5 mmol), in ethylene glycol (2.0 mL) were mixed and then capped. The mixture was irradiated by microwave at 300 W and 150°C for a given time. The automatic mode stirring helped the mixing and uniform heating of the reactants. Upon completion, monitored by TLC, the reaction mixture was cooled to room temperature and then poured into cold water, filtered to give the crude products, which were further purified by recrystallization from 95% EtOH. The reaction time and the yields are listed in Table 3. The analytical data of new products are as following:

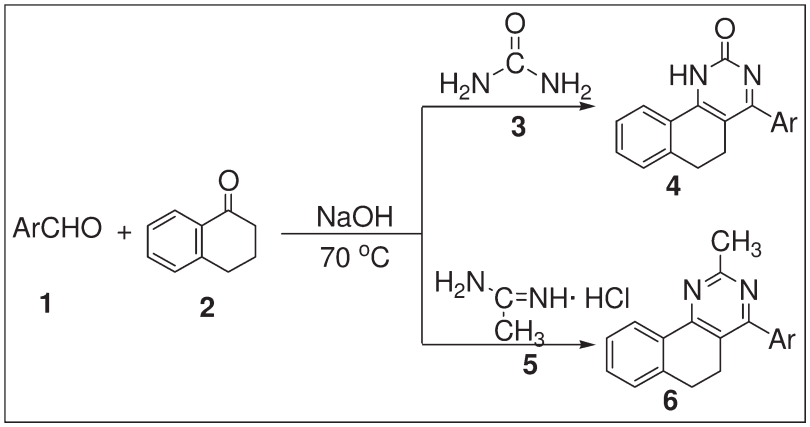
Published online 2 March 2010 in Wiley InterScience (www.interscience.wiley.com).



An efficient and convenient method for the preparation of 5,6-dihydrobenzo[*h*]quinazoline derivatives by the multicomponent reactions of aromatic aldehydes, 3,4-dihydronaphthalen-1(2*H*)-one and urea or acetamidine hydrochloride, in the presence of sodium hydroxide under solvent-free conditions was reported. This method has the advantages of excellent yields, mild reaction conditions, easy work-up, and environmentally friendly procedure.

## INTRODUCTION

The quinazoline skeleton is a very important and useful scaffold in medicinal chemistry: it can be found as a pharmacophore in a wide variety of biologically active compounds, such as antitumors [1], antimicrobials [2], antivirals [3,4]. Benzoquinazoline, the important containing quinazoline skeleton system derivatives, is often found in different natural alkaloids, and these compounds also display specific biological activities, and often used as asdiuretic, anticancer, anticonvulsant, and antihypertensive agents [5–8].

Recently, there was an increasing emphasis on developing new environmentally safer chemical transformations by lessening/removing the toxic waste, where by-products from the chemical processes were avoided or minimized making them ecologically more acceptable. It is highly desirable to develop eco-friendly methods for producing organic fine chemicals. One of the major problems encountered in various chemical processes is the use of organic solvents. Hence, the organic transformations under solvent-free conditions are attracting increasing attentions [9–11]. Herein, we would like to report an efficient and facile method to synthesize 5,6-dihydrobenzo[*h*]quinazoline derivatives under solvent-free conditions.

## RESULTS AND DISCUSSION

The synthesis process could be depicted as follows: at first, we try to prepare 4-aryl-5,6-dihydrobenzo[*h*]quinazolin-2(1*H*)-one derivatives under solvent-free conditions (Scheme 1). The aromatic aldehydes **1** (1 mmol), 3,4-dihydronaphthalen-1(2*H*)-one **2** (1 mmol) and urea **3** (1.5 mmol) were chosen as starting materials, and the reactants were blent enough in a mortar in presence of NaOH (0.1 g) as catalyst, then the mixture was introduced into a round flask and reacted under 70°C. To our delight, the reaction could be finished about 30 min and the 4-aryl-5,6-dihydrobenzo[*h*]quinazolin-2(1*H*)-one

**Scheme 1**

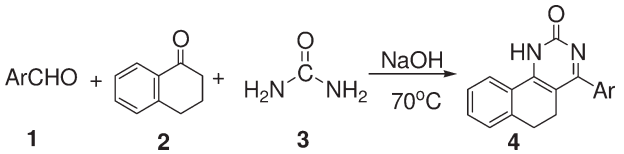

**Table 1**

The results of synthesis of 4-aryl-5,6-dihydrobenzo[*h*]quinazolin-2(1*H*)-one.

| Entry | Ar | Product | Yields (%) |
|---|---|---|---|
| 1 | $C_6H_5$ | **4a** | 80 |
| 2 | 4-$CH_3C_6H_4$ | **4b** | 85 |
| 3 | 3,4-$(CH_3)_2C_6H_3$ | **4c** | 83 |
| 4 | 3,4-$(CH_3O)_2C_6H_3$ | **4d** | 87 |
| 5 | 4-$FC_6H_4$ | **4e** | 90 |
| 6 | 4-$BrC_6H_4$ | **4f** | 88 |
| 7 | 2-$ClC_6H_4$ | **4g** | 80 |
| 8 | 4-$ClC_6H_4$ | **4h** | 91 |
| 9 | 2,4-$Cl_2C_6H_3$ | **4i** | 82 |
| 10 | 3,4-$Cl_2C_6H_3$ | **4j** | 80 |

**Table 2**

The results of synthesis of 4-aryl-5,6-dihydro-2-methylbenzo[*h*] quinazoline.

| Entry | $Ar^1$ | Product | Yields (%) |
|---|---|---|---|
| 1 | 4-$CH_3C_6H_4$ | **6a** | 78 |
| 2 | 4-$CH_3OC_6H_4$ | **6b** | 80 |
| 3 | 3,4-$(CH_3O)_2C_6H_3$ | **6c** | 76 |
| 4 | 4-$FC_6H_4$ | **6d** | 85 |
| 5 | 3-$ClC_6H_4$ | **6e** | 79 |
| 6 | 4-$ClC_6H_4$ | **6f** | 89 |
| 7 | 3,4-$Cl_2C_6H_3$ | **6g** | 88 |

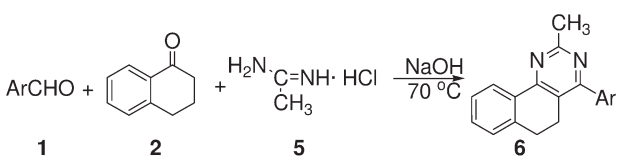
derivatives could be gained with excellent yields. The result of reaction is shown in Table 1. From Table 1 we could see the reaction was carried out smoothly and a series of 4-aryl-5,6-dihydrobenzo[*h*]quinazolin-2(1*H*)-one derivatives were obtained ignoring the properties of substitute groups on the aromatic aldehydes. So, we could say that substitute groups on the aromatic aldehydes do not affect this reaction. In addition, in this reaction the catalyst NaOH was necessary.

To extend this reaction to prepare more benzo[*h*]quinazoline derivatives, we replaced urea by acetamidine hydrochloride to react with aromatic aldehydes **1** and 3,4-dihydronaphthalen-1(2*H*)-one **2** under similar condition (Scheme 2), and we found that other benzo[*h*]quinazoline derivatives, 4-aryl-5,6-dihydro-2-methylbenzo[*h*]-quinazoline could be gained with good yields. The result of reaction was listed in Table 2. In this reaction, we thought that two functions were played by NaOH, one it was used as catalyst to promote the reaction, and the another it reacted with acetamidine hydrochloride to release acetamidine.

The structures of **4** and **6** were characterized by $^1$H NMR, IR, and HRMS spectra, and the structures of **6d** [12] was additionally confirmed by X-ray diffraction analysis. The crystal structure of is shown in Figure 1.

In conclusion, we have developed an efficient and facile process to synthesize a variety of 4-aryl-5,6-dihydrobenzo[*h*]quinazolin-2(1*H*)-one and 4-aryl-5,6-dihydro-2-methylbenzo[*h*] quinazoline derivatives *via* one-pot reaction of different aromatic aldehydes, 3,4-dihydronaphthalen-1(2*H*)-one, and urea or acetamidine hydrochloride under solvent-free conditions. The mild reaction conditions, short reaction times, good to high yields, low cost, easy preparation, easy handling, and reusability of catalyst are the advantages of this method.

**Scheme 2**



## EXPERIMENTAL

Melting points were determined on XT-5 microscopic melting-point apparatus and were uncorrected. IR spectra were recorded on a FT Bruker Tensor 27 spectrometer. $^1$H NMR spectra were obtained from solution in DMSO-$d_6$ with $Me_4Si$ as internal standard using a Bruker-400 spectrometer. X-ray diffractions were recorded on a Siemens P4 or Simart-1000 diffractometer. HRMS spectra were obtained with a Bruker micrOTOF-Q 134 instrument.

**General procedure for the synthesis of 5,6-dihydrobenzo[*h*]quinazoline derivatives.** The mixture of aromatic aldehydes **1** (1 mmol), 3,4-dihydronaphthalen-1(2*H*)-one **2** (1 mmol), urea **3** (1.5 mmol) or acetamidine hydrochloride **5** (1.5 mmol), and NaOH (0.1 g) was put in a reaction flask, and the reagents were reacted at 70°C about 30 min. When the reactions were completed, the reaction mixture was poured into water (0.5% HCl), and then washed with water thoroughly. The product was filtered, dried, and recrystallized from 95% ethanol.

A green procedure for the synthesis of 1,8-dioxo-decahydroacridine derivatives is developed under microwave irradiation without catalyst in water. This method provides several advantages such as excellent yields (86–96%), simple workup procedure, and environment friendliness.

## INTRODUCTION

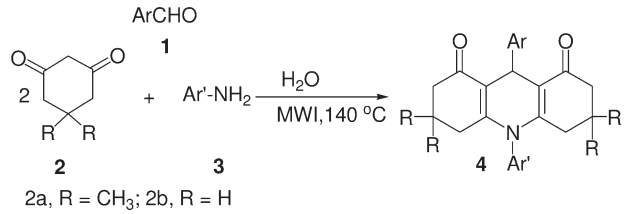
Water as a solvent has many advantages in organic synthesis, both from economic and from environmental points of view. Water has, therefore, become an attractive medium for many organic reactions. Many important types of heterocyclic compounds, such as triazines [1], acridines [2], quinolines [3], pyridines [4], indoles [5], pyrazines [6], furans [7], and pyrimidines [8] have been synthesized in aqueous media.

4-Aryl-1,4-dihydropyridines (1,4-DHPs) have proved to be valuable as drugs for the treatment of cardiovascular disorders [9] and constitute an important class of calcium channel blockers [10]. It is well established that slight structural modification on the DHP ring may result in remarkable change of pharmacological effect [11–14]. With a 1,4-DHP parent nucleus, acridine-1,8-diones have been shown to have very high lasing efficiencies [15] and used as photoinitiators [16]. Recently, many methods have become available for the synthesis of these important class of derivatives, We have synthesized these compounds from schiff's base and dimedone or 1,3-cyclohexanedione or three-component (aldehyde, dimedone, and arylamines) in glycol under microwave [17,18]. Jin et al. [19] reported that this reaction could be carried out catalyzed by *p*-dodecylben-zensulfonic acid (DBSA) in water. However, these reactions must be carried out by impetus of catalyst or in organic solvents. Wang et al. [20] reported the same reaction proceeded in an ionic medium, and Wang and Miao [21] achieved the reactions in aqueous solvent at traditional heating. The reaction time was 10 h, the yield was 72–75%. Arylamine used was only *p*-toluidine. Microwave-assisted organic reaction using water as solvent has peculiarity of ''safe solvents'' and ''energy efficiency.'' It was widely used in the organic synthesis [22]. In this article, we would like to report the green synthesis of 1,8-dioxo-9,10-diaryl-decahydracidines without catalyst *via* the combination of aqueous solvent and microwave heating, using a variety of arylamines including the anilines contained electron-withdrawing groups and electron-donating groups (Scheme 1).

## RESULTS AND DISCUSSION

When treating aldehyde **1** with dimedone or 1,3-cyclohexanedione **2** and primary arylamines **3** under microwave irradiation, the target compound **4** were obtained.

**Scheme 1**



To demonstrate the efficiency and the applicability of this method, we investigated the reaction of a variety of aromatic aldehydes **1**, dimedone, and a variety of primary arylamines **3** at 140°C in aqueous media. As shown in Table 1, a series of **1** and **3**, in which the aromatic ring contained electron-withdrawing groups (such as halo or nitro) or electron-donating groups (such as methyl or methyloxy), reacted with **2a** under the same reaction conditions to give the corresponding product **4** in good yields (entries 1–14), We thus concluded that there were no obvious electronic effect of the substituents on the aromatic rings. To further expand the scope of the present method, the replacement of dimedone **2a** with 1,3-cyclohexanedione **2b** was examined. To our delight, under the same conditions, the reactions proceeded steadily to afford a series of 1,8-dioxo-decahydroacridine derivatives in good yields (Table 1, entries 15–25).

The structures of all the synthesized compounds were established on the basis of their spectroscopic data (IR and $^1$H NMR). In addition, the X-ray diffraction analysis of product **4e** [23], **4k** [24], **4l** [25], **4n** [26], was carry out to confirm its structure. The crystal structure of **4k** is shown in Figure 1.

In conclusion, we have developed a green chemistry method for the synthesis of 1,8-dioxo-decahydroacridine derivatives. Excellent yields were obtained not only for anilines substituted with electron-donating groups but also for ones containing electron-withdrawing groups, The method avoided using organic solvents and had the main advantages of convenient procedure and environmental friendliness.

## EXPERIMENTAL

Microwave irradiation was carried out with microwave oven Emrys$^{TM}$ Creator from Personal Chemistry, Uppsala, Sweden. Melting points were determined in open capillaries and were uncorrected. IR spectra were taken on a TENSOR 27 spectrometer in KBr and reported in cm$^{-1}$. $^1$H NMR spectra were measured on a Bruke DPX 400 MHz spectrometer in DMSO-$d_6$ with chemical shift (δ) given in ppm relative to TMS as internal standard, Elemental analyses were determined by using a Perkin-Elmer 240c elemental analysis instrument. X-Ray crystallographic analysis was performed with a Siemens SMART CCD and a Semens P4 diffractometer.

**General procedure for the synthesis of compound 4 with microwave irradiation.** In a 10 mL Emrys$^{TM}$ reaction vial, an aldehyde **1**(1 mmol), dimedone or 1,3-cyclohexanedione **2**(2 mmol), primary arylamines **3**(1 mmol) and water (1.0 mL)

**Table 1**

Physical data of compounds **4**.

| Entry | Product | Ar | 2 | Ar′-NH$_2$ | Time (min) | Mp (°C) | Yield (%) |

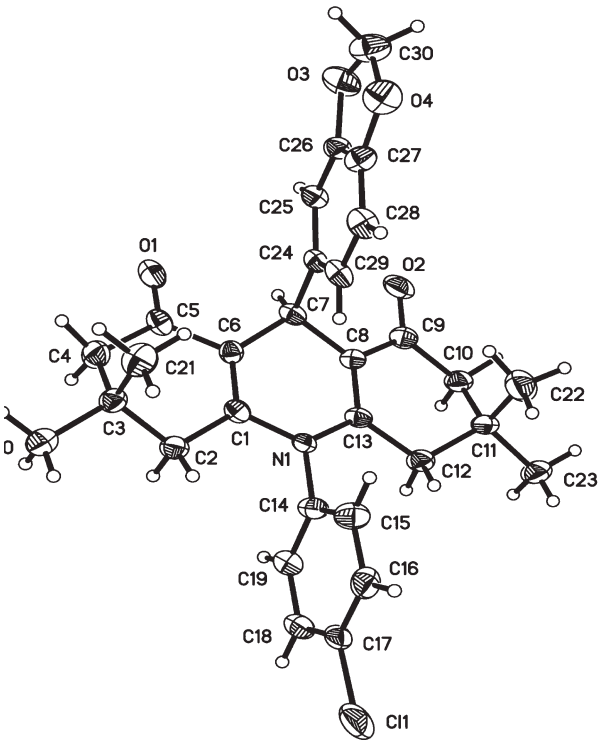

**Figure 1.** Molecular structure of **4k**.

was mixed and then capped. The mixture was irradiated for a given time at power of 200 W at 140°C. Upon completion, monitored by TLC, the reaction mixture was cooled to room temperature. The solid product was filtered to give the crude product, which was further purified by recrystallization from EtOH (95%).

At the process of ethyl 6-methyl-4-aryl-2-thioxo-1,2,3,4-tetrahydropyrimidine-5-carboxylates condensation with aryl aldehydes and chloroacetic acid the unexpected formation of 5-arylidenethiazolidine-2,4-diones was determined in high yields as the reaction time was increased to 20 h. The latter represent the products of destructive hydrolyzes of ethyl 2-benzylidene-7-methyl-3-oxo-5-aryl-2,3-dihydro-5*H*-[1,3]thiazolo[3,2-*a*]pyrimidine-6-carboxylates which have been proved by independent synthesis.

## INTRODUCTION

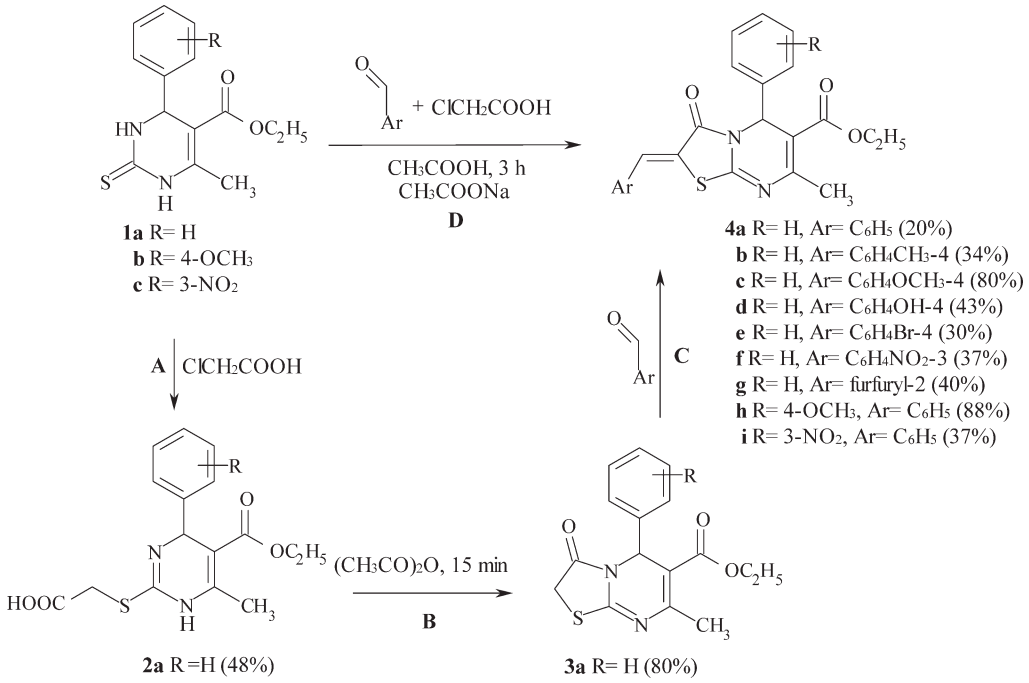
Multicomponent reactions (MCRs) have been widely used in organic and medicinal chemistry over the last years for producing a number of libraries for bioscreening [1]. A three-component condensation of aromatic aldehydes with ureas (thioureas) and β-ketoesters known as Biginelli reaction [2] takes an important place among MCRs. The reaction allows forming a dihydropyrimidine cycle where the nature of the subsistent in the basic structure can be widely modified. Dihydropyimidines (DHPMs) found their use as antimicrobial [3], antiviral [4], antiinflammatory [5], anticarcenogenic preparations [6], and calcium channel modulators [7]. The principle of Biginelli condensation is employed to construct complex heterocyclic scaffolds analogous to those isolated from Batzelladines A-B which have been found to be potent HIVgp-120-CD4 inhibitors [8]. To broaden the study on the range of biological activity of 2-thioxo-DHPM derivatives the library of substituted ethyl 5-aryl-3-oxo-7-methyl-2,3-dihydro-5*H*-thiazolo[3,2-*a*]pyrimidine-6-carboxylates (**4a–i**) have been synthesized [9].

A standard method of a multicomponent one-step condensation of substituted pyrimidine-2-thiones **1a** [9], **1b** [9], **1c** [2(b,f)], haloacetic acids, aryl(heteryl)aldehydes and surplus of anhydrous sodium acetate using glacial acetic acid as solvent has been employed. The formation of corresponding thiazolo[3,2-*a*]pyrimidine derivatives **4a–i** (**D**, Scheme 1) results in three consecutive stages which include alkylation leading to the compound **2a** (**A**, Scheme1) formation [2(c)], intramolecular heterocyclisation **3a** (**B**, Scheme 1) [9(c,h)], and condensation (**C**, Scheme 1) [9(a)] of primary DHPMs **1a–c**. Thus, a newly formed heterocyclic system **3a**, readily reacts with carbonyl compounds giving rise to substituted arylidene derivarives **4a–i**. The reaction time depends on the carbonyl reagent and lasts for 1–3 h. It is obvious that at the condensation of this type 7*H* isomer may be formed together with the 5*H* one (**4a–i**). Unambiguous formation of **4a–i** type ending products has been previously established with the extensive X-ray study [9(c)].

## RESULTS AND DISCUSSION

Quite unexpectedly, as the reaction time (**D**, Scheme 1) was increased to 18–20 h, the final products, extracted from the reaction mixture, were identified as 5-arylidene-2,4-thiazolidinediones (**5a–g**, Scheme 2) [10]. Thus, thiazolo[3,2-*a*]pyrimidines **4a–i** represent

**Scheme 1**



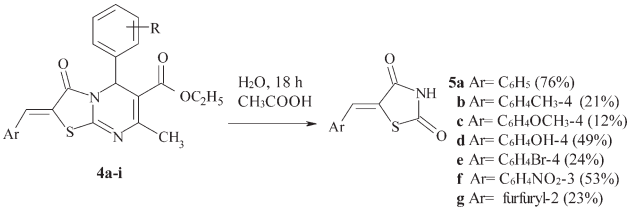
intermediate products for the synthesis of **5**-arylidene-2,4-thiazolidinediones (**5a–g**).

To determine the conditions when the destruction process takes place, a series of technical mixtures extracted from the mother liquor on different stages of the reaction time has been studied. A sample, taken in 30 min of reaction mixture reflux revealed the presence of the primary compound **1a** 27% and the intermediate product **4a** 72%. The destruction product **5a** was not determined on this reaction stage. Specimen, extracted in 3 h of reflux, revealed the presence of thiazolo[3,2-*a*]pyrimidine **4a** at the amount of 88% and 11% of 5-arylidene-thiazolidine-2,4-dione (**5a**). Sample, taken in 18 h of reaction mixture reflux contained both **5a** 76 and **4a** 20%, respectively. It should be noted that refluxing **4a** as a starting compound under the condensation conditions (glacial acetic acid, anhydrous sodium acetate, corresponding aromatic aldehyde), for 20 h did not reveal the presence of 5-arylidene thiazolidine-2,4-dione (**5a**). As water was added to the analogous reaction mixture to **4e**, the ratio of target products was **5e** 24, to **4e** 30%. 5-Arylidenethiazolidine-2,4-dione (**5a**) was formed in 55% yield when alkylated dihydropyrimidine-2-thione (**2a**) was used as a primary compound and cyclization took place under standard reaction duration and conditions. As analogous reaction conditions were followed excluding presence of water for **3a** as a primary compound the destruction process was not determined and reaction mixture contained 95% of thiazolo[3,2-*a*]pyrimidine **4a**. The exclusion of anhydrous sodium acetate from the reaction somewhat speeds up the destruction process and in 8 h of reaction time the ratio of **4a** to **5a** was 38 to 42%.

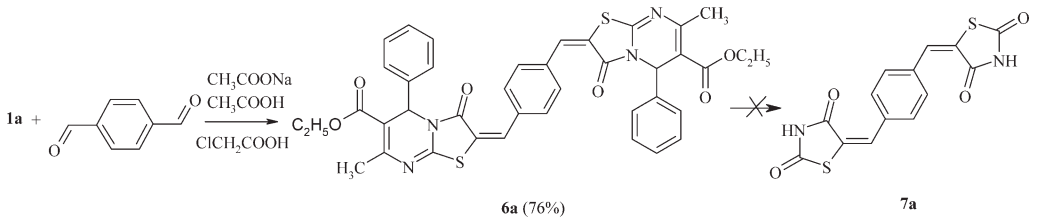
Thus, it may be concluded that the destruction process takes place due to slow hydrolyses of **4a–i** with water emitted during the condensation course. Therefore, the presence of anhydrous sodium acetate is obviously not enough to exclude the influence of water on the reaction course. As acetic anhydride surplus is added to the reaction mixture the process of destructive hydrolyses had not been determined either on the 3rd or on the 18th h of the reaction duration and the presence of formed thiazolo[3,2-*a*]pyrimidines (**4a**) was 97% and 98% respectively.

As terephthalic aldehyde was employed in ethyl thiazolo[3,2-*a*]pyrimidine-6-carboxylates synthesis, bis-thiazolo[3,2-*a*]pyrimidine of **6a** type (Scheme 3) has been obtained as a target product. It should be mentioned that possible destruction product (**7a**, Scheme 3) was not determined even under rigid reaction conditions such as

**Scheme 2**



**Scheme 3**



synthesis of **6a** in a sealed tube at 180°C for 12 h due to **6a** possessing low ability to dissolve in organic solvents.

The structure of compounds **5a–g** has been determined by NMR ($^1$H, $^{13}$C), IR, elemental, LC/MS analyses. $^1$H NMR spectra of compounds **5a–g** are characterized with the presence of the representative singlet at 6.0–6.1 ppm corresponding to the one of pyrimidine cycle at C4, and also with the singlet at 7.6–7.9 ppm relevant to the proton of methine group of the multiple bond C=CH-Ar. For **6a** corresponding signals are determined at 6.52 and 8.31 ppm at $CF_3COOD$.

$^{13}$C NMR spectroscopy was also applied to determine the structure of **5a** revealing eight signals. APT experiment determined the presence of four quaternary carbon atoms including two carbonyle and four protonated tertiary carbon atoms: δ = 167.65 (q), 167.09 (q), 132.85 (q), 131.61 (t), 130.20 (t), 129.83 (t), 129.10 (t), 123.36 (q) ppm. IR spectra of **5a–g** (KBr platelets) revealed broadened picks due to the intermolecular bonds of ÑH and C=O groups. The structure of **5a** has been unambiguously determined by the single crystal X-ray diffraction. The perspective view of the molecule **5a** and selected geometrical parameters are given in Figure 1. The molecule **5a** is almost planar (deviations of nonhydrogen atoms from the least-square plane do not exceed 0.069 Å). The N(1) atom has trigonal-planar bond configuration (sum of the bond angles 360.0°).

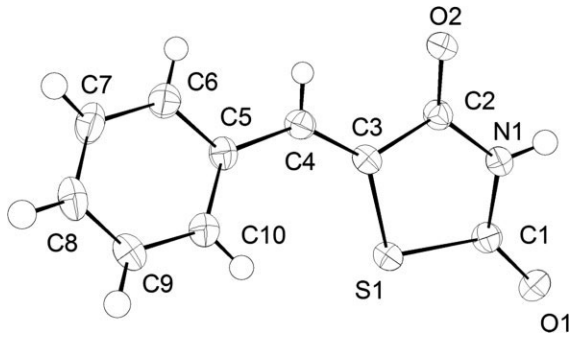


**Figure 1.** Perspective view and labeling scheme for the molecule **5a.** Selected bond lengths (Å) and angles (°): S(1)-C(1) 1.786(2), S(1)-C(3) 1.756(2), N(1)-C(1) 1.369(2), N(1)-C(2) 1.365(2), C(2)-C(3) 1.484(2), C(3)-C(4) 1.331(2); C(1)S(1)C(3) 91.68(8), C(1)N(1)C(2) 117.9(1).

Because of the $n_N$-$\pi_{C=O}$ conjugation both the N(1)-C(1) 1.369(2) Å and the N(1)-C(2) 1.365(2) Å bonds are significantly shortened in comparison with the standard value for the N($sp^2$)-C($sp^2$) single bonds of 1.43–1.45 Å [11,12]. In the solid state the molecules of **5a** are joined in the centrosymmetric dimers by the N(1)-H...O(2) (N...O 2.834(2), O...H 1.96(2) Å, NHO 169(23)° intermolecular hydrogen bonds.

## CONCLUSIONS

The formation of 5-arylidene-2,4-thiazolidinediones has been determined during the synthesis of substituted ethyl 5-aryl-3-oxo-7-methyl-2,3-dihydro-5*H*-thiazolo[3,2-*a*]pyrimidine-6-carboxylates library. Therefore, it is strongly suggested to reconsider the traditional reaction conditions and to take special care on the exclusion of water influence on the reaction process (*e.g.* acetic anhydride should be employed at the reaction rather than waterfree sodium acetate). Otherwise, as the reaction time expanded for the period of 18 h and more, allowing the emitted water to hydrolyze the desired thiazolo[3,2-*a*]pyrimidines the formation of 5-arylidene-2,4-thiazolidinediones reaches up to 76%.

## EXPERIMENTAL

All chemicals were obtained from commercial sources and used without further purification. Melting points (mp) were measured on an electrothermal capillary melting point apparatus and are uncorrected. IR spectra were recorded with a UR-20 spectrophotometer (KBr platelets). The NMR measurements were carried out on a Varian GEMINI 2000 spectrometer with $^1$H and $^{13}$C frequencies of 400.07 and 100.61 MHz, respectively at 293 K. $^1$H NMR spectra were recorded with spectral width 8000 Hz and numbers of points 32,000; $^{13}$C NMR spectra were recorded with spectral width 30,000 Hz and numbers of points 128,000. DMSO-$d_6$ and $CF_3COOD$ were used as solvents and TMS as internal standard. HPLC-MS was carried out on a system consisting of an Agilent 1100 Series high-pressure liquid chromatograph equipped with a diode matrix and Agilent LC/MSD SL mass-selective detector. HPLC-MS parameters: column: Zorbax SB-C18, 1.8 μm, 4.6 × 30 mm$^2$; solvents: Me-CN-$H_2O$ (95:5), 0.1% TFA; eluent flow: 3 mL s$^{-1}$; injected sample volume: 1 μL; UV detector: λ = 215, 254, 265 nm; ionization method: chemical ionization

under atmospheric pressure (APCI); ionization mode; simultaneous scanning of positive and negative ions in *m/z* range 100–650. Microanalyses were performed in the Microanalytical Laboratory of the Institute of Organic Chemistry, National Academy of Sciences of Ukraine. Crystallographic data of **5a** including atomic coordinates, bond lengths and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre (CCDC). These data can be obtained free of charge *via* www.ccdc.cam.uk/conts/retrieving.html (or from CCDC, 12 Union Road, Camridge CB2 1EZ, UK, fax: +44 1223 336 033, or deposit@ccdc.cam.ac.uk). Any request to the CCDC for data should quote the full literature citation and CCDC reference number 734605.

**General procedures.** ***4-Phenyl-5-carbethoxy-6-methylpyrimidine-2-mercaptoacetic acid (2a).*** A solution of **1a** 2.76 g (0.01 mole) and bromoacetic acid 1.5 g (0.011 mole) was refluxed in 15 mL acetic acid for 30 min. Then the mixture was taken to dryness *in vacuo*. The remained residue was neutralized with sodium carbonate solution to pH 5, filtered, washed with 100 mL of hot water. Recrystallized from EtOH. Compound **2a** was obtained as yellow solid in 68% yield. Mp and spectral data has appeared to be identical to those reported in literature [2(c)].

***Ethyl 5-phenyl-7-methyl-3-oxo-2,3-dihydro-5H-thiazolo [3,2-a]pyrimidine-6-carboxylate (3a).*** Compound **2a** 1.82 g, (0.005 mole) was dissolved in 5 mL acetic anhydride and refluxed for 15 min, and then allowed to cool. The precipitate formed was filtered off and recrystallized from *i*-PrOH. Compound **3a** was obtained as yellow solid in 80% yield. Mp and spectral data has appeared to be identical to those reported in literature [2(c),10(a,b)].

**General procedure for the synthesis of ethyl 5-arylmethylene-3-oxo-7-methyl-2,3-dihydro-5H-thazolo[3,2-*a*]pyrimidine-6-carboxylates (4a–i).** A mixture of **1a–c** (0.01 mole), anhydrous sodium acetate 1.0 g, (0.015 mole), chloroacetic acid 1.0 g, (0.011 mole), and the appropriate aldehyde (0.01 mole) was refluxed for 3 h in 10 mL of glacial AcOH. After cooling, the mixture was poured onto crushed ice. The precipitate formed **4a–i** was filtered off and recryatllized from *i*-PrOH.

Compounds (Yield) **4a** [9(c)] (20%), **4b** [9(c)] (34%), **4c** [9(c,g)] (80%), **4e** [9(f)] (30%), **4h** [9(e)] (88%), **4i** [9(c)] (37%) have been described in the literature.

***Ethyl 5-phenyl-2-(4-hydroxyphenylmethylene)-7-methyl-3-oxo-2,3-dihydro-5H-thiazolo[3,2-a]pyrimidine-6-carboxylate (4d).*** Yellow solid, yield 43%, mp 192°C (*i*-PrOH); IR (KBr): ν 1545 (C=N), 1695 (C=O), 2990 (CH) 3430 (OH) $cm^{-1}$. $^1H$ NMR (400 MHz, DMSO-$d_6$): δ = 10.22 [s, 1 H, OH], 7.66 [s, 1H, $HOC_6H_4CH$], 7.39 [d, $^3J$(H,H) = 8.8 Hz, 2 H, H2 H6 $C_6H_4OH$], 7.30 [m, 5 H, $C_6H_5$], 6.87 [d, $^3J$(H,H) = 8.8 Hz, 2 H, H3 H5 $C_6H_4OH$], 6.03 [s, 1 H, $C_6H_5CH$], 4.05 [m, 2 H, $CH_2CH_3$], 2.40 [s, 3 H, $NCCH_3$], 1.16 [t, $^3J$(H,H) = 8.0 Hz, 3 H, $CH_2CH_3$]; ms: *m/z* 419 ($M^-$). *Anal*. *C*alcd. for $C_{23}H_{20}N_2O_4S$: C, 65.70; H, 4.79; N, 6.66. Found: C, 64.39; H, 4.70; N, 6.73.

***Ethyl 5-phenyl-2-(3-nitrophenylmethylene)-7-methyl-3-oxo-2,3-dihydro-5H-thiazolo[3,2-a]pyrimidine-6-carboxylate (4f).*** Yellow solid in 37% yield, mp 173°C (*i*-PrOH); IR (KBr): ν 1330, 1540 ($NO_2$), 1610 (C=N), 1690, 1730 (C=O) 2980 (CH) $cm^{-1}$. $^1H$ NMR (400 MHz, DMSO-$d_6$): δ = 8.39 [deg. s, 1 H, H2 $C_6H_4NO_2$], 8.25 [d, $^3J$(H,H) = 8.0 Hz, 1 H, H6 $C_6H_4NO_2$], 7.96 [d, $^3J$(H,H) = 7.6 Hz, 1 H, H4 $C_6H_4NO_2$], 7.90 [s, 1 H, $O_2NC_6H_4CH$], 7.78 [m. 1 H, H5 $C_6H_4NO_2$], 7.32 [m, 5 H, $C_6H_5$], 6.08 [s, 1 H, $C_6H_5CH$], 4.08 [m, 2 H, $CH_2CH_3$], 2.42 [s, 3 H, $CH_3$], 1.16 [t, $^3J$(H,H) = 6.8 Hz, 3 H, $CH_2CH_3$]; ms: *m/z* 450 ($M^+$). *Anal*. ***Ethyl 5-phenyl-(2-furfuryl)-7-methyl-3-oxo-2,3-dihydro-5H-thiazolo[3,2-a]pyrimidine-6-carboxylate (4g).*** Grey solid in 40% yield, mp 149–150°C (*i*-PrOH); IR (KBr): ν 1600 (C=N), 1690 (C=O) 2960 (CH) $cm^{-1}$. $^1H$ NMR (400 MHz, DMSO-$d_6$): δ = 8.06 [deg. s, 1 H, 5-H fur], 7.61 [s, 1 H, furCH], 7.33 [m, 5 H, $C_6H_5$], 7.09 [deg. s, 1 H, 3-H fur], 6.74 [deg. s, 1 H, 4-H fur], 6.05 [s, 1 H, $C_6H_5CH$], 4.06 [m, 2 H, $CH_2CH_3$], 2.39 [s, 3 H, $CH_3$], 1.13 [t, $^3J$(H,H) = 7.2 Hz, 3 H, $CH_2CH_3$]; *m/z* 395 ($M^+$). *Anal*. Calcd. for $C_{21}H_{18}N_2O_3S$: C, 63.95; H, 4.60; N, 7.10. Found: C, 62.69; H, 4.53; N, 7.18.

**General procedure for the synthesis of substituted 5-arylidene-2,4-thiazolidinedione (5 a–g).** A mixture of **1a–c** (0.01 mole), anhydrous sodium acetate 1.0 g (0.015 mole), chloroacetic acid 1.0 g (0.011 mole), and the appropriate aldehyde (0.01 mole) was refluxed for 18 h in 10 mL of glacial AcOH. Sodium acetate was separated by decantation. The reaction mixture was left for 24 h at ambient temperature, and the precipitate (**5a–g**) was filtered off and purified by recrystallization from 2-PrOH/DMF.

Compounds (Yield) **5a** [10(a,g,h,i)] (76%), **5b** [10(b,e)] (54%), **5c** [10(a,g)] (12%), **5d** [10(b,d,g)] (49%), **5e** [10(g)] (24%), **5f** [10(b,c)] (53%), **5g** [10(b,f)] (23%) have been described in the literature.

***4,4′-Bis(5-phenyl-6-carbethoxy-7-methyl-3-oxo-2,3-dihydro-5H-thiazolo[3,2-a]pyrimidinyl-2-ylmethylene)benzene (6a).*** A mixture of **1a** 2.76 g (0.01 mole), anhydrous sodium acetate 1.0 g (0.015 mole), chloroacetic acid 1.0 g (0.011 mole), terephthalic aldehyde 0.67 g (0,005 mole) at 10 mL glacial AcOH was thoroughly sealed in a tube and allowed to stand at 180°C for 12 h. The precipitate formed was filtered off, washed with 100 mL of hot water, and purified with recrystallization from DMF.

Red solid, yield 76%, mp: <300°C (DMF); IR (KBr): ν 1560 (C=N), 1715 (C=O) 2990 (CH) $cm^{-1}$. $^1H$ NMR (400 MHz, $CF_3COOD$): δ = 8.31 [s, 2 H, $C_6H_4(CH)_2$], 7.81 [s, 4 H, $C_6H_4$], 7.47 [m, 10 H, 2 × $C_6H_5$], 6.52 [s, 2 H, 2 × $C_6H_5CH$], 4.34 [m, 4 H, 2 × $CH_2CH_3$], 2.75 [s, 6 H, 2 × $NCCH_3$], 1.32 [t, 6 H, 2 × $CH_2CH_3$]. *Anal*. Calcd. for $C_{40}H_{34}N_4O_6S_2$: C, 65.74; H, 4.69; N, 7.67. Found: C, 64.45; H, 4.61; N, 7.81.

**X-ray structure determination of 5a.** ***Crystal data.*** $C_{10}H_7NO_2S$, $M$ = 205.2, monoclinic, $a$ = 9.5115(6), $b$ 11.6786(7), $c$ = 8.2306(6) Å, β = 96.146(4)°, $V$ = 909.0(1) $Å^3$, $Z$ = 4, $d$ = 1.50 g $cm^{-1}$, space group $P2_1/c$ (N 14), μ = 3.24 $cm^{-1}$, $F(000)$ = 424, crystal size ca. 0.12 × 0.44 × 0.45 $mm^3$. All crystallographic measurements were performed at 293°C on a Bruker Apex II CCD diffractometer. The intensity data were collected within the range $2.8 < \theta < 26.3°$ ($-11 < h < 11$, $-14 < k < 14$, $-10 < l < 8$) using graphite monochromated Mo-$K_\alpha$ radiation (λ = 0.71073 Å). Intensities of 6416 reflections (1846 unique, $R_{int}$ = 0.003) were measured. Data were corrected for Lorentz and polarisation effects and an absorption correction using the Sadabs procedure was applied [13]. The structure was solved by direct methods and refined by full-matrix least-squares technique in the anisotropic

approximation using the CRYSTALS program package [14]. In the refinement 1313 reflections with $I > 3\sigma(I)$ were used. All hydrogen atoms were located in the different Fourier maps and refined isotropically). Convergence was obtained at $R = 0.029$ and $R_w = 0.030$, GOF = 1.109 (155 refined parameters; obs./variabl. 8.5). Chebushev weighting scheme [15] with parameters 1.59, 1.50, 1.79, 0.55, and 0.47 was used.

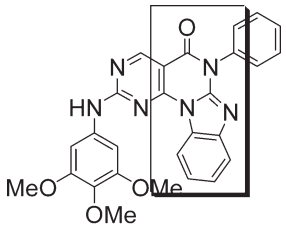
Benzimidazo[1,2-*a*]pyrimidinone and its derivatives were easily prepared in good to excellent yields *via* tandem reactions of 2-aminobenzimidazole with Baylis–Hillman acetates, alcohols, and amines without the use of catalyst and additive in one-pot process. The method provided an efficient and facile route to the title fused heterocyclic compounds with different functional groups.

*J. Heterocyclic Chem.*, **47**, 373 (2010).

## INTRODUCTION

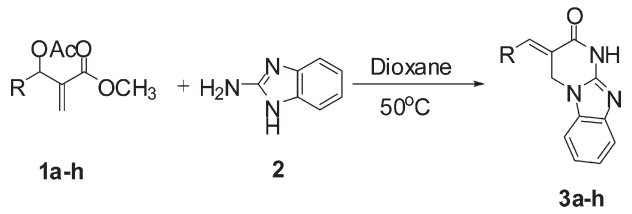
Imidazo[1,2-*a*]pyrimidines are very important intermediates and widely used in pharmaceutical chemistry [1]. Among them, benzimidazo[1,2-*a*]pyrimidinone and its derivatives have attracted considerable attention [2,3]. For example, the compound **A** is a kind of inhibitor of Lck kinase, which is a member of Src family of cytoplasmic tyrosine kinases. The inhibitor might be a useful immunosuppressive agent for the treatment of graft rejection and/or T-cell-mediated autoimmune diseases [4]. There were several approaches to develop the benzimidazo[1,2-*a*]pyrimidinones: the intramolecular substitution reaction of halide with amines [2], the reaction of 2-aminobenzimidazole with propiolic esters and α,β-unsaturated esters [3], and so on. To enhance the diversity of benzimidazo[1,2-*a*]pyrimidinone compounds, a new type of substrate is still required.



Compound **A**

Recently, it was noteworthy that the reactions of 2-aminobenzimidazole with several electrophiles, including nitrile, α,β-unsaturated carbonyl compounds, cyanoacetate, and acetylene-dicarboxylate, have been developed to construct heterocyclic structural unit [5]. The Baylis–Hillman adduct offers an excellent platform for several chemical transformations because of the presence of three functional groups including hydroxyl

**Scheme 1**



(or substituted amino), double bond, and electron-withdrawing group (alkoxycarbonyl or nitrile) in close proximity. The Baylis–Hillman adducts were illustrated as valuable precursor for the synthesis of heterocycles and many biologically active molecules [6]. It was envisaged that the reaction of 2-aminobenzimidazole with Baylis–Hillman adducts and their derivatives would provide an efficient route for the synthesis of annulated benzimidazole derivatives.

Herein, we wish to report the catalyst-free reactions of Baylis–Hillman acetates, alcohols, and amine for the synthesis of benzimidazo-[1,2-*a*]pyrimidinone and their derivatives bearing different functional groups with significant convenience [7].

## RESULTS AND DISCUSSION

**The reactions of Baylis–Hillman acetates (1) with 2-aminobenzoimidazole (2).** Initially, the reaction of Baylis–Hillman acetate **1a** (R = Ph) and 2-aminobenzimidazole **2** was carried out in dioxane at room temperature without any catalyst, but no reaction was observed even after long period of time. However, on raising the temperature to 50°C, light yellow precipitates formed only after 30 min, affording (*E*)-6-benzylidene-5,6-dihydro-8*H*-benzo[4,5]imidazo[1,2-*a*]-pyrimidin-7-one **3a** in 93% yield (Scheme 1, Table 1, entry 1).

In $^1$H-NMR spectrum of **3a**, only one signal of N—H was observed, which showed the formation of cyclic product. The formation of lactam structure was further supported by the IR spectrum, in which an amide carbonyl vibration band appeared at 1657 cm$^{-1}$. The stereochemistry of the newly formed double bond in the products was established as (*E*)-configuration by X-ray diffraction analysis of the single crystal of the product **3d** (R = 2-$F_3CC_6H_4$) (Fig. 1). The structure of the single crystal was also an evidence for the formation of the three nitrogen-containing fused heterocycle.

As shown in Table 1, the substrate scope for the benzimidazo[1,2-*a*]pyrimidine forming process was quite broad, and the reaction demonstrated that various Baylis–Hillman acetates bearing aryl, heteroaryl, or alkyl groups can be used for this transformation. The reaction proceeded smoothly regardless of the electronic character of the substituents existed on the Baylis–Hillman acetates to afford the desired fused heterocycle, benzimidazo[1,2-*a*]pyrimidine derivatives in good to excellent yields (71–97%).

**Table 1**

Reaction of B-H acetates (**1**) with **2**.[a]

| Entry | B-H acetate | Time (h) | Product (R) | Yield[b] (%) |

## THE REACTIONS OF BAYLIS–HILLMAN ALCOHOLS (4) WITH 2

In contrast, when the Baylis–Hillman alcohols were used, the hydroxyl group remained in the product. However, as indicated by Batra and coworkers [8], the hydroxyl group was very sensitive to the reaction condition and ease to be removed out during the intramolecular cyclization by debenzylation. To our delight, under the same reaction conditions for Baylis–Hillman acetate, the fused heterocyclic compounds bearing hydroxyl group could be obtained in one-pot process (Scheme 2). As shown in Table 2, various Baylis–Hillman alcohols (**4a–i**) derived from aryl aldehydes reacted smoothly with **2** to give 6-[aryl(hydroxyl)methyl]-benzoimidazo[1,2-*a*]pyrimidines (**5a–i**) in good to excellent yields. The presence of substitute in the *ortho* position of the phenyl ring (**4f–g**) resulted in slow reactivity of the Baylis–Hillman adduct leading to increase in

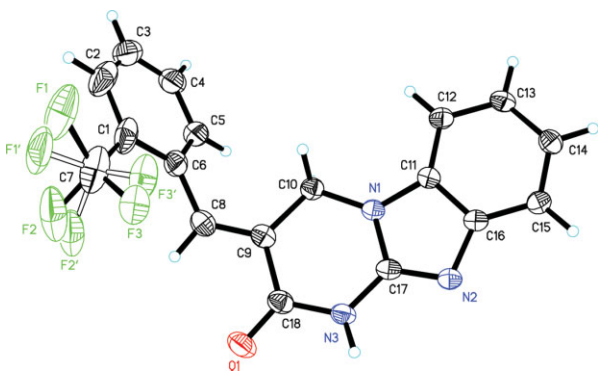

**Figure 1.** ORTEP drawing of **3d**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

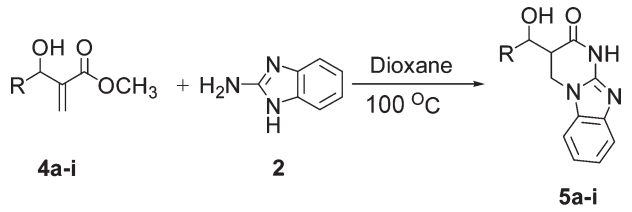
**Scheme 2**



reaction time (entries 6 and 7). Moreover, the substrate bearing aromatic heterocyclic (**4h**) and alkyl group (**4i**) also exhibited good ability for the reaction with **2**, affording the corresponding products (**5h** and **5i**) in 78 and 93% yields, respectively (entries 8 and 9).

**The reactions of Baylis–Hillman amines (6) with 2.** Recently, Lamaty and coworkers assimilated all applications of the aza-Baylis–Hillman adducts for the synthesis of nitrogen-containing compounds. It was demonstrated that when the aza-Baylis–Hillman adduct (Baylis–Hillman amine) was attacked by a nucleophile, the reaction could afford a Michael addition product or an allylic substitution product depending on the reaction conditions, which resulted in the amino group of aza-Baylis–Hillman adducts remaining either in the product or eliminating from the product [9]. When various Baylis–Hillman amines (**6a–g**) were used in the reaction with **2**, under the same condition for Baylis–Hillman acetate the reactions carried out smoothly to afford the Michael addition products **7** in high yields (Table 3). When the substituents in the phenyl ring were electron-withdrawing groups (**6b–f**), the reactions proceeded better than the substrate bearing electron-donating group in the phenyl ring (**6g**) (Entry 7) (Scheme 3).

In conclusion, we have developed an efficient method for the synthesis of benzimidazo[1,2-*a*]pyrimidine derivatives in good to excellent yields. The developed protocol was simple, and no additives or catalysts were required to promote the reaction. The reaction underwent the Michael addition or allylic substitution reaction, followed by intramolecular cyclization. The produced compounds possessed different functions, double bond, hydroxyl and amino groups, which provided an opportunity to do derivatization further for enhancing the diversity of benzimidazo[1,2-*a*]pyrimidine compounds.

**Table 2**

Reaction of B-H alcohols (**4**) with **2**.[a]

| Entry | B-H alcohol | Time (h) | Product (R) | Yield[b] (%) |
|---|---|---|---|---|

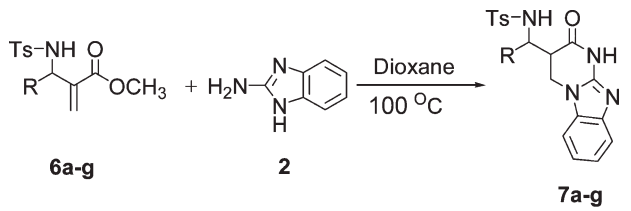
## EXPERIMENTAL

IR spectra were recorded with a Perkin–Elmer 782 IR spectrometer. $^1$H-NMR and $^{13}$C-NMR spectra were obtained with a Bruker DMX-300 (300 MHz) spectrometer. Chemical shifts are given in ppm relative to tetramethylsilane (TMS), and the center of the multiplet of the DMSO was also defined as 39.53 ppm for $^{13}$C-NMR spectra. HRMS (EI) spectra were measured on a JEOL JMS-DX303. Melting points were measured with a Beijing-Taike X-4 apparatus and are uncorrected. Unless otherwise noted, all reagents were obtained from commercial suppliers and were used without further purification.

According to reference's method [10], starting from α,β-unsaturated ester, with aryl or alkyl aldehydes the B-H alcohols (**4a–i**), and with imines the B-H amines (**6a–g**) were synthesized, respectively. B-H acetates (**1a–h**) were derived from B-H alcohols by acetyl chloride.

**General procedure for the reaction of Baylis–Hillman acetates (1a–h) with 2-aminobenzimidazole (2).** To a solution of B-H acetate **1a–h** (1 mmol) in dioxane was added 2-aminobenimidazole **2** (1.2 mmol), and the resultant reaction mixture was heated at 50°C. Upon completion as judged by TLC or the reaction time given in Table 1, precipitates were formed, which were filtered and washed with ether. The crude product was recrystallized from dichloromethane/

**Scheme 3**



petroleum ether to give corresponding products, benzimidazo[1,2-*a*]pyrimidinone derivatives (**3a–g**).

New amino psoralen derivatives have been synthesized *via* bromination. Bromination of 3,5-substituted psoralens has been studied. The second position of the furan ring is more susceptible to bromination than the α-position of the chromen-2-one ring in psoralens. Hence, the target psoralenamines were synthesized starting with 3-bromo-7-hydroxy-4-methyl-chromen-2-one, which was condensed with different α-halo ketones and cyclized in ethanolic potassium hydroxide to get the desired 6-bromo psoralens, which were finally converted into psoralenamines.

*J. Heterocyclic Chem.*, **47**, 379 (2010).

## INTRODUCTION

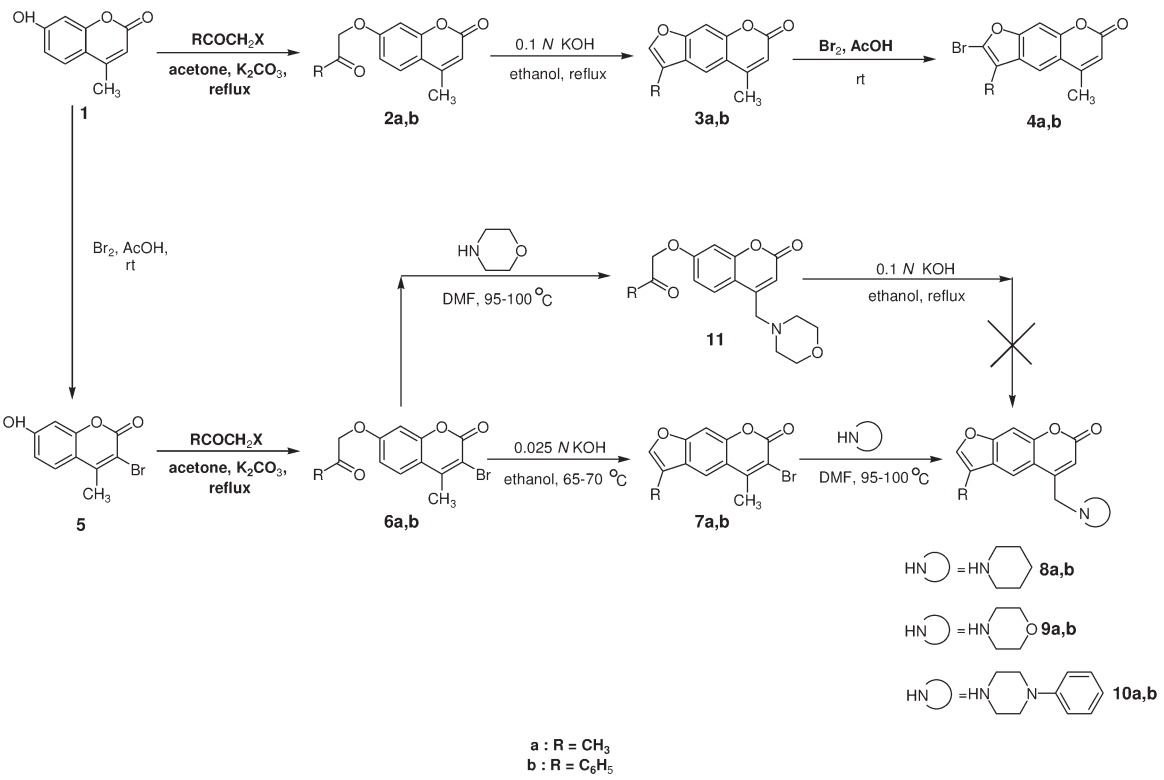
Furocoumarins such as Psoralens (5-methoxy psoralen or bergapton, 8-methoxy psoralen or xanthotoxin, 4,5′,8-trimethyl psoralen) are well known photosensitizing drugs used in Psoralen Ultra Violet-A therapy for the treatment of dermatological disorders, such as psoriasis, vitiligo, mycosis, and atropic eczema [1]; as well as fungal, viral, and bacterial infections [2]. Recently, Psoralen derivatives have also been used in the treatment of cutaneous T-cell lymphoma [3], human immunodeficiency diseases [4], and prevention of rejection of organ transplants [5]. Introduction of aminomethyl group in furocoumarins enhances antibacterial activity [6]. Aminopsoralens are used for nucleic acid probe preparations, preparation of conjugates, inhibition of cell proliferation, inactivation of virus for vaccine preparation, and in particular, for the inactivation of pathogens in blood products [7].

Because of the wide spread and increasing interest in aminopsoralens for their pharmacological action, this study was undertaken to synthesize some new amino psoralen derivatives *via* bromination. Moreover, it was of considerable interest to study the reactivity and orientation of 3,5-substituted psoralens toward bromination. Although it is evident that the third position of furan ring in psoralens is the most reactive towards electrophilic substitution, the behaviour of psoralens in which the third position is blocked has not been reported for bromination. The synthetic pathway followed by MacLeod *et al*. [8] has been employed to prepare the title compounds as outlined in Scheme 1.

## RESULTS AND DISCUSSION

β-Methyl umbelliferone (7-hydroxy-4-methyl-chromen-2-one) **1**, [9] was condensed with different α-haloketones, *e.g*., mono chloroacetone and phenacylbromide to give the aryloxyketones **2** which when subjected to cyclization in 0.1*N* ethanolic potassium hydroxide gave the corresponding furocoumarin (psoralen) **3** as shown

**Scheme 1**

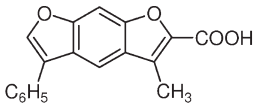


in Scheme 1. Furocoumarin **3** was brominated with bromine in acetic acid to get the desired 6-bromo psoralen, but from the $^1$H nuclear magnetic resonance (NMR) it was revealed that the product formed was 2-bromo psoralen **4**. This shows that the second position of the furan ring is more reactive towards halogenation compared to the α-position of the chromen-2-one ring in psoralens. In the $^1$H-NMR of compound 2-bromo-3,5-dimethyl-furo[3,2-*g*]chromen-7-one **4a**, signal at δ 6.27–6.28 ppm corresponding to one proton for C6—H (or α-H of chromen-2-one) and the absence of signal at δ 7.5 ppm for C2—H proton alongwith C3—$CH_3$ signal at δ 2.24 ppm confirmed the structure. The UV spectrum in dichloromethane showed absorption at 284, 302, 324, 333, 340, and 347 nm. Consequently, the target amino psoralens could not be prepared.

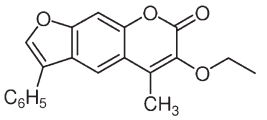
In a slightly modified methodology, β-methyl umbelliferone (7-hydroxy-4-methyl-chromen-2-one) **1** was first brominated using bromine in acetic acid to give 3-bromo-7-hydroxy-4-methyl-chromen-2-one **5** [10] in an addition-elimination reaction, which was then condensed with different α-halo ketones and cyclized to 6-bromo psoralens **7** in a similar fashion as shown in Scheme 1. In the $^1$H NMR of compound 6-bromo-3,5-dimethyl-furo[3.2-*g*]chromen-7-one **7a**, the absence of signal at δ 6.28 ppm for C6—H proton and singlet for C5—$CH_3$ signal at δ 2.74 ppm confirmed the substitution of bromine at C—6 position. Further doublets at δ 7.50 ppm (1H, $J$ = 1.6 Hz) for C2—H and δ 2.31–2.32 ppm (3H, $J$ = 1.6 Hz) for C3—$CH_3$ corroborated the structure **7a**. The mass spectrum (LCMS) was obtained as *m/z* (relative intensity, 100%): 317 (8.88) M+23 (from $Na^+$), 295.1 (100) M+1, 292.9 (100) $M^+$ using mobile phase Acetonitrile: Ammonium acetate 1 m*M* (90:10% v/v). The UV spectrum in dichloromethane showed absorption at 282, 302, 323, 331, 342, 355, and 362 nm. Cyclization of 3-bromo aryloxyketones **6** to 6-bromo psoralens **7** was the bottleneck of the process. Cyclization in 0.1*N* ethanolic potassium hydroxide at reflux temperature lowered the over all yield of the reaction drastically due to the formation of mixture of products. One of the product was identified as furocoumarilic acid formed due to alkaline ring contraction [11], which has been confirmed from the $^1$H NMR and infrared (IR) spectra of 3-methyl-5-phenyl-benzo[1,2-*b*;5,4-*b*′]difuran-2-carboxylic acid **12** obtained during cyclization of 3-bromo-4-methyl-7-(2-oxo-2-phenyl-ethoxy)-chromen-2-one **6b**. The furocoumarilic acid was obtained as white amorphous powder; mp 250°C dec. and whose sodium and potassium salts are hydrophobic. The other product was identified as 6-ethoxy-5-methyl-3-phenyl-furo[3,2-*g*]chromen-7-one **13** formed by nucleophilic attack of ethanol, which also has been confirmed from $^1$H NMR. The yield of 6-bromo psoralen was lowered due to these

side reactions. Weaker bases like tri ethylamine and potassium carbonate failed to give the expected results. Cyclization in polyphosphoric acid and phosphorus (III) oxychloride failed. Even the idea of first condensing 3-bromo aryloxyketones **6** with amines, followed by cyclization to yield amino psoralens failed, since the cyclization reaction gave several decomposition products. Condensation of 3-bromo-4-methyl-7-(2-oxy-propoxy)-chromen-2-one **6a** with morpholine gave 4-morpholin-4-ylmethyl-7-(2-oxo-propoxy)-chromen-2-one **11** as confirmed from $^1$H NMR, but could not be cyclized as shown in Scheme 1. Consequently the concentration of ethanolic potassium hydroxide was reduced from 0.1 to 0.025*N* and the cyclization of 3-bromo aryloxyketones **6** to 6-bromo psoralens **7** was carried out at 65–70°C, which gave the desired results. Finally, 6-bromo psoralens were condensed with different amines to give the corresponding amino methyl psoralens **(8, 9, 10)**. $^1$H NMR of compound 3-methyl-5-piperidin-1-ylmethyl-furo[3,2-*g*]chromen-7-one **8a** showed singlets at δ 6.51 ppm corresponding to one proton for C6—H proton and δ 3.66 ppm corresponding to two protons for C5—$CH_2$—, which confirmed the formation of 5-amino methyl psoralens. In the $^{13}$C NMR, δ values 99.59 ppm for C6 and 59.91 ppm for C5—*C*$H_2$— further confirmed the structure. The UV spectrum in dichloromethane showed absorption at 281, 301, 305, 329, 337 nm. The mass spectrum (LCMS) for 3-methyl-5-morpholin-4-ylmethyl-furo[3,2-*g*]chromen-7-one **9a**. was obtained as *m/z* (relative intensity, 100%): 338.1 (7.27) M+39 (from $K^+$), 322.2 (38.18) M+23 (from $Na^+$), 301.2 (70.90) M+2, 299.9 (100) M+1 using mobile phase acetonitrile:ammonium acetate 1 m*M* (90:10% v/v).

The structures of all compounds have been established on the basis of their elemental analyses and spectral (IR, NMR) data.



**3-Methyl-5-phenyl-benzo[1,2-*b*;5,4-*b*']difuran-2-carboxylic acid 12**



**6-Ethoxy-5-methyl-3-phenyl-furo[3,2-*g*]chromen-7-one 13**

## EXPERIMENTAL

Melting points (uncorrected) were determined using a scientific capillary melting point apparatus. Purity of the compounds was checked by thin layer chromatography on Acme's silica gel G plates using UV/Iodine vapour as visualizing agent and Acme's silica gel (60–120 mesh) was used for column chromatographic purification. Elemental analyses were carried out on Perkin-Elmer C, H, N, S analyzer (Model-2400). IR spectra were recorded on Perkin-Elmer FTIR spectrometer (spectrum RX1) using potassium bromide optics. UV spectra were recorded on Perkin Elmer Lambda 35 UV/Vis spectrophotometer. The mass spectrum was obtained on Perkin-Elmer Sciex Triple Quadrupole LC/MS/MS Mass Spectrometer (Model-016932) using Ion Spray source. NMR spectra were recorded on Brucker 400 MHz. Spectrophotometer. Chemical shifts are relative to tetramethylsilane on δ-scale. Coupling constants are given in Hz and relative peak areas were in agreement with all assignments.

**General procedure for the preparation of 2a, 2b, 6a and 6b.** To a stirred solution of 7-hydroxy-4-methyl-chromen-2-one **1** (5 g, 0.028 moles), anhydrous potassium carbonate (4.90 g, 0.035 moles) and catalytic amount(0.05–0.1g) of potassium iodide in (40 mL) of dry acetone was added dropwise a solution of mono chloroacetone (2.62 g, 0.028 moles) in (20 mL) dry acetone at reflux temperature. It was refluxed for 12 h. The reaction mixture was concentrated to dryness and then poured into ice water and the solid collected by filtration. The crude product was crystallized from ethanol to give white crystals (3 g, 46%) of 4-methyl-7-(2-oxo-propoxy)-chromen-2-one **2a**, mp 154–156°C lit. [12] 157°C; IR (KBr): $\nu_{max}$, cm$^{-1}$: 3061, 1705, 1609, 1591, 1454, 1384, 1360, 1288, 1220, 1166, 958; $^1$H NMR ($CDCl_3$, 400 MHz): δ 2.32 (d, 3H, $J$ = 0.8 Hz, C4—$CH_3$), 2.42 (s, 3H, —$COCH_3$), 4.66 (s, 2H, —$OCH_2CO$—), 6.18 (d, 1H, $J$ = 0.8 Hz, C3—H), 6.77–6.78 (d, 1H, $J$ = 2.8 Hz, C8—H), 6.89–6.92 (dd, 1H, $J$ = 2.8 Hz and $J$ = 8.8 Hz, C6—H), 7.54–7.56 (d, 1H, $J$ = 8.8 Hz, C5—H). Anal. calcd. for $C_{13}H_{12}O_4$ (232.23): C, 67.23; H, 5.20. Found: C, 67.02; H, 5.11. Potassium iodide is not required for the preparation of compounds **6a** and **6b**.

***4-Methyl-7-(2-oxo-2-phenyl-ethoxy)-chromen-2-one (2b).*** This compound was obtained by column chromatographic purification using petroleum ether (60–80°C): ethyl acetate eluent, as white crystals, 43% yield, mp 169–171°C lit. [13] 173°C; IR (KBr): $\nu_{max}$, cm$^{-1}$: 3071, 1698, 1612, 1596, 1451, 1391, 1366, 1283, 1230, 1160, 968; $^1$H NMR ($CDCl_3$, 400 MHz): δ 2.34 (d, 3H, $J$ = 0.9 Hz, C4—$CH_3$), 4.58 (s, 2H, —$OCH_2CO$—), 6.19 (d, 1H, $J$ = 0.9 Hz, C3—H), 6.79–6.80 (d, 1H, $J$ = 2.8 Hz, C8—H), 6.89–6.93 (dd, 1H, $J$ = 2.8 Hz and $J$ = 8.8 Hz, C6—H), 7.52–7.68 (m, 6H, C5—H and C2′-H to C6′-H phenyl protons). Anal. calcd. for $C_{18}H_{14}O_4$ (294.30): C, 73.46; H, 4.79. Found: C, 72.99; H, 4.34.

***3-Bromo-4-methyl-7-(2-oxy-propoxy)-chromen-2-one (6a).*** This compound was obtained as white crystals (DMF/ethanol), 68% yield, mp 204–206°C; IR (KBr): $\nu_{max}$, cm$^{-1}$: 3062, 2910, 1719, 1698, 1628, 1593, 1392, 1218; $^1$H NMR ($CDCl_3$, 400 MHz): δ 2.32 (s, 3H, C4—$CH_3$), 2.62 (s, 3H, —$COCH_3$), 4.67 (s, 2H, —$OCH_2CO$—), 6.78–6.79 (d, 1H, $J$ = 2.4 Hz, C8—H), 6.92–6.95 (dd, 1H, $J$ = 2.4 Hz and $J$ = 9.2 Hz, C6—H), 7.60–7.62 (d, 1H, $J$ = 9.2 Hz, C5—H). Anal. calcd. for $C_{13}H_{11}O_4Br$ (311.12): C, 50.18; H, 3.56. Found: C, 50.06; H, 3.23.

***3-Bromo-4-methyl-7-(2-oxo-2-phenyl-ethoxy)-chromen-2-one (6b).*** This compound was obtained as white crystals (toluene), 63% yield, mp 181–182°C; IR (KBr): $\nu_{max}$, cm$^{-1}$: 3060, 2907, 1717, 1698, 1623, 1598, 1384, 1210; $^1$H NMR ($CDCl_3$, 400 MHz): δ 2.36 (s, 3H, C4—$CH_3$), 4.61 (s, 2H, —$OCH_2CO$—), 6.79–6.80 (d, 1H, $J$ = 2.4 Hz, C8—H), 6.93–

6.95 (dd, 1H, $J$ = 2.4 Hz and $J$ = 9.2 Hz, C6—H), 7.50–7.66 (m, 6H, C5—H and C2′-H to C6′-H phenyl protons). Anal. calcd. for $C_{18}H_{13}O_4Br$ (373.20): C, 57.93; H, 3.51. Found: C, 57.61; H, 3.31.

**General procedure for the preparation of 3a, 3b, 7a and 7b.** Compound 4-methyl-7-(2-oxo-propoxy)-chromen-2-one **2a** (1 g, 0.0043 moles) was dissolved in 0.1*N* ethanolic potassium hydroxide (100 mL) and refluxed for 12 h. The excess ethanol was removed by distillation *in vacuo* and the reaction mixture was poured into ice-hydrochloric acid and the solid collected by filtration. The crude product was crystallized from ethanol to give white crystals (0.38 g, 41%) of 3,5-dimethyl-furo[3,2-*g*]chromen-7-one **3a**, mp 224–226°C lit. [12] 220°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3090, 1728, 1639, 1610, 1580, 1388, 1144, 1082; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 2.21–2.22 (d, 3H, $J$ = 1.5 Hz, C3—$CH_3$), 2.51–2.52 (d, 3H, $J$ = 1.08 Hz, C5—$CH_3$), 6.27–6.28 (d, 1H, $J$ = 1.08 Hz, C6—H), 7.36 (s, 1H, C9—H), 7.52 (d, 1H, $J$ = 1.5 Hz, C2—H), 7.58 (s, 1H, C4—H). Anal. calcd. for $C_{13}H_{10}O_3$ (214.21): C, 72.88; H, 4.70. Found: C, 72.62; H, 4.51.

In the preparation of compounds **7a** and **7b** the concentration of ethanolic potassium hydroxide was reduced from 0.1 to 0.025*N* and the reaction was maintained at 65–70°C for 12 h.

***5-Methyl-3-phenyl-furo[3,2-g]chromen-7-one (3b).*** This compound was obtained as white crystals (ethanol), 41% yield, mp 181–182°C lit. [13] 185°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3090, 1720, 1632, 1612, 1575, 1385, 1142, 1075; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 2.48–2.49 (d, 3H, $J$ = 1.1 Hz, C5—$CH_3$), 6.29–6.30 (d, 1H, $J$ = 1.1 Hz, C6—H), 7.48–7.49 (m, 1H, C4′-H), 7.54–7.59 (m, 2H, C3′-H and C5′-H), 7.54 (s, 1H, C2—H), 7.65–7.67 (m, 2H, C2′-H and C6′-H), 7.86 (s, 1H, C9—H), 7.90 (s, 1H, C4—H). Anal. calcd. for $C_{18}H_{12}O_3$ (276.28): C, 78.25; H, 4.37. Found: C, 77.85; H, 4.30.

***6-Bromo-3,5-dimethyl-furo[3.2-g]chromen-7-one (7a).*** This compound was obtained as yellow crystals (toluene), 30% yield, mp 224–226°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3088, 2925, 1733, 1693, 1639, 1602, 1556, 1350, 1151, 1074; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 2.31–2.32 (d, 3H, $J$ = 1.6 Hz, C3—$CH_3$), 2.74 (s, 3H, C5—$CH_3$), 7.42 (s, 1H, C9—H), 7.50 (d, 1H, $J$ = 1.6 Hz, C2—H), 7.74 (s, 1H, C4—H); LCMS: *m/z* (relative intensity, 100%): 317 (8.88) M+23 (from $Na^+$), 295.1 (100) M+1, 292.9 (100) $M^+$. Anal. calcd. for $C_{13}H_9O_3Br$ (293.11): C, 53.27; H, 3.09. Found: C, 52.98; H, 3.11.

***6-Bromo-5-methyl-3-phenyl-furo[3,2-g]chromen-7-one (7b).*** This compound was obtained as yellow crystals (ethanol), 24% yield, mp 208–210°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3085, 2925, 1734, 1687, 1631, 1605, 1559, 1345, 1154, 1070; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 2.69 (s, 3H, C5—$CH_3$), 7.47–7.49 (m, 1H, C4′-H), 7.54–7.58 (m, 2H, C3′-H and C5′-H), 7.56 (s, 1H, C2—H), 7.64–7.66 (m, 2H, C2′-H and C6′-H), 7.87 (s, 1H, C9—H), 8.02 (s, 1H, C4—H). Anal. calcd. for $C_{18}H_{11}O_3Br$ (355.18): C, 60.86; H, 3.12. Found: C, 60.50; H, 3.07.

**General procedure for the preparation of 4a and 4b.** Compound 3,5-dimethyl-furo[3,2-*g*]chromen-7-one **3a** (1 g, 0.0046 moles) was dissolved in acetic acid (40 mL) by warming and to this stirred solution, a solution of bromine (0.24 mL, 0.0046 moles) in acetic acid (10 mL) was added gradually. It was stirred for 3 h at room temperature and then poured into ice water and the solid collected by filtration. The crude product was crystallized from ethanol to give yellow crystals (0.9 g, 66%) of 2-bromo-3,5-dimethyl-furo[3,2-*g*]chromen-7-one **4a**, mp 230–232°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3085, 1758, 1689, 1640, 1577, 1341, 1121; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 2.24 (s, 3H, C3—$CH_3$), 2.52 (d, 3H, $J$ = 1.08 Hz, C5—$CH_3$), 6.27–6.28 (d, 1H, $J$ = 1.08 Hz, C6—H), 7.36 (s, 1H, C9—H), 7.58 (s, 1H, C4—H). Anal. calcd. for $C_{13}H_9O_3Br$ (293.11): C, 53.27; H, 3.09. Found: C, 52.98; H, 3.11.

***2-Bromo-5-methyl-3-phenyl-furo[3,2-g]chromen-7-one (4b).*** This compound was obtained as yellow crystals (ethanol), 61% yield, mp 238–239°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3084, 1750, 1686, 1636, 1578, 1347, 1110; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 2.46 (d, 3H, $J$ = 1.05 Hz, C5—$CH_3$), 6.28 (d, 1H, $J$ = 1.05 Hz, C6—H), 7.47–7.64 (m, 6H, C3—phenyl protons and C9—H), 7.75 (s, 1H, C4—H). Anal. calcd. for $C_{18}H_{11}O_3Br$ (355.18): C, 60.86; H, 3.12. Found: C, 60.82; H, 2.94.

**General procedure for the preparation of 8a, 8b, 9a, 9b, 10a and 10b.** A solution of 6-bromo-3,5-dimethyl-furo[3.2-*g*]chromen-7-one **7a** (0.5 g, 0.0017 moles) and piperidine (0.35 mL, 0.0035 moles) in dry DMF (10 mL) was heated at 95–100°C for 1 hour. The reaction mixture was poured into ice water and the solid collected by filtration. The crude product was crystallized from ethanol to give light brown crystals (0.28 g, 55%) of 3-methyl-5-piperidin-1-ylmethyl-furo[3,2-*g*]chromen-7-one **8a**, mp 185°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3059, 2971, 1718, 1639, 1616, 1579, 1454, 1337, 1158, 1120, 1096; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 1.47–1.48 (t, 2H, C4′—$CH_2$-), 1.59–1.65 (m, 4H, C3′—$CH_2$- and C5′—$CH_2$—), 2.27–2.28 (d, 3H, $J$ = 1.2 Hz, C3—$CH_3$), 2.51 (t, 4H, C2′—$CH_2$- and C6′—$CH_2$—), 3.66 (s, 2H, C5—$CH_2$—), 6.51 (s, 1H, C6—H), 7.35 (s, 1H, C9—H), 7.43–7.44 (d, 1H, $J$ = 1.2 Hz, C2—H), 7.92 (s, 1H, C4—H); $^{13}C$ NMR ($CDCl_3$, 100 MHz): δ 7.84 (C2—*C*$H_3$), 24.10 (C3′ and C5′), 26.07 (C4′), 55.05 (C2′ and C6′), 59.91 (C5—*C*$H_2$—), 99.59 (C6), 112.51 (C9), 114.92–115.73 (C4, C4a and C3), 126.23 (C3a), 143 (C2), 151.86 (C8a), 153.04 (C9a), 156.42 (C5), 161.57 (C7). Anal. calcd. for $C_{18}H_{19}O_3N$ (297.35): C, 72.70; H, 6.44; N, 4.71. Found: C, 72.56; H, 6.18; N, 4.44.

***3-Phenyl-5-piperidin-1-ylmethyl-furo[3,2-g]chromen-7-one (8b).*** This compound was obtained by column chromatographic purification using petroleum ether (60–80°C): ethyl acetate eluent, as light brown crystals, 52% yield, mp 158–160°C; IR (KBr): $\nu_{max}$, $cm^{-1}$: 3051, 2971, 1710, 1633, 1611, 1571, 1450, 1333, 1158, 1122, 1091; $^1H$ NMR ($CDCl_3$, 400 MHz): δ 1.51 (t, 2H, C4′—$CH_2$—), 1.64–1.66 (t, 4H, C3′—$CH_2$— and C5′—$CH_2$-), 2.52 (t, 4H, C2′—$CH_2$- and C6′—$CH_2$—), 3.67 (s, 2H, C5—$CH_2$—), 6.52 (s, 1H, C6—H), 7.43–7.70 (m, 5H, C3—phenyl protons), 7.55 (s, 1H, C2—H), 7.86 (s, 1H, C9—H), 8.50 (s, 1H, C4—H).

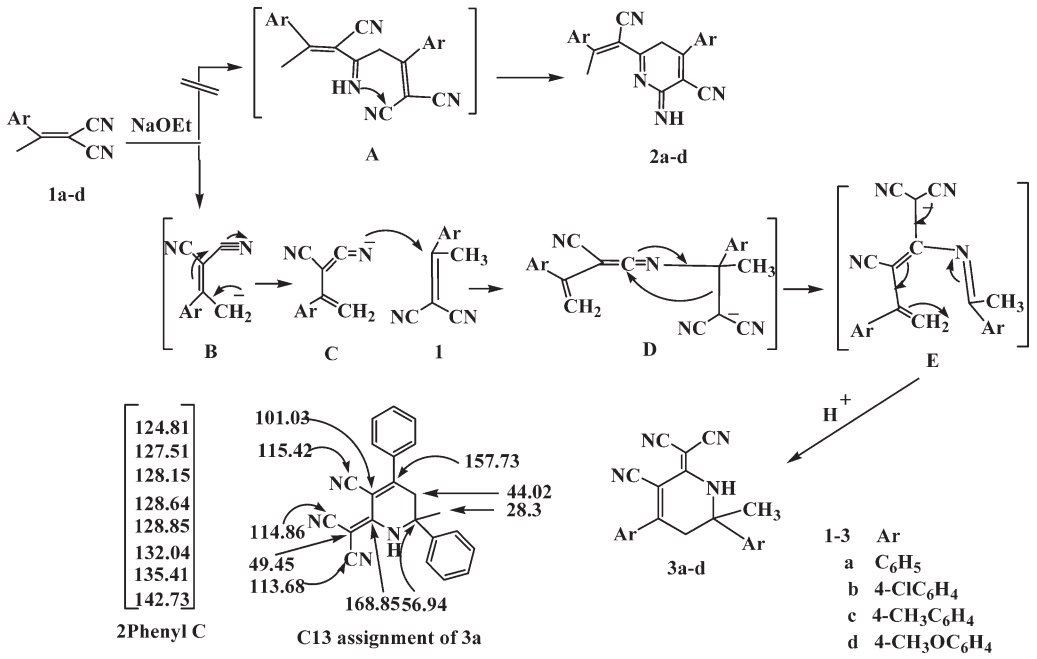
## INTRODUCTION

Pyridines and pyrido-fused derivatives are important heterocyclic compounds that find many pharmaceutical and agrochemical applications [2–6]. In the last two decades, we have been involved in a program aiming to develop new simple routes for the synthesis of heterocyclic compounds of biological interest [7–18]. In the context of this program, some newly substituted pyridines and pyrido-fused heterocyclic derivatives were required for biological evaluation. 2-(1-Arylethylidene)-malononitrile derivatives **1a-d** seemed good candidates to fulfill this objective *via* their dimerization through the intermediate **A** to afford the pyridine-imine derivatives **2a-d** and then coupling of these expected pyridine derivatives (Scheme 1) with arene diazonium salts followed by cyclization of the products to afford pyrido[3,2-c]pyridazine derivatives.

## RESULTS AND DISCUSSION

Thus 2-(1-phenyl-ethylidene)-malononitrile derivative **1a** (obtained from the condensation of acetophenone with malononitrile according to the literature method) [19] was refluxed in ethanol catalyzed by sodium ethoxide and we could isolate an analytically pure product with mp 202°C and in quantitative yield. The mass spectrum of this obtained product showed a molecular ion peak at $m/z = 336$; which points out to a dimer of **1a**. Theoretically different possible structures can be assumed for this dimmer, however, based on the spectral data it was thought that we have obtained the pyridine-imine derivative **2a** (Scheme 1). The $^1$H NMR spectrum of this product revealed signals at δ 1.74 (s, 3H,) assignable to one methyl group, 3.33 (d, 1H; $J = 18.6$ Hz), 3.75 (d, 1H; $J = 18.6$ Hz) assignable to two chemically nonequivalent protons of a methylene group and

**Scheme 1.** Preparation of compounds **3a-d**.



aromatic multiplet (10H) at 7.29–7.56 beside an exchangeable singlet (1H) at δ 8.55 ppm assignable to NH. These $^{1}$H NMR data seemed applicable to a structure like **2a**. However the $^{13}$C NMR spectrum of this reaction product revealed 18 signals at $\delta_C$ = 28.3 (q); 44.02 (t); 49.45 (s), 56.94 (s); 101.03 (s); 113.68 (s); 114.86 (s); 115.42 (s); [124.81 (d), 127.51 (d), 128.15 (d), 128.64 (d), 128.85 (d), 132.04 (d), 135.41 (s), 142.73 (s) phenyl carbons], 157.73 (s), 168.85 (s). (*cf.* Scheme 1 and Experimental section). These $^{13}$C NMR values are not completely applicable to structure **2a**.

Furthermore, when this product was allowed to couple with the diazotized aromatic amines **4a-d** (aniline, *p*-chloroaniline, *p*-toluidine and *p*-anisidine) it afforded highly colored hydrazo derivatives analyzed correctly as derivatives of **2a**; however, trials to cyclize these hydrazo derivatives into the expected pyrido[3,2-c]pyridazine derivatives failed under the different conditions reported to effect such cyclizations[14,20]. This behavior led us to the fact that the hydrazo group is not in the vicinity of the cyano group and the structure is not **2a**. Thus it was mandatory to have an X-ray crystallographic picture of this compound. Fortunately, we could obtain this X-ray [21,22] (Fig. 1). It shows clearly that the cyano groups are located far away from the hydrazo groups attached to the active methylene and that the methyl and one phenyl group are attached to the same carbon (C-2). The X-ray picture shows also that the structure appears with one molecule of ethyl acetate; the crystallization solvent. Thus structure **3a** was unambiguously established for this product (Scheme 1). All spectral and analytical data are now completely applicable to this structure and also those of the hydrazo derivatives **5a-d** (*cf.* Schemes 1 and 2 and the Experimental section).

It is assumed that the ethoxide anion abstracts one proton from **1** to afford the anion **B**, which is electronically rearranged to the keteneimine **C**. This latter attacks another molecule of **1** at the C=C to afford **D**, which undergoes rearrangement with migration of the malonyl anion to the C=N to afford **E**. Such rearrangement in the keteneimine series are known in the literature [23]. The intermediate **E** undergoes cyclization and regains its lost proton to afford the final isolable product **3a**. The cyclization of alkylidenemalononitriles under Michael reaction conditions is reported also to afford pyridine derivatives [24].

The ethylidenemalononitrile derivatives **1b-d** (obtained from the condensation of the corresponding aryl methyl ketone with malononitrile according to literature method) [19] followed the same pathway under the same reaction conditions, and we could obtain the pyridine derivatives **3b-d**, respectively (Scheme 1). All analytical and spectral data are in complete agreement with their proposed structures (*cf.* Experimental).

It is worth to mention that this dimerization of **1** to give **3** could be catalyzed by aqueous NaOH in ethanol, aqueous $Na_2CO_3$ in ethanol, or NaOEt in ethanol. All these led to the same product in each case however the maximum yields and the cleanest products were achieved with NaOEt.

Although the obtained products are not the same which we expected, however these products were found

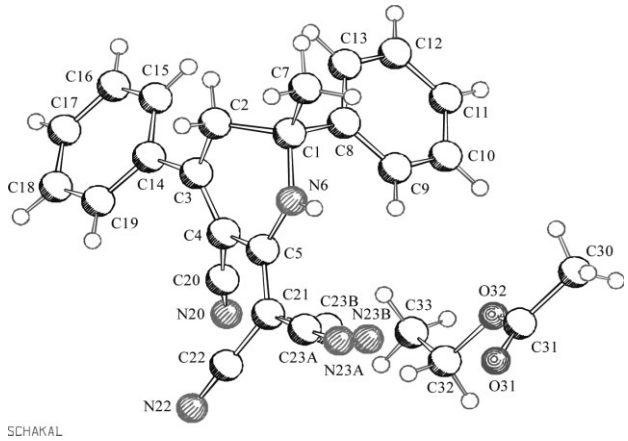


**Figure 1.** X-ray crystallographic structure of compound **3a** [21,22].

suitable also to fulfill our objective. Recently pyrazoles were found to be potentially biologically active compounds [25–27]. Also naphthyridine derivatives represent an important class of heterocyclic compounds due to their marked wide range of biological activities, such as anticonvulsant, antibacterial, anticancer, insecticidal, and fungicidal effects [28–31]. Thus, in continuation with our interest in naphthyridine synthesis [32], we describe here the synthesis of some novel fused naphthyridine derivatives.

Thus compound **3a** reacts with hydrazine hydrate and phenyl hydrazine **6a,b** to afford the pyrazolo-naphthyridine derivatives **7a,b**, respectively.

Compound **3a** reacts also with the urea derivatives **8a,b** to afford the pyrimido-naphthyridine derivatives **9a,b**, respectively. It is apparent that the hydrazines and ureas undergo cycloaddition to the two gem cyano groups with the aid of the labile hydrogen of the pyridine NH followed by further addition of the resulting $NH_2$ to the 5-cyano group.

The IR spectra of compounds **7a,b** and **9a,b** are all void of any cyano absorption bands at the region of $\upsilon_{max}$= 1980–2240 $cm^{-1}$. All spectral and analytical data are in complete agreement with these structures (*cf.* Experimental).

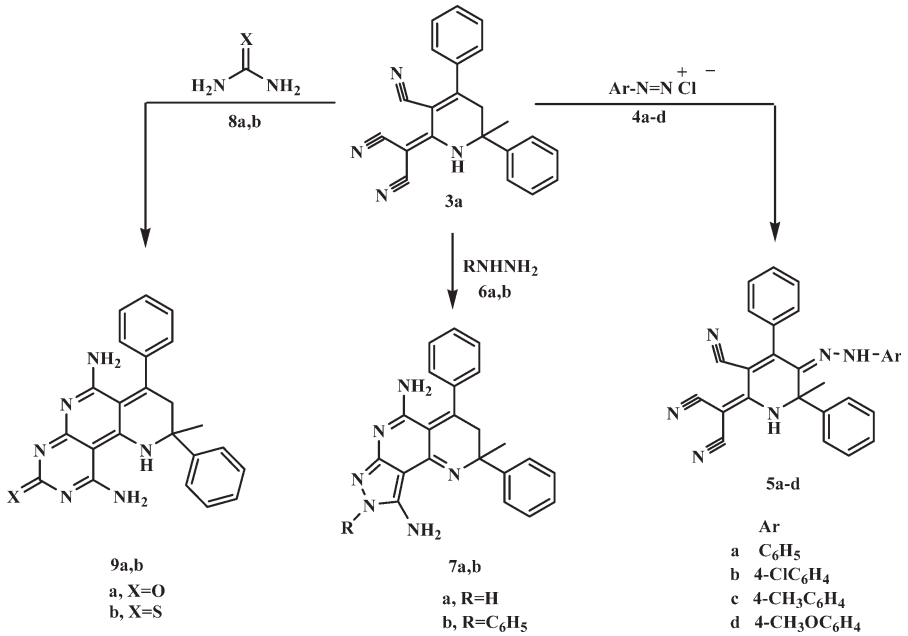
## CONCLUSION

We could prepare some novel heterocyclic derivatives of biological interest. All the reactions were carried out using simple and clean eco-friendly synthetic methods. No heavy metals or hazardous solvents are involved: just ethanol, DMF, or water as solvents, sodium salts are used as a catalyst.

## EXPERIMENTAL

Melting points were determined on an electrothermal (9100) apparatus and are uncorrected. IR spectra were recorded as KBr pellets on a Perkin Elmer 1430 spectrophotometer. The $^1$H NMR and $^{13}$C NMR spectra were taken on a Varian Gemini 300 MHz spectrometer in DMSO-$d_6$ using TMS as internal standard and chemical shifts are expressed in δ (ppm) values. Mass spectra were taken on a Shimadzu GCMS-GB 1000 PX (70 eV). Elemental analyses were carried out by the Microanalytical Center at Cairo University. The X-ray crystallography was carried out in the Institute of Organic Chemistry, Technical University of Dresden, Germany.

**Scheme 2.** Preparation of compounds **5**, **7**, and **9**.



**The dimerization of 2-(1-aryl-ethylidene)-malononitrile derivatives 1a-d: [Preparation of 3a-d].** To a solution of each of **1a-d** (10 mmol) in 15 mL of absolute ethanol was added 2 mL of saturated sodium ethoxide solution (obtained by dissolving 0.1 g of sodium metal in the least amount of absolute ethanol). The reaction mixture was refluxed on a water bath for 1 h, then left to cool to room temperature and poured on ice cold water and acidified with drops of conc. HCl till just neutral. The precipitated solids were collected by filtration, washed with water, dried, and recrystallized to afford **3a-d,** respectively.

Several 2–amino-6-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-4-phenylpyridine-3-carbonitrile have been synthesized by Tandem Michael addition/imino-nitrile cyclization and the structures of these compounds were established by MS, IR, CHN, and $^1$H NMR spectral data. The crystal structure of 2-amino-6-[1-(4-methoxyphenyl)-5-methyl-1*H*-1,2,3-triazol-4-yl]-4-phenylpyridine-3-carbonitrile was established by X-ray diffraction.

*J. Heterocyclic Chem.,* **47**, 389 (2010).

## INTRODUCTION

The pyridine ring is one of the most well-known systems among the naturally occurring heterocycles [1]. Pyridine and fused pyridine moieties was shown in numerous natural products such as quinoline and isoquinoline alkaloids [2], and nicotine and its analogs [3], 2-aminopyridines are promising substituted pyridines which have been shown to be biologically active molecules [4]. Additionally, because of their chelating abilities, 2-aminopyridines are commonly used as ligands in inorganic and organometallic chemistry [5]. If substituted with optically active groups, they could potentially serve for chiral auxiliaries or chiral ligands in asymmetric reactions. For this reaction, 2-aminopyridine derivatives are valuable synthetic target compounds. The synthesis of 2-aminopyridine derivatives has been extensively reviewed [4–10]. In addition there have been some reports concerning biological interest for 1,2,3-triazole nucleus have been reported as antibacterial [11], antifungal [12], antiviral [13], anti-inflammatory and analgesic [14] and 1,2,3-triazole derivatives have been synthesized to inhibit tumor proliferation, invasion, and metastasis [15]. However, there is a little data describing compounds containing the two heterocyclic moieties, thiazoline and 1,2,3-triazole. Interest in this class of compounds prompted the synthesis, several new 2-amino-6-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-4-phenylpyridine-3-carbonitrile have been synthesized by Tandem Michael addition/amino-nitrile cyclization.

## RESULTS AND DISCUSSION

The some new 2-amino-6-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4yl)-4-phenylpyridine-3-carbonitrile (**3a–j**) have been synthesized by Tandem Michael addition/imino-nitrile cyclization [16] with (*E*)-1-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-3-phenylprop-2-en-1-one from 1-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-ethanone derivatives (Scheme 1).

Our own interest in the development of new 2–amino-6-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-4-phenylpyridine-3-carbonitrile derivatives and in extending this type of tandem reaction prompted us to examine potential applications and generalizations to the synthesis of substituted pyridine. The reactivity of (*E*)-1-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-3-phenylprop-2-en-1-one would be regarded particularly closely during the cyclization step to shed further light on the course of this short transformation and, also, to gain further insight into the mechanistic aspects of this tandem reaction.

**2a, 3a** Ar=4-$CH_3C_6H_4$-; **2b, 3b** Ar=Ph; **2c, 3c** Ar=4-$ClC_6H_4$-; **2d, 3d** Ar=2,5-di$ClC_6H_3$-; **2e, 3e** Ar=3-$ClC_6H_4$-; **2f, 3f** Ar=2-$ClC_6H_4$-; **2g, 3g** Ar=4-$BrC_6H_4$-; **2h, 3h** Ar=β-$C_{10}H_7$-; **2i, 3i** Ar=3-$BrC_6H_4$-; **2j, 3j** Ar=4-$MeOC_6H_4$-

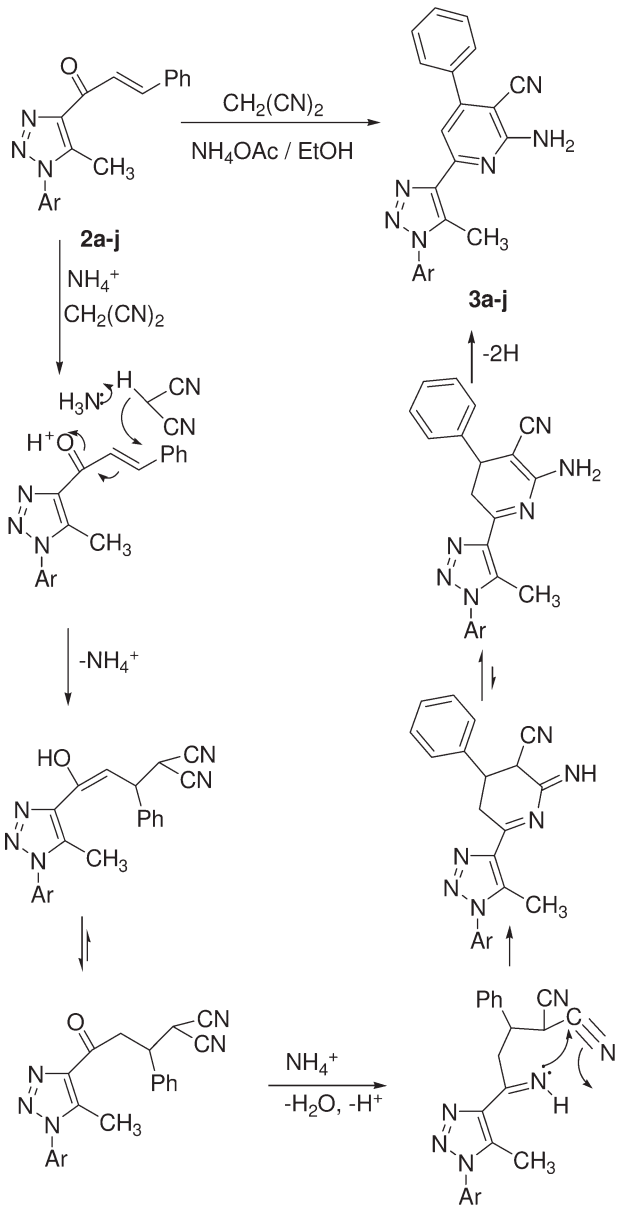
Identified as a cyano compound showing IR absorption at 2207–2213 $cm^{-1}$ and amino at 3436–3494, 3353–3374 $cm^{-1}$ of **3a–j**, as a carbonyl compound showing strong IR absorption at 1679–1683 $cm^{-1}$ of **1a–j** and 1659–1666 $cm^{-1}$ of **2a–j**. $^1$H NMR —CO—$CH_3$ peak at 2.694–2.778 ppm of **1a–j** and showing  $^1$H NMR dual peak 8.057–8.173 ppm, 7.809–8.076 ppm, $J$ = 15.6–15.9 Hz of **2a–j** but it is disappearance in compounds **3a–j** (Scheme 2).

**Compound 2-amino-6-[1-(4-methoxyphenyl)-5-methyl-1*H*-1,2,3-triazol-4-yl]-4-phenylpyridine-3-carbonitrile.** This consists of a substituted triazolyl ring and a phenyl ring is not planar (torsion angles is shown for dihedral angle of $C_{triazolyl}$—$N_{triazolyl}$—$C_{phenyl}$—$C_{phenyl}$ is 48.6(4)° by the hindering of triazole ring C9—$CH_3$ and benzene ring C2—H or C6—H, and so dihedral angle of $C_{pyridyl}$—$C_{pyridyl}$—$C_{phenyl}$—$C_{phenyl}$ is 38.3(4)° in stable conformation of the crystal). The substituted triazolyl ring and substituted pyridyl ring is an approximation planar (torsion angles is shown for dihedral angle of $N_{triazolyl}$—$C_{triazolyl}$—$C_{pyridyl}$—$N_{pyridyl}$ is 176.5(3)°) by the π–π conjugation of triazole ring π bond and pyridine ring π bond, C10—C11 bond 1.475 Å is shorter than nonconjugation $Csp^2$-$Csp^2$ bond C13—C17 1.484 Å (Fig. 1; Table 1).

On pyridine ring, the p-π conjugation was indicated between amino N5 and ring C15, N5—C15 length is 1.343(4) Å, C15—N5—H, H—N5—H angle is 120°, dihedral angle of C11—N4—C15—N5 is 179.4°, dihedral angle of N5—C15—C14—C13 is 178.2°, N5 is came under the action of $sp^2$ hybridized.

On pyridine ring, 2-amino has two N—H bond and two intermolecular hydrogen bonds as the superamolecular structure in the crystal. The intermolecular O′1···H5A-N5 hydrogen-bond between the O1 atoms of the $CH_3O$ group and N5—H, intermolecular N′6···H5A—N5 hydrogen bond between the N atoms of the CN group and N5—H was given (Fig. 2; Table 2). The orderly range of the structure forms stratification polymer in the crystal. The intermolecular hydrogen bond connects the translated molecules into an infinite chain on a layer.

**Scheme 2**



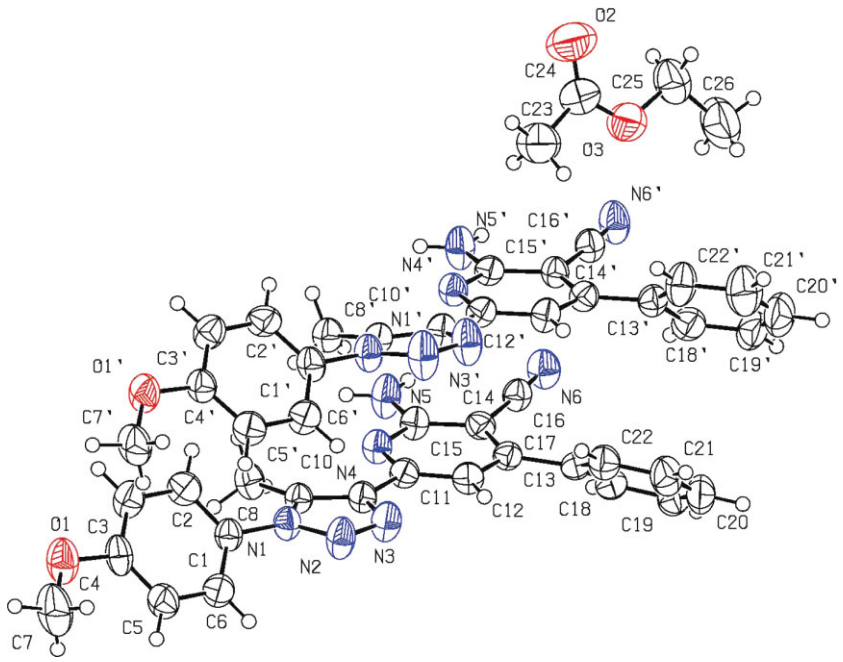


**Figure 1.** A *PLATON* (Spek, 2001) view of the molecular structure of (*I*), the asymmetric unit showing 50% probability displacement ellipsoids. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

## EXPERIMENTAL

All melting points were determined on an XT4-100× microscopic melting point apparatus and are uncorrected. Mass spectrum was performed on a ESQ6K esquire6000 spectrometer (**3a–j**) and HP-5988A (**2a–j**) spectrometer (EI at 70 eV). IR spectra were obtained in KBr discus using a Nicolet NEXUS 670 FTIR spectrometer. $^1$H NMR spectroscopy ($CDCl_3$) was recorded on Avance Mercury plus-300 with TMS as an internal standard. Elemental analyses were carried out on a Yanaco CHN Corder MT-3 analyzer.

**General procedure for the preparation of 1-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-ethanone derivatives (1a–j).** 1-(1-Aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)-ethanone **1a–j** was prepared following condensation methods of 1-azido-4-methylbenzene [17] with pentane-2,4-dione. A cold solution of sodium methanolate (0.23 mol, in 120 mL absolute methanol) was added to the mixture of pentane-2,4-dione (17 mL, 0.165 mol) and 1-azido-4-methylbenzene (about 0.15 mol) and stirred for 1 h at 0–5°C. Then the mixture was heated under reflux on an oil-bath for 10 h. Finally the mixture was neutralized with concentrated hydrochloric acid. 1-(1-Aryl-5-methyl-1*H*-1,2,3-triazol-4-yl)ethanone **1a–j** was separated and crystallized from methanol.

**General procedure for the preparation of 2-amino-6-(1-aryl-5-methyl-1*H*-1,2,3-triazol-4yl)-4-phenylpyridine-3-carbonitrile derivatives (3a–j) [20].** Chalcone **2a–j** (10 mmol), malononitrile (10 mmol, 0.66 g, 1 equiv.), and ammonium acetate (80 mmol, 0.62 g, 8 equiv.) were dissolved in EtOH (10 mL) and refluxed for 15 h, whereupon no starting material was evident by TLC. The reaction mixture was allowed to cool to RT and the solvent was evaporated to leave a yellow solide, dried, and purified by column chromatography using a mixture of EtOAc /petroleum ether 60–90°C 1:4 as eluent to give the corresponding **3a–j.**

1,3-Dipolar cycloaddition reaction involving nitrones and benzoquinones resulting in the formation of benzisoxazolidene is described. As the nitrone is selectively added to carbon–carbon double bond of the benzoquinone, the quinone-nitrone reaction is considered as a special case among quinone-1,3-dipole cycloaddition reactions. Molecular orbital calculation was performed to examine the electronic effects involved in the regioselectivity of the reaction.

## INTRODUCTION

The 1,3-dipolar cycloaddition reactions of nitrones with alkenes leading to the formation of isoxazolidenes is a fundamental reaction in organic chemistry [1]. In 1982 Deshong *et al*. reported the first 1,3-dipolar cycloaddition reaction of electron rich alkenes, such as vinyl acetate and vinyl ethers, with nitrones [2]. This work was extended to other functionalized alkenes synthesizing a variety of isoxazolidenes that served as key synthetic intermediates in the synthesis of γ-amino acids, β-lactams, amino sugars, and alkaloids [3]. A variety of isoxazolidines have been prepared using 1,3-dipolar nitrone cycloaddition to functionalized alkenes. In most cases, the nitrone cycloadditions to alkenes proceeded with high regioselectivity to yield isoxazolidenes with three new contiguous stereogenic centers. The stereoselectivity seems to be influenced by both electronic and steric factors. Recently, several asymmetric syntheses of isoxazolidines giving special emphasis on their effective use as chiral auxilaries in the synthesis of biologically active molecules have been reported [3e,4]. Shortly, decades ago itself nitrone cycloaddition chemistry was enriched with versatility of substrates, catalysts, and solvents used in the reaction. Still, organic chemistry demands for new reactions for the synthesis of appropriately substituted isoxazolidenes.

The quinones and their derivatives have attracted the continuous attention in view of their antitumor activitites [5]. The biological processes involved with the antitumor activities of quinones are DNA intercalation, bioreductive alkylation of biomolecules, and generation of oxyradicals through redox cycling. The chemistry of *o*-quinones has invoked considerable interest, and the cycloaddition reactions of these versatile compounds have been the subject of a number of investigations [1,6]. A wide variety of dipolar species, including diazomethane [3], nitrile oxides [7–10], and mesoionic compounds [11–15], have been used in these reactions. Most of the dipolar cycloadditions to quinones, however, involved addition across carbon–oxygen double bonds. In contrast, nitrone cycloaddition occur across carbon–carbon double bond of the *o*-quinones to afford substituted benzisoxazolidenes, and it is the subject matter of present investigations.

## RESULTS AND DISCUSSION

Present studies were initiated by the reaction of 3,5-di-*tert*-butyl-1,2-benzoquinone with 1,2-diphenylnitrone. Preliminary investigations showed that the nitrone cycloaddition to 1,2-benzoquinone occured at carbon–carbon

double bond to afford benisoxazolidene **3a**, which is a rare case among the 1,3-dipole-quinone cycloaddition reactions. Then, suitable reaction condition for the proposed cycloaddition was identified by treating 3,5-di-*tert*-butyl-1,2-benzoquinone with 1,2-diphenylnitrone under different conditions (Scheme 1, Table 1). Under most of the reaction conditions, the quinone was easily reduced to corresponding catechol. To our surprise, even under perfectly dry conditions using aprotic solvents like benzene and toluene, the catechol formation dominated over the product formation. Close investigations on the reaction made us to conclude that any proton source including the cycloaddition product facilitate the catechol formation, and so, the yield of the reaction is decreased. At higher temperature, quinone underwent cycloaddition with another molecule of quinone, and the nitrones were fragmented to corresponding amines and aldehydes. However, the expected cycloaddition product was obtained in moderate yield, when a dilute solution of 3,5-di-*tert*-butyl-1,2-benzoquinone and 1,2-diphenyl

nitrone in toluene was refluxed at 110°C for 18 h. The yield was further optimized by screening the number of equivalents of the substrates. Thus, when 3,5-di-*tert*-butyl-1,2-benzoquinone (2 mmol) was treated with 1,2-diphenyl nitrone (1 mmol) in toluene (20 mL) for 18 h at 110°C, bezisoxazolidene **3a** was obtained in 57% yield. The product **3a** was characterized on the basis of common spectroscopic analysis and ultimately by single crystal X-ray analysis (Fig. 1).

To explain the mechanism of cycloaddition of nitrone to quinone, we have carried out some MNDO and AM1 calculations on 3,5-di-*tert*-butyl-1,2-benzoquinone and 1,2-diphenyl nitrone using MOPAC (version 5.01) program. The HOMO and LUMO energies were derived from this program. Most of the 1,3-dipolar cycloaddition reactions of *o*-quinones undergo inverse electron demand Diels-Alder reaction (Type II mechanism) [4–13] at carbon–oxygen double bond. The molecular orbital coefficients calculated from the eigen vectors for the orbital interactions of 3,5-di-tert-butyl-1,2-benzoquinone and 1,2-diphenyl nitrone (Fig. 2) favoured the addition of nitrone oxygen to a highly substituted carbon atom to form 6,7a-di(*tert*-butyl)-2,3-diphenyl-2,3,3a,7a-tetrahydro-1,2-benzisoxazole-4,5-dione **3a**, which follows a normal diels-Alder mode of cyclization involving $HOMO_{nitrone}$-$LUMO_{quinone}$ interaction (Type I mechanism).

On extending the strategy to other benzoquinones and diaryl nitrones, tetrahydrobenzisoxazolediones **3a-f** and **5a-b** were synthesized (Scheme 2, Table 2). However, the presence of bulky substituents like anthraceneyl groups on nitrone and diphenylmethane group on quinone adversely affected the product formation.

## CONCLUSION

The reaction of nitrones with benzoquinones resulted in the formation of benzisoxazolidenes. As the nitrone is selectively added to carbon–carbon double bond of the benzoquinone, the quinone–nitrone reaction is considered as a special case among quinone-1,3-dipole cycloaddition reactions.

## EXPERIMENTAL

**General remarks.** Melting points were recorded on a Büchi melting point apparatus and are uncorrected. NMR spectra were recorded at 300 MHz ($^1H$) and 75 MHz ($^{13}C$), respectively on a Brüker Avance DPX-300 MHz NMR spectrometer. Chemical shifts are reported (δ) relative to TMS ($^1H$) and $CDCl_3$ ($^{13}C$) as the internal standards. Coupling constants (*J*) are reported in Hertz (Hz). High-resolution mass spectra were recorded under EI/HRMS (at 5000 resolution) using JEOL JMS 600H mass spectrometer. IR spectra were recorded on Nicolet Impact 400D FTIR spectrophotometer. Commercial grade solvents were distilled before use.

**General procedure for the synthesis of 6,7a-di(*tert*-butyl)-2,3-diaryl-2,3,3a,7a-tetrahydro-1,2-benzisoxazole-4,5-diones (3a-e) and 5,7a-Di(*tert*-butyl)-2,3-diphenyl-2,3,3a,7a-tetrahydro-1,2-benzisoxazole-4,7-dione (5a-b).** A solution of 3,5-di-*tert*-butyl-1,2-benzoquinone (220 mg, 1 mmol) and 1,2-diaryl nitrone (0.5 mmol) in toluene (10 mL) was refluxed at 110°C for 18 h. The solvent was removed under vacuum, and the crude reaction mixture was purified by silica gel (100-200 mesh) column chromatography using hexane-ethyl acetate (98:2) as the eluent to get the title compounds in good to moderate yields.

A one-step preparation procedure of 8,10a-epoxypyrido[2,1-*a*]isoindoles and their 7-carboxylic derivatives is reported. The key synthetic step includes the intramolecular *exo*-Diels–Alder reaction (IMDAF) of *N*-furfurylacrylamide, produced *in situ* from 2-furylpiperidin-4-ones and α,β-unsaturated acid anhydrides. The synthesis of the title compounds can be performed under mild conditions with a high level of regio- and stereoselectivity. The same strategy has been successfully used for the synthesis of 9,11a-epoxyimidazo[4′,5′:3,4]pyrido[2,1-*a*]isoindole-8-carboxylic acid from maleic anhydride and the spinacine derivatives – 4-(2-furyl)-4,5,6,7-tetrahydro-3*H*-imidazo[4,5-*c*]pyridines.

*J. Heterocyclic Chem.,* **47**, 400 (2010).

## INTRODUCTION

Substituted and hydrogenated pyrido[2,1-*a*]isoindoles possess a wide range of pharmacological activity. For example, they are known to have a protective effect against nitrogen-induced hypoxia [1] and are potential inhibitors of tumor cell proliferation [2]. It is known as well that compounds containing heterocyclic fragments of spinacine and β-carboline are of great biological importance. Thus, the aminoacid spinacine (separated first from shark liver [3], found also in ginseng roots [4] and cheese [5]) shows the properties of an inhibitor of γ-aminobutyric acid uptake in neurons [6]. The heterocyclic structure of β-carboline serves as a framework for well-known alkaloids: *Elaeagnine*, *Harman*, and *Harmine* [7] (Fig. 1).

Therefore, one of the aims of this work was the development of a convenient method of synthesis for potentially biologically active heterocycles—benzo[1,2]indolizino[8,7-*b*]indole and imidazo[4′,5′:3,4]pyrido[2,1-*a*]isoindole, combining the above fragments into one structure.

To achieve the aforementioned goal, we used an intramolecular variant of the Diels-Alder reaction in the piperidone series (IMDAF), containing the unsaturated moiety [8–10]. We have used the same strategy before for various preparations of heterocyclics – particularly for isoindolo[2,1-*a*]quinolines [11], isoindolo[2,1-*b*][2]benzazepines [12], and isoindolo[1,2-*a*]isoquinolines [13], with the structure close to natural alkaloids.

## RESULTS AND DISCUSSION

Starting materials for pyrido[2,1-*a*]isoindoles preparation, the furfuryl amines **1**, were synthesized from readily accessible ketones and from furfural (5-methylfurfural), according to the known method [14] with small variations

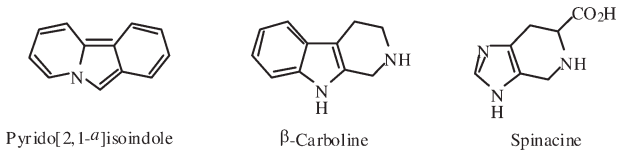

**Figure 1.** Some of the targeted alkaloid-like structures.

(see Experimental section). The piperidones **1a–d** were separated after the recrystallization in moderate yield (Scheme 1) as individual *all-e*-diastereoisomers.

It should be noted that the yields of symmetrically substituted amino ketones **1b**,**d** turned out ~20% higher than for unsymmetric **1a**,**c**.

Interaction of α,β-unsaturated acid derivatives (methacrylic and cinnamic acid chlorides) with symmetric furfuryl amines **1b**,**d** proceeds smoothly in boiling toluene (Scheme 2). It was established during experiment that after initial acylation on the nitrogen atom, a spontaneous intramolecular [4+2] cycloaddition of an unsaturated fragment to the furan ring occurs in intermediate *N*-acryloyl amides. The final products of the reaction are hydrogenated 2*H*-8,10a-epoxypyrido[2,1-*a*]isoindole-2,6(6a*H*)-diones **2**, **3**. The substituent's size in olefin moiety exerts a considerable influence on the yield of adducts **2**, **3**—the yield of 6a-methylsubstituted derivatives **2** is 15–30% higher compared to their more sterically hindered 7-phenyl analogues **3**.

In both cases the Diels-Alder reaction occurs stereoselectively as *exo*-[4+2]-cycloaddition with *endo*-position of methyl (phenyl) group in oxabicyclo[2.2.1]heptene fragment of adducts **2** and **3**. Axial-axial constant of piperidine ring protons $^3J_{1,10b} = 11.8-12.2$ Hz and vicinal constant of bicyclic fragment's low-field protons $^3J_{9,10} = 5.5-6.2$ Hz are most evident in their $^1$H NMR spectra.

Acylation of piperidones **1b**,**d** by citraconic anhydride proceeds in both carbonyl groups, leading to the formation of stereoisomers **4bA**,**4dA/4bB**,**4dB** mixtures with different methyl group positions (see Scheme 2 for the total yield of stereoisomeric mixture). 7-Methylsubstituted isomers **4bA**, **4dA** dominate in crude reaction mixtures; the A/B ratio fluctuates in different experiments and is usually within the 4:1–3:1 interval. Major isomers **4bA**, **4dA** were separated as individual compounds by fractional recrystallization from *i*-PrOH–DMF mixture (their yields are summarized in Experimental section).

Cycloaddition of methacryloyl chloride, crotonyl chloride, and cinnamoyl chloride to unsymmetric difurylpiperidines **1a**,**c** proceeds stereoselectively as well as regioselectively, giving *exo*-products of Diels-Alder **2a**,**c**, **3a**,**c**,**e** with moderate yield (Scheme 3). Citraconic anhydride, being added to piperidones **1a**,**c**, forms diastereomeric mixtures, from which we could separate only major adducts **4aA**, **4cA** after the recrystallization.

It should be noted if the three-fold excess of dienophile is used in reaction with furfuryl amines **1**, the cycloaddition of a second alkene molecule to the free furan nucleus of isoindoles **2–4** does not occur.

Interestingly enough, from two furan fragments (**X** and **Y**) present in unsymmetrical piperidones **1a**,**c**, [4+2]-cycloaddition passes regiospecifically to 2-furyl ring **Y**. In our opinion, such selectivity is related to the fact that the furan cycle **Y** in intermediate lactam **4*** (Scheme 4) is fixed strictly favorably to the Diels-Alder reaction (due to steric interaction with 3-alkyl substituent). Alternative 6-furyl substituent (**X**) can rotate freely, and is consequently less predisposed to cycloaddition.

Cycloaddition adducts of 2,6-dioxo-8,10a-epoxypyrido[2,1-*a*]isoindole-7-carboxylic acids (**4**) are white powders with low solubility in most organic solvents, so for the unequivocal determination of their spatial structure we have synthesized methyl ester **5** from the acid **4aA** (Scheme 5). Slow recrystallization of this ester from a hexane-ethyl acetate mixture gave us a monocrystal suitable for X-ray analysis.

Adduct **5** comprises a fused tetracyclic system containing three five-membered (pyrrolidinone, dihydro- and tetrahydrofurans) rings and one six-membered ring (piperidinone) (Fig. 2). The five-membered rings have the usual *envelope* conformation. The six-membered ring adopts a *twist-boat* conformation (the C3 and C10B carbon atoms are out of the mean plane as defined by the other atoms of the ring by 0.577 and 0.559 Å, respectively). The N5 nitrogen atom has a trigonal-planar geometry (the sum of the bond angles about N5 is 359.5°). The dihedral angle between the planes of the pyrrolidinone and piperidinone rings is 19.1°. The methyl substituent at the C1 carbon atom is in equatorial position, whereas the furyl substituent at the C4 carbon

**Scheme 1.** Synthesis of the initial piperidones **1a-d**.

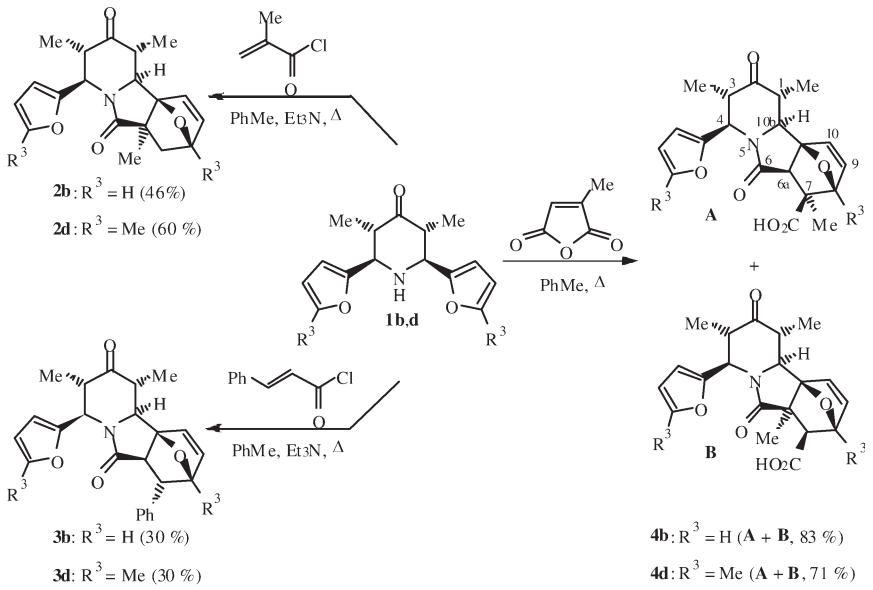
| **1a** | H | Me | H | 34 |
| **1b** | Me | Me | H | 63 |
| **1c** | H | Et | H | 33 |
| **1d** | Me | Me | Me | 41 |

**Scheme 2.** Cycloaddition with symmetrical substituted piperidones **1b**,**d**.



atom is in axial position. The sterically unfavorable axial arrangement of the furyl substituent is apparently explained by both the structure of the initial compound **1a** and the structure of the [4+2] cycloaddition reaction intermediate.

The synthesis of 2,6-unsymmetrically substituted piperidine-4-ones by condensation of α,β-unsaturated ketone, an aldehyde and ammonia was described earlier for the dendrobatid frog alkaloid 241D [15]. In this case the yield of target piperidine-4-ones did not exceed 10−12%. We used this method for the synthesis of 6-aryl-2-furylpiperidine-4-ones **6** (Scheme 6). The reaction conditions were standard [14c,15], and furfural and 5-methylfurfural were used as aldehydes. The usual work-up gives a mixture of products, from which the target piperidones **6** can be separated easily (although with low yield) as hydrochlorides (see Experimental section). 2-Furylpiperidones **6a-c** react smoothly with acryloyl chloride and maleic anhydride in boiling toluene, giving *exo*-products of cycloaddition—2*H*-8,10a-epoxypirido[2,1-*a*]isoindoles (**8**) and their 7-carboxylic acids (**7**)—with moderate yields.

The most low-field chemical shifts of C-2 (δ 208−211 ppm) and C-6 (δ 170−176 ppm) carbon atoms, together with well-identified C-10a and C-8 (δ

79−91 ppm) carbon atom signals are the most characteristic in $^{13}$C NMR spectra of cycloaddition products **2**−**5**, **7**, **8**.

A large number of methods for pentacyclic indolizinoindole core synthesis are known [16], and the similarity of this heterocyclic system to some alkaloids encourages further research. Several short studies [17] dedicated to the synthesis of benzo[1,2]indolizino[8,7-*b*]indol-4-carboxylic acids of type **10** from maleic anhydride and *N*-furfurylidene(indol-3-yl)ethanamines have been published recently. An elegant reaction sequence (acylation/ Pictet-Spengler/ IMDAF) proceeds in mild conditions (Scheme 7). To build some alkaloid-like polycyclic structures by Suzuki coupling, we needed to synthesize 3-halosubstituted adducts **10**.

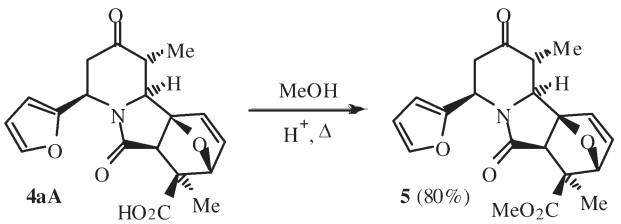
As was shown earlier [17], the condensation of *N*-furfurylidenetriptamines **9a**,**b** with maleic anhydride proceeds stereoselectively, yielding the single *exo*-diastereoisomer **10a**,**b**. Analogous interaction of azomethine **9c** with citraconic anhydride leads with good yield to the mixture of polycycles **12A** and **12B** (in approximatively equal amounts), isomeric by methyl group position, that we could not separate by recrystallization.

Haloderivatives **10a**,**b** are white powders, low soluble even in DMSO, so to determinate their structure by $^{1}$H and $^{13}$C NMR we have synthesized esters **11**. The spatial structure of these latter was established by NOE spectra, in which we can observe a significant change of H-13b proton integral intensity, while irradiating H-4a (and *vice versa*). This fact indicated the spatial closeness (*cis*-orientation) of the above protons.

In the last part of our work we have applied an analogous method for the synthesis of spinacines annelated with epoxyisoindole moiety. The condensation of histamine with aromatic aldehydes in an alkaline medium leading to spinacines (Fig. 1) was already described [18]. However, no examples of 4-furyl substituted imidazo[4,5-*c*]pyridines have been published until now. Furylspinacines **13** were synthesized with moderate yield according to modified method [18b] (Scheme 8).

Acylation of spinacines **13** with maleic anhydride at room temperature occurs exclusively on the *N*-5 nitrogen atom of the tetrahydropyridine ring – products of anhydride addition to imidazole cycle were not found in the reaction mixture. Acylation (same as in previous cases) is accompanied by simultaneous [4+2] cycloaddition giving *exo*-adducts **14**. We suppose the *cis*-position of H-7a and H-11b protons by analogy with adducts **2**-**4**, **7**, **8**, and **10**. Cycloaddition products are extremely hard-soluble and hard-crystallizing tawny powders. The low-field singlet signal of H-2 proton at δ ∼7.5 ppm and broaded one of H-11b at δ ∼5.3 ppm, as well as associated *exo*-protons H-7a, H-8 with $^{3}J_{7a,8}$ = 8.9−9.1 Hz (at δ 2.5−3.0 ppm), can be considered as characteristic. In the carbon spectrum, C-2 and C-11a peaks at δ 135−136 and 90−91 ppm, respectively, are remarkable.

**Scheme 5.** Esterification of the carboxylic acid **4aA**.



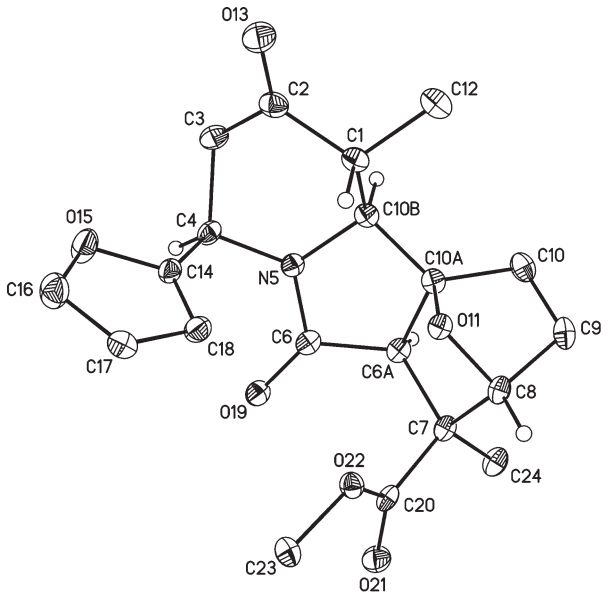


**Figure 2.** Molecular structure of ester **5**, depicting anisotropic displacement ellipsoids at the 50% probability level. Only hydrogen atoms at the asymmetric centers are shown.

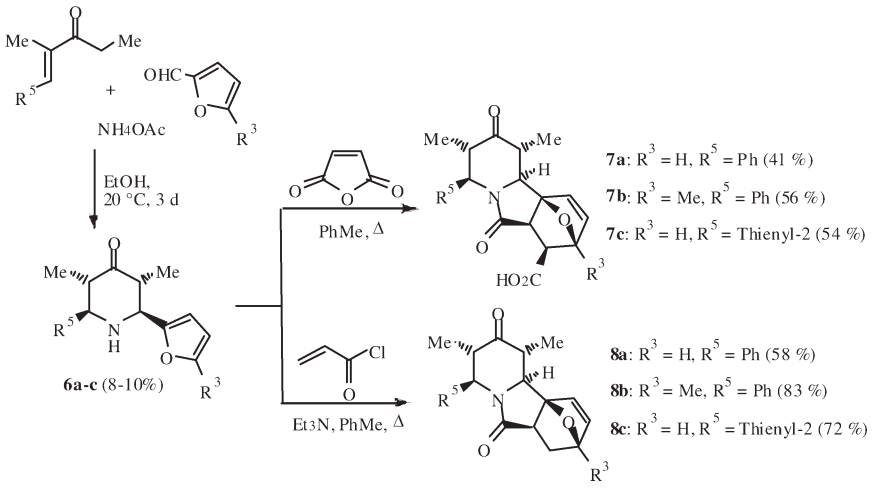
**Scheme 6.** Synthesis and [4+2] cycloaddition of 2-aryl-6-furylpiperidine-4-ons **6**.

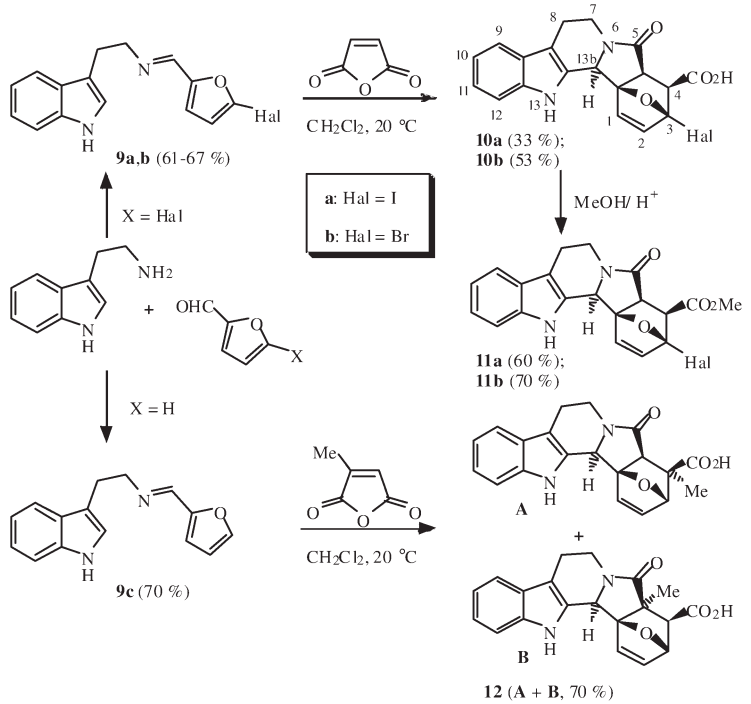


Therefore, in the current study we have demonstrated the possibility of synthesis of various heterocyclic systems condensed with an epoxyisoindole fragment: 8,10a-epoxypyrido[2,1-*a*]isoindoles, 3,13c-epoxybenzo[1,2]indolizino[8,7-*b*]indoles and 9,11a-epoxyimidazo[4′,5′:3,4]pyrido[2,1-*a*]isoindoles, based on IMDAF-reaction of annelated furfuryl amines with α,β-unsaturated acid anhydrides. It was shown that in the majority of cases the Diels-Alder reaction proceeds with a high degree of regio- and stereoselectivity as *exo*-[4+2] cycloaddition.

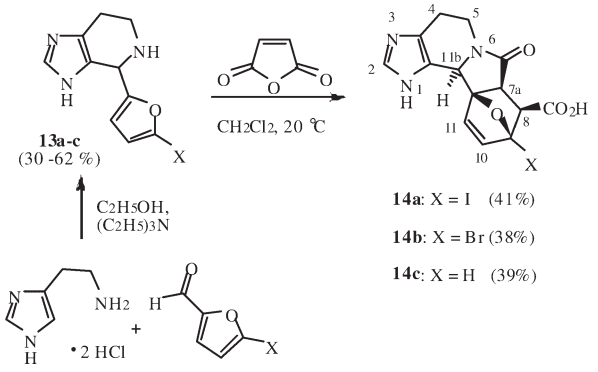
## EXPERIMENTAL

All reagents were purchased from Acros Chemical Co. All solvents were used without further purification. Melting points were determined using SMP10 and are uncorrected. IR spectra were obtained in KBr pellets using an IR-fourier spectrometer Infralum FT-801. $^{1}$H and $^{13}$C NMR spectra were recorded on Jeol JNM-ECA 600 (600 MHz for $^{1}$H and 150.9 MHz for $^{13}$C) or Bruker Uniti + (400 MHz for $^{1}$H and 100.6 MHz for $^{13}$C) spectrometers in $CDCl_3$ or DMSO-$d_6$ at 27°C, and residual signals of chloroform ($^{1}$H NMR δ 7.26 ppm and $^{13}$C NMR 76.9 ppm) or DMSO-$d_5$H ($^{1}$H NMR δ 2.49 ppm and $^{13}$C NMR 39.4 ppm) were used as the internal standard. Mass spectra

**Scheme 7.** Synthesis of 3,13c-epoxybenzo[1,2]indolizino[8,7-*b*]indol-4-carboxylic acids **10-12**.



**Scheme 8.** Synthesis of 9,11a-epoxyimidazo[4′,5′:3,4]pyrido[2,1-*a*]isoindole-8-carboxylic acids **14a-c**.



were measured either on Thermo Focus DSQ II (electron ionization, 70 eV, ion source temperature 200°C, gas chromatographic inlet with Varian FactorFour VF-5ms column) or on Thermo Trace DSQ (electron ionization, 70 eV, ion source temperature was 200°C, direct inlet probe) spectrometers. Positive-ion electrospray ionization (ESI+) mass spectra were acquired using an API4000 instrument (Applied Biosystems) in the ESI+ mode (sample MeOH-$H_2O$ solution). Nitrogen was used as nebulizer and argon as collision gas, needle voltage was set at 3000 V with ion source at 100°C. The purity of the obtained substances and the composition of the reaction mixtures were controlled by TLC Sorbfile plates. The separation of the final products was carried out by column chromatography on $Al_2O_3$ (activated, neutral, 50–200 mm) or by fractional crystallization. Microanalyses were performed for C, H, N on a Vario Macro Cube C,H,N,O,S-analyser and were within ±0.4% of theoretical values.

The crystal of ester **5** ($C_{20}H_{21}NO_6$, $M$ = 371.38) is monoclinic, space group $P2_1/c$, at $T$ = 100 K: $a$ = 18.8819(12), $b$ = 8.6778(5), $c$ = 10.7027(7) Å, β = 102.2460(10)°, $V$ = 1713.77(18) Å$^3$, $Z$ = 4, $d_{calc}$ = 1.439 g/cm$^3$, $F(000)$ = 784, μ = 0.107 mm$^{-1}$. 19,911 total reflections (4560 unique reflections, $R_{int}$ = 0.053) were measured on a Bruker SMART APEX II CCD diffractometer (λ(MoK$_\alpha$)-radiation, graphite monochromator, ω and ϕ scan mode, $2\theta_{max}$ = 58°). The structure was determined by direct methods and refined by full-matrix least squares technique on $F^2$ with anisotropic displacement parameters for nonhydrogen atoms. The hydrogen atoms were placed in calculated positions and refined within the riding model with fixed isotropic displacement parameters ($U_{iso}$(H) = 1.5 $U_{eq}$(C) for the $CH_3$-groups and $U_{iso}$(H) = 1.2 $U_{eq}$(C) for the other groups). The final divergence factors were $R_1$ = 0.043 for 3182 independent reflections with $I > 2\sigma$ ($I$) and $wR_2$ = 0.083 for all independent reflections, $S$ = 1.007. All calculations were carried out using the *SHELXTL* program [19]. CCDC No. 741777 contains the supplementary crystallographic data for this article. These data can be obtained free of charge *via* www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12, Union Road, Cambridge CB2 1EZ, UK; fax: +44 1223 336033).

**General procedure for preparation of piperidones 1a-d.** A solution of corresponding furaldehyde (~25 mL, 0.3 mol) and ammonium acetate (23 g, 0.3 mol) in ethanol (150 mL) was added to a solution of ketone **1a–d** (0.15 mol) in ethanol (50 mL). The resulting clear mixture was allowed to remain at room temperature for 3 d. Then the obtained brown mixture was diluted with diethyl ether (400 mL) and washed with water (3 × 200 mL). The organic layer was separated, dried ($MgSO_4$), filtered, evaporated, and purified by column chromatography on alumina (eluant: hexane) to give corresponding piperidones **2a-d** as white prisms in good to moderate yields.

**General procedure for preparation of 7-phenylepoxypyrido[2,1-*a*]isoindolones 3a-d.** A mixture of corresponding piperidone **1a-d** (4.0 mmol), cinnamoyl chloride (1.0 g, 6.0 mmol) and triethylamine (1.7 mL, 12.0 mmol) in toluene (25 mL) was refluxed for 5–6 h. The reaction progress was monitored by TLC (until disappearance of the starting compound's spot). At the end of the reaction the mixture was poured into water (100 mL), an aq. (5%) solution of HCl added until pH ~6 and extracted with ethyl acetate (3 × 80 mL). The organic layers were combined, dried ($MgSO_4$), and concentrated to give crude products. Further crystallization from hexane-ethyl

acetate gave corresponding compounds **3a–d** as colourless needles.

**General procedure for preparation of carboxylic acids 4a-d.** A solution of piperidone **1a-d** (4.0 mmol) and citraconic anhydride (0.54 mL, 6.0 mmol) in toluene (30 mL) was refluxed for 4−6 h. At the end of the reaction the resulting mixture was cooled, and formation of white, yellow, or brown solids was observed. The crystals were filtered off, washed first with toluene (2 × 30 mL), then with acetone (2 × 20 mL) and air-dried to give corresponding acids **4a-d** as regioisomer mixtures (total yields of isomers **4b**,**dA** and **4b**,**dB** given on the Scheme 2). After recrystallization from isopropanol-DMF mixture the major isomers **4a-dA** were isolated as white powders.

**General procedure for preparation of carboxylic acids 7a-c.** A solution of piperidone **6a-c** (21.0 mmol) and maleic anhydride (2.06 g, 21.0 mmol) in toluene (30 mL) was refluxed for 6–8 h. At the end of the reaction, the resulting mixture was cooled, and formation of yellow-brown solids was observed. The crystals were filtered off, washed first with toluene (2 × 30 mL), then with acetone (2 × 20 mL) and air-dried to give corresponding acids **7a–c**. Subsequent recrystallization from isopropanol-DMF mixture gave target products as colourless powders.

**General procedure for preparation of isoindolones 8a-c.** A mixture of corresponding piperidone **6a-c** (10 mmol), acryloyl chloride (1.3 mL, 15 mmol) and triethylamine (2.5 mL, 20 mmol) in benzene (25 mL) was refluxed for 6 h. The reaction progress was monitored by TLC. At the end of the reaction, the mixture was poured into water (100 mL), an aq. (5%) solution of HCl added until pH ~6 and extracted with ethyl acetate (3 × 80 mL). The organic layers were combined, dried ($MgSO_4$), and concentrated to give crude products. Further crystallization from hexane-ethyl acetate gave corresponding compounds **8a–c** as colourless prisms.

**General procedure for preparation of esters 11a,b.** Corresponding acid **10a**,**b** (10.5 mmol) was dissolved in methanol (130 mL) and sulphuric acid (0.5 mL) was added. The resulting solution was refluxed for 12 h. The reaction progress was monitored by TLC. At the end of the reaction the mixture was cooled, poured into water (400 mL) and extracted with $CH_2Cl_2$ (5 × 80 mL). The organic layers were combined, dried over $MgSO_4$, and concentrated. Further crystallization of solid residue from ethanol gave the corresponding esters **11a**,**b** as pale-brown powders.

Synthesis of novel 3-substituted-1,2,3-triazolo[1,5-a]quinazolinones in high yields was performed *via* anionic hetero-domino reaction of appropriate substituted 2-azidobenzoates prepared from isatines and acetonitriles activated by 1,3-thiazole, 1,3-benzothiazole, 1,3,4-oxadiazole, and 1,2,4-oxadiazole rings. It was shown that acetonitriles exhibited high reactivity and were convenient methylenic compounds for such reactions providing rapid structural variation.

## INTRODUCTION

1,2,3-Triazolo[1,5-a]quinazolines are an important class of heterocycles, which have been the subject of great interest because of their biological activities. For instance, in the works of Jones and coworkers [1] the synthesis and evaluation of the biological affinity of a large number of C-5 substituted 1,2,3-triazolo[1,5-a]quinazolines are reported. It was shown that compounds of the current class were new ligands for $GABA_A$ receptors and potentially pharmaceutically acceptable for treatment of Alzheimer's disease. Moreover, Biagi et al [2]. found the activity of some 3-ethoxycarbonyl- or 3-phenyl-substituted 1,2,3-triazolo[1,5-a]quinazolines towards benzodiazepine, $A_1$ and $A_{2A}$ adenosine receptors. The promising biological activity and the unique structure of these families make them attractive synthetic targets. Furthermore, in the article [1b,c] it was underlined that 1,2,3-triazolo[1,5-a]quinazolines were first synthesized in 1966 [3], however, this class of compounds has subsequently received little attention [1,4]. Their syntheses, using readily available raw materials with short and facile routes, continue to be challenging endeavors.

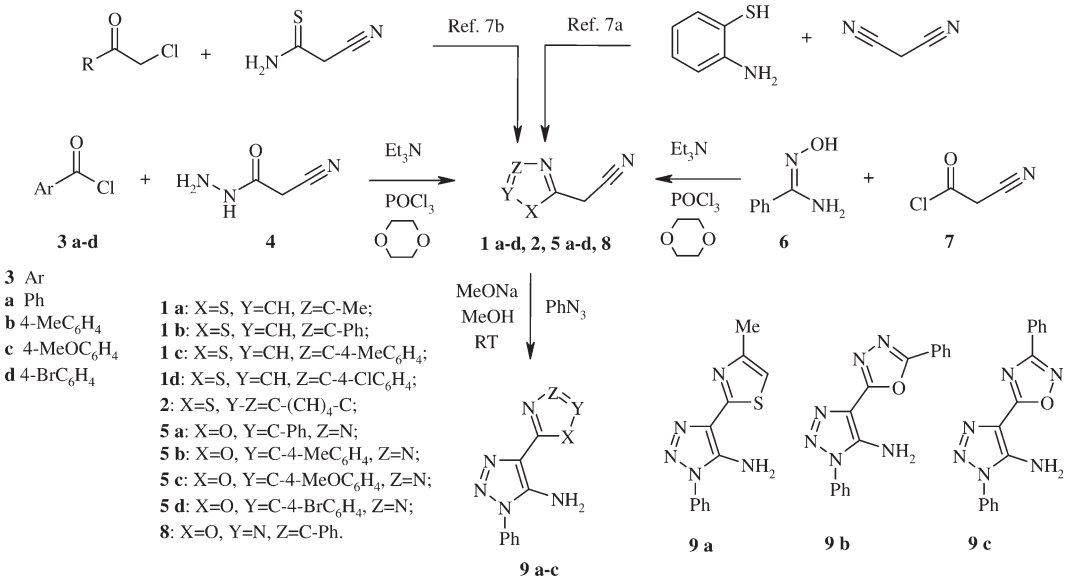
It is noteworthy that more attention was drawn to synthetic strategies, which have been developed to allow easy variation of the C-5 position of triazoloquinazolinone [1]. On the contrary, diversification of other positions has been discussed insufficiently. 2-Azidobenzoic acid and cyanoacetic acid derivatives were mostly used for construction of triazoloquinazolinone framework [4]. At the same time, the reaction of azides with acetonitriles activated by (het)aryl substituents is a perspective synthetic approach. The exclusive examples of the reaction of arylazides with (5-methylisoxazol-3-yl)acetonitrile [1] and phenylacetonitrile [5] have been described. In addition, introduction of new heterocyclic fragments to the C-3 position may extend the spectrum of biological activity of such compounds.

Recently, we have reported [6] the synthesis of 1*H*-1,2,3-triazole derivatives by cyclization of arylazides with (1,3-benzothiazol-2-yl)/(4-aryl-1,3-thiazol-2-yl)acetonitriles. It was shown that (1,3-benzothiazol-2-yl)acetonitrile undergoes an anionic domino reaction with methyl 2-azidobenzoate or 2-azidobenzonitrile to give [1,2,3]triazolo[1,5-a]quinazoline derivatives [6a]. Furthermore, it was found that acetonitrile possesses high reactivity, as an active methylenic compound for such reactions, for construction of [1,2,3]triazolo[1,5-a]pyrimidines system [6b] with heterocyclic substituents.

## RESULTS AND DISCUSSION

In the current work we present the results of a study of hetarylacetonitriles in the reaction with substituted methyl 2-azidobenzoates. Starting hetarylacetonitriles were obtained by several synthetic procedures. First the required precursors **1a–d**, **2** were synthesized in moderate to good yields according to the literature procedure [7]. Then we developed a synthetic protocol for preparation of acetonitriles activated by 1,3,4-oxadiazole and 1,2,4-oxadiazole. Compounds containing the oxadiazole

**Scheme 1**



ring have been widely studied recently since they exhibit biological activity [8] and possess some attractive photophysical properties [9]. Initial (5-aryl-1,3,4-oxadiazol-2-yl)acetonitriles **5a–d** were synthesized by one-pot cyclization of diacylhydrazines prepared *in situ* by acylation of cyanoacetic acid hydrazide **4** with the corresponding substituted benzoyl chlorides **3a**–**d**, *via* modification of known procedures [10]. (5-Phenyl-1,2,4-oxadiazol-2-yl)acetonitrile **8** was prepared by heating phenylamide oxime **6** with cyanoacetyl chloride **7** in anhydrous DMF in the presence of pyridine (Scheme 1).

The obtained hetarylacetonitriles **1a, 5a, 8** were examined in the reaction with phenylazide in sodium methoxide solution at room temperature. These conditions allowed to avoid possible Dimroth rearrangement [11] occurring when 5-aminotriazoles were heated in a strong base medium. As a result, new triazole derivatives **9a–c** were isolated in high yields and no by-products were formed. The corresponding 1,2,3-triazoles **9a–c** precipitated in good yields from the reaction medium.

In an effort to diversify the azido component, the method of 2-azidobenzoate synthesis from isatines, prepared from the corresponding anilines **10** by the Sandmeyer method [12], was used. By the reaction of anilines **10a,b** with chloral hydrate and hydroxylamine hydrochloride in aqueous sodium sulfate, isonitrosoacetanilides were formed. The obtained isonitrosoacetanilides were treated with concentrated sulfuric acid and yielded isatines **11b,c** [12]. Compounds **11d,e** were prepared from isatine **11a** by the reaction with brome [13] or chlorine generated *in situ* from HCl and hydrogen peroxide [14] correspondingly. Isatines **11a–e** were oxidated with alkaline hydrogen peroxide to form substituted 2-aminobenzoic acids [15], which were converted into esters **12a–e** by the following reaction with methanol in the presence of sulphuric acid [16]. It is of note that compound **12d** can be prepared from commercially available methyl anthranilate **12a** *via* chlorization by the use of calcium hypochlorite [17]. Finally, compound **12f** was prepared by subsequent nitration and reduction of dimethyl benzene-1,4-dicarboxylate. Anthranilates **12a–f** were readily converted into 2-azidobenzoic acid esters **13a–f** by diazotisation and displacement with sodium azide (Scheme 2).

To obtain [1,2,3]triazolo[1,5-*a*]quinazolines, substituted methyl 2-azidobenzoates were allowed to react with acetonitriles **1, 2, 5, 8**. The reaction was carried out using 1 equiv. of sodium methoxylate at room temperature. It was found that the reaction exhibited an appreciable exothermal effect and was completed within 1–2 min. In general, the reaction product was formed immediately after mixing the reagents and precipitated from the reaction medium. The polycyclic compounds **14a–o** were isolated in excellent yields (84–98%) (Table 1). It is noteworthy that esters **13** used in such a reaction are more convenient instead of 2-azidobenzoic acids. In the reaction of 2-azidobenzoic acids, yields were lower and the reaction required more time. Moreover, in some cases the reaction mixture must be heated. For instance, in the work [1a] triazoloquinazolinone framework was prepared by treatment of an equimolar mixture of 2-azidobenzoic acid with isoxazole acetonitrile in the presence of sodium ethoxide at 80°C for 5 h. Bertelli et al. [2b] reported that 2-carboxy-4/5-chloro-phenylazide reacted with ethyl cyanoacetate in absolute ethanol in the presence of two equivalents of sodium ethoxide at

[a] Recorded at 400 MHz.

room temperature, affording 1-(4- or 5-chloro-2-carboxy-phenyl)-4-ethoxycarbonyl-5-amino-1H-1,2,3-triazole intermediates, and the corresponding triazoloquinazolinones were formed after acidification of the alkaline solution. The reaction of such azides with phenylacetonitrile required refluxing of the reaction mixture but it proceeded in the same manner [2b]. Obviously, replacement of the carboxylic group into the carboxylate one increased the rate of the reaction of the amino group in the intermediate triazole **A**, which was formed at the first stage of the reaction. The carboxylate function provided the formation of the pyrimidine ring without any additional procedures.

The structures of all new compounds were confirmed by analytical and spectroscopic data (Tables 1 and 2, Fig. 1). In the $^1$H NMR spectra of compounds **14a–o** there were characteristic shift values for the H6, H7, H8, and H9 protons typical for the 1,2,3-triazolo[1,5-a]quinazoline system (Table 2). Furthermore, aryloxadiazolyl fragments were easily identified *via* low-field shifted aromatic protons *ortho* to the oxadiazole rings, usually found at 8.03–8.19 ppm.

In conclusion, in the current work we described efficient and economic routes to 1,2,3-triazolo[1,5-a]quinazolines from cheap abundant starting materials and with a possibility of substituent variation in triazoloquinazoline framework. Moreover, new active methylenic compounds were used for anionic domino reactions leading to formation of triazoloquinazolines.

## EXPERIMENTAL

All melting points were determined in capillary tubes in a Thiele apparatus and are uncorrected. $^1$H NMR spectra were recorded on a Varian Mercury 400 instrument (400 MHz for $^1$H) and Bruker 500 (500 MHz for $^1$H, 125 MHz for $^{13}$C) with

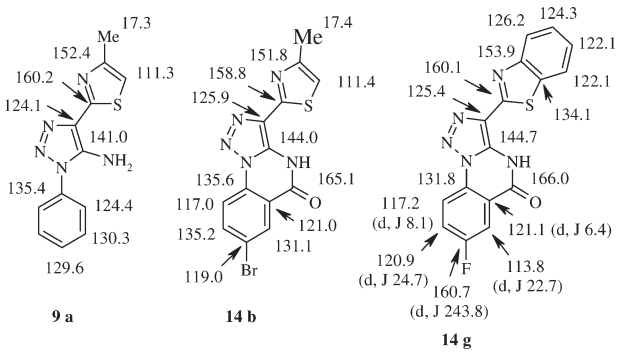

**Figure 1.** $^{13}$C NMR chemical shifts of compounds **9a**, **14b**, **14g**.

TMS or deuterated solvent as an internal reference. Mass spectra were run using Agilent 1100 series LC/MSD with an API-ES/APCI ionization mode. IR spectra were recorded on a Specord 80M spectrophotometer in KBr pellets. The evolution of the reactions and purity of the synthesized compounds were monitored chromatographically on Silufol UV-254 plates. $^{13}C$ NMR spectra of product **9b**,**c** and **14a**, **c–f**, **h–o** are not reported due to their very low solubility.

**(5-Aryl-1,3,4-oxadiazol-2-yl)acetonitriles 5a–d (general procedure).** The solution of 21 mmol of substituted benzoyl chloride **3** in 10 mL of anhydrous dioxane was added under continuous stirring to the solution of 2.1 g (21 mmol) of 2-cyanoacetohydrazide and 2.9 mL (21 mmol) of triethylamine in 30 mL of anhydrous dioxane. The mixture was stirred for 0.5 h at room temperature and 10 mL of $POCl_3$ was added. The mixture was heated for 3 h at 80°C, cooled to room temperature and poured onto ice. The precipitate was filtered off and dried in air. The crude product was purified by flash chromatography followed by recrystallization from ethanol.

**(3-Phenyl-1,2,4-oxadiazol-5-yl)acetonitrile 8.** Cyanoacetyl chloride **6** (0.52 g, 5 mmol) was added to the solution of 5 mmol of *N*'-hydroxybenzenecarboximidamide **7** in 2 mL of pyridine. The mixture was kept for 0.5 h and 5 mL of DMF was added. The mixture was heated for 3 h at 80°C, cooled to room temperature and mixed with 30 mL of water. The precipitate was filtered off, washed with water on a filter, recrystallized from alcohol and dried in air.

**Azides 13a–f preparation.** The solution of sodium nitrite (7.1 g, 0.1 mol) in water (30 mL) was added dropwise to a stirred solution of substituted anthranilic esters (0.1 mol) in 40 mL of concentrated HCl and 20 mL of water keeping the temperature below 5°C. After that the mixture was stirred for 10 min and rapidly filtered. To the obtained solution $NaN_3$ (6.5 g, 0.1 mol) in water (125 mL) was added dropwise. The mixture was stirred for 15 min at 0°C and then for 30 min at room temperature. Azides **13a,b** were extracted by diethyl ether (3 × 10 mL). Ether was evaporated *in vacuo*. Azides **13c–f** were filtered and washed with water twice. Azides were used without subsequent cleaning: **methyl 2-azidobenzoate 13a**, yield 11.5 g, 65%; dark red oil; MS: (CI) *m*/*z* (%) = 178 (100%) [M+H$^+$]; **methyl 2-azido-5-methylbenzoate 13b**, yield 13.7 g, 72%; dark red oil; MS: (CI) *m*/*z* (%)= 192 (100%) [M+H$^+$]; **methyl 2-azido-5-fluorobenzoate 13c**, yield 13.8 g, 71%; pink solid, mp: 28–29°C; MS: (CI) *m*/*z* (%)= 196 (100%) [M+H$^+$]; **methyl 2-azido-5-chlorobenzoate 13d**, yield 16.7 g, 79%; white pink solid, mp: 50–52°C; MS: (CI) *m*/*z* (%) = 212(100%) [M+H$^+$]; **methyl 2-azido-5-bromobenzoate 13e**, yield 20.8 g, 81%; white solid, mp: 71–72°C; MS: (CI) *m*/*z* (%) = 256 (100%) [M+H$^+$], 258 (100%) [M+H$^+$]; **dimethyl 2-azidobenzene-1,4-dicarboxylate 13f**, yield 17.7 g, 75%; white solid, mp: 83–85°C; MS: (CI) *m*/*z* (%) = 236 (100%) [M+H$^+$]. (Caution! All azides are potentially explosive and should not be heated).

**General procedure for the synthesis of 1*H*-1,2,3-triazol-5-amines 9a–c and [1,2,3]triazolo[1,5-*a*]quinazolin-5(4*H*)-one 14a–o.** To the solution of sodium methoxide (540 mg, 10.0 mmol) in dry methanol (20 mL) an appropriate substituted acetonitrile **1, 2, 5** or **8** (10.0 mmol) was added. To this solution substituted methyl 2-azidobenzoate **2** (10.0 mmol) in dry methanol (2 mL) was added dropwise and the solid started to precipitate. The mixture was stirred for 1 h. The resulting suspension was filtered and the solid product was washed with water and methanol to give the corresponding 1*H*-1,2,3-triazol-5-amines **9a–c** and [1,2,3]triazolo[1,5-*a*]quinazolin-5(4*H*)-ones **14a–o**.

**4-(4-Methyl-1,3-thiazol-2-yl)-1-phenyl-1*H*-1,2,3-triazol-5-amine (9a).** Yield: 2.2 g (87%); as white crystals; mp 168–169°C (DMF–EtOH); $^1H$ NMR (DMSO-$d_6$ 400MHz): δ 2.45 (s, 3H, Me), 6.47 (s, 2H, $NH_2$), 6.95 (s, 1H, thiazole), 7.52 (t, $^3J$ = 7.1 Hz, 1H, $H_{Ph}$-4), 7.61 (t, $^3J$ = 7.2 Hz, 2H, $H_{Ph}$-3,5), 7.66 (d, $^3J$ = 7.2 Hz, 2H, $H_{Ph}$-2,6); MS: (CI) *m*/*z* (%) = 258 (100%) [M+H$^+$]. ## INTRODUCTION

Multicomponent reactions (MCRs) have been frequently used by synthetic chemists as a facile means to generate molecular diversity from bifunctional substrates that react sequentially in an intramolecular fashion [1,2]. Devising such types of MCRs that achieve the formation of multiple bonds in a single operation is one of the major challenges in modern organic synthesis [3,4]. As such processes avoid time-consuming and costly purification processes, and protection-deprotection steps, they are inherently more environmentally benign and atom economic [5]. They provide a powerful tool toward the one-pot synthesis of diverse and complex compounds and small and drug-like heterocycles [6]. Designing of MCRs in water is another attractive area in green chemistry [7], because water is a cheap, safe, and environmentally benign solvent. There is need for developing MCRs in water with a suitable catalyst and without the use of any harmful organic solvents.

Indole moiety is probably the most well-known heterocycle and a common and important feature of a variety of natural products and medicinal agents [8]. Furthermore, it has been reported that sharing of the indole 3-carbon atom in the formation of spiroindoline derivatives highly enhances biological activity [9,10]. The spirooxindole system is the core structure of many pharmacological agents and natural alkaloids [11–13]. Therefore, a number of methods have been reported for the preparation of spirooxindole fused heterocycles [14–17].

Substituted amino-pyrans take a significant place among the 6-membered oxygen-containing heterocycles. Some of them possess anticancer and antimicrobial activity [18,19]. Serotonin receptor modulators (pteropodine and its stereoisomers) and natural alkaloids, containing both spiro-indole and pyran cycles, were isolated from stem bark of *Uncaria tomentosa* (Fig. 1) [11]. Several spiroheterocycles containing both indole and pyran heterocycles possess anticonvulsant and analgetic [20], herbicidal and antibacterial activities [21].

Pyrimidine and its derivatives have been studied for over a century because of a variety of chemical and biological significance. They have been reported as antibacterial, antiviral, and antitumor agents [22]. A number of heterocyclic compounds fused with pyrimidines are known for their varied biological activities [23–26]. Similarly, naphthopyran derivatives are an important class of compounds with excellent photochromic properties [27–29], some of which are also structural motifs present in many biologically active compounds [30–32]. For example, some naphthopyran derivatives could have potential applications in biochemical research as photoswitch tag compounds [33].

As part of our continuing efforts on the synthesis of biologically active heterocyclic compounds [34–41], we recently described an efficient synthesis of spiropyrimidoquinoline-pyrrolopyrimidines and spiroindoline-pyridodipyrimidines via a condensation reaction between amino-uraciles and isatines [42,43]. We have also

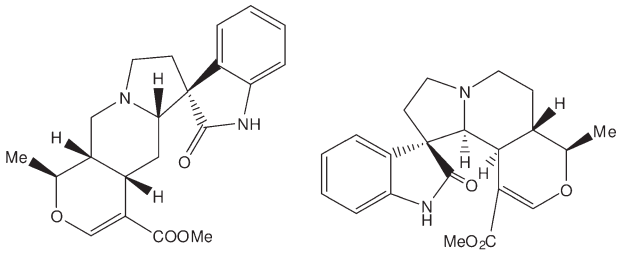

**Figure 1.** Spirooxindole natural alkaloids.

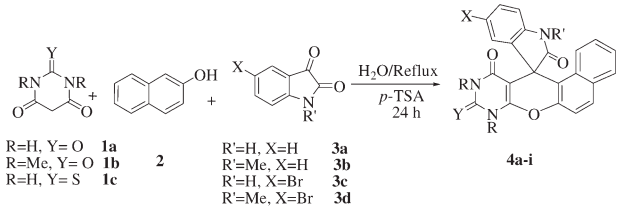
developed an efficient synthesis of spiro[dibenzo[*b*,*i*]-xanthene-13,3′-indoline]-pentaones via a reaction of isatins and 2-hydroxy-naphthoquinone in water [44].

Considering the important biological properties of spirooxindole-fused heterocycles, we report herein a one-pot, three-component and clean synthesis of spironaphthopyrano[2,3-*d*]pyrimidine-5,3′-indolines 4 through a one-pot, three-component condensation reaction of barbituric acids **1a–c**, 2-naphthol **2**, and isatins **3a–d** in water (Scheme 1).

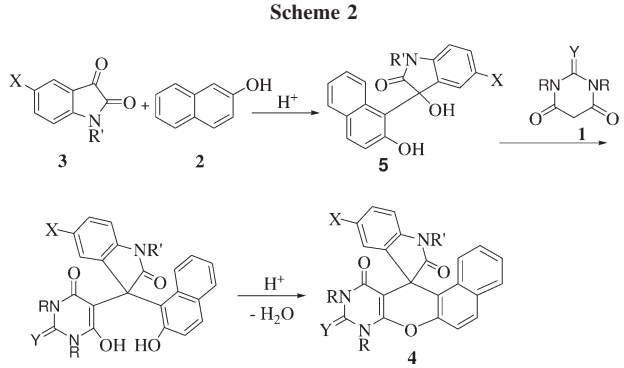
## RESULTS AND DISCUSSION

In a pilot experiment, a mixture of barbituric acid **1a**, 2-naphthol **2**, and isatin **3a** at refluxing water was stirred in the presence of catalytic *p*-toluenesulfonic acid (*p*-TSA) as an inexpensive and available catalyst to afford the spiro[naphtho[1′,2′:5,6]pyrano[2,3-*d*]pyrimidine-5,3′-indoline]2,2′,4(1*H*,3*H*)-trione **4a** in 85% for 24 h. Then, to delineate this approach, particularly in regard to library construction, this methodology was evaluated using three commercially available barbituric acids **1a–c**, 2-naphthol **2**, and four substituted isatins **2a–d**, and the corresponding spironaphthopyrano[2,3-*d*]pyrimidine-5,3′-indoline derivatives **4a–i** were synthesized by the one-pot, three-component condensation reaction for good yields under similar conditions (Table 1). $^{1}$H- and $^{13}$C-NMR spectra of the crude products clearly indicated the formation of spirooxindol-fused naphthopyranopyrimidine **4**. The nature of these compounds as 1:1:1 adducts was apparent from their mass spectra, which displayed, in each case, the molecular ion peak at appropriate *m*/*z* values. Compounds **4a–i** are stable solids whose structures were established by IR, $^{1}$H- and $^{13}$C-NMR spectroscopy and elemental analysis.

**Scheme 1**



**Scheme 2**



The results were good in terms of yields and product purity in the presence of *p*-TSA, whereas without *p*-TSA the yields of products were trace even after 48 h.

To the best of our knowledge, this new procedure provides the first example of an efficient and three-component method for the synthesis of spironaphthopyrano[2,3-*d*]pyrimidine-5,3′-indoline derivatives. This method, based on three-component *p*-TSA-catalyzed reaction in water, is the most simple and convenient and would be applicable for the synthesis of different types of spironaphthopyranopyrimidine-indolines.

We have not established an exact mechanism for the formation of spironaphthopyranopyrimidine-indolines **4**; however, the formation of products **4** can be rationalized via initial formation of intermediate **5** by condensation of 2-naphthol **2** and isatin **3** [45]. Subsequent addition of barbituric acids **1** to the intermediate **5**, followed by cyclization afforded the **4** and water (Scheme 2).

In conclusion, we have demonstrated an efficient, a clean, and a simple method for the preparation spironaphthopyranopyrimidine-indolines using readily available starting materials. Prominent among the advantages of this new method are novelty, operational simplicity, good yields, and easy work-up procedures used. Moreover, it is worth noting that two C—C and one C—O bonds were formed with concomitant creation of a spirooxindol-fused naphthopyranopyrimidine in this one-pot, three-component process.

## EXPERIMENTAL

Melting points were measured on an Elecrtothermal 9100 apparatus. Mass spectra were recorded on a FINNIGAN-MAT 8430 mass spectrometer operating at an ionization potential of 70 eV. $^{1}$H- and $^{13}$C-NMR spectra were recorded on a BRUKER DRX-300 AVANCE spectrometer at 300.13 and 75.47 MHz, respectively. IR spectra were recorded using a Shimadzu IR-470 apparatus. Elemental analyses were performed using a Heracus CHN-O-Rapid analyzer.

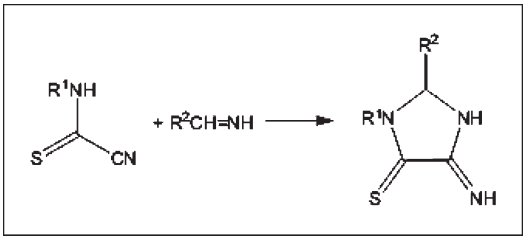
Published online 4 March 2010 in Wiley InterScience (www.interscience.wiley.com).



The reaction of *N*-methyl- (**3a**) or *N*-phenylcyanothioformamide (**3b**) with acetaldimine (**5a**, as 1-amino-1-ethanol) gives 5-(amino)imidazolidine-4-thiones **6B**. Product **6a** reacts with a second equivalent of **3a** to give **8** which in turn is oxidized to disulfide **9**. Using araldimines **5b**,**c**, only 1:2 intermediates **10** derived from **3a**, **b** and two moles of the imine **5** are formed, but proved to be easily oxidized to disulfides **11**. Acetylation of **6** occurs chemoselectively on the exocyclic nitrogen and finally also on the thione sulfur to give **14** *via* **13**.

*J. Heterocyclic Chem.*, **47**, 425 (2010).

## INTRODUCTION

There is continuing interest in the design and evolution of novel antioxidants as a means to alleviate oxidative stress in biochemical processes [1–3]. For the heterocyclic chemist, an attractive lead structure appears to be the unusual amino acid family of ovothiols **1a–c** [4–7]. So, imidazole-4-thiols **2** have become attractive targets for synthesis (Scheme 1).

*N*-Acylaminoacid thioamides are possible precursors of ovothiols **1** [4], but their cyclization is not always reproducible [5]. Similarly, the *Asinger* group has reported the formation of imidazolethiols **2** from α-oxothioamides and aldimines [8]. Recently, we have reported the synthesis of oxazolidines **4** from cyanothioformamides **3** and aldehydes or ketones [9] as part of our study on heterocyclic ring-closure reactions [10–16] and now envisaged that cyanothioformamides **3** and *N*-unsubstituted aldimines should give products of type **2**, though with a 5-amino group as additional feature which may assist in free-radical trapping. However, the position of the tautomeric equilibrium in the probable cyclization products **6** between iminothiones **6A**, aminothiones **6B**, and aminothiols **6C** is a priori open (Scheme 2). On the other hand, heterocycles **6** are also of special interest as precursors of the elusive bicyclic heteroaromatic products of type **12** (Scheme 5).

## RESULTS AND DISCUSSION

We selected *N*-methyl- (**3a**) and *N*-phenylcyanothioformamide (**3b**) as nucleophiles, and acetaldimine **5a** (as 1-amino-1-ethanol [17]) or benzaldimines **5b**,**c** as electrophiles. Triethylamine was used as a catalyst.

Thioamide **3a** and acetaldimine **5a** give a smooth reaction to furnish 1:1 product **6a** as the only defined

**Scheme 1.** Imidazole-4-thiols.

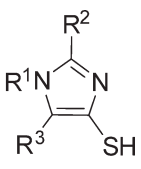
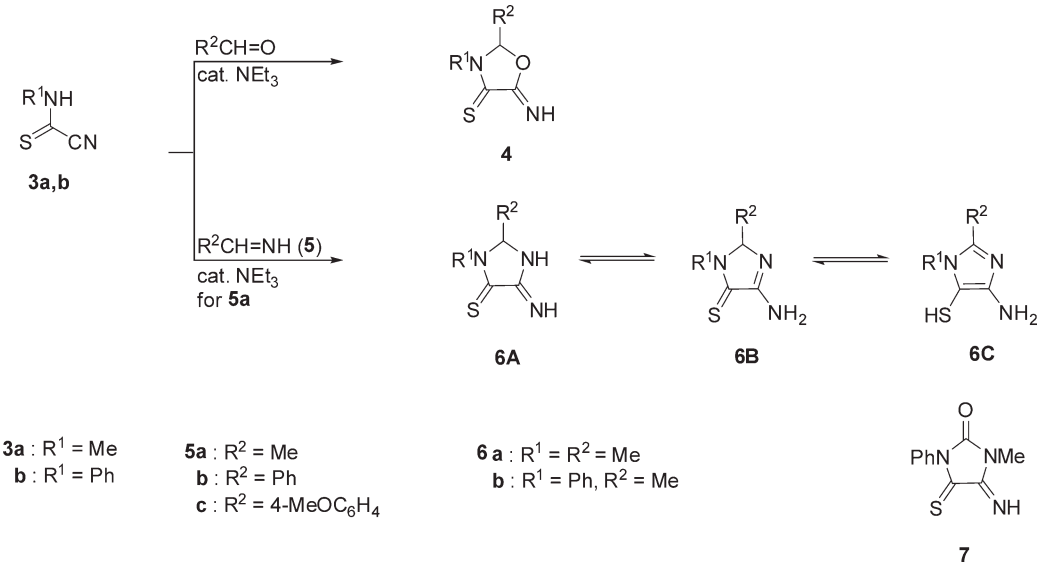
**1b**: $NR_2$ = NHMe
**1c**: R = Me



**2**

**Scheme 2.** Reactions of cyanothioformamides with aldehydes or acetaldimine.



product. An analogous product **6b** is formed from thioamide **3b** und **5a** (Scheme 2). As to the position of the tautomeric equilibrium, appearance of the 2-methyl signal of **6a** as a doublet in the $^1$H NMR spectrum and a low-field $^{13}$C NMR signal (ca. 182 ppm) pointing toward the presence of a thiocarbonyl carbon as in **6A** and **6B** allow to rule out tautomer **6C**. Another low-field $^{13}$C NMR peak at δ about 159 ppm occurs at definitely lower field than for the exocyclic imino group in model compound **7** (δ 154.2 ppm) [10,11,18], and in the $^1$H NMR spectrum, the two NH protons are magnetically equivalent as expected for **6B**. Moreover, the IR spectra lack a strong vibration in the 1650–1670 cm$^{-1}$ range which is observed for **7** (1659 cm$^{-1}$) and in other authentic 5-imino-imidazolidine-4-thiones [13,18]. So obviously, tautomer **6B** is preferred indicating that the greatest degree of stabilization is achieved by conjugation within the transoid S═C─C═N unit of tautomer **6B** when compared with the corresponding cisoid system in **6A** or the aromaticity of **6C**.

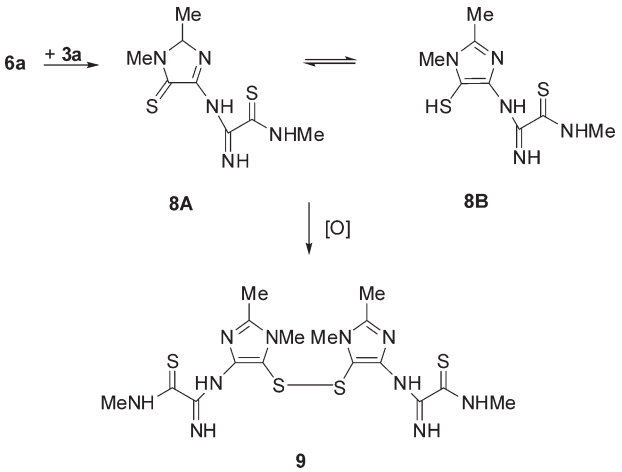
Prolonged reaction times in the addition of **3a** to **5a** showed that the thioamide **3a** adds faster to cyclization product **6a** than to **5a** giving rise to a 2:1 adduct **8** as well as aromatic disulfide **9** as oxidation product (Scheme 3).

An X-ray crystallographic study revealed the structure of **9** and so implicitly also of precursor **8**. As the spectroscopic data for **8** are similar to those of **6**, we assume that the imidazole unit in **8** has structure **B** as in the preferred tautomer **B** of **6**. In the formation of **8**, the second mole of **3a** has been incorporated *via* its nitrile function by addition to the exocyclic imino group of **6a** and this is obviously followed by aromatization and oxidation to the disulfide **9** (Fig. 1).

Reactions of thioamides **3** with aromatic aldimines **5b**,**c** take a different course (Scheme 4). Here, invariably dehydrogenated 2:1 products **11a–c** are formed obviously *via* intermediate **6**, followed by Schiff base formation with a second equivalent of the imine **5** to give azomethines **10** with loss of ammonia, and finally oxidative aromatization. Even when the reactions were run under nitrogen, conventional work-up led to oxidation to give the aromatic disulfides **11**. So, there is a striking difference in the sensitivity to oxidation between the 2-methyl ($R^2$ = Me) products **6a**,**b** and their 2-aryl congeners **10**.

Attempts to cyclize **6a**,**b** using acetic anhydride gave no indication for the formation of the bicyclic hetarene **12**, but simple monoacetylation is observed (Scheme 5). The spectroscopic data allow no unambiguous

**Scheme 3.** Oxidation of imidazolinethione **6a**.



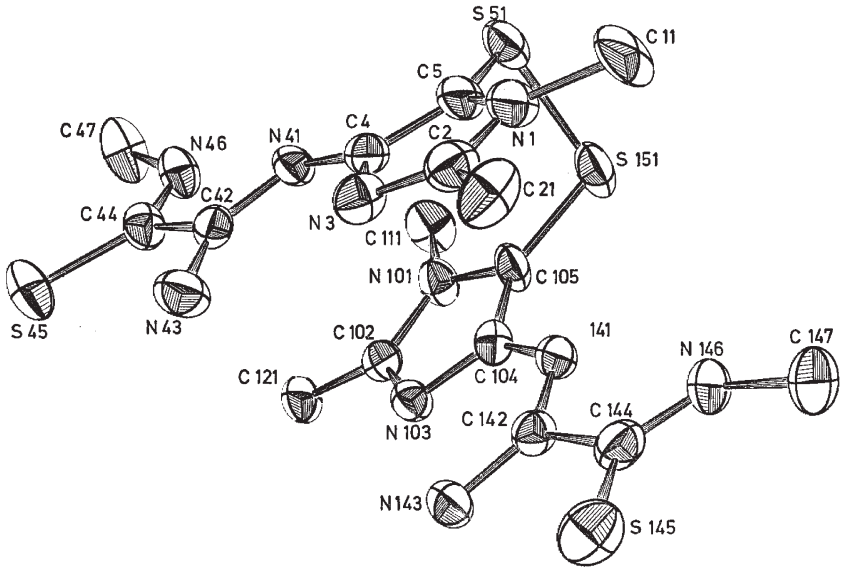


**Figure 1.** ORTEP drawing of disulfide **9** with salient bond lengths [Å]: S51-C5 1.840(9), S51-S151 2.176(4), N1-C2 1.367(11), N3-C2 1.323(10), N3-C4 1.402(10), C4-C5 1.395(10), N41-C42 1.298(9), N43-C42 1.385(10), S45-C-44 1.676(8), N46-C44 1.295(9), S151-C105 1.712(7), N101-C105 1.405(9), N101-C102 1.356(9), N103-C102 1.320(9), N103-C104 1.365(8), C104-C105 1.401(10), N141-C142 1.270(8), N143-C142 1.331(9), S145-C144 1.751(8), N146-C144 1.303(10).

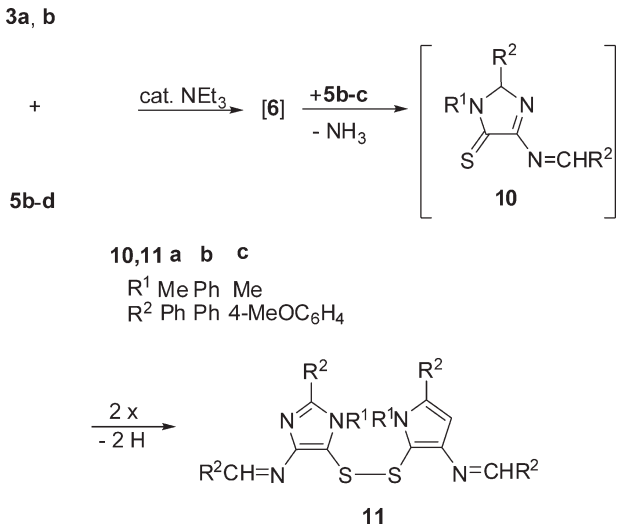
distinction between acetylation of the endocyclic or the exocyclic nitrogen, but further acetylation of the product derived from **6b** yields a triacetylated product for which structure **14** is suggested based on the magnetic equivalence of two acetyl residues. Mutatis mutandis this leads to structure **13** for the *N*-monoacetylated products. Similarly, monoacetylation in the exocyclic position is observed when the hydrolysis product **15** of imine **6a** is acetylated to give apparently an ester derivative **16**. This is evident particularly from the high-wavenumber carbonyl absorptions (1762, 1731 $cm^{-1}$) of the product.

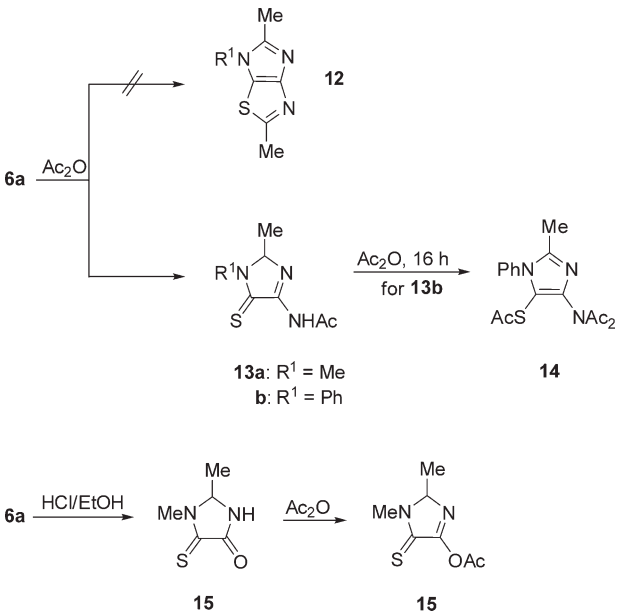
## CONCLUSIONS

The reaction of cyanothioformamides **3** with aldimines **5** takes the expected initial course when the

**Scheme 4.** Cyanothioformamides and araldimines.



**Scheme 5.** Acylation of imidazolinethiones **6**.



nitrogen in the thioamide moiety in **3** attacks the electrophilic imine carbon of **5**, whereas the nitrile function provides the opportunity for subsequent cyclization to give imidazolidines **6**. However, among the possible tautomers **6B** is apparently preferred and can be isolated for $R^2$ = methyl whereas compounds with $R^2$ = aryl tend to add a second equivalent of imine **5** and easily undergo oxidative dimerization. The ready oxidation of imidazole-4-thiols had been seen before in similar examples [5,8]. Unfortunately, the disulfide form of L-ovothiol A (**1a**) is biologically inactive [6] and this may also be anticipated for the disulfides of this work.

## EXPERIMENTAL

**General.** NMR: Bruker WP 80–FT, AMX 400, or Varian FT–80A; $CDCl_3$ as solvent unless stated otherwise, with TMS as internal standard; coupling constants *J* are given in Hz. IR: Perkin–Elmer FTIR 1720 X or Pye-Unicam SP3-200 spectrometers. Elemental analyses: Institut für Pharmazeutische Chemie, TU Braunschweig.

*N*-Methylcyanothioformamide (**3a**) [9] and cyanothioformanilide (**3b**) [19] were prepared as previously described, though in the preparation of **3b** we found use of THF as solvent advantageous. For the synthesis of imine **5a** see ref. [17], for benzaldimine (**5b**) see ref. [20]; imine **5c** [21] was prepared analogously.

***5-Amino-2,3-dimethyl-5-imidazoline-4-thione (6a).*** An ethereal (20 mL) solution of **3a** (2.38 g, 20 mmol), **5a** (3.66 g, 20 mmol), and triethylamine (three drops) was stirred for 30 min at 20°C to give **6a** as reddish–brown crystals (745 mg, 26%); m.p. 137°C (dec.). IR (KBr): $\tilde{\nu}$ = 3370, 3180, 2950, 1470, 1140 $cm^{-1}$. $^1H$ NMR: δ = 1.44 (d, *J* = 6.4, 3 H, $CCH_3$), 3.36 (s, 3 H, $CH_3N$), 5.13 (q, *J* = 6.4, 1 H, CH), 5.58 (broad, 2 H, NH). $^{13}C$ NMR: δ = 181.96 (C═S), 159.37 (N═C), 84.64 (C─Me), 32.28 (N─Me), 18.80 (Me). MS: m/z (%) = 143 (100) [M], 128 (23) [M─$CH_3$], 74 (28), 69 (31). HRMS for ($C_5H_9N_3S$ + H): calcd 144.0595, found 144.0601.

***5-Amino-2-methyl-3-phenyl-5-imidazoline-4-thione (6b).*** An ethereal (25 mL) solution of **3b** (1.62 g, 10 mmol), **5a** (1.83 g, 10 mmol), and triethylamine (three drops) was stirred for 15 min and then diluted with hexane. The gummy residue was extracted several times with hexane. These extracts were combined with the ether-hexane solution. Removal of the solvents under reduced pressure gave **6b** as reddish brown crystals (308 mg, 15%); m.p. 125–127°C. IR (KBr): $\tilde{\nu}$ = 3350, 3270, 2950, 1470, 1130 $cm^{-1}$. $^1H$ NMR: δ = 1.33 (d, *J* = 6.4 Hz, 3 H, $CH_3$), 5.78–5.60 (q, *J* = 6.4, 1 H, CH and broad, 2 H, $NH_2$, exchangeable with $D_2O$), 7.48 (m, 5 H, ArH). $^{13}C$ NMR: δ = 181.80 (C═S), 159.03 (N═C), 129.49, 128.44, 125.01 (Ph), 85.47 (*C*─Me), 19.63 (Me). MS: *m/z* (%) = 205 (68) [M], 204 (8), 190 (7), 135 (12), 70 (100). $C_{10}H_{11}N_3S$ (205.3); calcd C 58.51, H 5.40, N 20.47, S. 15.62; found C 58.31, H 5.52, N 20.10, S 15.23.

***5-Imino-1-methyl-3-phenyl-4-thioxoimidazolidin-2-one (7).*** The compound had been prepared before [10,16]. IR (KBr): 1766 (C═O), 1659 (C═N) $cm^{-1}$. $^{13}C$ NMR ($CH_3$): δ =181.9 (C═S), 154.8 (C═O), 154.2. (C═NH), 132.5 (Ar), 129.4, 129.3, 126.9 (ArH), 26.8 ($NCH_3$).

***2-(1,2-Dimethyl-5-mercaptoimidazol-4-yl)amino-2-imino-N-methyl-thioacetamide (8B) and bis[4-(imino-(N-methylthiocarbamoyl)methyl)amino-1,2-dimethylimidazol-5-yl] disulfide (9).*** An ethereal (20 mL) solution of **3a** (3.24 g, 20 mmol), **6a** (3.66 g, 20 mmol), and triethylamine (three drops) was stirred at 20°C for 30 min and then allowed to stand for 16 h. The solid product was extracted several times with cold ethanol. The remaining solid was recrystallized from boiling ethanol to give **8** as yellow crystals (9.73 g, 20%); m.p. 173–175°C. IR (KBr): $\tilde{\nu}$ = 3150–3300, 2930–2970, 1450, 1130 $cm^{-1}$. $^1H$ NMR: δ = 2.50 (s, 3 H, $CCH_3$), 2.90 (d, *J* = 6 Hz, 3 H, NHC*H*$_3$, collapses to s with $D_2O$), 3.56 (s, 3 H, $CH_3N$), 7.63, 9.33, 10.40 (each s, 3H, broad NH, exchanges with $D_2O$). Concentration of the ethanolic extract from earlier gave **9** as reddish crystals (145 mg, 30%); m.p. 195–197°C. IR (KBr): $\tilde{\nu}$ = 3350–3230 (broad, NH), 2910–2980, 1470, 1150 $cm^{-1}$. $^1H$ NMR: δ = 2.29 (s, 6 H, $CH_3C$), 3.21 (s, 6 H, C*H*$_3$NH), 3.3 (s, 6 H, $CH_3N$), 7.47, 8.99, 9.88 (each broad, NH; exchanges with $D_2O$). $C_{16}H_{24}N_{10}S_4$. (484.7): calcd. C 39.65, H 4.99, N 28.90, S 26.46; found C 39.60, H 5.00, N 29.00, S 26.50.

***Bis(4-benzylidenamino-1-methyl-2-phenyl-imidazole)-5,5′-diyl disulfide (11a).*** An ethereal solution (20 mL) of **3a** (1.0 g, 10 mmol), **5b** (1.05 g, 10 mmol), and triethylamine was stirred at 20°C for 0.5–2 h to provide yellow crystals (750 mg, 51%), m.p. 187–190°C. IR (KBr): $\tilde{\nu}$ = 1605, 1573. $^1H$ NMR: δ = 3.85 (s, 3 H, $CH_3$), 7.2–7.78 (m, 10 H, Ph, CH), 8.99 (s, 1 H, PhCH═N). $^{13}C$ NMR: δ = 158.6 (N═CH), 155.7 (C-2), 149.8 (C-4), 136.3, 130.9, 128.9, 128.7, 128.6, 128.4, 128.2 (Ar), 116.4 (C-5), 32.5 ($NCH_3$). MS: m/z (%) = 585 (48) [M + H], 481 (58), 437 (59), 393 (92), 349 (100). $C_{34}H_{28}N_6S_2$ (584.8): calcd. for C 69.83, H 4.83, N 14.37, S 10.97; found C 69.13, H 4.96, N 14.51, S. 10.65.

***Bis(4-benzylidenamino-1,2-diphenyl-imidazole)-5,5′-diyl disulfide (11b).*** An ethereal solution (20 mL) of **3a** (1.62 g, 10 mmol), benzaldimine **5b** (2.10 g, 20 mmol), and triethylamine (three drops) was stirred for 30 min and allowed to stand overnight. The yellow crystals were collected and recrystallized from dichloromethane/methanol; yield 1.60 g (45%). m.p. 195°C (dec.). Repeated crystallization afforded a product with m.p. 207°C (dec.). IR (KBr): $\tilde{\nu}$ = 1605, 1573, 1503, 1316 $cm^{-1}$. $^1H$ NMR: δ = 6.96–7.48 (m, 13H), 9.11 (s, 1 H, PhCH═N). $^{13}C$ NMR: δ = 159.3 (N═CH), 155.7 (C-4), 148.6 (C-2), 136.62, 136.41, 129.52 (Ar), 130.94, 129.07, 128.90, 128.58, 128.48, 128.43, 127.88 (ArH), 119.0 (C-5). MS: *m/z* (%) = 709 (100) [M + H], 337 (18), 289 (9), 161 (19), 105 (8). $C_{44}H_{32}N_6S_2$ (708.9): calcd C 74.55, H 4.55, N 11.86; S 9.05 found C 74.19; H 4.69; N 11.82; S 8.82.

***Bis[4-(4-methoxybenzylidenamino)-1-methyl-2-(4-methoxyphenyl)-imidazole]-5,5′-diyl disulfide (11c).*** Prepared by the procedure described for **11** using **5c** in place of **5b**. Yield 55%, m.p. 155°C. IR (KBr): $\tilde{\nu}$ = 1600, 1470, 1210 $cm^{-1}$. MS: *m/z* (%) = 352 (25) [M/2], 351 (100), 176 (14), 151 (48). $C_{38}H_{36}N_6O_4S_2$ (704.86) calcd. C 64.75 H 5.15 N 11.92, S 9.10; found C 64.70, H 5.50, N 12.00, S 9.10.

**N-*(1,2-Dimethyl-5-thioxo-3-imidazolin-4-yl)acetamide (13a).*** A solution of **6a** (100 mg, 0.7 mmol) in acetic anhydride (1.4 mL, 14.8 mmol) was allowed to stand for 16 h. Removal of acetic anhydride under reduced pressure gave a gummy product which was triturated with water to afford dark pink crystals of **13a** (36 mg, 28%); m.p. 107–109°C. IR: $\tilde{\nu}$ = 3191, 1686, 1666, 1537 $cm^{-1}$. $^1H$ NMR: δ = 1.63 (d, *J* = 5.6, 3 H, $CH_3CN_2$), 2.67 (s, 3 H, $CH_3CO$), 3.39 (s, 3 H, $CH_3N$), 5.51

(q, $J$ = 5.6, 1 H, CH). $^{13}$C NMR: δ = 181.02 (C═S), 170.07 (C═O), 155.77 (C═N), 74.28 (C-2), 84.64 (C─Me), 31.2 (N─Me), 25.72 (Ac-$CH_3$), 18.68 (2-Me). MS: $m/z$ (%) = 185 (89) [M], 143 (100), 128 (14). HRMS for ($C_7H_{11}N_3OS$ + H): calcd 186.0701, found 186.0696.

**N-*(2-Methyl-1-phenyl-5-thioxo-3-imidazolin-4-yl)acetamide (13b).*** A solution of **6b** (4.10 g, 20 mmol) in acetic anhydride (10 mL) was allowed to stand at 20°C for 30 min. Removal of the reagent under reduced pressure gave **13b** as yellow crystals (990 mg, 20%); m.p. 115–117°C. IR (KBr): $\tilde{\nu}$ = 3210, 1720, 1450, 1120 cm$^{-1}$. $^1$H NMR: δ = 1.5 (d, $J$ = 6.0, 3 H, 2-$CH_3$), 2.7 (s, 3 H, $CH_3CO$), 5.5 (q, $J$ = 6.0, 1 H, 2-H), 7.5 (m, 5 H, ArH,), 9.4 (broad s, 1 H, NH, exchanges with $D_2O$). $C_{12}H_{13}N_3OS$ (247.3): calcd C 58.28, H 5.30, N 16.99, S 12.97; found C 58.19, H 5.16, N 17.11, S 12.89.

**N-*(5-Acetylthio-2-methyl-1-phenyl-imidazol-4-yl)diacetamide (14).*** The earlier reaction was repeated, but allowed to run for 16 h to give **14** as yellow crystals (1.66 g, 25%); m.p. 110–111°C. IR (KBr): $\tilde{\nu}$ = 2970, 2910, 1690 cm$^{-1}$. $^1$H NMR: δ = 2.1, 2.3 (each, s, 3 H, $CH_3$), 2.4 (s, 6 H, $Ac_2N$), 7.0–7.6 (m, 5 H, ArH). MS: $m/z$ (%) = 331 (3) [M], 289 (20), 247 (93), 205 (100). $C_{16}H_{17}N_3O_3S$ (331.4): calcd. C 57.99, H 5.17, N 12.68, S 9.68; found C 57.80, H 5.26, N 12.66, S 9.55.

***1,2-Dimethyl-5-thioxoimidazolidin-4-one (15) and (1,2-dimethyl-5-thioxo-3-imidazolin-4-yl) acetate (16).*** A suspension of thione **6a** (50 mg, 0.35 mmol) in EtOH (2.1 mL), and 2*M* HCl (0.35 mL) was refluxed for 30 min. After cooling, water (3.5 mL) was added. Sticky yellow crystals could be removed by filtration and were used as such in the subsequent step. Yield 20 mg (40%). IR (KBr): 3455, 3368, 3211, 1731 cm$^{-1}$. $^1$H NMR (MeOD): 1.64 (d, $J$ = 6.2 Hz, 2-$CH_3$), 3.42 (d, $J$ = 1.2 Hz, 1-$CH_3$), 5.52 (q + q), $J$ = 1.2; 6.2 Hz, 2-H). $^{13}$C NMR (MeOD): δ =177.7 (C═S), 157.5 (C═O), 77.9 (C-2), 32.9 (1-$CH_3$), 18.2 (2-$CH_3$). Lactam **15** (17 mg, 0.12 mmol) was added to $Ac_2O$ (0.24 mL, 2.54 mmol) and the mixture allowed to stand at room temperature for 16 h. After concentration *in vacuo*, water was added and the precipitate isolated by filtration. Yield 10 mg (46%), m. p. 125°C. IR: $\tilde{\nu}$ = 1762, 1731, 1533 cm$^{-1}$. $^1$H NMR: δ = 1.68 (d, $J$ = 5.8 Hz, 3 H, 2-$CH_3$), 2.65 (s, 3 H, Ac─$CH_3$), 3.42 (s, 3 H, $CH_3N$), 5.44 (q, $J$ = 5.8 Hz, 1 H, 2-H). $^{13}$C NMR: δ = 180.6 (C═S), 169.8 (C═O), 156.1 (C═N), 72.3 (C-2), 33.3 (1-$CH_3$), 25.2 (Ac─$CH_3$), 18.7 (1-$CH_3$). MS: m/z (%) = 186 (74) [M], 144 (75), 129 (18), 74 (100).

***Crystal structure determinations of disulfide 9.*** Intensity data were collected with a CAD 4-SDP single-crystal diffractometer (Enraf-Nonius) using graphite-monochromated Cu Kα radiation in the rage θ < 60°. The final refinements were based on 1657 symmetry-independent reflections with $I > 3\sigma$ for I. The structure was solved by the direct-methods program MULTAN. The $E$ map revealed the position of all the heavy atoms. Because of the thinness of the crystal, the positions of the hydrogen atoms were geometrically calculated, but difficult to refine. Convergence was achieved at $R$ = 0.060 ($R_w$ = 0.071). $C_{16}H_{24}N_{10}S_4$, $M_r$ = 484.7, monoclinic, $a$ = 755.2(1), $b$ = 22726(1), $c$ = 1992.8(1) pm, β = 100.32(1)°, $V$ = 2.352 × 10$^9$ pm$^3$, $T$ = room temp., space group Cc, $Z$ = 4, $d_{cal.}$ 1.38 g cm$^{-1}$, $\mu_{Cu\ K\alpha}$ = 38.7 cm$^{-1}$ [22].

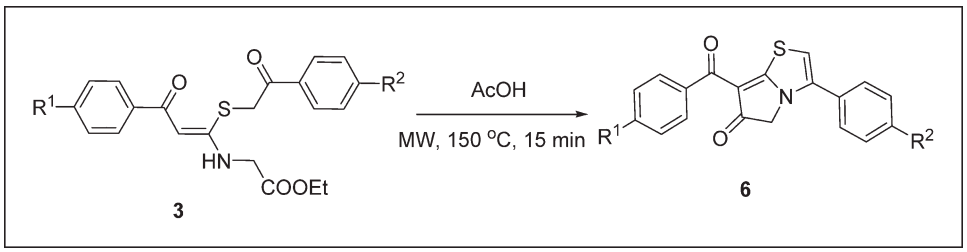
*This article is dedicated to our research guide Dr. C. V. Asokan who died on February 3, 2007.*



α-Aroyl ketene-*N*,*S*-acetals **3** prepared by the reaction of β-oxothioamides **1** with phenacyl bromides **2**, underwent sequential cyclizations under microwave irradiation to afford pyrrolo[2,1-*b*]thiazol-6-ones **6** in good yields. A double cyclization takes place regioselectively in one pot and variety of functionalized pyrrolo[2,1-b]thiazol-6-ones were prepared by this protocol. The mode of cyclization under microwave condition is different from conventional heating.

*J. Heterocyclic Chem.*, **47**, 430 (2010).

## INTRODUCTION

The structural diversity and biological importance exhibited by pyrrolothiazoles have made them attractive targets for synthesis [1]. Pyrrolo[2,1-*b*]thiazoles are known to display a wide range of biological activities such as antileukemic [2], platelet-activating factor antagonistic [3] and for prevention and treatment of various liver diseases [4]. The common strategy for their syntheses involves ring annelation of appropriately functionalized pyrroles [5,6] or thiazoles [7,8]. Other approaches are based on the cycloaddition reactions of thiazolium ylides [9], imidazo[2,1-*b*]thiazoles [10] or mesoionic thiazolo[3,2-*c*]oxazoles [2] with dimethyl acetylenedicarboxylate and related unsaturated acid derivatives. Recently, thiazadiene, an unsymmetrical polyhetropolyene, on sequential reaction with α-carbonyl bromide was converted into pyrrolo[2,1-*b*]thiazoles [11]. Ring contraction strategy is also used for constructing this heterobicyclic system [12]. All these reported methods needed multistep reaction sequences. Recently, microwave-assisted organic synthesis has attracted considerable attention due to enhanced reaction rates, high yields, improved selectivity, and cleaner products [13]. Herein, we report an efficient, microwave assisted, and environmentally benign one pot method for the preparation of pyrrolo[2,1-*b*]thiazol-6-ones **6** from easily accessible α-aroyl ketene-*N*,*S*-acetals **3**. To the best of our knowledge, this is the first report on the direct transformation of an open chain system into pyrrolo[2,1-*b*]thiazole derivative using a one pot strategy.

Direct alkylation of thioamides using alkyl halide affords ketene-*N*,*S*-acetals which is widely used as a synthon in heterocyclic synthesis [14]. Recently we have explored the synthetic potential of α-aroyl ketene-*N*,*S*-acetals prepared by the alkylation of β-oxothioamides **1** for the synthesis of functionalised pyrroles [15]. α-Aroyl ketene-*N*,*S*-acetals were previously prepared in our laboratory as an intermediate for the synthesis of functionalized thiophenes *via* alkylation of thioamides using 1,2-bielectrophiles in presence of base [16].

## RESULTS AND DISCUSSION
