## CONCLUSIONS

In conclusion, we found a mild and efficient method for the synthesis of *trans*-cryptotackiene derivatives via three-component reactions of aromatic aldehyde, 3-amino-9-ethylcarbazole, and 2,3-dihydrofuran or 3,4-dihydro-2*H*-pyran catalyzed by iodine. The features of this procedure are mild reaction conditions, good to high yields, operational simplicity, and high stereoselectivity.

## EXPERIMENTAL

Melting points were determined in open capillaries and are uncorrected. IR spectra were recorded on a TENSOR 27 spectrometer in KBr pellet. $^1$H NMR spectra were obtained from solution in DMSO-$d_6$ with $Me_4Si$ as internal standard using a Bruker-400 spectrometer. HRMS analyses were carried out using Bruker-micro TOF-Q-MS analyzer.

**General procedure for the syntheses of *trans*-4-aryl-8-ethyl-3,3*a*,4,5,8,12*d*-hexahydro-2*H*-furo[3,2-*c*]indolo[3,2-*f*]quinoline or *trans*-5-aryl-9-ethyl-2,3,4,4*a*,5,6,9,13*d*-hexahydropyrano[3,2-*c*]indolo[3,2-*f*]quinoline derivatives 4.** A dry 50 mL flask was charged with aromatic aldehyde (2.0 mmol), 2,3-dihydrofuran or 3,4-dihydro-2*H*-pyran (3.0 mmol), 3-amino-9-ethylcarbazole (0.420 g, 2.0 mmol), $I_2$ (0.026 g, 0.1 mmol), and THF (10 mL). The reaction mixture was stirred at reflux condition for 12–20 h, and then cooled to room temperature. The generated yellow solid was filtered off. The crude yellow products were washed with ethanol and purified by recrystallization from DMF and water, followed by being dried at 50°C several hours at vacuum to give **4**.

Acid-mediated condensation between benzoylpyruvates and various dinucleophiles in alcoholic solvent furnished the heterocyclic imprint in moderate to good yield. Combining a range of symmetric as well as nonsymmetric nitrogen/nitrogen or nitrogen/carbon centered dinucleophiles resulted in excellent regioselectivity. γ-Difunctionalized fused pyrimidines, pyridazines, and pyridines were produced in this manner. The protocol was designed to obviate chromatographic purification.

## INTRODUCTION

Addition of ambivalent nitrogenous nucleophiles to β-diketones offers an attractive entry to the preparation of aromatic heterocyclic structures carrying distinct functional motifs. Acting as a template, the structural features of the β-diketone provide the central framework to be resonated in the resulting aza-heterocycle. We have in particular directed our attention towards the application of benzoylpyruvates **1** as the means to prepare pyridine and pyrimidine derivatives incorporating a γ-related aryl ester pattern.

From a pharmaceutical point of view, the spatial arrangement of substituents conferred on heterocycles via benzoylpyruvate chemistry is highly interesting, as it can give rise to pronounced biological activity. For example, pyrazoles, isoxazoles, pyrimidines, and pyridines carrying a γ-aryl carboxy motif are associated with such diverse effects as GPCR antagonism [1–4], ion-channel modulation [5], and kinase inhibition [6,7].

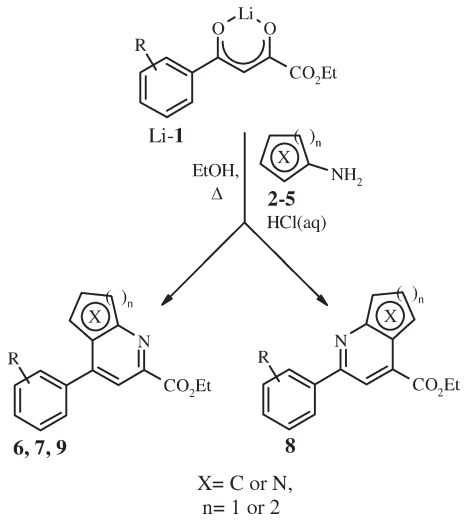
Herein, we want to report a convenient route for the preparation of novel γ-arylated aza-heterocyclic esters by highly chemo- and regioselective condensation of lithio benzoylpyruvate **1** with aromatic amines **2–5** (Scheme 1). Considering the number of different benzoylpyruvates **1** readily available from commercial acetophenones **10**, this protocol can be seen as an alternative to arylation of the parent heterocyle via cross-coupling reactions. Indeed, the preparation of prerequisite substrate for the corresponding cross-coupling may be a nontrivial matter. In contrast, merited by the ease of execution, the delineated condensation strategy is amenable for parallel synthesis.

## RESULTS AND DISCUSSION

As is expected for β-diketones lacking a mirror plane, the ambiphilic nature of benzoylpyruvates poses a potential regiochemical problem. However, in the latter case, the reactivity gets further complicated by the presence of the ester functionality. Although the ester functionality imparts the adjacent carbonyl with an augmented electron deficiency, it might itself undergo nucleophilic attack, thereby giving rise to a potential chemoselective problem as well (Fig. 1) [8].

In general, the stipulated benzoylpyruvate **1** can readily be accessed by reacting the metal enolate of the

**Scheme 1**



corresponding acetophenone **10** with diethyl oxalate **11** [9–11]. In particular, owing to the excellent chelating ability of β-diketones, the *en route* lithium salt of benzoylpyruvate **1** can usually be isolated as a shelf-stabile solid by simple filtration [11]. Thus, sequential treatment of **10** with LDA and diethyl oxalate **11** was the preferred method to prepare the needed starting material (Scheme 2). Initially, we opted for the *p*-Br-substituted benzoylpyruvate Li-**1** as a model compound, expecting it to be conducive in terms of product identification, based on its isotopic fingerprint (LC-MS) and crystallographic properties (X-ray). However, in some cases we found that the parent benzoylpyruvate Li-**1** (R = H) proved superior for crystallographic purposes.

Although the binding of lithium was beneficial with regard to the isolation of **1**, the chelated form proved to have an adverse effect on the cyclodehydration. Without *in situ* quenching of Li-**1**, concomitant retro-aldol reaction was observed on the application of any prospect dinucleophile in refluxing ethanol. Consequently, the initial attempts only returned acetophenone **10** as the breakdown product.

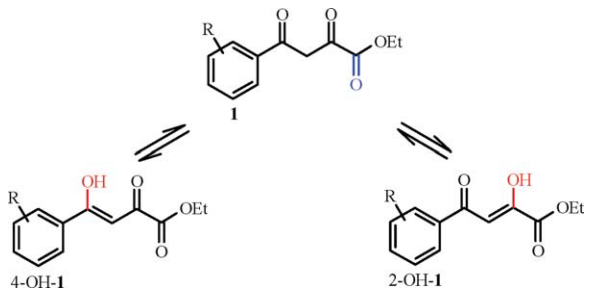


**Figure 1.** Tautomery in benzoylpyruvates. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

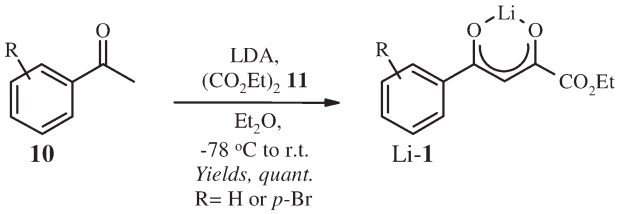
**Scheme 2**



Gratifyingly, when first having treated Li-**1** with two equivalents of hydrochloric acid, subsequent cyclodehydration could be realized for a range of aromatic amines **2–5** *vide infra*. Furthermore, the reaction displayed a distinct regiochemical preference in each case.

In accordance with the delineated protocol, a selection of five-membered aza-heterocyclic amines **2** was reacted with Li-**1** to furnish the corresponding [*a*]-fused pyrimidines **6** (Scheme 3). However, the influence exerted by the individual N,N-dinucleophiles on the success of cyclodehydration implicated a dependency on the p$K_a$ of the protonated parent heterocyclic system (Table 1). To expand upon the latter point, the p$K_a$-values of pyrazole, 1,3,4-triazole, and tetrazole are 2.5, 2.2, and –3.0, respectively [12,13], whereas the p$K_a$ of imidazole is 7.0 [12]. This may provide an explanation for the failure of imidazole **2b** and benzimidazole **2f** to react under the given conditions.

By the means of single-crystal diffraction technique, it was subsequently possible to make an unambiguous regiochemical assignment of **6b** (Fig. 2), resulting from cyclodehydration with pyrazole **2a**. Curiously, a reversal of regiochemistry takes place when interchanging the ester moiety in Li-**1** for a $CF_3$-group, *i.e.*, turning the system into a conventional β-diketone. Thus, applying a similar protocol as ours, Filyakova *et al.* have reported on the preparation of an analogous 5-phenyl-7-(trifluoromethyl)pyrazolo[1,5-*a*]pyrimidine, which was verified by crystallography [14]. The two opposing results indicate the ability of the ester to act as regiochemical handle (*vide infra*).

With respect to regiochemistry, the fused system obtained through condensation of tetrazole **2d** posed the intriguing possibility of valence tautomery [15]. At the outset, it was expected that the initially formed tetrazolo[1,5-*a*]pyrimidines **6f** and **6g** could undergo

equilibration to 2-azidopyrimidines **12f, g** (Fig. 3). However, the ''pseudo symmetry'' of **12f, g** would then obliterate the existing regiochemical preference via the erosive interconversion to **13f, g**. Subsequently, it was indeed demonstrated by the application of X-ray crystallography that in the solid state the tentatively assigned structure of fused tetrazole **6f** actually was 2-azidopyrimidine **12f** (Fig. 4).

Having established the feasibility of cyclodehydration on Li-**1** utilizing selected N,N-dinucleophiles, the focus of the protocol was aimed at fusion with other types of five-membered aza-heterocylic amines, *i.e.*, prospective C,N-dinucleophiles. Following this line of reasoning, Li-**1** was allowed to react with N-amino heterocycles **3** to provide [*b*]-fused pyridazines **7** (Scheme 4). In the selected cases, the observed regiochemistry corresponded to the results obtained with aryl amines **2**. Here, however, the degree of aza-functionalization had a dramatic influence on the efficiency, with regard to product formation (Table 2).

Five-membered aza-heterocycles with an encased ethylene amine motif could in principle be rendered operational C,N-dinucleophiles via blocking or replacing the active ring-nitrogen. Hence, it was envisioned that the ''aniline-type'' aryl amines **4** would furnish [*b*]-fused pyridines. Although the primary projection was correct, the regiochemistry was at variance with the preceding examples. Thus, when Li-**1** was reacted with C,N-dinucleo-philes **4**, the resultant cyclodehydration provided the [*b*]-fused pyridine **8** (Scheme 5).

Applied on the product originating from condensation between Li-**1** (R = H) and ''enamine'' **4a**, X-ray crystallography provided the conclusive structural information, showing **8b** to be the resulting regioisomer (Fig. 5).

Though, seemingly contradictory, with regard to benzoylpyruvate **1**, the sequence of addition leading to the different fused systems could well be the same (*vide supra*). Instead, it was surmised that the origin of regiochemical divergence resided on the nature of the applied dinucleophile. Depending on the hard/soft character of the aryl amine, in analogy with enamines, either the interconnected nitrogen or carbon could take precedence in the cyclodehydration. However, it also became clear

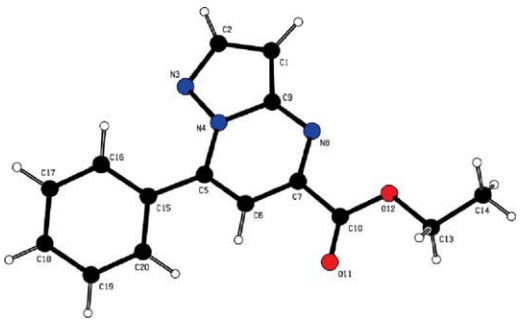

**Figure 2.** Crystal structure of compound **6b** determined by single-crystal diffraction technique at 200 K. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

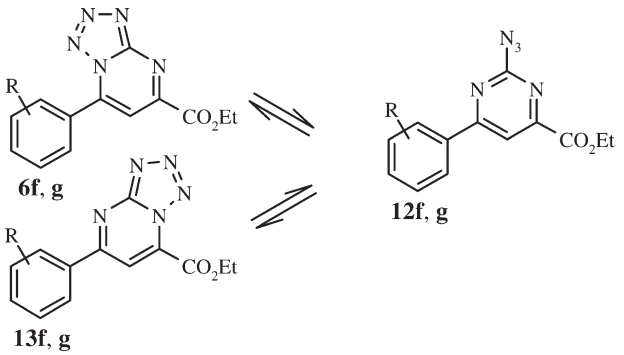

**Figure 3.** Valence tautomery in tetrazolo[1,5-a]pyrimidine **6f** and **6g**.

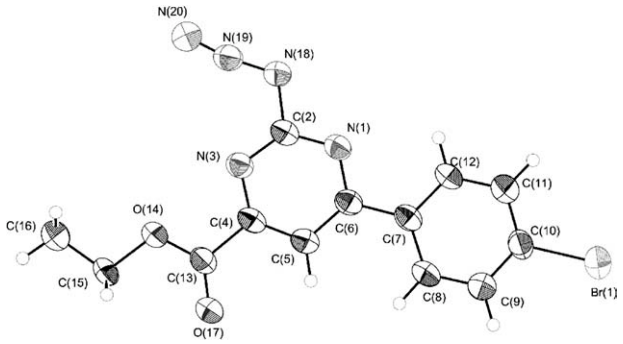

**Figure 4.** ORTEP presentation of compound **12f**.

that the choice of C,N-dinucleophiles **4** was rather limited (Table 3).

By extending the ensemble of C,N-dinucleophiles to six-membered aryl amines **5**, *i.e.*, *bona fide* anilines, it was anticipated that the regiochemistry would realign with the initially observed preference to provide [*b*]-fused pyridines **9** (Scheme 6). However, if the underlying assumption regarding the regiochemical preference of benzoylpyruvate **1** proved correct, the resulting quinolines **9** would have the reversed structure compared with the Skraup–Doebner–von Miller protocol [15].

Upon reacting Li-**1** with anilines **5**, it became evident that cyclodehydration could only be achieved when strongly electron donating substituents were present on the aryl moiety of the prospective C,N-dinucleophile (Table 4). The interplay of electronic properties is however more subtle than what might initially be gleaned from the reaction scheme. Thus, when Li-**1** was treated

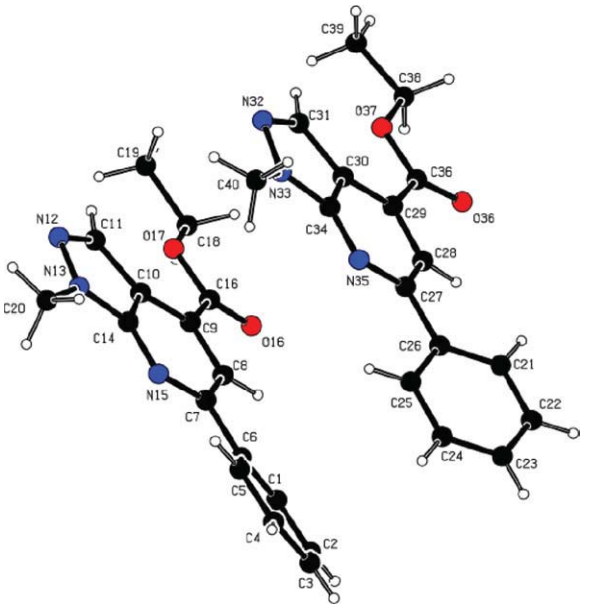

**Figure 5.** Crystal structure of compound **8b** determined by single-crystal diffraction technique at 200 K. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

with 4-amino-1H-indole **5d**, cyclization proceeded smoothly (entry 8 and 9). While, in contrast, the reaction with 6-amino-1H-indole **5e** was exceedingly sluggish (entry 11). Yet in both instances, the position *ortho* to the aniline functionality is activated by an indole-nitrogen (Fig. 6).

Another aspect of the 4-amino-1H-indole derivatives **9f** and **9g** is the comprehensive prototropic tautomery available to the fused rings. Thus, in the pertinent case, $^1$H NMR indicates that the extended 14 π-electron system

[b] Time to achieve full conversion or no further reaction occurred by HPLC or LC-MS.
[c] Isolated yield.
[d] Preparative HPLC due to instability.

behaves less aromatic than anticipated. The repositioning of the active proton also involves carbon prototropes and the only specie observed by NMR-spectroscopy was attributed to the 4H-tautomer (Fig. 7). This behavior probably reflects the ''quinone-like'' nature of the compound.

By comparison, the linear isomer **9i** resulting from condensation of Li-**1** (R = H) with 6-amino-1H-indole **5e** behaves more like an aromatic 14 π-electron system and prototropic tautomery is less pronounced. However, in general the quinolines **9** were less stabile than the previous classes of cyclodehydration products **6**, **7**, and **8**.

With regard to the identity of the resulting compounds, we once again resolved to address the issue of regiochemical preference by capitalizing on X-ray crystallography. Applied to the cyclodehydration of Li-**1** (R = Br) with 3-(*N*,*N*-dimethylamino)aniline **5d**, the structure was shown to be **9d** (Fig. 8). Thus, the condensation between benzoylpyruvates **1** and anilines **5** provide verily regioisomeric quinolines not attainable via the classic Skraup–Doebner–von Miller procedure [15].

## CALCULATIONS

In the light of some contrasting findings published by Filyakova *et al*. regarding condensation on selected β-diketones [14], we wanted to make a side-by-side comparison with benzoylpyruvate **1**, applying high-level QM calculations to gain insight into the origin of the observed regio-divergence.

Discounting the reactive nature of the ester moiety, a cursory inspection of benzoylpyruvate **1** might pin down the system as merely a benzoylacetone with an electron withdrawing group append to its terminus. Indeed from

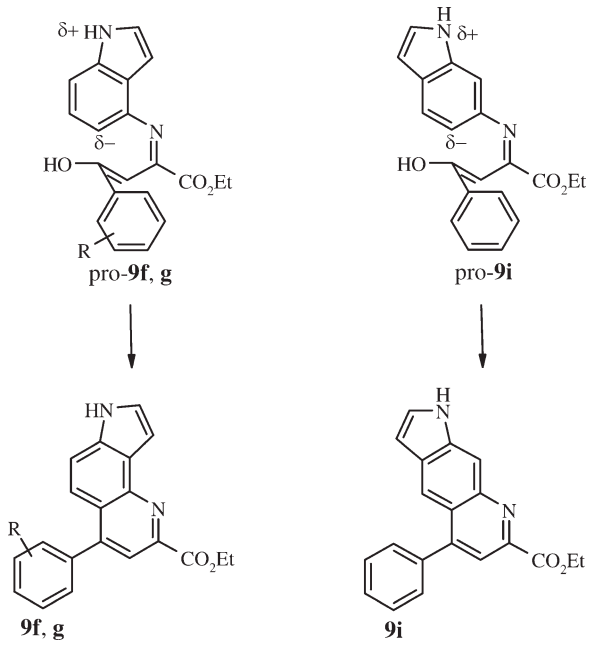

**Figure 6.** Tricycles resulting from condensation with 4-amino-1H-indole **5e** and 6-amino-1H-indole **5f**.

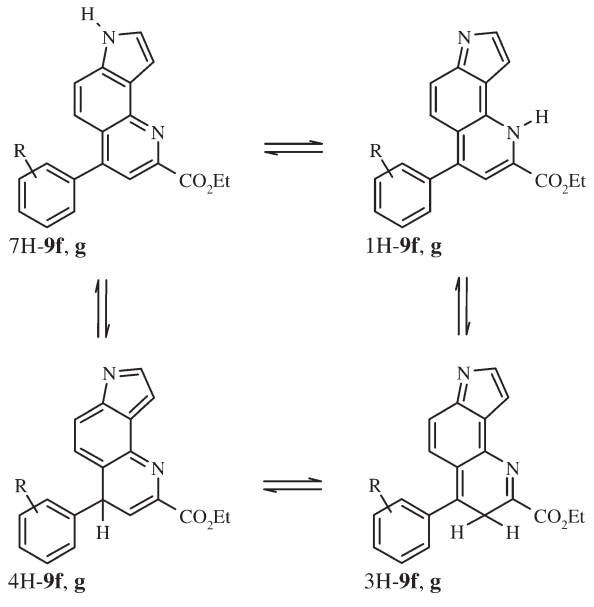

**Figure 7.** Tautomery in pyrrolo[2,3-h]quinolines **9f** and **9g**.

**Figure 8.** Crystal structure of compound **9d** determined by single-crystal diffraction technique at 200 K. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

this vantage point, benzoylpyruvate **1** compares well with the fluorinated β-diketone **14** used by Filyakova *et al*. [14]. Thus, in both cases, the keto-functionalities might be projected to exhibit ''pseudo-degenerate'' behavior (Fig. 9). As an initial conjecture, one would consequently expect cyclodehydration on benzoylpyruvate **1** and fluorinated β-diketone **14** to give rise to similar regioselectivity. Indeed, our calculations on the relative energies of protonated β-diketone **14** only differ with 0.3 kcal/mol for the two positions. This is within the error margin of the applied method [16].

Taking into account, the participation of the ester moiety in benzoylpyruvate **1** alters the picture dramatically: The ability of the ester function to act as a hydrogen bond acceptor facilitates formation of a five-membered chelate with the adjacent carbonyl. According to the performed calculations, using methyl derivative **15** as a model compound, the individual protonated forms of the β-diketo system alone are energetically comparable. However, when the protonated forms involving a five-membered chelate are introduced, the energy of the system is markedly lower by 2.6 and 3.2 kcal/mol, respectively (Fig. 10) [16,17]. Thus, these calculations lend support to the hypothesis that the ester moiety in benzoylpyruvate **1** may serve as a regiochemical handle.

## CRYSTALLOGRAPHY

**Data collection, structure solution, and refinement.** Diffraction data for (**6b**), (**8b**), (**9f**), and (**12a**) were collected at 200(2) K using either a Nonius Kappa-CCD or a Bruker APEX-II CCD diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The structures were solved by direct methods and refined with $F^2$ against all reflections. All but one had one molecule in the asymmetric unit, which for **8b** contained two crystallographically unique molecules. Figures 2–5 and 8 show the molecular conformation, with the atom-labeling schemes. Compounds **6b**, **8b**, **9d**, and **12a** do not contain H-bond donor atoms and consequently do not form classical H-bonds [18].

## CONCLUSIONS

This article outlines a simple and versatile approach to furnish fused heterocycles grafted on the benzoylpyruvate backbone. Depending on the nature of the applied dinucleophilic class, an alternation of regiochemistry could be observed. However, in each case the process was highly regioselective. At the basis of the observed selectivity, we postulate the participation of the ester portion in benzoylpyruvates as a decisive factor.

## EXPERIMENTAL

NMR spectra were recorded either on a Bruker DPX400 NMR spectrometer operating at 400 MHz for $^1$H, and 101 MHz for $^{13}$C equipped with a four-nucleus probe-head with Z-gradients, or a Bruker Avance III 500 NMR spectrometer, operating at 500 MHz for $^1$H and 126 MHz for $^{13}$C equipped

with a 5mm TCI cryo probe-head with Z-gradients. Chemical shifts are given in ppm down- and upfield from tetramethylsilane (0.00 ppm). DMSO-$d_6$ $\delta_H$ 2.49; $\delta_C$ 39.51 and $CDCl_3$ $\delta_H$ 7.27; $\delta_C$ 77.00 were used as reference signals. All experiments were performed at a sample temperature of 26°C ± 2°C. LC-MS analyses were performed on a LC-MS system consisting of a Waters Alliance 2795 HPLC, a Waters PDA 2996 diode array detector, a Sedex 75 ELS detector, and a ZQ 2000 single quadrupole mass spectrometer. The mass spectrometer was equipped with an electrospray ion source (ES) operated in positive and negative ion mode. The capillary voltage was set to 3.3 kV and the cone voltage to 28 V, respectively. The mass spectrometer was scanned between *m*/*z* 100–700 with a scan time of 0.3 s. The diode array detector scanned from 200–400 nm. The temperature of the ELS detector was adjusted to 40°C and the pressure was set to 1.9 bar. Separation was performed on Gemini C18 3.0 × 50, 3 μm (Phenomenex) run at a flow rate of 1 mL/min. A linear gradient was applied starting at 100% A (A: 10 m*M* ammonium acetate in 5% acetonitrile) ending at 100% B (B: acetonitrile) in 4 min followed by 100% B until 5.5 min. The column oven temperature was set to 40°C. HPLC analyses were performed on an Agilent HP1100 system consisting of a G1322A Micro Vacuum Degasser, a G1311A Quaternary Pump, a G1367 Well-Plate Autosampler, a G1316A Thermostated Column Compartment and a G1315A Diode Array Detector. The diode array detector was scanned from 200 to 400 nm, step and peak width were set to 2 nm and 0.01 min, respectively. The column used was Gemini C18, 3.0 × 50 mm, 3.0 μm, 110 Å run at a flow rate of 1.0 mL/min. The column oven temperature was set to 40°C. A linear gradient was applied, starting at 100% A (A: 10 m*M* ammonium acetate in 5% acetonitrile) and ending at 95% B (B: acetonitrile) after 6.5 min then 95% B for 0.5 min. High resolution mass spectra (HRMS) were recorded on a Micromass Q-Tof micro mass spectrometer equipped with a LockSpray source and connected to an Acquity UPLC system with a PDA detector. All analyses were acquired using positive mode electrospray ionisation (ESI+) in full scan and Leucine Enkephalin (Sigma) was used as the lock mass (*m*/*z* 556.2771) at a concentration of 0.9 pmol/μL and a flow rate of 100 μL/min with a 1:10 split, ion source:waste. Cone Voltage was set to 54 to achieve ∼ 200 counts for Leucine Enkephalin. Nitrogen was used as the nebulizing and desolvation gas, with the source operated at 120°C and the desolvation gas at 300°C. Capillary voltage was about 3000 V and cone voltage was about 30 V. Argon was used as the collision gas. Chromatographic separation for HRMS was achieved with a 2.3 min linear gradient from 95% A (A: 10 m*M* ammonium acetate in MilliQ water + 5% acetonitrile) to 95% B (B: acetonitrile) over an ACQUITY UPLC BEH C18 1.7 μm, 2.1 × 50 mm column maintained at 65°C and run at a flow rate of 0.7 mL/min with a 1:5 split, ion source:waste. Analytes were diluted in $H_2O$:ACN (50:50) until suitable concentration for the LC-MS analysis.

**General methods for the condensation of benzoylpyruvates (Li-1, R = H, Br) with dinucleophiles (2–5).** Lithio 2,4-dioxo-4-phenylbutyric acid ethyl ester (Li-**1**, R = H) (0.226 g, 1.00 m*M*) or lithio 2,4-dioxo-4-(4′-bromophenyl)butyric acid ethyl ester (Li-**1**, R = Br) (0.305 g, 1.00 m*M*) and the appropriate dinucleophile (**2–5**) (1.00 m*M*) were mixed together, suspended in ethanol (5.0 mL) and conc. aqueous hydrochloric acid (166 μL, 12.0*M*, 2.00 m*M*) was added. The resulting homogeneous mixture was heated and refluxed for the times given (*vide supra*). After heating, the reaction mixture was allowed to slowly cool to ambient temperature. In case of precipitation, the deposited material was collected, washed with ethanol, and the mother liquor was evaporated *in vacuo*. Upon evaporation, the remnant was recrystallized from ethanol and further cropped.

If no initial precipitation occurred, the reaction mixture was evaporated *in vacuo*, whereupon the remnant was dissolved in chloroform and washed with dilute aqueous sodium hydroxide. The organic phase was subsequently evaporated *in vacuo* and the remnant was dissolved in hot methanol, ethanol, or extracted with boiling hexane. Subsequently, upon cooling crystallization ensued and the deposited material was cropped.

***Ethyl 4-(4-bromophenyl)-1H-pyrazolo[3,4-b]pyridine-6-carboxylate (6a).*** The title compound was obtained by the reaction of lithio 2,4-dioxo-4-(4′-bromophenyl)butyric acid ethyl ester (Li-**1**, R = Br) and 3-aminopyrazole (**2a**). Yield: 0.259 g (75%). $^1$H NMR ($CDCl_3$): δ 1.49 (t, 3H, *J* = 7.2 Hz), 4.56 (q, 2H, *J* = 7.1 Hz), 7.05 (d, 1H, *J* = 2.3 Hz), 7.70 (s, 1H), 7.7–7.8 (m, 2H), 8.0–8.1 (m, 2H), 8.28 (d, 1H, *J* = 2.3 Hz). $^{13}$C NMR ($CDCl_3$): δ 14.3, 62.8, 100.0, 106.7, 126.1, 129.4, 130.8, 132.0, 145.98, 146.01, 146.3, 148.9, 164.0. HRMS: Found 346.0198, Calcd. for $C_{15}H_{13}BrN_3O_2$: 346.0191.

***Ethyl 4-phenyl-1H-pyrazolo[3,4-b]pyridine-6-carboxylate (6b).*** The title compound was obtained by the reaction of lithio 2,4-dioxo-4-phenylbutyric acid ethyl ester (Li-**1**, R = H) and 3-aminopyrazole (**2a**). Yield: 0.185 g (69%). $^1$H NMR ($CDCl_3$): δ 1.50 (t, 3H, *J* = 7.1 Hz), 4.57 (q, 2H, *J* = 7.1 Hz), 7.05 (d, 1H, *J* = 2.5 Hz), 7.6–7.7 (m, 3H), 7.71 (s, 1H), 8.1–8.2 (m, 2H), 8.29 (d, 1H, *J* = 2.3 Hz). $^{13}$C NMR ($CDCl_3$): δ 14.3, 62.7, 99.8, 106.9, 128.8, 129.3, 130.6, 131.4, 146.0, 146.4, 147.2, 149.0, 164.1. HRMS: Found 268.1097, Calcd. for $C_{15}H_{14}N_3O_2$: 268.1086.

***Ethyl 7-(4-bromophenyl)-[1,2,4]triazolo[1,5-a]pyrimidine-5-carboxylate (6d).*** The title compound was obtained by the reaction of lithio 2,4-dioxo-4-(4′-bromophenyl)butyric acid ethyl ester (Li-**1**, R = Br) and 3-amino-1,2,4-triazole (**2c**). Yield: 0.255 g (73%). $^1$H NMR ($CDCl_3$): δ 1.50. (t, 3H, *J* = 7.2 Hz), 4.57 (q, 2H, *J* = 7.1 Hz), 7.78 (d, 2H, *J* = 8.6 Hz), 8.03 (s, 1H), 8.11 (d, 2H, *J* = 8.60 Hz), 8.70 (s, 1H). $^{13}$C NMR ($CDCl_3$): δ 14.2, 63.2, 108.6, 127.4, 128.0, 130.9, 132.4, 147.8, 151.9, 155.7, 157.6, 163.5. HRMS: Found 347.0151, Calcd. for $C_{14}H_{12}BrN_4O_2$: 347.0144.

***Ethyl 7-phenyl-[1,2,4]triazolo[1,5-a]pyrimidine-5-carboxylate (6e).*** The title compound was obtained by the reaction of lithio 2,4-dioxo-4-phenylbutyric acid ethyl ester (Li-**1**, R = H) and 3-amino-1,2,4-triazole (**2c**). Yield: 0.187 g (70%). $^1$H NMR ($CDCl_3$): δ 1.40 (t, 3H, *J* = 7.1 Hz), 4.57 (q, 2H, *J* = 7.1 Hz), 7.6–7.7 (m, 3H), 8.04 (s, 1H), 8.1–8.2 (m, 2H), 8.70 (s, 1H). $^{13}$C NMR ($CDCl_3$): δ 14.2, 63.1, 108.8, 129.1, 129.3, 129.5, 132.4, 149.0, 151.8, 155.7, 157.6, 163.5. HRMS: Found 269.1039, Calcd. for $C_{14}H_{13}N_4O_2$: 269.1039.

***Ethyl 2-azido-6-(4-bromophenyl)pyrimidine-4-carboxylate (12f).*** The title compound was obtained by the reaction of lithio 2,4-dioxo-4-(4′-bromophenyl)butyric acid ethyl ester (Li-**1**, R = Br) and 5-aminotetrazole (**2d**). Yield: 0.277 g (79%). $^1$H NMR ($CDCl_3$): δ 1.46 (t, 3H, *J* = 7.1 Hz), 4.51 (q, 2H, *J* = 7.2 Hz), 7.6–7.7 (m, 2H), 8.0–8.1 (m, 2H), 8.11 (s, 1H). $^{13}$C

NMR ($CDCl_3$): δ 14.2, 62.9, 111.9, 127.2, 128.9, 132.4, 133.9, 158.2, 163.0, 163.7, 167.0. HRMS: Found 348.0099, Calcd. for $C_{13}H_{11}BrN_5O_2$: 348.0096.

***Ethyl 2-azido-6-phenyl-pyrimidine-4-carboxylate (12g).*** The title compound was obtained by the reaction of lithio 2,4-dioxo-4-phenylbutyric acid ethyl ester (Li-**1**, R = H) and 5-aminotetrazole (**2d**). Yield: 0.182 g (68%). $^1$H NMR ($CDCl_3$): δ 1.47 (t, 3H, *J* = 7.1 Hz), 4.51 (q, 2H, *J* = 7.1 Hz), 7.5–7.6 (m, 3H), 8.15 (s, 1H), 8.2 (m, 2H). $^{13}$C NMR ($CDCl_3$): δ 14.1, 62.8, 112.2, 127.5, 129.1, 132.2, 134.5, 157.9, 162.9, 163.8, 168.2. Tetrazolo[1,5-*a*]pyrimidines are capable of serving as masked azides in copper-catalyzed Huisgen cyclization with a variety of terminal alkynes, providing a simple protocol for the generation of novel 4′-substituted 2-(1′,2′,3′-triazol-1′-yl)pyrimidines.

*J. Heterocyclic Chem.*, **47**, 887 (2010).

## INTRODUCTION

In recent years, the application of transition metals to promote 1,3-dipolar cycloaddition between organic azides and alkynes has effected a revitalization of the field pioneered by Huisgen *et al.* in the 1960s [1]. This surge of attention has been brought about by reports from the research groups of Meldal and Sharpless, independently demonstrating how the catalytic presence of copper(I) facilitates a remarkable enhancement of reactivity and regioselectivity, in the case of terminal alkynes acting as the dipolarophile [2,3].

The intrinsic affinity of organic azides toward terminal alkynes, realized in the established protocol, has prompted Sharpless to coin the term ''Click Chemistry'' [4]. However, despite the many merits publicized to endorse copper-catalyzed azide-alkyne cycloaddition (CuAAC) [5,6], there is a notable absence of examples involving electron deficient 1,3-dipoles.

In the instance of electron deficient hetaryl azides, the authors of this article have only come across a handful of articles entailing CuAAC [7–9]. The obvious reason is the ability of the appended heterocycle to disperse negative charge residing on the azide, thereby disrupting its innate dipolar nature and hampering the concomitant cycloaddition.

The reactivity can be improved through the introduction of electron donating substituents on the heterocyclic moiety, enabling the CuAAC to take place under non-forcing conditions [7,8]. Conversely, the absence of any mitigating functionality may result in a sluggish reaction that demands elevated temperature and auxiliary reagent to bring about conversion [9,10].

Observing the facile reaction between β-diketones **1** and 5-aminotetrazole **2** as an entry to 2-azidopyrimidines **4**, we wanted to explore their ability to undergo alkyne cycloaddition within the context of copper(I) catalysis [11].

## RESULTS AND DISCUSSION

The electron deficient 1,3-dipoles, projected as the investigative starting point for CuAAC, were synthesized by performing cyclodehydration on the appropriate β-diketone **1** with 5-aminotetrazole **2**, capitalizing on the tautomeric equilibrium existing between tetrazolo[1,5-*a*]-pyrimidine **3** and 2-azidopyrimidine **4** (Scheme 1). It was found that the presence of either Brönsted or Lewis acid in refluxing alcoholic solvent advanced cyclodehydration, allowing the prerequisite azides to be isolated in high purity by simple filtration upon cooling of the reaction media (Table 1).

The coexistence of **3** and **4**, through valence tautomery, seems to be an inherent feature of fused tetrazoles. However, the directional preference of the equilibrium is subject to several factors, including phase, solvent, temperature, and pH [12].

[a] The reactions were run with equimolar proportions of diketone **1** and aminotetrazole **2**.
[b] The corresponding dimethyl acetal **1a** was used.
[c] Method A: 10 mol % of conc. HCl (aq) in refluxing solvent. Method B: Preincubated solution of 10 mol % $CuCl_2$ and 10 mol % Vitamin C at ambient temperature.
[d] Isolated yield.
[e] The measured exotherms are >800 J/g, the compounds should thus be treated as potentially explosive. We strongly advise to take safety precautions, as e.g. described in *Bretherick's Handbook of Reactive Chemical Hazards* [14].

When applying single-crystal diffraction technique on a select cyclodehydration product, subsequent X-ray analysis clearly demonstrated that the compound preferred the azido-tautomer in the solid state (Fig. 1) [13].

Considering the generally high nitrogen content manifest in 2-azidopyrimidines **4**, the prepared compounds were submitted to differential scanning calorimetry (DSC) for the purpose of establishing safety margins (Table 1). Based on the relative thermal stability and yield, **4c** was subsequently selected as the candidate dipole to be tested in CuAAC (Scheme 2).

In accordance with the precognized conditions published by Sharpless and coworkers [3], cycloaddition was initially attempted utilizing an *in situ* generated Cu(I)-catalyst and a polar solvent. However, no product formation was observed and the reaction remained unresponsive to alteration of temperature as well as electronic modulation of the dipolarophile **5** (Table 2; entry 1,2).

Surprisingly, when the catalytic constellation was interchanged and Cu(I) instead was added directly, reaction proceeded at elevated temperatures. Furthermore, it became evident that the nature of the alkyne substituent dramatically affected the rate. Thus, with an aryl appendage, cycloaddition occurred only reluctantly, while the ester counterpart participated readily (Table 2; entry 3,4).

To encourage swifter conversion, it was in turn opted to perform the CuAAC in a nonpolar solvent. Seeing the ability to delocalize charge within its interior, the pyrimidine featured in **4c** effectively acts as an electronic

[a] The reactions were performed on an 0.47 mmol scale with equimolar proportions of azide **4c** and alkyne **5**.
[b] The reaction was run overnight.
[c] Isolated yield after recrystallization.
[d] The reactions were monitored by HPLC and LC-MS.

sink, draining the azide of its latent reactivity. Running the CuAAC in a nonpolar solvent would thus *a priori* act as a counter, disfavoring charge separation and ensure a more well-behaved dipole. Gratifyingly, the choice solvent proved efficacious in bringing about the reaction: By changing from ethanol to toluene, rapid reaction was realized with both aryl and ester appended alkyne **5**. Additionally, the catalytic mediation of copper was underpinned on the account that 4′-substituted 2-(1′,2′,3′-triazol-1′-yl)pyrimidine **6** was the sole cyclized product observed. In contrast to the preceding literature [3], neither additional base nor the exclusion of oxygen was needed, as none of the reported by-products were formed.

Having established workable conditions, the generality of the CuAAC was tested by subjecting 2-azidopyrimi-dine **4c** to an ensemble of terminal alkynes **5**, exploring both electronic and steric effects (Table 2; entry 5–18). In the majority of cases, full conversion was realized smoothly within a couple of hours and at the latest after 24 h. The isolated yield of compound **6** varied between 51 and 91% after recrystallization, which was performed to remove the catalyst.

## CONCLUSIONS

This article outlines a novel protocol for highly selective copper-catalyzed 1,3-dipolar cycloaddition between electron deficient hetaryl azides and a variety of terminal alkynes. Applied on 2-azidopyrimidines, the protocol allows smooth transformation to the corresponding 4′-substituted 2-triazolylpyrimidines in the absence of any auxiliary reagents.

## EXPERIMENTAL

NMR spectra were recorded either on a Bruker DPX400 NMR spectrometer operating at 400 MHz for $^1$H, and 101

MHz for $^{13}C$ equipped with a 4-nucleus probe-head with Z-gradients, or a Bruker Avance III 500 NMR spectrometer, operating at 500 MHz for $^{1}H$ and 126 MHz for $^{13}C$ equipped with a 5 mm TCI cryo probe-head with Z-gradients. Chemical shifts are given in ppm down- and upfield from TMS (0.00 ppm). DMSO-$d_6$ $\delta_H$ 2.49; $\delta_C$ 39.51 and $CDCl_3$ $\delta_H$ 7.27; $\delta_C$ 77.00 were used as reference signals. All experiments were performed at a sample temperature of 26°C ± 2°C. LC-MS analyses were performed on a LC-MS system consisting of a Waters Alliance 2795 HPLC, a Waters PDA 2996 diode array detector, a Sedex 75 ELS detector, and a ZQ 2000 single quadrupole mass spectrometer. The mass spectrometer was equipped with an electrospray ion source (ES) operated in positive and negative ion mode. The capillary voltage was set to 3.3 kV and the cone voltage to 28 V, respectively. The mass spectrometer was scanned between *m/z* 100 and 700 with a scan time of 0.3 s. The diode array detector scanned from 200 to 400 nm. The temperature of the ELS detector was adjusted to 40°C, and the pressure was set to 1.9 bar. Separation was performed on an Gemini C18 3.0 × 50, 3 μm (Phenomenex) run at a flow rate of 1 mL/min. A linear gradient was applied starting at 100% A (A: 10 m*M* $NH_4OAc$ in 5% $CH_3CN$) ending at 100% B (B: $CH_3CN$) in 4 min followed by 100% B until 5.5 min. The column oven temperature was set to 40°C. HPLC analyses were performed on an Agilent HP1100 system consisting of a G1322A Micro Vacuum Degasser, a G1311A Quaternary Pump, a G1367 Well-Plate Autosampler, a G1316A Thermostated Column Compartment and a G1315A Diode Array Detector. The diode array detector was scanned from 200 to 400 nm, step and peak width were set to 2 nm and 0.01 min, respectively. The column used was an Gemini C18, 3.0 mm × 50 mm, 3.0 μm, 110 Å run at a flow rate of 1.0 mL/min. The column oven temperature was set to 40°C. A linear gradient was applied, starting at 100% A (A: 10 m*M* $NH_4OAc$ in 5% $CH_3CN$) and ending at 95% B (B: $CH_3CN$) after 6.5 min then 95% B for 0.5 min. High resolution mass spectra (HRMS) were recorded on a Micromass Q-Tof micro mass spectrometer equipped with a LockSpray source and connected to an Acquity UPLC system with a PDA detector. All analyses were acquired using positive mode electrospray ionization (ESI+) in full scan, and Leucine Enkephalin (Sigma) was used as the lock mass (m/z 556.2771) at a concentration of 0.9 pmol/μL and a flow rate of 100 μL/min with a 1:10 split, ion source:waste. Cone Voltage was set to 54 to achieve ~200 counts for Leucine Enkephalin. Nitrogen was used as the nebulizing and desolvation gas, with the source operated at 120°C and the desolvation gas at 300°C. Capillary voltage was 3000 V, Cone voltage 30 V. Argon was used as the collision gas. Chromatographic separation for HRMS was achieved with a 2.3 min linear gradient from 95% A (A: 10 m*M* NH4OAc in MilliQ water + 5% MeCN) to 95% B (B: MeCN) over an ACQUITY UPLC BEH C18 1.7 μm, 2.1 mm × 50 mm column maintained at 65°C and run at a flow rate of 0.7 mL/min with a 1:5 split, ion source:waste. Analytes were diluted in H2O:ACN (50:50) until suitable concentration for the LC-MS analysis. DSC was performed in a Mettler Toledo DSC 820 equipped with a high-pressure gold-plated capsule in the temperature range of 30–500°C using a heating rate of 5 K/min.

**2-Azido-4-methylpyrimidine (4a)**

***Method B.*** $CuCl_2$ (10.1 mg, 0.07 mmol) was dissolved in MeOH (2 mL), resulting in a green solution. Ascorbic acid (13.3 mg, 0.07 mmol) was added and the mixture was stirred for 5 min, to give a colorless solution. 4,4-Dimethoxybutan-2-one (**1a**) (100 mg, 0.76 mmol) and 1H-tetrazol-5-amine (**2**) (64.4 mg, 0.76 mmol) were added in sequence and the mixture was stirred at ambient temperature for 3 h. Saturated $NH_4Cl$ (10 mL) was added and the resulting suspension was extracted with EtOAc (5 × 30 mL). The organic layers were dried with $NaSO_4$ and evaporated *in vacuo*. The crude material was washed with hot heptane, yielding the title compound as a pink solid after failed recrystallization with MeOH/$H_2O$. Yield: 19 mg, 17%. $^{1}H$ NMR (400 MHz, DMSO-$d_6$): δ 2.93 (s, 3H), 7.48 (d, $J$ = 4.3 Hz, 1H), 9.02 (d, $J$ = 4.3 Hz, 1H). MS: (ES) *m/z* 136 [M+1].

**2-Azido-4,6-dimethylpyrimidine (4b)**

***Method A.*** Pentane-2,4-dione (**1b**) (0.103 mL, 1.00 mmol) was dissolved in EtOH (2.5 mL) and hydrochloric acid, 37% (0.1 mL) to give a colorless solution. 1H-Tetrazol-5-amine (**2**) (85 mg, 1.00 mmol) was added and the resulting mixture refluxed for 4 h. The formed suspension was evaporated to dryness yielding a white solid, and the solid was redissolved in a minimal amount of hot EtOH. The title compound precipitated on cooling and was collected by suction filtration as a white solid. Yield: 63 mg, 42%.

***Method B.*** $CuCl_2$ (13.4 mg, 0.01 mmol) was dissolved in EtOH (3 mL), resulting in a green solution. Ascorbic acid (17.6 mg, 0.01 mmol) was added and the mixture was stirred for 5 min to give a colorless, homogenous, mixture. Pentane-2,4-dione (**1b**) (0.103 mL, 1.00 mmol) and 1H-tetrazol-5-amine (**2**) (85 mg, 1.00 mmol) were added in sequence, and the resulting mixture was stirred at ambient temperature for 3 h. Saturated $NH_4Cl$ (10 mL) was added and the resulting suspension was extracted with EtOAc (5 × 30 mL). The organic layers were dried with $NaSO_4$ and evaporated *in vacuo*, yielding the title compound as a white solid. Yield: 132 mg, 98%. $^{1}H$ NMR (400 MHz, DMSO-$d_6$): δ 2.61 (m, 3H), 2.86 (s, 3H), 7.39 (s, 1H). MS: (ES): *m/z* 150 [M+1], 148 [M–1].

**2-Azido-4-methyl-6-phenylpyrimidine (4c)**

***Method A.*** 1-Phenylbutane-1,3-dione (**1c**) (100 mg, 0.62 mmol) was dissolved in EtOH (2.5 mL) and hydrochloric acid, 37% (0.06 mL) to give a colorless solution. 1H-Tetrazol-5-amine (**2**) (52.5 mg, 0.62 mmol) was added and the resulting mixture was refluxed for 2 h. The formed suspension was evaporated *in vacuo*, yielding a white solid. The solid was dissolved in hot EtOH and cooled to ambient temperature, followed by storage in the refrigerator overnight. The precipitated material was collected by suction filtration to yield the title compound as colorless, needle-like crystals. Yield: 111 mg, 84%. $^{1}H$ NMR (400 MHz, DMSO-$d_6$) δ 2.97 (s, 3H), 7.6–7.7 (m, 3H), 8.18 (s, 1H), 8.3–8.4 (m, 2H). MS; ES *m/z* 212 [M+1].

***Method B.*** $CuCl_2$ (4.2 mg, 0.03 mmol) was dissolved in EtOH (3 mL), resulting in a green solution. Ascorbic acid (17.6 mg, 0.03 mmol) was added, and the mixture was stirred for 5 min to give a colorless, homogenous mixture. 1-Phenylbutane-1,3-dione (**1c**) (100 mg, 0.62 mmol) and 1H-tetrazol-5-amine (**2**) (52 mg, 0.62 mmol) were added in sequence, and the resulting mixture was stirred at ambient temperature for 72 h. Saturated $NH_4Cl$ (10 mL) was added and the resulting suspension was extracted with EtOAc (5 × 30 mL). The organic layers were dried with $NaSO_4$ and evaporated *in vacuo*. The crude material was recrystallized in MeOH/$H_2O$, yielding the titled compound as colorless, needle-like, crystals. Yield: 56 mg, 43%.

**2-Azido-4,6-diphenylpyrimidine (4d)**

***Method A.*** 1,3-Diphenylpropane-1,3-dione (**1d**) (100 mg, 0.45 mmol) was dissolved in EtOH (2.5 mL) and hydrochloric acid 37% (0.04 mL, 0.48 mmol) to give a colorless solution. 1H-

Tetrazol-5-amine (**2**) (40 mg, 0.45 mmol) was added and the resulting mixture was refluxed for 48 h. The mixture was cooled to ambient temperature, followed by storage in the refrigerator overnight. The precipitated material was collected by suction filtration to yield the title compound as colorless, needle-like crystals. Yield: 27.8 mg, 23%. $^1$H NMR (400 MHz, DMSO-$d_6$): δ 7.5–7.8 (m, 6H), 8.3–8.5 (m, 5H). MS: (ES) *m*/*z* 274 [M+1].

**Methyl 2-azido-6-phenylpyrimidine-4-carboxylate (4e)**

***Method A.*** Methyl 2,4-dioxo-4-phenylbutanoate (**1e**) (100 mg, 0.48 mmol) was dissolved in EtOH (3 mL) and hydrochloric acid 37% (0.04 mL, 0.48 mmol) to give a colorless mixture. 1H-Tetrazol-5-amine (**2**) (41.3 mg, 0.48 mmol) was added and the resulting mixture was refluxed for 48 h. The solution was cooled to ambient temperature, followed by storage in the refrigerator overnight. The precipitated material was collected by suction filtration to yield the title compound as colorless, needle-like crystals. Yield: 43.4 mg, 35%. $^1$H NMR (400 MHz, DMSO-$d_6$): δ 3.96 (s, 3H), 7.6–7.7 (m, 3H), 8.2–8.3 (m, 3H). MS: (ES) *m*/*z* 256 [M+1].

**General procedure for the synthesis of 4′-substituted 2-(1′,2′,3′-triazol-1′-yl)pyrimidines (6).** Copper(I) iodide (9 mg, 0.05 mmol) was suspended in toluene (2 mL), whereupon the alkyne (**5**) (0.47 mmol) was added, followed by 2-azido-4-methyl-6-phenylpyrimidine (**4c**) (100 mg, 0.47 mmol) to yield a heterogeneous mixture. The resulting reaction mixture was heated to 80°C for the time specified (Table 2) and full conversion was observed according to HPLC. The volatiles were evaporated *in vacuo* to afford the crude as a solid. The solid was suspended/dissolved in a minimum of hot EtOH, and water was subsequently added until a turbid liquid phase was observed. Upon refrigeration/cooling precipitation ensued and the product was isolated and dried to give the yield specified.

***4-Methyl-6-phenyl-2-(4-phenyl-1H-1,2,3-triazol-1-yl)pyrimidine (6a).*** Starting alkyne: Ethynylbenzene (**5a**). Reaction time: 2 h. Yield: 95 mg, 64%. $^1$H NMR (500 MHz, $CDCl_3$): δ 2.77 (s, 3H), 7.40 (t, $J$ = 7.5 Hz, 2H), 7.65 (s, 1H), 8.01 (d, $J$ = 7.8 Hz, 2H), 7.61–7.54 (m, $J$ = 7.1 Hz, 3H), 7.49 (t, $J$ = 7.5 Hz, 2H), 8.21 (dd, $J$ = 6.8 Hz, 7.8 Hz, 2H), 8.94 (s, 1H). $^{13}$C NMR (126 MHz, $CDCl_3$): δ 24.6, 58.5, 115.5, 118.5, 126.1, 127.4, 128.5, 128.9, 129.1, 130.1, 131.8, 135.4, 147.9, 154.5, 166.0, 170.8. Published online 17 June 2010 in Wiley InterScience (www.interscience.wiley.com).

The 1,3-dipolar cycloaddition of unstabilized azomethine ylide **1** with meta-dinitrobenzene fused with nitrogen heterocycles affords the corresponding decahydropyrrolo[3,4-*e*]isoindole cycloadducts in good yields. This is a first example of [3+2]-cycloaddition of azomethine ylides to nitroarenes.

*J. Heterocyclic Chem.,* **47**, 893 (2010).

## INTRODUCTION

The 1,3-dipolar cycloaddition (1,3-DC) reactions play one of the most important roles in modern organic synthesis, being simple and available method for the preparation of different five-membered heterocycles. It is important that 1,3-DC usually proceeds regio- and stereoselectively [1]. A number of dipoles, including azomethine ylides, readily undergo cycloaddition reactions with conjugated nitroalkenes [2]. As a result, pyrrolidine derivatives are formed (Scheme 1); this heterocycle is a part of many natural compounds and pharmaceuticals [3].

## RESULTS AND DISCUSSION

We have found that nitro arenes, e.g. 1,3-dinitrobenzene and 1,3,5-trinitrobenzene, do not form the cycloaddition products with azomethine ylides. We believe that 1,3-DC with nitro arenes requires the reduction of their aromaticity in order to carbon–carbon double bond of C— C—$NO_2$ fragment would approach to that of conjugated nitro alkenes. It is known that isoelectronic process – [4+2]-cycloaddition to unsaturated compounds (Diels-Alder reaction) takes place in case of meta-dinitroarenes, fused with some aromatic nitrogen heterocycles [4]. In this connection, we studied an interaction of *N*-methyl azomethine ylide **1** with meta-dinitrobenzene annelated with number of aromatic nitrogen heterocycles. Azomethine ylide **1** was generated *in situ* from sarcosine and paraformaldehyde refluxing in toluene [2(a)] in the presence of dinitro compounds **2a-e** [5] as dipolarophiles (Scheme 2).

In all cases, the double cycloaddition afforded the previously unknown tetracyclic heterosystems – fused decahydropyrrolo[3,4-*e*]isoindoles **3a-e**.

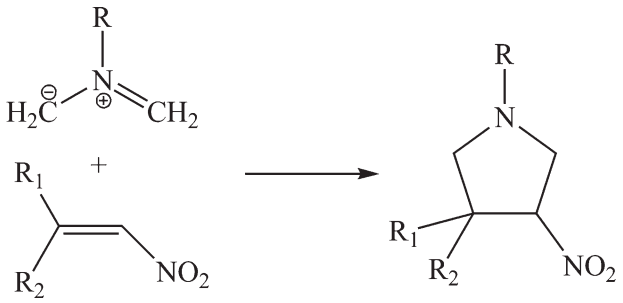
It should be noted that azomethine ylide **1** formed cycloaddition products more readily than dienes: dinitro compounds **2a** and **2d** did not undergo Diels-Alder reactions with dienes though they form cycloaddition adducts with azomethine ylide **1**.

Diels-Alder reactions can be carried out in case of aromatic nitro carbocycles only if they are fused with some strong electron-withdrawing five-membered nitrogen heterocycles – furoxan, furazan, and some of their analogs [4]. This increases the electrophilicity dramatically (by many orders of magnitude), e.g. the ability to add nucleophiles to the benzene ring that indicates the considerable reduction of aromaticity in comparison with 1,3,5-trinitrobenzene [6].

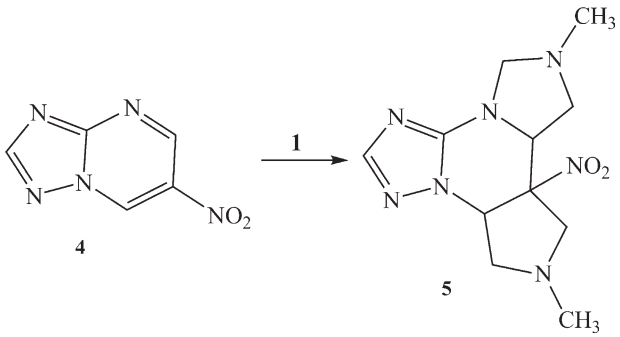
In case of azomethine ylide **1**, the cycloaddition takes place also if less electron-deficient *N*-heterocycle is fused with dinitro arene.

The formation of cycloaddition products **3a-e** seems to be diastereoselective. In case of compound **3a**, the crystal and molecular structure (Fig. 1) confirmed the expected cis-addition of the azomethine ylide [7].

**Scheme 1**



**Scheme 3**



X-ray analysis data shows that the cycloaddition occurred from the opposite sides of the dinitro arene plane.

Interestingly that double cycloaddition of azomethine ylide **1** was possible even in the presence of one nitro group as was illustrated by the reaction with nitrotriazolo[1,5-a]pyrimidine [8] (**4**) (Scheme 3):

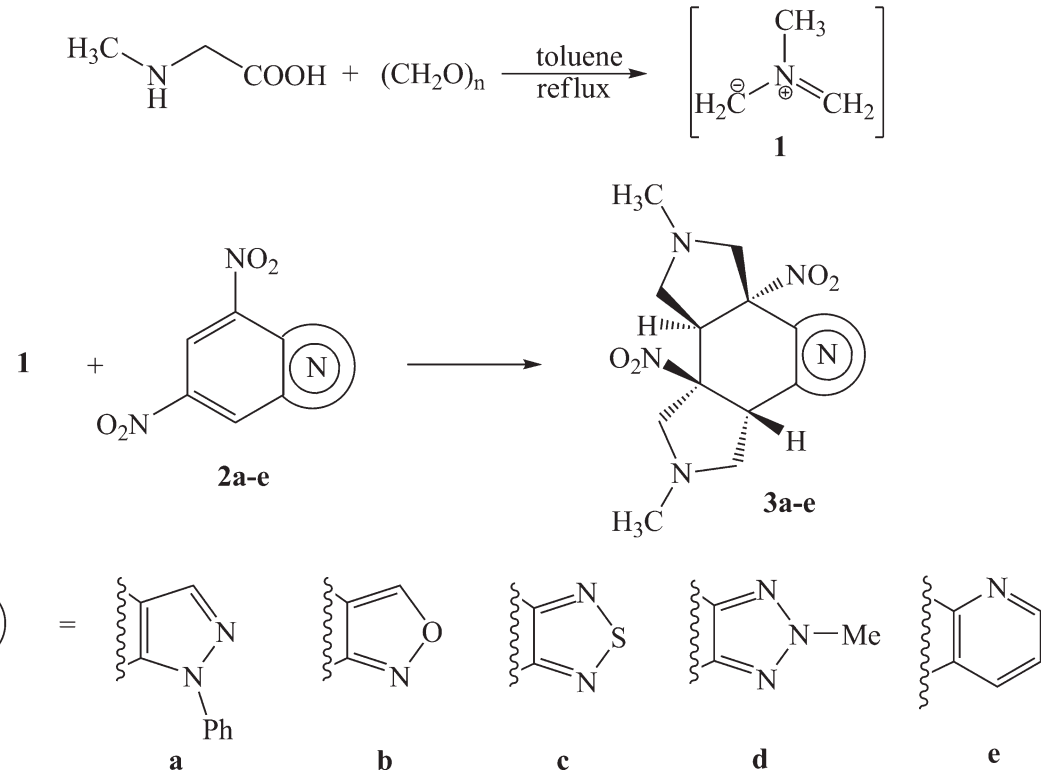
In summary, the 1,3-dipolar cycloaddition of meta-dinitrobenzene fused with nitrogen heterocycles with unstabilized *N*-methylazomethine ylide generated *in situ* from sarcosine and paraformaldehyde in refluxing toluene affords decahydropyrrolo[3,4-*e*]isoindole cycloadducts in good yields.

## EXPERIMENTAL

Melting points were uncorrected and were determined on a Reichert Kofler thermopan apparatus. NMR spectra were measured in $CDCl_3$ using the Bruker DRX 500 spectrometer operating at 500.13 MHz ($^1$H), 125.77 MHz ($^{13}$C). Tetramethylsilane was used as internal standard for $^1$H (δ 0.05). The $^{13}$C NMR spectra were standardized by means of the middle signal of the solvent multiplet (δ 76.9).

**General procedure for the reaction of compounds 2a–e and 4 with sarcosine and paraformaldehyde.** A mixture of compound **2** or **4** (1 mmol), paraformaldehyde (0.18 g, 6 mmol), and *N*-methylglycine (0.44 g, 5 mmol) in dry toluene (15 mL) was refluxed for 2 h until all the starting material disappeared by TLC. Then the reaction mixture was cooled,

**Scheme 2**



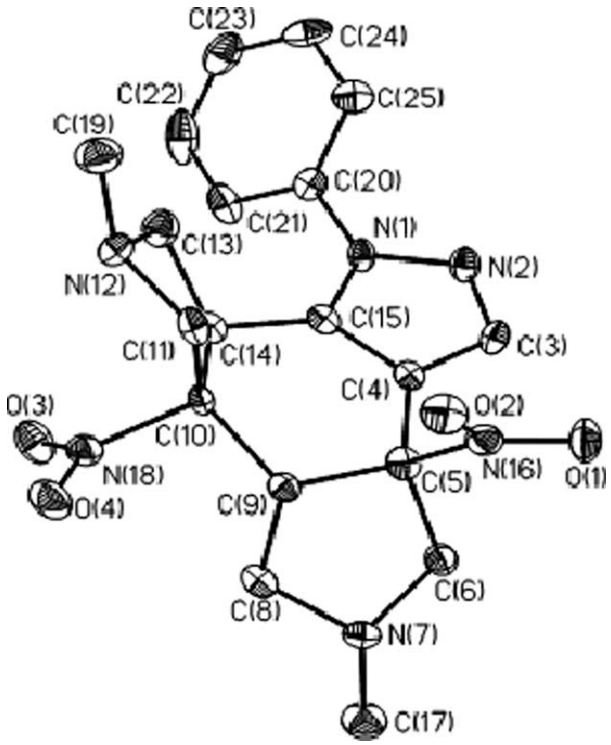


**Figure 1.** General view of **3a**. Hydrogen atoms are omitted for clarity. Thermal ellipsoids are drawn with probability 50%.

filtered and the solvent was removed by rotary evaporation. The products were purified by dissolving in minimal volume of THF, following by adding of excess of hexane to this solution with further filtering of the precipitate formed.

A series of ethyl 2-(1,5-diaryl-1*H*-pyrazol-3-yloxy)acetate derivatives (**5a–5i**) have been efficiently synthesized by the reaction of 1,5-diaryl-1*H*-pyrazol-3-ols (**4a–4i**) with ethyl 2-bromoacetate. The structures of the newly synthesized compounds were characterized by $^1$H NMR spectra and elemental analysis, and the crystal structure of the compound ethyl 2-(5-(4-chlorophenyl)-1-phenyl-1*H*-pyrazol-3-yloxy)acetate (**5c**) was determined by single crystal X-ray diffraction analysis. The compound **5c** belongs to triclinic system with space group P(-1), $a = 5.8170(12)$ Å, $b = 11.804(2)$ Å, $c = 12.783(2)$ Å, $\alpha = 83.89(2)^\circ$, $\beta = 89.24(3)^\circ$, $\gamma = 89.73(3)^\circ$, Formula weight: 356.80, Triclinic $V = 872.7(3)$ Å$^3$, $D_c = 1.358$ mg/m$^3$, $Z = 2$, $F$ (000) = 372. Bioassay results indicated that the compound ethyl 2-(5-(4-fluorophenyl)-1-phenyl-1*H*-pyrazol-3-yloxy)acetate (**5d**) exhibited moderate inhibitory activity against *Gibberella zeae* at the dosage of 10 μg/mL.

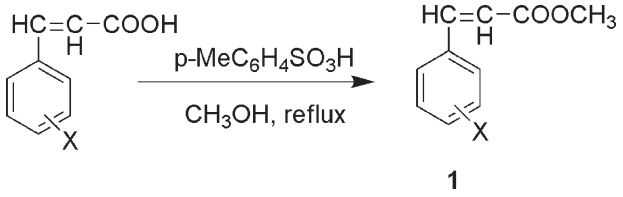
## INTRODUCTION

Biological studies of the pyrazole nucleus have been shown to posses a variety of biological activities such as fungicidal [1], insecticidal [2], herbicidal [3], and plant growth regulatory activities [4]. Furthermore, several biological studies have also pointed out the value of alkyloxyacetate [5] and aryloxyacetate [6] as biologically active groups. These findings primarily focused on incorporating alkyloxyacetate and aryloxyacetate groups with 1*H*-pyrazole derivatives in the hope of obtaining compounds of potential insecticidal, fungicidal, and herbicidal activities.

1,5-Diaryl-1*H*-pyrazol-3-ols, one important kind of 1*H*-pyrazole derivatives, have been developed for their synthesis since the early twentieth century. The first synthesis of 1,5-diaryl-1*H*-pyrazol-3-ol from a pyrazolidone derivative was published by Japp and Maitland [7]. Then the reaction of arylpropiolic acids and their esters with phenylhydrazine became one of the most popular methods for the synthesis of 1,5-diaryl-1*H*-pyrazol-3-ols [8–11]. In recent years, synthesis of 1,5-diaryl-1*H*-pyrazol-3-ols by the reactions of 4-arylidene-1-phenyl-3,5-pyrazolidinediones with oxidizing agents has been achieved [12]. However, very few representatives of biologically active 1,5-diaryl-1*H*-pyrazol-3-oxyacetate derivatives have hitherto been described in the literature.

3-Arylacrylic acids and their esters are convenient and easily available starting materials or intermediates for the synthesis of a wide variety of heterocyclic compounds [13,14]. In our previous studies, we have successfully improved the procedure for the synthesis of 1,5-diaryl-1*H*-pyrazol-3-ols by the reaction of methyl 3-arylacrylates with arylhydrazines in high yields and have reported some crystal structures [15–17]. In continuation of our program directed toward the synthesis of

**Scheme 1**



**1**

biologically active novel 1,5-diaryl-1*H*-pyrazol-3-oxyacetate derivatives, we report herein the synthesis and fungicidal activity of a series of novel ethyl 2-(1,5-diaryl-1*H*-pyrazol-3-yloxy)acetates (**5a–5i**), and the single crystal structure of the compound ethyl 2-(5-(4-chlorophenyl)-1-phenyl-1*H*-pyrazol-3-yloxy)acetate (**5c**). A preliminary *in vitro* bioassay indicated that some of these newly synthesized compounds displayed fungicidal activity.

## RESULTS AND DISCUSSION

Methyl 3-arylacrylates (**1**) (Scheme 1) were prepared by the reaction of 3-arylacrylic acids with methanol, using *p*-toluenesulfonic acid as catalyst. Intermediates arylhydrazines (**2**) (Scheme 2) were prepared according to the reported methods from the substituted anilines through diazotization reactions [18].

A previous report by Gaede and McDermott [19] described that addition of methylhydrazine to a variety of haloalkyl-substituted α,β-unsaturated ethers could give 1,5-disubstituted-3-hydroxypyrazoles. Motivated by this finding, in our procedure, methyl 3-arylacrylates (**1**) were allowed to react with arylhydrazines (**2**) in boiling *n*-butanol in the presence of sodium methoxide to afford 1,5-diarylpyrazolidin-3-ones (**3a–3i**) (Scheme 3) as sole isolable products. No other pyrazoline type compounds could be detected in the crude products. It was found that the desired mode of initial Michael addition to methyl 3-arylacrylates (**1**) could be achieved. The crude solid 1,5-diarylpyrazolidin-3-ones (**3a–3i**) were recrystallized from ethyl acetate.

The conversions from 1,5-diarylpyrazolidin-3-ones (**3a–3i**) to 1,5-diaryl-1*H*-pyrazol-3-ols (**4a–4i**) (Scheme 3) were carried out in organic solvents, using oxygen as oxidizing agent and iron (III) chloride as catalyst. To optimize the reaction conditions, different organic solvents, such as ethanol and DMF were tested in the synthesis of 1,5-diphenyl-1*H*-pyrazol-3-ol (**4a**). When the conversion was carried out using iron (III) chloride in refluxing ethanol, the yield was low and the separation of the product from the iron (II) salts was tedious. However, the conversion in DMF gave good results. Moreover, the most satisfactory result was obtained when the reaction was stirred in DMF at 80°C for 2 h, and then at 30°C for another 20 h. The crude solid 1,5-diaryl-1*H*-pyrazol-3-ols (**4a–4i**) were recrystallized from ethanol.

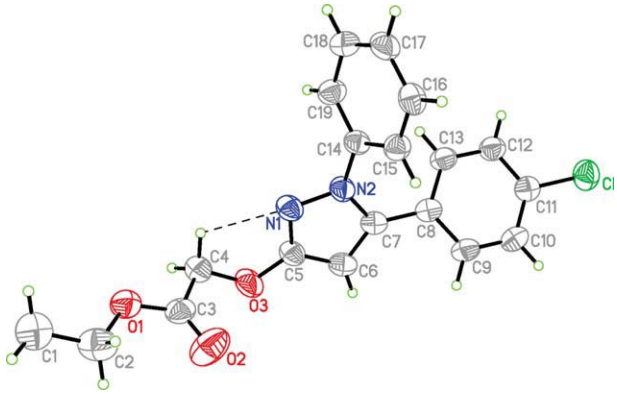


**Figure 1.** The molecular structure of **5c**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

The reactions of 1,5-diaryl-1*H*-pyrazol-3-ols (**4a–4i**) with ethyl 2-bromoacetate were carried out in a molar ratio 1:1.1 in acetone as solvent, and all the reactions were monitored by thin-layer chromatography (TLC). The most satisfactory results were obtained when the reactions were performed under hot acetone for 3 h. The crude residues were purified *via* flash chromatography to give the pure products ethyl 2-(1,5-diaryl-1*H*-pyrazol-3-yloxy)acetates (**5a–5i**) (Scheme 3).

A suitable crystal of ethyl 2-(5-(4-chlorophenyl)-1-phenyl-1*H*-pyrazol-3-yloxy)acetate (**5c**) was obtained by dissolving the compound in ethyl acetate and evaporating the solvent slowly at room temperature for about 10 days. Its solid-state structure was determined by single crystal X-ray diffraction. Details of the structure determination and refinement are given in the experiment section. The drawing of the molecular structure with the

atom-numbering scheme and higher occupancy in the three-dimensional packing arrangement is shown in Figures 1 and 2. Hydrogen bond is shown as a dashed line. Atomic coordinates of nonhydrogen atoms ($\times 10^{-4}$) and their thermal parameters are summarized in Table 1. The crystal data and structure refinement of **5c** are listed in Table 2.

The compounds **5a–5i** were screened for activity against two fungi, namely *Gibberella zeae* and *Rhizoctonia cerealis*, at a concentration of 10 μg/mL according to a reported method [20]. As the results in Table 3 show, most of the compounds have weak fungicidal activity. Among these compounds, only compound **5d**, in which X is F group in position 4 of the phenyl ring and Y is H, exhibited moderate inhibitory activity against *G. zeae*. This might imply that the introduction of the F group to the phenyl ring of 1*H*-pyrazoles was important for its fungicidal activity. In terms of X, the substituents with electron-attracting groups on the phenyl rings seem to have somewhat higher fungicidal activity. For example, compounds **5c** and **5d** showed better activity than

compounds **5a** and **5b**. Switching the substituent Y from H to isopropyl has no effective impact on the inhibition rates. Furthermore, compound **5d** with the F group in position 4 of the phenyl ring showed better activity than **5f**.

## EXPERIMENTAL

All reagents were of analytical reagent grade or were chemically pure. All solvents were dried by standard methods and distilled before use. Reactions were monitored by TLC. Analytical TLC was performed on silica gel GF254. Flash column chromatography was carried out using 200–300 mesh silica gel at increased pressure. *G. zeae* and *R. cerealis* were obtained from Jiangsu Research and Development Center for Pesticides, China.

The melting points were measured on an X-4 microscope electrothermal apparatus (Taike, China) and were uncorrected. Elemental analyses were determined on a Vario EL III elemental analyzer. The $^1$H NMR (solvent $CDCl_3$ or DMSO-$d_6$) spectra was obtained on a Bruker AV 500 or AV 300 spectrometer at room temperature using tetramethylsilane as an internal standard. Chemical shift values (δ) are given in parts per million. X-ray intensity data were recorded on a Bruker SMART 1000 CCD diffraction meter using graphite monochromated Mo Kα radiation (λ = 0.71073) Å.

**The synthesis of 1,5-diarylpyrazolidin-3-ones (3a–3i).** A mixture of *n*-butanol (40 mL) and ethanolamine (60 mmol) was added to a solution of sodium (36 mmol) in anhydrous methanol (9 mL). Then, methanol was removed by distillation, and methyl 3-arylacrylate **1** (30 mmol) was added. The mixture was refluxed for 40 min, after which arylhydrazine **2** (33 mmol) was added. The mixture was refluxed for another 8 h and then left to cool to room temperature. It was then acidified with acetic acid (36%), allowed to stand and filtered. The solid was recrystallized from ethyl acetate to give the compounds **3a–3i**.

**5-(3-Fluorophenyl)-1-phenylpyrazolidin-3-one (3f).** Yellow crystal; mp 165–167°C; yield, 75%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 2.50 (d, 1H, CH), 3.30 (q, $J$ = 9.15, 16.85 Hz, 1H, CH), 4.98 (d, 1H, CH), 7.03–7.40 (m, 9H, Ar-H), 8.41 (s, 1H, NH); Anal. Calcd for $C_{15}H_{13}FN_2O$: C 70.30, H 5.11, N 10.93; found C 70.23, H 5.10, N 10.96.

**1-(4-Isopropylphenyl)-5-phenylpyrazolidin-3-one (3g).** Yellow crystal; mp 136–137°C; yield, 78%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.22 (d, $J$ = 6.85 Hz, 6H, $CH_3$), 2.50 (q, $J$ = 3.35, 16.75 Hz, 1H, CH), 2.86 (m, 1H, CH), 3.26 (q, $J$ = 9.15,16.75 Hz, 1H, CH), 4.87 (q, $J$ = 3.35, 8.98 Hz, 1H, CH), 6.99–7.48 (m, 9H, Ar-H); Anal. Calcd for $C_{18}H_{20}N_2O$: C 77.11, H 7.19, N 9.99; found C 77.05, H 7.21, N 9.94.

**1-(4-Isopropylphenyl)-5-(4-methoxyphenyl)pyrazolidin-3-one (3h).** Yellow crystal; mp 143–145°C; yield, 81%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.22 (d, $J$ = 6.90 Hz, 6H, $CH_3$), 2.55 (m, 1H, CH), 2.87 (m, 1H, CH), 3.21 (m, 1H, CH), 3.83 (s, 3H, $OCH_3$), 4.82 (m, 1H, CH), 6.92–7.39 (m, 8H, Ar-H); Anal. Calcd for $C_{19}H_{22}N_2O_2$: C 73.52, H 7.14, N 9.03; found C 73.46, H 7.16, N 8.99.

**5-(4-Fluorophenyl)-1-(4-isopropylphenyl)pyrazolidin-3-one (3i).** Yellow crystal; mp 126–127°C; yield, 79%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 1.25 (d, $J$ = 6.87 Hz, 6H, $CH_3$), 2.52 (q, $J$ = 3.78, 16.82 Hz, 1H, CH), 2.89 (m, 1H, CH), 3.33 (q, $J$ = 9.12, 16.8 Hz, 1H, CH), 4.87 (q, $J$ = 3.69, 9.14 Hz, 1H, CH), 6.94–7.19 (m, 8H, Ar-H); Anal. Calcd for $C_{18}H_{19}FN_2O$: C 72.46, H 6.42, N 9.39; found C 72.42, H 6.44, N 9.35.

**1,5-Diaryl-1H-pyrazol-3-ols (4a–4i).** Using oxygen as oxidizing agent, compound **3a–3i** (10 mmol) was dissolved in DMF (40 mL) and mixed with $FeCl_3$ (0.162 g, 1 mmol). The mixture was heated to 80°C and maintained at that temperature for 2 h, and then stirred at 30°C for another 20 h. The reaction mixture was then poured into water (500 mL) with good stirring. The precipitate which formed was filtered off, washed with water and dried under reduced pressure. The crude product was then recrystallized from ethanol to give the compounds **4a–4i**.

**1,5-Diphenyl-1H-pyrazol-3-ol (4a).** White crystal; mp 258–259°C; yield, 81%. $^1$H NMR (DMSO-$d_6$, 300 MHz, ppm): δ 5.92 (s, 1H, CH), 7.14–7.33 (m, 10H, Ar-H), 10.36 (s, 1H, OH); Anal. Calcd for $C_{15}H_{12}N_2O$: C 76.25, H 5.12, N 11.86; found C 75.32, H 5.09, N 11.82.

**1-Phenyl-5-p-tolyl-1H-pyrazol-3-ol (4b).** White crystal; mp 254–255°C; yield, 84%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 2.33 (s, 3H, $CH_3$), 5.89 (s, 1H, CH), 7.09–7.36 (m, 9H, Ar-H); Anal. Calcd for $C_{16}H_{14}N_2O$: C 76.78, H 5.64, N 11.19; found C 76.69, H 5.63, N 11.25.

**5-(4-Chlorophenyl)-1-phenyl-1H-pyrazol-3-ol (4c).** White crystal; mp 285–286°C; yield, 82%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 5.92 (s, 1H, CH), 7.13–7.46 (m, 9H, Ar-H); Anal. Calcd for $C_{15}H_{11}ClN_2O$: C 66.55, H 4.10, N 10.35; found C 66.46, H 4.08, N 10.38.

**5-(4-Fluorophenyl)-1-phenyl-1H-pyrazol-3-ol (4d).** White crystal; mp 266–267°C; yield, 81%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 5.90 (s, 1H, CH), 6.98–7.33 (m, 9H, Ar-H), 11.35 (s, 1H, OH); Anal. Calcd for $C_{15}H_{11}FN_2O$: C 70.86, H 4.36, N 11.02; found C 70.78, H 4.34, N 11.06.

**1-Phenyl-5-(3,4,5-trimethoxyphenyl)-1H-pyrazol-3-ol (4e).** Brown crystal; mp 203–205°C; yield, 85%. $^1$H NMR (DMSO-$d_6$, 500 MHz, ppm): δ 3.62 (s, 9H, $OCH_3$), 5.97 (s, 1H, CH), 6.46 (s, 2H, Ar-H), 7.21–7.39 (m, 5H, Ar-H), 10.09 (s, 1H, OH); Anal. Calcd for $C_{18}H_{18}N_2O_4$: C 66.25, H 5.56, N 8.58; found C 66.29, H 5.55, N 8.53.

**5-(3-Fluorophenyl)-1-phenyl-1H-pyrazol-3-ol (4f).** White crystal; mp 274–275°C; yield, 78%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 6.45 (s, 1H, CH), 6.90–7.35 (m, 9H, Ar-H); Anal. Calcd for $C_{15}H_{11}FN_2O$: C 70.86, H 4.36, N 11.02; found C 70.78, H 4.35, N 11.06.

**1-(4-Isopropylphenyl)-5-phenyl-1H-pyrazol-3-ol (4g).** Yellow crystal; mp 203–205°C; yield, 76%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.24 (d, $J$ = 6.75 Hz, 6H, $CH_3$), 2.90 (m, 1H, CH), 5.90 (s, 1H, CH), 7.14–7.28 (m, 9H, Ar-H); Anal. Calcd for $C_{18}H_{18}N_2O$: C 77.67, H 6.52, N 10.06; found C 77.60, H 6.49, N 10.09.

**1-(4-Isopropylphenyl)-5-(4-methoxyphenyl)-1H-pyrazol-3-ol (4h).** Yellow crystal; mp 193–194°C; yield, 72%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.25 (d, $J$ = 7.00 Hz, 6H, $CH_3$), 2.90 (m, 1H, CH), 3.80 (s, 3H, $OCH_3$), 5.86 (s, 1H, CH), 6.80–7.26 (m, 8H, Ar-H); Anal. Calcd for $C_{19}H_{20}N_2O_2$: C 74.00, H 6.54, N 9.08; found C 73.94, H 6.53, N 9.12.

**5-(4-Fluorophenyl)-1-(4-isopropylphenyl)-1H-pyrazol-3-ol (4i).** Yellow crystal; mp 225–227°C; yield, 78%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 1.21 (d, $J$ = 6.96 Hz, 6H, $CH_3$), 2.85 (m, 1H, CH), 6.34 (s, 1H, CH), 6.90–7.26 (m, 8H, Ar-H); Anal. Calcd for $C_{18}H_{17}FN_2O$: C 72.95, H 5.78, N 9.45; found C 72.88, H 5.76, N 9.42.

**Ethyl 2-(1,5-diaryl-1H-pyrazol-3-yloxy)acetates (5a–5i).** To a solution of **4a–4i** (10 mmol) in acetone (30 mL) was added potassium carbonate (2.07 g, 15 mmol). Then, the mixture was refluxed and ethyl 2-bromoacetate (1.84 g, 11 mmol) was added slowly. The mixture was refluxed and monitored by TLC for about 3 h. The potassium carbonate was filtered off and the solvent was evaporated under reduced pressure. After the removal of the solvent, the residue was chromatographed over silica gel (500 g) eluting with a mixture of ethyl acetate and petroleum ether to gain the target compounds **5a–5i**.

**Ethyl 2-(1,5-diphenyl-1H-pyrazol-3-yloxy)acetate (5a).** White crystal; mp 79–80°C; yield, 89%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 1.31 (t, $J$ = 7.17, 14.25 Hz, 3H, $CH_3$), 4.28 (q, $J$ = 7.17, 14.28 Hz, 2H, $CH_2$), 4.88 (s, 2H, $CH_2$), 6.04 (s, 1H, CH), 7.20–7.27 (m, 10H, Ar-H); Anal. Calcd for $C_{19}H_{18}N_2O_3$: C 70.79, H 5.63, N 8.69; found C 70.72, H 5.62, N 8.73.

**Ethyl 2-(1-phenyl-5-p-tolyl-1H-pyrazol-3-yloxy)acetate (5b).** White crystal; mp 106–107°C; yield, 85%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.30 (t, $J$ = 7.15, 14.25 Hz, 3H, $CH_3$), 2.33 (s, 3H, $CH_3$), 4.28 (q, $J$ = 7.15, 14.28 Hz, 2H, $CH_2$), 4.86 (s, 2H, $CH_2$), 6.00 (s, 1H, CH), 7.09–7.29 (m, 9H, Ar-H); Anal. Calcd for $C_{20}H_{20}N_2O_3$: C 71.41, H 5.99, N 8.33; found C 71.34, H 5.97, N 8.28.

**Ethyl 2-(5-(4-chlorophenyl)-1-phenyl-1H-pyrazol-3-yloxy)acetate (5c).** Yellow crystal; mp 51–52°C; yield, 88%. $^1$H NMR ($CDCl_3$, 300 MHz, ppm): δ 1.30 (t, $J$ = 7.20, 14.28 Hz, 3H, $CH_3$), 4.28 (q, $J$ = 7.20, 14.19 Hz, 2H, $CH_2$), 4.86 (s, 2H,

$CH_2$), 6.03 (s, 1H, CH), 7.13–7.38 (m, 9H, Ar-H); Anal. Calcd for $C_{19}H_{17}ClN_2O_3$: C 63.96, H 4.80, N 7.85; found C 63.88, H 4.82, N 7.82.

**Ethyl 2-(5-(4-fluorophenyl)-1-phenyl-1H-pyrazol-3-yloxy)acetate (5d).** White crystal; mp 76–77°C; yield, 81%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.33 (t, $J$ = 7.15, 14.3 Hz, 3H, $CH_3$), 4.31 (q, $J$ = 7.15, 14.2 Hz, 2H, $CH_2$), 4.90 (s, 2H, $CH_2$), 6.08 (s, 1H, CH), 7.01–7.28 (m, 9H, Ar-H); Anal. Calcd for $C_{19}H_{17}FN_2O_3$: C 67.05, H 5.03, N 8.23; found C 67.14, H 5.04, N 8.19.

**Ethyl 2-(1-phenyl-5-(3,4,5-trimethoxyphenyl)-1H-pyrazol-3-yloxy)acetate (5e).** Yellow crystal; mp 75–76°C; yield, 84%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.21 (t, $J$ = 7, 14.2 Hz, 3H, $CH_3$), 3.58 (s, 6H, $OCH_3$), 3.65 (s, 3H, $OCH_3$), 4.17 (q, $J$ = 7.2, 14.2 Hz, 2H, $CH_2$), 4.83 (s, 2H, $CH_2$), 6.26 (s, 1H, CH), 6.49 (s, 2H, Ar-H), 7.22–7.39 (m, 5H, Ar-H); Anal. Calcd for $C_{22}H_{24}N_2O_6$: C 64.07, H 5.87, N 6.79; found C 63.98, H 5.85, N 6.75.

**Ethyl 2-(5-(3-fluorophenyl)-1-phenyl-1H-pyrazol-3-yloxy)acetate (5f).** White crystal; mp 67–68°C; yield, 81%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.30 (t, $J$ = 7.2, 14.25 Hz, 3H, $CH_3$), 4.28 (q, $J$ = 7, 14.35 Hz, 2H, $CH_2$), 4.87 (s, 2H, $CH_2$), 6.05 (s, 1H, CH), 6.91–7.27 (m, 9H, Ar-H); Anal. Calcd for $C_{19}H_{17}FN_2O_3$: C 67.05, H 5.03, N 8.23; found C 67.14, H 5.04, N 8.20.

**Ethyl 2-(1-(4-isopropylphenyl)-5-phenyl-1H-pyrazol-3-yloxy)acetate (5g).** Yellow crystal; mp 133–134°C; yield, 88%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.22 (d, $J$ = 6.85 Hz, 6H, $CH_3$), 1.30 (t, $J$ = 7.15, 14.3 Hz, 3H, $CH_3$), 2.87 (q, $J$ = 7, 13.8 Hz, 1H, CH), 4.28 (q, $J$ = 7.15, 14.15 Hz, 2H, $CH_2$), 4.87 (s, 2H, $CH_2$), 6.02 (s, 1H, CH), 7.12–7.29 (m, 9H, Ar-H); Anal. Calcd for $C_{22}H_{24}N_2O_3$: C 72.50, H 6.64, N 7.69; found C 72.43, H 6.66, N 7.66.

**Ethyl 2-(1-(4-isopropylphenyl)-5-(4-methoxyphenyl)-1H-pyrazol-3-yloxy)-acetate (5h).** Yellow crystal; mp 127–128°C; yield, 83%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.22 (d, $J$ = 6.8 Hz, 6H, $CH_3$), 1.30 (t, $J$ = 7.15, 14.25 Hz, 3H, $CH_3$), 2.88 (t, $J$ = 6.8, 13.75 Hz, 1H, CH), 3.80 (s, 3H, $OCH_3$), 4.28 (q, $J$ = 7.15, 14.25 Hz, 2H, $CH_2$), 4.86 (s, 2H, $CH_2$), 5.96 (s, 1H, CH), 6.81–7.26 (m, 8H, Ar-H); Anal. Calcd for $C_{23}H_{26}N_2O_4$: C 70.03, H 6.64, N 7.10; found C 70.12, H 6.67, N 7.08.

**Ethyl 2-(5-(4-fluorophenyl)-1-(4-isopropylphenyl)-1H-pyrazol-3-yloxy)-acetate (5i).** Yellow crystal; mp 81–82°C; yield, 89%. $^1$H NMR ($CDCl_3$, 500 MHz, ppm): δ 1.22 (d, $J$ = 6.75 Hz, 6H, $CH_3$), 1.30 (t, $J$ = 7.2, 14.2 Hz, 3H, $CH_3$), 2.88 (q, $J$ = 6.85, 13.8 Hz, 1H, CH), 4.15 (q, $J$ = 7.15, 14.18 Hz, 2H, $CH_2$), 4.83 (s, 2H, $CH_2$), 6.19 (s, 1H, CH), 7.07–7.26 (m, 8H, Ar-H); Anal. Calcd for $C_{22}H_{23}FN_2O_3$: C 69.09, H 6.06, N 7.33; found C 69.15, H 6.11, N 7.31.

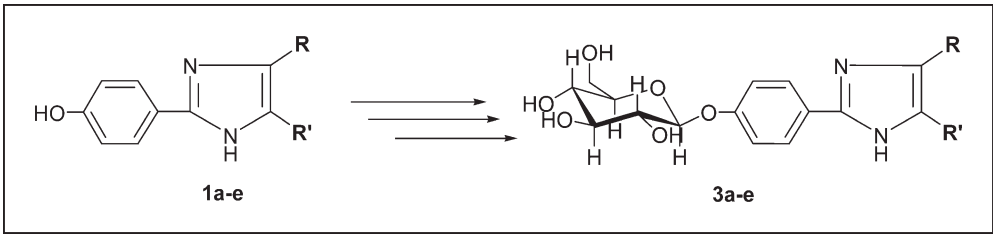
Published online 17 June 2010 in Wiley InterScience (www.interscience.wiley.com).



A series of 2-(4-hydroxyphenyl)-4,5-disubstituted imidazoles (**1a–e**) prepared from α-diketones, ammonium acetate, and *p*-hydroxybenzaldehyde, which were glucosylated by using α-acetobromoglucose to form 2-(4-*o*-β-D-2,3,4,6-tetra-*o*-acetyl-glucosidoxyphenyl)-4,5-disubstituted imidazoles (**2a–e**) which on catalytic deacetylation with $CH_3ONa$ in methanol afforded the title compound 2-(4-*o*-β-D-glucosidoxyphenyl)-4,5-disubstituted imidazoles (**3a–e**). Compounds were characterized by elemental analysis and by instrumental technique, similarly the title compounds were investigated for antimicrobial and antifungal activity.

## INTRODUCTION

In continuation of our work [1] with imidazole ring which were very important in living systems like vitamin $B_{12}$. Imidazole also forms a part of some important compounds such as purine, adenine, xanthine, guanine, co-enzyme-a. It is also distributed in essential amino acid, e.g., 1-histidine. Imidazoles possess, various biological activities, *viz*., antibacterial [2,3], antifungal [4], anti-inflammatory [5], antihistaminic [6], and hypertensive [7]. Glucoconjugate and the carbohydrate containing structure [8,9] exhibit a variety of biological and therapeutic properties [10]. As a result, the formation of glucosidic linkage continues to be a dominant theme in carbohydrate chemistry [11,12]. The attached sugar molecules increase water solubility and tissue penetration. In addition to acting as a modifier, carbohydrate can induce biological activity. In view of various biological activities of imidazoles and the importance of glucose moiety in the metabolism, several compounds containing imidazole and glucose moiety have been synthesized. Herein, we reported the synthesis of 2-(4-hydroxyphenyl)-4,5-disubstituted imidazoles and 2-(4-*o*-β-D-glucosidoxyphenyl)-4, 5-disubstituted imidazoles.

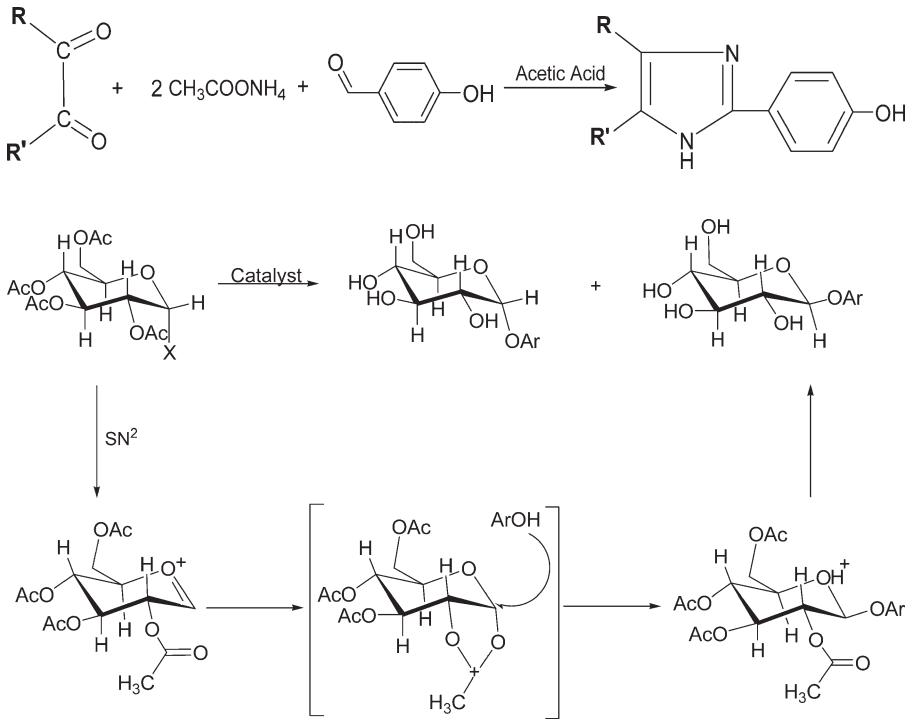
## RESULTS AND DISCUSSION

Our general synthetic route starts with the aglycon synthesis **1** it was prepared by condensation between α-diketones, *p*-hydroxybenzaldehyde, and ammonium acetate in the acetic acid medium [13]. The series of these aglycon prepared by changing substitutions at 4,5 positions (**1a–e**). The glucosylation is carried out by using modified Koenigs-Knorr method [14] (Scheme 1).

The mechanism of *o*-glucosylation reaction gained immense importance due to its stereo-and regeoselective nature. Glucosylation of 2-(4-hydroxyphenyl)-4,5-disubstituted imidazole with α-acetobromoglucose (ACBG) followed by deacetylation leads to the desired *o*-glucoside with distereoselectivity in favors of β-anomer. *o*-Glucosylation takes place *via* $S_N1$ and $S_N2$ mechanism. In the absence of heavy metal salts or Lewis acid catalyst mostly follows $S_N2$ mechanism which mainly leads to β-anomer as the preferred product. In contrast, the presence of Lewis acid catalyst follows $S_N1$ mechanism and is less distereoselective and regioselective.

This leads to the formation of α- and β-anomers. An ester protecting group on the 2-hydroxyl group of the donor will lead to the neighboring group participation during *o*-glucosylation reaction and only the 1,2-trans-diaxial glucoside (β-anomer) is the preferred product.

**Scheme 1**



Glucosylation of 2-(4-hydroxyphenyl)-4,5-disubstituted imidazoles with acetobromoglucose (ACBG) followed by deacetylation leads the desired *o*-glucoside FT-IR data of the *o*-glucoside are in agreement with the assigned structure. Anomeric configuration confirmed by $^1$H NMR since the coupling constant of the compound 8.5 Hz was observed between H-1 and H-2 proton. $^{13}$C NMR spectrum, C-1 resonated downfield of the other glucosyl carbon at δ 100.26 consistent with the formation of *o*-β-glucosides. $S_N2$ mechanism for 1,2-trans glucoside formation 1,2-dioxyacylcarbonium ion (Scheme 2).

## BIOLOGICAL ASSAY

**Antibacterial activity.** The compounds (**3a–e**) were screened for their antibacterial activities against various pathogenic bacteria *Escherichia coli*, *Klebisilla aerogens*, *Staphyllococcus aureus*, and *Bacillus substilis* by the cup plate diffusion of 100 μg/mL by using standard ciprofloxacin and sulphacetamide (100 μg/mL) for bacteria. The zone of inhibition after 24 h of incubation at 37°C was compared with standard drugs (Table 1).

**Antifungal activity.** The compounds (**3a–e**) were screened for antifungal activity tasted at 100 μg/mL concentration in methanol against *Aspergillus niger and Candida albicans* by adopting cup plate diffusion method. The zone of inhibition after 7 days at 37°C was compared with standard drugs gentamycin and clotrimazole (100 μg/mL).

## EXPERIMENTAL

The melting points (mp) are taken by using open capillary method and are uncorrected. The FT-IR spectra were recorded on Perkin-Elmer spectrophotometer using KBr disc. The $^1$H NMR spectra are recorded on Bruker DRX-300 (300 MHz FT-NMR) instrument using DMSO-d6 as a solvent and TMS as internal standard, and the chemical shift are expressed in δ ppm values. EI-MS were recorded by direct insertion technique with a Hitachi Perkin Elmer RMU 6D mass Spectrophotometer. Elemental analysis was determined by the FLASH EA 1112 CHN analyzer, Thermo Finigin, Italy.

**General procedure for 2-(4-hydroxyphenyl)-4,5-disubstituted imidazoles (1a–e).** A mixture of 4-hydroxy benzaldehyde (5 mmol), α-diketones (5 mmol), ammonium acetate (10 mmol), and glacial acetic acid (50 mL) was refluxed for 2 h. It was poured on to cold water (200 mL) and neutralized with $NH_4OH$. The solid obtained was filtered, washed with water, and crystallized from alcohol.

**2-(4-Hydroxyphenyl)-4,5-diphenyl imidazole (1a).** Yield 1.4 g (75%), mp 260°C, $R_f$ = 0.78, FT-IR spectrum showed the 3569.4 (—OH, broad) due to the presence of free phenolic hydroxyl group and 1608 (C=N, str.), 3165.3–2793.3 cm$^{-1}$

[c] Activity index against std. 1.
[d] Activity index against std. 2.For antibacterial activity: Std. 1 = Ciprofloxacin and Std. 2 = Sulphacetamide, for antifungal activity: Std. 1 = Gentamycin and Std. 2 = Clotrimazole.

(m, 12H, aromatic). Anal. Calcd. for $C_{21}H_{14}Cl_2N_2O$ (380): C, 66.16; H, 3.70; N, 7.35; Found: C, 66.32; H, 3.76; N, 7.32.

**General procedure for 2-(4-*o*-β-D-2,3,4,6-tetra-*o*-acetyl-glucosidoxyphenyl)-4,5-disubstituted imidazoles (2a–e).** A solution of 3 g potassium salt of 4,5-disubstituted-2-(4-hydroxyphenyl)-imidazole in 10 mL of 5% methanolic KOH was added drop wise to a solution of 5 g of a acetobromoglucose in 20 mL of dry acetone. The resulting mixture was stirred at 0°C for 2 h. The reaction was allowed to proceed for an additional 24 h and the solvent remove under reduced pressure. The reaction was monitored by TLC, A brown syrupy mass of 4,5-disubstituted-2-(4-*o*-β-D-2,3,4,6-tetra-*o*-acetyl glucosidoxyphenyl)imidazoles were obtained.

**2-(4-*o*-β-D-2,3,4,6-Tetra-*o*-acetyl glucosidoxyphenyl)-4,5-diphenyl imidazole (2a).** Yield 3.57 g (65%). $R_f = 0.28$. The compound was found to be optically active and the specific rotation $[\alpha]_D^{30}$ in DMSO was found to be −8.12. FT-IR spectrum of the compound showed following characteristic bands at $\nu_{max}$ 3424 (—NH), 1607 (C=N), and 1074 (C—O) $cm^{-1}$. The characteristic band due to phenolic hydroxyl group (3300–3500 $cm^{-1}$) was absent and the band due to C—O—C which appear at 1231 $cm^{-1}$ confirms the formation of *o*-glucoside.$^1$H NMR: 2.02, 1.95,1.97, 2.01 (s, 3H) ($COCH_3$), 4.8 (d, 1H, anomeric proton), 6.4–7.1 (m, 14H, Ar—H), 10.5 (s, 1H, —NH). Anal. Calcd. for $C_{35}H_{34}N_2O_{10}$ (642): C, 65.41; H, 5.33; N, 4.36; Found: C, 65.35; H, 5.30; N, 4.38.

**2-(4-*o*-β-D-2,3,4,6-Tetra-*o*-acetyl glucosidoxyphenyl)-5-phenyl imidazole (2b).** Yield 72%; $[\alpha]_D^{30} = -12.56$ (c, 0.1, DMSO); brown syrup; $R_f = 0.12$; FT-IR: 3420 (—NH), 2855 (glucosidic CH), 2420 (Ar—CH), 1610 (C=N), 1089 (C—O), and 1225 $cm^{-1}$ (C—O—C). $^1$H NMR: 2.02, 1.94, 1.97, 2.01 (s, 3H) ($COCH_3$), 5.1 (d, 1H, anomeric proton), 6.2 −7.0 (m, 9H, Ar—H), 9.6 (s, 1H, —NH). Anal. Calcd. for $C_{29}H_{30}N_2O_{10}$ (566): C, 61.48; H, 5.34; N, 4.94; Found: C, 61.42; H, 5.30; N, 4.93.

**2-(4-*o*-β-D-2,3,4,6-Tetra-*o*-acetyl glucosidoxyphenyl) imidazole (2c).** Yield 82%; $[\alpha]_D^{30} = -2.24$ (c, 0.1, DMSO); brown syrup; $R_f = 0.22$; FT-IR: 3428 (—NH), 2828 (glucosidic CH), 2610 (Ar—CH), 1618 (C=N), 1085 (C—O), and 1210 $cm^{-1}$ (C—O—C). $^1$H NMR: 2.02, 1.90, 1.96, 2.01 (s, 3H) ($COCH_3$), 5.4 (d, 1H, anomeric proton), 6.0–7.3 (m, 4H, Ar—H), 9.8 (s, 1H, —NH). Anal. Calcd. for $C_{23}H_{26}N_2O_{10}$ (490): C, 56.32; H, 5.34; N, 5.71; Found: C, 56.38; H, 5.32; N, 5.76.

**2-(4-*o*-β-D-2,3,4,6-Tetra-*o*-acetyl glucosidoxyphenyl)-4,5-dimethyl imidazole (2d).** Yield 78%; $[\alpha]_D^{30} = -8.16$ (c, 0.1, DMSO); brown syrup; $R_f = 0.21$; FT-IR (KBr): 3430 (—NH), 2832(glucosidic CH), 2612(Ar—CH), 1625 (C=N), 1087 (C—O), and 1218 $cm^{-1}$ (C—O—C). $^1$H NMR: 2.00, 1.92, 1.98, 2.01 (s, 3H) ($COCH_3$), 5.1 (d, 1H, anomeric proton), 6.2–6.9 (m, 4H, Ar—H), 10.2 (s, 1H, —NH). Anal. Calcd. for $C_{25}H_{30}N_2O_{10}$ (518): C, 57.91; H, 5.83; N, 5.40; Found: C, 57.95; H, 5.84; N, 5.42.

**2-(4-*o*-β-D-2,3,4,6-Tetra-*o*-acetyl glucosidoxyphenyl)- 4,5-bis-(4-chlorophenyl) imidazole (2e).** Yield 75%; $[\alpha]_D^{30} = -4.10$ (c, 0.1, DMSO); brown syrup; $R_f = 0.28$; FT-IR (KBr): 3440 (—NH), 2795 (glucosidic CH), 2610 (Ar—CH), 1620 (C=N), 1090 (C—O), and 1215 $cm^{-1}$ (C—O—C). $^1$H NMR: 2.00, 1.94, 1.96, 2.02 (s, 3H) ($COCH_3$), 5.5 (d, 1H, anomeric proton), 6.2–6.8 (m, 12H, Ar—H), 11.4 (s, 1H, —NH). Anal. Calcd. for $C_{35}H_{32}Cl_2N_2O_{10}$ (710): C, 59.08; H, 4.53; N, 3.94; Found: C, 59.05; H, 4.56; N, 3.96.

**General procedure for 2-(4-*o*-β-D-glucosidoxyphenyl)-4,5-disubstituted imidazoles (3a–e).** A solution of 4,5-disubstituted-2-(4-*o*-β-D-2,3,4,6-tetra-*o*-acetyl glucosidoxyphenyl) imidazole (2 g) in 25 mL of dry methanol was added 1.5 mL of 5% $CH_3ONa$ solution .The reaction mixture was kept at room temperature for additional 24 h. It was neutralized with ion-exchange resin (Amberlite IR 120, s.d. fine, $H^+$ form) filtered and concentrated in vacuum to afford viscous, strongly hygroscopic brown colored syrupy.

**2-(4-*o*-β-D-Glucosidoxyphenyl)-4,5-diphenyl imidazole (3a).** Yield 65%; $[\alpha]_D^{30} = -9.88$ (c, 0.1, DMSO); brown syrup; $R_f = 0.12$; FT-IR: 3200–3391.7 (—OH, broad, stretching). 2361.9 (aromatic str.), 1073.7 (C—O—C), 1609.9 $cm^{-1}$ (C=N). $^1$H NMR: 6.8–7.7 Hz (H, Ar—H), 10.5 (s, —NH), 4.8 (d, 1H, $J_{1,2} = 8.5$ Hz, 1′H) anomeric proton, 3.9 (1H, 2′H), 3.4 (dd, 1H, 3′H), 3.7 (1H, 4′H), 3.2 (1H, 5′H). $^{13}$C NMR: δ115–128 (Ar—C), sugar moiety: δ 100.26 (s, C-1′) anomeric carbon, 81 (s, C-6′), 77 (s, C-5′), 72 (s, C-4′), 70.5 (s, C-3′), 62 (s, C-2′). EI-MS the molecular ion peak were observed at 474 (M + 1) (46%) base peak observed at 312 (100 %), 118 (10 %), 77 (08 %). Anal.Calcd. for $C_{27}H_{26}N_2O_6$ (474): C, 68.34; H, 5.52; N, 5.90; Found: C, 68.37; H, 5.50; N, 5.86.

**2-(4-*o*-β-D-Glucosidoxyphenyl)-5-phenyl imidazole (3b).** Yield 58%; $[\alpha]_D^{30} = -15.20$ (c, 0.1, DMSO); brown syrup; $R_f = 0.8$; FT-IR: 3300 (—OH, broad), 2718.1 $cm^{-1}$ (aromatic str.), 1079.2 (C—O—C), 1620.6 $cm^{-1}$ (C=N). $^1$H NMR: 6.8–7.8 (m, 9H, Ar—H), 10.4 (s, 1H, —NH), 3.3 (1H,5′H), 3.5 (1H,4′H), 3.4 (1H,3′H), 3.8 (1H,2′H), 5.0 (dd, 1H, $J_{1,2} = 8.8$ Hz, 1′H).$^{13}$C NMR: δ115–128 (Ar—C), sugar moiety: δ108 (s, C-1′) anomeric carbon, 80 (s, C-6′), 76 (s, C-5′), 71.5 (s, C-4′), 70.5 (s, C-3′), 60 (s, C-2′). EI-MS: 398 (M) (20%), 220 (58%) 116 (100%) base peak, 105 (10%), 78(4%). Anal.Calcd. for $C_{21}H_{22}N_2O_6$ (398): C, 63.31; H, 5.57; N, 7.03; Found: C, 63.34; H, 5.50; N, 7.06.

**2-(4-*o*-β-D-Glucosidoxyphenyl) imidazole (3c).** Yield 60%; $[\alpha]_D^{30} = -5.22$ (c, 0.1, DMSO); brown syrup; $R_f = 0.15$; FT-IR: 3400 (—OH, broad), 2818.1 (aromatic str.), 1088.2 (C—O—C) glucosidic linkage, 1624 $cm^{-1}$ (C=N). $^1$H NMR: 6.5–7.9 (m, Ar—H), 11.4 (s, 1H,—NH), 3.2 (1H, 5′H), 3.4 (1H, 4′H), 3.5 (1H, 3′H), 3.9 (1H, 2′H), 5.5 (dd, 1H, $J_{1,2} = 10.2$ Hz, 1′H) anomeric proton. $^{13}$C NMR: δ116–130 (Ar—C), sugar moiety: δ110 (s, C-1′) anomeric carbon, 82 (s, C-6′), 77 (s, C-5′), 72.5 (s, C-4′), 71.5 (s, C-3′), 63 (s, C-2′). EI-MS: 322 (M) (28 %), 160 (100 %) base peak 146 (15 %), 77 (4 %). Anal.-Calcd. for $C_{15}H_{18}N_2O_6$ (322): C, 55.90; H, 5.63; N, 8.69; Found: C, 55.88; H, 5.60; N, 8.65.

**2-(4-*o*-β-D-Glucosidoxyphenyl)-4,5-dimethyl imidazole (3d).** Yield 68%; $[\alpha]_D^{30} = -11.10$ (c, 0.1, DMSO); brown syrup; $R_f = 0.16$; FT-IR: 3380 (—OH, broad), 2910 (aromatic str.), 1085.0 (C—O—C) glucosidic linkage, 1630 $cm^{-1}$ (C=N). $^1$H NMR: 6.0–7.4 (m, Ar—H), 10.2 (s,1H,—NH), 3.0 (1H,5′H), 3.2 (1H,4′H), 3.5 (1H,3′H), 3.7 (1H,2′H), 5.6 (dd, 1H, $J_{1,2} = 9.8$ Hz, 1′H) anomeric proton.$^{13}$C NMR: δ120–136 (Ar—C), sugar moiety: δ115 (s, C-1′) anomeric carbon, 88 (s, C-6′), 86 (s, C-5′), 76 (s, C-4′), 70. (s, C-3′), 65 (s, C-2′). EI-MS: 350 (M) (25 %), 170 (100 %) base peak 118 (12 %), 78 (8 %). Anal.Calcd. for $C_{17}H_{22}N_2O_6$ (350): C, 58.28; H, 6.33; N, 8.00; Found: C, 58.32; H, 6.36; N, 8.05.

**2-(4-*o*-β-D-Glucosidoxyphenyl)-4,5-bis-(4-chlorophenyl) imidazole (3e).** Yield 62%; $[\alpha]_D^{30} = -6.80$ (c, 0.1, DMSO); brown syrup; $R_f = 0.20$; FT-IR: 3420 (—OH, broad), 3015 (aromatic str.), 1088.0 (C—O—C) glucosidic linkage, 1630 $cm^{-1}$ (C=N).

2-(4-Substituted aryl)-4H-[1,3]thiazolo[3,2-a][1,3,5]triazine-4-thiones (**3a-3b**) and 2-(2-thiophene)-4H-[1,3]thiazolo[3,2-a][1,3,5]triazine-4-thione (**3d**) were synthesized by the reaction of arylisothiocyanates/thiophene-2-isothiocyanate with 2-aminothiazole in the presence of tetrabutylammonium bromide as phase transfer catalyst. Compound **3c** was synthesized by the catalytic reduction (10% Pd-C) of **3a**. Compounds **3a–d** were characterized by IR, $^{1}$H NMR, $^{13}$C NMR, and elemental analysis. All the compounds were tested *in vitro* against *Fusarium solani, A.fumigatus,* and *Aspergillus flavus* using standard drugs. The crystal structure of **3a** was determined from single crystal X-ray diffraction data.

## INTRODUCTION

Heterocyclic compounds containing nitrogen and sulphur possess potential pharmacological activities [1–4]. Recent years have seen a dramatic increase in fungal infections, mostly caused by *Candida albicans*; these infections are often spread through the use of broad-spectrum antibiotics, immunosuppressive agents, anticancer, and anti-AIDS drugs [5]. The main problem in the treatment of fungal infections is the increasing prevalence of drug resistance, especially in patient's chronically subjected to antimycotic therapy such as persons infected with HIV [6]. For these reasons, serious attention has recently been directed toward the discovery and development of new antifungal drugs.

Fused heterocyclic 1,3,5-triazines possess a wide array of biological activities such as herbicidal and fungicidal activity [7], antitumor activity [8], and inhibitory activity against the enzymes phosphodiesterase (PED) [9,10], which is expected to be the target for the treatment of diseases such as asthma, diabetes mellitus, and thrombosis. They are also able to block dihydrofolate reductase, the inhibition of which leads to cell death [11]. The title compounds are examples of such fused heterocyclic 1,3,5-triazines.

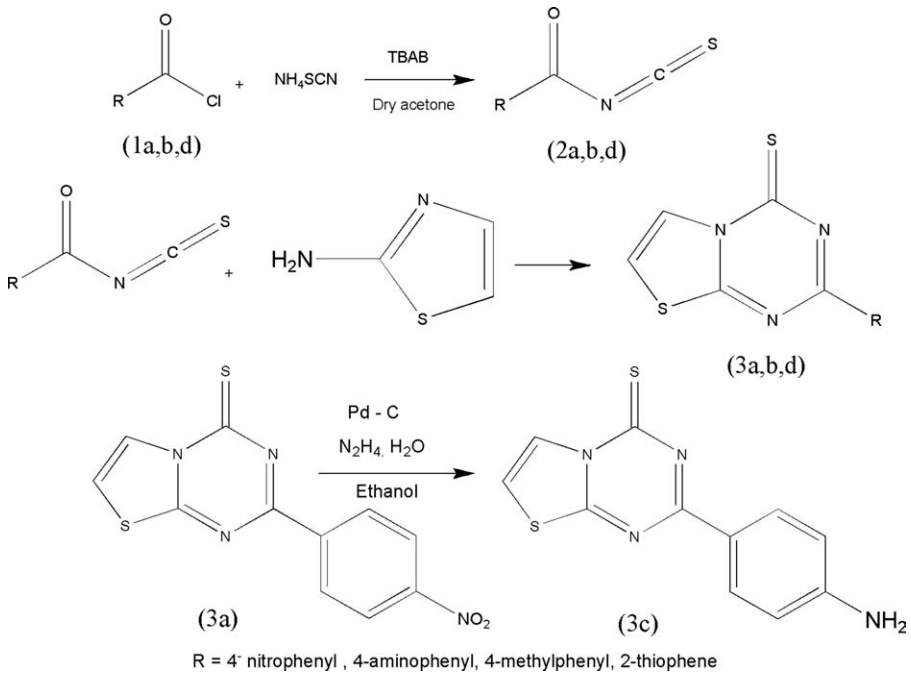
We became interested in the synthesis of fused heterocyclic 1,3,5-triazine compounds containing aryl and thiophene moieties and in the systematic study of their biological activity. All the structures of these novel target compounds were characterized by spectroscopic techniques. We have also confirmed the structure of one representative by X-ray crystallography.

## RESULTS AND DISCUSSION

A series of new fused heterocyclic 1,3,5-triazines **3a–d** with thiophene and aroyl substituents (Scheme 1) were prepared by slight modification of published procedures [12,13]. The use of phase transfer catalysts (PTCs) as a method of agitating a heterogeneous reaction system is gaining recognition [14,15]. In search of improved methods to prepare the target fused heterocyclic 1,3,5-triazines by reacting isothiocyanates with nucleophiles, we have found the use of tetrabutylammonium bromide (TBAB) as PTC, which can afford thiophenoyl and aroyl isothiocyanates in good yield, as reported here.

All the structures of newly synthesized compounds were assigned on the basis of their elemental analysis and spectroscopic data, IR, and $^{1}$H NMR. All the

**Scheme 1.** Preparation of compounds (**3a–d**).



compounds were soluble in DMF, DMSO, ethanol, and ethyl acetate.

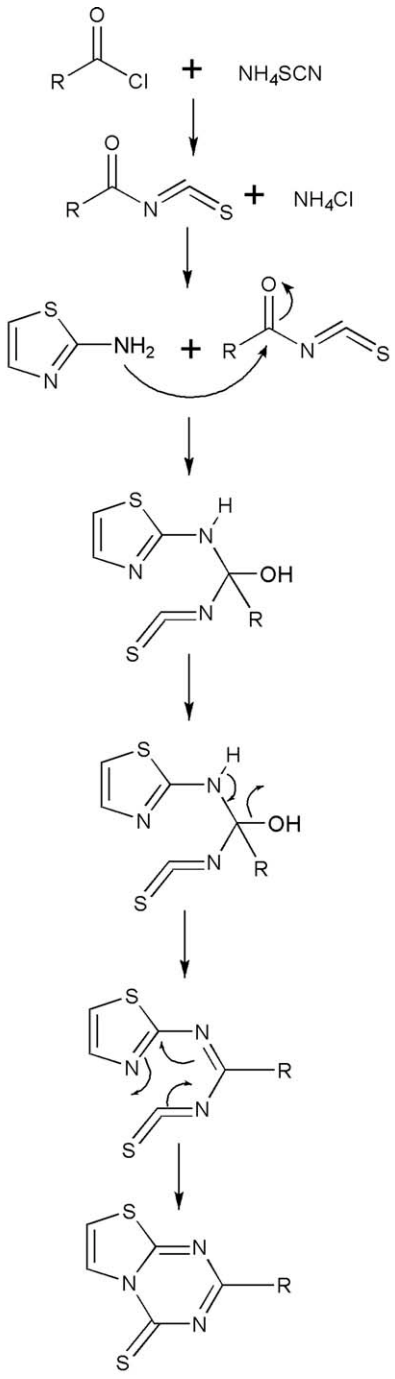
Surprisingly, to the best of our knowledge, 2-(4-substituted phenyl)-4H-[1,3]thiazolo [3,2-a][1,3,5]triazine-4-thiones (**3a–c**) and 2-(2-thiophene)-4H-[1,3]thiazolo [3,2-a][1,3,5]triazine-4-thione (**3d**) have never been described in the literature. The formation of **3a–d** would be explained through the formation of an unstable intermediate form containing thiazole, alcoholic, and isothiocyanate functional groups as shown in Scheme 2. The yield of the target products was very sensitive to the reaction conditions. Two types of products were obtained during the reaction of arylisothiocyanate with 2-aminothiazole. The major product, using a molar ratio of 1:1 between arylisothiocyanate and 2-aminothiazole, was a fused heterocyclic 1,3,5-triazine with about 75% yield and the minor product was a thiourea derivative with about 20% yield. Initially, the experiments were performed three times and these yields remained. However, the yield of fused heterocyclic 1,3,5-triazine products increased to above 90% when the molar concentration of 2-aminothiazole was doubled and refluxed time increased to 4.5 h.

The cyclization of **2a–d** to fused heterocyclic 1,3,5-triazines **3a–d** was monitored by the IR spectra, where the carbonyl chloride peak disappeared on the expense of the appearance of thioamide (C=S) peak in the region of 1445–1440 $cm^{-1}$. The thioamide group was also confirmed by $^{13}C$ NMR, with signals at δ 182–179 ppm.

Single crystals of **3a** suitable for X-ray diffraction studies were obtained by evaporation from dichloromethane/ethanol. The molecular structure is shown in Figure 1. Molecular dimensions may be regarded as normal. The bicyclic thiazolotriazine system is planar (mean deviation 0.01 Å) and subtends an interplanar angle of 11.9° to the phenyl ring. The molecular packing (Fig. 2) displays two contacts, H16···O2 2.36 Å and S1···O1 3.01 Å, which combine to form ribbons parallel to the vector [100] and to the plane (012). These ribbons are connected by N1···O2 3.03 Å (not shown).

Primary bioassay screening provides the first indication of bioactivities and helps in the selection of lead compounds for secondary screening for detailed pharmacological evaluation. The synthesized fused heterocyclic 1,3,5-triazines **3a–d** were checked for their antifungal activity against three fungal strains: *Fusarium solani, A.fumigatus,* and *Aspergillus flavus*. The antifungal activity was carried out in DMSO using the agar tube dilution method [16]. Growth in the media was determined by measuring linear growth (mm) and growth inhibition was calculated with reference to the negative control. No significant activity against yeast was detected. All the compounds in the series showed weak antimicrobial activity against *Fusarium solani, A.fumigatus,* and *Aspergillus flavus* with 30–40% inhibition, which shows low activity. However, the compound 2-(2-thiophene)-4H-[1,3]thiazolo [3,2-a][1,3,5]triazine-4-thione (**3d**) showed 40% inhibition.

**Scheme 2.** Proposed reaction mechanism.



## EXPERIMENTAL

Melting points were recorded on Electrothermal IA9000 series digital melting point apparatus. The proton NMR and $^{13}C$ spectra were recorded in DMSO-$d_6$ solvent on Bruker 300 MHz spectrophotometer using tetramethylsilane as an internal reference, respectively. The apparent resonance multiplicity is described as s (singlet), br s (broad singlet), d (doublet), dd (doublet of doublets), t (triplet), q (quartet), and m (multiplet). Infrared measurements were recorded in the range 400–4000 $cm^{-1}$ on spectrum 2000 by Perkin Elmer. Elemental analysis was carried out using Perkin Elmer CHNS/O 2400. Obtained results were within 0.4% of the theoretical values. Thin layer chromatography (TLC) analysis were carried out on 5 × 20 cm plate coated with silica gel $GF_{254}$ type 60 (25–250 mesh) using an ethyl acetate-petroleum ether mixture (1:2) as solvent.

**2-(4-Nitrophenyl)-4H-[1,3]thiazolo[3,2-a][1,3,5]triazine-4-thione (3a).** A solution of 4-nitrobenzoyl chloride (1.85 g, 0.01 mol) in anhydrous acetone (80 mL) and 3% TBAB in acetone was added dropwise to a suspension of ammonium thiocyanate (0.76 g, 0.01 mol) in acetone (50 mL), and the reaction mixture was refluxed for 45 min. After cooling to room temperature, a solution of 2-aminothiazole (1.0 g, 0.01 mol) in acetone (25 mL) was added and the resulting mixture refluxed for 4.5 h. The reaction mixture was poured into five times its volume of cold water, to precipitate the product, which was recrystallized from ethanol: dichloromethane (1:2) as intensely yellow crystals. Yield: 1.50 g (93%), m.p. 196°C; IR (KBr pellet) in $cm^{-1}$: 1529 (benzene ring), 1512 ($NO_2$), 1401 (C—N stretching), 1140 (C=S); $^1H$ NMR (300 MHz, DMSO-$d_6$) in δ (ppm) and $J$ (Hz): 8.10(2H, d, $J$ = 8.41), 7.34 (2H, d, $J$ = 8.7 Hz); $^{13}C$ NMR (300 MHz, DMSO-$d_6$) in δ (ppm): 179.2 (C=S), 165.5 (C), 162.0 (C), 150.4 (C), 145.6 (C), 141.3 (C), 135.1 (C), 128.4 (C) .*Anal*.Calcd. for $C_{11}H_6N_4O_2S_2$ (290.32): C, 45.51; H, 2.08; N, 19.30; S, 22.09. **2-(4-Methylphenyl)-4H-[1,3]thiazolo[3,2-a][1,3,5]triazine-4-thione (3b).** A solution of 4-methylbenzoyl chloride (1.54 g, 0.01 mol) in anhydrous acetone (80 mL) and 3% TBAB in acetone was added dropwise to a suspension of ammonium thiocyanate (0.76 g, 0.01 mol) in acetone (50 mL), and the reaction mixture was refluxed for 45 min. After cooling to room temperature, a solution of 2-aminothiazole (1.0 g, 0.01 mol) in acetone (25 mL) was added and the resulting mixture refluxed for 4.5 h. The reaction mixture was poured into five times its volume of cold water to precipitate the product, which was recrystallized from ethanol as a pale yellow power. Yield: 1.50 g (90%), m.p. 175°C; IR (KBr pellet) in $cm^{-1}$: 1531 (benzene ring), 1403 (C—N stretching), 1143 (C=S); $^1H$ NMR (300 MHz, DMSO-$d_6$) in δ (ppm) and $J$ (Hz): 8.04(2H, d, $J$ = 8.33), 7.24 (2H, d, $J$ = 8.5 Hz), 2.46 (3H,s, —$CH_3$); $^{13}C$ NMR (300 MHz, DMSO-$d_6$) in δ (ppm) : 180.1 (C=S), 165.0 (C), 162.7 (C), 150.4(C), 145.5 (C), 140.7 (C), 135.3 (C), 127.8(C), 25.0 (C). *Anal*.Calcd. for $C_{12}H_9N_3S_2$ (259.35): C, 55.57; H, 3.50; N, 16.20; S, 24.73.Found: C, 55.59; H, 3.52; N, 16.18; S, 24.72.

**2-(4-Aminophenyl)-4H-[1,3]thiazolo[3,2-a][1,3,5]triazine-4-thione (3c).** Compound **3a** (2.60 g, 0.01 mol), 5 mL hydrazine monohydrate, 70 mL ethanol and 0.03 gm of 10% Pd—C was transferred into 250-mL two-necked round-bottom flask and refluxed for 18 h. The reaction was monitored by TLC. After completion, the reaction mixture was allowed to stand for 1 day and then filtered. The solvent was removed by rotary evaporation. The crude product was recrystallized from ethyl acetate. Yield: 1.50 g (85%), m.p. 165°C; IR (KBr pellet) in $cm^{-1}$: 1529 (benzene ring), 1405 (C—N stretching), 1140 (C=S); $^1H$ NMR (300 MHz, DMSO-$d_6$) in δ (ppm) and $J$ (Hz): 8.10(2H, d, $J$ = 8.41), 7.34 (2H, d, $J$ = 8.7 Hz), 4.01(2H, br s, $NH_2$); $^{13}C$ NMR (300 MHz, DMSO-$d_6$) in

## ANTIFUNGAL SCREENING

The antifungal activity was carried out in DMSO using the agar tube dilution method. Sabouraud dextrose agar (Merck) was prepared by dissolving 6.5 g/mL in distilled water and the pH was adjusted to 5.6. The contents were dissolved and dispensed in 4-mL aliquots into screw-capped tubes and were autoclaved at 121°C for 21 min. The tubes were allowed to cool to 50°C and nonsolidified SDA was loaded with 66.6 μL of compound by pipette from stock solution, giving a final concentration of 200 μg/mL. The tubes were then allowed to solidify in a leaning position at room temperature. Tubes were prepared in triplicate for each fungus species. The tubes containing solidified media and test compound were inoculated with 4-mm diameter pieces of inocula, taken from a 7-day-old culture of fungus. Other media supplemented with DMSO and nystatin were used as negative and positive control, respectively. The tubes were incubated at 27°C for 7 days. Cultures were examined twice weekly during the incubation. Growth in media was determined by measuring linear growth (mm) and growth inhibition was calculated with reference to the negative control.

In this study, the possibility of 5-substituted 1-*H*-tetrazoles synthesis using clays as catalyst was investigated. The reaction of a series of aromatic nitriles with sodium azide was catalyzed by montmorillonite K-10 or kaolin clays in water or DMF as solvent. Conventional heating or ultrasonic irradiation was used to promote reaction. The amount of nitrile to sodium azide mole ratio, amount of catalyst, reaction time, and solvent type were optimized. The versatility of this method was checked by using various nitriles, which showed reasonable yields of tetrazole formation. It was found that using nitriles with electron-withdrawing groups result in both higher yields and lower reaction times. The catalysts could be reused several times without significant loss of their catalytic activity. Compared to conventional heating, ultrasonic irradiation reduced reaction times and increased catalyst activity. The present procedure is green and offers advantages, such as shorter reaction time, simple workup, and recovery and reusability of catalyst.

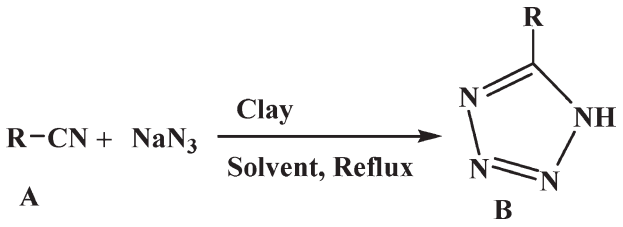
## INTRODUCTION

Tetrazoles are important heterocyclic compounds in medicinal chemistry [1–3]. Among them 5-substituted 1-*H*-tetrazoles are often used as metabolically stable surrogates for carboxyl group and for cis-amide bond [4,5]. Also, an enormous number of biologically active compounds are known, which contain tetrazole [6–8]. The [2+3] cycloaddition of nitriles and azides is a common method for the synthesis of tetrazole derivatives. Because of biological importance of tetrazoles, various synthetic methodologies have been developed for their synthesis. In most of these methods, highly toxic and explosive hydrazoic acid generates through activation of the azide by using strong Lewis acids [9,10], expensive and toxic metals [11–13], or amine salts [14]. The ''click'' chemistry approach using zinc catalysis in aqueous solution is a magnificent improvement over previous methods [15,16], but still requires the tedious and time-consuming steps such as removal of zinc salts from the acidic products. Clay-catalyzed organic transformations have been recently developed and obtained great interest as green methods. This has been attributed to their inexpensive nature and special catalytic activity under heterogeneous reaction conditions [17–22]. Acidic clays are suitable replacement of various homogeneous acid catalysts. They have been used in the synthesis of 1,5-benzodiazepines [23], acetonide protection [24], alkylation of benzene [25], Diels-Alder reaction [26], dihydrofuran synthesis [27], and bromination and chlorination of aromatic compounds [28]. In continuing with our research in tetrazole chemistry [29–31] and application of clays in organic transformations [32,33], herein we report a new process for synthesis of 1-*H*-5-substituted tetrazoles using clays as safe, environmentally benign, and inexpensive catalysts.

## RESULTS AND DISCUSSION

**Synthesis of tetrazoles derivatives under reflux condition.** In the reaction between benzonitrile **1a** and sodium azide (Scheme 1), effect of the catalyst amount was investigated. The different catalyst amounts (20, 50, and 100 mg) were used, and it was found that the maximum reaction yield obtained using 50 mg of catalyst. The results show that for K-10 when the catalyst amount

**Scheme 1.** Clay-catalyzed synthesis of 5-substituted 1-*H*-tetrazoles.



Clay=Montmorillonite K-10; Kaolin

increased to 20 and 50 mg, the conversion increased to 45 and 94% and 56 and 95% in water and DMF as solvent, respectively. However for kaolin, increase of catalyst amount from 20 to 50 mg increased the conversion from 27 to 95% and 43 to 94% in water and DMF, respectively. Also, it is obvious that the catalyst amount more than 50 mg has no significant effect on the conversion of benzonitrile to corresponding tetrazole. Any attempts to carry out the reactions in the absence of montmorillonite K-10 and kaolin were failed, and no products were found despite prolonged reaction times, which emphasis the clay catalytic role. To see whether the action of clays is truly catalytic, we reduced the amount of clays in the reaction between sodium azide and benzonitrile from 20 to 10 mg.

Upon our results, it is evident that a low loading of K-10 and kaolin is still effective, although the reactivity was decreased consequently (see Table 1, entries 13, 14). Even 10 mg of K-10 and kaolin afforded the desired product after 24 h in 29 and 40% yields in water and 38 and 17% yields in DMF, respectively. Although the activity of K-10 in DMF was slightly higher than kaolin, but there is no significant difference between specific activities of these two catalysts in both solvents. One important advantage of clays as catalyst is the easy workup of the reaction. After completion of the reaction, simple filtration of the reaction mixture followed by acidification of filtrate result in precipitating the product as a white powder. Another advantage of this method is its large-scale applicability. For this, we examine a run with 30 mmol of benzonitrile in DMF as the solvent, and the results were comparable to those obtained in the small-scale experiments. The effect of solvent was examined using water and DMF. The results showed that DMF because of its higher boiling point is more efficient. However, the use of water as a clean, inexpensive, and universal solvent combines features of both economic and environmental advantages. A close look at Figure 1 reveals that conversion rate of benzonitrile to phenyl tetrazole for both K-10 and kaolin in the DMF is faster. For example, with using montmorillonite K-10 as catalyst after 6 h, benzonitrile conversion was 72 and 53% in DMF and water, respectively. At the same condition, the conversion values for kaolin were 66 and 54% in DMF and water, respectively (see Fig. 1). The variation of the reaction conversion with the amount of sodium azide was studied, and the experimental results are tabulated in Table 1. It is apparent that the reaction conversion increased as the mole ratio of benzonitrile to sodium azide increased from 1:1 to 1:3 (from 50 to 94% and 69 to 95% for K-10 and from 20 to 95% and 27 to 94% for kaolin in DMF and water, respectively).

[a] Reaction time (24 h).
[b] Conversion was calculated using HPLC. Left (K-10) and right (kaolin).

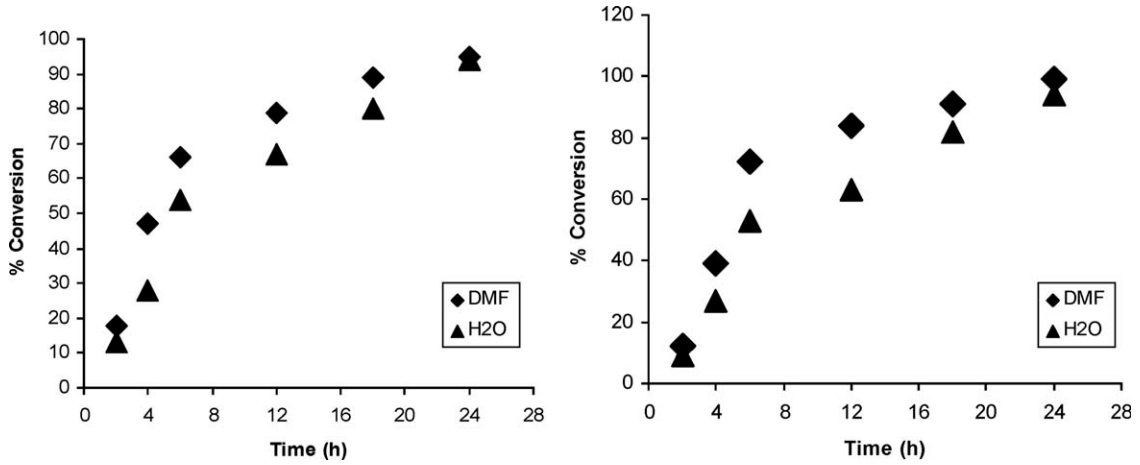

**Figure 1.** Effect of time on conversion of benzonitrile to phenyl tetrazole in DMF and water under reflux condition using montmorillonite K-10 and kaolin. Condition: 2 mmol benzonitrile and 6 mmol sodium azide.

Further increase in mole ratio to 1:5, the benzonitrile conversion decreased slightly to 74 and 75% for K-10 and 81 and 78% for kaolin in the DMF and water, respectively (Table 1, entries 11, 12). This observation suggesting that the excess values of sodium azide may block active sites of catalysts.

The catalytic role of clays in the synthesis of tetrazoles was investigated by two reaction without use of catalysts. The results indicate that no progress was observed. (Table 1, entries 15 and 16).

The effect of time on the product yield using montmorillonite K-10 and kaolin is shown in Figure 1. The conversion increases from 12 to 91% and 9 to 82% as the time increased from 2 to 18 h. With further increase in reaction time to 24 h, formation of phenyl tetrazole marginally increases and reaches to 94 and 95% for K-10 in the water and DMF, respectively. Moreover for kaolin, as the time increased from 2 to 24 h conversion increases from 18 and 13% to 95 and 94% in the water and DMF, respectively.

One of the most important advantages of heterogeneous catalysis over the homogeneous counterpart is the possibility of reusing the catalyst by simple filtration, without loss of activity. The recovery and reusability of the catalyst was investigated in the tetrazole formation with benzonitrile. After completion of the reaction, the catalyst was separated by filtration, washed three times with 5 mL acetone, then with doubly distilled water several times, and dried at 110°C. Then, the recovered catalyst was used in the next run. The results of three consecutive runs showed that the catalyst can be reused several times without significant loss of its activity (see Fig. 2).

Several substituted nitriles reacted with sodium azide to give the corresponding tetrazoles in good yields. Heteroaromatic nitriles such as 2, 3, and 4-pyridinecarbonitriles give the corresponding tetrazoles with excellent yields (Table 2, entries 3–5). Interestingly, phthalonitriles afford the monoaddition product (Table 2, entries 7–9). The nature of the substituents on the nitriles has a significant effect on the tetrazole yield (Table 2). The highest conversions were observed for nitriles with electron-withdrawing substituents (Table 2, entries 1–11).

However, electron-donating groups (*e.g.*, OH and $NH_2$) were the least reactive ones. With acetylation of 4-hydroxy benazonitrile, the reaction yield was improved, but for acetylated 4-amino benzonitrile even with long reaction times no product was formed (Table 2, entries 14–16). A probable mechanistic pathway for synthesis of tetrazoles from nitriles has been shown in Figure 3. Based on this mechanism, the nitrile activated

by clay in the first stage and this activated fragment attacked by azide ion to produce the imidoyl azide. The imidoyl azide then converted to tetrazole derivative.

**Synthesis of tetrazole derivatives under ultrasonic irradiation.** Ultrasound has been used recently to accelerate a number of synthetically useful reactions [34,35]. The ultrasound effects observed on organic reactions are due to cavitation, a physical process that create, enlarge, and implode gaseous and vaporous cavities in an irradiated liquid. Impulsion of the cavitational bubbles, extreme temperatures, and pressures is generated at the center of the collapsed bubble [36–38]. These effects may enhance liquid–solid mass transfer and cause physicochemical change in the processed medium considerably [39,40]. Advantages and attractive features of sonochemistry led us to explore the effect of ultrasonic waves on this catalytic system. For this reason, reactions were exposed to ultrasonic irradiation using two clay catalysts in the water as the solvent.

The obtained results within reaction conditions are summarized in Table 3. The effect of catalyst amount on reaction times tested, and it was found that with increasing of catalyst amount all reaction times reduced. For example, for phenyl tetrazole with increase of catalyst amounts from 50 to 100 mg, the reaction times reduced from 90 to 40 and 120 to 50 min for montmorillonite and kaolin, respectively (Table 3 entry 1). Again a close look at Table 3 reveals that there is no significant difference between montmorillonite K-10 and kaolin, although the activity of K-10 in water under ultrasound irradiation is slightly higher than kaolin. A comparison of results obtained with nonultrasound reactions (Tables 1 and 2) shows that with ultrasound irradiation the reaction times reduced.

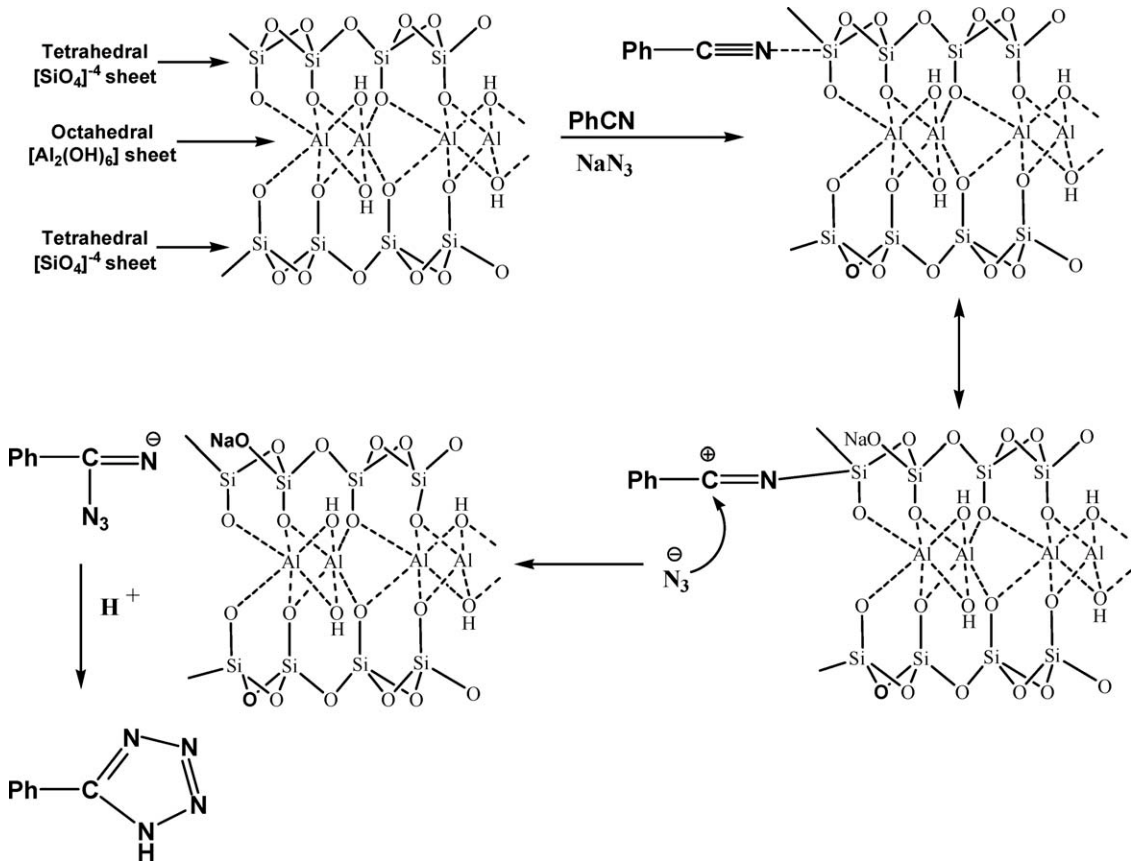

**Figure 3.** Proposed mechanism for conversion of nitriles to tetrazoles over K-10 clay.

## CONCLUSION

In conclusion, we developed a simple, environmentally benign, and efficient method for the preparation of 5-substituted 1-*H*-tetrazoles using clay catalysts. Various nitriles reacted with $NaN_3$ at 100–130°C to yield the corresponding 5-substituted 1-*H*-tetrazoles with moderate to good yields. This methodology may find widespread use in organic synthesis for the preparation of tetrazoles. The advantages of this catalytic system are as follows: mild reaction condition, high product yields, easy preparation of the catalysts, nontoxicity of the catalysts, and simple and clean workup of the desired products.

## EXPERIMENTAL

**Materials and instruments.** Montmorillonite K-10, kaolin, sodium azide, and nitriles all were procured from Aldrich and Merck. A JASCO FT/IR-680 PLUS spectrometer was used to record IR spectra using KBr pellets. NMR spectra were recorded on a Bruker 400 Ultrasheild NMR, and DMSO-$d_6$ was used as a solvent. Melting points reported were determined by open capillary method using a Galen Kamp melting point apparatus and are uncorrected. Mass spectra were recorded on a Shimadzu gas chromatograph mass spectrometer GCMS-QP5050A/Q P5000 apparatus. HPLC analysis was performed using a series 1100 Agilent instrument equipped with Zorbax eclips $C_{18}$ as column, detection at 254 nm, and 30% methanol in water as mobile phase. Reactions under ultrasonic irradiation were performed in an ultrasonic bath with heating system (Tecno-GAZ SPA Ultra Sonic System) at 40 kHz of frequency and 500 W of power. Catalysts were activated before the reaction runs with HCl (2*M*) in the solid to liquid ratio of 1:4 (40 mL, 2*M* HCl for 10 g clay) for a period of 45 min and then filtered. To remove chloride ions, catalysts were washed thoroughly with doubly distilled water and dried in an air oven at 100°C for 6 h.

**General procedure for preparation of tetrazoles under reflux condition.** The procedure for the synthesis of the tetrazole **2a** (Scheme 1) is representative. In a round bottom flask, benzonitrile (0.2 g, 2 mmol), sodium azide (0.4 g, 6mmol), montmorillonite K-10 (50 mg), and DMF or water (20 mL) were charged. Then, the reaction mixture was refluxed for 24 h. The progress of reaction (after 2, 4, 6, 12, 18, and 24 h) was followed by HPLC and TLC (75:25 ethyl acetate/*n*-hexane). After that the reaction was cooled to room temperature, and insoluble material was filtered and washed with doubly distilled water and acetone to separate the catalyst. The solution was acidified with HCl (5 mL, 12*M*). The precipitate was collected, dried, and recrystallized from water/ethanol to afford pure 5-phenyl-1*H*-tetrazole (**1b**) as a white powder weight, mp = 212–214°C; 0.26 g (90% yield). $^1$H NMR (DMSO-$d_6$, 400

**General procedure for preparation of tetrazoles under ultrasonic irradiation.** In a round bottom flask, benzonitrile (0.2 g, 2 mmol,), sodium azide (0.4 g, 6mmol), and DMF or water (20 mL) were charged. The flask was suspended into the ultrasonic bath at the reaction temperature (333 K). Then, 50 mg of catalyst (montmorillonite K-10 or kaolin) was added and the reaction time measured. The flask was suspended at the center of the bath. The progress of the reaction was monitored by TLC. After that the reaction was cooled to room temperature, and product was recovered as mentioned.

**Acknowledgment.** Support from Yasouj University (YU) is gratefully acknowledged. The authors thank the faculty members in the Instrumental Analysis Center of Isfahan Payame Noor University for the measurements of mass spectra.

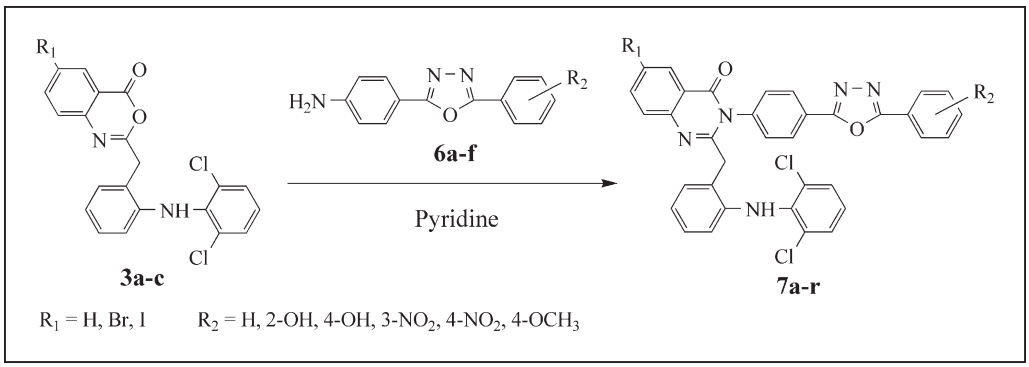
Published online 18 June 2010 in Wiley InterScience (www.interscience.wiley.com).



A series of 1,3,4-oxadiazolyl-quinazolin-4(3*H*)ones have been synthesized using known methods. All the compounds have been established on basis of elemental analysis, IR and NMR spectral data. The *in vitro* antimicrobial screening of the synthesized compounds were carried out against two gram-positive bacteria (*S. aureus*, *S. pyogenes*), two gram-negative bacteria (*E. coli*, *P. aeruginosa*), and three fungal species (*C. albicans*, *A. niger*, *A. clavatus*) using the broth microdilution method. The compounds **7d**, **7g**, **7l**, **7o**, **7p**, and **7r** possessed pronounced antibacterial activity whereas compound **7p** exhibited promising antifungal activity.

*J. Heterocyclic Chem.*, **47**, 923 (2010).

## INTRODUCTION

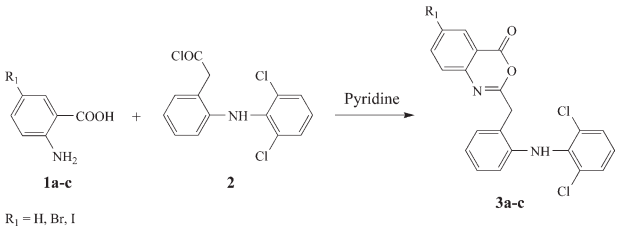
Heterocyclic skeleton contained nitrogen atom is the basic of many pharmaceuticals, to be an active compound. 1,3,4-Oxadiazoles are five member nitrogen atom contained heterocycles, represent broad spectrum of biological activity in both agrochemicals and pharmaceuticals such as insecticidal [1], herbicidal [2], antibacterial [3], antifungal [4], analgesic [5], anti-inflammatory [6], antimalarial [7], antiviral [8], anti-HBV [9], antianexiety [10], anticancer [11], anti-HIV [12], antitubercular [13], and anticonvulsant [14]. Quinazolin-4(3*H*)one derivatives are six member fused heterocycles, possess potent pharmacological activities like antibacterial [15], antifungal [16], analgesic [17], anti-inflammatory [18], anthelminthic [19], antitumor [20], anticonvulsant [21], antihistaminic [22], anti HIV [23], antiproliferative [24], antitubercular [25], antiviral [26], CNS depressant [27], cytotoxicity [28], diuretic [29], and hypolipidemic [30].

The 1,3,4-oxadiazole and quinazolin-4(3*H*)one containing various heterocycle exhibited good pharmacological activities. The aim of this work was to attach 1,3,4-oxadiazole to quinazolin-4(3*H*)one in order to find new biologically active molecule. Thus, synthesis of novel 1,3,4-oxadiazolyl-quinazolin-4(3*H*)one derivatives has been achieved.

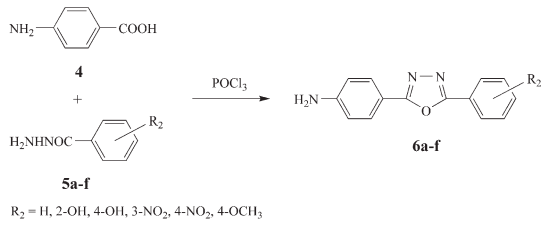
## RESULT AND DISCUSSION

2-[2-(2,6-Dichlorophenyl)amino]benzyl-3,1-benzoxazin-4(*H*)ones **3a-c** were synthesized from substituted anthranilic acids and acid chloride according to the reported process (Scheme 1) [31,32]. The required 2-[(2,6-dichlorophenyl)amino]phenyl acetyl chloride **2**, which is moisture sensitive and easily hydrolysable compound, was synthesized by reported method [33] and used directly in the next step. The cyclization reaction of acid chloride and substituted anthranilic acid in highly basic medium of pyridine at 0–5°C afforded 2-[2-(2,6-dichlorophenyl)-amino]benzyl-3,1-benzoxazin-4(*H*)ones **3a-c**. The structural determinations of these compounds have been

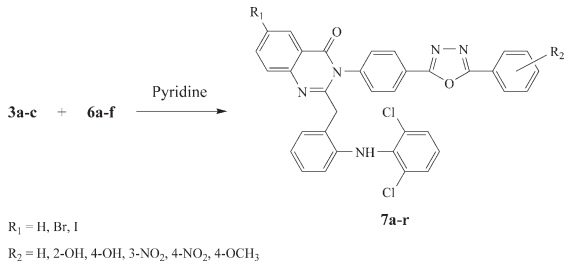
**Scheme 1**



**Scheme 2**



**Scheme 3**



carried out using IR and NMR spectral data. IR spectra showed strong C=O and C=N stretching at around 1740 and 1620 $cm^{-1}$ while $^{13}$C-NMR spectra showed C=O and C=N signal at around δ 159 ppm and δ 165 ppm respectively. 2-(4-Aminophenyl)-5-substitutedphenyl-1,3,4-oxadiazoles **6a-f** were synthesized according to reported method (Scheme 2) [34]. All amino substituted 1,3,4-oxadiazole derivatives showed satisfactory IR and NMR spectral results. Finally the condensation reaction of 4-benzoxazinones **3a-c** with amino substituted 1,3,4-oxadiazoles **6a-f** in pyridine afforded the desired compounds **7a-r** (Scheme 3) [35]. IR spectra showed strong C=O and C=N stretching of quinazolin-4(3*H*)ones at around 1680 and 1610 $cm^{-1}$, respectively. $^{13}$C-NMR spectra showed C=O and C=N signal of quinazolin-4(3*H*)ones near δ 161 ppm and δ 163 ppm respectively. All the synthesized compounds showed satisfactory $^{1}$H-NMR spectral results and for all compounds satisfactory elemental analyses were obtained.

The *in vitro* antibacterial activities of the synthesized compounds are shown in Table 1. The antibacterial activities are expressed in terms of Minimal Bactericidal Concentrations (MBCs μg/mL). The synthesized compounds were screened against two gram positive bacteria (*S. aureus* MTCC 96, *S. pyogenes* MTCC 443) and two

gram negative bacteria (*E. coli* MTCC 442, *P. aeruginosa* MTCC 441). Ampicillin was used as a standard drug. The results show that some of the amino substituted 1,3,4-oxadiazoles possessed good activity against *S. aureus* while moderate activity against *S. pyogenes*, *E. coli* and *P. aeruginosa* compared to ampicillin but its 4-quinazolinonyl derivative displayed very good activity in some cases. Compounds **7d**, **7e**, **7g**, **7l**, **7n**, **7o**, **7p**, **7q**, and **7r** showed very good activity (150–250 μg/mL) against *S. aureus*. Compounds **7b**, **7d**, **7e**, **7f**, **7g**, **7l**, **7o**, **7p**, **7q**, and **7r** exhibited moderate activity (150–250 μg/mL) against *S. pyogenes*. Compounds **7g**, **7l**, **7n**, **7o,** and **7r** possessed good activity (100–125 μg/mL) while **7a**, **7b**, **7c**, **7d**, **7f**, **7h**, **7i**, **7j**, **7m**, and **7p** showed moderate activity (150–250 μg/mL) against *E. coli*. Compounds **7b** and **7f** exhibited good activity (100 μg/mL) while **7a**, **7c**, **7d**, **7g**, **7h**, **7i**, **7l**, **7m**, **7n**, **7o**, **7p**, **7q**, and **7r** possessed moderate activity (150–250 μg/mL) against *P. aeruginosa*.

*In vitro* antifungal activity results are shown in Table 2. Antifungal activities are shown in minimal fungicidal concentrations (MFCs μg/mL). The synthesized compounds were screened against three fungal species *C. albicans*, *A. niger* and *A. clavatus*. Greseofulvin was used as a standard drug. Results show that amino substituted 1,3,4-oxadiazoles possessed good activity while its 4-quinazolinonyl derivative showed increased activity against *C. albicans*. Compounds **7d**, **7e**, **7g**, **7j**, **7k**, **7l**, **7m**, **7p**, and **7q** showed pronounced activity (200–250 μg/mL) against *C. albicans*. Amino substituted 1,3,4-oxadiazoles possessed poor activity against *A. niger* and *A. clavatus* while some of its 4-quinazolinonyl derivative exhibited moderate activity. Compound **7p** was found active against *A. niger* (MFC = 250 μg/mL) whereas compounds **7b**, **7c**, and **7p** were found active against *A. clavatus* (MFC = 200–250 μg/mL) among the whole series.

## CONCLUSION

The *in vitro* antimicrobial screening results were found satisfactory. Amino substituted 1,3,4-oxadiazoles possessed good antibacterial activity but its 4-quinazolinonyl derivative showed increased activity in most of cases. All the compounds displayed very good antifungal activity

against *C. albicans* while poor activity was observed against *A. niger* and *A. clavatus*, except **7p**, **7b**, and **7c** (**7p** was found active against *A. niger* and *A. clavatus* while **7b** and **7c** were found active against *A. clavatus*).

## EXPERIMENTAL

All chemical were of analytical grade and used directly. Melting points were determined in PMP-DM scientific melting point apparatus and are uncorrected. The purity of compound was confirmed by TLC using Merck silica gel 60 F254. Infrared spectra were recorded on a Perkin-Elmer RX 1 FTIR spectrophotometer, using potassium bromide (KBr) pellets, the frequencies are expressed in $cm^{-1}$. The nuclear magnetic resonance spectra were recorded with a Bruker Avance II 400 NMR spectrometer, using tetramethylsilane (TMS) as the internal reference, with dimethylsulphoxide (DMSO-$d_6$) as solvent. The chemical shifts are reported in parts per million (δ ppm). Elemental analyses were performed on a Heraeus Carlo Erba 1180 CHN analyzer.

**General procedure for the synthesis of 2-[2-(2,6-dichlorophenyl)amino]benzyl-3,1-benzoxazin-4(*H*)ones (3a-c).** The mixture of 3.05 g (0.01 mole) of acid chloride (2) and 1.37 g (0.01 mole) of anthranilic acid (1a) in 20 mL of dry pyridine were stirred at 0–5 °C for 1 h, further stirred for 1 h at room temperature. Progress of reaction was check by TLC using toluene:ethylacetate (80:20) as mobile phase. After completion of reaction, a pasty mass obtained, was washed thoroughly with sodium bicarbonate (5% w/v) to remove unreacted acid. A solid separated was filtered, dried and recrystallized from methanol. Other benzoxazinone derivatives **3b, c** were synthesized by the same method.

**General procedure for the synthesis of 2-(4-aminophenyl)-5-substitutedphenyl-1,3,4-oxadiazoles (6a-f).** A mixture of 0.69 g (0.005 mole) of 4-amino benzoic acid and substituted benzoic acid hydrazides (0.005 mole) in 5 mL of phosphorus oxychloride was refluxed on water bath for 7–10 h. The progress of the reaction was monitored by TLC using toluene:ethylacetate:methanol (70:20:10) as mobile phase. After the completion of reaction, it was cooled and poured onto crushed ice with continuous stirring. The solid mass separated was neutralized with sodium bicarbonate solution (10% w/v). The resulting solid thus obtained was collected by filtration, washed well with cold water, dried and crystallized from absolute ethanol.

**General procedure for *in vitro* antimicrobial screening.** The MICs of synthesized compounds were carried out by broth microdilution method as described by Rattan [36]. Antibacterial activity was screened against two gram-positive bacteria (*S. aureus* MTCC 96, *S. pyogenes* MTCC 443) and two gram-negative bacteria (*E. coli* MTCC 442, *P. aeruginosa* MTCC 441). Ampicillin was used as a standard antibacterial agent. Antifungal activity was screened against three fungal species *C. albicans* MTCC 227, *A. niger* MTCC 282 and *A. clavatus* MTCC 1323. Greseofulvin was used as a standard antifungal agent.

All MTCC cultures were collected from Institute of Microbial Technology, Chandigarh and tested against above mentioned known drugs. Mueller Hinton broth was used as nutrient medium to grow and dilute the drug suspension for the test. Inoculum size for test strain was adjust to $10^8$ CFU (Colony Forming Unit) per milliliter by comparing the turbidity. DMSO was used as diluents to get desired concentration of drugs to test upon standard bacterial strains. Serial dilutions were prepared in primary and secondary screening. The control tube containing no antibiotic was immediately sub cultured (before inoculation) by spreading a loopful evenly over a quarter of plate of medium suitable for the growth of the test organism and put for incubation at 37°C overnight. The tubes were then incubated overnight. The MIC of the control organism was read to check the accuracy of the drug concentrations. The lowest concentration inhibiting growth of the organism was recorded as the MIC. All the tubes not showing visible growth (in the same manner as control tube described above) was sub cultured and incubated overnight at 37°C. The amount of growth from the control tube before incubation (which represents the original inoculum) was compared. Subcultures might show: similar number of colonies indicating bacteriostatic; a reduced number of colonies indicating a partial or slow bactericidal activity and no growth if the whole inoculum has been killed. The test must include a second set of the same dilutions inoculated with an organism of known sensitivity. Each synthesized drug was diluted obtaining 2000 μg/mL concentration, as a stock solution. In primary screening 500, 250, and 125 μg/mL concentrations of the synthesized drugs were taken. The active synthesized drugs found in this primary screening were further tested in a second set of dilution against all microorganisms. The drugs found active in primary screening were similarly diluted to obtain 100, 50, 25, 12.5, 6.250, 3.125, and 1.5625 μg/mL concentrations. The highest dilution showing at least 99 % inhibition is taken as MIC.

**Acknowledgments.** The authors are thankful to Veer Narmad South Gujarat University for providing necessary facilities. We also thank SAIF Lucknow for elemental analysis and SAIF Chandigarh for spectral analysis of the compounds.

Lophine hydroperoxides underwent base-triggered 1,5-phenyl migration in DMSO to afford imidazolones in high yields, instead of amidines with chemiluminescence (CL). The corresponding imidazolols were believed to intermediates and they were successfully obtained by treating the peroxides with DMSO without the base. The diminished CL was because of the reduction of the hydroperoxides with DMSO. The imidazolols subsequently underwent smooth base-mediated rearrangement to afford imidazolones. Furthermore, the chiral imidazolols provided stereoselective imidazolones in high enantiomeric excess (>92%), which supported the mechanism of an intramolecular ring for the migration.

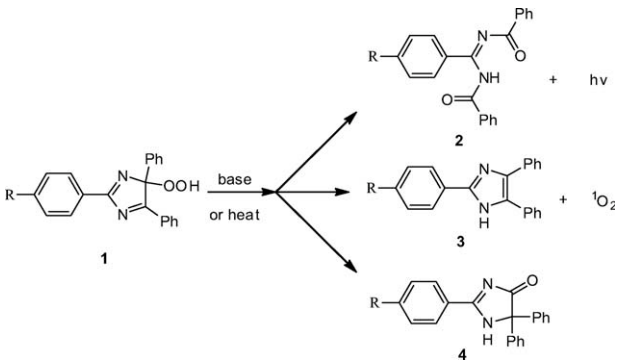
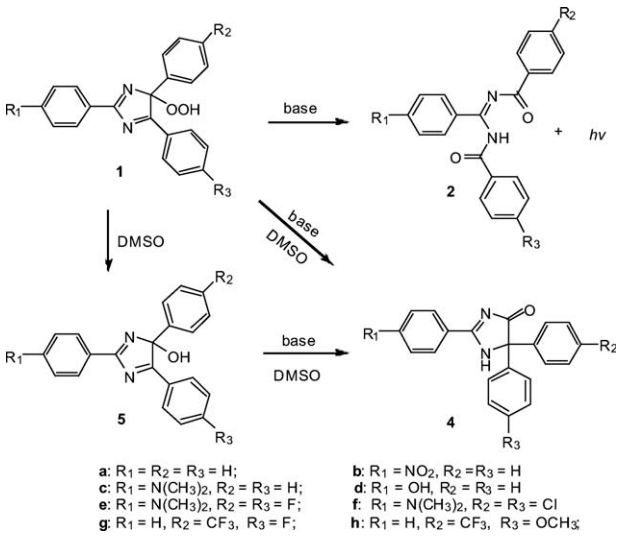
## INTRODUCTION

The chemiluminescent reactions of lophine hydroperoxides (**1**) have attracted considerable attention for many decades [1,2]. Many studies have been reported [3] and these studies mainly focused on the chemiluminescence (CL) efficiency. The other reactions occurring in this chemiluminescent process are still not clear. Recently, we reported that **1** underwent three different but simultaneous reactions upon treatment with a base to yield the corresponding amidines (**2**) accompanied with CL, imidazoles (**3**) with singlet oxygen, and a trace of imidazolones (**4**) (Scheme 1) [4]. However, the CL of peroxides **1** can be observed by base-triggered reactions in typical solvents, but not in DMSO. It is well known that a CL system like dioxetane can provide the most efficient CL in DMSO [5]. We first believed that a polar aprotic solvent like DMSO should enhance the CL efficiency of lophine peroxides. However, the CL efficiency of hydroperoxides **1** in was so low that it could not be detected. The results were quite unexpected, and therefore, they attracted our attention. The subsequent investigation showed that hydroperoxides **1** underwent an exclusive 1,5-phenyl migration in DMSO to afford imidazolones **4** in high yields via imidazolols (**5**) as intermediates (Scheme 2) [6]. Further investigation showed that these imidazolols **5** could be easily obtained under milder conditions, when treated with DMSO without the trigger base [6b]. In addition, these imidazolols **5** subsequently underwent base-mediated rearrangement to afford imidazolones in high yields.

**Scheme 1**



**Scheme 2**



Although imidazolol has been long proposed as one of the intermediate byproducts in the CL reaction of lophine, it has not been obtained thus far because it is unstable under basic reaction conditions [1b]. The present research provides an easy method to obtain these intermediates, and this should help in completely understanding the reactions occurring in the CL reaction of lophine peroxides. In addition, the sigmatropic migration of an aryl group is known for 1,2,3,4,5-pentaphenylcyclo-pentadienol [7], which is a π-conjugated analogue of **5**; however, its stereochemistry has not yet been investigated. In a previous investigation, [6a] the 1,5-phenyl rearrangement of silyl-protected hydroperoxides was reported. However, the stereospecificities were low under thermal conditions and the enantiomeric excesses (EEs) were less than 60%; these factors made it difficult to understand the stereochemistry. In the previous study, we first believed that the low stereospecificities resulted from the racemization of imidazolones through a ring opening/closing sequence, and therefore, a control experiment was carried out with imidazolone; however, it was found that it did not racemize. Therefore, we believed that the alkoxide racemized through a ring opening/closing sequence under strong thermal conditions that lowered the stereochemical specificities. In this study, the absence of strong thermal activation prevents ring opening from occurring, as a result of which imidazolols can serve as a good system for the study of 1,5-phenyl migration.

Furthermore, it should be noted that many natural compounds include imidazolol and/or imidazolone moieties [8]. In this article, we report the preparation and the stereoselective 1,5-phenyl rearrangement of imidazolols. We expect that imidazolols will find numerous applications in the synthesis of natural compounds.

## RESULTS AND DISCUSSION

The reaction of the peroxides **1** proceeded smoothly proceeded to afford imidazolols in good yields in DMSO at room temperature (entries 1–8, Table 1). The reaction completed within 4–6 h. Aromatic substituents containing electron-donating as well as electron-withdrawing groups underwent the elimination of oxygen facilely. In the case of unstable **1c**, which is difficult to isolate, [2] **5c** was consequently prepared by treating the mixture by the photooxidation of the corresponding imidazole with DMSO. In the cases of **1g**, **h**, the mixtures with their isomers (**1′g**, **h**) were used to afford mixtures of **5g**, **h** with their isomers (**5′g**, **h**), as shown in Scheme 3.

On treatment with the base, the imidazolols **5** were smoothly converted into the imidazolones **4** via phenyl migration from C4 to C5 within 3 h in good yields in DMSO at room temperature (Table 1). From the Woodward–Hoffmann rules, the phenyl migration is recognized as a thermally allowed 1,5-sigmatropic migration.

To elucidate the stereochemistry of the migration, imidazolols **5g**, **h** were successfully isolated from their mixtures with their isomers **5′g**, **h** by crystallization from 2-propanol, respectively. The chiral imidazolols (**5g** and **h**) were isolated using a chiral HPLC column. To determine the absolute configurations, the circular dichroism (CD) spectra were recorded, and the calculated CD spectra were processed using Gaussian 03w software package [6a,9]. The absolute configurations were assigned by comparing the experimental CD spectra with the calculated ones (for details, see Experimental section). When the chiral imidazolols (**5g** and **h**)

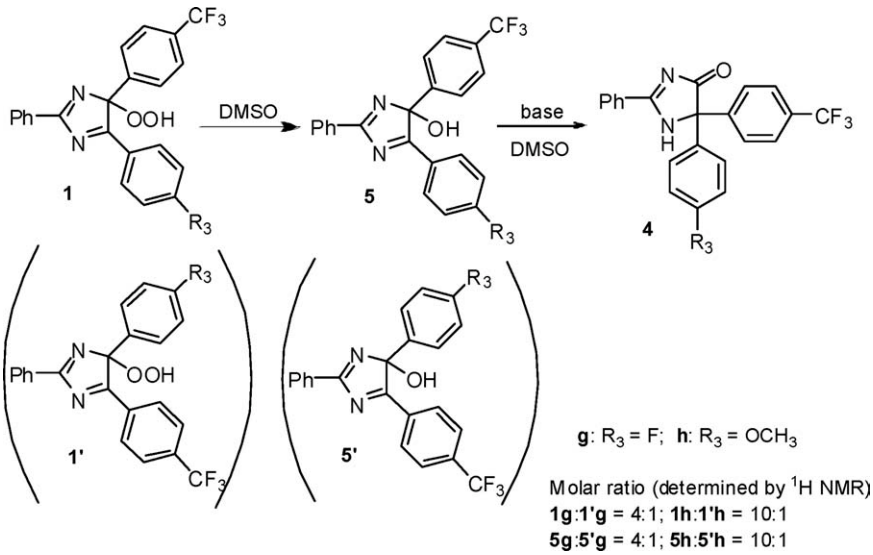
**Scheme 3**



were subjected to phenyl migration under the action of the base (Scheme 4), the corresponding imidazolones **4g** and **h** were exclusively obtained in >92% EE in DMSO (Table 2). When compared with the previous study in which silyl-protected peroxides under thermal condition were used, the stereoselectivities were largely increased. The reaction mechanism was confirmed to be stereoselective 1,5-phenyl migration via an intramolecular ring (Scheme 5).

In conclusion, we have demonstrated that an imidazolol derivative can easily be prepared in good yield from the corresponding peroxide. The imidazolol can be smoothly converted to an imidazolone via a stereoselective phenyl migration from C4 to C5 under the action of a base.

## EXPERIMENTAL

**General procedure.** All melting points were measured using a Yanagimoto micro melting point apparatus. The IR spectra were recorded by a JASCO FT/IR-5000 spectrophotometer. The UV-vis spectra were measured by a JASCO V-530 spectro-photometer. The $^{1}H$ and $^{13}C$ NMR spectra were recorded using a Varian MERCURY (FT, 300 MHz) spectrometer or a Varian VXR-500 (FT, 500 MHz) spectrometer. Elemental analyses were performed by a Perkin Elmer CHNS/O

The analyses of the enantiomeric excess.

| Entry | Imidazolols | Products[a,b] | | |
|---|---|---|---|---|
| | | R-4 | S-4 | EE (%) |
| 1 | **R-5g** | 2 | 98 | 96 |
| 2 | **S-5g** | 97 | 3 | 94 |
| 3 | **R-5h** | 3 | 97 | 94 |
| 4 | **S-5h** | 96 | 4 | 92 |

[a] Yields calculated on the base of HPLC integral quantity.
[b] The conversion was estimated to be 100% because of no other peak appearing on the $^1$H NMR spectra.

Analyzer 2400. The fast atom bombardment (FAB) mass spectra were recorded by a Micromass 70-SE. 2,4,5-Triarylphenyl-1*H*-imidazoles were prepared by the method of Davidson *et al*. [6,8a]. 4-Hydroperoxy-2,4,5-triphenyl-4*H*-imidazoles were prepared by the method of White and Harding [2]. HPLC analyses were performed on a Hitachi 655 liquid chromatography and recorded on a Hitachi 561 recorder; Column for EE and optical resolution was Daicel Chiralpak AD-H: 4.6 mm × 250 mm. CD spectra were recorded on a JASCO J-820 spectropolarimeter.

**Preparation of imidazolols.** A solution of hydroperoxides **1** (0.2 mmol) in DMSO (5 mL) was stirred for 4–6 h at room temperature. After the reaction, the solution was poured into water, and the crude product **5** was obtained by filtration. The crude product was purified by chromatography (silica, hexane:AcOEt = 10 ∼ 8:1).

**HPLC analysis.** The resolution of the racemic imidazolols **5** and the analysis of the EE were carried out using a chiral HPLC column and a HITACHI 561 recorder, as shown in Figure 1. The conditions are summarized in Table 3.

**Assignment of absolute configuration by comparison of experimental and calculated CD spectra.** To determine the absolute configuration, the CD spectra were recorded and calculated using the Gaussian 03w software package, [9] as shown in Figures 2 and 3. A geometry optimization was performed using the B3LYP functional with 6-31G* basis sets. The absolute configurations of **5-I** and **5-II** in the HPLC spectra were assigned as **S-5** and **R-5**, respectively, as shown in

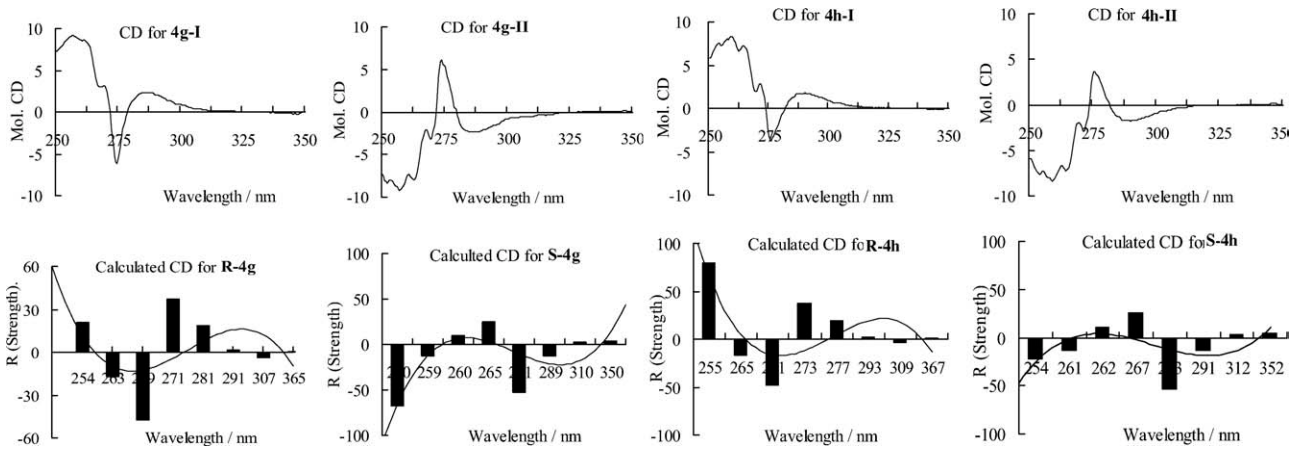

**Figure 3.** The CD spectra (above) of **4g**, **h** recorded in EtOH and the calculated CD spectra (below) of **4g**, **h** using the TDDFT-B3LYP method. Rotational strengths (*R*) are given in cgs ($10^{-40}$ erg esu cm/Gauss).

Figure 2. In the same manner, the absolute configurations of products **4-I** (HPLC: first fraction) and **4-II** (HPLC: second fraction) were also assigned to **R-4** and **S-4**, respectively, as shown in Figure 3.

A facile synthetic method using $SnCl_2 \cdot 2H_2O$ system to promote the novel reductive cyclization of 2-nitrobenzamides and isothiocyanates is described. Sequentially, a series of 2,3-dihydro-2-thioxoquinazolin-4(1*H*)-ones were synthesized in good yields.

*J. Heterocyclic Chem.*, **47**, 939 (2010).

## INTRODUCTION

It has been reported that quinazolineones are responsible for a variety of biological responses, including applications for hypertension [1], diabetes [2], cancer [3], inflammation [4], and immunosuppression [4]. The quinazolindione moiety, in particular, is widely found in natural purine bases [5], alkaloids, intermediates in organic synthesis [6], and many biologically active compounds. For example, 6,7-dimethoxy-1*H*-quinazoline-2,4-dione is a key intermediate for the production of the following medicines (Prazosin (Minipress) [7], Bunazosin (Detantol) [8], and Doxazosin (Cardenalin [9]). 7-Chloro-1*H*-quinazoline-2,4-diones is also a key intermediate for the production of the medicines such as FK366 [10] and KF31327 [11].

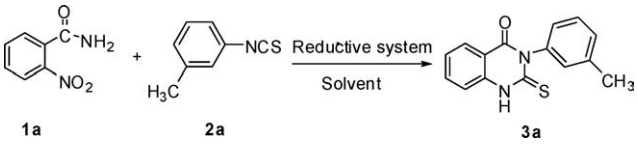
The conventional syntheses of quinazolinedione ring system are carried out by anthranilic acid with urea [12a,b], anthranilamide with phosgene [13], and anthranilic acid with potassium cyanate [14] or chlorosulfonyl isocyanate [15]. Recently, several methods have been developed for synthesizing this heterocyclic system, for example, Mizuno and Iahino have reported the simple solvent-free synthesis of 1*H*-quinazoline-2,4-diones using supercritical carbon dioxide and catalytic amount of base [16]. Buckman and Mohan have reported the solid-phase synthesis of quinazoline-2,4-diones [17–20]. Li *et al*. reported the synthesis of 2,4(1*H*,3*H*)-quinazolinediones and 2-thioxoquinazolines [21]. Alagarsamy *et al*. reported the synthesis of 3-phenyl-2-substituted-3*H*-quinazolin-4-ones by reaction of the amino group of 2-hydrazino-3-phenyl-3*H*-quinazolin-4-one with different aldehydes and ketones [22]. Our group also have reported the synthesis of quinazolinones [23], quinazoline-2,4-diones [24], imidazo[1,2-*c*]quinazolinones [24], and 2-thioxo- quinazolinones [25,26] by the reaction of nitro-compounds with orthoformates, triphosgene, ketones, and isothiocyanates, respectively, induced by low-valent titanium reagent. However, these methods suffer from some disadvantages such as drastic conditions, unsatisfactory yields, long-reaction time, higher temperature, complex manipulation, and inaccessible starting materials. Therefore, the development of more efficient methods for preparing this kind of compounds with milder reaction conditions is highly desired.

In recent years, our interest has been focused on the usage of $SnCl_2$ reagent. We have previously reported the synthesis of 2-aryl-2*H*-indazoles [27], 1-hydroxy quinazolinones [28], imidazo[1,2-*c*]quinazoline-5(6*H*)-thione, and imidazo[1,2-*c*]quinazolin-5(6*H*)-one [29], respectively, mediated by $SnCl_2$ reagent. As our earlier works goes, herein, we will describe a new approach to synthesizing 2,3-dihydro-2-thioxoquinazolin-4(1*H*)-ones by treating 2-nitrobenzamides with isothiocyanates mediated by $SnCl_2$ reagent.

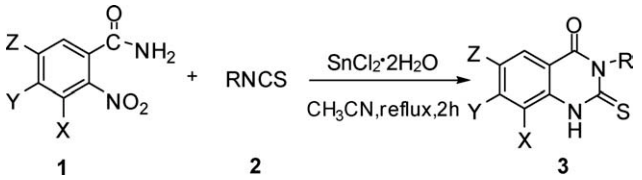
## RESULTS AND DISCUSSION

On the basis of our previous experience, we selected 2-nitrobenzamide **1a** and the 3-methylphenyl isothiocyanate **2a** as model substrates to optimize the experimental conditions for the proposed reductive cyclization reaction (Scheme 1). The results are summarized in Table 1.

**Scheme 1**



**Scheme 2**



As shown in Table 1, we firstly examined the effect of different reductive systems (entries 1–4), and concluded that $SnCl_2{\cdot}2H_2O$ was the best. Then, we also briefly examined the effect of different temperatures, different solvents, and ratio of **1a**:$SnCl_2{\cdot}2H_2O$. The results showed that at refluxing temperature the reaction preceded smoothly in high yield. To further evaluate the influence of the ratio of **1a**:$SnCl_2{\cdot}2H_2O$, the reaction was carried out in acetonitrile using a 1:1 to 1:5 ratio of **1a**:$SnCl_2{\cdot}2H_2O$ (Table 1, entries 8, 9, 10, 1, 11), leading to **3a** in 26%, 33%, 60%, 75%, and 72% yields, respectively. We concluded the best ratio of **1a**:$SnCl_2{\cdot}2H_2O$ was 1:4. Moreover, different organic solvents were further investigated as shown in Table 1; we concluded that acetonitrile was the best solvent for this reaction.

With the optimized conditions in hand, we then performed the reaction of a variety of 2-nitrobenzamides **1** and isothiocyanates **2** *via* tin(II) chloride systerm (Scheme 2, Table 2).

As shown in Table 2, it can be seen that this protocol can be applied not only to the aryl isothiocyanates with electron-withdrawing groups (such as halide groups) or electron-donating groups (such as alkyl groups) but also to aliphatic isothiocyanates under the same conditions, which highlighted the wide scope of this reaction. Furthermore, it was particularly noteworthy that the effects of substituted *o*-nitrobenzamides were also investigated. 3-Methyl and 4-chloro substitution can also give moderate to good yields.

Moreover, we also studied the reaction of a variety of *N*-substitued-*o*-nitrobenzamides **4** and isothiocyanates **2** under optimized conditions. The desired products **3** were obtained in good yields (Scheme 3, Table 3).

Similarly, *N*-substitued-o-nitrobenzamides containing electron-donating and electron-withdrawing substituents were reacted well with aryl isothiocyanates and aliphatic isothiocyanates; therefore, we can conclude that the electronic nature of the substituents has no significant effect on this reaction. Meanwhile, it was found that *o*-nitrobenzamides showed better reactivity trends than *N*-substituted-*o*-nitrobenzamides.

A plausible mechanistic pathway to products **3** is illustrated in Scheme 4, although the details are still unclear. In the initial step, **1** or **4** are reduced by tin (II) chloride to **A**. The amine compounds **A** then reacted with isothiocyanates to give intermediate **B**. Intermediate **C** was formed by attack of the amino group onto the the central carbon atom of the carbonyl. Finally, products **3** were obtained by eliminating of an amine molecule.

For the investigation of the reaction mechanism, the intermediate of **3j** (2-amino-*N*-(4-methoxy- phenyl)benzamide) was isolated and characterized by spectroscopic methods. When the intermediate and 1-isothiocyanato-4-

methylbenzene **2j** were reacted under the same reaction conditions, the product **3j** was obtained in 82% yield.

The structures of products **3** were confirmed by IR and $^1$H NMR.

In summary, a series of 2,3-dihydro-2-thioxo-quinazolin-4(1*H*)-ones were synthesized *via* $SnCl_2{\cdot}2H_2O$ induced reductive cyclization of isothiocyanates with 2-nitrobenzamides. A variety of substrates can participate in the process with good yields. The new method has advantages such as easily accessible starting materials, handy manipulation (only one pot), moderate to high yields, and isolation of products *via* simple recrystallization to give higher purities.

## EXPERIMENTAL

Commercial solvents and reagents were used as received. Melting points are uncorrected. IR spectra were recorded on Varian F-1000 spectrometer in KBr with absorptions in cm$^{-1}$. $^1$H NMR was determined on Varian-400 MHz spectrometer in DMSO-$d_6$ or $CDCl_3$-$d_6$ solution. *J* values are in Hz. Chemical shifts are expressed in ppm downfield from internal standard TMS.

**General procedure for synthesis of 2,3-dihydro-2-thioxo-quinazolin-4(1*H*)-ones 3.** A solution of **1** or **4** (1 mmol), isothiocyanates **2** (1 mmol), and $SnCl_2{\cdot}2H_2O$ (4 mmol) in $CH_3CN$ (5 mL) was stirred at reflux for 2–3 h. After this period, the TLC analysis of the mixture showed the reaction to be completed. The mixture was quenched with 3% HCl (10 mL) and filtered, and the crude product was purified by recrystallization from 95% ethanol and DMF.

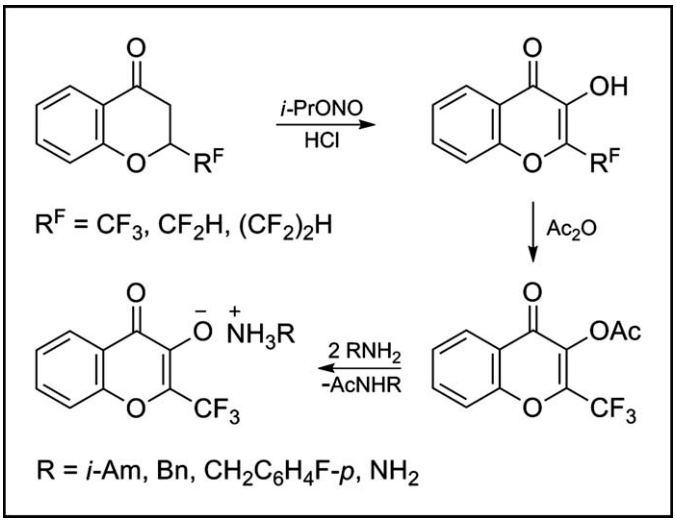
Published online 21 June 2010 in Wiley InterScience (www.interscience.wiley.com).



3-Hydroxy-2-(polyfluoroalkyl)chromones were obtained in good yields via the nitrozation reaction of 2-(polyfluoroalkyl)chroman-4-ones with isopropyl nitrite in the presence of hydrochloric acid. Treatment of 3-acetoxy-2-(trifluoromethyl)chromone with primary amines and hydrazine gave the corresponding ammonium salts. Reaction of 3-hydroxychromone, prepared by this method, with formaldehyde and α-aminoacids has been studied.

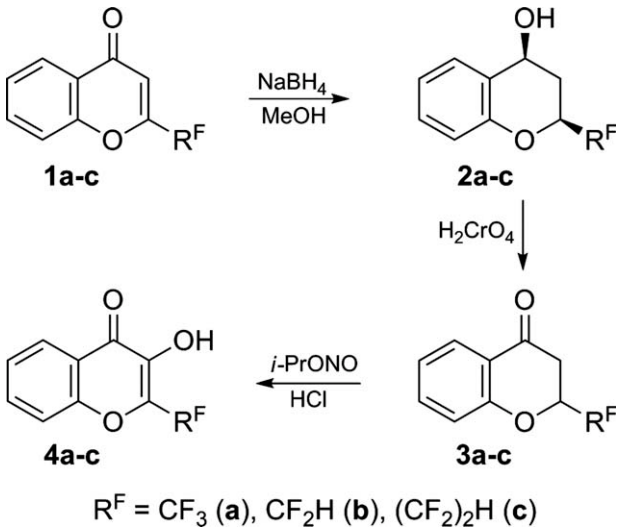
## INTRODUCTION

The chromone ring is an integral part of many natural and biologically active substances. The biological potency of chromone derivatives and, in particular, halogen-containing chromones, has been widely documented [1,2]. Therefore, considerable efforts have been paid to explore new synthetic route to halogenated derivatives of chromone and to study their chemical properties. Polyfluoroalkyl groups, especially the $CF_3$ group, are highly important substituents in the field of organic chemistry. The introduction of these groups into organic molecules can bring about some remarkable changes in the physical properties, chemical reactivity, and biological activity of the derived fluorinated compounds [3]. Thus, it is well known that the insertion of polyfluoroalkyl substituents into the 2-position of chromones activates molecules of these compounds and reveals significant differences in the reactivity of 2-alkyl- and 2-(polyfluoroalkyl)chromones with respect to nucleophilic reagents [4]. The variety of the reactions of 2-$R^F$-chromones makes this class of compounds very useful for synthesis of $R^F$-containing heterocycles with potential biological activity [2].

However, to the best of our knowledge, very little is known about the synthesis and properties of 3-substituted 2-$R^F$-chromones. There have been only some papers on the preparation of 3-chloro- [5], 3-bromo- [6], 3-cyano- [7], 3-carbamoyl- [7], and 3-carbethoxychromones [8] with a $R^F$ group at the 2-position. 2-(Polyfluoroalkyl)chromones containing electron-donating substituents at the 3-position had not been described yet. In view of the unique biological properties displayed by chromones [1,2] on one hand and by many fluorine-containing heterocycles [9] on the other hand, it was of interest to obtain 2-$R^F$-chromones with an electron-donating hydroxy group at the C-3 atom and their derivatives. It is worth to note that 3-hydroxyflavone is the most simple model of aglucones of polyhydroxyflavones

**Scheme 1**



which, linked by glucoside bond at the C-3 atom, are very widely spread heterocycles in the nature.

Recently [10], we have reported that reduction of readily available 2-(polyfluoroalkyl)chromones **1** with sodium borohydride provides a simple preparative procedure to *cis*-2-(polyfluoroalkyl)chroman-4-ols **2**, the oxidation of which to 2-(polyfluoroalkyl)chroman-4-ones **3** was performed with chromic acid in ethyl ether. We regarded these compounds as desirable targets because of their relationship to naturally occurring benzopyran derivatives and usefulness as $R^F$-containing building blocks for the preparation of more complex partially fluorinated heterocycles and other highly functionalized biologically and medicinally important products.

## RESULTS AND DISCUSSION

Now we wish to report the successful nitrozation reaction of 2-$R^F$-chroman-4-ones **3** for the synthesis of previously unknown 3-hydroxy-2-(polyfluoroalkyl)chromones **4**. We found that treatment of an alcoholic solution of **3a–c** with an excess of isopropyl nitrite (3.0 equiv) and concentrated hydrochloric acid at 0–80°C for 3 h gave chromones **4a–c** in 42–68% yields as colorless crystals (Scheme 1). In the $^1$H NMR spectra of these products in DMSO-$d_6$, a singlet at δ 10.4–10.7 ppm for the OH proton appeared in place of the disappearance of signals at δ 2.9–3.0 and 4.8–4.9 ppm associated with the C-3 methylene and C-2 methine protons of the starting 2-$R^F$-chroman-4-ones **3**. It was also observed that all protons of the benzene ring shifted to lower field and, hence, formation of the pyrone ring took place under the action of isopropyl nitrite.

To demonstrate the ability of compounds **4** to undergo alkylation and acylation reactions, chromone **4a** as a representative example was allowed to react with MeI and $Ac_2O$. Our results showed that **4a** smoothly reacts with an excess of MeI (refluxing acetone, $K_2CO_3$, 8 h) and $Ac_2O$ (pyridine, ~20°C, 2 days) to produce the expected 3-methoxy- and 3-acetoxy-2-(trifluoromethyl)-chromones **5** and **6** in 87% and 77% yields, respectively (Scheme 2). The most notable feature in the $^1$H NMR spectra of **5** and **6** is the absence of a signal of the hydroxy group and the appearance of singlets at δ 4.04 and 2.41 ppm due to the MeO and MeCO groups. Previously, their non-fluorinated analogs, 3-methoxy-, 3-acetoxy-, and 3-hydroxy-2-methylchromones, were obtained by reaction of ω-bromo-2-hydroxyacetophenone with acetic acid anhydride and sodium acetate [11]. The synthesis of 3-hydroxy-2-methylchromone has been also achieved by oxidation of 2-methylchroman-4-one with isoamyl nitrite [12].

It is known that reactions of 2-$R^F$-chromones **1** with amines and hydrazines proceed at the C-2 atom with pyrone ring opening to form β-aminovinylketones [13] and pyrazoles [14]. However, the acetylated derivative **6** did not show any analogous behavior to **1** and reacted with isoamyl-, benzyl-, and *p*-fluorobenzylamines in ethanol at room temperature immediately to give the corresponding salts **7a–c** as the sole isolated products in 47–85% yields. Similarly, reaction with hydrazine hydrate leads to hydrazinium 4-oxo-2-(trifluoromethyl)-4*H*-chromen-3-olate **7d** in 69% yield (Scheme 2). These salts are stable compounds and can be stored at room

**Scheme 2**

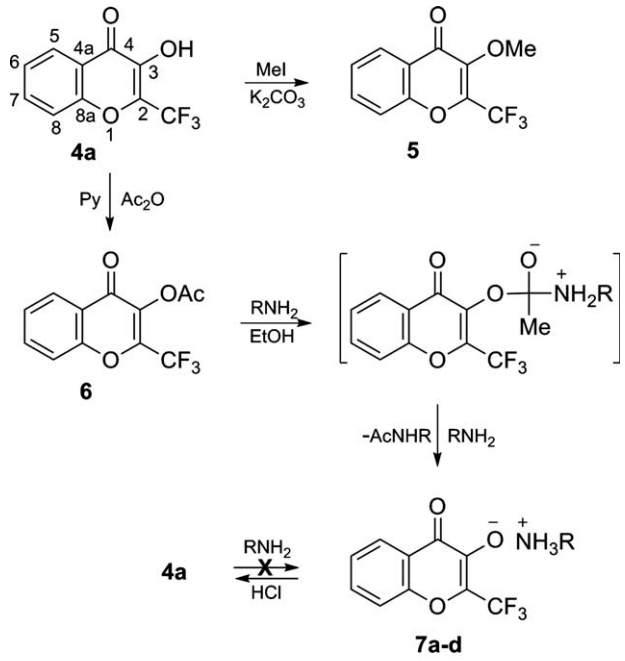


**Table 1**

Selected $^{13}C$ NMR data of chromones **1a** [16], **6**, **4a**, **7a**, and **8** [17a].

| Chromone | Chemical shifts, δ (ppm) | | |
|---|---|---|---|
| | C-2 | C-3 | C-4 |
| **1a**[a] | 152.2 | 110.4 | 176.8 |
| **6**[a] | 144.8 | 135.2 | 171.7 |
| **4a**[b] | 133.7 | 141.3 | 173.6 |
| **7a**[b] | 131.8 | 152.3 | 180.4 |
| **8**[a] | 139.9 | 142.1 | 174.0 |

[a] In $CDCl_3$.
[b] In DMSO-$d_6$.

temperature within several months. Thus, the salts formation was achieved without destruction of the chromone ring system. However, when an ethanolic solution of **4a** or **6** with benzylamine or hydrazine was heated, the reaction did not occur and only resinification was observed. Also, we were unable to obtain the corresponding salts from **6** and *tert*-butylamine, cyclohexylamine, and ethylenediamine. It should be noted that 3-hydroxychromone reacts with hydrazine hydrate in methanol to give 4-hydroxy-3-(2-hydroxyphenyl)-1*H*-pyrazole [15].

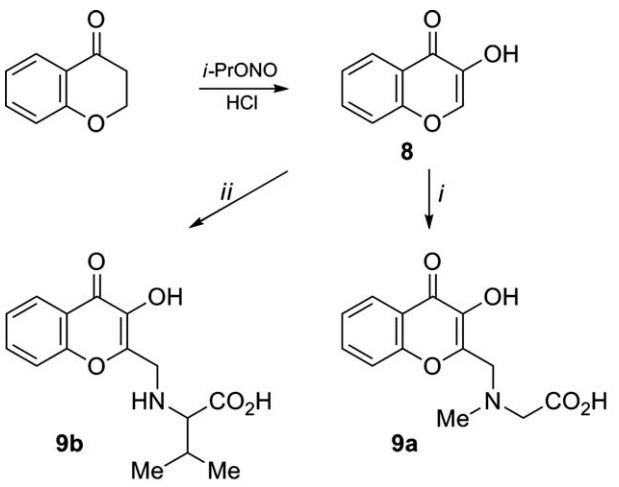
Reaction of the chromone derivative **6** with amines and hydrazine under mild conditions represents an easy access to the ammonium salts of 3-hydroxy-2-(trifluoromethyl)chromone **7a–d**, which could not be directly prepared from chromone **4a** and amines. The salts produced by this addition-elimination sequence gave the starting compound **4a** when treated by an ethanolic solution of hydrochloric acid at −30°C. The lack of chromone reactivity towards amines and hydrazine can be caused by the conjugation effect of the electron releasing OH and OAc groups, which decrease the electrophilic character of the C-2 atom, which is usually attacked first in the reaction of a chromone system with nucleophiles [2].

The IR spectra of **7a–d** display two distinct absorption bands at approximately 1630 and 1610 $cm^{-1}$ assigned to the C=O and C=C functions, respectively, as in the case of the protonated form **4a**. In the $^1H$ NMR spectra of these compounds, the ammonium protons appeared as broad singlets within the range δ 3.0–7.2 ppm ($CDCl_3$). The $^{13}C$ spectra of compounds **7a,d** are much more informative and display low field signals at ca. δ 180.3, 154.2, and 152.1 ppm, which are assigned to C-4, C-8a, and C-3, respectively. The aromatic carbons fall within the range δ 118–133 ppm; the C-2 atom, adjacent to the $CF_3$ group, appeared as a quartet at δ 131.8–132.0 ppm ($^2J_{C,F}$ = 32.0 Hz), shifted upfield compared with C-2 of chromones **1**, **4**, and **6**. The $^1H$-coupled $^{13}C$ NMR spectrum of **7a** was used to assign signals for the quaternary carbon atoms. The chemical shifts of the pyrone carbon atoms are presented in Table 1 to demonstrate the deshielding and shielding effects of the oxygen substituent at the 3-position on the C-3 and C-2 atoms compared with H-3 of chromone **1a**. As can been seen from Table 1, the appearance of the 3-OH group leads to considerable shielding of the C-2 atom, which is related to the lack of usual chromone reactivity.

Next, taking into account the above results and that the 3-hydroxychromone ring is an important structural fragment of many natural and biologically active substances [18], we decided to investigate the possibility of preparing 3-hydroxychromone **8** through nitrozation reaction of chroman-4-one under our reaction conditions. Previously, this compound was prepared by oxidation of chromone and 3-formylchromone using different reagents in two steps [17]. We found that the reaction between commercially available chroman-4-one and isopropyl nitrite is a useful method for the preparation of **8** because it requires only one step, cheap common reagents, and short reaction times (2–3 h in this case), albeit in only 35% yield (Scheme 3).

The replacement of a H-3 atom in 2- and 3-unsubstituted chromones by an alkyl- or dialkylaminomethyl group in the Mannich reaction is well known [19]. Very recently [20], it has been shown that 3-formylchromones react with α-aminoacids in the presence of excess formaldehyde to produce *N*-(chromone-3-ylmethyl)-α-aminoacids by a deformylative Mannich type reaction. It was also observed that α-aminoacids can be used as the amine component in a Mannich reaction with kojic acid [21]. However, the use of 3-hydroxychromones in this reaction has not been reported in the literature. Our preliminary results showed that 3-hydroxychromone **8** smoothly reacted with such α-aminoacids as sarcosine

**Scheme 3**



*Reaction conditions: i*, $CH_2O$, sarcosine; *ii*, $CH_2O$, valine

and valine in the presence of 37% formalin in refluxing ethanol for 5 h to give the corresponding chromone derivatives **9a,b** in high yields (70–80%). The resulting products represent an important class of chromone derivatives, in which two different fragments with remarkably interesting biological and pharmaceutical activities are linked at the same carbon atom.

In conclusion, we have shown that the reaction of 2-(polyfluoroalkyl)chroman-4-ones with isopropyl nitrite is a simple and practical method for the preparation of 3-hydroxy-2-(polyfluoroalkyl)chromones and 3-hydroxychromone. Treatment of 3-acetoxy-2-(trifluoromethyl)chromone with primary amines and hydrazine gave the corresponding ammonium salts. 3-Hydroxychromone reacts with formaldehyde and α-aminoacids to form previously unknown *N*-(3-hydroxychromone-2-ylmethyl)-α-aminoacids.

## EXPERIMENTAL

$^1$H (400 MHz), $^{19}$F (376 MHz), and $^{13}$C (100 MHz) NMR spectra were recorded on a Bruker DRX-400 spectrometer in DMSO-$d_6$ and $CDCl_3$ with TMS and $CFCl_3$ as the internal standards. IR spectra were recorded on Perkin-Elmer Spectrum BX-II and Bruker Alpha instruments as KBr discs and ATR (ZnSe), respectively. Elemental analyses were performed at the Microanalysis Services of the Institute of Organic Synthesis, Ural Branch, Russian Academy of Sciences. Melting points are uncorrected. All solvents used were dried and distilled per standard procedures. The starting 2-(polyfluoroalkyl)chroman-4-ones **3a–c** were prepared according to described procedure [10].

**General procedure for the synthesis of 3-hydroxy-2-(polyfluoroalkyl)chromones (4a–c).** Concentrated hydrochloric acid (3.4 mL) was added dropwise over 1 h to a cold stirred solution of chroman-4-one **3** (2.0 mmol) and isopropyl nitrite (6.0 mmol) in ethanol (5 mL) and methanol (2 mL). On completion of the addition, the reaction mixture was allowed to warm to room temperature (1 h) and was then heated to 80°C for 2–3 h. After cooling, the precipitated product was isolated by filtration and washed with water to give colorless crystals.

***3-Hydroxy-2-(trifluoromethyl)chromone (4a).*** Yield 290 mg (68%), mp 166–167°C; IR (ATR) 3275, 1634, 1612, 1576 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 7.53 (ddd, 1H, H-6, $J$ = 8.0, 7.1, 1.0 Hz), 7.73 (dd, 1H, H-8, $J$ = 8.6, 1.0 Hz), 7.88 (ddd, 1H, H-7, $J$ = 8.6, 7.1, 1.7 Hz), 8.14 (dd, 1H, H-5, $J$ = 8.0, 1.7 Hz), 10.71 (s, 1H, OH); $^{19}$F NMR (376 MHz, DMSO-$d_6$) δ −64.90 (s, $CF_3$); $^{13}$C NMR (100 MHz, DMSO-$d_6$) δ 118.48 (C8), 120.33 (q, $CF_3$, $^1J_{C,F}$ = 273.4 Hz), 121.48 (C4a), 125.16 (C5/6), 125.39 (C6/5), 133.71 (q, C2, $^2J_{C,F}$ = 36.5 Hz), 135.04 (C7), 141.29 (C3), 154.07 (C8a), 173.59 (C=O). ***3-Hydroxy-2-(difluoromethyl)chromone (4b).*** Yield 180 mg (42%), mp 184–185°C; IR (KBr) 3265, 1633, 1609 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 7.33 (t, 1H, $CF_2H$, $^2J_{H,F}$ = 51.8 Hz), 7.51 (ddd, 1H, H-6, $J$ = 8.0, 7.1, 1.0 Hz), 7.73 (dd, 1H, H-8, $J$ = 8.6, 1.0 Hz), 7.86 (ddd, 1H, H-7, $J$ = 8.6, 7.1, 1.7 Hz), 8.13 (dd, 1H, H-5, $J$ = 8.0, 1.7 Hz), 10.38 (s, 1H, OH); $^{19}$F NMR (376 MHz, DMSO-$d_6$) δ −122.80 (d, $CF_2H$, $^2J_{F,H}$ = 51.8 Hz). Anal. Calcd. for $C_{10}H_6F_2O_3$: C, 56.61; H, 2.85. Found: C, 56.72; H, 2.86.

***3-Hydroxy-2-(1,1,2,2-tetrafluoroethyl)chromone (4c).*** Yield 470 mg (66%), mp 134–135°C; IR (KBr) 3238, 1628, 1611, 1575 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 6.96 (tt, 1H, $CF_2CF_2H$, $^2J_{H,F}$ = 51.9 Hz, $^3J_{H,F}$ = 5.5 Hz), 7.54 (ddd, 1H, H-6, $J$ = 8.0, 7.1, 1.0 Hz), 7.71 (dd, 1H, H-8, $J$ = 8.6, 1.0 Hz), 7.88 (ddd, 1H, H-7, $J$ = 8.6, 7.1, 1.7 Hz), 8.14 (dd, 1H, H-5, $J$ = 8.0, 1.7 Hz), 10.70 (s, 1H, OH). Anal. Calcd. for $C_{11}H_6F_4O_3$: C, 50.40; H, 2.31. Found: C, 50.66; H, 2.46.

**3-Methoxy-2-(trifluoromethyl)chromone (5).** To a solution of chromone **4a** (400 mg, 1.74 mmol) and MeI (740 mg, 5.22 mmol) in acetone (10 mL) was added $K_2CO_3$ (600 mg, 4.35 mmol) and the mixture was reflux for 8 h. After cooling, the inorganic salts were filtered off and washed with acetone (10 mL). Evaporation of the filtrate at heating gave a solid, which was recrystallized from hexane to give colorless crystals. Yield 370 mg (87%), mp 57°C; IR (ATR) 1614 cm$^{-1}$; $^1$H NMR (400 MHz, $CDCl_3$) δ 4.04 (s, 3H, MeO), 7.46 (ddd, 1H, H-6, $J$ = 8.1, 7.1, 1.0 Hz), 7.55 (dd, 1H, H-8, $J$ = 8.6, 1.0 Hz), 7.75 (ddd, 1H, H-7, $J$ = 8.6, 7.1, 1.7 Hz), 8.24 (dd, 1H, H-5, $J$ = 8.1, 1.7 Hz). Anal. Calcd. for $C_{11}H_7F_3O_3$: C, 54.11; H, 2.89. Found: C, 54.03; H, 3.14.

**3-Acetoxy-2-(trifluoromethyl)chromone (6).** A solution of **6** (330 mg, 1.43 mmol) and acetic anhydride (300 mg, 2.87 mmol) in pyridine (5 mL) was kept at room temperature for 2 days. Then the reaction mixture was poured into diluted hydrochloric acid (1:10) and allowed to stand for 1 day at room temperature. The resulting colorless solid was filtered and washed with water. Yield 300 mg (77%), mp 110°C; IR (ATR) 1790, 1664, 1611 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO-$d_6$) δ 2.41 (s, 3H, Me), 7.64 (ddd, 1H, H-6, $J$ = 8.0, 7.1, 1.0 Hz), 7.85 (ddd, 1H, H-8, $J$ = 8.6, 1.0, 0.4 Hz), 7.98 (ddd, 1H, H-7, $J$ = 8.6, 7.1, 1.7 Hz), 8.13 (ddd, 1H, H-5, $J$ = 8.0, 1.7, 0.4 Hz); $^{19}$F NMR (376 MHz, $CDCl_3$) δ −67.87 (s, $CF_3$); $^{13}$C NMR (100 MHz, $CDCl_3$) δ 20.00 (Me), 118.44 (C8), 118.75 (q, $CF_3$, $^1J_{C,F}$ = 275.8 Hz), 123.56 (C4a), 126.27 (C5/6), 126.29 (C6/5), 135.18 (C7/3), 135.26 (C3/7), 144.80 (q, C2, $^2J_{C,F}$ = 37.7 Hz), 154.73 (C8a), 167.17 (OC=O), 171.73 (C=O). Anal. Calcd. for $C_{12}H_7F_3O_4$: C, 52.95; H, 2.59. Found: C, 52.99; H, 2.79.

**General procedure for the synthesis of ammonium salts of 3-hydroxy-2-(trifluoromethyl)chromone (7a–d).** To a solution of **6** (270 mg, 1.0 mmol) in absolute ethanol (5 mL) was added the corresponding amine (4.0 mmol). The resulting colorless solid was filtered, washed with cooled ethanol, and dried at 60–70°C.

***Isoamylammonium 2-(trifluoromethyl)chromone-3-olate (7a).*** Yield 150 mg (47%), mp 132–133°C; IR (ATR) 3035, 2958, 2874, 1633, 1609, 1584, 1557 cm$^{-1}$; $^1$H NMR ($CDCl_3$) δ 0.70 (d, 6H, 2Me, $J$ = 6.6 Hz), 1.29–1.36 (m, 2H, $CH_2$), 1.48 (sept, 1H, CH, $J$ = 6.6 Hz), 2.85–2.90 (m, 2H, $NCH_2$), 6.70 (br s, 3H, $NH_3^+$), 7.31 (ddd, 1H, H-6, $J$ = 8.1, 7.0, 1.0 Hz), 7.46 (d, 1H, H-8, $J$ = 8.6 Hz), 7.63 (ddd, 1H, H-7, $J$ = 8.6, 7.0, 1.7 Hz), 8.17 (dd, 1H, H-5, $J$ = 8.1, 1.7 Hz); $^{13}$C NMR (100 MHz, DMSO-$d_6$) δ 22.60 (qm, 2 Me, $J_{C,H}$ = 125.0 Hz), 25.50 (dm, CH, $J_{C,H}$ = 127.0 Hz), 36.70 (tm, $CH_2$, $J_{C,H}$ = 127.0 Hz), 37.77 (tm, $CH_2$, $J_{C,H}$ = 140.0 Hz), 118.60 (dd, C8, $J_{C,H}$ = 165.4, 7.0 Hz), 121.99 (dd, C4a, $J_{C,H}$ = 7.7, 4.0 Hz), 123.40 (dd, C5/6, $J_{C,H}$ = 163.6, 7.3 Hz), 123.84 (q, $CF_3$, $^1J_{C,F}$ = 270.7 Hz), 125.75 (dd, C6/5, $J_{C,H}$ = 164.3, 8.0 Hz), 131.75 (q, C2, $^2J_{C,F}$ = 31.5 Hz), 133.10 (dd, C7, $J_{C,H}$ = 164.3, 8.8 Hz), 152.27 (br s, C3), 154.20 (t, C8a, $J_{C,H}$ = 8.8 Hz), 180.38

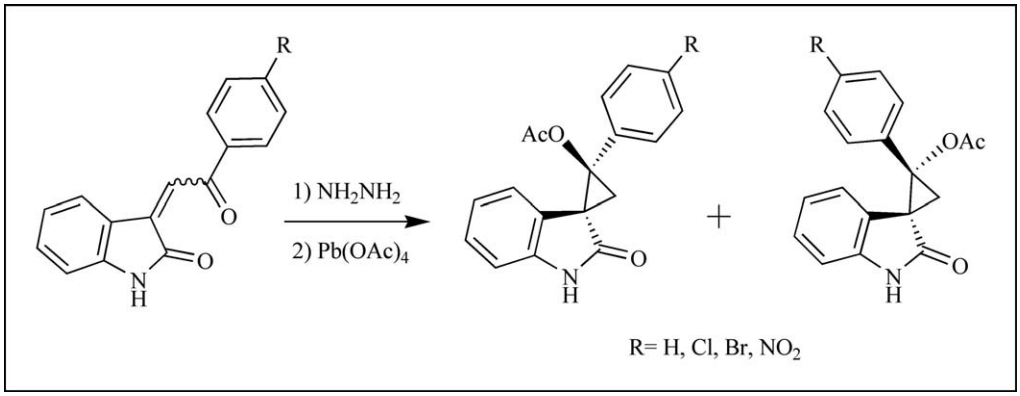
Published online 21 June 2010 in Wiley InterScience (www.interscience.wiley.com).



In a one-pot procedure, the 3-phenacylideneoxindoles **1a–d** were reacted with hydrazine and then *in situ* with lead(IV) acetate and new diastereoisomers of spiro[cyclopropane-1,3′-[3*H*]indol]-2′(1′*H*)-ones were prepared. Compounds **1a–d** underwent a highly diastereoselective cyclopropanation leading to diastereoisomers **2a–d**. These new compounds containing both 2-oxindole and cyclopropane moieties may be valuable in medicinal chemistry.

*J. Heterocyclic Chem.,* **47**, 949 (2010).

## INTRODUCTION

Isatin or 1*H*-indole-2,3-dione is an indole derivative. This compound was found in many plants. Isatin is an endogenous compound identified in humans that possesses wide range of biological activities. It has anxiogenic, anticonvulsant activity, and acts as a potent antagonist on atrial natriuretic peptide receptors *in vitro* [1]. Isatin Mannich or Schiff bases had antibacterial, antifungal, antiviral, anti HIV, antiprotozoal, anticancer, muscle relaxant, and antiallergic activity [2–5].

The cyclopropane ring is a main structural part in many synthetic and natural compounds that exhibits a wide range of biological activities from enzyme inhibition to antibiotic, herbicidal, antitumor, and antiviral properties [6–18]. Some derivatives of cyclopropane have shown potent HIV antiviral activities as non-nucleoside reverse transcriptase inhibitors [19]. Because of diversity of cyclopropane-containing compounds with biological activity, chemists have tried to find novel and facile methods for synthesis of these compounds [20–24].

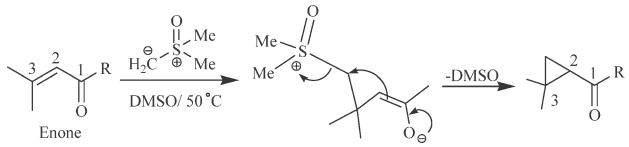
In this study along our pervious works on the synthesis of spiro derivatives of isatins and other biologically active compounds [25,26], we report a simple one-pot procedure for the synthesis of some spiro[cyclopropane-1,3′-[3*H*]indol]-2′(1′*H*)-ones **2a–d** and **3a–d**, which directly prepared from various 3-phenacylideneoxindoles **1a–d** derivatives of isatin. These new compounds containing both active 2-oxindole and cyclopropane moieties may be of value in pharmaceutical and medicinal chemistry.

## RESULTS AND DISCUSSION

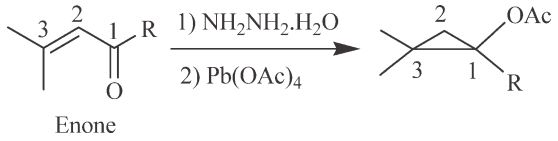
Among the synthetic procedures for preparation of cyclopropane rings, the Michael initiated ring closure reaction [6,14,21,23,24] of α,β-unsaturated carbonyl compounds such as α,β-enones with dimethylsulfoxonium methylides or Corey–Chaykovsky reaction [27,28] is the well-known method. In this reaction, the cyclopropane ring forms between carbon atoms of positions 2 and 3 of enones by addition of a new methylene group (Scheme 1).

The Kishner cyclopropanation reaction is another procedure [29–31]. In the Kishner's method, the cyclopropane derivatives were prepared by thermal decomposition of 2-pyrazolines. The Kishner reaction needs higher

**Scheme 1**



**Scheme 3**



temperatures for removing the nitrogen from 2-pyrazoline to afford cyclopropane (Scheme 2).

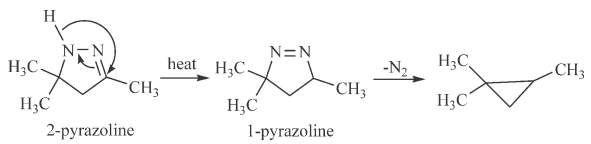
In this work, we report a novel one-pot procedure to synthesis the cyclopropane derivatives with connecting the C-1 and C-3 positions of α,β-enones (Scheme 3). This is a direct and useful method toward preparation of cyclopropanes through the 2-pyrazoline intermediate. Using the lead(IV) acetate renders decomposition of 2-pyrazolines easy [32] and formation of highly substituted cyclopropanes will be possible [33].

For the synthesis of new spiro molecules in this study, we needed the various 3-phenacylideneoxindoles **1a–d**. They have been prepared in our pervious work by the reaction of isatin with acetophenones in a solvent free condition catalyzed first by dimethylamine and then with glacial acetic acid and hydrochloric acid (Scheme 4) [26].

The **1a–d** were reacted with hydrazine hydrate in toluene and then *in situ* with lead(IV) acetate to afford a series of new spiro[cyclopropane-1,3′-[3*H*]indol]-2′(1′*H*)-one derivatives **2a–d** and **3a–d** (Scheme 5).

The reaction intermediate was a spiro[[3*H*]indole-3,3′-[3*H*]pyrazol]-2(1*H*)-one **4** which is the product of hydrazine addition to 3-phenacylideneoxindoles. This reaction is the main method used for preparation of 2-pyrazolines in last century [34–36]. The intermediate **4** was not separated and reacted *in situ* with lead(IV) acetate to form new diastereoisomers **2a–d** and **3a–d**. The reaction of 2-pyrazolines with lead(IV) acetate was performed by Freeman [32] and Kennedy *et al*. [33]. The reaction intermediate is a 1-pyrazoline similar to compound **5**. Particularly, Kennedy's method is a general approach for synthesis of highly substituted cyclopropanes. Bonding of oxidant atom lead(IV) to the nitrogen atom of intermediate **4** increases the polarity of imino group of 2-pyrazoline ring and will facilitate the attack of the acetate anion to the carbon of imino double bond. Therefore, the unstable intermediate **5** forms and readily decomposes to the products by loss of nitrogen. The mechanism of the reaction may be as the Scheme 6.

**Scheme 2**



In comparison with the Kishner reaction, the lead(IV) acetate used here catalyzed the reaction and reacted with intermediate **4** and caused rapid nitrogen extrusion and then the reaction carried out in lower temperatures, whereas the Kishner reaction needs higher temperatures [29–31] for nitrogen loss. This is an advantage of this work. Furthermore, the starting material in the Kishner's method was a 2-pyrazoline derivative, but we used α,β-enones (3-phenacylideneoxindoles) as the starting compounds and then the separation and purification steps for intermediate **4** were omitted. Therefore, the overall yield of the reaction increased.

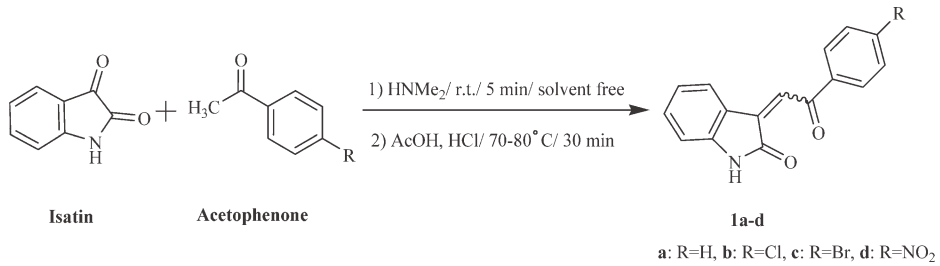
The reaction gave diastereoisomers **2a–d** as major products together with their isomers **3a–d** as minor products. In this case, a high diastereoselectivity was obtained. For instance, the diastereomeric ratios were determined by integration of separated signals in the $^1$H NMR spectra of the mixture of compounds **2c** and **3c** in the reaction product (Fig. 1). The resulted diastereomeric ratios for products were **2a:3a** = 2.70:1, **2b:3b** = 4.26:1, **2c:3c** = 1.78:1, **2d:3d** = 1.94:1.

All compounds **2a–d** and **3a–d** are new derivatives of spiro[cycloprapane-1,3′-[3*H*]indol]-2′(1′*H*)-ones and have not reported in literature. Their structures were deduced from their IR, $^1$H, and $^{13}$C NMR spectra. Their purity was tested by CHN elemental analysis. The experimentally obtained CHN data have shown good agreements (about ±0.2%) with calculated values.

For example, the $^1$H NMR spectrum of **2b** indicated two doublets at δ 2.18 and 2.69 ppm ($J$ = 7 Hz), which belong to diastereotopic methylene protons at position 3 of cyclopropane ring and a singlet at δ 2.04 ppm for methyl protons of acetate group. The multiplets at δ 6.85–7.95 ppm showed the aromatic protons. A singlet at δ 8.91 ppm indicates the secondary amino proton. The $^1$H decoupled $^{13}$C NMR spectrum of **2b** exhibited spiro carbon at δ 37.97, C-2 carbon atom of cyclopropane ring at δ 70.84, methyl carbon at δ 21.25, methylene carbon at δ 27.05, carbonyl carbon of acetate group at δ 169.76, and amido carbon of 2-oxindole moiety at δ 175.42 ppm.

In the $^1$H NMR spectrum of compound **3a**, a doublet was appeared at δ 5.65 ppm ($J$ = 0.02 × 400 = 8 Hz) for the H-4′ hydrogen of 2-oxindole part. This proton

**Scheme 4**



was shielded by the magnetic anisotropy effect of phenyl ring attached to the position 2 of cyclopropane ring (Fig. 2, the structure was not optimized). Similar doublets were appeared for other synthesized compounds **3b–d**.

## CONCLUSION

In summary, some novel spiro[cyclopropane-1,3′-[3*H*]indol]-2′(1′*H*)-ones were synthesized from 3-phenacylideneoxindoles in a one-pot simple and rapid procedure, and the products were obtained in good yields. These compounds may be active biological substances and worthy of attention for the medicinal and pharmaceutical chemists.

## EXPERIMENTAL

All chemicals used in this study were purchased from Merck and Fluka companies. Melting points were measured on a Qallenkamp melting point apparatus in open capillary tubes. The melting point measurement showed that the synthesized compounds decompose before they melt because they have highly crowded structure at cyclopropane ring. The IR spectra were taken from a Bruker Vector 22 FTIR spectrometer, and samples were used as a potassium bromide pellet. $^1$H NMR was recorded on a Bruker DRX-400 Avance instrument, and $^{13}$C NMR (125 MHz) was run on a Bruker DRX-500 Avance instrument using deuteriochloroform as the solvent and tetramethylsilane as the internal standard. The purity of prepared spiro compounds was tested by the elemental analysis of C, H, and N elements using a Heraus CHN rapid analyzer. All prepared compounds were filtered and fractionally crystallized from ethanol/water solution.

The starting materials, 3-phenacylideneoxindoles **1a–d**, were prepared in this laboratory according to the procedure reported in literature [26].

**General procedure for preparation of spiro[cyclopropane-1,3′-[3*H*]indol]-2′(1′*H*)-ones 2a–d and 3a–d.** The **1a–d** (10 mmoles) were dissolved in toluene (20 mL) and then hydrazine hydrate (11 mmoles) was added to this solution and the mixture was stirred and refluxed at 70–80°C for 1 h. Then, 11 mmoles of solid lead(IV) acetate was added to the reaction mixture at 40–50°C and nitrogen extrusion began. The reaction was continued for about 10–20 min, and the spiro compounds **2a–d** and **3a–d** were prepared (Scheme 5). The products were filtered and fractionally crystallized from ethanol-water.

A series of isoxazolidine derivates (isomeric 2,3,5-trisubstitutedperhydropyrrolo[3,4-d]isoxazole-4,6-diones) used as anti-inflammatory, immunosuppressive, antibacterial agent, and inhibitor for some enzymes were synthesized. These compounds were prepared by 1,3-dipolar cycloaddition of *N*-methyl maleimide and *N*-phenyl maleimide with nitrones. Diastereomeric products obtained in this reaction were separated by column chromatography and recrystallized. All compounds synthesized were characterized by elemental analysis and spectroscopic methods ($^1$H NMR, $^{13}$C NMR, and FTIR).

*J. Heterocyclic Chem.,* **47**, 954 (2010).

## INTRODUCTION

1,3-Dipolar cycloaddition reactions have been used for the synthesis of heterocyclic compounds [1]. High stereospecificity/stereoselectivity associated with these reactions make them synthetically important [2–5]. It has been found that 1,3-dipolar cycloaddition reactions proceed through a concerted mechanism [6]. The nitrone-olefin 1,3-dipolar cycloaddition reaction is interesting, as it can create as many as three new contiguous stereogenic centers in a single step [7,8]. Both inter and intramolecular nitrone–alkene cycloaddition reactions have received attention because they are useful methods for the formation of heterocycles of biological interest [9–12].

Isoxazolidines, the products of 1,3-dipolar cycloaddition reactions [13–20] between nitrones and alkenes, are saturated, five membered heterocycles containing adjacent nitrogen and oxygen atoms. As a result of the labile nature of the N—O bond under mildly reducing conditions, isoxazolidines have long been regarded as important synthetic intermediates and have been extensively utilized as 1,3-amino alcohol in a similar way to a wide variety of natural products and related molecules, particularly alkaloids [20] amino acids and amino sugars. Among a plethora of functional groups, the nitrone functionality has etched a place of distinction in organic synthesis. Remarkable regio-, stereo-, face-, and chemoselectivity along with efficient incorporation of multiple stereocenters have made nitrone cycloaddition reactions an attractive and efficient key step in the synthesis of a great many natural products of biological interest. In recent years, focus has been shifted toward asymmetric nitrone cycloaddition reactions; enantioselective [21], catalytic enantioselective [22], and diastereoselective [23] synthetic methodologies, as well as metal-assisted stereocontrol [24] have been reported. Isoxazolidines have been found to exhibit antimicrobial activity [25–28] and have been used as enzyme inhibitors [29–31]. Isoxazolidine nucleoside analogues, in which a furanose ring has been replaced by an N,O-heterocyclic system, are a particularly interesting group of compounds due to their potential antiviral activity [32–36]. Isoxazolidines have also been used as useful building blocks in the synthesis of various natural and unnatural compounds, including alkaloids, biologically active β-aminoacids, β-lactams, amino sugars, and simple 1,3-aminoalcohols owing to the facile cleavage of the N—O bond [37–39].

A review of the literature revealed that no more reports have been published on the synthesis of sulphur containing isomeric 2,3,5-trisubstitutedperhydropyrrolo[3,4-d] isoxazole-4,6-diones. The aim of this work is to synthesis a new type of isoxazolidine derivatives and characterizes their structures by using spectroscopic techniques such as $^1$H NMR, $^{13}$C NMR.

## RESULTS AND DISCUSSION

The 1,3-dipolar cycloaddition reactions between nitrones and an alkene is an extremely powerful synthetic method for the creation of complex heterocyclic structures. Best regarded as a concerted but asynchronous [4π + 2 π] suprafacial process, the reaction allows up to three contiguous carbon stereocentres to be created in a single step. In a manner analogous to the famous [4π + 2π] cycloaddition reactions first noted by Diels and Alder [40], nitrone–alkene cycloadditions can occur with the nitrone and alkene approaching each other. The reaction results in two possible products an endo- or exo- fashion; the two possible transition states giving rise to two diastereomeric products [41].

The 1,3-dipolar cycloaddition of nitrones to alkenes has been the most efficient approach used for the construction of isoxazolidines because the stereochemistry of the reaction is predictable, and the mechanism has been established. A wide range of acyclic and cyclic nitrones has been reacted with substituted alkenes leading to the formation of structurally diverse and highly functionalized nitrogen-containing compounds. Studies on both inter- and intramolecular nitrone to alkene dipolar cycloadditions have received much interest from a stereochemical point of view, as up to three new stereogenic centers can be created in the isoxazolidines depending on the structural features of the starting materials. Despite the known existence of acyclic nitrones as mixtures of (*E*)- and (*Z*)-isomers, or as single isomer in the case of cyclic analogues, the diastereoselectivity of cycloaddition depends also on the structures of the alkene dipolarophiles. In most cases, cycloadducts were formed in a predictable stereocontrolled manner due to steric and electronic effects [42].

In this study, a diastereomeric couple of two isoxazolidines was produced by 1,3 dipolar cycloaddition reaction of nitrons to alkenes, and the 1,3 dipolar cycloaddition reactions of substituted-*N*-methyl nitrons with *N*-methyl and *N*-phenyl maleimide were investigated (Schemes 1 and 2).

The evaluation of $^1$H NMR spectra of *cis*-isomers of isoxazolidines exhibited that Ha protons have chemical shifting between 4 and 5 ppm giving doublet peak with a coupling constant ($J \sim 7$ Hz); chemical shift value of Hb protons 3–4 ppm and doublet's doublet peak $J$ = 8/7 Hz; Hc chemical shifting 3–4 ppm and doublet peak with $J$ = 8.5 Hz.*Cis*-isomers of isoxazolidines have greater coupling constant of Hb-Hc protons ($J$ = 6–8 Hz) than *trans*-isomers ($J$ = 2–5 Hz). Hc proton gives a double peak approximately at 3.8–4.0 ppm for cis- isomers but a broad singlet peak at 4.3–4.5 ppm for *trans* isomers. It was observed that *cis*-isomers were obtained in higher yield than *trans*-isomers in the reaction of *N*-methyl-C-substituted nitrons with *N*-methyl maleimide.The peak multiplicity due to the spin spin coupling of Ha and Hb protons are clearly seen from $^1$H NMR spectra of the *trans* addition products. On the other hand, the spin spin coupling between Hb and Hc protons could not be seen. The peak belonging to Hc proton, appeared as a wide singlet. This situation is well

adjusted with the literatures. Because of the free rotation of N—C single bond, the proton in the methyl group and the Hc proton are sterically push each other. The electronic circle of Hc proton is consistently changed. Therefore, the peak due to Hc proton and methyl protons bonded to N atom on the isoxazolidine ring caused to occur a wide peak. The Ortep diagrams obtained from X-Ray analyzes of isoxazolidines (for example, *cis*-4c compound [43] and *cis*-4e compound [44]) it exhibited that Ha, Hb, and Hc protons are at the same side of the plane.The $^{13}C$ NMR spectra of the *trans* addition products showed that some singlet's carbons did not appear. However, the other data (such as X-Ray analyses of these compounds) confirm the proposed structures.

## EXPERIMENTAL

All melting points were determined by an Electrothermal 9100 apparatus and are uncorrected. $^1H$ NMR and $^{13}C$ NMR spectra were recorded on a Bruker 400 (400 MHz) NMR spectrometer. Samples were prepared in $CDCl_3$ and DMSO-$d_6$ with TMS as internal standard. Chemical shifts are given in ppm and coupling constant are given in Hz. Microanalyses were performed on a LECO-932 CHNS-O element analyzer. FTIR spectra were recorded on a Mattson 1000 spectrometer as KBr pellets. Column chromatography was carried out on Merck Kieselgel (particle size 0.063–0.200 mm) and solvents were distilled before use. *N*-Methylhydroxylamine hydrochloride, *N*-methylmaleimide, *N*-phenylmaleimide and substituted aldehydes, and other chemicals were obtained from Sigma–Aldrich.

**General procedure for the synthesis of substituted nitrones (2a–j).** Substituted aldehydes (10 mmol) were added to a solution of *N*-methylhydroxylamine hydrochloride (1.65 g, 20 mmol) in $CH_2Cl_2$ (50 mL). $K_2CO_3$ (3.03 g, 22 mmol) and $MgSO_4$ (0.60 g, 5 mmol) were added and the mixture refluxed for 12 h, and the reaction was monitored by TLC. The reaction mixture was filtered and solvent was evaporated. Then, column chromatography of the residue (*n*-hexane/ethyl acetate 1:1) gave nitrone (compound 2). The crude product was recrystallized from $CH_2Cl_2$/*n*-hexane [45].

**General procedure for the synthesis of substituted 2,5-dimethy tetrahydro-pyrrolo[3,4-d]isoxazole-4,6-dione, (exemplified by cis-4a, trans-4a).** A mixture of *N*-methyl-*C*-(thiophene-2-yl) nitrone **2a** (3 mmol, 0,429 g) and *N*-methylmaleimide **3a** (3.3 mmol, 0.370 g) was dissolved in 50 mL benzene. The reacting mixture was refluxed for 6–12 h. During this time, the reaction was monitored by TLC. Then, the solvent was evaporated. The products were separated by column chromatography [46]. The mixture of ethylacetate and petroleum ether was used as an eluent. The *cis*- and *trans*-isomers were recrystallized separately from $CHCl_3$/*n*-hexane mixture. Spectroscopic and analytical data of new compounds are given below.

Naphthoquinones undergo 1,3-dipolar cycloaddition with bicyclic münchnones generated from thiazolidines affording new pyrrolo-thiazoles with a fused quinone nucleus. The products were obtained as single enantiomers in good yields. These benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-diones are comprised of four fused rings and present a very planar structure. The evaluation of their anticancer activity against melanoma A375 and colorectal adenocarcinoma WiDr human cell lines showed only moderate activity but gave insight into the modeling of new structures. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

## INTRODUCTION

Quinone-containing drugs such as adriamycin, daunorubicin, and mitoxantrone have been established as one of the most effective classes of antitumor agents in clinical use. However, the drawbacks are the risk of dose-related cardiotoxicity and the development of resistance toward these compounds. To overcome these problems, there is a demand for the search of new lead compounds retaining the ''core quinone'' chromophore [1–4]. Hence, there is particular interest in combining the nucleus of a quinone with heterocyclic rings to achieve molecules with anticancer activity [5,6]. On the other hand, the thiazolidine ring is known to be involved in biologically active compounds with anti-inflammatory [7], anti-HIV [8], antimicrobial [9,10], or anticancer properties [11,12]. Particularly relevant is the anticancer activity of 2-arylthiazolidine carboxylic acid derivatives that are effective against the melanoma [13,14].

Our goal was to prepare structures combining the ''core quinone'' chromophore with a thiazolidine ring via the construction of the 1*H*,3*H*-pyrrolo[1,2-*c*]thiazoles ring system. One important mechanism of action of quinone-containing drugs is thought to be related to intercalation processes with DNA in which planarity of the active nucleus is important.[6] Thus, a naphthoquinone ring system fused to a pyrrolo[1,2-*c*]thiazole should allow the system to attain the required planarity. On the other hand, pyrrolo[1,2-*c*]thiazoles are a class of compounds some of which showing biological activity namely antitumoral activity [15,16].

We have been interested in exploring a straightforward approach to new chiral 1*H*,3*H*-pyrrolo[1,2-*c*]thiazole derivatives via 1,3-dipolar cycloaddition of bicyclic münchnones [17–19]. Therefore, we used this synthetic strategy to prepare a range of new chiral 1*H*,3*H*-pyrrolo[1,2-*c*]thiazoles retaining the ''core quinone''

chromophore using 1,4-naphthoquinones as dipolarophiles. The new heterocycles were tested against two cancer cell lines namely A375 melanoma and WiDr colorectal adenocarcinoma.

## RESULTS AND DISCUSSION

**Chemistry.** (*R*)-2-Substituted-thiazolidine-4-carboxylic acids **1** was obtained as mixture of the (*2S*,*4R*) and (*2R*,*4R*)-diastereoisomers from the reaction of an aldehyde and L-cysteine [20]. The synthesis of the corresponding 1*H*,3*H*-pyrrolo[1,2-*c*]thiazoles **4** was carried out by heating a solution of the appropriate thiazolidine in acetic anhydride in the presence of 1,4-naphthoquinone. In this process, the thiazolidine undergoes *in situ* acylation followed by cyclodehydration to give a bicyclic münchnone **3**, which reacts further with 1,4-naphthoquinone to afford the corresponding 1,3-dipolar cycloadduct. The benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-diones **4** was obtained in yields ranging from 60 to 76%. It is worth to emphasize that derivatives **4b**–**4e** were isolated as single enantiomers with *R* configuration (Scheme 1).

The structure of compound **4b** was established by X-ray crystallography (Fig. 1) determining the absolute configuration of chiral 1*H*,3H-pyrrolo[1,2-*c*]thiazole derivatives **4b** as being *R*. The compound **4b** crystallizes in the chiral space group $P3_2$, with three symmetry related molecules in the unit cell. The molecules are comprised of four fused rings that are essentially planar. Only the carbon atom C3′ deviates significantly from the molecular plane, the C1-S2-C3-C3′ torsion angle is 124.1(2)°. In the solid state, due to the lack of conventional donors, only weak C—H. . .O and C—H. . .π intermolecular interactions join the molecules in a three-dimensional network.

The selectivity observed can be explained considering that 2-substituted-1,3-thiazolidine-4-carboxylic acids can undergo selective inversion at C-2 through a mechanism involving the opening of the ring with the formation of the corresponding Schiff base. However, the N-acylation of the 2-substituted-1,3-thiazolidine-4-carboxylic acids prevents this epimerization and allows the isolation of pure diastereoisomers [22–26]. Therefore, starting with (*2S*,*4R*) and (*2R*,*4R*)-2-substituted-1,3-thiazolidine-4-carboxylic acids mixture **1**, diastereoisomerically pure *N*-acetyl-2-substituted-1,3-thiazolidine-4-carboxylic acids **2** was generated allowing the synthesis of chiral cycloadducts. The chirality of the thiazolidine at C-4 is lost, and the chirality at C-2 is retained.

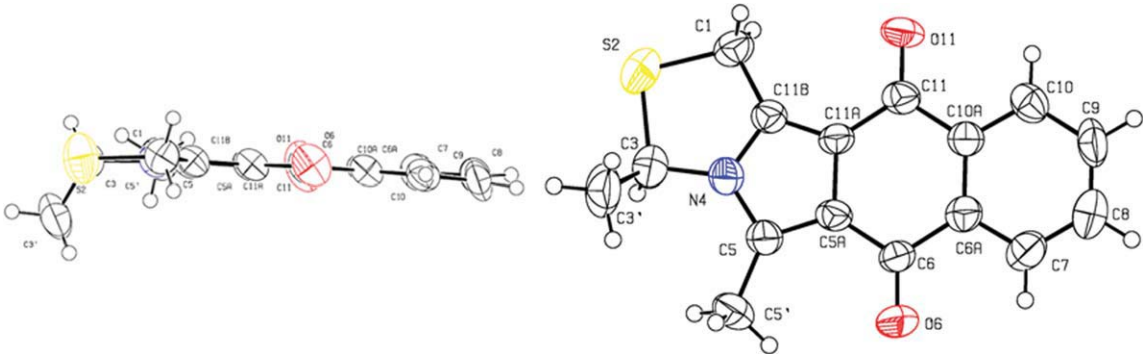

**Figure 1.** Ortep diagrams [21] for (*R*)-3,5-dimethylbenzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-dione **4b**. The displacement ellipsoids are drawn at the 50% probability level. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

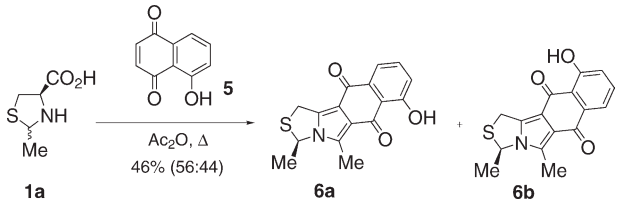
**Scheme 2**



Juglone (5-hydroxy-1,4-naphthoquinone) **5** can also be used as dipolarophile in the 1,3-dipolar cycloaddition of the bicyclic münchnone generated from thiazolidine **1a**. However, a mixture of the two possible regioisomers **6a** and **6b** was obtained in 46% overall yield (Scheme 2).

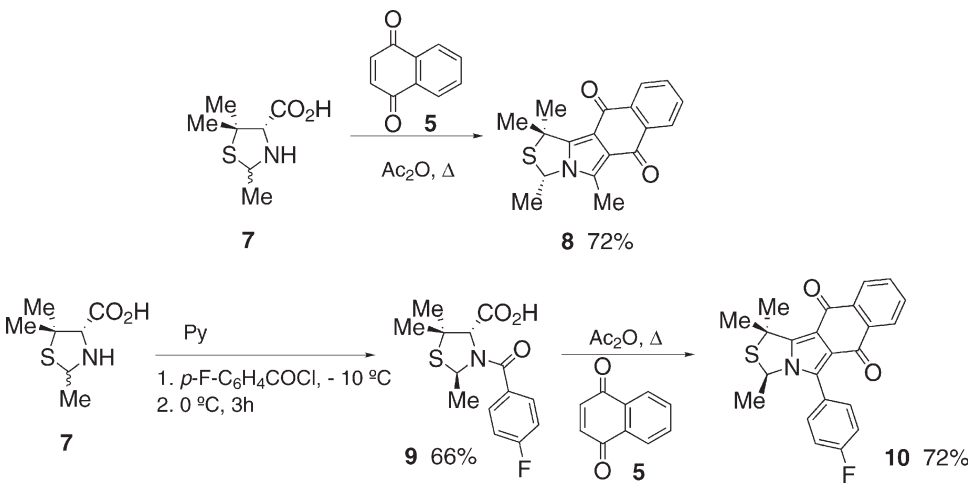
Similar chemistry can be carried to prepare the chiral benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-dione **8**. In this case, D-penicilamine, an α-amino acid with *S* configuration, was condensed with acetaldehyde leading to (*4S*)-2,5,5-trimethyl-1,3-thiazolidine-4-carboxylic acid (**7**) [27]. Therefore, the 1,3-dipolar cycloaddition of the bicyclic münchnone generated from thiazolidine **7** with 1,4-naphthoquinone afforded heterocycle **8** with *S* configuration (Scheme 3).

The synthetic strategy to prepare the chiral benzo[*f*]-thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-dione **10** required the synthesis of (2*R*,4*S*)-3-(4-fluorophenylcarbonyl)-2,5,5-trimethylthiazolidine-4-carboxylic acid (**9**) in diastereoisomeric pure form. Thus, the *N*-acylation of the starting thiazolidine **7** was carried out with the 4-fluorobenzoyl chloride following a general procedure previously reported [28,29]. Heating a solution of the heterocycle **9** in acetic anhydride in the presence of 1,4-naphthoquinone afforded the corresponding cycloadduct **10** with *R* configuration (Scheme 3).

**Anticancer activity.** Studies of the anticancer activity of the new benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-diones (except compound **4a** due to low solubility) have been carried out against WiDR colorectal adenocarcinoma and A375 melanoma human cancer cell lines. The results of the cell viability using different concentrations of the compounds in cultures of WiDr and A375 cells are presented in Figures 2 and 3. Cells were incubated during 48 h with DMSO solution of the selected compounds, washed, and then cell viability was evaluated by MTT test and compared with control experiments, where the incubation was carried out with only DMSO solution.

Values of cell viability show that the pyrrolo-thiazoles do not show considerable anticancer activity against the two cell lines tested. Nevertheless, the compounds are more active against melanoma cells than against colon adenocarcinoma cells. The comparison of the activity is clearer when the corresponding $IC_{50}$ values (Table 1) calculated from the dose-response curves (Figs. 2 and 3) are analysed. In the case of WiDr cells, with the exception of compound **4b** ($IC_{50} = 86$ μ*M*), using concentrations of up to 100 μ*M*, the $IC_{50}$ was not reached. For melanoma cells, with exception of compounds **8** and **6**, the values for $IC_{50}$ allow a comparison of the activity of the different structures. In this case, the anticancer activity order is **4c** > **10**,**4b**,**4e** > **4d** > **8**,**6**. Looking at the results of the two cell lines, it seems that compound **4b** with a methyl groups at positions 3 and 5 is the most active. Curiously, the similar structure **6** with only an additional hydroxyl substituent at the naphthoquinone moiety showed a much lower activity. Relatively to A375 melanoma cells, the pyrrolo-thiazole compounds synthesized are less active than 2-arylthiazolidine compounds described [14]. Also the activities of the pyrrolo-thiazoles are lower than those observed for 4-thiazolidinones for human colon carcinoma, albeit refering to different cell line [12]. The only exception to our results is

**Scheme 3**



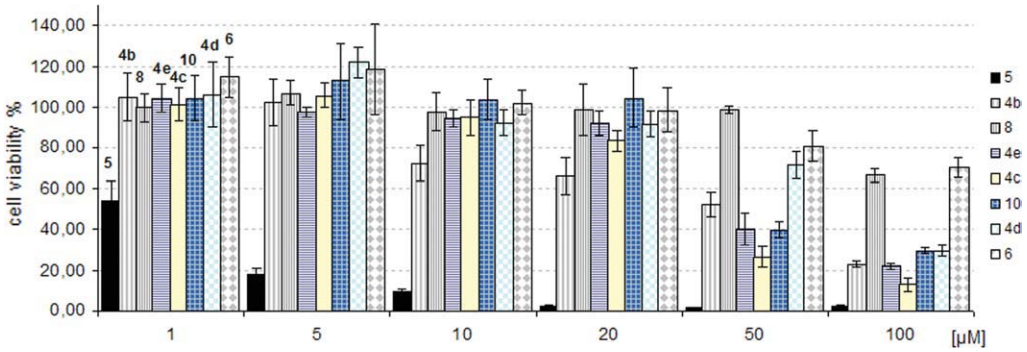


**Figure 2.** Values of cell viability of tested compounds against A375 melanoma cells. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

the parent quinone, juglone (**5**), which shows potent cytotoxicity against the two cell lines, particularly in the case of the melanoma cells with lower $IC_{50}$, 1.23 μ*M* for A375 cells and 8.8 μ*M* for WiDr cells.

It is evident from the results that the incorporation of a thiazolidine ring to the quinone structure drastically reduce the anticancer activity as can be seen by the observed activity of juglone (**5**) and that of the corresponding 1,3-dipolar cycloadducts **6**. This can be explained by the fact that one important mechanism of action of quinones is related to the oxidation–reduction properties [30], which are probably altered by the introduction of the extra ring in compound **6**. Another plausible explanation for the observed low activity is related to the fact that juglone or quinone derivatives are good Michael acceptors that can react with the thiol group of proteins causing their deactivation as described for Pin 1 isomerase [31]. Our pyrrolo-thiazole compounds without the α,β-unsaturated carbonyl system lost this ability. Nevertheless, the low cytotoxycity of the pyrrolo-thiazole compounds was somewhat unexpected considering the geometry of the molecule (see Fig. 1). Molecular shape of thiazolidinones, characterized by the preferencial ''butterfly-like'' conformation, is particularly important regarding the activity as HIV [8]. However, in the case of quinones others suggest that planarity is an important factor to achieve biological activity because DNA intercalation is another possible mechanism of action [6]. For anthracene-9,10-diones which interfere with topoisomerase II, the derivatives need to be planar and also need another structural feature, like alkyl amino side chains, to interact with protein as observed for mixoxantrone [32]. In our case, the very planar structure of the benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-diones caused by the extended conjugation is not sufficient to allow a high anticancer activity possible because of the lack of this type of side chains. Studies are underway to construct new structures via our synthetic methodology aiming to obtain higher activities.

## CONCLUSIONS

Herein, we describe the successful synthesis of new naphthoquinone-containing heterocyclic compounds. Two kinds of chiral benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-diones, one derived from 1,4-naphthoquinone and the other from juglone, were prepared in good yield and high stereoselectivity. The new heterocylic systems are comprised of four fused rings that are

essentially planar, only the substituent at C-3 deviates significantly from the molecular plane.

Anticancer activity of the synthesized compounds against WiDR colorectal adenocarcinoma and A375 melanoma cancer cells lines was determined. These heterocyclic compounds bearing a range of different functionalities showed low anticancer activity.

## EXPERIMENTAL

Reagents were commercial grade and were used as supplied. Chromatographic separations were performed using 70–230 mesh silica gel. Juglone (**5**) was prepared by a known procedure [33]. $^1$H NMR spectra were recorded on an instrument operating at 300 MHz or at 400 MHz. $^{13}$C NMR spectra were recorded on an instrument operating at 75.5 MHz or at 100 MHz. The solvent is deuteriochloroform except where indicated otherwise; chemical shifts are expressed in parts per million related to internal TMS, and coupling constants ($J$) are in hertz. Microanalyses were performed using an EA 1108-HNS-O Fisons instrument. Mass spectra were recorded under electron impact (EI) at 70 eV. HRMS spectra were obtained on a VG Autospect M spectrometer (TOF MS EI$^+$).

**General procedure for the synthesis of benzo[*f*]thiazolo[4,3-*a*]isoindole-6,11(1*H*,3*H*)-diones 4, 6, and 8.** The appropriate 1,3-thiazolidine-4-carboxylic acid (5 mmol), 1,4-naphthoquinone or juglone (7.5 mmol), and acetic anhydride (20 mL) were heated at 110–120°C for 2 h. The crude product was purified by flash chromatography [hexane/ethyl acetate].

***Crystal data for (R)-3,5-dimethylbenzo[f]thiazolo[4,3-a]isoindole-6,11(1H,3H)-dione (4b).*** $C_{16}H_{13}N_1O_2S_1$, M = 283.33, hexagonal, *a* = 16.1968(3) Å, *c* = 4.44350(10) Å, *V* = 1009.52(3) Å$^3$, *T* = 293(2) K, space group $P3_2$, *Z* = 3, $m(MoK\alpha) = 0.240$ $mm^{-1}$, 3340 reflections measured, of which 1677 unique, used for direct methods structure determination [34] and full matrix least-squares refinement. The H atoms were placed at calculated idealized positions and refined as riding atoms. The final *R* ($F^2$) was 0.053 (for $I > 2\sigma(I)$) and $R_W(F^2)$ was 0.150 (for all reflections). The crystal used in data collection was twinned. Twin ratios refined to nearly 0.80:0.20. The Flack parameter refined to 0.0(2) [35].

***Measurement of cell viability.*** The *in vitro* cytotoxic effect of the molecules was evaluated in human colorectal adenocarcinoma (WiDR) and human melanoma (A375) cell lines both purchased from American Type Culture Collection. The cells were cultured in Dulbecco's Modified Eagle Medium supplemented with 10% heat-inactivated fetal bovine serum and 100 μ*M* sodium piruvate at 37°C, in a humidified incubator 95% air and 5% $CO_2$. For each experiment, cells were plated in 48-well plates, in a concentration of 40,000 cells/mL and kept overnight in the incubator, allow the attachment of the cells. The molecules tested were reconstituted on dimethylsulfoxide (DMSO) to achieve solutions with a concentration of 4 mg/mL. Several concentrations (1, 5, 10, 20, 50, and 100 μ*M*) of the molecules were tested by addition to the cell media. Final concentration of DMSO varied from 0.17 to 0.99%. For each experiment, two controls were performed: untreated cell cultures and cells treated with 1% DMSO, the vehicle of administration of the molecules. Cell-plates were incubated for 48 h. To analyze the proliferation inhibition, the MTT assay was performed. The ratio of absorbance of treated cultures to that of DMSO control cultures was obtained for all concentrations of every drug. From the dose-response curve obtained, a 50% inhibitory concentration ($IC_{50}$) was determined. Each experiment was performed in triplicate and repeated in two different sets of tests.

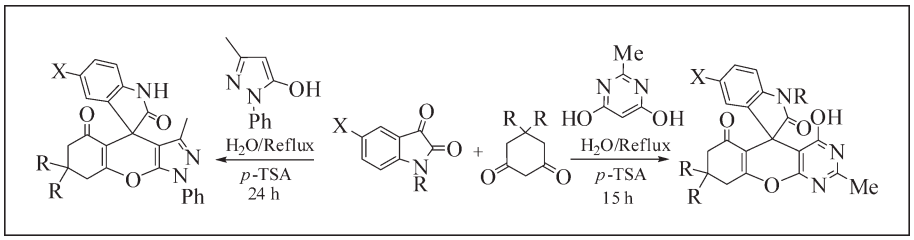
Published online 21 June 2010 in Wiley InterScience (www.interscience.wiley.com).



A novel, clean, one-pot and three-component synthesis of new spiro[chromeno[2,3-*d*]pyrimidine-5,3′-indoline]-2′,6(7*H*)-diones and spiro[chromeno[2,3-*c*]pyrazole-4,3′-indoline]-2′,5(6*H*)-diones via cyclocondensation reaction of isatins, 1,3-cyclohexadiones, and 2-methylpyrimidine-4,6-diol or 3-methyl-1-phenyl-1*H*-pyrazol-5-ol, in aqueous media is reported.

*J. Heterocyclic Chem.,* **47**, 967 (2010).

## INTRODUCTION

Multi-step reactions usually produce significant amount of waste, principally due to a series of isolation procedures which often involves toxic, hazardous, and expensive solvents after each step. Thus, multi-component reactions (MCRs) constitute an efficient synthetic strategy for the rapid and effective libratory organic transformations. Because, products are prepared in a one-pot and the diversity can be obtained directly by changing the reacting components [1,2]. On the other hand, polyfunctionalized heterocycles play considerable roles in the drug discovery process, and analysis of drugs shows that most of them are polyfunctionalized heterocycles [3]. Therefore, research on the multi-component synthesis of polyfunctionalized heterocyclic compounds is an interesting challenge.

Pyrimidine and its derivatives are important heterocyclic compounds with wide applications in medicinal chemistry, as antibacterial, antiviral, and antitumor agents [4]. A number of heterocycles fused with pyrimidines are known for their varied biological activities [5–8]. Similarly, chromene derivatives are an important group of compounds, widely exist in plants, including edible vegetables and fruits [9]. Synthetic analogues were developed over the years, some of them displaying remarkable effects as pharmaceuticals [10–13], including antifungal [12,14] and antimicrobial activity [15–17].

The indole skeleton is common in many natural products and medicinal agents [18]. Furthermore, it has been reported that sharing of the indole 3-carbon atom in the formation of spiroindolines can highly enhance biological activity [19–21]. The spirooxindole nucleus occurs in several natural alkaloids and pharmacologically active substances displaying a broad range of biological activity [22–25]. Therefore, a number of methods have been reported for the preparation of spirooxindole fused heterocycles [26–30].

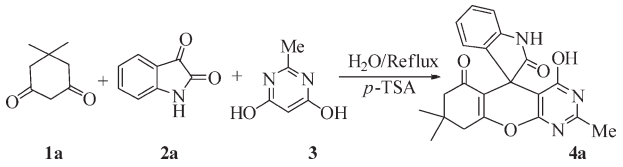
In continuation of our previous works for the synthesis of heterocyclic compounds [31–43], we performed the preparation of some new spirooxindole containing chromene ring fragments via three-component condensation reaction employing water as the reaction medium. Organic transformations in water without using toxic organic solvents are one of the current focuses today especially in our environmentally conscious society.

## RESULTS AND DISCUSSION

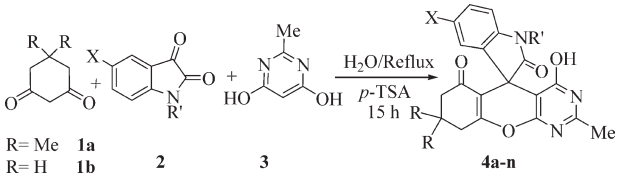
First, we carried out the three-component reaction of dimedone 1a, isatin **2a**, and 2-methylpyrimidine-4,6-diol **3** as a model reaction in different solvents in the presence of *p*-toluenesulfonic acid (*p*-TSA) as an inexpensive catalyst (Scheme 1). It was found that refluxing water was a best condition for the reaction and the desired product obtained in good yield after 15 h (Table 1).

Encouraged by this result, we extended the reaction of cyclic 1,3-dicarbonyls 1a,b and 2-methylpyrimidine-4,6-diol 3 with a range of isatins 2 under similar

**Scheme 1**



**Scheme 2**



conditions (Water/*p*-TSA) for 15 h, furnishing the respective 4-hydroxy-2-methyl-8,9-dihydrospiro[chromeno [2,3-*d*]pyrimidine-5,3′-indoline]-2′,6(7*H*)-diones **4a–n** in good yields (Scheme 2, Table 2).

The results were good in terms of yields and product purity in the presence of *p*-TSA, while without *p*-TSA the yields of products were very low (<30%) even after 48 h.

To the best of our knowledge, this new procedure provides the first example of an efficient and three-component method for the synthesis of 8,9-dihydrospiro [chromeno[2,3-*d*]pyrimidine-5,3′-indoline]-2′,6(7*H*)-diones.

Compounds **4a–n** are stable solids whose structures were established by IR, $^1$H NMR, and $^{13}$C NMR spectroscopy and elemental analysis. We have not established an exact mechanism for the formation of spiro [chromeno[2,3-*d*]pyrimidine-5,3′-indoline]-2′,6(7*H*)-dione 4, however, a reasonable possibility is shown in Scheme 3.

To further explore the potential of this protocol for spiro-heterocyclic synthesis, we investigated reaction of malononitrile 5 instead of 1,3-cyclohexadione 1 and obtained spiro[indoline-3,5′-pyrano[2,3-d]pyrimidine]-6′-carbonitriles 6a–d selectively, in good yields for 24 h (Scheme 4, Table 3).

To further expand the scope of the reaction, we replaced 2-methylpyrimidine-4,6-diol **3** with 3-methyl-1-phenyl-1*H*-pyrazol-5-ol **7** and desired spiro[chromeno[2,3-*c*]pyrazole-4,3′-indoline]-2′,5(6*H*)-diones **8** was selectively synthesized in good yields for 24 h (Scheme 5, Table 4).

Finally, when we extended this reaction to acenaphthylene-1,2-dione **9**, product of 3′,7′,7′-trimethyl-1′-phenyl-7′,8′-dihydro-1′*H*,2*H*-spiro[acenaphthylene-1,4′-chromeno[2,3-*c*]pyrazole]-2,5′(6′*H*)-dione **10** was generated in 70% yield after 24 h (Scheme 6).

**Table 1**

Conditions effect on the reaction.[a]

| Entry | Conditions | Time (h) | Yield (%) |
|---|---|---|---|
| 1 | Water (80°C) | 24 | 63 |
| 2 | Water (reflux) | 15 | 85 |
| 3 | $CH_3CN$ (reflux) | 24 | 60 |
| 4 | EtOH (reflux) | 24 | 67 |
| 5 | DMF (100°C) | 24 | 60 |

[a] Dimedone (1 mmol), 2-methylpyrimidine-4,6-diol (1 mmol), isatin (1 mmol), and *p*-TSA (0.05 g).

## EXPERIMENTAL

Melting points were measured on an Electrothermal 9100 apparatus. Mass spectra were recorded on a FINNIGAN-MAT 8430 mass spectrometer operating at an ionization potential of 70 eV. $^1$H NMR and $^{13}$C NMR spectra were recorded on a BRUKER DRX-300 AVANCE spectrometer at 300.13 and 75.47 MHz, respectively. IR spectra were recorded using a Shimadzu IR-470 apparatus. Elemental analyses were performed using a Heracus CHN-O-Rapid analyzer.

**Typical procedure for the preparation of 4-hydroxy-2-methyl-8,9-dihydrospiro[chromeno[2,3-*d*]pyrimidine-5,3′-indoline]-2′,6(7*H*)-diones (4a–n).** A mixture of dimedone or 1,3-cyclohexadione (1 mmol), 2-methylpyrimidine-4,6-diol (1 mmol), isatins (1 mmol), and *p*-TSA (0.05 g) in refluxing water (5 mL) was stirred for 15 h (the progress of the reaction was monitored by TLC). After completion, the reaction mixture was filtered and the precipitate washed with water (10 mL) and recrystallized by EtOH to afford the pure product **4**.

2-(Alkyl/arylamino)chromone-3-carbaldehyde reacts with Meldrum's acid, hippuric acid, 4-hydroxycoumarin, diethyl malonate, ethyl acetoacetate, or ethyl benzoylacetate to produce 1-benzopyrano[2,3-*b*]pyridine-2,5-dione moiety, but ethyl cyanoacetate and malononitrile react differently.

*J. Heterocyclic Chem.*, **47**, 973 (2010).

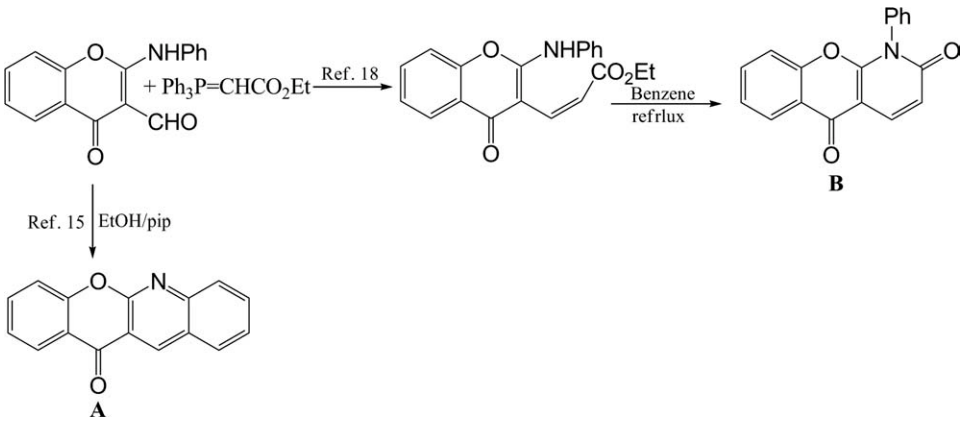
## INTRODUCTION

1-Benzopyranopyridine derivatives have found diverse application in the field of medicinal chemistry. 1-Benzopyrano[3,4-*c*]pyridine-5-ones act as human dopamine $D_4$ receptor antagonists and serve as potential antipsychotic agents [1]. Some nonsteroidal human androgen receptor agonists were synthesized based on 4-(trifluoromethyl)-2*H*-pyrano[3,2-*g*]-2-quinolone [2]. 1-Benzopyrano[2,3-*b*]pyridine-2,5-dione **1** ($R^2$ = H, G = $COCH_2COCH_3$) functions as a polyketide, which are involved in the biosynthesis of natural products [3]. Some chromenopyridines are designed and synthesized as an analogue of tetracycline [4]. 5-Salicyloyl-2-oxopyridine-3-carbonitriles play comparable roles as the nonglycosidic cardiotonic agents milrinone or amrinone [5]. Compounds **1**($R^2$ = H, G = CN, $CO_2R$, $CO_2H$) exhibit antiallergic properties and are used in the preparation of bronchodialators [6]. 1-Benzopyrano[2,3-*b*]pyridine-4,5-dione having a $CO_2H$ group at 3-position provides 100% inhibition in the passive cutaneous anaphylaxis screen when applied in a dose of 0.9 mg/kg [7]. Recently, some chromenopyridines are proved to be effective sensitizers for europium and terbium luminescence [8].

Synthesis of the 1-Benzopyrano[2,3-*b*]pyridine motif have been accomplished (a) from chromone-3-carbonitrile by reaction either with acetylacetone in the presence of piperidine [9] or with 1-ethoxy-1,3-bis(trimethylsilyloxy)-1,3-butadiene in the presence of $Me_3SiOTf$ [10], (b) from chromone-3-carbaldehyde by the reaction of 2-aminochromone [11] or with aniline in the presence of TMSCl in DMF [12]. 2-Aminochromone-3-carbaldehyde **3** ($R^2$ = H) has also been used for the synthesis of **1**($R^2$ = H) [13].

Although the reactions of 2-aminochromone-3-carbaldehyde **3** ($R^2$ = H) and 2-(*N*,*N*-dialkylamino)chromone-3-carbaldehyde **3** ($NR_2$ in place of $NHR^2$) have been studied in detail [13], the chemistry of 2-(mono substituted amino)chromone-3-carbaldehyde **3** has only been little explored. Most of its reactions were carried out by converting it into *N*,*N*-disubstituted analogue [14a,b]. Reaction of **3** with primary amine produces corresponding Schiff base [14], but with aliphatic secondary amines like diethylamine or piperidine compound **3** ($R^2$ = aryl) produces 1-benzopyranoquinolones (**A**) (Scheme 1) [15]. Recently, diethyl 1-benzopyrano[2,3-*b*]pyridine-2,3-dicarboxylate has been synthesized from **3** and diethyl acetylenedicarboxylate in the presence of $Ph_3P$ [16]. Synthesis of 2-pyridone moiety having ester or carbamoyl functionality at its 3-positions from β-formyl-β-nitroenamine has recently been reported [17].

**Scheme 1**



A literature survey revealed that functionlization at the 3-position of 1-benzopyrano [2,3-*b*]pyridine-2,5-dione made this system medicinally efficacius [6]. 1-Benzopyrano[2,3-*b*]pyridine-2,5-dione (**B**) having no functionality at its 3-position had been synthesized by the reaction of **3** ($R^2$ = Ph) with ethyl (triphenylphosphoranylidene)acetate followed by heating in benzene (Scheme 1) [18].

Our objective was to synthesize **1** with varying substituents at its 3-position utilizing the C3N1 building block of the β-amino-α, β-unsaturated aldehyde moiety of **3.** We report herein a few new one-pot syntheses of compound **1** from **3** by condensation with 2,2-dimethyl-1,3-dioxan-4,6-dione (Meldrum's acid), *N*-benzoylglycine (hippuric acid), 4-hydroxycoumarin, and other active methylene compounds under suitable reaction conditions. Compound **3** can readily be obtained from *N*-alkyl/aryl-*C*-(4-oxo-4*H*-1-benzopyran-3-yl)nitrones **2** [19] or directly from chromone-3-carbaldehyde [20].

## RESULTS AND DISCUSSION

Meldrum's acid (**4**), an active methylene compound having strong electrophillic centres, has made its position in the synthesis of many organic compounds having use in the fields of drugs and pharmaceuticals [21]. Very recently, its chemical bonding and structure-reactivity relation have been studied both experimentally and theoretically [22]. Its chemical versatility has also been discussed in several review articles [23]. We have used Meldrum's acid in the synthesis of 1-benzopyrano[2,3-*b*]pyridine-2,5-dione moiety from **3**.

An equimolar mixture of **3** and **4** was heated under reflux in ethanol in the presence of catalytic amount of pyridine for 2–4 h. White solids (**1a–e**) were found to precipitate under this reaction condition in moderate to good yields (Table 1, entries 1–5). Compound **3** undergoes Knoevenagel condensation with Meldrum's acid to form **5**, which cyclizes to **1a–e** under the reaction condition (Scheme 2, path-a). The structures of the

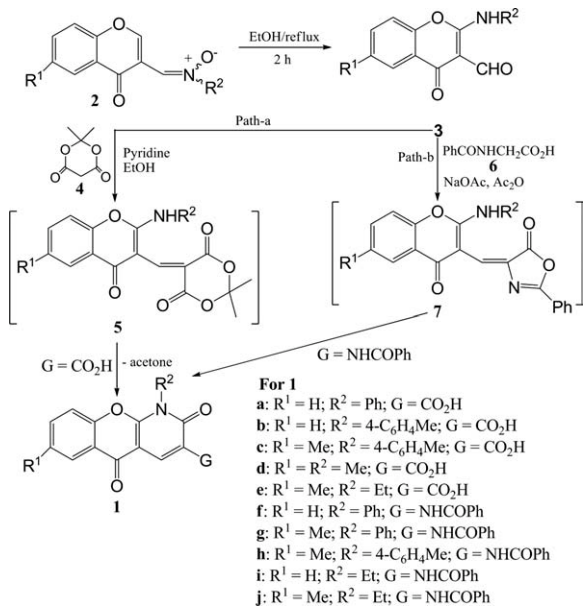
Ar stands for 4-$C_6H_4Me$.

**Scheme 2**



compounds were established on the basis of IR, $^1$H NMR, and mass spectral analysis. It is to be mentioned here that the carboxylic acid protons for compounds **1a** and **1b** were not observed in their $^1$H NMR spectra. The presence of carboxylic acid group in **1a** and **1b** was confirmed from their mass spectral analyses and the singlet appearance of $C_4$-H in the $^1$H NMR spectra of **1a,b**.

In connection to our earlier studies [24] on the reactions of different nitrogenous nucleophiles on 4-[(4-oxo-4*H*-1-benzopyran-3-yl)methylene]-2-phenyl-5-oxazolone **7** ($R^1$ = $NHR^2$ = H)(Scheme 2), derived from 3-formylchromone, it has been observed that nitrogenous nucleophiles are prone to interact on the carbonyl function of oxazolone moiety. Compound **3** can be considered as 3-formylchromone moiety having an inbuilt amino function in appropriate position. To utilize this special structural feature of **3**, an equimolar mixture of **3** ($R^2$ = aryl) and hippuric acid (**6**) was heated in the presence of excess amount of fused sodium acetate in acetic anhydride on water bath for 6–7 h and after usual work-up, compounds **1f–h** were obtained as white solids in moderate yields (Table 1, entries 6–8). On similar treatment of **3** ($R^2$ = alkyl), the reaction mixture yielded **1i** and **1j** (entries 9, 10) after chromatographic separation on silica gel using 10% ethyl acetate in benzene as eluent. Formation of **1f–j** from **3** may be rationalized by the initial formation of azlactone **7**, followed by intramolecular attack of the amino function to the carbonyl carbon of oxazolone moiety (Scheme 2, path-b).

This reaction was further extended by using 4-hydroxycoumarin (**8**). On heating an equimolar mixture of **3** and **8** in ethanol under reflux for 5–6 h in the presence of catalytic amount of pyridine, the reaction mixture produced compound **10** in good yields *via* the Knoevenagel condensate **9** (Scheme 3) (Table 1, entries 11–13). Suitably placed $NHR^2$ group in **9** reacted intramolecularly on the carbonyl function with a lesser decrease in entropy compared to the Michael addition of second molecule of **8**, which is the common feature for the reaction of an aldehyde with **8** [25].

With an endeavor to synthesize **1**(G = $CO_2$Et), compound **3** ($R^2$ = aryl) was stirred at room temperature with diethyl malonate in pyridine, but no change in **3** was observed (Table 2, entry 1). Ethyl acetoacetate also failed to cause any change in **3** on stirring at room temperature in pyridine (entry 2), even on heating **3** with ethyl acetoacetate in ethanol for 25 h in the presence of pyridine showed no considerable change (entry 3). On stirring an ethanolic solution of **3** ($R^2$ = aryl) with diethyl malonate at room temperature in the presence of piperidine for 40 h resulted in the formation of 1-benzopyrano[2,3-*b*]-12-quinolone (**A**) [15,18,19] (Scheme 1) (Table 2, entry 4). No pure compound could be isolated from the reaction mixture obtained by heating a mixture of **3**, diethyl malonate, fused NaOAc in $Ac_2O$ on a water bath for 5 h (entry 5). Surprisingly, compound **3** reacted with diethyl malonate in $CHCl_3$ under reflux in the presence of piperidine to produce **1k,l** (entries 6, 7) (Scheme 4). It was observed that more than stoichiometric amounts of diethyl malonate (1.5 equiv) and piperidine (1.5 equiv) were required for complete consumption of **3**. This methodology was then applied for the synthesis of **1** having various substituents at its 3-position. On heating **3** ($R^2$ = aryl) with ethyl acetoacetate and piperidine in equimolar amounts in $CHCl_3$ for 4 h produced **1o** (entry 8). Similarly, ethyl benzoylacetate reacted stoichiometrically with **3** ($R^2$ = aryl) within 2 h to produce **1q,r** (entries 9, 10).

**Scheme 3**

''Py'' stands for Pyridine; ''Pip'' stands for piperidine; ''RT'' stands for room temperature.
''N. R.'' stands for No Reaction.
[a] 80% **3** was recovered.
[b] 40% of compound **A** was isolated.

The reaction was extended with **3** ($R^2$ = alkyl). Ethyl benzoylacetate (entries 11,12), ethyl acetoacetate (entry 13), and diethyl malonate (entries 14, 15) produced corresponding **1** but in lower yields. On changing the solvent from $CHCl_3$ to ethanol, the yield of **1** ($R^2$ = alkyl) was found to improve, but a little longer reaction time was required (entries 12,16 and 13, 18). Similar reaction with **3** ($R^2$ = aryl) in ethanol always produced some 1-benzopyrano quinolone (**A**) along with **1** (entry 17). Use of triethylamine or pyridine as a base in the reaction between **3** and $PhCOCH_2CO_2Et$ either in $CHCl_3$ or in EtOH failed to show the formation of **1** even after heating under reflux for 30 h. Piperidine was found to be a better reagent than morpholine or diethylamine for this transformation (entries 9, 19, 20).

Compound **3** reacted differently when ethyl cyanoacetate or malononitrile were used as active methylene component. On stirring an equimolar mixture of **3** and ethyl cyanoacetate in ethanol in the presence of piperidine at room temperature, followed by usual work-up [*vide* experimental Section ''General procedure for the reaction of ethyl cyanoacetate on 2-alkyl/arylaminochromone-3-carbaldehyde (3)''] and chromatographic purification produced **11** (G' = $CO_2Et$) (Scheme 5, path a). But malononitrile yielded **12** when reacted with **3** under similar reaction condition (Scheme 5, path b). In an attempt to purify compound **12** (G' = CN) by column chromatography, a partial change in **12** was observed and finally the new compound was assigned to be **11** (G′ = CN). This observation led us to check the silica-induced conversion of **12** (G′ = CN) to **11** (G′ = CN). A chloroform solution of **12** (G′ = CN) containing some silica gel was heated under reflux for 5 h with stirring. Indeed, complete conversion of **12** (G′ = CN) to **11** (G′ = CN) was observed. Use of benzene in place of chloroform also accomplished this transformation under identical condition. However, on heating under reflux in ordinary $CHCl_3$ or benzene in the absence of silica gel, compound **12** failed to show any change. In an earlier report [17], β–allylamino-2-nitroacrolein was made to react with malononitrile and was supposed to

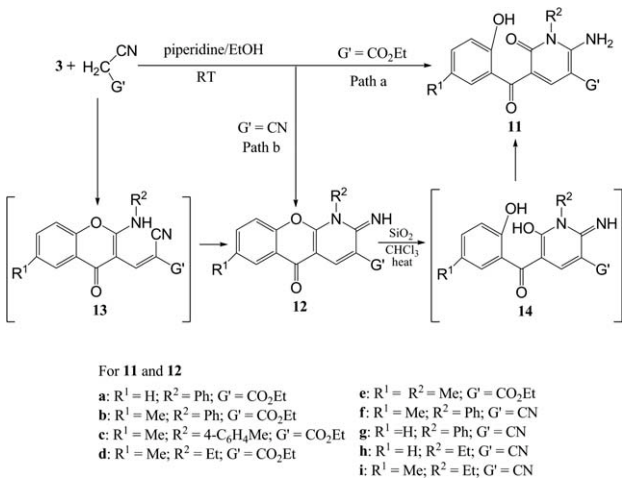
**t**: $R^1$ = H; $R^2$ = Et; G = COPh

**Scheme 5**



For **11** and **12**

**a**: $R^1$ = H; $R^2$ = Ph; G' = $CO_2Et$
**b**: $R^1$ = Me; $R^2$ = Ph; G' = $CO_2Et$
**c**: $R^1$ = Me; $R^2$ = 4-$C_6H_4$Me; G' = $CO_2Et$
**d**: $R^1$ = Me; $R^2$ = Et; G' = $CO_2Et$
**e**: $R^1$ = $R^2$ = Me; G' = $CO_2Et$
**f**: $R^1$ = Me; $R^2$ = Ph; G' = CN
**g**: $R^1$ =H; $R^2$ = Ph; G' = CN
**h**: $R^1$ = H; $R^2$ = Et; G' = CN
**i**: $R^1$ = Me; $R^2$ = Et; G' = CN

pass through an amidine like intermediate as in **12**, but the intermediate could not be isolated. Isolation of **12** (G′ = CN) gave us an impetus to take an attempt for the isolation of **12** (G′ = $CO_2Et$). But careful investigation of the solid [*vide* experimental Section ''General procedure for the reaction of ethyl cyanoacetate on 2-alkyl/arylaminochromone-3-carbaldehyde (3)''] obtained from the reaction mixture of **3** ($R^1$ = H, $R^2$ = Ph) and ethyl cyanoacetate revealed that there was more than one product (TLC). However, chromatographic separation yielded only **11a** in moderate yield. The other components were separated by preparative TLC and the bands corresponding to two different spots were extracted separately with $CHCl_3$. Unfortunately, the isolated compounds were same in both cases and the compound was **11a**. Compound **12** ($R^2$ = aryl, G′ = $CO_2Et$) could not be isolated even after using neutral $Al_2O_3$ as adsorbent in the column chromatography. The only such compound **12d** was obtained by stirring a pyridine solution of **3** ($R^1$ = Me, $R^2$ = Et) and ethyl cyanoacetate at room temperature. Compound **12d** was readily converted to **11d** within 1 h when heated in ordinary $CHCl_3$ in the presence of silica gel. Formation of **12** can be rationalized *via* the Knoevenagel condensate **13** (Scheme 5). It was presumed that the conversion of **12** to **11** took place by silica-induced hydration. The source of water was supposed to be from silica adsorbent or solvent or atmosphere. Water molecule attacks **12** and opens the pyran ring to form **14** and subsequently tautomerizes to **11**. To justify this presumption, compound **12** was heated in dry $CHCl_3$ in the presence of dry silica gel and under argon atmosphere and indeed compound **12** failed to show any change.

## CONCLUSION

We have reported a few new efficient one-pot methods for the synthesis of 1-benzopyrano [2,3-*b*]pyridine-2,5-dione moiety bearing various functionalities at its 3-position. The differential behavior of the active methylene compounds bearing cyano group toward **3** has also been reported.

## EXPERIMENTAL

**General.** The recorded mps are uncorrected. IR spectra were recorded in KBr on a Beckman IR 20a, $^1$H NMR/$^{13}$C NMR spectra on a bruker 300 MHz/75 MHz spectrometer, mass spectra on a Qtof micro YA 263 instrument and elemental analysis on a Perkin Elmer 240c elemental analyzer. Light petroleum refers to the fraction with 60–80°C. All chemicals used were of commercial grade and were used as such.

**General procedure for the synthesis of 1-alkyl/aryl-2*H*,5*H*-1-benzopyrano[2,3-*b*]pyridine-3-carboxylic acids (1a–e).** An ethanolic solution (10 mL) of a mixture of **3** (1 mmol), **4** (144 mg, 1 mmol), and catalytic amount of pyridine (2 drops) was heated under reflux for 2–4 h. The white solid separated out during the reaction was filtered off and crystallized from benzene to obtain **1a–e** as white crystalline solids.

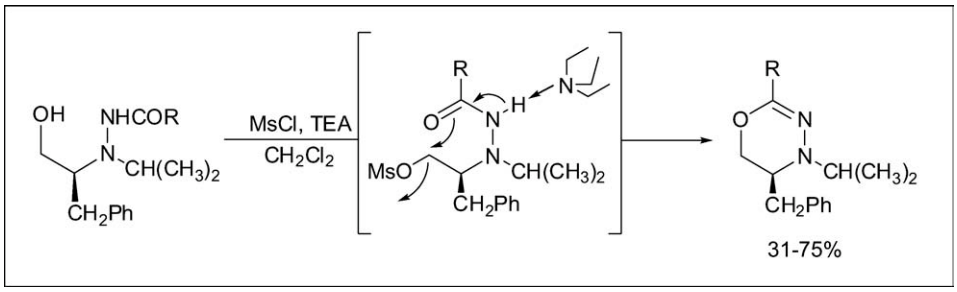
Published online 24 June 2010 in Wiley InterScience (www.interscience.wiley.com).



A series of chiral, nonracemic oxadiazines have been prepared from (1*R*,2*S*)-ephedrine, (1*R*,2*S*)-norephedrine, and L-phenylalaninol. The synthesis of the *Ephedra*-based oxadiazines was accomplished by a process of *N*-nitrosation, reduction, acylation, and acid-catalyzed cyclization. The *trans*- and *cis*-diastereomeric oxadiazines derived from (1*R*,2*S*)-ephedrine were analyzed by $^1$H NMR spectroscopy and by single crystal X-ray crystallographic analysis. The stereochemistry of the (1*R*,2*S*)-norephedrine–derived oxadiazines was assigned based on $^1$H NMR spectroscopy and by analogy with the X-ray crystal structure of the (1*R*,2*S*)-ephedrine–based oxadiazines. In addition, L-phenylalaninol was used as a template to prepare a series of oxadiazines substituted at the $N_4$-nitrogen with an isopropyl group. This was accomplished by a reductive alkylation of L-phenylalaninol with acetone and subsequent hydrazide formation. These hydrazides were reacted with methanesulfonyl chloride to yield the corresponding oxadiazines by a base-mediated cyclization.

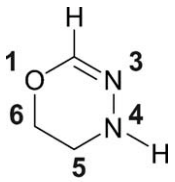
*J. Heterocyclic Chem.*, **47**, 982 (2010).

## INTRODUCTION

Many heterocyclic systems such as oxazolidinones [1] and oxazolines [2] have been well-developed in terms of their synthetic [3,4] and medicinal applications [5,6]. In contrast, the heterocycles known as 5,6-dihydro-4*H*-1,3,4-oxadiazines (oxadiazines, **1**) have not been the subject of much interest (Fig. 1). The first report concerning this ring system was described by Ishidate *et al.* and the oxadiazine that was formed only considered to be a contaminant [7]. Research that was directly focused on oxadiazines, as synthetic targets of medicinal worth was launched by the Pitman-Moore division of Dow chemical in the early 1960s [8a]. Consequently, chiral, nonracemic oxadiazines derived from *Ephedra* alkaloids were first prepared by Dow chemists Trepanier *et al.* [8a–f]. The synthetic pathway that was developed involved the preparation of β-hydrazido-alcohols, which were converted into their corresponding oxadiazines by acid-catalyzed cyclization (Scheme 1) [8a–f]. Specifically, ephedrine was converted to *N*-aminoephedrine by *N*-nitrosation and $LiAlH_4$ reduction. The resultant β-hydrazido-alcohol was treated with two equivalents of benzoyl chloride to generate the bis(benzoylated) derivative **4**. Hydrolysis of the ester yielded the required β-hydrazido-alcohol **5**. Trepanier *et al.* used this sequence of steps because of the competitive nucleophilicity between the hydrazine and alcohol. The β-hydrazido-alcohol **5** was then treated with acid [8a–e] to induce cyclization to afford a diasteroemeric mixture of oxadiazines **6** and **7**. The dominant oxadiazine was dependent on the acid that was used. Oxadiazine **6** was the dominant diastereomer [8a–c] when sulfuric acid was used, and oxadiazine **7** was dominant when an acetic acid/HBr mixture was used [8d]. On the basis of seminal efforts of Trepanier *et al.* [8] and the later research efforts of others [9–11] who have investigated the preparation of oxadiazines, we became interested in the synthesis of these compounds as potential tools for conducting asymmetric syntheses via intramolecular chiral relay [12–14,15a].

## RESULTS AND DISCUSSION

The first course of action that was taken involved the preparation of the (1*R*,2*S*)-ephedrine–derived oxadiazines **6** and **7** for the sake of evaluating the literature



**1**

**Figure 1.** 5,6-Dihydro-4*H*-1,3,4-oxadiazine.

method for preparing these compounds. The (1*R*,2*S*)-ephedrine hydrazine was prepared in the same manner as in Trepanier's work using an experimental procedure (*N*-nitrosation/reduction) developed in the our laboratories (Scheme 2) [15]. In contrast to the earlier work involving the use of excess benzoyl chloride (Scheme 1), the hydrazine was treated with one equivalent of benzoic anhydride via dropwise addition at 0°C to afford the corresponding hydrazide **5** in 66% yield without the need for the bis(acylation).

The $H_2SO_4$-catalyzed cyclization of **5** gave a 7:1 ratio of the *trans*-oxadiazine **6** to the *cis*-oxadiazine **7**. This mixture of diastereomers, which presumably arose from stereochemical inversion/retention at the benzylic position, was purified by multiple recrystallizations to afford the diastereomerically enriched **6** in 22%. The low yield was attributed to the competitive process of hydrolysis of the hydrazide to hydrazine **3**. Despite numerous attempts, we were not able to reproduce the yields for this compound that Trepanier *et al*. obtained in his early work perhaps due to the purification [8a].

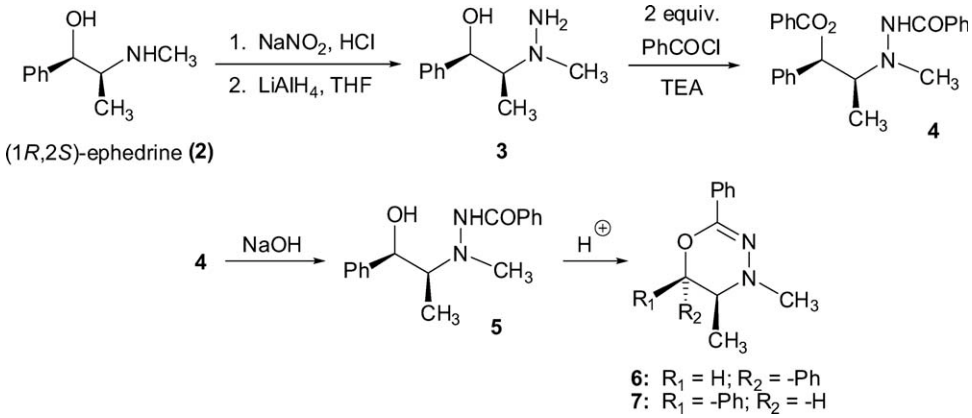
Nonetheless, we were also interested in conducting the hydrobromic acid/propanoic acid cyclization pathway. Under these conditions, treatment of **5** afforded a 6:1 diastereomeric mixture of oxadiazines favoring the *cis*-isomer **7**. Purification by flash chromatography yielded the diastereomerically enriched **7** in 36% isolated yield.

Base-induced cyclization was of interest as there was the possibility that such a pathway might afford improved diastereoselectivities in the oxadiazine products. Trepanier had demonstrated that the base-mediated cyclization (Scheme 1) was limited due to the failure of the intramolecular nucleophilic substitution. The cyclization pathway was investigated through a different synthetic route involving the generation of the mesylate of hydrazide **5**. To pursue this idea, **5** was reacted with methanesulfonyl chloride in the presence of excess triethylamine (TEA) to generate benzylic mesylate intermediate **10**, which presumably underwent further cyclization to **6** (Scheme 2). This process yielded oxadiazine **6** in only 9% yield after flash chromatography from a complex mixture, suggesting that the base-mediated cyclization for the *Ephedra* series was not viable.

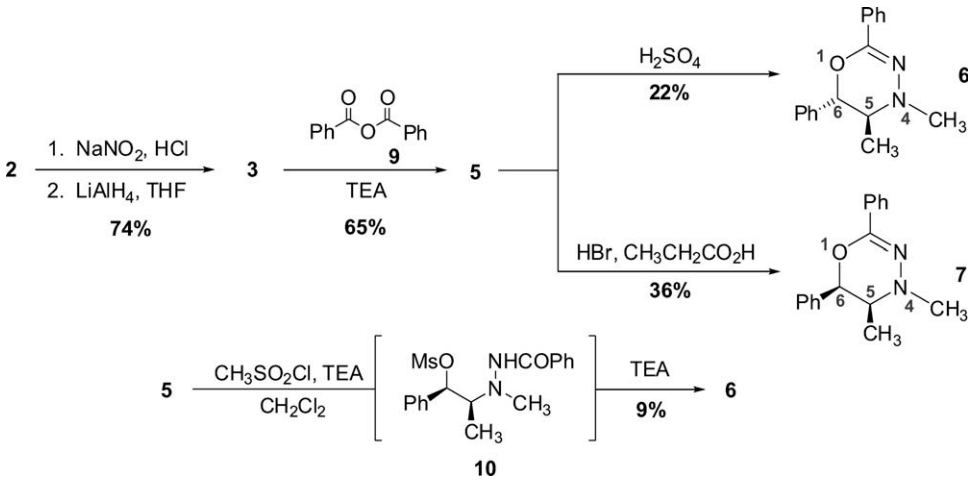
Trepanier originally assigned the configurations of the *trans*- and *cis*-oxadiazines based on the observed coupling constants for the $C_5$ and $C_6$ methine protons (Scheme 2). The $J_{H5–H6}$ coupling constant of the proposed *trans*-isomer **6** was calculated to be 7.4 Hz, whereas the $J_{H5–H6}$ coupling constant of the *cis*-isomer was determined to be 2.9 Hz. The calculated coupling constants were in agreement with the expected values based on the Karplus relation [16], but we were still interested in determining the relative and absolute stereochemistry of these compounds beyond the $^1$H NMR analysis. Thus, the stereochemical structures of **6** and **7** were unambiguously determined by single crystal X-ray crystallography (Figs. 2 and 3) [17].

The oxadiazines **6** and **7** were determined to have relatively planar structures as compared with the twist boat conformations that the related oxadiazinanones possess [18]. In addition to this observation, it was determined that there was a difference in terms of conformational

**Scheme 1.** Trepanier's synthesis of oxadiazines **6** and **7**.



**Scheme 2.** Synthesis of oxadiazines **6** and **7**.



behavior of the $N_4$-nitrogen with regard to the *cis*-oxadiazine **7** as compared with the related oxadiazinanones. Oxadiazine **7** possesses an equatorial $N_4$-methyl group, whereas the corresponding oxadiazinanone possesses an axial $N_4$-methyl group.

Once the stereochemistry of the oxadiazines was unambiguously determined, the synthesis of related oxadiazines derived from (1*R*,2*S*)-norephedrine was pursued (Scheme 3). The (1*R*,2*S*)-ephedrine hydrazine **3** was treated with either 1-naphthoyl chloride or propanoic anhydride to afford the corresponding hydrazides **12** (68%) and **13** (71%), respectively. Hydrazide **12** was reacted with either $H_2SO_4$ or HBr in propanoic acid to afford *trans*-oxadiazine **15** (28%) and *cis*-oxadiazine **16** (21%), respectively. The relative stereochemistry for the oxadiazines **15** and **16** were assigned based on the coupling constants [$J_{H5–H6}$(*trans*) = 7.4 Hz and $J_{H5–H6}$(*cis*) = 3.0 Hz] and correlation with the collected X-ray crystallographic data for **6** and **7**. Interestingly, cyclization of the propanoyl hydrazide **13** with sulfuric acid gave *trans*-oxadiazine **17** in 64% after flash chromatography. With regard to the higher yield of oxadiazine **17**, it is proposed that the 1-naphthoyl group of hydrazide **12** undergoes acid-catalyzed hydrolysis at a rate that is competitive with the cyclization; whereas the propanoyl group of hydrazide **13** does not.

The modifications that were made to prepare oxadiazines **15–17** varied the $C_2$-position. The $N_4$-position was also of interest as this position has been proposed to be the primary means of asymmetric induction in the related oxadiazinanone family of chiral auxiliaries [19]. To examine the impact of altering the $N_4$-position of the oxadiazine core, hydrazine **11** [19] was benzoylated by reaction with benzoic anhydride to yield hydrazide **14** in 31% after chromatography. The lower yield for the acylation process was attributed to the competitive nucleophilicity between the amino group of the hydrazine and the β-hydroxy group due to the presence of the *N*-

isopropyl group. The hydrazide **14** was cyclized with $H_2SO_4$ to yield the *trans*-oxadiazine **18** in 40% yield.

We became interested in determining if it would be possible to prepare chiral oxadiazines from a variety of α-amino acids. We had previously prepared hydrazine **19** from L-phenylalaninol [20] and sought to use this material to prepare a series of oxadiazines (Scheme 4). Thus, hydrazine **19** was acylated at nitrogen using either propanoyl chloride, benzoyl chloride, or 1-naphthoyl chloride to afford the corresponding hydrazides **20a–c**, respectively. The use of acyl chlorides proved to be as effective as the use of anhydrides when the reactions were conducted in 0.1*M* solutions of dichloromethane. The hydrazide **20c** was not directly isolated due to difficulties associated with the crystallinity of the hydrazide and the byproduct naphthoic acid.

The use of an acid-catalyzed process to induce the cyclization of these hydrazides was not pursued as these systems contained primary alcohols that might be susceptible to degradation. Ultimately, a base-mediated process for the cyclization of compounds **20a–c** was used. Thus, the hydrazides were treated with methanesulfonyl chloride and an excess of TEA to afford the desired oxadiazines **22a–c** through putative intermediates **21a–c**. The isolated yields for the oxadiazines were significantly better than the acid-catalyzed pathway perhaps due to the circumvention of the hydrolysis of the hydrazide.

## CONCLUSIONS

We have synthesized a series of *Ephedra*-based oxadiazines using a modified method based on the earlier works of Trepanier *et al*. The stereochemistry of the *Ephedra*-based oxadiazines were evaluated by $^1$H NMR spectroscopy and by X-ray crystallography. The preparation of the oxadiazines from L-phenylaninol was accomplished using a hydrazide pathway with formation on a labile mesylate intermediate.

## EXPERIMENTAL

**General remarks.** Methylene chloride ($CH_2Cl_2$) was purchased as an anhydrous reagent. Unless otherwise stated, all reactions were run under anhydrous conditions and a nitrogen atmosphere. $^1H$ and $^{13}C$ NMR spectra were recorded in $CDCl_3$ operating at 400 and 100 MHz, respectively, or at 300 and 75 MHz as specified. Chemical shifts are reported in parts per million (δ scale), and coupling constants (*J* values) are listed in hertz (Hz). Infrared spectra are reported in reciprocal centimeters ($cm^{-1}$) and are measured either as a neat liquid or as a KBr window. Melting points were recorded on a Mel-Temp apparatus and are uncorrected. Mass spectral analyses were conducted using a quadrupole time of flight mass spectrometer hybrid with MS/MS capability. Optical activities were measured at 589 nm using a digital polarimeter purchased with NSF grant.

**(5*S*,6*R*)-*N*′-(2-Hydroxy-1-methyl-2-phenylethyl)-*N*′-methyl) benzoic acid hydrazide (5).** To a flame dried, nitrogen purged round bottom, the (1*R*,2*S*)-ephedrine–derived hydrazine **4** (2.50 g, 13.9 mmol), dichloromethane (70 mL), and TEA (2.13 mL, 15.3 mmol) was added. The reaction mixture was then cooled to 0°C. The reaction stirred for 5 min and benzoic anhydride (3.30 g, 14.6 mmol) was added by means of a dropping funnel. After 24 h, the reaction was quenched by the addition of a saturated aqueous solution of ammonium chloride (100 mL) and diluted with $CHCl_3$ (100 mL). The organic layer was washed with brine (100 mL) and then dried ($MgSO_4$). The solvent was removed via rotary evaporation to afford the title compound: white solid (66%), Mp = 163–165°C, $[\alpha]_D^{24} = -61.9$ (*c* 0.59, $CHCl_3$). $^1H$ NMR (400 MHz, $CDCl_3$): δ 0.94 (d, *J* = 6.6 Hz, 3H), 2.83 (s, 3H), 2.99 (qd, *J* = 6.6, 2.2 Hz, 1H), 5.16 (d, *J* = 2.2 Hz, 1H), 7.20–7.52 (m, 8H), 7.76 (d, *J* = 7.4 Hz, 2H), 8.01 (s, 1H). $^{13}C$ NMR (100 MHz, DMSO-$d_6$): δ 9.9, 42.3, 65.8, 71.5, 125.6, 126.3, 127.2, 127.7, 128.3, 131.3, 133.4, 142.7, and 165.7 ppm. IR (nujol mull): 3205 and 1641 $cm^{-1}$. ESI-HRMS calcd. for $C_{17}H_{21}N_2O_2$ ($M + H^+$): 285.1603. Found: 285.1604.

***trans*-(5*S*,6*S*)-4,5-Dimethyl-2,6-diphenyl-5,6-dihydro-4*H*-1,3,4-oxadiazine (6).** Hydrazide **5** (1.00 g, 3.40 mmol) and concentrated sulfuric acid (18*M*, 10 mL) were combined and stirred at room temperature. After 2 h, the solution was diluted with water (100 mL) and treated with a saturated solution of sodium bicarbonate until the solution was neutralized as determined by the use of pH paper. The organic layer was extracted with EtOAc (100 mL), treated with $NaHCO_3$ (50 mL), and washed with brine (50 mL). The organic layer was dried ($MgSO_4$), and the solvent was removed by rotary evaporation to afford the title compound as a 7:1 mixture of the *trans*- and *cis*-isomers of the oxadiazine. The title compound was recrystallized thrice with hexanes and ethyl acetate to afford the isomerically pure *trans*-isomer as a white solid (22%). Mp = 139–141°C, $[\alpha]_D^{24} = +160.8$ (*c* 0.91, $CHCl_3$). $^1H$ NMR (400 MHz, $CDCl_3$): δ 1.06 (d, *J* = 6.6 Hz, 3H), 2.69 (dq, *J* = 7.4, 6.6 Hz, 1H), 2.88 (s, 3H), 5.05 (d, *J* = 7.4 Hz, 1H), 7.30–7.40 (m, 8H), 7.82–7.85 (m, 2H). $^{13}C$ NMR (100 MHz, $CDCl_3$): δ 14.3, 43.6, 57.5, 82.3, 125.3, 127.4, 128.0, 128.5, 128.6, 128.9, 132.5, 138.1, and 146.0 ppm. IR (nujol mull): 1622 and 1448 $cm^{-1}$. ESI-HRMS calcd. for $C_{17}H_{19}N_2O$ $(M + H)^+$: 267.1497. Found: 267.1487.

***cis*-(5*S*,6*R*)-4,5-Dimethyl-2,6-diphenyl-5,6-dihydro-4*H*-1,3,4-oxadiazine (7).** Hydrazide **5** (1.00 g, 3.40 mmol) and HBr in propanoic acid (15 mL, 30% by weight) were combined in 100 mL flask and stirred for 24 h. The solution was diluted with $H_2O$ (100 mL) and neutralized with $NaHCO_3$. The organic layer was diluted with EtOAc (100 mL), washed with brine (50 mL), and dried with $MgSO_4$. Solvents were removed via rotary evaporator. The title product was isolated by flash column chromatography (hexanes:EtOAc, 98:2). White solid (36%), Mp = 94–97°C. $[\alpha]_D^{24} = -176.2$ (*c* 1.00, $CHCl_3$). $^1H$ NMR (400 MHz, $CDCl_3$) δ: 0.81 (d, *J* = 6.5 Hz, 3H), 2.88 (s, 3H), 3.35 (dq, *J* = 6.5, 2.9 Hz, 1H), 5.52 (d, *J* = 2.9 Hz, 1H), 7.24–7.91 (m, 10H). $^{13}C$ NMR (100 MHz, $CDCl_3$) δ: 7.9, 42.9, 54.8, 79.1, 125.2, 126.2, 127.9, 128.0, 128.3, 128.8, 132.5, 138.2, and 144.3. The solution was diluted with $H_2O$ (100 mL) and neutralized with $NaHCO_3$. The organic layer was diluted with EtOAc (100 mL), washed with brine (50 mL), and dried ($MgSO_4$). The title compound was isolated by trituration with pentane. This process afforded the title compound as a ~7:1 mixture of the *trans*- and *cis*-isomers of the title oxadiazine. Yellow solid (28%), Mp = 140–142°C. $[\alpha]_D^{25} = +56.9$ (*c* 0.70, $CHCl_3$). $^1$H NMR (400 MHz, $CDCl_3$) δ: 1.13 (d, *J* = 6.4 Hz, 3H), 2.88 (dq, *J* = 7.4, 6.4 Hz, 1H), 2.95 (s, 3H), 5.19 (d, *J* = 7.4 Hz, 1H), 7.36–7.85 (m, 8H), 7.81–7.84 (m, 3H), 8.79 (d, *J* = 8.5 Hz, 1H). $^{13}$C NMR (100 MHz, $CDCl_3$) δ: 14.4, 43.7, 57.4, 82.8, 124.9, 125.7, 126.1, 126.8, 127.5, 128.3, 128.6, 128.7, 129.7, 130.7, 133.9, 137.9, and 147.1. IR (nujol): 1614, 1020, 759, and 706 $cm^{-1}$. ESI-HRMS calcd. for $C_{21}H_{21}N_2O$ ($M + H^+$): 317.1654. Found: 317.1643.

***cis*-(5*S*,6*S*)-4,5-Dimethyl-2-(1-naphthyl)-6-phenyl-5,6-dihydro-4*H*-1,3,4-oxadiazine (16).** Hydrazide **13** (1.00 g, 3.40 mmol) and a 30% solution of HBr in propanoic acid (15 mL) were combined in a 100-mL round-bottom flask and this reaction mixture stirred. After 24 h, the reaction was diluted with $H_2O$ (100 mL) and neutralized with $NaHCO_3$. The organic layer was diluted with EtOAc (100 mL), washed with brine (50 mL), dried with $MgSO_4$, and the solvents were removed via rotary evaporation. The title compound was isolated by flash chromatography (95:5, hexanes:EtOAc). Yellow solid (21%), Mp = 125–128°C. $[\alpha]_D^{23} = -86.4$ (*c* 0.53, $CHCl_3$). $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm): 0.94, (d, *J* = 6.6 Hz, 3H), 2.95 (s, 3H), 3.46 (dq, *J* = 6.6, 3.0 Hz, 1H), 5.65 (d, *J* = 3.0 Hz, 1H), 7.39–7.53 (m, 8H), 7.84–7.89 (m, 3H), 8.74 (d, *J* = 8.4 Hz, 1H). $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm): 8.2, 43.0, 54.8, 79.6, 124.9, 125.7, 126.1, 126.3, 126.5, 126.8, 127.9, 128.3, 129.7, 130.0, 130.8, 133.9, 138.1, and 145.5. IR (nujol): 1613, 995, 746, and 709 $cm^{-1}$. ESI-HRMS calcd. for $C_{21}H_{21}N_2O$ ($M + H^+$): 317.1654. Found: 317.1642.

***trans*-(5*S*,6*S*)-2-Ethyl-4,4-dimethyl-6-phenyl-5,6-dihydro-4*H*-1,3,4-oxadiazine (17).** Hydrazide **13** (0.25 g, 1.06 mmol) and $H_2SO_4$ (3 mL, 12*M*) were combined in 100-mL round-bottom flask and stirred for 24 h. The solution was diluted with $H_2O$ (100 mL) and neutralized with $NaHCO_3$. The organic layer was diluted with EtOAc (100 mL), washed with brine (50 mL), dried with $MgSO_4$, and the solvents were removed via rotary evaporation. The title product was isolated by flash column chromatography (hexanes:EtOAc, 9:1). Yellow oil (64%). $[\alpha]_D^{23} = +288.8$ (*c* 0.10, $CHCl_3$). $^1$H NMR (400 MHz, $CDCl_3$) δ: 0.90 (d, *J* = 6.3 Hz, 3H), 1.1 (t, *J* = 7.5 Hz, 3H), 2.17 (q, *J* = 7.5 Hz, 2H), 2.37–2.43 (m, 6.3 Hz, 1H), 2.63, (s, 3H), 4.79 (d, *J* = 7.8 Hz, 1H), 7.19–7.30 (m, 5H). $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm): 11.1, 14.3, 26.6, 43.5, 57.8, 82.3, 127.4, 128.5, 128.6, 138.0, and 151.9. IR (neat): 1656, 1066, 756, and 700 $cm^{-1}$. ESI-HRMS calcd. for $C_{13}H_{19}N_2O$ ($M + H^+$): 219.1497. Found: 219.1489.

**(5*S*,6*S*)-4-Isopropyl-5-methyl-2,6-diphenyl-5,6-dihydro-4*H*-1,3,4-oxadiazine (18).** Hydrazide **14** (0.50 g, 1.60 mmol) was combined with $H_2SO_4$ (5 mL, 12*M*) and stirred for 2 h. The solution was diluted with $H_2O$ (100 mL) and neutralized with $NaHCO_3$. The organic layer was diluted with EtOAc (100 mL), washed with brine (50 mL), dried with $MgSO_4$, and the solvents were removed via rotary evaporation. The title product was isolated by flash column chromatography (hexanes:-TEA, 97.5:2.5). White solid (40%), Mp = 160–162°C. $[\alpha]_D^{24} = +175.0$ (*c* 0.25, $CHCl_3$). IR (diamond): 1625, 1027, 756, and 686 $cm^{-1}$. $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm): 1.00 (d, *J* = 6.2 Hz, 3H), 1.04 (d, *J* = 6.2 Hz, 3H), 1.40 (d, *J* = 6.6 Hz, 3H), 2.92 (dq, *J* = 12.9, 6.6 Hz, 1H), 3.52 (septet, *J* = 6.6 Hz, 1H), 5.04 (d, *J* = 6.6 Hz, 1H), 7.25–7.86 (m, 10H). $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm): 13.9, 15.6, 21.4, 50.2, 53.4, 82.4, 125.1, 127.6, 127.9, 128.5, 128.6, 133.2, 138.6, and 145.3. ESI-HRMS calcd. for $C_{19}H_{23}N_2O$ ($M + H^+$): 295.1810. Found: 295.1798.

**General procedure for the formation of hydrazides 20a and 20b.** Hydrazine **19** (0.700 g, 3.36 mmol) was combined with dichloromethane (17 mL) and TEA (0.515 g, 3.70 mmol) and this mixture was cooled to 0°C. The anhydride (0.798 g, 3.53 mmol) was then added. After 24 h, the reaction was diluted by the addition of a saturated solution of ammonium chloride (100 mL) and diluted with $CH_2Cl_2$ (100 mL). The organic layer was washed with brine (100 mL), dried ($MgSO_4$), and the solvent was removed by rotary evaporation.

***N′*-(1-Benzyl-2-hydroxyethyl)-*N′*-isopropyl benzoic acid hydrazide (20a)** The use of benzoic acid afforded the title compound as a yellow solid (55%) contaminated with <5% of benzoic acid: Mp = 126–128°C, $[\alpha]_D^{22} = +27.4$ (*c* 1.24, $CHCl_3$). $^1$H NMR (400 MHz, $CDCl_3$): δ 1.16 (d, *J* = 6.6 Hz, 3H) 1.22 (d, *J* = 6.6 Hz, 3H), 2.53 (m, 1H), 2.91 (d, *J* = 13.3, 3.9 Hz, 1H), 3.23–3.33 (m, 1H), 3.44–3.50 (m, 1H), 7.05 (s, 1H), 7.13–7.74 (m, 5H). $^{13}$C NMR (100 MHz, $CDCl_3$): δ 20.6, 32.4, 53.5, 61.3, 63.3, 126.3, 127.1, 128.6, 128.6, 128.9, 131.7, 138.5, and 168.9 ppm. IR (nujol mull): 3203 and 1648 $cm^{-1}$. ESI-HRMS calcd. for $C_{19}H_{25}N_2O_2$ ($M + H^+$): 313.1916. Found: 313.1909.

***N′*-(1-Benzyl-2-hydroxyethyl)-*N′*-isopropyl propanoic acid hydrazide (20b)** The use of propanoic anhydride afforded a white solid (65%). Mp = 118–120°C, $[\alpha]_D^{24} = -7.28$ (*c* 0.82, $CHCl_3$). $^1$H NMR (400 MHz, $CDCl_3$): δ 1.08 (d, *J* = 6.3 Hz, 3H), 1.14 (d, *J* = 6.3 Hz, 3H), 1.21 (t, *J* = 7.4 Hz, 3H), 2.20 (q, *J* = 7.4 Hz, 2H), 2.38–2.50 (m, 1H), 2.83 (d, *J* = 13.2, 4.1 Hz, 1H), 3.11–3.23 (m, 2H), 3.33–3.45 (m, 2H), 4.52 (broad singlet, 1H) 6.26 (s), 7.12–7.32 (m, 5H). $^{13}$C NMR (100 MHz, $CDCl_3$): δ 10.1, 20.5, 27.3, 31.7, 52.7, 61.1, 62.8, 126.1, 128.4, 128.7, 138.5, and 175.5 ppm. IR (nujol mull): 3225 and 1666 $cm^{-1}$. ESI-HRMS calcd. for $C_{15}H_{25}N_2O_2$ ($M + H^+$): 265.1916. Found: 265.1921.

***N′*-(1-Benzyl-2-hydroxyethyl)-*N′*-isopropyl 1-naphthoic acid hydrazide (20c)** Hydrazine **19** (1.00 g, 4.80 mmol) was combined with dichloromethane (24 mL) and TEA (0.736 mL, 5.28 mmol) and the solution was cooled to 0°C. The reaction was stirred for 5 min and 1-naphthoyl chloride (0.76 mL, 5.0 mmol) was added by syringe. After 24 h, the reaction was quenched by the addition of a saturated solution of ammonium chloride (100 mL) and diluted with $CH_2Cl_2$ (100 mL). The aqueous layer was drawn off and the organic layer was washed with brine (100 mL), dried ($MgSO_4$), and the solvent was

removed by rotary evaporation to afford hydrazide **20c**. This product proved to be difficult to handle due to its poor solubility and was directly converted to oxadiazine **21c**.

**General procedure for the formation of oxadiazines 21a and 21b.** Hydrazide **20a** (0.500 g, 1.60 mmol) was combined with dichloromethane (5 mL), TEA (0.22 mL, 1.6 mmol), and methanesulfonyl chloride (0.130 mL, 1.68 mmol). After 24 h, the reaction was quenched by the addition of a saturated solution of ammonium chloride (50 mL) and diluted with dichloromethane (50 mL). The organic layer was separated, washed with brine (50 mL), dried ($MgSO_4$), and the solvent was removed by rotary evaporation. The crude product was then purified by column chromatography using hexanes and ethyl acetate (98:2).

***(S)-5-Benzyl-4-5,6-dihydro-isopropyl-2-phenyl-4H-1,3,4-oxadiazine (21a)*** The title compound was obtained as yellow oil (75%). $[\alpha]_D^{21} = +197.9$ (*c* 1.45, $CH_2Cl_2$). $^1$H NMR (400 MHz, $CDCl_3$): δ 1.15 (d, $J = 6.3$ Hz, 3H), 1.37 (d, $J = 6.3$ Hz, 3H), 2.69 (dd, $J = 13.5$, 9.9 Hz, 1H), 3.03 (dd, $J = 13.5$, 4.7 Hz, 1H), 3.32–3.53 (m, 2H), 3.98 (dd, $J = 10.3$, 2.8 Hz, 1H), 4.14 (dd, $J = 10.3$, 4.4 Hz, 1H), 7.20–7.36 (m, 8H), 7.78–7.83 (m, 2H). $^{13}$C NMR (100 MHz, $CDCl_3$): δ 17.9, 20.6, 34.5, 52.3, 53.5, 65.7, 124.8, 126.4, 127.8, 128.2, 128.4, 129.2, 133.0, 137.7, and 143.4 ppm. IR: 1628, 1176, 766, and 694 cm$^{-1}$. ESI-HRMS calcd. for $C_{19}H_{23}N_2O$ $(M + H^+)$: 295.1810. Found: 295.1809.

***(S)-5-Benzyl-2-ethyl-5,6-dihydro-4-isopropyl-4H-1,3,4-oxadiazine (21b)*** Hydrazide **12b** was used in the cyclization process to yield **21b**. The product was purified by column chromatography using hexanes and ethyl acetate (97:3) and was obtained as yellow oil (59%). $[\alpha]_D^{24} = +6.12$ (*c* 0.76, $CH_2Cl_2$). $^1$H NMR (300 MHz, $CDCl_3$): δ 1.07 (d, $J = 6.3$ Hz, 3H), 1.11 (t, $J = 7.4$ Hz, 3H), 1.28 (d, $J = 6.3$ Hz, 3H), 2.18 (q, $J = 7.4$ Hz, 2H), 2.57 (dd, $J = 13.5$, 9.9 Hz, 1H), 2.97 (dd, $J = 13.5$, 4.4 Hz, 1H), 3.18–3.3.26 (m, 1H), 3.33 (septet, $J = 6.3$ Hz, 1H), 3.91–3.93 (m, 1H), 7.16–7.33 (m, 5H). $^{13}$C NMR (75 MHz, $CDCl_3$): δ 10.7, 17.0, 20.7, 26.4, 33.1, 51.0, 52.6, 66.5, 126.3, 128.5, 129.1, 138.0, and 149.5 ppm. IR: 1662, 1176, 741, and 701 cm$^{-1}$. ESI-HRMS calcd. for $C_{15}H_{23}N_2O$ $(M + H^+)$: 247.1810. Found: 247.1822.

***(S)-5-Benzyl-5,6-dihydro-4-isopropyl-2-naphthyl-4H-1,3,4-oxadiazine (21c)*** The hydrazine **20c** (1.00 g, 4.80 mmol) was combined with dichloromethane (24 mL) and TEA (0.736 mL, 5.28 mmol) and the solution was cooled to 0°C. The reaction was stirred for 5 min and 1-naphthoyl chloride (0.760 mL, 5.04 mmol) was added. After 24 h, the reaction was quenched by the addition of a saturated solution of ammonium chloride (100 mL) and diluted with $CH_2Cl_2$ (100 mL). The aqueous layer was drawn off and the organic layer was washed with brine (100 mL), dried ($MgSO_4$), and the solvent was removed by rotary evaporation to afford hydrazide **20c**. This product proved to be difficult to handle due to its solubility and was directly converted to oxadiazine **21c**. The hydrazide was combined with dichloromethane (15 mL), TEA (1.34 mL, 9.60 mmol), and methanesulfonyl chloride (0.39 mL, 5.04 mmol) and stirred. After 24 h, the reaction was quenched by the addition of a saturated solution of ammonium chloride (50 mL) and dichloromethane (50 mL). The layers were separated and the organic layer was washed with brine (50 mL), dried ($MgSO_4$), and the solvent was removed by rotary evaporation. The resultant oxadiazine **21c** was purified by column chromatography with hexanes. This process afforded a yellow oil (31%). $[\alpha]_D^{24} = +158.2$ (*c* 1.64, $CH_2Cl_2$). $^1$H NMR (400 MHz, $CDCl_3$): δ 1.33 (d, $J = 6.3$ Hz, 3H), 1.56 (d, $J = 6.3$ Hz, 3H), 2.91 (dd, $J = 13.3$, 9.8 Hz, 1H), 3.21 (dd, $J = 13.3$, 5.1 Hz, 1H), 3.64 (septet, $J = 6.3$ Hz, 1H), 4.23 (dd, $J = 10.2$, 2.7 Hz, 1H), 4.35 (dd, $J = 10.2$, 4.3 Hz, 1H), 7.38 (t, $J = 5.9$ Hz, 2H), 7.44–7.46 (m, 2H), 7.56–7.62 (m, 3H), 7.69 (m, 1H), 7.95 (t, $J = 6.6$ Hz, 2H), 8.01–8.03 (m, 1H), 9.09 (d, $J = 8.6$ Hz, 1H). $^{13}$C NMR (100 MHz, $CDCl_3$): δ 18.1, 20.9, 34.6, 52.5, 53.6, 66.0, 124.8, 125.5, 126.1, 126.2, 126.4, 126.5, 128.2, 128.5, 129.3, 130.0, 130.5, 133.9, 137.8, and 144.5 ppm. IR: 2970, 1627, 1131, 740, and 700 cm$^{-1}$. ESI-HRMS calcd. for $C_{23}H_{25}N_2O$ $(M + H)^+$: 345.1967. Found: 345.1958.

**Acknowledgments.** The authors thank Ms. Brittany S. Morgan (Project SEED) for her technical assistance in conducting polarimetric measurements. The authors gratefully acknowledge support for this work by the National Science Foundation (NSF grant no. CHE 644950). The collected X-ray crystallographic data is based upon the work supported by the US National Science Foundation (CHE-0348158 and CHE-0725294 to GMF). They also thank Youngstown State University's Matthias Zeller for X-ray data collection and useful discussion.

A series of tricyclic 7,8,10,11-tetrahydro-5*H*-benzo[*e*]pyrimido[4,5-*b*][1,4]diazepin-9(6*H*)-ones were prepared in moderate to high yields using TFA-promoted iminium-cyclization reactions of 3-(6-(butylamino)-4-chloropyrimidin-5-ylamino)cyclohex-2-enones and various aldehydes.

*J. Heterocyclic Chem.*, **47**, 990 (2010).

## INTRODUCTION

Benzodiazepines have long been associated with interesting biological activities. For example, clozapine is used to treat schizophrenia; pirenzepine acts selectively as a muscarinic receptor (M1) antagonist; and apafant acts as the platelet activating factor inhibitors [1]. Consequently, syntheses of benzodiazepine derivatives or diazepine-containing heterocycles are of interest to organic and medicinal chemists. Thus, dibenzo[b,e][1,4]-diazepines and other tricyclic systems with a 1,4-diazepine moiety are well documented in the literature [2–9].

As part of our program to prepare heterocyclic libraries, we developed a series of methodologies to rapidly access various heterocyclic scaffolds with benzodiazepine as the core [10–15]. These methodologies entail Bischler–Napieralski cyclization reactions and iminium cyclization reactions as the key transformation steps. To expand the scope of the iminium-cyclization reaction, we envisioned that enaminones **1** could be reacted with various aldehydes to prepare 7,8,10,11-tetrahydro-5*H*-benzo[*e*]pyrimido[4,5-*b*][1,4]diazepin-9(6*H*)-ones [16], as depicted in Scheme 1. Although syntheses of dibenzo [b,e][1,4]diazepines are frequently reported, there is few report of aminopyrimidines as substrates for such cyclization reactions [16]. Given the large structural differences between a pyrimidine and benzene, optimization of the cyclization reaction was investigated. Herein, we reported the development of this method to prepare 7,8,10,11-tetrahydro-5*H*-benzo[*e*]pyrimido[4,5-*b*][1,4]diazepin-9(6*H*)-ones.

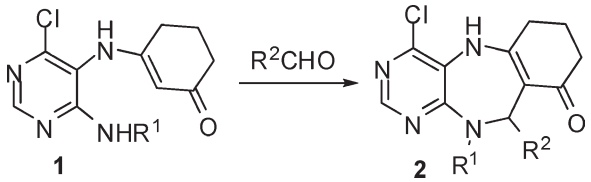
## RESULTS AND DISCUSSION

The desired enaminones **1** were readily prepared *via* condensation of **3** [17] with 1,3-cyclohexandione in acetic acid in 78% yields, as depicted in Scheme 2.

To identify the optimal reaction conditions, the formation of the pyrimido-benzodiazepine nucleus was initially studied using benzaldehyde as the substrate, and results are summarized in Table 1.

The standard conditions of AcOH-EtOH are often reported for similar type of cyclization reactions of anilines leading to dibenzo[b,e][1,4]diazepines [2,4]. Therefore, these conditions were studied initially. No desired product was detected at room temperature (entry 1, Table 1) and only trace amount was isolated after prolonged heating (entry 2, Table 1). The lower reactivity of pyrimidines **1** compared to standard anilines is likely because of the large structural differences between pyrimidine and benzene. It is possible that the pyrimidine ring nitrogens are protonated under the acidic reaction conditions, which decreased the propensity of the n-butylamino group toward imine formation. It was reasoned that a stronger acid, such as TFA might help to promote the key imine formation step. Thus, switching the acid from acetic acid to stronger acids, such as TFA and sulfuric acid led to low yields of desired product **2**, entries 3–5, Table 1. The conditions of TFA-acetonitrile proved to be productive in other iminium cyclization reactions, therefore they were investigated next. Treatment of pyrimidine **1** and benzaldehyde in the presence of TFA at room temperature led to product **2** in 22% yield (entry 6, Table 1). On the hand, moderate heating at 60°C produced the desired product **2** in 56% yield. The reaction temperature to reflux shortened the reaction time to 18 h, producing compound **2** in 59% yield (entry 8, Table 1). To test the solvent effect of acetonitrile, the reaction was repeated using AcOH with $CH_3CN$ (entry 9), and after reflux for 18 h only 11% of the desired product was obtained. Another

**Scheme 1**



condition investigated was $Py/SOCl_2$-$CH_2Cl_2$ [18], which was reported for aniline cyclization reactions. Reflux for 78 h, the desired product was isolated in 40% yield (entry 10). Thus, the TFA-acetonitrile conditions (entry 8, Table 1) were identified as optimal, which were applied to other aldehydes and results are summarized in Table 2.

As disclosed in Table 2, both aliphatic and aromatic aldehydes are compatible for the current reactions, producing the expected 7,8,10,11-tetrahydro-5*H*-benzo[*e*]-pyrimido[4,5-*b*][1,4]diazepin-9(6*H*)-ones **2** in moderate to good yields. The reactions with aliphatic aldehydes (entries 1–3) proceeded at room temperature to generate the desired products in moderate yields. Various functional groups ranging from electron-donating (methyl or methoxy; entries 4–6) to electron-withdrawing groups (halo, cyano, or nitro; entries 8–14) were tolerated under the reaction conditions. The Results presented in Table 2 seem to suggest that both electronic and steric effects may affect the yields when benzaldehydes were used. For example, electron-withdrawing groups tend to give higher yields (entries 11–14) compared to electron-donating groups (entries, 4–6). The presence of an ortho substituent (entries 3 and 8) led to lower yields compared to the corresponding meta- and para-substituted analogs (entries 4 and 9), which suggests steric hindrance may lead to lower yields.

In summary, a novel heterocyclic scaffold entailing 7,8,10,11-tetrahydro-5*H*-benzo[*e*]pyrimido[4,5-*b*][1,4]diazepin-9(6*H*)-one was prepared efficiently from *N*-substituted pyrimidinediamine and aldehydes. The standard AcOH-EtOH conditions commonly used to prepare dibenzo[b,e][1,4]diazepines proved to unsuitable for aminopyrimidines. Thus, a new TFA-acetonitrile condition was successfully developed to produce the desired 4-chloro-7,8,10,11-tetrahydro-5*H*-benzo[*e*]pyrimido[4,5-*b*][1,4]diazepin-9(6*H*)-ones in moderate to excellent yields.

[c] Some starting material **1** was recovered.

## EXPERIMENTAL

Acetonitrile ($CH_3CN$) was dried with $CaH_2$ and distilled. All other commercial reagents were used as received without purification. Melting points were uncorrected. Mass spectra and HPLC data were recorded on a LC/MS system with ELSD detection. The $^1H$ and $^{13}C$ NMR data were obtained on a Varian 300 (300 and 75 MHz, respectively) spectrometer with TMS as the internal standard and $CDCl_3$ as the solvent unless otherwise stated. Multiplicities are indicated as the following: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; dd, doubled doublet; br, broad. Coupling constants (*J* values) are quoted in Hertz.

**3-(6-(Butylamino)-4-chloropyrimidin-5-ylamino)cyclohex-2-enone (1).** A solution of 5-amino-4-chloro-6-(butylamino)-pyrimidine **3** (1.5 g, 7.5 mmol), 1,3-cyclohexandione (0.84 g, 7.5 mmol), and a catalytic amount of acetic acid (30 μL, 0.52 mmol) in cyclohexane (40 mL) was heated in an azeotropic distillation apparatus for 2 days. The solvent was removed *in vacuo* to give the crude product, which was recrystallized from acetone to give 1.71 g (78%) of **1**, mp 190–192°C.$^1H$ NMR: 8.29 (s, 1H), 5.74 (s, 1H), 5.32 (s, 1H), 4.93 (s, 1H), 3.47 (q, 2H, $J = 6.9$ Hz), 2.51 (t, 2H, $J = 5.4$ Hz), 2.35 (t, 2H, $J = 6.3$ Hz), 2.10–2.02 (m, 2H), 1.61–1.29 (m, 2H), 1.41–1.29 (m, 2H), 0.92 (t, 3H, $J = 7.2$ Hz). The synthesis of 2-(4-amino-2-alkylaminothiazol-5-oyl)benzothiazoles and 2-[2,4-bis(arylamino)thiazol-5-oyl]benzothiazoles as benzothiazoloylthiazole analogs of the cytotoxic marine alkaloid dendrodoine is reported. The highly decorated thiazole ring assembly was achieved using 2-bromoacetybenzothiazole to supply the C5 ring carbon and amidinothioureas of the type $R^1NH—CS—NH—C(=NHR^2)—(NHR^3)$ to provide the four ring atoms [C4—N3—C2—S1] in a [4+1] thiazole ring construction strategy. The antibacterial activity of these new analogs is reported.

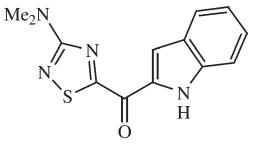
## INTRODUCTION

A recent review [1] on marine pigments highlights the rich variety of colored molecules that can be found in marine organisms. These pigments have structures that in many instances have no counterpart in any terrestrially derived molecules. Many among these are alkaloidal pigments. One among these, the pale yellow, bisheterocyclic, cytotoxic alkaloid dendrodoine, 3-*N*,*N*-dimethylamino-5-indol-3-oyl-1,2,4-thiadiazole 1, isolated from the tunicate *Dendrodoa grossularia* [2], is considered unique in being the first and only naturally occurring 1,2,4-thiadiazole derivative [1]. It is reported to be cytotoxic to lymphoma cells L1210 in culture [2,3].



**1**

We have recently been interested in synthesizing [4] and cytotoxicity screening [5] of thiazole analogs of dendrodoine in the light of its reported cytotoxicity and the difficulty in its synthesis [6]. Two approaches were adopted by us; in the first, to overcome the limited opportunity for substitution positions in the 1,2,4-thiadiazole ring, it was replaced by a 1,3-thiazole ring [4a]. In the second, the indoloyl unit was varied to other benzofused heterobicyclic rings [7]. This allowed us to introduce much structural diversity leading to a large portfolio of dendrodoine analogs. We were also enthused by the recently reported *in vitro* cytotoxicity of bis(indolyl)thiazoles [8] and indolylthiazoles [9]. Further, noting the remarkable cytotoxic activity of benzothiazole derivatives as reviewed recently [10,11], we decided to extend our work on the synthesis and bioactivity screening of dendrodoine analogs to 2-(2,4-diaminothiazol-5-oyl)benzothiazoles.

## RESULTS AND DISCUSSION

Several modifications of the classic Hantzsch 2-aminothiazole synthesis have recently been developed for the direct ring assembly of highly decorated thiazole derivatives. Among such methods, the use cyanothioureas [12,13] RNH—CS—NH—CN, our reports [14–16] on the use of amidinothioureas RNH—CS—NH—C(=NH)—$NH_2$ and RNH—CS—NH—C(=NH)—$NHNO_2$, or the recent use of *S*-alkyldithiobiurets [17] RNH—CS—NH—C(SR)—$NH_2$, as the source of the four [S1—C2—N3—C4] ring atoms for the thiazole ring construction are noteworthy. The remaining ring C5 atom could be sourced from α-haloketones, which reacted with the above thioureas to afford 4-amino-5-acyl-2-(substituted amino)thiazoles. Nevertheless, our report [14,16] on the use of amidinothioureas of the type $R^1NH—CS—NH—C(=NHR^2)—(NHR^3)$ seems to be the only direct ring synthesis of 5-acyl-2,4-bis(substituted amino)thiazoles. Based on these considerations, we have now chosen the reaction between the amidinothiourea derivatives **2a–g** and 2-(2-bromoacetyl)benzothiazole 3 to access hitherto unreported 2-(4-amino-2-alkylaminothiazol-5-oyl)benzothiazoles and 2-[2,4-bis(arylamino)thiazol-5-oyl]benzothiazoles.

Accordingly, the reaction of 1-ethyl-3-(*N*-nitroamidino)thiourea 2a in *N*,*N*-dimethylformamide (DMF) with 2-(2-bromoacetyl)benzothiazole 3 afforded a yellow

crystalline compound which showed in the thin layer chromatogram a single fluorescent yellow spot. Based on the elemental analysis, the molecular composition of the compound was found to be $C_{13}H_{12}N_4OS_2$. The IR spectrum shows distinct bands at 3467, 3285, 3233, and 3175 $cm^{-1}$, which are ascribed to $\nu_{N-H}$ vibrations. The aliphatic C—H stretching bands were seen at 2972, 2928, and 2850 $cm^{-1}$ and a strong band at 1623 $cm^{-1}$ indicated the presence of a conjugated carbonyl group. The $^1$H NMR spectrum consisted of a three-hydrogen triplet at δ 1.18, due to methyl hydrogens. The peak due to the methylene hydrogens could not be seen as it appeared to be submerged in the broad solvent-based peak. The multiplet at δ 7.45–7.62 was assignable to the H-5 and H-6 of the benzothiazole ring. The two one-hydrogen doublets at δ 8.07 and 8.16 were attributed to H-4 and H-7 of the benzothiazole ring, respectively. The broad peak at δ 8.39 was due to the NH hydrogen of the NHR group. The FAB MS showed a strong $MH^+$ peak at m/z 305. Based on these, the compound was formulated as 2-(4-amino-2-ethylaminothiazol-5-oyl)benzothiazole **4a**; the reaction steps involved in its formation

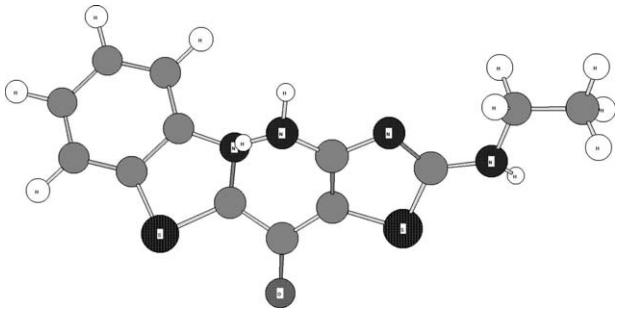

**Figure 1.** Energy minimized structure of **4a**.

is presented in Scheme 1. Three other thiazoloylbenzothiazoles **4b–d** were also synthesized. An interesting feature of the $^1$H NMR spectrum of **4a–d** was the appearance of the two hydrogens of the 4-amino group as two well separated broad singlets. For example, in the case of **4a**, these hydrogens were seen at δ 8.78 and 8.94. The results of energy minimized computations on **4a** obtained using MOPAC by the AM1 method are shown in Figure 1. These computed structures showed that one of the two hydrogens of the amino group could be strongly hydrogen bonded to the ring nitrogen of the benzothiazole unit. In addition, the 4-amino group in **4a** could also be amide like as it could be viewed as a vinylogous amide —CO—$C^5$=$C^4$—$NH_2$, which would also impede the rotation of the $C^4$—N bond.

Next, 1-phenyl-3(*N*,*N*′-diphenylamidino)thiourea **2e** was reacted with **3** to obtain a deep yellow compound with molecular composition $C_{23}H_{16}N_4OS_2$. Based on the FAB-MS, $^1$H and $^{13}$C NMR spectra, the structure of the compound was assigned as 2-[2,4-bis(phenylamino)thiazol-5-oyl]benzothiazole **4e**. In a similar reaction, two other 2-[2,4-diarylaminothiazol-5-oyl]benzothiazoles **4f–g** were also obtained.

To assess the bioactivity, the benzothiazoles **4a–g** were screened against the bacterial strains *Escherichia coli, Salomonella typhi*, *Staphylococcus aureus*, and *Bacillus subtilis* and the results are shown in Table 1.

## EXPERIMENTAL

Melting points are uncorrected and were determined by open capillary method using an immersion bath of silicon oil. Thin layer chromatography was performed using silica gel-G (E. Merck, India) coated on glass plates. The spots were visualized in iodine vapour or under UV light. The spectra were recorded on: JEOL DRX 300 or DPX 300 NMR spectrometer (300 MHz for $^1$H and 75 MHz for $^{13}$C NMR spectra), JEOL SX 102/DA-6000 mass spectrometer (using Argon/Xenon, 6 KV, 10 mA as the FAB gas and m-nitrobenzyl alcohol as the matrix) for FAB mass spectra, and Nicolet 400D FTIR spectrometer fot IR spectra. Reagents and solvents were from Merck India and Fluka. Elemental analysis was done at Central Drug Research Institute, India. The antibacterial acticity was evaluated by the Kirby-Baur method [18].

**General procedure for the synthesis of 2-(2,4-diaminothiazol-5-oyl)benzothiazoles (4a–g).** A solution of 2-(2-bromoacetyl)benzothiazole **3** (0.254 g, 1 mmol), obtained from 2-(1-hydroxyethyl)benzothiazole [19,20], in DMF (2mL) was added to 1-alkyl-3-(*N*-nitroamidino)thiourea (**2a–d**) or 1-aryl-3-(*N*,*N*′-diarylamidino)thiourea (**2e–g**) (1 mmol) in DMF (2 mL). The reaction mixture was stirred well and triethylamine (0.3 mL, 2 mmol) was added and warmed at 50–60°C for 15 min. It was then cooled and poured into ice-cold water with constant stirring. The yellow precipitate thus obtained was filtered, washed with water, and dried. The crude product was purified by crystallization from methanol–water (2:1), then from benzene–petroleum ether (1:1) in the case of **4a–d**, and from ethanol–water (3:1) in the case of **4e–g**.

Novel double CH-insertion and rearrangement products (**5**, **6**, and **7**) were isolated from treatment of **1** or **2** with dimethyl diazomalonate (**3**) under dirhodiumtetrakis mediated carbenoid chemistry conditions. A new possible reaction pathway is suggested and discussed. Also other diazo compounds were tested.

## INTRODUCTION

Furoquinolinones belong to a class of molecules exhibiting a wide variety of biological activities, including antifungal, antibacterial, antiviral (HIV), antimicrobial, antimalarial, insecticidal, antineoplastic, antidiuretic, antiarrhythmic, and sedative properties [1,2]. Examples of natural alkaloids containing the furoquinolinone core structure include oligophyline [3], araliopsine [4], and almeine [5] (Fig. 1).

These naturally occurring alkaloids, and others belonging to the furoquinolinone class of molecules, are obvious derivatives of a common core structural unit **1**, having a double bond in the **C** ring. Structure **1** is therefore a good choice for functionalization to important synthons for natural product synthesis and medicinal chemistry applications. To our knowledge, this potentially reactive core structure has not yet been exploited in synthesis.

It was envisaged that an electrophilic metal carbenoid, which is readily generated by metal catalyzed decomposition of a diazo reagent [6], could be used to probe reactivity of the **C** ring double bond of the furoquinolinone core structure. Previous studies on related structures have used metal carbenoid chemistry, such as simple furans [7], benzofurans [8], and tris-2-furylmethane derivatives [9].

## RESULTS AND DISCUSSION

We wish to report unexpected results from metal carbenoid-mediated chemistry using two analogues, **1** and **2**, as substrates and dimethyl diazomalonate (**3**) as the carbene precursor (Fig. 2). We have previously reported a novel synthesis of the common furoquinolinone core structure (**1**), describing the use of a palladium mediated intramolecular Heck coupling as a key step [10] and an alternative route to literature precedents [11]. The second core structure **2** was synthesized through modification of that protocol by using SEM in place of a methyl substituent as protecting group to facilitate formation of intermediate **9**. Treatment of **9** with dry HCl yielded the unprotected core structure **4**, which could easily be converted to the corresponding imine form **2** by further treatment with $POCl_3$ and sodium methoxide in two separate steps (Scheme 1). The carbene precursor **3** was synthesised by known methods [12].

All reactions were carried out in dichloromethane, with 2 mol % dirhodiumtetraacetate as catalyst and

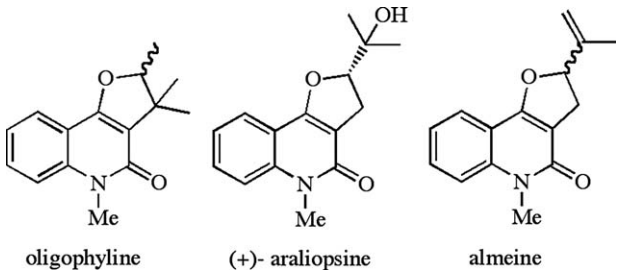

**Figure 1.** Natural alkaloids with furoquinolinone core structure.

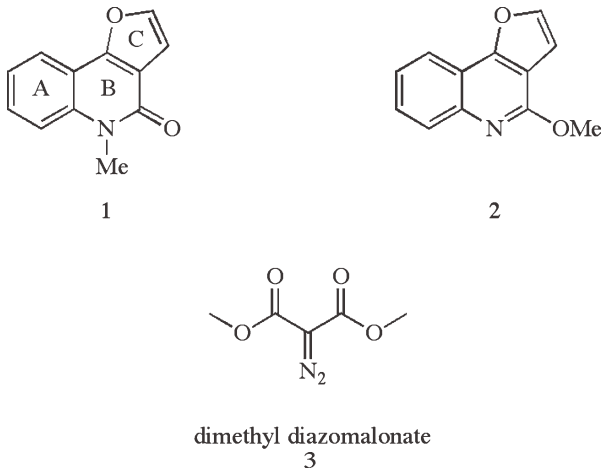

**Figure 2.** Starting materials (**1** and **2**) and carbene precursor (**3**).

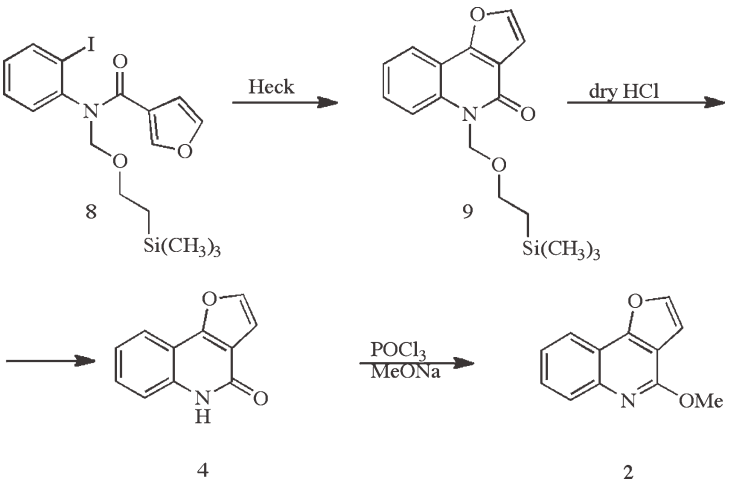
substrate **1** serving as a template for optimizing the reaction conditions. Treating **1** with **3** using previous reported literature procedures [8] with the aim of installing a cyclopropane functionality, did not consume starting material (**1**) in all cases (<5%). Optimized reaction conditions were found using 3.2 eq of **3** (Experimental), leading to 100% consumption of **1** and formation of furo products. Strikingly, the major product was the double CH-insertion product **5**, and the minor product was a cyclopropanated double CH-insertion product **6** (Scheme 2).

However, treatment of the analogue substrate **2** with **3**, under the same optimized conditions used as above, gave only the unsaturated product **7** (Scheme 3). Two aliquots of the carbene species must have reacted with one substrate giving two CH-insertions on the one scaffold, followed by ring opening of the furan ring, rearrangement and ring closure to give **5**. Due to the excess of the metal carbenoid present in the reaction mixture, product **5** can also react further to the minor product **6**. Opening of the furan ring has been noticed before for related structures under similar reaction conditions [7(d),13] This is similar here, indicated by the presence of the quarternary carbon at the C-2 position in both products **5** and **7**. Interestingly, when reacting **2** with **3**, only the pyrano structure **7** was produced.

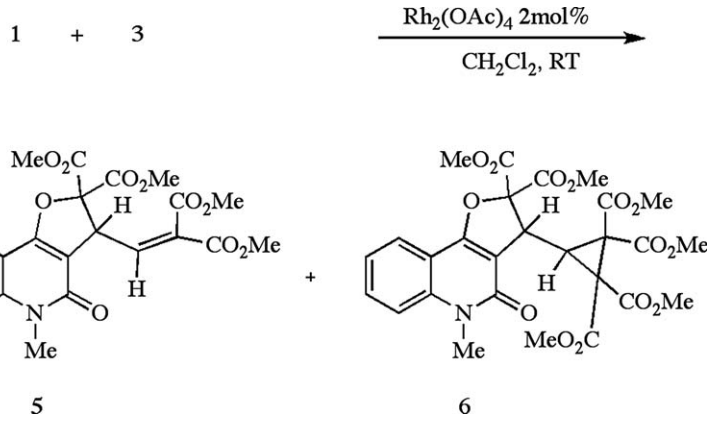
These quite different outcomes are most likely due to two different initial reaction intermediates/transition states **A** and **A'** forming from **1** and **2**, respectively, as substrates (Scheme 4). Possibly substrate **1** reacts with **3** in the C-3 position first, while substrate **2** reacts with **3** in the C-2 position. This suggests that intermediate **A** is formed and is sufficiently stable to undergo a second addition to form transition state **B**, followed by ring opening/ring closing to form **5** (Scheme 5).

In contrast, transition state **A'** cannot undergo such addition and is further stabilized by ring opening/rearrangement to give product **7** (Scheme 6). The ring closing pathway to form **7** proceeds most likely in a similar fashion as suggested for product **5**. These two early reaction intermediates/transition states (**A** and **A'**) can explain the two different outcomes observed and, ultimately, this reflects the inherent electronic differences

**Scheme 1**



**Scheme 2**



5 6

of **1** and **2**. Interestingly, it was noted product **7** does not react further in the presence of excess of **3**.

When changing dimethyl diazomalonate (**3**) for ethyl 2-diazopropionate (**8**) and optimizing the reaction protocol (Experimental), reaction of either **2** or **3** with **8** [14] gave the expected cyclopropanated outcomes **9** and **10** in isolated yields of 43 and 69%, respectively (Scheme 7). No ring opened product was observed in either case. Treatment of either **2** or **3** with the less stabilized carbene precursor 2-diazopropane under a range of conditions, including with/without catalyst and/or lowered/elevated temperatures, starting material was recovered quantitatively in all attempts.

In summary, three novel rearrangement products (**5**, **6**, and **7**) can be derived from two relatively similar substrates **1** and **2**, both belonging to the furoquionolinone class of molecules. The outcomes can be explained by different initial reaction intermediates/transition states, such as **A**, **B**, and **A'**, due to inherently different electronic properties of **1** and **2**. Thus, changing the relatively remote functionality from an amide to an imine (**1** to **2**) determines the reaction under the carbene chemistry conditions. Other reaction intermediates such as a dimerized diazomalonate in the presence of rhodium could possibly act as a carbene precursor. However, this may only be formed in higher concentrations of dimethyl diazomalonate, low consumption of **1** being observed until a certain excess of **3** is present. Alternatively, a direct rhodium mediated opening of the furan ring between the oxygen and C1 occurs [7(b),15]. Further, the expected cyclopropanated products **9** and **10** were obtained from treatment of **1** and **2** with ethyl 2-diazopropionate, however, no reaction was observed when using 2-diazopropane as the carbene precursor.

Most interestingly products **5**, **6**, and **7** are, to our knowledge, unprecedented rearrangement products. Thus, for product **5** (and **6**), this suggests a new reaction pathway is taking place and might serve as a useful application in related areas.

MS (ESI): *m*/*z* 445 $[M+H]^+$, 467 $[M+Na]^+$, 910 $[2M+Na]^+$. Anal. Calcd. for $C_{17}H_{22}INO_3Si$: C, 46.05; H, 5.00; N, 3.16. Found: C, 46.09; H, 5.01; N, 3.02.

**5-((2-(Trimethylsilyl)ethoxy)methyl)furo[3,2-c]quinolin-4(5*H*)-one (9).** A mixture of **8** (90 mg, 0.20 mmol), KOAc (26 mg, 0.26 mmol), *n*-$Bu_4NCl$ (11 mg, 0.04 mmol), and PdO (2.5 mg, 0.02 mmol) was stirred in DMA (0.4 mL) at 150°C under a nitrogen atmosphere for 18 h. The crude mixture was then concentrated under reduced pressure followed by flash chromatography (EtOAc:hexane/15:85) to afford 55 mg of **9** (87%) as a slightly yellowish solid. Mp 61–62°C. IR (KBr, $\nu_{max}$): 3158, 3133, 2949, 2900, 1662, 1584, and 1499 $cm^{-1}$. UV (MeOH) $\lambda_{max}(\varepsilon)$: 227 nm (38358), 276 nm (7485), 286 nm (8934), 316 nm (9261), 331 nm (9435). $^1H$ NMR ($CDCl_3$, 500 MHz): δ -0.022 (s, 9H, H-SiMe3), 0.96 (t, *J* 8.5, 7.5 Hz, 2H, H-2″), 3.74 (t, *J* 8.5, 8 Hz, 2H, H-1″), 5.86 (s, 2H, H-1′), 7.08 (s, 1H, H-3), 7.35 (app t, *J* 7.5 Hz, 1H, H-8), 7.56 (app t, *J* 8.0 Hz, 1H, H-7), 7.65 (s, 1H, H-2), 7.72 (d, *J* 8.0 Hz, 1H, H-6), 8.02 (d, *J* 8.1 Hz, 1H, H-9). $^{13}C$ NMR ($CDCl_3$, 125 MHz) δ 0.0 (SiMe3), 18.4 (C-2″), 66.6 (C-1″), 71.7 (C-1′), 108.8 (C-3), 113.7 (C-3a), 115.1 (C-9a), 116.8 (C-6), 121.3 (C-9), 123.1 (C-8), 129.8 (C-2), 137.9 (C-5a), 144.3 (C-7), 156.1 (C-9b), 160.2 (C=O). MS (ESI): *m*/*z* 316 [M+H]+, 338 [M+Na]+. Anal. Calcd. for $C_{17}H_{21}NO_3Si$: C, 64.73; H, 6.71; N, 4.44. Found: C, 64.76; H, 6.70; N, 4.45.

**Furo[3,2-c]quinolin-4(5*H*)-one (4).** To a premixed solution of acetyl chloride (43 mL), ethanol (73 mL) and water (5 mL), was added **9** (1.82 g, 5.77 mmol) at RT with stirring. After all substrate was dissolved, the reaction flask was fitted with a reflux condenser and heated to 80°C for 11 h, and the reaction mixture was then concentrated under reduced pressure. Purification was straightforward by flash chromatography when using (EtOAc:hexane/1:1) as eluent mixture which afforded 0.90 g of furo[3,2-*c*]quinolin-4(5*H*)-one (84%) as an off white solid. $^1H$ NMR (DMSO-$d_6$, 400 MHz): δ 7.04 (d, *J* 2.0 Hz, 1H, H-3), 7.25 (app t, *J* 7.4 Hz, 1H, H-8), 7.47 (app d, *J* 7.4 Hz, 1H, H-7), 7.53 (app t, *J* 7.4 Hz, 1H, H-9) 7.88 (d, *J* 7.4 Hz, 1H, H-6), 8.06 (d, *J* 2.0 Hz, 1H, H-2), 11.73 ( br s, 1H, NH). $^{13}C$ NMR (DMSO-$d_6$, 100 MHz): δ 108.4, 111.9, 116.2, 116.7, 120.8, 122.9, 130.1, 137.7, 146.1, 156.1, 159.5. MS (ESI): *m*/*z* 185 $[M+H]^+$.

**(4-Chlorofuro[3,2-c]quinoline).** A mixture of furo[3,2-*c*]quinolin-4(5*H*)-one (0.87 g, 4.7 mmol), phosphorusoxychloride (10.0 mL) and water (0.5 mL) was refluxed at 135 °C for 4 h. The cold reaction mixture was quenched by adding water (10 mL) and with 25% ammonia. The aqueous layer was extracted with DCM (3 × 150 mL) and EtOAc (3 × 150 mL). The organic layers were combined, dried with $MgSO_4$ and concentrated under reduced pressure to afford 0.90 g of the desired 4-chlorofuro[3,2-*c*]quinoline (94%). $^1H$ NMR ($CDCl_3$, 400 MHz): δ 7.03 (d, *J* 2.2 Hz, 1H, H-3), 7.64 (m, 1H, H-8), 7.73 (m, 1H, H-7), 7.82 (d, *J* 2.2 Hz, 1H, H-2), 8.14 (dd, *J* 8.0, 2.0 Hz, 1H, H-9), 8.25 (dd, *J* 7.4, 2.0 Hz, 1H, H-6). $^{13}C$ NMR ($CDCl_3$, 100 MHz): δ 106.3, 116.6, 119.8, 120.1, 127.2, 128.8, 129.2, 144.3, 145.0, 145.2, 156.4. MS (ESI): *m*/*z* 204 $[M+H]^+$.

**4-Methoxyfuro[3,2-c]quinoline (2).** A mixture of the 4-chlorofuro[3,2-*c*]quinoline (125 mg, 0.49 mmol) and a methanolic solution of sodium methoxide (approximately 1.2 M, generated from 230 mg sodium in 10 mL of methanol) at RT under nitrogen atmosphere, was stirred until all starting material was consumed (monitored by TLC). The reaction mixture was extracted with EtOAc (3 × 100 mL). The organic layers were combined, dried with $MgSO_4$ and concentrated under reduced pressure. Purification by flash chromatography (EtOAc:hexane/0 to 2.5:100 to 97.5) afforded 100 mg of **2** (80%). $^1H$ NMR ($CDCl_3$, 400 MHz): δ 4.20 (s, 3H, OMe), 6.95 (m, 1H, H-3), 7.46 (app t, *J* 7.2 Hz, 1H, H-8), 7.61 (app t, *J* 7.2 Hz, 1H, H-7), 7.72 (m, 1H, H-2), 7.95 (app d, *J* 7.2 Hz, 1H, H-6), 8.15 (app d, *J* 7.2 Hz, 1H, H-9). $^{13}C$ NMR ($CDCl_3$, 100

MHz): δ 53.7 (OMe), 105.4 (C-3), 111.4 (C-3a), 116.0 (C-9a), 120.1 (C-9), 124.4 (C-8), 127.7 (C-6), 128.6 (C-7), 144.3 (C-1), 144.5 (C-5a), 157.64 (C-9b), 157.68 (C-4). MS (ESI): *m*/*z* 200 $[M+H]^+$.

**Rearrangement/CH-insertion products (5) and (6).** To a solution of 1.30 (100 mg, 0.50 mmol) and dirhodium tetraacetate (5 mg, 0.01 mmol, 2 mol %) in DCM (2.5 mL) under a nitrogen atmosphere was added a solution of dimethyl diazomalonate (293 mg, 1.85 mmol, 3.7 eq) in DCM (0.5 mL) over 3 h period followed by 17 h stirring at ambient temperature (monitored by tlc). The crude was then filtered through a short silica plug using EtOAc as eluent (2 × 20 mL), dried with MgSO4 and concentrated *in vacuo*. Flash chromatography (EtOAc:hexane/1:1) afforded 180 mg of a clear oil as a mixture of the two products, **5** and **6**, in the ratio of 75:25. Reverse phase chromatography (HPLC, MeOH:$H_2O$/7:3) afforded an analytically pure sample of each product.

1,3-Dipolar cycloadditions of benzonitrile oxide and carbethoxyformonitrile oxide (CEFNO) with various facially perturbed polycyclic symmetrical dienophiles (**1**–**6**) were investigated. Cycloadditions took place chemoselectively at the norbornyl double bond and were found to be exclusively exo. Cycloadditions of benzonitrile oxide with dienophiles **4** and **5** led to mixture of inseparable products, however, that with CEFNO gave single products. Cycloadduct of dienophile **5** with CEFNO was found to be unstable, and it readily isomerized to more stable aromatic form.

*J. Heterocyclic Chem.,* **47**, 1004 (2010).

## INTRODUCTION

1,3-Dipolar cycloaddition of nitrile oxides are well documented [1] and provide efficient entries to the synthesis of isoxazolines [2]. Remarkable stereoselectivity has been observed in 1,3-dipolar cycloadditions with bicyclic systems [1a,3,4] and indeed, that with norbornene proceeds exclusively on the exo face [5]. Even unsymmetrically substituted norbornenes are reported to cycloadd completely stereoselectively [6]. The desired exo-isomers are the one in which oxygen of the dipole is attached to the more substituted center of the dipolarophiles (Scheme 1).

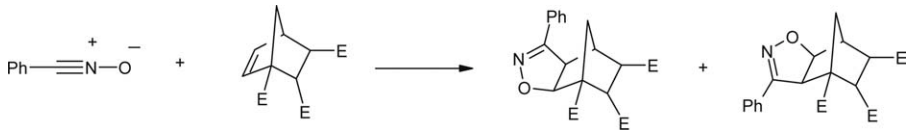
Formation of single regio- and stereoisomers were also noticed in the intramolecular cycloaddition of norbornene tethered nitrile oxides [6c]. Recently, Namboothiri *et al*. [7a] have studied the behavior of multi π-facial dipolarophiles, dicyclopentadiene (DCP), and its analogues toward nitrile oxides. In their study on DCP, the cycloaddition of nitrile oxide was found to be both chemo- and steroselective. However, cycloadducts were reported to be mixture of two regioisomers. In a similar study, Trivedi and coworkers [8] and Tanaka *et al*. [9] have also noticed comparable regio-, chemo-, and stereoselectivity during the cycloaddition of DCP with substituted acetonitrile oxides. As against this, the cycloadducts derived from Thiele's esters were regio-, stereo- and chemoselective [7].

It is interesting to note that the stereochemistry of Diels-Alder additions to norbornene systems, for example, 2,3-norbornenobenzoquinone (NPBQ) [10], 2,3-norbornanobenzoquinone (DNPBQ) have been extensively investigated by Mehata *et al*. [11]. However, complementory investigations involving the cycloaddition of facially perturbed dienophiles to 1,3-dipoles has not received matching attention. This study is, therefore, focused on the 1,3-dipolar cycloaditions of two different types of nitrile oxides *viz*. benzonitrile oxide and carbethoxyformonitrile oxide (CEFNO) toward multi π-facial tricyclic and polycyclic systems incorporating bicyclo-[2.2.1]-heptenyl moity (Figure 1).

## RESULTS AND DISCUSSION

Dipolarophile **1** was prepared by treatment of compound **5** with acetic anhydride and pyridine [10]. Compound **5** in turn was obtained by Diels-Alder cycloaddition of cyclopentadiene and *para*-benzoquinone (1:1 eq) [10]. Diels-Alder cycloaddition of cyclopentadiene and *para*-benzoquinone in 2:1 eq gave dipolarophile **6**. Dipolarophile **5** was reduced chemoselectively to dipolarophile **4** by using Zn and acetic acid. Chemoselective reduction of compounds **4** and **5** were carried out using $NaBH_4$ and $CeCl_3.7H_2O$ to get dipolarophiles **2** and **3**, respectively.

**Scheme 1**



Preference to the symmetrical dipolarophiles was given to negate regiochemistry question. The results presented here deal with both the questions of chemoselectivity and stereoselectivity. As Mayo *et al*. [6c] have noticed dependence of cycloadduct stereochemistry on the methods and conditions of generation of nitrile oxides. Therefore, we have adopted two methods for the generation of nitrile oxides. First one involves *in situ* preparation of benzonitrile oxide by commonly used bleach method in dichloromethane solvent, whereas second one involves *in situ* preparation of carbethoxyformonitrile oxide in ionic liquid medium as described by Taddei *et al* [12].

For initial studies, we have chosen dipolarophiles with only one double bond (**1** and **2**) so as to get rid of chemoselectivity aspect. In these cases, approach of dipole can take place from two faces of dipolarophiles leading to the possibility of two products. However, we observed that dipolarophiles **1** undergo cycloaddition with benzonitrile oxide **7a** giving exclusively exo cycloadduct **1a** (Scheme 2). In $^1$H-NMR disappearance of signal at δ 5.66 (s, 2 H) and appearance of signal at δ 4.16 (d, 1 H, $J$ = 8.1 Hz) for $H^a$ and 5.08 (d, 1 H, $J$ = 8.1 Hz) for $H^b$ confirmed formation of cycloadduct. The protons $H^a$ and $H^b$ appeared as doublets coupled only to each other but not to bridgehead protons indicating endo orientation [6c,7a]. Diol **2** also underwent cycloaddition with benzonitrile oxide affording exclusively exo-cycloadduct **2a** as indicated by spectral data (Scheme 2). Cycloaddition of **1** and **2** with carbethoxyformonitrile oxide **7b** took place similarly yielding corresponding cycloadducts **1b** and **2b**, respectively.

To further investigate cycloaddition reaction, we have increased the number of π-faces in dipolarophiles to two (two C=C). When dipolarophile **3** was subjected to cycloaddition to benzonitrile oxide, we observed remarkable stereoselectivity along with chemoselectivity. Cycloaddition took place selectively to the olefin of norbornene moity with exclusively exo selectivity giving rise to only one cycloadduct **3a** (Scheme 3). Similar results were obtained in cycloaddition of carbethoxyformonitrile oxide with dipolarophile **3** resulting in formation of cycloadduct **3b**.

Encouraged by these results, we attempted cycloaddition of benzonitrile oxide on more complex systems **4** and **5** containing three (two C=O and one C=C) and four (two C=O and two C=C) π-faces, respectively. In principle, dipolarophile **5** could react with either of the double bonds and/or with the carbonyl groups. In the event, if each of the π-component reacts with the dipole formation of upto three cycloadducts could be envisaged, provided the ''exo addition rule'' prevails [7]. However, the reaction ended up with a complex intractable mixture. To overcome the eventualities arising out of the side reactions due to multiple π-faces, it was decided to reduce the number of reactive sites by saturating the α,β-unsaturated double bond in the dienedione **5**. In such systems, amongst the constituents π-systems, the norbornenyl double bond is expected to deliver the cycloadducts in a chemoselective fashion. However, to our dismay, the cycloaddition reaction with benzonitrile oxide under the chosen condition ended up with the inseparable multiple products (Scheme 4).

However, when dipolarophile **4** was subjected to cycloaddition reaction with carbethoxyformonitrile oxide instead of multiple products as expected from our earlier studies only single product **9** was obtained. Cycloaddition took place chemoselectively to the olefinic double bond of dipolarophile **4**, and it was found to be exclusively exo product. Encouraged by these results, we expected similar chemo- and stereoselectivity in the cycloaddition of CEFNO to the dipolarophile **5**. Although the product of this cycloaddition was found to be pure by thin layer chromatography, the $^1$H and $^{13}$C-

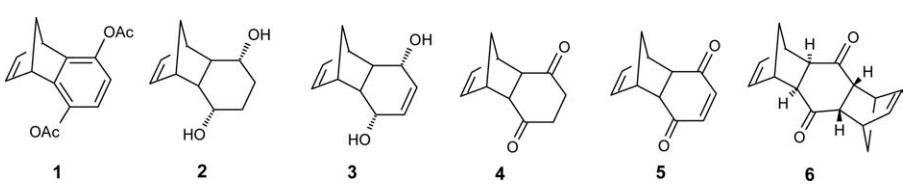


**Figure 1.** Symmetrically substituted dipolarophiles.

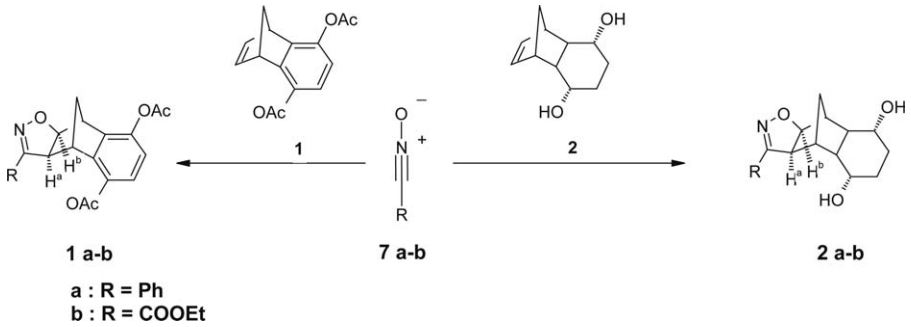
**Scheme 2**



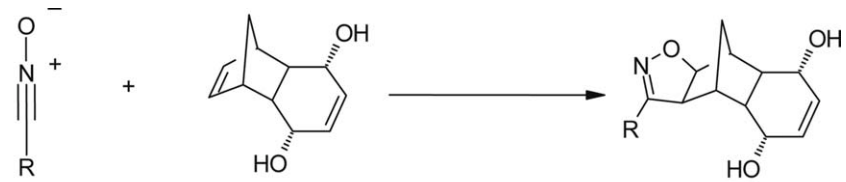
spectral data were little ambiguous and insufficient to confirm the exact structure of cycloadduct. The doublet observed in $^1$H spectra at δ 8.6 for two protons with $J$ = 8.7 Hz could not be explained. In $^{13}$C-spectra also, no signal for carbon of carbonyl was observed indicating absence of C=O group. IR spectrum showed strong absorptions in 3300–3600 cm$^{-1}$ range. To get the more details about the structure, spectral correlation studies were carried out. $^1$H-$^1$H COSY spectrum (Figure 2) showed only two correlations, one between proton of $CH_2$ and $CH_3$ of the ethyl group and another between two protons at δ 3.5 and δ 4.8 ppm. $^1$H-$^{13}$C HETCOR spectra (Figure 3) was more informative. It showed absence of correlation for two protons observed at 8.6 in $^1$H NMR spectrum and absence of protons on four carbon atoms (δ 128.40, 133.05, 143.97, and 144.71). Further, $D_2O$ exchange studies showed that doublet observed at 8.6 is $D_2O$ exchangeable. All these results led us to conclude the structure of adduct as **8** (Scheme 5). The cycloadduct was found to be exclusively exo as indicated by $^1$H-NMR spectrum.

As compound **5b** could not be obtained directly by cycloaddition of dipolarophile **5** with carbethoxyformonitrile oxide, we thought of preparing it by oxidation of cycloadduct **3b**. When we subjected the cycloadduct **3b** to PCC oxidation, expecting product **5b** as shown in Scheme 6, we ended up with **8** indicating that **5b** is not stable and gets isomerized to more stable form **8**. It further confirms the structure of cycloadduct of **3** with CEFNO as **3b**.

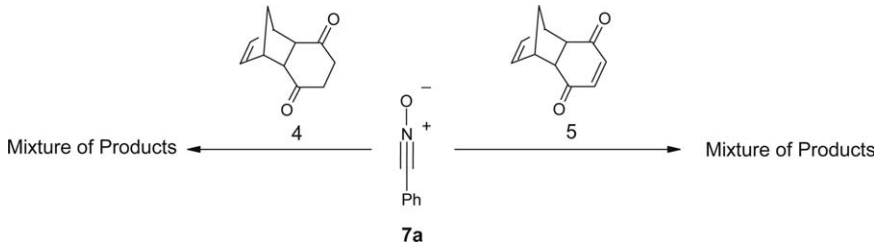
The next dipolarophile used for the study was endo-anti-endo bisadduct **6**. It has four π-faces (two C=C and two C=O). Although we were expecting behaviour of dipolarophile **6** in cycloaddition to benzonitrile oxide similar to that of **4** and **5**, we were surprised to observe exo monoadduct **6a** as the sole product as indicated by $^1$H and $^{13}$C spectral data. Cycloaddition of **6** with carbethoxyformonitrile oxide also resulted in similar results leading to formation of cycloadduct **6b** (Scheme 7).

In conclusion, we have studied the 1,3-dipolar cycloaddition of benzonitrile oxide and carbethoxyformonitrile oxide with various polycyclic dipolarophiles possessing norbornene moiety. Cycloaddition of dipolarophiles **1** and **2** with both the dipoles were found to be stereoselective as only exo cycloadduct was obtained. Dipolarophile **3** reacted with both the dipoles stereoselectively as well as chemoselectively at the norbornene double bond giving corresponding exo cycloadduct. Cycloaddition of dipolarophiles **4** and **5** with benzonitrile oxide led to the formation of mixture of products which could not be characterized; however, cycloaddition of **4** and **5** with carbethoxyformonitrile oxide gave corresponding cycloadducts stereoselectively and chemoselectively. Dipolarophile **6** also reacted with both the dipoles giving corresponding monoadduct stereo and chemoselectively. Hence, from the above study, we can

**Scheme 3**



**Scheme 4**



conclude that exo-rule prevails for the norbornene entities present in the polycyclic molecules.

## EXPERIMENTAL

All reactions were carried out in oven-dried glassware under an atmosphere of $N_2$. Progress of reactions was monitored by TLC (silica gel 60 F254, 0.25 mm, Merck) and purification was effected using silica gel column chromatography. NMR spectra were recorded at 300 ($^1$H) and 75 ($^{13}$C) MHz on Jeol-300 MHz spectrophotometer. Chemical shifts (δ) were reported relative to TMS ($^1$H) and $CDCl_3$ ($^{13}$C) as the internal standards. IR spectra were recorded on a Nicolet Impact 400 series FTIR spectrophotometer. All commercial grade solvents were distilled before use.

**Preparation of dipolarophile 4.** To a solution of compound **6** (1.044 g, 6 mmol) in glacial acetic acid (60 mL) was added activated zinc (4.2 g, 64.2 mmol). The reaction mixture was stirred for 3 h at room temperature. The acetic acid was removed under high vacuum *via* dry ice-acetone trap. The residue was dissolved in diethyl ether and filtered through a pad of celite. The filtrate was washed with saturated aq. $NaHCO_3$ (120 mL), brine and dried over anhydrous $Na_2SO_4$. The solvent was evaporated under reduced pressure, and the residue was purified by column chromatography to furnish the product (0.580 g, 55%). Yellow oil. IR ($CHCl_3$): 3020, 2925, 1705, 1423, 1300 cm$^{-1}$. $^1$H NMR (300 MHz, $CDCl_3$): δ = 1.32–1.51 (m, 2H), 2.30 (m, 2H), 2.65 (m, 2H), 3.22 (s, 2H), 3.46 (s, 2H), 6.18 (s, 2H). $^{13}$C NMR (75 MHz, $CDCl_3$): δ = 37.81, 47.31, 48.61, 51.71, 136.51, 209.55.

**Preparation of dipolarophile 2.** Compound **4** (0.35g, 2 mmol) was dissolved in a solution of cerium (III) chloride heptahydrate (1.5g, 4 mmol) in methanol (6 mL). The resulting solution was cooled to 0°C by external application of an ice bath. Sodium borohydride (0.15 g, 4 mmol) was then added at such a rate that the temperature of the reaction mixture did not rise significantly above 0°C. The reaction mixture was analyzed by TLC 2 h after addition of the sodium borohydride had been completed: The reaction was then quenched via addition of water (2.5 mL) and the resulting mixture was then extracted with chloroform and combined organic layer was concentrated *in vacuo* to yield crude diol. Recrystallization from DCM and petroleum ether afforded pure diol (0.099g, 27.76%). White solid, Mp 127–126°C. IR ($CHCl_3$): 3307, 3224, 2910, 1563, 1527 cm$^{-1}$. $^1$H NMR (300 MHz, $CDCl_3$): δ = 1.38 (dd, 2 H, $J$ = 7.5 and 8.0 Hz), 1.79 (s, 4 H), 1.86 (bs, 1 H), 2.38 (s, 2 H), 2.77 (bs, 1 H), 2.91 (s, 2 H), 4.12 (s, 2 H), 6.21 (s, 2 H). $^{13}$C NMR (75 MHz, $CDCl_3$): δ = 27.04, 45.11, 45.83, 52.39, 67.04, 134.56.

**Procedure for PCC oxidation of 3b.** In a 50-mL round-bottomed flask fitted with a reflux condenser was suspended PCC (0.161 g, 0.75 mmol) in anhydrous dichloromethane (5 mL). Cycloadduct **3a** (0.073 g, 0.25 mmol) was added to it in small portions and stirring was continued till reaction goes to completion. The progress of reaction was monitored on TLC.

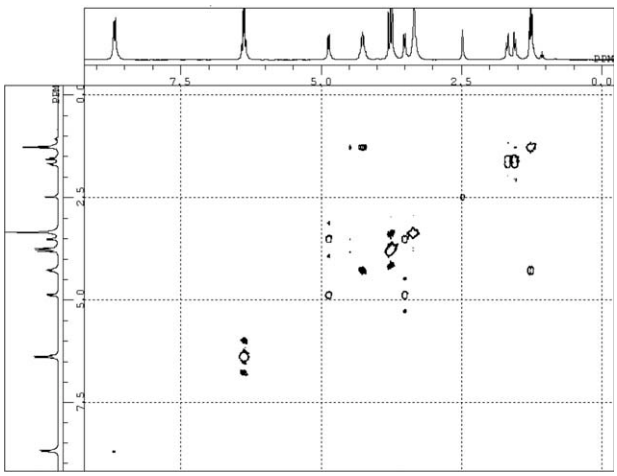


**Figure 2.** ($^1$H-$^1$H) COSY spectrum of compound **8**.

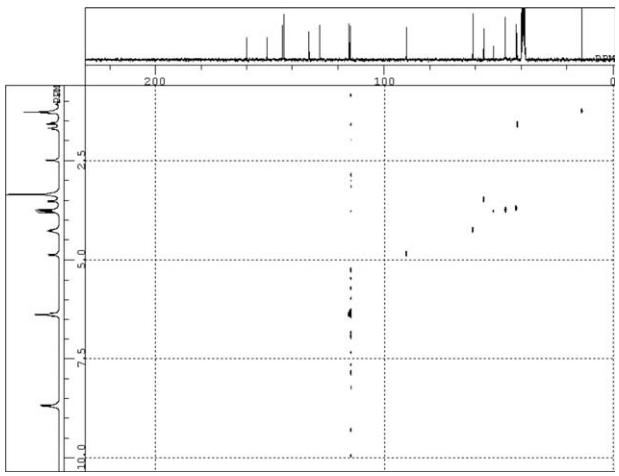

**Figure 3.** ($^{13}$C-$^1$H) HETCOR spectrum of compound **8**.

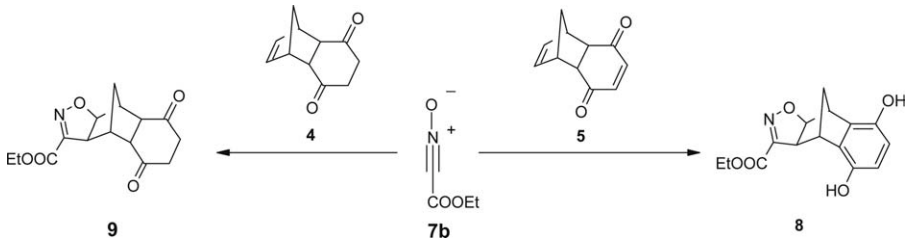
**Scheme 5**



After completion of the reaction, dichloromethane was removed under vacuum and product was extracted into diethyl ether (4 × 5 mL). All the extracts were dried by using anhydrous sodium sulfate and evaporated under reduced pressure to get the product which was purified by column chromatography, (0.055 g, 76%).

**General procedure for cycloaddition of benzonitrile oxides with dipolarophiles.** A solution of the benzaldoxime (dipole precursor) (1.2 mmol), dipolarophile (1 mmol) and triethylamine in dichloromethane (10 mL) was cooled to 0°C, sodium hypochlorite (4%, 10 mL) was added dropwise with stirring at 0°C. The reaction mixture was warm to room temperature and kept for 6–8 h with stirring. On disappearance of starting material (TLC), the reaction phases were separated and the aqueous phase was extracted with dichloromethane. The combined layers were washed with brine, dried with sodium sulphate, and the solvent evaporated under reduced pressure to yield crude cycloadduct. The crude product was chromatographed on a silica gel column. Thus, all cycloadducts were prepared following the aforementioned general protocol and characterized by IR, $^1$H-NMR, and $^{13}$C-NMR spectroscopy. The data for cycloadduct obtained from 1,3-dipolar cycloaddition are presented below.

**General procedure for cycloaddtion of carbethoxyformonitrile oxide with dipolarophiles.** In a typical experimental procedure, dipolarophile (1 mmol) was mixed with $NaHCO_3$ (1 mmol) in [bmim]$BF_4$ (0.5 g) ionic liquid. Ethyl chloroximidoacetate (1 mmol) was added, and the mixture was stirred at room temperature for 3–4 h when starting material disappeared (TLC); the reaction mixture was treated with diethyl ether to extract the product. Diethyl ether was removed under reduced pressure to get the product. In case of cycloaddition with dipolarophile **3**, due to poor solubility in diethyl ether, cycloadduct **3b** was isolated by dissolving ionic liquid in water followed by filtration. If required, the crude products were chromatographed on silica gel column. Cylcoadducts obtained were characterized by IR, $^1$H-NMR, and $^{13}$C-NMR spectroscopy.

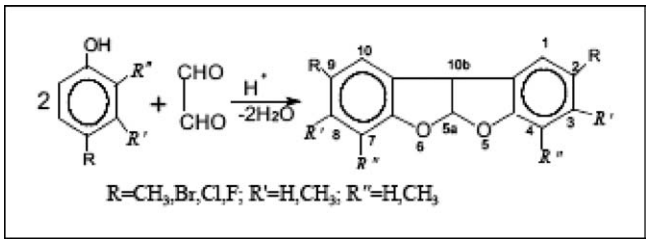
Published online 11 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



Condensation reactions of glyoxal with *p*-substituted phenol derivatives **1a–f** have been carried out and the corresponding 5a,10b-dihydrobenzofuro[2,3-b]benzofuran **4a–f** type compounds were obtained in good to excellent yields. The resulting dimeric products carrying methyl groups **4a–d** were converted to the corresponding carboxylic acid derivatives as the new polymer forming monomers. Many of these reactions gave novel structures. No definite product was obtained by the similar reactions of glyoxal with thiophenol and aniline in place of phenols.

## INTRODUCTION

Some of dialdehydes and especially their synthetic equivalents are interesting reactive precursors in organic chemistry and are regarded as useful starting material for the preparation of the thermally stable polymers [1–9]. Condensation of unsubstituted phenols with glyoxal bisulfite or glyoxal has been reported to produce insoluble resins [10]. The reaction of 2-naphthol with glyoxal has been reported by Dischendorfer and assigned the reaction product after alkaline fusion as structure **5** with a benzofurobenzofuran moiety in its structure [8]. The preparation of novel aromatic compounds with one or two dihydrofurofuran moieties starting from 2-naphthol and glyoxal has been reported [11].

Recently, we have reported the possibility of using trifluoroacetic acid as suitable medium for the condensation of *p*-substituted phenolic compounds with malonaldehydetetramethyl acetal as very reactive protected dialdehyde [12]. In this context, we have also reported the synthesis of 1,1,4,4–tetrakis (2-hydroxyphenyl)butane type compounds from the condensation of phenols with 2,5-dimethoxytetrahydrofuran using trifluoroacetic acid as both solvent and catalyst [13]. In our previous studies, condensation reaction of *p*-substituted phenols with glutaraldehyde bisulfite in the presence of trifluoroacetic acid as both solvent and catalyst and formation of propano-dibenzo [2, 1 − *d* : 1′, 2′ −*g*] [1,3] dioxocin type compounds were reported [14].

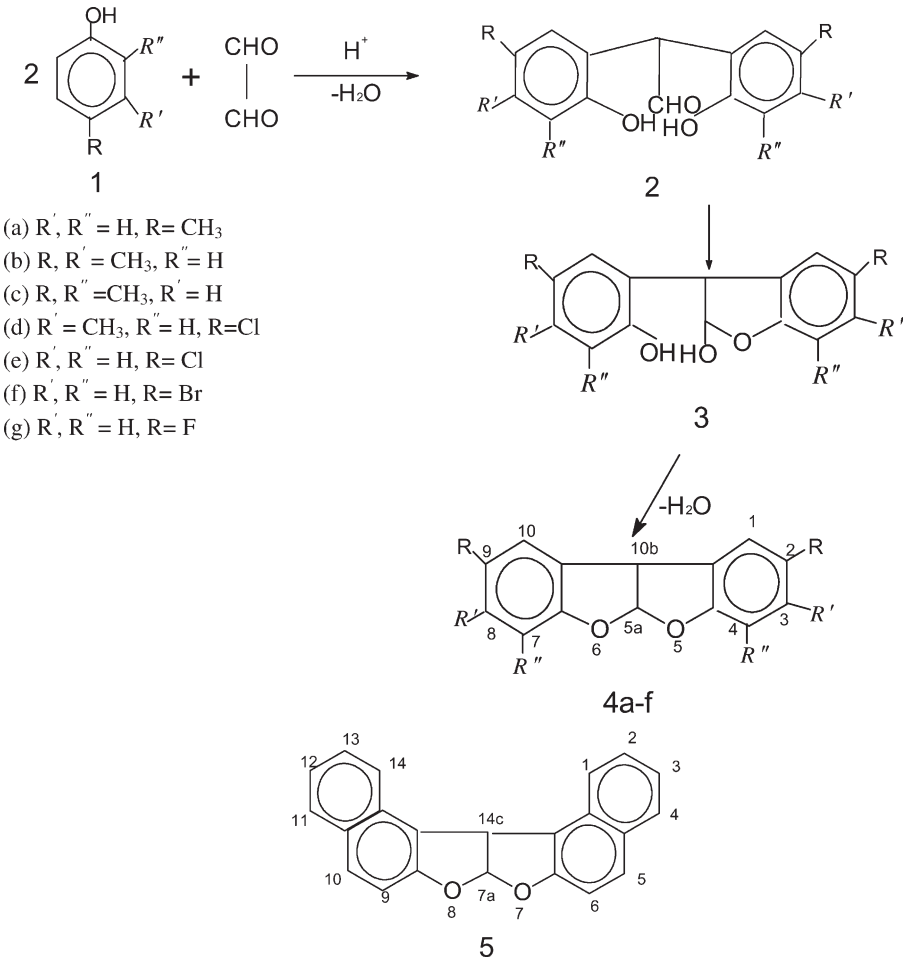
Condensation of 2-naphthol with glyoxal bisulfite in the presence of formic acid at 50–60°C has been shown to give dimeric product, namely 7a,14c-dihydronaphtho[2,1-b] naphtha [2′, 1′ : 5,6] furo[3,2-d] furan in only 22% yield [15]. The base catalyzed reaction of 2-naphthol with glyoxal was also investigated in which the final product was considered to be similar to that obtained from the acid catalyzed reaction [16–18].To the best of our knowledge, condensation reaction of *p*-substituted phenols with glyoxal has not been exploited for polymer forming monomers. However, the yield of formation of dimeric products was low and not enough for further transformations when we used sulphuric acid and formic acid as condensing agent [5,15,19].

To increase the yield in dimeric product and to examine more accurately the experimental conditions for the condensation reaction of *p*-substituted phenols and 2-naphthol with glyoxal and also in continuation of our research on the synthesis of thermally stable polymers from polymerisable monomers [20], we have also studied synthetic routes towards 5a,10b-dihydrobenzofuro[2,3-b]benzofuran type compounds as new model compounds and their related derivatives having suitable functional groups(e.g., dicarboxylicacid, dianhydride) which can be used as important monomers for the preparation of a variety of thermally stable polymers.

## RESULTS AND DISCUSSION

To study the possibility of using the reported method for condensation of 2-naphthol and glyxoalbisulfite with

**Scheme 1**



different phenols, we performed the reaction of phenols with glyoxalbisulfite under the reported conditions [15]. It was observed that this method cannot work for phenolic compounds. These observations led us to design another applied synthetic method for the condensation of *p*-substituted phenolic compounds with glyoxal. The possibility of condensation of different phenols with glyoxal bisulfite in acetic acid in the presence of sulfuric acid as catalyst were studied. Condensation of phenols with glyoxal bisulfite occurred and the corresponding 5a,10b-dihydrobenzofuro[2,3-b]benzofuran type compounds (**4a–f**) were obtained in low to moderate yields. To increase the yields of the products, we tried the same reactions using glyoxal solution in the presence of methane sulphonic acid as catalyst. The reaction of phenols carrying alkyl groups (**1a–c**) or having both alkyl and halogen (**4d**) gave excellent yields of their corresponding 5a,10b-dihydrobenzofuro [2, 3-b]benzofuran (**4a–f**). The reaction of phenols carrying only halogens (**1e,f**) gave moderate yields (Scheme 1).

For the study of structure–reactivity relationship, the reaction of *p*-substituted phenols having electron withdrawing substituents such as **1g** and 2,4-dichlorophenol with glyoxal under the same reaction condition was also investigated. No dimeric products as structure **4** with a benzofuro-benzofuran moiety (acetal type structure) in their structures were detected (Scheme 1). The results with the structurally different *p*-substituted phenolic compounds are shown in the Table 1.

It was found that the electron withdrawing groups retard the reaction and the electron donating substituents such as methyl were favorable in the reaction. These observations are in good agreement with the suggested mechanism as shown in Scheme 1.

We next decided to produce the dimeric product similar to that of **4a–f** but with sulfur or nitrogen in place of oxygen in the furan rings. However, we were not successful in using a similar reaction of glyoxal and thiophenols and/or aniline in place of phenols to reach our objective. No definite product was obtained by the reactions. When we treated glyoxal with aniline, for example, the expected product, a dihydroindole ring, was never produced. As is well-known, an amine and an aldehyde always react to produce a schiff base as a classical reaction.

**Table 1**

Reaction of phenolic compounds (**1a–f**) and 2-naphthol with glyoxal.

| Substrate | Method of preparation[a] | Reaction time (h) | Product (yield/%)[b] |
|---|---|---|---|

[a] A: glyoxal in $CH_3SO_3H$; B: glyoxalbisulfite in $H_2SO_4$.
[b] Yields refer to isolated products.
[c] No reaction.

Condensation of 2 moles of phenols (**1a–f**) with glyoxal solution and bisulfite occurs first through Friedel-Crafts reaction (one carbonyl group) to give **2** followed by an intramolecular acetalization reaction as suggested for the condensation of phenols with malonaldehyde tetramethyl acetal, 2,5-dimethoxytetrahydrofuran and glutaraldehyde [12–14], (Scheme 1).

The structure of all compounds **4a–f, 5** were deduced from their IR, $^1$H, $^{13}$C-NMR and mass spectral data. The IR spectra show no carbonyl and hydroxyl groups. In all cases, the $^1$H-NMR spectra indicated that the compounds had the acetal structure. The spectra of all these compounds showed a doublet ($J$ = 6–7 Hz) in the region δ 4.8–5.82 (assigned to the hydrogen on the diarylmethyl carbon (10b-H), (14c-H) and a doublet ($J$ = 6–7 Hz) in the region δ 6.8–7 ppm assigned to the hydrogen on the acetal carbon (5a-H), (7a-H). The $^{13}$C-NMR spectra show two aliphatic resonances for the diaryl methyl (10b-C, 14C) in the region δ 48–50.85 and acetal carbons (5a-C, 7a-C) at region δ 111–112.4 ppm respectively, consistent with the overall mirror symmetry. In all of these compounds (**4a–f**,**5**) bands arising from the aromatic protons partially overlapped the doublet assigned to the hydrogen on the acetal carbon. It was found that, by expanding the NMR spectra in the aromatic region, the acetal hydrogen doublet was clearly separated from the bands attributed to the aromatic protons, and that overlapping was removed.

In conclusion, the simplicity of this method, good to excellent yields, readily available starting materials and the possibility of applying this method to phenols and naphthols make this method very useful for this type of transformation in organic synthesis.

To prepare the polymer forming monomers from dimeric products having two and tetramethyl groups (**4a–d**), we performed the ordinary aromatic side chain oxidation reaction of **4a–d** using $KMnO_4$ in the next stage. It was observed that the resulting reaction products had structures different from to that of our expected and a surprising result was obtained. Spectral investigations showed that aromatization had occurred in the products (**6a–d**) in addition to oxidation of the methyl groups as shown in Scheme 2.

The IR spectra of the compounds **6a–d** showed broad absorption bands around 2530–3500 (acidic H,s) and the acidic C=O stretching absorption in the region 1680–1715 cm$^{-1}$, confirming the presence of carboxylic acid groups in the structures. The $^1$H-NMR spectra showed no peaks associated with methyl groups and no doublets around 4.88–4.92 ppm for diaryl methyl protons (10b). There appeared only a complicated collection of peaks around the aromatic hydrogen region in the $^1$H-NMR spectra of the products. In other words, using $KMnO_4$ as an oxidizing agent causes a dehydrogenation reaction on 5a and 10b hydrogens which leads to the production of diacids **6a**, **6d** and tetra acids **6a**, **6c**, respectively. The tetra acid (**6b**) did not melt, but it underwent thermal

**6b** **7**

cyclodehydration to the dianhydride. The $^1$H-NMR also show a peak in the region 12.8–13 ppm assigned to the acidic protons.

All the evidence, ie., no peaks for the 10b and 5a hydrogens in $^1$H-NMR spectra and a twofold difference between our expected molecular weights and that of experimental results in GC-MS, led us to the conclusion that the exact structures for the oxidation reaction products must be as structures **6a–d**, a series of molecules with fully aromatic structures (Scheme 2).

Finally, the dianhydride (**7**) was prepared by dehydration of the tetra acid (**6a**) in acetic acid and acetic anhydride (Scheme 3).

After compound **6b** was dehydrated into dianhydride **7**, the absorption bands of O—H and C=O stretching disappeared and the characteristic absorptions of the C=O groups in cyclic anhydride were observed at 1851 (asymmetric stretching) and 1782 (symmetric stretching) $cm^{-1}$, hence confirming the presence of an anhydride ring in the structure. The $^1$H-NMR spectrum of dianhydride (**7**) showed no acidic protons, and the remaining protons were only aromatic hydrogens. The mass spectral data completed the structural confirmation of dianhydride **7** in which the peak appeared at m/z 348 ($MH^+$, 100%)

In conclusion, we successfully prepared a series of new wholly aromatic polymer forming monomers from a relatively cheap raw material and through a high yield route, that involves the use of common, in expensive reagents. Specially, because of their complete aromatic structures, these monomers may be the good candidates in the synthesis of several types of heat stable polymers such as polyimide, polyamide, polyesters, polybenzimidazoles, etc. Synthesis and study of the corresponding polymers derived from the diacids (**6a**, **6d**) and dianhydride (**7**) and the preparation of their derivatives having several types of functional groups, to reach some kinds of polymers are underway and the results will be reported soon.

## EXPERIMENTAL

**Materials and instruments.** Solvents and chemical materials were obtained from Merck chemical company (Germany) and Fluka(Switzerland). Melting points were determined with a Buchi 535 melting point apparatus. IR and FTIR spectra were recorded using a Perkin–Elmer 781 and Unicam Matteson 1000 spectrometers, respectively. UV spectra were recorded on a Pharmacia biotech ultra spec 3000 model 80-2106-20 spectrometer. $^1$H-NMR and $^{13}$C-NMR spectra were recorded on a 250 MHz Bruker Avance DPX-250 and 400 MHz Bruker spectrometers using tetramethyl silane (TMS) as an internal standard at 25°C with frequencies of 400, 250, and 62.9 MHz for the $^1$H and $^{13}$C spectra, respectively. Mass spectra were recorded under electron impact at 70eV on a shimadzu GCMS-QP1000 Ex instrument. Elemental analysis was performed by RIPI.

**Glyoxal bisulfite.** To a solution of sodium bisulfite (30%) was added glyoxal in 2/1 mole ratio at room temperature. The bisulfite adduct was precipitated by addition of ethanol to the solution and dried *in vacuo* at 60°C.

**General procedures for (4a–f).** ***Method A.*** To a 500 mL round bottomed flask was charged with phenolic compound (**1a–f**) (0.10 mol) glyoxal, (0.05 mol of a 30% aqueous solution) and acetic acid (100 mL). The mixture was dissolved in acetic acid. Methane sulphonic acid (25–30 mL) was added drop by drop, with stirring, the temperature of the reaction mixture being kept between 30 and 35°C. During the addition of the methane sulphonic acid (20–50 min) the acetal began to precipitate from solution. The mixture was then stirred at 30–35°C until the total time of addition and stirring 1–2 h. The cooled reaction mixture was then poured into water (500 mL), and the crude product was collected by filtration and wash with water and ethanol. Details concerning the purification of each individual reaction product are given under the appropriate title in the following part of the experimental.

***Method B.*** In a fume cupboard, to a 500 mL round bottomed flask with a hot water bath $H_2O$ (150 mL), acetic acid (70 mL), glyoxal bisulfite(13 g, 0.05 mol) and phenolic compounds (**1a–f**) (0.1 mol) were added. The glyoxalbisulfite was dissolved upon stirring and increasing the temperature. After the temperature reached 80°C, concentrated sulfuric acid (40–45 mL) was added drop by drop and the temperature of the reaction mixture was kept between 85 and 90°C. During the addition of sulfuric acid (40–60 min) the reaction product began to precipitate from solution. The mixture was then stirred at 85–90°C until the total time of addition and stirring was 1.5–4 h. The cooled reaction mixture was filtered and the crude product was then poured into water (500 mL), collected by filtration and washed with water and ethanol. Reaction products were purified by appropriate methods specified below.

**7a,14c-Dihydronaphtho[2,1-b]naphtho[2′,1′:5,6]furo[3,2-d]furan (5).** This compound has been obtained from the reaction of 2-naphthol with glyoxal following the general procedure and purified by recrystallizing from acetic acid or acetone to give white solid; mp = 236–237°C (lit., 236–237°C, [15,6]); [Found; C; 85.13; H,4.60. $C_{22}H_{14}O_2$ requires C, 85.14; H, 4.55%]; $\nu_{max}$ (KBr)845,805,735 $cm^{-1}$; $\delta_H$ (250 MHz, DMSO-$d_6$) 5.82 (1H, d, *J* 6 Hz, 14c-*H*), 7.20–8.40 (13H, m, ArH + 7a-*H*); $\delta_c$ (62.9 MHz, DMSO-$d_6$) 48.5 (d, 14c-*C*), 111.5, 114.4, 118.6, 122.9, 123.3, 126.4, 128.7, 129.5, 129.7, 130.1, 155.6 (aromatic *C*+7a-*C*); m/z (EI) 310(100, $MH^+$), 281(39%).

**General procedure for 6a–d.** A two-necked round bottomed flask with an effective stirrer, was charged with a solution of **6a–d** (0.032 mol) in a mixture of pyridine (200 mL) and water (100 mL). The temperature was elevated to near refluxing and $KMnO_4$ (0.29–0.58 mol) was added in small portions. Refluxing was continued for 8–24 h. After cooling to room temperature, the mixture was filtered and the residual $MnO_2$ was washed thoroughly with boiling water. The combined filtrates in an ice-water bath were acidified with hydrochloric acid. The white solid precipitate was filtered off, washed several times with water, and dried to afford **6a–d**. The products were purified by appropriate methods specified below.

**Benzofuro [2,3-b]benzofuran-2,3,8,10tetracarboxylic dianhydride(7).** In a 500 mL round bottomed flask, 8.7 g (0.025 mol) of tetra acid **6b** was suspended in 100 mL of glacial acetic acid and 200 mL of acetic anhydride. The mixture was boiled under reflux for 4h. Then, the mixture was filtered and left to crystallized overnight. The precipitated product was filtered out, washed with dry toluene, and dried to give white solid in 86% yield; [Found: C, 61.891; H,1.11. $C_{18}H_4O_8$ requires C, 62.08; H, 1.10%]; $\nu_{max}$ (KBr) 3125, 3051, 1858 (asym. C=O str.), 1780 (sym. C=O str.), 1629, 1439, 1185, 1152, 1130, 885 (C—O str.) $cm^{-1}$; $\delta_H$ (250MHz, DMSO-$d_6$) 8.78-8.32(s, 4H, Ar).

**Benzofuro[2,3-b]benzofuran-2,9-dicarboxylic acid (6a). 6a** was obtained from oxidation of **4a** with $KMnO_4$ (45.82g) in a 2:1 (v/v) pyridine: water mixture by heating to gentle reflux for 8h, following the general procedure and purified by recrystallizing from dilute ethanol to give white solid in 81 %yield; mp>300°C (lit. [19]); $\nu_{max}$(KBr) 3500-2800, 1680 (C=O str.), 1450, 1237, 1157 $cm^{-1}$; $\delta_H$ (400MHz, DMSO-$d_6$) 12.92(2H,

s,-O*H* ), 6.8–8.20(6H, m, Ar*H* ); m/z (EI) 296(100, $MH^+$), 269(45.8), 241(75.1%);

**Benzofuro[2,3-b]benzofuran-2,3,8,9-tetracarboxylic acid (6b). 6b** was obtained from oxidation of **4b** with $KMnO_4$ (91.649) in a 2:1 (v/v) pyridine: water mixture by heating to gentle reflux for 24h, following the general procedure and purified by recrystallizing from a mixture of ethanol/water(2:1 v/v) to give white solid in 82% yield; mp>300°C;[Found: C, 55.89; H, 2.791. $C_{18}H_8O_{10}$ requires C, 56.25; H, 2.783%], $\nu_{max}$ (KBr) 3445-2530, 1710(C═O str.), 1609, 1482, 1422(C─O str.), 1264 $cm^{-1}$; $\delta_H$(400MHz, DMSO-$d_6$) 12.81(4H, s, ─O*H*), 6.80–8.80 (4H, m, Ar*H*); m/z (EI) 366(84.6), 348 (94.5), 322 (27.2), 304 (32.6), 276 (95.7), 232 (14.5), 204 (48.6), 148 (35.8), 116(21.2), 98(62. 4), 74(100), 44(77.7%).

**Benzofuro[2,3-b]benzofuran–2,4,7,9-tetracarboxylic acid (6c). 6c** was obtained from oxidation of **4c** with $KMnO_4$(91.64g) in a 2:1(v/v) pyridine : water mixture by heating to gentle reflux for 24 h, following the general procedure and purified by recrystallizing from mixture of DMF/water (2:1 v/v) to give white solid in 84% yield; mp > 300°C;[Found: C, 56.89;H, 2.61. $C_{18}$ $H_8$ $O_{10}$ requires C, 56.25; H, 2.783%]; $\nu_{max}$ (KBr) 3450-2530, 1715 (C═O str.), 1609, 1482, 1450, 1421(C─O str.), 1265 $cm^{-1}$; $\delta_H$ (400 MHz, DMSO-$d_6$) 13(4H, s, ─O*H*), 6.80–8.80 (4H, m, Ar-*H*); m/z(EI) 384 (29.1, $MH^+$), 322(27), 294(23.9), 276(9.2), 266(15.9), 232(16.6), 204(41), 194(14.1), 166 (12.8), 98 (21), 79(100), 52(97%).

**2,9-Dichloro-benzofuro[2,3-b]benzofuran-3,8-dicarboxylic acid(6d). 6d** was obtained from oxidation of **4d** with $KMnO_4$ (55.4g) in a 2:1 (v/v) pyridine: water mixture by heating to gentle reflux for 12 h, following the general procedure and purified by recrystallizing from mixture of DMAc/water (2:1 v/v) to give white solid in 83% yield; mp>300 °C; [Found: C, 62.15; H, 3.32. $C_{16}H_{10}O_2Cl_2$ requires C, 62.95; H, 3.2787%]; $\nu_{max}$ (KBr) 3450-2800, 1695 (C═O str.), 1605, 1465, 1451,1425(C─O str.), 1240, 1145 $cm^{-1}$; $\delta_H$(400MHz, DMSO-d6) 13(2H, s-O*H*), 6.85–8.35(4H, m, Ar*H*); m/z(EI)305 (81,$MH^+$), 306(19, $MH^+$+1), 307(12.7, $MH^+$+2), 308 (9.1, $MH^+$+3), 261(100), 243(56), 217(41), 208(19), 180(29), 165(24), 76(32.2%).

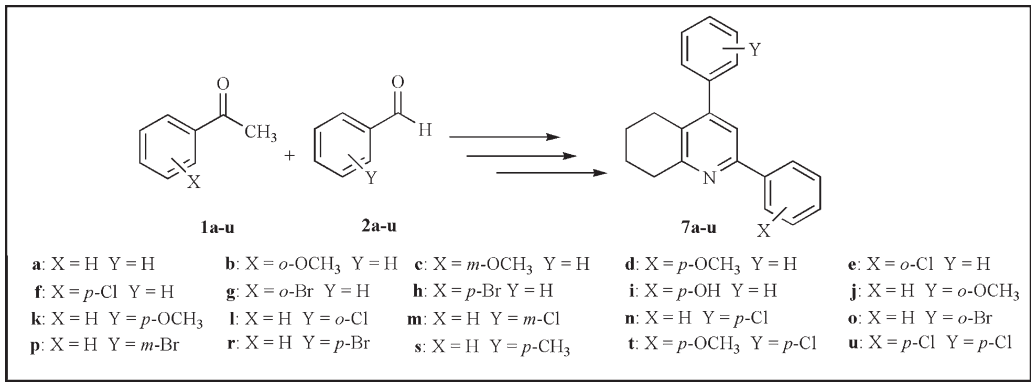
Published online 11 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



Addition of cylohexanone to chalcones, obtained from the appropriate acetophenone and benzaldehyde derivatives, under solvent-free conditions gave 1,5-diketones in good yields. Treatment of 1,5-diketones with ammonium acetate in acetic acid afforded directly 2,4-diaryl-5,6,7,8-tetrahydroquinoline derivatives **(7a–u)** in high yields. The structures of **7a–u** were elucidated by $^{1}$H NMR, $^{13}$C NMR, IR, and elemental analysis.

## INTRODUCTION

The synthesis of oxygen, nitrogen, or sulfur-containing heterocycles is of importance in the organic and medicinal chemistry [1]. Among these structures, quinolines [2], tetrahydroquinolines [3], and their derivatives are excellent precursor of potential drugs [4]. Quinoline and their derivatives, which usually possess diverse biological activities, play important roles as versatile building blocks for the synthesis of natural products and as therapeutic agents [5]. In particular, 2-arylquinolines are biologically active and occur in structures of a number of antimalarial compounds and antitumor agents [6]. The biological activity of quinoline compounds has been found to possess antiasthmatic, antibacterial, antianflammatory, and antihypertensive properties [7]. Therefore, the synthesis of quinolines has attracted much attention in organic synthesis. The classic methods for the synthesis of quinolines include Skraup [8], Doebner-Von Miller [9], Conrad and Limbach [10], Combes [11], and Pfizinger [12] quinoline syntheses. A number of general synthetic methods have also been reported [13]. However, some of these methods suffer from several disadvantages such as harsh reaction conditions, multi steps, a large amount of promoters, and long reaction time [14].

In this study, we report that the synthesis of novel 2,4-diaryl-5,6,7,8-tetrahydroquinoline derivatives **7a–u** via cyclization of 1,5-diketones **5a–u** with ammonium acetate in acetic acid.

## RESULTS AND DISCUSSION

The general synthetic strategy used to prepare the chalcone derivatives (**3a–u**) was based on Claisen-Schmidt condensation, which was reported previously [15]. Chalcone derivatives (**3a–u**) were prepared by base-catalyzed condensation of appropriate substituted acetophenone with benzaldehyde in good yields (Scheme 1). All chalcone derivatives (**3a–u**) are well-known [16–26] according to our literature surveys. The structures of **3a–u** were characterized on the basis of spectral data (IR, $^{1}$H NMR, and $^{13}$C NMR) and comparison with authentic samples. After the structures of **3a–u** were determined, they were submitted to additional reaction of cyclohexanone (**4**). Addition of cyclohexanone to chalcones was performed according to our previously published method [27] in the presence of PTC (phase transfer catalyst = triethylammonium chloride) in solvent-free conditions. 1,5-Diketone derivatives **5a–u** were obtained in moderate to good yields (Scheme 1,

**Scheme 1**

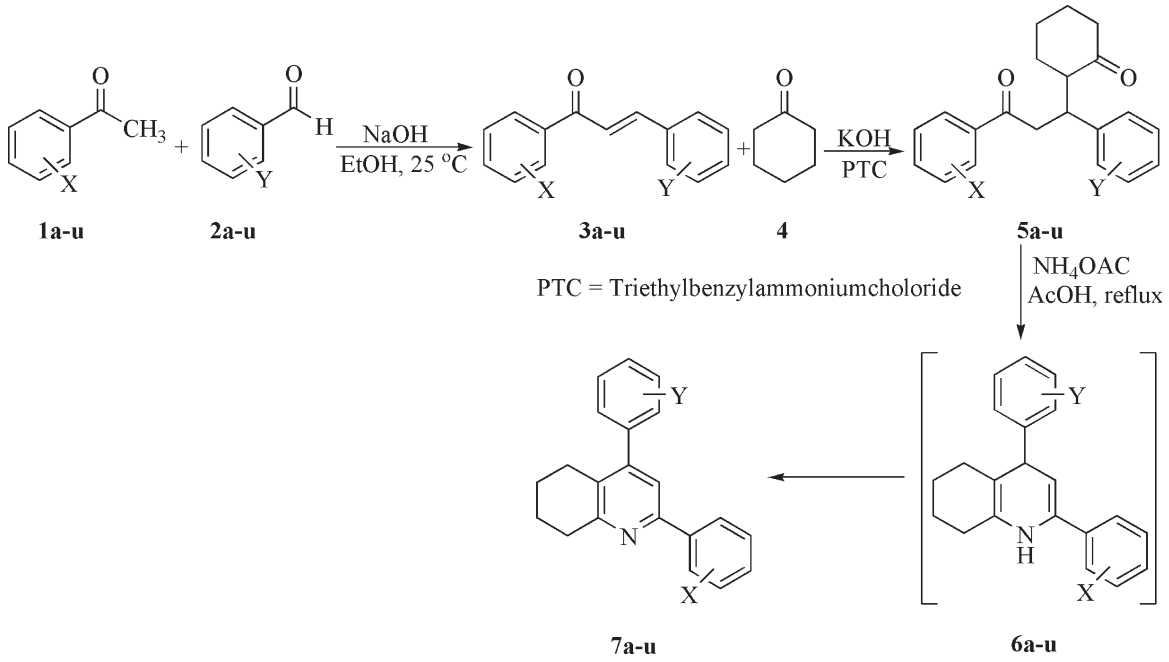

Table 1). In this series, the compounds **5a–g** are known in the literature [21,27–29]. The structures of other 1,5-diketones (**5h–u**) were determined by spectroscopic studies ($^1$H, $^{13}$C NMR, IR, and elemental analysis). In the $^1$H NMR spectrum of **5a–h**, the protons of $PhCOCH_2$ gave an AB system that is characteristic signals for these compounds. While part A of the AB system is shown as a doublet of doublet at $\delta = 3.50–3.42$ ($J = 15.7–16.7$ and 3.9–4.5 Hz) and that of part B is shown as a doublet of doublet at $\delta = 3.23–3.15$ ($J = 15.7–16.7$ and 9.5–9.6 Hz).

Treatment of 1,5-diketones **5a–u** with $NH_4OAc$ (ammonium acetate) in AcOH at reflux condition for 2.5–5 h afforded directly 2,4-diaryl-5,6,7,8-tetrahydroquinoline derivatives **7a–u** in excellent yields (Scheme 1, Table 2). The compounds **7a–u** were purified by column chromatography (on a silica gel) eluting $CHCl_3$/*n*-hexane (1:1).

Structures of **7a–u** were confirmed by their spectral (IR, NMR, and elemental analyses) data. In the $^1$H NMR spectrum of **7a–u**, the H4 proton gave a singlet (between $\delta = 7.60$ and 7.30 ppm) that is characteristic signals for these compounds. All spectral data are consistent with the titled compounds.

In conclusion, we have described a mild, efficient, and convenient method for the synthesis of 2,4-diaryl-5,6,7,8-tetrahydroquinoline derivatives from cheap and easily available materials such as acetophenone and benzaldehyde derivatives, cyclohexanone and ammonium acetate.

## EXPERIMENTAL

$^1$H and $^{13}$C NMR spectra were recorded with Bruker AC 400 instruments. As internal standards, we used TMS ($\delta$ 0.00) for $^1$H NMR and $CDCl_3$ ($\delta$ 77.0) for $^{13}$C NMR spectroscopy. *J* values are given in hertz. The multiplicities of the signals in the $^1$H NMR spectra are abbreviated to s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad), and combinations thereof. IR spectra were recorded on a Jasco FT/IR-430 spectrometer. Elemental analyses were performed using a LECO CHNS 932 elemental analyzer. Melting points were measured on Electrothermal 9100 apparatus. All column chromatographies were performed on silica gel (60–230 mesh, Merck).

**General procedure for the synthesis of chalcones 3a–u.** To a solution of acetophenone derivative (1 mmol) in ethanol (20 mL) was added NaOH (8 mL, 2.5*M* NaOH) and benzaldehyde derivative (1 mmol) at room temperature. The mixture was stirred for 3 h. Then the mixture was washed with diluted HCl and extracted with $CHCl_3$. The organic layer was dried over $Na_2SO_4$ and the solvent was removed in vacuum. The residue was purified on a silica gel column eluting with $CHCl_3$/*n*-hexane (3:7) and/or crystallized from $CHCl_3$/*n*-hexane (3:7).

**General procedure for the synthesis of 1,5-diketones 5a–u.** To a mixture of chalcone (**1a**) (10 mmol) and cycylohexanone (**4**) (20 mmol) were added solid KOH (0.06% mol) with a few drop of water and PTC (benzyltrithylammonium chloride) (0.06% mol) and stirred for 3–4 h at room temperature. Then, the mixture was extracted with 20 mL of $CHCl_3$ and dried over $Na_2SO_4$. After the solvent was taken off in vacuum, the crude product was crystallized from $CCl_4$/hexane (3:1).

**General procedure for synthesis of 2,4-diaryl-5,6,7,8-tetrahydroquinoline derivatives (7a-5u).** The 1,5-diketone (**5**) (1.5 mmol) and ammonium acetate ($NH_4OAc$) (4.5 mmol) were dissolved in acetic acid (10 mL) and refluxed for 2–5 h. After the removal of acetic acid in vacuum, the residue was added with $CHCl_3$ (30 mL) and washed with diluted $NaHCO_3$. Organic layer was dried over $Na_2SO_4$. Removal of the solvent in vacuum gave the 2,4-diaryl-5,6,7,8-tetrahydroqinoline derivative (**7**). The crude product was purified by column chromatography (on a silica gel) eluting with hexane/$CHCl_3$ (1:1).

The 3,5-diacetyl-4-methylpyrazole diketone has been synthesized and its crystal structure has been determined. This diketone reacts with hydroxylamine hydrochloride to give the dioxime derivative. This reaction, conducted in presence of copper II ions, leads to the formation of $L_2M_2$ copper II complexes.

## INTRODUCTION

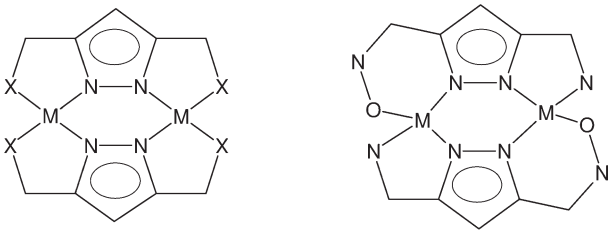
Research on transition metal complexes is a flourishing field with major interests focused on biological mimicry and cooperative phenomena in catalysis and magnetism. In this respect, pyrazol-based ligands have received a great deal of attention over the last decades due to their interesting coordination chemistry [1]. The pyrazole entity appears indeed particularly suited owing to its ability to bind simultaneously two metal centers in close proximity providing moreover an intramolecular pathway for spin-exchange interactions [2–9]. Further control of the metal–metal separation as well as the steric and electronic properties of the individual metal ions can be achieved by appropriates chelating side arms. Attached to the 3 and 5 positions of the heterocycle, these side arms are able to afford bis(μ-pyrazolato) bridged species $L_2M_2$.

In most cases, e.g. in type 1 complexes, the chelated metal atoms form only five-membered rings involving the four nitrogen atoms of the two depronated pyrazole rings and the four chelating heteroatoms bore by the 3,5-substituted side arms as shown in Scheme 1 [4–9]. Interestingly, the use of functional groups such as oximes as chelating side arms has a singular attractiveness. Oximes are indeed not only generally easy to prepare but can also take advantage of two different bridging modes as shown in Scheme 1 (type 2). In type 2 complexes, the metal atom can bind either to the N atom, either to the deprotonated O-atom of the oxime moiety thus forming a six-membered ring. In this purpose, we have already employed pyridazine and pyrazolate units, such as 3,6-diformylpyridazines [10,11], 3,6-dibenzoylpyridazines [10], and 3,5-diacetyl-4-methylpyrazole [12] and related dioxime species. The synthesis, crystal structure, and magnetic properties of two binuclear copper (II) complexes of the 3,5-diacetyl-4-methylpyrazole dioxime ($dampdoH_3$), involving the two bridging modes of the oxime function has been also reported [13]. In the present study, we describe the synthesis and crystal structure of the 3,5-diacetyl-4-methylpyrazole ligand used in a new one-step preparation of $L_2M_2$ copper II complexes.

## RESULTS AND DISCUSSION

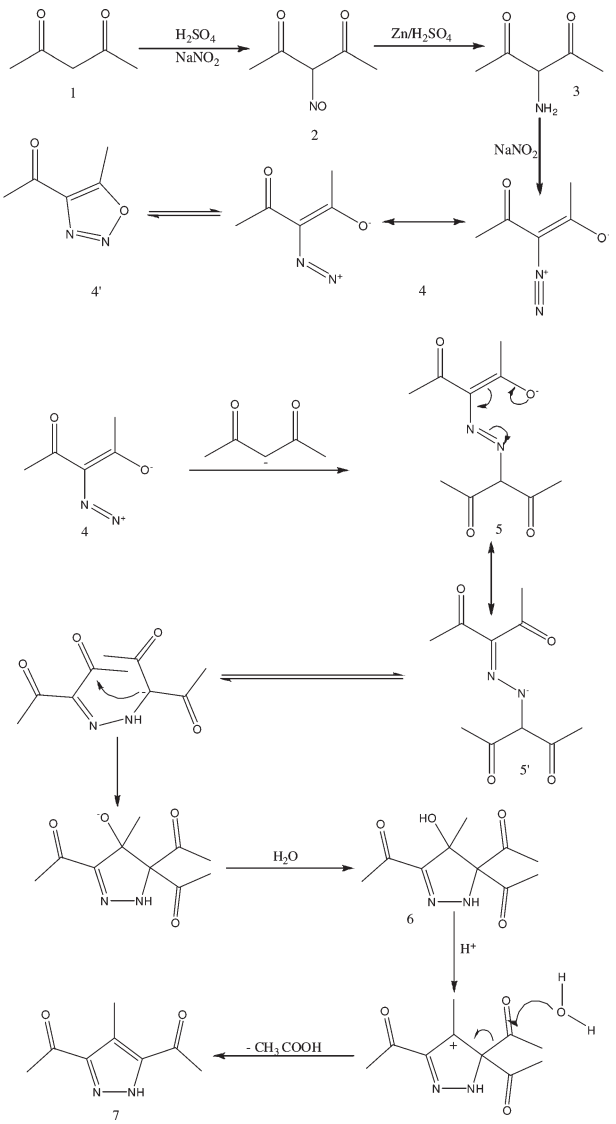
The 3,5-diacetyl-4-methylpyrazole is prepared by the method of Wolff [12]. Reduced by $Zn/H_2SO_4$, the isonitrosoacetylacetone (**2**) gives the aminoacetylacetone (**3**). This compound is then diazoted by sodium nitrite in acid medium (Scheme 2), affording the crude diazoacetylacetone (**4**) as an oily product which was in fact expected to be the 4-acetyl-5-methyl-oxadiazole (**4′**).

**Scheme 1.** $L_2M_2$ dinuclear complexes of pyrazolate anion.



To provide insight into the thermodynamics and kinetics of the possible internal cyclization of diazoacetylacetone (**4**) affording 4-acetyl-5-methyl-1,2,3-oxadiazole (**4′**), theoretical calculations were carried out at the B3LYP/6-31+g(d) DFT level. A thorough inspection of the frontier orbitals (HOMO and LUMO) of diazoacetylacetone (**4**) was first performed. The HOMO and LUMO for its most stable geometry in gas-phase show energy values of −7.5 and −2.7 eV, respectively. As depicted in Figure 1, the two frontier orbitals are distributed in the molecular plane. Although HOMO is mainly composed by lone pairs of the two carbonyl oxygen atoms, LUMO is an antibonding-π orbital located exclusively around the N≡N triple bond. This orbital distribution suggests that the unique pathway for the internal cyclization of diazoacetylacetone (**4**) should reside in the attack of one of carbonyl oxygen atom lone pairs at the π-orbital located on the terminal nitrogen atom of the diazonium moiety.

**Scheme 2.** Synthesis of 3,5-diacetyl-4-methylpyrazole.



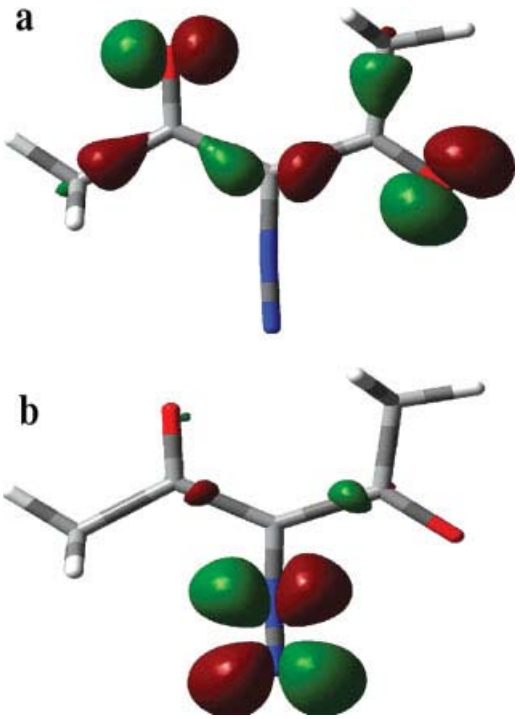


**Figure 1.** Isodensity surface plots of the HOMO (a) and LUMO (b) for the lowest-energy gas-phase geometry of diazoacetylacetone (**4**). [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

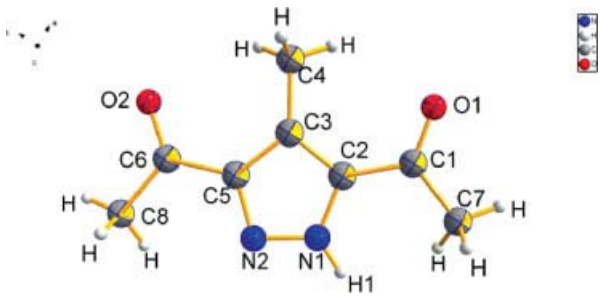

**Figure 2.** Perspective view of dampH structure. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

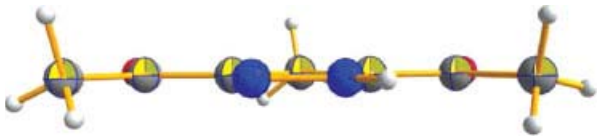

**Figure 3.** Projection view of dampH structure. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

The optimized geometry for transition state joining compounds (**4**) and (**4′**) on the potential energy surface has a single imaginary frequency ($\nu_i = 163\ cm^{-1}$) corresponding to the stretching vibration of the forming N—O bond. The distance of the N—O forming bond in transition state geometry is 1.902 Å. The reaction from diazoacetylacetone (**4**) leading to the formation of oxadiazole (**4′**) is predicted slightly endothermic (+7.3 kcal/mol in gas-phase and 8.5 kcal/mol in water). Diazoacetylacetone (**4**) is then thermodynamically more stable than 4-acetyl-5-methyl-1,2,3-oxadiazole (**4′**).

Furthermore, the barrier height calculated from diazoacetylacetone (**4**) is 8.0 kcal/mol (9.3 kcal/mol in water) indicating that formation of 4-acetyl-5-methyl-1,2,3-oxadiazole (**4′**) is not kinetically favored, at least at ambient temperature. This product is thus very unstable and must react immediately with carbanion of the 2,4-pentanedione as previously described [14]. This condensation and the subsequent heterocyclization give a pyrazoline (**6**), which was not isolated. In aqueous acidic medium, this compound gives the pyrazole (**7**) after elimination of acetic acid as described in Scheme 2. Slow evaporation of an ethanolic solution of **7** gives finally single crystals suitable for X-ray diffraction.

The main features of the crystal structure of compound dampH (**7**) result from the planarity of the whole entity (Figs. 2 and 3).

The crystal structure is formed by layers of planar dampH molecules stacked along the axis c direction.

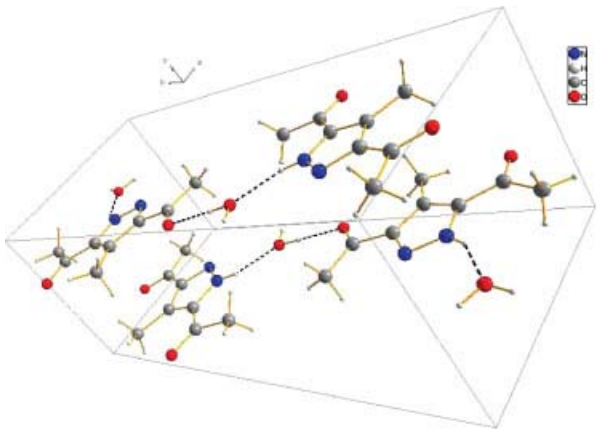

**Figure 4.** View of dampH crystal structure with its stabilizing hydrogen bond network (dashed lines). [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

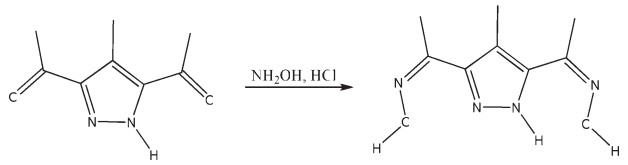
**Scheme 3.** Synthesis of $dampdoH_3$.



The layered crystal structure is also stabilized by an intermolecular hydrogen bond network forming dimeric ligand associations. The hydrogen bond interactions between two coplanar and adjacent 3,5-diacetyl-4-methylpyrazole ligands are mediated by a water molecule. The oxygen atom O3 of this water molecule gives an hydrogen bond with the hydrogen atom H1 bound to the nitrogen atom of pyrazole ring in the first ligand (O3—H1 = 1.9571 Å). Furthermore, one of the two hydrogen atoms H1w of the water molecule is also involved in a second hydrogen bond interaction with the oxygen atom O2 of the ketonic function of the second ligand molecule (H1w—O1 = 1.9207 Å) (Fig. 4).

This diketone (**7**) reacts with hydroxylamine hydrochloride to give the diacetyl dioxime derivative ($dampdoH_3$) as described in Scheme 3. On reaction with copper II cations $dampdoH_3$ leads to the bis(μ-pyrazolato) bridged $L_2M_2$ species [13] as described in Scheme 4, with L = dampdoH.

From $dampdoH_3$ ($H_2L$) and $CuCl_2{\cdot}6H_2O$, two structurally isomeric complexes $[Cu_2(HL)_2Cl_2]6H_2O$, which differ only from the hydrogen bonding, were previously obtained [10]. One of these complexes can be obtained directly from **7** by a one-step reaction with copper II ions in the presence of hydroxylamine hydrochloride. This reaction using $CuCl_2$, $CuClO_4$, $Cu(NO_3)_2$, or $CuSO_4$, leads, after several days, to the formation of dark green crystals of the copper II complexes previously described [13]. In this complex, the axial ligand is a chloride ion even in presence of perchlorate, nitrate, or sulphate ions, indicating that chloride ions are better complexing species.

## EXPERIMENTAL

Melting points were determined on an IA 9000 series Electrothermal apparatus and are uncorrected. Elemental analyses of C, H, N, and S were performed at the Elemental Analysis service of CNRS, Vernaison, France. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker F.T. AC 300 spectrometer (300 MHz for $^1$H NMR and 75 MHz for $^{13}$C NMR) using chloroform ($CDCl_3$) as solvent. Matrix-assisted laser desorption ionization (MALDI) and time-of-flight mass spectrometry (TOF-MS) are used to record the mass spectra of the correspondent compounds. All starting materials were of reagent grade and were used as purchased.

All theoretical calculations were performed using the Gaussian 03 suite of programs [15]. The gas-phase geometries of diazoacetylacetone (**4**), 4-acetyl-5-methyl-1,2,3-oxadiazole (**4′**), and related transition state were optimized using hybrid density functional theory (B3LYP) [16] and the 6-31+g(d) basis set. Frequency calculations were used to verify the nature of the computed stationary points. Geometries obtained for **4** and **4′** were real minima with all real vibrational frequencies while that of transition state was indeed a first-order saddle point with a single imaginary frequency. To ensure that the transition state joins the two compounds (**4**) and (**4′**) on the potential energy surface, an intrinsic reaction coordinate (IRC) [17] analysis was performed. Frequency calculations also allowed us to calculate the zero-point energy (ZPE) corrections, which were finally added to electronic energies. The energies computed in water include the ZPE-corrected electronic energy plus the solvation energy as obtained from the polarizable continuum model (PCM) [18].

Single crystals of 3,5-diacetyl-4-methylpyrazole hydrated (dampH) were obtained in the form of brown needles, by slow evaporation at room temperature in aqueous solution of dampH. A single crystal of compound **7** was mounted on a Brucker AXS SMART three-circle diffractometer using graphite monochromated MoKα radiation (λ = 0.71073 Å), equipped with a CCD 4K two-dimensional detector [19]. A total of 1653 independent reflections were collected in the range of $2.22 < \theta < 31.03$ with $R_{int} = 2.64$. Data were corrected for Lorentz and polarization using program SaintPlus (Table 1). Atomic positions were determined using SHELXS [20] and refined using full matrix least squares [21]. Hydrogen positions were calculated and included in the final cycles of refinement in constrained positions and with fixed isotropic

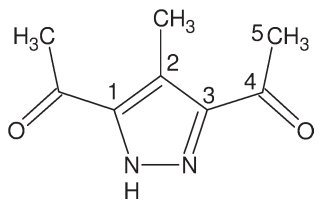
thermal parameters. Absorption corrections were not made due to the small value of the absorption coefficients (Table 1). Extinction was refined for all the three structures but was minimal. Figure 2 shows a perspective view of this compound with the numbering scheme, while in Table 2 bond distances and angles in the molecule (dampH) are reported. Atomic coordinates and equivalent displacement for dampH are reported in Table 3; anisotropic displacement parameters for dampH are reported in Table 4.

**General procedure for the synthesis of compounds 1, 4, and 7.** Starting material acetylacetone (**1**) was commercialized. The formula of the parent compounds with corresponding numbers to carbons scheme is given below.



**Synthesis of isonitroacetylacetone (2).** A suspension of acetylacetone (**1**) (50 g, 0.5 mol) in 7% sulphuric acid (500 mL) was stirred until it was completely dissolved. Sodium nitrite (35 g, 0.5 mol) in water (150 mL) was added, and the stirring was continued for 90 min. The reaction mixture was extracted with ether, dried (magnesium sulfate), filtered, and evaporated. The solid was recrystallized from ethanol: mp 75°C, yield 50 g, 77.5%.

**Synthesis of the acetylacetonate diazonium (4).** Isonitrosoacetylacetone 2 (10 g, 0.07 mol) dissolved in 30% sulphuric acid (100 mL) was cooled under 0°C. Zinc powder (15 g, 0.23 mol) was added, and the reaction mixture was allowed for 15 min. The limpid solution was filtered and diluted with water. A solution of sodium nitrite (6 g, 0.085 mol) in water (30 mL) was added and cooled. The reaction mixture was extracted with ether, and treated with 5% sodium carbonate. The residue was dried (magnesium sulfate), filtered, and evaporated to give an oil product: yield 4 g, 45%. The crude powder was used for the next step for the synthesis without further purification.

**Synthesis of 3,5-diacetyl-4-methylpyrazole (7).** A mixture of the acetylacetonate diazonium (**4**) (2 g, 0.016 mol), acetylacetone (**1**) (1.6 g, 0.015 mol), and sodium hydroxide (0.6 g, 0.015 mol) in water (30 mL) was heated at 50°C for 90 min. The resulting solution was concentrated under vacuum using a rotatory evaporator. After cooling, the obtained solution was neutralized by slow addition of aqueous sulfuric acid solution (0.5*M*). The obtained solid was filtered and recrystallized from ethanol: mp 112°C; yield 2 g, 75 %; $^1$H NMR ($CDCl_3$) δ (ppm) 10.78 (s, 1H); 2.51 (s, 6H); 2.46 (s, 3H); $^{13}$C NMR ($CDCl_3$) δ (ppm) 192.96; 144.94; 121.58; 28.57; 10.21. MALDI-TOFMS: *m/z* 167 (M +1). Anal. Calcd for $C_8H_{10}N_2O_2$: C, 57.82; H, 6.08; N, 16.86. Found: C, 58.02; H, 5.98; N, 16.75.

**Synthesis of 3,5-diacetyl-4-methylpyrazole dioxime.** A solution of hydroxylamine hydrochloride (1.4 g, 20 mmol) and NaOH (0.8 g, 20 mmol) in methanol/water solution (in ratio 50:50) was added to a solution of 3,5-diacetyl-4-methylpyrazole (1.5 g, 9 mmol) in water (20 mL) and heated under reflux for 2 h. After cooling, the solid product was filtered and recrystalized from ethanol: mp 218°C; yield 81%; $^1$H NMR (DMSO-d6) δ (ppm) 12.96 (s, H, NH); 11.33 (s, 1H, OH); 10.97 (s, 1H, OH); 2.27 (s, 3H); 2.14 (s, 6H); $^{13}$C NMR (DMSO-d6) δ (ppm) 150.39; 141.51; 134.62; 111.88; 11.70. MALDI-TOFMS: *m/z* 197 (M + 1). Anal. Calcd for $C_8H_{12}N_4O_2$: C, 48.97; H, 6.16; N, 28,56. Found: C, 49.02; H, 5.98; N, 28.78.

**Preparation of complexes.** A solution of copper II chloride dehydrate (85 mg, 0.5 mmol) and hydroxylamine hydrochloride (69,5 mg, 1 mmol) in water (20 mL) was added to a solution of dampH (92 mg, 0.5 mmol) in ethanol (10 mL) and heated under reflux a few minutes. The mixture was filtered to remove any precipitated material. Slow evaporation at room temperature during 3 days affords dark green crystals which were filtered, washed with water and dried in vacuo. The crystals were found to have the formula $[Cu_2(dampdoH)_2Cl_2)_2H_2O]$ yield 110 mg; 70%. Anal. Calcd: C, 30.75; H, 4.20; Cl, 11.35; Cu, 20.35; N, 17.95; O, 15.40 Found: C, 30.69; H, 4.21; Cl, 11.37; Cu, 20.29; N, 18.00; O, 15.44.

## INTRODUCTION

Multicomponent reactions (MCRs) have been frequently used by synthetic chemists as a facile means to generate molecular diversity from bifunctional substrates that react sequentially in an intramolecular fashion [1,2]. Devising such types of MCRs that achieve the formation of multiple bonds in a single operation is one of the major challenges in modern organic synthesis [3,4]. As such processes avoid time consuming and costly purification processes, as well as protection–deprotection steps, they are inherently more environmentally benign and atom economic [5]. They provide a powerful tool toward the one-pot synthesis of diverse and complex compounds as well as small and drug-like heterocycles [6].

Indenone-fused heterocycles represent important biological and medicinal scaffolds. Thus, the indenopyridine skeleton is present in the 4-azafluorenone group of alkaloids, represented by its simplest member onychnine (Fig. 1) [7]. Indenopyrazoles (**A**) and indenopyridazines (**B**) have been investigated as cyclin-dependent kinase [8] and selective monoamine oxidase B (MAO-B) [9] inhibitors, respectively.

Further, indenopyridines (**C**) exhibit cytotoxic [10], phosphodiesterase inhibitory [11], adenosine A2a receptor antagonistic [12], anti-inflammatory/antiallergic [13], coronary dilating [14], and calcium modulating activities [15]. These compounds have also been investigated for the treatment of hyperlipoproteinemia and arteriosclerosis [16] as well as neurodegenerative diseases [17].

Indole and indoline fragments are important moieties of a large number of a variety of natural products and medicinal agents [18], and some of indolines, spiro-annulated with heterocycles in the 3-position, have shown high biological activity [19–21]. The spirooxindole system is the core structure of many pharmacological agents and natural alkaloids [22–24]. Therefore, a number of methods have been reported for the preparation of spirooxindole fused heterocycles [25].

As part of our continuing efforts on the synthesis of biologically active heterocyclic compounds [26], we recently described an efficient synthesis of spiropyrimidoquinoline-pyrrolopyrimidines and spiroindoline-pyridodipyrimidines *via* a condensation reaction between amino-uraciles and isatines [27]. We have also developed an efficient synthesis of spiro[dibenzo[*b*,*i*]xanthene-13,3′-indoline]-pentaones via a reaction of isatins and 2-hydroxy-naphthoquinone in water [28].

Considering the important biological properties of spirooxindole fused heterocycles, we report herein a one-pot, pseudo four-component synthesis of spiro[diindeno[1,2-*b*:2′,1′-*e*]pyridine-11,3′-indoline]-triones 4 through a one-pot condensation reaction of 1,3-indandione 1, ammonium acetate 2 and isatins 3 in refluxing acetic acid (Scheme 1).

## RESULTS AND DISCUSSION

In a pilot experiment, a mixture of 1,3-indandione **1**, ammonium acetate **2**, and isatin **3a** at refluxing acetic acid were stirred to afford the 5*H*-spiro[diindeno[1,2-*b*:2′,1′-*e*]pyridine-11,3′-indoline]-2′,10,12-trione **4a** in 87% for 4 h.

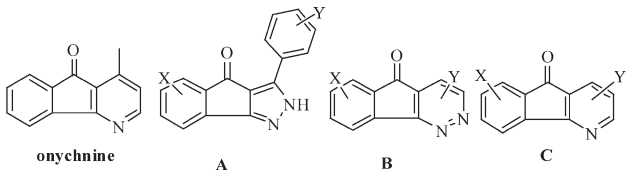

**Figure 1.** Representatives of important indenone-fused heterocycles

Encouraged by this success, we extended this reaction of 1,3-indandione **1** and ammonium acetate **2** with a range of other isatins **2b-l** under similar conditions, furnishing the respective 5*H*-spiro[diindeno[1,2-*b*:2′,1′-*e*]pyridine-11,3′-indoline]-2′,10,12-triones **4b-l** in good yields. The optimized results are summarized in Table 1. We have shown that the use of a wide diversity of substituents in isatins **3** in this reaction makes possible the synthesis of libraries under similar circumstances.

$^1$H and $^{13}$C NMR spectra of the crude products clearly indicated the formation of spirooxindol fused diindenopyridines **4**. The nature of these compounds as 2:1:1 adducts was apparent from their mass spectra, which displayed, in each case, the molecular ion peak at appropriate m/z value. Compounds **4a–l** are stable solids whose structures were established by IR, $^1$H and $^{13}$C NMR spectroscopy and elemental analysis.

For the investigation of the reaction mechanism, it is notable that when the 1,3-indandione **1**, ammonium acetate **2**, and isatin **3a** were reacted for 2 h, the intermediate **6** were isolated and characterized by spectroscopic methods. When intermediate **6** was reacted with $NH_4OAc$ **2** under the same reaction conditions, the product **4a** was obtained in 83% yield (Scheme 2).

Therefore, the formation of products **4** can be rationalized *via* initial addition of 1,3-indanedione **1** to the isatins **3** to yield intermediate **5**, which reacted further with another molecule of **1**. Finally, reaction of ammonium acetate **2** with the intermediate **6**, followed by cyclization afforded the corresponding product **4** (Scheme 3).

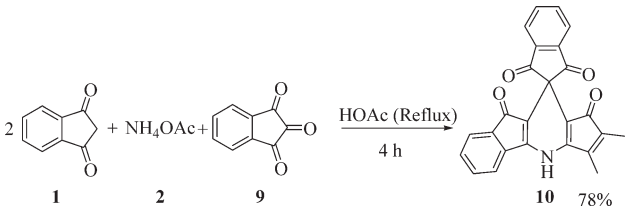
As expected, when the isatins **3** was replaced by acenaphthylene-1,2-dione **7**, 2*H*,5′*H*-spiro[acenaphthylene-1,11′-diindeno[1,2-*b*:2′,1′-*e*]pyridine]-2,10′,12′-trione **8** was obtained in 82% yield under the same reaction conditions (Scheme 4).

To further explore the potential of this protocol for spirofused heterocycle synthesis, we investigated reaction of 1,3-indandione **1** and ammonium acetate **2** with ninhydrine **9** and obtained 5*H*-spiro[diindeno[1,2-*b*:2′,1′-*e*]pyridine-11,2′-indene]-1′,3′,10,12-tetraone **10** in 78% yield (Scheme 3).

**Table 1**

Synthesis of spiro[diindenopyridine-indoline]-triones **4**.

| Product **4** | R | X | Yield (%) |
|---|---|---|---|
| **a** | H | H | 87 |
| **b** | Me | H | 85 |
| **c** | Et | H | 82 |
| **d** | $PhCH_2$ | H | 80 |
| **e** | H | Br | 91 |
| **f** | H | Me | 88 |
| **g** | H | F | 79 |
| **h** | H | $NO_2$ | 92 |
| **i** | Me | Br | 76 |
| **j** | Et | Br | 78 |
| **k** | Me | $NO_2$ | 79 |
| **l** | Et | $NO_2$ | 77 |

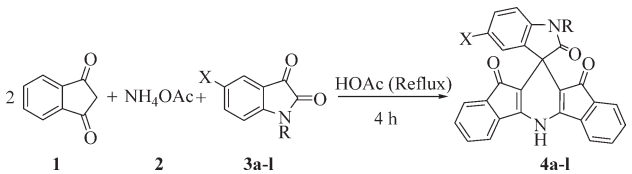


In conclusion, we have demonstrated an efficient and simple method for the preparation of some spirooxindole fused heterocycles using readily available starting materials. Prominent among the advantages of this new method are operational simplicity, good yields, and easy work-up procedures employed. Moreover, it is worth noting that two C—C and one two C—N bonds were formed with concomitant creation of a spirooxindoles in this one-pot, pseudo four-component process.

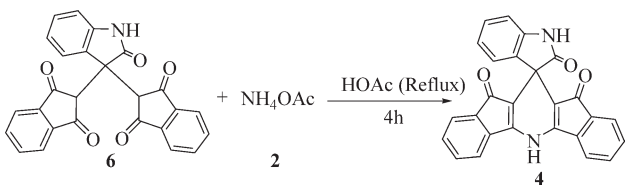
## EXPERIMENTAL

Melting points were measured on an Elecrtothermal 9100 apparatus. Mass spectra were recorded on a FINNIGAN-MAT 8430 mass spectrometer operating at an ionization potential of 70 eV. $^1$H and $^{13}$C NMR spectra were recorded on a BRUKER DRX-300 AVANCE spectrometer at 300.13 and 75.47 MHz, respectively. IR spectra were recorded using a Shimadzu IR-470 apparatus. Elemental analyses were performed using a Heracus CHN-O-Rapid analyzer.

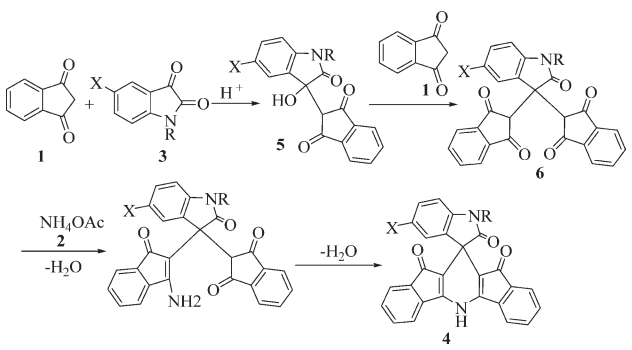
**Scheme 1**



**Scheme 2**



**Scheme 3**



Because of very low solubility of the products, we cannot report the $^{13}C$ NMR data for these products.

**Typical procedure for the preparation of 5*H*-Spiro[diindeno[1,2-*b*:2′,1′-*e*]pyridine-11,3′-indoline]-2′,10,12-trione (4a).** A mixture of 1,3-indandione **1a** (0.30 g, 2 mmol), ammonium acetate **2** (0.46 g, 3 mmol), and isatin **3a** (0.15 g, 1 mmol) in refluxing (5 mL) was stirred for 4 h (the progress of the reaction was monitored by TLC). After completion, the reaction mixture was filtered and the precipitate washed with water (10 mL) and recrystallized by EtOH to afford the pure product **4a** as red powder (87%); m.p >300°C (dec). IR (KBr) ($\nu_{max}/cm^{-1}$): 3169, 2996, 1694, 1672, 1631. MS (EI, 70 eV) *m/z*: 402 ($M^+$). $^1H$ NMR (300 MHz, DMSO-$d_6$): $\delta_H$ 6.83–7.74 (m, 12H, ArH), 10.66 (s, 1H, NH), 11.62 (s, 1H, NH). Anal. A general and versatile one-pot three-component procedure for the selective synthesis of mono substituted quinazolin-4(3*H*)-ones and 2,3-dihydroquinazolin-4(1*H*)-ones were described. The selectivity could be controlled by the ratio of iodine concentration.

*J. Heterocyclic Chem.*, **47**, 1035 (2010).

## INTRODUCTION

2,3-Dihydroquinazolin-4(1*H*)-ones are an important class of heterocycles with a broad spectrum of biological and pharmaceutical activities, such as antitumor, analgesic, anticancer, and diuretic [1–3]. Traditional procedure for the synthesis of these compounds involves the condensation of anthranilamides, as well as the reductive cyclization of *o*-nitrobenzamide or *o*-azidobenzamide with aldehydes or ketones in the presence of Brφnsted or Lewis acid catalyst [4–12]. On the other hand, quinazolin-4(3*H*)-ones, the oxidized products of 2,3-dihydroquinazolin-4(1*H*)-ones [13], were important precursors for the synthesis of natural and pharmacological compounds including febrifugine and isofebrifugine [14]. It can also be obtained by the cyclization of anthranilamides with aldehyde and other similar methods [15]. With the one-pot multicomponent reactions (MCRs) emerged as a powerful tool to routinely find out novel biologically active compounds [16], recently, various approaches to 2,3-dihydroquinazolin-4(1*H*)-ones and quinazolin-4(3*H*)-ones, promoted by Brφnsted or Lewis acid, or by supported acid with the help of special instrument, were explored independently in a one-pot three-component protocol starting from isatoic anhydride **A**, primary amine, and aldehyde [17–23]. However, there is a paucity of efficient synthetic route to implement the selectivity of two such compounds, an extra-oxidize step was always required to complete the fusion of the quinazolin-4(3*H*)-ones. Although Chen reported quinazolin-4(3*H*)-ones could be obtained by employing DMSO as solvent instead of EtOH, which was utilized to prepare 2,3-dihydroquinazolin-4(1*H*)-ones in the same protocol [23], novel flexible strategies for selective synthesis of 2,3-dihydroquinazolin-4(1*H*)-ones and quinazolin-4(3*H*)-ones without toxicity, unavailable or expensive agent should benefit both synthetic and medicinal chemistry in terms of Green Chemistry.

As an oxidant, iodine is widely used for the oxidation of alcohols, aldehydes, sulfides, and amines; for the oxidation to aromatics; for the introduction of protecting groups; for the deprotection, and so on [24]. Meanwhile, iodine has a wide range of application as a mild Lewis acid catalyst in organic synthesis, such as the Michael addition, the mannich reaction, the hantzsch reaction and many other transformations [25,26]. However, a literature survey suggested that few studies have been performed on applying both the oxidizing and catalyzing abilities of iodine simultaneously to organic functional group conversions. As a cheap, less toxic, easily accessible, and eco-benign reagent, iodine would be more practical for organic synthesis if the selectivity could be controlled quantificationally via modulating the ratio in as much as the oxidizing ability require more iodine to fulfill. Herein, we would like to disclose a versatile procedure for the fabrication of mono substituted quinazolin-4(3*H*)-ones and 2,3-dihydroquinazolin-4(1*H*)-ones selectively in the presence of different ratio of iodine.

## RESULTS AND DISCUSSION

Following our continued interest in the iodine-catalyzed MCRs [26a–d], 20 mol % of iodine was initially selected to catalyze the model reaction of isatoic anhydride, 1.2 equiv. of ammonium acetate, and 4-methoxybenzaldehyde in refluxing ethanol, aimed at obtaining the compound **N**1. After 40 min stirring, the white flocs were totally precipitated from the reaction solution, the final pure product yielded in 63% after work up, unexpectedly melted at 241°C, which is the melt point of compound **M**1 exactly. Subsequent $^1$H NMR and LC-MS analysis certified that the white floc was just **M**1. Therefore, the optimization of the reaction conditions was carried out. First, the addition order of reactants was considered. As the enamine could be formed *in situ* and thus influence the yield of desired product, the aldehyde was added at last to the stirring solution at room temperature, which was increased to refluxing temperature as soon as possible, to our delight, the yields of product **M**1 could be up to 86%. With these conditions in hand, the solvent, ratio of **A** and $AcONH_4$, and the iodine concentration were screened subsequently. The results in Table 1 showed that refluxing the **A**, 4-methoxylbenzaldehyde and $AcONH_4$ rationed at 1:1:1.2 in the presence of 20 mol % of iodine about 25 min would provide the best result. Increasing the iodine amounts was ineffective for improvement of final yields. Interestingly, product **N**1 was detected and increased with the iodine concentration decreased from 20 mol % (Table 1, Entries 6–9), the pure product **N**1 could not be obtained until the amount of iodine reduced to 5 mol %, which was the right concentration to catalyze this three-compound reaction to give product **N**1, more iodine may present the oxidizing ability, resulting in mixed products of **M**1 and **N**1 (Table 1, Entries 8 and 9). As all the reactions were exposed in air, the $O_2$ may play the role of oxidant in the preparation of **M**1, so we employed the $N_2$ as an inert gas to perform the reaction (Table 1, Entry 7), and found that only the oxidated product **M**1 was detected in the reaction mixture by LC-Ms, which indicate that the catalytic iodine (20 mol %) played the roles of both catalyst and oxidant. Preliminary results unprecedentedly implied that we can selectively construct the structure of **M**1 and **N**1 promoted by 20 and 5 mol % of iodine, respectively.

In a comprehensive study, a sampling of the aldehydes was employed to explore the scope of this one-pot three-component reaction under optimal conditions (Table 2). Generally, all of the aldehydes participated smoothly and afforded the desired products in good to excellent yields, except for the 4-nitrobenzaldehyde yielded in 77% of **M** and 56% of **N** (Table 2, Entry 9 and 15). According to LC-MS monitoring of reaction mixtures, the benzylaldehyde and aromatic aldehydes bearing 4-Cl, 2-Cl, 4-Br demand more iodine to furnish the pure product **M** (Table 2, Entry 2, 4, 5, 8). The reaction time was slightly extended in the cases of producing pure product **N**.

[a] Reaction conditions: 1 equiv. of aldehyde(5 mmol) was added to the solution containing **A**(5 mmol), iodine, and 1.2 equiv. of $AcONH_4$(5 mmol) at room temperature, which was then increased the to refluxing temperature.
[b] Isolated yield
[c] Determined by LC-MS

Besides, benzylaldehyde and 3-chlorobenzaldehyde provide somewhat lower yields and probable reason for this may be the lack of electron-influence.

Encouraged by these successes, we evaluated orthoester and *p*-toluidine for the MCR performance to furnish 3-substituted quinazolin-4(3*H*)-ones **E** and 2,3-dihydroquinazolin-4(1*H*)-ones **F** under the same conditions. Fortunately, the desired product 3-*p*-tolylquinazolin-4(3*H*)-one was favourably generated in 78% yield (Table 3, Entry 1). Thereafter, 5 mol % of iodine was tested aiming at constructing the structure 3-*p*-tolylquinazolin-2,3-dihydroquinazolin-4(1*H*)-one **F** (Fig. 1), whereas the same product 3-*p*-tolylquinazolin-4(3*H*)-one was obtained again in a 99% LC yield (Table 3, Entry 2). After carefully literature search, it was found that all of the methods reported [9,10,21] starting from orthoester were apt to form quinazolin-4(3*H*)-ones, for this may be the potential hydrogen-acquiring ability of —OEt dissociated from orthoester. Further attempt to optimize the conditions suggested that increasing the amount of amine up to 1.5 equiv. and replace the EtOH with $H_2O$ could improve the yield up to 89% and shorten the reaction time. As the pure product should be crystallized from EtOH, we chose EtOH as the solvent to exam other representative aromatic amine. As shown in Table 3, all of the substrates were compatible and the aromatic amine possessing electron-withdrawn group would lead to longer reaction time and slightly lower yield (Table 3, Entry 3).

In conclusion, we have developed a novel and versatile method for the first time to selectively synthesize 2-substituted-quinazolin-4(3*H*)-ones and 2-substituted-2,3-dihydroquinazolin-4(1*H*)-ones from isatoic anhydride, primary amine and various aldehydes in one-pot MCR protocol via modulating the iodine concentration, and also prepared 3-substituted-quinazolin-4(3*H*)-ones under the same conditions in the presence of 5 mol % of iodine. All of the reactions provided good to excellent yields of products that could be crystallized from the reaction solution. The operational simplicity, conditional generality, electively controllability made this method attractive to extensive application in organic chemistry.

## EXPERIMENTAL

The isatoic anhydride and iodine were obtained from commercial suppliers and used without further purification. All of the products are known and their physical data, mass data, and $^1H$

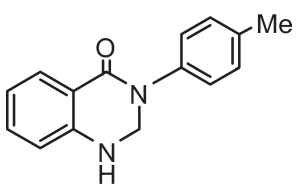
| 4 | H | EtOH | 5 | 55 | 84 |

[a] Reaction conditions: 1 equiv. of othoester(5 mmol) was added to the solution containing **A**(5 mmol), iodine, and aromatic amine at room temperature, which was then increased the to refluxing temperature.
[b] Isolated yield.
[c] 1 equiv. of *p*-toluidine was added.
[d] 1.5 equiv. of *p*-toluidine was added.

NMR were essentially identical with those of authentic samples. Mass spectra were taken on an Agilent LC-MS 1100 series instrument in the electrospray ionization (positive ESI) mode. $^1$H NMR spectra were recorded at 300 MHz in DMSO-*d*6, and chemical shifts were reported in ppm from internal TMS (δ).

**The typical procedure for the preparation of 2-substituted-quinazolin-4(3*H*)-ones M.** 4-methoxylbenzaldehyde (0.68 g, 5 mmol), was added to the stirring solution containing **A**(0.815 g, 5 mmol), iodine(0.253 g, 1 mmol), and $AcONH_4$(0.462 g, 6 mmol) at room temperature in EtOH, then refluxing the mixture, after 25 min the white solid precipitated and EtOH was added till the solid dissolved again. The mixture was cooled to room temperature and the white flocs were crystallized slowly. After simple filtration and dryness, the product **M**1 was yielded in 86% (1.09 g, white flocs, m.p. 241°C). 2-(4-Methoxyphenyl)quinazolin-4(3*H*)-one (Table 2, Entry 1): $^1$H NMR(300 MHz, DMSO-*d*6) δ 3.81 (s, 3H), 7.04–7.07 (d, 2H), 7.42–7.47 (m, 1H), 7.65–7.68 (d, 1H), 7.76–7.78 (m, 1H), 8.08–8.11 (d, 1H), 8.14–8.17 (d, 2H), 12.53 (br s, NH); MS ($ES^+$) *m*/*z* 253(M + H); 2-(4-Chlorophenyl)quinazolin-4(3*H*)-one (Table 2, Entry 2): $^1$H NMR(300 MHz, DMSO-*d*6) δ 7.52–7.57 (m, 1H), 7.62–7.65 (m, 2H), 7.74–7.76 (d, 1H), 7.83–7.88 (m, 1H), 8.15–8.22 (m, 3H), 12.83 (br s, NH); MS ($ES^+$) *m*/*z* 257(M + H).



**F**

**Figure 1.** The expected structure 3-*p*-tolylquinazolin-2,3-dihydroquinazolin-4(1*H*)-one **F**.

The 2-substituted-2,3-dihydroquinazolin-4(1*H*)-ones **N** were synthesized by a similar procedure except that 5 mol % of iodine(0.063 g, 0.25 mmol) was used. The products **N** were white flake. 2-(4-Methoxyphenyl)-2,3-dihydroquinazolin-4(1*H*)-one (Table 2, Entry 12): $^1$H NMR(300 MHz, DMSO-*d*6) δ 3.73 (s, 3H), 5.68 (s, 1H), 6.66–6.74 (m, 2H), 6.92 (d, 2H), 6.94 (s, NH), 7.23 (m, 1H), 7.39–7.41 (d, 2H), 7.58–7.60 (d, 1H), 8.21 (s, NH); MS ($ES^+$) *m*/*z* 255(M + H); 2-(4-Chlorophenyl)-2,3-dihydroquinazolin-4(1*H*)-one (Table 2, Entry 12): $^1$H NMR(300 MHz, DMSO-*d*6) δ 5.78 (s, 1H), 6.69–6.77 (m, 2H), 7.16 (s, NH), 7.22–7.28 (m, 1H), 7.44–7.53 (m, 4H), 7.60–7.63 (m, 1H), 8.36 (s, NH); MS ($ES^+$) *m*/*z* 259(M + H).

**The typical procedure for the preparation of 3-substituted-quinazolin-4(3*H*)-ones E.** Orthoester (5 mmol) was injected slowly into the stirring solution of **A**(0.815 g, 5 mmol), iodine(0.063 g, 0.25 mmol) and *p*-toluidine (0.8 g, 7.5 mmol) in EtOH at room temperature, increasing the temperature and refluxing the mixture 25 min followed by adding hot ethanol to further dissolve the solid formed, the product **E** was precipitated from the homogeneous solution slowly with the temperature decreased. Simple filtration and dryness would afford the pure 3-*p*-tolylquinazolin-4(3*H*)-one (1.04 g, 88%, white solid, m.p. 146–148°C) (Table 3, Entry 1): $^1$H NMR(300 MHz, DMSO-*d*6) δ 2.40 (s, 3H), 7.35–7.44 (m, 4H), 7.57–7.62 (m, 1H), 7.73–7.76 (d, 1H), 7.85–7.91 (m, 1H), 8.19–8.21 (d, 1H), 8.32 (s, 1H); MS ($ES^+$) *m*/*z* 237(M + H); 3-(4-Methoxyphenyl)quinazolin-4(3*H*)-one (Table 3, Entry 2): $^1$H NMR(300MHz, DMSO-*d*6) δ 3.83 (s, 3H), 7.09–7.12 (m, 2H), 7.45–7.48 (m, 2H), 7.57–7.62 (m, 1H), 7.73–7.75 (m, 1H), 7.85–7.91 (m, 1H), 8.18–8.21 (m, 1H), 8.31 (s, 1H); MS ($ES^+$) *m*/*z* 253(M + H).

Compound of 4-(ethoxycarbonyl)-1,5-diphenyl-1*H*-pyrazole-3-carboxylic acid **2** was obtained from the reaction of ethyl 4,5-dioxo-2-phenyl-4,5-dihydrofuran-3-carboxylate and 1-benzylidene-2-phenylhydrazine. A number of substitute pyrazole dicarboxylic acid derivatives (**4, 5a–c, 6, 7, 8, 9a–m, 10, 11, 12, 13, 14**) were synthesized from 1,5-diphenyl-1*H*-pyrazole-3,4-dicarboxylic acid **3** which was prepared from basic hydrolysis of **2**. Structures of synthesized compounds were characterized by $^{1}$H NMR, $^{13}$C NMR, Mass, FTIR, and elemental analysis.

## INTRODUCTION

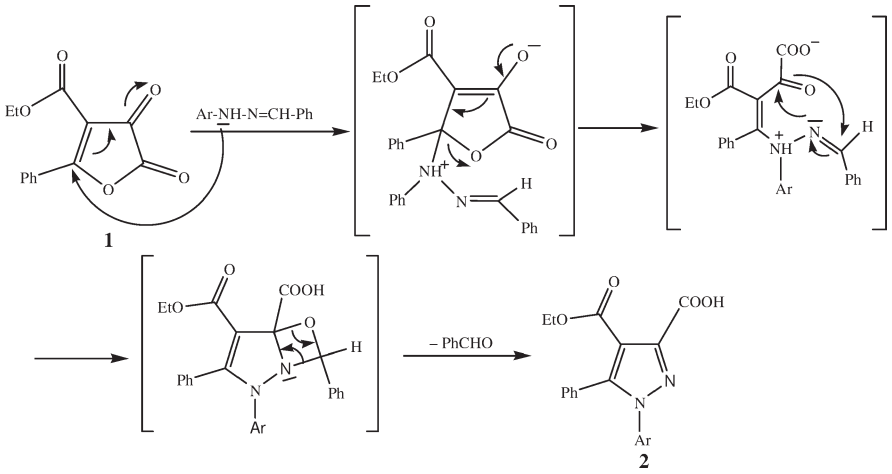
The chemistry of pyrazole derivatives have been the subject of much research because of their importance in various applications and their widespread potential biological and pharmacological activities such as antimicrobial, antiviral, antitumor, anti-inflammatory, pesticidal, antifungal, antidepressant, antipyretic, and analgesic [1–10]. Thus, these compounds have been the focus of high attention among medicinal chemists [11–16]. It is also known that biological activities of pyrazole derivatives which include substituted heteroaryl groups increase and that some pyrazolo-pyridazine compounds which include the same heteroaryl groups are used as a cure for many diseases [17–25].

Pyrazole-3-carboxylic acid derivatives in general are well-known nitrogen-containing heterocyclic compounds, and various procedures have been developed for their syntheses [26–31]. In the literature, there is not much research related to the reactions of derivatives of 1,5-diphenyl-1*H*-pyrazole-3,4-dicarboxylic acids although a number of new derivatives of pyrazoles some of which have bicyclic structure were synthesized [26–29]. In this research, we decided to extend our previous studies to satisfy this deficiency and to synthesize different derivatives of pyrazole compounds that show biological activity [20,21,26,29].

## RESULTS AND DISCUSSION

1,5-Diphenyl-1*H*-pyrazole-3,4-dicarboxylic acid **3**, which was our initial compound, was prepared after various reaction steps. First, ethyl 4,5-dioxo–2-phenyl-4,5–dihydrofuran–3-carboxylate **1** compound was prepared from the reactions of ethyl 3-oxo-3-phenylpropanoate and oxalyl dichloride [32,33]. Keeping in mind that H-active nucleophiles attack the C-2, C-3, and C-4 positions of furandiones and it starts the reactions in which intermediate products were formed, NH group attacks to

**Scheme 1**

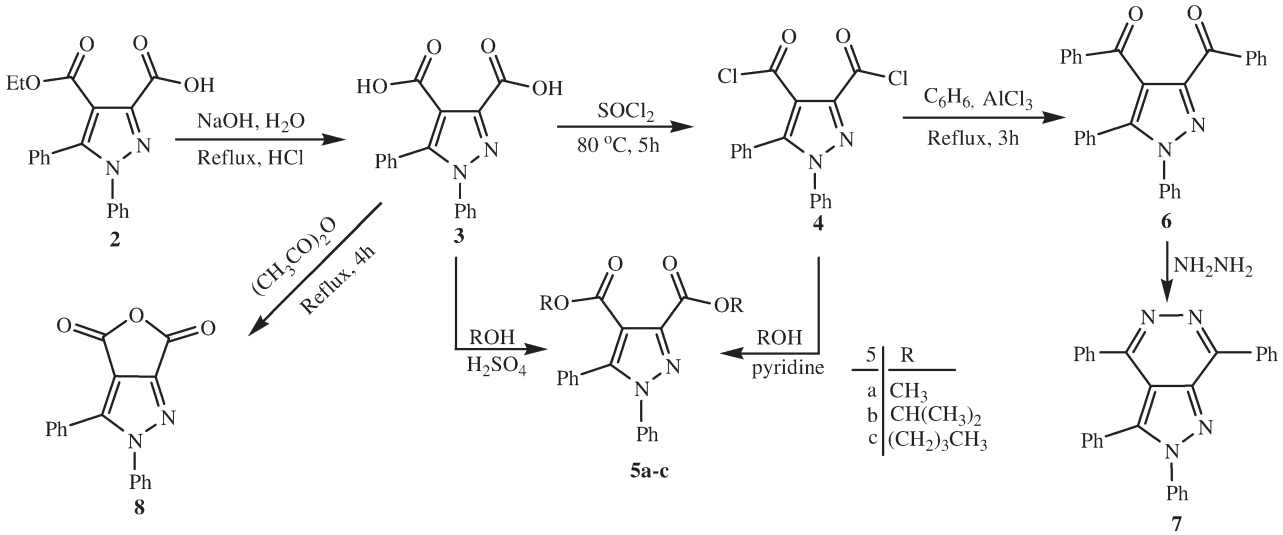


C-3 and C-4 positions of furandione in the condensation reaction of **1** with 1-benzylidene-2-phenylhydrazine in no solvent media [26,27,30]. The possible reaction steps of 4-(ethoxycarbonyl)-1,5-diphenyl-1H-pyrazole-3-carboxylic acid **2** was given in Scheme 1.

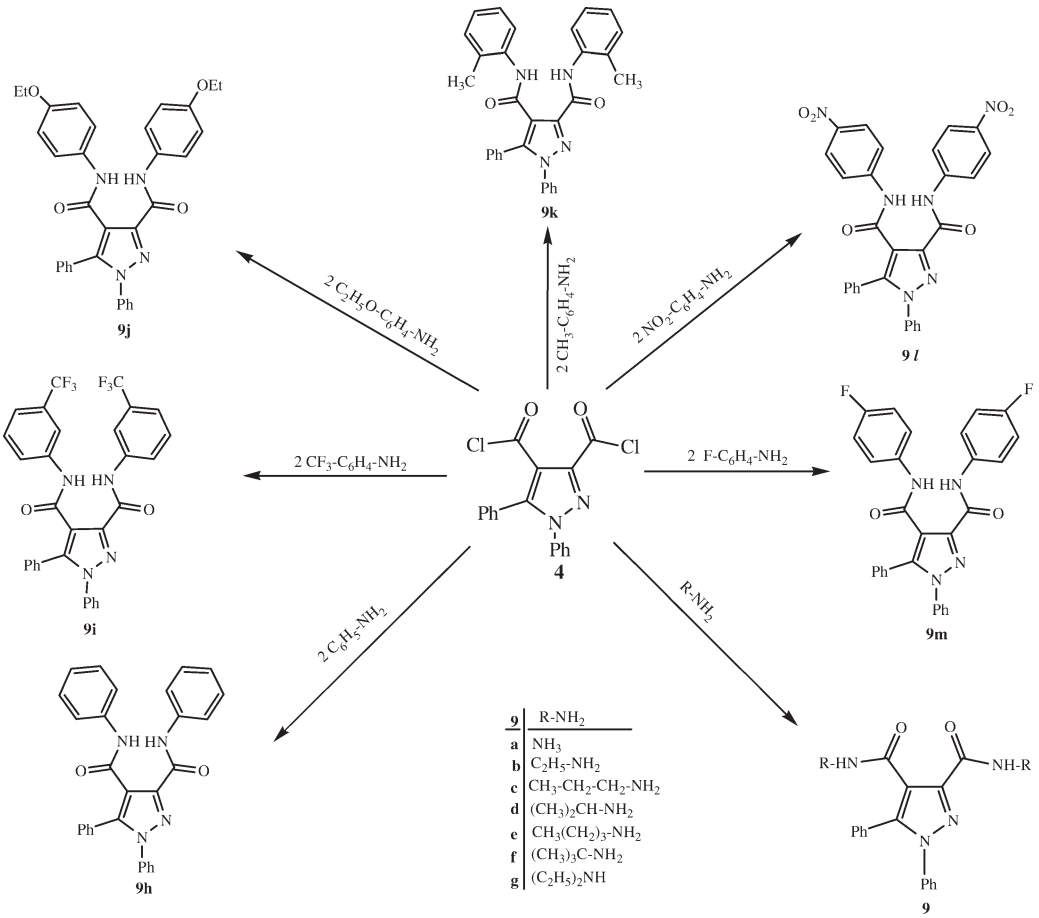
1,5-Diphenyl-1*H*-pyrazole-3,4-dicarboxylic acid **3** compound was prepared from the basic hydrolysis of **2** at a high yield (92%). The long reaction time increased the yield. The structure was confirmed with the characteristic IR absorption bands at 3354–2454 $cm^{-1}$ (COOH), 3064 $cm^{-1}$ (Ar CH ), 1670 $cm^{-1}$ (acid, C=O), 1597–1486 $cm^{-1}$ (C=C and C=N) and the $^{13}C$ NMR signals at $\delta = 163.75$ and $\delta = 164.61$ (acid, C=O). 306 m/z (M-2) value in mass spectra for **3** showed the existence of molecular ion structure.

Diester derivatives of Compound **3** were obtained in two different methods. In the first method, carboxylic groups of **3** were activated with $SOCl_2$ and gave the **4**. Afterward, the diester derivatives **5a–c** were obtained from the reaction of **4** with various alcohols with pyridine catalyst. However, it was understood from TLC works that synthesized products by this method contained impurity. This impurity was probably resulted from pyridine and was difficult to remove. In the second method, compound **3** gave the purer diester products **5a–c** about in yield of 61–75%. For this reason, the compound **3** was heated with various alcohols in benzene with sulfuric acid catalyst (Scheme 2). The second method was chosen in this study. On the other hand, heating the compound **4** in dry benzene with $AlCl_3$

**Scheme 2**



**Scheme 3**



catalyst [34] gave 1-phenyl-1H-pyrazole-3,4-diyl) bis(phenylmethanone **6** (Scheme 2).

$NH_2$ groups of hydrazine which have strong nucleophilic property attacks to benzoyl carbons when the compound **6** was heated with anhydrous hydrazine. In the second stage, cyclization occurred with the removal of two moles water, and pyrazolo-pyridazine derivative **7** was obtained (Scheme 2).

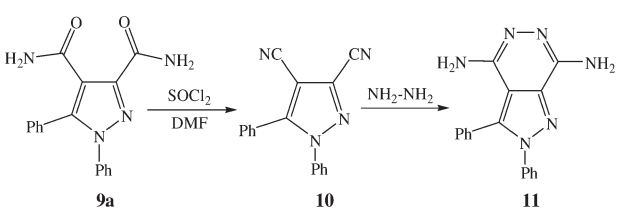
Moreover, heating of **3** in acetic anhydride caused the leaving of one mole water. As a result of this, furo[3,4-c] pyrazole-4,6-dione **8** (Scheme 2) was synthesized [35–37]. However, it was also observed from TLC controls that this compound was very sensitive to oxidation in air and returned to its initial compound. Therefore, it is suitable to handle this compound in desiccator by being dried with $P_2O_5$.

Derivatives of pyrazole-3,4-dicarboxamide **9a–m** were prepared easily by reaction of **4** with ammonia, substituted aryl amines, and a series of alkyl amines (Scheme 3). Structures of the compounds were confirmed with spectral data.

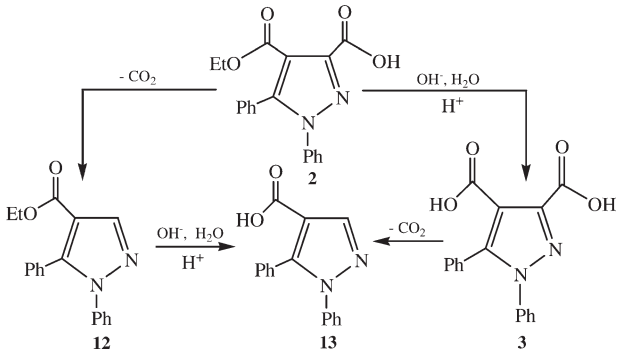
As a result of dehydration of **9a** in cold DMF and $SOCl_2$ mix, dinitrile **10** compound occurred at 96% yield [20,26]. Compound **10** showed characteristic IR absorption band at 2231 $cm^{-1}$ (C≡N). IR spectra of compound **10** showed no absorption bands corresponding to the COOH group such as 3300–2500 $cm^{-1}$ (COOH) and 1700–1750 $cm^{-1}$ (acid, C=O) like the 1,5-diphenyl-1*H*-pyrazole-3,4-dicarboxylic acid. Furthermore, $^{13}C$ NMR signals at $\delta$ = 110.77–110.80 ppm were related to carbon of nitrile (C≡N).

Reaction of **10** with anhydrous hydrazine in absolute ethanol led to the formation of the 2,3-diphenyl-2H-pyrazolo[3,4-d]pyridazine-4,7-diamine **11** in about 69% yield (Scheme 4). Structure of the compound was confirmed with spectral data (See Experiments).

**Scheme 4**



**Scheme 5**



As a result of decarboxylation of **2** at high temperature (200–220°C), the compound **12** was obtained and the compound **13** was synthesized after basic hydrolysis of **12**. It was understood from TLC and spectral data that basic hydrolysis of **12** and decarboxylation of **3** gave the same products 1,5-diphenyl-1*H*-pyrazole-4-carboxylic acid **13**. After decarboxylation of **3**, it was shown that leaving carboxyl group bonded the adjacent carbon to nitrogen (Scheme 5).

On the other hand, cyclo-condensation reaction of **2** and **5a** with hydrazine hydrate gave the same product pyrazolo[3,4-d]pyridazine-4,7-dione **14** [6,26]. IR, $^1$H NMR, and $^{13}$C NMR spectra [IR: 3158–2629), $^1$H NMR: 10.40 (br. s, 1H, NH—C=O), 5.30 (br. s, 1H, N=C—OH), $^{13}$C NMR: 161.79 and 161.58 (C=O, C-4), 156.58 and 152.33 (C=O, C-7)] showed evidence of the presence of a tautomeric equilibrium (HN—C=O↔N=C—OH) between the two tautomers (keto-enol) of compound **14** (Scheme 6).

In this research, a number of derivatives of substituted pyrazole dicarboxylic acids were gained to pyrazole chemistry and characterization of each compound were performed with the help of spectral data (See Experiments).

## EXPERIMENTS

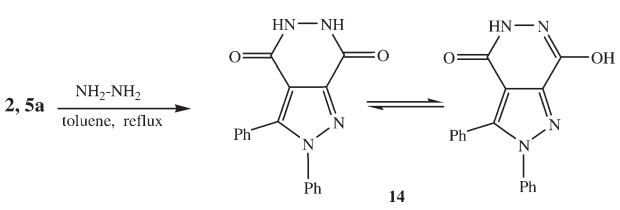
The optimum reaction conditions were determined considering the time, concentration, solvent, and structure of reactive compounds which were effective on yield and velocity of chemical reactions. Chemical compounds used in this research were at analytical purity, and the solvents were purified by using appropriate purifying agents and distillation. At the end of the each experiment, TLC was performed using DC Alufolien Kiesegel 60F/254 Merck and Camag TLC devices. Melting points were measured with Barnstead Electrothermal 9200 apparatus and were not corrected. IR spectrum data of compounds were determined by Mattson 1000 FTIR with using of KBr pellets. $^1$H NMR and $^{13}$C NMR spectra were evaluated by BRUKER DPX-400, (400MHz), and High Performance Digital FT-NMR (100MHz) spectrometers. Mass spectra data were determined by Varian Mat III 80 eV. Elemental analyses were carried out on a Leco CHNS-932 instrument.

**1,5-Diphenyl-1*H*-pyrazole-3,4-dicarboxylic acid (3).** Compound **2** of 0.336 g (1 mmol) was refluxed in solution of 0.1 g (2.5 mmol) NaOH for about 1.5 h. Mixed solution was cooled down to room temperature. It was stirred for a while by adding 1.5 mL concentrated HCl and water at equal volume. Precipitated white solid product was filtered and washed with water again. It was purified from water–ethanol mixture by crystallization. (283 mg, 92%); mp 224–225°C; IR (ν, cm$^{-1}$): 3354–2454 (OH, COOH), 3064 (CH, aromatic), 1670 (C=O), 1597–1486 (C=C and C=N); $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm): 7.27–7.40 (m, 10H, ArH); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm): 164.61 and 163.76 (C=O, acid), 144.85 (C–3), 144.31(C–5), 116.14 (C–4), 138.93, 130.53, 129.74, 129.52, 129.21, 128.67, 128.54, 126.32; MS(CI) m/z 306.0 (M–2, $COO^-$); Anal. Calcd. for $C_{17}H_{12}N_2O_4$: C, 66.23; H, 3.92; N, 9.09. Found: C, 66.56; H, 3.65; N, 9.12.

**1,5-Diphenyl-1*H*-pyrazole-3,4-dicarbonyl dichloride (4).** Compound **3** of 0.308 g (1 mmol) was refluxed with excessive $SOCl_2$ at 80°C for about 5 h. Excessive $SOCl_2$ was evaporated. Remaining oily product was purified in ether–hexane mixture. (259 mg, 75%); mp 86–89°C; IR (ν, cm$^{-1}$): 3060 (CH, aromatic), 1735 (C=O), 1620–1487 (C=C and C=N); $^1$H NMR (400 MHz, $CDCl_3$) δ (ppm): 7.00–7.72 (m, 10H, ArH); $^{13}$C NMR (100 MHz, $CDCl_3$) δ (ppm): 161.39 and 161.09 (C=O), 146.54 (C–3), 143.96 (C–5), 120.35 (C-4), 137.82, 130.60, 130.09, 129.56, 129.35, 128.90, 126.13, 125.51; Anal. Calcd. for $C_{17}H_{10}Cl_2N_2O_2$: C, 59.15; H, 2.92; N, 8.12. Found: C, 59.35; H, 2.79; N, 8.10.

**General procedure for compounds 5a–c.** Compound **3 of** 1 mmol was dissolved in 10 mL dry benzene, and 2 mL alcohol (MeOH, *i*-PrOH, BuOH) and 0.2 mL $H_2SO_4$ was added to this solution. Mixture was refluxed for 4–5 h. After evaporation, some water was added to the product remaining at the bottom of the flask and transferred to separate funnel. 10 mL of ether was added

**Scheme 6**



to the mixture and was washed with 10% $Na_2CO_3$ solution. Ether was evaporated after separation of organic phase. The synthesized crude products **5a–c** were purified from hexane.

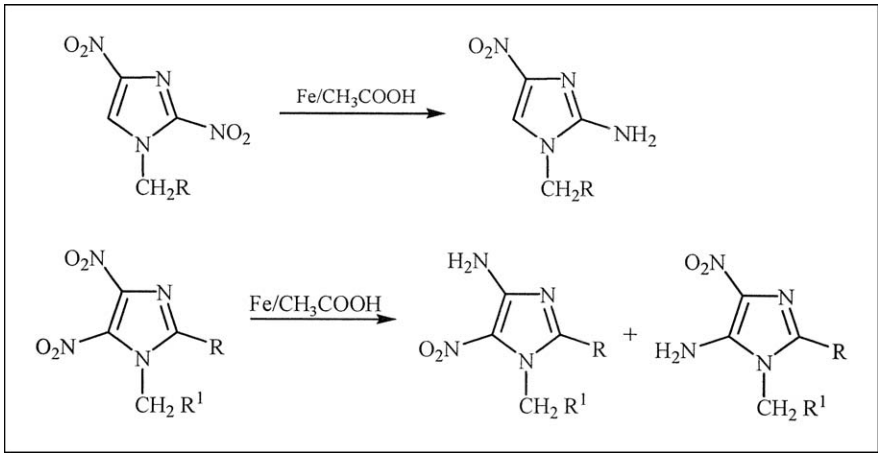
Received November 23, 2009
DOI 10.1002/jhet.418
Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



A series of *N*-substituted 2,4-dinitroimidazoles, 4,5-dinitroimidazoles, and 2-methyl-4,5-dinitroimidazoles have been selectively reduced to the corresponding aminonitroimidazole derivatives, using iron dust in glacial acetic acid at room temperature. 2,4-Dinitroimidazoles have been reduced to the 2-amino-4-nitro-derivatives only but 4,5-dinitroimidazoles have given 4-amino-5-nitro- or 5-amino-4-nitro-derivatives depended on the structure of the *N*-substituent.

*J. Heterocyclic Chem.,* **47**, 1049 (2010).

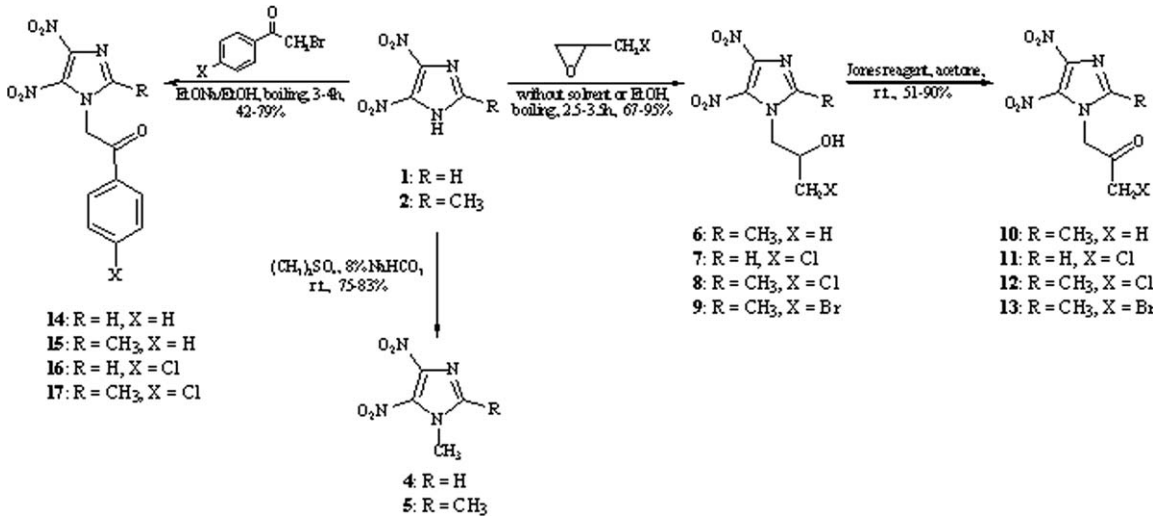
## INTRODUCTION

Imidazoles and their derivatives are very important group of compounds for their pharmacological properties [1,2]. Particularly, the nitroimidazole class of medicines mainly shows activity against bacteria [3,4]. Also, these drugs have become the important agents for treatment of serious infections caused by protozoa. Some of them have been tested against HIV [5]. 2-Nitroimidazoles played a major role as bioreductive markers for tumour hypoxia [6] and as radiosensitizers [7,8]. Our earlier investigations have been devoted to synthesis and antifungal as well as antibacterial properties of *N*-phenacyl-4,5-dinitroimidazole and 4-substituted amino-5-nitroimidazole derivatives, which have been prepared by nucleophilic displacement of the nitro group in 4,5-dinitroimidazole derivatives by primary or secondary amines [9,10].

Reduction of the nitro compounds has been one of the most important reactions in organic chemistry used as a routine method for the preparation of various nitrogen derivatives such as amines, nitrosocompounds, or hydroxylamines. The reported reduction methods of aromatic nitro compounds to prepare amino derivatives are very numerous. The reduction of the nitroazoles is readily achieved by using of one of many possible reagents like for instance iron in an acidic medium [11,12], hydrogen in the presence of palladium [13,14], Raney nickel [15] sodium borohydride [16]. Only limited number of all reduction methods have described the selective reduction of one nitro group in dinitro-compounds with remain unchanged of other functional groups. For example, reduction of 2,4-dinitrophenol using sodium sulfide has led to 2-amino-4-nitrophenol [17], but 4-amino-2-nitro-carboxamide mustard have been obtained by selective 4-nitro group reduction of 2,4-dinitrobenzamide derivative with $SnCl_2$ in concentrated HCl [18]. Lin and Sun [17] have found that using either Zn in $HCOONH_4$ or tin (II) chloride dihydrate can deliver traceless synthesis of 2-quinoxalinone analogues, an *o*-nitroaniline intermediate without further reduction of another nitro group under microwave irradiation or by conventional heating.

Products of reductions of nitroimidazole derivatives exhibit potential biological significance and are intermediates in syntheses of a variety of biologically active imidazoles. The compounds containing amino group in azoles ring can show good antimicrobial activity. In particular, the introduction of a bromine or two chlorine atoms or one phenyl group to the phenyl ring, except for the amino group in 2-amino-4(5)-arylimidazoles

**Scheme 1**



leads to compounds provided some antimicrobial activity [19]. Moreover, compound with the amino and the nitro groups have played important role as potent inhibitor of Coxackie virus B3 replication [20]. Synthetic 2-aminoimidazole derivatives including 2-aminohistamine have shown to have $H_1$ and $H_2$ receptor agonist and antagonist activity. Other 2-aminoimidazole derivatives are selective 5-$HT_3$ receptor antagonists, which may be potentially useful in the treatment of chemotherapy induced emesis [21]. Imidazole alkaloids containing the amino group at *C*-2 position in the heterocyclic ring also show interesting biological property such as anthelminthic activity (dorimidazole A, preclathridine A) [1].

## RESULTS AND DISCUSSION

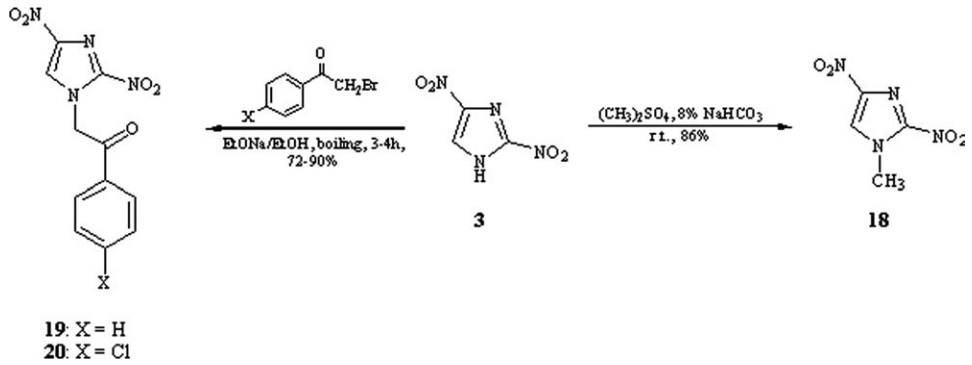
The reduction of *N*-substituted 2,4-dinitroimidazole, 4,5-dinitroimidazole, and 2-methyl-4,5-dinitroimidazole to the corresponding aminonitroderivatives by use of iron dust in glacial acetic acid at room temperature exhibits high selectivity. It is very surprising that iron dust in an acidic medium is capable of reducing one nitro group without further reduction of second nitro group. It is known that iron in the presence of acid is not selective agent [11]. In our experiments, treatment of dinitroimidazole derivatives with iron dust afforded, after purification, the crystalline aminonitro-compounds. Stability of these compounds depended on the position of the amino group, decreased in a series of 2-amino, 5-amino and 4-amino compounds.

The starting 4,5-dinitroimidazole (**1**), 2-methyl-4,5-dinitroimidazole (**2**), and 2,4-dinitroimidazole (**3**) were prepared according to the methods described in the literature [22,23]. The *N*-substituted derivatives of 4,5-dinitroimidazoles (**4–17**) were obtained in the reaction of **1** or **2** with $(CH_3)_2SO_4$, epoxypropane, epichlorohydrin, or phenacyl bromides in accordance with the method described in the literature [9,23,24]. The *N*-(2-hydroxypropyl) and *N*-(3-chloro-2-hydroxypropyl) compounds (**6–8**) were oxidized by Jones reagent to the desired carbonyl derivatives (**10–12**) [24]. Additionally, 2-methyl-4,5-dinitroimidazole was alkylated with epibromohydrin according to the method described for prepared epichlorohydrin derivatives [9]. The treatment of **2** with an excess of epibromohydrin (1:2) under reflux without solvent for about 3 h led to new 1-(3-bromo-2-hydroxypropyl)-2-methyl-4,5-dinitroimidazole (**9**). This new derivative was oxidized by Jones reagent to the 1-(3-bromo-2-oxopropyl)-2-methyl-4,5-dinitroimidazole (**13**) in accordance with the method described earlier [24]. Synthesis of *N*-substituted 4,5-dinitroimidazole derivatives **4–17** is shown in the Scheme 1.

Also, the 2,4-dinitroimidazole (**3**) was put on the reactions with $(CH_3)_2SO_4$ and phenacyl bromides according to the methods described in the literature [9,23,25]. The reactions of **3** with appropriate reagents resulted in the formation of *N*-substituted derivatives of 2,4-dinitroimidazole (**18–20**), as shown in the Scheme 2.

The *N*-methyl (**18**) and *N*-phenacyl derivatives of 2,4-dinitroimidazole (**19,20**) in the reduction gave only respective 2-amino-4-nitroimidazole with yield 54–82% (Scheme 3). When the reaction was complete, the excess of iron and its oxidation products were filtered off and the reaction mixture was diluted with water. The 2-amino-1-methyl-4-nitroimidazole (**21**) was isolated by extraction. After removal of the solvent, the crude product was crystallized. The precipitated crude reduction products (**22, 23**) were filtered off. A large, lipophilic phenacyl group facilitated obtaining the aminonitroderivatives. Reduction

**Scheme 2**



of *N*-substituted 2,4-dinitroimidazole derivatives **18**–**20** is shown in the Scheme 3.

The structures of **21–23** were confirmed by full spectral data. The infrared spectra showed absorptions at about 3400 and 3265 $cm^{-1}$ and also 1560 and 1300 $cm^{-1}$ indicative for the N—H and $NO_2$ resonances, respectively. The mass spectra exhibit strong molecular ions at 142, 246, and 280, respectively. In addition to the molecular ions, in spectra of compounds **22** and **23** strong signal (rel. int. 100%) corresponding to ion from phenacyl (*m*/*z* 105) or *p*-chlorophenacyl group (*m*/*z* 139) was observed. In the $^1H$ NMR spectra, the signals of the amino groups are as singlets at about 6.30 ppm, $CH_2$ protons of the phenacyl groups resonated as singlet at 5.56 and 5.54 ppm. The aromatic protons at *C*-5 position of the imidazole ring were observed at about 7.84 ppm.

Reduction of 4,5-dinitroimidazole alkyl derivatives led to *N*-alkylaminonitroimidazoles, as well. The iron dust in glacial acetic acid reduced with facility one nitro group but the second remained unreactive. In the same conditions, mixture of two isomers: 4-amino-5-nitro- and 5-amino-4-nitro- with predomination of the latter mentioned were formed (Scheme 4). The 4,5-diaminoimidazoles were not observed in the reaction mixtures. Formation of the aminonitroimidazoles depended on the position of the new formed amino group and yielding of 4-amino-compounds was the poorest. The low efficiency in reduction reactions of 4,5-dinitroimidazole alkyl derivatives probably is connected with structures and stability of compounds obtained. Moreover, the isolation of pure, definite, aminonitroderivatives was very inconvenient. Some of them were obtained after complex extraction, then purification by column chromatography and additional crystallization.

Reduction of *N*-substituted 4,5-dinitroimidazole derivatives **4**,**5**,**7–17** is shown in the Scheme 4.

Reaction of the compounds containing *N*-methyl group (**4, 5**) with iron dust afforded 4-amino-5-nitroimidazoles (**24, 25**) only that were separated after extraction with chloroform. In the reduction of the *N*-halohydroxypropyl derivatives (**7–9**) were formed 5-amino-4-nitro-compounds (**26–28**). These substances were obtained as solid products. Other 4,5-dinitroimidazoles (**10–17**) containing the carbonyl group in the chain

at *N*-1 position of the imidazole ring provided mainly 4-amino-5-nitro- derivatives, after extraction **(29–34, 36, 37**). Only in the reduction of 2-methyl-4,5-dinitro-1-phenacylimidazole (**15**) and (**17**), the mixtures of two products were obtained. After reduction of **15**, isomers: 4-amino-2-methyl-5-nitro-1-phenacylimidazole (**34**) and 5-amino-2-methyl-4-nitro-1-phenacylimidazole (**35**) were obtained. Compound **35** was separated by the filtration and purified by crystallization. Dominating product, **34**, was obtained after extraction and was purified by column chromatography. Similarly, the 4-amino-1-(*p*-chlorophenacyl)-2-methyl-5-nitroimidazole **(37**) and 5-amino-1-(*p*-chlorophenacyl)-2-methyl-4-nitroimidazole **(38**) were obtained as products of the reduction of 1-(*p*-chlorophenacyl)-2-methyl-4,5-dinitroimidazole (**17**). These derivatives were separated by column chromatography. In all cases, 4,5-diamino derivatives were not observed.

The infrared spectra of **24–38** showed absorptions at about 3400 and 3260 $cm^{-1}$ and also 1560 and 1300 $cm^{-1}$ indicative for the N—H and $NO_2$ resonances, respectively. The mass spectra confirmed that only one nitro group in the dinitroimidazoles was reduced. The $^1H$ NMR spectra of new products provided evidence for the presence of the amino group. The $NH_2$ protons were observed as a singlet at about 7.40 ppm (**24, 25**) or within the range of 7.57–7.71 ppm (**26–38**). In the $^{13}C$ NMR spectra of **26–28**, signal for the carbon jointed with hydroxyl group was near 67 ppm. Moreover, the signal corresponded to the C=O group of **29–38** resonated in the range of 190.88–201.22 ppm. The position of the amino group in **26–38** was connected with the place of a signal of a methylene group at *N*-1 position of the heterocylic ring. In the $^{13}C$ NMR of **26–28**, the signal in the range 46.29–47.09 ppm was assigned to the $CH_2$ group. It is also observed that in the $^{13}C$ NMR of **29–32**, the resonances due to $CH_2$ occurred in the range 52.21–54.40 ppm. It is very interesting that the signals of the methylene groups of the pairs **34, 35** and **37, 38** occurred at different values: 52.01 and 50.27 ppm or 51.96 and 49.65 ppm, respectively. In the spectra of 5-amino-4-nitro-products, the signals of the carbons in the imidazole ring appeared in lower values, too. Additionally, the X-ray structures determination of the pair of isomers (**34,35**) facilitated the interpretation of NMR data and to determine the position of the amino group. The geometry of the molecules confirmed that the compound **35** is 5-amino-4-nitro- derivative but the second is 4-amino-5-nitro-isomer (**34**). The results obtained were in agreement with our interpretation of NMR spectra. The signals of the methylene group and carbon atoms of the imidazole ring of the all 5-amino-4-nitro compounds were shifted toward the lower field.

In conclusion, we have demonstrated very selective nitro group reduction method in the dinitroimidazole derivatives using iron dust in the acetic acid solution at room temperature. This method provided the products with the amino and the nitro group simultaneously. The presence of an electron-donating amino group at a position neighbouring to the nitro group can have influence on the many biological properties, which depended on the kind of substituents at positions *N*-1 and *C*-2 in the heterocyclic ring, as well.

To recapitulate, the *N*-derivatives of 2,4-dinitroimidazoles were reduced only to the 2-amino-4-nitro compounds. It was found that the reduction process among the *N*-derivatives of 4,5-dinitroimidazoles is more complicated, but it concerns mainly the 4-$NO_2$ group. Nitro group at *C*-5 position of imidazole ring is susceptible to reduction when there is a hydroxy group in the *N*-1 alkyl chain connected with tetrahedral carbon atom. Probably, some specific trigonal arrangements have the influence on the direction of nitro group reduction process.

## EXPERIMENTAL

Melting points were determined on a Boetius apparatus and were uncorrected. The $^1H$ and $^{13}C$ NMR spectra were recorded on Varian Gemini 300 VT spectrometer (300 and 75 MHz respectively). Chemical shifts (δ) are expressed in ppm, relative to tetramethylsilane (TMS) as an internal standard, using DMSO–$d_6$ as solvents. Coupling constants (*J* values) are expressed in Hertz (Hz). Splitting patterns are designated as follows: s, singlet; d, doublet; t, triplet; m, multiplet. MS spectra were recorded on a 402 AMD INTECTRA apparatus by the electron impact technique, operating at 75 eV. The infrared (IR) spectra were recorded in KBr tablets using a Specord 75–IR spectrophotometer and were expressed in $cm^{-1}$ scale. Elemental analysis was performed on a Vario EL III model of elemental analyzer and data of C, H, and N were within ±0.4% of calculated values. The progress of reactions and purity of products were controlled with thin-layer chromatography method (TLC) on silica gel plates (60 $F_{254}$ from Merck) in a $CHCl_3$/MeOH (9:1, v/v) as a developing system. The spots on the plates were observed in the UV light (λ = 254nm). Solid products of amino-nitro-derivatives were purified in the crystallization process using acetonitrile. Crude, oily products were purified by column chromatography on silica gel using the mixture of chloroform and methanol (50:0 → 50:5) as eluent. Among substances, which were used as substrates, the epichlorohydrin, epoxypropane, epibromohydrin, phenacyl bromides, and iron dust were commercial products. Compounds **4–8, 10–12**, and **14–18** were obtained according to the literature method [9,23–25].

**1-(3-Bromo-2-hydroxypropyl)-2-methyl-4,5-dinitroimidazole (9).** The 2-methyl-4,5-dinitroimidazole (3.44 g, 20 mmol) was added to epibromohydrin (3.42 mL, 40 mmol). The mixture was heated under reflux for about 3 h. Then, cooled and poured into the water. The precipitate was filtered off, washed with water, air-dried and crystallized from 40% EtOH as yellow needles; 5.40 g (87.5%); mp 103–105°C; $R_f$ = 0.64; IR: 3380, 1520, 1340; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 5.92 (m, 1H, OH), 4.49 (m, 1H, CH), 4.21 and 4.00 (2 m, 2H,

$CH_2Br$), 3.59 (m, 2H, N-$CH_2$), 2.49 (s, 3H, $CH_3$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 145.42, 139.29, 130.68, 67.97, 50.09, 35.81, 13.72; ms: m/z 308 (2) and 310 (2) ($M^+$), 182 (100.0); Anal. calc. for $C_7H_9N_4O_5Br$: C, 27.29; H, 2.94; N, 18.19; found: C, 27.25; H, 2.98; N, 18.22.

**1-(3-Bromo-2-oxopropyl)-2-methyl-4,5-dinitroimidazole (13).** To a solution of **9** (3.10 g, 10 mmol) in acetone (50 mL), at room temperature was dropped Jones reagent (10 mL). After 24 h, *i*-PrOH (10 mL) was added. The dark green precipitate was filtered and washed with a small volume of acetone. The combined filtrates were poured into the water (200 mL) and the solution was held 2–3 days to afford the crystalline solid. The precipitate was filtered off, washed with water, air-dried, and crystallized from MeOH as yellow needless; 2.32 g (76.0%); mp 117–119°C; $R_f$ = 0.64; IR: 1720, 1510, 1380; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 5.54 (s, 2H, $CH_2$), 4.59 (s, 2H, $CH_2Br$), 2.43 (s, 3H, $CH_3$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 193.95, 146.10, 140.06, 129.42, 53.28, 33.62, 13.31; ms: m/z 308 (15) and 306 (16) ($M^+$), 156 (100); Anal. calc. for $C_7H_7N_4O_5Br$: C, 27.47; H, 2.92; N, 18.31; found: C, 27.52; H, 2.97; N, 18.28.

**General procedure for synthesis of *N*-phenacyl-2,4-dinitroimidazole derivatives (19–20).** The solution of Na (1.38 g, 60 mmol) in absolute EtOH (40 mL) was added dropwise under stirring to a solution of 2,4-dinitroimidazole (**3**) (7.90 g, 50 mmol) in absolute ethanol (50 mL). Subsequently, a solution of phenacyl bromide or *p*-chlorophenacyl bromide (50 mmol) in absolute ethanol (100 mL) was dropped and heated under reflux for 4 h. The mixture was cooled and the precipitate was filtered off, air-dried, and crystallized from EtOH.

***2,4-Dinitro-1-phenacylimidazole (19).*** This compound was obtained as cream needles (EtOH), 12.50 g (90.6%); mp 123–125°C; $R_f$ = 0.64; IR: 1680, 1526, 1320; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 8.72 (s, 1H, 5-Im), 8.09 (m, 2H, 2,6-Ph), 7.76 (m, 1H, 4-Ph), 7.66 (m, 2H, 3,5-Ph), 6.27 (s, 2H, $CH_2$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 190.84, 142.30, 141.69, 134.87, 133.34, 129.27, 128.27, 126.86, 57.24; ms: *m*/*z* 276 (28) ($M^+$), 105 (100); Anal. calc. for $C_{11}H_8N_4O_5$: C, 47.86; H, 2.92; N, 20.29; found: C, 47.90; H, 2.94; N, 20.32.

***1-(*p*-Chlorophenacyl)-2,4-dinitroimidazole (20).*** This compound was obtained as cream needles (EtOH), 11.20 g (72.2%); mp 154–156°C; $R_f$ = 0.62; IR: 1680, 1526, 1320; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 8.71 (s, 1H, 5-Im), 8.12 (m, 2H, 2,6-Ph), 7.74 (m, 2H, 3,5-Ph), 6.26 (s, 2H, $CH_2$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 190.02, 142.29, 141.65, 139.80, 132.05, 130.18, 129.42, 126.85, 57.16; ms: m/z 312 (11), 310 (32) ($M^+$), 139 (100); Anal. calc. for $C_{11}H_7N_4O_5Cl$: C, 42.61; H, 2.27; N, 18.07; found: C, 42.58; H, 2.24; N, 18.10.

**General procedure for synthesis of Aminonitroimidazoles (21–38).** Appropriate *N*-substituted 2,4-dinitro-, 4,5-dinitro-, or 2-methyl-4,5-dinitroimidazole derivatives (2 mmol) were dissolved in glacial AcOH (25 mL), and the excess of iron dust (0.37 g, 6.60 mmol) was added. The resulting mixtures were then left for about 3 days at room temperature shaking them from time to time. Upon completion reaction, the excess of iron and its oxidation products were filtered off, and the reaction mixtures were diluted with water (75 mL). The precipitated crude products were filtered off. If products not solidified, then the filtrate was extracted with $CHCl_3$ (4 × 5 mL) and the combined organic phases were dried ($MgSO_4$), filtered off. After removal of the solvents, the crude product was purified by column chromatography on silica gel. All new products were crystallized from MeCN.

***2-Amino-1-methyl-4-nitroimidazole (21).*** This compound was obtained as yellow needles (MeCN), 0.15 g (53.6%); mp 216–218°C; $R_f$ = 0.18; IR: 3425, 3265, 1627, 1554, 1300; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 7.88 (s, H, 5-Im), 6.23 (s, 2H, $NH_2$), 3.44 (s, 3H, $CH_3$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 149.38, 143.29, 119.93, 32.30; ms: m/z 142 (68) ($M^+$), 42 (100); Anal. calc. for $C_4H_6N_4O_2$: C, 33.82; H, 4.25; N, 39.44; found: C, 33.86; H, 4.20; N, 39.42.

***2-Amino-4-nitro-1-phenacylimidazole (22).*** This compound was obtained as yellow needles (MeCN), 0.40 g (81.3%); mp 243–245°C; $R_f$ = 0.41; IR: 3400, 3270, 1680, 1627, 1560, 1295; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 8.03 (m, 2H, 2,6-Ph), 7.84 (s, H, 5-Im), 7.73 (m, H, 4-Ph), 7.60 (m, 2H, 3,5-Ph), 6.31 (s, 2H, $NH_2$), 5.56 (s, 2H, $CH_2$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 192.16, 149.51, 143.63, 134.34, 134.06, 128.92, 128.11, 119.67, 51.83; ms: m/z 246 (14) ($M^+$), 105 (100); Anal. calc. for $C_{11}H_{10}N_4O_3$: C, 53.68; H, 4.09; N, 22.76; found: C, 53.73; H, 4.11; N, 22.81.

***2-Amino-1-(*p*-chlorophenacyl)-4-nitroimidazole (23).*** This compound was obtained as yellow needles (MeCN), 0.42 g (75.0%); mp 260–262°C; $R_f$ = 0.43; IR: 3375, 3265,1675, 1634, 1565, 1285; $^1H$ NMR (300 MHz, DMSO–$d_6$): δ = 8.05 (m, 2H, 2,6-Ph), 7.82 (s, H, 5-Im), 7.70 (m, 2H, 3,5-Ph), 6.33 (s, 2H, $NH_2$), 5.54 (s, 2H, $CH_2$); $^{13}C$ NMR (75 MHz, DMSO–$d_6$): δ = 191.33, 149.48, 143.64, 138.87, 133.03, 130.00, 129.05, 119.54, 51.83; ms: m/z 282 (6) and 280 (18) ($M^+$), 139 (100); Anal. calc. for $C_{11}H_9N_4O_3Cl$: C, 47.17; H, 3.23; N, 20.00; found: C, 47.15; H, 3.26; N, 20.05.

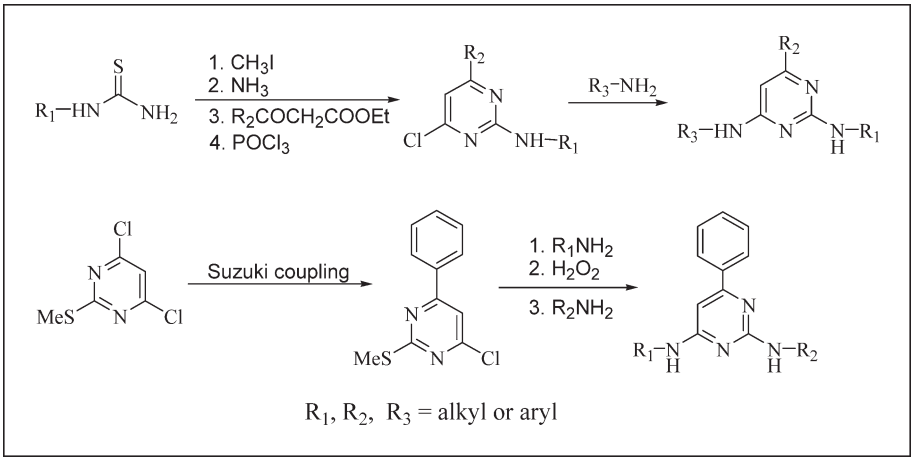
Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



Facile methods were developed to prepare a series of 6-phenyl and 6-alkyl-2,4-diaminopyrimidine derivatives. The pyrimidine ring of the final products was constructed by treatment of a 1,3-dicarbonyl derivative with an amidine or guanidine. The 6-phenyl-pyrimidine derivatives were also prepared by Suzuki coupling reaction, using 2-methylthio-4,6-dichloropyrimidine as the starting material.

## INTRODUCTION

As part of our efforts in search of malaria prophylactic and/or therapeutic agents, a series of imidazolidinedione (IZ) derivatives was found to possess profound activity against liver stage malarias in rodent and nonhuman primate models [1–4]. Subsequently, the IZ compounds were found to metabolize to *s*-triazine derivatives in microsomal preparations and in rodents [4]. Active in mice tests, the *s*-triazines were considered the active metabolite of the IZ compounds. This finding prompted us to develop methods to prepare a series of *N,N′*-di-substituted 2,4-diamino-1,3,5-triazines and 2,4-diamino-pyrimidine derivatives as potential antimalarial agents. This report focused on the method development for the synthesis of the latter class of compounds.

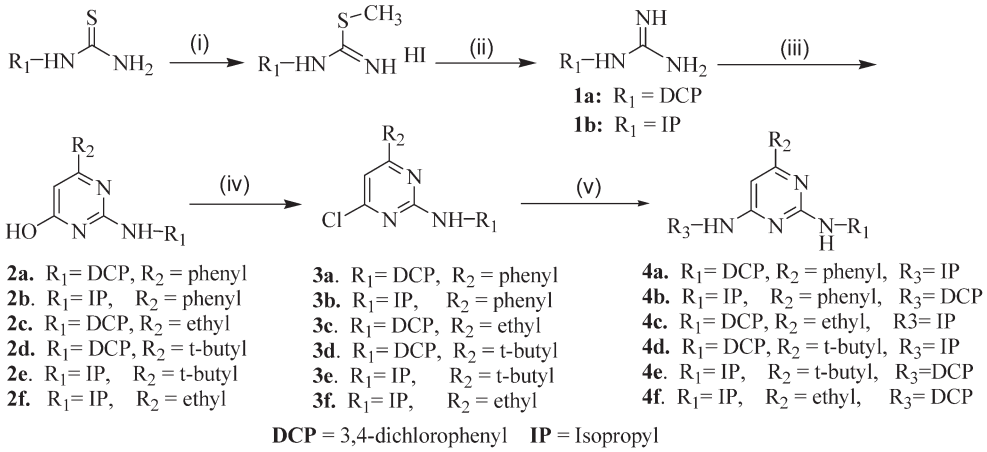
Polyamino-pyrimidines play a very important role in biological and pharmaceutical chemistry. A number of applications as therapeutic agents have been documented [5]. The most general method for the synthesis of 2,4,6-trisubstituted pyrimidines involves the treatment of two essential starting materials, a 1,3-dicarbonyl component and a N—C—N fragment such as urea, amidine, or guanidine [6,7]. The other method involved Suzuki coupling or Grignard reactions to insert various aryl or alkyl groups into 2,4,6-trichloropyrimidine [8] followed by stepwise amination with appropriate amines.

In this study, facile methods were developed to prepare substituted 6-alkyl or 6-aryl-2,4-diaminopyrimidines.

## RESULTS AND DISCUSSION

Methods were developed to prepare substituted 6-alkyl or 6-arylpyrimidine-2,4-diamines. The pyrimidine ring of the desired products was constructed by condensation of a 1,3-dicarbonyl component with an amidine, isopropylguanidine, or 3,4-dichloroguanidine as shown in Scheme 1. The hydroxypyrimidines (**2a–f**) obtained were converted to the corresponding chloropyrimidines (**3a–f**) in high yields with phosphorus oxychloride [9–11]. The amination of chloropyrimidine derivatives was achieved via acid- or base-mediated nucleophilic substitution [12]. Hartung et al. reported that the chloro group of chloropyrimindines can be easily displaced with an aromatic amine under acidic conditions, but it can only be displaced by an aliphatic amino group under basic

**Scheme 1.** Synthesis of 6-phenyl or alkyl-2,4-diaminopyrimidine derivatives.

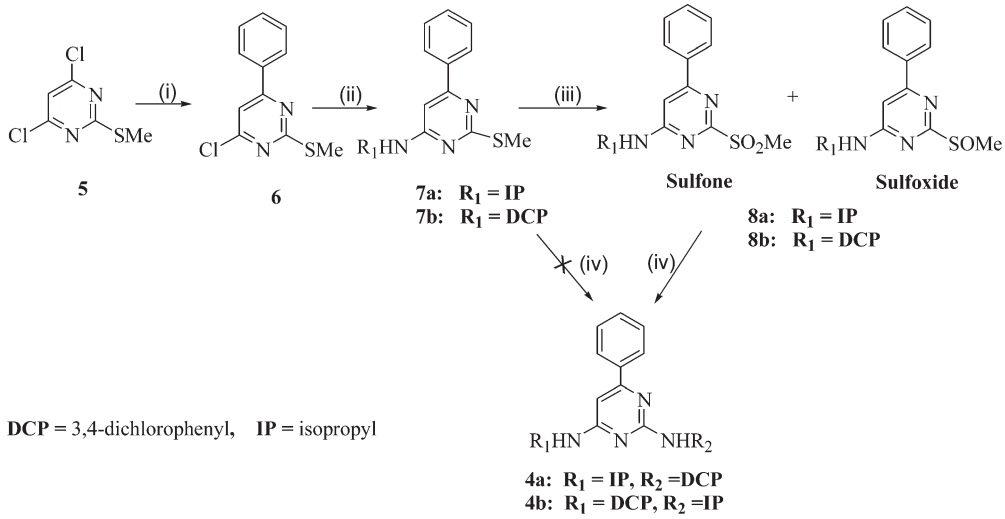


*Reagents and Conditions*: (i) $CH_3I$, acetone, reflux; (ii) $NH_3$, EtOH, 100 °C; (iii) $R_2COCH_2COOEt$, DMF, 100 °C, 48hr; (iv) $POCl_3$; (v) $R_3NH_2$, 110 °C.

conditions [12]. The method was adapted to insert the 3, 4-dichloroanilino, and the isopropylamino groups into the pyrimidine ring in high yield under the acidic and basic conditions, respectively (Scheme 1). Likewise, 4-alkyl analogs **4c–f** were prepared using ethyl propionylacetate or ethyl pivaloylacetate as 1,3-dicarbonyl component.

The Suzuki coupling method was an alternative approach used to make the 2,4-diamino-6-phenylpyrimidine derivatives (**4a** and **4b**) (Scheme 2). Initially, the Suzuki coupling reaction was attempted using 2,4,6-trichloropyrimidine as the starting material to introduce a phenyl group at either the 4- or 6-position, followed by amination. However, the success of this approach depends on the relative reactivity of the 2- and 4-chloro groups toward amination reactions, allowing for insertion of an amino group selectively to either 2- or 4-position of the pyrimidine ring. Although the Suzuki reaction of 2,4,6-trichloropyrimidine gave a good yield of 2,4-dichloro-6-phenyl-pyrimidine, the followed up

**Scheme 2.** Method involved Suzuki reaction on 4,6-dichloro-2-methylthiopyrimidine.



*Reagents and Conditions*: (i) $C_6H_5B(OH)_2$, $Pd(OAC)_2II$, TPP, $Na_2CO_3$, Glyme, reflux, 18h; (ii) $R_1NH_2$, 1-butanol, reflux, 6h; (iii) 30% $H_2O_2$, $NaWO_4$, EtOAc/toluene (1:1 v/v), 0 °C for 30 min then RT for 2h; (iv) $R_2NH_2$, neat, 140 °C, 2h.

amination gave a mixture consisting almost equal amount of 2-amino- and 4-aminopyrimidine derivatives. The low selectivity of 2,4-dichloro-6-phenyl-pyrimidine in the amination reaction led us to use 4,6-dichloro-2-methylthio-pyrimidine as the starting material. On treatment with phenylboronic acid in the presence of triphenylphosphine and palladium acetate, 4,6-dichloro-2-methylthio-pyrimidine (**5**) gave 4-chloro-2-methylthio-6-phenylpyrimidine (**6**) in very high yield. The first amination of compound **6** gave intermediate **7a** or **7b** readily, whereas the second amination on the 2-methylthio group failed to produce the desired products **4a** and **4b** [13–15]. Thus, oxidative activation of the 2-methylthio group in **7a** and **7b** was necessary before the amination reaction on the 2-position can be carried out. The oxidation was achieved by treatment of the 2-methylthiopyrimidine derivative with hydrogen peroxide under the catalysis of sodium tungstate dehydrate [14,15]. The mixture of sulfone and sulfoxide (**8**) formed was used without purification for further reactions with 3, 4-dichloroaniline or isopropylamine to give the products **4a** (11%) and **4b** (84%), respectively. The striking disparity in yields between **4a** and **4b** is, most likely, a result of difference in nucleophilicity of the two amines used.

The major difference between the two methods used in Scheme 1 (Method 1) and Scheme 2 (Method 2) to prepare compounds **4a** and **4b** is the order of introduction of 2-amino, 4-amino-, and 6-phenyl groups to the pyrimidine ring. The former method assembled the 2-amino and the 6-phenyl groups during the formation of the pyrimidine ring followed by insertion of the arylamino or alkylamino group at either 2- or 4-posion under the acidic or basic conditions, respectively. The overall yield of the Method 1 is good and the reaction conditions are mild. The latter method as described in Scheme 2 started from the commercially available starting material 4,6-dichloro-2-methylthio-pyrimidine. The 6-phenyl substituent was constructed first by the Suzuki coupling reaction followed by stepwise amination reactions to yield the substituted 2, 4-diamino-6-phenylpyrimidines **4a** or **4b**. The yield of the 2nd nucleophilic substitution reaction is good when alkylamines were used, but poor when aromatic amines were the nucleophiles.

In conclusion, the method described in Scheme 1 is superior to that of Scheme 2 for the preparation of the desired pyrimidine derivatives **4a-f**, with better yield, milder reaction conditions and cheaper reagents.

## EXPERIMENTAL

Melting points were determined on a Mettler FP62 melting point apparatus and are uncorrected. Analytical thin layer chromatography (TLC) was performed using HPTLC-HLF normal phase 150 microns silica gel plates (Analtech, Newark, DE). Visualization of the developed chromatogram was performed by UV absorbance, or spreading with aqueous potassium permanganate or ethanolic anisaldehyde. Liquid chromatography was performed using a Horizon HPFC System (Biotage, Charlottesville, VA) with Flash 25M or 40M cartridges (KP-Sil™ Silica, 32–63 μm, 60 Å). Preparative TLC was performed using silica gel GF Tapered Uniplates (Analtech, Newark, DE). $^1$H NMR and $^{13}$C NMR spectra were recorded in deuteriochloroform, unless otherwise noted, on a Bruker Avance 300 spectrometer (Bruker Instruments, Wilmington, DE). Chemical shifts are reported in parts per million on the δ scale from an internal standard of tetramethylsilane. Combustion analyses were performed by Atlantic Microlab, (Norcross, GA). Where analyses are indicated by symbols of the elements, the analytical results obtained were within +/− 0.4% of the theoretical values.

**2-(3,4-Dichlorophenylamino)-4-hydroxy-6-phenylpyrimidine (2a).** Ethyl benzoylacetate (15 mL) was added dropwise to a suspension of 3,4-dichlorophenylguanidine (**1a**, 7.23g. 35.4 mmol) [2] in 100 mL of anhydrous DMF. The mixture was heated at 100°C for 48 h. After cooling, the reaction mixture was poured into 500 mL of ice water. The precipites were collected, washed with water, and dried to give 64% yield of compound **2a** as a pink solid. The product was used for further reactions without purification. $^1$H NMR ($CD_3OD$): δ 8.24 (d, 1H, $J$ = 2.4Hz), 8.00 (m, 2H), 7.57 (m, 2H), 7.47 (m, 3H), 6.45 (s, 1H). ms: $m/z$ 331 ($M^+$).

**4-Hydroxy-2-isopropylamino-6-phenylpyrimidine (2b).** Ethyl benzoylacetate (11.7 mL) was added dropwise to a suspension of isopropylguanidine (**1b**) [2] (2.3 g, 22.7 mmol) in 50 mL of anhydrous DMF. The reaction mixture was heated at 100°C for 3 days. After cooling, the solution was poured into crushed ice water. The mixture was extracted with EtOAc three times and the EtOAc extracts were combined, washed with water, and brine successively, dried over $Na_2SO_4$ and evaporated to dryness in vacuole. The residue was applied to a silica gel flash column and eluted with 2.5% MeOH in $CHCl_3$ to give 35% yield of compound **2b** as a white solid. $^1$H NMR ($CDCl_3$): δ 8.01 (d, 2H, $J$ = 3.6 Hz), 7.48 (m, 3H), 6.24 (s, 1H), 4.37 (m, 1H), 1.36 (d, 6H, $J$ = 6.6 Hz). ms: $m/z$ 229 ($M^+$).

**2-(3,4-Dichlorophenylamino)-6-ethyl-4-hydroxy-pyrimidine (2c).** Compound **2c** was prepared by the same method for the preparation of **2a**, using ethyl propionylacetate as starting material to yield 75% of **2c** as a white solid. $^1$H NMR ($CD_3OD$) δ 8.06 (d, 1H, $J$ = 2.2 Hz), 7.46 (dd, 1H, $J$ = 2.2 Hz, 8.7 Hz), 7.42 (d, 1H, $J$ = 8.7 Hz), 5.82 (s, 1H), 2.54 (q, 2H, $J$ = 7.5 Hz), 1.25 (t, 3H, $J$ = 7.5 Hz). ms: $m/z$ 283 ($M^+$).

**6-*t*-Butyl-2-(3,4-dichlorophenylamino)-4-hydroxy-pyrimidine (2d).** The title compound was prepared by the same method as for the preparation of **2a**, using ethyl pivaloylacetate as starting material to yield 60% of **2d** as an off-white solid. $^1$H NMR ($CD_3OD$): δ 8.22 (s, 1H), 7.41 (m, 2H), 5.93 (s, 1H), 1.28 (s, 9H). ms: $m/z$ 311 ($M^+$).

**6-*t*-Butyl-4-hydroxy-2-isopropylamino-pyrimidine (2e).** Compound **2e** was prepared by the same method as for the preparation of **2b**, using ethyl pivaloylacetate as starting material to afford the product as a white solid (33% yield). $^1$H NMR ($CDCl_3$): δ 5.73 (s, 1H), 4.17 (m, 1H), 1.21 (m, 15H). ms: $m/z$ 209 ($M^+$).

**6-Ethyl-4-hydroxy-2-isopropylamino-pyrimidine (2f).** Compound **2f** was prepared by the same method as for the preparation of **2b**, using ethyl propionylacetate as starting material to give 31% yield of the desired product as a white solid. $^1$H NMR ($CDCl_3$): δ 6.04 (s, 1H), 4.17 (m, 1H), 2.45 (q, 2H, $J$ = 7.2 Hz), 1.25 (t, 3H, $J$ = 7.2 Hz), 1.21 (d, 6H, $J$ = 6.6 Hz). ms: $m/z$ 181 ($M^+$).

**4-Chloro-2-(3,4-dichlorophenylamino)-6-phenylpyrimidine (3a).** 2-(3, 4-Dichlorophenylamino)-4-hydroxy-6-phenylpyrimidine (**2a**) in 100 mL of $POCl_3$ was stirred at room temperature overnight. The excess $POCl_3$ was removed under reduced pressure to give a gummy residue which solidified upon addition of excessive amount of crushed ice. The solid was purified by silica gel flash column chromatography, eluting with 10% EtOAc in hexane to afford the desired compound **3a** in 82% yield as a light yellow solid. $^1$H NMR ($CDCl_3$): δ 8.07 (m, 3H), 7.56 (m, 3H), 7.46 (m, 1H), 7.42 (d, 1H, $J$ = 8.7 Hz), 7.24 (s, 1H). ms: $m/z$ 349 ($M^+$).

**4-Chloro-2-isopropylamino-6-phenylpyrimidine (3b).** The title compound was prepared by the same method for the preparation of **3a**, using hydroxyl intermediate **2b** as the starting material giving the desired 4-chloro product **3b** as light yellow oil in 47% yield. $^1$H NMR ($CDCl_3$): δ 8.01 (d, 2H, $J$ = 3.6 Hz), 7.48 (m, 3H), 6.97 (s, 1H), 4.28 (m, 1H), 1.27 (d, 6H, $J$ = 6.5 Hz). ms: $m/z$ 247 ($M^+$).

**2-(3,4-Dichlorophenylamino)-4-chloro-6-ethylpyrimidine (3c).** The title compound was prepared by the same method as for the preparation of **3a**, using compound **2c** as the starting material, to give 75% yield of the desired compound as off-white solid. $^1$H NMR ($CDCl_3$,): δ 8.06 (s, 1H), 7.38 (s, 1H), 7.10 (s, 1H), 6.70 (s, 1H), 2.70 (q, 2H, $J$ = 7.5 Hz), 1.30 (t, 3H, $J$ = 7.5 Hz). ms: $m/z$ 301 ($M^+$).

**6-*t*-Butyl-4-chloro-2-(3,4-dichlorophenylamino)-pyrimidine (3d).** Compound **3d** was prepared by the same method as for the preparation of **3a**, using **2d** as the starting material to give 83% yield of the product as off-white solid. $^1$H NMR ($CDCl_3$): δ 8.01 (s, 1H), 7.38 (s, 2H), 6.83 (s, 1H), 1.38 (s, 9H). ms: $m/z$ 329 ($M^+$).

**6-*t*-Butyl-4-chloro-2-isopropylamino-pyrimidine (3e).** Compound **3e** was prepared from **2e** using the same method as for the preparation of **3a**; giving 50% yield of the desired compound as white oil. $^1$H NMR ($CDCl_3$): δ 6.55 (s, 1H), 4.97 (brs, 1H), 4.15 (m, 1H), 1.25 (m, 15H). ms: $m/z$ 227 ($M^+$).

**4-Chloro-6-ethyl-2-isopropylamino-pyrimidine (3f).** Compound **3f** was prepared by the same method as for the preparation of **3a**, starting from **2f** to get the desired compound as white oil in 47% yield. $^1$H NMR ($CDCl_3$): δ 6.44 (s, 1H), 5.04 (brs, 1H), 4.15 (m, 1H), 2.58 (q, 2H, $J$ = 7.2 Hz), 1.25 (m, 9H). ms: $m/z$ 199 ($M^+$).

**2-(3,4-Dichlorophenylamino)-4-isopropylamino-6-phenylpyrimidine.HCl (4a)**

***Method 1.*** 4-Chloro-2-(3,4-dichlorophenylamino)-6-phenylpyrimidine (**3a**, 5g) in 100 mL of isopropylamine was heated in a sealed tube at 110°C overnight. Upon cooling, the reaction mixture was poured into ice water and the mixture was extracted with EtOAc three times. The EtOAc extracts were combined, washed with brine, dried over $Na_2SO_4$ and concentrated. The residue was applied to a silica gel flash column and eluted with hexane: EtOAc (10:1, v/v) to give the desired product **4a** as light yellow solid in 90% yield, mp 277.6°C (decomposed). $^1$H NMR ($CDCl_3$): δ 8.16 (br, 1H), 7.95 (m, 2H), 7.47 (m, 3H), 7.33 (d, 2H, $J$ = 1.8 Hz), 7.00 (brs, 1H), 6.28 (s, 1H), 4.72 (s, 1H), 4.14 (m, 1H), 1.32 (d, 6H, $J$ = 6.4Hz). ms: $m/z$ 372 ($M^+$). *Anal*. calcd. for $C_{19}H_{18}Cl_2N_4$.HCl: C, 55.69; H, 4.67; N, 13.67; Cl, 25.96. Found: C, 55.80; H, 4.65; N, 13.66; Cl, 25.90.

***Method 2.*** A mixture of sulfone/sulfoxide **8a** (2.0 g) and 3,4-dichloroaniline (3.34 mL, 3.0 equiv) was heated in a sealed tube at 140°C for 2 h. The mixture was cooled and the crude product was purified by a silica gel flash column, eluting with hexane/EtOAc (4:1 v/v) to give the desired compound **4a** in 11% yield. The NMR and MS spectra data are identical to compound **4a** prepared by method 1 as shown in Scheme 1.

**4-(3,4-Dichlorophenylamino)-2-isopropylamino-6-phenylpyrimidine (4b)**

***Method 1.*** Concentrated hydrochloric acid (1.5 mL) was added to a solution of 4-chloro-2-isopropylamino-6-phenylpyrimidine (**3b**) (886 mg) and 3,4-dichloroaniline (815 mg, 1.5 equiv) in 15 mL of isopropanol. The reaction mixture was heated at 100°C overnight. The crude product was purified by silica gel flash column chromatography and eluted with 2.5% MeOH in $CH_2Cl_2$ to give the desired compound as an off-white solid, yield 97%, mp 79.7°C. $^1$H NMR ($CDCl_3$): δ 7.93 (m, 3H), 7.43 (m, 2H), 7.37 (s, 1H), 7.28 (d, 1H, $J$ = 2.6 Hz), 7.25 (d, 1H, $J$ = 2.6 Hz), 6.48 (s, 1H), 6.36 (s, 1H), 4.98 (br, 1H), 4.25 (m, 1H), 1.32 (d, 6H, $J$ = 6.4 Hz). $^{13}$C NMR: ($CDCl_3$) δ 163.21, 161.89, 161.74, 141.51, 138.41, 131.35, 130.68, 130.27, 129.01, 126.74, 122.72, 120.45, 119.27, 92.51, 79.64, 42.77, 23.00. ms: $m/z$ 374 ($M^+$). *Anal*. calcd. for $C_{19}H_{18}Cl_2N_4$.HCl: C, 55.69; H, 4.67; N, 13.67; Cl, 25.96. Found: C, 55.40; H, 4.62; N, 13.50; Cl, 25.69.

***Method 2.*** The mixture of sulfone/sulfoxide **8b** (3.0g) and isopropylamine (6.21mL, 10.0 equiv) was heated in a sealed tube at 140°C for 20 min. The mixture was cooled and the crude product was purified by silica gel flash column chromatography and eluted with hexane/EtOAc (4:1 v/v) to give compound **4b** in 84% yield. The NMR and MS spectra data are identical to compound **4b** prepared by method 1 as shown in Scheme 1.

**2-(3,4-Dichlorophenylamino)-6-ethyl-4-isopropylamino-pyrimidine (4c).** Compound **4c** was prepared by the same method as for the preparation of **4a**, using **3c** as starting material to give the gummy desired compound. The product was dissolved in anhydrous ether and 2.0*M* HCl ether solution was added to form HCl salt. The HCl salt was recrystallized from hexanes/$CHCl_3$ to give a white solid in 95% yield, mp 211.3°C. $^1$H NMR ($CD_3OD$): δ 8.02 (s, 1H), 7.55 (d, 1H, $J$ = 8.7 Hz), 7.42 (d, 1H, $J$ = 8.7 Hz), 6.05 (s, 1H), 4.24 (m, 1H), 2.65 (q, 2H, $J$ = 7.5 Hz), 1.31 (m, 9H). $^{13}$C NMR ($CDCl_3$): δ 170.9, 162.9, 159.3, 140.2, 132.2, 129.9, 123.8, 120.0, 117.8, 94.0, 42.8, 30.7, 22.8, 12.7. ms: $m/z$ 324 ($M^+$). *Anal*. calcd. for $C_{15}H_{18}Cl_2N_4$: C, 55.39; H, 5.58; N, 17.23; Cl, 21.80. Found: C, 55.18; H, 5.67; N, 16.95; Cl, 22.05.

**6-*t*-Butyl-2-(3,4-dichlorophenylamino)-4-isopropylamino-pyrimidine (4d).** Compound **4d** was prepared by the same method as for the preparation of **4a**, starting from **3d** to give the desired compound in 99% yield as an off-white solid, mp 125.8–126.5°C. $^1$H NMR ($CDCl_3$): δ 8.20 (s, 1H), 7.30 (m, 2H), 7.05 (br, 1H), 5.88 (s, 1H), 4.59 (s, 1H), 4.08 (m, 1H), 1.30 (s, 9H), 1.25 (d, 6H, $J$ = 6.4 Hz). $^{13}$C NMR ($CDCl_3$): δ 177.1, 162.9, 158.9, 140.5, 132.2, 129.9, 123.5, 119.9, 117.5, 91.9, 42.7, 37.1, 19.3, 22.9. ms: $m/z$ 352 ($M^+$). *Anal*. calcd.

for $C_{17}H_{22}Cl_2N_4$: C, 57.79; H, 6.28; N, 15.86; Cl, 20.07. Found: C, 58.01; H, 6.18; N, 15.80; Cl, 20.05.

**6-*t*-Butyl-4-(3,4-dichlorophenylamino)-2-isopropylamino-pyrimidine (4e).** Compound **4e** was prepared by the same method as for the preparation of **4b**, using 6-t-butyl-4-chloro-2-isopropylamino-pyrimidine (**3e**) as starting material to give the desired compound as a white solid in 71% yield, mp 249.5–250.8°C. $^1$HNMR ($CDCl_3$): δ 11.94 (s, 1H), 11.04 (s, 1H), 8.30 (d, 1H, $J$ = 6.9 Hz), 8.25 (s, 1H), 7.71 (d, 1H, $J$ = 8.7 Hz), 7.33 (d, 1H, $J$ = 6.9 Hz), 6.78 (s, 1H), 4.14 (m, 1H), 1.36 (s, 9H), 1.32 (t, 6H, $J$ = 6.5 Hz). ms: $m/z$ 352 ($M^+$). *Anal*. calcd. for $C_{17}H_{22}Cl_2N_4$.HCl: C, 52.39; H, 5.95; N, 14.38; Cl, 27.29. Found: C, 52.46; H, 5.96; N, 14.33; Cl, 27.16.

**4-(3,4-dichlorophenylamino)-6-ethyl-2-isopropylamino-pyrimidine (4f).** Compound **4f** was prepared by the same method as for the preparation of **4b**, using compound **3f** as the starting material to afford the desired compound as a pink solid in 92% yield, mp 251.3°C (decomposed).$^1$H NMR ($CDCl_3$): δ 7.92 (d, 1H, $J$ = 2.5 Hz), 7.33 (d, 1H, $J$ = 8.7 Hz), 7.20 (dd, 1H, $J$ = 2.5Hz, 8.7Hz), 6.47 (br, 1H), 5.80 (s, 1H), 4.82 (d, 1H, $J$ = 7.0 Hz), 4.11 (m, 1H), 2.48 (q, 2H, $J$ = 7.6 Hz), 1.25 (d, 6H, $J$ = 6.5 Hz), 1.21 (t, 3H, $J$ = 7.6 Hz). $^{13}$C NMR ($CDCl_3$): δ 161.7, 158.8, 154.1, 138.7, 131.5, 131.1, 126.3, 122.7, 121.4, 95.9, 43.9, 25.8, 22.3, 11.8. ms: $m/z$ 324 ($M^+$). *Anal*. calcd. for $C_{15}H_{18}Cl_2N_4$.HCl: C, 49.81; H, 5.29; N, 15.49; Cl, 29.41. Found: C, 49.98; H, 5.28; N, 15.52; Cl, 29.31.

**4-Chloro-2-methylthio-6-phenylpyrimidine (6).** A catalytic amount of palladium acetate (0.286 g, 0.05 equiv) and triphenylphosphine (0.668 g, 0.10 equiv) were added to the solution of 4,6-dichloro2-methylthio-pyrimidine (**5**) (5.0 g, 25.42 mmol), phenylboronic acid (3.10 g, 1.0 equiv), and sodium carbonate (8.3 g, 3.1 equiv dissolved in a minium amount of water) in 250 mL of glyme. The reaction mixture was heated to reflux for 18 h, and the solvent was removed under reduced pressure. The crude product was extracted with methylene chloride and the extracts were combined, washed with water three times, dried over $Na_2SO_4$ and evaporated to dryness. The residue was purified by flash column chromatography, using hexane/ethyl acetate as eluent to yield compound **6** as a white solid in 84% yield, mp 59.8°C. $^1$H NMR ($CDCl_3$): δ 8.06 (m, 2H), 7.68 (m, 3H), 7.38 (s, 1H), 1.54 (s, 3H). $^{13}$C NMR ($CDCl_3$): δ 173.55, 165.29, 161.53, 135.31, 131.66, 128.98, 127.35, 111.70, 14.41. ms: $m/z$ 236 ($M^+$).

**4-Isopropyl-amino-2-methylthio-6-phenylpyrimidine (7a).** A suspension of 4-chloro-2-methylthio-6-phenylpyrimidine (**6**, 2.0g) and isopropylamine (1.0 mL, 1.5 equiv) in 100 mL of 1-BuOH was heated under reflux for 6 h. The solution was evaporated to dryness under reduced pressure. The residue was purified by silica gel column chromatography, and eluted with hexane/EtOAc (8:2 v/v) to yield 68% of the desired compound **7a**, mp 89.6°C. $^1$H NMR ($CDCl_3$): δ 7.98 (d, 2H, $J$ = 6.0 Hz), 7.43 (m, 3H), 6.38 (s, 1H), 4.77 (br, 1H), 4.10 (m, 1H), 1.54 (s, 3H), 1.27 (d, 6H, $J$ = 6.4 Hz). $^{13}$C NMR ($CDCl_3$): δ 171.5, 162.7, 162.0, 137.7, 94.9, 42.8, 22.7, 14.0. ms: $m/z$ 259 ($M^+$).

**4-(3,4-Dichlorophenylamino)-2-methylthio-6-phenylpyrimidine (7b).** The title compound was prepared by the same method as for the preparation of **7a** using 3,4-dichloroaniline as nucleophile to give compound **7b** in 65% yield. $^1$H NMR ($CD_3OD$): δ 8.13 (d, 1H, $J$ = 2.4 Hz), 7.82 (m, 2H), 7.62 (m, 3H), 7.57 (s, 1H), 7.54 (d, 1H, $J$ = 2.4 Hz), 6.85 (s, 1H), 2.73 (s, 3H). $^{13}$C NMR ($CD_3OD$):: δ 169.6, 160.3, 157.5, 137.3, 132.1, 131.8, 130.4, 129.1, 127.9 127.1, 123.3, 121.1, 99.7, 13.1. ms: $m/z$: 361 ($M^+$). *Anal*. calcd. for $C_{17}H_{13}Cl_2N_3S$: C, 56.36, H, 3.62, Cl, 19.57, N, 11.60. Found: C, 56.74, H, 3.98, Cl, 20.08, N, 12.10.

**4-Isopropylamino-2-methanesulfonyl/sulfinyl-6-phenylpyrimidine (mixture of sulfone and sulfoxide) (8a).** 4-Isopropylamino-2-methylthio-6-phenylpyrimidine (**7a)** (2.0g, 7.7 mmol) was dissolved in 50 mL of ethyl acetate/toluene mixture. Water (2 ml) was added to the solution followed by a catalytic amount of sodium tungstate dihydrate (0.18 g, 0.1 equiv). The mixture was cooled to 0°C and hydrogen peroxide (30% aqueous solution, 1.69 mL, 10 equiv) was added dropwise. The reaction was stirred for 30 min, warmed to room temperature, and monitored by TLC until the disappearance of the starting material **7a** (~2 h). The mixture was cooled to 0°C again and excess $H_2O_2$ was decomposed carefully by addition of saturated sodium sulfide (20 mL). The organic layer was separated, concentrated under vacuum at 50°C to a volume of 100 mL. The mixture was cooled to room temperature and diluted with hexanes (20 mL). Compound **8a**, as a mixture of sulfone and sulfoxide, precipitated out from the solution, was collected and washed with hexanes to give **8a** in yield 71%. The product was used for further reaction without purification. $^1$H NMR ($CD_3OD$): δ 7.50 (d, 2H, $J$ = 6.0 Hz), 7.27 (m, 3H), 6.77 (s, 1H), 4.77 (m, 1H), 1.59 (s, 6H), 1.32 (d, 6H, $J$ = 6.4 Hz). $^{13}$C NMR (DMSO-d6): δ 166.3, 163.2, 160.7, 136.2, 131.2, 129.4, 127.5, 126.9, 103.1, 98.8, 42.7, 22.4. ms: $m/z$ 291 ($M^+$).

**4-(3,4-Dichlorophenylamino)-2-methanesulfonyl/sulfinyl-6-phenylpyrimidine (mixture of sulfone and sulfoxide) (8b).** Compound **8b** was prepared from **7b** according to the same method for the preparation of **8a** to give the desired product in 74 % yield. $^1$H NMR (DMSO-d6): δ 10.59 (s, 1H), 8.18 (d, 1H, $J$ = 2.8 Hz), 8.10 (m, 2H), 7.64 (m, 3H), 7.60 (d, 1H, $J$ = 2.8 Hz), 7.40 (s, 1H), 2.73 (s, 3H). ms: $m/z$ 393 ($M^+$).

A clean, one-pot and three-component synthesis of new dibenzo[*a*,*i*]xanthene-diones derivatives by cyclo-condensation reaction of 2-hydroxynaphthalene-1,4-dione, aromatic aldehydes and dimedone or 2-naphthol in aqueous media is reported.

*J. Heterocyclic Chem.,* **47**, 1062 (2010).

## INTRODUCTION

*ortho*-Quinone methides (*o*-QMs) are highly reactive intermediates that have been extensively harnessed by nature. Despite the general knowledge of *o*-QMs for over a century these intermediates still lie outside the synthetic mainstream [1,2]. Very recently, Pettus described the methods by which *o*-QMs are prepared, the benefits and limitations associated with each method as well as current applications in total synthesis [3]. The pseudo three-component condensation reaction of 2-naphthol with aldehydes in the presence of various catalysts to form xanthenes has been studied widely. The reaction proceeds through the *in situ* formation of *ortho*-quinone methides with 2-naphthol acting as a nucleophile [4]. However, the three-component condensation reactions of 2-naphthol and aldehydes with other nucleophiles is rarely reported in literature [5].

Xanthenes and benzoxanthenes have been reported to posses diverse biological and therapeutic properties, such as antibacterial [6], antiviral [7], and anti-inflammatory activities [8], as well as photodynamic therapy [9] and for antagonism of the paralyzing action of zoxazolamine [10]. The other useful applications of this heterocycles are as dyes [11], fluorescent materials for visualization of biomolecules [12], and in laser technologies [13]. Therefore, a number of methods have been reported for the preparation of xanthene derivatives [4,5f–h, 14–17].

Molecules with the naphthoquinone structure constitute one of the most interesting classes of compounds in organic chemistry, because of their biological properties, their industrial applications, and their potential as intermediates in the synthesis of heterocycles [18]. Naphthoquinone moiety occurs in different natural products, including β-lapachone **A**, α-xiloidone **B**, lambertellin **C**, WS-5995A **D**, and pyranokunthone B **E** [19]. Compounds **F** and **G** were extracted from marine actinomycete strain CNQ-525 bacteria; these bacteria were isolated from ocean sediments, which were collected at a depth of 152 m near La Jolla, California (Fig. 1). Compounds **F** and **G** possess significant antibiotic properties and cancer cell cytotoxicities activities [20].

In continuation of our previous works on synthesis of heterocycles containing naphthoquinone or xanthene moiety [21–25], herein we report a simple and efficient method for the preparation of benzo[*b*]xanthene-triones and dibenzo[*a*,*i*]xanthene-diones in aqueous media.

## RESULTS AND DISCUSSION

We found that a mixture of 2-hydroxynaphthalene-1,4-dione **1**, 2-naphthol **2** and aromatic aldehydes **3a–i**,

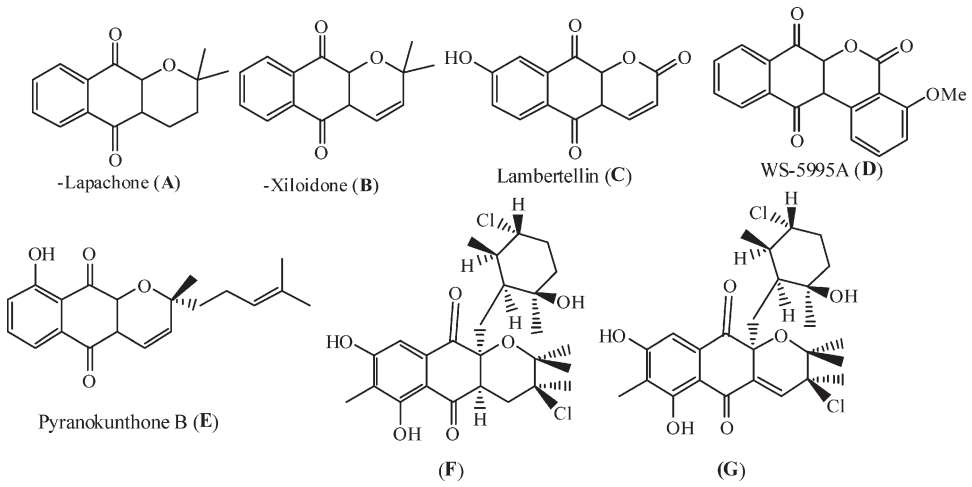

**Figure 1.** Examples of biologically active naphthoquinone derivatives.

in the presence of a catalytic amount of *p*-toluenesulfonic acid (*p*-TSA) as an inexpensive and readily available catalyst at refluxing water for 8–10 h, afforded 14-aryl-8*H*-dibenzo[*a*,*i*]xanthene-8,13(14*H*)-diones **4a–i** in 83–91% yields (Scheme 1). The optimized results are summarized in Table 1. In all cases, aromatic aldehydes substituted with either electron-donating or electron-withdrawing groups underwent the reaction smoothly and gave the products in good yields.

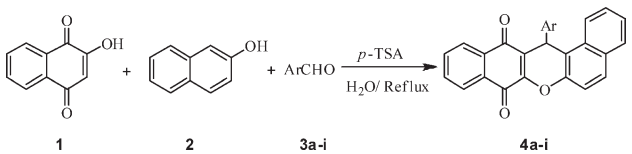
The results were good in terms of yields and product purity in the presence of *p*-TSA, while without *p*-TSA and over long period of time (24 h) the yields of products were low (<30%).

When this reaction was carried out with aliphatic aldehyde, such as butanal or pentanal, TLC and $^1$H NMR spectra of the reaction mixture showed a combination of starting materials and numerous products, the yield of the expected product was very poor.

By referring to the literature [4], the formation of products **4** can be rationalized by initial formation of *ortho*-quinone methides intermediate **5**. Subsequent addition of **1** to the intermediate **5**, followed by elimination of water afforded the corresponding products **4** (Scheme 2).

To further explore the potential of this protocol for xanthene synthesis, we investigated reaction of 1,3-cyclohexadione **6** instead of 2-naphthol **2** and obtained 3,4-dihydro-1*H*-benzo[*b*]xanthene-1,6,11(2*H*,12*H*)-trione **7a–i**, in good yields for 14–16 h (Scheme 3). The optimized results are summarized in Table 2.

**Scheme 1**



The nature of the compounds **4** and **7** as 1:1:1 adducts was apparent from their mass spectra, which displayed, in each case, the molecular ion peak at appropriate *m*/*z* values. Compounds **4** and **7** are stable solids whose structures are fully supported by IR, NMR spectroscopy, and elemental analysis.

In summary, a novel, simple, convenient, and practical method for the synthesis of substituted benzo[*b*]xanthene-triones and dibenzo[*a*,*i*]xanthene-diones has been reported by one-pot and three component reaction using *p*-TSA as an inexpensive and readily available catalyst. This protocol includes some important aspects like the use of water as a ''green'' reaction medium, high atom economy, mild reaction conditions, and excellent yields.

## EXPERIMENTAL

Melting points were measured on an Electrothermal 9100 apparatus and are uncorrected. Mass spectra were recorded on a FINNIGAN-MAT 8430 mass spectrometer operating at an ionization potential of 70 eV. IR spectra were recorded on a Shimadzu IR-470 spectrometer. $^1$H and $^{13}$C NMR spectra were recorded on a BRUKER DRX-300 AVANCE spectrometer at

1,4-Diethyl-1,2,3,4-tetrahydro-6-nitroquinoxaline **4** was synthesized by alkylative reduction of 6-nitroquinoxaline. Catalytic reduction of **4** followed by cyclocondensation with heterocyclic malondialdehydes afforded novel 8-(heteroaryl)-1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxalines. The solutions of these novel compounds having 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline framework as an electron releasing system showed absorption in the range of 424–426 nm in the visible region and exhibited brilliant bluish-green fluorescence. The thermogravimetric curve obtained by thermogravimetric analysis displayed that these fluorophores possess excellent thermal stability with one-step thermal decomposition.

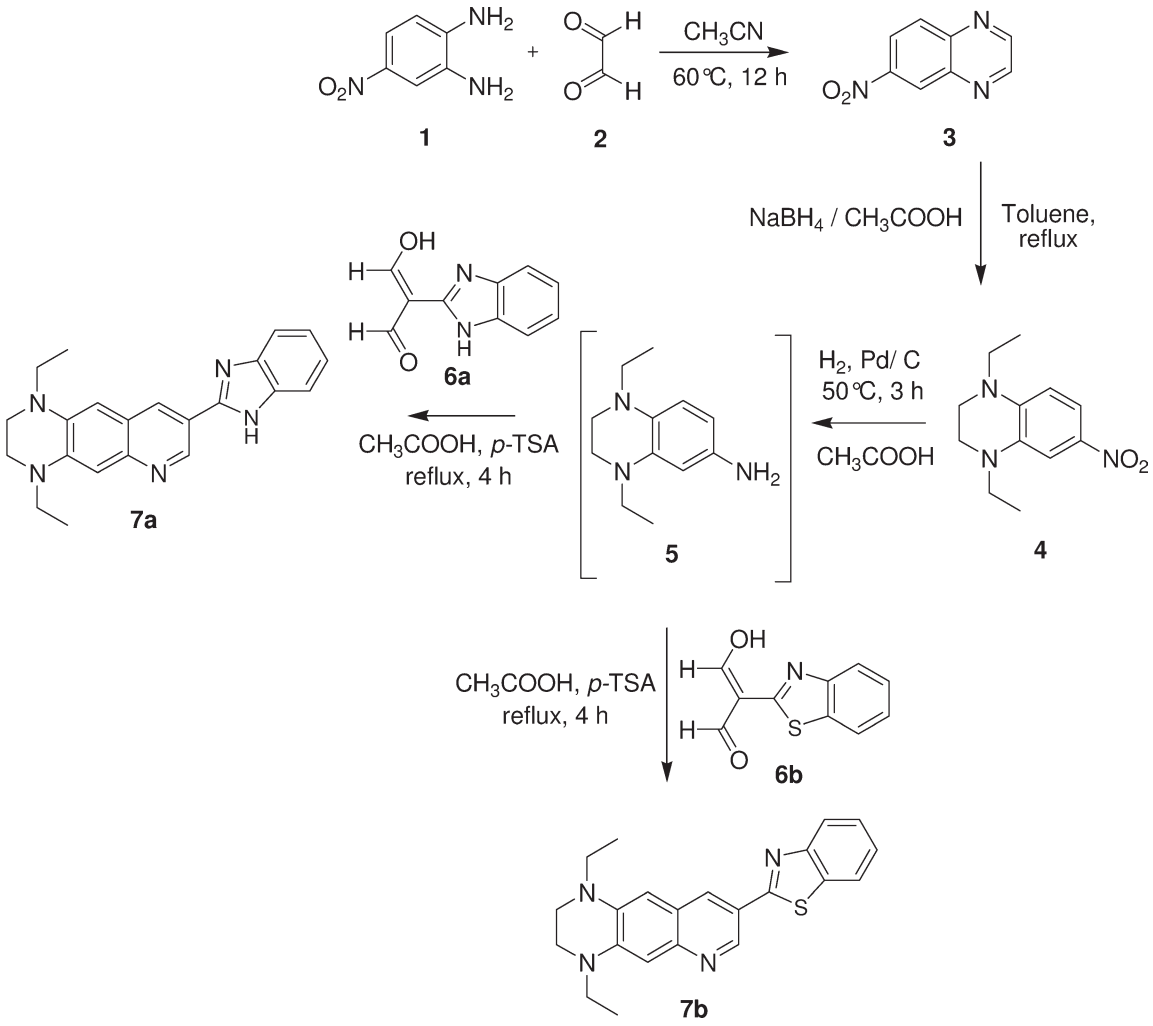
## INTRODUCTION

The structural diversity, stability, and biological importance of heterocycles have made them attractive synthetic targets over many years, and they have found potential applications in various fields of science and technology. Especially in the field of colorants, heterocycles have gained extreme importance because of their planar and rigid π-conjugation system. Many heterocycles based on rigid ring systems such as coumarins [1], thiazoles [2], benzimidazoles [3], pyrazines [4], naphthalimides [5], and oxadiazoles [6] are well-established fluorescent dye chromophores. Heterocyclic fluorescent compounds have been extensively investigated for various potential applications including tunable dye lasers [7], molecular probes for biochemical research [8], and traditional textile and polymer fields [9].

Quinoxaline is one of the interesting heterocyclic systems. Many quinoxaline scaffolds are found as a core unit in a number of biologically active compounds [10,11]. Its derivatives are used in the development of novel organic dyes and organic semiconductors [12]. Fluorescent styryl dyes based on fused quinoxaline system are reported in the literature. In earlier work from our laboratory, the versatility of quinoxaline has been demonstrated [13–16]. Quinoxalines can be easily reduced to 1,2,3,4-tetrahydroquinoxalines by reducing agents such as lithium aluminium hydride [17] and sodium borohydride [18] in excellent yields. Sequential reduction and alkylation of N-heterocycles such as indole to N-alkylated indoline and quinoline to 1,2,3,4-tetrahydroquinoline by sodium borohydride and trifluoroacetic acid is well known [19–22]. Quinoxalines can also be sequentially reduced and dialkylated using sodium borohydride and carboxylic acids. 6-Nitroquinoxaline has been subjected to similar reductive alkylation using sodium borohydride and glacial acetic acid to obtain 1,4-diethyl-1,2,3,4-tetrahydro-6-nitroquinoxaline [23]. The 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline framework is rigid and highly electron rich. We have

**Scheme 1.** Synthetic pathway of compounds **7a–7b**.



reported mono- and bis-styryl dyes derived from 1,4-diethyl-1,2,3,4-tetrahydro-6-methoxyquinoxaline [24]. These dyes having orange to violet hue displayed pronounced bathochromicity and good thermal stability. A series of highly fluorescent coumarin derivatives based on 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline framework, synthesized by us, exhibited excellent bathochromicity [25]. These results encouraged us to envisage that, the molecular structures possessing a strong electron donating and rigid 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline unit in conjugation with heterocyclic π-conjugated system should exhibit brilliant fluorescence and display absorption maxima in the yellow region of the electromagnetic spectrum.

In this communication, we report the synthesis and spectroscopic properties of novel pyrido[2,3-g]quinoxaline derivatives having 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline framework as an electron releasing unit in conjugation with electron accepting heterocycles like benzimidazole and benzothiazole. The electronic properties of these highly fluorescent compounds were analyzed by UV-vis absorption spectroscopy and fluorescence emission spectroscopy. The fluorescent compounds **7a** and **7b** were also evaluated for thermal stability by thermogravimetric analysis. The spectroscopic properties of these pyrido[2,3-g]quinoxaline derivatives were compared with the closely related coumarin analogs **8a**–**8b** and styryl derivatives **9a**–**9b**.

## RESULTS AND DISCUSSION

**Synthesis of compounds 7a–7b.** Substituted 1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxalines **7a–7b** were synthesized by cyclocondensation of 6-amino-1,4-diethyl-1,2,3,4-tetrahydroquinoxaline **5** and suitable malondialdehyde derivatives **6a–6b** as depicted in Scheme 1. 4-Nitro-1,2-phenylenediamine **1** was condensed with glyoxal **2** in dry acetonitrile to obtain 6-nitroquinoxaline **3** in excellent yield. Reductive

alkylation of 6-nitroquinoxaline with sodium borohydride and glacial acetic acid in dry toluene yielded 1,4-diethyl-6-nitro-1,2,3,4-tetrahydroquinoxaline **4** as a bright red solid, which was then hydrogenated over 10% palladium charcoal in glacial acetic acid to afford 6-amino-1,4-diethyl-1,2,3,4-tetrahydroquinoxaline **5**. The catalyst was filtered under nitrogen atmosphere and filtrate was immediately used for further reactions as the amino compound **5** was unstable and rapidly oxidized. The reaction of 6-amino-1,4-diethyl-1,2,3,4-tetrahydroquinoxaline **5** with appropriate malondialdehyde derivatives **6a–6b** took place readily in glacial acetic acid in the presence of equivalent amount of *p*-toluenesulphonic acid to yield 8-(heteroaryl)-1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxalines **7a–7b**. This cyclocondensation reaction proceeded in a facile manner owing to the presence of electron releasing 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline framework. The structures of the compounds were confirmed by FT-IR, $^1$H NMR spectroscopy, mass spectrometry, and elemental analysis. The results are summarized in the experimental section.

**Spectral characteristics of compounds 7a–7b.** Basic spectral characteristics of the chromophores such as absorption maxima ($\lambda_{max}$), emission maxima ($\lambda_{em}$), and extinction coefficient (ε) were measured in different solvents and are presented in Tables 1 and 2. The electronic absorption spectra of the compounds **7a–7b** displayed absorption maxima in the visible region from 412 to 427 nm. Compound **7a** showed absorption maxima at 412 nm in hexane, lowest among two derivatives, whereas compound **7b** showed well-pronounced absorption maxima at 427 nm in DMF which is the highest between the two derivatives. To investigate the influence of solvents on the absorption maxima of compounds **7a** and **7b**, their absorption spectra were measured in different solvents such as toluene, chloroform, ethyl acetate, hexane, methanol, DMF, acetonitrile, and ethyl acetate. The solvents differ considerably in polarity and ability to form H-bonds. From the presented values in Tables 1 and 2, it is apparent that practically no solvatochromism was observed. Only in the case of **7a** in hexane, significant hypsochromic shift in the absorption maxima was noticed. Figure 1 displays absorption maxima of the compounds **7a–7b** in methanol.

These 8-(heteroaryl)-1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxalines were expected to be strongly fluorescent in view of the conjugation of rigid and electron rich 1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxaline ring with electron accepting heterocycles. To our delight, both compounds exhibited strong bluish-green fluorescence with large Stokes shift values (Tables 1 and 2). Especially, fluorophore **7b** containing benzothiazole ring showed remarkably high Stokes shift value of 107 in methanol. Figure 2 displays emission maxima of

**Table 2**

| **7b** | 427 | 528 | 101 | 24,995 | 425 | 527 | 102 | 24,235 | 421 | 519 | 98 | 24,972 |

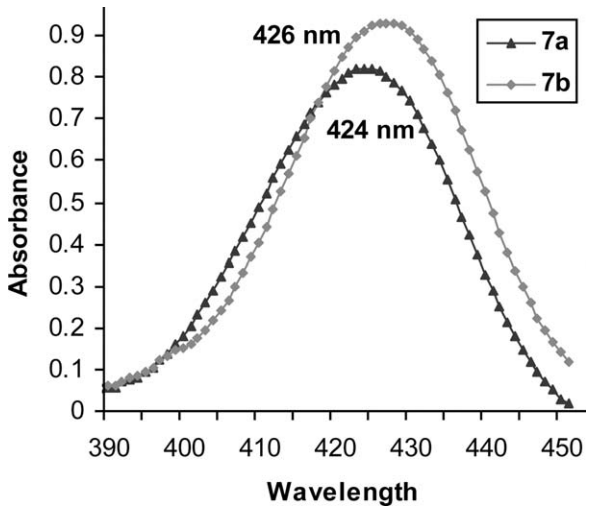

**Figure 1.** Absorption maxima of compounds **7a–7b** in methanol.

the compounds **7a–7b** in methanol. Figure 3 shows photographs of the fluorophores **7a** and **7b** in UV light (366 nm).

As stated earlier, the fluorophores **7a** and **7b** have rigid and electron rich 1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxaline ring in conjugation with electron accepting heterocycles. The situation is rather similar to the coumarin fluorophores **8a** and **8b** (Table 3) reported by us [25]. Also, the styryl dyes **9a** and **9b** (Table 3) were derived from the same electron donor and acceptors [24]. In short, compounds **7a–7b** are structural analogs of compounds **8a–8b** and **9a–9b**. Hence, the spectral properties of **7a** and **7b** in methanol were also compared with the established dyes **8a–8b** and **9a–9b**. The comparative data are summarized in Table 3. Compounds **7a** and **7b** showed intense yellow hue with absorption maxima at 424 and 426 nm, respectively, whereas compounds **8a** and **8b** showed bright orange

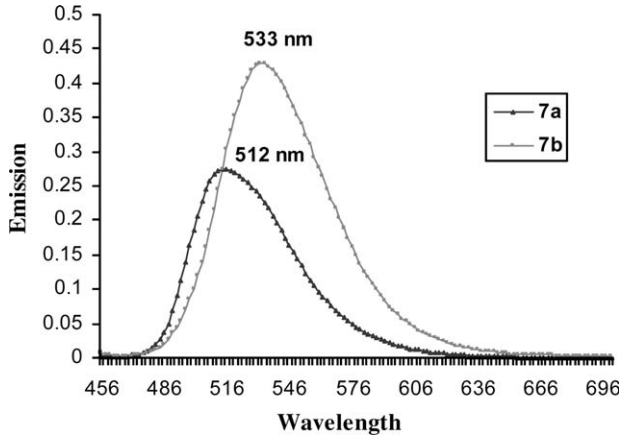

**Figure 2.** Emission maxima of compounds **7a–7b** in methanol.

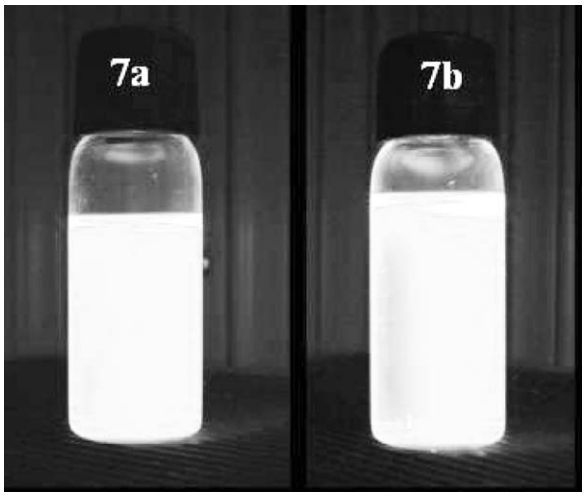

**Figure 3.** Photographs of fluorophores **7a–7b** in UV light (366 nm).

hue and absorbed at 483 and 501 nm, respectively. The large bathochromic shift in the case of **8a** and **8b** is clearly due to the presence of lactone ring. The compounds **8a** and **8b** were highly fluorescent, as it is usual with coumarin compounds. Stokes shift value of **8a** was almost close to that of **7a**, whereas Stokes shift value of **8b** was lower than that of **7b**. It must be noted that the styryl dyes **9a** and **9b**, having same electron donating 1,4-diethyl-1,2,3,4-tetrahydroquinoxaline skeleton in conjugation with electron accepting benzimidazole and benzothiazole rings, respectively, were nonfluorescent. The absence of fluorescence was probably due to lack of rigidity provided by pyrido ring as in the case of compounds **7a–7b** and lactone ring as in the case of compounds **8a–8b**. However, the styryl dyes **9a** and **9b** showed remarkably higher bathochromic shift with absorption maxima at 501 and 528 nm, respectively, owing to the presence of an additional electron

**Table 3**

[a] Quantum yields were measured in methanol using Rhodamine-6G (Φ = 0.94) as standard [26,27].

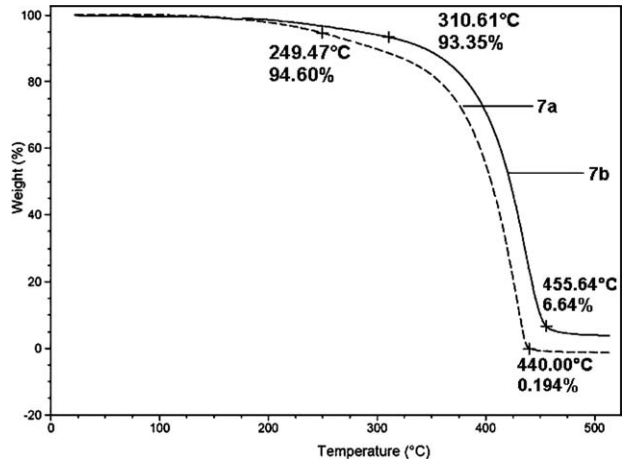

**Figure 4.** Thermogravimetric curves of fluorophores **7a–7b**.

accepting cyano group. In all the three classes, the compounds **7b**, **8b**, and **9b** having benzothiazole ring underwent bathochromic shift relative to their respective analogs having benzimidazole ring, owing to high electronegativity of sulfur atom in the ring.

To complement this study, spectral properties of fluorescent compounds **7a–7b** and **8a–8b** were compared with that of commonly encountered commercial fluorescent coumarin dyes **10a** (Coumarin 535) and **10b** (Coumarin 540) (Table 3) having same electron accepting groups. As expected, the rigid coumarins **8a** and **8b** showed significant bathochromic shift in absorption maxima compared with the nonrigid coumarins **10a** and **10b**. The compounds **10a** and **10b**, however, have remarkably high molar extinction coefficient values and absorb at longer wavelength compared with quinoxaline derivatives **7a** and **7b**. The Stokes shift values of compounds **10a** and **10b** are lower than that of compounds **7a–7b** and **8a–8b**. The fluorescence quantum yields ($\Phi$) of the compounds were measured in methanol using Rhodamine-6G ($\Phi = 0.94$) [26,27] as standard. Compound **7b** showed $\Phi$ value of 0.14 which is marginally higher than that of **7a** ($\Phi = 0.1$). The fluorescence quantum yields of compounds **7a** and **7b** were found to be lower than that of coumarin derivatives. Although, the quinoxaline derivatives **7a–7b** possess similar electron donor and acceptor groups as coumarins **8a–8b** and **10a–10b**, they exhibit significant hypsochromic shift in absorption maxima and lower fluorescence quantum yields. The lower fluorescence in quinoxaline derivatives is due to the absence of lactone framework in coumarins which impart rigidity, high electronegativity, and excellent planarity to the molecule.

**Thermal properties of fluorophores 7a and 7b.** The fluorophores were subjected to the thermogravimetric analysis to investigate their thermal stability. The change in weight of the compound was measured as a function of temperature. Figure 4 displays thermograph of the fluorophores **7a** and **7b**. The thermogravimetric curves for the compounds show a clear plateau followed by a sharp and smooth decomposition curve. The loss in weight of the compound **7a** was rapid when heated above 250°C. This fact indicates that the compound is stable up to 250°C after which it decomposes rapidly and decomposition completes at 440°C. Among the two compounds, compound **7b** in particular showed excellent thermal stability up to 310°C. Rapid decomposition of **7b** occurred when it was heated above 310°C. The decomposition completed at about 455°C. Both the fluorophores underwent one-step thermal decomposition. Coumarin chromophores **8a–8b** and styryl dyes **9a–9b** also showed thermal stability above 250°C with smooth, one step thermal decomposition curve [24,25].

## CONCLUSION

In conclusion, novel 8-(heteroaryl)-1,4-diethyl-1,2,3,4-tetrahydropyrido[2,3-g]quinoxalines are valuable as new fluorescent chromophores having absorption maxima at 412–427 nm and emission maxima at 502–533 nm in different solvents. These compounds did not show any appreciable solvatochromism and have lower fluorescence quantum yields than coumarins having same electron donating and accepting groups. The compounds displayed good thermal stability.

## EXPERIMENTAL

All melting points were uncorrected and are in °C. IR spectra were recorded on a Bomem Hartmann and Braun MB-Series FT-IR spectrometer (KBr). $^1$H NMR spectra were recorded on Varian 300 MHz mercury plus spectrometer, and chemical shifts are expressed in $\delta$ ppm using TMS as an internal standard. Mass spectra were recorded on Micromass: Q-T of micro (YA-105) mass spectrometer. Microanalysis for C, H, N, and S were performed on Thermofignnin elemental analyzer. Electronic spectra were recorded on Spectronic spectrophotometer. The fluorescence maxima of the compounds were recorded on Jasco FP-1520 fluorimeter. Thermogravimetric analysis was carried out on SDT Q600 v8.2 Build 100 model of TA instruments.

**Synthesis of 6-amino-1,4-diethyl-1,2,3,4-tetrahydroquinoxaline (5).** 1,4-Diethyl-1,2,3,4-tetrahydro-6-nitroquinoxaline **4** [23] (5.0 g, 0.021 moles) and catalytic amount of palladium on charcoal (10%) in glacial acetic acid (100 mL) were stirred in Parr hydrogenator at 50°C under an atmosphere of hydrogen until think layer chromatography (TLC) (eluent: 10% ethyl acetate in *n*-hexane) of the reaction mixture showed no red colored spot of reactant. The reaction mixture was then filtered under nitrogen atmosphere to separate the catalyst. 6-Amino-1,4-diethyl-1,2,3,4-tetrahydroquinoxaline **5** thus obtained was not isolated and subsequently used for further reaction immediately after filtration as it was found to be unstable [23]. (The

pale yellow reaction mixture was filtered under nitrogen blanket as it turns black on exposure to air).

**General method for the synthesis of compounds (7a–7b).** Above reaction mixture, appropriate malondialdehyde derivative **6a** or **6b** [28] (0.021 moles) and *p*-toluenesulphonic acid (*P*-TSA) (3.6 g, 0.021 moles) were heated to reflux under nitrogen atmosphere for 4 h. The reaction mixture was then cooled to room temperature, neutralized with dilute sodium hydroxide solution (10%) maintaining the temperature below 15°C. Dark brown solid obtained was filtered, washed with water and dried. The crude compound was purified by column chromatography on activated neutral aluminium oxide using toluene–ethyl acetate (7:3) system.

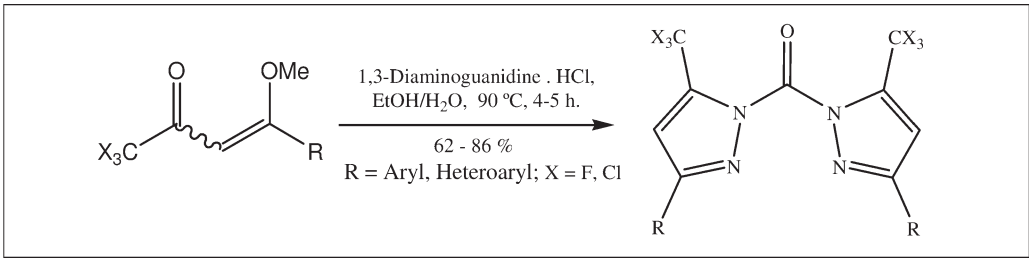
Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



Two new series of 1,1′-carbonyl-bis[3-aryl(heteroaryl)-5-trihalomethyl-1*H*-pyrazoles], where aryl = $C_6H_5$, 4-$CH_3C_6H_4$, 4-$FC_6H_4$, 4-$OCH_3C_6H_4$, 4-$NO_2C_6H_4$, 4,4′-BiPh, 1-naphthyl, and heteroaryl = 2-thienyl and 2-furyl have been synthesized, in a one-pot methodology, from the reaction of 4-methoxy-4-aryl(heteroaryl)-1,1,1-trihalobut-3-en-2-ones with 1,3-diaminoguanidine monohydrochloride. The heterocycles were obtained regioselectively in good yields (62–86%) and in a short reaction time. Ring-opening reactions with 1,2-dinuleophiles and the synthesis of ethyl carboxylate derivative from a pyrazolycarbohydrazide is also reported.

## INTRODUCTION

The linked pyrazole ring represents an interesting block for synthesis strategies as well as studies on their biological and chemical properties. Moreover, pyrazoles are a class of heterocyclic compounds with many derivatives, and of note, the fluorinated pyrazoles have been demonstrated to play key pharmacophore functions in many pharmaceutical and agrochemical fields [1,2].

The introduction of fluorine(s) into heterocyclic rings is still limited and the trifluoromethyl substituted α,β-unsaturated ketones represent a practical way to access such compounds [3–11]. In recent years, the synthesis of trifluoromethyl pyrazoles has drawn much attention and the literature has reported a series of specific 5-$CF_3$ substituted pyrazoles. The main synthetic methods to prepare such compounds involve CCC and NN atom fragments in cyclization reactions of substituted hydrazines or derivatives thereof with 4-alkoxy-1,1,1-trifluoro-3-alken-2-ones [3–9].

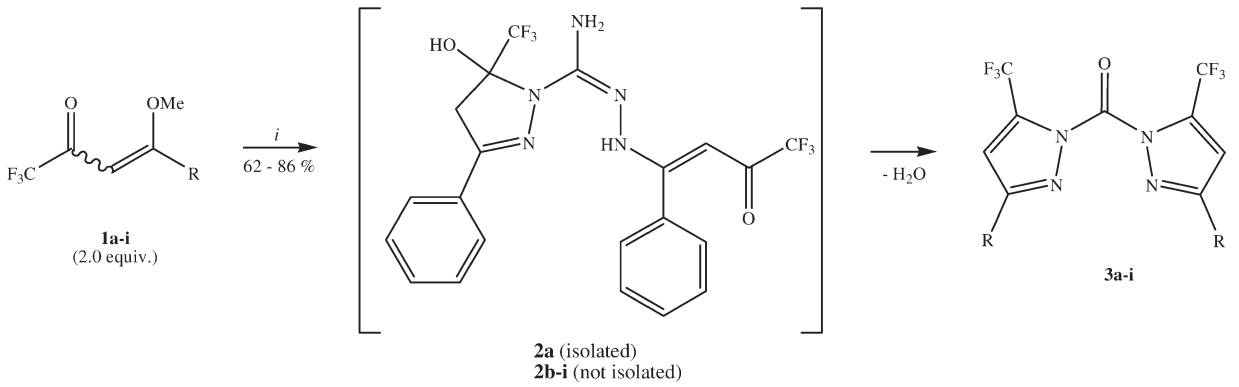
This [3+2] cyclization approach has been shown to be an efficient method to prepare such compounds, where the pyrazole ring is linked to another pyrazole. On the other hand, carbonyl-bispyrazoles are not so common in the literature. For instance, new synthetic routes to obtain these compounds and studies on their potential as pharmaceuticals and agrochemicals have been relatively little explored [10–12].

1,1′-Carbonyl-bispyrazoles have been most commonly synthesized by substitution reaction involving phosgene and other derivatives with pyrazoles [13–19]. However, this synthetic procedure is efficient only when the starting materials are symmetric substituted or nonsubstituted pyrazoles, because nonsymmetric 3- or 5-substituted pyrazoles may exist in two tautomeric structures in solution and their $N^1$-substitution reactions lead undoubtedly to three possible carbonyl-bispyrazoles isomers.

Soliman and Darwish [13] have reported that substituted 3,5-dimethyl-1*H*-pyrazoles reacted with ethyl chloroformate, in the presence of anhydrous potassium carbonate, giving bis-(3,5-dimethyl-1*H*-pyrazole)methanone, in good yields, as a possible hypoglycemic agent. However, a very limited scope is observed when the bis-pyrazole synthesized by this procedure has only methyl substituents at the position 3 and 5 of both pyrazole rings.

More recently, Higgs and Carrano [20] reported the synthesis of carbonyl-bispyrazoles prepared by the

**Scheme 1.** Synthetic route to prepare bis-pyrazoles **3**. Reagents and conditions: (*i*) 1,3-diaminoguanidine. HCl (1.0 equiv), EtOH/$H_2O$, 90°C, 4–5 h.



| 1-3 | a | b | c | d | e | f | g | h | i |
|---|---|---|---|---|---|---|---|---|---|
| R | $C_6H_5$ | 4-$CH_3C_6H_4$ | 4-$FC_6H_4$ | 4-$OCH_3C_6H_4$ | 4-$NO_2C_6H_4$ | 4,4'-$BiC_6H_4$ | 2-Naphthyl | 2-Thienyl | 2-Furyl |

reaction of 3,5-substituted 1*H*-pyrazoles (R and $R^1$ = H, $CH_3$, *i*-Pr) with phosgene, using triethylamine in anhydrous THF as solvent. In this procedure, symmetric carbonyl-bispyrazoles (R = $R^1$ = H or $CH_3$) were obtained, except when R = H and $R^1$ = *i*-Pr. In the previous example, a mixture of isomeric bis-pyrazoles was not obtained due to a steric hindrance between the *i*-propyl substituents.

Recently, we have reported the one-step and regioselective procedure for the synthesis of a novel series of 1,1′-carbonyl-bis[3-alkyl(aryl/heteroaryl)-5-trifluoromethyl-5-hydroxy-4,5-dihydro-1*H*-pyrazoles] [21] from the cyclocondensation reactions of 4-alkoxy-4-aryl(heteroaryl)-1,1,1-trifluoroalk-3-en-2-ones with carbohydrazide. Subsequently, as an example, 1,1′-carbonyl-bis(5-trifluoromethyl-5-hydroxy-3-phenyl-4,5-dihydro-1*H*-pyrazole) was subjected to dehydration reactions, using acetic acid/ethanol [22,23], at reflux for 4 h or sulfuric acid/ethanol [24] at reflux for 4 h. In both the cases, the aromatic 1*H*-pyrazole was obtained with the simultaneous removal of the carbonyl function. Because of the relative elimination difficulty, the presence of trifluoromethyl, and the carbonyl groups at positions 5 and 1 of the pyrazole, respectively, another synthetic procedure was performed. After a review of the literature and in an attempt to obtain the aromatic bis-pyrazole, we chose thionyl chloride/pyridine [24,25] as the dehydration agent. Again, the isolation of 1*H*-pyrazole was observed with the cleavage of both C(O)—N bonds.

## RESULTS AND DISCUSSION

As an alternative strategy for the synthesis of trifluoromethylated aromatic bis-pyrazoles, in this study we describe firstly the full regioselective synthesis and characterization of a new series of 1,1′-carbonyl-bis(3-substituted-5-trifluoromethyl-1*H*-pyrazoles) (**3**) from the reaction of trifluoromethyl vinyl ketones (**1**) with 1,3-diaminoguanidine monohydrochloride (Scheme 1).

In principle, β-alkoxyvinyl trihalomethyl ketones (**1a–i** and **8a–f**) are prepared by trihaloacetylation reaction of acetals derived from ketones, according to the previously described procedures [5,26–28].

1,1′-carbonyl-bis(3-substituted-5-trifluoromethyl-1*H*-pyrazoles) (**3a–i**) were obtained from the reaction of two equivalents of 4-methoxy-1,1,1-trifluorobut-3-en-2-ones (**1a–i**) and one equivalent of 1,3-diaminoguanidine monohydrochloride, in a one-pot reaction and in 62 to 86% yields. All reactions were carried out in ethanol/water (20:1), monitored by TLC, and the optimal reaction time and temperature were 4–5 h at 90°C. After this time, the compounds (**3a–i)** were isolated by extraction with chloroform/water (1.5:1). The organic layer was dried and evaporated under reduced pressure. The products (**3a–i**) were purified by recrystallization from *iso*-propyl ether, to give pure yellow solids.

According to our previous experience, trifluoromethyl vinyl ketones **1a–i** readily react with substituted hydrazines to give only 5-$CF_3$ substituted pyrazoles [3–9]. In this study, we found that 1,3-diaminoguanidine monohydrochloride reacted specifically as a bis-1,2-dinucleophile with enones **1a–i** and **8a–f** to give bis-pyrazoles linked through a carbonyl carbon. As for the reaction mechanism, firstly, the cyclization of enones **1a–i** takes place furnishing 1,1′-carbonyl-bis(4,5-dihydro-pyrazole) intermediates linked through an imino group. These intermediates undergo *in situ* water elimination and hydrolysis of the imino group to give the respective bis-pyrazoles **3a–i**. The evidence of this mechanism is given

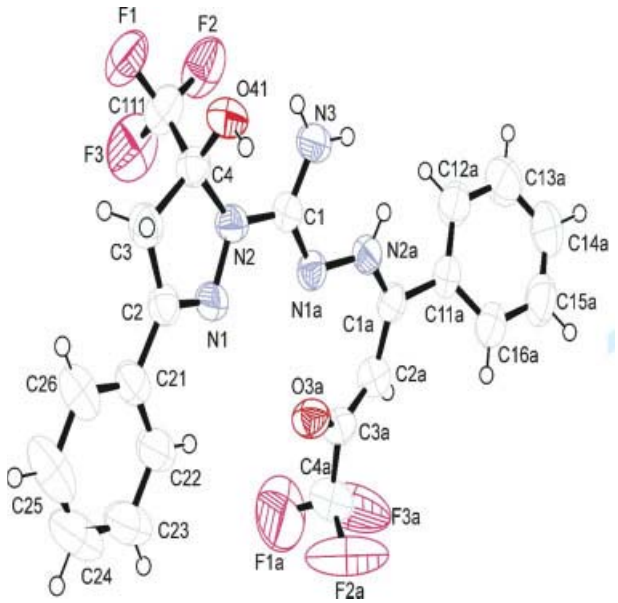


**Figure 1.** ORTEP plot of the intermediate **2a**. Thermal ellipsoids are shown at the 50% probability level. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

by the isolation of the intermediate **2a**, the only intermediate that was isolated and whose was structure confirmed by single-crystal x-ray diffraction (Fig. 1) [29].

The optimal condition to isolate product **3a** together with a trace of the intermediate **2a** was when the reaction was carried out in ethanol/water, at 90°C for 3 h.

The structures of **3a–i** and **9a–f** were deduced from their NMR spectra ($^1$H and $^{13}$C) and by comparison with NMR data of other pyrazoles formerly synthesized in our laboratory [5–9].

The symmetrical carbonyl heterocycles **3a–i** show a symmetrical pattern with one set of signals for the hydrogens and carbons of the 3-substituted pyrazole rings. The compounds **3a–i** show the $^1$H NMR chemical shifts in DMSO-$d_6$ for the H-4 as a sharp singlet in the range of 5.85–6.41 ppm. The signals for the other aromatic hydrogens are in the range of 6.53–8.23 ppm.

The compounds **3a–i** present the typical $^{13}$C chemical shifts of pyrazole rings at an average of 148.1 ppm (C-3) and 86.7 ppm (C-4). The C-5 exhibit signals at around 169.3 and appear as a characteristic quartet with $^2J$ = 28 Hz, because they are attached to a $CF_3$ group. The $CF_3$ group shows a typical quartet at an average of 118.2 ppm, with $J_{C\text{-}F}$ = 291 Hz. The $^{13}$C chemical shifts of the other aromatic carbons present a signal in the range of 113.2–147.3 ppm. The carbonyl carbon interfacing the two pyrazole rings shows signals in the range of 185.6 ppm.

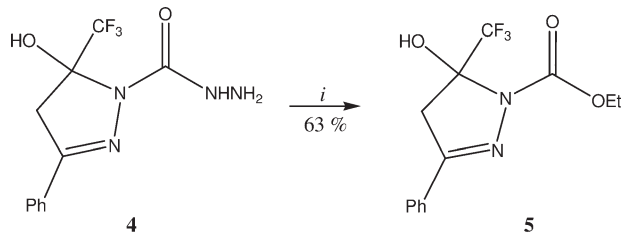
Subsequently, aiming to obtain examples of heterocyclic derivatives, the reaction of carbohydrazide **4** with a 1,3-diketone (2,4-pentanedione) was performed. In this case, the well-known ester **5** [30] was isolated in 63% yield, instead the desired nonsymmetrical bis-pyrazole, showing an interesting and promising employment of pyrazolyl carbohydrazides such as **4** (Scheme 2). Compound **4** was obtained when the reaction of pure carbohydrazide [$(NH_2NH)_2CO$] and 4-methoxy-4-phenyl-1,1,1-trifluorobut-3-en-2-one was carried out at a molar ratio 1:1, in ethanol, according to the literature [21].

Finally, the new ketone **3b** was subjected to reactions with phenylhydrazine [31] and hydroxylamine hydrochloride [32] to verify the possibility of an induced ring-opening reaction followed by recyclization with these two dinucleophiles (Scheme 3).

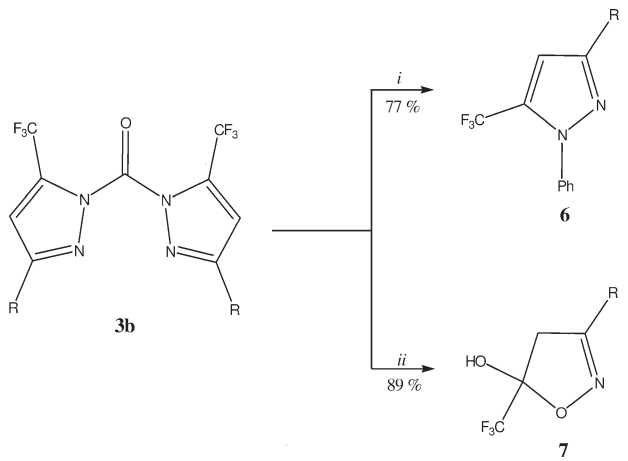
Although **3b** is not the best precursor to synthesize pyrazole **6** and isoxazoline **7**, these well-known heterocycles were easily isolated in good yields (77–89%) from this type of reaction.

In addition to the interest inherent in the chemical attributes of these novel trifluoromethylated condensation products **3**, it seemed appropriate to evaluate the cyclization reactions involving now the β-alkoxyvinyl trichloromethyl ketones **8a–f** and 1,3-diaminoguanidine monohydrochloride (Scheme 4).

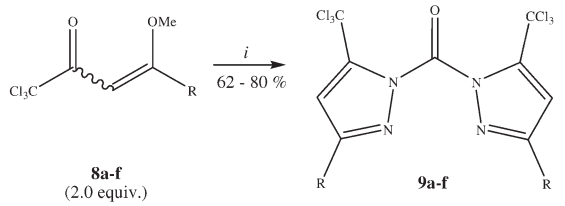
**Scheme 2.** Synthesis of nonsymmetrical ketone **5**. Reagents and conditions: (*i*) 2,4-pentanedione, EtOH, reflux, 20 h.



**Scheme 3.** Preparation of pyrazole **6** and isoxazole **7** from ketone **3b**. Reagents and conditions: (*i*) $NH_2NHPh$, EtOH, reflux, 4 h; (*ii*) $NH_2OH{\cdot}HCl$, Py, $H_2O$, 45°C, 24 h (R = 4-Tolyl).



**Scheme 4.** Synthetic route to prepare bis-pyrazoles **9**. Reagents and conditions: (*i*) 1,3-diaminoguanidine. HCl (1.0 equiv), EtOH/$H_2O$, 90°C, 4–5 h.



**8a-f** (2.0 equiv.) **9a-f**

| 8-9 | a | b | c | d | e | f |
|---|---|---|---|---|---|---|
| R | $C_6H_5$ | 4-$CH_3C_6H_4$ | 4-$ClC_6H_4$ | 4-$BrC_6H_4$ | 4-$NO_2C_6H_4$ | 2-Thienyl |

We reported now the results of reactions of ketones **8** with 1,3-diaminoguanidine monohydrochloride which were expected to deliver 1,1′-carbonyl-bis(5-trichloromethyl-1*H*-pyrazoles) **9a–f** bearing an carbonyl moiety on the newly formed bis-trichoromethyl substituted heterocyclic system. We carried out the reactions of 4-methoxy-1,1,1-trichlorobut-3-en-2-ones **8** with 1,3-diaminoguanidine monohydrochloride, in 2:1 molar ratio, respectively, and in ethanol/water (20:1) as solvent.

When the mixtures were heated at 90°C, after stirring for 4–5 h, the TLC showed that the reactions proceeded smoothly and gave the products **9** in 62–80% yields (Scheme 4). The derivatives **9** were all stable, white crystalline solids, which showed no significant signs of decomposition after being stored for many months under refrigeration and were unaffected by the recrystallization method.

NMR spectroscopic studies alone allow convincing structural assignments for this heterocyclic system and consequently unequivocal determination of structures of **9**. The symmetrical carbonyl heterocycles **9a–f** show a symmetrical pattern with one set of signals for the hydrogens and carbons of the 3-substituted pyrazole rings. The compounds **9a–f** show the $^1$H NMR chemical shifts in DMSO-$d_6$ for the H-4 as a sharp singlet in the range of 6.21–6.98 ppm. The signals for the other aromatic hydrogens are in the range of 7.21–8.30 ppm.

The compounds **9a–f** present the typical $^{13}$C chemical shifts of pyrazole rings in average of 175.0 ppm (C-3) and 85.6 ppm (C-4). The carbonyl carbon bonding the two pyrazole rings shows signals in the range of 182.8 ppm. The two $CCl_3$ groups show a typical singlet in average of δ 98.9 ppm. All the signals are consistent with $^1$H and $^{13}$C NMR chemical shifts of the pyrazoline moieties for these symmetrical systems.

In conclusion, we have developed a useful, simple, and convenient procedure to obtain new 1,1′-carbonyl-bis[3-aryl(heteroaryl)-5-trihalomethyl-1*H*-pyrazoles] (**3**, **9**), starting from the cyclocondensation reactions with β-alkoxyvinyl trihalomethyl ketones (**1**, **8**) and 1,3-diaminoguanidine monohydrochloride in a one-pot method leading to high yields (62–86%). In addition, the reaction was proven to be regioselective because only the 1,1′-carbonyl-bis(5-trihalomethyl-1*H*-pyrazole) isomer was isolated. Moreover, we think that alkylcarboxylate heterocycles such as **5** and many other ring-opening reactions can be induced in this new heterocyclic system using several dinucleophiles.

## EXPERIMENTAL

Unless otherwise indicated all common reagents and solvents were used from commercial suppliers without further purification. All melting points were determined using open capillaries on an Electrothermal Mel-Temp 3.0 apparatus. $^1$H and $^{13}$C NMR spectra were acquired on a Bruker DPX 200 spectrometer ($^1$H at 200.13 MHz and $^{13}$C at 50.32 MHz), 5 mm sample tubes, 298 K, digital resolution ± 0.01 ppm, in DMSO-$d_6$ for **3**, **5**, **9** and in $CDCl_3$ for **6** and **7**, using TMS as internal reference. Mass spectra were registered in a HP 5973 MSD connected to a HP 6890 GC and interfaced by a Pentium PC. The GC was equipped with a split-splitless injector, autosampler, cross-linked HP-5 capillary column (30 m, 0.32 mm of internal diameter), and He was used as the carrier gas.

**Synthetic procedures. General procedure for the preparation of 1,1′-carbonyl-bis[3-aryl(heteroaryl)-5-(trihalomethyl)-1*H*-pyrazoles] (3a–i, 9a–f).** A stirred mixture of 4-methoxy-1,1,1-trifluorobut-3-en-2-ones (**1a–i**) or 4-methoxy-1,1,1-trichlorobut-3-en-2-ones (**8a–f**) (2.0 mmol) and 1,3-diaminoguanidine monohydrochloride (1.0 mmol), diluted in ethanol (20 mL) and water (1 mL) was heated in an oil bath for 4–5 h at 90°C. After cooling, water (10 mL) was added to the reaction and the product extracted with chloroform (2 × 15 mL). The organic layer was dried ($Na_2CO_3$) and evaporated under reduced pressure. The solid residues were recrystallized from iso-propyl ether to give white solids.

**1,1′-Carbonyl-bis(3-phenyl-5-trifluoromethyl-1*H*-pyrazole) (3a).** This compound was obtained as a yellow solid, yield 75%, Mp. 211–212°C. $^1$H NMR (DMSO-$d_6$) δ = 7.75–7.79 (m, 4H, aromatic-H), 7.38–7.42 (m, 6H, aromatic-H), 5.94 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 186.1 (C=O), 169.3 (C-5, $J$ = 28), 141.7 (C-3), 130.2; 128.1; 126.8; 126.6 (aromatic-C); 118.2 (q, $CF_3$, $J$ = 291), 87.3 (C-4).

**1,1′-Carbonyl-bis[3-(4-nitrophenyl)-5-trifluoromethyl-1*H*-pyrazole] (3e).** This compound was obtained as a yellow solid, yield 62%, Mp. 258–260°C. $^1$H NMR (DMSO-$d_6$) δ = 8.23 (d, 4H, Ar), 7.99 (d, 4H, Ar), 5.94 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 183.1 (C=O), 170.2 (q, $^2J$ = 28, C-5), 148.1 (C-3), 147.3, 127.8, 123.5, 123.3 (4C, Ar), 118.3 (q, $^1J$ = 292, $CF_3$), 87.7 (C-4).

**1,1′-Carbonyl-bis[3-(4,4′-biphenyl)-5-trifluoromethyl-1*H*-pyrazole] (3f).** This compound was obtained as a yellow solid, yield 83%, Mp. 170–172°C. $^1$H NMR (DMSO-$d_6$) δ = 8.02 (s, 4H, Ar), 7.71–7.76 (m, 8H, Ar), 7.45 (d, 6H, Ar), 6.41 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 187.3 (C=O), 170.5 (q, $^2J$ = 31, C-5), 143.2 (C-3), 138.9, 137.7, 137.4, 128.8, 127.9, 127.7, 126.6, 126.5 (8C, Ar), 119.2 (q, $^1J$ = 287, $CF_3$), 89.2 (C-4).

**1,1′-Carbonyl-bis[3-(1-naphthyl)-5-trifluoromethyl-1*H*-pyrazole] (3g).** This compound was obtained as a yellow solid, yield 74%, Mp. 186–188°C. $^1$H NMR (DMSO-$d_6$) δ = 7.98–8.07 (m, 4H, Ar), 7.70–7.75 (m, 2H, Ar), 7.43–7.60 (m, 8H, Ar), 6.37 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 177.5 (C=O), 176.5 (q, $^2J$ = 33, C-5), 132.8 (C-3), 132.4, 129.8, 129.6, 128.2, 127.5, 126.8, 126.1, 126, 125.1, 123.7 (10C, Ar), 115.7 (q, $^1J$ = 293, $CF_3$), 94.4 (C-4).

**1,1′-Carbonyl-bis[3-(thien-2-yl)-5-trifluoromethyl-1*H*-pyrazole] (3h).** This compound was obtained as a yellow solid, yield 86%, Mp. 237–239°C. $^1$H NMR (DMSO-$d_6$) δ = 7.63 (d, 2H, Thienyl), 7.56 (d, 2H, Thienyl), 7.08 (d, 2H, Thienyl), 5.89 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 178.9 (C=O), 168.9 (q, $^2J$ = 28, C-5), 149 (C-3), 129.7, 127.8, 126.9, 126.7 (4C, Thienyl), 118.7 (q, $^1J$ = 291, $CF_3$), 86.7 (C-4).

**1,1′-Carbonyl-bis[3-(fur-2-yl)-5-trifluoromethyl-1*H*-pyrazole] (3i).** This compound was obtained as a yellow solid, yield 67%, Mp. 259–261°C. $^1$H NMR (DMSO-$d_6$) δ = 7.69 (s, 2H, Furyl), 6.90 (d, 2H, Furyl), 6.53–6.54 (m, 2H, Furyl), 5.85 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 175.8 (C=O), 169.4 (q, $^2J$ = 28, C-5), 155.3 (C-3), 144, 143.8, 111.7, 111.6 (4C, Furyl), 118.9 (q, $^1J$ = 291, $CF_3$), 86.8 (C-4).

**1,1′-Carbonyl-bis(3-phenyl-5-trichloromethyl-1*H*-pyrazole) (9a).** This compound was obtained as a white solid, yield 80%, Mp. 150–152°C. $^1$H NMR (DMSO-$d_6$) δ = 7.43–7.53 (m, 2H, Ar), 7.42–7.48 (m, 8H, Ar), 6.21 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 185.6 (C=O), 175.2 (C-3), 141.8 (C-5), 130.1, 128.6, 128.1, 126.4 (4C, Ar), 100.4 ($CCl_3$), 83.4 (C-4).

**1,1′-Carbonyl-bis(3-tolyl-5-trichloromethyl-1*H*-pyrazole) (9b).** This compound was obtained as a white solid, yield 62%, Mp. 204–206°C. $^1$H NMR (DMSO-$d_6$) δ = 7.68 (d, 4H, Ar), 7.21 (d, 4H, Ar), 6.36 (s, 2H, H-4), 2.33 (s, 6H, Me). $^{13}$C NMR (DMSO-$d_6$) δ = 185.8 (C=O), 174.6 (C-3), 139.6 (C-5), 129.1, 128.6, 128.2, 126.5 (4C, Ar), 100.8 ($CCl_3$), 82.9 (C-4), 20.9 (Me).

**1,1′-Carbonyl-bis[3-(4-chlorophenyl)-5-trichoromethyl-1*H*-pyrazole] (9c).** This compound was obtained as a white solid, yield 76%, Mp. 168–169°C. $^1$H NMR (DMSO-$d_6$) δ = 7.77 (d, 4H, Ar), 7,44 (d, 4H, Ar), 6.98 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 184.1 (C=O), 177.9 (C-3), 138.4 (C-5), 130.7, 130.4, 129.1, 129.0 (6C, Ar), 94.6 ($CCl_3$), 89.5 (C-4).

**1,1′-Carbonyl-bis[3-(4-bromophenyl)-5-trichoromethyl-1H-pyrazole] (9d).** This compound was obtained as a white solid, yield 64%, Mp. 142–144°C. $^1$H NMR (DMSO-$d_6$) δ = 7.72 (d, 4H, Ar), 7.60 (d, 4H, Ar), 6.3 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 184.1 (C=O), 175.3 (C-3), 140.9 (C-5), 131.7, 131.0, 130.0, 128.5 (6C, Ar), 100.3 ($CCl_3$), 83.2 (C-4).

**1,1′-Carbonyl-bis[3-(4-nitrophenyl)-5-trichoromethyl-1*H*-pyrazole] (9e).** This compound was obtained as a white solid, yield 73%, Mp. 191–193°C. $^1$H NMR (DMSO-$d_6$) δ = 8.30 (d, 4H, Ar), 7.71 (d, 4H, Ar), 6.32 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 178.7 (C=O), 174.9 (C-3), 148.2 (C-5), 140.5, 129.8, 123.8, 123.2 (4C, Ar), 97.0 ($CCl_3$), 91.8 (C-4).

**1,1′-Carbonyl-bis[3-(thien-2-yl)-5-trichoromethyl-1*H*-pyrazole] (9f).** This compound was obtained as a white solid, yield 68%, Mp. 183–185°C. $^1$H NMR (DMSO-$d_6$) δ = 7.61 (d, 2H, Thienyl), 7.50 (d, 2H, Thienyl), 7.08 (d, 2H, Thienyl) 6.29 (s, 2H, H-4). $^{13}$C NMR (DMSO-$d_6$) δ = 179 (C=O), 174.7 (C-3), 149.6 (C-5), 129.4, 128.7, 127.8, 126.3 (4C, Thienyl), 100.4 ($CCl_3$), 82.9 (C-4).

**General procedure for the synthesis of ethyl 5-(trifluoromethyl)-3-phenyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole-1-carboxylate (5).** A solution of 5-trifluoromethyl-3-(phenyl)-5-hydroxy-4,5-dihydro-1*H*-pyrazolylcarbohydrazide (**4**) (1 mmol) and 2,4-pentanedione (1 mmol), in ethanol as solvent (4 mL) was stirred under reflux for 20 h. After the reaction time, the solvent was removed under reduced pressure. The solid residue was recrystallized from ethanol and isolated in high purity.

**Ethyl 5-(trifluoromethyl)-3-phenyl-5-hydroxy-4,5-dihydro-1*H*-pyrazole-1-carboxylate (5).** This compound was obtained as a white solid, yield 63%, Mp. 127–129°C [30]. $^1$H NMR (DMSO-$d_6$) δ = 8.08 (s, 1H, OH), 7.76–7.74 (m, 2H, Ar), 7.47 (s, 3H, Ar), 4.23 (q, 2H, $CH_2$, $J$ = 7), 3.86 (d, 1H, H-4a, $J$ = 19), 3.55 (d, 1H, H-4b, $J$ = 19), 1.26 (t, 3H, $CH_3$, $J$ = 7). $^{13}$C NMR (DMSO-$d_6$) δ = 151.08 (C=O), 150.79 (C-3), 130.17, 130.09, 128.46, 126.2 (Ar), 123.4 (q, $CF_3$, $J$ = 285), 91,2 (q, $J$ = 41), C-5), 61.4 (C-4), 44.4 ($CH_2$), 13.9 ($CH_3$). GC-MS (EI, 70 eV): $m/z$ (%) = 302 ($M^+$, 19), 212 (46), 189 (42), 161 (100), 77 (72).

**General procedure for the synthesis of 3-(4-methylphenyl)-5-(trifluoromethyl)-1H-1-phenylpyrazole (6).** A stirred solution of ketone (**3b**) (2 mmol) with phenylhydrazine (2 mmol) in 15 mL of dry ethanol was stirred at 80°C during 4 h. After the reaction time, the solvent was removed under reduced pressure, and the product **6** was dried under reduced pressure, and isolated in high purity.

**3-(4-Methylphenyl)-5-(trifluoromethyl)-1H-1-phenylpyrazole (6).** This compound was obtained as an oil, yield 77%. $^1$H NMR ($CDCl_3$) δ = 7.34 (s, 5H, Ar), 7.11 (s, 4H, Ar), 6.72 (s, 1H, H-4), 2.34 (s, 3H, $CH_3$). GC-MS (EI, 70 eV): $m/z$ (%) = 302 ($M^+$, 100), 281 (19), 233 (5), 77 (10).

**General procedure for the synthesis of 5-hydroxy-3-(4-methylphenyl)-5-(trifluoromethyl)-4,5-dihydroisoxazole (7).** To a stirred solution of ketone (**3b**) (2 mmol) in pyridine (2 mmol), was added a solution of hydroxylamine hydrochloride (2 mmol) in $H_2O$ (1 mL). The mixture was stirred at 45°C for 24 h. After 24 h, water (25 mL) was added and extracted with diethyl ether (3 × 15 mL). The organic layer was dried with $Na_2CO_3$, filtered and evaporated under reduced pressure. The solid was recrystallized from diethyl ether and obtained in high purity.

**5-Hydroxy-3-(4-methylphenyl)-5-(trifluoromethyl)-4,5-dihydroisoxazole (7).** This compound was obtained as a yellow solid, yield 89%, Mp. 62–63°C. $^1$H NMR ($CDCl_3$) δ = 7.53 (d, 2H, Ar, $J$ = 8), 7.23 (d, 2H, Ar, $J$ = 8), 3.66 (d, 1H, H-4a, $J$ = 18), 3.47 (d, 1H, H-4b, $J$ = 18), 2.39 (s, 3H, $CH_3$). GC-MS (EI, 70 eV): $m/z$ (%) = 245 ($M^+$, 100), 176 (30), 133 (21), 91 (53).

Reaction of *N*-arylisoindolines with benzyne afforded predominantly 10-arylisoindolo[2,1-*f*]phenanthridines. On the other hand, *N*-arylisoindolines react with dimethyl acetylenedicarboxylate to give dimethyl 2-(2-aryl-2*H*-isoindol-1-yl)fumarates. Possible reaction mechanisms are discussed.

*J. Heterocyclic Chem.*, **47**, 1079 (2010).

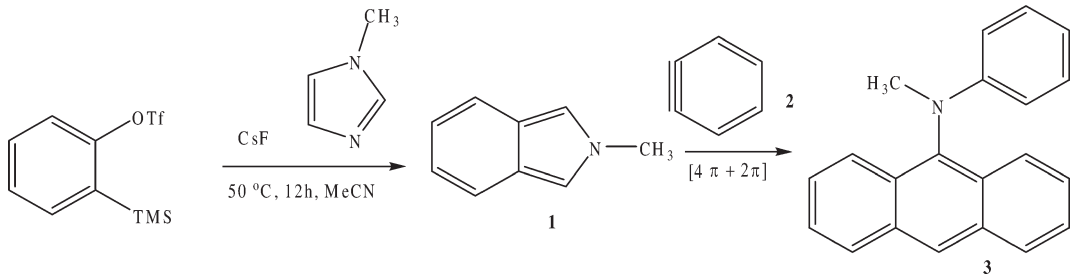
## INTRODUCTION

Previously, it was demonstrated that *N*-arylisoindolines underwent charge-transfer complexation [1,2] and deep seated chemical transformations with 1,4-benzo- or 1,4-naphthoquinones [2] under initial α-H-atom abstraction to give α-oxygenated products [3,4]. Also and in a multistep reaction, 3,3′-(2-aryl-2*H*-isoindol-1,3-ylene)-di-(1,4-naphthoquinone-2-carbonitriles) have been formed in 25–61% yield from a series of *N*-aryl-isoindolines with (1,3-dioxo-2,3-dihydro-1*H*-inden-2-ylidene)propanedinitrile in aerated pyridine [5]. On the other side, *N*-arylisoindolines react with ethenetetracarbonitrile (TCNE) in aerated benzene with the formation of [3-(2-aryl-3-dicyanomethylene-2,3-dihydro-1*H*-isoindol-1-ylidene)-2-aryl-2,3-dihydro-1*H*-isoindol-1-ylidene]propanedinitriles, *N*-aryl-3-dicyanomethylene-isoindol-2-ones, and *N*-aryl-phthalimides as well as ethanetetracarbonitrile [4,6]. The highly reactive parent system, benzyne, reacts with imine compounds to give (*o*-anilinobenzyhydryl)-aniline [7] and phenanthridine derivatives [8] as well as acridines [8] *via* [2π + 2π] and/or [4π + 2π] cycloaddition reactions. We investigated the cycloaddition reactions of aromatic diimines [9], azomethine compounds having [2.2]paracyclophane [10] and ethenyl-[2.2]-paracyclophanes [11] with selected dienophiles including benzyne aiming to synthesize various heterocycles and heterophanes. Synthesis of biologically active heterocycles has also been one of our interests [12,13]. Aryne chemistry has been applied to the synthesis of aryl amines in a tandem reaction including two Diels-Alder reactions, with three benzyne molecules reacting with one imidazole molecule (Scheme 1) [14]. The reaction proceeds *via* formation of 2-methyl-2*H*-isoindole (**1**), which reacted with two more molecules of benzyne (**2**) to give the corresponding *N*-methyl-*N*-phenylanthracen-9-amine (**3**, Scheme 1) [14]. Accordingly, we were encouraged to investigate the reaction of *N*-arylisoindolines **4a–d** [2,15] with benzyne (**2**) and dimethyl acetylenedicarboxylate (DMAD, **11**).

## RESULTS AND DISCUSSION

Herein, we report the cycloaddition reactions of *N*-arylisoindolines **4a–d** with benzyne (dehydrobenzene, **2**), which was generated by diazotization of 1,2-anthranilic acid [11,16–19]. We chose *N*-arylisoindolines **4a–d** bearing electron donating and withdrawing substituents on the benzene ring, to examine their effect on the course of reaction. Scheme 2 outlines the reaction of **4a–d** with **2** in dry acetonitrile under $N_2$ atmosphere.

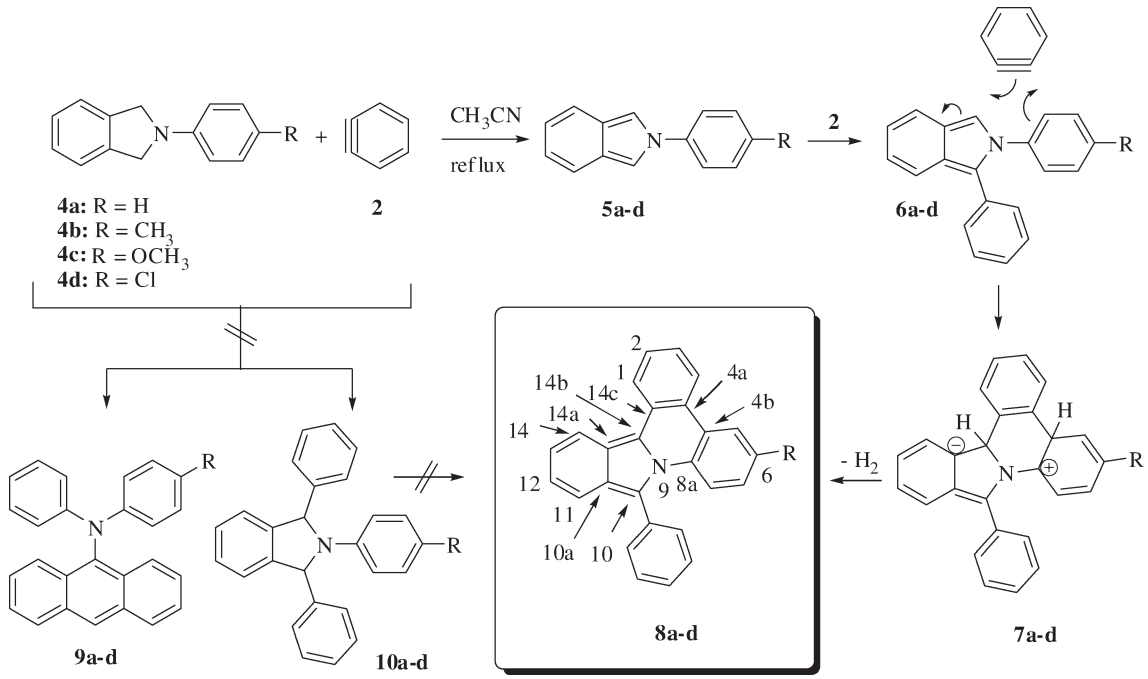
**Scheme 1.** Reaction of *N*-methylisoindolone with benzene.



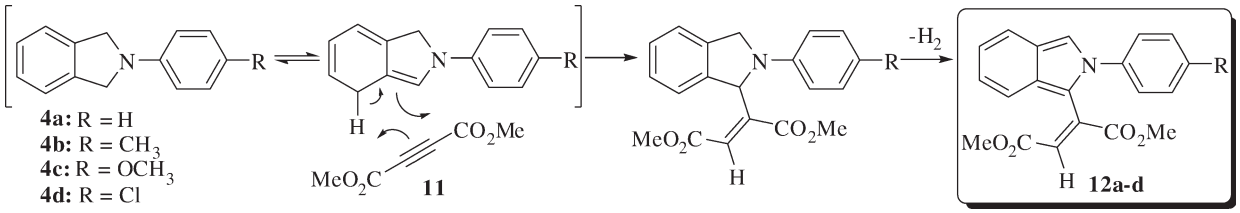
The reaction proceeded to yield, after chromatographic purification and recrystallization, compounds **8a–d** (58–68%) (Scheme 2). The NMR and mass spectra, and elemental analyses, confirm the addition of two molecules of **2** to **4** (Scheme 2).

NMR spectra confirmed the absence of the isoindoline $CH_2$ protons and their corresponding carbons. In **8a**, a double-doublet at $\delta_H = 8.46$ corresponded to H-11 ($J =$ 7.8, 1.2 Hz). Another multiplet at $\delta_H = 8.40$–8.34 was assigned to H-8,12,13,14. Another two double-doublets at $\delta_H = 8.00$ and 7.76 corresponded to H-5 and H-4 ($J =$ 7.8, 1.2 Hz), respectively. The $^{13}C$ NMR spectrum of **8a** showed C-14b, C-10a, C-4a, C-8a at $\delta_C = 150.2$, 141.0, 137.4, and 131.0, respectively. The absence of the symmetrical anthracene ring system from the $^{13}C$ NMR spectra [20] excluded the formation of compounds **9a-d**. One can also envision that the regioisomers **10a–d** might be formed. Of compounds **10a–d,** 1,2,3-triphenylisoindole (**10a**) is known [21]. However, the NMR spectra of **10a** should show the molecular symmetry, which is absent from **8a**. Autoxidation of **10a** is reported to give ring opening, not closure to **8a** [22]; thus, we exclude **10a–d** as intermediates in our pathways leading to **8a–d**. Published syntheses of isoindoles from isoindolines proceed *via N*-oxidation, followed by *O*-acylation and elimination [17,23]. However, benzyne is reported to oxidize dihydropyridines to pyridines [24], presumably by a hydrogen-transfer mechanism like a diimide reduction. We, therefore, propose that **2** oxidizes isoindolines **4a–d** to the corresponding isoindoles **5a–d**, which undergo electrophilic substitution by **2,** selectively at C-1 [25], to give compounds **6a–d**. (The order of these steps may be reversed: see below) Subsequently, compounds **6a–d** react with a second molecule of **2** by intermolecular cycloaddition, followed by oxidation *in situ* to produce the stable heterocyclic compounds **8a–d**. Interestingly, the reaction of isoindolines having electron-donating substituents in the arylidene groups, such as **4b** and **4c**, with

**Scheme 2.** Reaction of *N*-arylisoindolines **4a–d** with benzyne (**2**). **8a**: 6 h, 62%; **8b**: 8 h, 64%; **8c**: 4 h, 68%; **8d**: 10 h, 58%.



**Scheme 3.** Reaction of *N*-arylisoindolines **4a–d** with DMAD (11). **12a**: 14 h, 82%; **12b**: 14 h, 82%; **12c**: 12 h, 87%; **12d**: 18 h, 78%.



**2** yielded the main products **8b**,**c** in higher percentage yields compared with **8d**.

Surprisingly, the reactions of **4a–d** with dimethyl acetylenedicarboxylate (DMAD, **11**), in refluxing ethanol, afforded dimethyl 2(2-aryl-2*H*-isoindole-1-yl)fumarates **12a–d** (Scheme 3). Structure **12a** has formula $C_{20}H_{17}NO_4$, consistent with the molecular ion of $m/z$ = 335. The $^1$H NMR spectrum of **12a** showed the two methyl esters as two singlets at $\delta_H$ = 3.86 and 3.78. Another singlet at $\delta_H$ = 7.00 denoted the vinylic H of the ethylenic bond. The $^{13}$C NMR spectrum of **12a** showed two carbonyl carbons at $\delta_C$ = 170.0 and 168.5. The remaining carbons of **12a** showed signals at $\delta_C$ = 138.9, 138.4, 127.6, 123.2, 120.5, 120.0, 118.8, 116.2, 115.2, 112.8, 102.0, 52.0, and 51.7 corresponding to (Ar-C—N), (vinylic-C-2′), (Ar-CH-6), (Ar-CH-7), (Ar-CH-5), (C-1), (Ar-CH-4), (CH-3), (C-3a), (vinylic-CH-1′), (C-7a), (ester-CH3) and (ester-$CH_3$), respectively. Formally, compounds **12a–d** arise by ene reaction between **11** and a tautomer of **4a–d**, followed by oxidation (Scheme 3). The same kind of sequence can be written for reaction of **4a–d** with benzyne, which would lead the substitution invoked above (Scheme 2) to occur before oxidation.

## CONCLUSIONS

In conclusion, *N*-arylisoindolines react with benzyne to form arylisoindolophenanthridines and with DMAD to form (2-aryl-2*H*-isoindol-1-yl)fumarates. The mechanisms of these transformations are uncertain but appear to involve both concerted reactions and oxidations.

## EXPERIMENTAL SECTION

**General.** Melting points are uncorrected. $^1$H NMR and $^{13}$C NMR spectra were measured in deuterochloroform solutions on Bruker AM-400 or AV-400 spectrometers (400.13 MHz for 1H and 100.6 MHz for 13C). The AV-400 was purchased with assistance from the National Science Foundation (CHE 03-42251). For preparative thin layer chromatography (PLC), glass plates (20 × 48 cm) were covered with a slurry of silica gel Merck $PF_{254}$ and air-dried using the solvents listed for development. Zones were detected by quenching of indicator fluorescence upon exposure to 254 nm UV light. Elemental analyses were carried in Assiut Microanalysis Center of Assiut University. Mass spectroscopy was performed with a Finnigan Mat 8430 spectrometer at 70 eV Institute of Organic Chemistry, TU-Braunschweig. Germany. IR spectra were run on a Shimadzu 470 spectrometer using KBr pellets.

**Starting materials.** 2-Aryl-2,3-dihydro-1*H*-isoindoles **4a–d** were prepared according to published procedures [2,15]. Dimethyl acetylene-dicarboxylate (DMAD, **10**) was bought from Fluka.

**Reaction of isoindolines 4a-d with benzyne (2).** Benzenediazonium carboxylate was prepared by the procedure described in [16–19]. Under nitrogen atmosphere, 6 mmol of benzyne (**2**) precursor was slowly added to the stirred and refluxed solutions of **4a–d** (2 mmol) in dry acetonitrile (250 mL) for 1 h. The reaction mixture was refluxed till the consumption of the starting materials was completed (reaction progress monitored by TLC analysis) in 4–10 h. The solvent was concentrated and the residue was filtered off. The precipitate was washed with dichloromethane (200 mL). The filtrate was then concentrated in vacuum and the residue was applied to PLC using toluene as an eluent. The migrating zones contained the products **8a–d** were recrystallized from the stated solvents. All zones were extracted with acetone and the products recovered.

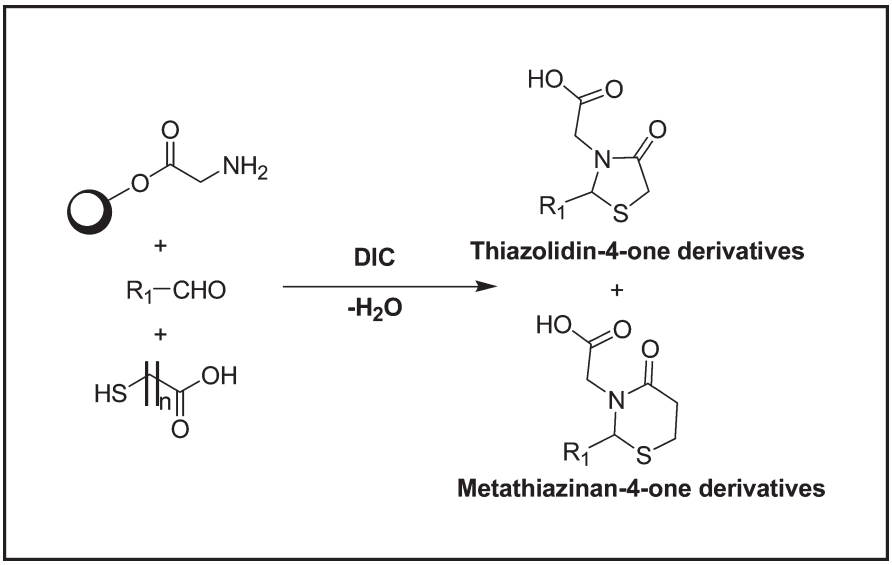
Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



A diisopropylcarbodiimide (DIC) mediated small library of thiazolidin-4-one and 1,3-Thiazinan-4-one derivatives were efficiently synthesized using one pot three component condensation of amino acid, aldehyde, and mercapto carboxylic acid on a polymer support. The study shows significantly higher yields of the thiazolidin-4-one derivatives thereby indicating a lower dependence on the nature of the amino acid and aldehyde components. As an obvious extension of this protocol, the reactions were performed using heterocyclic aldehydes and substituted hindered aromatic aldehydes instead of simple aromatic aldehydes. The synthesized library compounds were also screened for their antifungal acitivity against these three pathogenic fungi: *Candida albicans (Ca), Candida parapsilosis (Cp)*, and *Cryptococcus neoformans (Cn)*.

*J. Heterocyclic Chem.,* **47**, 1084 (2010).

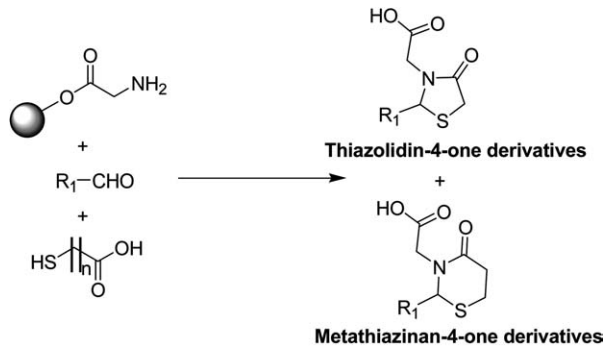
## INTRODUCTION

The categorical imperative of modern drug discovery is to produce better clinical candidates that are less prone to failure at later stage. Solid phase organic synthesis is regarded as one of the key disciplines for providing constant supply of chemical compounds that may be monitored for their biological activity on the vastly increasing number of biological targets. Solid phase organic synthesis together with high throughput synthesis and efficient data management, undoubtedly lead to acceleration in the process of drug discovery [1].

There are numerous biologically active molecules whose framework includes a five-membered and six-membered ring containing two hetero atoms. Thiazolidin-4-one and thiazinan-4-one are biologically important scaffolds known to be associated with several biological activities. These structures contain one **S** and one **N** atom in skeleton as heterocyclic atoms [2–3].

Several protocols for the synthesis of thiazolidin-4-one and thiazinan-4-one derivatives are available in the literature [4–12] (Scheme 1). Essentially these are three component reactions involving an amine, a carbonyl compound and a mercapto acid. The process can be either a one-pot three-component condensation or a two-step process. The reaction has been suggested to proceed via imine formation followed by the attack of sulfur nucleophile on the imine carbon. The last step involves intramolecular cyclization with the elimination of water to give the final compound. This step appears to be

**Scheme 1.** Schematic representation for synthesis of thiazolidin-4-one and metathiazinan-4-one derivatives on solid support.



critical for obtaining high yields. Therefore, variations have been affected in this step to facilitate removal of water. Most commonly used protocols utilize azeotropic distillation, molecular sieves, and use of other desiccants like anhydrous zinc chloride [13], sodium sulfate [14], or magnesium sulfate [15]. These protocols require prolonged heating at 70–80°C for 17–20 h and give moderate to good yields. More recently, an improved protocol has been reported wherein *N*,*N*-dicyclohexylcarbodiimide (DCC) or 2-(1H-benzotrizole-1-yl)-1,1,3,3 tetramethyluraniumhexafluorophospate (HBTU) is used as an acid amine coupling and dehydrating agent to accelerate intramolecular cyclization, resulting in faster reaction and improved yields [16,17]. First time Holmes *et al*. [18] reported solution and polymer-supported synthesis of thiazolidin-4-one and thiazinan-4-one derivatives, derived from amino acids. In amino acids, the carboxylic acid function serves as an anchor group for attachment to the site of support. The condensation of this support bound amine with several aldehydes and mercapto acetic acids in a one-pot reaction, afforded desired products. A series of experiments were performed using different proportions to optimize the ratio of reactants. The ratio of reactants in 1:2:3 for amino acid, aldehyde, and mercapto acetic acid, respectively, as in case of solution phase HBTU protocol gave poor yields. Quantitative yields were obtained by using the ratio of reactants in 1:4:6 for amino acid, aldehyde, and mercapto acetic acid, respectively. This is in agreement with the earlier observation by Holmes *et al*. In a typical experiment, amino acid and aldehyde were shaken in dry tetrahydrofuran (THF) for 15 min, followed by addition of mercapto acetic acid and HBTU, and shaking of reaction mixture for an additional 5 h. The resin was then filtered, washed successively with *N*,*N*′-dimethyl formamide (DMF) (3 × 2 mL), methanol (MeOH) (3 × 2 mL), dichloromethane (DCM) (3 × 2 mL), and diethylether (3 × 2 mL) and dried in vacuum. After cleavage of the final compounds from the resin by treating it with trifluroacetic acid (TFA): dichloromethane (DCM) (1:1) mixture, the desired products in almost quantitative yields were obtained. It was observed that in the case of phenylalanine, the yields were significantly lower than that with glycine, using HBTU in both the reactions. Fast decomposition of HBTU and steric hindrance could be a major reason for lower yield with phenylalanine.

Previous studies suggest that the use of carboxylate activating reagents have facilitated cyclization [19]. Therefore it was thought to explore *N, N*′-diisoproplylcarbodiimide (DIC) as a coupling and dehydrating agent by keeping *N*,*N*- dicyclohexylcarbodiimide (DCC) mediated protocol in mind, which is usually used in solid phase peptide coupling reactions [20–21]. The generality of the DIC mediated reactions have been demonstrated by synthesizing a variety of thiazolidin-4-one and thiazinan-4-one derivatives. In previous study, it was observed that sterically hindered amino acids react sluggishly during cyclization and lead to poor yields or sometimes do not react at all. To avert these shortcomings, in this study, sterically hindered amino acids were examined and the results obtained were excellent (Table-2).

*Candida albicans, Candida parapsilosis*, and *Cryptococcus neoformans* are the common opportunistic fungi responsible for infections. Out of these *Candida albicans* infections may become problematic in severely immunocompromised patients and may induce oral candiasis,

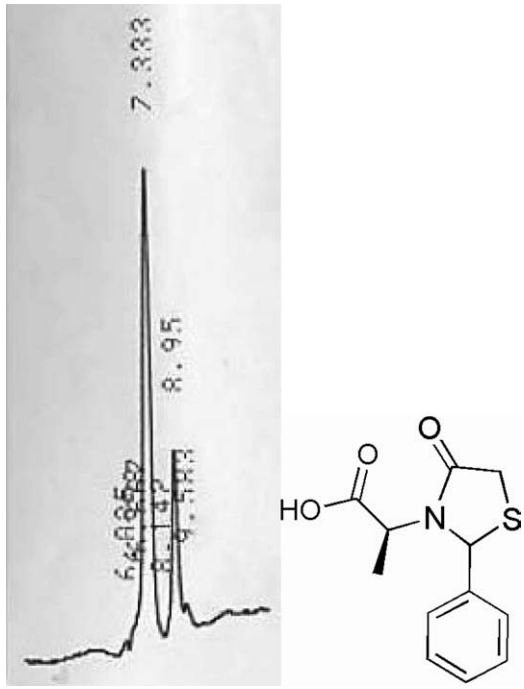


**Figure 1.** The HPLC data of the final compound VI. HPLC trace of diastereomeric thiazolidin-4-one (VI) (7.333 and 8.95 min) after TFA cleavage from solid support at 220 nm.

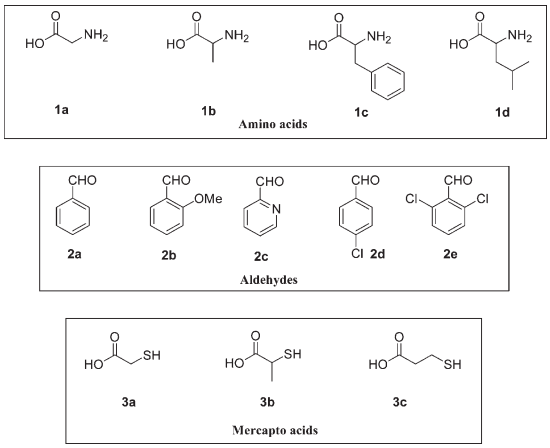
oesophageal candiasis, and vaginal candiasis. *Candida parapsilosis* is second to *Candida albicans* as a cause of candida endocarditis. Approximately 25% of candidal endocarditis cases reported have been caused by *Candida parapsilosis*. On the contrary *Cryptococcus neoformans* is the causative agent of cryptococcosis, which is the leading cause of morbidity and mortality due to fungi in patients with AIDS. Thus, there is urgent need for more effective and novel antifungal therapies. Therefore in the first instance, synthesized library compounds were screened for their antifungal activity, against these three pathogenic fungi: *Candida albicans (Ca), Candida parapsilosis (Cp)*, and *Cryptococcus neoformans (Cn)*.

**Table 1**

Building blocks for solid phase synthesis.



## EXPERIMENTAL

The reagents used in the study are figured in Table 1. Unless otherwise stated, the materials were of the highest grade available from commercial sources and used without further purification. The solvents and reagents were purchased from the following sources: Wang resin (1% divinylbenzene, 200–400 mesh, 0.5–1.2 mmol/g substitutions) from Novabiochem; Fmoc protected amino acids, *N*,*N*′-diisopropylcarbodiimide, piperidine, diisopropylamine, and trifluoroacetic acid from Aldrich and mercapto acid derivatives from Lancaster.

The reactions on solid phase were optimized using polypropylene syringes of 5 mL capacity (Becton and Dickinson) with fritt (12 mm diameter and 2 mm thickness for 5 mL syringes) inserted at the bottom of the syringes. They were shaken on an orbital shaker (IKA-Vibrax-VXR). The syringes were capped at the bottom with Leur positive (VSG-0419, Roland Vetter) cap. The compounds after cleavage from the resin were dried under $N_2$. $^1$H NMR spectra were obtained on Brucker Evans DRX-600 spectrometer and chemical shifts (δ) were reported in ppm relative to TMS. Because of solubility properties, the solvents used was $CDCl_3$. RP-HPLC analysis of crude products was carried using a 5 μm, 4.8 × 150 mm C-18 reverse-phase column with a linear gradient of Acetonitrile:Water (80:20 v/v) with 100 μL TFA over 25 min. The flow rate was 0.4 mL/min, and UV detection was observed at 220 nm. The retention time of compounds has been expressed in minutes as $t_R$ (Fig. 1). Mass spectra were recorded using electron spray ionization (ESI) technique or FAB.

**Ninhydrine test for aliphatic primary amines.** Ninhydrine test is used to detect the presence and absence of free aliphatic $-NH_2$ group on resin beads after de-protection of Fmoc group. The test was performed by taking small aliquot of the resin in an eppendorf followed by the addition of few drops of following solutions:

1. 80% solution of phenol in absolute alcohol.
2. 2% solution of aqueous KCN (0.001*M*) in Pyridine.
3. 5% solution of Ninhydrine in absolute alcohol.

The eppendorf was then heated at 100°C in a water bath, for 5 min. and colour of the beads was examined. The presence of free aliphatic $-NH_2$ group of amino acids was indicated by blue resin beads (Positive Ninhydrine test), whereas its absence was confirmed by colorless beads (Negative Ninhydrine test).

## GENERAL PROCEDURE

**Loading of amino acid on resin.** The Wang resin (500 mg) was swelled by shaking on an orbital shaker (IKA-Vibrax-VXR) at 600 rpm in 5 mL DCM:DMF (1:1) for 30 min. The resin was then filtered and washed with DMF. The resin so obtained was then coupled with a preactivated solution of amino acid (5 equiv., 2.825 mmol), DIC (3 equiv., 1.695 mmol, 267.38 μL) and DMAP (3 equiv., 1.695 mmol, 207 mg) in dry DMF (2 mL) and the reaction mixture was allowed to shake at room temperature for 6–7 h. The resin was filtered and washed, successively, with DMF (3 × 2 mL), MeOH (3 × 2 mL), DCM (3 × 2 mL), and diethylether (3 × 2 mL) and dried in vacuum. A second repeat cycle was made with a preactivated solution of amino acid (2 equiv., 1.13 mmol), DIC (1.5 equiv., 0.847 mmol, 133.5 μL) and DMAP (1.5 equiv., 0.847 mmol, 103.5 mg) in dry DMF (2 mL), and the reaction mixture was allowed to shake at room temperature for 6–7 h to achieve complete loading of amino acids on resin. The resin was filtered and washed, successively, with DMF (3 × 2 mL), MeOH (3 × 2 mL), DCM (3 × 2 mL), and diethylether (3 × 2 mL) and dried in vacuum. (Scheme 2).

**Deprotection of Fmoc groups of resin bound amino acids.** This was carried out by treating the resin twice with 30% (v/v) piperidine/DMF solution at room temperature for 15 and 25 min, respectively. Then the resin was filtered and washed successively with DMF (3 × 2

mL), MeOH (3 × 2 mL), DCM (3 × 2 mL), and diethylether (3 × 2 mL) and dried in vacuum.

**Preparation of resin bound thiazolidin-4-one and thiazinan-4-one derivatives.** The Fmoc-deprotected amino acids loaded Wang resin (200 mg in a polypropylene syringe) was swelled in dry THF for 30 min. After 30 min (hetero)/aromatic aldehyde (4 eq.) in THF was added and shook on an orbital shaker (IKA-Vibrax-VXR) at 600 rpm for 30 min. Then, an appropriate mercapto acid (6 eq.) was poured into the reaction mixture. After 5 min diisopropylcarbodiimide (DIC) (4 eq.) was added to the reaction mixture. The reaction mixture was then allowed to shake at room temperature for 8 h. Diisopropylurea (DIU) was separated during reaction was removed by washing. The resin was then filtered, washed successively with DMF (3 × 2 mL), MeOH (3 × 2 mL), DCM (3 × 2 mL), and diethylether (3 × 2 mL) and dried in vacuum.

**Cleavage of final compounds (I–XXIII).** The final compounds (Table 2) were cleaved from the resin by treating it with TFA:DCM (1:1) mixture. The resulting mixture was filtered and the filtrate was evaporated to dryness in vacuum.

## ANTIFUNGAL ACTIVITY

The $IC_{50}$ values of library compounds were determined against the test fungi by using micro-broth dilution technique as per guidelines of NCCLS M-27A [22]. $IC_{50}$ values of standard antifungal (Miconazole) and synthetic compounds were measured in 96 well tissue culture plate (CellStar Greiner Bio One, Germany) using RPMI 1640 media buffered with MOPS [3-(*N*-Morpholino) propanesulfonic acid, Sigma]. Starting inocula of test culture were maintained at 1.0–5.0 × 103 cfu/mL. A solution of 2 mg/mL of library compounds in 10% DMSO was used. Microtitre plates were incubated at 35°C in a moist dark chamber and $IC_{50}$ and MIC values were recorded spectrophotometrically (Softmax pro 4.3, Versamax microplate reader, molecular devices) after 48 h for *candida albicans* and *candida parapsilosis* and 72 h for *cryptococcus neoformans*. The antifungal

***2-(4-Oxo-2-phenyl-thiazolidin-3-yl)-3-phenyl-propionic acid (X).*** mp 75–81°C (3:1 mixture of diastereomers): IR (KBr) 1681.81, 1745.46; $^1$H NMR ($CDCl_3$, 600 MHz) δ major isomer 3.23–3.27 (m, 1H, $CH_2$-Ph), 3.31–3.48 (m, 1H, $CH_2$-Ph), 3.66–3.76 (m, 2H, $H_A$ & $H_B$), 3.89 (q, $J$ = 6.0, 0.5H, CH), 5.07 (q, $J$ = 6.0, 0.5H, CH), 6.74 (bs, 1H, OH), 6.87 (s, 0.5H, C-2), 6.98 (s, 0.5H, C-2), 7.14–7.41 (m, 7H, Ar-H), 7.48 (t, $J$ = 7.2, 1H, H5-benzyl), 7.68 (d, $J$ = 7.20, 2H, $H_{2\&6}$-Ph); $^{13}$C NMR (CDCl3) δ major isomer (32.66, 33.00), (33.10, 34.30), (58.97, 59.25), (65.49, 65.94), (126.65, 127.12), (128.48, 128.53), (128.62, 128.69), (128.84, 129.05), (129.24, 129.45), (129.72, 132.00), (133.48, 135.77), (136.44) 137.39), (172.22, 172.49), (173.67, 174.02).

The above findings draw attention to address the scope and limitations of the present protocol. The work concentrated on aldehydes having electron-donating and electron-withdrawing substituents. It is evident from the yields that the present method obviates the limitations of earlier methods and is more versatile. Furthermore, this method shows significantly higher yields of the thiazolidin-4-one derivatives thereby indicating a lower dependence on the nature of the amino acid and aldehyde components (Table 2). As an obvious extension of this

protocol, the reactions were performed using heterocyclic aldehydes and substituted hindered aromatic aldehydes instead of simple aromatic aldehydes. The corresponding thiazolidin-4-one derivatives were obtained in quantitative yield. Generally, low yields of thiazolidin-4-one derivatives were reported in the literature when amino acids were used as a source of amine; however, with this protocol, excellent to moderate yields were obtained. The versatility of the protocol and to further enhance the scope of this reaction, efforts were made on adaptation of the method for synthesis of thiazinan-4-one, another biologically active chromophore. It is apparent from the variety of reactants that this method has the potential to generate a battery of thiazolidin-4-one and thiazinan-4-one derivatives by solid phase combinatorial synthesis.

The results for the antifungal assay of the synthesized library compounds are summarized in Table 3. As is evident that out of 23 synthesized molecules, compound XIV exhibited best inhibitions in comparison to others with $IC_{50}$ values of 22.01 μ*M* against *Ca*, 13.54 μ*M* against *Cp*, and 12.16 μ*M* against *Cn*.

Our studies thus suggest that activity is strongly dependent on the nature of the substituent at C-2 and N-3 positions of thiazolidin-4-one ring. In particular, a high activity level was observed for compounds possessing a 2,6-dihalophenyl group at C-2 position and a phenethyl ring at N-3 position.

The results presented in this study indicate that changes at C-2 position of thiazolidin-4-one moiety, except for 2,6-dihalophenyl, may lead to reduction in antifungal activity of these compounds. However, introduction of phenethyl moiety at the N-3 position in the thiazolidin-4-one ring is well-supported.

Piperidine catalyzes efficiently the one-pot, four-component reaction of β-ketoesters, hydrazine hydrate, malononitrile, and isatines in aqueous media. The reaction was done at room temperature and the spiro[indoline-3,4′-pyrano[2,3-*c*]pyrazole]-5′-carbonitriles were obtained with high yields and purity *via* an easy work-up procedure. These compounds were also investigated *in vitro* for antibacterial activities.

## INTRODUCTION

Multicomponent reactions (MCRs) are of increasing importance in organic and medicinal chemistry because the strategies of MCR offer significant advantages over conventional linear-type syntheses. MCRs leading to interesting heterocyclic scaffolds are particularly useful for the creation of diverse chemical libraries of ''drug-like'' molecules for biological screening, as the combination of three or more small molecular weight building blocks in a single operation leads to a high combinatorial efficacy [1,2]. Designing of MCRs in water is another attractive area in chemistry [3] because water is a cheap, safe, and environmentally benign solvent. There is need for developing MCRs in water with a suitable catalyst and without the use of any harmful organic solvents.

The indole moiety is probably the most well-known heterocycle, a common and important feature of a variety of natural products and medicinal agents [4]. Furthermore, it has been reported that sharing of the indole 3-carbon atom in the formation of spiroindoline derivatives highly enhance biological activity [5–7]. The spirooxindole system is the core structure of many pharmacological agents and natural alkaloids [8–10]. Therefore, a number of methods have been reported for the preparation of spirooxindole-fused heterocycles [11–14].

Substituted amino-pyrans take a significant place among the six-membered oxygen-containing heterocycles. Some of them possess anticancer and antimicrobial activity [15,16]. Serotonin receptor modulators (pteropodine and its stereoisomers), natural alkaloids, containing both spiro-indole and pyran cycles, were isolated from stem bark of *Uncaria tomentosa* (Fig. 1) [8]. Several spiroheterocycles, containing both indole and pyran heterocycles, possess anticonvulsant and analgetic [17], herbicidal [18], and antibacterial activities [19]. Similarly, pyrano[2,3-*c*]pyrazoles play an essential role in biologically active compounds and therefore represent an interesting template for medicinal chemistry [20–22].

As part of our continuing efforts on the synthesis of biologically active heterocyclic compounds [23–32], especially spirooxindole derivatives [33–35], we report herein a novel and clean synthesis of spiro[indoline-3,4′-pyrano[2,3-c]pyrazole]-5′-carbonitriles 5 through a one-pot, four-component condensation reaction of β-ketoesters 1, hydrazine hydrate 2, malononitrile 3, and isatins 4 in water (Scheme 1).

## RESULTS AND DISCUSSION

We found that the one-pot, four-component condensation reaction of β-ketoesters **1a,b**, hydrazine hydrate **2**, malononitrile **3**, and isatins **4** proceeded rapidly in water at ambient temperature and were complete after 5 h to afford spiro[indoline-3,4′-pyrano[2,3-*c*]pyrazole]-5′-carbonitriles **5a–l**, in high yields (Table 1). $^{1}H$ and $^{13}C$ NMR spectra of the crude products clearly indicated the formation of spirooxindol-fused pyranopyrazole **5**. The nature of these compounds as 1:1:1:1 adducts was apparent from their mass spectra, which displayed, in each case, the molecular ion peak at appropriate m/z values. Compounds **5a–l** are stable solids whose structures were

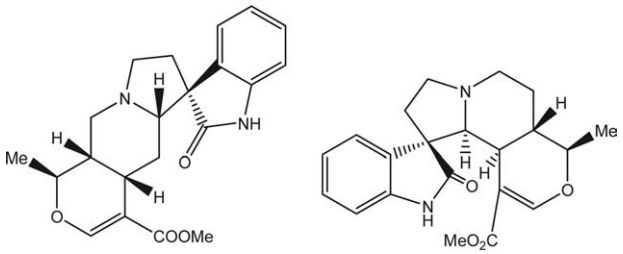

**Figure 1.** Spirooxindole natural alkaloid.

established by IR, $^{1}H$ and $^{13}C$ NMR spectroscopy, and elemental analysis. The structures of **5j** were confirmed by a single-crystal X-ray analysis [36] (Fig. 2).

The results were good in terms of yields and product purity in the presence of piperidine, whereas without piperidine the yields of products were very low (<40%) even after 24 h.

To the best of our knowledge, this new procedure provides the first example of an efficient and four-component method for the synthesis of spiro[indoline-3,4′-pyrano[2,3-*c*]pyrazole]-5′-carbonitriles. This method, based on four-component piperidine-catalyzed reaction in water, is the most simple and convenient and would be applicable for the synthesis of different types of spiroindoline-pyranopyrazoles.

For the investigation of the reaction mechanism, it is notable that when the ethyl acetoacetate **1a**, hydrazine hydrate **2**, malononitrile **3**, and isatin **4a** were reacted for 1 h, the intermediate **6** and **7** were isolated and characterized by spectroscopic methods. When intermediate **6** and **7** were isolated and reacted in the presence of piperidine under the same reaction conditions, the product **5a** was obtained in 75% yield (Scheme 2).

According to the results, the formation of products **5** can be rationalized by initial formation of pyrazol-5-ol **6** *via* condensation of **1** and **2**. Subsequent Michael-type addition of **6** to the intermediate **7** (formed *in situ* by reaction of the malononitrile **3** and isatin **4**), followed by cyclization and tautomerization afforded the corresponding products **5** (Scheme 3).

To further explore the potential of this protocol for spiro-heterocyclic synthesis, we investigated reaction of acenaphthylene-1,2-dione **8** instead of isatin **4** and

**Scheme 1**

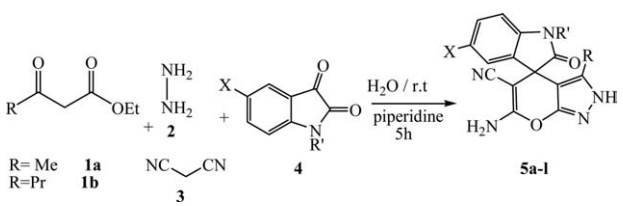

**Table 1**

Synthesis of spiroindoline-pyranopyrazoles **5**.

obtained spiro[acenaphthylene-1,4′-pyrano[2,3-*c*]pyrazole]-5′-carbonitrile **9** in 87% yield (Scheme 4).

Finally, all synthesized compounds were screened for antimicrobial activity. The microorganisms used in this study were *Escherichia coli* ATCC 25922, *Pseudomonas aeruginusa* ATCC 85327, (Gram-negative bacteria), *Enterococcus faecalis* ATCC 29737, *Bacillus subtilis* ATCC 465, *Bacillus pumilus* PTCC 1114, *Micrococcus luteus PTCC* 1110, *Staphylococcus aureus* ATCC 25923, *Staphylococcus epidermidis* ATCC 12228, *Sterptococcus mutans* PTCC 1601 (Gram-positive bacteria). The minimum inhibitory concentration of the synthesized compounds determined by microdilution method [37] and compared to two commercial antibiotics (Table 2).

As can be seen from Table 2, good to improved antibacterial activity was observed for most of the compounds against all species of Gram positive and Gram negative bacteria used in the study. Almost, all of the

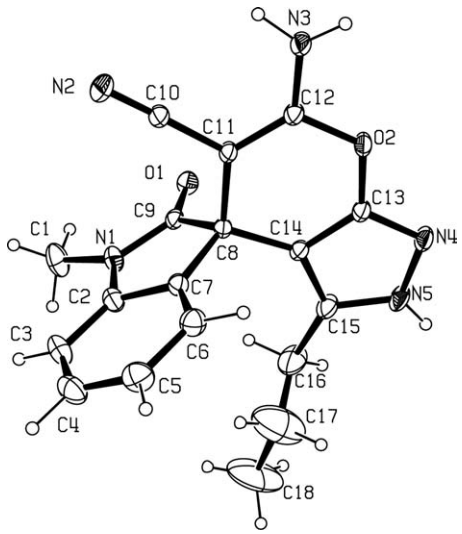

**Figure 2.** X-ray crystal structure of **5j**.

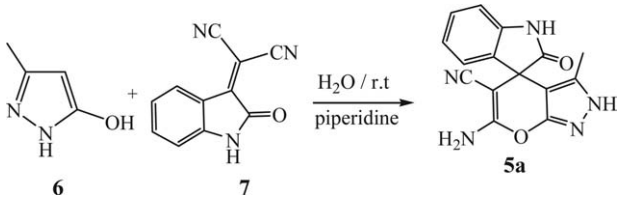
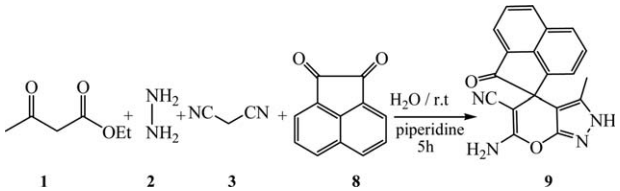
**Scheme 2**



**Scheme 4**



compounds were found to be more active than Gentamicin against all tested strains.

In conclusion, we have developed a facile, one-pot and four-component procedure for the preparation of 1′*H*-spiro[indoline-3,4′-pyrano[2,3-*c*]pyrazole]-5′-carbonitriles of potential synthetic and biological interest. The method is simple, starts from readily accessible commercial reagents, and provides biologically interesting spirooxindol derivatives in good yields. Almost most of the compounds exhibited good to excellent antibacterial activity against all the tested strains.

## EXPERIMENTAL

Melting points were taken on an Electrothermal 9100 apparatus and left uncorrected. IR spectra were obtained on a Shimadzu IR-470 spectrometer. $^1$H and $^{13}$C NMR spectra were recorded on a BRUKER DRX-300 AVANCE spectrometer at 300.13 and 75.47 MHz. NMR spectra were obtained on solutions in DMSO using TMS as internal standard. All of the chemicals were purchased from Fluka, Merck, and Aldrich and used without purification.

**Typical procedure for the preparation of 6′-amino-3′-methyl-2-oxo-2′*H*-spiro[indoline-3,4′-pyrano[2,3-*c*]pyrazole]-5′-carbonitrile (5a).** To a magnetically stirred solution of ethyl acetoacetate **1a** (1 mmol) and hydrazine hydrate 96% **2** (1 mmol) in water (5 mL) for 0.5 h were added isatin **4a** (1 mmol), malononitril **3** (1 mmol), and piperidine (0.3 mmol) at room temperature. The mixture was finally stirred for 4.5 h. After completion of the reaction (TLC), the reaction mixture was filtered off and the residue was washed with water (10 mL) and then residue recrystallized from EtOH to afford the pure product **5a** as brown powder (89%). m.p. 224°C (dec). **8** **2**

*trans*-Octahydropyrrolo[3,4-*b*][1,4]oxazine is an important heterocycle within the pharmaceutical industry for the preparation of biologically active analogs, including the phase III drug, finafloxacin. A practical synthesis of the title compound (**2**) is described in eight steps and ca. 10% overall yield. The key synthetic step is the formation of the pyrrolo[3,4-*b*][1,4]oxazine core **20** *via* a one pot double *N*-alkylation of the corresponding bis-tosylate **18** with 4-nitrobenzenesulfonamide. Subsequent removal of the nosyl group occurred under mild conditions.

*J. Heterocyclic Chem.*, **47**, 1095 (2010).

## INTRODUCTION

The morpholine ring is utilized extensively in drug discovery research. Due to its hydrophilic nature, medicinal chemists will often look for opportunities to incorporate morpholine into their analogs as a means to increase solubility. Within a chemical series, morpholine, with its lower pKa compared to isosteric piperidine (8.3 *vs*. 11.1), has been shown to reduce hERG activity [1], which is an early indicator of cardiovascular risk. Numerous drugs incorporating the morpholine ring have been approved for the treatment of human diseases; a snapshot of some recent examples is shown in Chart 1, including linezolid (Zyvox®) [2], gifitinib (Iressa®) [3], and reboxetine [4]. Finafloxacin, which is currently undergoing clinical trials for the treatment of *Helicobacter pylori (H. pylori)* infections [5], possesses a morpholine ring fused onto a pyrrolidine ring, giving rise to the *trans*-pyrrolo[3,4-*b*][1,4]oxazine heterocycle. The ring fusion restricts the spatial orientation of the morpholine ring compared to the unfused analog; this restriction is presumably important for optimal binding to the biological receptor. In addition, the pyrrolidine nitrogen provides a chemical handle for attaching the heterocycle to the analog of interest.

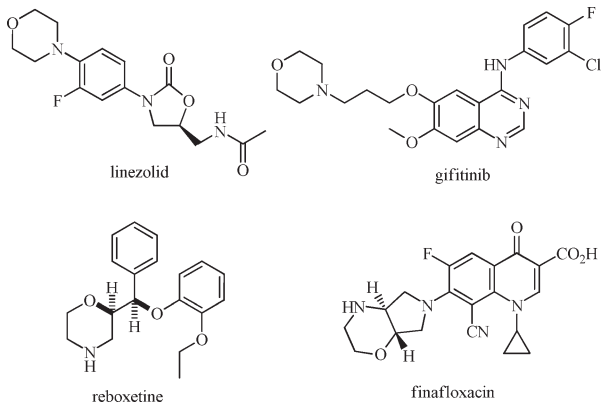

**Chart 1.**

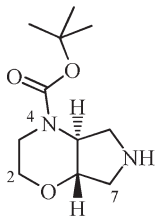
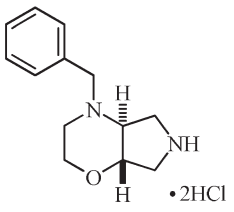
Recently, Hong *et al*. [6] have disclosed a synthesis of enantiomerically pure (4a*S*,7a*S*)-*tert*-butyl hexahydro pyrrolo [3,4-*b*][1,4]oxazine-4(4a*H*)-carboxylate [(4a*S*,7a*S*)-**1**], wherein the morpholine nitrogen is differentially protected with respect to the pyrrolidine nitrogen. In connection with our own medicinal chemistry efforts, we were also interested in preparing this novel heterocycle wherein the morpholine nitrogen was selectively protected. We detail below a stereoselective synthesis of (+/−)-*trans*-4-benzyloctahydropyrrolo[3,4-*b*][1,4]oxazine (**2**).



(*4aS, 7aS*)-**1**



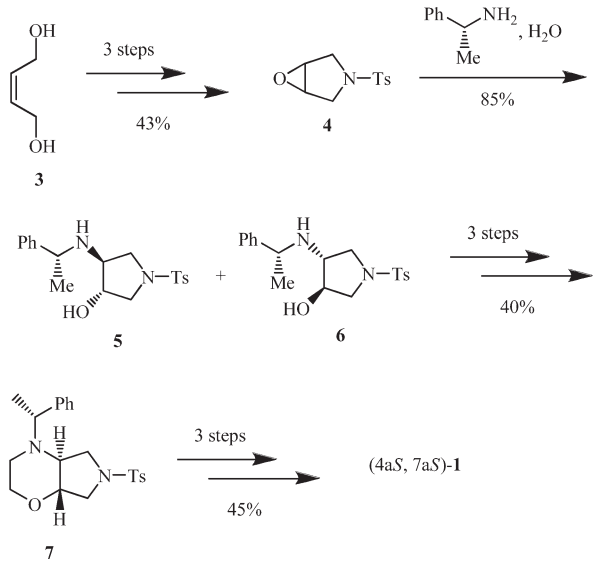
**2**

## RESULTS AND DISCUSSION

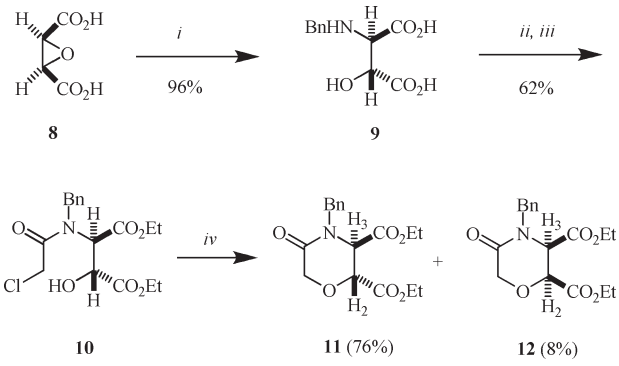
Hong prepared enantiomerically pure pyrrolo[3,4-*b*][1,4]oxazine (4a*S*,7a*S*)-**1** by a ten step synthesis outlined in Scheme 1 [6]. Thus, epoxypyrrolidine **4** was prepared in three steps from commercial (*Z*)-but-2-ene-1,4-diol (**3**). Opening epoxide **4** with (*R*)-α-methylbenzylamine led to diastereomers **5** and **6**, which were readily separated by solvent extraction and crystallization techniques. Treatment of diastereomer **5** with chloroacetyl chloride, followed by exposure to base effected ring closure, and subsequent reduction of the lactam carbonyl afforded the intact pyrrolo[3,4-*b*][1,4]oxazine heterocycle **7**. Exchanging the α-methylbenzyl protecting group on N(4) for a *tert*-butoxycarbonyl (BOC) group and deprotection of the pyrrolidine nitrogen led to pyrrolo[3,4-*b*][1,4]oxazine (4a*S*,7a*S*)-**1**.

Our approach toward synthesizing the *trans*-fused pyrrolo[3,4-*b*][1,4]oxazine heterocycle focused on stereoselectively preparing a 2,3-disubstituted morpholine wherein the sustituents at C(2) and C(3) are *trans* with respect to each other. Thus, the known dicarboxylic acid **9** [7], prepared in near quantitative yield from commercial *cis*-epoxysuccinic acid (**8**), served as the logical starting point (Scheme 2). Esterification of **9** with absolute ethanol and hydrogen chloride, generated *in situ*

**Scheme 1**



**Scheme 2.** Reagents and conditions: (i) $BnNH_2$ (excess), $H_2O$, reflux, 3 h; (ii) AcCl, EtOH, 0°C, 1h; add substrate, reflux, 72 h; (iii) chloroacetyl chloride, $CH_2Cl_2$-aq. 1 *N* NaOH, 0°C, 15 min; (iv) NaH (1.8 eq.), THF-$CH_3CN$-DMF (90:5:5), 0°C, 1 h.



from ethanol and acetyl chloride, provided the corresponding diester in good yield. Esterification with ethanol in the presence of thionyl chloride was also effective; however, the yield was significantly lower, and chromatography was necessary to remove the impurities formed during the reaction. Treatment of the diester with chloroacetyl chloride under Shotten-Baumann conditions afforded α-chloroacetamide **10**. Under these conditions, 5–10% of the corresponding *o*-acylated product was formed along with 1–2% of di-acylated product. However, the *o*-acylated product could be easily removed by extracting the crude reaction mixture with aqueous hydrochloric acid. Subjection of chloroalcohol **10** to sodium hydride gave rise, after purification, to a 9:1 mixture [8] of morpholinones **11** and **12**, respectively. Fortuitously, whereas the desired *trans*-diester **11** was a solid (mp 117–118°C), the undesired *cis*-diester **12** was an oil. Thus, a simple trituration of the product mixture efficiently removed the undesired **12**, affording a 76% yield of pure **11**.

The structural assignments of **11** and **12** were based on a combination of 1D and 2D NMR experiments. For *trans*-diester **11**, the vicinal coupling constant between $H_2$ and $H_3$ was 1.7 Hz, which suggested that the ester groups adopt a pseudo *trans*-diaxial orientation to avoid $A^{1,2}$ strain between the C(3) ester moiety and the benzylic hydrogens (Fig. 1). This interpretation is consistent

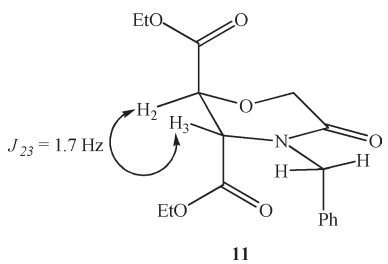


**Figure 1.** 3D representation of diester **11.** Arrow shows vicinal coupling relationship.

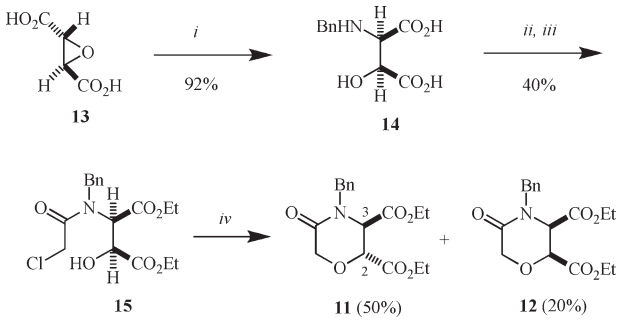
**Scheme 3.** Reagents and conditions: (i) $BnNH_2$ (excess), $H_2O$, reflux, 3 h; (ii) AcCl, EtOH, 0°C; add substrate, reflux, 72 h; (iii) chloroacetyl chloride, $CH_2Cl_2$-aq. 1.0 *N* NaOH, 0°C, 15 min; (iv) NaH (1.8 eq.), THF-$CH_3CN$-DMF (90:5:5), 0°C, 1 h.



with observations made by others on similar ring systems [9]. Also, once the pyrrolidine ring was fused onto **11** (*vide infra*), the $H_2$–$H_3$ vicinal coupling constant changed to ca. 9 Hz, which is consistent with a *trans*-diaxial orientation of the two vicinal hydrogens. The $H_2$–$H_3$ vicinal coupling constant for *cis*-diester **12** was 2.7 Hz, which is consistent with an axial-equitorial orientation of the two ester moieties.

Unexpectedly, subjection of alcohol **15**, prepared according to Scheme 3, to identical cyclization conditions [NaH (1.8 eq.), THF-$CH_3CN$-DMF (90:5:5), 0°C, 30 min] afforded a 2.5:1 mixture of **11** and **12**, respectively [8]. Clearly, equilibration of one of the esters is taking place during the reaction. Furthermore, it is likely that equilibration is occurring after ring closure based on the following observations: (1) resubmitting pure *trans*-diester **11** to the cyclization conditions for 30 min led to a 10:1 mixture of **11** and **12**, respectively. Likewise, resubmitting pure *cis*-diester **12** to the cyclization conditions for 30 min led to a 6:1 ratio of **11** and **12**, respectively; (2) stopping the cyclization reaction of **10** prior to completion (Scheme 2) and analysis of the reaction mixture found no evidence of diastereomer **15**.

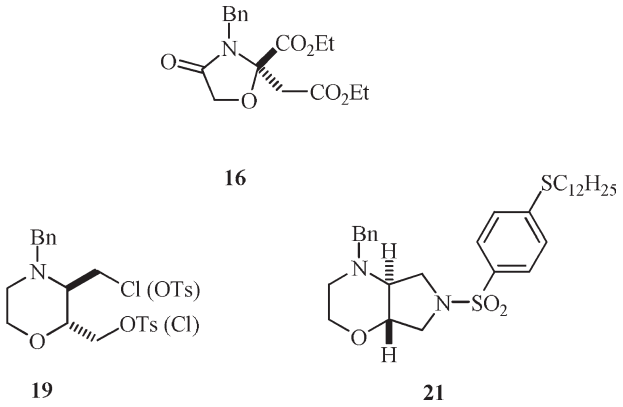


**Chart 2.**

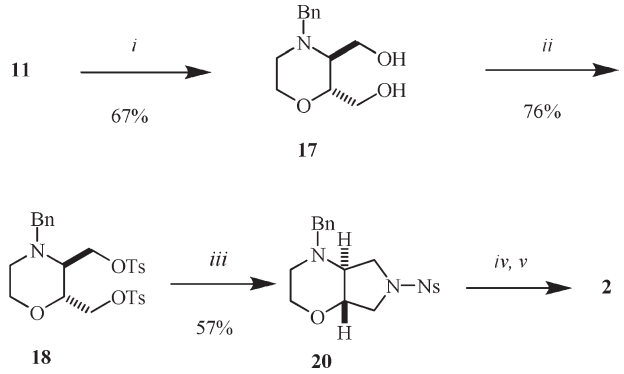
**Scheme 4.** Reagents and conditions: (i) $LiAlH_4$ (5.0 eq.), THF, 0° → room temperature, 30 min, room temperature → reflux, 30 min; (ii) $Ts_2O$ (3.0 eq.), pyridine (3.0 eq.), $CH_2Cl_2$, 0°C, 30 min; (iii) 4-nitrobenzenesulfonamide (3.0 eq.), DBU (2.0 eq.), $CH_3CN$, 70°C, 2 h; (iv) $C_{12}H_{25}SH$ (2.0 eq.), $LiOH•H_2O$ (2.0 eq.), DMF, room temperature, 2 h, 77%; (v) 4 *M* HCl-dioxane, MeOH, room temperature→40°C, 60%.

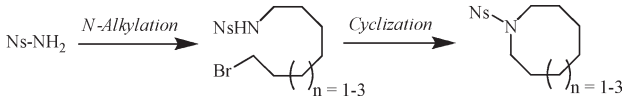


Interestingly, prolonged exposure of either **11** or **12** to sodium hydride in tetrahydrofuran at 0°C resulted, in addition to decomposition, in the formation of a new product, which, based on spectral data, we have assigned as ethyl 3-benzyl-2-(2-ethoxy-2-oxoethyl)-4-oxooxazolidine-2-carboxylate (**16**, Chart 2) [10].

With the stereochemistry at C(2) and C(3) secure, efforts were directed toward installing the remaining pyrrolidine ring. Toward this end, reduction of **11** with lithium aluminum hydride afforded diol **17** (Scheme 4). Bis-tosylate **18** was realized in 76% yield by treating diol **17** with tosic anhydride. The use of tosyl chloride in pyridine led, in addition to bis-tosylate **18**, a significant amount of monotosylate-monochloride products **19** (Chart 2).

Fukuyama has popularized the use of 2-nitro- and 4-nitrobenzenesulfonamide (2-Ns-$NH_2$, Ns-$NH_2$, respectively) as useful starting materials for the efficient construction of cyclic secondary amines [11]. The protocol involves a two-step alkylation-cyclization sequence (Scheme 5). Since this two-step protocol was primarily developed for the preparation of medium-sized rings, we were curious as to whether a pyrrolidine ring could be formed in a single pot *via* a double *N*-alkylation with Ns-$NH_2$. While we could find no examples of pyrrolidine ring formation *via* a double *N*-alkylation with Ns-$NH_2$, pyrrolidine ring formation *via* double *N*-alkylation with *para*-toluenesulfonamide (Ts-$NH_2$) is well precedented [12], including one example by Hong *et al*. [6] to prepare (4a*S*,7a*S*)-**1**. However, Ts-$NH_2$ was a less

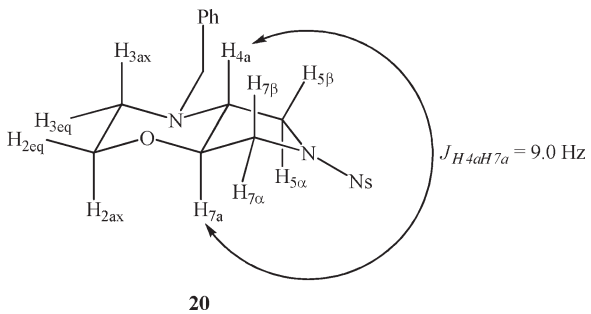
**Scheme 5.** Fukuyama's nitrobenzenesulfonamide methodology for the construction of secondary cyclic amines.



attractive nucleophile to us in that subsequent removal of the tosyl group typically requires either strongly reducing conditions, such as sodium naphthalide, or strongly acidic conditions. On the contrary, the nosyl group is typically removed under mild conditions [11]. We were pleased to find that heating an acetonitrile solution of bis-tosylate **18** with 4-nitrobenzenesulfonamide in the presence of DBU gave rise (57%) to pyrrolo[3,4-*b*][1,4]oxazine **20** (Scheme 4). While other bases, such as sodium hydride, potassium carbonate, or diisopropylethylamine, did effect ring closure, the reactions did not go to completion, even when additional base was added. No other organic-soluble product could be isolated from this reaction. Given the presence of DBU and the ease of bis-tosylate **18** forming an anti-periplanar relationship between the carbon-oxygen bond of one of the tosylates and the axial carbon-hydrogen bond at C(2) or C(3), it is possible that the elimination pathway was competing with substitution. However, no elimination byproducts could be isolated upon workup. That pyrrolo[3,4-*b*][1,4]oxazine **20** possessed a *trans*-ring fusion was readily confirmed based on the large coupling constant (9.0 Hz) between the bridgehead protons, $H_{4a}$ and $H_{7a}$ in the $^1$H-NMR spectrum (Fig. 2). Additional 2D NMR experiments on **20** were also in support of the proposed structure (data not shown).

Cleavage of the nosyl group to afford pyrrolo[3,4-*b*][1,4]oxazine **2** was realized in 77% yield *via* treatment of sulfonamide **20** with dodecanethiol in the presence of lithium hydroxide [13] (Scheme 4). Under these conditions, ca. 15% of aryl thioether **21** was formed (Chart 2). This was not surprising given others have also observed this byproduct during thiol-mediated deprotection of nosyl-protected cyclic amines [14]. Wuts *et al*. [14a] has further observed that 2-nitrobenzenesulfonamide (2-Ns-$NH_2$) was less likely to produce the corresponding byproduct. Unfortunately, the use of 2-Ns-$NH_2$ in the pyrrolidine cyclization reaction led to inferior yields (20% *vs*. 57%).

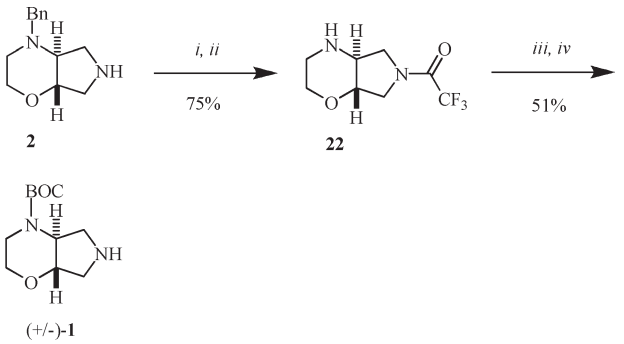
As a final proof of structure, we have converted benzyl-protected pyrrolo[3,4-*b*][1,4]oxazine **2** into



**20**

**Figure 2.** 3D Representation of compound **20**. Arrow shows vicinal coupling relationship.

**Scheme 6.** Reagents and conditions: (i) $(CF_3CO)_2O$ (2.0 eq.), $Et_3N$ (4.0 eq.), $CH_2Cl_2$, 0°C → room temperature, 1.5 h; (ii) $H_2$, 10% Pd/C, MeOH, 42 psi, room temperature, 48 h; (iii) $(BOC)_2O$, $CH_2Cl_2$, room temperature, 24 h; (iv) $K_2CO_3$ (2.0 eq.), MeOH-water (5:1), room temperature, 1 h.



Hong's BOC-protected pyrrolo[3,4-*b*][1,4]oxazine **1** by the sequence outlined in Scheme 6. Thus, trifluoroacetylation of **2** and subsequent hydrogenolysis of the benzyl group led to amine **22**, which should serve as a useful intermediate for the preparation of pyrrolo[3,4-*b*][1,4]oxazine analogs connected through N(4). BOC protection of N(4) and hydrolysis of the trifluoroacetamide group afforded (+/−)-**1**. The spectral properties of our racemic (+/−)-**1** were consistent with those of (4a*S*,7a*S*)-**1** [6,15].

## CONCLUSIONS

In summary, we have reported a practical and stereoselective eight-step synthesis of (+/−)-*trans*-4-benzyloctahydropyrrolo[3,4-*b*][1,4]oxazine (**2**) from inexpensive starting materials and reagents. Only two intermediates required chromatographic purification; otherwise, the remaining compounds were purified by precipitation or trituration. The conditions developed for the one pot double *N*-alkylation-pyrrolidine ring formation using 4-nitrobenzenesulfonamide and DBU will likely be of general interest to the synthetic community.

## EXPERIMENTAL

Proton ($^1$H), carbon ($^{13}$C), and fluorine ($^{19}$F) nuclear magnetic resonance (NMR) spectra were recorded on a Bruker 400 spectrometer. Chemical shifts are reported in parts per million (δ) relative to tetramethylsilane (δ 0.0). Assignments of key NMR signals were made by a combination of gHSQC, gHMBC, and ROESY experiments. Stereochemical assignments for compounds **11**, **12**, **20** and (+/−)-**1** were made based on a combination of ROESY and non-overlapping *J* coupling constants. Infrared (IR) spectra were recorded on a Bruker Vector 33 FTIR. High resolution mass spectra (MS) were acquired on an Agilent 1200 series LCMS TOF with UV detection. Combustion analyses were performed by QTI Intertek, Whitehouse, NJ. Melting points were recorded on an ®Electrothermal Mel-Temp 3.0 device and are uncorrected.

Reactions were monitored by thin layer chromatography (TLC) using Analtech silica gel GF 250 micron plates. The plates were visualized either by UV inspection or by staining with an ammonium molybdate/ ceric sulfate mixture. Flash chromatography was performed as described by Still *et al*. [16] using Aldrich column chromatography grade silica gel (200–400 mesh). All reagents were purchased from either the Aldrich Chemical Co. or TCI America Chemical Co. and used without further purification. All solvents were HPLC grade unless otherwise stated. Anhydrous solvents were purchased from EMD Chemical Co. and used as supplied.

***N*-Benzyl-*threo*-β-hydroxy-DL-aspartic acid (9).** This compound was prepared according to the procedure of Liwscitz [7] with slight modification:

To a stirred solution of *cis*-epoxysuccinic acid (8, 30 g, 227 mmol) in water (50 mL), benzylamine (84 mL, 770 mmol) was added. The mixture was heated to reflux for 3 h. The mixture was cooled to room temperature, followed by the addition of 15% aqueous sodium hydroxide until pH = 13. The aqueous layer was extracted with ether (3×) to remove the benzylamine. The ethereal layer was discarded. The aqueous layer was acidified with concentrated hydrochloric acid to pH = 4, which caused a white precipitate to form. The precipitate was filtered and washed with water. The pH of the mother liquor was re-adjusted to 4 with concentrated hydrochloric acid and additional precipitation occurred. The precipitate was filtered, washed with water. The combined precipitates were dried *in vacuo* to afford 52 g (96%) of 9 as a white solid: $^1$H-NMR (400 MHz, DMSO-$d_6$) δ 11.0–10.0 (br s, 2H), 7.35–7.22 (m, 5H), 4.25 (d, 1H, $J$ = 5.5 Hz), 3.92 (ABq, 2H, $J_{AB}$ = 12.9 Hz, $\Delta\nu_{AB}$ = 61.6 Hz), 3.58 (d, 1H, $J$ = 5.9 Hz); $^{13}$C-NMR (100 MHz, DMSO-$d_6$) δ 173.5, 171.0, 137.1, 129.2, 128.9, 128.1, 69.79, 61.55, 50.75; high resolution MS (ESI) Calcd. for $C_{11}H_{14}NO_5$ [M + H] *m*/*e* 240.0892. Found: 240.0866. An analytical sample was prepared *via* recrystallization from water: mp 224–225°C (dec.) (Ref. [7] 225–226°C).

**Diethyl *N*-benzyl-*threo*-β-hydroxy-DL-aspartate.** To a stirred solution of dry ethyl alcohol (550 mL) at 0°C, acetyl chloride (54 mL, 760 mmol) was added. After complete addition, the solution was stirred at 0°C for 1 h. To this solution, diacid **9** (45.0 g, 190 mmol) was added, and the whole mixture was heated to reflux for 72 h. The mixture was cooled to room temperature, and the ethanol was removed *in vacuo* to afford a clear oil. The oil was partitioned between ether and saturated aqueous potassium carbonate solution. The ethereal layer was washed with aqueous potassium carbonate solution and brine. The ethereal layer was dried over anhydrous sodium sulfate, filtered, and concentrated *in vacuo* to afford 43 g (77%) of diethyl *N*-Benzyl-*threo*-β-hydroxy-DL-aspartate as a white solid: $R_f$ 0.31 (hexanes-ethyl acetate, 3:1), IR ($CH_2Cl_2$) 3490, 3347, 3028, 2982, 2906, 2872, 1741, 1465, 1454, 1258, 1190, 1107, 740, 700 cm$^{-1}$; $^1$H-NMR (400 MHz, $CDCl_3$) δ 7.27 (m, 5H), 4.46 (d, 1H, $J$ = 2.7 Hz), 4.22 (q, 2H, $J$ = 7.0 Hz), 4.25–4.16 (m, 1H), 4.13–4.05 (m, 1H), 3.74 (ABq, 2H, $J_{AB}$ = 13.3 Hz, $\Delta\nu_{AB}$ = 124 Hz), 3.59 (d, 1H, $J$ = 2.8 Hz), 1.26 (t, 3H, $J$ = 6.8 Hz), 1.16 (t, 3H, $J$ = 7.2 Hz); $^{13}$C-NMR (100 MHz, $CDCl_3$) δ 172.4, 171.7, 139.5, 128.3, 128.2, 127.1, 72.10, 62.03, 61.93, 61.43, 52.15, 14.17, 14.00; high resolution MS (ESI) Calcd. for $C_{15}H_{22}NO_5$ [M + H] *m*/*e* 296.1529. Found: 296.1492. An analytical sample was prepared *via* recrystallization from hexanes-ethyl acetate: mp 40–41°C. Anal. Calcd. for $C_{15}H_{21}NO_5$: C, 61.00; H, 7.17; N, 4.74. Found: C, 61.06; H, 7.13; N, 4.67.

**Diethyl 2-(*N*-benzyl-2-chloroacetamido)-*threo*-3-hydroxysuccinate (10).** To a rapidly stirred solution of diethyl *N*-Benzyl-*threo*-β-hydroxy-DL-aspartate (20.0 g, 67.7 mmol) in dichloromethane (160 mL) at 0°C, ice cold sodium hydroxide (102 mL of a 1.0 *M* aqueous solution) was added, followed by dropwise addition of a solution of chloroacetyl chloride (8.1 mL, 102 mmol) in dichloromethane (8.0 mL). After complete addition, the mixture was stirred at 0°C for 15 min. Sodium hydroxide (20 mL of a 1.0 *M* aqueous solution) was added, followed by separation of the layers. The aqueous layer was extracted with dichloromethane. The combined organic layers were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo*. The remaining oil was dissolved in ether and extracted three times with 3.0 *M* aqueous hydrochloric acid (to remove *o*-acylated byproduct). The ethereal layer was washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo* to afford an oil. Trituration of the oil in hexanes-ether (9:1) gave 20.2 g (80%) of **10** as a white solid: mp 69–71°C; $R_f$ 0.20 (hexanes-acetone, 85:15); IR ($CH_2Cl_2$) 3427, 2984, 1738, 1660, 1452, 1267, 1026, 737 cm$^{-1}$; 1H-NMR (400 MHz, $CDCl_3$) δ 7.35–7.18 (m, 5H), 4.95–4.83 (m, 2H), 4.69 (ABq, 2H, $J_{AB}$ = 17.2 Hz, $\Delta\nu_{AB}$ = 85.6 Hz), 4.25–4.10 (m, 4H), 4.00–3.85 (m, 2H), 1.51 (br s, 1H), 1.25 (t, 3H, $J$ = 7.0 Hz), 1.18 (t, 1H, $J$ = 7.0 Hz); $^{13}$C-NMR (100 MHz, $CDCl_3$) δ 171.5, 169.2, 167.4, 135.4, 128.9, 128.1, 126.9, 70.94, 62.26, 62.13, 62.03, 53.58, 41.43, 13.99, 13.91; high resolution MS (ESI) Calcd. for $C_{17}H_{23}ClNO_6$ [M + H] *m*/*e* 372.1247. Found: 372.1208. Anal. Calcd. for $C_{17}H_{22}ClNO_6$: C, 54.92; H, 5.96; N, 3.77. Found: C, 54.87; H, 5.73; N, 3.70.

**Diethyl *trans*-4-benzyl-5-oxomorpholine-2,3-dicarboxylate (11) and diethyl *cis*-4-benzyl-5-oxomorpholine-2,3-dicarboxylate (12).** To a stirred suspension of sodium hydride (60% oil dispersion, 1.98 g, 49.4 mmol) in dry tetrahydrofuran (150 mL) at 0°C under nitrogen atmosphere, a solution of alcohol **10** (10.2 g, 27.4 mmol) in tetrahydrofuran-acetonitrile (50 mL, 4:1) *via* canula was added. After complete addition, DMF (10 mL) was added, and the mixtue was stirred at 0°C for 1 h. Once the reaction was complete (TLC monitoring), it was poured over a rapidly stirred solution of 10% aqueous acetic acid (100 mL). Note: once the cyclization was complete, the mixture becomes dark orange in color. If the reaction was not quenced shortly after the orange color appeared, 4-oxooxazolidine **16** began to form. In latter runs, we found that adding solid alcohol **10** directly to a 0°C suspension of 1.4 equivalents of sodium hydride in tetrahydrofuran-acetonitrile-DMF (9:0.5:0.5) for 1 h minimized the formation of **16**. The mixture was concentrated *in vacuo* to a volume of ca. 80 mL. The remaining liquid was extracted with ethyl acetate. The organic layer was extracted with saturated aqueous potassium carbonate solution (to remove carboxylic acid byproducts). The organic layer was washed with brine and dried over anhydrous magnesium sulfate. The organic layer was passed through a short plug of silica gel to remove base-line impurities. The organic layer was concentrated *in vacuo* to a tan solid. Trituration of the remaining solid in hexanes-ether (9:1) gave 5.9 g (64%) of **11** as a fluffy white solid. The mother liquor was concentrated *in vacuo* and purified by flash chromatography on silica gel. Elution with hexanes-ethyl acetate (70:30) afforded

an additional 1.1 g of **11** as a fluffy white solid (76% combined yield of **11**). Further elution afforded 0.70 g (8%) of *cis*-diester **12** as a clear oil.

**2,2,2-Trifluoro-1-(*trans*-hexahydropyrrolo[3,4-*b*][1,4] oxazin-6(2H)-yl)ethanone (22).** To a stirred suspension of **2** (100 mg, 0.34 mmol) in dichloromethane (3 mL) at 0°C were added triethylamine (190 μL, 1.37 mmol) and trifluoroacetic anhydride (95 μL, 0.69 mmol). The mixture was allowed to warm to room temperature and stirred for 1.5 h. The reaction was diluted with dichloromethane and washed with water and brine. The organic layer was dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo* to an oil. The crude product was purified by chromatography on silica gel. Elution with hexanes-ethyl acetate-triethylamine (75:24:1) afforded 85 mg (79%) of 2,2,2-trifluoro-1-(*trans*-hexahydropyrrolo[3,4-*b*][1,4] oxazin-6(2H)-yl)ethanone as an oil: $R_f$ 0.62 (hexanes-ethyl acetate, 1:1); $^1$H-NMR [400 MHz, $CDCl_3$, two rotomers present (1:1)] δ 7.30–7.18 (m, 5H), 3.98–3.58 (m, 4H), 3.41–3.08 (m, 3H), 2.67 (t, 1H, $J$ = 12.5 Hz), 2.37 (m, 1H), 2.18 (m, 1H); $^{13}$C-NMR [100 MHz, $CDCl_3$, two rotomers present (1:1)] δ 156.1 (q, $J$ = 37 Hz), 155.9 (q, $J$ = 37 Hz), 136.7, 136.5, 129. 1, 129.0, 128.4, 128.3, 127. 7, 127.6, 116.0 (q, $J$ = 286 Hz), 115.9 (q, $J$ = 285 Hz), 78.14, 77.01, 67.94, 67. 89, 65.69, 63.85, 61.32, 61.01, 52.34, 52.08, 48.24, 48.15, 47.76, 47.72; $^{19}$F-NMR [376 MHz, methanol-$d_4$, 2 rotomers present (1:1)] δ − 73.68, −73.90; low resolution MS (ESI) *m*/*e* 315 [M + H].

The product from above (85 mg, 0.27 mmol) was dissolved in methanol (15 mL), and 80 mg of 10% palladium on activated carbon was added. The suspension was placed in a Parr hydrogenation bottle and hydrogenated (42 PSI, room temperature) for 48 h. The reaction mixture was filtered through Celite and washed with methanol. The solution was concentrated *in vacuo* to afford 57 mg (95%) of **22** as an oil: $R_f$ 0.40 (hexanes-ethyl acetate, 1:1); $^1$H-NMR [400 MHz, $CDCl_3$, 2 rotomers present (1:1)] δ 3.90–3.77 (m, 3H), 3.70–3.59 (m, 1H), 3.50–3.39 (m, 1H), 3.34 (t, 0.5H, $J$ = 10.1 Hz), 3.26–3.15 (m, 1H), 3.06 (t, 0.5H, $J$ = 11.3 Hz); 3.00–2.73 (m, 3H), 1.91 (br s, 1H); $^{13}$C-NMR [100 MHz, $CDCl_3$, 2 rotomers present (1:1)] δ 156.1 (q, $J$ = 37 Hz), 155.9 (q, $J$ = 37 Hz); 116.0 (q, $J$ = 284 Hz); 78.90, 77.74, 68.05, 67.99, 59.31, 57.68, 48.54, 48.50, 47.80, 47.62, 45.83, 45.72; $^{19}$F-NMR [376 MHz, $CDCl_3$, 2 rotomers present (1:1)] δ −72.51, −72.76; low resolution MS (ESI) 225 [M + H].

***tert*-Butyl (+/−)-*trans*-hexahydropyrrolo[3,4-*b*][1,4] oxazine-4(4a*H*)-carboxylate [(+/−)-1].** To a stirred solution of **22** (55 mg, 0.25 mmol) in dichloromethane (1.0 mL), di-*tert*-butyl dicarbonate (60 mg, 0.27 mmol) was added. The mixture was stirred under nitrogen atmosphere for 4 h. The reaction mixture was purified by chromatography on silica gel. Elution with heptane-ethyl acetate (9:1 → 1:1) afforded 55 mg (70%) of *tert*-butyl *trans*-6-(2,2,2-trifluoroacetyl)hexahydropyrrolo[3,4-*b*][1,4]oxazine-4(4a*H*)-carboxylate as an oil: $R_f$ 0.58 (hexanes-ethyl acetate, 1:1); $^1$H-NMR [400 MHz, $CDCl_3$, 2 rotomers present (1:1)] δ 4.43 (m, 0.5H), 4.35 (m, 0.5H), 4.00–3.94 (m, 1H), 3.93–3.75 (m, 3H), 3.69–3.59 (m, 2H), 3.57–3.42 (m, 1H), 3.34 (t, 0.5H, $J$ = 10.6 Hz), 3.20 (t, 0.5H, $J$ = 10.9 Hz), 3.11–2.87 (m, 2H), 1.40 (s, 9H); $^{13}$C-NMR [100 MHz, $CDCl_3$, 2 rotomers present (1:1)] δ 160.0 (q, $J$ = 37 Hz), 159.9 (q, $J$ = 37 Hz), 155.3, 155.2, 116.0 (q, $J$ = 288 Hz), 115.9 (q, $J$ = 288 Hz), 81.50, 78.51, 77.49, 67.40, 67.37, 57.96, 56.59, 49.06, 48.97, 46.67, 46.61, 28.15, 28.09; $^{19}$F-NMR [376 MHz, $CDCl_3$, 2 rotomers present (1:1)] δ −72.22, −72.63; high resolution MS (ESI) Calcd. for $C_{13}H_{19}N_2O_4F_3Na$ [M + Na] *m*/*e* 347.1222. Found: 347.1189.

To a stirred solution of *trans*-6-(2,2,2-trifluoroacetyl) hexahydropyrrolo[3,4-*b*][1,4]oxazine-4(4a*H*)-carboxylate (27 mg, 0.83 mmol) in methanol-water (600 μL, 5:1) at room temperature, potassium carbonate (23 mg, 0.17 mmol) was added. The mixture was stirred at room temperature for 1 h. The mixture was diluted with water and ethyl acetate, and the layers were separated. The aqueous layer was extracted with ethyl acetate, and the combined organic layers were washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated *in vacuo* to afford 18 mg (95%) of (+/−)-**1** as an oil:

$R_f$ 0.42 (dichloromethane-methanol-ammonium hydroxide, 89:10:1); $^1$H-NMR (500 MHz, $CD_3CN$) δ 3.99 (ddd, 1H, $J$ = 11.8, 3.9, 1.56 Hz), 3.81 (ddd, 1H, $J$ = 13.5, 3.06, 1.53 Hz), 3.64 (td, 1H, $J$ = 11.9, 3.1 Hz), 3.6–3.5 (br m, 1H), 3.48 (app. q, 1H, $J$ = 9.6 Hz), 3.15–2.90 (br m, 2H), 2.99–2.94 (m, 1H), 2.91 (ddd, 1H, $J$ = 13.5, 12.0, 3.8 Hz), 2.85–2.68 (br m, 1H), 1.46 (s, 9H); $^{13}$C-NMR (125 MHz, $CD_3CN$) δ 155.9, 81.3, 79.8, 67.2, 59.9, 47.8, 45.0, 44.6, 27.9; high resolution MS (ESI) Calcd. for $C_7H_{13}N_2O_3$ [M – $^t$Bu + 2H] *m/e* 173.0945. Found: 173.0920.

***N*-Benzyl-*erythro*-β-hydroxy-DL-aspartic acid (14).** This material was prepared according to the established procedure with slight modification:

To a stirred solution of (+/−)-*trans*-epoxysuccinic acid (**13**, 20.0 g, 151 mmol) in deionized water (70 mL), benzylamine (50 mL, 460 mmol) was added. The mixture was heated to reflux under nitrogen atmosphere. A precipitant began to form after ∼15 min at reflux. After 4 h of heating, the reaction was cooled to room temperature and treated with 2.5 N aqueous sodium hydroxide (∼140 mL) to adjust the pH to ∼11. The aqueous layer was extracted with ether (4 × 100 mL) to remove the benzylamine. The aqueous layer was acidified with concentrated hydrochloric acid to pH ∼4 (ca. 19 mL), which caused a white precipitate to form. The precipitate was collected by suction filtration, washed with water (2 × 100 mL) and dried *in vacuo* (vacuum oven, 65°C, house vacuum) to afford 30.4 g (84%) of **14** as a white solid: $^1$H-NMR (400 MHz, $D_2O$) δ 7.41 (s, 5H), 4.10–4.34 (m, 3H), 3.81 (d, 1H, $J$ = 4.1 Hz); $^{13}$C-NMR (100 MHz, $D_2O$) δ 175.9, 170.1, 130.6, 129.9, 129.6, 129.2, 70.24, 64.06, 50.60; high resolution MS (ESI) Calcd. for $C_{11}H_{14}NO_5$ [M + H] *m/e* 240.0892. Found: 240.0866. An additional 3.0 g of **20** was obtained from the filtrates upon standing overnight. Combined yield: 92%.

**Diethyl *N*-benzyl-*erythro*-β-hydroxy-DL-aspartate.** To a stirred solution of dry ethyl alcohol (250 mL) at 0°C under nitrogen atmosphere, acetyl chloride (18 mL, 250 mmol) was added dropwise. After complete addition, the reaction was stirred at 0°C for 30 min. Diacid **14** (12.0 g, 50 mmol) was added in one portion, and the suspension was slowly heated to reflux for 72 h. The reaction mixture was filtered, and the collected precipitate (unreacted **14**) was set aside. The filtrate was concentrated under reduced pressure. The remaining residue was partitioned between ether (100 mL) and half-saturated aqueous potassium carbonate solution (50 mL). The ethereal layer was extracted with potassium carbonate solution. The combined aqueous layers were back-extracted with ether. The combined ethereal layers were washed with brine, dried over anhydrous sodium sulfate, filtered and concentrated *in vacuo* to afford 6.1 g (41%) of diethyl *N*-Benzyl-*erythro*-β-hydroxy-DL-aspartate as a tan oil: $R_f$ 0.20 (heptane-ethyl acetate, 75:25); IR ($CDCl_3$) 3475, 2983, 1734, 1189, 1116, 1026, 739, 669 cm$^{-1}$; $^1$H-NMR (400 MHz, $CDCl_3$) δ 7.39–7.25 (m, 5H), 4.51 (d, 1H, $J$ = 3.4 Hz), 4.29–4.15 (m, 4H), 3.98 (d, 1H, $J$ = 13.0 Hz), 3.77 (d, 1H, $J$ = 13.0 Hz), 3.71 (d, 1H, $J$ = 3.1 Hz), 3.43 (br s, 1H), 2.30 (br s, 1H), 1.29 (t, 6H, $J$ = 7.2 Hz); $^{13}$C-NMR (100 MHz, $CDCl_3$) δ 171.9, 171.0, 139.3, 128.5, 128.3, 127.2, 71.83, 63.23, 61.81, 61.38, 52.60, 14.18, 14.13; high resolution MS (ESI) Calcd. for $C_{15}H_{22}NO_5$ [M + H] *m/e* 296.1529. Found: 296.1492. Anal. Calcd. for $C_{15}H_{21}NO_5$: C, 61.00; H, 7.17; N, 4.74. Found: C, 60.87; H, 7.23; N, 4.73.

**Diethyl 2-(*N*-benzyl-2-chloroacetamido)-*erythro*-3-hydroxysuccinate (15).** To a stirred solution of diethyl *N*-benzyl-*erythro*-β-hydroxy-DL-aspartate (5.0 g, 17 mmol) in dichloromethane (40 mL) in an ice-brine bath (−10°C) under nitrogen atmosphere, sodium hydroxide (25 mL of 1.0 N aqueous solution) was added. The mixture was vigorously stirred while a solution of chloroacetyl chloride (2.0 mL, 25 mmol) in dichloromethane (4.0 mL) was added dropwise *via* syringe (addition time ∼10 min). Halfway through the addition, the reaction mixture began to thicken. The ice-brine bath was replaced with an ice bath. After complete addition, the reaction mixture was stirred at 0°C for an additional 15 min. Sodium hydroxide (10 mL of a 1.0 *N* aqueous solution) was added, and the layers were separated. The aqueous layer was extracted with dichloromethane (2 × 50 mL). The combined organic layers were washed with brine, dried over anhydrous sodium sulfate, filtered, and concentrated *in vacuo*. The remaining residue was dissolved in ether (100 mL) and extracted with 3 *N* hydrochloric acid (to remove *o*-acylated byproduct). The ethereal layer was washed with brine (2×), dried over anhydrous sodium sulfate, and concentrated *in vacuo* to afford 6.2 g (99%) of **15** as a viscous tan oil: $R_f$ 0.17 (heptane-ethyl acetate, 75:25); IR ($CDCl_3$) 3462, 2983, 1738, 1163, 1203, 1127, 1203, 1025, 669 cm$^{-1}$; $^1$H-NMR (400 MHz, $CDCl_3$) δ 7.43–7.23 (m, 5H), 5.56 (s, 1H), 4.96–4.81 (m, 2H), 4.44 (br s, 1H), 4.31 (q, 2H, $J$ = 7.2 Hz), 4.26–4.00 (m, 4H), 3.71 (d, 1H, $J$ = 2.4 Hz), 1.34 (t, 3H, $J$ = 7.2 Hz), 1.24 (t, 3H, $J$ = 7.1 Hz); $^{13}$C-NMR (100 MHz, $CDCl_3$) δ 171.4, 168.8, 167.6, 136.6, 129.0, 127.8, 126.1, 70.85, 62.70, 62.02, 61.34, 51.17, 41.61, 14.11, 13.97; high resolution MS (ESI) Calcd. for $C_{17}H_{23}ClNO_6$ [M + H] *m/e* 372.1247. Found: 372.1208. %Water(KF): 0.46. Anal. Calcd. for $C_{17}H_{22}ClNO_6$•0.46% $H_2O$: C, 54.66; H, 5.98; N, 3.75. Found: C, 54.32; H, 5.98; N, 3.61.

**Diethyl *trans*-4-benzyl-5-oxomorpholine-2,3-dicarboxylate (11) and diethyl *cis*-4-benzyl-5-oxomorpholine-2,3-dicarboxylate (12).** To a stirred suspension of sodium hydride (60% oil dispersion, 0.22 g, 5.5 mmol) in dry tetrahydrofuran (25 mL) at 0°C under nitrogen atmosphere, a solution of alcohol **15** (0.99 g, 2.7 mmol) in tetrahydrofuran-acetonitrile (5 mL, 4:1) was added dropwise *via* syringe (addition took ∼10 min). During the addition, the reaction turned from a grey suspension to a yellow suspension. After complete addition, the reaction mixture was stirred at 0°C for 30 min. The reaction mixture was poured into a rapidly stirred solution of 10% aqueous acetic acid (20 mL). The mixture was concentrated *in vacuo* to a volume of ca. 15 mL. The remaining residue extracted with ethyl acetate (3 × 50 mL). The combined organic layers were washed with 1.0 *N* aqueous sodium hydroxide solution (to remove minor carboxylic acid byproducts), brine, dried over anhydrous sodium sulfate, and concentrated *in vacuo* to afford an orange solid (0.9 g). The crude product was purified by Biotage® on silica gel. Elution with heptane-ethyl acetate (95:5) afforded 0.45 g (50%) of *trans*-product **11** as a white solid and 0.18 g (20%) of *cis*-product **12** as an oil. The spectral properties of compounds **11** and **12** from this experiment were identical in all respects to compounds **11** and **12** obtained above.

**Acknowledgments.** The authors thank Shen Yang for $^1$H-, 1D-, and 2D-NMR studies and Professor William R. Roush for stimulating discussions during the preparation of this manuscript. We thank Donn Wishka and Geeta Yalamanchi for analytical support.

The Gould-Jacob type of reaction for the synthesis of ethyl 5-ethyl-8-oxo-5,8-dihydro-[1,3]-dioxolo[4,5-g]quinoline-7-carboxylate **4** has been carried out conventionally by the condensation between *N*-ethyl-3,4-methylenedioxyaniline **1** and diethyl ethoxymethylenemalonate **2** gave the unsaturated ester **3** and thermal cyclization in refluxing diphenyl oxide gave quinolone ethyl ester **4** and the results obtained were compared with single step microwave irradiation under solvent free conditions for the synthesis of **4**. The esters on basic hydrolysis formed free acid **5,** which, upon treatment with thionyl chloride gave the acid chloride **6**. Treatment of acid chloride with *o*-phenylenediamine, hydrazine hydrate, ammonia, urea, and thiourea gave the amides (**7–11**). $CS_2$ treatment in presence of KOH on **8** gave **12**. We prepared **7–12** derivatives by conventional as well as microwave irradiation. These compounds have been characterized on the basis of IR, $^1$H NMR, MS, and elemental analysis. All the compounds prepared herein were screened for their antibacterial activity. Compounds **4**, **5** possess promising antibacterial activity and compound **8** showed significant antibacterial activity.

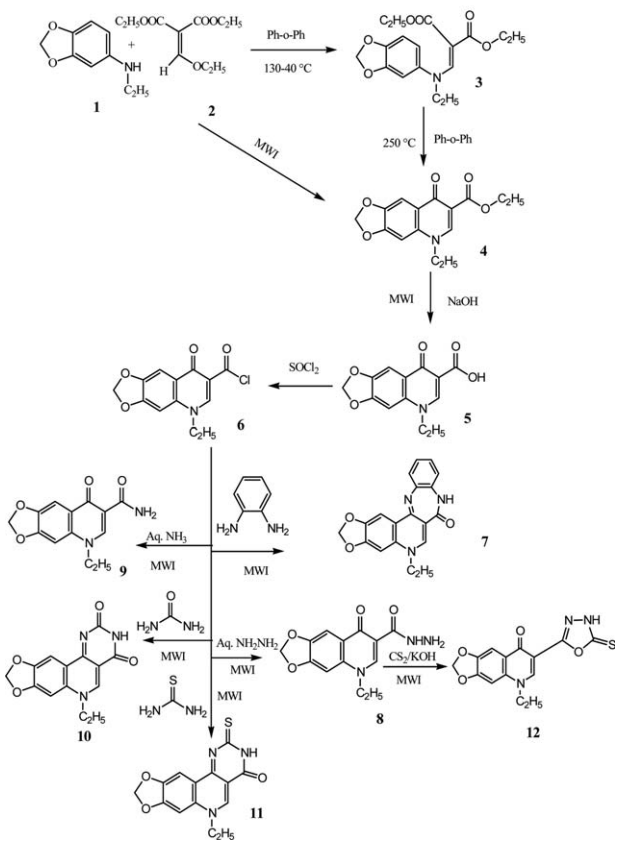
## INTRODUCTION

Nalidixic acid and its quinolone analogs for example oxolinic acid, norfloxacin, pefloxacin, ciprofloxacin, and ofloxacin have been used for treatment of various bacterial infections (urology, ophthalmology) [1]. The purpose of this investigation was to provide a novel and more advantageous method that the synthesis of 5-ethyl-8-oxo-5,8-dihydro-[1,3]dioxolo[4,5-g]quinoline-7-carboxylic acid **5** and its chloride **6** and then different derivatives of amides **7–12** by conventional as well as microwaves irradiation and comparative study of both the method have been carried out. The solvent free reactions [2–6] under microwave condition are especially for providing an environmentally benign system. Thus microwave assisted synthesis becomes a part of ''Sustainable chemistry''. Microwave accelerated organic synthesis is an effective and an alternative route proposed during the last decade due to drastic reduction in the reaction time, to minimize cumbersome work-up and better yield [7–10]. We report herein the synthesis of quinolone derivatives and related compounds using conventional as well as microwave methodologies and comparative study of both the method have been carried out. These compounds were evaluated for antibacterial activity *in vitro* and *in vivo* in comparison with nalidixic acid [11–14].

## RESULTS AND DISCUSSION

The aim of this work was to synthesize 5-ethyl-8-oxo-5, 8-dihydro-[1,3]dioxolo[4,5-g] quinoline -7- carboxylic acid (oxolinic acid) and its chloride **6** and different derivatives of amides. In conventional method, *N*-ethyl methylene dioxyaniline **1** was condensed with EMME **2** at 130–140°C for 1.5–2 h to obtain unsaturated ester **3**, which on thermal cyclization in boiling diphenyl oxide at 250°C for 2–3 h provided quinolone ethyl ester **4** in 70% overall yield on the basis of compound **1**. On the other hand, single step microwave assisted reaction of **1** with EMME **2** without solvent (Method B) provided identical compound **4** within 8–10 min in 88% overall yield (Scheme 1). Thus microwave assisted synthesis quinolone ethyl ester **4** has remarkable advantages over the conventional techniques because of easier work up, better yield, rapid and solvent free cleaner reaction. Compound **4** on hydrolysis gave compound **5**, which upon treatment with thionyl chloride gave acid chloride **6**. Treatment of this acid chloride **6** with *o*-phenylenediamine, hydrazine hydrate, ammonia solution, urea, and thiourea gave the amides **7–11** and Compound **8** when refluxed with ethanol and carbon disulfide in presence of potassium hydroxide yielded the corresponding 5-ethyl-7-(5-thioxo-4, 5-dihydro-[1,3,4] oxadiazol-2-yl)-5-H-[1, 3] dioxolo [4, 5-g] quinolin-8-one **12** by conventional heating as well as under microwave irradiation (Scheme 1). The comparison between conventional and microwave methodologies has been shown in Table 1. Compounds obtained from both methods were identical and were confirmed on the basis of TLC, mp, elemental, and spectral analysis.

**Scheme 1**



In conclusion, we have developed a simple, fast, solvent free, and high yielding method for the synthesis quinolone derivatives and related compounds, in which compounds **4** and **5** displayed very promising activity as expected (*in vitro* as well as *in vivo* activity better than the standard Nalidixic acid), whereas synthesized novel compound 8 exhibited significant antibacterial activity. Rest of the novel compounds displayed weak antibacterial activity.

## EXPERIMENTAL

Melting points were determined in open capillaries on a BÜCHI melting point apparatus B-540 and are uncorrected. Infrared (ir) spectra were recorded on a PerkinElmer paragon 1000 FTIR spectrophotometer (potassium bromide pellets). The $^1$H NMR spectra were recorded on Varians 400 MHz spectrophotometer in deuteriodimethyl sulfoxide using TMS as internal standard and the chemical shifts are expressed in ppm.

Mass spectral (MS) data were obtained using an Agilent 1100LC/MSD VL system (G1946C) with a 0.4 mL/min flow rate using a binary solvent system of 95:5 metanol/water. Microwave irradiation was carried out in modified microwave oven fitted with a condenser BPL microwave oven, Model BMO 700T, (2450 MHz, 700 W). The purity of compounds was checked by TLC using silica gel G plates.

**Synthesis of 5-ethyl-8-oxo-5, 8-dihydro-[1, 3] dioxolo[4, 5-g] quinoline-7-carboxylic acid (5).** ***Three step conventional method A.*** *Step 1: 2-[(Benzo[1,3]dioxolo-5-yl-ethyl-amino) methylene]-malonic acid diethyl ester (3).* A mixture of benzo[1,3]dioxol-5yl-ethyl-amine **1** (3.30 g, 0.02 mol), diethyl ethoxy methylenemalonate **2** (4.40 g, 0.02 mol), and diphenyl oxide (10 mL) was heated at 130–140°C for 1.5 h, and the alcohol generated from reaction mixture was allowed to escape. The reaction mixture was keep for further step.

*Step 2: Ethyl 5-ethyl-8-oxo-5, 8-dihydro-[1,3]dioxolo [4, 5-g] quinoline-7-carboxylate (4).* 2-[(Benzo[1,3]dioxolo-5-yl-ethyl-amino)-methylene]-malonic acid diethyl ester **3** (6.70 g) was dissolved in boiling diphenyl oxide (10 mL) and heated at 250°C for 1.5–2 h. The liberated alcohol was collected in a Dean-Stark trap. Then the mixture was cooled to room temperature, the resulting solid was filtered and washed with petroleum ether and dried *in vacuo*, yielding 4.1 g (70%) of (**4),** mp 169–173°C (ref. [15], mp 172–173°C).

*Step 3: 5-Ethyl-8-oxo-5, 8-dihydro-[1, 3] dioxolo [4, 5-g] quinoline-7- carboxylic acid (5).* This compound was obtained in 82% yield as a white solid, (ref. [16,17]).

***Two step microwave assisted method B.*** *Step 1: Ethyl 5-ethyl-8-oxo-5, 8-dihydro-[1, 3] dioxolo [4, 5-g] quinoline-7-carboxylate (4).* A neat mixture of benzo[1,3]dioxol-5yl-ethyl-amine **1** (3.30 g, 0.02 mol) and diethyl ethoxymethylenemalonate **2** (4.40 g, 0.02 mol) was taken in an open Pyrex tube and subjected to microwave irradiation in domestic microwave oven (BPL, BMO 700T) at an output of about 700 watts for specified time given in (Table 1). Progress of reaction was monitored through TLC at an interval of 45 sec. On completion, the reaction mixture was allowed to cool at room temperature; the resulting solid was filtered and washed with petroleum ether and dried *in vacuo*, to give 5.1 g (88%) of **4**.

mp 169–173°C (ref. [15], mp 172–173°C).

*Step 2: 5 - Ethyl-8-oxo-5, 8-dihydro-[1, 3] dioxolo [4, 5-g] quinoline-7- carboxylic acid (5).* A neat mixture of ethyl 5-ethyl-8-oxo-5, 8-dihydro-[1, 3] dioxolo [4, 5-g] quinoline -7-carboxylate **4** (4.0 g, 0.014 mol) was dissolved in 20 mL of 10% NaOH. The reaction mixture was subjected to microwave irradiation in Pyrex glass round bottle flask attached with air condenser from outside with special arrangement for 3 min. After cooling at room temperature, the reaction mixture was acidified using concentrated HCl. The resulting precipitated was filtered and washed with water, and recrystallized from aqueous DMF to give 3.4 g (93%) of **5**.

***5-Ethyl-8-oxo-5,8-dihydro-[1,3]-dioxolo[4,5-g]quinoline -7-carbonyl chloride (6).*** This compound was obtained in 86% yield as a light brown solid (ref. [17,18]).

***5-Ethyl-5,8-dihydro-[1,3]dioxolo-5,8,13-triaza-benzo[5,6]cyclohepta[1,2-a]naphthalen-7-one(7).*** *Method A.* To a solution of **6** (0.28 g, 0.001 mol) in 10 mL of xylene was added *o*-phenylenediamine (0.162 g, 0.0015 mol) and the reaction mixture was refluxed for 8–10 h. The liberated water was collected in Dean-Stark trap. After the mixture was cooled to room temperature, the solid precipitated was filtered and recrystallized from ethanol to afford 0.20 g (60%) of 7 as dark yellow solid.

*Method B.* To a solution of compound **6** (0.28 g, 0.001 mol), *o*-phenylenediamine (0.162 g, 0.0015 mol) in 10 mL of xylene, acidic alumina (2 g) was added. The reaction mixture was stirred well, air dried, and subjected to the MWI intermittently at 30 s intervals for specified time (Table 1). On completion of reaction as monitored by TLC, the product was extracted into ethanol (3 × 5 mL). Removal of solvent under reduced pressure yielded the product, which was recrystalized from ethanol to give 0.29 g (87%) of (**7**) as dark yellow solid.

mp 335–337°C; IR (KBr): 3422, 3218, 2924, 2853, 1676, 1624, 1599, 1555, 1538, 1500, 1473, 1455, 1376, 1299, 1277, 1254, 1202, 1032 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 1.39 (t, 3H), 4.70 (q, 2H), 6.43 (s, 2H), 7.08–7.21 (m, 3H) 7.56 (d, d 1H), 7.85 (s, 1H), 8.75 (s, 1H), 9.10 (s, 1H), 10.50 (s, 1H); MS (ESI, *m/z*):334 $[M+H]^+$. Anal.Calcd. For $C_{19}H_{15}N_3O_3$: C, 68.46; H, 4.54; N, 12.61. Found: C, 68.76; H, 4.36; N, 12.54.

***5-Ethyl-8-oxo-5,8-dihydro-[1,3]dioxolo[4,5-g] quinoline -7-carbohydrazide (8).*** *Method A.* To a solution of **6** (0.42 g, 0.0015 mol) dissolved in 10 mL of ethanol was added hydrazine hydrate (2.5 mL). The mixture was stirred for 1 h at room temperature, and then poured into water. The precipitate was collected by filtration and recrystallized from ethanol to give 0.32 g (78%) of **8** as yellow solid.

*Method B.* To a solution of compound **6** (0.42 g, 0.0015 mol) and hydrazine hydrate (2.5 mL) in ethanol (10 mL) acidic alumina (2 g) was added. The reaction mixture was stirred well, air dried, and subjected to MWI intermittently at 30 s intervals for specified time (Table 1). On completion of

reaction, as monitored by TLC the product was extracted into ethanol (3 × 5 mL). Removal of solvent under reduced pressure yielded the product, which was recrystallized from ethanol to give 0.38 g (92%) of **8** as yellow solid.

mp 300–302°C; IR (KBr): 3400, 3245, 2986, 1647, 1618, 1592, 1506, 1474, 1375, 1269, 1256, 1238, 1197, 1038 $cm^{-1}$; MS (ESI, *m/z*):276 $[M+H]^+$. Anal. Calcd. For $C_{13}H_{13}N_3O_4$: C, 56.72; H, 4.76; N, 15.27. Found: C, 56.87; H, 4.56; N, 15.54.

***5-Ethyl-8-oxo-5,8-dihydro-[1,3]dioxolo[4,5-g] quinoline-7-carboxamide (9).*** *Method A*. This compound was obtained in 77% yield as a white solid (ref. [19]).

*Method B*. To a solution of **6** (0.28 g, 0.001 mol), ammonia solution (5 mL) in ethanol, basic alumina (2 g) was added. The reaction mixture was stirred well, air dried, and subjected to MWI intermittently at 30 s intervals for specified time (Table 1). On completion of reaction, as monitored by TLC the product was extracted into ethanol (3 × 5 mL). Removal of solvent under reduced pressure yielded the product which was recrystallized from ethanol to give 0.24 g (92%) of **9** as a white solid. mp 334–336°C; (lit. ref. [19] 336°C).

***6-Ethyl-6H-8, 10-dioxa-1, 3, 6 triaza-cyclopenta [b] phenanthrene-2, 4-dione (10).*** *Method A*. A mixture of **6** (0.28 g, 0.001 mol), urea (0.1 g, 0.002 mol), 5% aq. KOH (2 mL) and methanol (10 mL) was refluxed for 2 h and cooled. The precipitate obtained after dilution with water was filtered, washed with water, and recrystallized from methanol to give 0.20 g (70%) of **10** as a white solid.

*Method B*. To a solution of compound **6** (0.28 g, 0.001 mol), urea (0.1 g, 0.002 mol) in methanol (10 mL), 5% aq KOH (2 mL), and basic alumina 2 g was added. The reaction mixture was stirred well, air dried, and subjected to MWI intermittently at 30 s intervals for specified time (Table 1). On completion of reaction, as monitored by TLC the product was extracted into ethanol (3 × 5 mL). Removal of solvent under reduced pressure yielded the product which was recrystallized from methanol to give 0.25 g (88%) of **10** as a white solid.

mp 285–287°C; IR (KBr): 3431, 2926,2853,1721, 1685, 1658, 1604, 1574, 1557, 1508, 1472, 1416, 1335, 1292, 1251, 1216, 1181, 1114, 1084,1024 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 1.42 (t, 3H), 4.66 (q, 2H), 6.35 (s, 2H), 7.74 (s, 1H), 8.26 (s, 1H), 9.11 (s, 1H), 15.62 (s, 1H); MS (ESI, *m/z*):286 $[M+H]^+$. Caution: Although we did not have any accident in this work, it is highly recommended that the reaction should be performed in an efficient hood.

***In vitro* antibacterial activity**. Minimal inhibitory concentrations (MICs) were determined by means of an agar dilution method, using Mueller Hinton agar plates containing a series of twofold dilutions of drug. Overnight cultures in Mueller Hinton broth were used for precultures of tested strains. MICs were determined after overnight incubation at 37°C, with an inoculum equivalent to 1:100 dilution of an 18 h culture in Mueller Hinton broth (about$10^8$ cells/mL). Each inoculum was seeded onto agar plates by using an inoculum-replicating apparatus and transferred by a 0.005 mL (about $10^4$ cells) calibrated loop. The MIC was the lowest drug concentration that inhibited the development of visible growth on agar plate.

The *in vivo* antibacterial activities of drugs were determined in the systemic infections of mice with bacteria. Ten female Swiss albino mice weighing 18 to 22 g were used for each dose level. Microorganisms grown on Mueller Hinton agar plates were suspended in physiological saline solution. Mice were intraperitoneally challenged with bacteria. Mice infected with *Escherichia coli* ML 4707 were treated at 1 h after infection. Mice infected with *Klebsiella pneumoniae* ML 4730 and *Proteus morganii* ML 4731 were treated, respectively, at 1, 6, and 24 h and then immediately and at 3 h after infection. Drugs to be tested were administered PO. The total number of surviving mice was recorded 1 week after infection, and the

**Table 2**

Biological activity.

| Compound no. | MIC (μg/mL) | $ED_{50}$(PO) (mg/kg bw) |
|---|---|---|
| **4** | 16 | 30 |
| **5** | 0.5 | 4.7 |
| **7** | 256 | >50 |

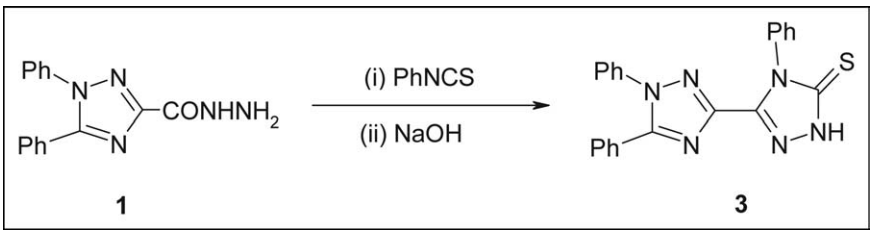
# Preparation and Evaluation of Antibacterial Activity of Some New 1,2,4-Triazole Derivatives

W. A. A. Arafa*

Department of Chemistry, Fayoum University, Fayoum, Egypt
*E-mail: waelarafa156@yahoo.com

Received October 21, 2009
DOI 10.1002/jhet.431
Published online 16 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



Cyclizations of 1,5-diphenyl[1,2,4]triazole-3-carbohydrazide **1** and the thiosemicarbazide **2** (derived from **1** by addition to phenylisothiocyanate) under various conditions afforded novel biheterocyclic systems. The newly prepared compounds were screened for their antibacterial activity. The results showed that several of these compounds exhibited significant antibacterial activity.

*J. Heterocyclic Chem.,* **47**, 1109 (2010).

## INTRODUCTION

Many compounds consisting of five-membered heterocyclic rings such as triazoles, oxazdiazoles, and thiadiazoles were synthesized and evaluated for their biological activities [1–5]. During recent years, microorganisms have increased their resistance against commonly used antibiotics. Therefore, it was crucial to develop new antimicrobial and antiviral compounds [6]. Studies on 1,2,4-triazole compounds have a wide range in the area of pharmacology [7–14]. 4-Thiazolidinones are known to possess antibacterial [15–20], antifungal [21], antiviral [22,23], and antituberculosis [24] properties (Fig. 1).

4-Thiazolidinones have a novel mechanism for action that involves the inhibition of bacterial protein synthesis at a very early stage [25,26]. The traditional method for the preparation of thiazolidinones includes the reaction of an aromatic amine with substituted benzaldehyde in the presence of mercaptoacetic acid [26,27]. In addition, the method reported recently for the synthesis of thiazolidinones involved the reaction of thiosemicarbazides with chloroacetic acid [25]. During the recent years, there has been a broad investigation on different classes of thiadiazoles, many of which were found to possess an extensive spectrum of pharmacological activities [28–32]. Also, 1,2-pyrazole derivatives were found to possess various biological activities [33,34].

The cyclization of relatively small and linear molecules is one of the most common methods leading to the formation of heterocyclic compounds. For example, compounds that contain a thiosemicarbazide structure can be considered as suitable precursors for this purpose [34–37]. The $NH_2$ group of the hydrazide structure behaves as a good nucleophile in most reactions leading to formation of new heterocyclic rings such as 1,2,4-triazoles, 1,3,4-thiadiazoles [37–39].

In view of these facts, hereby we report the preparation of new 1,2,4-triazoles, connected to another heterocyclic ring such as 1,2,4-triazole, 1,3,4-thiadiazole, and 1,3-thiazolidin-4-one rings.

## RESULTS AND DISCUSSION

The structure of the prepared compounds was elucidated using IR, $^1$H NMR, $^{13}$C NMR, and mass spectroscopic methods besides elemental analyses. The pathways leading to the products obtained have been depicted in Schemes 1 and 2. The key intermediate in this study is the 1,5-diphenyl-1*H*-[1,2,4]triazole-3-carboxylic acid hydrazide **1**, which was prepared according to a previously described procedure [40].

Acid hydrazide **1** and thiosemicarbazide **2** are of considerable interest as building blocks for nitrogen and/or sulfur containing heterocyclic systems, which might show biological activities. Therefore, our attempts are to prepare new five-membered heterocycles of expected biological activities utilizing compounds **1** and **2** as starting material.

When compound **1** was refluxed with phenylisothiocyanate, the expected thiosemicarbazide **2** was obtained in good yield. In the IR spectrum of compound **2**, the hydrazone NH stretching frequencies were observed at 3291, 3198, and 3146 $cm^{-1}$. The absorption band at

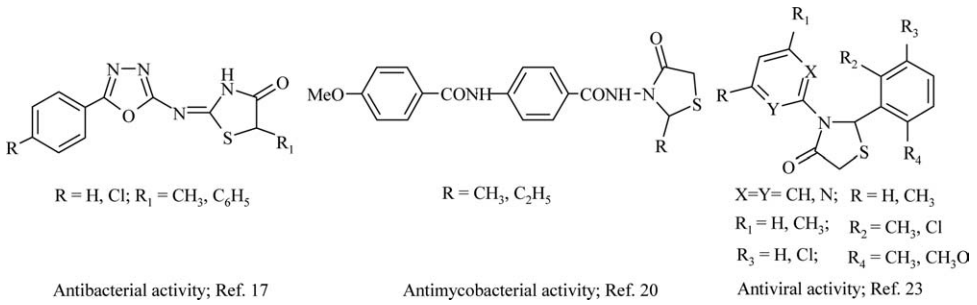


**Figure 1**

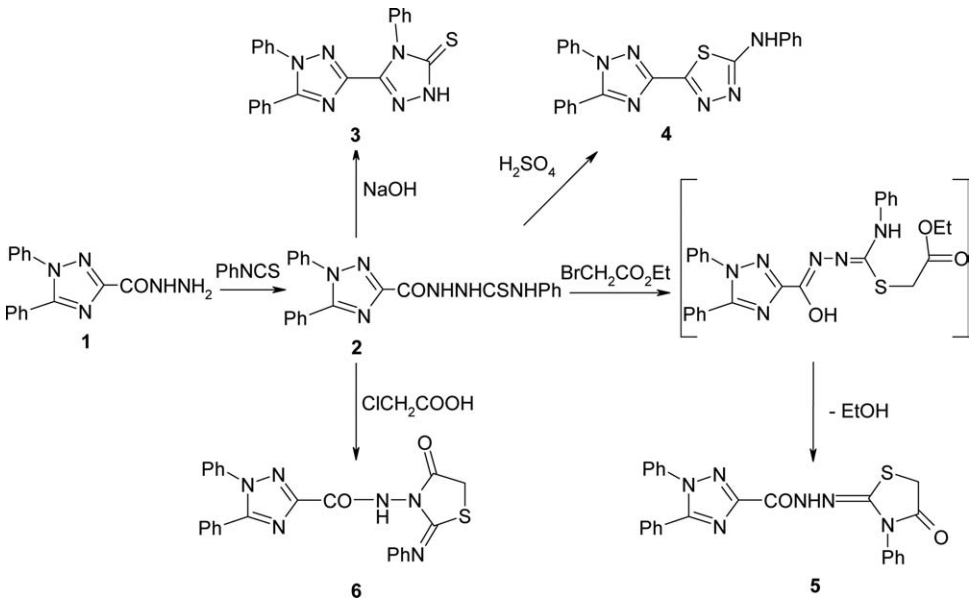
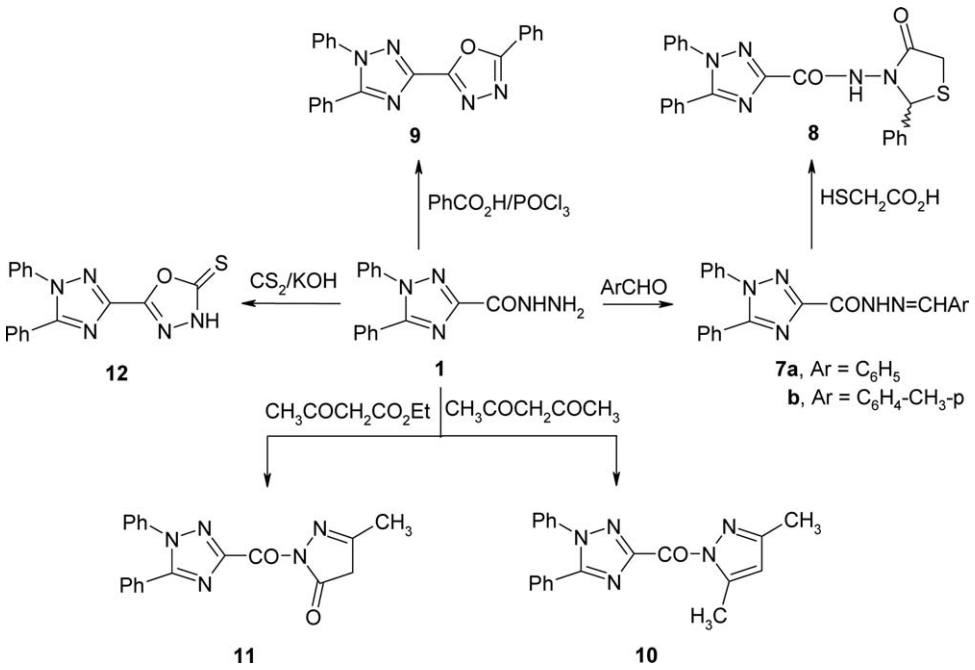
1666 $cm^{-1}$ is due to the presence of C=O stretch. The C=S stretching frequency was observed at 1373 $cm^{-1}$. Further evidence for the formation of compound **2** was obtained by recording its mass spectrum. The mass spectrum of **2** showed the molecular ion at *m*/*z* 414 corresponding to $C_{22}H_{18}N_6OS$ and the base peak at *m*/*z* 220. Alkaline cyclization of the thiosemicarbazide **2** using 2*N* sodium hydroxide solution afforded the corresponding 4,1′,5′-triphenyl-1,4-dihydro-1′*H*-[3,3′]bi[1,2,4] triazolyl]-5-thione **3**. This reaction began with nucleophilic attack of thiosemicarbazide N-5 to carbonyl group in the side chain of compound **2**. The structure of compound **3** was confirmed on the basis of elemental analysis, IR, $^1$H NMR, $^{13}$C NMR, and mass spectroscopic methods. It is interesting to note that compound **3** is present in solid state in thionic form, C=S, as indicated by its IR spectrum, which showed the absence of absorption in the region of 2500–2660 $cm^{-1}$ cited for SH group [41] and the presence of maximum at 1455 $cm^{-1}$ characteristic for C=S group. Moreover, in the $^1$H NMR spectrum of compound **3**, NH was observed as singlet at 9.32 ppm, therefore it was proved that compound **3** was found in thionic form also in DMSO. Furthermore, reacting thiosemicarbazide **2** with cold concentrated sulfuric acid resulted in the formation of the corresponding N-phenyl[5-(1,5-diphenyl-1*H*-[1,2,4]triazol-3-yl)-[1,3,4]thiadiazol-2-yl]-amine **4**. The reaction involved the nucleophilic attack of the C=S sulfur atom on the carbonyl C of compound **2**. In the $^1$H NMR spectrum of compound **4** the presence of only one singlet for NH group integrated for one proton confirming the cyclization at the side chain of triazole ring in compound **2** to afford the thiadiazole **4**. Also, the mass spectrum of compound **4** gave molecular ion peak in agreement with its molecular formula. The thiazolidinone derivative **5** was obtained from the treatment of thiosemicarbazide **2** with ethyl bromoacetate in the presence of anhydrous sodium acetate in absolute ethanol. The first

**Scheme 1**



**Scheme 2**



step of this reaction is thought to be an S-alkylation of **2**. The second step is a release of ethanol to give thiazolidinone **5**, the IR spectrum of which showed the lactam C=O stretching band at 1708 $cm^{-1}$. The mass spectrum was also in agreement with the formation of thiazolidinone ring. In an extension of the above reaction to obtain another thiazolidinone derivative **6**, thiosemicarbazide **2** undergoes a ring closure reaction, on boiling in ethanol with monochloroacetic acid. The structure of compound **6** was elucidated on the basis of IR, $^1H$ NMR, and mass spectra as well as correct elemental analysis. The IR of **6** exhibited absorption bands at 3212 due to NH group and at 1719, 1665 $cm^{-1}$ because of two carbonyl groups. $^1H$ NMR of **6** revealed a singlet at 3.62 because of $CH_2$ of thiazolidinone ring and singlet at 9.01 ppm for NH.

Additionally, the condensation of the acid hydrazide **1** with a variety of aromatic aldehydes in ethanol leading to the formation of compounds **7a**, **b**. Structure elucidation of the Schiff's bases **7a**, **b** was based on microanalysis and spectral data (Tables 1 and 2). 1,5-Diphenyl-1*H*-[1,2,4]triazole-3-carboxylic acid (4-oxo-2-phenyl-thiazolidin-3-yl)-amide **8** was obtained by refluxing the Schiff's base **7a** and thioglycolic acid in dry benzene for 10 h using a Dean-Stark water separator. The thiazolidinone **8** was characterized by IR absorption bands at

| **12** | IR (KBr, $cm^{-1}$): 3321 (NH).<br>$^1$H NMR (DMSO-$d_6$, δ ppm) 6.99–7.50 (10H, m, aromatic protons) and 10.85 (1H, s, NH).<br>ms: *m/z* (%): 321 ($M^+$, 25.47). |

3251, 1722, and 1704 $cm^{-1}$ for NH and the two C=O groups, respectively. Its $^1$H NMR exhibited two signals appearing as doublets at 3.41 ppm and 3.81 ppm because of the nonequivalent geminal $CH_2$ protons [42]. This splitting was not observed with derivatives **5**, **6**, and **11** which may be attributed to the lacking of the asymmetric carbon atom. A convenient method for the preparation of oxadiazole derivative **9** was deduced from refluxing the acid hydrazide **1** with an equimolar amount of benzoic acid in the presence of an excess of phosphorous oxychloride. The IR spectrum of compound **9** showed no absorption for NH groups, this indicating the cyclization of **1** into oxadiazole **9**. Also, the mass spectrum of **9** gave a molecular ion at *m/z* 365 corresponding to $C_{22}H_{15}N_5O$. The hydrazide **1** was allowed to react with acetyl acetone and ethyl acetoacetate to give dimethyl pyrazole derivative **10** and methyl pyrazolone derivative **11**, respectively. The IR of **11** showed absorption band at 1728 $cm^{-1}$ characteristical for the pyrazole carbonyl group. $^1$H NMR spectra of

compounds **10** and **11** showed singlets at 1.81 ppm and 2.01 ppm assigned for the methyl groups, respectively. The preparation of oxadiazole-2-thione **12** was achieved, according to a reported method of Young and Wood [43], by adopting a simple one-pot procedure that involves reacting **1** with carbon disulfide under strong basic conditions followed by acidification with diluted HCl. The oxadiazole derivative **12** was characterized by IR which showed band at 3321 $cm^{-1}$ attributed to NH. The $^1H$ NMR spectrum of **12** displayed the NH resonance of the oxadiazole ring at 10.85 ppm.

## ANTIBACTERIAL STUDIES

The newly prepared compounds were screened for their antibacterial activity against Gram positive (*Bacillus subtitis* and *Streptococci*) and Gram negative (*Klebsiella pneumoniae* and *Escherichia coli*) bacterial strains by the disc diffusion method [44], and the results are summarized in Table 3. The results obtained showed that Schiff's bases **7a** and **7b** were found to be the most active compounds against the employed microorganisms; this is probably due to their ability to increase the penetration in the bacterial cell [45]. In addition, the substituted thiazolidinones **5**, **6**, and **8** as well as the substituted pyrazole **11** exhibited promising activity against both Gram positive and negative bacteria. However, the pyrazole derivative **10** exhibited a low activity against Gram positive only. No satisfactory level of inhibition was observed with the other compounds.

## CONCLUSIONS

This study reports a successful preparation and characterization of new 1,2,4-triazole derivatives. The antibacterial study revealed that, compounds **5**, **6**, **7a**, **7b**, **8**, and **11** showed low to moderate antibacterial activities. This result suggesting that Schiff's base, thiazolidinone, and pyrazole moieties play an important role in enhancing the antibacterial activities of this class of compounds.

## EXPERIMENTAL

**Chemistry.** Melting points were determined in open-glass capillaries on a Stuart electric melting point apparatus and were uncorrected. Elemental analyses were performed by the Microanalysis center, Faculty of Science, Cairo University. Infrared spectra were recorded on Satellite 2000 spectrometer using KBr discs. Mass spectra were determined on GC-MS (QP/000 EX) Shimadzu spectrometer at an ionizing voltage of 70 eV. Nuclear magnetic resonance spectra were recorded on Varin Mercury 300 MHz spectrometer using TMS as an internal standard; chemical shifts are reported in δ units. Solvents were dried by standard procedures. Reaction progress and purity of the compounds were checked by TLC, making use of silica gel plates (Silica gel F254 on aluminum sheets).

***Preparation of thiosemicarbazide 2.*** A solution of **1** (0.01 mol) and equimolar amount of phenylisothiocyanate in 50 mL of ethanol was heated under reflux for 5 h. The solid product obtained after concentration of the solution was collected by filtration and recrystallized from methanol to give yellow crystals.

***Preparation of 4,1′,5′-triphenyl-1,4-dihydro-1′H-[3,3′]bi[[1,2,4]triazolyl]-5-thione 3.*** The thiosemicarbazide **2** (0.01 mol) in sodium hydroxide (2*N*, 15 mL) was refluxed for 8 h. The solution was cooled and neutralized using diluted hydrochloric acid. The formed solid was collected by filtration, washed with water, and recrystallized from methanol to give colorless crystals.

***Preparation of N-phenyl[5-(1,5-diphenyl-1H-[1,2,4]triazol-3-yl)-[1,3,4]thiadiazol-2-yl]-amine 4.*** To an ice-cold stirred solution of thiosemicarbazide **2** (0.01 mol) in absolute ethanol (10 mL), concentrated sulfuric acid (10 mL) was added over a period of 30 min, the stirring was maintained at room temperature for an additional 5 h. Then, the reaction mixture was poured onto ice/water mixture. The solid was filtered off and recrystallized from dioxane to give colorless crystals.

***Preparation of 1,5-diphenyl-1H-[1,2,4]triazole-3-carboxylic acid (4-oxo-3-phenyl-thiazolidin-2-ylidene)-hydrazide 5.*** A mixture of **2** (0.01 mol), ethyl bromoacetate (0.01 mole), and anhydrous sodium acetate (0.03 mol) in ethanol (30 mL) was refluxed for 5 h. The solid product obtained after concentration of the reaction mixture was collected by filtration and recrystallized from methanol to give pale yellow crystals.

***Preparation of 1,5-diphenyl-1H-[1,2,4]triazole-3-carboxylic acid (4-oxo-2-phenylimino-thiazolidin-3-yl)-amide 6.*** A solution of **2** (0.01 mol) in ethanol (30 mL) was treated with monochloroacetic acid (0.01 mol), and the reaction mixture was refluxed for 5 h. The solid product obtained after concentration of the solution was collected by filtration and recrystallized from ethanol to give yellow crystals.

***Preparation of 1,5-diphenyl-1H-[1,2,4]triazole-3-carboxylic acid benzylidene-hydrazide 7a, b.*** A solution of **1** (0.01 mol) and an appropriate aldehyde (0.01 mol) in ethanol (30 mL)

was refluxed for 5 h. The solid separated upon cooling was filtered and recrystallized from dioxane to give yellow crystals.

***Preparation of 1,5-diphenyl-1H-[1,2,4]triazole-3-carboxylic acid (4-oxo-2-phenyl-thiazolidin-3-yl)-amide 8.*** A mixture of **7a** (0.01 mol) and thioglycolic acid (0.01 mol) was refluxed in dry benzene (75 mL) for 10 h, using a Dean-Stark water separator. The solvent was evaporated, and the reaction mixture was neutralized with cold dilute sodium bicarbonate solution. The formed solid was filtered off, dried, and recrystallized from ethanol to give yellow crystals.

***Preparation of 2-(1,5-diphenyl-1H-[1,2,4]triazol-3-yl)-5-phenyl-[1,3,4]oxadiazole 9.*** A mixture of **1** (0.01 mol) and benzoic acid (0.01 mol) in $POCl_3$ (15 mL) was refluxed for 10 h. The reaction mixture was slowly poured onto ice/water mixture and then neutralized with sodium bicarbonate solution. The solid formed was filtered, washed with water, and recrystallized from ethanol to give pale yellow crystals.

***Preparation of compounds 10 and 11.*** A mixture of **1** (0.01 mol) and acetyl acetone or ethyl acetoacetate (0.01 mol) in ethanol (50 mL) was refluxed for 5 h. The solid product obtained after concentration and cooling of the solution was collected by filtration and recrystallized from dioxane to give yellow crystals.

***Preparation of 5-(1,5-diphenyl-1H-[1,2,4]triazol-3-yl)-3H-[1,3,4] oxadiazole-2-thione 12.*** To a mixture of **1** (0.01 mol) in ethanol (50 mL) was added a solution of potassium hydroxide (0.015 mol) in ethanol (50 mL), followed by carbon disulfide (30 mL). The reaction mixture was refluxed for 20 h. The solid product obtained after cooling and acidification with dilute HCl was collected by filtration and recrystallized from ethanol to give yellow crystals.

**Antibacterial assay.** Antibacterial screening of prepared compounds was done by the paper disc agar diffusion method [44] against Gram positive (*B. subtitis* and *Streptococci*) and Gram negative (*K. pneumoniae* and *E. coli*) strains. The compounds were dissolved in DMSO at a concentration of 1 mg $mL^{-1}$. Antibacterial activity of DMSO against the test microorganisms was investigated and was found to be nil. The nutrient agar medium was sterilized by autoclaving at 120°C for 15 min; the Petri dishes were sterilized in hot air oven at 160°C for an hour. Into each sterilized Petri plate, about 30 mL of molten agar medium inoculated with the respective strain of bacteria (6 mL inoculums to 300 mL of nutrient medium) was transferred. The plates were left at room temperature to allow solidification. Six-millimeter diameter holes were then punched carefully using a sterile cork borer and completely filled with the test solutions. The plates were incubated for 24 h at 37°C. The antibacterial activity was evaluated by measuring the diameter of the inhibition zone. All the experiments were carried out in doublet, and the average value was reported. The antibacterial activity results were summarized in Table 3.

**Acknowledgment.** The author expresses his thanks to Miss A. Salah, Department of Medicinal Chemistry, Theodor Bilharz Research Institute, Egypt, for antibacterial screening.

An efficient approach for stereoselective synthesis of cyclopropyl indolyl ketone from olefin and arsonium ylied was achieved. Its advantages are of mild condition, high yield, and good stereoselectivity. In addition, the one-pot cycloproparation of olefins with bromides and triphenylarsine was studied.

## INTRODUCTION

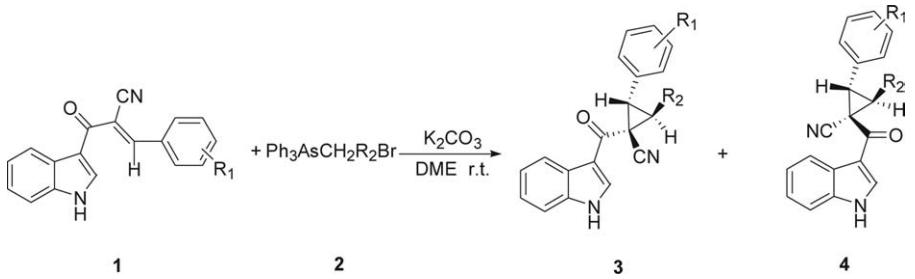
Cyclopropyl ketones occupy an important position in cyclopropane chemistry owing to their wide utility as potent synthetic blocks which have been extensively applied for the synthesis of complex molecules including heterocycles [1]. Therefore, the great efforts have been made to develop new method for synthesis of cyclopropyl ketones [2].

In recent years, the concept of privileged structures, which repeated occurrence in biologically active molecules, become important for the design and synthesis of drug candidates. The indole framework is a versatile and important structural motif frequently found in natural products, pharmaceuticals, and other synthetic compounds [3]. Thus, it is not surprising that a great deal of attention has been directed to development of efficient routes for the synthesis of these interesting compounds. Now, we become interested in the design and synthesis of the cyclopropyl indolyl ketones. Because of their unique ring strain and high reactivity, these novel cyclopropanes may serve as new and useful building blocks for construction of complex indoles. To the best of our knowledge, no approaches have been previously reported for synthesis of cyclopropyl indolyl ketones. Here, we report an effect procedure for preparation of cyclopropyl indolyl ketones *via* cyclopreparation of indolylidene with arsonium ylide (Scheme 1).

The needed indolylidenes were prepared according to the reported literature [4]. We tested some bases first. In the model experiment, a mixture of indolylidene **1a** (1 equiv), benzoylmethyltriphenylarsonium bromide **2a** (1.1 equiv) and base (3 equiv) in dimethoxyethane (DME) was stirred at room temperature to give compound **3a** and **4a**. The results showed that the $K_2CO_3$ as base provided the highest yield (entry 1, Table 1). And then, the screening for a suitable solvent was performed in the presence of $K_2CO_3$ at room temperature. It was found that DME was the best solvent for this reaction. The results were listed in Table 1. At the same time, the results in Table 1 also showed that bases, solvents, and temperature have no obvious influence on the ratio of product **3** and **4**.

To investigate the scope of this reaction, some indolyldienes and arsenium salts are examined with the optimized conditions and the results are shown in Table 2. It is worth noting that only compounds **3e–k** were obtained (entries 6–11, Table 2), when methoxycarbonylmethyltriphenylarsonium bromide and cyanomethyltriphenylarsonium bromide were used as arsonium salts instead of benzoylmethyltriphenylarsonium bromide.

**Scheme 1**



1 2 3 4

The structures of compounds **3a–k** and **4a–d** were characterized by $^1$H NMR, $^{13}$C NMR, MS, IR, elemental analysis, and X-ray diffraction (Fig. 1; Table 3). The relative configurations of product **3** and **4** are confirmed from NOE experiments of compounds **3b** (Fig. 2) and **4b** (Fig. 3). The cyclopropyl hydrogen with a trans configuration is deduced by the absence of NOE correlation between two protons situated at adjacent carbons in the cyclopropane ring of these compounds.

One-pot methodology has recently attracted increasing attention. Because it offers significant advantages such as a reduction in the number of synthetic steps, energy consumption and waste production, and high efficiency [5]. Thus, considerable efforts have been taken in developing new one-pot process. Our attention turned next to one-pot cyclopropanation reaction with triphenylarsine and bromide. (Scheme 2).

Initial studies focused on screening the optimum reaction conditions, in the model experiments, a mixture of triphenylarsine **6** (0.1 equiv), methyl bromoacetate **5** (1.2 equiv), indolyidiene **1** (1.0 equiv), and bases (3.0 equiv) in solvent (5 mL) was stirred under reflux. The results are shown in Table 4. We found that the highest yield of cyclopropane **3f** was obtained in acetonitrile/$K_2CO_3$ system (entry 2, Table 4). Then, the amount of $Ph_3As$ was tested under the similar condition. Through an effort to investigate the reaction condition, we chose 0.75 equiv of $Ph_3As$ /acetonitrile/$K_2CO_3$ system as the optimum reaction condition. Because the amount of triphenylarsine changes from 0.75 equiv to 1 equiv, the differences in the yield and rate of cyclopropanation are not significant (entries 10 and 11, Table 4).

The scope of the one-pot of cyclopropanation with indolyidienes and bromides in the presence of trephenylarsine was further explored. The results are shown in Table 5.

A plausiblemechanism for the formation of product **3** and **4** is shown in Scheme 3. (1) The arsonium yilde **B** is generated from arsonium salt **A** with $K_2CO_3$ as base. (2) The ylide **B** nucleophilically attacks the olefin **C** to result in either transition state **D** or **E**. Apparently, the **E** should be favored over **D**, with the latter being higher energy given the steric repulsion between bulky X and Ar groups in the conformation of **D**. (3) The six-membered ring, locking conformation of intermediate **F**, is formed by nonbonding interactions between the negatively polarized oxygen in enolate ion and positively polarized X group, and the product **3** is given *via* cyclopropanation reaction. (4) When the X is benzoyl group, the intermediate **G** is formed due to the steric repulsion between bulky benzoyl and indolyl groups, and then the product **4** is yielded from **G**.

In conclusion, we have developed an efficient approach for stereoselective synthesis of cyclopropyl indolyl ketone from olefin and arsonium ylied. The advantages of this approach are of mild condition, high yield, and good stereoselectivity. In addition, the one-pot cycloproparation of olefins with bromides and triphenylarsine was also studied.

## EXPERIMENTAL

**General Experimental Conditions.** All reagents and solvents were obtained from commercial sources and used without purification. All melting points were uncorrected. Melting points were determined on WRS-1 digital melting point apparatus made by Shanghai physical instrument factory (SPOIF), China. IR spectra were measured in KBr on a PE-580B spectrometer. $^1$H NMR spectra were recorded at a Bruker AM-500, using $CD_3COCD_3$ as solvent and TMS as internal reference. Mass spectra were taken with a HP5989A mass spectrometer at an ionizing voltage of 70 eV. Elemental analyses were measured on the elementar vario EL III. X-Ray crystal data were collected with Bruker Smart Apex2 CCD

**General procedure for preparing 3a–k and 4a–d.** A mixture of indolylidene 1 (1 mmol), arsonium bromide **2** (1.1 mmol) and $K_2CO_3$ (0.414 g, 3 mmol) in dimethoxyethane (DME) (5 mL) was stirred at room temperature. The completion of the reaction was determined by TLC. The DME was removed off under reduced pressure, and the residue was run on a silica-gel chromatographic column (eluant: petroleum ether–ethyl acetate (v: v = 6:1)). The desired products **3** and **4** can be obtained and triphenylarsine recovered, respectively.

**General procedure of one-pot method for 3a–k and 4a–d.** A mixture of indolyidiene 1 (1 mmol), bromide **5** (1.2 mmol), triphenylarsine 6 (0.225 g, 0.75 mmol), and $K_2CO_3$ (0.414 g, 3 mmol) was stirred in the refluxing $CH_3CN$ (5 mL). The completion of the reaction was determined by TLC.The $CH_3CN$ was removed off under reduced pressure, and the residue was run on a silica-gel chromatographic column (eluant: petroleum ether–ethyl acetate (v: v = 6:1)). The desired products **3** and **4** can be obtained and triphenylarsine recovered, respectively.

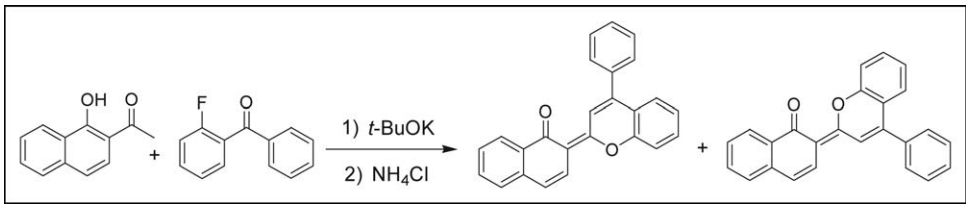
Published online 16 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



The reaction between 1-hydroxy-2-acetonaphthone and 2-fluorobenzophenone in basic medium afforded two diastereoisomeric carbonyl dyes whose structures were unambiguously established using spectroscopic methods. A mechanism for the formation of these dyes involving a base-catalysed addition followed by dehydration and intramolecular aromatic nucleofilic substitution is proposed.

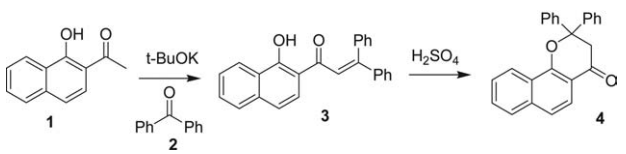
## INTRODUCTION

Reaction between 1-hydroxy-2-acetonaphthone **1** and benzophenone **2** in the presence of sodium *tert*-butoxide is known to produce, after acid treatment, mainly 2,2-diphenylnaphthopyran-4-one **4**, a useful compound in the synthesis of photochromic naphthopyrans [1,2]. The reaction involves a base-catalysed addition of **1** to **2** followed by dehydration that provides the yellow intermediate **3**. Then the acid catalyzed intramolecular 1,4-addition of the phenolic hydroxyl group to the α,β-conjugated ketone produces the diphenylnaphthopyran-4-one **4** (Scheme 1) [3]. This low yielding reaction (56%) requires an excess of base and ketone and is thus far limited to diarylketones [4–6].

Recently, we have reported that the reaction between **1** and 2-fluorobenzophenone **5** in the presence of 5 equivalents of potassium *tert*-butoxide in toluene under reflux, followed by reflux in AcOH/HCl gives rise to a small amount of a blue dye (5.7%). Spectroscopic characterization using high-resolution NMR techniques established the highly conjugated structure **6** for this product [7].

**Scheme 1.** Synthesis of 2,2-diphenylnaphthopyran-4-one **4**.



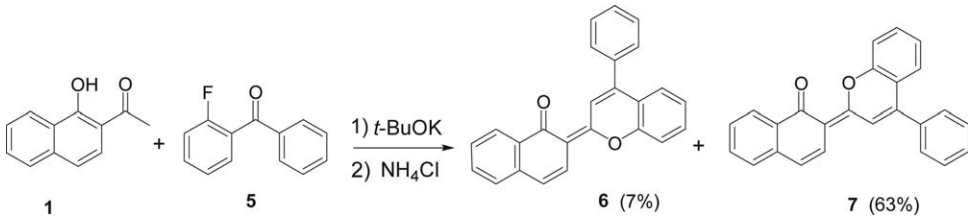
## RESULTS AND DISCUSSION

To improve the yield and understand how this dye is formed, we re-investigated this reaction and found out that, in fact, two different dyes are formed after the first step of the reaction between **1** and **5** (*t*-BuOK in toluene under reflux). $NH_4Cl$(aq) hydrolysis of the basic reaction mixture afforded a yellow dye **7** (less polar, 63% yield) as well as a small amount of the already known dye **6** (more polar, 7% yield) (Scheme 2).

Spectroscopic characterization of the new yellow dye **7** using DEPT, COSY, HMBC, HSQC provided the complete assignment of all proton and carbon resonances and showed that this compound is a diastereoisomer of the previously isolated dye **6** (Table 1). Long-range C—H correlations in the HMBC spectrum established the connectivity between all atoms and are shown in Figure 1.

The spectroscopic data for compounds **7** and **6** are quite similar. Both exhibit the same molecular formula and similar patterns in the Mass spectra and in the $^{1}H$ and $^{13}C$ NMR spectra. The main differences between these two diastereoisomeric dyes in the NMR spectra were the chemical shifts of protons H-3′ found at 6.04 (s) for dye **7** and at 9.12 (s) for dye **6** and the chemical shift of the carbonyls found at 195.36 ppm for **7** and at 183.58 ppm for **6**. The NOESY spectrum showed an important correlation between H-3′and H-3 for compound **7**, which was not observed for compound **6** and thus establishes a *Z*-configuration for the double bond between carbons 2 and 2′ of dye **7**.

**Scheme 2.** Synthesis of dyes **6** and **7**.



The UV-vis spectra of these two dyes are very different. While the blue dye **6** exhibits a large band in the visible spectrum with a maximum at 538 nm (ε 1.1 × $10^4$), a sub-maximum at 577 nm (ε 1.1 × $10^4$), and two shoulders at 504 nm (ε 0.83 × $10^4$) and 630 nm (ε 0.50 × $10^4$), the yellow dye **7** presents a maximum at 394 nm (ε 0.74 × $10^4$) (Figure 2). The lower $\lambda_{max}$ for dye **7** suggests a less efficient conjugation that may be due to the repulsion between the oxygen atoms at C-2′ and C-1 that would led to a less planar structure of this *Z*-isomer.

The formation of both dyes under basic medium led us to propose the following mechanism: subsequent to the base-catalyzed addition between **1** and **5**, proton transfer and dehydration would form the phenolate **A**, which might adopt two configurations, that upon intramolecular nucleophilic aromatic substitution would lead to the two diastereoisomeric dyes **6** and **7** (Scheme 3) [8,9].

Although both dyes were formed under basic conditions, a small amount of the blue dye **6** was also formed when the yellow dye **7** was refluxed in acid medium (AcOH/HCl). This can be explained through an acid catalyzed isomerization of **7** to **6** (Scheme 4).

## EXPERIMENTAL

The reagents were obtained from Aldrich and were used as supplied. Solvents were of analytical grade. The reactions were monitored by thin-layer chromatography on aluminum plates precoated with Merck silica gel 60 F254 (0.25 mm). Melting point was determined in capillary tubes and are

uncorrected. The new compounds were determined to be >95% pure by $^1$H NMR spectroscopy. UV-Vis spectra were recorded on a CARY 50 Varian spectrophotometer. IR spectra were obtained on a Perkin-Elmer FTIR 1600 spectrometer using KBr disks (wavenumbers in $cm^{-1}$). Electronic impact mass spectra were measured on a AutoSpecE spectrometer. The $^1$H and $^{13}$C NMR spectra were recorded at 298 K in $CDCl_3$ using a Bruker ARX400 spectrometer (at 400.13 for $^1$H and 100.62 MHz for $^{13}$C). Chemical shifts (δ) are reported in ppm and coupling constants (*J*) in Hz. Resonance multiplicities for $^{13}$C were established via the acquisition of DEPT spectra. Heteronuclear $^1$H-$^{13}$C HSQC and HMBC experiments were carried out using standard procedures.

**General procedure for the synthesis of dyes (6) and (7).** 1-Hydroxy-2-acetonaphthone **1** (0.186 g, 1.0 mmol) and potassium *tert*-butoxide (0.336 g, 3 mmol) in toluene (15 mL) were refluxed for 20 min. 2-Fluorobenzophenone **2** (0.400 g, 2.0 mmol) was added and the reaction mixture was refluxed for another 40 min. The dark red solution was hydrolyzed with $NH_4Cl$ (aq) and then extracted with $Et_2O$ (3 × 20 mL). The organic extracts were dried over anhydrous $Na_2SO_4$ and evaporated leaving a deep red residue, which was purified by column chromatography (2–10% ethyl acetate/petroleum ether) over silica gel. Two compounds were isolated: **7**, 0.220 g (63%) and **6**, 0.025 g (7%).

**(2Z)-2-(4′-phenyl-2H-chromen-2′-ylidene)naphthalene-1(2H)-one (7).** This compound was obtained as a yellow powder, mp 130°C dec. IR: 3060, 3026, 2976, 1620, 1594, 1569, 1450, 1320, 1254, 1203, 1059. For $^1$H NMR and $^{13}$C NMR data see Table 1. MS: *m*/*z* (%): 348 (75), 331 (12), 291 (8), 271 (14), 170 (100). Exact mass for $C_{25}H_{16}O_2$: 348.1150; Found 348.1146.

**(2E)-2-(4′-phenyl-2H-chromen-2′-ylidene)naphthalene-1(2H)-one (6).** This compound was obtained as blue needles, mp 155–158°C. IR: 3050, 2923, 2852, 1624, 1593, 1541, 1505, 1468, 1371, 1315, 1273, 1235, 955, 923. For $^1$H NMR

The article focuses synthesis of novel 4-aminomethyl-7,8-dihydroxy coumarins and their crown ether derivatives. The purified novel coumarins and their crown ether derivatives were identified by $^{1}H$ NMR, $^{13}C$ NMR, mass spectrometry and elemental analysis. The 1:1 binding constants of $Ca^{2+}$, $Mg^{2+}$, $Fe^{2+}$, $Zn^{2+}$, $Ni^{2+}$, $Cd^{2+}$, $Co^{2+}$, and $Mn^{2+}$ ions at 25°C ± 0.1 with the 4-aminomethyl-7,8-dihydroxy coumarins and their crown ether derivatives estimated using extraction procedure with Inductively Coupled Plasma-Atomic Emission Spectroscopy in dichloromethane/water membrane systems. Synthesized compounds were investigated for complexation and biological activity properties. Best results in biological activity studies were observed for antioxidant activity.

## INTRODUCTION

Coumarins are members of the class of compounds called benzopyrones and display a variety of pharmacological properties [1] depending on their substitution pattern. They are also known to possess antifungal and antibacterial properties [2,3], natural [4], and synthetic origin [5]. The diverse biological activity of chromenone derivatives as anticoagulants and antithrombotics is well known [6].

3-Alkyl and 4-alkylcoumarins are well known [7] for their anthelmintic, hypnotic, insecticidal, antifungal activities, and anticoagulant effect on blood and diuretic properties. Extensive work has been done on the synthesis [8] of these classes of compounds. Methylene halide that is attached at the 4th position is a very highly reactive group in coumarins. Some coumarine compounds obtained from reaction of coumarin-4-methylene halide group with various amino compounds have been investigated for complexation [9], biological [10], photopysical [11,12], and spectroscopic [13–15] properties.

Macrocyclic molecules have attracted much attention because of their potential use in a variety of chemical processes, complexation ability, selective complexing

agents for metal ions, and photoinduced electron transfer since its discovery by Pedersen [16,17]. The complexation selectivity of crown ethers has often been explained in terms of the size-fit concept that the crown ether forms a more stable complex with the cation which is more suitable in size for the crown ether cavity. From many investigations of crown ether and cation interactions it was determined that crown ethers can form variable complexes with cations that are too large to fit into the macrocyclic cavity [18–23]. This led to the synthesis of new crown ethers derivatives which are attachment of functional side arm.

In ion-pair extractive separation of metal cations using a neutral chelation reagent and a counter anion, selection of the chelation reagent is one of the most important factors to realize preferable separation. Especially, investigation of effect of steric structure around electron donor atoms in the reagent on the separation ability is very important for the development of novel reagents having high separation performance. The determination of complexation constants of organic ligands-metal ion complexes in water can be examined with different methods by following the extraction of metals to the varied organic solvents with organic ligands [24–29]. The solvent extraction of metal cations which contains macrocyclic ligands is preferred to use for its easy determination by spectrophotometric methods [23,30,31].

We report in this study the synthesis, complexation, and biological activity studies of novel 4-aminomethyl-7,8-dihydroxy coumarins and their crown ether derivatives.

## RESULTS AND DISCUSSION

**Synthesis of compounds.** 4-chloromethyl 7,8-dihydroxy coumarin compound (**2**) was synthesized by reaction of 1,2,3-trihydroxybenzene with ethyl-4-chloroacetoacetate. The 4-aminomethyl coumarins (**2–9**) were synthesized at room temperature by stirring and then refluxing the reaction mixture of amino compound and triethylamine with 4-chloromethyl coumarin in dry acetone. (Scheme 1). Next stage, the substituted 4-aminomethyl coumarin crown ether derivatives (**10–17**) were synthesized by refluxing 4-aminomethyl coumarins, tetraethyleneglycole ditosylate and $Na_2CO_3$ in $CH_3CN$ for 3–4 days.

**Complexation studies.** $K_{ex}$ is extraction equilibrium constant; $[M^{+m}]$ and $[MLA_m]$ are the concentrations of metal cation in aqueous phase and organic phase, respectively. $K_{D,L}$ denotes a distribution constant of ligand between organic solvent and water [25,32,33]. Extraction values, complexation, and distribution constants of synthesized ligands collected in Table 1.

$$M^{+m}_{(aq)} + L_{(org)} + mA_{(aq)} \overset{K_{ex}}{\rightleftharpoons} (MLA_m)_{(org)}, \quad (1.1)$$

$$K_{ex} = \frac{[MLA_m]_{(org)}}{[M^{+m}]_{(aq)}[L]_{(org)}[A]^m_{(aq)}}, \quad (1.2)$$

$$K_{D,L} = [L]_{(org)}/[L]_{(L)}. \quad (1.3)$$

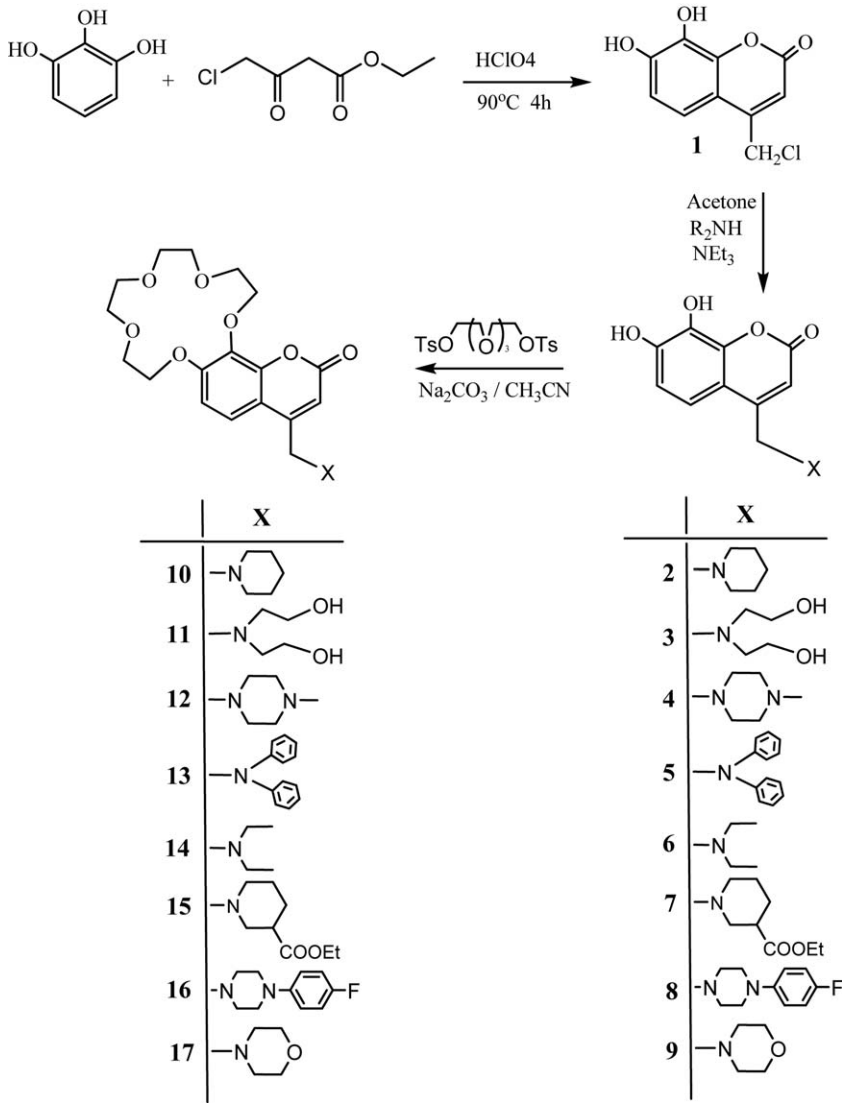
The complexation of metal cations $Ca^{2+}$, $Mg^{2+}$, $Fe^{2+}$, $Zn^{2+}$, $Ni^{2+}$, $Cd^{2+}$, $Co^{2+}$, and $Mn^{2+}$ have been examined with the synthesized ligands and extracting solvent. Association constants based on 1:1 stoichiometry of various metal complexes of these ligands were calculated from eqs. (1.1)–(1.3) (see Table 1) as the interactions of the ligands with different metal ions in dichloromethane solvent media. Assuming that formation of 1:1 complexes of the metal cations have been extracted at the natural pH of the aqueous metal salt solutions. The results are interesting, namely, the binding order of hydroxycoumarin compounds observed for only **3**,**7**,**8**, and **9** as ($Ni^{2+} > Co^{2+} > Mn^{2+} > Fe^{2+} > Ca^{2+} > Zn^{2+} > Cd^{2+} > Mg^{2+}$), ($Cd^{2+} > Ca^{2+} > Co^{2+} > Fe^{2+} > Ni^{2+} > Zn^{2+} > Mn^{2+} > Mg^{2+}$), ($Co^{2+} > Ni^{2+} > Cd^{2+} > Mn^{2+} > Fe^{2+} > Ca^{2+} > Zn^{2+} > Mg^{2+}$), ($Co^{2+} > Cd^{2+} > Fe^{2+} > Ca^{2+} > Zn^{2+} >>> Ni^{2+} = Mn^{2+} = Mg^{2+}$), respectively. It is found that the values of stability constants of coumarine crown derivatives were nearly in the same range for most examined metal cations except for $Cd^{2+}$ and $Co^{2+}$ cations. $Cd^{2+}$ is found to be the best extracted metal cation for the coumarine crowns. It followed by $Co^{2+}$ for all synthesized coumarine crown derivatives. One of the most important findings was the increase in $Mg^{2+}$ selectivity for only **8** and **11** among the all examined ligands. However, the five hydroxycoumarins (**1**,**2**,**4**,**5**, and **6**) and two coumarin crown compounds (**10** and **13**) did not show any complexation towards metal cations.

The synthesized compounds were tested for antibacterial (Table 2), antituberculosis (Table 2), antifungal (Table 2), and antioxidant (Table 3) activity. High values were obtained in antimicrobial activity studies especially for some hydroxycoumarin compounds. Best results in biological activity studies were observed for antioxidant activity. In comparison with the control substance, extremely high values have been obtained for **2**,**3**,**4**,**6**, and **8** ligands.

## EXPERIMENTAL

**General.** The starting chemicals were purchased from Aldrich or Merck unless otherwise cited. $CaCl_2$, $MgCl_2$, $ZnCl_2$, $CoCl_2$, $FeSO_4$, $MnCl_2$, $NiCl_2$, and $CdCl_2$ were analytical grade reagents from Fluka dried over $P_2O_5$ for 48 h at 0.1

**Scheme 1.** Synthesized compounds.



torr. The $CH_2Cl_2$ used was of analytical reagent grade. FT-IR spectra have taken as a KBr pellet with a Perkin Elmer Spectrum spectrometer, model BX-II, High resolution EI mass spectra have been obtained with Agilent 1100 LC/MSD, NMR spectra have been obtained with a Bruker-Specrospin AvanceDPX-400 Ultra-Shield $^1$H: 400 MHz $^{13}$C: 100 MHz. CPX and TMS was the initial standard. All melting points reported are uncorrected. The concentrations of metal ions in the aqueous phases have been determined spectroscopically: ICP-AES (Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP-AES): Perkin Elmer Optima 3100 XL).

**Organic synthesis.** ***4-Chloromethyl-7,8-dihydroxy-2H-chromen-2-one(1).*** A mixture of pyrogallol (0.03 mol), ethyl 4-chloroacetoacetate (0.06 mol) and $HClO_4$ (10 mL, 70%) was heated to 90°C for 4 h. The resulting mixture was cooled, diluted with water and the precipitates were collected by filtration. The dried crude product was purified by recrystallisation from ethanol. Yield (brown):48%. mp; 105–107°C. $^1$H NMR (400 MHz, Acetone/TMS) δ(ppm): 7.5 (s), 7.2 (d), 6.9 (d), 6.6 (s), 6.4 (s), 4.9 (s).

***General synthesis of 4-aminomethyl 7,8-dihydroxy coumarins.*** A mixture of 4-chloromethyl-7,8-dihydroxy coumarin (0.010 mol), amino compound (0.010 mol) and acetone (300 mL) was stirred to room temparature under $N_2$ for 24 h. Triethyl amine (0.010 mol) added and stirred for 1 h and then the mixture was refluxed for 3 h. After the removal of solution by evaporation, the resulting mixture was triturated with water, and the precipitates were collected by filtration. The crude product was dried under vacuum.

## EXTRACTION PROCEDURE

The extraction measurements were done in 100 mL glass thermostated cell compartment with a mechanical stirrer where a solution 10 mL ($1 \times 10^{-5}$ *M*) of an aqueous salt and ligand in $CH_2Cl_2$ organic solvent in appropriate concentration were placed and stirred for 120 min at 25 ± 0.1°C and subsequently allowed to stand for 60 min to complete the phase separation. The optimum concentrations of the ligands were determined by extracting the alkali salts with 10 mL aliquot of various concentrations of the ligands ($1 \times 10^{-5}$ *M*).

After extraction, the metal concentrations in the aqueous phase were determined using ICP-AES. Each value was the average of three subsequent measurements. Complexation and distribution constants summarized in Table 1.

## BIOLOGICAL ASSESSMENTS

Antibacterial and antifungal activities studies; Disc diffusion method was used [34]. The compounds were tested against standard bacterial strains; *E. coli*, *S. aureus*, *M. smegmatis*, *M. tuberculosis*, *M. simiae*, *M. kansasii*, *M. terrae*, *M. szulgai*, and a fungi *C. albicans*. Disc diffusion method was applied for the determination of antimicrobial activities of the samples. Compounds were dissolved in dichloromethane ($CH_2Cl_2$) and then filter-sterilized using a 0.20-μm membrane filter. A suspension of the tested microorganism (0.1 mL of $10^8$ cells/mL) was spread over the surface of agar plates (MHA and SDA). Filter papers having a diameter of 6 mm, soaked with 10 μL of samples and 10 μg compound in solution were placed on the inoculated agar plates. Before incubation all petri dishes were kept in the refrigerator (4°C) for 2 h. Then they were incubated at 37°C for 24 h for bacteria and at 30°C for 48 h for the yeasts. The diameters of the inhibition zones were measured in millimeters. The biological activity results of synthesized compounds are displayed in Table 2.

## ANTIOXIDANT ACTIVITY STUDIES

Antioxidant activity studies were measured by using the cuprac method in the literature [35]. Antioxidant activity studies results are showed in Table 3.

**Acknowledgment.** The authors are grateful to the Research Fund of the TUBITAK for their support with the TBAG-105T214.

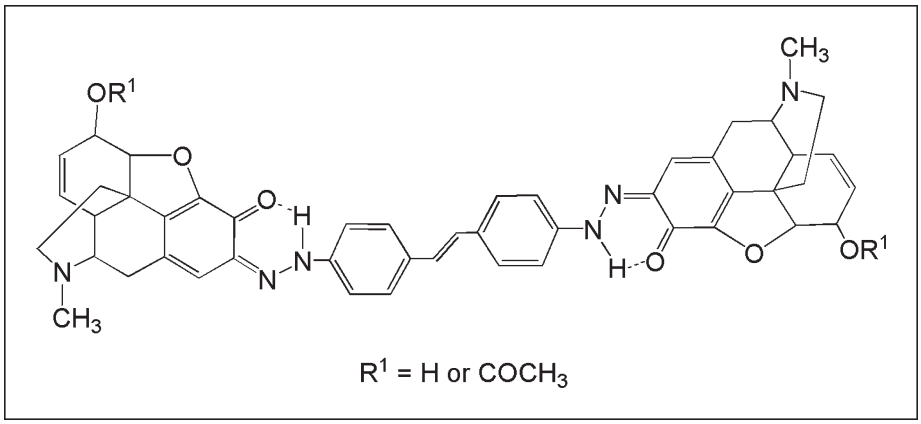
Published online 19 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



An applicable strategy of chemical labeling of morphine (M) and 6-acetyl morphine (6-AM) using diazonium salts is described. M or 6-AM was coupled with aryl diazoinum salts to give morphine azo dyes. The coupling of the diazotized 4,4′-diaminostilbene with M or 6-AM in ratio 1:2 gave stilbene-based azo dyes containing two M or 6-AM units, respectively. Diazotization of 5-(*p*-aminophenyl)-10,15,20-triphenylporphyrin and subsequent azo coupling of the diazoniun salt with M and with 6-AM was our route to get highly fluorescent morphine dyes. The resulting dyes can exist in two possible tautomeric structures, azo and hydrazone, stabilized to a significant extent by intramolecular H-bonding. It was shown that these dyes exists predominantly or exclusively in their hydrazone form. This conclusion is drawn from the lack of a distinct band in the 380–420 nm region of the absorption spectra (a region in which the long wavelength absorption band for the azo-form is observed), together with results of NMR studies in deuterated DMSO. The tautomeric properties of the compounds were judged by density functional calculations at the B3LYP/6-31G* and B3LYP/6-31G** levels. The analysis of spiked compounds in human urine samples was studied by capillary electrophoresis (CE) with UV-fluorescence photo-diode array detectors.

## INTRODUCTION

A great amount of attention continues to be devoted to the development of synthetic molecular receptors with the ability to recognize neutral organic species, including abused drugs. The morphine alkaloids comprise a family of structurally related natural products of unique clinical importance in medicine [1]. Morphine is a fascinating compound that has been used as an efficient analgesic and is indispensable in treating pains associated with cancer [2]. Morphine (M) is also found in normal brain, blood, and liver tissue [3]. However, it is strictly controlled by authorities due to its addictive nature. On the other hand, the unusual architecture of M has offered a continuing challenge to the art and science of organic synthesis (Fig. 1) [4,5]. Hence, a number of morphine derivatives have been reported to date [6]. Heroin, which is obtained synthetically from the acetylation of M, has an analgesic potency two to three times that of the parent drug and, due to the two acetyl groups, has better penetration across the blood-brain barrier [7]. Heroin itself is rarely present in detectable quantities in body fluids. The drug hydrolyses rapidly to 6-acetylmorphine (6-AM), which in turn hydrolyses to M. Therefore, heroin consumption can be confirmed by identifying its two primary metabolites [8,9]. In addition, heroin is different from most other opioids in that it has little or no affinity for opioid receptors in the brain. The analgesic effects of the drug are attributed to the combined effect of 6-AM and M [2].

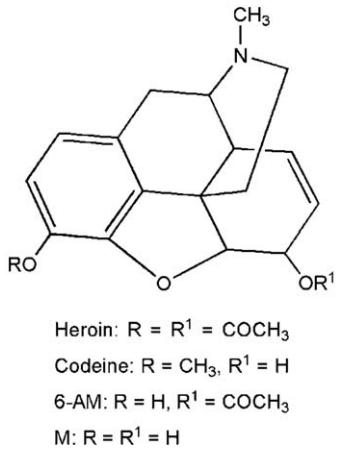

**Figure 1.** Schematic structures of some abused drugs [heroin, codeine, 6-acetylmorphine (6-AM), and morphine (M)].

It is generally accepted that two sites, the basic nitrogen and the phenol moiety, are necessary for analgesic binding to its receptors [10,11]. The phenolic hydroxyl group is recognized as a requisite for the formation of a hydrogen bond with a dipolar site on the receptor and for good antinociceptive activity [11,12]. However, the free hydroxyl group is also a potential site for metabolism, conjugation, and excretion resulting in low oral bioavailability and short duration of action [13,14]. One of the approaches to improve the pharmacological properties of analogues is to modify this phenolic hydroxyl function. Several potent compounds have been synthesized and identified by replacing the hydroxyl moiety of morphinans with other functional groups (amino, carboxamido, 2-aminothiazole) [15,16].

The use of dyes in chemistry, biology, and medicine is growing continuously, with many new applications in the diagnosis and treatment of disease [17–19]. Moreover, azo dyes have been known for over forty years, where they were used for investigations in cancer treatment [20]. Numerous fluorescent probes for monosaccharides based on azo dyes have been described in the literature. Moreover, many abused drugs (*i.e.*, heroin, codine, 6-AM and M) are tertiary amines (Fig. 1) and are not compatible with the most commonly utilized amine reactive fluorescent dyes. These dyes include compounds such as fluorescein isothiocyanate isomer I (FITC) [21], 4-(4,6-dichloro-*s*-triazin-2-ylamino)fluorescein (DTAF) [22], 4-fluoro-7-nitrobenzofurazan (NBD-F) [23], and 3-(4-carboxybenzoyl)-2-quinolinecarboxaldehyde (CBQCA) [24]. Other fluorogenic reagents specifically made for derivatization of the tertiary amine group such as the malonic acid/acetic anhydride system [25] and the aconitic acid method [26] result in a deteriorating effect on the fluorescence of the reaction product. In addition, the products of these reactions are unstable, light sensitive, and give many components that seem to be associated with the reagent blank.

The most important problems for development of a new morphine detector are tedious and time-consuming reaction steps. In an effort to develop novel morphine derivatives that are effective as chemosensors for heroin use at very low concentrations, herein we report fast, economic, and simple approaches to the synthesis of a novel series of highly fluorescence azo-morphine dyes. Compared with the previously reported methods [20–27], the present test produces an intense color which is not affected by the presence of any diluents or adulterants and which is easily adapted to field use. Diaminostilbene and porphyrin related dyes are strongly light absorbing and highly luminescent [28,29]. These dyes are covalently attached to proteins and other biological and nonbiological materials to make these materials fluorescent so that they can be detected. The binding advantage of *trans*-4,4′-bis-diazostilbene or diazoporphyrin over diazobenzene is production of highly fluorescent dyes that can be detected even at very low morphine concentration. The developed method was used for determination of highly diluted M and 6-AM in spiked human urine sample with very high accuracy and precision.

## EXPERIMENTAL

**Materials.** All chemicals and reagents were commercially available and were used as received. Most of solvents were at least of reagent grade and were used without further purification. M, 6-AM, and codeine were obtained from Lipomed Inc. (One Broaway, Cambridge, MA, USA). 5-(*p*-Aminophenyl)-10,15,20-triphenylporphyrin was prepared according to the literature [30]. Analytical thin layer chromatography (TLC) was performed on a glass plates of silica gel 60 $GF_{254}$ (Merck). Visualization was accompanied by UV light (254 nm). Column chromatography was conducted on silica gel 60 (Merck 70–230 mesh). $^{1}H$ NMR and $^{13}C$ NMR spectra were measured on JEOL JNM-AL 300 (300 MHz) and VARIAN UNITY-INOVA 400 (400 MHz) spectrometers. Chemical shifts of $^{1}H$ NMR and $^{13}C$ NMR were expressed in parts per million (ppm, δ units), and coupling constant was expressed in units of Hertz (Hz). Elemental analyses were performed by a Perkin-Elmer 2400 automatic elemental analyzer. All compounds gave elemental analysis within ±0.4%. Electrospray ionization (ESI) mass spectra were recorded on a Shimadzu LCMS-2010 eV spectrometer in $CH_3OH$. The UV–vis data were measured on Shimadzu 3101 PC instrument. The fluorescence (excitation and emission) spectra were determined with Perkin Elmer Lambada 50 PC spectrophotometer: excitation slit width = 5 nm, emission slit width = 5 nm. AP/ACE MDQ CE system coupled with photo-diode array detectors (PAD) supplied from Beckman (Fullerton, CA, USA) was used throughout the experiments. Separation was carried out in a 50.2 cm long × 50 μm (10 cm to the detector, short way). After each

experiment, the capillary was washed with 0.1 mol $dm^{-3}$ sodium hydroxide for 2.0 min, distilled water for 1.0 min, and the separation electrolyte for 2.0 min. Hydrodynamic injection mode was applied for sample loading. 32 Karat version 7.0 supplied from Beckman (Fullerton, CA, USA) was used for controlling the CE system as well as data acquisition and processing.

**General procedure for the synthesis of compounds 1–6.** ***Diazotization.*** A 0–5°C solution of substituted aniline (0.5 mmol) and 1*N* HCl (2 mL) in deionized (DI) water (5 mL) was treated with a 0–5°C solution of $NaNO_2$ (100 mg, 1.5 mmol) in DI water (5 mL) and the diazotization continued for 10 min.

***Coupling.*** The resulting diazonium salt solution was poured into a 0–5°C solution of M or 6-AM (0.5 mmol) in NaOH (50 mg, 1.25 mmol, 5 mL). The mixture was stirred at 0–5°C for another 10 min. The resulting precipitate was filtered off, washed with NaCl, DI water, and dried *in vacuo*. The products were purified by flash column chromatography using hexane and ethylacetate in ratio 2:1 as eluent. Upon storage of the azo coupling products **1–6** at ambient temperature for several months neither change in their UV–vis spectra nor appearance of foreign signals in their $^1$HNMR spectra were observed, which provides evidence of their stability.

**General procedure for the synthesis of compounds 10 and 11.** A 0–5°C solution of sodium nitrite (0.12 g, 1.74 mmol) in water (2 mL) was added dropwise to a stirred solution of 5-(*p*-aminophenyl)-10,15,20-triphenylporphyrin (785 mg, 1.25 mmol) in 1*N* HCl (5 mL). The mixture was stirred at 5°C for 15 min. A solution of sodium acetate (0.14 g, 1.71 mmol) in water (5 mL) and M or 6-AM (1.11 mmol) in 3% aqueous NaOH (5 mL) were added to the diazonium salt solution. Then, the reaction mixture was stirred at room temperature for 15 min and diluted to 100 mL with water and filtered. The filtrate was neutralized with HCl to pH 7, the porphyrin filtered off, washed with aqueous ammonia solution (10%), then with water, and dried to constant weight at room temperature. For purification, the porphyrin was dissolved in boiling ether (50 mL) and chromatographed on a column (2.5 cm × 60 cm) of silica gel eluting with ether. The elute was evaporated to 5 mL and porphyrin (**10** or **11**) was precipitated with hexane (20 mL).

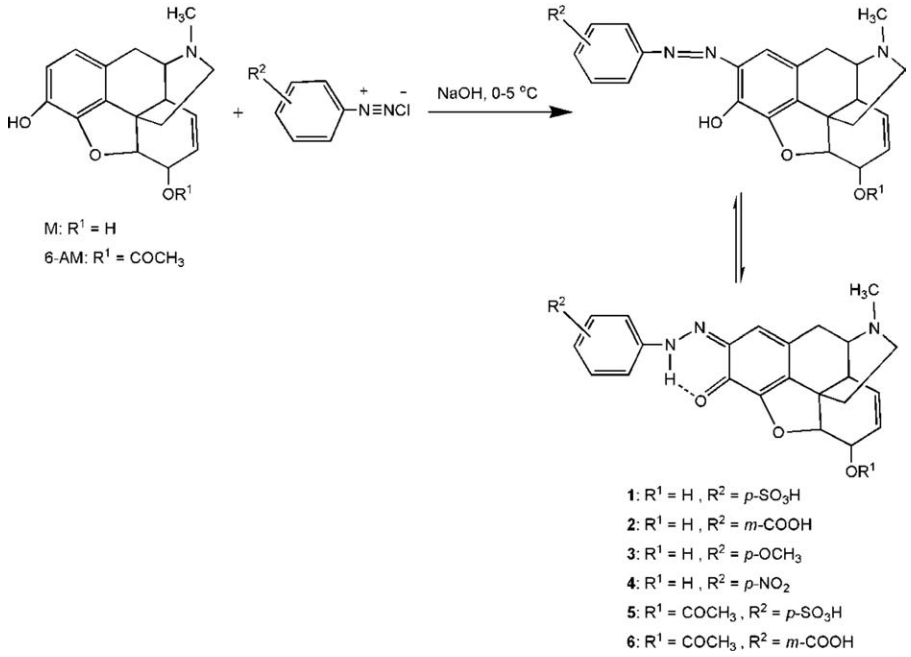
**Biological studies.** A 500 mg Bond Elut SPE column was used for the extraction. The SPE columns were conditioned by

**Scheme 1**



the sequential passage of 2 × 3 mL of methanol, 2 × 3 mL of water, and 2 × 5 mL of water adjusted to pH 9.5 with $NH_4OH$. Ten millilitres of human urine sample adjusted to pH 9.5 with $NH_4OH$ was vortex, centrifuged, and applied to the SPE columns at a rate of 1.0 mL/min. The columns were washed with 2 × 5 mL of distilled water and left to dry for 10 min. The drugs were eluted with a solution consisting of a single phase mixture of dichloromethane/acetone (50/50) and collected in glass tubes. The elution solvent was evaporated to dryness under a nitrogen stream. The dried residues were then reconstituted in slightly warm water, and derivatization was carried out and then the samples were analyzed using AP/ACE MDQ CE system coupled with photo-diode array detectors (PAD).

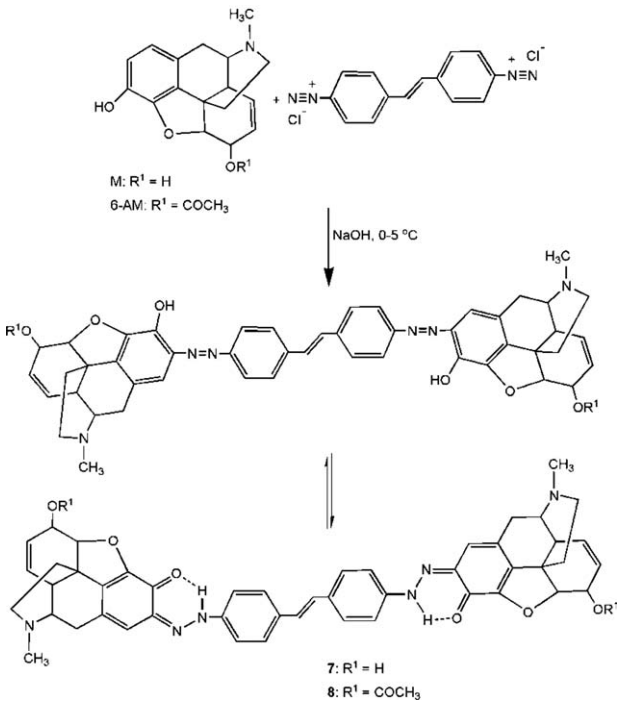
## RESULTS AND DISCUSSION

**Synthesis.** Our straightforward synthesis of morphine azo dyes (**1**–**6**) is outlined in Scheme 1. In a first step, the diazonium ions of aniline derivatives were generated with sodium nitrite in 1*N* HCl. The diazonium ions were then coupled by nucleophilic substitution with the corresponding substrates M or 6-AM. Azo coupling reactions were performed using the diazonium salts of 4-aminosulfonic acid, 3-aminobenzoic acid, 4-methoxyaniline, and 4-nitroaniline to yield 2-(arylazo)morphines **1**–**6**, respectively, (Scheme 1). No reaction was found, however, to occur with codeine under the same reaction conditions.

Synthesis of fluorescent azostilbene morphine dyes was achieved by reaction of *trans*-4,4′-diazostilbene dihydrochloride with M or 6-AM in 1:2 stoichiometric ratio to give stilbene based azo dyes containing two M (**7**) or two 6-AM (**8**) moieties as shown in Scheme 2. The resulting bis-azo dye are belong to the class of direct dyes [31,32]. Furthermore, we have established that *5*-(*p*-aminophenyl)-10,15,20-triphenylporphyrin (**9**) [30] is readily diazotized with sodium nitrite in aqueous mineral acid solution. The diazonium salt obtained is fairly stable; it decomposes significantly at temperature greater than 25 °C. The reaction of porphyrin diazonium salt with M or 6-AM leads to porphyrins containing residues of azo dyes in *meso* position of **10** or **11**, respectively (Scheme 3). The resulting colored compounds were purified by flash column chromatography using hexane/ethyl acetate (2:1) as eluent to produce azo-M (**1**–**4**, **7**, and **10**) and azo-6-AM (**5**, **6**, **8**, and **11**) with excellent yields. Azo coupling reactions of morphines occur predominately ortho to the electron donating hydroxyl group of the morphine aromatic ring. Hence, the inclusion of this design motif in the target dyes avoids potentially difficult separation of isomers.

**Spectroscopic studies.** Overall characterization of dye structures was carried out by elemental analysis, NMR, UV–vis, IR, and mass spectrometry (see experimental section for details). The NMR spectra of compounds **1**–**8**, **10**, and **11** are consistent with proposed structures, showing the expected features with correct integration ratios. Both $^1H$ and $^{13}C$ NMR spectra indicated the appearance of new signals corresponding to the aryl moiety of each azo-compound (Fig. 2). Spectral

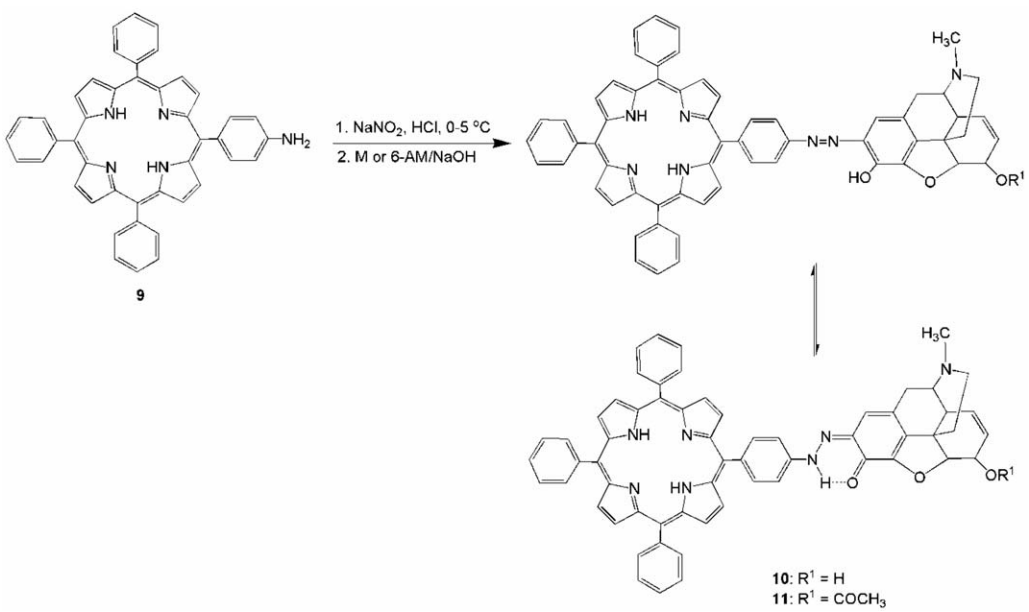
**Scheme 2**



properties of synthesized dyes were affected by intramolecular hydrogen bond between the phenolic hydroxyl group of morphine moiety and the central nitrogen atom of the azo bridge of the azo dye residues. Azo dyes in which the azo group is conjugated with a hydroxyl group can exhibit azo-hydrazone tautomerism, and NMR spectroscopy is established as an effective technique to study tautomer composition [33–35]. The intramolecular hydrogen bond ring is essentially planar and coplanar with its adjacent phenyl ring, which stabilized the hydrazone form. 2-Arylazomorphine derivatives (dyes **1**–**8**, **10**, and **11**) exist predominantly in the hydrazone form via intramolecular hydrogen bonds, which result in the linearity and coplanar conformation of the dyes [28]. The proton peaks involved in hydrogen bonds appear at much lower field than normal proton peak of hydroxyl group and these (12.75–13.52 ppm for dyes **1**–**8**, **10**, and **11**) were confirmed by $^{1}$H NMR. The downfield position of the resonance from the hydrazone proton is attributed to internal hydrogen bonding in which the carbonyl oxygen is hydrogen bonded to this proton [33]. Dyes that occur as the azo tautomer show a $^{13}$C resonance at *ca*. 160 ppm from the carbon attached to the phenolic hydroxyl group, whereas those that occur as the hydrazone tautomer show a resonance at *ca*. 180 ppm for the same carbon atom within a carbonyl group (Fig. 2). Dyes that occur as both tautomers show a single resonance between these limits, due to rapid tautomerisation, with the position determined by the relative concentrations of the two tautomers [34–36]. $^{13}$C NMR spectra from DMSO samples of **1**–**8**, **10**, and **11** confirmed the hydrazone structure by detecting a new carbonyl peak at 181–183 ppm assigned to C3 of M or 6-AM and, thus, morphine dyes **1**–**8**, **10** and **11** are present as the hydrazone tautomer (*ca*. 100%).

According to DFT calculations at the B3LYP/6-31G* level, the hydrazono toutomers of **1**–**8**, **10**, and **11** are

**Scheme 3**



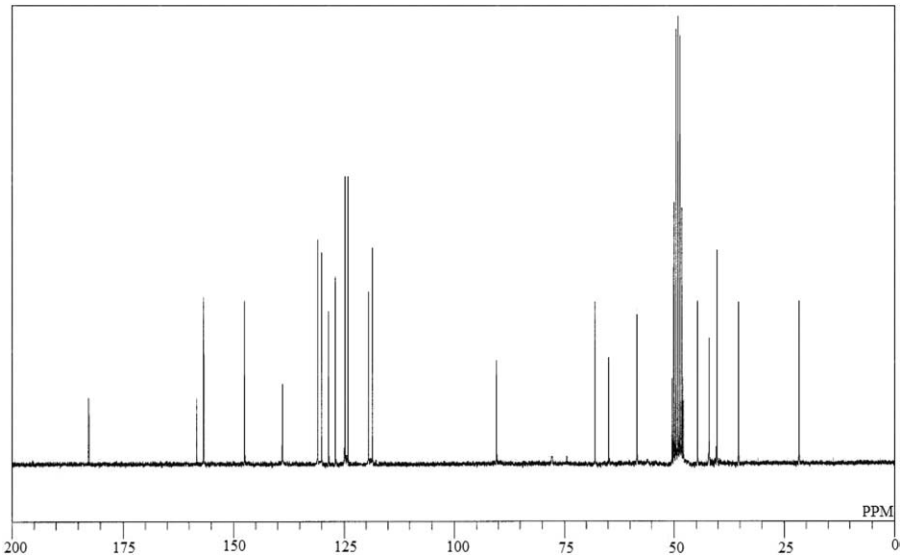


**Figure 2.** $^{13}C$ NMR spectrum of compound **3** in DMSO($d_6$) at 20°C.

favored over the azo toutomers by 2.4–3.6 kcal mole$^{-1}$. As major entropy differences and crystal lattice effects are not to be expected here, these results should secure the hydrazone formulas. Consequently, it can be considered that morphine azo dyes (**1–8**, **10**, and **11**) have such structures as shown in Schemes 1–3.

IR spectra assigned with the aid of the NMR data, provide fingerprints for hydrazone form and hydrogen bonding. The IR spectra of all the resulting colored compounds confirmed the presence of a C═O bond which resonates at 1625–1618 cm$^{-1}$. IR spectrum of compound **4** showed absorption bands at 1517 and 1334 cm$^{-1}$ due to the presence of a $NO_2$ group, whereas the $SO_2$ group of compound **1** and **5** has two vibrational frequencies at 1350 and 1150 cm$^{-1}$. Moreover, the vibrational frequency of aliphatic OH band ν(O─H) of M or the $COCH_3$ band ν(C═O) of 6-AM was not found to be sensitive to the connection of M or 6-AM with the azo derivatives. For compounds **1–4** and **7** ν(O─H) lies in the range of 3385–3375 cm$^{-1}$, and for compounds **5**, **6** and **8** ν(C═O) from 1730 to 1718 cm$^{-1}$, comparable to the frequencies of M ν(O─H) at 3373 cm$^{-1}$, and 6-AM ν(C═O) at 1713 cm$^{-1}$, indicating that the intra bonding of the morphine moiety was not perturbed by substitution on the phenyl ring.

Evidence in support of structures **1–8**, **10**, and **11** is presented by mass spectrometry. The ESI-MS spectra of these compounds in MeOH showed molecular ion peaks ($M^+$) corresponding to the formula of each compound. Mass spectra of all compounds showed molecular ion peaks corresponding to their expected pattern of abundance ranging from 85 to 100% (Fig. 3).

The electronic absorption spectra (EAS) of the investigated morphine dyes **1–8**, **10**, and **11** in ethanolic solutions were studied. There is no visual evidence for a band around 380–420 nm, which could be assigned to the azo form. The compounds comprised two to three bands in the UV region and one band in the visible region (Fig. 4). The band of shortest wavelength appearing in the range 210–255 nm was best ascribed to π–π* transition of the benzenoid system of the compounds. The second band observed in UV region, in the wavelength range 270–285 nm was attributed to π–π* transition within the furan heterocyclic moiety of the compounds. The third band observed in the UV region at 285–290 nm was assigned to n–π* electronic transition

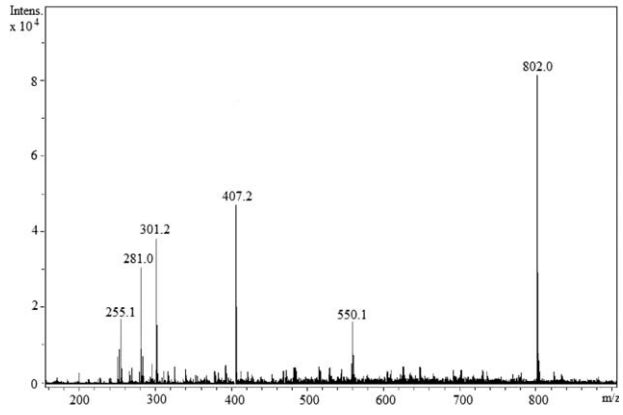

**Figure 3.** ESI-MS of compound **7** in $CH_3OH$.

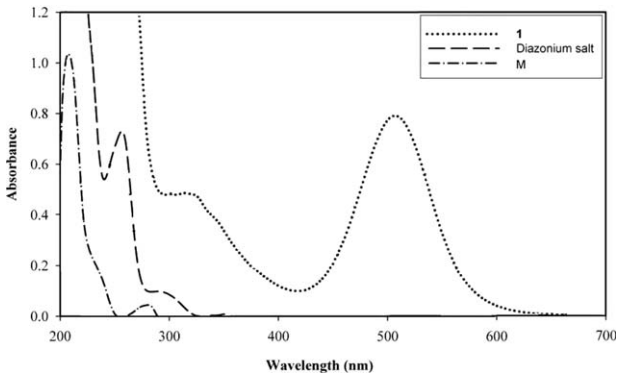

**Figure 4.** Electronic absorption spectra of $2 \times 10^{-5}$ mol dm$^{-3}$ of **1**, diazonium salt of sulfanilic acid and M.

of OH groups. The long wavelength band at about 510 nm corresponds to the hydrazone form [37] (Fig. 4). This band was capable of being assigned to π–π* transition involving the whole electronic system of the compounds with a considerable charge-transfer (CT) character. Such a CT originated mainly from the aryl azo to the morphine moiety, *i.e.*, this band was due to intramolecular CT transition. When analyzing EAS of the porphyrin azo dyes (**10** and **11**), it was difficult to draw an unambiguous conclusion as to whether the π system of the azo dye interacts with the π system of porphyrin ring. The Soret band of tetraphenyporphyrin ($\lambda_{max} \sim$ 400 nm; $\varepsilon \sim 4.75 \times 10^5$ dm$^3$ mol$^{-1}$ cm$^{-1}$) is found alongside with the broad absorption band of azo dye residue ($\lambda_{max} \sim$ 590 nm; $\varepsilon \sim 3.35 \times 10^4$ dm$^3$ mol$^{-1}$ cm$^{-1}$), which does not permit a confident judgment to be made on whether transfer of π electron density from the azo dye residue to the porphyrin ring has taken place. However, the sharp reduction in intensity of the Soret band and the growth in intensity of the electronic transition bands and also their bathochromic shift indicate the existence of such interactions.

The compounds (**1**–**8**) exhibited emission fluorescence peak even at very low concentration (5–8 $\times 10^{-9}$ mol dm$^{-3}$) in aqueous solution as indicated by capillary electrophoresis (CE) with UV-fluorescence photo diode-array detectors. However, compounds **10** and **11** showed highly intense fluorescence peaks at 665 and 670 nm, respectively. The synthesis of **10** and **11** will provide new insight into the role of morphine determination using simple and fast chemistry as well as highly sensitive techniques [*e.g.*, CE with laser induced fluorescence detector (LIF)].

**Biology.** The determination of M in biological samples has become almost a routine assay in many toxicology laboratories owing to the spread of the abuse of

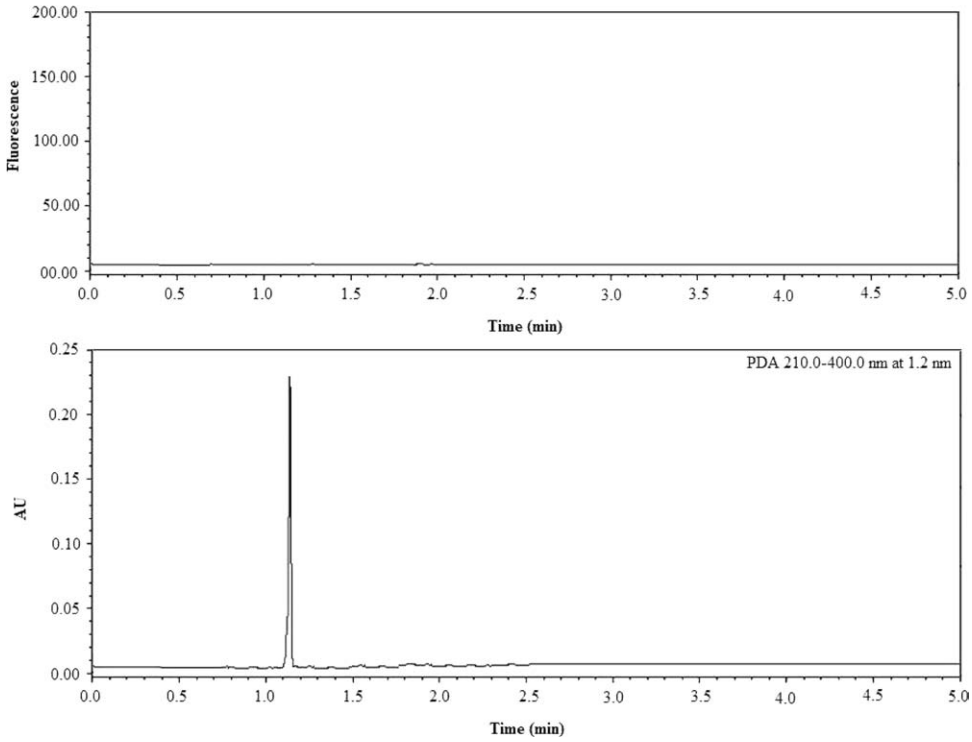

**Figure 5.** Electropherograms of $5 \times 10^{-6}$ mol dm$^{-3}$ diazonium salt of sulfanilic acid in water under the optimized conditions: 10.0 s injection time, applied voltage 25 kV, 25°C, 100 mmol dm$^{-3}$ borate electrolyte concentration, and pH 9.0.

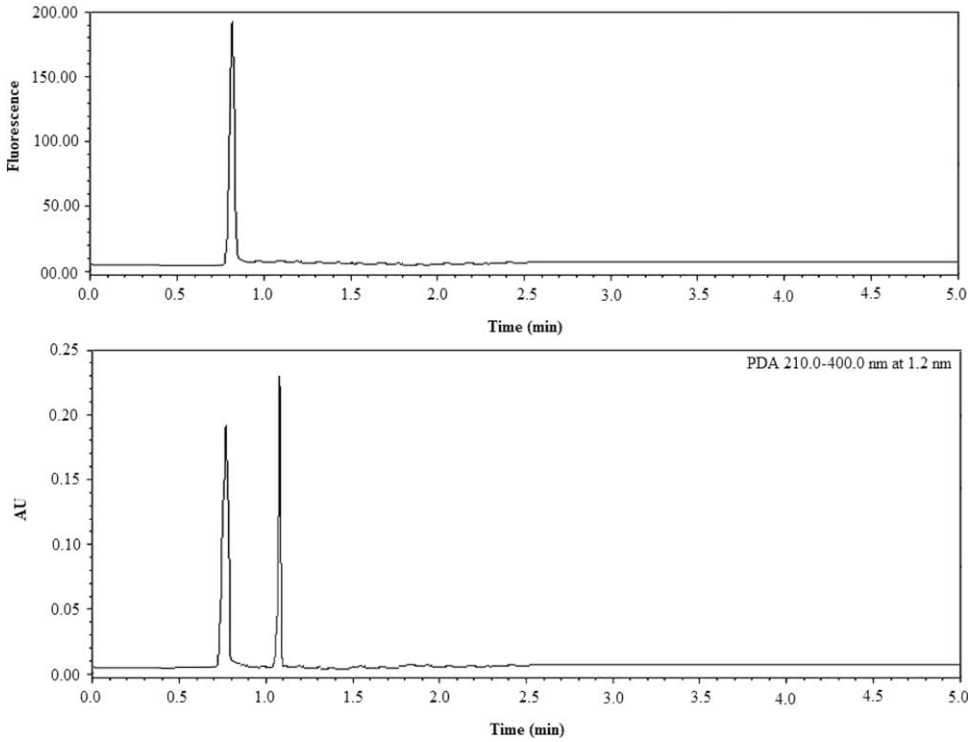

**Figure 6.** Electropherograms of human urine sample spiked with $5 \times 10^{-9}$ mol dm$^{-3}$ of M coupled with $5 \times 10^{-6}$ mol dm$^{-3}$ diazonium salt of sulfanilic acid under the optimized conditions: 10.0 s injection time, applied voltage 25 kV, 25°C, 100 mmol dm$^{-3}$ borate electrolyte concentration, and pH 9.0.

heroin, which is mainly biotransformed into M. In this experiment, the coupling reaction of diazonium salt of sulfanilic acid was carried out with drug-free urine sample and with urine sample spiked with M and 6-AM. No remarkable change was observed for the drug-free urine sample as indicated by CE (data not shown). For urine sample spiked with the M, a deep red color appeared at once which was measured by CE, giving two peaks after 45 s and 65 s corresponding to azo-M (**1**) and diazonium salt of sulfanilic acid, respectively, (Figs. 4 and 5). The extraction recoveries were found to be >99.5% and RSD values of the recovery did not exceed 0.92% indicating good repeatability of the adopted method.

## CONCLUSIONS

A number of M and 6-AM azo dyes were synthesized and the possibility of using these dyes as color chemosensors of abused drugs is reported. The synthesis starts from commercially available aniline derivatives and can be completed in one step with an overall yield of 76–92%. *Trans*-4,4′-diaminostilbene or 5-(*p*-aminophenyl)-10,15,20-triphenylporphyrin in azo dye reaction gave highly fluorescent morphine dyes which could be easily detected at very low concentrations using CE techniques. It is found that between the phenolic OH and the central N atom intramolecular proton transfer exists with the hydrazone form being major component. The compounds existed in hydrazone forms exclusively, being stabilized by the intramolecular hydrogen bonds. The resulting azo compounds are highly fluorescent in ethanol and water. Low detection limit was obtained ranging from 5–8 nmol dm$^{-3}$ for M or 6-AM coupled with freshly prepared diazonium salts. Consequently, this method is characterized by simple, rapid, and economic determination of abused drugs in forensic cases as an initial test and clinical analysis to prevent overdose-induced toxicity.

In this work, tricyclic 1-amino-4-(substituted phenyl)[1,2,4]triazolo[4,3-*a*]quinazolin-5(4*H*)-one **3** was synthesized by treatment of 2-hydrazinyl-3-(substituted phenyl)quinazolin-4(3*H*)-one **2** with cyanogen bromide, which on cyclization with ethylacetoacetate to get the targeted fused tetracyclic derivatives of quinazoli-4(3H)one **4**. The synthesized compounds have been characterized using IR and $^1$H NMR, mass spectral data together with elemental analysis.

*J. Heterocyclic Chem.*, **47**, 1144 (2010).

## INTRODUCTION

Quinazoline derivatives have attracted considerable attention due to their significant biological activities [1,2], especially antifungal [3,4], insecticidal [5], antihistaminic [6], anti-inflammatory [7], antibacterial [8], anticonvulsant [9,10], antithrombotic [11], antitubercular [12], and antitumor [13]. In this article, we report a new route for the synthesis of triazolo and tetracyclic derivatives of quinazolinone.

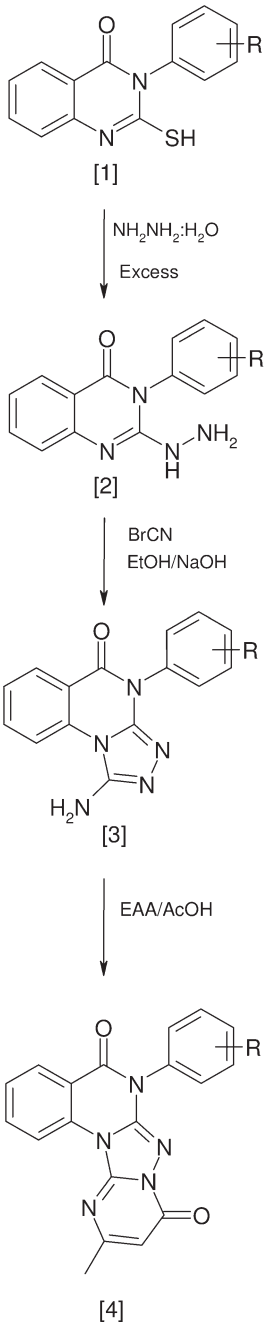
## RESULT AND DISCUSSION

The new triazolo and tetracyclic derivatives of quinazolinone were prepared following the reaction sequences depicted in Scheme 1 and supported mechanism in Scheme 2. The starting compound **1** was prepared by sequential treatment of anthranilic acid with thiocarbamate salts of substituted aniline and carbon disulphide according to the reported method [14]. The appearance of broad band at 3330–3110 cm$^{-1}$ in IR spectrum and a singlet displayed at δ, 10–11 ppm in the PMR spectrum due to —SH supports their formation. Compounds **1a–g** were heated with excess hydrazine hydrate to form 2-hydrazino derivatives **2a–g** in good yield [15]; the formation of which has been explained by the appearance of IR band at 3390–3300 cm$^{-1}$ due to —NHNH$_2$ and disappearance of singlet displayed at δ, 10–11 ppm due to —SH and two additional singlets appeared between δ, 9–11 and δ, 2–6 ppm due to —NH and —NH$_2$ protons, respectively, in their PMR spectra. The condensation of **2** with cyanogens bromide in absolute alcohol gave the corresponding desired tricyclic amino triazoles **3a–g**; the formation of which was confirmed by the observation of a broad IR band at 3420–3000 cm$^{-1}$ and singlet between δ, 3–6 ppm due to —NH$_2$ protons in their PMR spectrum. The compounds **3a–g** were cyclocondensed with ethylacetoacetate to get the targeted tetracyclic compounds **4a–g**. The formation of **4** has been established by the disappearance of singlet between δ, 3–6 due to —NH$_2$ protons and appearance of additional singlets due to Ar—CH$_3$ and =CH in their PMR spectrum.

## EXPERIMENTAL

All melting points reported are incorrect and were determined by open capillary method. All chemicals used were of A.R. grade and have been used without further purification. IR spectra (in KBr, cm$^{-1}$) were recorded on a Perkin-Elmer 783 (FTIR) spectrophotometer. $^1$H NMR spectra recorded in

**Scheme 1**



$CDCl_3$/DMSO-$d_6$ were scanned on a Bruker A-300 F-NMR spectrometer (Table 1). TMS was used as an internal standard with chemical shifts δ in ppm from down field to up field. Mass spectra were analyzed by EI technique on Shimadzu QP 2010 PLUS GC-MS system. The purity of products, in addition to the elemental analysis (Table 2), was checked by TLC.

**3-(4-Methoxyphenyl)-2-sulfanylquinazolin-4(3*H*)-one (1).** These compounds were prepared according to the reported method [14].

**2-Hydrazinyl-3-(4-methoxyphenyl)quinazolin-4(3*H*)-one (2a).** A compound **la** (4.824 gm, 0.018 mol) was refluxed with 5 mL hydrazine hydrate in ethanol (15 mL) with constant stirring at 100°C for about 1.5 h, then cooled and thus the solid obtained was recrystallized from ethanol to furnish 2a [15], yield, 4.118 gm (86%), m.p. 207°C, IR: 3386–3328, 1664 $cm^{-1}$. $^1H$ NMR ($CDCl_3$): δ (ppm), 2.65 (s, 3H, Ar—$CH_3$), 6.25(s, 2H, —$NH_2$), 6.9–8.1 (m, 8H, Ar—H), 10.9 (s, 1H, br, —NH); ms: m/z 282(12), 266(26), 251(45), 175(100), 107(55), 31(10). *Anal. Calcd.* for $C_{15}H_{14}O_2N_4$ (266): C, 63.82%; H, 5.00%; N, 19.85%. Found: C, 63.89%; H, 5.04%; N, 19.81%.

**1-Amino-4-(4-methoxyphenyl)[1,2,4]triazolo[4,3-*a*]quinazolin-5(4*H*)-one (3a).** A compound **2a** (5.054 gm, 0.019 mole) in ethanolic NaOH (50 mL) and cyanogen bromide (1 $cm^3$, 0.019 mole) were stirred for 3 h at room temperature. After neutralization of it with 10% sodium bicarbonate, the solid obtained was filtered and further recrystallized from ethanol to give **3a**, yield, 4.423 gm (80%), m.p. 270°C. IR: 3420–3010, 1685, 1615 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ (ppm), 2.56 (s, 3H, Ar—$CH_3$), 5.62 (s, 2H, —$NH_2$), 7.1–8.2 (m, 8H, Ar—H); ms: m/z 307(50), 291(20), 276(62), 200(100), 107(72), 31(16). *Anal. Calcd.* for $C_{16}H_{13}ON_5$ (291): C, 62.53%; H, 4.26%; N, 22.79%. Found: C, 62.61%; H, 4.32%; N, 22.71%.

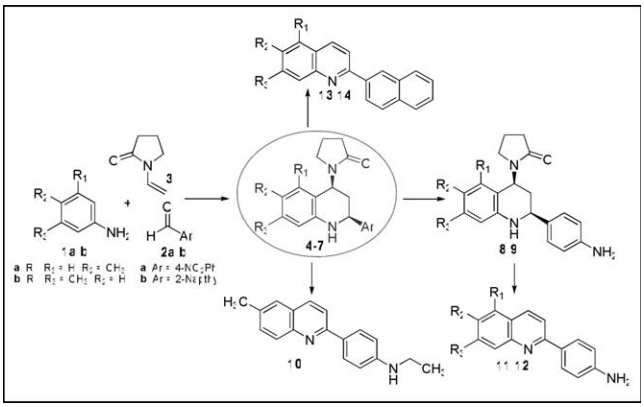
Published online 26 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



Synthesis and spectral characterization of new series of 2-aryl-4-(2-oxopyrrolidinyl-1)-1,2,3,4-tetrahydroquinolines and their aromatic analogs, 2-arylquinolines are reported. It was found that substituted tetrahydroquinoline precursors are easily prepared using $BiCl_3$-catalyzed three-component Povarov reaction between 4-nitrobenzaldehyde or 2-naphtylcarboxyaldehyde, anilines and *N*-vinylpyrrolidin-2-one, and could be transformed *via* oxidation and reduction processes into potentially bioactive 2-arylquinoline derivatives, unsubstituted at the C-4 position. The all set of (tetrahydro)quinolines were characterized by IR, $^1H$ and $^{13}C$-NMR spectroscopy.

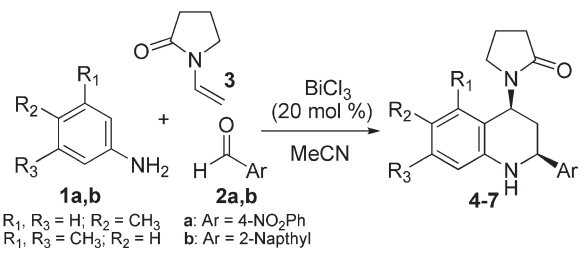
## INTRODUCTION

Quinoline and tetrahydroquinoline structures are essential feature of many natural products. These heterocycles play a key role in heterocyclic and medicinal chemistry. Their syntheses by various methodologies have been published extensively [1–4]. Polyfunctionalized tetrahydroquinolines (THQs) are molecules of great interest in organic synthesis because many natural products present this system in their structure, and these compounds exhibit diverse biological activities [5–9]. Apart from their marked bioactivities, THQs are also important and reliable precursors in quinoline preparation, another group of heterocyclic molecules that has a great number of pharmacological properties [10]. However, general syntheses of functionalized quinolines substituted at the C-2 position and unsubstituted at the C-3 and C-4 positions are less common [11], and often suffer from harsh reaction conditions, expensive reagents, or both. Moreover, the number of these commercially available reagents is exceedingly small that limits the preparation of quinolines substituted on the quinoline aryl moiety.

For these reasons, the synthesis of new THQs is still of great interest. An efficient route for the preparation of THQs is the acid-catalyzed Povarov reaction that is classified as imino Diels-Alder cycloaddition [11,12]. Moreover, this methodology that permits the condensation of anilines, aldehydes, and electron-rich alkenes using acidic catalysts under mild conditions to afford new tetrahydroquinolines, can overcome synthetic limitations for the construction of functionalized quinolines substituted at the C-2 position and unsubstituted at the C-3 and C-4 positions and are useful tool for the generation of quinoline derivatives with several degrees of structural diversity. Then, appropriate choice of aldehydes and alkenes in this cycloaddition reaction

**Scheme 1**



provides a facile entry to heterocyclic systems which is an essential moiety in many active pharmaceuticals.

As a part of our research program on the *N*-aryl imines towards the synthesis of bioactive substituted tetrahydroquinolines and quinolines, we are pursuing investigations on the synthesis of small drug-like (tetrahydro)quinoline molecules containing C-2 aryl fragment, those synthesis could be accomplished *via* cycloaddition reactions. We now want to report simple preparation of new 2-aryl-4-(2-oxopyrrolidinyl-1)-1,2,3,4-tetrahydroquinolines using $BiCl_3$-catalyzed three component Povarov reaction between 4-nitrobenzaldehyde or 2-naphtylcarboxyaldehyde, anilines and *N*-vinylpyrrolidin-2-one (NVP), and their transformations into potentially bioactive 2-arylquinoline derivatives, unsubstituted at the C-4 position.

## RESULTS AND DISCUSSION

Planning synthesis of new 2-arylquinoline derivatives, we paid attention the following considerations: (i) *N*-vinylpyrrolidin-2-one (NVP) is very active electron-rich alkene in this reaction [13–16] and it is an available, stable, and cheap reagent. Moreover, 2-oxopyrrolidinyl moiety on the tetrahydroquinoline ring could be easily removed; (ii) 4-nitrobenzaldehyde could provide 4-aminophenyl fragment, those synthetic utilization to construct *N*-heterocycles is well recognized; (iii) 2-naphtylcarboxyaldehyde was chosen for the preparation of new 2-naphtylquinolines, aromatic planar molecules, and interesting models in biological tests (anticancer activity).

So, using $BiCl_3$-catalyzed (20 mol %) three component Povarov reaction between anilines **1a,b**, aldehydes **2a,b** and NVP **3** in MeCN, a new series of the functionalised THQs **4–7** was easily prepared in excellent yields (Scheme 1).

Structural elucidation of obtained solid substances (Table 1) was started with IR analysis that indicated at the presence of characteristic intensive bands in zone 3394, 3271, and 1666 $cm^{-1}$ (NH and C=O for all comp. **4–7**), and also 1512 and 1342 $cm^{-1}$ ($NO_2$ for comp. **4,5**). From their spectral analyses ($^1$H-, $^{13}$C-NMR and COSY), it was found that the *cis*-diastereoisomer was prevalent in all of the cases studied. For example, from $^1$H-NMR spectrum of comp. **4**, it could clearly observed two doublets of doublets at 5.69 ppm ($J_{3,4}$ = 11.1 and 6.4 Hz) and 4.65 ppm ($J_{2,3}$ = 10.7 and 3.1 Hz) that correspond to the THQ protons 4-H and 2-H, respectively.

The large vicinal coupling confirmed strongly axial–axial dispositions of the THQ protons 4-H and 2-H and, consequently, the substituents at C-4 and C-2 should have an equatorial disposition that indicates at a *cis* configuration of the THQ ring.

Having stable solid THQ derivatives in our hands, we realized some simple chemical transformations, which resulted in the efficient preparation of quinoline molecules **10–14** (Scheme 2). First, to obtain new 2-(4-aminophenyl)-THQs **8,9**, we analysed reduction process of nitro derivatives **4,5** under different reaction conditions. The conventional hydrogenation process [$H_2$/Pd-C (10%)/MeOH] always gave in moderate yields the desired products, contaminated with side-products. The change of solvent nature (MeOH → MeOH/$CH_2Cl_2$) in $H_2$/Pd-C hydrogenation reaction (method **A**) did not improve this situation. Thus, we addressed to another reduction reaction that uses $NaBH_4$ and $NiCl_2$ in MeOH/$CH_2Cl_2$ (method **B**) that resulted an efficient and selective system, which satisfied to our plans. Under these reaction conditions, it was possible to prepare desired *cis*-2-(4-aminophenyl)-THQs **8,9** in good yields. However, it should be noted that among different attempts to find ideal conditions for hydrogenation process of comp. **4** we tested also a $H_2$/Pd-C/MeCN-MeOH system (method **C**) that allowed obtaining an unexpected quinoline product **10**. This formation could be assumed as a result of subsequent three processes: (1)

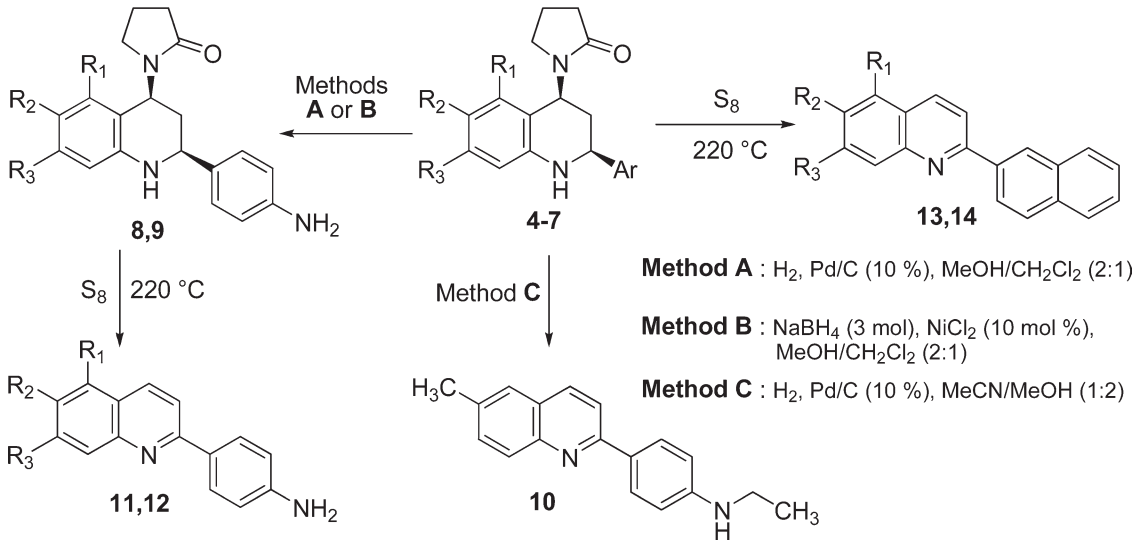
**Scheme 2**



ring aromatization reaction with pyrrolidine fragment elimination, (2) nitro group reduction into amine function, (3) N-ethylation of amine group to give *N*-ethylamino derivative **10** (Scheme 2). Its quinoline structure was strongly confirmed by $^1$H-, $^{13}$C-NMR spectra and 2D NMR spectroscopy.

Other quinoline derivatives **11–14** were easily prepared from the respective tetrahydroquinolines by use of their rapid fusion with elemental sulfur following our developed protocol [17]. These quinoline molecules are stable, yellowish substances that were purified by means of a short chromatographic column (Table 1).

Finally, the obtained THQs **6–9** were subjected into oxidation process using our rapid fusion-sulfur protocol to prepare new corresponding2-(4-aminophenyl)quinolines **11,12** and 2-(2-naphtyl)quinolines **13,14**. This aromatization reaction was achieved by its fusion with elemental sulfur at 220–240°C in 5–10 min. All new compounds were directly isolated without previous extraction using flash column chromatographic and were completely identified using NMR spectroscopy.

In conclusion, we reported the efficient synthesis of new series of 2-aryl-4-(2-oxopyrrolidinyl-1)-1,2,3,4-tetrahydroquinolines and their aromatic analogs, 2-arylquinolines, unsubstituted at the C-4 position. These potentially bioactive 2-(aryl)quinoline derivatives could be important models in antioxidant, antiparasitic or/and anticancer studies [18].

## EXPERIMENTAL

The melting points (uncorrected) were determined on a Fisher-Johns melting point apparatus. The IR spectra were recorded on a Lumex Infralum FT-02 spectrophotometer in KBr. $^1$H, $^{13}$C-NMR spectra were recorded on Bruker AM-400 spectrometer. Chemical shifts are reported in ppm (δ) relative to the solvent peak ($CHCl_3$ in $CDCl_3$ at 7.24 ppm for protons). Signals are designated as follows: s, singlet; d, doublet; dd, doublet of doublets; ddd, doublet of doublets of doublets; t, triplet; td, triplet of doublets; q, quartet; sp, septet; m, multiplet; b, broad. A Hewlett Packard 5890a series II Gas Chromatograph interfaced to an HP 5972 Mass Selective Detector (MSD) with an HP MS Chemstation Data system was used for ms identification at 70 EV using a 60 m capillary column coated with HP-5 [5%-phenyl-poly(dimethyl-siloxane)]. Elemental analyses were performed on a Perkin–Elmer 2400 Series II analyzer and were within ±0.4 of theoretical values. The reaction progress was monitored using thin layer chromatography on a silufol UV254 TLC aluminium sheet.

**General procedure for the imino Diels-Alder reaction of anilines, aldehydes and NVP.** To a solution of the appropriate aniline (1.00 mmol) and aldehyde (1 mmol) in anhydrous $CH_3CN$ (20 mL) under $N_2$ atmosphere, was added 20 mol % $BiCl_3$ (0.57 mmol) and *N*-vinylpyrrolidone (1.2 mmol). The reaction mixture was stirred at room temperature for 4 h and then quenched with a solution of $Na_2CO_3$. The organic layer was separated, and dried with $Na_2SO_4$. The organic solvent was removed *in vacuo* and the product purified with chromatography column (hexane/ethyl acetate).

A safe and efficient method was developed for the dibromination of pyrazolones and 5-hydroxypyrazoles by use of dibromoisocyanuric acid (DBI). The reaction gave the corresponding dibrominated pyrazolones in excellent yields (≥91%).

## INTRODUCTION

Halogenated pyrazolone compounds attracted attentions for some of them displaying interesting biological activities [1]. Among the compounds, 4,4-dibromo-5-pyrazolone have been reported as fungicides against *Helminthosporium oryzae* [2], α-glucosidase inhibitors, and used for the treatment of tumor metastasis, AIDS, diabetes, hyperlipidemia, autoimmune disease, allergy, and rejection in organ transplant [3]. They are also useful synthetic intermediates for the preparation of diazo-dyes [4], and fused- [5] and spiro-hetercyclic compounds [6].

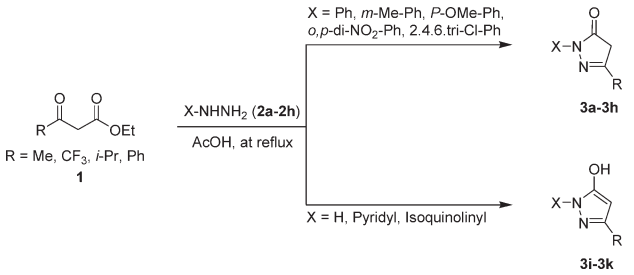
Traditional method for the synthesis of brominated pyrazolone is the use of $Br_2$ in acetic acid [7]. However, harsher conditions and manipulations with care are required. Use of the mild brominating reagent *N*-bromosuccinimide (NBS) [8b] or 1,3-dibromo-5,5-dimethylhydantoin [8c] does not also provide the corresponding dibrominated products in satisfactory yields as the monobrominated and coupling by-products were accompanied to form. As a mild brominating agent, dibromoisocyanuric acid (DBI) has been reported to brominates primary amides [9] and *N*,*N*-dimethylanilines [10]. For the structural similarity of the substrates, it is possible to extend the reagent to pyrazolones. Herein, we report an efficient method for the dibromination of pyrazolones and 5-hydroxypyrazoles by using DBI. A series of 4,4-dibromo-5-pyrazolones could be obtained in excellent yields (≥91%) by this method. Comparison with the use of NBS as the brominating agent, we found the use of DBI toward pyrazolones was more efficient.

## RESULTS AND DISCUSSION

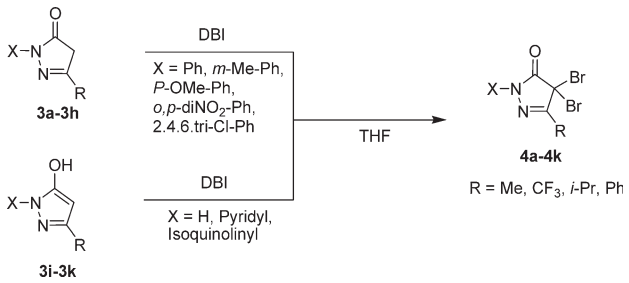
5-Pyrazolones were prepared as the substrates for the investigation of dibromination by DBI through tandem condensation and thermal cyclization following the reported procedure [11]. α-Keto esters **1** were heated at reflux in AcOH with equal equivalent of arylhydrazines **2a**–**2h** possessing various substituents including *m*-Me, *p*-OMe, *o*, *p*-di-$NO_2$, and 2,4,6,-trichloro at the phenyl ring for 4.0 h. The corresponding 5-pyrazolones (keto form) were obtained in good to excellent yields (>75%, see Scheme 1 and Chart 1) [11]. Use of hydrazine, and pyridyl and isoquinolinyl hydrazines as the starting material provided the corresponding 5-hydroxypyrazoles **3i**–**3k** (enol form) in >86% yields (see Scheme 1, and Chart 1). The experiment results were consistent with the literature reported [12].

To search an efficient and reproducible procedure, we carried out a model study by treating 5-pyrazolone (**3a**)

**Scheme 1**



**Scheme 2**



with DBI [13] in THF at room temperature for 30 min (see Chart 1 and Scheme 2). The reaction afforded the desired 4,4-dibromo-5-pyrazolone (**4a)** in 95% yield. Compound **4a** was fully characterized by spectroscopic method and the results were consistent with the reported data from literature [14]. In a control experiment by reacting **3a** with NBS, the reaction was less efficient which provided **4a** in 78% yield.

By using the newly developed method shown in Scheme 2, we successful applied this synthetic strategy to 5-pyrazolones **3b–3h** with *N*-substituted group, including *m*-Me, *p*-OMe, *o*,*p*-di-$NO_2$, and 2,4,6-trichloro. The corresponding products **4b–4h** were obtained in the ≥91% yields (see Table 1). This synthetic strategy is applicable to 5-hydroxypyrazole (enol form of 5-pyrazolone) that bear *N*-substituted group, such as H, pyridyl, and isoquinolinyl (**3i–3k**). The desired compounds **4i–4k** were afforded in 91–95% yields and fully characterized by spectroscopic methods. For example, compound **4k** possessed characterization absorptions at δ 42.5 ppm for O=C—$^{13}C(Br)_2$ in pyrazolone ring and IR absorptions showed peaks at 1751 $cm^{-1}$ for stretching of the —C=O group.

We proposed a plausible mechanism for the dibromination of 5-pyrazolones by use of DBI as shown in Scheme 3. When 5-hydroxypyrazoles **3a–3h** were treated with DBI, the compounds favored the enol form in the acidic condition and underwent the smoothly nucleophilic substitution reaction to generate the corresponding mono-bromo-5-pyrazolone intermediates **6** with *N*-monobromoisocyanuric acid **5**. Application of 5-hydroxy-3-phenyl-1*H*-pyrazole (**3i**), 5-hydroxy-3-phenyl-1-(pyrid-2-yl)-1*H*-pyrazole (**3j**), and 5-hydroxy-3-phenyl-1-(3-isoquinolinyl)-1*H*-pyrazole (**3k**) as the model demonstrated that the enol species could also proceeded the nucleophilic substitution in the same reaction condition. For the further conjunction conversion, mono-bromo-5-pyrazolones **6** were converted to the mono-bromo-5-hydroxypyrazoles **7** under the reaction mixture. Finally, mono-bromo-5-hydroxypyrazole intermediates **7** consequential trapped the secondary equivalent bromine from the *N*-monobromoisocyanuric acid **5** to generate final dibrominated products **4a–4k** and cyanuric acid **8**. Cyanuiric acid **8** can be isolated by column chromatography and identified by IR and $^{13}C$ NMR spectroscopic methods to demonstrate the plausible mechanism.

In conclusion, we have successfully developed a dibrominating method for the conversion of the keto form pyrazolone and the enol form 5-hydroxypyrazole substrates by use of DBI as the reagent. The reaction provided 4,4-dibromo-pyrazolones **4a–4k** in excellent yields (≥91%). This newly developed bromination method was a safe and efficient would be useful in the large-scale preparation of the dibrominated pyrazolones.

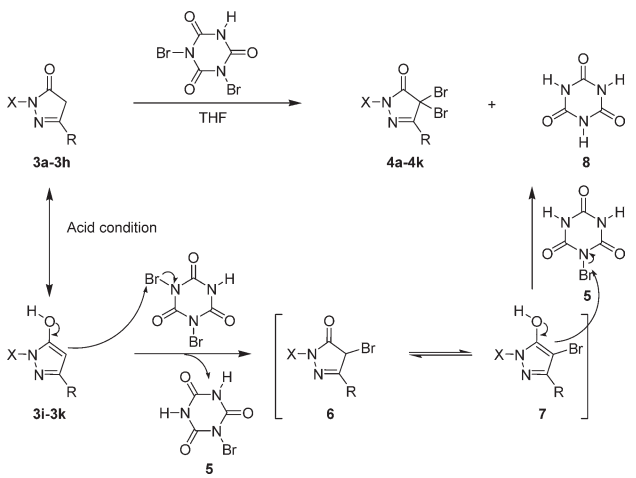
**Scheme 3**



## EXPERIMENTAL

**General procedure.** All chemicals were reagent grade and used as purchased. All reactions were carried out under nitrogen atmosphere and monitored by TLC analysis. Flash column chromatography was carried out on silica gel (230–400 mesh). Commercially available reagents were used without further purification unless otherwise noted. Dichloromethane, ethyl acetate, hexanes, and methanol were purchased from Mallinckrodt Chemical Co. Dry tetrahydrofuran (reagent grade) was used. The following compounds were purchased from Acoros Chemical Co: *o*-tolyhydrazine hydrochoide, *tert*-butyl acetoacetate, ethyl isobutylacetate, phenylhydrazine 4-methoxyphenylhydrazine hydrochloride, and 2,4-dinitrophenyl hydrazine. 2,4,6-Trichlorophenyl hydrazine, 2-hydrazinopyridine, and isonicotinic acid hydrazide were purchased from TCI Chemical Co. Ethyl trifluoroacetoacetate and *tert*-butyl acietoacetate from Alfa Chemical Co. Purification by gravity column chromatography was carried out by use of Merck Reagents Silica Gel 60 (particle size 0.063–0.200 mm, 70–230 mesh ASTM). Infrared (IR) spectra were measured on a Bomem Michelson Series FTIR spectrometer. The wavenumbers reported are referenced to the polystyrene 1601 cm−1 absortion. Absorption intensities are recorded by the following abbreviations: s, strong; m, medium; w, weak. Proton NMR spectra were obtained on a Bruker (200 MHz) spectrometer by use of $CDCl_3$, $CH_3OD$, and *d6*-DMSO as solvent. Carbon-13 NMR spectra were obtained on a Bruker (50 MHz) spectrometer by used of $CDCl_3$, $CH_3OD$, and *d6*-DMSO as solvent. Carbon-13 chemical shifts are referenced to the center of the CDCl3 triplet (δ 77.0 ppm). Multiplicities are recorded by the following abbreviations: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; *J*, coupling constant (Hz). Elemental analyses were carried out on a Heraeus CHN–O RAPID element analyzer.

**Standard procedure for dibromination to prepare 4,4-dibromo-5-pyrazolone derivatives 4a–4k.** To a solution of pyrazolones **3a–3h** or 5-hydroxypyrazoles **3i–3k** (1.0 equiv) in THF (20 mL) was added DBI (2.1 equiv). The reaction mixture was stirred at room temperature for ∼1 h. The solution was concentrated under reduced pressure and the resultant oil was redissolved in $CH_2Cl_2$ (50 mL). The solution was washed with $H_2O$ (20 mL × 2), brine (20 mL × 2), and concentrated under reduced pressure. The residue was purified by column chromatography on silica gel (30% EtOAc in hexanes as eluant) to give 4,4-dibromo-5-pyrazolones **4a–4k** as solids in 91–98% yields.

***4,4-Dibromo-3-methyl-1-phenyl-2-pyrazolin-5-one (4a).*** To a solution of pyrazolones **3a** (20 g, 0.114 mol, 1.0 equiv) in THF (150 mL) was added DBI (69.2 g, 0.242 mol, 2.1 equiv). The reaction mixture was stirred at room temperature for ∼1 h. The solution was concentrated under reduced pressure and the resultant oil was redissolved in $CH_2Cl_2$ (200 mL). The solution was washed with $H_2O$ (80 mL × 2), brine (80 mL × 2), and concentrated under reduced pressure. The residue was purified by column chromatography on silica gel (30% EtOAc in hexanes as eluant) to give 4,4-dibromo-5-pyrazolones **4a** as solids in 95 % yields. mp 80–82°C; $^1$H NMR ($CDCl_3$, 200 MHz) δ 2.42 (s, 3 H, $CH_3$), 7.21 (d, 1 H, $J$ = 2.6 Hz, ArH), 7.39 (dd, 2 H, $J$ = 7.4, 2.6 Hz, ArH), 7.84 (d, 2 H, $J$ = 7.4 Hz, ArH); $^{13}$C NMR ($CDCl_3$, 50 MHz) δ 20.0, 41.7, 118.9, 125.0, 128.8, 138.1, 159.9, 170.6; IR (KBr) 3199 (m), 2960 (m), 1706 (s, C=O), 1508 (s, C=N), 1348 (m), 1227 (m), 972 (m), 754 (m) $cm^{-1}$; EIMS m/z (relative intensity) 362 (M + 2, 7), 360 ($M^+$, 14), 358 (M – 2, 7), 281 (84), 279 (84), 265 (3), 201 (20), 200 (13), 184 (3), 171 (4), 131 (3), 105 (11), 95 (7), 92 (4), 77 (100), 65 (8), 51 (13). The 1,3-dipolar cycloaddition of an azomethine ylide generated by a decarboxylative route from sarcosine and isatin to 2,5-bis(arylmethylidene)-cyclopentanones afforded novel dispiro oxindole/pyrrolidines in moderate yields. Further cycloaddition of these dispiro oxindole/pyrrolidines with nitrile oxide afforded trispiro[oxindole-pyrrolidine]-cyclopentanone-isoxazolines in moderate yields with high regio- and stereoselectivity.

*J. Heterocyclic Chem.*, **47**, 1157 (2010).

## INTRODUCTION

Spiro-compounds are an important class of organic compounds based on their biological activities [1], which are motifs in many pharmacologically important alkaloids, as typified by rhyncophylline, corynoxeine, mitraphylline, horsifiline, and spirotryprostatins [2]. Therefore, the synthesis of spiro-compounds has recently attracted the interest of organic chemists.

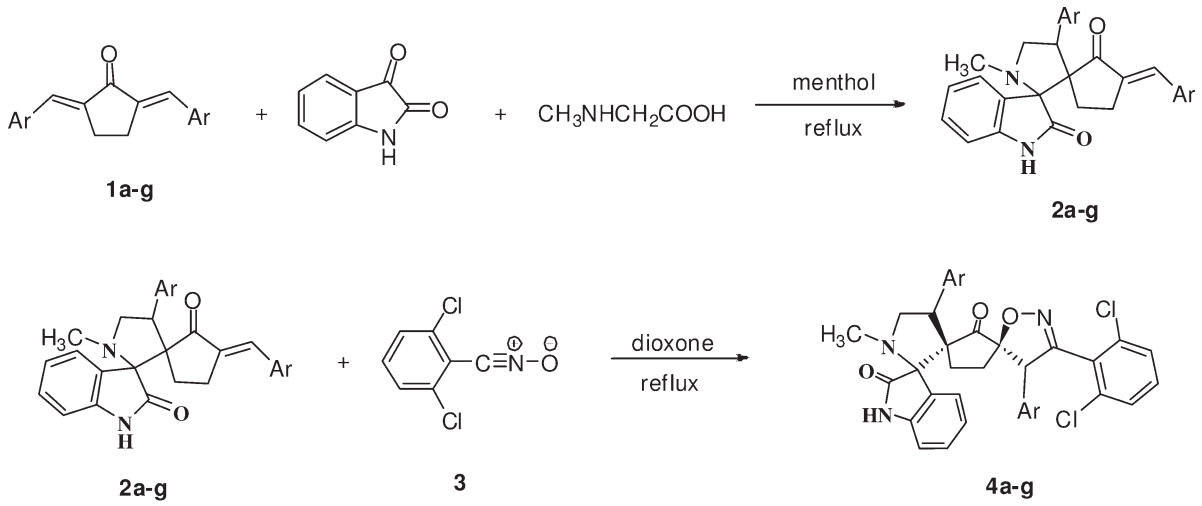
On the other hand, one of the most widely used methods for the synthesis of these compounds is via the intermolecular 1,3-dipolar cycloaddition reaction to exocyclic double bonds [3,4]. Therefore, the substrate with two exocyclic double bonds could be transformed to different spiro-groups by appropriate methods. Kumar and Perumal [5] used 1-methyl-3,5-bis[(E)-arylmethylidene]-tetrahydro-4(1H)-pyridinones through a tandem sequence comprising nitrile oxide cycloaddition to obtain cycloreversion mono-spiro-isoxazoline compounds other than the presumed tri-spiro product.

In the present work, we report the results of a tandem azomethine ylide/nitrile oxide cycloaddition of 2,5-bis(arylmethylidene)-cyclopentanone to obtain trispiro-[oxindole-pyrrolidine]-cyclopentanone-isoxazoline compound **4** (Scheme 1).

## RESULTS AND DISCUSSION

The 1,3-dipolar cycloaddition of the azomethine ylide generated *in situ* from isatin and sarcosine to 2,5-bis(arylmethylidene)-cyclopentanone (**1a–g**) afforded novel dispiroheterocycles (**2a–g**) in moderate to good yields (80–85%) (Scheme 1). This cycloaddition reaction proceeded with high stereo- and regioselectivity to afford only one isomer, which was evidenced from TLC and $^1$H-NMR of the crude reaction mixture. The $^1$H-NMR spectrum of **2a** demonstrated the presence of four multiplet of cyclopentanone $CH_2$ at δ 1.23–1.30, 2.12–2.16, 2.17–2.21, 2.35–2.40: one doublet of doublets at δ 4.37

**Scheme 1**



Ar: **a** $C_6H_5$; **b** 4-$ClC_6H_4$; **c** 4-$CH_3OC_6H_4$; **d** 2,4-$Cl_2C_6H_3$; **e** 3,4,5-$(CH_3O)_3C_6H_2$; **f** 2-$ClC_6H_4$; **g** 4-$CH_3SC_6H_4$

and two triplets at δ 3.60, 3.99 assigned as pyrrolidine protons, and two singlets at δ 2.25 and 8.31 assignable to the —$NCH_3$ and —NH, respectively. The $^{13}$C-NMR spectrum of **2a** demonstrated the presence of two spiro carbons at δ 65.61 and 77.73, two carbonyl carbons at δ 178.99 and 206.90.

The dispiroheterocycles **2** were reacted subsequently with nitrile oxide (Scheme 1) and tri-spiroheterocycles **3** were obtained in 70–85% yields. The stereo- and regioselectivity of this cycloaddition reaction was evidenced from TLC and $^1$H-NMR of the crude reaction mixture. The structures of **4a–g** were confirmed by IR, NMR, elemental analyses together with X-ray. For example, the IR spectrum of **4a** exhibited two carbonyl peaks locating at 1746.7 and 1709.8 $cm^{-1}$, which was assigned to the carbonyl group in cyclopentanone ring and the carbonyl group of lactam, respectively. What is more, the mass spectrum of **4a** showed a molecular ion peak at *m/z* 623 (M+1), which confirmed the addition of **3** to the exocyclic double bonds of **2a**.

The $^1$H-NMR spectrum of **4a** revealed a singlet at δ 2.15 resulting from N—CH3, four multiplets in the range of δ 0.99–1.02, 1.37–1.40, 1.53–1.55, and 1.66–1.70 resulting from the C**H**$_2$ in cyclopentanone ring, a triplet at δ 4.20 for C**H** and two triplets at δ 3.55 and 3.97 for C**H**$_2$ in pyrrole ring and a characterize singlet at δ 4.69 for PhC**H**. The $^{13}$C-NMR spectrum of the product **4a** exhibited the presence of methyl carbon at δ 34.8; two **C**$H_2$ in cyclopentanone ring at δ 28.6 and 28.8; three spiro carbons at δ 92.4, 77.4, and 65.5; N—**C**$H_2$ at δ 59.4; benzylic carbons at δ 58.2 and 51.6, respectively; and carbonyl carbons at δ 177.7 and 213.4. Further, the structure of the product was confirmed by X-ray diffraction analysis of **4a** [6] (Fig. 1).

## EXPERIMENTAL

**1** [7] and **3** [8] were prepared according to the reported procedures. All NMR spectra were recorded on a Bruker AV-II 500 MHz NMR spectrometer, operating at 500 MHz for $^1$H, and 125 MHz for $^{13}$C. TMS was used as an internal reference for $^1$H and $^{13}$C chemical shifts. $CDCl_3$ was as solvent. Elemental analysis was measured by an Elementar analyzer (varioELII). MS was measured by a Finnigan LCQ Advantage MAX mass spectrometer; IR spectra were recorded on Perkin-Elmer spectrometer. Melting points were measured by a Yanaco MP500 melting points apparatus and uncorrected.

**General procedure for the synthesis of spirooxindoles (2a–g).** A solution of isatin (1mmol), sarcosine (1mmol), and 2,5-diarylidene-cyclopentanone **1** (1mmol) in methanol (30 mL) was refluxed overnight. Completion of the reaction was evidenced by TLC analysis. The solvent was removed *in vacuo*. The crude product was subjected to column chromatography using petroleum ether-ethyl acetate (v/v 5:1) as eluent to afford the corresponding **2**.

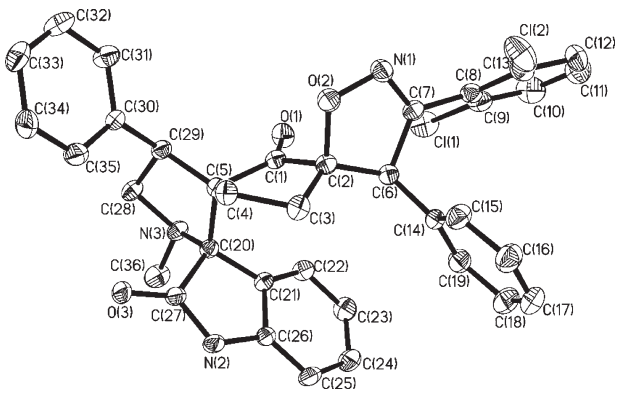


**Figure 1.** ORTEP diagram of **4a** (H atoms have been omitted for clarity).

Completion of the reaction was evidenced by TLC analysis. The solvent was removed *in vacuo*. The crude product was subjected to column chromatography using petroleum ether-ethyl acetate (v/v 5:1) as eluent to afford the corresponding **4**.

New tricyclic pyrimidinone derivatives were obtained from the corresponding thiazolopyrimidinone or hydrazino systems. The annelation of tricyclic hydrazino compound with 1,2,4-triazole and tetrazole moieties gave novel tetracyclic condensed pyrimidinones. The investigation of the antimicrobial properties of tricyclic and tetracyclic pyrimidinones, by agar-well diffusion assay, was carried out against six pathogenic bacteria (*Bacillus cereus*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella spp*, and *Salmonella typhyrium*) and four pathogenic fungi (*Aspergillus flavus*, *Aspergillus niger*, *Aspergillus fumigatus*, and *Trichderma horozianum*). Most of the compounds tested exhibited some degree of antimicrobial activity against microorganisms. Among these compounds, 4-benzylidenhydrazino-8-cyano-7-(furan-2-yl)thiazolo[3,2-*a*:4,5-*d*']dipyrimidin-9-one (**12**) showed the most favorable antibacterial activity, while compound **17** showed the highest effect on fungi. Interestingly, tetrazole derivative **19** displayed a remarkable effect on fungi much more than the corresponding 3-substituted triazole derivatives on the one hand, whereas the lowest effect on bacteria on the other.

## INTRODUCTION

Pyrimidine and its derivatives are ubiquitous in nature. As such, the pyrimidine subunit has found widespread applications in therapeutically active compounds. Most importantly, pyrimidine bases are fundamental constituents of the building blocks of DNA and RNA and hence play a significant role in biochemical vital processes for human beings and animals [1,2]. Various analogs of thiopyrimidinones display antibacterial, antifungal, antiviral [3–5], and antileishmanial activities [3,6], whereas some derivatives of dihydropyrimidine (DHPM) have interesting biological properties such as antimicrobial [7], antiviral [8], and anticancer [9] activities and moreover are found to be useful in the treatment of benign prostatic hyperplasia [10]. More recently, these partly reduced DHPMs have emerged as anti-inflammatory agents [11]. Very recently, *S*-alkylpyrimidines possessing antifungal and antibacterial activities have been also reported in the literature [12]. Some time ago, a series of chloropyrimidines were identified as a new class of antimicrobial agents [13]. Also,

numerous nucleosides containing 1-substituted pyrimidines have found utility as anticancer and antiviral chemotherapeutic agents [8,14,15]. It should be kept in mind that thiazoles have occupied a unique place and have remarkably contributed to biological and medicinal chemistry [16–18]. Such medicines as sulfathiazole, phthalylsulfathiazole and related compounds are widely used in medical practice [19]. The thiazole ring unit is a useful structural component of natural compounds, *e.g*., Vitamin B1 (thiamine), penicillin, and carboxylase [19,20]. The 2-aminothiazole ring system has been employed in the preparation of a number of important drugs required for treatment of hypertension [21], inflammation [22], bacterial [23], and HIV infections [24]. Furthermore, aminothiazoles are well known for their antifungal [25], antimicrobial [26–28], antiviral [29], anti-inflammatory, and antioxidant [30] applications and also have been utilized for the treatment of both breast and prostate cancer [31,32], as a novel class of adenosine receptor antagonists [33,34] and in the development of cyclin-dependent kinase (CDK) inhibitors [35]. Moreover, some of the thiazole analogues are used as fungicides, inhibiting *in vivo* the growth of *Xanthomonas* and as an ingredient of herbicides or an schistosomicidal and anthelmintic drugs [36]. Literature survey reveals that triazole-containing substances are also well known for their diverse pharmaceutical activities including antimicrobial [37], insecticidal [38], antitumor [37,39], and anticonvulsant [40] effects, and moreover, triazolopyrimidines have recently been identified as adenosine $A_3$ receptor antagonists [41]. Interestingly, the fused tetrazoles have been found to exhibit similar biological properties to those of their corresponding triazole analogs [42].

On the basis of the above data and continuing our studies on condensed heterocycles as a part of a chemotherapeutic research program [43–45], it was envisaged that the combined effect of all the above pharmacophores could result in interesting chemotherapeutic activity. Therefore, the goal of the present work was to synthesize substances containing a fused pyrimidine-thiazole scaffold as part of a tricyclic framework **8**, **10–12** and tetracyclic compounds of the same tricyclic structure with a heterocycle anellated to the pyrimidine ring **13**, **16–19** and to screen for their antibacterial and antifungal activities.

## RESULTS AND DISCUSSION

Treatment of the 2-thioxopyrimidines **1a**,**b** [4,46] with bromomalononitrile, in ethanol containing potassium hydroxide, provided bicyclic products. Principally, there are three possible cyclization sites, *i.e*., either at *N*-3 or *N*-1 or partial cyclization at both, depending on the mode of cyclization. In practice, these reactions led to, in each case, the formation of only one isolable product as evidenced by TLC analysis. The structure of the isolated products was considered to be 5-one structure **3** rather than the related isomeric 7-one structure **2** based on the fact that the *N*-3 nitrogen atom of the pyrimidine ring in 2-thiouracil analogues has higher nucleophilic character when compared with *N*-1 atom, and hence, *N*-3 nitrogen is more reactive towards electrophiles than the *N*-1 position, which is part of a push-pull system with the cyano group in the 5-position of the pyrimidine ring. Therefore, the *N*-3 and not the *N*-1 always participates in the cyclization processes as clearly indicated from literature reports [4,47–52]. The IR and $^{13}C$ NMR spectra provide further evidence for the proposed structure by comparison of these spectra with those of similar annelated pyrimidinones. The IR spectra of the products isolated from the studied reactions showed among its peaks those for carbonyl carbon of the pyrimidinone ring at ν 1692 and 1690 $cm^{-1}$, respectively. This high frequency absorption is in favor of structure **3** [47,51,52]. Literature reports [47,53] have shown that the chemical shift for the carbonyl carbon in pyrimidin-4-one derivatives is markedly affected by the nature of the adjacent nitrogen (*N*-3) (pyrrole type in our structure **3** and pyridine type as in structure **2**). For instance, the $^{13}C$ NMR spectrum of compound **3a**, as a typical example, displayed the signal of the carbonyl carbon residue at δ 160.8 ppm. Such an upfield chemical shift value is in agreement with pyrimidin-5-one **3** rather than with pyrimidin-7-one **2**, for which carbonyl stretching frequencies would be expected to appear in the region ν 1640–1660 $cm^{-1}$, and the cyclic carbonyl groups would be expected to resonate in the lower field region ($\delta_C \sim 170$ ppm) as reported by Shawali *et al*. [47]. Consequently, it is reasonable to conclude that the studied reactions are completely regioselective and the structure of the isolated products is pyrimidin-5-one **3**; the alternative cyclization mode to the respective 7-one **2** is therefore discarded. Condensation of 3-amino-2-cyanothiazolopyrimidines **3a**,**b** with triethyl orthoformate gave the corresponding imino ethers **4a**,**b** while with dimethylformamide dimethylacetal (DMFDMA), the amidines **4c**,**d** were obtained (Scheme 1).

Closure of a second pyrimidine ring of the thiazolodipyrimidine ring system was carried out by heating *N*-ethoxymethylene derivative **4a** at reflux in an alcoholic solution of hydrazine hydrate (Scheme 2) to yield a reaction product of molecular formula $C_{13}H_7N_7O_2S$, which corresponded to the addition of the hydrazine to **4a** and the loss of one molecule of ethanol. The IR spectrum of the reaction product was characterized by the absence of one absorption for the cyano group and the presence of an absorption band in the region ν 3382–3200 $cm^{-1}$ due to the hydrazino moiety in

addition to a single cyano group at ν 2219 $cm^{-1}$ and carbonyl function at ν 1697 $cm^{-1}$. The $^1H$ NMR spectrum of that product indicated the disappearance of the resonance signals from protons of the ethyl unit and the appearance of signals from the hydrazino moiety and a pyrimidine methine in their proper positions, besides the expected furyl resonances. Accordingly, this compound could be formulated as the tricyclic hydrazino derivative **8a**, formed most likely *via* a Dimroth-type rearrangement [54–56] of the initial cyclization product **5a**. The $^{13}C$ NMR spectrum of the isolated product was also in accordance with the proposed structure (see Experimental section). The pathway of this reaction, as illustrated in Scheme 2, may involve, first, the anticipated formation of imino compound **5a** followed by subsequent covalent hydration under the applied reaction conditions to afford the 2-hydroxy intermediate **6a**. Then, the pyrimidine ring opens and forms the formyl intermediate **7a**, which undergoes spontaneous heteroannelation with the more nucleophilic imino group to give the rearranged hydrazino compound **8a** (Scheme 2). A similar treatment of amidine **4d** with hydrazine hydrate resulted in the formation of the Dimroth rearrangement product **8b**. Intermediacy of **5b**, **6b**, and **7b** are most likely. It is worth mentioning that the latter products of the reaction of **4a**,**d** with hydrazine hydrate were recovered completely unchanged when subjected to conditions leading to hydrolysis of the imino group to carbonyl function, thus supporting the Dimroth rearrangement of **5a**,**b** to **8a**,**b** (Scheme 2).

Nevertheless, a proof of structure **8** was accomplished by using an alternative synthetic route involving the cycliztion of aminonitrile **3a** with formic acid to give the dione **10** through the intermediate formation of carboxamide **9**. A further reaction of **10** with phosphorus

oxychloride produced the respective chloro derivative **11**, hydrazinolysis of which led to the hydrazino compound **8a** (61% yield), whose spectral characteristics were completely coincident with the previously isolated sample (Scheme 2).

Treatment of **8a** with benzaldehyde, in boiling absolute ethanol in the presence of piperidine furnished the corresponding acyclic condensation product **12**. Oxidative cyclodehydrogenation of Schiff's base **12** by boiling in nitrobenzene or by treatment with ethanolic iron(III) chloride solution led to, in every case, a single product for which the tetracyclic-condensed structure **13** was established on the basis of its analytical and spectroscopic data. The absence of the methine proton of the hydrazone **12** in the $^1$H NMR spectrum of **13** confirmed the structure. It is interesting to note that the same product **13** could be also obtained directly from cyclocondensation of the hydrazino derivative **8a** with benzoic acid in boiling phosphorus oxychloride. This fact was supported by heating compound **8a** at reflux in an excess of benzoyl chloride, wherein compound **13** was also isolated.

It is remarkable to report here that an unexpected reaction took place on reacting **8a** with ethyl benzylidenecyanoacetate in the presence of piperidine in an attempt to obtain the pyrazolyl derivative **15**. To our surprise, this reaction did not give the desired **15** and instead the Schiff's base **12** was isolated as indicated from TLC analysis, mp, mixed mp, and IR data of the reaction product. This result can be explained by assuming the formation of Michael adduct **14** as a first step. Subsequent ethyl cyanoacetate elimination leads eventually to the final benzylidene derivative **12**, what is in agreement with a previous literature report [37].

Another new tetracyclic pyrimidinone derivative **16** was synthesized from the hydrazino compound **8a** by reaction with one carbon inserting agents. Thus, interaction of **8a** with phenyl isothiocyanate in ethanolic sodium ethoxide solution gave the target **16** (Scheme 3). This reaction is assumed to proceed most likely with *in situ* evolution of aniline. In support of this hypothesis, the desired **16** was also obtained by an independent route involving the reaction of **8a** with carbon disulfide at reflux in pyridine, leading to a reaction product that was identical to **16** obtained by the prescribed method according to TLC analysis, mp, mixed mp, and IR data.

The hydrazino derivative **8a** proved to be a useful precursor for the synthesis of other tetracyclic pyrimidinones. Thus, reaction of **8a** with an excess of ethyl chloroformate, at reflux in pyridine, led to the triazolone

analogue **17**, while with diethyl malonate, the ethyl ester **18** was isolated in acceptable yield. Elucidation of structure for the latter products was established on the basis of elemental and spectroscopic analyses in each case (see Experimental section).

As an extension to this synthetic route, treatment of compound **8a** with sodium nitrite resulted in the formation of a similar product with annelated tetrazole ring **19**, formed most likely *via* diazotization, by the action of *in situ* generated nitrous acid on **8a**, followed by self-condensation. A similar diazotization of hydrazinopyrimidines with sodium nitrite has been reported previously [42,49,54].

**Antimicrobial evaluation.** As shown by the results in Tables 1 and 2, the majority of the new tricyclic and tetracyclic compounds tested displayed *in vitro* antibacterial and antifungal activities. In general, the chemical structure of the whole molecule, comprising the nature of the heterocyclic system as well as the type of the substituted function present in the heterocyclic ring structure, has a pronounced effect on antimicrobial activity. In particular, it has been found that antimicrobial activity was highly dependent on the type of substituent at the 4-position of pyrimidine ring in the tricyclic core (compounds **8a** and **10–12**, respectively). The most toxic compound to the test bacterial isolates was that containing a benzylidenhydrazino moiety at position 4 of pyrimidine ring in the tricyclic ring system (compound **12**) as compared with the other 4-substituted analogues (compounds **8a**, **10**, and **11**). Replacement of the benzylidenhydrazino moiety by a chlorine atom diminished slightly the activity of **11**; however, 4-chloro analog **11** exhibited more pronounced antibacterial activity than the corresponding 4-hydrazino **8a** or 4-oxo **10** derivatives. Fusion of 3-substituted 1,2,4-triazoles with the parent thiazolodipyrimidine structure (compounds **13** and **16–18**) led in general to a decrease in antibacterial activity relative to the corresponding tricyclic products. However, the antifungal activity of tetracyclic triazole derivative **17** was found to be the highest. This was followed by the tetrazole derivative **19**, which displayed a remarkable effect on fungi much more than the other 3-substituted triazole derivatives (compounds **13**, **16**, and **18**). Despite promising *in vitro* antifungal activity of **19**, only poor activity was found against test bacterial isolates (*Staphylococcus aureus*, *Klebsiella spp*, and *Bacillus cereus*).

## CONCLUSION

New heterocyclic motifs were obtained from the reaction of aminonitriles **3a**,**b** and hydrazino compound **8a** with several commercially available reactants. All the tricyclic and tetracyclic compounds described in this work retain a thiazolodipyrimidinone core, while a fourth fused heterocyclic nucleus (triazole or tetrazole)

was constructed by cyclocondensation reactions of tricyclic hydrazino compound **8a** with various chemical reagents. The biological potential of all the fused pyrimidinone derivatives was further investigated by screening for their antimicrobial activity. The test compounds displayed different levels of antibacterial and antifungal activities, with the assays carried out on six pathogenic bacteria and four pathogenic fungi. The most potent compounds against test bacterial and fungal isolates were 4-benzylidenhydrazino compound **12** and dione derivative **17**, respectively. Further studies on structure–activity relationships (SAR) combined with molecular modeling approaches of these condensed heterocyclic derivatives are currently underway, and the results of this research will be reported in due course. We believe that research in this direction should be encouraged in order to broaden the applicability of these new heterocyclic frameworks to serving as leads for designing novel chemotherapeutic agents.

## EXPERIMENTAL

Melting points are uncorrected. IR spectra were recorded (KBr) on a Pye Unicam SP-1000 spectrophotometer. NMR spectra were obtained on a Varian Gemini 300 MHz spectrometer in DMSO-$d_6$ as solvent and TMS as internal reference. Chemical shifts are expressed in δ ppm. EI mass spectra were recorded on a Shimadzu GC MS-QP 1000 EI mass spectrometer at 70 eV. Compounds **1a**,**b** were prepared according to known methods [4,46].

**General procedure for the preparation of 7-substituted-3-amino-5-oxo-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitriles (3a,b).** To a warm ethanolic potassium hydroxide solution [prepared by dissolving potassium hydroxide (0.005 mol) in ethanol (30 mL)] of either pyrimidinethione **1a** or **1b** (0.005 mol), bromomalononitrile (0.005 mol) was added portionwise with stirring. The reaction content was then left overnight at room temperature, whereby the solid product so precipitated upon dilution with water was filtered off, dried, and recrystallized from the appropriate solvents to give the title compounds **3a** (0.64 g; 45%) and **3b** (0.61 g; 41%), respectively.

**3-Amino-7-(2-furyl)-5-oxo-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitrile (3a).** This compound was obtained as a yellow solid (DMF/$H_2O$), mp 267–268°C; IR (ν/$cm^{-1}$): 3380, 3272 ($NH_2$), 2221, 2202 (2CN), 1692 (CO); $^1$H NMR (δ ppm): 6.74 (dd, 1H, $J$ = 1.6, 3.7 Hz, furan H-4), 7.31 (d, 1H, $J$ = 3.7 Hz, furan H-3), 7.90 (d, 1H, $J$ = 1.6 Hz, furan H-5), 8.48 (s, 2H, $NH_2$, $D_2O$-exchangeable); $^{13}$C NMR (δ ppm): 79.9, 98.5 (C-2, C-6), 111.2, 112.1 (furan C-3,4), 116.8 (CN), 118.0 (CN), 144.2 (furan C-5), 155.0 (furan C-2), 158.5, 159.0 (C-8a, C-3), 160.8 (CO), 167.9 (C-7); *Anal*. **3-Amino-5-oxo-7-(2-thienyl)-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitrile (3b).** This compound was obtained as a yellowish white solid (DMF), mp 251-252 °C; IR (ν/$cm^{-1}$): 3374, 3260 ($NH_2$), 2218, 2202 (2CN), 1690 (CO); $^1$H NMR (δ ppm): 7.05 (dd, 1H, $J$ = 3.5, 4.9 Hz, thiophene H-4), 7.89 (d, 1H, $J$ = 3.5 Hz, thiophene H-3), 8.04 (d, 1H, $J$ = 4.9 Hz, thiophene H-5), 8.72 (s, 2H, $NH_2$, $D_2O$-exchangeable); Anal. Calcd. for $C_{12}H_5N_5OS_2$ (299.337): C, 48.15; H, 1.68; N, 23.40; S, 21.42. Found: C, 47.87; H, 1.53; N, 23.31; S, 21.15.

**General procedure for the preparation of 7-substituted-3-(ethoxymethylene)amino-5-oxo-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitriles (4a,b).** A mixture of either **3a** or **3b** (0.005 mol) and triethyl orthoformate (10 mL) was heated at reflux for 10 h. After distillation of the ortho ester, the viscous mass was treated with ether or petroleum ether (3 mL). The precipitated crystals of products **4a**,**b** were collected by filtration and recrystallized from the proper solvents to give the imino ethers **4a** (0.85 g; 50%) and **4b** (0.59 g; 33%), respectively.

**3-(Ethoxymethylene)amino-7-(2-furyl)-5-oxo-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitrile (4a).** This compound was obtained as a pale brown solid (EtOH/$H_2O$), mp 214°C; IR (ν/$cm^{-1}$): 2225, 2216 (2CN), 1700 (CO), 1621 (C=N); $^1$H NMR (δ ppm): 1.41 (t, 3H, $J$ = 7.3 Hz, $CH_3$ ethoxy), 4.43 (q, 2H, $J$ = 7.3 Hz, $OCH_2$), 6.68 (dd, 1H, $J$ = 1.6, 3.8 Hz, furan H-4), 7.35 (d, 1H, $J$ = 3.8 Hz, furan H-3), 7.85 (d, 1H, $J$ = 1.6 Hz, furan H-5), 8.36 (s, 1H, methylenic CH); MS: $m/z$ (%) = 339 ($M^+$, 18%); Anal. Calcd. for $C_{15}H_9N_5O_3S$ (339.334): C, 53.09; H, 2.67; N, 20.64; S, 9.45. Found: C, 52.93; H, 2.51; N, 20.37; S, 9.30.

**3-(Ethoxymethylene)amino-5-oxo-7-(2-thienyl)-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitrile (4b).** This compound was obtained as a golden yellow solid (EtOH), mp 201–202°C; IR (ν/$cm^{-1}$): 2221, 2215 (2CN), 1704 (CO), 1621 (C=N); $^1$H NMR (δ ppm): 1.39 (t, 3H, $J$ = 7.4 Hz, ethoxy $CH_3$), 4.45 (q, 2H, $J$ = 7.4 Hz, $OCH_2$), 7.24 (dd, 1H, $J$ = 3.7, 4.8 Hz, thiophene H-4), 7.95 (d, 1H, $J$ = 3.7 Hz, thiophene H-3), 8.10 (d, 1H, $J$ = 4.8 Hz, thiophene H-5), 8.36 (s, 1H, methylenic CH); Anal. **General procedure for the preparation of 7-substituted-3-(dimethylaminomethylenamino)-5-oxo-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitriles (4c,d).** To a solution of either **3a** or **3b** (0.005 mol), in dry xylene (30 mL), DMFDMA (0.006 mol) was added and the reaction content was then heated under reflux for 6 h. The reaction mixture was cooled and triturated with petroleum ether (40–60). The solid product obtained was filtered off, dried and recrystallized from the appropriate solvents to give the amidines **4c** (0.52 g; 31%) and **4d** (0.82 g; 46%), respectively.

**3-(Dimethylaminomethylenamino)-7-(2-furyl)-5-oxo-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitrile (4c).** This compound was obtained as an orange solid (EtOH), mp 239–241°C; IR (ν/$cm^{-1}$): 2225, 2214 (2CN), 1700 (CO), 1618 (C=N); $^1$H NMR (δ ppm): 3.05, 3.14 (2s, 6H, $NMe_2$), 6.85–7.17 (m, 2H, furan H-3,4), 7.83 (d, 1H, $J$ = 1.9 Hz, furan H-5), 8.23 (s, 1H, methylenic CH); Anal. Calcd. for $C_{15}H_{10}N_6O_2S$ (338.340): C, 53.25; H, 2.98; N, 24.84; S, 9.48. Found: C, 52.99; H, 2.81; N, 24.57; S, 9.20.

**3-(Dimethylaminomethylenamino)-5-oxo-7-(2-thienyl)-5*H*-thiazolo[3,2-*a*]pyrimidine-2,6-dicarbonitrile (4d).** This compound was obtained as a brown solid (1,4-dioxane), mp 232–233°C; IR (ν/$cm^{-1}$): 2220, 2212 (2CN), 1695 (CO), 1617 (C=N); $^1$H NMR (δ ppm): 2.89, 2.99 (2s, 6H, $NMe_2$), 7.30 (dd, 1H, $J$ = 3.9, 5.2 Hz, thiophene H-4), 7.81 (d, 1H, $J$ = 3.9

Hz, thiophene H-3), 7.97 (d, 1H, $J$ = 5.2 Hz, thiophene H-5), 8.12 (s, 1H, methylenic CH); Anal. Calcd. for $C_{15}H_{10}N_6OS_2$ (354.417): C, 50.83; H, 2.84; N, 23.71; S, 18.09; Found: C, 50.55; H, 2.72; N, 23.46; S, 17.91.

**General procedure for the preparation of 7-substituted-8-cyano-4-hydrazinothiazolo[3,2-*a*:4,5-*d*′]dipyrimidin-9-ones (8a,b).** ***Method A for compounds 8a,b.*** A mixture of either **4a** or **4d** (0.005 mol), hydrazine hydrate (0.05 mol, 2.5 mL) and absolute ethanol (12 mL) was refluxed for 5 h. The precipitates formed after cooling overnight were collected by filtration, washed with cold alcohol, and recrystallized from the proper solvents to give the hydrazino compounds **8a** (0.89 g; 55%) and **8b** (0.55 g; 32%), respectively.

*8-Cyano-7-(2-furyl)-4-hydrazinothiazolo[3,2-a:4,5-d′]dipyrimidin-9-one (8a).* This compound was obtained as a light brown solid (EtOH), mp 246–247°C; IR (ν/cm$^{-1}$): 3382–3200 (NH, $NH_2$), 2219 (CN), 1697 (CO); $^1$H NMR (δ ppm): 4.76 (s, br, 2H, $NH_2$, $D_2O$-exchangeable), 6.69 (dd, 1H, $J$ = 1.6, 3.7 Hz, furan H-4), 7.25 (d, 1H, $J$ = 3.7 Hz, furan H-3), 7.81 (d, 1H, $J$ = 1.6 Hz, furan H-5), 7.95 (s, 1H, pyrimidine H-2), 10.15 (s, br, 1H, NH, $D_2O$-exchangeable); $^{13}$C NMR (δ ppm): 95.3, 99.0, 111.5, 112.2 (furan C-3,4), 117.1 (CN), 143.5 (furan C-5), 155.2 (furan C-2), 157.4, 158.0, 158.5, 159.6, 161.4 (CO), 167.8 (C-7); *Anal*. Calcd. for $C_{13}H_7N_7O_2S$ (325.311): C, 48.00; H, 2.17; N, 30.14; S, 9.86. Found: C, 47.73; H, 1.99; N, 29.88; S, 9.72.

*8-Cyano-4-hydrazino-7-(2-thienyl)thiazolo[3,2-a:4,5-d′]dipyrimidin-9-one (8b).* This compound was obtained as canary yellow crystals (MeOH), mp 261°C; IR (ν/cm$^{-1}$): 3370–3208 (NH, $NH_2$), 2219 (CN), 1702 (CO); $^1$H NMR (δ ppm): 4.95 (s, br, 2H, $NH_2$, $D_2O$-exchangeable), 7.16 (dd, 1H, $J$ = 4.3, 4.8 Hz, thiophene H-4), 7.88–7.92 (m, 2H, thiophene H-3, pyrimidine H-2), 8.06 (d, 1H, $J$ = 4.8 Hz, thiophene H-5), 10.54 (s, br, 1H, NH, $D_2O$-exchangeable); MS: $m/z$ (%) = 341 ($M^+$, 26%); Anal. Calcd. for $C_{13}H_7N_7OS_2$ (341.378): C, 45.74; H, 2.07; N, 28.72; S, 18.79. Found: C, 45.60; H, 1.92; N, 28.46; S, 18.51.

***Method B for compound 8a.*** Chloro compound **11** (0.002 mol) was mixed with hydrazine hydrate (0.006 mol), in absolute ethanol (20 mL). The mixture was stirred under reflux for 3 h. The precipitate formed during reflux was collected by filtration and found, after recrystallization from EtOH, identical in all respects to that obtained from method A (61% yield).

**8-Cyano-7-(2-furyl)-4,9-dioxo-3,4-dihydro-9*H*-thiazolo[3,2-*a*:4,5-*d*′]dipyrimidine (10).** Compound **3a** (0.003 mol) was heated under reflux in formic acid (10 mL) for 7 h. The reaction mixture was then diluted with cold water and allowed to stand overnight. The resulting precipitate was filtered off, washed with ethanol (20 mL), dried, and recrystallized from DMF/EtOH (2:1) as reddish brown crystals (0.52 g; 56%), mp 256–257°C; IR (ν/cm$^{-1}$): 3157 (NH), 2221 (CN), 1697, 1670 (2CO); $^1$H NMR (δ ppm): 6.64 (dd, 1H, $J$ = 1.7, 4.0 Hz, furan H-4), 7.33 (d, 1H, $J$ = 4.0 Hz, furan H-3), 7.76 (d, 1H, $J$ = 1.7 Hz, furan H-5), 8.01 (s, 1H, pyrimidine H-2), 12.52 (s, br, 1H, NH, $D_2O$-exchangeable); Anal. Calcd. for $C_{13}H_5N_5O_3S$ (311.280): C, 50.16; H, 1.62; N, 22.50; S, 10.30. Found: C, 49.87; H, 1.54; N, 22.42; S, 10.13.

**4-Chloro-8-cyano7-(2-furyl)thiazolo[3,2-*a*:4,5-*d*′]dipyrimidin-9-one (11).** A suspension of compound **10** (0.002 mol) in phosphorus oxychloride (30 mL) was refluxed with stirring for 5 h and then left aside to cool to room temperature overnight under stirring. Excess reagent was removed under reduced pressure. The residue was poured to ice/water with stirring and the precipitate was filtered off, dried, and recrystallized from acetone to give the chloro compound **11** as a dark brown solid (0.51 g; 77%), mp > 300°C; IR (ν/cm$^{-1}$): 2223 (CN), 1699 (CO); $^1$H NMR (δ ppm): 6.72 (dd, 1H, $J$ = 1.8, 3.9 Hz, furan H-4), 7.31 (d, 1H, $J$ = 3.9 Hz, furan H-3), 7.84 (d, 1H, $J$ = 1.8 Hz, furan H-5), 8.45 (s, 1H, pyrimidine H-2); Anal. Calcd. for $C_{13}H_4ClN_5O_2S$ (329.726): C, 47.35; H, 1.22; Cl, 10.75; N, 21.24; S, 9.72. Found: C, 47.09; H, 1.10; Cl, 10.62; N, 20.98; S, 9.56.

**4-Benzylidenhydrazino-8-cyano-7-(2-furyl)thiazolo[3,2-*a*:4,5-*d*′]dipyrimidin-9-one (12).** ***Method A.*** Compound **8a** (0.005 mol) was dissolved in absolute ethanol (20 mL), then benzaldehyde (0.006 mol) and piperidine (0.5 mL) were added. The reaction mixture was heated at reflux for 1.5 h. On cooling, the deposited solid product was filtered off and dried. Recrystallization from EtOH gave yellow crystals of the title compound **12** (0.83 g; 40%), mp 261–262°C; IR (ν/cm$^{-1}$): 3330 (NH), 3080 (arom. CH), 2223 (CN), 1698 (CO), 1626 (C=N); $^1$H NMR (δ ppm): 6.71–6.76 (m, 1H, furan H-4), 7.42–7.76 (m, 6H, furan H-3, Ph), 7.86 (d, 1H, $J$ = 2.0 Hz, furan H-5), 7.95 (s, 1H, pyrimidine H-2), 8.49 (s, 1H, CH=N), 11.92 (s, 1H, NH, $D_2O$-exchangeable); *Anal*. Calcd. for $C_{20}H_{11}N_7O_2S$ (413.419): C, 58.11; H, 2.68; N, 23.72; S, 7.76. Found: C, 57.86; H, 2.52; N, 23.50; S, 7.49.

***Method B.*** To a solution of **8a** (0.002 mol) and few drops of piperidine (0.5 mL) in ethanol (10 mL), ethyl benzylidenecyanoacetate (0.002 mol) was added. The reaction content was heated under reflux for 3 h. After cooling, the obtained crystalline product was collected by filtration, washed several times with water, and dried. Recrystallization from EtOH gave, upon air drying, a yellow product (0.44 g; 53%) identical in all aspects (mp, mixed mp, and IR data) to that described in method A.

**9-Cyano-10-(2-furyl)-3-phenylpyrimido[2′,1′:2,3]thiazolo[5,4-*e*][1,2,4]triazolo[4,3-*c*]pyrimidin-8-one (13).** ***Method A.*** Compound **12** (0.002 mol) was heated at reflux in nitrobenzene (10 mL) for 1 h. The final mixture was concentrated and the product deposited after cooling was recrystallized from dilute acetic acid to give the 3-phenyl derivative **13** as a brown solid (0.59 g; 72%), mp > 300°C; IR (ν/cm$^{-1}$): 3064 (arom. CH), 2220 (CN), 1697 (CO); $^1$H NMR (δ ppm): 6.75 (dd, 1H, $J$ = 1.7, 3.8 Hz, furan H-4), 7.34–7.79 (m, 6H, furan H-3, Ph), 7.89 (d, 1H, $J$ = 1.7 Hz, furan H-5), 8.30 (s, 1H, pyrimidine H-5); Anal. Calcd. for $C_{20}H_9N_7O_2S$ (411.404): C, 58.39; H, 2.21; N, 23.83; S, 7.79. Found: C, 58.21; H, 2.08; N, 23.56; S, 7.80.

***Method B.*** To a solution of **12** (0.0025 mol) in ethanol (50 mL), ethanolic iron(III) chloride solution [prepared by dissolving iron(III) chloride (0.005 mol) in ethanol (10 mL)] was added portionwise while stirring. The reaction content was then boiled for 15 min and left at room temperature overnight. The solid product that separated out was collected by filtration and recrystallized from dilute acetic acid to give a tetracyclic product (0.65 g; 63%) that was found to be identical in all aspects (mp, mixed mp, and IR data) to the product prepared by method A.

***Method C.*** A mixture of **8a** (0.002 mol) and benzoic acid (0.004 mol) was refluxed with phosphorus oxychloride (10 mL) for 30 min. Excess phosphorus oxychloride was distilled off under reduced pressure. The residue was triturated with dilute sodium hydroxide solution to remove the unreacted material. The solid residue was recrystallized from dilute acetic acid to give a solid product (0.49 g; 59%). Again, this product was identified as **13**.

***Method D.*** A mixture of **8a** (0.002 mol) and benzoyl chloride (10 mL) was refluxed for 4 h. The excess of benzoyl chloride was extracted with benzene and the residue was

recrystallized from dilute acetic acid to give a solid product (0.51 g; 62%). The material proved to be **13**.

**9-Cyano-10-(2-furyl)-3-thioxo-2,3-dihydropyrimido[2′,1′:2,3]thiazolo[5,4-*e*][1,2,4]triazolo[4,3-*c*]pyrimidin-8-one (16).** ***Method A.*** To a solution of **8a** (0.002 mol) in ethanolic sodium ethoxide [prepared by dissolving sodium metal (0.002 mol) in absolute ethanol (25 mL)], phenyl isothiocyanate (0.002 mol) was added dropwise. The mixture was refluxed with stirring for 10 h and then left to cool to room temperature overnight under stirring. The reaction mixture was then poured onto iced water and neutralized with dilute hydrochloric acid. The resulting precipitate was collected by filtration, washed several times with water and recrystallized from DMF to give pale brown crystals of the thione derivative **16** (0.55 g; 75%), mp 285–288°C; IR (ν/cm$^{-1}$): 3305–3110 (NH), 2225 (CN), 1700 (CO), 1395 (C=S); $^1$H NMR (δ ppm): 6.64 (dd, 1H, $J$ = 1.6, 3.7 Hz, furan H-4), 7.26 (d, 1H, $J$ = 3.7 Hz, furan H-3), 7.80 (d, 1H, $J$ = 1.6 Hz, furan H-5), 8.40 (s, 1H, pyrimidine H-5), 9.55 (s, 1H, NH, $D_2O$-exchangeable); Anal. Calcd. for $C_{14}H_5N_7O_2S_2$ (367.372): C, 45.77; H, 1.37; N, 26.69; S, 17.46. Found: C, 45.60; H, 1.27; N, 26.39; S, 17.36.

***Method B.*** A mixture of compound **8a** (0.002 mol) and carbon disulfide (0.02 mol) in dry pyridine (10 mL) was heated under reflux for 6 h. The precipitated crystals were filtered off, dried, and recrystallized from DMF to produce the thione derivative **16** (0.47 g; 64%). Mixed melting points with a sample of **16** prepared from phenyl isothiocyanate according to method A showed no depression. The spectral data of compound **16** obtained from both sources were superimposable.

**9-Cyano-10-(2-furyl)-3,8-dioxo-2,3-dihydro-8*H*-pyrimido[2′,1′:2,3]thiazolo[5,4-*e*][1,2,4]triazolo[4,3-*c*]pyrimidine (17).** To a mixture of dry pyridine (10 mL) and **8a** (0.0012 mol) was carefully added ethyl chloroformate (1 mL, 0.01 mol) and the mixture was refluxed for 48 h. After cooling, the reaction mixture was poured onto iced water containing a few drops of hydrochloric acid. The solid that separated out was filtered off, washed with water several times, dried, and then recrystallized from EtOH to give the dione derivative **17** as a yellow solid (0.38 g; 89%), mp > 300°C; IR (ν/cm$^{-1}$): 3300 (NH), 2221 (CN), 1702, 1680 (2CO); $^1$H NMR (δ ppm): 6.88–7.15 (m, 2H, furan H-3,4), 7.78 (d, 1H, $J$ = 2.0 Hz, furan H-5), 8.11 (s, 1H, pyrimidine H-5), 10.92 (s, br, 1H, NH, $D_2O$-exchangeable); MS: $m/z$ (%) = 351 ($M^+$, 16%); Anal. Calcd. for $C_{14}H_5N_7O_3S$ (351.305): C, 47.87; H, 1.43; N, 27.91; S, 9.13. Found: C, 47.58; H, 1.33; N, 27.74; S, 8.96.

**Ethyl {9-cyano-10-(2-furyl)-8-oxo-8*H*-pyrimido[2′,1′:2,3]thiazolo[5,4-*e*][1,2,4]triazolo[4,3-*c*]pyrimidin-3-yl}acetate (18).** A suspension of compound **8a** (0.002 mol) in diethyl malonate (10 mL) was gently heated under reflux for 10 h. The reaction mixture was triturated with ethanol (15 mL) and then allowed to cool. The formed precipitate was collected by filtration and purified by recrystallization from 1,4-dioxane to give light brown crystals of the ethyl ester **18** (0.58 g; 69%), mp 209–210°C; IR (ν/cm$^{-1}$): 2960, 2835 (aliph. CH), 2223 (CN), 1730, 1698 (2CO); $^1$H NMR (δ ppm): 1.25 (t, 3H, $J$ = 7.2 Hz, ester Me), 4.20 (q, 2H, $J$ = 7.2 Hz, ester $CH_2$), 5.11 (s, 2H, $CH_2CO$), 6.90–7.19 (m, 2H, furan H-3,4), 7.75 (d, 1H, $J$ = 1.9 Hz, furan H-5), 8.70 (s, 1H, pyrimidine H-5); $^{13}$C NMR (δ ppm): 14.0 (ester Me), 34.5 ($CH_2$), 60.7 (ester $CH_2$), 98.7 (C-9), 111.4, 112.5 (furan C-3,4), 118.3 (CN), 133.1, 138.5, 143.8 (furan C-5), 148.0, 155.6 (furan C-2), 156.3, 158.4, 160.1, 161.6 (ring CO), 166.9, 168.0 (ester CO, C-10); Anal. Calcd. for $C_{18}H_{11}N_7O_4S$ (421.395): C, 51.30; H, 2.63; N, 23.27; S, 7.61. Found: C, 51.06; H, 2.49; N, 22.99; S, 7.50.

**9-Cyano-10-(2-furyl)pyrimido[2′,1′:2,3]thiazolo[5,4-*e*]tetrazolo[1,5-*c*]pyrimidin-8-one (19).** Compound **8a** (0.003 mol) was dissolved in glacial acetic acid (15 mL) containing concentrated hydrochloric acid (1.5 mL), a small amount of insoluble material was filtered off, then the liquid was cooled in ice bath at 0–5°C. The mixture was stirred at this temperature and treated gradually with a cold saturated solution of sodium nitrite [1g of sodium nitrite (0.015 mol) in water (10 mL)] over a period of 15 min. The mixture was kept in ice bath at 0–5°C with continuous stirring for further 2 h, then it was left to stand overnight at room temperature and diluted with water, whereon precipitation took place. The solid thus formed was isolated by filtration, washed abundantly with cold water, recrystallized from aqueous DMF, and air dried to give the fused tetrazole derivative **19** as a yellow solid (0.58 g; 60%), mp 221–222°C; IR (ν/cm$^{-1}$): 2218 (CN), 1701 (CO); $^1$H NMR (δ ppm): 6.75 (dd, 1H, $J$ = 1.8, 4.0 Hz, furan H-4), 7.30 (d, 1H, $J$ = 4.0 Hz, furan H-3), 7.84 (d, 1H, $J$ = 1.8 Hz, furan H-5), 9.80 (s, 1H, pyrimidine H-5); MS: $m/z$ (%) = 336 ($M^+$, 22%); Anal. Calcd. for $C_{13}H_4N_8O_2S$ (336.288): C, 46.43; H, 1.20; N, 33.32; S, 9.53. Found: C, 46.25; H, 1.12; N, 33.07; S, 9.41.

**Antimicrobial activity.** The preliminary antimicrobial activity of the synthesized tricyclic and tetracyclic derivatives was evaluated *in vitro* by means of the agar-well diffusion assay. The assay was carried out according to the method of Hufford *et al*. [57] with some modifications. A total of 10 test microorganisms were used for the current antimicrobial activity studies: two gram positive bacteria (*Staphylococcus aureus* and *Bacillus cereus*), four gram negative bacteria (*Pseudomonas aeruginosa*, *Escherichia coli*, *Salmonella typhyrium*, and *Klebsiella spp*), and four fungi (*Aspergillus flavus*, *Aspergillus fumigatus*, *Aspergillus niger*, and *Trichoderma horozianum*). The culture media used were Nutrient agar for bacteria and Czapek's agar (Difco) for fungi. Twenty-five milliliters of the specified molten agar (45°C) was aseptically mixed with either 100 μL of a bacterial suspension or 1 mL of a fungal suspension and poured into 15 mm sterile Petri dishes. For the preparation of the inocula colonies of bacteria were suspended in nutrient broth incubated overnight and fungi were suspended in sterile saline solution (NaCl, 0.85%), respectively. Once the agar was hardened, 9-mm wells were bored using a sterile cork borer. One hundred milliliters of the DMF extract (2 μm) were placed into the wells and the plates were incubated for 24 h at 37°C for the bacteria and 24–72 h at 28°C for the fungi. The antimicrobial activity was measured as the diameter (mm) of clear zone of growth inhibition. Solvent controls (DMF) were included in every experiment as negative controls. DMF was used for dissolving the crude extracts and gave negative results, confirming that it did not influence on antimicrobial activity observed for the compounds tested.

**Acknowledgments.** H. M. Gaber would like to express his gratitude and thanks for the Research Fellowship grant in School of Chemistry, Cardiff University, UK, and for all facilities provided to this fellowship. Financial support from Cardiff University, the Engineering and Physical Sciences Research Council (EPSRC) and the Biotechnology and Biological Sciences Research Council (BBSRC), in collaboration with the University of Wales College of Medicine, UK, is gratefully acknowledged.

3,4-Dihydro-2-H-pyran and oxalyl chloride react, depending on the conditions, to keto esters, a pyran-3-carboxylic acid or derivatives thereof, or to an hitherto unknown bicyclic acetal containing a vinyl chloride moiety. The structure of the latter product has been unambiguously elucidated by single-crystal X-ray structure analysis. A mechanism for its formation is proposed.

*J. Heterocyclic Chem.,* **47**, 1171 (2010).

## INTRODUCTION

Despite their structural simplicity, tetrahydropyran-3-carboxylic acid and its esters display interesting biological activities as attractants for cockroaches [1–3]. One approach toward these compounds proceeds via hydrogenation of dihydropyran-3-carboxylic acid derivatives **3**, which are in turn available by trichloroacetoxylation of dihydropyran (**1**) and subsequent methanolysis or basic hydrolysis of the intermediate trichloromethyl ketones **2**, as outlined in Scheme 1 [4–6]. A Cobalt-catalyzed methoxycarbonylation of vinyl bromides has also been investigated, but is less commonly used [7].

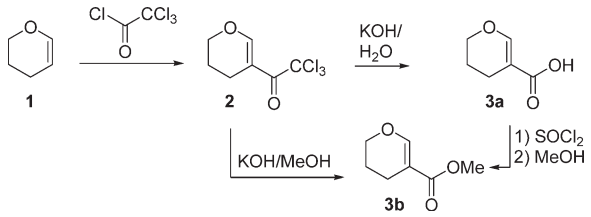
5,6-Dihydro-4*H*-pyran-3-carboxylic acid (**3a**) has also been used as an intermediate in the synthesis of pharmacologically active heterocycles, for example, pyrimidines with activity against cancer [8], anti-inflammatory peptide conjugates [9,10], or fungicides [11]. The corresponding carboxaldehyde is a useful intermediate in the synthesis of renin inhibitors [12] and anti-inflammatory agents [13].

In light of the relevance of dihydropyran-3-carboxylic acid and its derivatives, in particular for the synthesis of heterocycles, we investigated the route described in Scheme 1 in detail. While the carboxylic acid **3a** is indeed conveniently accessible via basic hydrolysis of the trichloromethyl ketone **2**, less satisfactory results were obtained for the methanolysis. However, the ester **3b** is more conveniently synthesized by converting **3a** to its chloride, which is subsequently treated with methanol. We thought that the strongly basic conditions used for the conversion of **2** to **3a** and the additional steps required to obtain the ester **3b** are disadvantageous and therefore sought for a more straightforward alternative.

## RESULTS AND DISCUSSION

The reaction of alkyl vinyl ethers with oxalyl chloride was investigated by Effenberger. Thus, by adjusting the appropriate stoichiometry, symmetrical 1,2-diketones were synthesized in good yields [14]. Later, Tietze *et al.* demonstrated that the intermediate α-keto acid chlorides undergo a clean decarbonylation at temperatures above 100°C to give acyclic *E*-3-alkoxy acryloyl chlorides [15], which are useful intermediates in the synthesis of heterocycles [16]. This approach should also be applicable to dihydropyran-3-carboxylic acid (**3a**) and its derivatives, with dihydropyran (**1**). In contrast to the established two- to four-step route depicted in Scheme 1, this

**Scheme 1.** Established routes to tetra- and dihydropyran-3-carboxylic acids.



synthesis might potentially be conducted as a one-pot reaction. A literature search revealed that the reaction of dihydropyran (**1**) with oxalyl chloride followed by treatment with methanol gives exclusively the α-keto ester **4**, which was used as a substrate in hetero-Diels-Alder reactions [17,18]. However, this transformation was not documented in full detail in the literature, and we therefore decided to start at this point. We could indeed obtain **4** in fair yield if **1** was treated with 1.5 equivalents of oxalyl chloride at low-temperature, followed by the addition of methanol. Next, we tried to synthesize methyl ester **3b** by inducing a decarbonylation before methanolysis. To this end, the reaction mixture was heated to 120°C, after the addition of the oxalyl chloride. To our surprise, the desired ester **3b** was only obtained as a minor product. The major product showed an $M^+$ signal at $m/z = 174$, with the characteristic isotopic pattern for compounds with one chlorine atom. In the IR spectrum absorptions at 1793 $cm^{-1}$ and 1771 $cm^{-1}$ suggested the presence of a lactone moiety. On the basis of the information gathered from NMR- and mass spectra, a molecular formula of $C_7H_7O_3Cl$ was deduced. From the $^1$H-NMR spectra, it became obvious that the six-membered oxacycle was still intact and that the protons of the $CH_2$-groups are no longer chemically equivalent, but are diastereotopic. This is indicative for the formation of a new stereogenic center in the course of the reaction. In the $^{13}$C-NMR-spectrum two signals arising from quaternary olefinic carbon atoms at 166 ppm and 118 ppm, and a signal at 98 ppm were observed. The latter was interpreted as a cyclic acetal carbon. The proton that is attached to this carbon atom was observed at 5.59 ppm as a singlet. Notably, no methanol was incorporated in the molecule. From this information, we tentatively assigned the bicyclic structure **5** to the new compound (Scheme 2).

Unambiguous proof for this structural assignment came from a single crystal X-ray structure analysis. Compound **5** has the structure of a bicyclic acetal. One chlorine atom is attached to a C-C-double bond, which is in conjugation to the carbonyl group. As the compound crystallizes in the centrosymmetric space group $P\bar{1}$, both enantiomers are found in the cell. Two molecules are present in the asymmetric unit, which are symmetry independent and therefore show slight differences in their structural parameters. Representative bond lengths and angles for both symmetry independent molecules (denoted as A and B) are listed in Table 1. A representation of both symmetry-independent molecules is given in Figure 1.

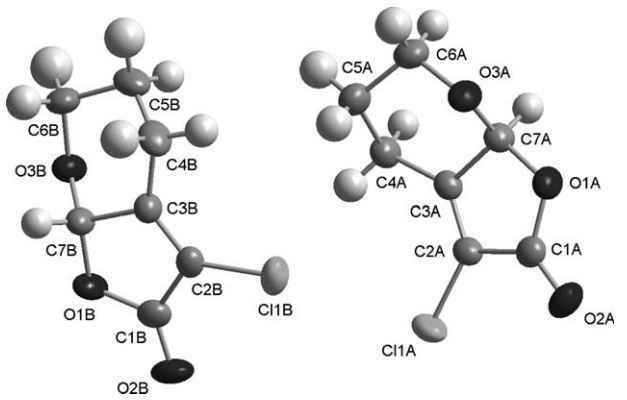

**Figure 1.** Molecular structure of compound **5** with thermal ellipsoids drawn at the 50% probability level.

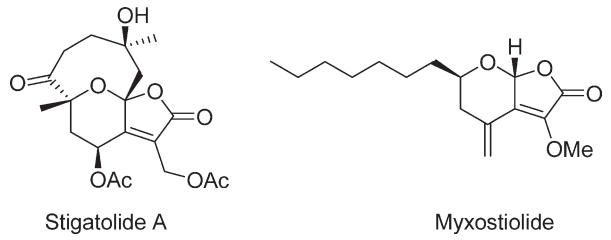

**Figure 2.** Structures of spicatolide A and myxostiliolide.

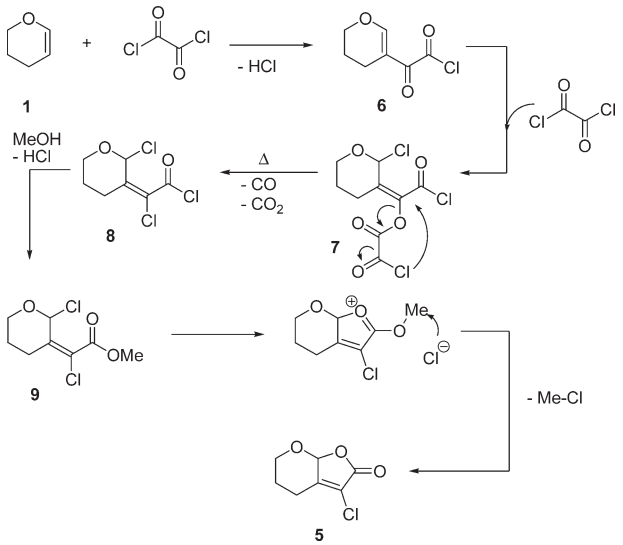
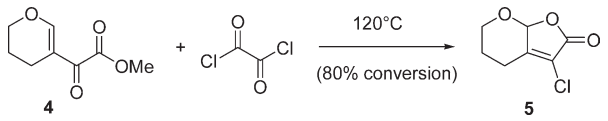
A literature search revealed, that there is ample precedence for bicyclic saturated γ-butyrolactones annellated to six-membered oxacycles. In most cases, these products result from an addition of 1,3-dicarbonyl compounds to cyclic enol ethers via a radical pathway [19–25]. In contrast, only comparatively few 3,4-unsaturated bicyclic γ-butyrolactones such as **5** have been described in the literature. Interestingly, this structural pattern is found in some biologically active natural products such as the anti-inflammatory germacranolide spicatolide A [26] or the plant-growth regulator myxostiliolide (Fig. 2) [27].

Elucidation of the mechanism for the formation of **5** is hampered by a lack of isolable intermediates. We propose the following tentative mechanism: in the first step, oxalyl chloride will most likely attack at carbon atom C3 to give the α-keto acid chloride **6**. We assume that now excess oxalyl chloride reacts with one carbonyl oxygen of **6** to give the intermediate vinyl ester **7**. Upon heating, **7** undergoes a fragmentation to CO, $CO_2$, and a vinyl chloride **8**, which is eventually trapped by methanol in the presence of pyridine. Most likely, the sequence is terminated by demethylation of the methyl ester **9** with a chloride ion and intramolecular nucleophilic attack of the carboxylate at the anomeric carbon, resulting in the product **5** (Scheme 3).

**Scheme 3.** Mechanistic proposal for the formation of the unexpected bicyclic acetal **5**.



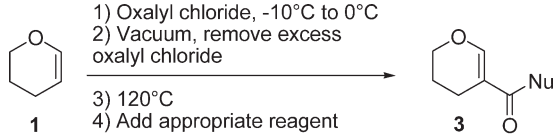
**Scheme 4.** Formation of bicyclic product **5** from keto ester **4**.



It should be noted that the crucial step of this sequence, the formation of the vinyl chloride moiety from a ketone, is not without precedence. A somewhat related reaction was reported for 7-keto steroids, which react with oxalyl chloride in refluxing toluene to vinylic 7-chloro steroids [28]. We do not have definite evidence that the individual steps leading to the formation of **5** indeed proceed in this order. It is, however, quite unlikely that the chlorination of the ketone moiety occurs after methanolysis of the acid chloride, because a considerable amount of the oxalyl chloride would also be destroyed. Strong support for the final demethylation step proposed by us comes from an experiment, in which pure keto ester **4** was treated with oxalyl chloride. After heating the mixture to 120°C, an 80% conversion to the expected bicyclic product **5** was observed by NMR-spectroscopy of the crude reaction mixture. The only other component that could be detected was unreacted starting material **4** (Scheme 4).

From the results discussed above, we concluded that the selective formation of the desired dihydropyran-3-carboxylic acid derivatives **3** requires careful removal of excess oxalyl chloride before the reaction mixture is heated to induce the decarbonylation. This was achieved by applying vacuum at moderately high-temperatures before the mixture is heated to 120°C to induce the decarbonylation. After completion of the decarbonylation step, different nucleophiles were added to obtain the desired derivatives **3**. Thus, with an aqueous solution of $Na_2CO_3$ the carboxylic acid **3a** was obtained, whereas addition of methanol and pyridine gave the ester **3b**. By using diisopropyl amine as a nucleophile,

**Scheme 5.** Synthesis of dihydropyran-3-carboxylic acid derivatives **3** via decarbonylation of α-keto acid chlorides.



| No | Nu | Reagent | Yield |
|---|---|---|---|
| **3a** | -OH | $Na_2CO_3$ (aq) | 78% |
| **3b** | -OMe | MeOH/pyridine | 64% |
| **3c** | $-N(Pr^i)_2$ | $HN(Pr^i)_2/NEt_3$ | 96% |

the expected amide **3c** was obtained in nearly quantitative yield (Scheme 5).

## CONCLUSION

The reaction of oxalyl chloride with dihydropyran, followed by thermal decarbonylation and trapping with an appropriate nucleophile, is a useful alternative synthesis of dihydropyran-3-carboxylic acid derivatives. An unexpected reaction pathway was observed in the course of this synthesis, leading to an interesting bicyclic vinyl chloride. The structure of this product was unambiguously elucidated by X-ray crystal structure analysis.

## EXPERIMENTAL

All reactions were run under an atmosphere of dry nitrogen in dried glassware. Commercial reagents were used as received. Methanol was obtained dried and degassed in a septum bottle under argon and used as received. $^1$H-NMR-spectra were obtained at 300 MHz in $CDCl_3$ with $CHCl_3$ ($\delta = 7.26$ ppm) as an internal standard. Coupling constants are given in Hz. $^{13}$C-NMR spectra were recorded at 75 MHz in $CDCl_3$ with $CDCl_3$ ($\delta = 77.0$ ppm) as an internal standard. IR spectra were recorded as films on NaCl or KBr plates or as KBr-discs. The peak intensities are defined as strong (s), medium (m), or weak (w). Mass spectra were obtained at 70 eV.

**Methyl 2-(5,6-dihydro-4H-pyran-3-yl)-2-oxoacetate (4).** Oxalyl chloride (2.20 mL, 24.9 mmol) was cooled to −10°C. 3,4-Dihydro-2*H*-pyran (**1**, 1.50 mL, 16.6 mmol) was slowly added, and the mixture was warmed to ambient temperature. Stirring at ambient temperature was continued for 12 h, and the mixture was then recooled to 0°C. Triethyl amine (4.60 mL, 33.2 mmol) followed by methanol (1.40 mL, 33.2 mmol) were slowly added. Water was added to the reaction mixture, which was then extracted with dichloromethane, dried with $Na_2SO_4$, filtered, and evaporated. The residue was purified by chromatography on silica (eluent hexane/MTBE mixtures of increasing polarity) to give the title compound **4** (1.32 g, 47%) as a colourless oil. Analytical data match those reported in the literature [29]. $^1$H-NMR (500 MHz, $CDCl_3$): δ 7.82 (s, 1H, H-2), 4.14 (t, 2H, $J = 5.2$ Hz, H-6), 3.83 (s, 3H, OMe), 2.28 (t, 2H, $J = 6.2$ Hz, H-4), 1.87 (m, 2H, H-5); $^{13}$C-NMR (75 MHz, $CDCl_3$): δ 184.3 (O=*C*—COOMe), 163.9 (*C*OOMe), 163.4 (C-2), 114.1 (C-3), 67.8 (C-6), 52.4 (OMe), 20.5, 17.4 (C-4, C-5); IR: 1731 (s), 1653 (m), 1599 (s), 1172 (s) cm$^{-1}$; MS (EI): *m*/*z* 170 ($M^+$), 111 ($M^+$-$CO_2$Me), 83.

**3-Chloro-5,6-dihydro-4*H*-furo[2,3-b]pyran-2-(7a*H*)-one (5).** Oxalyl chloride (2.00 mL, 23.2 mmol) was cooled to −10°C. 3,4-Dihydro-2*H*-pyran (**1**, 1.40 mL, 15.5 mmol) was slowly added, and the mixture was warmed to ambient temperature. Stirring at ambient temperature was continued for 12 h. The solution was then heated to 120°C for 0.5 h, cooled to ambient temperature, and then to 0°C. Pyridine (1.30 mL) and methanol (0.7 mL) were added and stirring was continued at ambient temperature for 2 h. All volatiles were removed in vacuo, and the residue was purified by chromatography on silica (eluent hexane/MTBE mixtures of increasing polarity). The title compound **5** (1.11 g, 42%) was obtained as a colourless solid, mp 49°C. $^1$H-NMR (300 MHz, $CDCl_3$): δ 5.58 (s, 1H, H-7a), 4.10 (dddm, 1H, $J = 1.9$, 4.1, 12.2 Hz, H-6), 3.76 (dt, 1H, $J = 2.4$, 12.2 Hz, H-6), 2.98 (dm, 1H, $J = 14.5$ Hz, H-4), 2.47 (ddm, 1H, $J = 6.4$, 14.5 Hz, H-4), 1.95 (m, 1H, H-5), 1.77 (ddm, 1H, $J = 4.8$, 12.4 Hz, H-5); $^{13}$C-NMR (75 MHz, $CDCl_3$): δ 165.6 (C-2), 156.5 (C-3a), 118.4 (C-3), 98.1 (C-7a), 65.3 (C-6), 25.7, 23.9 (C-4, C-5); IR: 1793, 1771, 1086, 990 cm$^{-1}$; MS: *m*/*z* 176/174 ($M^+$), 145/147; Anal. calcd. for $C_7H_7ClO_3$: C, 48.2; H, 4.0. Found: C, 47.9; H, 4.1.

**Single crystal X-ray structure determination of 5.** Suitable crystals were obtained by dissolving a sample of **5** in dichloromethane and slowly evaporating the solvent at 4°C in an open vessel. Single-crystal diffraction data were measured at 210 K on an imaging plate diffraction system IPDS-II (Stoe) using graphite-monochromated Mo-$K_\alpha$ radiation ($\lambda = 0.71073$ Å). One hundred eighty frames were collected with ω scan widths of 0.5° and 3 min exposure times. The data were corrected by a spherical absorption correction using the program X-Area [30] as well as for Lorentz, polarization and extinction effects. Crystal data: $C_7H_7ClO_3$, $M_r = 174.58$, space group $P\bar{1}$, $a = 8.4324(16)$ Å, $b = 8.6447(17)$ Å, $c = 10.8716(19)$ Å, $\alpha = 77.477(15)°$, $\beta = 78.056(15)°$, $\gamma = 76.460(15)°$, $V = 741.9(2)$ Å$^3$, $Z = 4$, $d_{calc} = 1.563$ g·cm$^{-3}$, colorless block, 0.55 × 0.31 × 0.19 mm, $\mu = 0.464$ mm$^{-1}$, 4819 total reflections ($2\theta_{max} = 50.00°$), 2452 independent ($R_{int} = 0.0571$), 1854 observed [$I < 2\sigma(I)$], 256 parameters. Final $R1$ [$I < 2\sigma(I)$] = 0.0393, $wR2$ (all data) = 0.0947, $S = 0.955$, largest difference peak and hole 0.272 and −0.220 e·Å$^3$. The structure was solved by direct methods using the SHELXS-97 [31] program and refined by full-matrix least-squares of $F^2$ using the program SHELXL-97 [32]. All nonhydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms were located in a difference Fourier map. CCDC 755365 contains the supplementary crystallographic data for this compound. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

**5,6-Dihydro-4H-pyran-3-carboxylic acid (3a).** Oxalyl chloride (3.60 mL, 41.5 mmol) was cooled to 0°C, and 3,4-dihydro-2*H*-pyran (**1**, 2.50 mL, 27.7 mmol) was added. The solution was slowly warmed to ambient temperature and stirring was continued for 1 h. Excess oxalyl chloride was evaporated in vacuo (10 mbar) at 30°C. The mixture was then heated to 120°C for 0.5 h, cooled to ambient temperature, and poured into an ice-cold aqueous solution of $Na_2CO_3$. The alkaline solution was extracted with dichloromethane, and then acidified with hydrochloric acid (6 M). The aqueous layer was extracted with dichloromethane, and the organic solution was dried with $MgSO_4$, filtered, and evaporated to yield the title compound **3a** (2.76 g, 78%) as a colourless solid, mp 72–74°C. Analytical data match those reported in the literature [5]. $^1$H-NMR (300 MHz, $CDCl_3$): δ 10.42 (bs, 1H, COOH), 7.69 (s, 1H, H-2), 4.07 (t, 2H, $J = 5.2$ Hz, H-6), 2.23 (dt, 2H, $J = 6.5$, 1.2 Hz, H-4), 1.86 (m, 2H, H-5); $^{13}$C-NMR (75 MHz, $CDCl_3$): δ 173.4 (C=O), 157.4 (C-2), 105.1 (C-3), 66.8 (C-6), 20.9, 18.8 (C-4-5); IR: 1661 (s), 1623 (s), 1431 (s), 1175 (s) cm$^{-1}$; MS (EI): *m*/*z* 128 ($M^+$), 83 ($M^+$-$CO_2$H), 55; Anal. calcd. for $C_6H_8O_3$: C, 56.3; H, 6.3. Found: C, 56.3; H, 6.2.

**Methyl 5,6-dihydro-4H-pyran-3-carboxylate (3b).** Oxalyl chloride (3.60 mL, 41.5 mmol) was cooled to 0°C, and 3,4-dihydro-2H-pyran (**1**, 2.50 mL, 27.7 mmol) was added. The solution was slowly warmed to ambient temperature and stirring

was continued for 1 h. Excess oxalyl chloride was evaporated in vacuo (10 mbar) at 30°C. The mixture was then heated to 120°C for 0.5 h, and subsequently cooled to ambient temperature. A mixture of methanol (2.60 mL, 64.2 mmol) and pyridine (5.00 mL) was added, and the solution was stirred at ambient temperature for 12 h. All volatiles were evaporated, and the residue was purified by chromatography on silica (eluent hexane/MTBE mixtures of increasing polarity) to give the title compound **3b** (2.52 g, 64%) as a colourless liquid. The compound was found to be sufficiently pure by $^1$H-NMR spectroscopy, although repeated attempts to obtain microanalytical data within the usual limits were unsuccessful. Analytical data match those reported in the literature [6]. $^1$H-NMR (300 MHz, $CDCl_3$): δ 7.52 (s, 1H, H-2), 3.99 (t, 2H, $J$ = 5.3 Hz, H-6), 3.65 (s, 3H, OMe), 2.21 (t, 2H, $J$ = 6.4 Hz, H-4), 1.82 (m, 2H, H-5); $^{13}$C-NMR (75 MHz, $CDCl_3$): δ 168.1 (C=O), 155.3 (C-2), 105.7 (C-3), 66.5 (C-6), 50.9 (OMe), 21.0, 19.1 (C-4-5); IR: 1700 (s), 1628 (s), 1261 (s), 1171 (s) cm$^{-1}$; MS: $m/z$ 142 ($M^+$), 111 ($M^+$-OMe), 83 ($M^+$-$CO_2$Me), 55.

***N*,*N*-Diisopropyl-5,6-dihydro-4H-pyran-3-carboxamide (3c).** Oxalyl chloride (1.40 mL, 16.6 mmol) was cooled to 0°C, and 3,4-dihydro-2H-pyran (**1**, 1.00 mL, 11.0 mmol) was added. The solution was slowly warmed to ambient temperature and stirring was continued for 1 h. Excess oxalyl chloride was evaporated in vacuo (10 mbar) at 30°C. The mixture was then heated to 120°C for 0.5 h, and subsequently cooled to ambient temperature. A mixture of diisopropyl amine (3.00 mL, 21.2 mmol) and triethyl amine (3.00 mL) was added, and the solution was stirred at ambient temperature for 12 h. All volatiles were evaporated, and the residue was purified by chromatography on silica (eluent hexane/MTBE mixtures of increasing polarity) to give the title compound **3c** (2.25 g, 96%) as a highly viscous oil. The compound was found to be sufficiently pure by $^1$H-NMR spectroscopy. Repeated attempts to purify the compound by crytallization were unsuccessful. $^1$H-NMR (300 MHz, $CDCl_3$): δ 6.46 (s, 1H, H-2), 3.88 (t, 2H, $J$ = 5.1 Hz, H-6), 3.73 (sept, 2H, $J$ = 6.8 Hz, C*H*-$Me_2$), 2.12 (t, 2H, $J$ = 6.2 Hz, H-4), 1.79 (m, 2H, H-5), 1.16 (d, 12 H, $J$ = 6.8 Hz, Me); $^{13}$C-NMR (75 MHz, $CDCl_3$): δ 170.3 (C=O), 143.6 (C-2), 111.3 (C-3), 65.3 (C-6), 47.8 (2*C*H-$Me_2$), 21.5, 21.1 (C-4-5), 20.8 (4*Me); IR: 1612 (s), 1434 (s), 1157 (s)1029 (s) cm$^{-1}$; MS: $m/z$ 211 ($M^+$), 111 [$M^+$-CO($NPr^i$)$_2$].

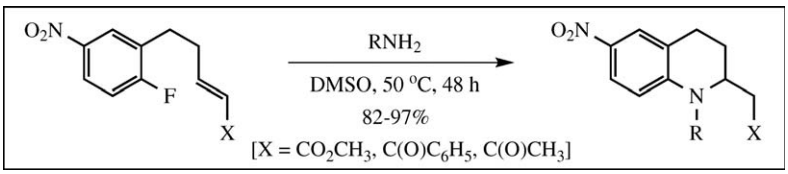
Published online 26 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



A synthesis of ester- and ketone-substituted (±)-1-alkyl-6-nitro-1,2,3,4-tetrahydroquinolines has been developed from 2-pentenoates and 2-penten-1-ones substituted at C5 by a 2-fluoro-5-nitrophenyl group. The cyclization involves an $S_NAr$ reaction followed by a Michael addition that occurs *exo* to the final ring. A previously reported version of this annulation proceeded by an initial *endo* Michael addition (acceptor became part of the final ring) followed by an $S_NAr$ ring closure. The current reactions proceed in 82–97% yields in DMSO using primary amines that are unbranched at the α carbon. The synthesis of the reaction substrates as well as process optimization, mechanistic studies to elucidate the reaction chronology and comparisons with the *endo* Michael variant are presented.

*J. Heterocyclic Chem.*, **47**, 1176 (2010).

## INTRODUCTION

We recently described the use of a tandem Michael-$S_NAr$ reaction sequence for the preparation of 1-alkyl-2,3-dihydro-1(4*H*)-quinolinones [2]. In that initial report, the Michael reaction occurred *via* an *endo* pathway such that the acceptor moiety became part of the final ring [3]. In the current project, we have employed a similar process to prepare ester- and ketone-substituted (±)-1-alkyl-6-nitro-1,2,3,4-tetrahydroquinolines [4,5], but the Michael reaction occurs *exo* to the final ring. These strategies offer efficient and potentially valuable routes to new members of this important family of heterocycles.

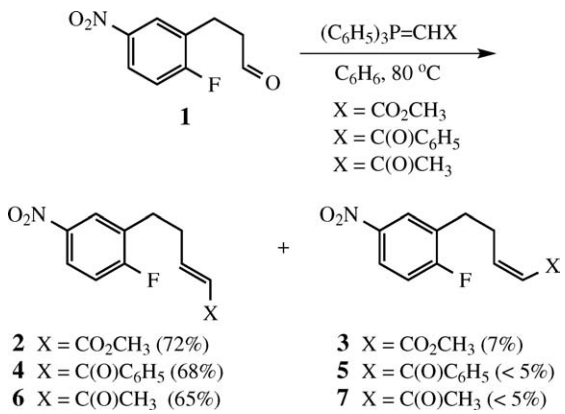
Tetrahydroquinolines are widely distributed in nature [6] and comprise the core structure in numerous pharmaceutical agents [7,8]. Specifically, tetrahydroquinoline-2-acetic esters have been used in the synthesis of 9-azasteroid antimycotic agents [7a], pyrrolobenzodiazepine antitumor antibiotics [7b], and quinoxalinediones for limiting neuronal damage in stroke and heart attack victims [8]. Efficient access to new tetrahydroquinoline derivatives bearing alternative substitution patterns could potentially yield new drugs with improved bioactivities.

## RESULTS AND DISCUSSION

The synthesis of our cyclization substrates is shown in Scheme 1. Treatment of 3-(2-fluoro-5-nitrophenyl)propanal (**1**) [5e,f] with (carbomethoxymethylene)triphenylphosphorane in benzene at reflux for 12 h gave methyl (*E*)-5-(2-fluoro-5-nitrophenyl)-2-pentenoate (**2**) in 72% yield and its double bond isomer **3** in 7% yield following purification. The unsaturated ketones **4** and **6** were formed in 68 and 65% yields, respectively, almost exclusively as the *E* isomers by reacting **1** with (benzoylmethylene)triphenylphosphorane and (acetylmethylene)-triphenylphosphorane.

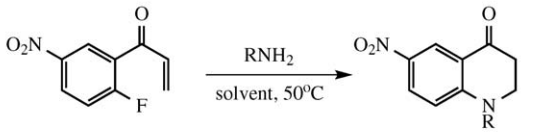
Our cyclization study sought to demonstrate the feasibility of preparing 1-alkyl-6-nitro-1,2,3,4-tetrahydroquinolines from substrates **2**, **4**, and **6** and primary amines by a tandem sequence involving the Michael and $S_NAr$ reactions. In contrast to our earlier report [2], where Michael addition occurred to an acceptor that became

**Scheme 1.** Synthesis of the cyclization substrates.

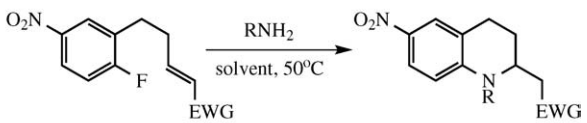


**Scheme 2.** Endo and Exo cyclization.

A. *Endo*: Michael acceptor becomes part of the developing ring [2]



B. *Exo*: Michael acceptor remains outside of ring



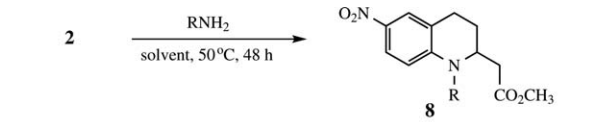
EWG = electron withdrawing group

part of the final ring (*endo* addition), the current reaction requires addition to an acceptor that remains *exo* to the ring [3] (Scheme 2). The success of this process would dramatically expand the scope of this annulation method.

We began our study by reacting unsaturated ester **2** with a series of primary amines in *N*,*N*-dimethylformamide (DMF) at 50°C. This protocol had proven successful in earlier reactions of this type. The reaction proceeded in reasonable yields of 64–81%, but the product was always accompanied by 5–10% of recovered starting material along with 2–4% of a product resulting from amine exchange with the solvent [9] and substitution of dimethylamine on the activated aromatic ring. In most cases, this substitution product was readily removed by preparative thin layer chromatography, but we sought a method that would provide the tetrahydroquinoline without this contaminant. Further experimentation showed that dimethyl sulfoxide (DMSO) was a superior solvent for this reaction and gave higher yields of the heterocycle without the dimethylamine substitution product [10].

The reaction is run by dissolving 1.00 eq of the ketone in DMSO, then adding 1.25 eq of the amine and stirring at 50°C for 48 h. Optimum yields are obtained when one additional 0.10-eq portion of the amine is added to the reaction after the first 24 h. The amine must be primary since it must react at two sites within the molecule. A major limitation of the current process is its sensitivity to steric hindrance near the nitrogen. Amines with branching at the α carbon gave tetrahydroquinolines in lower yields along with numerous other products [11]. Higher temperatures and longer reaction times in these cases yielded complex mixtures that could not be separated.

The results of our current study with ester **2** are summarized in Figure 1 and show the comparison of yields obtained in DMF and DMSO. Reaction of **2** with unbranched primary amines gave the target tetrahydroquinolines **8a-d** in 64–81% yields in DMF and in 82–93% yield in DMSO. Using the optimized conditions in DMSO, more hindered amines, such as cyclohexylamine, gave tetrahydroquinoline **8e** in significantly lower yield (48%), with the remainder being $S_NAr$ product **9** (23%) and recovered **2** (5%).



**8**

| R | DMF Yield of **8** (%)[a,b] | DMSO Yield of **8** (%)[a,b] |
|---|---|---|
| Unbranched | | |
| **a** $C_6H_5CH_2$ | 72 | 88 |

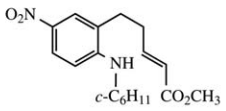
| **d** $(CH_3)_2CHCH_2$ | 75 | 82 |
| Branched | | |
| **e** *c*-$C_6H_{11}$ | 11[c] | 48[c] |

[a]Each reaction also gave 5-10% of recovered starting material.
[b]These reactions also gave 2–4% of a product arising from amine exchange with solvent and substitution of dimethylamine on the aromatic ring.
[c]Compound **9** was also isolated.



**9**

**Figure 1.** Cyclization of **2** and solvent study.

Further cyclization results with ketones **4** and **6** are shown in Figure 2. Using our standard protocol in DMSO solvent, the annulation with ketones proceeded somewhat better than for the ester substrate, giving the products in 88–97% yield. Again, the yields dropped precipitously when the amine was branched at the α carbon.

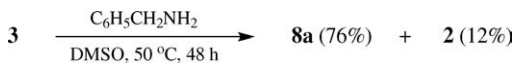
[a]Major product from a complex reaction mixture.

**Figure 2.** Cyclization of ketones **4** and **6**.

**Scheme 3.** Cyclization of *Z* substrate **3**.

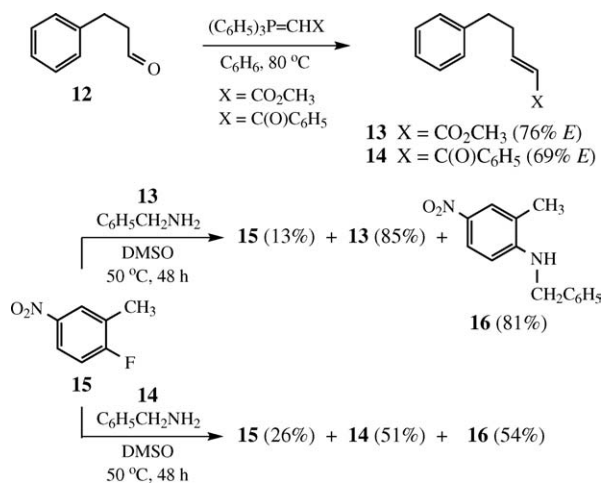


Finally, in an additional experiment, reaction of benzylamine with the *Z* substrate **3** in DMSO was attempted (Scheme 3). This reaction proceeded to give tetrahydroquinoline **8a** in slightly lower yield (76%) than that isolated from the corresponding *E* substrate **2** (88%). Interestingly, the unsaturated ester recovered from this reaction (12%) proved to be **2** rather than **3**. This observation provides experimental evidence for the reversibility of the Michael addition under the reaction conditions used [12].

The isolation of the $S_NAr$ product from the reaction of cyclohexylamine with the unsaturated ester substrates suggests that the $S_NAr$ reaction initiates the current annulation sequence [12]. The reaction chronology is less clear in the case of the ketones. Ketones are better Michael acceptors [13], but are also susceptible to other condensative processes. Thus, cyclohexylamine gave a much more complex product mixture in reactions with these substrates and it was not possible to identify the other products.

In an effort to elucidate the reaction chronology, competitive reaction studies were carried out (Scheme 4) using unsaturated ester **13** and ketone **14**, prepared from 3-phenylpropanal (**12**). These substrates lack the aromatic substitution necessary for the $S_NAr$ reaction [10], and thus, can only undergo a Michael addition. If these are reacted with benzylamine in the presence of 2-fluoro-5-nitrotoluene (**15**), it should be possible to observe whether the Michael addition or the $S_NAr$ process occurs faster in compounds having reactive environments similar to those found in our annulation substrates. Thus, in separate experiments, **13** and **14** were heated at 50°C with **15** and benzylamine in DMSO for 48 h. In each case, workup resulted in isolation of the $S_NAr$ product, *N*-benzyl-2-methyl-4-nitroaniline (**16**), with none of the Michael product detected. The mass balance in the reaction of ester **13** was high, while the more reactive ketone **14** gave a lower return of **16** and unreacted material. Thus, it seems clear that the $S_NAr$ reaction initiates the annulation process for the ester, but the scenario is less certain for the ketone. Though we did not detect the product from conjugate addition of benzylamine to **14**, a reverse Michael reaction [13] from such an adduct followed by reaction of the free amine with **15** could deliver the observed $S_NAr$ product **16**.

**Scheme 4.** Synthesis of **13** and **14** and their competitive reactions with benzylamine in the presence of **15**.



## CONCLUSION

We have developed an approach to the synthesis of (±)-1-alkyl-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetates based on a tandem Michael-$S_NAr$ reaction. The reaction gives high yields in many cases but is sensitive to steric hindrance, with branching at the α carbon of the amine dramatically lowering the yield. Observations from the study suggest that the $S_NAr$ reaction initiates the annulation sequence, and this is supported by a competitive reaction study. However, because the Michael reaction is reversible, our study does not provide incontrovertible proof of this assertion. The current study broadens the scope of tandem reactions involving the $S_NAr$ and Michael reactions to include cyclizations that involve an *exo* Michael process.

## EXPERIMENTAL

All reactions were run under dry nitrogen. Anhydrous *N*,*N*-dimethylformamide (DMF) and dimethyl sulfoxide (DMSO) were purchased commercially and syringed into reactions where they were used. Reactions were monitored by thin layer chromatography on silica gel GF plates (Analtech 21521). Preparative separations were performed by one of the following methods: (1) flash column chromatography [14] on silica gel (grade 62, 60–200 mesh) containing UV-active phosphor (Sorbent Technologies UV-5) packed into quartz columns or (2) preparative thin layer chromatography on 20 cm × 20 cm silica gel GF plates (Analtech 02015). Band elution for all chromatographic methods was monitored using a hand-held UV lamp. Melting points were uncorrected. IR spectra were run as thin films on NaCl disks. $^1H$ and $^{13}C$ NMR spectra were measured in $CDCl_3$ at 300 MHz and 75 MHz, respectively, using tetramethylsilane as the internal standard; coupling constants (*J*) are given in Hz. Unless otherwise indicated, mass spectra (electron impact/direct probe) were obtained at 70 eV.

**General procedure for Wittig olefination: Methyl (*E*)-5-(2-fluoro-5-nitrophenyl)-2-pentenoate (2) and methyl (*Z*)-5-(2-fluoro-5-nitrophenyl)-2-pentenoate (3).** A 100 mL benzene solution of 1.00 g (5.08 mmol) of 3-(2-fluoro-5-nitrophenyl)propanal (**1**) [5e,f] and 3.35 g (10.0 mmol) of (methoxycarbonylmethylene)triphenylphosphorane was heated under reflux for 12

h, then cooled and concentrated under vacuum. Flash chromatography of the resulting material on a 30 cm × 2.5 cm column eluted with 5% ether in hexanes gave two bands: band 1, 0.09 g (7%) of **3** as a light yellow solid, mp 58–60°C; band 2, 0.92 g (72%) of **2** as a light yellow oil. The spectral data for **2** were: IR: 1714, 1655, 1521, 1350, 1244 $cm^{-1}$; $^1H$ NMR: δ 8.14 (m, 2H), 7.18 (t, 1H, $J$ = 9.0), 6.97 (dt, 1H, $J$ = 15.9, 6.6), 5.87 (dt, 1H, $J$ = 15.9, 1.1), 3.73 (s, 3H), 2.90 (t, 2H, $J$ = 7.5), 2.58 (q, 2H, $J$ = 7.5); $^{13}C$ NMR: δ 166.6, 164.6 (d, $J$ = 256.5), 146.4, 144.3, 129.4 (d, $J$ = 18.8), 126.2 (d, $J$ = 6.9), 124.2 (d, $J$ = 10.3), 122.4, 116.3 (d, $J$ = 25.2), 51.1, 31.8, 27.5. *Anal*. **(*E*)-6-(2-Fluoro-5-nitrophenyl)-3-hexen-2-one (6).** This compound was prepared as above from 1.00 g (5.08 mmol) of **1** and 3.18 g (10.0 mmol) of (acetylmethylene)triphenylphosphorane. Purification by flash chromatography on a 30 cm × 2.5 cm column eluted with 5–10% ether in hexanes afforded 0.78 g (65%) of **6** as a light yellow oil. IR: 1675, 1630, 1528, 1351, 1248 $cm^{-1}$; $^1H$ NMR: δ 8.14 (m, 2H), 7.20 (t, 1H, $J$ = 9.3), 6.81 (dt, 1H, $J$ = 15.9, 7.1), 6.10 (d, 1H, $J$ = 15.9), 2.93 (t, 2H, $J$ = 7.7), 2.60 (q, 2H, $J$ = 7.1), 2.26 (s, 3H); $^{13}C$ NMR: δ 198.1, 164.5 (d, $J$ = 256.5), 145.0, 144.2, 132.2, 129.3 (d, $J$ = 18.0), 126.2 (d, $J$ = 6.9), 124.2 (d, $J$ = 10.3), 116.3 (d, $J$ = 25.2), 32.1, 27.5, 27.0. *Anal*. Calcd for $C_{12}H_{12}FNO_3$: C, 60.76; H, 5.06; N, 5.91. Found: C, 60.69; H, 5.04; N, 5.94. A small amount of **7**, contaminated with **6**, was isolated, but not used.

**General procedure for the tandem $S_NAr$-Michael reaction: Methyl (±)-1-benzyl-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetate (8a).** To a solution of 61 mg (0.24 mmol) of **2** in 2 mL of anhydrous DMSO was added 32 mg (0.033 mL, 0.30 mmol) of benzylamine. The reaction was stirred at 50°C for 48 h; one additional 0.10 mmol portion (0.011 mL) of the amine was added to the reaction after the first 24 h. The reaction was cooled and added to 20 mL of aqueous NaCl and extracted with 20 mL of ether (3×). The combined ether layers were washed with 20 mL of aqueous NaCl (1×), dried ($MgSO_4$) and concentrated under vacuum to give a yellow oil. Preparative thin layer chromatography on a 20 cm × 20 cm plate eluted with 20% ethyl acetate in hexanes afforded two major bands: band 1, 5 mg (8%) of recovered starting material; band 2, 72 mg (88%) of **8a** as a yellow solid, mp 135–138°C. IR: 1734, 1510, 1321 $cm^{-1}$; $^1H$ NMR: δ 7.94 (s, 1H), 7.86 (d, 1H, $J$ = 9.3), 7.38–7.23 (complex, 3H), 7.16 (d, 2H, $J$ = 7.1), 6.40 (d, 1H, $J$ = 9.3), 4.72 (d, 1H, $J$ = 17.3), 4.62 (d, 1H, $J$ = 17.3), 4.09 (apparent sextet, 1H, $J$ = 4.2), 3.67 (s, 3H), 3.03–2.80 (complex, 2H), 2.70 (dd, 1H, $J$ = 15.4, 4.9), 2.57 (dd, 1H, $J$ = 15.4, 8.8), 2.06 (m, 2H); $^{13}C$ NMR: δ 171.3, 149.1, 137.1, 136.4, 128.9, 127.4, 126.0, 125.2, 124.3, 120.5, 110.6, 55.4, 53.8, 51.9, 37.8, 24.6, 23.1; ms: $m/z$ 249 ($M^+$-$C_7H_7$). *Anal*. Calcd for $C_{19}H_{20}N_2O_4$: C, 67.06; H, 5.88; N, 8.24. Found: C, 67.09; H, 5.91; N, 8.20.

For reactions run in DMF, 2 mL of dry DMF was substituted for DMSO. The yields are given in Figure 1. These reactions all gave 5–10% of recovered substrate as well as 2–4% of a product resulting from amine exchange with the solvent and substitution of dimethylamine on the aromatic ring. This product was identified by $^1H$ NMR, but could not be isolated in pure form.

**Tandem $S_NAr$-Michael reaction using the *Z* substrate: Methyl (±)-1-benzyl-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetate (8a).** This same procedure was carried out using 50 mg (0.20 mmol) of **3** and a total of 28 mg (0.029 mL, 0.27 mmol) of benzylamine in 2 mL of anhydrous DMSO to give 52 mg (76%) of **8a** along with 6 mg (12%) of **2**. The spectral data for these two materials matched those given above.

**Methyl (±)-1-(2-phenylethyl)-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetate (8b).** This compound was prepared from 61 mg (0.24 mmol) of **2** and a total of 48 mg (0.050 mL, 0.40 mmol) of phenethylamine. Purification by preparative thin layer chromatography eluted with 20% ethyl acetate in hexanes gave 71 mg (84%) of **8b** as a yellow oil. IR: 1734, 1510, 1322 $cm^{-1}$; $^1H$ NMR: δ 8.02 (dd, 1H, $J$ = 9.3, 2.7), 7.93 (d, 1H, $J$ = 2.2), 7.38–7.22 (complex, 3H), 7.19 (d, 2H, $J$ = 7.2), 6.62 (d, 1H, $J$ = 9.3), 3.80 (ddd, 1H, $J$ = 14.8, 7.7, 4.9), 3.73 (obscured m, 1H), 3.70 (s, 3H), 3.47 (dt, 1H, $J$ = 14.8, 8.2), 3.02–2.68 (complex, 4H), 2.55 (dd, 1H, $J$ = 15.4, 5.5), 2.42 (dd, 1H, $J$ = 15.4, 8.8), 1.83 (dm, 1H, $J$ = 13.8), 1.66 (m, 1H); $^{13}C$ NMR: δ 171.5, 148.4, 138.2, 136.7, 128.75, 128.70, 126.8, 125.5, 124.5, 120.4, 109.5, 55.2, 51.9 (2C), 37.5, 33.0, 24.2, 22.9; ms: $m/z$ 263 ($M^+$-$C_7H_7$). *Anal*. Calcd for $C_{20}H_{22}N_2O_4$: C, 67.80; H, 6.21; N, 7.91. Found: C, 67.84; H, 6.24; N, 7.79.

**Methyl (±)-1-hexyl-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetate (8c).** This compound was prepared from 61 mg (0.24 mmol) of **2** and a total of 40 mg (0.053 mL, 0.40 mmol) of hexylamine. Purification by preparative thin layer chromatography eluted with 5% ethyl acetate in hexanes gave 75 mg (93%) of **8c** as a yellow oil. IR: 1736, 1510, 1321 $cm^{-1}$; $^1H$ NMR: δ 7.97 (dd, 1H, $J$ = 9.2, 2.7), 7.90 (d, 1H, $J$ = 2.2), 6.49 (d, 1H, $J$ = 9.2), 3.96 (m, 1H), 3.72 (s, 3H), 3.51 (ddd, 1H, $J$ = 14.8, 8.2, 5.5), 3.20 (dt, 1H, $J$ = 14.8, 8.2), 2.94–2.70 (complex, 2H), 2.62 (dd, 1H, $J$ = 15.4, 4.9), 2.48 (dd, 1H, $J$ = 15.4, 8.8), 1.98 (dm, 1H, $J$ = 13.7), 1.87 (m, 1H), 1.62 (m, 2H), 1.33 (m, 6H), 0.90 (distorted t, 3H, $J$ = 6.6); $^{13}C$ NMR: δ 171.5, 148.8, 136.3, 125.4, 124.5, 120.2, 109.5, 54.8, 51.9,

50.3, 37.5, 31.5, 26.8, 26.6, 24.4, 22.9, 22.6, 14.0; ms: *m/z* 263 ($M^+$-$C_5H_{11}$). *Anal*. Calcd for $C_{18}H_{26}N_2O_4$: C, 64.67; H, 7.78; N, 8.38. Found: C, 64.78; H, 7.82; N, 8.29.

**Methyl (±)-1-isobutyl-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetate (8d).** This compound was prepared from 61 mg (0.24 mmol) of **2** and a total of 29 mg (0.040 mL, 0.40 mmol) of hexylamine. Purification by preparative thin layer chromatography eluted with 5% ethyl acetate in hexanes gave 60 mg (82%) of **8d** as a yellow oil. IR: 1735, 1510, 1321 $cm^{-1}$; $^1H$ NMR δ 7.95 (dd, 1H, $J$ = 9.3, 2.7), 7.92 (s, 1H), 6.48 (d, 1H, $J$ = 9.3), 3.96 (apparent sextet, 1H, $J$ = 4.4), 3.72 (s, 3H), 3.50 (dd, 1H, $J$ = 14.3, 4.9), 3.00–2.75 (complex, 3H), 2.58 (dd, 1H, $J$ = 15.4, 5.5), 2.45 (dd, 1H, $J$ = 15.4, 8.8), 2.12 (m, 1H), 1.99 (m, 2H), 0.97 (d, 3H, $J$ = 6.6), 0.95 (d, 3H, $J$ = 6.6); $^{13}C$ NMR δ 171.6, 149.0, 136.5, 125.6, 124.2, 119.9, 110.0, 57.8, 55.7, 52.0, 36.6, 26.6, 24.0, 22.7, 20.1; ms: *m/z* 263 ($M^+$-$C_3H_7$). *Anal*. Calcd for $C_{16}H_{22}N_2O_4$: C, 62.75; H, 7.19; N, 9.15. Found: C, 62.84; H, 7.22; N, 9.09.

**Methyl (±)-1-cyclohexyl-6-nitro-1,2,3,4-tetrahydroquinoline-2-acetate (8e).** This compound was prepared from 61 mg (0.24 mmol) of **2** and a total of 39 mg (0.046 mL, 0.40 mmol) of cyclohexylamine. Purification by preparative thin layer chromatography eluted with 5% ethyl acetate in hexanes gave 38 mg (48%) of **8e** as a yellow solid, mp 94–96°C. IR: 1734, 1510, 1321 $cm^{-1}$; $^1H$ NMR: δ 7.96 (dd, 1H, $J$ = 9.3, 2.7), 7.93 (s, 1H), 6.68 (d, 1H, $J$ = 9.3), 4.19 (m, 1H), 3.71 (overlapping m, 1H and s, 3H), 3.00–2.72 (complex, 3H), 2.53 (dd, 1H, $J$ = 15.4, 9.3), 2.45 (dd, 1H, $J$ = 15.4, 4.9), 1.95 (m, 5H), 1.74 (m, 3H), 1.58 (m, 1H), 1.40 m, 1H), 1.22 (m, 1H); $^{13}C$ NMR: δ 171.5, 149.5, 136.5, 126.0, 124.1, 120.8, 111.1, 59.0, 51.9, 47.5, 38.4, 31.0, 30.3, 26.1 (2C), 25.5, 24.2, 22.8; MS: *m/z* 332 ($M^+$). *Anal*. Calcd for $C_{18}H_{24}N_2O_4$: C, 65.06; H, 7.23; N, 8.43. Found: C, 64.97; H, 7.19; N, 8.45.

This reaction also afforded 3 mg (5%) of recovered **2** as a light yellow oil and 18 mg (23%) of methyl (*E*)-5-(2-cyclohexylamino-5-nitrophenyl)-2-pentenoate (**9**) as a yellow oil. The spectral data for **9** were: IR: 3397, 1721, 1657, 1532, 1314 $cm^{-1}$; $^1H$ NMR: δ 8.05 (dd, 1H, $J$ = 9.3, 2.7), 7.95 (d, 1H, $J$ = 2.2), 7.02 (dm, 1H, $J$ = 15.4), 6.59 (d, 1H, $J$ = 9.3), 5.92 (d, 1H, $J$ = 15.4), 4.21 (br d, 1H, $J$ = 6.0), 3.74 (s, 3H), 3.43 (m, 1H), 2.59 (apparent 2s, 4H), 2.05 (m, 2H), 1.80 (m, 2H), 1.70 (m, 1H), 1.44 (m, 2H), 1.26 (m, 3H); $^{13}C$ NMR: δ 166.6, 149.9, 147.0, 137.2, 124.9 (2C), 122.9, 122.2, 108.8, 51.6, 51.5, 33.0, 30.3, 28.9, 25.6, 24.7; ms (30 eV): *m/z* 332 ($M^+$). *Anal*. **(*E*)-1,5-Diphenyl-2-penten-1-one (14).** This compound was prepared as described for **2a** from 1.00 g (7.46 mmol) of **12** and (11.2 mmol) of (benzoylmethylene)triphenylphosphorane. Flash chromatography on a 30 cm × 2.5 cm column eluted with 8–12% ether in hexanes gave 1.21 g (69%) of **14** as a yellow oil [15]. IR 1670, 1623 $cm^{-1}$; $^1H$ NMR: δ 7.87 (d, 2H, *J* = 7.4), 7.54 (t, 1H, *J* = 7.4), 7.44 (t, 2H, *J* = 7.4), 7.30 (t, 2H, *J* = 7.4), 7.22 (m, 3H), 7.08 (dt, 1H, *J* = 15.4, 7.1), 6.86 (d, 1H, *J* = 15.4), 2.85 (t, 2H, *J* = 7.1), 2.64 (q, 2H, *J* = 7.1); $^{13}C$ NMR: δ 190.8, 148.4, 140.7, 137.8, 132.6, 128.5, 128.4 (2C), 128.3, 126.5, 126.1, 34.47, 34.44; ms (30 eV): *m*/*z* 236 ($M^+$). *Anal*. Calcd for $C_{17}H_{16}O$: C, 86.44; H, 6.78. Found: C, 86.37; H, 6.74.

**Control experiment: Competitive reaction of benzylamine with 13 and 15.** A mixture of 95 mg (0.50 mmol) of **13**, 75 mg (0.50 mmol) of **15** and 54 mg (0.055 mL, 0.50 mmol) of benzylamine in 3 mL of anhydrous DMSO was heated at 50°C for 48 h. The mixture was cooled, worked up with aqueous NaCl and purified by preparative thin layer chromatography eluted with 10% ethyl acetate in hexanes to give three major bands: band 1, 10 mg (13%) of recovered **15**; band 2: 81 mg (85%) of recovered **13**; band 3, 92 mg (81%) of *N*-benzyl-2-methyl-4-nitroaniline (**16**) as a yellow solid, mp 99–100°C. The spectral data for **16** were: IR: 3417, 1531, 1328 $cm^{-1}$; $^1H$ NMR: δ 8.00 (dd, 1H, *J* = 8.2, 2.2), 7.99 (s, 1H), 7.42–7.30 (complex, 5H), 6.54 (d, 1H, *J* = 8.2), 4.66 (br s, 1H), 4.48 (d, 2H, *J* = 4.9), 2.21 (s, 3H); $^{13}C$ NMR: δ 151.3,

137.4, 134.8, 129.0, 127.8, 127.3, 126.0, 124.6, 121.2, 108.3, 47.8, 17.3; ms: *m*/*z* 151 ($M^+$-$C_7H_7$). *Anal*. Calcd for $C_{14}H_{14}N_2O_2$: C, 69.42; H, 5.79; N, 11.57. Found: C, 69.45; H, 5.79; N, 11.52.

**Control experiment: Competitive reaction of benzylamine with 14 and 15.** A mixture of 118 mg (0.50 mmol) of **14**, 75 mg (0.50 mmol) of **15** and 54 mg (0.055 mL, 0.50 mmol) of benzylamine was reacted, worked up and purified as above to give: band 1, 20 mg (26%) of recovered **15**; band 2: 60 mg (51%) of recovered **14**; band 3, 61 mg (54%) of **16**. This reaction mixture was more complex due to the greater reactivity of the ketone, but none of the conjugate addition product was detected.

**Acknowledgments.** E. J. L. thanks Oklahoma State University for a Niblack Scholarship. Funding for the 300 MHz NMR spectrometer of the Oklahoma Statewide Shared NMR Facility was provided by the NSF (BIR-9512269), the Oklahoma State Regents for Higher Education, the W. M. Keck Foundation, and Conoco Inc. Finally, the authors wish to thank the OSU College of Arts and Sciences for funds to upgrade our departmental FTIR and GC–MS instruments.

[11] Other amines singly branched at the α-carbon were not explored since cyclohexylamine is a relatively unhindered case. Aniline and *tert*-butylamine gave none of the ring-closed product.

[12] In our earlier work, which focused on unhindered substrates that close by an *endo* process, evidence suggested that the Michael addition initiated the annulation sequence (see Ref 2). Subsequent experiments, however, have shown that increased substitution on the β-carbon of the Michael acceptors results in a reversal of the steps in this reaction. The results of this study will be reported in due course.

A series of novel *bis*-heterocyclic compounds **12–20** were synthesized by integrating fused heterocyclic pyrimidines, such as thienopyrimidine and pyrazolopyrimidine into the scaffold of thienotriazolopyrimidines, and pyrazolotriazolopyrimidines through a sulfur-linkage.

*J. Heterocyclic Chem.*, **47**, 1183 (2010).

## INTRODUCTION

The chemistry of heterocycles containing pyrimidine moiety have attracted considerable interest for many years because of their diverse biological activities, such as anti-inflammatory, anti-HIV-1, antimicrobial, and antitumor activities [1–4]. Some fused heterocyclic pyrimidines have acquired much importance because of their wide range of biological applications.

For instance, pyrazolopyrimidine **1** was as shown in Figure 1 investigated as antifungal and antibacterial agents [5], and other similar pyrazolopyrimidines were also reported to possess inhibitory activities of the insulin-like growth factor receptor (IGF-IR) and human cyclin-dependent kinase 2 [6,7]. Various triazolopyrimidine derivatives were known as dual thrombin/factor Xa inhibitors, human adenosine $A_{2A}$ receptor ligands, and herbicides [8–10]. Also, new thienopyrimidine derivatives have been identified as potent inhibitors of VEGF receptor-2 kinase and selective and potent ligands for the 5-$HT_3$ receptor [11,12]. Furthermore, it has been noticed that introduction of an additional ring to the fused heterocyclic pyrimidines tends to exert profound influence in conferring new biological activities in these molecules. Recently, thienotriazolopyrimidine **2** and pyrazolotriazolopyrimidine **3** derivatives as tricyclic heterocyclic compounds (five-six-five ring systems) have been explored for adenosine $A_1/A_{2A}$ or $A_{2A}/A_3$ receptor antagonists [13,14].

Starting from using the thienotriazolopyrimidine derivatives **4** and **5** which have been recently reported from our laboratories [15] and in continuation to our works for biologically active heterocyclic compounds [16] we now report the synthesis of new *bis*-heterocyclic compounds **12–20** prepared by integrating fused heterocyclic pyrimidines, such as thienopyrimidines and pyrazolopyrimidines into the scaffold of thienotriazolopyrimidines and pyrazolotriazolopyrimidines through a sulfur-linkage in the hope of obtaining compounds of diverse pharmaceutical activities.

## RESULTS AND DISCUSSION

For the synthesis of key intermediates **9**, **10**, and **11**, 2-aminothiophene-3-carbonitrile and 3-aminothiophene-2-carboxamide as starting materials were obtained, respectively, according to the modified Gewald method [17]. 5-Amino-1-phenyl-1*H*-pyrazole-4-carbonitrile was also prepared by the reaction of phenylhydrazine with ethoxymethylenemalonitrile in refluxing ethanol [18]. Compounds **6** and **8** were obtained from the reaction of starting materials with triethyl orthoformate and subsequent cyclization with hydrazine. Condensation of 3-aminothiophene-2-carboxamide with aqueous formic acid and subsequent treatment with $POCl_3$ and hydrazine gave **7**, as shown Scheme 1 [15]. Electrophilic attack of $CS_2$ in the presence of ethanolic KOH on the hydrazines **6**, **7**, and **8** gave via further intramolecular cyclization and elimination of $H_2S$ fused 1,2,4-triazolopyrimidine-3-thiones **9–11**, respectively, which exhibit a

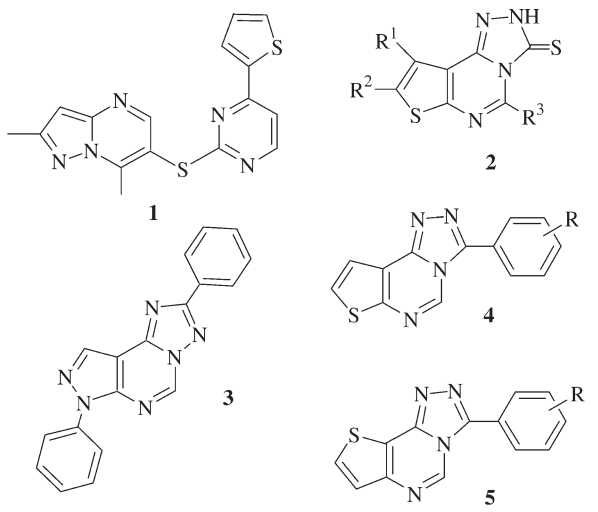

**Figure 1.** Compounds **1–5**.

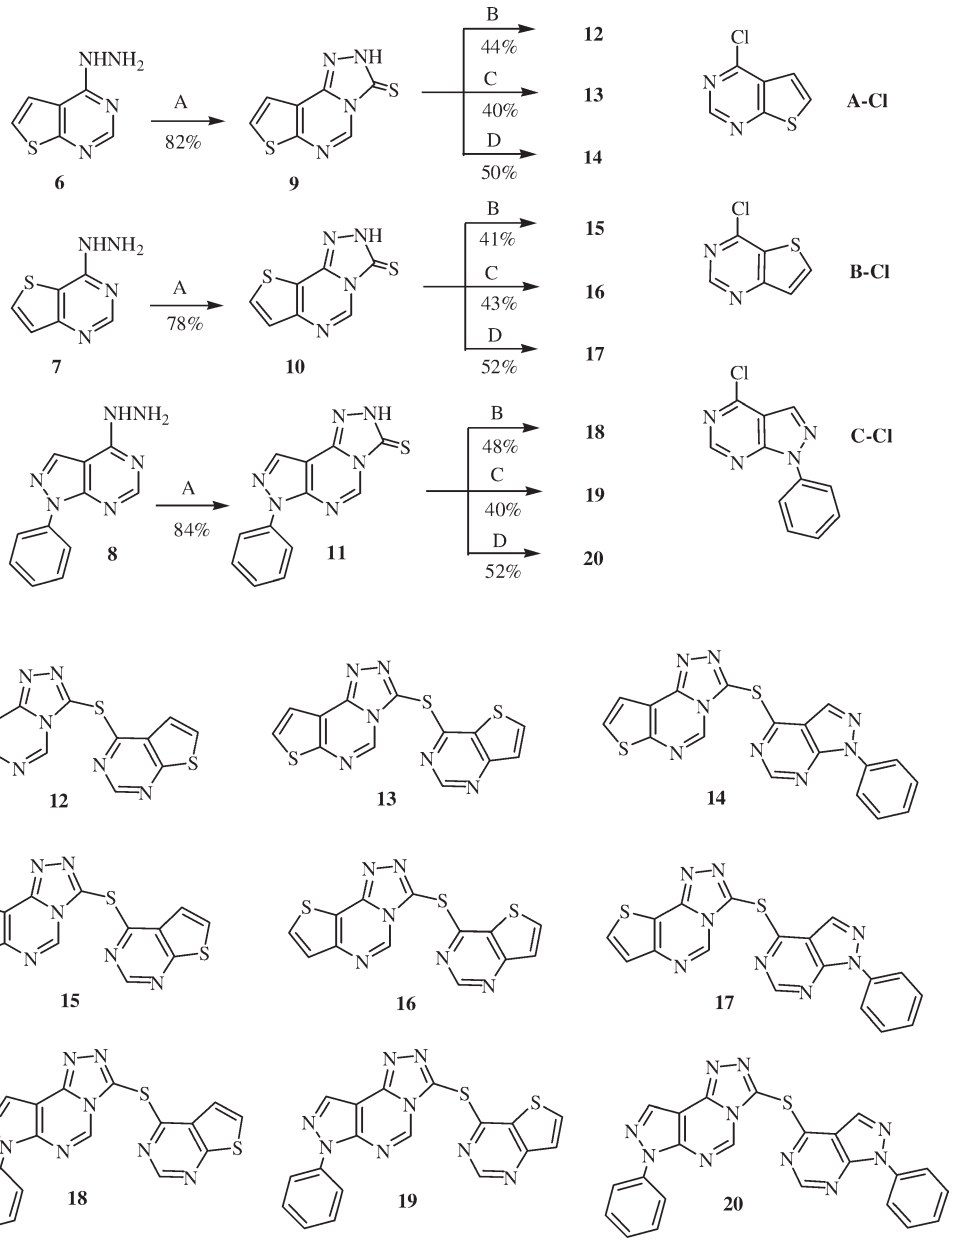
thione-thiol equilibrium. The structure of these compounds was confirmed by elemental analysis, $^1$H-NMR and IR spectra. The IR spectra showed characteristic peaks at 1200 (weak) and 3190 cm$^{-1}$ for the C=S and NH groups, respectively. The disappearance of the primary amino protons and the appearance of the secondary amino signal near at δ 14.0 in $^1$H-NMR spectrum indicated the thione tautomer of cyclization products. The mass spectral data of **9** and **10**, for instance, showed a molecular ion peak at m/z 208, and also showed ion at m/z 135 which could be attributed to the loss of N—NH—C=S from the molecular ion.

The compounds **12–20** were prepared as shown Scheme 2 in moderate yield by treatment of fused 1,2,4-triazolopyrimidine-3-thiones **9–11** with chlorothienopyrimidines (**A-Cl** and **B-Cl**) or chlorophenylpyrazolopyrimidine (**C-Cl**) in refluxing ethanol containing sodium acetate. The structures of **12–20** were established on the basis of their spectral data and elemental analysis. The IR spectra of these compounds exhibited absorption bands in the region of 1630–1490 cm$^{-1}$ for aromatic C=C, C=N stretching vibrations, and disappearance of NH and C=S stretching signals of cyclic thiourea. The $^1$H-NMR spectra of 3-(thieno[2,3-*d*]pyrimidin-4-ylthio)-thieno[3,2-*e*][1,2,4]triazolo[4,3-*c*] pyrimidine **(12)**, for example, showed four doublet signals because of protons of two thiophenes, and two singlet signals attributed to protons of two pyrimidine rings. Thus, one pair of doublet signals at δ 8.11 and 7.85 corresponded to thiophene protons (H-8 and H-9) of thieno[3,2-*e*][1,2,4] triazolo[4,3-*c*]pyrimidine ring, and the other one at δ 8.03 and 7.50 attributed to thiophene protons (H-5′ and H-6′) of thieno[2,3-*d*]pyrimidine ring. Two singlets at δ 9.77 and 8.81 were observed for pyrimidine proton (H-5) of thieno[3,2-*e*][1,2,4]triazolo[4,3-*c*]pyrimidine ring, and pyrimidine proton (H-2′) of thieno[2,3-*d*]pyrimidine ring, respectively. The mass spectrum of **12** revealed m/z = 342 corresponding the molecular formula, $C_{13}H_6N_6S_3$. The ions at 208, 135 were fragments obtained from cleavage of sulfide bond of **12**. The more deshielded α proton (H-6′) of thiophene of thieno [3,2-*d*]pyrimidine ring in 3-(thieno[3,2-*d*]pyrimidin-4-ylthio)thieno[3,2-*e*][1,2,4]tri-azolo[4,3-*c*]pyrimidine **(13)** appeared as a doublet at δ 8.43, whereas the β proton (H-7′) was found to appear at δ 7.68 in little higher field as a doublet when compared with **12**. The mass fragmentation pattern of **13** was in agreement with the pattern of **12**, giving a molecular ion peak at 341. The $^1$H-NMR of 3-(1-phenyl-1*H*-pyrazolo [3,4-*d*]pyrimidin-4-ylthio)thieno[3,2-*e*][1,2,4]triazolo [4,3-*c*]pyrimidine **(14)** displayed two singlets at δ 8.75 and 8.65, respectively for pyrimidine (H-6′) and pyrazole protons (H-3′) of phenylpyrazolopyrimidine ring. Multiplets responsible for phenyl ring appeared at δ 8.15, 7.54, and 7.71 as a doublet and two triplets, and the proton resonance of the thieno[3,2-*e*][1,2,4]triazolo[4,3-*c*] pyrimidine ring was observed as two doublets at δ 8.19 and 8.00 for thiophene (H-8 and H-9) and as a singlet at δ 9.34 for pyrimidine (H-5), respectively. The mass spectrum of **14** revealed m/z = 402 corresponding the molecular formula, $C_{18}H_{10}N_8S_2$. The ions at 228, 208, and 195 were fragments due to cleavage of sulfide bond of **14**.

The $^1$H-NMR spectra of **15–16** and **17** showed patterns similar to those of corresponding **12–13** and **14**. It is noteworthy that the chemical shifts of thiophene and pyrimidine protons for thieno[2,3-*e*][1,2,4]triazolo[4,3-*c*]pyrimidine ring were changed at δ 9.78–7.69 in higher field or in more downfield because of sulfur-linked fused heterocycles, such as thienopyrimidines or pyrazolo-

**Scheme 1.** Reagent and conditions: A: $HC(OEt)_3$, reflux; B: $NH_2NH_2$-$H_2O$, reflux; C: HCOOH, reflux; D: (i) $POCl_3$, reflux, (ii) $NH_2NH_2$-$H_2O$, reflux; E: $HC(OEt)_3$, reflux; F: $NH_2NH_2$-$H_2O$, reflux.

**Scheme 2.** Reagents and conditions: A: $CS_2$/KOH, ethanol, reflux; B: **A-Cl**, $CH_3CO_2Na$, ethanol, reflux; C: **B-Cl**, $CH_3CO_2Na$, ethanol, reflux; D:**C-Cl**, $CH_3CO_2Na$, ethanol, reflux.



pyrimidine. The mass spectra of **15–16** and **17** revealed the very similar fragmentations compared with corresponding **12–13** and **14** having the same molecular formulas, respectively.

The compounds **18–19** were also characterized by $^1$H-NMR spectra, which exhibited three singlets at δ 9.79–8.56 and two doublets at δ 8.45–7.45 for fused heterocycles and multiplet signals at δ 8.15–7.47 for phenyl ring, like patterns of **14** and **17**. The $^1$H-NMR spectrum of **20** containing two phenylpyrazolopyrimidine moieties showed four singlets for pyrimidine and pyrazole protons of two rings. The signals attributed to pyrimidine (H-5) and pyrazole protons (H-9) of phenylpyrazolo triazolopyrimidine ring were observed at δ 8.84 and 8.32, whereas the similar signals attributed to pyrimidine (H-6′) and pyrazole protons (H-3′) of phenylpyrazolopyrimidine ring were observed δ 8.68 and 8.58, respectively. Data from the elemental analysis and molecular ion recorded in the mass spectrum further confirmed the assign structure.

The compounds **12–20** were examined preliminarily for the antibacterial activity *in vitro* against *Escherichia coli* and were found to be slightly less active than that of compound **1**. They are under evaluation for other

biological activities and the results will be published elsewhere.

In conclusion, we have reported the synthesis of new sulfur-linked *bis*-heterocyclic compounds **12–20** with potential biological activities.

## EXPERIMENTAL

Melting points were determined in capillary tubes on Büchi apparatus and are uncorrected. Each compound of the reactions were checked on thin-layer chromatograpohy of Merck Kieselgel $60F_{254}$ and purified by column chromatography Merck silica gel (70–230 mesh). The $^1$H-NMR spectra were recorded on Bruker DRX-300 FT-NMR spectrometer (300 MHz) with $Me_4Si$ as internal standard and chemical shifts are given in ppm (δ). IR spectra were recorded using a JASCO FT/IR-200 spectrophotometer. Electron ionization mass spectra were recorded on a HP 59580 B spectrometer. Elemental analyses were performed on a Carlo Erba 1106 elemental analyzer.

**General procedure for the preparation of fused 1,2,4- triazolopyrimidine-3-thione derivatives (9–11).** A solution of potassium hydroxide (10 mmol) and $CS_2$ (2 mL) in ethanol (30 mL) was added dropwise to a solution of appropriate thienopyrimidinyl hydrazine or pyrazolopyrimidinyl hydrazine **6-8** (20 mmole) in ethanol (20 mL). The reaction mixture was then refluxed for 8 hours. After cooling and evaporation of the solvent, the residue was dissolved in water and acidified by adding 10% HCl. The solid product was purified by recrystallization from ethanol.

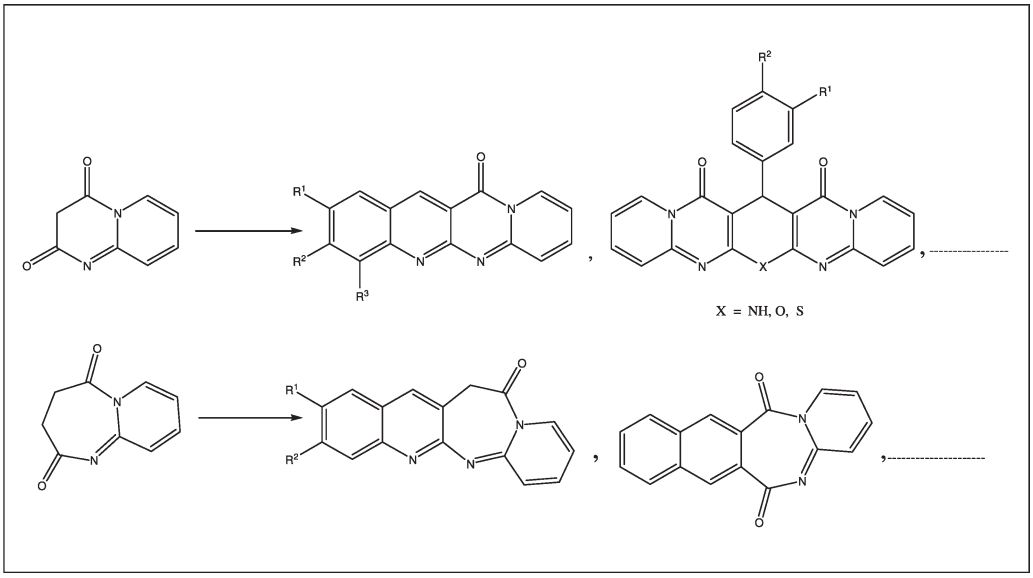
# Synthesis of Novel and Biologically Potent Heteropolycyclics Containing Bridge Head Nitrogen

Poonam Gupta, Shallu Gupta, Anand Sachar, and R. L. Sharma*

Department of Chemistry, University of Jammu, Jammu 180006, India
*E-mail: rlsharma_hod@rediffmail.com

Received July 3, 2009
DOI 10.1002/jhet.465
Published online 26 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



A facile one pot synthesis of 2,3,4,5-tetrahydropyrido [1,2-*a*] [1,3] diazepine-2,5-dione **2** and 3,4-dihydro-2*H*-pyrido [1,2-*a*] pyrimidine-2,4-dione **3** has been achieved. Condensation of **3** with *o*-aminobenzaldehydes produced the linear product **4** and not the angular one **5**. Cyclocondensation of **3** with 1,5-diketones afforded a tricyclic linear system **6**, a bis assembly system **7** and two novel heterotetracyclic nitrogen bridged linear systems **8** and **10**. Condensation of *o*-aminobenzaldehydes with **2** produced a novel linear system **12** and a new doubly fused hexacyclic system **11**. Cyclodehydration of **2** with 1,2-dicarbaldehydes produced **1**, **13**, and a new heterotetracyclic nitrogen bridged system **14**. Condensation of **3** with aromatic aldehydes in presence of ethylene glycol as solvent without the use of catalyst generated the doubly nitrogen bridged linear pentacyclic systems **15–17**. The synthesized compounds have been adequately characterized and screened for bronchodilatory and antimicrobial activities with promising results.

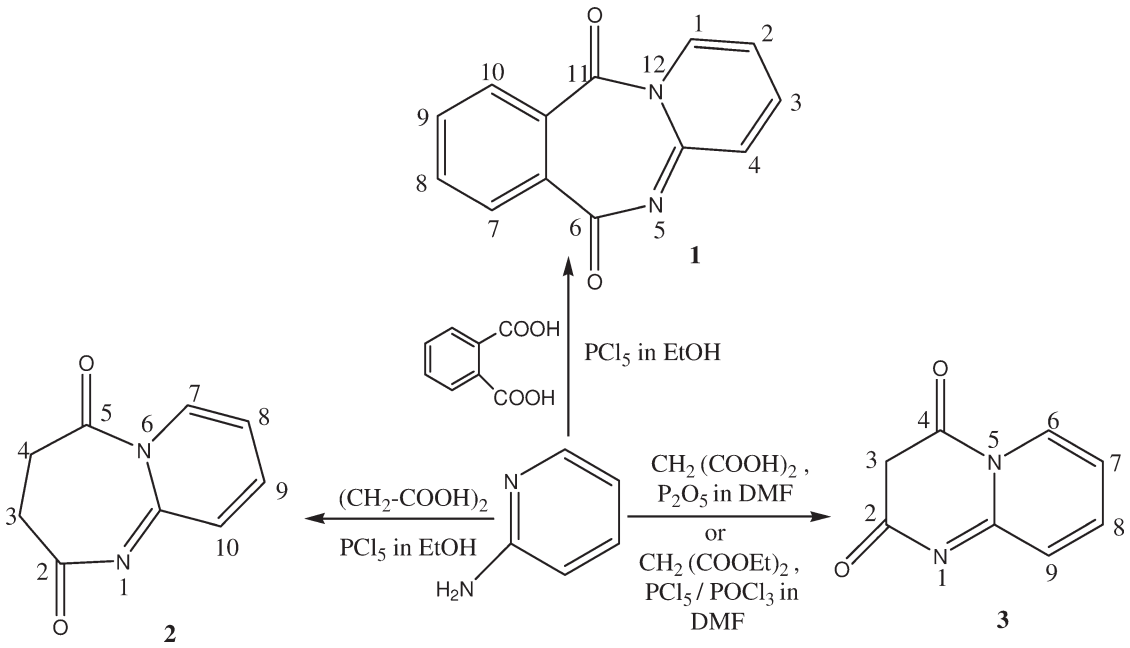
## INTRODUCTION

Diazepines and benzodiazepines are known to exhibit a wide variety of biological activities such as anticonvulsant, antianxiety, analgesic, sedative, antidepressive, and hypnotic activity [1–3]. Some of the benzodiazepine derivatives particularly 7-(*p*-methoxyphenyl)-8-phenoxy-1, 5-benzo-3-azanonem (1,5-BDZ-OMe) and 7-phenyl-8-phenoxy-1,5-benzo-3-azanonem (1,5-BDZ-H) possess hypnotic activity [4]. Pyrrolo [2,1-*c*] [1,4] benzodiazepines such as anthramycin and DC-81 are well-known antitumor antibiotics (PBDS) derived from streptomyces species [5].

Compounds possessing quinazoline and quinazolinone nuclei show potent biological activities including bronchodilatory, anticancer, anticonvulsant, antibacterial, anti-HIV properties [6,7], anthelmintic [8], antiparkinsonium [9], antitubercular [10], hypoglycemic [11], antiviral [12], anticoagulant [13], antifibrillatory [14], cardiac stimulant [15], CNS depressant [16], neuroleptic [17], and hypnotic [18]. Vasicine and vasicinone, the two known alkaloids and a synthetic compound 7,8,9,10-tetrahydroazepino [2,1-*b*] quinazolin-12(6*H*)-one (RLX) all bearing quinazoline moiety have been evaluated as potent bronchodilatory and oxytocic agents [19–22]. The latter compound has been found to be six times more potent than aminophylline [23].

Quinoline and its derivatives are known for their antimalarial and therapeutic properties. A number of quinoline derivatives are known to possess antitumour, antibacterial, antifungal, hypotensive, anti-HIV, analgesic,

**Scheme 1**



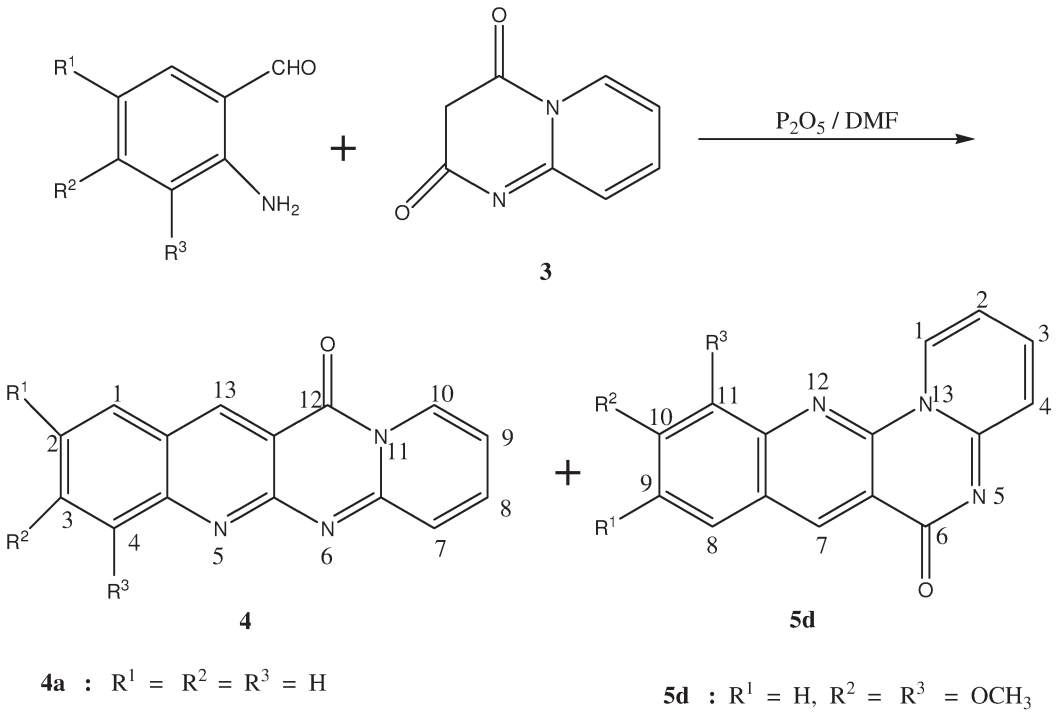
anti-Leishmanial, and anti-inflammatory activities [24]. In addition, the synthesis of pyrido [1,2-*a*] pyrimidin-4-ones provided a wide spectrum of biological activities [25–31] such as tranquilizer, antiallergic, antiulcerative, antiasthmetic and bronchodilatory activity, analgesic activity, and human platelet aggregation inhibitory properties. Biologically active evaluations of these constituent moieties in the recent years encouraged us to generate the novel condensed heteropolycyclic systems containing bridge head nitrogen atom, most of them hitherto unknown in literature and comprising of one or more than one of these moieties. Such novel systems might expectedly prove to be the potent therapeutic agents in near future.

## RESULTS AND DISCUSSION

In this work, 6*H*,11*H*-pyrido[1,2-*b*][2,4]benzodiazepine-6,11-dione **1** and 2,3,4,5-tetrahydropyrido[1,2-*a*] [1,3]diazepine-2,5-dione **2** were designed and generated by the condensation of 2-aminopyridine with phthalic acid and succinic acid, respectively, both in presence of $PCl_5$ in ethanol. An active methylene heterocycle, 3,4-dihydro-2*H*-pyrido [1,2-*a*] pyrimidine-2,4-dione **3** was produced by the condensation of 2-aminopyridine either with malonic acid in presence of anhydrous $P_2O_5$ in DMF or with diethyl malonate in the presence of $PCl_5$/ $POCl_3$ in DMF (Scheme 1). Compound **3** has been known in literature, having been prepared through other approaches [32–34]. Literature m.p, analytical data, and spectral data confirmed the structure assigned to it in this study. Presence of peculiar bands between 1590 to 1600 $cm^{-1}$ and 1675 to 1710 $cm^{-1}$ in IR spectra of compounds **1** and **2** favored the presence of C=N and CON< (tertiary amide) functionalities. Presence of signal of aromatic protons only for compound **1**, a downfield multiplet due to two methylene groups around δ 2.35 to 2.43 ppm for compound **2**, and the absence of any $D_2O$ exchangable proton in $^1H$ NMR spectra of either of these two compounds confirmed the heterocyclisation and their structures unambigously.

The active methylene compound **3** was put to Knoevenagel condensation with some *o*-aminobenzaldehydes followed by subsequent heterocyclodehydration affording a single product (**4a–c**) and in one case affording the main product **4d** associated with another very minor product (TLC). The compounds **4a–d** have been characterized as 12*H*-pyrido [1′,2′:1,2] pyrimido [4,5-*b*] quinolin-12-ones belonging to a linear ''ortho fused'' system. The minor product which could not be separated from **4d** might be the angular product, 6*H*-pyrido [1′, 2′:1, 2] pyrimido [4,5-*b*] quinolin-6-one **5d** (Scheme 2). The literature report [35] regarding compound **4a** confirmed its structure by comparing m.p, analytical, and spectral data of **4a** of this study with that known in literature. The appearance of peaks of methylenedioxy protons at δ 6.10 ppm in **4c**, two methoxyl group protons at δ 3.70 and 3.75 ppm in compound **4b**, and two methoxyl group protons at δ 3.72 and δ 3.78 ppm for compound **4d** in $^1H$ NMR spectra confirmed their structures unequivocally. Other signals in $^1H$ NMR spectra of **4b–d** were almost identical with those for compound **4a**.

**Scheme 2**



**4a** : $R^1 = R^2 = R^3 = H$

**4b** : $R^1 = R^2 = OCH_3$ ; $R^3 = H$

**4c** : $R^1 + R^2 =$  ; $R^3 = H$

**4d** : $R^1 = H$, $R^2 = R^3 = OCH_3$

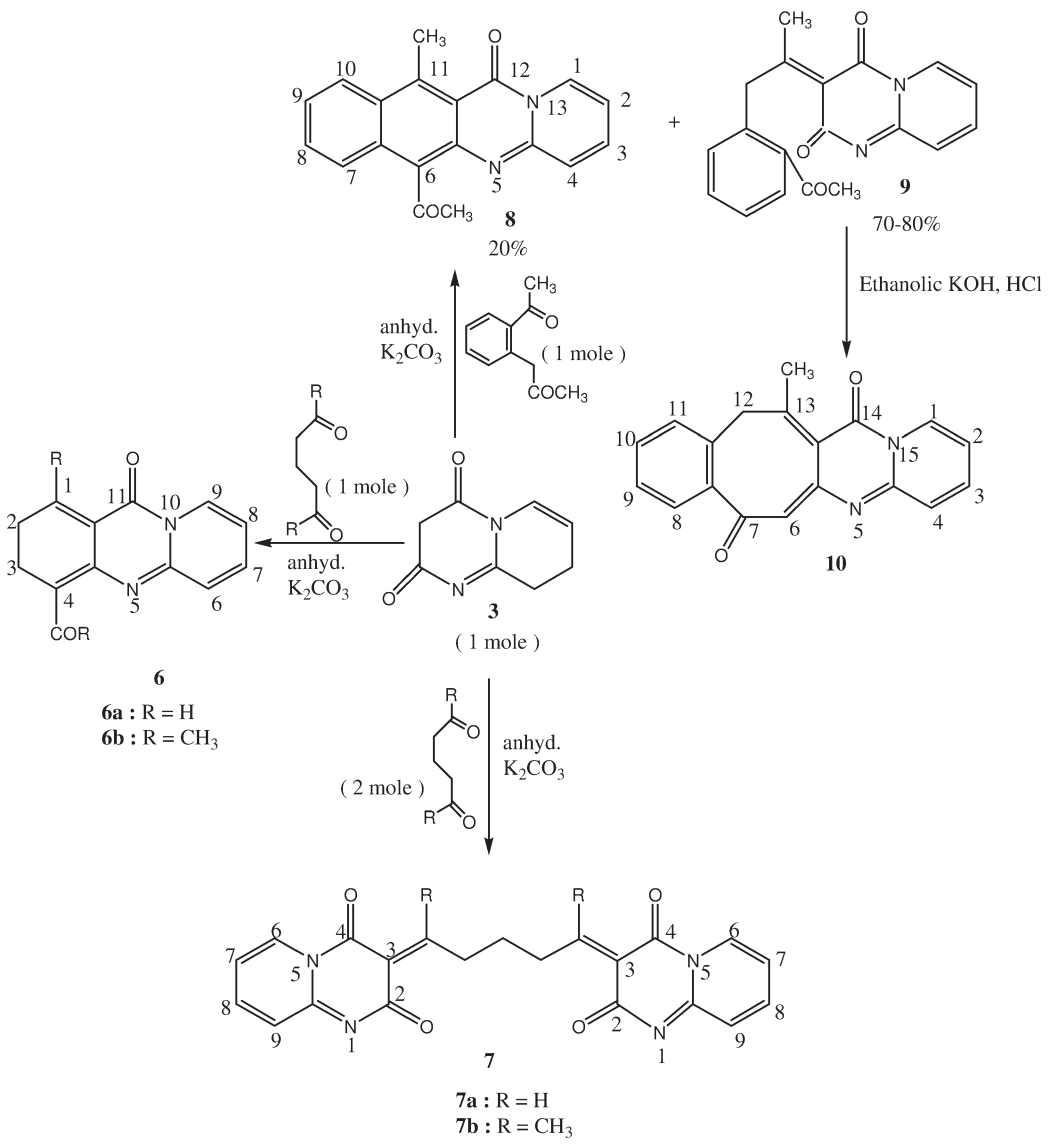
**5d** : $R^1 = H$, $R^2 = R^3 = OCH_3$

Working on the similar route of synthesis, cyclocondensation of **3** with 1,5-dicarbonyl compounds like glutaraldehyde and heptane-2,6-dione in the mole ratio of 1:1 and 1:2 in presence of anhydrous $K_2CO_3$ was carried producing two entirely different product systems, a quinazoline based linearly fused tricyclic system, 4-acyl-2,3-dihydro-11*H*-pyrido[2,1-*b*]quinazolin-11-one **6a–b**, and a bis heterocyclic ring assembly system, 1,5-bis (2,4-dioxo-3,4-dihyro-2*H*-pyrido [1,2-*a*] pyrimidin-3-ylidine) pentane **7a–b**, respectively, in each case. The compound **6a** obtained from 1:1 condensation showed a characteristic downfield singlet at δ 9.96 ppm due to proton of CHO at C-4, a downfield triplet at δ 5.70 ppm due to ethylenic proton at position 1, and a multiplet at δ 1.7 to 1.85 ppm due to four methylenic protons besides four aromatic protons as multiplet in its $^1$H NMR spectrum. The compound **6b** had two prominent singlets of three protons each at δ 2.43 and 2.15 ppm due to $COCH_3$ and $CH_3$ protons, respectively. The appearance of a multiplet due to six protons of three methylene groups and a triplet due to two ethylenic protons in the acyclic portion confirmed unequivocally the structure of **7a**. Similarly, 6-aceto-12*H*-11-methylbenzo [*g*] pyrido[2,1-*b*]quinazolin-12-one **8** and 12*H,14H*-13-methylbenzo [5,6] [8] annuleno [1,2-*d*] pyrido [1,2-*a*] pyrimidine-7,14-dione **10** were also generated from compound **3**, the latter through the intermediacy of **9** (Scheme 3).

Under slightly different conditions, a highly hybrid quinoline-based doubly fused hexacyclic system, tetrasubstituted pyrido[1′,2′:1,2]quino [3″,2″:6,7][1,3] diazepino[4,5-*b*] quinoline **11** and a novel linear disubstituted system, pyrido[1′,2′:1,2] [1:3] diazepino[4,5-*b*]quinolin-12(13*H*)-one **12** were generated from **2** whose characterization was done as usual (details in experimental part). Again, cyclodehydration of **2** with malealdehyde and succinaldehyde produced **1** and its dihydro analogue **13**, respectively, and the condensation between **2** and phthalaldehyde produced a new heterotetracyclic system 6*H*,13*H*-pyrido[1,2-*a*]naphtho[2,3-*e*] [1,3] diazepine-6,13-dione **14** (Scheme 4).

In extension of our earlier work [36,37], it was thought worthwhile to study the condensation of active methylene compound **3** with aromatic aldehydes in ethylene glycol as solvent without the use of catalyst. Knoevenagel condensation, Michael addition, and cyclodehydration took place simulataneously resulting in the formation of a novel linear and heteropentacyclic system **16** containing a central pyran ring. The

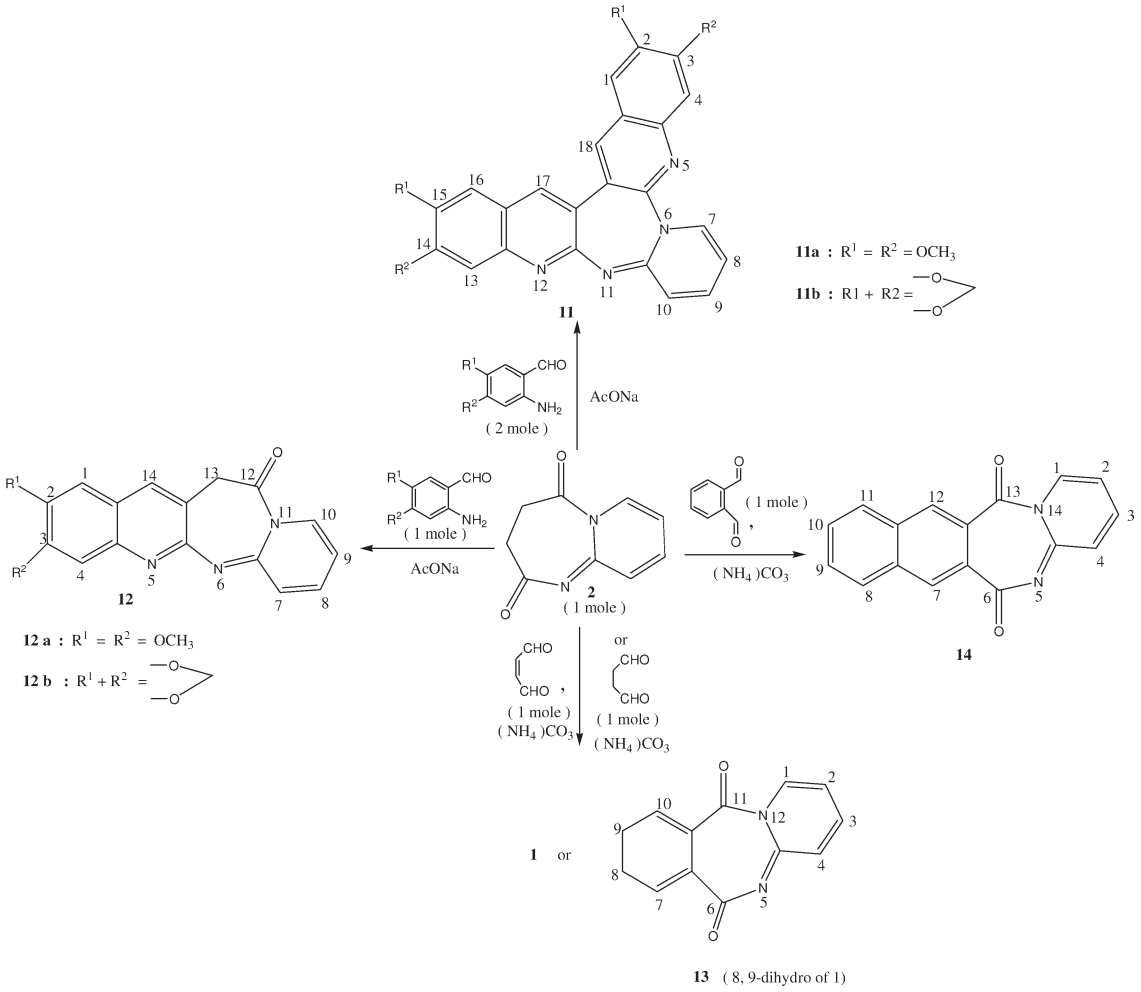
**Scheme 3**



intermediates could not be isolated but the second intermediate after the two transformations seemed to be more interesting for exploitation in the ring closure heterocyclising reaction. Hence, compound **3** was treated with different aromatic aldehydes in ethylene glycol producing compound **16** and refluxed in DMF in presence of ammonium acetate, $P_2O_5$ and $P_2S_5$ giving similar results in each case producing three novel linear heteropentacyclic systems **15**, **16**, and **17** with pyridine, pyran, and thiopyran central ring, respectively (Scheme 5). The characterization has been made for these systems on the basis of elemental analysis and spectral studies. The present exposition has twofold importance, firstly the study of the versatility and reactions of compound **3** and **2** with different aldehydes under different conditions resulting in generation of various novel-fused heterocyclic systems most of which are hitherto unknown in literature and secondly the study of physiological nature of these systems.

**Pharmacology.** On preliminary pharmacological investigations, the compounds **4a–d**, **6a–b**, **8**, **11a–b**, and **12a–b** have been found to be promising bronchodilatory and oxytocic agents having activities comparable to those of alkaloid vasicine and its natural and synthetic analogues. The detailed study of the evaluation of these biological activities is under active exploration from our research laboratory. The drugs employed in this study are 7,8,9,10-tetrahydroazepino [2,1-*b*] quinazolin-12(6*H*)-one; Aminophyllin injection I.P (Burroughs Welcome & Co.); Histamine diphosphate (Sigma); Adrenaline tartarate (IP); Propanolol HCl (ICI); 5-hydroxytryptamine; and Egg albumin (BDH).

**Scheme 4**



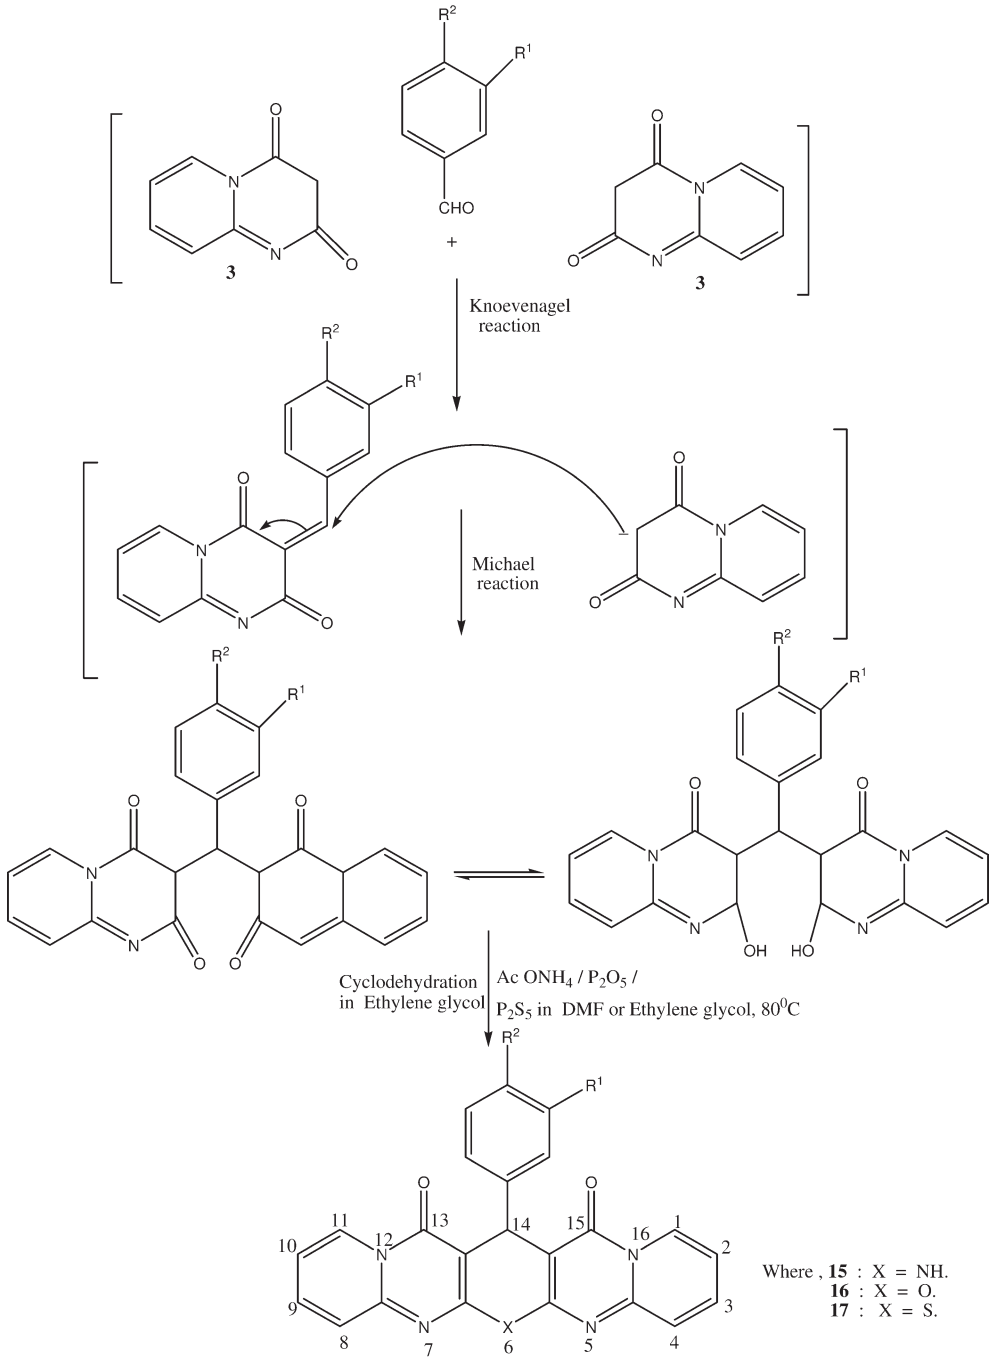
The comparative SAR of various compounds [38] and the results of other details regarding these activities are being currently determined. The compounds **4a–d**, **6a–b**, **8**, **11a–b**, and **12a** have been found to be weakly to moderately active antimicrobial agents. Compounds **4a–d**, **6a–b**, **11a–b**, and **12a** have been found to be highly promising, as regards ''Tracheal smooth muscle activity'' and ''Antitussive activity.''

**Antimicrobial activity.** The compounds **3**, **7a–b**, **15a–d**, and **4a–d** have been screened for their antifungal activity against Aspergillus, Penicillium, and Cladosporium species. For antibacterial activity, these compounds have been screened against *E.coli*, *Bacillus subtilis*, and *Bacillus cereus*. Both the activities were evaluated at the same concentration of 1000 μg and through well diffusion technique. The standard antifungal agent fluconazole and the antibacterial agent norfloxacin were also screened under similar conditions for a comparative study. The inhibition zones formed were measured in mm and are listed in (Table 1).

**Broncodilatory activity**

***Tracheal smooth muscle activity.*** Preparation of tissue was similar to that described by Castillow and de Beer [39] except that the tracheal ring was opened by severing the cartilage. Guineapigs (350–500 g) of either sex were sacrificed by a blow to the head and the tracheae rapidly excised. The tracheal chain was prepared and suspended in a 20 mL tissue bath containing Krebs-henselet solution (KHS) continuously aerated with 95% $O_2$ and 5% $CO_2$ and maintained at 37°. The composition (mM) of (KHS) was NaCl 118, KCl 4.7, $MgSO_4 \cdot 7H_2O$ 1.2, $CaCl_2$ 2.2, $KH_2PO_4$ 1.2, $NaHCO_3$ 24.9, and (+)-glucose 11.1. The responses were recorded isotonically on a kymograph. The tissue was adjusted to an initial tension of 1.5 g and allowed to equilibrate (60–90) min. Relaxation effect of the drug was studied on tracheal chain precontracted with histamine diphosphate ($1 \times 10^{-6}$ g/mL) or acetylcholine chloride ($1 \times 10^{-6}$ g/mL). The test drugs were added 8 min after the tonic contraction reached plateau. The responses were calculated as percent to relaxing of

**Scheme 5**



**15a, 16a, 17a :** $R^1$ = H, $R^2$ = $OCH_3$ **15b, 16b, 17b :** $R^1$ = H, $R^2$ = $CH_3$

**15c, 16c, 17c :** $R^1$ = $R^2$ = $OCH_3$ **15d, 16d, 17d :** $R^1 + R^2$ =

precontracted muscle back to base line tension (10% relaxation). If there was relaxation to muscle slightly below the base line, it was also taken as 100% relaxation.

***Antitussive activity.*** Kobayshi's [40] method was used in this study. Guineapigs (300–400 g) were aneasthetised by I/P urethane (6.5 mL/kg; 25%) and fixed in

dorsal position. The trachea was exposed and a small incision made at a distance of 1.5 cm from the clavicle. A fine and very thin polythene tube was inserted into the incision as deep as 3 cm to give the stimulus. The stimulus was applied two times before and 15, 30, 45, 60, 90 and 120 min after the drug administration by oral route. If no coughing occurred in two or more out of five trails after drug administration, the drug was estimated as effective percent inhibition was recorded. Results are shown in (Table 2) as follows:

## EXPERIMENTAL

**General.** Melting points were measured in open capillaries on perfit melting point apparatus and are uncorrected. IR spectra on KBr were recorded on Brucker—4800 infrared spectrometer. NMR and EIMS/HRMS spectra were recorded on Brucker AC-400 (400 MHz and 100 MHz) and JEOL D-300 mass spectrometer, respectively. Elemental analysis was carried out on simple CHNS analyzer (CHNS-932, LECO Corporation, USA). $^{1}H$ and $^{13}C$ chemical shifts are reported in parts per million (ppm) from tetramethylsilane (TMS) as internal standard. All experiments were performed in oven dried glass

apparatus. SISCO silica was used as adsorbent for TLC (0.5 mm thick plates) and TLC plates were eluted with 1:9 ratios of ethyl acetate and *n*-hexane. The column chromatography was performed over silica gel (60–120 mesh) with graded solvent systems of ethyl acetate-pet ether (60–80).

**General procedure for the synthesis of 1–3.** A mixture of 2-aminopyridine (0.01 mole) and appropriate dibasic acid/ester (0.01 mole) was initially grinded for about 20 min and then fused or refluxed as such for about 1 h without any solvent in a round bottom flask and finally refluxed on water bath in presence of 15 mL of ethanol and $PCl_5$ or at 150–160°C in presence of anhydrous $POCl_3/PCl_5$ in 20 mL of DMF or $P_2O_5$ in 20 mL of DMF. After the reaction time (TLC), the solvent was evaporated under reduced pressure and 100 mL of $H_2O$ was added. The precipitates obtained were filtered, dried, and then crystallized from hot ethanol to generate pure 1–**3**.

***6H,11H-Pyrido [1,2-b] [2,4]benzodiazepine-6,11-dione (1).*** It was obtained from phthalic acid (8.30 g, 0.01 mole) and 2-aminopyridine (4.70 g, 0.01 mole) as colorless solid; m.p.150–152°C ; yield 78%; IR (KBr) ν/cm$^{-1}$: 1320–1325 (C—N), 1600 (C=N), 1610–1620 (C=C), 1675 (C=O); MS: m/z = 224 ($M^+$); $^1$H NMR (200 MHz, $CDCl_3$): δ (ppm) = 7.01–7.81 (m, 8H, ArHs); $^{13}$C NMR (50 MHz, $CDCl_3$): δ (ppm) = 110.2, 114.0, 125.4, 126.8, 128.7, 130.4, 132.4, 133.7, 135.1, 136.1, 154.1, 158.9, 162.8. Anal. Calcd. for $C_{13}H_8N_2O_2$: C, 69.6; H, 3.5; N, 12.5. Found: C, 68.9; H, 3.3; N, 12.1.

***2,3,4,5-Tetrahydrohyropyrido [1,2-a] [1,3] diazepine-2,5-dione (2).*** It was obtained from succinic acid (5.90 g, 0.01 mole) and 2-aminopyridine (4.70 g, 0.01 mole); m.p. 102–104°C; yield 72%; IR (KBr) ν/cm$^{-1}$: 1305–1320 (C—N), 1594 (C=N), 1685–1710 (C=O); MS: m/z = 176 ($M^+$); $^1$H NMR (200 MHz, $CDCl_3$): δ(ppm) = 2.35–2.43 (m, 4H, 2×$CH_2$), 7.2–7.6 (m, 4H, ArHs); $^{13}$C NMR (50 MHz, $CDCl_3$): δppm) = 25.7, 31.2, 110.4, 115.5, 120.3, 124.5, 162.9, 165. 8, 180.7. Anal. Calcd for $C_9H_8N_2O_2$. C, 61.3; H, 4.5; N, 15.9. Found: C, 58.2; H, 4.4; N, 15.4.

***3,4-Dihydro-2H-pyrido [1,2-a] pyrimidine-2,4-dione (3).*** Crystallized from DMF, m.p. 301–303°C, (literature m.p. 296–298°C [32]; 295–298°C [33]; 305–308°C [34]).The observed analytical and spectral data were found in complete conformity with the literature values.

**General procedure for the synthesis of 4.** Dissolved (0.01 mole) of substituted *o*-aminobenzaldehyde in 40 mL of hot rectified spirit and added to it a solution of 3,4-dihydro-2*H*-pyrido[1,2-*a*]pyrimidine-2,4-dione (0.01 mole) **3** in 25 mL of rectified spirit and 0.02 mole of fused anhydrous sodium acetate. Swirled to mix and set aside for 5–6 h and finally refluxed the mixture for an hour. Distilled off the ethanol and added 100 mL of $H_2O$. Filtered, washed, the crystalline product with water twice and with a little cold ethanol and crystallized from about 100 mL of hot rectified spirit to obtain the pure and dry product 4.

***12H-Pyrido[1′,2′:1,2]pyrimido[4,5-b]quinolin-12-one (4a).*** Crystallized from butanone, m.p. 272–273°C. The observed and literature [35] analytical and spectral data were in complete agreement with each other, thus conforming the structure of the synthesized compound.

***12H-2,3-Dimethoxypyrido[1′,2′:1,2]pyrimido[4,5-b]quinolin-12-one (4b).*** It was obtained from 6-aminoveratraldehyde (1.81 g, 0.01 mole) and **3** (1.62 g, 0.01 mole); m.p. 246–248°C; yield 67%; IR (KBr) ν/cm$^{-1}$: 1320–1330 (C—N), 1590 (C=N), 1692 (C=O); MS: m/z = 307 ($M^+$); $^1$H NMR (200 MHz, $CDCl_3$): δ (ppm) = 3.70 (s, 3H, $OCH_3$), 3.75 (s, 3H, $OCH_3$), 7.10–7.90 (m, 7H, ArHs); $^{13}$C NMR (50 MHz, $CDCl_3$): δ (ppm) = 56.0, 56.3, 110.1, 120.3, 121.4, 122.7, 123.6, 128.9, 130.1, 140.2, 145.7, 158.2, 159.4, 164.3, 165.6, 169.8, 189.0. **General procedure for the synthesis of 15a–15d.** A mixture of 3,4-dihydro-2*H*-pyrido[1,2-*a*]pyrimidine-2,4-dione (3.24 g, 20 mmol) **3** and the aromatic aldehyde (10 mmol ) in ethylene glycol (30 mL) in presence of ammonium acetate (20 mmol) was heated at 140°C for about 4–5 h and then cooled to room temperature. The reaction mixture was poured into 300 mL water. The solid was filtered and then washed with water twice to remove excess of ammonium acetate. The crude solid was crystallized from 80–85% EtOH.

A new strategy involving domino Knoevenagel hetero-Diels-Alder reaction is described for the preparation of pyrano[3,4-*c*]chromenes scaffold. Reaction of *O*-propargylated salicylaldehyde with benzoylacetonitrile or Meldrum's acid in the presence of CuI and diammonium hydrogen phosphate affords pyrano[3,4-*c*]chromenes with good yields and high bond-forming efficiency.

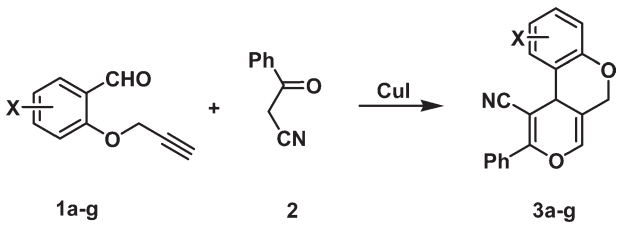
*J. Heterocyclic Chem.*, **57**, 1200 (2010).

## INTRODUCTION

The hetero-Diels-Alder reaction is one of the most powerful methods for the preparation of heterocyclic compounds and it has wide applications in the synthesis of biologically active compounds and natural products [1]. Among these reactions, domino Knoevenagel hetero-Diels-Alder reactions provide efficient and rapid means for the construction of polyheterocyclic compounds [2], especially pyran moieties. 2H-pyran derivatives are present in many natural products with different biological activities [3]. A family of xanthone natural products with potent antiviral activity has been isolated from plants, and it is a potent inhibitor of human immunodeficiency virus-1 reverse transcriptase [4]. Some 2H-chromene family are effective photoaffinity reagents for the cytochrome P450 superfamily of enzymes and probably other proteins as well [5]. Because of the unique properties of pyranochromene skeletons, the developments of synthetic methods that enable facile access to these useful entities are desirable.

In most reported reactions, in domino Knoevenagel hetero-Diels-Alder reactions, alkenes were used as a dienophile. The use of alkynes was limited due to their less reactivity when compared with alkenes. The activation of alkynes toward a variety of organic transformations is an exciting field in organic synthesis. In the recent years, the most important strategy for this aim usually consists of applying transition metal catalysts [6]. The activation of alkynes using various metals has

**Scheme 1.** Synthesis of pyrano[3,4-*c*]chromene in the presence of CuI.



1a-g 2 3a-g

been extensively investigated and described in the literature [7]. Selection of the proper Lewis acid to achieve this purpose is more important. Among the metal catalysts, coinage metals including copper, silver, and gold play an essential role in this field [8]. Therefore, development of new synthetic strategy based on coinage metals is very attractive.

During the past decade, copper (Cu) (I)-catalyzed cyclization of alkynes has represented a convenient tool for the preparation of heterocycles [8]. Copper (I) iodide (CuI), which has been applied in the synthetic and medicinal chemistry, has received much attention due to several advantages over the other coinage metals; including the low cost, insensitivity to air, simple experimental procedure, and no toxicity. Therefore, discovery of novel Cu (I)-catalyzed reaction of alkynes is of great interest [9].

## RESULTS AND DISCUSSION

Following our research work to introduce domino Knoevenagel hetero-Diels-Alder reaction using unactivated alkynes with CuI [10] and to enlarge the scope of this synthetic methodology, herein, we report a domino Knoevenagel hetero-Diels-Alder reaction using *O*-propargylated salicyclaldehyde derivatives **1**(**a**–**g**) and benzoylacetonitrile **2** as unactivated terminal alkynes and an active methylene compound, respectively, in the presence of CuI (Scheme 1). The products are functionalized pyrano[3,4-*c*]chromenes **3**(**a**–**g**).

Initially, *O*-propargylated salicylaldehydes as the starting material were prepared in excellent yields using reaction of propargyl bromide and salicylaldehydes derivatives in dimethyl formamide and in the presence of $K_2CO_3$. To optimize the desired reaction conditions, the reaction of compound **1a** with benzoylacetonitrile **2** was used as the model system. The experimental results are summarized in Table 1.

Heating aldehyde **1a** and **2** in methanol under reflux condition for 72 h did not lead to the desired product. So, CuI was used as the Lewis acid. The reaction was done using different ratios of CuI in the presence of diammonium hydrogen phosphate (DAHP) or triethylamine as the base. The yields and reaction times are summarized in Table 1.

According to the obtained results, methanol was selected as the best solvent and the optimized molar ratio of CuI was 40%.

Under the optimal reaction conditions, pyrano[2,3-*c*]chromenes **3a**–**g** were prepared in 61–75% yields (Table 2). The best result was obtained using aldehyde **1d** (entry 4) that contained a nitro group. It seems that the electron-withdrawing substituent increase the yields of this transformation, as opposed to decreased yield obtained with electron-donating substituent (entry 3).

Structures of the products were confirmed by their spectroscopic data. In $^1$H NMR of compounds **3a**–**g**, the —$OCH_2$ group resonates at $\delta = 4.60$ and 4.72 ppm as a doublet with $J = 11.5$–11.8 Hz. The —CH proton appears at $\delta = 4.79$–4.93 ppm as a singlet, and the olefinic proton =CH resonates at $\delta = 7.12$–7.22 ppm as a singlet. The corresponding signal of the —$OCH_2$ and the shielded olefinic =C—CN carbons in $^{13}$C NMR appear at 65.0–66.4 and 83.8–85.7 ppm, respectively.

This reaction involves two steps: (a) the Knoevenagel condensation between benzoylacetonitrile **2** and the propargylated salicylaldehydes **1a**–**g**. DAHP acts as a mild base for Knoevenagel condensation and formation of 1-oxa-1,3-butadiene that could react as a heterodiene to form the intermediate. (b) hetero-Diels-Alder reaction of olefinic intermediate in the presence of CuI to afford compounds **3a**–**g**. Although the mechanism for this transformation is not clear, it seems that CuI could active the unactivated triple bond to act as a dienophile in hetero-Diels-Alder reaction (Scheme 2).

As a logical extension of domino Knoevenagel hetero-Diels-Alder reaction with unactivated alkynes, we became interested in the synthesis of functionalized pyranochromene derivatives, whose structures have been found in vast numbers of natural products and pharmaceuticals. Reaction of *O*-propargylated salicylaldehyde

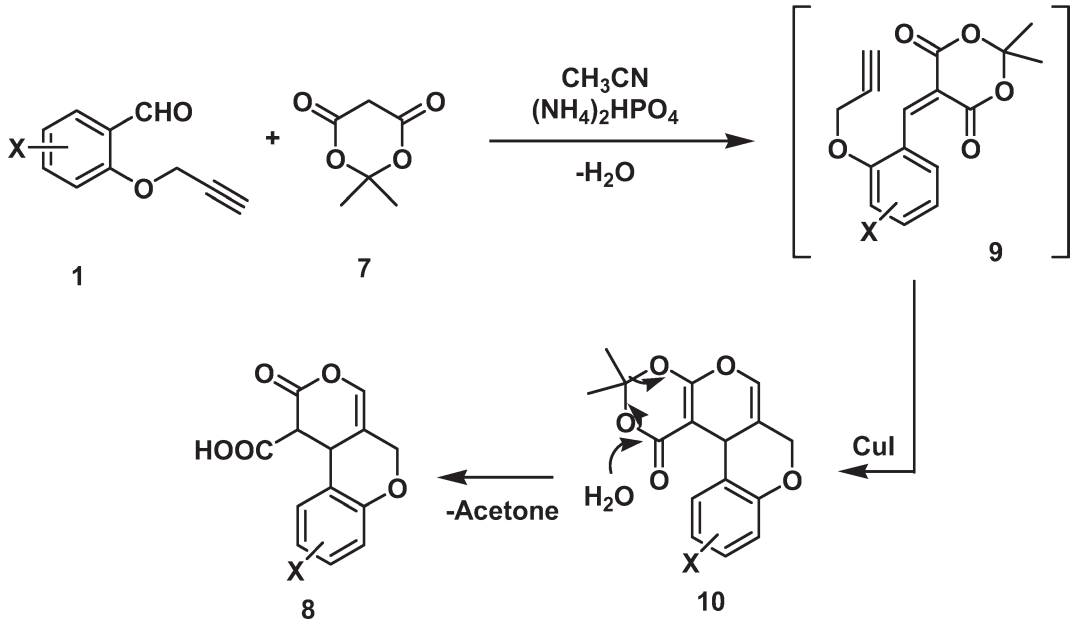
**Scheme 4.** Plausible mechanism for the synthesis of pyrano[3,4-*c*]chromene skeleton *via* activation of π-triple bond using CuI.



with Meldrum's acid **7** in the presence of CuI should afford the desired pyranochromenes **8** (Scheme 3).

Reaction of *O*-propargylated salicylaldehyde **1a** with Meldrum's acid **7** was selected as a model, and the reaction was done in the presence of different ratios of CuI and also diammonium hydrogen phosphate as a base. The details were summarized in Table 3. In this reaction, the best yield was obtained using 40% CuI. The presence of CuI is necessary for the progress of reaction and without CuI, the Knoevenagel product were obtained as the sole product.

On the basis of established Meldrum's acid chemistry, it is reasonable to assume that the formation of aryliden Meldrum's acid apparently results from initial addition of Meldrum's acid with *O*-propargylated salicylaldehyde to obtain *in situ* dieneone **8** (Scheme 4). This intermediate under the reflux conditions and hetero-Diels-Alder reaction converted to pyran skeleton.

The presence of the pyran skeleton is supported by the spectroscopic data. In the $^1$H NMR of compound **8a**, the —$OCH_2$ group shows two separated doublet with $J = 12$ Hz and also a carboxylic acid peak at $\delta = 12.75$ ppm. The high $J$ value is related to the torsion angle that is 174.6°. The structure of compound **8a** was confirmed using X-ray structure data. The product **8a** could form a dimmer *via* intermolecular hydrogen bonding between two carboxylic acid groups (Figs. 1 and 2).

Under the optimal reaction conditions, the best result was obtained using aldehyde **1d** (entry 4) that contained a nitro group (Table 4). In entry 4, the desired product could be decarboxylated and the final product does not contain the carboxylic acid functional group and the product **8d** is the sole product of reaction. Existence of a catalyst such as CuI is necessary to activate the triple bond through complexation. CuI could coordinate the triple bond and the activated triple bond is ready to proceed hetero-Diels-Alder reaction to form pyrano[3,4-*c*]chromene. Reactions were done under Argon conditions to prevent the oxidation of Cu (I) to Cu (II).

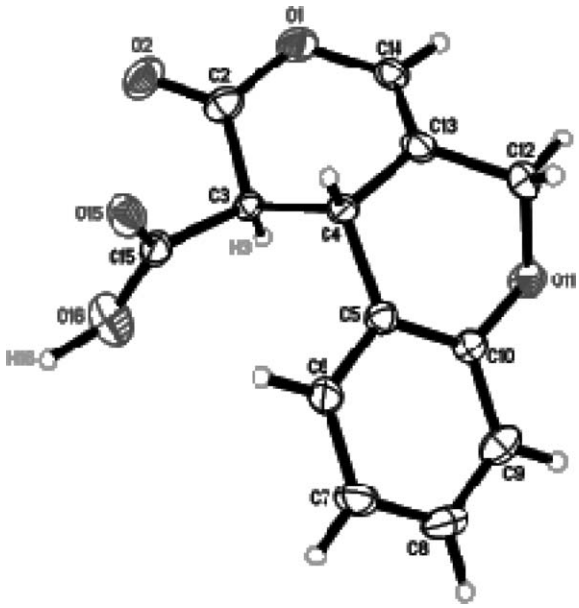


**Figure 1.** X-ray structure of compound **8a**.

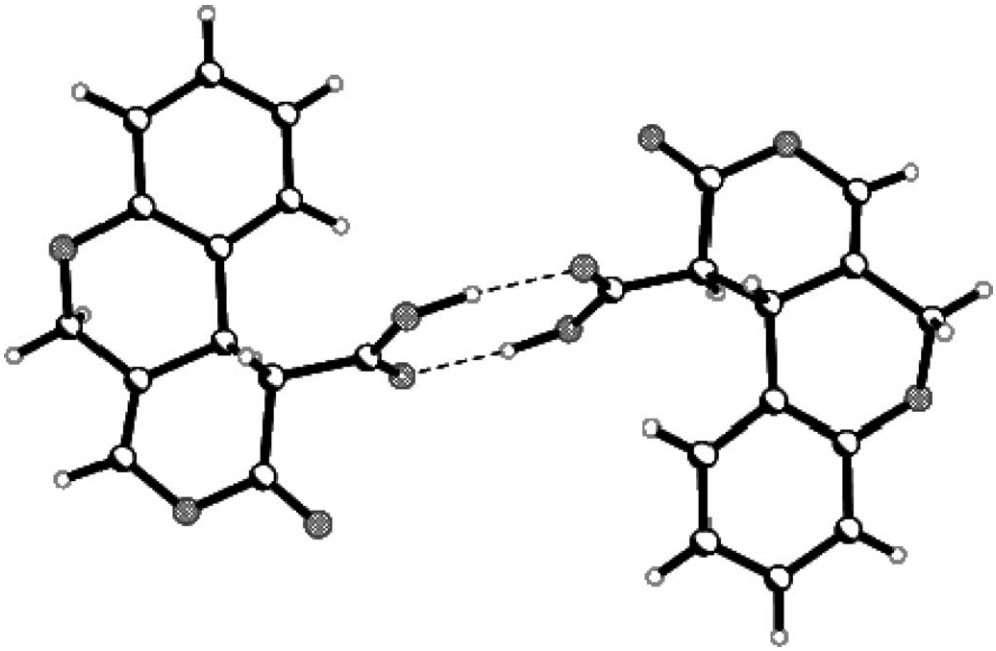

**Figure 2.** Intermolecular hydrogen bonding in compound **8a**.

## CONCLUSIONS

In conclusion, we have described an efficient approach with a high bond-forming efficiency for the synthesis of pyrano[3,4-*c*]chromene skeleton *via* domino Knoevenagel hetero-Diels-Alder reaction started from simple and inexpensive materials. Reaction of *O*-propargylated salicylaldehyde with active methylene compounds such as benzoylacetonitrile and Meldrum's acid leads to functionalized pyranochromenes. In this reaction, CuI (40%) was used as Lewis acid for the activation of unactivated alkynes and DAHP (20%) as the base. The products have nitrile and carboxylic acid functional groups that could be used for further conversion.

## EXPERIMENTAL

Commercially available materials were used without further purification. Melting points were determined with Electrothermal 9100 apparatus and were uncorrected. IR spectra were obtained on an ABB FTIR (FTLA 2000) spectrometer. $^{1}$H NMR and $^{13}$C NMR were run on a Bruker DRX-300 AVANCE at 500 and 300 MHz for $^{1}$H NMR and 125 and 75 MHz for $^{13}$C NMR. $CDCl_3$ and DMSO-$d_6$ were used as solvents. High resolution mass spectra were recorded on JEOL JMS-700 (HR-EI) spectrometer and Mass spectra were obtained using a GC-MS Hewlett Packard (EI, 70 eV) instrument.

**General procedure for the synthesis of pyranochromenes 3a–g derivatives *via* hetero-Diels-Alder reactions.** A solution of *O*-propargylated salicylaldehydes **1a–g** (1 mmol), benzoylacetonitrile (174 mg, 1.2 mmol), CuI (0.4 equiv., 76 mg), and $(NH_4)_2HPO_4$ (28 mg, 0.2 equiv.) in methanol (25 mL) was refluxed. The progress of reaction was monitored by thin layer chromatography (Petroleum ether: EtOAc 3:1). After completion of the reaction, the mixture of reaction was filtered and the solvent was evaporated under reduced pressure. The obtained oil was crystalizated in diethyl ether.

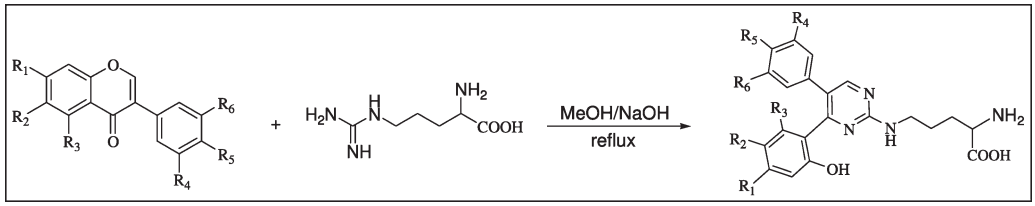
Published online 28 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



A simple and straightforward methodology toward the synthesis of novel 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)pentanoic acid has been developed by one-step reaction of isoflavones with arginine. A series of 14 new compounds was reported. All of them were characterized by FTIR, NMR, and elemental analysis. A variety of substrates can participate in the process with good yields and high purities making this methodology suitable for library synthesis in drug discovery.

## INTRODUCTION

Pyrimidines are well known and widely investigated six-membered nitrogen-containing heterocyclic compounds that exhibit important biological activity [1–4]. Amino acid groups are found widely in a large variety of compounds that exhibit important biological activity, such as amino acids, are interesting drug targets because they are found on proteins, are well-known papain inhibitor [5], and present potential anti-HIV [6], anticonvulsant [7], and antiproliferative activity [8]. It is convenient to synthesize substituted pyrimidines by reaction of amidines or guanidines with α,β-unsaturated ketones [9,10], β-diketones [11,12], β-alkoxy- and β-aminovinyl ketones [13–16], and *N*-arylacetyleneic imines [17,18]. Natural isoflavones display a wide range of biological activities [19]. For instance, soybean isoflavones (daidzein and genistein) have shown pharmacological effects as antidysrhythmic [20], antioxidant [21], and anticardio-cerebral vascular disease [22]. Ipriflavone has been reported to be efficient in preventing and treating osteoporosis [23]. It was reported that the chromone fragment present in isoflavones can generate a 1,3-diketone equivalent, which readily reacts with amidines [24], guanidine [2], carbamide [25], and sulfocarbamides [26] to form the corresponding 2-substituted pyrimidines. The use of combinatorial approaches to the high-throughput synthesis of this drug-like scaffold would be a powerful advance in helping to speed up drug discovery. Recently, we have reported the high-throughput synthesis of 3,4-diarylpyrazoles and 4,5-diphenyl-2-pyrimidinylguanidine by using a one-pot reaction of hydrazine [27] or bisguanidine [28] with isoflavones. Herein, we report a new strategy for the preparation of the unknown class of 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)-pentanoic acid by the cyclocondensation of isoflavones (**1**) with arginine (**2**) (Table 1).

## RESULTS AND DISCUSSION

We turned our attention to optimize the condition of the cyclocondensations of isoflavones (**1**) with arginine (**2**) and designed a process by the cyclocondensation of 4′,7-dimethoxylisoflavone (**1a**) with arginine (**2**) as a model substrate (Table 2). As shown in Table 2, we used $K_2CO_3$ as base and **3a** yield was 37% (Table 2, entry 1). It was also found that triethylamine (TEA) was ineffective in providing the desired condensation product (Table 2, entry 2). A comparative reactivity study of bases in the reaction showed that NaOH proved to be more effective for this cyclocondensation (Table 2, entry 3). As it was shown, solvents MeOH, EtOH, THF, MeCN, *n*-BuOH, and DMF have been attempted, MeOH gave expected result (Table 2, entry 3). Further study with varying NaOH equivalents revealed that 3.0 equiv of base is necessary to obtain a high yield of the condensation product (Table 2, entry 9). Finally, the ratio of **1a** and **2** was also evaluated. The ratio of **1a**:**2** (1:3),

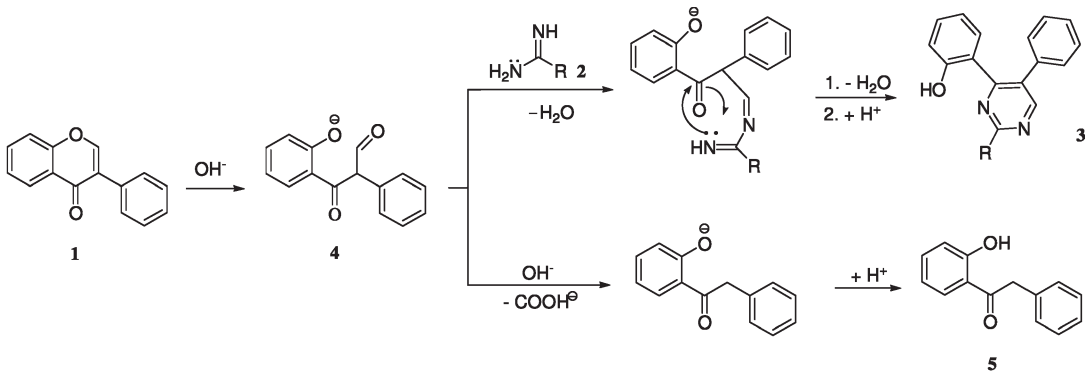
[a] All reaction were carried out in the appropriate solvent (15 mL) using 4′,7-dimethoxylisoflavone (**1a**, 1 mmol), arginine (**2**), and base until complete disappearance of **1a** (refluxing for 8 h, TLC check).
[b] Isolated yield after silica chromatography.
[c] No reaction.

**Scheme 1.** Proposed mechanism for the formation of **3**.



[a] R= - $NH(CH_2)_3CH(NH_2)COOH$.

the yield of **3a** was high for the cyclocondensation reaction (Table 2, entry 12).

With the optimized reaction conditions and proven results in hand, the condensation of variety of structurally divergent isoflavones (**1**) and arginine (**2**) were studied to illustrate this concise and general method for the synthesis of 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)pentanoic acid. All substrates reacted smoothly to give the corresponding 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)pentanoic acid in 5–12 h in good to excellent yields, and the results were summarized in Table 1. All products were characterized by IR, $^1$H NMR, $^{13}$C NMR, and elemental analysis.

In general, isoflavone **1** substituted with alkoxy, benzyoxyl groups gave high yields. In contrast, the presence of the hydroxyl groups gave lower yields. As shown in Table 1, isoflavones **1a–h** (Table 1, entries 1–8) that do not contain hydroxyl groups, gave yields of **3** about 85%. Isoflavones with one hydroxyl group, **1i–l** (Table 1, entries 9–12) only gave yields of **3** about 75%, whereas those with two free hydroxyls, **1m**, **1n** (Table 1, entries 13 and 14) gave yields of roughly 60%. Condensation of trihydroxy isofalvone genistein (4′,5,7-trihydroxy-isoflavone) with **2** failed to produce product **3**. The yields of **3** are directly dependant on the number of free hydroxyl group present on the engaged isoflavone. Because the hydroxyls of isoflavone **1** under basic condition would be oxygenions, which possess stronger electron donability than alkoxy and benzyoxyl groups of the isoflavone, it is not favorable to the condensation reaction.

To explain the mechanism for the formation of 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)pentanoic acid (**3**) by the cyclocondensation of isoflavones (**1**) with arginine (**2**) in the presence of NaOH, a postulated reaction course was illustrated in Scheme 1. As it was reported that isoflavone may undergo ring-opening reaction when refluxing in the presence of alkali to form a β-diketone intermediate **4** [29]. Subsequently, attack of the primary amine group from the arginine (**2**) on the aldehyde carbon in **4**, followed by ring closure reaction between secondary amine and the carbonyl carbon to produce **3**. Meanwhile, intermediate **4** at high concentration of base may eliminate HCOOH to generate byproduct **5** [29].

## CONCLUSIONS

In summary, a convenient method for the synthesis of substituted pyrimidines bearing amino acid moiety in the 2 position was described. The protocol accepted a variety of isoflavones, arginine as starting materials and gave 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)pentanoic acid in good to high yield. Efforts to expand the scope of the method in combination with its application to the synthesis of pharmaceutical molecules are ongoing in our laboratory.

## EXPERIMENTAL

All other commercially obtained reagents were used as received. The silica gel used for the column chromatography was purchased from Qingdao Haiyang Chemistry Plant. Thin Layer chromatography (TLC): silica gel 60 $GF_{254}$ plate; the eluant of column chromatography was the mixture of chloroform and methanol at volume ratio of 5:1. Arginine, ipriflavone, daiazein, genistein, formonone, and 5-methyl-7-methoxy-isoflavone are without further purification. Substrates **1d** and **1l** are derived from ipriflavone. Substrates **1a**, **1h**, **1i**, **1j**, and **1n** are derived from daiazein. Substrate **1b** is derived from genistein. Substrate **1g** is derived from formonone. Substrate **1e** is derived from irisolidone (4′,6-dialkoxy-5,7-dihydroxy-isoflavone), which was separated from the flower of *Pueraria lobata* by one of the authors. Melting points were measured on X-5 micromelting point apparatus and were uncorrected. IR spectra were recorded on Fourier transform infrared spectrometer using KBr pellets. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker DRX-300 Advance spectrometer at 300.00 MHz in DMSO-$d_6$ with TMS as internal standard (chemical shifts in

ppm). The elemental analyses were performed with an Elementar Analysensyteme GmbH Vario EL III.

**General procedure for the preparation of 2-amino-5-(4,5-diphenylpyrimidin-2-ylamino)pentanoic acid (Table 1, entries 1–14).** The corresponding isoflavones **1** (1 mmol), arginine **2** (3 mmol), and sodium hydroxide (3, 4, and 5 mmol were used for 0, 1, and 2 free hydroxyl of **1**, respectively) were refluxed in methanol (15 mL) for 5–12 h. All reactions were monitored by TLC, which showed the disappearance of **1** that was indicative of the reaction being complete. The reaction mixture was added into water (30 mL) and adjusted to neutrality with the solution of 5% HCl. A yellow precipitate appeared and was filtered. The yellow precipitate was dissolved in a solution of 10% HCl (15 mL) and filtered. The mother liquid was neutralized with sodium hydroxide until crude product was completely precipitated. The crude product was filtered and purified by column chromatography on silica gel using chloroform–methanol (5:1) to give the corresponding pure product.

Oxindole was found to react readily with thionyl chloride to give (in an excellent yield) the isolable sulfine (**13a**), which on heating (refluxing acetonitrile) gave isoindigo (**15a**). The dark violet 3-sulfinato-oxindole (**13a**) readily reacted with 2,3-dimethylbutadiene to give a colorless cyclo-adduct (**14a**). The sulfine also reacted readily with various nucleophilic reagents, thus, thioloacetic acid gave 3-carboxymethylthiolo-oxindole (**23a**).

*J. Heterocyclic Chem.,* **47**, 1215 (2010).

## INTRODUCTION

Sulfines, which can be considered as oxides of thiones, are nonlinear and have the general structure **1**, and as indicated in Figure 1, E and Z isomers are possible [1–6].

Several synthetic methods [1–6] for the production of sulfines are available and perhaps the simplest and most general route is given by Zwanenburg, which involves treatment of silylated molecules, such as silylated ketones with thionyl chloride [5–7]. In a few cases, keto derivatives have been reported to yield α-oxo-sulfines directly (*i.e.*, without activation). For example, Hull and Faull reacted the anion of ethyl 4-chloroacetoacetate with phenyl isothiocyanate in dimethoxyethane and obtained 52% of the thiophene derivative **2**. By changing the solvent to dioxane, the yield of **2** could be improved to 87%. The thiophene **2** reacted readily with thionyl chloride to yield the isolable α-oxosulfine **3** [8]. In terms of yields, acetonitrile was found to be a more suitable solvent than dimethoxyethane. The α-oxosulfine **3** could readily be intercepted by 2,3-dimethylbutadiene to give **4**, which could be fully characterized by $^{1}$H and $^{13}$C NMR spectroscopy. In Scheme 1, the sulfine **3** is drawn as the more stable E-isomer although the Z-isomer is more likely to be formed initially due to attack of $SOCl_2$ on the enol tautomer of **2**, which would yield an intermediate sulfinyl chloride stabilized by hydrogen bonding. This sulfinyl chloride is then biased to give primarily the Z-sulfine. However the E-isomer is thermodynamically more stable and will eventually be formed. The structure (determined by X-ray technique) of **4** showed that its sulfine precursor **3** leading to **4** had indeed exclusively been the E-isomer [6].

Interestingly, the related (to **2**) molecule **5**, when treated with $SOCl_2$, failed to yield an isolable sulfine. Instead, the coupled molecule **6** was isolated [8] indicating that the intermediate sulfine is unstable in this case. Interception with 2,3-dimethylbutadiene is however possible [6], which gave a separable mixture of diastereomers; thus, indicating that the kinetic product (the Z-isomer) only had been partially converted to the E-isomer. This type of cycloaddition with 2,3-dimethylbutadiene is a standard operation to trap and to characterize sulfines, as have been done with intermediate sulfines generated

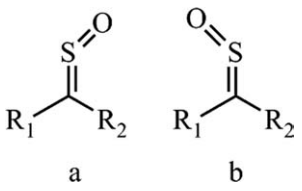

**Figure 1.** E and Z isomers of sulfines.

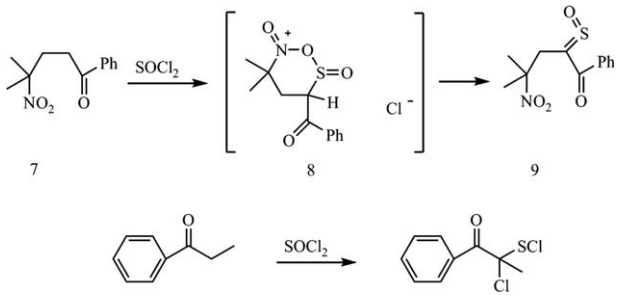
from doubly activated methylene compounds, such as dibenzoylmethane [2,7,9,10].

Another stable α-oxosulfine is given by Black, who reported formation of the α-oxosulfine **9** from the nitroketone **7**. The nitro group is considered to play an important role as indicated in Scheme 2. The intermediate **8** could not be isolated but its presence was supported by an ABX pattern observed during an NMR study of the reaction [11]. The product, the stable α-oxo-sulfine **9**, featured diagnostic resonances at 188.9 and 189.3 ppm in the $^{13}C$ NMR spectrum.

The structure of **9** was confirmed by X-ray crystallography [11]. Simple aromatic ketones (like propiophenone) gave α-chlorosulfenyl chlorides and not α-oxosulfines (Scheme 2) [11].

**Scheme 2**



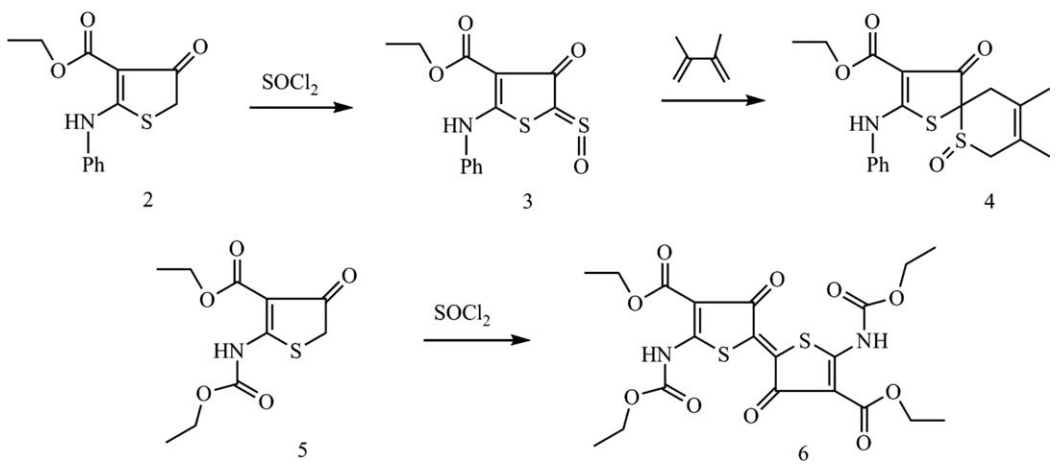
## RESULTS AND DISCUSSION

It has now, somewhat surprisingly, been found that several sulfines in the indole series can readily and quickly (2–3 min) be prepared in excellent yields by the reaction of oxindole itself (**11a**) with thionyl chloride in acetonitrile at 30–35°C that gave the α-oxosulfine **13a** as a dark violet solid. *N*-Methyloxindole similarly gave **13b**. Many years ago, oxindole had been treated with thionyl chloride as reagent and solvent at reflux temperature. Under these conditions isoindigo (**15a**) was the sole product [12] and it seems that the sulfine **13a** has never been isolated before. The sulfine **13a** was isolated in 95% yield accompanied with a small amount of 3-chloro-oxindole (2%, isolated) and can be recrystallized from acetonitrile but prolonged heating in this medium will convert **13a** to isoindigo (Scheme 3).

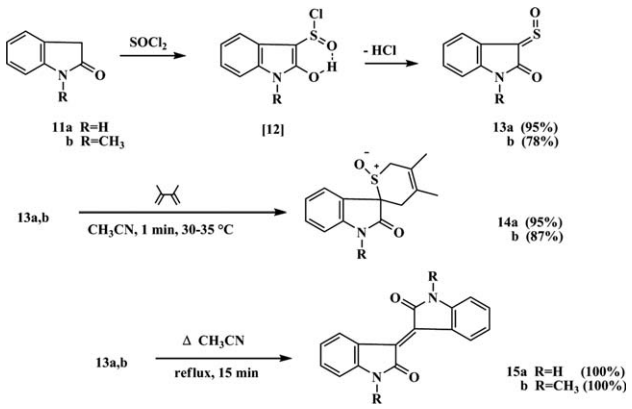
In analogy with the known sulfine **3**, the indolic sulfine **13a** and 2,3-dimethylbutadiene readily (within 2 min at 30–35°C in acetonitrile) gave the colorless adduct **14a** as a single diastereomer. The same is true for the *N*-methyl derivative **13b**, which gave **14b**. It is assumed that the sulfine **13a** is formed *via* an initial electrophilic attack in 3-position of oxindole leading to the nonisolable intermediate sulfinyl chloride **12**, which quickly will eliminate HCl leading to the α-oxosulfine **13a** (E-isomer). However, it is assumed that initially the kinetic product, the Z-isomer, is formed but that it will quickly be converted to the more stable E-isomer. This E-stereochemistry was deduced from the fact that only one isomer of the *S*-oxide **14a** was obtained. Interestingly, other sulfines generated in other ways, for example, *via* diazo compounds, usually will give diastereomeric mixtures with 2,3-dimethylbutadiene [13–16].

A solution of **13a** in DMSO-$d_6$ features a $^{13}C$ NMR spectrum similar to but distinctively different from that of isatin [17,18]. In isatin (**10**), the signals from carbon

**Scheme 1**



**Scheme 3**



atoms 2 and 3 appeared at 159.4 and 184.3 ppm [17], respectively, whereas the corresponding signals from the sulfine **13a** appeared at 160.0 and 168.9 ppm, respectively. In the proton NMR spectrum, the signal from the 4-H proton was shifted significantly more downfield in the spectrum of **13a** (8.08 ppm) as compared with 7.47 for isatin **10** and actually even more so in isoindigo **15a** (9.10 ppm). These data clearly indicate that the proton in position 4 is strongly influenced by the anisotropic deshielding of the cone of interaction from the SO group (for **13a**) and the C═O group in the neighboring ring (for **15a**).The general similarity of the spectra of **10** and **13a**, however, was taken as evidence that the species present in the solution is (**13a**) actually not an adduct, as a result of nucleophilic addition of DMSO to **13a**. A solution of **13a** in DMSO is, however, not permanently stable and after 7 days 90% of the sulfine will be converted to isoindigo **15a**. This type of conversion was faster for derivatives substituted with halogen atoms in the benzene ring.

The sulfines **13a** and **13b** can, under dry conditions, be stored for several months at room temperature without decomposition. In the presence of moisture, the sulfines will eliminate $SO_2$ and the starting materials, that is, the oxindoles **11a** and **11b**, will be formed slowly. This type of decomposition has been observed previously for other sulfine derivatives on several occasions [11,19]. When **13a** and **13b** are dissolved in chloroform and saturated with water, the cleavage process is quite quick (*e.g.*, total decomposition within 15 min at 40°C).

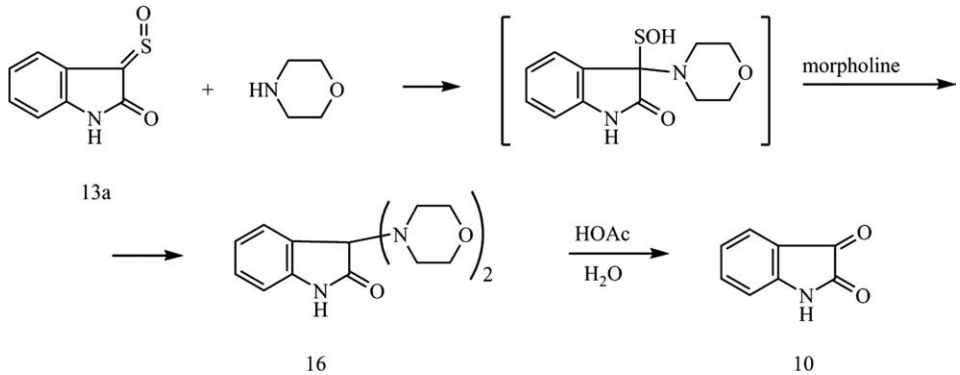
A number of substituted oxindoles, for example, [20–25] 6-chloro-oxindole, 6-bromo-oxindole, and 5-nitro-oxindole likewise could be converted to sulfines as well as adducts with 2,3-dimethyl-butadiene. All these derivatives of **13a** substituted in the benzene ring could readily be converted to ring-substituted derivatives of isoindigo.

As expected, the sulfine **13a** reacted readily with a number of nucleophilic reagents. Thus, morpholine gave the known [26] adduct **19** (previously prepared form isatin and morpholine) as shown in Scheme 4. Thus, addition of morpholine to a solution of the sulfine **13a** in acetonitrile at 35°C quickly faded the dark violet color and a solid precipitated within 2 min, which consists of **16** and morpholinium sulfite, which could be easily removed by extraction of the mixture with water. The nature of the side-product, morpholinium sulfite, was established in an independent experiment, wherein morpholine dissolved in water was reacted with sulfur dioxide. As indicated in Scheme 4, the sulfine **13a** could be converted to isatin **10**. However, simple treatment with water could not effect this transformation.

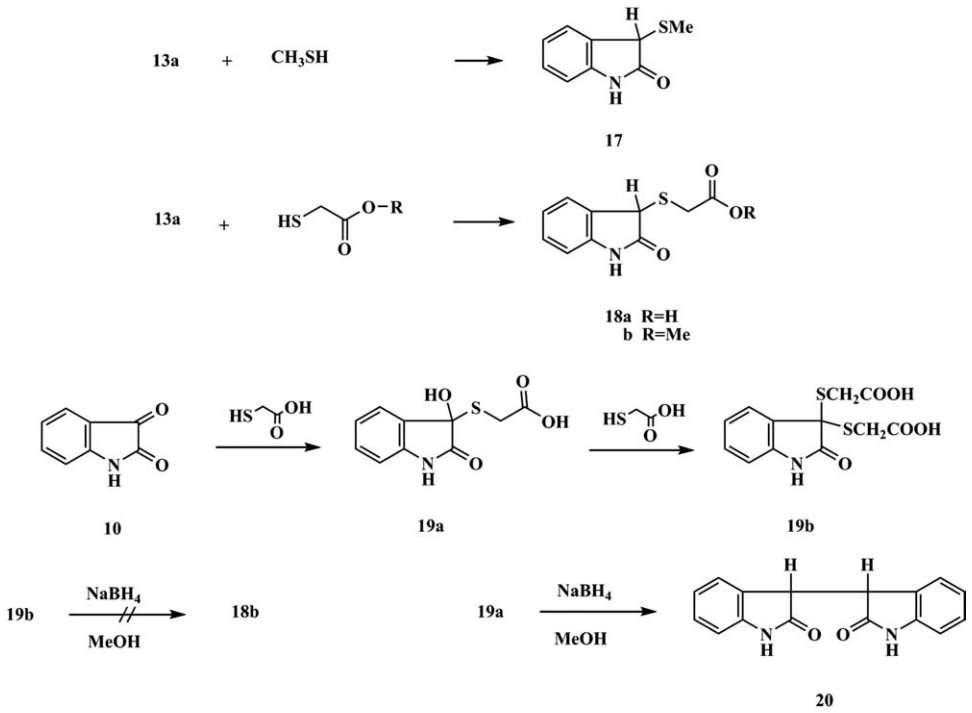
Thiols also reacted readily with the sulfine **13a**, thus, methanethiol gave the known [17] compound **17** and thiolacetic acid and methyl thiolacetate, respectively, the new molecules **18a** and **18b**, both in excellent yields. The NMR data of **18a** are in disagreement with those reported in the literature, wherein a mixture composed of isatin, pentafluoroaniline, and thiolacetic acid has been claimed to give **18a**. This unusual experiment should be repeated [27].

Although isatin and thiolacetic acid readily could be converted to the adduct **19a**, this molecule could not be converted to **18a** because the adduct **19a** is quite labile

**Scheme 4**



**Scheme 5**



under basic as well as acidic conditions. The product formed was a coupled reduction product of isatin, namely isatid **20**, a well-known molecule [28,29]. Treatment of the adduct **19a** with acetic anhydride at ambient temperature quickly cleaved the adduct yielding isatin **10**. The bis-adduct **19b**, however, is quite stable under these conditions (Scheme 5).

## EXPERIMENTAL

Melting points were uncorrected and determined using a Büchi B-545 apparatus. NMR spectra were obtained in DMSO-$d_6$ on a Bruker 300-MHz spectrometer. IR (neat) was recorded with an Avatar 330 FTIR apparatus (Thermo Nicolet).

**Ethyl 2-phenylamino-4-oxo-4,5-dihydrothiophene-3-carboxylate (2).** Ethyl 4-chloro-acetoacetate (16.5 g, 0.1 mol) in dioxane (80 mL) was treated with sodium hydride (4.5 g, 60% in oil) at 30°C. When the evolution of hydrogen had ceased (~20 min), phenyl isothiocyanate (13.5 g, 0.1 mol) in dioxane (20 mL) was added at 25–30°C to the stirred mixture. The temperature was allowed to reach 40°C, and at this point, a thick slurry was formed. After 1 h at 35–40°C, the mixture was poured into water and the solid formed was collected, washed with water, and recrystallized from ethanol, 22.9 g (87%), mp. 146–148°C (lit. [8] 146–148°C). IR 3198, 2983, 2926, 1643, 1555, 1548, 1406, 1382, 1344, 1283, 1223, 1152, 1037, 997, 800, 784, 754 $cm^{-1}$; $^1H$ NMR δ: 1.25 (t, 3H, $CH_3$), 3.67 (s, 2H, $CH_2$), 4.22 (q, 2H, $OCH_2$), 7.36–7.51 (m, 5H, arom CH), 11.2 (br s, 1H, NH); $^{13}C$ NMR δ: 14.4 (q), 38.0 (t), 59.3 (t), 97.0 (s), 125.1 (d), 127.8 (d), 129.5 (d), 137.3 (s), 156.1 (s), 182.7 (s), 190.5 (s).

**Ethyl 2-phenylamino-4-oxo-5-sulfinato-4,5-dihydrothiophene-3-carboxylate (3).** The ester **2** (2.63 g, 10 mmol) in acetonitrile (35 mL) was treated with thionyl chloride (1.25 mL, 15 mmol) at 35°C. A precipitate of yellow needles was collected after 1 h, (2.90 g, 96%), mp. >260°C dec.; IR 3161, 2968, 1641, 1538, 1408, 1377, 1172, 1018, 941, 788 $cm^{-1}$; $^1H$ NMR δ: 1.44 (t, 3H, $CH_3$), 4.24 (q, 2H, $OCH_2$), 7.38–7.57 (m, 5H, arom CH), 11.4 (br. s, 1H, NH); $^{13}C$ NMR δ: 14.3 (q), 59.6 (t), 97.5 (s), 125.9 (d), 129.1 (d), 129.4 (d), 137.0 (s), 163.5 (s), 172.1 (s), 178.8 (s), 191.0 (s).

**The adduct (4).** The yellow sulfine **3** (3.09 g, 10 mmol) was suspended in acetonitrile (85 mL) and 2,3-dimethylbutadiene in excess was introduced to the stirred mixture at 50–55°C. The solution obtained was concentrated and the colorless product was collected (3.25 g, 86%); mp. 200–202°C (lit. [6] 200–202°C); IR 3162, 3058, 2974, 1660, 1548, 1415, 1400, 1210, 1063, 1032, 800, 769, 696 $cm^{-1}$; $^1H$ NMR δ: 1.27 (t, 3H, $CH_3$), 1.59 (s, 6H, 2 $CH_3$), 2.75 (2H, $CH_2$), 3.45 (2H, $CH_2$), 4.26 (q, 2H, $OCH_2$), 7.40–7.55 (m, 5H, arom CH), 11.4 (s, 1H, NH); $^{13}C$ NMR δ: 14.3 (q), 19.0 (q), 19.2 (q), 39.7 (t), 52.3 (t), 59.7 (t), 79.0 (s), 97.2 (s), 119.1 (s), 125.4 (d), 126.7 (s), 128.3 (d), 129.7 (d), 137.2 (s), 164.2 (s), 180.4 (s), 188.1 (s).

**2-Oxindole-3-thione *S*-oxide 13a.** Thionyl chloride (15.0 mL) was added during 3 min to a stirred solution of oxindole (13.3 g, 0.1 mol) in acetonitrile (120 mL) at 25–30°C. The dark violet product started to separate within 1 min and the reaction is completed in 10 min. The sulfine **13a** was collected and dried in a desiccator (17.08 g, 95%); mp. ~120°C dec; IR: NH 3240 (br), 1702, 1666, 1607, 1456, 1326, 1201, 1126, 1089, 1070, 764 $cm^{-1}$; $^1H$ NMR δ: 6.83 (d), 7.00 (d), 7.40 (d), 8.07 (d, 4-H), 10.9 (s, NH); $^{13}C$ NMR δ: 110.5 (d), 122.1 (s), 122.6 (d), 126.1 (d), 134.3 (d), 140.7 (s), 166.0 (s), 169.0 (s); Anal. calcd. for $C_8H_5NO_2S$: C, 53.2; H, 2.88; N, 7.78 Found: C, 53.5; H, 3.15; N, 7.65.

***N*-Methyl-2-oxindole-3-thione *S*-oxide 13b.** The procedure given for the parent compound **13a** was used, except that methyl acetate was used as medium starting with *N*-methyl-oxindole. Before isolation of the product, part of the solvent was partially evaporated; (Yield 78%); mp 130–140°C (violent dec);$^1$H NMR δ: 3.12 (s, 3H, $NCH_3$), 7.05–7.11 (dd+d, 2H arom CH), 7.49 (dd, 1H, arom CH), 8.10 (d, 1H, 4-H); $^{13}$C NMR δ: 125.8 (q), 109.5 (d), 120.9 (s), 121.7 (d), 125.8 (d), 134.2 (d), 141.8 (s), 164.5 (s), 168.2 (s); Anal. calcd. for $C_9H_7NO_2S$: C, 56.1; H, 3.70; N, 7.28. Found: C, 55.7, H, 3.80; N, 7.35.

**The adduct 14a.** The sulfine **13a** (179 mg, 1 mmol) was suspended in acetonitrile (5.0 mL), and 2,3-dimethyl-butadiene (123 mg, 1.5 mmol) was introduced at 30–35°C. The dark violet starting material went into solution and was soon replaced by the colorless adduct **14a**, which has a low solubility in acetonitrile, 247 mg, (95%); mp. 195–196°C; IR 3255, 2919, 2888, 1716 (s), 1617, 1469, 1324, 1186, 1030, 738, 678 cm$^{-1}$; $^1$H NMR δ: 1,63 (s, 3H, $CH_3$), 1.79 (s, 3H, $CH_3$), 2.61 (2H, $CH_2$), 3.60 (2H, $CH_2$), 6.91 (d, 1H), 7.03 (dd, 1H), 7.20 (d, 1H), 7.33 (dd, 1H), 10.8 (s, 1H, NH) $^{13}$C NMR δ: 19.2 (q), 19.6 (q), 35.4 (t), 50.1 (t), 66.1 (s), 109.8 (d), 118.2 (s), 122.1 (s), 125.3 (s), 125.3 (d), 125.8 (s), 129.7 (d), 143.1 (s), 174.5 (s). Anal. calcd. for $C_{14}H_{15}NO_2S$: C, 64.33; H, 5.78; N, 7.25; Found, C, 64.12; H, 5.90; N, 7.15.

**The adduct 14b.** The same procedure as for **14a** was used. Yield (94%), mp. 191–192°C; IR; 3060 (w), 1704 (s), 1609, 1468, 1372, 1344, 1052 (s), 755 (s) cm$^{-1}$; $^1$H NMR δ: 1.69 (s, 3H, $CH_3$), 1.80 (s, 3H, $CH_3$), 2.62 (2H, $CH_2$), 3.17 (s, 3H, $NCH_3$), 3.62 (2H, $CH_2$), 7.10–7.46 (m, 4H, arom CH); $^{13}$C NMR δ: 19.2 (q), 19.6 (q), 26.6 (q), 35.3 (t), 50.2 (t), 65.5 (s), 108.9 (d), 118.2 (s), 122.7 (d), 124.6 (s), 125.0 (d), 125.7 (s), 129.8 (d), 144.5 (s), 172.9 (s). **6-Bromo-2-oxindole-3-thione *S*-oxide.** The procedure given for **13a** was used, starting with 6-bromo-oxindole [24]. Yield 98%, mp. 140°C dec. $^1$H NMR δ 7.10 (dd, 1H, 5-H), 7.18 (d, 1H, 7-H), 7.94 (d, 1H, 4-H). $^{13}$C NMR δ: 113.3 (d), 123.5 (s), 125.3 (d), 127.1 (d), 127.2 (s), 141.8 (s), 165.7 (s), 167.8 (s). Anal. calcd. for $C_8H_4BrNO_2S$: C, 37.61; H, 1.57; N, 5.46 Found: C, 37.40; H, 1.66; N, 5.30.

**Adduct between 6-bromo-2-oxindole-3-thione *S*-oxide and 2,3-dimethylbutadiene.** The procedure described for **14a** was used. Yield 98%, mp. 220°C dec. IR 3110, 3080, 1720, 1609, 1447, 1038, 821 cm$^{-1}$; $^1$H NMR δ 1.68 (s, 3H, $CH_3$), 1.77 (s, 3H, $CH_3$), 2.62 (2H, $CH_2$), 3.61 (2H, $CH_2$), 7.06 (d, 1H, 7-H, $J$ = 1.83 ppm), 7.11 (d, 1H, 4-H, $J$ = 8.25), 7.22 (dd, 1H, 5-H), 11.0 (s, 1H, NH). $^{13}$C NMR δ; 19.7 (q), 20.1 (q), 35.7 (t), 50.8 (t), 66.7 (s), 113.2 (d), 118.8 (s), 123.1 (s), 125.0 (s), 125.2 (d), 126.4 (s), 127.6 (d), 145.3 (s), 175.1 (s). Anal. calcd. for $C_{11}H_{14}BrNO_2S$: C, 49.39; H, 4.13; N, 4.09 Found: C, 49.19; H, 4.29; N, 3.97.

**6-Chloro-2-oxindole-3-thione *S*-oxide.** The procedure above was used. Yield 92%, IR 3102, 1712, 1606, 1330, 1104, 1067, 808, 719 cm$^{-1}$; $^{13}$C NMR δ 109.1 (d), 120.8 (d), 124.7 (s), 125.7 (s), 131.7 (d), 145.1 (s), 165.9 (s), 167.8 (s).

**Adduct between 5-bromo-2-oxindole-3-thione *S*-oxide and 2,3-dimethylbutadiene.** Yield: 87%, mp. 220°C dec. IR 3176, 3145, 2902, 1715, 1618, 1468, 1300, 1227, 1039, 823 cm$^{-1}$; $^1$H NMR δ 1.70 (s, 3H, $CH_3$), 1.78 (s, 3H, $CH_3$), 2.57 (2H, $CH_2$), 3.62 (2H, $CH_2$), 6.88 (d, 1H, 7-H), 7.26 (d, 1H, 4-H), 7.53 (dd, 1H, 6-H), 11.0 (s, 1H, NH). $^{13}$C NMR δ 19.2 (q), 19.6 (q), 34.7 (t), 50.0 (t), 65.9 (s), 111.7 (s), 113.6 (d), 117.8 (s), 125.7 (d), 127.7 (s), 127.9 (s), 132.4 (d), 142.3 (s), 174.1 (s).

**Adduct between 6-chloro-2-oxindole-3-thione *S*-oxide and 2,3-dimethylbutadiene.** Yield: 92%, mp. 190°C dec. IR 3193, 1720, 1614, 1481, 1449, 1322, 1238, 1040, 926, 806 cm$^{-1}$; $^1$H NMR δ 1.68 (s, 3H, $CH_3$), 1.77 (s, 3H, $CH_3$), 2.56 (2H, $CH_2$), 3.62 (2H, $CH_2$), 6.93 (d, 1H, 7-H), 7.09 (dd, 1H, 5-H), 7.17 (d, 1H, 4-H), 11.0 (br s, 1H, NH). $^{13}$C NMR δ; 19.2 (q), 19.6 (q), 35.1 (t), 50.2 (t), 66.0 (s), 109.9 (d), 113.6 (s), 121.7 (d), 124.0 (s), 125.8 (s), 126.7 (d), 134.1 (s), 144.6 (s), 174.6 (s). Anal. calcd. for $C_{14}H_{14}ClNO_2S$. C, 56.90; H, 4.75; N, 4.69. Found: C, 56.71; H, 4.90; N, 4.58.

**6,6′-Dichloroisoindigo.** The 6-chloro-S-oxide (2.0 g) obtained above was heated at reflux in acetonitrile (50 mL) for 1 h and the dark blue precipitate of 6,6′-dichloroisoindigo was collected and washed with ethanol. Yield: 96% mp. > 300°C. The spectroscopic data were in agreement with those in the literature [30,31].

**5-Nitro-2-oxindole-3-thione *S*-oxide.** The procedure above was used. Yield: 75%, mp. (violent dec.) 140°C. $^1$H NMR δ; 7.03 (d, 7-H, $J_1$ = 8.75), 8.27 (dd, 6-H, $J_1$ = 8.75, $J_2$ = 2.31), 8.72 (d, 4-H, $J_2$ = 2.31), 11.6 (s, NH). $^{13}$C NMR δ; 110.7 (d), 120.4 (d), 121.4 (s), 129.6 (d), 142, 2 (s), 145.7 (s), 166.0 (s), 167.0 (s). No acceptable elemental analysis data could be obtained for this molecule, but its adduct could be analyzed.

**Adduct between 5-nitro-2-oxindole-3-thione *S*-oxide and 2,3-dimethylbutadiene.** The procedure above was used. Yield: 84%, mp. 150°C dec. $^1$H NMR δ: 1.67 (s, 3H, $CH_3$), 1.73 (s, 3H, $CH_3$), 2.50 (2H, $CH_2$), 3.65 (2H, $CH_2$), 7.09 (d, 1H, 7-H), 7.93 (d, 1H, 4-H), 8.30 (dd, 1H, 6-H, $J_1$ = 8.75, $J_2$ = 2.31), 11.5 (s, 1H, NH). $^{13}$C NMR δ; 19.2 (q), 19.5 (q), 34.4 (t), 50.3 (t), 65.9 (s), 109.9 (d), 118.1 (s), 120.5 (d), 125.9 (s), 126.1 (s), 126.8 (d), 142.4 (s), 149.3(s), 175.0 (s). Anal. calcd. for $C_{14}H_{14}N_2O_4S$: C, 31.30; H, 4.59; N, 4.56. Found: C, 31.19; H, 4.63; N, 4.45.

**Isoindigo 15a.** The sulfine **13a** (1.79 g, 10 mmol) in acetonitrile (35 mL) was refluxed until no more precipitate of the product **15a** was formed (∼15 min). Yield: (100%); mp. >300°C; $^1$H NMR δ; 6.83 (d), 6.91 (dd), 7.40 (dd), 9.06 (d), 10.9 (s, NH); $^{13}$C NMR δ; 109.5 (d), 121.1 (d), 121.7 (s), 129.4 (d), 132.4 (d), 133.4 (s), 144.2 (s), 169.1 (s). UV in agreement with data in ref. 30. The $^1$H NMR data were in agreement with those in the literature [32,33]. However, the signal just above 9.0 ppm was incorrectly reported as a singlet.

***N*,*N*′-Dimethylisoindigo 15b.** The same procedure as for **15a** was used, Yield 100%, mp. 270–271°C (lit. [33] 270°C; 267–269°C [34]); IR 3130 (w), 2980 (w), 1681 (s), 1605, 1469, 1374, 1338, 1089, 1076, 944, 866, 773, 740 cm$^{-1}$; $^1$H NMR δ: 3.20 (s, 6H, $2NCH_3$), 7.0–7.5 (m, 6H, arom CH), 9.12 (2d, 2H, 4-H); $^{13}$C NMR δ: 26.1 (q), 108.5 (d), 120.6 (s), 121.8 (d), 129.1 (d), 132.7 (d), 132.8 (s), 145.1 (s), 168.0 (s).

**3,3′-Bis(morpholino)oxindole 16.** Morpholine (261 mg, 3 mmol) was added to the sulfine **13a** (358 mg, 2 mmol) in acetonitrile (6 mL). A white solid appeared within 2 min, which was collected and washed with water after 30 min at 25°C, 395 mg (64%), mp. 177–179°C (lit. [26] 177–179°C). The spectral data were in agreement with those in the literature [26].

***S*-Methyl-3-thiolo-oxindole 17.** A stream of methanthiol was introduced into a stirred suspension of the sulfine **13a**, 1.79 g, 10 mmol) in acetonitrile (80 mL) at 35°C. When the dark violet starting material had been consumed (~1 h) the solution was evaporated and the crude product recrystallized form ethanol, 1.41 g (72%) mp. 125–127°C (lit. [18] 125.5–127°C). The NMR data were in agreement with those reported in the literature [21]. The signal from the 3-C carbon atom resonated at 45.5 ppm.

***S*-Carboxymethyl-3-thiolo-oxindole 18a.** The sulfine **13a** (358 mg, 2 mmol) was added to a solution of thioloacetic acid (202 mg, 2.3 mmol) in acetonitrile (8 mL). As there seemed to be no reaction at ambient temperature the reaction mixture was heated at reflux for 20 min. During this period, the solution became colorless. After concentration and treatment with ether, the product was obtained as colorless crystals, 360 mg, (81%) mp. 160–162°C. IR 3280, 1700, 1621, 1469, 1177, 1120, 872, 740 $cm^{-1}$; $^1H$ NMR δ: 3.48 (q, 2H, $CH_2$, $J = 15.2$ ppm), 4.81 (s, 1H, 3-CH), 6.85–7.34 (m, 4H, arom CH), 10.6 (s, 1H, NH), 12.8 (br. s, 1H, OH). $^{13}C$ NMR δ: 40.7 (t), 50.6 (d), 109.6 (d), 121.8 (d), 124.9 (d), 126.4 (s), 129.5 (d), 143.0 (s), 170.0 (s), 175.2 (s). Anal. calcd. for $C_{10}H_9NO_3S$: C, 53.80; H, 4.07; N, 6.27; Found: C, 53.63; H, 4.20; N, 6.05.

**Methyl *S*-carboxymethyl-3-thiolo-oxindole 18b.** Methyl thioloacetate (233 mg, 2.3 mmol) was added to the sulfine **13a** (351 mg, 2.0 mmol) in acetonitrile (6.0 mL) at 45°C. The color faded quickly. After 10 min the solution was evaporated and the oil obtained was treated with methyl acetate/diisopropyl ether (1:4), which gave crystals of the product, 371 mg (79%), mp. 109–110°C; IR: 3146, 1730, 1704, 1673, 1617, 1470, 1281, 1266, 1005, 743, 676 $cm^{-1}$; $^1H$ NMR 3.53 (q, 2H, $CH_2$), 3.63 (s, 3H, $OCH_3$), 4.84 (s, 1H, 3-CH), 6.83–7.33 (m, 4H, arom CH), 10.6 (s, 1H, NH); $^{13}C$ NMR 40.1 (t), 50.6 (q), 52.2 (d), 109.7 (d), 121.8 (d), 125.2 (d), 126.3 (s), 129.4 (d), 143.0 (s), 169.1 (s), 175.1 (s). Anal. calcd. for $C_{11}H_{11}NO_3S$: C, 55.68; H, 4.67; N, 5.90 Found: C, 55.73; H, 4.78, N, 5.90.

**The monocarboxylic acid 19a.** Isatin (14.7 g, 0.1 mmol) and thioloacetic acid (9.2 g, 0.1 mol) was heated in dioxan (30 mL) for 0.5 h. After concentration, the residue was treated with methanol/water 1:2, which gave the title compound, 20.1 g (84%), mp. 191–193°C. IR 3288, 3100–2550, 1728, 1693, 1613, 1469, 1422, 1267, 1131, 916, 822, 749 $cm^{-1}$; $^1H$ NMR δ: 3.75 (2H, q), 6.88 (d, 1H), 7.02 (dd, 1H), 7.13 (dd, 1H), 7.39 (d, 1H), 10.4 (s, 1H); $^{13}C$ NMR δ: 29.7 (t), 77.9 (s), 109.9 (d), 121.9 (d), 124.0 (d), 129.1 (s), 130.1 (d), 139.8 (s), 171.1 (s), 174.6 (s). Anal. calcd. for $C_{10}H_8NO_4S$: C, 50.20; H, 3.79; N, 5.84; Found: C, 49.81; H, 3.85; N, 5.72.

**The dicarboxylic acid 19b.** Isatin (14.7 g, 0.1 mmol) and thioloacetic acid (20.2 g, 0.22 mmol) in dioxane (50 mL) was heated to reflux for 3 h. After concentration, the residue was treated with methanol/water 1:1, which quickly yielded crystals of the product 26.8 (86%); mp. 202–204 °C. IR 3288, 3170–2300, 1731, 1697, 1615, 1469, 1175, 1057, 904, 750 $cm^{-1}$; $^1H$ NMR δ: 3.96 (s, 4H), 6.90 (d, 1H), 7.03 (dd, 1H), 7.29 (dd, 1H), 7.33 (d, 1H), 10.9 (s, 1H, NH), 12.7 (s, 2H, OH); $^{13}C$ NMR δ: 32.4 (t), 55.1 (s), 110.3 (d), 122.4 (d), 124.3 (d), 127.8 (s), 130.1 (d), 140.3 (s), 170.0 (s), 173.6 (s). Modified nitration of tetraphenylporphyrin at para of phenyl with $HNO_3/Cl_3CCOOH$ and one-pot nitration of free tetraarylporphyrins to metalized 2-nitroporphyrin in high yield are described. A novel reducer of $Zn/HCOONH_4$ has been developed for above nitro of porphyrin into amino effectively.

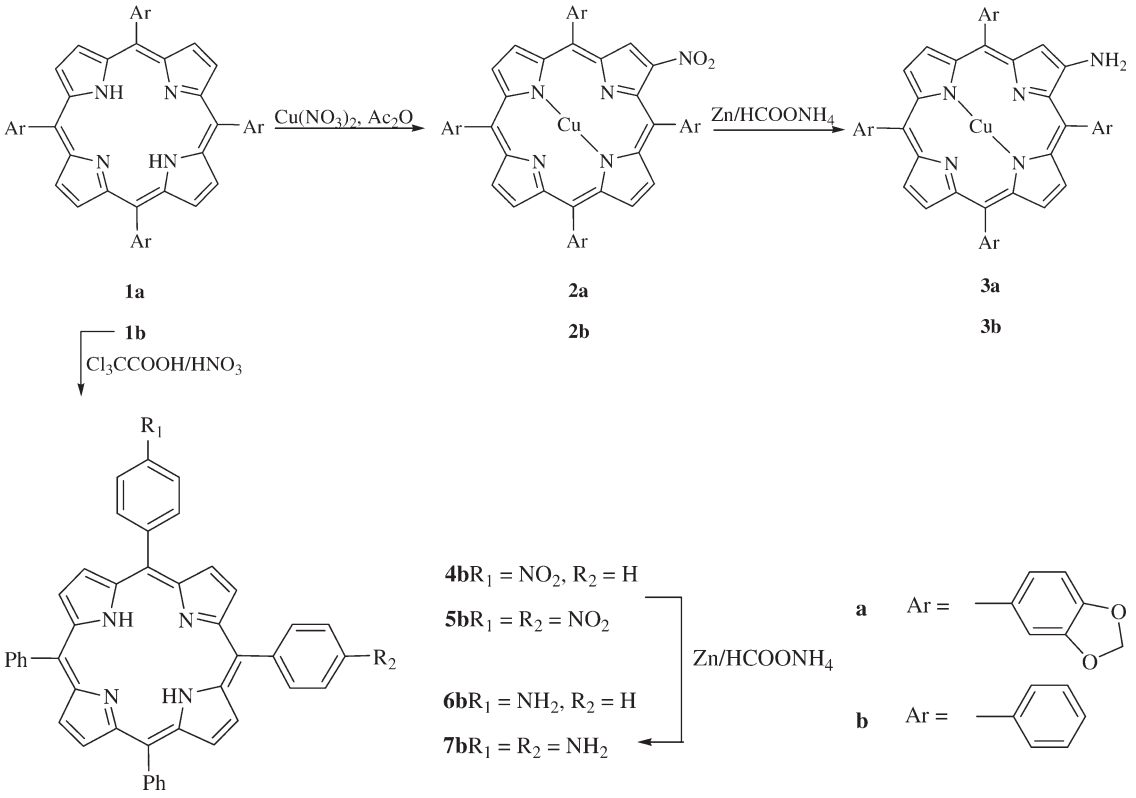
*J. Heterocyclic Chem.*, **47**, 1221 (2010).

## INTRODUCTION

Over the last three decades, functionalization of porphyrins has received considerable attention for introducing functions into porphyrins could varied the properties of porphyrins and afford availability of diverse porphyrin architecture by arising a energetic bond for further functionalization [1]. Therefore, fairish efforts were underway in various laboratories to explore novel and available approach to modify porphyrins [2]. *meso*-Tetraarylporphyrin (TAP) including tetraphenylporphyrin (TPP) is one of the most readily available synthetic porphyrin [3], so modifying its porphyrin macrocycle or aryl around was an available way to get various novel porphyrins [4]. The nitration modification has been investigated in detail by many reagents [5]. The sort of porphyrin containing amino function has wide use in the architecture of porphyrins with extended π-system, chlorines, porphyrin assembly, supermolecule propertie [6].

We have afforded access to nitro TPP by nitration of para of phenyl, which was transformed into widely useful amino function for subsequent modification [7].

**Scheme 1.** Synthesis of amino porphyrin via nitration and reduction.



Herein, we report the synthesis of TAP by modified Alder–Longo method condensing pyrrole with acid sensitive 3,4-methylenndioxyphenylaldehyde, sequent modified nitration of phenyl, as well as one-pot nitration of porphyrin periphery. A rapid and efficient process for reduction of nitro group at phenyl or β of porphyrin into amino has been developed.

## RESULTS AND DISCUSSION

On account of the fact that *meso*-TPP **1b** was particularly readily prepared, it should be a handy way to achieve a variety of substituted porphyrins by introducing suitable group to TPP, especially at the phenyl rings. A few workers reported phenyl para nitration of TPP with fuming nitric acid, or $NaNO_2$/TFA (trifluoroacetic acid). As shown in Scheme 1, condensation of pyrrole with aromatic aldehyde in refluxing xylene under *meta*-nitrobenzoic acid provided porphyrin **1a** and **1b** in moderate yield of somewhat 50%. The starting porphyrin TPP was subjected to nitration to afford porphyrin containing mono and bis-nitro phenyl. Instead of TFA/$NaNO_2$, which was used in the Smith's method, the solid trichloroacetic acid and concentrated nitric acid was found to be effect, preferable control for this reaction. In chloroform, TPP was translated into porphyrins **4b** and **5b** at room temperature under air condition with total yield 81%.

In the molecule of TAP, β-site of pyrrolic is another active site as well as para-site of phenyl, and nitration at this site with various reagents and the further reduction had been investigated in detail by many researchers [8]. The earlier works showed that there were two steps, including metallization of free porphyrins with chloride or acetate and nitration using nitrate salt. Cuprous ion was found to readily insert into core of free porphyrins during treatment with cuprous ion, implying that metallization and nitration both could be likely conducted by sole cuprous nitrate. The previous nitration through two steps may be pieced together. The attempt to ''one-pot'' nitration with acetic anhydride and cuprous nitrate was successful in excellent yield. Nitration of free base porphyrins **1a** and **1b** by $Cu(NO_3)_2$ and $Ac_2O$ for 2 h resulted in **2a** and **2b** with nitro group at β-site.

Nitrobenzenes were successfully converted into corresponding azoaryl by Zn/$HCOONH_4$ [9], similarly, we would prepare azoaryl porphyrin [10] from nitro compound. As shown in Scheme 1, an unpredicted amino porphyrin was achieved starting with **4b** under similar conditions. No azoaryl products came into being no matter how we regulated the reaction conditions, such as

temperature, stoichiometry of reagent, solvent, and reaction times. Treatment of nitro porphyrins **4b** and **5b** at room temperature in $CHCl_3$ with large excess Zn/$HCOONH_4$ gave rapidly corresponding amino porphyrins over a few minutes in yield up to 90%. As alike as **4b** and **5b** with *para*-nitrophenyl porphyrin, easy reduction of **2a** and **2b** with nitro at β-site produced **3a** and **3b** in high yield.

Most reductions of nitro were actualized by $SnCl_2$/HCl or hydrogenation with Pd/C. However, many functions were sensitive to strong acid, as well as the hardness of separating inorganic objects was trying. Although Pd/C is high efficient, it is somewhat inconstant. An attempt of reduction was unsuccessful, the great mass of material spared when crude nitration product from TPP was performed with Pd/C. The value of here process is nevertheless very obvious: milder conditions, simpler experimental procedure.

In summary, we have shown an effective nitration at para of phenyl of tetraphenylporphyirn with $HNO_3$/$Cl_3CCOOH$, and ''one-pot'' nitration of free TAPs by $Cu(NO_3)_2$/$(CH_3CO)_2O$ excellently. The process for reduction of nitro at above porphyrins into amino using Zn/$HCOONH_4$ was rapid, convenient, and excellent. Further transformation for application of amino porpyrins is underway.

## EXPERIMENTAL

**General.** Pyrrole was purchased from Aldrich and distilled under reduced pressure immediately before use. All other reagents and solvents were used as received from Aldrich. Solvents were reagent grade unless otherwise specified and were dried and distilled by standard method. The UV-visible spectra were obtained on a Perkin-Elmer LS-5B spectrofluroimeter. $^1H$ NMR spectra were recorded on BRUKER AVANCE DMX 500 spectrometer. Elementary analyses were obtained on a Carlo Erba 1106 Elemental Analyzer.

Porphyrins **1b**, **1a** were synthesized by literature methods [7]. Spectra of porphyrins **1b–7b** were agreement with literature.

***5,10,15,20-Tetra (3,4-methylendioxy)phenylporphyrin (1a).*** Porphyrin **1a** was synthesized in yield 48%. $^1H$ NMR (deuterichloroform): δ 8.92–8.80 (8H, m, β -pyrrole), 7.70–7.63 (m, 8H), 7.24–7.17 (m, 8H), 6.25 (s, 4H), −2.73 (s, 2H). UV $\lambda_{max}$: 419.0, 516.0, 554.0, 597.0, 648.0 nm. *Anal*. Calcd. for $C_{48}H_{30}N_4O_8$: C, 72.90; H, 3.82; N, 7.09. Found: C, 72.73; H, 3.91; N, 7.17.

***5-(4-Nitrophenyl)-10,15,20-triphenyl-porphyrin (4b) and 5,10-di(4-nitrophenyl)-15,20-diphenyl-porphyrin (5b).*** To a solution of porphyrin **1b** (1 g, 1.6 mmol) and trichloroacetic acid (30 g) in chloroform (100 mL) was slowly added $HNO_3$ (6.0 mL, 75%, 15.5 mmol) over 2 min with fierce stir at room temperature under atmosphere. The mixture was stirred for 5 min. Reaction was quenched with water, and the mixture was neutralized with ammonium hydroxide aqueous solution to pH = 7. Chloroform (100 mL) was added, and the organic layer was washed with water (4 × 150 mL), and dried over magnesium sulfate. Solvent was removed with evaporation under reduced pressure. The crude product was purified by column chromatography to provide **4b** (370 mg, 36%) and **5b** (506 mg, 45%).

**General procedure for nitration of β at porphyrin.** To a solution of porphyrins in $Ac_2O$ and chloroform, $Cu(NO_3)_2$ was added. The mixture was heated to reflux, kept for 2 h. Solvent was evaporated in a vacuum. Purification on silica gel gave nitro porphyrins in yields of about 90%.

***(2-nitro-5,10,15,20- tetra (3,4-methylendioxy)phenylporphyrinato)copper-II (2a).*** Porphyrin **1a** (500 mg, 0.8 mmol) in $Ac_2O$ (20 mL, 0.2 mol) by $Cu(NO_3)_2 \bullet 3H_2O$ (800 mg, 3.3 mmol) gave porphyrin **2a** in yield 86%. IR: $NO_2$ 1508, 1345 $cm^{-1}$. UV: $\lambda_{max}$ 432, 552.5, 595.5 nm. *Anal*. Calcd. for $C_{48}H_{27}CuN_5O_{10}$: C, 64.25; H, 3.03; N, 7.80. Found: C, 64.33; H, 3.09; N, 7.65.

**General procedure for reduction of nitro function to amino function.** To a solution of nitro porphyrins in $CHCl_3$, Zn powder, and $HCOONH_4$ was added with fierce stirring. The mixture was kept at room temperature for a little of 5 min. The solid inorganic was removed by filtration. Solution of porphyrin was washed by water, followed by drying with magnesium sulfate. Solvent was evaporated in a vacuum. The crude product was purified on a silica gel column, providing amino porphyrins in yield of 82–90%.

***(2-Amino-5,10,15,20-tetra (3,4-methylendioxy)phenylporphyrinato)copper-II (3a).*** Porphyrin **2a** (200 mg, 0.8 mmol) in $CHCl_3$ (50 mL) with Zn powder (5.0 g, 0.1 mol) and $HCOONH_4$ (8.0 g, 0.1 mol) gave porphyrin **3a** in yield 86%. IR: $NH_2$, 3475, 1483, 1247, 1036 $cm^{-1}$. UV: $\lambda_{max}$ 419, 547, 596nm. *Anal*. Calcd. for $C_{48}H_{29}CuN_5O_8$: C, 66.47; H, 3.37; N, 8.07. Found: C, 66.32; H, 3.43; N, 8.16.

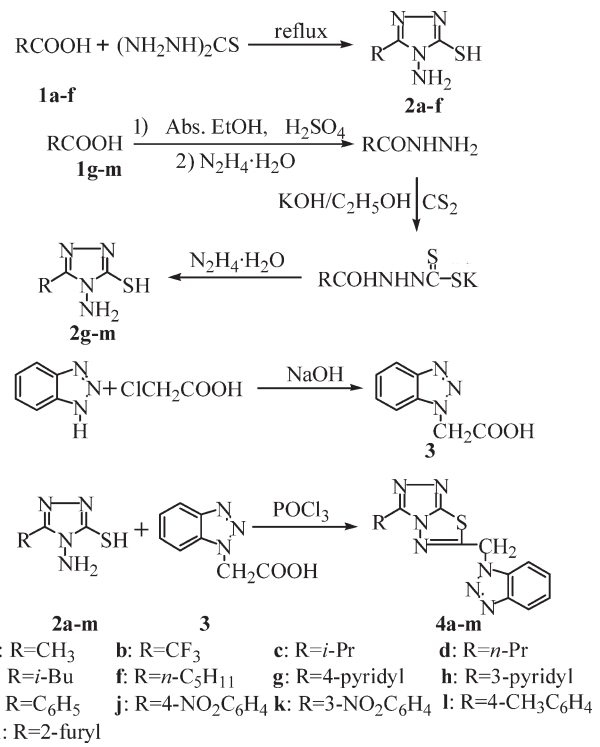
## INTRODUCTION

1,2,4-Triazoles and their heterocyclic derivatives represent an interesting class of compounds possessing a wide spectrum of biological activities, such as antifungal [1], antibacterial [2], antihypertensive [3], antileishmanial [4], anti-inflammatory [5], antiviral [6] activities. A large number of thiadiazole-containing ring system exhibits antibacterial [7] and antituberculosis [8] properties. Moreover, a survey of literature reveal that [1,2,4]triazolo[3,4-*b*][1,3,4]thiadiazole rings received much attention during recent years on account of their prominent utilization as antifungal [9], anti-inflammatory [10,11], antiviral, analgesic [12], anthelmintic [13], anti-HIV-1 [14], and antibacterial agents [15]. A triazolo thiadiazole system may be viewed as a cyclic analogue of two very important components thiosemicarbazide [16] and biguanide [17], which often display diverse biological activities. On the other hand, benzotriazole derivatives are of wide interest because of their diverse biological activity and potential clinical applications such as anti-inflammatory, antiviral, inactivator of Severe acute respiratory syndrome (SARS) protease and so on [18]. Therefore, it is envisaged that chemical entities with both [1,2,4]triazolo[3,4-*b*][1,3,4]thiadiazoles and benzotriazole would generate new interesting biological activities. In continuation of our ongoing research program aimed at developing new biologically active nitrogen and sulphur containing heterocycles, here we report the reaction of 3-alkyl/aryl substituted-4-amino-5-mercapto-1,2,4-triazoles **2a–m** with benzotriazole-1-yl acetic acid **3** in the presence of phosphorous oxychloride to give 3-alkyl/aryl-6-((1*H*-benzo[*d*][1,2,3]-triazol-1-yl)methyl)-[1,2,4]triazolo[3,4-*b*][1,3,4]thiadizoles **4a–m** (Scheme 1). In view of the reported biological activities of triazolo thiadiazoles, two selected compounds **4l** and **4m** are studied for their anti-inflammatory and analgesic activities.

## RESULTS AND DISCUSSION

The reaction sequences employed for synthesis of title compounds are shown in Scheme 1. The 3-alkyl-4-amino-5-mercapto-1,2,4-triazoles **2a-f** are synthesized by reacting alkyl acid with thiocarbohydrazide [19]. The required aromatic hydrazides are prepared by esterification of aromatic acid **1g-m** followed by treatment with hydrazine hydrate in absolute ethanol. The aromatic hydrazides are allowed to react with carbon disulphide in the presence of potassium hydroxide in ethanol to afford the corresponding intermediate potassium dithiocarbazinate. This salt undergoes ring closure with an excess of 80% hydrazine hydrate to give 4-amino-3-aryl-5-mercapto-1,2,4-triazoles **2g-m** [20]. Benzotriazole-1-yl acetic acid **3** is prepared by treating benzotriazole with chloroacetic acid in sodium hydroxide solution

**Scheme 1**



[21]. Condensation of 3-alkyl/aryl substituted-4-amino-5-mercapto-1,2,4-triazoles **2a–m** with benzotriazole-1-yl acetic acid **3** in presence of boiling phosphorous oxychloride yield 3-alkyl/aryl substituted-6-((1*H*-benzo[*d*][1,2,3]triazol-1-yl)methyl)-[1,2,4]triazolo[3,4-*b*][1,3,4]thiadizoles **4a–m** in 53–98% yields. Phosphorous oxychloride is necessary for this condensation, which activate the carbonyl group of acids and increase its electrophilicity to enhance the addition of 1,2,4-triazoles to the target compounds.

The structural elucidation of **3** is completed by analysis of gHSQC and gHMBC data. We can see that $^{3}J_{H7\text{-}C6}$ (Fig. 1). In addition, we get the single crystal of compound **3**. So compound **3** is benzotriazol-1-yl-acetic acid but not benzotriazol-2-yl-acetic acid.

**Figure 1.** Benzotriazole-1-yl acetic acid.

The structure assignments to new compounds **4a–m** are based on their elemental analyses and spectral data (IR, $^{1}$H NMR). The IR spectra of the cyclized products **4a–m** show a characteristic absorption at 1445–1592 $cm^{-1}$ attributed to benzene ring of benzotriazole stretching. The band in the range of 1610–1614 $cm^{-1}$ indicate the absorption of C=N. In the $^{1}$H NMR spectra of compounds **4a-m**, the absorption bands characteristic of the $-CO_2H$ and $-NH_2$ groups are absent, thereby indicating the involvement of the amino group of triazole and the carboxylic group of benzotriazole-1-yl acetic acid in the condensation reaction. Moreover, we discover $CH_2$ resonance appear singlets at 6.08–6.79 ppm. Thus, it is further confirmed the involvement of these functional groups in the cyclization of triazoles to triazolo thiadiazoles.

The inhibition ratio of compounds **4l** and **4m** are 8 and 22%, they show weak anti-inflammatory activity (Table 1). **4l** and **4m** are further tested for their analgesic activity; unfortunately the results are not very good, as they show no analgesic activity (Table 2).

## EXPERIMENTAL

The IR spectra are obtained as potassium bromide pellets with a FTS-40 spectrometer (BIO-RAD, U.S.A). The one-dimensional ($^1$H) and two-dimensional (gHSQC, gHMBC) NMR spectra are obtained on a Varian Inova-400 (400 MHz) spectrometer using $CDCl_3$ or DMSO-$d_6$ as solvent (shown in detail in data part) and tetramethylsilane as an internal standard, chemical shifts are given in ppm. Elemental analyses (C, H, N) are performed on a Perkin-Elmer Analyzer 2400. Melting points are determined using a Büchi B-540 instrument and are uncorrected (Tables 3–6).

**Table 3**

Crystal data and summary of data collection and structure refinment.

| Compound | $C_8H_7N_3O_2$ |
|---|---|
| Color/shape | Colorless/chip |
| Formula weight | 177.17 |
| Temperature (°C) | 293(2) |
| Crystal system | Monoclinic |
| Space group | P2(1)/c |
| Cell constants | |
| a (Å) | 13.234(2) |
| b (Å) | 4.4889(7) |
| c (Å) | 15.142(2) |
| α (°) | 90.00 |
| β (°) | 113.135(3) |
| γ (°) | 90.00 |
| Volume (Å$^3$) | 827.2(2) |
| Formula units/units cell | 4 |
| $D_{calc}$ (g cm$^{-3}$) | 1.423 |
| $F$ (000) | 368.0 |
| Absorption coefficient, m $\mu^{-1}$ | 0.106 |
| Diffractometer/Scan | Enraf-Noius CAD4, ω/2θ |
| Radiation, graphite | λ = 0.71073 Å |
| Monochromator Mo Kα | |
| Reflections for cell measurement and θ range (°) | 27.48, 3.35–27.48 |
| Index ranges | $-17 \le h \le 17$; $-5 \le k \le 5$; $-19 \le l \le 19$ |
| Reflection observed [$1 > 2\sigma(I)$] | 1775 [R(int) = 0.0249] |
| Maximum value of θ(°) | 27.48 |
| Computing | Data collection CAD4<br>Cell refinement CAD4<br>Data reduction PCSDP |
| Structure solution | SHELXL-97 |
| Structure refinement | SHELXL-97 |
| Data/restrains/parameters | 1775/0/123 |
| Goodness-of-fit on $F^2$ | 1.071 |
| Final $R$ indices | $R_1 = 0.0406$; $wR_2 = 0.1115$ |
| Largest diff. peak and hole (e Å$^{-3}$) | 0.208 and −0.186 |

**Benzotriazole-1-yl acetic acid (3).** Add 4.8 g (40 mmol) benzotriazole, 3.8 g (40 mmol) chloroacetic acid, 3.2 g (80 mmol) sodium hydroxide, and 100 mL water into a round bottom flask, reflux slowly for 3 h, filter immediately after reflux. The filtrate is cooled at room temperature and acidified with dilute hydrochloric acid till no deposit appear. It is filtered and washed thoroughly with cold water, dried, and recrystallized from butanol, Yield 78%, mp 216–218°.

gHMBC: (DMSO-$d_6$): $^3J_{H3\text{-}C1}$, $^3J_{H5\text{-}C1}$, $^3J_{H4\text{-}C2}$, $^3J_{H5\text{-}C3}$, $^3J_{H2\text{-}C4}$, $^3J_{H3\text{-}C5}$, $^3J_{H4\text{-}C6}$, $^3J_{H2\text{-}C6}$, $^3J_{H7\text{-}C6}$. Anal. Calcd. for $C_8H_7N_3O_2$ (177.16): C, 54.24; H, 3.98; N, 23.72. found: C, 54.43; H, 3.92; N, 23.61.

**General procedure for preparation synthesis of 3-alkyl/aryl substituted-6-((1*H*-benzo[*d*][1,2,3]triazol-1-yl)methyl)-[1,2,4]triazolo[3,4-*b*][1,3,4]thiadiazoles (4a–m).** An equimolar mixture of respective triazole **2a–m** (1 mmol) and benzotriazole-1-acetic acid (1 mmol) in phosphorus oxychlorid (8 mL) are refluxed for 7 h. Excess of phosphorus oxychlorid is removed under reduced pressure. The resulting reaction mass is cooled and gradually poured onto crushed ice with stirring, the result mixture is allowed to stand overnight and the solid separated out is filtered. Finally, the filter cake is washed thoroughly with water till the pH of the filtrate is raised to 7, dried, and recrystallized from a mixture of DMF and ethanol.

**6-((1*H*-Benzo[*d*][1,2,3]triazol-1-yl)methyl)-3-methyl-[1,2,4]triazolo[3,4-*b*][1,3,4]thiadiazole (4a).** This compound was obtained as white needle solid, 87% yield, mp 141–142°; IR (KBr): 3090, 2986, 2933, 1608, 1592, 1536, 1494, 1464, 1290 cm$^{-1}$; $^1$H NMR ($CDCl_3$): δ 2.75 (s, 3H), 6.13 (s, 2H), 7.45–8.16 (m, 4H). Anal. Calcd. for $C_{11}H_9N_7S$ (271.30): C, 48.70; H, 3.34; N, 36.14. Found: C, 48.82; H, 3.28; N, 36.27.

**6-((1*H*-Benzo[*d*][1,2,3]triazol-1-yl)methyl)-3-(trifluoromethyl)-[1,2,4]triazolo[3,4-*b*][1,3,4]thiadiazole (4b).** This compound was obtained as white solid, 93% yield, mp 148–151°; IR (KBr): 3094, 2937, 1613, 1592, 1544, 1524, 1497, 1295 cm$^{-1}$; $^1$H

Anal. Calcd. for $C_{14}H_9N_7OS$ (323.33): C, 52.01; H, 2.81; N, 30.32. Found: C, 52.22; H, 2.75; N, 30.45.

**Anti-inflammatory activity.** This activity is performed by the following procedure of Winter *et al*. [22] on groups of six animals each. A freshly prepared suspension of carrageen in (1.0% w/v, 0.1 mL) is injected in the planter region of right hind paw of each rat. One group is kept as control and the animals of the other group are pretreated with the test drugs suspended in 1.0% CMC given orally 1 h before the carrageenin treatment. The volume is measured before and after 4 h of carrageenin treatment with the help of pleythysmometer. The percent anti-inflammatory activity is calculated according to the formula given below:

$$\%\text{Anti-inflammatory activity} = (V_c - V_t/V_c) \times 100$$

where $V_t$ represents the mean increase in paw volume in rats treated with test compounds and $V_c$ represents the mean increase in paw volume in control group of rats. Data are expressed as mean ± S.E.M., Student's *t*-test is applied to determine the significance of the difference between the control group and rats treated with the test compounds.

**Analgesic activity.** This activity is performed by Eddy's hot plate technique [23], Mice (Swiss strain) of either sex weighing between 25 and 35 g are used for the experiment. In this method heat is used as a source of pain. Animals are individually placed on a hot plate, maintained at constant temperature (55°C) and the reaction of animals, such as paw licking or jumping response (whichever appears first) is taken as the end point. A cut-off time of 15 s is taken as maximum analgesic response to avoid injury to the paws. The tested compounds and diclofenac sodium (standard) at a dose of 30 mg/kg body weight in 1% gum acacia are given as suspension orally to animals and observe the reaction time of animals on the hot plate at 20, 40, and 60 min after the compound administration.

**Acknowledgments.** We gratefully thank the National Natural Science Foundation of China (No. 20662009) and Specialized Research Fund for the Doctoral Program of Higher Education (No. 20050755003) for their support.

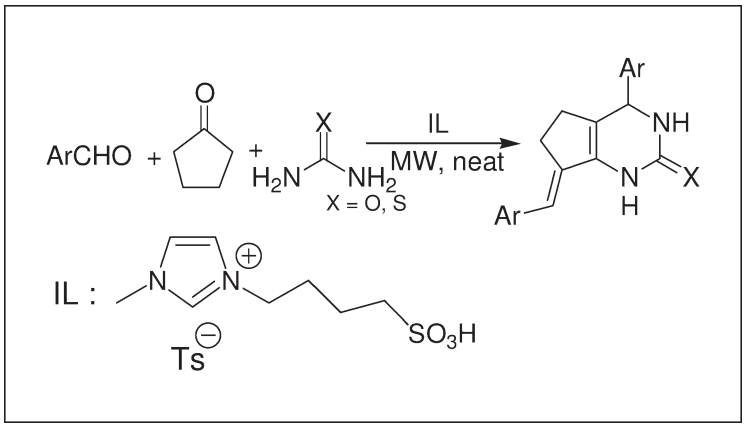
Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



A simple and efficient method has been developed for the synthesis of heterobicyclic dihydropyrimidinone derivatives through a solvent-free one-pot three-component condensation of aromatic aldehydes, cyclopentanone, and urea or thiourea in the presence of Brønsted acidic ionic liquid under microwave irradiation. The catalyst can be reused at least six times without any noticeable decrease in catalytic activity.

*J. Heterocyclic Chem.*, **47**, 1230 (2010).

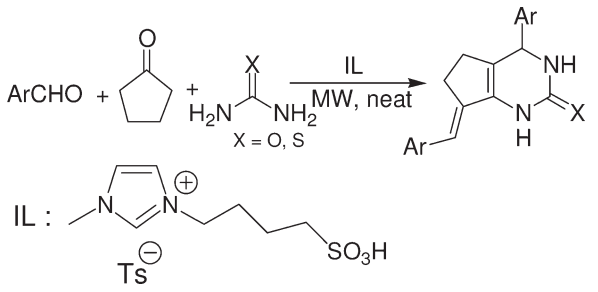
## INTRODUCTION

Dihydropyrimidinones and their derivatives are a very important class of bioactive compounds because of their pharmacological properties [1]. They are known to exhibit a wide range of biological activities, such as calcium channel blockers [2], antihypertensive agents [3], α-adrenergic antagonists [4], and neuropeptide Y antagonists [5]. The biological activity of some recently isolated alkaloids has also been attributed to the presence of dihydropyrimidinone moiety in the molecules [6]. Most notable among these are the batzelladine alkaloids, which have been found to be potent HIV gp-120-CD4 inhibitors [7]. Therefore, such a wide spectrum of biological activity allows consideration of the dihydropyrimidinone structural unit as one of the most important drug-like scaffolds.

The Biginelli reaction, which was discovered more than a century ago is one of the most important reactions in the synthesis of dihydropyrimidinones based on acid-catalyzed three-component condensation of 1,3-dicarbonyl compound, aldehyde, and urea [8]. The scope of the original condensation reaction was gradually extended by variation of all three building blocks, allowing access to a large number of structurally diversified multifunctionalized dihydropyrimidinones [9]. The use of the common open-chain β-dicarbonyl compounds in Biginelli reactions has been extended to the use of cyclic β-diketones, β-ketolactones, cyclic β-diesters or β-diamides, benzocyclic ketones, and α-keto acids.

Microwave- (MW-) promoted reactions have been attracting increasing research interest from chemists in recent years, not only because these reactions exhibit some particular or unexpected reactivities in some cases but also because they are significantly useful for green chemistry [10]. In our corresponding investigations, we have reported few MW-promoted multicomponent coupling reactions for various chemical transformation as well as synthesis of useful heterocyclic compounds [11]. The application of Brønsted acidic task-specific ionic liquids (TSILs) as catalytic materials is growing continuously in the catalytic field. Combining the useful characteristics of solid acids and mineral acids, TSILs have been synthesized to replace traditional mineral liquid acids, such as hydrochloric acid and sulfuric acid in chemical reactions. In view of green chemistry, the

**Scheme 1**



substitution of harmful liquid acids by reusable TSILs is the most promising catalyst in chemistry [12].

Recently, it was found that some fused pyrimidinones carrying an arylidene moiety are potential antitumor agents [13]. In addition, some of these analogues also showed a distinctive pattern of selectivity toward individual cell line, such as that of leukemia [14]. Because of the various therapeutic utility of arylidene heterobicyclic pyrimidinones, a number of synthetic procedures for this type of derivatives were developed using different protocols [15]. Pan and coworkers described an efficient alternative for the synthesis of these fused pyrimidinones by a three-component condensation with aromatic aldehyde, cyclopentanone, and urea or thiourea in presence of stoichiometric amounts of TMSCl as additional reagent and mixed DMF/$CH_3CN$ as reaction solvent appeared to be necessary to obtain satisfactory results [16a]. Very recently, Xu and Shen revealed that ytterbium chloride could efficiently promote this one-pot three-component condensation under solvent-free conditions without using any additional reagents [16b]. In connection with our earlier work on the synthesis of dihydropyrimidinones [17], herein we report an efficient Brønsted acidic ionic liquid catalyzed this Biginelli-type reaction of aromatic aldehyde, cyclopentanone, and urea or thiourea for the synthesis of arylidene heterobicyclic pyrimidinones using MW irradiation under solvent-free conditions (Scheme 1). To the best of our knowledge, this is the first report of a functionalized ionic liquid-catalyzed synthesis of heterobicyclic dihydropyrimidinones.

## RESULTS AND DISCUSSION

The experimental procedure is very simple. To optimize the reaction conditions, the reaction of benzaldehyde, cyclopentanone, and urea was selected as the model in presence of catalytic amount of acidic ionic liquid under MW irradiation. The best result was obtained when the reaction of cyclopentanone, benzaldehyde, and urea was carried in a 2:2:1.2 mole ratio in presence of acidic ionic liquid (5 mol %) under MW irradiation (250 W, 90°C) for 5 min. In a blank reaction, without acidic ionic liquid, no desired product was obtained in 5 min. But, very low yield (10–15%) was obtained after longer time irradiation (15–20 min).

Under these optimized conditions, the reaction between various aromatic aldehydes and cyclopentatone in presence of urea was investigated (Table1). It was found that all the reactions proceeded smoothly to give the corresponding arylidene pyrimidinones in high yields. Both aromatic aldehydes bearing electron-donating and electron-withdrawing gave excellent yields. The mildness of the procedure makes it very selective, as it tolerates a variety of functionalities, including bromo, chloro, fluro, methoxy, nitro, and methylenedioxy groups. The present procedure was equally effective for thiourea also. The results are summarized in Table 1, which clearly demonstrates the generality and scope of the reaction with respect to various aromatic aldehydes. No organic solvents were required to isolate the product from the reaction mixture. Only ethanol was used for recrystallization to provide analytically pure samples. Use of just 5 mol % IL is sufficient to push the reaction forward. Higher amount of IL did not improve the reaction forward.

Our interest in the preparation of novel scaffolds prompted us to attempt the extension of this reaction to condensations of cyclohexanone and /or aliphatic aldehydes in the Biginelli-type reaction. Unfortunately, the

**Table 1**

IL promoted microwave-assisted one-pot synthesis of pyrimidinone.

| 3 |  | 5 min | 67 | 5 h | 50 | 2–3 h | 78 |

[a] Present reaction conditions: acidic ionic liquid (5 mol%) at 90°C (250 W microwave).
[b] Reported reaction conditions: 3 mol% $YbCl_3$ at 90°C.
[c] Reported reaction conditions: stoichiometric amount of TMSCl in DMF/$CH_3CN$ solvent at rt.

reaction did not produce the corresponding benzylidene pyrimidinones under the present reaction conditions, instead leads to multiple products whose identities are yet to be established.

The recovery and reusability of the ionic liquid were investigated. After completion of the reaction, crushed ice (20 g) was added to the reaction mixture and the solid product was filtered. The aqueous layer consisting of the acidic IL was extracted with diethyl ether (5 mL) to remove the organic impurities. The catalyst was recovered after removal of water under reduced pressure and reused for subsequent reactions. It showed the same activity as a fresh catalyst with out any loss of activity in terms of yield and purity. After six recycles, the catalyst had a high activity and gave the desired product in good yield (78%, entry 1).

The efficiency of the present protocol can be realized by comparing some of the results presented here with recently reported two methods as shown in the Table 2, which compares reaction time, yields, and reaction conditions. Thus, it is clear form the Table 2 that the present protocol can act as an effective method with respect to times and reaction conditions.

The mechanism of this reaction is uncertain. The reaction may proceed through the formation of acyl imine intermediate, by the reaction of the aldehyde with urea and activated acid [16a]. Another hypothesis is that dibenzylidene cyclopentanone is the key intermediate produced by reaction of benzaldehyde with cyclopentanone in presence of acidic IL [16b].

## CONCLUSIONS

In conclusion, the present MW-assisted one-pot procedure provides an efficient synthesis of heterobicyclic dihydropyrimidinones by acidic IL-catalyzed condensation of aldehyde, cyclopentanone, and urea or thiourea under solvent-free conditions. We believe our procedure will find important applications in the synthesis of biologically active scaffolds to cater the needs of academia as well as pharmaceutical industries. Further exploration of this chemistry and biological evaluation of the synthesized scaffolds are in progress and will be reported in due course.

## EXPERIMENTAL

Melting points were determined on a glass disk with an electrical bath and are uncorrected. $^1H$ NMR (400 MHz) and $^{13}C$ NMR (100 MHz) spectra were run in DMSO-$d_6$ solutions. IR spectra were taken as KBr plates. Elemental analyses were done by Perkin–Elmer autoanalyzer. The synthesis of the Brønsted acidic ionic liquid, 1-butane sulfonic acid-3-methylimidazolium tosylate, [BSMIM]Ts was carried out using a method similar to that reported [18].

**Typical procedure for the synthesis of 4-benzo[1,3]-dioxol-5-yl-7-benzo[1,3]dioxol-5-ylmethylene-1,3,4,5,6,7-hexahydrocyclopentapyrimidin-2-one (entry 10, Table 1).** To a mixture of piperonal (300 mg, 2 mmol), cyclopentanone (177 μL, 168 mg, 2 mmol), and urea (72 mg, 1.2 mmol) acidic ionic liquid (39 mg, 5 mol %) was added. The mixture was irradiated in a MW reactor (CEM, Discover) at 90°C (250 W) for 5 min as required to complete the reaction. The mixture, after being cooled to room temperature was poured into crushed ice (20 g) and stirred for 5–10 min. the solid separated was filtered under suction (water aspirator), washed with ice-cold water (20 mL) and then recrystallized from hot ethanol to afford pure product (320 mg, 82%) as white powder. mp 253–255°C; IR (KBr): 1679, 1492, 1452, 1242 $cm^{-1}$; $^1H$ NMR (400 MHz, DMSO-$d_6$): δ = 8.61 (s, 1H), 7.07 (s, 1H), 6.87 (s, 3H), 6.79–6.71 (m, 3H), 6.52 (s, 1H), 5.98 (s, 4H), 5.04 (s, 1H), 2.76 (s, 2H), 2.76 (br, 1H), 2.48 (br, 1H); $^{13}C$ NMR (100 MHz, DMSO-$d_6$): δ = 153.5, 147.9, 147.8, 146.9, 145.9, 137.9, 137.7, 136.3, 132.5, 122.6, 120.1, 118.1, 116.9, 108.9, 108.5, 107.8, 107.2, 101.4, 101.3, 57.4, 28.7, 28.6; Anal. Cald for $C_{22}H_{18}N_2O_5$: C, 67.69; H, 4.65; N, 7.18. Found: C, 67.51; H, 4.54; N, 7.01.

The catalyst recovered for the aqueous layer was dried under vacumn and reused for subsequent reactions.

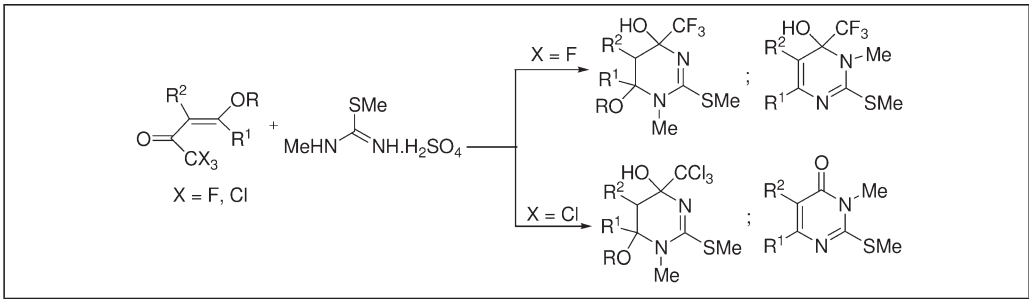
Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).



The synthesis and chemoselective study of a novel series *N*-methyl-2-methylthio-tetrahydropyrimidines and or *N*-methyl-2-methylthiodihydropyrimidines, from the cyclocondensation reaction of β-alkoxyvinyl trihalomethyl ketones (enones) with 1,2-dimethylisothiourea sulfate is described. It was found that the chemoselectivity depends on both the reaction conditions and the steric and electronic effects of the substituents on the enones.

*J. Heterocyclic Chem.*, **47**, 1234 (2010).

## INTRODUCTION

Pyrimidines have a long history of biological activity in fields ranging from pharmaceutics to agriculture. The $N^1$-alkylation of pyrimidines is one way of functionalizing the pyrimidine ring to achieve important physical and bioactive properties. For example, *N*-alkylated nucleic acid bases are widely known for being the most effective antiviral [1] and antitumoral agents, [2] as well as for exhibiting anti-inflammatory [3] and herbicidal activity [4]. In addition, *N*-alkylated pyrimidines, obtained by alkylating agents, such as diazoalkanes [5], alkyl halides [6], and alkylsulfates, among others [7], are important compounds for mutagenic and carcinogenic studies in living systems.

Very few studies have reported on the synthesis of *N*-alkylated 2-methylthiopyrimidines by cyclocondensation reactions using nonsymmetric *S*-alkylthioureas. Probably, the main reason for this is that thioureas are weak nucleophiles, and they do not react very well with 1,3-dicarbonyl compounds or derivatives thereof in a [3 + 3] atom fragment synthesis, which is the main strategy for the preparation of pyrimidine compounds. β-Alkoxyvinyl ketones, however, allow the possibility of direct cyclization with weak nucleophiles because it has been demonstrated that these enones readily react with weak nucleophiles, such as ureas [8], *N*-methylurea [9], *N*-methylthioureas [10], and 2-methyl-2-thiopseudourea [11].

We have reported the synthesis of a series of 4-trihalomethyl-2-methylthiopyrimidines from the reaction of 1,1,1-trifluoro[chloro]-4-alkoxy-alk-3-en-2-ones (tri-halomethylated enones) with 2-methyl-2-thiopseudourea sulfate in the presence of pyridine or acid catalysis [12]. More recently, we reported the synthesis of a new series of 2-methylthiotetrahydropyrimidines from the same enones under a modified procedure [11].

Continuing in our interest in the synthesis of pyrimidine derivatives from trihalomethylated enones, this article aims to study the chemoselectivity and yields of the synthesis of a series of *N*-methyl-2-methylthio-pyrimidines carried out by the cyclocondensation of trihalomethylated enones with the nonsymmetric dinucleophile 1,2-dimethylisothiourea. A detailed NMR study of the structure of the pyrimidines derivatives was carried out to determine the correct position of the *N*-methyl group on the pyrimidine scaffold and to understand the factors that led to such chemoselectivity.

## RESULTS AND DISCUSSION

The reaction of enones **1a–d** and **2a–d** with 1,2-dimethylisothiourea sulfate, carried out in the presence of 1 *M* sodium hydroxide solution under mild conditions, furnished *N*-methyl-2-methylthiotetrahydropyrimidines or *N*-methyl-2-methylthiodihydropyrimidines depending

on the reaction conditions and the type and positions of the substituents on the trihalomethylated enones (Scheme 1). Table 1 reports the optimized reaction conditions, the yields, and the correct structure of the obtained compounds.

The reaction of enones **1a** and **2a** with 1,2-dimethylisothiourea sulfate in the presence of 1 *M* sodium hydroxide solution at room temperature furnished tetrahydropyridines **3a** and **5a**, respectively. Both products **3a** and **5a** were composed of two diastereo-isomers, whose structure and composition are described in the next section. When the reaction of enone **2a** was carried out at 50°C for 5 h, 3-methyl-2-(methyl-thio)pyrimidin-4-(3*H*)-one (**6a**) was obtained in 92% yield.

Enones bearing a methyl group at the β-position ($R^1$ = Me) such as **1b** and **2b** reacted with 1,2-dimethyl-isothiourea sulfate in the presence of sodium hydroxide solution furnishing dihydropyrimidine **4b** and **6b** with the *N*–methyl group at the $N^3$–position of the pyrimidine ring. We speculate that a steric effect between the *N*–methyl group and β-methyl group of enones **1b** and **2b** was responsible for the formation of compounds **4b** and **6b** ($N^3$**–**regioisomers). In addition, the methoxy group was eliminated because hemi-aminals from ketones are less stable than those from aldehydes. Furthermore, in compound **6b** the elimination of the $CCl_3$ group was expected for reactions carried out under aqueous basic conditions [13]. In a previous study, compound **4b** exhibited significant inhibition of ATP and ADP hydrolysis in synaptosomes from rat cerebral cortex [14].

The reaction of enones **1c** and **1d** with 1,2-dimethylisothiourea sulfate in the presence of 1 *M* sodium hydroxide solution furnished hexahydrofuro[2,3-*d*]pyrimidin-4-ol (**3c**) and hexahydro-1*H*-pyrano[2,3-*d*]pyrimidin-4-ol (**3d**), respectively. Although, products **3c** and **3d** show three stereogenic centers and additionally the possibility of two regioisomers due to the $N^1$**–** and $N^3$–methylation, only a single compound of each product was isolated, which means that the reactions were highly stereoselective and regioselective for these two enones under the conditions given in Table 1.

Enone **2d** reacted with 1,2-dimethylisothiourea sulfate in the presence of 1 *M* sodium hydroxide solution to furnish 3-methyl-2-(methylthio)-4a,5,6,7-tetrahydro-3*H*-pyrano[2,3-*d*]pyrimidin-4(8a*H*)-one (**5d**) in good yields. Under the same condition used to obtain compound **5d**, the enone **2c** failed to give the expected product **5c** and only starting material was isolated. One can observe that enones **2a**–**d** showed the elimination of the trichloro-methyl group instead of the hydroxyl group, except for the reaction of enone **2a** when carried out at room temperature. The elimination of the trichloromethyl group under basic reaction conditions has been reported previously [13].

## STRUCTURAL STUDIES

All compounds were fully analyzed by $^1$H and $^{13}$C NMR as well as 2D NMR experiments such as COSY HH [15], NOESY [16], HMQC [17], and HMBC [18]. Figure 1 shows the atom numbering used for NMR assignment of compounds **3**–**6**. Yields, selected physical and $^1$H and $^{13}$C NMR spectral data are presented in the experimental part.

The correct position of the *N*–methyl group ($N^1$– or $N^3$–positions) of all *N*–methyl-2-methylthiopyrimidines was determined by two-dimensional HMBC NMR experiments, as shown in Figure 1 [9,10]. In this experiment, when the *N*–methyl group is at the $N^1$–position, two cross-peaks between the hydrogen atoms of the *N*–methyl group and C–2 and C–6 are observed (Fig. 1, structure **I**). When the *N*–methyl group is at the $N^3$–position, two cross-peaks between the hydrogen atoms of the *N*–methyl group and C–2 and C–4 are observed (Fig. 1, structure **II**). The cross-peak between the hydrogens of the SMe group and the C–2 assigns this carbon in both structures **I** and **II**. The same strategy was used to assign all the other compounds obtained in this study.

Compound **3a** was obtained as a mixture of two stereoisomers (**3a** and **3a′**), as shown in Figure 2.

The major isomer, isolated in 82%, shows both hydroxy- and ethoxy-groups in an axial position whereas the minor isomer shows the hydroxyl group at an axial position and the ethoxy group at an equatorial position. Compound **3a** was obtained as the major isomer probably because of the formation of a hydrogen-bond between the hydroxyl hydrogen and the oxygen atom of the ethoxy group, which could stabilize this structure. The structure of **3a** and **3a′** was proposed from the interpretation of the coupling constant of H–6 with H–5 and H–5′ as reported previously [11]. A similar trend as observed for **3a** was observed for **5a**.

**Table 1**

Optimized reaction conditions and structure of the obtained compounds.

| Entry | Enone | Reaction conditions[a] | | Structure of the obtained products | Yield (%)[d] |
|---|---|---|---|---|---|
| | | Molar ratio[b] Enone/Nu[c]/Base | *T* (°C)/ time (h) | | |
| 1 | **1a** | 1.0:1.5:1.5 | r.t./1 |  **3a**[e] | 77 |
| 2 | **1b** | 1.0:1.5:1.5 | 0/2.2 |  **4b** | 98 |
| 3 | **1c** | 1.0:1.1:1.1 | 10/0.7 |  **3c** | 64 |

[e] Obtained as a mixture of two diastereoisomers.

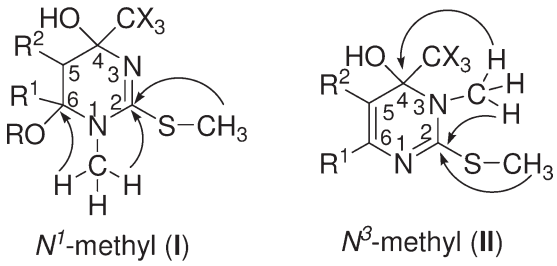

**Figure 1.** Strategy for the assignment of the position of the *N*-methyl group by HMBC.

Compound **3c** has, besides three asymmetric carbons, the possibility of two regioisomers due to the $N^1$– and/or $N^3$–alkylation. However, this compound showed only one set of signals in both $^1$H and $^{13}$C NMR spectra indicating that the reaction was both highly stereoselective and regioselective. Observation of a strong cross-peak between H–4a and H–7a in the NOESY experiment indicates that these hydrogens are close in space, which suggests that the furopyrimidine ring closure was accomplished with *cis* configuration. The most probable structure for **3d** is the furopyrimidine rings in the *cis* configuration, the $CF_3$ group in pseudo-equatorial positions *cis* to H–4a and *trans* to C–5, and the methyl group bound to $N^1$ because three bond cross-peaks between the hydrogens of the *N*–methyl group and C–2 and C–7a were observed in the HMBC spectrum (Fig. 3). Compound **3d** also has three asymmetric carbons and the possibility of $N^1$–Me and/or $N^3$–Me isomers. As observed for **3c**, **3d** also showed only one set of signals in both $^1$H and $^{13}$C NMR spectra indicating that the reaction was both highly stereoselective and regioselective. The coupling constant between H–4a and H–8a of 12.2 Hz indicates a *trans*-diaxial position of these two hydrogens, consequently, the pyranopyrimidine ring closure occurred with *trans* configuration. The methyl

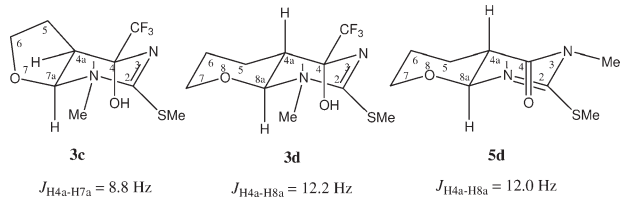

**Figure 3.** Structure of compounds **3c**, **3d**, and **5d**.

group is attached to $N^1$ because three bond cross-peaks between the hydrogens of the *N*–methyl group and C–2 and C–8a were observed on the HMBC spectrum (Fig. 3). Compound **5d** showed the same general structure as **3d**, however, **5d** exhibited the $N^3$–methyl group and the $CCl_3$ group was eliminated with the formation of a carbonyl group, which was the tendency for all trichloromethyl-bearing enones when the reaction was carried out in basic medium [13].

The tridimensional structure of tetrahydropyrimidines proposed in this study are consistent with the structure of related pyrimidines proposed by Saloutin, *et al*. [19]

Presumably, the reaction starts with the Michael addition of the amino groups of the 1,2-dimethylisothiourea at the β-carbon atom of enone **1** or **2** furnishing both structures **I** (path 1) and/or **II** (path 2), as shown in Scheme 2.

Both hemi-aminals and trifluoromethyl groups are stable under basic conditions, although, hemi-aminals derived from aldehydes are more stable than those from ketones. Thus, after the addition of the first nitrogen of 1,2-dimethylisothiourea at the carbon–carbon double

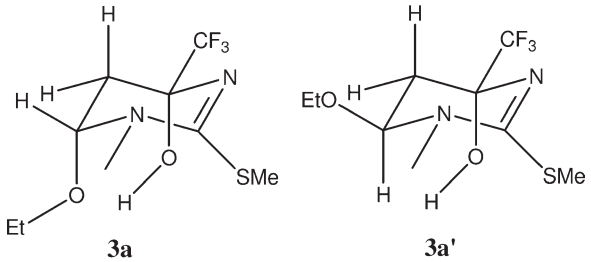

**Figure 2.** Structure of compounds **3a** and **3a′**.

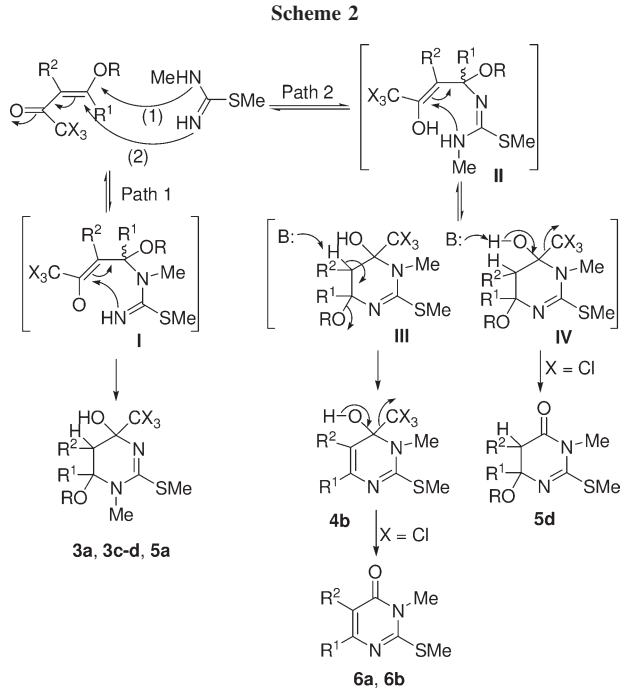
**Scheme 2**



bond, the carbonyl becomes activated for the addition of the second nitrogen furnishing the tetrahydropyrimidines **3a**, **3c–d**, and **5a**. When enones **1** and **2** were β-methyl substituted ($R^1$ = Me), they reacted with 1,2-dimethylisothiourea giving $N^3$-methyldihydropyrimidines **4b** and **6b**, probably due to a steric effect between the *N*-methyl group and β-methyl group of enones **1b** and **2b**. In addition, the formation of compounds **4b** and **6b** occurred with the elimination of the methoxy group because hemi-aminals from ketones are less stable than those from aldehydes. Enones **2** bearing a trichloromethyl group also furnished $N^3$-methylpyrimidines because of the easy elimination of the trichloromethyl group under basic conditions [13].

In summary, from these results it can be concluded that steric and electronic effects determined the position of the methyl group at the $N^1$– *versus* $N^3$–positions of the pyrimidine ring according to the following observations: when $R^1$ = H, $N^1$–methyltetrahydropyrimidines were the only regioisomer isolated (**3a**, **3c–d**, **5a**, and **5d**). This is because hemi-aminals from aldehydes are more stable than those from ketones. An exception to this rule was observed when X = Cl. In this case, due to the facile elimination of the $CCl_3$ group under basic conditions only $N^3$–methylpyrimidinones **6a**, **6b**, and **5d** were obtained. We speculate that a steric effect between the *N*–methyl group and β-methyl group of the enones **1b** was responsible for the formation of compounds **4b**, where $N^3$–methyldihydropyrimidines were obtained.

## EXPERIMENTAL

The 1,1,1-trihalo-4-alkoxy-3-alken-2-ones (**1**, **2**) were prepared according to ref. [20]. All melting points were determined on a Reichert Thermovar apparatus and are uncorrected. IR spectra were measured on a Bruker IFS 28 spectrophotometer on KBr pellets. Elemental analysis was performed on a Vario EL Elementar Analysensysteme. 1H, 13C, and 2D NMR spectra were acquired on a Bruker DPX 400 spectrometer ($^1$H at 400.13 MHz and $^{13}$C at 100.62 MHz) in $CDCl_3$ or DMSO-$d_6$, using TMS as the internal reference.

**General procedure for the synthesis of *N*-methyl-2-methylthio-pyrimidines (3–6).** A solution of 1.0 *M* sodium hydroxide (7.5 mL, 7.5 mmol) and 1,2-dimethylisothiourea sulfate (1.14 g, 7.5 mmoles) was added drop wise under vigorous magnetic stirring to the enones **1a–d, 2a–d** (5.0 mmoles). The mixture was stirred for a period of time and temperature specified at Table 1 and extracted with chloroform (3 × 15 mL). The organic layer was dried under anhydrous sodium carbonate, filtered, and the solvent evaporated. Products were purified by recrystallizations and the solvent used for the purification is reported for each compound together with the melting point.

***6-Ethoxy-1-methyl-2-(methylthio)-4-(trifluoromethyl)-1,4,5,6-tetrahydro-pyrimidin-4-ol (3a, 3a′).*** This compound was obtained as an orange powder in 77% yield, mp 68°C (hexane/ethyl acetate, 9:1). **3a**: $^1$H NMR: δ 1.24 (t, 3H, *J* = 7.0 Hz, $CH_3$), 2.02 (dd, 1H, *J* = 14.0, 3.6 Hz, H–5), 2.37 (s, 3H, S-$CH_3$), 2.47 (dd, 1H, *J* = 14.0, 3.0 Hz, H–5), 3.04 (s, 1H OH), 3.14 (s, 3H, *N*–$CH_3$), 3.62 (qua, 2H, *J* = 7.0 Hz, $CH_2$), 4.62 (dd, 1H, *J* = 3.6, 3.0 Hz, H–6); $^{13}$C NMR: δ = 13.7 (S–$CH_3$), 15.0 ($CH_3$), 30.1 (C–5), 37.6 (*N*–$CH_3$), 64.2 ($CH_2$), 80.3 (q, $J_{C\text{-}F}$ = 31.0 Hz, C–4), 86.4 (C–6), 123.7 (q, $J_{C\text{-}F}$ = 283.2 Hz, $CF_3$), 160.1 (C–2). **3a′**: $^1$H NMR: δ 1.24 (t, 3H, *J* = 7.0 Hz, H–8), 2.03 (dd, 1H, *J* = 13.8, 9.0 Hz, H–5), 2.15 (s, 1H OH), 2.33 (s, 3H, S–$CH_3$), 2.40 (dd, 1H, *J* = 13.8, 0.8 Hz, H–5), 2.98 (s, 3H, *N*–$CH_3$), 3.70 (q, 2H, *J* = 7.0 Hz, $CH_2$), 4.39 (dd, 1H, *J* = 9.6, 0.8 Hz, H–6); $^{13}$C NMR: δ 14.5 (S–$CH_3$), 15.0 ($CH_3$), 30.8 (C–5), 32.1 (*N*–$CH_3$), 64.2 ($CH_2$), 80.5 (q, $J_{C\text{-}F}$ = 31.0 Hz, C–4), 83.7 (C–6), 123.9 (q, $J_{C\text{-}F}$ = 284.0 Hz, $CF_3$), 158.4 (C–2). A variety of 2-aryl quinazolines were synthesized from the condensation of 2-aminobenzylamines and aryl aldehydes to form 2-aryl-1,2,3,4-tetrahydroquinazolines and subsequent oxidation of the intermediates with $MnO_2$.

*J. Heterocyclic Chem.*, **47**, 1240 (2010).

## INTRODUCTION

The quinazoline ring is a frequently encountered moiety in organic syntheses as well as in medicinal chemistry [1–10]. Many alkaloids containing a quinazoline skeleton in the molecule exhibit anticonvulsant, antibacterial, antidiabetic, and anticancer activities [6,11–14]. A number of methods for the synthesis of quinazolines are known [15–19]. We found five basic types of synthetic strategies for the synthesis of 2-substitued quinazolines: (1) three-step reaction from aryl azides to form 2-alkylquinazolines [20], (2) reaction of amidines with cyano- or nitro-activated *o*-fluorobenzaldehydes [21], (3) condensation of *o*-phenyl oxime of 2-aminoacetophenone with aldehydes or ketones by irradiation with microwaves to form 4-methylquinazolines [22], (4) reaction of 2-aminobenzaldehyde with an acyl halide and by heating the obtained amide in a sealed tube with saturated alcoholic ammonia [19,23–26], and then dehydrogenation with mercuric EDTA complex or aromatization with alkaline potassium ferricyanide [27,28], (5) condensation of 1,3-diamines **1** with aromatic aldehydes **2** to form 2-aryl-1,2,3,4-tetrahydroquinazolines **3**, and then oxidation of **3** to form the 2-aryl substituted quinazolines **4** (Scheme 1).

The fifth synthetic strategy involves two steps: condensation and oxidation. The condensation products, 2-aryl-1,2,3,4-tetrahydroquinazolines, have been prepared in solvent-free [29] and a number of solvents, including benzene or xylene, methanol or ethanol/acetic acid mixtures [30,31], alkali media [32,33], $H_2O$ [34], and ionic liquids [35]. Vandeneynde et al. reported alternative methods where aldehydes were converted, *in situ*, to *N*-(1-chloroalkyl)pyridinium, which reacted with 2-aminobenzylamine to yield tetrahydroquinazoline hydrochloride salts **3**·**HCl** [36]. Two oxidation regents were used to oxidize 2-aryl-tetrahydroquinazolines to the corresponding quinazolines **4**. One is 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) and the other tetrachloro-1,4-benzoquinone (TCQ) [36]. More recently, Coskun reported a reaction where the *in situ* formed 2-substituted-1,2,3,4-tetrahydroquinazolines were oxidized to quinazolin-1-oxides [37].

No one-pot reaction to synthesize 2-arylquinazolines was reported. The methods described above to synthesize the 2-arylquinazolines either require multistep preparations of special reagents/reactants, or suffer severe limitations such as tedious experimental procedure and poor yields. Here we report the first one-pot synthesis of 2-aryl substituted quinazolines, from condensation of 1,3-diamines **1** with aryl aldehydes **2** to form 2-aryl-1,2,3,4-tetrahydroquinazolines **3**, and oxidation of **3** to form the 2-aryl substituted quinazolines **4**, using $MnO_2$ as the oxidant.

## RESULTS AND DISCUSSION

The condensation of 2-aminobenzylamine and benzaldehyde was selected as the model reaction. Among the

| Entry | Solvent | Time (h) | Yield[a] (%) |
|---|---|---|---|
| 1 | $H_2O$ | 4 | 85 |
| 2 | $CHCl_3$ | 10 | 84 |
| 3 | THF | 16 | 66 |
| 4 | $CH_3OH$ | 17 | 73 |
| 5 | $CH_3CN$ | 16 | 74 |
| 6 | $CH_2Cl_2$ | 18 | 63 |

[a] Isolated yield based on 2-aminobenzylamine.

solvents we screened, we found $CHCl_3$ or $H_2O$ was the best solvent to give the product in high yield (Table 1, entries 1 and 2). Other solvents such as THF, $CH_3OH$, $CH_3CN$, and $CH_2Cl_2$ gave lower yields (entries 3–6). This is consistent with the findings of Gawinecki et al. [38].

Several oxidants were evaluated for the transformation of tetrahydroquinazoline **3** to quinazoline **4** in $CHCl_3$ (Table 2). Among the oxidants we used, only DDQ and $MnO_2$ were effective for the transformation from the tetrahydroquinazoline to the quinazoline (Table 2, entries 4–5).

We then evaluated the solvent effects on the oxidation of the tetrahydroquinazoline to the quinazoline. The reaction did not proceed in water or in $CH_3COOH$ (Table 3, Entries 1 and 2). Moderate yields were obtained in $CH_3OH$, $C_2H_5OH$, $CH_2Cl_2$, $CH_3CN$, Dioxane, DMF, and THF (Entries 3–9). The best yield was obtained in $CHCl_3$ (Entry 10). Because both condensation and oxidation reactions proceed well in $CHCl_3$, we envisioned that the synthesis of quinazolines might proceed in one pot.

We then investigated the one-pot reactions of 2-aminobenzylamines and benzaldehydes to synthesize 2-arylqunazolines without isolating the tetrahydroquinazoline intermediate. First, the reaction of 2-aminobenzylamine with benzaldehyde gave tetrahydroquinazoline in $CHCl_3$ at room temperature. After TLC indicated the reaction was completed, we added 4.0 mol equivalents of $MnO_2$. After refluxing for 12 h, the corresponding quinazoline was isolated in 70% yield. To explore the generality and scope of this one-pot reaction, we synthesized 2-arylquinazolines from a variety of 2-aminobenzylamines and aryl aldehydes (Table 4).

A variety of substituents are tolerated on both 2-aminobenzylamines and benzaldehydes. For the 2-aminobenzylamines, ortho F or $CF_3$ substituents slowed the reaction, probably due to the electronic and steric effect in the first step (entries 15–18). For benzaldehydes, the electron-withdrawing substituents speeded the reaction. Overall the reaction gave 2-arylquinazolines in yields from 26 to 75%.

## CONCLUSION

In summary, We have developed an one-pot method to synthesize a variety of 2-arylquinazoline derivatives, from the condensation of 1,3-diamines and aryl aldehydes to form 2-aryl-1,2,3,4-tetrahydroquinazolines and subsequent oxidation of tetrahydroquinazolines with

$MnO_2$ in moderate to high yield. This method provided quick access to different quinazolines.

## EXPERIMENTAL

Melting points were determined on an Electrothermal 9100 capillary melting point apparatus. $^1$H NMR spectra were recorded on a Bruker AV400 (400 MHz) spectrometer, and chemical shifts (δ) are reported in parts per million relative to tetramethylsilane. $^{13}$C NMR spectra were recorded on a Bruker AV400 spectrometer, and chemical shifts are reported in parts per million relative to solvent resonance as the internal standard ($CDCl_3$, δ 77.16). IR spectra were recorded as solid in pellets on a Perkin-Elmer FTIR 683 spectrometer. Mass spectra were obtained with a TRIO 2 (electronic ionization 70 eV) spectrometer and a Perkin-Elmer Claruss 500 mass spectrometer (electronic ionization 20 eV).

**General procedure for the synthesis of 2-aryltetrahydroquinazolines.** A mixture of 2-aminobenzylamine (1.1 mmol), aryl aldehyde (1.0 mmol), and 10 mL of solvent were stirred at room temperature. The reaction was followed by TLC. When the reaction was completed, 4 mmol of active $MnO_2$ was added and refluxed. After the reaction was completed, the organic material was extracted with ethyl acetate. The organic layer was dried over $Na_2SO_4$, and the solvents were removed. The residue was purified by flash chromatography on silica gel column, using petroleum/ethyl acetate as eluate to give products.

***2-Phenylquinazoline.***[37] This compound was obtained as yellow solid, mp 91–92°C; $^1$H NMR (dimethyl sulfoxide $d_6$): δ 7.53–7.56 (m, 3H, Ar—H), 7.69–7.73 (m, 1H, Ar—H), 8.00–8.04 (m, 2H, Ar—H), 8.13 (d, $J$ = 8.0 Hz, 1H), 8.54–8.56 (m, 2H, Ar—H), 9.67 (s, 1H); $^{13}$C NMR (deuteriochloroform): δ 123.6, 127.1, 127.3, 128.6, 128.7, 130.6, 134.1, 138.0, 150.8, 160.5, 161.1.

***2-(4-Nitro-phenyl)quinazoline.***[33] This compound was obtained as yellow solid, mp 197–198°C; $^1$H NMR (deuteriochloroform): δ 7.70 (t, 1H, $J$ = 7.2 Hz), 7.89–7.96 (m, 1H), 8.38 (d, 2H, $J$ = 8.8 Hz), 8.83 (d, 2H, $J$ = 8.8 Hz), 9.50 (s, 1H); $^{13}$C NMR (deuteriochloroform): δ 123.8, 123.9, 127.2, 128.3, 128.9, 129.4, 134.6, 143.8, 149.2, 150.6, 158.8, 160.7.

***2-(3-Nitro-phenyl)quinazoline.***[33] This compound was obtained as yellow solid, mp 194–195°C; $^1$H NMR (deuteriochloroform): δ 7.68–7.73 (m, 2H), 7.98 (t, $J$ = 8.0 Hz, 2H), 8.14 (d, $J$ = 8.0 Hz, 1H), 8.34 (d, $J$ = 8.0 Hz, 1H), 8.98 (d, $J$

= 7.6 Hz, 1H), 9.51 (s, 2H); $^{13}$C NMR (deuteriochloroform): δ 123.6, 123.9, 125.1, 127.3, 128.1, 128.8, 129.6, 134.2, 134.6, 139.9, 150.6, 158.7, 160.8.

***2-(2-Nitro-phenyl)quinazoline.***[37] This compound was obtained as yellow solid, mp 91–92°C; $^1$H NMR (deuteriochloroform): δ 7.68–7.73 (m, 2H), 7.98 (t, $J$ = 8.0 Hz, 2H), 8.14 (d, $J$ = 8.0 Hz, 1H), 8.34 (d, $J$ = 8.0 Hz, 1H), 8.98 (d, $J$ = 7.6 Hz, 1H), 9.51 (s, 2H); $^{13}$C NMR (deuteriochloroform): δ 123.6, 124.0, 125.1, 127.2, 128.1, 128.8, 129.6, 134.2, 134.6, 139.8, 148.9, 150.6, 158.7, 160.8.

***2-(4-Chloro-phenyl)quinazoline.***[33] This compound was obtained as yellow solid, mp 116–117°C; $^1$H NMR (deuteriochloroform): δ 7.49 (d, $J$ = 7.6 Hz, 2H), 7.62–7.65 (m, 1H, Ar—H), 7.90–7.95 (m, 2H, Ar—H), 8.07 (d, $J$ = 8.4 Hz, 1H), 8.58 (d, $J$ = 8.8 Hz, 2H, Ar—H), 9.46 (s, 1H); $^{13}$C NMR (deuteriochloroform): δ 123.6, 127.2, 127.5, 128.6, 128.9, 129.9, 134.3, 136.5, 136.9, 150.7, 160.1, 160.6.

***2-(4-Bromo-phenyl)-quinazoline.*** This compound was obtained as yellow solid, mp 131–132°C; IR (potassium bromide): 2925, 1693, 1618, 1582, 1546, 1405, 1369, 1067 cm$^{-1}$. $^1$H NMR (deuteriochloroform): δ 7.62–7.68 (m, 3H, Ar—H), 7.91–7.95 (m, 2H), 8.08 (d, 1H, $J$ = 8.4 Hz), 8.51 (d, 2H, $J$ = 8.4 Hz), 9.46 (s, 1H); $^{13}$C NMR (deuteriochloroform): δ 123.7, 125.5, 127.2, 127.6, 128.6, 130.2, 131.8, 134.4, 136.9, 150.7, 160.1, 160.6. The reaction of β-naphthol with arylaldehydes and 2H-indene-1,3-dione in the presence of sulfamic acid (3 mol %) under solvent-free conditions led to 13-aryl-indeno[1,2-*b*]naphtho[1,2-*e*]pyran-12(13*H*)-ones in good yields.

## INTRODUCTION

Multicomponent reactions have attracted considerable attention as they are performed without need to isolate any intermediate during their processes; this reduces time and saves both energy and raw materials [1]. They have merits over two-component reactions in several aspects including the simplicity of a one-pot procedure, possible structural variations and building up complex molecules.

Natural compounds possessing naphthopyran moiety have been attracted by their antimicrobial [2], antitumor [3], antifungal [4], cytotoxic [5], antioxidative, and 5-lipoxygenase inhibitory activity [6]. A variety of naphthopyran derivatives have been isolated and identified as natural phytochemicals [7]. A plethora of biological activities have also been associated with a large number of synthetic naphthopyran analogs [8]. Indenopyrans are a ''privileged medicinal scaffolds,'' which are used for the development of pharmaceutical agents of various applications. Compounds with the motif show a wide range of pharmacological activities, such as antiulcer [9], antiallergenic [10], and antidepressant activities [11].

Molecule frame works for the development of 12-aryl-8,9,10,12-tetrahydrobenzo[*a*] xanthen-11-ones have also been described [12]. However, there is no report about the synthesis of 13-aryl-indeno[1,2-*b*]naphtho[1,2-*e*]pyran-12(13*H*)-ones, which may show potential pharmaceutical activities.

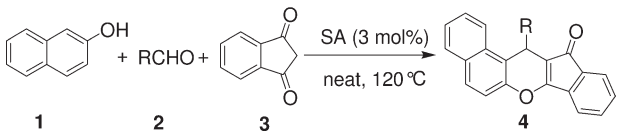
In recent years, the use of solid acidic catalysts has offered important advantages in organic synthesis, for example, operational simplicity, environmental compatibility, nontoxic, low cost, and ease of isolation. A tremendous upsurge of interest in various chemical transformations processes by catalysts under heterogeneous conditions has occurred. One of those heterogeneous catalysts is sulfamic acid (SA). It makes reaction processes convenient, more economic, and environmentally benign. Owing to the numerous advantages associated with this cheap and nonhazardous catalyst, SA has been explored as a powerful catalyst for various organic transformations [13]. We now report a highly efficient procedure for the preparation of 13-aryl-indeno[1,2-*b*]naphtho[1,2-*e*]pyran-12(13*H*)-ones using SA as an efficient and versatile catalyst under solvent-free conditions (Scheme 1).

## RESULTS AND DISCUSSION

Initially, to optimize the reaction temperatures, the reaction of β-naphthol (1 mmol) with benzaldehyde (1 mmol) and 2H-indene-1,3-dione was studied under solvent-free conditions in the presence of 3 mol % SA at different temperatures. The results are summarized in Table 1. As shown in Table 1, the reaction at 120°C proceeded in highest yield.

To optimize the catalyst loading, 0, 1, 2, 3, 4, and 5 mol % of was tested, respectively. The results are

**Scheme 1**



summarized in Table 2. A 3 mol % loading of SA was sufficient to push the reaction forward and 2 mol % of SA was not enough. Higher amounts of SA did not lead to significant change in the reaction yields.

Based on the optimized reaction conditions, a range of 13-aryl-indeno[1,2-*b*]naphtho[1,2-*e*]pyran-12(13*H*)-ones (**4**) was synthesized by the reaction of β-naphthol (**1**, 1 mmol) with arylaldehydes (**2**, 1 mmol) and 2H-indene-1,3-dione (**3**, 1 mmol). The reaction proceeded at 120°C within 4 h in excellent yields after the addition of the catalyst SA (Table 3). All of the products **4** exhibited a singlet in their $^1$H spectra at δ = 5.58–6.01 ppm for H-13 and also a distinguishing peak at δ = 28.8–35.7 ppm for C-13 in their $^{13}$C NMR spectra. The resonance of carbonyl group in their $^{13}$C NMR spectrum of **4** appeared at δ = 191.7–192.4 ppm. When this reaction was carried out with aliphatic aldehyde, such as butanal or pentanal, TLC and $^1$H NMR spectra of the reaction mixture showed a mixture of starting materials and numerous products, the yield of the expected product was very poor. In 2-naphthol, the electron density at the benzylic C-1 position (which is in conjugation with the aromatic ring) is higher than that at the C-3 position. Thus, the regioselective formation of the *ortho*-quinone methide from this compound involving the C-1 and C-2 positions is favored. In simple phenolic compounds and 1-naphthol (which are weaker nucleophiles compared with 2-naphthol), the electron density at the *ortho* position of the hydroxyl group is not sufficient for the reaction of these compounds with the aldehydes leading to the formation of the corresponding *ortho*-quinone methides. When the reaction of 1-naphthol (1 mmol) with benzaldehyde (1 mmol) and 2H-indene-1,3-dione was carried out under solvent-free conditions in the presence of 3 mol % SA at 120°C, the yield of the expected product was 0%.

In conclusion, we have demonstrated a rapid and very efficient SA-catalyzed one-pot synthesis of 13-aryl-indeno[1,2-*b*]naphtho[1,2-*e*]pyran-12(13*H*)-ones under solvent-free conditions. The current methodology has the advantages of operational simplicity, neutral and mild reaction conditions, high to excellent yields of products, lack of toxicity, and low costs.

## EXPERIMENTAL

NMR spectra were determined on Bruker AV-400 spectrometer in $CDCl_3$ and were expressed in δ values relative to tetramethylsilane, coupling constants (*J*) were measured in Hz; IR spectra were determined on FTS-40 infrared spectrometer; Mass spectra were recorded on a Finnigan LCQ Advantage mass spectrometer; Elemental analysis were recorded on a Vario ELIII elemental analyzer; Melting points were determined on a Mel-Temp capillary tube apparatus and were uncorrected; Commercially available reagents were used throughout without further purification unless otherwise stated.

[a] Reaction conditions: β-naphthol (1 mmol); arylaldehyde (1 mmol); 2H-indene-1,3-dione (1 mmol); SA (0.03 mmol); solvent-free;120°C.
[b] Isolated yield after chromatographic purification.

**General procedure for the preparation of 4.** To a mixture of β-naphthol (1 mmol), aldehyde (1 mmol) and 2H-indene-1,3-dione (1 mmol), SA (0.03 mmol) was added. The mixture was stirred (use a high power electric mixer) at 120°C for an appropriate time (Table 3). After completion of the reaction (TLC), the reaction mixture was treated with water (10 mL) and extracted with $CH_2Cl_2$ (2 × 10 mL), filtered and the solvent evaporated *in vacuo*. Products were puried by silica gel column chromatography using petroleum ether:chloroform (2:3) as eluent.

***13-Phenyl-indeno[1,2-b]naphtho[1,2-e]pyran-12(13H)-one (4a).*** Yellow solid, mp 202–203°C. IR (KBr) ν: 3080, 1660, 1236, 1006 $cm^{-1}$. $^1H$ NMR (400 MHz, $CDCl_3$) δ: 7.89–7.82 (m, 3H), 7.51 (d, $J$ = 8.8 Hz, 1H), 7.43–7.29 (m, 8H), 7.23 (t, $J$ = 8.0 Hz, 2H), 7.12 (t, $J$ = 7.6 Hz, 1H), 5.64 (s, 1H) ppm. $^{13}C$ NMR (100 MHz, $CDCl_3$) δ: 192.3, 167.3, 149.0, 143.7, 136.9, 132.4, 132.2, 131.9, 131.8, 130.1, 129.6, 128.5, 128.4, 128.1, 127.1, 126.6, 125.2, 124.4, 121.6, 118.3, 117.1, 116.6, 111.0, 35.7 ppm. Published online 13 July 2010 in Wiley Online Library (wileyonlinelibrary.com).

A novel series of pyrazolo [1,5-a] pyrimidines were synthesized by the condensation of substituted chalcones with 5-amino pyrazole in presence of dimethyl formamide. All the synthesized products were characterized by the spectral analysis. Further, all newly synthesized compounds were screened for their antimicrobial activity. Most of the compounds showed potent activity.

## INTRODUCTION

Pyrazole nucleus has wide applications in medicinal chemistry. The ring system plays an important role in many biological processes, and many therapeutic agents contain pyrazole moiety. Several pyrazoles with antimicrobial, antiviral, and anticancer properties have been reported [1]. Certain alkyl pyrazoles have shown significant antiallergic, anti-inflammatory, and antiarthritic properties [2,3]. Many pyrazole-fused heterocyclic compounds have been to exhibit biological activity and widely used studied in pesticide and medicine [4–6]. Pyrazolopyrimidines are of considerable chemical and pharmacological importance as purine analogues [7,8], and have antitumor, antileukemic activities. Pyrazolo [1,5-a] pyrimidines useful properties, as antimetabolites in purine biochemical reactions [9–11]. These interesting biological activities reported for pyrazolopyrimidines have stimulated chemists to develop new class of these compounds.

## RESULTS AND DISCUSSION

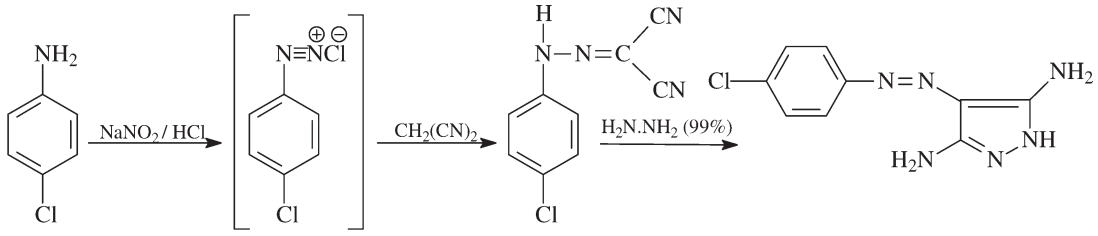
In continuation of our work on the synthesis of some new bioactive heterocyclic compounds [12–15], herein we report a new series of pyrazolo [1,5-a] pyrimidines by the condensation of chalcones with the 5-amino pyrazole in dimethyl formamide (DMF).

The starting 5-amino pyrazole was prepared in two steps from the corresponding amine by the diazotization and then treatment with malononitrile followed by reaction with hydrazine hydrate [16] (Scheme 1), while the novel α,β-unsaturated carbonyl compounds **2(a–h**) were prepared in the presence of base by conventional Claisen–Schmidt condensation of substituted acetophenones and 5-chloro-3-methyl-1-phenyl-1*H*-pyrazole-4-carbaldehyde (Scheme 2). Finally, the synthesis of pyrazolo [1,5-a] pyrimidines **3(a–h**) were attempted by the reacting 5-amino pyrazole with α,β-unsaturated carbonyl compounds (chalcones) using NaOH in presence of DMF as reaction solvent (Scheme 3).

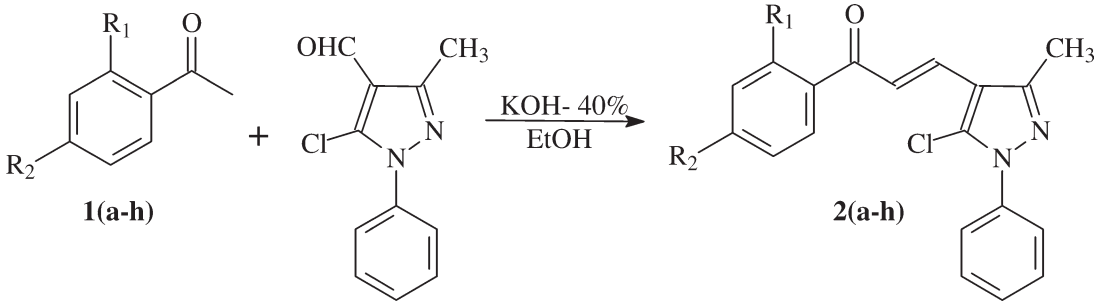
The formation of products were assumed to proceed through the Micheal-type addition of the ring nitrogen in 5-amino pyrazole (which is more active) to the activated double bond followed by intramolecular cyclization [17,18] with the elimination of water and dehydrogenation. The structures of compounds were appropriately established by the spectroscopic and analytical methods.

The results of the antimicrobial screening data are given in Table 1. In comparison with reference drugs, compounds **3a**, **3b**, and **3c** showed effective activity against all the tested microbes. Compounds **3a** and **3b** showed near to par activity against *Bacillus subtilis*. Only the compound **3a** was showed potent activity against *Escherichia coli* than standard penicillin drug.

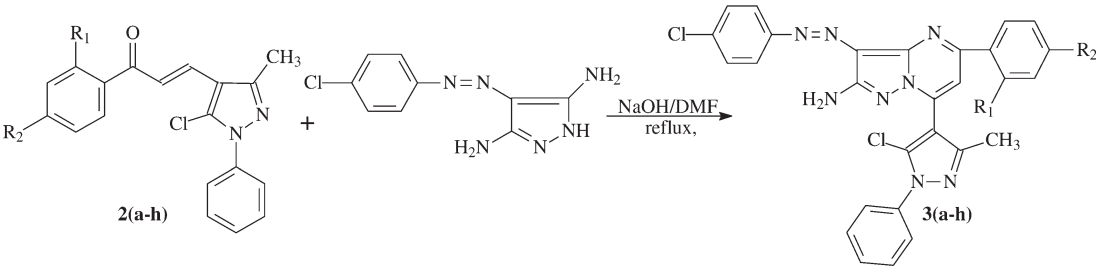
**Scheme 1.** Synthesis of 5-amino pyrazole.



**Scheme 2.** Synthesis of chalcones.



**Scheme 3.** Synthesis of pyrazolo [1,5-a] pyrimidines.



Compound **3b** showed stronger activity against *Aspergillus flavus* than reference Nystatin drug. On the other hand, compounds **3(d–h)** displayed moderate antimicrobial activity.

**Table 1**

Antimicrobial activity of synthesized compounds **3(a–h)**.

| Product | A | B | C | D |
|---|---|---|---|---|
| **3a** | 25 | 27 | 17 | 15 |
| **3b** | 22 | 26 | 16 | 18 |
| **3c** | 22 | 27 | 16 | 15 |
| **3d** | 18 | 15 | 14 | 12 |
| **3e** | 20 | 18 | 11 | 10 |
| **3f** | 18 | 21 | 12 | 11 |
| **3g** | 14 | 16 | 10 | 8 |
| **3h** | 16 | 20 | 12 | 15 |
| Reference1 | 24 | 28 | NA | NA |
| Reference2 | NA | NA | 18 | 16 |

Zone of inhibitions are expressed in mm.
A = *Escherichia coli*, B = *Bacillus subtilis*, C = *Fusarium moniliformae*, D = *Aspergillus flavus*, Reference 1 = Penicillin, Reference 2 = Nystatin, NA = Not Applicable.

As far as the antimicrobial results are concerned only the three compounds displayed very good activity. Pyrazolo [1,5-a] pyrimidines carrying *p*-chloro phenyl, *p*-hydroxy phenyl, and *p*-methoxy phenyl at $C_5$-position emerged as active in both antibacterial and antifungal screening. The substitution of *o*-hydroxy phenyl may increase the antimicrobial activity against various pathogens. When we compared the activity of substituted compounds with a nonsubstituted compound (**3g**), the substituted compounds showed higher activity.

## CONCLUSIONS

In summary, we have designed and synthesized some novel pyrazolo [1,5-a] pyrimidines by the condensation of substituted chalcones with 5-amino pyrazole in presence of a base (solid sodium hydroxide) in dimethylformamide. The preliminary *in vitro* antimicrobial screening of this series revealed that compounds **3a**, **3b**, and **3c** showed potent activity when compared with standard drug. Therefore, the present study is useful drugs in

medicinal investigation against bacterial and fungal diseases.

## EXPERIMENTAL

Melting points were uncorrected and determined in an open capillary tube. IR spectra were recorded on FTIR Shimadzu spectrometer. $^1$H NMR spectra were recorded in DMSO-$d_6$ on Avance 300 MHz spectrometer using TMS as an internal standard. The mass spectra were recorded on EI-Shimadzu-GC-MS spectrometer. Elemental analyses were performed on a Carlo Erba 106 Perkin-Elmer model 240 analyzer.

**General procedure for the synthesis of chalcone derivatives 2(a–h).** A mixture of substituted acetophenone **1** (1 mmol), 5-chloro-3-methyl-1-phenyl-1*H*-pyrazole-4-carbaldehyde (1 mmol) and NaOH (2 mmol) were dissolved in ethanol (20 mL) solution. The reaction mixture was heated for 2 h. The progress of the reaction was monitored by TLC. After completion of the reaction, the contents were poured in ice cold water and then acidified by dil. HCl. The solid obtained was filtered and washed with cold water. Then crude product was crystallized from acetic acid to give the corresponding product **2**.

**Typical procedure for the synthesis of pyrazolo [1,5-a] pyrimidines 3(a–h).** A mixture of **2a** (1 mmol), 5-amino pyrazole (1 mmol), and 1–2 pallets of NaOH were dissolved in DMF (15 mL). The reaction mixture was refluxed for the period as shown in Table 2. The progress of the reaction was monitored by TLC. After completion, the reaction mixture was extracted with diethyl ether (2 × 20 mL). The combined organic layers were dried over anhydrous $Na_2SO_4$, and the solvent was evaporated under reduced pressure. The crude product was recrystallized from aqueous acetic acid to give the product **3a**. Similarly, other analogues of this were synthesized by using the same procedure.

**Antimicrobial activity.** The antimicrobial activities of the synthesized compounds **3(a–h)** were determined by agar well diffusion method [19]. The compounds were evaluated for antibacterial activity against *Escherichia coli* (MTCC 2939) and *Bacillus subtilis* (MTCC 1789). The antifungal activity was evaluated against *Fusarium moniliformae* (MTCC 156) and *Aspergillus flavus* (MTCC 2501) were procured from Institute of Microbial technology (IMTech), Chandigarh, India. The antibiotic penicillin (25 μg/mL) and nystatin (25 μg/mL) was used as reference drug for antibacterial and antifungal activity, respectively. Dimethyl sulphoxide (1%, DMSO) was used a control with out compound.

The culture strains of bacteria were maintained on nutrient agar slant at 37 ± 0.5°C for 24 h. The antibacterial activity was evaluated using nutrient agar plate seeded with 0.1 mL of respective bacterial culture strain suspension prepared in sterile saline (0.85%) of $10^5$ CFU/mL dilutions. The wells of 6 mm diameter were filled with 0.1 mL of compound solution at fixed concentration 25 μg/mL separately for each bacterial strain. All the plates were incubated at 37 ± 0.5°C for 24 h. Zone of inhibition of compounds in mm were noted.

For antifungal activity, all the culture strains of fungi maintained on potato dextrose agar (PDA) slant at 27 ± 0.2°C for 24–48 h, until sporulation. Spore of strains were transferred into 5 mL of sterile distilled water containing 1% Tween-80 (to suspend the spore properly). The spores were counted by haemocytometer ($10^6$ CFU/mL). Sterile PDA plate was prepared containing 2% agar; 0.1 mL of each fungal spore suspension was spread on each plate and incubated at 27 ± 0.2°C for 12 h. After incubation well prepared using sterile cork borer and each agar well was filled with 0.1 mL of compound solution at fixed concentration 25 μg/mL. The plates were kept in refrigerator for 20 min for diffusion and then incubated at 27 ± 0.2°C for 24–28 h. After incubation, zone of inhibition of compounds were measured in mm along with standard.

**Acknowledgments.** The authors gratefully acknowledge UGC-New Delhi for the Postdoctoral Research Award (No. F.30-1/2009, SAII). The authors are also thankful to Principal, Yeshwant Mahavidyalaya, Nanded, for providing laboratory facilities and Director, IICT, Hyderabad, for providing necessary instrumental facilities.

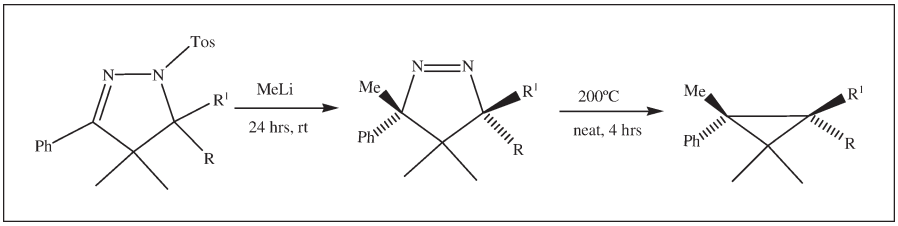
Published online 18 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



Addition of methyllithium to the 3-position of 4,5-dihydro-3,4,4,5,5-pentasubstituted-*N*-tosyl-1H-pyrazoles [**1a** 4,4,5,5-tetramethyl-3-phenyl; **1b** 4,4,5-trimethyl-3,5-diphenyl; **1c** 4,4-dimethyl-3,5,5-triphenyl] produced the corresponding hexasubstituted pyrazolines, **2a-c**, as the only isolable products. For **2b**, the 3,5-phenyl groups were found to be exclusively *cis*, indicative of facial specificity for the addition reaction. The reaction of phenyllithium with **1b** yielded **2c** as the minor product. For phenyllithium addition, direct attack on sulfur of the tosyl group with subsequent loss of phenyl *p*-tolylsulfone was the major pathway *vs*. the $S_N2i$ attack at carbon-3. Thermolysis of pyrazolines **2a-c**, at 200°C, smoothly produced the hexasubstituted cyclopropanes [**3a** 1,1,2,2,3-pentamethyl-3-phenylcyclopropane; **3b** cis-1,1,2,3-tetramethyl-2,3-diphenylcyclopropane; **3c** 1,1,2-trimethyl-2,3,3-triphenylcyclopropane] in excellent yield.

## INTRODUCTION

We have an ongoing interest in the development of general methods for the synthesis of highly substituted cyclopropanes, particularly hexasubstituted systems. Historically, preferred methods for cyclopropane synthesis include pyrazoline thermolysis [For a review and recent articles see ref 1] and carbene/carbenoid addition [2] to alkenes. However, the latter method generally does not work well for the preparation of hexasubstituted compounds. Our approach has focused on synthesis and subsequent thermolysis of highly substituted pyrazolines. We have developed a methodology for the efficient synthesis of a series of 1-alkoxy and 1-acetoxy-1,2,2,3,3-pentasubstituted cyclopropanes [3]. However, routes to hexa(alkyl/aryl) substituted cyclopropanes are scarce and often highly specialized. [For cyclopropanation with dimethylcarbene, From photolysis of hexaalkylcyclohexane-1,3,5-trione, From reduction of α,γ-dibromides see ref. 4]. We report here a route to hexa(methyl/phenyl) substituted cyclopropanes *via* the synthesis and subsequent thermolysis of hexasubstituted pyrazolines.

## RESULTS AND DISCUSSION

Addition of methylithium to 4,5-dihydro-3,4,4,5,5-pentasubstituted-N-tosyl-1H-pyrazoles, **1a-c**, under argon (rxn 1) yielded the hexasubstituted pyrazolines, **2a-c**, respectively, as the only isolated products, in variable yields. Recovered (unreacted) starting materials accounted for the remaining product balance. The 3,5-phenyl groups in

**b** R = Ph; R¹ = Me (59%)
**c** R = R¹ = Ph (55%)

**2b** were found to be exclusively cis based on NMR data, indicating preferential reaction of the methyllithium with only one face of **1b**. Compounds **2a-c** were characterized by spectra and physical data.

The synthesis of **2c** was also accomplished in 25% yield by the reaction of phenyllithium with **1b**. The remaining products were indicative of the formation of 4,5-dihydro-4,4,5,5-tetramethyl-3-phenyl-1H-pyrazole [with subsequent air oxidation and decomposition] and phenyl tolylsulfone. Unlike the reaction with methyllithium, that with phenyllithium yielded products

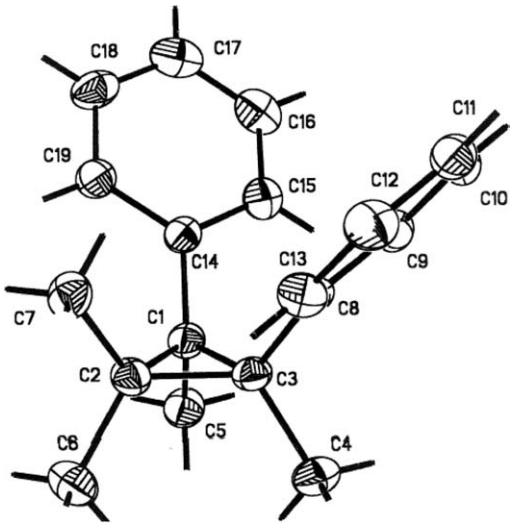

**Figure 1.** X-ray structure of **3b**.

indicative of preferential attack of phenyllithium on the tosyl group.

Thermolysis of pyrazolines **2a-c**, neat, at 200°C, produced the hexasubstituted cyclopropanes in excellent yield (rxn 2). The thermolysis of *cis* **2b** yielded *cis* **3b** in

**2a-c**

**3a** R = R$^1$ = Me
**b** R = Ph; R$^1$ = Me (major)
**c** R = R$^1$ = Ph

84% isolated yield. Analysis of the reaction mixture indicated that the product was a 95%/5% mixture of the *cis*/*trans* cyclopropane. Retention of configuration occurred with 95% efficiency. The cyclopropanes were characterized by spectra and physical data. The structure of **3b**, the major product, was confirmed by X-ray crystallography (Fig. 1) to have the *cis*-2,3-diphenyl configuration.

The addition of methyllithium to the 3-position of N-tosylated 4,5-dihydro-1H-pyrazoles to yield a tetrasubsti-

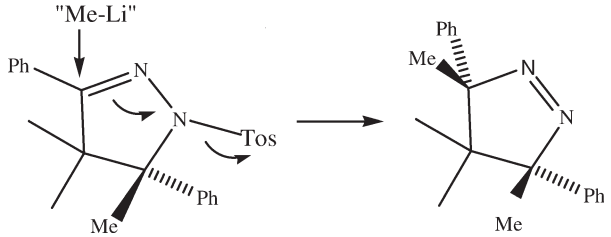
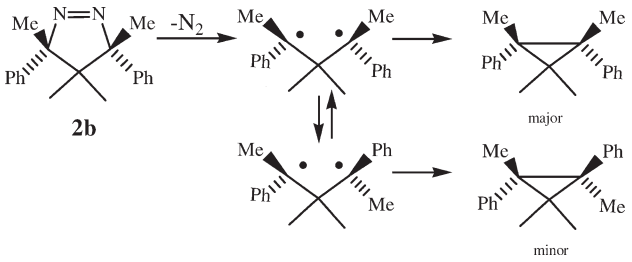


**Scheme 2.** Proposed mechanism for the thermolysis of **2b**.



tuted pyrazoline (4H-pyrazole) had been documented, but there appear to be no additional reports since that early work [5]. This is likely due to the inherent properties (air sensitivity, etc.) of selected 4,5-dihydro-1H-pyrazoles [6]. In addition, attempted N-tosylation of 4,5-dihydro-1H-pyrazoles with tosyl chloride, surprisingly, can yield unexpected products, 3-chloro pyrazolines [7] rather than the expected N-tosylated compounds. Recent development of synthetic methodology for the synthesis of 4,5-dihydro, *N*-tosyl-1H-pyrazoles was the key for the preparation of the required starting materials [8]. The addition of methyllithium to the *N*-tosyl 4,5-dihydro-1H-pyrazoles proceeded smoothly to generate the highly substituted pyrazolines. Interestingly, the results for conversion of **1b** to **2b** indicate a facial specificity of the attack of the methyllithium by an $S_N2i$ mechanism as shown in Scheme 1 below.

For methyllithium, this route appears to be the favored mode of attack. Results with phenyllithium showed this route to be the minor pathway with direct reaction of phenyllithium with the sulfur of the tosyl group being the major pathway that appears to limit the scope of reaction 1.

Thermolysis of pyrazolines to cyclopropanes, in high yield, is a well established route [1]. Thermal decomposition of pyrazolines to cyclopropanes generally is thought to occur *via* a diradical mechanism that favors retention of configuration [1,9]. The present results are consistent with the diradical mechanism shown below in Scheme 2 for thermolysis of **2b**.

In conclusion, the addition of methyllithium to *N*-tosyl-4,5-dihydro-1H-pyrazoles and subsequent thermolysis of the pyrazolines is a useful method for the synthesis of highly substituted cyclopropanes. The method has obvious limitations in that the substituents must be stable to organolithium reagents but appears to provide a more general route to this type of highly substituted strained ring compound. Work is in progress to explore the scope of this route.

## EXPERIMENTAL

The *N*-tosylated-4,5-dihydro-1H-pyrazoles, **1a-c**, were prepared according to published results [8]. Methyllithium (1.6*M*)

in diethyl ether and phenyl lithium (1.8*M*) in cyclohexane-ether were purchased from Sigma–Aldrich Company and used without further purification. All solvents were commercially available. Anhydrous toluene, anhydrous ether, and methanol were purchased from Aldrich Company and used without further purification. Tetrahydrofuran (Aldrich) was distilled from sodium and benzophenone before use. Acetone, ethanol, and hexane were purchased from Fisher Scientific Company. All $^1$H and $^{13}$C NMR spectra were obtained from a Varian Unity Plus 300 MHz instrument. Mass spectra were obtained from a Shimadzu GP-5000 Mass Spectrometer. Elemental analyses were performed at the Department of Chemistry at Georgia State University and at Atlantic Microlab, Atlanta, Georgia. Melting points were recorded in a calibrated Thomas Hoover Unimelt apparatus. Exact mass analyses were performed at the Georgia Institute of Technology. X-ray crystallography was performed at Emory University.

**Synthesis of 3,3,4,4,5-pentamethyl-5-phenyl-4,5-dihydro-3H-pyrazole (2a).** 4,4,5,5-Tetramethyl-3-phenyl-1-(toluene-4-sulfonyl)-4,5-dihydro-1H-pyrazole (**1a**) (0.30 g, 0.8415 mmol) was dissolved in anhydrous toluene (25 mL) under argon atmosphere. The solution was cooled to 0°C with an ice bath. Then, methyllithium (2 mL, 3.2 mmol, 3.8 mole equiv) was added to the solution using a dried glass syringe. The solution was stirred for 30 min at 0°C and 24 h at room temperature. Then, the reaction was quenched with 10 mL of saturated, degassed ammonium chloride solution. Diethyl ether (20 mL) was added to the mixture before washing with saturated sodium bicarbonate (2 × 20 mL) solution and deionized water (30 mL). The organic layer was dried over magnesium sulfate. The solvent was removed under reduced pressure. The crude product was purified by flash chromatography (hexane/ethyl acetate [95:5]) to give **2a** in an isolated yield of 87% (0.158 g, 0.732 mmol) as a clear and viscous liquid; $^1$H NMR ($CDCl_3$) 300 MHz: δ 0.34 (s, 3H), δ 1.07 (s, 3H), δ 1.30 (s, 3H), δ 1.35 (s, 3H), δ 1.60 (s, 3H), δ 7.25–7.36 (m, 5H); $^{13}$C NMR ($CDCl_3$) 300 MHz: 20.5, 23.9, 23.9, 24.1, 25.1, 41.8, 91.7, 96.0, 125.5, 126.8, 128.0, 143.8; Exact Mass Anal. Calcd. for $C_{14}H_{21}N_2$ = 217.17047. Found: 217.17060.

**Synthesis of *cis*-3,4,4,5-tetramethyl-3,5-diphenyl-4,5-dihydro-3H-pyrazole (2b).** 4,4,5-Trimethyl-3,5-diphenyl-1(toluene-4-sulfonyl)-4,5-dihydro-1H-pyrazole (**1b**) (1.0 g, 2.389 mmol) was dissolved in 50 mL of anhydrous THF under argon atmosphere. The solution was cooled to 0°C with an ice bath. Then, methyllithium (4.48 mL, 7.17 mmol, 3 equiv) was added to the solution using a dried glass syringe. The solution was stirred for 30 min at 0°C and 24 additional hours at room temperature. The mixture was quenched with 10 mL of saturated, degassed ammonium chloride solution. Diethyl ether (20 mL) was added to the mixture before washing with saturated sodium bicarbonate (2 × 20 mL) solution and deionized water (40 mL). The organic layer was dried over magnesium sulfate. The solvent was removed under reduced pressure. The crude product was purified by flash chromatography (hexane/ethyl acetate [97:3]) to give **2b** in an isolated yield of 59% (0.391 g, 1.409 mmol) mp = 144–145°C; $^1$H NMR ($CDCl_3$) 300 MHz: δ 0.26 (s, 3H), δ 1.34 (s, 3H), δ 1.68 (s, 6H), δ 7.25–7.36 (m, 10H); $^{13}$C NMR ($CDCl_3$) 300 MHz: 20.2, 23.9, 28.5, 42.9, 96.7, 125.3, 126.9, 128.1, 143.6; IR peaks: 3064 cm$^{-1}$, 2990 cm$^{-1}$, 1599 cm$^{-1}$, 703 cm$^{-1}$; Anal. Calcd. for $C_{19}H_{22}N_2$ = C, 81.97, H, 7.97, N, 10.06% Found: C, 81.79, H, 8.19, N, 9.66%.

**Synthesis of 3,4,4-trimethyl-3,5,5-triphenyl-4,5-dihydro-3H-pyrazole (2c).** 4,4-Dimethyl-3,5,5-triphenyl-1-(toluene-4-sulfonyl)-4,5-dihydro-1H-pyrazole (**1c**) (0.5 g, 1.040 mmol) was dissolved in anhydrous THF (50 mL) under argon atmosphere. The solution was cooled to 0°C with an ice bath. Then, methyllithium (2.6 mL, 4.16 mmol, 4 Eq.) was added to the solution using a dried glass syringe. The solution was stirred for 30 min at 0°C and 36 additional hours at room temperature. The mixture was quenched with 10 mL of saturated, degassed ammonium chloride solution. Diethyl ether (20 mL) was added to the reaction before washing with saturated sodium bicarbonate (2 × 40 mL) solution and deionized water (40 mL). The organic layer was dried over magnesium sulfate. The solvent was removed under reduced pressure. The crude product was purified by chromatatron (hexane/ethyl acetate) to give **2c** in an isolated yield of 55% (0.19 g, 0.558 mmol) mp = 117–118°C; $^1$H NMR $CDCl_3$) 300 MHz: δ 0.15 (s, 3H), δ 1.16 (s, 3H), δ 1.56 (s, 3H), δ 7.16–7.97 (m, 15H); $^{13}$C NMR ($CDCl_3$) 300 MHz: 20.7, 21.8, 27.3, 46.6, 96.6, 97.6, 125.7, 126.5, 126.7, 127.0, 127.2, 128.0, 128.1, 142.6, 143.5, 143.9; Anal. Calcd. for $C_{24}H_{24}N_2$: C, 84.67, H, 7.11, N, 8.23% Found: C, 84.73, H, 7.19, N, 8.26%.

**Synthesis of 1,1,2,2,3-pentamethyl-3-phenylcyclopropane (3a).** 3,3,4,4,5-Pentamethyl-5-phenyl-4,5-dihydro-3H-pyrazole (**2a**) (0.100 g, 0.462 mmol) was placed in an NMR tube and purged with argon gas. The tube was then heated in a silicon oil bath at 200°C ± 2 for 4 h. When the viscous liquid was heated, evolution of gas (nitrogen) was observed. The NMR tube was removed from the oil bath after 4 h of heating and hexane was added to dissolve the products. The crude product was purified by chromatatron (hexanes) to yield 93% of **3a** (0.081 g, 0.429 mmol) as a clear viscous liquid. $^1$H NMR ($CDCl_3$) 300 MHz: δ 0.92 (s, 6H), δ 1.16 (s, 6H), δ 1.23 (s, 3H), δ 7.1–7.3 (m, 5H); lit. $^1$H NMR δ 0.91 (s, 6H), δ 1.15 (s, 6H), δ 1.23 (s, 3H), δ 7.12 (m, 5H) (Gloss *et al*., 1966; $^{13}$C NMR ($CDCl_3$) 300 MHz: 18.5, 21.70, 21.74, 23.9, 29.7, 33.6, 125.0, 127.9, 130.7, 146.0.

**Synthesis of *cis*-1,1,2,3-tetramethyl-2,3-diphenylcyclopropane (3b).** 3,4,4,5-Tetramethyl-3,5-diphenyl-3H-pyrazole (**2b**) (0.1 g, 0.359 mmol) was placed in an NMR tube and purged with argon gas. The tube was then heated in a silicon oil bath at 200°C ± 2 for 4 h. When heated, the crystals melted and evolution of nitrogen gas was observed. The NMR tube was removed from the oil bath after 4 h of heating and hexane was added to dissolve the product. The crude product was purified by chromatatron (hexanes) and recrystallized from methanol to give **2b** in 84% yield (0.075 g, 0.301 mmol) as colorless crystals, mp = 79–81°C. $^1$H NMR ($CDCl_3$) 300 MHz: δ 1.12 (s, 3H), δ 1.37 (s, 3H), δ 1.47 (s, 6H), δ 7–7.4 (m, 10H); $^{13}$C NMR ($CDCl_3$) 300 MHz: 18.7, 23.2, 25.4, 27.0, 35.5, 125.3, 127.4, 131.1, 145.6; X-ray structure was obtained at Emory University; IR peaks: 3083–2927 cm$^{-1}$, 1599 cm$^{-1}$, 1577 cm$^{-1}$, 699 cm$^{-1}$. Anal. Calcd. for $C_{19}H_{22}$: C, 91.14, H, 8.86; found: C, 90.93, H, 9.04%.

**Synthesis of 1,1,2-trimethyl-2,2,3-triphenylcyclopropane (3c).** 3,4,4-Trimethyl-3,5,5-triphenyl-4,5-dihydro-3H-pyrazole (**2c**) (0.1 g, 0.2937 mmol) was placed in an NMR tube and purged with argon gas. The tube was then heated in a silicon oil bath at 200°C ± 2 for 4 h. When heated, the crystals

melted and evolution of nitrogen gas was observed. The NMR tube was removed from the oil bath after 4 h of heating, and hexane was added to dissolve the products. The crude product was purified by chromatatron (hexanes) to give **2c** in 91% yield (0.83 g, 0.267 mmol) as a colorless viscous liquid. $^{1}$H NMR ($CDCl_3$) 300 MHz: δ 1.32 (s, 3H), δ 1.33 (s, 3H), δ 1.38 (s, 3H), δ 6.9–7.6 (m, 15H); $^{13}$C NMR ($CDCl_3$) 300 MHz: 22.2, 26.8, 27.2, 28.1, 37.9, 46.2, 125.0, 125.3, 125.5, 127.5, 127.9, 128.1, 131.0, 131.3, 143.9, 144.3, 144.4. MS Molecular Ion – 312. Anal. Calcd. for $C_{24}H_{24}$: C, 92.24, H, 7.74%; Found: C, 92.39, H, 7.60%.

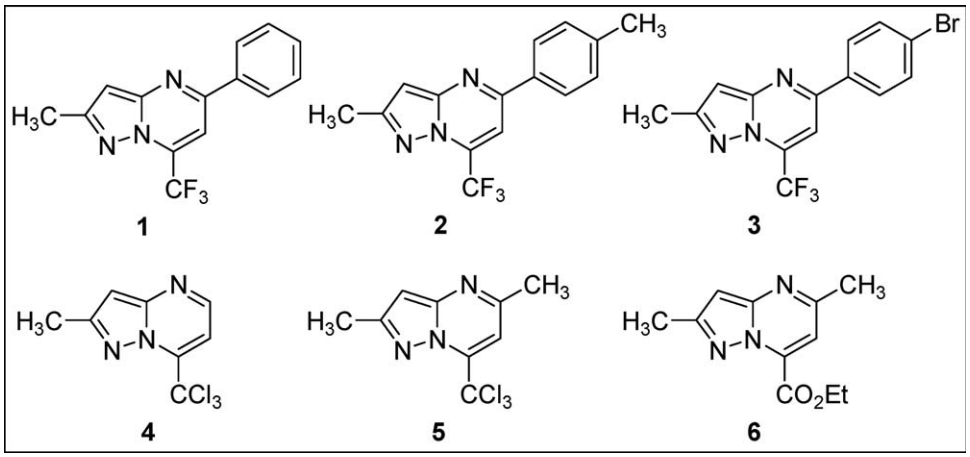
*Dedicated to our friend Professor Luis Castedo on the occasion of his 70th birthday.*



Six pyrazolo[1,5-*a*]pyrimidines bearing a 7-trifluoromethyl (three compounds), a 7-trichloromethyl (two compounds), and a 7-ethoxycarbonyl (one compound) have been structurally characterized. The new X-ray structures of 2-methyl-5-(*p*-bromophenyl)-7-trifluoromethylpyrazolo[1,5-*a*]pyrimidine (**3**) and 2-methyl-7-trichloromethylpyrazolo[1,5-*a*]pyrimidine (**4**) are reported. The combined use of GIAO/B3LYP/6-311++G(d,p) calculations with NMR spectroscopy in solution and in the solid state allows to establish some general rules that can be useful for characterizing related compounds. Compounds **3** and **4** present in the solid-state interesting intra- and intermolecular halogen bonds.

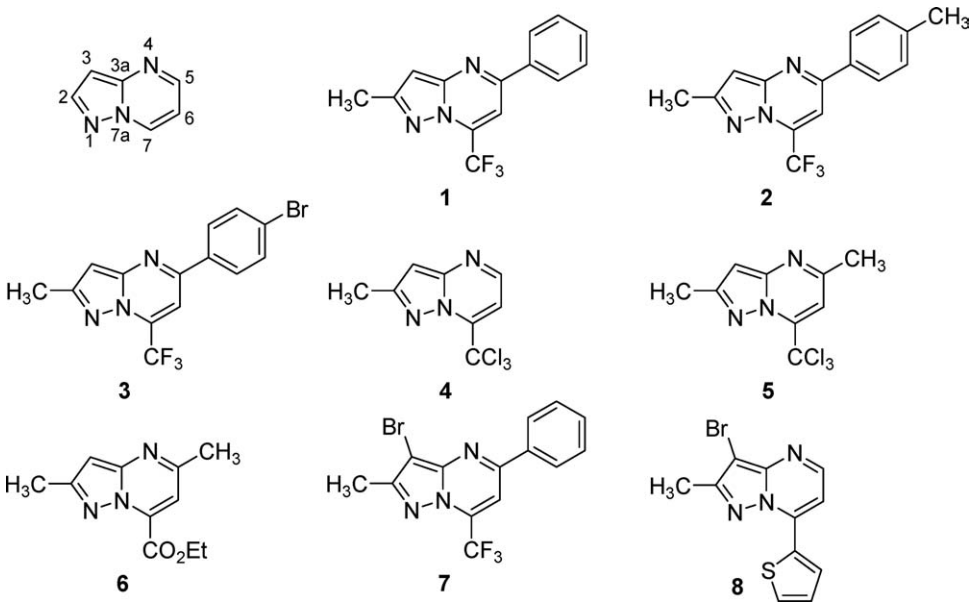
## INTRODUCTION

Pyrazolo[1,5-*a*]pyrimidines are purine analogues and as such have useful properties as antimetabolites in purine biochemical reactions. Compounds of this class have attracted wide pharmaceutical interest because their activity as inhibitors of HMG-CoA reductase [1], COX-2 [2], AMP phosphodiesterase [3], KDR kinase [4], and as selective peripheral benzodiazepine receptor ligands [5] as well as antianxiety agents [6]. Recently, other pharmaceutical activities have been reported, for example, as compounds for the treatment of sleep disorders [7], as oncological agents [8], and estrogen receptor ligands [9]. Other activities include hypnotic [10] inhibitors of human cyclin-dependent kinase 2 [11] and high affinity for $GABA_A$ receptors [12].

These examples explain the high interest in variously substituted pyrazolo[1,5-*a*]pyrimidines. As a consequence, the synthesis of these compounds has been approached by different methods [13]. In the literature, there is a large number and variety of such type of fused heterocycles bearing a $CF_3$ substituent at position 7 [14] but 7-trichloromethyl substituted pyrazolo[1,5-*a*]pyrimidines are much less frequent [15].

Because most studies on these compounds are related to their synthesis or to their biological properties, we decided to devote one paper to a structural study to establish the general patterns for their characterization. The six compounds **1–6** that we have analyzed are reported in Scheme 1 together with their atom numbering.

**Scheme 1**



## RESULTS AND DISCUSSION

The synthesis of the following compounds was already described: 2-methyl-5-phenyl-7-trifluoromethylpyrazolo[1,5-*a*]pyrimidine (**1**) [14], 2-methyl-5-(*p*-tolyl)-7-trifluoromethylpyrazolo [1,5-*a*]pyrimidine (**2**) [16], 2-methyl-7-trichloromethylpyrazolo[1,5-*a*]pyrimidine (**4**) [17], and 2,5-dimethyl-7-trichloromethylpyrazolo[1,5-*a*]pyrimidine (**5**) [17,18].

Even if 2-methyl-5-(*p*-bromophenyl)-7-trifluoromethylpyrazolo[1,5-*a*]pyrimidine (**3**) is commercially available (from Asinex), it was never described before and our preparation has been included here. Ethyl 2,5-dimethylpyrazolo[1,5-*a*]pyrimidine-7-carboxylate (**6**) is a new compound.

Some of us already reported the X-ray molecular structures of derivatives **2** and **5** [16,18] and those of compounds **7** (a 3-bromo derivative of **1**) and **8** had also been published [14a,17].

**Crystallography.** In the molecule of the title compounds (Scheme 1 and Fig. 1), the bond lengths are within the related range (Table 1) [19–22]. In particular, the formally single C(3a)-N(4) and C(7)-N(7a) bonds are only slightly longer than the formally double C(2)-N(1) bond, although each of these single bonds is significantly shorter than the formally single C(3a)-N(7a) bond. Similarly, the lengths of the C(2)-C(3) and C(3)-C(3a) bonds, formally single and double bonds, respectively, differ by less than 0.02 Å. These observations, together with the planarity at atom N1, suggest that this heterocyclic system exhibits a degree of naphthalene-type delocalization, involving a peripheral system of 10 π electrons with only modest participation by the cross-

ring bond (C3a-N7a) [23]. Five-membered pyrazole ring is planar with r.m.s. deviations from the plane of 0.0015 and 0.0025 Å in compounds **3** and **4**, respectively. The six-membered pyrimidine ring is also planar with r.m.s. deviations from the plane of 0.0062 and 0.0131 Å in compounds **3** and **4**, respectively. The angle torsion N(1)-N(7a)-C(3a)-N(4) for compounds **3** and **4** is –179.4(5) and 178.1(17)°, showing that the pyrazole and pyrimidine rings are in the same plane. The geometry of the pyrazolopyrimidine system is similar to that reported in the literature [16].

The molecular structure of compounds **3** and **4** reveals that the intermolecular interactions are related to the nature of substituent. Compound **4** that is not substituted in position 5 of the pyrazolopyrimidine ring shows intra- and intermolecular interactions similar to those found in a related compound with a 5-methyl group [18]: it shows two intramolecular interactions between Cl(2)···N(1) and Cl(3)···N(1) with interatomic distances of 3.097(6) and 3.093(6) Å, respectively. In this molecule, the crystal packing forms an infinite chain along plane *ab* through the intermolecular interaction Cl(1)···N(4) with interatomic distances of 3.115(3) Å ($x+1/2, -y+1, z$) (Fig. 2).

The crystal structure of compound **3** shows that the pyrazolopyrimidine and phenyl rings are almost in the same plane with a C(6)-C(5)-C(51)-C(52) torsion angle of 11.2(8)°. This finding indicates that there is a small π-resonance between the pyrazolopyrimidine system and the aryl ring [18,24,25]. In addition, interesting intermolecular interactions between the halogens atoms as F(1) atom of the trifluoromethyl group of one molecule and the F(3) atom of the trifluoro methyl group of another molecule, with an interatomic distance of 2.899(6) Å ($x+1,y,z$) are observed.

The fluorine atom as halogen bonding has been related to noncovalent interactions, however, while, the Ar-ArF stacking motif formed between nonfluorinated and perfluorinated aromatic rings is rated an important supramolecular synthon [26], the contacts of C-F···H [27,28], C-F···F [29] and C-F···πF [30] type are not yet sufficiently clear [31,32]. On the other hand, the ability of the fluorine–fluorine intermolecular interactions in directing the supramolecular structure of synthons concerning atoms of aliphatic systems is unknown. Thus,

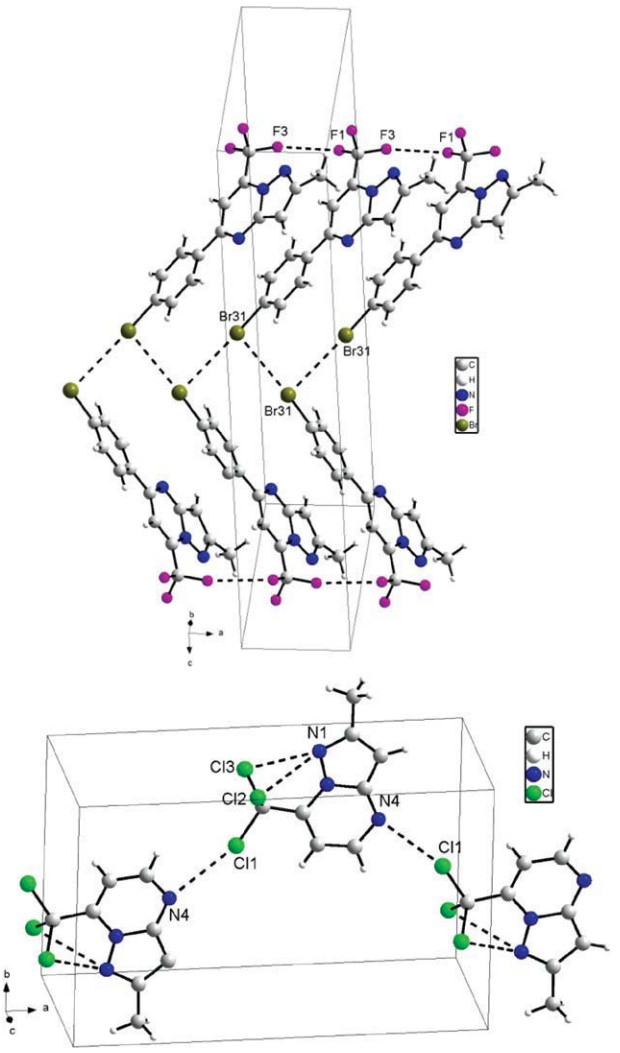

**Figure 2.** A stereoview of part of the crystal structure of **3** and **4** showing the packing along the *ab* plane. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

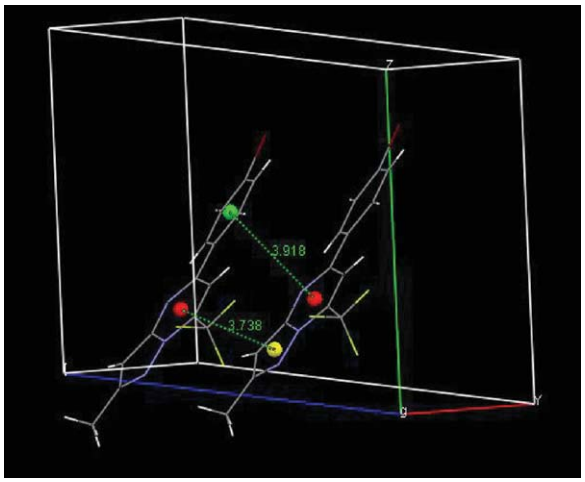

**Figure 3.** A 3D-view of part of the crystal structure of compound **3** showing π-π interactions between pyrazole···pyrimidine and pyrimidine···phenyl ring-centroid. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

we present here, for the first time, an intermolecular noncovalent interaction between fluorine atoms of aliphatic systems that fix the supramolecular structure of a pyrazolopyrimidine bearing a trifluoromethyl group. The interatomic distance appeared to be less than the sum of van der Waals radii of the atoms involved in the interaction [33].

The bromine atoms are also involved in the molecular packing of compound **3**, which forms an infinite chain along plane *ab* through the intermolecular interaction Br(31)···Br(31) with an interatomic distance of 3.6584(9) Å ($x+1/2,-y+3/2,-z+2$) (Fig. 2). In case of bromine–bromine intermolecular interaction, the interatomic distance also appeared to be less than the sum of van der Waals radii of the atoms involved in the interaction [33]. Recently, we have reported intermolecular Br···Br contacts of about 3.9 Å in crystals of bromopyrazoles [34]. Moreover, pyrazolopyrimidines are interlinked by noncovalent π-π stacking interactions between aromatic rings. As a result, the molecules of **3** and **4** form chains by means of F···F, Br···Br, and Cl···N interactions, respectively, and these chains are themselves linked into sheets by π-π stacking interaction.

In **3**, the weak π-π stacking interactions involve the pyrimidine rings of two adjacent molecules at ($x$, $y$, $z$) and ($1+x$, $y$, $z$), where the ring-centroid separation with the pyrazole ring is 3.738 Å; the ring-centroid separation between the pyrimidine and the phenyl is 3.918 Å (Fig. 3). In **4**, the π-π stacking interaction involves the fused heterocyclic rings of the molecules at ($x$, $y$, $z$) and ($1.5 - x$, $-y$, $-0.5 + z$), with a ring-centroid separation of 3.813 Å between the pyrimidines and of 3.631 Å between the pyrazoles (Fig. 4). These values are similar to those reported in the literature for similar compounds [35].

**NMR.** We have reported in Tables 2–4 the NMR results concerning compounds **1–6**.

The CPMAS chemical shifts, although less precise (some signals overlap) than those in solution, are linearly related to the DMSO-$d_6$ values: CPMAS (ppm) = (0.993 ± 0.002) DMSO (ppm), $n = 79$, $R^2 = 0.9997$.This means that the structures in solution (mainly the torsion angles) are similar to those in the solid-state determined by X-ray crystallography.

**Computational studies.** Initially, we optimized the geometries of pyrazolo[1,5-*a*]pyrimidines **1-6** at the B3LYP/6-31G(d) level verifying that they correspond to the minima (frequency calculations). A further optimization was carried out at the B3LYP/6-311++G(d,p) level and represented the result in Figure 5.

The calculated geometries are very similar (bond distances and bond angles) to those determined experimentally for compounds **2**, **3**, **4**, and **5**; even the sensitive torsion angles are much alike. On these geometries, we calculated [GIAO/B3LYP/6-311++G(d,p)//B3LYP/6-311++ G(d,p)] the absolute shieldings (σ, ppm) and transformed them into chemical shifts (δ, ppm) by means of the following three equations: $\delta^1H = 31.0 - 0.970\ \sigma^1H$; $\delta^{13}C = 175.7 - 0.963\ \sigma^{13}C$; $\delta^{15}N = -152.0 - 0.946\ \sigma^{15}N$ that we have previously devised based on a statistic analysis of many data [36].

In these works, we established that the absolute shieldings corresponding to carbon atoms bearing halogen atoms systematically deviate. In this article and based on the previous reports[36], we have corrected the C-Br atom in *para* position of compound **3** by –20.1

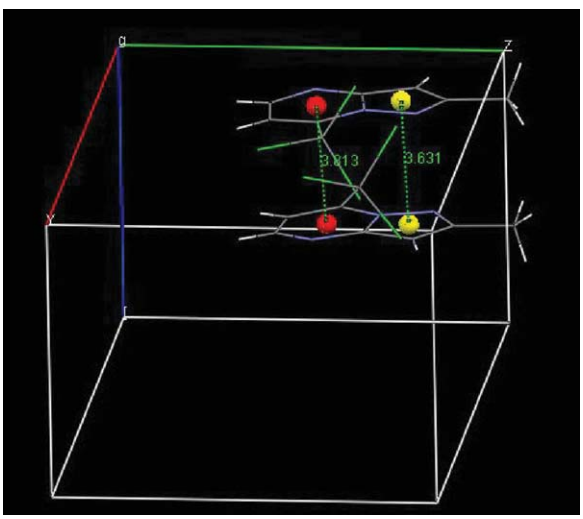

**Figure 4.** A 3D-view of part of the crystal structure of compound **4** showing π-π interactions between pyrazole···pyrazole and pyrimidine··· pyrimidine ring-centroid. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

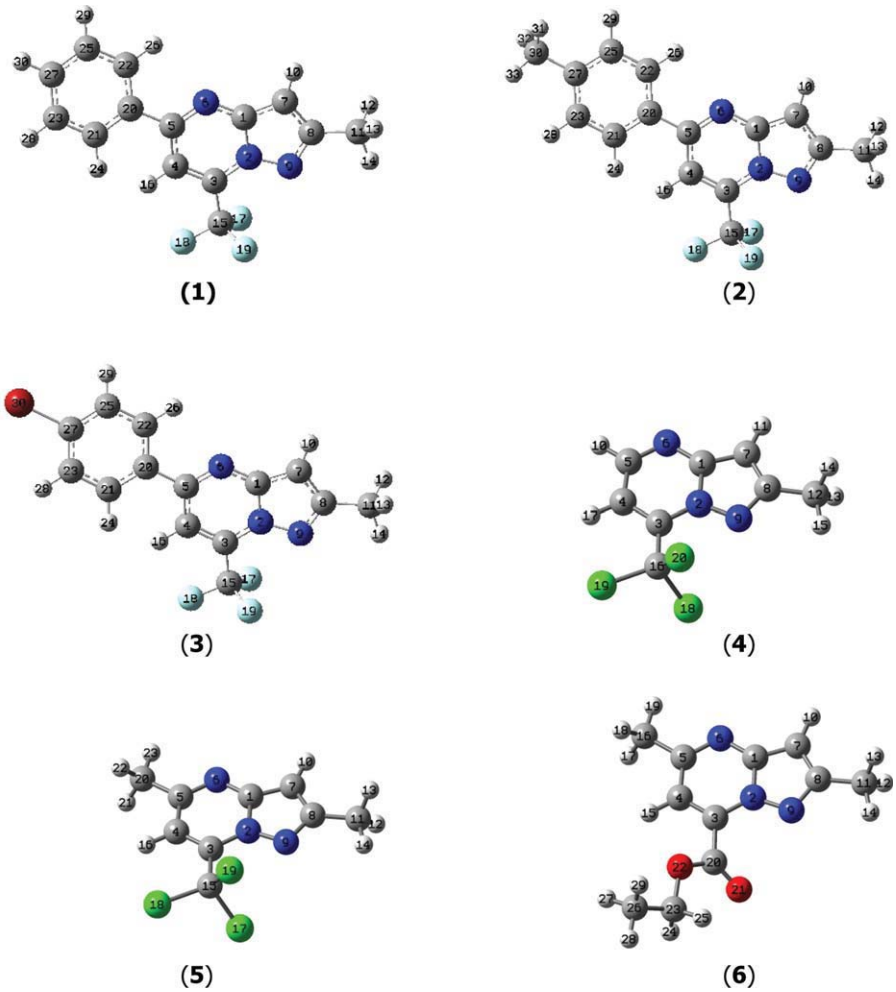

**Figure 5.** The six optimized structures. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

ppm, the $CF_3$ atoms of compounds **1**, **2**, and **3** by +2.8 ppm and the $CCl_3$ atoms of compounds **4** and **5** by –33.3 ppm. With these corrections, we obtained the plot of Figure 6. The trendline corresponds to Exp. DMSO-$d_6$ (ppm) = (0.999 ± 0.001) Calc. (ppm), $n$ = 114, $R^2$ = 0.9998. The very good quality of this regression verifies the signals assignment.

In solution, the *ortho* and *meta* signals correspond to averaged values (the same for the H atoms of the methyl groups) but in the solid state the splittings present in compound **2** probably correspond to the absence of free rotation of the *p*-tolyl group at position 5 (Scheme 2).

## CONCLUSIONS

The main conclusions of our investigations are:

1. In the gas-phase, theoretical calculations [B3LYP/6-311++G(d,p) optimized geometries and GIAO/B3LYP/6-311++G(d,p)//B3LYP/6-311++G(d,p) abso-

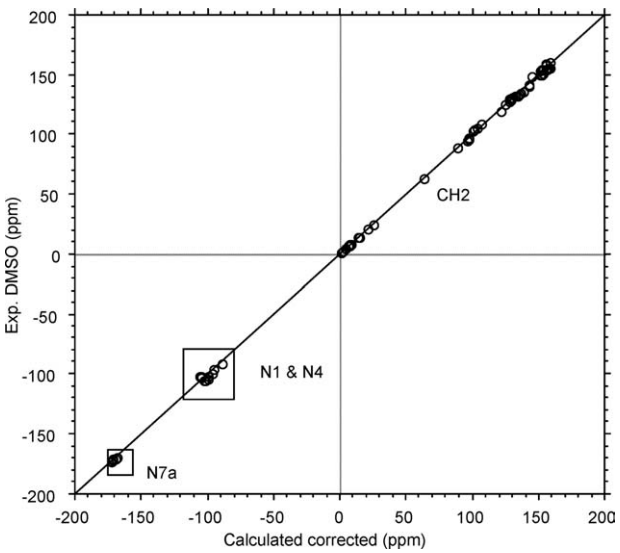

**Figure 6.** Plot of experimental *vs.* calculated chemical shifts.

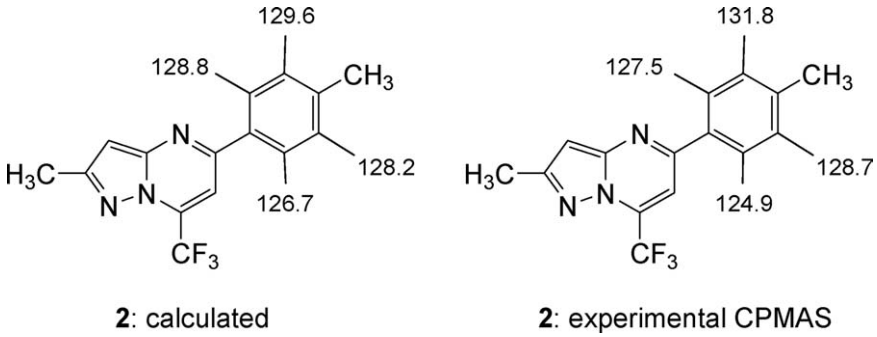
**Scheme 2**



**2**: calculated **2**: experimental CPMAS

lute shieldings] of each monomer account well for the properties in condensed phases: solution (NMR) and solid state (NMR and crystallography).

2. In DMSO-d6 solution, NMR results are consistent with the proposed structures providing chemical shifts (in brackets mean values in ppm) useful for characterizing new series of pyrazolo[1,5-a]pyrimidines: δN7a(−172) < δN1(−103.5) < δN4(−98); δC2-Me(155) ≈ δC5-Ar(154) > δC7(135) > δC6(105); δC2-Me(155) > δC5-H(149) > δC7(135) > δC6(105); δC5-Me(158) > δC2-Me(155) > δC7(135) > δC6(105). The CPMAS data show similar trends, meaning that the structures in solution are close to those in the solid state.
3. X-Ray crystallographic studies show interesting halogen interactions (X...X, X...N), both the F···F at 2.90 Å and the Br...Br at 3.66 Å for 3 and the Cl...N at 3.115 Å for 4, of great importance in crystal engineering [37,38].

## EXPERIMENTAL

**General.** 3-Amino-5-methyl-1*H*-pyrazole was obtained commercially from Aldrich (ACS grade) and used without further purification. The heterocyclic precursors were synthesized in accordance with methodologies developed in our laboratory [37]. The crystals used for the data collection were obtained by crystallization of compounds from hexane followed by slow evaporation at room temperature. All solvents (Merck) were dried in accordance with procedures carried out in our laboratory [38]. Melting points were determined on a Microquimica MQAPF–302 melting point apparatus.

**2-Methyl-7-trifluoromethyl-5-(p-bromophenyl)pyrazolo[1,5-a]pyrimidine (3).** A solution of 3-amino-5-methyl-1*H*-pyrazole (1.0 mmol) in acetic acid (5 mL) was added to a stirred solution of 4-(*p*-bromophenyl)-1,1,1-trifluoro-4-methoxy-3-buten-2-one (1.0 mmol) in acetic acid (5 mL). The mixture was stirred for 16 h and after the reaction time the product was extracted with chloroform (3 × 10 mL), washed with distilled water (3 × 10 mL), and dried on magnesium sulfate. The solvent was removed in a rotary evaporator and compound **3** was purified by recrystallization from hexane, and was obtained in 86% yield. M.p. 171–173°C.

**Ethyl 2,5-dimethylpyrazolo[1,5-a]pyrimidine-7-carboxylate (6).** A solution of 3-amino-5-methyl-1*H*-pyrazole (1.0 mmol) in acetic acid (5 mL) was added to a stirred solution of ethyl 4-methoxy-2-oxo-3-pentenoate (1.0 mmol) in acetic acid (5 mL). The mixture was stirred for 16 h and after the reaction time, the product was extracted with chloroform (3 × 10 mL), washed with distilled water (3 × 10 mL), and dried on magnesium sulfate. The solvent was removed in a rotary evaporator and the product was purified by crystallization from hexane, and was obtained in 91% yield. M.p. 74–76°C.

**Crystallography.** The diffraction measurements were carried out by graphite-monochromated Mo Kα radiation with λ = 0.71073 Å on a Bruker SMART CCD diffractometer [39]. The structures were solved with direct methods using the SHELXS-97 program and refined on *F2* by full-matrix least-squares with the SHELXL97 package [40]. Absorption correction was performed by the Gaussian method [41]. Anisotropic displacement parameters for nonhydrogen atoms were applied. The hydrogen atoms were placed at calculated positions with 0.96 Å (methyl CH3), 0.97 Å (methylene CH2), 0.98 Å (methyne CH), 0.93 Å (aromatic CH) and 0.82 Å (OH) using a riding model. Hydrogen isotropic thermal parameters were kept equal to *U*iso(H) = *xU*eq (carrier C atom), with $x = 1.5$ for methyl groups and $x = 1.2$ otherwise. The valence angles C—C—H and H—C—H of methyl groups were set to 109.5° and H atoms were allowed to rotate around the C—C bond. Molecular graphics were prepared using ORTEP for Windows [42]. The crystal data and details concerning data collection and structure refinement are given in Table 5.

Crystallographic data for structures have been deposited with the Cambridge Crystallographic Data Center (2-methyl-7-trichloromethylpyrazolo[1,5-*a*]pyrimidine CCDC 734995; 2-methyl-5-(*p*-bromophenyl)-7-trifluoromethylpyrazolo[1,5-*a*]pyrimidine CCDC 734998). Copies of the data can be obtained, free of charge, on application to CCDC 12 Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336033 or e-mail: deposit@ccdc.cam.ac.uk).

**NMR measurements.** $^{1}$H (400.13 MHz), $^{13}$C (100.61 MHz), and $^{15}$N (40.56 MHz) spectra in solution were obtained with a Bruker DRX-400 instrument, with a 5-mm inverse-detection H-X probe equipped with a gradient coil, at 300 K. Chemical shifts (δ in ppm) are given from solvent DMSO-$d_6$ 2.49 for $^{1}$H and 39.5 for $^{13}$C, external nitromethane (0.00) for $^{15}$N NMR. Coupling constants (*J* in Hz) are accurate to ± 0.2

Hz for $^1$H and ± 0.6 Hz for $^{13}$C and $^{15}$N. 2D-inverse-proton-detected heteronuclear-shift-correlation spectra ($^1$H-$^{13}$C) gs-HMQC, ($^1$H-$^{13}$C) gs-HMBC and ($^1$H-$^{15}$N) gs-HMBC were acquired and processed using standard pulse sequences [43]. Solid-state $^{13}$C (100.73 MHz) and $^{15}$N (40.60 MHz) CPMAS-NMR spectra have been obtained with a Bruker WB-400 spectrometer at 300 K with a wide-bore 4-mm DVT probehead. Samples were carefully packed in $ZrO_2$ rotors. $^{13}$C spectra were originally referenced to a glycine sample and then the chemical shifts were recalculated to the $Me_4Si$ [for the carbonyl atom δ (glycine) = 176.1 ppm] and $^{15}$N spectra to $^{15}NH_4Cl$ and then converted to nitromethane scale using the relationship: δ $^{15}$N ($MeNO_2$) = δ $^{15}$N($NH_4Cl$)-338.1 ppm. Typical acquisition parameters for $^{13}$C CPMAS were: spectral width, 40 kHz; recycle delay, 5–60 s; acquisition time, 30 ms; contact time, 2–4 ms; and spin rate, 12 kHz. In order to distinguish protonated and unprotonated carbon atoms, the NQS (Non-Quaternary Suppression) experiment by conventional cross-polarization was recorded; before the acquisition the decoupler is switched off for a very short time of 25 (s. Typical acquisition parameters for $^{15}$N CPMAS were: spectral width, 40 kHz; recycle delay, 5–60 s; acquisition time, 35 ms; contact time, 7 ms; and spin rate, 6 kHz [44].

**Computational details.** The optimization of the geometries of the structures were first carried out at the B3LYP/6-31G(d) and afterwards reoptimized at the B3LYP/6-311++G(d,p) computational level [45–50] within the Gaussian-03 package [51]. Frequency calculations at the first level were carried out to confirm that the obtained structures correspond to energy minima. GIAO absolute shieldings [52,53] were calculated on the B3LYP/6-311++G(d,p) optimized geometries.

**Acknowledgment.** This work was carried out with financial support from the Ministerio de Ciencia y Tecnología (Project No. CTQ2006-14487-C02-01/BQU and CTQ2007-62113) and Comunidad Autónoma de Madrid (Project MADRISOLAR, ref. S-0505/PPQ/0225). Thanks are given to the CTI (CSIC) for allocation of computer time. One of the authors (CPF) is greatly indebted to Fundaçao Coordenação de Aperfeiçoamento de Pessoal de Nível Superior— CAPES, Ministério da Educaçao, Brasil, for a fellowship.

A novel class of coumarin-thiazole conjugated systems (**1–31**) were synthesized by Hantzsch condensation between α-bromo-3-acetyl coumarin and several thiosemicarbazone intermediates. This scaffold was also evaluated for selective antibacterial activity against 20 isolates of *H. pylori* clinical strains, including four metronidazole resistant ones.

*J. Heterocyclic Chem.*, **47**, 1269 (2010).

## INTRODUCTION

*Helicobacter pylori* are spiral-shaped Gram-negative bacteria with polar flagella that live near the surface of the human gastric mucosa. They have evolved specific mechanisms to avoid the bactericidal acid environment in the gastric lumen to survive near, to attach to, and to communicate with the human gastric epithelium and host immune system. This interaction sometimes results in severe gastric pathology. In fact, *H. pylori* infection is indeed the most known risk factor for the development of gastroduodenal ulcers, gastric adenocarcinoma, and gastric mucosa-associated lymphoid tissue lymphoma.

*H. pylori* infections are difficult to cure and successful treatment generally requires the simultaneous somministration of several antibacterial agents. Antibiotic resistance has resulted in unsatisfactory eradication with dual and now triple therapy in many countries. Newer antibiotics and changes in dosing and duration of therapy may overcome resistant strains but may only provide limited improvement in eradication rates [1–3].

In our previous works [4,5] and from the analysis of the structure of natural coumarins reported as potent anti-*H. pylori* agents [6], we have pointed out that the coumarin ring might play an important role in determining activity and seemed to be crucial for the selective antimicrobial activity of such compounds. Recently, we have synthesized and chemically and biologically characterized some new conjugated coumarin-thiazole systems, which were endowed with interesting industrial properties and especially antimicrobial activity on *H. pylori* clinical strains [7].

Furthermore, interest in these structures has renewed due to the recent discovery of their promising antibacterial, antifungal, and antimycobacterial activity [8–11].

Moving from these indications, in this report we described the synthesis and selective antimicrobial evaluation of a new series of 4-(coumarin-3-yl)thiazol-2-ylhydrazone derivatives which differ for the electronic and steric characteristics on the hydrazone nitrogen (aliphatic chains, cycloaliphatic moiety, and heterocyclic rings).

## RESULTS AND DISCUSSION

The coumarin-thiazole derivatives (**1–30**) were prepared in high yields (69–99%) according to a protocol

**Table 1**

Structure of derivatives **1–31**.

| Comp | R | $R_1$ |
|---|---|---|
| **1** [ref. 12] | $CH_3$ | $CH_3$ |

used in our laboratory (Table 1). Different carbonyl compounds reacted directly with thiosemicarbazide in ethanol with catalytic amounts of acetic acid, and the obtained thiosemicarbazones were subsequently converted into 4-(coumarin-3-yl)-2-thiazolylhydrazones by reaction with α-bromo-3-acetyl coumarin in the same solvent at room temperature (Hantzsch condensation). α-Bromo-3-acetyl coumarin has been synthesized by direct halogenation of 3-acetyl coumarin with bromine in chloroform. Moreover, knowing that all reported structures possess an imine bond, which could be hydrolyzed in the acidic environment of the stomach (reproduced in the biological assay), we also synthesized and assayed their common intermediate (**31**) by direct reaction between thiosemicabazide and α-bromo-3-acetyl coumarin in ethanol at room temperature.

All synthesized products were purified with petroleum ether and diethyl ether and, if requested, by chromatography before characterization by spectroscopic methods (IR and $^1$H NMR) and elemental analysis. The compounds, correctly analyzed for their molecular formula, showed in the IR spectrum strong bands at 1710 and 1600 $cm^{-1}$ due to the presence of a δ-lactone C=O and C=N group, respectively.

Moreover, the presence of a C=N double bond can give rise to isomeric geometry E/Z. The $^1$H NMR (in $CDCl_3$) spectra analysis revealed that the E isomer was more favored and stable than the Z-configuration. The amounts of both conformers were measured by area integration of the signal relative to the $CH_3$ ($R^1$) protons (area ratio of proton signals E:Z was generally 6:1). The low-field signal was assigned to the E isomer, as it is widely accepted in thiosemicarbazone derivatives [17]. Our choice, as reaction medium, of a polar alcoholic solvent appeared to be preferred to obtain the E-configuration and limit the interconversion according to the results of our previous theoretical and chromatographic study for similar compounds [18].

Then, all compounds were evaluated, as mixture of E/Z conformers, against 20 clinical strains of *H. pylori*, which are more resistant to conventional therapy. Metronidazole was used as standard antibacterial drug (Table 2).

Most of the assayed compounds showed no anti-*H. pylori* activity or comparable activity with respect to Metronidazole (MIC $\geq$ 16 μg/mL). Only some compounds (**14**, **21**, and **26**), bearing a specific heterocyclic ring (furan, pyridine, and naphthalene) on the hydrazone nitrogen, possessed MIC values slightly inferior to the reference drug (MIC = 8 μg/mL) against some clinical *H. pylori* strains. Unfortunately, it was not possible to correlate this biological activity with lipophilicity (Clog*P*).

## EXPERIMENTAL

The chemicals, solvents for synthesis and spectral grade solvents were purchased from Aldrich (Italy) and used without further purification. Melting points are uncorrected and were determined automatically on an FP62 apparatus (Mettler-Toledo). $^1$H NMR spectra were recorded at 400 MHz on a Bruker spectrometer. Chemical shifts are expressed as δ units (parts per millions) relative to the solvent peak. Coupling constants *J* are valued in Hertz (Hz). IR spectra were registered on a Perkin Elmer FTIR Spectrometer Spectrum 1000 in KBr. Elemental analysis for C, H, and N were recorded on a Perkin-Elmer 240 B microanalyzer and the analytical results were within ±0.4% of the theoretical values for all compounds. All reactions were monitored by TLC performed on 0.2-mm-thick silica gel plates (60 $F_{254}$ Merck). Lipophilicity parameter, Clog*P*, has been calculated for each molecule by using ChemDraw ultra 8.0. The synthesis of some compounds has been described in previous references (Table 1) and was performed with slight changes. Their analytical and spectral data were in full agreement with those reported in the literature.

**Typical procedure for the thiosemicarbazones synthesis.** The appropriate carbonylic compound (50 mmol) was dissolved in 100 mL of ethanol and stirred vigorously at

room temperature with an equimolar amount of thiosemicarbazide for 24 h with catalytic amount of acetic acid. The desired thiosemicarbazone precipitated from reaction mixture was filtered and crystallized from suitable solvent and dried.

**Typical procedure for the Hantzsch protocol for the preparation of derivatives 1–30.** Equimolar amounts of the prepared thiosemicarbazones (50 mmol) and freshly synthesized 3-α-bromo-acetyl coumarin (50 mmol), both dissolved in ethanol, were reacted at room temperature under magnetic stirring for 4 h. The precipitate was filtered and dried to give compounds **1–30** in 69–99% yield.

**Procedure for the synthesis of derivative 31.** 3-α-Bromoacetyl coumarin (50 mmol) was dissolved in 2-propanol and reacted with an equimolar amount of thiosemicarbazide at room temperature under magnetic stirring for 4 h. The precipitate was filtered and dried to give intermediate **31**.

***H. pylori* culture.** The *H. pylori* strains used in this study were maintained at −80°C in Wilkins Chalgren broth with 10% (v/v) horse serum (Seromed) and 20% (v/v) glycerol (Merck) until required for the experiments. Before being used the bacteria were subcultured twice on Columbia agar base (Difco Laboratories) supplemented with 10% horse serum and 0.25% Bacto yeast extract (Difco). Plates were incubated for 72 h at 37°C in an atmosphere of 10% $CO_2$ in a gas incubator.

**Anti-*Helicobacter pylori* activity.** Antimicrobial activity against *H. pylori* was determined by the agar dilution standard method [19]. The strains were inoculated onto Columbia agar base (Difco) supplemented with 10% horse serum and 0.25%

bacto yeast extract (Difco) and were incubated for 72 h at 37°C in an atmosphere of 10% $CO_2$ in a gas incubator. Colonies were suspended in Wilkins Chalgren broth to achieve a turbidity equivalent to 0.5 Mc Farland. Columbia agar plates with 10% horse serum were prepared by using twofold dilutions of the antimicrobial agents (128–0.0039 μg/mL). The inoculum was delivered to the surface of the agar plates with a Steer's replicator to obtain $\sim 5 \times 10^5$ CFU per spot. Growth control plates without antibiotics were inoculated in each series of tests. All plates were incubated at 37°C for 72 h under conditions (10% $CO_2$ in a gas incubator). The minimal inhibitory concentration was defined as the lowest concentration of drug inhibiting visible bacterial growth.

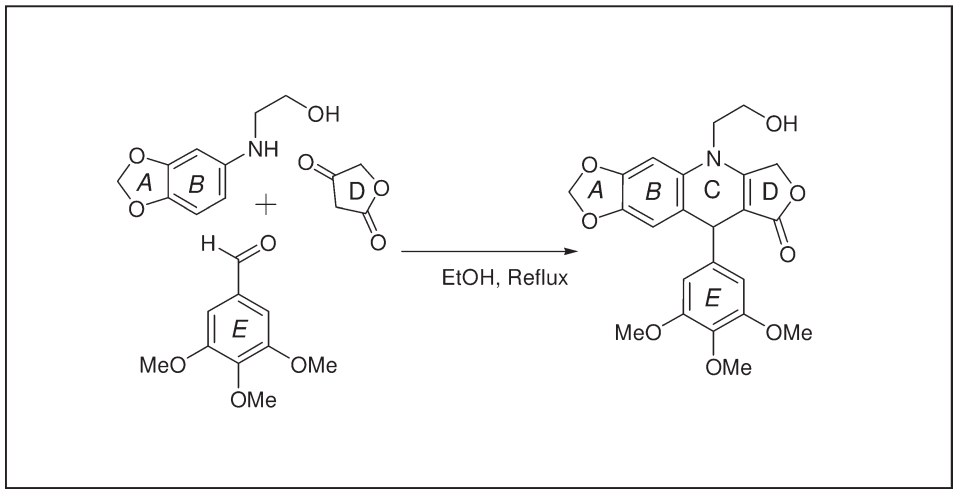
# Synthesis of Novel Functionalized 4-Aza-2,3-didehydropodophyllotoxin Derivatives with Potential Antitumor Activity

Ajay Kumar and Antonio E. Alegria*

Department of Chemistry, University of Puerto Rico, Humacao, Puerto Rico
*E-mail: antonio.alegria1@upr.edu

Received February 12, 2010
DOI 10.1002/jhet.467
Published online 20 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



Novel arylamino alcohols were synthesized and these alcohols were used to prepare 12 novel *N*-(2-hydroxy-ethyl)-2,3-didehydroazapodophyllotoxins, in one step, by simple reflux in ethanol. Isolated yields in the range of 50–70% were obtained.

*J. Heterocyclic Chem.,* **47**, 1275 (2010).

## INTRODUCTION

Podophyllotoxin (Fig. 1) is the starting material for the semi-synthesis of the anticancer drugs etoposide, etopophos and tenoposide. These antineoplastic pharmaceuticals block DNA topoisomerase II and have been used for the treatment of small and large cell lung, refractory testicular, stomach and pancreatic cancers, as well as myeloid leukemias [1a]. The podophyllotoxin core structure possesses a dual mode of action, i.e., inhibition of DNA topoisomerase II and of microtubule assembly through binding to tubulin, both of which are considered to be responsible for its antitumor activity. Podophyllotoxin is the precursor to a new derivative, CPH-82 or Reumacon®, which is being used to treat active rheumatoid or psoriatic arthritis in Europe. It is used to reduce inflammation. Podophyllotoxin is also the precursor of other derivatives used for the drug development of psoriasis and malaria [1b]. Several podophyllotoxin preparations are in the market for dermatological use to treat genital warts, e.g., imiquimod. Several new members of the podophyllotoxin derivatives have emerged as potentially superior chemotherapeutics, displaying improved water solubility and bioavailability, such as Nippon-Kayaku's NK-611 [2], GL-331 and Taiho's TOP-53 [3,4]. Podophyllotoxin derivatives also display anti-HIV-1 [5,6] and antibacterial [7] activities.

Currently, the commercial sources of podophyllotoxin are the rhizomes and roots of plants, such as *Podophyllum peltatum, Podophyllum emodi,* and American mayapple. *Podophyllum emodi* is an endangered species from the Himalayas [8]. Synthesis of podophyllotoxin is a multistep process, involving multicomponents and expensive reagents. The latest reported method for the synthesis of podophyllotoxin involves 5 steps and 20 reagents with 7.6% overall yield [9]. This tedious synthesis limits the new derivatives research of podophyllotoxin core. Podophyllotoxin contains 5 rings denoted as A, B, C, D, and E (Fig. 1). The basic structure of podophyllotoxin with rings A, B, C, D, and E was modified in different but limited ways since decades, in search of new chemical entities for drug discovery [10,11]. Derivatives of 4-aza-2,3-didehydropodophyllotoxin derivatives have also been synthesized as a strategy to develop podophyllotoxin analogs aimed at improving biological activity (Fig. 2) [12–14]. Some of those derivatives showed twice the cytotoxicity against P-388 leukemia cells as compared with podophyllotoxin [13].

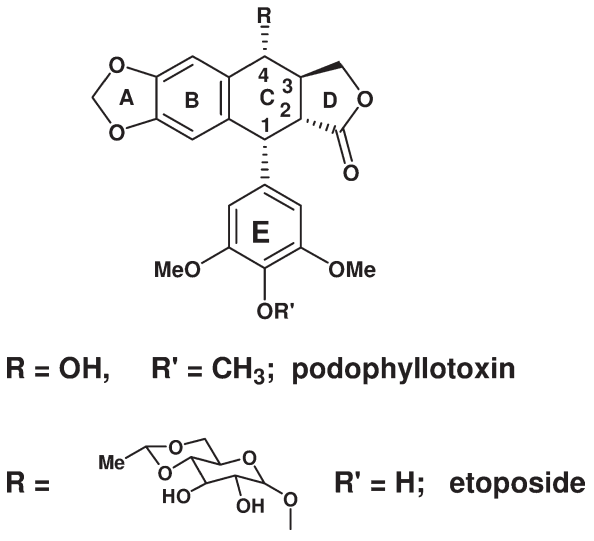


**Figure 1.** Structures of podophyllotoxin and etoposide.

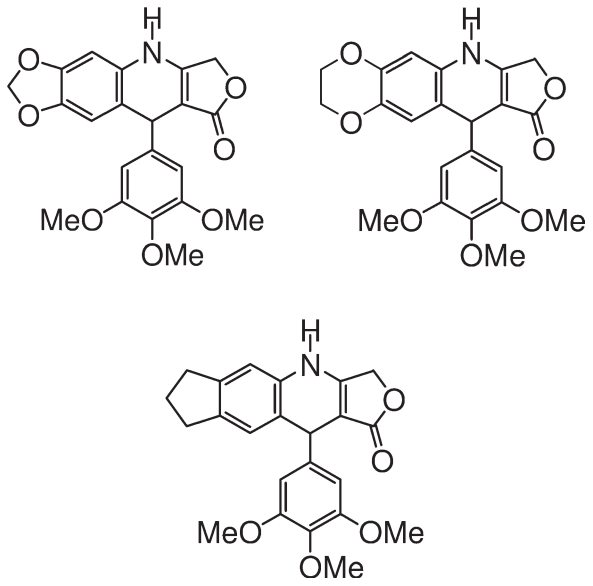

**Figure 2.** Structures of 4-aza-2,3-didehydropodo-phyllotoxin derivatives [13].

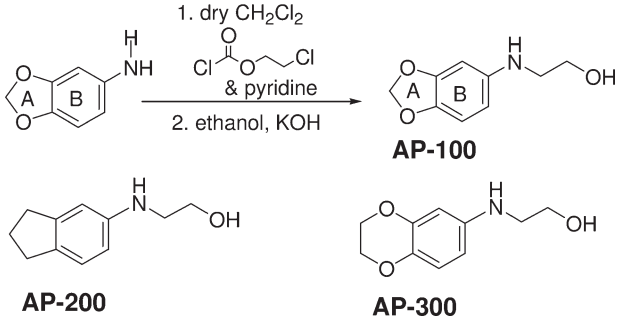
Many cytotoxic drugs have been conjugated to carriers for the selective targeting of organs and tissues [15]. To our best knowledge, no podophyllotoxin derivative has been conjugated to carriers for selective tissue targeting. In this work we report a facile and high-yielding synthetic procedure for the preparation of *N*-(2-hydroxy-ethyl)-2,3-didehydroazapodophyllotoxin derivatives with the potential to be conjugated to tissue-targeting carriers.

## RESULTS AND DISCUSSION

Although there is an N—H bond at position 4 in the ''C'' ring of 4-aza-2,3-didehydropodophyllotoxin derivatives, nucleophilic substitution to electrophiles, such as acetic anhydride or an acyl chloride to form amides was not successful in our laboratory. Furthermore, attempts to use a strong base such as NaH or LDA to abstract the proton of the amine was not effective. Therefore, for the synthesis and biological activity studies of OH-functionalized derivatives of 4-aza-2,3-didehydropodophyllotoxin at the N atom in ring ''C,'' we synthesized some new arylamino alcohols (**AP-100** to **AP-300**, Scheme 1) to prepare N-(2-hydroxy-ethyl)-2,3-didehydroazapodophyllotoxins in one step, by simple refluxing in ethanol as reported previously [14]. The novelty in our work is the preparation of hydroxy-functionalized 2,3-didehydroazapodophyllotoxin derivatives, in two simple steps, which have a functional group which is available for further modifications. The novel arylamino alcohols were prepared by reacting commercially-available substituted anilines with 2-chloroethylchloroformate in dry dichloromethane in the presence of pyridine followed by reacting with KOH in ethanol (Scheme 1). These arylamino alcohols are not stable for long periods of time at room temperature and, thus, were synthesized freshly before used. Compounds **AP-101** to **AP-304** were prepared following the procedure reported by Tratrat et. al. [14] by reacting novel arylamino alcohol with tetronic acid and substituted aldehyde in ethanol (Fig. 3). Isolated yields were in the order of 60%. This is a straightforward one-step multicomponent synthesis, which involves simple isolation of the products by filtration and recrystallization. Isolated yields were in the 50–70% range.

Structures were corroborated with the help of $^{1}$H, COSY, $^{13}$C, DEPT45, DEPT90, DEPT135, HETCOR NMR, as well as $^{1}$H-NMR coupled with deuterium exchange experiments, FTIR spectroscopy, HRMS and elemental analyses.

**Scheme 1.** Synthesis of arylamino alcohols. Structures of three examples of *N*-(2-hydroxy-ethyl)-2,3-didehydroazapodophyllotoxins are shown to indicate the structural variation of the arylamino alcohol precursor used.



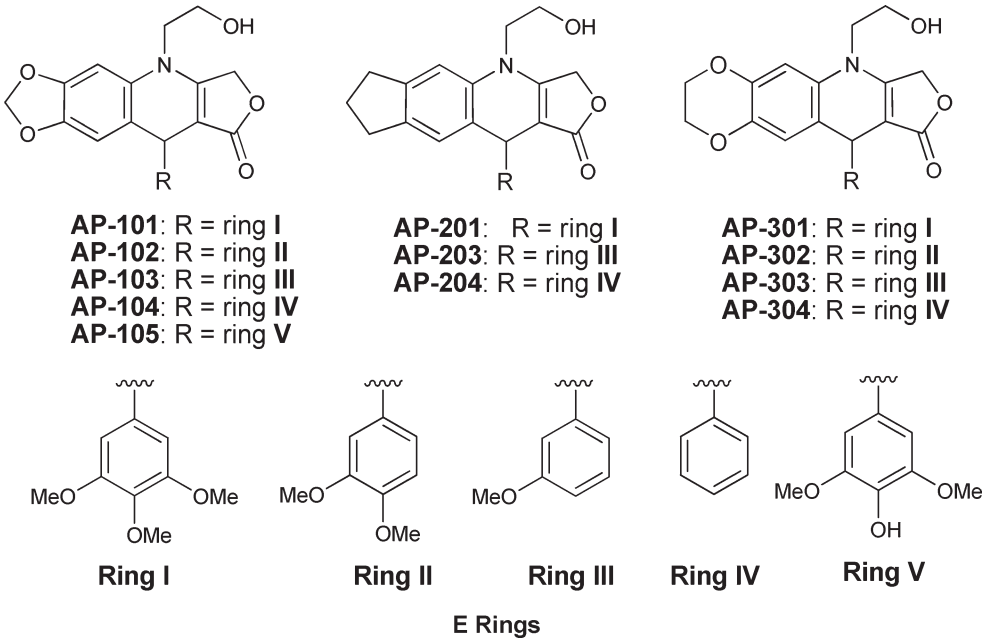


**Figure 3.** Structures of 4-aza-2,3-didehydropodo-phyllotoxin derivatives prepared in this work.

Compounds **AP-101** to **AP-304** were prepared following the procedure reported by Tratrat et al. [14] by reacting novel arylamino alcohol with tetronic acid and substituted aldehyde in ethanol (Fig. 3). The mechanism for the formation of **AP-101** is shown in Scheme 2. When the final ring closure is completed, the carbon atom, here assigned as **9**, has a unique $^{13}$C-NMR chemical shift of ca. 39 ppm (Fig. 5). The proton attached to this carbon also has a unique chemical shift (s, 1H, 4.8 ppm, Fig. 4). Both types of chemical shifts for this carbon and proton were found uniform in the entire azapodophyllotoxin derivatives synthesized in this work. Some other specific carbons also corroborate the structure of the cyclisized scaffold, i.e. **8a** at 95 ppm and **5a** at 160 ppm. These chemical shifts were also uniformly found in the entire series of the azapodophyllotoxins synthesized in this work.

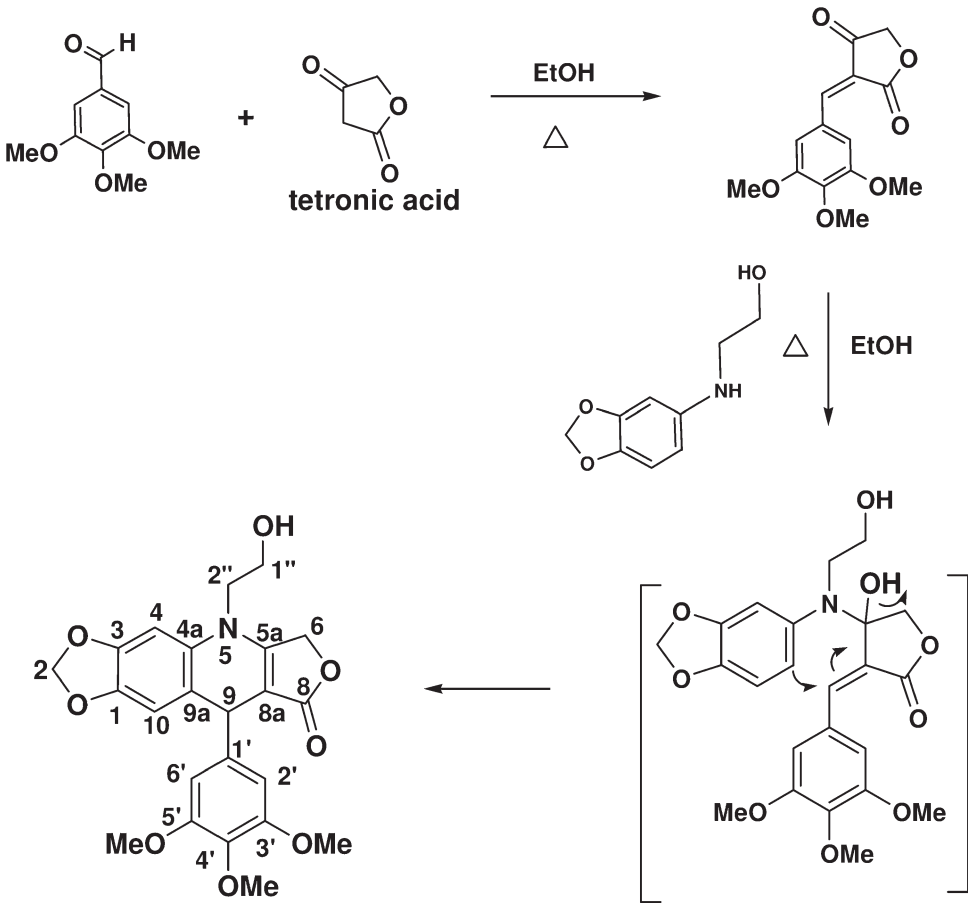
HETCOR NMR studies reveal other interesting findings (Fig. 5). Protons at carbon **2″** of all the azapodophyllotoxin derivatives are expected to be equivalent but these are not. One of them appears at ~3.6 ppm and the other at ~3.8 ppm and the latter may be interacting with protons at carbons **6** (Fig. 5). In fact, protons at position 6 are showing a broad peak probably due to that interaction. Also, protons at carbon **1″** are expected to be splitted into a triplet by two equal protons. However, these are unusually shaped as a doublet of doublets with J values of ~22 Hz and ~15 Hz, as protons at **2″** are not equivalent.

Itokawa and Takeya [12] have previously shown that (-)-4-aza-4-deoxypodophyllotoxin, which possess exactly the same enantiomeric form like podophyllotoxin, showed the same $IC_{50}$ value of 0.0050 μg/mL against P388 leukemia cells. But interestingly, when strain between ring ''C'' and ''D'' was eliminated in 4-aza-2,3-didehydropodophyllotoxin analogue by dehydration at the 2,3 positions, the enhanced $IC_{50}$ against P388 leukemia cells was observed, i.e., 0.0018 μg/mL as compare to 0.0043 μg/mL for podophyllotoxin [13]. Therefore, the synthesis of 4-aza-2,3-didehydro podophyllotoxin analogues with hydroxyl functionality, as in podophyllotoxin, has an excellent potential for the development of new drug entities not only as anti-tumor drugs but also for the treatment of psoriatic arthritis, HIV-1, genital warts, malaria, and bacterial infections as well.

In this work we have further modified the 4-aza-2,3-didehydropodophyllotoxin core by functionalizing position 4 at the ''C'' ring in a similar fashion as that occurring in podophyllotoxin derivatives. Libraries of these new heterocyclic compounds should be accessible by this straightforward one-step multicomponent synthesis, which involves simple isolation of the products by filtration and recrystallization and requires no further purification steps. Although the new compounds are racemic, we hope that the separation and testing of individual enantiomers may lead to more potent compounds.

This work will open a new area of 4-aza-2,3-didehydropodophyllotoxin analogues having almost similar structural functionalities to podophyllotoxin and will help to develop a library of new bioactive chemical entities which could be conjugated to carriers for tissue targeting. Whether these compounds may exert their

**Scheme 2.** Synthesis of **AP-101**.



cytotoxic effect through podophyllotoxin-like antitubulin mechanism, target topoisomerase II, or have a totally independent mode of action, constitutes the subject of further investigation, which will be reported in due course.

## EXPERIMENTAL

Melting points were determined on a MEL-TEMP instrument and are uncorrected. IR spectra were recorded on a Perkin Elmer Spectrum 100 FTIR Spectrometer on ATS mode. $^{1}$H, COSY, $^{13}$C, DEPT45, DEPT90, DEPT135 and HETCOR NMR spectra were measured on a Bruker 400 Ultra shield Spectrometer using DMSO-$d_6$ as solvent. All chemical shifts are reported in parts per million relative to tetramethylsilane. Coupling constants ($J$) are reported in Hz. HRMS analyses were performed at the University of Florida (Gainesville) Mass Spectrometry facility. Absorption spectra were obtained in DMSO, using DMSO as blank, with an Agilent 8453 absorption spectrometer. Elemental analysis were performed at Atlanta Microlab GA.

**Synthetic procedure for compounds AP-100 to AP-300.**

***2-[(3,4-Methylenedioxy)anilino]ethanol (AP-100).*** To a solution of 3,4-(-methylenedioxy)-aniline (5 g, 35.37 mmol) in dry dichloromethane (100 mL) and pyridine (3.6 mL, 44.57 mmol) at room temperature 2-chloroethylchloroformate (3.8 mL, 35.37 mmol) was slowly added. The mixture was stirred at room temperature (25°C) for 2.5 h and washed with water (5.0 mL × 4), dried over anhydrous magnesium sulphate and concentrated under vacuum. The residue was dissolved in ethanol (100 mL), treated with potassium hydroxide (8.6 g, 141.48 mmol) and heated at 90°C for 4 h. The mixture was dried under vacuum and the residue was dissolved in dichloromethane (150 mL), the precipitate was washed with dichloromethane twice (25 mL each). The combined organic phases were washed with water (5× mL) and brine. The organic phase was dried over anhydrous magnesium sulphate and concentrated under vacuum. The solid was purified by silica gel (120 g) flash chromatography with hexane-ethylacetate gradient to give compound **AP-100** (3.89 g, 61%) as brown needles. MP: 53–54°C, IR ($cm^{-1}$); 3283, 3162, 2869, 16360, 1496, 1232, 1190, 1122, 1073, 1031, 931, 883, 847, 782, 720, 692; $^{1}$H-NMR (DMSO-*d*6, 400 MHz): δ (ppm) 3.01 (q, $J$ = 11.84 Hz and 5.9 Hz, 2H), 3.54 (q, $J$ = 11.64 Hz and 5.78 Hz, 2H), 4.64 (t, $J$ = 5.71 Hz, 1H), 5.17 (t, $J$ = 5.76 Hz, 1H), 5.82 (s, 2H), 6.00 (dd, $J$ = 8.58 Hz and 2.16 Hz, 1H), 6.30 (d, $J$ = 2Hz, 1H), 6.65 (d, $J$ = 8.58 Hz, 1H); $^{13}$C-NMR (DMSO-*d*6, 100 MHz): δ 59.42, 94.85, 99.65, 102.88, 108.18, 137.63, 144.66, 147.51; HRMS *m*/*z*: 182.0818 found (Calculated for $C_9H_{11}NO_3$, $[M+H]^+$ requires 182.0812).

***2-(Indan-5-ylamino)-ethanol (AP-200).*** 2-(Indan-5-ylamino)-ethanol (AP-200) was synthesized from a similar reaction

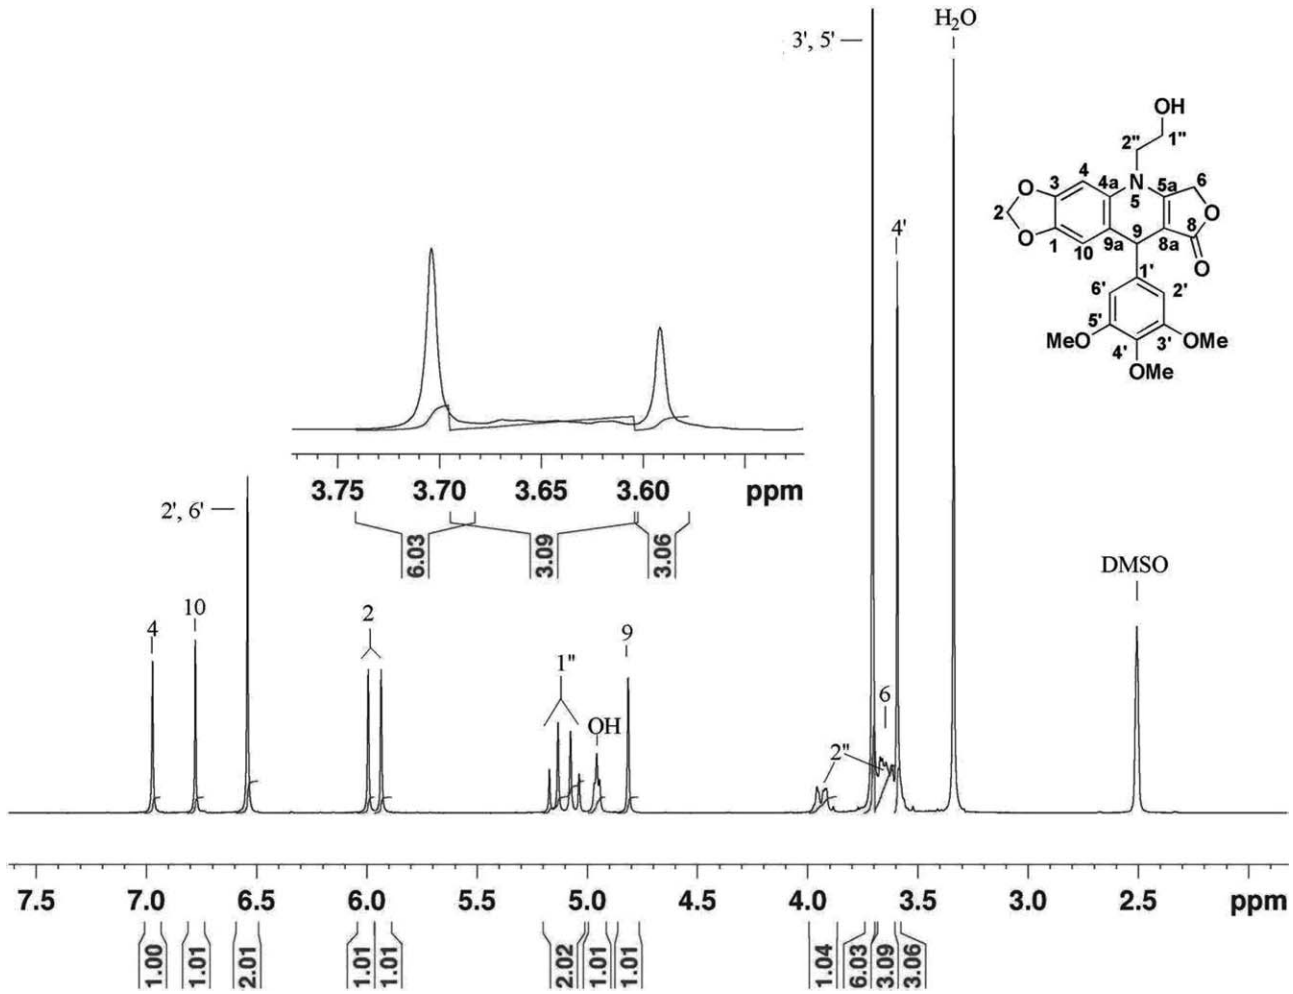


**Figure 4.** $^{1}$H-NMR spectrum of AP-101 in DMSO-$d_6$.

between 5-aminoindan (9.04 gm, 64.50 mmol) and 2-chloroethylchloroformate (6.86 mL, 64.50 mmol). After flash chromatography, **AP-200** was obtained (6.79 g, 59% yield) as a dark brown oil showing: IR ($cm^{-1}$); 3345, 2940, 2837, 1615, 1494, 1456, 1329, 1290, 1260, 1212, 1157, 1119, 1058, 949, 840, 802, 703; $^{1}$H-NMR ($CDCl_3$, 400 MHz),: δ (ppm) 2.01 (m, 2H), 2.78 (q, $J$ = 15.43 Hz, and 7.72 Hz, 4H), 3.20 (t, $J$ = 5.20 Hz, 2H), 3.27 (s, 2H), 3.74 (t, $J$ = 5.22 Hz, 2H), 6.42 (dd, $J$ = 8.03 Hz and 2.27 Hz, 1H), 6.53 (s, 1H), and 6.99 (d, $J$ = 8.11 Hz, 1H); $^{13}$C-NMR ($CDCl_3$, 100 MHz): δ 25.44, 31.69, 32.87, 46.56, 60.91, 109.43, 111.65, 124.53, 133.56, 145.22, 146.58; HRMS *m/z*: 178.1229 found (Calculated for $C_{11}H_{15}NO$, $[M+H]^+$ requires 178.1226).

***2-(2,3-Dihydro-benzo[1,4]dioxin-6-ylamino)-ethanol (AP-300).*** 2-(2,3-Dihydro-benzo[1,4]dioxin-6-ylamino)-ethanol (AP-300) was synthesized from a similar reaction between 1,4-benzodioxan-6-amine (9.33 gm, 61.11 mmol) and 2-chloroethylchloroformate (6.5 mL, 61.11 mmol). The solid crude product was purified by silica gel (200 g) flash chromatography with hexane-ethyl acetate gradient to give the title compound (7.68 g, 64%) as a dark brown oil showing IR ($cm^{-1}$); 3373, 2928, 2876, 1625, 1595, 1502, 1460, 1325, 1276, 1205, 1171, 1062, 961, 919, 883, 828, 794, 745; $^{1}$H-NMR ($CDCl_3$, 400 MHz): δ (ppm) 3.10 (t, $J$ = 5.19 Hz, 2H), 2.80 (m, 4H), 3.20 (t, 2H), 3.27 (br, 2H), 3.74 (t, $J$ = 5.18 Hz, 2H), 6.43 (d, $J$ = 2.0 Hz), 6.65 (d, $J$ = 8.58 Hz, 1H); $^{13}$C-NMR ($CDCl_3$, 100 MHz): δ 47.00, 61.09, 64.21, 64.76, 102.21, 107.37, 117.69, 136.03, 143.15, 144.06; HRMS *m/z*: 196.0968 found (calculated for $C_{10}H_{13}NO_3$, $[M+H]^+$ requires 196.0980).

**General synthesis of 4-aza-2,3-didehydropodophyllotoxin derivatives.** An equimolar mixture of tetronic acid, a substituted aniline and an aromatic aldehyde dissolved in the minimum volume of ethanol was refluxed for 30 to 90 min. After cooling, the precipitate was filtered off, washed with minimal cold ethanol and then recrystallized from ethanol.

***5-(2-Hydroxyethyl)-9-(3,4,5-trimethoxyphenyl)-6,9-dihydro-[1,3]dioxolo[4,5-g]furo[3,4-b]quinolin-8(5H)-one (AP-101).*** Reaction time: 30 min. The product was washed with cold ethanol and dried under high vacuum, recrystallization from ethanol yielded 70% as a white crystalline powder, MP: 241–243°C; UV–Vis $\lambda_{max}$ (nm): 261, 322; IR ($\nu_{max}$, $cm^{-1}$); 3498, 2936, 1727, 1652, 1589, 1504, 1476, 1320, 1232, 1192, 1117, 1033, 1011, 931, 787, 760, 686; 1 H-NMR (DMSO-$d_6$, 400 MHz): δ 3.59 (s, 3H, 4′C—$OCH_3$), 3.64 (m, 3H, 6C—H and 2″C—H), 3.70 (s, 6H, 3′-$OCH_3$ and 5′-$OCH_3$) 3.92 (m,1H, 2″C—H), 4.81 (s, 1H, 9C—H), 4.95 (t, 1H, OH),

A series of new indeno[1,2-*b*]pyrazolo[4,3-*e*]pyridin-5(1*H*)-one derivatives were synthesized by three-component reactions of 1,3-indandione, 3-methyl-1*H*-pyrazol-5-amine, and aldehyde in water under microwave irradiation without any catalyst.

*J. Heterocyclic Chem.*, **47**, 1283 (2010).

## INTRODUCTION

Many recent efforts were made to make organic synthesis eco-friendlier. In this way, usual but hazardous volatile organic solvents were replaced with water and/or conventional heating was substituted by microwave irradiation (MW). Green chemistry is brewing which protects the environment, not by cleaning it up, but by inventing new chemistry and new chemical processes that prevent pollution [1]. In essence, it prompts the chemical and pharmaceutical manufacturer to consider how human life is impacted after these chemicals are generated and introduced into their society [2]. Thus, it has become clear that the combined approach of microwave heating and aqueous medium offers a nearly synergistic strategy in the sense that the combination in itself offers greater potential than the two parts in isolation [3].

Now, with growing concern over the environmental impact of chemicals, cleaner green reaction conditions in organic reaction have been advocated. Multicomponent reactions, an important class of organic tandem reactions, are one-pot processes with at least three components to form a single product, which incorporates most or even all of atoms of the starting materials [4]. Such reactions offer a wide range of possibilities for the efficient construction of highly complex molecules in a single procedural step, thus avoiding complicated purification operations and allowing savings both of solvents and of reagents.

Six-membered nitrogen-containing heterocycles, especially onychine derivatives (Fig. 1) are abundant in nature and exhibit diverse and important biological properties [5]. Indenopyridines [6], as a member of this family exhibit cytotoxic [7], phosphodiesterase inhibitory [8], adenosine A2a receptor antagonistic [9], antiinflammatory/antiallergic [10], coronary dilating [11], and calcium modulating activities [12]. The synthesis of these molecules has attracted considerable attention [13]. Shi *et al.* [14] reported the reaction of 5-amino-3-methyl-1-phenylpyrazole with arylaldehyde and 1,3-indandione to give indeno[2,1-*e*]pyrazolo derivatives in ionic liquid with the disadvantage of long time and pollution to the environment. Considering the significance of this kind of organic molecules, a more efficient and environmental friendly approach would be established to synthesis the set of onychine derivatives so as to provide candidate compounds for bioassay and enrich compound libraries. As the continuation of our research devoted to the development of green organic chemistry by performing reactions under using water conditions [15], we describe the synthesis of indeno[1,2-*b*]pyrazolo[4,3-*e*]pyridin-5(1*H*)-ones in water under microwave irradiation without catalyst (Scheme 1).

## RESULTS AND DISCUSSION

Choosing an appropriate solvent is of crucial importance for successful microwave-promoted synthesis in

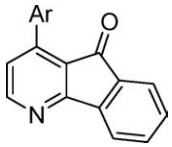

**Figure 1.** Structure of oychine.

view of a rapid rise of temperature in the reaction mixture. To search for the optimal solvent, the reaction of 1,3-indandione **1**, 3-methyl-1*H*-pyrazol-5-amine **2** and *p*-chlorobenzaldehyde **3a** were examined by using solvents of ethanol, DMF, ethylene glycol, acetic acid, and water, respectively. All the reactions were carried out at 120°C with the maximum power of 250 W and the results are summarized in Table 1. As shown in Table 1, the reaction in water resulted in higher yields and shorter reaction time than others. So water was chosen as the appropriate solvent.

Moreover, to further optimize the reaction temperature, the synthesis of **4a** was performed in water at the temperatures ranging from 100 to 140°C in the increment of 10°C each time at the maximum power of 250 W. As illustrated in Table 2, when the temperature was increased from 100 to 130°C, the yield of **4a** was obviously improved from 50 to 83%. However, no significant increase in the yield of **4a** was observed as the reaction temperature was further raised to 140°C. Therefore, the temperature of 130°C was chosen for all further microwave-assisted reactions.

Based on these optimized conditions [water, 130°C], the reactions proceeded smoothly. A series of compounds **4** were synthesized with this simple procedure. The results were summarized in Table 3 and the results indicated that aromatic aldehydes bearing either electron withdrawing or electron donating functional groups, such as chloro, nitro, bromo, or methyl are suitable for the reaction.

A tentative mechanism for the formation of products **4** is outlined in Scheme 2, which proceeded *via* a reaction sequence of condensation, addition, cyclization, dehydration, and aromatization. First, the condensation of 1,3-indandione **1** and aldehyde **3** gave the intermediate product **5**. The addition of **2** to **5** then furnished the intermediate product **7**, which cylices to dihydropyrine **9** and subsequently dehydrogenated to afford the fully aromatized compound **4**.

**Scheme 1**

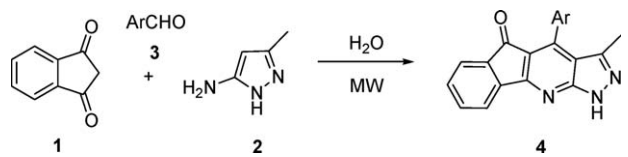

**Table 1**

Solvent optimization for the synthesis of **4a**.

| Entry | Solvent | Time (min) | Yield (%) |
|---|---|---|---|
| 1 | EtOH | 13 | 40 |
| 2 | DMF | 18 | trace |
| 3 | Glycol | 12 | 50 |
| 4 | HOAc | 10 | 70 |
| 5 | Water | 10 | 77 |

All the products were characterized by IR, $^1$H NMR, and HRMS (ESI).

In summary, we demonstrated an efficient and clean route for the one-pot, three-component synthesis of highly functionalized indeno[1,2-*b*]pyrazolo[4,3-*e*]pyridin-5(1*H*)-one derivatives in good yields. This method has the obvious advantages on short reaction time, high yield, operational simplicity, and environmental friendliness. Besides, this method may provide a shortcut for further investigations on the pharmacological activities of this type of compounds as important and novel onychine analogues.

## EXPERIMENTAL

Microwave irradiation was carried out in a monomodal Emrys™ Creator from Personal Chemistry, Uppsala, Sweden. Melting points were determined in XT5 apparatus and are uncorrected. IR spectra were recorded on a FTIR-Tensor 27 spectrometer. $^1$H NMR spectra were measured on a DPX 400 spectrometer operating at 400 MHz, using DMSO-$d_6$ as solvent and TMS as internal standard. HRMS (ESI) was determined by using micrOTOF-QII HRMS/MS instrument (BRUKER).

**General procedure for the synthesis of compounds 4 with microwave irradiation.** Typically, a mixture of aromatic 1,3-indandione **1** (1.0 mmol), 3-methyl-1*H*-pyrazol-5-amine **2** (1.0 mmol), aldehyde **3** (1.0 mmol), and water (2.0 mL) was added to the reaction vessel of the monomodal Emrys™ Creator microwave synthesizer and allowed to react under MW at 250 W power (initial power 100 W) and 130°C for several minutes. Upon completion, monitored by TLC, the reaction vessel was cooled to room temperature. The solid compound was collected by filtration and recrystallized from EtOH (95%) to give pure azapodophyllotoxin derivatives **4**.

**Table 2**

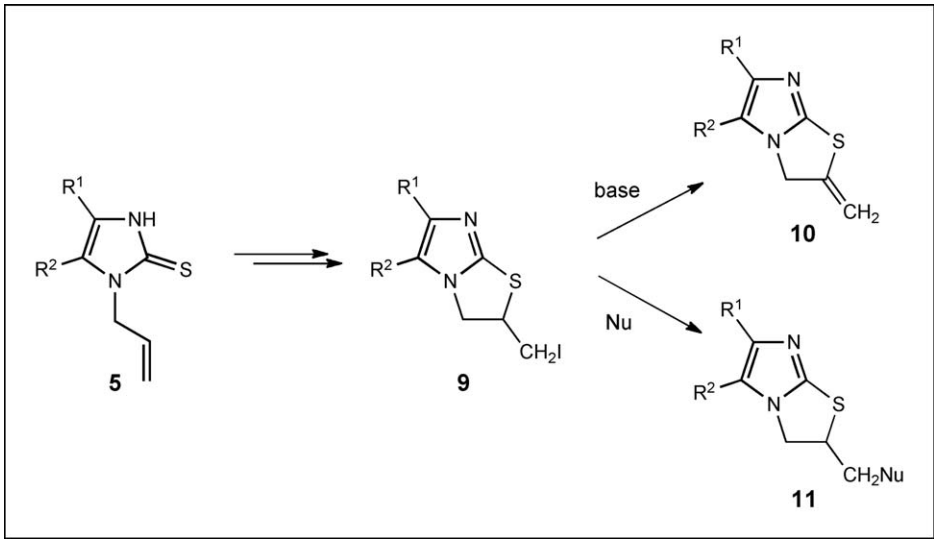
Published online 20 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



A novel method for the preparation of 2,3-dihydroimidazo[2,1-*b*]thiazole **9** by iodination and subsequent cyclization of the easily available *N*-allylimidazoline-2-thiones **5**, is described. Selected transformations of the iodomethyl derivatives **9**, leading to methylidene compounds **10** or the sulfide **11** (Nu = RS), via elimination with a base or via substitution with an enolizable imidazoline-2-thione (the term ''1,3-dihydroimidazole-2-thione'' will be used alternatively), respectively, are presented.

*J. Heterocyclic Chem.,* **47**, 1287 (2010).

## INTRODUCTION

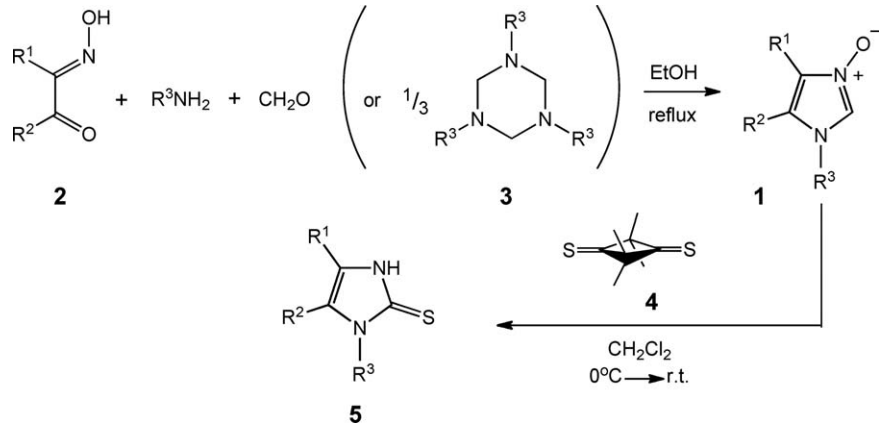
In a series of recent articles, a convenient approach to 2-unsubstituted imidazole *N*-oxides **1**, including optically active derivatives, has been reported [2]. In general, the applied method is based on the condensation of α-(hydroxyimino)ketones **2** with a primary aliphatic amine and formaldehyde. Alternatively, the corresponding hexahydro-1,3,5-triazines **3**, being trimers of formaldehyde imines, can be used (Scheme 1).

Irrespective of the substitution pattern, the reaction of **1** with 2,2,4,4-tetramethylcyclobutane-1,3-dithione (**4**) resulted in the ''sulfur transfer reaction'' leading to 1,3-dihydroimidazole-2-thiones **5** in high-yield [2b,2d,3]. In addition to *N*-alkyl and *N*-cycloalkyl substituted imidazole *N*-oxides **1**, some of the corresponding *N*-allyl derivatives were also obtained in good yields [2a]. However, the latter have not been explored for further conversions yet.

In spite of the fact that *N*-allyl-1,3-dihydroimidazole-2-thiones seem to be attractive starting materials for diverse cyclization reactions involving the allyl group, there are only few reports on their synthesis available to date. The first approach, reported already in 1895, was the condensation of *N*-allylthiourea with 2-hydroxy-1,2-diphenylethanone (benzoine) [4]. The second synthesis described the condensation of isothiocyanic acid and acetals of *N*-allyl α-aminoacetaldehyde [5]. In addition, the reaction of allylisothiocyanate with glucosamine is reported to yield the desired product [6], and the analogous condensation with 1-amino-3-methylbutan-2-one gave *N*-allyl-5-isopropylimidazoline-2-thione [7].

The goal of this study was the preparation of a series of less known *N*-allyl-1,3-dihydroimidazole-2-thiones and their subsequent cyclization to corresponding fused *N*,*S*-heterocycles. Heterocyclic thiones with an allyl-substituted *N*-atom attached to the C=S group are known

**Scheme 1**



to undergo an intramolecular 1,5-cyclization to yield fused thiazoles. Thus, treatment of the *N*-allyltriazolethione **6** with iodine in ethanol at room temperature gave the thiazolo[2,3-*c*][1,2,4]triazole hydroiodide **7** [8] (Scheme 2). The analogous bromide was obtained from the reaction with bromine in chloroform.

To the best of our knowledge, there are no analogous reactions with imidazoline thiones, described so far. However, in the case of benzimidazoline-2-thiones, a similar cyclization has been observed [9].

## RESULTS AND DISCUSSION

In accordance with the known procedure [2], heating of 1,3,5-triallylhexahydro-1,3,5-triazine (**3a**, $R^3$ = allyl) and 3-(hydroxyimino)butan-2-one (**2a**, $R^1 = R^2$ = Me) in ethanol gave the expected 1-allyl-4,5-dimethylimidazole *N*-oxide (**1a**) in 78% yield (Scheme 1, Table 1). The imidazoline-2-thione **5a** was prepared from **1a** by treatment with 0.5 mol equivalents of **4** in dichloromethane at room temperature. The same procedures were applied for the synthesis of **5b**–**5f**.

Solutions of the purified imidazoline-2-thiones **5** in ethanol were treated with iodine at room temperature, and the corresponding hydroiodides **8** precipitated directly from the reaction mixture. The subsequent neutralization with aqueous sodium acetate solution gave 2,3-dihydroimidazo[2,1-*b*]thiazoles **9** as crystalline products, with the exception of **9e** (Scheme 3, Table 1).

The structure of products **9** was proved by means of spectroscopic methods. For example, the $^{13}$C-NMR spectrum of **9b** showed the signals for three imidazole C-atoms at 145.3, 141.7, and 133.6 ppm as well as two triplets for $CH_2$ groups at 49.3 and 7.3 ppm (assigned to $CH_2N$ and $CH_2I$, resp.), and a doublet for a CH group at 52.2 ppm.

The presence of the iodomethyl group in compounds **9** enables further transformation with basic and nucleophilic agents. In fact, treatment of **9a** with triethylamine in ethanol afforded, after elimination of HI, the exomethylidene derivative **10a**. Furthermore, the attempted substitution of iodide with potassium cyanide, carried out either in acetone or in ethanol, led to the same elimination product **10a**. On the other hand, the reaction of **9f** with the enolizable 1,4,5-trimethylimidazoline-2-thione (**5g**) in ethanol, led successfully to the sulfide **11** in good yield (Scheme 4).

## CONCLUSIONS

The presented study shows that treatment of the easily available *N*-allyl-1,3-dihydroimidazole-2-thiones **5** with iodine results in the cyclization leading to imidazo[2,1-*b*]thiazole derivatives **9**, bearing an iodomethyl group as an additional reaction center. As selected transformations of these products, the elimination of HI and the substitution with 1,4,5-trimethylimidazoline-2-thione, as an example of an *S*-nucleophile, are presented.

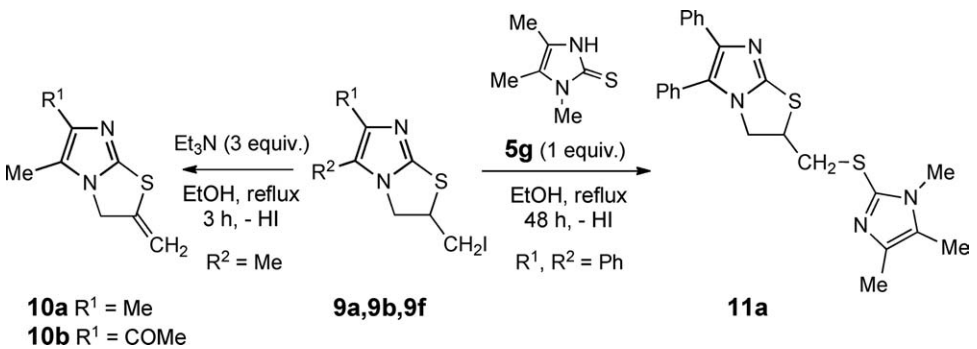
The importance of imidazo[2,1-*b*]thiazoles is well documented, as many derivatives of them display diverse biological activities [10] (see also [11]). The presented synthetic approach supplements the already reported methods for the preparation of 2,3-dihydroimidazo[2,1-*b*]thiazoles, which are based on reactions either of appropriate imidazole or thiazole derivatives. In the case of imidazole derivatives, the bis-alkylation of imidazoline-2-thiones with 1,2-dibromoethane was most frequently applied [12]. Another approach is the thermal cyclization of *N*-vinylimidazoline-2-thiones, which leads to the aromatized fused system [13]. The non-aromatized parent system was obtained via a formal vinyl transfer reaction of the parent imidazoline-2-thione with *S*-vinyl-*S*-(4-methylphenyl)-*N*-tosylimine [14]. The reactions starting with 1,3-thiazole derivatives are described to a comparable extent. As a typical example, the cyclocondensation of an α-bromoacetophenone with 2-amino-1,3-thiazoles can be mentioned [11a]. A very recent report deals with a multistep procedure, in which the alkylation of 2-amino-1,3-thiazole with propargyl bromide and subsequent cyclization are the key steps [11c]. In the light of the already reported approaches, our method, presented in this article, enlarges the number of synthetic tools for the preparation of new, diversely substituted imidazo[2,1-*b*]thiazoles. Of special importance is the availability of differently substituted α-(hydroxyimino)ketones **2**, which are key starting materials for the presented multi-step procedure.

## EXPERIMENTAL

Melting points were determined in capillaries using a Melt-Temp II apparatus (Aldrich) and are uncorrected. IR Spectra were recorded on a NEXUS FT-IR spectrophotometer as KBr pellets; absorptions in $cm^{-1}$. $^1H$- and $^{13}C$-NMR spectra were measured on a Tesla BS567A (80 MHz) or Varian Gemini 200 (200 and 50 MHz, resp.) instrument or a Bruker AC 400 instrument (400 and 100 MHz, resp.) in a suitable solvent ($CDCl_3$, $CD_3OD$ or DMSO-$d_6$); chemical shifts (δ) were given in ppm (TMS = 0 ppm), coupling constants *J* in Hz. The multiplicity of the $^{13}C$ signals was deduced from DEPT spectra. The HRMS spectra were registered on a Finnigan MAT-95 instrument.

**Synthesis of 4,5-disubstituted 1-allyl-1*H*-imidazole 3-oxides (1a–f).** In the cases of **1a**, **1d**, **1e**, and **1f**, the solution of 1,3,5-triallylhexahydro-1,3,5-triazine (**3a**, 0.69g, 3.3 mmol) and the corresponding α-(hydroxyimino)ketone of type **2** (10 mmol) in ethanol (15 mL) was refluxed for the required time (ca. 3 h, TLC monitoring, silica gel, MeOH). The solvent was removed under reduced pressure and the crude product was

**Scheme 4**



washed several times with $Et_2O$ and purified thereby. In the cases of **1b** and **1c**, a solution of **3a** (0.94g, 4.5 mmol) in $Et_2O$ (2 mL) was added to the magnetically stirred and cooled solution (water/ice external bath) of the corresponding α-(hydroxyimino)ketone **2** (10 mmol) in 5 mL $Et_2O$. When the addition was complete, the cooling bath was removed and the stirring was continued for 24 h at room temperature. Then, the colorless precipitate was filtered off and purified by flash chromatography ($SiO_2$). Acetone was used first as an eluent to remove the remaining **2**, followed by a mixture of ethyl acetate and MeOH (1:1). Next, the same reaction was repeated using recovered **2**. The combined fractions of the crude product **1** were purified by recrystallization from an appropriate solvent. The 1-allyl-4-methyl-5-phenyl-1*H*-imidazole 3-oxide (**1e**) could not be obtained in pure form and, therefore, the crude product was converted immediately into the corresponding imidazole-2-thione **5e**. The protocol for the synthesis of thiones of type **5**, as well as spectroscopic and analytical data for 1-allyl-4,5-diphenyl-1*H*-imidazole 3-oxide (**1f**), were already reported [2a].

***1-Allyl-4,5-dimethyl-1H-imidazole 3-oxide (1a).*** The crude product was purified by flash chromatography on silica using AcOEt with increasing amounts of MeOH (up to 1:1 ratio) to give **1a** in 78% yield (1.19 g). **Synthesis of 5,6-disubstituted 2,3-dihydro-2-(iodomethyl)-imidazo[2,1-*b*]thiazoles (9a–f).** To a solution (or suspension) of the corresponding imidazoline-2-thione **5** (10 mmol) in dry ethanol (*ca*. 20 mL), an equimolar amount of nicely powdered iodine (2.54 g) was added in small portions, and vigorous stirring was continued for 24 h at room temperature. The resulting mixture was cooled and the yellow precipitate of crude **8** was filtered off. After evaporation of the solvent, the residue was washed with few portions of ether, filtered off and combined. If necessary, the crude hydroiodide **8** was recrystallized from hot EtOH. The obtained salt was suspended in ethanol (*ca*. 10 mL), an aqueous solution (5%) of AcONa (1.64 g, 20 mmol) was added, and stirring was continued for 1 h at room temperature. The resulting product **9** was filtered off and crystallized from an appropriate solvent.

***2,3-Dihydro-2-iodomethyl-5,6-dimethylimidazo[2,1-b]thiazole (9a).*** The isolated hydroiodide **8a** was dissolved in ethanol (*ca*. 5 mL), an aqueous solution (5%) of AcONa (20 mmol) was added, and the solution was stirred for 30 min at room temperature. The mixture was extracted with chloroform, the combined organic phases were washed with an aqueous solution (10%) of $Na_2S_2O_3$, dried ($CaCl_2$), and after filtration the solvent was evaporated. The crude product was purified by flash chromatography on silica ($CHCl_3$) to give 1.06 g (36%) of **9a** as a colorless solid; mp 83–86°C (decomp., $CHCl_3$). IR (KBr): ν 3010–2870vs (br.), 1585m, 1483s, 1452m, 1421m, 1382m, 1367m, 1314m, 1227m, 1187m, 807m. $^1$H-NMR (200 MHz, $CDCl_3$): δ 4.42–4.29 (m, 1H); 4.00–3.85 (m, 2H); 3.45 (dd, $J$ = 10.2, 4.7, 1H); 3.31 (t, $J$ = 10.5, 1H); 2.02, 1.99 (2s, 6H, 2 Me). $^{13}$C-NMR (50 MHz, $CDCl_3$): δ 143.2, 137.8, 121.3 (3s, 3 C(imidazole)); 51.9 (d, CH); 49.4 (t, $CH_2$N); 12.8, 8.8 (2q, 2 Me); 8.1 (t, $CH_2$I). Reaction of 6-aryl-5-cyano-2-mercapto-3,4-dihydropyrimidin-4-ones with formaldehyde and primary amines in suitable solvent via a double Mannich reaction gave the corresponding 8-aryl-7-cyano-3-*N*-substituted-pyrimido[2,1-b]-1,3,5-thiadiazin-6-ones rather than the isomeric products 6-aryl-7-cyano-3-N-substituted-pyrimido[2,1-b]-1,3,5-thiadiazin-8-ones. The cyclization method was found to be the most favored for the formation of the linear products rather than the angular isomers. This was confirmed not only by using spectral analysis and molecular mechanical calculations but also by X-ray single crystal structure determination.

*J. Heterocyclic Chem.,* **47**, 1294 (2010).

## INTRODUCTION

Although a few publications have been appeared since last 12 years describing the synthesis of 1,3,5-thiadiazines but literature survey on this class of heterocyclic system showed that 1,3,5-thiadiazines and its fused heterocycles possess a broad spectrum of biological interest [1]. It was found that functionalized thiadiazines have insecticidal [2], antibacterial [3], herbicidal [4], and fungicidal [5] effects. The broad biological activities of pyrimidine [6–12] and fused pyrimidine derivatives, prompted us to synthesize new derivative of pyrimidines fused heterocycles. During last decade, we were investigating the behavior of Mannich reaction toward the multifunctional heterocyclic compounds such as 5-mercapto-3-aryl-1,2,4-triazole (Fig. 1). We investigated this reaction in acidic, basic, and neutral mediums, and we concluded that in all cases only one isomeric product **1** was isolated, rather than the other isomeric products **2** [13–15].

Those findings encouraged us to investigate continually the use of functionality factor and the reaction medium. One of the advantages of this reaction is a wide variety to synthesize a number of varieties of poly heterocyclic compounds in one pot reaction which is difficult to obtain by another procedure. Pyrazolothiadiazines [13], Triazolothiadiazines [13,15], and thiadiazinobenzimidazoles [14] were also obtained in high-yields using double or triple Mannich reaction in one pot reaction. We have recently described that similar compounds could be synthesized *via* modification of Mannich reaction using di-functional compounds [13–15]. We found that the cyclization reactions to form the corresponding thiadiazines 1 are different from that reported by Wang and co-workers [16]. They suggested that the thiadiazine derivatives **2** were formed rather than the isomeric derivatives **1**.

In our laboratory, we investigated the Mannich reaction of polyfunctional heterocyclic compounds like 5-mercaptotriazoles, 5-aminopyrazoles, and 2-mercaptobenzimidazoles, which gave the corresponding 1,2,4-triazolo[3,2-b]-1,3,5-thiadiazines **1**, pyrazolo[3,4-d]pyrimidines **3**, and 1,3,5-thiadiazino[3,2-a]benzimidazoles **4**, respectively in high-yield [13–15] (Fig. 2).

## RESULTS AND DISCUSSION

In this study, we focused on the susceptibility and selectivity of the cyclization of 6-aryl-5-cyano-2-thioxo-1,2,3,4-tetrahydropyrimidin-4-one (**5a–d**) towards the double Mannich reaction. On treatment of the poly

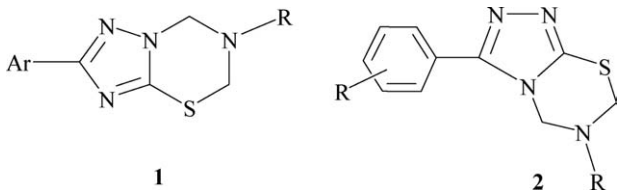

**Figure 1.** 1,2,4-Triazolo[3,2-b]-1,3,5-thiadiazines **1** and **2**.

functional compounds **5a–d** with one equivalent of variant primary aliphatic and aromatic amines with excess of formaldehyde (37%) in ethanol, ethanol/dioxane and ethanol/acetic acid at room temperature the reaction might proceed to afforded the corresponding 8-aryl-7-cyano-3-N-substituted-pyrimido[2,1-b]-1,3,5-thiadiazin-6-ones (**6–9**) or the other isomeric products 6-aryl-7-cyano-3-N-substituted-pyrimido[2,1-b]-1,3,5-thiadiazin-8-ones (**10–13**) or possible a mixture of both isomeric products. However, based on TLC the reaction gave only single isolable products **6–9** in high-yields, (Scheme 1).

The IR spectra of the products lacked the NH absorption peaks and showed the C≡N and C=O peaks at 2220–2240 and 1650–1700 $cm^{-1}$, respectively, whereas the $^1$H-NMR spectra of the reaction products were characterized by the appearance of two signals at δ 5.9–4.8 and 6.1–5.0 attributed to the two methylene groups $SCH_2N$ and $NCH_2N$ respectively in addition to the other protons at the expected chemical shifts. The Mass spectra of the synthesized compounds showed the expected molecular ion peaks and its CHNS analysis were found to be in agreement with the calculated ones. All these data presented here can't confirm which one of these isomers, **6–9** and **10–13** is formed.

We need a solid argument to prove whether the isomeric products formed **6–9** or **10–13**. This directed us to think about the tautomerism of compound **5a–d**, whether their structure existed in the form A or B. For example compound **5a** ($R$ = Ph) is in equilibrium with the two forms A and B as shown in Figure 3.

Based on resonance effect, the tautomer A is more favorable than B as both the CN and CO groups are conjugated with the diene system. Further, this assumption was supported by the molecular mechanics calculations–MMXE, which showed that tautomer A is more stable than B. If double Mannich reaction occurred with tautomer A the product will be the isomeric compounds **6–9**, whereas, the isomeric products **10–13** could be obtained in case of the existence of the tautomer B in the reaction medium (Figure 3).

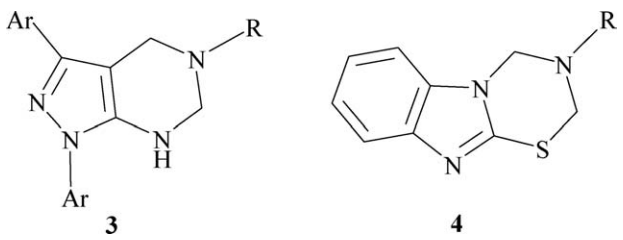

**Figure 2.** Pyrazolo[3,4-d]pyrimidines **3** and 1,3,5-thiadiazino[3,2-a]benzimidazoles **4**.

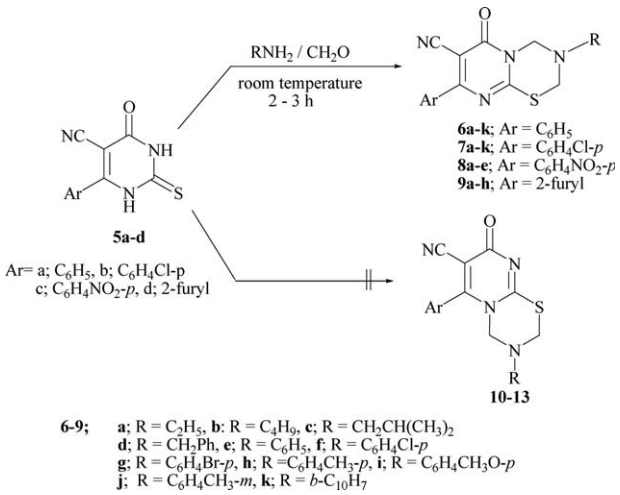
**Scheme 1.** Synthesis of pyrimido[2,1-b]-1,3,5-thiadiazines **6–9**.



Mechanistically, the formation of the cyclized compounds could be explained either by the addition of SH (route a) or NH (route b) group to the formed imines, which resulted from the condensation of formaldehyde with primary amine, (Scheme 2; Table 1). Based on both molecular modeling study and X-ray analysis of **6h** (Figures 4 and 5), the structure of the reaction product was assigned as the isomeric products **6–9** of lower energy rather than the isomeric products **10–13**. The formation of single product only indicates that the reaction is proceeded regioselectively. Recently, similar results were obtained by Dotsenko et al [17].

CHL, chloramphenicol as standard.

The antimicrobial activity study revealed that all compounds screened showed moderate to weak antimicrobial activity, except compounds **6f**, **8b**, and **8d** have good effect.

## EXPERIMENTAL

Melting points were determined using Gallen Camp melting point apparatus and are uncorrected. The IR-spectra were measured on a Shimatzu-470 spectrometer using KBr technique (ν $cm^{-1}$). The $^1$H-NMR spectra were measured on a Varian EM-390,90MHz spectrometer (Spectral Unit, Assuit University, Egypt) and dx 500.13 MHz spectrometer (Department of Physical Chemistry, Geneva) using $CDCl_3$, DMSO- $d_6$ as a solvent and TMS was used as internal standard, δ ppm. The $^{13}$C-NMR spectra were measured on dx 125.77 MHz spectrometer. The mass spectra were recorded on Jeol-Jms-600H spectrometer using the direct inlet system. The elemental analyses were performed using Perkin-Elmer elemental analyzer 240-C and the X-ray diffraction analysis from faculty of science, Geneva University.

**General procedures for synthesis of 8-Arylpyrimido[2,1-b]-1,3,5-thiadiazine derivatives.** A mixture of 5-Cyano-4-oxo-6-aryl-2-thioxo-1,2,3,4-tetrahydropyrimidine (1.0 mmole), primary amines (1.1 mmole) and formaldehyde (2 mL) was stirred in appropriate solvent (20 mL) at room temperature for 2–3 h. The resulting precipitate was collected by filtration, washed with water several times and dried well. The crude product was crystallized from the proper solvent to give the corresponding 8-phenyl-pyrimido[2,1-b]-1,3,5-thiadiazine derivatives.

A series of novel methylene-bis-fused pyrazoles **12a–e** and methylene-bis-2-(4-methylsulfonyl)-phenyl substituted fused pyrazoles **15a–d** have been synthesized by the reaction of methylene-bis-aryl-6-hydroxymethylene-2-cyclohexenones **10** with hydrazine hydrate or (4-methylsulfonyl)-phenyl hydrazine **13**. Chemical structures of all the newly synthesized compounds were elucidated by their IR, $^1$H NMR, $^{13}$C NMR, and MS spectral data. The compounds **15a–d** were evaluated for their cyclooxygenase-2 (COX-2) inhibitory activity, and the compound **15b** showed appreciable COX-2 inhibition and selectivity. Further, all the new compounds were screened for their antimicrobial activity against Gram-positive, Gram-negative bacteria, and fungi. Amongst the screened compounds, **12c**, **15a**, and **15b** were found to be the most active against almost all the test bacteria. The compound **15b** displayed notable antibacterial activity against *Bacillus subtilis* (ATCC 6633), *Staphylococcus aureus* (ATCC 6538p), *Micrococcus luteus* (IFC 12708), *Proteus vulgaris* (ATCC 3851), and *Salmonella typhimurium* (ATCC 14028), equal to that of ampicillin. Similarly, these compounds also showed potent antifungal activity against *Candida albicans* (ATCC 10231), *Aspergillus fumigatus* (HIC 6094), *Trichophyton rubrum* (IFO 9185), and *Trichophyton mentagrophytes* (IFO 40996).

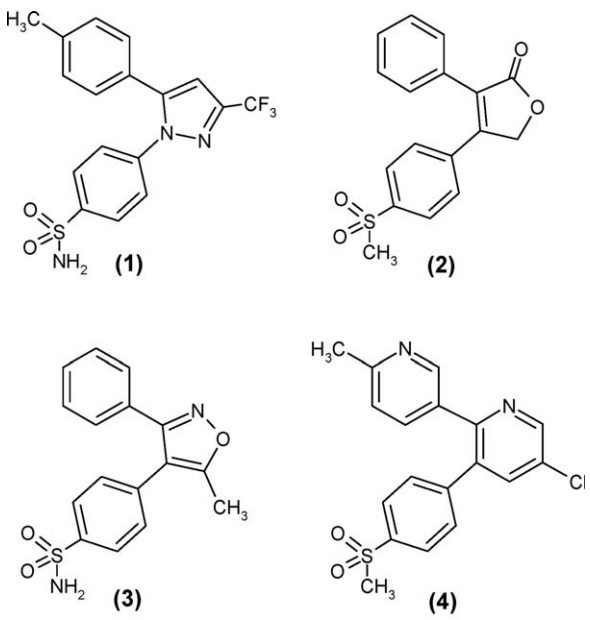
## INTRODUCTION

Pyrazole and its derivatives could be considered as possible antimicrobial agents [1,2]. The other activities include antidepressant [3], inhibitors of protein kinases [4], antiagreegating [5], antiarthritic [6], and cerebroprotectors [7]. Recently some aryl pyrazoles were reported to have non-nucleoside HIV-1 reverse transcriptase inhibitors [8], cyclooxygenase-2 (COX-2) inhibitors [9], potent activator of the nitric oxide receptor, and soluble guanylate cyclase [10] activity. Besides, great interest in the pyrazole molecule has been stimulated by some promising pharmacological, agrochemical, and analytical applications of its derivatives [11].

The role of COX-2 isoform in inflammation and the attractiveness of COX-2 as a therapeutic target for the development of anti-inflammatory drugs are very well recognized [12]. The traditional nonsteroidal anti-inflammatory drugs (NSAIDs) are nonselectively inhibit both COX-1 and COX-2, and hence, downregulate prostaglandin formation in almost all cells and tissues, which may induce gastrointestinal side effect, adversely affect the mucus-bicarbonate secretion, acid secretion, and mucosal blood flow. COX-1 inhibition may also elicit an

**Scheme 1.** COX-2 selective inhibitors.



increase in 5-lipoxygenase (5-LO) activity that would potentiate production of leukotriene-$B_4$ ($LTB_4$) and vasoconstrictor peptide-leukotrienes (p-LTs) by the lipoxygenase pathway, and this may also contribute to the vascular and other mucosal damage by NSAIDs [13]. Hence, it was proposed that a selective inhibitor of COX-2 would be an attractive approach to the treatment of inflammatory conditions, without concomitant gastric and renal side effects. There are four COX-2 selective inhibitors, such as celecoxib (1), rofecoxib (2), valdecoxib (3), and etoricoxib (4) (Scheme 1), which are currently prescribed for the treatment of arthritis and inflammatory diseases. They show anti-inflammatory activity with reduced gastro intestinal side effects to traditional NSAIDs. However, the long term use of both traditional NSAIDs and coxibs has been reported to cause significant cardiovascular side effects [14].

Following the successful introduction of antimicrobial agents and COX-2 inhibitors, in continuation of our research on biologically active heterocycles [15–18] it was considered worthwhile to design and synthesize more selective COX-2 analogs, incorporating two active pharmacophores would enhance further the activity and selectivity towards the COX-2 enzyme. In this article, we explored fused pyrazoles **12a–e** and 2-substituted fused pyrazoles **15a–d** in which central five-membered scaffold is similar to that of celecosib 1, and 4-(methylsulfonyl) benzene, used as a COX-2 pharmacophore, and evaluated their *in vitro* antimicrobial and COX-2 inhibitory activity.

## RESULTS AND DISCUSSION

**Synthesis.** The key intermediate, **10** required for the synthesis of title compounds was prepared according to the procedure outlined in the Scheme 2. Condensation of commercially available salicylaldehyde **5** and trioxane in the presence of a mixture of conc. sulfuric acid and acetic acid gave methylene-bis-salicylaldehyde **6** in good yield [19]. Compound **6** was then reacted with the corresponding acetophenone in presence of alc. KOH at room temperature to give methylene-bis-chalcones **7a–e** (yield over 90%) [20]. Knoevenagel condensation of compounds **7a–e** with ethyl acetoacetate gave methylene-bis-aryl-6-carbethoxycyclohexenones **8a–e** (yield over 80%). Decarboxylation of **8a–e** in the presence of HCl/AcOH at reflux temperature resulted methylene-bis-aryl-cyclohexenones **9a–e** (yield over 80%), which on Claisen-like condensation with ethylformate in the

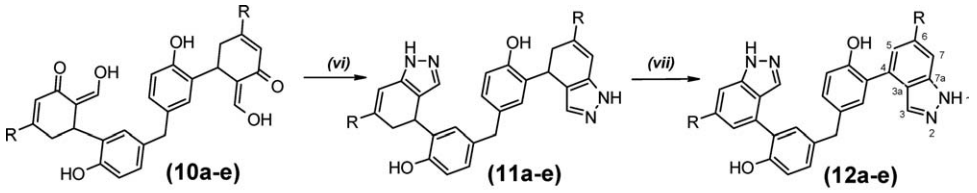
R = **a)** $C_6H_5$; **b)** 4-Br-$C_6H_4$; **c)** 4-$NH_2$-$C_6H_4$; **d)** 4-Cl-$C_6H_4$; **e)** 4-MeO-$C_6H_4$

**Scheme 3.** Reagents and conditions: (vi) hydrazinehydrate/AcOH, reflux, 80%; (vii) DDQ, $N_2$-atm, reflux, 76–83%.



R = **a**) $C_6H_5$; **b**) 4-Br-$C_6H_4$; **c**) 4-$NH_2$-$C_6H_4$; **d**) 4-Cl-$C_6H_4$; **e**) 4-MeO-$C_6H_4$

presence of sodium methoxide at room temperature afforded methylene-bis-aryl-6-hydroxy-methylene-2-cyclohexenones **10a–e** in good yields.

The compounds **10a–e** on cyclocondensation with the hydrazine hydrate in refluxing acetic acid resulted dihydropyrazole derivatives **11a–e** in good to excellent yields (yield over 80%). Subsequent aromatization of **11a–e**, with dichlorodicyanoparabenzoquinone (DDQ) under $N_2$-atmosphere at reflux temperature gave fused pyrazoles **12a–e** in good yields (Scheme 3). The chemical structure of the compounds was elucidated by their IR, $^1$H NMR, $^{13}$C NMR, and MS spectral data. In the IR spectra of compounds **12a–e**, C═N and N─H bands were observed in the regions 1560–1585, 3390–3410 $cm^{-1}$ respectively. According to the IR spectral data, the compounds **12a–e** have pyrazole structure. In the $^1$H NMR spectra of **12a–e**, the absence of signals corresponding to methine and methylene protons of cyclohexadiene ring indicates that aromatization has indeed taken place. The ─NH proton of the pyrazole ring was observed as a broad singlet at about 8.87–8.80 ppm. The signal because of the methylene bridge proton, present in all compounds, appeared at 4.06–4.00 ppm as singlet. The N═CH proton of compounds **12a–e** appeared at 7.95–7.90 ppm as singlet. All the other aromatic and aliphatic protons of compounds **12a–e** were observed at the expected regions. In the $^{13}$C NMR spectra of compounds **12a–e**, the prominent signals corresponding to C-3, C-3a, C-4, and C-7a, for all the compounds, observed nearly at 137.2, 137.4, 155.6, 145.3 ppm, respectively.

Further, the intermediate **10** when treated with the commercially available 4-(methylsulfonyl)-phenylhydrazine **13** in refluxing ethanol gave methylsulfonyl derivative of pyrazole **14a–d** in good yield. This reaction is a regioselective transformation and the 2-substituted pyrazole could be generated almost exclusively by carrying out the condensation in the presence of hydrochloric acid and one equivalent of 4-(methyl- sulfonyl)phenyl hydrazine **13**. The compounds **14a–d** when aromatized with DDQ under $N_2$-atmosphere at reflux temperature gave 4-(methylsulfonyl)-phenyl substituted fused pyrazoles **15a–d** in good yields (Scheme 4). The chemical structures of all the synthesized compounds were confirmed by their IR, $^1$H NMR, $^{13}$C NMR, and MS spectral data. In the IR spectra of compounds **15a–d**, C═N band was observed in the region 1560–1585 $cm^{-1}$ and $SO_2$ group symmetric, asymmetric stretching bands at about 1300–1328, 1155–1165 $cm^{-1}$. In the $^1$H NMR spectrum of compounds **15a–d**, absence of the signal corresponding to NH group proved that these compounds have pyrazole nucleus with (4-methyl- sulfonyl)-phenyl group at nitrogen. Further, the ─$CH_3$ proton signal was seen as singlet at about 2.96–2.90 ppm, and the signal of N═CH proton of compounds **15a–d** appeared at 6.68–6.65 ppm proved that these compounds have pyrazole nucleus with (4-methylsulfonyl)phenyl group at nitrogen. All the other aromatic and aliphatic protons of

compounds **15a–d** were observed at the expected regions. In the $^{13}C$ NMR spectra of compounds **15a–d**, the prominent signals corresponding to C-3, C-3a, C-4, and C-7a, for all the compounds, observed nearly at 125.4, 124.0, 136.0, 153.1 ppm, respectively, provide further evidence for their structures. Mass spectra of all the synthesized compounds showed $M^+/M^+ + 1$ peaks, in agreement with their molecular formulae.

**Antibacterial activity.** The *in vitro* antibacterial activity of the newly prepared compounds, **12a–e** and **15a–d**, was assayed against gram-positive bacteria *viz. Bacillus subtilis* (ATCC 6633), *Staphylococcus aureus* (ATCC 6538p), and *Micrococcus luteus* (IFC 12708), Gram-negative bacteria *viz. Proteus vulgaris* (ATCC 3851), *Salmonella typhimurium* (ATCC 14028), and *Escherichia coli* (ATCC 25922) by the broth dilution method, recommended by National Committee for Clinical Laboratory standards (NCCLS) [21]. Amphicillin was used as a standard drug, the lowest concentration (highest dilution) required to arrest the growth of bacteria was regarded as minimum inhibitory concentration (MIC, μg/mL), was determined and compared with the controls, the MIC values of the compounds assayed are presented in Table 1.

Investigation of the antibacterial screening data revealed that all the tested compounds exhibit interesting biological activity, however, with a degree of variation. Compound **15b** is highly active against all the microorganisms used (accept *E. coli*) at 1.56 μg/mL concentration, and is almost equal to the standard. Compound **12c** is also highly active against *M. luteus* and *P. vulgaris* only at the same concentration as **15b**. The compound **15a** also showed good antibacterial activity against *B. subtilis*, *S. aureus*, *M. luteus,* and *P. vulgaris*. Compound **12a** is almost inactive towards all the microorganisms used. Other compounds were also inactive towards *E. coli* bacteria. The remaining compounds showed moderate to good activity.

**Antifungal activity.** The newly prepared compounds were screened for their antifungal activity against *Candida albicans* (ATCC 10231), *Aspergillus fumigatus* (HIC 6094), *Trichophyton rubrum* (IFO 9185), and *Trichophyton mentagrophytes* (IFO 40996). The antifungal activity of each compound was compared with standard drug Amphotericin B. MIC (μg/mL) was determined and compared with controls; the MIC values of the compounds screened are given in Table 2. The antifungal screening data showed only moderate activity of the test compounds. Among the screened compounds, only **15b** showed the highest activity against all the microorganisms used. Similarly compound **12c** is also highly active but only against *T. rubrum* and *T. mentagrophytes*. The activities of these two compounds are almost equal to

**Table 2**

Antifungal activity of compounds **12a–e** and **15a–d**.

| Compound | Minimum inhibitory concentration (MIC, μg/mL) | | | |
|---|---|---|---|---|
| | *C. albicans* | *A. fumigatus* | *T. rubrum* | *T. mentagrophytes* |
| **12a** | — | — | — | 25.0 |
| **12b** | 12.5 | 25.0 | 12.5 | 25.0 |
| **12c** | 12.5 | 12.5 | 6.25 | 6.25 |

—, Indicates fungi are resistant to the compound >50 μg/mL concentration.

the standard, the remaining compounds showed moderate to good activity.

**COX-2 inhibitory activity.** The compounds synthesized **15a–d** was evaluated as COX inhibitors in human whole blood (HWB). Among the four compounds, **15b** showed good inhibition and selectivity. Some interesting features can be deduced from the comparison of the structure of compound **15b** with that of celecoxib **1**. (i) The sulfonamide group present in celecoxib is replaced by methyl sulfonyl group, believed to be crucial for increasing the COX-2 selectivity. (ii) The 4-methylphenyl and the trifluoromethyl groups on pyrazole ring are replaced and is fused with 1,3-diarylbenzene. (iii) Two similar pharmacophores were introduced in a single molecular frame work, linked by a methylene bridge. We evaluated the compound **15b** for COX inhibition in the HWB assay, performed essentially as described [22]. The 2-(4-methylsulfonyl)phenyl-substituted compound **15b** showed 69.51% of COX-2 inhibition at 3 μM in HWB assay, compared with 90.90% inhibition observed for celecoxib **1** at the same concentration. The compound **15b** showed only moderate COX-1 inhibition at a very high concentration (50 μM) for about 21.02%.

In conclusion, a series of novel methylene-bis-fused pyrazoles **12a–e** and methylene-bis-2(4-methylsulfonyl)-phenyl substituted fused pyrazoles **15a–d** have been designed and synthesized. The antimicrobial activity of these compounds was evaluated against various Gram-positive, Gram-negative bacteria, and fungi. Among the synthesized compounds, **12c**, **15a**, and **15b** showed good activity against bacteria and fungi and emerged as potential molecules for further development. The compounds were also evaluated for their COX-2 selective inhibition, **15b** showed an appreciable COX-2 inhibition and selectivity. With this set of analogs, we are now in a position to investigate the multiple biological activities for these compounds.

## EXPERIMENTAL

Research chemicals were either purchased from Aldrich Company or Fluka or used without further purification in the reactions, or were prepared according to procedures described in the literature. Reactions were monitored by thin layer chromatography on silica gel plated (60 $F_{254}$; Merck) visualizing with ultraviolet light or iodine. Column chromatography was performed on silica gel 60 (0.043–0.060 mm), Merck. The reported yields of the products are unoptimized. Melting points were determined with a Fisher-Johns apparatus and are uncorrected. IR spectra were recorded on a Perkin-Elmer FTIR 5000 spectrometer, using KBr pellet. $^1$H NMR, $^{13}$C NMR spectra were recorded on a Varian Gemini spectrometer, operating at 300, 75 MHz, respectively. Chemical shifts (δ) are reported as parts per million downfield from tetramethyl silane. Mass spectra were obtained on a VG micromass 7070H spectrometer.

**Ethyl-6-(5-{3-[6-(ethoxycarbonyl)-5-oxo-3-phenyl-3-cyclohexenyl]-4-hydroxybenzyl}-2-hydroxyphenyl)-2-oxo-4-phenyl- 3-cyclohexene-1-carboxylate (8a).** In a solution sodium metal (2 g) in ethanol (30 mL), a mixture of freshly distilled ethylacetoacetate (3.9 mL, 0.03 mol) and compound **7a** (4.6 g, 0.01 mol) dissolved in ethanol (20 mL) was added. The resulting solution was refluxed on a water bath for 4 h. Allowing the reaction mixture to cool and crystallization of the ppt. from ethanol to give **8a** as brown solid; Yield 82%; m.p. 150–52°C; IR (KBr): ν 3452, 3065, 1702, 1695, 1597, 1245 cm$^{-1}$; $^1$H NMR (DMSO-$d_6$): δ 7.10–7.14 (m, 10 H, ArH), 6.80 (s, 2H, ArH), 6.79 (d, $J$ = 9.2 Hz, 2H, ArH), 6.62 (d, $J$ = 9.2 Hz, 2H, ArH), 6.10 (s, 2H, CH), 5.20 (s, 2H, OH), 4.06 (q, 4H, $CH_2$), 3.87 (q, 2H, CH), 3.81 (d, 2H, CH), 3.72 (s, 2H, $CH_2$), 2.87 (d, 4H, $CH_2$), 1.10 (t, 6H, $CH_3$); $^{13}$C NMR (DMSO-$d_6$): δ 190.1, 176.7, 154.6, 149.5, 142.3, 133.4, 130.0, 128.7, 128.2, 127.9, 125.5, 123.8, 121.9, 117.4, 61.2, 60.6, 42.1, 37.0, 30.7, 17.0. MS: $m/z$ 685 ($M^+$ + 1). The other compounds **8b–e** were prepared by the similar procedure.

**5-{2-Hydroxy-5-[4-hydroxy-3-(5-oxo-3-phenyl-3-cyclohexenyl)benzyl]phenyl-3-phenyl}-2-cyclohexen-1-one (9a).** To a mixture of glacial acetic acid (100 mL) and conc. HCl (50 mL) was added compound **8a** (6.5 g, 0.01 mol) in portions. The mixture was heated to reflux for 10 h. After cooling to room temperature, the reaction mixture was concentrated *in vacuo*. The residue was taken up with ethyl acetate and washed with water and brine, dried over $MgSO_4$, filtered, and evaporated in *vacuo* to give oil, which soon solidified; it was purified by recrystallization from ethanol to give the compound **9a** as brown solid; Yield 79%; m.p. 132–34°C; IR (KBr): ν 3357, 3025, 2932, 1687, 1596 cm$^{-1}$; $^1$H NMR (DMSO-$d_6$): δ 7.10–7.14 (m, 10H, ArH), 7.00 (d, $J$ = 9.2 Hz, 2H, ArH), 6.82 (s, 2H, ArH), 6.62 (d, $J$ = 9.2 Hz, 2H, ArH), 6.10 (s, 2H, CH), 5.20 (s, 2H, OH), 3.83–3.87 (m, 2H, CH), 3.72 (s, 2H, $CH_2$), 2.70 (d, 4H, $CH_2$), 2.67 (d, 4H, $CH_2$); $^{13}$C NMR (DMSO-$d_6$): δ 190.0, 155.2, 150.1, 140.5, 132.3, 131.2, 128.5, 127.8, 127.4, 126.2, 124.5, 122.6, 116.1, 47.5, 42.0, 38.9, 31.0; MS: $m/z$ 541 ($M^+$ + 1). The other compounds **9b–e** were prepared by the similar procedure.

**5-[2-Hydroxy-5-(4-hydroxy-3-{6-[(*Z*)-1-hydroxymethylidene]-5-oxo-3-phenyl-3-cyclohexenyl}benzyl)phenyl]-6-[(*Z*)-1-hydroxymethylidene]-3-phenyl-2-cyclohexen-1-one (10a).** In a solution of 10% sodium methoxide (10 mL) in benzene (25 mL), ethylformate (2.24 mL, 0.03 mol) was added and afterward over 30 min, compound **9a** (5.4 g, 0.01 mol) dissolved in benzene (10 mL) was added. The resulting solution was stirred for 10 h at room temperature and allowed to stand over night, then evaporated to dryness. The suspension obtained was mixed with cold water and acidified with dil HCl (20 mL) and extracted three times with ether (40 mL). The organic layer was dried over $MgSO_4$ and evaporated *in vacuo* to give solid, was purified by crystallization in ethanol to afford pure **10a** as yellow solid; Yield 81%; m.p. 143–45°C; IR (KBr): ν 3320, 3028, 2952, 1662, 1620, 1597 cm$^{-1}$; $^1$H NMR (DMSO-$d_6$): δ 8.97 (s, 2H, OH), 7.92 (s, 2H, CH), 7.14–7.10 (m, 10H, ArH), 6.80 (s, 2H, ArH), 6.49–6.40 (m, 4H, ArH), 5.67 (s, 2H, CH), 4.12 (t, 2H, CH), 3.72 (s, 2H, $CH_2$), 3.22 (d, 4H, $CH_2$); $^{13}$C NMR (DMSO-$d_6$): δ 191.3, 167.6, 156.1, 149.7, 142.0, 131.1, 130.6, 130.2, 128.9, 128.0, 127.9, 127.6, 126.2, 116.7, 115.5, 44.1, 42.0, 37.8; MS: $m/z$ 596 ($M^+$). The other compounds **10b–e** were prepared by the similar procedure.

**4-[4-Hydroxy-3-(6-phenyl-4,5-dihydro-1*H*-4-indazolyl)benzyl]-2-(6-phenyl-4,5-dihydro-1*H*-4-indazolyl)phenol (11a).** To a solution of **10a** (5.9 g, 0.01 mol) in glacial acetic acid (50 mL), hydrazine hydrate (1.5 g, 0.03 mol) was added. After stirring at 80°C for 10 h, the mixture was concentrated *in vacuo*. To the residue was added water and twice extracted with ether, washed the organic layer with saturated $NaHCO_3$ solution, subsequently with water and brine, dried over $MgSO_4$, and evaporated to dryness. The residue could be recrystallized from ethanol to afford **11a** as brown solid; Yield 79%; m.p. 123–25°C; IR (KBr): ν 3390, 3037, 2972, 1595, 1585 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 8.12 (bs, 2H, NH), 7.65 (s, 2H, ArH), 7.63 (s, 2H, ArH), 7.32 (d, $J$ = 9.2 Hz, 4H, ArH), 7.21 (s, 2H, ArH), 6.99–7.05 (m, 6H, ArH), 6.84 (d, $J$ = 9.1 Hz, 2H, ArH), 6.73 (d, $J$ = 9.0 Hz, ArH), 6.62 (s, 2H, OH), 4.92 (t, 2H, CH), 3.72 (s, 2H, $CH_2$), 2.92 (d, 4H, $CH_2$); $^{13}C$ NMR (DMSO-$d_6$): δ 156.2, 148.7, 143.4, 140.3, 132.8, 132.0, 130.9, 130.0, 128.9, 127.8, 126.9, 126.5, 125.4, 118.7, 117.2, 42.1, 39.3, 38.1; MS: $m/z$ 589 ($M^+$ + 1). The other compounds **11b–e** were prepared by the similar procedure.

**4-[4-Hydroxy-3-(6-aryl-1*H*-4-indazolyl)benzyl]-2(6-aryl-1*H*-4-indazolyl)phenol (12a–e).** To a solution of corresponding compound **11** (0.01 mol) in dry benzene (20 mL), DDQ (0.03 mol) dissolved in dry benzene (20 mL) was added in portions. The mixture was heated to reflux and stirred for 5 h under a nitrogen atmosphere. The precipitated DDQ-$H_2$ was filtered off and the filtrate was subjected to column chromatography on silica gel (60–120 mesh) to afford pure compounds.

**4-[4-Hydroxy-3-(6-phenyl-1*H*-4-indazolyl)benzyl]-2(6-phenyl-1*H*-4-indazolyl)phenol (12a).** This was obtained as yellow solid; Yield 83%; m.p. 137–39°C; IR (KBr): ν 3392, 3062, 2985, 1584 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 8.87 (bs, 2H, NH), 7.47 (s, 2H, ArH), 7.32–7.26 (m, 8H, ArH) 6.94 (d, $J$ = 9.0 Hz, 2H, ArH) 4.05 (s, 2H, $CH_2$); $^{13}C$ NMR (DMSO-$d_6$): δ 159.0, 155.6, 147.9, 146.1, 145.3, 141.7, 139.0, 137.2, 136.5, 134.2, 128.8, 126.9, 126.5, 125.4, 123.8, 118.2, 112.7, 42.1; MS: $m/z$ 585 ($M^+$ + 1).

**2-[6-(4-Bromophenyl)-1*H*-4-indazolyl]-4-3-[6-(4-bromophenyl)-1*H*-4-indazolyl]-4-hydroxybenzylphenol (12b).** This was obtained as brown solid; Yield 82%; m.p. 142–44°C; IR (KBr): ν 3400, 3037, 2962, 1585, 712 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 8.86 (bs, 2H, NH), 8.15 (s, 2H, ArH), 8.10 (s, 2H, ArH), 7.94 (s, 2H, ArH), 7.47 (s, 2H, ArH), 7.41 (d, $J$ = 8.3 Hz, 4H, ArH), 7.32–7.26 (m, 6H, ArH), 6.94 (d, $J$ = 9.0 Hz, 2H, ArH), 4.02 (s, 2H, $CH_2$); $^{13}C$ NMR (DMSO-$d_6$): δ 159.0, 155.6, 149.3, 146.1, 141.7, 139.1, 137.4, 137.1, 136.5, 134.3, 131.2, 129.4, 125.4, 123.9, 118.3, 112.7, 42.1; MS: $m/z$ 743 ($M^+$ + 1).

**2-[6-(4-Aminophenyl)-1*H*-4-indazolyl]-4-3-[6-(4-aminophenyl)-1*H*-4-indazolyl]-4-hydroxybenylphenol (12c).** This was obtained as orange solid; Yield 76%; m.p. 151–53°C; IR (KBr): ν 3395, 3061, 2937, 1585 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 8.84 (bs, 2H, NH), 8.15 (s, 2H, ArH), 8.10 (s, 2H, ArH), 7.94 (s, 2H, ArH), 7.62 (d, $J$ = 8.4 Hz, 4H, ArH), 7.47 (s, 2H, ArH), 7.28 (d, $J$ = 9.0 Hz, 2H, ArH), 6.94 (d, $J$ = 9.0 Hz, 2H, ArH), 6.62 (d, $J$ = 8.4 Hz, 4H, ArH), 6.32 (bs, 4H, $NH_2$), 4.02 (s, 2H, $CH_2$); $^{13}C$ NMR (DMSO-$d_6$): δ 159.1, 155.6, 149.7, 146.1, 142.4, 141.6, 139.0, 137.2, 136.5, 134.9, 134.2, 130.2, 124.2, 123.8, 118.2, 113.1, 112.7, 42.2; MS: $m/z$ 615 ($M^+$ + 1).

**2-[6-(4-Clorophenyl)-1*H*-4-indazolyl]-4-{3-[6-(4-chlorophenyl)-1*H*-4-indazolyl]-4-hydroxy}benzylphenol (12d).** This was obtained as yellow solid; Yield 81%; m.p. 115–17°C; IR (KBr): ν 3387, 3042, 2932, 1585, 686 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 8.86 (bs, 2H, NH), 8.15 (s, 2H, ArH), 8.10 (s, 2H, ArH), 7.94 (s, 2H, ArH), 7.82 (d, $J$ = 8.2 Hz, 4H, ArH), 7.41 (s, 2H, ArH), 7.32–7.26 (m, 6H, ArH), 7.00 (s, 2H, ArH) 6.94 (d, $J$ = 9.0 Hz, 2H, ArH) 4.02 (s, 2H, $CH_2$); $^{13}C$ NMR (DMSO-$d_6$): δ 158.7, 155.6, 147.4, 146.1, 141.7, 139.0, 137.2, 136.5, 134.9, 134.2, 134.0, 128.7, 126.4, 125.4, 123.8, 118.3, 112.7, 42.2; MS: $m/z$ 654 ($M^+$).

**4-{4-Hydroxy-3-[6-(4-methoxyphenyl)-1*H*-4-indazolyl]benzyl}-2-[6-(4-methoxyphenyl)-1*H*-4-indazolyl]phenol (12e).** This was obtained as brown solid; Yield 80%; m.p. 122–24°C; IR (KBr): ν 3400, 3042, 2962, 1584, 1030 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 8.87 (bs, 2H, NH), 8.14 (s, 2H, ArH), 8.10 (s, 2H, ArH), 7.94 (s, 2H, ArH), 7.47 (s, 2H, ArH), 7.39 (d, $J$ = 8.4 Hz, 4H, ArH), 7.32 (d, $J$ = 9.0 Hz, 2H, ArH), 6.94 (d, $J$ = 9.0 Hz, 2H, ArH), 6.84 (d, $J$ = 8.4 Hz, 4H, ArH), 4.02 (s, 2H, $CH_2$), 3.84 (s, 6H, $OCH_3$); $^{13}C$ NMR (DMSO-$d_6$): δ 161.2, 159.0, 155.6, 149.5, 146.1, 141.7, 139.2, 137.4, 136.5, 134.2, 133.2, 129.4, 129.0, 125.7, 124.3, 123.8, 118.2, 112.7, 112.0, 54.7, 42.2; MS: $m/z$ 645 ($M^+$ + 1).

**4-{6-(4-Bromophenyl)-4-[5-(3-{6-(4-bromophenyl)-2-[4-(methylsulfonyl)phenyl]-4,5-dihydro-2*H*-4-indazolyl}-4-hydroxy benzyl)-2-hydroxyphenyl]-4,5-dihydro-2*H*-2-indazolyl}-1-benzene sulfonic acid (14a).** To a stirred solution of **10b** (7.5 g, 0.01 mol) in ethanol (100 mL) and 6 *N* HCl (14.8 mL, 0.892 mol) was added 4-(methylsulfonyl)phenyl hydrazine **13** (4.1 g, 0.022 mol). The mixture was heated to reflux and stirred for 10 h. After cooling to room temperature, the reaction mixture was concentrated *in vacuo*. The residue was taken up with ethyl acetate and washed with water and brine, dried over $MgSO_4$, filtered, and evaporated *in vacuo* to give a solid that was crystallized from diisopropyl ether (100 mL) to give pyrazole **14a** as brown solid; Yield 82%; m.p. 222–24°C; IR (KBr): ν 3400, 3062, 2937, 1585, 1328, 1165, 732 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 7.91 (s, 2H, ArH), 7.67–7.62 (m, 6H, ArH), 7.50–7.42 (m, 12H, ArH), 7.23 (s, 2H, ArH), 6.94 (s, 2H, OH), 6.84 (d, $J$ = 8.9 Hz, 2H, ArH), 6.77 (d, $J$ = 8.9 Hz, 2H, ArH), 4.87 (t, 2H, CH), 3.72 (s, 2H, $CH_2$), 3.12 (d, 4H, $CH_2$), 2.94 (s, 6H, $CH_3$); $^{13}C$ NMR (DMSO-$d_6$): δ 156.1, 154.2, 153.5, 142.7, 138.8, 133.5, 132.3, 130.4, 129.9, 129.1, 128.0, 126.8, 126.4, 124.6, 124.2, 122.4, 120.7, 119.4, 118.2, 43.5, 42.3, 41.6, 38.7; MS: $m/z$ 1056 ($M^+$). The other compounds **14c–d** were also prepared by the similar procedure.

**4-{6-(aryl)-4-[5-(3-{6-(aryl)-2-[4-(methylsulfonyl)phenyl]-2*H*-4-indazolyl}-4-hydroxybenzyl)-2-hydroxyphenyl]-2*H*-2-indazolyl}-1-benzenesulfonic acid (15a–d).** To a solution of **14** (0.005 mol) in dry benzene (20 mL), DDQ (0.015 mol) in dry benzene (20 mL) was added in portions. The mixture was heated to reflux and stirred for 5 h under a nitrogen atmosphere. The precipitated DDQ-$H_2$ was filtered off and the filtrate was subjected to column chromatography on silica gel (60–120 mesh), to afford pure compounds.

**4-{6-(4-Bromophenyl)-4-[5-(3-{6-(4-bromophenyl)-2-[4-(methylsulfonyl)phenyl]-2*H*-4-indazolyl}-4-hydroxybenzyl)-2-hydroxyphenyl]-2*H*-2-indazolyl}-1-benzenesulfonic acid (15a).** This was obtained as brown solid; Yield 80%; m.p. 210–12°C; IR (KBr): ν 3400, 3062, 2937, 1585, 1328, 1165, 736 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): δ 8.14 (s, 2H, ArH), 7.80 (s, 2H, ArH), 7.72 (d, $J$ = 8.3 Hz, 4H, ArH), 7.53–7.48 (m, 8H, ArH), 7.32–7.28 (m, 6H, ArH), 6.84–6.78 (m, 4H, ArH, OH), 6.72 (s, 2H, ArH), 4.02 (s, 2H, $CH_2$), 2.94 (s, 6H, $CH_3$); $^{13}C$ NMR

(DMSO-$d_6$): δ 153.1, 152.0, 143.3, 142.9, 136.7, 136.2, 133.3, 130.7, 129.8, 129.0, 128.7, 127.9, 125.4, 124.0, 123.9, 122.3, 119.7, 117.6, 111.3, 110.4, 44.3, 42.4; MS: *m*/*z* 1050 ($M^+$).

**4-{6-(4-aminophenyl)-4-[5-(3-{6-(4-aminophenyl)-2-[4-(methylsulfonyl)phenyl]-2*H*-4-indazolyl}-4-hydroxybenzyl)-2-hydroxyphenyl]-2*H*-2-indazolyl}-1-benzenesulfonic acid (15b).** This was obtained as orange solid; Yield 84%; m.p. 240–42°C; IR (KBr): ν 3400, 3065, 2932, 1589, 1328, 1162 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 8.14 (s, 2H, ArH), 7.80 (s, 2H, ArH), 7.72 (d, $J$ = 8.2 Hz, 4H, ArH), 7.67 (d, $J$ = 8.6 Hz, 4H, ArH), 7.53 (d, $J$ = 8.2 Hz, 4H, ArH), 7.32 (d, $J$ = 8.6 Hz, 2H, ArH), 6.94 (d, $J$ = 9.1 Hz, 2H, ArH), 6.72 (d, $J$ = 8.6 Hz, 4H, ArH), 5.96 (s, 2H, OH), 4.96 (bs, 4H, $NH_2$), 4.02 (s, 2H, $CH_2$), 2.94 (s, 6H, $CH_3$); $^{13}C$ NMR (DMSO-$d_6$): δ 153.1, 152.0, 147.3, 145.2, 143.3, 138.2, 136.7, 130.7, 129.7, 129.0, 126.2, 125.6, 124.0, 123.9, 122.3, 121.0, 119.7, 117.6, 111.9, 110.4, 44.3, 42.4; MS: *m*/*z* 924 ($M^+ + 1$).

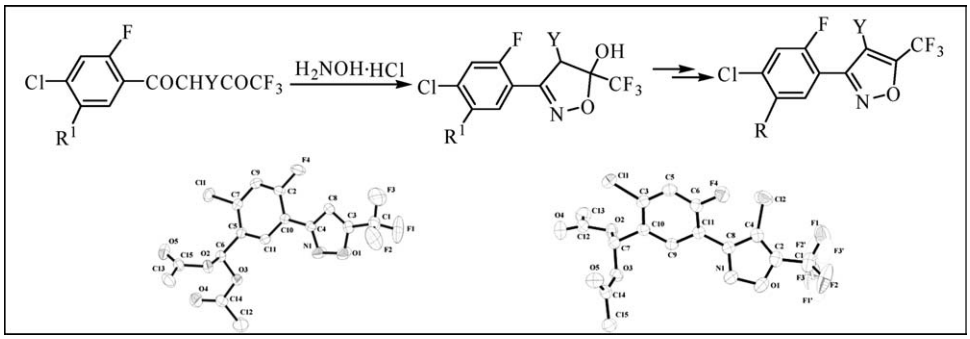
Published online 20 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



The several novel 3-substituted phenyl isoxazole derivatives were prepared from substituted phenyl-butan-1,3-dione. Their structures were confirmed by element analysis, IR, MS, and $^1$H NMR. X-ray structure analysis indicated that the dihedral angles of the phenyl ring with the isoxazole ring in compounds **4a** and **4b** were 19.46° and 49.18°, respectively. Preliminary bioassay showed that the title compounds had good activity to various weeds, and **4a** exhibited almost the same activity with **4b**. This was different from the former works, which showed that the big dihedral angle of the phenyl ring with the heterocyclic moiety was necessary for high-herbicidal activity.

## INTRODUCTION

Herbicides inhibiting protoporphyrinogen oxidase (Protox) are the ones of the most important class of herbicides. Targeting the porphyrin pathway, these herbicides have shown high-activity and low-toxicity, and thus have become a hot-point of novel pesticides research [1]. Besides di-phenylether-type herbicides, which have been commercialized for more than 30 years, many other chemical classes belong to this family, such as azafenidin, oxadiazon, carfentrazone, etc. Substituted phenyl heterocyclic compounds are thought to be potent Protox-inhibitors, because they are similar to one half of the protoporphyrinogen IX, which is the target of Protox. Research on heterocyclic Protox inhibitors has been actively pursued, and a large number of compounds with high-bioactivity were reported [2–6]. Some samples of commercial Protox inhibitors are shown in Figure 1. Substituted phenyl isoxazoline derivatives have been reported, and some of them have high-activities [7]. We have also reported several novel 3-(substituted phenyl) isoxazole in a previous letter [8], considering that some isoxazole derivatives have displayed good biological activity [9–12], and that isoxazole moiety is more similar to the substructure of protoporphyrinogen IX than isoxazoline moiety. More importantly, a further study shows these isoxazole derivatives exhibit different structure-activity relationship from other phenyl heterocyclic compounds. Herein, details of the study, including the synthesis, their X-ray structures and the herbicidal activity of these isoxazole derivatives, are reported.

## RESULTS AND DISCUSSION

The title compounds were prepared from substituted phenyl-butan-1,3-dione. At first, the isoxazole cycle was built via a ring closure reaction of phenylbutan-1,3-dione with hydroxylamine chloride [13]. In this reaction, what we obtained were isoxazolines (**2**), which could be changed into isoxazoles via a dehydration reaction in hot concentrated sulfuric acid (98%). When **2c** was employed as the substrate, the C—O band of the methoxy group was cleaved and **3c** was obtained (Scheme 1). From compounds **3a** or **3b**, different aimed compounds can be obtained by derivation of the methyl group on Position 5 of the phenyl cycle. It can be transformed into an aldehyde through a diester, via an oxidation reaction and a hydrolytic reaction. Otherwise, the methyl group on Position 5 of the phenyl cycle can be oxidized into a carboxyl group with chromium trioxide/

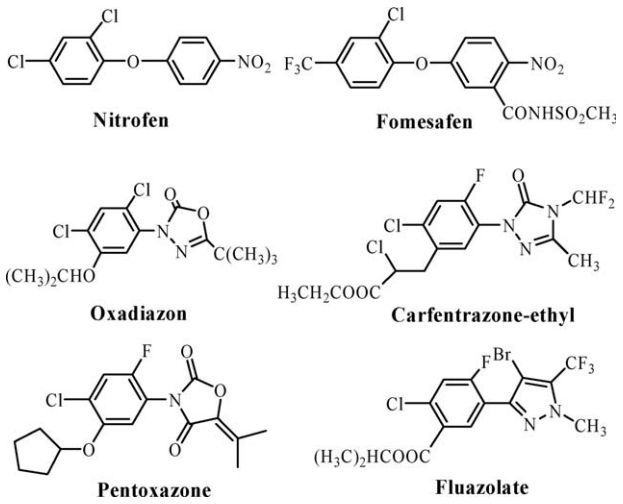

**Figure 1.** Samples of commercial Protox inhibitors.

sulfuric acid, and further transformed to an ester or amide via an acyl chloride intermediate. From compounds **3c**, different aimed compounds can be obtained via an alkylation reaction (Scheme 2).

To investigate further the structure-activity relationship of the aimed compounds, the single crystals of compounds **4a** and **4b** were prepared, and their structures were determined. The details of crystals, data collections and final refinement for compounds **4a** and **4b** are listed in Table 1. The selected bond distances (Å), angles (°) and torsion angles (°) of compounds **4a** and **4b** were given in Table 2. Both of the compounds have two planar rings, that is, the phenyl ring and the isoxazole moiety. However, the dihedral angle in **4a** [shown as C(2)—C(10)—C(4)—C(8)] is much different from that in **4b** [shown as C(5)—C(11)—C(8)—C(4)]. In compound **4a** (Fig. 2), it is 19.46°, whereas 49.18° in compound **4b** (Fig. 3). It indicated that the chlorine substitution could increase the dihedral angle of the two rings for the steric effect, which agreed with our former work [14].

Preliminary bioassay showed that compounds **4**, **5**, **7**, **8** have good activity to various weeds. Compared with fomesafen, which was a high-activity herbicide widely used, the herbicidal activity of these compounds to different weeds by stem and leaf treatment at a dosage of 1.5 kg/hm$^2$ and 150 g/hm$^2$, were shown in Table 3. Some of them have higher activity than fomesafen, especially at a lower dosage.

Here, we noticed that both compounds with chlorine substitution on isoxazole (**4b**, **5b**, **7a**∼**e**) and those without chlorine substitution on isoxazole (**4a**, **5a**, **8a**∼**f**) have high-activity.

It was reported that the ortho-position (to the phenyl ring) substituted groups on the heterocyclic moiety was necessary for high-activity to force the heterocyclic moiety out of planarity with the attached phenyl ring and to match closely the angle of the methylene bridge between two pyrrole rings of the protoporphyrinogen structure [15]. And it was reported recently that the dihalopyrrole nucleus was important for biological activity in 3-arylpyrroles [16]. However, in this research, the result was different from these former works. The tested isoxazole derivatives had high-activity no matter that Y was hydrogen or chlorine. Although the compounds with chlorine substituted had higher activity than those unsubstituted, the difference was quite little. Meanwhile, our former work indicated that the dihedral angle of the phenyl ring and the isoxazole moiety in the compound with chlorine on isoxazole ring was much bigger than those without chlorine substitution in solution [14]. These results suggest that the big dihedral angle of the phenyl ring and the isoxazole moiety may be not a key point for high-activity. We think a molecule may adjust the angle to fit closely the Protox in cells in bio-assaying. However, it needs further research.

## EXPERIMENTAL

$^1$H NMR spectra were measured on a Varian VA400MHz spectrometer with TMS as an internal standard. $^{13}$C NMR spectra were obtained with broadband proton decoupling. MS was performed on a HP1100 high-performance liquid chromatography/mass selective detector. Melting points were determined using a YanacoMP-500 apparatus and were uncorrected. IR spectra were run on Nicolet 20DBX FT-IR. Elemental analysis was measured on MOD.1106 elemental analysis instrumentation.

Compounds **1a** and **1c** were synthesized by methods described in [17]. Compounds **1b** were prepared from **1a** following the procedure given in [7].

**General procedure for the preparation of compound 2.** To a solution of **1** (34 mmol) in acetic acid (100 mL), hydroxylamine chloride (5 g, 72 mmol) was added. Then the

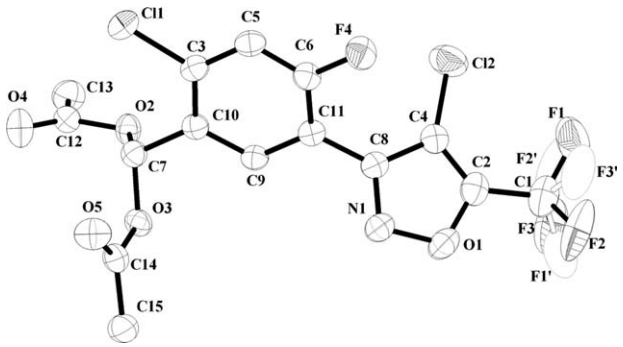

**Figure 3.** ORTEP (ellipsoids at 30% probability) diagram of compound **4b**. All hydrogen atoms are omitted for clarity.

mixture of 4-chloro-3-(4-chloro-2-fluoro-5-methyl)phenyl-5-trifluoromethylisoxazole (**3b**) (12 g, 38 mmol), acetic acid (150 mL) and concentrated sulfuric acid (98%, 15 mL), was added chromium oxide (about 10 g, 0.1 mol) in small portion, maintaining the temperature under 25. The reaction was monitored by TLC. After the reaction was completed, it was poured into water, recrystallized from alcohol, resulting in a white solid precipitate 10 g (79%).

**General procedure for the preparation of compound 7.** To a solution of 2-chloro-4-fluoro-5-[(4-chloro-5-trifluoromethyl)isoxazole-3-yl]benzoic acid (**6**) (1.8 g, 5.2 mmol) in toluene (10 mL), thionyl chloride (1 mL, 14 mmol) and *N*,*N*-dimethyllformamide (3 drops) were added. Then, after the mixture was refluxed for 2 h, the solvent was removed in vacuum. After the oil obtained was cooled, methanol (10 mL) was added and refluxed for 2 h. After the solution was cooled, it was poured into water, resulting in a white solid precipitate.

***Methyl 2-chloro-4-fluoro-5-[(4-chloro-5-trifluoromethyl)isoxazole-3-yl]benzoate (7a).*** This compound was obtained as a white solid, yield 89%. A sample suiting for analysis was obtained by recrystallization with alcohol; mp 60.5∼61.5°C; IR (KBr): 1711 (C=O) $cm^{-1}$; $^1H$ NMR (400 MHz, $CDCl_3$) δ: 8.17 (d, 1H, $J$ = 7.2 Hz, Ph), 7.42 (d, 1H, $J$ = 9.2 Hz, Ph), 3.95 (s, 3H, $CH_3$); MS (API-ES, positive), $m/z$: 379.8 ($[M+Na]^+$).

*Anal*. Calcd. for $C_{12}H_5O_3NCl_2F_4$ (358.1): C, 40.25; H, 1.41; N, 3.91. Found: C, 40.01; H, 1.50; N, 4.13.

***Ethyl 2-chloro-4-fluoro-5-[(4-chloro-5-trifluoromethyl)isoxazole-3-yl]benzoate (7b).*** This compound was obtained as a white solid, yield 83%. A sample suiting for analysis was obtained by recrystallization with alcohol; mp 25.5∼26.0°C; IR (KBr): 1793 (C=O) $cm^{-1}$; $^1H$ NMR (400 MHz, $CDCl_3$) δ: 8.15 (d, 1H, $J$ = 7.2 Hz, Ph), 7.41 (d, 1H, $J$ = 9.6 Hz, Ph), 4.42 (q, 2H, $J$ = 7.2 Hz, $CH_2$), 1.41 (t, 3H, $J$ = 7.2 Hz, $CH_3$); MS (API-ES, positive), $m/z$: 393.7 ($[M+Na]^+$).

*Anal*. Calcd. for $C_{13}H_7O_3NCl_2F_4$ (372.1): C, 41.96; H, 1.90; N, 3.76. Found: C, 42.09; H, 1.98; N, 3.84.

***Isopropyl 2-chloro-4-fluoro-5-[(4-chloro-5-trifluoromethyl)isoxazole-3-yl]benzoate (7c).*** This compound was obtained as a white solid, yield 84%. A sample suiting for analysis was obtained by recrystallization with alcohol; mp 40.0∼40.5°C; IR (KBr): 1735 (C=O) $cm^{-1}$; $^1H$ NMR (400 MHz, $CDCl_3$) δ: 8.12 (d, 1H, $J$ = 7.6 Hz, Ph), 7.41 (d, 1H, $J$ = 9.6 Hz, Ph), 5.29 (sept, 1H, $J$ = 6.4 Hz, CH), 1.40 (d, 6H, $J$ = 6.4 Hz, $2CH_3$); MS (API-ES, positive), $m/z$: 407.7 ($[M+Na]^+$).

*Anal*. Calcd. for $C_{14}H_9O_3NCl_2F_4$ (386.1): C, 43.55; H, 2.35; N, 3.63. Found: C, 43.28; H, 2.27; N, 3.42.

***N-phenyl 2-chloro-4-fluoro-5-[(4-chloro-5-trifluoromethyl)isoxazole-3-yl]benzamide (7d).*** This compound was obtained as a yellow solid, yield 86%. A sample suiting for analysis was obtained by recrystallization with alcohol; mp 173.0∼175.0°C; IR (KBr): 1651 (C=O) $cm^{-1}$; $^1H$ NMR (400 MHz, $CDCl_3$) δ: 7.0∼8.1(m, 8H, Ph+NH); MS (API-ES, positive), $m/z$: 440.8 ($[M+Na]^+$).

*Anal*. Calcd. for $C_{17}H_8O_2N_2Cl_2F_4$ (419.2): C, 48.71; H, 1.92; N, 6.68. Found: C, 48.53; H, 2.01; N, 6.86.

***N,N-diethyl 2-chloro-4-fluoro-5-[(4-chloro-5-trifluoromethyl)isoxazole-3-yl]benzamide (7e).*** This compound was obtained as a yellow solid, yield 80%. A sample suiting for analysis was obtained by recrystallization with alcohol; mp 87.5∼88.5°C; IR (KBr): 3272 (N—H), 1640 (C=O) $cm^{-1}$; $^1H$

*Anal*. Calcd. for $C_{16}H_{15}O_3N_2ClF_4$ (394.7): C, 48.68; H, 3.83; N, 7.10. Found: C, 49.04; H, 3.59; N, 7.01.

***3-[4-Chloro-2-fluoro-5-(2′-methyl)allyl]phenyl-5-trifluoromethylisoxazole (8f).*** This compound was obtained as a white solid (refluxed for 6 h), yield 88%. A sample suiting for analysis was obtained by recrystallization with alcohol; mp 82.0∼82.5°C; $^1$H NMR (400 MHz, $CDCl_3$) δ: 7.54 (d, 1H, $J$ = 6.4 Hz, Ph), 7.28 (d, 1H, $J$ = 10.0 Hz, Ph), 7.15 (d, 1H, $J$ = 3.6 Hz, isoxazole), 5.18 (s, 1H, =CH), 5.05 (s, 1H, =CH), 4.55(s, 2H, $OCH_2$), 1.87 (s, 3H, $CH_3$); MS (API-ES, negative), $m/z$: 333.9 ($[M-H]^-$).

*Anal*. Calcd. for $C_{14}H_{10}O_2NClF_4$ (335.7): C, 50.09; H, 3.00; N, 4.17. Found: C, 49.89; H, 2.90; N, 3.98.

**Crystal structure determination.** Saturated solution of **4a** and **4b** in EtOAc were covered with n-hexane, and stand in air at room temperature to give single crystals. The data were obtained on a Bruker SMART APEX CCD diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å). Empirical absorption corrections were performed using the SADABS program. Structures were solved by direct methods and refined by full-matrix least-squares based on all data using $F^2$ using shelx97. All of the non-hydrogen atoms were refined anisotropic ally. All of the hydrogen atoms were generated and refined in ideal positions.

**Post-emergence herbicidal activity test.** Compounds were formulated as 22 g/L emulsible concentrates, which were diluted with water to the required concentration and applied to pot-grown plants in a greenhouse.

Seeds of assayed weeds (*Echinochloa crusgalli*, *Setaria viridis, Abutilon theophrasti*, and *Acalypha australis*) were germinated in water at 30°C under dark conditions for 48 h. The germinated seeds were placed in a pot (0.1 $m^2$) as 10 seeds per-pot. While *Echinochloa crusgalli* was in the third-leaf stage, *Setaria viridis* was in the second-leaf stage, *Abutilon theophrasti* and *Acalypha australis* had two or three leaves, the diluted formulation was applied. Fifteen days after treatment, the upper-soil parts of the plants were cut off, and their weights were measured freshly (*FW*). The degree of weeds control by the test compounds was calculated with the following formulation:

$$\text{Inhibition} = \frac{CK - FW}{CK} \times 100\%$$

where *CK* is the fresh weight of untreated weed.

Each test was repeated three times.

**Acknowledgments.** The authors are grateful to the National Natural Science Foundation of China (No. 20606005), the Doctor Foundation of Liaoning Province, China (No. 20031068), and the Program for Changjiang Scholars and Innovative Research Team in University (No. IRT0711) for financial support of this work.

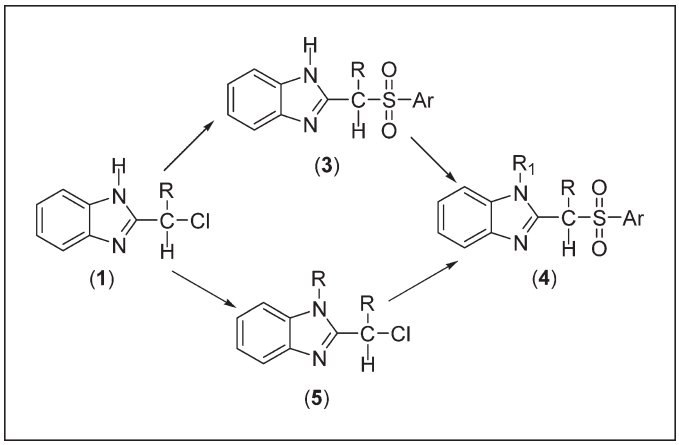
Published online 23 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



Reaction 2-(α-chloroalkyl)benzimidazoles **1** with aryl sulphinate sodium salt **2** under solvent-free conditions in the presence of tetrabutylammonium bromide as surface catalyst, by simple physical grinding using mortar and pestle, gives 1*H*-2-(α-arylsulfonylalkyl)benzimidazoles **3**. The latter on treatment with alkylating agents under solvent-free conditions results in 1-alkyl/aralkyl-2-(α-arylsulfonylalkyl)benzimidazoles **4**. Alternatively, **4** can also be prepared directly from 1-alkyl/aralkyl-2-(α-chloroalkyl)benzimidazoles **5** by reaction with **2**, which in turn could be prepared by reaction of **1** with alkylating agents under solvent-free conditions and all these reactions are free from organic solvents including experimental procedures.

*J. Heterocyclic Chem.*, **47**, 1317 (2010).

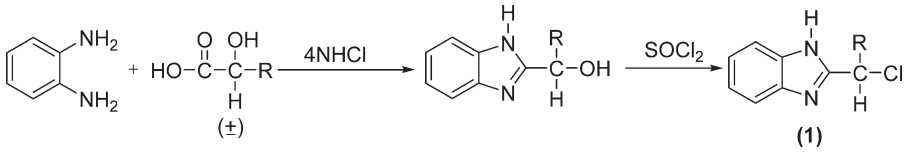
## BACKGROUND

Benzimidazoles are an important class of heterocyclic compounds, several derivatives of which have been found to be useful as intermediates/subunits for the development of molecules of pharmaceutical or biological interest. Substituted benzimidazole derivatives have applications in diverse therapeutic areas including antiulcers, antihypertensive, antiviral, antifungal, anticancer, and antihistaminics to name just a few [1–3]. Sulphones exhibit noteworthy antibacterial, antimalarial, antifungal, and antitubercular properties [4–10]. In recent years, considerable attention has been paid to the reactions done under solvent-free conditions [11,12]. One of the areas of central attention in this field includes reaction between solids [13,14]. These reactions are not only of interest from an economical point of view, in many cases, but also they offer considerable synthetic advantages in terms of yield, selectivity, and simplicity of the reaction procedure. Another important goal in green chemistry is represented by the elimination of volatile organic solvents, in fact, solvent-free conditions that makes synthesis simpler, saves energy, and prevents solvent waste, hazards, and toxicity [15]. Tetrabutylammonium bromide (TBAB) is widely used as phase transfer catalyst (PTC) in many organic reactions [16–22], such as coupling reactions, Heck reaction, Suzuki-coupling of O, O-acetals to S, S-acetals and so forth. Quite a few organic reactions proceed well in solid state [23–27]. All these merits are in accord with the ''green'' requirements of energy saving and high efficiency.

## RESULTS

In continuation of our earlier work [28–31] on synthesis of new benzimidazole derivatives with potential biological activity, we now wish to report the preparation of the title compounds under solvent-free conditions, that is, without using any organic solvent, in the presence of TBAB as surface catalyst (SC) at room temperature, followed by alkylations on various types of these

**Scheme 1**



derivatives and the work up was carried out with water, without using of any organic solvent, such as ethyl acetate, $CHCl_3$, DCM, and so forth. This is totally free from organic solvent. Among alternatives, water is very benign. The use of water for organic reactions offers ''green'' chemistry benefits [32]. The results of these studies are presented in this communication.

## RESULTS AND DISCUSSION

2-(α-Chloromethyl)benzimidazole **1a** (*i.e.*, **1**, R = H) [33] (Scheme 1) on reaction with *p*-tolylsulphinate sodium salt **2a** [*i.e.*, **2**, Ar = $C_6H_4$—$CH_3$(*p*)] in solid phase by simple physical mixing/grinding in a mortar and pestle in the presence of TBAB as SC yielded a neat product on simple aqueous work up. The product has been characterized as 1*H*-2-(*p*-tolylsulfonylmethyl)benzimidazole **3a** [*i.e.*, **3**, R = H, Ar = $C_6H_4$—$CH_3$(*p*)], based on spectral and analytical data and also it was found to be identical with product reported in solution phase [34].

Previously [34], alkylations were carried out under solution phase, that is, using acetonitrile/acetone as solvent, $K_2CO_3$ as base, and TEBAC as PTC. In this work, reaction of **3a** [R = H, Ar = $C_6H_4$—$CH_3$(*p*)] with dimethylsulphate (DMS) as alkylating agent, $K_2CO_3$ as base in the presence of TBAB as SC in solid phase, that is, by simple grinding of reaction mixture in a mortar and pestle, gave the corresponding N-methylated product **4a** (Scheme 2, Table 1).

The above reaction has been found to be a general one and has been extended to other **1a** and **2a** and followed by reaction of **3a** with DMS was extended to DES and benzyl chloride to obtain N-alkyl/aralkyl-substituted derivatives of **4**, the products thus obtained were assigned structure **3**/**4** based on spectral data and analytical data (Scheme 2, Table 1), and also that were found to be identical with those reported earlier in literature [34] from solution-phase reactions. Similarly, reaction of **1a** (*i.e.*, **1**, R = H) with DMS as alkylating agent using $K_2CO_3$ as base in the presence of TBAB as catalyst in solid-phase resulted in the formation of **5a** (*i.e.*, **5**, R = H, $R^1 = CH_3$).

This reaction of **1a** with DMS was extended to DES and benzyl chloride to obtain N-alkyl/aralkyl-substituted derivatives of **5**. Alternatively, **4a** could also be obtained directly from reaction of **5a** with **2a** [*i.e.*, **2**, Ar = $C_6H_4$—$CH_3$(*p*)], under solvent-free conditions in the presence of TBAB, as a catalyst in solid phase by simple physical mixing/grinding in a mortar and pestle, yielded a neat product on simple aqueous work up. The product has been characterized as 1*H*-2-(*p*-tolylsulfonylmethyl)benzimidazole **3a**, which is identical with the product obtained from **3a** with DMS under solvent-free conditions (Scheme 3) with all respects (*i.e.*, TLC, M.P., mmp). Further, it has been extended to its other derivatives in the similar manner; the structure of the compound structure was assigned based on spectral and analytical data. (Scheme 3, Table 2).

It was found that above reactions between **1** and sodium benzenesulphinate did not occur in the absence of TBAB even after grinding the mixture of solids for 2–3 h (Scheme 4). Thus, it appears that TBAB acts like SC and that is why the addition of sodium benzenesulphinate makes the reaction much faster, because TBAB enhances the neucleophilicity of the sulphinate ion and facilitating reaction between **1** and sodium benzenesulphinate (Scheme 5). Similarly in the alkylation reactions, reaction between **1** and alkylating agent did not occur in the absence of TBAB even after grinding the mixture of solids for 2 h. But in the presence of TBAB reaction completes smoothly in short times.

As per literature search, there are number of reports for various organic transformations/methodologies under solvent-free conditions, but they were using organic solvents, such as ethyl acetate, dichloromethane, chloroform, ether, and so forth, in the work up procedure. But, in our present method, we have not used any organic solvents in the work up procedure; we have isolated the

## CONCLUSIONS

In summary, we have developed a simple and efficient method for the preparation of 1-alkyl/aralkyl-2-(α-chloroalkyl)benzimidazole and 1-alkyl/aralkyl-2-(1-arylsulfonylalkyl)benzimidazoles using TBAB as SC under solvent-free conditions by simple physical grinding in mortar and pestle at room temperature. The present protocol has several advantages, completely free from organic solvents, in work up procedure water was used, which is free from organic solvent usage, fast reaction times, high yields, eco-friendly operational and experimental simplicity, readily available catalyst, and with high generality.

## EXPERIMENTAL

Melting points were determined in open glass capillaries using Buchi melting point apparatus and are uncorrected. IR spectra were recorded using potassium bromide pellets with a Perkin IR spectrometer. All $^1$H NMR spectra were recorded on a VARIAN 200-MHz instrument with an internal standard of tetramethylsilane. Mass spectra were recorded on Agilent-LC-MS instrument giving only $M^+$ values using ($M^+ + 1$) mode. Analytical TLC was performed with Silica gel GF-254 from Merck (Germany) containing fluorescent indicator. Spots were detected with UV-light or iodine. The following experimental procedures are representative of the general procedures used to synthesize all compounds.

**Typical procedure for 3.** A mixture of **1** (10 mmol), **2** (10.1 mmol), and TBAB catalytic amount (10 mol %) were ground together in a mortar with pestle at RT till the reaction was complete, as shown by TLC. The solid mixture was then suspended in water to remove inorganic impurities and the insoluble product was filtered, washed with water, and dried, gave pure product **3** (Table 1).

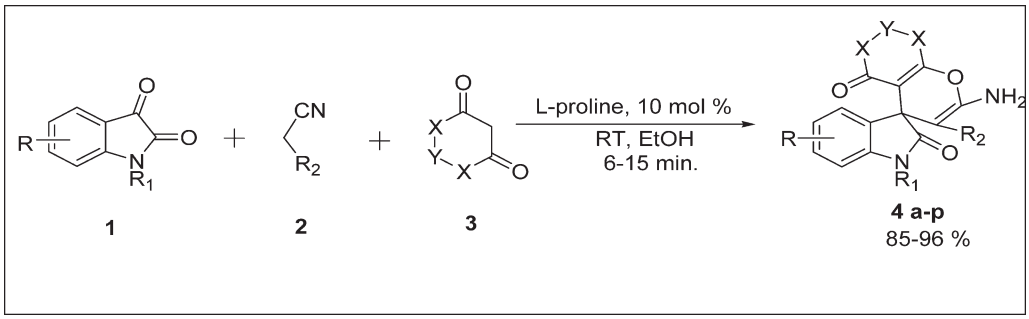
Published online 23 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



An efficient three-component one-pot synthesis of medicinally important spirooxindoles is described by the reaction of isatin, malononitrile/ethyl cyanoacetate, and dimedone/barbituric acid using L-proline as catalyst in ethanol at room temperature. This approach is convenient, mild, and affords the products in high yields without the use of chromatography.

*J. Heterocyclic Chem.*, **47**, 1323 (2010).

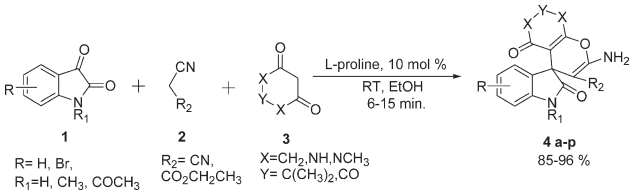
## INTRODUCTION

Indole nucleus is the most common and important feature of a variety of natural products and pharmaceuticals [1,2]. Sharing of the indole 3-carbon atom in the formation of spirooxindole system has stimulated much interest in medicinal and biological chemistry [3–9]. The unique structural array and the pharmacological activity displayed by the class of functionalized spirooxindole compounds have made them attractive synthetic targets [10]. Azaspiro derivatives are well-known [10,11], but the preparation of the corresponding oxa analogues has evolved at a relatively slow pace [12]. Among the oxygen-containing heterocycles fused with indole ring system, chromene-based structures are found to manifest diverse activities such as antidepresssant, antihypertensive, anti-tubulin, antiviral, antioxidative, *etc*., [13–23]. The current interest in 5,6,7,8-tetrahydro-4H-chromene derivatives bearing nitrile functionality, especially 2-amino-5-oxo-5,6,7,8-tetrahydro-4*H*-chromene-3-carbonitriles, arises from their potential application in the treatment of human neurodegenerative disorders [24]. Owing to their medicinal utility, some reports on the multicomponent entry to chromene based spirooxindoles have appeared employing TEBA-$H_2O$ (2–6 h, 60°C) [25], electrocatalytic strategy (NaBr/ROH, 32–64 min) [26], and $InCl_3/SiO_2$ (1.5 h; MW, 3–3.5 min) [27]. Despite the availability of these methods, there remains enough scope for an efficient, high yielding, and mild approach to achieve such systems.

Multicomponent reactions (MCRs) have recently emerged as valuable tool in the preparation of structurally diverse drug-like heterocyclic compounds [28,29]. The MCR strategy offers significant advantages over conventional linear-type synthesis due to its flexible, convergent, and atom efficient nature [30]. Reactions using organocatalysts have attracted a great deal of attention in recent years to avoid the use of expensive transition metals [31]. Several amino acids have undoubtedly been the most successful catalysts in enamine- and iminium-type transformations. L-Proline has been regarded as the simplest 'enzyme' and has been elegantly used as a versatile organocatalyst in various synthetic routes for carbon—carbon and carbon—heteroatom bonds [32–34]. The rigid ring structure, easy availability, nontoxic nature, economical viability, and simple to use make this tiny molecule a remarkable organocatalyst in synthesizing molecules of biological interest.

Considering the biomedical applications of spirooxindole derivatives and in view of the limitations of the existing methods, we were prompted to exploit the catalytic potential of L-proline (10 mol %) for a facile and efficient multicomponent synthesis of functionalized spirooxindoles by the reaction of isatins, malononitrile or

**Scheme 1**



ethyl cyanoacetate, and barbituric acids or dimedone at room temperature (Scheme 1).

## RESULTS AND DISCUSSION

To optimize the reaction conditions, a typical reaction of isatin **1a**, malononitrile **2**, and dimedone **3a** was carried out in the presence of various catalysts in ethanol and water at different temperatures. The outcome is given in Table 1. The optimum concentration of the catalyst L-proline was also determined for the model reaction at 5, 10, and 15 mol % in ethanol at room temperature, affording the product **4a** in 75, 92, and 92% yields respectively. After systematic screening, the best result is obtained when the reaction is carried out with 10 mol % of L-proline in ethanol at room temperature (*cf.* entry 9). Organocatalytic activity of L-proline is mainly due to its Lewis base character, capability for inducing enamine formation, and hydrogen bonding with electronegative atoms of other functionalized groups. It is worthwhile to mention that the reaction is also catalyzed significantly by an ionic liquid [bmim]$BF_4$ in water. The use of ionic liquid alone as solvent could improve the yield of the product further (entries 14 and 15), but not comparable to the yield obtained under L-proline catalyzed conditions in ethanol (entry 9). The other catalysts viz., $ZnCl_2$, $K_2CO_3$, and KF/$Al_2O_3$ did not work well under the investigated conditions.

Under the optimized set of reaction conditions (entry 9), isatin, 5-bromoisatin, N-methylisatin, and N-acetylisatin **1** were allowed to undergo L-proline (10 mol %) catalyzed multicomponent reaction with malononitrile or ethyl cyanoacetate **2** and barbituric acid or dimedone **3** in an equimolar ratio in ethanol at room temperature. The results are given in Table 2. After the reaction was over (TLC), the resulting solid was filtered and washed from ethanol/methanol to yield pure substituted spirooxindoles **4a–4p**. All the products were crystalline and fully characterized based on their melting points, elemental analyses, and spectral data (IR, $^1$H NMR, $^{13}$C NMR).

## CONCLUSIONS

The present report describes L-proline catalyzed multicomponent synthesis of spirooxindoles in excellent yields. This protocol is efficient, simple, mild, ecofriendly, and also advantageous in terms of short reaction time and easy workup.

## EXPERIMENTAL

IR spectra were recorded on a JASCO FT/IR-5300 spectrophotometer; whereas, NMR was run on a JEOL AL300 FT NMR spectrometer. The chemical shifts are given in δ ppm with respect to TMS as internal standard. Elemental analysis (C, H, N) for final compounds were performed on a Model

[a] Yields based on isatins.

CE-440 CHN Analyzer. The TLC spots were detected using iodine chamber. All commercially available chemicals were purchased from Aldrich (USA) and E. Merck (Germany).

**General experimental procedure for the synthesis of spirooxindoles 4.** L-Proline (10 mol %) was added to a mixture of isatin (**1**, 1 mmol), malononitrile or ethyl cyanoacetate (1 mmol), and dimedone or barbituric acid (1 mmol) in ethanol (2 mL), and the resulting mixture was stirred at room temperature for 6–15 min. Upon completion of the reaction (TLC), the mixture was allowed to cool to room temperature. The resulting solid was filtered and washed successively with water (2 × 20 mL) and cold ethanol (2 × 0.5 mL) to afford pure product **4** (white shiny powder).

Twenty-four novel tetramic acid derivatives (*Z*)-3-((*E*)-1-(alkyloxyimino)ethyl)-5-arylidene-4-hydroxypyrroline-2-ones **6a–x** were synthesized by the reaction of (*Z*)-3-acetyl-5-arylidene-4-hydroxypyrroline-2-ones **4** with *O*-alkyl hydroxylamines **5** under reflux conditions in good yields (77.2–92.4%). Their structures were confirmed by IR, $^1$H-NMR, MS, and elemental analysis. The preliminary bioassays showed that most of the title compounds exhibited noticeable fungicidal activities against *Colletotrichum orbiculare* and a certain degree of fungicidal activities against *Fusarium gramineaum* and *Rhizoctonia cerealis* at a concentration of 100 μg/mL.

## INTRODUCTION

Some hundreds of natural products containing the ring system pyrrolidine-2,4-dione (also known as tetramic acid) (Fig. 1) have been isolated from plants, fungi, and more recently from marine sponges [1–3]. The spectrum of biological activities displayed by these natural products is remarkable in its diversity [4–6]. An important representative of the tetramic acids is tenuazonic acid, which is a metabolite produced by some phytopathogenic fungi [7]. Since its isolation in 1957 from the culture filtrates of *Alternaria tenuis* [8], it has been found possessing antitumor, antiviral, antibacterial, and herbicidal activities [9–12]. Reutericyclin [13] is a typical 1,3-bisacyltetramic acid that is extracted from cells and culture filtrates of *Lactobacillus reuteri* and found to inhibit the growth of *Salmonella* and *Helicobacter*, the latter being the causative agent of stomach ulcers. The melophlins [14] are a class of *N*-methyl-3-acyltetramic acids recently isolated from the marine sponge *Melophlus sarassinorum*. Melophlin A and B displayed cytotoxic activity against HL60 cells at 0.2 and 0.4 μg/mL, respectively [15]. In 1971, Yuki *et al* synthesized a series of 5-subsitituted-3-(1-anilinoethylidene)pyrrolidine-2,4-dione derivatives and studied antitumor activities [16]. Zhu *et al* reported a series of 3-[(α-hydroxy-substituted)benzylidene]pyrrolidine-2,4-dione derivatives showing higher herbicidal activities [17].

Oxime ether derivatives have occupied an important position in medicinal and pesticide chemistry with a wide range of bioactivities [18]. As pesticides, they were used as insecticides, fungicides, and herbicides. Alloxydim [19], the first cyclohexanedione herbicide with an oxime ether group has been commercialized. The advantages of oxime ether derivatives, such as, high-activity against the target, low-toxicity toward the mammalians, and low-residue, have prompted chemists to design and synthesize more novel oxime ether derivatives [20].

In 1981, Tatsuaki *et al* synthesized thirteen 3-acetyl-5-subsititutedbenzylidenetetramic acids [21], the novel structures and infusive biological activities of which have aroused great interest to us. Herein, we introduced oxime ether groups into 3-acetyl-5-subsititutedbenzylidenetetramic acids to synthesize a series of novel (*Z*)-3-((*E*)-1-(alkyloxyimino)ethyl)-5-arylidene-4-hydroxy-pyrroline-2-one derivatives for the purpose of searching

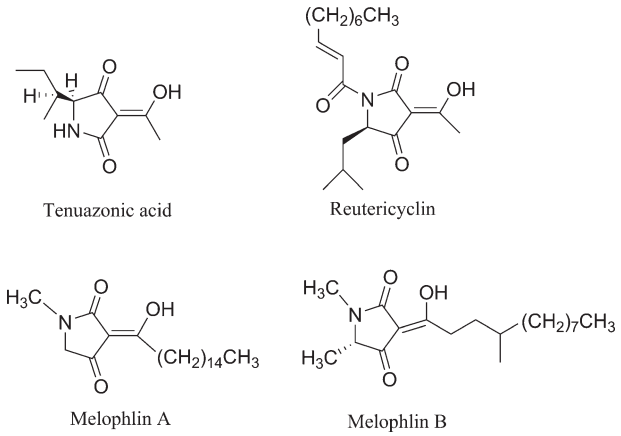

**Figure 1.** Some bioactive naturally occurring tetramic acids.

new potential pesticides with an excellent biological activities. The synthetic route is shown in Scheme 1.

## RESULTS AND DISCUSSION

**Chemistry.** The synthesis of compounds (*Z*)-3-acetyl-5-arylidene-4-hydroxypyrroline-2-ones **4** involved the condensation of **3** (1 equivalent) with substituted benzaldehydes (2 equivalent) in the presence of dry hydrochloride [21]. The dry hydrochloride as a key catalyst was obtained by the reaction of acetyl chloride with anhydrous ethanol. In the $^1$H-NMR spectra of the compounds **4a**, **4c**, and **4e**, the protons of CH═ and NH showed the characteristic pair of signals, indicating these compounds in deuteriochloroform solution existed to a great extent as tautomers [22]. According to the literature based on a comparison of the $^1$H-NMR chemical shift data for the vinyl proton signals at the region of 6.42–6.65 ppm with those of similar tetramates, the *Z* configuration of the compounds could be assigned, and this inference was consistent with crystal structure of **6e**.

In the IR spectra of the title compounds **6**, there were medium or weak absorption bands for the enolic hydroxyl group (ν O—H) at around 3300 cm$^{-1}$ and relatively strong absorption bands for the carbonyl at around 1680 cm$^{-1}$. The characteristic absorption peak of oxime ether group existed at around 1620 cm$^{-1}$. The main characteristic of the $^1$H-NMR spectra of **6a–x** was the presence of high-frequency downfield broad singlet $\delta_H$ 7.53–9.72 presumably arising from the deshielded N—H proton linked to the carbonyl group. The singlet at $\delta_H$ 6.21–6.49 assigned to the C—H proton of CH═C and singlet at $\delta_H$ 2.32–2.57 assigned to the C—H protons of $CH_3C$═N. The signal of protons of OH group at the 4-position in NMR spectra was not been found, and this phenomena might be caused by the lability of these protons of compounds **4** and **6**, which involved in internal tautomerization in the enol form. Furthermore, the MS spectra of all the compounds **6** showed the molecular ion peak ($M^+$, 3–100%), and other fragmentation ions were consistent with their structures and could be clearly assigned.

In the crystal structure of compound **6e** (Fig. 2), the bond length C(5)—N(2) [1.295(3) Å] was close to the C═N double bond distance (1.34 Å). The bond lengths C(7)—C(9) and C(10)—C(11) were 1.354(3) Å and 1.338(3) Å, respectively, and they were close to the C═C double bond distance (1.34 Å). As a result, the benzene ring, C(10)—C(11), C(7)—C(9), C(5)—N(2), and C(8)═O(1) [1.237(2) Å] formed a large conjugated system. The bond length C(8)—N(1) [1.376(2) Å] was shorter than the normal C—N single bond (1.49 Å), suggesting the occurring of an electron density delocalization. The dihedral angle between benzene ring and pyrroline-2-one ring [N(1), O(1), O(2), C(7), C(8), C(9), C(10)] was 15.928(54)°. In addition, there was a weak π···π interaction between the parallel benzene rings (the

[a] Average of three replicates.
[b] N.A. = Not active.
Values are the mean ± S.D. of three replicates.

centroid-centroid distance was 4.36 Å) to pivotally maintain a 3D supramolecular network structure.

Furthermore, the crystal structure of compound **6e** simultaneously confirmed *E* configuration of 1-(alkyloxyimino)ethyl group and *Z* configuration of arylidene group, especially the enolic form at 4-position of the title compounds.

**Biological activity.** The results of fungicidal activities *in vitro* at a concentration of 100 μg/mL were listed in Table 1. Most of the compounds **6** exhibited notable fungicidal activities against *C. orbiculare*, thereby the inhibitory rates of the compounds **6a**, **6k**, **6l**, **6m**, **6n**, **6p**, and **6q** all exceeded 50%. Comparatively, the fungicidal activities against *R. oerealis* were moderate, but more than half of the compounds **6** were more active than tenuazonic acid. The preliminary estimation of structure-activity relationships indicated that the title compounds showed more remarkable fungicidal activities against *C. orbicular* when $R^2$ was saturated aliphatic alkyl, for example, the compound **6a** ($R^1$ was H and $R^2$ was $CH_3$) gave a best activity with $EC_{50}$ value of 1.15 μg/mL (Table 2), indicating it was significant to further modify the structure of the title compounds.

**Table 2**

$EC_{50}$ values of compounds **6a**, **6n**, and **6p** against *C. orbiculare*.

| Compound | Regression eq. | $EC_{50}$[a](μg/mL) | r[b] |
|---|---|---|---|
| **6a** | $y = 0.36423x + 4.97749$ | 1.15 | 0.99 |
| **6n** | $y = 0.92570x + 3.62689$ | 30.43 | 0.96 |
| **6p** | $y = 0.50225x + 4.19465$ | 40.13 | 0.90 |

[a] $Ec_{50}$ refer to median effect concentration.
[b] Refer to correlative coefficient.

It was worthy to clarify that the herbicidal activities of the title compounds were evaluated too. *Brassica campestris* and *Echinochloa crusgalli* (L.) *Beauv* were chosen as samples of annual dicotyledonous and monocotyledonous plants. But the herbicidal activities of all the title compounds were found to be quite weak.

## CONCLUSIONS

A series of new tetramic acid derivatives containing oxime ether group at 3-position and arylidene group at 5-position were designed and synthesized by the

reaction of (*Z*)-3-acetyl-5-arylidene-4-hydroxypyrroline-2-ones with *O*-substituted hydroxylamine hydrochlorides. The data of IR, MS, $^1$H-NMR spectra, and X-ray single-crystal structure diffraction confirmed the structures of the title compounds that contained enol structure and (3*E*, 5*Z*)-configuration. The bioassay results demonstrated that most of the title compounds, especially **6a**, possessed good activity against *C. orbiculare*. Further studies on structural modification are currently underway.

## EXPERIMENTAL

The melting points of the products were determined on a WRS-1B digital melting-point apparatus and were uncorrected. IR was recorded on a Bruker Tensor 27 FT-IR spectrometer with KBr disk. Elemental analyses were performed on Elementar Vario-III CHN analyzer. Mass spectra were recorded on a GC/MS-QP2010 spectrometer using direct-injection technique. $^1$H-NMR spectra was taken on a Mercury plus varian-300 spectrometer with TMS as the internal reference and DMSO-$d_6$ or $CDCl_3$ as the solvent. X-ray diffraction was performed with a Brucker Smart APEX II CCD diffractometer. All reagents were analytical-reagent grade or were chemically pure. The solvents were dried before use as needed.

Intermediate **3** was prepared according to the reported method [23]. The intermediates **5** *O*-allyl, *O*-methyl, and *O*-benzyl hydroxylamine hydrochlorides were synthesized starting from ethyl acetate and hydroxylamine hydrochloride via a facile three-step procedure including acetylamination, etherification, and hydrolyzation [24–26]. *O*-Propyl, *O*-isopropyl, and *O*-butyl hydroxylamine hydrochlorides were synthesized starting from hydroxylamine hydrochloride and phthalic anhydride in satisfactory yield according to the method reported by Han [27].

**General procedure for the synthesis of intermediate (*Z*)-3-acetyl-5-arylidene-4-hydroxy-pyrroline-2-ones (4).** To the solution of compound **3** (16 mmol) in ethanol (15 mL) added 8% HCl (18 mmol) in anhydrous ethanol and stirred until it dissolved, after that a substituted benzaldehyde (32 mmol) was added. The reaction mixture was refluxed for 3 h, and then cooled to give a red precipitate, which was filtered off and recrystallized from ethanol to afford the products **4a–e** in 35.2–60.8% yields.

**General procedure for the preparation of the title compounds 6a–x.** To a solution of (*Z*)-3-acetyl-5-arylidene-4-hydroxypyrroline-2-one **4** (1.5 mmol) and *O*-substituted hydroxylamine hydrochloride **5** (1.6 mmol) in ethanol (25 mL) was added 0.2 mol/L NaOH (8 mL). Then, the reaction mixture was refluxed for 3 h. After cooling to room temperature, the mixture was poured into water (30 mL), and the precipitate was filtered. The filtrate was extracted with chloroform and the organic layer was dried over anhydrous magnesium sulfate. The solvent was removed under reduced pressure to give a yellow solid. Finally, the solid was collected together and recrystallized from ethanol or ethyl acetate to give title compounds **6a–x**.

**Crystal structure determination.** The single crystal of **6e** was selected and glued on the tip of a glass fiber. Both cell dimensions and intensities were measured on a Bruker Smart APEX CCD diffractometer with graphite monochromated Mo Kα radiation (λ = 0.71073 Å) at 296(2) K. $\theta_{max}$ = 25.99; 6205 measured reflections; 3113 independent reflections ($R_{int}$ = 0.0385) of which 2421 had $I > 2\delta$ ($I$). Data was corrected for Lorentz and polarization effects and absorption ($T_{min}$ = 0.9781, $T_{max}$ = 0.9831). Crystal structure was solved by direct methods using the SHELXS-97 program [28]. All nonhydrogen

atoms were refined anisotropically. The C—H hydrogen atoms were positioned geometrically and refined using a riding model. The hydrogen atoms linked to nitrogen and oxygen were located from the difference Fourier map and were set as isotropic. Full-matrix least squares refinement based on $F^2$ using the weight of $1/[\sigma^2(F_o^2) + (0.1206P)^2 + 0.0717P]$ gave final values of $R = 0.0575$, $\omega R = 0.1770$, and GOF($F$) = 1.044. The maximum and minimum difference peaks and holes were 0.352 and –0.381 e $Å^{-3}$, respectively.

The crystallographic data have been deposited with Cambridge crystallographic data center, CCDC No. 734371. Copies of this information can be obtained free of charge from the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK (fax: +44 1223 336 033; or E-mail: deposit@ccdc.cam.ac.uk).

**Fungicidal assay.** Inhibition effects of the title compounds **6a–x** on phytopathogenic fungi (*Fusarium gramineaum*, *Colletotrichum orbiculare*, and *Rhizoctonia cerealis*) were tested using a radial growth inhibition technique according to literature [29]. Each compound was diluted with 0.5 mL DMF and added to potato sucrose agar medium (PSA), respectively to obtain a concentration of 100 μg/mL immediately before pouring into the petri dishes. Each concentration was tested in triplicate. Parallel controls were maintained with 0.5 mL DMF mixed with PSA medium. The discs of mycelial felt (0.5 cm diameter) of fungi were transferred aseptically to the center of Petri dishes. The treatments were incubated at 25°C in the dark. The diameter of the mycelium was measured after the fungal growth in the control treatments had covered two-thirds of the Petri dishes. The growth inhibition rates were calculated with the following equation: $I = [(C - T)/C] \times 100\%$. Here, $I$ was the growth inhibition rate (%), $C$ was the control settlement radius (mm), and $T$ was the treatment group fungi settlement radius (mm).

**Acknowledgments.** The authors thank the financial support of the National High Technology Research and Development Program of China (863 Program, 2006AA10A214) and the Science and Technology Development Foundation of Nanjing Agricultural University (0506F0005). They are grateful to Lu, A. M. for MS analysis and Yuan, L. M. for the single crystal data collection.

A series of novel 11-amino-3,3-dimethyl-8-substituted-12-aryl-3,4,7,8,9,12-hexahydro-2*H*-benzopyran[2,3-*b*]quinoline-1,10-dione derivatives **4** were synthesized by 2-amino-3-cyano-4-aryl-5,6,7,8-tetrahydro-7,7-dimethyl-5-oxo-4*H*-benzopyran **2** with 5-substituted-1,3-cyclohexanedione using *p*-toluenesulfonic acid, $K_2CO_3$, and $Cu_2Cl_2$ as catalysts. The compounds **2** as easily accessible precursors were obtained from 5,5-dimethyl-1,3-cyclohexanedione by Michael addition with β-dicyanostyrenes **1**, prepared by Knoevenagel condensation of different aromatic aldehydes and malononitrile. The synthesis of the title compounds **4** completed by one-pot reaction of 4-aryl-4*H*-benzopyran derivatives with 5-substituted-1,3-cyclohexanediones by refluxing in toluene using TsOH as catalyst. The structures of all compounds were characterized by elemental analysis, IR, MS, and $^1$H NMR spectra.

## INTRODUCTION

Many of the multirings occurring products containing simultaneously oxygen and nitrogen atoms on their carbon frameworks display various pharmacological activities [1]. Tacrine, a potent and reversible AChE inhibitor, was the first drug approved in the United States for the palliative treatment of Alzheimer's disease [2]. Jose [2] reported some new multipotent tetracyclic tacrine analogs, which had the similar structure with the title compounds and these tacrine analogs are modest AChE inhibitors but proved to be very selective. And some of them show a significant neuroprotective effect on neuroblastoma cells subjected to $Ca^{2+}$ overload or free radical induced toxicity. In addition, these compounds bind AChE to the peripheral anionic site of AChE. And, consequently, are potential agents that can prevent the aggregation of *b*-amyloid.

Among which benzopyran[2,3-*b*]quinolinone not only possesses the structure of benzopyran but also contains a quinoline ring. Benzopyran, as the parent ring of many natural products, are widely found in the nature. Their derivatives have been approved to possess good biological activity, and also exhibit antitumor activity. In addition, benzopyran derivatives could serve as the moderator for the potassium ion channel [3–5]. Quinoline belongs to the class benzopyridines (a class with six-membered nitrogened heterocyclic-fused polycyclic rings). The compounds of quinoline with aromatic or heterocyclic compounds have rigid planar with a conjugated structure. These compounds exhibit strong fluorescence properties as well as a variety of biological activities. They can be used by DNA and other biological macromolecules to embed into the body, and also can be served as the fluorescent probes and synthetic drugs. They have been widely used in the medical and molecular biology [6]. Nitrogen-containing

heterocyclic compounds have shown a strong trend of development and broad application prospects in the fields of sterilization, anti-malaria, and anti-malignant tumor [7].

To search for medicinal compounds, and enrich the tetracyclic compounds, we first synthesized a series of new six-membered tetracyclic compounds, benzopyran [2,3-*b*]quinolinone derivatives with oxygen and nitrogen atoms inlaying in the ring.

## RESULTS AND DISCUSSION

11-Amino-12-aryl-2,3,4,7,8,9,10,12-octahydro-3,3-dimethyl-1*H*-chromeno[2,3-*b*]quinoline-1-one derivatives have been synthesized by 4-aryl-4*H*-chromenes and cyclohexanone using $AlCl_3$ as catalyst in 1,2-dicholonethane [2]. Pyrano[2,3-*b*]pyridines were achieved by the Friedlander reaction of 2-amino-3-cyano-4*H*-pyrans with cyclopentanone/cyclohexanone using $SnCl_2{\cdot}2H_2O$ under solvent-free condition [8]. Both methods have been tried in our investigation, but they are found to suffer from several drawbacks, such as low yield, no reaction, more byproducts, and long reaction time. Compared with these methods, our method has many advantages, such as higher yield, shorter reaction time, less side reaction and so on. In this study, β-dicyanostyrene **1** were prepared as building block from aromatic aldehyde, malononitrile in dry ethanol with $KF{\cdot}2H_2O$ as catalyst. And 4-aryl-4*H*-benzopyran derivatives **2** were synthesized by β-dicyanostyrene and 5,5-dimethyl-1,3-cyclohexanedione in ethylene glycol. The intermediate enamines **3** were obtained by condensation reaction of compounds **2** with 5-substituted-1,3-cyclohexanedione using *p*-toluenesulfonic acid as catalyst in toluene. 11-Amino-3,3-dimethyl-8-substituted-12-aryl-3,4,7,8,9,12-tetrahydro-2*H*-benzopyran[2,3-*b*]quinoline-1,10-dione derivatives **4** were synthesized by cyclization of the intermediate enamines **3** in the presence of $K_2CO_3$ and $Cu_2Cl_2$ [9,10]. Meanwhile, these series of novel compounds **4** could also be obtained via a one-step reaction by 4-aryl-4*H*-benzopyran **2** with 5-substituted-1,3-cyclohexanedione, using *p*-toluenesulfonic acid as catalyst in toluene. The synthetic pathway was shown in Scheme 1.

Each of compounds **4a–c**, **4f–g** should be as a diastereomeric mixture. It was speculated from the $^1$H NMR spectrum that the yields of the major product was above 90%. The diastereomeric were difficult to be isolated by silica gel flash chromatography, and therefore, the major product was purified by multiple-step crystallizing. As

**Table 1**

Synthesis of 2-*N*-(5-Substituted-3-oxo-1-cyclohexanyl)-amino-3-cyano-4-aryl-5,6,7,8-tetrahydro-5-oxo-benzopyran (compounds **3**).

| Entry | $R^1$ | $R^2$ | R | Yield (%) |
|---|---|---|---|---|
| **3a** | $C_6H_5$ | H | H | 60.2 |
| **3b** | $C_6H_5$ | H | 4-$OCH_3$ | 45.3 |
| **3c** | $C_6H_5$ | H | 3,4-$(OCH_3)_2$ | 64.8 |
| **3d** | $CH_3$ | $CH_3$ | 4-$OCH_3$ | 48.5 |
| **3e** | $CH_3$ | $CH_3$ | 4-Cl | 50.6 |

shown in the $^1$H NMR spectrum, it was a single peak for the C12—H. The specific stereostructure of the main product need to be further studied.

The data of $^1$H NMR, MS, and IR shown in the experimental section are in accordant with the chemical structures of the target compounds. In the $^1$H NMR spectrum of compound **3a**, the broad single proton peaks at δ 6.38 was the characteristic absorption proton peak of the amino group. The single peak at δ 5.84 was the typical proton peak of the vinyl group. In the $^1$H NMR spectrum of compound **4a**, two broad single peaks at δ 5.07 and δ 9.14 were observed. They disappeared after $D_2O$ exchange, and therefore, were attributed to the two N—H of the amino group. Because of the existing of intramolecular hydrogen bond between one proton of the amino group and the oxygen atom of the carbonyl group nearby, its proton peak was drifted to δ 9.14. The structures of these compounds were further supported by their IR spectra. Server typical absorption bands at 2204 $cm^{-1}$ for **3a** (C≡N), 1655 $cm^{-1}$ for **4a** (C—O), and 3410 $cm^{-1}$ for (N—H) were observed, respectively.

## CONCLUSIONS

During our investigate, it is found that the toluene, TSOH, and raw materials are drier, the corresponding yields are more excellent and the side reactions are less; and when the ratio of 4-aryl-4*H*-benzopyran derivatives and 5-substituted-1,3-cyclohexanedione is 1:1.2, it can give the corresponding products in best yields. It is also found that the intermediate enamines **3** can be obtained using 4-aryl-4*H*-benzopyran derivatives and 5-substituted-1,3-cyclohexanedione in water with catalytic amount of HCl, and the corresponding yields are also relatively high, however, the side reactions are more. Therefore, using this method to synthesize our target compounds need to be further investigated.

In summary, during the synthesis of benzopyran[2,3-*b*]quinolinone derivatives, we used two methods and both could obtain the target compounds. Compared with the two methods, the method B extended the first step reaction time based on the method A. But we achieved one-step ring closure, reduced the kinds of catalysts and organic solvents, and shortened the total reaction time. Both the method and the benzopyran[2,3-*b*]quinolinone derivatives have not been reported. The purpose to enrich the tetracyclic heterocyclic compounds was achieved. These compounds contain atoms and groups that they can be modified according to the need, which can conduct further reaction.

## EXPERIMENTAL

Melting points were determined on an electrothermal apparatus and the temperature was not calibrated. Microanalysis was performed by the Perkin-Elmer 2400 Microanalytical Service. Infrared spectra were recorded as thin films on KBr using a Perking-Elmer 1700 spectrophotometer. The NMR spectra were recorded by a Bruker ARX-300 spectrometer. Sample solutions were prepared in $CDCl_3$ or DMSO containing TMS as an internal reference. Mass spectra were recorded by JMS-DX300 at 70 eV. All chemical reagents were commercially available and purified with standard methods before use. Solvents were dried in routine ways and redistilled. 5-Substituted-1,3-cyclohexanedione were obtained from aromatic aldehyde, acetone and diethyl malonate according to the literature [1] method with slightly modification.

**General method for the synthesis of β-dicyanostyrene(1).** To a solution of the corresponding aldehyde (1 equiv) in dry ethanol (1 mL/mmol), malonodinitrile (1 equiv), and a catalytic amount of $KF{\cdot}2H_2O$ [11] were added. The mixture was stirred at 60°C for 2–4 h. Then, the reaction mixture was cooled to rt. To this mixture was added 100 mL water and the precipitated solid was isolated by filtration, washed with cold ethanol, recrystallized from 95% ethanol.

**General method for the synthesis of 2-Amino-3-cyano-4-aryl-5,6,7,8-tetrahydro-7,7-dimethyl-5-oxo-4*H*-benzopyran(2).** To a solution of the corresponding β-dicyanostyrene (1 equiv) in ethylene glycol (1 mL/mmol), 5,5-dimethyl-1,3-cyclohexanedione (1 equiv) were added. The mixture was stirred at 80°C for 2–4 h. Then, the resultant mixture was cooled to rt. To this mixture was added 100 mL water and the precipitated solid was isolated by filtration, washed with water, recrystallized from methanol.

**General method for the synthesis of 2-*N*-(5-substituted-3-oxo-1-cyclohexenyl)-amino-3-cyano-4-aryl-7,7-dimethyl-5,6,7,8-tetrahydro-5-oxo-4*H*-benzopyran (3a–3e).** 2-Amino-3-cyano-4-aryl-5,6,7,8-tetrahydro-7,7-dimethyl-5-oxo-4*H*-benzopyran (1 equiv) and 5-substituted-1,3-cyclohexanedione (1.2 equiv) were suspended in toluene (1 mL/mmol) containing *p*-

## INTRODUCTION

Since Butula *et al*. prepared the first optically active bis(oxazoline) in 1976, the design and development of effective chiral bis(oxazoline) ligands have played a significant role in advancement of asymmetric catalysis and have attracted a great deal of attention because they hold special structural characters and provide high enantioselectivities in a variety of asymmetric catalytic reactions [1–6]. Chiral bis(oxazoline) ligands have widespread uses in asymmetric hydrosilylation [7], cyclopropantion reaction [8], Friedel-Crafts reaction [9], Diels-Alder reaction [10], Aldol addition [11], Michael reaction [12], Henry reaction [13], allylic oxidation [14], 1,3-dipolar cycloaddition [15], and so on.

Chiral bis(oxazoline)s have various structures, which determine the diversity of their synthetic methods. At present, two general synthetic routes are summarized from various synthesis [2,3,16]: (a) Reaction of dintriles with chiral amino alcohol or diols afford the target compound *via* a one or multiple-step reaction in the presence of Lewis acid or base. (b) Dicarboxylic acids or their derivatives (diacyl halide, diacylamide or diesters) react with chiral amino alcohol, *via* the corresponding bis(β-hydroxylamide)s as the successive intermediates, that cyclize to produce the target compounds. The latter method requires activating agents, with thionyl chloride, also cyclizing agent being the most commonly used, which results in more side reactions and low yields. Therefore, a simpler and more efficient synthesis approach should be explored to meet the needs of bis(oxazoline) ligands.

In this article, we report the results of the reaction of dicarboxylic acids with β-amino alcohols under reflux through water deprivation to obtain chrial bis(oxazoline)s **1a**–**1e**, **2a**–**2c**, and a novel achiral bisoxazoline **3** (Fig. 1 and Scheme 1–3) *via* a one-pot reaction. This method afforded high yields with simple workup procedure.

## RESULTS AND DISCUSSION

Gao *et al*. reported that chiral bis(oxazoline)s **1a**–**1e** were synthesized from thiophene-2,5-dicarboxylic acid by sequential amidation with a chiral ethanolamine, conversion of hydroxyl to chloro group, and base-promoted oxazoline ring formation [17,18]. Kanazawa *et al*. described the synthetic procedure of chiral 1,3-bis[4′-substitutedoxazolin-2′-yl]benzene including bis(oxazoline)s **2a**–**2c**, which isophthaloyl dichloride reacted with chiral β-amino alcohols at 0°C to form the corresponding diamide-dialcohols as the successive intermediates and then cyclized to obtain the target compounds in the presence of methanesulfonyl chloride at 0°C [19]. As described above, the syntheses of chiral bis(oxazoline)s involve multistep reactions, which result in more side reactions and low yields.

To address above issues, we successfully developed a new, facile, and efficient method for the synthesis of

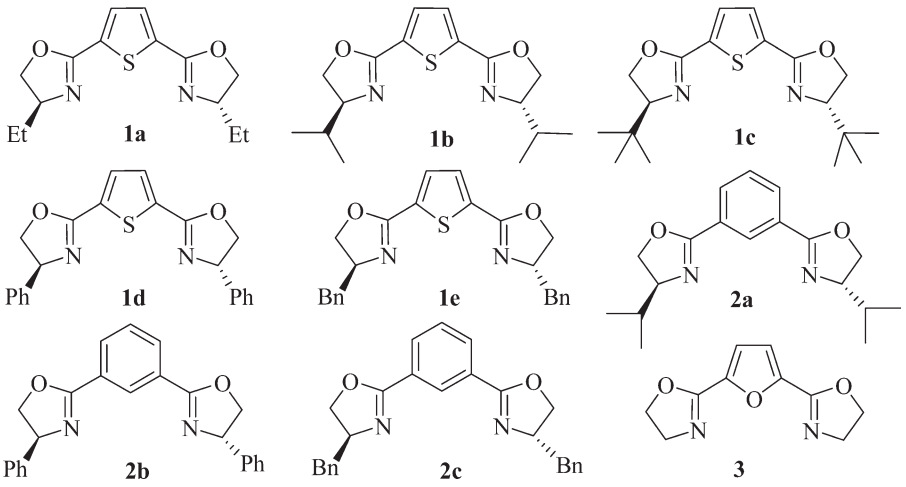

**Figure 1.** Chemical structures of bis(oxazoline)s.

bis(oxazoline)s starting from dicarboxylic acids. With this convenient method, bis(oxazoline)s **1** or **2** were readily synthesized in high yields from thiophene-2,5-dicarboxylic acid (TDA) or benzene-1,3-dicarboxylic acid (BDA) and β-amino alcohols (Scheme 1 and 2). Briefly, a mixture of dicarboxylic acid and β-amino alcohol was refluxed in toluene through water deprivation for 24 h. After cooling to ambient temperature, the solvent was removed under reduced pressure, and the residue was purified by silica gel column chromatography to give the desired product in high yield. The conditions and results of reaction of carboxylic acids with β-amino alcohols have been listed in Table 1 (entries 1–8).

Instead of thiophene-2,5-dicarboxylic acid (TDA) or benzene-1,3-dicarboxylic acid (BDA), furan-2,5-dicarboxylic acid (FDA) reacted with 2-aminoethanol to afford a new achiral bis(oxazoline) **3** in high yield under the same reaction condition (Scheme 3 and Table 1, entry 9).

In conclusion, a facile one-pot synthetic method of bis(oxazoline)s (**1**–**3**) was described, which is simple and efficient, deserving great application potentials in the research and development in the area of bis(oxazoline)s.

## EXPERIMENTAL

**General.** Melting points were determined by the capillary method and are uncorrected. $^1$H-NMR spectra were measured on a Varian UNITY INOVI-500 NMR spectrometer, a Bruker Avance DPX300 NMR spectrometer or a Bruker DRX-400 NMR spectrometer, using TMS as internal standard. Mass spectra were taken on a MDS Sciex API 2000 LC/GC/MS instrument. Elemental analyses were carried out on a Perkin-Elmer 240C elemental analyzer. Optical rotation values were measured on a POLARTRONIC HNQW 5 polarimeter.

All solvents used for the synthesis were of analytical grade and were dried and freshly distilled under a nitrogen atmosphere prior to use. Chiral β-amino alcohols, furan-2,5-dicarboxylic acid, and benzene-1,3-dicarboxylic acid were purchased from Fluka Chemical Co. Thiophene-2,5-dicarboxylic acid was synthesized in our own laboratory. Other reagents were all of analytical grade.

**General procedure for the synthesis of 2,5-bis[4′(*S*)-substituted-oxazolin-2′-yl]thiophene (1a–1e).** Thio-phene-2,5-dicarboxylic acid (100.0 mg, 0.58 mmol), chiral β-amino alcohol (1.16 mmol), and toluene (20 mL) were added to a three-neck flask with a water segregator, a reflux condenser, and a magnetic stirring bar. The mixture was refluxed and dehydrated for 24 h. After cooling to room temperature, the solvent was removed under reduced pressure, and the residue was purified by silica gel column chromatography with dichloromethane and ethanol (50:1) as eluent to give the pure title compound.

The synthesis of a number of indolylacetamides and indolylacetohydrazides in very good yields from the reaction of pyranoindolones with aliphatic amines and *N*,*N*-dimethylhydrazine, respectively, is described. The reactivity difference with aromatic amines but also with methylhydrazine and aromatic hydrazines is discussed.

*J. Heterocyclic Chem.*, **47**, 1344 (2010).

## INTRODUCTION

From the reaction between 1-methylpyranoindolone and aromatic amines in boiling bromobenzene, only Schiff bases **1** were isolated [1], whereas from the same reaction in boiling isopropanol, 2-acetyl-indoloacetic acid amides **2** were formed [2] (Fig. 1).

Concerning the reaction of pyranoindolones with aliphatic amines as nucleophiles only some scattered reports were found in the literature. Thus, by refluxing 1-methylpyranoindolone with ethanolic ammonia (2-acetyl-3-indolyl)acetamide was formed [3], whereas with methanolic dimethyl amine, the corresponding *N*,*N*-dimethylacetamide was isolated in 44% [4]. Recently, the synthesis of the *N*-benzyl-(2-acetyl-3-indolyl)acetamide was reported from the reaction of 1-methylpyranoindolone with benzylamine in boiling DMF, which was eventually cyclized to a β-carbolinone by reflux with triethylamine in acetic acid [5].

In addition, recently, we studied the reaction of pyranoindolones with bisnucleophiles, such as methylhydrazine, whereupon 1,2-diazepinoindoles were isolated [6], and also the reaction with aromatic hydrazines, such as phenyl- and benzoylhydrazine, leading to the synthesis of β-carbolinones [7].

## RESULTS AND DISCUSSION

In the light of the above results and in continuation of our research into the synthesis of compounds containing the indole ring [6,7], we embarked in a more detailed study of the reactions between pyranoindolones and aliphatic amines and also *N*,*N*-dimethylhydrazine.

Since the reaction of pyranoindolone **3a** with dimethylamine in protic solvents (boiling methanol) has been, as mentioned above, reported to give the *N*,*N*-dimethyl-2-acetyl-1*H*-indole-3-acetamide (**5a**) in 44% yield and since such reactions show a strong solvent effect, initially the pyranoindolones **3a**–**3f** were allowed to react with two molar equivalents of dimethylamine in refluxing bromobenzene for 20 min, whereupon the indole-3-acetamides **5a**–**5f** were isolated in much better yields (Table 1, Scheme 1).

The reaction proceeded smoothly also at lower temperatures (refluxing toluene or benzene for 4–6 h) and even at room temperature, though a longer reaction time (12 h) was necessary for the completion of the reaction (Table 1). Next, the reaction was repeated with another secondary amine morpholine, but also with the primary amine benzylamine at room temperature for 12 h, and in all cases, the corresponding indole-3-acetamides 6 and 7 were isolated as the only reaction products in very good yields (Table 1). Indolylacetohydrazides 8 were isolated, when *N*,*N*-dimethylhydrazine was used as nucleophile. Compounds 7 and 8 were isolated as a mixture of two rotamers, as was confirmed from their NMR spectra ranging from 10:1 (major to minor) in compound **7a** to 2:1 in compound **8d** (see Experimental). The molar ratio of the rotamers depends on their relative stability, which is based on the volume and the electronic properties of

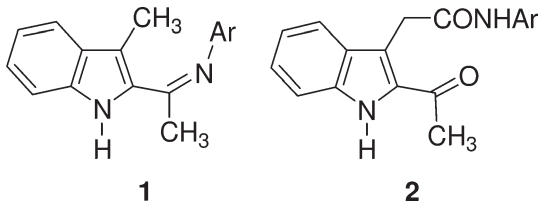

**Figure 1.** Products from the reaction of pyranoindolones with aromatic amines.

the substituents. The formation of the two rotamers is expected due to the high proportion of double bond character of the C—N amide bond resulting thus to hindered free rotation at low and ambient temperatures. As a result, in the case of different *N*-substituents, the NMR spectra of the two rotamers (in products 7 and 8) are practically different. In the case of two identical *N*-substituents (products 5 and 6), these substituents are in different magnetic environment and experience different chemical shifts.

Concerning the reaction mechanism for the formation of products **5–8** attack of the amines to the carbonyl carbon, being the strongest electrophilic center (Scheme 2) is observed in all cases. This result is not in agreement with the results previously obtained with aromatic amines, and also with the bisnucleophiles methylhydrazine, phenyl-, and benzoylhydrazine, where under the same reaction conditions, initial attack to the less electrophilic center, namely C-1 was always observed [1,6,7]. The different behavior can be explained by the enhanced nucleophilicity of the aliphatic amines thus attacking the strongest electrophilic center. All isolated products **5–8** are new, with exception of **5a** and **7a**.

**Table 1**

Reaction conditions and products.

| Entry | Amine | Solvent | Temp (°C) | Time | Product | Yield (%) |
|---|---|---|---|---|---|---|
| **3a** | **4a** | PhBr | 156 | 20 min | **5a** | 69 |

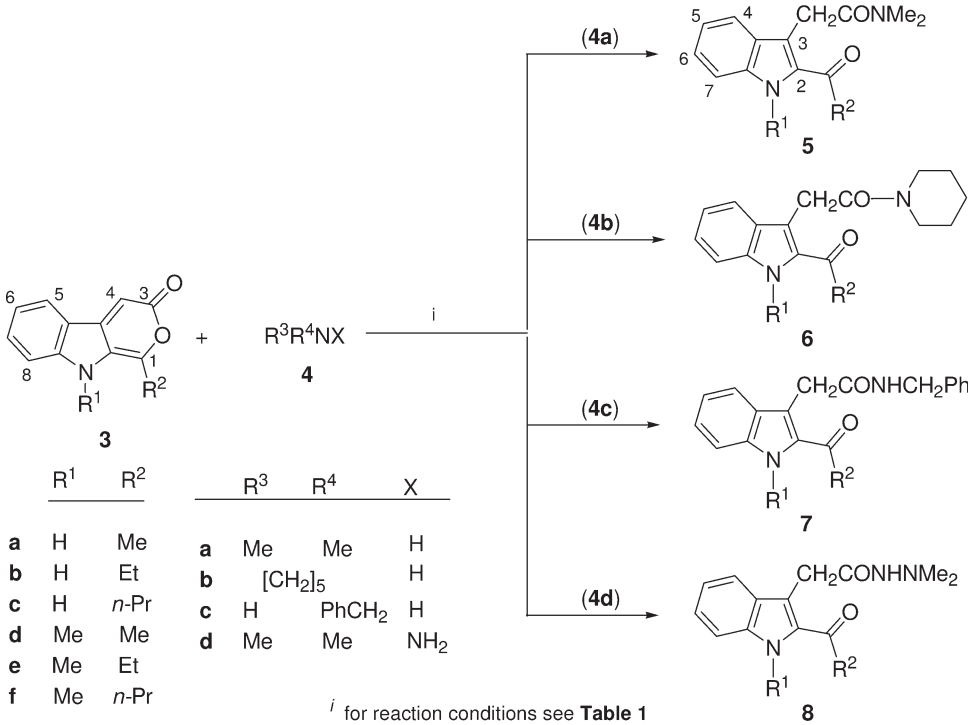
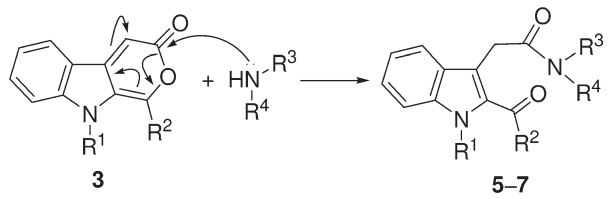
| **3e** | **4a** | $C_6H_6$ | 80 | 6 h | **5e** | 78 |
| **3e** | **4a** | $C_6H_6$ | 25 | 12 h | **5e** | 65 |
| **3a** | **4b** | $C_6H_6$ | 25 | 12 h | **6a** | 71 |
| **3d** | **4b** | $C_6H_6$ | 25 | 12 h | **6d** | 68 |
| **3e** | **4b** | $C_6H_6$ | 25 | 12 h | **6e** | 82 |
| **3a** | **4c** | $C_6H_6$ | 25 | 12 h | **7a** | 61 |
| **3d** | **4c** | $C_6H_6$ | 25 | 12 h | **7d** | 65 |
| **3e** | **4c** | $C_6H_6$ | 25 | 12 h | **7e** | 97 |
| **3b** | **4d** | $C_6H_6$ | 25 | 12 h | **8b** | 53 |
| **3d** | **4d** | $C_6H_6$ | 25 | 12 h | **8d** | 51 |
| **3e** | **4d** | $C_6H_6$ | 25 | 12 h | **8e** | 47 |

The assigned molecular structures of all compounds **5–8** are based on rigorous spectroscopic analysis including IR, NMR ($^1$H, $^{13}$C, COSY, NOESY, HETCOR, and COLOC), MS, and elemental analysis data.

**Scheme 1**



**Scheme 2**



Regarding the structure of the isolated indole-3-acetamides **5–8**, the assignment of **5e** is described. The elemental analysis and mass spectra unequivocally established the reaction of one molecule of pyranoindolone **3e** with one molecule of dimethylamine with the loss of a water molecule, a fact that was also confirmed from the $^{13}C$ NMR spectrum, where 16 different signals were observed. Moreover, in the IR spectra, a carbonyl at 1657 $cm^{-1}$ was identified. In the $^1H$ NMR, the presence of the four indole aromatic protons resonating as a double doublet of doublets at δ 7.60 ($J$ = 8.0 Hz, $J$ = 1.0 Hz, and $J$ = 0.5 Hz), a double doublet of doublets at δ 7.12 ($J$ = 8.0 Hz, $J$ = 7.1 Hz, and $J$ = 1.1 Hz) [8], a multiplet at δ 7.33–7.34 for two protons with their carbons resonating at 120.4, 120.3, 125.3, and 110.2 ppm, respectively, was identified. The 3-position methylene protons appear as a singlet at δ 4.09, whereas in addition to the ethyl group, three *N*-methyl groups appeared at δ 3.00, 3.16, and 3.93 with their carbons resonating at 35.8, 37.4, and 32.6 ppm, respectively. Moreover, in addition to the characteristic COLOC correlations for the indole aromatic ring protons, the indole *N*-methyl group protons gave COLOC correlations with the quaternary carbons at 135.0 (C-2) and at 138.5 ppm (C-7a), whereas the 3-methylene protons correlated with the quaternary carbons at 135.0 (C-2) and at 126.9 (C-3a), 114.9 (C-3), and with the amide carbonyl carbon at 170.0 ppm, as depicted in Figure 2. In **8e**, the amide carbonyl carbon correlates as expected with the amide proton instead of the *N*-methyl protons.

In conclusion, a direct method for the systematic synthesis of a number of indolylacetamides and indolylacetohydrazides has been described. Moreover, the reaction of pyranoindolones with aliphatic amines and *N,N*-dimethylhydrazine does not show a solvent effect and proceeds with initial attack to the strongest electrophilic center, a result which is not in agreement with the results previously obtained with aromatic amines, and also with the bisnucleophiles methylhydrazine, phenyl-, and benzoylhydrazine, where initial attack to the less electrophilic center was always observed.

## EXPERIMENTAL

Melting points were measured on a Büchi apparatus and are uncorrected. Column chromatography was carried out using Fluka silica gel 60. TLC was performed using precoated silica gel glass plates 0.25 mm containing fluorescent indicator $UV_{254}$ purchased from Macherey–Nagel using a 3:1 mixture of petroleum ether–ethyl acetate. Petroleum ether refers to the fraction boiling between 60 and 80°C. NMR spectra were recorded at room temperature on a Bruker AM 300 spectrometer at 300 MHz for $^1H$ and 75 MHz for $^{13}C$, respectively, using $CDCl_3$ as solvent. In the case of insoluble substances, 5–20% of DMSO-$d_6$ was added, whereas in one case, only DMSO-$d_6$ was used, as indicated. Chemical shifts are expressed in δ values (ppm) relative to TMS as internal standard for $^1H$ and relative to TMS (0.00 ppm) or to $CDCl_3$ (77.05 ppm) for $^{13}C$ NMR spectra; in the case of DMSO-$d_6$ solutions, the signal of the solvent at 39.7 ppm was used for calibration. Coupling constants $^nJ$ are reported in Hz. Second order $^1H$ NMR spectra were analyzed by simulation [8]. IR spectra were recorded on a Perkin–Elmer 1600 series FTIR spectrometer and are reported in wave numbers ($cm^{-1}$). Low-resolution electron impact mass spectra were recorded on a 6890N GC/MS system (Agilent Technology); in some cases, LC-MS (ESI, 1.65 eV) spectra were recorded on LCMS-2010 EV system (Shimadzu). Elemental analyses performed with a Perkin–Elmer 2400-II CHN analyzer. Structural assignments of the derived compounds were established by analysis of their IR, MS, and NMR spectra ($^1H$, $^{13}C$, DEPT, COSY, NOESY, HETCOR, and COLOC).

**General procedure for the reaction of pyrano[3,4-b]indol-3(9H)-ones (3a–3f) with amines 4.** To a stirred and refluxing solution of pyranoindolone **3** (1.0 mmol) in bromobenzene (15 mL), amine **4a** (1.5 mmol) was added and refluxing and stirring was continued for 20 min. The solvent was distilled off under reduced pressure and the resulting residue was subjected to column chromatography on silica gel using petroleum ether–EtOAc (5:1) as eluent, slowly increasing the polarity up to 3:1 to give 2-(2-acyl-1H-indol-3-yl)-*N,N*-dimethylacetamide **5**.

The reaction conditions given in Table 1 are followed for the preparation of compounds **6–8**.

The chalcones, **2a-2l** reacted with *o*-aminobenzenthiol to give a series of 1,5-benzothiazepines, **3a-3l**. The [3+2] 1, 3-dipolar cycloaddition reactions of **3a-3l** with ethyl chlorooximidoacetate in the presence of $Et_3N$ afforded the target compounds, **4a-4l** possessing an additional 1,2,4-oxadiazole ring fused to the heptaatomic nucleus. The structures have been elucidated by spectral methods and X-ray crystallographic analysis.

## INTRODUCTION

The Synthesis of benzothiazepine derivatives has attracted considerable attention of organic and medicinal chemists due to their broad spectrum of biological activity. The 1,5-benzothiazepine derivatives have been used as cardiovascular modulators [1], coronary vasodilators [2], elastase [3]/ACE inhibitors [4], anti-HIV [5], antihypertensives [6], anti-depressants [7], and anti-bacterial activity [8]. In recent years, a large number of 1,5-benzothiazepine derivatives containing anticancer activity [9,10], hemodynamic effects [11], antiulcer activity [12,13], and spasmolytic activities [14–18] have also been reported. Some of the 1,5-benzothiazepine derivatives were also used clinically for CNS disorders which include quetiapine fumarate and thiazesim [19–21].

Oxadiazoles are naturally occurring five-membered heterocycles with utility in synthetic and medicinal chemistry. They serve as the core components of a large number of substances that possess a wide range of interesting biological activities. The 1,2,4-oxadiazole scaffolds are associated with significant biological activities, such as anti-hypertensive [22], antikinetoplastid [23], antimicrobial and anti-inflammatory [24].

Recent work has demonstrated the interest to fix an additional heterocycle on 1,5-benzothiazepines. Pharmaceutical properties of such compounds are magnified when the heterocycle is bound to the heptatomic nucleus [25,26]. Keeping these observations in mind and in continuation of our interest to prepare a seven-membered ring [27,28], we report herein the reaction of 1,5-benzothiazepines **3a-3l** with ethyl chlorooximidoacetate through 1,3-dipolar cycloaddition to afford a new series of tricyclic system, [1,2,4]oxadiazolo[5,4-*d*][1,5]benzothiazepine derivatives, which might have useful biological and therapeutic activities (Table 1).

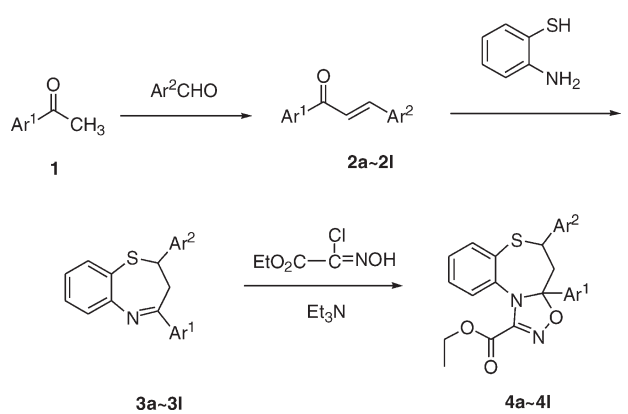
## RESULTS AND DISCUSSION

The title compounds were prepared according to the Scheme 1. The chalcones, **2a-2l** were readily prepared by condensation of aryl aldehydes with substituted acetophenones [29]. **2a-2l** were subsequently reacted with *o*-aminobenzenthiol in MeOH/AcOH to give the desired 2,4-diaryl-2,3-dihydro-1,5-benzothiazepines, **3a-3l**. The formation of **3** may proceeded via two steps [30,31]. In the first step, nucleophilic attack by the sulfhydryl electrons of 2-aminobenzenethiol takes place on the activated β-carbon atom of the α, β-unsaturated carbonyl compounds to give Michael-adduct type intermediates, which simultaneously undergo dehydrative cyclization to give final products in the second step. Finally, the 1, 3-dipolar cycloaddition reaction between 1,5-benzothiazepine derivatives, **3a-3l** and nitrile oxide, generated *in situ* from ethyl chlorooximidoacetate and triethylamine, leads to the target compounds; 1,2,4-oxadiazolo[5,4-*d*]-1,5-benzothiazepine derivatives, **4a-4l** (Scheme 1) in which an oxadiazole ring is fused at the ''d'' edge of the heptatomic nucleus.

**Scheme 1**



The structures of title compounds have been characterized by IR, $^1$H-NMR, mass, and elemental analysis. The infrared spectra of these compounds show C=O absorption bands around 1740 $cm^{-1}$. In the nuclear magnetic resonance spectra, title compounds exhibited multiplet between δ 8.15–6.55ppm due to the aromatic protons, the signal for ethoxycarbonyl $CH_2$ and $CH_3$ appeared at δ 4.30–4.38 ppm and δ 1.29–1.31 ppm respectively, 3 distinct double doublets in the ABX pattern (a CH proton and 2 anisochronous protons of a $CH_2$) appeared at δ 3.60–2.50 ppm, as has been

observed in 2,3-dihydro-1,5-benzothiazepines. In MS spectra, molecular ion peaks of all title compounds were obtained from EI-MS, but the intensities of molecular ion peaks were very weak.

A plausible intramolecular 1,3-diploar cycloaddition mechanism is proposed as shown in Scheme 2. According to the literatures [32], the conformations of the central heteroazepine ring in 2,4-disubstituted 2,3-dihydro-1,5-benzothiazepines adopt boat-like conformations and the 1,3-diploar cycloaddition reactions occurred in a concerted mechanism. In the presence of $Et_3N$, the nitrile oxide generated *in situ* and C═N double bond in benzothiazepine formed a cyclic transition state, then the σ-bonds of C─N and C─O were formed simultaneously to afford the 1,2,4-oxadiazole ring, the central thiazepine ring of the cycloadduct also adopts a boat-like conformation.

The X-ray crystallography of **4e** identified the structure of the desired products (Fig. 1). The higher occupancy in the 3-dimensional packing arrangement is shown in Figure 2. The crystal data and structure refinement of **4e** are listed in Table 2. Selected bond distances and angles of **4e** are tabulated in Table 3.

Figure 1 is the stereo structure of compound **4e**. There is a five-membered ring in the molecule, resulting from the cycloaddition reaction. All atoms [N(1), C(7), N(2), C(12), O(3)] in the ring are nearly coplanar with similar bond angles (N(1)─O(3) ─C(12) 106.32(14)°, O(3) ─C(12) ─N(2) 101.36(14)°, C(12) ─N(2) ─C(7) 102.60(14)°, N(2) ─C(7) ─N(1) 115.39(18)°, C(7) ─N(1) ─O(3) 105.94(16)°), indicating the ring is stable. The five-membered ring is characterized by the endocyclic torsion angles (enumerated clockwise and starting with O(3)─N(1)─C(7)─N(2)): −2.1(2)°, 19.7(2)°, −28.29(17)°, 25.87(17)°, −16.1(2)°. The five-membered ring plane adopts an envelope conformation with atom C(12) deviating from the plane defined by N(2), O(3), N(1), C(7) of 0.1684Å. The bond length of N(1)─C(7), 1.286(3)Å, indicates it is a double bond.

There is also a seven-membered ring in the molecule. 1,5-Benzothiazepine ring is characterized by the endocyclic torsion angles (enumerated clockwise and starting with S(1)─C(1)─C(6)─N(2)): 0.7(3)°, −53.6(3)°, −1.8(3)°, 82.5(2)°, −48.60(19)°, −35.20(15)°, 64.81(17)°. N(2), S(1), C(12) and C(20) are coplanar, while C(1), C(6) and C(19) are all above the plane. Therefore, the seven-membered ring adopts a boat-like conformation.

CCDC-768069 (for **4e**) contains the supplementary crystallographic data for this paper. These data can be obtained free of charge at www.ccdc.cam.ac.uk/const/retrieving.html.

In conclusion, we have achieved an efficient one step synthesis of new [1,2,4]oxadiazolo[5,4-d][1,5]benzodiazepinones, **4a-4l** by way of highly regioselective 1,3-dipolar cycloaddition of ethyl chlorooximidoacetate to 2,4-diaryl-2,3-dihydro-1,5-benzothiazepines, **3a-3l**.

## EXPERIMENTAL

All reagents were of commercial availability. Reactions were monitored by thin-layer chromatography (TLC). Melting points were measured on a mettler FP-5 capillary melting point apparatus and were uncorrected. Elemental analyses were performed on a Perkin-Elmer 2400 elemental analyzer. The IR spectra were determined as potassium bromide pellet on a Bruker Equinox 55 FTIR spectrophotometer. The $^1$H-NMR spectra were recorded on a Varian Inova-400 spectrophotometer using TMS as an internal standard. EI-ms spectra were recorded with an Agilent 5975 apparatus. X-ray crystal

structure was obtained using R-AXIS SPIDER X-ray diffraction. The ethyl chlorooximidoacetate was obtained according to the known procedure [33–34].

**General procedure for the preparation of the 2,4-diaryl-2,3-dihydro-1,5-benzothiazepines (3a-3l).** Chalcone **2** (6 mmol) and *o*-aminobenzenthiol (6 mmol) were dissolved in 25 ml containing glacial acetic acid methanol. After the mixture had cooled to room temperature, piperidine (5 drops) was added. Yellow floccule appeared in 0.5h, then a little methanol was added and the slurry was heated until all material dissolved. Glacial acetic acid (2 ml) was added and the mixture was allowed to stand overnight at a room temperature. The solid product was collected and recrystallized from anhydrous ethanol and benzene to give **3a-3l** as yellow crystals (Table 4).

**General procedure for the preparation of the 2,4-diaryl-2,3-dihydro-1,5-benzothiazepine derivatives containing 1,2,4-oxadiazole (4a-4l).** To a stirred solution of 1,5-benzothiazepine derivatives **3a-3l** (1 mmol) and ethyl chlorooximidoacetate (1.5 mmol) in $CH_2Cl_2$ (20 ml), a solution of triethylamine (0.5 ml) in the same solvent (5 ml) was added dropwise over a few minutes. The reaction mixture was kept under stirring at room temperature for 2 days. After the removal of the solvent at reduced pressure, ethyl acetate was added to the residue and the triethylamine hydrochloride was filtered. The solvent was then evaporated off and the residue subjected to silica gel column chromatography with ethyl acetate/light petroleum (V:V = 1:8). A series of compounds **4a-4l** were crystallized from ethyl acetate and light petroleum.

***Ethyl 3a,4-dihydro-3a,5-diphenyl-5H-[1,2,4]oxadiazolo[5,4-d][1,5]benzothiazepine-1-carboxylate (4a).*** This compound was obtained as colorless crystals in 34% yield, mp 177–178°C. IR(KBr): 3072 (Ar—H), 1736 (C=O), 761 $cm^{-1}$. $^1$H-NMR ($CDCl_3$, 400 MHz) δ: 8.21–6.78 (m, 14H, Ar—H), 4.34 (q, 2H, $CH_2$), 3.49 (dd, 1H, H-5x, $J_{bx}$ = 5.53 Hz, $J_{ax}$ = 10.01 Hz), 3.06 (dd, 1H, H-4b, $J_{bx}$ = 5.53 Hz, $J_{ab}$ = 14.90 Hz), 2.66 (dd, 1H, H-4a, $J_{ax}$ = 10.01 Hz, $J_{ab}$ = 14.90 Hz), 1.30 (t, 3H, $CH_3$). ## INTRODUCTION

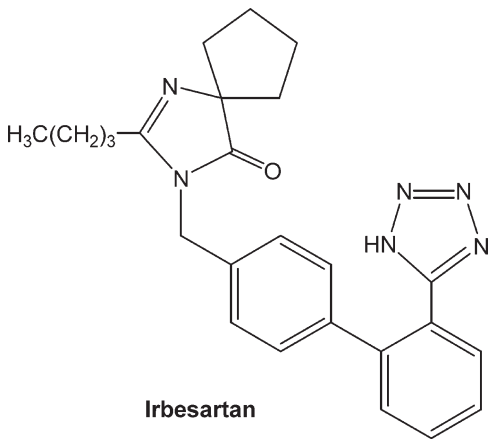
A number of substituted 4,5-dihydro-1*H*-imidazol-5-ones belong among still applied selective and non-toxic herbicides [1]. Our previous articles dealt with their synthesis, characterisation, and study of mechanism of their formation [2]. Other possible applications of 4,5-dihydro-1*H*-imidazol-5-ones lie in their use as ligands that form coordination compounds with selected metal ions [3]. Some of such complexes have been successfully adopted as catalysts of deallylation reactions of diallyl malonates [3b,f] in the Henry reaction [3c,e], or in allyl oxidation [3i]. Another example of application of this heterocyclic system is represented by 2-butyl-1,3-diazaspiro[4.4]non-1-en-4-one, which is an important starting compound for the synthesis of medical drug Irbesartan (2-butyl-3-[[2′-(1*H*-tetrazol-5-yl)-[1,1′-biphenyl]-4-yl]methyl]-1,3-diazaspiro[4.4]-nonen-4-on). Irbesartan is an antagonist of angiotensin II and is clinically applied in the treatment of hypertension [4].



The existing methods of synthesis of 2-butyl-1,3-diazaspiro[4.4]non-1-en-4-one use the acylation of amide or nitrile of 1-aminocyclopentancarboxylic acid with pentanoic acid chloride followed by ring closure reaction [5]. Another method of preparation of 2-butyl-1,3-

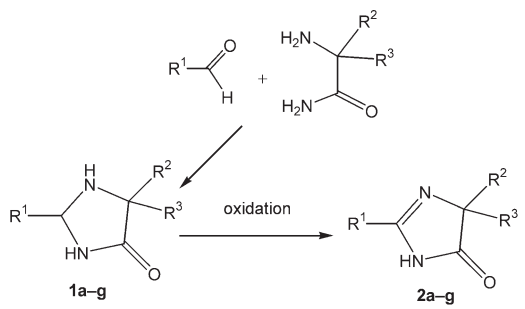
diazaspiro[4.4]non-1-en-4-one consists in acid catalyse condensation of ethyl 1-aminocyclopentancarboxylate with ethyl pentanimidate [6]. The third synthetic way described is based on the reaction of 1-aminocyclopentanecarboxamide with trimethyl orthopentanoate [7]. The described variant of synthesis of 2-butyl-1,3-diazaspiro[4.4]non-1-en-4-one is the reaction of pentanoic acid with 1-aminocyclopentannitrile [8]. The aim of the research described here is to elaborate a new alternative synthetic method for 2-butyl-1,3-diazaspiro[4.4]non-1-en-4-one and other substituted 4,5-dihydro-1*H*-imidazol-5-ones. This alternative adopts oxidation of substituted imidazolidin-4-ones to give 4,5-dihydro-1*H*-imidazol-5-ones.

## RESULTS AND DISCUSSION

The reaction of aldehydes (pentanal, benzaldehyde, 4-methoxybenzaldehyde, 4-nitrobenzaldehyde, salicylaldehyde, pyridin-2-carbaldehyde) with 1-aminocyclopentancarboxamide [5] or (*S*)-2-amino-2,3-dimethylbutanamide [1] was used to prepare cyclic aminals, *i.e.*, the corresponding imidazolidin-4-ones **1a–g** (**a**: $R^1 = CH_3(CH_2)_3$; **b**: $R^1 = C_6H_5$; **c**: $R^1 = 4\text{-}CH_3OC_6H_4$; **d**: $R^1 = 4\text{-}NO_2C_6H_4$; **e**: $R^1 = 2\text{-}HOC_6H_4$; **f**: $R^1 = 2$-pyridyl; for $R^2 = R^3 = (CH_2)_4$) and **g**: $R^1 = 2$-pyridyl; for $R^2 = CH_3$; $R^3 = CH(CH_3)_2$) (Scheme 1). The ring closure reaction was performed with acid catalysis (acetic acid) by heating the starting substances in methanol. Recrystallization gave the respective imidazolidin-4-ones **1a–i** in the yields of 53–83%. In the case of (5*S*)-4-isopropyl-4-methyl-2-(pyridin-2-yl)imidazolidine-4-one (**1g**), the reaction creates another chiral centre at the carbon atom at 2-position of the imidazolidin-4-one cycle. In this case, the reaction produces a diastereomeric mixture with the configurations 2*S*, 5*S* and 2*R*, 5*S*, in the ratio of 1:1, which resulted in doubling of signals in the NMR spectra.

The second reaction step leading to the substituted 4,5-dihydro-1*H*-imidazol-5-ones **2a-g** was the oxidation of the prepared imidazolidin-4-ones **1a–g** (Scheme 1). The following oxidizing agents were used for this oxidation reaction: palladium on carbon carrier (Pd/C), 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ), and activated manganese (IV) oxide ($MnO_2$). The results presented in the following table show that the first method (Pd/C) gives the highest yields; however, in most cases the other two (cheaper) variants are also applicable (Table 1).

**Scheme 1**



**1, 2a–i** **a**: $R^1 = CH_3(CH_2)_3$; **b**: $R^1 = C_6H_5$; **c**: $R^1 = 4\text{-}CH_3OC_6H_4$; **d**: $R^1 = 4\text{-}NO_2C_6H_4$; **e**: $R^1 = 2\text{-}HOC_6H_4$; **f**: 2-pyridyl; for $R^2 = R^3 = (CH_2)_4$ and **g**: $R^1 = 2$-pyridyl; for $R^2 = CH_3$; $R^3 = CH(CH_3)_2$

**Table 1**

Oxidations 1 → 2, yields obtained with individual reagents.

| | | Catalyst/yield [%] | | |
|---|---|---|---|---|

| 4 | **2d** | 93 | 80 | 30 |
| 5 | **2e** | 72 | 77 | 67 |
| 6 | **2f** | 90 | 75 | 70 |
| 7 | **2g** | 72 | 38 | 64 |

Structures of the prepared products **1a–i and 2a–i** were verified by $^1$H NMR and $^{13}$C NMR spectroscopy, EI-MS and elemental analysis. In the case of 2-(4-nitrophenyl)-1,3-diazaspiro[4.4]non-1-en-4-one (**2d**), the NMR spectra revealed the presence of two tautomeric forms; a similar case was described and discussed in Ref. 2b,c. The structure of product 2-(2-hydroxyphenyl)-1,3-diazaspiro[4.4]nonan-4-one (**1e**) and its oxidation product 2-(2-hydroxyphenyl)-1,3-diazaspiro[4.4]non-1-en-4-one (**2e**) was also verified using X-ray diffraction. In molecule **1e** (Fig. 1), the bond distances in the central heterocyclic ring clearly show that all of them are single bonds. The only shortening of bond length is found in the case of N3—C1 bond, which can be attributed to the

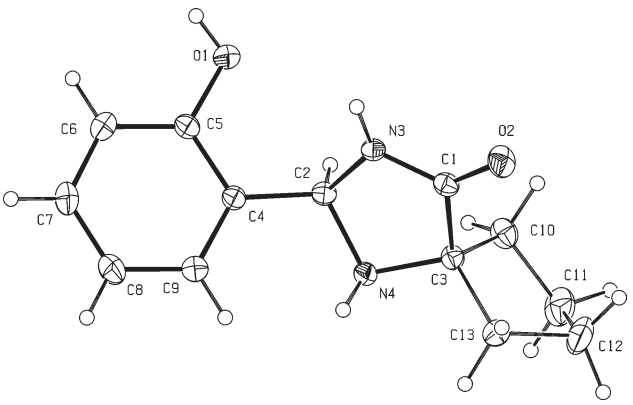

**Figure 1.** Molecular structure of **1e**, ORTEP 30% probability level. **Figure 2.** Molecular structure of **2e**, ORTEP 30% probability level. Selected interatomic distances [Å] and angles [°]:O(2)—C(2) 1.222(2), C(2)—C(3) 1.522(3), C(3)—N(1) 1.476(3), N(1)—C(1) 1.285(3), C(1)—N(2) 1.392(3), N(2)—C(2) 1.369(3), O(2)—C(2)—C(3) 128.50(19), C(2)—C(3)—N(1) 103,75(16), C(3)—N(1)—C(1) 107.77(17), N(1)—C(1)—N(2) 114.03(18), C(1)—N(2)—C(2) 108,72(17), N(2)—C(2)—C(3) 105.73(17), N(2)—C(2)—O(2) 125.8(2).

amido-character of the whole NH—C=O group. Also the C1—O2 interatomic distance corresponds to this character. From the values of bond angles and interplanar angles in this molecule is seen that the central ring is fairly deformed by a distortion of N4 atom from the ring core, and only five atoms (C1, C2, C3, N3, and O2) tend to lie in a plane.

Both molecules **1e** and **2e** are mutually similar. The main difference between them consists in the significant shortening of N1—C1 distance in the case of **2e** (Fig. 2), which corresponds to a typical double bond [9]. This fact the absence of the hydrogen atom at N1 atom and high degree of planarity of the central heterocyclic ring in this molecule are a proof of the oxidation of **1e**–**2e**.

The molecules of compound **1e** are interconnected to the layered supramolecular structure *via* H-bonding (Fig. 3). In the case of compound **2e**, two independent molecules were found in the crystal unit cell. The H-bonding in compound **2e** is slightly less extensive,

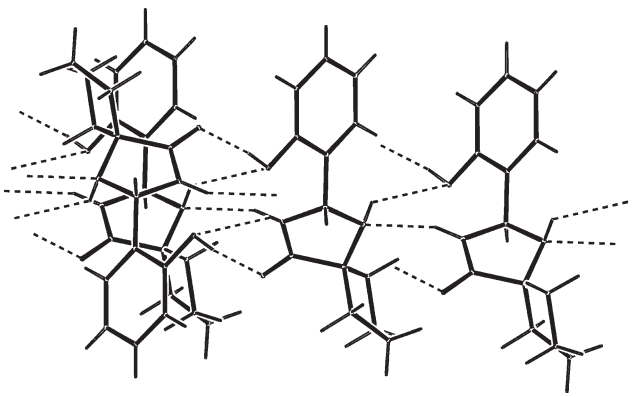

**Figure 3.** Crystal packing diagram of **1e** with hydrogen bonding system.

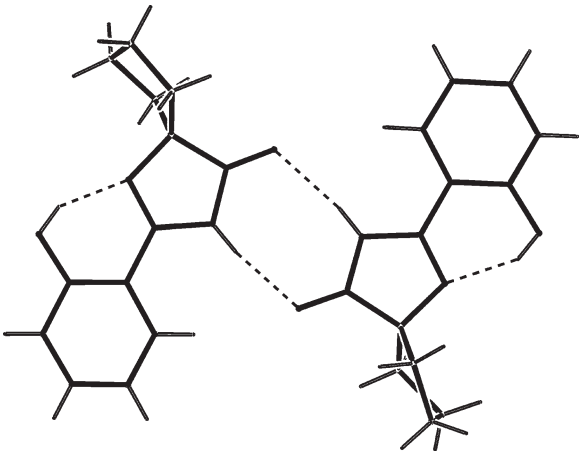

**Figure 4.** Crystal packing diagram of **2e** with hydrogen bonding system.

and only dimers are formed by the connection of amido group, and the imidazole nitrogen atom is connected to the O—H group *via* the intramolecular H-bond which fixed up the coplanarity of the aromatic ring (Fig. 4).

## EXPERIMENTAL

If not stated otherwise, the starting substances were purchased from Sigma-Aldrich. The melting point temperatures have not been corrected. $^1$H NMR and $^{13}$C NMR spectra were recorded on a Bruker Avance 500 instrument (500.13 MHz for $^1$H, and 125.77 MHz for $^{13}$C). Chemical shifts δ are referenced to solvent residual peak (2.50 ppm $^1$H, 39.43 ppm $^{13}$C for DMSO–$d_6$, and 7.26 ppm $^1$H, 77.00 ppm $^{13}$C for $CDCl_3$). The mass spectra were measured with a set of Agilent Technologies (gas chromatograph 6890 N with mass detector 5973 Network); (the samples were dissolved in dichloromethane or acetone). The elemental microanalysis was carried out using an apparatus of FISONS Instruments EA 1108 CHN. The optical rotation was measured on a Perkin–Elmer 341 instrument; the concentration *c* was given in g/100 mL (Optical rotatory power determination).

**Crystallography.** The X-ray data for colorless crystals of **1e** and **2e** were obtained at 150 K using an Oxford Cryostream low-temperature device on a Nonius KappaCCD diffractometer with Mo $K_\alpha$ radiation ($\lambda = 0.71073$ Å), a graphite monochromator, and the ϕ and χ scan mode. Data reductions were performed with DENZO-SMN [10]. The absorption was corrected by integration methods [11]. Structures were solved by direct methods (Sir92) [12] and refined by full matrix least-square based on $F^2$ (SHELXL97) [13]. Hydrogen atoms were mostly localized on a difference Fourier map; however, to ensure uniformity of treatment of crystal, all the hydrogen atoms were recalculated into idealized positions (riding model) and assigned temperature factors $H_{iso}$ (H) = 1.2 $U_{eq}$(pivot atom) or of 1.5 $U_{eq}$ for the methyl moiety with C—H = 0.96, 0.97, 0.98, and 0.93 Å for methyl, methylene, methane, and aromatic-ring hydrogen atoms, respectively; 0.86 Å or 0.93 Å for N—H, and 0.82 Å for O—H bonds. The crystallographic data for structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC no. 757,260 and 757,259

for **1e** and **2e**, respectively. [(Copies of this information may be obtained free of charge from The Director, CCDC, 12 Union Road, Cambridge CB2 1EY, UK (fax: +44-1223-336033; e-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam.ac.uk.)] In Figure 2, there is a disordered cyclopentane ring. The disorder was treated by splitting of carbon atoms into two positions with similar occupancy.

**General method of preparation of imidazolidin-4-ones (1a–g).** A mixture of 1-aminocyclopentancarboxamide [5a] (4.35 g; 34 mmol) or (*S*)-2-amino-2,3-dimethylbutanamide [1] (4.40 g; 34 mmol) and the respective aldehyde (37 mmol), in methanol (20 mL) with a drop of acetic acid was refluxed 12 h. The mixture was evaporated, and the residue was recrystallized from the solvent given.

***2-Butyl-1,3-diazaspiro[4.4]nonan-4-one (1a).*** Yield: 6.3 g (96%); mp 72–74°C (hexane). $^1$H NMR ($CDCl_3$): δ 0.85–0.87 (m; 3H, $CH_3$), 1.25–1.32 (m; 4H, $(CH_2)_2$), 1.36–1.54 (m; 2H, $CH_2$), 1.55–1.64 (m; 6H, $(CH_2)_3$), 1.82–1.88 (m; 2H, $CH_2$), 4.23 (t; 1H; $J$ = 6 Hz; CH), 8.13 (s; 1H; NH). $^{13}$C NMR ($CDCl_3$, ppm): δ 13.7, 22.4, 25.1, 25.2, 26.7; 36.1; 36.5; 37.5; 68.5; 69.2; 182.0. **General methods of preparation of 4,5-dihydro-1*H*-imidazol-5-ones (2a–g)**

***Method A (Pd/C).*** A mixture of the respective imidazolidin-4-one (5 mmol) and Pd/C (5%, 0.2 g) in methanol (50 mL) was refluxed 24 h. The final product was isolated after filtration, evaporation, and (sometimes) recrystallisation from the solvent given. In the case of isolation of compound **2d** the reaction mixture was evaporated, the residue was dissolved in NaOH solution (5%, 25 mL), the solution was filtered and the filtrate acidified to pH ∼ 7–8. The separated crystals of compound **2d** were collected by filtration and dried. The final product was recrystallized from DMF.

***Method B (DDQ).*** A mixture of the respective imidazolidin-4-one (5 mmol) and 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) (1.3 g, 5.7 mmol) in dioxane (50 mL) was refluxed 10 min. The reaction mixture was filtered through a silica gel layer (2 cm), evaporated and (sometimes) recrystallized from the solvent given. In the case of isolation of compound **2d** the reaction mixture was evaporated, the residue was dissolved in NaOH solution (5%, 25 mL), the solution was filtered and the filtrate acidified to pH ∼ 7–8. The separated crystals of compound **2d** were collected by filtration and dried. The final product was recrystallized from DMF.

***Method C ($MnO_2$).*** A mixture of the respective imidazolidin-4-one (5 mmol) and activated manganese (IV) oxide (5 g, 91 mmol) in acetone (100 mL) was refluxed 24 h. The final product was isolated after filtration with kieselguhr, evaporation, and (sometimes) recrystallization from the solvent given. In the case of isolation of compound **2d,** the reaction mixture was evaporated, the residue was dissolved in NaOH solution (5%, 25 mL), the solution was filtered and the filtrate acidified to pH ∼ 7–8. The separated crystals of compound **2d** were collected by filtration and dried. The final product was recrystallized from DMF. The yields of individual compounds are presented in Table 1.

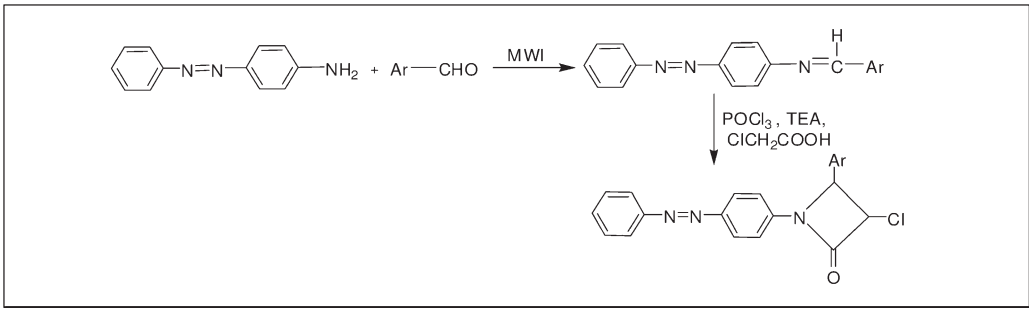
Published online 24 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



*N*-Benzylidene-4-(phenyldiazenyl)aniline (**Ia–Ij**) has been prepared from *p*-aminoazobenzene with different aromatic aldehydes under microwave irradiation, which on further treatment with chloro acetic acid and $POCl_3$ in the presence of triethyl amine gave the title compounds. The structure of the compounds has been confirmed by spectroscopic techniques (IR and $^1H$ NMR) and elemental analysis. These azetidinones analogues were screened for their antimicrobial activities against strains of different microorganisms. Some of the compounds displayed the promising antibacterial activities against some bacterial strains.

*J. Heterocyclic Chem.*, **47**, 1361 (2010).

## INTRODUCTION

The β-lactam skeleton is the key structural element of the most widely used family of antimicrobial agents to date, the β-lactam antibiotics, which includes as representative structural classes (Fig. 1) the Penams 1, Cephems 2, Penems 3, Monobactams 4, Carbapenems 5, and Trinems 6, among others [1]. The first member of this class of compounds was synthesized by Staudinger in 1907 [2]. An interesting group of β-lactams are the monocyclic β-lactams, which are molecules that do not contain another ring fused to the β-lactam. The development of several synthetic 2-azetidinone was due to the growing resistant of bacteria toward the β-lactam antibiotics and need for medicines with a more specific antibacterial activities [3,4]. A large number of monocyclic β-lactams reported to have some other types of biological activity such as antifungal, antitubercular, antitumor, anti-inflamatory, anticonvulsant, cholesterol absorption inhibition, and enzyme inhibition activity [5–10].

Because of such versatile applications, these moieties always attracted the interest of synthetic and medicinal organic chemists [11–14]. A large number of chemical methods for the production of β-lactams have been developed, and the topic has been amply documented and reviewed several times [15]. The hydroxamate cyclization [16], the metalloester enolate-imine condensation [17], the chromium carbene-imine reaction [18], the isocyanate-alkene cycloaddition [19], and the ketene-imine cycloaddition [20] are the approaches most often used for the construction of the azetidin-2-one ring. In particular, the most common method for the synthesis of 2-azetidinone is the Staudinger Ketene-imine cycloaddition, which involves the reaction of imine (Schiff Base) with acid chloride in the presence of tertiary base [21]. This reaction, however, depends on many factors including temperature and reaction time, which often needs to be optimized [22,23].

Hence, to further assess the pharmacological activities of these class of molecules, it was thought worthwhile to synthesize some new derivatives of β-lactam heterocycles by incorporating the *p*-aminoazobenzene and 2-azetidinone moieties in a single framework. We herein report a novel, convenient, and highly efficient method for the preparation of 3-chloro-4-(aryl)-1-(4-(phenyldiazenyl)phenyl)azetidin-2-one **IIa–IIj** in good yields involving two steps. It involves the formation of different Schiff's bases **Ia–Ij** of *p*-aminoazobenzene and aromatic aldehydes followed by the cycloaddition reaction

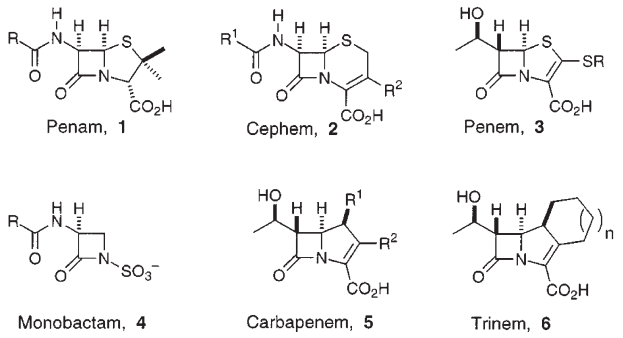


**Figure 1.** Some representative structural classes of β-lactam antibiotics.

of **Ia–Ij** with ketene, which is generated *in situ* from chloroacetic acid in presence of trimethylamine and $POCl_3$ (Scheme 1). The Schiff bases were also prepared by using microwave method [24].

However, the synthesis of Schiff bases **Ia–Ij** under the classical reaction was plagued by a number of serious disadvantages such as low yield of the product as given in Table 1. Therefore, to overcome the drawbacks of the classical method, modern version of this reaction by microwave superheating in solvent and solvent free condition has been adopted. All the synthesized compounds were characterized on the basis of different spectral analysis techniques such as IR and $^1$H NMR and elemental analysis techniques. Also in the present communication, we report the antibacterial activities of the titled compounds (**IIa–IIj**) against nine different bacterial strains.

## RESULTS AND DISCUSSION

As evident from data presented in Table 1, we were able to obtain *N*-arylbenzylidene-4-(phenyldiazenyl)aniline **Ia–Ij** in good yields by using neat conditions under microwave irradiation in presence of solvent and also in solvent free conditions when compared to that of conventional reflux reactions in ethanol. The comparison of isolated yields and reaction time of the three conditions used showed microwave-assisted solvent-free reactions as the most efficient synthetic method in terms of energy and time consumption. All the compounds synthesized were adequately characterized by their elemental analysis and spectral techniques such as IR, $^1$H NMR, and mass spectra.

**Antibacterial activity.** Antibacterial activities of all the compounds were studied against nine different bacterial strains (*E. coli* (mixed), *B. subtilis*, Pseudomonas sp., *S. aureus*, *P.vulageris*, Salmonella sp., *E. coli*(+ve strai,), Rhodococci, *B. stearothermophilus*) by measuring the zone of inhibition on agar plates. The compounds possess moderate to good activity against all strains in comparison with standard drug (Table 2). It can be observed from these results that compounds **IIa–IIj** have shown positive bacterial activity against different bacterial species, which are also known as human pathogenic bacteria. It was also observed that within the synthesized compound extracts, highest zone of inhibition recorded in 3-chloro-4-(furan-2-yl)-1-(4-(phenyl diazenyl) phenyl)azetidin-2-one **(IIe)** extract against the *P. vulageris* 22 mm, which is more than standard, *i.e.*, 17 mm zone of inhibition.

**Scheme 1.** Synthesis of Schiff base with different synthetic path and 3-chloro-4-aryl-1-(4-(phenyldiazenyl)phenyl)azetidin-2-one.

## EXPERIMENTAL

**General.** All the chemicals and solvents were obtained from E-Merck, India (AR grade) and were used without further purification. Melting points were taken in an open capillary tube. The microwave assisted synthesis of Schiff base compounds were carried out in a CEM–908010, bench mate model, 300 watts laboratory microwave reactor. IR spectra were recorded on a Shimadzu Dr-8031 instrument. Elemental analyses were carried out using a Perkin-Elmer, CHN elemental analyzer model 2400. $^1$H NMR spectra of the synthesized compounds were recorded on a Bruker-Avance (300 MHz) and Varian-Gemini (200 MHz) spectrophotometer using $CDCl_3$ solvent and TMS as an the internal standard. EI-MS spectra were determined on a LCQ ion trap mass spectrometer (Thermo Fisher, San Jose, CA, USA), equipped with an EI source.

**Synthesis of Schiff base (Ia–Ij).** ***Microwave method without solvent.*** Equimolar amount of *p*-aminoazo benzene (0.001 mol) and aromatic aldehyde (0.001 mol) were thoroughly mixed in a glass tube, which was loosely closed. The reaction mixture was irradiated for 1min 20 sec with 100 W microwaves at 110°C in MW oven in the temperature control mode. The completion of the reaction was monitored by TLC. The crude product was recrystallized with methanol.

***Microwave method with solvent.*** Equimolar amount of *p*-aminoazobenzene (0.001 mol) and aromatic aldehyde (0.001 mol) and ethanol were taken in a glass tube which was loosely closed and irradiated in MW oven for 1min 20 sec. The completion of the reaction was monitored by TLC. The reaction mixture was allowed to attain room temperature. The solvent was removed, and the crude product was recrystallized with methanol.

**Classical method.** Equimolar amount of *p*-aminoazobenzene (0.001 mol), aromatic aldehyde (0.001 mol), and 10 mL of ethanol was refluxed for 2 hr 30 min. The reaction was monitored by TLC. After completion of the reaction, the reaction mixture was set on one side to cool. Then, the reaction mixture was poured in ice cold water and the solid precipitate was separated out. The precipitate was filtered and collected crude product was recrystallized using methanol.

**General procedure for the preparation of 3-chloro-4-aryl-1-(4-(phenyldiazenyl) phenyl) azetidin-2-one (IIa-IIj).** A mixture of Schiff base **Ia–Ij** (0.002 moles) and chloroacetic acid (0.002 moles) was dissolved in dichloromethane (10 mL) in stoppered conical flask, cooled, and stirred. In cold condition of the reaction mixture, triethylamine [TEA] (0.002 moles) was added in it, followed by dropwise addition of $POCl_3$ in dichloromethane (0.002 moles) with vigorous stirring. The reaction mixture was then stirred for additional 16 hr. The completion of the reaction was monitored by TLC. The reaction mixture was washed with water and dried over sodium sulphate. The products that were obtained after removing the solvent were purified from chloroform.

## CONCLUSIONS

A new method for the synthesis of Schiff base **Ia–Ij** using microwave irradiation offers significant improvements over existing procedures. Also, this simple and reproducible technique affords the products with short reaction times, excellent yields, and without formation of undesirable side products. From data of antimicrobial activity, it could be observed that compounds of the series **IIa–IIj** showing good comparable activity against standard drugs.

**Acknowledgment.** The authors greatly acknowledge Head of the Chemistry Department RTM Nagpur University, for laboratory facilities.

Synthesis of a series of 2-substituted benzimidazoles was carried out for screening anti-inflammatory activities. 2-(*N*-benzylpyrrolyl)-benzimidazoles **9a–k** were synthesized from *N*-benzyl-2-pyrrole carboxylic acids **8a–d** and 4-substituted-1,2-phenylenediamines by cyclocondensation utilizing polyphosphoric acid (PPA) as condensing agent. The *N*-benzyl-2-pyrrole carboxylic acids were prepared by standard method of *N*-benzylation of 2-pyrrole carboxylate using NaH/DMF and appropriately substituted benzyl halides followed by alkaline hydrolysis.

*J. Heterocyclic Chem.*, **47**, 1367 (2010).

## INTRODUCTION

Benzimidazole derivatives are known to possess varied biological activities. Substituted benzimidazole derivatives have been reported to possess anticancer, antiulcer, antiviral, antifungal, antimicrobial, and anti-inflammatory activities [1–6]. Prostaglandins and leukotriens from oxidative metabolism of arachidonic acid play established roles in the pathophysiology of inflammatory disorders [7,8]. Pharmacological interference with cyclooxygenase (COX) and 5-lipooxygenase (5-LOX), enzymes involved in production of prostaglandins and leukotriens is a hallmark feature of virtually all marked nonsteroidal anti-inflammatory drugs (NSAIDs). This property is believed to play an important role in their therapeutic effects and certain mechanism-based side effects including gastrointestinal bleeding, nephrotoxicity, and cardiovascular problems in the case of highly selective cyclooxygenase-2 inhibitors [9–14]. There have been remarkable efforts in developing new classes of compounds to minimize the side effects of the existing NSAIDs. Recent investigations on triazole, imidazole, pyrrole, benzimidazole, and indole derivatives Figure 1 have shown that these classes of heterocycles received much attention as potential NSAIDs [15–25]. Literature survey also revealed that when one bioactive heterocyclic system was coupled with another, a molecule with enhanced biological activity was produced [26–28]. Based on these considerations, in the course of research devoted to the development of new classes of anti-inflammatory agents [29–31], we have speculated that incorporating pyrrole ring into the 2-position of benzimidazole moiety result in compounds with single

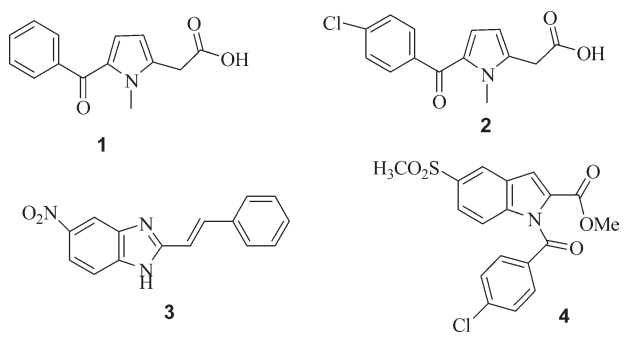

**Figure 1.** Structures of some pyrrole, benzimidazole, and indole derivatives with anti-inflammatory activity.

molecular scaffold that could enhance biological activities. Herein, we report the synthesis of this new class of compounds. The screening of anti-inflammatory activities of these compounds is underway.

## RESULTS AND DISCUSSION

The synthetic routes for the title compounds are outlined in Scheme 1. Pyrrolylbenzimidazoles, **9a–k** were synthesized starting from the commercially available 2-pyrrole carboxylic acid in four steps. Esterification of an acid by refluxing in thionylchloride/methanol mixture afforded the corresponding ester **6**. *N*-benzylation of **6** by treating with NaH/DMF followed by appropriately substituted benzyl halides afforded the corresponding *N*-benzyl-2-pyrrole carboxylates **7a–d**. Alkaline hydrolysis of **7** using 30% aqueous potassium hydroxide gave the carboxylic acids **8a–d**, as key intermediates for the preparation of the targeted benzimidazoles. Cyclocondensation of **8** with 4-substituted-1,2-phenylenediamine carried out utilizing polyphosphoric acid (PPA) as condensing agent afforded the titled compounds in fair to good yield. The chemical structures of all new compounds were established by infrared (IR), $^1$H NMR spectra as well as elemental analysis. The IR-spectral characteristics (all spectra taken in KBr) are quite similar and could be summarized as: ν (N—H): 3150–3185 cm$^{-1}$; ν (C—H) 2900 cm$^{-1}$; ν (—C=N—): 1620–1760 cm$^{-1}$. Detailed $^1$H NMR spectra of the targeted and intermediate compounds is given in the experimental section. The elemental analysis indicated by the symbols of the elements was within ±0.4% of theoretical values. Relevant physical data of the targeted compounds were collected and summarized in Table 1.

## EXPERIMENTAL

Melting points (mp) were determined on Gallenkamp melting point apparatus and are uncorrected. Reagents and solvents were purchased from Sigma-Aldrich Chemical Company (Milwaukee, WI) and used as received. The structures of the products described were confirmed by IR, $^1$H NMR, and elemental analysis data. The IR spectra were run with KBr pellets on Perkin-Elmer 1430 FT spectrometer and are reported in cm$^{-1}$. $^1$H NMR spectra were recorded on Varian Gemini HX-300 MHz spectrometer. All $^1$H chemical shifts (in ppm) are reported relative to tetramethylsilane as internal standard for solutions in DMSO-$d_6$ and $CDCl_3$ as the solvent unless otherwise specified. Elemental microanalysis was performed in Galbraith Laboratories (Knoxville, Tennessee). Analysis indicated by the symbols of the elements was within ±0.4% of the theoretical values. Analytical thin layer chromatography was performed on 250 μm-layer flexible plates. Spots were visualized under Ultraviolet illumination. Reaction products were purified, when necessary, by column chromatography on silica gel 60 (200–425 mesh), with the solvent system indicated. Solvents were evaporated *in vacuo*. Anhydrous sodium sulphate was used as drying agent.

**Preparation of *N*-benzyl-2-pyrrole carboxylates (7a–d); general procedure A.** To a cooled solution of methyl-2-pyrrol carboxylate **6** (1 equiv, 10 mmol), in 12 mL of DMF, NaH (1.5 equiv, 15 mmol) was added in small portions. The reaction mixture was stirred at 0°C for 20 min, the appropriately substituted benzyl halide (1 equiv, 10 mmol) in 0.6 mL DMF was added dropwise. The mixture was warmed to room temperature and stirred for 2 h. Excess hydride was decomposed with a small amount of methyl alcohol. After evaporation to dryness under reduced pressure, the crude residue was washed with water and extracted with ethyl acetate. The combined organic layers were dried over $Na_2SO_4$, and the solvent was evaporated *in vacuo*. The resulting solid was purified by column chromatography (ethyl acetate: hexane) to afford *N*-(4-substitutedbenzyl)-2-pyrrole carboxylates (**7a–d**).

MHz, $CDCl_3$): δ 7.78 (d, $J$ = 7.6 Hz, 2H, $C_{3'}$,$C_{5'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.15–7.22 (m, 3H, $C_{2'}$, $C_{4'}$, $C_{6'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 4.98 (s, 2H, benzyl-$CH_2$), 3.77 (s, 3H, —$COOCH_3$).

***Methyl-N-(4-methylbenzyl)-pyrrole-2-carboxylate (7b).*** Isolated as light yellow oily liquid. Crystallized from absolute ethanol as white crystalline solid, yield 1.68 g (73.3%); $^1$H NMR (300 MHz, $CDCl_3$): δ 7.0–7.4 (m, 4H, $C_{2'}$,$C_{3'}C_{5'}$,$C_{6'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_{4'}$H), 5.08 (s, 2H, benzyl-$CH_2$), 3.72 (s, 3H, —$COOCH_3$), 2.32 (s, 3H, Ar-$CH_3$).

***Methyl-N-(4-chlorobenzyl)-pyrrole-2-carboxylate (7c).*** Isolated as white solid, yield 1.52 g (60.8%); $^1$H NMR (300 MHz, $CDCl_3$): δ 7.08 (d, $J$ = 8.1 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.26 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.20 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, $C_{5'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_{4'}$H), 5.28 (s, 2H, benzyl-$CH_2$), 3.67 (s, 3H, —$COOCH_3$).

***Methyl-N-(4-nitrobenzyl)-pyrrole-2-carboxylate (7d).*** Isolated as white solid, yield 1.68 g (64.6%); $^1$H NMR (300 MHz, $CDCl_3$): δ 7.98 (d, $J$ = 8.1 Hz, 2H, $C_{3'}$,$C_{5'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.20 (d, 2H, $J$ = 8.4 Hz, $C_{2'}$, $C_{6'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.58 (s, 2H, benzyl-$CH_2$), 3.77 (s, 3H, —$COOCH_3$).

**Preparation of *N*-benzyl-2-pyrrole carboxylic acids (8a–d): general procedure B.** A suspension of the *N*-benzyl-pyrrole-2-carboxylates **7a–d** (1 equiv, 10 mmol) was dissolved in MeOH/$H_2O$ (3:1) and 30% KOH (4 equiv). The mixture was heated under reflux for 1–2 h. After cooling to room temperature, the reaction mixture was acidified using 2*N* HCl. The resulting precipitate was filtered and washed with water and petroleum ether to give the desired acids **8a–d**.

***N-benzyl-2-pyrrol carboxylic acid (8a).*** Isolated as white solid, yield 1.92 g (95.5%); $^1$H NMR (300 MHz, $CDCl_3$): δ 13.66 (br, s, 1H, —COOH), 7.7 (d, $J$ = 7.6 Hz, 2H, $C_{3'}$,$C_{5'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.25–7.32 (m, 3H, $C_{2'}$, $C_{4'}$, $C_{6'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 4.98 (s, 2H, benzyl-$CH_2$).

***N-(4-methylbenzyl)-2-pyrrole carboxylic acid (8b).*** Isolated as white solid, yield 2.07 g (96.2%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 13.78 (br, s, 1H, —COOH), 7.06–7,4 (m, 4H, $C_{2'}$,$C_{3'}$ $C_{5'}$, $C_{6'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 6.38 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.20 (m, 1H, pyrrole-$C_4'$H), 5.58 (s, 2H, benzyl-$CH_2$), 2.32 (s, 3H, Ar-$CH_3$).

***N-(4-chlorobenzyl)-2-pyrrole carboxylic acid (8c).*** Isolated as white solid, yield 2.18 g (93%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 13.80 (br, s, 1H, —COOH), 7.11 (d, $J$ = 8.1 Hz,

2H, $C_{3'}$,$C_{5'}$ Ar-H), 7.27 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.20 (d, 2H, $J$ = 8.4 Hz, $C_{2'}$, $C_{6'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.21 (m, 1H, pyrrole-$C_4'$H), 5.52 (s, 2H, benzyl-$CH_2$).

***N-(4-nitrobenzyl)-2-pyrrole carboxylic acid (8d).*** Isolated as white solid, yield 2.22 g (90.2%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 13.78 (br, s, 1H, —COOH), 7.96 (d, $J$ = 8.1 Hz, 2H, $C_{3'}$,$C_{5'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.20 (d, 2H, $J$ = 8.4 Hz, $C_{2'}$, $C_{6'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.58 (s, 2H, benzyl-$CH_2$).

**Preparation of *N*-benzylpyrrole-2-benzimidazoles (9a–k); general procedure C.** To a suspension of PPA (5.2 g) in xylene (15 mL) at 80°C, 4-substituted-1,2-phenylenediamine (1 equiv, 0.2 mmol) and the corresponding acid **(8a–d)** (1 equiv, 0.2 mmol) were added. The temperature was raised to 145°C and stirred for 4 h. The reaction mixture was cooled and diluted with hot water with stirring. The hot reaction mixture was filtered through a Buchner funnel and solid was isolated. The solid was taken in water (60 mL) and neutralized with $NaHCO_3$. The solid was filtered and washed with hot water (2 × 40 mL) and recrystallized from THF.

***2-(N-benzyl-2-pyrrolyl)-benzimidazole (9a).*** Isolated as white solid, yield 2.06 g (75.4%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.59 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_4$,$C_7$—H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.33 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_5$,$C_6$—H), 7.02–7.16 (m, 5H, Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.28 (s, 2H, benzyl-$CH_2$), 5.02 (br, s, 1H, NH).

***2-(N-benzyl-2-pyrrolyl)-5-methylbenzimidazole (9b).*** Isolated as white solid, yield 1.15 g (80.14%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.52 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_7$H), 7.34 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.13 (s, 1H, Bzi-$C_4$H), 7.05 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_6$H), 6.98–7.02 (m, 5H, Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.56 (s, 2H, benzyl-$CH_2$), 5.11 (br, s, 1H, NH), 2.30 (s, 3H, Bzi-$CH_3$).

***2-(N-benzyl-2-pyrrolyl)-5-nitrobenzimidazole (9c).*** Isolated as pale yellow solid, yield 1.06 g (67%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.59 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_7$H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.32 (s, 1H, Bzi-$C_4$H), 7.23 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_6$H), 6.98–7.11 (m, 5H, Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.39 (s, 2H, benzyl-$CH_2$), 5.06 (br, s, 1H, NH).

***N-benzyl-2-pyrrole-5-chlorobenzimidazole (9d).*** Isolated as yellow solid, yield 1.21 g (79%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.59 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_7$H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.33 (s, 1H, Bzi-$C_4$H), 7.23 (d, 1H, $J$ = 8.7Hz, Bzi-$C_6$H), 7.02–7.16 (m, 5H, Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.44 (s, 2H, benzyl-$CH_2$), 5.11 (br, s, 1H, NH).

***2-[N-(4-methylbenzyl)-2-pyrrolyl]-benzimidazole (9e).*** Isolated as white solid, yield 1.07 g (74%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.61 (d, J 7.6 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.59 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_4$,$C_7$—H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.33 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_5$,$C_6$—H), 7.22 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, $C_{5'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.43 (s, 2H, benzyl-$CH_2$), 5.0 (br, s, 1H, NH), 2.32 (s, 3H, Ar-$CH_3$).

***N-(4-methylbenzyl)-2-pyrrolyl-5-nitrobenzimidazole (9f).*** Isolated as white solid, yield 1.24 g (74.7%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.64 (d, $J$ 7.6 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.61 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_7$H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 7.33 (s, 1H, Bzi-$C_4$H), 7.23 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_6$H), 7.22 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, $C_{5'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 5.48 (s, 2H, benzyl-$CH_2$), 5.04 (br, s, 1H, NH), 2.42 (s, 3H, Ar-$CH_3$).

***N-(4-chlorobenzyl)-2-pyrrolylbenzimidazole (9g).*** Isolated as white solid, yield 1.21 g (78.8%). $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.60 (d, $J$ 7.6 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.58 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_4$,$C_7$—H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.33 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_5$,$C_6$—H), 7.22 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, $C_{5'}$-Ar-H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 5.52 (s, 2H, benzyl-$CH_2$), 5.0 (br, s, 1H, NH).

***N-(4-chlorobenzyl)-2-pyrrolyl-5-nitrobenzimidazole (9h).*** Isolated as white solid, yield 1.09 g (61.9%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 7.61 (d, 2H, $J$ 7.6 Hz, $C_{2'}$,$C_{6'}$ Ar-H), 7.62 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_7$H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.31 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_4$H), 7.23 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_6$H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 7.22 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, $C_{5'}$-Ar-H), 5.49 (s, 2H, benzyl-$CH_2$), 5.06 (br, s, 1H, NH).

***N-(4-nitrobenzyl)-2-pyrrolylbenzimidazole (9i).*** Isolated as white solid, yield 0.98 g (61.6%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 8.02 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, $C_{5'}$-Ar-H), 7.59 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_4$,$C_7$—H), 7.54 (d, $J$ 7.6 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 7.33 (d, 2H, $J$ = 8.7 Hz, Bzi-$C_5$,$C_6$—H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_{4'}$H), 5.35 (s, 2H, benzyl-$CH_2$), 5.20 (br, s, 1H, NH).

***N-(4-nitrobenzyl)-2-pyrrolyl-5-methylbenzimidazole (9j).*** Isolated as white solid, yield 1.06 g (63.85%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 8.02 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$, 7.59 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_7$H), $C_{5'}$-Ar-H), 7.54 (d, $J$ 7.6 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 7.33 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_4$H), 7.23 (d, 1H, $J$ = 6 Hz, $C_6$H). 5.44 (s, 2H, benzyl-$CH_2$), 5.20 (br, s, 1H, NH), 2.51 (s, 3H, Ar-$CH_3$).

***N-(4-nitrobenzyl)-2-pyrrolyl-5-chlorobenzimidazole (9k).*** Isolated as white solid, yield 1.12 g (63.6%); $^1$H NMR (300 MHz, DMSO-$d_6$): δ 8.02 (d, 2H, $J$ = 8.4 Hz, $C_{3'}$,$C_{5'}$-Ar-H), 7.59 (d,1H, $J$ = 8.7 Hz, Bzi-$C_7$H), 7.54 (d, $J$ 7.6 Hz, 2H, $C_{2'}$,$C_{6'}$ Ar-H), 7.37 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{5'}$H), 6.4 (d, 1H, $J$ = 1.5 Hz, pyrrole-$C_{3'}$H), 6.23 (m, 1H, pyrrole-$C_4'$H), 7.33 (d, 1H, $J$ = 8.7 Hz, Bzi-$C_4$H), 7.23 (d, 2H, $J$ = 6 Hz, $C_6$H). 5.51 (s, 2H, benzyl-$CH_2$), 5.18 (br, s, 1H, NH).

The reaction of 3-(2-nitrophenyl)-3-hydroxypropanones with $Zn/NH_4Cl$ gave the corresponding quinoline *N*-oxides in 80–90% yields. The reaction initiated the reduction of nitro group to afford the corresponding hydroxylamine, which intramolecularly condensed and followed by dehydration to give quinoline *N*-oxide. Although treatment of 2-nitrochalcone with $Zn/NH_4Cl$ in $EtOH/H_2O$ resulted in the formation of quinoline *N*-oxide in low yield, the reaction of 2-nitrochalcone with $Sn/NH_4Cl$ in refluxing $EtOH/H_2O$ afforded quinoline *N*-oxide in 80% yield.

## INTRODUCTION

Quinoline ring framework can be found in many synthetic and natural compounds of biological importance. Especially, quinoline *N*-oxides (**1**) are important compounds because of their biological activity [1]. The quinoline *N*-oxide core unit has been found in drugs exerting microsomal Na, K-ATPase [2], antiviral [3], or antimalarian activities [4]. The synthetic method of quinoline *N*-oxide mainly devoted to the oxidation of the corresponding quinolines, which were synthesized from 2-aminochalcones or 2-nitrochalcones and Sn/HCl or with Pd/C hydrogenation and cyclization [5]. We have also reported the synthesis of quinolines by the reaction of 2-aminochalcones with NIS or $I_2$ [6]. Direct palladium-catalyzed arylation of quinoline *N*-oxides to 2-arylquinoline *N*-oxides was recently reported [7]. Although Baylis-Hilman adducts reacted with trifluoroacetic acid to give 3,4-substituted quinoline *N*-oxides in 49–82% yields [8], there are few reports on the direct synthesis of quinoline *N*-oxides from chalcones or 3-hydroxy ketones, which afforded mixtures of quinolines and quinoline *N*-oxides [9]. These results prompted us to investigate the direct synthesis of quinoline *N*-oxides from 3-hydroxy ketones (**2**) or 2-nitrochalcones. Herein, we would like to report a direct synthesis of quinoline *N*-oxides from easily available 3-hydroxy ketones **2** and 2-nitrochalcones.

## RESULTS AND DISCUSSION

3-Hydroxy ketones **2** were synthesized by the reaction of 2-nitrobenzaldehydes (**3**) and acetophenones (**4**) in the presence of sodium carbonate by the method recently described by Wang et al. [10] (Scheme 1).

We first tried the metal mediated reductive cyclization of 3-hydroxy-3-(2-nitrophenyl)-1-phenylpropan-1-one **2a** whether 2-phenylquinoline *N*-oxide **1a** or 2-phenylquinoline **5a** would be formed. The results were shown in Table 1. Treatment of **2a** with Sn/HCl resulted in the formation of *N*-oxide **1a** and **5a** in 26 and 60% yields, respectively (entry 1). When Zn/HCl was allowed to react with ketone **2a**, *N*-oxide **1a** was obtained in 46% yield (entry 2). When $Sn/NH_4Cl$ was treated with **2a** at 60°C for 12 h, *N*-oxide **1a** and quinoline **5a** were obtained in 7 and 6% yields, respectively (entry 4). Finally, when $Zn/NH_4Cl$ was used as reducing reagents at 60°C, *N*-oxide **1a** was exclusively obtained in 85% yield (entry 6).

As the optimum conditions (4 equiv Zn/ 3 equiv of $NH_4Cl$, $EtOH/H_2O$, 60°C) were determined, we then tried other 3-hydroxy ketones **2** to investigate the scope and limitation of this method. Treatment of 3-hydroxy-3-(2-nitrophenyl)-1-*p*-tolylpropan-1-one (**2b**) with $Zn/NH_4Cl$ in $EtOH/H_2O$ resulted in the formation of 2-(*p*-tolyl)quinoline *N*-oxide (**1b**) in 90% yield (entry 2). When methyl, methoxy, or chloro groups were substituted on aromatic ring (ketones **2c**–**e**), the corresponding

*N*-oxides **1c–e** were obtained in high yields (entries 2–6). Naphthyl substituted ketone **2g** also afforded 2-naphtylquinoline *N*-oxide **1g** (entry 7). Interestingly, 4-hydroxy-4-(2-nitrophenyl)butan-2-one **2j** also reduced and cyclized to afford 2-methylquinoline *N*-oxide (**1j**) in 86% yield (entry 10). Other quinolines were obtained in high yields (Table 2). Thus, general synthesis of *N*-oxides **1** from easily available 3-hydroxy ketones **2** under mild conditions was achieved.

The reaction might proceed as follows: 3-hydroxy ketone **2a** was reduced by $Zn/NH_4Cl$ to give hydroxylamine **6a** which was easily cyclized under these conditions and dehydrated to give quinoline *N*-oxide **1a** (Scheme 2).

The present method has some advantage over direct Pd-catalyzed arylation of quinoline *N*-oxides [7], which requires $Pd(OAc)_2$ as a catalyst and refluxing toluene for 16 h in 55–91% yields. Additionally, 3 equiv of starting quinoline *N*-oxides were required. The present method requires shorter reaction time (5–6 h) and relatively lower temperature (60°C).

We then tried the reductive cyclization of 2-nitrochalcone (**7a**) whether *N*-oxide **1a** would be exclusively formed. Previously, Barros et al. [9] have reported the reductive cyclization of 2-nitrochalcones with $SnCl_2$/HCl, which led to the mixtures of 2-substituted quinoline *N*-oxides **1** and quinolines **5** in moderate yields. To the best of our knowledge, only one report on the practical synthesis of *N*-oxide **1** from chalcone **7** was appeared, whereas yields were low [11]. Thus, the method of exclusive formation of *N*-oxides **1** from **7** must be required. When chalcone **7a** was treated with Sn/HCl at RT for 1 h, quinoline **5a** was isolated in 80% yield (Table 3, entry 1). Treatment of chalcone **7a**, Pd/C (0.1 equiv), and $H_2$ gas in ethanol (5 h), followed by refluxing for 13 h resulted in the formation of quinoline

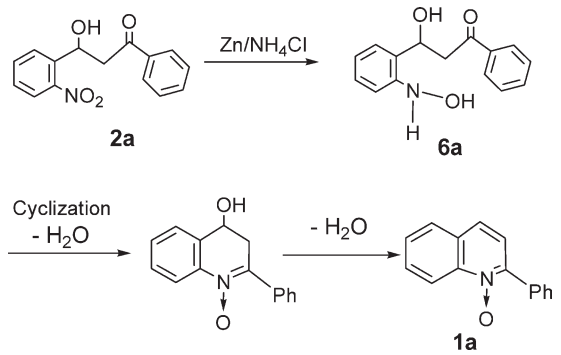
**Scheme 2.** Reaction mechanism.



**5a** in 78% yield (entry 4). In both case, no quinoline *N*-oxide **1a** was obtained. When $Zn/NH_4Cl$ was treated with **7a** at 60°C, *N*-oxide **1a** was obtained in 21% yield along with 15% of starting chalcone **7a** (entry 5). When the reaction was carried in refluxing ethanol for 24 h by using $Sn/NH_4Cl$ as a reducing reagent, *N*-oxide **1a** and quinoline **5a** were obtained in 80% and 4% yields, respectively (entry 8). Prolonged heating resulted in the further reduction of **1a**–**5a** (entries 9–10). Other substituted nitrochalcones **7b–d** also afforded quinoline *N*-oxides **1** in good yields, however, small amount of starting chalcones **7b–d** were still remained unreacted (entries 11–13).

By using metal/HCl as reducing reagents, 2-nitrochalchone **7a** was reduced to give hydroxylamine **8a**. Since carbonyl moiety at trans position of hydroxylamine **8a** prevent intramolecular cyclization, part of which further reduced to give aniline **9a**, then cyclized to afford quinoline **5a** (entries 1–4). On the other hand, by using $Sn/NH_4Cl$, which have lower reducing ability than Sn/HCl, as reducing reagents, target quinoline *N*-oxides **1a** were obtained in acceptable yields, while careful tuning of the reaction time must be required (Scheme 3). Compared to the reductive cyclization of 3-hydroxy ketones **2** (Table 2), the reduction of 2-nitrochalcones required prolonged reaction time.

In summary, we have synthesized 2-substituted quinoline *N*-oxides by one-pot process from 3-hydroxylpropanones or 2-nitrochalcones. This procedure provides a general synthesis of quinoline *N*-oxides from easily available 3-hydroxypropanones or 2-nitrochalcones.

## EXPERIMENTAL

**General.** All chemicals were obtained from commercial suppliers and were used without further purification. Analytical TLC was carried out on precoated plates (Merck silica gel 60, F254) and flash column chromatography was performed with silica (Merck, 70-230 mesh). NMR spectra ($^1H$ at 400 MHz; $^{13}C$ at 100 MHz) were recorded in $CDCl_3$, and chemical shifts are expressed in ppm relative to internal TMS ($\delta = 0.00$) and $CDCl_3$ ($\delta = 77.00$) for $^1H$- and $^{13}C$-NMR. Melting points were uncorrected.

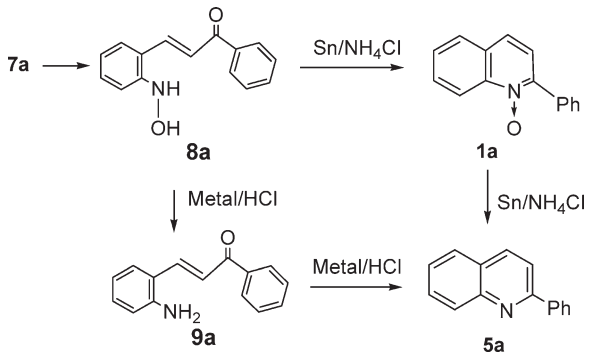
[a] Starting chalcone **7a** was recovered in 5% yield.
[b] 1-(4-Methylphenyl)-3-(2-nitrophenyl)-2-en-1-one **7b** was recovered in 4% yield.
[c] 1-(4-Chlorophenyl)-3-(2-ntrophenyl)-2-en-1-one **7c** was recovered in 3% yield.
[d] 1-Naphtyl-3-(2-nitrophenyl)prop-2-en-1-one **7d** was recovered in 4% yield.

**Scheme 3**



**Materials.** Benzaldehydes **3a–3b** and ketones **4a–4j** were purchased from TCI and Aldrich. Zn powder (<50 nm) was purchased from Aldrich. Sn powder (200 mesh) was purchased from Wako.

**Preparation of 3-hydroxy-3-(2-nitrophenyl)-1-phenylpropan-1-one (2a).** To a solution of acetophenone (1.20 g, 10.0 mmol) and sodium carbonate (0.55 g, 5.2 mmol) in water (60 mL) was added a solution of 2-nitrobenzaldehyde (1.51 g, 10.0 mmol) in ethanol (15 mL) in dropwise. After stirring for 17 h at RT, the reaction mixture was extracted with dichloromethane (10 mL × 3). The combined extract was dried over sodium sulfate, filtered, and evaporated to give brown solid, which was chromatographed over silica gel by elution with hexane-ethyl acetate (5:1) to afford green crystals of **2a** (1.95 g, 7.2 mmol). mp 106–107°C (ref. [11] mp 106–107°C). $^1$H-NMR ($CDCl_3$) δ = 8.00–7.96 (m, 4H), 7.71 (dd, *J* = 8.0, 7.4 Hz, 1H), 7.60 (t, *J* = 7.4, 1.2 Hz, 1H), 7.45–7.50 (m 3H), 5.86 (dd, *J* = 9.3, 2.4 Hz, 1H), 4.01 (d, *J* = 3.1 Hz, 1H), 3.73 (dd, *J* = 17.7, 2.4 Hz, 1H), 3.22 (dd, *J* = 17.7, 9.3 Hz, 1H). $^{13}$C-NMR ($CDCl_3$) δ = 200.2, 147.5, 138.8, 138.6, 136.6, 134.1, 134.0, 129.0(2C), 128.7, 128.5(2C), 128.4, 124.7, 66.2, 46.7.

**1-(5-Bromo-2-hydroxyphenyl)-3-hydroxy-3-(2-nitrophenyl)propan-1-one (2h).** Yield: 74%, purple crystals, mp 92–93°C. $^1$H-NMR ($CDCl_3$) δ = 11.9 (s, 1H), 8.02 (dd, *J* = 7.9, 1.4 Hz, 1H), 7.98 (d, *J* = 7.9, 1.3 Hz, 1H), 7.79 (d, *J* = 2.4 Hz, 1H), 7.73 (ddd, *J* = 7.9, 7.8, 1.3 Hz, 1H), 7.57 (dd, *J* = 8.9, 2.4 Hz, 1H), 7.50 (ddd, *J* = 7.9, 7.8, 1.4 Hz, 1H), 6.93 (d, *J* = 8.9 Hz, 1H), 5.90 (dd, *J* = 9.2, 2.1 Hz, 1H), 3.66 (dd, *J* = 17.8, 2.1 Hz, 1H), 3.41(br, 1H), 3.30(dd, *J* = 17.8, 9.2 Hz, 1H). $^{13}$C-NMR ($CDCl_3$) δ = 204.7, 161.7, 147.4, 139.8, 138.4, 134.3, 132.4, 128.9, 128.6, 124.8, 120.9, 120.6, 111.0, 65.5, 46.9. Calcd for $C_{15}H_{12}NO_3$; C, 67.25; H, 5.05; N, 4.13. Anal. Found; C, 67.49; H, 4.77; N, 4.04.

**2-Bromo-3-hydroxy-3-(2-nitrophenyl)-1-phenylpropan-1-one (2i).** Yield: 52%, colorless crystals, mp 103–104°C. $^1$H-NMR ($CDCl_3$) δ = 8.06 (d, *J* = 8.2 Hz, 1H), 7.94 (d, *J* = 7.2 Hz, 2H), 7.87 (d, *J* = 7.9 Hz, 1H), 7.67 (dd, *J* = 8.2, 7.6 Hz, 1H), 7.55 (dd, *J* = 7.9, 7.6 Hz, 1H), 7.45–7.40 (m, 3H), 5.02 (d, *J* = 5.0 Hz, 1H), 4.83 (d, *J* = 5.0 Hz, 1H). $^{13}$C-NMR ($CDCl_3$) δ = 191.4, 147.4, 135.2, 134.3, 134.2, 130.3, 129.8,

129.5, 129.0(2C), 128.5(2C), 124.9, 60.3, 58.1. Anal. Calcd for $C_{15}H_{12}NO_3$ (-HBr); C, 66.91; H, 4.12; N, 5.20. Found; C, 66.84; H, 4.38; N,5.24.

**4-Hydroxy-4-(2-nitrophenyl)butan-2-one (2j).** Yield: 66%, yellow crystals, mp 55–56°C (ref. [13] mp 52–55°C). $^1$H-NMR ($CDCl_3$) δ = 7.91 (d, *J* = 7.9 Hz, 1H), 7.68 (dd, *J* = 7.9, 7.7 Hz, 1H), 7.45 (dd, *J* = 8.1, 7.7 Hz, 1H), 5.69 (dd, *J* = 9.4, 2.0 Hz, 1H), 3.15 (dd, *J* = 17.8, 2.0 Hz, 1H), 2.73 (dd, *J* = 17.8, 9.4 Hz, 1H), 2.24(s, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 209.1, 147.4, 138.6, 134.1, 128.5, 128.4, 124.7, 65.9, 51.3, 30.7.

**3-Hydroxy-3-(*b*-nitrobenzo[1,3]dioxol-5-yl)-1-phenylpropan-1-one (2k).** Yield: 50%, pale yellow crystals, mp 96–97°C. $^1$H-NMR($CDCl_3$) δ = 7.96 (d, *J* = 7.4 Hz, 2H), 7.60 (dd, *J* = 7.4, 7.4 Hz, 1H), 7.54 (s, 1H), 7.48 (dd, *J* = 7.4, 7.4 Hz, 2H), 7.43 (s, 1H), 6.13 (s, 2H), 5.88 (dd, *J* = 9.2, 2.0 Hz, 1H), 4.03 (d, *J* = 2.2 Hz, 1H), 3.72 (dd, *J* = 17.6, 2.0 Hz, 1H), 3.11 (dd, *J* = 17.6, 9.2 Hz, 1H). $^{13}$C-NMR ($CDCl_3$) δ = 200.3, 152.9, 147.4, 141.3, 136.8, 136.6, 134.0, 129.0(2C), 128.5(2C), 107.4, 105.4, 103.2, 66.4, 46.7. Anal. Calcd for $C_{16}H_{13}NO_6$; C, 60.95; H, 4.16; N, 4.44. Found; C, 60.67; H, 4.36; N, 4.40.

**Reductive cyclization of 2a by using tin and hydrochloric acid.** To a solution of **2a** (0.136 g, 0.5 mmol) and conc HCl (0.17 mL, 0.20 mmol) in EtOH (12 mL) was added Sn powder (0.178 g, 1.5 mmol) in one portion. After being stirred for 1h at 60°C, the reaction mixture was evaporated, washed with water, and extracted with $CH_2Cl_2$ (5 mL × 3). The combined extract was dried over sodium sulfate, filtered, and evaporated to give pale green oily solid, which was chromatographed over silica gel by elution with dichloromethane to afford 2-phenylquinoline *N*-oxide **1a** (0.029 g, 0.13 mmol) and 2-phenylquinoline **5a** (0.062 g, 0.30 mmol). mp 79–80°C (ref. [1] mp 78–79°C).

2-Phenylquinoline *N*-oxide **1a**: yield: 89%, pale yellow crystals, mp 74–75°C (ref. [14] mp 76°C). $^1$H-NMR ($CDCl_3$) δ = 8.87 (d, *J* = 8.8 Hz, 1H), 7.98 (d, *J* = 7.9 Hz, 2H), 7.87 (d, *J* = 7.8 Hz, 1H), 7.80–7.75 (m 2H), 7.65 (dd, *J* = 7.6, 7.4 Hz, 1H), 7.55–7.45 (m 4H). $^{13}$C-NMR ($CDCl_3$) δ = 144.9, 142.2, 133.5, 130.5, 129.6(2C), 129.5, 129.5, 128.4(2C), 128.3, 128.0, 125.2, 123.3, 120.2.

**Reductive cyclization of 2j by using zinc and ammonium chloride.** To a solution of 4-hydroxy-4-(2-nitropohenyl)-2-butanone **2j** (0.142 g, 0.50 mmol) and ammonium chloride (0.080 g, 1.5 mmol) in ethanol-water (1:1, 40 mL) was added zinc powder (0.098 g, 1.5 mmol) in one portion. After stirring for 6 h at 60°C, the reaction mixture was poured into water (20 mL), and extracted with dichloromethane (10 mL × 3). The combined extract was dried over sodium sulfate, filtered, and evaporated to give pale yellow solid, which was recrystallized from methanol to afford 2-methylquinoline *N*-oxide **1j** (0.094 g, 0.43 mmol) colorless crystals. mp 54–55°C (ref. [15] mp 76°C). $^1$H-NMR ($CDCl_3$) δ = 8.80 (d, *J* = 8.6 Hz, 1H), 7.84 (d, *J* = 7.8 Hz, 1H), 7.76 (dd, *J* = 8.6, 8.2 Hz, 1H), 7.66 (d, *J* = 8.6 Hz, 1H), 7.60 (dd *J* = 8.6, 8.2 Hz, 1H), 7.33 (d, *J* = 7.8 Hz, 1H), 2.73 (s, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 146.0, 141.8, 130.5, 129.4, 128.2, 128.0, 125.4, 123.2, 119.8, 19.0.

Other reactions were carried out in a similar manner.

**2-(4-Methylphenyl)quinoline *N*-oxide (1b).** Yield: 90%, orange crystals, mp 112–113°C (ref. [7] mp 127–128°C). $^1$H-NMR ($CDCl_3$) δ = 8.86 (d, *J* = 9.0 Hz, 1H), 7.90 (d, *J* = 8.2 Hz, 2H), 7.85 (d, *J* = 8.2 Hz, 1H), 7.77 (dd, *J* = 8.2, 7.8 Hz, 1H ), 7.73 (d, *J* = 9.0 Hz, 1H), 7.62 (dd *J* = 8.4, 7.8 Hz, 1H), 7.50 (d, *J* = 8.4 Hz, 1H), 7.33 (d, *J* = 8.2 Hz, 2H), 2.43 (s, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 145.4, 142.5, 139.9, 130.8, 129.9, 129.7(2C), 129.7(2C), 129.2, 128.5, 128.2, 125.5, 123.5, 120.5, 21.7.

**2-(3-Methylphenyl)quinoline *N*-oxide (1c).** Yield: 88%, orange crystals, mp 110–111°C. $^1$H-NMR ($CDCl_3$) δ = 8.87 (d, *J* = 8.8 Hz, 1H), 7.88–7.62 (m, 5H), 7.64 (dd, *J* = 7.5, 7.5 Hz, 1H), 7.50 (d, *J* = 8.7 Hz, 1H ), 7.42 (dd *J* = 7.6, 7.6 Hz, 1H), 7.29 (d, *J* = 7.6 Hz, 1H), 2.45(s, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 145.5, 142.6, 138.2, 133.7, 130.8, 130.5, 130.3, 129.8, 128.6, 128.5, 128.2, 126.9, 125.3, 123.7, 120.6, 21.7. Anal. Calcd for $C_{13}H_{15}NO_4$; C, 81.86; H, 5.57; N, 5.95. Found; C, 81.52; H, 5.41; N, 5.78.

**2-(2-Methylphenyl)quinoline *N*-oxide (1d).** Yield: 90%, orange crystals, mp 109–110°C (ref. [7] mp 103–104°C).$^1$H-NMR ($CDCl_3$) δ = 8.85 (d, *J* = 8.7 Hz, 1H), 7.90 (d, *J* = 8.1 Hz, 1H), 7.82–7.71 (m, 2H), 7.66 (dd, *J* = 8.1, 8.1 Hz, 1H ), 7.43–7.29 (m, 5H), 7.62 (dd, *J* = 7.8, 7.8 Hz, 1H), 2.27 (s, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 146.7, 142.0, 137.7, 133.9, 130.4, 130.1, 129.9, 129.3, 129.1, 128.4, 128.0, 125.9, 124.6, 123.8, 120.3, 19.7.

**2-(4-Methoxylphenyl)quinoline *N*-oxide (1e).** Yield: 89%, pale yellow crystals, mp 123–124°C (ref. [7] mp 125–126°C). $^1$H-NMR ($CDCl_3$) δ = 8.86 (d, *J* = 8.8 Hz, 1H), 8.03 (d, *J* = 9.0 Hz, 2H), 7.86 (d, *J* = 8.0 Hz, 1H), 7.78 (ddd, *J* = 8.0, 8.0, 1.4 Hz, 1H), 7.74 (d, *J* = 8.4 Hz, 1H), 7.63 (ddd *J* = 8.4, 8.0, 1.2 Hz, 1H), 7.53 (d, *J* = 8.8 Hz, 1H), 7.05 (d, *J* = 9.0 Hz, 2H), 3.89(s, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 160.7, 144.9, 142.5, 131.5(2C), 130.7, 129.5, 128.4, 128.1, 125.9, 125.4, 123.3, 120.4, 113.9(2C), 55.6.

**2-(4-Chlorophenyl)quinoline *N*-oxide (1f).** Yield: 82%, greenish yellow crystals mp 170–171°C. $^1$H-NMR ($CDCl_3$) δ = 8.84 (d, *J* = 8.8 Hz, 1H), 7.98–7.94 (m, 2H), 7.88 (d, *J* = 8.4 Hz, 1H), 7.80 (dd, *J* = 8.2, 7.8 Hz, 1H), 7.76 (d, *J* = 8.8 Hz, 1H), 7.66 (dd, *J* = 7.8, 7.8 Hz, 1H), 7.52–7.48 (m, 3H). $^{13}$C-NMR ($CDCl_3$) δ = 144.1, 142.6, 135.8, 132.1, 131.2(2C), 131.0, 129.9, 128.9, 128.8(2C), 128.3, 125.6, 123.1, 120.5. Anal. Calcd for $C_{15}H_{10}ClNO_4$; C, 70.46; H, 3.94; N, 5.48. Found; C, 70.51; H, 4.18; N, 5.53.

**2-(1-Naphthyl)quinoline *N*-oxide (1g).** Yield: 80%, colorless crystals, mp 168–169°C (ref. [7] mp 168–169°C). $^1$H-NMR ($CDCl_3$) δ = 8.88 (d, *J* = 9.3 Hz, 1H), 8.02–7.91 (m, 3H), 7.85–7.77 (m, 2H), 7.69(ddd, *J* = 8.1, 6.8 and 1.2 Hz, 1H ), 7.60(d, *J* = 5.6 Hz, 2H), 7.60(d, *J* = 5.6 Hz 2H), 7.55–7.41(m, 4H). $^{13}$C-NMR ($CDCl_3$) δ = 145.6, 142.1, 133.4, 132.1, 130.7, 130.5, 130.1, 129.9, 128.6, 128.6, 128.1, 127.7, 126.9, 126.2, 125.4, 125.4, 124.7, 124.5, 20.4.

**2-(5-Bromo-2-hydroxyphenyl)-quinoline *N*-oxide (1h).** Yield: 89%, pale yellow crystals, mp 167–168°C (ref. [9] mp 167–168°C). $^1$H-NMR ($CDCl_3$) δ = 11.30 (s, 1H, OH), 8.91 (d, *J* = 8.8 Hz, 1H), 8.00 (d, *J* = 8.8 Hz, 1H), 7.96 (d, *J* = 8.2 Hz, 1H), 7.92 (dd *J* = 8.5, 7.9 Hz, 1H), 7.75 (dd, *J* = 8.2, 7.9 Hz, 1H), 7.67 (d, *J* = 8.5 Hz, 1H), 7.62 (s, 1H), 7.57 (d, *J* = 8.8 Hz, 1H), 7.05 (d, *J* = 8.8 Hz, 1H). $^{13}$C-NMR ($CDCl_3$) δ = 159.4, 147.5, 141.1, 135.3, 133.6, 132.2, 129.9, 129.4, 129.2, 128.3, 124.2, 123.5, 122.7, 120.3, 112.0.

**3-Bromo-2-phenylquinoline *N*-oxide (1i).** Yield: 89%, yellow crystals mp 124–125°C (ref. [16] mp 125–127°C). $^1$H-NMR ($CDCl_3$) δ = 8.64 (d, *J* = 7.2 Hz, 1H), 7.70 (d, *J* = 7.6

Hz, 1H), 7.60–7.52 (m, 4H), 7.52 (dd, $J$ = 7.8, 7.8 Hz, 2H), 7.44 (dd, $J$ = 7.4, 7.2 Hz, 1H), 7.27 (s, 1H). $^{13}$C-NMR ($CDCl_3$) δ = 130.1(2C), 129.9, 129.8, 129.7, 129.0, 128.7(2C), 128.6, 128.2, 128.0, 127.6, 127.1, 120.0, 111.3.

**6-Phenyl-[1,3]dioxolo[4,5-g]quinoline *N*-oxide (1k).** Yield: 85%, pale yellow crystals, mp 224–225°C. $^1$H-NMR ($CDCl_3$) δ = 8.22 (s, 1H), 7.91 (dd, $J$ = 8.2, 1.2 Hz, 2H), 7.58 (d, $J$ = 8.6 Hz, 1H), 7.52–7.44 (m, 3H), 7.35 (d, $J$ = 8.6 Hz, 1H), 7.09 (s, 1H), 6.17 (s, 2H). $^{13}$C-NMR ($CDCl_3$) δ = 152.2, 149.5, 133.9, 129.8(2C), 129.5, 129.4, 128.7, 128.4(2C), 127.0, 124.7, 121.9, 103.4, 102.6, 98.5. Anal. Calcd for $C_{16}H_{11}NO_3$; C, 72.45; H, 4.18; N, 5.28. Found; C, 72.28; H, 4.43; N, 5.27.

**Reductive cyclization of 2-nitrochalcone with Sn/HCl.** To a solution of 2-nitrochalchone **7a** (0.253 g, 1.0 mmol) and conc. HCl (0.33 mL, 4.0 mmol) in EtOH (15 mL) was added Sn powder (0.356 g, 3.0 mmol) in one portion. After stirring for 1h at RT, the reaction mixture was evaporated to afford dark solid, which was extracted with EtOAc (5 mL × 3), dried over sodium sulfate, filtered, and evaporated to afford yellow solid. Chromatographic separation of the solid ($SiO_2$, EtOAc:hexane = 1:1) gave 2-phenylquinoline **5a** (0.164 g, 0.80 mmol).

**Reductive cyclization of 2-nitrochalcone with Pd/C.** To a solution of 2-nitrochalcone **7a** (0.253 g, 1.0 mmol) in EtOH (15 mL) was added Pd/C (10%, 0.053 g, 0.05 mmol) in one portion. After stirring for 3 h under hydrogen atmosphere, the reaction mixture was refluxed for 8h, and evaporated to give dark brown oily crystals, which was chromatographed over silica gel by elution with EtOAc:Hexane (1:5) to give **5a** (0.160 g, 0.78 mmol).

**Reductive cyclization of 2-nitrochalcone with Sn/$NH_4Cl$.** To a solution of 2-nitrochalcone **7a** (0.127 g, 0.50 mmol) and ammonium chloride (0.080 g, 1.5 mmol) in ethanol-water (1:1, 40 mL) was added tin powder (0.178 g, 1.5 mmol) in one portion. After refluxing for 26 h, the reaction mixture was poured into water (20 mL), and extracted with dichloromethane (10 mL × 3). The combined extract was dried over sodium sulfate, filtered, and evaporated to give pale yellow crystals, which was chromatographed over silica gel to afford 2-phenyllquinoline *N*-oxide **1a** (0.088 g, 0.40 mmol) and 2-phenylquinoline **5a** (0.004 g, 0.02 mmol).

Other reactions were carried out in a similar manner.

2-(4-Methylphenyl)quinoline *N*-oxide **1b** (0.109 g, 0.41 mmol): mp 112–113°C. 2-(4-Chlorophenyl)quinoline *N*-oxide **1f** (0.115 g, 0.40 mmol): mp 170–171°C. 2-Naphtylquinoline *N*-oxide **1g** (0.124 g, 0.41 mmol): mp 168–169°C.

A series of pyrazolo [3,4-d] pyrimidine, pyrazolo [1,5-a] pyrimidine, and pyrazolyl triazoles have been prepared *via* reaction of ethyl 5-amino-3-phenylpyrazole-4-carboxylate with isothiocyanic esters, α,β-unsaturated nitriles, and some active methylene reagents.

*J. Heterocyclic Chem.,* **47**, 1379 (2010).

## INTRODUCTION

In the past decade, we have been involved in a program aiming at the synthesis of new heterocyclic compounds that may possess biologically active properties to be used as potential biodegradable agrochemicals [2–5]. In continuation of our earlier interest in 3(5)-aminopyrazole, we report here an efficient synthesis of the *hitherto* unreported ethyl 5-amino-3-phenyl-1*H*-pyrazole-4-carboxylate **3** and its exploitation for the synthesis of some new fused pyrazole derivatives.

## RESULTS AND DISCUSSION

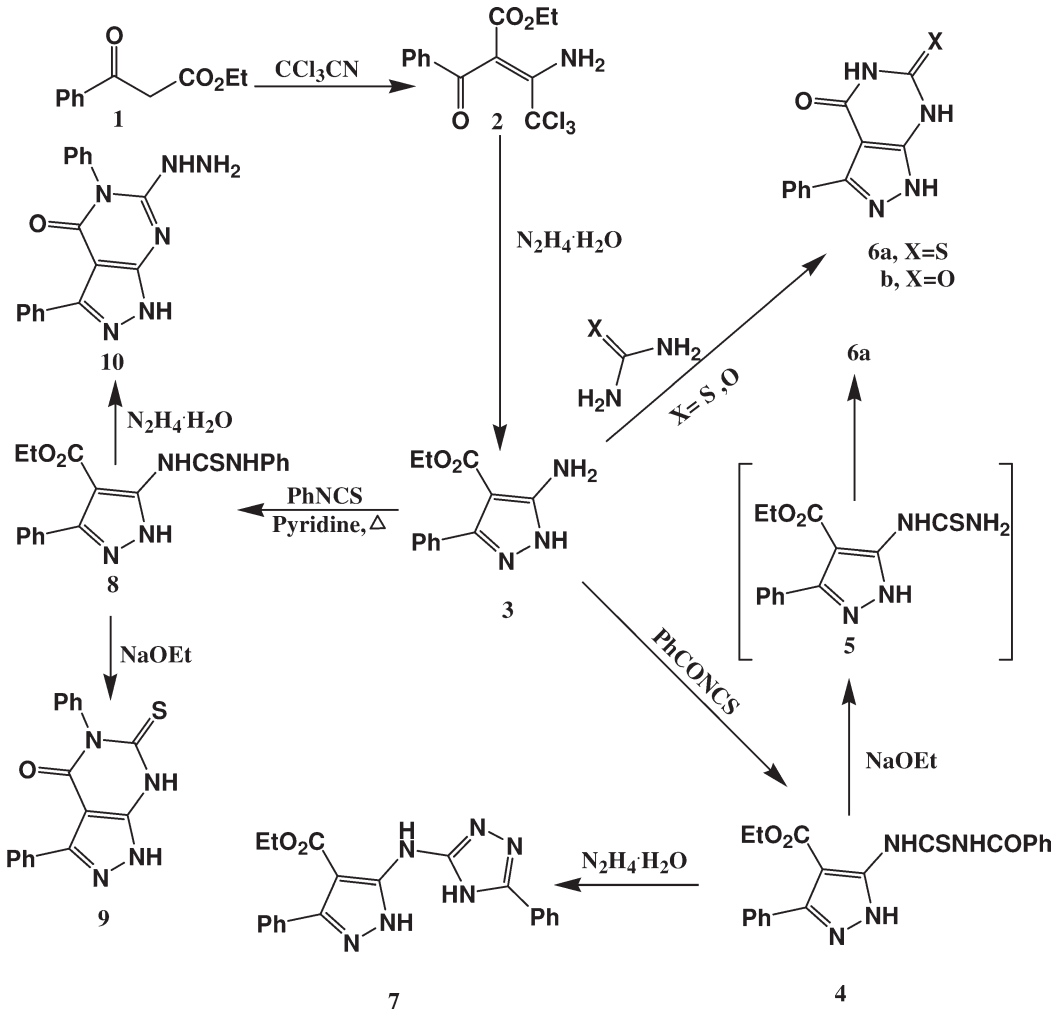
Thus, ethyl benzoylacetate **1** reacts with trichloroacetonitrile in ethanol catalyzed by sodium acetate to afford 1:1 adduct, which could be formulated as ethyl 3-amino-2-benzoyl-3-trichloromethyl acrylate derivative **2**. Structure **2** was assigned to this adduct on the basis of analytical and spectral data (cf. Experimental part). The reaction of **2** with hydrazine hydrate in refluxing pyridine afforded directly ethyl 5-amino-3-phenyl-1*H*-pyrazole-4-carboxylate **3**. The formation of **3** is assumed to occur *via* nucleophilic attack of hydrazine $NH_2$ on **2** with elimination of chloroform followed by the condensation of the hydrazide $NH_2$ with the benzoyl-carbonyl group with elimination of water. This cyclization was expected to occur with elimination of ethanol; however, all spectral evidence showed the presence of the ester function.

Thus, IR spectrum of the product showed that absorption bands at $\upsilon_{max}$ = 1651, 3415, and 3365 $cm^{-1}$ attributable to carbonyl and amino groups. The $^1H$ NMR spectrum revealed a triplet at δ = 1.17–1.24 ppm ($J$ = 10.6 Hz) and quartet at δ = 4.12–4.23 ppm ($J$ = 10.6 Hz) characteristic for ethyl ester group, a singlet (2H, $D_2O$ exchangeable) at δ = 6.21 ppm for amino group, a multiplet (5H) at δ = 7.42–7.66 ppm for aromatic protons, and a broad singlet (1H) at δ = 12.05 ppm for the pyrazole NH. Moreover, the mass spectrum of the reaction product showed a strong absorption at $m/z$ = 231 (48%), which is compatible with the molecular formula $C_{12}H_{13}N_3O_2$ for compound **3**.

Aminopyrazoles are the most extensively utilized heterocyclic amines in heterocyclic synthesis due to their ready availability as well as their stability, which makes them useful precursors in dyes, pharmaceuticals, and agrochemical industries [6–13].

In conjunction with our interest in exploring the potential utility of functionally substituted pyrazoles

**Scheme 1.** Preparation of compounds **2**, **3**, **4**, **6a,b**, **7**, **8**, **9** and **10**.

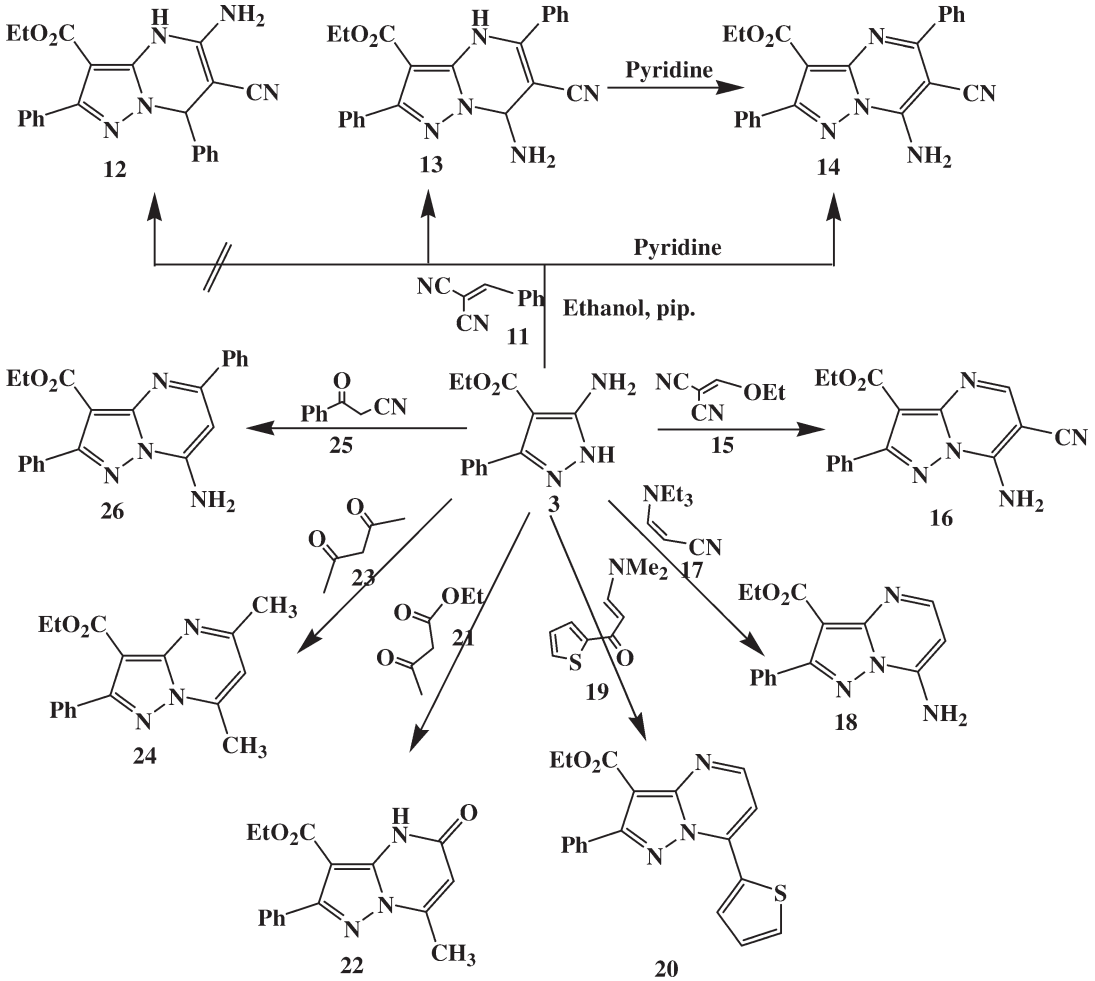


[14–16], we report here a simple and efficient synthesis of some new polyfunctionally substituted pyrazolopyrimidines of expected biological interest starting with our new pyrazole **3**.

Thus, ethyl 5-amino-3-phenyl-1*H*-pyrazole-4-carboxylate **3** reacts with benzoyl isothiocyanate and phenyl isothiocyanate to afford the 1:1 adducts **4** and **8**, respectively, *via* electrophilic attack at the amino group, which was considered most likely for these adducts based on their stability under the conditions reported to effect decomposition of *N*-thiocarbamoyl pyrazoles [16–18]. Attempts to effect cyclization of both reaction products **4** and **8** by boiling in ethanolic sodium ethoxide has resulted in the formation of pyrazolo[3,4-d]pyrimidines **6a** and **9**, respectively. Structures **6a** and **9** are identified on the basis of analytical and spectral data, where the $^1$H NMR spectrum of **6a** revealed the presence of a multiplet at $\delta$ = 7.45–8.15 ppm (5H) for aromatic protons and three singlets at $\delta$ = 11.82, 12.99, and 13.88 ppm for NH-pyrazole and two NH-pyrimidine protons. The formation of **6a** from **4** seemed to proceed *via* alcoholysis with loss of the benzoyl moiety and the formation of the nonisolable intermediate **5**, which undergoes cyclization through ethanol elimination to give **6a** (Scheme 1). An authentic sample of **6a** has been obtained from the reaction of the pyrazole **3** with thiourea by fusion in an oil bath at 120°C (The same melting point, mixed melting point, and same analytical and spectral analyses). The loss of the benzoyl moiety in similar reaction is reported in [16–18].

The thiourea derivatives **4** and **8** reacted with hydrazine hydrate and afforded products for which structures **7** and **10** were assigned on the basis of analytical and spectral analyses, where the $^1$H NMR spectrum of **7** showed the presence of a triplet at $\delta$ = 1.13 ppm ($J$ = 7.2 Hz), a quartet at $\delta$ = 4.15 ppm ($J$ = 7.2 Hz), a

**Scheme 2.** Preparation of compounds **13**, **14**, **16**, **18**, **20**, **22**, **24** and **26**.



multiplet at δ = 7.45–8.15 ppm for 10 protons (aromatic protons), a singlet at δ = 9.20 ppm for Pyrazole-NH, and two singlets at δ = 11.90 and 13.05 ppm for both exocyclic NH and triazole-NH protons.

On the other hand, the $^{1}$H NMR of **10** revealed the presence of a singlet at δ = 5.56 ppm for the amino group protons, a multiplet at δ = 7.11–8.39 ppm integrated for 10H (2-Ph protons), a singlet at δ = 9.47 ppm for pyrazole-NH, and a singlet at δ = 13.18 ppm for hydrazine-NH. The $^{13}$C NMR spectrum of **10** revealed signals at 102.64 (C-4 pyrazolopyrimidine), 121.62, 123.60, 127.54, 128.18, and 128.62 (CH aromatic), 132.77 (C-9 pyrazolopyrimidine), 136.28, 138.25, and 147.12 (CH aromatic), 150.91 (C-3 pyrazolopyrimidine), 153.76 (C-7 pyrazolopyrimidine), and 157.59 (C-6 pyrazolopyrimidine) (CO).

The pyrazolo[3,4-*d*]pyrimidine-4,6-dione analogue **6b** has been obtained *via* reaction of the 5-aminopyrazole **3** with urea on fusion in oil bath at 120°C. Structure **6b** was assigned on the basis of elemental analysis and spectral data (cf. Experimental section).

Pyrazolo[1,5-*a*]pyrimidines are important due to their ability to inhibit 3′,5′-cyclic phosphodiestrase and their cardiotropic properties [19,20]. Moreover, the reported activities of pyrazolo[1,5-*a*]pyrimidines as antipyretics, anti-inflammatory, anticancer, and antischistosomal agents [21–23] prompted us to prepare some of their new derivatives *via* reacting our new 5-aminopyrazole derivative **3** with some α,β-unsaturated nitriles and active methylene reagents.

Thus, ethyl 5-amino-3-phenyl-1*H*-pyrazole-4-caboxylate **3** reacts with the cinnamonitrile derivative **11** in refluxing ethanol with few drops of piperidine as a catalyst to afford products for which structures **12** or **13** seemed possible (cf. Scheme 2).

The spectral data of the reaction products suggested structure **13** to be assigned to this product rather than **12** (cf. Experimental section). Compound **13** was transformed into the fully aromatic pyrazolo[1,5-*a*]pyrimidine derivative **14** on reflux in pyridine. When the reaction of **3** with **11** was carried out in refluxing pyridine compound **14** was also obtained. The identity of the two

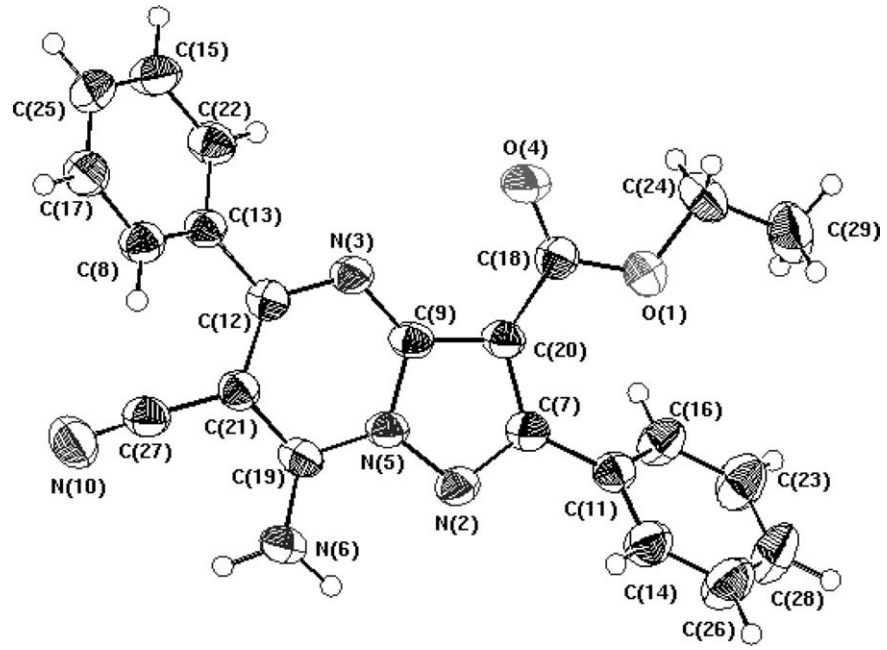


**Figure 1.** Single crystal X-ray structure of compound **14** [24–26].

products was inferred from melting points and spectral data. Structure **14** was assigned on the basis of the $^{13}C$ NMR and $^{1}H$ NMR spectra which revealed the disappearance of the pyrimidine-4-H signal and presence of a singlet at $\delta = 6.83$ ppm integrated for two protons ($NH_2$ protons) in addition to the other expected signals for aromatic and ethyl ester protons (cf. Experimental). The formation of **14** from **13** apparently takes place *via* auto-oxidation under the reaction conditions. Similar reactions have been reported [22,23].Structure **14** was unambiguously confirmed on the basis of the single crystal X-ray analysis [24–26] (cf. Fig. 1).

The aminopyrazole **3** reacted with ethoxy-methylene malononitrile **15** and afforded a product for which structure **16** is established based on analytical and spectral analyses.

On the other hand, when the 5-aminopyrazole **3** was condensed with both the enaminonitrile **17** and the enaminone **19**, it yielded the pyrazolo[1,5-*a*]pyrimidine derivatives **18** and **20**, respectively.

Structure **18** could be established on the basis of spectral analysis where the $^{1}H$ NMR spectrum revealed the amino group as a singlet at $\delta = 9.94$ ppm and the appearance of two doublets at $\delta = 6.56$ ppm ($J = 7.2$ Hz) and $\delta = 8.26$ ppm ($J = 7.2$ Hz) which may be attributed to H-5 and H-6.

5-Aminopyrazole-4-carboxylate **3** was also condensed with ethyl acetoacetate **21**, acetylacetone **23**, and benzoylacetonitrile **25** by fusion on oil bath at 100–120°C to yield products for which structures **22**, **24**, and **26** have been established, respectively, on the basis of analytical and spectral analyses. The IR spectrum of compound **22** revealed an absorption band at $\nu_{max} = 1712$ cm$^{-1}$ for carbonyl ester and another band at $\nu_{max} = 1662$ cm$^{-1}$ for amide carbonyl group.

The $^{1}H$ NMR spectrum of **24** showed two singlets at $\delta = 2.70$ and 2.80 ppm for the two methyl groups and a singlet at $\delta = 6.75$ ppm for pyrimidine-CH proton, beside the other expected signals for aromatic and ethyl ester protons. The formation of **26** apparently proceeds in a manner similar to the addition of the cinnamonitrile **11** shown above (cf. Scheme 2, Fig. 1, Experimental).

## EXPERIMENTAL

The melting points were determined on a Stuart melting point apparatus and are uncorrected. The IR spectra were recorded as KBr pellets using a FTIR unit Bruker-Vector 22 spectrophotometer. The $^{1}H$ and $^{13}C$ NMR spectra were recorded in DMSO-$d_6$ as solvent at 300 MHz and 75 MHz, respectively, on Varian Gemini NMR spectrometer using TMS as internal standard. Chemical shifts are reported in $\delta$ units (ppm). Mass spectra were measured on a Shimadzu GCMS - QP-1000 EX mass spectrometer at 70 eV. The elemental analyses were performed at the Micro analytical Center, Cairo University. The single crystal structure [24–26] was determined by X-ray unit at the National Research Center, Dokki, Giza, A. R. Egypt.

**3-Amino-2-benzoyl-4,4,4-trichloro-butyric acid ethyl ester (2).** To a solution of ethyl benzoylacetate **1** (1.92 g, 10 mmol) in absolute ethanol (50 mL) containing sodium acetate,

trichloroacetonitrile (1.44 g, 10 mmol) was added. Stirring lasted overnight at room temperature then the reaction mixture was poured into cold water. The resulting product obtained was filtered off, dried, and recrystallized from ethanol. White crystal (yield 80%), m.p. 107°C. $\nu_{max}$ $cm^{-1}$ = 3375, 3240 ($NH_2$), 1674, 1645 (CO). MS: *m/z* 336 ($M^+$). Anal. Calcd. for $C_{13}H_{12}Cl_3NO_3$ (336.05): C, 46.38; H, 3.59; N, 4.16; Cl, 31.59%. Found: C, 46.31; H, 3.52; N, 4.11; Cl, 31.53%.

**5-Amino-3-phenyl-1*H*-pyrazole-4-carboxylic acid ethyl ester (3).** To a suspension of **2** (3.36 g, 10 mmol) in ethanol was added the equivalent amount of hydrazine hydrate (0.50 mL, 10 mmol) and triethylamine as catalyst. The reaction mixture was refluxed for 5 h and then concentrated in *vacuo*. The solid product obtained upon cooling was isolated by filtration and recrystallized from a mixture of ethanol/dioxane. White crystal (yield 50%). m.p. 172°C. $\nu_{max}$ $cm^{-1}$ = 3415, 3365 ($NH_2$), 3245, 1651 (CO). MS: *m/z* 231 ($M^+$). $\delta_H$ = 1.17 (t, 3H, *J* = 10.6 Hz, $CH_3$), 4.12 (q, 2H, *J* = 10.6 Hz, $CH_2$), 6.21 (s, 2H, $NH_2$), 7.42–7.66 (m, 5H, Ar-H), 12.04 (s, 1H, NH-pyrazole). Anal. Calcd. for $C_{12}H_{13}N_3O_2$ (231.26): C, 62.32; H, 5.66; N, 18.17%. Found: C, 62.25; H, 5.60; N, 18.08%.

**5-(3-Benzoyl-thioureido)-3-phenyl-1*H*-pyrazole-4-carboxylic acid ethyl ester (4).** A solution of **3** (2.31 g, 10 mmol) and benzoyl isothiocyanate (1.63 g, 10 mmol) in dry acetone (50 mL) were refluxed for 5 h. The reaction mixture was evaporated under vacuo. The resulting solid was collected by filtration and crystallized from ethanol. White crystal (yield 50%), m.p. 158°C. $\upsilon_{max}$ $cm^{-1}$ = 3425, 3193 (NH), 1720, 1681 (CO). MS: *m/z* 394 ($M^+$). Anal. Calcd. for $C_{20}H_{18}N_4O_3S$ (394.45): C, 60.89; H, 4.59; N, 14.20; S, 8.12%. Found: C, 60.81; H, 4.53; N, 14.13; S, 8.08%.

**Synthesis of (6a). Method 1.** Compound **4** (10 mmol) was treated with ethanolic sodium ethoxide (0.23 g sodium in 50 mL ethanol), the reaction mixture was refluxed for 3 h and allowed to cool then poured into cold water and neutralized with dil. HCl. The resulting product was collected by filtration and crystallized from ethanol to afford **6a** in 72% yield.

**Synthesis of (6a, b).** Compound **3** (2.31 g, 10 mmol) was treated with thiourea (0.76 g, 10 mmol) or urea (0.60 g, 10 mmol) and the reaction mixture was heated in oil bath at 100–120°C for 2 h. The mixture was allowed to cool at room temperature. The formed solid product was crystallized from ethanol/dioxane to afford **6a** and **6b**, respectively.

***3-Phenyl-6-thioxo-1,5,6,7-tetrahydro-pyrazolo [3,4-d] pyrimidin-4-one (6a).*** Pale brown crystal (yield 65%), m.p > 300°C. $\upsilon_{max}$ $cm^{-1}$ = 3215, 3120 (NH), 1593 (CO). MS: *m/z* 244 ($M^+$). $\delta_H$ = 7.50–8.15 (m, 5H, Ar-H), 11.82 (s, 1H, NH-pyrazole), 12.99 (s, 1H, NH-pyrimidine), 13.88 (s, 1H, NH-pyrimidine). Anal. Calcd. for $C_{11}H_8N_4OS$ (244.27): C, 54.09; H, 3.30; N, 22.93; S, 13.34%. Found: C, 54.02; H, 3.27; N, 22.85; S, 13.29%.

***3-Phenyl-1,7-dihydro-pyrazolo [3,4-d] pyrimidine-4,6-dione (6b).*** Pale yellow crystal (yield 60%), m.p > 300°C. $\upsilon_{max}$ $cm^{-1}$ = 3430, 3223 (NH), 1730, 1640 (CO). MS: *m/z* 228 ($M^+$). $\delta_H$ = 7.43–8.14 (m, 5H, Ar-H), 10.65 (s, 1H, NH-pyrazole), 11.35 (s, 1H, NH-pyrimidine), 13.55 (s, 1H, NH-pyrimidine). Anal. Calcd. for $C_{11}H_8N_4O_2$ (228.21): C, 57.89; H, 3.53; N, 24.55%. Found: C, 57.81; H, 3.48; N, 24.49%.

**3-Phenyl-5-(3-phenyl-thioureido)-1*H*-pyrazole-4-carboxylic acid ethyl ester (8).** Phenyliso-thiocyanate (1.35 g, 10 mmol) was added to a solution of **3** (2.31 g, 10 mmol) in pyridine and were refluxed for 3 h and then allowed to cool at room temperature. The reaction mixture was poured into ice cold water and neutralized with dil. HCl. The resulting solid was collected by filtration and crystallized from ethanol. The product is identified as **8**. Pale yellow crystal (yield 50%), m.p. 218°C. $\upsilon_{max}$ $cm^{-1}$ = 3355, 3210 (NH), 1654 (CO). MS: *m/z* 366 ($M^+$). Anal. Calcd. for $C_{19}H_{18}N_4O_2S$ (366.49): C, 62.26; H, 4.95; N, 15.28; S, 8.74%. Found: C, 62.21; H, 4.89; N, 15.23; S, 8.68%.

**3,5-Diphenyl-6-thioxo-1,5,6,7-tetrahydro-pyrazolo [3,4-*d*] pyrimidin-4-one (9).** Compound **8** (10 mmol) was treated with ethanolic sodium ethoxide solution (0.23 g sodium in 50 mL absolute ethanol). The reaction mixture was heated under reflux for 3 h, allowed to cool, then poured onto ice cold water and neutralized with dil. HCl. The resulting solid product is collected by filtration and crystallized from ethanol and identified as **9**. White crystal (yield 55%), m.p. > 300°C. $\upsilon_{max}$ $cm^{-1}$ = 3153, 3056 (NH), 1696 (CO). MS: *m/z* 320 ($M^+$). Anal. Calcd. for $C_{17}H_{12}N_4OS$ (320.37): C, 63.73; H, 3.77; N, 17.48; S, 10.00%. Found: C, 63.64; H, 3.69; N, 17.40; S, 9.92%.

**General method for preparation of (7) and (10).** Compound **4** or **8** (10 mmol) reacted with hydrazine hydrate (0.50 mL, 10 mmol) in pyridine (25 mL) and heated under reflux for 3 h, then allowed to cool at room temperature. The reaction mixtures were poured onto ice cold water and neutralized with dilute HCl. The resulting solids were collected by filtration and crystallized from ethanol.

***3-Phenyl-5-(5-phenyl-4H-[1,2,4]triazol-3-ylamino)-1H-pyrazole-4-carboxylic acid ethyl ester (7).*** Pale brown crystal (yield 70%), m.p. > 300°C. $\upsilon_{max}$ $cm^{-1}$ = 3325, 3175, 3150 (NH), 1676 (CO). MS: *m/z* 374 ($M^+$). $\delta_H$ = 1.13(t, 3H, *J* = 7.2 Hz, $CH_3$), 4.15 (q, 2H, *J* = 7.2 Hz, $CH_2$), 7.45–8.15 (m, 10H, 3Ar-H), 9.20 (s, 1H, NH-pyrazole). 11.90 (s, 1H, NH), 13.05 (s, 1H, NH-triazole). Anal. Calcd. for $C_{20}H_{18}N_6O_2$ (374.41): C, 64.42; H, 4.84; N, 22.44%. Found: C, 64.38; H, 4.80; N, 22.37%.

***6-Hydrazide-3,5-diphenyl-1,5-dihydro-pyrazolo [3,4-d] pyrimidin-4-one (10).*** White crystal (yield 50%), m.p. 295°C. $\upsilon_{max}$ $cm^{-1}$ = 3350, 3235 ($NH_2$), 3150 (NH). MS: *m/z* 318 ($M^+$). $\delta_H$ = 5.56 (s, 2H, $NH_2$), 7.11–8.39 (m, 10H, 2Ar-H), 9.47 (s, 1H, NH-pyrazole), 13.18 (s, 1H, NH-hydrazide). $\delta_C$ = 102.64 (C-4 pyrazolopyrimidine), 121.62, 123.60, 127.54, 128.18, and 128.62 (CH aromatic), 132.77 (C-9 pyrazolopyrimidine), 136.28, 138.25, and 147.12 (CH aromatic), 150.91 (C-3 pyrazolopyrimidine), 153.76 (C-7 pyrazolopyrimidine), 157.59 (C-5 pyrazolopyrimidine) (CO). Anal. Calcd. for $C_{17}H_{14}N_6O$ (318.34): C, 64.14; H, 4.43; N, 26.39%. Found: C, 64.09; H, 4.38; N, 26.31%.

**7-Amino-6-cyano-2,5-diphenyl-4,7-dihydro-pyrazolo[1,5-*a*] pyrimidine-3-carboxylic acid ethyl ester (13).** Compounds **11** (1.54 g, 10 mmol) were refluxed for 3 h with compound **3** (2.31 g, 10 mmol) in ethanol (50 mL) and few drops of piperidine as catalyst. The reaction mixture was then poured into ice-cold water and neutralized with dilute HCl. The resulting solid product was collected by filtration and crystallized from ethanol. White crystal (yield 65%), m.p. 220°C. $\upsilon_{max}$ $cm^{-1}$ = 3446, 3400 ($NH_2$), 3315 (NH), 2190 (CN), 1686 (CO). MS: *m/z* 385 ($M^+$). $\delta_H$ ($CDCl_3$) = 1.18 (t, 3H, *J* = 7.2 Hz, $CH_3$), 4.17 (q, 2H, *J* = 7.2 Hz, $CH_2$), 5.48 (s, 3H, $NH_2$, CH-pyrimidine), 6.72 (s, 1H, NH-pyrimidine), 7.39–7.70 (m, 10H, 2Ar-H). Anal. Calcd. for $C_{22}H_{19}N_5O_2$ (385.43): C, 68.55; H, 4.96; N, 18.17%. Found: C, 68.50; H, 4.92; N, 18.08%.

**7-Amino-6-cyanio-2,5-diphenyl-pyrazolo[1,5-*a*]pyrimidine-3-carboxylic acid ethyl ester (14).** Compound **13** (3.85 g, 10 mmol) was dissolved in 25 mL pyridine (or 25 mL DMF) and heated under reflux for 3 h, then evaporated in vacuo and diluted with cold water (50 mL) then treated with few drops of dil. HCl. The resulting solid product is filtered off, washed well with cold water, and crystallized from ethanol/dioxane mixture. The solid product is identified as **14**. Brown crystal (yield 55%), m.p. 208°C. $\upsilon_{max}$ $cm^{-1}$ = 3415, 3365 ($NH_2$), 2219 (CN), 1685 (CO). Published online 25 August 2010 in Wiley Online Library (wileyonlinelibrary.com).

Sulfamic acid catalyzed the synthesis of substituted 1,3-oxazines by one-pot three-component reaction of aniline, alkynoates, and formaldehyde in excellent yields. The catalyst possesses distinct advantages shows ease of handling, good yields, cleaner reactions, nonhygroscopic, noncorrosive, and high activity. Sulfamic acid is a green alternative for metal-containing acidic materials, which are toxic and deleterious for human health and environmental protection.

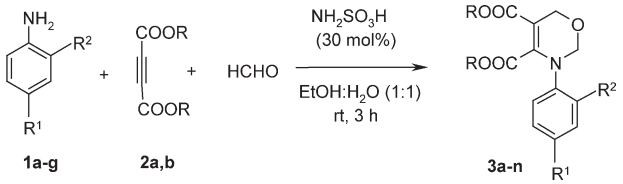
## INTRODUCTION

The rapid assembly of molecular diversity is an important goal of synthetic organic chemistry and one of the key paradigms of modern drug discovery. Domino reactions, which result from the combination of multiple transformations in a single pot, are highly efficient means for the improvement of reaction efficiency [1]. Hence, domino reactions and multicomponent reactions (MCRs) [2] involves three or more reactants in a single reaction flask to generate a product incorporating most of the atoms contained in the starting material. Because of intrinsic atom economy, simpler procedure, equipment, time, and energy saving MCRs are gaining much importance in both academia and industry [3]. In domino reactions, each new bond delivers a reactive species, which undergoes further steps without changing the reaction conditions. The main advantage of this strategy is that prefunctionalization of one or both coupling partners are not required; this simplifies the preparation of substrates, shortens the synthetic route, and therefore, minimizes waste production.

Sulfamic acid ($NH_2SO_3H$) has emerged as a substitute for conventional acidic catalysts and is a dry, nonvolatile, nonhygroscopic, odorless, and white crystalline solid with an outstanding stability. It possesses distinctive catalytic features related to its zwitterionic nature and displays an excellent activity over a vast array of acid catalyzed organic transformations, as witnessed by numerous reports published in the past years [4]. Subsequently, there are reports of sulfamic acid-catalyzed tetrahydropyranylation of hydroxy compounds [5], esterification of cyclic olefins with aliphatic acids under solvent-free conditions [6], and transesterification of β-ketoesters in ionic liquids [7], synthesis of quinoline [8], sulfamic acid is recyclable, easy to handle owing to its immiscibility with common organic solvents and it's intrinsic zwitter ionic property prompted us to explore further applications of $NH_2SO_3H$ as an acidic catalyst in other carbon-heteroatom forming reactions.

The synthesis of 1,3-oxazines has attracted attention in the past because of their potential as antibiotics [9], antitumor [10], analgesics [11], and anticonvulsants [12]. 1,3-Oxazines have generated great interest as antipsychotic agents and as possible effectors for serotonin and dopamine receptors [13]. The ring-chain tautomeric interconversion of N-unsubstituted 1,3-*N*-*O*-heterocycles and the corresponding hydroxyalkylimines can often be exploited advantageously in different areas of organic synthesis. Hence, synthesis of these derivatives is of considerable interest. The synthesis of dihydro-2*H*-1,3-oxazines was reported using hydrochloric acid as catalyst [14]. The disadvantage of this methodology is longer reaction time and hazardous acid catalyst. In a broad program of developing efficient eco-friendly synthetic method for pharmacologically important moieties, we

**Scheme 1.** Sulfamic acid-catalyzed synthesis of substituted 1,3-oxazines at room temperature.



explored an alternative procedure, which resulted in an operationally efficient process. More recently we have reported the synthesis of heterocyclic compounds promoted by sulfamic acid [15]. In our ongoing efforts on one-pot multicomponent synthesis [16] and organic synthesis using solid acid catalysts [17], herein we report the synthesis of 3,4,5-trisubstituted-3,6-dihydro-2*H*-1,3-oxazines using sulfamic acid as catalyst. The reactions proceeded in short reaction times. The catalytic activity of sulfamic acid showed enhanced effect in 1:1 mixture of ethanol and water.

## RESULTS AND DISCUSSION

The reactions were carried out using aniline **1a** (1 eq.), diethyl acetylenedicarboxylate **2a** (1 eq.), and formaldehyde (3 eq.) in the presence of 20 mol % sulfamic acid in 1:1 mixture of ethanol and water (Scheme 1). It was found that all the reactions proceeded rapidly and afforded the desired products in 70% yield. It was also found that increasing the amount of sulfamic acid (20–40 mol %.) increased the yield of the reaction. Further, increasing the amount of sulfamic acid (40–60 mol %) did not affect the rate of the reaction as well as yield. We tried using different acid catalysts, such as $KClO_4$, $Ce(SO_4)_2$, $Cd(OAc)_2$, tetrabutylammmoniumhydrogen suphate, and oxalic acid (Table 1) and found that sulfamic acid is the most effective catalyst in terms of reaction time as well as yield (80%) (Table 2), whereas in presence of other catalysts formed the products with varying yields (0–40%).

**Table 1**

Screening of different catalysts on the synthesis of substituted 1,3-oxazine **3a** at room temperature in EtOH/$H_2O$ (1:1).

| Entry | Catalyst | Time (h) | Yield (%) |
|---|---|---|---|
| 1 | $NH_2SO_3H$ | 3 | 80 |
| 2 | $KClO_4$ | 12 | 20 |
| 3 | Oxalic acid | 12 | 40 |
| 4 | TBAHS | 12 | trace |
| 5 | $Ce(SO_4)_2$ | 12 | trace |
| 6 | $Cd(OAc)_2$ | 12 | No product |

**Table 2**

Solvent effect on the synthesis of substituted 1,3-oxazine **3a** catalyzed by sulfamic acid at room temperature.

| Entry | Solvent | Time (h) | Yield (%) |
|---|---|---|---|
| 1 | EtOH/$H_2O$ (1:1) | 3 | 80 |
| 2 | EtOH | 12 | 70 |
| 3 | MeOH | 12 | 50 |
| 4 | $CH_3CN$ | 12 | 50 |
| 5 | Toluene | 12 | trace |
| 6 | $CHCl_3$ | 12 | 30 |
| 7 | DCM | 12 | 45 |

Also it has been observed that 1:1 mixture of ethanol and water is the best solvent for carrying out this reaction using sulfamic acid (30 mol %) (Table 3). For reaction of dimethyl acetylenedicarboxylate **2b**, aniline **1a** and formaldehyde, similar yields were obtained (Table 3, entries 1–7).

An evident electronic effect was observed on the yields of the products **(3a–n)**. The yield of the products decreased when electron donating groups were present on the phenyl ring. When diethyl acetylenedicarboxylate was used, there was no change in yields (Table 3, entries 8–14).

## CONCLUSIONS

We have developed a novel and highly efficient method for the synthesis of 3,4,5-trisubstituted-1,3-oxazine from alkynoates, amines, and formaldehyde with a simple experimental workup procedure. Sulfamic acid has proved to be an efficient catalyst and green alternative for metal-containing acidic materials, which are toxic and deleterious for human health and environmental protection.

## EXPERIMENTAL

**Materials and methods.** $CDCl_3$ and DMSO-$d_6$ was purchased from Aldrich. IR measurements were done using Perkin Elmer Spectrum RXI FT-IR. The $^1H$ and $^{13}C$ NMR were recorded in $CDCl_3$ with JEOL 500 MHz high resolution NMR spectrometer. $CDCl_3$ was used as the solvent for the NMR spectral measurements and spectra were recorded in ppm with TMS as internal standard. The mass spectra were recorded by using an Electrospray Ionization method with Thermo Finnigan mass spectrometer and EI method with JEOL DX-303 mass spectrometer. Melting points were determined in capillary tubes and were uncorrected. Analytical TLC was performed on precoated plastic sheets of silica gel G/UV-254 of 0.2 mm thickness (Macherey-Nagel, Germany). Elemental analysis data were recorded using a Thermo Finnigan FLASH EA 1112 CHN analyzer.

[a] Isolated yield.

**Representative procedure for the synthesis of 3,4,5-trisubstituted-3,6-dihydro-2*H*-1,3-oxazines 3a–n.** To a mixture of diethyl acetylenedicarboxylate **2a** (1 mmol) and aniline **1a** (1 mmol), ethanol (3 mL) was added. The mixture was stirred at room temperature for 10 min. Subsequently, sulfamic acid (30 mmol %) and formaldehyde (3.5 mmol) were added. After 30 min, water (3 mL) was added and stirring was continued for 3 h. After completion of the reaction, the reaction mixture was extracted with diethyl ether (3 × 15 mL) and organic layer was separated and the combined extract was dried with anhydrous $Na_2SO_4$. Solvent was removed, and the residue was separated by column chromatography on silica gel (Merck, 100–200 mesh), ethyl acetatepetroleum ether (20:80) to obtain pure product **3a**. $^1$H NMR, $^{13}$C NMR, IR, and mass data of the products **3a–c**, **3e**, **3f**, **3h–j**, **3l**, and **3m** are in full agreement with those reported previously (Ref. 14).

Synthetic method for the preparation of (±)-*trans*-hexahydropyrrolo[3,4-*d*]oxazol-2-one and its derivatives has been developed. By one route, an efficient preparation of these fused heterobicyclic moieties could be achieved, which are prepared by using *N*-(*tert*-butyloxycarbonyl)-3-pyrroline as precursor. These fused heterobicyclic systems could be useful to develop a series of 2-oxazolidinone analogues.

*J. Heterocyclic Chem.*, **47**, 1392 (2010).

## INTRODUCTION

Diverse biological activities are encountered in fused heterocyclic systems containing the pyrrolidine and 2-oxazolidinone moieties [1]. In continuation of our interest in this field of 2-oxazolidinones [2], it was thought worthwhile to incorporate 2-oxazolidinone (**2**) to the 3-pyrroline ring by using *N*-(*tert*-butyloxycarbonyl)-3-pyrroilne (**1b**) as a precursor for building of newly fused heterobicyclic systems, (±)-*trans*-hexahydropyrrolo[3,4-*d*]oxazol-2-one and its derivatives (**3**) (Fig. 1).

*N*-Substituted-3-pyrrolines are an important class of compounds which exhibit biological activity and serve as useful synthetic intermediates [3]. The alkene moiety of 3-pyrroline can serves as a handle for various functional group transformations.

The oxazolidinone family represents one of only two new chemical classes of antibiotics disclosed in the past 40 years [4]. Linezolid (Fig. 2), the first approved oxazolidinone, demonstrates good activity against all major pathogenic Gram-positive bacteria, including methicillin-resistant *Staphylococcus aureus* (MRSA*a*), vancomycin-resistant *Enterococcus faecium* (VREF), and penicillin-resistant *Streptococcus pneumoniae* [5]. However, not long after the commercial release of linezolid, oxazolidinone resistant strains of MRSA and VREF began to appear in the clinic [6], underscoring the increasingly urgent need for improved antibiotics that overcome bacterial resistance mechanisms. A particularly attractive goal would be a next-generation oxazolidinone with improved spectrum and binding affinity, while retaining properties for good oral exposure and safety [7].

Several SAR studies of the 2-oxazolidinones have demonstrated a high tolerance for structural variation at the 4-position of the phenyl ring [8], while the oxazolidinone ring is essential for biological activity [9]. These fused heterobicyclic systems could be useful to develop a series of oxazolidinone analogues where the morpholine moiety of linezolid could be replaced with these heterobicyclic systems such as RWJ-416457 [10] (Fig. 2).

## RESULTS AND DISCUSSION

The literature survey of the titled compound reveals the *cis* fusion of pyrrolidine and 2-oxazolidinone rings for the preparation of (±)-*cis*- and (3a*R*,6a*S*)-hexahydro-3-methylpyrrolo[3,4-*d*]oxazol-2-one only [11]. Furthermore, it is very important to find out a general methodology to synthesize (±)-*trans*-hexahydropyrrolo[3,4-*d*]oxazol-2-one and its derivatives (**3**). The key challenge of the synthesis is the effective *trans* fusion of 2-oxazolidinone ring using alkene moiety between 3 and 4 positions of 3-pyrroline (**1a**). We required a general

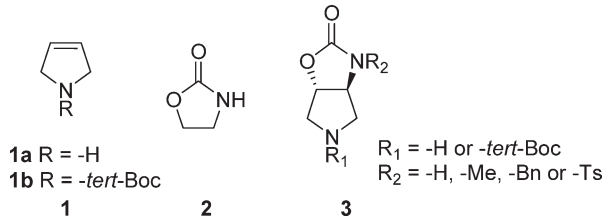

**Figure 1.** Chemical structures of 3-Pyrroline (**1a**), *N*-Boc-3-pyrroline (**1b**), 2-oxazolidinone (**2**), and (±)-*trans*-hexahydropyrrolo[3,4-*d*]oxazol-2-one and its derivatives (**3**).

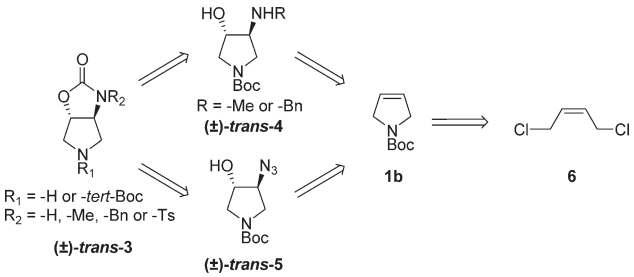
**Scheme 1.** Retrosynthetic analysis to prepare (±)-*trans*-**3**



method for the preparation of these *trans* fused heterobicyclic systems (**3**) which should be the most attractive in terms of practical and economical. Based on retrosynthetic analysis, we designed two synthetic routes to **3** and are shown in Scheme 1. Each synthetic route includes a key intermediate amino alcohol (**4**) or azido alcohol (**5**) which gives the targeted moieties (**3**).

To prepare these intermediates, *N*-(tert-butyloxycarbonyl)-3-pyrroline (**1b**) or *cis*-1,4-dichloro-2-butene (**6**) are regarded as a common starting material. Recently, **1b** was prepared by us with high purity in large scale starting from *cis*-1,4-dichloro-2-butene **6** *via* Delépine reaction [12] and subsequent *in situ* cyclization in the presence of potassium carbonate ($K_2CO_3$) followed by *N*-Boc protection with di-*tert*-butyldicarbonate ($Boc_2O$) in methanol [3]. This is an efficient and commercial viable synthetic method for *N*-(*tert*-butyloxycarbonyl)-3-pyrroline.

Reaction of **1b** with *N*-bromosuccinimide (NBS) in DMSO–$H_2O$ at room temperature afforded the racemic *trans* bromohydrin (**7**) [13]. The $^1$H NMR spectra of the latter product revealed disappearance the triplet corresponding to alkenyl protons at δ 5.78 ppm, whereas broad singlet for hydroxyl signal appeared at δ 2.8 ppm and also the mass spectrum showed in addition to molecular ion peak, bromine isotopic peak ($M^+$+2) at *m*/*z* 268.

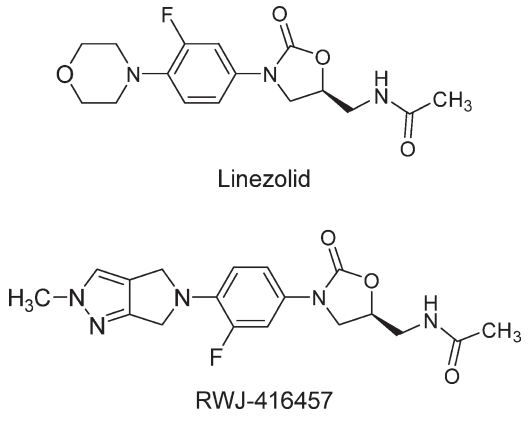


**Figure 2.** 2-Oxazolidinone antibacterials with different *N*-substitutents.

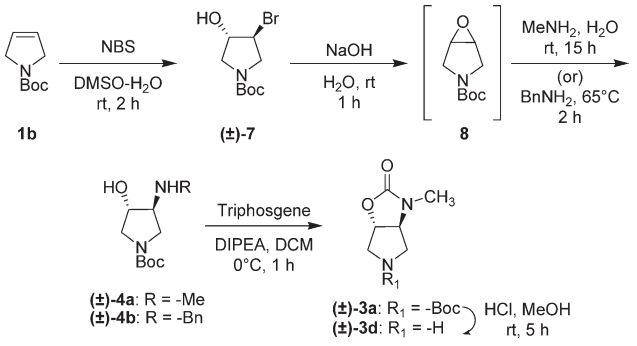
Under basic conditions (NaOH), the bromohydrin (±)-**7** was converted to the epoxide **8**, followed by treatment with methylamine or benzylamine furnished the desired intermediates **4a** or **4b**. However, the carbonyl insertion between β-amino alcohol of **4b** with various reagents, such as *N*,*N*′-carbonyldiimidazole (CDI), diethyl carbonate or triphosgene in different reaction conditions were not successful. Although in case of **4a**, after screening of several reaction conditions the required 2-oxazolidinone **3a** was obtained in low yield (36%) with triphosgene using *N*,*N*-diisopropylethylamine (DIPEA) as a base at 0°C. On treatment of **3a** with HCl in methanol, to remove the *N*-Boc protection, **3d** was obtained in good yield (Scheme 2).

On the other hand, **4b** on protection with $Boc_2O$ gives the di-*tert*-boc protected compound which on further treatment with mesyl chloride, tosyl chloride, or thionyl chloride, the corresponding fused 2-oxazolidinone was not achieved [14]. Thus, we have studied the scope of this approach by opening of epoxy compound **8** with different amines. We were not obtained the right results on the formation of 2-oxazolidinone heterobicyclic systems using different methodologies, such as direct carbonyl insertion or *tert*-boc protection of the amines **4** followed by reaction with mesyl chloride or tosyl chloride.

Finally, our attention was altered to another approach (Scheme 3). The major difference in this strategy is ring opening of epoxy compound **8** with sodium azide instead of amines. In the previous approach, the alkyl substituent on exo cyclic amine of **4** may hinders the formation of 2-oxazolidinone ring due to steric factor. Probably, by choosing alternative strategy, 2-oxazolidinone ring formation followed by alkylation, could be succeeded due to lower steric factor. The epoxide **8** was readily opened with sodium azide in AcOH—$H_2O$ at room temperature gave the corresponding azido alcohol, (±)-*trans*-**5**. The infra-red spectrum of **5** showed clearly a new band at $\upsilon = 2096\ cm^{-1}$ for $N_3$ group.

Azido alcohol (±)-**5** on further treatment with phenyl chloroformate using pyridine in dichloromethane at room temperature yielded the phenyl carbonate **9**. The $^1$H NMR spectra of the latter product **9** divulged a

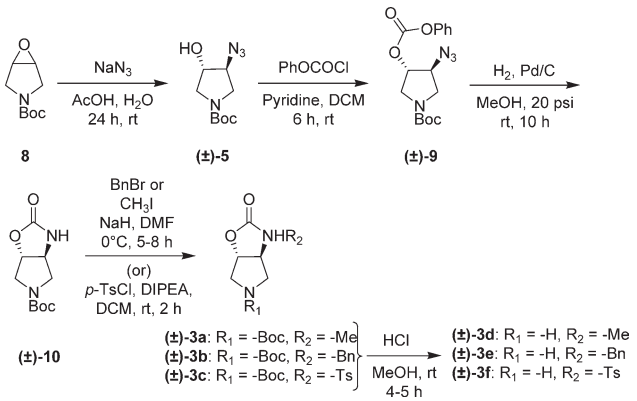
**Scheme 2**

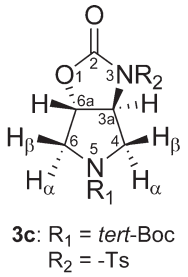


multiplet at δ 5.08–5.14 ppm due to deshielding of the $C_3$—H signal attached to phenyl carbonate and also two bands were appeared at ν = 1757, 1682 $cm^{-1}$ corresponding to carbonyl (C=O) groups in the infra-red spectrum. Reduction of azide in phenyl carbonate (±)-**9** could be achieved by hydrogenation (10% Pd/C, 20 psi, methanol) gave the corresponding amine which undergoes *in situ* cyclisation produced the required basic fused heterobicyclic compound (±)-**10**. Whereas the same reaction is performed in ethyl acetate instead of methanol, *in situ* cyclisation was not occurred. The spectral analysis of the latter product **10** showed the absence of phenyl protons in the $^1$H NMR spectrum and disappearance of azido absorption band at ν = 2122 $cm^{-1}$ in addition, two bands were appeared at ν = 1749, 1694 $cm^{-1}$ corresponding to carbonyl (C=O) groups in the infra-red spectrum. This heterobicyclic compound (±)-**10** was utilized to make derivatization with various substituents at 2-oxazolidinone site.

Compound (±)-**10** was alkylated with benzyl bromide or iodomethane using sodium hydride (NaH) in *N*,*N*-dimethylformamide (DMF) at 0°C gave the related *tert*-butylhexahydro-3-alkyl-2-oxopyrrolo[3,4-*d*]oxazole-5-carboxylate, **3a-b**. On the other hand, the alkylation of (±)-**10** with *p*-toluenesulfonyl chloride was attempted under similar conditions (NaH, DMF, 0°C), the reaction was very slow and also observed the incompletion of the reaction even at elevated temperatures. Finally, sulfonylation was achieved by the reaction of (±)-**10** with tosyl chloride using DIPEA in dichloromethane at 0°C.

**Scheme 3**





H-H interaction in NOE spectra (DMSO-d6)
H6a-$H_\beta$4: NOE (due to same spatial arrangement)
H6a-$H_\alpha$4: no NOE (due to different spatial arrangement)
$H_\beta$4-$H_\alpha$4: strong NOE (due to geminal coupling)
$H_\alpha$4-H3a: strong NOE (due to same spatial arrangement)
$H_\beta$4-H3a: minimal NOE
(due to different spatial arrangement)

**Figure 3.** H–H interaction of compound **3c** in NOE spectra (DMSO-*d*6).

Compounds **3a-c** are well characterized by spectral data. The $^1$H NMR spectrum of **3a-c** showed the corresponding alkylation peaks at *N*-3 site. Compound **3a-c** on *N*-*tert*-boc deprotection was achieved with HCl in methanol afforded the targeted hexahydro-3-alkylpyrrolo [3,4-*d*]oxazol-2-one **3e-f** in high yield (Scheme 3). Compounds **3d-f** have been characterized by spectral and elemental analyses.

The *trans* fusion of the two rings, pyrrolidine and 2-oxazolidinone, was assigned by using NOESY studies. To demonstrate the *trans* fusion of the synthesized compounds **3a-f**, the example chosen for NOESY experiments is **3c**. Upon irradiation of H-6a of compound **3c**, led to enhancement of the $H_\beta$-4 and no cross peak of $H_\alpha$-4, which suggested that both H-6a and $H_\beta$-4 are in the same spatial arrangement in addition H-6a and $H_\alpha$-4 are in different special arrangement. Whereas irradiation of $H_\alpha$-4 revealed that H-3a and $H_\alpha$-4 are in the same spatial arrangement (strong enhancement of H-3a signal). This indicates *trans* fusion at the ring junction, which was further confirmed by the very low NOE signal of H-3a upon irradiation of $H_\beta$-4 (Fig. 3). A similar spectral phenomenon was also observed in case of compound **9**.

As a conclusion, a simple and straightforward method was developed to synthesis (±)-*trans*-hexahydropyrrolo [3,4-*d*]oxazol-2-one and its derivatives. Further studies on the application of these compounds to prepare a series of 2-oxazolidinone analogues where the morpholine moiety of linezolid could be replaced with these

heterobicyclic systems are actively underway in our laboratories.

## EXPERIMENTAL

*N*-(*tert*-Butyloxycarbonyl)-3-pyrroline (**1b**) was synthesized in-house (purity >99%) [3]. All reagents and solvents used were of commercial grade and were used as such, unless otherwise specified. Reaction flasks were oven-dried at 200°C, flame-dried, and flushed with dry nitrogen prior to use. All moisture and air-sensitive reactions were carried out under an atmosphere of dry nitrogen. TLC was performed on Kieselgel 60 $F_{254}$ silica-coated aluminium plates (Merck) and visualized by UV light ($\lambda = 254$ nm) or by spraying with a solution of ninhydrin. Organic extracts were dried over anhydrous $Na_2SO_4$. Flash chromatography was performed using Kieselgel 60 brand silica gel (230–400 mesh). The melting points were determined in an open capillary tube using a Büchi B-540 melting point instrument and were uncorrected. The IR spectra were obtained on a Nicolet 380 FTIR instrument (neat for liquids and as KBr pellets for solids). NMR spectra were recorded with a Varian 300 MHz Mercury Plus Spectrometer at 300 MHz ($^1$H) and at 75 MHz ($^{13}$C). Chemical shifts were given in ppm relative to trimethylsilane. Mass spectra were recorded on Waters quattro premier XE triple quadrupole spectrometer using either electron spray ionisation (ESI) or atmospheric pressure chemical ionization (APCI) technique.

**Preparation of (±)-*trans-tert*-butyl 3-bromo-4-hydroxy pyrrolidine-1-carboxylate, 7 [13].** To a stirred solution of **1b** (60 g, 0.355 mol), DMSO (420 mL) and $H_2O$ (22 mL), NBS (75.3 g, 0.423 mol) was gradually added over 30 min at 0°C. After stirring at room temperature for 2 h, water (490 mL) was added and the mixture was extracted with AcOEt (3 × 200 mL). The organic layer was washed with brine, dried over anhydrous $Na_2SO_4$ and the solvent removed under vacuum to leave a crude **7** as oil in 99.6% yield (94.0 g); $^1$H NMR ($CDCl_3$): δ 1.47 (s, 9H, *t*-butyl), 2.8 (br s, 1H, OH), 3.36–3.45 (m, 1H, $C_5$—H), 3.62–3.96 (m, 2H, $C_5$—H and $C_2$—H), 3.98–4.14 (m, 1H, $C_2$—H), 4.15–4.20 (m, 1H, $C_3$—H), 4.40–4.48 (m, 1H, $C_4$—H); APCI-MS: *m/z* (%) 266.0 (90, $M^+$+1), 268.0 (88, $M^+$+2), 533.1 (100, $2M^+$+3); IR (neat): ν 3387 (OH), 1655 (C=O) $cm^{-1}$.

**Preparation of (±)-*trans-tert*-butyl 3-hydroxy-4-(methyl amino)pyrrolidine-1-carboxylate, 4a.** A mixture of crude **7** (47.0 g, 0.177 mol) and aqueous NaOH (1N, 222 mL, 0.222 mol) was stirred at room temperature for 1 h. The mixture was treated with 40% methylamine-water (182 mL, 2.344 mol) and stirred at room temperature for 15 h. After evaporation of the solvent, the residue was triturated with *i*-$Pr_2O$ to give **4a** as white crystals in 71% yield relative to **1b** (27.2 g), mp 98–100°C; $^1$H NMR (DMSO-$d_6$): δ 1.40 (s, 9H, *t*-butyl), 2.38 (dd, 1H, $C_2$—H), 2.43 (s, 3H, $CH_3$), 3.1 (dd, 1H, $C_5$—H), 3.2 (m, 2H, $C_2$—H and $C_5$—H), 3.51 (br s, 2H, OH, and NH), 4.0 (m, 1H, $C_4$—H), 4.17 (m, 1H, $C_3$—H); ESI-MS: *m/z* (%) 161 (100), 217 (85, $M^+$+1); IR (KBr): ν 3309 (OH), 2972, 1694 (C=O) $cm^{-1}$.

**Preparation of (±)-*trans-tert*-butyl 3-(benzylamino)-4-hydroxypyrrolidine-1-carboxylate, 4b.** A mixture of crude **7** (47.0 g, 0.177 mol) and aqueous NaOH (1N, 222 mL, 0.222 mol) was stirred at room temperature for 1 h. The mixture was treated with benzylamine (47.2 g, 0.44 mol) and stirred at 65°C for 2 h, then cooled to 0°C. The resultant precipitates were collected by filtration, washed with water and *i*-$Pr_2O$ and dried to afford **4b** as white crystals in 60% yield relative to **1b** (31.1 g), mp 140–141°C; $^1$H NMR ($CDCl_3$): δ 1.46 (s, 9H, *t*-butyl), 1.8 (br s, 2H, OH and NH) 3.10–3.30 (m, 3H, $C_2$—2H and $C_5$—H), 3.57–3.75 (m, 2H, $C_3$—H and $C_5$—H), 3.82 (d, 2H, $NCH_2$—Ph), 4.1 (m, 1H, $C_4$—H), 7.21–7.38 (m, 5H, ArH); ESI-MS: *m/z* (%) 291.2 (100, $M^+$−1), 293.2 (15, $M^+$+1); IR (KBr): ν 3255 (OH), 1694 (C=O) $cm^{-1}$.

**Preparation of (±)-*trans-tert*-butyl hexahydro-3-methyl-2-oxopyrrolo[3,4-*d*]oxazole-5-carboxylate, 3a.** The amino alcohol **4a** (5.0 g, 0.023 mol) was dissolved in dichloromethane (30 mL) and the solution was cooled to 0°C. Triphosgene (8.23 g, 0.028 mol) was added followed by DIPEA (9.0 g, 0.07 mol) at 0°C. After 1 h, the mixture was washed with water, dried over anhydrous $Na_2SO_4$ and then concentrated under reduced pressure. The residue was purified by column chromatography eluting with ethyl acetate: hexane (1:1) to give **3a** as colourless liquid in 36% yield.

**Preparation of (±)-*trans-tert*-butyl 3-azido-4-hydroxy pyrrolidine-1-carboxylate, 5.** To a stirred mixture of **1b** (150 g, 0.89 mol), DMSO (1050 mL) and $H_2O$ (55 mL), NBS (188.3 g, 1.06 mol) was gradually added over 30 min at 0°C. After stirring at room temperature for 2 h, water (1225 mL) was added and the mixture was extracted with AcOEt (3 × 500 mL). The organic layer was washed with saturated NaCl, dried over anhydrous $Na_2SO_4$ and then concentrated under reduced pressure to give crude **7** as oil. To this crude **7**, aqueous NaOH (1N, 1110 mL, 1.11 mol) was added at room temperature. After 1 h, the reaction mixture was extracted with AcOEt (3 × 500 mL). The organic layer was washed with saturated NaCl solution, dried over anhydrous $Na_2SO_4$ and then concentrated under reduced pressure to give compound **8** as oil.

To a solution of sodium azide (274 g, 4.21 mol) and water (1250 mL), compound **8** was added at room temperature. To this solution, acetic acid (350 mL) was slowly added at room temperature over 40 min. After the reaction mixture was stirred at room temperature for 24 h, the mixture was extracted with AcOEt (3 × 500 mL). The organic layer was washed with saturated sodium bicarbonate followed by saturated NaCl solution, dried over anhydrous $Na_2SO_4$ and then concentrated under reduced pressure to give **5** as pale yellow color oil (162 g). This pale yellow color oil compound was proceeded to next step without further purification; $^1$H NMR ($CDCl_3$): δ 1.47 (s, 9H, *t*-butyl), 2.75 (br s, 1H, OH), 3.23–3.54 (m, 2H, $C_2$—H and $C_5$—H), 3.56–3.80 (m, 2H, $C_2$—H and $C_5$—H), 3.90–4.01 (m, 1H, $C_3$—H), 4.20–4.30 (m, 1H, $C_4$—H); ESI-MS: *m/z* (%) 229 (100, $M^+$+1); IR (neat): ν 3419 (OH), 2096 ($N_3$), 1668 (C=O) $cm^{-1}$.

**Preparation of (±)-*trans*-1-(*tert*-butoxycarbonyl)-4-azido pyrrolidin-3-yl phenyl carbonate, 9.** To a solution of **5** (50 g, 0.22 mol) in dichloromethane (500 mL), pyridine (50 mL) was added at 0°C. To this mixture, phenyl chloroformate (41 g, 0.262 mol) was slowly added at 0°C over 1 h. After the reaction mixture was stirred at room temperature for 6 h, the mixture was washed with water (250 mL) followed by saturated NaCl solution, dried over anhydrous $Na_2SO_4$ and then concentrated under vacuum. The residue was triturated with *n*-heptane and filtered to give **9** as a white solid in 80% yield

(61 g), mp 92–94°C; $^1$H NMR ($CDCl_3$): δ 1.43 (s, 9H, *t*-butyl), 3.42–3.80 (m, 4H, $C_2$—2H and $C_5$—2H), 4.20–4.24 (m, 1H, $C_4$—H), 5.08–5.14 (m, 1H, $C_3$—H), 7.18–7.42 (m, 5H, ArH); $^{13}$C NMR ($CDCl_3$): δ 153.9, 150.7, 129.6, 126.4, 120.8, 80.4, 79.7, 78.9, 63.1, 62.3, 49.4, 49.0, 48.9, 48.5, 28.4; ESI-MS: *m*/z (%) 349.28 (100, $M^+$+1); IR (KBr): ν 2122 ($N_3$), 1757 (C=O), 1682 (C=O) cm$^{-1}$.

**Preparation of *tert*-butyl hexahydro-2-oxopyrrolo[3,4-*d*] oxazole-5-carboxylate, 10.** A solution of **9** (20 g, 0.057) in methanol (200 mL) was treated with palladium carbon (2 g, 10% palladium content) and hydrogenated at 20 psi for 10 h. The reaction mixture was filtered and concentrated in vacuum. The residue was purified by column chromatography eluting with ethyl acetate: hexane (2:1) to give *tert*-butyl hexahydro-2-oxopyrrolo[3,4-*d*]oxazole-5-carboxylate (**10**) as a colorless oil in 62% yield (8.1 g), $^1$H NMR ($CDCl_3$): δ 1.38 (s, 9H, *t*-butyl), 3.56–3.61 (m, 1H, $C_4$—H), 3.65–3.78 (m, 4H, $C_4$—H, $C_6$—2H and $C_{3a}$—H) 4.80–4.96 (m, 1H, $C_{6a}$—H), 8.02 (br s, 1H, NH); ESI-MS: *m*/z (%) 229.2 (100, $M^+$+1); IR (neat): ν 2972 (NH), 1749 (C=O), 1694 (C=O) cm$^{-1}$.

**General procedure for the preparation of *tert*-butyl hexa hydro-3-alkyl-2-oxopyrrolo[3,4-*d*]oxazole-5-carboxylate, 3a-b.** To a solution of **10** (1.0 g, 0.0044 mol) in DMF (30 mL), sodium hydride (0.5 g, 60% dispersion in mineral oil) was added in one portion at room temperature. After 1 h, benzyl bromide or iodomethane (0.0044 mol) was added in a drop wise fashion. The reaction was left to stir for 5–8 h at room temperature. The reaction mixture was then poured into ice (20 mL) and the aqueous phase was extracted with dichloromethane (3 × 20 mL). The combined dichloromethane layer was washed with water and dried over anhydrous $Na_2SO_4$. The solvent was removed under vacuum and the obtained residue was purified by column chromatography eluting with ethyl acetate: hexane (1:1) to give corresponding 2-oxazolidinone.

***tert*-Butyl hexahydro-3-methyl-2-oxopyrrolo[3,4-d]oxazole-5-carboxylate, 3a.** This compound was obtained as colorless liquid in 66% yield; $^1$H NMR ($CDCl_3$): δ 1.46 (s, 9H, *t*-butyl), 3.20–3.30 (m, 1H, $C_4$—H), 3.4–3.7 (m, 4H, $C_4$—H, $C_6$—2H and $C_{3a}$—H), 3.82 (s, 3H, $CH_3$), 4.8 (m, 1H, $C_{6a}$—H); ESI-MS: *m*/z (%) 243.15 (100, $M^+$+1); IR (neat): ν 2975, 1695 (C=O), 1423 cm$^{-1}$.

***tert*-Butyl hexahydro-3-benzyl-2-oxopyrrolo[3,4-d]oxazole-5-carboxylate, 3b.** This compound was obtained as pale yellow color liquid in 55% yield; $^1$H NMR ($CDCl_3$): δ 1.46 (s, 9H, *t*-butyl), 3.1–3.37 (m, 1H, $C_4$—H), 3.39–3.63 (m, 2H, $C_6$—H, and $C_4$—H), 3.6–3.82 (m, 2H, $C_6$—H, and $C_{3a}$—H), 4.56 (s, 2H, *N*$CH_2$—Ph), 4.8 (m, 1H, $C_{6a}$—H), 7.26–7.35 (m, 5H, ArH); $^{13}$C NMR ($CDCl_3$): δ 154.7, 137.7, 128.5, 127.8, 127.7, 127.6, 83.7, 82.9, 79.4, 71.5, 55.5, 54.5, 51.8, 51.4, 50.5, 49.5, 48.6, 28.4; ESI-MS: *m*/z (%) 319 (100, $M^+$+1); IR (neat): ν 2973, 1690 (C=O), 1409 cm$^{-1}$.

**Preparation of tert-butyl hexahydro-2-oxo-3-tosylpyrrolo [3,4-d]oxazole-5-carboxylate, 3c.** To a solution of **10** (1.0 g, 0.0044 mol) in dichloromethane (30 mL), DIPEA (1.7 g, 0.013 mol) was added in one portion at room temperature. *p*-Toluene sulfonyl chloride (1.0 g, 0.005 mol) was slowly added to the reaction mixture at 0°C. After 2 h, the reaction mixture was diluted with water. The organic layer was washed with water and dried over anhydrous $Na_2SO_4$. The solvent was removed under vacuum and the obtained residue was purified by column chromatography eluting with ethyl acetate: hexane (1:1) to give **3c** as yellow viscous liquid in 69% yield (upon long standing in the refrigerator converted to semi-solid); $^1$H NMR (DMSO-$d_6$): δ 1.4 (s, 9H, *t*-butyl), 2.4 (s, 3H, $CH_3$), 3.05–3.1 (m, 1H, $C_4$—H), 3.22–3.33 (m, 2H, $C_6$—H and $C_4$—H), 3.52–3.61 (m, 1H, $C_6$—H), 3.7–3.73 (m, 1H, $C_{3a}$—H), 4.8–4.83 (m, 1H, $C_{6a}$—H), 7.4–7.45 (m, 2H, ArH), 7.78–7.80 (m, 2H, ArH); $^{13}$C NMR ($CDCl_3$): δ 154.5, 154.1, 143.8, 136.6, 129.8, 127.1, 80.4, 79.5, 78.1, 56.6, 55.7, 55.2, 50.0, 49.1, 48.5, 28.3, 21.5; IR (neat): ν 2973, 1753 (C=O), 1690 (C=O) cm$^{-1}$; ESI-MS: *m*/z (%) 193.14 (100), 383.26 (45, $M^+$+1).

**General procedure for the preparation of hexahydro-3-alkylpyrrolo[3,4-*d*]oxazol-2-one, 3d-f.** To a solution of **3a-c** (0.003 mol) in methanol (10 mL), 10% HCl in methanol (2.2 mL, 0.006 mol) was added slowly at 10°C. The reaction mixture was stirred at room temperature for 4–5 h. The solvent was removed under reduced pressure and the residue is diluted with saturated sodium bicarbonate solution. The mixture is extracted with dichloromethane, washed with saturated NaCl solution and dried over anhydrous $Na_2SO_4$. The solvent was removed under vacuum and the obtained residue was purified by column chromatography eluting with ethyl acetate: hexane (2:1) to give **3d-f**.

***Hexahydro-3-methylpyrrolo[3,4-d]oxazol-2-one, 3d.*** This compound was obtained as yellow color liquid in 92% yield; $^1$H NMR ($CDCl_3$): δ 2.8 (s, 3H, $CH_3$), 3.12–3.25 (m, 4H, $C_6$—2H and $C_4$—2H), 4.21–4.26 (m, 1H, $C_{3a}$—H), 4.81–4.86 (m, 1H, $C_{6a}$—H), 6.0 (br s, 1H, NH); IR (neat): ν 3223 (NH), 1690 (C=O) cm$^{-1}$; ESI-MS: *m*/*z* (%) 143.10 (100, $M^+$+1). *Anal*. *Calcd*. for $C_6H_{10}N_2O_2$: C 50.69; H 7.09; N 19.71. Found: C 50.42; H 6.88; N 19.92.

***Hexahydro-3-benzylpyrrolo[3,4-d]oxazol-2-one, 3e.*** This compound was obtained as yellow color liquid in 89% yield; $^1$H NMR ($CDCl_3$): δ 3.07–3.34 (m, 1H, $C_4$—H), 3.36–3.61 (m, 2H, $C_6$—H and $C_4$—H), 3.63–3.78 (m, 2H, $C_6$—H and $C_{3a}$—H), 4.5 (s, 2H, *N*$CH_2$—Ph), 4.68–4.72 (m, 1H, $C_{6a}$—H), 7.16–7.28 (m, 5H, ArH); IR (neat): ν 3310 (NH), 1692 (C=O) cm$^{-1}$; ESI-MS: *m*/*z* (%) 219.09 (100, $M^+$+1). *Anal*. *Calcd*. for $C_{12}H_{14}N_2O_2$: C 66.04; H 6.47; N 12.84. Found: C 66.32; H 6.27; N 12.51.

***Hexahydro-3-tosylpyrrolo[3,4-d]oxazol-2-one, 3f.*** This compound was obtained as yellow color liquid in 87% yield (upon long standing in the refrigerator converted to semi-solid); $^1$H NMR (DMSO-$d_6$): δ 2.4 (s, 3H, $CH_3$), 2.43–2.77 (m, 1H, $C_4$—H), 2.95–3.0 (dd, 1H, $C_6$—H), 3.1–3.3 (m, 2H, $C_6$—H and $C_4$—H), 3.58–3.60 (m, 1H, $C_{3a}$—H), 4.81–4.84 (m, 1H, $C_{6a}$—H), 7.26–7.33 (d, 2H, ArH), 7.75–7.78 (d, 2H, ArH); IR (neat): ν 3305 (NH), 1694 (C=O) cm$^{-1}$; ESI-MS: *m*/*z* (%) 283.10 (100, $M^+$+1). *Anal*. *Calcd*. for $C_{12}H_{14}N_2O_4S$: C 51.05; H 5.00; N 9.92. Found: C 51.35; H 4.88; N 9.71.

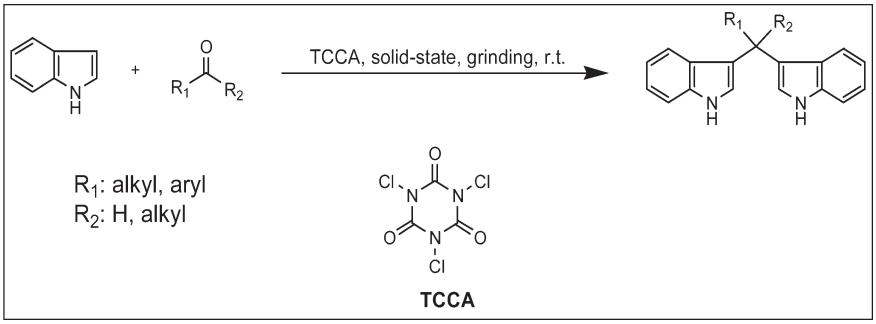
Published online 30 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



Trichloroisocyanuric acid is found to be an efficient catalyst for the electrophilic substitution reaction of indole with aldehydes/ketones to afford the corresponding bis-indolyl, tris-indolyl, di(bis-indolyl), tri(bis-indolyl), and tetra(bis-indolyl)methanes under solid-state conditions by pulverization-activation method at room temperature with excellent yields. The remarkable features of this new procedure are high conversions, shorter reaction times, cleaner reaction profiles, and simple experimental and work-up procedures.

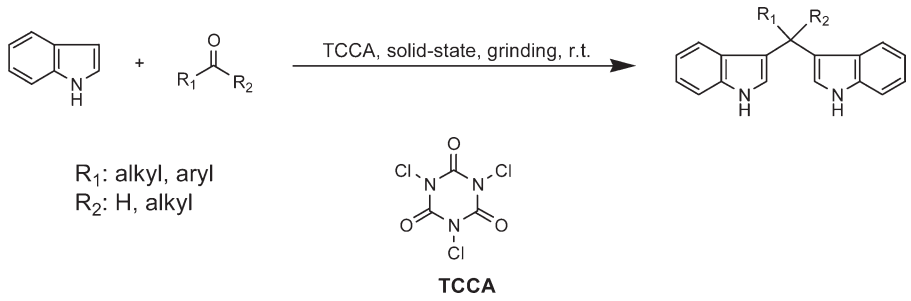
## INTRODUCTION

The development of bis(indolyl)alkane synthesis has been of considerable interest in organic synthesis because of their wide occurrence in various natural products possessing biological activity and usefulness for drug design [1]. Bis(indolyl)methanes are found in cruciferous plants and are known to promote beneficial estrogen metabolism [2] and induce apoptosis in human cancer cell. Thus, the development of facile and environmentally friendly synthetic methods for the preparation of these compounds constitutes an active area of investigation in pharmaceutical and organic synthesis [3–5].

Synthetically the reaction of 1H-indole with aldehydes or ketones produces azafulvenium salts that react further with a second 1H-indole molecule to form bis(indol-3-yl)methanes [6]. In recent years, synthesis of this class of molecules under mild conditions have been reported, with promoters, such as montmorillonite clay K-10 [7], trichloro-1,3,5-triazine [8], $AlPW_{12}O_{40}$ [9], sodium dodecyl sulfate [10], $ZrCl_4$ [11], $H_2NSO_3H$ [12], $I_2$ [13], zeolites [14], bentonite [15], $In(OTf)_3$/ionic liquid [16], $CuBr_2$ [17], $Dy(OTf)_3$/ionic liquid [18], $HClO_4$-$SiO_2$ [19], $InCl_3$ [20], MW/Lewis acids ($FeCl_3$, $BiCl_3$, $InCl_3$, $ZnCl_2$, $CoCl_2$) [21], $NaHSO_4$ and Amberlyst-15 [22], sulfated zirconia [23], $ZrOCl_2/SiO_2$ [24], silica sulfuric acid [25], $TiO_2$ [26], $(NH_4)_2HPO_4$ [27], acidic ionic liquid [28], $NaBF_4$ [29], metal hydrogen sulfates [30], tetrabutylammonium tribromide [31], superacid $SO_4^{2-}/TiO_2$ [32], $NaHSO_4$/ionic liquid [33], NBS [34], $Ph_3CCl$ [35], $H_3PW_{12}O_{40}$ [36], $LiClO_4$ [37], Zr(DS)4 [38], and $Bi(NO_3)_3.5H_2O$ [39]. However, most of the existing methods involve toxic metal ions and solvent, high cost and cumbersome work-up procedures. Consequently, new procedures that address these drawbacks are desirable. Although TCCA has been produced on large scale for use in household and industry since the 1950s, it has never had a real breakthrough in organic chemistry laboratories. It also has not found its way into textbooks in

**Scheme 1**



organic chemistry and even books on heterocyclic chemistry fail to mention this very useful reagent. Also there is a nice article review by Tilstam [40] that they have shown that trichloroisocyanuric acid (TCCA) is a safe and efficient reagent, useful for chlorination and oxidation reactions.

## RESULTS AND DISCUSSION

In continuation of our interest in the application of N-halo reagents in organic synthesis [41–44], we report the use of TCCA as an catalyst in the electrophilic substitutions of indole with a variety of aldehydes and ketones under solid-state conditions to afford bis(indolyl)methanes by pulverization-activation method at room temperature with excellent yields (Scheme 1).

As TCCA contain chlorine atoms, which are attached to nitrogen atoms, it is also possible that it release $Cl^+$ *in situ*, which can act as Lewis acid to activate the carbonyl oxygen to form the bis-indole derivatives.

First, we examined the TCCA in the model reaction of indole with benzaldehyde in different reaction media to investigate the best conditions. The results are summarized in the Table 1 and show that under solvent-free conditions TCCA (0.1 mmol) led to the best result (Table 1, Entry 8). However, the solvent-free (grinding at solid-state condition) was found to be best for the catalytic reaction at room temperature in terms of yield, reaction time, and product isolation.

These results promoted us to investigate the scope and the generality of this new protocol for various aldehydes and ketones under optimized conditions. As shown in Table 2, a series of aromatic, aliphatic and heterocyclic aldehydes underwent electrophilic substitution reaction with indole smoothly to afford a wide range of substituted bis(indolyl)methanes in good to excellent yields. The electron deficiency and nature of the substituents on the aromatic ring effect the conversion rate; aromatic aldehydes having electron-withdrawing groups on the aromatic ring (Table 2, entries 10, 11) react slower than electron-donating groups (Table 2, entries 4, 8, 9, 12). Furthermore, unsaturated aldehydes, such as cinnamaldehyde, give the corresponding bis(indolyl)methanes without polymerization or halogenation under the above reaction conditions. Ketones required longer reaction times, which is most probably because of the electron-donating and steric effects of the methyl group.

This reaction was further explored for the synthesis of tri-indolylmethane (**3**), (**4**) by the condensation of indol-3-carbaldehyde (**1**) or isatin (**2**) with two equivalents of indole under similar conditions with our method in good yields (Scheme 2).

Selective condensation of a dialdehyde, that is, terephthaldialdehyde to the corresponding bis-indolyl methane was achieved by controlling the molar ratio of indole (Scheme 3). The results showed that addition of 2 equivalents of indole to terephthaldialdehyde, gives (**5**) in good yield (Scheme 3). Treatment of 4 equivalents of indole with terephthaldialdehyde gives the corresponding di(bis-indolyl methanes), (**6**) in excellent yield at room temperature under same conditions [38].

This reaction was further explored for the synthesis of tri(bis-indolyl)methane (**8**) and tetra(bis-indolyl)methanes (**10**) as new triarylmethanes, by the condensation of aldehyde (**7**) with 6 equivalents indole and aldehydes (**9**) with 8 equivalents indole under similar condition (solid-state, grinding) in high yields (Schemes 4 and 5).

**Table 1**

Screening of the reaction conditions for the synthesis of bis(indolyl)methane by reaction of benzaldehyde and indole.

| Entry | Condition | Time | Yield (%) |
|---|---|---|---|
| 1 | MeCN/no reagent | 12 h | 0 |
| 2 | MeCN/(0.1 mmol) TCCA | 1 h | 95 |
| 3 | $CH_2Cl_2$/(0.1 mmol) TCCA | 2 h | 85 |
| 4 | $CHCl_3$/(0.1 mmol) TCCA | 2 h | 80 |
| 5 | EtOH/(0.1 mmol) TCCA | 1.5 h | 90 |
| 6 | MeCN/(0.2 mmol) TCCA | 1 h | 95 |
| 7 | Solvent-free/(0.05 mmol) TCCA/grinding | 5 min | 90 |
| 8 | Solvent-free/(0.1 mmol) TCCA/grinding | 1 min | 98 |
| 9 | Solvent-free/(0.2 mmol) TCCA/grinding | 1 min | 98 |

[a] Products were characterized from their physical properties, comparison with authentic samples and by spectroscopic methods.

3-Substituted indole was examined for this reaction under the above reaction conditions with aldehydes (Scheme 6). As the more active site (C-3) in indole was blocked in this case electrophilic substitution took place at C-2 in indole giving the corresponding bis(indolyl)-methane in high yield under solid-state conditions.

The chemo selectivity of the present method is also demonstrated by competitive reactions of indol with arylaldehydes in the presence of aliphatic ones and ketones. For example, when a 1:1 mixture of benzaldehyde and propionaldehyde was allowed to react with 2 equivalents of indole in the presence of TCCA under grinding conditions, it was found that the arylaldehydes was chemo selectively converted to the corresponding bis(indolyl)methane but the aliphatic ones was converted slightly. Also, in an equimolar mixture arylaldehyde and ketone, only arylaldehyde was converted to the corresponding bis(indolyl)methane, whereas ketone remained (Scheme 7). The reaction was clean and the products were obtained in high yields without the formation of any side products, such as N-alkylated products.

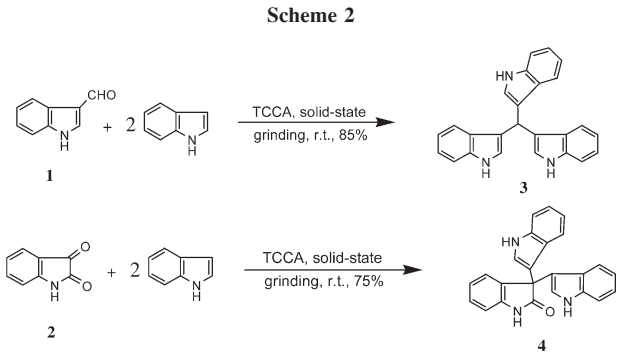
## CONCLUSIONS

In conclusion, we have introduced TCCA as a catalytic reagent for the efficient preparation of bis-indolyl, tris-indolyl, di(bis-indolyl), tri(bis-indolyl), and tetra(bis-indolyl)methanes from indole with various aldehydes and ketones under solid-state conditions by pulverization-activation method at room temperature with excellent yields. This method is applicable to a wide range of aldehydes, including aromatic, aliphatic, α,β-unsaturated, heterocyclic substrates, and ketones. In addition, efficiency, mild reaction conditions, easy work up, simplicity and chemoselectivity of this protocol provide a fast, green, and low cost procedure for the synthesis of these compounds.

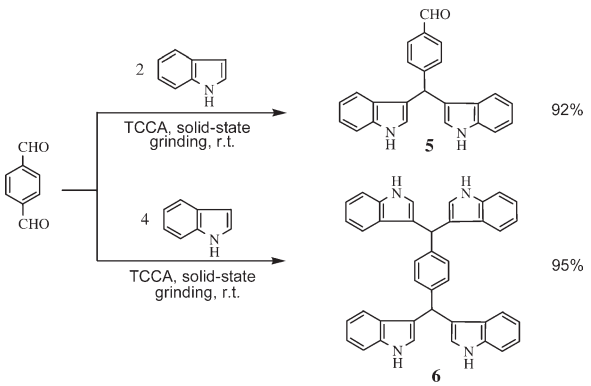
## EXPERIMENTAL

**Synthesis of bis(indolyl)methanes in solid-state grinding catalyzed by TCCA.** A mixture of indole (2.0 mmol), aldehyde or ketone (1.0 mmol), and TCCA (0.1 mmol) were

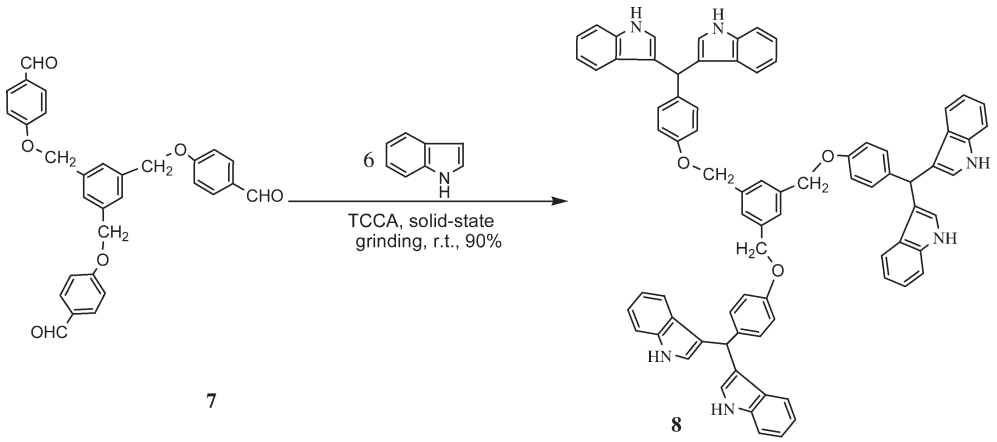
**Scheme 2**



**Scheme 3**



**Scheme 4**



added to a mortar and the mixture was pulverized with a pestle. A spontaneous reaction took place [1–5 min, Table 2, monitored by TLC (4:1, hexane/ acetone)]. After completion of the reaction, $CH_2Cl_2$ (10 mL) was added, and insoluble reagents were removed by filtration. The filtrate was evaporated under reduced pressure and the resulting crude material was purified by recrystallization from ethanol-water to afford pure products.

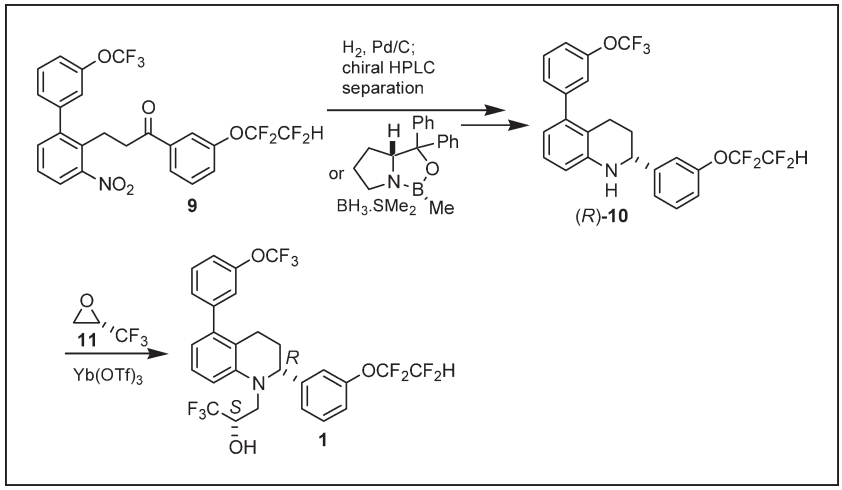
Published online 30 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



An efficient and scalable synthesis of the potent CETP inhibitor, (2*R*,α*S*)-3,4-dihydro-2-[3-(1,1,2,2-tetrafluoroethoxy)phenyl]-5-[3-(trifluoromethoxy)phenyl]-α-(trifluoromethyl)-1(2*H*)-quinolineethanol **1**, is described. One of the important intermediates, tetrahydroquinoline **10**, was readily prepared by reductive cyclization of nitroketone **9** in high yield. Asymmetric synthesis of **10** with high enantiomeric excess (>80% ee) was also developed.

*J. Heterocyclic Chem.*, **47**, 1406 (2010).

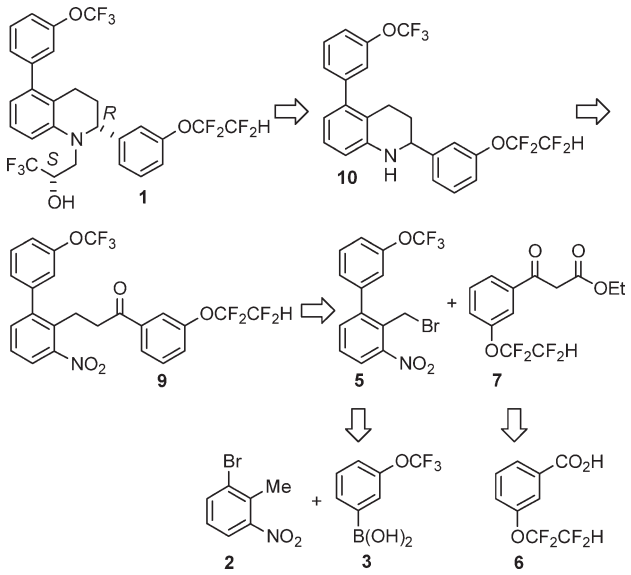
## INTRODUCTION

Low levels of high density lipoprotein-cholesterol (HDL-C) and high levels of low density lipoprotein-cholesterol (LDL-C) are independent risk factors for the development of atherosclerosis and eventually coronary heart disease (CHD), which remain the leading cause of death in the developed countries [1–3]. HDL-C plays important role in removal of excess cholesterol from peripheral cells to the liver for metabolic degradation in a reverse cholesterol transport (RCT) process [4–6]. Therefore, the increase in HDL-C level offers a new and promising therapeutical principle for treatment of CHD [7]. Plasma protein cholesteryl ester (CE) transfer protein (CETP) mediates the transfer of CE from HDL to very low density lipoprotein (VLDL) and LDL in exchange for triglyceride [8,9]. As a result, the disadvantage of this action is a reduction in HDL-C level and with increase in VLDL-C and LDL-C levels. Inhibition of CETP has been proposed as a strategy to raise HDL-C level [10], thus increases the efficiency of RCT.

Compound **1** has been identified as a potent CETP inhibitor [11]. It showed $IC_{50}$ in 34–44 n*M* range and increased HDL-C in human CETP transgenic mice. The original preparation of **1** [11c] was lengthy and involved the use of some highly toxic and potentially explosive chemicals. To supply a large quantity of material **1** for further *in vivo* and toxicity studies, an efficient and scalable synthesis was required. In this article, we describe the chemical synthesis that was used successfully in the preparation of multigram quantities of compound **1**.

As illustrated by the retrosynthetic analysis in Scheme 1, the feature of our strategy involved efficient construction of the piperidine ring. We envisioned that transforming nitroketone **9** to tetrahydroquinoline **10** would be the key step in achieving our goal. This could be realized by reductive cyclization of nitroketone **9** to a racemic mixture of **10** from which the (*R*)-enantiomer

**Scheme 1.** Retrosynthetic analysis



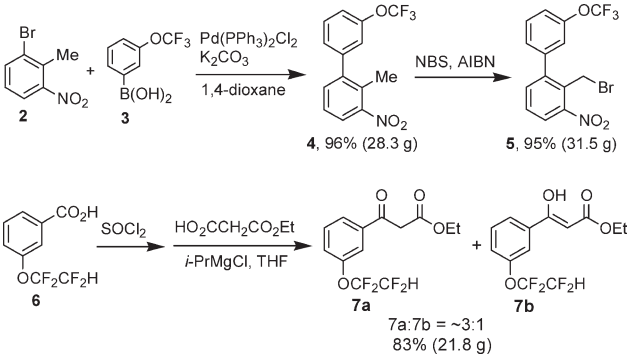
could be isolated by chiral HPLC separation. (*R*)-**10** might also be prepared in a stepwise fashion by asymmetric reductive cyclization of **9**. The nitroketone **9** could be derived from benzyl bromide **5** and β-keto ester **7** by alkylation and decarboxylation. The synthons **5** and **7** should be easily assembled from commercially available 5-bromo-6-methylnitrobenzene **2**, 3-(trifluoromethoxy)phenyl-boronic acid **3**, and 3-tetrafluoroethoxybenzoic acid **6**, respectively.

The preparation of benzyl bromide **5** and β-keto ester **7** is shown in Scheme 2, and the reaction scale is given in parentheses. Suzuki reaction [12] of 5-bromo-6-methylnitrobenzene **2** with 3-(trifluoromethoxy)phenylboronic acid **3** provided 28 g of **4** in 96% yield. In a solvent-free system, bromination [13] of **4** (26 g) with *N*-bromosuccimide and AIBN at 90°C for 5 h gave benzyl bromide **5** in 95% yield. The β-keto ester **7** was synthesized by acylation of ethyl hydrogen malonate with 3-tetrafluoroethoxybenzoyl chloride, followed by decarboxylation during acidic work-up procedure [14]. The product was a mixture of β-keto ester **7a** and its tautomer enol **7b** in ~3:1 ratio.

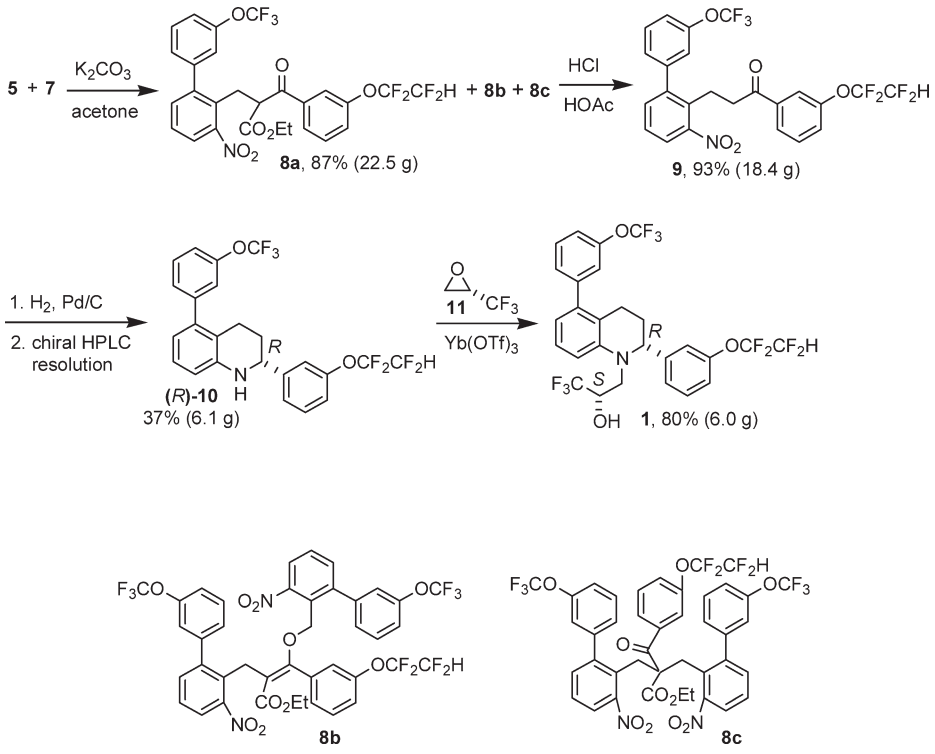
With both building synthons **5** and **7** available, the stage was set to generate the important intermediate **8a** by alkylation of β-keto ester **7** with benzyl bromide **5** (Scheme 3). However, the reaction was complicated by the formation of **8a**, *C*,*O*-dialkylation compound **8b**, and α,α-dialkylation by-product **8c**. Different reaction conditions were explored by varying a variety of bases (such as $NaN(SiMe_3)_2$, NaH, *n*-BuLi, $Cs_2CO_3$, and $K_2CO_3$), solvents (such as THF, DMF, $CH_3CN$, and acetone), reaction temperature, the order of reagent addition. It was found that using $K_2CO_3$ in acetone was the best conditions tried to give the desired product **8a** in 87% yield, along with 5% of *C*,*O*-dialkylation by-product **8b**. Without separation of the two compounds, the mixture was converted to the same nitroketone **9** upon treatment with hydrochloric acid in hot acetic acid [15]. Under normal catalytic hydrogenation conditions, reductive cyclization of nitroketone **9** occurred to form tetrahydroquinoline **10** in essentially quantitative yield. The (*R*)-**10** was collected by chiral HPLC resolution of the racemic mixture. The *R* configuration at the 2 position of the tetrahydroquinoline ring of (*R*)-**10** was known by comparing its optical rotation, $[\alpha]_D^{20}$ –13.3° (*c*1.0, $CHCl_3$), with that of (*R*)-**10**, $[\alpha]_D^{20}$ –12.9° (*c* 1.0, $CHCl_3$), obtained from an asymmetric synthesis shown below in Scheme 4. In the presence of catalytic amount of Lewis acid ytterbium trifluoromethanesulfonate, N-alkylation of (*R*)-**10** with commercially available ~90% enriched (*S*)-1,1,1-trifluoro-2,3-epoxypropane **11** occurred to produce the target **1** in 80% yield [16]. Under these conditions, the ring opening of the epoxide proceeded with complete regioselectivity.

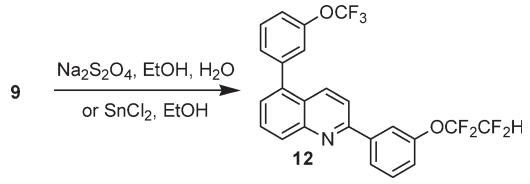
Although this route is attractive due to its simplicity and rapid access to **1**, it suffers from the obvious need for resolution of racemic tetrahydroquinoline **10** and economy of synthesis. We then turned our attention toward the development of an asymmetric approach to (*R*)-**10**. It was hoped that by controlling reaction conditions, the hydrogenation of nitroketone **9** could stop at aminoketone or cyclic-imine stage, and both of the materials could be reduced to (*R*)-**10** in high enantiomeric purity by subjecting to chiral sodium triacyloxyborohydride [17] as demonstrated in our syntheses of similar analogues [18]. However, preliminary investigation by changing $H_2$ pressure, solvents, and catalysts only yielded a mixture of starting material **9** and partially reduced intermediates. The strategy of stepwise reduction of nitroketone **9** to aminoketone and subsequently enantioselective reductive cyclization of which to (*R*)-**10** was also attempted by using inorganic reducing reagents such as $Na_2S_2O_4$, $SnCl_2$, and $FeSO_3$. Unfortunately, it only resulted in the formation of quinoline **12** (eq. 1):

**Scheme 2**



**Scheme 3**

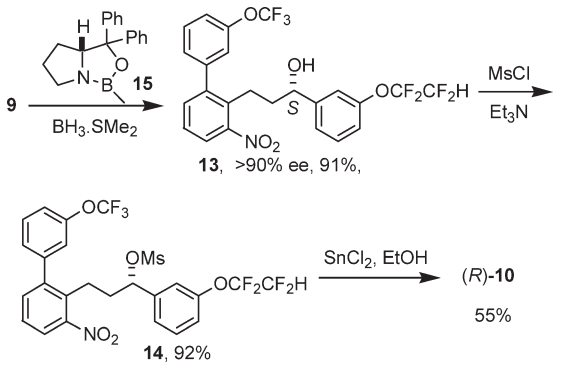




(1)

Alternatively, the required stereocenter was introduced by utilizing Corey's oxazaborolidine-borane methodology [19]. Using the *R*-Me CBS oxazaborolidine reagent **15**, nitroketone **9** was enantioselectively reduced to (*S*)-alcohol **13** in 91% yield and >90% enantiomeric excess (% ee) [20] (Scheme 4). The *S* configuration of alcohol **13** was assigned based upon the precedent illustrated in Corey and Helal's article [19]. The hydroxyl group in **13** was then converted to a good leaving group mesylate **14**. Upon treatment of **14** with $SnCl_2$ in ethanol, the nitro group was reduced to amino functionality [21] and followed by spontaneous intramolecular displacement of the mesylate to yield the ring closed (*R*)-**10** in 80–85% ee [20]. During this transformation, the inversion of the original stereocenter occurred to give the *R* absolute configuration at the 2 position of the tetrahydroquinoline ring of **10**. A small erosion of ee was observed during the cyclization step due to a competitive ionization pathway.

**Scheme 4**



In conclusion, we have developed a very efficient, scalable, and high yielding synthesis of (2*R*,α*S*)-3,4-dihydro-2-[3-(1,1,2,2-tetrafluoroethoxy)phenyl]-5-[3-(trifluoromethoxy)phenyl]-α-(trifluoromethyl)-1(2*H*)-quinolineethanol **1**. This method provides access to **1** in multigram quantities reliably.

## EXPERIMENTAL

**2-Methyl-3-nitro-3′-trifluoromethoxy-biphenyl (4).** A mixture of 2-bromo-6-nitrotoluene **2** (21.5 g, 99.5 mmol), 3-trifluoromethoxylbenzeneboronic acid **3** (27.0 g, 131.1 mmol), $Pd(PPh_3)_2Cl_2$ (3.50 g, 5.0 mmol), and 2.0*M* $K_2CO_3$ (120 mL, 240 mmol) in dioxane (330 mL) was degassed with $N_2$ and then heated at 100°C for 3 h. After cooling to room temperature, the reaction mixture was passed through Celite and partitioned between EtOAc and brine. The combined organic

phases were dried ($MgSO_4$), concentrated, and purified by flash column chromatography (1–10% EtOAc in hexane) to give 28.27 g (96%) of **4** as a light yellow oil. $^1$H NMR (300 MHz, $CDCl_3$) δ 7.85 (d, $J$ = 7.8 Hz, 1 H), 7.74–7.38 (m, 3 H), 7.31–7.23 (m, 2 H), 7.19 (s, 1 H), 2.37 (s, 3 H).

**2-Bromomethyl-3-nitro-3′-trifluoromethoxy-biphenyl (5).** A mixture of **4** (26.1 g, 87.8 mmol), NBS (20.3 g, 114 mmol), and AIBN (1.44 g, 8.77 mmol) was degassed with $N_2$ and then heated at 85°C. After 20 min, it began to react vigorously. After 2 h, the temperature was raised to 90°C, and the mixture was heated for 3 more hours. After cooling to room temperature, the reaction mixture was diluted with hexane. The solid was filtered off, and the filtrate was concentrated to give 31.47 g (95%) of **5** as a yellow oil. $^1$H NMR (300 MHz, $CDCl_3$) δ 8.00 (dd, $J$ = 2.0, 2.0, 1 H), 7.58–7.49 (m, 3 H), 7.41–7.28 (m, 3 H), 4.69 (s, 2 H).

**3-Oxo-3-[3-(1,1,2,2-tetrafluoro-ethoxy)-phenyl]-propionic acid ethyl ester (7).** To an ice-cooled solution of 3-tetrafluoroethoxy-benzoic acid **6** (40.0 g, 0.168 mol) was added $SOCl_2$ (59.0 mL, 0.809 mol) dropwise. After addition, the ice-bath was removed, and the mixture was stirred at room temperature for 3 h followed by heating at 50°C for 2 h and 75°C for 3 h. The reaction mixture was left stirring at room temperature overnight. After removing of $SOCl_2$ *in vacuo*, to the residue was added dry toluene and concentrated (20 mL × 3). After on high vacuum line for 5 h, the acyl chloride was obtained as a clear oil (41.0 g, 95%).

To a solution of $EtOCOCH_2CO_2H$ (16.1 g, 0.122 mol) in THF (120 mL) at –78°C was added *i*-PrMgCl (2.0*M* in THF, 122 mL, 0.244 mol) dropwise through an additional funnel. After stirring at –78°C for 1 h, the above prepared acyl chloride (20.9 g, 0.0815 mol) in THF (80 mL) was added via an addition funnel. The reaction mixture was stirred at –78°C for 1 h and RT for 2 h. The reaction flask was cooled in an ice-bath, and ∼100 mL of 1*N* HCl was added dropwise until pH < 1. Upon addition of 1*N* HCl, some precipitate formed and stirring became difficult. The precipitated solid gradually dissolved during further addition of 1*N* HCl. The organic layer was separated and the aqueous layer was extracted with EtOAc. The combined organic phases were dried, concentrated, and purified by flash column chromatography (5–10% EtOAc in hexane) to give 21.8 g (83%) of **7** as a yellow oil.

***7a.*** $^1$H NMR (300 MHz, $CDCl_3$) δ 7.89–7.85 (m, 1 H), 7.80 (s, 1 H), 7.56–7.51 (m, 1 H), 7.48–7.45 (m, 1 H), 5.95 (tt, $J$ = 53.0, 2.5 Hz, 1 H), 4.23 (q, $J$ = 7.2 Hz, 2 H), 3.98 (s, 2 H), 1.27 (t, $J$ = 7.2 Hz, 3 H); MS (ES) $m/z$: 331 ($M+Na^+$); HRMS (ESI) calcd for $C_{13}H_{12}F_4O_4$ ($M + H^+$) $m/z$ 309.0750, found $m/z$ 309.0751.

***7b.*** $^1$H NMR (300 MHz, $CDCl_3$) δ 12.6 (s, 1 H), 7.71–7.68 (m, 1 H), 7.63 (s, 1 H), 7.45–7.42 (m, 1 H), 7.34–7.31 (m, 1 H), 5.94 (tt, $J$ = 53.0, 2.5 Hz, 1 H), 5.68 (s, 1 H), 4.29 (q, $J$ = 7.2 Hz, 2 H), 1.35 (t, $J$ = 7.2 Hz, 3 H); MS (ES) $m/z$: 331 ($M+Na^+$).

**2-(3-Nitro-3′-trifluoromethoxy-biphenyl-2-ylmethyl)-3-oxo-3-[3-(1,1,2,2-tetrafluoro-ethoxy)-phenyl]-propionic acid ethyl ester (8a).** To a mixture of β-keto ester **7** (13.5 g, 43.8 mmol) and benzyl bromide **5** (15.7 g, 41.7 mmol) in 270 mL of acetone was added $K_2CO_3$ (8.66 g, 62.6 mmol). After stirring at room temperature for 1 h, TLC (15% EtOAc in hexane) showed the completion of reaction. The reaction mixture was filtered through Celite and the solid was washed with EtOAc. The filtrate was concentrated and purified by flash column chromatography (5–15% EtOAc in hexane) to give 22.5 g (87%) of **8a** as a yellow oil. $^1$H NMR (300 MHz, $CDCl_3$) δ 7.85 (dd, $J$ = 6.5, 2.7 Hz, 1 H), 7.59–7.54 (m, 2 H), 7.48–7.36 (m, 5 H), 7.26–7.21 (m, 2 H), 7.14 (s, 1 H), 5.92 (tt, $J$ = 53.0, 2.5 Hz, 1 H), 4.21 (t, $J$ = 7.0 Hz, 1 H), 4.02–3.82 (m, 2 H), 3.74–3.59 (m, 2 H), 0.96 (t, $J$ = 7.1 Hz, 3 H); MS (ES) $m/z$: 626 ($M+Na^+$). Anal. Calcd for $C_{27}H_{20}F_7NO_7$: C, 53.74; H, 3.34; N, 2.32. Found: C, 54.00; H, 3.02; N, 2.36.

**3-(3-Nitro-3′-trifluoromethoxy-biphenyl-2-yl)-1-[3-(1, 1,2,2-tetrafluoro-ethoxy)-phenyl]-propan-1-one (9).** A solution of **8a** (22.5 g, 37.3 mmol) in concentrated HCl (85 mL) and HOAc (140 mL) was heated at 100°C for 9 h. TLC (20% EtOAc in hexane) showed the completion of reaction. After cooling down to room temperature, HOAc was evaporated through a rotary evaporator. The residue was diluted with water (200 mL) and cooled in an ice-bath. To the mixture was added 6*N* NaOH (∼80 mL) until basic judged by pH paper. The aqueous solution was extracted with EtOAc (×3), and the combined organic layers were dried ($Na_2SO_4$), concentrated, and purified by flash column chromatography (10–20% EtOAc in hexane) to give 18.4 g (93%) of **9** as a yellow oil. $^1$H NMR (400 MHz, $CDCl_3$) δ 7.90–7.84 (m, 1 H), 7.71–7.64 (m, 2 H), 7.50–7.37 (m, 5 H), 7.28–7.22 (m, 2 H), 7.17 (s, 1 H), 5.91 (tt, $J$ = 53.0, 2.7 Hz, 1 H), 3.21–3.08 (m, 4 H); MS (ES) $m/z$: 554 ($M+Na^+$); HRMS (ESI) calcd for $C_{24}H_{16}F_7NO_5$ ($M + H^+$) $m/z$ 532.0995, found $m/z$ 532.0989. Anal. Calcd for $C_{24}H_{16}F_7NO_5$: C, 54.25; H, 3.01; N, 2.64. Found: C, 54.38; H, 2.59; N, 2.89.

**2-[3-(1,1,2,2-Tetrafluoro-ethoxy)-phenyl]-5-(3-trifluoromethoxy-phenyl)-1,2,3,4-tetrahydro-quinoline (10).** A mixture of **9** (5.70 g, 10.7 mmol) and 10% Pd/C (615 mg) in EtOAc (∼100 mL) was shaken in a par-shaker under 50 psi $H_2$ for 19 h. The reaction mixture was filtered through Celite and the solid was washed with EtOAc. The filtrate was concentrated and dried under vacuum to give 5.20 g (100%) of **10** as a yellow oil. $^1$H NMR (400 MHz, $CDCl_3$) δ 7.40–7.29 (m, 3 H), 7.28–7.23 (m, 2 H), 7.20–7.05 (m, 4 H), 6.61 (d, $J$ = 7.8 Hz, 2 H), 5.92 (tt, $J$ = 53.0, 2.8 Hz, 1 H), 4.50 (dd, $J$ = 8.9, 3.3 Hz, 1 H), 2.75 (ddd, $J$ = 16.4, 10.6, 5.1 Hz, 1 H), 2.51 (dt, $J$ = 16.5, 4.9 Hz, 1 H), 2.10–2.02 (m, 1 H), 1.91–1.81 (m, 1 H); MS (ES) $m/z$: 486 ($M+H^+$). Anal. Calcd for $C_{24}H_{18}F_7NO_2$: C, 59.39; H, 3.74; N, 2.89. Found: C, 59.80; H, 3.50; N, 2.80.

**(2*R*)-1,2,3,4-Tetrahydro-2-[3-(1,1,2,2-tetrafluoroethoxy)-phenyl]-5-[3-(trifluoromethoxy)phenyl]quinoline (10).** Chiral HPLC resolution of racemate (±)-**10**: 16.5 g of (±)-**10** was separated by using Chiralcel OJ eluting with 80% heptane–20% ethanol at 80 mL/min and wavelength 220 nm. A total of 6.46 g of (*R*)-**10** and 5.91 g of (*S*)-**10** were obtained in 99.99% and 99.5% ee, respectively. (*R*)-**10**: $[\alpha]_D^{20}$ –13.3° (*c*1.0, $CHCl_3$).

Cyclization of (*S*)-**14**: A solution of **14** (105 mg, 0.172 mmol) and EtOH (2 mL) was degassed under vacuum and then filled with $N_2$ for three times. To the solution $SnCl_2{\cdot}2H_2O$ (244 mg, 1.08 mmol) was added and the reaction mixture was stirred at room temperature under $N_2$ for 4.5 h. After removal of EtOH under vacuum, to the residue were added $CH_2Cl_2$ and saturated $NH_4OH$. The precipitated solid was filtered through Celite, and rinsed with $CH_2Cl_2$ and EtOAc. The filtrate was separated and the aqueous layer was extracted with $CH_2Cl_2$. The combined organic phases were dried, concentrated *in vacuo*, and purified by flash column chromatography (10–15% EtOAc in hexane) to give 46 mg (55%) of (*R*)-**10** as an oil. $^1$H NMR (400 MHz, $CDCl_3$) δ

7.42–7.30 (m, 3 H), 7.29–7.23 (m, 2 H), 7.21–7.07 (m, 4 H), 6.61 (d, $J$ = 7.8 Hz, 2 H), 5.91 (tt, $J$ = 53.1, 2.8 Hz, 1 H), 4.51 (dd, $J$ = 9.0, 3.4 Hz, 1 H), 4.20 (brs, 1 H), 2.76 (ddd, $J$ = 16.3, 10.6, 5.2 Hz, 1 H), 2.53 (dt, $J$ = 16.6, 5.0 Hz, 1 H), 2.11–2.04 (m, 1 H), 1.93–1.83 (m, 1 H); MS (ES) $m/z$: 486 ($M+H^+$); HRMS (ESI) calcd for $C_{24}H_{18}F_7NO_2$ $m/z$ 485.1226, found $m/z$ 485.1219. $[\alpha]_D^{20}$ –12.9° ($c$ 1.0, $CHCl_3$). A total of 80–85% ee was analyzed by chiral HPLC (Chiralcel OJ; isocratic elution 10/90 isopropanol/hexane, 0.8 mL/min, area integration at 210 nm).

**(α*S*)-3-Nitro-α-[3-(1,1,2,2-tetrafluoroethoxy)phenyl]-3′-(trifluoromethoxy)-[1,1′-biphenyl]-2-propanol (13).** To a solution of THF (0.2 mL) and 1.0*M* (*R*)-2-methyl-CBS-oxazaborolidine (0.186 mL, 0.186 mmol) in toluene was added 2.0*M* $BH_3{\cdot}SMe_2$ (0.137 mL, 0.274 mmol) in THF. After stirring at room temperature for 15 min, the mixture was cooled to –25°C and to which a solution of **9** (132 mg, 0.249 mmol) in THF (2 mL) was added. The reaction mixture was stirred from –20°C to –10°C for 3.5 h and then quenched with a few drops of MeOH followed by a few drops of 1*N* HCl. The reaction mixture was partitioned between $CH_2Cl_2$ and water. The organic layer was dried, concentrated, and purified by flash column chromatography (10–20% EtOAc in hexane) to provide 114 mg (86%) of **13** as an oil. $^1$H NMR (300 MHz, $CDCl_3$) δ 7.88–7.77 (m, 1 H), 7.43–7.37 (m, 3 H), 7.28–7.23 (m, 2 H), 7.14–6.99 (m, 5 H), 5.90 (tt, $J$ = 53.1, 2.8 Hz, 1 H), 4.54 (brs, 1 H), 2.89–2.79 (m, 1 H), 2.73–2.63 (m, 1 H), 1.92–1.76 (m, 2 H), 1.73 (brs, 1 H); MS (ES) $m/z$: 556 ($M+Na^+$). Anal. Calcd for $C_{24}H_{18}F_7NO_5$: C, 54.04; H, 3.40; N, 2.63. Found: C, 54.10; H, 2.89; N, 2.50. $[\alpha]_D^{20}$ –10.6° ($c$ 1.0, $CHCl_3$). A total of >90% ee was determined by chiral HPLC (Chiralcel OJ; isocratic elution 10/90 isopropanol/hexane, 0.8 mL/min, area integration at 210 nm).

**(α*S*)-3-Nitro-α-[3-(1,1,2,2-tetrafluoroethoxy)phenyl]-3′-(trifluoromethoxy)-[1,1′-biphenyl]-2-propanol methanesulfonate (14).** To a solution of **13** (220 mg, 0.413 mmol) and $CH_2Cl_2$ (3 mL) was added methanesulfonyl chloride (0.040 mL, 0.52 mmol) and $Et_3N$ (0.086 mL, 0.62 mmol). After stirring at room temperature for 2 h, water was added and the mixture was acidified with 1*N* HCl until acidic by pH paper. The organic layer was separated and the aqueous layer was extracted with $CH_2Cl_2$. The combined organic phases were dried and concentrated to give 250 mg (99%) of **14** as a yellow oil. $^1$H NMR (400 MHz, $CDCl_3$) δ 7.88–7.83 (m, 1 H), 7.49–7.45 (m, 1 H), 7.42 (d, $J$ = 4.6 Hz, 2 H), 7.36–7.29 (m, 2 H), 7.20–7.15 (m, 2 H), 7.09–7.07 (m, 2 H), 7.03 (s, 1 H), 5.92 (tt, $J$ = 53.0, 2.7 Hz, 1 H), 5.38 (dd, $J$ = 7.3, 5.8 Hz, 1 H), 2.85 (td, $J$ = 12.6, 4.8 Hz, 1 H), 2.72 (s, 3 H), 2.67 (dd, $J$ = 13.1, 4.8 Hz, 1 H), 2.18–1.98 (m, 2 H); MS (ES) $m/z$: 634 ($M+Na^+$).

**(2*R*,α*S*)-3,4-Dihydro-2-[3-(1,1,2,2-tetrafluoroethoxy)phenyl]-5-[3-(trifluoromethoxy)phenyl]-α-(trifluoromethyl)-1(2*H*)-quinolineethanol (1).** To a mixture of (*R*)-**10** (6.10 g, 10.2 mmol) and 1,1,1-trifluoro-2,3-epoxypropane **11** (5.71 g, 51.0 mmol) in $CH_2Cl_2$ (60 mL) under $N_2$ was added $Yb(OTf)_3$ (1.58 g, 2.55 mmol). The reaction mixture was heated at 50°C for 48 h and then cooled to ambient temperature. EtOAc was added and the mixture was washed with saturated $NaHCO_3$, $H_2O$ and brine, dried, concentrated and purified by flash column chromatography (5–15% EtOAc in hexane) to give 6.00 g (80%) of **1** as an oil. $^1$H NMR (400 MHz, $CDCl_3$) d 7.40–7.34 (m, 2 H), 7.25–7.12 (m, 6 H), 7.05 (s, 1 H), 6.74 (d, $J$ = 8.1 Hz, 1 H), 6.68 (d, $J$ = 7.3 Hz, 1 H), 5.89 (tt, $J$ = 53.1, 2.8 Hz, 1 H), 4.90 (t, $J$ = 4.4 Hz, 1 H), 4.46–4.41 (m, 1 H), 3.92 (d, $J$ = 15.4 Hz, 1 H), 3.32 (dd, $J$ = 15.4, 9.6 Hz, 1 H), 2.49 (dt, $J$ = 16.2, 4.6 Hz, 1 H), 2.41–2.34 (m, 2 H), 2.19–2.10 (m, 1 H), 2.00–1.94 (m, 1 H); MS (ES) $m/z$: 598 ($M+H^+$); HRMS (ESI) calcd for $C_{27}H_{21}F_{10}NO_3$ $m/z$ 597.1362, found $m/z$ 597.1378. Anal. Calcd for $C_{27}H_{21}F_{10}NO_3$: C, 54.28; H, 3.54; N, 2.34. Found: C, 54.10; H, 3.40; N, 1.99. $[\alpha]_D^{20}$ –112.0° ($c$1.0, $CHCl_3$).

**Acknowledgment.** The authors thank Sandra Damon for determining enantiomeric excess of some of the compounds.

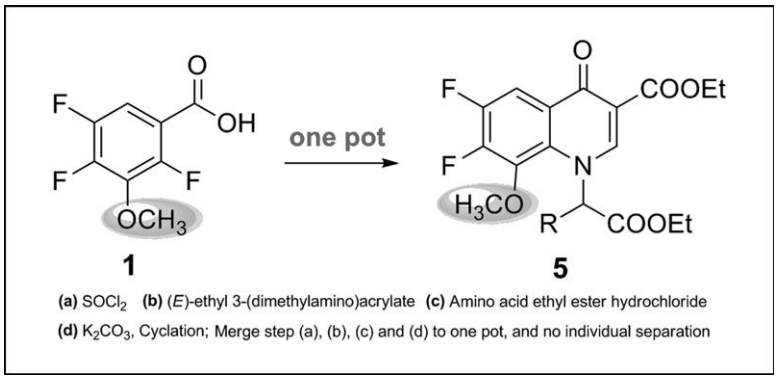
Published online 30 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



A series of novel quinolone heterocyclic derivatives from natural amino acid were synthesized in one-pot method, which is very beneficial for the industrial operation to save manufacturing costs. These new compounds were characterized by $^{1}$H NMR, $^{13}$C NMR, infrared spectrum, mass spectrum, and elemental analysis. The preliminary bioassays results revealed that they had certain antimicrobial activity against *Bacillus subtilis* and *Staphylococcus aureus*.

*J. Heterocyclic Chem.*, **47**, 1411 (2010).

## INTRODUCTION

Interests in heterocycle compounds [1], especially quinolone heterocyclic compounds, have flourished for many years, largely as a result of the wide spread use on anti-asthmatic, anti-bacterial, anti-malarial, tyrosine-kinase PDGF-RTK inhibitor agent, etc. [2]. Because of such a wide range of applicability in medicine and bioorganic chemistry, there has been increasing interests in exploring new quinolone heteocyclic compounds to enrich this domain [3]. Enlightened and encouraged by the bioactivity of quinolone heterocyclic compounds and the abundant existence of amino acid in nature, we attempt to introduce amino acid piece into quinolone heterocycle and wish to discover some new bioactive compounds.

Generally, there are several steps and much complicated post-treatment and purification process to synthesize the quinolone and fluoroquinolone derivatives, such as 4-oxoquinoline, 8-nitrofluoro-quinolone, and other quinolone derivatives [4–7]. Therefore, we wish to develop a concise route with simple post-treatment to synthesize a series of novel quinolone heterocyclic compounds. Fortunately, when we use one-pot method to synthesize compounds **5** from compound **1**, the whole reaction goes well and smoothly. This method is very beneficial for the industrial operation to save time and manufacturing costs. Herein a series of novel quinolone heterocyclic derivatives from natural amino acid salts were designed and prepared according to this method. The title compounds were characterized by $^{1}$H NMR, $^{13}$C NMR, infrared spectrum, mass spectrum, and elemental analysis. To investigate their preliminary antimicrobial bioactivities, these compounds were screened by *Bacillus subtilis*, *Staphylococcus aureus*, *Aspergillus fumigatus*, and *Candida albicans*. The preliminary bioassays results revealed that they had certain bactericidal activity against *Bacillus subtilis* and *Staphylococcus aureus*. The synthetic routes are shown in Figure 1.

## RESULTS AND DISCUSSION

**Chemistry.** As part of our ongoing interests to find new quinolone heterocyclic derivatives, we try to obtain the quinolone compounds *via* intramolecular cyclization reaction, which contain natural amino acid piece at N1-position of quinolone heterocyclic ring. We selected the 2,4,5-trifluoro-3-methoxybenzoic acid **1** as started materials to synthesize quinolone derivatives **6**. At first, we synthesized compounds **6** step by step from **1** to **5** with complicated post-treatment and purification in each step. Interestingly, when we attempt to synthesize compounds **5** from compound **1** in one-pot to cut off much troublesome separation and purification in the middle process we found the whole reaction goes well. So a facile and simple rout

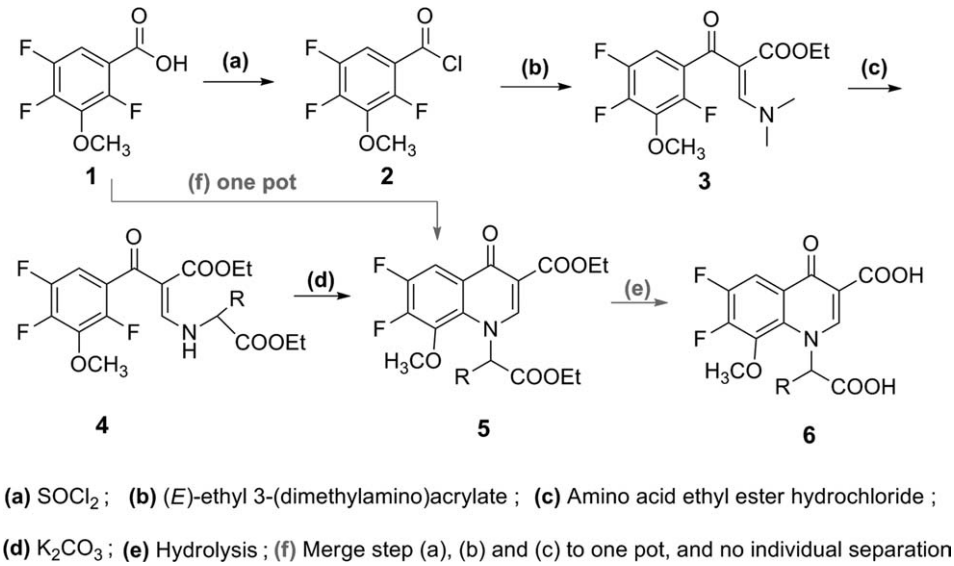


**Figure 1.** (a) $SoCl_2$; (b) (E)-ethyl 3-(dimethylamino)acrylate; (c) Amino acid ethyl ester hydrochloride; (d) $K_2CO_3$; (e) Hydrolysis; (f) Merge step (a), (b), and (c) to open-pot, and no individual separation.

for the synthesis of compound **5** in one-pot way without any separation was developed, which is very beneficial for the industrial operation to save manufacturing costs.

The structures of quinolone heterocyclic compounds of **6a–6f** were confirmed by IR, $^1$H NMR, $^{13}$C NMR, MS, and elemental analysis. The infrared spectra of all compounds showed easily distinguishable carboxylic group stretching at 1789–1799 $cm^{-1}$ and 1721–1747 $cm^{-1}$ because of the two kind of carboxylic groups. In $^1$H NMR spectrum, two kind of carboxylic group signals appear between 13.42–13.73 ppm and 14.42–14.58 ppm, which demonstrate the existence of amino acids and quinolone cycle. In $^{13}$C NMR spectrum, the typical signals of carboxylic group and aromatic ring appear between 164.47–176.71 ppm and 102.85–158.97 ppm, which reveal the existence of the quinolone cycle.

**Biological activities.** All the title compounds were tested preliminarily for their antibacterial and antifungal activity. From the screening results, all the title compounds have certain activity against *Bacillus subtilis* and *Staphylococcus aureus* and nearly have no activity against *Aspergillus fumigatus* and *Candida albicans*. The detail results are listed in Table 1.

From the preliminary biological results, all the new compounds have certain antibacterial and antifungal bioactivity, which intrigued us to study its QSAR further and synthesize higher activity compound, the in-depth research work is undergoing.

In conclusion, we have developed a simple one-pot way of preparing quinolone heterocyclic compounds and synthesized a series of novel quinolone heterocyclic derivatives from natural amino acid. This method facilitates the industrial operation to save manufacturing costs. The preliminary bioassays results reveal that they have certain antimicrobial activity against *Bacillus subtilis* and *Staphylococcus aureus*.

## EXPERIMENTAL

All the reagents were purchased commercially and used without further purification. The melting point was determined

**Table 1**

The preliminary antimicrobial activity of title compounds.

using a XT-4 melting-point apparatus and uncorrected. IR spectra were recorded on a Bruker Equinox-55 spectrophotometer using KBr discs in the 4000–400 $cm^{-1}$ region. The $^1H$ NMR and $^{13}C$ NMR data were obtained on a Bruker AC-400 (400 MHz) instrument in DMSO-$d_6$ using TMS as internal standard. Chemical shifts (δ) are expressed in ppm and coupling constants *J* are given in Hz. Mass spectra were obtained on a Agilent 5973N mass spectrometer operating at 70 eV by electron ionization technique (EI/MS). Elemental analyses were performed on an EA-1110 instrument.

General synthesis procedure of compound **6a** is described below and other compounds were synthesized in similar way. The chemical structure, yields, and melt points of the synthesized compounds are listed in Table 2.

**1-(Carboxymethyl)-6,7-difluoro-8-methoxy-4-oxo-1,4-dihydroquinoline-3-carboxylic acid (6a).** 2,4,5-trifluoro-3-methoxybenzoic acid 4.12 g (0.02 mol) was dissolved in thionyl chloride 22 mL in a 50 mL round-bottomed flask, stirring and reflux for 3 h, removing the superfluous $SOCl_2$ on a rotary evaporator. (E)-ethyl-3-(dimethylamino) acrylate 2.86 g (0.02 mol) was added dropwise to the toluene solution of above leavings with stirring at 40–50°C, monitoring with TLC [PE/EA = 1/1 (v/v)] to the end of reactants, adding amino acid ethyl ester hydrochloride (0.02 mol) directly and stirring for about 5–8 h at room temperature, checking the reaction *via* TLC, then potassium carbonate 4.14 g (0.03 mol) was added and stirring for 8–10 h at 100°C. When the reaction was complete (determined by TLC), the mixture was acidified with diluted hydrochloride acid (5%) to PH = 2–3. The reaction mixture was poured into separatory funnel and separated. The organic layer was concentrated under reduced pressure and the residual was chromatographed on silica gel (PE/EA=2/1 (v/v)) to give compound **5**, which was added to the 20% sulfuric acid solution, refluxing for about 6–8 h, cooled to room temperature and filter. The filter cake was crystallized using 20% alcohol aqueous solution to afford compounds **6a**. IR (KBr) *v*: 3493, 2981, 2809, 1799, 1746, 1632, 1581, 1484, 1348, 1215, 1062 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$, 400 MHz): δ 4.02 (s, 3H, $OCH_3$), 5.37 (s, 2H, $CH_2$), 8.03–8.07 (m, 1H, ArH), 9.01 (s, 1H, C=CH), 13.42 (br s, 1H, COOH), 14.55 (br s, 1H, COOH); $^{13}C$ NMR (DMSO-$d_6$, 100 MHz): δ 59.33, 63.59, 107.56, 107.21 (d, $^2J_{C-F}$ = 17.8 Hz), 122.90 (d, $^3J_{C-F}$ = 7.20 Hz), 131.86 (d, $^3J_{C-F}$ = 3.39 Hz), 140.64 (d, $^2J_{C-F}$ = 11.7 Hz), 147.45 (dd, $^1J_{C-F}$ = 107.2 Hz, $^2J_{C-F}$ = 15.4 Hz), 149.96 (dd, $^1J_{C-F}$ = 104.1 Hz, $^2J_{C-F}$ = 15.6 Hz), 153.57, 165.50, 169.37, 176.43; MS (70 eV): *m/z* (%) = 313 ($M^+$); Anal. **1-(1-Carboxy-2-phenylethyl)-6,7-difluoro-8-methoxy-4-oxo-1,4-dihydroquinoli-ne-3-carboxylic acid (6f).** IR (KBr) *v*: 3495, 2958, 2868, 1798, 1747, 1617, 1568, 1474, 1353, 1279, 1110 cm$^{-1}$; $^1$H NMR (DMSO-$d_6$, 400 MHz): δ 3.23–3.27 (m, 2H, $CH_2$), 3.89–3.92 (m, 1H, CH), 4.21 (s, 3H, $OCH_3$), 7.31–7.42 (m, 5H, ArH), 8.11–8.14 (m, 1H, ArH), 9.02 (s, 1H, C=CH), 13.42 (br s, 1H, COOH), 14.58 (br s, 1H, COOH); $^{13}$C NMR (DMSO-$d_6$, 100 MHz): δ 36.89, 74.09, 106.78 (d, $^2J_{C-F}$ = 16.8 Hz), 107.94, 123.14, 127.08, 127.24, 128.74, 129.33, 129.71, 129.89 (d, $^3J_{C-F}$ = 5.2 Hz), 136.91, 140.05 (d, $^3J_{C-F}$ = 6.1 Hz), 145.32 (d, $^2J_{C-F}$ = 15.6 Hz), 148.16 (dd, $^1J_{C-F}$ = 107.4 Hz, $^2J_{C-F}$ = 15.6 Hz), 150.41 (dd, $^1J_{C-F}$ = 108.1 Hz, $^2J_{C-F}$ = 14.7 Hz), 154.03, 165.16, 172.41, 176.15; MS (70 eV): *m*/*z* (%) = 403 ($M^+$); Anal. Calcd. for $C_{20}H_{15}F_2NO_6$: C, 59.56; H, 3.75; N, 3.47; Found: C, 59.62; H, 3.69; N, 3.51.

All of the synthesized compounds were tested for their antibacterial and antifungal activity *in vitro* by broth dilution method with some bacteria *Bacillus subtilis*, *Staphylococcus aureus*, *Aspergillus fumigatus*, and *Candida albicans* according to the literature [8]. The antimicrobial discs (diameter, 0.55 cm) were prepared at concentrations of 1, 0.2, and 0.1 mg/mL and applied to each of the culture plates previously seeded with the test bacteria. These culture plates were then incubated at 37°C for 24 h. The preliminary antimicrobial activity was determined by the diameter of inhibition zone. For each compound, three replicate trials were conducted against each organism.

A series of 3′-(4-(2-methyl/phenyl/benzylthiazol-4-yl)phenyl)spiro[indoline-3,2′-thiazolidine]-2,4′-diones was synthesized. The structures of the synthesized compounds were evaluated by analytical and spectral (IR, $^1$H NMR, $^{13}$C NMR, LC-MS, and elemental analysis) methods. All the synthesized compounds were screened for qualitative (Zone of inhibition) and quantitative antimicrobial activities (MIC). Most of the derivatives showed good activity towards Gram-positive and Gram-negative bacteria.

## INTRODUCTION

The chemistry of spiro derivatives of isatin continues to draw attention of synthetic organic chemists due to their varied biological activities [1–4]. Of these, spiro[indol-thiazolidenes] has attracted our attention because they show a broad spectrum of pharmacological properties [5,6]. On the basis of these observations it was thought that it would be worthwhile to design and synthesize some new isatin based spirothiazolidine derivatives derived by coupling spiro[indol-thiazolidenes] with biologically active thiazole nucleus. Hence, we have synthesized several 3′-(4-(2-substituted thiazol-4-yl)phenyl)spiro[indoline-3,2′-thiazolidine]-2,4′-diones **13–32** and screened for their antimicrobial activity.

## RESULTS AND DISCUSSION

The synthesis of 3′-(4-(2-methyl/phenyl/benzylthiazol-4-yl)phenyl)spiro[indoline-3,2′-thiazolidine]-2,4′-diones **13–32** is illustrated and outlined in Figure 1. The starting materials 2-methyl-4-(4-aminophenyl)thiazole **3**, 2-aryl-4-(4-aminophenyl)thiazole **4–6**, 2-benzyl-4-(4-aminophenyl)thiazole **7–12**, were prepared according to reported procedure [7]. The spiro compounds were synthesized by the reported procedure [8–13]. All the compounds were purified by column chromatography or recrystallized from hexane: ethyl acetate (9:1). The structures of the compounds were established by IR, $^1$H NMR, $^{13}$C NMR, LCMS, and elemental analysis and the results are presented in the experimental section. The spectral data of compounds **13–32** were in accordance with the assumed structures. The mass spectra of all the compounds revealed the molecular ion peak $M^+$ and M+2 ion peak due to S, Br, and/or Cl. The IR spectra showed presence of characteristic absorption peaks at 3200–3400 cm$^{-1}$ (>NH), 1730 and 1695 cm$^{-1}$ (C=O) indicating that cyclocondensation has occurred which was confirmed by its $^1$H NMR and $^{13}$C NMR data. The $^1$H NMR spectra revealed a double doublet integrating for two geminal protons of thiazolidine nucleus. $^{13}$C NMR spectra showed all expected characteristic peaks in the aromatic and aliphatic region along with δ 110–111 (spiro carbon atom) [13]. As a representative case, the IR spectrum of compound **27** showed peaks at 3238 cm$^{-1}$(>NH), 1735 and 1694 cm$^{-1}$ (C=O), 1619 cm$^{-1}$ (C=N) indicating that the cycloaddition has occurred. This was further confirmed by its $^1$H NMR spectrum which revealed an AB quartet of thiazolidine methylene at δ 3.75 and 4.42 with $J$ = 15 Hz. The benzylic methylene protons appeared at δ 4.18. All the aromatic protons appeared between δ 6.88 and 7.67. The lactam N—H appeared at δ 10.17. Further the $^{13}$C NMR spectrum of **27** revealed two signals at δ 33.00 and 38.8 for

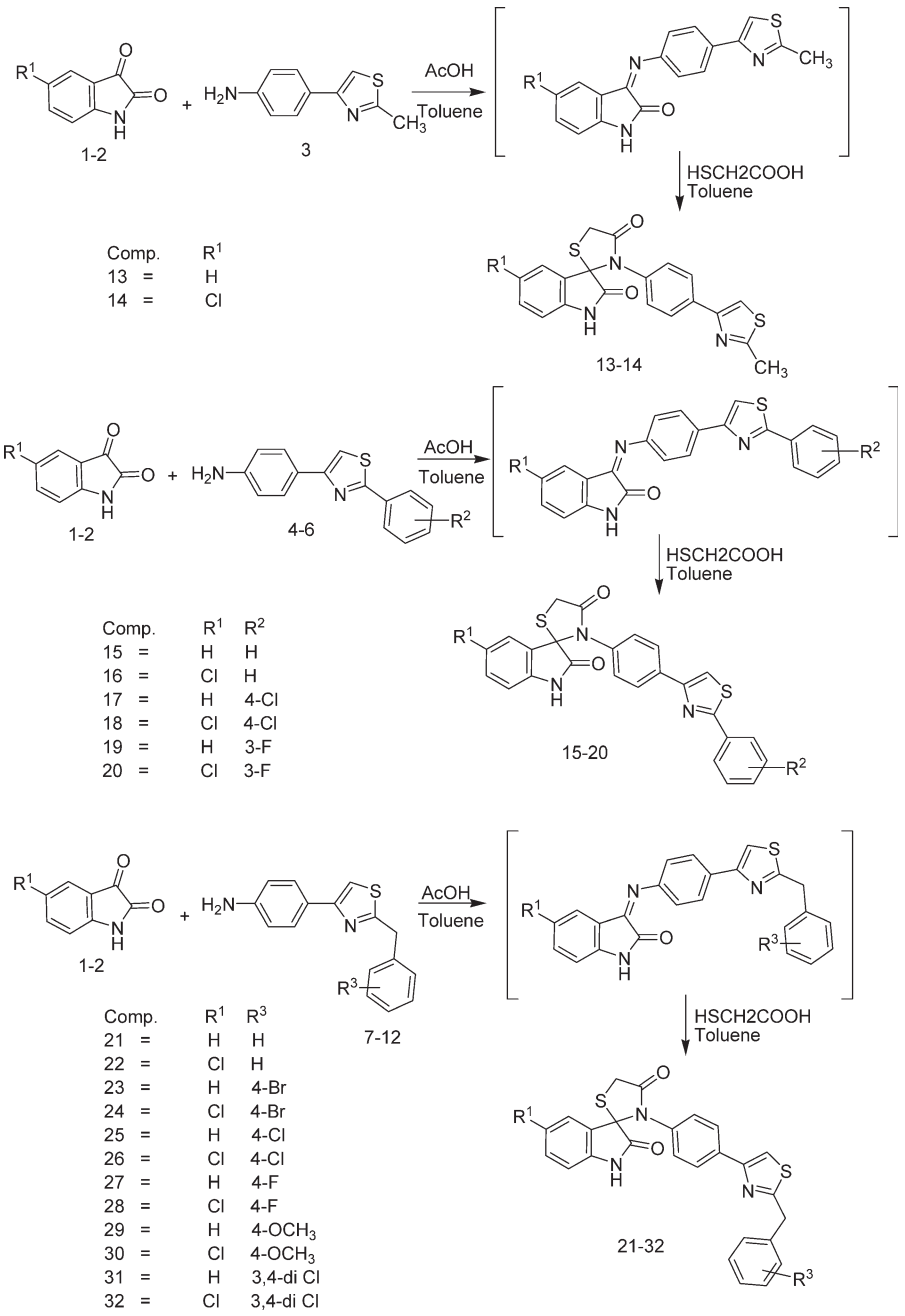

**Figure 1.** Synthetic pathway for the formation of the compounds **13–32**.

benzylic and thiazolidine methylene carbons, in addition the spiro carbon appeared at δ 110.9. The aromatic ipso carbon attached to fluorine appeared as doublet with $^1J$ = 246.8 Hz (C—F). The ortho and the meta carbon atoms in the same ring also appeared as doublets with $^2J$ = 21.5 Hz and $^3J$ = 8.3 Hz. All other aromatic carbon atoms appeared between δ 113–119 and 163.8 and the two carbonyl carbons appeared downfield at δ 172.6 and 176.8. The mass spectrum showed a molecular ion peak $M^+$ at *m/z* 427. The elemental analysis C (63.71), H (3.93), N (9.06), and S (12.87) was within ±0.4% of the calculated.

**Antimicrobial evaluation.** The *in vitro* antibacterial activity was performed against Gram-positive bacteria including *Staphylococcus aureus* (NCIM 2079), *Bacillus subtilis* (NCIM 2250), and Gram-negative bacteria including *Escherichia coli* (NCIM 2109). The antifungal activity was against fungi including *Candida albicans*

(NCIM 3471) and *Aspergillus niger* (NCIM 545). To evaluate the activity of the synthesized compounds against bacteria, the zone of inhibition and minimum inhibitory concentrations (MICs) were determined. Known antibiotic Ciprofloxacin (the reference for antibacterial drugs) and Nystatin (the reference antifungal drug) were used for comparison. The zone of inhibition and MIC against micro organisms tested is reported in (Tables 1 and 2), respectively.

The results of the antibacterial activity showed that the tested compounds are effective against the Gram-positive bacteria *S. aureus and B. subtilis* and Gram-negative bacteria *E. coli*. The investigation showed moderate inhibitory effects, with the majority of the compounds with the MIC values between 50 and 100 μg/mL. As shown in Table 2, all the compounds were active against *S. aureus* except compound **24**. The 4-methoxy substituted compounds **29** and **30** were active against all the three species. In general, compound with methyl group and the benzyl ring at 2 position of thiazole moiety showed enhanced activity.

The results of antifungal activity showed that all the compounds were inactive except compound **21**, which showed moderate activity against *C. albicans and A. niger*.

MIC in μg/mL.

## EXPERIMENTAL

Melting points were determined in an open capillary using Veego melting point apparatus and are uncorrected. The purity of the compounds was checked on silica gel-G plates. Infrared spectra ($cm^{-1}$) were recorded in KBr on a Shimadzu Model FTIR-435 spectrophotometer. $^1H$ NMR and $^{13}C$ NMR spectra were recorded in $CDCl_3$ and DMSO-$d_6$ solution on a Varian Mercury YH-300 spectrometer operating at 300 MHz or on BRUKER ADVANCE II 400 spectrometer operating at 400 MHz for $^1H$ and 75 MHz for $^{13}C$. Chemical shifts are expressed relative to tetramethylsilane (TMS) and were reported as δ (ppm). LCMS measurements were made on a Jeol-JMS-DX 303 mass spectrometer. The elemental analysis was performed on FLASH EA 1112 analyzer.

**General procedure for compounds (13–32).** To a solution of isatin **1** (0.37 g, 2.5 mmol) in glacial acetic acid (1 mL) and dry toluene (30 mL), 2-methyl-4-(4-aminophenyl)thiazole, **3** (0.48 g, 2.5 mmol) was added. The mixture was refluxed using a Dean-Stark apparatus for 5–8 h to obtain the Schiff's base. After the completion of the reaction as monitored on TLC, thioglycolic acid (3.0 mmol) was added and mixture was further refluxed for 7–10 h. The solvent was removed under reduced pressure and the residue was treated with saturated solution of $NaHCO_3$ to remove the unreacted acid. The product was extracted with ethyl acetate, washed with water, brine and dried ($Na_2SO_4$). The solvent was removed under vacuum, the thick liquid thus obtained was added dropwise to a stirred solution of hexane to obtain crystalline solid.

**Antimicrobial activity.** Compounds **14–32** were screened for their *in vitro* antimicrobial activity against the standard strains *B. subtilis, S. aureus*, and *E. coli* by the disk diffusion method [14,15]. Disks measuring 6 mm in diameter were punched from Whatman no.1 filter paper. Batches of 100 disks were dispensed to each screw-caped bottle and sterilized by dry heat at 145°C for 1 h. The test compounds were prepared with 100 μg/mL concentration in dimethyl sulfoxide. Disks of each concentration were placed in nutrient agar medium inoculated with fresh bacteria strains separately. The incubation was carried out at 37°C for 48 h. Ciprofloxacin was used as standard drugs at a concentration of 10 μg/mL. Solvent and growth controls were kept and zones of inhibition were noted.

The two-fold dilution technique [16] was followed to determine the minimum inhibitory concentration (MIC) of the synthesized compounds. The test compounds were dissolved in dimethyl sulfoxide and then diluted with culture medium (Mueller-Hinton agar medium) at the required final concentration 150–155 μg/mL. A plate containing only the culture medium and DMSO in the same dilution was used as negative control. The MIC values were recorded after incubation at 37°C for a period of 24 h. The lowest concentration of the test substance that completely inhibited the growth of the microorganism was reported as MIC expressed in terms of μg/mL.

The compounds were screened for their antifungal activity against *C. albicans* (MTCC 1637) *and A. niger* (AIIMS) in DMSO by disc diffusion method under standard conditions using Sabourad Dextrose Agar medium as described by NCCLS [17]. Sterile filter paper discs (6 mm diameter) containing specific amount of anti fungal agent (100 μg for the synthesized compounds) were placed on the surface of an agar plate inoculated with the standardized suspension of microorganisms tested. The plates were incubated at 37°C for 7 days for evaluating antifungal activity. The diameters of inhibition zones (in mm) were measured. Nystatin was used as standard drug at a concentration of 10 μg/mL.

## CONCLUSIONS

In conclusion, a series of new 3′-(4-(2-methyl/phenyl/benzylthiazol-4-yl)phenyl)spiro[indoline-3,2′-thiazolidine]-2,4′-diones **13–32** was synthesized. The pharmacological studies were undertaken to evaluate the effects of substituents on the antimicrobial activities. Most of the synthesized compounds exhibited moderate activity towards Gram-positive and Gram-negative bacteria. These compounds, however, did not show any promising antifungal activity except compound **21**. Compounds with methyl group and benzyl ring at 2-position of thiazole nucleus showed enhanced antibacterial activity.

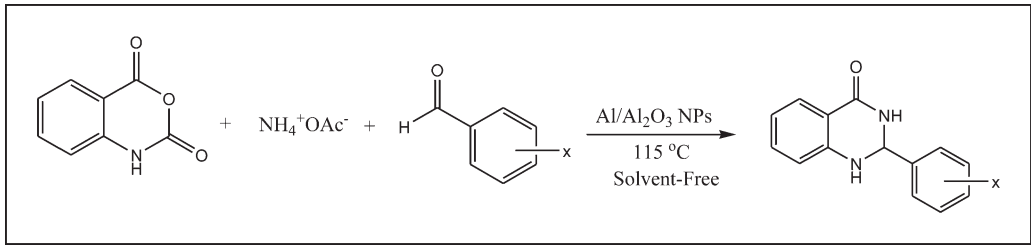
Published online 30 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



An efficient one-pot, solvent-free method is reported for the synthesis of 2-phenyl-2,3-dihydroquinazoline-4(1H)-one as well as its *o*-Cl, *o*-OMe, *m*-Br, *m*-$NO_2$, *p*-OH, *p*-$NO_2$, *p*-CN, *p*-$PhCH_2O$, *p*-Cl, *p*-F, *p*-Br, *p*-Me, and *o,m*-dichloro derivatives, using our ''as-prepared'' arc discharge fabricated $Al/Al_2O_3$ nanoparticles. Compared with our previous report and other known methods, this route gives higher yields with shorter reaction times, whereas its green catalyst appears recyclable at least four times-with minor decrease in its catalytic activity, under mild conditions.

## INTRODUCTION

Dihydroquinazolinones and their derivatives are important heterocyclic compounds, which influence numerous cellular processes. They are analgesic, diuretic, and vasodilating agents, displaying a broad range of biological, medicinal, and pharmacological properties [1–10]. Also, they are constituents of antitumor, antibiotic, antidefibrillatory, antipyretic, antihypertonic, antihistamine, and antidepressant drugs. In addition, these compounds can easily be oxidized to their quinazolin-4(3H)-one analogues [11], which also include important pharmacologically active compounds [12]. Several routes, including our recent method, using iodine as the catalyst, have been reported for the synthesis of 2,3-dihydroquinazolinones [13–19]. Yet, development of a green, simple, efficient, and general method for the synthesis of these widely used organic compounds, from readily available reagents, remains one of the major challenges in organic synthesis. In this manuscript, we have made use of the novel, recently reported metal and metal oxide nanoparticles, which exhibit high-surface/volume ratio, quantum size, and quanta tunnel effects [20–23]. We think our new procedure is cleaner and more environment friendly than our previous one, where we used the relatively toxic iodine catalyst [19]. Specifically, we employ small amounts of novel, recyclable, nontoxic, and inexpensive $Al/Al_2O_3$ nanocatalyst with a high-surface/volume ratio in, a three-component one-step synthesis of 2,3-dihydroquinazolin-4(1H)-ones (Scheme 1).

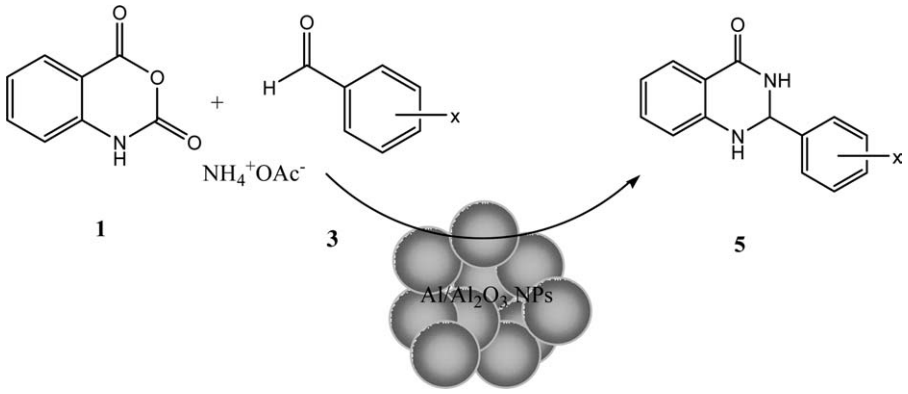
## RESULTS AND DISCUSSION

After demonstrating the impact of media and current on the arc fabrication of Al nanoparticles [24], we wondered if we could substitute $Al/Al_2O_3$ nanoparticles for iodine in the preparation of 2,3-disubstituted quinazolin-4(3H)-ones through multicomponent reactions, which we had already reported [19]. The reason was our immense desire to adopt rather green and economical reaction conditions, since the vapor of iodine was toxic at high-temperatures, and to remove the excess iodine we had to use saturated $Na_2S_2O_3$. Also the previous catalyst was not reusable.

The scanning electron microscopy (SEM) images showed spherical arc fabricated $Al/Al_2O_3$ NPs with a size range of 30 – 40 nm (Fig. 1).

The X-ray diffraction (XRD) pattern confirmed the formation of $Al/Al_2O_3$ NPs with similar average grain size range estimated *via* Scherer's equation [25], using the maximum peak (111) was used (Fig. 2). At a scanning speed of 2°/min from 20° to 80° (2θ), the XRD pattern showed five peaks, which were characteristic of

**Scheme 1.** Three-component one-step synthesis of 2,3 dihydroquinazolin-4(1H)-ones.



aluminum ($2\theta$ = 38.56°; 44.84°; 65.25°; 78.33°, and 82.59°), corresponding to Miller indices (111), (200), (220), (311), and (111), revealing the formation of face-centered cubic (fcc) Al NPs. Besides, it illustrated the lines (110), (104), and (220) at $2\theta$ = 45.93°; 66.98°; 85.09°, respectively, for $\gamma$-$Al_2O_3$.

Catalytic amounts of this as-prepared $Al/Al_2O_3$ NPs was added to a well-stirred mixture of isatoic anhydride (**1**), an aromatic aldehyde (**3**, either with electron-donating or electron-withdrawing groups), and ammonium acetate. It gave the corresponding 2,3-dihydroquinazolin-4(1H)-ones (**5a – o**) in 65 – 98% yields, at 115°C, under solvent-free conditions (Table 1).

Reactions were completed under smooth conditions within 8 – 30 min, and the products were isolated by a simple workup procedure. Thus an easy and rather green method for the synthesis of a novel class of the quinazolinone family was found. However, no simple relationship was observed between the electronic properties of the aryl groups and the corresponding quinazolinone products. Specifically, the amount of the catalyst ($Al/Al_2O_3$ NPs) for this condensation reaction was probed at 0.00, 0.06, 0.012, 0.036, and 0.048 g against isatoic anhydride (0.163 g, 1.0 mmol), ammonium acetate, and 4-chlorobenzaldehyde (0.14 g, 1.0 mmol), under solvent-free condition, at 115°C (Table 2).

The best results were obtained using 0.036 g of catalyst (yield = 94%). Increasing the amount of catalyst higher than 0.048 g did not affect the reaction time and yield. The absence of the catalyst required considerably higher reaction time giving the lowest yield (75%).

To check the reusability of our catalyst, the prepared $Al/Al_2O_3$ NPs (0.036 g) was stirred for 2 min with isatoic anhydride (0.163 g, 1 mmol), aromatic aldehyde (0.14 g, 1 mmol), and ammonium acetate, at room temperature. Then the mixture was heated in a paraffin bath at 115°C, for different periods of time (Table 1). After completion of the reaction excess ammonium acetate was washed away by water (5 mL). Subsequently, the hydroquinazolinone products were extracted by ethanol (50 mL). The solid residue was our catalyst, which was dried and reused for at least four cycles (Fig. 3).

The question is how this catalyst works? Evidently, the $Al/Al_2O_3$ NPs function as a good Lewis acid, which attracts and activates the carbonyl and imine groups involved and provides a surface on which the reactions

occur sequentially leading to the desired products (Scheme 2).

Specifically, decarboxylation of **1** occurs through its condensation with ammonium acetate in the presence of $Al/Al_2O_3$ NPs, affording antranylamide intermediate **2**, which reacts with the aromatic aldehyde **3** and gives the imine intermediate **4** that cyclizes to yield the corresponding hydroquinazolinone **5**.

## CONCLUSION

We have employed $Al/Al_2O_3$ NPs as an effective catalyst in the one-pot multicomponent synthesis of 2,3-dihydroquinazolin-4(1H)-ones. This catalyst is highly efficient, easily available, economical, operationally simple, and requires mild reaction conditions. Also the products were formed in excellent yields with short reaction times. This method offers several advantages, such as omitting toxic solvents or catalyst, very simple workups, and needs no chromatographic method for purification of the products. The starting materials are also inexpensive and commercially available.

## EXPERIMENTAL

**General remarks.** Melting points were recorded on a Buchi B-540 apparatus. IR spectra were recorded on an ABB Bomem Model FTLA200-100 instrument. $^1H$ and $^{13}C$ NMR spectra were measured on a Bruker DRX-300 spectrometer, at 300 and 75 MHz, using TMS as an internal standard. Chemical shifts (δ) were reported relative to TMS, and coupling constants (*J*) were reported in hertz (Hz). Mass spectra were recorded on a Shimadzu QP 1100 EX mass spectrometer with 70-eV ionization potential. Elemental analyses of new compounds were performed using a Vario EL III 0 Serial No.11024054 instrument. The particle shape and morphology were characterized by SEM of a Holland Philips XL30 microscope with an accelerating voltage of 20 kV. A Holland

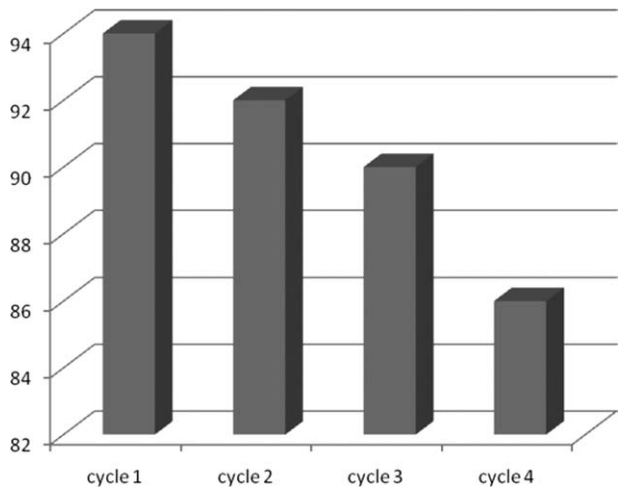

**Figure 3.** Catalytic recyclability of $Al/Al_2O_3$ NPs.

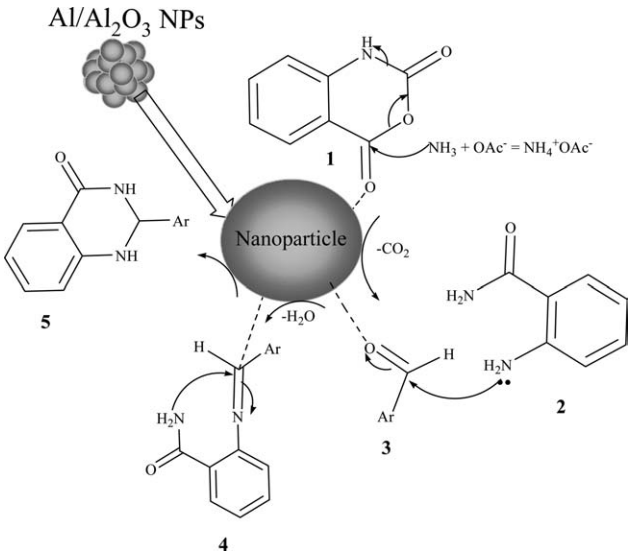
**Scheme 2.** A provisional mechanism for the synthesis of dihydroquinazoline in the presence of $Al/Al_2O_3$ NPs.



Philips X-pert X-ray powder diffraction (XRD) diffractometer was employed for characterization of nanoparticles.

**Fabrication of $Al/Al_2O_3$ NPs.** Nanoparticles used in this work were fabricated through arc discharge. The electrodes were customized by cutting commercial 2 mm diameter rather pure aluminum rods (95.50%) into 40 mm length segments. A current of 100 A was passed through the electrodes in ethylene glycol, until visible explosions occurred (0.01 – 1s). To maintain a stable current discharge, with an average voltage of 25 V, the cathode-anode gap was set at $\sim$ 1 mm with an angle of 85°.

**General procedure for the synthesis of hydroquinazolinone.** Prepared $Al/Al_2O_3$ NPs (0.036 g) was stirred for 2 min with isatoic anhydride (0.163 g, 1 mmol), aromatic aldehyde (1 mmol), and ammonium acetate at room temperature. Then the mixture was heated in a paraffin bath at 115°C for different periods of time (Table 1). After completion of the reaction (monitored by thin-layer chromatography, TLC; *n*-hexane and EtOAc, 2:1), excess ammonium acetate was washed away by water (5 mL). Subsequently the hydroquinazolinone products were crystallized from ethanol.

**Spectral data for some compounds.** ***4-(1,2,3,4-tetrahydro-4-oxoquinazolin-2-yl)benzonitrile (5c).*** This compound was obtained as a white crystalline solid, mp 350 – 351°C (Lit. mp 350 – 351 [19]), IR: 1602, 1677, 2225, 3027, 3124, 3169 $cm^{-1}$; $^1H$ NMR (300 MHz, $CDCl_3$): $\delta$ = 5.84 (s, 1H, CH), 7.55 (t, $J$ = 6.0 Hz, CH), 7.76 (d, $J$ = 6.0 Hz, 1H, CH), 7.87 (m, 1H, CH), 8.02 (d, $J$ = 6.0 Hz, 2H, CH), 8.16 (d, $J$ = 6.0 Hz, 1H, CH), 8.32 (d, $J$ = 6.0 Hz, 2H, CH), 12.7 (s, 1H, NH); $^{13}C$ NMR (75 MHz, DMSO-*d6*): $\delta$ = 65.5, 113.6, 118.3, 121.2, 125.9, 127.2, 127.7, 128.6, 132.5, 134.7, 136.9, 150.9, 162.1; MS (EI): $m/e$ = 249 ($M^+$), 247, 119, 92, 50.

A novel, concise, and convenient synthesis of 5-(3′-indolyl)oxazoles using relatively benign reagent [hydroxy(2,4-dinitrobenzenesulfonyloxy)iodo]benezene has been described. The advantages of this procedure include operational simplicity, good yield, and avoidance of the use of toxic metal.

*J. Heterocyclic Chem.*, **47**, 1425 (2010).

## INTRODUCTION

The 5-(3′-indolyl)oxazole is a naturally occurring an important heterocyclic motif of immense medicinal and therapeutic potential. Many 5-(3′-indolyl)oxazoles have been isolated from different microorganisms and are known to display interesting biological activities [1]. The 2,5-disubstituted (3′-indolyl)oxazoles, such as pimprinine (2-methyl-5-(3′-indolyl)oxazole); pimprinethine (2-ethyl-5-(3′-indolyl)oxazole), and pimprinaphine (2-benzyl-5-(3′-indolyl)oxazole) were isolated from *Streptoverficillium oliva reticuli*. The pimprinine is known to inhibit monoamine oxidase and showed antiepileptic effects [1a]. Analogs WS-30581 A and B isolated from *Streptoverticillium waksmanii* are shown to display potent inhibitory effects of platelet aggregation [1b]. Recently isolated, the Labradorin 1 (2-isobutyl-5-(3′-indolyl)oxazole) and Labradorin 2 (2-*n*-pentyl-5-(3′-indolyl)oxazole) from *Pseudomonas syringae pv. coronafaciens* are reported to exhibit very good inhibitory activity against various human cancer cells [1c].

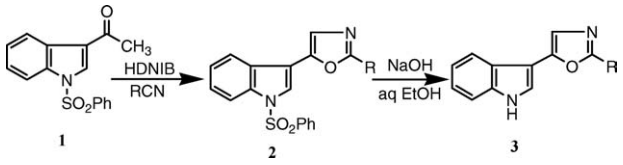
Many procedures are reported for the synthesis of 5-(3′-indolyl)oxazoles, however, straightforward and simple methods are quite limited [2]. Direct synthesis of 5-(3′-indolyl)oxazoles involve rhodium catalyzed reaction of diazoacetylindole with nitriles [2a] and aza-Wittig-type reaction of iminophosphorane derived from 3-azidoacetyl-1-methylindole with isocyanates and acid chlorides [2b]. In general, most of the methods involve multiple synthetic steps, which often require harsh reagents and reaction conditions and afford products in moderate yields. Thus, it is desirable to develop a simple and direct method for the synthesis of 5-(3′-indolyl)oxazoles that can be achieved under milder reaction conditions from readily available starting material.

Hypervalent iodine reagents have found broad utility in organic synthesis due to their low toxicity, ready availability, and ease of handling [3]. The α-[(2,4-dinitrobenzene)sulfonyl]oxyketones are very useful intermediate in organic synthesis, and can be easily prepared from the reaction of enolizable ketone with [hydroxy(2,4-dinitrobenzene-sulfonyloxy)iodo]benzene (PhI(ODNs)OH, HDNIB) [4]. More recently, we have reported a multistep synthesis of 5-(3′-indolyl)oxazoles involving preparation of key intermediate α-aminoketones and cyclization of acylamidoketones using *p*-toluenesulfonic acid [5]. To further improve synthesis of 5-(3′-indolyl)-oxazoles, and to continue our efforts to explore hypervalent iodine reagents in the syntheses of biological important heterocyclic compounds [6], we report herein HDNIB mediated one-pot conversion of 3-acetyl-1-benzenesulfonylindole **1** into naturally occurring 5-(3′-indolyl)oxazoles **3**.

## RESULTS AND DISCUSSION

The reaction of 3-acetyl-1-benzenesulfonylindole **1** with 2-(pyridin-3-yl)acetonitrile in presence of HDNIB at 100°C produced pure 5-(1′-benzenesulfonylindol-3′-yl)-2-(3′-pyridinylmethyl)oxazole (**2a**) in 63% yield (Scheme 1). The benzenesulfonyl moiety of oxazole **2a** was removed by treatment with sodium hydroxide to obtain pure 2-(3′-pyridinylmethyl)-5-(3′-indolyl)oxazole **3a** in quantitative yield. Similarly, analogs 5-(3′-indolyl)oxazoles **2b–h** were obtained and removal of benzenesulfonyl group led to the corresponding 5-(3′-indolyl) oxazoles **3b–h** (Table 1). The spectral data of 5-(3′-indolyl)]oxazoles **3a–h** are in agreement with the proposed structures.

**Scheme 1**



In the reaction of 3-acetyl-1-benzenesulfonylindole **1** with HDNIB in 2-(pyridin-3-yl)acetonitrile, two additional spots on TLC were initially observed, probably corresponding to the 3-α-(2,4-dinitrobenzenesulfonyloxy)-acetylindole and **2a**, which upon further heating converted exclusively to a single spot, that is, **2a**. The 3-acetyl-1-benzenesulfonylindole **1** reacted equally well with benzonitrile, alkylnitriles, and heteroaryl nitriles to afford corresponding oxazoles **2**. Attempts to isolate probable intermediate 3-α-(2,4-dinitrobenzenesulfonyloxy)acetyl indole could not be successful because of its instability. It is, however, to be noted that the reaction of 3-acetylindole with HDNIB in acetonitrile generated a complex mixture.

It is proposed that initial nucleophilic addition of enol **I** on HDNIB forms species **II**, which subsequently loses iodobenzene and water to afford intermediate 3-[α-(2,4-dinitrobenzenesulfonyloxy)]acetyl indole **III** (Scheme 2). The nucleophilic displacement of ODNs in **III** by nitrile, results in the formation of species **IV**, which finally cyclizes to oxazole **2**. Apparently, ODNs being a better leaving group may be responsible for the efficient cyclization, but reaction fails to proceed with the intermediacy of 3-[α-(tosyloxy)]acetylindole obtained from the reaction of 3-acetyl-1-benzenesulfony-lindole **1** with [hydroxy(tosyloxy)iodo]benzene.

## CONCLUSIONS

We have introduced a novel, short, and efficient protocol for the preparation of naturally occurring 5-(3′-indolyl)-oxazoles from readily available 3-acetylindole **1** using metal free [hydroxy(2,4-dinitrobenzenesulfonyloxy)iodo]benezene. This protocol should be complementary to other approaches in the synthesis of 5-(3′-indolyl)oxazoles described.

**Table 1**

Synthesis of 5-(3′-indolyl)oxazoles **2** and **3**.

| Entry | R | Yield (%)[a] (**2a–h**) | Overall Yield (%)[b] (**3a–h**) |
|---|---|---|---|
| **a** | 3-Pyridinylmethyl | 63 | 60 |
| **b** | $C_6H_5$ | 65 | 61 |
| **c** | $CH_3$ | 66 | 60 |

## EXPERIMENTAL

Melting points were recorded on EZ-Melt automated melting point apparatus (Stanford Research Systems, USA) and are uncorrected. IR spectra were recorded on Jasco IR-Report-100 using KBr pellet. $^1$H and $^{13}$C NMR spectra were recorded on Bruker Avance II (400 MHz) and Bruker (200 MHz) spectrophotometer using $CDCl_3$ and DMSO as solvent. Mass spectra were taken on a Agilent Mass spectrometer using FAB mode. All the reagents and solvents were commercially purchased and further purified according to the standard procedures.

**General procedure for the preparation of 2-substituted-5-(1′-benzenesulfonylindol-3′-yl)oxazoles (2a–h).** A mixture of 3-acetyl-1-benzenesulfonylindole **1** [7] (0.150 g, 0.501 mmol), HDNIB (0.281 g, 0.602 mmol) and appropriate nitrile (2.51 mmol) were heated at 100°C for 18 h. After completion of the reaction, the crude reaction mixture was percolated through a silica-gel column using ethyl acetate-hexane elution system.

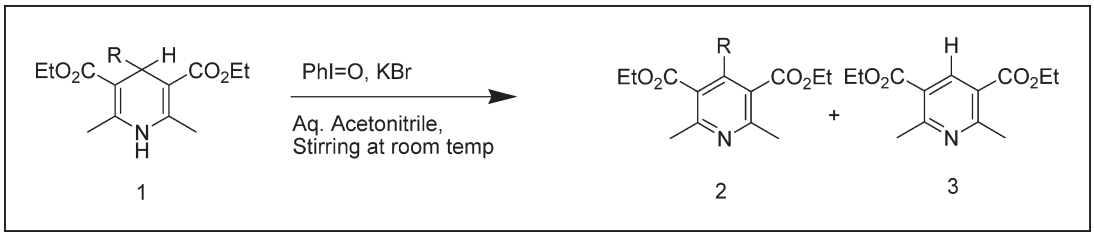
DOI 10.1002/jhet.504
Published online 30 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



An easy, safe, effective and handy method for oxidative aromatization of Hantzsch 1,4-dihydropyridines catalyzed by hypervalent iodine (iodosobenzene) and potassium bromide to corresponding pyridine derivatives in high-yields and within short span of time was described. Dealkylation in case of 4-n-alkyl substituted 1,4-dihydropyridines was not obtained.

*J. Heterocyclic Chem.*, **47**, 1429 (2010).

## INTRODUCTION

Hantzsch 1,4-dihydropyridines, six member nitrogen, containing heterocyclic compound, are often regarded as the class of the naturally reduced nicotinamine adenine dinucleotide [NADH] coenzyme that functions as redox reagent for biological reactions. 1,4-Dihydropyridines motif is found in a number of chemotherapeutic agents for the treatment of the cardiovascular disease [1,2] such as hypertension and angina pectoris, for example, amlodipine, felodipine, nifedipine, nicardipine, nimodipine, and nitrendipine. These compounds generally undergo oxidative metabolism in the liver by the action of cytochrome P450 to form the corresponding pyridine derivatives. Some representatives of this class show certain pharmacological activities such as acaricidal, insecticidal, bactericidal, and herbicidal activities [3]. Because of the relevance of this oxidative event to the biological NADH redox process [4–6], this transformation has attracted the attention of several research groups.

A variety of reagents have been utilized for this oxidative conversion: nitric acid [7], nitric oxide [8], urea nitrate [9], peroxodisulfate-Co(II) [9], clay-supported ferric and cupric nitrate[10], $BrCCl_3/h\nu$ [11], *N*-methyl-*N*-nitroso-*p*-toluenesulfonamide [12], DDQ [13], $Zr(NO_3)_4$ [14], $Mn(OAc)_3$ [15], Pd/C [16], $I_2$/MeOH [17], manganese dioxide–bentonite clay [18], chromium trioxide [19], potassium permanganate [20], pyridinium chlorochromate [21], ceric ammonium nitrate (CAN) [22], clayfen [23], bismuth trinitrate [24], ruthenium trichloride [25], $Fe(ClO_4)_3$/HOAc [26], tert-butylhydroperoxide [27], silica gel supported ferric nitrate (silfen) [28], $MnO_2$ [29], and vanadium salts [30].

Despite a plethora of methods for this protocol, extended reaction times, poor yields and use of strong or toxic oxidant has led to the investigation of many alternative procedures. Therefore, development and introduction of convenient, milder, and efficient method for the oxidation of 1,4-dihydropyridines to the corresponding pyridines is of practical importance and is still in demand.

Iodosobenzene (PhIO) has wide synthetic application as a starting material in the preparation of numerous iodine (III) compounds and in oxidation reactions [31]. Because of poor solubility of polymerized iodosobenzene [(PhIO)n] in organic solvent, its oxidizing property is not much examined as compared with the other hypervalent organoiodanes. Activation is required to carryout the oxidation reaction with iodosobenzene. Literature review shows that the aromatization of Hantzsch 1,4-dihydropyridines by using hypervalent iodine (IBX, HTIB, PIFA, and IBD) has been reported earlier [32]. To my knowledge oxidative aromatization of 1,4-DHPs with iodosobenzene has not been reported in the literature. Although reported hypervalent iodine based aromatization of Hantzsch 1,4-dihydropyridines are efficient, but these methods suffer from relatively acidic by products [32], long reaction time[32(d)] and high-temperature [32(e)]. Therefore, the biological importance of 1,4-dihydropyridines oxidation and my ongoing attention to

the development of new methodology [32(b)], prompted me to investigate the aromatization of 1,4-DHPs by iodosobenzene with KBr in aqueous acetonitrile.

## RESULTS AND DISCUSSION

A long series of 1,4-DHP derivatives were synthesized to study their catalytic conversion to the analogous pyridines. I used iodosobenzene with KBr as catalyst to have an effect on these organic transformations. Iodosobenzene with KBr serves as an excellent oxidative catalyst for a variety of 4-substituted Hantzsch 1,4-DHPs system as shown in the generalized Scheme 1 and results are reported in Table 1. In a preliminary experiment, oxidative aromatization 4-phenyl substituted 1,4-DHP was carried out using iodosobenzene in aqueous acetonitrile at room temperature. It gave none or insignificant amount of the corresponding pyridine. However, when KBr is added in the reaction mixture, there is recognizable change in the yield of the oxidized product. The reaction is fast and gives quantitative yield. Reaction was smooth, clean, and occurred at room temperature with short span of time (less than 5 min). Therefore, I investigated the activation of PhI=O in this reaction with a variety of alkali metal salts. As a result, the addition of bromide ions such as LiBr, NaBr, and KBr was found to amazingly activate PhI=O to give **2e** in good yields [95% yield with KBr, 75% yield with NaBr and 62% with LiBr], whereas salts excluding bromide (LiCl, NaCl, KCl, NaF, NaOAc, NaI and KI) did not catalyze the reaction effectively. Therefore, the most economical alkali metal bromide, that is, KBr was chosen for further studies. The oxidation proceeds smoothly

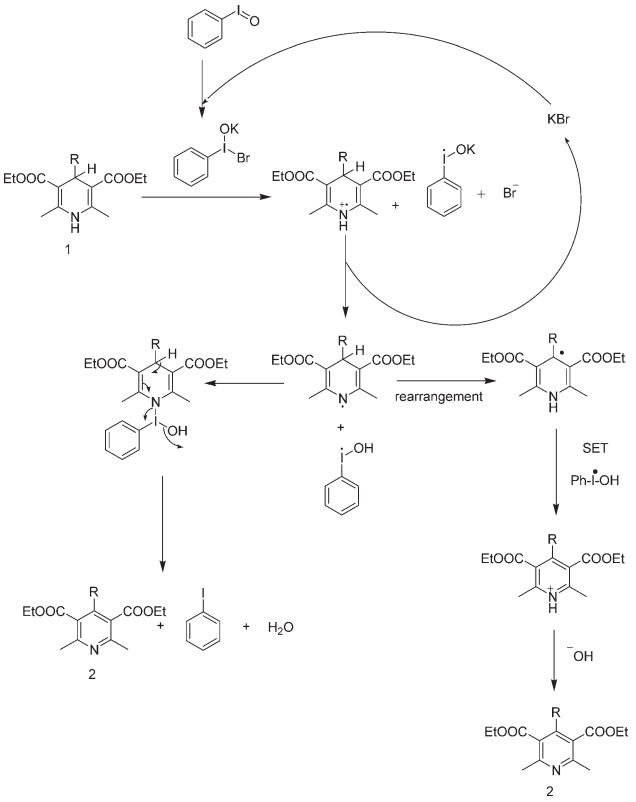
**Scheme 2.** Proposed mechanism for aromatization of 1,4-DHPs.



with 1,4-dihydropyridine substrates bearing substituents at the 4-position such as hydrogen, methyl, n-alkyl, aryl, and heterocyclic groups. However, in the case of oxidation of the 1,4-DHP with isopropyl and benzyl group at 4-poition underwent simultaneous dealkylation to give **3** as a sole product (Table 1). This may be because of either their electron donating ability of the corresponding radicals and these substituents are debarred with the formation of dealkylated products [15] or because of the stability of radical cation formed during the reaction via single electron mechanism [32(a)] (Scheme 2). The influence of various solvents on the yield of reaction was investigated using ethyl acetate, dichloromethane, chloroform, and aqueous acetonitrile. The reaction takes place smoothly in the aqueous acetonitrile may be because of solubility of iodosobenzene and KBr.

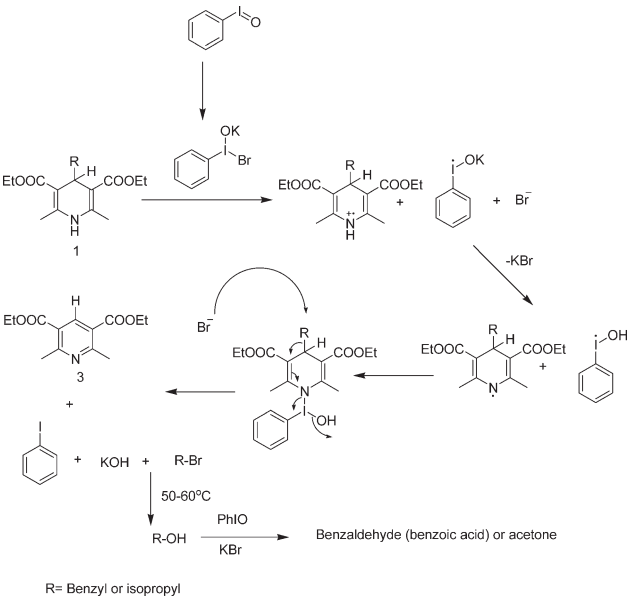
After that catalytic effect of KBr was investigated, and it was found that only 0.1 mmol of KBr is sufficient for 1.1 mmol of iodosobenzene (Scheme 3). However, in case of the 1,4-DHP with isopropyl and benzyl group at 4-poition oxidation depend upon the amount of KBr also as shown in Scheme 3. This is because of formation of isopropyl or benzyl bromide, and it is confirmed by GC. However, reaction mixture was found basic in nature and turn red litmus to blue when the reaction was carried out at 0°C. It is also observed that, when the temperature is raised to 60°C the reaction proceeds smoothly with catalytically amount of KBr (0.1 mmol). However, at elevated temperature, time required for these organic transformations is very short, but the amount of iodosobenzene required for this conversion is doubled. This is because of hydrolysis of benzyl bromide or isopropyl bromide with water to benzyl alcohol or isopropyl alcohol, which is oxidized to corresponding carbonyl derivatives.

In summary author have described a general and practical route for the oxidation of 1,4-dihydropyridines in excellent yields using catalytic amount KBr with iodosobenzene in aqueous acetonitrile. Aromatization is clean with this reagent, and the products are obtained in high-yield within short span of time. Novelty of this protocol is the reagents used in reaction are recovered as iodobenzene and KBr, which can be reused. Another salient feature of this method is that any acidic byproducts are not produced during reactions, which are toxic to the environment.

## EXPERIMENTAL

All chemicals used in this study were of the highest purity available and purchased from Lancaster, Merck, and Fluka companies (India). Melting points were determined on a buchi oil heated melting apparatus and are uncorrected. $^1$H NMR spectra were recorded in $CDCl_3$ on Brucker-300 Hz spectrometer using TMS as internal standard (chemical shift in δ, ppm). IR spectra were taken on a Perkin Elmer 1600, FTIR spectrophotometer using KBr pellets and peaks are reported in $cm^{-1}$. All the starting 1, 4-DHPs were prepared according to the literature procedure [33].

**Scheme 3.** Proposed mechanism for debenzylation or dealkylation.



**General procedure for oxidative aromatization of 1,4-dihydropyridines with iodosobenzene and KBr.** In a typical experimental procedure, the iodosobenzene (1.1 mmol) and KBr (0.1 mmol) were added to aqueous acetonitrile (15%, 20 mL), and mixture was stirred at room temperature for 5 min. To this reaction mixture an appropriate 1,4-dihydropyridine (1.0 mmol) was added and stirred at room temperature for time as indicated in Table 1. The progress of reaction was monitored by TLC. After completion of the reaction and the solvent was removed under vacuum to obtain the crude product, which was purified by column chromatography (ethyl acetate-hexane = 1:5).

**General procedure for oxidative aromatization of 4-isopropyl/4-benzyl-1,4-dihydropyridines.** The iodosobenzene (1.1 mmol) and KBr (1.1 mmol) were added to aqueous acetonitrile (15%, 20 mL), and mixture was stirred at room temperature for 5 min. Then 4-isopropyl/4-benzyl-1,4-dihydropyridines (1.0 mmol) was added and reaction mixture was stirred at room temperature for time indicated in Table 1. The progress of reaction was monitored by TLC. After completion of the reaction, added acetic acid (1 mL) and the solvent was removed under vacuum to obtain the crude product, which was purified by column chromatography (ethyl acetate-hexane = 1:7).

All compounds were fully characterized by mp, IR, and $^1$H NMR. These data are in full agreement with those previously reported in literature [32].

Some molecular modifications were attempted to find antiviral active compounds in the class of triarylmethanes against herpes simplex virus type 1 (HSV-1). All the synthesized compounds were evaluated for antiviral activity with HSV-1 by a plaque reduction assay. Some of the compounds showed significant antiviral activities.

*J. Heterocyclic Chem.*, **47**, 1434 (2010).

## INTRODUCTION

In our synthetic studies on antiviral compounds, we found that some triarylmethane derivatives showed significant activity against herpes simplex virus type 1 (HSV-1) in a plaque reduction assay [1–3]. Most of the compounds, which were synthesized previously, showed a wide range of activities against the HSV-1 virus. Molecular modifications of this class of compounds seemed interesting, and we therefore carried out further synthetic investigation and evaluation of this new class of derivatives.

In this series, we recently reported that the triarylmethane scaffold derivative **1a** showed a higher level of antiviral activity ($EC_{50}$ = 2.1 μM) and lower cytotoxicity ($IC_{50}$ = 79.3 μM) than those of the corresponding 4,4′-dihydroxytriphenylmethane derivative **2**, showing antiviral activity ($EC_{50}$ = 5.5 μM, $IC_{50}$ = 38.1 μM) [1]. Compound **1a** is composed of a heterocyclic methylenedioxy group instead of the 4-methoxyphenyl group in **2**. Phosphorylated aciclovir and many nucleoside phosphates have also shown significant antiviral activity [4–6]. A methane-based symmetrical tri-indolemethane **3** for enhancement of chemically induced HL-60 cell differentiation has recently been reported [7]. The corresponding tri-indolemethyl cation (turbomycin A) was isolated from soil microbial DNA, and it exhibited broad antibiotic activity against gram-negative and gram-positive organisms [8]. Therefore, the alteration of a phenyl ring to other heterocycles or the introduction of phosphoryl ester functionalities into the products has attracted our attention as a potential approach to find new antiviral active compounds.

We describe here, the preparation of some new heteroaryl (pyridine or pyrrole ring)-substituted triarylmethane derivatives. For the purpose of structural comparison nonheterocyclic 4,4′,4″-trihydroxytriphenylmethane **4a** was chosen. We also attempted the transformation of hydroxyl groups of products to phosphoryl ester functionalities. Results of plaque reduction assays to assess the anti-HSV-1 activities of these compounds are also presented.

## RESULTS AND DISCUSSION

**Chemistry.** We have already reported [1] the procedure for synthesis of compound **1a** by condensation of phenol and aldehyde using various Brønsted acids. The reaction of phenol and aldehyde (piperonal) with sulfuric acid in the shade for **1a** improved the yield to 93%.

Heteroaryl-substituted triarylmethane derivatives **5a** or **7** containing pyridine or pyrrole rings were easily synthesized in excellent yield by the reaction of phenol and nicotinaldehyde or the reaction of pyrrole and vanillin using trifluoroacetic acid (TFA) as a Brønsted acid. For compound **6a**, the reaction of bromomagnesium phenolate of sesamol with nicotinaldehyde at a reaction

[a] Consistent and correct mp could not be obtained because this compound is a viscous material.

temperature of 30°C and a long reaction time (2 d) gave an excellent result (84% yield).

The phosphorylation of hydroxyl groups of tri- or dihydroxytriarylmethanes **1a** and **4–6b** gave tris- or bis- phosphoryl esters (**1b** and **4–6a**) by the reported procedures [9,10]. Thus, the phosphorylation of hydroxygroups was accomplished by a slight excess of $(EtO)_2POH$ in the presence of $Et_3N$ in $CCl_4$ from 0°C to room temperature overnight to give the products **1b** and **4–6b** in 11–89% yields. Compounds **5b** and **6b** were obtained under the conditions of a slight excess of $(EtO)_2POCl$ in the presence of NaH at room temperature for 1 h in 43% and 66% yields, respectively. In both methods, the yields of phosphorylated products depend on the solubility of the starting tri- or dihydroxytriarylmethanes. In fact, the addition of THF or DMF to improve the solubility of the reaction solvent resulted in better yields of the corresponding phosphorylated products (see experimental).

All of the structures of the new compounds synthesized were determined by using spectroscopic data and elemental analyses, and the signal assignments were confirmed by 2D-NMR analyses (Tables 1 and 2).

**Biological activities**

***Antiviral activities.*** The anti-HSV-1 activities of the synthesized compounds were estimated by using plaque reduction assays in Vero cells [11]. The results of the assays are summarized in Table 3 together with the data for the original compounds **1a** [1] and **6a** [1].

Substitution with a pyridine ring (compound **5a**) resulted in antiviral activity ($EC_{50}$ = 6.8 μM, $IC_{50}$ =

[b] Two signals coincided.

**Table 3**

Antiviral activity ($EC_{50}$) and cytotoxicity ($IC_{50}$) against HSV-1.

| | $EC_{50}$ (μM) | I $C_{50}$ (μM) | $IC_{50}/EC_{50}$ |
|---|---|---|---|
| **1a**[a] | 2.1 | 79.3 | 38.2 |
| **1b** | >16 | 21.3 | <1.3 |
| **4a** | 22.6 | 127 | 5.6 |
| **4b** | 8.6 | 19.8 | 2.3 |
| **5a** | 6.8 | 54.1 | 7.9 |
| **5b** | >36 | 39.6 | <1.1 |
| **6a**[a] | 7.3 | >135 | >18.5 |
| **6b** | 49.1 | 87.6 | 1.8 |
| **7** | >150 | 190 | <1.3 |

[a] The data of the compounds from [1].

54.1 μM) similar to that of compound **6a** ($EC_{50}$ = 7.3 μM, $IC_{50}$ > 135 μM) previously reported [1]; however, its cytotoxicity was increased to that of 2,2′-dihydroxytriarylmethane **6a**. The introduction of two pyrrole rings with an N—H group (compound **7**) resulted in no significant antiviral activity at a concentration of 150 μM. Thus, two hydroxyl groups on the triphenylmethane scaffold might be necessary to show significant antiviral potency.

The phosphorylation of hydroxyl groups of **1a**, **5a**, and **6a** resulted in increased cytotoxicity in both transformations into **1b**, **5b**, and **6b**, respectively. Transformation of nonheterocyclic derivative **4a** into **4b** also showed a similar tendency. Phosphorylated triphenylmethane derivative **4b** showed a higher level of antiviral activity than that of original compound **4a**, but antiviral activities of both heteroaryl-substituted derivatives **5b** and **6b** were lower than those of the corresponding **5a** and **6a**, respectively. With reference to the phosphorylated hetero-ring substituted derivative **1b**, its antiviral activity was also lower than that of the corresponding nonphosphorylated original compound **1a**. Compounds synthesized in this study showed inhibitory concentrations ($EC_{50}$) ranging from 6.8 to > 150 μM. Among these compounds, we found that **5a** has the highest level of activity against HSV-1 ($EC_{50}$ = 6.8 μM), but its selectivity index was 7.9.

In this study on modification of triarylmethanes by alteration of heteroaryl rings and transformation into phosphorylated derivatives, unfortunately, we could not find more potent antiviral compounds than the 4,4′-dihydroxytriarylmethane **1a** reported previously [1]. Throughout this work, however, it is notable that compounds **5a** and **6a** containing a heteroaryl group (pyridine) showed higher levels of antiviral activity than that of $C_3$ symmetrical 4,4′,4″-trihydroxytriphenylmethane **4a** ($EC_{50}$ = 22.6 μM), and the $C_3$ symmetry structure of both compounds (a prochiral symmetrical molecule) was destroyed by introducing a different heteroaryl ring in the molecule. To elucidate these phenomena, further molecular modifications of triarylmethanes and evaluation of their activity against HSV-1 are underway.

## EXPERIMENTAL

Melting points were determined using a micro melting point apparatus (Yanagimoto MP-S3) without correction. IR spectra were measured by a Shimadzu FTIR-8100 IR spectrophotometer. Low- and high-resolution mass spectra (LR-MS and HR-MS) were obtained by a JEOL JMS HX-110 double-focusing model equipped with a FAB ion source interfaced with a JEOL JMA-DA 7000 data system. $^1$H- and $^{13}$C-NMR spectra were obtained by JEOL JNM A-500. Chemical shifts were expressed in δ ppm downfield from an internal tetramethylsilane signal for $^1$H-NMR and the carbon signal of the corresponding solvent [$CDCl_3$ (77.00 ppm), $CD_3OD$ (39.50 ppm), and dimethyl sulfoxide (DMSO)-$d_6$ (39.50 ppm)] for $^{13}$C-NMR. Microanalyses were performed with a Yanaco MT-6 CHN corder. Routine monitoring of reactions was carried out using precoated Kieselgel $60F_{254}$ plates (E. Merck). Centrifugal or flash column chromatography was performed on silica gel (Able-Biott or Fuji Silysia FL60B, respectively) with a UV detector. Preparation of compounds (**1a** [1], **4a** [1], and **6a** [4]) have already been reported. Commercially available starting materials including **4a** were used without further purification.

**4,4′-(1,3-Benzodioxol-5-ylmethylene)bisphenol (1a) [1].** To a solution of phenol (755 mg, 8.0 mmol) and 3,4-methylenedioxybenzaldehyde (600 mg, 4.0 mmol) in AcOH (2.3 mL) was added conc. $H_2SO_4$ (0.43 mL, 8.0 mmol). In the shade, the solution was stirred for 20 h at room temperature. The reaction mixture was poured into ice water (50 mL) and extracted from AcOEt (100 mL × 3). The organic layer was washed with brine and dried over $MgSO_4$. After evaporation, the residue was purified by centrifugal chromatography on silica gel (1% EtOH/$CH_2Cl_2$) to give **1a** (1.192 g, 3.7 mmol, 93% yield). Recrystallization from water/*iso*PrOH gave pale reddish crystals.

**General procedure of phosphorylation for preparation of 4,4′-(1,3-benzodioxol-5-ylmethylene)bisphenylphosphoric acid tetraethyl ester (1b).** This compound was prepared according to the method reported by Huffman *et al*. [9]. Thus, diethyl phosphite (3.6 mmol) was added to a stirred solution of **1a** (1.5 mmol) in $CCl_4$ (5 mL) at 0°C, followed by the addition of $Et_3N$ (4.2 mmol) dropwise. The reaction mixture was stirred overnight at 0°C to room temperature for 18 h. After dilution with $CH_2Cl_2$, the resulting mixture was washed with water, 10% aqueous HCl, and brine and then dried over $MgSO_4$. After filtration and evaporation, the residue was purified by centrifugal chromatography ($SiO_2$: 30–40% AcOEt in *n*-hexane), which gave **1b** (0.281 mmol, 19% yield) as a pale yellow oil.

**4,4′,4″-Methylidynetriphenyl-phosphoric acid hexaethyl ester (4b).** In a manner similar to that for the preparation of **1b**, after reaction of **4a** (2.0 mmol) in $CCl_4$ (3 mL), diethyl phosphite (7.4 mmol) and $Et_3N$ (8.2 mmol) at temperatures in the range of 0°C to room temperature for 17 h, purification by flash chromatography ($SiO_2$: 2–10% EtOH in $CH_2Cl_2$) gave **4b** (1.78 mmol, 89% yield) as a pale yellow oil.

**4,4′-(3-Pyridinylmethylene)bisphenol (5a).** A mixture of phenol (941 mg, 10.0 mmol) and nicotinaldehyde (536 mg, 5.0 mmol) and TFA (3.85 mL, 50 mmol) was stirred in the shade at room temperature for 20 h. After evaporation, purification by centrifugal chromatography (50–70% AcOEt in *n*-hexane) gave **5a** (1.380 g, 5.0 mmol) as a colorless solid quantitatively. Recrystallization from $CH_3CN$—$H_2O$ gave an analytically pure colorless powder **5a**.

**4,4′-(3-Pyridinylmethylene)bisphenylphosphoric acid tetraethyl ester (5b)**

***[Method A].*** In a manner similar to that for the preparation of **1b**, after the reaction of **5a** (1.0 mmol) in $CCl_4$ (3 mL), diethyl phosphate (3.7 mmol), and $Et_3N$ (4.1 mmol) in the range of 0°C to room temperature for 18 h, purification by centrifugal chromatography ($SiO_2$: 3–5% EtOH in $CH_2Cl_2$) gave **5b** (0.281 mmol, 11% yield) as a pale yellow viscous solid.

***[Method B].*** According to the method reported by Asaad *et al* [10], NaH (60% in oil, 10 mmol) was added to a stirred solution of **5a** (1.0 mmol) in dry THF-$CH_2Cl_2$ (1, 3 mL) at room temperature under an $N_2$ atmosphere. After stirring for 0.5 h, diethyl chlorophosphate (3.0 mmol) in dry $CH_2Cl_2$ (2 mL) was added to the reaction mixture dropwise for 20 min and then stirred for more 1 h. The reaction mixture was then poured into a saturated $NaHCO_3$ solution (40 mL) and extracted with $CH_2Cl_2$ (30 mL × 2), and its organic layer was washed with water, dried over $MgSO_4$, and evaporated. The resulting products were purified by centrifugal chromatography ($SiO_2$: 5% EtOH in $CH_2Cl_2$) to give **5b** (0.432 mmol, 43% yield).

**6,6′-(3-Pyridinylmethylene)bis-1,3-benzodioxol-5-ol (6a) [1].** Under $N_2$ atmosphere, a solution of sesamol (2.76 g, 20.0 mmol) in dry ether ($Et_2O$; 50 mL) was added dropwise to a solution of 3 M EtMgBr (6.7 mL, 20 mmol) in dry $Et_2O$ (60 mL) with stirring at room temperature, and the mixture was kept for 10 min, then the solvent was removed in vacuo. After addition of dry $CH_2Cl_2$ (300 mL) to the residue, a solution of nicotinaldehyde (536 mg, 5.0 mmol) in dry $CH_2Cl_2$ (50 mL) was added with stirring under $N_2$ atmosphere. The resulting mixture was sonicated at 30°C for 2 days. The reaction was quenched with saturated aqueous $NH_4Cl$ (100 mL), and the mixture was extracted with AcOEt (100 mL × 3). The organic layer was dried over $MgSO_4$ and concentrated in vacuo to give the solid. The residue was recrystallized from MeOH to give **6a** as a pale green powder (1.53 g, 4.2 mmol) in 84% yield.

**Preparation of 6,6′-(3-pyridinylmethylene)bis-1,3-benzodioxol-5-ylphosphoric acid tetraethyl ester (6b)**

***[Method A].*** In a manner similar to that of the preparation of **1b**, after reaction of **6a** (1.0 mmol) in $CCl_4$ (3 mL), diethyl phosphite (3.7 mmol), and $Et_3N$ (4.1 mmol) at temperatures in the range of 0°C to room temperature for 18 h, purification by centrifugal chromatography ($SiO_2$: 3–5% EtOH in $CH_2Cl_2$) gave **6b** (0.505 mmol, 51% yield) as a yellow oil.

***[Method B].*** In a manner similar to that for the preparation of **5b**, after the reaction of **6a** (1.0 mmol) in dry THF-$CH_2Cl_2$-DMF (3, 3, 2 mL) and 60% NaH (2.6 mmol) with diethyl chlorophosphate (2.4 mmol) in dry $CH_2Cl_2$ (2 mL) for 1.5 h, the reaction mixture was poured into a saturated $NaHCO_3$ solution (50 mL) and extracted with AcOEt (40 mL × 3). Centrifugal chromatography ($SiO_2$: 70–100% AcOEt in *n*-hexane) gave **6b** (0.663 mmol, 66% yield) as a yellow oil.

**2,2′-[(4-Hydroxy-3-methoxy-phenyl)methylene]bis-1*H*-pyrrol (7).** A mixture of pyrrole (16.4 mL, 240 mmol) and vanillin (912 mg, 6.0 mmol) and TFA (94 μL, 1.2 mmol) was stirred in the shade at room temperature for 20 h. After evaporation, purification by flash chromatography (5% AcOEt in $CHCl_3$) gave **7** (1.288 g, 4.8 mmol) as a colorless solid in 80% yield. Recrystallization from *iso*-PrOH gave analytically pure pale violet crystals **7**.

**Antiviral activity assay and cytotoxicity of target compounds.** The antiviral activities of synthesized compounds were measured using a plaque reduction assay [11] as described in our previous article [1]. Results of antiviral activity ($EC_{50}$) and cytotoxicity values ($IC_{50}$) with Vero cells are summarized in Table 3.

**Acknowledgments.** The authors would like to thank Mr. Masahiko Ishii, Mr. Junya Ueno, and Ms Yoko Tomioka for their valuable technical assistance.

Reaction of 4-phenylthiosemicarbazide with dialkyl acetylenedicarboxylate in $CH_2Cl_2$ at 0°C lead to construction of alkyl 3-amino-2-phenyliminothiazolidine-4-one-5-ylidene acetate in a few minutes and good yields. Alternatively, the use of thiosemicarbazide has given the corresponding 3-amino-2-imino-thiazolidine-4-one-5-ylidene acetate, while application of di-*t*-butylacetylenedicarboxylate in these reactions has not entailed with cyclization.

*J. Heterocyclic Chem.,* **47**, 1439 (2010).

## INTRODUCTION

Thiazolidine-4-ones are important building blocks in variety of pharmaceutical agents and biologically active products [1]. Several substituted thiazolidinones have been found to possess hypnotic, anesthetic, sedative, anticonvulsant, and microbiological activities [2–4]. Some thiazoline derivatives show interesting anti-HIV or anticancer activities and can inhibit cell division [5–10]. Because of the various physiological activities of thiazolidinones, many thiazolidinone derivatives have been prepared and several new methods for the preparation of substituted thiazolidine-4-one have been recently reported [11,12]. Despite the synthetic importance of these methods, they commonly suffer from the need to elevated temperatures and also from long reaction times. Therefore, it is reasonable that development of mild and efficient methods for their synthesis still is more desired. In this context, we present here a mild and expedient method for synthesis of 2-iminothiazolidine-4-one-5-ylidene acetate derivatives in fairly good yields.

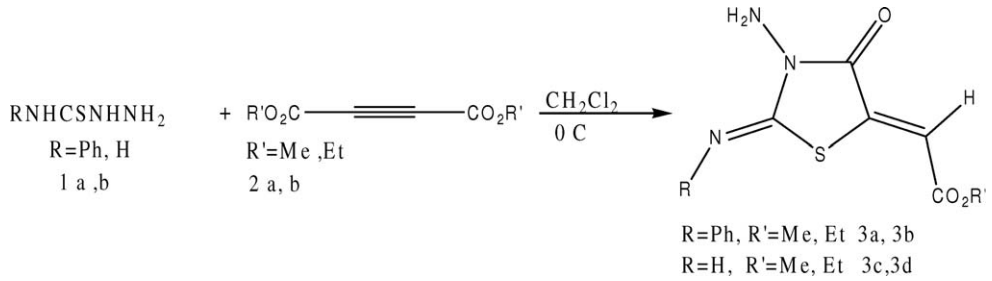
## RESULTS AND DISCUSSION

As is shown in Scheme 1, the synthesis of 2-imino-thiazolidine-4-one-5-ylidene acetate was simply effected by a two component reaction between thiosemicarbazide and an acetylenic ester. The reaction proceeds smoothly without using any catalyst by mixing the two reactants in dry $CH_2Cl_2$ media at room temperature and needs no more care on controlling the temperature or using special techniques of activation. Only the thiazolidine products were formed and separated from the reaction mixture. An attracting feature of this reaction is the synthesis of a multifunctionalized complex heterocycle from simple starting materials.

Thus, 4-Phenylthiosemicarbazide **(1a)** and dimethyl acetylenedicarboxylate undergo a smooth reaction in dry $CH_2Cl_2$ at 0°C to produce methyl 3-amino-2 phenylimino-thiazolidine-4-one-5-ylidene acetate **(3a)** in 94% yield (Scheme 1). In a similar manner, thiazolidine-4-ones **(3c,d)** were formed on reaction between thiosemicarbazide and the corresponding acetylenic ester in excellent yields (Scheme 1). Surprisingly, di-*tert*-butyl acetylenedicarboxylate showed up a different behavior as instead of cyclocondensation with thiosemicarbazide their reaction lead to addition of the two components and solely formation of thiosemicarbazone derivatives (Scheme 2).

Structures of all the compounds were deduced from their IR, $^1$H NMR, $^{13}$C NMR, and mass spectral data as well as elemental analyses. The mass spectra of these compounds displayed molecular ion peaks at the appropriate m/z values. The $^1$H NMR spectrum of **3a**, for example, in $CDCl_3$ showed three singlet peaks arising from resonances of methoxy δ 3.48, amino δ 4.89, and olefinic protons δ 7.00, along with multiplets at δ 7.03–7.42 ppm for the aromatic protons. The $^{13}$C NMR

**Scheme 1**



spectrum of **3a** showed 10 signals in agreement with the proposed structure. Partial assignments of these resonances are given in the experimental section. The $^{1}$H- and $^{13}$C NMR spectra of **3b–3d** are very similar to those of **3a**, except for the ester and aryl moieties, which exhibit characteristic signals at appropriate chemical shift.

On the basis of well established chemistry of electrophilic acetylenes [10], it is reasonable to assume that the synthesis proceeds through initial conjugate addition of the sulfur atom of **1** onto the acetylenic ester following cyclocondensation of the thus formed 1:1 adduct [13,14] to yield the products **3** (Scheme 3).

In the cases of using di-*t*-butyl acetylenedicarboxylate, the reactions are prevented from proceeding through above mechanism due to steric hindrance of bulky alkyl groups, so are unable to give the desired thiazolidine products.

In conclusion, we have made a contribution to the synthesis of thiazolidine-4-one compounds [13,14] by using the reaction between 4-phenylthiosemicarbazide or thiosemicarbazide with a dialkyl acetylenedicarboxylate to produce some novel thiazolidine-4-one derivatives. The method carries the advantage that is not only the reaction performed under neutral conditions but also the substrates can react by mixing without any activation or modification.

## EXPERIMENTAL

Melting points were measured on an Electrothermal 9100 apparatus. Elemental analyses for C, H, and N were performed using a Heraeus CHN–O-Rapid analyzer. IR spectra were measured on a Shimadzu IR-460 spectrometer. $^{1}$H and $^{13}$C NMR spectra were recorded by a Bruker DRX-300 AVANCE instrument with deuteriochloroform as solvent at 300 and 75 MHz, respectively. Mass spectra were recorded on a Finnigan-MAT 8430 mass spectrometer operating at an ionization potential of 70 eV. 4-Phenylthiosemicarbazide, thiosemicarbazide, dimethyl acetylenedicarboxylate, and diethyl acetylenedicarboxylate were obtained from Fluka (Buchs, Switzerland) and were used without further purification.

**Typical procedure for the preparation of compounds 3.** To a stirred solution of **1** (2 mmol) in 10 mL of dichloromethane was added dropwise a mixture of **2** (2 mmol) in 2 mL dichloromethane at 0°C over 1 min. The reaction quickly went to complete, as monitored by tlc on silica-gel 60 using 1:1 solution of ethyl acetate:petroleum ether, and the solid product precipitate. After 5 min, the solid was filtered and recrystallized from diethyl ether to afford the pure products.

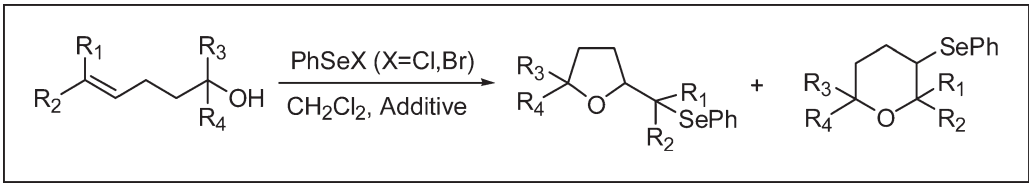
Published online 25 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



Studies on the phenylselenoetherification of some $\Delta^4$-alkenols in the presence of pyridine and some Lewis acids are described. All alkenols underwent intramolecular cyclization yielding corresponding tetrahydrofuran or tetrahydropyran derivatives. Yield and diastereomeric ratio of the cyclic products depend on counterion of selenylating reagent used. We found that external additives, such as pyridine and some Lewis acids coordinating to the electrophilic and/or nucleophilic species are used to control the course of cyclizations with high degrees of efficiency and improve the level of stereoinduction.

## INTRODUCTION

Cyclization of unsaturated alcohols leading to cyclic ethers is well documented in a literature as convenient pathways in the synthesis of natural products and related compounds [1].

Substituted tetrahydrofuran and tetrahydropyran rings are common in many natural products and play important role as building blocks for the synthesis of various biologically active organic target molecules [2]. Stereoselective synthesis [3] of substituted cyclic ethers is important since cyclic ether units are frequently found in polyether antibiotics [4], C-glycosides [5], and polyene mycotoxins [6]. A number of these compounds exhibit remarkable antibiotic [4], neurotoxic [7], antiviral [8], and cytotoxic [9] effects, which have opened perspective for selected clinical applications [10]. This circumstance has brought about a growing demand for cyclic ethers in general. Since their supply cannot be covered from natural sources alone, the invention of methods for stereoselectively constructing the tetrahydrofuran and tetrahydropyran nucleus from unsaturated alcohols has received considerable attention [11].

Among the various kinds of ring-forming reactions, those based on the reaction of an electrophilic reagent with an alkene holding a suitably positioned hydroxyl group are certainly very useful. The term of cycloetherification is generally used to describe this kind of process which can be promoted by several electrophilic reagents [12]. The increasing popularity gained in recent years by selenium reagents induced ring closure reactions [13]. Different electrophilic selenium reagents and a variety of reaction conditions have been used and recent reviews are highlighting the broad scope of this general process [14]. Scheme 1 illustrates the possible modes of cyclization depending on the relative position of hydroxyl group and the double bond in the starting alkene.

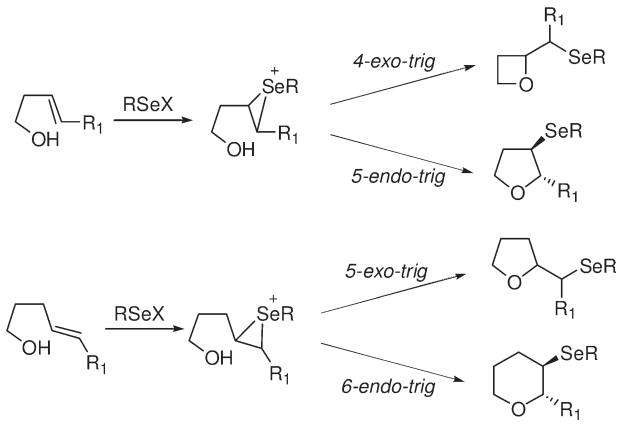
Outcome of this reaction is influenced by the nature of selenium reagent used, and the reactivity of the selenium electrophile also depends on the nature of counterion. Although standard conditions can be used for these cyclizations, the interactions between the selenium electrophile, counterion, the solvent, and the substrate are not fully understood, and we describe herein our recent investigations toward these cyclizations.

Lewis acids are widely used as catalysts and mediators in many organic reactions [15] and stereoselective synthesis [16]. However, PhSeCl in combination with equimolar amount of $ZnCl_2$ is known as strong chlorophenilselenilating reagent for olefins [17]. These findings prompt us to extend the use of Lewis acids to phenylselenoetherification of some $\Delta^4$-alkenols. Now, we are interested in the behavior toward additives such as Lewis acids and pyridine in the reaction conditions to study reactivity and regiochemical and stereochemical outcome of the cyclization.

## RESULTS AND DISSCUSION

In recent years, we have studied intramolecular cyclization of some $\Delta^4$- and $\Delta^5$-alkenols by means of phenylselenyl

**Scheme 1**



halides, PhSeX (X = Cl, Br) [18]. Intramolecular heterocyclization is the main reaction in the case of all investigated primary and secondary alkenols, while tertiary alkenols, under the same experimental conditions, are not converted into cyclic products at all by PhSeBr and in a small amount with PhSeCl. Although the additional products are expected, we have found that all investigated tertiary alkenols in the reaction with PhSeBr afforded γ- and δ-bromoalkanols in high yields [19].

Recently, we found that cyclizations of $\Delta^5$-alkenols can be facilitated in the presence of pyridine, $Ag_2O$, and some Lewis acids as catalysts [18d]. In this article, we wish to present the extension of the method to $\Delta^4$-alkenols. These alkenols envisage to the *5-exo* and/or *6-endo* cyclizations. Prompted by this fact, we considered it synthetically interested to study the influence of additives, pyridine, and some Lewis acids ($ZnCl_2$ and $FeCl_3$) on reactivity and regioselectivity and stereoselectivity in selenocyclization reaction.

The reactions are performed with two selenylating reagents, PhSeCl and PhSeBr, and equimolar amount of additives, in dichloromethane as solvent, at room temperature. All reactions proceeded to form five- and/or six-membered oxygen heterocycles bearing the phenylseleno moiety. The results of our investigation are shown in Scheme 2 and Table 1.

Primary **1a** and secondary **1c** alkenols gave expected tetrahydropyran-type cyclic ether products, while tertiary alkenols **1d–f** gave anti-Markovnikoff tetrahydrofuran-type products predominantly due to stereoelectronic effects.

Cyclization is facilitated by the presence of pyridine and Lewis acids. It became clear that phenylselenyl halides in combination with these additives usually gave rise to cleaner reactions and improved yields compared with phenylselenyl halides alone. Also, the additives increased the reaction rate dramatically. In the case of tertiary alkenols with larger substituents **1d**,**f**, the yields of products decreased regarding to the effects of steric hindrance. Depending on mechanism, this can indeed be expected. As it can be seen from Table 1, pyridine gave the best results, conversion to cyclic products was quantitative in all cases. It appears that the presence of pyridine is beneficial to the cyclizations process due to its basic properties. Function of external base was to neutralize hydrohalogenic acid generated on cyclizations. In the absence of external base, the halide counterion must fulfill this role and an undesired acid-promoted reaction was competitive. All additives could enhance the nucleophilicity of the hydroxyl group of the alkenol and also mediate the stabilization of oxonium ion intermediates.

Although phenylselenoetherification with nonhiral selenium reagents is generally known to give low stereoselectivity [20], very good results were obtained in the cyclizations of $\Delta^3$-alkenols [21]. However, in all cases, stereoselectivity of the ring closure reaction was strongly influenced by the presence and the nature of allylic substituent in the starting alkenol.

In this context, we initiated our study of phenylselenoetherification of (*Z*)- and (*E*)-hex-4-en-1-ols **1b** under kinetic conditions using both selenium reagents and pyridine, in dichloromethane at temperature ranging from −78°C to room temperature. *cis*-Alcohol is envisage to facilitate the *5-exo*-favored cyclization, while *trans*-isomer facilitate the *6-endo*-unfavored cyclizations by the

| 1a | 69 | 100 | 96 | 92 | 63 | 100 | 100 | 98 |
| 1b (*E*) | 81 | 100 | 90 | 92 | 65 | 100 | 96 | 95 |
| 1b (*Z*) | 72 | 100 | 98 | 96 | 75 | 100 | 99 | 98 |
| 1c | 56 | 100 | 78 | 81 | 18 | 100 | 74 | 76 |
| 1d | 37 | 100 | 71 | 75 | 0 | 100 | 60 | 62 |
| 1e | 46 | 100 | 58 | 62 | 0 | 100 | 52 | 55 |
| 1f | 23 | 100 | 53 | 58 | 0 | 100 | 48 | 52 |

Baldwin's rules, yielded regioselectively tetrahydrofurans **2b** (*threo* and *erythro*) and tetrahydropyrans **3b** (*trans* and *cis*), respectively (Scheme 3).

The experimental results, summarized in Table 2, show that more electrophilic PhSeCl was used to drive reaction more completely and maintain better stereoselectivity but the poorer electrophile, PhSeBr, gave reversal stereoselectivity. The results reveal the effect of reaction temperature, which drove the reaction further toward completion and better stereoselectivity. Superior results are obtained with pyridine. Conversion to cyclic ethers was quantitative with increased and reversal stereoselectivity regardless to reagent used. (*E*)-Hex-4-en-1-ol affords six-membered *cis*-izomer predominantly, while (*Z*)-hex-4-en-1-ol affords five-membered *erythro*-isomer as unique product.

We also studied the reactivity and stereoselectivity of these reactions in the presence of equimolar amount of some Lewis acids, which were considered as the perspective candidates. $ZnCl_2$, $FeCl_3$, and $AlCl_3$ were tested at room temperature. As it can be seen from the results obtained, Lewis acids also promoted cyclization process (Table 3). In all cases, reactions were high yielded. Diastereomeric ratio was improved and reversal stereoselectivity in the reactions with PhSeBr was not noticed. (*Z*)-Hex-4-en-1-ol affords five-membered *threo*-isomer, while (*E*)-hex-4-en-1-ol affords six-membered *trans*-isomer predominantly. In the presence of Lewis acids, reactivity of selenium electrophile is independent of nature of counterion.

All used additives can bound counter ion from reagent, increase electrophilicity of PhSe group, and eliminate $X^-$ as a concurrent of hydroxyl group in cyclization step. They could also enhance the nucleophilicity of hydroxyl group of the alkenol and also mediate the stabilization of the oxonium ion intermediates.

In summary, we found that external additives, such as pyridine and Lewis acids coordinating to the electrophilic species are used to control the course of cyclizations with high degrees of efficiency and improve the level of stereoinduction. The course of cyclization can be directed as desired by the choice of the electrophile and the additives used in the reaction.

## EXPERIMENTAL

Gas chromatography/mass spectrometry analyses were obtained with an Agilent Technologies instrument, model 6890 N with HP-5NS columns. $^1H$ and $^{13}C$ NMR spectra were run in $CDCl_3$ on Varian Gemini 200-MHz NMR spectrometer. IR spectra were obtained with Perkin-Elmer FTIR spectrophotometer model Spectrum one. Microanalyses were performed by ''Dornis and Colbe'' and found to be in good agreement with the calculated values. Thin layer chromatography was carried out on 0.25-mm E. Merck precoated silica gel plates (60F-254)

using UV light for visualization. For column chromatography, E. Merck silica gel (60, particle size 0.063–0.200 mm) was used. Alkenols used as substrates are commercially available. Reagents (PhSeCl and PhSeBr) were used as supplied by Aldrich. Dichloromethane was distilled from calcium hydride.

**General procedure.** All reactions were carried out on a 1 mmol scale. To a magnetically stirred solution of 1 mmol of alkenol and 1 mmol of additive (0.162 g $FeCl_3$, 0.136 g $ZnCl_2$, or 0.134 g $AlCl_3$) in 5-mL dry dichloromethane was added 0.212 g solid PhSeCl (1.1 mmol) or 0.260 g PhSeBr (1.1 mmol) at room temperature until the solid dissolved. The reaction went to completion virtually instantaneously. Solution was washed with saturated $NaHCO_3$ aqueous solution and brine. Organic layer was dried over $Na_2SO_4$, concentrated, and chromatographed. The products were obtained after the elution of the traces of diphenyl diselenide on a silica gel–dichloromethane column. All the products were characterized and identified on the basis of their spectral data. Cyclic ether products were known compounds and their spectral data have been presented previously [18a].

The usefulness of 3-iodoindole available for introduction of an indole unit is presented. The reaction of 3-iodoindole with 2-bromo(or methyl)-1,4-naphthoquinone in acetic acid gave 2-bromo(or methyl)-3-(3-indolyl)-1,4-naphthoquinone. On the other hand, the reaction of 3-iodoindole with 2-bromo-1,4-naphthoquinone in the presence of cesium carbonate in acetonitrile produced 2-(1-indolyl-3-iodo)-1,4-naphthoquinone.

*J. Heterocyclic Chem.*, **47**, 1447 (2010).

## INTRODUCTION

An indole unit naturally occurs in indole alkaloids and many of the naturally occurring compounds have physiologically important activities [1]. Some reports have appeared concerning the reaction of indoles with the 1,4-naphthoquinones. For example, Bu'Lock and Mason [2] reported that the reaction of indole (**1**) with 1,4-naphthoquinone (**2**) gave 2-(3-indolyl)-1,4-naphthoquinone (**3**) in acetic acid at room temperature for 7 days without describing the yield. Prota and coworkers [3] found that the reaction of **1** with **2** afforded **3** in acidic ethanol at room temperature for 1 h in the moderate yield.

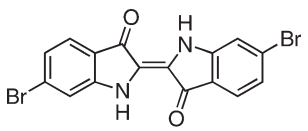
In previous articles [4,5], we reported the syntheses of Tyrian purple (**4**) (Fig. 1) [6] and its related compounds using 3-iodoindoles. Moreover, we have revealed the usefulness of 3- iodoindoles available for introduction of an indole unit [7]. The 3-iodoindole compounds are labile, therefore, not commercially available. However, the compounds are easily synthesized from the corresponding indoles. This article describes the reaction of 3-iodoindole with 1,4-naphthquinones.

## RESULTS AND DISCUSSION

The reaction of 3-iodoindole (**5**) with 2-bromo-1,4-naphthoquinone (**6**) in acetic acid at room temperature for 3 days gave the 2-bromo-3-(3-indolyl)-1,4-naphthoquinone (**7**) in 72% yield. The mass spectrum of the product (**7**) exhibits the molecular ion peak at *m*/*z* 351 and 353 in the ratio of 1 to 1. The $^1$H NMR spectrum of **7** shows a doublet peak ($J$ = 2.8 Hz) at $\delta$ = 8.24 due to H-2′.

On the other hand, the same reaction was carried out in the presence of cesium carbonate in acetonitrile at room temperature for 1 day to give 2-(1-indoly-3-iodo)-1,4-naphthoquinone (**8**) in 19% yield with **7** in 5% yield (Scheme 1). The structure of the product (**8**) was mainly based on the NMR spectral data and MS spectral data. The $^1$H NMR spectrum shows signals at $\delta$ = 7.17 (singlet) and 7.68 (singlet) due to H-3 and H-2′, respectively. The $^{13}$C NMR spectrum shows a signal at $\delta$ = 64.28 due to C-I. The mass spectrum clearly exhibits a molecular ion peak at *m*/*z* 399.

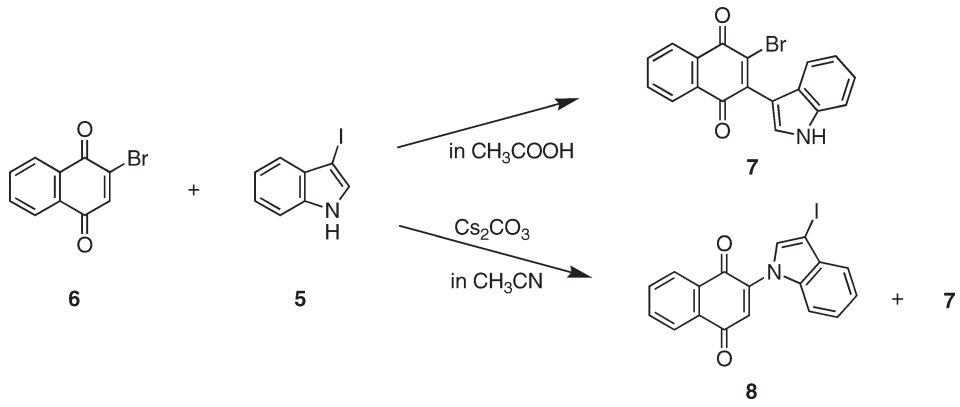
We have already reported the reaction of **5** with **2** in acetic acid at 90°C for 40 min to give **3** in 74% yield [7]. The same reaction was carried out in the presence



**4**

**Figure 1.** Tyrian purple.

**Scheme 1**



of cesium carbonate in acetonitrile at room temperature for 1 day, but the iodo compound (**8**) was not obtained (Scheme 2).

We next applied the reaction of Scheme 1 to 2-methyl-1,4-naphthoquinone (**9**) (Scheme 3). The treatment of **5** with **9** in acetic acid at room temperature for 4 days gave 2-methyl-3-(3-indolyl)-1,4-naphthoquinone (**10**) in 62% yield.

The structure of the product (**10**) was mainly determined on the basis of the NMR spectral data and MS spectral data. The $^1$H NMR spectrum shows signals at $\delta = 2.21$ (singlet) and $\delta = 7.43$ (singlet) due to $CH_3$ and H-2′, respectively. The $^{13}$C NMR spectrum shows a signal at $\delta = 15.76$ due to $CH_3$. The mass spectrum clearly exhibited a molecular ion peak at *m*/*z* 287. The same reaction was carried out in the presence of cesium carbonate in acetonitrile at room temperature for a day, but the compound (**10**) instead of the iodo compound was obtained in 23% yield.

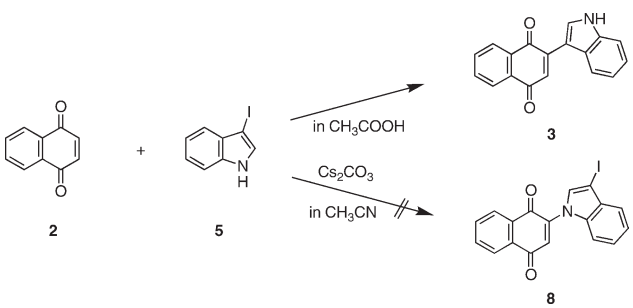
## EXPERIMENTAL

The $^1$H NMR and $^{13}$C NMR spectra were obtained using a JEOL JNM-A500 (500 MHz) spectrometer at room temperature. The chemical shifts are given in ppm relative to tetramethylsilane as an internal reference standard. The EI mass spectra were performed using a JEOL JMS-SX 102A mass spectrometer. The infrared spectra were recorded using a Shimadzu IR 470 spectrometer in potassium bromide pellets. The melting points were obtained using a Yanaco MS-S3 micro melting point apparatus (hotplate type). For the preparative column chromatography, Wakogel C-200 silica gel was employed. Thin-layer chromatography (TLC) was accomplished on precoated plates of silica gel 60 $F_{254+366}$ (Merck). 2-Bromo-1,4-naphthquinone and 2-methyl-1,4-naphthoquinone were purchased from Aldrich (USA) and Tokyo Kasei Kogyo Co. (Tokyo, Japan), respectively.

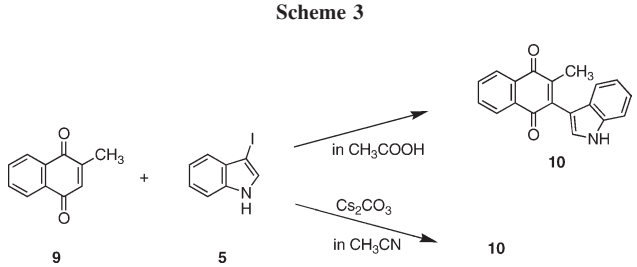
**3-Iodoindole (5).** 3-Iodoindole was prepared using a modified procedure of Arnold's method [8]. To a solution of indole (**1**) (100 mg, 0.85 mmol) in methanol (10 mL) was added sodium hydroxide (34 mg, 0.85 mmol). After the mixture was stirred at room temperature for 10 min, iodine (217 mg, 0.85 mmol) and an aqueous solution (1 mL) of potassium iodide (142 mg, 0.85 mmol) was added. The mixture was further stirred at room temperature for 10 min and the water was then added. The resulting precipitate was collected by filtration, washed with water, and dried *in vacuo* to obtain **5** (167 mg), which was used for the following reaction without its purification because of its lability.

**2-Bromo-3-(3-indolyl)-1,4-naphthoquinone (7).** A solution of 3-iodoindole (**5**) (149 mg, 0.61 mmol) and 2-bromo-1,4-naphthoquinone (**6**) (145 mg, 0.61 mmol) in acetic acid (10 mL) was stirred at room temperature for 3 days. After the mixture was concentrated under reduced pressure, the residue was chromatographed on silica gel with chloroform to give **7** (62 mg) in 29% yield with the starting material **6** (86 mg). The yield based on the amount of the consumed quinone was 72%. The product **7** was recrystallized with ethyl acetate–hexane (1:1), mp 202–205°C; ir (potassium bromide): 3335 (NH), 1661, 1588, 1547, 1421, 1269, 745, 717 cm$^{-1}$; $^1$H NMR

**Scheme 2**



**Scheme 3**



($CDCl_3$): δ 7.30 (m, 1H, H-5′), 7.46 (m, 2H, H-6′, 7′), 7.76 (m, 2H, H-4′, 6), 7.99 (m, 1H, H-7), 8.13 (m, 1H, H-8), 8.17 (m, 1H, H-5), 8.24 (d, 1H, $J$ = 2.8 Hz, H-2′), 8.74 (s, 1H, NH); $^{13}$C NMR ($CDCl_3$): δ 109.00, 111.92, 113.29, 117.48, 120.44, 121.90, 123.37, 125.89, 126.89, 129.73, 130.98, 132.24, 133.31, 136.32, 142.03, 144.47, 178.39 (C=O), 182.06 (C=O); MS (EI) *m/z* (relative intensity) 353 (M+2, 52%), 351 ($M^+$, 47), 274 (57), 273 (100), 272 (63), 217 (62), 216 (45), 189 (37); HRMS (EI) calcd. for $C_{18}H_{10}O_2NBr$, $M^+$ 350.9895, found 350.9884.

**2-(1-Indolyl-3-iodo)-1,4-naphthoquinone (8).** A mixture of 3-iodoindole (**5**) (142 mg, 0.58 mmol), 2-bromo-1,4-naphthoquinone (**6**) (139 mg, 0.58 mmol), and cesium carbonate (190 mg, 0.58 mmol) in acetonitrile (10 mL) was stirred at room temperature for 1 day. The reaction mixture was filtered and the filtrate was concentrated. The residue was chromatographed on silica gel with chloroform, followed by chromatography of TLC (silica gel; $CHCl_3$: $CH_3CN$ = 20:1) to give **8** (44 mg) in 19% yield along with **7** (11 mg) in 5% yield. The product **8** was recrystallized with ethyl acetate–hexane (3:1), mp 196–198°C; ir (potassium bromide): 1670, 1654, 1609, 1603, 1591, 1573, 1448, 1287, 1204, 732, 717 $cm^{-1}$; $^1$H NMR ($CDCl_3$): δ 7.17 (s, 1H, H-3), 7.31–7.38 (m, 2H, H-5′, 6′), 7.51 (dd, 1H, $J$ = 1.0, 7.5 Hz, H-7′), 7.56 (dd, 1H, $J$ = 1.0, 7.5 Hz, H-4′), 7.68 (s, 1H, H-2′), 7.80–7.86 (m, 2H, H-6, 7), 7.17 (dd, 1H, $J$ =1.0, 7.5 Hz, H-5), 8.22 (dd, 1H, $J$ = 1.0, 7.5 Hz, H-8); $^{13}$C NMR ($CDCl_3$): δ 64.28 (C-I), 112.03, 122.15, 123.10, 124.57, 125.95, 126.28, 127.34, 131.54, 131.77, 132.12, 132.84, 134.04, 134.69, 135.45, 141.95, 181.05 (C=O), 184.32 (C=O); MS (EI) *m/z* (relative intensity) 399 ($M^+$, 100%), 272 (59), 244 (21), 216 (36), 136 (20); HRMS (EI) calcd. for $C_{18}H_{10}O_2NI$, $M^+$ 398.9756, found 398.9760.

**2-Methyl-3-(3-indolyl)-1,4-naphthoquinone (10).** A solution of 3-iodoindole (**5**) (167 mg, 0.69 mmol) and 2-methyl-1,4-naphtoquinone (**9**) (118 mg, 0.69 mmol) in acetic acid (10 mL) was stirred at room temperature for 4 days. After the mixture was concentrated under reduced pressure, the residue was chromatographed on silica gel with chloroform, followed by TLC (silica gel; $CHCl_3$: $CH_3CN$ = 20:1) to give **10** (31 mg) in 16% yield with the starting material **9** (77 mg). The yield based on the amount of the consumed quinone was 62%. The product **10** was recrystallized with ethyl acetate–hexane (2:1), mp 252–254°C; ir (potassium bromide): 3340 (NH), 1653, 1594, 1288, 746, 718 $cm^{-1}$; $^1$H NMR ($CDCl_3$): δ 2.21 (s, 3H, $CH_3$), 7.15–7.18 (m, 1H, H-5′), 7.22–7.26 (m, 1H, H-6′), 7.32 (d, 1H, $J$ = 8.2 Hz, H-7′), 7.43 (s, 1H, H-2′), 7.46 (d, 1H, $J$ = 8.2 Hz, H-4′), 7.74 (m, 2H, H-6, 7), 8.16 (m, 2H, H-5, 8), 9.38 (broad, 1H, NH); $^{13}$C NMR ($CDCl_3$): δ 15.76 ($CH_3$), 108.28, 111.69, 111.74, 120.37, 120.42, 122.30, 126.19, 126.70, 127.22, 132.48, 132.52, 133.46, 133.53, 135.80, 140.43, 143.30,184.76 (C=O), 185.99 (C=O); MS (EI) *m/z* (relative intensity) 287 ($M^+$, 100%), 270 (56), 230 (16), 154 (10); HRMS (EI) calcd. for $C_{19}H_{13}O_2N$, $M^+$ 287.0946, found 287.0973.

**Acknowledgment.** We are grateful to the Center for Instrumental Analysis, Kyushu Institute of Technology, for the mass spectra and NMR spectra.

Novel carbazolyl-oxazolones, **3a–d**, were synthesized with 3-[*N*-(2-hydroxycarbonylmethyl)-carboxamide]-4-methyl-9*H*-carbazole and several aryl aldehydes for the first time. Photo physical characterization of synthesized 2-carbazolyl-4-arylidene-5-oxazolones (**3a–d**) in dichloromethane, chloroform, and toluene was performed.

*J. Heterocyclic Chem.*, **47**, 1450 (2010).

## INTRODUCTION

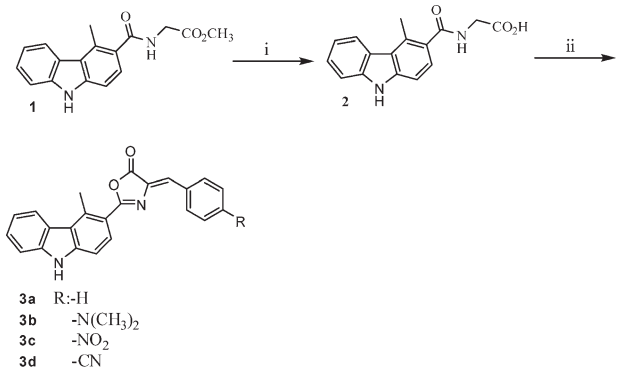
Carbazole [1–6] and oxazolone [7,8] moieties have received great attention by chemist not only because of their biological properties, but also for their technological importance. Oxazolones that are internal anhydrides of acyl amino acids are important class of five-membered heterocycles. They are highly versatile intermediates used for the synthesis of several organic molecules, including amino acids, peptides, antimicrobial or antitumor compounds, immunomodulators, heterocyclic precursors, for biosensors coupling, and/or photosensitive composition devices for proteins. They can be easily prepared from *N*-acyl amino acids by dehydration. 5-Oxazolones also have a wide range of applications including their use in semiconductor devices because of their promising photophysical and photochemical activities [9]. Carbazole derivatives are important optical materials due to their special photorefractive, electrical, and chemical properties [2–6].

2-Aryl-4-carbazolyliden-5-oxazolones were first synthesized *via* an Erlenmeyer reaction of the carbazole aldehyde derivatives with several *N*-benzoyl glycine derivatives and their optical properties were studied [10,11]. We recently synthesized several 5-oxazolone derivatives and investigated their basic photophysical and sensor characteristics by using UV-vis and fluorescence spectroscopy [12–18]. Herein, we prepared novel 2-carbazolyl-4-arylidene-5-oxazolones (**3a–d**) with a carbazole glycine derivative for the first time. This work also describes the photophysical characterization of 2-carbazolyl-4-arylidene-5-oxazolones (**3a–d**) in dichloromethane, chloroform, and toluene. We also examined the correlation between the molecular structures and their fluorescent properties.

## RESULTS AND DISCUSSION

We synthesized novel 2-carbazolyl-4-arylidene-5-oxazolones (3a–d) with a carbazole glycine derivative for the first time (Fig. 1). Thus, we aimed to combine the advantages of carbazole structures and 5-oxazolone derivatives. We used a carbazole glycine ester 1 derivative as a starting material, which was synthesized previously by our group [19]. Then, the hydrolysis of carbazole glycine ester 1 in basic conditions gave the glycine derivative of carbazole 2 [20]. Finally, 2-carbazolyl-4-arylidene-5-oxazolones were synthesized with carbazole glycine derivative 2 and several aryl aldehydes by an Erlenmeyer reaction.

Also, the absorption and emission spectral properties of (**3a–d**) were also investigated in dichloromethane, chloroform, and toluene (Table 1). The results obtained show that the nature of the substituent groups on the aryl moiety influences the absorption and fluorescence emission maxima. The absorption maxima of **3a–d** derivatives were observed between 393 and 470 nm (Table 1, Fig. 2). The excitation wavelengths were chosen as 410, 473, 442, and 441 nm for **3a–d**, respectively, and the emission spectra were recorded.



**Reagent and Conditions: i)** $LiOH.H_2O$, ethanol; **ii)** NaOAc, $Ac_2O$, ArCHO

**Figure 1.** The synthesis route and structural formulas of **3a–d**.

Emission and related excitation spectra of **3c** in dichloromethane are shown in Figure 3. The excitation spectral data were acquired by exciting the molecule at its emission maximum. The chromophore system is affected by the electron donor group (carbozolyl groups) and electron acceptor groups (4-nitrophenyl and cyanophenyl) of **3c** and **3d** derivatives. Thus, the emission maxima are red shifted for **3c** and **3d** in comparison to **3a**. As the nitro group is a stronger electron acceptor than a cyano group, **3c** has a longer emission wavelength maximum. A bathocromic shift was also observed for **3b**, which has an *N*,*N*-dimethylamino moiety, a strong electron donor group. The Stokes' shift values were calculated for all derivatives and the highest Stokes' shift values were obtained for **3c** and **3d**. For all derivatives studied, the Stokes shift values are higher in chloroform and dichloromethane, in comparison to the values obtained in toluene. This result indicates that as the solvents polarity decreases, the Stokes shift values decrease as well.

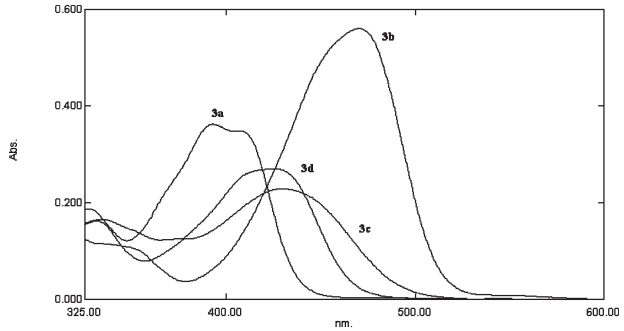


**Figure 2.** Absorption spectra of compounds **3a–3d** measured in dichloromethane ($1 \times 10^{-5}$ *M*).

HPTS was used as reference quantum yield standard $\lambda_{ex} = 400$ nm, quantum yield = 1, in acidic water for 3a; and $\lambda_{ex} = 470$ nm, quantum yield = 1, in basic water for **3c–d**. Fluorescence quantum yields ($\Phi_F$) were determined by the formula [21]:

$$\Phi = \Phi_{std} \times (FA_{std}\eta^2)/(FA_{std}\eta_{std}^2)$$

where $F$ and $F_{std}$ are the areas under the fluorescence emission curves of the samples and the standard, respectively. $A$ and $A_{std}$ are the respective absorbance of the samples and standard at the excitation wavelength, respectively, and $\eta$ and $\eta_{std}$ the refractive indexes of solvents used for the samples and standard, respectively. **3c** and **3d** in toluene exhibited the highest quantum yield values of 0.7675 and 0.9323, respectively. This can be explained by the charge transfer efficiency of the molecules in the excited state. Electron accepting 4-nitro and cyano substituents increase π-electron mobility much more than the electron donating 4-dimethylamino substituent at the same position resulting in high charge separation properties of **3c** and **3d**. This can also be attributed to the fact that, more polar solvents provide

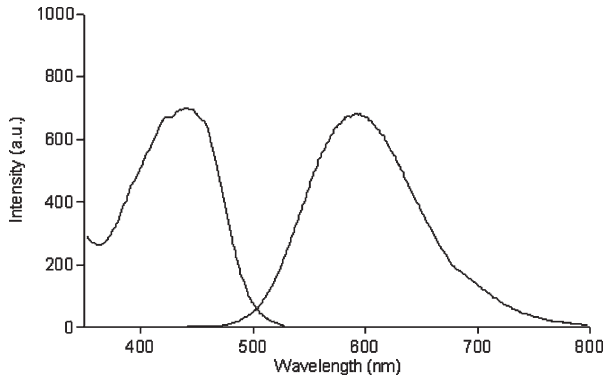

**Figure 3.** Emission and excitation spectra of **3c** in dichloromethane.

**3c** and **3d** freedom to rotate and vibrate which serve as the nonradiative transitions.

The photostabilities of **3a–d** derivatives were recorded with a steady-state spectrofluorimeter in dichloromethane, chloroform, and toluene (Fig. 4). The data were acquired at their maximum emission wavelengths after exposure to xenon arc lamp for 1 h of monitoring. All derivatives exhibited excellent photostability in three of the solvents studied.

## CONCLUSION

Four different carbazolyl–oxazolones derivatives were synthesized for the first time. All derivatives displayed emission maxima in the range of 438–592 nm and excellent photostabilities. The highest quantum yield value was determined for 3d in toluene, 0.9323, which is quite promising. Considering the absorption and fluorescence emission maxima, 3c and 3d are expected to be good probes for biological applications. Our next goal is to investigate their performance as ion sensors for biological applications.

## EXPERIMENTAL

All solvents were of analytical grade and purchased from Merck (Darmstadt, Germany), Fluka (Buchs, Switzerland), and Riedel (Seelze, Germany). All melting points were measured in sealed tubes using an electrothermal digital melting points apparatus (Southend, UK) and are uncorrected. Infrared spectra were recorded on a Perkin Elmer (Massachusetts, USA) FTIR infrared spectrometer (spectrum BX-II). $^1$H NMR spectra were obtained on a high resolution fourier transform Bruker WH-400 NMR spectrometer (Coventry, UK) with tetramethylsilane as an internal standard. Mass spectra were determined on the electron impact mode by direct insertion at 70 eV with a Micromass UK Platform II LC-MS spectrometer (Manchester, UK). Combustion analysis of compounds was obtained on a CHNS-932-LECO (St. Joseph, MI). Analytical and preparative thin layer chromatographies (TLC) were carried out using silica gel 60 $F_{254}$ (Merck). Column chromatography was carried out by using 70–230 mesh silica gel (0.063–0.2 mm, Merck). UV/visible absorption spectra were recorded with Schimadzu UV-1601 spectrophotometer (Tokyo, Japan). All fluorescence measurements were undertaken by using Varian-Carry Eclipse spectrofluorimeter (Mulgrave, Australia). 1-hydroxypyrene-3,6,8-trisulfonate trisodium salt (HPTS) purchased from Fluka was used as reference standard for fluorescence quantum yield calculations of **3a–d**.

**3-[*N*-(2-Hydroxycarbonylmethyl)-carboxamide]-4-methyl-9H-carbazole (2).** A solution of 1 (1.5 g, 5 mmol) and lithium hydroxide monohydrate (0.21 g, 5 mmol) in 25 mL of ethanol was stirred for 2 h. The solvent was removed under reduced pressure and the residue was diluted with water and acidified with concentrated hydrochloric acid. The solution was extracted with ethyl acetate and the organic layer was dried over anhydrous magnesium sulphate. The solvent was evaporated under reduced pressure and the resulting residue was recrystallized from ether to afford 1.30 g (91%) of 2 as a white solid, mp 273°C; ir (potassium bromide): ν 3403(NH), 3260 (NH), 2921 (CH), 1703 (ester C=O), 1631 (amide C=O) cm$^{-1}$; $^1$H NMR ($d_6$-dimethyl sulfoxide): δ 2.88 (s, 3H, $CH_3$), 3.92 (d, 2H, CONHC$H_2$, $J$ = 6.0 Hz), 7.18 (d, 1H, $J$ = 8.0 Hz, ArH), 7.33 (d, 1H, $J$ = 8.4 Hz, ArH), 7.37–7.44 (m,1H, ArH) 7.50 (d, 1H, $J$ = 8.4 Hz, ArH), 8.18 (d, 1H, $J$ = 8.4 Hz, ArH), 8.42 (t, 1H, $J$ = 6.0 Hz, CON$H$CH$_2$), 11.40 (s, 1H, NH), 12.50 (bs,1H, OH); ms (70 eV): *m*/*z*% 284 (7.7), 283 (65), 209 (13.1), 208 (100), 73 (26.7). **General methods for the synthesis of phenyl carbazole oxazolones (3a–d).** Aldehyde (6 mmol), 3-[*N*-(2-hydroxycarbonylmethyl)-carboxamide]-4-methyl-9*H*-carbazole (6 mmol), acetic anhydride (2.49 mL, 12 mmol), and sodium acetate (0.87 g, 6 mmol) was heated until the mixture just liquefied, and then heating was continued for further 2 h. After completion of the reaction (determined by thin layer chromatography), ethanol (25 mL) was added and mixture was kept at room temperature for 18 h. The solid product thus obtained was purified by washing with cold ethanol, hot water, and small amount of hexane. The solid was recrystallized from hot ethanol to afford carbazolyl-oxazolone.

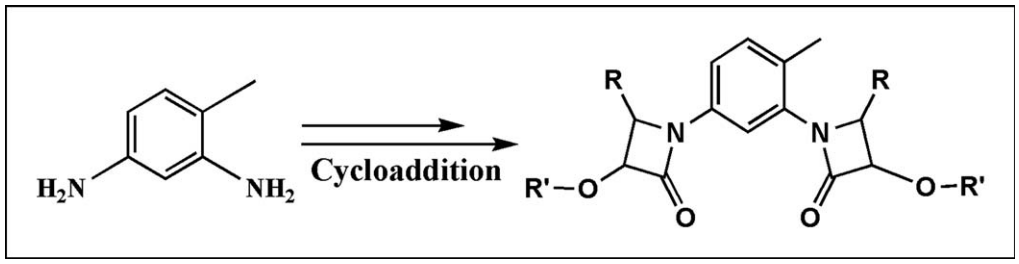
Published online 24 August 2010 in Wiley Online Library (wileyonlinelibrary.com).



A facile synthesis of bis-β-lactams has been executed using chloromethylenedimethylammonium chloride (Vilsmeier reagent), prepared easily from *N*,*N*-dimethylformamide and phosphorus oxychloride. It works out as a versatile acid activator reagent for the direct [2 + 2] ketene–imine cycloaddition of substituted acetic acid and bis-imines in one-pot synthesis under mild conditions. Thus, this method has been proved as a high yielding, efficient, and cheap protocol for bis-β-lactam synthesis.

## INTRODUCTION

The β-lactam skeleton is the key structural unit of the most widely employed β-lactam antibiotics [1]. The constant need for new drugs displaying broader antibacterial activity and the necessity for new β-lactam antibiotics to combat the microorganisms that have built up resistance against the most traditional drugs [2] have maintained the interest of organic chemists in β-lactams for decades. In addition to its use in the synthesis of variety of β-lactam antibiotics, the β-lactam skeleton has been recognized as a useful building block by exploiting its strain energy associated with four member ring [3]. Efforts have been made in exploring such new aspects of β-lactam chemistry using pure β-lactams as versatile intermediates for organic syntheses [4]. Ojima *et al*. [5] have shown the utility of bis-β-lactams for the synthesis of peptides. The synthesis of bis-β-lactams, in general, has been reported by a step-wise construction of β-lactam rings [6]. In continuation of our work on synthesis of bis-β-lactams [7], we were interested in building bis-β-lactams from bis-imines using the Staudinger cycloaddition reaction.

Among the various methods available for the synthesis of β-lactams, the Staudinger cycloaddition reaction (ketene–imine cycloaddition reaction) is the most widely used [8] mainly because of the simplicity in reaction procedures. This method has been used for the synthesis of a large number of monocyclic, bicyclic, tricyclic, and spirocyclic β-lactams [9]. The ketenes are commonly generated *in situ* from acyl halides in the presence of tertiary amines [10]. In addition to the utilization of acyl halides, a variety of other methods have been described to activate carboxylic acids [11]. These methods are conventionally useful when the acid halides are not commercially available, difficult to prepare or when they are unstable. Some acid activating agents include 1,1-carbonyldi-imidazole [12], triphosgene [13], ethyl chloroformate [14], trifluoroacetic anhydride [15], p-toluenesulfonyl chloride [16], phosphorus-derived reagents [17], cyanuric chloride [18], the Mukaiyama reagent [19], and acetic anhydride [20].

Herein this communication, we report the synthesis of bis-β-lactams using Vilsmeier reagent. Chloromethylenedimethylammonium chloride (Vilsmeier reagent) has been known as a formylating agent [21]. It has also emerged as an efficient synthetic auxiliary for the synthesis of some important class of organic compounds. This white solid is easily synthesized by reaction of *N*,*N*-dimethylformamide (DMF) and chlorinating agents such as $POCl_3$ or $SOCl_2$ [22]. But in our methodology, we have generated this reagent *in situ* using DMF and $POCl_3$ in dichloromethane as reported [23]. This reagent was reported for the synthesis of monobactams by Jarrahpour and Zarei [24]. We have extended its applicability in the synthesis of bis β-lactams by generating it *in situ*. In this article, we wish to describe the versatility and utility of the Vilsmeier reagent for the activation of carboxylic acids in bis-β-lactam synthesis under simple

and mild conditions. It has proved to be a high yielding protocol for the synthesis.

## RESULTS AND DISCUSSION

We selected toluene-2,4-diamine for the preparation of various bis-imines from different aldehydes and this imine were used for the construction of bis-β-lactams. The bis-imines **3a–h** were prepared by refluxing toluene-2,4-diamine with 2 mol equivalent of aldehydes (benzaldehyde, 2-hydroxybenzaldehyde, 4-hydroxybenzaldehyde, 2-nitrobenzaldehyde, 3-nitrobenzaldehyde, 4-methoxybenzaldehyde, 2-chlorobenzaldehyde, 4-chlorobenzaldehyde, and 4-methoxy-benzaldehyde in ethanol for about 1 to 1.5 h as shown in Scheme 1 according to known method [23]. Crude bis-imines were recrystallized with hot methanol.

Chloromethylenedimethylammonium chloride **4** was prepared from DMF and phosphorus oxychloride in dry $CH_2Cl_2$. We have successfully employed the Vilsmeier reagent for the one-step cycloaddition reaction of various imines **3a–h** and substituted phenoxyacetic acid to obtain bis-β-lactams **5a–h** (Scheme 2). Solution of Chloromethylenedimethylammonium chloride **4** was added to a solution of mixture of acid, imines, and triethylamine in $CH_2Cl_2$ between 0 and −5°C, and the reaction mixture was stirred at room temperature for 10 h. The usual work-up and then crystallization from hot methanol gave pure bis-β-lactams **5a–h** in high yields. We found that this method was very efficient, simple, and clean. The DMF and triethylammonium salt are two by-products, which were removed by simple aqueous work-up. In all cases the cycloaddition afforded only *cis*, *cis* bis-β-lactams **5a–h**.

The *cis* steriochemistry for bis-β-lactam **5a–h** was assigned on the basis of $^1$H NMR spectral analysis. The $^1$H NMR spectra showed two doublets between 5.24 and 5.56 ppm for cis-β-lactam ring protons ($J$ = 4.6 to 4.8 Hz for *cis* β-lactam protons). The absence of —CH=N protons in **5a–h** show the azetidinone ring formation. The IR spectra of the bis-imines **3a–h** were compared with those of the bis-β-lactams to draw conclusion on cycloaddition. There were some guide peaks in the spectrum of the bis-imines and bis-lactams, which were helpful in achieving this goal. The position and the intensities of these peaks are expected to change upon cycloaddition. In the spectrum of bis-imines, the characteristic absorption around 1618–1650 $cm^{-1}$ can be assigned to (—C=N) azomethine linkage, which

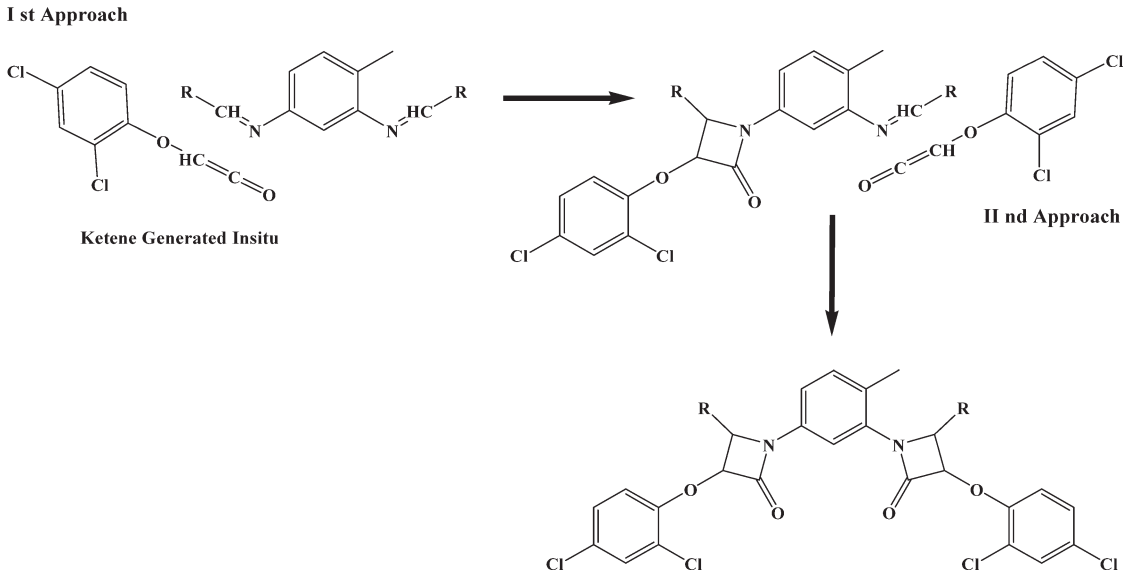
**Scheme 3.** Approaches in the formation of *cis, cis* bis-β-lactam.



disappears in the spectrum of the bis-β-lactams confirming the cycloaddition. In the spectrum of bis-lactams, the characteristic absorption around 1750–1700 $cm^{-1}$ can be assigned to (—C=O) linkage. The mass spectra of these compounds displayed a molecular ion peak at their respective *m/z* values, which are corresponding well with the respective molecular mass. All the compounds have given the satisfactory elemental analysis.

We believe that mono-β-lactam is initially formed by the reaction of the most stable bis-imine (I approach) with ketene. The approach of the ketene in the Staudinger cycloaddition reaction is such that the steric interaction between the aryl group of the imine and phenoxy group of the ketene is minimum in the transition state (Scheme 3) resulting in the formation of *cis*-β-lactam. However, the formation of trans-β-lactam is unfavorable due to severe steric interaction between the aryl group of imine and phenoxy group of ketene in the transition state. The mono β-lactam further undergoes cycloaddition reaction with the second molecule of ketene to give bis-β-lactam (Scheme 3). The approach of the second ketene towards the imine is from the opposite site of the preformed azetidinone ring to give bis-β-lactam **5a**. In this approach, the ketenes are generated directly from the carboxylic acid using Vilsmeier reagent instead of acid chloride. Thus, the Staudinger reaction of imines with carboxylic acids using Vilsmeier reagent **4** as an activator proceeded smoothly under milder reaction conditions. As acid chlorides are usually unstable, this approach is quite practical as starting carboxylic acid can be easily handled and stored as compared to respected acid chloride.

## EXPERIMENTAL

The solvents and reagents used in the synthetic work were of analytical grade obtained from Qualigens India and were purified by distillation or crystallization, where necessary and their boiling or melting points were compared with the available literature values. Melting points were determined in open capillaries and are uncorrected. $^1H$ NMR spectra were recorded on a Perkin Elmer FT NMR Cryo-magnet Spectrometer 400 MHz (Bruker) instrument using tetramethylsilane (TMS) as an internal standard and DMSO-$d_6$ as a solvent. Chemical shifts are given in parts per million (ppm). Infrared spectra were recorded on Schimadzu-IR Prestige 21. Mass spectra were recorded on a Waters Micromass Q-T of Micro spectrometer. The reactions were monitored, and the purity of products was checked out on pre-coated TLC plates (Silica gel 60 F254, Merck), visualizing the spots under ultraviolet light and iodine chamber.

**General procedure for the preparation of bis-imines 3a–h.** A mixture of freshly distilled benzaldehyde (2.78 g, 26.3 mmol) and toluene-2,4-diamine (2.20 g, 17.5 mmol) in ethanol (30 mL) was refluxed for 1–1.5 h. The completion of the reaction was monitored by thin layer chromatography. After disappearance of the starting materials, the reaction mixture was allowed to attain the room temperature during which solid precipitated out. It was filtered out and recrystallized from hot methanol to afford **3a** as yellow crystalline solid. Following this procedure, bis-imines **3b–h** were prepared in excellent yield. All the bis-imines are well known in the refs. 25–27 and identified by comparison of their physical and spectral data.

**A typical procedure for the preparation of bis-β-lactams 5a–h.** In a 100 mL Round Bottom Flask, (1.0 g, 3.35 mmol) bis-imine **3a** was charged followed by (10 mL) dichloromethane. To it (1.48 g, 6.70 mmol), 2,4-dichlorophenoxyacetic acid followed by (1.35 g, 13.40 mmol) triethylamine was charged. It was chilled to −5°C. To a separate 50 mL Round Bottom Flask, (1.2 g, 8.04 mmol), $POCl_3$ in (10 mL) dichloromethane was charged. The solution was cooled to 10°C and a

solution of DMF (0.50 g, 6.7 mmol) in 5 mL dichloromethane was added over 10 min maintaining the temperature between 10 and 15°C. When the addition was complete, the mixture was allowed to stir at room temperature for 30 min. This Vilsmeier solution was then added gradually to the above prepared bis-imine solution over 15 min, maintaining the temperature between 0 and −5°C. After the addition was complete, the reaction mixture was allowed to warm up to room temperature and stirred for 10 h. The reaction mixture was then washed with water (2 × 20 mL), saturated sodium bicarbonate solution (20 mL) and saturated brine solution (20 mL). The organic layer was then dried over anhydrous $Na_2SO_4$ and concentrated to give the crude bis-β-lactams. It was recrystallized from hot methanol to give pure bis-β-lactams. Following this procedure other β-lactams **5b–h** were prepared.

***3-(2,4-Dichlorophenoxy)-1-(3-(3-(2,4-dichlorophenoxy)-2-oxo-4-phenylazetidin-1-yl)-4-methyl phenyl)-4-phenylazetidin-2-one 5(a).*** This compound was obtained as white solid, 81%, m.p. 193–194°C, IR (KBr): 3120, 2965, 2970, 1755, 1365 $cm^{-1}$. $^1H$ NMR (DMSO-$d_6$): 2.34 (s, 3H, —$CH_3$), 6.80–7.62 (m, 19H, Ar), 5.25 (d, 1H, $J$ = 4.7 Hz), 5.51 (d, 1H, $J$ = 4.7 Hz), 5.26 (d, 1H, $J$ = 4.6 Hz), 5.56 (d, 1H, $J$ = 4.6 Hz).
