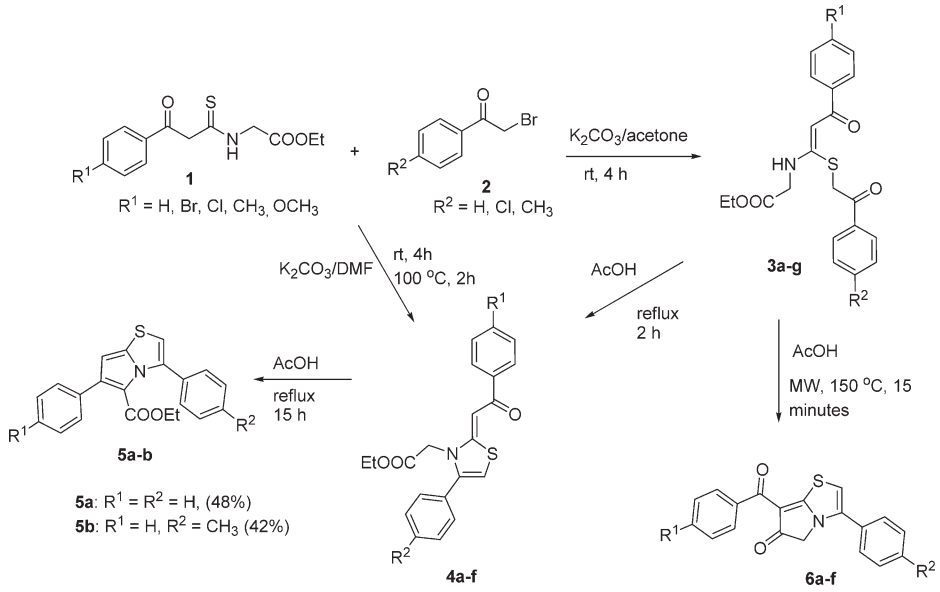
Initially, alkylation of thioamide **1** with one equiv. of a 1,2-bielectrophile—phenacyl bromide in the presence of $K_2CO_3$ (2 equiv.) as the base in acetone at room temperature was carried out expecting monoalkylation at sulphur followed by *in situ* cyclization to form thiazole **4**, which could be further transformed into the pyrrolothiazoles. However, we isolated only the monoalkylated α-aroyl ketene-*N*,*S*-acetals **3** in nearly quantitative yields (Scheme 1, Table 1). The unexpected complex pattern of peaks observed in the $^1$H NMR (360 MHz) spectrum of **3** is apparently due to the diastereotopic nature of the methylene protons. For example, in **3a**, ethyl moiety showed a triplet at δ 1.27 and two sets of doublets each at δ 3.40 and 3.50 ($J$ = 12). Another doublet of doublet appeared at 3.79 (1H, $J$ = 12 Hz) and 4.08 (1H, $J$ = 12 Hz) due to S$CH_2$ moiety. The N$CH_2$ moiety showed a

**Scheme 1**



multiplet at δ 4.18–4.26 ppm. By recording the $^1$H NMR spectrum at higher frequency (500 MHz), we further confirmed these sets of peaks as doublet of doublet rather than peaks arising from the possible geometrical isomeric forms.

Next, taking **3a** as a model substrate, its cyclization to thiazole **4a** was attempted. Initial experiments using $K_2CO_3$ as the base in acetone under reflux conditions failed to afford thiazole. Use of a strong base like KOH in ethanol or NaH in DMF afforded only intractable mixture of products. Further studies using acid catalysts showed that the ketene-*N*,*S*-acetals **3** can be easily transformed into thiazoles **4**. Thus, a solution of the ketene-*N*,*S*-acetal **3a** in acetic acid was heated at 70°C for 4 h; the thiazole **4a** was formed quantitatively. Using a similar protocol the thiazole **4b** was prepared (Table 2). Alternatively, when the alkylation of the thioamide **1a** was attempted in the presence of excess of $K_2CO_3$ (8 equiv.) in DMF, thiazole **4a** was formed in good yields. The same strategy was used for the preparation of thiazoles **4b–f** (Table 2).

Since the thiazole **4** containing structural units that can be easily transformed into pyrrolo[2,1-*b*]thiazoles, we attempted their pyrrole ring annulation studies. Similar cyclization has been previously reported by our group for the synthesis of pyrroles from ketene-*N*,*S*-acetals using Vilsmeier Haack reagent ($POCl_3$/DMF) [15]. Tverdokhlebov *et al*. used the same reagent for the synthesis of pyrrolo[2,1-*b*]thiazoles from thiazoles [17]. Attempts using base catalysts or Vilsmeier Haack reagent failed to afford pyrrolothiazoles. However, the thiazole **4a** or **4b** after heating under reflux in acetic acid for a period of 15 h, we observed the formation of pyrrolo[2,1-*b*]thiazoles **5a** and **5b** in 48% and 42% yields respectively (Scheme 1). To our surprise, other thiazoles (**4c–4f**) even after refluxing in acetic acid for 24 h, it was possible to isolate only the unreacted starting material. Failure of the above cyclization was apparently due to the unfavorable orientation of the aroyl moiety in the thiazole **4**.

The observation that the *N*,*S*-acetal **3a** underwent facile cyclization in presence of acetic acid prompted us to irradiate a solution of **3a** in acetic acid under

**Table 1**

Ketene-*N*,*S*-acetals **3** prepared from thioamide **1**.

| Product | $R^1$ | $R^2$ | Yield (%) |

microwave. Thus, by dissolving **3a** in acetic acid followed by microwave irradiation for 15 min at 150°C in a microwave synthesizer, transformation to the corresponding pyrrolo[2,1-*b*]thiazole **6a** was observed in 81% yield. Using a similar protocol we have prepared other pyrrolothiazoles (**6b–f**) in good yields (Table 3). Electron withdrawing or donating substituents have little effect on the mode of cyclization or on the overall yield of the pyrrolothiazoles **6** formed. When we reduced only the reaction time to 10 min, the reaction was incomplete and could be possible to isolate a mixture of the intermediate thiazole **4a** and the pyrrolothiazole **6a** in a ratio 1 : 3. In an independent experiment, transformation of **4a** to **6f** was observed under microwave heating. It is interesting to note that the mode of cyclization during pyrrole ring annelation step in conventional heating is different from that in microwave conditions. Thus, under microwave conditions pyrrolothiazoles **6** were formed which is structurally different form the pyrrolothiazoles **5**, formed during conventional heating. This is apparently due to the fact that under microwave conditions, the geometry of the exocyclic double bond present in the initially formed thiazole **4** was affected to a lesser extend and the ethyl carboxylate functionality underwent rapid conformational changes favoring the regioselective formation of pyrrolothiazoles **6**. While in conventional heating the reverse is true leading to the formation of pyrrolothiazole **5**.

In summary, we have developed a convenient and efficient one-pot procedure for the synthesis of a variety of pyrrolo[2,1-*b*]thiazoles from less expensive as well as easily accessible ketene-*N*,*S*-acetals under microwave conditions in a regioselective and efficient manner. The reaction is very fast and the product can be easily separated from the reaction medium by dilution using water followed by filtration.

## EXPERIMENTAL

Thioamide **1** was prepared as reported [15(b)]. Microwave-assisted reactions were done in a multimode microwave reactor (Biotage Initiator™). Melting points were obtained on a Buchi-530 melting point apparatus and are uncorrected. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker DRX-300 MHz or AM-360 MHz spectrometer in $CDCl_3$. Chemical shifts are expressed in parts per million. Coupling constants *J* are given in Hertz. Mass spectra-EIMS, FAB, were obtained on a Finngen-Mat 312, Jeol SX 102/Da-600 instruments respectively. Elemental analyses were recorded on an elementar vario EL III analyzer.

**General procedure for the synthesis of α-aroyl ketene-*N*,*S*-acetals (3).** A suspension of the thioamide **1** (10 mmol) and anhyd $K_2CO_3$ (20 mmol) in dry acetone (30 mL) was refluxed with stirring for 30 min. The mixture was cooled and phenacyl bromide **2** (10 mmol) was added followed by stirring at room temperature for 4 h. When the reaction was completed (TLC), the mixture was poured into ice-cold water and extracted using $CH_2Cl_2$ (2 × 50 mL). The organic layer was washed with water (2 × 100 mL), dried using anhyd $Na_2SO_4$ and evaporated. The crude product thus obtained was purified by column chromatography over silica gel using hexane: ethyl acetate (7 : 3) as eluent afforded the α-aroyl ketene-*N*,*S*-acetals **3a–g** (Table 1).

The novel reaction of [hydroxyl (((+)-10-camphorsulfonyl)oxy)iodo]benzene (1) with alkenoic acids was reported. When **1** reacted with various 4-pentenoic acids in $CH_3CN$, camphorsulfonylactons were obtained in excellent yields in short times, some had two diastereoisomers, whereas **1** reacted with 5-hexenoic acid, giving middle yield of camphorsulfonylacton; however, 3-butenoic and *trans*-3-hexenoic acids reacted with **1** slowly in $CH_2Cl_2$, only unsaturated lactones were provided.

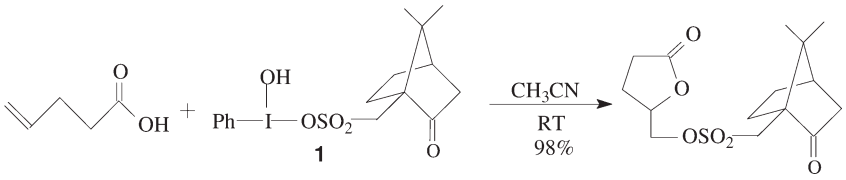
## INTRODUCTION

Lactonizations have been studied extensively, and this type of transformation serves as an important key reaction in a variety of syntheses [1]. Among them, halolactonization and phenylselenolactonization are general used methods [2]. Recently, organic hypervalent iodine reagents have found broad application in organic chemistry and frequently used in synthesis due to their chemical properties and reactivity are similar to those of Hg (II), Tl (III), and Pb (IV), but without the toxic and environmental problems of these heavy metal congeners [3]. Koser and coworkers first reported the tosyloxylactonization of alkenoic acids with the hypervalent iodine reagent, [hydroxyl(tosyloxy)iodo]benzene (HTIB, Koser's reagent), which mechanism was different with halolactonization and phenylselenolactonization and received much attention [4]. The ability of HTIB to introduce the tosylate ligand into alkenoic acids prompted us to investigate the camphorsulfonyloxylactonization of alkenoic acids with the analogous reagent, [hydroxyl (((+)-10-camphorsulfonyl)oxy)iodo]benzene (1) [5], a stable and incorporating a chiral ligand hypervalent iodine reagent. Here, we would like to report a novel and convenient camphorsulfonyloxylactonization of alkenoic acids, a series of new 5-camphorsulfonyloxy-4-pentanolactones and 6-camphorsulfonyloxy-5-hexanolactone were synthesized.

Initially, we prepared [hydroxyl (((+)-10-camphorsulfonyl)oxy)iodo]benzene (1) according to the literature procedure [5]. Then, we investigated the reaction of 4-pentenoic acid with **1**, we found that when the equal equivalent of both them were mixed and stirred in $CH_3CN$ at room temperature, the reaction was carried out fluently and finished in 0.5 h, the novel compound of 5-camphorsulfonyloxy-4-pentanolactone was obtained in nearly quantitative (Scheme 1). Prompted by the good result, a series of experiments were performed on the reaction of 4-pentenoic acid with **1** in order to determine the suitable reaction conditions, and $CH_3CN$ and $CH_2Cl_2$ were found to be the most preferred solvents. Finally, the reaction of a series of alkenoic acids (2) with **1** in $CH_3CN$ or $CH_2Cl_2$ at room temperature were investigated, several new camphorsulfonylactons (3) were provided (Scheme 2), the good results are summarized in Table 1.

It is shown from Table 1 that 4-pentenoic acid (2a), 2-methyl-4-pentenoic acid (2b), 3-methyl-4-pentenoic acid (2c) and 2, 2-dimethyl-4-pentenoic acid (2d) all reacted with **1** fast, and gave the corresponding 5-camphorsulfonyloxy-4-pentanolactones, respectively, in excellent yields (entries **1–4**); Similar treatment of 5-hexenoic acid needed longer time compared with 4-pentenoic acid and provided 6-camphorsulfonyloxy-5-hexanolactone (3e) in middle yield (entry **5**), which meant that five-membered lactone ring was formed easier than six-membered lactone ring in the camphorsulfonyloxylactonization of alkenoic acids. We also checked the reaction of 6-heptenoic acid with **1**, found that after 48 h it had not been completed and the desired seven-membered lactone ring was obtained in poor yield. When 3-butenoic and *trans*-3-hexenoic acids were treated with **1**

**Scheme 1**



in same reaction conditions, the reaction was somewhat difficult to carry out in $CH_3CN$ and slowly; then using $CH_2Cl_2$ in place of $CH_3CN$, we found that after 24 h the reaction was finished. However, the products were not the desired camphorsulfonylactons, two unsaturated lactones were found (entries **6** and **7**). It was revealed by $^1$H-NMR technique that the desired 3-sulfonyloxy-4-butanolactones were first formed, but then transformed into the unsaturated lactones during workup procedure by elimination. 2-Cyclopenteneacetic acid reacted with **1** also fluently, but gave another unsaturated lactone (entry **8**), which agreed with Koser and coworkers report [4].

Koser et al. in 1988 reported another lactonizaton using the similar hypervalent iodine reagent, [hydroxyl ((bis(phenyloxy)phosphoryl)oxy)iodo]benzene, and they found that when 2-methyl-4-pentenoic acid was treated with the hypervalent iodine reagent, the products were a mixture of diastereomers, with a ratio varied from 1.2 to 1.4:1 [6]. Because of [hydroxyl (((+)-10-camphorsulfonyl)oxy)-iodo]benzene is a chiral hypervalent iodine reagent, the lactonizaton of it may be stereoselectivity, and some evidence was obtained by examination of the $^1$H-NMR spectrum of camphorsulfonylactons: when 2-methyl-4-pentenoic acid (2b) and 3-methyl-4-pentenoic acid (2c) were treated with **1** at room temperature, the provided products were mixtures of diastereomers, the ratios of them were 3.1:1 and 2.3:1, respectively. Then, we checked the effect of temperature on the stereoselectivity of **2b** and found that the camphorsulfonylactonization got diastereomers with higher ratio at lower of temperature; The reaction was investigated at room temperature, $-20^\circ$C and $-50^\circ$C, respectively, the ratios of diastereomers varied from 3.1, 4.0 to 4.8:1. However, except **2b** and **2c**, other alkenoic acids were not observed having the stereoselectivity in the camphorsulfonylactonization at room temperature. Solvents also had small effect on the stereoselectivity, we found that $CH_3CN$ was better than $CH_2Cl_2$ to get high diastereomers ratio for **2b** in the reaction.

[Hydroxyl (((+)-10-camphorsulfonyl)oxy)iodo]benzene was made from (diacetoxyiodo)benzene and (+)-10-camphorsulfonic acid in $CH_3CN$. To extend the scope of camphorsulfonylactonization, find simpler and more convenient camphorsulfonylactonization, the ''one-pot'' reaction was investigated; when equal equivalent of (diacetoxyiodo)benzene, (+)-10-camphorsulfonic acid and 4-pentenoic acid were mixed in $CH_3CN$ at room temperature and stirred the mixture, we found that the reaction was completed in 0.5 h, giving the desired **3a** in 95% of yield. When [bis(trifluoroacetoxy)iodo]benzene was used in place of (diacetoxyiodo)benzene, the same result was obtained in 94% of yield. Therefore, the simpler and more convenient ''one-pot'' camphorsulfonylactonization was found (Scheme 3). Further investigation of the reaction will be reported later.

The plausible mechanism is similar to the literature procedure [4], which included the electrophilic addition of hypervalent iodine reagent **1** on the alkene, then an intramolecular nucleophilic displacement was happened, followed by another nucleophilic displacement to give the camphorsulfonylactone (Scheme 4).

In conclusion, we have successfully developed a novel and convenient reaction of [hydroxyl-(((+)-10-camphorsulfonyl)oxy)iodo]benzene with alkenoic acids, several new 5-camphorsulfonyloxy-4-pentanolactones in excellent yields and 6-camphorsulfonyloxy-5-hexanolactone in middle yield were prepared. The camphorsulfonylactonization has some advantages, such as, mild reaction conditions, simple procedure, and good yields. Furthermore, the scope of hypervalent iodine reagents in organic synthesis could be extended.

**Scheme 2**

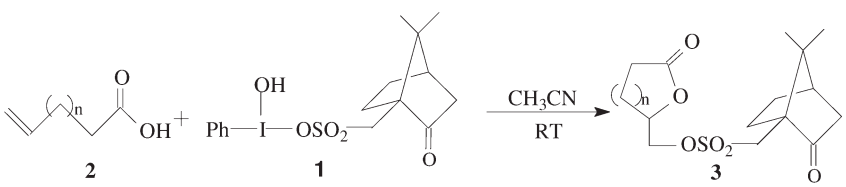


**Table 1**

The result of the camphorsulfonylactonization of alkenoic acids.

| Entry | Alkenoic acids (2) | Camphorsulfonyloxylactones (3)[a] | Time (h) | Yield (%)[b] |
|---|---|---|---|---|
| 1 | $CH_2=CH(CH_2)_2CO_2H$ **2a** |  **3a** | 0.5 | 98 |
| 2 |  **2b** |  **3b** | 0.5 | 95 |
| 3 |  **2c** |  **3c** | 0.5 | 93 |
| 4 |  **2d** |  **3d** | 1.0 | 95 |
| 5 | $CH_2=CH(CH_2)_3CO_2H$ **2e** |  **3e** | 2.5 | 63 |

## EXPERIMENTAL

**General procedure for the iodination of terminal alkynes.** To $CH_3CN$ or $CH_2Cl_2$ (2 mL), alkenoic acid **2** (0.3 mmol), [hydroxyl (((+)-10-camphorsulfonyl)oxy)iodo]benzene **1** (0.3 mmol) were added. The mixture was stirred at room temperature for 0.5–24 h (shown in Table 1) and then separated on a silica gel plate using (3:1, hexane–ethyl acetate) as eluant to give camphorsulfonyloxylacton **3** in good to excellent yields.

**3a**: Oil. $^1$H-NMR (500 MHz, $CDCl_3$): 4.82–4.79 (m, 1H), 4.51 (ddd, $J$ = 22.0, 11.5, 3.0 Hz, 1H), 4.37 (ddd, $J$ = 21.5, 11.0, 4.5 Hz, 1H), 3.62 (dd, $J$ = 15.5, 6.0 Hz, 1H), 3.08 (dd, $J$ = 15.0, 4.0 Hz, 1H), 2.69–2.52 (m, 2H), 2.43–2.37 (m, 3H), 2.20–2.02 (m, 3H), 1.97 (d, $J$ = 17.5 Hz, 1H), 1.75–1.65 (m, 1H), 1.51–1.45 (m, 1H), 1.10 (s, 3H), 0.88 (s, 3H). $^{13}$C-NMR (125 MHz, $CDCl_3$): 214.2, 176.1, 76.7 (d, $J$ = 7.5 Hz), 70.1, 69.9, 57.8 (d, $J$ = 2.5 Hz), 48.1, 47.2, 42.6 (d, $J$ = 2.5 Hz), 42.4 (d, $J$ = 1.3 Hz), 27.9, 26.8, 24.8 (d, $J$ = 7.5 Hz), 23.3 (d, $J$ = 8.8 Hz), 19.5 (t, $J$ = 2.5 Hz). ## INTRODUCTION

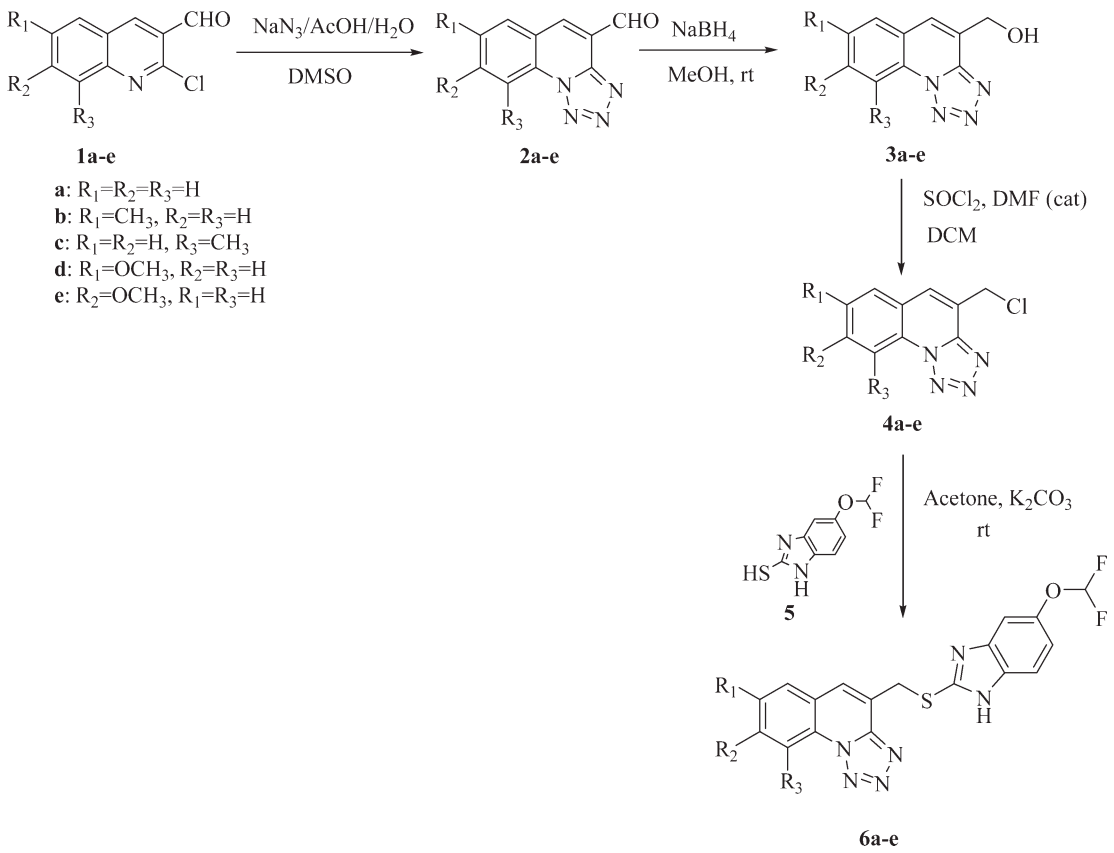
Quinoline ring systems represent a major class of heterocycles in which benzene ring is fused with pyridine ring. The derivatives of quinoline exhibit diverse biological and physiological activities such as antimalarial [1a], anti-inflammatory [1b], antitumor [1c], DNA binding capacity [1d], and antibacterial properties [1e]. Recently, quinoline has been employed in the study of bio-organic and bio-organometallic processes [1f]. The quinoline skeleton is often used as a key intermediate for the design of many pharmacologically important synthetic compounds [2].

The tetrazole group has considered analogous to carboxylic group [3] as a pharmacophore. Several substituted tetrazoles show pronounced activities such as antifertility [4a], CNS depressant [4b], antimicrobial [4c], anti-inflammatory [4d], and antiaids [4e]. The most prominent pharmaceutical application of tetrazoles is as angiotensin II receptor antagonists for the treatment of high-blood pressure [5]. The fusion of quinoline to the tetrazole ring is known to increase the biological activity [6]. In particular, tetrazolo[1,5-a]quinoline-4-carbaldehyde serves as a key synthetic intermediate for the synthesis of novel medicinally valuable compounds [7].

Benzimidazole scaffold has received extensive attention since the fact that it is a component of vitamin $B_{12}$ [8]. The derivatives of benzimidazole are possessed broad spectrum of biological activities including antibacterial, antiviral [9a], antitumor [9b], antimutagens [9c], cardiovascular [9d], anticalmodulin [9e], and many other activities are well documented [10]. In particular, mercapto benzimidazole is used for the synthesis of the most known prazole drugs pantoprazole [11a], omeprazole [11b], rabeprazole [11c], and lansoprazole [11d] which are antiulcerous agents useful in the treatment of stomach and duodenal ulcers. By all means, benzimidazole acts as ''privileged substructure'' for drug design [12]. Among these, pantoprazole is the proton pump inhibitor drug used in gastroesophageal reflux disease and as antihelicobacter agent [13] for the treatment of gastrointestinal disorders. Pyridine and 5-difluoromethoxy-2-mercapto-1*H*-benzimidazole are the two key constituents of this drug.

After the extensive literature search, it was observed that quinoline, tetrazole, 2-mercapto-1*H*-benzimidazole

**Scheme 1**



are the important pharmacophore, but till date enough efforts have not been made to combine these three moieties as a single molecular scaffold. So, our object was to synthesize and biological screening of a series of new compounds incorporating these moieties.

## RESULTS AND DISCUSSION

In continuation of our work [14] herein, we report a simple method for the synthesis of novel 4-((5-(difluoromethoxy)-1*H*-benzo[d]imidazol-2-ylthio)methyl)tetrazolo [1,5-a]quinolines in excellent yields (Scheme 1).

The derivatives of tetrazolo[1,5-a]quinoline-4-carbaldehyde **2a–e** were prepared from substituted 2-chloroquinoline-3-carbaldehyde **1a–e** on treatment with sodium azide in the presence of acetic acid. The reactions were carried out using DMSO as a solvent at 40°C. The products formed in 81–85% yields (Table 1, entries 1–5).

The synthesized tetrazolo[1,5-a]quinoline-4-carbaldehydes **2a–e** on reduction with sodium borohydride at room temperature stirring in methanol formed the derivatives of (tetrazolo[1,5-a]quinolin-4-yl)methanol **3a–e** in excellent 94–97% yields within only 10 min (Table 1, entries 6–10).

These (tetrazolo[1,5-a]quinolin-4-yl)methanol **3a–e** derivatives when reacted with thionyl chloride in the presence of catalytic amount of DMF formed substituted 4-(chloromethyl)tetrazolo[1,5-a]quinolines **4a–e**. The reactions were carried out in DCM at reflux temperature to give the products in excellent yields (97–98%) (Table 1, entries 11–15).

The reaction of 4-(chloromethyl)tetrazolo[1,5-a]quinoline **4a–e** with 5-(difluoromethoxy)-1*H*-benzo[d]imidazole-2-thiol **5** afforded the titled compounds 4-((5-(difluoromethoxy)-1*H*-benzo[d]imidazol-2-ylthio)methyl) tetrazolo[1,5-a]quinolines **6a–e**. The mixture was stirred at room temperature in acetone. The progress of the reaction was monitored by thin layer chromatography (8:2—hexane: ethyl acetate solvent system). The reaction proceeded smoothly under basic condition ($K_2CO_3$ was used as a base), and completed in 1 h to afford the corresponding titled compounds in very high yields (93–98%) (Table 1, entries 16–20). The chemical structures of all the new compounds were confirmed by IR, $^1$H NMR, $^{13}$C NMR, mass spectroscopic data, and elemental analysis.

The titled compounds (**6a–e**) were screened for antibacterial activities against Gram positive *Bacillus subtilis*, *Staphylococcus aureus*, and Gram negative *Escherichia coli*, *Salmonella aboney* bacteria. The compounds

tested are compared against the standard (Streptomycin) by measuring the diameter of zone of inhibition. Almost all the compounds tested exhibited moderate activity against Gram positive bacteria and a few compounds were found to be active against Gram negative bacteria used in this study (Table 2).

## EXPERIMENTAL

All the melting points were determined in open capillaries in a paraffin bath and are uncorrected. $^1$H NMR spectra were recorded on Mercury Plus Varian in DMSO-$d_6$ at 400 MHz and Bruker DRX-300 in $CDCl_3$ at 300 MHz using TMS as an internal standard. IR spectra were recorded on a Perkin-Elmer FTIR model as KBr discs. $^{13}$C NMR spectrum was recorded on Bruker DRX-300 at 75 MHz using TMS as an internal standard. Mass spectra were recorded on Micromass Quattro II using Electrospray Ionization technique. The elemental analysis was carried out on Flash EA 1112, 50/60 Hz, 1400 VA CHN analyzer. The progress of the reactions was monitored by TLC.

**General procedure.** ***Tetrazolo[1,5-a]quinoline-4-carbaldehydes (2a–e).*** A mixture of 2-chloroquinoline-3-carbaldehyde (10 mmol), sodium azide (1.0 g) in water (5 mL), acetic acid (2 mL), and dimethyl sulphoxide (100 mL) was stirred at 40°C for 3 h. The reaction mixture was allowed to remain at room temperature overnight. A white crystalline solid formed was filtered off, washed with water, dried, and recrystallized from acetone.

***(Tetrazolo[1,5-a]quinolin-4-yl)methanol (3a–e).*** To the stirred solution of tetrazolo[1,5-a]quinoline-4-carbaldehydes (10 mmol) in 15 mL methanol was slowly added sodium borohydride (0.25 g) at room temperature. The progress of reaction was monitored on TLC (8:2—petroleum ether:ethyl acetate). After the completion of the reaction (10 min), the reaction mixture was concentrated under reduced pressure to obtain residue. To this residue, ice cold water was added and the solid obtained was filtered off to get product **3**. ES-MS: m/z 201 (m + 1).

***4-(Chloromethyl)tetrazolo[1,5-a]quinolines (4a–e).*** To the stirred solution of (tetrazolo[1,5-a]quinolin-4-yl)methanol (10 mmol) in DCM (10 mL) was added dropwise a solution of $SOCl_2$ (2 mL) in 5 mL DCM. After the complete addition, four to five drops of DMF was added to this mixture and stirred it for 1 h at reflux temperature. The reaction progress was monitored by the TLC (9:1—petroleum ether:ethyl acetate), after complete conversion, distilled out the solvent in a rota-evaporator under reduced pressure to get the product.

***4-((5-(Difluoromethoxy)-1H-benzo[d]imidazol-2-ylthio)methyl) tetrazolo[1,5-a]quinolines (6a–e).*** To the stirred solution of 5-(difluoromethoxy)-1*H*-benzo[d]imidazole-2-thiol **5** (10 mmol) in 20 mL of acetone was added $K_2CO_3$ (15 mmol) stirred the contents for 10 min. To this solution, 4-(chloromethyl)tetrazolo[1,5-a]quinoline (10 mmol) was added and continued the stirring for 50 min at room temperature. The reaction progress was monitored by the TLC (8:2—petroleum ether:ethyl acetate), after complete conversion, the solvent was removed in a rota-evaporator under reduced pressure. The obtained product was purified by silica gel (60–120 mesh) column chromatographic technique using petroleum ether:ethyl acetate (8:2) as an eluent.

**Antibacterial activity.** All the compounds (**6a–e**) were screened for antibacterial activities against Gram positive *Bacillus subtilis*, *Staphylococcus aureus* (ATCC 6538), and Gram negative *Escherichia coli* (ATCC 8739), *Salmonella aboney* (NCTC 6017) bacteria using Streptomycin (Strept.) as a standard. Petri dishes and necessary glassware were sterilized in hot air oven (190°C, 45 min). The nutrient agar and saline (0.82% NaCl) were sterilized in autoclave (121°C, 15 psi, 20 min). Inoculum was prepared in sterile saline (0.82% NaCl) and the optical density of all pathogens was adjusted to 0.10 at 625 nm on a Chemito Spectrascan UV 2600 Spectrophotometer that is equivalent to 0.5McFarland Standards [15]. The nutrient

agar plates were prepared by the pour plate method. The activity of the compounds was tested by disc diffusion method (paper disc method). All the bacterial cells were cultured in nutrient agar plates and the compounds to be tested were dissolved in *N,N*-dimethylformamide and were soaked on paper disc. The discs were placed into the plates and incubated at 37°C for 24 h. The diameter (mm) of the zone of inhibition around each disc was measured and results were recorded (Table 2).

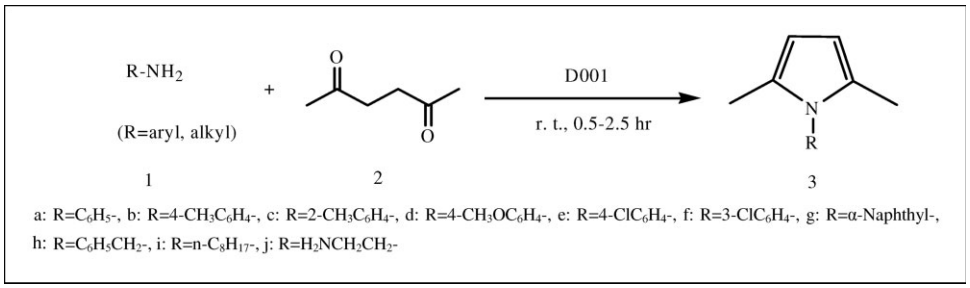
Published online 23 February 2010 in Wiley InterScience (www.interscience.wiley.com).



A simple and effective Paal-Knorr condensation of 2, 5-hexanedione with most amines has been carried out at room temperature under solvent-free condition. The pyrroles were obtained in high yields and in short reaction times.

*J. Heterocyclic Chem.*, **47**, 446 (2010).

## INTRODUCTION

Pyrroles and their derivatives are very important heterocyclic compounds. They constitute the core unit of many natural products and serve as building blocks for porphyrin synthesis [1–3]. A few substituted pyrroles have been shown to possess extensively pharmacological activities and various interesting biological activities including anticancer, antimycobacterial, and antiviral properties [4–6].

The Paal-Knorr reaction is an important method for the synthesis of substituted pyrroles. Recently, clay-catalyzed [7,8], iodine [9], aluminum oxide [10], proton acid [11,12], Lewis acid [13,14], ionic liquids [15], microwave-assisted reactions [16,17], and solvent-free reaction [18,19] have been utilized for the preparation of pyrroles under Paal-Knorr condition. However, they are not very satisfactory with regard to reaction conditions, such as the use of the toxic solvent, prolonged reaction time, violence of reaction, difficulty of separation and purification. Therefore, it is necessary to develop a simple, efficient, and more general method for the synthesis of this useful heterocyclic nucleus.

## RESULTS AND DISCUSSION

Herein, we wish to report our study on the synthesis of pyrroles by using heterogeneous catalysts. It has been observed that macroporous strongly acidic styrene resin (D001), which equals to Amberlite 200 (USA) and Lewatit SP-210 (Germany), is an efficient catalyst for construction for substituted pyrroles from amines and 2,5-diketone (Scheme 1). Our initial study was started by reacting aniline with 2,5-diketone under various catalysts. The results are summarized in Table 1.

It was found that pyrrole **3a** products (**3**, Scheme 1) were obtained in low yields by using D152 as catalyst (entries **1**, Table 1). Although reaction yields were very high when the NKC-9 and NR-50 were first performed

**Scheme 1**

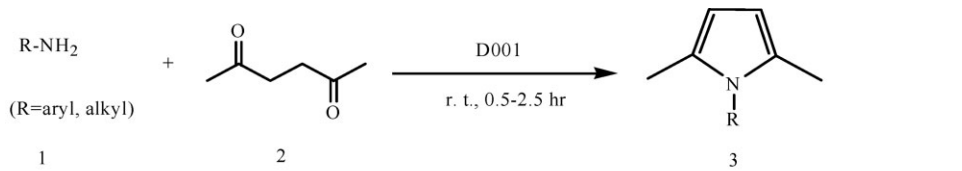


**Table 1**

Effect of various resin catalysts on the Paal-Knorr reaction between aniline (2.4 mmol) with 2,5-diketone (2.0 mmol).

| Entry | Catalyst | Functional group | Resin type | Raw catalyst yield (3a)/%[a,b,c] | Recycling catalyst yield (3a)/% [a,b,c] |
|---|---|---|---|---|---|
| 1 | D152 (0.05g) | —COOH | Acrylic acid | 47 | 31 |
| 2 | D072 (0.05g) | $-SO_3H$ | Styrene | 81 | 76 |
| 3 | NKC-9 (0.05g) | $-SO_3H$ | Styrene | 95 | 83 |
| 4 | NR-50 (0.05g) | $-SO_3H$ | Nafion-vinyl | 91 | 85 |
| 5 | D001 (0.05g) | $-SO_3H$ | Styrene | 90 | 88 |
| 6 | D001 (0.1g) | $-SO_3H$ | Styrene | 93 | 91 |
| 7 | D001 (0.15g) | $-SO_3H$ | Styrene | 91 | 90 |

[a] Products were identified by IR, $^1$H-NMR, $^{13}$C-NMR, and HRMS.
[b] Reaction time was 1.0 h.
[c] The reaction medium is solvent-free.

in this reaction as catalysts, the reaction yields were sharply decreased when recycling these catalysts (entries **3**, **4**, Table 1). Inspiringly, the reaction yield little reduced when recycling D001 as catalyst (entries **5**, **6**, **7**, Table 1). However, increasing amount of catalyst in excess had hardly raised yields of pyrrole **3a** (entries **7**, Table 1). After a comprehensive survey of the reaction conditions, acidic styrene resin (D001) was considered as appropriate catalysis for Paal-Knorr reaction. Subsequently, a variety of amines were examined using this method (Scheme 1). The results are listed in Table 2.

Aniline and its derivatives bearing whether electron withdraw group or electron donating group could implement Paal-Knorr reaction with 2,5-hexanedione in good yields at room temperature (entries **2**, **3**, **4**, **5**, **6**, Table 2). The position of substitution group seldom had effect on reaction yields. However, it was necessary that reaction time was prolonged when *meta*-substituted substrate was used for this reaction (entries **3**, **6**, Table 2). Moreover, naphthylamine and aliphatic amines also could afford the corresponding pyrroles under the same condition smoothly (entries **7**, **8**, **9**, **10**, Table 2). Inspiringly, when ethylene diamine was used in the present reaction, the product **3j** [1, 2-di (2, 5-dimethyl-1-pyrrole)-ethane] was formed with two units of pyrrole ring (entries **10**, Table 2).

## EXPERIMENTAL

IR (Perkin-Elmer, 2000 FTIR), $^1$H-NMR ($CDCl_3$, 500 MHz), $^{13}$C-NMR ($CDCl_3$, 125.7 MHz), and MS-GC (HP5890 (II)/HP 5972, EI) spectra were obtained at the Center of Analytical Configuration of University of Science and Technology of China. Flash chromatographic sheet employed was purchased from Anhui Liangchen Silicon Material Co., and all material from Aldrich and used directly as received.

**General procedure for the synthesis of pyrroles.** To a mixture of an amine (3 mmol) and hexane-2,5-dione (3 mmol) resin (D001, 100 mg) was added. The mixture was stirred at room temperature and the reaction was monitored by TLC. After completion of the reaction, the mixture was extracted with $CH_2Cl_2$, and filtered, the organic phase washed with saturated brine, dried over anhydrous magnesium sulfate, and concentrated

**Table 2**

Resin (D001) catalyzed Paal-Knorr condensation between amines and 2,5-dione.

| Entry | $RNH_2$ | Time (h) | Product[a,b] (Yield)/% | Ref | Entry | $RNH_2$ | Time (h) | Product[a,b] (Yield)/% | Ref |

[a] Products were identified by IR, $^1$H-NMR, $^{13}$C-NMR, and HRMS.
[b] Isolated yields.
[c] Reaction temp was at 60°C.

*in vacuo*. The pure products were obtained by flash chromatography on silica gel eluting with petroleum ether/EtOAc (1:4, *V*:*V*), and identified by IR, $^{1}$H-, $^{13}$C-NMR, and HRMS.

***1-Octyl-2,5-dimethylpyrrole (3i).*** IR: 3035.2, 2983.5, 1593.6, 1466.5, 1340.2, 976.3, 810.3 $cm^{-1}$; $^{1}$H-NMR ($CDCl_3$, 300 MHz) δ: 5.76 (s, 2H, 2×*CH*), 3.73 (t, $J$ = 7.8, 2H, $CH_2N$), 2.19 (s, 6H, 2×$CH_3$), 1.68–1.74 (m, 2H, $CH_2$), 1.33–1.45 (m, 12H, 6×$CH_2$), 0.97 (t, $J$ = 7.6, 3H, $CH_3$); $^{13}$C-NMR ($CDCl_3$, 75 MHz) δ: 12.71, 14.21, 24.62, 30.50, 31.10, 31.59, 32.30, 35.73, 47.82, 107.66, 129.84; HRMS: calcd for $C_{14}H_{27}N$: 209.3707, found: 209.3695.

In conclusion, it was very appropriate that macroporous strongly acidic styrol resin (D001) was employed as catalyst for the Paal-Knorr reaction. Various amines underwent the earlier reaction with 2,5-hexanedione to produce different substituted pyrroles in high yields. The majority of reactions were carried out at room temperature and a shorter period of time (0.5–2.5 h). The reaction conditions are very mild, and no solvent was used to carry out the reaction.

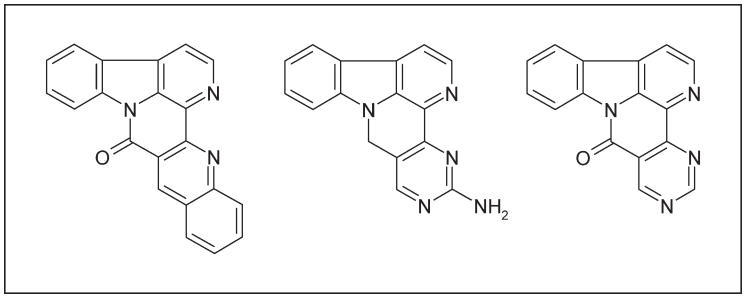
Published online 23 February 2010 in Wiley InterScience (www.interscience.wiley.com).



Starting from 5,6-dihydrocanthin-4-one, new penta- and hexacyclic ring systems (1,7b,14-triazadibenzo[e,k]acephenanthrylenes, 1,7b,10,12-tetraazabenzo[e]acephenanthrylenes) were built up using ring annelation reactions. The new compounds represent hybrids between the canthinones and several bioactive aromatic alkaloids

*J. Heterocyclic Chem.,* **47**, 449 (2010).

## INTRODUCTION

Polycyclic aromatic compounds, especially alkaloids from terrestric and marine sources [1], have been shown to exhibit significant biological activities. Some prominent examples are the marine pyridoacridone type alkaloids [2], e.g., the cytotoxic metabolites ascididemine (**1a**) [3] and 2-bromoleptoclinidinone (**1b**) [4] from tunicates, the antifungal alkaloid sampangine (**2**) [5] from Annonaceae, the cytotoxic alkaloid camptothecin (**3**) [6], and the antileishmanial β-carboline annomontine (**4**) [7] (Scheme 1).

Very recently, we reported on the first efficient entry to the canthin-4-one ring system starting from 1-acyl-β-carbolines, including total syntheses of the alkaloids tuboflavine and norisotuboflavine [8]. In continuation of our concept on the synthesis of hybrids between biologically active natural products and established drugs [9], we intended to attach additional heterocyclic rings to the canthin-4-one ring system, to combine the said tetracyclic ring system with structural elements of the alkaloids **1**–**4**. Of special interest were polycyclic aromatic compounds containing quinoneimine partial structures, as can be found in the alkaloids **1a/b** and **2**. This structural element seems to be of importance for the biological activities of the alkaloids, even though hetero analogues missing the carbonyl group have been described to exhibit significant antimicrobial activities as well [10]. The new polycyclic compounds might act as DNA intercalators in cancer and microbial cells.

The target compounds were envisaged to contain either an anellated quinoline ring, to gain similarity to ascididemine (**1a**), related pyridoacridones, and camptothecin (**3**), or a pyrimidine ring, to obtain rigid analogues of the aminopyrimidyl-β-carboline alkaloid annomontine (**4**).

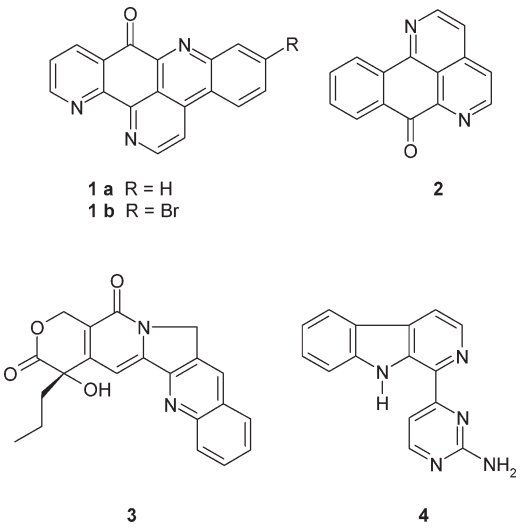
We intended to prepare the target compounds starting from 5,6-dihydrocanthin-4-one (**7**) [11] using established methods for the synthesis of fused heterocyclic ring systems.

## RESULTS AND DISCUSSION

So the first objective of this project was to work out an efficient synthesis of the central building block **7**. For this purpose different strategies were tackled.

In the first approach, canthin-4-one (**5**), which is conveniently accessible from 1-acetyl-β-carboline and Bredereck's reagent (*tert*-butoxy-bis(dimethylamino)-methane) [8] in a 1-pot reaction, was submitted to catalytic hydrogenation. Using Pd on charcoal as catalyst we observed only very poor (<5%) conversion, with the secondary alcohol **6** being produced in traces, accompanied by products of over-reduction. Hydrogenation with $PtO_2$ (Adams catalyst), however gave the alcohol **6** in 70% yield. Subsequent oxidation with manganese dioxide gave the desired 5,6-dihydrocanthin-4-one (**7**) in good yield (71%) (Scheme 2).

**Scheme 1**



We investigated an alternative approach to the ketone **7** via a Parham cyclization [12]. This reaction represents a convenient, but poorly applied method for the preparation of cyclic aryl ketones starting from an aryl bromide containing a neighboring alkoxycarbonylalkyl chain *via* intermediate bromo-lithium exchange, followed by intramolecular nucleophilic attack of the organolithium species at the ester group. A suitable precursor **9** for our purpose was obtained by Michael-type nucleophilic addition of 1-bromo-β-carboline (**8**) [13] to methyl acrylate. Bromo-lithium exchange of **9** was performed with *n*-butyllithium in THF at –100°C; upon warming to room temperature cyclization took place to give 5,6-dihydrocanthin-4-one (**7**) in 29% yield.

In conclusion, the first approach starting from canthin-4-one (**5**) remains the more effective one for the preparation of ketone **7**.

Friedländer-type condensation [14] of the ketone **7** with 2-aminobenzaldehyde, freshly prepared from 2-nitrobenzaldehyde [15], and ethanolic KOH gave the quinoline derivative **10** in 87% yield. This hexacyclic 1,7b,14-triazadibenzo[e,k]acephenanthrylene ring system has not yet been described in literature. To achieve a quinoneimine-like partial structure (compare the alkaloids **1a/b**, **2**) the methylene group in **10** had to be oxidized. This reaction proceeded with ease using manganese dioxide in chloroform [16], and the carbonyl compound **11** was obtained in 54% yield (Scheme 3).

The anellation of an aminopyrimidine ring to give a rigid analogue of annomontine (**4**) was performed in close analogy to our total synthesis of annomontine [14b]. Thus, 5,6-dihydrocanthin-4-one (**7**) was heated with Bredereck's reagent in DMF to give the enaminoketone **12**, which was further heated with guanidinium carbonate to give the aminopyrimidine **13** in 78% overall yield. Again, the resulting 1,7b,10,12-tetraazabenzo[e]acephenanthrylene ring system has not been described in literature before.

By treating the intermediate enaminoketone **12** with ammonium formate and formamide in formic acid [17] the pyrimidine **14** was obtained in 40% yield. Once again oxidation with manganese dioxide gave the corresponding carbonyl compound **15** containing a quinoneimine partial structure in high yield.

In conclusion, an effective approach towards 5,6-dihydrocanthin-4-one (**7**) has been developed. This ketone served as a versatile building block for the synthesis of hitherto unknown penta- and hexacyclic ring systems.

Presently, the new compounds undergo screenings for cytotoxic and antimicrobial activities, the results will be presented elsewhere in due time.

## EXPERIMENTAL

**General.** Elementar analysis: Heraeus CHN Rapid; MS: Hewlett Packard MS-Engine, electron ionization (EI) 70 eV, chemical ionization (CI) with $CH_4$ (300 eV); NMR: Jeol GSX 400 ($^1$H: 400 MHz, $^{13}$C: 100 MHz); Melting points were determined on a Büchi Melting Point B-540 apparatus and are uncorrected, flash column chromatography (FCC): silica gel 60 (230–400 mesh, E. Merck, Darmstadt).

**(±)-5,6-Dihydro-4*H*-indolo[3,2,1-de][1,5]naphthyridin-4-ol (6).** A suspension of canthin-4-one (**5**) [8] (100 mg, 0.454 mmol) and $PtO_2$ (25 mg) in 35 mL ethanol was stirred under a hydrogen atmosphere at atmospheric pressure for 30 min. After filtration and evaporating the solvent, the residual solid was purified by FCC (dichloromethane:ethanol, 14:1, v/v) to give 71 mg (70%) **6** as a light yellow solid. mp 171°C; $^1$H nmr (deuterochloroform): δ 8.26 (d, $J$ = 5.5 Hz, 1H, 2-H), 8.12 (ddd, $J$ = 8.0 Hz, $J$ = 1.7 Hz, $J$ = 0.7 Hz, 1H, 11-H), 7.82 (d, $J$ = 5.5 Hz, 1H, 1-H), 7.61 (ddd, $J$ = 8.3 Hz, $J$ = 7.2 Hz, $J$ = 1.2 Hz, 1H, 9-H), 7.48 (d, $J$ = 8.3 Hz, 1H, 8-H), 7.29 (ddd, $J$ = 8.0 Hz, $J$ = 7.2 Hz, $J$ = 1.0 Hz, 1H, 10-H), 5.35 (m, 1H, 4-H), 4.38 (m, 3H, 6-H, OH), 2.57 (m, 2H, 5-H); $^{13}$C nmr (deuterochloroform): 143.6 (C-3a), 141.0 (C-7a), 137.5 (C-2), 132.9 (C-11c), 128.5 (C-9), 126.8 (C-11b), 122.7 (C-11), 121.4

The long-lasting problematic low yield in the D-ring cyclization of ellipticine (**1a**) was dramatically improved through *N*-(1,4-dimethylcarbazol-3-ylmethyl)-*N*-tosylaminoacetaldehyde diethyl acetal with microwave irradiation. The overall yield of **1a** starting from indole was significantly increased by 25-fold. This new approach is superior to reported methods in yields and, reaction time, and it provides efficient access to a broad spectrum of ellipticine derivatives.

*J. Heterocyclic Chem.*, **47**, 454 (2010).

## INTRODUCTION

Ellipticine (5,11-dimethyl-6*H*-pyrido[4,3-*b*]carbazole, **1a**), a tetracyclic natural alkaloid, was isolated from *Ochrosia elliptica* Labill. in 1959 [1] and found to be a potent anticancer agent [2]. Analogs bearing substituents on N-1 and C-9 of ellipticine such as 9-hydroxyellipticine (**2**) [3] and 9-hydroxy-2-methylellipticium (**3**) [4] possess potent antitumor activities as well. The structures of ellipticine and its analogs are shown in Figure 1.

In view of the interesting biological activity, it has attracted great attention to functionalize ellipticine. As shown in Scheme 1, a five-step synthetic pathway of ellipticine was first reported by Cranwell and Saxton [5]: starting from indole (**6a**) to give 1,4-dimethylcarbazole (C-ring formation), then through Vilsmeier-Haack formylation and Schiff base formation followed by reduction and isoquinoline cyclization (D-ring formation) to afford ellipticine. However, the final step of isoquinoline cyclization suffered a 9% low yield, and the total yield of **1a** starting from indole was as low as 0.8%.

The low yield of the D-ring closure leading to ellipticine has been improved to 30% *via* treating azomethine with orthophosphoric acid by Dalton et al. [6]. A perusal of literature revealed the general synthetic strategy to build up the tatracycline skeleton involving a connection of substituted indoles and various pyridines through Diels-Alder annulation, Friedel-Crafts acylation, and radical reactions. These methods could be simplified as [2 + 1] concept. For examples, Diels-Alder annulation from 1,3-dimethyl-4-(phenylsulfonyl)-4*H*-furo[3,4-*b*] indole and 3,4-pyridyne gave a mixture of **1a** and isoellipticine (**4**) in Gribble's investigation [7]. In addition, synthesis of ellipticine quinone (**5**), which could be converted into ellipticine [8], demonstrated an alternative pathway of [2 + 1] annulation. Intramolecular reaction between 2-indolylacyl radicals derived from phenyl selenoester with pyridines [9] furnished polycyclic indolylpyridyl ketones including ellipticine quinone.

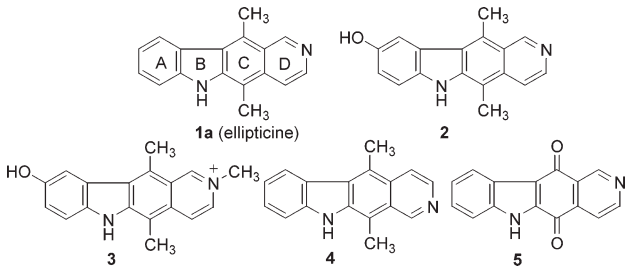

**Figure 1.** Ellipticine and its derivatives.

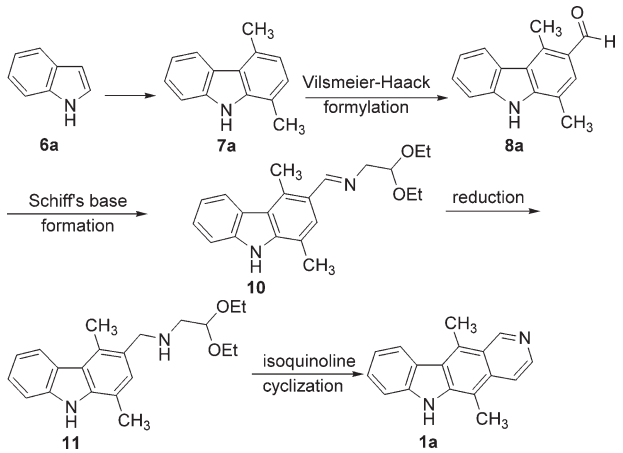
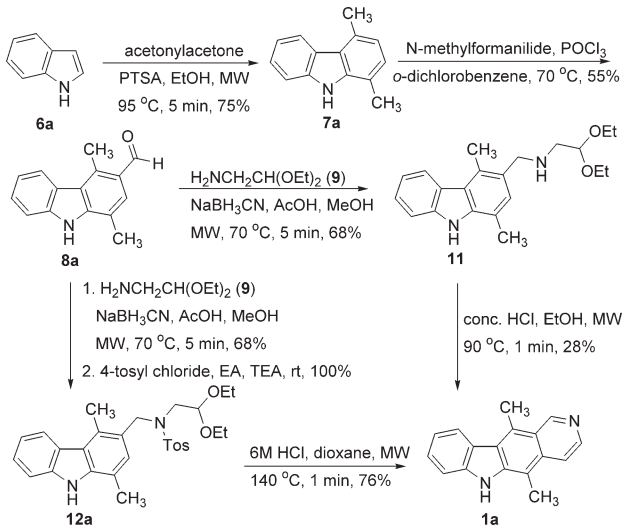
Friedel-Crafts acylation of *N*-protected indole with 3-chlorocarbonylisonicotinic acid methyl ester [8a] was followed by regioselective C-2 lithiation to yield ellipticine quinine (**5**). Recently, a radical cascade protocol has been used for the synthesis of ellipticine in higher yield [10]. Although these approaches provided better reaction yields and could be comprehensively applied in the development of ellipticine analogs, it underwent an intensively synthetic works to prepare intermediates for the last annulation steps in comparison to the Saxton's approach. Nevertheless, the reported methods were still unsatisfactory in preparing a number of derivatives for the development of ellipticine derivatives as potential anticancer drugs. Microwave (MW) irradiation has been illustrated to give superior results and to shorten reaction times in various aspects [11]. Further, MW irradiation has been widely applied to the organic synthesis including the total synthesis of natural products such as quinazolinobenzodiazepine alkaloids by a one-pot reaction [12] and biphenomycin B by the intramolecular Suzuki-Miyaura reaction [13] Herein, we report an efficient approach for the preparation of ellipticine by a modified Saxton's method with the assistance of MW irradiation.

A treatment of indole (**6a**) with acetonylacetone in the presence of *p*-toluenesulfonic acid (PTSA) in ethanol

**Scheme 1.** Saxton approach for the synthesis of ellipticine (**1a**).



**Scheme 2.** Synthesis of ellipticine (**1a**).



at 100°C for 5 min under MW irradiation afforded 1,4-dimethylcarbazole (**7a**) in 75% yield (Scheme 2). MW irradiation shortened the reaction time and improved the yield as compared with those in the conventional heating method (45 min, 36%) [5]. Subsequently, Vilsmeier-Haack formylation of **7a** by *N*-methylformanilide and $POCl_3$ in *o*-dichlorobenzene afforded aldehyde **8a** in 55% yield. The reaction was proceeded by Bobbitt-modified Pomeranz-Fritsch reaction [14] in which a Schiff base would be reduced to an amino-acetal and followed by a cyclization to isoquinoline. First, a one-pot reaction of **8a**, aminoacetaldehyde diethyl acetal (**9**), and $NaBH_3CN$ in the presence of catalytic amount of acetic acid at 70°C for 3 h furnished the desired hydrogenated *N*-(1,4-dimethylcarbazol-3-ylmethyl)-aminoacetaldehyde diethyl acetal (**11**) in 31% yield. Then, the use of MW irradiation in this one-pot reaction resulted in a twofold increase in the yield (68%). This modified MW-assisted one-pot reaction dramatically shortened the reaction time and increased the yield for the synthesis of secondary amine **11** in comparison to the Saxtons's method (2 h, 61%) [5]. Accordingly, **11** was subjected to cyclization reaction with concentrated HCl in ethanol at reflux by conventional heating. Unsurprisingly, ellipticine (**1a**) was obtained in a low yield of 9.0% as reported [5]. Then again, MW irradiation was used for the cyclization under the same condition to furnish **1a** in 28% yield. MW irradiation improved the long-lasting problematic low yield in the D-ring cyclization.

Nevertheless, a yield of 28% for the D-ring cyclization is still unsatisfactory in preparing a number of ellipticine derivatives. Birch et al. [15] illustrated that *N*-tosylated *N*-benzylaminoacetaldehyde dimethyl acetals were cyclized under mild acidic conditions and in good

**Table 1**

Comparison of reaction time and yields by microwave irradiation and conventional heating.

| | MW irradiation | | Heating[a] | |
|---|---|---|---|---|
| Reaction | Time (min) | Yield (%) | Time (min) | Yield (%) |
| **6a** → **7a** | 5 | 75 | 45 | 36 |
| **8a** → **11** | 5 | 68 | 120[b] | 61[b] |
| **8a** → **12a** | 5 | 68 | | |
| **11** → **1a** | 1 | 28 | 60 | 9 |
| **12a** → **1a** | 1 | 76 | | |

Overall yield from **6a** to **1a**

| Path | Method | Yield (%)[a] |
|---|---|---|
| **6a** → **7a** → **8a** → **10** → **11** → **1a** | Heating | 0.8 |
| **6a** → **7a** → **8a** → **11** → **1a** | MW | 7.8 |
| **6a** → **7a** → **8a** → **12a** → **1a** | MW | 21.3 |

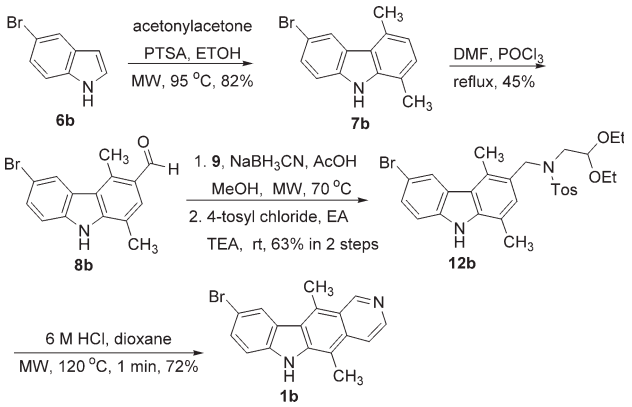
[b] Total yield in 2 steps of **8a** → **10** → **11**.

yields to isoquinolines in a one-pot reaction when the benzyl groups were substituted with sufficiently activating groups. The carbazole moiety is a well known strong electron donor [16]. We expected that the 1,4-dimethylcarbazol-3-ylmethyl group could act as an activated group, and an *N*-tosylated derivative of **11** might lead to ellipticine in an improved yield. Thus, *N*-(1,4-dimethylcarbazol-3-ylmethyl)-*N*-tosylaminoacetaldehyde diethyl acetal (**12a**) was obtained by a treatment of **11** with tosyl chloride in quantitative yield. Subsequently, *N*-tosylated diethyl acetal **12a** was subjected to cyclization to afford **1a** in 76% yield in a reaction time of 1 min under the same condition as for the cyclization of **11** to **1a**. As a result, a 51% yield of ellipticine from aldehyde **8a** was obtained through an *N*-tosylated acetal **12a** together with the assistance of MW irradiation. This approach improves the yield by nine folds in comparison to the Saxton's method (5.5%). Importantly, the overall yield of ellipticine starting from indole (**6a**) was significantly increased by 25-fold (21%) as compared to that (0.8%) reported by Saxton (Table 1).

To explore the general application of this approach, condensation of 5-bromoindole (**6b**) with acetonylacetone was proceeded, and the resulting carbazole **7b** was formylated to the aldehyde **8b** by *N*,*N*-dimethylformamide (DMF) and $POCl_3$ (Scheme 3). Compound **8b** then reacted with aminoacetaldehyde diethyl acetal (**9**) under MW irradiation, and the resulting Schiff base was reduced *in situ*. Removal of solvent followed by tosylation afforded *N*-tosylated derivative **12b**, which was cyclized under acidic condition with MW irradiation to 9-bromoellipticine (**1b**) in 72%. As a result, the bromo substituent has little effect to the reactions in this

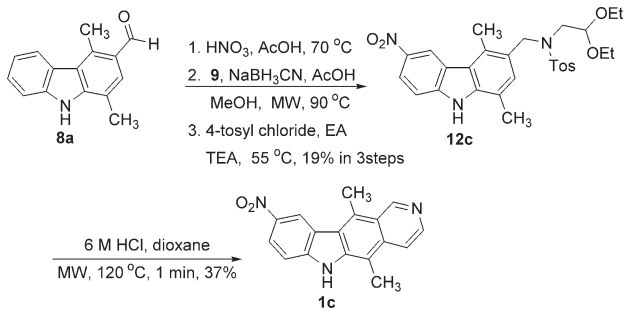
**Scheme 3.** Synthesis of 9-bromoellipticine (**1b**).



approach with MW irradiation. The slightly decrease in overall yield of **1b** with regard to ellipticine (**1a**) was due to the lower yield in the formylation reaction of 6-bromo-1,4-dimethylcarbazole (**7b**).

Birch et al. [15] reported that sufficiently activating substituents on the benzyl group were required for the cyclization of the *N*-benzyl-*N*-tosylaminoacetaldehyde dimethyl acetals to isoquinolines. Otherwise, cyclization failed and the *N*-benzyl-*N*-tosyl acetals would be first hydrolyzed to *N*-benzyl-*N*-tosylaminoacetaldehyde and then *N*-tosylbenzylamine. To investigate this substituent effect in the synthesis of ellipticine derivatives, a direct nitration of **8a** led to 1,4-dimethyl-6-nitrocarbazole-3-carbaldehyde (**8c**) which was condensed with aminoacetaldehyde diethyl acetal (**9**) to the Schiff base and reduced *in situ* under MW irradiation (Scheme 4). Without further isolation and purification, a subsequent treatment with tosyl chloride at 55°C yielded the *N*-tosylated compound **12c** in 19% (three steps). Then, compound **12c** was cyclized to 9-nitroellipticine (**1c**) in 37% yield under the same conditions as described above. The cyclization to isoquinoline was proposed as electrophilic substitution on the benzene ring [15], and lacking of sufficiently activated substituents on the aromatic ring failed in cyclization. Although a lower yield of 37% was obtained, the cyclization to 9-nitroellipticine was

**Scheme 4.** Synthesis of 9-nitroellipticine (**1c**).



still succeeded in this case. Apparently, the 1,4-dimethylcarbazole moiety could serve as an electron-efficient aromatic moiety even with a strong deactivated nitro group substituted at position 6.

In summary, we have developed a fast, efficient, and high-yield approach for the synthesis of ellipticine and its derivatives through *N*-(1,4-dimethylcarbazol-3-ylmethyl)-*N*-tosylaminoacetaldehyde diethyl acetals by the use of MW irradiation. In this modified process, MW irradiation increased the overall yield by 10-fold as compared with the reported yield (0.8%) in considerably shortened reaction time. In an effort to synthesize the derivatives of ellipticine efficiently, the key step of D-ring construction is modified by converting the secondary amine to *N*-tosylated derivative based on Birch's investigation [15]. The long-lasting problematic low yield in the D-ring cyclization was dramatically improved in this study. Even a strong electron-withdrawing substituent on the 1,4-dimethylcarbazole moiety was endured in this method. This new approach is superior to previously reported methods in yields, reaction time, and versatility, and it will allow a broad evaluation of this highly promising class of potential antitumor drugs.

## EXPERIMENTAL

The reactions assisted by microwave were achieved on Biotage Emrys™ Optimizer and Biotage Initiator™. Reaction temperatures were observed using built-in IR-sensor. Melting points were taken on Laboratory Devices, INC. (Box 6402) melting point apparatus and are uncorrected. $^1$H and $^{13}$C nuclear magnetic resonance spectra were obtained on Bruker AMX-400 and DPX-200 spectrometers. Mass spectra were obtained on Finnigan TSQ 7000 mass spectrometer. Elemental analysis for C, H, S, and N was carried out on Heraeus VarioEL III-CHNS apparatus. Thin layer chromatography (TLC) was carried out on precoated plates (silical gel, Kieselgel 60$F_{254}$, Merck). Column chromatography was performed with Kieselgel Si 60 (40–63 μm, Merck). All starting materials were obtained from commercial suppliers (Acros, Lancaster and Riedel-de Haën) and used without purification.

**General procedure for the synthesis of *N*-(2,2-Diethoxyethyl)-*N*-(1,4-dimethyl-9*H*-carbazol-3-ylmethyl)-4-methylbenzenesulfonamide (12).** A mixture of 3-formyl-1,4-dimethylcarbazole (8a, 1.0 g, 4.48 mmol), sodium cyanoborohydride (0.35 g, 5.57 mmol), 9 (0.7 mL, 5.25 mmol) and acetic acid (0.1 mL) in methanol (4 mL) was placed in a sealed tube. Reaction was heated by microwave (75 W) at 70°C for 5 min. Methanol was removed *in vacuo*, and then ethyl acetate (EA, 100 mL) was added. The solution was purified through column chromatography to afford viscous residue. To the residue, 4-tolueneulfonyl chloride (0.9 g, 4.72 mmol), triethylamine (0.5 mL, 4.94 mmol), and EA (30 mL) were added and stirred at room temperature for 2 h. The mixture was subsequently purified with column chromatography.

A four fused rings containing heterocyclic compound is formed in the reaction between 2-bromo-*N*-quinoline-8-yl-acetamide, 2-(4-methoxyphenyl)ethylamine, and acetone in the presence of potassium carbonate; the heterocycle undergoes further reaction with perchloric acid to form a perchlorate salt of a quinoxaline derivative.

*J. Heterocyclic Chem.,* **47**, 459 (2010).

## INTRODUCTION

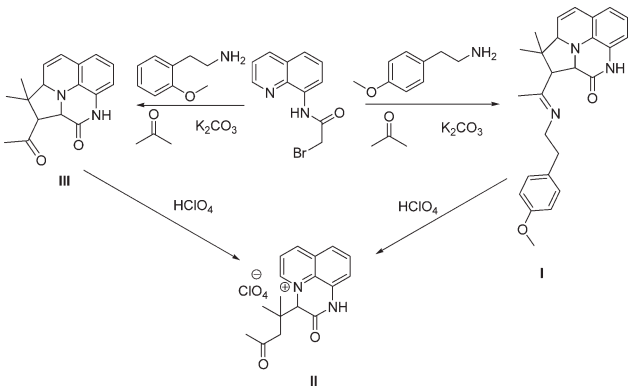
Intramolecular cyclization processes are very useful in heterocycle synthesis [1–6] and they are used for synthesis of variety of natural products and drugs. Among them, *N*-acylinium ion cyclization reactions are very attractive [7–10]. Such intramolecular reactions are carried out under catalytic conditions [11–18]. Several of these reactions require multiple steps [1]. Multicomponent reactions to prepare heterocycles help to reduce the inconvenience caused by the extra work involved in product purification [19–24] in each step and also to reduce the reaction time. We have serendipitously observed formation of a heterocycle from a reaction of 2-bromo-*N*-quinoline-8-yl-acetamide, 2-(4-methoxyphenyl)ethylamine and acetone. The characterization of the fused four-member heterocyle along with its subsequent rearrangement to a quinoxaline derivative is described here. Some quinoxaline derivatives [1] have medicinal value, so new method of synthesis for such compounds are desirable.

## RESULTS AND DISCUSSION

A multicomponent reaction between 2-bromo-*N*-quinoline-8-yl-acetamide, 2-(4-methoxyphenyl)ethylamine, and acetone in the presence of potassium carbonate gives a fused ring heterocyclic compound **I** as illustrated in Scheme 1. However, analogous multicomponent reaction between 2-bromo-*N*-quinoline-8-yl-acetamide, 2-(2-methoxyphenyl)ethylamine, and acetone in the presence of potassium carbonate gives a fused ring heterocyclic carbonyl compound **III**, not the imine that was obtained while 2-(4-methoxyphenyl)ethylamine was used. This compound transforms to perchlorate salt **II** of another heterocycle on reaction with perchloric acid. The compound **III** also undergoes rearrangement reaction with perchloric acid to form perchlorate salt **II**. The use of excess acetone in these reactions serves dual purposes of reactant as well as solvent.

All these compounds were characterized from their spectroscopic properties. The compound **I** has IR absorptions at 1676 $cm^{-1}$ and at 1635 $cm^{-1}$ due to carbonyl and C=N stretching, respectively. The high resolution mass spectrum of the compound shows the mass for the $M^+$ peak at 415.2688, that supports the composition. The $^1H$ NMR and $^{13}C$ NMR of the compounds have the desirable numbers of peaks to support the structure (for assignments of peaks please refer to supporting figures). The compound **I** is further characterized by X-ray crystallography and the structure of the compound is shown in Figure 1(a).

**Scheme 1.** Reaction leading to product **I** and **III**, which react with perchloric acid to form salt **II**.



As mentioned the compound **I** undergoes hydrolysis followed by ring opening reactions to give a quinoxaline derivative in the form of a perchlorate salt **II**. The salt **II** is characterized by conventional spectroscopic techniques as well as by X-ray crystallography [Fig. 1(b)]. The IR spectra of the salt **II** have characteristic sharp perchlorate absorption at 1100 $cm^{-1}$ and its carbonyl absorption appears at 1705 $cm^{-1}$.

Plausible reaction paths (Scheme 2) for the formation of the compound **I** may be through an initial condensation reaction of two molecules of acetone to form aldol type intermediate. The carbonyl group of the aldol gets condensed with 2-(4-methoxyphenyl)ethylamine to form an imine derivative as an intermediate species. This imine containing molecule has a hydroxy group, which is attached to a tertiary carbon and it would like to form C—C bond with the quinoiline ring through elimination of a water molecule. Presumably, this intermediate compound forms a bromide salt through cyclization reaction. The cyclized product thus formed, undergo a hydride shift to form a derivative that is suitable for further nucleophilic attack of an anion generated next to the C=N group. It forms the desired product **I**. Thus, by these reaction steps, two additional rings over the quinoline rings are constructed. The added advantage of this reaction is that it does not stop at the stage of formation of one ring, but continues to form multiple rings; that generally does not happen in intramolecular cyclization reactions [2–6].

The formation of the salt **II** can be explained by a three steps mechanistic path as illustrated in Scheme 2. The first step could be the generation of ketone from a hydrolytic reaction of perchloric acid by the conversion of imine to keto group. The keto group containing compound thus formed gets protonated under acidic condition to form enolised form of a cationic species with perchlorate as a counter anion. This process leads to opening of the five-member ring of the parent compound. The enolic cation thus formed, on aromatization leads to concomitant cleavage of a C—C bond along with the formation of a new C—C bond at a tertiary

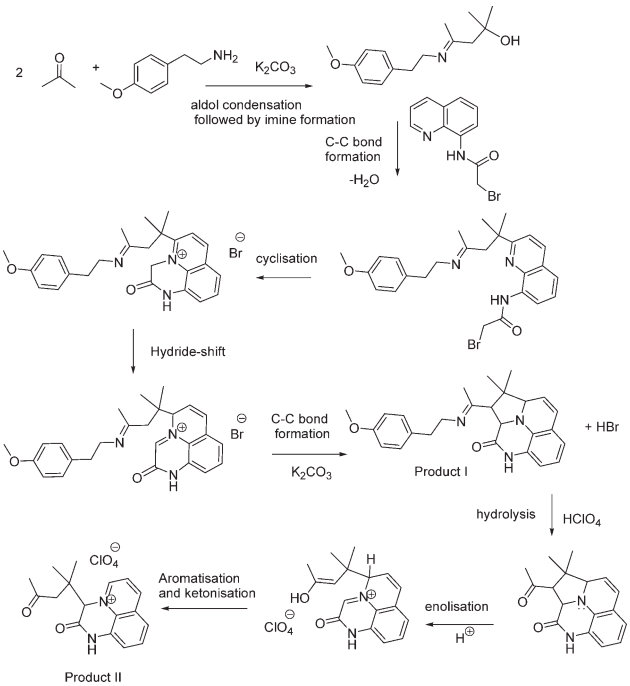
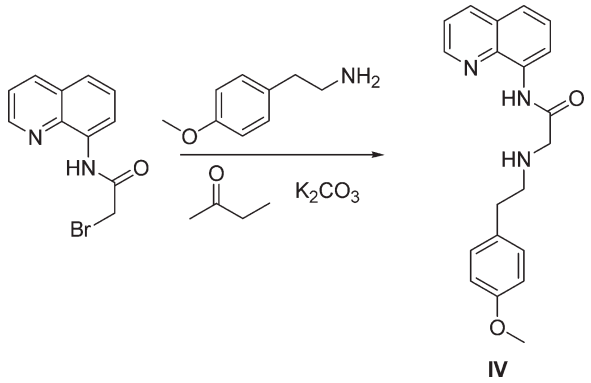


**Scheme 3.** Formation of product **IV** in ethyl methylketone.



**IV**

carbon. This new C—C bond formation along with enol to keto transformation as illustrated in Scheme 2 gives the final product **II**.

Furthermore, we did not observe any aldol condensation and cyclization reactions from the reaction between 2-bromo-*N*-quinoline-8-yl-acetamide and acetone in the presence of potassium carbonate without using an amine. When 2-(4-methoxyphenyl)ethylamine was reacted with acetone in the presence of potassium carbonate, it led to the corresponding imine. However, this imine did not react with 2-bromo-*N*-quinoline-8-yl-acetamide to give product **I**. This suggests that the aldol condensation and the formation of imine took place concomitantly in the presence of 2-bromo-*N*-quinoline-8-yl-acetamide. When the same reaction was carried out with 2-(2-methoxyphenyl)ethylamine, we obtained the product **III**. The formation of product, product **II** on treatment of **III** with perchloric acid, shows that formation of **II** does not depend on the amine used. The formation of a ketone instead of imine as the final product while using 2-(2-methoxyphenyl)ethylamine may be due to the hydrolysis of the corresponding imine. We also carried out similar reactions of 2-bromo-*N*-quinoline-8-yl-acetamide with other amines such as benzylamine, picolylamine, and no reaction was observed under analogous reaction conditions. However, aromatic amines such as 8-aminoquinoline replaced the bromide of 2-bromo-*N*-quinoline-8-yl-acetamide to form C—N bonded derivative. Use of ethylmethyl ketone as solvent did not lead to the aldol condensation reaction; instead, 2-(4-methoxyphynelamino)-*N*-(quinoline-8-yl)acetamide (**IV**) was formed by substitution of bromine by 2-(4-methoxyphenyl)ethylamine (Scheme 3).

In conclusion, these results demonstrate a new reaction leading to a novel heterocylic quinoxaline derivative **II**. The formation of compound **I** in one pot is advantageous, as synthesis of this compound by alternative routes would require multiple steps and less common reagents.

## EXPERIMENTAL

### Synthesis and characterization of compounds

***Compound I.*** 2-Bromo-*N*-quinoline-8-yl-acetamide (1.4 g, 5 mmol), 2-(4-methoxyphenyl)ethylamine (0.735 mL, 5 mmol) and anhydrous potassium carbonate (1.03 g, 7.5 mmol) were added to dry acetone (20 mL), and the reaction mixture was stirred at 70°C for 12 h (progress of the reaction was monitored at regular intervals by using TLC). The reaction mixture was filtered to remove the residue and the solvent was removed under reduced pressure. The product obtained was purified by preparative thin layer chromatography using silica gel with 30% ethylacetate in petroleum ether as eluant. Yield: 41%. IR (KBr, $cm^{-1}$): 3125 (w), 3059 (m), 3008 (m), 2960 (m), 2923 (m), 1676 (s), 1658 (w), 1635 (m), 1613 (m), 1584 (m), 1511 (s), 1482 (s), 1387 (s), 1369 (w), 1270 (m), 1246 (s), 1172 (m), 1028 (m), 798 (m), 724 (m). $^1$H NMR ($CDCl_3$): 8.4 (s, 1H), 7.1(d, $J$ = 8.4 Hz, 2H), 6.8 (d, $J$ = 6.4 Hz, 2H), 6.5 (m, 3H), 6.3 (d, $J$ = 10 Hz, 1H), 5.7 (dd, $J$ = 5.2, 10 Hz, 1H), 4.5 (dd, $J$ = 5.2, 10 Hz, 1H), 3.7 (s, 3H), 3.53 (s,1H), 3.50 (t, $J$ = 7.2 Hz, 2H), 2.8 (t, $J$ = 7.2 Hz, 2H), 2.5 (d, $J$ = 10.4 Hz,1H), 1.7 (s, 3H), 1.1 (s, 3H), 1.0 (s, 3H). $^{13}$C NMR ($CDCl_3$): 20.3, 24.7, 27.1, 36.6, 44.6, 53.2, 55.5, 59.5, 66.4, 71.5, 109.9, 113.9, 114.6, 118.7, 120.3, 121.8, 123.5, 124.8, 125.2, 129.0, 130.0, 132.9, 158.1, 166.5. LC-MS [$M^+$] calcd for $C_{26}H_{29}N_3O_2$, 415.2260; found 415.2688.

***Compound II.*** Compound **I** (0.41 g, 1 mmol) was dissolved in dilute perchloric acid (3*M*) and heated for 10 min. The solution was kept undisturbed, yellow colored crystal of compound **II** appeared after 6 days. Yield: 46%. IR (KBr, $cm^{-1}$): 3258 (m), 3110 (w), 3083 (m), 2962 (m), 1705 (s), 1608 (w), 1587 (m), 1541 (s), 1471 (m), 1427 (s), 1384 (m), 1361(m), 1239 (w), 1177 (m), 1100 (s), 927 (m), 839 (s), 764 (m), 623 (s). $^1$H NMR ($CDCl_3$/DMSO-$d_6$): 12.0 (s,1H), 9.4 (d, $J$ = 6 Hz, 1H), 9.2 (d, $J$ = 8.4 Hz, 1H), 8.2 (m, 1H), 8.0 (d, $J$ = 8.4 Hz, 1H), 7.9 (t, $J$ = 8.0 Hz, 1H), 7.6 (d, $J$ = 7.6 Hz, 1H), 6.0 (s, 1H), 2.9 (d, $J$ = 18.4 Hz, 1H), 2.6 (d, $J$ = 19.2 Hz, 1H), 2.1 (s, 3H), 1.0 (s, 3H), 0.7 (s, 3H). $^{13}$C NMR (DMSO-$d_6$): 24.0, 24.7, 31.5, 51.2, 72.9, 118.9, 122.9, 123.2, 127.3, 129.8, 131.0, 131.5, 148.3, 149.8, 162.1, 206.9. Published online 4 March 2010 in Wiley InterScience (www.interscience.wiley.com).

New 2-aryl-4-chloro-3-hydroxy-1*H*-indole-5,7-dicarbaldehydes were synthesized in three steps from acetophenone derivatives. By oxidation of acetophenones to aryl glyoxals using selenium dioxide and condensation with acetylacetone in the presence of ammonium acetate in water 3-acetyl-5-aryl-4-hydroxy-2-methyl-1*H*-pyrrols were obtained. 2-Aryl-4-chloro-3-hydroxy-1*H*-indole-5,7-dicarbaldehydes were synthesized *via* Vilsmeier-Haack reaction of pyrrole derivatives in moderate yields.

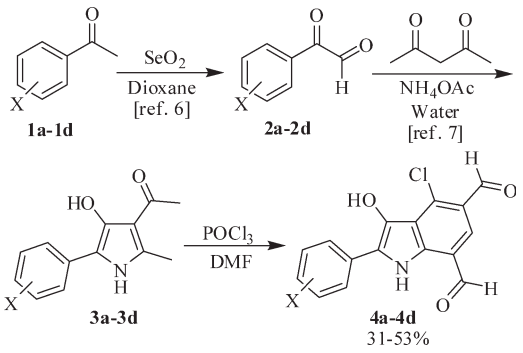
## INTRODUCTION

The synthesis of indoles has occupied organic chemists for well over a century [1]. And the invention of new synthetic routes to substituted indoles continues to command wide interest due to the numerous natural products [2], physiologically active natural products and important pharmaceuticals [3] whose structures incorporate this heterocyclic system. Indole derivatives are used as neuroprotective agents affecting oxidative stress [3f], potent opioid receptor agonists [3g], highly functionalized pharmacophores [3h], potent PPAR-γ binding agents with potential application for the treatment of osteoporosis [3i], drugs for the treatment of peripheral neuropathy and neurodegenerative diseases [3j,k], glucokinase activators [3l,m], the cytotoxic antibiotic CC-1065 and prodrugs [3n], PPAR-delta activators for the treatment of cardiovascular diseases [3o] and dyestuffs [4]. The combination of traditional and modern methods has provided accessibility to a wide variety of structural variations of this important class of heterocycles [3e,5]. A number of useful strategies are now available for the synthesis of indoles substituted on the five-membered ring, the majority of which involve the elaboration of the heterocyclic system from aniline, *o*-halo aniline, or other 2-substituted aniline derivatives. In contrast, few existing methods provide efficient and regiocontrolled access to indoles that are highly substituted on the benzenoid ring. Herein we disclose a method, based on Vilsmeier-Haack reaction of 3-acetyl-4-hydroxy-2-methyl-5-phenyl-1*H*-pyrrols **3**, to provide new highly substituted indoles **4** with substituted on both five-membered and benzenoid ring of indole (Scheme 1).

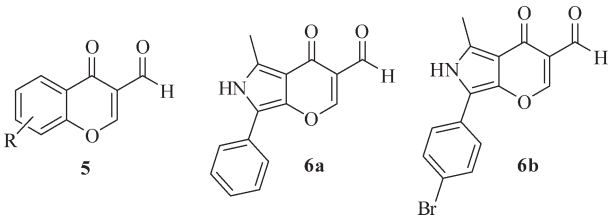
The Vilsmeier–Haack reaction is a widely used method for the formylation of activated aromatic and heteroaromatic compounds [8]. The reactions of aliphatic substrates [9], particularly carbonyl compounds [10] with chloromethylene iminium salts are highly versatile. They lead to multiple iminoalkylations in the presence of excess reagent and the resulting intermediates undergo cyclization to afford aromatic or heterocyclic compounds [11]. Multifunctional intermediates derived from these reactions (*e.g.*, β-chloroenaldehydes) are subsequently exploited for the synthesis of functionalized heterocycles or other valuable target molecules [12].

**Scheme 1.** Three steps synthesis of 2-aryl-4-chloro-3-hydroxy-1*H*-indole-5,7-dicarbaldehydes.



## RESULTS AND DISCUSSION

The reaction of 2-hydroxyacetophenones with Vilsmeier-Haack reagent also involves an iminoalkylation-cyclization sequence, leading to the formation of 3-formyl chromones **5** [13]. Similarly we expected to synthesis the 5-methyl-4-oxo-7-phenyl-4,6-dihydro-pyrano[2,3-c]pyrrole-3-carbaldehyde **6a** from the reaction of 3-acetyl-4-hydroxy-2-methyl-5-phenyl-1*H*-pyrrol **3** with Vilsmeier-Haack reagent, but we did not obtained the expected compound **6a** instead the reaction gave compound **4**. In the case of 4-bromoacetophenone **1c**, not only **4c** was formed but also **6b** was obtained in low yield.



Four examples of the conversion of acetophenones **1a–1d** to various 2-aryl-4-chloro-3-hydroxy-1*H*-indole-5,7-dicarbaldehydes **4a–4d** are listed in Table 1.

As shown in Scheme 2, the proposed mechanism involves the addition of enol **7** to the 2 equiv. chloromethyleneiminium salt **8**, then bis-iminium salt **9** undergoes iminoalkylation to result enamine **10**, that undergo cyclization and elimination of dimethylamine to afford the bis-iminium salt **12** which on hydrolysis leads to the formation of 2-aryl-4-chloro-3-hydroxy-1*H*-indole-5,7-dicarbaldehydes **4** [14].

4-Chloro-2-phenyl-5,7-bis-phenyliminomethyl-1*H*-indol-3-ol **14** and 4-chloro-5,7-bis[(2,4-dinitrophenyl)-hydrazonomethyl]-2-phenyl-1*H*-indol-3-ol **16** were synthesized from the reaction of **4a** with aniline **13** and 2,4-dinitrophenylhydrazine **15** in the presence of catalytic amount of $H_2SO_4$ respectively (Scheme 3).

In conclusion, we have reported the synthesis of new 2-aryl-4-chloro-3-hydroxy-1*H*-indole-5,7-dicarbaldehydes *via* Vilsmeier-Haack reaction starting from acetophenone derivatives.

## EXPERIMENTAL

**General methods.** Chemical shifts of the $^1$H NMR spectra are reported in δ (ppm) from tetramethylsilane with the solvent as the internal standard (deuteriodimethyl sulfoxide, δ = 2.5 ppm), and coupling constants *J* were measured in Hz. Data are reported as follows: chemical shifts, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, dd = doublet of doublets, m = multiplet, br = broad). $^{13}$C NMR spectra were recorded with complete proton decoupling. Chemical shifts are reported in ppm from tetramethylsilane with the solvent as the internal standard (deuteriodimethyl sulfoxide, δ = 39.0 ppm). Elemental analyses were carried out by using a CHN analyzer. IR analyses were performed with an FT-IR spectrophotometer. IR spectra of compounds are expressed by wavenumber ($cm^{-1}$).

***General procedure for synthesis of 2-aryl-4-chloro-3-hydroxy-1H-indole-5,7-dicarbaldehydes 4.*** $POCl_3$ (3 mmol) was added dropwise to dimethylformamide (DMF) (1.5 mL)

with stirring at 30–35°C, after the addition, the mixture was stirred at 50°C for 1 h. Then the solution of 3-acetyl-5-aryl-4-hydroxy-2-methyl-1*H*-pyrrol **3** (0.5 mmol) at least amount of DMF was added dropwise with stirring to the above mixture. After that the mixture was stirred at 45–55°C for 2 h, kept over the night at room temperature and poured over mixture of ice and water (10 g). Product was stirred for 0.5 h, then filtered off and recrystallized from ethanol.

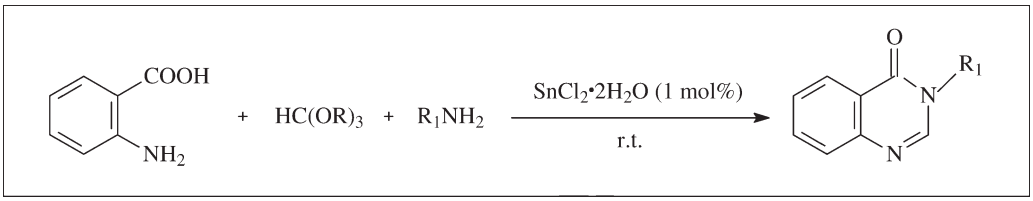
Published online 20 January 2010 in Wiley InterScience (www.interscience.wiley.com).



A simple, efficient, and green procedure for the one-pot synthesis of 4(3*H*)-quinazolinones by three components condensation of anthranilic acid, ortho esters, and amines in the presence of $SnCl_2 \cdot 2H_2O$ has been developed. The reaction occurred within short reaction time at room temperature under solvent-free conditions to afford the title products in excellent yields.

*J. Heterocyclic Chem.,* **47**, 468 (2010).

## INTRODUCTION

It has been more than a century since the initial studies on 4(3*H*)-quinazolinones [1], and they are well-known as important fused heterocycles because of their pharmacological and therapeutic properties such as antimalarial, antitumor, anticonvulsant, antiinflammatory, fungicidal, and antimicrobial activities [2]. Moreover, the 4(3*H*)-quinazolinone moiety is found in several bioactive natural products [3]. Because of the importance of 4(3*H*)-quinazolinones different strategies for their synthesis have been described in the literature: (a) cyclocondensation of anthranilamide with aryl, alkyl, or heteroaryl aldehydes in refluxing ethanol [4]; (b) poly(ethylene glycol) supported by aza-Wittig reaction [5]; (c) intramolecular cyclization of fluorine-containing *S*-ethyl *N*-benzoylisothioureas [6]; (d) cyclocondensation of 2-fluorobenzoyl chlorides with 2-amino-*N*-heterocycles [7]; (e) copper-catalyzed cascade reactions of the substituted 2-halobenzoic acids with amidines [8]; (f) reaction of polymer-bound isothiourea with isatoic anhydride [9]; (g) reaction of anthranilic acids and ammonium or triethylammonium *N*-aryl-dithiocarbamates [10].

Multicomponent reactions (MCRs) are especially attractive synthesis strategies due to the fact that the products are formed in a single step and also the diversity could be achieved simply by varying the reacting components. In this type of reaction, at least three easily accessible components are reacted to form a single product, which incorporates essentially all of the atoms of the starting materials. MCRs are highly flexible, chemoselective, convergent, and atom efficient processes. Therefore, very efficient way to access heterocycles is by using MCRs in the past decade. Several groups have reported MCRs preparation methods for synthesis of 4(3*H*)-quinazolinones from anthranilic acid, orthoesters, and amines using $NaHSO_4$ or Amberlyst-15 [11], Yb(III)-resin [12], $Yb(OTf)_3$ [13], $Bi(TFA)_3$-[nbp]$FeCl_4$ ionic liquid [14], $La(NO_3)_3 \cdot 6H_2O$ or *p*-toluenesulfonic acid [15], Keggin-type heteropolyacid under microwave irradiation [16], and $SiO_2$—$FeCl_3$ [17] *etc*. However, some of these methods associated with certain drawbacks such as expensive catalyst, high temperature (60–80°C), long reaction time (20 h), and using harmful organic solvent. In addition, aniline having strong electron-withdrawing substitutes, *e.g*., Cl and $NO_2$, gave generally no products at room temperature in previous reports. Therefore, it is desirable to develop green and efficient methods for the synthesis of 4(3*H*)-quinazolinones.

During the course of our study on Lewis acid–catalyzed organic reactions, we found that stannous chloride, as an inexpensive and commercially available catalyst, can catalyze one-pot three components Mannich-type reaction efficiently [18]. As an extension of our study on efficient synthesis of 4(3*H*)-quinazolinones, we reported here a one-pot MCR of anthranilic acid **1**, orthoesters **2**, and primary amines **3** in the presence of 1 mol % $SnCl_2 \cdot 2H_2O$ at room temperature without solvent (Scheme 1). Most products were formed within several minutes in excellent yields.

**1** **2** **3** **4 (a-n)**

## RESULTS AND DISCUSSION

First, a controlled experiment of an anthranilic acid, a triethyl orthoformate, and an aniline in the absence of catalyst was investigated. The result showed that only 5% product was obtained after 1 h. However, various 4(3*H*)-quinazolinones **4** were prepared efficiently using anthranilic acid **1**, trimethyl or triethyl orthoformate **2**, and different substituted aryl amines or alkyl amine **3** in the presence of $SnCl_2 \cdot 2H_2O$ at room temperature without solvent (Table 1). All condensations mediated by $SnCl_2 \cdot 2H_2O$ proceeded smoothly. Anilines carrying either electron-donating or electron-withdrawing groups all afford high yields. Steric hindrance seems to have no effects on the efficiency of this transformation. The reaction could tolerate different functional groups, such as alkyl, halogen, and nitro present in the anilines. The products derived from triethyl orthoformate were formed in somewhat higher yields than those from trimethyl orthoformate. Furthermore, trimethyl orthoformate required a comparatively longer reaction time. The condensation yield with primary aliphatic amines was lower than those with aniline derivatives.

A mechanism for this reaction has also been postulated as shown in Scheme 2. The first step in this reaction involves the $SnCl_2 \cdot 2H_2O$ catalyzed formation of imidic ester **5**, which stabilized by $Sn^{2+}$. The imidic ester **5** may be very prone to react with an aryl amine **3**,

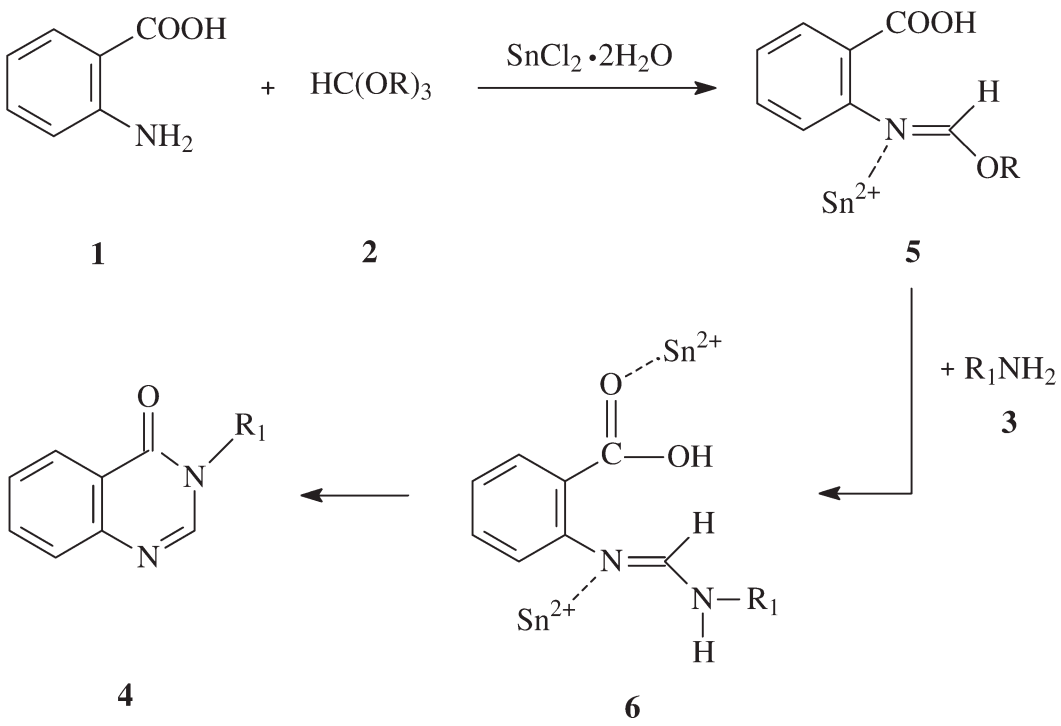
[a] The structures of the products were determined from spectral and analytical data (IR, $^1H$ NMR and elemental analysis).

**Scheme 2**



thus leading to the amidine intermediate **6**. Then, amidine intermediate **6** activated by $Sn^{2+}$ cyclized to form the quinazolinone **4**. A similar mechanism had also been described by Wang *et al*. [13].

In conclusion, we have demonstrated a simple and efficient one-pot three components coupling condensation from an anthranilic acid, orthoesters, and primary amines in the presence of $SnCl_2 \cdot 2H_2O$ for the preparation of 4(3*H*)-quinazolinones. The mild and solvent-free conditions, short reaction time (0.1–7 h), excellent yields (45–97%), inexpensive, nontoxic, and commercially available catalysts, and simple workup make it a useful process for the synthesis of 4(3*H*)-quinazolinones.

## EXPERIMENTAL

Melting points were determined using RY-1 micromelting point apparatus and were uncorrected. Infrared spectra were recorded on Scimitar 2000 series Fourier Transform instrument of VARIAN. $^1$H NMR spectra were recorded on Bruker ARX-500 spectrometer in DMSO-$d_6$ using TMS as an internal standard. Elemental analyzes were performed on EA 2400II elemental analyzer (Perkin–Elmer).

**General procedure for the synthesis of 4(3*H*)-quinazolinones.** To a mixture of anthranilic acid (10 mmol), an orthoester (12 mmol), and an amine (12 mmol), $SnCl_2 \cdot 2H_2O$ (0.1 mmol) was added. The mixture was stirred at room temperature for an appropriate time (Table 1). The reaction was monitored by TLC. After completion, the solid obtained was crystallized in ethanol. The pure products were identified by IR, $^1$H NMR, and elemental analysis. The spectral properties of some representative 4(3*H*)-quinazolinones are given below:

***3-(2-Methylphenyl)quinazolin-4(3H)-one (4b).*** White solid. IR (KBr): 1687, 1594, 1489 cm$^{-1}$. $^1$H NMR (500 MHz, DMSO-$d_6$): δ 8.56 (s, 1H), 8.31 (d, $J$ = 7.2 Hz, 1H), 7.75–7.52 (m, 2H), 7.23–7.07 (m, 5H), 2.31 (s, 3H). Anal. Calcd. for $C_{15}H_{12}ON_2$: C, 76.26; H, 5.12; O, 6.77. Found: C, 76.35; H, 5.10; O, 6.72.

***3-(2-Methoxyphenyl)quinazolin-4(3H)-one (4e).*** White solid. The 1*H*-pyrazole-3-carboxylic acids **2** were converted via reactions of their acid chlorides **3** with some semi- and thiosemicarbazide derivatives into the corresponding new phenylsemi- and thiosemicarbazides **4a–e**, **6**, 5-(pyrazol-3-yl)-4*H*-1,2,4-triazol-3-thiones **5a**,**b**, and 2-(pyrazol-3-yl)-1,3,4-thiadiazol **7** derivatives, in good yields (45-97%, respectively). The reactions of **4a,c,e** with *Lawesson* reagent lead to the products **6** and **7** formation. The structures of these newly synthesized compounds were determined from the IR, $^{1}$H- and $^{13}$C-NMR spectroscopic data and elemental analyses.

## INTRODUCTION

2,3-Furandiones in general are considered as convenient and versatile synthons in heterocyclic synthesis [1,2]. A convenient method for their synthesis, the mechanism of reactions, and semiempirical (AM1 and PM3) and *ab initio* (DFT) calculations on the interaction of 4-benzoyl-5-phenyl-2,3-dihydro-2,3-furandione (**1**) with several semicarbazones, ureas, thioureas, and anilides have been reported recently [3–7]. The reactions of 2,3-furandione **1** and various hydrazines or hydrazones result in new pyrazole-3-carboxylic acids, pyrazolopyridazinones, and some of their derivatives. The pyrazole carboxylic acids can be easily transformed into the corresponding acid chloride, ester, or amide derivatives by the general chemical procedures [8–13]. Pyrazole derivatives are generally well-known nitrogen containing heterocycles, and various procedures have been developed for their syntheses [14–17].

Pyrazole derivatives are very important organic compounds because they are widely used in pharmaceuticals and agrochemicals. Their excellent control activities in regard to various plant diseases are studied [18,19]. They can also be used as antifungal [20], antibacterial [21], antimicrobial [22,23], and anti-inflammatory agents [24–28]. The possible biological properties of the pyrazol, pyridazinone, pyrazolopyridazinone [29], and oxazin derivatives make it attractive to study these compounds.

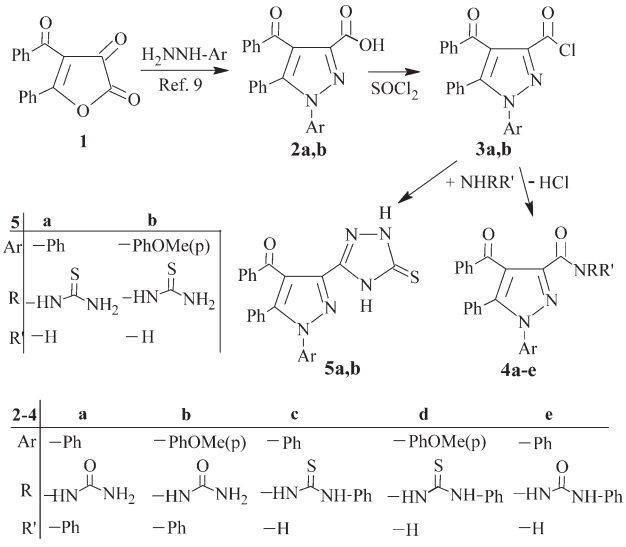
In view of these important properties, we decided both to prove reproducibility of the reaction of 4-benzoyl-1,5-diphenyl-1*H*-pyrazole-3-carboxylic acid (**2a**) and -acid chloride (**3a**) with some semi- and thiosemicarbazide derivatives and to extend our investigations related to preparing new heterocycles, which include the pyrazole ring in their structure. Here, we report the chemical behavior of **3** toward various semi- and thiosemicarbazides (see Scheme 1). As a result of these reactions, new phenylsemi- and thiosemicarbazides **4a–e**, **6**, 5-(substituted pyrazol-3-yl)-4*H*-1,2,4-triazol-3-thiones **5a**,**b**, and 2-(substituted pyrazol-3-yl)-1,3,4-thiadiazol **7** derivatives were synthesized, and their structures were identified by spectroscopic and elemental analyses.

## RESULTS AND DISCUSSION

Treatment of the yellow furandione **1** with arylhydrazines under reflux in benzene for 1–6 h, the corresponding white coloured 1*H*-pyrazole-3-carboxylic acids **2** [8] were obtained. The compounds **2** can easily be transformed into the corresponding 1*H*-pyrazole-3-carboxylic acid chloride **3** by usual chemical procedures [9]. Substituted 2,3-furandione **1**, -acid **2** and -acid chloride **3**, which are used as an important initial materials in the synthesis of the target heterocycles, were prepared using the literature procedures (**2b** and **3b** were synthesized by us, yet) [1,8,9,15] (see Scheme 1).

The compounds **3** treatment with various semi- and thiosemi-carbazide derivatives in boiling benzene or xylene gave the corresponding new structures **4**,**5** as main

**Scheme 1**

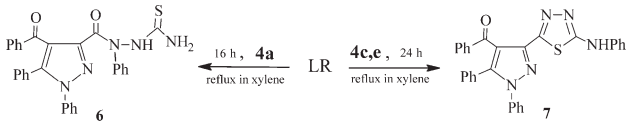


product. The progress of the reactions was monitored by thin-layer chromatography until complete consumption of the starting materials. The compounds **4a–e**, **5a**,**b** were obtained in excellent yields (70–97%), except **5a** (45%), after evaporation of the organic solvents and recrystallization from proper solvent (like methanol or butanol, see Experimental part). The reaction of the compound **3b** with 1-phenylsemicarbazide led to the formation of **4b**, under reflux in xylene for 8 h, in 76% yield without opening the pyrazole ring. To make the reaction selective, we had to determine its parameters, in other words, the reaction pathway, leading to such results. The excellent yield of the reaction can be explained by the chemical behavior of the compound **3** toward H-active nucleophiles, such as semi- and thiosemicarbazides. It should start with a nucleophilic attack of the nitrogen atoms' lone pair electrons of the semicarbazide to the antibonding (π*) orbital at the carbonyl carbon at C3 position of the pyrazol ring. Simultaneous attack of the other nitrogen atoms of the semicarbazide to the carbonyl carbon of the **3** could form some by-products. We assume that the reaction occurs under thermodynamic control. The by-products formed in this way are removed when the raw products are treated with diethyl ether. Previously, analogs reactions have been reported with hydrazines, ureas, diamines, aminophenols, and the corresponding open chain compounds [9–13]. In the IR spectrum of compound **4b**, the ═NH absorption bands were observed between 3480 and 3300 $cm^{-1}$, and the C═O absorption was at 1682 $cm^{-1}$. The $^1$H-NMR signals were found at δ equal to 9.09 ppm (s, 1H, NH), 7.68–6.92 (m, 19H, ArH), 6.20 (b, 2H, $NH_2$), and 3.77 ppm (s, 3H, $OCH_3$), and $^{13}$C NMR signals at δ such as 190.56 (t, PhCO), 159.98, 158.23 (two s, C═O), 159.50 (C─$OCH_3$), 144.28, 143.45 (C-3, C-5), 118.40 (C-4), and 55.90 ppm (q, $OCH_3$). Finally, the elemental analysis data along with spectroscopic data (details see Experimental) confirm the structure of **4b**.

Interaction of the pyrazole-3-carboxylic acid chlorides **3** with some semi- and thiosemicarbazide derivatives at reflux results in the corresponding new products **4a–e**. Surprisingly, using thiosemicarbazide in reaction with **3**, the 5-(substituted pyrazol-3-yl)-4*H*-1,2,4-triazol-3-thione derivatives **5a**,**b** were obtained exclusively. At this point, the reaction of **3** with thiosemicarbazide in boiling benzene for 4 h with no catalytic amounts of pyridine or triethylamine gave the product **5a**, which was obtained in 65% yield by recrystallizing from *n*-butanol (see Scheme 1). The moderate to good yield of the reaction can be explained by the chemical behavior of acid chlorides, similar to the behavior of the compound **3** toward *N*-nucleophiles [8–13]. The formation of **5** can easily be explained by a nucleophilic attack on the carbonyl group of the acid chloride **3**. It appears, that this process can be followed by elimination of a molecule of hydrogen chloride, and finally, loss of a molecule of water, to give **5**, whose formation is confirmed by TLC using authentic specimens of **5** and strongly supported by the results of all analytical and spectroscopic measurements. A Beilstein test did not give a green colour for compound **5**. The IR spectrum of **5a** showed characteristic absorption bands between 3500 and 2900 $cm^{-1}$ (b, NH), and at 1662 $cm^{-1}$ (s, CO). The $^1$H-NMR signals were found to be at δ equal to 10.49 (b, 1H, NH), 9.34 (b, 1H, NH), 7.77–7.08 ppm (m, 15H, ArH), and the $^{13}$C-NMR signals at δ such as 191.70 (t, PhC═O), 159.84 (C═S), 154.68–114.88 (arom. C's), 144.27, 143.66 (C-3, C-5), and 123.08 ppm (C-4).

To examine, if that kind of chemistry can be extended to somewhat modified systems, several attempts to change functional groups in **4** have now been made, e.g. transformation of carbonyl groups into the corresponding C═S-moieties using the *Lawesson* reagent [2,4-bis-(4-methoxyphenyl) 1,3,2,4-dithiadiphosphetane-2,4-disulfide] [30–33]. According to the usual experimental procedures applied to achieve sulfurization of carbonyls with aid of the Lawesson reagent (LR) [30–33], the phenylsemicarbazide derivatives **4a**, **4c,** or **4e** and LR were refluxed in dry xylene on an oil bath for 16 or 24 h, thus, forming a yellow solution. After cooling, white coloured crystals (**6**) or yellow needles (**7**) could be obtained in moderate yields (39–20%). Surprisingly, the outcome of these experiments did not follow the expected routes, but novel, potential, and biologically active pyrazole derivated heterocycles were obtained from those reactions as shown in Scheme 2.

**Scheme 2**



## CONCLUSION

This article reported the facile synthesis of new phenylsemi- and thiosemicarbazides **4a–e**, **6**, 5-(substituted pyrazol-3-yl)-4*H*-1,2,4-triazol-3-thiones **5a**,**b**, and 2-(substituted pyrazole-3-yl)-1,3,4-thiadiazol **7** derivatives from the nucleophilic substitution or recyclization of a pyrazole-3-carbonyl chlorides **3** with various semi- and thiosemicarbazides. The products were easily purified and obtained with a good yield and characterized by spectroscopic techniques as well as microanalyses. All newly synthesized compounds are soluble in most of organic solvents, but their limited solubility in most of inorganic solvents could be a drawback for subsequent applications. However, it may happen these compounds possess interesting biological properties [18–29] that would deserve further investigations. These functionalized products are amenable to further transformations, and we anticipate that they may have important applications in medicinal and synthetic organic chemistry.

## EXPERIMENTAL

Melting points are uncorrected and recorded on Electrothermal 9200 digital melting point apparatus. Microanalyses were performed on a Leco-932 CHNS-O Elemental Analyser. A Jasco 460 Plus FTIR and a Shimadzu FTIR-8400 model spectrophotometers were used for IR spectra (in the range of 400–4000 $cm^{-1}$ region), using KBr pellets or ATR techniques. The $^1$H-and $^{13}$C-NMR spectra were measured with Bruker 300 MHz and Bruker Avance III 400 MHz spectrometers and the chemical shifts were recorded in ppm units. After completion of the reactions, solvents were evaporated with rotary evaporator (Buchi RE model 111). The reactions were followed by TLC using DC Alufolien Kieselgel 60 $F_{254}$ Merck and Camag TLC lamp (254/366 nm). Solvents and all other chemical reagents were purchased from Merck, Sigma, Aldrich and Fluka and used directly without further purification. Solvents were dried by refluxing with the appropriate drying agents and distilled before use.

**4-Benzoyl-5-phenyl-1-*p*-methoxyphenyl-1*H*-pyrazole-3-carboxylic acid (2b).** A mixture of furandione **1** (0.28 g, 1 mmol) and 4-methoxyphenylhydrazine hydrochloride (0.17 g, 1 mmol) was refluxed in 30 mL of dry benzene for 6 h by adding 2–3 drops pyridine. After cooling, the precipitate was filtered off and treated with dry ether to give a crude solid that was recrystallized from methanol. The yield 0.25 g (63%) of **2b**, mp 232°C; IR (ATR): 3400–2400 (b, OH, COOH), 3065, 3030 (arom. CH), 2951–2897 (aliph. CH), 1674 (s br, CO's), 1604–1464 (phenyl and pyrazole rings C⋯C, C⋯N), 1248 $cm^{-1}$ (C—O); $^1$H-NMR (400 MHz, $CDCl_3$): δ 7.69–6.81 (m, 14H, ArH), 3.86 ppm (s, 3H, $OCH_3$); $^{13}$C-NMR (100 MHz, $CDCl_3$): δ 183.34 (t, PhC=O), 170.15 (s, COOH), 159.75 (MeO—Ph), 158.75 (N—Ph), 143.90, 143.12 (C-3, C-5), 139.82 (C—Ph), 134.99, 134.25, 132.03, 130.51, 128.90, 128.63, 128.44, 128.13, 128.10, 127.60, 127.28, 127.25 (C—Ph), 116.50 (s, C-4), 114.02, 114.00 (C—Ph), 55.53 ppm (q, $OCH_3$). Anal. Calcd. for $C_{24}H_{18}N_2O_4$ (398.41): C, 72.35; H, 4.55; N, 7.03. Found: C, 72.13; H, 4.72; N, 6.94.

**4-Benzoyl-5-phenyl-1-*p*-methoxyphenyl-1*H*-pyrazole-3-carbonyl chloride (3b).** Compound **2b** (0.40 g, 1 mmol) and thionyl chloride (1 mL, 13.8 mmol) were refluxed on a steam bath for 6 h. After cooling, the crude precipitate formed was filtered off and recrystallized from xylene or toluene, yield 0.31 g (68%), mp 177°C; IR (ATR): 3060, 3013 (arom. CH), 2967–2870 (aliph. CH), 1761, 1648 (s, CO), 1595–1454 (phenyl and pyrazole rings C⋯C, C⋯N), 1250 $cm^{-1}$ (C—O); $^1$H-NMR (400 MHz, DMSO-$d_6$): δ 7.80–6.74 (m, 14H, ArH), 3.78 ppm (s, 3H, $OCH_3$). $^{13}$C-NMR (100 MHz, DMSO-$d_6$): δ 191.35 (t, $J$ = 4.4 Hz, PhCO), 162.75 (s, COCl), 159.61 (MeO—Ph), 143.44, 142.58 (C-3, C-5), 138.15 (C—Ph), 133.81, 132.05, 130.08, 129.59, 129.49, 129.06, 128.83, 128.30, 127.75, 127.60 (C—Ph), 122.97 (s, C-4), 114.60 (C—Ph), 55.90 ppm (q, $OCH_3$). Anal. Calcd. for $C_{24}H_{17}N_2O_3Cl$ (416.86): C, 69.15; H, 4.11; N, 6.72. Found: C, 69.23; H, 4.29; N, 6.60.

**1-[(4-Benzoyl-1,5-diphenyl-1*H*-pyrazol-3-yl)carbonyl]-1-phenylsemicarbazide (4a).** Acid chloride **3a** (0.39 g, 1 mmol) and 1-phenylsemicarbazide (0.15 g, 1 mmol) were refluxed in xylene on an oil bath for 2 h. After cooling, the crude precipitate that formed was filtered off and recrystallized from methanol, yield 0.44 g (88%) of **4a**, mp 232–233°C; IR (KBr): 3488, 3334, 3256 (NH⇄OH and $NH_2$), 3057 (aromatic CH), 1713, 1658 (s, CO), 1597–1452 $cm^{-1}$ (C⋯C, C⋯N); $^1$H-NMR (300 MHz, DMSO-$d_6$): δ 9.10 (s, 1H, NH), 7.58–7.10 (m, 20H, ArH), 6.19 ppm (b, 2H, $NH_2$); $^{13}$C-NMR (75 MHz, DMSO-$d_6$): δ 190.50 (t, $J$ = 4.3 Hz, PhCO), 159.13 (s, C=O), 158.21 (C=O), 155.83 (N—Ph), 143.42, 142.54 (C-3, C-5), 138.95 (C—Ph), 134.52, 133.18, 132.11, 131.86, 130.53, 129.59, 129.03, 128.82, 128.67, 128.56, 128.26, 126.08 (C—Ph), 122.51, 119.94 ppm (C-4). Anal. Calcd. for $C_{30}H_{23}N_5O_3$ (501.54): C, 71.84; H, 4.62; N, 13.96. Found: C, 72.03; H, 4.79; N, 13.64.

**1-[(4-Benzoyl-5-phenyl-1-*p*-methoxyphenyl-1*H*-pyrazol-3-yl) carbonyl]-1-phenylsemicarbazide (4b).** Acid chloride **3b** (0.42 g, 1 mmol) and 1-phenylsemicarbazide (0.15 g, 1 mmol) were refluxed in xylene on an oil bath for 8 h. After evaporation, the oily residue obtained was treated with dry ether. The crude product formed was filtered off and recrystallized from a mixture of benzene-cyclohexane (1:3), yield 0.40 g (76%) of **4b**, mp 129°C; IR (ATR): 3480, 3383, 3309 (NH⇄OH and $NH_2$), 3065, 2912, 2849 (arom. and aliph. CH), 1682 (s br, CO's), 1590–1447 (C⋯C, C⋯N), 1248 $cm^{-1}$ (C—O); $^1$H-NMR (400 MHz, DMSO-$d_6$): δ 9.09 (s, 1H, NH), 7.68–6.92 (m, 19H, ArH), 6.20 (b, 2H, $NH_2$), 3.77 ppm (s, 3H, $OCH_3$); $^{13}$C-NMR (100 MHz, DMSO-$d_6$): δ 190.56 (t, $J$ = 4.2 Hz, PhCO), 159.98 (s, C=O), 159.50 (MeO—Ph), 158.23 (C=O), 155.30 (N—Ph), 144.28, 143.45 (C-3, C-5), 141.15 (C—Ph), 138.17, 134.21, 132.10, 131.93, 130.55, 130.08, 129.49, 128.92, 128.76, 128.15, 127.96, 127.59, 126.79 (C—Ph), 124.91, 118.40 (C-4), 116.61 (C—Ph), 55.90 ppm (q, $OCH_3$). Anal. Calcd. for $C_{31}H_{25}N_4O_4$ (517.55): C, 71.94; H, 4.87; N, 10.83. Found: C, 72.03; H, 4.77; N, 10.68.

**1-[(4-Benzoyl-1,5-diphenyl-1*H*-pyrazol-3-yl)carbonyl]-4-phenylthiosemicarbazide (4c).** Acid chloride **3a** (0.30 g, 0.8 mmol) and 4-phenylthiosemicarbazide (0.13 g, 0.8 mmol) were refluxed in benzene for 1 h. After cooling, the crude precipitate that formed was filtered off and recrystallized from *n*-butanol to give 0.27 g of **4c** (68%), mp 250–251°C; IR (KBr): 3393, 3209 (NH⇄OH ve NH), 3065 (arom. CH), 2415 (w, tautomeric SH), 1674 (CO), 1610–1460 (C⋯C, C⋯N), 1360 $cm^{-1}$ (C=S); $^1$H-NMR (400 MHz, DMSO-$d_6$): δ 12.61 (s, 1H, NH⇄SH), 10.02 (b, 1H, NH), 9.72 (b, 1H, NH), 7.54–6.92 ppm (m, 20H, ArH); $^{13}$C-NMR (100 MHz, DMSO-$d_6$): δ 191.50 (t, $J$ = 4.4 Hz, PhCO), 161.63 (C=S), 158.26 (C=O, amide), 156.60 (N—Ph), 145.17, 142.56 (C-3, C-5 exchangeable), 140.24 (C—Ph), 138.86, 137.06, 133.96, 130.46, 129.11, 128.99, 128.91, 128.60, 128.18, 127.87, 127.71, 126.13 (C—Ph), 123.17 (C-4), 117.08, 116.88 ppm (C—Ph). Anal. Calcd. for $C_{30}H_{23}N_5O_2S$ (517.60): C, 69.61; H, 4.48; N, 13.53; S, 6.19. Found: C, 69.88; H, 4.80; N, 13.91; S, 6.00.

**1-[(4-Benzoyl-5-phenyl-1-*p*-methoxyphenyl-1*H*-pyrazol-3-yl) carbonyl]-4-phenylthiosemicarbazide (4d).** Acid chloride **3b** (0.42 g, 1 mmol) and 4-phenylthiosemicarbazide (0.17 g, 1 mmol) were refluxed in xylene for 6 h. After evaporation, the oily residue obtained was treated with dry ether. The crude product formed was filtered off and recrystallized from *n*-butanol to give 0.38 g of **4d** (70%), mp 202°C; IR (ATR): 3400–3100 (NH⇄OH and NH), 3065, 2966, 2873 (C—H), 2450 (w, tautomeric SH), 1674 (s br, CO's), 1604–1475 (C⋯C, C⋯N), 1370 $cm^{-1}$ (C=S); $^1$H-NMR (400 MHz, DMSO-$d_6$): δ 12.59 (s, 1H, NH⇄SH), 10.39 (b, 1H, NH), 9.96 (t, 1H, NH), 7.74–6.92 (m, 19H, ArH), 3.76 ppm (s, 3H, $OCH_3$); $^{13}$C-NMR (100 MHz, DMSO-$d_6$): δ 191.30 (t, $J$ = 4.2 Hz, PhCO), 160.06 (C=S), 159.85 (MeO—Ph), 159.61 (C=O, amide), 156.62 (N—Ph), 144.07, 142.19 (C-3, C-5 exchangeable), 140.68 (C—Ph), 138.15, 137.63, 134.74, 133.63, 132.19, 131.03, 130.17, 129.58, 129.22, 128.85, 128.56, 128.33, 128.13, 127.85, 127.77, 126.39 (C—Ph), 122.09 (C-4), 117.86, 116.88, 114.52 (C—Ph), 55.90 ppm (q, $OCH_3$). Anal. Calcd. for $C_{31}H_{25}N_4O_3S$ (533.62): C, 69.77; H, 4.72; N, 10.50; S, 6.01. Found: C, 69.85; H, 4.80; N, 10.32; S, 6.14.

**1-[(4-Benzoyl-1,5-diphenyl-1*H*-pyrazol-3-yl)carbonyl]-4-phenylsemicarbazide (4e).** Acid chloride **3a** (0.30 g, 0.8 mmol) and 4-phenylsemicarbazide (0.15 g, ∼0.8 mmol) were refluxed in benzene for 4 h. After cooling, the crude precipitate was filtered off and recrystallized from *n*-butanol, yield 0.40 g (97%) of **4e**, mp 219°C; IR (KBr): 3435, 3329 (NH⇄OH), 3060 (arom. CH), 1696, 1641 (s, CO), 1601–1478 $cm^{-1}$ (C⋯C, C⋯N); $^1$H-NMR (300 MHz, $CDCl_3$/DMSO-$d_6$): δ 9.79 (s, 1H, NH), 8.37 (s, 1H, NH), 7.99 (s, 1H, NH), 7.71–6.85 ppm (m, 20H, ArH); $^{13}$C-NMR (75 MHz, $CDCl_3$/DMSO-$d_6$): δ 190.26 (t, $J$ = 4.3 Hz, PhCO), 159.51, 154.52 (HNC=O), 143.16, 142.70 (C-3, C-5), 138.48, 137.87, 137.09, 132.21, 128.87, 128.46, 128.21, 127.88, 127.76, 127.68, 127.47, 126.96, 124.65 (C—Ph), 121.37, 121.18, 117.62 ppm (C-4). Anal. Calcd. for $C_{30}H_{23}N_5O_3$ (501.54): C, 71.84; H, 4.62; N, 13.96. Found: C, 71.47; H, 4.77; N, 14.21.

**5-(4-Benzoyl-1,5-diphenyl-1*H*-pyrazol-3-yl)-4*H*-1,2,4-triazol-3-thione (5a).** Acid chloride **3a** (0.50 g, 1.3 mmol) and thiosemicarbazide (0.12 g, 1.3 mmol) were refluxed in benzene for 4 h. After cooling, the crude precipitate was filtered off and recrystallized from *n*-butanol, yield 0.36 g (65%) of **5a**, mp 208°C; IR (KBr): 3600–2900 $cm^{-1}$ (b, NH, peak max.: 3468, 3339, 3182), 3055 (arom. CH), 1662 (s, CO), 1602–1497 (C⋯N, C⋯C), 1367 $cm^{-1}$ (C=S); $^1$H-NMR (400 MHz, DMSO-$d_6$): δ 10.49 (b, 1H, NH), 9.34 (b, 1H, NH), 7.77–7.08 ppm (m, 15H, ArH); $^{13}$C-NMR (100 MHz, DMSO-$d_6$): δ 191.70 (t, $J$ = 4.5 Hz, PhCO), 159.84 (C=S), 154.68 (N—Ph), 144.27, 143.66, 143.25 (C-3, C-5 or C-5′ exchangeable), 140.23 (C—Ph), 139.21, 138.18, 136.39, 135.24, 133.67, 132.26, 131.75, 130.41, 129.68, 129.31, 128.91, 128.27, 127.74, 125.32 (C—Ph), 123.08 (C-4), 117.18, 114.88 ppm (C—Ph). Anal. Calcd. for $C_{24}H_{17}N_5OS$ (423.49): C, 68.07; H: 4.05; N: 16.54; S: 7.57. Found: C, 67.90; H, 4.25; N, 16.40; S. 7.30.

**5-(4-Benzoyl-5-phenyl-1-*p*-methoxyphenyl-1*H*-pyrazol-3-yl)-4*H*-1,2,4-triazol-3-thione (5b).** Acid chloride **3b** (0.50 g, 1.2 mmol) and thiosemicarbazide (0.11 g, 1.2 mmol) were refluxed in xylene for 8 h. After cooling, the crude precipitate was filtered off and recrystallized from a mixture of carbon tetrachloride and cyclohexane (1:3), yield 0.45 g (83%) of **5b**, mp 140°C; IR (ATR): 3320, 3156 (NH), 3057, 2935 (C—H), 2450 (w, tautomeric SH), 1670 (s, CO), 1598–1452 (C⋯C, C⋯N), 1362 $cm^{-1}$ (C=S); $^1$H-NMR (400 MHz, DMSO-$d_6$): δ 12.58 (s, 1H, NH⇄SH), 10.36 (b, 1H, NH), 7.76–6.92 (m, 14H, ArH), 3.76 ppm (s, 3H, $OCH_3$); $^{13}$C-NMR (100 MHz, DMSO-$d_6$): δ 191.30 (t, $J$ = 4.6 Hz, PhCO), 161.93 (C=S), 159.81 (MeO—Ph), 156.63 (N—Ph), 144.07, 143.47, 142.21 (C-3, C-5 or C-5′ exchangeable), 140.68 (C—Ph), 138.15, 137.87, 134.73, 133.82, 132.19, 131.87, 130.32, 129.74, 129.28, 128.86, 128.33, 127.85, 126.39 (C—Ph), 122.10 (C-4), 116.80, 114.60, (C—Ph), 55.93 ppm (q, $OCH_3$). Anal. Calcd. for $C_{25}H_{19}N_5O_2S$ (453.52): C, 66.21; H: 4.22; N: 15.44; S: 7.07. Found: C, 66.08; H, 4.25; N, 15.15; S. 7.33.

**1-[(4-Benzoyl-1,5-diphenyl-1*H*-pyrazol-3-yl)carbonyl]-1-phenylthiosemicarbazide (6). 4a** (0.50 g, 1.1 mmol) and LR (0.54 g, 1.3 mmol) were refluxed in xylene on an oil bath for 16 h. Than the solvent was evaporated and remaining oily residue was treated with dry diethyl ether to give a crude product that was recrystallized from xylene. Yield 0.20 g (39%) of **6**, mp 263°C; IR (KBr): 3600–2950, (b, NH, peak max.: 3446, 3220, 3196), 3055 (arom. CH), 1690, 1637 (CO), 1594–1472 (C⋯C, C⋯N), 1364 $cm^{-1}$ (C=S); $^1$H-NMR (300 MHz, $CDCl_3$): δ 7.80 (d, 1H, NH), 7.77 (d, 1H, NH), 7.66–6.86 (m, 20H, ArH and 1H, NH). Anal. Calcd. for $C_{30}H_{23}N_5O_2S$ (517.60): C, 69.61, H, 4.48, N, 13.53, S, 6.19. Found: C, 69.47, H: 4.63; N: 13.76, S: 6.04.

**5-Anilino-2-(4-benzoyl-1,5-diphenyl-1*H*-pyrazol-3-yl)-1,3,4-thiadiazol (7). 4e** (0.50 g, 1 mmol) and LR (0.54 g, 1.3 mmol) were refluxed in xylene on an oil bath for 24 h. Than the solvent was evaporated and remaining oily residue was treated with dry diethyl ether to give a crude product that was recrystallized from xylene. Yield 0.11 g (20%) of **7**, mp 323°C; IR (KBr): 3196 (NH), 3058 (arom. CH), 1640 (CO), 1594–1491 $cm^{-1}$ (C⋯C, C⋯N); $^1$H-NMR (300 MHz, DMSO-$d_6$): δ 14.27 (s, 1H, NH), 7.46–6.97 ppm (m, 20H, ArH);$^{13}$C-NMR (75 MHz, DMSO-$d_6$): δ 175.44 (t, $J$ = 4.2 Hz, PhCO), 149.00 (N=C—S), 148.60 (S—C—NH), 141.60, 139.21, 137.65, 133.98, 131.07, 130.10, 129.93, 129.51, 129.25, 129.17, 128.84, 128.74, 128.58, 128.26, 128.08, 127.92, 126.96, 126.42, 126.06, 111.49 ppm (arom. C's). Anal. Calcd. for $C_{30}H_{21}N_5OS$ (499.59): C, 72.12; H, 4.24; N, 14.02; S, 6.42. Found: C, 72.40; H, 4.50; N, 13.80; S, 6.71.

3-Arylazo-2-(4-methyl-2-phenylthiazol-5-yl)imidazo[1,2-*a*]pyrimidine, 2-(4-methyl-2-phenyl-1,3-thiazol-5-yl)-3-phenylazoimidazo[1,2-*a*]pyridine, 3-arylazo-2-(4-methyl-2-phenylthiazol-5-yl)-6-phenyl-5*H*-imidazo[1,2-*b*]pyrazole, 6-(4-methyl-2-phenyl-thiazol-5-yl)-5-phenylazo3-phenyl-imidazo[2,1-*b*]thiazole, 3-(4-methyl-2-phenylthiazol-5-yl)-2-phenylhydrazino-(1*H*)-quinoxaline, 3-(4-methyl-2-phenylthiazol-5-yl)- 2-phenylazoquinoxaline, 3-(4-methyl-2-phenylthiazol-5-yl)-2-phenylhydrazinobenzo-[1,4] thiazine, 3-(4-methyl-2-phenyl-thiazol-5-yl)-2-phenylhydrazinobenzo[1,4]oxazine, and 3-(4-methyl-2-phenyl-thiazol-5-yl)-2-phenylazo-1*H*-pyrido[2,3-*b*]pyrazine derivatives were synthesized *via* reaction of 2-(4-methyl-2-phenyl-1,3-thiazol-5-yl)-2-oxo-*N*-arylethanehydrazonoyl bromide with each of 2-aminopyrimidine, 2-aminopyridine, 3-aminopyrazoles, 2-amino-4-phenylthiazole, *o*-phenylenediamine, *o*-aminothiophenol, *o*-aminophenol, or 2, 3-diaminopyridine, respectively. All structures of the newly synthesized compounds were elucidated by elemental analysis, spectral data, and alternative synthetic route whenever possible. The entire newly synthesized compounds are tested toward different microorganisms.

*J. Heterocyclic Chem.*, **47**, 477 (2010).

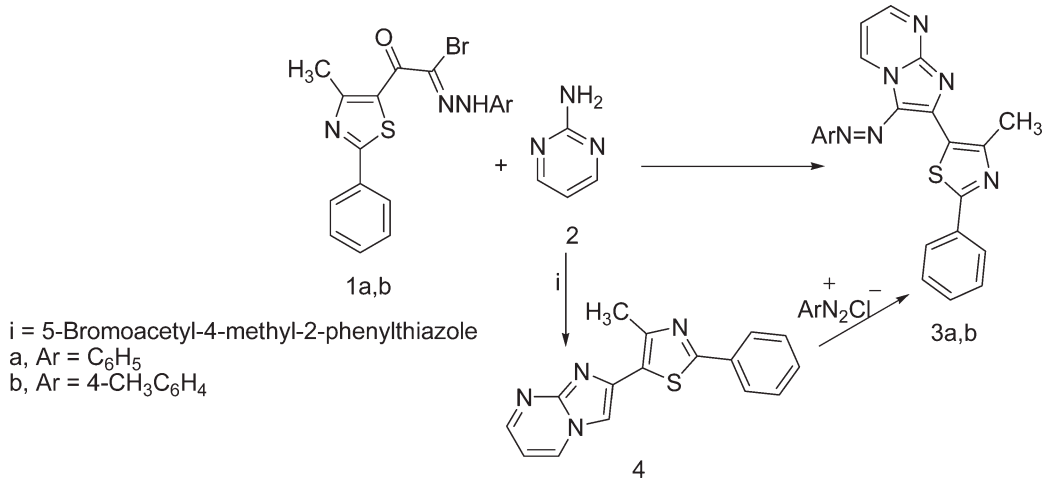
## INTRODUCTION

Our continuous interest in the chemistry of hydrazonoyl halides [1–9] originates from our persistent trials to obtain pyridines, pyrimidines, pyridazines, and their analogs. The importance of such compounds lies in their diverse pharmaceutical activities, namely antibacterial [10,11], antidiabetic [12], anti-HIV [13], antiviral [14,15], and analgesic activities. We report herein the reactivity of 2-(4-methyl-2-phenyl-1,3-thiazol-5-yl)-2-oxo-*N*-arylethanehydrazonoyl bromides toward 2-aminopyrimidine, 2-aminopyridine, 3-aminopyrazoles, 2-amino-4-phenylthiazole, *o*-phenylenediamine, *o*-aminothiophenol, *o*-aminophenol, and 2,3-diaminopyridine.

## RESULTS AND DISCUSSION

Treatment of 2-aminopyrimidine (**2**) with the appropriate 2-(4-methyl-2-phenylthiazol-5-yl)-2-oxo-*N*-arylethanehydrazonoyl bromide (**1a**, **b**) in ethanol gave 3-arylazo-2-(4-methyl-2-phenylthiazol-5-yl)imidazo[1,2-*a*] pyrimidine (**3a**, **b**) in a good yield (Scheme 1). Structure **3** was elucidated by elemental analysis, spectral

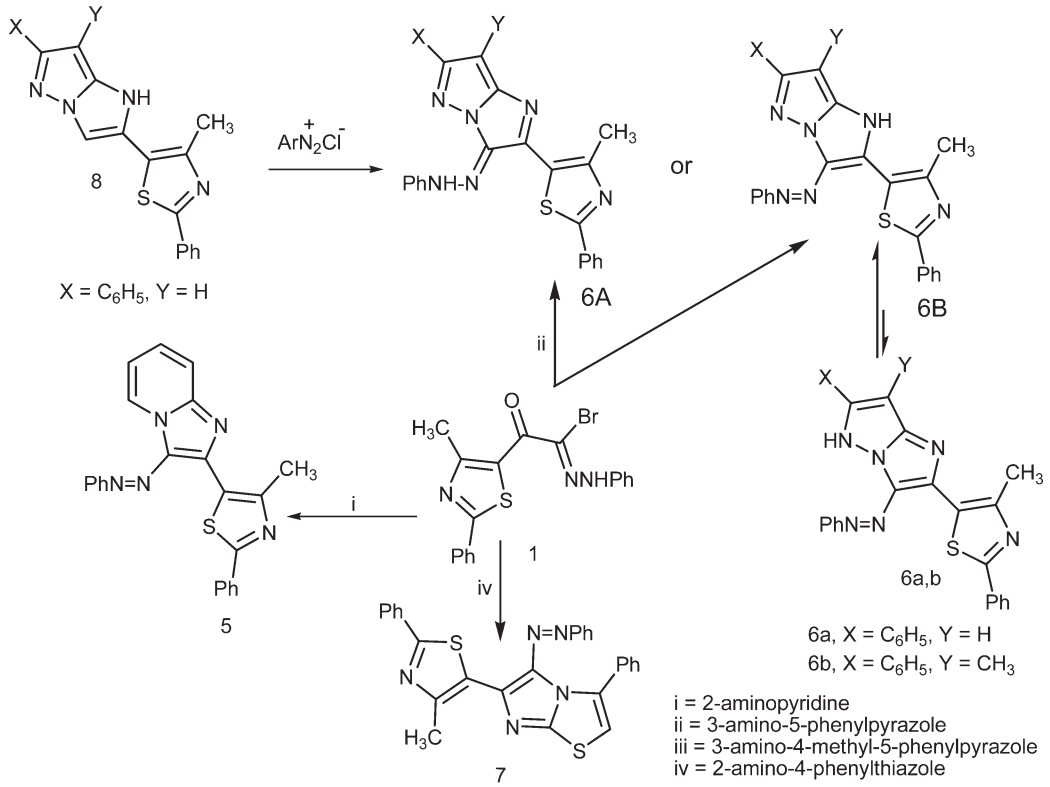
**Scheme 1**



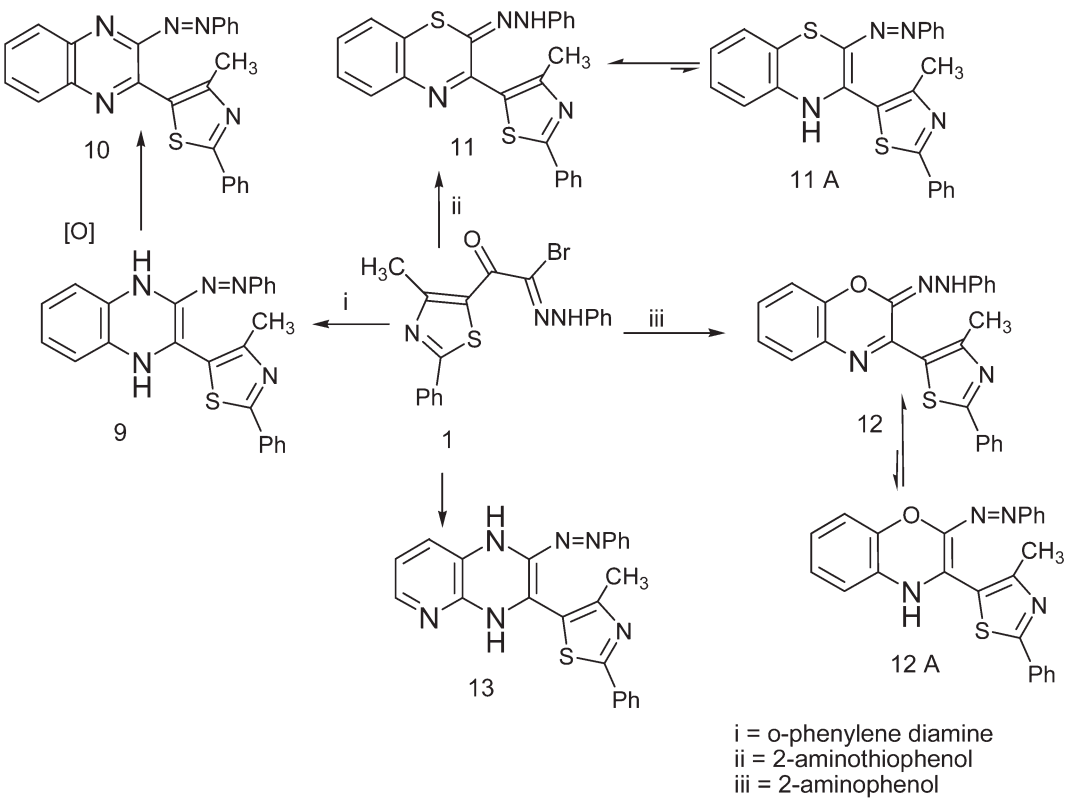
data, and alternative synthesis. $^1$H-NMR spectrum of **3a** showed signals at $\delta = 2.46$ (s, 3H, 4-methylthiazole), 6.86–6.70 (t, 3H, pyrimidine H-5), 7.36–7.37 (d, 2H, ArH), 7.62–7.67 (m, 3H, ArH), 7.70–7.81 (m, 3H, ArH), 8.53–8.54 (d, 1H, pyrimidine H-4), 8.65–8.66 (d, 1H, pyrimidine H-6). Its IR (cm$^{-1}$) spectrum revealed bands at 3060, 2923 (CH), 1645 (C=N), 1599 (C=C), 1321 ($CH_3$), and no band between 1800 and 1650 cm$^{-1}$ attributed the absence of carbonyl group. Thus, treatment of 2-(4-methyl-2-phenylthiazol-5-yl)imidazo[1,2-*a*]pyrimidine (**4**), which was synthesized *via* reaction of 2-aminopyrimidine with 2-bromo-1-(4-methyl-2-phenyl-1,3-thiazol-5-yl)ethanone, with the appropriate arenediazonium chloride in ethanolic sodium acetate gave a product identical in all aspects (mp., mixed mp., and spectra) with **3a** and **3b**, respectively.

Analogously, the appropriate 2-aminopyridine, 3-amino-5-phenylpyrazole, 3-amino-4-methyl-5-phenylpyrazole, or 2-

**Scheme 2**



**Scheme 3**



amino-4-phenylthiazole was reacted with 2-(4-methyl-2-phenyl-1,3-thiazol-5-yl)-2-oxo-*N*-phenylethanehydrazonoyl bromide (**1a**) in boiling ethanol gave 3-phenylazo-2-(4-methyl-2-phenylthiazol-5-yl)imidazo[1,2-*a*]pyridine (**5**), 3-phenylazo-2-(4-methyl-2-phenyl-thiazol-5-yl)-6-phenyl-5*H*-imidazo [1,2-*b*]pyrazole (**6a**), 2-(4-methyl-2-phenyl-thiazol-5-yl)-5-methyl-6-phenyl-3-phenylazo-5*H*-imidazo[1,2-*b*]pyrazole (**6b**), and 6-(4-methyl-2-phenyl-thiazol-5-yl)-5-phenylazo3-phenylimidazo[2,1-*b*]thiazole (**7**), respectively (Scheme 2).

Structures **5**–**7** were elucidated by elemental analyses, spectral data, and alternative synthetic route. Thus, treatment of 2-(4-methyl-2-phenylthiazol-5-yl)-6-phenyl-1*H*-imidazo[1,2-*b*]pyrazole (**8**), which was synthesized from 2-bromo-1-(4-methyl-2-phenyl-1,3-thiazol-5-yl)ethanone with 3(5)-amino-5(3)-phenylpyrazole in boiling ethanol, with benzenediazonium chloride in ethanolic sodium acetate solution gave product identical in all aspects (mp., mixed mp., and spectra) with **6a**.

Attention was then turned to the tautomeric structure of the product **6a** as they can exist in the tautomeric hydrazone form **A** or phenylazoenamine form **B** (Scheme 2). Unfortunately, their spectra (IR and $^1$H-NMR) were not of too much help to decide the actual tautomeric form of the compound in question. This problem was solved by examining UV spectrum and M.O. calculation. The electronic absorption of compound **6a** in ethanol was also compatible with the azo form **B**. The product exhibits in ethanol two bands at $\lambda_{nm} = 315$ (log $\varepsilon =$ 3.3416) and 466 (log $\varepsilon = 4.1734$). Such an absorption pattern is similar to that of typical azo-form [16,17]. M.O. calculation using HyperChem semi-empirical method AM1, for structure **6A**, showed $E = -6034.948$ kcal/mol and heat formation = 365.522 kcal/mol, for structure **6B** showed $E = -6096.498$ kcal/mol and heat formation = 303.972 kcal/mol, and for structure **6a**, $E = -6113.009$ kcal/mol and heat formation = 287.460 kcal/mol. These results indicted that the structure **6a** was more compatible tautomeric form.

Treatment of **1a** with *o*-phenylenediamine in boiling ethanol under reflux gave 3-(4-methyl-2-phenylthiazol-5-yl)-2-phenylhydrazino-(1*H*)-quinoxaline (**9**). Structure **9** was confirmed by elemental analysis, spectral data, and its oxidation with hydrogen peroxide in acetic acid to afford 3-(4-methyl-2-phenyl-thiazol-5-yl)-2-phenylazoquinoxaline (**10**) (Scheme 3).

Analogously, treatment of **1a** with the appropriate of each of 2-aminothiophenol, 2-aminophenol, or 2,3-diaminopyridine gave 3-(4-methyl-2-phenyl-thiazol-5-yl)-2-phenylhydrazinobenzo[1,4]thiazine (**11**), 3-(4-methyl-2-phenyl-thiazol-5-yl)-2-phenylhydrazinobenzo[1,4]oxazine (**12**), and 1-(1,4-dihydro-3-(4-methyl-2-phenylthiazol-5-yl)-2-phenylazopyrido[2,3-*b*]pyrazine (**13**), respectively. Structures **11A** and **12A** were ruled out according to UV spectra. Thus, UV spectra of **11** and **12** exhibit

$\lambda_{max}$ = 357 (log ε = 4.022) and 345 (log ε = 2.716), whereas spectrum of **13** exhibits two bands at $\lambda_{max}$ = 345 (log ε = 4.0177) and 466 (log ε = 4.6467).

**Antimicrobial screening.** Ten selected compounds were screened for their antimicrobial activity using five selected standard isolates, which have been chosen as representative examples of different types of microorganisms as follows: Gram-positive both nonsporulated bacteria as *Staphylococus aureus* and sporulated as *Bacillus subtilis*, Gram-negative as *Escherichia coli* and *Pseudomonas aeruginosa*, and a fungus as *Candida albicans*.

***Method: Agar dilution technique.*** The appropriate volume of membrane filtered stock solution of 0.05 g/5 mL of each compound was prepared by the twofold dilution method to obtain the concentrations: 400, 200, 100, 50, and 25 μg/mL [18]. The volumes were added to the molten LB agar (about 50°C). After mixing, the media were allowed to harden and dry by placing in an incubator at 37°C for 10 min. Plates containing serial dilutions of each compound were inoculated with a sterile multiinoculator onto the surface of the agar medium so that the final inoculum of each isolate on the agar surface was in the order of $10^4$–$10^5$ CFU/spot. Ciprofloxacin and triflucan were used as positive controls and the solvent, dimethylsulfoxide (DMSO), as negative control. Minimum inhibitory concentrations (MICs) were read after 18 h incubation at 37°C for bacteria and 25°C for fungus. The MIC is reported as the lowest concentration of the compound that prevents the growth of visible colonies. The obtained MICs of 10 representative examples are presented in Table 1.

As shown in Table 1, there is variability in the susceptibilities of the different organisms to the different compounds. *S. aureus* was the most resistant organism. Some compounds showed antibacterial activity, whereas others showed antifungal activity.

## EXPERIMENTAL

All melting points were determined on an electrothermal apparatus and are uncorrected. IR spectra were recorded (KBr discs) on a Shimadzu FTIR 8201 PC Spectrophotometer. $^1$H-NMR and $^{13}$C-NMR spectra were recorded in $CDCl_3$ solution on a Varian Mercury 300 MHz spectrometer, and chemical shifts are expressed as δ using TMS as an internal reference. The ultraviolet spectrum was recorded using Shimadzu UV–vis 1601 PC double beam spectrophotometer. Mass spectra were recorded on a GC-MS QP1000. Elemental analyses were carried out at the Micro analytical center of Cairo University. The hydrazidoyl bromides **1**(**a**, **b**) were prepared as previously reported [19].

**General procedure for the synthesis of (3a, b), (5), (6a, b), (7), (9), (11), (12), and (13).** A mixture of the appropriate hydrazonoyl bromide **1a**, **b** (5 mmol), the appropriate 2-aminopyrimidine, 2-aminopyridine, 3-amino-5-phenylpyrazole, 3-amino-4-methyl-5-phenylpyrazole, 2-amino-4-phenylthiazole, *o*-phenylenediamine, 2-aminothiophenol, 2-aminophenol or 2,3-diaminopyridine (6 mmol), and triethylamine (0.5 g, 0.75 mL, 5 mmol) in ethanol (25 mL) was heated under reflux for 3 h and then cooled. The solid precipitated was collected, washed with water, and then crystallized from the appropriate solvent to give **3**(**a**, **b**), **5**, **6**(**a**, **b**), **7**, **8**, **11**–**13**, respectively.

**General procedure for the synthesis of 4 and 8.** A mixture of 2-bromo-1-(4-methyl-2-phenyl-1,3-thiazol-5-yl)ethanone [20] (1.48 g, 5 mmol) and 2-aminopyrimidine (0.48 g, 6 mmol) or 2-amino-4-phenylthiazole (0.56 g, 6 mmol) in ethanol (25 mL) was heated under reflux for 3–4 h. The resulting solid was neutralized with sodium bicarbonate solution, collected by filtration, and then was crystallized from ethanol to give **4** and **8**, respectively.

***2-(4-Methyl-2-phenylthiazol-5-yl)imidazo[1,2-a]pyrimidine (4).*** This compound was obtained as yellow crystals (EtOH), mp 223–26°C, yield (62%); IR ($cm^{-1}$): 3060.3, 2928 (CH), 1655 (C=N), 1599 (C=C), 1369 ($CH_3$). $^1$H-NMR: δ = 2.46 (s, 3H, 4-methylthiazole), 6.91 (d, 1H, pyrimidine H-5), 7.62 (t, 2H, ArH), 7.68 (t, 1H, ArH), 7.76 (d, 2H, ArH), 7.91 (s, 1H, imidazole H-4), 8.50 (d, 1H, pyrimidine H-6), 8.57 (d, 1H, pyrimidine H-4). $^{13}$C-NMR: δ = 13.85 ($CH_3$), 114.21, 150.71, 160.82 (thiazole), 111.62, 124.45, 149.10 (imidazole), 125.00, 126.58, 131.10, 136.24 (phenyl), 110.12, 135.77, 151.28 (pyrimidine). MS: 293 (8.8%), 292 (30%), 202 (19.9%), 203 (10%), 188 (22.9), 144 (15.9), 92 (7.1%), 66 (10.6%). Anal. Calcd. for $C_{16}H_{12}N_4S$ (292.36): C, 65.73; H, 4.14; N, 19.16; S, 10.97. Found: C, 65.90; H, 4.33; N, 19.02; S, 10.70.

***2-(4-Methyl-2-phenylthiazol-5-yl)-6-phenyl-1H-imidazo[1,2-b]pyrazole (8).*** This compound was obtained as orange crystals (DMF), mp 244–47°C, yield (60%); $^1$H-NMR $(CD_3)_2SO$: δ = 2.46 (s, 3H, 4-methylthiazole), 6.15 (s, 1H, pyrazole H-4), 7.40 (s, 1H, imidazole H-4), 7.45–7.92 (m, 10H, ArH), 8.42 (s, br., 1H, NH). Anal. Calcd. for $C_{21}H_{16}N_4S$ (356.44): C, 70.67; H, 4.52; N, 15.72; S, 9.00. Found: C, 70.55; H, 4.31; N, 15.50; S, 9.07.

***Alternative synthesis of 3a, b and 6a.*** A solution of the appropriate arenediazonium chloride (10 mmol) was added dropwise to a stirred solution of the appropriate reactant (**4**, **8**) (10 mmol) in ethanol (50 mL) containing sodium acetate trihydrate (1.3g, 10 mmol) at 0–5°C. The reaction mixture was stirred for 3 h at 0°C, the resulting solid was collected and crystallized from ethanol to give **3**(**a**, **b**) and **6a**, respectively.

***3-(4-Methyl-2-phenyl-thiazol-5-yl)-2-phenylazoquinoxaline (10).*** A mixture of compound **9** (0.5 g) in ethanol (20 mL) and hydrogen peroxide (3 mL, 30%) was stirred at room temperature for 24 h. The solvent was evaporated under reduced pressure, the resulting solid was collected and recrystallized to give **10**. This compound was obtained as red crystals (DMF/EtOH), mp > 300°C, yield (78%); $^1$H-NMR $(CD_3)_2SO$: δ = 2.46 (s, 3H, 4-methylthiazole), 7.26–8.13 (m, 14H, ArH). $^{13}$C-NMR: δ = 15.57 ($CH_3$), 109.58, 162.11, 167.00 (thiazole), 138.32, 139.54, 146.61, 145.45 (pyrazine), 124.12, 125.54, 126.28, 129.23, 129.65, 129.89, 132.52, 133.21, 154.94 (phenyl groups). Anal. Calcd. for $C_{24}H_{117}N_5S$ (407.49): C, 70.74; H, 4.21; N, 17.19; S, 7.87. Found: C, 70.90; H, 4.31; N, 17.33; S, 7.60.

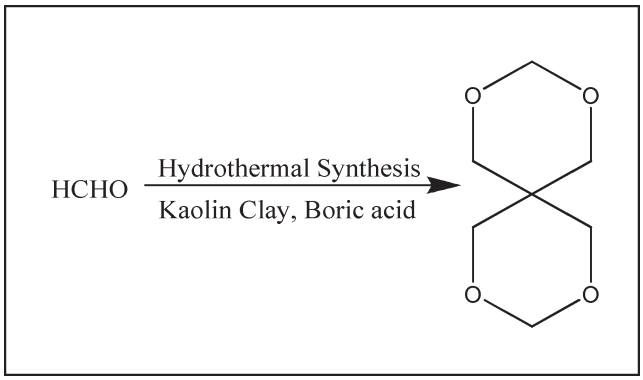
Published online 2 March 2010 in Wiley InterScience (www.interscience.wiley.com).



We report here the hydrothermal synthesis of 2,4,8,10-tetraoxaspiro[5.5]-undecane by using formaldehyde, the only precursor, in the presence of kaolin clay and boric acid. The reported method is the simplest one to synthesize the aforementioned product.

*J. Heterocyclic Chem.,* **47**, 483 (2010).

## INTRODUCTION

The spectacular nature of the hydrothermal systems provides a great deal of new synthetic routes in innovative, unconventional, as well as safest ways. This is exemplified by a number of novel synthetic discoveries in the realm of hydrothermal synthesis [1,2]. Also, a novel method for the translation of sodium hydrogen carbonate into phenol depicts that hydrothermal reaction routes have diverse applications [2]. Not only this but the hydrothermal synthesis also provides intriguing clues to the origin of life [1,3]. Furthermore, such kind of synthetic routes occupy a special place because of their pollution free nature. Also, the reactions take place safely within closed systems and do not need expensive materials as used in normal organic synthesis. Here, we present a simplest route to synthesize 2,4,8,10-tetraoxaspiro[5.5]-undecane **(1)** under the simplest hydrothermal conditions and demonstrate the versatility of the hydrothermal techniques.

Compound **1** is a very important synthetic precursor of many organic compounds. It has multifarious applications, from simple organic synthesis to medicines. One derivative, like 3,9-bis(2-hydrazidoethyl)-**1**, is used as a curing agent to produce a sufficient amount of cured epoxy resin [4]. Many derivatives of **1** are used as stabilizers for polyolefins and other polymers [5]. Similarly the binary blends of the acrylate rubber and chlorinated polypropylene give dynamic mechanical properties with 3,9-bis[1,1-dimethyl-2{β-(3-*tert*-butyl-4-hydroxy-5-methylphenyl)-propionyloxy}ethyl]-1 [6] and 3,9-di-2-furyl-1 type compounds serve as important intermediates in the synthesis of pesticides [7]. Moreover, its derivatives serve as prominent parts of many patents, *i.e*., 3,9-bis[2-{3-(3-*tert*-butyl-4-hydroxy-5-methylphenyl) propionyloxy}-1,1-dimethylethyl]-1 is used in the synthesis of high quality antioxidants for many polymers [8,9], 3,9-bis [1,1-dimethyl-2-{β-(3-*tert*-butyl-4-hydroxy-5-methylphenyl)propionyl-oxy}ethyl]-1 serves as an oxidant in the synthesis of molding materials with excellent properties [10], while its many derivatives serve as essential components to bestow excellent chemical makeup for decorating ceramics [11]. Its derivatives enjoy a special place in the field of medicine and surgery, *e.g*., -1-3,9-dipropamine(11′) is used in the synthesis of anti-inflammatory drug derivatives like pyrimidine and bispyrimidine [12] derivatives, 3,9-diethylidene-1 has potential applications in dental surgery [13], 3,9-dimethylene-1, is used in the synthesis of biodegradable polymers for the controlled release of paracetamol [14]. 1 has been synthesized in many ways, but the most remarkable

synthetic routes are achieved by the transacetalization of triols [15]. Here, we report the hydrothermal synthesis of **1** by using formaldehyde as the only starting reagent, by using a mixture of boric acid and kaolin as catalyst, hence it presents the simplest route to synthesize the intended product.

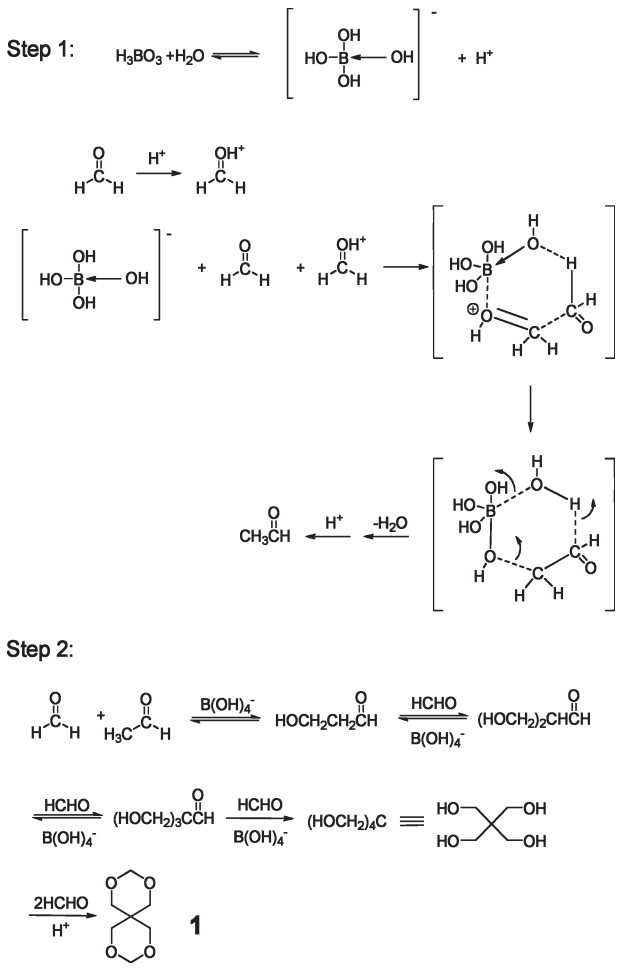
## RESULTS AND DISCUSSION

Compound **1** was successfully synthesized. The yield of the reaction was 0.4%. The proposed mechanism for the reaction is described in the Scheme 1.

In the first step (Step 1) of Scheme 1, boric acid hydrolyzes and reacts with formaldehyde which results in the protonation of formaldehyde and another molecule of formaldehyde to form acetaldehyde through a cyclic transition state. In the second step (Step2), this acetaldehyde molecule further undergoes a series of mechanistic steps, to form the product.

Many parameters influence this reaction pathway, *i.e.*, temperature, pH, presence of catalysts. We have found that with any change in anyone of the above described parameters, the reaction fails to occur. Moreover, all of these parameters facilitate the synthesis of **1**. We were interested to know the effect of temperature on our pathway. Hence, we performed the reaction below 100°C. Most interestingly, we found that temperature window of 80–90°C gives a series of small open chained oxygenated products like carbon dioxide, formic acid *etc*. Also, temperature exceeding 100°C, causes degradation and decomposition of the product, implying that the above described method to synthesize **1** is only feasible at 100°C. The presence of catalyst mixture (boric acid and kaolin) is also essential, which is mainly responsible for the condensation, cyclization and stabilization of the formaldehyde units. Similarly, the reaction time and pH are also critical factors for the reaction.

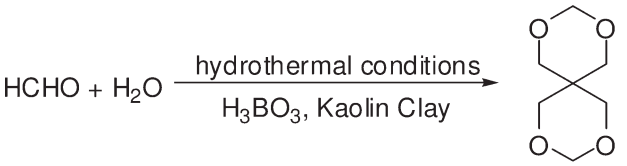
**Scheme 1.** Mechanism of reaction.



## EXPERIMENTAL

In our synthesis, 2 mL formaldehyde and 12 mL doubly distilled water [16] were added into each steel alloy (Fe-Cr-Ni, alloy GB1220-92) autoclaves with a filling capacity of 90% and recrystallized boric acid and kaolin clay (0.1 g each) were also added into the reaction mixture of each of the autoclaves. The final pH of the reaction mixture was nearly 3. The autoclaves were then sealed tightly and placed in the ovens at a temperature range from 100–200°C for 3 days. However, the reaction was successful at 100°C. After 3 days the autoclaves were taken out and analyzed.

The reaction can be written as follows:



## CHARACTERIZATION BY GC-MS

The product was identified and characterized by the GC-MS (Thermo Co.). Figure 1 shows the GC-MS of product as well as that of standard.

## CONCLUSIONS

As discussed above, in our synthesis, the presence of boric acid and kaolin was essential. Our experiment clearly proves that hydrothermal synthesis provides unique reaction pathways, which in other ways are very difficult to obtain [1,2]. Moreover, in similar ways, many other polymerization reactions can be obtained by utilizing simple precursors [2]. Also, we synthesized our product without using any harmful or expensive reagent.

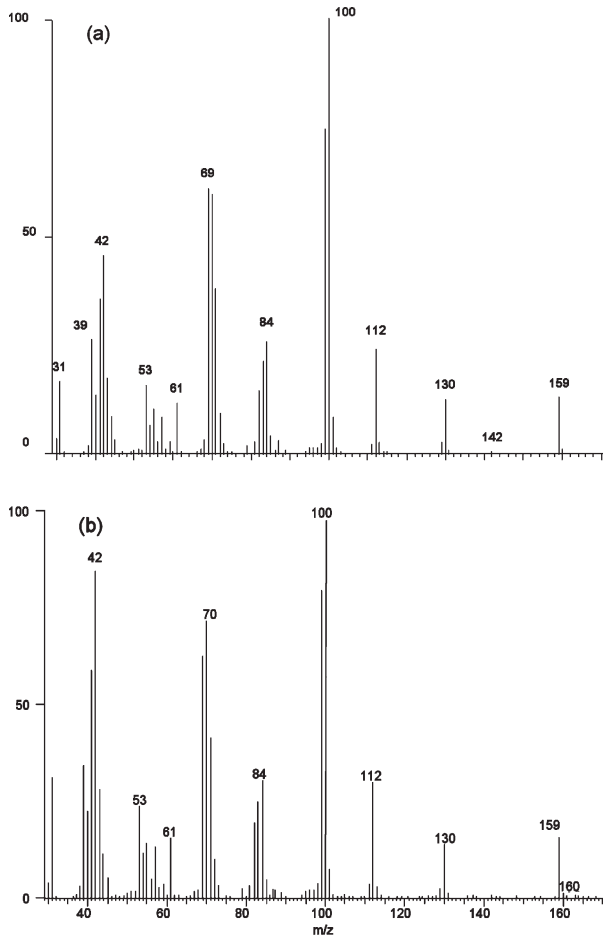


**Figure 1.** (a) Shows the GCMS of the standard (b) shows the GCMS of the product.

As we know that the progress of today's society depends on the synthesis and development of the advanced materials, which need consumption of energy as well as utilization of very toxic solvents and other chemicals. This all can play havoc with the environment and life. In addition, it is well known that our earth is a closed system with limited resources for use. This provokes an urge of recycling the materials in safest ways, *i.e*., to ensure maximum recycling at the expense of minimum energy.

Finally, our synthetic route to synthesize 1 clearly proves that hydrothermal routes of synthesis enjoy an important position in the field of synthetic chemistry and a very likely candidate for recycling of waste and conversion of industrial waste (like formaldehyde, carbon monoxide, carbon dioxide, *etc*.) into useful products and the most likely candidate to promote ''Green Chemistry''.

Cationic exchange resin has been utilized for the first time as a novel and recyclable heterogeneous catalyst for the synthesis of *N*-substituted pyrroles from variety of 1,4-diketones and aniline. This simple synthesis has been accomplished with excellent yields. The recovered catalyst can be reused for subsequent runs with only a gradual decrease in activity.

*J. Heterocyclic Chem.*, **47**, 486 (2010).

## INTRODUCTION

Pyrrole rings have great importance in organic chemistry as they can be found in several natural products [1], organic materials [2], and bioactive molecules [3]. Especially, substituted pyrroles present antibacterial [4], antiviral [5], anti-inflammatory, and antioxidant activities [6]. One of the most important approaches to pyrrole synthesis is the Paal–Knorr reaction, which involves the reaction of 1,4-dicarbonyl compounds and their masked equivalents with primary amines. Generally, the most used conditions include *p*-TsOH in toluene or benzene [7], AcOH/methanol [8], $TiCl_4$ in toluene [5a], $Ti(OPr)_4$ in benzene [9], $Bi(OTf)_3$/[bmim]$BF_4$ [10], $Bi(NO_3)_3$ in $CH_2Cl_2$ [11]. However, some of these methods often suffer from certain drawbacks, such as hazardous organic solvents, metals, and high costs. As the increase environmental consciousness in chemical research and industry, the challenge for a sustainable environment calls for clean procedures that can avoid using harmful organic solvents and metals. Therefore, the development of green and facile methods for the synthesis of pyrroles is desirable. Besides, on the other hand, reactions in water have recently attracted significant attention because water is a cheap, safe, and nontoxic solvent [12]. In addition, if aqueous reactions can be efficiently mediated by heterogeneous catalysts that can be recycled and reused, the result will be nearly ideal processes in terms of both greeness and simplicity [13]. Therefore, we wish to report a high-yielding and straightforward synthesis of *N*-substituted pyrroles using water as solvent and a cationic exchange resin as a recyclable heterogeneous catalyst.

## RESULTS AND DISCUSSION

In our initial investigation, the condensation of aromatic 1,4-dione (**5a**) with two equivalents of aniline was carried out in 1 *M* HCl aqueous at reflux for 24 h. To our surprise, it gave furan **5d** in 100% yield instead of

**Scheme 1.** Condensation of **5a** with 2 equivalents of aniline under different reaction conditions.

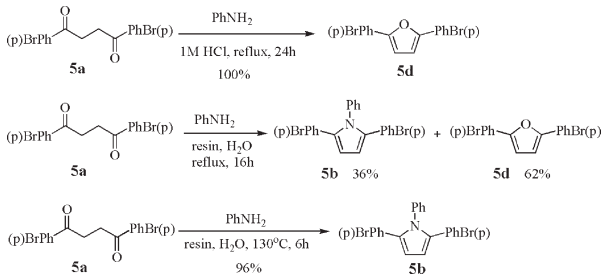

**Table 1**

Condensation of 1,4-diketones and aniline into pyrroles using cationic exchange resin in water.[a]

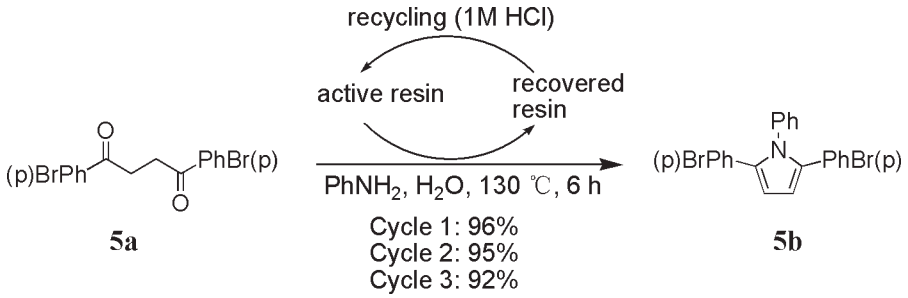
pyrrole **5b** (Scheme 1). Then, the reaction was performed in acidic Dowex 50 W × 8-200 (1.7 meq $mL^{-1}$) cationic exchange resin in water at reflux for 16 h, which provided pyrrole **5b** in 36% yield accompanied by furan **5d** in 62% yield. It suggested that the presence of cationic exchange resin can facilitate the pyrrole condensation, while 1 *M* HCl aqueous only catalyzed the formation of furan. To improve the reaction rate and to observe the effect of temperature on the condensation, the reaction was carried out in a sealed tube at increased temperature. Higher temperatures than 140°C led to thermal decomposition of the resin. We therefore set the reaction at

**Scheme 2.** Recovery of the cationic exchange resin for recycling and use in subsequent Paal–Knorr pyrrole synthesis.



130°C; the starting material **5a** was consumed in 6 h. We pleasurably found that the reaction exclusively provided the *N*-substituted pyrrole **5b** in excellent yield of 96%. It seems that the higher temperature favors the formation of pyrrole in the presence of resin in water.

Encouraged by this new finding, we further investigated the reaction by using wide range of diketone compounds. The condensation of substituted 1,4-diketones and aniline proceeded smoothly and gave the corresponding pyrroles in good to excellent yields in water in the presence of cationic exchange resin (Table 1). The reactions were carried out in sealed tubes at 130°C. In this manner, the reactions can be run as a batch in sealed tubes within an oven without stirring. The reactions were complete in 5–8 h, and the two equivalents of amine were used to afford a valuable increase of the yields. To assess the generality of the method, variety of 1,4-dicarbonyl compounds including aromatic and aliphatic, di- and tri-substituted 1,4-dicarbonyl compounds were subjected to the condensation with aniline to give the corresponding pyrrole derivatives. When the 1,4-diphenyl-1,4-diones (**3–6a**, entries 3–6) were used, The excellent yields of 94–96% were obtained. Triphenyl 1,4-dione (**8a**, entry 8) gave the best yield of 97%. Nevertheless, methyl substituted 1,4-diones (**1a** and **7a**, entries 1 and 7) provided the products in slightly decreased yields (85 and 87%, respectively). Although 1,4-di(thienyl)butane-1,4-dione (**2a**, entry 2) required longer reaction time, the product was received in excellent yield of 95%. Interestingly, when ethyl 2-acetyl-4-oxo-4-phenylbutanoate (**9a**, entry 9) was submitted to the reaction conditions described earlier, the corresponding ester substituted pyrrole **9b** was obtain in 56% yield, accompanied by decarboxylated product pyrrole **7b** in 34% yield.

Finally, to verify that the solid catalyst could be recycled, the resin was recovered from the condensation between **5a** and aniline by filtration, reactivated it by treatment with a small amount of 1 *M* HCl [13] and used it in subsequent cyclizations. The reaction was performed three times using the same resin, and only a small decrease in the isolated yield of **5b** was observed. (Scheme 2).

## CONCLUSION

In summary, a new catalytic protocol to synthesize pyrroles by Paal–Knorr condensation in water has been developed. Compared to previous reported methods, the present procedure avoids the use of metals and organic solvents, and instead employs cationic exchange resin as a cheap and readily available heterogeneous catalyst that is easily removed from the product mixture, which can be recycled and reused. This method has great potential for future application.

[19] Typical experimental procedure for the synthesis of N-substituted pyrroles. To a mixture of 1,4-diphenylbutane-1,4-dione (**6a**) (133 mg, 0.56 mmol) in $H_2O$ (3 mL) was added cationic exchange resin (1.63 g, Dowex 50 W $\times$ 8-200) and aniline (0.12 mL, 1.12 mmol). The reaction mixture was heated at 130°C in a sealed tube for 6 h within an oven without stirring. After cooling to room temperature, the catalyst was filtered off and washed with diethyl ether. The filtrate was extracted with diethyl ether. The combined extracts were washed with water, brine, dried ($Na_2SO_4$), and filtered. The solvents were removed and purified by flash chromatography (petroleum ether/$CH_2Cl_2$ 2:1) to give compound **6b** (155 mg, 94% yield), identical to that previously reported [16].

# Biological Importance of the Indole Nucleus in Recent Years: A Comprehensive Review

## INTRODUCTION

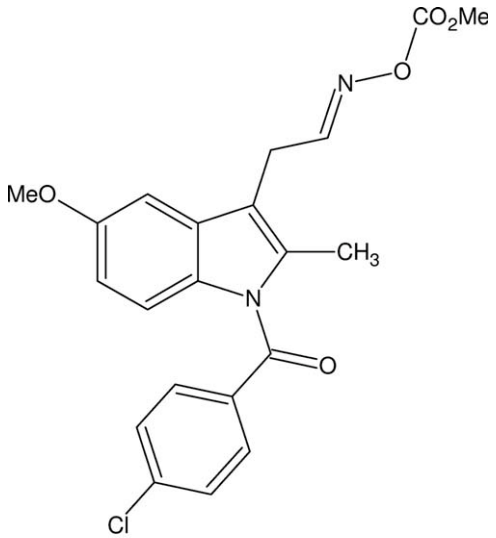
Heterocyclic compounds are those cyclic compounds in which one or more of the ring carbons are replaced by another atom. The non-carbon atoms in such rings are referred to as ''heteroatoms.'' Such bicyclic heterocyclic compounds containing pyrrole ring with benzene ring fused to α,β-position are known as Indoles. Indole has a benzene ring and pyrrole ring sharing one double bond. It is a heterocyclic system with 10 electrons from four double bonds and the lone pair from the nitrogen atom.

Indole is an important heterocyclic system because it is built into proteins in the form of amino acid tryptophan, because it is the basis of drugs like indomethacin and because it provides the skeleton of indole alkaloids—biologically active compounds from plants including strychnine and LSD.

The incorporation of indole nucleus, a biologically accepted pharmacophore in medicinal compounds (Table 1), has made it versatile heterocyclic possessing wide spectrum of biological activities (Table 2). In the present study, we have made an attempt to collect biological properties of imidazole nucleus reported in the new millennium.

## BIOLOGICAL ACTIVITIES OF INDOLE NUCLEUS

**Anti-inflammatory and analgesic activity.** Abele *et al*. synthesized isatin and indole oximes and carried out the chemical reactions and biological activities of the synthesized compounds where the compound (**1**) was found to be most active analgesic and anti-inflammatory agent [1].



**(1)**

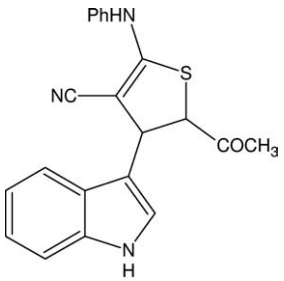
Radwan *et al*. carried out the synthesis and biological evaluation of 3-substituted indole derivatives as potential anti-inflammatory and analgesic agents. They reported 3-(3-indolyl) thiophene derivative (**2**) as a

**Table 1**

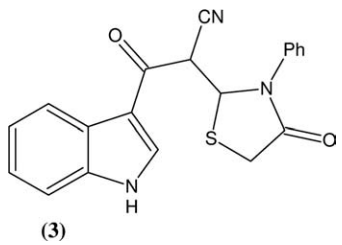
Various biological activities of compounds possessing indole nucleus are as follows.

| S. No. | Biological activities | References |
|---|---|---|
| 1. | Anti-inflammatory and analgesic | [1–5] |
| 2. | Antifungal | [1,6] |
| 3. | Antimicrobial | [7,8] |
| 4. | Insecticidal activity | [1,9] |
| 5. | Anticancer | [1,10–13] |
| 6. | 5-Lipoxygenase inhibitors | [14] |
| 7. | AntiHIV | [1,15] |
| 8. | Antioxidant | [16,17] |
| 9. | Antitubercular | [1,18] |
| 10. | Antiviral | [1] |
| 11. | Plant growth regulator | [1] |
| 12. | Antidepressant, tranquillizing, anticonvulsant | [1,19] |
| 13. | Cardiovascular activity | [1,20] |
| 14. | Antihypertensive | [1] |
| 15. | Antihistaminic | [21] |
| 16. | Opioid antagonist | [22] |
| 17. | Photochemotherapeutic activity | [23] |
| 18. | Antidiabetic activity | [24] |
| 19. | LXR receptor agonist | [25] |
| 20. | ACAT inhibitor | [26] |
| 21. | IL-1 inhibitors | [27] |
| 22. | $LTB_4$ production inhibitor | [28] |
| 23. | Steroid 5α-reductase inhibitor | [29] |
| 24. | Glycoprotein IIb\IIIa inhibitor | [30] |
| 25. | Thrombin catalytic activity | [31] |
| 26. | Peroxisome proliferator-activated receptor agonist | [32] |
| 27. | Cytosolic phospholipase A2α inhibitors | [33] |
| 28. | Galanine $GAL_3$ receptor antagonist | [34] |
| 29. | Selective CB2 receptor agonist | [35] |
| 30. | Selective dopamine agonist | [36,37] |

potent anti-inflammatory compound whereas thiazolidine-4-one derivative (**3**) exhibit analgesic activity [2].

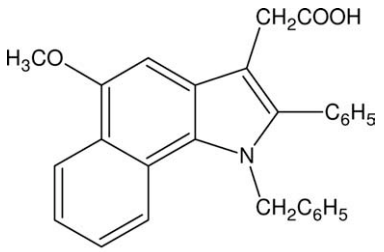


**(2)**



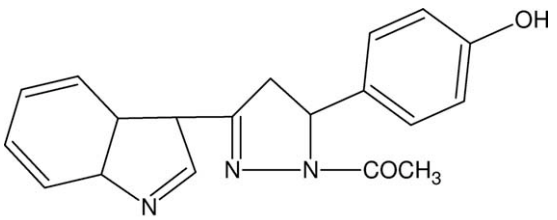
**(3)**

Kalaskar *et al*. synthesized indole-3-acetic acids and evaluated them for their *in vivo* anti-inflammatory activity. The compound 1,2-disubstituted-5-methoxyindole/benz(g)indole-3-acetic acid (**4**) showed significant activity [3].



**(4)**

The synthesis and anti-inflammatory activity of heterocyclic indole derivatives was performed by Rani *et al*. The compound **(5)** was found to be most potent (inhibition of oedema at 50 μg/Kg dose) [4].



**(5)**

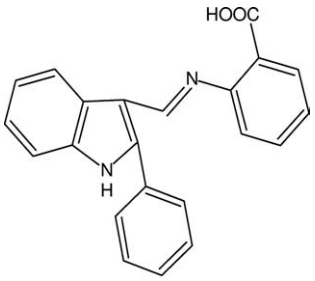
Amir *et al*. carried out synthesis and anti-inflammatory activity of various indole and indazole derivatives where the compounds 2-Phenyl-3-(2′-carboxyphenyliminomethyl)-

**Table 2**

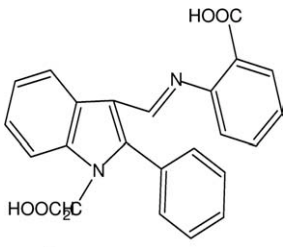
Importance of indole derivatives in medicinal chemistry.

| S.No. | Indole derivative | Biological activity |
|---|---|---|
| 1. | Indomethacin | Anti-inflammatory and analgesic |
| 2. | Fendosal | Analgesic |
| 3. | Etodolac | Antiarthritis |
| 4. | Sumatriptan | Antimigraine |
| 5. | Besipirdine | Nootropic |
| 6. | Noratriptan | CNS stimulant |
| 7. | Pindolol | Antihypertensive |
| 8. | Indolmycin | Antibiotic |
| 9. | Indigo carmine | As a dye in functional kidney test and in milk testing |
| 10. | Adrenochrome | Hemostatic |

indole (**6**) and 2-phenyl-3-(2′-carboxyphenyliminomethyl)-indol-1-acetic acid (**7**) were found to be most potent [5].

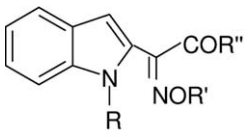


**(6)**



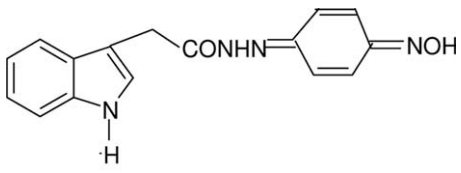
**(7)**

**Antifungal activity.** Some of the isatin and indole oximes synthesized by Abele *et al*. were found to be exhibiting high fungicidal activity where the oxime derivates of 2-substituted indoles **(8)** and 3-substituted indoles **(9)** demonstrated significant antifungal activity [1].



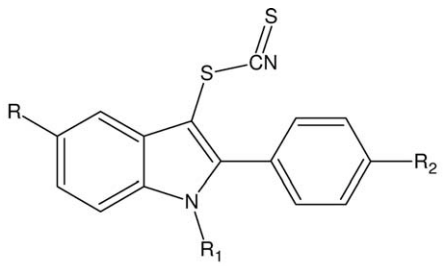
R,R' = Alkyl
R'' = OAlk, SAlk, NHAlk, NAlk

**(8)**



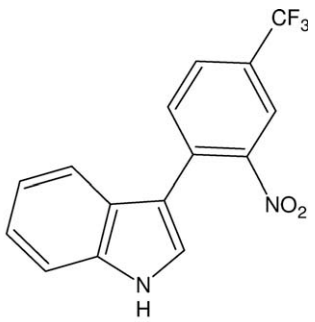
**(9)**

A series of S-(indolyl-3)diethyl dithiocarbamates was synthesized and evaluated for their activity by Skii *et al*. The compounds (**10a–e**) were found to be exhibiting highest antifungal activity [6].



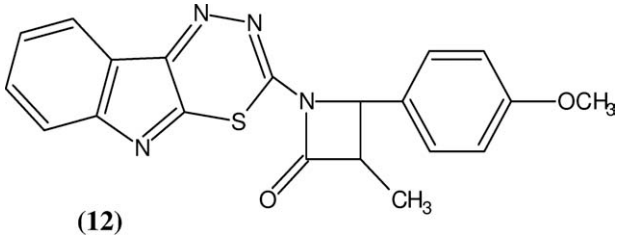
**10a:** R= $R_1$ = $R_2$ = H
**10b**: R = H, $R_1$ =$CH_2$Ph
**10c**: R = $R_2$ = H, $R_1$ = Ph
**10d**: R = $R_1$ = H, $R_2$ = Br
**10e**: R = $R_2$ = Br, $R_1$ = H

**Antimicrobial activity.** The synthesis and antibacterial activity of some substituted 3-(aryl) and 3-(heteroaryl) indoles were reported by Hiari *et al*. The most active compound was reported to be 3-(4-trifluoromethyl-2-nitrophenyl) indole **(11)** exhibiting MIC $\approx$ 7 μg/$cm^3$ against *Escherichia coli* and *Staphylococcus aureus* [7].

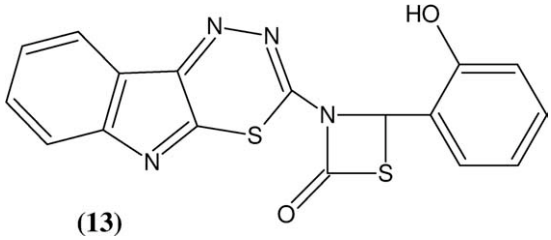


**(11)**

Panwar *et al*. synthesis substituted azetidonyl and thiazolidinonyl-1,3,4-thiadiazino[6,5-b]indoles as prospective antimicrobial agents. The compounds (**12**) and (**13**) were found to exhibit most inhibitory effect against *E. coli* and *S. aureus* [8].

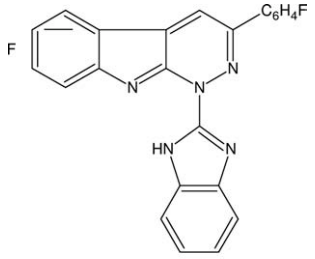


**(12)**

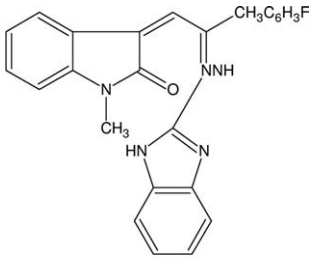


**(13)**

**Insecticidal activity.** Sharma *et al*. investigated the insecticidal activity of synthesized novel indole derivatives. The compounds **(14)** and **(15)** exhibited promising results against *Spodoptera liture* (eighth instar larvae) and *Jeliothis armigera* [9].

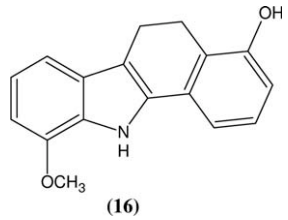


**(14)**

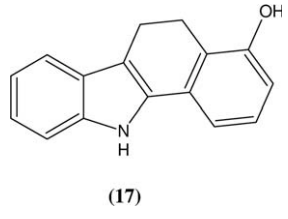


**(15)**

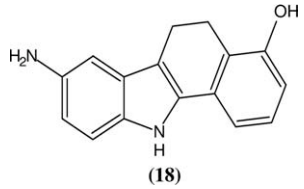
**Anticancer activity.** The series of various tricyclic and tetracyclic indoles synthesized by Hong *et al*. were evaluated for their anticancer activity where the compounds **16, 17, 18,** and **19** were found to exhibit highest *in vitro* activity against human nasopharyngeal carcinoma (HONE-1) and gastric adenocarcinoma (NUGC-3) cell lines [10].



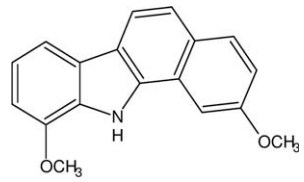
**(16)**



**(17)**

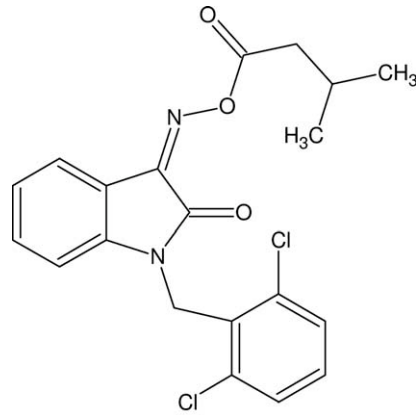


**(18)**



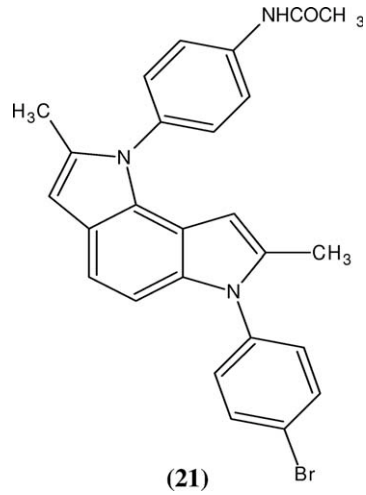
**(19)**

The compound **(20)** synthesized by Abele *et al*. was reportedly showing highest anticancer activity [1].



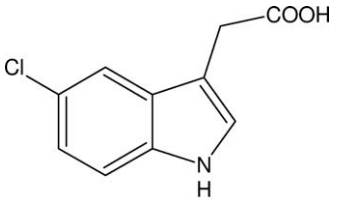
**(20)**

Garcia *et al*. synthesized pyrrolo[2,3-e] indole derivatives and evaluated them for possible *in vitro* cytotoxic activity. The most active compound was found to be (**21**), which shows best result in PC-3 (prostate) cell line [11].



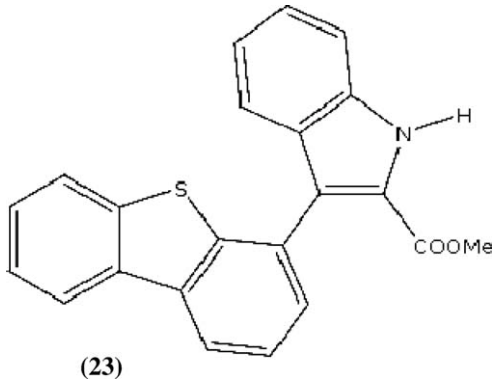
**(21)**

A series of halogenated indole-3-acetic acids as oxidatively activated prodrugs with potential for targeted cancer therapy were reported by Rossiter *et al*. These derivatives were oxidized by horse radish peroxidase (HRP) and toxicity against V79 Chinese hamster lung fibroblasts was determined and the compound (**22**) was found to possess highest cytotoxicity and it was the best drug for targeted cancer therapy [12].



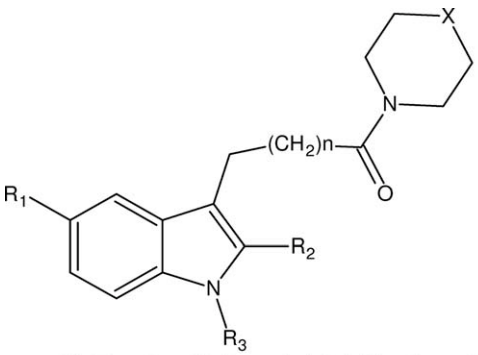
**(22)**

Queiroz *et al*. studied the inhibitory activity of the heteroarylindoles and of the phenylbenzothienoindole on the growth of human tumor cell lines, MCF-7 (breast adenocarcinoma), NCI-H460 (non-small cell lung cancer), and SF-268 (CNS cancer). The results showed that the methyl 3-(dibenzothien-4-yl)indole-2-carboxylate (**23**) had most potent growth inhibitory activity in all the tumor cell lines tested (with $GI_{50}$ values ranging from11 to 17 μ*M*) [13].



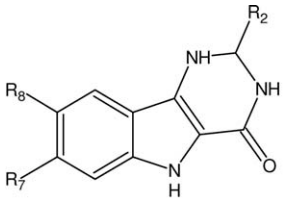
**(23)**

**Lipoxygenase inhibitor.** Zheng *et al*. synthesized a series of indole derivatives as possible 5-lipoxygenase inhibitors. In all, four compounds **24, 25, 26,** and **27** exhibited the most potent inhibitory activity with $IC_{50}$ values ranging from 0.74 μ*M* to 3.17 μ*M* [14].

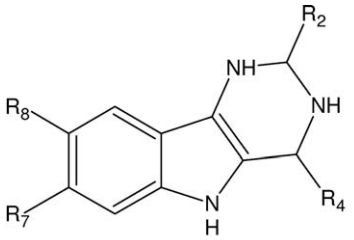


**24**: $R_1 = R_2 = H$, $R_3$ = 3, 4-Dichlorobenzyl, X = O, n = 0
**25**: $R_1$ = Cl, $R_2 = CH_3$, $R_3$ = Benzyl, X = O, n = 2
**26**: $R_1 = R_2 = R_3 = H$, X = BocN, X = O, n = 2
**27**: $R_1 = R_2 = H$, $R_3$ = Benzyl, X = NH, n = 2

**HIV inhibitors.** The analogs of pyrimido[5,4-b]indoles were synthesized and biologically evaluated by Merino *et al*. for their possible HIV inhibitory activity. The derivative **(28)** formed by substitution at position 2 in analog-I and derivative **(29)** at position 2, 4 in analog II (formed in 65% and 64% maximum yield) were reported to be the inhibitors of wild and mutant HIV-1 RT types in an ''*in vitro*'' recombinant HIV-1 RT screening assay as well as anti-infectives in $HLT4lacZ\text{-}1_{IIIB}$ cells [15].



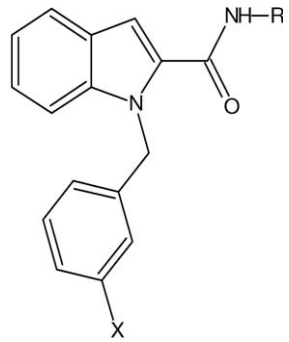
**Analog I**
**28**: $R_2$ = methyl-N-[4-(2′-methoxyphenyl)]piperazinyl, $R_7 = R_8 = H$



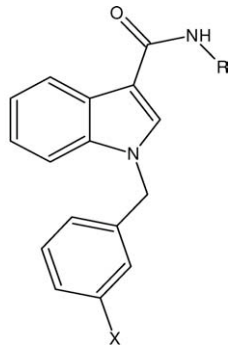
**Analog II**
**29:** $R_2$ = 2′-pyridyl, $R_4$ = N-morpholinyl, $R_7 = R_8 = H$

**Antioxidant activity.** A series of indole derivatives were synthesized and biologically evaluated by Enien *et al*., and found that Indole-2 and 3-carboxamides were having antioxidant properties by Chemoluminesence and Electron spin resonance spin trapping. They further reported that the derivatives **30** and **31** have strongest scavenging effect on $OH^-$ radicals, *i.e*., quenching >30%

and the derivatives **31** and **32** have strongest effect on scavenging of superoxide radicals [16].

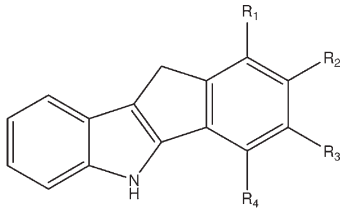


Indole-2-carboxamide
**30**: X=H, R=Phenyl



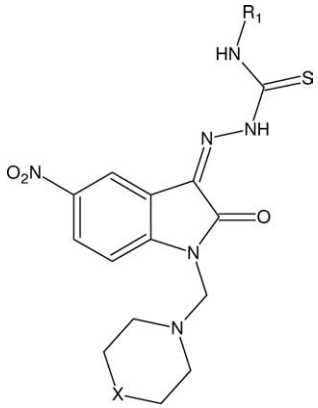
Indole-3-carboxamide
**31:** X=H, R=Thiazolyl
**32:** X=F, R=Thiazolyl

Talaz *et al*. described the synthesis of 5,10-dihydroindeno[1,2-b]indoles containing substituents such as methoxy, hydroxyl, and halogen (F, Cl, and Br) on indeno part and their antioxidant activity and radical scavenging activities were assessed by various *in vitro* assays and compared with the activities of synthetic and standard antioxidant compounds. The compounds **(33)** and **(34)** were found to have maximum $Fe^{3+}$–$Fe^{2+}$ reducing ability whereas compound **(35)** was found to have maximum $Cu^{2+}$–$Cu^{+}$ reducing ability [17].

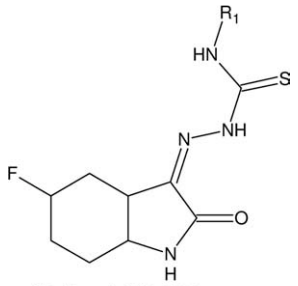


**33**: $R_1$=OMe, $R_2$= H, $R_3$= H, $R_4$= OMe
**34**: $R_1$=OH, $R_2$= OH, $R_3$= H, $R_4$= H
**35**: $R_1$=OH, $R_2$= H, $R_3$= H, $R_4$= OH

**Antituberculosis activity.** A new series of 1H-indole-2,3-dione derivatives were synthesized and evaluated for *in vitro* antituberculosis activity against *Mycobacterium tuberculosis* H37Rv by Karali *et al*. Among the tested compounds, 5-nitro-1H-indole-2,3-dione-3-thiosemicarbazones and its 1-morpholinomethyl (**36, 37, 38,** and **39**) derivatives exhibited significant inhibitory activity with MIC values $\geq$ 75% [18].

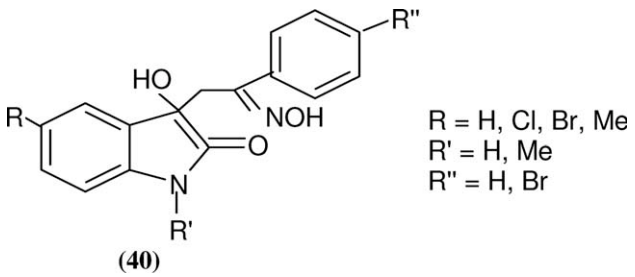


**36:** $R_1 = CH_3$
**37:** $R_1 = C_6H_5$
**38:** $R_1 = 4\text{-}CH_3C_6H_4$



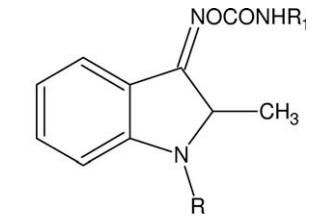
**39:** $R_1 = 4\text{-}CH_3C_6H_4$

Among the series of isatin and indole oximes synthesized and evaluated by Abele *et al*., the highest broad spectrum antibacterial activity was exhibited by oxime derivatives of 2-indolinone **(40)** against *M. tuberculosis* [1].



**(40)**

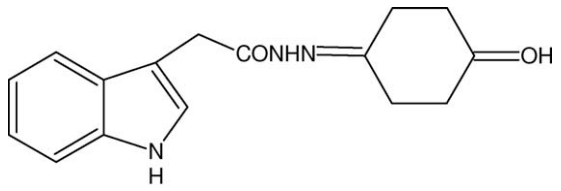
**Antiviral activity.** The indole oxime, carbamoyl derivative of indole-3-oxime **(41),** exhibited the most potent antiviral activity among the isatin and indole oximes synthesized by Abele *et al*. [1].



**(41)**

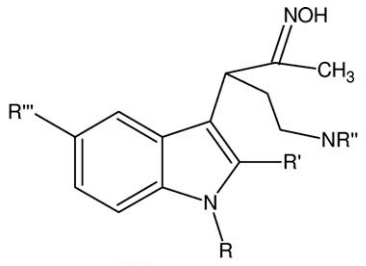
R = H, methyl, ethyl
$R_1$ = methyl, phenyl

**Plant growth regulator.** The 3-substituted indole **(42)** was reported to be a plant growth regulator by Abele *et al*. among the various isatin and indole oximes synthesized and evaluated by them [1].



**(42)**

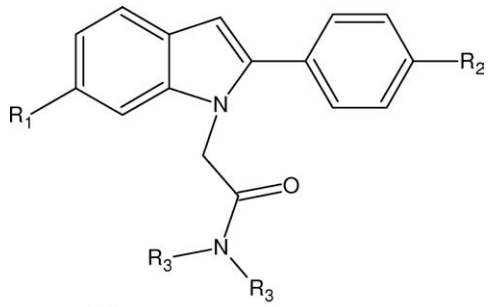
**Antidepressant, tranquillizing, and anticonvulsant activity.** The oxime of indole aminoketone **(43)** exhibited high antidepressant activity among the isatin and indole oximes synthesized and evaluated for their biological activity by Abele *et al*. [1].



**(43)**

R = H R' = H, methyl R'' = methyl, ethyl R''' = H, Cl, OMe

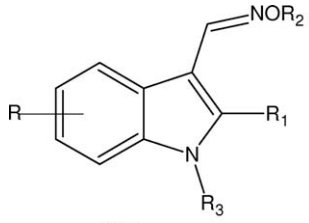
A series of N-substituted indoles were synthesized by Falco *et al*., and afterwards, *in vitro* screening and *in vivo* spontaneous motor activity in mice had revealed molecules with good *in vitro* affinities for the $\alpha_1$-subunit of $GABA_A$ receptor and potent *in vivo* induction of sedation and **(44)** was found most potent compounds [19].



**(44)**

$R_1 = R_2$ = methyl, $R_3$ = propyl

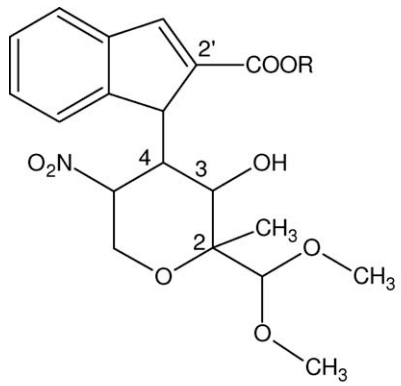
**Cardiovascular activity.** The isatin oxime **(45)** exhibited the highest antiarrhythmic activity among the isatin and indole oximes synthesized by Abele *et al*. [1].



**(45)**

R = H, Alkyl, OH, Halogen, $NO_2$, $NH_2$
$R_1$ = Halogen, OH, SH, $NH_2$
$R_2$ = H, Alkyl, Ar
$R_3$ = H

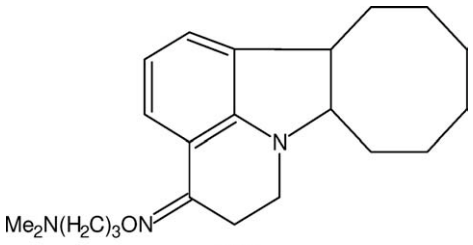
A number of benzopyranyl indoline and indole analogs were synthesized and evaluated for Cardioselective anti-ischemic ATP-sensitive potassium channel ($K_{ATP}$) opener activity by Lee *et al*. The compounds **(46)** and **(47)** showed the best cardioprotective activity [20].



**46**: (2-S, 3-R, 4-S, 2'-S) = R= Ethyl
**47**: (2-R, 3-S, 4-R, 2'-R) = R= Ethyl

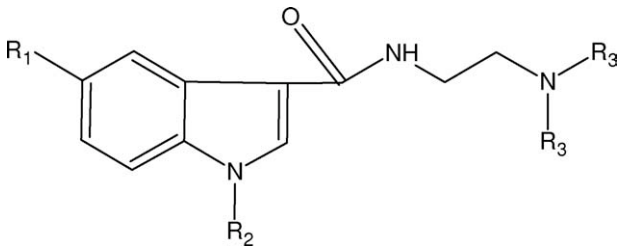
**Antihypertensive activity.** Among the various isatin and indole oximes reported by Abele *et al*., compound

(**48**), a tetracyclic derivatives of indole oximes, was found to have hypotensive activity lowering the blood pressure in rats by 28% [1].



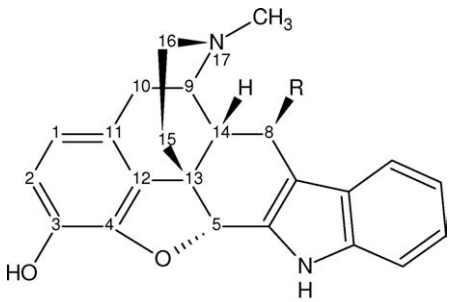
**(48)**

**Antihistaminic activity.** A number of indole amide derivatives bearing a side chain, in which the indole ring replaces the isoster benzimidazole nucleus typical of some well known antihistamines, were prepared and tested for the antihistaminic activity by Battaglia *et al*. The most active compounds **49, 50, 51, 52, 53,** and **54** were tested *in vivo* for their ability to antagonize histamine induced cutaneous vascular permeability in rats [21].



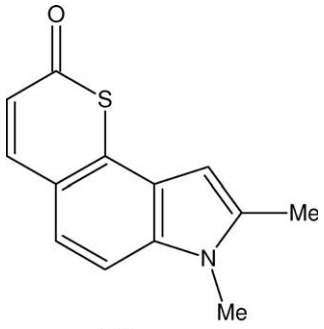
| Compound No. | $R_1$ | $R_2$ | $R_3$-N-$R_3$ |
|---|---|---|---|
| **49** | H | $CH_2C_6H_5$ | $CH_3/CH_3$ |
| **50** | H | $CH_2C_6H_5$ | Piperidine |
| **51** | H | $CH_2C_6H_4$-p-F | $CH_3/CH_3$ |
| **52** | H | $CH_2C_6H_4$-p-F | Piperidine |
| **53** | H | $CH_2C_6H_4$-p-Cl | $CH_3/CH_3$ |
| **54** | H | $CH_2C_6H_4$-p-Cl | Piperidine |

**Opioid antagonist.** The synthesis and biological activity of 8β-substituted hydromorphone indole derivatives were carried out by Yu *et al*. The compound 6,7-dehydro-4,5α-epoxy-8β-methyl-6,7,2′,3′-indolomorphinan **(55)** was found to be a δ antagonist with submolar affinity (0.7 n*M*) for the opioid receptor, and to have good δ-selectivity (μ/δ = 322 n*M*) [22].



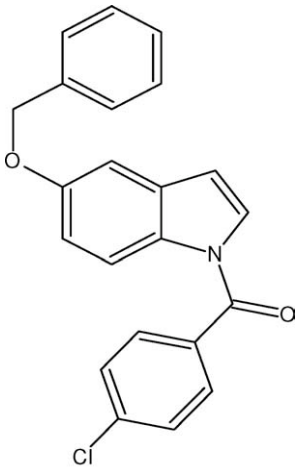
**(55)**

**Photochemotherapeutic activity.** The synthesis and photochemotherapeutic activity of thiopyrano[2,3-e]indol-2-ones was performed by Barraja *et al*., wherein the compound thiopyrano[2,3-e]-indol-2-ones **(56)** showed the maximum phototoxicity on two cultured cell lines: HL-60 and LoVo [23].



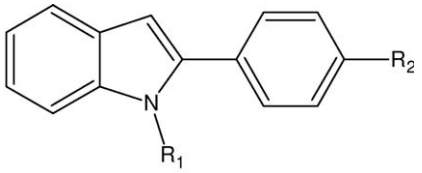
**(56)**

**Antidiabetic activity.** Some of the indole derivatives were evaluated for their insulin sensitizing and glucose lowering effects by Li *et al*. The indole derivative **(57)** showed increase in activity of PPARγ agents, which shows decreased serum glucose and contributing to antidiabetic activity [24].



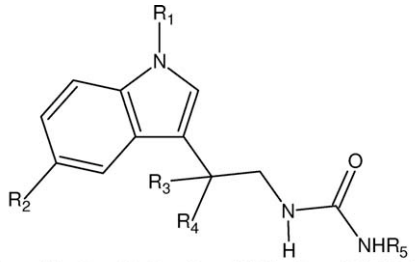
**(57)**

**LXR receptor agonist.** A series of 2-Aryl-*N*-acyl indole derivatives was synthesized and biologically evaluated as liver X receptor (LXR) agonists by Kher *et al*. The compound **(58)** was found to be most active with $EC_{50} = 0.012$ μ*M* [25].



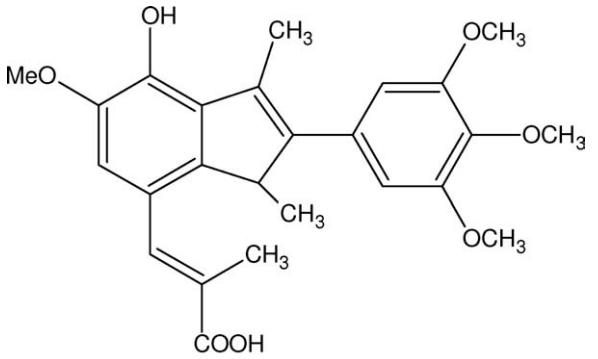
**(58)**
$R_1 = COPh$, $R_2 = (CH_2)_2CN$

**ACAT inhibitors (hypocholestrolemic activity).** The indole derivatives synthesized by Bellemin *et al*., were evaluated for their hypocholestrolemic activity. The compounds **(59)** and **(60)** were found to be most effective ACAT inhibitor with $ED_{25}$ values of 0.098 and 0.063 mg/Kg, respectively [26].



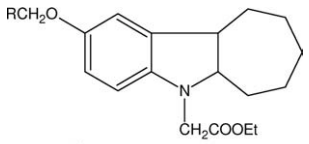
**(59):** $R_1 = CH_3$, $R_2 = H$, $R_3 = R_4 = (CH_2)_4$, $R_5 = 2,6\text{-}(i\text{-}Pr)_2C_6H_3$
**(60):** $R_1 = (CH_3)_2N(CH_2)_2$, $R_2 = H$, $R_3 = R_4 = (CH_2)_4$, $R_5 = 2,6\text{-}(i\text{-}Pr)_2C_6H_3$

**IL-1 inhibitors.** Among the series of hydroxyindole derivatives synthesized and evaluated for IL-1 generation inhibitors by Tanaka *et al*., the compound **(61)** was found to be potent inhibitors of IL-1 generation with IL-1α = 6.4 μ*M* and IL-2 = 8.6 μ*M* [27].

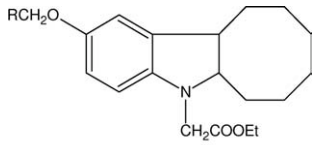


**(61)**

**$LTB_4$ production inhibitor.** The compounds **(62)** and **(63)** exhibited the highest inhibitory activity against $LTB_4$ production among the series of novel thiopyrano[3,2-b] and cycloalkeno[1,2-b]indole derivatives synthesized and evaluated by Caubere *et al*. [28].

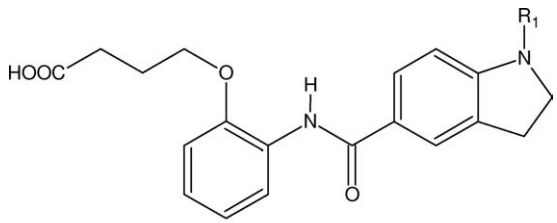


**(62)**
R = 2-quinolyl

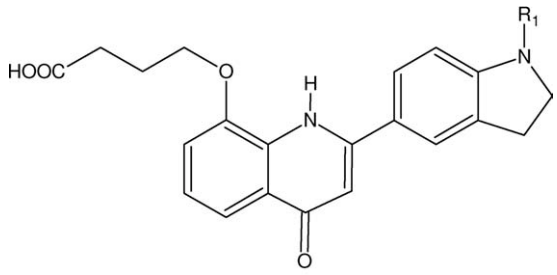


**(63)**
R = 2-quinolyl

**Steroid 5α-reductase inhibitor.** A class of indole and benzimidazole derivatives were synthesized and evaluated for their inhibitory activity against rat prostatic 5α-reductase by Takami *et al*. The compounds **(64)** and **(65)** were found to be showing most potent inhibitory activity against rat prostatic 5α-reductase with $IC_{50} = 9.6 \pm 1.0$ n*M* and $19 \pm 6.2$ n*M*, respectively [29].

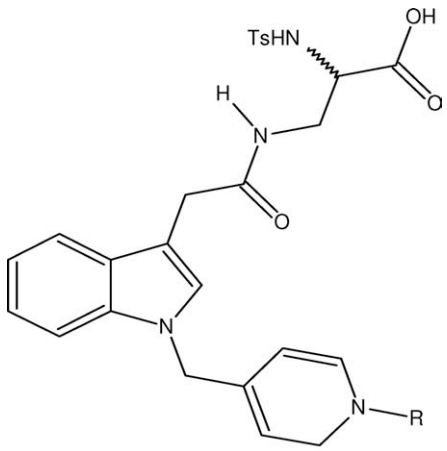


**(64)**
$R_1$ = 4, 4′-dipropylbenzhydryl



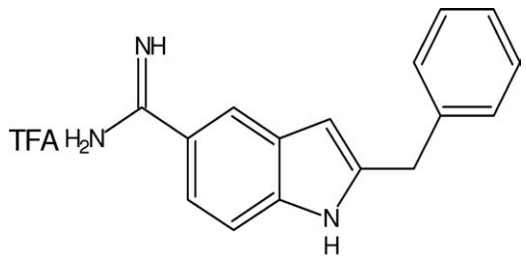
**(65)**
$R_1$ = 4-isobutyl-α-methylbenzyl

**Glycoprotein IIb\IIIa inhibitors.** Grumel *et al*. synthesis 1,3-disubstituted indole derivatives as glycoprotein IIb/IIIa antagonists wherein the compound **(66)** was found to exhibit highest Glycoprotein IIb/IIIa inhibitory activity with $IC_{50} = 4.5$ μ*M* [30].



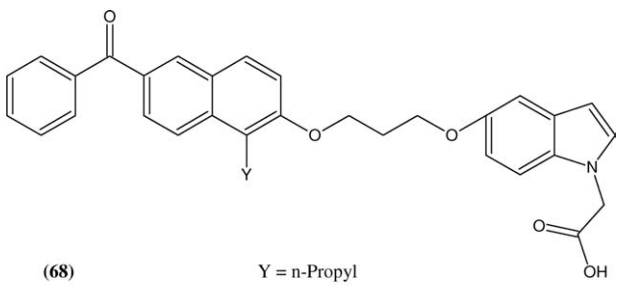
**(66)**
R = H, HCl

**Thrombin catalytic activity.** The substituted 5-amide indoles were evaluated as inhibitors of thrombin catalytic activity by Iwanowicz *et al*. The compound **(67)** was found to be the most potent inhibitor of thrombin catalytic activity with an inhibition constant, $K_i = 260$ n*M* [31].



**(67)**

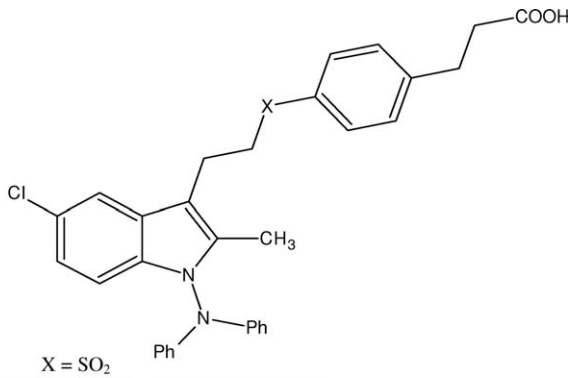
**Peroxisome proliferator-activated receptor agonist.** A series of indole based PPAR agonist were synthesized and biologically evaluated by Mahindroo *et al*. [32]. The compound **(68)** was found to be most potent PPAR agonist with $IC_{50} = 0.050$ μ*M* and $EC_{50} = 0.070$ μ*M*.



**(68)** Y = n-Propyl

**1.2.27 Cytosolic Phospholipase A2α inhibitors**

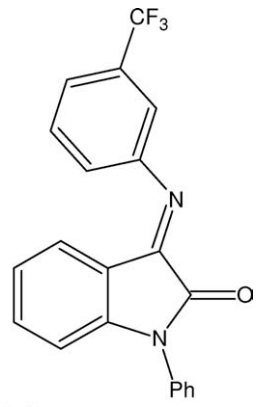
**Cytosolic phospholipase A2α inhibitors.** The potential of indole nucleus as Cytosolic Phospholipase A2α inhibitors was evaluated by Mckew *et al*. The compound **(69)** was found to be most potent $IC_{50} = 0.5$ μ*M* in the GLU assay and $IC_{50} = 0.8$ μ*M* in the rat whole blood assay [33].



**(69)** X = $SO_2$

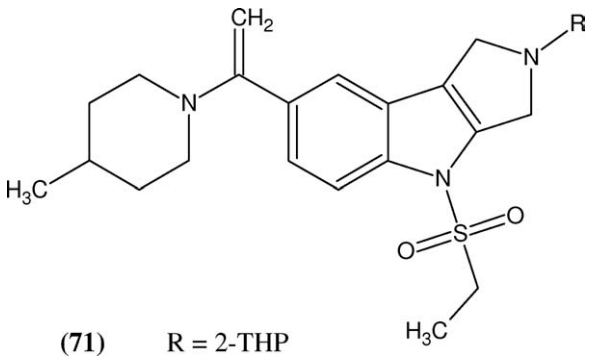
**1.2.28 Galanine $GAL_3$ receptor antagonist**

**Galanine $GAL_3$ receptor antagonist.** A series of 3-arylimino-2-indolones were reported to be as Galanine $GAL_3$ receptor antagonists by Konkel *et al*. The compound **(70)** was found to be most potent antagonist with $K_b = 29$ n*M* [34].



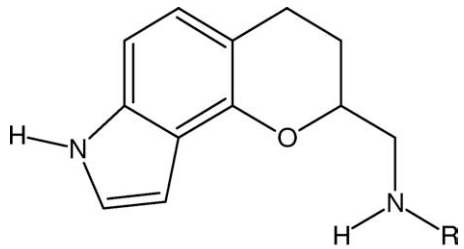
**(70)**

**Selective CB2 receptor agonist.** The preparation and evaluation of a class of CB2 receptor agonist based on a 1,2,3,4-tetrahydropyrrolo[3,4-b] indole moiety were reported by Page *et al*. The compound **(71)** showed to be most potent CB2 receptor agonist [35].



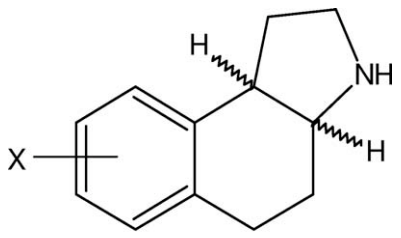
**(71)** R = 2-THP

**Selective dopamine agonist.** A series of 2-(aminomethyl)-3,4,7,9-tetrahydro-2H-pyrano[2,3-e]indole and indole-8-one derivatives were synthesized and evaluated by Mewshaw *et al*. The compound **(72)** was found to be most potent agonist [36].



**(72)** R = Benzyl

The class of cis- and trans-2,3,3a,4,5,9b-hexahydro-1H-binz[e]indoles synthesized by Song *et al*. were evaluated for dopamine $D_2$ and $D_3$ receptor binding affinity. The cis-diastereoisomer **(73)** was found to be more potent among the synthesized compounds [37].



**(73)** X = 8-OH

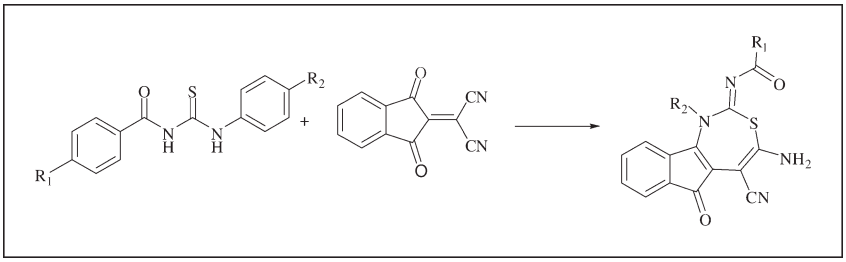
Published online 31 March 2010 in Wiley InterScience (www.interscience.wiley.com).



The reaction between *N*-aroyl-*N*′-arylthioureas with 2-(1,3-dioxoindan-2-ylidene)malononitrile furnished indeno[1,2-*d*][1,3]thiazepines in 70–85% yields. The mechanism of the products' formation is discussed. Some of the products showed effective antitumor and antioxidant activities. The results revealed that compound indenothiazepine derivative showed a high inhibition of the cell growth of Hep-G2 cells is compared with the growth of untreated control cells, as concluded from their low $IC_{50}$ value 21.73 μ*M*. On the other hand, two indenothiazepine derivatives have an effective antioxidant activity with $SC_{50}$ values of 62.5 m*M* and 87.4 m*M*, respectively.

*J. Heterocyclic Chem.,* **47**, 503 (2010).

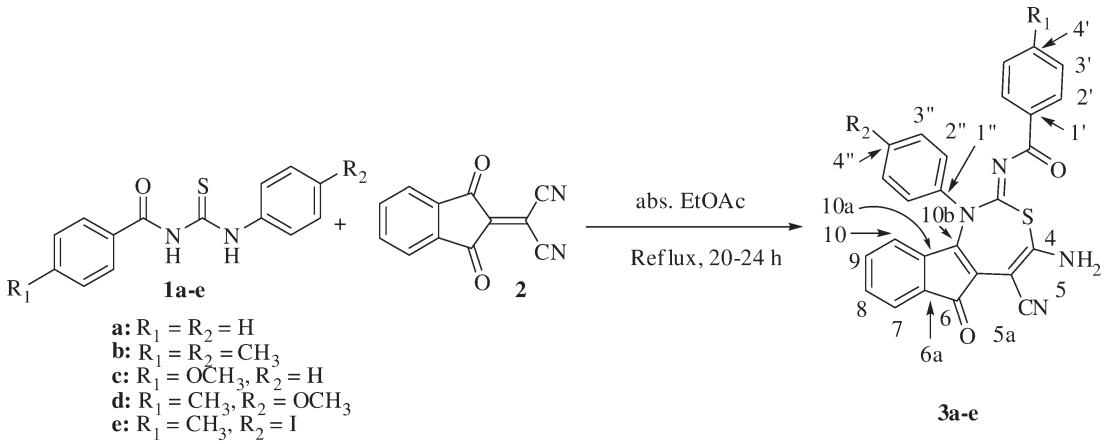
## INTRODUCTION

The importance of *N*-aroyl-*N*′-arylthioureas is found largely in heterocyclic syntheses. Many of these substrates have interesting biological activities and are used as a rich source for materials for development of agrochemical and pharmaceutical products [1]. Additionally, it was known that the reaction of amidinothioureas, imidoylthioureas, thioacylamidines, amidino-thioureas, *o*-methyl-1-aryl-2-thioisobiurets, and 1-aryl-isodithiobiurets with diethyl azodicarboxylate gave the corresponding thiadiazoles by the oxidative cyclic S—N bond formation [2]. A series of 3-alkyl-5-methylene-2-arylimino-1,3-thiazolidin-4-ones were obtained from the reaction of *N*-alkyl-*N*′-arylthioureas with dimethyl but-2-ynedioate [3]. Hyrazino-thioureas, such as 1-acylthiosemicarbazides reacted with phenyl propiolate in acetic acid under reflux to afford triazolothiazines [3]. In light of the aforementioned, it appears that the reaction pathways of substituted thioureas vary from one reagent to another. Our synthetic program uses cycloadditions as efficient methods of preparation of novel heterocycles, rather than those suffering from low yields because of the multiple steps described in their preparation [4]. Aly *et al*. [5] reported the synthesis of a series of 1,3-thiazines by the reaction of *N*-aroyl-*N*′-substituted thioureas with ethyl propiolate, dimethyl but-2-ynedioate, and (*E*)-1,4-diphenyl-but-2-ene-1,4-dione. Herein we report on our findings for the synthesis of various novel thiazepines, during the reaction of various *N*-aroyl-*N*′-aryl-thioureas **1a–e** [6] with 2-(1,3-dioxo-1*H*-inden-2(3*H*)-ylidene)-malononitrile (**2**).

## RESULTS AND DISCUSSION

**Chemistry.** Scheme 1 outlines the reaction of **1a–e** with **2** in dry ethyl acetate under $N_2$ atmosphere. The

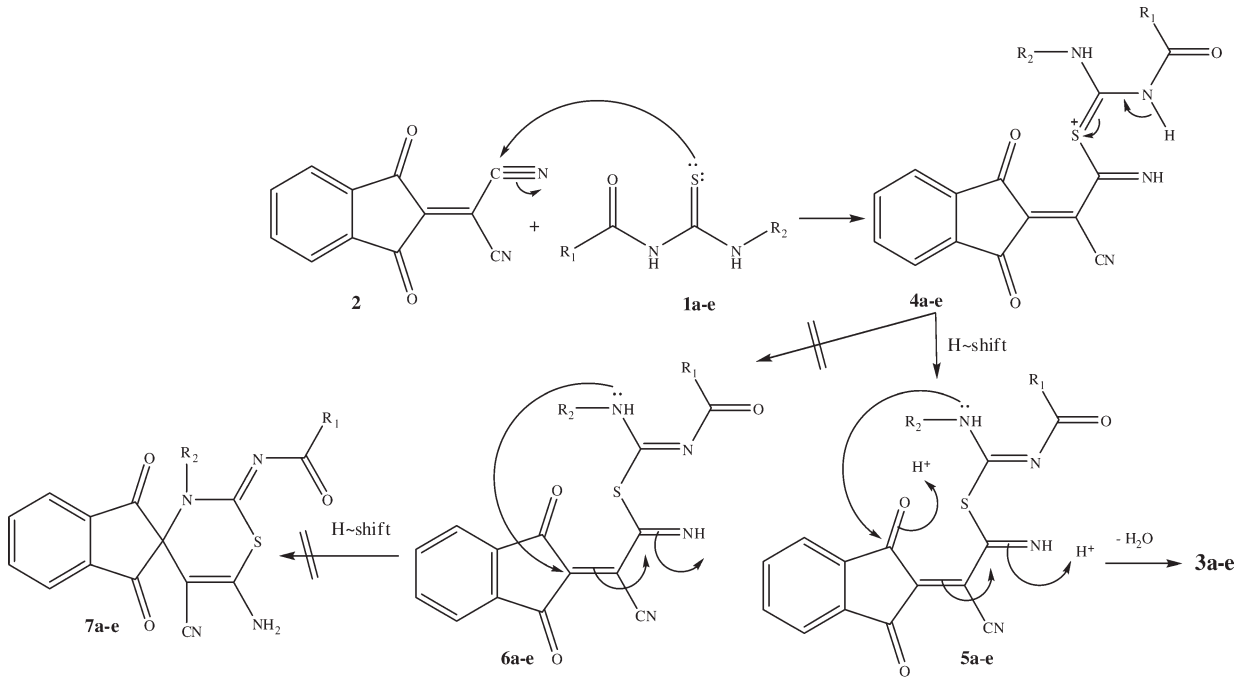
**Scheme 1.** Reactions of aroyl thioureas **1a–e** with **2**; synthesis of (*Z*)-*N*-((*E*)-4-amino-1-aryl-5-cyano-6-oxo-1*H*-indeno[1,2-*d*][1,3]thiazepin-2(6*H*)-ylidene)-4-arylamides **3a–e**. **3a**: 75%; **3b**: 80%; **3c**: 85%; **3d**: 82%; **3e**: 70%.



reaction proceeded to yield, after chromatographic purification and recrystallization, compounds **3a–e** (70–85%). We chose *N*-aroyl-*N*′-arylthioureas **1a–e** having aryl groups with electron donating and withdrawing substituents on the benzene ring to examine their effect on the course of reaction. The structure of **3a–e** was established on the basis of mass, IR, $^{1}$H NMR, $^{13}$C NMR spectra, and elemental analyses. Mechanistically, the formation of compounds **3a–e** can be explained as because of addition of the sulfur atom nonbonded pair of **1a–e** to the nitrile group in **2** (Scheme 2). The formed intermediate **4** undergoes a hydrogen shift to give **5**. Cyclization then occurs *via* addition of the NH lone-pair to the carbonyl group, followed by elimination of water, to give the stable heterocyclic compounds **3a–e**. The NMR spectra excluded the formation of *spiro*-indolothiazines **7a–e**, but all the data are consistent with indeno[1,2-*d*][1,3]thiazepines **3a–e** (Scheme 2).

Compounds **3a–e** show IR absorptions at $\nu = 3120–3350$, 2222–2200, 1733–1665, and 1649–1595 cm$^{-1}$ corresponding to the $NH_2$, nitrile, carbonyl, and azomethine groups, respectively. The spectra are strikingly similar: clearly the products are of the same general type, and share some substructures. The spectra show

**Scheme 2.** Suggested mechanism of the reaction of **1a–e** with **2**.



local symmetry only in the aryl rings, which can apparently rotate about their axes; the indanedione-derived substructures show individual signals for each proton and each carbon, requiring these substructures to lack the plane of symmetry present in **2** and the alternative products **7a–e**. Each $^1$H NMR spectrum showed a broad, 2H signal near $\delta_H = 8.20$ ppm, which gives no heteronuclear multiple quantum coherence (HMQC) or heteronuclear single quantum coherence (HSQC) correlation, suggesting that these protons are not attached to carbon. In **3e**, the *p*-tolyl C—$CH_3$ group is distinctive at $\delta_H = 2.31$ and $\delta_C = 21.2$ ppm. The proton signal at $\delta_H = 2.31$ ppm gives heteronuclear multiple bond correlation correlation (HMBC) correlation with one of the signals at $\delta_C = 143.3$ ppm, which is assigned as C-4′. The C—$CH_3$ $^1$H signal gives COSY correlation with $\delta_H = 7.21$ ppm, and C-4′ gives HMBC correlation with $\delta_H = 7.69$ ppm; these correlations suggest that $\delta_H = 7.21$ and 7.69 ppm are H-3′ and H-2′, respectively. These signals showed HMQC correlation with $\delta_C = 129.0$ and 129.3 ppm, respectively. The *p*-toluamide carbonyl at $\delta_C = 175.2$ ppm gives HMBC with $\delta_H = 7.69$ but not 7.21 ppm, which is consistent with the foregoing. The spectra of **3b** contain signals identical to those just described within $\delta_H = 0.02$, $\delta_C = 0.07$ ppm, and $J = 0.1$ Hz; these signals are assigned to the toluamide substructure of **3b**. In the HMBC spectrum of **3b**, correlation is observed between H-3′ and $\delta_C = 132.6$ not 133.3 ppm; therefore, the former is assigned as C-1′. By analogy with the chemical shifts of **3e**, $\delta_C = 132.6$ is assigned as C-1′, and $\delta_C = 143.3$ ppm is assigned as C-4′. Similarly, in **3c** the methoxy group is distinctive at $\delta_H = 3.77$ and $\delta_C = 55.4$ ppm. This proton signal gives HMBC correlation with a signal at $\delta_C = 163.0$ ppm, which is assigned as C-4′. C-4′ gives HMBC correlation with proton signals at $\delta_H = 7.75$ and 6.91 ppm, which thus must be H-2′ and H-3′. The amide carbonyl at $\delta_C = 174.6$ gives HMBC correlation with $\delta_H = 7.75$ ppm, which leads to assignment of this proton signal as H-2′. By elimination, $\delta_H = 6.91$ ppm must be H-3′. H-2′ and H-3′ give HSQC correlation with $\delta_C = 132.6$ and 113.7 ppm, which therefore are assigned as C-2′ and C-3′, respectively. H-3′ gives HMBC correlation with the nonprotonated carbon at $\delta_C = 127.4$ ppm, which is assigned as C-1′. The signals at $\delta_C = 115.0$–116.0 ppm are assigned as nitrile carbons [7]. The carbons at $\delta_C = 136.6$, 132.2, 125.5, and 125.0 give HMQC correlation with proton signals at $\delta_H = 7.76$, 7.76, 7.98, and 6.69 ppm, again with little variation in the chemical shifts.

The most distinctive of these proton signals is that at $\delta_H = 6.69$ ppm, which is a doublet in **3b** and **3c**, suggesting that it is one of the end protons of the four-spin system (either H-7 or H-10). For the moment arbitrarily assigning this proton as H-10, the attached carbon (HMQC: $\delta_C = 125.0$ ppm) is assigned as C-10. H-10 also gives COSY correlation with one of the two unresolved protons at $\delta_H = 7.76$ ppm, which therefore is H-8, 9. These protons give HMQC correlation with the carbons at $\delta_C = 136.6$ and 132.2 ppm. The latter carbons give HMBC correlation to H-10; the former does not. C-9 is two bonds from H-10, C-8 is three bonds away; as three-bond C—H couplings usually give stronger HMBC correlations than two-bond couplings, $\delta_C = 132.2$ ppm is assigned as C-8 and $\delta_C = 136.6$ ppm is assigned as C-9. C-9 gives HMBC correlation with the signal at $\delta_H = 7.98$ ppm, which thus is assigned as H-7 and its attached carbon ($\delta_C = 125.5$ ppm) as C-7. In **3b**, H-7 appears as a double of doublet with large and small coupling constants ($J = 6.6$, 1.4 Hz), as expected in this position. The remaining $^{13}$C signals are those at $\delta_C = 193.2$, 170.2, 165.9, 143.4, 133.4, 105.0, 70.9, and 53.1 ppm. The remaining carbon atoms are C-6, 2, 4, 10a, 6a, 10b, 5a. and 5; they are assigned in the order stated. In **3b** and **3c**, the signal at $\delta_C = 105.2$ ppm gives HMBC correlation to H-10, so it was assigned as C-10b. Also in **3b** and **3c**, the signal at $\delta_C = 143.5$ ppm gives HMBC correlation to H-7 and either H-8 or H-9; this is expected for C-10a, as which this signal is therefore assigned. In **3e** and **3b**, the signal at $\delta_C = 53.2$ ppm gives HMBC correlation to the remaining proton signal at $\delta_H = 8.22$ ppm, which has an integral of 2H, and gives no HMQC correlation in any of the compounds; its only other HMBC correlation is in **3b** to $\delta_C = 165.9$. This idea is consistent with chemical-shift simulation using ChemNMR, which predicts for **3b** that C4, 5, and 5a will resonate at $\delta_C = 152$, 9, and 107.0 ppm, respectively.

The most surprising thing here is the predicted chemical shift of C-5, which is unusually far upfield for an $sp^2$-hybridized carbon. The rationale would be that the electron density at C-5 is higher than normal, due to resonance donation by the nitrogen on C-4. However, the assigned experimental shifts are very close to those of 1,1-dimethoxyethene, and enamines behave similarly to enol ethers (Fig. 1). The $\delta_C$ values for C-4 and C-5 are in accordance with the observed trends in the $\delta_C$ values in push–pull system in alkenes [8]. It is consistent with these assignments, however, that the amine protons give HMBC correlation to C-4 and C-5. The remaining upfield signal at $\delta_C = 70.9$ ppm is assigned as C-5a.

**Biological section.**

***Anticancer activity.*** The cytotoxicity testing of compounds **3b–d** was carried out using solid tumor (Hep-G2) cells, which were treated with different doses of the tested compounds and submitted to MTT assay [9]. The yellow tetrazolium salt is reduced by mitochondrial enzyme succinate dehydrogenase, present in living cells, to form insoluble purple formazan crystals, which are solubilized by the addition of detergent. The relative viable cells were determined by the amount of MTT

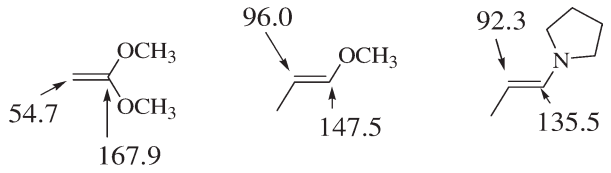


**Figure 1.** Assigned chemical shift values of the carbon signals in 1,1-dimethoxyethene and enamines.

converted to the insoluble formazan crystals. The data were expressed as the mean percentage of the viable cells as compared with the respective control cultures treated with solvent. Half-maximal growth inhibitory concentration ($IC_{50}$) values were calculated from the line equation of the dose-dependent curve of each compound. Compound **3b** resulted in a high inhibition of the cell growth of Hep-G2 cells compared with the growth of untreated control cells, as concluded from the $IC_{50}$ value of 21.73 μ*M*. on the other hand, compounds **3c**,**d** led to insignificant change in the growth of Hep-G2 cells as indicated from their $IC_{50}$ values (>100 μ*M*). Results are represented as percentage of control untreated cells as shown in Figures 2–4.

**Antioxidant activity.** 1,1-Diphenyl-2-picrylhydrazyl (DPPH) is a stable nonphysiological radical, which could provide a relative figure of the radical scavenging activity of the tested compounds [10]. The DPPH assay showed that **3c** possessed no scavenging activity to DPPH with high $SC_{50}$ values (>100 μ*M*) compared with the scavenging activity ($SC_{50}$ 8.41) of the well-known antioxidant (ascorbic acid); on the other hand, compounds **3b** and **3d** had effective antioxidant activity with $SC_{50}$ values of 62.5 and 87.4 μ*M*, respectively (Fig. 5).

## EXPERIMENTAL

**Chemistry: General methods.** *N*-Aroyl-*N*′-arylthioureas **1a–e** were prepared according to literature [6], whereas 2-(1,3-dioxoindan-2-ylidene)-malononitrile (**2**) was prepared according to literature [8]. IR spectra were measured of KBr pellets; absorption frequencies (ν) are stated in $cm^{-1}$. NMR spectra were measured in DMSO-$d_6$ solution, at 400.13 MHz for $^1H$ and 100.6 MHz for $^{13}C$; chemical shifts are stated in ppm (δ), and coupling constants are stated in Hz.

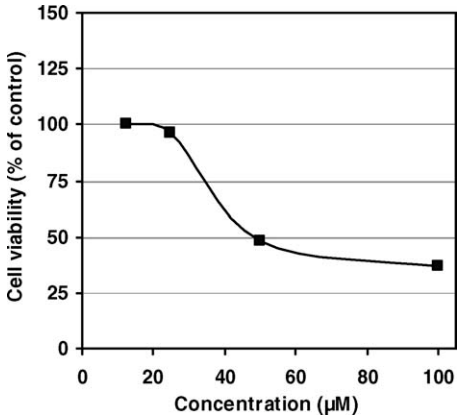

**Figure 3.** The effect of compound **3c** on the growth of Hep-G2 cells. As measured by MTT assay. As measured by MTT assay. Results are represented as percentage of control untreated cells.

**Chemistry**

***Reaction between N-aroyl-N′-arylthioureas 1a–e and 2-(1,3-dioxo-1H-inden-2(3H)-ylidene)malononitrile (CNIND, 2).*** To a solution of **2** (0.208 g, 1 mmol) in dry ethyl acetate (10 mL) a solution of **1a–e** (1 mmol) in dry ethyl acetate (10 mL) was added over 10 min at room temperature with stirring. The reaction mixture was continued with stirring at refluxing temperature for 24–20 h. The reaction mixture was concentrated and the residue was separated by preparative TLC (silica gel) using toluene:ethyl acetate (2:1) as eluant. The major zones were extracted with acetone. The isolated products **3a–e** were recrystallized from the stated solvents.

**Biological section**

***Cell culture.*** Human hepatocellular carcinoma (HepG2) cells were routinely cultured in Dulbeco's Modified Eagle's Medium. Media were supplemented with 10% fetal bovine serum, 2 mM L-glutamine, containing 100 units/mL penicillin G sodium, 100 units/mL streptomycin sulphate, and 250 ng/mL amphotericin B. Cells were maintained at subconfluency at 37°C in humidified air containing 5% $CO_2$. For subculturing, monolayer cells were harvested after trypsin/EDTA treatment at 37°C. Cells were used when confluence had reached 75%. Tested samples were dissolved in dimethyl sulphoxide (DMSO). All cell culture material was obtained from Cambrex BioScience (Copenhagen, Denmark). All chemicals were obtained from Sigma/Aldrich, USA, except mentioned. All experiments were repeated three times, unless mentioned.

*Cytotoxicity assay*. Cytotoxicity of tested samples was measured using the MTT cell viability assay. MTT (3-[4,5-

dimethylthiazole-2-yl]-2,5-diphenyltetrazolium bromide) assay is based on the ability of active mitochondrial dehydrogenase enzyme of living cells to cleave the tetrazolium rings of the yellow MTT and form a dark blue insoluble formazan crystals, which is largely impermeable to cell membranes, resulting in its accumulation within healthy cells. Solubilization of the cells results in the liberation of crystals, which are then solubilized. The number of viable cells is directly proportional to the level of soluble formazan dark blue color. The extent of the reduction of MTT was quantified by measuring the absorbance at 570 nm [9].

*Reagents preparation.* MTT solution: 5 mg/mL of MTT dissolved in 0.9% NaCl. Acidified isopropanol: 0.04 N HCl in absolute isopropanol.

*Procedure.* Cells ($0.5 \times 10^5$ cells/well) in serum-free media were plated in a flat bottom 96-well microplate, and treated with 20 μL of different concentrations of each tested compound for 20 h at 37°C in a humidified 5% $CO_2$ atmosphere. After incubation, media were removed and 40 μL MTT solution/well were added and incubated for an additional 4 h. MTT crystals were solubilized by adding 180 μL of acidified isopropanol/well, and the plate was shaken at room temperature, followed by photometric determination of the absorbance at 570 nm using a microplate ELISA reader. Triplicate repeats were performed for each concentration and the average was calculated. Data were expressed as the percentage of relative viability compared with the untreated cells compared with the vehicle control, with cytotoxicity indicated by <100% relative viability.

*Calculations.* Percentage of relative viability was calculated using the following equation:

$$[\text{Absorbance of treated cells}/\text{Absorbance of control cells} \times 100$$

Then the half maximal inhibitory concentration $IC_{50}$ was calculated from the equation of the dose-response curve.

**Antioxidant activity (scavenging of DPPH).** DPPH is a stable deep violet radical because of its unpaired electron. In the presence of an antioxidant radical scavenger, which can donate an electron to DPPH, the deep violet color decolorizes to the pale yellow nonradical form [10]. The change of color and the subsequent fall in absorbance are monitored spectrophotometrically at $\nu = 520$ nm.

***Reagents preparation.*** Ethanolic DPPH: 0.1 m*M* DPPH/absolute ethanol. Standard ascorbic acid solution: Serial dilutions of ascorbic acid in concentrations ranging from 0 to 2.5 μ*M* in distilled water. A standard calibration curve was plotted using serial dilutions of ascorbic acid in concentrations ranging from 0 to 2.5 μ*M* in distilled water.

*Procedure.* In a flat bottom 96 well-microplate, a total test volume of 200 μL was used. In each well, 20 μL of different concentrations (0–100 μg/mL final concentration) of tested compounds were mixed with 80 μL of ethanolic DPPH were mixed and incubated for 30 min at 37°C. Triplicate wells were prepared for each concentration and the average was calculated. Then photometric determination of absorbance at 515 nm was done using a microplate ELISA reader.

*Calculations.* The half-maximal scavenging capacity ($SC_{50}$) values for each tested compounds and ascorbic acid was estimated *via* two competitive dose curves.

$$\text{Abs}_{50} \text{ of ascorbic acid} = (\text{Abs}_{100} - \text{Abs}_0)/2$$

$SC_{50}$ of ascorbic acid was calculated using the curve equation. $SC_{50}$ of each compound was determined using the curve equation using $Abs_{50}$ of ascorbic acid.

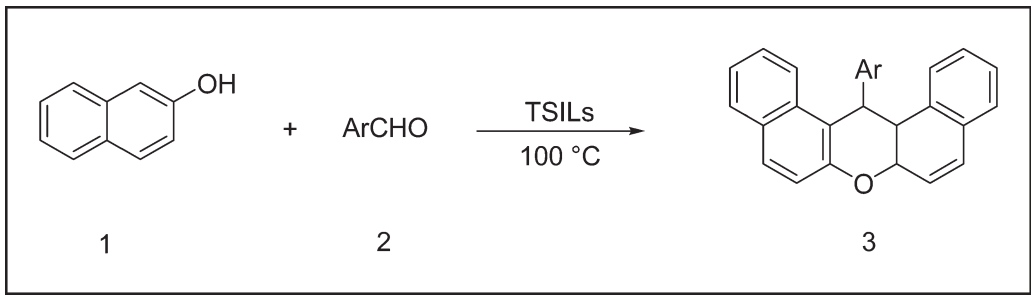
Published online 31 March 2010 in Wiley InterScience (www.interscience.wiley.com).



Some recyclable acyclic $SO_3H$-functionalized ionic liquids have been used as novel catalysts for the synthesis of 14-aryl-14*H*-dibenzo[*a*,*j*]xanthenes *via* the one-pot condensation of β-naphthol and aromatic aldehydes in aqueous medium. The condensation reaction was accomplished successfully with various aromatic aldehydes with good to excellent yields ranged from 86 to 96% within 5–30 min. After the reaction, the products could simply be separated from the catalysts by filtration. When separated from the reaction mixture, the catalysts could be recycled and reused for several times without noticeably reducing catalytic activity. The methodology gives the advantages of high yields, short reaction time, and easy work-up procedure.

*J. Heterocyclic Chem.*, **47**, 509 (2010).

## INTRODUCTION

The synthesis of xanthenes derivatives is of much importance because of their wide range of biological and pharmaceutical properties, such as antiviral, and anti-inflammatory activities as well as efficacy in photodynamic therapy [1,2]. Furthermore, these compounds can be used as dyes [3], pH-sensitive fluorescent materials for visualization of bimolecular [4] and used in laser technologies [5]. Recently, many synthetic methods for synthesis of these compounds have been reported by the condensation of aldehydes with β-naphthol in the presence of *p*-toluenesolfonic acid [6], sulfamic acid [7], fluoroboric acid/silica-gel [8], cellulose sulfuric acid [9], zirconium(iv) oxide chloride [10], $CBr_4$ [11], molecular ionine [12], heteropoly acid [13], silica sulfuric acid [14], Amberlyst-15 [15], and cyanuric chloride [16] as catalysts. However, the search for the new readily available and green catalysts is still being actively pursued.

With the increasing public concern over environmental degradation and future resources, it is of great importance for chemists to come up with new approaches that are less hazardous to human health and environment. Being used in large amounts and are usually volatile liquids, the solvents used in organic synthesis are high on the list of environmental pollutants. For overcoming these problems; one approach is to use the water as the green medium, another approach is to develop new processes involving the solvent-free conditions. In recent years, ionic liquids have been emerged as a powerful alternative to conventional molecular organic solvents because of their particular properties, such as undetectable vapor pressure, wide liquid range, as well as ease of recovery and reuse, and making them a greener alternative to volatile organic solvents. Combining the useful characteristics of solid acids and mineral acids, Brønsted acidic task-specific ionic liquids (TSILs) are designed to replace traditional mineral liquid acids, such as sulfuric acid and hydrochloric acid in chemical processes [17]. Such acidic TSILs have dual role (solvent and catalyst) in organic reactions [18–21]. In fact, the use of Brønsted-acidic TSILs as catalysts is an area of ongoing activity; however, development and exploration of acidic TSILs are currently in the preliminary stage.

We are especially interested in developing the potential use of efficient, simple, and inexpensive TSILs

catalysts. In our previous work, some novel and relatively cheap $SO_3H$-functional halogen-free acidic ionic liquids that bear an alkane sulfonic acid group in an acyclic trialkylammonium cation have been synthesized and their catalytic activity for acid-catalyzed reactions have also been investigated [22–24]. In continuation of our work in studying acid-catalyzed reactions in ionic liquids, we report here the synthesis of 14-aryl-14*H*-dibenzo[*a*,*j*]xanthenes in acidic ionic liquids.

## RESULTS AND DISCUSSION

For the beginning of this study, benzaldehyde and β-naphthol were used as the model reactants to compare the catalytic performance of the TSILs. As shown in Table 1, nearly no xanthenes could be detected in the absence of ionic liquids (entry 1), which indicated that the catalyst was absolutely necessary for this condensation reaction. All the prepared eight TSILs proved to be very active, leading to 86–95% yield of 14-aryl-14*H*-dibenzo[*a*,*j*]xanthenes in the presence of 5% TSILs (entries 4, 8–14). In addition, ionic liquids containing the shorter length of alkyl chain are relatively cheaper. Further, the better immiscibility of the resulted xanthenes with the shorter length of alkyl chain should facilitate the separation in work-up procedure. Hence, [TMPSA][$HSO_4$] should be the best catalyst for this condensation among the five acyclic TSILs, and the optimized reaction conditions were presented in Table 1 (entry 4).

| 6 | 5 | 90 |
| 7 | 6 | 90 |

[a] 5 mmol benzaldehyde, 10 mmol β-naphthol, 0.25 mmol catalyst, 100°C, 5 min.

Compared with the traditional methods, use of volatile solvents and catalysts, which is complex, and time and energy consuming, and environmentally malign, the easy recycling is an attractive property of the TSILs for the environmental protection and economic reasons. So, the recycling performance of [TMPSA][$HSO_4$] in the same model condensation reaction was subsequently explored. After the reaction, the products were isolated from the catalytic system by filtration, the catalyst was reused in the next run directly without further

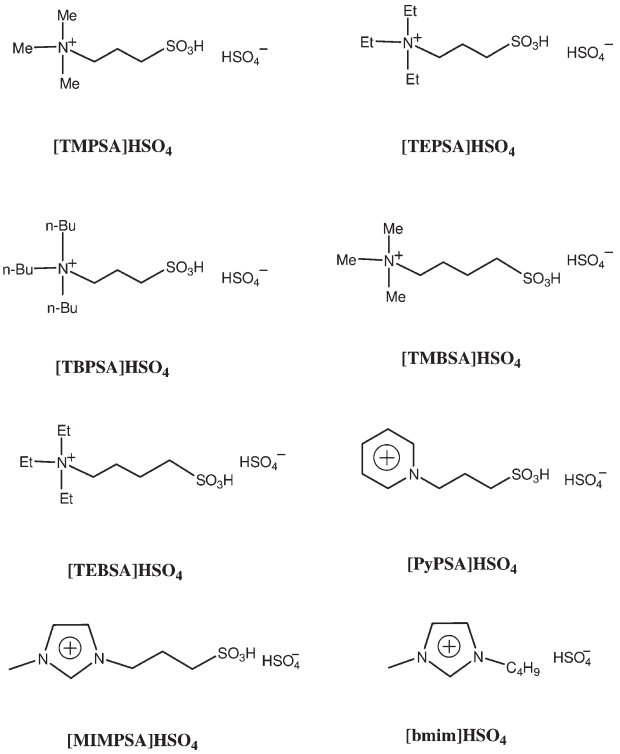
**Scheme 1**



purification. As shown in Table 2, the catalyst can be reused at least six times without appreciable decrease in yield and reaction rate, and the yield ranged from 94–90%.

The condensation reactions of other substituted benzaldehydes and β-naphthol in the presence of [TMPSA][$HSO_4$] were accomplished under the optimized reaction conditions described above and the results are presented in Table 3. It can easily be seen that all aromatic aldehydes with either electro-withdrawing or electro-donating substituents, such as nitro and methoxy groups gave reasonable to good yields ranged from 85–96% with 30 min. However, aromatic aldehydes with electron-withdrawing group are more actively than that with electro-donation one. Their physical properties were determined and structures were confirmed by $^1$H NMR spectral data.

In conclusion,, it was demonstrated that some readily available, economic TSILs have been used as recyclable catalysts for the condensation of benzaldehydes and β-naphthol to synthesis 14-aryl-14*H*-dibenzo[*a*,*j*]xanthenes. The merit of this methodology is that it is simple, high efficient, and eco-friendly.

## EXPERIMENTAL

Melting points were determined on X-6 microscope melting apparatus. $^1$H NMR spectra were recorded on Bruker DRX300 (300 or 500 MHz) and $^{13}$C NMR spectra on Bruker DRX300 (75.5 MHz) spectrometer. Mass spectra were obtained with automated FININIGAN Trace Ultra-Trace DSQ GC/MS spectrometer. All chemicals (AR grade) were commercially available and used directly without further purification.

**Synthesis of $SO_3$H-functional halogen-free acidic ionic liquid (TSILs).** All acyclic $SO_3$H-functionalized halogen-free acids, such as [TMPSA][$HSO_4$], [TEPSA][$HSO_4$] were synthesized according to our previous methods [18], the pyridine, imidazole-based $SO_3$H-functionalized ionic liquids for comparison were obtained according to reported methods [16]. The structures of TSILs were analyzed by $^1$H NMR, $^{13}$C NMR, and MS spectral data (Scheme 1).

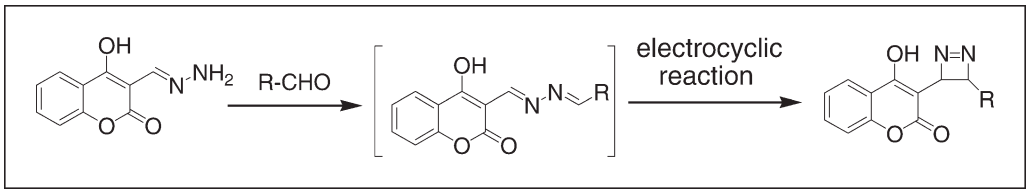
Published online 31 March 2010 in Wiley InterScience (www.interscience.wiley.com).



A new, short and efficient synthesis of 4-hydroxy-3-(4-aryl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one is described in which the 3,4-dihydro-1,2-diazete ring is constructed from arylmethylene hydrazone by 4π electron cyclization as per electrocyclic reaction.

## INTRODUCTION

Nitric oxide (NO) has been recognized as an important cellular mediator with diverse biological functions [1,2] including treatment for the respiratory, cardiovascular, infective, and other several diseases [3]. Derivatives of 3,4-dihydro-1,2-diazete-1,2-dioxide have recently been investigated as NO donors *in vitro* and *in vivo* and found to be highly effective vasodilators [4]. 1,2-Diazetine *N*,*N*-dioxides (diazetine dioxides) are a class of strained four-membered ring azo dioxide heterocycles. Although the first report of a diazetine dioxide was as early as 1971, only a handful of such compounds are currently known [5–9]. Diazetine dioxides have been used as highly effective low-energy triplet quenchers in photochemical reactions [10] and have been recently investigated for their biological activity as potent vasorelaxant and antiaggregant agents [7–9,11]. One of the more intriguing aspects of the reactivity of diazetine dioxides is their tendency to liberate 2 equiv of nitric oxide (NO) upon decomposition to yield the corresponding alkene [5,7]. It is the production of the biologically active molecule NO that has suggested the possibility of using diazetine dioxides as pharmaceutical agents [7,11]. The mechanism by which NO is liberated still remains a question [12,13]. Despite the marked pharmaceutical application of diazetidines [14], isosteric diazetenes [15], 1,2-dihydro-1,2-diazetenes [16], and 3,4-dihydro-1,2-dihydro-1,2-diazetenes [17] derivatives, their conjugation with heterocyclic compounds is less studied.

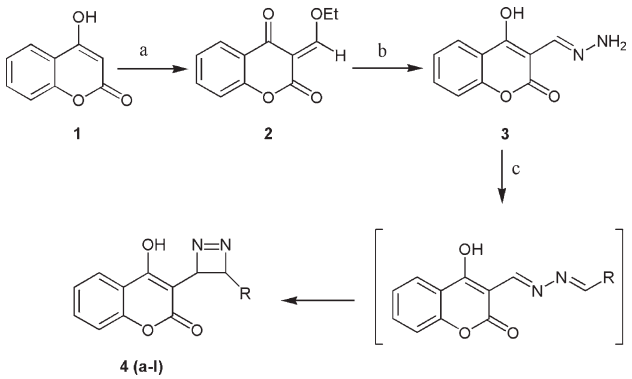
Coumarin and its derivatives represent one of the most active classes of compounds possessing a wide spectrum of biological activity [18–26]. Many of these compounds have proved to be active as antitumor [18,19], antibacterial [20,21], antifungal [22–24], anticoagulant [25], and anti-inflammatory [26]. In addition, these compounds are used as additives to food and cosmetics [27], dispersed fluorescent and laser [28].

The potential pharmaceutical utility of 1,2-diazete derivatives and 4-hydroxy coumarin derivatives prompted us to synthesize new 3,4-dihydro-1,2-diazete derivatives incorporated with 4-hydroxy coumarin framework **4**(**a**–**l**).

## RESULTS AND DISCUSSION

The synthesis of 4-hydroxy-3-(4-aryl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one derivatives **4**(**a**–**l**) is shown in Scheme 1. The precursor 4-hydroxy coumarin **1** was prepared by following the literature methods [29]. A mixture of **1** and triethyl orthoformate containing catalytic amount of *p*-toluene sulfonic acid (PTSA) was subjected to microwave irradiation at 240 W for 2 min to obtain 3-ethoxymethylene-3*H*-2,4-dione (**2**) in moderate yield (∼60%). The hydrolysis of **2** with $K_2CO_3$ resulted into 4-hydroxy coumarin-3-carbaldehyde [30]. Subsequent treatment of the **2** with hydrazine hydrate at ambient temperature afforded 4-hydroxy-2-oxo-2*H*-cromene-3-carbaldehyde- hydrazone (**3**) in excellent yield (∼90%). It was found that the reaction did not require any solvent or external heating. When hydrazone **3** reacted with various aldehydes at 100°C in DMSO containing con. HCl as a catalyst, 4-hydroxy-3-(4-aryl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one derivatives

**Scheme 1.** Reagents and conditions: (a) Triethyl orthoformate. Microwave irradiation at 240 W, 2 min; (b) $NH_2NH_2 \cdot H_2O$, r.t., Stirr.; (c) R-CHO, DMSO, con. HCl, 100°C, 30 min.



**4a–l** were obtained in good yield (Table 1). One can envisage that the intermediates 4-hydroxy-2-oxo-2*H* chromene-3-carbaldehyde (arylmethylene) hydrazones underwent 4π electron cyclization to form a four membered 1,2-diazete ring system incorporates with 4-hydroxy coumarin nucleolus **4a–l** (Scheme 1). The formation of 1,2-diazete ring system was confirmed by IR, Mass, $^1$H NMR, and $^{13}$C NMR spectral study.

The IR spectrum of **4a** exhibited O—H stretching vibration peak in the range of 3200–3400 $cm^{-1}$ and C=O Stretching vibration of coumarin at 1690 $cm^{-1}$ indicating the presence of hydroxyl group. The $^1$H NMR spectrum of compound **4a** displayed the hydroxyl proton at 14.04 δ ppm as a singlet. Two methine protons of diazete ring were observed at 8.8 and 8.6 δ ppm. The downfield chemical shift of these protons compared with simple 1,2-diazete ring system (4–5 δ ppm reported by G. W. Breton *et al*. [31] and 8.69 δ ppm reported by Yutaka Ishida *et al*. [32]) may be attributed to their conjugation with coumarin and phenyl ring system attached with the diazete structure. Moreover, the chemical shift of methine proton was also compared with that of compound **3** (7.19 δ ppm) also supporting the formation of diazete framework. The assignment of relative stereochemistry of both methine protons can be carried out based on coupling constant. The larger values of derived coupling constants place both protons in trans position. The mass spectrum of **4a** showed three signals $M^+$+1, $M^+$, and $M^+$-$N_2$ at 294, 293, and 264, respectively. Extrusion of $N_2$ from compound in the mass spectra reveals the existence of the cyclic product, which is in accordance with the assigned structure of **4a**.

The mechanism involved in the formation of 1,2-diazete ring follows the electrocyclic reaction. Arylmethylene hydrazone is a conjugated chain containing 4π electron system which undergoes 4π electron cyclization as per pericyclic reaction (Scheme 2).

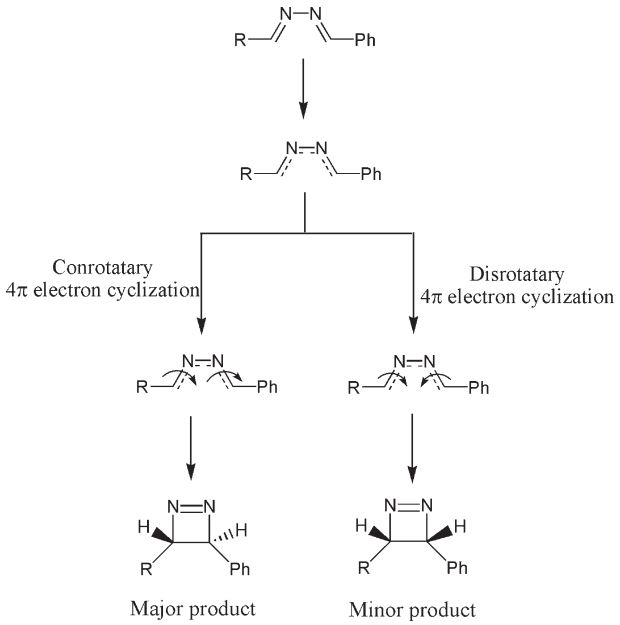
## CONCLUSIONS

In summary, novel 4-hydroxy-3-(4-aryl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one derivatives (**4a–l**) were prepared from 4-hydroxy-2-oxo-2*H*-cromene-3-carbaldehyde hydrazone and various aldehydes in DMSO *via* electrocyclic reaction through 4π electron cyclization. The pharmacological study of all compounds is currently under investigation.

**Scheme 2.** Plausible mechanism of 4π electron cyclization.



## EXPERIMENTAL

Melting points were determined on electro thermal apparatus using open capillaries and are uncorrected. Thin-layer chromatography was accomplished on 0.2-mm precoated plates of silica gel G60 $F_{254}$ (Merck). Visualization was made with UV light (254 and 365 nm) or with an iodine vapor. IR spectra were recorded on a FTIR-8400 spectrophotometer using DRS prob. $^1$H NMR spectra were recorded on a Bruker AVANCE II (400 MHz) spectrometer in DMSO. Chemical shifts are expressed in δ ppm downfield from TMS as an internal standard. Mass spectra were determined using direct inlet probe on a GCMS-QP 2010 mass spectrometer (Shimadzu). Solvents were evaporated with a BUCHI rotary evaporator. All reagents were purchased from Fluka, Sigma Aldrich, Merck, and Rankem and used without further purification.

**3-Ethoxymethylene-3*H*-chromene-2,4-dione (2).** A mixture of 6.2 mmol of 4-hydroxycoumarin (1.0 g, 6.2 mmol), triethyl orthoformate (7 mL), and *p*-toluenesulfonic acid monohydrate (0.02 g) was placed in a 50 mL beaker. The beaker was covered with a stem-less funnel and irradiated in the microwave oven for 2 min at 240 W. The resultant residue was cooled to room temperature, the solvent was decanted, and the residue was crystallized in chloroform to give pure yellow crystals. Yield: 0.81 g (60%); mp 140–141°C.

**4-Hydroxy-2-oxo-2*H*-cromene-3-carbaldehyde hydrazone (3).** 3-(Ethoxymethylene)-3*H*-chromene-2,4-dione (**2**, 2.18 g, 10 mmol) was stirred at room temperature with excess 50% hydrazine hydrate for about 10–15 min. The solid separated out was filtered and crystallized from chloroform to give **3**, yield: 1.83 (90%); mp 138–140°C. IR (KBr): 3528, 3245, 1689, 1545; $^1$H NMR (400 MHz, DMSO) δ 8.47 (s, 1H, OH), 7.98 (m, 1H, ArH), 7.55 (m, 1H, ArH), 7.23 (m, 2H, ArH), 7.19 (s, 1H, =CH), 5.88 (s, 2H, $NH_2$); MS(EI): 204 ($M^+$).

**General procedure for the synthesis of 4-hydroxy-3-(4-phenyl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one (4a).** A mixture of equimolar amount of 4-hydroxy-2-oxo-2*H*-chromene-3-carbaldehyde hydrazone **3** and benzaldehyde was dissolved in DMSO containing catalytic amount of con. HCl and heated at 100°C for 30 min with stirring. The reaction mixture was allowed to attain room temperature. The separated solid was filtered off and washed with methanol. The crude product obtained was recrystallized from chloroform to give 4-hydroxy-3-(4-aryl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one (**4a**) as a yellow solid. Yield 75%; mp 230–232°C; IR (KBr) 3200, 1690 cm$^{-1}$; $^1$H NMR (400 MHz, $CDCl_3$) δ 14.04 (s, 1H, OH), 8.80 (d, $J$ = 12.36 Hz, 1H, CH), 8.67 (d, $J$ = 15.52 Hz, 1H, CH), 7.96 (t, 1H, Ar), 7.73 (d, 2H, Ar), 7.57 (t, 1H, Ar), 7.45–7.39 (m, 3H, Ar), 7.26–7.17 (m, 2H, Ar); MS(EI) 292 $[M]^+$. **4-Hydroxy-3-[4-(4-methoxyphenyl)-3,4-dihydro-1,2-diazet-3-yl]-2*H*-chromen-2-one (4c).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3140, 1716 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO) δ 14.07 (s, 1H, OH), 8.86 (d, $J$ = 12.48 Hz, 1H, CH), 8.70 (d, $J$ = 10.08 Hz, 1H, CH), 8.02 (t, 1H, Ar), 7.73 (d, 2H, Ar), 7.62 (t, 1H, Ar), 7.31–7.23 (m, 2H, Ar), 7.00–6.98 (m, 2H, Ar), 3.86 (s, 3H, $OCH_3$); MS(EI) 322 $[M]^+$. Anal. Calcd. for $C_{18}H_{14}N_2O_4$: C, 67.07; H, 4.38; N, 8.69. Found: C, 67.11; H, 4.24; N, 8.58.

**3-[4-(3,4-Dimethoxyphenyl)-3,4-dihydro-1,2-diazet-3-yl]-4-hydroxy-2*H*-chromen-2-one (4d).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3210, 1699 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO) δ 14.07 (s, 1H, OH), 8.88 (d, $J$ = 12.30 Hz, 1H, CH), 8.64 (d, $J$ = 14.42 Hz, 1H, CH), 7.99 (t, 1H, Ar), 7.82 (d, 2H, Ar), 7.59 (t, 1H, Ar), 7.48–7.20 (m, 3H, Ar), 3.88 (s, 6H, $OCH_3$); MS(EI) 352 $[M]^+$. Anal. Calcd. for $C_{19}H_{16}N_2O_5$: C, 64.77; H, 4.58; N, 7.95. Found: C, 64.61; H, 4.49; N, 7.81.

**3-[4-(2,5-Dimethoxyphenyl)-3,4-dihydro-1,2-diazet-3-yl]-4-hydroxy-2*H*-chromen-2-one (4e).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3235, 1687 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO) δ 14.07 (s, 1H, OH), 8.96 (d, $J$ = 2.64 Hz, 1H, CH), 8.90 (d, $J$ = 12.4 Hz, 1H, CH), 8.03 (t, 1H, Ar), 7.91 (d, 2H, Ar), 7.62 (t, 1H, Ar), 7.44 (t, 1H, Ar), 7.30 (t, 1H, Ar); 7.26 (t, 1H, Ar), 3.88 (s, 6H, $OCH_3$); MS(EI) 352 $[M]^+$. Anal. Calcd. for $C_{19}H_{16}N_2O_5$: C, 64.77; H, 4.58; N, 7.95. Found: C, 64.59; H, 4.71; N, 7.84.

**3-[4-(2-Chlorophenyl)-3,4-dihydro-1,2-diazet-3-yl]-4-hydroxy-2*H*-chromen-2-one (4f).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3221, 1702 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO) δ 14.07 (s, 1H, OH), 8.80 (d, $J$ = 12.28 Hz, 1H, CH), 8.68 (d, $J$ = 18.06 Hz, 1H, CH), 7.99 (t, 1H, Ar), 7.73 (d, 2H, Ar), 7.61 (t, 1H, Ar), 7.43–7.49 (m, 3H, Ar), 7.22–7.27 (m, 1H, Ar); MS(EI) 326 $[M]^+$. Anal. Calcd. for $C_{17}H_{11}ClN_2O_3$: C, 62.49; H, 3.39; N, 8.57. Found: C, 62.37; H, 3.26; N, 8.47.

**3-[4-(4-Fluorophenyl)-3,4-dihydro-1,2-diazet-3-yl]-4-hydroxy-2*H*-chromen-2-one (4g).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3088, 1716 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO) δ 14.07 (s, 1H, OH), 8.81 (d, $J$ = 12.58 Hz, 1H, CH), 8.73 (d, $J$ = 10.02 Hz, 1H, CH), 7.99 (t, 1H, Ar), 7.74 (d, 2H, Ar), 7.58 (t, 1H, Ar), 7.44–7.49 (m, 2H, Ar), 7.23–7.26 (m, 2H, Ar); MS(EI) 310 $[M]^+$. Anal. Calcd. for $C_{17}H_{11}FN_2O_3$: C, 65.81; H, 3.57; N, 9.03. Found: C, 65.73; H, 3.51; N, 9.12.

**4-Hydroxy-3-[4-(2-hydroxyphenyl)-3,4-dihydro-1,2-diazet-3-yl]-2*H*-chromen-2-one (4h).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3400, 3259, 1696 cm$^{-1}$; $^1$H NMR (400 MHz, DMSO) δ 14.09 (s, 1H, OH), 9.57 (s, 1H, OH), 8.79 (d, $J$ = 12.30 Hz,

1H, CH), 8.66 (d, $J$ = 11.38 Hz, 1H, CH), 7.96 (t, 1H, Ar), 7.73 (d, 2H, Ar), 7.57 (t, 1H, Ar), 7.46–7.39 (m, 2H, Ar), 7.25–7.17 (m, 2H, Ar); MS(EI) 308 $[M]^+$. Anal. Calcd. for $C_{17}H_{12}N_2O_4$: C, 66.23; H, 3.92; N, 9.09. Found: C, 66.12; H, 4.06; N, 8.94.

**4-Hydroxy-3-[4-(4-nitrophenyl)-3,4-dihydro-1,2-diazet-3-yl]-2*H*-chromen-2-one (4i).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3490, 1697 $cm^{-1}$; $^1H$ NMR (400 MHz, DMSO) δ 14.07 (s, 1H, OH), 8.81 (d, $J$ = 12.18 Hz, 1H, CH), 8.68 (d, $J$ = 15.55 Hz, 1H, CH), 7.99 (t, 1H, Ar), 7.73 (d, 2H, Ar), 7.56 (t, 1H, Ar), 7.48–7.57 (m, 3H, Ar), 7.23–7.21 (m, 1H, Ar); MS(EI) 337 $[M]^+$. Anal. Calcd. for $C_{17}H_{11}N_3O_5$: C, 60.54; H, 3.29; N, 12.46. Found: C, 60.47; H, 3.18; N, 12.55.

**3-{4-[4-(Dimethylamino)phenyl]-3,4-dihydro-1,2-diazet-3-yl}-4-hydroxy-2*H*-chromen-2-one (4j).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3209, 1719 $cm^{-1}$; $^1H$ NMR (400 MHz, DMSO) δ 14.10 (s, 1H, OH), 8.87 (d, $J$ = 12.28 Hz, 1H, CH), 8.71 (d, $J$ = 14.68 Hz, 1H, CH), 8.02 (t, 1H, Ar), 7.75 (d, 2H, Ar), 7.60 (t, 1H, Ar), 7.40–7.32 (m, 2H, Ar), 7.27–7.23 (m, 2H, Ar), 2.97 (s, 6H, $N(CH)_2$); MS(EI) 335 $[M]^+$. Anal. Calcd. for $C_{19}H_{17}N_3O_3$: C, 68.05; H, 5.11; N, 12.53. Found: C, 67.88; H, 5.03; N, 12.64.

**4-Hydroxy-3-(4-pyridin-3-yl-3,4-dihydro-1,2-diazet-3-yl)-2*H*-chromen-2-one (4k).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3235, 1699 $cm^{-1}$; $^1H$ NMR (400 MHz, DMSO) δ 14.10 (s, 1H, OH), 8.80 (d, $J$ = 12.96 Hz, 1H, CH), 8.65 (d, $J$ = 14.93 Hz, 1H, CH), 7.95 (t, 1H, Ar), 7.74 (d, 2H, Ar), 7.58 (t, 1H, Ar), 7.14–6.81 (m, 4H, Pyr.); MS(EI) 293 $[M]^+$. Anal. Calcd. for $C_{16}H_{11}N_3O_3$: C, 65.53; H, 3.78; N, 14.33. Found: C, 65.37; H, 3.59; N, 14.15.

**3-[4-(2-Furyl)-3,4-dihydro-1,2-diazet-3-yl]-4-hydroxy-2*H*-chromen-2-one (4l).** This compound was obtained according to the earlier general procedure; Yellow solid; IR (KBr): 3266, 1689 $cm^{-1}$; $^1H$ NMR (400 MHz, DMSO) δ 14.08 (s, 1H, OH), 8.78 (d, $J$ = 11.08 Hz, 1H, CH), 8.64 (d, $J$ = 15.34 Hz, 1H, CH), 7.90 (t, 1H, Ar), 7.70 (d, 2H, Ar), 7.54 (t, 1H, Ar), 6.98–6.69 (m, 3H, Fur.); MS(EI) 282 $[M]^+$. Anal. Calcd. for $C_{15}H_{10}N_2O_4$: C, 63.83; H, 3.57; N, 9.92. Found: C, 63.78; H, 3.41; N, 9.84.

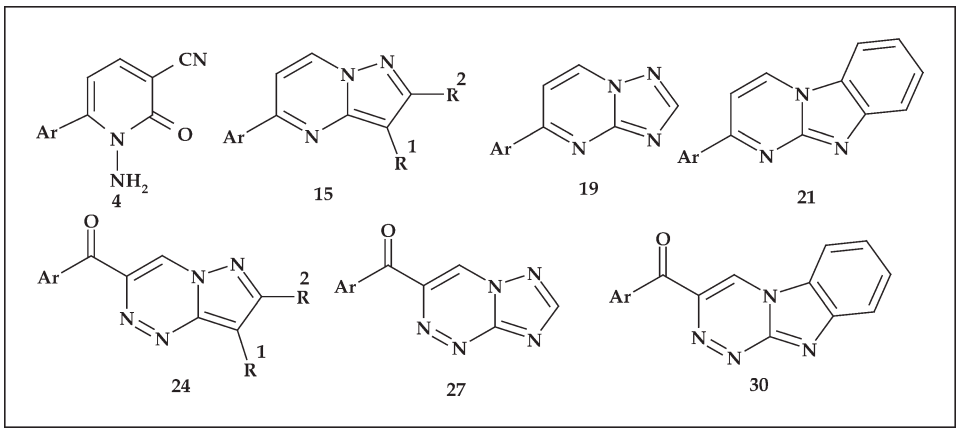
Published online 2 April 2010 in Wiley InterScience (www.interscience.wiley.com).



Cyclocondensation of hydrazides, 3-aminopyrazoles, 3-amino-1,2,4-triazole, 2-aminobenzoimidazole, pyrazole-3-diazonium salts, 1,2,4-triazol-3-diazonium salt, or benzoimidazole-2-diazonium salt with sodium salt of 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one gave 2-pyridones, pyrazolo[1,5-*a*]pyrimidines, triazolo[1,5-*a*]pyrimidine, benzo[4,5]imidazo[1,2-*a*]pyrimidine, (pyrazolo[5,1-*c*][1,2,4]triazin-3-yl)-methanone, [1,2,4]triazolo[5,1-*c*][1,2,4]triazin-3-yl-methanone, or benzo[4,5]imidazo[2,1-*c*] [1,2,4]triazin-3-yl-methanone derivatives, respectively, which will be tested for anti-tumor and anti-cancer activates.

*J. Heterocyclic Chem.,* **47**, 517 (2010).

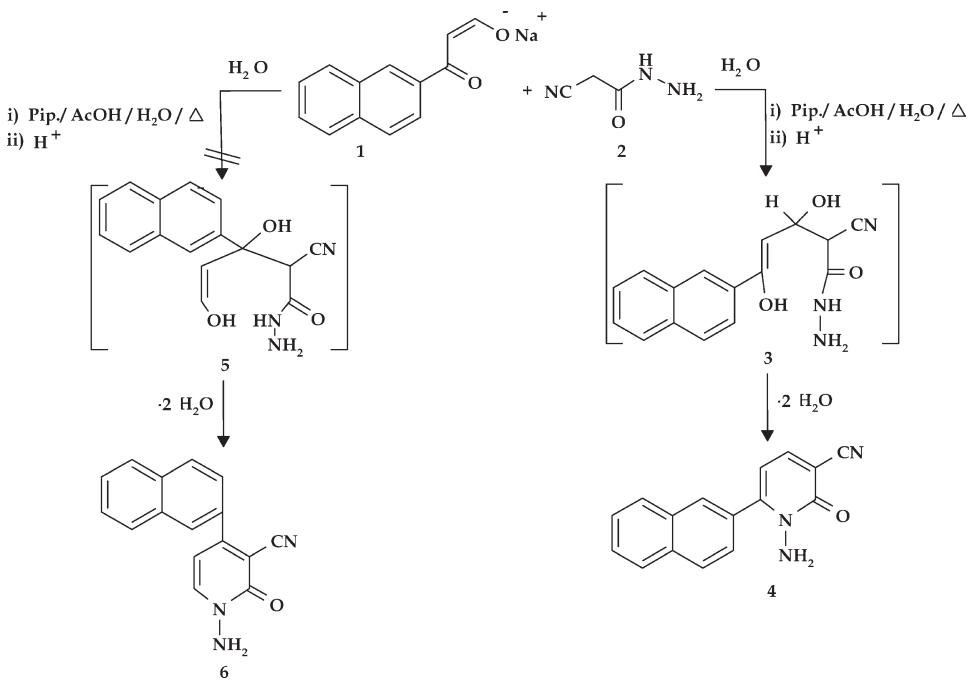
## INTRODUCTION

Chemotherapeutic anticancer agents continue to be an active area of research at many companies and research centers [1–3]. So that, pyridine, pyrazolopyrimidine, and trazine derivatives have received considerable attention due to their wide range of applications in chemotherapy, such as anti-inflammatory, anti-tumor, anti-mycobacterial, anti-fungal, and anti-viral activities [4–6]. Recently, it has been reported that many pyridine and pyrazolopyrimidine derivatives showed strong cytotoxicity against several human cancer cell lines [6–9]. Pyrazolo[4,3-*d*]pyrimidine and pyrazolo[1,5-*a*]pyrimidine derivatives were reported to be inhibitors of tyrosine kinase and cyclin-dependent kinases (CDK) which are involved in mediating the transmission of mitogenic signals and numerous other cellular events [3,10–15], including cell proliferation, migration, differentiation, metabolism, and immune response. It was also found that many of these derivatives may block proliferation of various cancer cell lines [16]. In view of these reports and in continuation with the previous work, here a successful trial for synthesizing new derivatives of pyridones, pyrazolo[1,5-*a*]pyrimidines, triazolo[1,5-*a*]pyrimidine, imidazo[1,2-*a*]pyrimidine, pyrazolo[5,1-*c*]triazine, triazolo[5,1-*c*]triazine, and imidazo [2,1-*c*]triazine derivatives which will be tested for anti-tumor and anti-cancer activates are reported.

## RESULTS AND DISCUSSION

As a part of our program directed for the development of efficient and simple procedures for the synthesis of antimetabolites [17–19], we have recently reported different and successful approaches for the synthesis of 2-pyridones [17,19]. The synthesized compounds act as intermediates for synthesis of deazafolic acid ring system and deazapyrimidine nucleosides, which reported to be significantly active, both *in vitro* and *in vivo* [20,21]. They also act as inhibitor of dihydrofolate reductase [22], cytotoxicity against various experimental tumors as potential as methotrexate [23,24], and one of the most effective antimetabolites currently used in treatment of various solid tumors [25,26]. This prompted our interest to the synthesis and study of the chemistry of this class of compounds [17,18]. Although *N*-amino-2-pyridones have proved to be useful synthetic intermediates, there are few procedures for their preparation and they are usually obtained in low yield by the reaction of hydrazine with 2-pyridones [27,28]. I have reported in this part, one step synthesis of 2-pyridones from the reaction

**Scheme 1**



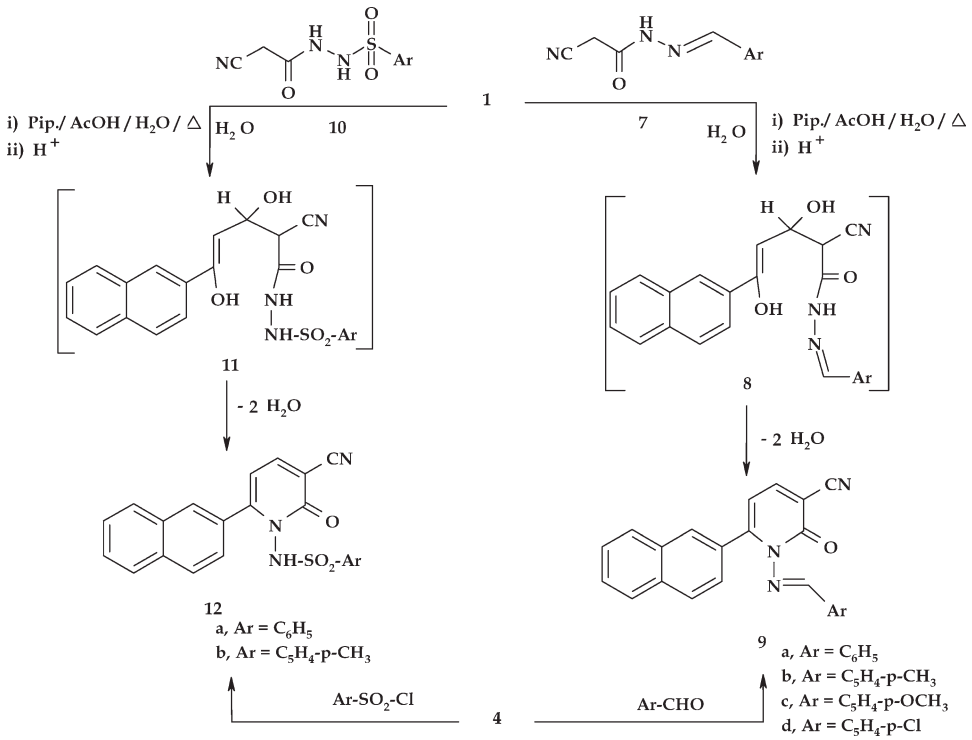
of 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one **1** with different hydrazides. Thus, it has been found that salt **1** reacted with cyanoacetic acidhydrazide **2** to give a trisubstituted 2-pyridone. Two modes of cyclization are feasible, giving a 1,2,3,6- or 1,2,3,4-tetrasubstituted products, as outlined in Scheme 1. First, initial attack by a methylene carbanion takes place at the formyl group of the salt **1** and subsequent Michael cyclization followed by elimination of two moles of water to give the 1,2,3,6-trisubstituted product **4**. Second, initial nucleophilic attack by the methylene carbon takes place at the ketonic group, followed by cyclization and elimination of water giving 1,2,3,4-trisubstituted isomer **6**. In fact, only one isomer was obtained, which was suggested to be **4** due to the fact that initial attack of the active methylene carbon at the unhindered formyl group leading to **4** being much more probable than attack at the hindered and electronically disfavored ketonic group [29]. Spectral studies did not allow us to distinguish between structures **4** and **6**. $^1$H-NMR for the product revealed the absence of $CH_2$ and the presence of 2-naphthyl protons from $\delta = 7.54$–8.66 ppm whereas the amino group has two protons at $\delta = 2.70$ ppm in solution. No significant amounts of the alternative regioisomers could be detected. To establish structure of the product, the crystal structure of a similar previous work has been reported [19,29,30]. The X-ray analysis of this work confirms the exclusive presence of the regioisomer **4** [29].

The reaction of sodium salts of 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one **1** with arylidenecyanoacetohydrazide **7** and arylsulfonylcyanoacetohydrazide **10** derivatives represents a novel, one step, synthesis of *N*-arylideneamino- and *N*-arylsulphonylamino-2-pyridones, respectively. Thus, it has been found that, salt **1** reacted with arylidenecyanoacetohydrazide **7** to give *N*-arylideneamino-2-pyridones **9,** whereas **1** reacted with arylsufonylcyanoacetohydrazide **10** to give *N*-arylsulfonylamino-2-pyridones **12**. The structure of compound **12b** was established on the basis of its elemental analysis and spectral data (IR, $^1$H-NMR, and MS). Thus, the mass spectra of **12b** was compatible with the molecular formula $C_{23}H_{17}N_3O_3S$ ($M^+$ 415) and the $^1$H-NMR showed a signal at $\delta = 2.35$ ppm assigned for methyl group. Moreover, both **7** and **12** can be obtained from the reaction of **4** with aldehydes or arylsufonylchlorides, respectively, as shown in Scheme 2.

Analogously, treatment of sodium 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one **1** with appropriate amounts of 3-aminopyrazoles **13** [31], in the presence of piperidine acetate afforded pyrazolo[1,5-*a*]pyrimidines **15**. Structure of the product **15b** was confirmed by elemental analysis and spectral data (IR, $^1$H–NMR, and MS). The mass spectra of **15b** was compatible with the molecular formula $C_{23}H_{17}N_3$ ($M^+$ 335) and $^1$H NMR for the product revealed the presence of a $CH_3$ protons at $\delta = 2.41$ ppm and methine H of pyrazole at $\delta = 6.22$ ppm and methine 2H of pyrimidine at $\delta = 8.52$ and 8.78 ppm in solutions as shown in Figure 1.

The reaction seemed to proceed via initial nucleophilic attack by the exocyclic amino group of

**Scheme 2**



aminopyrazoles **13** at the ketonic group, which formed *in situ* from salt **1** with water, followed by cyclization and elimination of two moles of water to give the products **15** Scheme 3. It has been suggested that the formation of the alternative isomeric products **17** is based on the initial attack of endocyclic amino group at the ketonic group. The latter suggestion is excluded due to the higher nucleophilicity of the exocyclic primary amino group than the endocyclic amino group which previously reported [17,29,30].

Similarly, treatment of sodium 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one **1** with 3-amino-1,2,4-triazole or 2-aminobenzoimidazole in the presence of piperidine acetate afforded 5-(naphthalen-2-yl)[1,2,4]triazolo[1,5-*a*]pyrimidine **19** or 2-(naphthalen-2-yl)benzo[4,5]imidazo[1,2-*a*]pyrimidine **21**, respectively, Scheme 4. The structure of **19** was confirmed by elemental analysis and spectral data (IR, $^1$H–NMR, and MS). The mass spectra of **19** was compatible with the molecular formula $C_{15}H_{10}N_4$ ($M^+$ 246) and $^1$H NMR for the product revealed the presence methine H of triazole at $\delta = 8.27$ ppm and methine 2H of pyrimidine at $\delta = 7.54$ and 8.52 ppm.

Finally, the reaction of sodium 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one **1** with pyrazole-3-diazonium salts **22**, 1,2,4-triazol-3-diazonium salt **25,** or benzoimidazole-2-diazonium salt **28** in the presence of piperidine acetate afforded naphthalen-2-yl-(pyrazolo[5,1-*c*][1,2,4] triazin-3-yl)-methanone derivatives **24,** naphthalene-2-yl-[1,2,4]triazolo[5,1-*c*][1,2,4]triazin-3-yl-methanone **27,** or benzo[4,5] imidazo[2,1-*c*][1,2,4]triazin-3-yl-naphthalen-2-yl-methanone **30,** respectively, Scheme 5. The structure of **24** was confirmed by elemental analysis and spectral data (IR, $^1$H-NMR, and MS). The mass spectra of **24a** was compatible with the molecular formula $C_{22}H_{14}N_4O$ ($M^+$ 350) and IR for the product revealed the presence carbonyl group at 1,665 cm$^{-1}$.

## EXPERIMENTAL

All melting points are uncorrected IR spectra were obtained (KBr disk) on a Perkin Elmer 11650 FT-IR instrument. The $^1$H-NMR spectra were measured on a Varian 400 MHz spectrometer for solutions in $(CD_3)_2$ SO using $Si(CH_3)_4$ as an internal standard. Mass spectra were recorded on a Varian MAT 112 spectrometer. Analytical data were obtained from the Microanalytical Data Center at Cairo University.

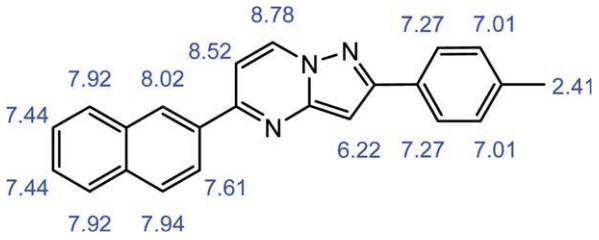


**Figure 1.** $^1$H NMR δ values for **15b.**

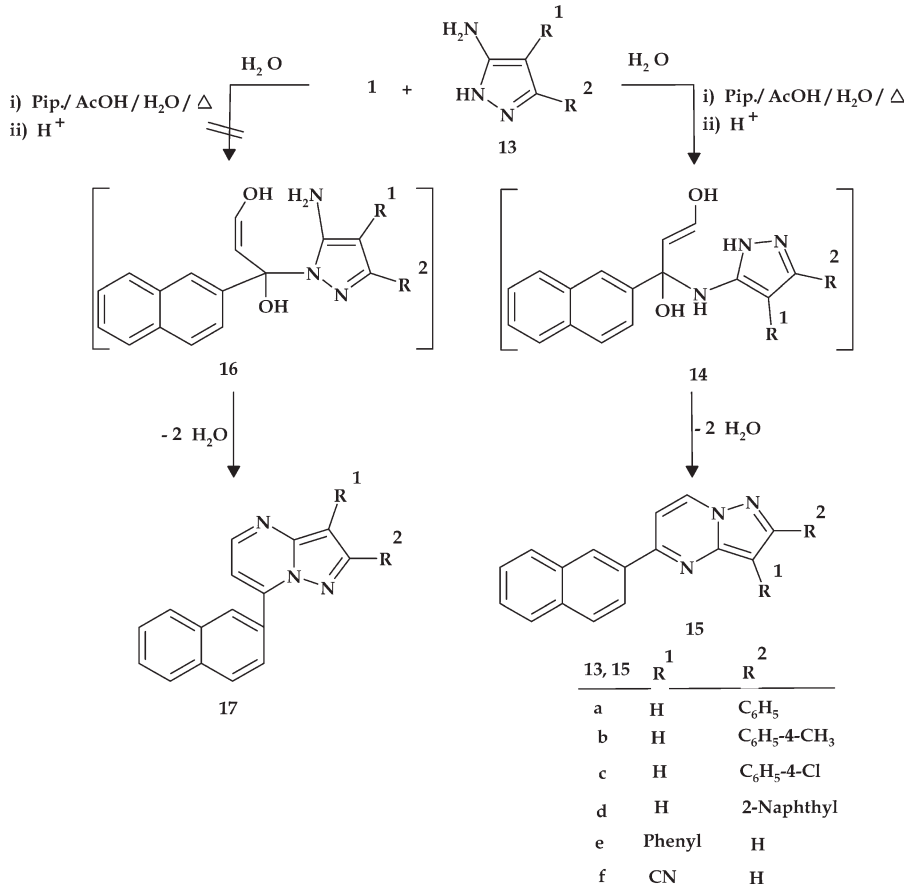
**Scheme 3**



| 13, 15 | $R^1$ | $R^2$ |
|---|---|---|
| a | H | $C_6H_5$ |
| b | H | $C_6H_5$-4-$CH_3$ |
| c | H | $C_6H_5$-4-Cl |
| d | H | 2-Naphthyl |
| e | Phenyl | H |
| f | CN | H |

**Scheme 4**

**2-Pyridones (4), (9a–d), (12a,b), Pyrazolo[1,5-*a*]pyrimidines (15a–f), Triazolo[1,5-*a*]pyrimidine (19), Benzo[4,5]imidazo[1,2-*a*]pyrimidine (21), (pyrazolo [5,1-*c*][1,2,4] triazin-3-yl)-methanones (24a–f), [1,2,4] Triazolo[5,1-*c*] [1,2,4]triazin-3-yl-methanone (27), or Benzo[4,5] imidazo [2,1-*c*][1,2,4]triazin-3-yl-methanone (30).** ***General method (A).*** A mixture of 3-hydroxy-1-(2-naphthyl)prop-2-en-1-one **1** (0.01 mole), cyanoacitic acidhydrazide **2**, arylidenecyanoacetohydrazides **7,** arylsulfonylcyanoacetohydrazides **10**, 3-aminopyrazoles **13**, 3-amino-1,2,4-triazole, 2-aminobenzoimidazole, pyrazole-3-diazonium salts **19,** 1,2,4-triazol-3-diazonium salts **22,** or benzoimidazole-2-diazonium salts **25** (0.01 mole) in piperidine acetate (1 mL), {pipridine + acetic acid + $H_2O$}, and $H_2O$ (3 mL) was refluxed for 5 min. Acetic acid (1.5 mL) was added to the hot solution and the performed solid product was filtered off and recrystallized from ethanol.

***Method (B) for preparation of 2-pyridones (9a–d) or (12a,b).*** An equimolar amount of aldehydes or arylsulfonylchlorides was added to a cold solution of compounds **4** in pyridine. The mixture was stirred for 12h and then poured over ice-water mixture and neutralized with dil. HCl. The formed solid product was filtered off to produce 2-pyridones **9** or **12**, respectively.

***2-Pyridone (4).*** Yellow crystals from EtOH, (yield 72%), m.p. 278–280°C, $\nu_{max}/cm^{-1}$ (KBr) 3388 and 3168 ($NH_2$), 3043 (CH, aromatic), 2210.9 (CN), 1643 (CO); $^1$H-NMR (300 MHz, DMSO-d6): $\delta$ = 2.49 (s, 2H, $NH_2$), 7.54–8.73 (m, 9H, aromatic); m/z 261 (Calcd for $C_{16}H_{11}N_3O$ (261.29):C, 73.55; H, 4.24; N, 16.08%. Found: C, 73.37; H, 4.36; N, 15.92%).

***2-Pyridones (9a–d).*** *9a.* Pale yellow crystals from EtOH, (yield 74%), m.p. 235°C, $\nu_{max}/cm^{-1}$ (KBr) 3048 (CH, aromatic), 2206.3 (CN), 1662 (CO); $^1$H-NMR (300 MHz, DMSO-d6): δ = 6.13–7.71 (m, 14H, aromatic), 8.10 (s, 1H, =CH); m/z 349 (Calcd for $C_{23}H_{15}N_3O$ (349.40): C, 79.07; H, 4.33; N, 12.03%. Found: C, 79.16; H, 4.14; N, 12.12%).

*9b.* Pale yellow crystals from EtOH, (yield 79%), m.p. 230°C, $\nu_{max}/cm^{-1}$ (KBr) 3033 (CH, aromatic), 2198.3 (CN), 1675 (CO); $^1$H-NMR (300 MHz, DMSO-d6): δ = 2.35 (s, 3H, $CH_3$), 6.27–7.70 (m, 13H, aromatic), 8.07 (s, 1H, =CH); m/z 363 (Calcd for $C_{24}H_{17}N_3O$ (363.42): C, 79.32; H, 4.72; N, 11.56%. Found: C, 79.38; H, 4.64; N, 11.62%).

*9c.* Pale yellow crystals from EtOH, (yield 77%), m.p. 220°C, $\nu_{max}/cm^{-1}$ (KBr) 3064 (CH, aromatic), 2208.3 (CN), 1671 (CO); $^1$H-NMR (300 MHz, DMSO-d6): δ = 3.76 (s, 3H, $CH_3$), 6.29–7.73 (m, 13H, aromatic), 8.09 (s, 1H, =CH); m/z 379 (Calcd for $C_{24}H_{17}N_3O_2$ (379.42): C, 75.98; H; 4.52; N, 11.07%. A short and facile synthesis of imidazo[1,2-*c*]quinazolin-5(6*H*)-ones and benzimidazo[1,2-*c*]quinazolin-6(5*H*)-ones was accomplished in good yields *via* the novel reductive cyclization of 2-(2-nitrophenyl)-imidazoles or 2-(2-nitrophenyl)benzoimidazoles with isocyanates promoted by low-valent titanium reagent.

*J. Heterocyclic Chem.*, **47**, 524 (2010).

## INTRODUCTION

Low-valent titanium reagents have an exceedingly high ability to promote reductive coupling of carbonyl compounds, and are attracting increasing interest in organic synthesis [1]. Many other functional groups can also be coupled [2]. Recently, we have reported the low-valent titanium induced intermolecular reductive coupling reaction of carboxylic derivatives with aromatic ketones [3], the intramolecular reductive coupling reaction of 4,4-dicyano-1,3-diaryl-1-butanone [4], the cyclodimerization of α,β-unsaturated ketones [5], and the intramolecular reductive coupling reaction of ketomalononitriles [6].

A literature survey reavealed that quinazolinones show antihypertonic, antirheumatic, antiana-phylactic, antiasthmatic, tranquilizing, neuro-stimulating, and benzodiazepine binding activity [7,8]. For example, 3-substituted quinazolinones, such as SGB-1534 (**1**) [9] and ketanserin (**2**) have been found to have antihypertensive activities mediated *via* α-adrenoceptor and serotonic receptor anatgonism, respectively. Addition of a (2-methoxyphenyl)piperazine side chain at the 2- or 3-position of the angular tricyclic 2,3-dihydroimidazo[1,2-*c*]quinazoline ring system of SGB-1534 resulted in the formation of potent antihypertensive agents such as 2-[[4-(2-methoxyphenyl)-piperazin-1-yl]methyl]-2,3-dihydroimidazo[1,2-*c*]-quinazolin-5(6*H*)-one (**3**) and 3-[[4-(2-methoxyphenyl)piperazin-1-yl]methyl]-2,3-dihydroimidazo[1,2-*c*]-quinazolin-5(6*H*)-one (**4**) that selectively antagonized the $\alpha_1$-adrenoceptor [10]. (Fig. 1).

The synthesis of quinazolinones is well studied, and recent development in combinatorial chemistry made the preparation of large number of quinazolinones in a short time possible. Sequential cyclizations of 2-isothio- cyanatobenzonitrile and 2-isocyanatobenzonitrile with α-aminoketones resulted 6*H*-imidazo[1,2-*c*]quinazolinones with high yields [11]. A series of 2-[(substituted- phenylpiperazin-1-yl)methyl]- and 2-[(substitutedphenyl-piperidin-1-yl)methyl]-2,3-dihydroimidzao[1,2-*c*]quinazolin-5(6*H*)-ones were synthesized by bromo-cyclization with NBS in THF at room temperature [10,12]. But many of these still suffer from drawbacks such as drastic conditions, unsatisfactory yields, long-reaction time, high temperature, complex manipulation, and inaccessible starting materials.

Therefore, the development of more efficient methods for the preparation of this kind of compounds is still an active ongoing research area, and there is scope for further improvement toward milder reaction conditions and improved yields. In recent years, our interest has been focused on the synthesis of quinazolines uing low-valent titanium reagent. We have previously reported the synthesis of quinazolines [13], quinazoline-2,4-diones [14], imidazo[1,2-*c*]quinazolines [15], 2-thioxoquinazolinones, imidazo[1,2-*c*]quinazolin-5-amines, and benzimidazo[1,2-*c*] quinazolin-5-amines [16] by the reaction of nitro-

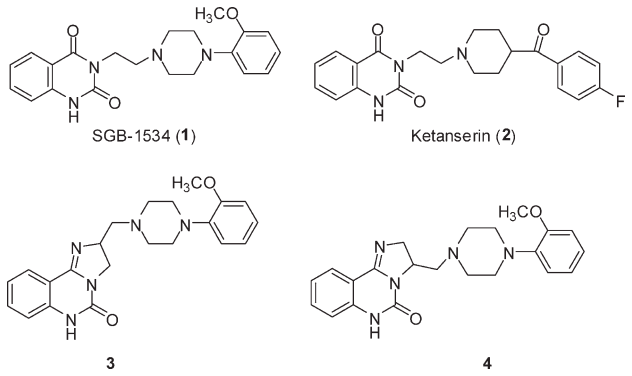

**Figure 1.** SGB-1534 (**1**), Ketanserin (**2**).

compounds with orthoformates, triphosgene, aldehydes, ketones, and isothiocyanates, respectively, induced by low-valent titanium reagent.

As our earlier works goes, herein, we wish to describe a method induced by low-valent titanium reagent for the preparation of imidazo[1,2-*c*]quinazolin-5(6*H*)-ones and benzimidazo[1,2-*c*]quinazolin-6(5*H*)-one using 2-(2-nitrophenyl)imidazole, 2-(2-nitrophenyl)benzoimidazole and isocyanates as starting materials.

## RESULTS AND DISCUSSION

On the basis of our previous experience, we selected 2-(2-nitrophenyl)-4,5-diphenyl-1*H*-imidazoles **1a** and the 1-isocyanato-4-methylbenzene **2a** as model substrates to optimize the experimental conditions for the proposed reductive cyclization reaction (Scheme 1). The results are summarized in Table 1.

As shown in Table 1, we briefly examined the effect of different temperatures and low-valent titanium systems. The results obtained from these experiments indicated that the reaction temperatures had a significant influence on the success of this reaction. To our delight at refluxed the reaction proceeded smoothly in high yield (entry 3). To further evaluate the influence of low-valent titanium system, this reaction was carried out with different low-valent titanium reagents. From the results it is obvious that the best system is $TiCl_4$/Zn.

Having established an optimal condition for the protocol, we performed a more detailed examination of the substrates. Thus, the behavior of a variety of substrates, which include different isocyanates as well as different

**Table 1**

Optimization for the reductive cyclization reaction.

| Entry | Temperature (°C) | $TiCl_4$/M | Isolated yield (%) |
|---|---|---|---|
| 1 | r.t. | $TiCl_4$/Zn | 42 |
| 2 | 40 | $TiCl_4$/Zn | 55 |
| 3 | reflux | $TiCl_4$/Zn | 89 |
| 4 | reflux | $TiCl_4$/Fe | 34 |
| 5 | reflux | $TiCl_4$/Mg | 48 |

2-(2-nitrophenyl)imidazoles or 2-(2-nitrophenyl) benzoimidazoles was examined.

First of all, we performed the reaction of a variety of 2-(2-nitrophenyl)imidazoles **1** and isocyanates **2** via $TiCl_4$/Zn system in anhydrous THF (Scheme 2, Table 2).

Furthermore, treatment of 2-(2-nitrophenyl)benzoimidazoles **4** and isocyanates **2** with $TiCl_4$/Zn in anhydrous THF under the same reaction conditions, the reductive cyclization products benzimidazo[1,2-*c*]quinazolin-6(5*H*)-ones **5** were obtained in good yields (Scheme 3). The results are summarized in Table 3.

As shown in Table 1 and Table 2, for series of **1** and **2**, either the aromatic ring containing weak electron-withdrawing groups (such as halides) or electron-donating groups (such as alkyl group), reacted well to give the corresponding products **3** in high yields under the same reaction conditions. So we concluded that no obvious effects from the electronic or nature of the aromatic ring substrates were observed in the above reactions.

Because the nitro compounds are easy to be reduced to amines by low-valent titanium reagent [17], we think this reaction may proceed through the intermediate amine **6**. As shown in Scheme 4, the nitro compound was reduced by low-valent titanium to generate amine **6**, which was then reacted with isocyanates to give intermediate **7**. Finally, the expected products **3** were produced by addition and elimination.

All the products were characterized by $^1$H-NMR and IR.

In conclusion, a series of imidazo[1,2-*c*]quinazolin-5(6*H*)-ones and benzimidazo[1,2-*c*]quinazolin-6(5*H*)-ones were synthesized induced by low-valent titanium reagent ($TiCl_4$/Zn). The process was carried out only

one step to generate diversity on the imidazo[1,2-c]quinazolines. The yields are higher and the reaction times are shorter than the protocol we reported earlier [14]. The short reaction times (0.5 h) and simple reaction conditions make this protocol attractive.

## EXPERIMENTAL

THF was distilled from sodium-benzophenone immediately prior to use. All reactions were conducted under $N_2$ atmosphere. Melting points are uncorrected. IR spectra were recorded on Tensor 27 spectrometer in KBr with absorptions in $cm^{-1}$. $^1$H-NMR spectra were determined on NMRststem-300 MHz or UNITY INOVA 400 MHz spectrometer in DMSO-$d_6$ solution. *J* values are in Hz. Chemical shifts are expressed in ppm downfield from internal standard TMS.

**General procedure for the synthesis of 3 and 5 is represented as follows.** $TiCl_4$ (0.3 mL, 3 mmol) was added dropwise using a syringe to a stirred suspension of zinc powder (0.384 g, 6 mmol) in freshly distilled anhydrous THF (10 mL) at r.t. under a dry $N_2$ atmosphere. After completion of the addition, the mixture was refluxed for 2 h. The suspension of the low-valent titanium reagent formed was cooled to r.t. and a solution of 2-(2-niteophenyl)imidazole or 2-(2-nitrophenyl) benzoimidazole (1 mmol) and isocycanates (1 mmol) in THF (5 mL) was added dropwise. The reaction mixture was then refluxed for 30 min under $N_2$. After this period, the TLC analysis of the mixture showed the reaction to be completed. The reaction mixture was quenched with 5% HCl (15 mL) and extracted with $ClCH_2CH_2Cl$ (3 × 20 mL). The combined extracts were washed with water (3 × 20 mL) and dried over anhydrous $Na_2SO_4$. After evaporation of the solvent under reduced pressure, the crude product was purified by recrystallization from 95% ethanol.

2-Dimethylaminomethylene-3-oxo-*N*-phenylbutyramide **1** reacts with malononitrile **2a** to afford the pent-2-enedioic acid 1-amide 5-phenylamide derivative **6**, which could be cyclized to give the 6-methyl-pyridone derivative **7**. Compound **1** reacts with cyanoacetamide **2b** to afford the same pyridone **7** and with cyanothioacetamide **2c** to afford the analogous pyridinethione **12**. Compound **12** reacts with DMAD to afford the pyridine derivative **15** and with *N*,*N*-dimethylchloroacetamide **16** to afford the thieno[2,3-d]pyridine derivative **18**. Compound **18** reacts with morpholine-4-carboxaldehyde **19**, *N*,*N*-diemthylformamide **20**, and 2,5-dimethoxy-tetrahydrofuran **21** to afford the fully aromatic thieno[2,3-d]pyridine derivatives **22**, **23**, and **24**, respectively.

*J. Heterocyclic Chem.,* **47**, 528 (2010).

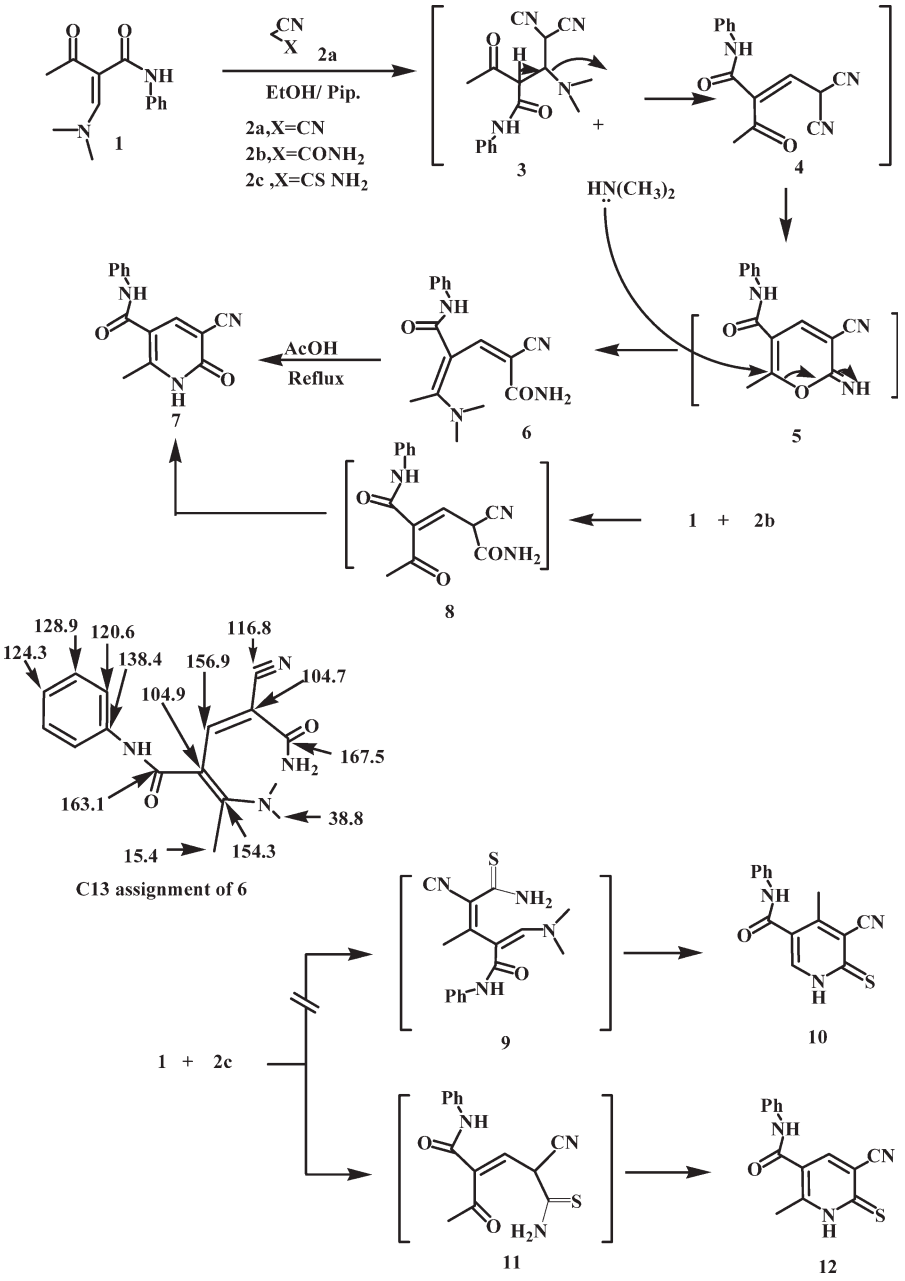
## INTRODUCTION

In the past 2 decades, we have been involved in a program aiming to develop new simple routes for the synthesis of heterocyclic compounds of biological interest to be evaluated as biodegradable agrochemicals [1–5]. Some functionally substituted pyridine and pyridone derivatives posses marked pharmaceutical activities such as anti HIV-1 reverse transcriptase agents, calcium channel blockers, anticongestive heart failure agents, and antagonists of P2 receptors for neurotransmitters [6–12]. The reaction of enaminones with active methylene nitriles represents one of the strategies for the preparation of 2-1*H*-pyridone [13–15]. Thus, some functionally substituted 2-1*H*-pyridone derivatives were required for biological activity studies. 2-Dimethylaminomethylene-3-oxo-*N*-phenylbutyramide (obtained from the reaction of acetoacetanilide with DMFDMA according to the literature method [16]) seemed a suitable synthone for the synthesis of the required 2-1*H*–pyridone derivatives through its reaction with active methylene reagents.

## RESULTS AND DISCUSSION

Thus, the enaminone compound **1** was prepared and allowed to react with the active methylene compounds **2a-c** (Scheme 1) according to the method reported earlier by us [17]. The reaction of **1** with malononitrile **2a** afforded a yellow crystalline solid of mp.197°C. The IR spectrum of this product showed absorption bands at $\upsilon_{max}$ = 2217, 1665, and 1656 $cm^{-1}$ corresponding to a cyano and two amide carbonyl functions. The mass spectrum of this product showed a molecular ion peak

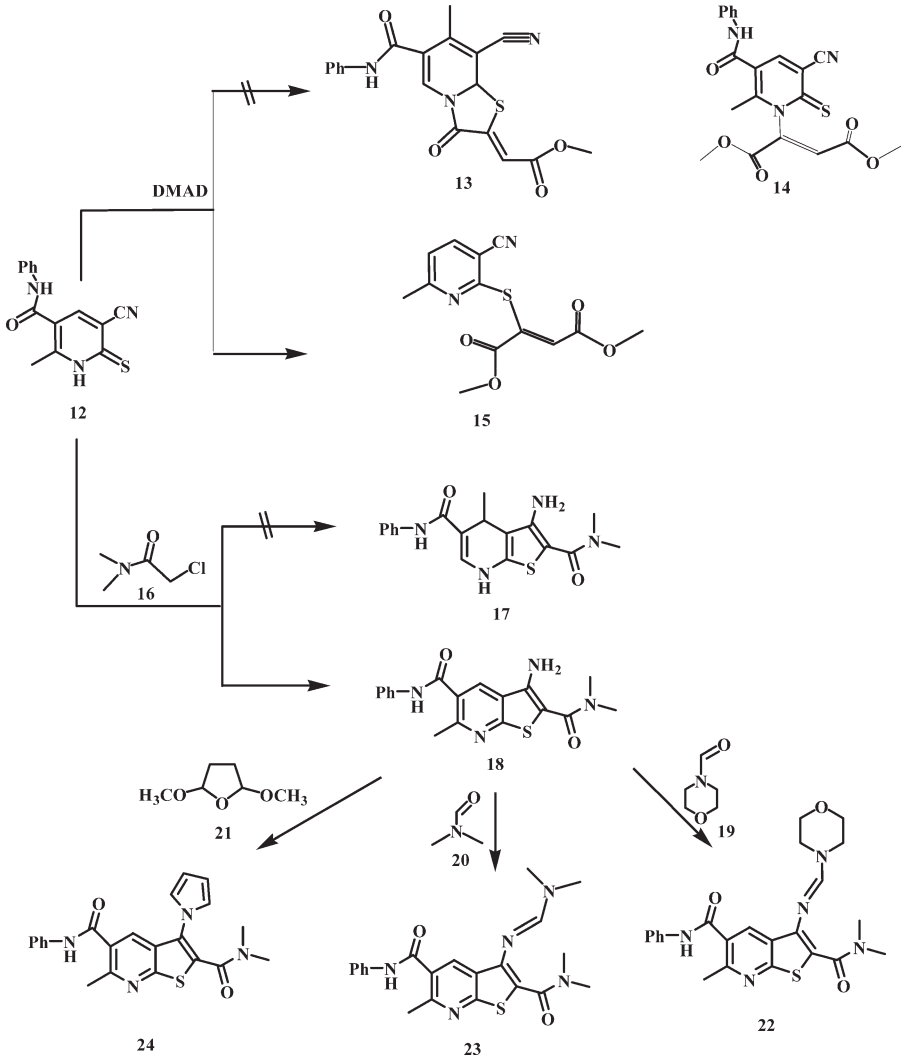
**Scheme 1.** Preparation of compounds **6**, **7**, and **12**.



at $m/z = 298$, which corresponds to the molecular formula $C_{16}H_{18}N_4O_2$ (M. Wt. 298.34). The $^1$H NMR spectrum of this product revealed a singlet (3H) at 1.69 corresponding to a methyl group, a singlet (6H) at 2.75 corresponding to the N($CH_3$)$_2$ groups, a singlet (1H) at 7.15 due to the =C*H* proton, a $D_2O$ exchangeable singlet at 8.35 (1H) attributable to an NH, beside an aromatic multiplet at 7.24–7.55 (7H, Ph+$NH_2$). Based on these data and on the analogy with our previous reported work [17], the 2-Cyano-4-(1-dimethylamino-ethylidene)-pent-2-enedioic acid 1-amide 5-phenylamide **6** was assigned to this product.

The formation of **6** from the reaction of **1** with **2a** is assumed to take place *via* the sequence shown in Scheme 1. The active methylene of malononitrile undergoes addition to the double bond of **1** to afford the intermediate **3**, followed by elimination of dimethyl amine to afford 2-acetyl-4,4-dicyanobut-2-enoic acid phenylamide **4** that directly undergoes ring closure *via* its enolized form to afford the iminopyran intermediate **5**. This newly formed iminopyran is attacked by the dimethyl amine (still present in the reaction medium) and undergoes ring opening to afford **6**. The ring opening of iminopyran under the effect ammonia and amines is well

**Scheme 2.** Preparation of compounds **15**, **18**, **22**, **23**, and **24**.



established in the literature [14,17]. The $^{13}C$ NMR data of this product are in complete agreement with structure **6** (*cf*. Scheme 1 and Experimental).

Compound **6** could be readily cyclized *via* elimination of dimethyl amine upon reflux in acetic acid to afford yellow crystals of mp. 217–219°C.

The $^{1}H$ NMR spectrum of **7** revealed the disappearance of the N$Me_2$ signal and the presence of a singlet integrated for 1H at $\delta = 8.65$, which is attributed to the C4-H, beside the other signals as expected (*cf*. Experimental). The 2-1*H*-pyridinone derivative structure **7** was assigned to this product based on the analytical and spectral data, and compound **7** has been previously described in the literature from other route, mp. 216–218°C [18].

The reaction of **1** with cyanoacetamide **2b** afforded the same 2-1*H*-pyridinone **7**. It is assumed that **2b** followed the same addition elimination sequence to afford the intermediate **8** (analogous to **4** in the above sequence) that undergoes directly the cyclization *via* elimination of water without passing through the iminopyran step, as the amide group is already present. The identity of the products obtained from the reactions of **1** with either **2a** or **2b** was deduced from the typical melting points and spectral data. A similar result has been previously observed [17].

The reaction of compound **1** with cyanothioacetamide **2c** was reported earlier to afford the pyridinthione **10** (No. **3** in the original article [19]) *via* the intermediate **9** (Number **2** in the original article). The author of ref. 19 incorrectly assumed that the reaction proceeds *via* a Knoevenagel condensation between the carbonyl group of **1** and the active methylene of **2c** to afford **9** (his **2**). On the basis of our aforementioned results, we have reinvestigated this reaction. This reaction of **1** and **2c** was found to follow the same pathway as that of **1** with **2b** to afford the intermediate **11** (analogous to **8**; Scheme 1) *via* the addition–elimination sequence, which

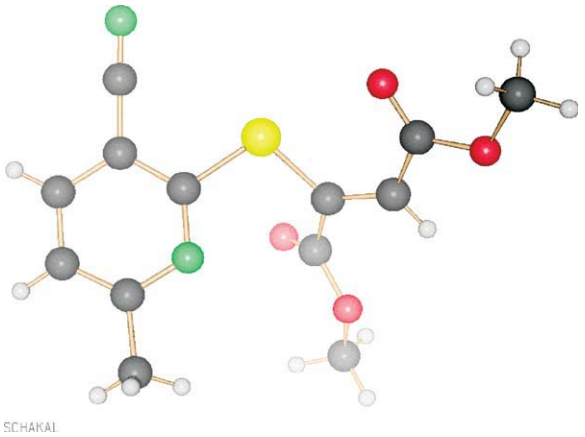


**Figure 1.** X-ray crystallographic structure of **15**. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

then undergoes cyclization *via* loss of water to afford the pyridinethione **12**. The melting point, analytical, and spectral data of our product are the same as those reported in [19]; however, the $^{13}C$ NMR data reported in [19] are wrong; the phenyl carbons should appear as four signals and not six as reported, and the whole spectrum showed only 12 signals.(*cf.* experimental).

The incorrect assignment in [19] leads to the pyridinethione **10** (his **3**) with the methyl group in the 4-position, whereas the correct structure is **12** carrying the methyl group in the 6-position. This has serious consequences for some other reactions described in this article. For example, all the reactions depicted in his Scheme 2 are all based on the imaginary presence of the methyl group in position-4 and are all vagaries.

The reaction of this pyridinethione **12** with dimethyl acetylenedicarboxylate was claimed to afford the thiazolopyridine derivative **13** (Scheme 2) (number **9** in the original article [19]). The formation of this thiazolopyridine seemed doubtful as the pyridinethione has only one proton on its nitrogen, so how the thiazole ring is formed while still retaining one hydrogen on C-2. Furthermore, the $^{13}C$ NMR data given to **13** (his **9**) cited only 10 carbons (excluding the repeated values for the aromatic carbons), while it should reveal 17 carbons. Based on all these discrepancies, we decided to reinvestigate this reaction.

Compound **12** was allowed to react with dimethyl acetylenedicarboxylate (DMAD) in chloroform (the same reaction conditions reported in [19]) to afford after recrystallization and purification on column with silica gel using pentane/ethyl acetate (3:1) as eluent a white crystalline product of mp. 126°C (Lit. mp. of compound **13** in Scheme 2 (his **9**); >300°C [19]). The mass spectrum of this product showed $m/z = 292$ [$M^+$]. From this molecular mass and the elemental analysis data (*cf.* experimental), we could calculate a molecular formula $C_{13}H_{12}N_2O_4S$ for this product, which is not applicable to **13** (old **9**) or **14** (assuming that the NH adds to the C≡C in DMAD). The IR spectrum of this product showed two carbonyl absorption at $\upsilon_{max} = 1712$ and 1710 assignable to two ester CO, a cyano absorption band at 2220 $cm^{-1}$ and no bands that could be assigned to the amide CO. The $^1H$ and $^{13}C$ NMR showed a pattern that could not be justified to either of the structures **13** (reported **9** [19]) or **14** (*cf.* experimental). From the presence of two ester carbonyl absorption bands and the presence of two methyl signals in the $^1H$ and $C^{13}$ NMR spectra, we got the impression that a Michael addition took place from either the NH in the pyridinethione or the SH in the tautomer mercapto pyridine to the activated C≡C of DMAD, and from the absence of the amide carbonyl absorption band in the IR spectrum and the presence of two doublets at $\delta = 7.36$ and 8.22 ppm with $j = 8.56$ Hz in the $^1H$ NMR spectrum, we got the impression that the amide group was eliminated either in the form of phenyl isocyanate or *via* hydrolysis of the amide linkage followed by decarboxylation. Thus, structure **15** was suggested to this product. This structure actually fulfills all the requirements of all the available data. However, it was mandatory to have an X-ray crystallographic picture for this compound. Fortunately, the X-ray picture [20,21] came exactly in complete agreement with our imagination; (see Fig. 1 and the experimental). It shows clearly the attachment of S to the DMAD, the absence of the anilide group, and also shows the methyl group at the 6-position of the pyridine ring (the *p*-position to the cyano group) which is a further proof to our suggested mechanism (*cf.* Scheme 1).

Compound **12** reacts also with *N,N*-dimethyl chloroacetamide **16** under the same reaction conditions described in ref. 19 to afford the fully aromatic thieno[2,3-*b*]pyridine derivative **18** rather than the claimed dihydro-derivative **17** (his **11** [19]). It should be stated that the $^1H$ NMR data reported for compound **17** (old **11**) are completely applicable to our compound **18** (*cf.* experimental part).

Compound **18** was allowed to react with morpholine-4-carboxaldehyde **19**, *N,N*-diemthylformamide **20**, and 2,5-dimethoxy-tetrahydrofuran **21** under the same reaction conditions described in ref. 19 to afford products very similar to those described (his numbers **15**, **16**, and **17** in his Scheme 4); however, the obtained products were found to be the fully aromatic thieno[2,3-*b*]pyridine derivatives **22**, **23**, and **24**, respectively (*cf.* Scheme 2). It should be stated also that the $^1H$ NMR data reported in reference [19] for compounds **22**, **23**, and **24** (Scheme 2; numbers **15**, **16**, and **17** in his Scheme 4) are completely not applicable to their assigned structures.

## EXPERIMENTAL

Melting points were measured on an Electrothermal (9100) apparatus and are uncorrected. IR spectra were recorded as

KBr pellets on a Perkin Elmer 1430 spectrophotometer. The $^1$H NMR and $^{13}$C NMR spectra were taken on a Varian Gemini 300 MHz spectrometer in DMSO-$d_6$ using TMS as internal standard and chemical shifts are expressed in δ ppm values. Mass spectra were taken on a Shimadzu GCMS-GB 1000 PX (70 ev). Elemental analyses were carried out at the Micro-analytical Center at Cairo University. X-ray data [20] were collected using a Bruker Nonius 5622 diffractometer and were corrected by SADABS factors and emperical absorption. The structure was solved by direct methods and expanded using Fourier technique. SCHAKAL 99 program system was used in the graphic representation of the structure [21]. The nonhydrogen atoms are refined anisotropically and the hydrogen atoms were refined according to theoretical models. X-ray crystallography, elemental and spectral data of compound **15** were made in the Institute of Organic Chemistry, TU-Dresden, Germany.

**2-Cyano-4-(1-dimethylamino-ethylidene)-pent-2-enedioic acid 1-amide 5-phenylamide 6.** To a mixture of 2-dimethylaminomethylene-3-oxo-*N*-phenylbutyramide **1** (2.32 g; 10 mmol) and malononitrile **2a** (0.66 g; 10 mmol) in ethanol (15 mL) was added few drops of piperidine as catalyst. The reaction mixture was refluxed for 2 h and then left to cool to room temperature. The solid product thus precipitated was collected by filtration and recrystallized from dioxan to give yellow crystals, yield (2.23 g, 75%); mp 197–198°C (Dioxan); $\upsilon_{max}$ = 3435–3284 ($NH_2$ and NH), 2217 (CN), 1665, and 1656 cm$^{-1}$ (2 CO); MS: *m*/*z* = 298 [M$^+$]; $\delta_H$ = 1.69 (s, 3H, $CH_3$), 2.75 (s, 6H, $2CH_3$), 7.15 (s, 1H, CH), 7.10–7.65 (m, 7H, Ph+$NH_2$), 8.35 (s, 1H, NH). $\delta_C$ = 15.4 (q), 38.8 (q), 104,7 (s), 104,9 (s), 116,8 (s), 120.6 (d), 124.3 (d), 128.9 (d), 138.4 (s), 154.3 (s), 156.9 (d), 163.1 (s), 167.5 (s).

Anal. Calcd. for $C_{14}H_{18}N_4O_2$: (298.34): C, 64.41; H, 6.08; N, 18.78. Found: C, 64.45; H, 6.10; N, 18.90.

**Synthesis of 5-cyano-2-methyl-6-oxo-1,6-dihydro-pyridine-3-carboxylic acid phenyl amide 7.** ***Method A: Cyclization of compound 6.*** Compounds **6** (2.98 g, 10 mmol) was refluxed in ethanolic sodium ethoxide (15 mL) for 30 min. The solvent was reduced to one third of its volume under reduced pressure and left to cool overnight. The solid precipitate that appeared was collected by filtration and crystallized from ethanol to afford **7** as yellow crystals, yield (2.15 g, 85%), mp. 219–220°C.

***Method B: The reaction of 2-dimethylaminomethylene-3-oxo-N-phenylbutyramide 1 with cyanoacetamide 2b.*** To a mixture of **1** (2.32 g, 10 mmol) and cyanoacetamide **2b** (0.84 g, 10 mmol) in ethanol (20 mL) was added a catalytic amount of piperidine (5 drops). The reaction mixture was refluxed for 6 h and then left to cool to room temperature. The contents of the flask were poured onto ice-cold water and acidified with few drops of conc. HCl till just neutral (pH paper). The precipitated solid product was filtered off, washed thoroughly with cold water, dried, and recrystallized from ethanol/DMF (4:1) to give **7** as yellow crystals, yield (1.97 g, 78%); mp. 217–219°C (Lit. mp. 216–218°C [18]); $\upsilon_{max}$ = 3382, 3275 (NH), 2235 (CN), and 1657 and 1638 cm$^{-1}$ (2CO); MS: *m*/*z* = 253 [M$^+$]; $\delta_H$ = 2.63 (s, 3H, $CH_3$), 7.12–7.68 (m, 5H, Ph), 7.82 (br.s., 1H, NH), 8.65 (s, 1H, H-4), 10.60 (br.s., 1H, NH). $\delta_C$ = 16.48 (q), 104.66 (s), 112.65 (s), 116.15 (s), 121.05 (d), 124.57 (d), 128.65 (d), 138.45 (s), 145.6 (s), 153.95 (d), 159.86 (s), 164.55 (s).

Anal. Calcd. *for* $C_{14}H_{11}N_3O_2$: (253.26): C, 66.40; H, 4.38; N, 16.59. Found: C, 66.45; H, 4.47; N, 16.70.

**5-Cyano-2-methyl-6-thioxo-1,6-dihydro-pyridine-3-carboxylic acid phenylamide 12.** A mixture of compound **1** (2.32 g, 10 mmol) and cyanothioacetamide **2c** (1.0 g, 10 mmol) in ethanol (25 mL) with sodium ethoxide catalyst was refluxed for 30 min. After cooling down, the reaction mixture was poured onto cold water and acidified with dil. HCl. The precipitated solid product thus formed was collected by filtration and recrystallized from ethanol to afford **12** as yellow crystals, Yield (1.94 g, 72%), mp. 225–227°C (lit. 235°C [19]), $\upsilon_{max}$ = 3345, 3228 (NH), 2215 (CN), and 1658 cm$^{-1}$ (CO); MS: *m*/*z* = 269 [M$^+$]; $\delta_H$ = 1.74 (s, 3H, $CH_3$), 7.05–7.68 (m, 5H, Ph), 8.15 (s, 1H, H-4), 9.25 (br.s., 1H, NH), 13.92 (br.s., 1H, NH). $\delta_C$ = 185.65 (s), 167.46 (d), 163.85 (s), 143.15 (s), 135.26 (s), 128.66 (d), 124.25 (d), 120.38 (d), 116.24 (s), 116.58 (s), 107.47 (s), 15.42 (q).

Synthesis of new heterocyclic compounds containing the pyridazinone moiety, which have a valuable biological activities, has been achieved through the nucleophilic addition of benzylamine to 4-(*p*-substituted phenyl)-4-oxo-2-butenoic acid **1a,b**, followed by cyclocondensation of the adducts **2a,b** to the corresponding pyridazin-3-one derivatives **3a,b**. The behavior of the latter compounds toward different nucleophilic and electrophilic reagents was investigated. The structures of the newly synthesized compounds were elucidated by elemental analysis and spectroscopic data.

*J. Heterocyclic Chem.*, **47**, 534 (2010).

## INTRODUCTION

A large number of pyridazinone derivatives were reported to exhibit insecticidal [1–5], herbicidal [2,6], antiallergenic [7], antihypertensive [8], analgesic [9], anti-inflammatory [10], and bacteriocidal activities [11]. This prompted us to synthesize a new series of heterocyclic pyridazinone derivatives through the reaction of 4-(*p*-bromophenyl) or 4-(*p*-methylphenyl)-4-oxo-2-butenoic acid **1a,b** [12] with benzylamine in dry benzene and yielded the addition products **2a,b**. The latters were reacted with hydrazine hydrate in ethanol to give the unexpected pyridazin-3-one derivatives **3a,b,** respectively, rather than the expected 4,5-dihydropyridazin-3(2*H*)-one derivatives **4a,b**. The products **3** were used for synthesis of some important heterocyclic compounds through their conversion to the corresponding 3-chloropyridazine derivatives **7a,b**, which act as a key factor in synthesis of different heterocyclic pyridazine derivatives.

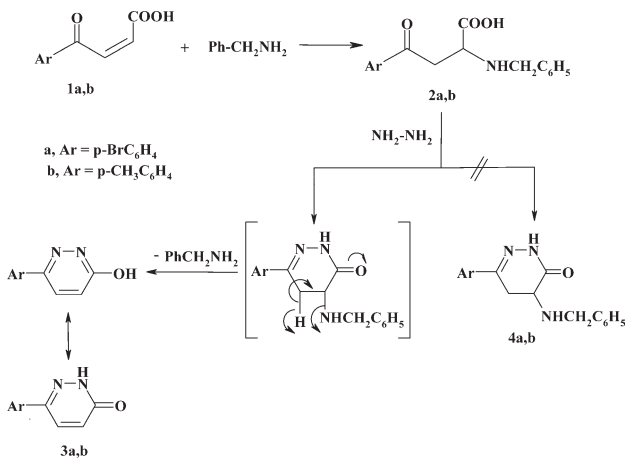
## RESULTS AND DISCUSSION

The reaction of 4-(*p*-bromo- and *p*-methylphenyl)-4-oxo-2-butenoic acid **1a,b** and benzylamine in dry benzene gave 4-(*p*-bromo- and tolyl)-4-oxo-2-(benzylamino)butanoic acid **2a,b**. Condensation of the acid derivatives **2a,b** with hydrazine hydrate in boiling ethanol afforded the unexpected 6-(*p*-substituted phenyl)pyridazin-3(2*H*)-one **3a,b** with the fission of the benzylamino group in position 4 and aromatization of the pyridazine ring [13,14] (Scheme 1).

Thus, structure of compound **2b** is supported by its correct elemental analysis, and its mass spectrum which revealed the molecular ion peak at $m/z = 297$ ($M^+$ 2.5%) for the molecular formula $C_{18}H_{19}NO_3$. Also, the structure of compounds **3** were elucidated by their elemental analysis and spectroscopic data. Thus, the $^1H$ NMR (DMSO) of compound **3a** showed signals at $\delta =$ 7.25–8.14 ppm (6H, m, Ar—H and —CH=CH— of pyridazine ring) and 8.98 (broad s, 1H, NH). Its mass spectrum showed molecular ion peak at $m/z = 252$ ($M^+ +1$, 24.2%) corresponding to the molecular formula $C_{10}H_7N_2OBr$.

In contrast, condensation of **2a,b** with hydroxylamine hydrochloride in boiling pyridine yielded the corresponding 3-(*p*-substituted phenyl)-4,5-dihydro-5-(benzylamino)-1,2-oxazin-6-ones **5a,b** with no fission of the benzylamino group. In support for the products **5a,b**, the acid **2b** was easily dehydrated in boiling acetic

**Scheme 1**

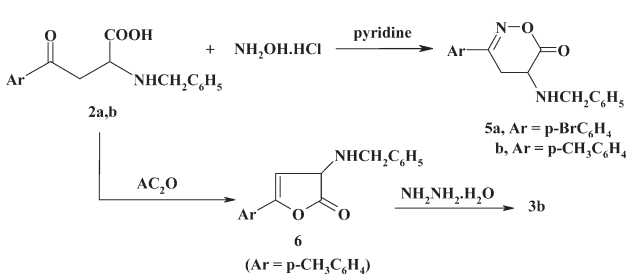


anhydride or heated at its melting point to yield 3-(benzylamino)-5-(4-methylphenyl)furan-2(3*H*)-one **6** (Scheme 2).

The structure of the oxazin-6-one derivative **5a** was confirmed by its correct elemental analysis and spectroscopic data. The IR of **5a** showed bands at 1683 $cm^{-1}$ (C=O), 1588 $cm^{-1}$ (C=N), and at 3287 $cm^{-1}$ (NH). Its mass spectrum showed a molecular ion peaks at $m/z$ = 359 ($M^+$, 7.7%) coincident with the molecular formula $C_{17}H_{15}N_2O_2Br$. The structure of the furanone derivative **6** was established by its correct elemental analysis, and its IR spectrum which showed a strong absorption at 1771 $cm^{-1}$ characteristic for the C=O of the five membered lactone ring and a band at 3195 $cm^{-1}$due to NH. The mass spectrum revealed the molecular ion peak at $m/z$ = 279 ($M^+$, 34.30%) for the molecular formula $C_{18}H_{17}NO_2$ and the base peak at $m/z$ = 106 (100%). Also, the structure of **6** was further established by its hydrolysis with hot alkali to the corresponding acid **2b**. In addition, the reaction of compound **6** with hydrazine hydrate in boiling ethanol gave the pyridazinone **3b,** which was identified by m.p. and mixed m.p. determination.

The keto-enol tautomerism in the pyridazinone ring is elucidated by the formation of its chloroderivative by the reaction of pyridazinones **3a,b** with nucleophilic

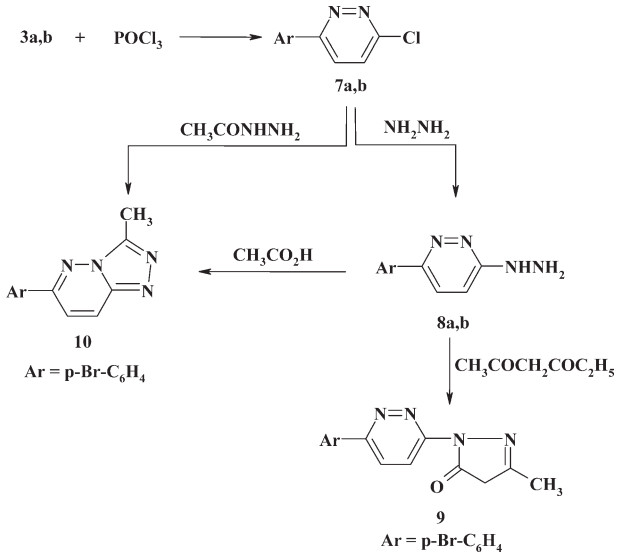
**Scheme 2**



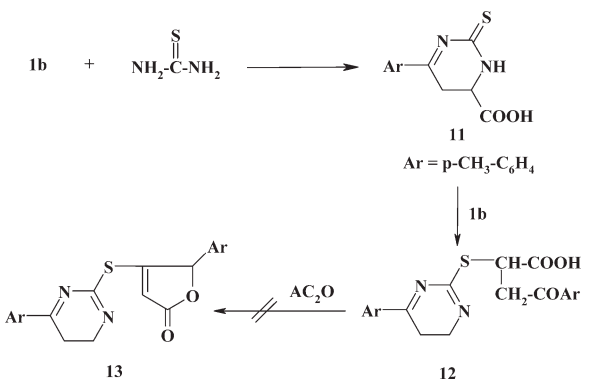
reagents like phosphorus oxychloride to give 3-chloropyridazines **7a,b** [15] which act as a key intermediate for the formation of different fused heterocyclic compounds which may have biological activities [16]. Thus, derivatives **7a,b** were submitted to react with hydrazine hydrate in boiling butanol to afford the corresponding hydrazine derivatives **8a,b** in good yield. On treatment of compound **8a** with ethylacetoacetate in boiling ethanol, 2-[6-(4-bromophenyl)pyridazin-3-yl]-5-methyl-2,4-dihydro-3H-pyrazol-3-one **9** was afforded. On the other hand, when compound **8a** was refluxed with acetic acid, the corresponding 6-(4-bromophenyl)-3-methyl[1,2,4]-triazolo[4,3-*b*]pyridazine **10** [17] was produced. The latter compound could be also obtained via the condensation of the chloropyridazine derivative **7a** with acetylhydrazine in boiling butanol (Scheme 3).

The structure of the compound **9** was confirmed by its elemental analysis and spectroscopic data. Thus, the IR of the compound showed absorption bands at 1643 $cm^{-1}$ (C=O) and at 1582 $cm^{-1}$ (C=N). The $^1$H NMR (DMSO) exhibited signals at δ = 2.04 ppm (s, 3H, $CH_3$); 2.23 (s, 2H, $CH_2$), 7.41–8.42 (m, 6H, Ar'H). The mass spectrum revealed the molecular ion peak at $m/z$ = 332 ($M^+$ +1, 100%) corresponding to the molecular formula $C_{14}H_{11}N_4OBr$. The structure of compound **10** was also elucidated by elemental analysis and spectroscopic data (IR, $^1$H NMR, and Ms). Thus, the $^1$H NMR of **10** showed signals at δ = 1.98 ppm (s, 3H, $CH_3$) and at 7.00–8.23 (m, 6H, $C_6H_4$, HC=CH). On the other hand, butenoic acid derivative **1b** was found to react with thiourea in boiling ethanol to give 6-(4-methylphenyl)-2-thioxo-2,3,4,5-tetrahydro-pyrimidine-4-carboxylic acid **11**. As a point of interest, the addition of the carboxylic acid **11** to another molecule of **1b** in dry benzene

**Scheme 3**



**Scheme 4**



containing a catalytic amount of pipredine has been achieved to afford the corresponding oxobutanoic acid derivative **12** but with cleavage of the carboxylic group of the pyridazine ring. An attempt to cyclize compound **12** through the dehydration with boiling acetic anhydride to afford the corresponding furanone derivative **13** has been failed (Scheme 4).

The structures of the compounds **11** and **12** were confirmed by their elemental analysis and spectroscopic data. Thus, the IR of the compound **11** showed bands at 3242 $cm^{-1}$ (NH), 1678 (C=O), and at 1491 (C=S). Its mass spectrum revealed the molecular ion peak at $m/z$ = 248 ($M^+$, 29.5%) related to the molecular formula $C_{12}H_{12}N_2O_2S$. The structure of **12** was also proved by its correct elemental analysis and spectroscopic data. The IR of the compound showed the absence of the band related to the NH group and exhibited bands at 1682 $cm^{-1}$ (C=O), and 1642 (C=O), and at 1355 (C—S—C). The mass spectrum of the compound revealed the molecular ion peak at $m/z$ = 394 ($M^+$, 4.0%) corresponding to the molecular formula $C_{22}H_{22}N_2O_3S$.

## EXPERIMENTAL

The Infrared spectra were recorded on a BRUKER IFS-25 FT-IR spectrophotometer using KBr at the region 400–4000 $cm^{-1}$, $^1H$ and $^{13}C$ on a BRUKER AVANCE/200 ULTRA-SHLIELD™ transform instrument using TMS as internal standard, Mass spectra were obtained with an Shimad 24 GCMS-QP 1000EX., Elemental analyses were determined on FISONS instruments DP200 series 2 and Euro EA3000 series Euro Vector. Elemental analyses for (CHNS) of all compounds are in accordance with the theoretical values within (0.4%) error. All melting points were uncorrected. Compounds **1a,b** were synthesized according to the literature procedure [18,19]. Compounds **3a,b**, **7a,b,** and **8a,b** could be obtained through other procedures [20,21].

**Synthesis of 2-(benzylamino)-4-(4-bromo- (methyl)-phenyl)-4-oxobutanoic acid 2a,b.** A mixture of compounds **1a,b** (0.01 mol) was refluxed with an equimolar amount of benzylamine for 3 h in 50 mL dry benzene. The reaction mixture was cooled and left at room temperature over night to precipitate the products as pale yellow needles. The solid products were collected and recrystallized from ethanol.

***2a.*** Pale yellow (76%), m.p. 177°C, $\nu_{max}/cm^{-1}$ (KBr) 3292 (NH), 1677 and 1651 (C=O); $m/z$ 362 (Calcd. for $C_{17}H_{16}NO_3Br$: C, 56.35; H, 4.42; N, 3.87% Found: C, 56.02; H, 4.41; N, 3.62%).

***2b.*** Pale yellow (67%), m.p. 187°C, $\nu_{max}/cm^{-1}$ (KBr) 3289 (NH), 1671 and 1655 (C=O); $^1H$ NMR (DMSO) $\delta$ = 1.98 ppm (s, 3H, $CH_3$), 2.26 (s, 2H, C—$CH_2$), 2.45 (s, 2H, N—$CH_2$) 3.42 (s, 1H, CH), 7.22–8.14 (m, 9H, ArH), 9.10 (s, 1H, NH), and 12.21 (s, 1H, COOH); $m/z$ 297 (Calcd. for $C_{18}H_{19}NO_3$: C, 72.72; H, 6.39; N, 4.71% Found: C, 72.50; H, 6.41; N, 4.62%).

**Synthesis of 6-(4-bromo-(methyl)phenyl)pyridazin-3(2*H*)-one 3a,b.** Equivalent amounts of **2a,b** (0.01 mol) and hydrazine hydrate were refluxed in 50 mL ethanol for 10 h. The reaction mixture was concentrated and left to precipitate the products, which were filtered off to give yellow crystals of **3a,b**.

***3a.*** Yellow (87%), m.p. 195°C, $\nu_{max}/cm^{-1}$ (KBr) 3311 (NH) and 1648 (C=O); $^1H$ NMR (DMSO) $\delta$ = 7.25–8.14 ppm (6H, m, Ar—H and —CH=CH— of pyridazine ring) and 8.98 (broad s, 1H, NH); $m/z$ 252 (Calcd. for $C_{10}H_7N_2OBr$: C, 47.80; H, 2.78; N, 11.15% Found: C, 47.55; H, 2.41; N, 11.00%).

***3b.*** Yellow (88%), m.p. 227°C, $\nu_{max}/cm^{-1}$ (KBr) 3294 (NH), 1648 (C=O); $m/z$ 186 (Calcd. for $C_{11}H_{10}N_2O$: C, 70.96; H, 5.37; N, 15.05% Found: C, 70.48; H, 5.66; N, 15.22%).

**Synthesis of 5-(benzylamino)-3-(4-bromo-(methyl)-phenyl)-4,5-dihydro-6*H*-1,2-oxazin-6-one 5a,b.** A mixture of **2a,b** (0.01 mol) and hydroxylamine hydrochloride (0.01 mol) in 20 mL pyridine was refluxed for 6 h. The reaction mixture was cooled and poured onto ice/HCl mixture. The obtained solid was collected by filtration and recrystallized from suitable solvent.

***5a.*** Pale brown (68%), m.p. 140°C, from benzene, $\nu_{max}/cm^{-1}$ (KBr) 3287 (NH), 1683 (C=O), 1588 (C=N); $m/z$ 359 (Calcd. for $C_{17}H_{15}N_2O_2Br$: C, 56.82; H, 4.18; N, 7.79% Found: C, 56.99; H, 4.42; N, 8.02.00%).

***5b.*** White (64%), m.p. 250°C, from EtOH, $\nu_{max}/cm^{-1}$ (KBr) 3289 (NH), 1684 (C=O), 1588 (C=N); $^1H$ NMR (DMSO) $\delta$ = 1.99 ppm (s, 3H, $CH_3$), 2.32 (s, 2H, C—$CH_2$), 2.58 (s, 2H, N—$CH_2$), 3.11 (s, 1H, CH), 7.00–8.24 (m, 9H, ArH), 9.14 (s, 1H, NH); $m/z$ 294 (Calcd. for $C_{18}H_{18}N_2O_2$: C, 73.46; H, 6.12; N, 9.52% Found: C, 73.26; H, 6.41; N, 9.50%).

**Synthesis of 3-(benzylamino)-5-(4-methylphenyl)furan-2(3*H*)-one 6.** Compound 2b (0.01 mol) was refluxed in 50 mL acetic anhydride for 8 h. The solution was concentrated over water bath and kept to separate the solid product which was collected and recrystallized from acetic acid.

***6.*** White (64%), m.p. 155°C, $\nu_{max}/cm^{-1}$ (KBr) 3195 (NH), 1771 (C=O), $^1H$ NMR (DMSO) $\delta$ = 1.84 ppm (s, 3H, $CH_3$), 2.11 (s, 2H, $CH_2$), 2.89–3.15 (s, 2H, 2CH), 6.98–8.01 (m, 9H, ArH), 8.99 (s, 1H, NH); $m/z$ 279 (Calcd. for $C_{18}H_{17}NO_2$: C, 77.42; H, 6.09; N, 5.01% Found: C, 77.11; H, 6.21; N, 4.89%).

**Synthesis of 3-(4-bromo- (methyl)phenyl)-6-chloropyridazine 7a,b.** A mixture of the pyridazinones **3a,b** (0.01 mol) and $POCl_3$ (10 mL) was heated in water bath for 4 h. After cooling, the reaction mixture was poured onto a mixture of ice/

water. The precipitate was collected by filtration, and the solid product was recrystallized from methanol.

***7a.*** Brown (77%), m.p. 199°C, $\nu_{max}/cm^{-1}$ (KBr) 1612 (C=N), (Calcd. for $C_{10}H_6N_2ClBr$: C, 44.56; H, 2.24; N, 10.39% Found: C, 44.24; H, 2.22; N, 10.41.00%).

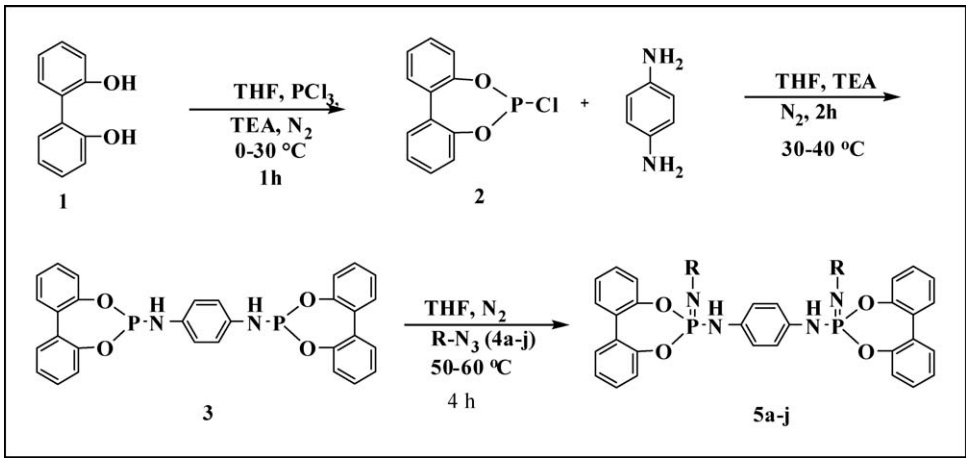
Published online 2 April 2010 in Wiley InterScience (www.interscience.wiley.com).



A new class of novel benzene-1,4-diamine-bis-dioxaphosphepine-6λ$^5$ iminophosphoranes (**5a–j**) were synthesized by the reaction of 6-chlorodibenzo[*d,f*][1,3,2]dioxaphosphepine (**2**) with 1,4-diaminobenzene to form bis-dibenzo[*d,f*][1,3,2]dioxaphosphepin-6-yl-benzene-diamine (**3**). Its subsequent reaction with different alkyl/aryl azides (**4a–j**) in tetrahydrofuran at 50–60°C under inert atmosphere yielded title compounds. Their structures were established by elemental analysis, IR, $^1$H, $^{13}$C, $^{31}$P NMR, and mass spectral studies. All the title compounds were screened for antioxidant properties and found to exhibit potent *in vitro* antioxidant and antimicrobial activity

*J. Heterocyclic Chem.,* **47**, 538 (2010).

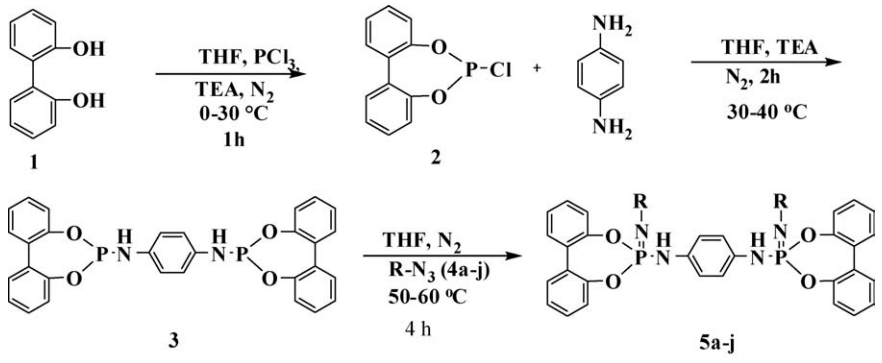
## INTRODUCTION

In recent years, the detailed mechanism of antioxidant action of organophosphorus compounds and their relationships between chemical structure and antioxidant activity have been comprehensively studied, in spite of their great practical importance. Depending on their structure and scavenging activity, phosphites and phosphonates may act as both primary and secondary antioxidants [1,2]. Reactive oxygen species (ROS) are produced by univalent reduction of dioxygen to superoxide anion which in turn disproportionate to $H_2O_2$ and $O_2$ spontaneously. The ROS are believed to play a major role in the inflammatory process in rheumatoid arthritis (RA) and contribute to the destruction of cartilage and bone [3,4]. The most important ROS implicated in inflammatory tissue injury are superoxide radical ($O_2^{\bullet -}$), hydrogen peroxide ($H_2O_2$), hydroxyl radical ($HO^{\bullet}$), and hypochlorous acid ($HOCl^{\bullet}$). In the inflammed joint, these ROS can be produced by macrophages, neutrophils, and chondrocytes [5]. The inflammed rheumatoid joint also undergoes a hypoxia–reperfusion cycle, which results in ROS generation [6]. Antioxidants may have a therapeutic role in RA by suppressing the inflammation. As our synthesized compounds are contrast in the structure to bisphosphonates, the aim of this study was to investigate the *in vitro* antioxidant profile of different bis-iminophosphoranes. To the best of our knowledge the antioxidant profile of different bis-iminophosphranes has not yet been systematically studied.

## RESULTS AND DISCUSSION

Cyclization of 2,2′-dihyroxybiphenyl (**1**) with phosphorus trichloride at 0°C under dry and inert conditions in the presence of triethylamine (TEA) in tetrahydrofuran (THF) afforded the corresponding 6-chlorodibenzo[*d,f*][1,3,2]dioxaphosphepine (**2**). Reaction of **2** with 1,4-diaminobenzene led to bis dibenzo[*d,f*][1,3,2]dioxaphosphepin-6-yl]-1,4-benzenediamine (**3**). Further reac-

**Scheme 1**



| Entry | R | Entry | R |
|---|---|---|---|
| 5a | $CH_3$ | 5f | $CH_2$-$CH(CH_3)_2$ |
| 5b | $CH_2$-$CH_3$ | 5g | $CH{=}CH_2$ |
| 5c | $CH_2$-$CH_2CH_3$ | 5h | $CH_2$-$CH{=}CH_2$ |
| 5d | $CH_2$-$(CH_2)_2$-$CH_3$ | 5i | $CH_2$-$C_6H_5$ |
| 5e | $CH(CH_3)_2$ | 5j | $CH_2$-$C_6H_4$-$NO_2$(4) |

tion of **3** with different organic azides **4a–j** in dry THF at 50–60°C led to **5a–j** in high yields (Scheme 1). The reactions were monitored by thin layer chromatography (TLC). The chemical structures of **5a–j** were confirmed by elemental analysis and spectral data (IR, $^1$H, $^{13}$C, $^{31}$P NMR, and mass spectra).

Characteristic IR absorptions were observed for C—N, P=N, and NH in the regions 1010–1081, 1206–1265, and 3280–3410 cm$^{-1}$, respectively [7]. The aromatic hydrogens resonated as multiplets at δ 6.45–7.99, the P—NH proton chemical shift appeared as a singlet at δ 3.75–5.20. The chemical shifts of other aliphatic hydrogens and carbon-13 **5a–j** appeared in the expected region [8]. $^{31}$P NMR chemical shifts were observed in the region δ 4.25–9.20 [7]. LCMS of **5a**, **5b**, **5e**, **5g**, **5i**, and **5j** gave molecular ion peaks and diagnostic daughter ions at their expected m/z values.

The radical scavenging capacity of **5a–j** was evaluated by using methods such as 1,1-diphenyl-2-picryl hydrazyl (DPPH) and nitric oxide scavenging activity. **5j** showed appreciable antioxidant activity. Because of —$NO_2$ substituents which affect the electron and hydrogen donating capacities, appears to be useful in inducing antioxidant activity. As —$NO_2$ is highly withdrawing moiety, thereby electron density around phosphonate moiety decrease and increases affinity toward oxygen derived free radicals and mobilizes ROS to be scavenged out of living system.

## EXPERIMENTAL

All melting points were determined in open capillary tubes on Mel-Temp apparatus and are uncorrected. Microanalyses were performed at the Central Drug Research Institute, Lucknow, India. Infrared spectra ($\nu_{max}$ in cm$^{-1}$) were recorded as KBr pellets on a Perkin-Elmer 283 double beam spectrophotometer. $^1$H, $^{13}$C, and $^{31}$P NMR spectra were recorded on AMX 400 MHz spectrophotometer operating at 400 MHz for $^1$H NMR, 100 MHz for $^{13}$C NMR, and 161.9 MHz for $^{31}$P NMR, using DMSO-$d_6$ as solvent. The $^1$H and $^{13}$C NMR chemical shifts were referenced to Tetra Methyl Silane (TMS) and $^{31}$P NMR chemical shifts to 85% $H_3PO_4$.

**Typical experimental procedure.**

***Preparation of alkyl azides.*** In a dry 100-mL round-bottomed flask fitted with dropping funnel, calcium chloride guard tube, sodium azide (0.64 g, 0.01 mole), and 10 mL of dry THF were placed and stirred. Alkyl/aryl bromide (0.01 mole) in 10 mL of dry THF was added to it at room temperature. Temperature of the reaction mixture was raised to 40–45°C and stirred for 4 h. After cooling to room temperature, it was filtered to remove sodium bromide. The filtrate containing alkyl/aryl azide was used for the next step reaction.

***N1,N4 Bis[6-(alkyl/arylimino)-6λ$^5$-dibenzo[d,f][1,3,2]dioxaphosphepine-6yl]benzene-1,4-diamine 5a–j.*** A solution of slight excess of phosphorus trichloride (0.43 g, 0.005 mole) in dry THF (25 mL) under nitrogen atmosphere, was added dropwise to a well-stirred solution of 2,2′-dihydroxybiphenyl(**1**) (0.930 g, 0.005 mole) and TEA (1.4 g, 0.01 mole) in dry THF(20 mL) at 0°C. After the addition, the temperature of the reaction mixture was slowly raised and kept at 25–30°C for 1 h. The reaction progress was monitored by TLC. The mixture was filtered to remove triethylamine hydrochloride and the filtrate was rota-evaporated. The residue-6-chlorodibenzo[*d,f*][1,3,2]dioxaphosphepine (**2**) was used for the next step.

To the intermediate **2** in dry THF (20 mL), 1,4-diaminobenzene (0.548 g, 0.05 mole) was added at 10°C in the presence of TEA at nitrogen atmosphere in dry THF. After the addition,

the reaction mixture was brought to 30–40°C and stirred for 2 h to complete the reaction. It was treated with alkyl/aryl azides (0.01 mole) in THF at 50–60°C and stirred for 4 h to complete the reaction. The progress of the reaction was monitored by TLC (ethyl acetate:hexane, 2:8) analysis. After completion of the reaction, solvent was removed in a rota-evaporator to get crude products. The residue was purified by column chromatography on silicagel (80–120 mesh) using petroleum ether-ethylacetate (8:2) as eluant. It was recrystallized from 2-propanol to afford pure (**5a–j**).

## ANTIOXIDANT ACTIVITY

**DPPH radical scavenging activity.** The hydrogen or electron donation abilities of title compounds were measured from the bleaching of the purple color methanol solution of DPPH [9]. This spectrophotometric assay uses the stable radical DPPH as a reagent. One milliter of various concentrations of the title compounds (20, 40, 60, 80, and 100 μg/mL) in methanol were added to 4 mL of 0.004% methanol solution of DPPH. After a 30 min incubation period at room temperature, the absorbance was red against blank at 517 nm.

[b] Reference compound.

The antioxidant activity of these compounds was expressed as $IC_{50}$ (Inhibition concentration, 50%) of **5j** which showed highest DPPH scavenging activity with 11 μg/mL when compared with other compounds (Table 1). The percent of inhibition of free radical production from DPPH was calculated by using the following equation. Butylated hydroxyl toluene (BHT) was used as a standard reference compound.

$$I = \frac{[(A_{\text{control}}) - (A_{\text{sample}})]}{\text{Blank}} 100 \quad (1)$$

where, $A_{\text{control}}$ is absorbance of the control.

Control reaction containing the entire reagent except the test compound.

$A_{\text{sample}}$ is absorbance of the test compound.

**Nitric oxide scavenging activity.** Nitric oxide scavenging activity was measured by slightly modified methods of Green *et al*. and Marcocci *et al*. [10]. Nitric oxide radicals were generated from sodiumnitropruside. One milliliter of sodiumnitroprusside (m*M*) and 1.5 mL of phosphate buffer saline (0.2*M*, $p_H$ 7.4) were added to the different concentrations (20, 40, 60, 80, and 100 μg) of the extract and incubated for 150 min at 25°C. After incubation, 1 mL of the reaction mixture was treated with 1 mL of Griess reagent (1% Sulfanilamide, 2% of $H_3PO_4$ and 0.1% naphthylethylene diamine dihydro chloride).

Absorbance was measured at 546 nm. **5j** showed highest DPPH scavenging activity with 14 mg/mL when compared with other compounds (Table 2). Butylated

hydroxy toluene was added as a standard. The percent of inhibition (I %) was calculated by using the following equation:

$$I = \frac{[(A_{\text{control}}) - (A_{\text{sample}})]}{\text{Blank}} 100 \qquad (2)$$

**Antibacterial activity.** Antibacterial activity of all the title compounds (**5a–j**) was assayed [11] against *Staphylococcus aureus* ATCC-25923 (Gram positive) and *Escherichia coli* ATCC-25922 (Gram-negative) at three different concentrations (100, 50, and 25 ppm) in DMF (Table 3). The compounds were diluted in DMF for bioassay. Solvent control was included although no antibacterial activity has been noted in the solvent employed. Penicillin G (Hi-media) controls (20 $\mu g/mL^1$) were included to compare with compounds (**5a–j**). All samples were tested in triplicate and average results were recorded.

**Antifungal activity.** The compounds (**5a–j**) were screened for their antifungal activity (Table 4) against *Aspergillus niger* and *Helminthosporium oryzae* species along with standard fungicide Griseofulvin at three different concentrations (100, 50, and 25 ppm) in DMF [12] All the compounds (**5a–j**) exhibited moderate to high antifungal activity when compared with that of the reference compound. The majority of the compounds exhibited high activity against fungi.

**Acknowledgment.** The authors thank Prof. C.D. Reddy, Department of Chemistry, S.V. University, Tirupati for helpful discussions and for UGC (33-299) New Delhi for providing financial assistance. The authors also express their thanks to Prof. Ch. Appa Rao and S. Swapna, Department of Biochemistry, S.V. University, Tirupati for conducting antioxidant and antimicrobial activity.

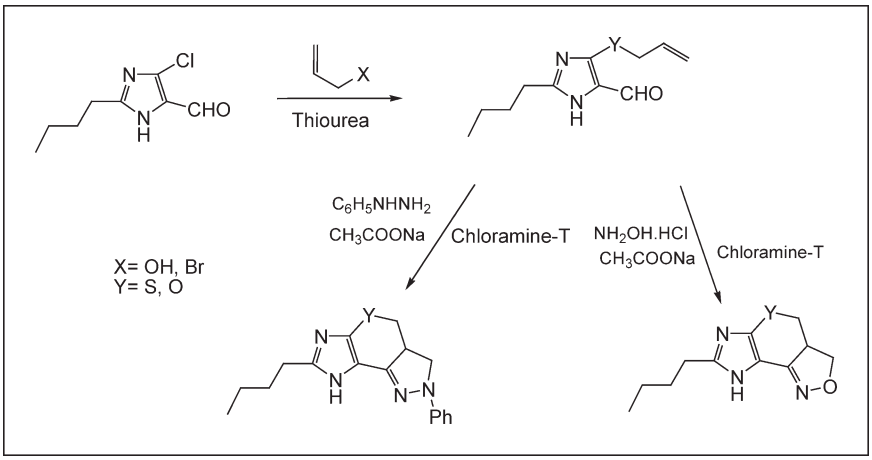
Published online 2 April 2010 in Wiley InterScience (www.interscience.wiley.com).



The title compound 2-butyl-5-chloro-3*H*-imidazole-4-carbaldehyde was transformed into tricyclic heterocycles by substituting the chlorine atom by an unsaturated thiolate or alkoxide and then converting aldehyde function into 1,3-dipole. Chloramine-T was used as an efficient reagent for the generation of 1,3-dipoles, which resulted the formation of fused ring heterocycles *via* intramolecular 1,3-dipolar cycloaddition reaction. The method is very useful for the construction of many biologically active fused heterocycles.

*J. Heterocyclic Chem.*, **47**, 543 (2010).

## INTRODUCTION

The intramolecular 1,3-dipolar cycloaddition is a powerful method for the construction of fused ring heterocycles [1,2]. In particular intramolecular nitrile oxide cycloaddition results dihydroisoxazole derivatives, which are precursors for γ-amino alcohols, β-hydroxy ketones and derivatives, useful in the synthesis of natural products [3]. Similarly intramolecular nitrile imine cycloaddition results 2-pyrazoline derivatives.

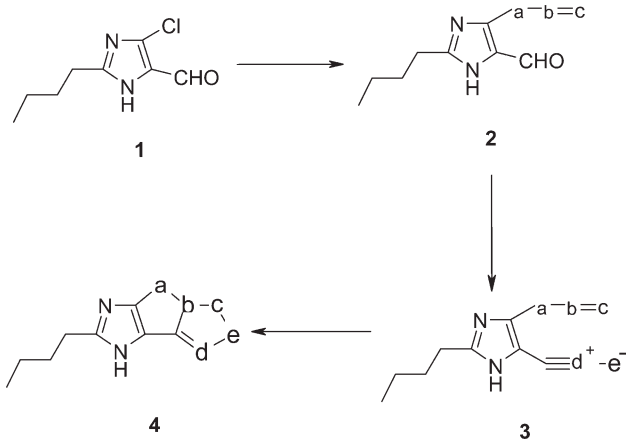
In our previous report, we have used chloramine-T for the generation of nitrile oxide [4], nitrile imine [5], nitroso alkene [6], and azoalkene [7] which are useful intermediates for the synthesis of biologically active 2-isoxazolines, 2-pyrazolines, 1,2-oxazines, and pyridazines, respectively. 2-Butyl-5-chloro-3*H*-imidazole-4-carbaldehyde **1**, a key intermediate for the synthesis of Losartan a nonpeptide angiotensin antagonist, which is an orally active antihypertensive drug [8], and also shows broad spectrum of activity [9–10]. Compounds of these types are interesting starting materials for intramolecular cycloaddition reaction due to the presence of chloro and formyl groups ortho to each other. The chlorine atom can be easily substituted by nucleophiles **2** and the formyl function is suitable for conversion into series of 1,3-dipoles. The final step is the intramolecular cycloaddition of dipole and dipolarophile **3** to give the fused ring system **4** (Scheme 1).

## CHEMISTRY

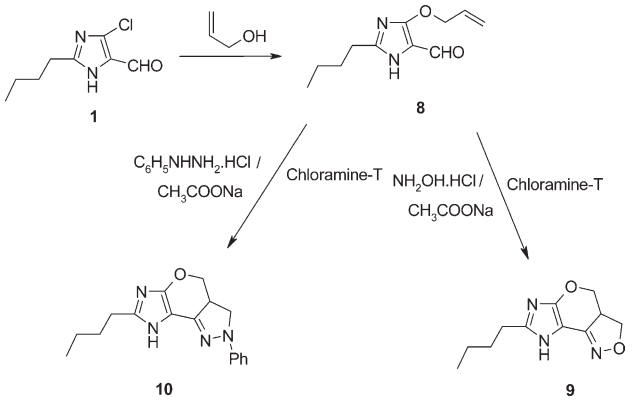
The starting compound 2-butyl-5-chloro-3*H*-imidazole-4-carbaldehyde was synthesized by literature procedure [9]. Substitution of chloro group with allyl thiols furnished 2-butyl-5-(allylsulfanyl)imidazole-4-carbaldehyde. This compound could be transformed into the tricyclic heterocycles by converting the aldehyde function into 1,3-dipoles (Scheme 2). Similarly, substitution with allyl alcohol furnished the 2-butyl-5-(allyloxyl)imidazole-4-carbaldehyde which could be transformed into corresponding tricyclic heterocycles by converting the aldehyde function into 1,3-dipoles (Scheme 3).

The aldehyde **5** was converted into the oxime and then oxidized with chloramine-T to give nitrile oxide,

**Scheme 1**



**Scheme 3**

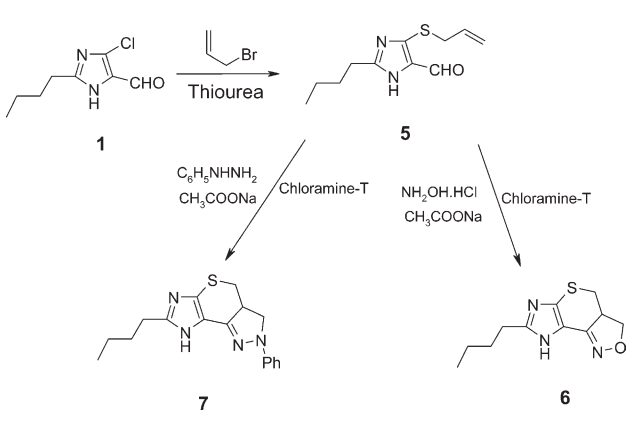


which undergoes intramolecular cycloaddition to form dihydroisoxazole **6**. The aldehyde **5** was converted to phenyl hydrazone and then oxidized with chloramine-T to give nitrile imine, which on intramolecular cycloaddition results pyrazole derivative **7**. The aldehyde **5** was prepared by substituting chloro group of aldehyde **1** with allyl thiol, generated by basic decomposition of the allyl isothiourea salt. Similarly, compounds **9** and **10** are synthesized to form aldehyde **1** by substituting chloro group with allyl alcohol.

## RESULTS AND DISCUSSION

$^1$H NMR, $^{13}$C NMR, IR, and elemental analyses characterized all the synthesized compounds. $^1$H NMR of aldehyde **5** showed a doublet at δ 3.89 for two protons due to $CH_2S$ group and two multiplets at δ 4.9–5.02 and 5.62–5.71 are due to vinylic $CH_2$ and vinylic CH groups, respectively. Aldehydic proton was observed at δ 9.63 and a broad singlet at δ 11.7 is due to NH group of imidazole ring. $^{13}$C NMR showed peak at δ 116.2 and 131.9 due to vinylic $CH_2$ and vinylic CH groups, respectively. The aldehydic carbon was observed at δ 184.2.

**Scheme 2**



$^1$H NMR of isoxazoline **6** showed multiplet at δ 2.92–2.98 for one proton due to CH group. A multiplet at δ 3.15–3.23 is due to $CH_2S$ group and a multiplet at δ 3.92–4.01 is due to $CH_2$ group of isoxazoline ring. $^{13}$C NMR showed doublet at δ 33.3 due to CH group. A triplet at δ 44.4 may be due to carbon of $CH_2S$ group and triplet at δ 63.3 is due to $CH_2$ group of isoxazoline ring. All other substituents are observed in the expected region. The moderate yield of 67% is obtained starting from aldehyde **5** because the intermediate impure oxime was taken directly for next step without purification. The yield of isoxazoline **6** can be improved by purifying the oxime.

$^1$H NMR of pyrazoline **7** showed multiplet at δ 2.85–2.92 for one proton due to CH group. A doublet was observed at δ 3.10 is due to $CH_2S$ group and a multiplet at δ 3.86–3.92 is due to $CH_2$ group of pyrazolines ring. The aromatic protons are observed in the region δ 6.85–7.12. In $^{13}$C NMR a triplet at δ 32.5 may be due to carbon of $CH_2S$ group and a triplet at δ 56.1 may be due to $CH_2$ group of isoxazoline ring. A doublet at δ 46.9 indicates the presence of CH group. All other substituents are observed in the expected region. The moderate yield of 65% is obtained starting from aldehyde **5**. The yield of pyrazoline **7** can be improved by purifying the intermediate phenyl hydrazone.

$^1$H NMR of aldehyde **8** showed a doublet at δ 4.79 for two protons due to $CH_2O$ group and two multiplets at δ 5.22–5.31 and 5.60–5.69 are due to vinylic $CH_2$ and vinylic CH groups, respectively. Aldehydic proton was observed at δ 9.89 and a broad singlet at δ 11.59 is due to NH group of imidazole ring. $^{13}$C NMR showed peak at δ 117.0 and 134.9 due to vinylic $CH_2$ and vinylic CH groups, respectively. The aldehydic carbon was observed at δ 182.1.

$^1$H NMR of isoxazoline **9** showed multiplet at δ 2.96–3.0 for one proton due to CH group. A doublet δ 4.16 is due to $CH_2O$ group and a multiplet at δ 3.96–4.04 is due to $CH_2$ group of isoxazoline ring. $^{13}$C NMR showed doublet at δ 44.3 due to CH group. A triplet at δ 73.3 may be due to carbon of $CH_2O$ group and triplet at δ 62.1 is due to $CH_2$ group of isoxazoline ring. All other substituents are observed in the expected region.

$^1$H NMR of pyrazoline **10** showed multiplet at δ 2.80–2.86 for one proton due to CH group. A multiplet at δ 3.76–3.83 is due to $CH_2$ group of pyrazolines ring. A doublet was observed at δ 4.22, which is due to $OCH_2$ group. The aromatic protons are observed in the region δ 6.85–7.12. $^{13}$C NMR showed doublet at δ 44.2 due to CH group. A triplet at δ 52.1 may be due to $CH_2$ group of isoxazoline ring and a triplet at δ 71.3 is due to $OCH_2$ group. All other substituents are observed in the expected region.

## CONCLUSIONS

In conclusion, we have demonstrated that 2-butyl-5-chloro-3*H*-imidazole-4-carbaldehyde can be used for intramolecular 1,3-dipolar cycloaddition by substituting chloro group with unsaturated nucleophiles and converting the aldehyde function into 1,3-dipole. Chloramine-T is found to be an efficient reagent for the generation of 1,3-dipole. Other compounds possessing a halogen and aldehyde group at ortho position are also potential candidates for carrying out similar reactions.

## EXPERIMENTAL

$^1$H NMR spectra were recorded on a Bruker AM 300 MHz spectrometer using $CDCl_3$ as solvent and tetramethylsilane as internal standard. $^{13}$C NMR spectra were measured on Jeol 400 (100 MHz) instrument. The chemical shifts are expressed in δ and following abbreviations were used, s = singlet, d = doublet, t = triplet, and m = multiplet. Infrared (IR) spectra were recorded on Shimadzu 8300 IR spectrometer. Elemental analyses were obtained on a Vario-EL instrument. Thin layer chromatography (TLC) was done with precoated silica gel G plates.

**2-Butyl-5-chloro-3*H*-imidazole-4-carbaldehyde 1 [7].** The aldehyde **1** was synthesized by literature procedure [9]. $^1$H NMR $CDCl_3$: δ 0.92 (t, $J$ = 7.5 Hz, 3H, $CH_3$), 1.32 (m, 2H, $CH_2$), 1.64 (m, 2H, $CH_2$), 2.61 (t, $J$ = 7.5 Hz, 2H, $CH_2$), 9.32 (s, 1H, CHO), 11.89 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.2 (q), 23.2 (t), 28.1 (t), 30.1 (t), 128.2 (s), 144.1 (s), 158.8 (s), 179.2 (d). IR (KBr pellets $cm^{-1}$) ν 3409, 3070, 2969, 2827, 1672, 1459. Anal. Calcd for $C_8H_{11}ClN_2O$: C, 51.48; H, 5.94; N, 15.01%. Found: C, 51.38; H, 5.98; N, 15.10%.

**5-Allylsulfanyl-2-butyl-3*H*-imidazole-4-carbaldehyde 5.** A solution of allyl bromide (4.87 g, 40.24 mmol) and thiourea (3.08 g, 40.52 mmol) in ethanol (50 mL) were refluxed for 1 h. Ethanolic NaOH solution (3.2 g, 50 mL) was then added and the reaction mass was refluxed for 1 h. The aldehyde **1** (5.0 g, 26.9 mmol) was added to the mixture, which was then refluxed for 2 h. Ethanol was removed under vacuum and the residue was extracted with diethyl ether (2 × 50 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed to give crude oil which was purified by column chromatography (chloroform:ethyl acetate, 7:3) to give **5** as a pale yellow oil (4.10 g, 68%). $^1$H NMR $CDCl_3$: δ 0.94 (t, 3H, $CH_3$), 1.33 (m, 2H, $CH_2$), 1.64 (m, 2H, $CH_2$), 2.60 (t, 2H, $CH_2$), 3.89 (d, 2H, $CH_2S$), 4.9–5.02 (m, 2H, vinylic $CH_2$), 5.62 (m, 1H,vinylic CH), 9.63 (s, 1H, CHO), 11.70 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.4 (q), 23.0 (t), 28.4 (t), 32.1 (t), 39.2 (t), 118.2 (t), 131.9 (d), 139.8 (s), 147.2 (s), 157.8 (s), 181.2 (d). IR (KBr pellets $cm^{-1}$) ν 3410, 2949, 2816, 1669, 1461. Anal. Calcd. for $C_{11}H_{16}N_2OS$: C, 58.90; H, 7.19; N, 12.49%. Found: C, 58.96; H, 7.10; N, 12.44%.

**7-Butyl-3a,4-dihydro-3*H*,8*H*-2-oxa-5-thia-1,6,8-triaza-as-indacene 6.** A solution of aldehyde **5** (2.0 g, 8.92 mmol) in ethanol (20 mL) was warmed with aqueous $NH_2OH.HCl$ (0.92 g 13.33 mmol) and $CH_3COONa$ (1.10 g, 13.40 mmol) for 1 h. Ethanol was removed under vacuum and the residue was extracted with ethyl acetate (2 × 25 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed. The resultant residue was dissolved in ethanol (20 mL), chloramine-T (3.0 g, 10.67 mmol) was added, and the mixture was warmed under vigorous stirring for 2–3 h. Ethanol was removed under vacuum and the residue was extracted with diethyl ether (2 × 25 mL), washed with 1*N* NaOH (2 × 25 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed. The residue left behind was purified by column chromatography (chloroform:ethyl acetate, 7:3) to give **6** as a pale yellow oil (1.41 g, 67%). $^1$H NMR $CDCl_3$: δ 0.92 (t, 3H, $CH_3$), 1.32 (m, 2H, $CH_2$), 1.64 (m, 2H, $CH_2$), 2.61 (t, 2H, $CH_2$), 2.92–2.98 (m, 1H, CH), 3.15–3.23 (m, 2H, $CH_2$), 3.92–4.01 (m, 2H, $CH_2$), 11.79 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.0 (q), 23.4 (t), 28.4 (t), 32.5 (t), 33.3 (d), 44.4 (t), 69.3 (t), 111.3 (s), 136.2 (s), 148.8 (s), 156.1 (s). IR (KBr pellets $cm^{-1}$) ν 3416, 2981, 1590, 1421, 1220, 1151. Anal. Calcd. for $C_{11}H_{15}N_3OS$: C, 55.67; H, 6.37; N, 17.71%. Found: C, 55.59; H, 6.41; N, 17.78%.

**7-Butyl-2-phenyl-2,3a,4,8-tetrahydro-3*H*-5-thia-1,2, 6,8-tetraaza-as-indacene 7.** A solution of aldehyde **5** (2.0 g, 8.92 mmol) in ethanol (20 mL) was warmed with aqueous phenyl hydrazine hydrochloride (1.93 g, 13.40 mmol) and $CH_3COONa$ (1.10 g, 13.41 mmol) for 1 h. The reaction mass was cooled and the solid formed was filtered. The solid was dissolved in ethanol (20 mL), chloramine-T (3.0 g, 10.67 mmol) was added, and the mixture was warmed under vigorous stirring for 2–3 h. Ethanol was removed under vacuum and the residue was extracted with diethyl ether (2 × 25 mL), washed with 1*N* NaOH (2 × 25 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed. The residue left behind was purified by column chromatography (chloroform:ethyl acetate, 8:2) to give **7** as a yellow oil (1.81 g, 65%). $^1$H NMR $CDCl_3$: δ 0.95 (t, $J$ = 7.5 Hz, 3H, $CH_3$), 1.35 (m, 2H, $CH_2$), 1.69 (m, 2H, $CH_2$), 2.65 (t, $J$ = 7.5 Hz, 2H, $CH_2$), 2.85–2.92 (m, 1H, CH), 3.10–3.15 (d, 2H, $CH_2$), 3.86–3.92, (m, 2H, $CH_2$), 6.85–6.95 (m, 3H, ArH), 7.12 (t, 2H, ArH),

11.77 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.1 (q), 23.6 (t), 28.9 (t), 30.7 (t), 32.5 (t), 46.9 (d), 56.1 (t), 110.3 (s), 112.9 (d), 118.1 (d), 119.9(s), 129.8 (d), 134.1 (s), 144.8 (s), 151.1 (s), 153.6 (s). IR (KBr pellets $cm^{-1}$) ν 3411, 3012, 2956, 1643, 1319, 1014. Anal. Calcd. for $C_{17}H_{20}N_4S$: C, 65.35; H, 6.45; N, 17.93%. Found: C, 65.45; H, 6.40; N, 17.90%.

**5-Allyoxy-2-butyl-3*H*-imidazole-4-carbaldehyde 8.** A mixture of aldehyde **1** (5 g, 26.9 mmol), allyl alcohol (2.34 g, 40.3 mmol), and potassium *tert*-butoxide (3.61 g, 32.23 mmol) in tetrahydrofuran (50 mL) were stirred at room temperature for 4 h. The reaction mass was diluted with diethyl ether (25 mL) and the solid was filtered. The filtrate was evaporated and the residue was purified by column chromatography (chloroform:ethyl acetate, 7:3) to give **8** as a pale yellow oil (4.02 g, 72%). $^1$H NMR $CDCl_3$: δ 0.92 (t, $J$ = 7.5 Hz, 3H, $CH_3$), 1.30 (m, 2H, $CH_2$), 1.65 (m, 2H, $CH_2$), 2.65 (t, $J$ = 7.5 Hz, 2H, $CH_2$), 4.79 (d, $J$ = 7.0 Hz, 2H, $CH_2S$), 5.22–5.41 (m, 2H, vinylic $CH_2$), 5.60–5.69 (m, 1H, vinylic CH), 9.89 (s, 1H, CHO), 11.59 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.8 (q), 23.0 (t), 28.4 (t), 32.1 (t), 76.2 (t), 118.2 (t), 122.2 (s), 134.9 (d), 149.8 (s), 155.8 (s), 182.1 (d). IR (KBr pellets $cm^{-1}$) ν 3422, 2959, 2856, 1669, 1641, 1215. Anal. Calcd. for $C_{11}H_{16}N_2O$: C, 63.44; H, 7.74; N, 13.45%. Found: C, 63.49; H, 7.70; N, 13.40%.

**7-Butyl-3a,4-dihydro-3*H*,8*H*-2,5-dioxa-1,6,8-triaza-as-indacene 9.** A solution of aldehyde **8** (1.0 g, 4.80 mmol) in ethanol (10 mL) was warmed with aqueous $NH_2OH.HCl$ (0.50 g 7.24 mmol) and $CH_3COONa$ (0.60 g, 7.30 mmol) for 1 h. Ethanol was removed under vacuum and the residue was extracted with ethyl acetate (2 × 10 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed. The resultant residue was dissolved in ethanol (10 mL), chloramine-T (1.62 g, 5.76 mmol) was added, and the mixture was warmed under vigorous stirring for 2–3 h. Ethanol was removed under vacuum and the residue was extracted with diethyl ether (2 × 20 mL), washed with 1*N* NaOH (2 × 25 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed. The residue left behind was purified by column chromatography (chloroform:ethyl acetate, 7:3) to give **9** as a pale yellow oil (0.65 g, 61%). $^1$H NMR $CDCl_3$: δ 0.92 (t, 3H, $CH_3$), 1.32 (m, 2H, $CH_2$), 1.64 (m, 2H, $CH_2$), 2.61 (t, 2H, $CH_2$), 2.96–3.0 (m, 1H, CH), 3.92–4.04 (m, 2H, $CH_2$), 4.16 (d, 2H, $CH_2$), 11.80 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.0 (q), 23.4 (t), 29.4 (t), 31.5 (t), 44.3 (d), 58.4 (t), 73.3 (t), 109.3 (s), 136.2 (s), 149.8 (s), 157.1 (s). IR (KBr pellets $cm^{-1}$) ν 3410, 2952, 1638, 1598, 1220, 1100. Anal. Calcd. for $C_{11}H_{15}N_3O_2$: C, 59.71; H, 6.83; N, 18.99%. Found: C, 59.61; H, 6.89; N, 19.04%.

**7-Butyl-2-phenyl-2,3a,4,8-tetrahydro-3*H*-5-oxa-1,2,6, 8-tetraaza-as-indacene 10.** A solution of aldehyde **8** (1.0 g, 4.8 mmol) in ethanol (10 mL) was warmed with aqueous phenyl hydrazine hydrochloride (1.03 g, 7.15 mmol) and $CH_3COONa$ (0.60 g, 7.31 mmol) for 1 h. The reaction mass was cooled and the solid formed was filtered. The solid was dissolved in ethanol (10 mL), chloramine-T (1.62 g, 5.76 mmol) was added, and the mixture was warmed under vigorous stirring for 2–3 h. Ethanol was removed under vacuum and the residue was extracted with diethyl ether (2 × 20 mL), washed with 1*N* NaOH (2 × 25 mL), washed with water, dried ($Na_2SO_4$), and the solvent was removed. The residue left behind was purified by column chromatography (chloroform:ethyl acetate, 8:2) to give **10** as a yellow oil (0.90 g, 63%). $^1$H NMR $CDCl_3$: δ 0.93 (t, $J$ = 7.5 Hz, 3H, $CH_3$), 1.33 (m, 2H, $CH_2$), 1.66 (m, 2H, $CH_2$), 2.64 (t, $J$ = 7.5 Hz, 2H, $CH_2$), 2.88–2.93 (m, 1H, CH), 3.86–3.92 (m, 2H, $CH_2$), 4.08–4.15, (m, 2H, $CH_2$), 6.90–7.05 (m, 3H, ArH), 7.24 (t, 2H, ArH), 11.75 (bs, 1H, NH). $^{13}$C NMR $CDCl_3$: δ 13.2 (q), 23.8 (t), 29.2 (t), 30.9 (t), 44.2 (d), 52.4 (d), 71.3 (t), 114.3 (s), 112.0 (d), 117.4 (d), 129.2 (d), 132.1 (s), 144.8 (s), 149 (s), 153.1 (s). IR (KBr pellets $cm^{-1}$) ν 3396, 3026, 2990, 1635, 1235. Anal. Calcd. for $C_{17}H_{20}N_4O$: C, 68.90; H, 6.80; N, 18.90%. Found: C, 68.99; H, 6.71; N, 18.84%.

Reaction of diacyl thiocarbohydrazides with dimethyl but-2-ynedioate in refluxing ethanol led to 4-oxa-thiazolidine-5-ylidene-acetates in good yields. Reaction of the newly prepared *N*-(2-(propan-2-ylidene) hydrazine-carbonothioyl)arylhydrazides with dimethyl but-2-ynedioate gave the corresponding (*Z*)-methyl-2-arylhydrazide-4-oxo-3-(propan-2-ylideneamino)thiazolidine-5-ylidene)-acetates. The mechanism is discussed. Antitumor and antioxidant activities have been also investigated.

*J. Heterocyclic Chem.*, **47**, 547 (2010).

## INTRODUCTION

The development of simple synthesis routes for widely used organic compounds from readily available reagents is one of the major tasks in organic synthesis. Recent report has shown that various *N*-ethyl hydrazine-carbothioamides can undergo different cyclization reactions to give five member heterocycles, which showed a general stimulation effect on B cell's response [1]. Thiazolidine-4-one ring systems are known to possess antibacterial [2,3], antituberculosis [4–6], antiviral [7–14], anticancer [15–18], and antioxidant [19]. In view of the various physiological activities of thiazolidinones, many thiazolidinone derivatives have been prepared. 4-Phenyl-thiosemicarbazide reacts smoothly with dimethyl but-2-ynedioate in the presence of aldehydes or ketones under solvent free conditions to produce highly functionalized thiazolidine-4-ones [20]. The reaction of thioureas with acetylenic esters has been reported to give a thiazolin-4-one, an imidazolinthion, or a 1,3-thiazin-4-one [21]. Recent reports by Aly *et al*. [22] demonstrated that the reaction of *N*-aroyl thioureas with of dimethyl but-2-ynedioate under reflux in acetic acid yielded the corresponding 1,3-thizinones. Additionally, diethyl maleate reacts with *N*-substituted-hydrazino-carbothioamides to form ethyl [1,2,4]triazolo[3,4-*b*][1,3]thiazine-5-carboxylates [23]. Reaction proceeds *via* bicyclization and oxidation processes [23]. Whilst 2,3-diphenylcyclopropenone reacts with ylidene-*N*-phenylhydrazine-carbothioamides to form the pyrrolo[2,1-*b*]-1,3,4-oxadiazoles *via* formal [2 + 3]cycloaddition [24]. On the other side, we reported on one pot synthesis of 1,3-thiazin-2-ylidene-substituted hydrazides *via* one-pot reaction of *N*-substituted-hydrazino-carbothioamides with 1,4-diphenylbut-2-

yne-1,4-dione [25]. On the basis of aforementioned encouraged results, we investigate the reaction of acyl thiocarbohydrazides with dimethyl but-2-ynedioate. Moreover antitumor and antioxidant activities of the isolated products have been investigated.

## RESULTS AND DISCUSSION

**Chemistry.** We have now reacted diacyl thiocarbohydrazides **1a–c** [26] with dimethyl but-2-ynedioate (**2**); the reactions gave mainly the corresponding (*Z*)-methyl-2-[(*Z*)-3-aroylamido-2-(2-arylhydrazono)]-4-oxa-thiazolidine-5-ylidene)-acetates (**3a–c**, Scheme 1). For structure prevalent, we choose one derivative identified as **3b** and investigate its NMR in comparative with its expected regioisomers **3bI–III** (Fig. 1). As IR and $^{13}C$ NMR did not reveal any absorbance of the C=S group. Moreover, the five C=S in $^{13}C$ chemical shifts are all too far upfield for a C=S. Therefore the upfield five carbon signals in the $^{13}C$ NMR spectra of compound 3b must represent three carbon signals of four C=O and one for the C=N carbon (see the EXPERIMENTAL SECTION). Accordingly the structure of the regioisomer **3bI** is excluded. The magnitude of the coupling constant ($J$ = 5.2 Hz) further argues that ring carbonyl (C-4) and vinylic-proton are mutually *cis*. Under gated decoupling, the ring carbonyl (C-4) couples to vinylic-proton with $J$ = 5.2 Hz, a value which requires a three- not two-bond coupling as depicted in structures **3b** and **3bIII** and excluded the formation of other regioisomers (**3bI** and **3bII**). It was reported, if the coupling constant for the vinylic-proton and endocyclic carbon atom in a condensation product is about ~5 Hz (*vicinal*-coupling), this product has a five-membered ring; if the coupling constant approaches a value of 1 Hz (*geminal*-coupling), the product should be assigned six-membered thiazine structure [27,28]. Most of the C—H coupling constants are within conventional ranges [29], except that the $J_{C-H}$ values for C-2′ and C-3′ are unusually small for benzenes. Presumably this arises from restricted rotation. In compound **3b** there are two *p*-toluoyl units, one slightly broadened, which is presumably due to restricted rotation. Toluamide rotation and NH exchange are independent processes, which in general occur at different rates. The methoxyl protons are distinctive at $\delta_H$ = 3.81; this signal gives HMQC correlation with the attached carbon at $\delta_C$ = 52.7 and HMBC correlation with the ester carbonyl at $\delta_C$ = 165.6. The signal ($\delta_C$ = 160.9) giving HMBC correlation to vinylic-H ($\delta_H$ = 6.96) is assigned as C-4. The carbon ($\delta_C$ = 116.8) giving HMQC correlation to vinylic-H is assigned as

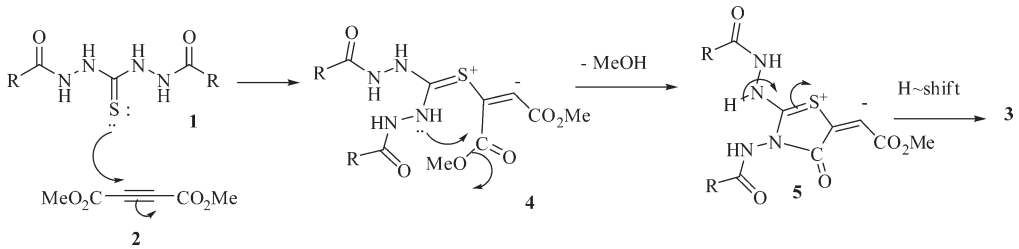
vinylic-CH. One other carbon ($\delta_C$ = 137.5) gives HMBC correlation to vinylic-H, and is assigned as C-5. The benzamido- and hydrazono-C=O appear distinctively at $\delta_C$ = 164.3 and 163.4, respectively. They give HMBC correlation to the ortho protons on the attached tolyl rings at $\delta_H$ = 7.88 and 7.77, respectively.

The signals at $\delta_C$ = 143 and 141.8 give HMBC correlation with the *ortho* protons and $CH_3$ ($\delta_H$ = 7.88, 2.41 and 7.77, 2.37) are assigned as C-4′ and C-4″, respectively. The assignment of distinctive hydrogen and carbon signals and their δ values as well as the corresponding coupling constants of compound **3b** are as shown in Table 1.

On the basis of well established chemistry of electrophilic acetylenes [21], it is reasonable to assume that compounds **4** resulted from the initial conjugate addition of the sulfur atom of **2** to the acetylenic ester. Then, the ester group of intermediate **4** was attacked by the amino moiety to yield **5** by elimination of methanol molecule (Scheme 2). Hydrogen shift is then proposed to be

**Scheme 2.** Plausible mechanism of 1,3-thiazolidine-4-ones **3a–c**.



**Scheme 3.** Synthesis of 1,3-thiazolidine-4-ones **8a–c**.

occurred in **5** to produce the stable heterocycle **3** (Scheme 2). Previously it was reported that thiocarbohydrazide (**6**) condensed with acetone to form the corresponding mono-condensed products [30] likewise in case of **7a–c** (Scheme 3). Herein we reacted compound **2** with aroyl chlorides in presence of acetone. The reaction proceeds successfully to give compounds **7a–c** in good yields (Scheme 3). Interestingly, on reacting the newly prepared compounds **7a–c** with dimethyl but-2-ynedioate ethyl ester (**2**), the reaction gave the corresponding thiazolidines **8a–c** in good yields (Scheme 3).

In compound **8a**, the $^1$H NMR spectrum showed the two methyl protons are distinctive at $\delta_H = 2.06$ and 1.94; this signals gives HMQC correlation with the attached carbon at $\delta_C = 25.0$ and 18.7 and HMBC correlation with the carbon at $\delta_C = 168.9$ which is assigned as $C(CH_3)_2$. The methoxyl protons are distinctive at $\delta_H = 3.87$; this signal gives HMQC correlation with the attached carbon at $\delta_C = 52.6$ and HMBC correlation with the ester carbonyl at $\delta_C = 166.1$. The signal ($\delta_C = 162.1$) giving HMBC correlation to vinylic-H ($\delta_H = 6.96$) is assigned as C-4. The carbon ($\delta_C = 117.3$) giving HMQC correlation to vinylic-H is assigned as vinylic-CH. One other carbon ($\delta_C = 139.4$) gives HMBC correlation to vinylic-H, and is assigned as C-5. The benzoyl C=O appear at $\delta_C = 166.0$ gives HMBC correlation with *ortho* protons at ($\delta_H = 7.91$).

**Biological section.**

***Cytotoxicity against Hep-G2 cells.*** Using MTT assay, we studied the effect of the compounds on the proliferation of human hepatocellular carcinoma after 48 h incubation. Incubation of Hep-G2 cell line with gradual doses of the compounds led to insignificant change in the growth of Hep-G2 cells as indicated from their $IC_{50}$ values (>100 μ*M*), except, compound **3c**, which resulted in a high inhibition of the cell growth of Hep-G2 cells compared with the growth of untreated control cells, as concluded from their low $IC_{50}$ value 36.14 μ*M*. However, compounds **8a** and **3b** represents a moderate antitumor agent against Hep-G2 cells. Figure 2 shows the effect of compounds **3a–c** and **8a,b** on the growth of Hep-G2 cells. As measured by MTT assay, results are represented as percentage of control untreated cells.

***Antioxidant activity.*** DPPH is a stable nonphysiological, radical, which could provide a relative figure of the radical scavenging activity of the tested compounds. The DPPH assay showed that some of the tested compounds possessed no scavenging activity to DPPH with high $SC_{50}$ values (>100 μ*M*) compared to the scavenging activity ($SC_{50}$ 8.41) of the well-known antioxidant (ascorbic acid, A.A), except compounds **3b**, **3c**, and **8a** which

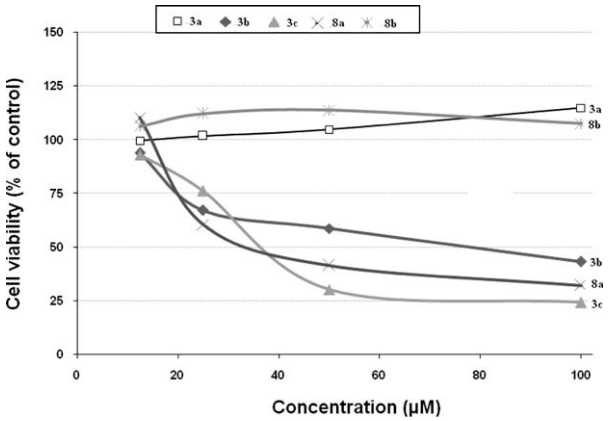

**Figure 2.** The effect of compounds **3a,c** and **8a,b** on the growth Hep-G2 cells. As measured by MTT assay. Results are represented as percentage of control untreated cells.

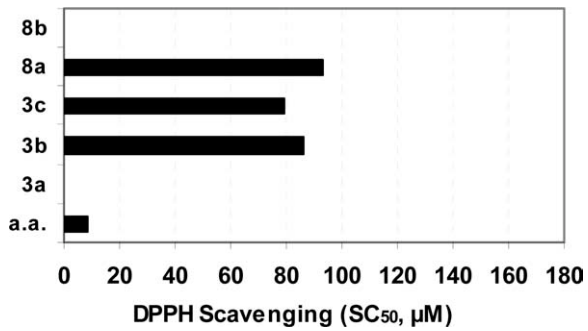

**Figure 3.** The antioxidant activity of **3b**, **3c**, and **8a** was investigated using DPPH assay. The results are represented as $SC_{50}$ values (μM) as (mean ± SE, $n = 4$)

had effective antioxidant activity with $SC_{50}$ values of 86.4, 79.2, and 92.8 μ*M*, respectively (Fig. 3).

## EXPERIMENTAL

**Chemistry.** TLC analysis was performed on analytical Merck 9385 silica aluminium sheets (Kiselgel 60) with $PF_{254}$ indicator. Melting points were determined on Stuart electrothermal melting point apparatus and were uncorrected. The IR spectra were recorded as KBr disks on Shimadzu-408 infrared spectrophotometer, Faculty of Science, El-Minia University. The NMR spectra were measured using Bruker AV-400, Florida Institute of Technology, USA. Chemical shifts were expressed as δ (ppm) with tetramethylsilane as internal reference. The samples were dissolved in chloroform-$d_6$ and/or dimethyl sulphoxide (DMSO)-$d_6$, s = singlet, d = doublet, dd = doublet of doublet, and t = triplet. Mass spectra were recorded on Varian MAT 312 instrument in E1 mode (70 eV), Technische Universität Braunschweig, Germany. Elemental analyses were performed using Varian Elementary device in National Research Center (Dokki, Giza, Egypt).

***Materials.*** Dimethyl but-2-ynedioate (**2**) and thiocarbohydrazide (**6**) were bought from Fluka. Diaroyl thiocarbohydrazides **1a–c** were prepared according to the literature [26].

***Reactions between diaroyl thiocarbohyhydrazides 1a–c with 2.*** An equal mixture of **1a–c** (1 mmol) and **2** (0.142 g, 1 mmol) was heated at reflux in absolute ethanol for 1–5 h (the reaction was followed by TLC analysis). The solvent was evaporated under vacuum and the obtained yellow precipitates were dissolved in dichloromethane and applied on column chromatography (dichloromethane, silica gel). The obtained products **3a–c** were recrystallized from the stated solvents.

***Synthesis of N-(2-propan-2-ylidene)-hydrazine-carbonothioyl)arylhydrazides 7a–c.*** To a suspension solution of **6** (0.106 g, 1 mmol) and $NaHCO_3$ (0.126 g, 1.5 mmol) in dry acetone (20 mL) was stirred at room temperature, the corresponding acid chloride (1 mmol) in dry acetone (5 mL) was added dropwise over a period of 20 min. The reaction mixture was stirred for further continued 3 h at room temperature then at refluxing temperature for 15 min. The reaction mixture was filtered and the salt precipitate was washed three times with chloroform (20 mL). The solvent of the filtrate was removed under vacuum. The obtained precipitate was then washed three times with 0.1*N* HCl (5 mL) followed by three times with water (30 mL). The obtained products **7a–c** were recrystallized from glacial acetic acid.

*4-Methyl-N-(2-propan-2-ylidene)hydrazinecarbono-thionyl)-benzamide (**7a**).* White crystals, yield = 225 mg (90%), m.p. 172–174°C. IR (potassium bromide): ν = 3230–3315 (NH), 3041–3009 (Ar-CH), 2981–2915 (aliph.-CH), 1674 (C=O), 1617 (C=N), 1365 (C=S) $cm^{-1}$. $^1H$ NMR (400.13 MHz, chloroform-$d_3$): $\delta_H$ = 9.98 (b, s, 1H, NH-2), 9.76 (b, s, 1H, NH-1), 9.24 (b, s, 1H, NH-3), 7.92 (d, 2H, H-2, $J$ = 7.8 Hz),

***Reactions between aroyl thiocarbohyhydrazides 7a–c with 2.*** As previously mentioned before: an equal mixture of **7a–c** (1 mmol) and 2 (0.142 g, 1 mmol) was heated at reflux in absolute ethanol for 10–14 h (the reaction was followed by TLC analysis). The solvent was evaporated under vacuum. The obtained products were then dissolved in dichloromethane and applied on column chromatography (dichloromethane, silica gel). The obtained pure products were recrystallized from the stated solvents.

*(Z)-Methyl-2-[(Z)-2-(2-benzoylhydrazono)-4-oxo-3-(propan-2-ylideneamino)-1,3-thiazolidin-5-ylidene]-acetate (**8a**)*. Yellow crystals (methanol), yield = 296 mg (82%), m.p. 216–218°C. **Biological section.**

***Cell culture.*** Human hepatocellular carcinoma (HepG2) cells were routinely cultured in Dulbeco's Modified Eagle's Medium. Media were supplemented with 10% fetal bovine serum, 2 m*M* L-glutamine, containing 100 units/mL penicillin G sodium, 100 units/mL streptomycin sulphate, and 250 ng/mL amphotericin B. Cells were maintained at subconfluency at 37°C in humidified air containing 5% $CO_2$. For subculturing, monolayer cells were harvested after trypsin/EDTA treatment at 37°C. Cells were used when confluence had reached 75%. Tested samples were dissolved in DMSO. All cell culture material was obtained from Cambrex BioScience (Copenhagen,

Denmark). All chemicals were from Sigma/Aldrich, except mentioned. All experiments were repeated three times, unless mentioned.

*Cytotoxicty assay*. Cytotoxicity of tested samples was measured using the MTT cell viability assay. MTT (3-[4,5-dimethylthiazole-2-yl]-2,5-diphenyltetrazolium bromide) assay is based on the ability of active mitochondrial dehydrogenase enzyme of living cells to cleave the tetrazolium rings of the yellow MTT and form a dark blue insoluble formazan crystals which is largely impermeable to cell membranes, resulting in its accumulation within healthy cells. Solubilization of the cells results in the liberation of crystals, which are then solubilized. The number of viable cells is directly proportional to the level of soluble formazan dark blue color. The extent of the reduction of MTT was quantified by measuring the absorbance at 570 nm [31].

*Reagents preparation*. MTT solution: 5 mg/mL of MTT in 0.9% NaCl. Acidified isopropanol: 0.04*N* HCl in absolute isopropanol.

*Procedure*. Cells ($0.5 \times 10^5$ cells/well) in serum-free media were placed in a flat bottom 96-well microplate and treated with 20 μL of different concentrations of each tested compound for 20 h at 37°C, in a humidified 5% $CO_2$ atmosphere. After incubation, media were removed and 40 μL MTT solution/well were added and incubated for an additional 4 h. MTT crystals were solubilized by adding 180 μL of acidified isopropanol/well and plate was shacked at room temperature, followed by the photometric determination of the absorbance at 570 nm using microplate ELISA reader. Triplicate repeats were performed for each concentration and the average was calculated.

Data were expressed as the percentage of relative viability compared with the untreated cells compared with the vehicle control, with cytotoxicity indicated by <100% relative viability.

*Calculations*. Percentage of relative viability was calculated using the following equation: [Absorbance of treated cells/Absorbance of control cells)] × 100.

Then the half maximal inhibitory concentration IC50 was calculated from the equation of the dose response curve.

***Antioxidant activity (scavenging of DPPH).*** 1,1-Diphenyl-2-picrylhydrazyl is a stable deep violet radical due to its unpaired electron. In the presence of an antioxidant radical scavenger, which can donate an electron to DPPH, the deep violet color decolorize to the pale yellow nonradical form [32]. The change in colorization and the subsequent fall in absorbance are monitored spectrophotometrically at $\nu = 520$ nm.

*Reagents preparation*. Ethanolic DPPH: 0.1 m*M* DPPH/absolute ethanol, standard ascorbic acid solution. Serial dilutions of ascorbic acid in concentrations ranging from 0–2.5 μ*M* in distilled water. A standard calibration curve was plotted using serial dilutions of ascorbic acid in concentrations ranging from 0–2.5 μ*M* in distilled water.

*Procedure*. In a flat bottom 96-well microplates, a total test volume of 200 μL was used. In each well, 20 μL of different concentrations (0–100 μg/mL final concentration) of tested compounds were mixed with 180 μL of ethanolic DPPH and incubated for 30 min at 37°C. Triplicate wells were prepared for each concentration and the average was calculated. Then, the photometric determination of absorbance at $\nu = 515$ nm was done using microplate ELISA reader.

*Calculations*. The half-maximal scavenging capacity ($SC_{50}$) values for each tested compounds and ascorbic acid was estimated via two competitive dose curves.

Abs50 of ascorbic acid = (Abs100 − Abs0)/2.

$SC_{50}$ of ascorbic acid was calculated using the curve equation.

$SC_{50}$ of each compound was determined using the curve equation using Abs50 of ascorbic acid.

New macrocyclic polyether compounds containing a 2,5-bis(2-hydroxyphenyl)-1,3,4-oxadiazole moiety are quickly prepared by a nucleophilic substitution reaction involving ethylene glycol ditosylate or polyethylene glycol ditosylate and a biphenol, the 2,5-bis(2-hydroxyphenyl)-1,3,4-oxadiazole, with solid anhydrous potassium carbonate as a base under microwave irradiation (monomode and multimode). The structures of new macrocyclic polyether compounds were confirmed by $^{1}H$, $^{13}C$ NMR, mass spectrometry, and elemental analysis.

*J. Heterocyclic Chem.,* **47**, 555 (2010).

## INTRODUCTION

The design and synthesis of artificial hart mimics possessing specific weak interactions and complexation properties to ion and neutral molecules has inspired many scientists during the past decades [1,2]. The Pedersen's [3] synthesis of crown ethers and the demonstrated ability of these molecules to chelate cations launched a whole search for further novel polyether macrocyclic structures that promote similar recognition phenomena [4]. The 1,3,4-oxadiazole ring is very rigid and as for the crown compounds containing a 1,3,4-thiadiazole moiety [5], the macrocyclic polyether containing it has potentially planar conformation [6]. A synthesis of such compounds containing 1,3,4-oxadiazole moiety has been previously effectuated by condensation of ethylene glycol or polyethylene glycol derivatives with the 2,5-bis(2-hydroxyphenyl)-1,3,4-oxadiazole by direct displacement reaction of halide with the bisphenolate and using the classical heating process. This synthesis requires long reaction time, and poor yields were obtained [7]. No macrocyclic compounds were found when we tried the heterocyclisation of the 2,5-bis(2-hydroxyphenyl)-1,3,4-oxadiazole with ethylene glycol ditosylate or polyethylene glycol ditosylate under classical heating using a previously described procedure [5]. In this article we report the microwave-assisted synthesis of crown compounds containing a 1,3,4-oxadiazole moiety.

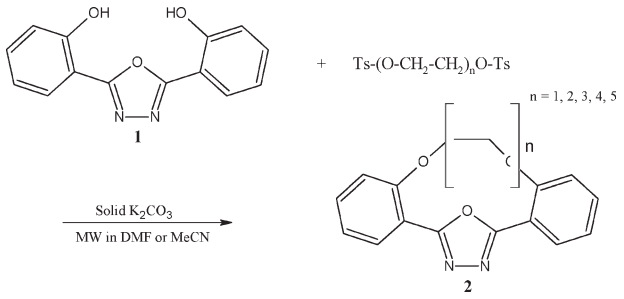
## RESULTS AND DISCUSSION

Macrocyclic compounds **2a–d** were prepared by a nucleophilic substitution reaction involving a glycol ditosylate with the bisphenoloxadiazole (1) (Scheme 1). This reaction was easily achieved by microwave irradiation and the macrocycles **2a–d** were obtained in moderate yields and excellent state of purity as in ref. 6 (Table 1).

A good achievement of this synthesis requires longer times (9 h) under irradiation using multimode microwave reaction compared with monomode one (2 h). However, no reaction product has been isolated using classical conventional heating.

To understand the pathway mechanisms that occur in the nucleophilic substitution reaction for cyclization of ditosyl polyether, quantum calculations at density functional theory (DFT) level were performed with thiadiphenol, both in vacuum and acetonitrile solvent, using polarized continuum method (PCM) method. The obtained results in the case of 1,3,4-thiadiazole moiety

**Scheme 1.** Synthesis of marcocyclic compounds containing a 1,3,4-oxadiazole moiety.



are analyzed in term of electronic energy of the calculated molecule conformations [6].

Specific microwave effect was observed in this reaction, the polarity is increased during the reaction from the ground state toward the transition state, and the stabilization of the transition state is more effective than that of the ground state (Scheme 2), this result in an enhancement of reactivity by a decrease in the activation energy [8].

Using the monomode irradiation process, the notable enhancement in the yields of the crown compounds synthesis, and the shorter time of the reaction, can be explained by the fact that the microwaves are focused through a wave guide on the reaction vessel. The power density is, therefore, higher than using a multimode microwave apparatus.

## EXPERIMENTAL

Melting points were determined with on an IA 9000 series electrothermal apparatus and are uncorrected. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker F.T. AC 300 spectrometer (300 MHz for $^1$H NMR and 75 MHz for $^{13}$C NMR) using chloroform-$d_1$ ($CDCl_3$) as solvent. Matrix-assisted laser desorption ionization (MALDI) and time-of-flight mass spectrometry (TOF-MS) are used to record the mass spectra of the macrocyclic polyether compounds **2a–d**. Elemental analyses were performed by the elemental analysis service of CNRS, Vernaison, France. All starting materials were of reagent grade and used as purchased.

**General procedure for the synthesis of macrocycles 2a–d.** A mixture of 2,5-bis(2-hydroxyphenyl)-1,3,4-oxadiazole **1** (0.75 g, 2.95 mmoles), anhydrous potassium carbonate (1.65 g, 12 mmoles), and ethylene glycol ditosylate or polyethylene glycol ditosylate (2.78 mmoles) in 30 mL of a nonprotic polar solvent, such as DMF or acetonitrile, was introduced into a fluoropolymeric cylindrical flask placed in a MARS5 XP-1500 PLUS CEM multimode microwave and irradiated for 9 h (300 W) at 150°C or irradiated for 2 h (150 W) in a CEM monomode microwave in DMF at 150°C with vigorous stirring. The precipitate was heated under reflux with 20 mL of aqueous potassium hydroxide solution for 1 h to destroy the unreacted tosylate, oxadiazole derivative **1**, or the open-chain intermediate of **2**. After cooling, the crude product was filtered, washed with water, recrystallized from ethanol, and dried under high vacuum. Yields, melting points, and results of the elemental analysis (C, H, and N) for compounds **2a–d** were given in Table 1.

The general formula of the parent macrocyclic compound with corresponding numbering scheme is given later. Localization of the methylene groups in the polyether macrocycle has been made using the International Union of Pure and Applied Chemistry rules concerning the different bicyclic systems.

Novel substituted 2-hydrazino-pyrimidin-4(3*H*)-one derivatives were synthesized and examined for their antifolate activity against DHFR from *Pneumocystis carinii* (pc), *Toxoplasma gondii* (tg), *Mycobacterium avium* (ma), and rat liver (rl). A novel, simple, and feasible methodology was developed for the synthesis of the titled compounds. Amongst these, compound **8** 6-phenyl-2-(2-(1-(thiophen-2-yl) ethylidene)hydrazinyl) pyrimidin-4(3*H*)-one exhibited 17.74 μ*M* activity against pcDHFR.

*J. Heterocyclic Chem.*, **47**, 558 (2010).

## INTRODUCTION

Dihydrofolate reductase (DHFR), a crucial enzyme required for the conversion of folic acid to dihydro and tetrahydro folic acid (a cofactor involved in one carbon transfer in purine and pyrimidine *de-novo* synthesis) has been successfully explored as a target for the treatment of various infective diseases. Opportunistic organisms such as *Pneumocystis carinii* (pc), *Toxoplasma gondii* (tg), and *Mycobacterium avium* (ma) cause life threatening infections in immunocompromised hosts. Majority of the DHFR inhibitors explored have a 2,4-diamino moiety on the aromatic/heteroaromatic ring as an important pharmacophoric feature which forms a crucial H-bonding interaction at the bottom of the active site in both microbial and human DHFR [1]. The structural requirements of potential DHFR inhibitors have been summarized in a recent review article [2]. Only few reports are found in literature for DHFR inhibitors lacking 2,4-diamino moiety on the pyrimidine/triazine nucleus.

Gschwend *et al*. screened a library of 50,000 compounds using the program DOCK to develop selective inhibitors towards *P. carinii* [3]. Several novel classes of compounds were identified as potential DHFR inhibitors, providing new avenues for lead optimization. The most potent compound (Threne Red Violet RH, Fig. 1) identified had $IC_{50}$ of 6.9 μ*M* towards the fungal enzyme.

This indicated that novel scaffolds could be designed inhibiting the folate pathway efficiently. In this light, virtual screening of ASINEX database using docking algorithm Glide was undertaken [4]. Crystal structure pcDHFR PDB ID: 1KLK, 2.30 Å resolution [5] was used for the docking studies. Initially, all compounds were docked using HTVS mode in Glide, top 10% hits from this study were again docked using SP (Standard precision mode). Finally, top 1% hits emerged from this study were redocked using XP (Extra precision mode). The scaffolds obtained from XP docking were used for novel inhibitor design.

Interestingly, in these virtual screening studies some of the new scaffolds lacking conventional 2,4-diamino pharmacophore, were also identified as hits but have not yet been reported as DHFR inhibitors. On the basis of the structural features of the new scaffolds obtained from virtual screening, 2-hydrazino-pyrimidin-4(3*H*)-one as the basic nucleus was chosen as a potential part of designed DHFR inhibitors.

The designed analogs were studied computationally to get an insight into the binding pattern of these compounds. When a 2-hydrazino-pyrimidin-4(3*H*)-one analog was superimposed on trimethoprim, in the active site of pcDHFR, conserved interactions were observed. It was also observed that the –NH of the pyrimidinone part forms hydrogen bonding with Ile123 in the active site of pcDHFR. The docking studies revealed that pyrimidinone part of the molecule is stabilized using van der Waals interactions with residues like Ile123, Ile10, Val11, Phe36, Glu32, Ile33, and Leu25. The bridge portion of the designed analogs are shown to form

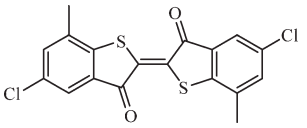

**Figure 1.** Hit identified from the study of Gschwend *et al.*

favorable interactions with Ile123, Thr61, whereas the distal part forms van der Waals interactions with Asn23, Ser64, Pro66, Ile65, Phe69, Leu72, and Phe36 in the active site of the enzyme. Pyrimidinone ring forms π-π stacking interactions with Phe36 (4.470 Å) at the bottom of the active site.

Substituted pyrimidin-4(3*H*)-one compounds have widespread biological activities [6]. However, to the best of our knowledge these types of molecules are not yet explored as DHFR inhibitors. Therefore, based on virtual screening and new scaffold design, synthesis and evaluation of 2-hydrazino-pyrimidin-4(3*H*)-one derivatives against DHFR from various opportunistic microorganisms were undertaken.

## RESULTS AND DISCUSSION

The reported methods for the synthesis of 2-hydrazino-pyrimidin-4(3*H*)-one derivatives involve acetic acid catalyzed condensation reaction of aromatic aldehydes with a cyclic intermediate of ethyl acetoacetate and semicarbazide [6,7]. Formic acid catalyzed condensation reaction of ketone with semicarbazide has also been reported [8].

However, reported methods for the synthesis of 2-hydrazino-pyrimidin-4(3*H*)-one derivatives suffer from several disadvantages such as use of commercially unavailable cyclic intermediates as starting material, multi-step reactions which in turn make the process costly, lengthy, time consuming and also affect the yield and quality of the final products. Moreover, the use of acetic acid or formic acid [8], makes the workup cumbersome. Therefore, designing an efficient protocol using commercially available starting materials, involving easy workup procedure for the synthesis of these compounds was taken into consideration.

In the present work, initially a two step process was developed using conventional heating (Method 1). The first step involves condensation of ethanolic solution of substituted ketones with semicarbazide hydrochloride to yield a substituted semicarbazone using absolute ethanol as solvent.

In step II, the ethanolic solution of semicarbazone was treated with various β- ketoesters in presence of a base to yield the desired analogs as shown in Scheme 1. Various bases such as triethylamine, pyridine and ammonium acetate were explored for this step. Triethylamine was found to give good yields, in less time than other bases.

Microwave (MW) assisted synthesis is known to be advantageous over conventional reaction reported in literature; with respect to time, yield and workup procedures [9].

In this light, the above synthetic scheme was carried out using microwave irradiation (Method 2). Although steps I and II took many hours to complete under conventional heating (Method 1) no more starting materials could be detected after 10–20 min under microwave irradiation.

Encouraged by the results obtained using microwave method, a one pot microwave assisted method was also investigated.

In case of one pot microwave assisted reaction, an ethanolic solution of β-ketoester, semicarbazide hydrochloride and substituted ketone was subjected to microwave irradiation with intermittent addition of triethylamine. Appropriate workup procedures followed by column purification led to the isolation of the desired compound as shown in Scheme 2. Thus, a one step process using microwave irradiation without isolating the intermediate was developed (Method 3). Thereafter, all

| 3 |  | $C_{20}H_{20}N_4O$ | 7 |  | $C_{11}H_{12}N_4OS$ |
| 4 |  | $C_{23}H_{26}N_4O$ | 8 |  | $C_{16}H_{14}N_4OS$ |

the compounds were synthesized using one pot microwave assisted method (Method 3).

The processes developed in this present work are feasible, simple, cost-effective and time saving.

The course of the reaction was monitored by thin layer chromatography (TLC) and the structures were confirmed by spectral data. The MS of all the compounds exhibited the molecular ion peak. $^1$H NMR spectra of 2-hydrazino-pyrimidin-4(3H)-one showed the presence of characteristic, $D_2O$ exchangeable –NH peaks at δ ranging from 7.0 to 8.0. All the other spectral data was found to be satisfactory. The list of synthesized compounds is given Table 1.

The synthesized compounds were evaluated for their ability to inhibit DHFR from pc, tg, ma, and rl using a continuous spectrophotometric assay measuring oxidation at 340 n*M* of NADPH at 37°C under conditions of saturating substrate and cofactor as previously described [10,11]. The results of this assay are given in Table 2, along with previously reported data for reference compounds [12].

The compound **5** showed 51.38 μ*M* activity against pcDHFR and 60.54 μ*M* activity against maDHFR. The Compound **8** also exhibited comparable potency as that of trimethoprim against pcDHFR. The Compound **6** exhibited micromolar potency against pc DHFR. However, the synthesized molecules were not selective.

In summary based on virtual screening experiments, 2-hydrazino-pyrimidin-4(3*H*)-one was designed as novel antifolate scaffold. An efficient, simple protocol was

**Table 2**

Dihydrofolate reductase inhibition by synthesized compounds.

Inhibitory concentration ($IC_{50}$, $\mu M$) against rlDHFR, pcDHFR, tgDHFR and maDHFR by target compounds. Triplicate assays were performed as previously described [10,11].

Because of lack of solubility the exact $IC_{50}$ could not be determined for some compounds; hence maximum soluble concentration was used to determine % inhibition. Number in parentheses indicates percent inhibition obtained at that concentration. For e.g., 138.102 (32) indicates 32% inhibition at 138.102 $\mu M$ concentration.

[a] Data taken from reference [12].

developed for synthesis of these molecules. The synthesized compounds were evaluated against DHFR of opportunistic organisms. Some of the evaluated compounds showed appreciable antifolate activity, thus validating our methodology. Therefore, these compounds could act as good leads for novel antifolates. The results would be used for design and synthesis of analogs with improved potency and selectivity.

## EXPERIMENTAL

Melting points (mp) were recorded on Thermomik Compbell electronics, having oil-heating system and were uncorrected. The microwave reactions were carried out using CEM Focused Microwave System in monomode, Model Discover. Analytical thin-layer chromatography (TLC) was carried out on precoated plates $SiO_2$ (silica gel 60, F 254, Merck). $SiO_2$ (Silica gel 420, Merck) was used for column chromatography using CombiFlash® RETRIEVE® system. FTIR spectra were recorded on ''Buck scientific infrared spectroscopy M500 spectrophotometer'' using KBr pellets. All the NMR spectra were recorded on FT-NMR JEOL, 60 MHz or JEOL AL 300 MHz spectrometer with DMSO-*d6* or $CDCl_3$ as solvent using tetramethyl silane (TMS) as internal reference: s = singlet, d = doublet, t = triplet, q = quartet, m = mutiplet, bs = broad singlet. The mass spectrum was recorded on a Waters Q/TOF Micromass spectrometer.

**General procedure method 1 (method using conventional reflux) Step I: synthesis of semicarbazone.** Substituted ketone (13.7 mmol) and semicarbazide hydrochloride (13.7 mmol) were stirred in 30 mL absolute ethanol in a round bottom flask and the mixture was refluxed on a sand bath with vigorous stirring for 14–18 hrs. After the reaction commenced, ketones reacted with semicarbazide hydrochloride giving a base spot on TLC (in solvent system EtOAc:Hexanes = 9:1). The reaction mixture was then concentrated under reduced pressure and the obtained solid residue was partitioned between 50 mL water and 50 mL EtOAc:hexanes (1:9) to extract unreacted starting materials in organic layer. Aqueous layer was stirred for 5 min with solid sodium bicarbonate (3 g) leading to precipitation of solid semicarbazone which was then filtered and washed with water (3 × 50 mL). The obtained solid was recrystallized from 40 mL of MeOH. This gave pure semicarbazone in free base form which was used for the cyclization with β-ketoester.

**Representative example.** 2-(bis(4-fluorophenyl)methylene) hydrazinecarboximidamide: To the ethanolic solution of bis(4-fluorophenyl)methanone (3g, 13.7 mmol); semicarbazide hydrochloride (1.51 g, 13.7 mmol) was added according to step 1, to yield 2.87g (yield: 76.12%) of pure yellow colored semicarbazone product ((2-(bis(4-fluorophenyl)methylene) hydrazinecarboximidamide).

**Step II: Synthesis of 2-hydrazino-pyrimidin-4(3*H*)-one derivatives.** The semicarbazone (6.16 mmol), the β-ketoester derivative (6.16 mmol) and triethylamine (3.08 mmol) as a catalyst were suspended in 30 mL absolute ethanol and the mixture was refluxed on a sand bath with stirring for 18–22 hrs. TLC showed a product spot ($R_f$ of 0.4–0.6 in the solvent system EtOAc:Hexanes (7:3)). The reaction mixture was concentrated under vacuum and was partitioned between EtOAc (25 mL) and water (25 mL). The organic layer was separated, and the aqueous layer was extracted further with EtOAc (2 × 25 mL). The combined organic layers were washed with brine (75 mL), dried ($NaSO_4$), and concentrated in vacuo. Column purification using flash chromatography ($SiO_2$, 5 g, 15% EtOAc/hexanes) of the crude product yielded pure 2-hydrazino-pyrimidin-4(3H)-one derivatives.

**Representative example.** 2-(2-(bis(4-fluorophenyl) methylene) hydrazinyl)-6-methylpyrimidin-4(3H)-one (**1**): The ethanolic solution of 2-(bis(4-fluorophenyl) methylene) hydrazinecarboximidamide (1 g, 3.6 mmol) was treated with ethylacetoacetate (0.47 g, 3.6 mmol) and triethyl amine (0.18 g, 1.8 mmol) according to step 2, to yield 0.521 g (yield: 42%) of 2-(2-(bis(4-fluorophenyl)methylene)hydrazinyl)-6-methyl pyrimidin-4(3H)-one as buff colored solid.

**Method 2: (method using microwave assisted reaction) Step I: Synthesis of semicarbazone.** A mixture of the ketone (13.7 mmol) and semicarbazide hydrochloride (13.7 mmol) suspended in 30 mL absolute ethanol. This reaction mixture was subjected to microwave irradiation at a power of 60 W, for 15 min (target temperature 100°C). After the completion of reaction the compounds were isolated and purified as described in step I of method 1.

**Representative example.** 2-(2-(bis(4-fluorophenyl) methylene) hydrazinyl)-6-methylpyrimidin-4(3H)-one: To the ethanolic solution of bis(4-fluorophenyl)methanone (3 g, 13.7 mmol); semicarbazide hydrochloride (1.51 g, 13.7 mmol) was added according to step 1, to yield 3.2 g (yield: 85.13%) of pure yellow colored semicarbazone product ((2-(bis(4-fluorophenyl)methylene) hydrazinecarboximidamide).

**Step II: Synthesis of 2-hydrazino-pyrimidin-4(3*H*)-one derivatives.** The semicarbazone (3.6 mmol), the β-ketoester derivative (3.6 mmol) and triethylamine (1.8 mmol) as a catalyst were suspended in 30 mL absolute ethanol. This reaction mixture was subjected to microwave irradiation at a power of 60 W, for 20 min (target temperature of 100°C). After the completion of reaction the compounds were isolated and purified as described in step II of method 1.

**Representative example.** 2-(2-(bis(4-fluorophenyl) methylene) hydrazinyl)-6-methylpyrimidin-4(3H)-one (**1**): The ethanolic solution of 2-(bis(4-fluorophenyl) methylene) hydrazinecarboximidamide (1 g, 3.6 mmol) was treated with ethylacetoacetate (0.47 g, 3.6 mmol) and triethyl amine (0.18 g, 1.8 mmol) according to step 2, to yield 0.583 g (yield: 47%) of 2-(2-(bis(4-fluorophenyl)methylene)hydrazinyl)-6-methyl pyrimidin-4(3H)-one as buff colored solid.

**Method 3: (One pot microwave assisted method).** A mixture of ketone (27.5 mmol), semicarbazide hydrochloride (27.5 mmol) and β-ketoester (27.5 mmol) were suspended in 30 mL absolute ethanol. This reaction mixture was subjected to microwave irradiation with power of 60 W, for 10 min (target temperature 100°C). After 10 min triethylamine (13.75 mmol) was added in and reaction mixture was subjected to microwave irradiation at the power range of 100 W, for 15–20 min (target temperature 100°C). Most of the starting material consumed after this time, the reaction mixture was then concentrated under reduced pressure and partitioned between water (50 mL) and EtOAc (50 mL). The organic layer was separated, and the aqueous layer was extracted further with EtOAc (2 × 25 mL). The combined organic layers were washed with brine (75 mL), dried ($NaSO_4$), and concentrated *in vacuo*. Column purification using flash chromatography ($SiO_2$, 5 g, 15% EtOAc/hexanes) of the crude product yielded pure 2-hydrazino-pyrimidin-4(3H)-one derivatives.

**Representative example.** 2-(2-(bis(4-fluorophenyl) methylene) hydrazinyl)-6-methyl pyrimidin -4(3H)-one (**1**): To the ethanolic solution of bis(4-fluorophenyl)methanone (3 g, 13.7 mmol), aminoguanide hydrochloride (1.51 g, 13.7 mmol) and ethylacetoacetate (1.41 g, 13.7 mmol) triethyl amine (0.69 g, 6.85 mmol) was added according to reaction described above to yield 1.93 g (yield: 40.6%) of buff colored product.

Regio- and stereo-controlled opening of 2,3-epoxy amines and 2,3-aziridine amines by the commercially available $MgBr_2$ is described. As reported, this new method could represent a general and useful approach for the preparation of promising intermediates. Moreover, in particular cases, the reaction evolves toward an interesting oxazolidin-2-one structure.

## INTRODUCTION

The human immunodeficiency virus (HIV) is the causative agent of the acquired immunodeficiency syndrome (AIDS); the HIV-protease (PR) is one of the essential viral enzymes to its maturation and infectivity. Actually, synergy of the two RT and PR inhibitors represents the most efficacious therapy for the treatment of this disease called Highly Active Antiretroviral Therapy (HAART). All the same, the widespread diffusion of the disease and the development of numerous mutant resistant viruses to this therapy have prompted the research toward new and selective inhibitors of HIV-PR, see review [1].

In this field, we synthesized two analogues of Saquinavir **1**, where the anti stereochemistry of the hydroxyethylene isoster core (anti HEA) was substituted with a syn one, as shown in Figure 1 [2].

Among the methods already reported for obtaining syn amino alcohols, see review [3], certainly the multisteps strategy largely used by us consisting in (1) Sharpless AE of allylic alcohols, (2) regio- and stereoselective opening of oxirane ring with halides, (3) substitution of the halogen with azide, and (4) catalytic hydrogenation to amine, represents, despite the number of steps, a very general and flexible route to build up the chiral β-amino alcohols. Following up this approach, we considered the epoxy amine **3**, having the Saquinavir characteristic

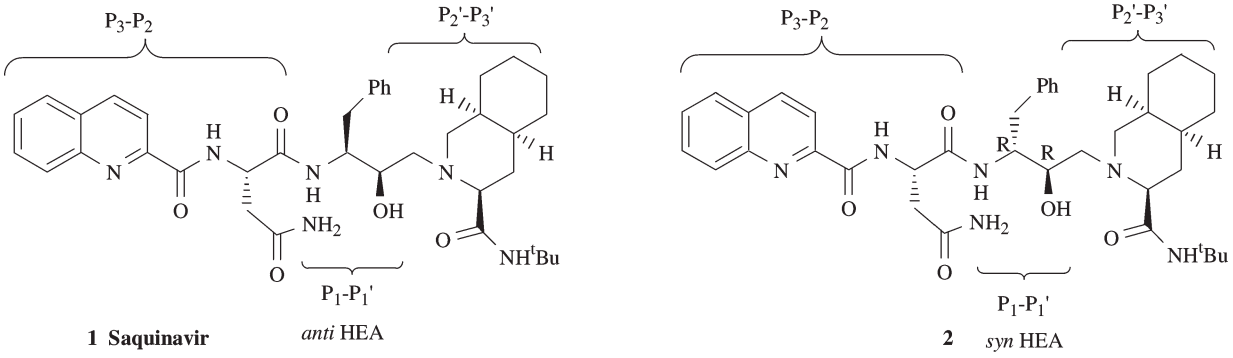

**Figure 1.** Saquinaver and *syn* HEA analog.

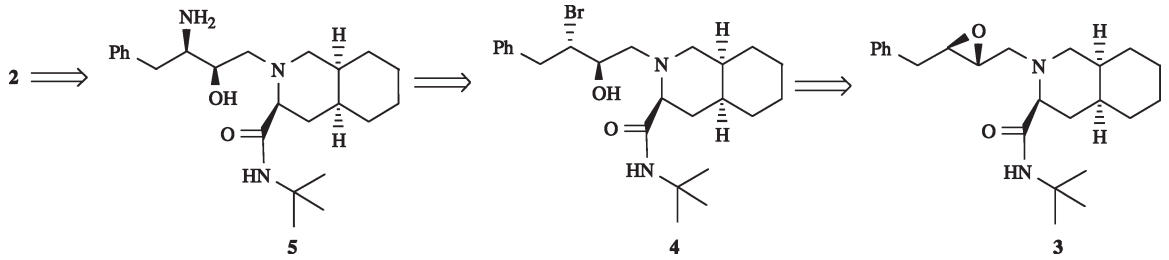
**Scheme 1**



residue (*S*,*S*,*S*)-decahydroisoquinoline-3-carboxylamide residue (DIQ) already introduced in the molecule, a straightforward precursor for our purpose. In fact, its stereo- and regioselective opening by halide, followed by steps (3) and (4), would have furnished the suitable syn amino alcohol **5**, as shown in retrosynthetic Scheme 1.

Apart from selected examples [4], to our best knowledge, the regio- and stereo-controlled opening of 2,3-epoxy amines by halides has never been exploited; therefore, we decided to better study this particular reactivity of these compounds.

## RESULTS AND DISCUSSION

During our studies, we have extensively investigated the metal halides-mediated opening of epoxy alcohols, esters (see review [5]), and aldehydes [6]. In every case, we established that the freshly prepared $MgI_2$, or the commercially available $MgBr_2$, as well as LiX/Amb15 system were able to direct the halide in C-3 position through a previously postulated chelated complex between the metal ($Mg^{2+}$, $Li^{+}$) and the two oxygen of the epoxide derivative. At this point, we hypothesized that also in the case of 2,3-epoxy amines, a possible chelate between metal, epoxide oxygen, and the nitrogen atom occurred, leading to a C-3 regioselective nucleophilic ring opening, Figure 2.

Our preliminary studies were restricted, for convenience, to racemic compounds; the 2,3-epoxy amines were synthesized in satisfactory yield from the corresponding 2,3-epoxy alcohols through the sequence described in Scheme 2: (1) transformation of the hydroxyl function in a good leaving group such as the mesilate (2) nucleophilic substitution with the suitable amine.

The prepared 2,3-epoxy amines were then submitted to the $MgBr_2$-mediated opening reaction employing dry $Et_2O$ as solvent at low temperature [7]. As shown in Table 1, the results confirmed our hypothesis: the nucleophilic attack of the bromine occurred preferentially in the C-3 position, as expected for chelation-controlled ring opening reactions. The regiochemistry of the products was assigned by spin–spin decoupling experiments carried out on the corresponding acetyl derivatives, whereas the anti stereochemistry was assigned in accordance with the $S_N2$ mechanism of the opening reaction.

As expected, the same reaction conditions applied to the 2,3-epoxy amine **3** afforded the desired bromoderivative **4**, in good yield and excellent regioselectivity (entry 5); the further elaboration of bromine carried out to our desired target, the syn amino alcohol **5**.

For the sake of completeness and for our interest on these compounds, the study was extended on 2,3-aziridine amines. Also in this case very few examples [8], regarding essentially aziridine-fused heterocycles, are already reported in literature. Likewise 2,3-aziridino alcohols [9], also for 2,3-aziridine amines, a cyclic chelate may be invoked to control the regioselectivity in the ring opening reaction by metal halides, Figure 3.

An expeditious sequence was employed to prepare the starting substrates, consisting on the direct introduction of the amines on C-1 position, followed by the usual transformation to the aziridine ring (Scheme 3) [10]. In this case, the chosen amines have been once again piperidine and, for our specific interest regarding the synthesis of D-*treo*-PDMP, morpholine [11].

When we submitted compounds **16–19** to $MgBr_2$ reaction, only one product was detected (Table 2); also

| 3 | 4 | 68 | 95:5 |

[a] Regioisomeric ratio was determined by $^1$H NMR spectra.

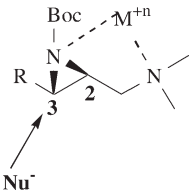

**Figure 3.** Possible cyclic chelate.

in this case, the ring opening occurred with an excellent C-3 regioselectivity (as demonstrated through spin–spin decoupling experiments), according to the proposed cyclic chelate model.

An unexpected behavior was observed when the C-3 position of the substrate was very reactive, as for **24** and **25**; in this case, the initial 3-bromo derivative underwent a rearrangement during the time (4–5 h), giving a new product, the physical data of which were in agreement with a 2-oxazolidinone structure (Scheme 4). This transformation could be explained through an intramolecular nucleophilic substitution of the bromine in benzylic and allylic position (Fig. 4).

In conclusion, the described new method represents a general and useful approach to the preparation of promising intermediates, due to the possible elaboration of the bromine [12]. Moreover, also when the reaction

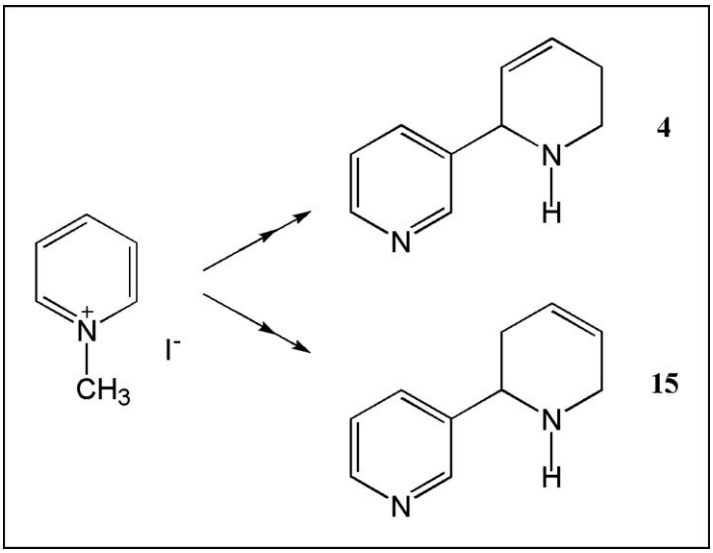
Published online 29 April 2010 in Wiley InterScience (www.interscience.wiley.com).



Anatabine is a major alkaloid in *Nicotiana tabacum* and its isomer, isoanatabine, was recently found in a marine worm. Reduction of 1-methylpyridinium iodide with sodium borohydride gave 1-methyl-3-piperideine, which was transformed with hydrogen peroxide into the *N*-oxide. Reaction of the *N*-oxide successively with trifluoroacetic anhydride and potassium cyanide gave 2-cyano-1-methyl-3-piperideine. Its reaction with 3-pyridylmagnesium chloride gave (±)-*N*-methyl-isoanatabine. This was transformed with *m*-chloroperbenzoic acid into the *N*-oxide which was *N*-demethylated with iron(II) sulfate, giving (±)-isoanatabine. The successive applications of literature procedures for the *N*-demethylation by decomposition of *N*-oxide contributed to the knowledge of the mechanism of this oxidative rearrangement. On the other hand, the reduction of 1-methylpyridinium iodide with sodium borohydride and with potassium cyanide present since the start of the reaction in a two layer ether-water system, gave 2-cyano-1-methyl-4-piperideine. This was transformed into (±)-anatabine by the same sequence of reactions used for the synthesis of (±)-isoanatabine.

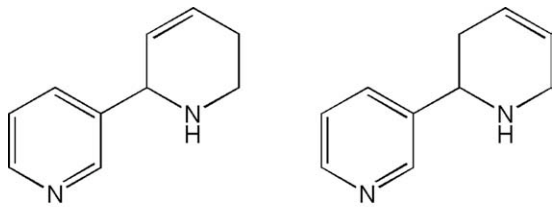
## INTRODUCTION

In fresh tobacco leaves of the *Nicotina tabacum* species, the alkaloid mixture consists of 93% (*S*)-nicotine, 3.9% (*S*)-anatabine, 2.4% (*S*)-nornicotine, 0.5% (*S*)-anabasine, and several other pyridine alkaloids which are detected in lower amounts [1]. (*S*)-Nicotine and several of its minor metabolites have potent modulatory effects on nicotinic acetylcholine receptors in the central and peripheral nervous systems. Thus, a variety of nicotinic agonists are being developed for the treatment of neurodegenerative and mental diseases [2]. As part of a search for biologically active compounds acting upon these receptors, we synthesized anatabine and isomeric isoanatabine (Scheme 1), found in a marine worm [3,4].

To our knowledge, only the procedure of Flann *et al*. has been published for the synthesis of (±)-isoanatabine, i.e., 2-(3-pyridyl)-3-piperideine [5] (Scheme 2). This multistep procedure starts with 3-butyn-1-ol and synthesized 1-amino-4-trimethylsilyl-but-3-ene. The condensation of the latter with 3-pyridinecarboxaldehyde gave the aldimine, which with trifluoroacetic acid cyclized by 1,2-addition to the imine group of the trimethylsilylated vinylcarbon, giving (±)-isoanatabine.

On the other hand, several procedures have been developed for the synthesis of anatabine, i.e., 2-(3-pyridyl)-4-piperideine (Scheme 3). In general, they start from a 3-substituted pyridine and the piperideine ring is constructed at the substituent moiety. Quan *et al*. started

**Scheme 1**



**Isoanatabine** **Anatabine**

from 3-formylpyridine [6]. The formyl group was transformed with ethyl carbamate into diethyl *N*,*N*′-(3-pyridylmethyl)-biscarbamate. With boron trifluoride etherate, the biscarbamate was decomposed by heating in benzene into an intermediate imine which cyclized with 1,3-butadiene (Diels Alder reaction), giving the *N*-ethoxycarbonyl-anatabine and, after hydrolysis, (±)-anatabine.

Deo and Crooks started from 3-(aminomethyl)-pyridine [7]. This was transformed with benzophenone into a ketimine. Its reaction with LDA gave the carbanion of the activated methylene, which was then monoalkylated with *cis*-1,4-dichloro-2-butene. Hydrolysis made free the 1-amino group which cyclized by reaction with the 5-chloro substituent of the pent-3-ene, giving (±)-anatabine.

Felpin *et al*. synthesized (*S*)-anatabine starting with the asymmetric addition of (+)-B-allyl-diisopinocampheylborane to 3-formylpyridine, giving the enantiomerically pure alcohol [8]. This was successively transformed into the mesylate, azide, and amine. The amino group previously transformed into carbamate was alkylated with allylbromide. Metathesis with the Grubb's ruthenium catalyst cyclized the two allyl groups into the *N*-carbamate protected (*S*)-anatabine, which was then deprotected.

Balasubramanian and Hassner synthesized (*S*)-anatabine starting from 3-pyridinecarboxaldehyde [9]. Its condensation with (*S*)-*p*-toluenesulfinamide gave an enantiomerically pure imine. After the enantioselective 1,2-addition to its imino group of the 4-carbanion of *cis*-1-hydroxy-4-phenylsulfonyl-but-2-ene (the dianion of which being obtained with LiHMDS), the amino group was deprotected. The Mitsunobu cyclization of the 1,5-unsaturated aminoalcohol generated the phenylsulfonyl substituted (*S*)-anatabine. Reductive elimination of the phenylsulfonyl substituent gave (*S*)-anatabine.

Ayers *et al*. synthesized (*S*)-anatabine starting with 3-(aminomethyl)-pyridine [10]. Its condensation with (+)-2-hydroxy-3-pinanone in the presence of boron trifluoride diethyl etherate gave an enantiomerically pure ketimine. The carbanion (generated with LDA) of the methylene α to the nitrogen of the imine group was enantioselectively monoalkylated with *cis*-1-bromo-4-(tetrahydropyran-2-yloxy)-but-2-en. The 4-tetrahydropyran and 2-hydroxy-3-pinanone groups were removed. The Mitsunobu cyclization of the unsaturated 1,5-aminoalcohol gave (*S*)-anatabine. The use of (−)-2-hydroxy-3-pinanone ketimine gave (*R*)-anatabine by the same procedure.

On the other hand, (*R*)-anatabine was synthesized starting with 1-(2,4-dinitrobenzene-1-yl)-pyridinium chloride and (*R*)-phenylglycinol [11].

The addition of lithium aluminum hydride to pyridine gives lithium tetrakis(*N*-dihydropyridyl)aluminate (LDPA) [12a]. The addition at 0°C of water to the solution of LDPA in pyridine, gives a mixture of 1,4-, 1,2-, and 2,5-dihydropyridines in a ratio of 26:37:38 [12b]. By conducting this hydrolysis under an atmosphere of oxygen, Yang and Tanner obtained (±)-anatabine with a yield of 59% [12c].

In this work, a short procedure has been developed for the synthesis of (±)-isoanatabine starting with 1-methylpyridinium iodide. By modifying the first reduction step, this procedure has been extended to the synthesis of (±)-anatabine.

## RESULTS AND DISCUSSION

### Synthesis of (±)-isonanatabine

***Synthesis of (±)-N-methyl-isoanatabine 3a and (±)-N-benzyl-isoanatabine 3b.*** Reaction of pyridine with methyl iodide in acetone gave 1-methylpyridinium iodide (Scheme 4). According to a described procedure, the reaction of 1-methylpyridinium iodide with sodium borohydride in methanol yielded 1-methyl-3-piperideine, which was not isolated [13]. Oxidation with hydrogen

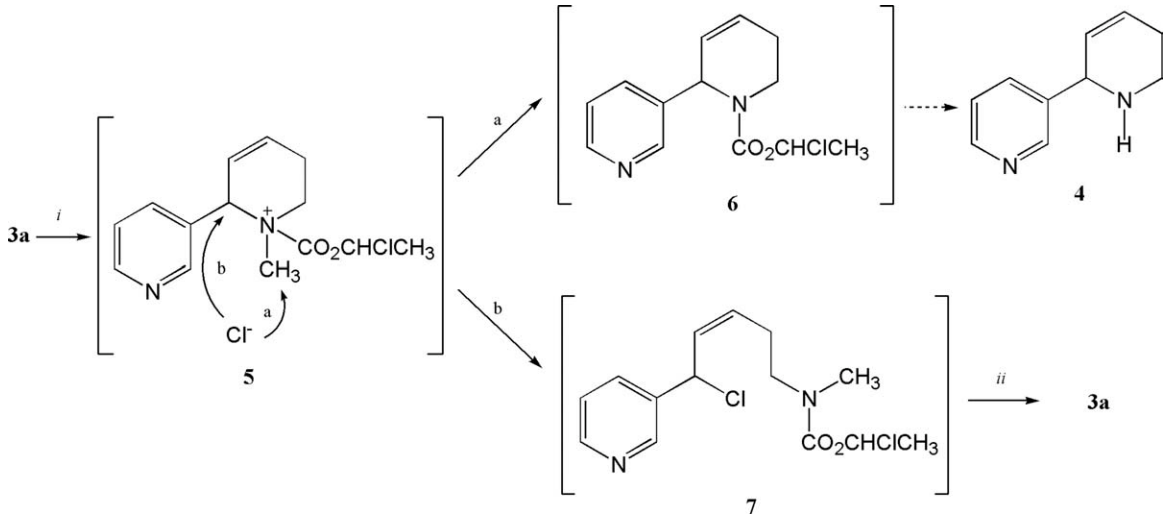
**Scheme 5.** Reagents and conditions: (*i*) ACE-Cl, 1,2-dichloroethane, reflux, 16 h. (*ii*) 2.5% NaOH, EtOH/$H_2O$ (9:1), 0°C (1 h) to rt (24 h), 75%.



peroxide gave 1-methyl-3-piperideine *N*-oxide. The *N*-oxide in methylene chloride was treated with trifluoroacetic anhydride. After 1 h, an aqueous solution of potassium cyanide was added while the pH of the aqueous layer was maintained at 4, giving (±)-2-cyano-1-methyl-3-piperideine **1a**.

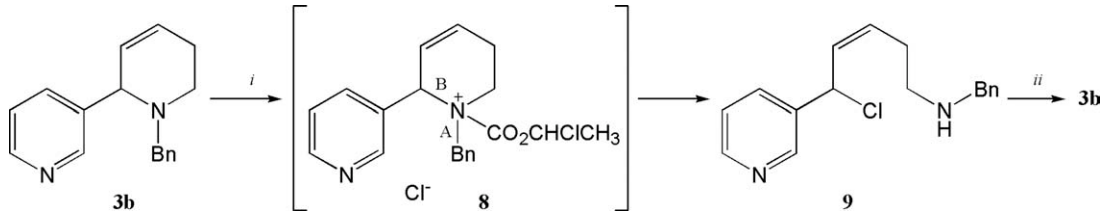
Alkylation of the α-amino nitrile **1a** with 3-pyridylmagnesium chloride (or 3-pyridylmagnesium bromide) was made according to the Bruylants reaction, i.e., the reaction of an α-tertiary-amino nitrile with a Grignard reagent [15]. The metal of the Grignard reagent probably mediates the formation of the conjugated iminium **2a**, on which subsequently adds the Grignard reagent. The stability and the reactivity of the iminium **2a** is the most likely reason why the Grignard reagent substitutes the CN in the α-aminonitrile **1a**, generating 1-methyl-2-(3-pyridyl)-3-piperideine **3a**, i.e., (±)-*N*-methyl-isoanatabine, rather than adding to it. The THF solution containing 5 equiv of the Grignard reagent was added at −10°C to a solution of the α-amino nitrile **1a**, also in THF. After stirring the mixture at room temperature overnight, **3a** was obtained with a yield of 77%. For the preparation of 3-pyridylmagnesium chloride, 1 equiv of 3-bromopyridine was added to 1 equiv of *i*-propylmagnesium chloride in THF at room temperature, and the mixture was stirred for 1 h [16].

The 3-pyridylmagnesium bromide was also used for the alkylation of α-amino nitrile **1a**. In this case, **3a** was obtained with a lower yield of 65%. The procedure previously described in the literature for the synthesis of 3-pyridylmagnesium bromide was modified [17]. The ratio of the reagents was changed and the reaction generating $MgBr_2$ was made in ether instead of THF, $MgBr_2$ being more soluble in ether than in THF as $MgBr_2$ forms a complex with ether. In this way, the transfer of the solution of $MgBr_2$ through a cannula under argon to the solution of 3-pyridyllithium was easier.

(±)-1-Benzyl-2-cyano-3-piperideine **1b** was synthesized according to the procedure of Bonin *et al*. [14]. This procedure is similar to the one used for the synthesis of **1a**, except for some modifications. Sodium borohydride was reacted with 1-benzyl-pyridinium bromide (obtained by reaction of benzyl bromide with pyridine in toluene [18]) in ethanol, giving the 1-benzyl-1,2,5,6-tetrahydropyridine, which was isolated with a yield of 75%. Its solution in dichloromethane was reacted with *m*-chloroperbenzoic acid, giving 1-benzyl-1,2,5,6-tetrahydropyridine-*N*-oxide isolated with a yield of 80%. To the solution of the *N*-oxide in dichloromethane was added trifluoroacetic anhydride; after 1 h at room temperature, an aqueous solution of potassium cyanide was added, during which the pH was maintained at 4. 1-Benzyl-2-cyano-3-piperideine **1b** was obtained with a yield of 57%. The subsequent alkylation of the α-amino nitrile **1b** with 3-pyridylmagnesium chloride was made according to the Bruylants reaction, generating (±)-1-benzyl-2-(3-pyridyl)-3-piperideine **3b**, i.e., (±)-*N*-benzyl-isoanatabine. The solution of the Grignard reagent in THF was added at 0°C to the solution of the α-amino nitrile **1b** in THF. The (±)-*N*-benzyl-isoanatabine **3b** was obtained with a yield of 67%.

***Attempts at N-demethylation and N-debenzylation by a chloroformate of the (±)-N-methyl- and (±)-N-benzyl-isoanatabines.*** To obtain (±)-isoanatabine **4**, the *N*-demethylation of **3a** was attempted by reacting **3a** with a chloroformate [19a]. The mixture of **3a** and 1 equiv of α-chloroethyl chloroformate (ACE-Cl) in 1,2-dichloroethane was refluxed for 16 h (monitored by TLC). After evaporation of the solvent, the residue was refluxed in methanol for 1 h, giving a mixture of unidentified

**Scheme 6.** Reagents and conditions: (*i*) ACE-Cl, $CH_2Cl_2$, 0°C to rt, 16 h. (*ii*) 2.5% NaOH, EtOH/$H_2O$ (9:1), 0°C (1 h) to rt, 5 h, 78%.



products. To solve the problem, the mixture of **3a** and ACE-Cl in 1,2-dichloroethane was refluxed for 16 h, but instead of the intermediate carbamate **6**, the *N*-[5-chloro-5-(pyridin-3-yl)-pent-3-enyl]-*N*-methyl-carbamic acid 1-chloro-ethyl ester **7** was isolated and analyzed (Scheme 5). Thereafter, **7** was treated with 2.5% sodium hydroxide in aqueous ethanol, and (±)-*N*-methyl-isoanatabine **3a** was recovered with a yield of 75% relative to the starting amount of **3a**.

The opening of the piperideine ring when **3a** is reacted with α-chloroethyl chloroformate can be explained by the intermediate formation of the quaternary ammonium salt **5** followed by the attack of the chloride ion at the benzylic carbon, following the pathway b instead of the attack at the methyl group (pathway a). This corresponds to the benzyl effect, i.e., the benzyl cleavage is preferred over the methyl loss on account of the great stability of the benzyl carbocation. The general rule indicates that the group that cleaves is the one that gives the most stable carbocation and the most reactive halide (e.g., benzyl or allyl); for simple alkyl groups, the smallest are the most readily cleaved [19]. A similar reactivity to that of **3a** is observed with nicotine. When nicotine is reacted with chloroformates, the pyrrolidine ring is opened and the δ-chlorocarbamates are obtained [20].

An assay was made for the *N*-debenzylation of **3b** by its reaction with α-chloroethyl chloroformate in dichloromethane at room temperature, as it is known that the benzyl group needs lower temperatures to be cleaved.

In the intermediate quaternary ammonium salt **8**, it was hoped that the breaking of the *N*-Bn (bond A) would be favored over the breaking of the *N*-(C-2 of the 3-piperideine) bond (bond B), generating (±)-isoanatabine **4** (Scheme 6). The reverse however occurred and 1-chloro-1-(3-pyridyl)-5-benzylamino-pent-2-ene **9** was formed. This could be due to the fact that the B bond breaking in **8** generates at the 2-C of the 3-piperideine a more stable carbocation because it is simultaneously a benzyl and allyl cation. The A bond breaking would generate a carbocation benzyl lacking the further allyl stabilization.

The treatment of **9** with 2.5% sodium hydroxide in aqueous ethanol permitted recovery of the starting (±)-*N*-benzyl-isoanatabine **3b** with a yield of 78%.

***Attempted N-debenzylation of (±)-N-benzyl-isoanatabine 3b with CAN.*** Yamaura *et al*. observed that the *N*-(4-methoxybenzyl) group on 2,5-piperazinediones can be oxidatively removed with $(NH_4)_2Ce(NO_3)_6$ (CAN), but not the unsubstituted benzyl group [21]. However, Bull *et al*. observed that the treatment of a range of *N*-unsubstituted benzyl tertiary amines with CAN at room temperature results in *N*-debenzylation to afford the corresponding secondary amine [22]. Therefore, the oxidative *N*-debenzylation of **3b** with CAN was assayed. A solution of **3b** and 2 equiv of CAN in 5:1 acetonitrile:water was stirred for 2 h at rt. Only the starting material **3b** was obtained. In another assay, 4 equiv of CAN were added to a solution of **3b** in 5:1 acetonitrile:water, and the solution was stirred 24 h at rt. Again only the starting **3b** was recovered. The concentration of CAN in the reaction mixture of each of these assays was greater than 0.25*M* as it is known that no oxidation is obtained at lower concentration [21]. A further assay was made with **3b** and 4 equiv of CAN, and stirring at 50°C overnight; isoanatabine **4** was not obtained but **3b** was completely transformed into a lot of unidentified products. The use of tetrahydrofuran instead of acetonitrile and higher concentrations of CAN at room temperature also led to the recovering of the starting (±)-*N*-benzyl-isoanatabine **3b**.

***N-Demethylation of the (±)-N-methyl-isoanatabine 3a by decomposition of its N-oxide 10 (nonclassical Polonovski reaction).*** Several possible methods for *N*-demethylation of **3a** were tested, starting from the *N*-oxide of **3a**, **10**. The *N*-oxide **10** was obtained by reaction of (±)-*N*-methyl-isoanatabine **3a** with *m*-chloroperoxybenzoic acid (1.1 equiv) in $CH_2Cl_2$ at 0°C to avoid the possible epoxidation of the double bond [23]. The usual work up, i.e., treatment of the reaction mixture by aq. NaOH to pH 10–11 and then extraction by $CHCl_3$ led to the isolation of the *N*-oxide only in low yield. The low yield was probably due to the high solubility of the *N*-oxide at basic pH. This problem was overcame by concentrating the reaction mixture and pouring the concentrate

over alumina and chromatographing. In this way, the (±)-*N*-methyl-isoanatabine-*N*-oxide **10** was obtained with a yield of 91% as a mixture of diastereomers in a 6:4 ratio (undefined stereochemistry). The diastereomers were not separated and were used in next step as a mixture.

The nonclassical Polonovski reaction for the *N*-demethylation of the *N*-oxide of (±)-*N*-methyl-isoanatabine **3a** was investigated [24a]. The desired reaction is the catalyzed decomposition of the tertiary amine *N*-oxide through an internal oxidation into the secondary amine, the *N*-methyl being oxidized to formaldehyde. When the reaction is catalyzed by an iron salt, the mechanism is believed to involve two successive one-electron transfers involving Fe(II)/Fe(III) redox reactions [24b,c]. Cations, free radicals and radical-cations ions stabilized as iminium ions and radicals, are considered as intermediates. Often the catalyst (the iron salt or complex, selenium dioxide, etc.) is engaged in stoichiometric amounts. The *N*-demethylation of the hydrochloride salts of the *N*-oxides of opiate alkaloids (codeine, codeine methyl ether, thebaine, thevinone, etc.) was realized with $FeSO_4 \cdot 7H_2O$ in methanol; the *N*-oxide of codeine gave norcodeine with a yield of 49%, in mixture with codeine, i.e., the product of *N*-deoxygenation [25]. When the same reaction was made using a porphyrin chelate of iron(II), the yield of norcodeine was increased to 91% [26]. The same reaction has been applied to the *N*-demethylation of the *N*-oxides of piperidines, benzomorphans, and morphinans using iron(II) chloride [27].

For the nonclassical Polonovski reaction of the *N*-oxides of tertiary amine catalyzed with iron salts in water or in nonpolar solvents, the ease of alkyl conversion to the corresponding carbonyl compound decreases in the order $C_6H_5CH_2 > CH_3 > RCH_2 > R_2CH$; this is the decreasing order for the ease of the breaking of the bond between the *N*-oxide nitrogen atom and one of the three alkyl groups linked to this nitrogen [24b,c]. This reactivity order for the rearrangement was assigned among others to the acidity of the protons on the carbon adjacent to the nitrogen atom; the greater stability of the intermediate benzyl carbocation, benzyl radical and benzyl radical-carbocation also explains the reactivity order and that benzyl cleavage is preferred over methyl loss (benzyl effect). For the *N*-demethylation of the *N*-oxides of opiates (codeine, codeine methyl ether, thebaine, thevinone, etc.) cited earlier, there was no benzyl group linked to the nitrogen atom; there was no competition from the benzyl effect and the *N*-demethylation was obtained with a good yield [25]. The *N*-oxide of *N*-methyl-isoanatabine and the *N*-oxide of the *N*-benzyl-isoanatabine are subjected to the benzyl effect. The failure of the trials for their *N*-demethylation and *N*-debenzylation with a chloroformate showed their high sensitivity to the benzyl effect and prompted to select assays able to avoid this benzyl effect.

Another secondary reaction that competes with the *N*-demethylation is the deoxygenation of the *N*-oxide, which is catalyzed by the iron salt or chelate. It generates back the tertiary amine from which was made the *N*-oxide. Moreover, the deoxygenation of the *N*-oxide may be accompanied by the oxidation (oxidative dehydrogenation) of the *N*-demethylated product or of the *N*-methylated one. Other secondary degradative reactions occur when the reaction temperature is too high.

Selective *N*-demethylation of the *N*-oxides of tertiary aminofumagillols to the corresponding secondary aminofumagillols has been made by heating the *N*-oxide with selenium dioxide in ethanol [28]. The *N*-oxides of tertiary aminofumagillols do not sustain the concurrence of the benzyl effect. However, they contain two epoxy and the α,β-unsaturated ester sensitive functionalities. These remained intact during the reaction.

Therefore, our first attempt at the *N*-demethylation of **10** by means of the nonclassical Polonovski reaction utilized $SeO_2$. A mixture of **10** and 1.5 equiv of $SeO_2$ in 95% ethanol was heated to reflux for 4 h under an atmosphere of argon. (±)-*N*-methyl-isoanatabine **3a** was formed with a yield of 65%, indicating that only *N*-deoxygenation occurred.

Several studies have been reported for the *N*-demethylation of the *N*-oxides of tertiary amines subjected to the benzyl effect, by means of their decomposition catalyzed by iron salts (generally engaged in stoichiometric amounts) in aqueous solutions containing large amounts of tartaric or citric acids (present as such or as their salts). The $FeSO_4$-catalyzed dealkylation of the *N*-oxide of *N*,*N*-dimethyl-benzylamine showed the importance of the benzyl effect relatively to the *N*-demethylation. When the *N*-oxide of *N*,*N*-dimethyl-benzylamine in an aqueous solution at pH 1–2 containing iron(II) sulfate was heated, benzaldehyde was produced with a yield of 85%, no *N*-demethylation being obtained [24b,c]. Under the same conditions at pH 1, the *N*-oxide of *N*,*N*-dimethyl-butylamine gave mainly formaldehyde and *N*-methyl-butylamine. On the other hand at pH 6–7, when the mixture in water of the *N*-oxide of *N*,*N*-dimethyl-benzylamine, L-(+)-tartaric acid and $FeSO_4 \cdot 7H_2O$ (or of $Fe(NO_3)_3 \cdot 9H_2O$) was heated, a mixture of formaldehyde (the product of *N*-demethylation) and benzaldehyde (2.3:1) was formed [24b,29]. At pH 6–7, the $Fe^{+2}/Fe^{+3}$ system is as a complex with the anion of tartaric acid. The *N*-oxide would occupy some coordination positions of this complex [30]. The rearrangement of the *N*-oxide would then occur at the coordination positions of the complex so the regioselectivity of the rearrangement would be directed by the geometry of the complex and thus by steric factors. This would explain the

production of formaldehyde and thus the *N*-demethylation, what did not occur when the iron ions were not chelated.

In previous experiments on the dealkylation of amine oxides, it was observed that reaction mixtures of iron (III) and tartaric or oxalic acid (reducing acids) generated iron(II) *in situ*, and that iron(II) was the initiator of the rearrangement [24b,c]. That iron(II) and not iron(III) was the initiator of the reaction was shown by experiments with iron(III) salts coordinated to nonreducing acids (sulfuric, succinic) [24b,c]. Under these conditions, the Polonovski reaction did not occur. When as little as 3% iron(II) sulfate was added to the reaction medium, secondary amine production began. On the other hand, iron(II) was converted to iron(III) during the course of the rearrangement; this was mainly due to the oxidation of iron(II) by the amine-oxide with formation of the tertiary amine (the secondary reaction of the amine-oxide: deoxygenation).

Noscapine (also called narcotine) has been converted by *N*-demethylation to nornarcotine in 35% overall yield *via* the noscapine *N*-oxide and in spite of the concurrence of a benzyl effect [31]. Therefore, the mixture of noscapine-*N*-oxide·HCl and iron(III) citrate, in water acidified to pH 1–2, was heated. Nicotine-*N*-oxide also suffers the competition of the benzyl effect during its *N*-demethylation by the nonclassical Polonovski reaction. A mixture in water at pH 6 of nicotine-*N*-oxide, $Fe(NO_3)_3$, L-(+)-tartaric acid and sodium carbonate was heated [32]. Nornicotine was obtained with a yield of 56%, besides several other alkaloids arising from the transformation of nicotine: myosmine (6.9%), *N*-methylmyosmine (2.1%), and nicotine (3.0%).

*N*-demethylation of (±)-*N*-methyl-isoanatabine **3a** by decomposition of its *N*-oxide **10** was attempted under the conditions used by Craig *et al*. for the *N*-demethylation of nicotine [32]. The pH of a mixture in water of **10**, 3 equiv of $Fe(NO_3)_3$, and 30 equiv of L-(+)-tartaric acid was adjusted to 6.3 by adding a solution of sodium carbonate. After heating at 80°C for 40 min, (±)-isoanatabine **4** was obtained but only with a low yield of 9%. The major compound isolated was the (±)*N*-methyl-anatabine **3a**, obtained with a yield of 49%, indicating that deoxygenation of the *N*-oxide was the main reaction.

The results obtained in the two preceding assays suggested that heating could induce the deoxygenation of **10** generating (±)-*N*-methyl-isoanatabine **3a**. Therefore, a method was searched for the decomposition of the *N*-oxide at room or lower temperature.

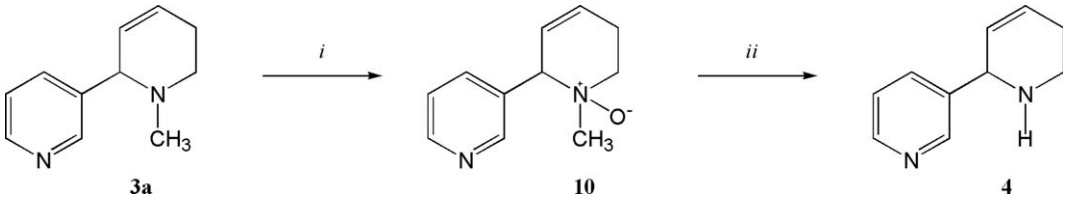
The secondary amine 5-dimethylamino-1-[4-[(2-methylbenzoyl)amino]benzoyl]-2,3,4,5-tetrahydro-1*H*-benzazepine is a metabolite of a new vasopressin V2 receptor antagonist [33]. The *N*-demethylation of its *N*-oxide was sensitive to the competition from the benzyl effect. However, the *N*-demethylation of the *N*-oxide was obtained by stirring a mixture of *N*-oxide, meso-(tetraphenylporphinato)iron(III) chloride, Fe(TPP)Cl, and imidazole in dichloromethane at room temperature. The product of *N*-demethylation was obtained with a yield of 68%, accompanied by 25% of the deoxygenation product of the *N*-oxide. When imidazole was replaced by tetrazole, the secondary amine was produced with a yield of 86%, and the product of deoxygenation was no more detected. This showed the influence of the additives imidazole or tetrazole. They could make some association with the *N*-oxide and the iron porphyrin, orienting in this way the decomposition of the *N*-oxide toward the *N*-demethylation, and overcoming the benzyl effect. In the *N*-demethylation of the *N*-oxides of the *N*,*N*-dimethyl-benzylamine [24b,c] noscapine [31] and nicotine [32] cited earlier, the chelation of the iron ions by the tartaric and citric acids and their salts present in large excess, would explain the orientation by steric effects of the rearrangement of the *N*-oxide toward the *N*-demethylation. The increase of the yield of the *N*-demethylation of the *N*-dimethyl benzazepine *N*-oxide by the use of the additives imidazole or tetrazole corroborated that hypothesis.

Therefore, *N*-demethylation of (±)-*N*-methyl-isoanatabine **3a** was assayed in the conditions used by Kawano *et al*. [33]. The mixture of **10**, 1 equiv of Fe(TPP)Cl and 1 equiv of tetrazole in dichloromethane was stirred at room temperature during 16 h in the dark. The *N*-oxide **10** was recovered untransformed with a yield of 80%. The assay was repeated but without the addition of tetrazole; again the *N*-oxide **10** was recovered untransformed.

The *N*-demethylation of the galanthamine-*N*-oxide is sensitive to the competition from the benzyl effect [34]. However, the *N*-demethylation has been obtained with a yield of 76% by stirring at 10°C the *N*-oxide in methanol containing iron(II) sulfate. No cleavage at the benzylic carbon was observed. The selective demethylation of the galanthamine-*N*-oxide in the presence of iron salts indicated the preference for oxidation at the methyl center of the *N*-methyl substituted amine oxide. This is at the opposite of the general rule which gives the preference to the oxidation of the benzylic carbon. The bulky structure of galanthamine would induce the *N*-demethylation by a steric effect, the *N*-methyl being deprotected to oxidation outside of the bulky structure.

The *N*-demethylation of the *N*-oxide of the alkaloid glaucine suffers also from the competition of the benzyl effect [35]. However, the *N*-demethylation has been performed under the same conditions as for galanthamine without addition of a complexing agent. The *N*-oxide of glaucine was treated in methanol with iron(II) sulfate at 10°C. Norglaucine was formed with a yield of 52%. It

**Scheme 7.** Reagents and conditions: (*i*) *m*-CPBA, $CH_2Cl_2$, 0°C, 1.5 h, 91%. (*ii*) $FeSO_4 \cdot 7H_2O$, $CH_3OH$, 10°C, 1.5 h, 55%.



was accompanied by the formation for 13% of the product of the benzyl effect, which was further reduced. When the reaction temperature was 50°C or when the reagent was changed to ferrous chloride, only the product due to the benzyl effect was formed.

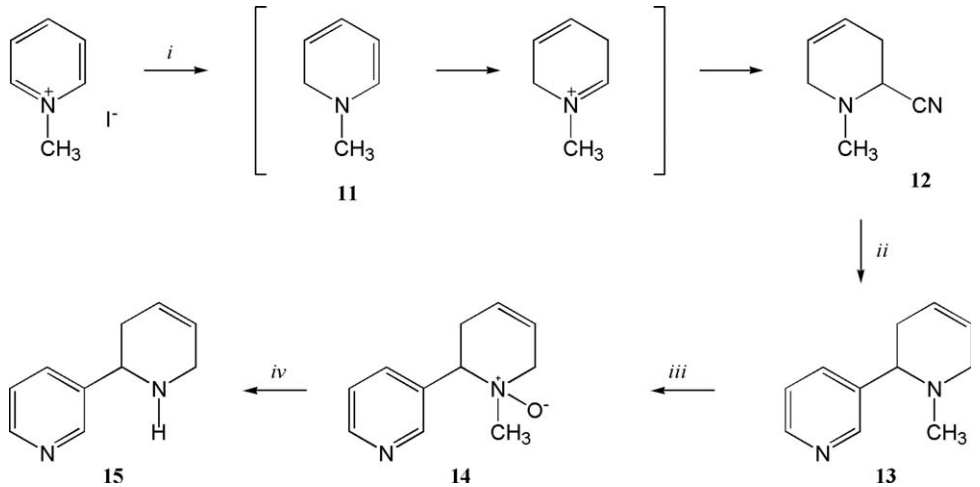
*N*-demethylation of the (±)-*N*-methyl-isoanatabine **3a** by decomposition of its *N*-oxide **10** was tested under the same conditions as the *N*-oxides of galanthamine [34] and glaucine [35] (Scheme 7). A mixture of **10** and 2 equiv of $FeSO_4 \cdot 7H_2O$ in methanol was stirred for 1.5 h at 10°C. The (±)-isoanatabine **4** was obtained with a yield of 55%. It was accompanied by the formation of 23% of (±)-*N*-methyl-isoanatabine **3a**, the product of deoxygenation. As with galanthamine and glaucine, the structure of the *N*-oxide **10** of isoanatabine would induce by a steric effect the *N*-demethylation without requiring an additive. The *N*-methyl would be more accessible to oxidation because of its greater exposure. For the *N*-demethylation by decomposition of the *N*-oxide, the search by the successive applications of described procedures thus contributes, by the analysis of the generated products, to the knowledge of the mechanism and of the experimental parameters orienting the selectivity of the oxidative rearrangement of the nonclassical Polonovski reaction.

**Synthesis of (±)-anatabine.** The procedure for the synthesis of (±)-isoanatabine **4** was extended to the synthesis of (±)-anatabine **15** (Scheme 8). (±)-2-Cyano-1-methyl-4-piperideine **12** is the isomer of (±)-2-cyano-1-methyl-3-piperideine **1a**. The sequence of transformations applied to compound **1a** for the synthesis of (±)-isoanatabine **4** could in principle be applied to **12** for the preparation of (±)-anatabine **15**. Therefore, a procedure for the synthesis of compound **12** was developed. Like for compound **1a** it started with the reduction of 1-methylpyridinium iodide with $NaBH_4$, but the experimental conditions were changed to obtain the double bond in the right position. A two phases solvent system was used [36]. To an aqueous solution of 4 equiv of potassium cyanide was added 1.5 equiv of hydrochloric acid at 0°C. This aqueous phase was layered with the same volume of ether. 1-Methylpyridinium iodide was added followed by 1.2 equiv of $NaBH_4$. After 5 h at room temperature, compound **12** was obtained with a yield of 95%.

The presence of the solution of potassium cyanide in water underlayering the ether phase since the beginning of the reduction of 1-methylpyridinium iodide by $NaBH_4$ permitted to limit the reduction to the formation of 1-methyl-1,2-dihydro-pyridine which in acidic condition was trapped by potassium cyanide, generating compound **12**.

The isomerization of (±)-2-cyano-1-methyl-4-piperideine **12** into (±)-2-cyano-1-methyl-3-piperideine **1a**

**Scheme 8.** Reagents and conditions: (*i*) $NaBH_4$, KCN, HCl, $H_2O/Et_2O$, 0°C to rt, 5 h, 95%. (*ii*) 3-PyrMgCl, THF, −10°C to rt, 16 h, 83%. (*iii*) *m*-CPBA, $CH_2Cl_2$, 0°C, 1.5 h, 88%. (*iv*) $FeSO_4 \cdot 7H_2O$, $CH_3OH$, 10°C, 3 h, 44%.



was attempted [37a,b]. If it succeeded, the aminonitrile **12** could be another starting point for the synthesis of (±)-isoanatabine **4**. The isomerization was attempted by heating **12** in 6*N* HCl. Thereafter, the solution was made basic by addition of potassium cyanide. However, the aminonitrile **12** was recovered untransformed.

The same sequence of transformations applied to compound **1a** for the synthesis of isoanatabine **4**, was applied to compound **12** for the preparation of anatabine **15**. The 3-pyridylmagnesium chloride was reacted with the α-amino nitrile **12** in THF, giving the *N*-methyl-anatabine **13** with a yield of 83%. Compound **13** was oxidized by *m*-CPBA in dichloromethane, giving the *N*-methyl-anatabine-*N*-oxide **14** with a yield of 88% as a mixture of two diastereomers in a 7:3 ratio. The diastereomers can be separated by chromatography on alumina.

The *N*-demethylation of **14** was made on the mixture of diastereomers by their decomposition at 10°C in methanol containing 2 equiv of $FeSO_4 \cdot 7H_2O$ leading to the anatabine **15** with a yield of 44%. It was accompanied by the formation of 44% of *N*-methyl-anatabine **13**, product of deoxygenation of the *N*-oxide **14** which could be recovered from the reaction mixture.

## EXPERIMENTAL

**General.** ESI-HRMS were performed on an Agilent 6210 TOF mass spectrometer. GC/CI analyses were performed on a Thermo Trace GC DSQ–Single Quadrupole. The $^1$H NMR spectra were recorded in $CDCl_3$ at 300 MHz with a Varian Mercury 300 and are reported in ppm from internal TMS on the δ scale. The $^{13}$C NMR spectra were recorded in $CDCl_3$ at 75.4 MHz with a Varian Mercury 300 instrument. The IR spectra were recorded with a Bruker Vector 22 instrument as films on a NaCl disk. Thin layer chromatography analyses (TLC) were performed with 0.20 mm Silica Gel 60, F-254 precoated plates (Selecto Scientific). Chromatographies were performed on silica gel columns (Fisher, Silica Gel Sorbent, 230–400 Mesh) using the flash technique or on alumina (Aluminoxid 90, Activity II–III, EMD).

***(±)-1-Methyl-2-(3-pyridyl)-3-piperideine: (±)-N-methyl-isoanatabine, 3a.*** 3-Bromopyridine (598 μL, 981 mg, 6.22 mmol) was added to *i*-PrMgCl (2*M*/THF, 3.11 mL, 6.22 mmol) in THF (1 mL) at room temperature under argon. After 2 h, the mixture was cooled at −10°C, then a solution of **1a** (152 mg, 1.24 mmol) in THF (2 mL) was added. The resulting reaction mixture was allowed to stir for 1 h at −10°C then left overnight at room temperature. After 16 h, water (5 mL) was added. Extraction with $CH_2Cl_2$ (3 × 10 mL), drying over magnesium sulfate and column chromatography using $CH_2Cl_2$/$CH_3OH/NH_3$ (95:5:1) as eluent afforded (±)-*N*-methyl-isoanatabine, **3a** (167 mg, 0.96 mmol, 77%). IR (NaCl): 3031, 2945, 2785, 1650, 1577, 1425, 1362, 1281, 1057, 850 cm$^{-1}$. $^1$H NMR (300 MHz, $CDCl_3$): δ 8.51 (d, 1H, $J$ = 2.4 Hz, ArH), 8.50 (dd, 1H, $J$ = 1.8, 4.8 Hz, ArH), 7.68 (dt, 1H, $J$ = 1.8, 7.8 Hz, ArH), 7.25 (ddd, 1H, $J$ = 0.6, 4.8, 7.8 Hz, ArH), 5.86 (m, 1H, C*H*=CH), 5.45 (dq, 1H, $J$ = 1.5, 9.9 Hz, CH=C*H*), 3.66 (app quintet, 1H, $J$ = 1.2 Hz, NC*H*Ar), 2.93 (m, 1H, NC$H_2$), 2.50 (m, 2 H, NC$H_2$ + C$H_2$—CH=CH), 2.12 (m, 1H, C$H_2$—CH=CH). $^{13}$C NMR (75.3 MHz, $CDCl_3$): δ 150.3 (CH), 149.0 (CH), 138.7 (C), 136.3 (CH), 129.3 (CH), 125.5 (CH), 123.8 (CH), 65.9 (CH), 51.9 ($CH_2$), 44.0 ($CH_3$), 26.2 ($CH_2$). ESI-HRMS: $m/z$ = 175.1244 (calculated for $[M + H]^+$: 175.1230); 197.1064 (calculated for $[M + Na]^+$: 197.1049); 371.2228 (calculated for $[2M + Na]^+$: 371.2206).

***(±)-1-Benzyl-2-(3-pyridyl)-3-piperideine: (±)-N-Benzyl-isoanatabine, 3b.*** 3-Bromopyridine (130 μL, 213 mg, 1.35 mmol) was added to *i*-PrMgCl (2*M*/THF, 675 μL, 1.35 mmol) in THF (1 mL) at room temperature under argon. After 2 h, the mixture was cooled at 0°C, then a solution of **1b** (51 mg, 0.26 mmol) in THF (1 mL) was added. The resulting reaction mixture was stirred overnight at room temperature. After 16 h, water (5 mL) was added. Extraction with $CH_2Cl_2$ (3 × 10 mL), drying over magnesium sulfate and column chromatography using $CH_2Cl_2/CH_3OH/NH_3$ (97:3:1) as eluent afforded **3b** (43 mg, 0.17 mmol, 67%). IR (NaCl): 3029, 2918, 2707, 1655, 1576, 1424, 1027, 849 cm$^{-1}$. $^1$H NMR (300 MHz, $CDCl_3$): δ 8.62 (d, 1H, $J$ = 2.1 Hz, ArH), 8.49 (dd, 1H, $J$ = 1.8, 4.8 Hz, ArH), 7.80 (dt, 1H, $J$ = 2.1, 7.8 Hz, ArH), 7.26 (ddd, 1H, $J$ = 0.6, 4.8, 7.8 Hz, ArH), 5.85 (m, 1H, C*H*=CH), 5.49 (dq, 1H, $J$ = 1.5, 9.9 Hz, CH=C*H*), 4.00 (app quintet, 1H, $J$ = 2.4 Hz, NC*H*Ar), 3.52 (d, $J$ = 13.5 Hz, 1H, C$H_2$ (Bn)), 3.43 (d, $J$ = 13.5 Hz, 1H, C$H_2$ (Bn)), 2.93 (m, 1H, NC$H_2$), 2.41–2.25 (m, 2H, NC$H_2$ + C$H_2$—CH=CH), 2.06 (bd, 1H, $J$ = 14.1 Hz, C$H_2$—CH=CH). $^{13}$C NMR (75.3 MHz, $CDCl_3$): δ = 150.4, 148.9, 139.4, 139.2, 136.3, 129.6, 128.8, 128.4, 127.1, 125.7, 123.8, 63.8, 59.0, 47.3, 25.9. ESI-HRMS: $m/z$ = 251.1567 (calculated for $[M + H]^+$: 251.1543); 273.1372 (calculated for $[M + Na]^+$: 273.1362).

**Assays of *N*-demethylation of (±)-*N*-methyl-isoanatabine 3a and *N*-debenzylation of (±)-*N*-benzyl-isoanatabine 3b with 1-chloroethyl chloroformate.**

***Attempted N-demethylation of (±)-N-methyl-isoanatabine 3a.*** 1-Chloroethyl chloroformate (80 μL, 106 mg, 0.74 mmol) was added at 0°C to a stirred solution of **3a** (107 mg, 0.61 mmol) in dry 1,2-dichloroethane (6 mL) under argon. The resulting mixture was heated to reflux for 16 h. The solvent was removed under reduced pressure to give the *N*-[5-chloro-5-(pyridin-3-yl)-pent-3-enyl]-*N*-

methyl-carbamic acid 1-chloro-ethyl ester (**7**). **7** was dissolved in 40 mL of 2.5% sodium hydroxide in aqueous ethanol (1:9) at 0°C; after 1 h at 0°C, the mixture was stirred at room temperature during 24 h. The mixture was extracted with dichloromethane (3 x 50 mL). The combined organic extracts were dried with $MgSO_4$ and the solvent removed under reduced pressure to yield **3a** as yellow oil (80.3 mg, 0.46 mmol, 75%). *N*-[5-chloro-5-(pyridin-3-yl)-pent-3-enyl]-*N*-methyl-carbamic acid 1-chloro-ethyl ester (**7**): $^1$H NMR (300 MHz, $CDCl_3$): δ 9.06 (m, 1H, ArH), 8.83 (d, 1H, $J$ = 4.5 Hz, ArH), 8.54 (d, 1H, $J$ = 8.4 Hz, ArH), 8.05 (m, 1H, ArH), 6.89 (m, 1H, CH=CH), 6.74 (m, 1H, CH=CH), 6.57 (m, 1H, *CH*ClCH$_3$), 4.66 (app quint., 1H, NC*H*Ar), 3.49 (m, 2H, NC*H*$_2$), 2.99 (s, 3H, NCH$_3$), 2.21 (m, 2H, C*H*$_2$—CH=CH), 1.83 (d, 3H, $J$ = 5.7 Hz, CHCl*CH*$_3$). - $^{13}$C NMR (75.3 MHz, $CDCl_3$): δ 153.5 (CO), 153.3 (CO), 142.5 (CH), 139.4 (CH), 139.0 (CH), 137.0 (CH), 136.9 (CH), 136.2 (C), 127.3 (CH), 125.0 (CH), 124.8 (CH), 124.7 (CH), 124.1 (CH), 83.3 (CH), 58.4 (CH), 46.7 ($CH_2$), 45.9 ($CH_2$), 36.2 ($CH_2$), 35.6 ($CH_2$), 35.4 ($CH_2$), 34.7 ($CH_2$), 25.4 ($CH_3$), 25.1 ($CH_3$).

***Attempted N-debenzylation of (±)-N-benzyl-isoanatabine 3b.*** 1-Chloroethyl chloroformate (9 μL, 12 mg, 0.08 mmol) was added at 0°C to a stirred solution of **3b** (21 mg, 0.08 mmol) in dry dichloromethane (3 mL) under argon. The resulting mixture was stirred at room temperature for 16 h. The solvent was removed under reduced pressure to give the 1-chloro-1-(3-pyridyl)-5-benzylamino-pent-2-en (**9**). Compound **9** was then stirred with 5 mL of 2.5% sodium hydroxide in aqueous ethanol (1:9) at 0°C; after 1 h at 0°C, the mixture was stirred at room temperature during 5 h. The mixture was extracted with dichloromethane (3 × 7 mL). The combined organic extracts were dried with $MgSO_4$, filtered and the solvent removed under reduced pressure to yield **3b** as a yellow oil (15.6 mg, 0.06 mmol, 78%). 1-Chloro-1-(3-pyridyl)-5-benzylamino-pent-2-en (**9**): $^1$H NMR (300 MHz, $CDCl_3$): δ 9.73 (bs, 1H, ArH), 9.32 (bs, 1H, ArH), 8.73 (bs, 1H, ArH), 8.03 (bs, 1 H, ArH), 7.74 (bs, 2 H, ArH), 7.35 (s, 3 H, Bn-H), 6.32 (bs, 1 H), 6.03 (bs, 1 H), 5.72 (bs, 1 H), 4.64 (bs, 2 H), 3.40 (bs, 1 H), 3.23 (bs, 1 H), 3.05 (m, 1 H), 2.42 (m, 1 H). The ESI-MS of **9** indicated polymeric material; this probably arised in the MS apparatus by the intermolecular substitution in **9** of the chlorine by the amino group. On the other hand, the GC-MS of **9** gave the MS spectrum of **3b**; at the temperature of the GC column oven (Rxi-5ms column, program: injector 200°C, detector 280°C, program: 40°C (1 min), 30°C/min to 280°C, 280°C (15 min); RT:12.08 min), **9** spontaneously cyclized into **3b** by the intramolecular substitution of the chlorine by the amino group.

**Assay for the *N*-debenzylation of (±)-*N*-benzyl-isoanatabine 3b with CAN (ammonium cerium (IV) nitrate).** To compound **3b** (37 mg, 0.15 mmol), dissolved in a 5:1 mixture of $CH_3CN$-$H_2O$ (2.4 mL), CAN (329 mg, 0.60 mmol) was added portionwise. After stirring 24 h at room temperature, the mixture was basified with an aqueous saturated solution of $NaHCO_3$ and then extracted with $CH_2Cl_2$. The organic phase was dried ($MgSO_4$), filtered, and concentrated *under vacuo* to obtain the starting compound **3b** (33 mg, 0.13 mmol, 88%).

***(±)-N-methyl-isoanatabine-N-oxide, 10.*** To a solution of **3a** (206 mg, 1.18 mmol) in $CH_2Cl_2$ (6 mL) at 0°C was added a solution of 70–75% aq. *m*-CPBA (320 mg, 1.3 mmol) in $CH_2Cl_2$ (11 mL). After stirring 1.5 h at 0°C under argon, the reaction mixture was concentrated *in vacuo* to a volume of 7 mL and then poured over alumina and chromatographed using $CH_2Cl_2$/$CH_3OH$ (95:5) as eluent to afford the *N*-oxide **10** as a mixture of two diastereomers in a 6:4 ratio (204 mg, 1.07 mmol, 91%). The diastereomers were not separated and were used in the next step as a mixture. $^1$H NMR (300 MHz, $CDCl_3$): δ 8.76 (d, 0.6 H, $J$ = 1.8 Hz, ArH), 8.68 (dd, 0.6 H, $J$ = 1.8, 4.8 Hz, ArH), 8.64 (d, 0.4 H, $J$ = 1.5 Hz, ArH), 8.63 (dd, 0.4 H, $J$ = 1.5, 4.8 Hz, ArH), 8.10 (dt, 0.4 H, $J$ = 2.1, 7.8 Hz, ArH), 7.97 (dt, 0.6 H, $J$ = 1.8, 7.8 Hz, ArH), 7.40 (ddd, 0.6 H, $J$ = 0.6, 4.8, 7.8 Hz, ArH), 7.36 (ddd, 0.4 H, $J$ = 0.6, 4.8, 7.8 Hz, ArH), 6.18 (m, 1H, C*H*=CH), 5.84 (dq, 0.6 H, $J$ = 1.8, 10.2 Hz, CH=C*H*), 5.66 (dq, 0.4 H, $J$ = 2.1, 10.5 Hz, CH=C*H*), 5.07 (app quintet, 0.6 H, $J$ = 2.7 Hz, NC*H*Ar), 4.90 (app quintet, 0.4 H, $J$ = 2.4 Hz, NC*H*Ar), 3.60 (m, 1.2 H, NC*H*$_2$), 3.43 (m, 0.8 H, NC*H*$_2$), 3.19 (s, 1.2 H, NC*H*$_3$), 2.92 (m, 0.6 H, C*H*$_2$CH=CH), 2.75 (s, 1.8 H, NC*H*$_3$), 2.58 (m, 1H, C*H*$_2$CH=CH), 2.41 (m, 0.4 H, C*H*$_2$CH=CH). $^{13}$C NMR ($CDCl_3$): Major diastereomer, δ 151.5 (CH), 150.5 (CH), 139.0 (CH), 129.1 (C), 126.4 (CH), 123.8 (CH), 123.1 (CH), 76.4 (CH), 64.2 ($CH_2$), 51.1 ($CH_3$), 24.1 ($CH_2$). $^{13}$C NMR ($CDCl_3$): Minor diastereomer, δ 152.0 (CH), 150.1 (CH), 139.8 (CH), 129.3 (C), 126.3 (CH), 123.6 (CH), 122.9 (CH), 73.2 (CH), 61.9 ($CH_2$), 56.9 ($CH_3$), 23.2 ($CH_2$). ESI-HRMS: $m/z$ = 191.1192 (calculated for $[M + H]^+$: 191.1179); 213.1006 (calculated for $[M + Na]^+$: 213.0998); 381.2312 (calculated for $[2M + H]^+$: 381.2285); 403.2114 (calculated for $[2M + Na]^+$: 403.2104).

**Attempted *N*-demethylation of (±)-*N*-methyl-isoanatabine-*N*-oxide 10.** ***With selenium dioxide.*** To a stirred mixture of **10** (193 mg, 1.02 mmol) in 95% ethanol (10 mL) was added portionwise selenium dioxide (169 mg, 1.52 mmol) for 10 min. The mixture was heated to reflux for 4 h under an atmosphere of argon. The reaction was monitored by TLC. After 4 h, the starting material was still present. The mixture was

refluxed for 4 h more. The residue obtained by evaporation of the reaction mixture was purified by column chromatography through silica gel column, using $CH_2Cl_2/CH_3OH/NH_3$ (90:10:1) as eluent to give 115 mg (0.66 mmol, 65%) of **3a** and 19 mg (0.1 mmol, 10%) of **10**.

***With $FeSO_4 \cdot 7H_2O$.*** *N*-oxide **10** (95 mg, 0.50 mmol) was dissolved in MeOH (10 mL) and cooled at 10°C. $FeSO_4 \cdot 7H_2O$ (278 mg, 1 mmol) was added then the reaction mixture was stirred at 10°C for 1.5 h. Evaporation of the solvent afforded an orange solid, which was dissolved in 0.1*M* EDTA. Then, the pH was raised to 10 by addition of concentrated $NH_4OH$. The solution was extracted with $CHCl_3$ (3 × 20 mL), and the dried organic extracts over $MgSO_4$ were filtered and evaporated to yield a mixture of **4** and **3a** (2.3:1). These were separated by column chromatography on silica gel using $CH_2Cl_2/CH_3OH/NH_3$ (90:10:1) as an eluent. Pure (±)-isoanatabine (**4**) was obtained with a yield of 55% (44 mg, 0.28 mmol); pure (±)-*N*-methyl-isoanatabine (**3a**) was obtained with a yield of 23% (20 mg, 0.12 mmol). (±)-Isoanatabine (**4**): IR (NaCl): 3285, 3029, 2914, 2832, 1650, 1578, 1477, 1102, 1028, 716 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): δ 8.59 (d, 1H, $J$ = 1.8 Hz, ArH), 8.51 (dd, 1H, $J$ = 1.5, 4.8 Hz, ArH), 7.70 (dt, 1H, $J$ = 1.5, 7.5 Hz, ArH), 7.25 (ddd, 1H, $J$ = 0.9, 5.1, 7.8 Hz, ArH), 6.01 (m, 1H, C*H*=CH), 5.71 (dq, 1H, $J$ = 1.8, 9.3 Hz, CH=C*H*), 4.52 (app quintet, 1H, $J$ = 2.7 Hz, NHC*H*Ar), 3.0 (m, 2 H, $NHCH_2$), 2.2 (m, 3 H, $CH_2$CH=CH + N*H*). $^{13}C$ NMR (75.3 MHz, $CDCl_3$): δ 149.7 (CH), 149.0 (CH), 139.3 (C), 135.6 (CH), 128.9 (CH), 127.6 (CH), 123.7 (CH), 56.2 (CH), 41.9 ($CH_2$), 25.7 ($CH_2$). ESI-HRMS: $m/z$ = 161.1087 (calculated for $[M + H]^+$: 161.1073); 183.0893 (calculated for $[M + Na]^+$: 183.0893).

***(±)-2-Cyano-1-methyl-4-piperideine, 12.*** To a stirred solution of potassium cyanide (5.45 g, 83.6 mmol) in water (11 mL) layered with ether (16 mL) was added a solution of 5*N* HCl (6.5 mL, 32.5 mmol). The mixture was stirred at 0°C, then 1-methylpyridinium iodide (5 g, 22.6 mmol) was added portionwise followed by $NaBH_4$ (1.03 g, 27.1 mmol). The stirring was continued for 5 h at room temperature. Water was added and the mixture was extracted with ether. The organic phases were combined, dried and evaporated to dryness. The resulting yellow oil was flash chromatographed on silica gel ($CH_2Cl_2/CH_3OH$ 95:5 + 1% conc. $NH_4OH$). This yielded **12** (2.62 g, 21.5 mmol, 95%) as a colorless oil. IR (NaCl): 3043, 2945, 2789, 2223, 1658, 1452, 1260, 1141, 1002, 793 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): δ 5.74 (m, 2H, C*H*=C*H*), 3.81 (dd, 1H, $J$ = 1.5, 6 Hz, NC*H*CN), 3.24 (bd, 1H, $J$ = 16.5 Hz, $NCH_2$), 2.96 (bd, 1H, $J$ = 16.5 Hz, $NCH_2$), 2.69 (m, 1H, $CH_2$—CH=CH), 2.44 (s, 3H, $NCH_3$), 2.33 (m, 1H, $CH_2$—CH=CH). $^{13}C$ NMR (75.3 MHz, $CDCl_3$): δ 125.5 (CH), 120.9 (CH), 116.3 (CN), 51.2 (CH), 50.0 ($CH_2$), 43.6 ($CH_3$), 29.5 ($CH_2$). ESI-HRMS: $m/z$ = 123.0925 (calculated for $[M + H]^+$: 123.0917); 145.0745 (calculated for $[M + Na]^+$: 145.0736).

**Attempt of isomerization of 12 into 1a.** The amino nitrile **12** (52 mg, 0.43 mmol) in 1 mL of 6*N* HCl was heated at 80°C. After refluxing for 4 h, the mixture was cooled and enough aqueous sodium cyanide was added until the final solution was alkaline (pH 10). After stirring for 2 h, the mixture was extracted by $CH_2Cl_2$ (3 × 10 mL). The $CH_2Cl_2$ extracts were combined, dried over $MgSO_4$ and concentrated to yield the starting amino nitrile **12** (48 mg, 0.39 mmol, 92%).

**(±)-1-Methyl-2-(3-pyridyl)-4-piperideine: (±)-*N*-methyl-anatabine, 13.** 3-Bromopyridine (210 μL, 346 mg, 2.19 mmol) was added to *i*-PrMgCl (2*M*/THF, 1.1 mL, 2.19 mmol) in THF (1 mL) at room temperature under argon. After 2 h, the mixture was cooled at −10°C, then a solution of **12** (89 mg, 0.73 mmol) in THF (2 mL) was added. The resulting reaction mixture was allowed to stir for 1 h at −10°C then left overnight at room temperature. After 16 h, water (5 mL) was added. Extraction with $CH_2Cl_2$ (3 × 10 mL), drying over magnesium sulfate and column chromatography using $CH_2Cl_2/CH_3OH/NH_3$ (95:5:1) as eluent afforded (±)-*N*-methyl-anatabine **13** (106 mg, 0.61 mmol, 83%). IR (NaCl): 3034, 2985, 2910, 2773, 1666, 1577, 1427, 1321, 1258, 1051, 718 $cm^{-1}$. $^1H$ NMR (300 MHz, $CDCl_3$): δ 8.53 (d, $J$ = 2.1 Hz, 1H, ArH), 8.52 (dd, $J$ = 1.8, 5.1 Hz, 1H, ArH), 7.70 (dt, $J$ = 2.1, 7.8 Hz, ArH), 7.29 (ddd, 1H, $J$ = 0.6, 4.8, 7.8 Hz, ArH), 5.80 (m, 2H, C*H*=C*H*), 3.35 (m, 2H, $NCH_2$ + NC*H*Ar), 2.95 (m, 1H, $NCH_2$), 2.32 (m, 2H, $CH_2$—CH=CH), 2.07 (s, 3H, $NCH_3$). $^{13}C$ NMR (75.3 MHz, $CDCl_3$): δ 149.8 (CH), 149.0 (CH), 138.6 (C), 135.6 (CH), 125.5 (CH), 124.9 (CH), 123.9 (CH), 63.1 (CH), 55.2 ($CH_2$), 44.6 ($CH_3$), 35.3 ($CH_2$). ESI-HRMS: $m/z$ = 175.1223 (calculated for $[M + H]^+$: 175.1230).

**(±)-1-Methyl-2-(3-pyridyl)-4-piperideine-*N*-oxide: (±)-*N*-methyl-anatabine-*N*-oxide, 14.** To a solution of **13** (210 mg, 1.2 mmol) in $CH_2Cl_2$ (17 mL) at 0°C was added, in several portions, 70–75% aq. *m*-CPBA (327 mg, 1.33 mmol). After stirring 1.5 h at 0°C under argon, the reaction mixture was concentrated *in vacuo* to a volume of 3 mL and then poured over alumina and chromatographed using $CH_2Cl_2/CH_3OH$ (95:5) as eluent to afford the *N*-oxide **14** as a mixture of two diastereomers in a 7:3 ratio. The major diastereomer was isolated as a white solid and the minor diastereomer as an oil (combined 200 mg, 1.06 mmol, 88%). Major diastereomer, $^1H$ NMR (300 MHz, $CDCl_3$): δ 8.68 (d, $J$ = 1.8 Hz, 1H, ArH), 8.64 (dd, $J$ = 1.5, 4.8 Hz, 1H, ArH), 8.40

(bd, $J$ = 7.8 Hz, 1H, ArH), 7.37 (dd, $J$ = 4.5, 8.1 Hz, 1H, ArH), 6.07 (m, 1H, CH=C*H*), 5.72 (m, 1H, CH=C*H*), 4.27 (dd, $J$ = 4.2, 10.8 Hz, 1H, NC*H*Ar), 4.16 (m, 1H, NC$H_2$), 3.92 (m, 1H, NC$H_2$), 3.24 (m, 1H, C$H_2$—CH=CH), 2.93 (s, 3H, NC$H_3$), 2.32 (m, 1H, C$H_2$—CH=CH). $^{13}$C NMR (75.3 MHz, $CDCl_3$): δ 150.9 (CH), 150.8 (CH), 137.8 (CH), 131.0 (C), 125.9 (CH), 123.7 (CH), 120.2 (CH), 71.4 (CH), 68.8 ($CH_2$), 58.6 ($CH_3$), 30.1 ($CH_2$). Minor diastereomer, $^1$H NMR (300 MHz, $CDCl_3$): δ 8.82 (d, $J$ = 2.1 Hz, 1H, ArH), 8.66 (dd, $J$ = 1.2, 4.8 Hz, 1H, ArH), 7.97 (dt, $J$ = 2.1, 8.1 Hz, 1H, ArH), 7.36 (dd, $J$ = 4.8, 8.1 Hz, 1H, ArH), 6.08 (m, 1H, CH=C*H*), 5.83 (m, 1H, CH=C*H*), 4.47 (m, 1H, NC*H*Ar), 4.15 (m, 1H, NC$H_2$), 3.97 (m, 1H, NC$H_2$), 2.98 (s, 3H, NC$H_3$), 2.31 (m, 2H, C$H_2$—CH=CH). $^{13}$C NMR (75.3 MHz, $CDCl_3$): δ 151.1 (CH), 150.8 (CH), 138.3 (CH), 129.7 (C), 124.9 (CH), 123.3 (CH), 121.9 (CH), 73.7 (CH), 68.5 ($CH_2$), 51.7 ($CH_3$), 29.1 ($CH_2$). ESI-HRMS (diastereomers): $m/z$ = 191.1176 (calculated for $[M + H]^+$: 191.1179); 213.0998 (calculated for $[M + Na]^+$: 213.0998); 381.2304 (calculated for $[2M + H]^+$: 381.2285); 403.2134 (calculated for $[2M + Na]^+$: 403.2104).

**(±)-2-(3-Pyridyl)-4-piperideine: (±)-Anatabine, 15.** A mixture of diastereomeric *N*-oxide **14** (171 mg, 0.9 mmol) was dissolved in MeOH (15 mL) and cooled at 10°C. $FeSO_4 \cdot 7H_2O$ (500 mg, 1.8 mmol) was added and the reaction mixture was stirred at 10°C for 3 h. Evaporation of the solvent afforded an orange solid which was dissolved in 0.1*M* EDTA (30 mL), then the pH was raised to 10 by addition of concentrated $NH_4OH$. The solution was extracted with $CHCl_3$ (3 × 30 mL), and the dried organic extracts over $MgSO_4$ were filtered and evaporated to yield a mixture of anatabine **15** and (±)-*N*-methyl-anatabine **13** (1:1). These were separated by flash column chromatography using $CH_2Cl_2/CH_3OH/NH_3$ (95:5:1) as eluent. Pure (±)-anatabine (**15**) was obtained in 44% yield (60 mg, 0.4 mmol); pure (±)-*N*-methyl-anatabine (**13**) was obtained with a yield of 44% (70 mg, 0.4 mmol). (±)-Anatabine **15**: IR (NaCl): 3280, 3031, 2916, 2830, 1655, 1578, 1427, 1311, 1100, 807 $cm^{-1}$. $^1$H NMR (300 MHz, $CDCl_3$): δ 8.62 (d, $J$ = 2.1 Hz, 1H, ArH), 8.52 (dd, $J$ = 1.8, 4.8 Hz, 1H, ArH), 7.73 (dt, $J$ = 2.1, 7.8 Hz, ArH), 7.27 (ddd, 1H, $J$ = 0.6, 5.1, 8.1 Hz, ArH), 5.84 (m, 2H, C*H*=C*H*), 3.90 (t, 1H, $J$ = 7.2 Hz, NC*H*Ar), 3.64 (bd, $J$ = 15.0 Hz, 1H, NC$H_2$), 3.49 (bd, $J$ = 15.0 Hz, 1H, NC$H_2$), 2.27 (m, 2H, C$H_2$—CH=CH). $^{13}$C NMR (75.3 MHz, $CDCl_3$): δ 148.9 (CH), 148.8 (CH), 140.1 (C), 134.3 (CH), 126.5 (CH), 125.3 (CH), 123.7 (CH), 55.5 (CH), 46.2 ($CH_2$), 34.1 ($CH_2$). ESI-HRMS: $m/z$ = 161.1084 (calculated for $[M + H]^+$: 161.1078).

**Acknowledgment.** The support of this research by a Florida SeaGrant is gratefully acknowledged. The authors thank the Mass Spectrometry Laboratory at the University of Florida for recording the mass spectra and Dr. Ferenc Soti for his comments on the manuscript.

Synthesis of some novel *N*-substituted 2-(chroman/6-bromochroman-2-yl)-1*H*-benzimidazoles by the condensation of 3,4-dihydro-2*H*-chroman-2-carboxylic acid and 6-bromo-3,4-dihydro-2*H*-chroman-2-carboxylic acid with *o*-phenylenediamine in ionic liquid (IL) [bmim]$BF_4$ and subsequent reactions at the benzimidazole-NH with different types of electrophiles in ILs [bmim]$BF_4$ = 1-butyl-3-methylimidazolium tetrafluoroborate, [bmim]$PF_6$ = 1-butyl-3-methylimidazolium hexafluorophosphate and [buPy]$BF_4$ = butylpyridinium tetrafluoroborate in the presence of sodium hydroxide as a base have been reported. All the synthesized compounds were screened for their antibacterial activity. Some compounds exhibited promising antibacterial activity against *Staphylococcus aureus* and *Salmonella typhimurium* when compared to Cephalexin as a reference standard.

## INTRODUCTION

There are a vast number of pharmacologically active heterocyclic compounds, many of which are in regular clinical use. Of the wide variety of heterocyclic systems known till date, the nitrogen heterocycles are of great importance and benzimidazole is one amongst such important heterocycles because of its synthetic utility and broad spectrum of pharmacological activity [1–10]. Various substituted benzimidazoles are known to have varied biological activities and among these, 2-substituted benzimidazoles are found to be more potent [11]. The biological activities of benzimidazoles containing compounds have been well documented [12–13]. Despite their wide applicability, available routes for their synthesis are limited. The reported synthesis of benzimidazoles included reactions of aryl acid with *o*-phenylenediamine (OPDA) in conventional [14,15], microwave-assisted [16], and ionic liquids (ILs) [17] methods. The *N*-alkylation and acylation of benzimidazoles has been reported to be accomplished by treatment with an appropriate base such as sodium hydride, sodium hydroxide, potassium carbonate, pyridine, etc. followed by reaction of the resulting salt with an alkylating reagent in various solvents, e.g. acetone, acetonitrile, pyridine, DMF, THF, etc. [18–20].

In the rapidly developing field of synthetic organic chemistry, an efficient, simple, and highly selective synthetic method for widely used organic compounds from readily available reagents is one of the major challenges. ILs are proving to be increasingly promising as viable media not only for potentially 'green' synthesis and separations, but also for novel applications. The unique property set of the IL materials provides new options based on different chemical and physical properties. The room temperature ILs are of special interest as 'green' recyclable alternative to the classical molecular solvents in the synthetic organic chemistry [21–24]. ILs are the best choice for *N*-alkylation of heterocyclic compounds bearing an acidic hydrogen attached to nitrogen. The reports on great improvement in the yields and rates of reaction using ILs [25] prompted us to study the *N*-alkylation and acylation of benzimidazoles in ILs. Hence it was thought that it would be worthwhile to design and synthesize the *N*-substituted benzimidazoles in ILs under environment-friendly conditions and screen them for potential biological activity.

## RESULTS AND DISCUSSION

Compound **3** was synthesized according to literature procedure in good yield [26]. Condensation of 3,4-dihydro-2*H*-chroman-2-carboxylic acid **(3)** with OPDA **(4)** was carried out in IL [bmim]$BF_4$ at 100°C for 6 h to obtain compound **5** in excellent yield (scheme 1).

For the synthesis of compound **3c**, 3,4-dihydro-2*H*-chroman-2-carboxylic acid **(3)** was treated with ethanolic-HCl at 85°C for 3 h to afford the corresponding ethyl ester derivative **3a** in a reasonable yield. Compound **3a** was brominated using bromine in glacial acetic acid at 25°C for 2 h to obtain 6-bromo-3,4-dihydro-2*H*-chroman-2-carboxylic acid ethyl ester **(3b)**, which

## BIOLOGICAL ACTIVITY

All the compounds prepared herein were screened for their antibacterial activity against *Staphylococcus aureus* NCIM 5021 (Gram positive) and *Salmonella typhimurium* NCIM 2501 (Gram negative) bacterial strains. Cephalexin was used as a reference standard. Antibacterial activity result of compounds **5**, **5a, 6a-6k,** and **6′a-6′m** is summarized in Table 2 and 3. Some of the compounds found to have good antibacterial activity against *S. aureus*; however, they were found to have less activity against *S. typhimurium* when compared to Cephalexin as a reference standard.

## CONCLUSION

In conclusion, we have successfully synthesized a novel series of *N*-substituted 2-(chroman/6-bromo-chroman-2-yl)-1*H*-benzimidazole derivatives by the

condensation of 3,4-dihydro-2*H*-chroman-2-carboxylic acid and 6-bromo-3,4-dihydro-2*H*-chroman-2-carboxylic acid with OPDA and subsequent reactions at the benzimidazole-NH with different electrophilic reagents under different reaction conditions in ILs and tested for antibacterial activity. Some of the compounds **6′g**, **6′j**, 6′m showed the most potent inhibition at 1 μg/mL, where as compounds **5, 6a–6d**, **6g**, **6j** and **5a**, **6′f**, **6′h**, **6′i**, **6′l** were found to possess good activity at 10 μg/mL against *S. aureus* and compounds **5**, **6a**, **6g**, **6k**, **6′f** showed the good activity at 10 μg/mL, where as other compounds showed minimal activity against a *S. typhimurium*.

## EXPERIMENTAL

All the solvents were of commercial grade and OPDA, alkylating and acylating agents were obtained from Aldrich. Melting points were recorded on a MRVIS series, Lab India Instrument and are uncorrected. IR spectra were recorded on a Perkin-Elmer Spectrum One FTIR spectrometer in potassium bromide pellets unless otherwise stated. $^1$H and $^{13}$C NMR spectra were recorded on a Varian Mercury VX SWBB 300 MHz spectrometer. Elemental analysis was carried out on a PerkinElmer Series-II C H N S O Analyzer 2400. Chemical shifts are reported in ppm from internal tetramethylsilane (TMS) standard and are given δ units. The solvent for NMR spectra was $CDCl_3$ unless otherwise mentioned. Mass spectra were recorded on *hp* 1100 LC/MSD mass spectrometer (positive and negative APCI ion source, 50–200 V, nitrogen). ILs [bmim]$BF_4$, [bmim]$PF_6$, and [buPy]$BF_4$ were synthesized in the laboratory according to reported procedures [27].

**Synthesis of 6-bromo-3,4-dihydro-2*H*-chroman-2-carboxylic acid (3c).** A solution of (34 mmol) of **3a** dissolved in glacial acetic acid (50 mL) was cooled to 10–15°C. The compound **3a** was brominated by slowly adding a solution of bromine (33 mmol) in glacial acetic acid (25 mL). After the addition was complete, the solution was stirred at 25–30°C for 3 h. The reaction mass was then diluted with water (100 mL). The product was isolated by extraction with ethyl acetate (50 mL × 3). The ethyl acetate layer was washed with 5% aqueous sodium bicarbonate solution (50 mL × 2) and water (50 mL × 2). The ethyl acetate layer was dried over anhydrous sodium sulfate and solvent was removed under reduced pressure to obtain 6-bromo-3,4-dihydro-2*H*-chroman-2-carboxylic acid ethyl ester **(3b)**.

A solution of (67 mmol) of **3b** dissolved in ethanol (25 mL) was hydrolysed by 0.5*M* sodium hydroxide solution (25 mL) at 25–30°C for 1 h. The solution was concentrated to about its half volume and acidified with 5*N* hydrochloric acid. The resultant solid was filtered to give **3c,** 4.5 g, Yield 85%; mp 170–172°C; $^1$H NMR ($CDCl_3$) (300 MHz): δ 2.13–2.25 (m, 2H, $CH_2$), 2.29–2.37 (m, 1H, CH), 2.72–2.91 (m, 2H, $CH_2$), 4.79 (dd, 1H, $J$ = 7.8, 7.8 Hz, CH), 6.81 (d, 1H, $J$ = 9 Hz, Ar-H), 7.19–7.26 (m, 2H, Ar-H), 11.63 (s, 1H, COOH).

**Synthesis of 2-(chroman-2-yl)-1*H*-benzimidazole using IL (5).** A solution of (10 mmol) of **3** in IL [bmim]$BF_4$ (2 mL) and (12 mmol) of OPDA **(4)** was heated at 100°C for 6 h (as monitored by TLC). After 6 h the mixture was cooled to 25°C and diluted with water (10 mL). The product was extracted with ethyl acetate (10 mL × 2). The ethyl acetate layer was washed with 5*N* HCl (10 mL), 5% aqueous sodium bicarbonate solution (10 mL) and water (10 mL). The ethyl acetate layer was dried over sodium sulfate and evaporated under reduced pressure to afford crude product, which was recrystallized from ethyl acetate to obtain as a white solid compound **5**. After isolation of the product in ethyl acetate IL was in aqueous layer, which was further washed with ethyl acetate (10 mL) and dried under vacuum. The suspension was filtered to remove insoluble and the recovered IL was recycled.

**2-(Chroman-2-yl)-1*H*-benzimidazole (5).** mp 225–227°C; ir (KBr): 3434, 2950, 1487, 1231 cm$^{-1}$; $^1$H NMR ($CDCl_3$): δ 2.20–2.35 (m, 2H, $CH_2$), 2.81–3.04 (m, 2H, $CH_2$), 5.47 (dd, $J$ = 8.6, 8.9 Hz, 1H, CH), 6.87–6.91 (m, 4H, Ar-H), 7.08–7.18 (m, 2H, Ar-H), 7.46 (d, $J$ = 7.4 Hz, 1H, Ar-H), 7.71 (d, $J$ = 7.6 Hz, 1H, Ar-H), 9.7 (bs, 1H, NH); ms: *m*/*z* 249.1 ($M^+$+1); Anal. Calcd. for $C_{16}H_{14}N_2O$: C, 76.78; H, 5.64; N, 11.19. Found: C, 76.52; H, 5.52; N, 11.36.

**Synthesis of 2-(6-bromochroman-2-yl)-*1H*-benzimidazole using IL (5a).** A mixture of **3c** (10 mmol), OPDA **(4)** (12 mmol) and IL [bmim]$BF_4$ (2 mL) was heated to 100°C for 6 h (as monitored by TLC). The reaction mixture was then cooled to room temperature and diluted with water (10 mL). The product was extracted with ethyl acetate (10 mL × 2) and ethyl acetate layer was washed with 5*N* HCl (10 mL), 5% aqueous sodium bicarbonate solution (10 mL) and water (10 mL). The ethyl acetate layer was dried over sodium sulfate and solvent was evaporated under reduced pressure to obtain crude product, which was recrystallized from ethyl acetate to yield the pure compound **5a**. The IL was recovered by the procedure described earlier.

**2-(6-Bromochroman-2-yl)-*1H*-benzimidazole (5a).** mp 210–211°C; ir (KBr): 3428, 2919, 1476, 1232 cm$^{-1}$; $^1$H NMR (DMSO-$d_6$): δ 2.26–2.38 (m, 2H, $CH_2$), 2.86–3.01 (m, 2H, $CH_2$), 5.46 (dd, $J$ = 8.7, 8.7 Hz, 1H, CH), 6.86 (d, $J$ = 9 Hz, 1H, Ar-H), 7.15–7.34 (m, 4H, Ar-H), 7.48 (d, $J$ = 6.9 Hz, 1H, Ar-H), 7.62 (d, $J$ = 6.9 Hz, 1H, Ar-H) 12.62 (bs, 1H, NH) ppm; $^{13}$C NMR (DMSO-$d_6$) (75 MHz): δ 23.36 ($CH_2$), 25.60 ($CH_2$), 72.25 (OCH), 111.77, 112.11, 119,01, 119.24, 121.64, 122.63, 125.01, 130.18, 132.18, 134.43, 142.95, 153.02, 153.23 (aromatic carbons) ppm; ms: *m*/*z* 329.32 ($M^+$+1); Anal. Calcd. for $C_{16}H_{13}BrN_2O$: C, 58.38; H, 3.98; N, 8.51. Found: C, 58.26; H, 3.75; N, 8.66.

**General procedure for the synthesis of compound 6′a-6′b using IL.** A solution (2 mmol) of **5a,** IL (2 mL), sodium hydroxide (4 mmol) and followed by the addition of respective alkylting reagents (3 mmol) at 25–30°C. After the addition was complete, the solution was heated to 50°C for 5 h (as monitored by TLC). The reaction mixture was then cooled to 25°C and diluted with water (10 mL). The product was extracted with ethyl acetate (10 mL × 2) and ethyl acetate layer was washed with water (10 mL × 2). The organic layer was dried over sodium sulfate and the solvent was evaporated under reduced pressure to obtain the corresponding *N*-substituted derivatives. The crude products were recrystallized from ethanol to give pure compounds **6′a** and **6′b,** respectively. The IL was recovered by the procedure described earlier.

**General procedure for the synthesis of compound (6a-6f, 6′c-6′g, and 6′m) using ILs.** To a solution of **5** and **5a** (2 mmol) in ILs (2 mL), pyridine (10 mmol), followed by the addition of appropriate acyl or arylsulfonyl chloride (3 mmol) were stirred (for reaction conditions, Table 1a). The reaction mixture was then cooled to 25°C and diluted with water (10 mL). The product was extracted with ethyl acetate (10 mL × 2), ethyl acetate layer was washed with 5% aqueous sodium bicarbonate solution (10 mL) followed by washed with water (10 mL). The ethyl acetate layer was dried over sodium sulfate and the solvent was evaporated to obtain the crude products, which were recrystallized from ethanol, to afford pure compounds (**6a-6f**), (**6′c-6′g** and **6′m**), respectively. The ILs was recovered by the procedure described earlier.

**General procedure for the synthesis of compound (6g-6k and 6′h-6′l) using ILs.** A solution of (2 mmol) of **5** and **5a**, (4 mmol) of sodium hydroxide in ILs (2 mL), followed by the addition of appropriate (3 mmol) benzyl bromides at 25–30°C. After the addition was complete, the solution was heated to 75°C for 5–6 h (as monitored by TLC). The reaction mass was then cooled to 25°C and diluted with water (25 mL). The resultant solid was filtered and washed with water (10 mL) to afford crude products. The crude products were recrystallized from ethanol, to obtain pure compounds **6g-6k** and **6′h-6′l**, respectively. The aqueous layer contains the ILs, which was recovered as described earlier procedure.

Silica gel supported Phosphomolybdic acid ($PMA.SiO_2$) catalyzes efficiently the one-pot three-component coupling reaction of anthranilic acid, orthoesters, and amines at room temperature to afford 4(3*H*)-Quinazolinones in high to excellent yields under solvent-free conditions. The supported catalyst can be recovered and reused.

*J. Heterocyclic Chem.,* **47**, 589 (2010).

## INTRODUCTION

The demand for increasingly clean and efficient chemical syntheses is continuously becoming more urgent from both an economic and an environmental standpoint. Organic reactions under solvent-free conditions are advantageous because of enhanced selectivity and efficiency, ease of manipulation, and more importantly, toxic and often volatile solvents are avoided. These would be especially important during industrial production. Hence, the organic transformations under solvent-free conditions are attracting increasing attention.

Heteropoly acids are economically and eco-friendly green Lewis acids. Development of methods using heteropoly acids (HPAs) as catalysts for organic synthetic processes related to fine chemicals, such as flavors, pharmaceuticals, and food industries [1–4] have been under attention in the last decade. Heteropolyacids are more active catalysts than conventional inorganic and organic acids for various reactions in solution [5–11]. They are used as industrial catalysts for several liquid-phase reactions[12–15], such as alcohol dehydration [16], alkylation [17], or esterification [18] reactions. They are not corrosive and environmentally benign, presenting fewer disposal problems. Phosphomolybdic acid (PMA, $H_3PMo_{12}O_{40}$) belongs to the class of heteropoly acids. The supported HPAs are more active than typical solid acids and attracted much attention in organic synthesis owing to easy workup procedures, easy filtration, and minimization of cost and waste generation due to reuse and recycling of the catalysts [19]. Supported reagents enhance their application in 'green synthesis'. Silica gel [17] is most commonly used as support, even though alumina, active carbon, and acidic ion-exchange resins are considered as suitable supports.

Natural products containing quinazolinone moiety possess a broad spectrum of biological properties, such as anticancer, antimalarial, anticonvulsant, analgesic, antihypertensive, antiviral, anti-tubercular, and anti-inflammatory activities [20–34]. Febrifugine and isofebrifugine natural products [35,36] containing 4(3*H*)quinazolinone scaffold have been used effectively against malarial fever in china for centuries (Fig. 1). Similarly, quinazolone containing compounds have been known as tyrosine kinase inhibitors [37,38], dihydrofolate reductase inhibitors [39], and tubulin polymerization inhibitors [40,41]. The interest in the quinazolone structural motif, led to a number of different synthetic methods to access this nucleus. The synthesis of 4(3*H*)-quinazolinone derivatives is achieved by cycloaddition reactions of anthranilic acid with imidates and imino halides [42–49]. The cyclization of cyano- and nitro- activated *o*-fluorobenzaldehydes with amidines and more recently, the

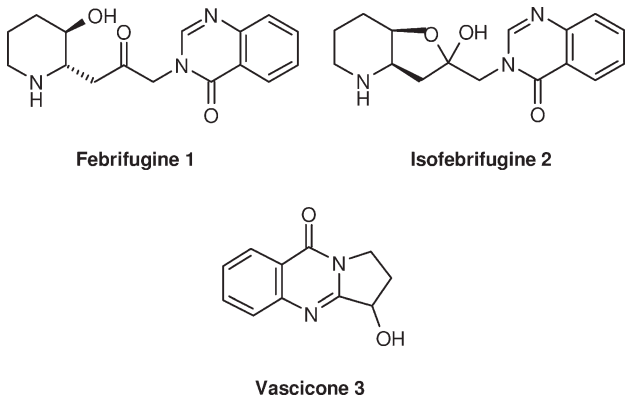

**Figure 1.** Quinazolinone moiety containing natural products.

condensation of fluoro substituted benzoyl chlorides with 2-amino-*N*-heterocycles represent one-pot approaches to quinazolines [50,51]. An intramolecular aza-Wittig type transformation of *o*-azidobenzamide derivatives has been employed as the key quinazolinone-forming step in the synthesis of the quinazoline alkaloid vasicinone [52]. Usually, 4*H*-3,1-benzaxazin-4-ones are valuable starting materials for the synthesis of these compounds [53]. Recently, 4(3*H*)-quinazolinones were prepared using $Bi(TFA)_3$-[nbp]$FeCl_4$ [54], $Yb(OTf)_3$ [55], $La(NO_3)_3.6H_2O$ [56], Silicagel/$FeCl_3$ [57], Silicagel/$NaHCO_3$ & Amberlist 15 [58]. Even-though, many reports appeared in the literature, some of these suffer from drawbacks, such as multi-step procedures, long reaction time, expensive reagents, low yields, harsh conditions, and cumber some product isolation.

As part of our program aimed at developing new green synthetic methodologies for the preparation of fine chemicals, we wish to report herein a remarkable catalytic activity of PMA for the one-pot synthesis of 4(3*H*)-quinazolinones.

## RESULTS AND DISCUSSIONS

Thus carrying out the reaction of anthranilic acid **1** with trimethyl/ethyl orthoformate **2** and primary amine **3** in1:1.2:1.2 mole ratio in the presence of 1 mol % of PMA.$SiO_2$ [59] at room temperature gave the desired 4(3*H*)-quinazolinone **4** in 98% yield (Scheme 1). The experimental procedure is simple and the reaction proceeds under solvent-free conditions. To expand the scope of this method, various 4(3*H*)-quinazolinones were synthesized under similar conditions in high to excellent yields. All the reactions proceeded efficiently at room temperature within 5–15 min in excellent yields under solvent-free conditions and all the products were characterized by NMR, IR and mass spectroscopy and also by comparison with authentic samples. As shown in Table 1, both aniline derivatives and benzyl amine reacted similarly under these reaction conditions without any difference to give the corresponding 4(3*H*)-quinazolinones in high yields. The present procedure does not require toxic or anhydrous organic solvents. The reaction is general, clean, rapid, and efficient. It is important to note that in the absence of catalyst the reaction did not yield the products and only the starting materials were isolated.

It is important to mention that in contrast to reported procedures, *m*-nitroaniline reacted at room temperature with anthranilic acid and trimethyl orthoformate to produce the product **4j** in 88% yield within 15 min, while many of the reports claim the reaction using aniline containing a nitro group requires heating at 60°C [54,56–58]. The one-pot reaction proceeded smoothly with the anilines containing electron-donating groups (such as methoxy and methyl) as well as containing electron-withdrawing groups (such as chloro, fluoro, and nitro).

In conclusion, we have demonstrated a three-component, one-pot procedure for the synthesis of 4(3*H*)-quinazolinones at ambient temperature using silica gel supported PMA. The noteworthy advantages of this method are mild solvent-free heterogeneous reaction conditions, improved yields, shorter reaction times, and operational simplicity, which make it a useful and attractive process for the synthesis of 4(3*H*)-quinazolinones. The supported catalyst can be recovered and reused.

## EXPERIMENTAL

All reactions were carried out under $N_2$ atmosphere and monitored by TLC on silica gel (60–120 mesh; Merck). IR spectra were recorded on a Thermo Nicolet Nexus-670 spectrometer; in *m*/*z*. $^1$H NMR spectra were recorded on Bruker (300/75 MHz) spectrometer in $CDCl_3$; δ in ppm, *J* in Hz. ESI Mass spectra were recorded on Agilent LC-MSD-Trap-SL apparatus; in *m*/*z*.

**General procedure for the preparation of Compound 4a.** To a mixture of anthranilic acid **1** (1 mmol), trimethyl or triethyl orthoformate **2** (1.2 mmol) and aniline **3a** (1.2 mmol), silicagel supported PMA [59] (0.01 mmol) was added. The reaction mixture was stirred at room temperature for 5 min. After completion of the reaction (monitored by TLC) 10 mL of $CH_2Cl_2$ was added to the reaction mixture and the catalyst

[a] All products are characterized by NMR and Mass spectra.
[b] Yields refer to isolated pure products.

was recovered by filtration. The filtrate was washed with aq HCl (5%) (2 × 10 mL) followed by $H_2O$ (2 × 5 mL). The organic layer was dried over $Na_2SO_4$ and the solvent was evaporated under reduced pressure to get the crude product. The residue was chromatographed on silica gel (*n*-hexane/ethyl acetate 5:1 as eluent) to afford the pure product **4a** in 98% yield.

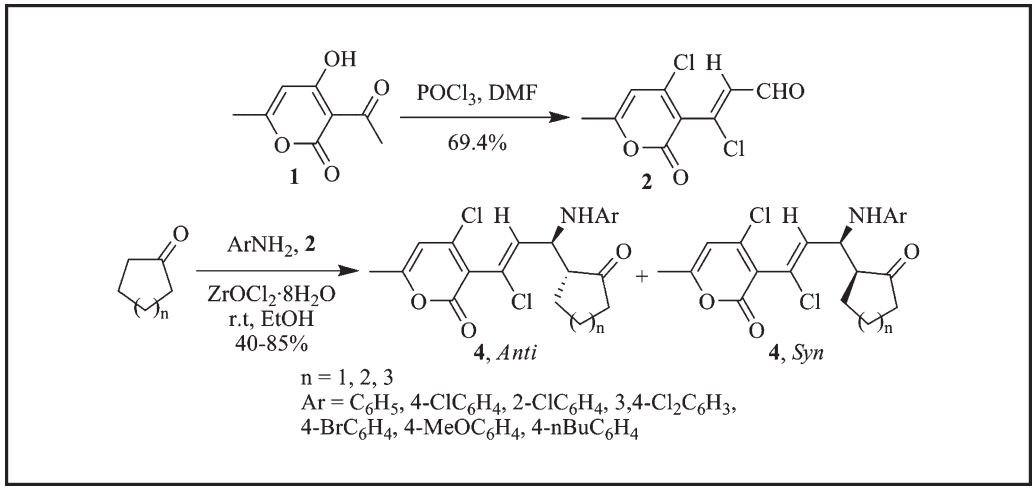
Published online 3 May 2010 in Wiley InterScience (www.interscience.wiley.com).



New *Z*-3-chloro-3-(4-chloro-6-methyl-2-oxo-2*H*-pyran-3-yl)acrolein was synthesized starting from dehydroacetic acid using Vilsmeier–Haack reaction and efficiently used in three component direct Mannich-type reaction with different anilines, cyclic and acyclic ketones catalyzed with zirconium oxychloride ($ZrOCl_2 \cdot 8H_2O$) in ethanol at room temperature. Also, comenic aldehyde was used in direct Mannich-type reaction at the same conditions. The reaction proceeds rapidly and affords the corresponding β-amino ketones in good to high yields with moderate to high stereoselectivity.

*J. Heterocyclic Chem.*, **47**, 594 (2010).

## INTRODUCTION

The Vilsmeier–Haack reaction is a widely used method for the formylation of activated aromatic and heteroaromatic compounds [1]. The reactions of aliphatic substrates [2], particularly carbonyl compounds [3] with chloromethylene iminium salts are highly versatile. One aspect of its importance is its reaction with a keto methylene group to produce β-chloroacroleins [4].

β-Amino carbonyl compounds are also attractive targets for chemical synthesis because of their wide utility as biologically active molecules [5]. The Mannich reaction is a classical method for preparation of the β-amino carbonyl compounds [5,6] and has been one of the most important basic reactions in organic chemistry for its use in natural product and pharmaceutical synthesis [7]. However, because of the drastic reaction conditions and long reaction times, the classical Mannich reaction is plagued by a number of serious disadvantages [6]. Therefore, catalytic Mannich reactions have been reported by several groups as an efficient method to prepare β-amino carbonyl compounds [8,9d].

Because of their easy availability [10] and low toxicity [11], Zr(IV) salts have recently attracted much attention as a catalyst for organic transformations [9]. To our knowledge, there have been only a few reports on the metal oxysalt-based organic reactions [12].

As part of our research on synthesis of pyrone derivatives[13], herein we report a simple and environmentally benign stereoselective synthesis of new β-amino ketones possessing β-[(2*H*-pyran-2-one)-3-yl]-β-chlorovinyl or 4-oxo-4*H*-pyran-2-yl moiety *via* direct Mannich-type reaction between *Z*-3-chloro-3-(4-chloro-6-methyl-2-oxo-2*H*-pyran-3-yl)acrolein **2** or *O*-protected comenic aldehyde **10**, anilines and ketones at room temperature using $ZrOCl_2 \cdot 8H_2O$ as catalyst.

## RESULTS AND DISCUSSION

A new β-chloroacrolein with 2*H*-pyran-2-one moiety **2** was synthesized from commercially available dehydroacetic acid **1** in 69.4% yield using Vilsmeier–Haack reaction as outlined in Scheme 1.

The structure of compound **2** was established from IR, $^1$H NMR, $^{13}$C NMR, 2D-NMRs (HMQC and HMBC), and mass spectral data and elemental analyses. The values of coupling constant $^3J$ of the proton signals of —ClC=C**H**—CO—**H** in the $^1$H NMR spectra equal to 6.8 Hz indicate that these atoms are located in the *s-cis* position [4h,i]. It was shown by the study of isomer composition of β-aryl-β-chloroacroleins, arising from aryl ketones [4j,k,o] and heteroaryl ketones [4o] in the reaction with Vilsmeier-Haack reagent, α-unsubstituted acroleins are obtained exclusively as a *Z* isomer. Therefore, **2** has *s-cis-Z*-configuration at the side chain. The HMBC spectral data of **2** [Fig. 1(a)] revealed long range correlations between the $H_1$ (δ 10.18) with $C_2$ (at δ 132.3); $H_2$ with $C_1$, $C_3$, and $C_{2'}$ (at δ 190.6, 142.8, and 120.1, respectively); $H_{4'}$ (δ 6.26) with $C_{2'}$, $C_{3'}$, $C_{5'}$, and $C_{6'}$ (at δ 120.1, 150.8, 164.1, and 20.4, respectively); $H_{6'}$ (δ 2.35) with $C_{4'}$ and $C_{5'}$ (at δ 107.1 and 164.1, respectively). There are no correlations between $C_{1'}$ (carbonyl group of α-pyrone ring) and protons. Also HMQC spectral data of **2** was shown in Figure 1(b) that revealed one bond correlation between $H_1$ (δ 10.18) with $C_1$ (δ 190.6); $H_2$ (δ 6.32) with $C_2$ (δ 132.3); $H_{4'}$ (δ 6.26) with $C_{4'}$ (δ 107.1); $H_{6'}$ (δ 2.35) with $C_{6'}$ (δ 20.4).

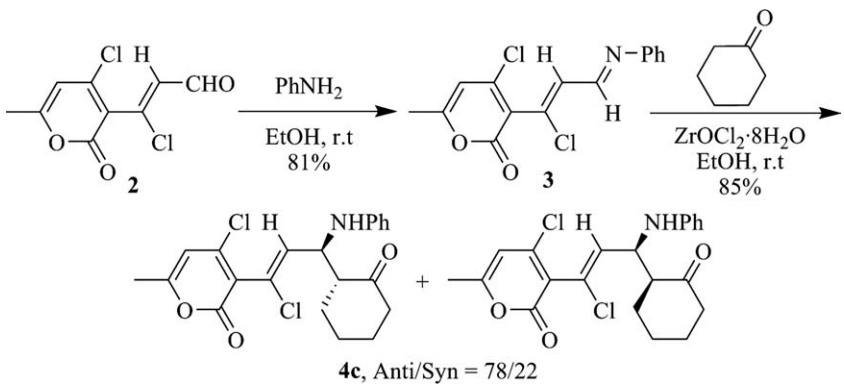
The $ZrOCl_2{\cdot}8H_2O$ catalyzed Mannich reaction was first studied with preformed imine **3**. As shown in Scheme 2, imine **3**, which was synthesized by reaction of **2** and aniline in EtOH at room temperature, was treated with cyclohexanone in the presence of catalytic amount of $ZrOCl_2{\cdot}8H_2O$ and Mannich adduct **4c** was isolated in 85% yield, with 78% anti selectivity.

Subsequently, a one-pot direct Mannich-type reaction of **2** with anilines and cyclic ketones were investigated (Scheme 3).

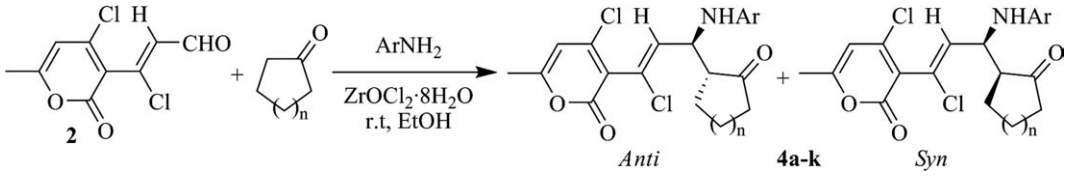
To examine the optimal conditions, Mannich reaction of **2** (1 mmol), aniline (1 equiv.), and cyclohexanone (2 equiv.), using $ZrOCl_2{\cdot}8H_2O$ as catalyst was carried out in different solvents such as acetonitrile, dichloromethane, ethanol, water, and solvent-free conditions. Ethanol was determined as a powerful solvent for high yield and anti selectivity of reaction and environmental acceptability. In dichloromethane, acetonitrile and under solvent-free conditions, in addition to Mannich adducts, side product **5** (Fig. 2), was obtained. In water, imine **3** was isolated as a sole product. Also 0.07 equiv. (7 mol %) of $ZrOCl_2{\cdot}8H_2O$ was determined as optimum amount of catalyst.

Eleven examples of the direct Mannich-type reaction of 2, anilines and cyclic ketones in ethanol are listed in Table 1. The reactions were performed by adding cyclic ketones (2 equiv.) to a mixture of the 2 (1 mmol) and anilines (1 equiv.) in ethanol in the presence of 0.07 equiv. of $ZrOCl_2{\cdot}8H_2O$ at room temperature to give the corresponding β-amino ketones 4a–k in 40–85% yields with moderate to high anti selectivity (Scheme 3).

**Scheme 2.** Synthesis of imine **3** and its Mannich reaction with cyclohexanone.



**Scheme 3.** One-pot Mannich-type reaction of **2**, anilines and cyclic ketones.



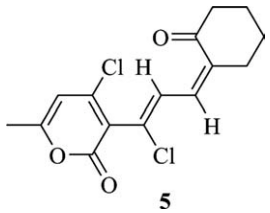


**Figure 2.** Structure of side product **5**.

According to the literature [8a,9d] anti/syn ratio was determined using $^1$H NMR spectra.

Exceptionally, in the case of cyclopentanone ($n = 1$), in addition to Mannich adducts **4a**,**b** the side product **6** was obtained. With increasing reaction time (over 2 h) the Mannich adducts **4a**,**b** were completely converted to **6** (Scheme 4). In the cases of cyclohexanone, product **4c** even after 24 h was not converted to adduct **5**. This can be attributed to more acidity of cyclopentanone protons in comparison with cyclohexanone ones. In the $^1$H NMR spectra of **5** and **6**, the values of coupling constant $^3J$ of the proton signals of —ClC=C**H**—C**H**= equal to 11.3 and 11.2 Hz, respectively, indicate that these atoms are located in the *s-trans* position.

Unexpectedly, from reaction of aliphatic amine such as *n*-butyl amine with **2** and cyclohexanone in the presence of $ZrOCl_2 \cdot 8H_2O$ in ethanol at room temperature, **5** was obtained as a sole product (Scheme 5). In fact, *n*-butyl amine acts as a base and aldol condensation was occurred instead of Mannich reaction.

Also, direct Mannich-type reaction of **2** and anilines with acyclic ketones such as acetone and acetophenone catalyzed with $ZrOCl_2 \cdot 8H_2O$ was investigated at room temperature and corresponding β-amino ketones **7a–d** were obtained in good to high yields in short reaction time. The overall reaction is best formulated in Scheme 6.

Methyl and Ethyl acetoacetate were also treated in the direct Mannich-type reaction with **2** and aniline, catalyzed with $ZrOCl_2 \cdot 8H_2O$ in ethanol at room temperature in 25 min, and interestingly corresponding dihydropyridines **8a**,**b** were isolated as sole products instead of Mannich adduct **9** (Scheme 7).

**11c** Ar = 3,4-$Cl_2C_6H_3$, 90% *Anti*/*Syn* = 75/25

Also, 5-(benzyloxy)-4-oxo-4*H*-pyran-2-carbaldehyde (*O*-protected comenic aldehyde) **10** was synthesized according to literature [14] and used in three component direct Mannich-type reaction with three different anilines and cyclohexanone. As shown in Scheme 8, $ZrOCl_2 \cdot 8H_2O$ efficiently catalyzed this reaction at room temperature and Mannich adducts **11a–c** were obtained in high yields with moderate stereoselectivity.

## CONCLUSIONS

In summary, new β-[(2*H*-pyran-2-one)-3-yl]-β-chloroacrolein was synthesized in good yield and was subjected to the three-component Mannich-type reaction with different anilines, cyclic and acyclic ketones, catalyzed with $ZrOCl_2 \cdot 8H_2O$ in ethanol. Moderate to good anti selectivity was observed in very short reaction times at room temperature. Similarly, Mannich-type reaction with protected comenic aldehyde was also investigated, and corresponding β-amino ketones were obtained in high yields with moderate to high stereoselectivity. Ethyl and methyl acetoacetate were also treated with aniline and β-[(2*H*-pyran-2-one)-3-yl]-β-chloroacrolein and interestingly corresponding dihydropyridines were synthesized instead of Mannich adduct.

## EXPERIMENTAL

**General.** All chemicals were purchased and used without any further purification. Melting points were determined on a Electrothermal MEL-TEMP apparatus (model 1202D) and are uncorrected. FTIR spectra were obtained with a Bruker Tensor 27 spectrometer. NMR spectra were recorded at 400 and 500 MHz for proton and at 100 and 125 MHz for carbon nuclei in $CDCl_3$. Elemental analyses were done by a Vario EL III, Elementar. The products were purified by PLC on silica gel by using hexane/acetone mixture as eluent. All compounds were characterized by their spectroscopic data and elemental analysis.

***Synthesis of Z-3-chloro-3-(4-chloro-6-methyl-2-oxo-2H-pyran-3-yl)acrolein (2).*** $POCl_3$ (14.8 g, 96.4 mmol) was added dropwise to dimethylformamide (DMF) (24 mL) with stirring at 30–35°C. The mixture was stirred at 50°C for 1 h. Then a solution of dehydroacetic acid **1** (4 g, 19.4 mmol) in least amount of DMF was added dropwise with stirring to the reaction mixture. After that the mixture was stirred at 45–55°C for 2 h, kept over night at room temperature and poured into the water (200 mL). The obtained solution was left at room temperature. Yellowish brown crystals were filtered off and dried in air. β-[(2*H*-Pyran-2-one)-3-yl]-β-chloroacrolein **2** was obtained in 69.4% yield. Mp. 90–92°C; FTIR (KBr): 3081, 3030, 2968, 2927 (CH), 2864, 2746 ($CH_{Aldehyde}$), 1718, 1679, 1616, 1545, 1304, 1248, 1121, 837, 768 $cm^{-1}$; $^1H$ NMR (500 MHz, $CDCl_3$): δ 10.18 (d, $^3J$ = 6.8 Hz, 1H, CHO), 6.32 (d, $^3J$ = 6.8 Hz, 1H, $CH_{Vinyl}$), 6.26 (s, 1H, $CH_{\alpha\text{-Pyrone}}$), 2.35 (s, 3H, $CH_3$) ppm; $^{13}C$ NMR (125 MHz, $CDCl_3$): δ 190.6 ($C{=}O_{Aldehyde}$), 164.1, 158.5, 150.8, 142.8, 132.3, 120.1, 107.1, 20.4 ($CH_3$) ppm; Ms: m/z = 233 ($[M+H]^+$, 4%; $[M+H+2]^+$, 2.8%; $[M+H+4]^+$, 1.3%), 205 (25%), 189 (36%), 169 (30%), 43 (100%); Anal. Calcd. for $C_9H_6Cl_2O_3$: C, 46.38; H, 2.60. Found: C, 46.56; H, 2.65.

***Synthesis of 4-chloro-3-[(1Z)-1-chloro-3-(phenylimino)-prop-1-enyl]-6-methyl-2H-pyran-2-one (3).*** β-[(2*H*-Pyran-2-one)-3-yl]-β-chloroacrolein **2** (1 mmol) was treated with Aniline (1 mmol) in ethanol (3 mL) at room temperature for 2 min. After completion of the reaction, mixture was poured into the water (20 mL). The resulting yellow solids were separated by filtration and dried in air. Imine **3** was obtained in 80.8% yield, Mp. 124–126°C; FTIR (KBr): 3100, 3020, 2967, 2922, 1717, 1684, 1625, 1542, 1266, 1154, 821, 764, 694 $cm^{-1}$; $^1H$ NMR (400MHz, $CDCl_3$): δ 8.62 (d, $^3J$ = 8.5 Hz, 1H, CH=N), 7.39–7.43 (m, 2H, $CH_{Ar}$), 7.22–7.30 (m, 3H, $CH_{Ar}$) 6.77 (d, $^3J$ = 8.5 Hz, 1H, $CH_{Vinyl}$), 6.24 (s, 1H, $CH_{\alpha\text{-Pyrone}}$), 2.33 (s, 3H, $CH_3$) ppm; $^{13}C$ NMR(100 MHz, $CDCl_3$): δ 161.9, 157.7, 155.7, 149.8, 149.3, 132.7, 131.6, 128.2, 126.0, 119.9, 119.3, 105.7, 18.8 ($CH_3$) ppm; Anal. Calcd. for $C_{15}H_{11}Cl_2NO_2$: C, 58.46; H, 3.60; N, 4.55. Found: C, 58.28; H, 3.91; N, 4.77.

**General procedure for Mannich-type reaction.** To a solution of β-[(2*H*-Pyran-2-one)-3-yl]-β-chloroacrolein **2** (1 mmol) in ethanol (5 mL) were added aniline (1 mmol), cyclohexanone (2 eq), and $ZrOCl_2 \cdot 8H_2O$ (0.022 g), successively at room temperature (20–25°C) and stirred for 25 min. After completion of the reaction, ethanol was evaporated under reduced pressure. The crude solid was dissolved in $CH_2Cl_2$ (10 mL) and catalyst was removed by filtration. Filtrate was washed with a 5% aqueous $NaHCO_3$ solution and brine, dried over anhydrous $Na_2SO_4$, and concentrated to dryness. The crude mixture was purified by PLC on silica gel using hexane/acetone (20:3) to afford the final product. Specific detail was given for each compound.

The facile syntheses of 2,3-dihydro-1*H*-benzodiazepines containing heterocyclic moieties and their ribofuranosides have been accomplished in ionic liquids at ambient temperature. The characterization of all these compounds has been done unambiguously by IR, $^1$H NMR, $^{13}$C NMR, GC-MS spectroscopy, and elemental analysis.

*J. Heterocyclic Chem.,* **47**, 603 (2010).

## INTRODUCTION

The 1,5-Benzodiazepines have attracted tremendous attention due to their diversified medicinal properties [1–4], *e.g.* analgesic, hypnotic, sedative, antianxiety, anticonvulsant, antidepressant, and anti-inflammatory activities. These derivatives have also been used in viral infections and cardiovasulcar disorders [5]. Commercial applications of this heterocyclic system as dyes for acrylic fibres and in photography have also been reported [6].

These derivatives also act as key intermediates for the synthesis of fused ring derivatives [7], viz., triazolo-, oxadiazolo-, oxazino-, furano-, and pyrido- benzodiazepines.

A survey of the literature reveals that the synthesis of 1,5-benzodiazepines involves the condensation of *o*-phenylenediamine with β-haloketones [8], α,β-unsaturated carbonyl compounds [9] or ketones in the presence of $BF_3$-etherate [10], polyphosphoric acid or $SiO_2$ [11], $NaBH_4$ [12], MgO-$POCl_3$ [13], $InBr_3$ [14], $InCl_3$ [15], ionic liquids [16], Amberlyst [17] or zinc montmorillonite [18], etc.

The chemistry of nucleosides has been an active area of research in academia and in industry as it has demonstrated significant importance in cancer and viral therapy [19]. Also, protected nucleosides serve as building blocks for the synthesis of oligonucleotides, which has been used as probes for diagnostic purposes [20] and in antisense therapeutics [21]. The antisense oligonucleotides and siRNA have been extensively employed in selective inhibition of gene expression [22]. To our knowledge, only scanty information is available in regard to the synthesis of 1,5-benzodiazepine derivatives containing heterocyclic moieties, their spiro derivatives [23] and nucleosides. Furthermore, the reported methods are associated with several drawbacks, such as expensive reagents, drastic reaction conditions, extended reaction times, formation of the side products, unsatisfactory yields, complex experimental procedures, and involving the use of environmentally black listed solvents, *e.g.* *N*,*N*-dimethylformamide, *N*-methylpyrrolidine, *etc*.

In view of our continuous interest in the synthesis of nucleosides [24] and the only report on ionic liquid promoted lipase catalysed synthesis of nucleosides [25], we have developed a facile synthesis of 2,3-dihydro-1*H*-1,5-benzodiazepines containing heterocyclic moieties and their spiro derivatives at ambient temperature in environmentally benign ionic liquid (IL). These derivatives could be subsequently transformed to their ribofuranosides in the same pot under mild conditions.

## RESULTS AND DISCUSSION

In our strategy, we first attempted the synthesis of 2,3-dihydro-1*H*-1,5-benzodiazepines containing heterocyclic moieties/spiro derivatives from the reaction between *o*-phenylenediamine and an heterocyclic ketone(s) in an IL, *viz*. 1,3-di-*n*-butylimidazolium bromide [BBIM]Br, 1,3-di-*n*-butylimidazolium tetrafluoroborate [BBIM]$BF_4$, 1,3-di-*n*-butylimidazolium hexafluorophosphate [BBIM]$PF_6$, 1-methoxyethyl-3-methylimidazolium trifluoroacetate [MOEMIM]TFA, and 1-

methoxyethyl-3-methylimidazolium mesylates [MOEMIM]Ms at ambient temperature (28 ± 2°). The reaction afforded 2,3-dihydro-1*H*-1,5-benzodiazepine containing heterocyclic moieties or their spiro derivatives in excellent yields (Table 1).

The chracterization of the compounds **3a-k** have been carried out by IR, $^1$H NMR, $^{13}$C NMR, GC-MS spectroscopy and elemental analysis.

A plausible mechanism of the reaction appears to involve nucleophilic attack of *o*-phenylenediamine on the carbonyl carbon of the heterocyclic ketone to generate diaminoalcohol followed by loss of water to afford diimine intermediate **A**. The latter may undergo 1,3-hydrogen shift to yield isomeric imine-enamine intermediate **B**, which on cyclization affords 2,3-dihydro-1*H*-1,5-benzodiazepines/spiro compounds *via* dipolar intermediate (Scheme 1).

To devise our goal of designing a one pot synthesis of 2,3-dihydro-1*H*-1,5-benzodiazepiene ribofuranosides **4a-k**, the solubility of the compounds **3a** and **3j** was checked in ionic liquids by dissolving till saturation in 1 mL of IL. These data are summarized in Table 2.

The data presented in Table 2 suggest that the compounds **3a** and **3j** show better solubility in [MOEMIM]Ms, [MOEMIM]TFA, which may therefore be used for ribofuranosylation. This may be attributed due to the ability of oxygenated cation to hydrogen bond with -NH of the 1,5-benzodiazepine.

In a one-pot synthesis of 1,5-benzodiazepine ribofuranosides, *o*-phenylenediame (entry 1 Table 1) was first reacted with heterocyclic ketone **2a** in [MOEMIM]TFA, the progress of the reaction being monitored by TLC. After completion of the reaction, the sugar, viz., β-D-ribofuranose-1-bromo-2,3,5-tribenzoate was added and the contents were further stirred. After workup compound **4a** was obtained in 92% yield. On carrying out this reaction in [MOEMIM]Ms, **4a** was obtained in 80% yield (Scheme 2).

These investigations suggest that [MOEMIM]TFA is a better protocol for the synthesis of compounds **4a**, which is in consonance with the earlier report [26]. Same method was employed for the synthesis of ribofuranosides **4a-k**.

The compounds **4a-k** have been characterized on the basis of IR, $^1$H NMR, $^{13}$C NMR, GC-MS spectroscopy, and elemental analysis.

We also checked the recyclability of the ionic liquid [MOEMIM]TFA for one pot synthesis of compound **4a** from *o*-phenylenediameine, and heterocyclic ketone **2a** as described earlier. The results of the recyclability are shown in Table 3, which suggest that the yield of the compound **4a** decreases by 5.6 and 10%, respectively in first and second recycling of [MOEMIM]TFA. However, in the third cycle, the decrease in yield was significant.

## SUMMARY

In summary, a facile one pot synthesis of 2,3-dihydro-1*H*-1,5-benzodiazepine derivatives containing heterocyclic moieties, their spiro derivatives and their ribofuranosides have been developed at ambient temperature in environmentally benign ionic liquids(s). [MOEMIM]TFA was found to be a better solvent for this purpose. The simplicity of the procedure, easy recovery and reuse of the reaction media *viz*. ionic liquid make this methodology a convenient, efficient, economic, and attractive.

## EXPERIMENTAL

Melting points were determined in open capillary tubes and are uncorrected. IR spectra were recorded on a SHIMADZU FT-IR spectrometer using KBr pellets. $^1$H NMR spectra were recorded on a JEOL AL-300 MHz NMR spectrometer in $CDCl_3$ using TMS as an internal standard (chemical shift in δ ppm). $^{13}$C NMR spectra were recorded on a JEOL AL-75 MHz NMR spectrometer in $CDCl_3$ using TMS as an internal standard. Mass spectra were measured on HP 5890 GC-MS (70eV.EI). The purity of the products was checked by TLC using silica gel 60F 254 aluminium sheets and visualization was accomplished by iodine/UV light. Ionic liquids were prepared by reported methods [27,28]. All reagents were used as obtained commercially.

**Synthesis of 2,3-dihydro-1H-1,5-benzodiazepines (3a-k).** *o*-Phenylenediamine (0.005 mol) and heterocyclic ketone (0.010 mol) were added to IL (0.015 mol). The contents were stirred magnetically at room temperature (28 ± 2°C). The progress of the reaction was monitored by TLC using silica gel 60F 254 aluminum sheet in pet.ether/EtOAc 7:3. Upon completion of the reaction, water (20 mL) was added to it. The organic compound was then extracted with EtOAc (2 × 15 mL). The combined organic layer was distilled under reduced pressure (10 mmHg) at 50°C to afford compounds **3a-k**. All these products were further purified by column chromatography on silica gel 60–120 mesh by eluting with pet.ether-EtOAc (7:3).

***Synthesis of 2,3,5-β-D-ribofuranose-1-bromo-2,3,5-tribenzoate.*** This has been synthesized by reported method [29].

***Synthesis of 2,3-dihydro-1,5-benzodiazepine ribofuranosides (4a-k).*** After completion of the reaction between OPD and heterocyclic ketone (monitored by TLC), 2,3,5-β-D-ribofuranose-1-bromo-2,3,5-tribenzoate equivalent to 1.1 mole of compound **3** was added to the reaction mixture. The contents were further stirred magnetically, till completion of the reaction (checked by TLC). The ribofuranoside was extracted with ethyl acetate (2 × 15 mL). The solvent was removed by distillation under reduced pressure and the product **4** so obtained was chromatographed over silica gel (60–120 mesh) column by eluting with pet.ether-EtOAc (7:3) to afford pure ribofuranosides.

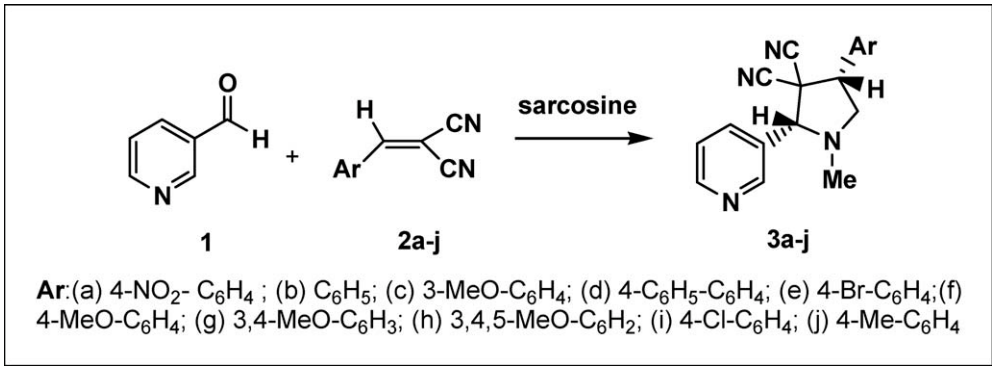
Published online 3 May 2010 in Wiley InterScience (www.interscience.wiley.com).



A simple diastereoselective route to nicotine derivatives is presented. The one-pot three component 1,3-dipolar cycloaddition reaction of the Knöevenagel adducts of a number of aromatic aldehydes and malononitrile with an azomethine ylide derived *in situ* from pyridine-3-carbaldehyde and sarcosine give access to nicotine derivatives in good yields.

*J. Heterocyclic Chem.,* **47**, 611 (2010).

## INTRODUCTION

(S)-Nicotine is present together with a number of minor alkaloids in tobacco and a wide variety of other plants (Fig. 1). Dried leaves of the tobacco plants *Nicotiana rustica* and *N. tabacum* contain as much as 2–8% of (S)-nicotine [1]. A large scale application of nicotine was its use as an insecticide, as ~2800 tons of (S)-nicotine was used as a crop protectant per year [2]. Aqueous solutions of nicotine sulfate are still used throughout the world as insecticides. (S)-Nicotine has drawn a lot of interest in the last few decades due to its potential role in therapeutics for the central nervous system (CNS) [1]. In particular, (S)-nicotine may have beneficial effects in the treatment of Parkinson's disease (PD), Alzheimer's disease (AD), Tourette's syndrome, anxiety, schizophrenia, uterative colitis, and other disorders [3]. Detrimental effects including actions on both the cardiovascular and gastrointestinal systems, sleep disturbance, and at higher doses, neuromuscular effects and seizures limit the use of nicotine as a therapeutic reagent [4]. These side effects are due to subtype selectivity, or a lack thereof, among the various *n*AChRs [5]. Hence, there has been a need to synthesize nicotine derivatives that are more selective in their binding to ACh sites to minimize side effects while retaining beneficial activity.

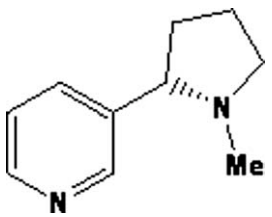


**Figure 1.** (S)-Nicotine.

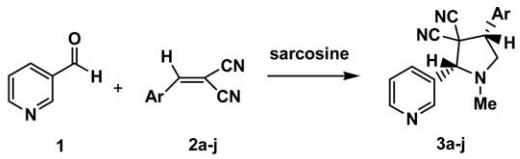
## RESULTS AND DISCUSSION

Considerable attention has been given to the synthesis of nicotine derivatives that would exhibit the beneficial biological properties at lower toxicity [6]. Most of the approaches have been directed toward the synthesis of nicotine [3] and nicotine analog derivatives [7] with modification on the pyridine ring. 1,3-Dipolar cycloaddition reactions of azomethine ylides with various alkenes and alkynes represent an efficient and convergent method for the construction of pyrrolidine and pyrrolizine units [8]. To the best of our knowledge, a few reports are present in literature for the preparation of nicotine derivatives with modification at the pyrrolidine ring *via* cycloaddition of azomethine ylides to chalcones. 1,3-Dipolar cycloaddition of phenylvinyl sulfone with azomethine ylide generated based on the

**Scheme 1.** Synthesis of Nicotine derivatives **3**.



**Ar**:(a) 4-$NO_2$- $C_6H_4$ ; (b) $C_6H_5$; (c) 3-MeO-$C_6H_4$; (d) 4-$C_6H_5$-$C_6H_4$; (e) 4-Br-$C_6H_4$;(f) 4-MeO-$C_6H_4$; (g) 3,4-MeO-$C_6H_3$; (h) 3,4,5-MeO-$C_6H_2$; (i) 4-Cl-$C_6H_4$; (j) 4-Me-$C_6H_4$

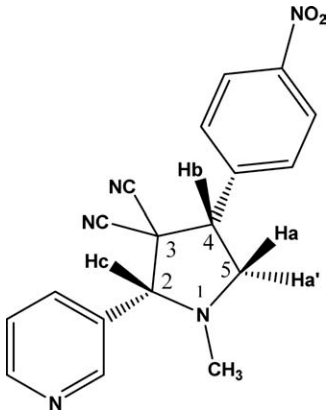
*in situ*, fluorine-mediated desilylation of cyanoaminosilane afforded 3-benzensulfonylnicotine [9]. Recently, Zhai and his coworkers utilized the azomethine ylide–alkene [3+2] cycloadditions toward the synthesis of conformationally restricted nicotine derivatives [10]. Herein, we describe a simple diastereoselective synthesis of nicotine derivatives *via* one-pot three component 1,3-dipolar cycloaddition reaction of the Knöevenagel adducts of a number of aromatic aldehydes and malononitrile with an azomethine ylide derived *in situ* from pyridine-3-carbaldehyde and sarcosine in refluxing toluene.

The Knöevenagel adducts **2a**–**j** were prepared from the condensation of malononitrile with a series of aromatic aldehydes *via* the previously reported procedure [8c]. These adducts were subsequently treated with pyridine-3-carbaldehyde **1** and sarcosine in refluxing toluene for 3 h (Scheme 1). After evaporation of solvent under reduced pressure, methanol was added, and the solid products were filtered and recrystallized from methanol resulting in nicotine derivatives **3a**–**j**.

Identification of the products was carried out by spectroscopic methods. The $^1$H NMR spectrum of **3a** (Scheme 2) exhibited a singlet at δ 2.42 for N—$CH_3$, a doublet of doublets appears as a triplet at δ 3.26 ($J$ = 10.3 Hz, Ha′), a doublet of doublets at δ 3.83 ($J$ = 10.3, 5.7 Hz, Ha), a singlet at δ 4.15 (Hc), a doublet of doublets at δ 4.25 ($J$ = 10.3, 5.7 Hz, Hb), a multiplet at δ 7.46 (pyridine-*m*-H), a doublet at δ 7.76 ($J$ = 8.6 Hz, Ar-*m*-2H), a broad doublet at δ 7.98 (pyridine-*p*-H), a doublet at δ 8.34 ($J$ = 8.6 Hz, Ar-*o*-2H), a broad doublet at δ 8.76 (pyridine-*o*-H), and a singlet at δ 8.82 (pyridine-*o*-H). The $^{13}$C NMR spectrum of **3a** showed 16 signals at δ 39.8, 50.4, 52.2, 58.6, 76.5, 111.7, 114.2, 124.4, 124.8, 128.8, 130.0, 136.3, 142.5, 148.9, 150.4, and 152.2. The MS (EI) spectrum revealed the molecular ion peak at *m*/*z* 333 corresponding to the molecular weight of **3a**.

The relative configuration of the stereocenters in **3a** was assigned using X-ray crystallographic study of its single crystal (Fig. 2), which implied a cis (syn diastereomer) arrangement between C-2 and C-4 [11]. On the basis of this result, we propose a transition-state model to account for the diastereoselectivity of the reaction (Scheme 3). Hence, the structure of the azomethine ylides generated *in situ* may be represented as *E* and *Z* diastereomers. These two can approach the chalcone *via* **I**, **II**, and **I**′, **II**′ structures, respectively. **I** and **I**′ are sterically favored relative to **II** and **II**′ since the latter two experience more steric hindrance from aryl and methyl groups which are eclipsed to each other (Scheme 3). The formation of the 2,4-syn diastereomer as the sole product in most cases reveals that the azomethine ylide with the structure of **I***E* configuration has been implicated in the reaction pathway. Since **3c** and **3h** are generated as a mixture of dl, and identified as syn and anti with the ratios of 3:2 and 2:1, respectively, the involvement of both **I***E* and **II***E* azomethine configurations in reaction should be taken into consideration. We believe that **2c** and **2h** albeit have different number of methoxy substituents, behave similarly since the electron withdrawing effect of the 5-methoxy group of **2h** on the Michael addition rate of zomethine ylide to ArCH=$C(CN)_2$ roughly offsets the electron donating effect of the 4-methoxy group. Therefore, the disfavored steric effect present in **II***E* in retarding the reaction rate of **2h** seems to be compensated by rate enhancement

**Scheme 2.** Strucure of derivative **3a**.



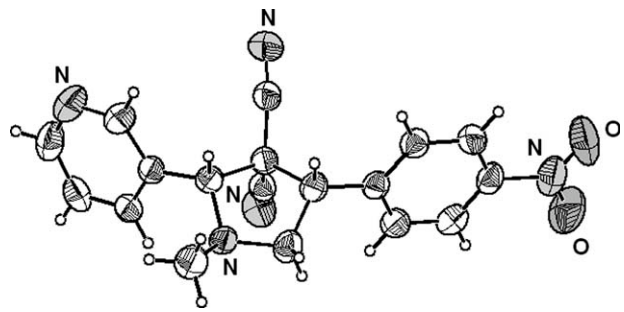


**Figure 2.** ORTEP diagram of **3a**.

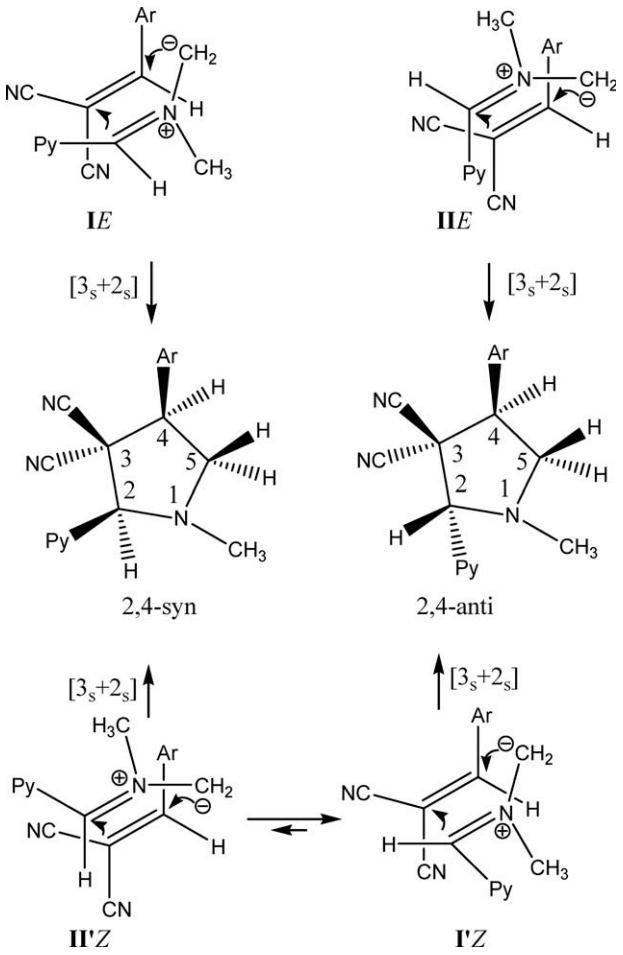
**Scheme 3.** Transition state models evoked to account for reaction diastereoselectivities.



due to the favored electronic effect of the 3-methoxy group.

Under similar conditions, utilization of the Knöevenagel adduct of fluorenone with malononitrile afforded the corresponding 4-spironicotine derivative **3k** in 75% yield (Scheme 4). This reaction exhibits the diversity of the method in applying different chalcones.

In summary, a range of nicotine derivatives have been synthesized *via* the one-pot three component 1,3-dipolar cycloaddition reaction of the Knöevenagel adducts of a number of aromatic aldehydes and malononitrile with an azomethine ylide derived *in situ* from sarcosine and pyridine-3-carbaldehyde.

## EXPERIMENTAL

All commercially available chemicals and reagents were used without further purification. Melting points were determined with an Electrothermal model 9100 apparatus and are uncorrected. IR spectra were recorded on a Shimadzu 4300 spectrophotometer; in $cm^{-1}$. $^1H$ and $^{13}C$ NMR Spectra: Bruker DRX-500-AVANCE spectrometer at 500 ($^1H$) and 125.7 MHz ($^{13}C$); $CDCl_3$ solns.; δ in ppm, *J* in Hz. Mass spectra of the products were obtained with a HP (Agilent technologies) 5937 Mass Selective Detector. Elemental analyses were carried out by a CHN-O-Rapid Heraeus elemental analyzer (Wellesley, MA).

**General procedure for the synthesis of *N*-methyl-4-(X-substituted)-2-(pyridine-3-yl)pyrrolidine-3,3-dicarbonitrile (3a–k).** A mixture of sarcosine (2.0 mmol), pyridine-3-carbaldehyde (2.0 mmol), and chalcone (2.0 mmol) in dry toluene (20 mL) containing molecular sieves 4 Å (1000 mg) was refluxed with stirring for 3 h. The progress of the reaction was followed by TLC. After completion, the solvent was removed under reduced pressure. After addition of methanol (1 mL), the resulting solid was filtered and recrystallized from methanol to afford a crystalline product (Table 1).

***N*-methyl-4-(4-nitrophenyl)-2-(pyridine-3-yl)pyrrolidine-3,3-dicarbonitrile (3a).** Yellow crystals; Yield: 70%; mp 188–189°C; IR (KBr): 2250 $cm^{-1}$; $^1$PH NMR: 2.42 (s, 3H), 3.26 (t, *J* = 10.3, 1H), 3.83 (dd, *J* = 10.3, 5.7, 1H), 4.15 (s, 1H), 4.25 (dd, *J* = 10.3, 5.7, 1H), 7.46 (m, 1H), 7.76 (d, *J* = 8.6, 2H), 7.98 (bd, 1H), 8.34 (d, *J* = 8.6, 2H), 8.76 (bd, 1H), 8.82 (s, 1H); $^{13}C$ NMR: 39.8, 50.4, 52.2, 58.6, 76.4, 111.7, 114.2, 124.4, 124.8, 128.8, 130.0, 136.3, 142.6, 148.9, 150.4, 152.2; MS: *m*/*z* = 333 [$M^+$]; Anal. The synthesis of medicinally important 1,3,4-thiadiazoles was achieved using structurally different urea and thiourea as hydrogen bond donor organocatalyst.

A simple and efficient procedure for the synthesis of 1,3,4-thiadiazoles has been achieved using thiourea as organocatalyst. In this study, the steric and electronic effects using structurally different derivatives of urea and thiourea in different solvents were evaluated. The best yields and the rate of the reactions were obtained using 30 mol % of thiourea as catalyst in acetonitrile at room temperature. The molecular structures of the products were established by $^{1}H$ and $^{13}C$ NMR spectral data.

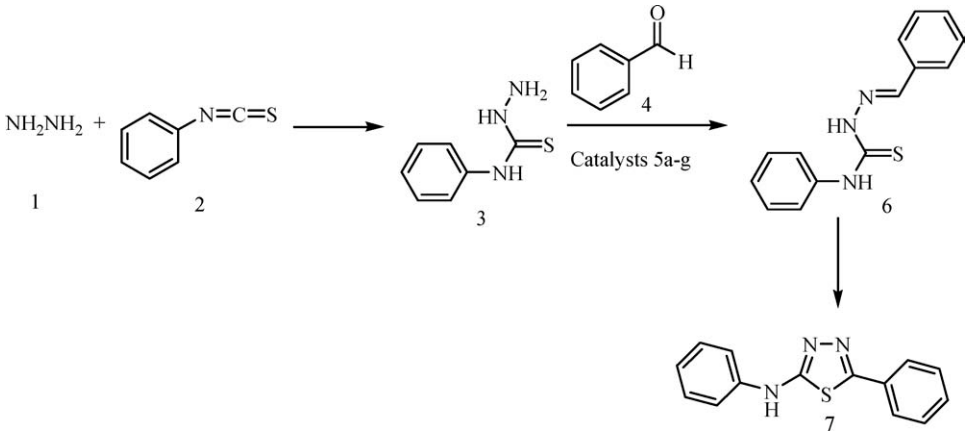
## INTRODUCTION

1,3,4-Thiadiazoles are a group of heterocyclic building blocks for which a wide variety of applications have been reported including dyes [1], lubricating agents [2], optically active liquid crystals [3], and photographic materials [4]. In the medicinal field, therapeutic properties such as antitumor [5], hypoglycemic [6], anticonvulsant [7], hypotensive [8], antiproliferative [9] and antituberculosis [10a,b], antileishmanial [11a,b], and anti-*Helicobacter pylori* [12a,b] activities have been assigned to their various derivatives. Moreover, these compounds have recently been the subject of some theoretical and computational studies because of their significance [13,14]. Also, the research on the synthesis and discovery of new 1,3,4-thiadiazole derivatives with specific medicinal properties is still an active area of research [15]. Literature survey of synthetic methods for these interesting compounds indicates that there are three main categories for the synthesis of 1,3,4-thiadiazoles: (1) cyclizations involving one-bond formation [16a–h], (2) cyclizations involving formation of two bonds [16a,d–g], and (3) cyclizations involving formation of three bonds [16a,h]. Very recently, we reported a new three-bond forming one-pot protocol for the synthesis of some 1,3,4-thiadiazoles with potential antituberculosis activity using Brönsted acidic ionic liquid [Bmim]$BF_4$ as dual solvent and catalyst [17].

With a view to designing more selective, robust, environmentally benign, and functional-group tolerant catalysts, chemists have begun to reconsider using the proton as the simplest Lewis acid. Therefore, taking their cue from natural enzymatic systems, chemists have attempted to explore the development of weak acid–base interactions/hydrogen bonding which is one of the most dominant forces in molecular interaction and recognition in biological systems [18], as a basis for catalyst design and as an impressive option to replace the proton and other commonly known Lewis and Brönsted acids. So, small organic molecules called organocatalysts [19,20], which can form hydrogen bonds, contain no metallic atoms and are favorable in terms of environmental viewpoints that can be used as efficient catalysts for various organic transformations [21]. Recently, thiourea derivatives have been the subject of extensive research in the field of designing hydrogen bond catalyst and several excellent reviews are available on this subject (for example see [22]). Various thiourea catalysts have been utilized to catalyze organic reactions through hydrogen bonding, either for asymmetric or for nonasymmetric catalysis. Herein, we only refer to some of

**Scheme 1.** Model reaction for the organocatalyzed synthesis of 1,3,4-thiadiazoles.



the most recently reported studies such as chlorohydrins synthesis [23], enantioselective Michael addition [24], asymmetric Bayliss-Hillman reaction [25], Diels-Alder reaction [26], acetallization of aldehydes and ketones [27], nitro-Michael addition [28], nucleophilic addition to acyl imines [29], and enantioselective tandem Michael-Knoevenagel reaction [30]. To the best of our knowledge, there is no report on the role and application of organocatalysts for the preparation of 1,3,4-thiadiazoles in the literature. On the basis of the aforementioned considerations, we decided to investigate the steric and electronic effect of urea and thiourea in different solvents to represent a novel efficient catalytic protocol for the synthesis of some 1,3,4-thiadiazoles derivatives possessing arylamino and aryl moieties on positions 3 and 5 of thiadiazole ring.

## RESULTS AND DISCUSSION

At the beginning to determine the appropriate catalyst, we examined the effect of hydrogen bond donor catalyst structure on the synthesis of 1,3,4-thiadiazoles. The model reaction is shown in Scheme 1. For this study, derivatives of urea and thiourea along with two guanidinium salts are used in different solvents and temperatures (Schemes 1 and 2, Tables 1 and 2). As can be deduced from Tables 1 and 2, the best results were obtained when 30 mol % of the thiourea as catalyst was used relative to reactants at room temperature (Table 1, entries 4–6).

The results shown in Tables 1 and 2 indicate an important point about the nature of catalysis and the proper type of solvent used in the process. In water as solvent, no reaction was observed for both urea and thiourea as catalyst (Table 1, entries 1 and 13). So, this solvent was not tested anymore in the case of other catalysts. This means that reactants do not form hydrogen bonds with catalysts in water because the catalysts form very stronger hydrogen bonds with water molecules, especially since the water molecules are present in such a great numbers as solvent [31]. In addition, when we chose ethanol as a hydroxylic solvent capable of forming hydrogen bonds weaker than water, the process did not proceed well either (Table 1, entries 2 and 14). In these two cases, we only obtained the semicarbazone intermediate 6 as the only product and not the desired heterocyclic compound. With a polar aprotic solvent such as acetonitrile, we managed to obtain the thiadiazole product with moderate to good yields and in relatively short reaction times (Table 1, entries 3, 4, and 7–12). This is undoubtedly due to the effective hydrogen bond formation between the substrates and the catalyst in acetonitrile. Solvents such as dimethylformamide (DMF) and dimehtylsulfoxide (DMSO) were also effective in the case of catalysts **5b**, **5c**, **5d**, **5e** but the yields were lower and the reaction times were much longer in these solvents (Table 1, entries 5 and 6, Table 2, entries 6–11), whereas in the case of catalysts **5f** and **5g**, no reaction was observed (Table 2, entries 12–15). Moreover, when the temperature was changed from 30°C to reflux condition, no remarkable change in the yield and the reaction time was observed (Table 1, entries 9–12). It is

**Scheme 2.** Urea, thiourea, and guanidinium salts as organocatalysts employed in this study.

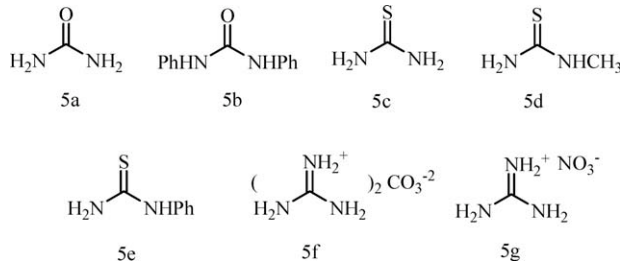


**Table 1**

Screening of the effect of temperature and the type solvent for the synthesis of 1,3,4-thiadiazoles using simple thiourea and urea.

| Entry | Catalyst type | Catalyst loading (%) | Solvent | Temperature (°C) | Reaction time | Comments[a] |
|---|---|---|---|---|---|---|
| 1 | **5a** | 30 | Water | 30 | 24 h | No reaction |

[a] Isolated yield.

worth mentioning that the reaction was best performed at 30°C (Table 1, entry 4).

The amount of 30 mol % of the catalyst was found to be the optimum amount for the present process. When we applied a lower amount of thiourea (20 mol %, Table 1, entry 7), the reaction yield was decreased to nearly half of that found with 30 mol % of the catalyst. Moreover, using higher amounts of catalyst (40 mol %, Table 1, entry 8) did not make any remarkable difference in the yield and the reaction time.

To find out which catalyst could be the most beneficial one for our purpose and what would be the nature of the catalytic effect, we examined five derivatives of urea and thiourea along with two guanidinium salts in this process (Tables 1 and 2, Scheme 2). The chemical nature of catalyst effect here in this process could be both steric and electronic. Taking a precise look at the results in Table 1, upon going from thiourea to *N*-methylthiourea, reveals that even a small change in the structure (replacing H with $CH_3$) has led to a drastic reduction in the reaction rate and a remarkable decrease in the yield of formation of thiadiazole (Table 1, entry 4 and Table 2, entry 2). This can be better deduced in the case of *N*, *N*′-diphenylurea and *N*-phenylthiourea (Table 2, entries 1 and 2) with their unsubstituted analogs (Table 1, entries 3 and 4). Observing a longer reaction time for *N*-phenylthiourea in comparison with the case of thiourea indicates that steric demands are the major factors governing the formation of the hydrogen bond between catalysts and the substrates. With a more sterically hindered catalyst like *N*-phenylthiourea, the catalyst is not capable of forming effective hydrogen bridges with

**Table 2**

Comparison of the urea and thiourea derivatives as organocalysts in the synthesis of 1,3,4-thiadiazoles.

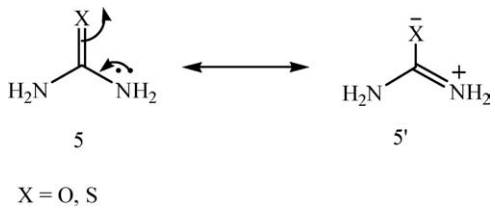
[a] Isolated yield.

**Scheme 3.** Resonance structures of urea and thiourea.



substrates. This will result in a decrease in the reactivity of the substrate, much longer reaction time, and much lower yield of the product (Table 2, entry 3). Moreover, the application of *N*,*N*′-diphenylurea, as a catalyst with two very bulky substituents on nitrogen atoms, led to the formation of the intermediate **6** (Scheme 1) in trace amounts and no sign of formation of thiadiazole ring (Table 2, entry 1).

The difference in catalytic activity of thiourea and urea can be clearly seen in Table 1 (entries 3 and 4) as one of the most interesting points of this study. Thiourea has catalyzed the reaction faster than urea in acetonitril as solvent at room temperature. The possible reason for this observation is the fact that in thiourea the sulfur heteroatom has more polarizability in comparison to oxygen. So, when drawing the resonance structures for urea and thiourea, the **5′** contribution in the resonance structure is higher for thiourea because the negative charge could be better stabilized on sulfur than on oxygen atom (Scheme 3). Accordingly, more positive charge on nitrogen and on the hydrogen atom in **5′** resonance structure has lead to stronger hydrogen bonding with the reactants and a more catalytic effect. Moreover, the p$K_a$ value for thiourea is less than the one for urea [32] which means thiourea is more acidic than urea. Therefore, thiourea should be able to catalyze the cyclization step better than urea.

To prove that the electronic effects do not play a distinct role in hydrogen bond catalyzed synthesis of 1,3,4-thiadiazoles, we repeated this process using various phenylisothiocyanate and benzaldehyde derivatives with different electron demands (Scheme 4, Table 3, compounds **7a–n**). Both the reaction times and isolated yields in Table 2 indicate no general pattern for derivatives with electron withdrawing or electron donating substituents. Reaction times are in the range of 30–75 min for all products and the yields vary between 81% and 95%. Taking these facts into consideration, we can only lay emphasis on the role of steric, and not, electronic effects on the preparation of 1,3,4-thiadiazoles using (thio)urea organocatalysts. Then, we performed some control experiments to confirm the role of thiourea as catalyst in this process. Primarily we performed the process by using equivalent amounts of phenylisothiocyanate, hydrazine hydrate, and benzaldehyde and the use of thiourea (30 mol % relative to reactants) in dry acetonitrile as solvent under $N_2$ inert atmosphere. As expected, we observed the formation of intermediate **6** (Scheme 1) as the only product and no sign of the desired thiadiazole product was observed. When we performed the test experiment in EtOH as solvent and in the absence of any catalyst, only trace amounts of intermediate **6** were obtained. These control experiments show that hydrogen bonds of thiourea are necessary to promote the reaction and solvents such as water and ethanol cannot play the role of a hydrogen bond donor to catalyze this process. According to these results, we proposed a reasonable reaction pathway for the preparation of 1,3,4-thiadiazoles using thiourea as catalyst (Scheme 5).

The main interesting point that can be observed through this proposed reaction pathway is that when one of the hydrogen on nitrogen atom of thiourea (nitrogen atom on the left side of thiourea) is replaced with a more sterically hindered substituent like methyl and phenyl, one of the hydrogen bond connections has actually been removed which prevents self formation of the template between the catalyst with the two reactants. In the case of thiourea as catalyst, this template of hydrogen bridges facilitates the approaching of 4-phenylthiosemicarbazide to benzaldehyde and the formation of 4-phenylthiosemicarbazone intermediate. The ease of hydrogen bond formation also facilitates the cyclization to 2,3-dihydrothiadiazoline intermediate in the second step.

**Scheme 4.** General reaction pattern used for the synthesis of substituted 1,3,4-thiadiazoles.

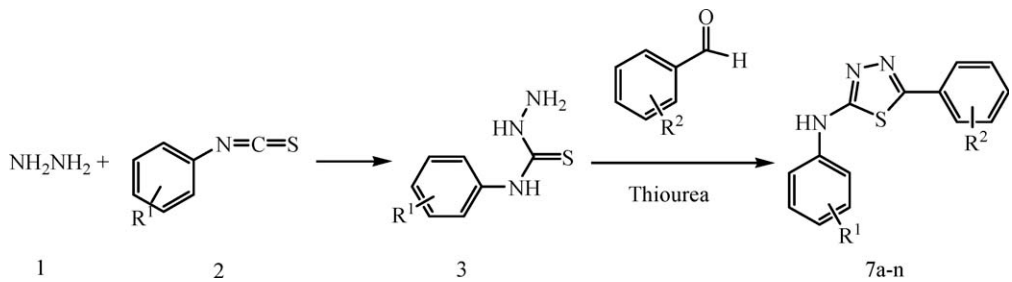


**Table 3**

Organocatalytic synthesis of 1,3,4-thiadiazoles using thiourea as hydrogen bond catalyst.

[a] Isolated yield.

The hydrogen bonding in this step of the reaction is responsible for the activation of C=N double bond and the motivation for cyclization. Herein, the existence of more bulky groups like methyl and phenyl also will result in improper hydrogen bonding of the catalyst to 4-phenylthiosemicarbazone.

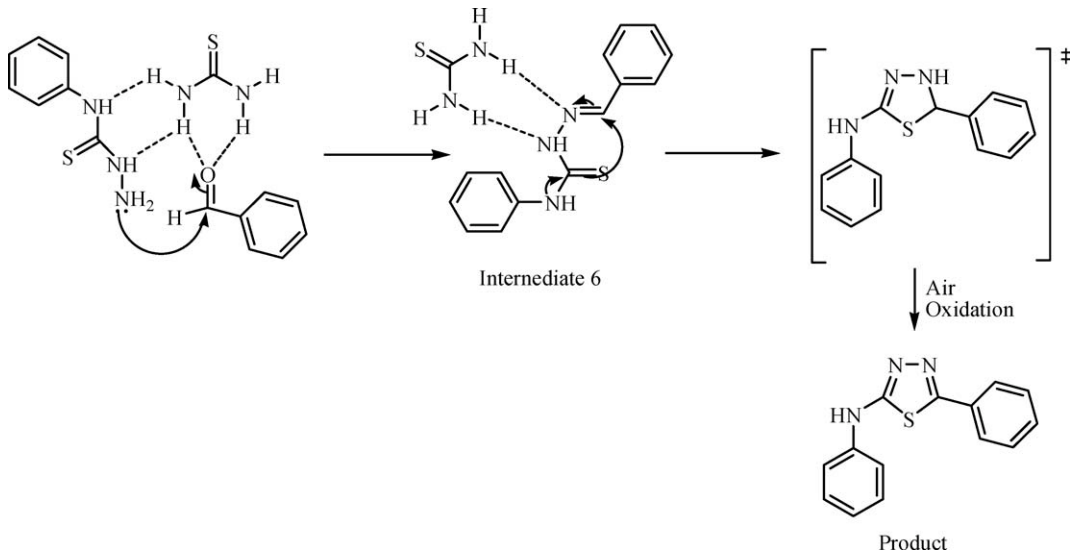
The case of guanidinium salts with no catalytic activity can simply be explained in another way. The guanidinium cations strongly form hydrogen bonds with their counterions carbonates or nitrates, and, consequently will not be able to form such bonds with the substrates in the reaction (Table 1, entries 18 and 19).

In comparison to our previous work [15], this study has several advantages. Apart from the similarity in yields, thiourea derivatives have been used which are cheaper than ionic liquids [bmim]. In addition, ionic liquids [bmim] $BF_4$ may release HF and decompose after some time, whereas thiourea derivatives do not have such a problem and can also be handled and kept more easily than ionic liquids. The only difference with this study is slightly longer reaction times.

## CONCLUSIONS

In summary, we have developed a study on hydrogen bond catalysis in the synthesis of 1,3,4-thiadiazoles as a group of medicinally important heterocyclic

**Scheme 5.** The proposed reaction pathway for the formation of 1,3,4-thiadiazole in which a template of hydrogen bond thiourea organocatalyst has the main role.



compounds. We examined several urea, thiourea, and gunidinium compounds to realize the major factors governing the catalytic activity of these compounds and realized that the true feature of the catalytic effect is steric, and not, electronic effect because the rates and yields of the reaction are strongly dependent on the steric bulk of the catalyst. Application of *N*-methyl- and *N*-phenylthiourea resulted in lower yields and slower reaction rates in comparison with thiourea. Finally, this process provides easy access to important thiadiazole heterocyclic building block in relatively short reaction times and various derivatives with different electron demands on substituents were prepared. We think that this process has a great potential to be applied for the catalytic purposes of synthetic protocols for other important heterocycles and we are working to develop this idea for the purpose of organic and heterocyclic synthesis.

## EXPERIMENTAL

Melting points were measured on a Büchi B-540 apparatus and are uncorrected. IR spectra were measured on Bomem FTIR ABB FTLA200-100 spectrometer. $^1$H and $^{13}$C NMR spectra were measured with a Bruker DRX-300 Avance spectrometer at 300 and 75 MHz using TMS as an internal standard. Chemical shifts are reported (δ) relative to TMS, and coupling constants (*J*) are reported in hertz (Hz). Mass spectra were recorded on a High Resolution Agilent Technology EX mass spectrometer. Chemicals were obtained from Merck, Darmstadt, Germany and Sigma-Aldrich Saint Quentin Falavier, Cedex, France and used without further purification.

**Typical experimental procedure for organocatalytic preparation of 1,3,4-thiadiazoles using (thio)urea derivatives.** To a round bottomed flask was added phenylisothiocyanate derivative (0.24 mL, 2 mmoles), acetonitrile as solvent (2 mL), and hydrazine hydrate (0.1 mL, 2 mmoles) (Scheme 3). This mixture was stirred at 25–30°C for 10 min, Then thiourea (0.045 g, 0.6 mmoles, 30 mol %) and substituted benzaldehyde (2 mmoles) were added to the reaction vessel. The reaction mixture was then stirred for the specified time at 30°C (Table 2). After completion of reaction (as monitored by TLC, ethyl acetate:petroleum ether, 1:4), the resulting precipitates were vacuum filtered using a Büchi funnel. The results are shown in Table 2. The precipitates were further purified with either ethanol or ethanol/water and were further characterized by mp, IR, NMR, and MS spectroscopy. This procedure was repeated the same in the case of other urea or thiourea derivatives (Table 1).

Monastrol derivatives were synthesized by environment-friendly three component condensation reaction of salicylaldehyde analogues, β-ketoester, and urea or thiourea under solvent-free conditions with $NaHSO_4$ as catalyst in high yields. The reactions formed two different monastrol products, 4-(2-hydroxyphenyl)pyrimidines **4** and 9- methyl- 11-oxo(or thioxo)-8-oxa-10,12-diazatricyclotrideca derivatives **5**.

## INTRODUCTION

It is well known that 3,4-dihydropyrimidin-2-(1*H*)-ones (DHPMs) and their derivatives are an important class of heterocyclic compounds having important biological activities, pharmaceutical and therapeutic properties, such as antiviral [1], antitumour [2], antibacterial, anti-inflammatory, and antihypertensive [3]. Therefore, the preparation of this heterocyclic nucleus has gained great importance in organic synthesis. One of the simple and direct method for the synthesis of this class of compounds is known as Biginelli reaction involving one-pot condensation of aldehyde, β-ketoester, and urea under strong acidic conditions, which was first reported by Biginelli in 1893 [4]. In this class of compounds, Monastrol, ethyl 6-methyl-4-(3-hydroxyphenyl)-2-thioxo-1,2,3,4-tetrahydropyrimidine-5-carboxylate, is a recently highlighted Biginelli compound [5,6], which showed promise in a new strategic approach to cancer research [7] and has been found to affect the function of mitotic kinesin Eg5, a motor protein responsible for spindle bipolarity [8]. Thus, kinesin spindle protein represents an attractive target for biochemical studies because human Eg5 inhibitors induce cell death *via* apoptosis [9]. Owing to the versatile biological activity of Monastrol derivatives, development of an alternative synthetic methodology is of paramount importance. This has led to the development of several new synthetic strategies involving combinations of Lewis acids and transition metal salts, e.g. $Sr(OTf)_2$ [10], *p*-TsOH [11,12], HPA [13], NiCl2.6H2O [14], $LaCl_3$ [15], $InBr_3$ [16] and Bakers' yeast [17]. Obviously, most of these catalysts

and solvents are not acceptable in the context of green synthesis. Thus, as a part of our program towards green synthesis [18], and continuing our studies on the Multi-Component reactions (MCRs) [19], we report herein, a simple, facile, and efficient MCRs for the preparation of some new Monastrol analogues with NaHSO4 as a non-toxic, inexpensive, and easily available reagent.

Herein we wish to report the utilization of NaHSO4 as a catalyst in Biginelli's reaction of substitued salicylaldehydes, β-ketoester and urea or thiourea for the synthesis of some new Monastrol derivatives under solvent-free conditions.

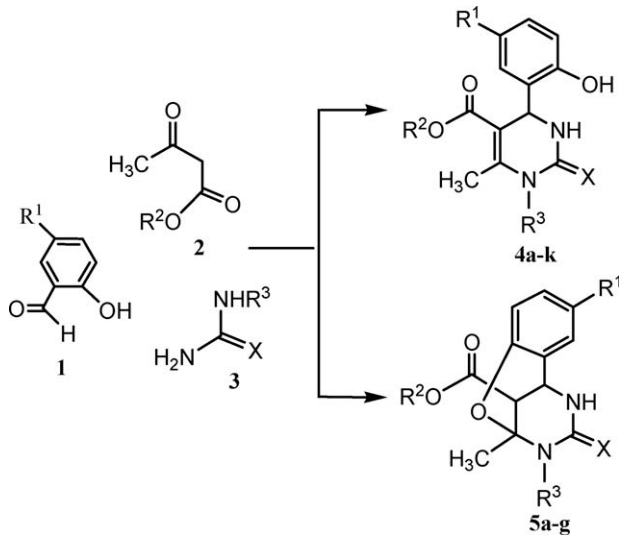
The three-component cyclocondensation reaction was performed under relatively simple reaction conditions by heating together the three components, salicylaldehyde, β-ketoester, and urea or thiourea, in the ratio of 1:1:1.5 and NaHSO4 (20 mol %), to 90°C with stirring. After the completion of the reaction, as indicated by TLC, the reaction mixture was poured onto crushed ice. From which the Monastrol derivatives were isolated by filtration and recrystallized from ethanol as indicated in Table 1.

Reactions of salicylaldehyde, methyl acetoacetate with urea (or thiourea, phenylurea) as well as reactions of 5-chloro or 5-bromo salicylaldehyde, methyl (or ethyl) acetoacetate with thiourea did not give the expected free hydroxyl compounds **4,** however, the product is the 9-methyl-11-oxo(or thioxo)-8-oxa-10,12-diazatricyclo [7.3.1.$0^{2,7}$]trideca-2,4,6-triene **5a-g** (Scheme 1).

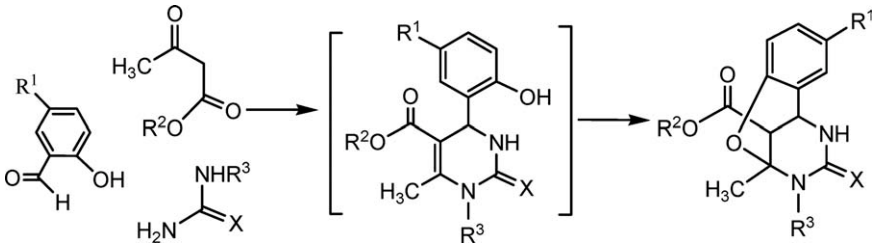
The results presented in the Table 1 indicate the scope and generality of the method, which is efficient, not only for urea or thiourea, but also for salicylaldehydes as well as 5-chloro and 5-bromo salicylaldehydes. In most cases, the reactions proceeded smoothly to produce the corresponding Monastrol derivatives in high yields.

In the course of our work, we have observed that the product from reactions involving salicylaldehyde, methyl acetoacetate with urea (or thiourea, phenylurea) is in fact the 9-methyl-11-oxo(or thioxo)-8-oxa-10, 12-diazatricyclo [7.3.1.$0^{2,7}$]trideca-2,4,6-triene **5a-c** rather than a free hydroxyl compounds, 4-(2-

**Scheme 1**



**Scheme 2**



hydroxyphenyl)pyrimidines **4**. However, this oxygen-bridged pyrimidine structures were not discussed in several recent reports [13–15,20,21], but were supported by others [12,16,17]. The product from reactions involving 5-chloro or 5-bromosalicylaldehyde, methyl (or ethyl) acetoacetate with thiourea is also an oxygen-bridged compounds **5d-g** rather than the corresponding 4-(2-hydroxyphenyl)pyrimidines.

The production of compounds **5a-g** can be explained by the isomerization reaction of the 4-(2-hydroxyphenyl) pyrimidines, **4** which were initially formed (Scheme 2).

In summary, we have described a convenient, environment-friendly method for the preparation of some new Monastrol derivatives by the Biginelli cyclocondensation reaction of salicylaldehyde analogues, β-ketoester with urea or thiourea using nontoxic, cheap $NaHSO_4$ catalyst. Additionally, when using salicylaldehyde as the aldehyde reagent, methyl acetoacetate as the active methylene compound, urea (or thiourea, phenylurea) as the condensation reagent, as well as using 5-chloro or 5-bromo salicylaldehyde as the aldehyde reagent, methyl (or ethyl) acetoacetate as the active methylene compound, thiourea as the condensation reagent, the Biginelli product will be an oxygen-bridged compound, 9-methyl-11-oxo(or thioxo)-8-oxa-10,12-diazatricyclo[7.3.1.$0^{2,7}$]trideca-2,4,6-triene **5** rather than 4-(2-hydroxyphenyl)pyrimidines **4**.

## EXPERIMENTAL

IR spectra were recorded on a Nicolet FTIR-500 spectrometer. $^1$H NMR and $^{13}$C NMR spectra were recorded on a Bruker AVANCE 400 MHz spectrometer at 400 MHz and 75 MHz. Elemental analysis was performed on an Elementar Vario EL III analyzer. Melting points were determined on a XT-5A digital melting-points apparatus and are uncorrected.

**General procedure for the synthesis of Monastrol derivatives 4a-k and 5a-g.** A mixture of the appropriate salicylaldehyde (2 mmol), β-ketoester (2 mmol), urea or thiourea (3 mmol), and NaHSO4 (0.4 mmol) was heated with stirring at 90°C for the time period as indicated in Table 1. After completion of the reaction (TLC analysis), ice water was added to the mixture, and the crude products collected by filtration were recrystallized from EtOH, to give the products **4a-k** or **5a-g** (Table 1). All products were characterized by $^1$H, $^{13}$C NMR, IR, MS spectral, and by elemental analyses.

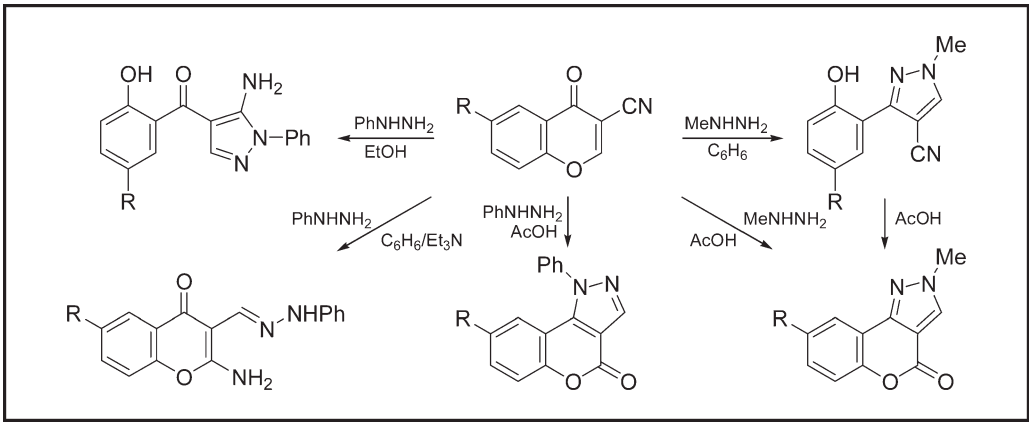
Published online 3 May 2010 in Wiley InterScience (www.interscience.wiley.com).



Reactions of 3-cyanochromones with phenylhydrazine gave the corresponding 5-amino-4-salicyloyl-1-phenylpyrazoles, 2-aminochromone-3-carbaldehyde *N*-phenylhydrazones, and 1-phenylchromeno[4,3-*c*]pyrazol-4(1*H*)-one, depending on the reaction conditions. With methylhydrazine, 3-(2-hydroxyaryl)-1-methylpyrazole-4-carbonitriles and 2-methylchromeno[4,3-*c*]pyrazol-4(2*H*)-ones were obtained in moderate to high yields.

*J. Heterocyclic Chem.*, **47**, 629 (2010).

## INTRODUCTION

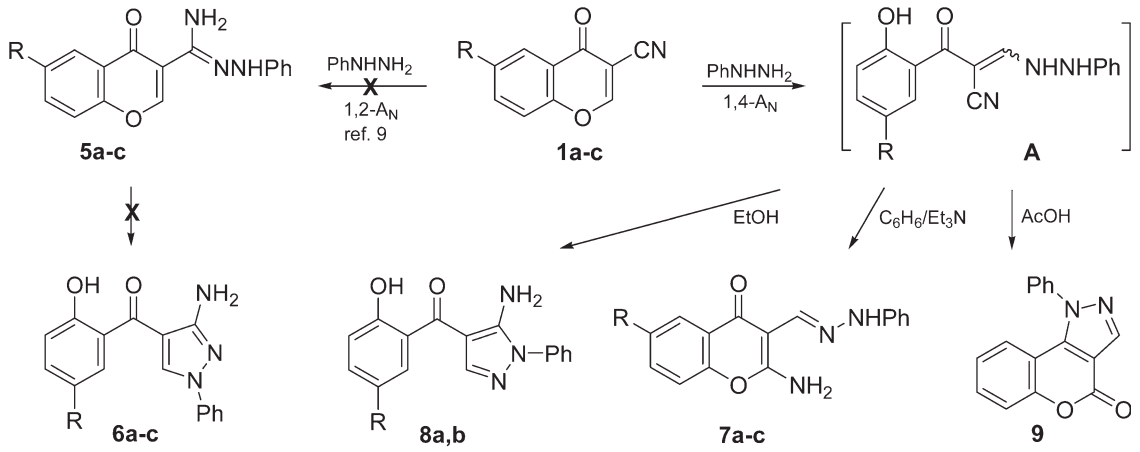
The chemistry of 3-cyanochromones has been developed since the mid-1970s after the simple and convenient Vilsmeier-Haack method was proposed for the synthesis of 3-formylchromones from 2-hydroxyacetophenones, DMF, and $POCl_3$ [1]. Treatment of 3-formylchromones with hydroxylamine via 3-formylchromone-3-oximes leads to 3-cyanochromones **1** [2,3]. In addition, **1** can be synthesized directly from 2-hydroxyacetophenones and hydroxylamine under the Vilsmeier-Haack conditions [4] and from O-methylated chromone-3-oximes [5].

The introduction of the electron-withdrawing CN group at the 3-position of the chromone system changes crucially the reactivity of the pyrone ring with respect to nucleophiles, and provides a broad synthetic potential of 3-cyanochromones **1** [6]. The diversity of properties of these compounds is due to the fact that, being highly reactive geminally activated push–pull alkenes (α,β-unsaturated ketones and nitriles simultaneously) with a good leaving group at the β-carbon atom, whose role is played by the phenolate anion (a fragment of the enol ether), they acquire the ability to undergo a nucleophilic 1,4-attack followed by additional transformations related to γ-pyrone ring opening and heterocyclizations at the C-4 atom and/or at the cyano group. However, although nucleophilic 1,4-addition occurs easily, which is clearly demonstrated by the transformation of 3-cyanochromones **1** into 2-amino-3-formylchromones under basic conditions [3,7], the reactions of **1** with dinucleophiles were further interpreted from both the viewpoint of 1,4-addition at the C-2 atom (this direction is equivalent to the 1,2-attack at the CHO group of 2-amino-3-formylchromone) and 1,2-addition to the cyano group, which inevitably led to contradictory results [6,8,9].

## RESULTS AND DISCUSSION

Recently [10], we reported on the ring transformations of the chromones **1** to 2-aminochromone-3-carboxamide, 3-amino-4*H*-chromeno[3,4-*d*]isoxazol-4-one, and 3-(diaminomethylene)chroman-2,4-dione under the action of hydroxylamine in alkaline medium, some of which were previously incorrectly formulated [6]. Now we were

**Scheme 1**



R = H (**a**), Me (**b**), Cl (**c**)

interested in the course of the reactions of 3-cyanochromones **1** with phenyl- and methylhydrazines. The reaction with phenylhydrazine has already been the subject of investigations and to the intermediate was assigned the structure **5** without NMR spectral data [9]. The authors believed that the reaction occurred via 1,2-addition of phenylhydrazine to the cyano group of **1a–c** to give amidohydrazones **5a–c**, which on prolonged refluxing in ethanol afforded 3-aminopyrazoles **6a–c** [6,9]. On the other hand, it was claimed that refluxing benzene induces the initial 1,4-addition of phenylhydrazine producing ultimately the phenylhydrazone derivatives **7** [8]. It should be noted that the pyrazole structure **6** was not established with certainly and in the light of our previous results [10] it seemed more logical to us that the more nucleophilic nitrogen atom of the phenylhydrazine would attack at the 2-position of the chromone rather than at the CN group.

We studied repeatedly the reactions of chromones **1** with phenylhydrazine under the conditions described in refs. 8 and 9 and confirmed the structure of compounds **7a–c**, which can easily be prepared in refluxing benzene in the presence of $Et_3N$ for 0.5 h (for **1c** this reaction occurs both in benzene and ethanol without $Et_3N$, whereas for **1b** the reaction in benzene without $Et_3N$ gives a complex mixture of isomeric open-chain intermediates and **7b**). However, we were unable to reproduce the claimed synthesis of **6a–c**; instead, 5-aminopyrazoles **8a**,**b** as mixtures with **7a**,**b** were obtained in refluxing ethanol (**8a**:**7a** = 82:18 and **8b**:**7b** = 76:26). When these mixtures were treated with 20% sulfuric acid in ethanol [9], 5-aminopyrazoles **8a**,**b** were isolated as pure compounds in 44–49% yields. Refluxing an ethanolic solution of **1c** with phenylhydrazine afforded only the hydrazone **7c** with no traces of **8c**.

On the basis of $^1H$ and $^{13}H$ NMR spectroscopy and using 2D HSQC, HMBC, and NOESY experiments we found that the reaction products of **1a**,**b** and phenylhydrazine were, in fact, 5-amino-1-phenyl-4-salicyloylpyrazoles **8a**,**b** (Scheme 1). The structural assignment for these compounds as the 5-aminopyrazoles was based on the presence of a NOESY cross-peak from the ortho protons of the phenyl (δ 7.55–7.60 ppm, H-2″, H-6″) onto the $NH_2$ group and the absence of cross-peak between pyrazole H-3 proton and *ipso*-C of N–Ph in the HMBC spectrum (for **8a**). In addition, all the signals in the $^1H$ and $^{13}C$ NMR spectra of compound **8a** were assigned on the basis of 2D $^1H$–$^{13}C$ HSQC and HMBC experiments. Besides the signals expected for the aromatic protons, the $^1H$ NMR spectra of **8a**,**b** in DMSO-$d_6$ showed three singlets due to the $NH_2$ group (δ 7.1 ppm), pyrazole H-3 proton (δ 7.7 ppm) and phenolic hydroxyl (δ 10.5–10.8 ppm). It is concluded that the series of the reported products such as **5**, was not in fact obtained. Moreover, based on the similarities between the $^1H$ NMR spectral data of **8** with those reported for **6** in $CDCl_3$ [9], it is clearly evident that the structure **6** should be revised to **8**.

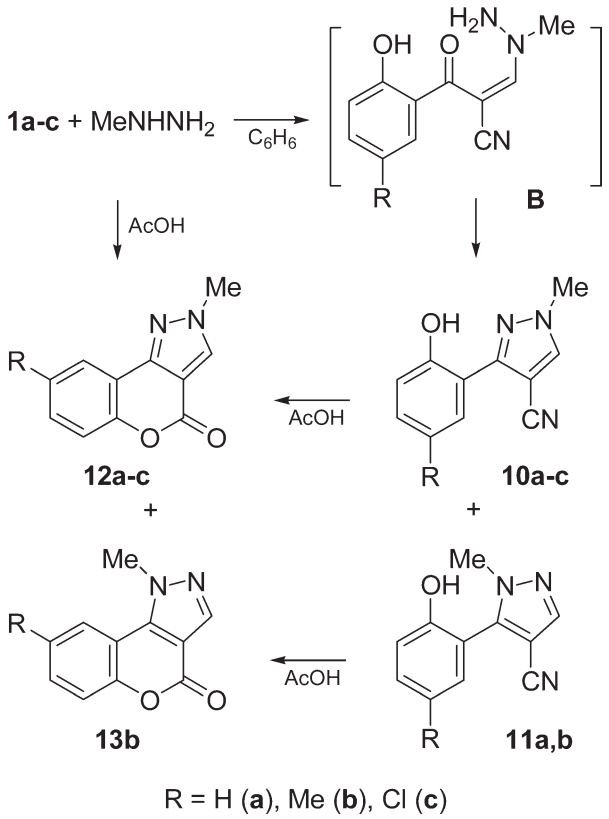
We also found that chromone **1a**, when treated with phenylhydrazine in refluxing AcOH, underwent transformation into 1-phenylchromeno[4,3-*c*]pyrazol-4(1*H*)-one **9** (55% yield). This observation is in line with other report on the condensation of 3-cyano-2-methylchromone with arylhydrazines, which leads to 1-aryl-3-methylchromeno[4,3-*c*]pyrazol-4(1*H*)-ones [11], and not to the claimed earlier 4-methyl-2-phenylchromeno[4,3-*c*]pyrazol-3(2*H*)-one [12]. Previously, compound **9** was obtained by the reactions of phenylhydrazine with chromone-3-carboxylic acid [13], 4-chloro-3-coumarincarbaldehyde [14], and 4-azido-3-coumarincarbaldehydes [15].

Products **7–9** can result from the initial nucleophilic 1,4-addition of phenylhydrazine to the C-2 atom of **1** to give, as a mixture of isomers, the open chain intermediate **A**, further transformation of which is controlled by the nucleophilicity of the OH and NH groups and depends on the reaction conditions. Two different reaction paths for **A** may be envisaged. In refluxing ethanol, intramolecular addition of the NHPh function to the CN group with subsequent hydrogen shift leads to 5-aminopyrazole **8** as a major product. The alternative cyclization of **A** involving the phenolic hydroxyl and the cyano group to form hydrazone **7** occurs in refluxing benzene in the presence of $Et_3N$. When **1** was allowed to react with phenylhydrazine in refluxing acetic acid, the initially formed hydrazone **7** could not be isolated and underwent intramolecular cyclization at the keto group to give chromeno[4,3-*c*]pyrazol-4(1*H*)-one **9**. Thus, the initial Michael addition of phenylhydrazine to **1** leads to three different types of products and the 1,2-addition at the CN group was not observed at all (Scheme 1). This clearly indicates that the C-2 atom of 3-cyanochromone is more susceptible to nucleophilic attack than the CN group. Note that in its reaction with sodium azide, it behaves as a simple arylnitrile to form 3-(1*H*-tetrazol-5-yl)chromone [2a,16].

It is of interest that chromones 1 react in different manner with methylhydrazine to provide a completely different regiochemistry pattern. When an equimolar mixture of **1a–c** and methylhydrazine was refluxed in benzene for 0.5 h, 3-arylpyrazoles **10a–c** were obtained in 40–46% yields (Scheme 2). This reaction exhibits high regioselectivity and pyrazole **10c** was isolated as the single product. However, in the case of **10a**,**b**, some amount of 5-arylpyrazoles **11a**,**b** was observed (7 and 25%, respectively). The determination of the isomers ratio can easily be performed by $^1$H NMR spectroscopic analysis. The $^1$H NMR spectra of compounds **10a–c** in DMSO-$d_6$ consisted of a characteristic singlet due to the phenolic hydroxyl in the region of δ 9.8–10.4 ppm and two singlets due to the resonances of the pyrazole proton and the MeN group at δ 8.56–8.58 and 3.94 ppm. The IR spectra are also of diagnostic value in this 4-cyanopyrazole series ($\nu_{CN} = 2230$ cm$^{-1}$).

The formation of these pyrazoles may be rationalized by initial 1,4-addition of the more nucleophilic secondary nitrogen atom of methylhydrazine on the C-2 atom of **1** with concomitant opening of the pyrone ring to give intermediate **B**. Further, the intramolecular heterocyclization occurs between the $NH_2$ group and the carbonyl, which seems more reactive than the cyano group. Compounds **10a–c**, so obtained, were then allowed to react under more vigorous conditions (boiling acetic acid for 5 h). This afforded coumarins **12a–c** in high yields (70–92%), which were also obtained directly

**Scheme 2**



from **1a–c** and methylhydrazine under the same reaction conditions, however, better yields were achieved if the transformation was performed in a two-step approach. The regioisomeric compounds **13** were not detected, except for the reactions of **1b**, in which case the $^1$H NMR spectra of the products showed the presence of **13b** (25–28%) along with compound **12b** as the major product (Scheme 2).

Spectral data and melting point of **12a** were consistent with previous reported [17], this confirms the regiochemistry of the reaction with methylhydrazine. Interestingly, although the chemistry of the tricyclic chromeno[4,3-*c*]pyrazol-4-one system has been well documented [11–15], we have found that compound **12a** has been obtained only very recently from chromeno[4,3-*b*][1,5]benzodiazepin-7(8*H*)-one and methylhydrazine [17], while derivatives **12b**,**c** are hitherto unreported. In conjunction with the pharmaceutical importance known for the fused heterocycles incorporating a coumarin moiety [18], this simple synthesis of chromeno[4,3-*c*]pyrazol-4-ones from readily available 3-cyanochromones is noteworthy and will complement the published synthetic methods.

In conclusion, 3-cyanochromone represents a very reactive system and its reactions with phenyl- and

methylhydrazines give a variety of products. As the identity of some of these products was in doubt, we have reinvestigated the reaction with phenylhydrazine and found that by varying the conditions, 5-amino-4-salisyloyl-1-phenylpyrazoles, 2-aminochromone-3-carbaldehyde *N*-phenylhydrazones, and 1-phenylchromeno[4,3-*c*]pyrazol-4(1*H*)-one could be prepared in moderate to good yields. With methylhydrazine, 3-(2-hydroxyaryl)-1-methylpyrazole-4-carbonitriles and 2-methylchromeno [4,3-*c*]pyrazol-4(2*H*)-ones were obtained. A simple and convenient synthesis of chromeno[4,3-*c*]pyrazol-4-ones was developed and the generality of this method is being investigated further.

## EXPERIMENTAL

$^1$H (400 MHz) and $^{13}$C (100 MHz) NMR spectra were recorded on a Bruker DRX-400 spectrometer in DMSO-$d_6$ with TMS as the internal standard. IR spectra were recorded on Perkin–Elmer Spectrum BX-II instrument (KBr) and Bruker Alpha instrument (ATR, ZnSe). Elemental analyses were performed at the Microanalysis Services of the Institute of Organic Synthesis, Ural Branch, Russian Academy of Sciences. Melting points are uncorrected. All solvents used were dried and distilled per standard procedures. The starting 3-cyanochromones **1a–c** were prepared according to described procedures [16].

**General procedure for the preparation of 2-aminochromone-3-carbaldehyde *N*-phenylhydrazones (7a–c).** A solution of chromone **1** (1.2 mmol), phenylhydrazine (130 mg, 1.2 mmol) and two drops of $Et_3N$ in benzene (5 mL) was refluxed for 0.5 h and the reaction mixture cooled. The deposited phenylhydrazone **7** was filtetred and washed with benzene. For **1c** this reaction occurs both in benzene and ethanol without $Et_3N$.

A series of fused thiophene derivatives, that is, representatives of thieno[2,3-*d*]pyrimidines, thieno[2,3-*d*][1,3]oxazines and thieno[2,3-*d*][1,3]thiazines, with the common 5-methyl-6-phenyl substitution pattern was synthesized. The target compounds, *e.g.*, **7** or **8**, were designed as cyclic analogs of ethyl 2-amino-4-methyl-5-phenylthiophene-3-carboxylate, an antagonist at the GluR6 kainate receptor. Thieno[2,3-*d*][1,3]oxazin-4-one **2** (R = $C_2H_5$) was identified as new a potent inhibitor ($IC_{50}$ = 17 μ*M*) of this receptor subtype. The inhibitory potency of **2** (R = $C_2H_5$) against human leukocyte elastase was also examined. The compound was characterized as a noncovalent inhibitor with an $IC_{50}$ value of 8.8 μ*M*.

## INTRODUCTION

Even well-established anticonvulsants, such as carbamazepine, valproic acid, phenytoin, or benzodiazepines can cause undesired side effects. Moreover, certain forms of epilepsy, that is, focal seizures, cannot be treated sufficiently with such drugs. This provided the impetus behind the development of new drugs to improve the prospects for mono- and combined therapy. In the course of the continuing search for new anticonvulsants, substituted quinazolines and the bioisosteric thieno[2,3-*d*]pyrimidines have been reported to be active [1,2]. Kainate glutamate receptors may represent an interesting new target for the development of innovative anticonvulsants [3,4]. The kainate receptor subtype GluR6, expressed in the excitatory pyramid cells of the hippocampus, appears to be particularly significant. The GluR6 and GlyR5 subtypes might play opposing roles during the hippocampal excitation [3,5].

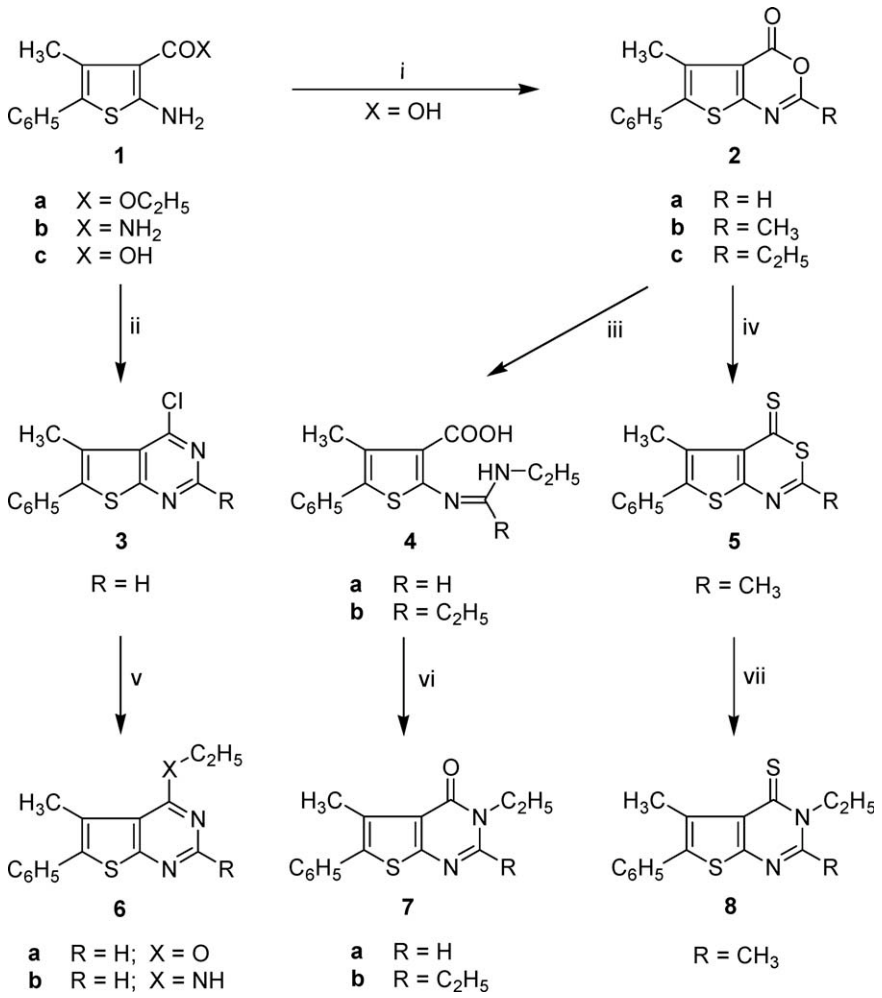
The know antagonists of the GluR6 kainate receptor comprise two groups, compounds which contain glutamate or its isosterically modified fragments on the one hand, and compounds with a structure not related to glutamate on the other hand. Diarylureas and quinoxalinediones are predominant examples of the latter group [6–10].

Substituted alkyl thiophene-3-carboxylates have been identified as a new class of selective GluR6 antagonists [11]. As a result of a screening of several thiophene esters, 2-amino-4-methyl-5-phenylthiophene derivatives proved to be particularly active. The ethyl ester **1a** ($IC_{50}$ = 0.75 μ*M*) exceeded other esters, e.g., methyl, propyl, with respect to selectivity for the GluR6 kainate receptor [11]. On the basis of these findings, we envisaged cyclic analogs of **1a** and focused on the synthesis of thienopyrimidines (Scheme 1). Selected compounds were also evaluated as inhibitors of human leukocyte elastase (HLE), a serine protease of the chymotrypsin family. Under normal conditions, the activity of HLE is regulated by endogenous inhibitors, but uncontrolled activity of HLE may result in several pathological states, including emphysema, chronic obstructive pulmonary disease, cystic fibrosis and rheumatoid arthritis. HLE inhibitors are therefore of relevance for the therapy of such afflictions [12–15].

## RESULTS AND DISCUSSION

The synthetic routes to bicyclic thiophenes with the common 5-methyl-6-phenyl substitution pattern are outlined in Scheme 1. Using known methods, the fused pyrimidine ring was formed in the reaction of the thiophene-3-carboxamide

**Scheme 1.** Conditions: i) $HC(OC_2H_5)_3$, 12 h, reflux, or $(RCO)_2O$, 1.5 h, reflux; ii) 1. $HC(OC_2H_5)_3$, 12 h, reflux, 2. $POCl_3$, 5 h, reflux; iii) $NH_2CH_2CH_3$ (70% aqueous solution); iv) $P_4S_{10}$ / toluene, 3 h, reflux; v) $NaOCH_2CH_3$ / $CH_2CH_3OH$, 12 h, or $NH_2CH_2CH_3$ (70% aqueous solution) / $CH_2Cl_2$; vi) $SOCl_2$, $CHCl_3$, 30 min, reflux; vii) $NH_2CH_2CH_3$ (70% aqueous solution).



**1b** [16] with ethyl orthoformate. Subsequent treatment with phosphorous oxychloride afforded the 4-chlorothienopyrimidine **3**. The conversion of **3** with sodium ethoxide gave **6a**, in which the carboxylic ester moiety of **1a** is replaced by a semicyclic ethyl imidate substructure. The corresponding replacement by an ethyl amidine substructure in **6b** was accomplished when **3** was treated with ethylamine. The reactions of the thiophene-3-carboxylic acid **1c** [17] with carboxylic anhydrides or carboxylic acid ortho esters provided an access to thieno[2,3-*d*][1,3]oxazin-4-ones **2**. Oxazinones **2** bear two electrophilic sites, C-2 and C-4. Ethylamine exclusively attacked **2** at the C-2 carbon, leading to the formation of amidino carboxylic acids **4**. Treatment of **4** with thionyl chloride furnished compounds **7a**, **b** with N-ethyl lactam structure. The thieno[2,3-*d*][1,3]thiazine-4-thione **5**, accessible by thionation of the corresponding oxazinone **2b** with diphosphorous pentasulfide [17], was reacted with ethylamine to give the thienopyrimidine **8** with N-ethyl thiolactam structure. It should be noted that **8** was directly produced and a corresponding ring-open thiophene derivative could not be isolated. Such a compound with amidine and dithiocarboxylate moieties, formed through an attack of ethylamine at C-2 of **5**, might remain in solution or undergo different transformations, thus accounting for the low yield of **8**. In the mass spectra of the thienopyrimidines **7** and **8**, the molecular peaks appear with highest intensities. Elimination of $C_2H_4$ was the main fragmentation reaction leading to the detection of fragment ions with the anticipated structure **9**. Similarly, the loss the ethyl chain was the predominant fragmentation of **6**.

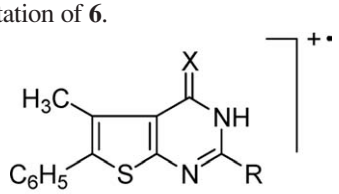


**Table 1**

Inhibition (% of Control) of fractional luminescence or $IC_{50}$ value.

| Compd. | GluR5 | GluR6 |
|---|---|---|
| **2c** | 11 | $IC_{50} = 17$ μ*M* |
| **6a** | 9 | 14 |
| **6b** | −7 | 3 |
| **7a** | −6 | 9 |
| **7b** | 7 | 5 |
| **8** | −11 | 0 |

The thienopyrimidines **6a**,**b**, **7a**,**b**, **8**, and the oxazinone **2c** were evaluated as antagonists of the kainate receptor subtypes GluR5 and GluR6 (Table 1). The experiments were performed with human embryonic kidney (HEK) cells stably expressing the GluR5 and GluR6 receptor. The antagonistic activity was determined by measuring the glutamate-mediated luminescence. The photoprotein aequorin was used as a bioluminescent reporter. The complete luminescence of the cells was determined with the detergent triton X-100 [11]. While the thienopyrimidines **6a**,**b**, **7a**,**b**, and **8**, at a concentration of 10 μ*M*, did barely influence the luminescence signal in the GluR5 and GluR6 assays, 2-ethylthieno[2,3-*d*][1,3]oxazin-4-one (**2c**) inhibited the glutamate response in the GluR6 aequorin assay with an $IC_{50}$ value of 17 μ*M*. Thus, this compound will serve as a lead for further chemical modification to develop new anticonvulsants.

Representatives of 3,1-benzoxazin-4-ones have been reported as alternate substrate inhibitors of HLE [18–20]. It has been shown that the introduction of small alkyl groups connected *via* an O, S, or N atom to the position 2 of the heterocyclic system resulted in potent inhibition [18]. Bioisosteric thieno[1,3]oxazin-4-ones react in an analogous manner as alternate substrate inhibitors with serine proteases and esterases [21–24]. The interaction involves the nucleophilic attack of the active site serine (SerOH), formation of an acyl-enzyme and hydrolytic cleavage to release the modified ring-opened inhibitor and the free enzyme (Fig. 1).

We have selected the thieno[2,3-*d*][1,3]oxazin-4-ones **2a**–**c** and determined their inhibitory activity against HLE. Compound **2c** was identified as an HLE inhibitor ($IC_{50} = 8.8$ μ*M*, Fig. 2), whereas **2a** was not sufficiently soluble in the assay medium, and **2b** failed to inhibit HLE ($IC_{50} > 40$ μ*M*). It can be suspected, that the ethyl group in **2c** interacts with the S1 pocket of HLE, thus reflecting the primary substrate specificity for small aliphatic amino acids at P1 position of a substrate.

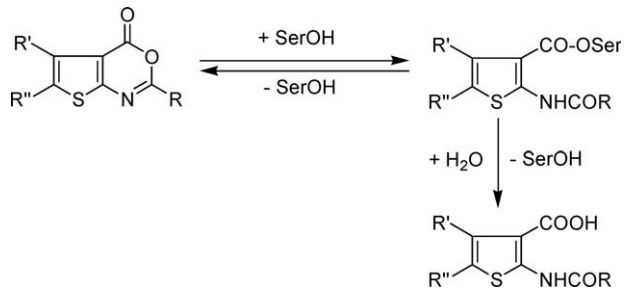

**Figure 1.** Enzyme-catalyzed conversion of thieno[2,3-*d*][1,3]oxazin-4-ones.

To elucidate the mechanism of elastase inhibition by **2c**, we examined a possible enzyme-catalyzed degradation of the inhibitor by means of HPLC. Compound **2c** was incubated at 25°C, pH 7.8, with HLE in a 200-fold higher concentration compared to that used in the inhibition assays. Despite the inhibition of HLE by **2c**, an accelerated hydrolysis in the presence of such a high amount of enzyme could be expected [24]. However, the decrease in concentration of **2c** was weak (<20% within 4 h) and similarly observed in the control experiment, where **2c** was incubated in the absence of HLE. It can therefore be concluded that **2c** does not act as an alternate substrate inhibitor of HLE, but most probably as a competitive noncovalent inhibitor. This behavior differs from that of thieno[1,3]oxazin-4-ones with alkoxy, alkylthio, or (di)alkylamino substituents at 2-position. Such compounds have been characterized [22] to interact with HLE in the way outlined in Figure 1.

## EXPERIMENTAL

Melting points were obtained on a Büchi melting point apparatus 535 and are uncorrected. Mass spectra (EI, 70 eV) were measured on a VG Analytics VG ZAB-HSQ spectrometer. ESI-HRMS spectra were recorded on a Bruker Daltonics

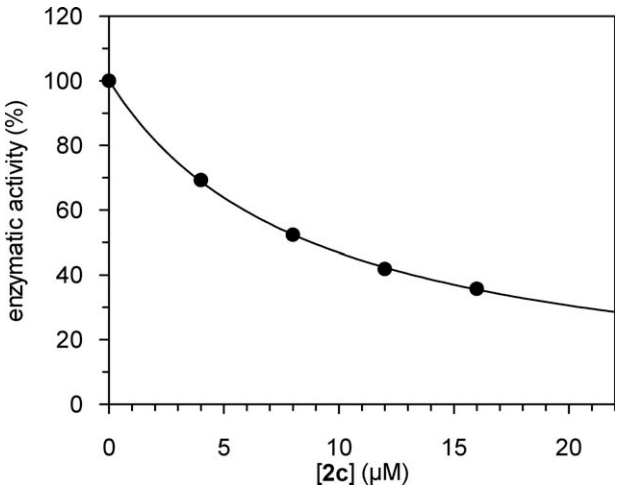

**Figure 2.** Inhibition of HLE by **2c** in the presence of 100 μ*M* of the chromogenic substrate MeO-Suc-Ala-Ala-Pro-Val-pNA. The data are mean values of duplicate measurements. The reactions were followed over 10 min, and the rates, *v*, were determined by linear regression. The rates in absence of inhibitor, $v_0$, were set to 100%. Nonlinear regression according to the equation $v = v_0/([I]/(IC_{50} + 1)$ gave a value $IC_{50} = 8.8 \pm 0.1$ μ*M*.

7T Apex II FT-ICR mass spectrometer. $^1$H NMR spectra were recorded on a Varian Gemini-300 spectrometer at 300.08 MHz. $^{13}$C NMR spectra were recorded on a Varian Gemini-300 spectrometer at 75.45 MHz. IR spectra were recorded on a Perkin–Elmer FT-IR PC 16 instrument. 5-Methyl-6-phenylthieno[2,3-*d*][1,3]oxazin-4-one (**2a**) [17], 2,5-dimethyl-6-phenylthieno[2,3-*d*][1,3]oxazin-4-one (**2b**) [17], and 4-chloro-5-methyl-6-phenylthieno[2,3-*d*]pyrimidine (**3**) [16] were prepared as reported.

**2-Ethyl-5-methyl-6-phenylthieno[2,3-*d*][1,3]oxazin-4-one (2c).** A mixture of compound **1c** [11] (2 g, 8.58 mmol) and propionic anhydride (10 mL, 78 mmol) was refluxed for 90 min. The precipitate, formed after cooling, was filtered off, dried, and recrystallized from ethanol. Yield 1.2 g (34%). Colorless crystals, mp 99–100°C; ms: *m/z* (%) 271 ($M^{+\cdot}$, 100), 242 (40); $^1$H NMR (deuteriochloroform): δ 1.33 (t, 3H, $CH_3$, $J$ = 7.5 Hz), 2.56 (s, 3H, $CH_3$), 2.72 (q, 2H, $CH_2$, $J$ = 7.5 Hz), 7.39–7.46 (m, 5H, phenyl-H); ir (potassium bromide): ν 1744 (C=O), 1596, 1158–1075 cm$^{-1}$. Anal. Calcd. for $C_{15}H_{13}NO_2S \times 0.5\ H_2O$: C, 64.26; H, 5.03; N, 5.00; S, 11.44. Found C, 64.03; H, 5.16; N, 5.37; S, 11.48.

**2-(Ethylaminomethylenamino)-4-methyl-5-phenylthiophene-3-carboxylic acid (4a).** Ethylamine (10 mL of a 70% aqueous solution, 0.126 mol) was added dropwise to compound **2a** [17] (1.4 g, 5.7 mmol). The mixture was kept at 0°C until the crystallization was finished. The precipitate was separated and dried to obtain a crude product which was not further purified. Yield 1.1 g (70%). Beige solid, mp 180–183°C; ms: *m/z* (%) 288 ($M^{+\cdot}$, 97), 215 (100); ESI-HRMS: *m/z* 577.19433 ($[2M+H]^+$)$^\cdot$ ($C_{30}H_{33}N_4O_4S_2^+$ requires 577.19377); 289.10042 ($[M+H]^+$)$^\cdot$ ($C_{15}H_{17}N_2O_2S^+$ requires 289.10052); 599.17642 ($[2M+Na]^+$)$^\cdot$ ($C_{30}H_{32}N_4NaO_4S_2^+$ requires 599.17572); 311.08269 ($[M+Na]^+$)$^\cdot$ ($C_{15}H_{16}N_2NaO_2S^+$ requires 311.08247); $^1$H NMR (DMSO-$d_6$): δ 1.16 (t, 3H, $CH_3$, $J$ = 7.2 Hz), 2.36 (s, 3H, $CH_3$), 3.29 (q, 2H, $CH_2$, $J$ = 7.0 Hz), 7.38–7.50 (m, 5H, phenyl-H), 8.14 (s, 1H, CH), 8.34 (s, br, 0.5H, NH, exchangeable with $D_2O$), 14.30 (s, br, 0.5H, OH, exchangeable with $D_2O$); ir (potassium bromide): ν 3221 (N—H), 3069–2873, 1694 (C=O), 1632, 1577 cm$^{-1}$.

**2-(1-Ethylaminopropane-1-ylidenamino)-4-methyl-5-phenylthiophene-3-carboxylic acid (4b).** Compound **4b** was prepared from **2c** (1.2 g, 4.4 mmol) following the aforementioned procedure. Yield 1.2 g (89%). Beige solid, mp 152–155°C (crude product); ms: *m/z* (%) 316 ($M^{+\cdot}$, 18), 242 (100); $^1$H NMR (DMSO-$d_6$): δ 1.20 (t, 6H, 2 $CH_3$, $J$ = 7.5 Hz), 2.41 (s, 3H, $CH_3$), 2.7 (q, 2H, $CH_2$, $J$ = 7.8 Hz), 3.27 (q, 2H, $CH_2$, $J$ = 7.5 Hz), 7.40–7.54 (m, 5H, phenyl-H), 8.42 (s, br, 1H, NH, exchangeable with $D_2O$); ir (potassium bromide): ν 3237 (N—H), 2978–2937, 1684 (C=O), 1592, 1490, 1238, 1073 cm$^{-1}$. Anal. Calcd. for $C_{17}H_{20}N_2O_2S$: C, 64.53; H, 6.37; N, 8.85; S, 10.13. Found C, 64.22; H, 6.34; N, 8.79; S, 10.07.

**2,5-Dimethyl-6-phenylthieno[2,3-*d*][1,3]thiazin-4-thione (5) [17].** Compound **2b** [17] (2.57 g, 10 mmol) was dissolved in 80 mL of dry toluene. After addition of diphosphorous pentasulfide (22.2 g, 100 mmol), the mixture was refluxed for 2 h. The formed inorganic precipitate was filtered off and washed several times with hot toluene. The combined toluene solutions were evaporated and the precipitated crude product was separated and recrystallized from ethanol. Yield 1.16 g (40%). Red crystals, mp 135°C ($C_2H_5OH$); ms: *m/z* (%) 291 ([$M^{+\cdot}$ + 2], 26), 289 ($M^{+\cdot}$, 100), 274 (10), 256 (12), 247 (15), 230 (11), 224 (12), 215 (41), 203 (13), 184 (9), 171 (31), 127 (10), 121 (17), 115 (27), 89 (9), 77 (14); $^1$H NMR (deuteriochloroform): δ 2.61 (s, 3H, $CH_3$), 2.78 (s, 3H, $CH_3$), 7.48–7.51 (m 5H, phenyl-H); $^{13}$C NMR (deuteriochloroform): δ 19.0 (5-$CH_3$), 25.5 (2-$CH_3$), 127.1 (C-4a), 128.7 (C-4′), 128.9 (C-2′, C-6′), 130.1 (C-3′, C-5′), 130.8 (C-6), 132.1 (C-1′), 132.8 (C-5), 136.8 (C-7a), 170.1 (C-2), 201.6 (C=S); ir (potassium bromide): ν 1545, 1262, 1052 cm$^{-1}$.

**4-Ethoxy-5-methyl-6-phenylthieno[2,3-*d*]pyrimidine (6a).** Compound **3** [16] (0.5 g, 1.9 mmol) was refluxed in 10 mL of a solution of sodium ethoxide in ethanol (1 mol/L) for 12 h. The solvent was evaporated, the precipitate was isolated, washed with water and recrystallized from ethanol. Yield 0.4 g (78%). Colorless crystals, mp 103°C ($C_2H_5OH$); ms: *m/z* (%) 270 ($M^{+\cdot}$, 100), 255 (36), 242 (78); $^1$H NMR (DMSO-$d_6$): δ 1.40 (t, 3H, $CH_3$, $J$ = 7.2 Hz), 2.50 (s, 3H, $CH_3$), 4.53 (q, 2H, $CH_2$, $J$ = 7.2 Hz), 7.44–7.52 (m, 5H, phenyl-H), 8.60 (s, 1H, CH); $^{13}$C NMR (deuteriochloroform): δ 14.9 ($CH_3$), 15.4 ($CH_3$), 63.3 ($OCH_2$), 120.2 ($C_q$), 126.3 ($C_q$), 129.3 (CH, Ph), 129.7 (2 × CH, Ph), 130.2 (2 × CH, Ph), 133.4 ($C_q$), 135.4 ($C_q$), 153.7 (CH), 164.7 ($C_q$), 167.1 ($C_q$); ESI-HRMS: *m/z* 271.09014 ($[M+H]^+$)$^\cdot$ ($C_{15}H_{15}N_2OS^+$ requires 271.08996); 563.15462 ($[2M+Na]^+$)$^\cdot$ ($C_{30}H_{28}N_4NaO_2S_2^+$ requires 563.15459); 293.07211 ($[M+Na]^+$)$^\cdot$ ($C_{15}H_{14}N_4NaOS^{+\cdot}$ requires 293.07190); ir (potassium bromide): ν 3446 (br, traces from water), 3064–2978, 1555–1450, 1332, 1063, 1044 cm$^{-1}$. Anal. Calcd. for $C_{15}H_{14}N_2OS \times H_2O$: C, 62.47; H, 5.59; N, 9.71; Found C, 62.69; H, 4.96; N, 9.67.

**4-Ethylamino-5-methyl-6-phenylthieno[2,3-*d*]pyrimidine (6b).** Compound **3** [16] (0.3 g, 1.15 mmol) was dissolved in dichloromethane (3 mL) and treated with ethylamine (100 mL of a 70% aqueous solution, 1.26 mol). If no crystallization occurred, water was added to the mixture. The precipitate was filtered off, dried, and recrystallized from ethanol. Yield 0.2 g (65%). Yellow crystals, mp 155–158°C ($C_2H_5OH$); ms: *m/z* (%) 269 ($M^{+\cdot}$, 100), 254 (27), 240 (30); $^1$H NMR (deuteriochloroform): δ 1.35 (t, 3H, $CH_3$, $J$ = 7.2 Hz), 2.63 (s, 3H, $CH_3$), 3.66–3.75 (m, 2H, $CH_2$, $J$ = 7.2 Hz), 5.57 (s, br, NH, exchangeable with $D_2O$), 7.41–7,50 (m, 5H, phenyl-H), 8.49 (s, 1H, CH); ir (potassium bromide): ν 3419 (NH), 2988–2863, 1574–1460, 1128–1012 cm$^{-1}$. Anal. Calcd. for $C_{15}H_{15}N_3S \times 0.5\ C_2H_5OH$: C, 65.72; H, 6.20; N, 14.37; S, 10.96. Found C, 65.30; H, 5.76; N, 14.75; S, 11.23.

**3-Ethyl-5-methyl-6-phenylthieno[2,3-*d*]pyrimidin-4-one (7a).** Compound **4a** (0.3 g, 1 mmol) was dissolved in anhydrous chloroform (10 mL). After addition of thionyl chloride (1.19 g, 10 mmol), the mixture was refluxed for 30 min. The solvent was evaporated at room temperature, the precipitate formed was filtered off, and dried. The crude product was purified by column chromatography on silica gel (63–200 μm, Merck) with ethanol. Yield 0.087 g (30%). Red solid, mp 90°C ($C_2H_5OH$); ms: *m/z* (%) 270 ($M^{+\cdot}$, 100), 242 (42); ESI-HRMS: *m/z* 541.17313 ($[2M+H]^+$)$^\cdot$ ($C_{30}H_{29}N_4O_2S_2^+$ requires 541.17264); 271.08999 ($[M+H]^+$)$^\cdot$ ($C_{15}H_{15}N_2OS^+$ requires 271.08996); 563.15500 ($[2M+Na]^+$)$^\cdot$ ($C_{30}H_{28}N_4NaO_2S_2^+$ requires 563.15459); 293.07208 ($[M+Na]^+$)$^\cdot$ ($C_{15}H_{14}N_4NaOS^+$ requires 293.07190); $^1$H NMR (deuteriochloroform): δ 1.43 (t, 3H, $CH_3$, $J$ = 7.2 Hz), 2.64 (s, 3H, $CH_3$), 4.07 (q, 2H, $CH_2$, $J$ = 7.3 Hz), 7.39–7.47 (m, 5H, phenyl-H), 7.97 (s, 1H, CH); $^{13}$C NMR (deuteriochloroform): δ 14.9 ($CH_3$), 15.4 ($CH_3$), 42.1 ($NCH_2$), 124.4 ($C_q$), 128.3 (CH, Ph), 128.9 (2 × CH, Ph),

129.9 (2 × CH, Ph), 130.3 ($C_q$), 133.6 ($C_q$), 135.5 ($C_q$), 146.0 (CH), 158.5 ($C_q$), 163.0 ($C_q$); ir (potassium bromide): ν 1666, 1658 (C=O), 1600, 1576, 1234–1083 $cm^{-1}$. Anal. Calcd. for $C_{15}H_{14}N_2OS$: C, 66.64; H, 5.22; N, 10.36. Found: C, 66.32; H, 5.40; N, 10.13.

**2,3-Diethyl-5-methyl-6-phenylthieno[2,3-*d*]pyrimidin-4-one (7b).** Thionyl chloride (2.38 g, 20 mmol) was added to a solution of **4b** (1.2 g, 3.8 mmol) in anhydrous chloroform (30 mL). The mixture was refluxed for 30 min. The solvent was evaporated at room temperature. The precipitate was filtered off and dried. The crude product was thoroughly washed with acetone and recrystallized from acetonitrile. Yield 0.5 g (40%). Beige solid, mp 175–179°C ($CH_3CN$); ms: *m/z* (%) 298 ($M^{+\cdot}$, 100), 270 (69), 215 (66); $^1$H NMR (DMSO-$d_6$): δ 1.24–1.32 (m, 6H, 2 $CH_3$, $J$ = 7.2 Hz, $J$ = 6.9 Hz), 2.53 (s, 3H, $CH_3$), 2.93 (q, 2H, $CH_2$, $J$ = 7.2 Hz), 4.10 (q, 2H, $CH_2$, $J$ = 6.9 Hz), 7.44–7.53 (m, 5H, phenyl-H); ir (potassium bromide): ν 3434 (br, traces of water), 1670 (C=O), 1596, 1543 $cm^{-1}$. Anal. Calcd. for $C_{17}H_{18}N_2OS$: C, 68.43; H, 6.08; N, 9.39, S 10.74. Found C, 68.16; H, 5.83; N, 8.92; S, 10.27.

**3-Ethyl-2,5-dimethyl-6-phenylthieno[2,3-*d*]pyrimidine-4-thione (8).** Ethylamine (3 mL of a 70% aqueous solution, 0.04 mol) was added dropwise to **5** (0.4 g, 1.38 mmol). The mixture was kept at 0°C until the crystallization was finished. The precipitate was separated and dried. Yield 0.1 g (24%). Light yellow crystals, mp 89–91°C ($CH_3CN$); ms: *m/z* (%) 302 ([$M^{+\cdot}$ + 2], 13), 300 ($M^{+\cdot}$, 100), 272 (51); $^1$H NMR (DMSO-$d_6$): δ 1.35 (t, 3H, $CH_3$, $J$ = 6.9 Hz), 2.74 (s, 3H, $CH_3$), 2.81 (s, 3H, $CH_3$), 4.79 (s, br, 2H, $CH_2$), 7.52–7.59 (m, 5H, phenyl-H), ir (potassium bromide): ν 3440 (br, traces of water), 2974–2926, 1557 (strong, C=S), 1493, 1444, 1191, 1093 $cm^{-1}$. Anal. Calcd. for $C_{16}H_{16}N_2S_2 \times 0.5\ H_2O$: C, 62.10; H, 5.54; N, 9.05; S, 20.72. Found C, 62.40; H, 5.23; N, 9.11; S, 20.88.

**Kainate receptor-aequorin assay.** Human embryonic kidney cells (HEK 293 cells) which stably express the GluR5 or GluR6 receptor, respectively, together with the luminescent protein aequorin were used as screening assay for kainate receptor antagonists. GluR5- (or GluR6-) and aequorin-expressing HEK 293 cells were cultivated in a MEM growth medium together with Earle's salts and Glutamax-I (Life Technologies), containing 10% FKS, 1% nonessential amino acids, 100 IU/mL penicillin, 100 μg/mL streptomycin, 600 μg/mL G 418 (Calbiochem) and 500 n*M* ouabaine. One day before the measurement, 60,000 cells per cavity were seeded into white, nontransparent 96-well microtiter plates (Costar). On the test day, cells were incubated with 5 μ*M* coelenterazine for 1 h at 37°C. Then the medium was poured off and replaced by 80 μL assay buffer, and 10 μL test compound was added. The assay buffer contained 150 m*M* NaCl, 2.5 m*M* KCl, 10 m*M* HEPES, 1 m*M* $MgCl_2$, 10 m*M* glucose, 0.3 mg/mL concanavaline A (ConA) and (for GluR6) 100 m*M* $CaCl_2$ (pH = 7.3). Afterwards the cells were incubated for 10 min at room temperature.

The luminescence measurement was performed in a luminometer (LUMIstar, BMG) equipped with two computer-controlled injectors, over a period of 26 s per cavity (13 intervals of 2 s). After the first second 10 μL of a 2.75 m*M* glutamate-solution in assay buffer was injected (to receive a glutamate concentration of 275 μ*M* per cavity, according to the $EC_{50}$ value of glutamate for GluR6) or 10 μL of 0.8 m*M* glutamate (due to 80 μ*M* = $EC_{50}$ for GluR5). A second injection of 100 μL triton X-100 in assay buffer (without $Ca^{2+}$) was carried out after 20 s into the same cavity.

The calculation of specific channel activity induced by an agonist was determined as fractional luminescence, which was calculated from respective sum of signals of agonist- and triton-induced luminescence. For determination of the $IC_{50}$ value, a Hill plot (4-parameter model) was used.

**HLE inhibition assay.** The spectrophotometric assay for HLE was done on a Varian Cary 50 Bio UV/VIS spectrometer with a cell holder equipped with a constant temperature water bath. HLE was available from a previous study [24]. Reactions were followed at 405 nm at 25°C for 10 min. Stock solutions of the inhibitors were prepared in DMSO. $IC_{50}$ values were calculated from the linear steady-state turnover of the substrate. Assay buffer was 50 m*M* sodium phosphate buffer, 500 m*M* NaCl, pH 7.8. An enzyme stock solution of 50 μg/mL was prepared in 100 m*M* sodium acetate buffer, pH 5.5 and diluted with assay buffer. A 50 m*M* stock solution of the chromogenic substrate MeOSuc-Ala-Ala-Pro-Val-pNA (Bachem, Bubendorf, Switzerland) was prepared in DMSO and diluted with assay buffer containing 10% DMSO. The final concentration of the substrate was 100 μ*M*, of DMSO was 1.5% and of HLE was 25 ng/mL. Into a cuvette containing 890 μL assay buffer, 10 μL of an inhibitor solution and 50 μL of a substrate solution were added and thoroughly mixed. The reaction was initiated by adding 50 μL of the HLE solution (500 ng/mL).

**HLE incubation experiment.** Compound **2c**, dissolved in acetonitrile, and a solution of HLE were added to assay buffer and incubated for 4 h at 25°C in a quartz cuvette. The final concentration of **2c** was 20 μ*M*, of acetonitrile was 2% and of HLE was 5 μg/mL. In the control experiment, **2c** was incubated in assay buffer without HLE. In 60-min intervals, 10 μL aliquots were injected into the HPLC system (Dionex P580, Phenomenex Gemini 5 μ, $C_{18}$, mobile phase A: $H_2O$/acetonitrile/$CF_3CO_2H$ (475:25:0.3), mobile phase B: $H_2O$/acetonitrile/tetrahydrofuran/$CF_3CO_2H$ (25:465:10:0.3), gradient 0–25 min: 70–10% A, 30–90% B, 27–30 min: 70% A, 30% B, UV detection, 310 nm). The retention time of **2c** was 17.33–17.35 min.

**Acknowledgment.** The work was supported by the European Fund for Regional Development 2000–2006, sector technology support, and by the Freistaat Sachsen, project number SAB8093. C.M.G.T. and M.G. are grateful to the German Research Foundation, Graduate College 677 for financial support.

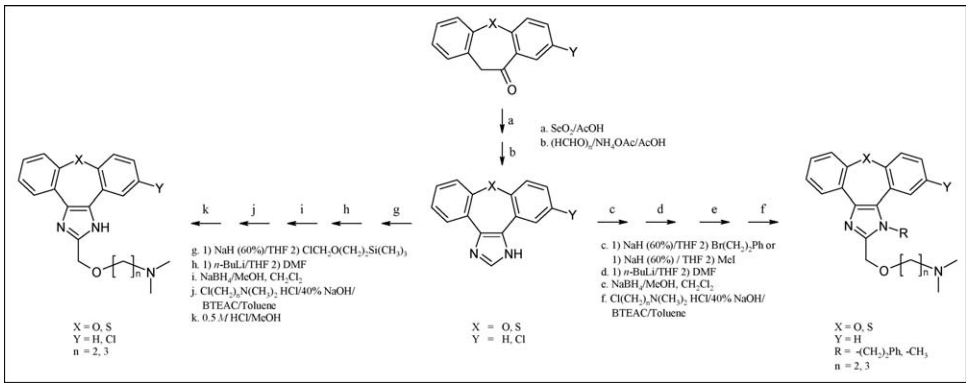
Received September 23, 2009
DOI 10.1002/jhet.376
Published online 3 May 2010 in Wiley InterScience (www.interscience.wiley.com).



A series of tetracyclic imidazole derivatives **9a–9v** and **10a–10h** are prepared by multistep route starting from the known tricyclic diketones **2a–2d**. Intermediary dibenzooxepin[4,5-*d*]imidazoles (**3a**, **3c**) and dibenzothiepin[4,5-*d*]imidazoles (**3b**, **3d**) are *N*-protected to **4e, 4f** and to the isomeric compounds **5a**, **5b** and **6a**, **6b**. The isomeric compounds **5** and **6** are separated. Compounds **4**, **5,** and **6** are formylated at C(2) to afford **7a–7j**. In the last steps, aldehyde group is reduced, then alkylated to the two sets of isomeric ω-dimethylaminoalkyl derivatives **9a–9v**. *N*-deprotection of **9i–9v** led to the compounds **10a–10h**. Assignment of the *syn*/*anti* structure to **5a** and **6a** was supported by 1D selective ROESY NMR spectra, whereas conformational mobility for the selected representatives **8a** and **8b** is studied by dynamic NMR. Activation energies (energy barriers for interconversion) are determined to be ∼11.5 and 16.2 kcal/mol, respectively. A series of derivatives **9** and **10** were tested *in vitro* for their anti-inflammatory activity.

## INTRODUCTION

In our continuing efforts toward the development of disease modifying treatments for rheumatoid arthritis (RA), we are targeting inhibition of overproduction of tumor necrosis factor alpha cytokine (TNF-α) that is recognized as a key cytokine in RA progression. A small molecule inhibitor of TNF-α would be a novel potent anti-inflammatory drug having this distinguished mechanism of action. In the frame of our project aimed toward synthesis, structure determination of tetracyclic imidazoles, and screening of their activity on the selected biological targets, we entered the study of a large series of dibenzo-oxepin- and dibenzo-thiepin imidazole derivatives. In our previous articles we have reported on the synthesis, properties, and preliminary biological results of oxa-, aza-, and thia-dibenzoazulenes, characterized by the annulated furane **I** [2], pyrrole **II**, **III** [3], and thiophene **IV**, **V** [4] ring (Fig. 1). Preliminary results have revealed activity of these polycyclic systems in the *in vitro* anti-inflammatory test in lipopolysaccharide (LPS) induced TNF-α production in human peripheral blood mononuclear cells (hPBMCs) that encouraged us to extend our effort on other five membered heterocyclic systems [5,6].

Generally, structural complexity of this specific class of recently studied non-steroidal anti-inflammatory compounds increases from diaryl-substituted heterocycles general formulae **VI**, to polycondensed heterocyclic structures **VII**. Representatives of the former are vicinaly substituted polycyclic aryl/pyridine-4-yls, potent inhibitors of p38 MAP kinase (p38) [7,8], while 2-substituted-4,5-diarylimidazoles **VIII** are claimed as *in vivo* anti-inflammatory active structures (Fig. 2) [9–14].

Moreover, polycondensed heterocycles with non-aromatic dibenzoazulene core and annelated 5-membered heterocycles are repeatedly claimed as anti-inflammatory active compounds. Among them are 2-substituted-1*H*-phenanthro[9,10-*d*]imidazoles **IX** [15], 2-substituted dibenzo[2,3:6,7]thiepino[4,5-*d*]imidazoles **X** [16–20], 2-substituted dibenzo[2,3:6,7]oxepino[4,5-*d*]imidazoles, and their corresponding sulfoxides and sulfones **XI** (Fig. 3) [21].

**Figure 3.** Polycondensed heterocycles with non-aromatic dibenzoazulene core.

Process for preparation of 2-formylimidazole acetals is also claimed [22], as well as 4,5-disubstituted imidazole derivatives and their use in CSBP/PK/p38 kinase mediated diseases [13]. First synthesis of tetracyclic, polycondensed imidazoles, presented by the formulae **X**, was reported by Lombardino [17], based on the general imidazole synthesis of Davidson *et al*. [23]. The same author claimed that a wide range of polycyclic compounds have anti-inflammatory and some other activities [16,18–20]. This method has been recently improved using microwave irradiation [24,25].

We have extended our effort to the imidazo-derivatives general formulae **XII**, wherein an extra basic unit was introduced at the imidazole ring to improve physicochemical properties of this series of compounds (Fig. 4).

**Figure 4.** Novel tetracyclic imidazole derivatives.

## RESULTS AND DISCUSSION

**Chemistry.** Tetracyclic imidazoles **3a–3d** were prepared starting from the known 11*H*-dibenzo[*b*,*f*]oxepin-10-ones **1a**, **1c** or 11*H*-dibenzo[*b*,*f*]thiepin-10-ones **1b**, **1d**, cyclic ketones characterized by activated methylene group in the α-position to carbonyl group [16–20]. This group was oxidized by selenium dioxide to give α-diketones **2a–2d.** Synthesis of imidazoles **3a–3d** was completed by condensation of dicarbonyl compounds **2a–2d** with paraformaldehyde and ammonium acetate in acetic acid, according to Davidson *et al*., Scheme 1 [23].

*N*-Alkylated compounds **4a–4f** were obtained from **3a**, **3b** using a modified method by Wolkenberg *et al*. [25], on treatment with sodium hydride in tetrahydrofuran at 0°C followed by alkylation at elevated temperatures, Scheme 2 [26].

We have used 2-trimethylsilyl-ethoxymethyl (SEM) as effective protecting group for imidazole N(1) atom

which was introduced using (2-trimethylsilyl)-ethoxymethyl chloride (SEMCl) [27].

In the polycondensed imidazole derivatives **3a**, **3b** (Y = H) two tautomeric forms are equivalent and, therefore, single isomers **4a–4f** are obtained on alkylation. However, *N*(1)-alkylation of **3c**, **3d** affords structural isomers **5** and **6**, Scheme 3.

*N*-Trimethylsylil-ethoxymethylated compounds **5a**, **6a** and **5b**, **6b** were separated by purification on silica gel SPE cartridge using step gradient system for elution with ethyl acetate/*n*-hexane. In both cases, regioisomers **5a**, **6a** and **5b**, **6b** are obtained in ~1:1 ratio, revealing minor effect of electron-withdrawing chlorine in the *meta*-position of the aromatic ring. 1D NMR spectra of compounds in the isomeric series **5** and **6** did not give any clue on exact position of the side-chain on N(1) atom of imidazole. Straightforward determination required combined use of 2D NMR techniques and 1D selective ROESY spectrum, as exemplified for the compounds **5a** and **6a** (Fig. 5).

Correlation peaks from COSY, HMBC, HMQC, and 2D TPPI NOESY spectra afforded ambiguous information due to the overlap of key signals, so final solution for this problem came from the analysis of the selective 1D ROESY spectrum. Selective excitation was applied to methylenic protons of N—$CH_2$—O unit at 5.356 and 5.372 ppm. NOE interactions were expected between methylenic protons of N—$CH_2$—O group and *ortho*-protons in the vicinal aromatic ring, $H_B$ for **5a** and $H_A$ for **6a**, which are close enough to engage in dipolar interaction through space, (Fig. 6).

Protons $H_A$ and $H_B$ in both **5a** and **6a** have very close chemical shifts at the applied magnetic field, and are unequivocally assigned on the basis of their coupling patterns. Thus, $H_A$ is coupled with *ortho*- and *meta*-proton giving dd at 7.84 ppm, whereas $H_B$ is coupled only with *meta*-situated proton giving doublet at 7.86 ppm. On selective excitation of methylenic protons of N—$CH_2$—O unit in **6a** doublet of $H_B$ proton disappeared, while resonance lines for proton $H_A$ remained, revealing its vicinity to the methylenic group, and thus *syn* (*cis*) orientation of the side chain on N(1) of imidazole ring to the aromatic ring that has no chlorine in *meta*-position to the annulated heterocycle.

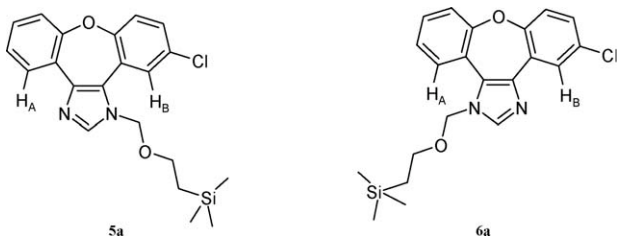

**Figure 5.** Regioisomeres determined by 2D NMR techniques and 1D selective ROESY spectrum.

Having this result in hands, ulterior synthetic steps have been performed on the separated isomers with known structure. From **4**, **5,** and **6** are obtained C(2) formylated derivatives **7** on generation of carbanion at C(2) of imidazole ring by *n*-butyllithium/tetrahydrofuran at −78°C, followed by treatment with DMF at r.t., Scheme 4 [9,28].

Reduction of **7a–7h** with sodium borohydride at r.t. afforded benzylic alcohols **8a–8h**. From **7i** and **7j** under the same conditions are obtained **8i** and **8j**. Both sets of hydroxymethyl imidazole derivatives are converted to dialkylaminoalkyl ethers **9a–9v** on treatment with ω-chloroalkyl-dimethylamines under phase transfer conditions in the presence of benzyltriethylammonium chloride (BTEAC), Scheme 5 [4,29].

Products **10a–10h** are obtained on cleavage of 2-(trimethylsilyl)ethoxymethyl group with 0.5*M* hydrochloric acid/methanol, Scheme 6 [9].

**Conformational properties of representative oxepin (8a) and thiepin (8b) tetracycles.** Conformational mobility and preferred conformation in solution of the 7-membered ring play an important role in biological activity of non-aromatic polycyclic compounds. Illustrative example represents octoclothepin **14** (Fig. 7), centrochiral, and planar-chiral compound with dibenzo-thiepine tricyclic core, wherein two conformers with inversed 7-membered ring are diastereotopic. An early study of (*S*)-**14** (Fig. 7), neuroleptic compound that binds on dopamine D-2 receptor [30], has revealed that stable conformation of (*S*)-**14**, which is responsible for the dopamine D-2 receptor antagonism, is significantly different from the one observed in the crystal [31].

On the other hand, conformational mobility of dibenzothiepines with sulfide **1b** and sulfoxide **15** unit in the bridge, was studied by dynamic NMR [32]. Huge difference in the activation energies for ring-inversion was observed; 9.3 kcal/mol for **1b** and 23 kcal/mol for **15**, revealing that at ambient temperature only the later may be separated into stable conformers (Fig. 8).

For many condensed non-aromatic heterocycles with one heteroatom in the 7-membered ring correlation between conformational properties and biological activities are studied. Detailed study of *N*-acylbenzazepines with interesting pharmacological properties [33], by dynamic NMR is an instructive case [34–36]. For dihydrobenz/*b*/azepines thermodynamic parameters for conformation equilibria are determined by dynamic NMR [37,38].

In view of the importance of conformational mobility of non-aromatic polycondensed heterocycles, we have determined difference in conformational mobility of the two representatives of oxepines and thiepines, compounds **8a** and **8b**, respectively. They are selected due

to their well resolved peaks for methylenic protons $H_A$, $H_B$, present in the 5-member chelate ring C(2)─$CH_AH_B$─O─H···N(3) formed by hydrogen bond to N(3) atom, formulae **8a**, **8b** (Fig. 9).

On the basis of the reported results, we expected notable difference of the energy for conformational inversion for these two compounds. To our satisfaction, dynamic NMR study has revealed two different temperature intervals for the collapse of the AB(X) system into $A_2$ system of the methylenic protons. Series of proton NMR spectra acquired in temperature range where the coalescence of proton signals occurs are shown in the Figures 10 and 11.

Activation energies (energy barriers for interconversion) for compounds **8a** and **8b** are determined and results are presented in Table 1.

**Biology.** Among many discovered biological targets in the past 30 years, TNF-α, interleukin 1 (IL-1), p38, and COX-2 enzyme belong to the group of the most studied and the most relevant mediators of

inflammation [39]. Overproduction inhibition of these cytokines which are responsible for inflammation has been proposed as a disease modifying approach towards the treatment of inflammatory disorders. The over-expression of TNF-α cytokine has been implicated in a number of serious inflammatory disorders. Consequently, agents that inhibit the production of TNF-α can decrease levels of inflammatory response, and thereby reduce inflammation and prevent further tissue destruction.

From medicinal chemistry point of view, connecting previous knowledge about anti-inflammatory properties of some compounds with today's understanding of important key players in inflammation mechanism could provide rational approach to the lead molecules that may be further optimized for better activity and

selectivity profile and desirable pharmacokinetic properties. Along this line we have continued our project of the synthesis of tetracyclic target structures and their testing on inhibition of LPS stimulated TNF-α production. *In vitro* biological tests are performed on some intermediates and all tetracyclic compounds **9** and **10** to test their ability to inhibit TNF-α production in LPS-activated hPBMC assay [5,6].

**Table 1**

Activation energies for compounds **8a** and **8b**.

| Compound | **8a** | **8b** |
|---|---|---|
| Solvent | Acetone-$d_6$ | DMSO-$d_6$ |
| Starting temperature (°C) | 25 | 25 |
| Ending temperature (°C) | −60 | 80 |
| Coalescence temperature $T_C$ (°C) | −40 | 50 |
| Separation between signals Δν (Hz) | 17.3 | 4.9 |
| Coupling constant $^2J_{A,B}$ (Hz) | 13.1 | 13.1 |
| Rate constant at the coalescence temperature $k_C$ (Hz) | 80.9 | 72.1 |
| Gibbs energy $\Delta G_C^{\ddagger}$ (kcal/mol) | 11.5 | 16.2 |

$^{\ddagger}$ Activated complex, transition state.

Compounds possessing alkoxymethylene linker (ether) at position C(2) on imidazole ring showed potency to inhibit TNF-α production *in vitro* in low micromolar range with IC50 values for the most potent compounds in the range of 1–3 μ*M*.

According to obtained results dibenzo-oxepin- and dibenzo-thiepin imidazole derivatives were recognized as a novel class of tetracyclic compounds with anti-inflammatory activity through specific inhibition of TNF-α secretion.

## EXPERIMENTAL

**Chemistry.** Commercial reagents were used as received without additional purification. All used chemicals and solvents were p.a. purity. Differential scanning calorimetry data were collected on a Mettler Toledo differential scanning calorimeter 822$^e$/500 using Mettler Toledo STAR$^e$ software. Samples about 5 mg were weighed into Al-pans (40 μL) with pierced cover. Dry nitrogen was used as purge gas (purge: 50 mL/min). The heating rate of 10°C/min over the range 25–300°C was used. The instrument was calibrated using certified indium and zinc. IR spectra were recorded as potassium bromide (KBr) pastilles or as a film on a sodium chloride plate, on a Nicolet Magna IR 760 FT IR-spectrophotometer, and on a Bruker Vertex 70 as ATR (ZnSe) powder or film cast from DCM solution. One- and two-dimensional NMR spectra were recorded on Bruker Avance DPX 300 (300 MHz), Bruker Avance DRX 500 (500 MHz), and Bruker Avance III 600 (600 MHz) spectrometers. Deuterated dimethylsulfoxide (DMSO-$d_6$) and deuterated chloroform ($CDCl_3$) were used as solvents and tetramethylsilan (TMS) as an internal standard. Purity of the compounds was obtained on a Waters HPLC-UV/MS Autopurification System with a Micromass ZQ and a Waters 996 Photodiode Array Detector, and on Varian Chrompack CP-3800 Gas Chromatograph with a Varian Chrompack Saturn 2000 MS/MS detector. HRMS data were acquired using Q-TOF 2 Waters system. Thin layer chromatography (TLC) was run on Merck Silica gel 60 $F_{254}$ plates, spots detected with UV light at 254 and/or 365 nm. Proportions of solvents used for TLC are by volume.

Products were purified using Solid Phase Extraction (SPE) columns on an automated SPE purification system (FlashMaster II).

**General procedure for reaction of ketones 1 with selenium dioxide (preparation of compounds 2).** To the suspension of selenium dioxide (1.74 g, 15.70 mmol) in glacial acetic acid (10 mL) was added a solution of ketone **1** (14.3 mmol) in glacial acetic acid (30 mL). The suspension was heated for 2 h at 100°C and undissolved material filtered off. The filtrate was diluted with water (50 mL) and extracted with dichloromethane (2 × 50 mL). Organic extracts were washed with water (3 × 50 mL), and saturated sodium hydrogencarbonate (3 × 50 mL), dried over anhydrous sodium sulfate, concentrated, and then precipitated from *n*-hexane/dichloromethane to give compound **2**.

The organic extract was washed with brine (50 mL), dried over anhydrous sodium sulfate, and evaporated. After purification on silica gel SPE cartridge using step gradient system for elution ethyl acetate/*n*-hexane structural isomers **5** and **6** were isolated.

**General procedure for preparation of compounds 9.** To a 40% aq sodium hydroxide (1.66 mL) solution of **8** (60 mg, 0.216 mmol) in toluene (2.8 mL), appropriate ω-chloroalkyldimethylamine (0.862 mmol), and a catalytic amount of benzyltriethylammonium chloride were added. Reaction mixture was heated at reflux until TLC indicated the reaction was complete, and then cooled to room temperature, diluted with water (30 mL), and extracted with ethyl acetate (3 × 15 mL). The organic extract was washed with brine (30 mL), dried over anhydrous sodium sulfate, and evaporated. After purification on silica gel SPE cartridge using step gradient system for elution *n*-hexane/(ethyl acetate/*n*-hexane/diethylamine 10:10:1.5) compound **9** was isolated.

**General procedure for preparation of compounds 10.** To a solution of **9** (61.6 mg, 0.132 mmol) in methanol (3.4 mL), 0.5*M* hydrochloric acid in methanol (1.15 mL) was slowly added. The reaction mixture was heated for 2 h at 60°C, then cooled to room temperature, and concentrated. Ethyl acetate (4 mL) and water were added (6 mL) and pH adjusted to 1.0 using a 3*M* hydrochloric acid. The layers were separated and the aqueous layer washed with diethyl ether (2 × 10 mL). The pH of the aqueous layer was adjusted to pH 9.5 with 5*M* sodium hydroxide and extracted with ethyl acetate (3 × 10 mL). The combined organic extracts were washed with brine (15 mL) and dried over anhydrous sodium sulfate. The drying agent was filtered off, and solvent was removed *in vacuo* to give the crude product **10**.

**Biology**

***Cell isolation.*** Peripheral blood mononuclear cells (PBMC) were obtained from buffy coat of healthy volunteer donors by a density gradient centrifugation. Buffy coat was mixed with one volume of sterile saline, sample layered over FicollPaqueTM Plus (Amersham Biosciences), and centrifuged at 400 × *g* for 30 min. PBMCs were collected, washed in RPMI 1640 medium, and centrifuged. Finally, cells were resuspended in RPMI 1640 containing 10% heat inactivated fetal bovine serum (Biowest) and counted.

***Cell culture.*** PBMCs were cultured at a concentration of 3.5 × 104 in 200 μL volumes in 96-well cell culture plates (Falcon, St. Albans, UK) at 37°C in humidified atmosphere containing 5% $CO_2$. The cells were either stimulated with LPS (serotype 0111:B4, Sigma) at 1 ng/mL final concentration or left unstimulated (cultured in medium alone). Compound stock solutions were prepared as 10 m*M* in DMSO. Final 10 μ*M* and 3 μ*M* (10–0.03 μ*M*) concentration made in cell culture medium were tested when they had been added together with LPS. The final DMSO volume ratio in all assays did not exceed 0.1%. Negative and LPS control samples were prepared in sextaplicates and tested compound samples in triplicates.

***Cytokine measurement.*** Cell free supernatants were taken after overnight period and quantified for TNF-α content by enzyme linked immunosorbent assay (ELISA). To ensure the detection specificity and sensitivity, assay was performed according to manufacturer instructions (R&D Systems) using suggested pair of antibodies specific for human TNF-α. Test sensitivity for measuring human TNF-α was under 5 pg/mL. To calculate results, standard curve was made out of measured OD values for recombinant TNF-α of known concentrations. TNF-α content in unknown samples was calculated out of OD values extrapolated from the standard curve. Inhibition values were calculated according to formula:

$$X = \frac{\text{Conc(compound)} - \text{Conc(medium control)}}{\text{Conc(LPS control)} - \text{Conc (medium control)}} \times 100(\%)$$

IC50 values are calculated using GraphPad Prism software.

**Acknowledgment.** The authors express gratitude to Josip Klešćić for his assistance with the synthesis, Željko Osman and Dubravka Gembarovski for the mass spectroscopy support, Štefica Flegar and Goran Landek for IR spectra, Biserka Metelko for the NMR spectroscopy, and Vitomir Šunjić for helpful discussions.

Novel 4-quinolone-3-carboxylates **6,7** and 4-quinolone-3-carboxylic acids **8–11** were synthesized from 4-hydroxyquinoline-3-carboxylates. Ethyl 1-[1-ethoxycarbonyl-2-(4-pyridyl)vinyl]-6-fluoro-4-oxoquinoline-3-carboxylate **7a** was found to show antimalarial activity from the screening data.

*J. Heterocyclic Chem.*, **47**, 657 (2010).

## INTRODUCTION

In previous articles [1–9], we reported the synthesis of the 1-alkyl-4-oxopyridazino[3,4-*b*]quinoxalines **1** (Chart 1) as candidates of antibacterial quinolone analogues, in which the 3-H [5], 3-methyl [3], 3-trifluoromethyl [4], and 3-bromo [6] derivatives showed good antibacterial, antifungal, and/or algicidal activities. To search for novel compounds with biological activities, we converted the target ring system from the 4-oxopyridazino[3,4-*b*]quinoxaline to the 4-quinolone nucleus, which was included in the excellent antibacterial agents such as new quinolones. A novel type of new quinolones is still developed nowadays as an antibacterial agents. On the other hand, Wentland et al. [10] reported the antiherpetic activity of the 7-(4-pyridyl)-4-quinolone-3-carboxamide **2** derived from its parent 3-carboxylic acid **3** (Chart 1).

Since quinolone antibacterials have been known to act on the DNA gyrase, some other biological activities such as antifungal and antiviral [10] activities are expected for quinolone analogues. In fact, some of our 1-methyl-4-oxopyridazino[3,4-*b*]quinoxalines **1** ($R^1$ = Cl, $R^2$ = $CH_3$, $R^3$ = H, $CH_3$, Br) exhibited antifungal activities in addition to antibacterial activities [9]. In this investigation, we undertook the structural transformation of ordinary new quinolones **4** into compounds **6–11** as shown in Scheme 1. Namely, the C7-basic moiety is shifted to the N1-side chain leading to compound **5**, and the linker part is inserted between the N1 and the basic moiety. Furthermore, a carboxyl group was introduced in the linker part to provide a proximal pair of the acid and base moieties. This article describes the synthesis of compounds **6–11**, some of which are found to exhibit antimalarial activity from the screening data.

## RESULTS AND DISCUSSION

**Synthesis of compounds 6–11.** The reaction of ethyl 7-chloro-6-fluoro-4-hydroxyquinoline-3-carboxylate **12** [11,12] with methyl bromoacetate or ethyl 6-fluoro-4-hydroxyquinoline-3-carboxylate **13** [11,12] with ethyl

| **11c** | 21 | >100 | >4.8 |

[a] Mouse breast cancer cell, F28-7 strain.

bromoacetate gave the methyl (7-chloro-6-fluoro-4-quinolon-1-yl)acetate **14** or ethyl (6-fluoro-4-quinolon-1-yl)-acetate **15**, respectively (Scheme 2). The reaction of compound **14** with 4- and 3-pyridinecarbaldehydes or the reaction of compound **15** with 4-, 3-, and 2-pyridinecarbaldehydes afforded the methyl 2-(7-chloro-6-fluoroquinolon-1-yl)-3-(4- and 3-pyridyl)acrylates **6a,b** or ethyl 2-(6-fluoroquinolon-1-yl)-3-(4-, 3-, and 2-pyridyl)acrylates **7a–c**, respectively. Reflux of compounds **6a,b** in sulfuric acid/acetic acid/water was clarified to hydrolyze the ethyl ester of quinolone nucleus from the analytical and spectral data, providing the quinolone-3-carboxylic acids **8a,b**, respectively. Similar reaction of

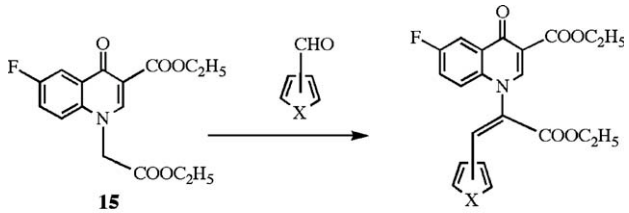
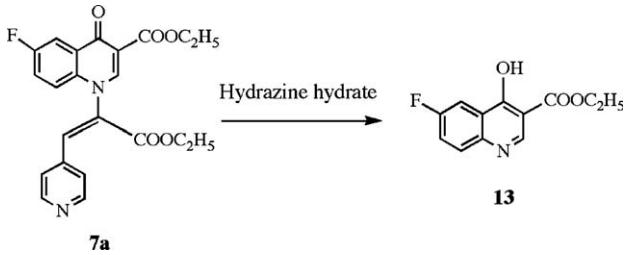
**10a,b**: X = Cl ; **11a-c**: X = H ; **a**: 4-Pyridyl ; **b**: 3-Pyridyl; **c**: 2-Pyridyl

**Scheme 3**



**Scheme 4**



compounds **7a–c** gave the quinolone-3-carboxylic acids **9a–c**, respectively. On the other hand, the hydrolysis of **6a,b** and **7a–c** with sodium hydroxide afforded the dicarboxylic acids **10a,b** and **11a–c**, respectively.

**Antimalarial activity.** The *in vitro* screening to antimalarial activity was carried out for compounds **6–11** according to a method in literatures [13], and the data are shown in Table 1. The $IC_{50}$ of the diester **7a** was 8.2 μmol to *Plasmodium falciparum*, whose value was referred as effective. The $IC_{50}$ of the diester **7a** to mouse FM3A cell F28-7 strain was 24 μmol, and the chemical therapeutic coefficient was the value of 2.9. The diester **7b** with the 3-pyridyl moiety had a weaker activity than the diester **7a** with the 4-pyridyl moiety. Moreover, compounds with carboxyl group in the quinolone nucleus and/or N1-side chain or compounds with the C7-chlorine atom in the quinolone nucleus represented no antimalarial activity, suggesting the unfavorable effect of such carboxyl group and chlorine atom on the activity.

The 4-pyridyl moiety in the N1-substituent of the diester **7a** was found not to be replaced with the nonbasic moiety. That is, compounds **16–18** (Scheme 3) with furyl or thienyl moiety in the N1-substituent were clarified to exhibit no antimalarial activity.

**Trial for modification of compound 7a.** An attempt was unsuccessful to convert the ester group into carbohydrazide group to install an additional basic moiety in the N1-side chain of compound **7a**. As shown in Scheme 4, the reaction of compound **7a** with hydrazine hydrate resulted in the bond cleavage between the N1 and acrylate moiety.

**Analytical and spectral data.** The structural assignment of novel compounds **6–11** was based on the analytical and spectral data. Especially, the NOE spectral data among the vinyl, pyridyl, and quinolone 8-H protons of compounds **7a–c** shown in Table 2 ascertained the presence of the pyridylacrylate moiety in the N1 of the quinolone nucleus. Moreover, the NOE between the vinyl and quinolone 8-H proton signals suggested the *E*-isomer for compounds **6–11** and **16–18**, whereas the NOE between the pyridine 3-H and quinolone 2-H proton signals supported the presence of the *Z*-isomer for compounds **7a** and **9a** (Table 2). There was no difference in the proton chemical shifts between the *E*- and *Z*-isomers in compounds **7a** and **9a**.

In the $^1$H-NMR spectra of compounds **6b**, **8a**, **11a**, and **17**, two kinds of quinolone 2-H proton signals were observed [14] (Table 3), which would not be due to the presence of the *E*- and *Z*-isomers, because compounds **7a** and **9a** existing as the *E*- and *Z*-isomers in solution exhibited a single quinolone 2-H proton signal.

**Table 2**

NOE data for compounds **7**, **9**, **11**, and **16–18**.

| Radiation | NOE | 7a | 7b | 7c | 9a | 9b | 9c | 11b | 16 | 17 | 18 |

**Table 3**

Compounds showing two kinds of quinolone 2-H proton signals [14].

| | Compound | $R^1$ | $R^2$ | $R^3$ | X | Chemical Shift (δ) | | |
|---|---|---|---|---|---|---|---|---|
| | | | | | | Quinolone 2-H | | Ratio |
|  | **6b** | $C_2H_5$ | $CH_3$ | 3-Pyridyl | Cl | 8.66 | 8.60 | 40 : 60 |
| | **8a** | H | $CH_3$ | 4-Pyridyl | Cl | 9.05 | 8.90 | 72 : 28 |
| | **11a** | H | H | 4-Pyridyl | H | 9.11 | 9.03 | 23 : 77 |
| | **17** | $C_2H_5$ | $C_2H_5$ | 2-Thienyl | H | 8.59 | 8.55 | 45 : 55 |

Moreover, two kinds of quinolone 2-H, 8-H, vinyl, pyridine 5-H, and ethyl ester $CH_2$ proton signals were observed in the $^1$H-NMR spectra of compound **6b**, suggesting the presence of two kinds of isomers [14]. Further investigation to clarify the aforementioned phenomena is in progress, and the results will be reported elsewhere.

The $^{13}$C-NMR spectral data are shown in Table 4, which includes the respective carbon chemical shifts of the typical our quinolones **6a**, **7a**, **14**, and **16** assigned by the dHSQC and gHMBC spectral data.

## EXPERIMENTAL

All melting points were determined on a Yazawa micro-melting point BY-2 apparatus and are uncorrected. The IR spectra (potassium bromide) were recorded with a JASCO FT/IR-200 spectrometer. The $^1$H-NMR and dHSOC/gHMBC spectra were measured with a Varian XL-400 and Varian INOVA 600 spectrometers at 400 and 600 MHz, respectively. The chemical shifts are given in the δ scale. The mass spectra (ms) were determined with a JEOL JMS-01S spectrometer. Elemental analyses were performed on a Perkin-Elmer 240B instrument.

Compounds **12** and **13** were synthesized by a method reported in literatures [11,12], refluxing in diphenyl ether at 250°.

**Methyl (7-chloro-3-ethoxycarbonyl-6-fluoro-1,4-dihydro-4-oxoquinolin-1-yl)acetate 14.** A mixture of compound **12** (5.0 g, 18.6 mmol), ethyl bromoacetate (5.09 g, 33.5 mmol), potassium carbonate (5.0 g, 36.2 mmol) in dry *N*,*N*-dimethylformamide (200 mL) was heated at 100–120° with stirring for 2 h and filtrated while the mixture was hot. Evaporation of the solvent *in vacuo* gave colorless crystals, which were recrystallized from *N*,*N*-dimethylformamide/ethanol/water to afford colorless needles **14** (5.13 g, 81%); mp: 251–252°; IR: ν 1725 $cm^{-1}$; ms: m/z 341 ($M^+$), 343 ($M^+ + 2$); NMR (deuteriodimethyl sulfoxide): 8.73 (s, 1H, 2-H), 8.06 (d, $J = 6.0$ Hz, 1H, 8-H), 8.02 (d, $J = 9.5$ Hz, 1H, 5-H), 5.39 (s, 2H, $CH_2$), 4.22 (q, $J = 7.0$ Hz, 2H, $CH_2$), 3.72 (s, 3H, $CH_3$), 1.27 (t, $J = 7.0$ Hz, 3H, $CH_3$). Anal. Calcd. for $C_{15}H_{13}ClFNO_5$: C, 52.72; H, 3.83; N, 4.10. Found: C, 52.45; H, 3.94; N, 4.36.

**Ethyl (3-ethoxycarbonyl-6-fluoro-1,4-dihydro-4-oxoquinolin-1-yl)acetate 15.** A mixture of compound **13** (5.0 g, 21.3 mmol), ethyl bromoacetate (5.33 g, 31.9 mmol), potassium carbonate (4.40 g, 31.9 mmol) in dry *N*,*N*-dimethylformamide (200 mL) was heated at 100–120° with stirring for 2 h and filtrated while the mixture was hot. Then, ethanol (100 mL) was added to the filtrate with stirring, and the solution was allowed to stand at room temperature to precipitate colorless needles **15**, which were collected by suction and then washed with *n*-hexane (5.97 g, 87%); mp: 274–275°; IR: ν 1740, 1720 $cm^{-1}$; ms: m/z 321 ($M^+$); NMR (deuteriotrifluoroacetic acid): 9.14 (s, 1H, 2-H), 8.11 (dd, $J = 7.5$, 2.8 Hz, 1H, 5-H), 7.82 (dd, $J = 10.0$, 4.0 Hz, 1H, 8-H), 7.75 (ddd, $J = 10.0$, 7.5, 2.8 Hz, 1H, 7-H), 5.50 (s, 2H, $CH_2$), 4.42 (q, $J = 7.0$ Hz, 2H, $CH_2$), 4.16 (q, $J = 7.0$ Hz, 2H, $CH_2$), 1.24 (t, $J = 7.0$ Hz, 3H, $CH_3$), 1.08 (t, $J = 7.0$ Hz, 3H, $CH_3$). Anal. Calcd. for $C_{16}H_{16}ClFNO_5$: C, 59.81; H, 5.02; N, 4.36. Found: C, 59.64; H, 5.09; N, 4.59.

**Ethyl 7-chloro-6-fluoro-1,4-dihydro-1-[(*Z*)-1-methoxycarbonyl-2-(4- and 3-pyridyl)vinyl]-4-oxoquinoline-3-carboxylates 6a,b.** ***General procedure.*** A solution of compound **14** (5.0 g, 14.6 mmol), 4- or 3-pyridinecarbaldehyde (2.50 g, 23.4 mmol), and 1,8-diazabicyclo[5.4.0]-7-undecene (1.19 g, 7.80 mmol) in dry dioxane (100 mL) was refluxed with stirring for 10 h. Acetic acid (5 mL) was added to the solution, and the solvent was evaporated *in vacuo* to give colorless crystals. Recrystallization from dioxane/water afforded colorless needles **6a** or **6b**.

Compound **6a** was obtained in 55% yield (3.48 g); mp 226–227°; IR: ν 1730 $cm^{-1}$; ms: m/z 430 ($M^+$), 432 ($M^+ + 2$); NMR (deuteriodimethyl sulfoxide): 8.65 (s, 1H, 2-H), 8.54 (d, $J = 6.5$ Hz, 2H, pyridine 2-H and 6-H), 8.24 (s, 1H, vinylic H), 8.07 (d, $J = 9.0$ Hz, 1H, 5-H), 7.81 (d, $J = 6.0$ Hz, 1H, 8-H), 7.12 (d, $J = 6.5$ Hz, 2H, pyridine 3-H and 5-H), 4.18 (q, $J = 7.0$ Hz, 2H, $CH_2$), 3.81 (s, 3H, $CH_3$), 1.22 (t, $J = 7.0$ Hz, 3H, $CH_3$). Anal. Calcd. for $C_{21}H_{16}ClFN_2O_5 \cdot 1/3H_2O$ [15]: C, 57.74; H, 3.85; N, 6.41. Found: C, 57.79; H, 3.81; N, 6.36.

Compound **6b** was obtained in 61% yield (3.82 g); mp 214–215°; IR: ν 1735, 1720 $cm^{-1}$; ms: m/z 430 ($M^+$), 432 ($M^+ + 2$); NMR (deuteriodimethyl sulfoxide): (isomer A) [14] 8.66 (s, 1H, 2-H), 8.29 (s, 1H, vinylic H), 8.08 (d, $J = 9.0$ Hz, 1H, 5-H), 7.81 (d, $J = 6.0$, Hz, 1H, 8-H), 7.41 (ddd, $J = 4.0$, 2.0, 2.0 Hz, 1H, pyridine 4-H), 7.34 (dd, $J = 8.0$, 4.0 Hz, 1H, pyridine 5-H), 8.57–8.52 (m, 2H, pyridine 2-H and 6-H), 4.21 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.17 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 3.81 (s, 3H, $CH_3$), 1.23 (dd, $J = 7.0$, 7.0 Hz, 3H, $CH_3$); (isomer B) [14] 8.60 (s, 1H, 2-H), 8.22 (s, 1H, vinylic H), 8.08 (d, $J = 9.0$ Hz, 1H, 5-H), 7.73 (d, $J = 6.0$ Hz, 1H, 8-H), 7.41 (ddd, $J = 4.0$, 2.0, 2.0 Hz, 1H, pyridine 4-H), 7.33 (dd, $J = 8.0$, 4.0 Hz, 1H, pyridine 5-H), 8.57–8.52 (m, 2H, pyridine 2-H and 6-H), 4.20 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.16 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 3.81 (s, 3H, $CH_3$), 1.23 (dd, $J = 7.0$, 7.0 Hz, 3H, $CH_3$). The 5-H, pyridine 4-H, ester methyl proton signals of the above isomers A and B were observed in the same magnetic field. Anal. Calcd. for $C_{21}H_{16}ClFN_2O_5 \cdot 1/2H_2O$ [15]: C, 57.35; H, 3.90; N, 6.37. Found: C, 57.39; H, 3.75; N, 6.42.

**Methyl 1-[(*Z*)-1-ethoxycarbonyl-2-(4-, 3-, and 2-pyridyl)-vinyl]-6-fluoro-1,4-dihydro-4-oxoquinoline-3-carboxylates 7a–c.** ***General procedure.*** A solution of compound **15** (5.0 g, 15.6 mmol), 4-, 3-, or 2-pyridinecarbaldehyde (2.50 g, 23.4 mmol), and 1,8-diazabicyclo[5.4.0]-7-undecene (1.19 g, 7.80 mmol) in dry dioxane (100 mL) was refluxed with stirring for 10 h. Acetic acid (5 mL) was added to the solution, and the solvent was evaporated *in vacuo* to give colorless crystals. Recrystallization from dioxane/water afforded colorless needles **7a**, **7b**, or **7c**.

Compound **7a** [16] was obtained in 59% yield (3.75 g); mp 226–227°; IR: ν 1725 $cm^{-1}$; ms: m/z 410 ($M^+$); NMR (deuteriodimethyl sulfoxide): 8.63 (s, 1H, 2-H), 8.54 (d, $J = 6.0$ Hz, 2H, pyridine 2-H and 6-H), 8.25 (s, 1H, vinylic H), 7.92 (dd, 9.3, 3.0 Hz, 1H, 5-H), 7.58 (ddd, 9.0, 8.0, 3.0 Hz, 1H, 7-H), 7.50 (dd, $J = 9.0$, 4.5 Hz, 1H, 8-H), 7.11 (d, $J = 6.0$ Hz, 2H, pyridine 3-H and 5-H), 4.28 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.24 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.18 (q, $J = 7.0$ Hz, 2H, $CH_2$), 1.22 (dd, $J = 7.0$, 7.0 Hz, 3H, $CH_3$), 1.21 (t, $J = 7.0$ Hz, 3H, $CH_3$). Anal. Calcd. for $C_{22}H_{19}FN_2O_5$: C, 64.39; H, 4.67; N, 6.83. Found: C, 64.39; H, 4.67; N, 6.86.

Compound **7b** was obtained in 49% yield (3.10 g); mp 140–141°; IR: ν 1725, 1690 $cm^{-1}$; ms: m/z 410 ($M^+$); NMR (deuteriodimethyl sulfoxide): 8.65 (s, 1H, 2-H), 8.55 (d, $J = 2.0$ Hz, 1H, pyridine 2-H), 8.53 (dd, $J = 4.5$, 2.0 Hz, 1H, pyridine 6-H), 8.29 (s, 1H, vinylic H), 7.92 (dd, 9.0, 3.0 Hz, 1H, 5-H), 7.57 (ddd, $J = 9.0$, 8.0, 3.0 Hz, 1H, 7-H), 7.50 (dd, $J = 9.0$, 4.5 Hz, 1H, 8-H), 7.39 (ddd, $J = 8.0$, 2.0, 2.0 Hz, 1H, pyridine 4-H), 7.33 (dd, $J = 8.0$, 4.5 Hz, 1H, pyridine 5-H), 4.28 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.24 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.22 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 4.17 (dq, $J = 11.0$, 7.0 Hz, 1H, methylene CH), 1.23 (dd, $J = 7.0$, 7.0 Hz, 3H, $CH_3$), 1.22 (dd, $J = 7.0$, 7.0 Hz, 3H, $CH_3$). Anal. Calcd. for $C_{22}H_{19}FN_2O_5$: C, 64.39; H, 4.67; N, 6.83. Found: C, 64.16; H, 4.67; N, 6.90.

Compound **7c** was obtained in 58% yield (3.73 g); mp 166–167°; IR: ν 1700 $cm^{-1}$; ms: m/z 410 ($M^+$); NMR (deuteriodimethyl sulfoxide): 8.56 (s, 1H, 2-H), 8.27 (ddd, $J = 5.0$, 1.5, 0.5 Hz, 1H, pyridine 6-H), 8.24 (s, 1H, vinylic H), 7.99 (dd, $J = 9.0$, 3.0 Hz, 1H, 5-H), 7.83 (ddd, 7.5, 7.5, 1.5 Hz, 1H, pyridine 4-H), 7.69 (ddd, $J = 7.5$, 1.0, 0.5 Hz, 1H, pyridine 3-H), 7.50 (ddd, $J = 9.0$, 8.0, 3.0 Hz, 1H, 7-H), 7.41 (dd, $J = 9.0$, 4.5 Hz, 1H, 8-H), 7.29 (ddd, $J = 7.5$, 5.0, 1.0 Hz, 1H, pyridine 5-H), 4.30 (dq, $J = 10.5$, 7.0 Hz, 1H, methylene CH), 4.25 (dq, $J = 10.5$, 7.0 Hz, 1H, methylene CH), 4.17 (q, $J = 7.0$ Hz, 2H, $CH_2$), 1.23 (dd, $J = 7.0$, 7.0 Hz, 3H, $CH_3$), 1.22 (t, $J = 7.0$ Hz, 3H, $CH_3$). Anal. Calcd. for $C_{22}H_{19}FN_2O_5$: C, 64.39; H, 4.67; N, 6.83. Found: C, 64.00; H, 4.69; N, 6.85.

**7-Chloro-6-fluoro-1,4-dihydro-1-[(*Z*)-1-methoxycarbonyl-2-(4- and 3-pyridyl)vinyl]-4-oxoquinoline-3-carboxylic acids 8a,b.** ***General procedure.*** A solution of compound **6a** or **6b** (1.0 g, 2.33 mmol) in concentrated sulfuric acid (0.4 mL), water (1.0 mL), and acetic acid (40 mL) was refluxed with stirring for 2 h. The solvent was evaporated *in vacuo* to give an oily product, which was dissolved in ethanol (10 mL) and then neutralized with sodium hydrogen carbonate to afford crystals. The crystals were collected by suction, and then recrystallization from *N*,*N*-dimethylformamide/ethanol/water provided yellow needles **8a** or **8b**.

Compound **8a** was obtained in 87% yield (810 mg); mp 244–245°; IR: ν 1740 $cm^{-1}$; ms: m/z 402 ($M^+$), 404 ($M^+ + 2$); NMR (deuteriodimethyl sulfoxide): 14.23 (brs, 1H, COOH), 9.05, 8.90 [14] (s, 1H, 2-H), 8.52 (d, $J = 6.0$ Hz, 2H, pyridine 2-H and 6-H), 8.28 (s, 1H, vinylic H), 8.25 (d, $J = 9.0$ Hz, 1H, 5-H), 8.07 (d, $J = 6.0$ Hz, 1H, 8-H), 7.09 (d, $J = 6.0$ Hz, 2H, pyridine 3-H and 5-H), 3.80 (s, 3H, $CH_3$). Anal. Calcd. for $C_{19}H_{12}ClFN_2O_5 \cdot 1/5H_2O$ [15]: C, 56.16; H, 3.08; N, 6.89. Found: C, 56.08; H, 3.07; N, 6.93.

Compound **8b** was obtained in 51% yield (470 mg); mp 216–217°; IR: ν 1725 $cm^{-1}$; ms: m/z 402 ($M^+$), 404 ($M^+ + 2$); NMR (deuteriodimethyl sulfoxide): 14.22 (brs, 1H, COOH), 9.06 (s, 1H, 2-H), 8.60 (s, 1H, pyridine 2-H), 8.55 (dd, $J = 3.6$, 1.0 Hz, 1H, pyridine 6-H), 8.34 (s, 1H, vinylic H), 8.26 (dd, 9.1, 1.0 Hz, 1H, 5-H), 8.08 (dd, $J = 4.0$, 1.0 Hz, 1H, 8-H), 7.34 (dd, $J = 5.0$, 1.0 Hz, 1H, pyridine 4-H), 7.30 (dd, $J = 5.0$, 3.6 Hz, 1H, pyridine 5-H), 3.82 (s, 3H, $CH_3$). Anal. Calcd. for $C_{19}H_{12}ClFN_2O_5 \cdot 1/3H_2O$ [15]: C, 55.83; H, 3.12; N, 6.85. Found: C, 55.83; H, 3.11; N, 6.96.

**1-[(*Z*)-1-Ethoxycarbonyl-2-(4-, 3-, and 2-pyridyl)vinyl]-6-fluoro-1,4-dihydro-4-oxoquinoline-3-carboxylic acids 9a–c.** ***General procedure.*** A solution of compound **7a**, **7b**, or **7c** (1.0 g, 2.44 mmol) in concentrated sulfuric acid (0.4 mL),

water (1.0 mL), and acetic acid (40 mL) was refluxed with stirring for 2 h. The solvent was evaporated *in vacuo* to give an oily product, which was dissolved in ethanol (10 mL) and then neutralized with sodium hydrogen carbonate to afford crystals. The crystals were collected by suction, and then recrystallization from *N*,*N*-dimethylformamide/ethanol/water provided yellow needles **9a**, **9b**, or **9c**.

Compound **9a** [16] was obtained in 67% yield (620 mg); mp 228–229°; IR: ν 1740, 1720 $cm^{-1}$; ms: m/z 382 ($M^+$); NMR (deuteriodimethyl sulfoxide): 14.45 (brs, 1H, COOH), 9.06 (s, 1H, 2-H), 8.51 (d, $J$ = 6.5 Hz, 2H, pyridine 2-H and 6-H), 8.30 (s, 1H, vinylic H), 8.09 (ddd, 9.0, 8.5, 2.0 Hz, 1H, 7-H), 7.77 (dd, 10.0, 2.0 Hz, 1H, 5-H), 7.74 (dd, $J$ = 9.0, 3.5 Hz, 1H, 8-H), 7.07 (d, $J$ = 6.5 Hz, 2H, pyridine 3-H and 5-H), 4.28 (dq, $J$ = 11.0, 7.0 Hz, 1H, methylene CH), 4.24 (dq, $J$ = 11.0, 7.0 Hz, 1H, methylene CH), 1.21 (dd, $J$ = 7.0, 7.0 Hz, 3H, $CH_3$). Anal. Calcd. for $C_{19}H_{15}FN_2O_5$: C, 62.83; H, 3.95; N, 7.33. Found: C, 62.66; H, 3.98; N, 7.42.

Compound **9b** was obtained in 64% yield (600 mg); mp 168–169°; IR: ν 1725, 1620 $cm^{-1}$; ms: m/z 382 ($M^+$); NMR (deuteriodimethyl sulfoxide): 14.48 (brs, 1H, COOH), 9.07 (s, 1H, 2-H), 8.56 (dd, $J$ = 1.5, 1.5 Hz, 1H, pyridine 2-H), 8.52 (dd, $J$ = 4.0, 2.5 Hz, 1H, pyridine 5-H), 8.35 (s, 1H, vinylic H), 8.09 (ddd, 8.5, 8.5, 1.5 Hz, 1H, 7-H), 7.74 ($J$ = 8.5, 6.0, 1.5 Hz, 2H, 5-H and 8-H), 7.28 [ (dd, $J$ = 4.0, 1.5 Hz, 1H), (dd, $J$ = 2.5, 1.5 Hz, 1H), pyridine 4-H and 6-H], 4.28 (dq, $J$ = 11.0, 7.0 Hz, 1H, methylene CH), 4.23 (dq, $J$ = 11.0, 7.0 Hz, 1H, methylene CH), 1.22 (dd, $J$ = 7.0, 7.0 Hz, 3H, $CH_3$). Anal. Calcd. for $C_{19}H_{15}FN_2O_5$: C, 62.83; H, 3.95; N, 7.33. Found: C, 62.57; H, 3.95; N, 7.36.

Compound **9c** was obtained in 70% yield (652 mg); mp 200–201°; IR: ν 1720, 1620 $cm^{-1}$; ms: m/z 382 ($M^+$); NMR (deuteriodimethyl sulfoxide): 14.75 (s, 1H, COOH), 8.99 (s, 1H, 2-H), 8.30 (s, 1H, vinylic H), 8.16 (dd, $J$ = 4.5, 2.5 Hz, 1H, pyridine 6-H), 8.06 (dd, $J$ = 8.5, 2.0 Hz, 1H, 5-H), 7.84 (ddd, $J$ = 8.0, 7.0, 2.5 Hz, 1H, pyridine 4-H), 7.80 (dd, $J$ = 8.0, 1.5 Hz, 1H, pyridine 3-H), 7.70 (ddd, $J$ = 7.0, 7.0, 2.0 Hz, 1H, 7-H), 7.66 (dd, $J$ = 7.0, 2.0 Hz, 1H, 8-H), 7.27 (ddd, $J$ = 7.0, 4.5, 1.5 Hz, 1H, pyridine 5-H), 4.30 (dq, $J$ = 11.0, 7.0 Hz, 1H, methylene CH), 4.25 (dq, $J$ = 11.0, 7.0 Hz, 1H, methylene CH), 1.23 (dd, $J$ = 7.0, 7.0 Hz, 3H, $CH_3$). Anal. Calcd. for $C_{20}H_{15}FN_2O_5$: C, 61.86; H, 4.07; N, 7.21. Found: C, 62.06; H, 3.98; N, 7.28.

**1-[(*Z*)-1-Carboxy-2-(4- and 3-pyridyl)vinyl]-7-chloro-6-fluoro-1,4-dihydro-4-oxoquinoline-3-carboxylic acids 10a,b.** ***General procedure.*** A solution of potassium hydroxide (290 mg, 5.13 mmol) in water (2 mL) was added to a solution of compound **6a** or **6b** (1.0 g, 2.33 mmol) in ethanol (40 mL), and the solution was refluxed for 2 h to precipitate crystals. After cooling of the reaction mixture and then neutralization with hydrochloric acid (1 mol solution), the solvent was evaporated *in vacuo* to afford crystals, which were collected by suction. Recrystallization from *N*,*N*-dimethylformamide/ethanol/water gave yellow needles.

Compound **10a** was obtained in 89% yield (800 mg); mp 285–286°; IR: ν 1730 $cm^{-1}$; ms: m/z 388 ($M^+$), 390 ($M^+$ + 2); NMR (deuteriodimethyl sulfoxide): 14.28 (brs, 1H, COOH), 9.01 (s, 1H, 2-H), 8.51 (d, $J$ = 6.5 Hz, 2H, pyridine 2-H and 6-H), 8.25 (d, $J$ = 9.0 Hz, 1H, 5-H), 8.22 (s, 1H, vinylic H), 8.01 (d, $J$ = 6.0 Hz, 1H, 8-H), 7.93 (s, formyl H of *N*,*N*-dimethylformamide), 7.10 (d, $J$ = 6.0 Hz, 2H, pyridine 3-H and 5-H), 2.81 (s, $CH_3$ of *N*,*N*-dimethylformamide), 2.71 (s, $CH_3$ of *N*,*N*-dimethylformamide). One of two COOH proton signals was not observed presumably due to flattening. Anal. Calcd. for $C_{17}H_{10}ClFN_2O_5 \cdot 1/3H_2O \cdot 2/3HCON(CH_3)_2$ [15]: C, 56.16; H, 3.08; N, 6.89. Found: C, 56.08; H, 3.07; N, 6.93.

Compound **10b** was obtained in 95% yield (860 mg); mp 284–285°; IR: ν 1720 $cm^{-1}$; ms: m/z 388 ($M^+$), 390 ($M^+$ + 2); NMR (deuteriodimethyl sulfoxide): 14.29 (brs, 1H, COOH), 9.02 (s, 1H, 2-H), 8.56 (d, $J$ = 2.0 Hz, 1H, pyridine 2-H), 8.52 (dd, $J$ = 4.5, 2.0 Hz, 1H, pyridine 6-H), 8.27 (s, 1H, vinylic H), 8.25 (d, $J$ = 9.0 Hz, 1H, 5-H), 7.99 (d, $J$ = 6.0 Hz, 1H, 8-H), 7.33 (ddd, $J$ = 8.0, 2.0, 2.0 Hz, 1H, pyridine 4-H), 7.28 (dd, $J$ = 8.0, 4.5 Hz, 1H, pyridine 5-H). [14] Conformational analysis might be necessary for the clarification of such NMR spectral data.

[15] Compounds **6a,b**, **8a,b**, **10a**, and **11a,b** were found to absorb moisture while the procedures of the elemental analyses.

[16] The NOE spectral data (Table 2) showed that compounds **7a** and **9a** were a mixture of the *E*- and *Z*-isomers.

[17] The integral curve of the COOH proton signal was less than 1H size presumably due to flattening by moisture in the sample tube.

# Application of 1,3-Azomethine Ylides Derived from α-Dicarbonyl Compounds and L-Proline to the Synthesis of Pyrrolizidines

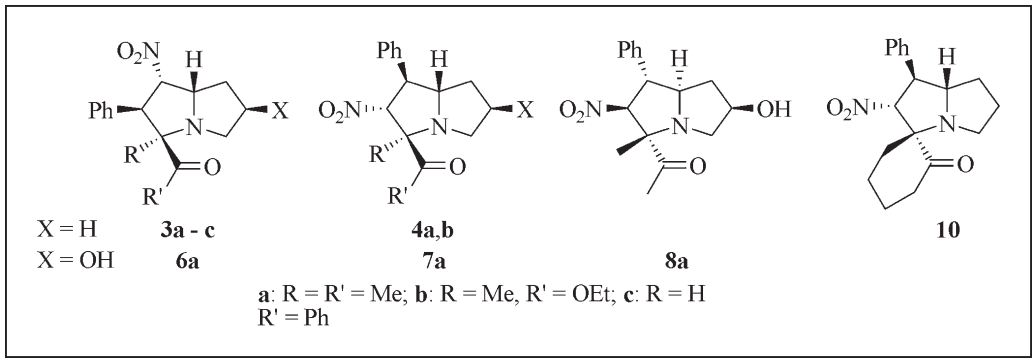
Published online 6 May 2010 in Wiley InterScience (www.interscience.wiley.com).



The reaction of 2,3-butanedione, ethyl pyruvate, and phenylglyoxal with β-nitrostyrene and L-proline in isopropanol at room temperature gives substituted pyrrolizidines, as a result of one-pot three component reaction. On the contrary, a spiropyrrolizidine is formed from 1,2-cyclohexanedione only when the reaction is carried out in refluxing isopropanol, whereas at room temperature, incorporation of the amine component into the products is not observed and bicyclo[3.2.1]octanones are formed, as a result of a tandem Michael-Henry reaction. In this latter case, L-proline acts as an organocatalyst, although with modest enantioselectivity. The stereochemistry of the products is given and the mechanism of formation of products is postulated, on the basis of stereochemical arguments.

## INTRODUCTION

The 1-azabicyclo[3.3.0]octane ring is part of naturally occurring and biologically active pyrrolizidine alkaloids, which are studied for their interesting diverse physiological properties [1]. Construction, also asymmetric, of the pyrrolizidine ring are usually made through multistep reactions [2] and also [3+2]cycloadditions between 1,3-azomethine ylides and activated olefins are widely used [3]. A possible source of 1,3-azomethine ylides is derived from activated carbonyl compounds and L-proline, which can loose carbon dioxide when heated. The resulting 1,3-dipoles can react with aldehydes, to give bicyclic 1,3-oxazolidines [4], or with α,β-unsaturated esters [3(a,e,f)], or nitroolefins [3(b)] to give pyrrolizidine derivatives.

In this work, we report the application of 1,3-azomethine ylides derived from α-dicarbonyl compounds and L-proline to the synthesis of pyrrolizidines by means of 1,3-dipolar cycloaddition reactions to β-nitrostyrene. The use of (2*S*,4*R*)-4-hydroxyproline gave enantiopure polysubstituted pyrrolizidines.

## RESULTS AND DISCUSSION

The α-dicarbonyl compounds examined in this study have been 2,3-butanedione **1a**, ethyl pyruvate **1b**, phenylglyoxal **1c** (Scheme 1), and 1,2-cyclohexanedione **9** (Scheme 3), which were reacted with β-nitrostyrene **2** in isopropanol at room temperature, in the presence of an equimolar amount of L-proline. The reaction of 2,3-butanedione **1a** with β-nitrostyrene **2** in isopropanol at room temperature for 3 days gave two regioisomeric cycloadducts in 3:2 ratio, which were assigned the structures **3a** and **4a**, respectively, on the basis of difference NOE measurements (Table 1). The analogous cycloaddition of ethyl pyruvate **1b** to **2** gave two adducts **3b** and **4b** in 9:1 ratio (Scheme 1), with structural assignments based on analogy and difference NOE measurements (Table 1), while the addition of phenylglyoxal **1c** to **2** furnished a single regioisomer **3c**.

To determine the mechanism of formation of the pyrrolizidines, a reaction was carried out between 2,3-butanedione **1a**, β-nitrostyrene **2** and (2*S*,4*R*)-4-hydroxyproline **5** in isopropanol, so to take advantage of the

| R = Me, R' = OEt | **1b** | 90% (9:1) | **3b** | **4b** |
| R = H, R' = Ph | **1c** | 80% | **3c** | |

presence of a stereocenter of known configuration. The reaction was much slower, owing to solubility problems, and gentle warming was necessary to drive the reaction to completion. The reaction products isolated were the pyrrolizidines **6a** and **7a**, analogous to **3a** and **4a**, together with a third isomer **8a**, whose formation can be surely ascribed to the higher temperature used. The relative ratio of compounds **6a–8a** was 1:4:1 (Scheme 2).

X-ray analysis of compound **6a** (Fig. 1) showed the geometry of the substituents and the *cis* fusion of the rings. To validate the use of NOE measurements to determine the geometry of the other pyrrolizidines, difference NOE experiments (Table 1) were carried out also on **6a**, whose results were in complete accordance with the X-ray determination. The ring junction in all pyrrolizidines was determined by an analysis of their IR spectra. The Bohlmann bands [5] between 2800 and 2600 $cm^{-1}$, which are correlated with the presence of a C—H bond antiperiplanar to the nitrogen lone pair, were present only for compound **8a** (2724 and 2671 $cm^{-1}$), which was therefore assigned the *trans* fusion, whereas pyrrolizidines **3a–c**, **4a**,**b** and **6a**, **7a** which lack these bands, were assigned the *cis* fusion.

1,2-Cyclohexanedione **9** has been chosen as another candidate for synthesizing pyrrolizidine target compounds. Indeed, the reaction of the substrate **9** with β-nitrostyrene **2**, carried out in refluxing isopropanol for 2 h gave as the main reaction product (90%) the nitrospiro pyrrolizidine **10** (Scheme 3, right side). Its stereochemistry was assigned as depicted in Scheme 3. The relative configuration of the spiro carbon atom C-3′ was confirmed by the resonance value found for the axial proton

at C-2 which is strongly deshielded with respect to its geminal equatorial one (3.20 *vs*. 2.39 ppm) by the anisotropic effect of the nitro group that is spatially close to it.

Interestingly, when the same reaction was carried out at room temperature, even under solvent-free conditions, two adducts were obtained in 9:1 ratio (Scheme 3, left side). These compounds were assigned the structures **11** and **12**, on the basis of $^1$H NMR spectra and X-ray analysis carried out on compound **12**. The two isomers were separated by flash chromatography and they proved weakly optically active ($[\alpha]_D^{25} = +0.05$ (*c* 2.65, MeOH) for **11** and $[\alpha]_D^{25} = -2.6$ (*c* 0.15, MeOH) for **12**, 14% e.e., determined by HPLC on chiral column), thus demonstrating the organocatalytic capability of L-proline, albeit modest, in this particular case.

X-ray analysis of compound **12** (Fig. 2) showed that the geometry of phenyl and the nitro group was *cis,* both groups being *exo* oriented. The stereochemistry of its diastereomer **11** was determined by $^1$H NMR analysis. In fact, in **12,** the coupling constant between H-6 and H-7 was larger than in **11** ($J_{6,7} = J_{endo,exo} = 5.8$ Hz for **11**, $J_{6,7} = J_{endo,endo} = 9.5$ Hz for **12**), thus demonstrating the *trans* relationship between the phenyl group and the nitro group in **11** [6]. The orientation of the phenyl group was assigned as *exo* also in **11**. In fact, the coupling constant between H-5 and the benzylic proton H-6 was zero, thus indicating a dihedral angle of 90° between them, which is only consistent with the *endo* orientation of the benzylic proton itself.

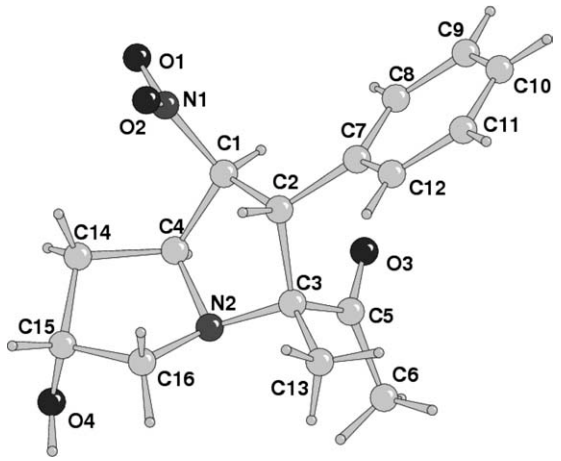

**Figure 1.** Molecular structure of compound **6a.**

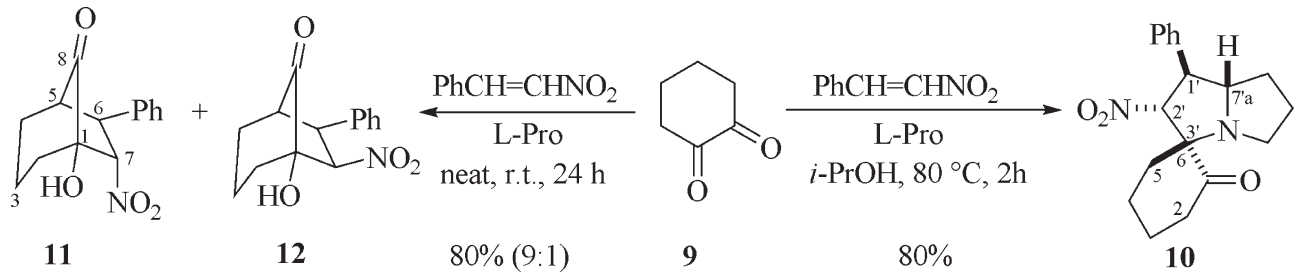
## MECHANISM OF THE REACTIONS

The mechanism of pyrrolizidine formation can be inferred from the stereochemistry of the products and in particular from compounds **6a** and **7a**, whose absolute configurations are known, given the *R* absolute configuration of the carbinol carbon atom. Since the majority of the pyrrolizidines in this work are *cis* fused [7], the first formed carbon—carbon bond (C1-C7a) occupies the same position as the carboxy group in the original pyrrolidine ring. Therefore, it seems reasonable to postulate that formation of the intermediate **13** (Scheme 4, illustrated for 2,3-butanedione **1a** as the substrate) is immediately followed by elimination of carbon dioxide with the creation of the 1,3-dipole **14**, existing in two resonance structures **a** and **b**. Both regioisomeric adducts **6a** and **7a** derived from the less encumbered *exo-anti* transition states, while adduct **8a** arose from the *exo-syn* transition state. The same reaction mechanism may be invoked for the formation of the other pyrrolizidines **3a–c**, **4a**,**b** derived from linear 1,2,-dicarbonyl compounds and **10** derived from 1,2-cyclohexanedione.

In the reaction of 1,2-cyclohexanedione **9** with β-nitrostyrene **2** performed at room temperature, L-proline initially reacts with the substrate **9** to give the corresponding cross-conjugated enaminone **15** (Scheme 5) which reacts with the nitroolefin in a Michael-type addition, through a two step mechanism, with subsequent ring closure in **16**, by collapse of the carbanion onto the carbonyl carbon atom. The consequent zwitterion **17** is hydrolysed *in situ* to afford eventually the two diastereomers **11** and **12**.

The easier loss of carbon dioxide observed for the adduct between L-proline and 2,3-butanedione with respect to the analogous intermediate from 1,2-cyclohexanedione could be ascribed to the s-*trans* geometry

**Scheme 3**



between the carbonyl group and the iminium group in the former which would facilitate the expulsion of carbon dioxide in the former compound.

## EXPERIMENTAL

IR spectra were recorded on a Jasco FT/IR 200 spectrophotometer. $^1$H NMR and $^{13}$C NMR spectra were run on a Jeol EX-400 spectrometer (400 MHz for proton, 100.1 MHz for carbon), and on a Jeol EX-270 spectrometer (270 MHz for proton, 68 MHz for carbon) using deuteriochloroform as the solvent and tetramethylsilane as the internal standard. Chemical shifts are expressed in parts per million (δ). Coupling constants are given in Hz. Optical rotations were determined on a Perkin Elmer Model 241 polarimeter. Mass spectra were recorded on a ion trap instrument Finnigan GCQ (70 eV). HPLC analysis were run on a Hewlett Packard Series 1100 instrument the chiral column being a Lux 5 μm Cellulose-2 (Phenomenex) with a Cellulose tris(3-chloro-4-methylphenylcarbammate) chiral stationary phase, eluent: *n*-hexane/isopropanol 75:25, detector UV 220 nm; TLC's were performed on Polygram® Sil G/UV$_{254}$ silica gel pre-coated plastic sheets. Flash chromatography was run on silica gel for flash-chromatography (BDH). Elemental analyses were determined on a Carlo Erba 1106 instrument, at the Department of Chemical Sciences and Technologies of the University of Udine, Italy. Light petroleum refers to the fraction with b.p. 40–70°C and ether to diethyl ether. 2,3-Butanedione, L-proline, (2*S*,4*R*)-4-hydroxyproline, and β-nitrostyrene were purchased from Sigma-Aldrich and 1,2-cyclohexanedione was purchased from Lancaster.

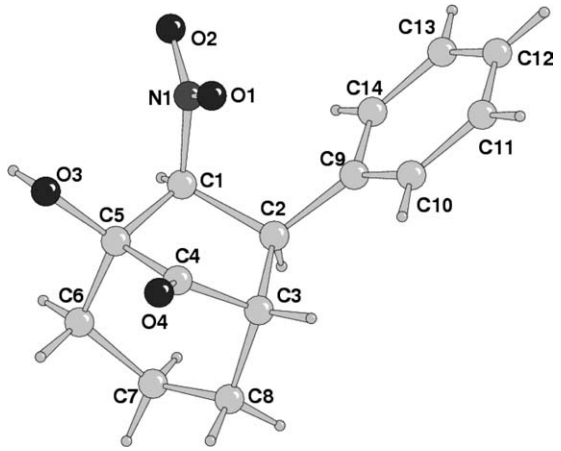


**Figure 2.** Molecular structure of compound **12**.

**General procedure for the reactions between α-dicarbonyl compounds 1a–c and 9, β-nitrostyrene 2 and L-proline or (2*S*,4*R*)-4-hydroxyproline 5.** To the α-dicarbonyl compound (1.0 mmol) in isopropanol (10 mL), β-nitrostyrene (1.0 mmol) and the appropriate proline derivative (1.0 mmol) were added. The mixture was set aside at room temperature until completion of the reaction, which needed different times depending on the substrate (96 h for diacetyl and 24 h for 1,2-cyclohexanedione). The solvent was eliminated and the crude reaction mixture was chromatographed on silica gel (eluent: *n*-heptane–ethyl acetate, gradient).

**Crystal structure determinations.** Diffraction data for the structures reported were collected at room temperature on a Nonius DIP-1030H system (Mo-K$\alpha$ radiation, $\lambda = 0.71073$ Å). Both the structures were solved by direct methods and refined by the full-matrix least-squares method based on $F^2$ with all observed reflections [8]. The calculations were performed using the WinGX System, Ver 1.80.05 [9].

**Crystal data for 6a.** $C_{16}{\cdot}H_{20}{\cdot}N_2{\cdot}O_4$, fw = 304.34 g/mol; Tetragonal, $P\ 4_1$, $a = 13.640(3)$, $c = 8.299(2)$ Å, $V = 1544.0(6)$ Å$^3$, $Z = 4$, $D_{calcd} = 1.309$ g/cm$^3$, $\mu$(Mo-K$\alpha$) = 0.095 mm$^{-1}$, $F(000) = 648$, $\theta = 24.71°$. Final $R_1 = 0.0426$, $wR_2 = 0.0996$, GOF = 0.850 for 132 parameters and 1370 unique reflections, of which 815 with $I > 2\sigma(I)$, residuals in $\Delta F$ map 0.186, –0.181 e. Å$^{-3}$.

**Crystal data for 12.** $C_{14}{\cdot}H_{15}{\cdot}NO_4$, fw = 261.27 g/mol; Monoclinic, $P\ 2_1$, $a = 8.323(2)$, $b = 6.309(2)$, $c = 12.535(3)$ Å, $\beta = 104.31(3)°$, $V = 637.8(3)$ Å$^3$, $Z = 2$, $D_{calcd} = 1.361$ g/cm$^3$, $\mu$(Mo-K$\alpha$) = 0.100 mm$^{-1}$, $F(000) = 276$, $\theta = 24.69°$. ## CONCLUSION

Although [3+2]cycloadditions between 1,3-azomethine ylides and activated olefins are known, the easy access to these polyfunctionalized pyrrolizidines is interesting, in particular, as far as the formation of the nitro spiro pyrrolizidine is concerned. In fact, a similar spiro pyrrolizidine of terpenoid nature, the (+)-nitropolyzonamine [10], extracted from a millipede, has been studied as a potential allomone to deter predators [11].

**Acknowledgment.** The authors thank MIUR (PRIN 2007) and the University of Trieste–Finanziamento Ricerca d'Ateneo for financial support.

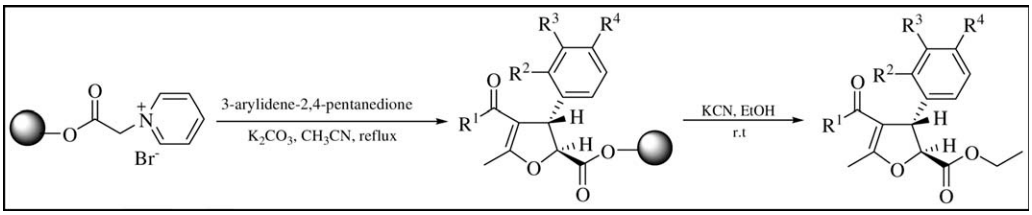
Published online 11 May 2010 in Wiley InterScience (www.interscience.wiley.com).



A facile synthesis of tetrasubstitude 2,3-dihydrofurans has been conducted using poly(ethylene glycol) (PEG) as a soluble polymer support. The PEG-supported pyridinium ylides react with 3-arylidene-2,4-pentanedione in the presence of triethylamine (TEA) via conjugate addition to form PEG-supported dihydrofuran derivatives, being cleaved by 1% KCN/EtOH to afford *trans*-tetrasubstitude-2,3-dihydrofurans, varying from good to excellent yields.

*J. Heterocyclic Chem.*, **47**, 671 (2010).

## INTRODUCTION

Dihydrofurans are the most important heterocycles not only because of their biological activities [1] but also to potential usefulness as synthetic intermediates, for example, they are precursors of furans by oxidation. Searching for new and efficient methods for their synthesis is always an area of synthetic interest. With a number of methods available, though, the synthesis of dihydrofurans using polymer as support has never been reported. Our laboratory has accumulated abundant experience in soluble polymer supported synthesis [2] and has successfully synthesized indolizines using poly(ethylene glycol) (PEG)-supported pyridinium ylides [3]. Based on our previous work, herein we report the facile synthesis of tetrasubstituted dihydrofuran deriatives via the reaction of 3-arylidene-2,4-pentanedione analogues **3** [4] with PEG-supported pyridinium ylides 2 (Scheme 1).

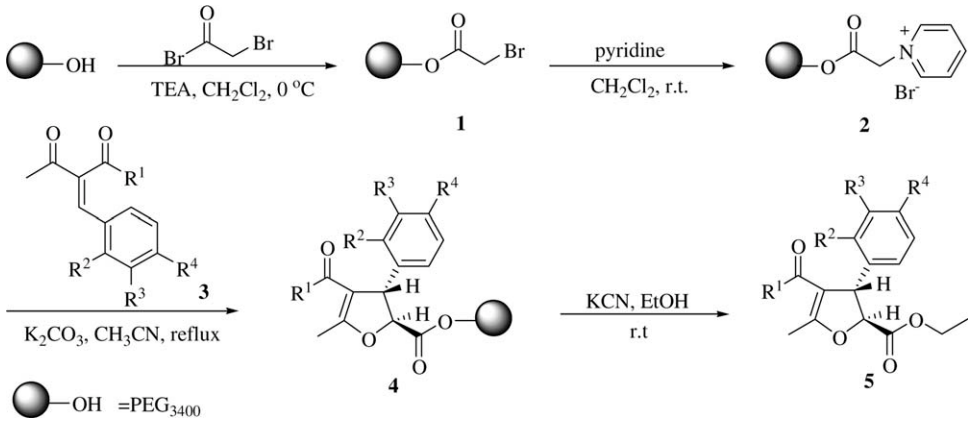
## RESULTS AND DISCUSSION

As shown in Scheme 1, $PEG_{3400}$ was first treated by two equivalent bromoacetyl bromide with equimultiple triethylamine (TEA) as base in dry dichloromethane at 0°C overnight to form **1**. The IR spectroscopy of **1** exhibits characteristic C=O absorption band at 1750 $cm^{-1}$ with the disappearance of the O—H absorption at 3448 $cm^{-1}$. After purification and vacuum drying, **1** was reacted with pyridine overnight in dry dichloromethane to afford PEG-supported pyridinium ylides **2**. The $^1H$ NMR spectroscopy of **2** shows a strong signal of the pyridine protons at δ 9.46, 8.62, and 8.20. The ylides reacted with 1.5 equivalent of 3-arylidene-2,4-pentanedione **3** at refluxing temperature via conjugate addition in dry acetonitrile using $K_2CO_3$ as a base, and **4** was obtained as brown powder in excellent yields. Finally, the 2,3-dihydrofuran **5** was cleaved from **4** by treating **4** with 1% KCN in dry ethanol solution at r.t. over night in 80–93% yields.

The earlier papers reported that using ylides react at 0°C or even −78°C gives birth to cyclopropane and dihydrofuran products, but if choosing higher temperature only dihydrofuran was obtained [5]. Probably because of the raise of temperature, the less stable carbon anionic intermediate **A** would transform to oxygen anionic intermediate **B**, thus resulting in the contrast of their chemselectivity; the higher the temperature is chosen the better chemselectivity is gained. Their common mechanism is shown in Scheme 2.

During the study of the mechanism, we envision that we could use PEG-supported pyridinium ylide to synthesize 2,3-dihydrofuran derivatives in acetonitrile at refluxing temperature. Indeed, we do obtain 2,3-dihydrofuran as the only product in our route. The stereochemistry of 5a is assigned from a combination of its COSY spectra in which a *trans*-geometry between the 4 and 5-

**Scheme 1**



positions is observed ($J = 4.2$ Hz) [6]. A plausible reaction mechanism is shown in Scheme 3. As the reaction conducts at refluxing temperature, the carbon anionic intermediate I is so instable that it would be transformed to oxygen anionic intermediate II, so no cyclopropane derives from a three-membered ring could be detected. There are two possible scenarios when the enolate oxygen attacks $C_2$ from the backside of leaving group ($Py^+$) such as III and IV. To be largely affected by the steric hindrance (Ar and PEG-OCO), especially by the group of PEG-OCO, IV is so instable as to be insignificant, thus *trans*-2,3-dihydrofuran is the only product detected in our route (Scheme 3).

Initial attempts worked perfectly with ethyl-2-(4-chlorobenzylidene)-3-oxobuancate **3a** and PEG-supported pyridinium ylieds **2** in acetonitrile at refluxing temperature with $K_2CO_3$ as base and *trans*-5-methyl-3-(3-nitrophenyl)-2,3-dihydrofuran-2,4-dicarboxylic acid diethyl ester **5e** was formed in 82% yield (based on the loading capacity of PEG). To probe into the generality of this finding, we extend the investigation to a number of substrates, of which 17 products have never been reported. The results are summarized in Table 1.

This method has a number of advantages including high yields, simple purification, and absence of competing side reactions such as C-cyclization, which are all based on the features of PEG supported synthesis [7]: (a) in each step, the excess low molecular regents are used to promote the balance movement to the product direction so as to obtain high yields; (b) the PEG supported group provides huge steric hindrance to restrict enolate oxygen to attack carbon at a certain direction, thus leading to high stereoselectivity; and (c) PEG-bound products can be conveniently recrystalled in cold ethyl ether, and the by-products are removed by simple filtration, which simplifies the purification a lot.

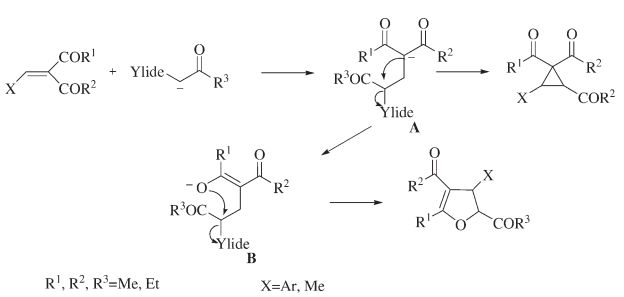
In conclusion, we have successfully synthesized 22 *trans*-tetrasubstituted 2,3-dihydrofuran derivatives via the reaction of 3-arylidene-2,4-pentanedione with PEG-supported pyridinium ylides in high yields, simple purification and 17 products have never been reported.

## EXPERIMENTAL

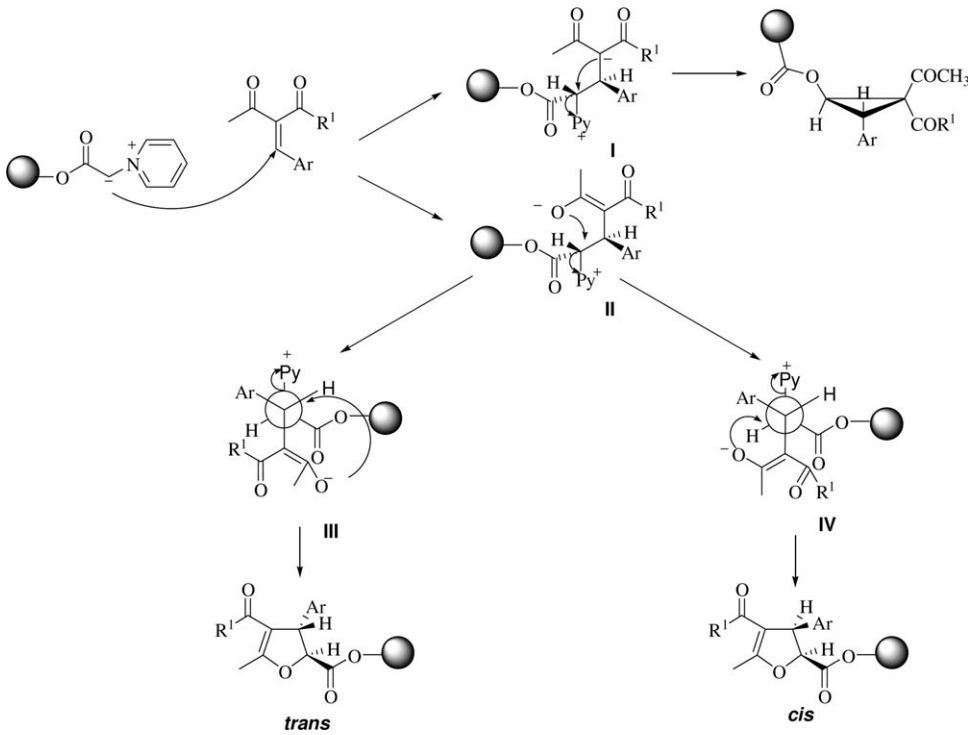
All organic solvents were dried by standard methods. $PEG_{3400}$ (Aldrich, 3015–3685) and PEG-supported compounds were melted in vacuum at 80°C for about 30 min before use, to remove any trace of moisture. Melting points were measured by a X-6 digital melting point apparatus and uncorrected. IR spectra were recorded in an IR-Spectrum One spectrometer (Perin Elmer), using NaCl pellets. Mass spectra were recorded on Finnigan LCQ DUO MS system. $^1H$ NMR (600 MHz) and $^{13}C$ NMR (150 MHz) spectra were recorded in a Varian Unity INOVA 600 spectrometer in $CDCl_3$ using TMS (0.03%) as internal standard.

**Preparation of PEG-supported pyridinium ylides 2.** A solution of bromoacetyl bromide (1.02 mL, 11.76 mmol) in dry $CH_2Cl_2$ (2 mL) was added dropwise to a solution of $PEG_{3400}$ (10.0 g, 5.88 mmol OH) and $Et_3N$ (1.65 mL, 11.76 mmol) in dry $CH_2Cl_2$ (30 mL) at 0°C and stirred at r.t. overnight. The mixture was washed with $H_2O$ to remove $Et_3N{\cdot}HBr$, dried over $Na_2SO_4$ and concentrated. After precipitation with cold $Et_2O$, washing with cold $Et_2O$ and drying under vacuum, a light yellow solid **1** was obtained. Pyridine (0.94 mL, 11.76 mmol) was added to a solution of **1** in dry $CH_2Cl_2$ (30 mL) and stirred at r.t overnight. After precipitation from cold $Et_2O$, the suspension was filtered and washed with cold $Et_2O$ to obtain solid **2** (11.0 g, 98%). TLC (EA:PE =

**Scheme 2**



**Scheme 3**



1:4) showed that the solid was free from any low molecular reactants and by-products. IR (NaCl): 3057, 2882, 1751, 1147, 1114, 730 $cm^{-1}$. $^1H$ NMR (600 MHz): δ = 9.46 (d, 2H, *J* = 4.2 Hz, α-pyridine), 8.62 (t, 1H, *J* = 6.4 Hz, γ-pyridine), 8.20 (t, 2H, *J* = 6.0 Hz, β-pyridine), 6.18 (s, 2H, —$CH_2COO$—), 3.64–3.51 (m, 4nH, —$O(CH_2CH_2O)n$—).

**Typical procedures for preparation of 2,3-dihydrofurans 5.** A mixture of PEG-supported pyridinium ylides **2** (2.3 mmol), 3-benzylidene-2,4-pentanedione (3.44 mmol), and $K_2CO_3$ (3.44 mmol) in $CH_3CN$ (20 mL) was refluxed for 12 h to form **4**. After the solvent was evaporated under vacuum, the residue was added to $CH_2Cl_2$ (5 mL) and recrystalled in cold $Et_2O$. Filtering the precipitation and being washed by the cold $Et_2O$ until no low molecular reactants and by-product, which were detected by the TLC (EA:PE = 1:4). Product **4** was treated with 1% solution of KCN in EtOH (30 mL) and stirred at r.t overnight, evaporated EtOH and precipitated with cold $Et_2O$ to obtain the crude products, which were purified by column chromatography on silica gel (EA:PE = 1:4) to afford the pure **5**.

A number of derivatives of isoxazolo[4,3-*d*]pyrimidine and isoxazolo[4,5-*d*]pyrimidine were prepared with potential anticancer activity. Condensation of 4-amino-5-benzoyl-isoxazolo-3-carboxylic acid hydrazide with ethyl orthoformate and then with different amines gave a series of 3-benzoyl-7-oxo-7*H*-isoxazolo[4,3-*d*]pyrimidin-6-yl-aryliden-formamidine. A series of 5-aminomethyl-7-phenyl-isoxazolo[4,5-*d*]pyrimidine-3-carboxamide was obtained from 4-amino-5-benzoylisoxazole-3-carboxamide with acetonitrile, and chloroacetonitrile with gaseous hydrogen chloride. Some of these compounds were tested for their cytotoxic activity.

## INTRODUCTION

The bases of the 9*H*-purines adenosine (adenine) and the adenosine metabolite inosine (hypoxantine) are endogenous ligands of different receptors. Adenosine is an endogenous ligand of adenosine receptors (AR). They are subdivided into four subtypes ($A_1$, $A_{2A}$, $A_{2B}$, and $A_3$) [1]. Adenosine receptors have been actively studied as potential therapeutic targets in several disorders, such as Parkinson's disease, schizophrenia, analgesia, and ischemia, and as cytostatics. Inosine is a highly selective ligand for the $A_3$ receptor subtype [2,3] and so is a ligand of the benzodiazepine receptor [4,5]. The nitrogen atoms at positions 3 and 7 of both purines and their derivatives take part in the formation of a hydrogen bond with these receptors [5,6]. For example, substitution of the nitrogen atom at position 7 in inosine gave 7-methylinosine, which was ineffective in binding to the benzodiazepine receptor [5]. Therefore, we have been working on synthetic derivatives of two isomers of isoxazolopyrimidine, 4,3-*d* and 4,5-*d*, which may be considered as 7,9-dideaza-7-oxa-8-aza purines, and which may have high biological and similar receptor activity. Only the isomers from four isomers of isoxazolopyrimidine have nitrogen and oxygen heteroatoms at positions analogous to the 9*H*-purines. The literature concerning derivatives of both isomers contains a few same papers in which the authors obtained isoxazolo[4,5-*d*]pyrimidine but did not assay their biological activity [7–9]. Some derivatives of isoxazolo[4,5-*d*]pyrimidine were shown to be CRF (corticotrophin releasing factor) antagonist and may be useful as cCMP phosphodiesterase inhibitors [10,11]. Another derivatives of isoxazolo[4,5-*d*]pyrimidine that are structurally similar to hypoxantine can have anxiolytic activity comparable to that of diazepam [12]. In contrast, compared with diazepam the derivatives of isoxazolo[4,3-*d*]pyrimidine are devoid of anticonvulsant and anxiolytic properties [13].

## RESULTS AND DISCUSSION

**Synthesis.** In continuation of our program we report the synthesis of new derivatives of the title compounds. The synthetic pathways used to obtain the target compounds are depicted in Scheme 1. The starting material **1** was obtained by the Thorpe reaction according to Gewald et al. [14], by which it could be converted into hydrazide **2** [15]. Hydrazide **2** with aldehydes gave the new hydrazido-hydrazones **3**-**5**, which were condensed with ethyl orthoformate in the presence of the acetic anhydride, yielding the new derivatives of isoxazolo[4,3-

**Scheme 1**

*d*]pyrimidines **6**-**8**. The acid hydrazide **2** was refluxed in a mixture with only equimolar amounts of triethyl ortho-formate, giving [4-amino-3-(1,3,4-oxadiazol-2-yl)isoxazol-5-yl]-(phenyl)methanone [15]. If hydrazide **2** was refluxed with an excess of triethyl orthoformate and acetic anhydride, then the derivatives of isoxazolo[4,3-*d*]pyrimidine **6**-**8** and **9**,**10** were formed, which with differ-rent amines formed new derivatives of 3-benzoyl-7-oxo-7*H*-isoxazole[4,3-*d*]pyrimidin-6-yl-aryliden-formamidine **11**–**14**. Compound **1** was heated in acetonitrile or chloroacetonitrile with gaseous hydrogen chloride to form the new derivatives of isoxazolo[4,5-*d*]pyrimidine **15**–**16**. Mechanism of the reaction was described earlier by Shishoo *et al* [16,17]. Compound **16** reacts with amines to form the new 5-(aminemethyl)-7-phenyl-isoxazolo[4,5-*d*]pyrimidine-3-carboxamide **17**–**20**. It is well

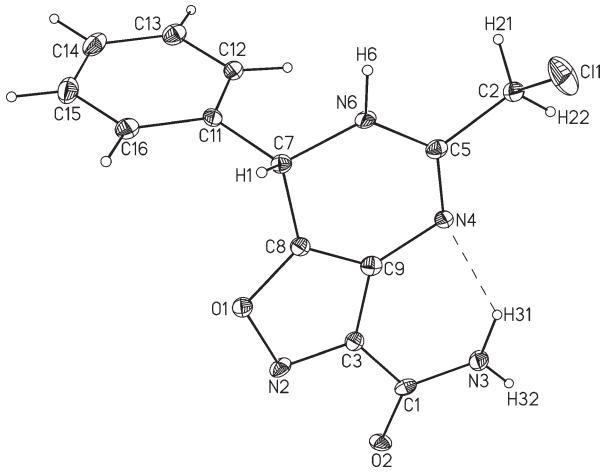

**Figure 1.** A view of the molecular structure of compound **21** with the atomic numbering scheme. Ellipsoids are at the 35% probability level.

known that isoxazole rings are readily cleaved by hydrogenation [18–21]. Thus the reduction of compound **16** followed by treatment with sodium borohydride in methanol at room temperature gave compound **21** with only one reduced double bond at position 6-7 from four. X-ray crystallography of compound **9** (Fig. 1) confirmed that the resulting structure was indeed compound **21** and **15**,**16**, and **17**-**20**.

However, amid **1** readily reacts with nitriles and forms compounds **15**,**16**. Of the compounds selected by the staff members of the NCI the derivatives isoxazole **3c**, isoxazole[4,3-*d*]pyrimidine **9**, and isoxazole[4,5-*d*]pyrimidine **19** were interesting.

**Crystallographic part.** X-ray diffraction studies: The X-ray diffraction data were collected at 100 K for a crystal of size 0.2 × 0.25 × 0.25 mm. All measurements were made on a KM4 CCD computer-controlled κ-axis diffractometer with graphite-monochromated $MoK_{\alpha}$(0.71073 Å) radiation. The intensities were corrected for Lorentz and polarization effects, but no corrections were made for absorption. The structure was solved by direct methods with SHELXS-97 and refined by full-matrix least-squares methods on $F^2$ using the SHELXL-97 [22] program. Nonhydrogen atoms were refined with anisotropic thermal parameters. All the H atoms were located using a differrence Fourier map and refined.

Figure 1 was drawn using the XP program [23]. Crystal data for 5-chloromethyl-7-phenyl-6,7-dihydro-isoxazlo[4,5-d]pyrimidine-3-carboxamide **21**: $C_{13}H_{11}N_4O_2Cl$, T = 100(2) K, $M$ = 290.71, orthorhombic, space group $Pna2_1$, with $a$ = 14.713(2) Å, $b$ = 16.745(2) Å, $c$ = 5.236(1) Å, $V$ = 1290.0(3) $Å^3$, $Z$ = 4, $D_c$ = 1.4969 g $cm^{-3}$, μ = 0.303 $mm^{-1}$. There were 2930 unique reflections, of which 2553 were considered as observed, with final $R$ = 0.0439 and wR = 0.079.

The molecular structure and atom numbering scheme are shown in Figure 1. Compound **21** crystallizes in a noncentrosymmetric $Pna2_1$ space group with one molecule per asymmetric unit. The determination of the structure of compound **21** confirms the S configuration of the chiral atom C7. The interatomic distances for C5-N4 [1.310(3) Å] and C3-N2 [1.320(3) Å] are typical of carbon-nitrogen double bonds [24] (1.279–1.329 Å) and the C9-N4 [1.401(3) Å] and C7-N6 [1.476(3) Å], bond lengths correspond to typical carbon-nitrogen single bonds (1.366–1.454 Å).

The isoxazole and pyrimidine rings are essentially planar, with maximum deviations from the calculated mean plane of 0.006(2) Å (C9) and 0.036(2) Å (C8), respectively. The dihedral angle between the best planes through the isoxazole ring and the pyrimidine ring is 3.0(2)°, indicating that the whole molecule is almost planar. The carboamide moiety deviates slightly from the isoxazole ring plane, the N3-C1-C3-N2 and O2-C1-C3-C9 torsion angles being −172.4(2)°, and –172.5(3)° respectively. The chloromethyl and phenyl moieties are nearly perpendicular, to the pyrimidine ring.

The dihedral angles between the pyrimidine ring plane and the Cl1-C2-C5 and C11-C16 planes are 66.6(1)° and 77.8(1)°, respectively.

In the present structure the nearly planar conformation of the title compound is stabilized by a network of intermolecular and intramolecular hydrogen bonds.

The hydrogen bond involving the amide H31 atom is bifurcated, H31 forming one intramolecular hydrogen bond with the N4 atom of the pyrimidine ring and the Cl1 atom of the chloromethyl moiety. The distances between the N(2)-H31...N(4) and N2-H31...Cl1(−x + 1, −y + 1, z − 1/2) atoms are 2.946(3) and 3.552(2) Å, respectively. Furthermore, the amide H6 forms an N6-H6...O2(x − 1/2, −y + 1/2, z + 1) hydrogen bond with the O2 atom of the carboamide group. The distances N6...O2 and H6...O2 are 2.908(3) and 2.22(3) Å, and the angle is 139(2)°. Additionally, the amide H32 atom on N2 interacts with the ring centroid Cg of the phenyl ring, forming a nonconventional hydrogen bond of the N2-H32...π (Cg) [H32... π, 2.71 Å N2... π 3.443(3) Å, N2-H32... π 149°; symmetry code: x + 1/2, −y + 1/2, z−1]. The molecules are also linked by the C7-H1...N4, C2-H21...O2, C12-H12...O2, and C15-H15...O1[3.523(3), 3.149(3), 3.550(3), and 3.437(3) Å] weak hydrogen bonds to form a chain running parallel to the axis. The distances H...O(N) [2.51(3)–2.85(3) Å] and angles [126(2)–163(2)°] suggest some kind of weak C—H...X hydrogen bond.

[a] Data obtained from the NCI's *in vitro* human tumor cell screen.

Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: (+44) 1223 336033; e-mail: deposit@ccdc.cam.uk).

**Cytotoxic screening.** The cytotoxic studies were performed at the National Cancer Institute, (NCI, Bethesda, MD). The screening is a two-stage process beginning with the evaluation of the compound against 60 different human tumor cell lines representing leukemia, melanoma, and cancers of the lung, colon, brain, breast, ovary, prostate, and kidney at a single dose of 10 μmol.

Evaluation of the cytotoxic activity was performed for compounds **5**, **6**, **9**, **11**, and **19**. Only compounds **5**, **9**, and **19** showed interesting activity in the panel 62 tumor cell lines, but chiefly on the renal cancer line UO-31. Data on the active compounds are presented in Table 1.

## EXPERIMENTAL

Melting points were determined with a Boethius apparatus and are uncorrected. The progress of the reaction and the purity of the compounds were monitored by TLC on analytical silica gel plates (Merck $F_{254}$, Darmstadt, Germany). IR spectra were recorded on a Specord M80 spectrometer (Zeiss/Analytic Jena, Germany) for KBr dises. $^1$H NMR spectra were recorded with a Bruker Avance ARX-300 instrument (Bruker Analytic, Karlsruhe, Germany; Bruker AG, Fallanden, Switzerland). Chemical shifts are reported in ppm downfield from the internal tetramethylsilane reference and the coupling constants are in Hz. Mass spectra were recorded on a Finningan Mat 95 GC-MS (Finningan, Bremen, Germany) with an ionization energy of 70 eV. Elemental analyses were performed on a Perkin Elmer 2400 analyzer (Waltham, MA) and the results are within ± 0.4% of the theoretical values obtained for the new compounds. The chemicals and reagents for synthesis were obtained from Alfa Aesar (Karlsruhe, Germany), Chempur (Piekary Sl., Poland), and Lancaster (Frankfurt am Main).

**General procedure for the synthesis of compounds 3-5.** To a stirred solution of acid hydrazide **2** (2.46 g, 0.01 mol) in 20 mL of anhydrous 1,4-dioxane heated at 80°C, the appropriate aldehyde (0.012 mol) was added. The reaction mixture was heated under reflux for 5 h and the solvent was rotoevaporated. The resulting solid was recrystallized from the appropriate solvent.

***4-Amino-5-benzoyl-N-(ethylideneamino)isoxazole-3-carboxamide (3).*** Yield: 1.78 g (65.5%), mp 191°C (1,4-dioxane); IR (potassium bromide): 3500, 3395 ($NH_2$), 3260 (NH), 1685, 1660 (CO), 1640 (C=N) cm$^{-1}$; $^1$H NMR (DMSO-$d_6$): δ 1.94–2.00 (d, 3H, $CH_3$, $J$ = 6.0 Hz ), 6.41 (s, 2H, $NH_2$), 7.68 (m, 3H, arom.), 7.80–7.90 (q, 1H, CH, $J$ = 6.0 Hz), 8.00–8.10 (d, 2H, arom.), 12.06 (s, 1H, HN-CO). *This work was performed under Professor Sayre's direction. Professor Lawrence M. Sayre passed away May 8, 2009, following an incapacitating stroke. His impact on the lives of his colleagues, students, and friends was profound and he is deeply missed [3]. We dedicate this article to him as a great mentor and brilliant scientist.*

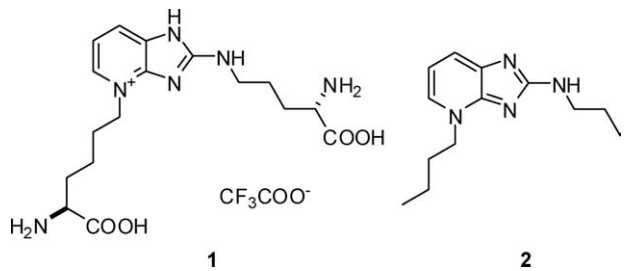
Pentosidine framework 4-butyl-2-propyl-4*H*-aminoimidazo[4,5-*b*]pyridine (**2**) was synthesized through a five steps reaction sequence. The regiochemistry of **2** was confirmed by an unambiguous synthesis, and the UV absorption and fluorescent properties of **2** were examined.

*J. Heterocyclic Chem.*, **47**, 683 (2010).

## INTRODUCTION

Pentosidine (**1**) is one of the major fluorescent advanced glycation end products that have been isolated and structurally characterized. It was isolated in trifluoroacetic acid salt form from dura mater by Sell and Monnier in 1989 [4]. It was postulated that pentosidine forms from a lysine residue and an arginine residue crosslinked by a pentose [4–6]. The fluorescent properties of pentosidine (ex/em 335/385 nm) make it an oxidative biomarker in many clinical conditions such as diabetes, kidney disease, and other vascular illnesses [7].



**1** **2**

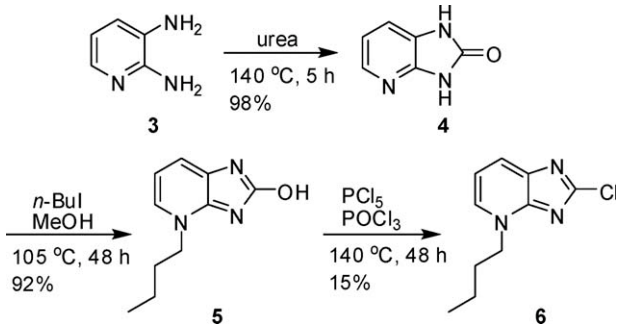
There has been only one total synthesis of pentosidine so far [8]. Shioiri and coworkers obtained 5.1 mg TFA salt of pentosidine (**1**) from their synthesis that involves an asymmetric alkylation of a chiral Schiff base to provide a lysine-like fragment, the intramolecular guanylation with mercury chloride, and the quaternization accompanied by the removal of trityl group as key steps [8].

In the investigation of the fluorescence properties of the pentosidine, one of our tasks was to evaluate the fluorescence property of the core of pentosidine, 4-alkyl-2-amino-4*H*-imidazo[4,5-*b*]pyridine, without the interference of amino acid chains. 2-Aminoimidazo[4,5-*b*]pyridine derivatives are important in medicinal chemistry because of their biological and pharmacological properties such as antihistamines, antibacterial agents, and integrin $\alpha_v\beta_3$ antagonists [9]. Therefore, a concise synthesis of the pentosidine framework 4-butyl-2-propyl-4*H*-aminoimidazo[4,5-*b*]pyridine (**2**) is of important for both biochemistry research of pentosidine and medicinal chemistry research. Herein, we report a straightforward synthesis of the pentosidine framework **2**.

## RESULTS AND DISCUSSION

Our synthesis of **2** commenced from 2,3-diaminopyridine **3** (Scheme 1). The reaction of **3** with urea furnished 1*H*-imidazo[4,5-*b*]pyridin-2(3*H*)-one (**4**) [10]. Alkylation of **4** gave 4-butyl-2-hydroxyimidazo[4,5-*b*]pyridine (**5**) in 92% yield. The transformation from **5** to **6** failed with most usual chlorodehydroxylation reagents such as thionyl chloride and phosphorus oxychloride,

**Scheme 1**

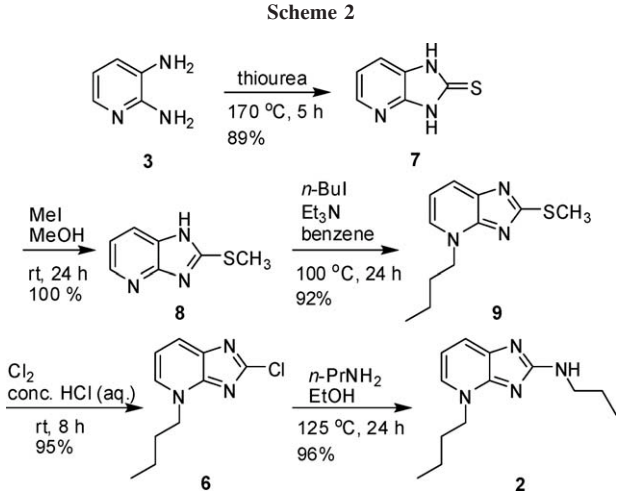


but compounds **6** could be obtained albeit in low yield (15%) after heating for 24 h in phosphorus oxychloride in the presence of phosphorus pentachloride [10].

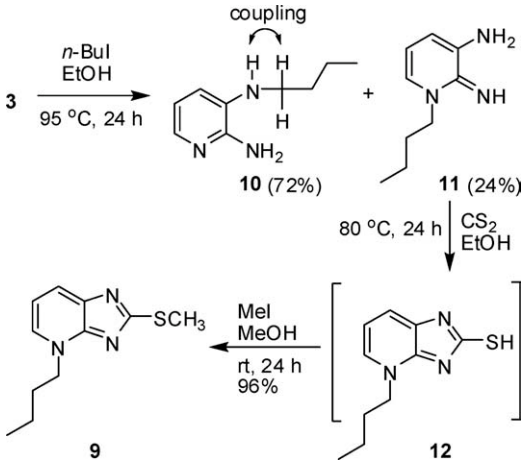
Our improved synthesis (Scheme 2) started with the reaction of 2,3-diaminopyridine **3** with thiourea, which afforded 1*H*-imidazo[4,5-b]pyridine-2(3H)-thione (**7**) [11]. Compound **7** is different from **4** in that alkylation of **7** would give an *S*-alkylated product instead of a pyridine *N*-alkylated product. Therefore, the sulfur in **7** was masked by prior methylation to give 2-(methylthio)imidazo[4,5-*b*]pyridine (**8**), which was alkylated by *n*-BuI regioselectively at the pyridine nitrogen to furnish **9** in good yields (78%) [12]. Compound **6** was obtained in good yield (96%) by bubbling $Cl_2$ through a concentrated hydrochloric acid solution of **9** followed by neutralization [13]. The reaction of **6** with *n*-$PrNH_2$ gave us the final target in good yields (97%) [14].

Although target compound **2** could be obtained according to the synthesis shown in Scheme 2 with satisfactory overall yields (75%), evidence for the regiochemistry of alkylation in **2**, **5**, **6**, and **9** was not fully discussed in the above description. We assigned both **5** and **9** as pyridine *N*-alkylated products based on the

**Scheme 2**



**Scheme 3**



expected greater nucleophilicity of the pyridine nitrogen relative to the imidazole nitrogens at positions **1** or **3** due to resonance [12]. To provide conclusive evidence for our structural assignment for **5** and **9**, as well as for compounds **6** and **2** that were obtained in subsequent steps, an unambiguous synthesis was used (Scheme 3). The synthesis started with alkylation of **3**, which was known to give only two alkylated products **10** and **11** [15]. The distinction of **11** from **10** could be made on the basis of both proton chemical shift and characteristic couplings. The chemical shift for the methylene group neighboring nitrogen in **10** is δ 3.08, whereas δ 4.22 in the case of **11** [15]. Furthermore, in **10**, the $HNCH_2$ vicinal coupling could be observed clearly in DMSO-$d_6$, whereas no such coupling was seen for **11**. The reaction of **11** with carbon disulfide and further methylation of sulfur could only provide 4-alkylated imidazo[4,5-*b*]pyridine structure **9** [16]. Compound **9** obtained through

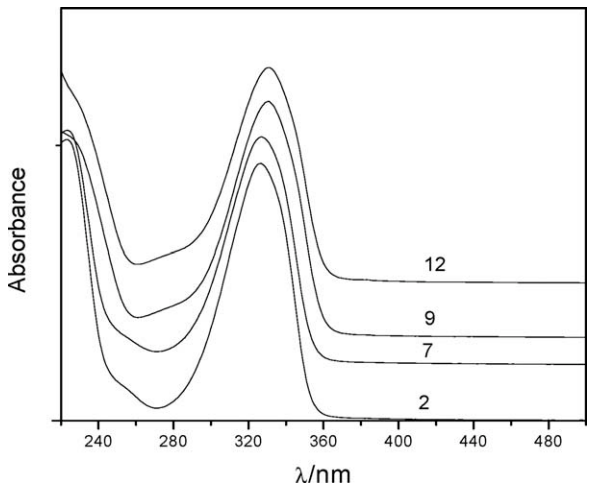


**Figure 1.** UV spectrum of **2** at pH = 2, 7, 9, and 12.

**Table 1**

Fluorescence property of pentosidine framework **2**.

| pH | Excitation $\lambda_{max}$ (nm) | Emission $\lambda_{max}$ (nm) | Relative fluorescence intensity[a] |
|---|---|---|---|
| 2 | 332 | 382 | 55 |
| 7 | 335 | 386 | 43 |
| 9 | 338 | 389 | 68 |
| 12 | | | None |

[a] When excitation $\lambda_{max}$ is 335 nm.

this route was found to be identical with the product obtained from the synthesis shown in Scheme 2. This conclusion was based not only by direct comparison of their NMR spectra run separately but also by the NMR spectrum of a 1:1 mixture.

The absorption spectra for the pentosidine framework **2** are shown in Figure 1, and its fluorescence properties (ex/em 335/385 nm) are listed in Table 1. The shifts of the $\lambda_{max}$ in different pH buffers were consistent with those of pentosidine **1** [4]. However, the variation of fluorescence intensity with pH values for **2** differed somewhat from that of **1**. Although we observed a decrease in fluorescence intensity upon increasing pH above 2, we did not observe the regain in fluorescence intensity observed for pentosidine at pH 12. As **2** lacks the free α-amino acid groups of pentosidine itself, we suggest that this is the basis of the different behavior.

In summary, pentosidine framework **2** was synthesized from readily commercially available 2,3-diaminopyridine in five steps, and the regiochemistry of the target was established by an unambiguous synthesis. This method is of material accessibility and operational simplicity and also serves as a general method to construct the 4-alkylated-2-amino-4*H*-imidazo[4,5-*b*]pyridines.

## EXPERIMENTAL

$^1$H-NMR (300 or 200 MHz) and $^{13}$C-NMR (75.1 or 50 MHz) were recorded on Varian Gemini 300 or Gemini 200 instruments. In the $^{13}$C-NMR line listings, attached proton test designations are given as (+) or (−) following the chemical shift. High-resolution mass spectra (HRMS) were obtained at 20 eV on a Kratos MS-25A instrument. UV–visible spectra were obtained with a Perkin-Elmer model Lambda 3B spectrophotometer, and fluorescence was determined using an Aminco-Bowman spectrofluorometer. TLC analysis was carried out on silica gel 60 F254 precoated aluminum sheets, and UV light was used for detection. Flash column chromatography was done using E. Merck silica gel 60 (230–400 mesh). Solvent removal was accomplished by a rotary evaporator operating at vacuum (40–50 Torr).

**1*H*-imidazo[4,5-*b*]pyridin-2(3*H*)-one (4).** A mixture of 2,3-diaminopyridine (**3**, 763.9 mg, 7.0 mmol) and urea (1.40 g, 23.3 mmol) was heated at 140°C for 5 h. The cooled reaction mixture was extracted with boiling ethanol (5 × 6 mL), leaving crystals that were collected by filtration. A second crop of crystals was obtained from the cooled filtrate after standing overnight. The combined yield of pure **4** was 929.7 mg (98%). **4**: $^1$H-NMR (DMSO-$d_6$) δ 6.93 (dd, $J$ = 7.1, 5.9 Hz, 1H), 7.21 (d, $J$ = 7.1 Hz, 1H), 7.85 (d, $J$ = 5.8 Hz, 1H), 10.82 (s, 1H, NH), 11.29 (s, 1H, NH); $^{13}$C-NMR (DMSO-$d_6$) δ 114.4 (−), 116.6 (−), 123.6 (+), 139.6 (−), 144.8 (+), 154.4 (+). HRMS calcd for $C_6H_5N_3O$ ($M^+$) 135.0433, found 135.0428.

**4-Butyl-2-hydroxy-4*H*-imidazo[4,5-*b*]pyridine (5).** A mixture of **3** (810.7 mg, 6.0 mmol) and *n*-butyl iodide (5.52 g, 30.0 mmol) in MeOH (8 mL) was sealed in a Teflon-screwed high-pressure vessel and stirred at 105°C for 48 h and concentrated. The resulting residue was diluted with a mixed solvent of $CH_2Cl_2$/MeOH (9:1), basified with 28% aqueous $NH_4OH$ solution, and subjected to chromatography ($CH_2Cl_2$/MeOH/28% aqueous $NH_4OH$ = 90:10:1) to afford **5** (1.055 g, 92%): $^1$H-NMR ($CD_3OD$) δ 0.98 (t, $J$ = 7.1 Hz, 3H), 1.41 (m, 2H), 1.92 (m, 2H), 4.42 (t, $J$ = 7.5 Hz, 2H), 7.06 (dd, $J$ = 7.5, 6.8 Hz, 1H), 7.45 (d, $J$ = 7.5 Hz, 1H), 7.84 (d, $J$ = 6.7 Hz, 1H); $^{13}$C-NMR ($CD_3OD$) δ 14.1 (−), 20.8 (+), 32.3 (+), 54.7 (+), 115.2 (−), 116.3 (−), 131.8 (−), 132.6 (+), 152.1 (+) (one quaternary peak is missing); HRMS calcd for $C_{10}H_{13}N_3O$ ($M^+$) 191.1059, found 191.1056.

**4-Butyl-2-chloro-4*H*-imidazo[4,5-*b*]pyridine (6).** A suspension of **5** (956.2 mg, 5.0 mmol) and $PCl_5$ (1.20 g, 5.40 mmol) in $POCl_3$ (120 mL) was sealed in a Teflon-screwed high-pressure vessel and stirred at 140°C for 48 h. Then, $POCl_3$ was removed under reduced pressure, and the residue was dissolved in water (10 mL) and basified to pH = 8 with 2*N* aqueous solution of NaOH. The aqueous solution was extracted with $CH_2Cl_2$, and the combined organic layers were dried over $Na_2SO_4$ and concentrated. The residue was purified by flash chromatography ($CH_2Cl_2$/MeOH, 5:1) to afford **6** (157.3 mg, 15%). $^1$H-NMR ($CDCl_3$) δ 0.93 (t, $J$ = 7.3 Hz, 3H), 1.36 (m, 2H), 1.98 (m, 2H), 4.57 (t, $J$ = 7.5 Hz, 2H), 7.09 (dd, $J$ = 7.5, 6.5 Hz, 1H), 7.68 (d, $J$ = 6.5 Hz, 1H), 8.05 (d, $J$ = 7.6, 1H); $^{13}$C-NMR ($CDCl_3$) δ 13.6 (−), 19.8 (+), 31.7 (+), 54.2 (+), 113.5 (−), 127.7 (−), 130.1 (−), 144.1 (+), 152.5 (+), 160.7 (+); HRMS calcd for $C_{10}H_{12}N_3Cl$ ($M^+$) 209.0720, found 209.0724.

**1*H*-imidazo[4,5-*b*]pyridine-2(3*H*)-thione (7).** A mixture of 2,3-diaminopyridine (**3**, 2.18 g, 20 mmol) and thiourea (7.6 g, 100 mmol) was heated at 170°C for 5 h. The reaction mixture was extracted with boiling ethanol (5 × 20 mL), leaving crystals that were collected by filtration. A second crop of crystals was obtained from the cooled filtrate after standing overnight. The combined yield of pure **7** was 2.7 g (89%). **7**: $^1$H-NMR (DMSO-$d_6$) δ 7.13 (dd, $J$ = 7.9, 5.0 Hz, 1H), 7.46 (d, $J$ = 7.9 Hz, 1H), 8.09 (d, $J$ = 5.0 Hz, 1H), 12.70 (s, 1H, NH), 13.12 (s, 1H, NH); $^{13}$C-NMR (DMSO-$d_6$) δ 116.2 (−), 118.1 (−), 125.4 (+), 142.3 (−), 146.4 (+), 169.8 (+). HRMS calcd for $C_6H_5N_3S$ ($M^+$) 151.0204, found 151.0204.

**2-(Methylthio)-1*H*-imidazo[4,5-*b*]pyridine (8).** A solution of **7** (2.26 g, 15.0 mmol) and methyl iodide (8.52 g, 60 mmol) in MeOH (30 mL) was stirred at room temperature for 24 h. Evaporation of the solvent and $CH_3I$ under reduced pressure gave pure **8** (3.32 g, 100%): $^1$H-NMR ($CD_3OD$) δ 2.75 (s, 3H), 7.20 (dd, $J$ = 7.9, 4.9 Hz, 1H), 7.82 (d, $J$ = 7.9 Hz, 1H), 8.21 (d, $J$ = 4.9 Hz, 1H); $^{13}$C-NMR ($CD_3OD$) δ 15.0 (−), 119.1 (−), 127.4 (−), 134.1 (+), 134.5 (−), 150.3 (+), 166.4

(+); HRMS calcd for $C_7H_7N_3S$ ($M^+$) 165.0361, found 165.0363.

**4-Butyl-2-(methylthio)-4*H*-imidazo[4,5-*b*]pyridine (9).** A suspension of **8** (1.65 g, 10.0 mmol) in a solution of *n*-butyl iodide (2.76 g, 15.0 mmol) and triethylamine (1.52 g, 15.0 mmol) in benzene (150 mL) was sealed in a Teflon-screwed high-pressure vessel and stirred at 100°C for 24 h and concentrated. The residue was diluted with mixed solvent of $CH_2Cl_2$/MeOH (9:1), basified with 28% aqueous $NH_4OH$ solution, and subjected to chromatography (EtOAc/acetone/MeOH/28%$NH_4OH$, 140:60:10:1) to afford **9** (2.03 g, 92%): $^1$H-NMR ($CDCl_3$) δ 0.97 (t, $J$ = 7.3 Hz, 3H), 1.38 (m, 2H), 2.01 (m, 2H), 2.78 (s, 3H), 4.60 (t, $J$ = 7.3 Hz, 2H), 7.07 (dd, $J$ = 7.7, 6.7 Hz, 1H), 7.45 (d, $J$ = 6.6 Hz, 1H), 7.84 (d, $J$ = 7.7 Hz, 1H); $^{13}$C-NMR ($CDCl_3$) δ 13.6 (−), 14.6 (−), 19.8 (+), 31.6 (+), 53.9 (+), 113.5 (−), 124.0 (−), 129.2 (−), 143.2 (+), 151.8 (+), 172.1 (+); HRMS calcd for $C_{11}H_{15}N_3S$ ($M^+$) 221.0987, found 221.0982.

**Preparation of 6 from 9.** Chlorine was introduced into a solution of **9** (664.0 mg, 3.0 mmol) in hydrochloric acid (12*N*, 300 mL) with stirring at room temperature for 8 h. After standing overnight, the reaction mixture was concentrated under reduced pressure. The resulting residue was diluted with ice water (400 mL), basified with 2*N* aqueous solution of NaOH, and extracted with $CH_2Cl_2$ (3 × 100 mL). The combined organic extracts were washed with brine, dried over $Na_2SO_4$, and concentrated resulting in a crude, which was subjected to chromatography ($CH_2Cl_2$/$CH_3OH$, 5:1) to afford **6** (597.5 mg, 95%). $^1$H-NMR, $^{13}$C-NMR, and HRMS data were identical with those of **6** prepared from **5**.

**4-Butyl-2-(propylamino)-4*H*-imidazo[4,5-*b*]pyridine (2).** A mixture of **6** (524.2 mg, 2.50 mmol) and propylamine (1.18 g, 20.0 mmol) in EtOH (30 mL) was sealed in a Teflon-screwed high-pressure vessel and stirred at 125°C for 24 h and was evaporated to result in a residue, which was subjected to chromatography ($CH_2Cl_2$/MeOH, 5:1) to afford **2** (557.2 mg, 96%). $^1$H-NMR ($CD_3OD$) δ 0.98 (t, $J$ = 7.5 Hz, 3H), 1.01 (t, $J$ = 7.3 Hz, 3H), 1.38 (m, 2H), 1.72 (m, 2H), 1.96 (m, 2H), 3.46 (t, $J$ = 6.9, 2H), 4.56 (t, $J$ = 7.3, 2H), 7.16 (dd, $J$ = 7.6, 6.6 Hz, 1H), 7.75 (d, $J$ = 7.6 Hz, 1H), 8.00 (d, $J$ = 6.6, 1H); $^{13}$C-NMR ($CDCl_3$) δ 11.5 (−), 13.6 (−), 19.6 (+), 22.8 (+), 31.4 (+), 44.9 (+), 53.3 (+), 114.2 (−), 118.1 (−), 129.9 (−), 152.6 (+), 156.7 (+), 161.8 (+); HRMS calcd for $C_{13}H_{20}N_4$ ($M^+$) 232.1688, found 232.1685.

**2-Amino-3-(butylamino)pyridine (10) and 1-butyl-3-amino-2-pyridone imine (11).** A mixture of **4** (1.09 g, 10.0 mmol) and *n*-butyl iodide (7.36 g, 40.0 mmol) in EtOH (60 mL) was sealed in a Teflon-screwed high-pressure vessel and stirred at 95°C for 24 h and concentrated. The resulting residue was dissolved in a mixed solvent of MeOH and water (1:1) (160 mL), adjusted to pH 10 with 2*N* aqueous solution of NaOH, and evaporated ending in a crude, which was subjected to chromatographic (EtOAc/MeOH, 4:1) separation to afford **10** (1.19 g, 72%) and **11** (396.6 mg, 24%). **10**: $^1$H-NMR ($CDCl_3$) δ 0.97 (t, $J$ = 7.2 Hz, 3H), 1.45 (m, 2H), 1.64 (m, 2H), 3.08 (t, $J$ = 6.7 Hz, 2H), 6.70 (dd, $J$ = 7.6, 4.8 Hz, 1H), 6.80 (d, $J$ = 7.6 Hz, 1H), 7.57 (d, $J$ = 4.8 Hz, 1H); $^{13}$C-NMR ($CDCl_3$) δ 14.0 (−), 20.4 (+), 31.5 (+), 43.6 (+), 115.8 (−), 116.7 (−), 132.5 (+), 135.8 (−), 148.7 (+); HRMS calcd for $C_9H_{15}N_3$ ($M^+$) 165.1266, found 165.1264. **11**: $^1$H-NMR ($CD_3OD$) δ 0.98 (t, $J$ = 7.3 Hz, 3H), 1.42 (m, 2H), 1.79 (m, 2H), 4.22 (t, $J$ = 7.6 Hz, 2H), 6.77 (dd, $J$ = 7.7, 6.5 Hz, 1H), 7.13 (d, $J$ = 7.7 Hz, 1H), 7.37 (d, $J$ = 6.5 Hz, 1H); $^{13}$C-NMR ($CD_3OD$) δ 14.1 (−), 20.5 (+), 30.8 (+), 55.4 (+), 115.3 (−), 120.9 (−), 128.8 (−), 135.8 (+), 146.4 (+); HRMS calcd for $C_9H_{15}N_3$ ($M^+$) 165.1266, found 165.1265.

**Preparation of 9 from 11.** A solution of **11** (165.2 mg, 1.0 mmol) and $CS_2$ (5 mL) in EtOH (8 mL) in a sealed Teflon-screwed high-pressure vessel was stirred at 80°C for 24 h and concentrated. The residue was mixed with MeI (1.41 g, 10.0 mmol) in MeOH (6 mL), stirred at room temperature for 24 h, and concentrated resulting in a crude mixture, which was subjected to chromatography (EtOAc/MeOH, 4:1) to afford **9** (179.3 mg, 81%). $^1$H-NMR, $^{13}$C-NMR, and HRMS data were identical with those of **9** prepared from **8**.

**Acknowledgments.** The authors thank the National Institutes of Health for support of this work through grants HL 53315 and AG 14249. Case Western Reserve University is acknowledged for supporting an alumina research fellowship for Y.L. (1998). They also thank Dr. D. R. Sell and Professor V. M. Monnier for helpful discussions.

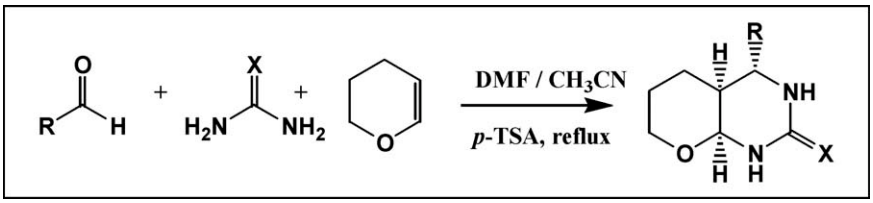
Published online 11 May 2010 in Wiley InterScience (www.interscience.wiley.com).



An efficient method for the synthesis of a series of 4-phenylhexahydro-*1H*-pyrano[2,3-*d*]pyrimidin-2(8a*H*)-one derivatives via the one-pot three-component reaction of aromatic aldehydes, urea or thiourea and 3,4-dihydro-2*H*-pyran in DMF/$CH_3CN$ using *p*-TSA catalyst is described. Although three chiral centers are created, only one diastereomer is formed in a highly selective way. This method has several advantages such as higher yield, lower cost, and shorter reaction times.

## INTRODUCTION

Multicomponent reactions (MCRs) are of increasing importance in organic and medicinal chemistry [1]. In times, where a premium is put on speed, diversity, and efficiency in the drug discovery process, MCR strategies offer significant advantages over conventional linear-type syntheses [2]. The synthesis of dihydropyrimidinones using variants of the well-established Biginelli reaction is one of the most recognized and often used MCRs for the generation of novel pyrimidine scaffolds [3]. Most notably are the batzelladine alkaloids, which were found to be potent HIV gp-120-CD4 inhibitors [4]. There is a widespread interest in the synthesis of pyranopyrimidinones and related fused ring pyrimidinones with diverse range of biological properties [5], such as antitumor, antibacterial, antihypertensive, vasodilator, bronchiodilator, hepatoprotective, cardiotonic, and antiallergic activities. Some of them also exhibit antimalarial, antifungal, analgesics, and herbicidal properties [6]. Recently, modified Biginelli reaction has been used in accessing fused pyrimidinones or spiro-fused pyrimidinones [3e,3f]. Recently, Wu and coworkers [7] reported a TMSCl catalyzed three-component diastereoselective reaction of 3,4-dihydro-(2*H*)-pyran with urea/thiourea and aromatic aldehydes to give respective 4-phenyl hexahydro-*1H*-pyrano[2,3-*d*] pyrimidin-2(8a*H*)-ones (thiones). In continuation of our previous work on the synthesis of heterocyclic compounds [8], we wish to report an efficient one-pot three-component method for the preparation of substituted 4-phenyl hexahydro-*1H*-pyrano[2,3-*d*] pyrimidin-2(8a*H*)-one derivatives using *p*-TSA as catalyst in DMF/$CH_3CN$ under reflux conditions. This method not only preserved the simplicity of Biginelli type one-pot condensation but also remarkably improved the yields of the pyrimidin-2-one derivatives in shorter reaction times (5–6 h) as against the longer reaction times required for the other catalysts (e.g., TMSCl).

## RESULTS AND DISCUSSION

Initially, we subjected the condensation of 4-fluoro benzaldehyde with urea and 3,4-dihydro-2*H*-pyran in the presence of various acid catalysts in different solvent systems at room temperature as well as under reflux conditions (Table 1). The best yield (95%) of product 4-(4-flurophenyl)hexahydro-*1H*-pyrano[2,3-*d*]pyrimidin-2(8 a*H*)-one **4g** was obtained when *p*-TSA was used as catalyst in DMF/$CH_3CN$ (1:1) under reflux conditions (entry 4, Table 1). The formation of product **4g** was confirmed by IR, $^1H$, $^{13}C$, and mass spectral analysis. Although theoretically three chiral centers are created, only one diastereomer was formed in a highly selective way. To access the stereochemistry of the product, we chose 4-methylbenzaldehyde as substrate and reacted with urea and 3,4-dihydro-2*H*-pyran in DMF/$CH_3CN$ (1:1) using *p*-TSA under identical reaction conditions. NMR spectral data determined the product as 4-(4-methylphenyl)hexa hydro-*1H*-pyrano [2,3-*d*]pyrimidin-2(8a*H*)-one **4a**. The spectral data obtained was closely identical to the literature reported [7], X-ray analyzed, diasteroselective product **4a**.

**Table 1**

Catalyst effect on the reaction of 4-fluorobenzaldehyde, urea, and 3,4-dihydro-2*H*-pyran.

| Entry | Catalyst | Solvent | Temperature (°C) | Time (h) | Yield (%) |
|---|---|---|---|---|---|
| 1 | Montmorillonite K10 | DMF/$CH_3CN$ | Reflux | 10 | 45 |
| 2 | PPA-$SiO_2$ | DMF/$CH_3CN$ | Reflux | 10 | No reaction |
| 3 | PPA-$SiO_2$ | Solvent free | 120 | 10 | No reaction |
| 4 | *p*-TSA | DMF/$CH_3CN$ | Reflux | 5.2 | 95 |
| 5 | TMSCl/NaI | $CH_3CN$ | Reflux | 10 | 62 |
| 6 | Silica sulfuric acid | DMF/$CH_3CN$ | Reflux | 10 | 35 |
| 7 | $HCLO_4$-$SIO_2$ | DMF/$CH_3CN$ | Reflux | 10 | 35 |
| 8 | *p*-TSA | DMF/$CH_3CN$ | r.t. | 24 | 15–20 |
| 9 | Montmorillonite K10 | DMF/$CH_3CN$ | r.t. | 24 | No reaction |

Because of its great facility and easy availability of catalyst, we further proceeded to examine the scope of this catalytic transformation. The reaction of 3,4-dihydro-2*H*-pyran with a range of other aromatic, and heterocyclic aldehydes and urea/thiourea under similar conditions using *p*-TSA, furnishing the respective pyrimidin-2-one derivatives **4a–4l** (Scheme 1) in excellent yields. The optimized results are listed in Table 2. All the products were fully characterized by IR, NMR, and Mass spectroscopic analysis. Many of the pharmacologically relevant substitution patterns on the aromatic ring could be introduced with high efficiency. A variety of substituted aromatic heterocyclic aldehydes carrying either electron donating or withdrawing substituents afforded high yields of products in high purity. Thiourea has also been used with similar success to provide corresponding pyrimidin-2-thione derivatives, which are also of much interest with regard to the biological activity [9].

In summary, we have developed an economically and environmentally friendly procedure for the synthesis of substituted 4-phenylhexahydro-*1H*-pyrano[2,3-*d*] pyrimidin-2(8a*H*)-ones (thiones) derivatives with excellent yields and short reaction times, which involves the use of inexpensive catalyst *p*-TSA under DMF/$CH_3CN$ reflux conditions. Furthermore, the present procedure is readily amenable to parallel synthesis and generation of combinatorial DHPMs libraries.

## EXPERIMENTAL

All reagents were obtained from commercial sources and used without further purification. $^1$H and $^{13}$C NMR spectra were recorded on Varian FT-200/50 MHz (Gemini) and Bruker UX NMR FT-300/75 MHz (Avance) instruments, in deuterated dimethylsulfoxide [D6]-DMSO. Chemical shifts are reported in parts per million relative to TMS as internal standard. LC-mass spectra were recorded on a LC-MSD-Trap-SL mass spectrometer. Elemental analyses were performed by Elementar analyzer Vario EL. Melting points has been recorded on an Electrothermal melting point apparatus. The IR spectra were obtained with Perkin Elmer 240-C instrument using potassium bromide pellets/neat. Analytical TLC of all reactions was performed on Merck precoated plates (silica gel 60F-254 on glass).

**General procedure.** Aromatic aldehyde (5 mmol), 3,4-dihydro-2*H*-pyran (5 mmol) and urea or thiourea (6 mmol) in anhydrous DMF/$CH_3CN$ (1.5 mL/3 mL) were mixed in a flask and *p*-TSA (0.3 mmol) was added at room temperature. The resulting reaction mixture was stirred at reflux for 5–6 h and then poured into crushed ice with stirring. The precipitation was isolated by filtered through a Buechner funnel and washed with water followed by pet–ether, and then dried to give the desired product. All products obtained were fully characterized by spectroscopic methods such as IR, $^1$H NMR, $^{13}$C NMR, and mass spectroscopy and have been identified by the comparison of the spectral data with those reported.

The ring transformation of *2H*-pyran-2-one by *N*-aryl amidine in the presence of KOH in DMF at room temperature resulted in a facile synthesis of the 2,6-diaryl-4-secondary aminonicotinonitrile and highly substituted unsymmetrical 2,2′-bipyridines in moderate yield.

*J. Heterocyclic Chem.,* **47**, 691 (2010).

## INTRODUCTION

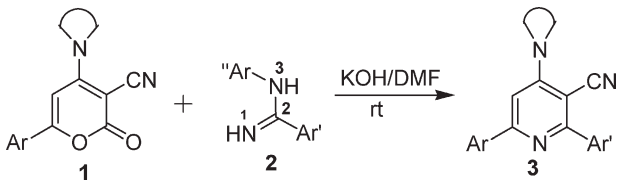
2*H*-pyran-2-ones are extensively used for the synthesis of a wide variety of heterocyclic compounds via ring transformation [1]. Ram and coworkers applied this strategy for the synthesis of various organic compounds like pyrimidine, fused heterocycles, congested benzene [1j], and pyridine [2]. The pyridine ring is one of the fundamental heterocycle present in many biologically active natural products. The compounds containing pyridine ring possess a broad range of biological activities [3]. Kawamura et al. have synthesized 4-substituted 2,6-diphenyl pyridines and reported there bleaching herbicidal activity [3b]. It was also found that 2-(*p*-aminobenzamido) pyridines exhibit a powerful inhibiting effect on gastric ulcers in rats [3g]. The pyridines 2,2′-bi- and 2,2′,2″-ter-pyridine were used as metal chelating legends with various substituents [4a]. Similarly, pyridine derivatives are of growing relevance in material science and supramolecular chemistry [4b]. Therefore, there is a continuous interest to develop the new synthetic methods for pyridines and their derivatives. Classical routes to pyridine preparation are Hantzsch [5], Chichibabin [6], Petrenko-Kritschenko and Zoneff [7], Krohnke [8], and Guareschi-Thorpe [9] condensation reactions. The condensation of 1,5-diketone with ammonia followed by nitric acid oxidation is a common approach for the synthesis of pyridines [10]. The reaction of dienamine and ketone in the presence of Vilsmeier type 1-substituted-1,2,3-benzotriazole reagent results in the formation of nicotinonitriles [11]. The construction of unsymmetrically substituted pyridines was achieved by the reaction of 1,3-dicarbonyl compounds and 3-aminoenones or nitriles [12]. Saikai et al. reported indium trichloride catalyzed synthesis of tetrasubstituted pyridines [13]. Penieres et al. have synthesized pyridine by using microwave irradiated Hantzsch reaction [14]. A transition metal mediated 6-endo-dig cyclization of *N*-propargylamine derivative was carried out by Abbiati et al. to generate a pyridine ring [15]. Combinatorial approach also has been used for the synthesis of pyridine derivatives [16]. 2,4,6-trisubstituted pyridine derivatives were prepared from aroylketene dithioacetal by Potts et al. [17]. Recently, Ram and coworkers [18] have described the use of 2*H*-pyran-2-one for the synthesis of substituted pyridines, prompted us to carry out the synthesis of novel pyridines.

## RESULT AND DISCUSSION

We investigated that compound **3** in moderate yield can be constructed from 2H-pyran-2-one **1** and the *N*-aryl amidine **2** via a ring transformation reaction using KOH in DMF at room temperature (Scheme 1).

Pyridine **3** isolated in this study could arise by nucleophilic attack of amidine N-1 at C-6 position of 2*H*-pyran-2-one. The intermediate **4** formed is unstable and it undergoes cyclization with a retro [2 + 2] process to yield **3a–i** with the loss of carbon dioxide. In the event of ring transformation of 2*H*-pyran-2-one **1** (Scheme 2) with *N*-aryl amidine **2**, the N-1 takes part in the reaction as a nucleophile rather than N-3. It might be due to the lone pair electrons on N-3 are delocalized over the

**Scheme 1.** Preparation of 2,6-diaryl-4-secondary aminonicotinonitriles **3** from 2*H*-pyran-2-one **1** and *N*-aryl amidine **2**.



benzene nucleus by orbital overlap with the π-orbital of the aromatic ring; therefore, they are less available for nucleophilic attack.

To generalize our strategy, we examined this method for the reaction of 2*H*-pyran-2-one **1** with *N*-heteroaryl amidine **6** in the presence of KOH/DMF catalytic system (Scheme 3). The reaction of 2*H*-pyran-2-one with *N*-heteroaryl amidine furnished the corresponding 2,6-disubstituted nicotinonitrile **3** in the poor yields (Table 1). The structure of the newly synthesized compounds was confirmed by spectroscopic data. It was observed that there is no improvement of yield even after 48 h also. The plausible mechanistic pathway is shown in Scheme 4.

In 2H-pyran-2-one **1**, three electrophilic centers are present C-3, C-4, and C-6, in which C-6 is more electrophilic in nature due to presence of an electron withdrawing group (—CN) at C-3 position of the ring system. The synthesis of 2,6-diaryl nicotonitrile involves the nucleophilic attack by more basic N-1 of amidine **6** at C-6 of *2H*-pyran-2-one. The attack of amidine N-1 leads to form unstable intermediate **7** followed by ring closure and a retro [2 + 2] process with the elimination of carbon dioxide to form 2,6-diaryl nicotonitrile **3**. It is noteworthy that the pyridine ring nitrogen of amidine does not involve in ring transformation reaction. The structures of compounds **3a–i** (Table 2) were determined based on the spectroscopic data and elemental analysis. Thus, in both cases (Schemes 1 and 3), the 2,6-diaryl nicotonitriles were formed exclusively without any side product.

Finally, we used our strategy to synthesize highly substituted unsymmetrical 2,2-bipyridines (Scheme 5) in presence of powdered KOH and DMF at room temperature. The results show that the yield of obtained bipyridine was moderate (Table 2). We believe that the reaction proceeds with the same mechanistic pathway as depicted in Scheme 2.

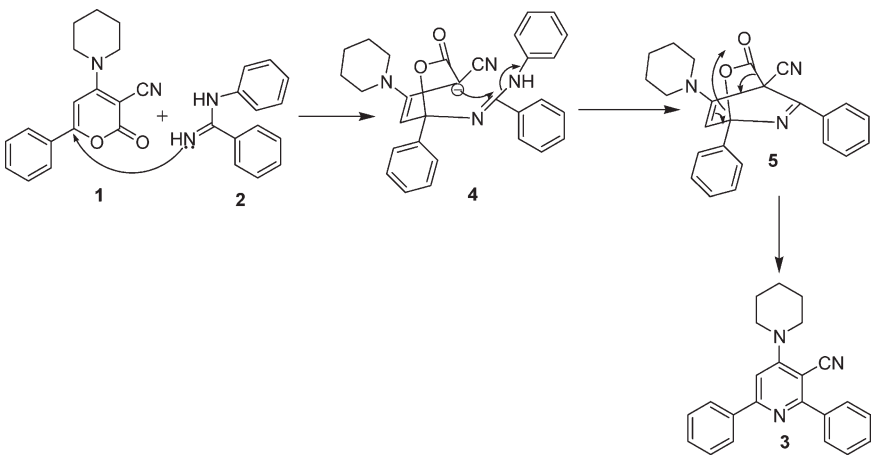
## CONCLUSIONS

In summary, this study demonstrates that the ring system proposed for nicotonitrile is correct with the substitution pattern. An additional finding is that the ring transformation of 2*H*-pyran-2-one by *N*-pyridyl amidine provides useful information for construction of the nicotonitrile ring system with 2,6-diaryl substituent. Furthermore, we synthesized highly substituted unsymmetrical bipyridine using this method. Further studies on the applications of this method for the synthesis of nicotonitrile with the 2,6-heteryl substituent are underway.

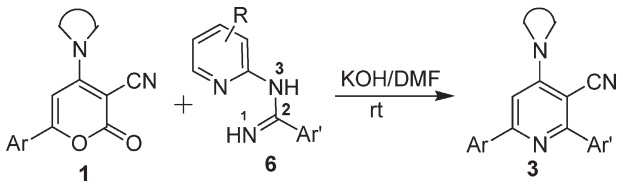
## EXPERIMENTAL

**General procedures.** Melting points were determined in open capillaries and are uncorrected. Progress of the reaction was monitored by TLC (visualization was effected by exposure to UV light). Commercial reagents were used without purification. IR spectra were recorded on a Perkin-Elmer Spectrum One spectrometer. Mass spectra were recorded under ESI mode, on Thermo Finnigan (model-LCQ Advantage MAX) mass spectrometer. $^1$H NMR and $^{13}$C NMR were recorded in $CDCl_3$ on a Bruker Spectrometers, operating at 300 MHz and 75 MHz for $^1$H NMR and $^{13}$C NMR, respectively, and shifts are given in ppm downfield from TMS as an internal standard.

**Scheme 2.** The plausible mechanism [18] for the formation of substituted compounds **3**.



**Scheme 3.** Reaction between 2*H*-pyran-2-one **1** and *N*-heteroaryl amidine **6** for synthesis of 2,6-disubstituted nicotinonitrile.



Elemental analysis was carried out on Thermo Quest microanalysis instrument, Whitehouse, NJ.

**General experimental procedure for the synthesis of 3a–l.** The mixture of 2H-pyran-2-one-3-carbonitrile (1.0 mmol), *N*-phenyl/heteroaryl benzamidine (1.0 mmol) and powdered KOH (2.0 mmol) in 5 mL DMF was stirred for 5–6 h at room temperature. The reaction was monitored by TLC. After completion of the reaction, excess DMF was removed under reduced pressure. Then the residue was poured into crushed ice with vigorous stirring. The aqueous solution was neutralized with 10% HCl, the precipitate obtained was filtered, and the obtained residue was purified by column chromatography on silica gel 60–120 by eluting 5% ethyl acetate:hexane.

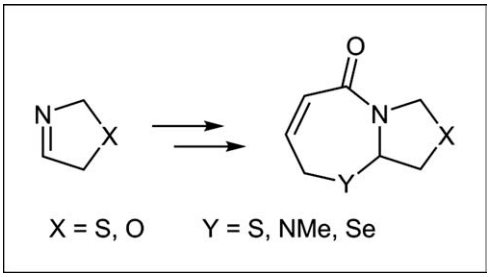
Received August 17, 2009 Revised 9 December 2009; accepted 22 December 2009
DOI 10.1002/jhet.381
Published online 11 May 2010 in Wiley InterScience (www.interscience.wiley.com).



New classes of α,β-unsaturated caprolactams containing variable heteroatoms in δ-position were synthesized from heterocyclic imines as a starting material. The synthetic route is based on an acid chloride addition followed by a ring-closing metathesis using a ruthenium catalyst.

*J. Heterocyclic Chem.*, **47**, 697 (2010).

## INTRODUCTION

α,β-Unsaturated lactams are categorized as interesting structures because of their high bioactivity depending on their functionalities as lactams and Michael acceptors. Derivatives of α,β-unsaturated caprolactams, for example, show central nervous system activity by causing convulsions and loss of muscle control [1]. Furthermore, anticancer activity was reported [2]. Saturated caprolactam derivatives, for example, were effective as anti-inflammatory agent [3] or growth-inhibiting activity on plants [4].

In the recent past, we were able to report the first synthesis of α,β-unsaturated δ-oxacaprolactams. This new substance class was synthesized by using heterocyclic imines as precursors [5]. The reaction of imines with unsaturated acid chlorides followed by treatment with allyl alcohol led to acryl amides, which were used as a starting material in ring-closing metathesis (RCM).

This synthetic route shows potential for further investigations (Fig. 1). Our aim to expand the application range of this technology was realized by inserting different heteroatoms in the lactam structure. In addition to sulfur and nitrogen, the insertion of selenium was shown in one example. Thus, the design of two new substance classes was achieved in case of nitrogen and selenium containing seven-membered lactam structures shown in Figure 1. A few derivatives of α,β-unsaturated δ-thiacaprolactams were yet known, but synthesized in a photochemical reaction [6].

## RESULTS AND DISCUSSION

We focused our attention on different heterocyclic imines serving as a starting material in the intended synthetic route. The monocyclic five-membered 2,5-dihydrothiazole **1a** [7] and 2,5-dihydrooxazole **1b** [8] were synthesized by a modified Asinger protocol [9] starting from the α-halogen aldehyde 2-chloro-2-methylpropanal.

In the first step of the synthesis, the heterocyclic imines 2,5-dihydrothiazole **1a** and 2,5-dihydrooxazole **1b** were used as precursors in the addition of unsaturated acid chloride. This type of reaction is based on Leuchs', Wulkow's, and Gerland's work [10], which described the addition of different acid chlorides to 3*H*-indole derivatives followed by addition of the nucleophiles, water, methanol, and ammonia. The insertion of thiols was published by Schwarze *et al*. [11]. Thus, the chosen acryloyl chloride and 2-methylacryloyl chloride were added to the heterocyclic imines **1** (Scheme 1). Without isolation of the α-chloro amides, allyl mercaptan or *N*-allylmethylamine was added in the presence of triethylamine to obtain the acryl amides **2** in yields up to 63% (Table 1).

The introduction of selenium into acryl amides is a demanding task because of the synthesis of allyl selenol. Because of exotic reagents used in known synthesis [12] of allyl selenol, we considered other procedures. The reaction of alkyl halogenides and sodium hydrogen selenide, formed in aqueous or ethanolic solution, leads to aliphatic selenols [13]. To prepare aromatic selenols,

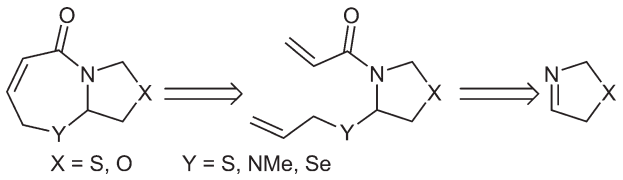


**Figure 1.** Retrosynthetical consideration of the target structure.

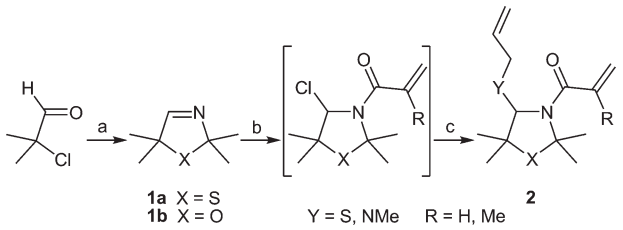
**Scheme 1.** Synthesis of acryl amides **2** starting from imines **1**. Reagents and conditions: (a) $(CH_3)_2CO$, $NH_3$, NaSH or $H_2O$, $CH_2Cl_2$, 0–5°C, (ii) r.t., 18 h; (b) (i) $H_2C{=}CRCOCl$, $CH_2Cl_2$, 0–5°C, (ii) r.t., 3 h; (c) (i) $H_2C{=}CHCH_2YH$, $Et_3N$, $CH_2Cl_2$, 0–5°C, (ii) **2d–f**: reflux, 5 h, 7–63%.



elementary selenium reacts with aryl magnesium halogenides (Grignard reagent) by inserting between magnesium and aryl moiety [14]. The first called option was not considered because water, respectively, ethanol in excess would act as nucleophile rather than the selenol. So, a selenium-Grignard reagent was formed and directly added to an α-chloro amide synthesized simultaneously of imine **1a** (Scheme 2). The acryl amide **2g** was obtained in small yield of only 6%.

Finally, the desired α,β-unsaturated caprolactams **3** were prepared from acryl amides **2** *via* RCM (Scheme 3). In the literature, only a few examples of RCM starting from acryl amides are described [5,15].

The optimized reaction conditions tested in the synthesis of α,β-unsaturated δ-oxacaprolactams [5] were transferred to the present reactions. The used ruthenium

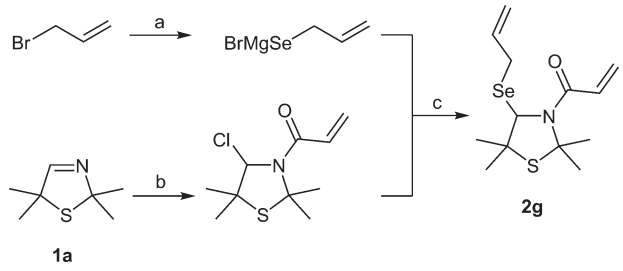
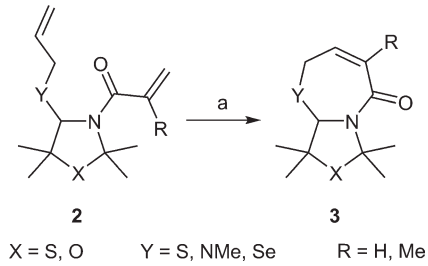
[a] The product was not obtained pure.

**Scheme 2.** Preparation of selenium containing acryl amide **2g**. Reagents and conditions: (a) (i) Mg, $Et_2O$, (ii) Se, reflux, 1 h; (b) (i) $H_2C{=}CHCOCl$, $Et_2O$, 0–5°C, (ii) r.t., 3 h; (c) r.t., 18 h, 6%.



**Scheme 3.** Ring-closing metathesis to form lactams **3**. Reagents and conditions: (a) 5 mol% catalyst **I**, toluene, r.t. up to 70°C, 2–6 h, 36–90%.



catalyst **I** is comparable to a Grubbs catalyst of the second generation (Fig. 2). The RCM was performed in toluene, starting at room temperature and slowly increasing the temperature up to 70°C. The lactams **3** were obtained in good yields up to 90% (Table 2). Accordingly, the catalyst shows a high tolerance to several functional groups.

## CONCLUSION

In conclusion, we synthesized new α,β-unsaturated caprolactams **3** containing sulfur, nitrogen, or selenium in δ-position. Starting from heterocyclic imines **1**, an addition of unsaturated acid chlorides followed by

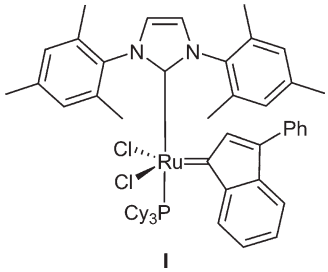


**Figure 2.** Used ruthenium catalyst **I**.

substituting the chloride with unsaturated nucleophiles and subsequent RCM led to lactams **3** offering opportunities for further functionalizations.

## EXPERIMENTAL

Synthetic procedures were performed on a vacuum line using standard Schlenk techniques under argon. All reagents and solvents were commercial grade and purified before use when necessary. The ruthenium catalyst **I**, catMETium®IMesPCy [CAS 254972-49-1], is available at Strem Chemicals. Preparative column chromatography was carried out using Grace $SiO_2$ (0.040–0.063 mm, type KG 60). TLC was performed on Merck $SiO_2$ F254 plates on aluminum sheets. $^1H$ and $^{13}C$ NMR spectra were recorded with Bruker AMX R 500 and AM 300 spectrometers. NMR chemical shifts are reported in ppm using TMS as an internal standard. Assignments of the signals in the $^{13}C$ NMR spectrum were supported by measurements applying COSY and *J* modulated techniques. CI-MS and HRMS spectra were recorded on a Finnigan MAT 212 spectrometer. IR spectra were recorded on a Bruker Tensor 27 spectrometer equipped with a GoldenGate diamond-ATR unit.

**General procedure for the preparation of acryl amides 2 (GP A)..** Under argon atmosphere, the respective imine **1** (1 equiv) dissolved in anhydrous dichloromethane (10 mL) was cooled down to 0–5°C before acid chloride (1.1 equiv) in anhydrous dichloromethane (15 mL) was added dropwise. After stirring for 3 h at room temperature, a mixture of allyl mercaptan or *N*-allylmethylamine (2 equiv) and anhydrous triethylamine (1.75 equiv) in anhydrous dichloromethane (10 mL) was added dropwise at 0–5 C. If *N*-allylmethylamine was used, the reaction mixture was refluxed for 5 h. After stirring overnight at room temperature, the solution was poured into ice-water (20 mL). The phases were separated and the aqueous phase was extracted with dichloromethane (3 × 20 mL). The combined organic phases were washed with saturated aqueous sodium hydrogen carbonate (20 mL), water (2 × 20 mL) and dried over magnesium sulfate. The solvent was removed under reduced pressure and the product was purified as described later.

**(*RS*)-1-(4-Allylsulfanyl-2,2,5,5-tetramethylthiazolidin-3-yl)-propenone (2a)..** Following **GP A**, 2,5-dihydrothiazole **1a** (0.20 g, 1.4 mmol), acryloyl chloride (0.14 g, 1.5 mmol), allyl mercaptan (70%) (0.30 g, 2.8 mmol), and triethylamine (0.25 g, 2.4 mmol) were used. A series of quinoxaline derivatives have been synthesized in excellent yields by the condensation of 1,2-diketones and 1,2-phenylenediamines in the presence of a catalytic amount of $NbCl_5$ at room temperature in short times.

*J. Heterocyclic Chem.*, **47**, 703 (2010).

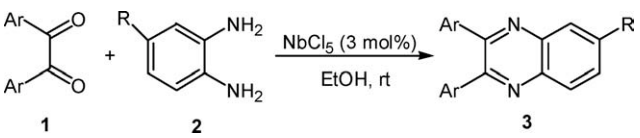
## INTRODUCTION

The quinoxaline derivatives are important heterocyclic compounds, which exhibit a diverse range of biological properties, such as antitumor [1], cytotoxic [2], antiviral, antibacterial, anti-inflammatory, and kinase inhibitor properties [3]. They have also been used as dyes, efficient electron luminescent material, organic semiconductors, DNA cleaving agents [4], photoinitiators in UV-cured coatings [5], and donor materials [6]. In addition, the quinoxaline ring is a part of a number of antibiotics, such as echinomycin, levomycin, and actinomycin that are known to inhibit the growth of gram-positive bacteria and are active against various transplantable tumors [7].

Therefore, the synthesis of this type of compounds has attracted considerable attention. Synthetic routes that are common to the preparation of these heterocycles typically involve the reaction of 1,2-diamine and 1,2-dicarbonyl compounds in refluxing ethanol or acetic acid. Various catalysts, such as bismuth(III) triflate [8], metal hydrogen sulfates [9], gallium(III) triflate [10], molecular iodine [11], cerium (IV) ammonium nitrate [12], stannous chloride [7], zirconium tetrakis(dodecyl sulfate) [13], amidosulfonic acid [14], montmorillonite K-10 [15], binary metal oxides supported on Si-MCM-41 mesoporous molecular sieves [4], polyaniline-sulfate salt [16], Wells-Dawson heteropoly acid [17], and ionic liquid 1-*n*-butylimidazolium tetrafluoroborate [18] have been used to promote this transformation. Alternative approaches, such as oxidative cyclization of α-hydroxyketones with *o*-phenylenediamines [19], reaction of *o*-phenylenediamine with α-bromoketonethe [20,21], reaction of α-keto oximes and 1,2-diamines [3], oxidative coupling of epoxides and ene-1,2-diamines [22], the coupling of α-diazoketones with aryl 1,2-diamines [23], reductive cyclization of 1,2-dicarbonyl compounds with 2-nitroanilines [7], heteroannulation of nitroketene *N*,*S*-aryliminoacetals with $POCl_3$ [24], intramolecular cyclizations of dialdimines [25], the reaction of aryl-1,2-diamines and diethyl bromomalonate [26], the reaction of *o*-phenylenediamines and ketones [27], reaction of *o*-phenylenediamines and vicinal-diols [28], and palladium-catalyzed reductive *N*-heteroannulation of enamines [29] have been also developed to prepare functionalized quinoxalines. However, the long reaction time [15], costly catalysts, such as bismuth(III) triflate [8] and gallium(III) triflate [10], requirement of special effect for catalyst preparation [4,16] and a special instrumentation, such as microwave [30], harsh reaction conditions, such as heating at 70°C [21] can not be avoided. Because of the importance of quinoxaline derivatives in organic synthesis, the development of a convenient, efficient and practically useful process for synthesis quinoxaline derivatives is in demand.

In recent years, niobium pentachloride has been considered as mild Lewis acid catalyst for a variety of organic transformations [31], such as one-pot Mannich-type reaction [32], alkoxide rearrangements [33], the intramolecular Friedel–Crafts acylation reaction [34], conversion of aldehydes and ketones to allylic halides [35], cyanosilylation of aldehydes [36], synthesis of α-aminonitriles [37], 1,1-diacetates [38], bis(indol)alkanes [39], and 1,5-benzodiazepine derivatives [40]. However, to the best of our knowledge, there is no report on the synthesis of quinoxaline derivatives using niobium pentachloride as a reagent. As part of our continuing interest in the development of new synthetic methodologies [41–46], we report herein an efficient and convenient

**Scheme 1**



procedure for the synthesis of quinoxaline derivatives by the condensation of 1,2-diketones and 1,2-phenylenediamines in the presence of a catalytic amount of niobium pentachloride at room temperature (Scheme 1).

## RESULTS AND DISCUSSION

At the onset of the research, we investigated the model reaction between 1,2-phenylenediamines and benzil in EtOH in the presence of a catalytic amount of $NbCl_5$ (3 mol%) at room temperature. To our delight, the product **3a** was formed and the complete conversion with 95% isolated yield was observed after 2 min. Further studies showed that EtOH was the best solvent among the solvents (MeOH, MeCN, THF, DMF, DMSO, $CH_2Cl_2$, and $CHCl_3$). Next, the amount of the catalyst was examined and we found that 3 mol% $NbCl_5$ was sufficient to drive the reaction completely in 95% yield. The less amount gave low yield even after a prolonged reaction time, and the more amount could not cause the obvious increase for the yield of product and could not shorten the reaction time. It is noteworthy to mention that the reaction gave only a 60% yield in the absence of $NbCl_5$ after 4 h.

To evaluate the generality of this method, we next investigated the scope and limitation of this reaction under optimized conditions (EtOH, 3 mol% of $NbCl_5$, RT) and the results are illustrated in Table 1. As shown in Table 1, a variety of structurally diverse 1,2-phenylenediamines and a wide of 1,2-diketones underwent the condensation reaction smoothly to afford the corresponding quinoxaline derivatives in excellent yields. The electronic property of the substituents on the aromatic ring of 1,2-phenylenediamines had an obvious effect on reaction time under the above optimal reaction conditions. It was observed that electron-withdrawing groups (Table 1, entries **i–o**) associated with 1,2-phenylenediamines decreased the reactivity of the substrate and long reaction times were required. It is worth noting that the reaction of 4-nitrobenzene-1,2-diamine with benzil failed to give the desired product. On the other hand, the effect of electronic factors associated with aromatic 1,2-diketons is opposite. For example, 4,4′-dibromolbenzil could react with 4-nitrobenzene-1,2-diamine to afford the corresponding product (**3o**) in 92% yield. Besides this, when 2,2′-furil and acenaphthylenequinone were subjected for condensation reaction, the corresponding products were obtained with excellent yields. All of the quinoxaline derivatives have been characterized by $^1H$ NMR, $^{13}C$ NMR, and IR spectra, and the known compounds were confirmed by comparison of their spectral data and melting points with those reported in the literature.

In conclusion, we have developed a simple, rapid, and efficient methodology for the synthesis of quinoxaline derivatives by the condensation 1,2-diketones and 1,2-phenylenediamines at room temperature using $NbCl_5$ as a novel catalyst. Simplicity of operation, high yields, short reaction time, and good substrate generality are the key advantages of this method.

## EXPERIMENTAL

Melting points were determined using an X-4 apparatus and are uncorrected. IR spectra were obtained using a Bruker-

[a] Isolated yields after column chromatography.

TENSOR 27 spectrometer instrument. NMR spectra were taken with a Bruker DRX-500 spectrometer using TMS as internal standard. Elemental analyses were carried out on a Vario EL III CHNOS elemental analyzer.

**General procedure for the synthesis of quinoxaline derivatives (3).** A mixture of 1,2-phenylenediamine (1 mmol), 1,2-diketone (1.0 mmol), and $NbCl_5$ (0.03 mmol) in EtOH (3 mL) was stirred at room temperature. The progress of reaction was monitored by TLC. After completion, water was added and the product was extracted with ethyl acetate. The organic layer was separated, dried over anhydrous sodium sulphate and the solvent evaporated under reduced pressure to afford the crude product. The crude product was subjected to column chromatography over silica gel using hexane/ethyl acetate as eluent to obtain pure product.

***9-Methylacenaphtho[1,2-b]quinoxaline (3h).*** This compound was obtained as yellow needles; IR: 3053, 1635, 1616, 1483, 1434, 1419, 1299, 1212, 1099, 983, 829, 781 $cm^{-1}$; $^1H$ NMR (500 MHz, $CDCl_3$): δ 2.63 (s, 3H), 7.59 (dd, $J$ = 8.5, 2.0 Hz, 1H), 7.83 (td, $J$ = 8.5, 2.0 Hz, 2H), 7.99 (s, 1H), 8.08–8.10 (m, 3H), 8.41 (t, $J$ =7.0 Hz, 2H); *Anal*. Published online 26 March 2010 in Wiley InterScience (www.interscience.wiley.com).

1-Acylamino-2,5-dimethylpyrroles were prepared in the exploration of heterocyclic structures useful for their antitubercular activity. The pyrroles were conveniently formed from the reaction of aromatic acid hydrazides with hexane-2,5-dione in water or ethanol, without resorting to acid catalysis. In each case, the procedure provided a single pyrrole in pure form, and the product was identified without difficulty on the basis of highly characteristic spectrometric features. Some members of this class have significant activities against drug-resistant tuberculosis *in vitro* and offer substantial protection in a rigorous mouse model of the disease.

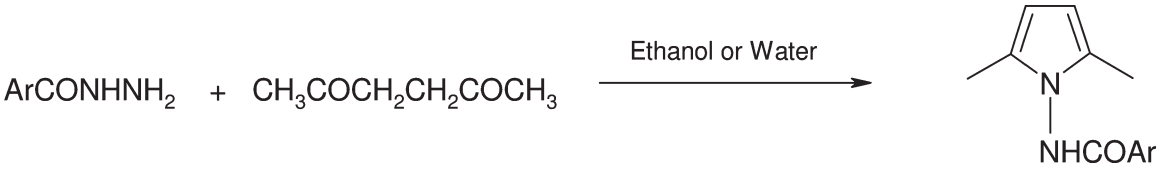
*J. Heterocyclic Chem.,* **47**, 707 (2010).

## INTRODUCTION

Worldwide, tuberculosis ranks first among the causes of death from a communicable disease [1]. This killer's designation as an international public health threat by the World Health Organization more than a decade ago [2] was followed by the mobilization of considerable resources from governments, pharmaceutical companies, philanthropic foundations, and public–private partnerships [3]. Even so, advances thus far against the disease have been hard-won, and fully one-third of the earth's population remains infected with the causative bacillus, *Mycobacterium tuberculosis* [4]. In industrialized countries, the unexpected reemergence of tuberculosis has come with substantial costs to the public health infrastructure. Among the populations of developing nations, the disease has persisted, and millions of deaths result each year from such infection [5]. Although tuberculosis can strike persons of any age, the sinister natural history of the disease makes it particularly devastating to those of middle years, during the most productive period of their lives. For those who do not themselves succumb, there is social and economic hardship as individuals, families, and communities struggle to deal with the collateral burdens of widespread infection. Progress in the development of strong new treatment regimens for tuberculosis has now been made both more difficult and more necessary by the emergence of strains of *M. tuberculosis* that are drug resistant or exceptionally virulent [6–9]. In the case of the most widely prescribed tuberculosis medication, isoniazid (isonicotinic acid hydrazide, INH), resistant strains have appeared that require drug concentrations 1000 times greater than those for susceptible bacteria. This renders the drug ineffective as a therapeutic mainstay for patients infected with those strains.

Against the urgency and seeming intransigence of this situation, there is increasing evidence that heterocyclic compounds will serve as significant leads for the discovery of robust new antitubercular medications and as valuable probes for gaining a better understanding of the life cycle of the pathogen [10–13]. Much, however, remains to be learned about the scope of heterocyclic structures that will possess this valuable antimicrobial activity [14,15]. As early as 1953, it had been reported that some pyrroles had antimycobacterial activity *in vitro* [16–20], but this perceptive observation was not given concerted follow-up at the time. More recently, significant work has resumed on antitubercular drug design using pyrroles as templates for synthesis [21–23], including elegant molecular modeling studies in conjunction with laboratory experiments [24,25]. Although much ground is still to be covered, it seems clear that the chemistry of pyrroles will provide both important lead compounds in the search for new antitubercular

**Scheme 1**



medications and tools for probing the complex interactions among pathogen, mammalian host, and drugs in tuberculosis treatment modalities.

Within this context, we wished to explore, using up-to-date methods, both the preparative chemistry and the antitubercular behavior of a class of acylaminopyrroles derived from acid hydrazides and diketones. We now report on the convenient preparation and useful antimycobacterial properties of a series of these compounds (**III**). We have found that the compounds are readily formed from aromatic carboxylic acid hydrazides (**I**) and 2,5-hexanedione (**II**) in excellent purity as stable highly crystalline solids (see Scheme 1). The reactions take place to give a single product without complication, and the resulting 1-acylamino-2,5-dimethylpyrroles may be characterized in clear-cut ways by standard spectrometric techniques. In a representative example, compound **II** was treated with INH (**I**, Ar = 4-$C_5H_4N$, 1.00 equivalent) in refluxing water for 2 h. After cooling and standing over night, the needles that formed were filtered off to give **III** (Ar = 4-$C_5H_4N$) in analytically pure form, with the distinguishing spectrometric features of the acylaminopyrrole. Notably, the features included: (1) the N—H band appropriate for the amide link near 3225 wavenumbers in the infrared spectrum; (2) the amide I and amide II peaks at 1673 and 1537 wavenumbers; (3) the N—H signal at δ 11.5 ppm in the hydrogen NMR spectrum, integrating for one hydrogen, quenched by the addition of $D_2O$; (4) the peak at δ 5.7, a singlet integrating for two hydrogens for the pyrrole ring protons; and (5) a signal at δ 11.3 ppm in the carbon nmr spectrum for the methyl groups at the 2- and 5-positions. The overall yield of the product was 67%. Our results on the preparation of these pyrroles **III** are summarized in Table 1.

In general, the preparation of a pyrrole by the reaction of a 2,5-dione with an amine, the Paal-Knorr synthesis [26], is sensitive to both the nucleophilicity of the amine and the specific reaction conditions employed. These issues have raised considerable interest within the synthesis community [27], and some trends have become apparent. Among aliphatic amines, for example, the steric environment of the carbon bearing the nitrogen appears to be crucial, with yields falling drastically as the carbon becomes more highly substituted [28]. Among substituted anilines, low reactivity is observed for those amines in which the aromatic ring is substituted with electron-withdrawing groups; thus 2,5-dichloroaniline fails to react with hexane-2,5-dione, whereas *o*-phenylenediamine is highly nucleophilic and reacts rapidly with two equivalents of the hexane-2,5-dione to produce a 1,2-dipyrrolyl benzene [28]. With respect to reaction conditions, some researchers have pointed out the accelerating role of acid catalysis [29], while others have noted that the amount of acid used, if any, should be adequate to allow for activation of the carbonyl functions of the dione but not enough to fully protonate the amine function and thereby render it nonnucleophilic [30]. In the present work, we found that in each case the terminal nitrogen of the hydrazide moiety was sufficiently nucleophilic to permit reaction in water or ethanol, without resorting to acid catalysis. This was true even for examples in which a strongly electron-withdrawing group was present, such as **IIIf**. The ability to carry out the reaction under neutral conditions considerably simplified the work-up and isolation of the products.

**Table 1**

Pyrroles **III**.

| Entry | Compound | Ar | % yield | mp (°C) | $\nu^{max}$ N—H ($cm^{-1}$) | $^1$H NMR, δ | $^{13}$C NMR, δ |
|---|---|---|---|---|---|---|---|
| 1 | **IIIa** | 4-$C_5H_4N$ | 67 | 151–153 | 3224 | 11.5 | 165 |
| 2 | **IIIb** | $C_6H_5$ | 89 | 175–177 | 3261 | 11.3 | 166 |
| 3 | **IIIc** | 4-$ClC_6H_4$ | 69 | 185 | 3274 | 11.3 | 165 |
| 4 | **IIId** | 4-$CH_3C_6H_4$ | 91 | 187–189 | 3281 | 11.2 | 166 |
| 5 | **IIIe** | 4-$BrC_6H_4$ | 77 | 207–210 | 3246 | 11.3 | 165 |
| 6 | **IIIf** | 4-$NO_2C_6H_4$ | 75 | 218–221 | 3278 | 11.3 | 165 |
| 7 | **IIIg** | 2-OH-4-$NH_2C_6H_3$ | 30 | 173–174 | 3270 | 10.9 | 162 |

**Table 2**

*In vitro* activities: Minimum inhibitory concentrations in fully susceptible Mtb Erdman.

| Entry | Compound | MIC (μg/mL)[a] |
|---|---|---|
| 1 | **IIIa** | 3.2[b] |
| 2 | **IIIb** | 16 |
| 3 | **IIIc** | 32 |
| 4 | **IIId** | >8 |
| 5 | **IIIe** | 32 |
| 6 | **IIIf** | 32 |
| 7 | **IIIg** | 2.6[c] |

[a] INH standard control MIC 0.06 μg/mL.
[b] Geometric mean of three determinations.
[c] Geometric mean of five determinations.

With respect to biological assessment, the pyrroles displayed a range of activities against both laboratory strains and drug-resistant clinical isolates of *M. tuberculosis*. Activities *in vitro* were initially determined for the pyrroles as minimum inhibitory concentration (MIC) values against *M. tuberculosis* strain Erdman (Mtb Erdman). The MIC represents the minimum concentration of the compound necessary to inhibit growth. Mtb Erdman is a fully drug-susceptible laboratory strain, often used in primary antimycobacterial assays. The determinations were referred to the known antitubercular INH as a standard control. Individual MIC values are reported in Table 2. The geometric mean of the MICs for the pyrroles tested was 12 μg/mL. For comparison purposes, tuberculosis drugs currently used in the clinic have MIC values typically ranging from 0.015 μg/mL (rifabutin) to 50 μg/mL (pyrazinamide) [31]. Of particular interest were compounds **IIIa** and **IIIg** with the lowest MICs of 3.2 and 2.6 μg/mL, respectively. These highly effective pyrroles were selected for further evaluation in a panel of three clinical strains isolated from patients showing significant drug resistance to INH, and the results are shown in Table 3. Compound **IIIa** was slightly more effective than INH itself, and compound **IIIg** clearly maintained its strong potency in the drug-resistant bacteria, demonstrating essentially the same activity *in vitro* for both INH-susceptible and INH-resistant strains.

**Table 3**

*In vitro* activities: Minimum inhibitory concentrations in drug-resistant clinical isolates.

| | | Clinical isolates | | |
|---|---|---|---|---|
| Entry | Compound | 303 | 1889 | 35829 |
| 1 | **IIIa** | 4 | 4 | 8 |
| | INH control | 8 | 4 | >8 |
| 2 | **IIIg** | 2 | 1 | 2 |
| | INH control | 64 | 8 | >64 |

**Table 4**

*In vivo* activities of pyrroles.

| Group | Log CFU/Lung |
|---|---|
| Untreated controls | 6.53 ± 0.16[a] |
| INH controls | 5.34 ± 0.22[a] |
| **IIIa** | 5.01 ± 0.73[a] |
| **IIIg** | 5.53 ± 0.16[b] |

[a] Six mice/group.
[b] Four mice/group.

For testing of compounds **IIIa** and **IIIg** *in vivo*, we used a short-course therapy model in mice, which has previously been described in detail [32]. This method provides an exacting test of the activities *in vivo* of investigational drugs and has the benefit of cutting in half the time required to produce data in animal studies, compared to the more traditional murine models. Our results are given in Table 4, in which the data are presented as the logarithms of bacterial colony-forming units (log CFU) per mouse lung, with and without administration of the candidate drugs. No overt toxicity or ill effects were observed when the drugs were administered at the therapeutic doses (see Experimental). For reference purposes, highly active drugs known to be tuberculocidal, such as INH, generally display a drop of one or more log CFU *versus* untreated controls when examined in the model. On the other hand, less-active drugs that have been characterized as tuberculostatic, as opposed to tuberculocidal, such as *p*-aminosalicylic acid (PAS), typically lead to a lowering of one-half log CFU *versus* untreated controls (see Experimental). In comparing the data for **IIIa** and **IIIg** with the untreated controls, there has been a reduction of 1.00 log CFU or more in each case, suggesting that both compounds **IIIa** and **IIIg** are bactericidal in tuberculosis-infected mice. Overall, the results *in vitro* and *in vivo* warrant further development of the antitubercular properties of pyrroles derived from aromatic acid hydrazides.

In conclusion, we have found that 1-acylamino-2,5-dimethylpyrroles, of interest in the investigation of heterocyclic structures for their antitubercular activity, can be conveniently prepared from the reaction of acid hydrazides with hexane-2,5-dione in water or ethanol without an acid catalyst. In each case, the process leads to a single pyrrole in pure form, product isolation is straightforward, and the resulting compound is readily identified on the basis of highly characteristic spectrometric features. Some members of this class have useful activities against drug-resistant tuberculosis *in vitro* and offer excellent protection in an animal model of the disease.

## EXPERIMENTAL

**General methods.** Elemental analyses were carried out by Galbraith Laboratories, Knoxville, TN. Melting points (mp; °C) were taken in open capillary tubes using a Mel-Temp apparatus (Laboratory Devices, Cambridge, MA) and are corrected. Infrared (IR) spectra were recorded on a Perkin-Elmer 1600 Fourier transform spectrometer as KBr pellets or Nujol mulls or on a Perkin-Elmer Spectrum One Fourier transform spectrophotometer fitted with a universal attenuated total reflectance sampling accessory, reported in wavenumbers (ν, $cm^{-1}$). Most reactants, reagents, and solvents were obtained from Aldrich Chemical Company (Milwaukee, WI) and Lancaster Synthesis (Windham, NH) and were used as received. Methyl 4-aminosalicylate was purchased from Nantong Chang Chemicals, Peking, China. Nuclear magnetic resonance (NMR) spectra were taken on a Bruker 300 Fourier transform instrument as dilute solutions in dimethyl sulfoxide-$d_6$ (DMSO-$d_6$) or chloroform-d, recorded at 300 MHz ($^1$H NMR) or 75 MHz ($^{13}$C NMR) and are reported in parts per million delta (δ) downfield from internal tetramethylsilane as reference, with coupling constants given in cycles per second (cps). In some proton spectra, only signals in the region 0–10 ppm are reported. Appropriate solvent blanks were recorded to account for water and DMSO. Gas chromatography (GC) and low-resolution mass spectrometry (LR-MS) analyses were recorded with an HP 5890 Series II Plus gas chromatograph, using a crosslinked 5% diphenyl- 95% dimethylsiloxane column from Hewlett Packard, and an HP 5972 electrical ionization mass detector. High-resolution mass spectroscopy (HR-MS) data were obtained using the JEOL HX-110 double focusing mass spectrometer of the Michigan State University Mass Spectrometry Facility, courtesy of Professor D. Gage and Ms. B. Chamberlin. This magnetic sector instrument is equipped with a fast atom bombardment (FAB) ionization source. It is capable of performing high-resolution (peak matching) and tandem mass spectrometry. Safety notes: gloves were worn during the chemical syntheses, and the reactions were carried out in the hood. In general, any scale up of preparations of compounds with relatively high proportions of nitrogen and oxygen was done with due caution. No specific safety problems were encountered with the methods given below. No attempt was made to optimize yields. To monitor the progress of the pyrrole-forming reactions, a thin-layer chromatography (TLC) system was devised. In general, we used plastic sheets coated with silica gel (Merck-Darmstadt), eluted with absolute ethanol, with starting materials the subjects of parallel reference runs. Details are given in individual procedures, where applicable, but typical $R_f$ values were 0.5 for the acid hydrazide and 0.8 for the acylaminopyrroles. The dione was not observed in these runs.

**Biological assessments.** *M. tuberculosis* ATCC 35801 (strain Erdman) was obtained from the American Type Culture Collection (ATCC, Manassas, VA). Drug-resistant clinical isolates of *M. tuberculosis* (isolates 303, 1889, and 35829) were kindly provided by Dr. Sheldon Morris, United States Food and Drug Administration. The mutational origins of the drug resistance of these organisms have been characterized and data are available from the authors upon request. PAS was a gift of Jacobus Pharmaceutical Company. INH was purchased from Sigma Chemical Company (St. Louis, MO). For testing, a given investigational compound was dissolved in dimethyl sulfoxide and subsequently diluted in distilled water. INH and PAS were dissolved in distilled water. Stock solutions were filter-sterilized by passage through a membrane filter 0.22-μm pore size and stored at -20°C until use. The drugs were prepared each morning, before experimentation. With respect to testing against these isolates, the MICs of all antimicrobial agents were determined in modified 7H10 broth (7H10 agar formulation with agar and malachite green omitted; pH 6.6) supplemented with 10% Middlebrook oleic acid-albumin-dextrose-catalase (OADC) enrichment (Difco Laboratories, Detroit, MI) and 0.05% Tween 80 [33]. The activities of the antimicrobial agents were determined by a broth dilution method [34]. The organism was grown in the modified 7H10 broth with 10% OADC enrichment and 0.05% Tween 80 on a rotary shaker at 37°C for 5 days. The culture suspension was diluted in modified 7H10 broth to yield 100 Klett units/mL (Photoelectric Colorimeter, Manostat Corporation, New York, NY), or approximately $5 \times 10^7$ CFU/mL. The size of the inoculum was determined by titration and counting from triplicate 7H10 agar plates (BBL Microbiology Systems, Cockeysville, MD) supplemented with 10% OADC enrichment. The plates were incubated at 37°C in ambient air for 4 weeks before counting of the colonies. MIC values are reproducible to within 1–2 dilutions. Results *in vitro* (strain $H_{37}R_v$) were also determined according to the fully-documented protocols of the Tuberculosis Antimicrobial Acquisition and Coordinating Facility, of the National Institutes of Health [35].

In brief, for the short-course therapy studies *in vivo*, 4-week-old female $C_{57}$BL/6 mice (Charles River, Wilmington, MA) were infected intranasally with approximately one million viable *M. tuberculosis* organisms. As a negative control, groups of infected but untreated mice were sacrificed at the initiation of therapy. The known antitubercular drug INH was used as a positive control. Treatment began 1 day post-infection and was administered for 2 days. The agents were introduced by gavage: the INH control and a given pyrrole were dosed daily at 25 and 100 mg/kg of body weight, respectively. No overt toxicity or ill effects were noted at these doses. Mice were sacrificed by carbon dioxide inhalation 3 days post-infection. Their right lungs were removed aseptically and were ground in a tissue homogenizer (IdeaWorks! Laboratory Devices, Syracuse, NY). The number of viable organisms was determined by titration on 7H10 agar plates. The plates were incubated at 37°C in ambient air for 4 weeks before counting of the bacterial colonies. Data are presented as the logarithms of colony-forming units. The complete procedure for the short-course therapy model has been reported [32] in detail. As standards of reference, such tuberculocidal drugs as INH generally display a drop of one or more log CFU versus untreated controls in the model. By way of contrast, PAS is tuberculostatic, as distinct from tuberculocidal, typically leading to a falling-off of one-half log CFU versus untreated controls. A typical data set for PAS is as follows: dose 500 mg PAS/kg/day, six mice per group, untreated controls 5.78 ± 0.38 log CFU, PAS 5.32 ± 0.22 log CFU, positive control (INH) 4.44 ± 0.62 log CFU. The use of experimental animals complied with institutional policies and federal guidelines.

**1-(4-Pyridoyl)amino-2,5-dimethylpyrrole (IIIa).** Isonicotinic acid hydrazide (0.82 g, 6 mmol) was dissolved in deionized distilled water (25 mL). 2,5-Hexanedione (0.68 g, 6 mmol) was added and the mixture was heated at a gentle boil with reflux for 2 h. The mixture was then allowed to cool

overnight, after which time crystals of **IIIa** formed in solution and were collected by vacuum filtration. The mother liquor was allowed to evaporate on a watch glass and the resulting crystals were collected separately. The total yield was 67%, mp 151–153°C; IR 3224, 3041, 2923, 1673, 1595, 1537, 1490, 1410, 1322, 1289; $^1$H NMR (DMSO-$d_6$) δ 11.5 (s, 1 H, disappeared after $D_2O$ shake), 8.8 (d, $J$ = 6 cps, 2 H), 7.9 (d, $J$ = 6 cps, 2 H), 5.7 (s, 2 H), 2.0 (s, 6 H); $^{13}$C NMR (DMSO-$d_6$) δ 165, 151, 139, 127, 122, 104, 11.

Anal. Calcd. for $C_{12}H_{13}N_3O$: C, 66.96; H, 6.09. Found: C, 66.84; H, 6.18.

**1-Benzoylamino-2,5-dimethylpyrrole (IIIb).** Benzoic acid hydrazide (0.82 g, 6 mmol) was heated to boiling in 35 mL deionized, distilled water with reflux. 2,5-Hexanedione (0.82 g, 7.2 mmol) was dissolved in 10 mL deionized, distilled water and added drop wise to the reflux flask without ever halting boiling. Reflux continued for 23 h. After cooling, crystals of **IIIb** appeared in solution and were collected by vacuum filtration (89%). A second crop of crystals was harvested by evaporation of the mother liquor (combined yield 97%). After recrystallization in a mixed system of ethanol/water, crystals were clean, very fine, and just slightly off-white in color, mp 175–177°C; IR 3261, 3061, 2919, 1684, 1602, 1580, 1536, 1488, 1440, 1282; $^1$H NMR (DMSO-$d_6$) δ 11.3 (s, 1 H, quenched by $D_2O$), 8.0 (d, second peak split, $J$ = 6, 2 cps, 2 H), 7.7 (tt, $J$ = 6, 2 cps, 1 H), 7.5 (t, $J$ = 6 cps, 2 H), 5.7 (s, 2 H), 2.1 (s, 6 H); $^{13}$C NMR (DMSO-$d_6$) δ 166, 133, 132, 129, 128, 127, 103, 11; major fragments in LR-MS *m/z* 105, 94; HR-MS (fast atom bombardment, $MH^+$) calculated for $C_{13}H_{15}N_2O$ 215.1184, found 215.1174.

Anal. Calcd. for $C_{13}H_{14}N_2O$: C, 72.87; H, 6.59. Found: C, 72.69; H, 6.61.

**1-(4-Chlorobenzoyl)amino-2,5-dimethylpyrrole (IIIc).** 4-Chlorobenzoic hydrazide (1.02 g, 6 mmol) was dissolved in absolute ethanol (100 mL) and heated to a gentle boil with reflux. 2,5-Hexanedione (0.82 g, 7.2 mmol) was dissolved in absolute ethanol (10 mL) and added dropwise to the hydrazide solution. Reflux was continued for 50 h, during which time no solid precipitated from solution. TLC was used to monitor reaction progress and showed gradual progression from 4-chlorobenzoic hydrazide ($R_f$ 0.5) to **IIIc** ($R_f$ 0.8). The mixture was cooled to room temperature and kept over night. Excess ethanol was boiled off and cold water added, causing the precipitation of white solid **IIIc**. After vacuum filtration and drying, this solid dissolved easily and cleanly in DMSO, yield 69%, consistently isolated as the hemihydrate and analyzed as such, mp 185°C with decomposition; IR 3449, 3274, 2998, 2961, 1656, 1623, 1594, 1521, 1483, 1448, 1299, 1272; $^1$H NMR (DMSO-$d_6$) δ 11.3 (s, 1 H, quenched with $D_2O$), 8.0 (dd, $J$ = 6, 2 cps, 2 H), 7.6 (dd, $J$ = 6, 2 cps, 2 H), 5.7 (s, 2 H), 2.0 (s, 6 H); $^{13}$C NMR (DMSO-$d_6$) δ 165, 137, 131, 130, 129, 128, 127, 104, 11; major fragments in LR-MS *m/z* 139, 94; HR-MS (fast atom bombardment $MH^+$) calculated for $C_{12}H_{14}N_2OCl$: 249.0795, found 249.0801.

Anal. Calcd. for $C_{12}H_{13}N_2OCl$ x $0.5H_2O$: C, 60.58; H, 5.48. Found: C, 60.29; H, 5.19.

**1-(4-Toluoyl)amino-2,5-dimethylpyrrole (IIId).** 4-Toluic acid hydrazide (0.90 g, 6 mmol) was reacted with 2,5-hexanedione (0.82 g, 7.2 mmol), in a manner similar to that for **IIIc**. Reflux continued for 70 h, during which TLC was used to track reaction progress and no solid appeared in solution. After 70 h, TLC (silica gel, absolute ethanol) showed no remaining traces of the 4-toluic hydrazide. The reaction mixture was allowed to cool and placed on ice. To the reaction mixture on ice was added 50 mL of cold water, provoking the gradual precipitation of **IIId**. An additional 100 mL of cold water was necessary to keep the solution thin enough to pour into the filter. Vacuum filtration of the precipitate yielded tiny, fluffy, off-white crystals, 1.25 g (91%); mp 187–189°C; IR 3281, 2980, 2935, 1665, 1610, 1531, 1491, 1324, 1301, 1276; $^1$H NMR (DMSO-$d_6$) δ 11.2 (s, 1 H, quenched with $D_2O$), 7.9 (d, $J$ = 6 cps, 2 H), 7.4 (d, $J$ = 6 cps, 2 H), 5.7 (s, 2 H), 2.4 (s, 3 H), 2.0 (s, 6 H); $^{13}$C NMR (DMSO- $d_6$) δ 166, 143, 130, 129, 128, 127, 103, 22, 11; major fragments in LR-MS *m/z* 119, 94; HR-MS (fast atom bombardment $MH^+$) calculated for $C_{14}H_{17}N_2O$ 229.1341, found 229.1337.

Anal. Calcd for $C_{14}H_{16}N_2O$: C, 73.65; H, 7.06. Found: C, 73.76; H, 7.13.

**1-(4-Bromobenzoyl)amino-2,5-dimethylpyrrole (IIIe).** 4-Bromobenzoic hydrazide (1.29 g, 6 mmol) was reacted with 2,5-hexanedione (0.82 g, 7.2 mmol) in the manner described for the synthesis of **IIIc**. After 1 h of reflux, a fine suspended solid clouded the mixture, which the addition of 100 mL ethanol did not clear. The solid was not filterable from the reaction mixture. TLC analysis (silica gel, absolute ethanol) revealed a mixture of three species: 4-bromobenzoic hydrazide ($R_f$ 0.5), **IIIe** ($R_f$ 0.8), and a third compound ($R_f$ 0.7) postulated to be a reactive intermediate, as suggested in the work of Amarnath et al. [36] for a different family of pyrroles. After 27 h of reflux, the solid had disappeared, and TLC monitoring began to show a preponderance of **IIIe**, with small amounts of the other two compounds still present. Reflux was stopped after 47 h, no solid having reappeared in the intervening day. Crystals were precipitated from solution by the addition of cold water to the reaction mixture on ice, with a total yield of 1.34 g (77%); mp 207–210°C; IR 3246, 1660, 1588, 1534, 1521, 1465, 1377, 1322, 1300, 1268; $^1$H NMR (DMSO-$d_6$) δ 11.3 (s, 1 H, quenched with $D_2O$), 7.9 (dd, $J$ = 6, 2 cps, 2 H), 7.8 (dd, $J$ = 6, 2 cps, 2 H), 5.7 (s, 2 H), 2.0 (s, 6 H); $^{13}$C NMR (DMSO-$d_6$) 165, 132, 131, 130, 127, 126, 104, 11; major fragment in LR-MS *m/z* 94; HR-MS (fast atom bombardment $MH^+$) calculated for $C_{13}H_{14}N_2OBr$ 293.0290, found 293.0281.

Anal. Calculated for $C_{13}H_{13}N_2OBr$: C, 53.26; H, 4.47. Found: C, 53.36; H, 4.57.

**1-(4-Nitrobenzoyl)amino-2,5-dimethylpyrrole (IIIf).** 4-Nitrobenzoic hydrazide (1.09 g, 6 mmol) was reacted with 2,5-hexanedione (0.82 g, 7.2 mmol) following the procedure for the synthesis of **(IIIc)**. Solid clouded the reflux solution after 1 h; addition of 100 mL ethanol did not improve homogeneity. After 66 h, cloudiness persisted but TLC analysis revealed the material present to be entirely **IIIf**, with no traces of starting material or an intermediate. Reflux was stopped, and the solution was filtered while hot. After cooling, cold water was used to provoke the precipitation of **IIIf** from the mother liquor, with a yield of 1.16 g (75%); mp 218–221°C (recrystallization from ethanol and water); IR 3278, 1674, 1604, 1523, 1468, 1343, 1270; $^1$H NMR (DMSO-$d_6$) δ 11.3 (s, 1 H, quenched with $D_2O$), 8.4 (dd, $J$ = 6, 2 cps, 2 H), 8.2 (dd, $J$ = 6, 2 cps, 2 H), 5.7 (s, 2 H), 2.1 (s, 6 H); $^{13}$C NMR (DMSO-$d_6$) δ 165, 150, 138, 129, 127, 124, 104, 11; major fragment in LR-MS m/z 94; HR-MS (fast atom bombardment $MH^+$) calculated for $C_{13}H_{14}N_3O_3$ 258.0879, found 258.0876.

Anal. Calculated for $C_{13}H_{13}N_3O_3$: C, 60.23; H, 5.05. Found: C, 60.30; H, 5.17.

**1-(4-Aminosalicyloyl)amino-2,5-dimethylpyrrole (IIIg).** 4-Aminosalicylic acid hydrazide (ASAH) was obtained (58%) in pure form from the hydrazinolysis of methyl 4-aminosalicylate by a method that we have previously described in detail [37]. ASAH thus obtained (1.67 g, 10.0 mmoles) was weighed into a 100 mL round-bottom flask fitted for reflux with a temperature-controlled heating mantle, reflux condenser, and magnetic stirrer. Deionized distilled water (25 mL) was added, and the mixture was brought to the boil. Just below the boiling point, the mixture was heterogeneous, but a clear solution was obtained at the boiling point. 2,5-Hexanedione (1.14 g, 10.0 mmoles) was added and the mixture was refluxed for 2 h. Heating was stopped, and stirring was continued for an hour as the mixture slowly cooled. The resulting white solid was filtered off to provide the title compound **IIIg** (0.722 g, 30%), mp 173–174°C; IR 3371, 3270, 1612, 1494, 1385, 1334, 1312, 1270, 1200, 1161, 1012, 967, 833, 786, 757, 692; $^1$H NMR (DMSO-$d_6$) δ 12.1 (s, 1H), 10.9 (s, 1H), 7.6 (d, $J = 7$ cps, 1H), 6.2 (d, $J = 7$ cps, 1H), 6.1–6.0 (overlapping s, 3H), 5.7 (s, 2H), 2.0 (s, 6H); $^{13}$C NMR (DMSO-$d_6$) δ 169, 162, 155, 129, 127, 106, 103, 101, 99, 11; HR-MS (fast atom bombardment $MH^+$) calculated for $C_{13}H_{16}N_3O_2$ 246.1243, found 246.1244.

Anal. Calcd. for $C_{13}H_{15}N_3O_2$: C, 63.66; H, 6.16. Found: C, 63.48; H, 6.28.

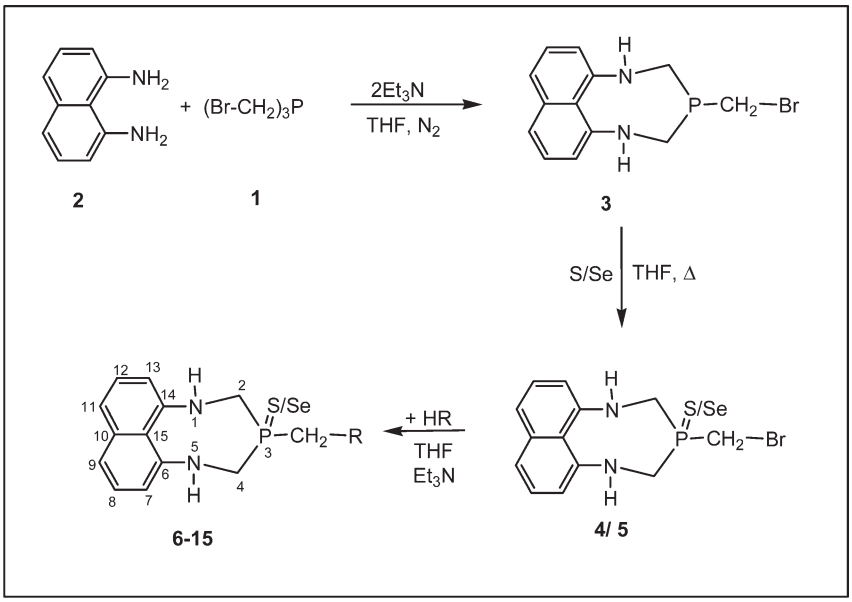
Published online 15 April 2010 in Wiley InterScience (www.interscience.wiley.com).



Synthesis of alkyl/aryl [2-(1,2,4,5-tetrahydro-3-sulfanylene/selenylene naphtha[1,8-*f*,*g*][1,5,3]diazaphosphocin-3-yl) methyl amino acid esters] (**6–15**) was accomplished in three steps. 1, 8-diamino naphthalene (**2**) was reacted with tris (bromomethyl) phosphine (**1**) in the presence of triethylamine in dry tetrahydrofuran (THF) under $N_2$ atmosphere to form a $P_{III}$ intermediate (**3**). It was converted to the corresponding sulfide (**4**) and selenide (**5**) by reacting with sulfur and selenium, respectively. The intermediates **4** and **5** were further reacted with amino acid esters to obtain the title compounds (**6–15**). The structures of the title compounds were established by elemental analysis and spectral data (IR, $^1$H, $^{13}$C, $^{31}$P NMR, and FAB mass). The antimicrobial activity of these compounds was evaluated and they exhibited significant activity.

## INTRODUCTION

Organophosphate moiety is an important pharmacophore in agricultural and pharmaceutical chemistry [1]. Phosphocin/phosphepin and their related derivatives containing this group represent an important class of pesticides, antibiotics, herbicides, and antiviral agents [2]. Some of them are well known for their insecticidal activities [3] and are known to degrade hydrolytically and enzymatically to nontoxic residues. Discovery of their fungicidal properties also promotes interest in this research area. New chiral phosphorus ligands play vital role in asymmetric synthesis [4–8]. Synthesis of eight-membered phosphorus heterocyclic compounds, phosphocins have currently gained considerable interest in the polymer and oil industry because of their potential use as antioxidants and stabilizers, considerable research work is going on in the chemistry of the phosphocins [9,10]. Keeping in view the importance of eight-membered organophosphorus heterocyclic compounds, we herein report the synthesis, spectral characterization, and antimicrobial activity of the title compounds.

## RESULTS AND DISCUSSION

Preparation of a few eight-membered phosphorus heterocyclic compounds such as alkyl/aryl [2-(1,2,4,5-tetrahydro-3-sulfanylene/selenylene naphtha[1,8-*f*,*g*][1,5,3]diazaphosphocin-3-yl) methyl amino acid esters] (**6–15**) was accomplished in three steps. The synthetic

*f*,*g*][1,5,3]diazaphosphocine (**3**). It was converted to the corresponding sulfide (**4**) and selenide (**5**) by reacting with sulfur and selenium, respectively. The compounds **4** and **5** were further reacted with amino acid esters in the presence of triethylamine in dry THF to obtain the title compounds (**6–15**) (Scheme 1) and mass fragments of compound **7** are given (Scheme 2).

The physical, elemental analyses, IR, and $^{31}$P NMR data of the compounds **6–15** are given in the Table 1. Compounds **6–15** exhibited characteristic P=S/Se stretching frequencies in the region 759–776 (P=S) and 625-637 (P=Se) cm$^{-1}$ [11]. Characteristic absorption bands for P—C $_{(aliphatic)}$ and N—H stretching vibrations were observed in the regions 717–758 and 3395–3429 cm$^{-1}$, respectively [12]. In the $^1$H NMR spectra, aromatic protons of the naphthyl ring of the **6–15** gave complex multiplets [13] in the region 6.53–7.17 ppm. The N—H proton resonated as a broad singlet at δ 4.02–4.18. The other aliphatic protons of **6–15** were observed in the expected region (Table 2). $^{13}$C NMR chemical shifts for aromatic carbons were observed in the expected region (Table 3). C-2 and C-4 which are directly linked to phosphorus experienced coupling with it and appeared as doublet in the region δ 54.21–55.26 ($J$ = 126–132 Hz). The carbons of amino acid esters resonated in the expected region [13].

The $^{31}$P NMR chemical shifts of 3-sulfides (**6–10**) appeared in the region 41.07–42.18 and the corresponding 3-selenides (**11–15**) were observed in the region

**Table 2**

$^1$H NMR spectral data[a] of the compounds **6–15**.

[a] Recorded in DMSO $d_6$, and $J$ (Hz) given in parentheses

82.45–86.17 ppm as expected [14]. Mass spectral data of compounds **7** and **11** are given (Table 4).

## ANTIMICROIBIAL ACTIVITY

The compounds **6–15** were screened by disc diffusion method [15,16] for their antimicrobial activity against the fungi, *Aspergillus niger* and *Helminthosporium oryzae* and bacteria, *Escherichia coli* and *Staphylococcus aureus* by comparing with standard fungicide Griseofulvin and standard bactericide Penicillin at three different concentrations (100, 75, 50 ppm). The results are presented in Table 5.

## EXPERIMENTAL

Melting points were determined in open capillary tubes on a Mel-temp apparatus and were uncorrected. Microanalysis was performed at the Indian Institute of Science, Bangalore and Central Drug Research Institute, Lucknow. IR Spectra were recorded in Environmental Engineering Lab, S.V.University, Tirupati as KBr discs on a Nicolet 380 FTIR spectrophotometer. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker AMX 400 MHz spectrometer operating at 400 MHz for $^1$H, 100 MHz for $^{13}$C and 161.9 MHz for $^{31}$P. The compounds were dissolved in DMSO-$d_6$. The $^1$H and $^{13}$C NMR chemical shifts were referenced to tetramethylsilane and $^{31}$P chemical shifts to 85% $H_3PO_4$. Mass spectra were recorded on a Jeol SX 102 DA/600 mass spectrometer using Argon/Xenon (6 keV, 10 mA) as the FAB gas.

**Preparation of tris (bromomethyl) phosphine (1).** Because of the sensitivity of the reagents and products to moisture and oxygen, all manipulations were performed in an anhydrous inert nitrogen atmosphere. In a dry 100 mL three-necked round bottomed flask fitted with dropping funnel, a reflux condenser attached to a calcium chloride tube, an inlet for dry nitrogen and a thermometer reaching close to the bottom in the flask were placed magnesium turnings (0.12 g, 0.005 mole) and dry THF (5.0 mL). The reaction mixture was kept under stirring and dibromo methane (0.78 g, 0.005 moles) in 10 mL of dry THF was added drop wise at 10–15°C. When the reaction started the temperature increased to 40–50°C. The mixture was cooled to room temperature and stirring was

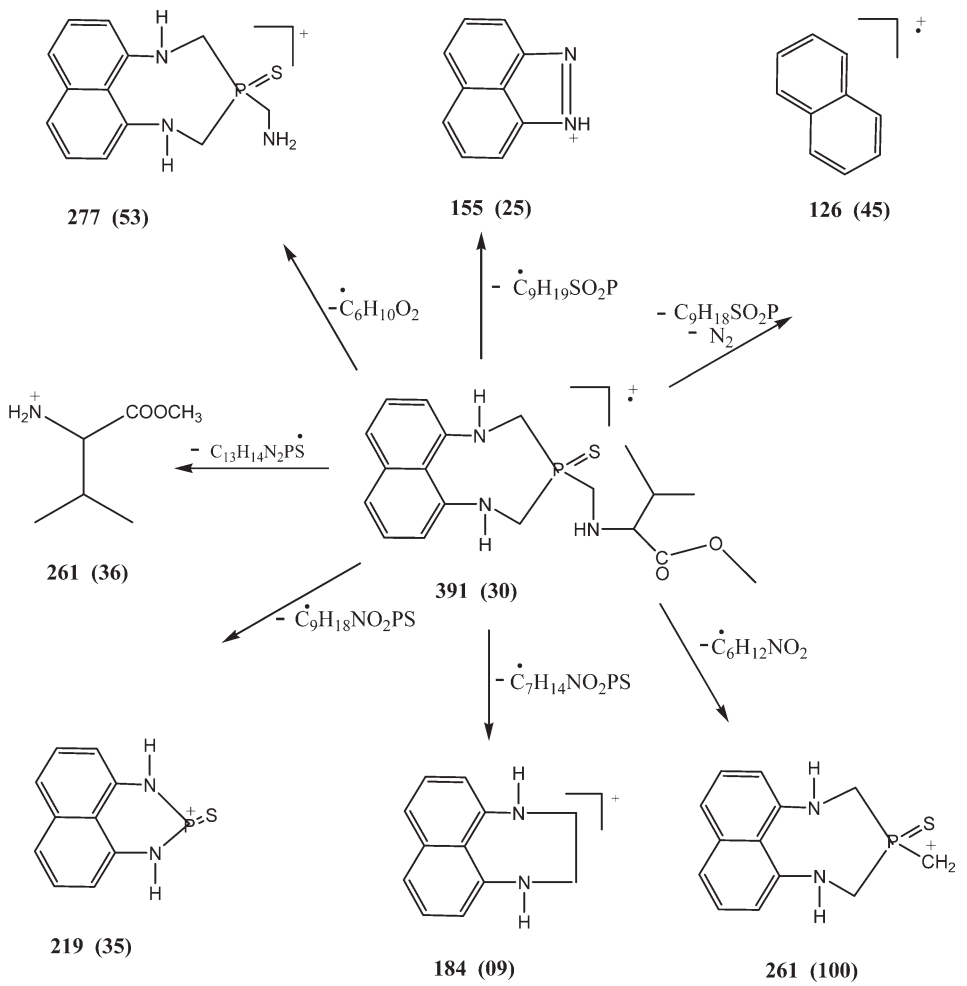
continued until the magnesium metal was dissolved to form bromo methyl magnesium bromide. It is further reacted with $PBr_3$ to form tris (bromo methyl) phosphine and magnesium bromide salt. The magnesium bromide salt was separated by filtration under nitrogen atmosphere and the solvent was distilled off to get tris (bromo methyl) phosphine (**1**).

**Scheme 2**



**3-(Bromomethyl)-2,3,4,5-tetrahydro-1*H*-naphtho [1, 8-*f*, *g*][1,5,3]diazaphosphocine (3).** To a cooled (10°C) and stirred solution of 1,8-diaminonaphthalene (**2**, 0.69 g, 0.005 mole) and triethyl amine (1.01g, 0.01 mole) in 10 mL of dry THF under nitrogen gas, a solution of tris (bromo methyl) phosphine(**1**, 1.35 g, 0.005 mole) in 10 mL of dry THF was added over a period of 20 min. After completion of the addition, the temperature of the reaction mixture was raised to room temperature and stirred for 1 h to form the intermediate (**3**).The progress of the reaction was judged by the TLC analysis. After completion of the reaction, it was filtered under nitrogen atmosphere and removed triethylamine hydrobromide.

**3-(Bromomethyl)-1,2,4,5-tetrahydro-3-sulfanylene/selenylene-1*H*-naphtho[1,8- *f*,*g*][1,5,3]diazaphosphocine (4/5).** The intermediate (3) in dry THF was cooled to 5°C, sulfur powder/ selenium metal was added to it and heated slowly up to gentle reflux with stirring and continued for 2 h for the completion of the reaction as indicated by TLC analysis. The solvent was removed in a rota-evaporator and the residue was extracted with ethyl acetate. The extract after drying over anhydrous $MgSO_4$ was removed in a rota- evaporator. The obtained crude products (4 and 5) were purified by column chromatography (hexane-ethylacetate 2:1) to yield 1.20 and 1.30 g (59, 70%) of 4 and 5, m.p. 180–182°C, 156–158°C, respectively.

**General procedure for the preparation of 6–15.** To the intermediate (**4**) in dry THF, phenyl glycine ethyl ester in dry THF (10 mL) was added in the presence of tri ethylamine at 10–15°C over a period of 30 min. After the addition, temperature of the reaction mixture was slowly raised to 30–35°C and continued stirring. The progress of the reaction was monitored by the TLC analysis. After completion of the reaction, Et3N.HBr was separated by filtration and the solvent was removed from the filtrate in a rota-evaporator. The resulting crude product was recrystallized from 2-propanol to obtain pure compound of **6**. The same procedure was adopted for the preparation of other compounds **7–15**.

**Acknowledgment.** The authors thank Prof. C. Devendranath Reddy and Dr. C. Suresh Reddy, Associate Professor, Dept. of Chemistry, Tirupati, India for encouragement and helpful discussion and the Directors, IISc, Bangalore and CDRI, Lucknow, India, for the analytical and spectral data.

The synthesis of a series of bis-8-hydroxyquinoline- and bis-8-hydroxyquinaldine-substituted *N*-benzyl or thiophenyl amines and their corresponding bis-8-hydroxyquinoline is reported. *In vitro* growth inhibitory effects of both series have been evaluated. It has been observed that analogs from the bis-8-hydroxyquinoline series exert nanomolar range activity, whereas the antiproliferative activity of the corresponding analogs from the bis-8-hydroxyquinaldine series was found to be drastically lower. Molecular docking and chemical–physical properties account for these observed growth inhibitory differences between the two series of analogs, which differ only by the presence of a methyl group at the 2 position of the heterocyclic ring.

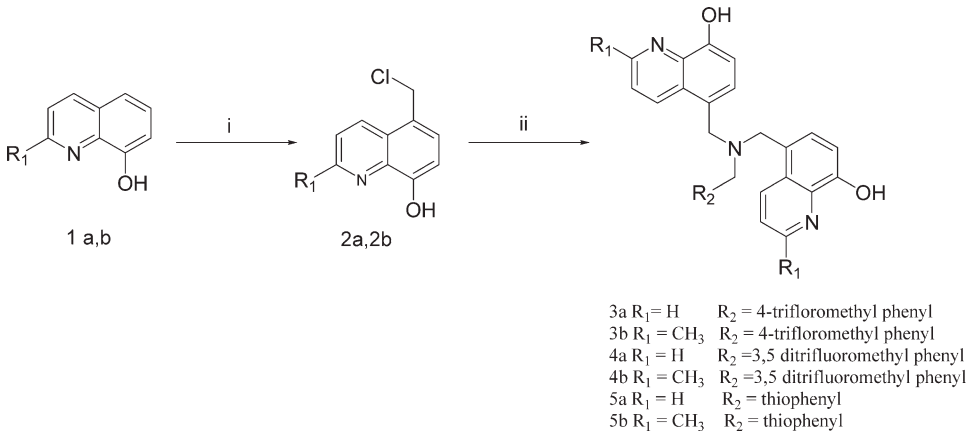
## INTRODUCTION

Hydroxyquinoline is a privileged structural moiety observed in many biologically active natural products; it is used as the source for many drugs diversely prescribed among a wide range of pathologies, including neurodegenerative [1], parasitic amoebic dysentery [2], and herpes viral diseases [3]. More specifically, 8-hydroxyquinoline (8-HQ) moiety has been mostly used for its capacity to strongly chelate metal ions, particularly $Cu^{++}$ and $Zn^{++}$ [4].

We have reported preliminary results on the antitumor activity of two analogs JLK1486 and JLK1472, which belong to the family of bis-8-hydroxyquinoline-substituted benzylamines [5]. From this work, we discover that a single methyl subtituent at the position 2 of the quinoline ring lead to what is called quinaldine series drastically that diminish the antiproliferative effect of the resulting compounds. For this purpose, we synthesized a new series of bis-8-hydroxyquinaldine *N*-substituted analogs, and we studied their anticancer activities in comparison with that of the corresponding bis-8-

**Scheme 1.** Reagents and conditions: (i) HCHO, 37% HCl in $H_2O$, HCl (gas), r.t., overnight, 80%; (ii) corresponding primary amine $K_2CO_3$, $CH_3CN$, r.t., overnight.



hydroxyquinoline *N*-substituted series. Molecular docking techniques and physicochemical studies were carried out to account for the observed differences in antitumor activity between the two families of 8-HQ and 8-hydroxyquinaldine (8-HQD) analogs.

## CHEMISTRY

Starting from 8-HQ (**1a**) or 8-HQD (**1b**), commercially available compounds, the corresponding 5-chloromethyl derivatives (**2a** and **2b**) were obtained in good yields by direct reaction with 37% formaldehyde in strong acidic conditions [6,7]. The solid compounds were directly collected by simple filtration and used without purification. The next step consisted in an addition on **2a** and **2b** of an excess of selected *N*-substituted primary amines that preferentially led to the formation of the desired bis-8-hydroxyquinoline or bis-8-hydroxyquinaldine benzyl or thiophenyl amines (Scheme 1). Under these experimental conditions, the desired bis-8-hydroxyquinoline and quinaldine derivatives (**3a**, **3b**, **4a**, **4b**, **5a**, **5b**) were obtained with moderate yields (40–50%), whereas mono-8-hydroxyquinoline or mono-8-hydroxyquinaldine by-products were only present as traces. The desired compounds were purified by column chromatography and fully identified by conventional spectral and centesimal analysis.

## RESULTS AND DISCUSSION

Compounds from the bis-8-hydroxyquinoline and bis-8-hydroxyquinaldine series were evaluated for their antiproliferative effect on a panel of 15 cancer cell lines [8–11].

The data in Table 1 clearly show that bis-8-hydroxyquinoline derivatives display higher *in vitro* antitumor activity than bis-8-hydroxyquinaldine derivatives. Indeed, in contrast to these bis-8-hydroxyquinoline derivatives for some of which antiproliferative effect could be observed in two digit n*M* range, the corresponding bis-8-hydroxyquinaldine analogs (**3b**, **4b**, **5b**) displayed antitumor effects higher than 5 μ*M*, and thus, revealing themselves 100–1000-fold weaker antiproliferative compounds when compared with 8-HQ derivatives. In addition, it must also be highlighted that the large variations observed in terms of antitumor activity for various bis-8-hydroxyquinoline derivative series on a given cancer cell line, say for example the BxPC3 pancreas cancer and the VM-47 melanoma cell lines.

These data prompted us to envisage preliminary structure–activity relationship analysis. Compounds (**2a**) and (**2b**), which are mono-8-hydroxyquinoline analogs and which include a chloromethyl moiety at the position 4 of the 8-HQ or 8-HQD nucleus, are found totally inactive in comparison with the *N*-substituted benzyl or thiophenylamine derivatives, a feature that reveals that the presence of a *N*-substituted amine moiety is essential for anticancer activity and also confirm that bis-8-hydroxyquinoline analogs are more potent antiproliferative compounds than the corresponding mono-8-hydroxyquinoline analog [5]. These observations led us, therefore, to try to understand why bis-8-hydroxyquinoline and bis-8-hydroxyquinaldine derivatives display such marked differences in terms of antiproliferative effect. Such observation that bis-8-hydroxyquinoline analogs are more potent bioactive molecules than their corresponding mono-8-hyroxy analog has been reported in the case of neurodegenerative diseases [12]. We have, thus, considered the possible electronic effects induced by the electron pair of the amine group in the 8-HQ or quinaldine system in terms of chemical reactivity, and the possible physical–chemical properties differences between the two scaffolds mainly in terms of nucleophilicity,

Compound *in vitro* antiproliferative effect has been performed in 5 carcinoma, 5 glioma, and 5 melanoma cell lines. The cancer cells have been cultured in the presence of the drugs for 3 days. The $IC_{50}$ values were determined by means of the MTT colorimetric assay as detailed previously [6,8]. The values reported in this table are means obtained on six distinct values. The standard errors are not reported for the sake of clarity, because they are <5% as compared with the mean values.

$IC_{50}$ are expressed in n*M* unless in μ*M* when specified in the table.

Cell lines: A549, human alveolar epithelial; BxPC3, pancreatic cancer; LoVo, colon cancer; MCF7, breast cancer; PC3, humanprozstate cancer; HS683, human glioma; T98G, human glioblastoma; U373, human glioblastoma-astrocytoma epithelial; U318, human glioma; GL19, glioblastoma multiform; VM-21 and VM-47 are mutant melanoma; SKMEL-28 and B16F10 are human melanoma.

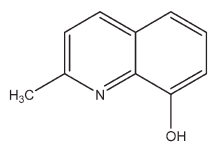
basicity, and hydrophobicity. There is a conceptual relationship between nucleophilicity and basicity. Both properties are involved in the formation of a new bond by donation of an electron pair to an electrophilic species. Basicity in the Brønsted sense involves formation of a bond to hydrogen, while generally nucleophilicity refers to the effect of a Lewis base on the rate of nucleophilic substitution reaction. The relative nucleophilicities may differ from reaction to reaction, and several parameters have significant influence on nucleophilicities. From literature reports [13], it can be seen that the presence of a methyl group in 8-HQD makes the nitrogen donor more basic in comparison with 8-HQ (Fig. 1).

Considering the possible biological mode of action of the compounds under study in which the proton of the hydroxyl group in the ground state could be involved in their antitumor mechanism(s) of action, the observed differences in pKa values (Fig. 1) could account for the observed differences in antiproliferative effects. Differences in the pKA values between the two systems could induce variations in the electronic driving force from the exocyclic nitrogen lone pair electron to the hydroxy group through the aromatic ring. Electronic effects induced by the presence of the methyl substituent at the 2 position of the quinoline ring influence the acidity of the OH proton and consequently, the conjugation between the nitrogen atom lone pair electron from the benzylamine moiety and the phenol group through the aromatic system.

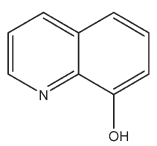
Next, we considered the differences in terms of hydrophobicity between the two scaffolds as a possible parameter which could influence cell permeation and consequently, the observed anticancer activities. The calculated clog*P* values determined for analogs **3a** (quinoline series) and **3b** (quinaldine series) were, respectively, 6.16 and 7.64 (calculated from ACD Labs/Log*P* dB 3.5 and ChemSketch 3.5). As expected, 8-HQD derivatives were slightly more hydrophobic than their corresponding analogs from the bis-8-hydroxyquinoline series, but these rather small differences in hydrophobicity cannot account alone for the observed drastic differences in antiproliferative effect.

As steric effects of substituted quinolines on lithium coordination geometry have been reported [14], we next examined the possible influence of steric hindrance induced by the methyl group at position 2 of the quinoline heterocycle. For this purpose, compounds **3a** and **3b** were selected as representative compounds for minimal energy conformational search. Minimal energy conformations for both analogs were generated and superimposed after a Monte Carlo Conformational Search (Macromodel version 6.5 was used for molecular mechanics calculations) [15].

After calculations, both lowest energy conformations for **3a** (132.8 kcal/mol) and **3b** (134.5 kcal/mol) were



8-hydroxy quinaldine scaffold



8 –Hydroxy-quinoline scaffold

**Figure 1.** pKa values: 8-hydroxyquinoline [$pK_{A1}$ = 5.13 ($NH_4$+/$NH_2$), $pK_{A2}$ = 9.89 ($OH/O^-$)] and 8-hydroxyquinaldine [$pK_{A1}$ = 5.67 ($NH_4$+/$NH_2$), $pK_{A2}$ = 9.97 ($OH/O^-$)].

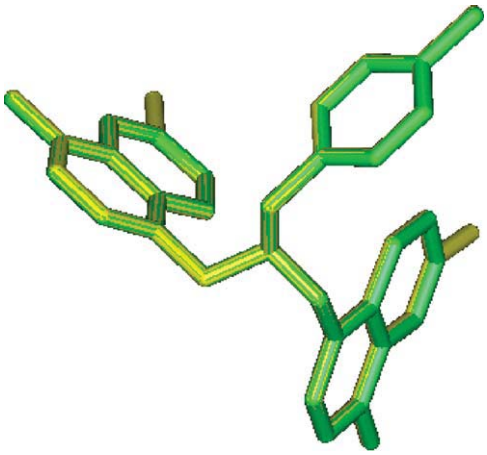


**Figure 2.** Superimposition of compounds **3a** (green) and **3b** (yellow)—best conformations obtained through a Monte Carlo conformational search. [Color figure can be viewed in the online issue, which is available at www.interscience.wiley.com.]

identical. They exhibit an energetic difference inferior to 2 kcal/mol between the two analogs, which could not account for the drastic drop in biological activity of the methylated compounds. Further, superimposition of the successively obtained conformations within a 3 kcal/mol span (from the lowest representative conformation) between these analogs revealed no differences between both analogs, which displayed similar poses with a similar energy difference in favor of the quinoline scaffold (Fig. 2).

From these results, steric effects induced by the presence of a methyl group at the position 2 appear to be too weak to entirely abolish the anticancer activity of all the 8-HQD analogs irrespective of the cancer cell lines (carcinoma, glioma, or melanoma) used in the assay.

## CONCLUSIONS

In conclusion, a series of bis-8-hydroxyquinolines *N*-benzyl or thiophenyl amines and their corresponding bis-8-hydroxyquinaldine derivatives have been prepared. We found that compounds that belong to the bis-8-hydroxyquinoline series have an *in vitro* potent antiproliferative effect on a large panel of cancer cell lines at lower nanomolar $IC_{50}$ values, while their corresponding 8-HQD counterparts display only weak (in the μ*M* range), if any, antiproliferative effect. Molecular docking studies and physico-chemical properties suggest that the presence of a methyl group in position 2 vicinal to the endocyclic nitrogen atom induces electronic factors (pKa values) that greatly influence the driving electronic force all along the aromatic system, including the exocyclic nitrogen. In contrast, Monte Carlo studies reveal only a small energy difference with less than 2 kcal/mol having been observed between the two series differing in the 2-methyl group only. The steric effect of a methyl group at the 2 position of the heterocycle and the difference in clog*P* values appeared to be too weak to account for the observed drastic antiproliferative differences between both series of analogs. Investigations on the mechanism of action and on the possible biological targets of those are underway.

## EXPERIMENTAL

Compounds **2a** and **3a** have been already reported [5]. Starting quinaldin-8-ol intermediate **2b** has been synthesized as follows:

**5-(Chloromethyl)-2-methylquinolin-8-ol hydrochloride (2b).** A mixture of 7.3 g (0.045 mol) of quinaldin-8-ol (Aldrich), 8 mL of concentrated hydrochloric acid, and 8 mL (0.05 mol) of 37% formaldehyde was treated with hydrogen chloride gas for 90 min. The yellow solid was collected on a filter and dried to give 8.5 g of compound (70% yield) mp 280°C $^1$NMR (250 MHz, DMSO): 9.14 (d, 1H, $J$ = 8.75 Hz), 8.05 (d, 1H, $J$ = 8.75 Hz), 7.83 (d, 1H, $J$ = 8 Hz), 7.56 (d, 1H, $J$ = 8 Hz), 5.233 (s, 2H), 2.5 (s, 3H). Anal. Calcd. for $C_{11}H_{11}NOCl_2$: C, 54.09; H, 4.51; N, 5.73. Found: C, 54.19; H, 4.45; N, 5.81.

**General procedure for the reaction of 5-chloromethyl 8-hydroxyquinaldine (2a) and (2b) with primary amines for the synthesis of analogs 4a, 5a, 3b, 4b, and 5b.** All of these reactions were carried out under a nitrogen atmosphere. To a solution of 5-chloromethyl quinolin-8-ol dihydrochloride (**2a)** or 5-chloromethylquinaldin-8-ol dihydrochloride (**2b)** (1.3 mmol) at 50°C in ethyl acetate (10 mL) was added appropriate primary amines (3.91 mmol). Stirring is maintained overnight. Then, the solution is cooled down to 0°C and filtrated; the filter cake is washed with cold ethyl acetate (5 mL). The filtrate is concentrated *in vaccuo*, diluted in diethyl ether (5 mL), and centrifuged. The ethereal phase is removed, and the obtained solid is washed two more time by centrifugation with diethyl ether at 0°C to give the desired products.

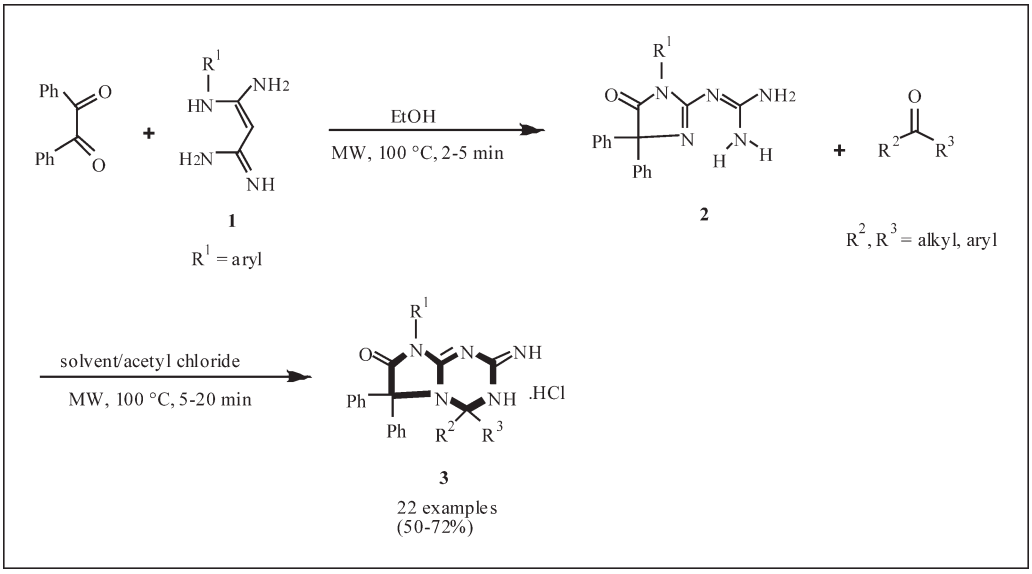
Published online 11 May 2010 in Wiley InterScience (www.interscience.wiley.com).



A simple, efficient, and general method has been developed for the synthesis of various 4-substituted 2-amino-6,6-diphenyl-8-aryl-6,8-dihydroimidazo[1,2-*a*] [1,3,5] triazine-7(4-*H*)ones **3a**–**3v**. This involved condensation of 1-(5-oxo-4,4-diphenyl-1-aryl-4,5-dihydro-1*H*-imidazol-2-yl)guanidines 2a and 2b, themselves obtained from the reaction of aryl biguanides 1a/b with benzil, with the requisite carbonyl compounds. Both steps were performed using microwave heating in sealed vessels.

*J. Heterocyclic Chem.*, **47**, 724 (2010).

## INTRODUCTION

Microwave-assisted organic synthesis (MAOS) has emerged over the past decade as a valuable technology for synthetic organic and medicinal chemistry. Replacing the conventional oil bath as a heat source by a microwave reactor results in a marked reduction in reaction time and an increase in reaction yield for many important transformations [1,2]. In particular, the need for rapid construction and modification of biologically active heterocyclic compounds, a major concern in drug development, has stimulated intense development of microwave synthesis technology. This is reflected in the exponential increase in the number of scientific papers, books, and reviews related to the use of this technology [3,4].

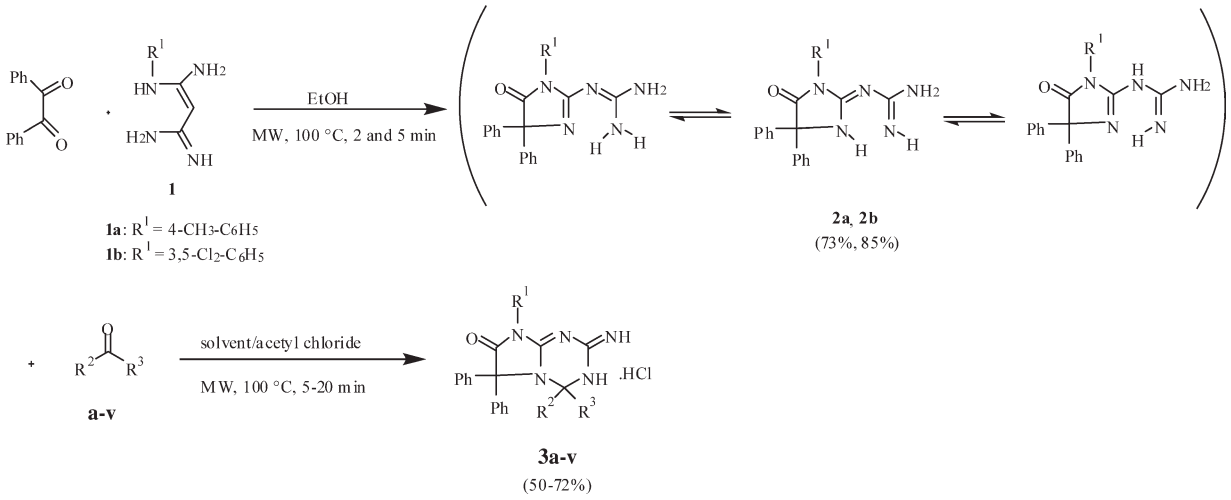
In this work, we report a simple and convenient method for the synthesis of 6,8-dihydroimidazo[1,2-a] [1,3,5] triazines under microwave irradiation conditions. The 6,8-dihydroimidazo[1,2-a] [1,3,5] triazine system is a core structure element in a number of molecules with potential application as antitumor, antibacterial, and antiparasitic agents, and as herbicide antagonists [5–21].

## RESULTS AND DISCUSSION

Imidazoltriazines with structure **3** have been obtained by a two-step procedure (Scheme 1) involving the heating of 1-substitued biguanides with benzil to give 1-(5-oxo-4,4-diphenyl-1-aryl-4,5-dihydro-1H-imidazol-2-yl)guanidine intermediates **2** as a mixture of tautomers, and subsequent ring closure of these mixtures to the target compounds on further heating [5,22–25].

Transposing this process to microwave conditions, it was found that the reaction of benzil (1 equiv) with the 1-substituted biguanides **1a** and **1b** (1 equiv) in ethanol in a sealed tube (pressure-rated reaction vial) at 100°C in a self-tuning single-mode microwave cavity (5CEM Discovery apparatus) was complete after only 2–5 min. On cooling, the precipitated material was isolated by simple filtration, washing with cold ethanol, and

**Scheme 1**



recrystallization to give the known 1-(5-oxo-4,4-diphenyl-1-aryl-4,5-dihydro-1H-imidazol-2-yl)guanidines **2a** and **2b** (73% and 85%, respectively) [22]. These intermediates were, in turn, reacted with a series of aldehydes and ketones using microwave irradiation to construct a 22 member library containing the novel 6,8-dihydroimidazo[1,2-a] [1,3,5] triazines **3a**–**3v** (Table 1). In the experiment, compounds **2a** or **2b** in acetone containing a catalytic amount of acetyl chloride (see Experimental) were place in a sealed vessel and reacted in the microwave cavity at 100°C. The reaction time was varied from 5 to 20 min in increments of 5 min. However, in general, the reactions were complete after heating for 10 min, as judged by TLC. When a temperature above 100°C was used a complex reaction mixture was obtained from which the product was obtained in lower yield. The mass, IR, and NMR spectra unambiguously confirmed the structures **3a–3w**.

[b] Method B in the Experimental section.

## CONCLUSIONS

An efficient, rapid, and clean method for the preparation of a 22-membered library of 6,8-dihydroimidazo[1,2-a] [1,3,5] triazines has been developed using microwave-assisted synthesis.

## EXPERIMENTAL

**Materials.** All commercially available reagents were used without further purification. Commercial solvents were distilled from an appropriate drying agent before use according to standard procedures.

**Analysis.** TLC analysis was performed on aluminum-precoated silica gel 60 plates. $^1$H NMR spectra were recorded on a Varian Unity Inova 400 MHz spectrometer using DMSO-$d_6$ as a solvent. Chemical shifts (δ) are expressed in ppm downfield from TMS as internal standard. The letters s, d, t, q, and m are used to indicate singlet, doublet, triplet, quadruplet, and multiplet, respectively. IR spectra were taken on a Perkin-Elmer FT-IR 2000 spectrometer. Low-resolution mass spectra were obtained in the atmospheric pressure chemical ionization (positive or negative APCI) mode. All melting points (uncorrected) were recorded on a SMP2 apparatus.

**Equipment.** Microwave syntheses were carried out on a CEM Corp. Discover laboratory microwave with Explorer unit. Reaction times refer to hold times at the temperatures indicated and not to total irradiation time.

**General procedure for synthesis of 1-(5-Oxo-4,4-diphenyl-1-aryl-4,5-dihydro-1H-imidazol-2-yl)guanidines 2a and 2b.** Arylbiguanide hydrochloride (**1a** and correspondingly **1b**, 5 mmol) was added to the solution of sodium (0.11 g, 5 mmol) in absolute ethanol (25 mL). Precipitated sodium chloride is filtered off and benzil (1.05 g, 5 mmol) dissolved in absolute ethanol (6 mL) was added to the filtrate in a 30 mL microwave vial equipped with a pressure and temperature sensor, as well as a magnetic stirrer. The sealed tube was placed in a homogeneous microwave synthesis system. After irradiation at 100°C, measured by an internal fiber-optic temperature sensor immersed in the reaction mixture, for 2 (**2a**) and 5 (**2b**) min, respectively, the reaction mixture was cooled, and the precipitate was collected, washed with cold ethanol, and recrystallized from ethanol to give highly pure title.

***2-[1-(4-Methylphenyl)-5-oxo-4,4-diphenyl-2-imidazolline-2-yl]-guanidines (2a).*** $^1$H NMR (400 MHz, DMSO) δ 2.34 (s, 3H), 7.53–7.90 (m, 14H); IR (KBr) $\upsilon_{max}/cm^{-1}$: 3115, 3166, 3061, 1593, 1537; UV–vis (MeOH) $\lambda_{max}$/nm 204 (0.406).

***2-[1-(3,5-Dichlorophenyl)-5-oxo-4,4-diphenyl-2-imidazolline-2-yl]-guanidines (2b).*** $^1$H NMR (400 MHz, DMSO) δ 7.21–7.98 (m, 13H); IR (KBr) $\upsilon_{max}/cm^{-1}$: 3430, 3176, 3084, 1709, 1640, 1611, 1597, 1536, 798, 747, 697; UV–vis (MeOH) $\lambda_{max}$/nm 206 (0.688).

**Method A: General procedure for synthesis of 6,8-dihydroimidazo[1,2-a] [1,3,5] triazines (3a–3c and 3m–3p) (carbonyl compounds with low boiling point).** To a suspension of 1 equiv arylbiguanide (**2a** or **2b**) (0.1 mmol, 38.3 mg or 43.8 mg) in 3 mL of ketone or aldehyde in a microwave vial, 5 equiv acetyl chloride (0.5 mmol, 57.5 mg) was added. The vial was sealed and irradiated in a microwave reactor at 100°C for 10–20 min. The precipitates were collected by filtration and recrystallized from ethanol to give corresponding compound **3**.

**Method B: General procedure for synthesis of 6,8-dihydroimidazo[1,2-a] [1,3,5] triazines (3d–3l and 3q–3v) (carbonyl compounds with high boiling point).** To a suspension of 1 equiv arylbiguanide (**2a** or **2b**) (0.1 mmol, 38.3 mg or 43.8 mg) and 5 equiv of the ketone or aldehyde (0.5 mmol) in ethanol (3mL) in a microwave vial, 5 equiv acetyl chloride (0.5 mmol, 57.5 mg) was added. The vial was sealed and irradiated in a microwave reactor at 100°C for 10–20 min. The precipitates were collected by filtration and recrystallized from ethanol to give corresponding compound **3**.

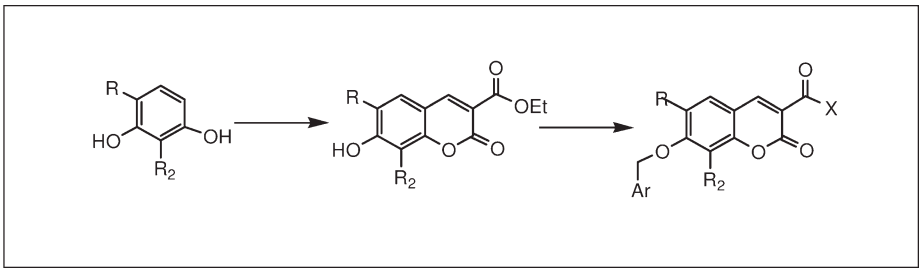
Published online 29 April 2010 in Wiley InterScience (www.interscience.wiley.com).



A new series of 3-acyl-6,7,8-substituted coumarin derivatives has been synthesized in high yields (79–99%) and characterized by means of elemental analysis, mass spectrometry, IR, and $^1$H NMR spectroscopy. We examined with particular attention the presence of an acyl group at position 3 (ethyl ester, carboxylic acid, and acyl chloride), and of a hydroxyl group at position 7 or a functionalized one like benzyloxy or phthalimido. The hydroxyl group has been modified by an etherification in presence of crown ether with substituted benzyl bromide or chloride to evaluate the influence on chemical characteristics and lipophilicity of coumarin nucleus. Halogens (Cl, Br) and methyl group were introduced in position 6 and 8 of the coumarin ring, respectively, in order to study their effect on reaction feasibility. Some of these 3-acyl derivatives have been recently assayed as MAO inhibitors and as intermediates (i.e. reactive chloride derivative) to design new anti-*Helicobacter pylori* agents.

## INTRODUCTION

Coumarins, (2*H*)-1-benzopyran-2-ones, represent a common type of phytochemicals, frequently encountered in plants of the *Apiaceae*, *Rutaceae*, *Fabaceae*, and *Hyppocastanaceae* [1]. Interest in this scaffold arose from the identification of both natural or synthetic pharmacologically active derivatives, which have been found to be useful in photochemotherapy, antitumor [2], and anti-HIV [3] therapy, and as stimulants for central nervous system, antibacterials, antioxidants [4], anti-inflammatory [5], anticoagulants, and dyes according to the nature and the substitution pattern. In particular we recently demonstrated that 3-acyl and 3-carboxyamido coumarins could be considered good lead compounds as reversible and effective human monoamine oxidase (hMAO) inhibitors [6,7].

The interesting biological properties of coumarins made these compounds very attractive for organic synthesis. There are many developed methods of coumarins synthesis, e.g. Pechman reaction, Perkin reaction, Knoevenagel condensation, and many others [1]. However, it is important to highlight that all the reported procedures have some disadvantages, as they lack generality and efficiency making the development of new reliable high-yielding methods for the synthesis of coumarins an important matter. For these reasons, we synthesized many molecules based on the coumarin ring system by utilizing classic and innovative synthetic techniques such as carbon suboxide [8] and microwave [9].

In particular, microwave irradiation usually accelerates some chemical transformations and offers numerous benefits for performing solventless procedures (green chemistry) and improving reaction yields, especially in heterocyclic chemistry [10].

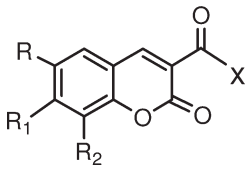
Hence, in this article, we report on synthesis and characterization by spectral data, such as IR, $^1$H NMR, and mass spectroscopy of coumarin analogues bearing an acyl function (ethyl ester, carboxylic acid, and acyl chloride) at position 3, halogens (Cl, Br) at position 6, different unsubstituted or substituted benzyloxy moieties at position 7, and methyl group at position 8 (Table 1).

## RESULTS AND DISCUSSION

Coumarin derivatives were synthesized starting from substituted salicylic aldehydes according to the pathway reported in Scheme 1.

**Table 1**

Structure and CLogP (ChemDraw Ultra 8.0) of synthesized coumarin derivatives.



| Comp | R | $R_1$ | $R_2$ | X | ClogP | *m/z* |
|---|---|---|---|---|---|---|
| **3a** | Cl | $CH_2Ph$ | H | OEt | 4.52 | 358.77 |

| **7g** | H | $OCH_2$(4-$NO_2$-Ph) | H | Cl | 2.68 | 359.72 |

The corresponding salicylic aldehydes were obtained by a Gattermann aromatic formylation starting from 2- or 4-substituted resorcinol in a strongly acidic environment (**1a**–**1c**). Ethyl esters of (2*H*)-1-benzopyran-2-one-3-carboxylic acids (**2a**–**2c**), were easily obtained by a Knoevenagel cyclization in 15–20 min (80°C) under microwave irradiation with an automatic single-mode reactor. All reactions were performed solventless in vials of 10 mL, confirming that the focused microwave irradiation was a very effective technique for accelerating thermal organic reactions and limiting solvent wasting, not being affected by substituents. These compounds, bearing a hydroxyl group at position 7, were subsequently functionalized by benzylation in the presence of *N*,*N*′-dicyclohexyl-18-crown-6-ether, which by chelating potassium ion facilitated the nucleophilic attack to improve the yields of the related compounds (**3a**–**3h**). Alkaline hydrolysis with 10% sodium hydroxide gave carboxylic acid compounds (**4a**–**4c** and **5a**–**5f**), which were treated with thionyl chloride at reflux to yield the desired and reactive acyl chloride derivatives (**6a**–**6c** and **7a**–**7g**). In general this synthetic procedure allowed us to obtain the desired compounds in high yields and simplify reaction work up, limiting the presence of by-products.

The compounds, correctly analyzed for their molecular formula, showed in the IR spectrum strong bands at 1695–1720 $cm^{-1}$ due to the presence of a δ-lactone C=O and eventually a carbonyl group, and characteristic bands at 1655, 1615, 1575, and 1500 $cm^{-1}$ (double bonds in the aromatic ring).

The lipophilicity (ClogP) of this coumarin scaffold has been calculated with the suitable algorithm for each molecule by using ChemDraw Ultra 8.0. because of its importance in modulating biological activity and pharmacodynamic profile of the molecules [11]. As expected, the introduction of a benzyloxy group at position 7 of the coumarin ring deeply affects this parameter. All compounds, and above all compound **5g**, which was insoluble in common organic solvents (dimethyl

## EXPERIMENTAL

Starting materials and reagents were obtained from commercial suppliers and were used without purification. Melting points (mp) were determined by the capillary method on an FP62 apparatus (Mettler-Toledo) and are uncorrected. $^1$H NMR spectra were recorded at 400 MHz on a Bruker spectrometer using DMSO-$d_6$ as solvent. Chemical shifts are expressed as δ units (ppm) relative to TMS. Coupling constants *J* are expressed in hertz (Hz). Elemental analyses for C, H, and N were determined with a PerkinElmer 240 B microanalyzer and the analytical results were within ±0.4% of the theoretical values for all compounds. All reactions were monitored by TLC performed on 0.2 mm thick silica gel plates (60 $F_{254}$ Merck). Preparative flash column chromatography was carried out on silica gel (230–400 mesh, G60 Merck). Organic solutions were dried over anhydrous sodium sulphate. Concentration and evaporation of the solvent after reaction or extraction was carried out on a rotary evaporator (Büchi Rotavapor) operating at reduced pressure. IR spectra were registered on a PerkinElmer FTIR Spectrometer Spectrum 1000 in potassium bromide. Mass spectra (EI) were obtained with a Fisons QMD 1000 mass spectrometer (70 ev, 200 μA, ion source temperature 200°C). The samples were introduced directly into the ion source. Compounds **2a**–**2c**, synthesized with the microwave method, were obtained with a Biotage Initiator$^{TM}$ 2.0.

The synthesis of some compounds (**1a**–**1c**, **2a**–**2c**, and **4a**–**4c**) has been previously described and was performed with slight changes. Their analytical and spectral data were in full agreement with those reported in the literature.

sulfoxide, chloroform, and acetone), have been characterized by mass spectral studies. In the mass spectra the fragment ion at *m*/*z* (%) = 173 (90) corresponding to the 3-acyl coumarin structure was always the most abundant observed. The fragmentation pattern of derivative **5g** was described in Figure 1. This compound showed the fragment at *m*/*z* (%) 341 (10), which likely represented the molecular ion. In fact, the base peak, referred to the 4′-nitro-benzyl fragment, was always present at 134 (100). In addition the mass spectrum revealed ion suggestive at *m*/*z* 297 (5), 250 (5), and 205 (20) because of the loss of COOH, $CO_2$, and $NO_2$.

In this article, we have synthesized, by using readily available and inexpensive reagents, and fully characterized a new series of heterocyclic derivatives (3-acyl-6,7,8-substituted coumarins), which could reveal their potentials as versatile biodynamic agents. The most important results of our approach are the optimization of the yields and of the reaction times using microwave irradiation. In addition, lower amount of solvent was used and a better workup was obtained. The introduction of a substituted benzyloxy group at position 7 could influence not only the physical–chemical properties, but also their biological activity. Halogens (Cl, Br) and methyl group were introduced in position 6 and 8 of the coumarin ring, respectively, to study their effect on reaction feasibility.

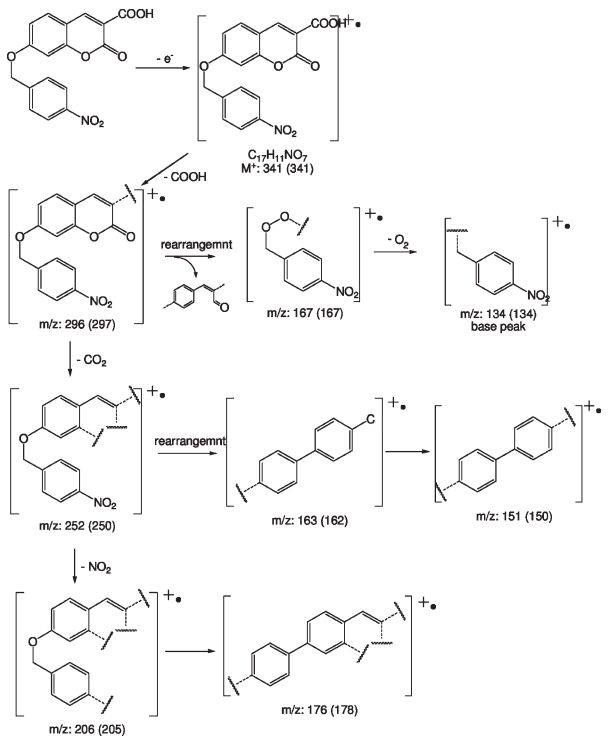

**Figure 1.** The fragmentation pattern of derivative **5g**.

**General procedure for the synthesis of coumarin derivatives 1a–1c.** The substituted salicylic aldehydes were prepared in a 500 mL bottle, fitted with a mechanical stirrer, a reflux water condenser and an inlet tube, with wide mouth to prevent clogging from the precipitate. Resorcinol derivatives (1 mmol), zinc cyanide (2 mmol), and potassium chloride (0.3 mmol) were suspended in anhydrous diethyl ether (40 mL). Gaseous HCl was bubbled inside the bottle and then water was added to hydrolyze the immine product into aldehyde. The zinc chloride, which was produced at the same time, acted as an effective condensing agent.

**General procedure for the synthesis of coumarin derivatives 2a–2c.** The starting ethyl ester of coumarin-3-carboxylic acid was prepared by Knoevenagel reaction between diethyl malonate (1 mmol) and the appropriate salicylic aldehyde (1 mmol) with catalytic amounts of piperidine (0.5 mL) in a 10 mL vial suitable for an automatic single-mode microwave reactor (2.45 GHz high-frequency microwaves, power range 0–300 W). The mixture was prestirred for 30 sec and then heated by microwave irradiation for 15–20 min at 80°C (irradiation power reaches its maximum at the beginning of reaction, then it decreases to lower and quite constant values). The internal vial temperature was controlled by an IR sensor. After cooling with pressurized air, the reaction mixture was poured onto ice, filtered, and dried under vacuum.

**General procedure for the synthesis of coumarin derivatives 3a–3h.** The etherification at position 7 was performed by adding suitable benzyl bromide (1 mmol) and potassium carbonate (1 mmol) in dry acetone (50 mL) for 48 h at room temperature, using *N*,*N*′-dicyclohexyl-18-crown-6-ether (1 mmol) as a chelating agent. The resulting reaction mixture was filtered and the crude product was purified by chromatography.

***Ethyl 7-(benzyloxy)-6-chloro-2-oxo-2H-chromene-3-carboxylate (3a).*** 85% yield; mp 211–212°C; $^1$H NMR (DMSO-$d_6$) δ 1.27–1.29 (t, 3H, $CH_3$), 4.29–4.31 (q, 2H, $CH_2$), 5.31 (s, 2H, $OCH_2Ar$), 7.30 (s, 1H, $C_8$H-chrom.), 7.31–7.50 (m, 5H, Ar), 8.18 (s, 1H, $C_5$H-chrom.), 8.68 (s, 1H, $C_4$H-chrom.). Anal. Calcd. for $C_{19}H_{15}ClO_5$: C, 63.61; H, 4.21. Found: C, 63.63; H, 4.22.

***Ethyl 7-(benzyloxy)-6-bromo-2-oxo-2H-chromene-3-carboxylate (3b).*** 87% yield; mp 215–216°C; $^1$H NMR (DMSO-$d_6$) δ 1.30–1.32 (t, 3H, $CH_3$), 4.32–4.34 (q, 2H, $CH_2$), 5.40 (s, 2H, $OCH_2Ar$), 7.19 (s, 1H, $C_8$H-chrom.), 7.21–7.49 (m, 5H, Ar), 8.10 (s, 1H, $C_5$H-chrom.), 8.60 (s, 1H, $C_4$H-chrom.). Anal. Calcd. for $C_{19}H_{15}BrO_5$: C, 56.59; H, 3.75. Found: C, 56.57; H, 3.76.

***Ethyl 7-(benzyloxy)-8-methyl-2-oxo-2H-chromene-3-carboxylate (3c).*** 89% yield; mp 154–155°C; $^1$H NMR (DMSO-$d_6$) δ 1.27–1.29 (t, 3H, $CH_3$), 2.20 (s, 3H, $ArCH_3$), 4.22–4.27 (q, 2H, $CH_2$), 5.31 (s, 2H, $OCH_2Ar$), 7.39 (s, 1H, $C_8$H-chrom.), 7.40–7.45 (m, 5H, Ar), 7.46 (s, 1H, $C_5$H-chrom.), 8.72 (s, 1H, $C_4$H-chrom.). Anal. Calcd. for $C_{20}H_{18}O_5$: C, 70.99; H, 5.36. Found: C, 71.01; H, 5.37.

***Ethyl 7-(2-chlorobenzyloxy)-2-oxo-2H-chromene-3-carboxylate (3d).*** 79% yield; mp 126–127°C; $^1$H NMR (DMSO-$d_6$) 1.28–1.30 (t, 3H, $CH_3$), 4.29–4.31 (q, 2H, $CH_2$), 5.44 (s, 2H, $OCH_2Ar$), 7.19 (s, 1H, $C_8$H-chrom.), 7.21–7.22 (m, 1H, $C_6$H-chrom.), 7.23–7.27 (m, 4H, Ar), 7.28–7.29 (m, 1H, $C_5$H-chrom.), 8.70 (s, 1H, $C_4$H-chrom.). Published online 3 May 2010 in Wiley InterScience (www.interscience.wiley.com).

An efficient methodology for the synthesis of 5-methyl-3-aryl-2-thiooxazolidin-4-ones from aryl isothiocyanates has been developed. Aryl isothiocyanates, synthesized from various anilines, were converted to the desired compounds by treating with ethyl lactate in presence of DIPEA and catalytic amount of lithium perchlorate. This method provides a convenient and cost-effective strategy, with no specific purification protocol.

## INTRODUCTION

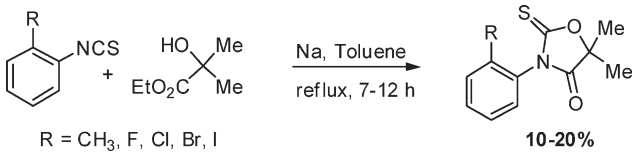
Oxazolidinones and thiooxazolidinones form an integral part of many drugs/intermediates [1,2]. They are well known as chiral directing agents in asymmetric synthesis [3,4]. Thiooxazolidinones were reported for various activities such as potassium channel openers [5], antidiabetics [2], and anticonvulsants [6]. A perusal of the literature shows that there is no report on the synthesis of 3-aryl-2-thiooxazolidin-4-ones having an α-proton, and the available methods in the case of 5,5-dimethyl-3-aryl-2-thiooxazolidin-4-ones, which lack α-protons are poor yielding (Scheme 1) [7–10]. Above all, the reported strategies relied on the kind of isothiocyanates used, and an extrapolation of the methodology to some of the substrates discussed in this article failed primarily due to the harsh reaction conditions [7,8] and the strong base employed [9], leading to the formation of very little of the desired product [10] together with unwanted side-products. The tight legislation on the maintenance of greenness in synthetic pathways and processes demands to prevent waste and minimize energy requirements which unfortunately could not be met in uneconomical low yielding reactions [11].

## RESULTS AND DISCUSSION

Various aryl isothiocyanates 2(a–j) were prepared by previously reported method [12] from corresponding anilines 1(a–j). A model reaction of 4-chlorophenyl isothiocyanate with ethyl lactate was experimented under various reaction conditions like sodium hydride, potassium-*tert*-butoxide, sodium metal, potassium hydroxide, 1,8-diazabicyclo[5,4,0]undec-7-ene (DBU), and *N*,*N*-diisopropylethylamine (DIPEA) (Experiments 1–6; Table 1), but the yields obtained were quite disappointing. This prompted us to employ an alternate strategy based on the assumption that the condensation between the reactants would become more facile if their reactivity could be enhanced by adequate co-ordination. Quite interestingly, as in agreement with our notion, a stirring solution of 4-chlorophenyl isothiocyanate and ethyl lactate in dichloroethane (DCE) when refluxed in presence of DIPEA and lithium perchlorate (Scheme 2) showed a drastic improvement in the yields (Experiments 8–10; Table 1); though the product was not formed when either of these was solely employed (Experiments 6 and 7; Table 1).

From the results obtained a plausible reaction mechanism could be depicted as shown in Figure 1. Lithium co-ordinates with the hydroxyl group of ethyl lactate forming the O—Li bond and simultaneously generates perchloric acid which reacts with DIPEA to produce the protonated base and perchlorate anion. Further, the alkoxide attacks the thiocarbonyl carbon of the aryl isothiocyanate resulting in an intramolecular cyclization followed by the protonation of the ethoxy group thereby expelling it as a good leaving group to afford

**Scheme 1.** Reported strategy for the synthesis of 5,5-dimethyl-3-aryl-2-thiooxazolidin-4-ones lacking α-proton.



5-methyl-3-aryl-2-thiooxazolidin-4-ones with the regeneration of lithium perchlorate in the final step.

Since lithium shows diagonal relationship with magnesium; magnesium perchlorate was also tested, but the reaction afforded poor results and so was the case with zinc perchlorate (Experiments 12 and 13; Table 1). Surprisingly, comparative results could not be obtained when lithium perchlorate was used with triethylamine (TEA) instead of DIPEA (Experiment 11; Table 1). The reason could be attributed to DIPEA having more basic character over TEA. Also the higher boiling point of DIPEA is advantageous under the reflux conditions. The Lewis acid catalyst lithium perchlorate was chosen based on the well known fact that lithium possess better co-ordination power due to its least ionic radius (0.76 Å) than other alkali metals and therefore the higher charge:size ratio increases its covalent character. Also lithium perchlorate is cheap, commercially available and soluble in various organic solvents. The efficiency of lithium perchlorate is well established in various reactions like Diels-Alder reaction [13,14], Friedel-Crafts acylation [15], aminophosphonation of aldehydes [16], Baylis-Hillman reaction [17], aromatic and heteroatom acylation [18], and Nazarov cyclization [19].

Further studies were carried out to determine the stoichiometric quantity of the functional group activator. Based on percentage conversion calculated from GC-MS traces at various concentrations of 0.1, 0.2, 0.6, and 1.2 equivalent of $LiClO_4$ (Fig. 2); it was ascertained that 0.2 equivalent of the Lewis acid would suffice the purpose. We also observed that solvents have a profound influence over the course of the reaction (Table 2). The reaction failed in polar protic medium. Aprotic solvents like toluene and benzene afforded the product in good yields while 1,2-dichloroethane turned out to be the best.

To generalize the methodology the standardized condition was employed on various substituted aryl isothiocyanates, and the respective products were obtained in good yields though the nature of the substituents was found to affect the course of the reaction.

Electron withdrawing functional groups which generally increase the electrophilicity of aryl isothiocyanate provided better yields (Entries 1–7; Table 3), where as electron donating groups led to longer reaction time

**Table 1**

Effect of reagent/catalyst in the synthesis of 5-methyl-3-aryl-2-thiooxazolidin-4-one.[a]

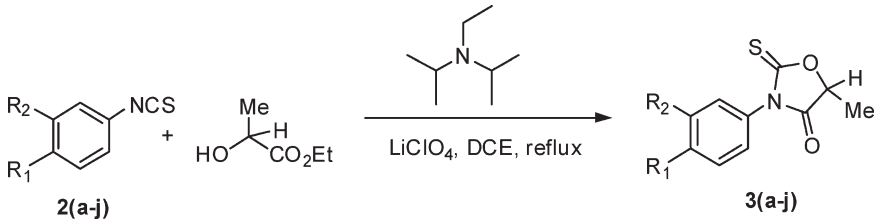
[a] The reaction was carried out by stirring a mixture of 4-chlorophenyl isothiocyanate (1.18 mmol, 1.0 equiv) and ethyl lactate (1.42 mmol, 1.2 equiv) in presence of reagent and/or catalyst and solvent (10 mL) at room temperature for 10 min and then refluxing for 1 h.
[b] The product was characterized by NMR and mass spectroscopic methods.
[c] 1.2 equiv was used.
[d] 0.2 equiv was used.
[e] 0.6 equiv was used.

**Scheme 2.** Synthesis of 5-methyl-3-aryl-2-thiooxazolidin-4-ones.



with lesser yields (Entries 8–10; Table 3). The reaction conditions were also compatible with disubstituted aryl isothiocyanates (Entries 6–7 and 9–10; Table 3).

In conclusion, an efficient and viable synthetic strategy for synthesis of 5-methyl-3-aryl-2-thiooxazolidin-4-ones has been developed.

## EXPERIMENTAL

The $^{1}H$ and $^{13}C$ NMR spectra were recorded at 400 MHz and 100 MHz, respectively on a Bruker Avance DPX 400 (400 MHz) spectrometer in $CDCl_3$ using TMS as an internal standard. The chemical shifts (δ) for $^{1}H$ and $^{13}C$ are given in ppm relative to residual signals of the solvent ($CHCl_3$). Coupling constants are given in Hz. The following abbreviations are used to indicate the multiplicity: s, singlet; d, doublet; m, multiplet; bs, broad signal. The IR spectra were recorded on a Nicolet Impact 400 spectrometer as KBr pellets for solid samples. Mass spectra were recorded on POLARIS Q (Thermo Scientific) GC-MSMS spectrometer and elemental analyses were done by Varion-EL elemental analyzer. The reactions were monitored by TLC (Merck). Evaporation of solvents was performed under reduced pressure using a Buchi rotary evaporator. Melting points are uncorrected.

Commercial grade reagents and solvents were used without further purification; ethyl lactate, lithium perchlorate, zinc perchlorate hexahydrate, magnesium perchlorate, 4-fluoro-3-chloroaniline, 4-chloro-3-trifluoromethylaniline (Aldrich), *N,N*-diisopropylethylamine, triethylamine, 4-bromoaniline, 4-fluoroaniline, 4-aminobenzonitrile, 4-methylaniline, 3,4-dimethylaniline, 3,4-dimethoxyaniline, thiophosgene, sodium metal, sodium hydride (60% suspension in mineral oil), potassium *tert*-butoxide, DBU, 1,4-dioxane, (Spectrochem); 4-chloroaniline (Merck); sodium hydrogen carbonate, THF, toluene (CDH); DCE (Loba Chemie), DME (Sigma), benzene, DMF (SISCO), 3-nitroaniline (S.D. Fine chemicals), potassium hydroxide (Qualigens).

**General procedure for the synthesis of aryl isothiocyanates.** In a 100 mL RB flask, a solution of sodium hydrogen carbonate (5.5 g, 65.7 mmol) in 20 mL water was stirred for 10 min and to it dichloromethane (20 mL) was added followed by 4-chloroaniline (2.0 mL, 21.9 mmol). The reaction mixture was cooled to 0°C, thiophosgene (2.5 mL, 32.85 mmol) was introduced dropwise over a period of 30 min and continuously stirred at room temperature for 1 h. The workup of the reaction mixture was carried out in dichloromethane and dried over anhydrous sodium sulphate. The organic layer upon concentration afforded a crude gummy compound,

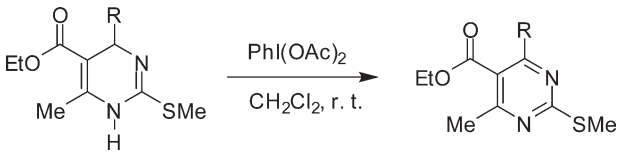
## INTRODUCTION

4-Aryl-3,4-dihydropyrimidin-2(1*H*)-ones (Biginelli compounds, DHPMs) represent an azaheterocyclic system of remarkable pharmacological profile [1]. It was investigated during 1980s and 1990s that DHPMs exhibit a similar pharmacological profile to the Hantzsch's 1,4-dihydropyridine calcium channel modulators of the nifedipine type drugs [2]. In particular, the 2-heterosubstituted 4-aryl-1,4-dihydro-6-methyl-5-pyrimidinecarboxylic acid esters were investigated by Atwal and coworkers as potent mimics of 1,4-dihydropyridine [3]. The metabolism of these drugs involves an oxidative dehydrogenation of 1,4-dihydro ring nucleus to the corresponding aromatic derivatives, which is catalyzed in the liver by cytochrome P-450 [4]. The chemical oxidation of 4-substituted-1,4-dihydropyrimidine also provides an easy access to multi-substituted pyrimidine derivatives, which are further known to exhibit anti-anoxic and anti-lipid peroxidation activities [5]. Recently, the S-alkylation of 4-aryl-3,4-dihydropyrimidin-2(1*H*)-thione followed by oxidative aromatization has been demonstrated for the generation of a variety of 2-substituted pyrimidines via displacement of the reactive sulfonyl group with nitrogen, oxygen, sulfur, and carbon nucleophiles [6]. In contrast to Hantzsch 1,4-dihydropyridine [7], the chemical oxidative aromatization of 1,4-dihydropyrimidine is relatively less investigated reaction. All the reported methods for the chemical oxidation of 4-substituted-1,4-dihydropyrimidine utilize mainly transition metal based oxidizing agents such as $Mn(OAc)_3$ [8], $MnO_2$ [6], $(NH_4)_2Ce(NO_3)_6$ [6], and $CuCl_2/Na_2CO_3$/*tert*-BuOOH [9]. The optimized conditions for the oxidative aromatization of 2-methylthio-1,4-dihydropyrimidine requires four or five equivalents of $Mn(OAc)_3$ or $MnO_2$ respectively under different reaction conditions. Thus, there is a need for the development of an efficient and general method for the oxidative aromatization of 4-aryl or alkyl-1,4-dihydropyrimidine.

Hypervalent iodine reagents are used extensively in organic synthesis as a mild, safe, and economical alternative to heavy metal reagents [10]. A literature survey showed that phenyliodine(III) bis(trifluoroacetate) [$PhI(OCOCF_3)_2$] can be used for the solid state oxidation of Hantzsch's 1,4-dihydropyridines under microwave irradiation conditions [11]. Similarly, (diacetoxyiodo)benzene has been reported for the oxidative aromatization of 1,3,5-trisubstituted pyrazolines [12] and 2-imidazolines [13]. Recently, we have reported a clean and efficient oxidative dehydrogenation of 3,4-dihydropyrimidin-2(1*H*)-ones to 1,2-dihydropyrimidines using a combination of (diacetoxyiodo)benzene and *tert*-butylhydroperoxide in $CH_2Cl_2$ [14]. The application of hypervalent iodine reagents for the oxidative aromatization of 1,4-dihydropyrimidines is hitherto unknown in the literature. Herein, we wish to report a simple and highly efficient oxidative dehydrogenation of 4-substituted-1,4-dihydropyrimidine to afford the multi-substituted pyrimidine derivatives by using (diacetoxyiodo)benzene (DIB) as the mild oxidizing agent (Scheme 1).

**Scheme 1**



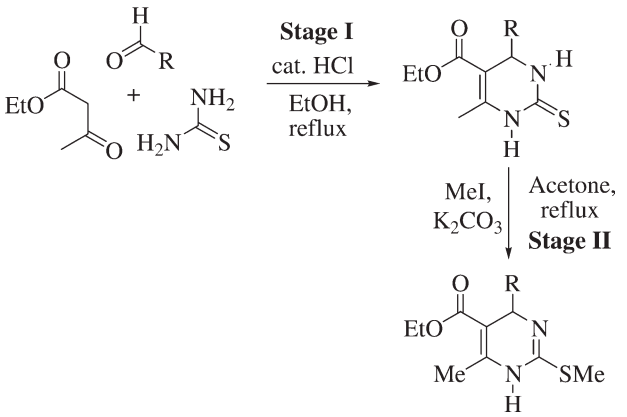
## RESULTS AND DISCUSSION

Variously substituted 4-aryl or alkyl-1,4-dihydropyrimidines precursor were prepared via two steps: (a) the Biginelli reaction involving three component condensation of ethyl acetoacetate, aldehyde and thiourea under reflux conditions in ethanol using a catalytic quantity of HCl to afford 3,4-dihydropyrimidin-2(1*H*)-thiones and (b) the S-methylation reaction of the resulting 3,4-dihydropyrimidin-2(1*H*)-thiones using MeI/$K_2CO_3$/acetone system (Scheme 2). The structures of 4-aryl or alkyl-1,4-dihydropyrimidines were confirmed by IR, $^1$H NMR, and LCMS spectra.

The oxidative aromatization of **1a** (R = $C_6H_5$) was selected as a model reaction using different iodine based oxidizing agents such as $I_2$, $I_2/K_2CO_3$, $KIO_3$, $PhI(OAc)_2$, and Dess-Martin periodinane and the results are summarized in Table 1. The oxidative aromatization using molecular iodine in MeOH was previously reported for the oxidative aromatization of Hantzsch's 1,4-dihydropyridine [15]. It is interesting to mention that molecular iodine and $I_2/K_2CO_3$ (Table 1, entry 1 and 2) did not produce oxidative aromatization of **1a** in satisfactory yields. The oxidation of **1a** to **2a** took place in 63% yield using the pentavalent hypervalent iodine reagent, Dess-Martin periodinane (DMP) but with a relatively long reaction time of 12 h. The trivalent hypervalent iodine reagent, $PhI(OAc)_2$ was found to be the most effective reagent to produce the aromatized product **2a** in 89% yield within 1 h.

With optimal conditions in hand, the reaction of different 4-substituted-1,4-dihydropyrimidines with DIB was examined to explore the scope of the reaction (Table 2). In all the cases, the expected products **2a–l** were obtained in excellent yields. All the reactions were carried out at room temperature using stochiometric use of DIB. 4-Aryl-1,4-dihydropyrimidine containing either an electron-withdrawing group or an electron-donating group all afforded the corresponding products smoothly (Table 2, entries 2a–h). The oxidative aromatization of 4-alkyl-1,4-dihydropyridine is most frequently accompanied by the dealkylation reaction. The side product formation due to the dealkylation reaction was also observed in the DIB mediated oxidative aromatization of 4-alkyl-1,4-dihydropyrimidine (Table 2). Dealkylation was a major pathway in the case of *i*-propyl at 4-position of 1,4-dihydropyrimidine. The aromatized products

**Scheme 2.** Preparation of 1,4-dihydropyrimidine.



**2a–k** except **2a** are new compounds in the literature and the structures of these products were confirmed from IR, $^1$H, and $C^{13}$ NMR spectroscopy and LCMS analysis. The $^1$H NMR of the precursor 4-aryl-1,4-dihydropyrimidine showed characteristic peak around δ 5.82 due to C-4 proton and a broad peak around δ 6.36 due to N-H proton. These two signals were found to be absent in the $^1$H NMR spectra of the aromatized product **2**. The methyl group at 6-position of 4-aryl-1,4-dihydropyrimidine appears at δ 2.37 which is shifted downfield to δ 2.55 in the case of aromatized product.

A tentative reaction mechanism is shown in Scheme 3. The oxidative aromatization takes place around the coordination sphere of trivalent iodine, DIB **3**. The ligand exchange reaction between 1,4-dihydropyrimidine **1** and DIB **3** forms a resonance stabilized carbocation **4** which is subsequently deprotonated to form **5**. The concomitant reductive elimination of iodobenzene from **5** leads to form aromatized product **2**.

## CONCLUSION

In summary we have developed a general and practical route for the oxidative aromatization of 4-substituted-1,4-dihydropyrimidine using (diacetoxyiodo)benzene as the safe oxidizing agent. The salient features of this methodology are: (a) mild reaction conditions, (b) transition metal-free protocol, (c) no excessive use of the oxidant, (d) short reaction time, and (e) an easy experimental procedure.

## EXPERIMENTAL

**General.** All melting points are uncorrected. The glassware was routinely oven-dried at 110°C for a minimum of 4 h. Column chromatography was performed on silica gel 70–230 mesh. $^1$H and $^{13}$C NMR spectra were recorded on a Bruker Advance 400 DPX spectrometer ($^1$H at 400 MHz and $^{13}$ C at 100 MHz) in $CDCl_3$ with TMS as the internal standard. FTIR spectra were determined on a PerkinElmer 100 FTIR spectrometer.

***General procedure for the preparation of 4-substituted-3, 4-dihydropyrimidin-2(1H)-thione.*** A mixture of appropriate aldehyde (20 mmol), ethyl acetoacetate (20 mmol), thiourea (22 mmol), and HCl (2 mL) in EtOH (40 mL) was refluxed for 24 h. The reaction was monitored by TLC. After completion of reaction, the mixture was slowly poured to crushed ice and the resulting solid was filtered off. The crude Biginelli compound was recrystallized from ethanol to afford the product in excellent purity. The products were characterized by the comparison of melting points with the literature value.

***General procedure for the preparation of 4-substituted-1, 4-dihydropyrimidines.*** A suspension of 4-substituted-3,4-dihydropyrimidin-2(1*H*)-thione (3 mmol) in acetone (15 mL) was treated with finely ground potassium carbonate (1.0 g, 7.25 mmol) and methyl iodide (3.5 mmol). The reaction was allowed to stir at room temperature overnight and was diluted with ethyl acetate. It was filtered and the filtrate was washed with water and brine and dried over magnesium sulfate. The solvent was evaporated and the residue was crystallized from ether-hexanes to provide 4-substituted-1,4-dihydropyrimidine as a colorless solid.

***General procedure for the oxidation/aromatization of 4-substituted-1,4-dihydro-(2-methylthio)-pyrimidines.*** To a stirred solution of appropriate 4-substituted-1,4-dihydro-(2-methylthio)-pyrimidine (2 mmol) in $CH_2Cl_2$ (10 mL) was added (diacetoxyiodo)benzene (0.644 g, 2 mmol) at room temperature. The reaction mixture was allowed to stir at room temperature for 1 h. The progress of the reaction was monitored by TLC. After the completion of reaction, the solvent was removed under vacuum and the crude product was purified using column chromatography (silica gel, petroleum ether-ethyl acetate) to give the corresponding aromatized product in good yield.

## 1. INTRODUCTION

Hydrazide compounds, such as indole-2-carbohydrazide derivatives have been shown to inhibit monoamine oxidase A activity [1]. Furan carbohydrazide, thiophene carbohydrazide, and isonicotinic acid hydrazide react with a series of 4-alkoxy-4-alkyl(aryl)-1,1,1-trifluoro-3-alken-2-ones to give 3-alkyl(aryl)-5-trifluoro-methyl substituted pyrazoles [1]. One-pot reactions between carboxylic hydrazides and 2-isothiocyanato-benzonitrile afforded pharmacologically relevant 1,2,4-triazolo[1,5-*c*]quinazoline-5-thiones [2]. Hydrazide compounds were also converted to triazole-3-thiols [3], imidazopyrazolopyrimidine [3], 1,3,4-oxadiazole [4], 1,3,4-oxadiazine [4], pyrazolotriazolopyrimidine [5,6], and pyrazolotriazoloquinoline derivatives [7]. Bis (pyridinyl-2,3-dihydrooxadiazolyl)benzenes were obtained by heating the corresponding bis(hydrazides) with benzaldehyde [7]. Such compounds have attracted attention not only as model compounds for polymers but also because many biologically active natural and synthetic products have molecular symmetry [7].

The condensation of an acyl hydrazide and an amidine to afford acylamidrazone, followed by thermal cyclization, provides a convenient method for preparing 3,5-disubstituted-1,2,4-triazoles [8].

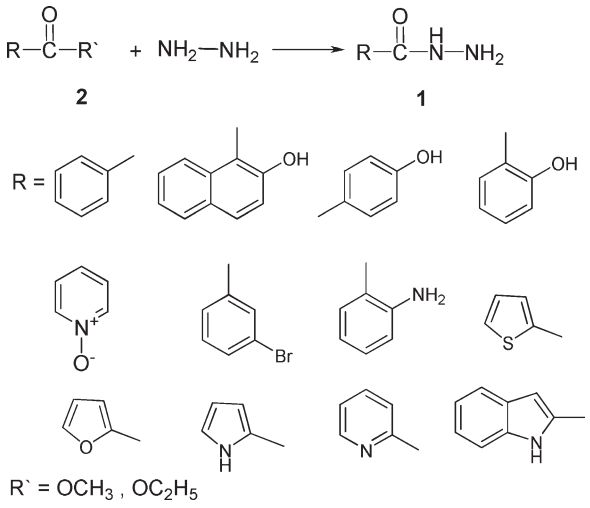
1,2,4-Triazines were formed *via* the condensation of 1,2-diketones with acylhydrazides in the presence of ammonium acetate under both traditional heating and dry media microwave assisted reaction conditions [9].

Carbohydrazides and their derivatives occupy a specific place among the other N,O-containing compounds used in the synthesis of heterocyclic systems because of their accessibility and ability to act as nucleophiles.

Accordingly, it is important to shed more light on the recent literatures dealing with that chemistry, especially in the field of heterocycles. Therefore, the present review was aimed at summarizing and systematizing available published data on the reactions of carbohydrazides with activated ethylenes, ethynes, benzo- and naphthoquinones, compounds containing C=N and C≡N moiety. Several types of reactions involving nucleophilic addition, condensation followed by heterocyclization were observed. Various heterocyclic and fused heterocyclic as well as spiro-heterocyclic compounds have been synthesized from carbohydrazides.

## 2. METHODS OF PREPARATION

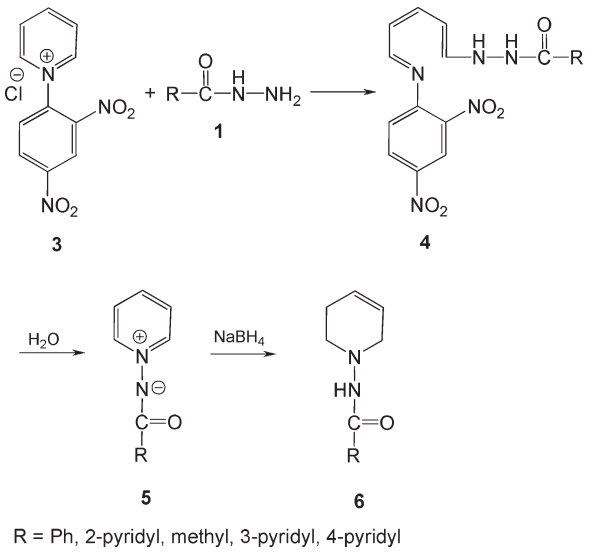
Carbohydrazides **1** can be prepared by refluxing aromatic carboxylic acid methyl or ethyl ester **2** with hydrazine hydrate in neat or in methanol. After cooling to room temperature, the resulting colorless solids were collected by filtration and dried *in vacuo* [10,11].



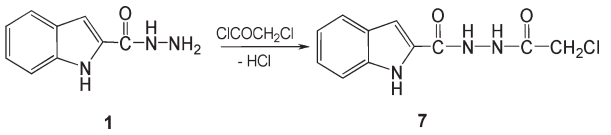
2-Thiophenecarbohydrazide 1 refluxed for 5 h [12], 2-pyridincarbohydrazide 1 refluxed for 4 h [13,14], 2-indolecarbohydrazide 1 refluxed for 15 h [4,15–18], and 2-furancarbohydrazide 1 refluxed for 2 h [19]. Some derivatives of carbohydrazide can be prepared like picolinic-*N*-oxidehydrazide [20] and 2-pyrrolecarbo-hydrazide [21]. Carbohydrazides have been prepared by hydrazinolysis of diethyl carbonate [22] and diphenyl carbonate [23] in satisfactory yields. The interaction of phosgene and hydrazine hydrate in refluxing benzene afforded carbohydrazides as dihydrochloride [24]. Also, hydrazinolysis of carbazic acid [25] and cyanuric acid [26] gave carbohydrazides.

## 3 REACTIONS OF CARBOHYDRAZIDES

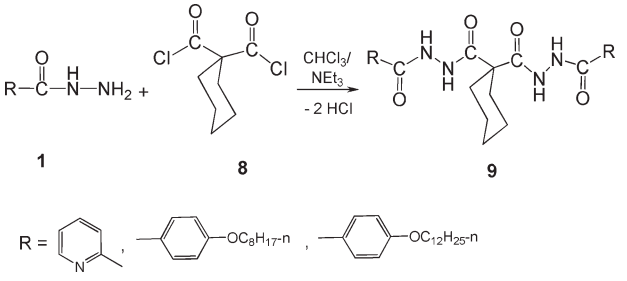
**3.1. Synthesis of linear compounds.** *N*-(2,4-Dinitrophenyl)pyridinium chloride **3** reacted with carbohydrazides **1** in methanol containing triethylamine at room temperature for 12 h to furnish 2,4-dinitroanilino derivatives **4**. Hydrolysis of **4** with water/*p*-1,4-dioxane mixture, at reflux temperature for 2 h, produced substituted carbonyliminopyridinium compounds **5**. Reduction of **5** with sodium borohydride in ethanol at 0°C for 4 h afforded alkyl substituted carbonylamino-1,2,3,6-tetrahydropyridines **6** [27–29].



A solution of chloroacetyl chloride was added dropwise to a solution of 2-indole carbohydrazide **1** in dry dioxane. After stirring at room temperature for 6 h, $N^2$-(2-chloroacetyl)indole-2-carbohydrazide **7** was formed [4].

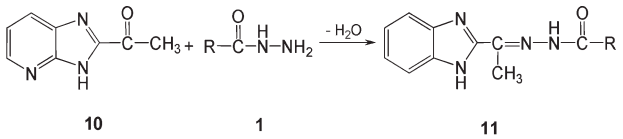


Substituted carbohydrazides **1** reacted with cyclohexane-1,1-dicarbonylchloride **8** in chloroform/triethylamine to yield cyclohexane-1,1-dicarboxylic acid-*N*,*N*′-di(2-octyloxybenzoyl)hydrazide **9** [30].



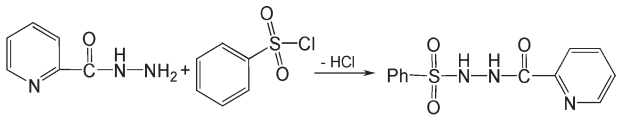
Condensation of carbohydrazides **1** with 2-acetyl-imidazo[4,5-*b*]pyridine **10** in absolute ethanol containing a

catalytic amount of piperidine afforded the corresponding hydrazones **11** [31].



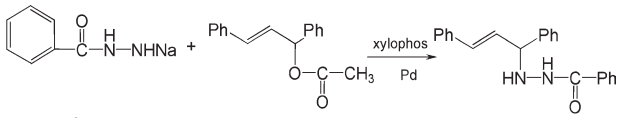
**10** **1** **11**

Benzenesulfonyl chloride **12** reacted with 2-pyridinecarbohydrazide **1** to give 1-isonicotinyl-2-benzene-sulfonyl hydrazine **13** [32].



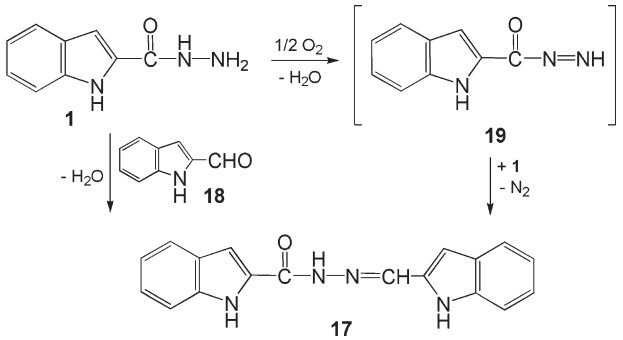
**1** **12** **13**

Allylic substitution of carbohydrazide was prepared by reaction of sodium derivative **14** with 1,3-diphenyl-prop-2-enylacetate **15** to give *N*′-1,3-diphenylallylbenzohydrazide **16** [33].



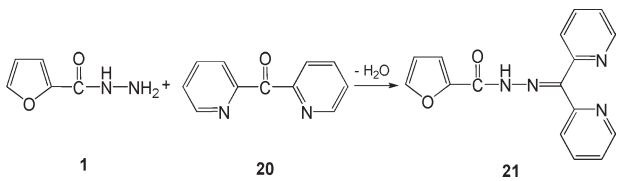
**14** **15** **16**

Hydrazone **17** was formed when 2-indole carbohydrazide **1** was dissolved in ethanol for 3 h at room temperature. On other hand, compound **17** was also obtained by condensing **1** with the aldehyde **18** [34].



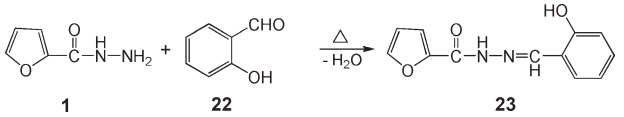
**1** **19** **18** **17**

Refluxing equimolar amounts of di-2-pyridyl ketone **20** and carbohydrazid **1** in ethanol for 3 h afforded di-2-pyridyl ketone 2-furoylhydrazone **21** [35].



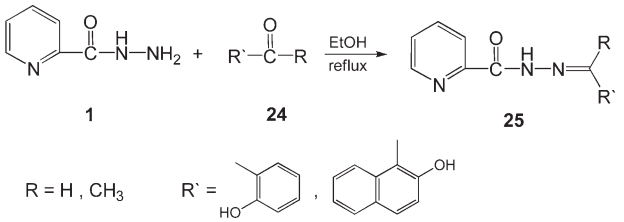
**1** **20** **21**

Refluxing an ethanolic solution of salicylaldehyde **22** and 2-furancarbohydrazide **1** for 30 min gave salicylaldehyde-2-furoic acid hydrazone **23** [36].



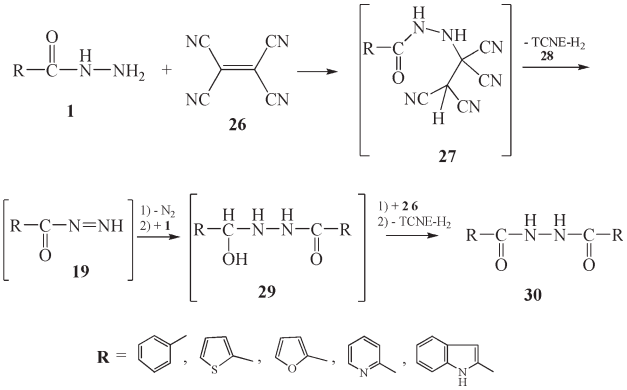
**1** **22** **23**

Condensation of 2-pyridine carbohydrazide **1** with some aldehydes or ketones **24** in ethanol gave the corresponding hydrazones **25** [37].

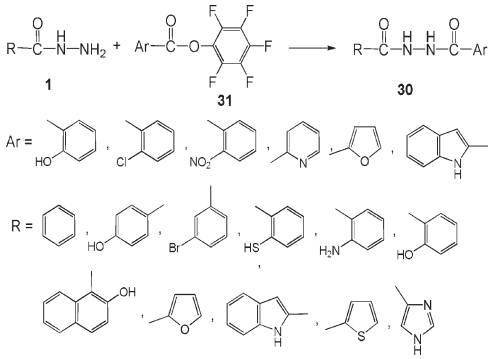


**1** **24** **25**

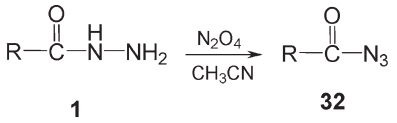
To a stirred solution of ethenetetracarbonitrile (TCNE) (**26**) in dimethylformamide (DMF), carbohydrazides **1** was added to give diaroylhydrazines **30** and 1,1,2,2-tetracyanoethane (TCNE-$H_2$) **28** [38]. Formation of these products may be rationalized *via* the following steps [38].

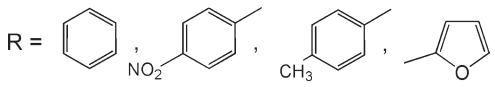


*N*,*N*′-Diaroylhydrazines **30** were formed by using pentafluorophenyl ester to activate arylcarboxylate **31** with carbohydrazides **1**, mild conditions which avoid intermediate were subjected; both symmetrical and unsymmetrical diaroylhydrazines **30** were formed in a high yields [39].

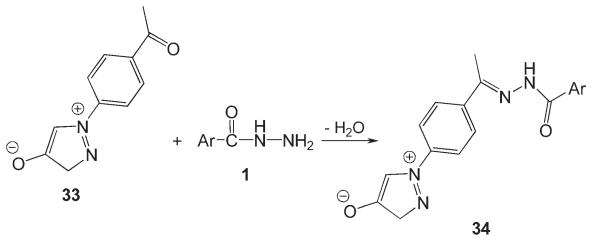


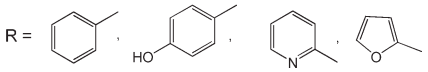
Carbohydrazides **1** reacted rapidly with dinitrogen tetraoxide ($N_2O_4$) [40] in acetonitrile at low temperature (−20 to −40°C) to give the corresponding azides **32** in mostly quantitative yields [41].



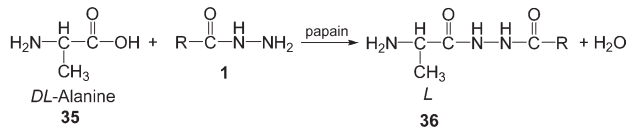


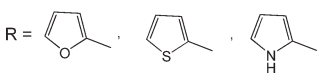
Mixtures of carbohydrazides **1** with 3-(4-acetylphenyl)-sydnone **33** were heated under reflux to produce hydrazone derivatives **34** [42].



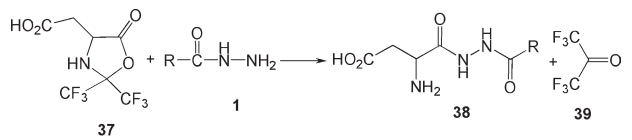


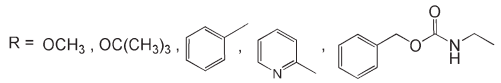
Reaction of carbohydrazides **1** with *DL*-alanine **35** under papain catalysis gave **36**; this represented an example of the power of papain to exert stereochemical preference during catalyzed reaction [43,44].



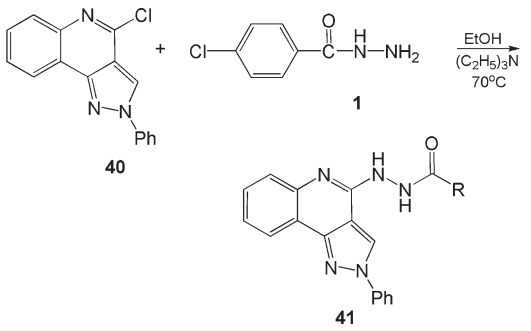


[(4-L)-2,2-Bis(trifluoromethyl)-5-oxo-1,3-oxazolidin-4-yl] acetic acid 37 reacted with carbohydrazides 1 in ethyl acetate at room temperature to give 38 [45].

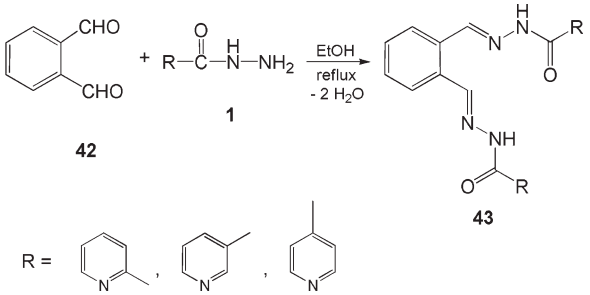




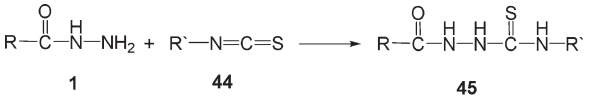
Reaction of carbohydrazides **1** with 4-chloro-2-phenyl-*2H*-pyrazolo[4,3-*c*]quinoline **40** in ethanol and in the presence of triethylamine afforded 4-chloro-*N*′-(2-phenyl-*2H*-pyrazolo[4,3-*c*]quinolin-4-yl)benzohydrazide **41** [46].

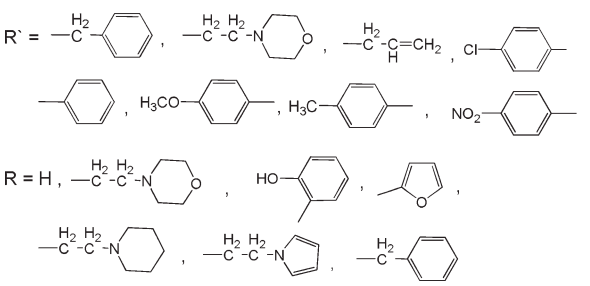


Reaction of phthalaldehyde **42** with carbohydrazides **1** in refluxing ethanol for 2–3 h afforded the corresponding bis(hydrazones) **43** [7].

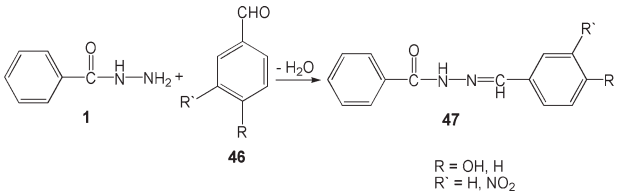


Reaction between an isothiocyanates **44** and carbohydrazides **1** in benzene gave acylthiosemicarbazides **45** in yields ranging from 88 to 95% [47–52].

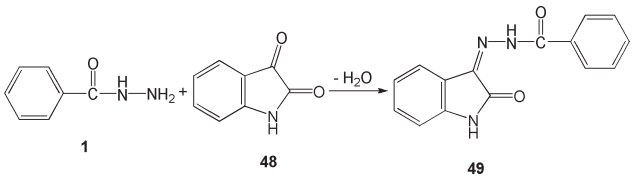




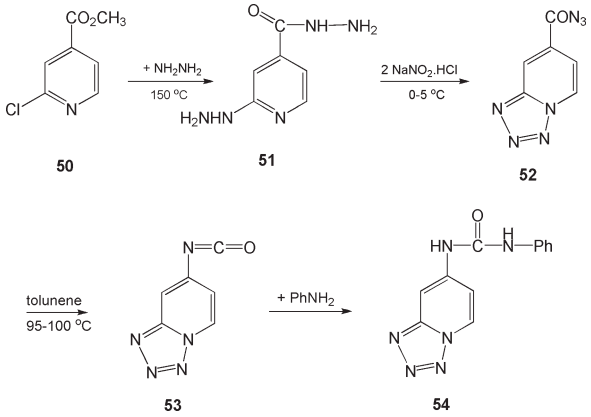
Substituted benzaldehyde **46** reacted with phenyl carbohydrazide **1** in ball-milled for 1 h to give *N*-substituted benzoylhydrazones **47** in spectroscopically pure form [53].



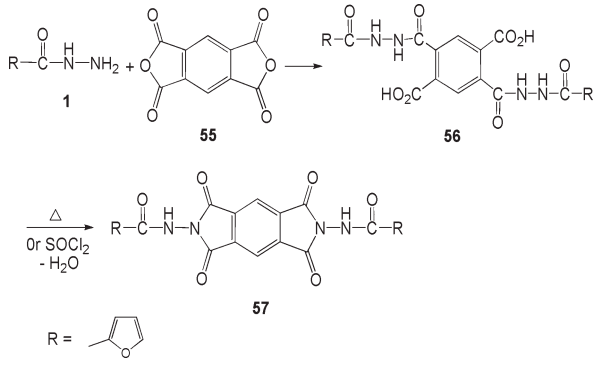
Condensation of isatin **48** with phenyl carbohydrazide **1** required 3 h ball-milling for complete reaction to give isatin-3-benzoylhydrazone **49** [53].



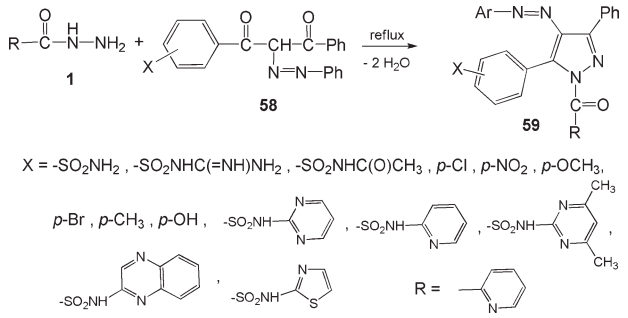
Heating methyl-2-chloroisonicotinate **50** with $N_2H_4.H_2O$ at 150°C in sealed tube gave the substituted carbohydrazide **51** [49]. Treatment of **51** with sodium nitrite in the presence of hydrochloric acid yielded carbonyl azide **52**, which was heated in toluene at 90–100°C for 1 h, sole product to form isocyanate **53** (*Curtius* rearrangement). The later was further reacted *in situ* with aniline at room temperature to give the expected urea derivative **54** [54].



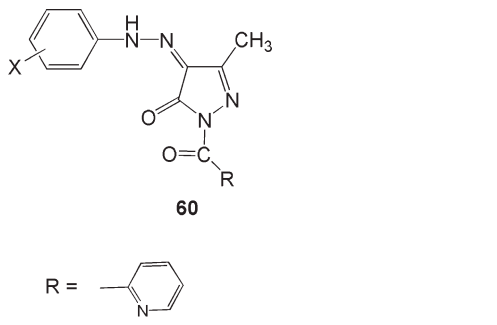
**3.2. Synthesis of pyrrole derivatives.** Reaction of carbohydrazide **1** with acid anhydride **55** to produce pyrrole derivative **57** was carried out *via* thermal cyclodehydration of the dicarboxylic acid **56** at 150°C or during heating with thionyl chloride [55].



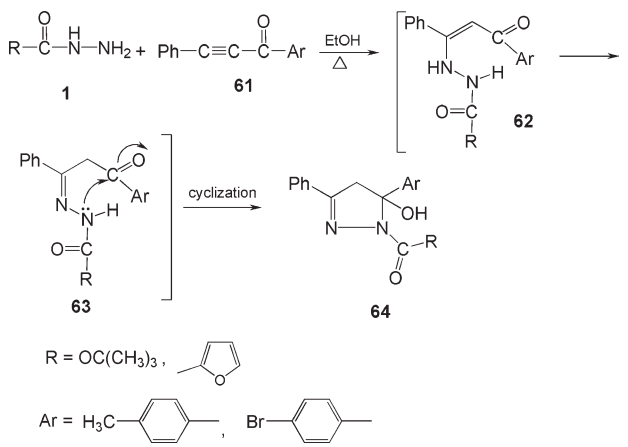
**3.3. Synthesis of pyrazole derivatives.** A mixture of substituted 2-phenylazo-1,3-diphenyl-propane-1,3-dione (**58**) and carbohydrazide **1** in glacial acetic acid was heated under reflux to form *N′*-picolinyl-3-phenyl-5-aryl-4-(substituted phenylazo)pyrazoles **59** [56].



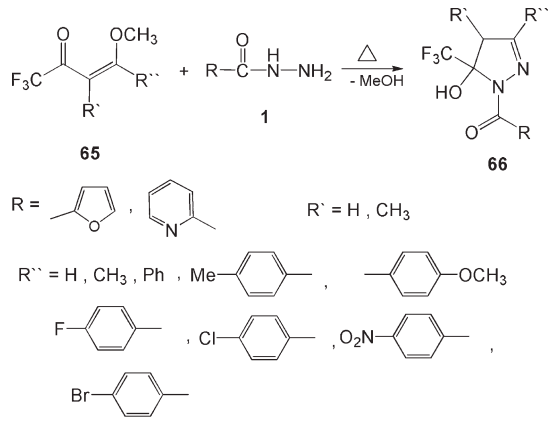
2-Pyridine carbohydrazides **1** reacted with sulpha-substituted phenylhydrazomethyl-2,3-dioxobutyrate in glacial acetic acid to form *N′*-(2-pyridinecarbonyl)-3-methyl-4-(substituted)hydrazono-2-pyrazoline-5-one **60** [57].



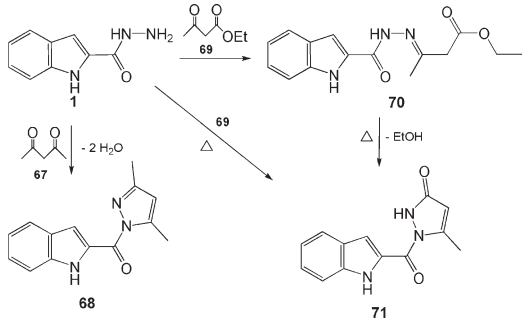
When aroylphenylacetylenes **61** was refluxed with carbohydrazides **1** in ethanol for 5 h, the reaction mixture afforded 5-aryl-4,5-dihydro-5-hydroxy-3-phenyl-1*H*-pyrazole derivatives **64** [58] rather than open chain compounds **63** [59–61].



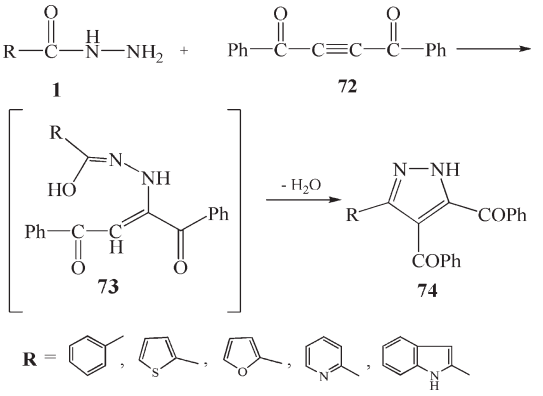
Cyclocondensation reaction of carbohydrazides **1** with a series of 4-methoxy-4-alkyl(aryl)-1,1,1-trifluoro-3-alken-2-one derivatives **65** in refluxing methanol afforded 3-alkyl(aryl)-5-hydroxy-5-trifluoromethyl-4,5-dihydro-1*H*-1(2-aryl) pyrazoles **66** [62].



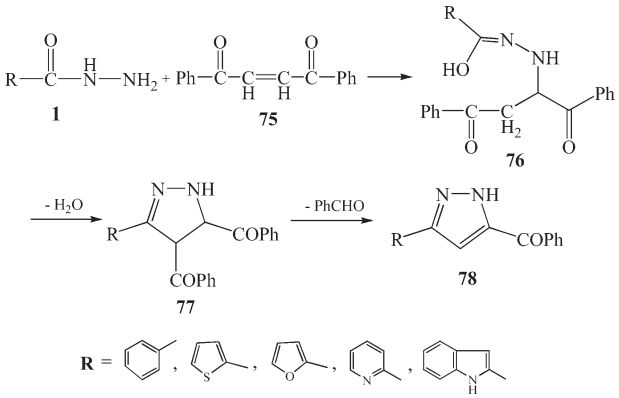
Condensation of 2-indole carbohydrazide **1** with acetyl acetone **67** in ethanol containing a catalytic amount of acetic acid resulted in the formation of the corresponding pyrazole derivative **68** [1]. Carbohydrazides **1** reacted with ethylacetoacetate **69** in the absence of solvent to give the ester derivative **70**, which could be cyclized to pyrazolone derivative **71** by heating above its melting point for 10 min followed by refluxing in methanol for further 2 h. Compound **71** was also obtained independently *via* direct refluxing of **1** with ethylacetoacetate **69** in ethanol/acetic acid mixture for 5 h [1].



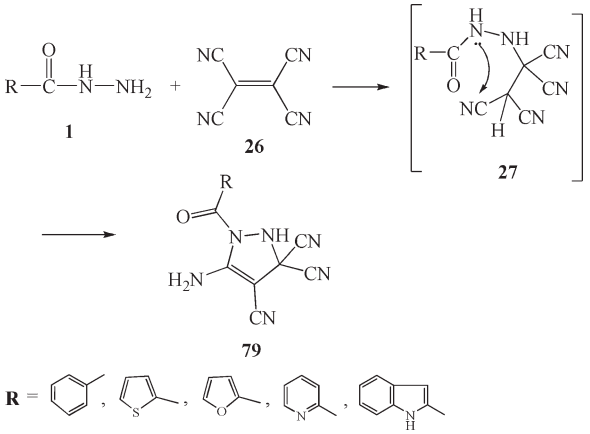
Addition of substituted carbohydrazides **1** to 1,4-dibenzoylacetylene **72** afforded the 4,5-dibenzoyl-3-substituted-1*H*-pyrazole **74** *via* the intermediate **73** [63].



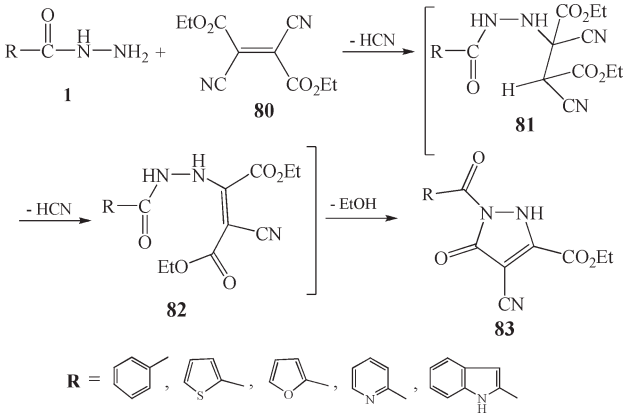
On the other hand, the reaction of substituted carbohydrazides **1** with 1,4-diphenylbut-2-ene-1,4-dione **75** in refluxing acetic acid gave 4-benzoyl-3-substituted pyrazoles **78** [63].



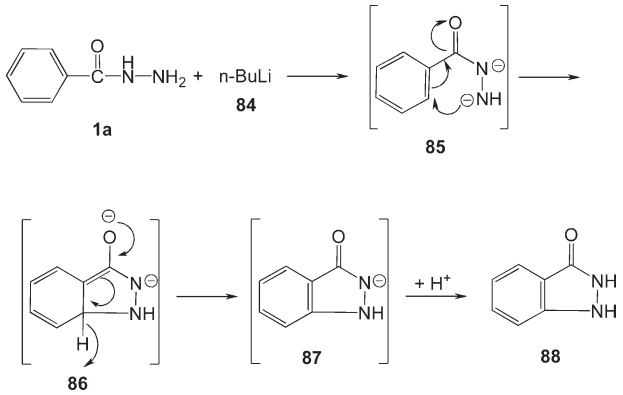
Reaction of substituted carbohydrazides **1** with **26** in DMF afforded 5-amino-1(substituted)-1*H*-pyrazole-3,3,4(2*H*)-tricarbonitriles **79** [38].



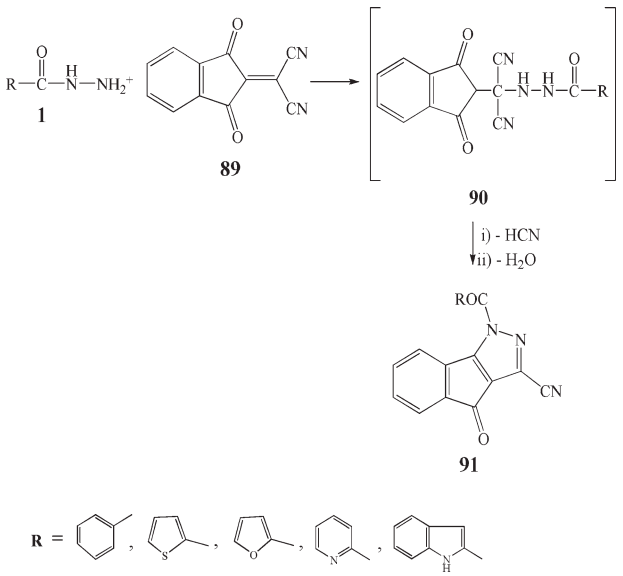
Mixing equimolar amount of carbohydrazides **1** with diethyl(*E*) 2,3-dicyanobutenedioate **80** in ethyl acetate under reflux led to the formation of pyrazole derivatives **83** [38].



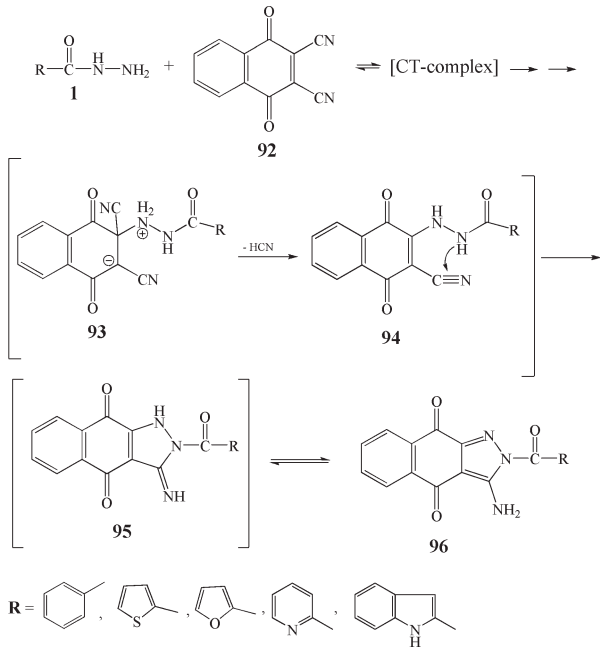
**3.4. Synthesis of fused pyrazole derivatives.** When phenyl carbohydrazide **1** in tetrahydrofuran (THF) was treated with n-butyl-lithium **84** in hexane under nitrogen atmosphere at −78°C for 1.5 h and allowed to reach the room temperature overnight, indazol-3(2*H*)-one **88** was isolated [64].



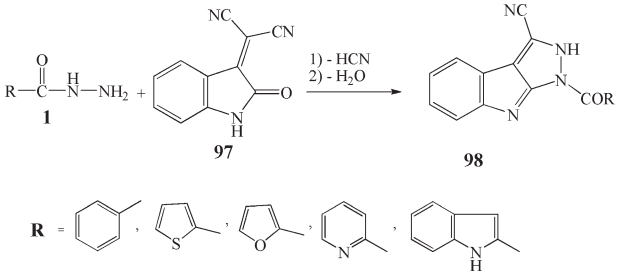
The reaction of (1,3-dioxo-2,3-dihydro-1*H*-inden-2-ylidene)propanedinitrile **89** and **1** in DMF with admission of air afforded 4-oxo-1-substituted-1,4-dihydroindeno[1,2-*c*]pyrazole-3-carbonitrile **91** [65].



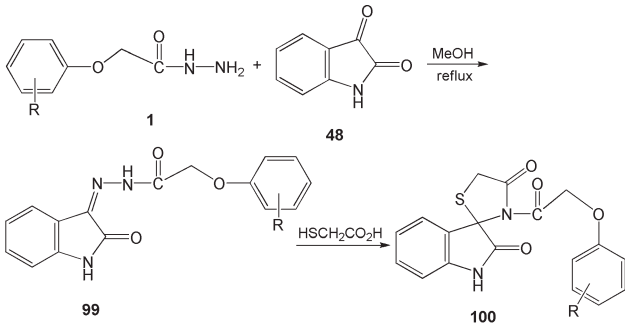
**3.5. Synthesis of indazole derivatives.** In a different manner, 1,4-naphthoquinone-2,3-dicarbonitrile **92** reacted with **1** to give substituted benzo[*f*]indazoledione **96** [66].



Carbohydrazides **1** reacted with 3-(dicyanomethylene)-2-indolone **97** in the presence of pipridine to give substituted carbonylpyrazolo[3,4-*b*]-indole-3-carbonitrile **98** [65].



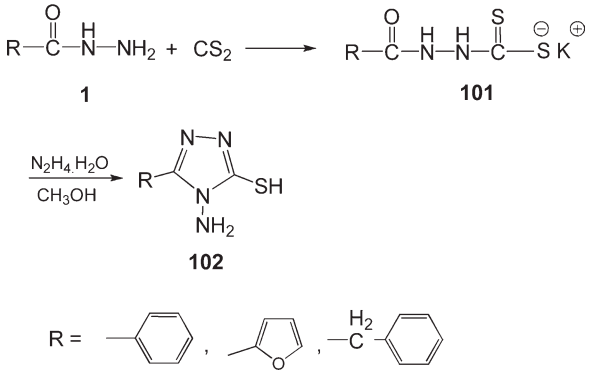
**3.6. Synthesis of thiazolidine derivatives.** Refluxing carbohydrazides **1** with **48** in methanol afforded isatin-β-arylhydrazones **99**, which reacted with 2-mercapto acetic acid in dioxane to furnish the interesting spiro[3*H*-indole-3,2ʾ-thiazolidine] derivatives **100** [67].



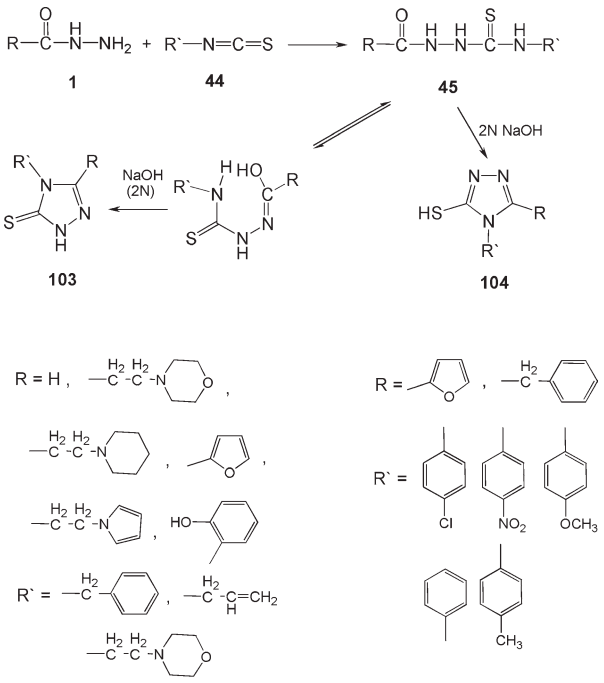
R = 2,4-$(CH_3)_2$ , 4-Cl , 4-$CH_3$ , 2-$CH_3$ , 4-Cl-3-$CH_3$ , 2-Cl , 3,4-$(CH_3)_2$ , 3,5-$(CH_3)_2$ , 2,5-$(CH_3)_2$

**3.7. Synthesis of 1,2,4-triazole derivatives.** Reaction of carbohydrazides **1** with carbon disulfide in ethanolic

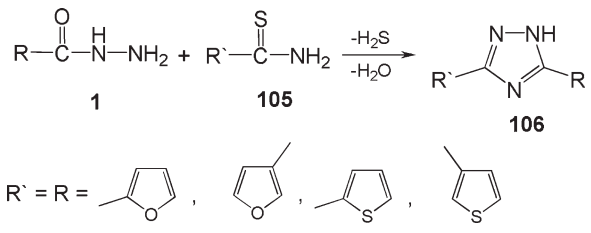
potassium hydroxide gave dithiocarbazate **101**, which reacted with hydrazine hydrate to form 4-amino-5-aryl-4*H*-1,2,4-triazole-3-thiol **102** [51].



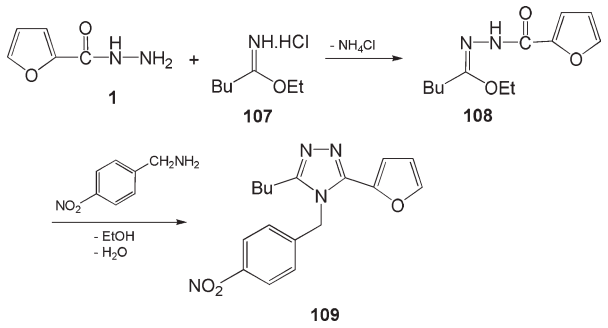
Ring closer acylthiosemicarbazides **45**, prepared by reacting **1** with **44**, in an alkaline medium, led to the formation of 1,2,4-triazole-3-thione derivatives **103** [51] and 1,2,4-triazolethiol derivatives **104** [47,48,68–70].



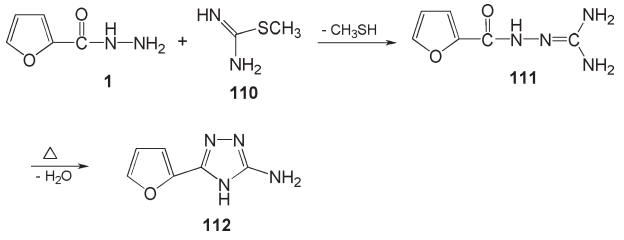
1,2,4-Triazole derivatives **106** were also obtained *via* the reaction of thiocarbamides **105** with carbohydrazides **1** [71].



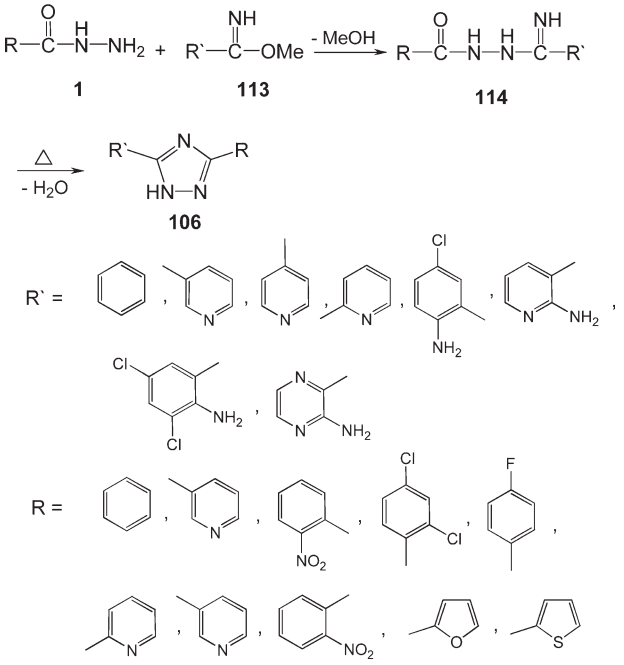
The reaction of carbohydrazide **1** with imidate hydrochloride **107** gave compound **108**, which was converted into 1,2,4-triazole derivative **109** upon heating with 4-nitrobenzylamine [72].



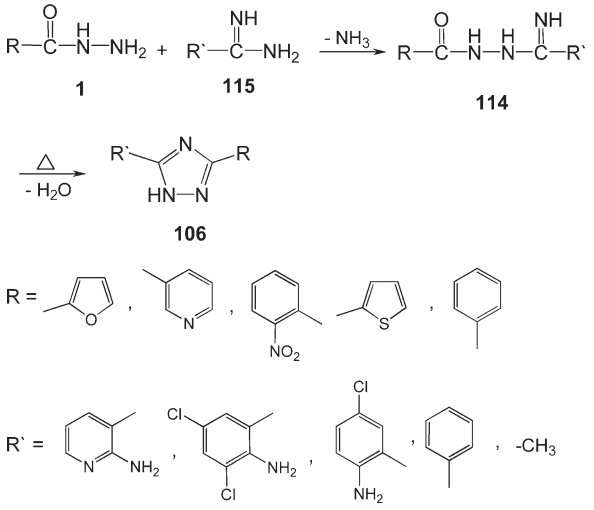
2-Furan carbohydrazide **1** reacted with *S*-methyl-isothiourea **110** to give the corresponding guanidine **111**. Upon heating **111**, 3-amino-1,2,4-triazole derivative **112** was formed [73,74].



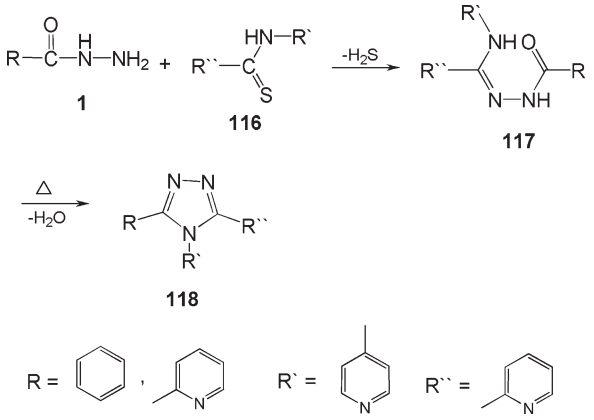
Most of 3,5-disubstituted-1,2,4-triazoles **106** were readily synthesized from imidates **113** and carbohydrazides **1**. For example, condensation of imidates **113** with carbohydrazides **1** gave acylamidrazones **114**, which underwent thermal cyclization to give 3,5-disubstituted-1,2,4-triazoles **106** [75–79].



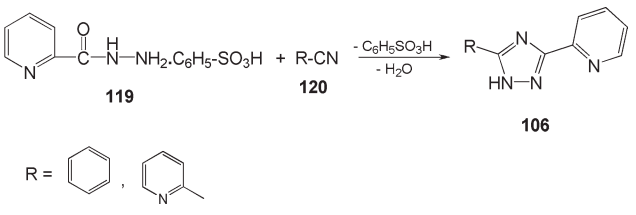
Also, reaction of carbohydrazides **1** with acetamidine or benzamidine **115** afforded 1,2,4-triazole derivatives **106** [80–82].



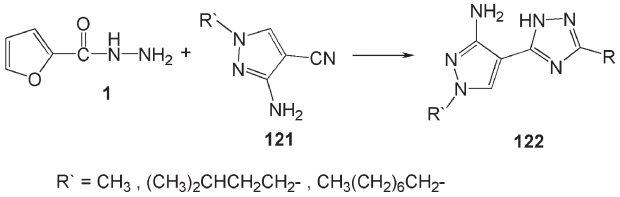
Substituted 1,2,4-triazoles **118** were synthesized by thermal cyclization of $N^3$-substiuted-$N^1$-acylamidrazone derivatives **117**, prepared by the reaction of carbohydrazides **1** with thioamides **116** in ethanol at room temperature [83–85].



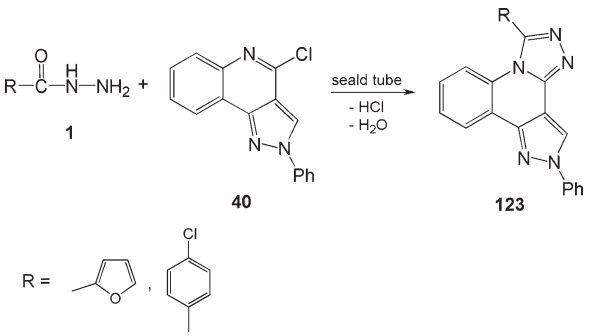
1,2,4-Triazole derivatives **106** were prepared *via* the reaction of 2-pyridine carbohydrazide benzenesulphonate **119** with substituted nitriles **120** [86] according to Pott's method [87–90].



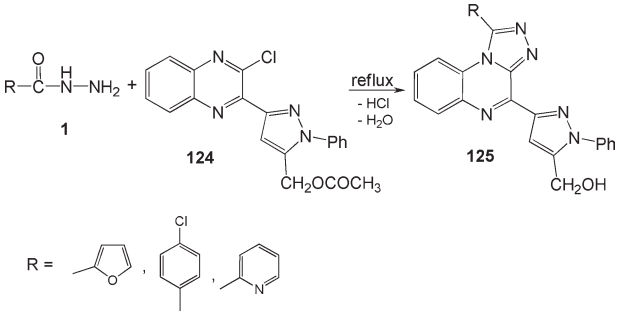
Reaction of pyrazole derivatives **121** with carbohydrazide **1** afforded 1,2,4-triazole derivatives **122** [91]. Also, the reaction of **121** with carbohydrazides **1** in refluxing diphenyl ether gave the 1,2,4-triazole derivatives **122** [3].



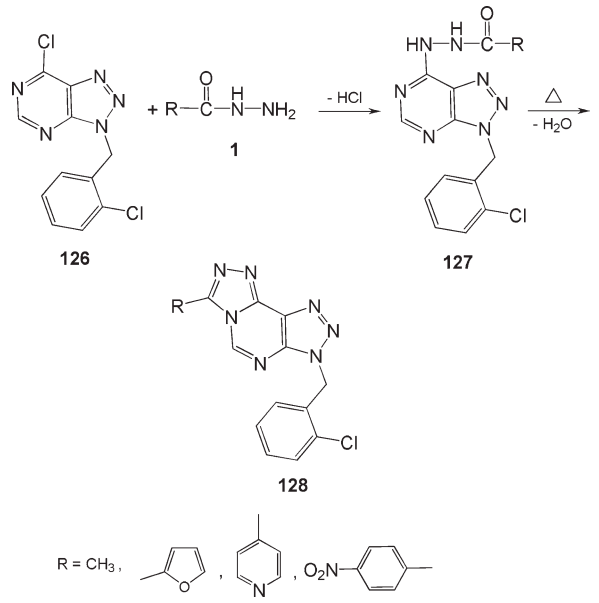
**3.8. Synthesis of fused triazole compounds.** 4-Chloro-2-phenyl-2*H*-pyrazolo[4,3-*c*]quinoline **40** reacted with carbohydrazides **1** in ethanol to form 2-phenyl-6-(furan-2-yl or 4-chlorophenyl)-2*H*-pyrazolo[4,3-*c*]-1,2,4-triazolo[4,3-*a*]quinolines **123** [46].



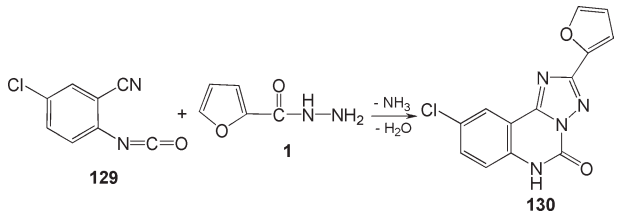
The reaction of carbohydrazides **1** with 2-chloro-3-[5-(acetoxymethyl)-1-phenylpyrazol-3-yl]quinoxaline **124** in boiling n-butanol resulted in the formation of the corresponding 1-aryl-4-[5-(hydroxymethyl-1-phenyl-pyrazol-3-yl]-1,2,4-triazolo[4,3-*a*]quinoxalines **125** [92].



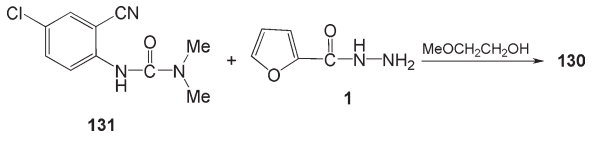
3-(2-Chlorobenzyl)-7-chloro-1,2,3-triazolo[4,5-*d*]-pyrimidine **126** reacted with carbohydrazides **1** in boiling ethanol to give hydrazo derivatives **127**, which underwent intramolecular thermal cyclization to form 3-(2-chlorobenzyl)-7-substituted-1,2,3-triazolo [4,5-*e*]-1,2,4-triazolo[4,3-*c*]-pyrimidine derivatives **128** [93].



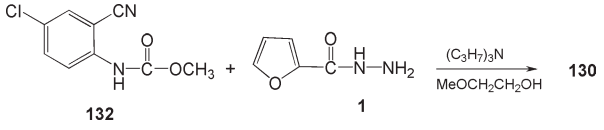
The reaction of carbohydrazide **1** with 5-chloro-2-isocyanatobenzonitrile **129** in presence of tripropylamine and 2-methoxyethanol afforded 9-chloro-2-(2-furyl)-1,2,4-triazolo[1,5-*c*]quinazolin-5-(6*H*)-one **130** [94,2].



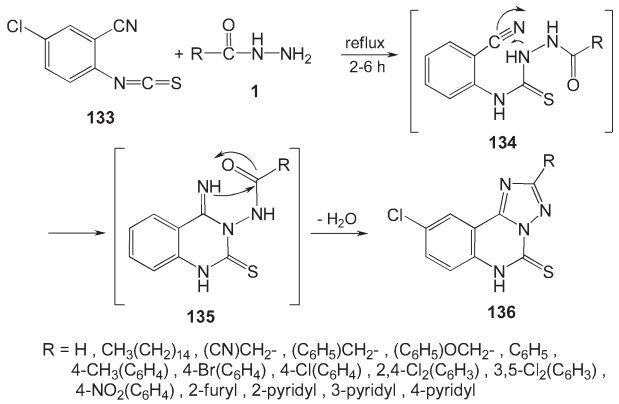
Also, the reaction of *N,N*-dimethyl-*N*\-(4-chloro-2-cyanophenyl)urea **131** with 2-furan carbohydrazide **1** in 2-methoxyethanol gave triazoloquinazolinone derivatives **130** [94].



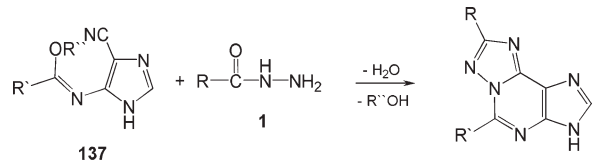
On the other hand, compound **130** was synthesized by the reaction of 5-chloro-2-[(methoxycarbonyl)-amino]-benzonitrile **132** with 2-furan carbohydrazide **1** in tripropylamine and 2-methoxyethanol [94].



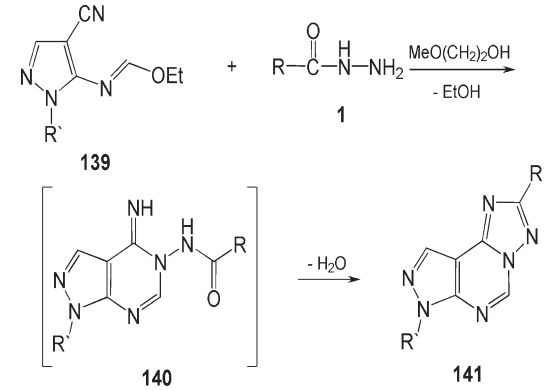
One-pot reaction between carbohydrazides **1** and 5-chloro-2-isothiocyanatobenzonitrile **133** afforded 1,2,4-triazolo[1,5-*c*]quinazoline-5(6*H*)-thiones **136**, in good yields [95].



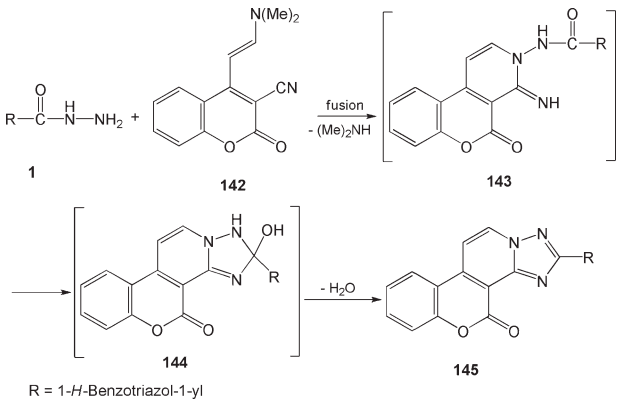
Refluxing alkyl-*N*-[4-cyano-1*H*-imidazol-5-yl]alkyl-imidate **137** with carbohydrazides **1** in DMF gave substituted 3*H*-1,2,4-triazolo[5,1-*i*]purines **138** [96].



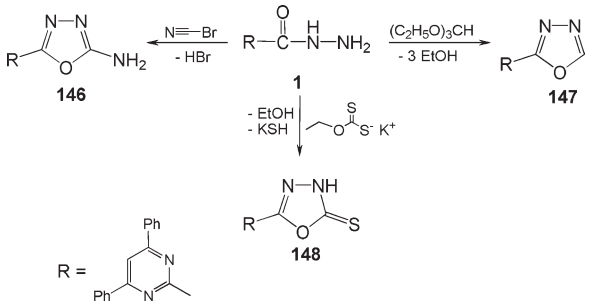
Reaction of 2-furan carbohydrazide **1** with imidate **139** in refluxing 2-methoxyethanol gave pyrazolo[4,3-*e*]-pyrimidine derivatives **140**, the non-isolable which converted *via* a thermally induced cyclization in diphenyl ether into pyrazolo[4,3-*e*]-1,2,4-triazolo[1,5-*c*]pyrimidine derivatives **141** [5, 6, 97–99].



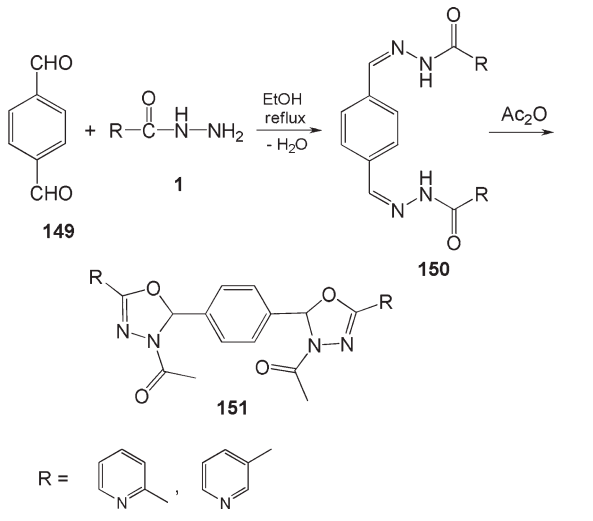
Fusion of *E*-dimethylaminoethylene derivatives **142** with carbohydrazide **1** afforded the corresponding 1,2,4- triazolo[1,5-*a*]pyrido[3\,4\-*c*]coumarin derivative **145** [100].



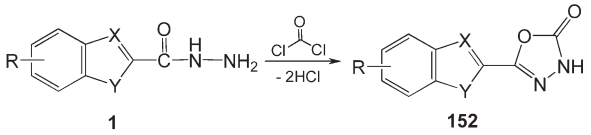
**3.9. Synthesis of oxadiazole derivatives.** Oxadiazole derivative **146** was obtained from the reaction of carbohydrazide **1** with cyanogen bromide [101]. Also, compound **1** reacted with triethoxymethane or potassium *o*-ethylxanthate to give, 1,3,4-oxadiazole and 1,3,4-oxadiazolethione **147** and **148** respectively [47].



Reaction of terephthalaldehyde **149** with carbohydrazides **1** in refluxing ethanol afforded the corresponding bis(carbohydrazone) **150**. Heating **150** in acetic acid/ethanol mixture at reflux temperature afforded bis(dihydroxadiazolyl)benzene derivatives **151** [102].

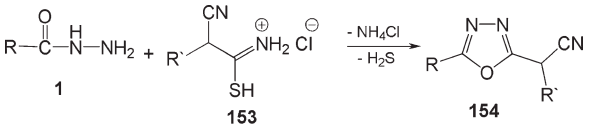


2-(2,3-Dihydro-2-oxo-1,3,4-oxadiazol-5-yl)benzo-heterocycles **152** were prepared by treatment of carbohydrazides **1** with excess of phosgene in methylene chloride at room temperature [103].



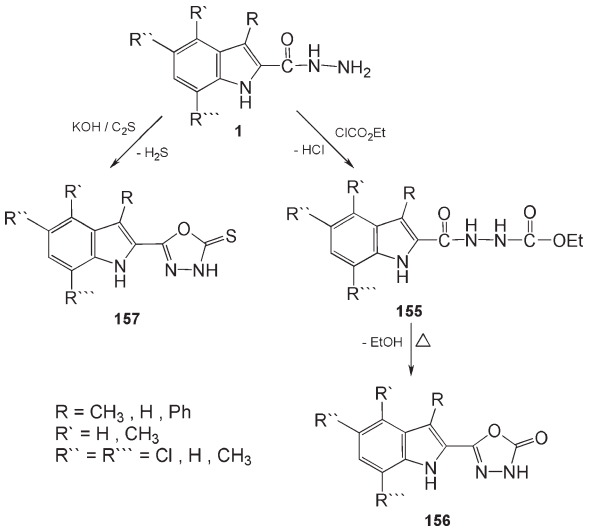
R = H , 5-Cl , 5-$CO_2CH_3$ , 7-$OCH_3$ , 6-$CH_3$
5-$CO_2Et$ , 4-$CH_3$ , 5-$CH_3$ , 6-$CH_3$ , 6-Cl
X = N , C-Cl , C-$CH_3$ , CH
Y = N-$CH_3$ , S , $CH_2$ , NH , O

Carbohydrazides **1** reacted with **153** in refluxing ethanol to give 2-cyanomethyl-5-substituted-1,3,4-oxadiazole **154** [103].

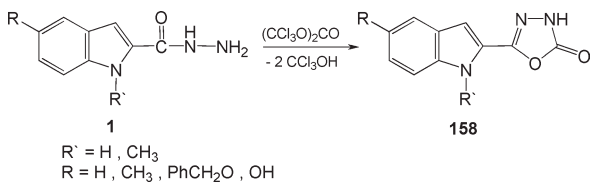


R` = H , n-Bu , $PhCH_2$
R = Ph , n-$C_{11}H_{23}$ , 2-indolyl

Carbohydrazides **1** underwent condensation with ethyl chloroformate to give *N*-carbethoxy-5-substituted indole-2-carbohydrazides **155**, which were refluxed in diethyl ether to give 2-(5′-oxo-1′,3′,4′-oxadiazol-2′-yl)indole derivatives **156** [104].

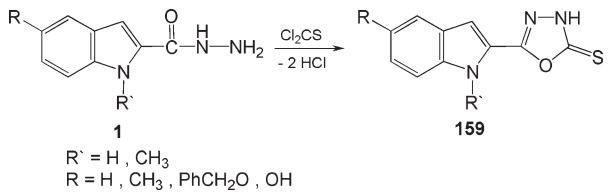


Treatment of carbohydrazides **1** with triphosgene afforded oxadiazolone derivatives **158** in one step [16].

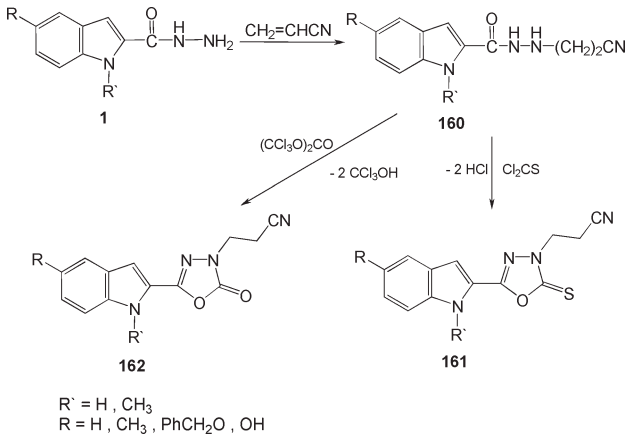


Also, **1** was refluxed with appropriate quantities of KOH and $CS_2$ in ethanol to give oxadiazolethione derivatives **157** [104].

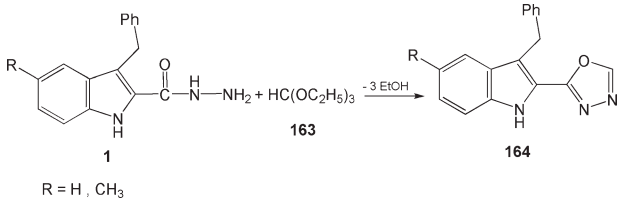
1,3,4-Oxadiazolethiones **159** were generated directly by treatment of the corresponding carbohydrazides **1** with thiophosgene [4].



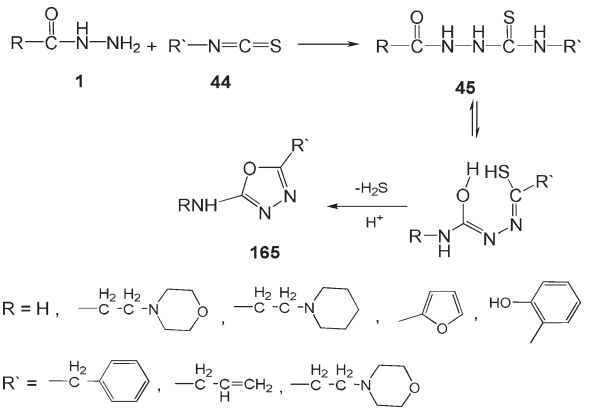
Monosubstituted indole-2-cyanoethylhydrazides **160**, prepared by Michael addition of acrylonitrile on the corresponding carbohydrazides **1**, were used as good precursors for the synthesis of indolyl-1,3,4-oxadiazole-3-(2-cyanoethyl)-2-one derivatives **161** and **162**, during the reaction with thiophosgene and triphosgene, respectively [4].



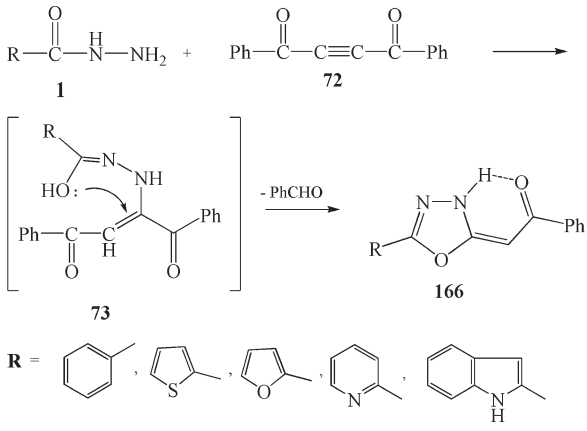
Refluxing carbohydrazides **1** with triethylorthoformate (TEO) **163** afforded 1,3,4-oxadiazole derivatives **164** [105].



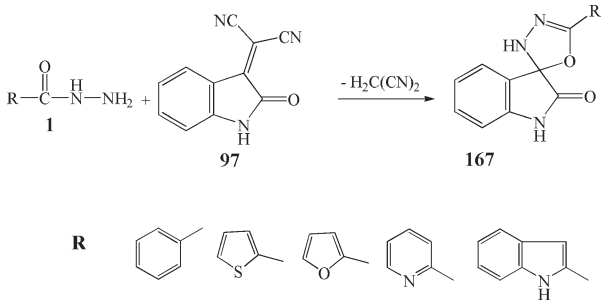
Isothiocyanates **44** reacted with carbohydrazides **1** to form acylthiosemicarbazides **45**. Ring closure of **45** in acidic medium gave 1,3,4-oxadiazole **165** derivatives [47,106].



Reaction of **1** with **72** in acetic acid gave the intermediate **73** which loss a molecule of PhCHO to form 1-phenyl-2-(5-substituted-1,3,4-oxadiazol-2-(3*H*)-ylidene) ethanone **166** [63].

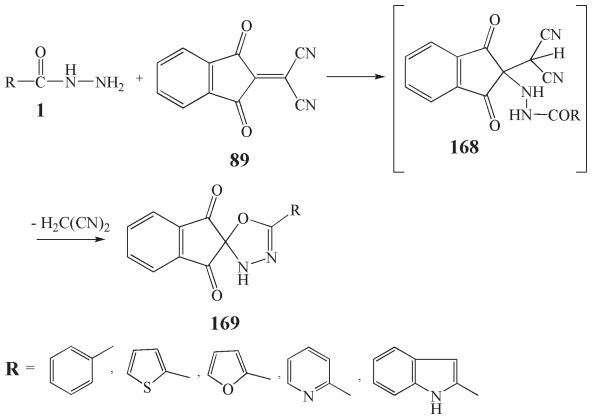


Carbohydrazides **1** reacted with 3-(dicyanomethylene)-2-indolone **97** in the presence of pipridine to give substituted spiro(indoline-3,2\-1,3,4-oxadiazol)-2-one **167**. Nucleophilic attack of **1** on C=C of **97** followed by loss of one molecule of malononitrile afforded **167** [65].

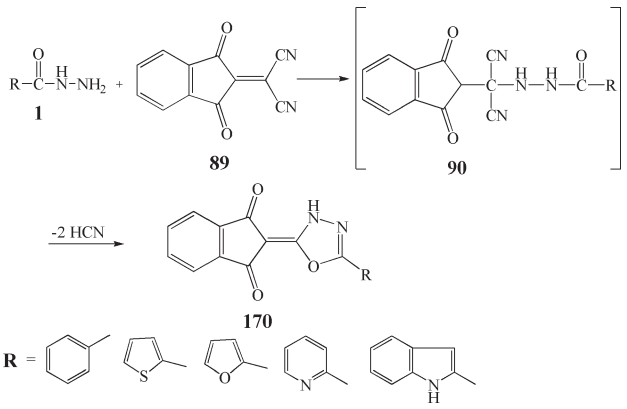


Carbohydrazides **1** reacted with (1,3-dioxo-2,3-dihydro-1*H*-inden-2-ylidene)propanedinitrile **89** in DMF with

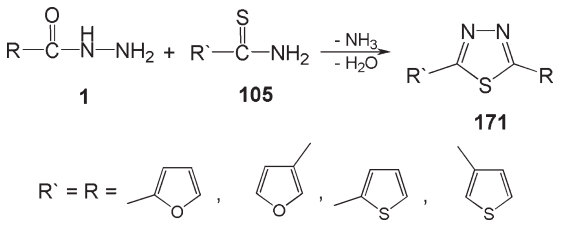
admission of air, to afford 5′-substituted-3′*H*-spiro(indene-2,2′-1,3,4-oxadiazole)-1,3-dione **169** [65].



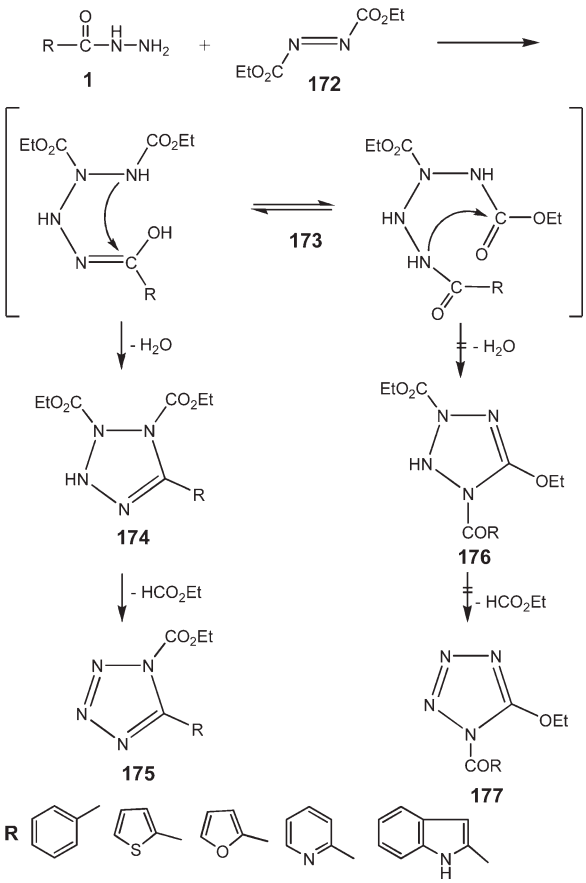
On the other hand, reaction of carbohydrazides **1** with **89** gave 2-(5-substituted-1,3,4-oxadiazol-2-(3*H*)-ylidene)-1*H*-indene-1,3-(2*H*)-diones **170** *via* the formation of the intermediate **90** and elimination of two molecules of HCN [65].



**3.10. Synthesis of thiadiazole derivatives.** Thiadiazole derivatives **17**1 were obtained from the reaction of carbohydrazides **1** and thiocarboxamides **105** [71].



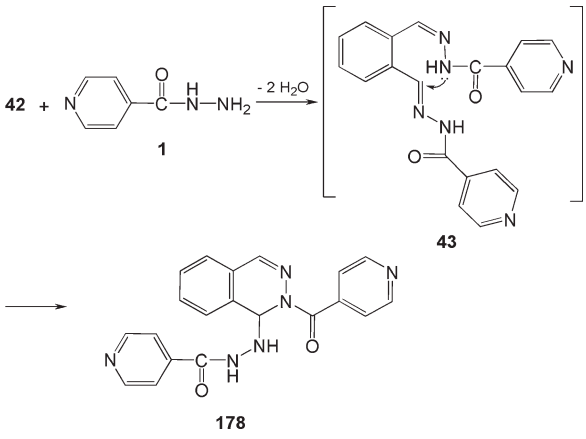
**3.11. Synthesis of tetrazole derivatives.** A mixture of **1** and diethyl diazene-1,2-dicarboxylate **172** in glacial acetic acid was heated at reflux temperature for 6-8 h, during which time tetrazole derivatives **175** were formed [63].



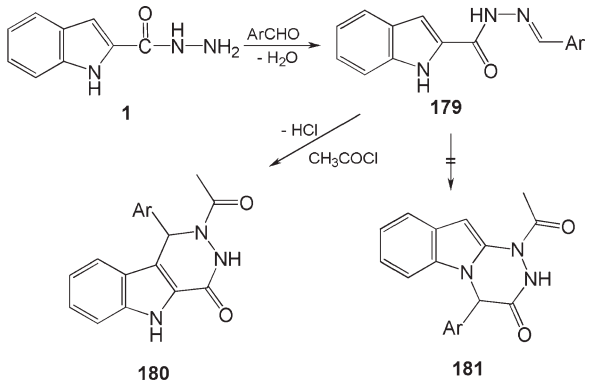
Nucleophilic attack of **1** to **172** with loss one molecule of $H_2O$ followed by elimination of another molecule of ethyl formate afforded tetrazole derivatives **175** rather than the alternative structure **177** [63].

**3.12. Synthesis of diazine derivatives.**

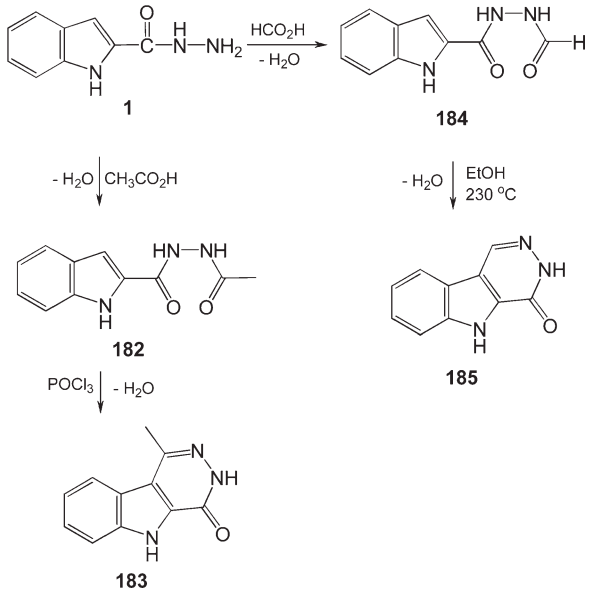
***3.12.1. Synthesis of phthalazine derivatives.*** Reaction of *o*-phthalaldehyde **42** with 4-pyridine carbohydrazide **1** in refluxing ethanol gave a pure sample of hydrazone **43**, which underwent intramolecular cyclization afford the phthalazine derivatives **178** [102].



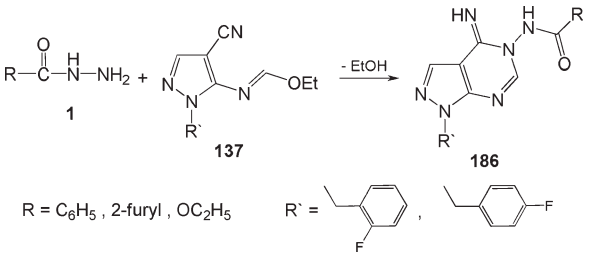
*3.12.2. Synthesis of pyridazine derivatives.* Condensation of indole carbohydrazide **1** with aromatic aldehydes gave the corresponding hydrazone derivatives **179** were obtained in varying yields, which heated to reflux in acetyl chloride to give the interesting tricyclic indolo[2,3-*d*]pyridazine derivatives **180** rather than indenotriazines **181** [64].



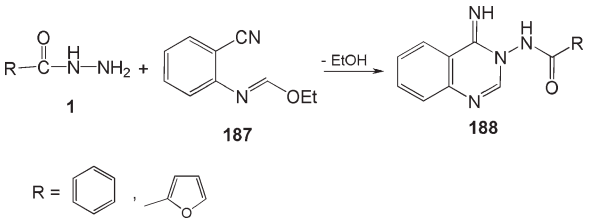
Acetylation of **1** by refluxing in acetic acid afforded 2-acetyl-hydrazinocarbonylindole **182**, in high yield. Compound **182** was cyclized directly by refluxing in dioxane containing $POCl_3$ to the indolo[3,2-*b*]pyradizines **183** [64]. On the other hand, refluxing **1** in formic acid for 5 h afforded the *N*-formyl derivative **184**, which was heated for 10 min in ethanol to afford 2,3-dihydro-indolo[3,2-*b*]pyridazin-1-one **185** [64].



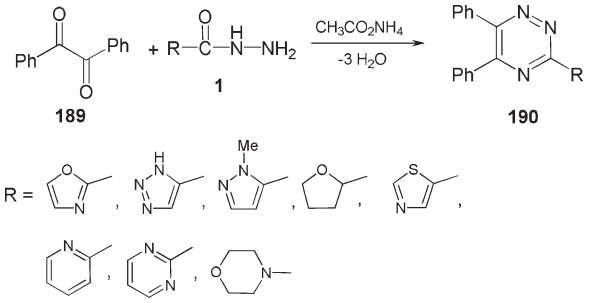
*3.12.3. Synthesis of pyrimidine derivatives.* Carbohydrazides **1** reacted with 4-cyano-5-[(ethoxymethylene)amino]pyrazoles **137** to give 5-acyl-amino-4-imino-4,5-dihydropyrazolo[3,4-*d*]pyrimidines **286** [91].



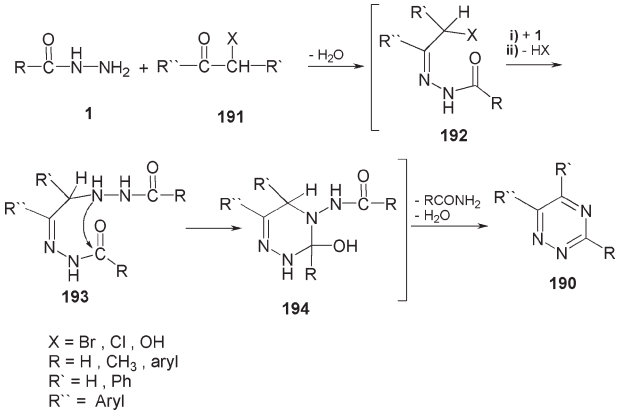
*3.12.4. Synthesis of quinazoline derivatives.* Refluxing of carbohydrazides **1** with *N*-ethoxy-methylene-2-amino-benzonitrile **187** in ethanol gave 3-acylamino-4-imino-3,4-dihydroquinazolines **188** [107].



**3.13. Synthesis of 1,2,4-triazine derivatives.** Benzil **189** reacted with carbohydrazides **1** in the presence ammonium acetate under microwave irradiation to give 1,2,4-triazine derivatives **190** [9,108–110].

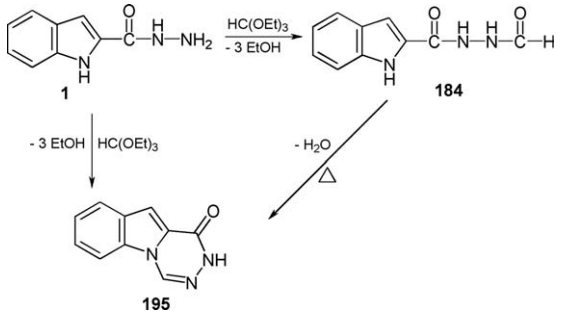


1,2,4-Triazine derivatives **190** were obtained by the reaction of carbohydrazides **1** with halomethyl ketone **191** [111,112].

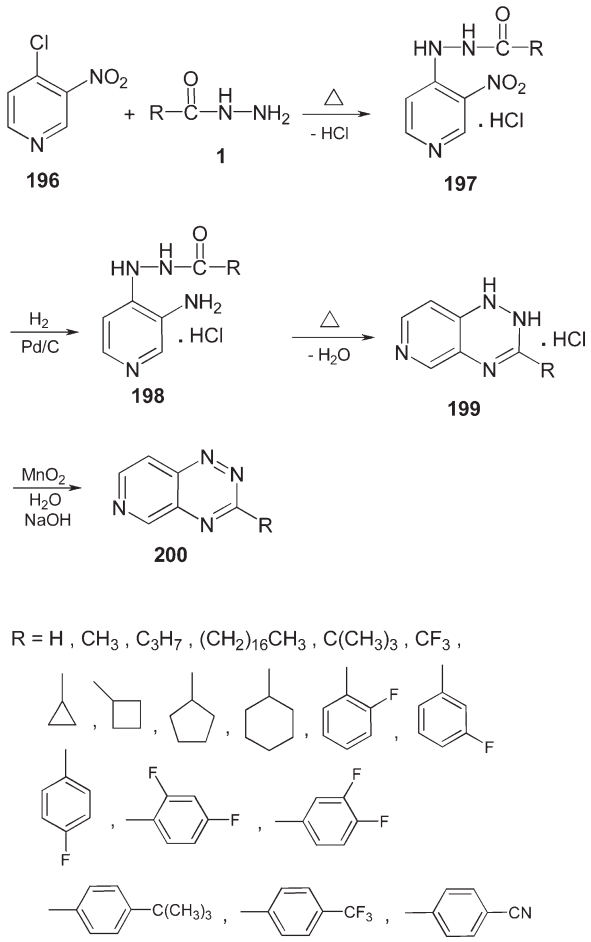


Boiling of 2-indole carbohydrazide **1** with triethyl-orthoformate in DMF, or thermal cyclodehydration of

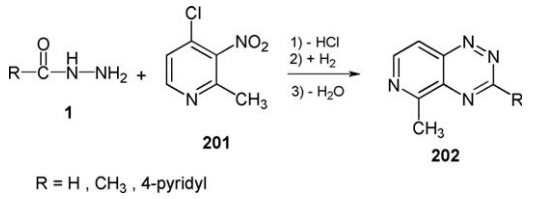
**184** gave 1,2-dihydro-1-oxo-1,2,4-triazino[4,5-*a*]indole **195** [113].



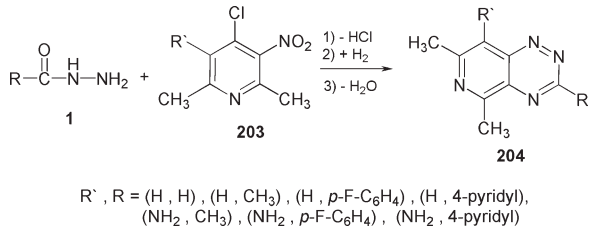
Carbohydrazides **1** reacted with 4-chloro-3-nitropyridine **196** in ethanol to form the acyl derivatives of 4-hydrazino-3-nitropyridine hydrochloride **197**. The nitro group in **197** was rapidly reduced over palladium catalyst to give **198**, ring closure of the latter compound under acidic conditions gave pyrido[3,4-*e*]-1,2,4-triazine derivatives **199**, which was oxidized by $MnO_2$ in presence of alkaline solution to form 3-substiuted pyrido[3,4-*c*]-1,2,4-triazine derivatives **200** [114,115].



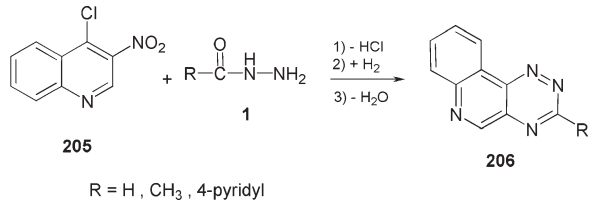
Similarly, carbohydrazides **1** reacted with 4-chloro-2-methyl-3-nitropyridine **201** to give 3,5-disubstituted pyrido[3,4-*c*]-1,2,4-triazine derivatives **202** [114,115].



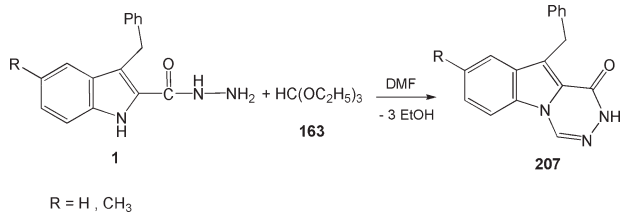
The reaction of carbohydrazides **1** with 5-substituted-4-chloro-2,6-dimethyl-3-nitropyridine **203** afforded pyridotriazine derivatives **204** [114,115].



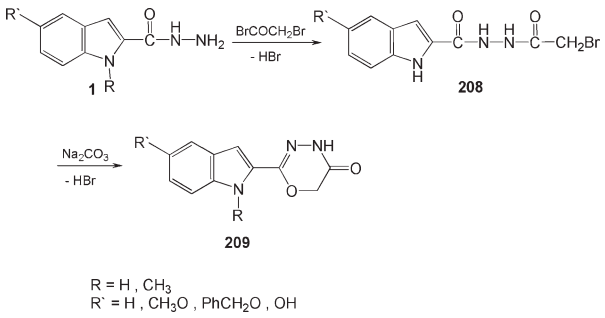
Reaction of 4-chloro-3-nitroquinoline **205** with carbohydrazides **1** gave 1,2,4-triazino[5,6-*c*]quinolines **206** [114,115].



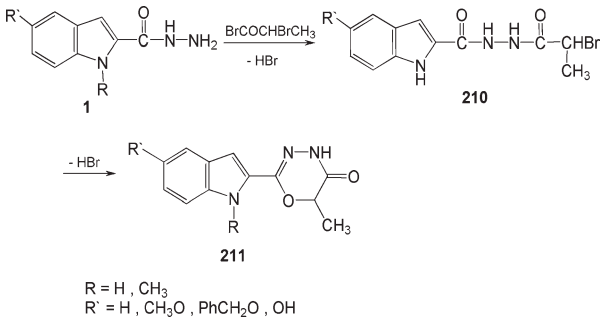
Reaction of carbohydrazides **1** with triethylorthoformate **163** in DMF gave 10-benzyl-1,2-dihydro-1-oxo-1,2,4-triazino[4,5-*a*]indole derivatives **207** [105].



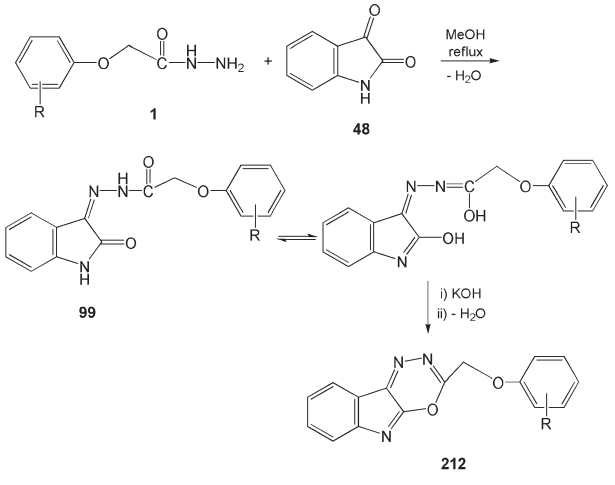
**3.14. Synthesis of 1,3,4-oxadiazine derivatives.** 2-Indolyl-4*H*-1,3,4-oxadiazine-5(6*H*)-one derivatives **209** have been synthesized by reaction of $Na_2CO_3$ with $N^2$-(2-bromoacetyl)indole-2-carbohydrazides **208**, prepared by reaction of carbohydrazides **1** with α-bromoacylbromide [4].



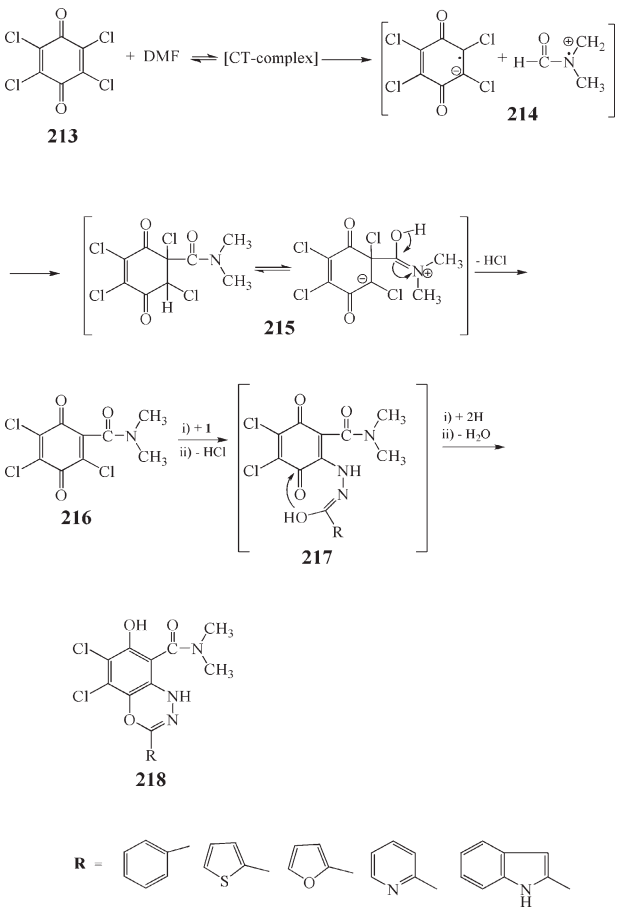
Reaction of carbohydrazides **1** with 2-bromopropanoylbromide gave $N^2$-(2-bromopropanoyl)-indole-2-carbohydrazide **210**, which cyclized to produce 2-indolyl-4*H*-1,3,4-oxadiazine-6-methyl-5-one derivatives **211** [4].



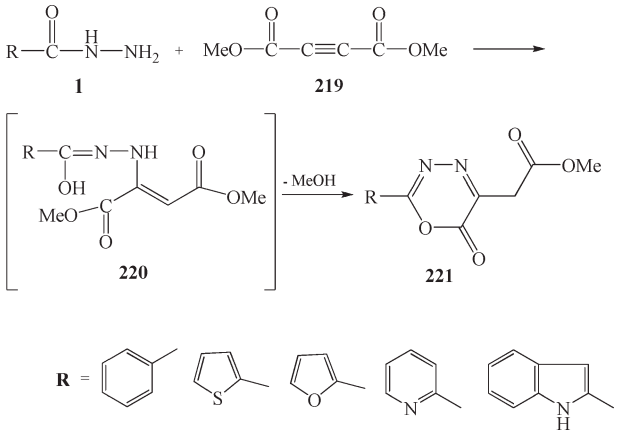
Isatin **48** was refluxed with carbohydrazides **1** in methanol to furnish isatin-β-aroylhydrazones **99**, which heated to reflux in aq. KOH to afford 2-aryl-1,3,4- oxadiazino[5,6-*b*]indole derivatives **212** [67].



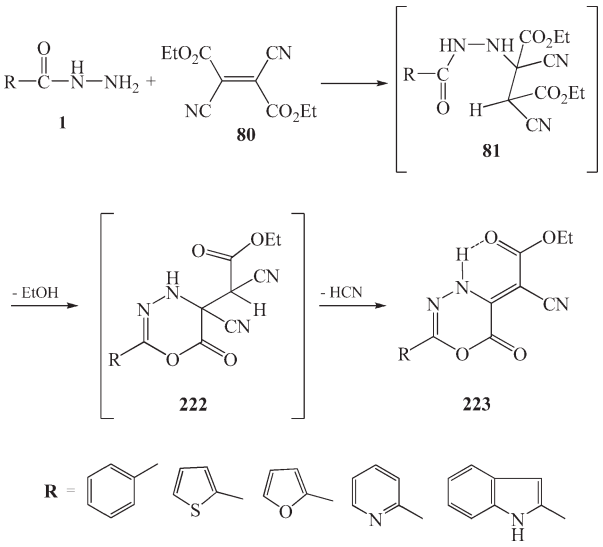
A mixture of 2,3,5,6-tetrachloro-1,4-benzoquinone **213** and **1** in DMF with admission of air afforded substituted benzo[1,3,4]oxadiazinecarboxamide **218** [66].



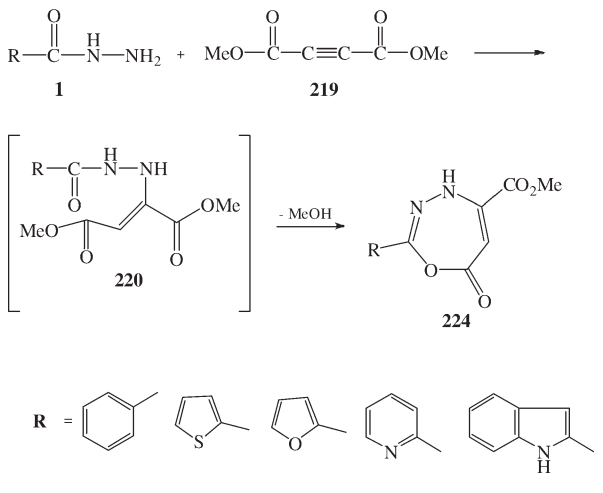
A mixture of dimethyl but-2-ynedicarboxylate **219** and substituted carbohydrazides **1** was refluxed in methanol to afford 1,3,4-oxadiazine derivatives **221** [63].



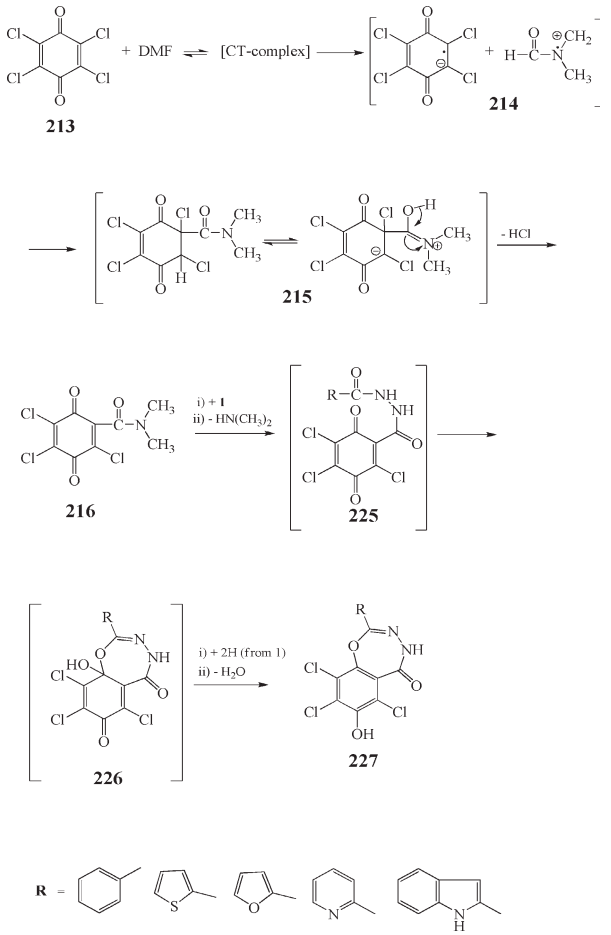
Solutions of diethyl (*E*) 2,3-dicyanobutenedioate **80** and **1** were refluxed for 4–18 h in ethyl acetate to give 1,3,4-oxadiazinone **223**, *via* elimination of one molecule of ethanol follwed by HCN [38].



**3.15. Synthesis of oxadiazepine derivatives.** A mixture of dimethyl but-2-ynedicarboxylate **219** and substituted carbohydrazides **1** was heated to reflux in methanol to afford 1,3,4-oxadiazepine derivatives **224**. Nucleophilic attack of the $NH_2$ group of **1** to the triple bond of **219** afforded the adduct **220**, followed by elimination of one molecule of methanol and intramolecular cyclization to give **224** [63].



The reaction of 2,3,5,6-tetrachloro-1,4-benzoquinone **213** and **1** in DMF, with admission of air, afforded substituted benzo[1,3,4]oxadiazepine **227** [66].



On the other hand, the reaction of 2,3-dichloro-1,4-naphthoquinone **228** with **1** in DMF afforded substituted naphtho[2,3-*f*]-1,3,4-oxadiazepine-5,6,11-(4*H*)-trione **230** [66].

This review summarizes published data on the behavior and reactions of dithiobiurea and thioureidoalkylthiourea derivatives, which lead to the formation of heterocyclic systems, including methods of preparation in addition to synthesis of imidazolidine, thiazole, thioazolidine, triazolidine, thiadiazine, and spiro compounds.

*J. Heterocyclic Chem.*, **47**, 764 (2010).

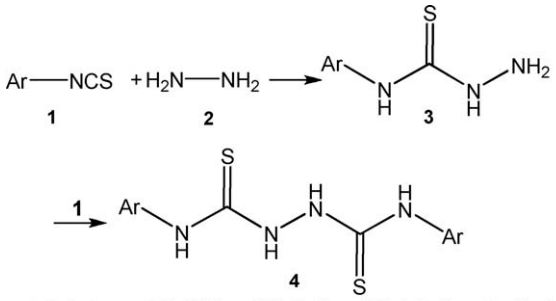
**Contents** **Page**

## 1. INTRODUCTION

In recent years, there has been increasing interest in the synthesis of heterocyclic compounds by cyclization of appropriate linear compounds [1–15]. Organosulfur compounds play an important role in modern organic synthesis, not only because they constitute a particularly useful class of synthons [16] but also because they are of great biological interest [17–23] such as fungicidal [24], bactericidal [25–27], insecticidal [28], and antitumor agents for thioureidoalkanethiourea [29–32]. Symmetrical and unsymmetrical 2,5-dithiobiureas have been utilized widely in the synthesis of heterocylic compounds and are considered as very good complexing agents for a variety of materials in the synthesis of complexes [33–39]. Substituted-2,5-dithiobiureas and their derivatives are versatile compounds, which have been extensively used in the preparation of heterocyclic ring systems. Also, oxidation of *S*-alkylisodithiobiureas resulted in the formation of thiadiazole derivatives [40], but oxidation of 1,5-diaryl-2-*S*-alkylisodithiobiuretes led to the formation of benzothiazolylisothiouereas [41]. Alkylation of 1-substituted-2,5-dithiobiureas by refluxing with appropriate alkyl halide in ethanol led to the formation of thiadiazole derivatives [42].

On the other hand, symmetrical 2,5-dithiobiureas underwent cyclization in the presence of alkali to form the corresponding 1,2,4-triazolidine-3,5-thione [43,44], and, therefore, the substituted dithiobiureas and their

**Scheme 1**



derivatives act as a key for the synthesis of many organic heterocyclic ring systems.

## 2. SYNTHESIS OF DITHIOBIUREAS AND THEIR DERIVATIVES

The reaction of aryl isothiocyanates **1** with hydrazine (**2**) in great excess and at low temperature in ethanol readily gave 4-arylthiosemicarbazides **3**, which reacted further with another molecule of **1** to give *N*,*N*′-di(arylthioformyl)hydrazines **4** (Scheme 1) [45].

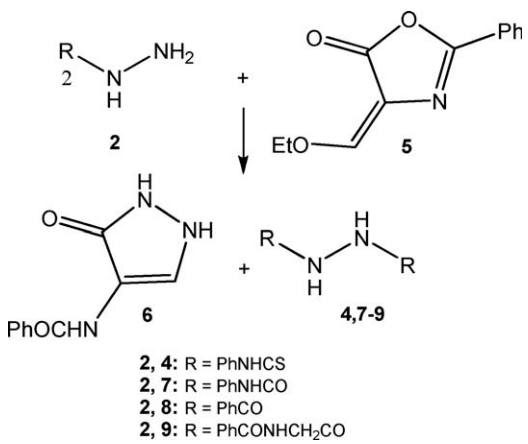
When oxazolone **5** was heated with two equivalents of appropriate hydrazine derivatives **2** in dioxane for 0.5–2 h, the products **6**, **4**, and **7–9** were separated (Scheme 2) [46].

Ammoniumthiocyanate **10** was added to a solution of dilute $H_2SO_4$, and thiosemicarbazide **3** to afford 2,5-dithiobiurea **4** in 52% yield (Scheme 3) [47].

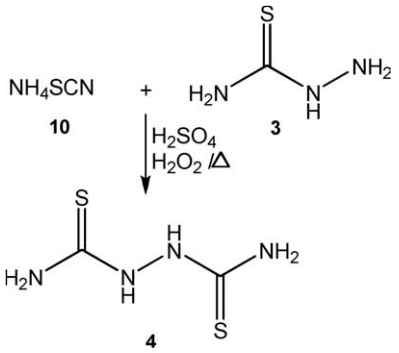
Egri [48,49] reported the synthesis of substituted dithiobiureas by treating $RNH_2$ and $R'NH_2$ with $CSCl_2$ and then with hydrazine hydrate (Figure 1).

Heating naphtho[1,2-*d*]oxazole-2(1*H*)-thione **12** (which was prepared by heating a mixture of 1-imino-2-hyroxynaphthalene hydrochloride **11** and phenyl isothiocyanate **1** in boiling ethanol) with hydrazine hydrate **2** in

**Scheme 2**



**Scheme 3**



ethanol did not give the expected product, 2-hydrazinonaphth[1,2-*d*]oxazole **13**, but the obtained product contained sulfur. This indicates that the reaction of **12** with hydrazine hydrate as nucleophile led to cleavage of the oxazolinethione ring and formation of 3-amino-1,3-dihydro-2*H*-naphth[1,2-*d*]imidazole-2-thione **14** or 4-(2-hydroxy-naphthaien-1-yl)thiosemicarbazide **15**. The spectral data are in agreement with the structure of thiosemicarbazide **15**, which reacted with the appropriate aryl isothiocyanate at room temperature to afford the derivatives of **4** (Scheme 4) [50].

1,2-Bis(thiocarbamoyl)hydrazine **4** was prepared by treating 4-substituted thiosemicarbazide **3** with allyl isothiocyanate **1** (Scheme 5) [51].

1,1-Bis(β-hydroxyethyl)thiocarbohydrazide **16** was heated with isothiocyantes **1** in ethanol to give dithiobiurea derivatives **4** (Scheme 6) [52].

When benzhydryl isothiocyanate was allowed to react with excess of hydrazine, a good yield of 4-benzhydrylthiosemicarbazide was obtained. Equivalent amounts of these reactants, however, gave a dithiobiurea **4** as the major product (Figure 2) [53].

Unsaturated 1,6-disbstituted-2,5-dithiobiureas **4** was obtained from the reaction of substituted isothiocyanates **1** with 4-substituted thiosemicarbazides **3** (Scheme 7) [54].

The reaction of thiocarbohydrazide **17** with 2*M* equivalents of benzaldehyde results in the formation of the monobenzylidene derivatives **18**, which further reacted with isobutyl isothiocyanate and triethylamine in

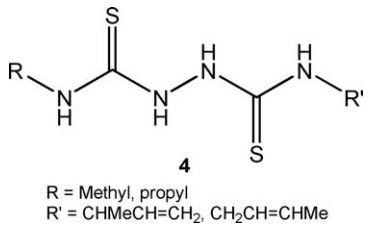


**Figure 1.** Substituted dithiobiureas from primary amines.

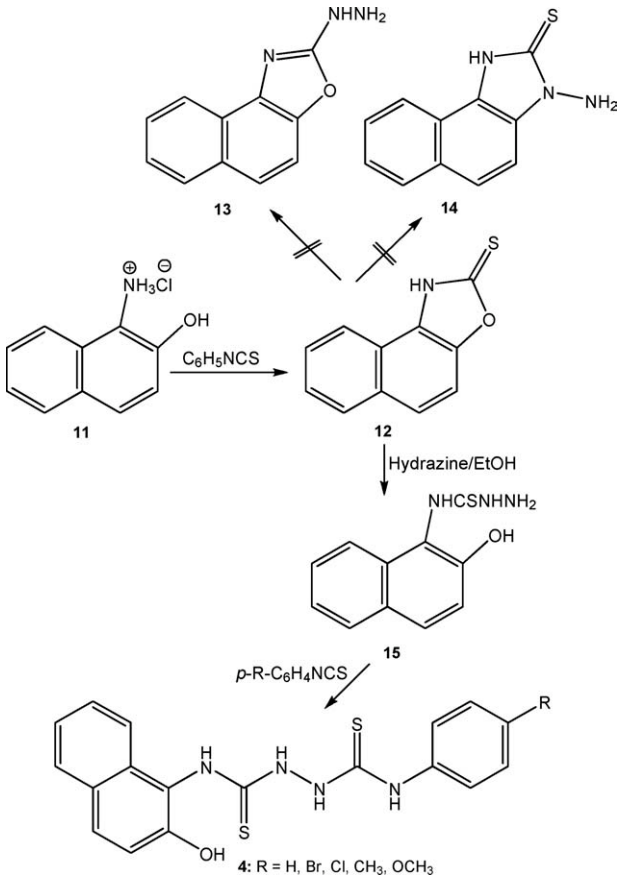
**Scheme 4**

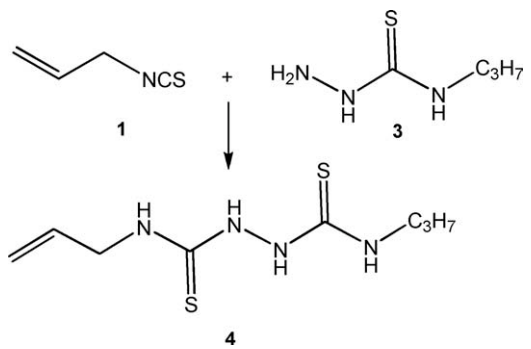


dimethylformamide (DMF) to gave 1-benzylidene-5-(*N*-isobutylthiocarbamoyl)-thiocarbohydrazide **4** (Scheme 8) [55].

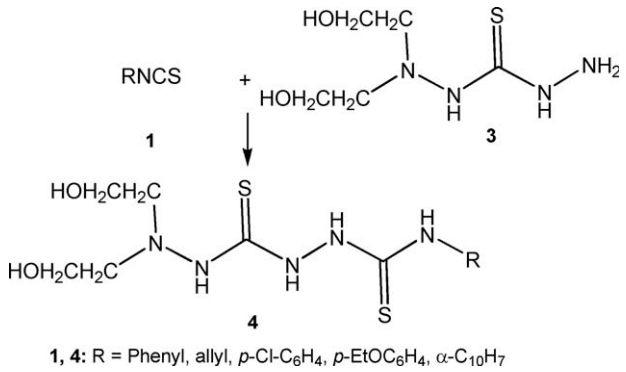
Refluxing phenyl thiosemocarbazide with appropriate isothiocyanates in absolute ethanol gave dithiobiurea derivatives **4** (Figure 3) [56].

The reductive debenzylation of 5-*S*-benzyliso-1-aryl-2-thiohydrazodicarbonamides **19** afforded **4** (Scheme 9) [57,58].

**Scheme 5**



**Scheme 6**



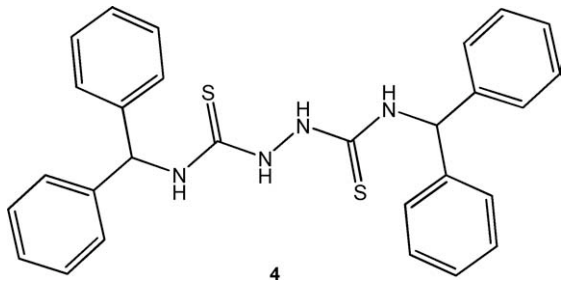


**Figure 2.** Dithiobiurea from benzhydryl isothiocyanate.

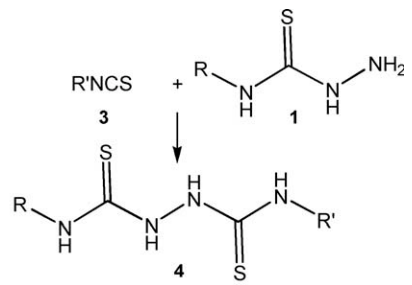
The reduction of 6-substituted amino-3-amino-1,2,4,5-dithiadiazines **20** under similar conditions of the above reaction gave **4** in good yields (Scheme 10) [57,58].

Thioureidoalkanethiourea derivatives **21** ($n$ = 2–4, 6, 7) were prepared from the reaction of diamines with isothiocyanates (Figure 4) [59].

When α-mannosyl isothiocyanate **1** was reacted with diamines **22** ($n$ = 2, 6), **21** was formed after deacetylation with sodium methanolate in methanol [24] (Scheme 11).

**Scheme 7**



**Scheme 8**

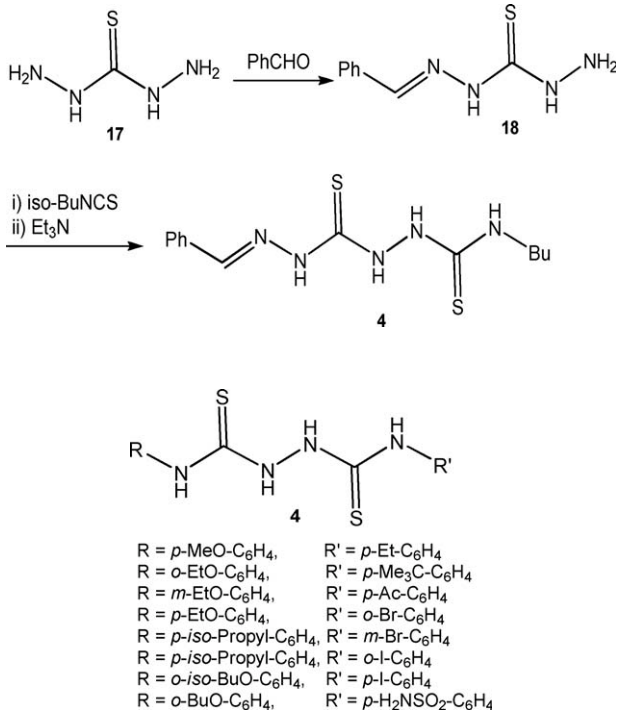


**Figure 3.** Dithiobiurea derivatives from phenyl thiosemicarbazide.

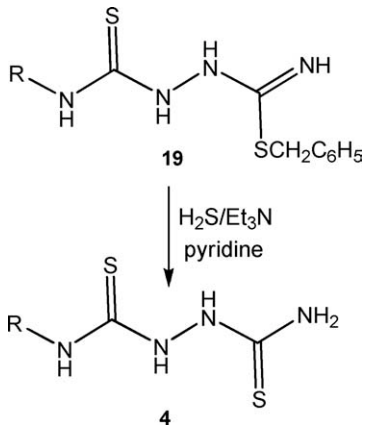
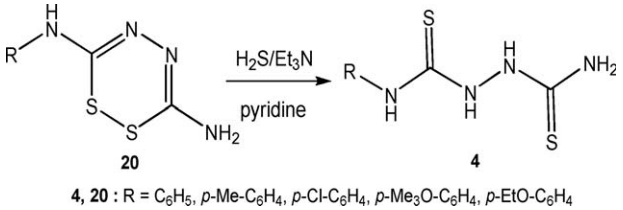
**Scheme 9**



**Scheme 10**



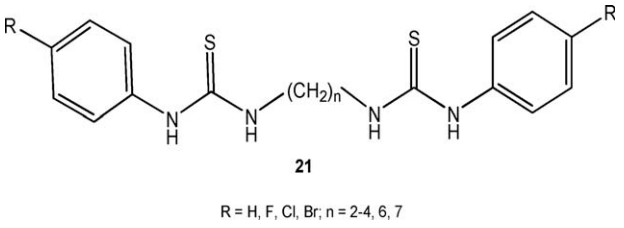


**Figure 4.** Thioureidoalkanethiourea derivatives from diamines.

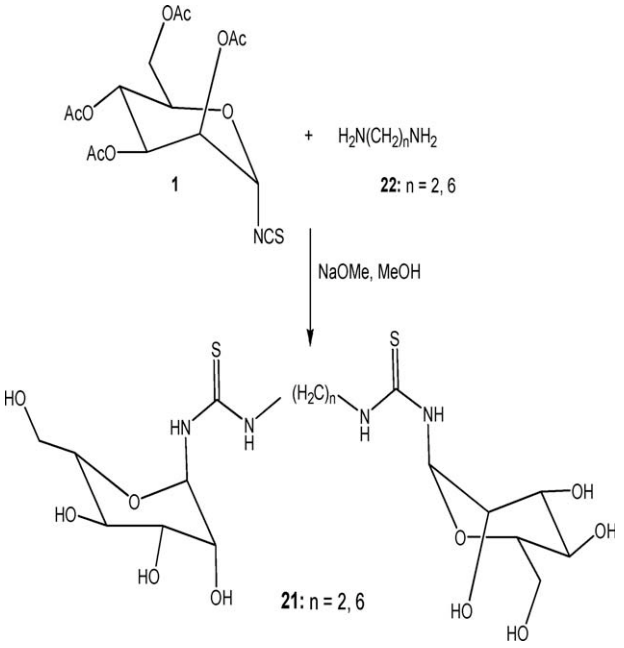
**Scheme 11**



Page and Roy [26] reported that, when *p*-amino-phenyl 2,3,4,6-tetra-*o*-acetyl-α-D-mannopyranoside **23** was dissolved in dichloromethane containing diisopropylethylamine (DIPEA) and thiophosgene, compound **1** was formed, which when added to a solution of diamine in dichloromethane containing a catalytic amount of DIPEA, derivatives of compounds **21** were formed (Scheme 12).

1,6-Bis(allylthioureido)alkanes **21** were prepared by treating of diamine (1,2-diaminoethane, 1,3-di-amino-propane, 1,4-diaminobutane, 1,5-diaminopentane, and 1,6-diaminohexane) with allyl isothio-cyanate (Figure 5) [60].

Disubstituted thioureidothioureas **21** were obtained from ethylenediamine **22** and isothiocyanates **1** (Scheme 13) [61].

Compound **21** was obtained by refluxing ethylenediamine **22** with EtOH, NaOH, and phenyl isothiocyanate, while when HCl was added to the solution, NaCl was precipitated together with imidazoline derivatives **24** (Scheme 14) [62].

**Scheme 12**

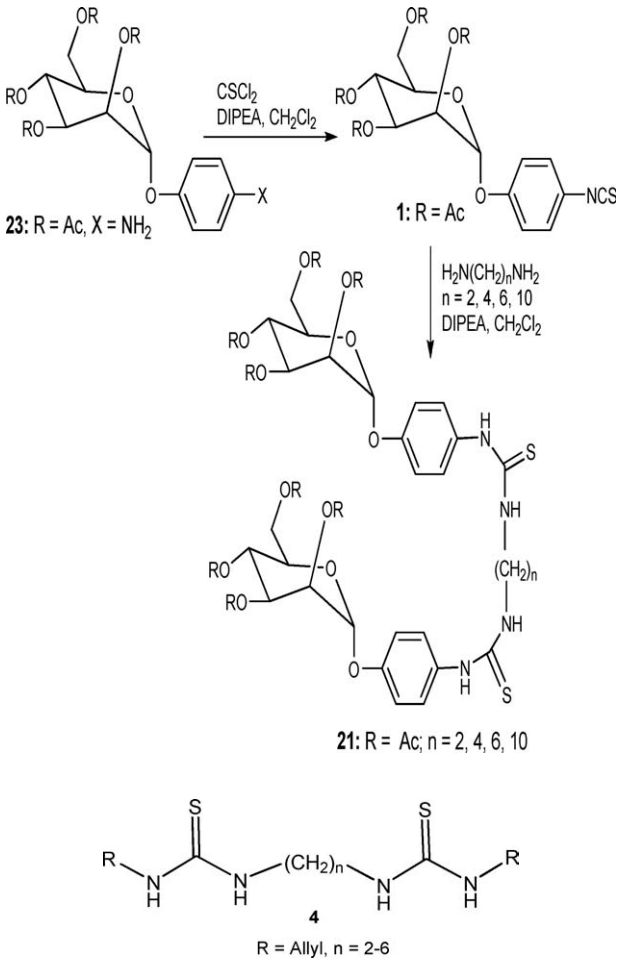


**Figure 5.** 1,6-Bis(allylthioureido)alkanes from different diamines.

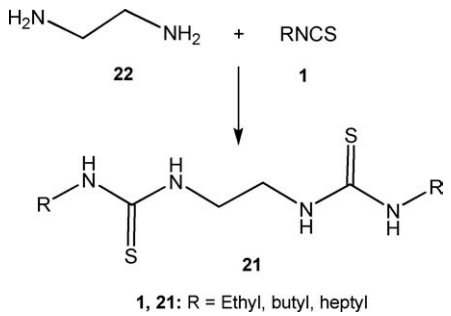
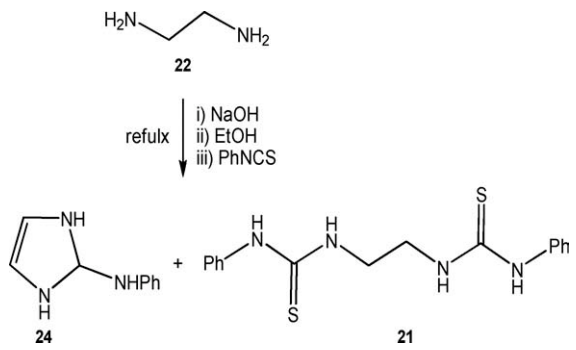
Ethylenediaryldithiocarboamides **21** were prepared by the action of 2 mol of isothiocyanates **1** with ethylenediamine **22** and boiling with concentrated HCl or KOH (Scheme 15) [63].

Ethylene diisothiocyanate **25** gave **21** and imidazolidine derivatives **26** when reacted with a nucleophilie (aniline or marpholine) (Scheme 16) [64].

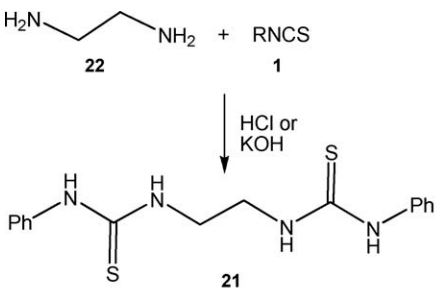
**Scheme 13**



**Scheme 14**



**Scheme 15**

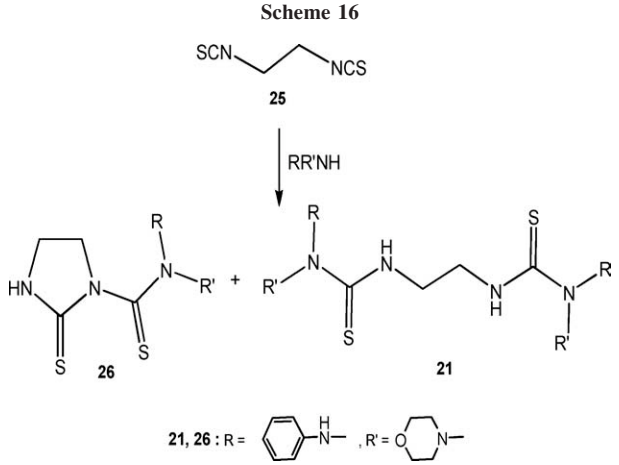


Also, trimethylene diisothiocyanate **27** and tetramethylene diisothiocyanate **28** gave linear mono-addition derivatives **29** and bis-adducts **21** when reacted with aniline or morpholine (Scheme 17) [64].

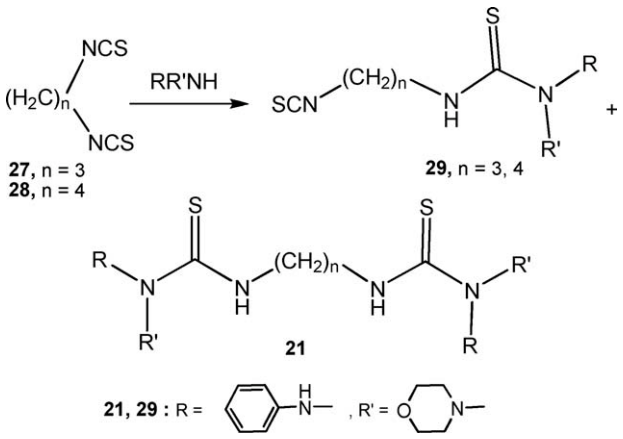
## 3. REACTIONS OF DITHIOBIUREAS AND THIOUREIDOALKYLTHIOUREAS

**3.1. Synthesis of imidazolidine derivatives.** The reaction of thioureidoethyl- and propylthioureas **21** with mercury bis(phenyl acetylide) **30** afforded corresponding

**Scheme 16**



**Scheme 17**



cyclic symmetrical mercaptides **31** and **32**. The thermal decomposition of **31** led to the formation of imidazolidines **35** (Scheme 18) [65].

4-Chloro-*N*′-(4,5-dihydro-1*H*-imidazo-2-yl)-benzene-1,2-diamine **36** was prepared by addition of ethylenediamine **22** to the corresponding 4-chloro-2-nitrophenylisothiocyanate **1** (Figure 6) [66].

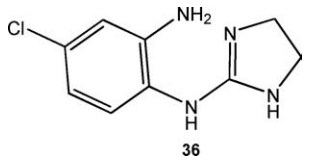


**Figure 6.** Substituted imidazoylbenzendiamine from ethylenediamine.

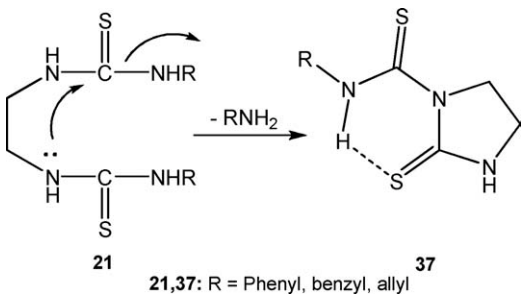
**Scheme 19**



Hassan *et al*. [67] reported that imidazolidine **37** can be formed on heating or microwave irradiation of thioureidoethylthiourea derivatives **21** (Scheme 19).

**3.2. Synthesis of thiazole, thiazolidine, and thiazolium derivatives.** 2,5-Dithiobiurea **4** reacted with methylphenylchloropyruvate exclusively as thiourea (Hantzsch reaction) forming dimethyl 2,2′-(hydrazine-1,2-diyl)-bis(5-phenylthiazol-4-carboxylate) **38** (Figure 7) [68].

It has been reported that bis(*N*-phenyl)thiourea **4** was cyclized to thiazolidine-4-one **39** when reacted with monochloroacetic acid in the presence of EtOH/AcONa (Scheme 20) [69].

Symmetrical azines of 3-allylthiazolidine-4-one **39** can be obtained by treating allyldithiourea **4** with acid derivatives **40** under reflux in alcohol in the presence of AcOK (Scheme 21) [70].

Trisubstituted thiazoles **42** can be obtained by heating a mixture of **4** and **41** (Scheme 22) [71].

Reaction of ethylenediamine **22** with allyl isothiocyanate **1** followed by treating by aq. HCl gave bisthiazoline **43** (Figure 8) [72].

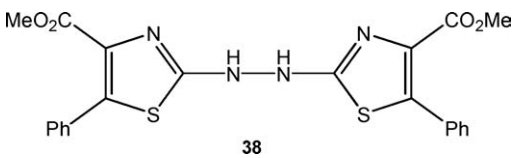


**Figure 7.** (Hydrazine-1,2-diyl)-bis(5-phenylthiazol-4-carboxylate) from dithiobiurea.

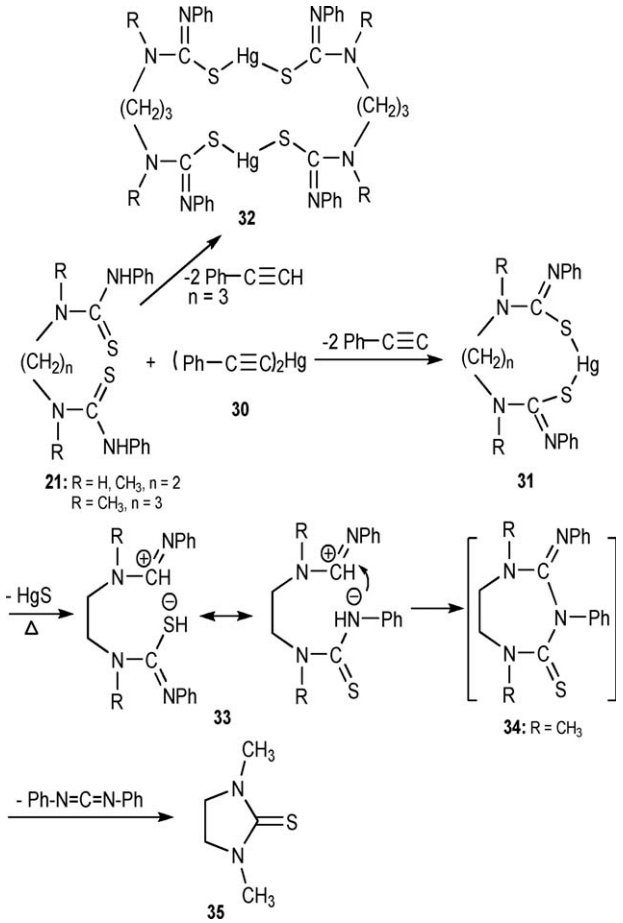
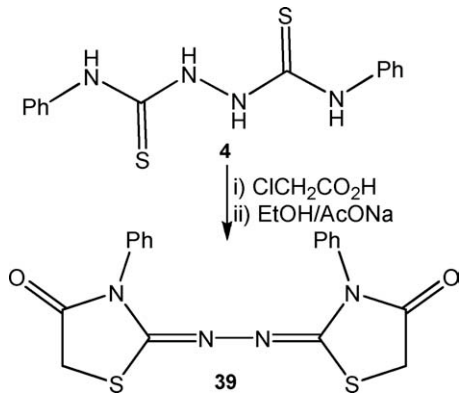
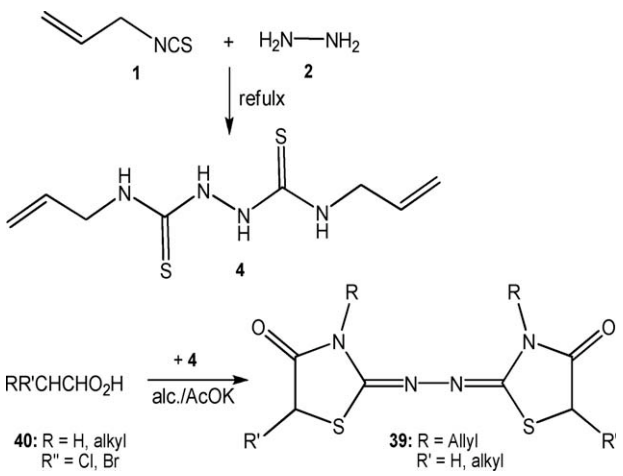
**Scheme 18**



**Scheme 20**



**Scheme 21**



Symmetrical bisthiazolidine **44** was obtained by heating *N*,*N*′-ethane-1,2-diylbis(thiourea) **21** with α-chloroacetic acid in butanol (Scheme 23) [73].

**3.3. Synthesis of thiadiazole derivatives.** 2-Amino-5-mercapto-1,3,4-thiadiazole **45** was obtained *via* cyclization of 2,5-dithiobiurea **4** in refluxing HCl (Scheme 24) [74].

Also, oxidation of 1-substituted-4-*S*-alkyl(aryl)-2,4-isodithiobiuretes **46** afforded 3-alkylmercapto-5-arylamino-1,2,4-thiadiazoles **47** (Scheme 25) [40].

On heating 1-substituted-5-*S*-alkyl(aryl)isodi-thiobiureas **48** in ethanol or water in the presence of hydrochloric acid, 5-alkylmercapto-2-substituted amino-1,3,4-thiadiazoles **49** were obtained (Scheme 26) [42].

On the other hand, alkylation of 1-substituted-2,5-dithiobiureas **4** with alkyl halide in ethanol gave substituted-1,3,4-thiadiazoles **49** (Scheme 27) [42].

**Scheme 22**

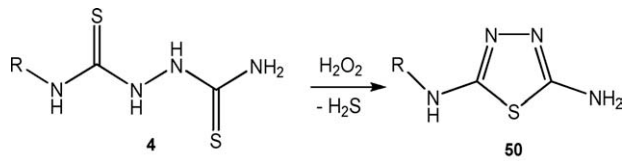
**Scheme 28**

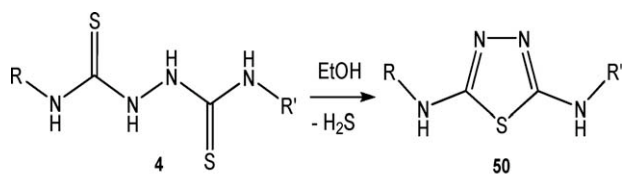


**4, 50:** R = $C_6H_5$, $CH_3$, $C_2H_5$, *p*-Me-$C_6H_4$

Oxidation of substituted-2,5-biueras **4** with either hydrogen peroxide or iodine in warm ethanolic medium afforded 2-amino-5-substituted amino-1,3,4-thiadiazoles **50** (Scheme 28) [42].

Thiadiazole derivatives **50** can be obtained by cyclization of compounds **4** in an alkaline medium with evolution of hydrogen sulfide (Scheme 29) [75].

**Scheme 29**



**4, 50:** R = R' = $C_6H_5$, *p*-Me-$C_6H_4$, *p*-Cl-$C_6H_4$, *p*-EtO-$C_6H_4$, *p*-MeO-$C_6H_4$

R = R' = *n*-$C_4H_9$, *n*-$C_3H_7$, $C_6H_5$
R = *p*-$CH_3$-$C_6H_4$, R' = $CH_3$
R = *p*-Cl-$C_6H_4$, R' = *n*-$C_3H_7$

**53**

R = *n*-$C_4H_9$, *n*-$C_3H_7$, $C_6H_5$, *p*-$CH_3$-$C_6H_4$, *p*-Cl-$C_6H_4$

2,4-Disubstituted thiosemicarbazide **51** was allowed to react with phenyl isothiocyanate **1** to give dithiobiurea **4** as an intermediate, followed by cyclization with elimination of hydrogen sulfide to give 5-anilino-3-methyl-2-phenylimino-2,3-dihydro-1,3,4-thiadiazole **52** (Scheme 30) [76].

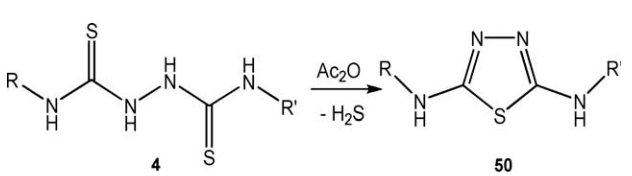
Alkali-catalyzed thermal cyclization of 1-alkyl and 1,6-dialkyl-2,5-dithiobiureas **4** gave 2-alkyl amino-$\Delta^2$-1,3,4-thiadiazoline-5-thiones **53** (Scheme 31) [77].

On the other hand, oxidative cyclization of 1,6-disubstituted-2,5-dithiobiueras **4** was occurred in the presence of $Ac_2O$ to produce the corresponding thiadiazoles **50** (Scheme 32) [78,79].

When 2,5-dithiobiurea **4** treated with $Me_2SO_4$ and hypophosphorous acid in $H_2O$; the reaction underwent formation of 2-amino-5-(methylthio)-1,3,4-thiadiazole **49** (Scheme 33) [80].

Wegner [81] has reported the synthesis of substituted thiadiazoles **54** by the reaction of substituted amine with

**Scheme 32**



**4, 50:** R = $C_2H_5$, R' = $CH_2$=CH-$CH_2$, *p*-F-$C_6H_4$, $C_6H_5$, $CH_2$=C($CH_3$)-$CH_2$

**Scheme 33**

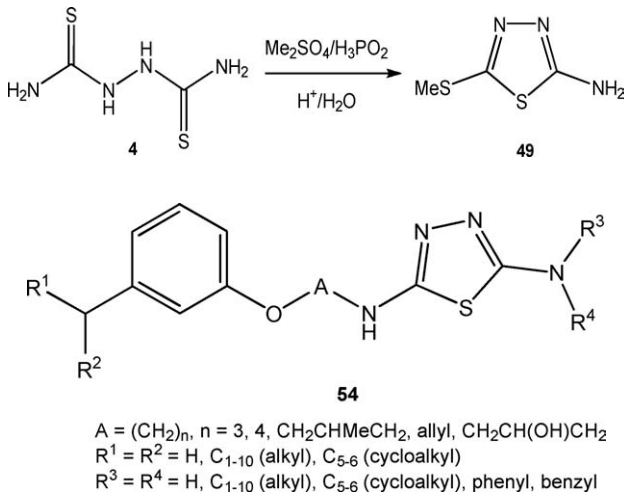


**Figure 9.** Substituted thiazoles from hydrazinecarbothioamide.

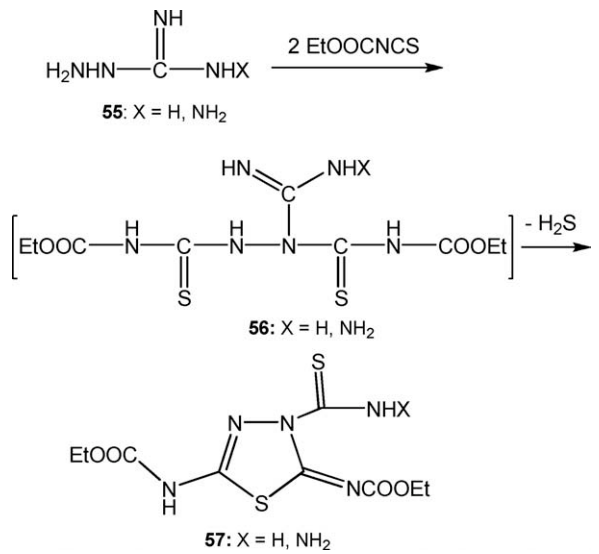
$ClCS_2Ph$, and the resulting product was allowed to react with hydrazine hydrate to form substituted hydrazinecarbothioamide **4**, which further reacted with phenyl isothiocyanate dichloride (Figure 9).

The interaction of guanidine derivatives **55** and ethoxycarbonyl isothiocyanate under mild conditions afforded the thiadiazole derivatives **57** (Scheme 34) [82].

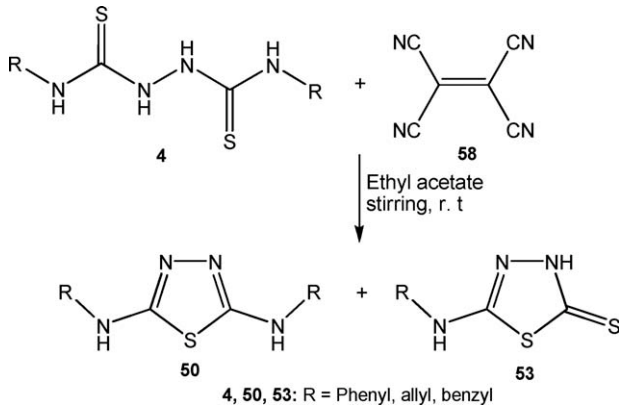
Addition of two equivalents of ethenetetracarbonitrile **58** to a solution of 1,6-disubstituted-2,5-dithiobiureas **4** in ethyl acetate at room temperature led to the formation of thiadiazole derivatives **50** and **53** as side products (Scheme 35) [83].

A phase transfer catalytic oxidation of hydrazinedicarbothioamide leads to a red colored solid **59**, the reduction of **59** with hydrazine or other reductants trans-

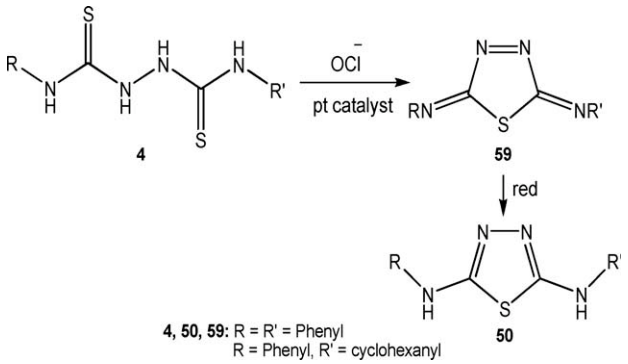
**Scheme 34**



**Scheme 35**



**Scheme 36**



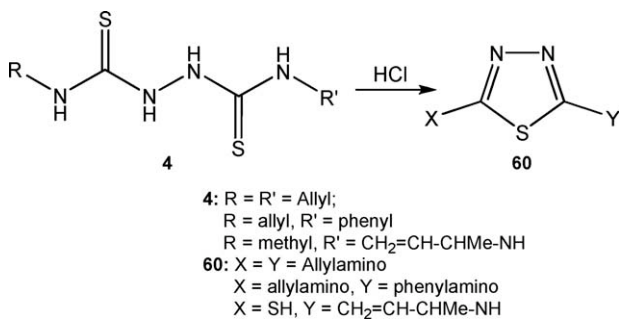
formed it into colorless compound, 2,5-diphenylamino-1,3,4-thiadiazole **50** (Scheme 36) [84].

Cyclization of symmetrical and unsymmetrical 1,6-bis(substituted)-2,5-dithiobiureas **4** in acid media gave 1,3,4-thiadiazoles **60** (Scheme 37) [85].

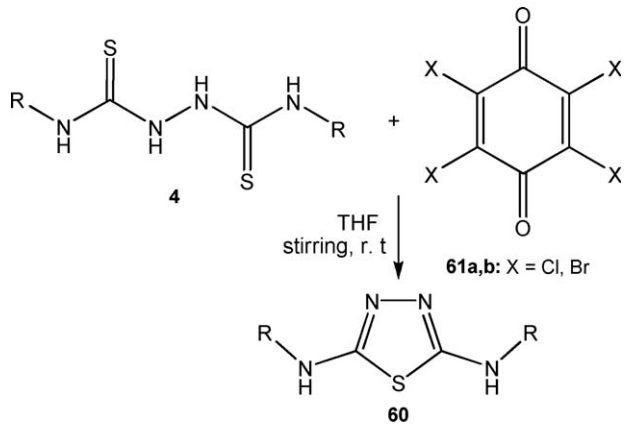
On adding tetrahydrofuran (THF) solution of 1,6-disubstituted-2,5-dithiobiureas **4** to a solution of chloranil or bromanil **61a,b** in the same solvent lead to the formation of thiadiazole derivatives **50** as a side product (Scheme 38) [86].

On the other hand, the addition of THF solution of 1-substituted-2,5-dithiobiureas **4** to a solutions of

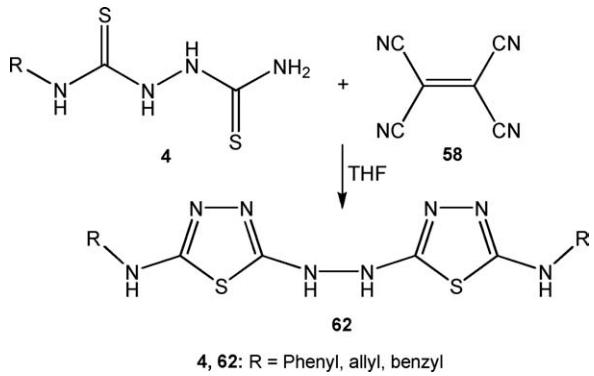
**Scheme 37**



**Scheme 38**



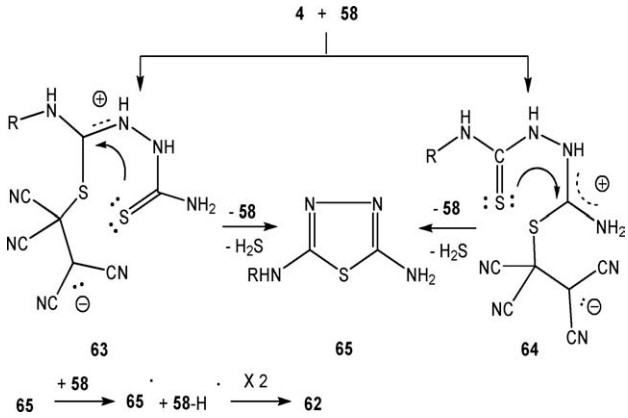
**Scheme 39**



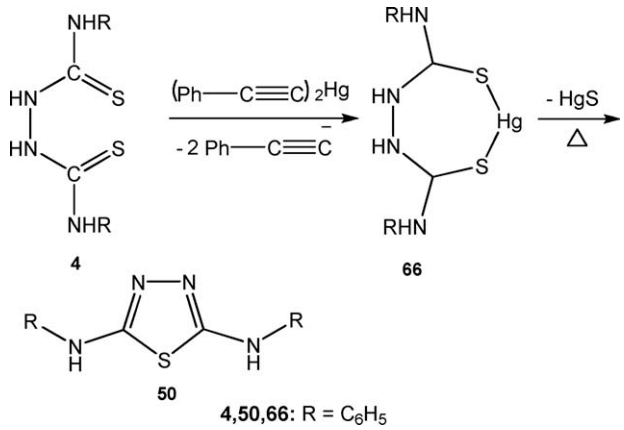
ethenetetracarbonitrile **58** in the same solvent lead to the formation of 1,2-bis[5-(substituted amino)-1,3,4-thiadiazole-2-yl)hydrazines **62** (Scheme 39) [87].

Scheme 40 showed the mechanism of formation of thiadiazole and bisthiadiazole derivatives from **4** by using ethnetetracarbonitrile **58**, which reacted as a mediator.

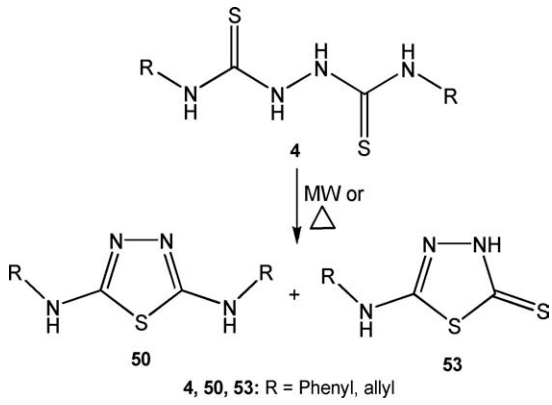
**Scheme 40**



**Scheme 41**



**Scheme 42**



Diphenylhydrazine-1,2-dicarbothioamide **4** reacted with mercury bis(phenyl acetylide) **30** to give the intermediate **66**, which under thermal decomposition afforded the thiadiazole derivatives **50** (Scheme 41) [88].

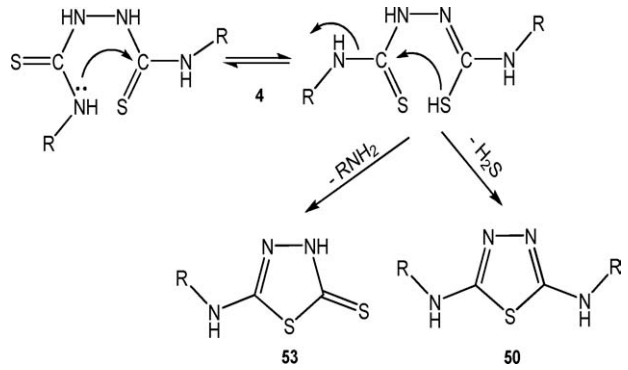
Microwave (MW) and thermal heterocyclization of *N*,*N*′-disubstituted hydrazinecarbothioamide **4** results in formation of 2,5-disubstituted amino[1,3,4]thiadi-azoles **50** and 5-substituted amino[1,3,4]thiadi-azole-2-thiones **53** (Scheme 42) [67].

A mechanism for the formation of thermal or MW irradiation for 1,6-disubstituted hydrazinecarbothio-amide **4** as shown in Scheme 43 [67].

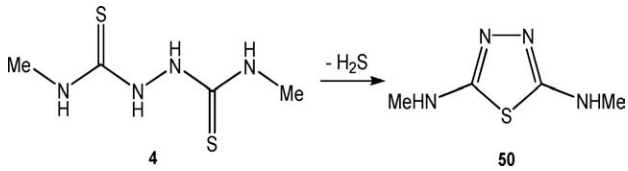
Thiadiazole derivatives **50** was prepared by cyclization of 1,6-dimethyl-2,5-dithiobiurea **4**, which was obtained by the reaction of methyl isothiocyanate with methylthiosemicarbazide (Scheme 44) [89].

1,6-Di(2-pyridyl)hydrazodithiocarbonamide **4** can be obtained from 2-pyridyl isothiocyanate and 2-pyridylthiosemicarbazide, which thermally cyclized to 2,5-di(2-pyridylamino)-1,3,4-thiadiazole **50** (Scheme 45) [90].

**Scheme 43**



**Scheme 44**



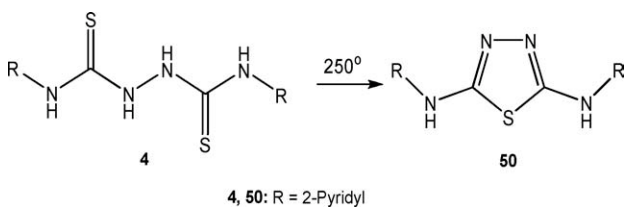
In case of the reaction of **4** with methyl iodide in the absence of the base, 5-acylamino-2-anilinidene-3-methyl-1,3,4-thiadiazoline **68** and 2-acylamino-5-methyl-thio-1,3,4-thidiazole **70** were formed (Scheme 46).

This reaction is presumed to be initiated by *S*- and *N*-methylation to form the intermediate **69**, followed by cyclization through the attack of SH group on C=N with elimination of dimethylaniline to afford **70**. On the other hand, **4** ($R^2 = CH_3$) was merely methylated on the sulfur atom, followed by elimination of $CH_3SH$ to give **68** [91].

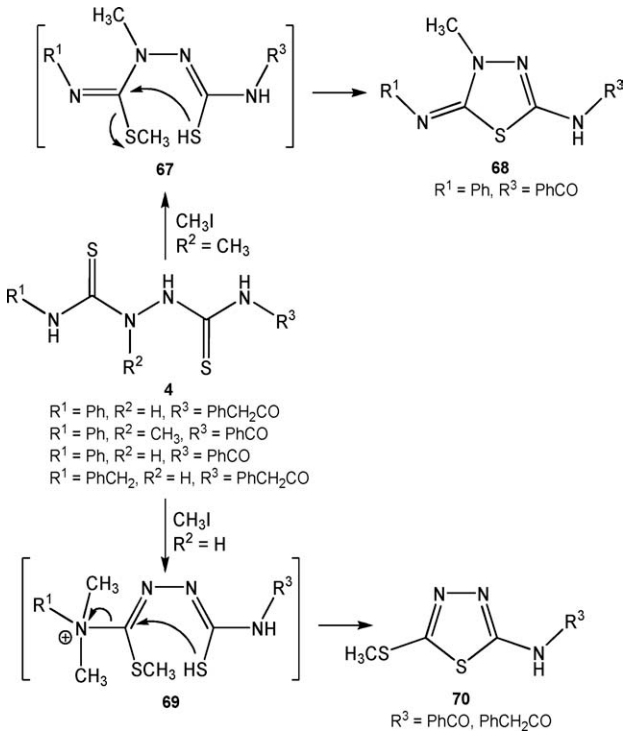
The reaction of trifluoroacetic acid with dithiobiurea **4** (R = $CH_3$) afforded 1,3,4-thiadi-azolineimine **71** and 1,3,4-thiadiazoline-2-thione **72** with loss of hydrogen sulfide and methylamine, respectively. On the other hand, dithiobiurea **4** (R = Ph) underwent ring closure with elimination of hydrogen sulfide and gave 1,3,4-thiadiazolineimine **71** as the only product. The different cyclization behavior of **4** (R = $CH_3$ and R = Ph) under acidic conditions appears to be caused in the different basicity of the R—NH moiety (Scheme 47) [92].

The reaction of ''nonalkylated'' carbothiohydrazide derivatives **73** with substituted isothiocyanates **1** at room

**Scheme 45**

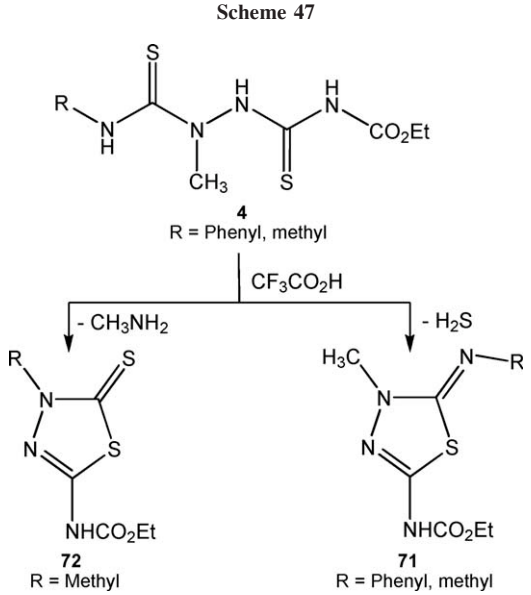


**Scheme 46**

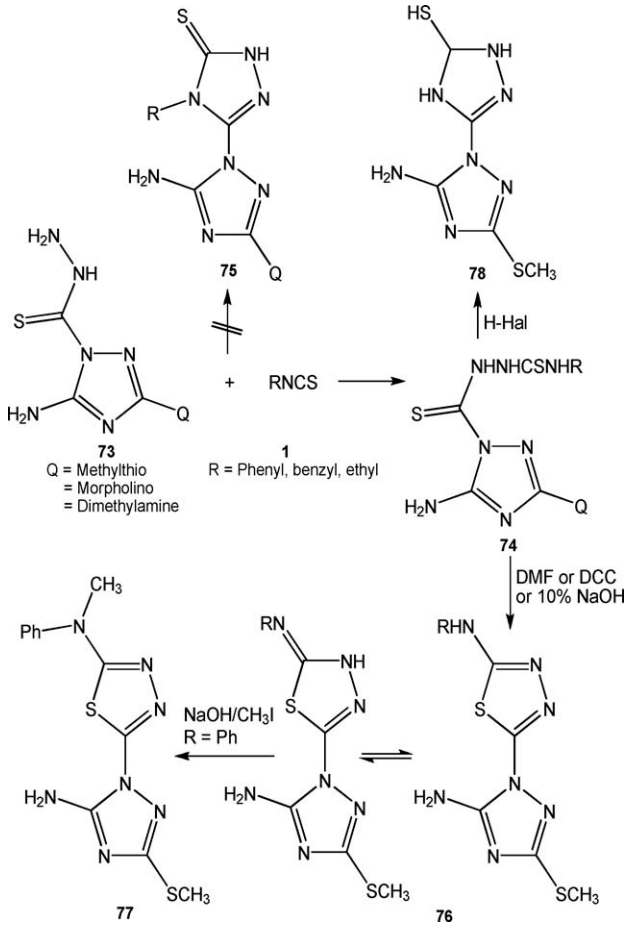


temperature in methanol or (Scheme 48) DMF as a solvent led to the thermally unstable thiocarbamoyl derivatives **74** and not **75** [93]. These were cyclized either in boiling DMF, or by reaction with dicyclohexyl carbodiimide (DCC), or by heating in 10 % sodium hydroxide to **76** and **78**. Compound **76** was changed to **77** after *N*-methylation. The alkylation of the ''nonalkylated'' derivatives **74** with methyl iodide and benzyl bromide in

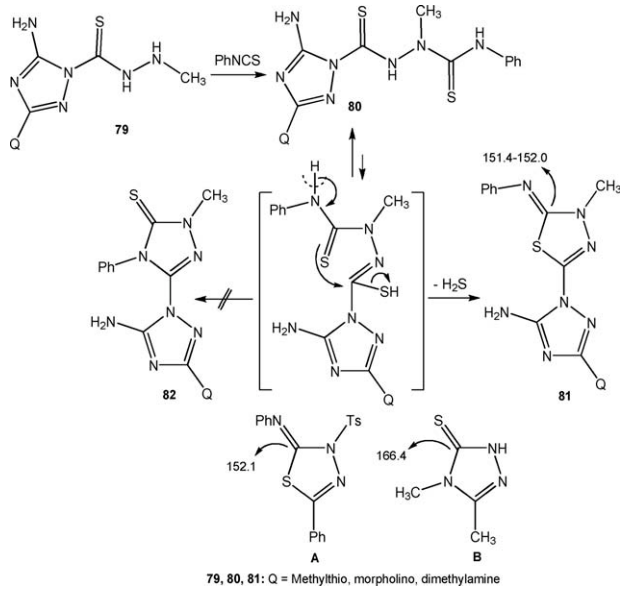
**Scheme 47**



**Scheme 48**



**Scheme 49**



either methanol or DMF afforded the corresponding **78** [94].

The reaction of **79** with phenyl isothiocyanate **1** afforded the expected phenylthiocarbomoyl derivatives **80** (Scheme 49).

The thermally unstable derivatives **80** could by easily cyclized probably through their tautomeric form to the thiadiazoles **81** by their short heating in DMF. It should be mentioned that the loss of $H_2S$ from derivatives **79** may, in principal, also lead to the formation of derivatives **82**, thus, the structure of derivatives **81** formed had to be confirmed [94]. The decision between structure **81**, **82** made possible the comparison of the chemical shifts of the thiadiazole carbon atoms 5 of derivatives **81** (δ C5 = 151.4–152.0 ppm) with those of corresponding carbon atoms of model compounds **A**, **B** (δ C5 = 152.1 and 166.4 ppm, respectively) to prove structure **81** unequivocally.

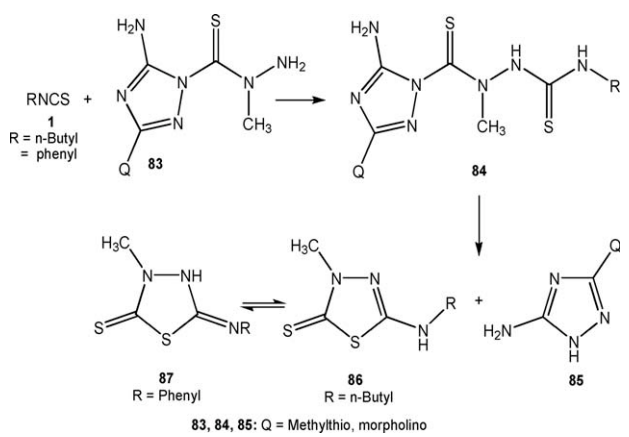
From the reaction of **83** and butyl- or phenyl-isothiocyanate instead of the corresponding thiocarbomoyl derivatives **84**, 2,3-dihydro-3-methyl-5-(*n*-butylamino)-1,3,4-thiadiazole-2-thione **86** or 2,3,4,5-tetrahydro-3-methyl-5-phenylimino-1,3,4-thiadiazole-2-thione **87**, respectively, were isolated besides 5-amino-3-(methylthio and merpholine)-1*H*-1,2,4-triazoles **85** (Scheme 50) [94].

**3.4. Synthesis of triazole, triazoline, and triazolidine derivatives.** Symmetrically substituted-2,5-dithiobiureas **4** lost ammonia or amine in the presence of alkali, giving 1,2,4-triazolidine-3,5-dithione derivatives **88** (Scheme 51) [43].

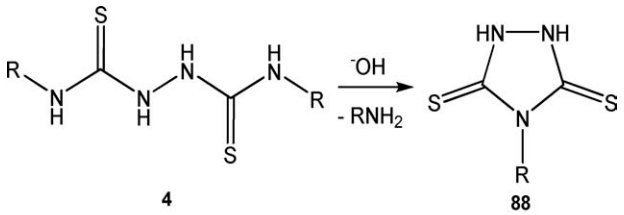
1,6-Dimethyl-2,5-dithiobiurea **4** cyclized under either strong or weak basic conditions to produce compound **88** as the major product and in minor amount of compound 4-methyl-5-methylamino-1,2,4-triazoline-3-thione **89** was also obtained (Scheme 52) [95].

When 1-alkyl-2,5-dithiobiureas **4** were refluxed with sodium methoxide in methanol, the reaction directly

**Scheme 50**

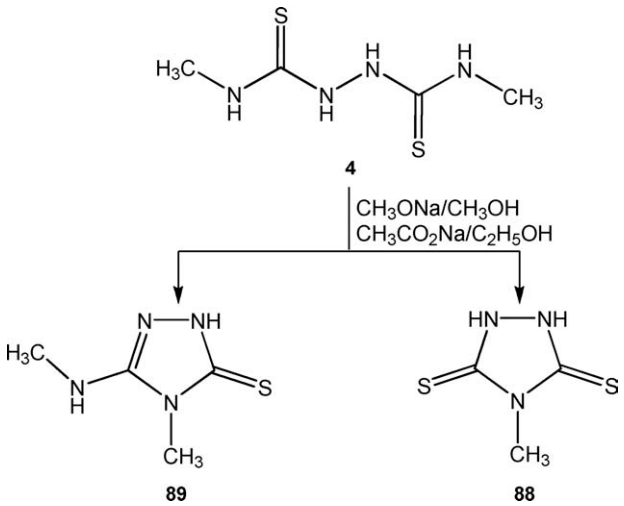


**Scheme 51**



**4, 88:** R = n-Butyl, benzyl, methyl

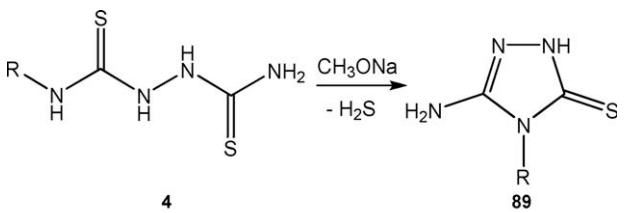
**Scheme 52**



produced 4-alkyl-5-amino-1,2,4-triazoline-3-thiones **89** (Scheme 53) [95].

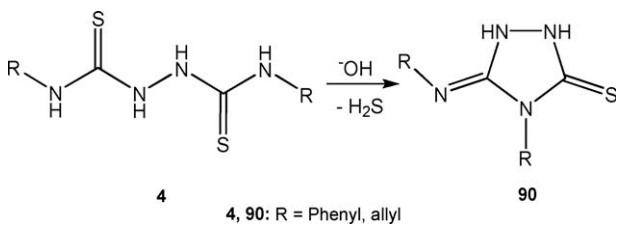
Similarly, cyclization of substituted-2,5-dithiobiueras **4** in alkaline medium took place with the elimination of $H_2S$ to give the 1,2,4-triazoles **90** (Scheme 54) [95].

**Scheme 53**



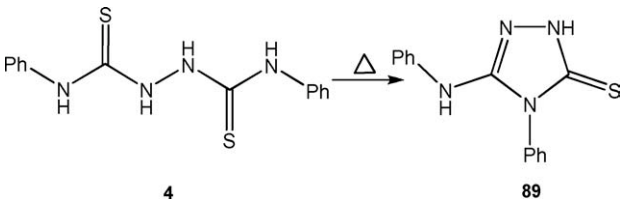
**4, 89:** R = *n*-Butyl, benzyl, methyl

**Scheme 54**

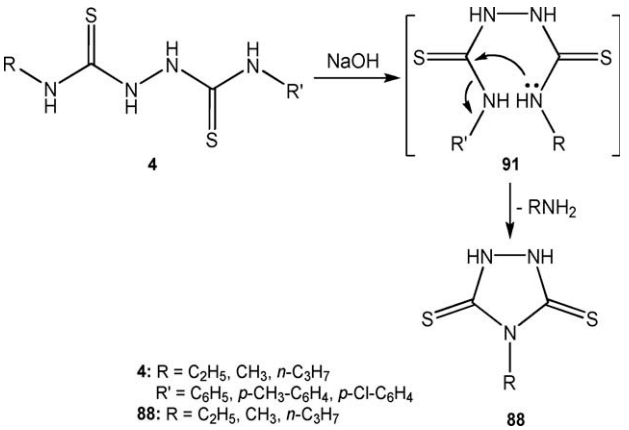


**4, 90:** R = Phenyl, allyl

**Scheme 55**



**Scheme 56**



**4:** R = $C_2H_5$, $CH_3$, *n*-$C_3H_7$
R' = $C_6H_5$, *p*-$CH_3$-$C_6H_4$, *p*-Cl-$C_6H_4$
**88:** R = $C_2H_5$, $CH_3$, *n*-$C_3H_7$

On the other hand, 1,6-diphenyl-2,5-dithiobiurea **4** was heated in the presence of alkali afforded 4-phenyl-3-phenyl amino-$\Delta^2$-1,2,4-triazoline-5-thione **89** (Scheme 55) [44].

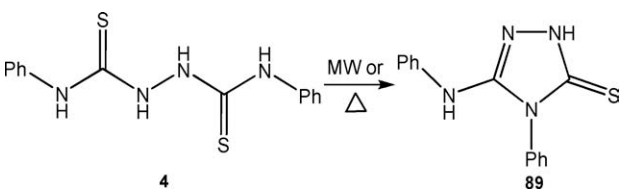
In a different manner, alkali-catalyzed thermal cyclization of 1-alkyl-6-aryl-2,5-dithiobiureas **4** led to the formation of 4-alkyl-1,2,4-triazolidine-3,5-dithiones **88** (Scheme 56) [96,97].

MW and thermal heterocyclization of *N,N′*-disubstituted hydrazinecarbothioamide **4** results in formation of 4-phenyl-5-phenylamino[1,2,4]triazole-3-thione **89** (Scheme 57) [67].

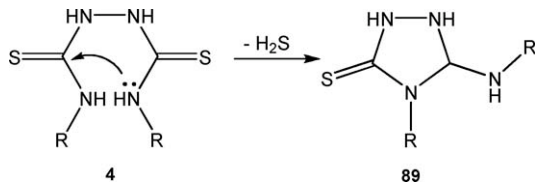
A mechanism for the formation of thermal or MW irradiation for 1,6-disubstituted hydrazinecarbothio-amide **4** to produce 4-phenyl-5-phenylamino[1,2,4]-triazole-3-thione **89** [67] as shown in Scheme 58.

The action of alkali or hydrazine on **4** produced moderate yields 3-amino-5-mercapto-1,2,3-triazole **92** or 4-

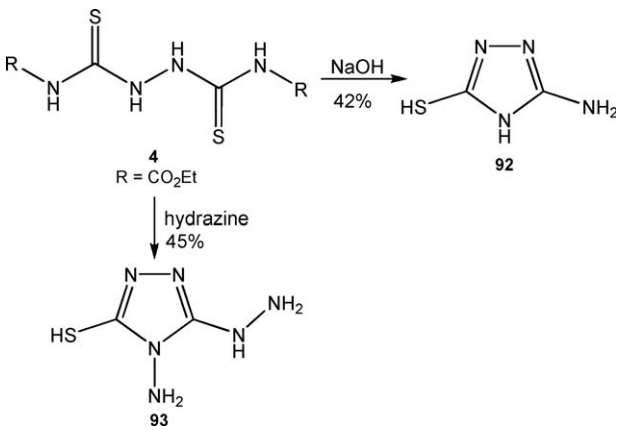
**Scheme 57**



**Scheme 58**



**Scheme 59**



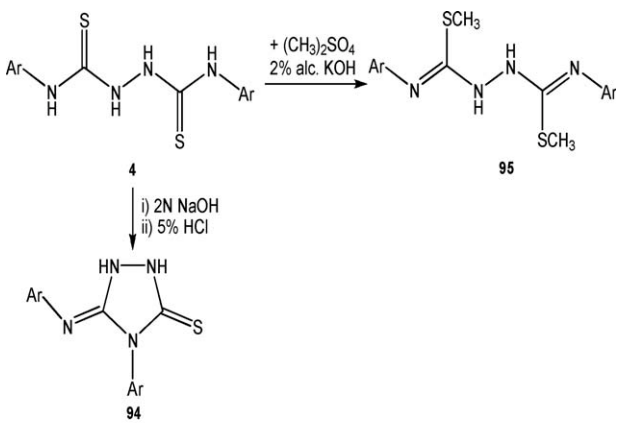
amino-3-hydrazino-5-mercapto-1,2,4-triazole **93** (Scheme 59) [82].

Dubenko *et al*. [98] reported the formation of 4-alkyl/aryl-1,2,4-triazolidine-3,5-dithiones **94**, during alkali-catalyzed thermal cyclization of 1,6-dialkyl/aryl-2,5-dithiobiureas **4**. Treatment of **4** with alcohol/KOH in presence $(CH_3)_2SO_4$ gave **95** (Scheme 60).

Triazolidines **88** and **94** can be obtained by cyclization of **4** with aqueous NaOH (Scheme 61) [99].

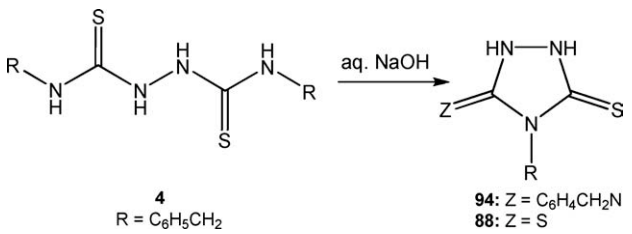
Framm and co-workers [44] reported that when 1,6-diphenyl-2,5-dithiobiurea **4** was heated in the presence

**Scheme 60**



**4, 94, 95:** Ar = *p*-Me-$C_6H_4$, *o*-Cl-$C_6H_4$, *p*-Cl-$C_6H_4$, *p*-Et-$C_6H_4$, *o*-MeO-$C_6H_4$, *p*-MeO-$C_6H_4$, *m*-Cl-$C_6H_4$, *o*-I-$C_6H_4$, $Me_2$-$C_6H_3$

**Scheme 61**



of alkali, the sole product obtained was 4-phenyl-3-phenylamino-$\Delta^2$-1,2,4-triazoline-5-thione **96** (Figure 10).

Alkali catalyzed thermal cyclization of 1,6-dialkyl-2,5-dithiobiureas **4** (R = R' = alkyl) results in the formation of 4-alkyl-1,2,4-triazolidine-3,5-dithiones **88** (alkyl = Me or Et) and 2-alkylamino-$\Delta^2$-1,3,4-thidiazoline-5-thione **52** (alkyl = *n*-Pr or *n*-Bu) (Scheme 62).

The anions **97** and **98**, respectively, formed from **4** carry a negative charge on the nitrogen and sulfur atoms and these can undergo cyclization by nucleophilic attack on the carbon atom at the other end, displacing

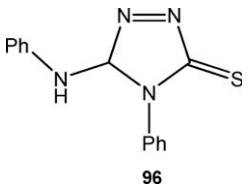


**Figure 10.** Triazolinethione from dithiobiurea.

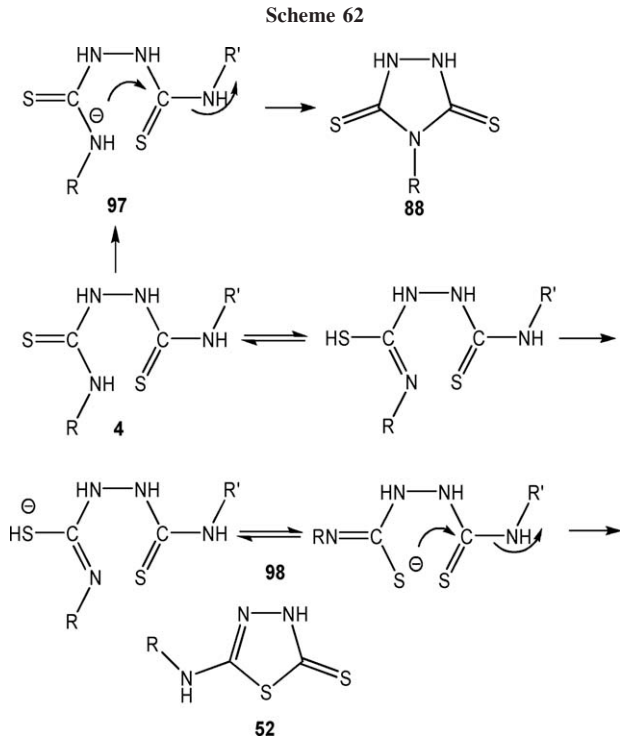
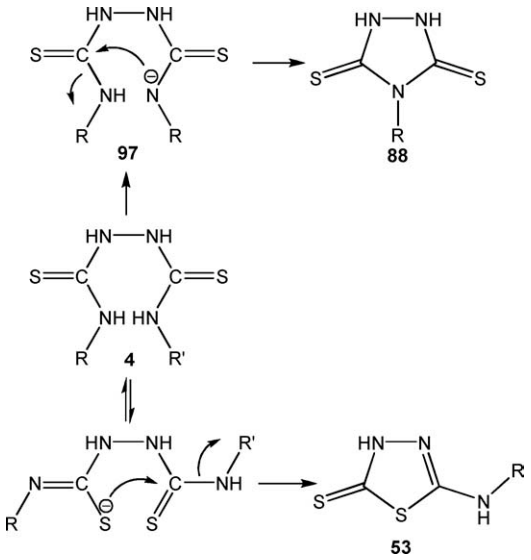
**Scheme 62**

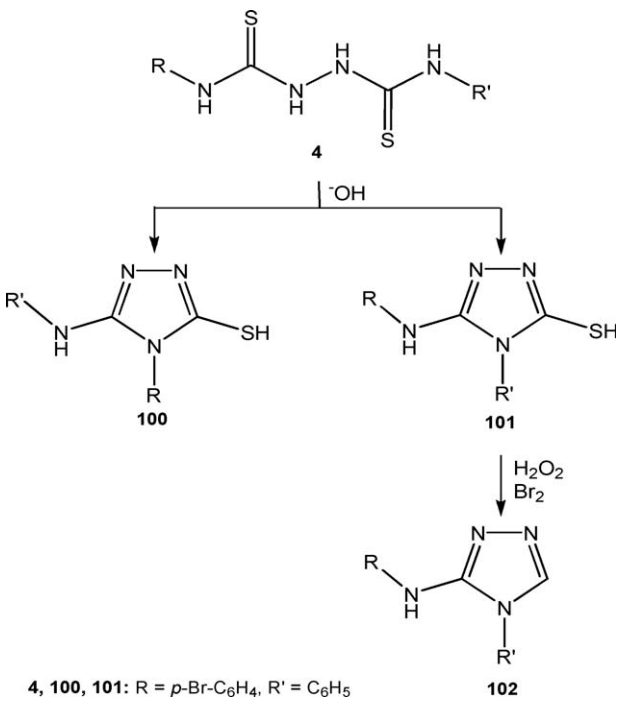


**Scheme 63**



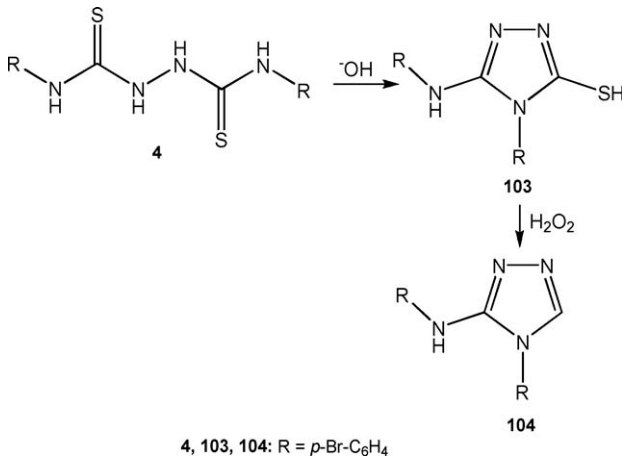
alkylamine. The formation of the different products during cyclization can be explained on the basis of the electronic and steric effects of the alkyl groups. When the alkyl groups are methyl or ethyl the electronic effect of the alkyl group is the major factor governing the mode of cyclization and the attack by the nitrogen atom carrying the alkyl substituent always occurs resulting in the formation of 4-ethyl/methyl-1,2,4-triazolidine-3,5-dithiones **88**. While going from methyl, ethyl, *n*-propyl to *n*-butyl, the inductive effect increase in the order

**Scheme 64**



**4, 100, 101:** R = *p*-Br-$C_6H_4$, R' = $C_6H_5$

**Scheme 65**

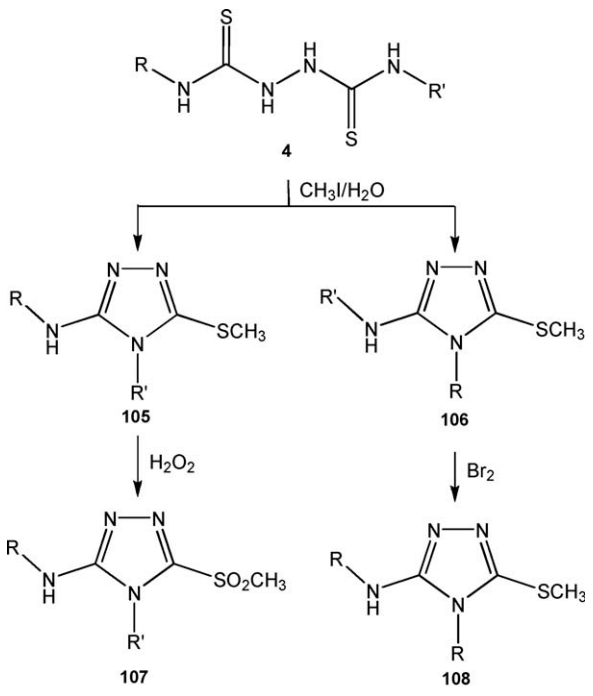


**4, 103, 104:** R = *p*-Br-$C_6H_4$

given. However, the steric effect of the alkyl group also increases and it exerts some influence on the mode of cyclization as follows [77].

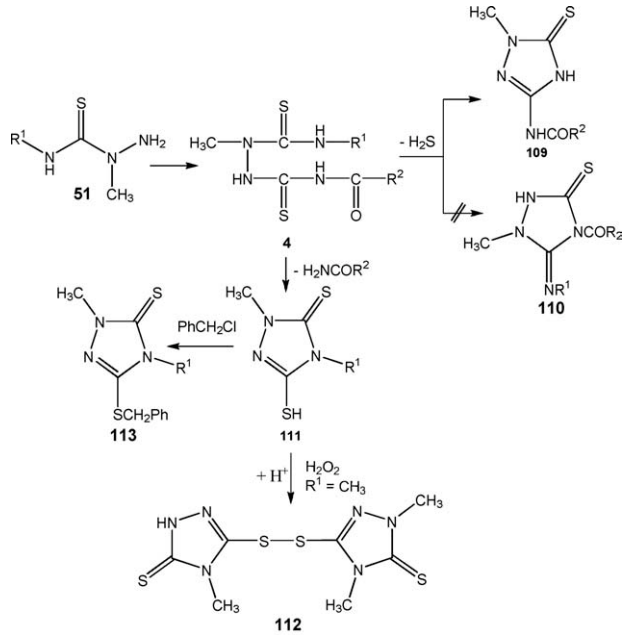
In view of the different modes of cyclization observed with alkyl substituted derivatives, a few 1-alkyl-6-aryl-2,5-dithiobiureas **4** (R = alkyl, R' = aryl) were also subjected to this cyclization reaction. The aryl groups chosen were; phenyl, 4-methylphenyl, *p*-chlorophenyl, and *p*-anisyl. When the alkyl group was methyl or ethyl, two products were obtained; one of the products was identified as 2-arylamino-$\Delta^2$-1,3,4-thiadiazolidine-5-thiones **53**, the other product was identified as 4-ethyl/

**Scheme 66**



**4, 105-108:** R = *p*-Br-$C_6H_4$, R' = $C_6H_5$

**Scheme 67**



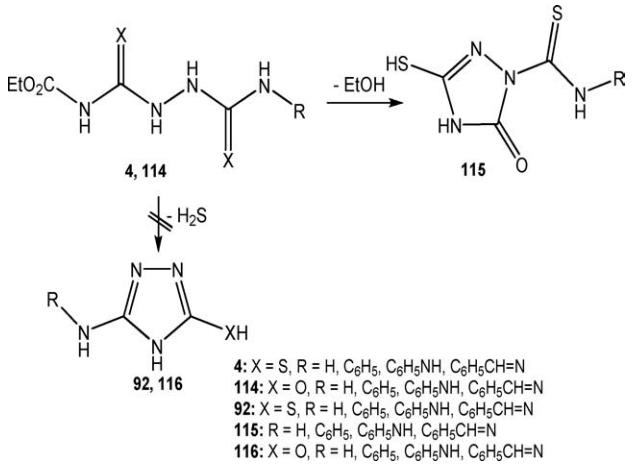
**4,109** : $R^1$ = Methallyl, phenyl, $R^2$ = Ethoxy, phenyl

methyl-1,2,4-triazoline-3,5-dithione **88** [77]. When the alkyl group was *n*-propyl or *n*-butyl, the sole product obtained was characterized as 2-arylamino-$\Delta^2$-1,3,4-thiadiazolidine-5-thion **53**. It was presumably formed by the elimination of alkylamine (Scheme 63).

Simiti and Marie [100] studied the behavior of symmetrical and asymmetrical *p*-bromodianilide of *N,N′*-bisthiocarbonic acid **4** toward —OH and $CH_3I$/—OH. The isomeric triazole **100** and **101** were formed from **4** in NaOH. Oxidation of **101** by $H_2O_2$ gave **102** (Scheme 64).

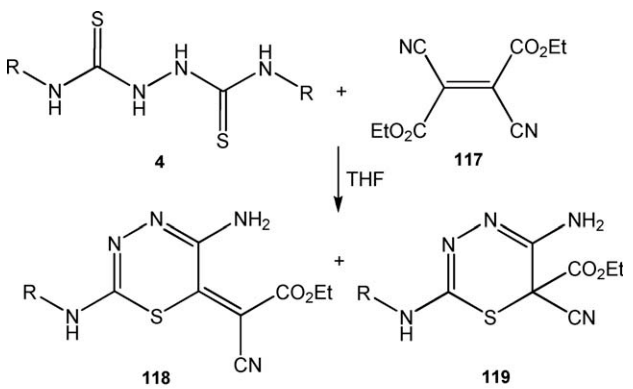
On the other hand, the action of NaOH on symmetrical **4** gave **103**, which oxidized by $H_2O_2$ to give **104** (Scheme 65) [100].

**Scheme 68**



**4:** X = S, R = H, $C_6H_5$, $C_6H_5NH$, $C_6H_5CH$=N
**114:** X = O, R = H, $C_6H_5$, $C_6H_5NH$, $C_6H_5CH$=N
**92:** X = S, R = H, $C_6H_5$, $C_6H_5NH$, $C_6H_5CH$=N
**115:** R = H, $C_6H_5$, $C_6H_5NH$, $C_6H_5CH$=N
**116:** X = O, R = H, $C_6H_5$, $C_6H_5NH$, $C_6H_5CH$=N

**Scheme 69**

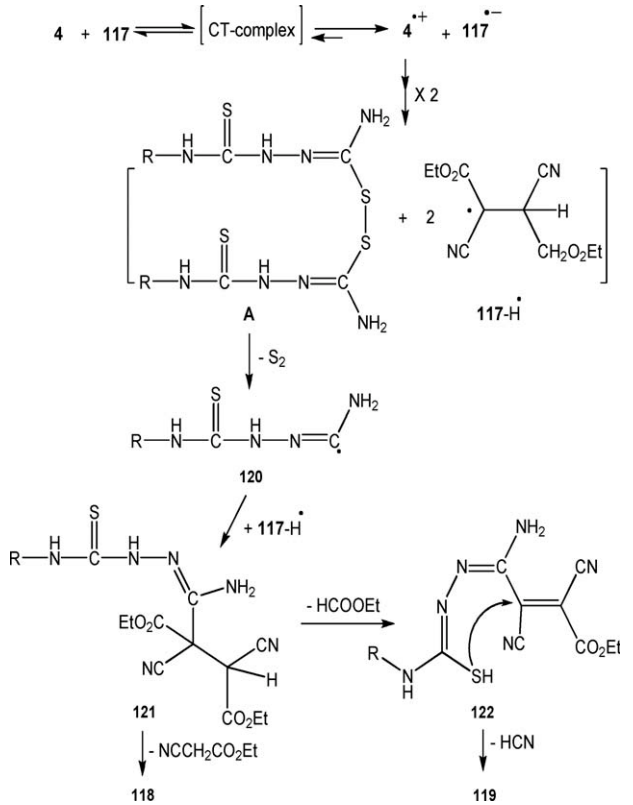


**4,118,119:** R = Phenyl, allyl, benzyl

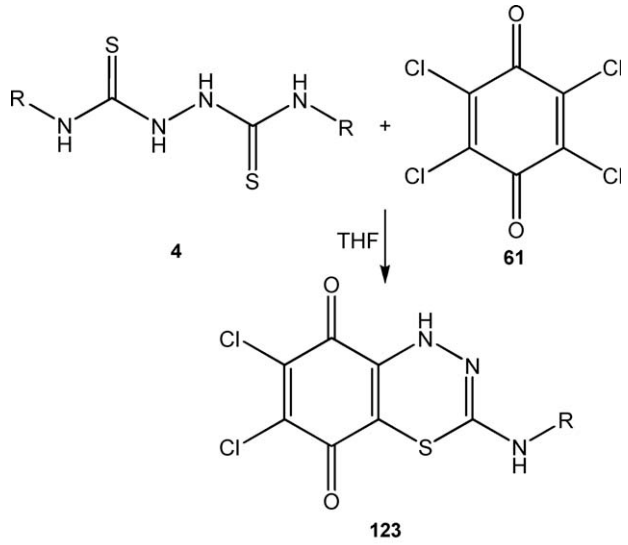
Also the action of NaOH and MeI, respectively, on **4** gave **105** and **106**. Oxidation of **105** by $H_2O_2$ gave **107**, while bromonation of **106** gave **108** (Scheme 66) [100].

2,4-Disubstituted thiosemicarbazides **51** reacted with acyl isothiocyanates to give dithiobiureas **4**, which cyclized to 1,2,4-triazoline-3-thiones **109** (not **110**) and 5-mercapto-1,2,4-triazoline-3-thiones **111** by the action of sodium ethanolate (Scheme 67).

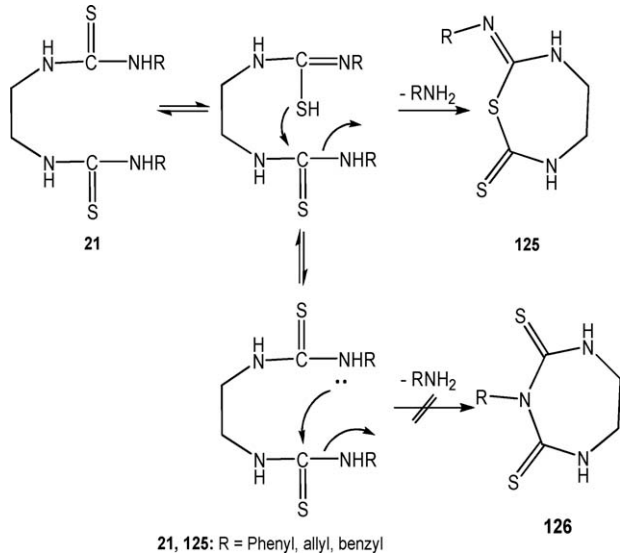
**Scheme 70**



**Scheme 71**



**Scheme 73**



Compound **111** was converted to the more stable *S*-benzyl derivatives **113**. However, **111** were oxidized by hydrogen peroxide to disulfide **112** [92].

Cyclization of dithiobiurea and thiobiurea derivatives involving the usual loss of hydrogen sulfide or $H_2O$ and did not convert compounds of type **4** and **114** into **92** or **116**, but occurs in fact with elimination of ethanol and formation of 1*H*-(thio)amide-1,2,4-triazoles **115** (Scheme 68) [101–103].

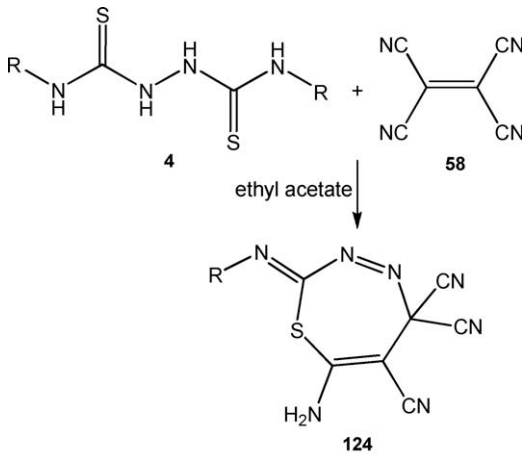
**3.5. Synthesis of thiadiazine derivatives.** 1-Substituted hydrazinecarbothioamide **4** reacted with ditheyl (*E*)-2,3-dicyanobutenedioate **117** in THF at room temperature to give ethyl (*Z*)-2-[-2-amino-2-(substituted amino)-6*H*-1,3,4-thiadiazine]-2-cyanoacetate **118** and ethyl 5amino-6-cyano-2-(substituted amino-6*H*-1,2,4-thiadiazine-6-carboxylate **119** (Scheme 69) [87].

A rationalization for the formation of thiadiazines compounds is given in Scheme 70 [87].

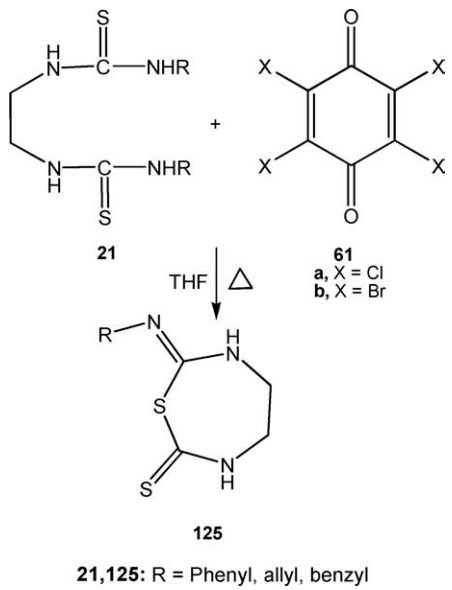
The interaction between 1,6-disubstituted hydrazinearbothioamides **4** and chloranil **61** in THF led to the formation of 3-substituted amino-6,7-dichloro-1*H*-benzo[*e*][1,3,4]thiadiazine-5,8-diones **123** (Scheme 71) [86].

**3.6. Synthesis of thiadiazepine and thiadiazepane derivatives.** Addition of two equivalents of ethenetetracarbonitrile **58** to 1,6-disubstituted-2,5-dithiobiureas **4** in ethyl acetate lead to the formation of 7-amino-2-

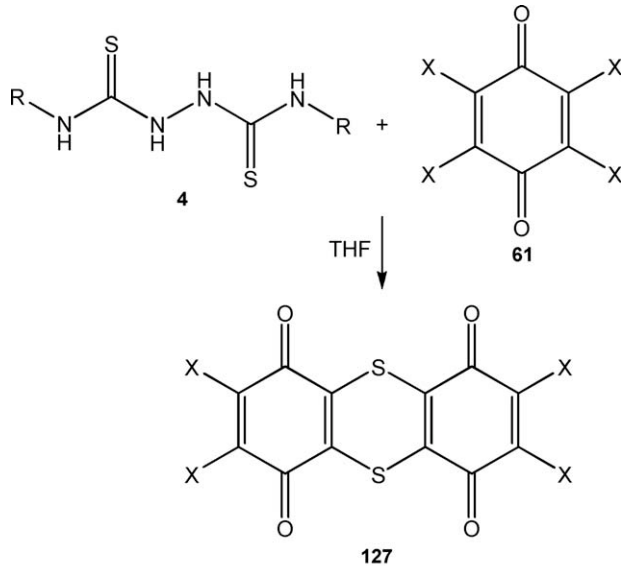
**Scheme 72**



**Scheme 74**



**Scheme 75**



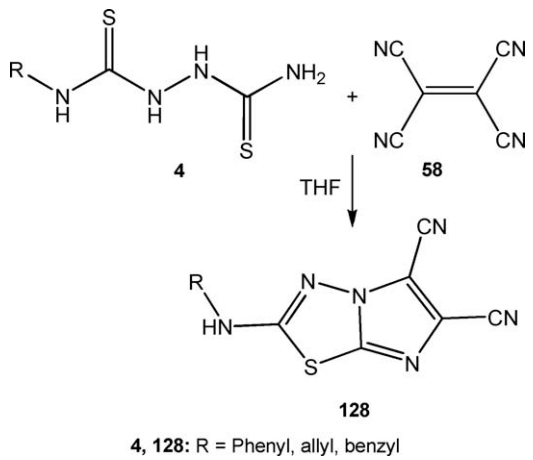
substituted imino-2*H*-[1,3,4]thiadiazepine-5,5,6-tri-carbonitriles **124** (Scheme 72) [83].

1,3,6-Thiadiazepane-2-thione **125** can be obtained on heating or microwave irradiation of thioureido-thioureas **21** [67]. The formation of **125** can be explained by nucleophilic attack of SH on C═S with elimination of a molecule of amine. The alternative structure **126** could be ruled out on the basis of spectral data of **125** (Scheme 73).

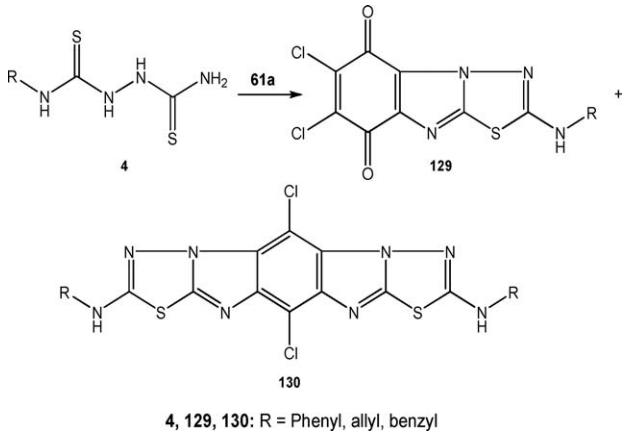
Also, 1,3,6-thiadiazepane-2-thione **125** was formed *via* interaction between thioureidothioureas **21** with chloranile or bromanile **61a,b** in boiling THF (Scheme 74) [86].

**3.7. Synthesis of thiantherne derivatives.** On adding 1,6-disubstituted-2,5-dithiobiureas **4** to chloranil or bromanil **61a,b**, 2,3,7,8-tetrahalothia-anthrene derivatives **127** were formed (Scheme 75) [86].

**Scheme 76**



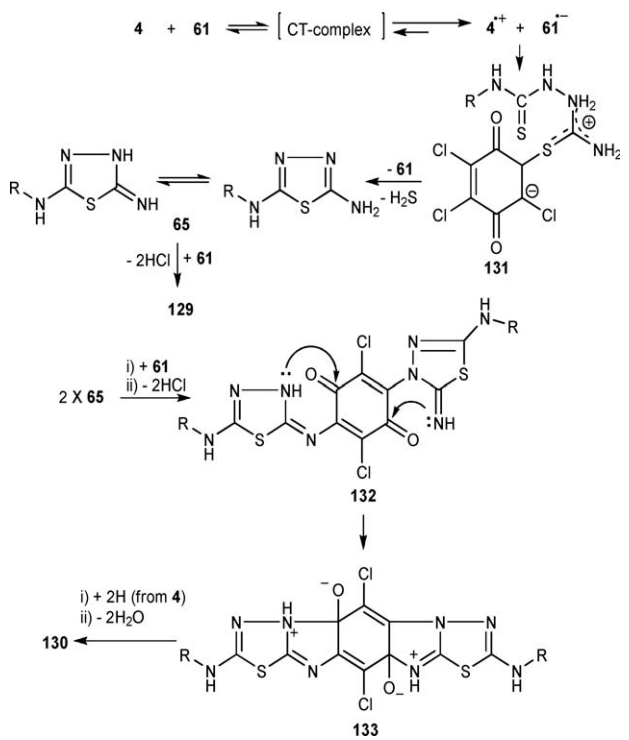
**Scheme 77**



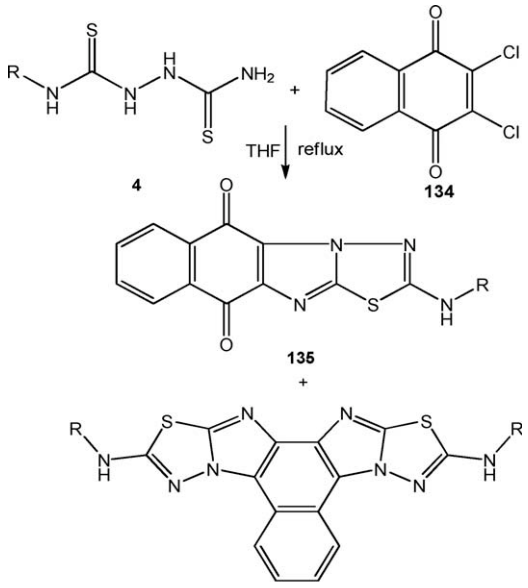
**3.8. Synthesis of imidazothiadiazole derivatives.** 2-(Substituted amino)imidazo[2,1-*b*][1,3,4]thiadi-azole-5,6-dicarbonitriles **128** were formed during the interaction between 1-substituted-2,5-dithiobiureas **4** with ethenete-tracarbonitrile **58** (Scheme 76) [87].

On the other hand, the reaction of chloranil **61a** with 1-substituted-2,5-dithiobiureas **4**, 2-substituted amino-6,7-dichlorobenzo[4,5]imidazo[2,1-*b*][1,3,4]-thiadiazole-5,8-diones **129** and 5,11-dichloro-2,8-disubstituted

**Scheme 78**



**Scheme 79**



**4,135,136:** R = Phenyl, allyl, benzyl

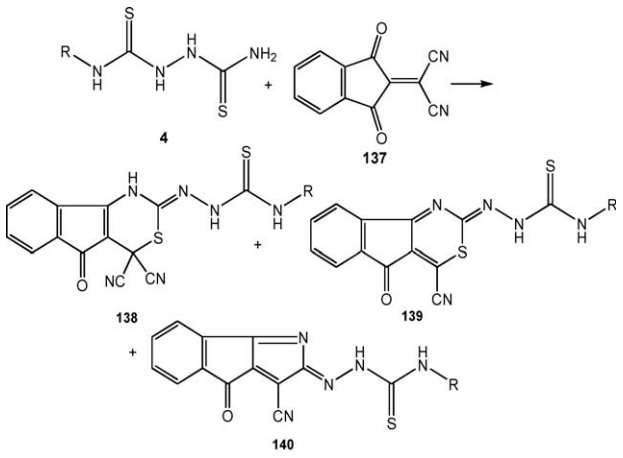
aminobenzo[21,3-*d*:6,5-*d*']bis(imidazo-[2,1-*b*][1,3,4]thiadiazoles) **130** were formed (Scheme 77) [104].

The formation of products **129** and **130** as in Scheme 78 [104]:

Also, the reaction between 1-substituted-2,5-dithiobiureas **4** and 2,3-dichloro-1,4-naphthoquinone **134** gave 2-substituted aminonaphtho[4,5]imidazo-[2,1-*b*][1,3,4] thiadiazole-5,10-diones **135** and 2,11-disubstituted aminonaphtho[1,2-*d*:4,3-*d*']bis-(imidazo[2,1-*b*][1,3,4]thidiazoles) **136** (Scheme 79) [104].

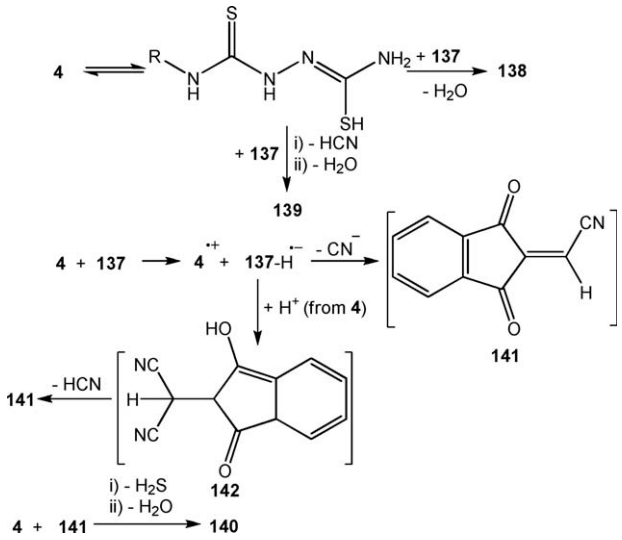
**3.9. Synthesis of oxoindenothiazine and oxoindenopyrrole derivatives.** (1,3-Dioxo-2,3-dihydro-1*H*-inden-2ylidene)-propanedinitrile **137** reacted with 1-substi-

**Scheme 80**



**4,138,140:** R = Phenyl, allyl, benzyl

**Scheme 81**

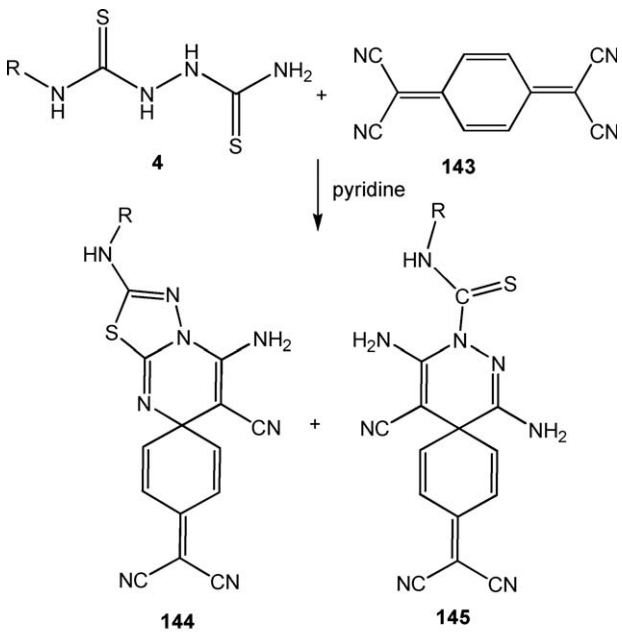


tuted-2,5-dithiobiureas **4** in ethyl acetate to give *N*-substituted-2(4,4-dicyano-5-oxoindeno[1,2-*d*][1,3]thiazin-2-(1*H*,4*H*,5*H*)-ylidene)hydrazinecarbothioamides **138**, *N*-substituted-2(4-cyano-5-oxoindeno-[1,2-*d*][1,3]-thiazin-2-(5*H*)-ylidene)hydrazinecarbothioamides **139** and *N*-substituted-2(3-cyano-4-oxoindeno[1,2-*b*]pyrrol-2-(4*H*)-ylidene)hydrazinecarbothioamides **140** (Scheme 80) [104].

A rationalization for the formation of products **138**–**140** is shown in Scheme 81 [104].

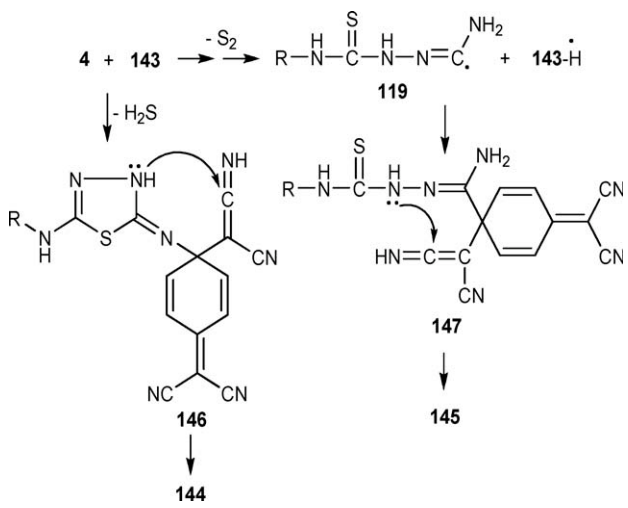
**3.10. Synthesis of spiro compounds.** The reaction of 1-substituted-2,5-dithiobiureas **4** with 7,7′,8,8′-

**Scheme 82**



**4,144,145:** R = Phenyl, allyl, benzyl

**Scheme 83**



tetracyanoquinodimethane **143** in dry pyridine lead to the formation of {5-amino-6-cyano-2-(substituted amino)spiro[1,3,4]thiadiazolo[3,2-*a*]-pyrimidine-7,1′-cyclohexa[2,5]diene-4′-ylidene}malononitriles **144** and 1,4-diamino-5-cyano-9-(dicyanomethylene)-*N*-substituted-2,3-diazospiro-[5,5′]undeca-1,4,7,10-tetraene-9-thioamides **145** (Scheme 82) [87].

The formation of compounds **144** and **145** can be rationalized by the following mechanism (Scheme 83) [87].

Because of important biological applications of chromones, some synthetic strategies leading to more complex derivatives have been widely explored in the past years. Thus, the purpose of this review is to report some recent improvements of the classical synthetic methods and of some nonclassical methods to obtain simple oxygenated chromones. The strategies for synthesis of heterocycle analogs containing phosphorus, nitrogen, and sulfur are also summarized.

*J. Heterocyclic Chem.*, **47**, 785 (2010).

## INTRODUCTION

Heterocycles play an important role in the design and discovery of new physiological/pharmacologically active compounds [1]. Chemically, chromones (4*H*-chromen-4-ones) are heterocyclic compounds with the benzo-γ-pyrone framework (Fig. 1). Molecules containing the chromone or benzopyranone ring have a wide range of biological activities. They have been shown to be tyrosine and protein kinase inhibitors [2–4], as well as anti-inflammatory [5], antiviral [6], antioxidant [7,8], and antihypertensive agents [6]. Chromone derivatives are also active at benzodiazepine receptors [9], and on lipoxygenase and cyclooxygenase [10]. In addition to this, they have been shown to be anticancer agents [11], possessing antimutagenic properties [12] and the ability to inhibit electron transport through inhibition at NADH: ubiquinone oxidoreductase and phorbol ester-inducedornithinedecarboxylase [13,14]. Chromones may also have application in cystic fibrosis treatment, as they activate the cystic fibrosis transmembrane conductance regulator [15]. Therefore, the vast range of biological effects associated with this scaffold has resulted in the chromone ring system being considered as a privileged structure [16]. The main objectives of chromones syntheses are not only for the development of more diverse and complex bioactive compounds for biological activity and structure-activity relationship (SAR) studies but also for other applications in Medicinal Chemistry, such as preparation of fluorescence probes, due to photochemical properties of chromones [17].

One of the first methods for the synthesis of chromones was introduced by Heywang and Kostanecki, which involved the decarboxylation of chromone-2-carboxylic acid [18]. Since then, several other routes with higher yields and less drastic experimental conditions have been developed.

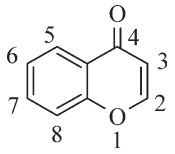

**Figure 1.** Chromone nucleus and numbering.

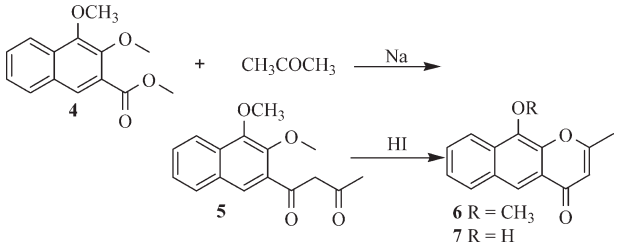
Chromones could be synthesized under either acidic or basic conditions. The classical 2,3-disubstituted benzopyranone (**3**) synthesis utilized acidic conditions (Scheme 1) and was by far the most common method [19]. It proceeded through an intramolecular condensation of molecules such as **2**, which were usually obtained through a Baker–Venkataraman rearrangement of compound **1**, or via a Claisen ester condensation (Scheme 1). Most synthesis required harsh acidic conditions as the final step. On the other hand, synthesis utilizing basic conditions typically consisted of piperidine in refluxing pyridine for several hours to affect ring closure. This was far less common [19]. Recently, microwave heating has also been used to affect ring cyclization [20]. In this review, our aim is to provide a comprehensive summary till the March 2009, with special emphasis on the synthesis of chromone ring based on different methods, and the same reactive condition in chromone ring closure will be cited along with the latest reported literature.

**Acid as catalyst in chromone ring closure.** Acid comprised a major catalyst in chromone ring closure, and many acids can be used including hydriodic acid, polyphosphoric acid (PPA), acetic acid, methanesulfonylchloride, hydrochloric acid, para toluene sulfonic acid (PTS), triflic anhydride, phosphorus oxychloride, perchloric acid, and sulfuric acid.

***Hydriodic acid as a catalyst.*** In 1952, Wawzonek and Ready [21] reported the synthesis of chromone using hydriodic acid as a catalyst in the ring closure (Scheme 2). Methyl 1,2-dimethoxy-3-naphthoate (**4**), which was prepared from 1,2-dihydroxy-3-naphthoic acid by a two-step methylation process, was condensed with acetone in the desired fashion to afford **5**. Cyclization of the diketone (**5**) with hydriodic acid gave products which depended upon the time of refluxing. A period of 7 h gave a mixture of 2-methyl-8-hydroxy-6,7-benzochromon (**7**) and 2-methyl-8-methoxy-6,7-benzochromone (**6**). Complete demethylation was achieved only after 24 h of heating. This chromone ring closure using hydriodic acid as a catalyst was not common because it required high temperature and long reaction time, and sometimes the reactant might decompose under these conditions.

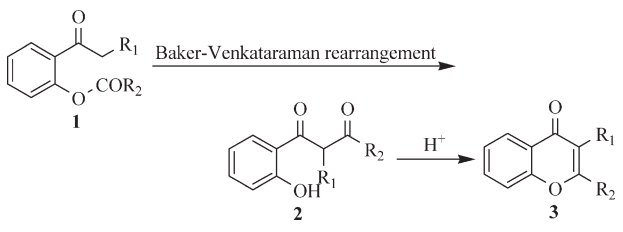
**Scheme 2**



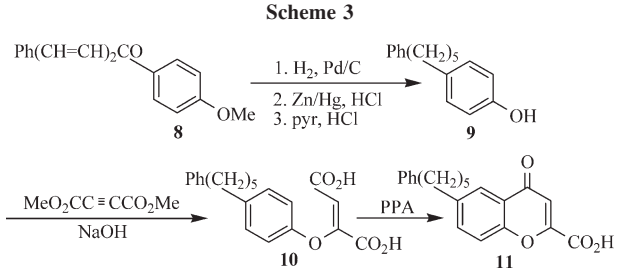
***Polyphosphoric acid as a catalyst.*** In 1977, Lee and coworkers [22] took PPA as a catalyst in the chromone ring closure; in their synthetic route (Scheme 3), they firstly applied a two-step reduction procedure to the chalcone **8** with subsequent demethylation provided the aralkylphenol **9**, which, by modification [23] of the process described by Ruhemann and Stapleton [24] for the formation of chromone-2-carboxylic acids from phenols, was converted to the chromone **11** through PPA as the catalyst in the last step. This method was more suitable in the phenolic hydroxyl side chain in a carboxylic acid of the cyclization.

***Acetic acid as a catalyst.*** In 1990, Harvey *et al*. [25] described a new synthesis of chromones and flavones based on the ortho-directed metalation of methoxymethyl aryl ethers with alkyllithium reagents (Scheme 4), and they applied acetic acid as a catalyst in the chromone ring closure. Their synthetic route entailed reaction of the ortho-lithiated intermediates **12** with a conjugated unsaturated aldehyde followed by oxidation of the allylic alcohol product **13** with ''periodinane'' to yield an ortho-allylic ketone **14**. The latter on heating in acetic acid undergoes loss of the methoxymethyl protecting group and cyclization to a chromanone (or flavanone, if a β-phenyl substitutent is present) **15**. Dehydrogenation by treatment with pyrrolidone hydrotribromide in dimethyl sulfoxide yielded the corresponding chromones

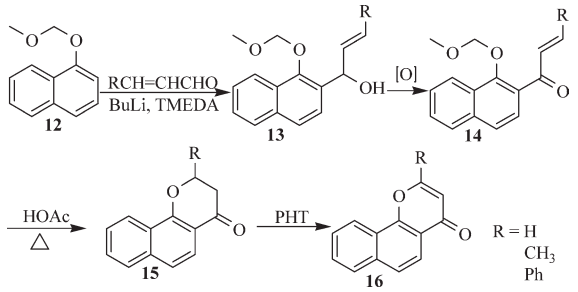
**Scheme 1**



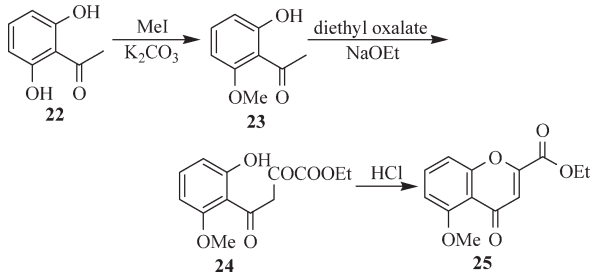
**Scheme 3**



**Scheme 4**



**Scheme 6**



(or flavones) **16**. This synthetic approach appeared general in its applicability. It has been applied to the synthesis of a series of polycyclic chromone and flavone compounds containing the naphthalene and pyrene ring systems that hold promise as agents for the chemoprevention of cancer.

***Methanesulfonylchloride as a catalyst.*** In 2001, Ismail and Abd El Aziem [26] reported the synthesis of the new 3-substituted-7-methoxy-4*H*-1-benzopyran-4-ones (**21**) starting from 2-hydroxy-4-methoxyacetophenone (**17**) according to Scheme 5. The key step in this synthesis involved the alkylation with alkyl halide using potassium tertiary butoxide of 2-(*t*-butyldimethylsilyloxy)-4-methoxyacetophenone (**18**) which was prepared by the protection of the hydroxyl group of **17** using *t*-butyldimethylsilylchloride. The *O*-silyl protected alkylacetophenone derivatives (**19**) were, therefore, treated with tetra-*n*-butylammonium fluoride to produce the corresponding 2′-alkyl-2-hydroxy-4-methoxyacetophenone (**20**) in good yield. Cyclization of the alkyl derivatives **20** was achieved via methanesulfonylchloride using boron trifluoride diethyl etherate at 0°C [27] to give the desired 3-substituted-7-methoxy-4*H*-1-benzopyran-4-ones (**21**). This reaction conditions was relatively mild, and the reaction yield was also relatively high.

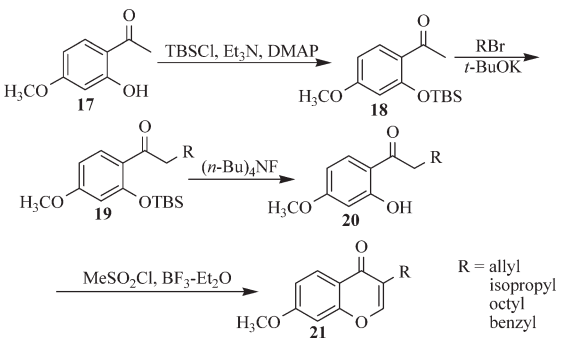
***Hydrochloric acid as a catalyst.*** In 2003, Boumendjel and coworkers [28] obtained chromone **25** in three steps starting from 2,6-dihydroxyacetophenone (Scheme 6); this time they used concentrated hydrochloric acid as a catalyst in the ring closure. Treatment of the 2,6-dihydroxyacetophenone (**22**) with methyl iodide gave 2-hydroxy-6-methoxyacetophenone (**23**). Condensation of **23** with diethyl oxalate in the presence of sodium ethoxide in EtOH and then concentrated HCl catalysted cyclization afforded ester **25**, and a lot of reactions have adopted this approach [29–32].

***Para toluene sulfonic acid as a catalyst.*** In 2004, Sabui and Venkateswaran [33] synthesized the chromone using PTS as a catalyst in the ring closure (Scheme 7). Condensation of the acetophenone **26** [34] with ethyl formate in the presence of sodium hydride followed by dehydration of the resulting chromanol furnished the 6-methoxy-7-methyl chromone **28** in an overall yield of 85%. This catalyst was especially suitable in the phenolic hydroxyl and aldehyde condensation cyclization.

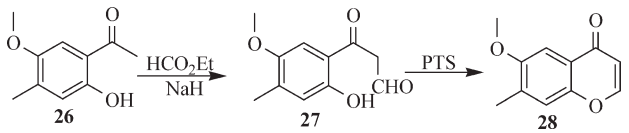
***Triflic anhydride as a catalyst.*** In 2005, Griffin *et al*. [4] used triflic anhydride as a catalyst to construct the chromone ring (Scheme 8). Reaction of the appropriate 2-hydroxyarylcarboxylate esters **31**, which were prepared by carboxylation-esterification of the corresponding phenols **30** by standard methods, with *N*-acetylmorpholine, *N*-acetylthiomorpholine, or *N*-acetylpiperidine afforded the β-ketoamides **32**, and ring closure to the required chromones **33** was readily effected with triflic anhydride. Although the effect of this catalyst was better, but higher prices due to trifluoroacetic anhydride, making its practical application being limited.

***Phosphorus oxychloride as a catalyst.*** This catalyst is most widely used in the chromone ring closure, and there are two ways in construction the chromone ring. One approach is that phenolic compounds and carbonyl compounds are refluxed in phosphorus oxychloride, another approach is that the phenolic compounds with the acyl side chain is refluxed in phosphorus oxychloride. In 2005, Balbi and coworkers [35] synthesized the

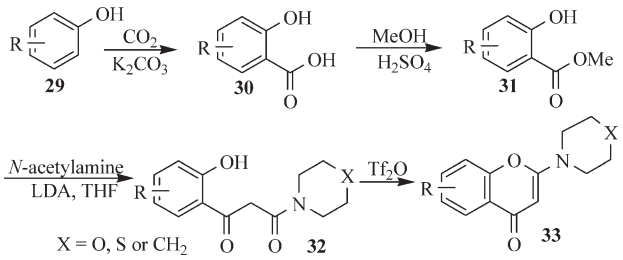
**Scheme 5**



**Scheme 7**



**Scheme 8**



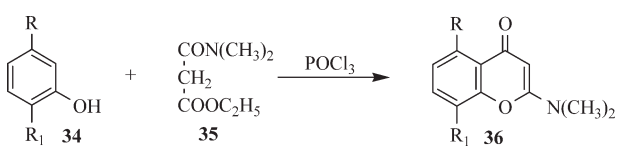
chromone ring via $POCl_3$ as a catalyst (Scheme 9). **36** was obtained by following their well-established method from substituted phenols and *N*,*N*′-(dimethyl)malonamide in the presence of phosphorus oxychloride [36,37].

In 2008, Yang and coworkers [38] prepared the 6-hydroxy-3-carbaldehyde chromone via a Vilsmeier reaction in another way (Scheme 10). 6-hydroxy-4-chromone-3-carbaldehydes **40** were easily prepared by the reaction of 2,5-dihydroxy-acetophenone **39** with DMF in $POCl_3$ solution [39–45].

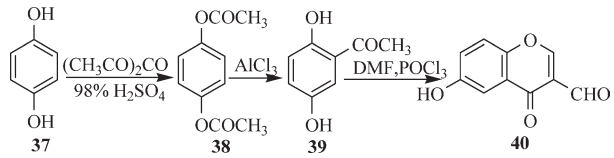
***Perchloric acid as a catalyst.*** In 2006, Langer and coworkers [46] synthesized chromone using perchloric acid as a catalyst (Scheme 11). The reaction of 3-formylchromones **41** with $Me_3SiOTf$ (**42**) and 1,3-bis(silyl enol ether) **43** afforded the 4-(2-hydroxybenzoyl)phenols **44**. The formation of the products could be explained by a domino ''Michael–retro-Michael–Aldol'' reaction. Compounds **44** were transformed into the novel chromones **45** by treatment with triethyl orthoformate and perchloric acid [47–49].

***Sulfuric acid as a catalyst.*** In 2007, Cushman and coworkers [50] reported the synthesis of chromone using $H_2SO_4$ as a catalyst (Scheme 12). Commercially available 2-hydroxy-6-methoxyacetophenone (**23**) was subjected to Elbs oxidation using sodium persulfate and aqueous sodium hydroxide to yield the substituted acetophenone **46**, followed by regioselective methylation using anhydrous potassium carbonate and dimethyl sulfate in acetone to afford 6-hydroxy-2,3-dimethoxyacetophenone (**47**) in 53% yield in two steps. The generation of the dilithium dianion **48** of the acetophenone **47** was ensured by treatment with four equivalents of lithium hexamethyldisilylazide in THF. Treatment of dilithium dianion **48** with commercially available 2,6-dimethoxybenzoyl chloride, followed by acidification, afforded the

**Scheme 9**



**Scheme 10**



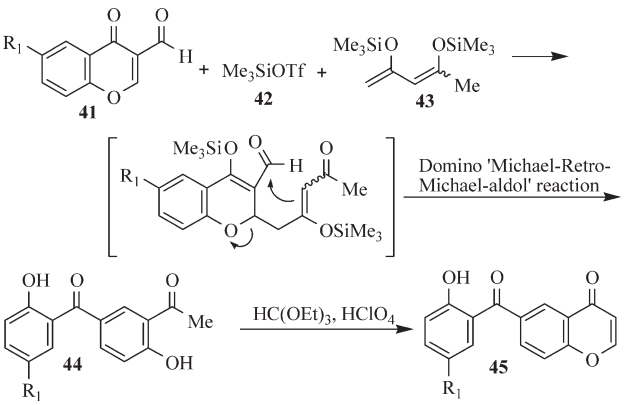
β-diketone intermediate **49**, which was used without purification for cyclization to zapotin (**50**) with the catalyst of $H_2SO_4$ [51–55]. This $H_2SO_4$ as catalyst and HCl as catalyst means were basically the same.

**Base as catalyst in chromone ring closure.** Although base as catalyst in the chromone ring closure is not common compared with acid, sometimes it can really bring some satisfactory results.

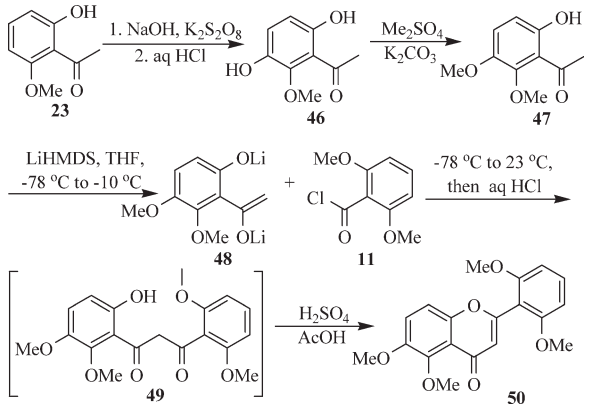
***Sodium formate as a catalyst.*** In 2001, Wallace and coworkers [56] reported the synthesis of enantiomerically pure (*S*)-2-methylchroman-4-one **53** based on the following procedure (Scheme 13): Treating methyl 5-methyl-salicylate **51** with an excess of lithium diisopropylamide followed by the lithium derivative of (*R*)-(+)-methyl *p*-tolyl sulfoxide gave the desired ketosulfoxide (*R*)-**52** directly and in good yield. Then, the formation of the chromone **53** was achieved conventionally using acetic formic anhydride and sodium formate [57,58]. But this method is only applicable to compounds with ketosulfoxide.

***Sodium methoxide as a catalyst.*** In 2001, Khan and coworkers [59] synthesized the chromone ring via cyclization on treating with 0.1*M* NaOMe solution (Scheme 14). The compounds **54** on bromination with the same reagent in $CH_2Cl_2$ gave the brominated products **55** in good yields. Various flavones (**57**) were obtained in good yields from the brominated products **55** by dehydrobromination followed by cyclization on treatment with 0.1*M* sodium methoxide solution. The main feature

**Scheme 11**



**Scheme 12**

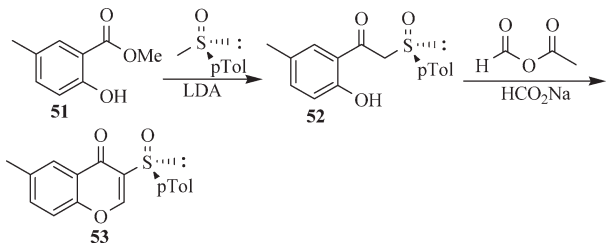


of this reaction was the bromination of the unsaturated olefinic bond.

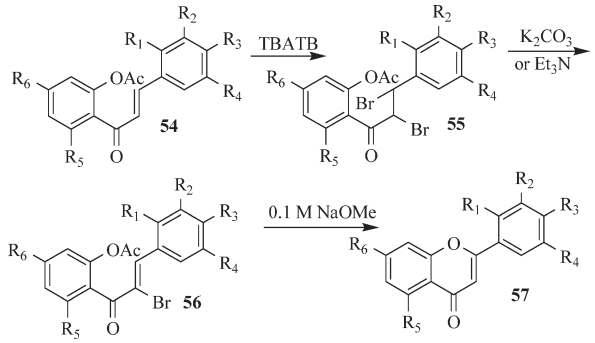
***Sodium hydride as a catalyst.*** In 2003, Samat and coworkers [60] developed the synthesis of a series of new nine 3-benzoyl-2-benzylchromones through a classical and an optimized Kostanecki–Robinson method involving an *o*-hydroxyphenyl-β-diketone **59** and an acid anhydride **61** (Scheme 15). Most of the *o*-hydroxyphenyl-β-diketones **59** were obtained using a traditional method involving a reaction between *o*-hydroxy acetophenone **58** and acid chloride, followed by a Baker–Venkataraman rearrangement. The homoveratric anhydride **61** prepared from the reaction of dicyclohexylcarbodiimide with the corresponding acid **60** had been used to perform the Kostanecki–Robinson reaction. In this last reaction, Sodium hydride was used also as base to favor the formation of the expected chromone **62** instead of byproducts. However, this method had one drawback, the anhydride was not easy to prepare, especially for the aromatic acid anhydride.

***Pyridine as a catalyst.*** In 2005, Lee *et al*. [61] synthesized the chromone using pyridine as a catalyst in the ring closure (Scheme 16). Dioxane-fused propiophenone (**64**) was prepared by Fries rearrangement of compound **63**, which was obtained from benzodioxane via two-step sequence, Friedel-Craft acylation with propionyl chloride and Bayer–Villiger oxidation. Chromone rings were

**Scheme 13**



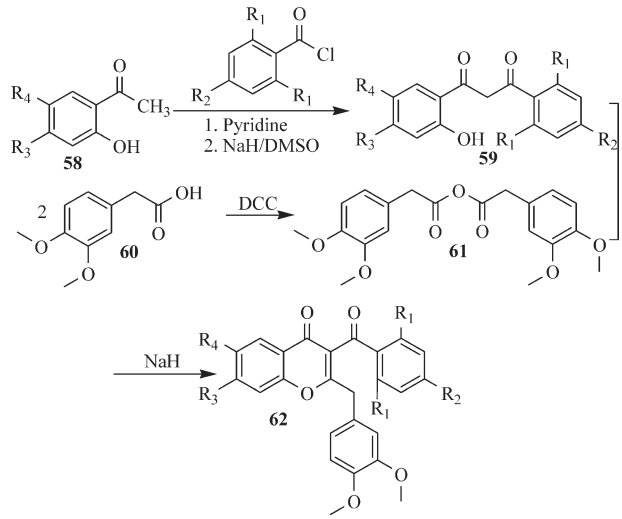
**Scheme 14**



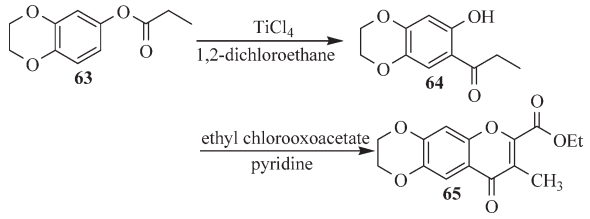
constructed by acylation of 2-hydroxyphenones **64** with ethyl chlorooxoacetate followed by *in situ* cyclization of the resulting esters in the presence of pyridine to provide compounds **65** [62]. This method of using pyridine as a catalyst was more suitable to acyl phenols and chloroacetyl carboxylic acid esters in the chromone ring closure.

***Sodium acetate as a catalyst.*** In 2005, Gabbutt and coworkers [63] synthesized 3-acylchromones by acylation of 2′-hydroxydibenzoylmethane with acid anhydrides in the presence of sodium acetate (Scheme 17). The requisite starting materials, 2′-hydroxydibenzoylmethanes **67**, were easily available by *O*-acylation of 2′-hydroxyacetophenone followed by Baker–Venkataraman (BV) rearrangement under standard conditions [64]. Acylation of the 1,3-diketones **67** with acetic anhydride gave the 2-alkyl-3-aroylchromones **68** in high yields [65]. This condensation reaction was not only applicable to acetic anhydride but also for other acid anhydride such as propionic anhydride and butyric anhydride.

**Scheme 15**



**Scheme 16**

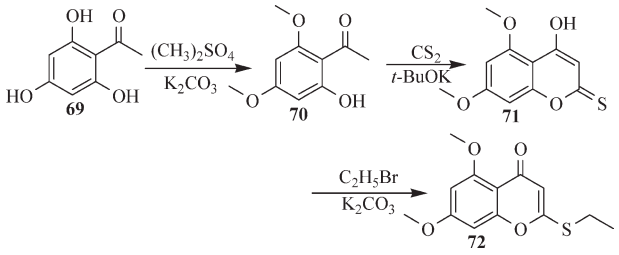


***Potassium tert-butoxide as a catalyst.*** In 2007, Wu and coworkers [66] prepared the chromone ring using potassium *tert*-butoxide in the ring closure during their total synthesis 6-demethoxycapillarisin (Scheme 18). Methylation of **69** with dimethyl sulfate in the presence of $K_2CO_3$ in $CH_3COCH_3$ afforded **70**. The intermediate **70** was readily reacted with $CS_2$ in the presence of *t*-BuOK in toluene to provide **71**. Without purification, the lactone **71** reacted with $C_2H_5Br$ and $K_2CO_3$ in $CH_3COCH_3$ to afford the key product **72** [67,68]. This reaction was very useful, which laid the foundation to expand the SAR of chromone ring with sulfur atom in the side chain.

***$Cs_2CO_3$ as a catalyst.*** In 2008, Arai *et al*. [69] described a practical and useful synthesis of heterocyclic-substituted chromones (Scheme 19) and also developed a one-pot synthesis by Michael aldol reaction of chromone derivatives bearing heterocycle units. The 2,3-heterocyclic-substituted chromones **75** were obtained in one step, as shown in scheme 19, 4′-benzyloxy-2′-hydroxyacetophenone (**73**) reacted with heterocyclic aldehydes **74** to give 2,3-disubstituted chromone **75** in high yield under $Cs_2CO_3$ conditions.

***Potassium carbonate as a catalyst.*** In 2009, Anwar and Hansen [70] used $K_2CO_3$ as a catalyst in the chromone ring closure during their first total synthesis of the marine natural product *all*-(*Z*)-5,7-dihydroxy-2-(4*Z*,7*Z*,10*Z*,13*Z*,16*Z*-nonadecapentaenyl)chromone (Scheme 20). In their synthetic route, aldehyde **76** was transformed to the terminal alkyne **77** in a Colvin rearrangement in 58% yield. Addition of aldehyde **78** in THF to the anion of **77** at −78°C yielded the secondary alcohol **79** in 60% yield. Oxidation of **79** with $MnO_2$ yielded MOM-protected ketone **80** in 88% yield. Mild deprotection of **80** with HCl in EtOH at ambient temperature, followed by intramolecular Michael addition under lenient basic conditions ($K_2CO_3$, acetone), afforded the natural product **81** in 49% yield for the latter two steps [71]. This reaction using phenol hydroxyl addition to the alkyne bond was relatively classical.

**Scheme 18**

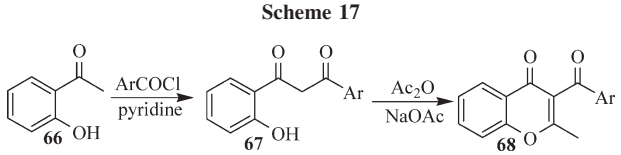


**Chromone ring closure under the microwave irradiation.** Recently, microwave irradiation [72,73] offers a considerable advantage over conventional heating because it results in substantial rate enhancements in a wide range of organic reactions. Cleaner reactions are also commonly achieved, together with improvements in yield and selectivity [74]. The increasing demand for clean and ''green'' chemical syntheses has resulted in increased use of microwave irradiation, so there have been several recent reports, describing the application of microwave irradiation to the synthesis of flavonoids.

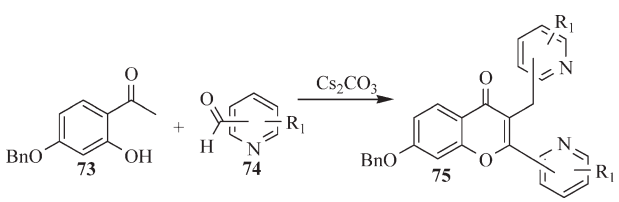
In 2005, Seijas *et al*. [75] reported an eco-friendly direct solvent-free synthesis of functionalized flavones **84** under microwave irradiation (Scheme 21). This method was valid for flavones with or without substitution in the B ring. Thus, the flavonoids were prepared from the corresponding ethyl benzoyl acetates **83** and phloroglucinol for 2–12 min of irradiation in 66–96% yields. The successful use of microwave irradiation in providing this rapid and direct route to flavones in comparison to classical procedures contributes to confirming the participation of specific effects in some microwave-assisted organic synthesis.

In 2005, Kabalka and Mereddy [76] reported a facile microwave synthesis of functionalized flavones and chromones via the cyclization of 1-(2-hydroxyaryl)-3-aryl-1,3-propanedione (Scheme 22). In their study, the intermediate 1,3-propanediones **85** were synthesized in 5 min via dehydrative cyclization to the corresponding flavones and chromones **86** in ethanol, in the presence of $CuCl_2$ under microwave irradiation.

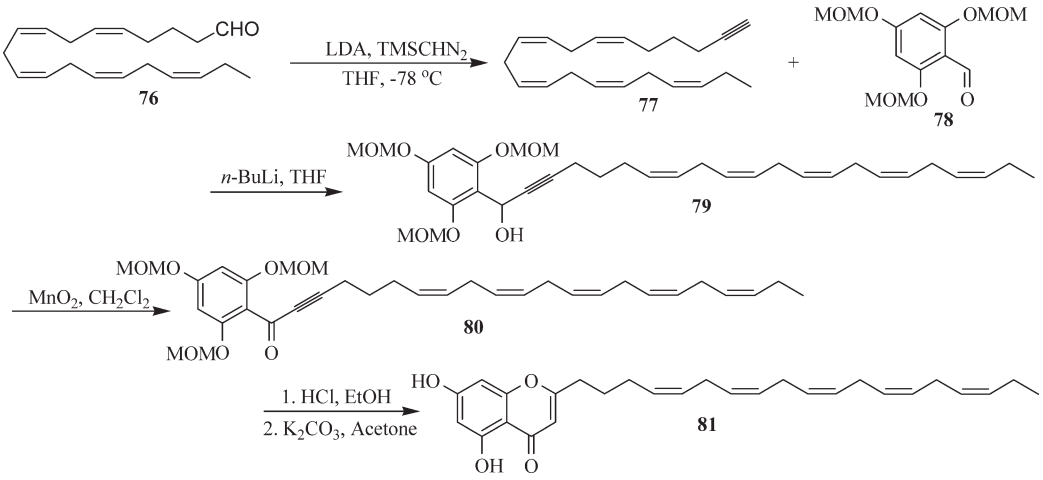
**Scheme 17**



**Scheme 19**



**Scheme 20**



In 2009, Luthman and coworkers. [77] reported a base-promoted condensation between 2-hydroxyacetophenones **87** and aliphatic aldehydes **88** (Scheme 23); they optimized the reaction to afford 2-alkyl-substituted 4-chromanones **89** in an efficient manner using microwave heating. Performing the reaction using diisopropylamine in EtOH at 170°C for 1 h gave high yield in 88%. The 4-chromanones could be further converted into highly functionalized 2,3,6,8-tetrasubstituted chromones in which a 3-substituent (acetate, amine, or bromine) was introduced via straightforward chemical transformations.

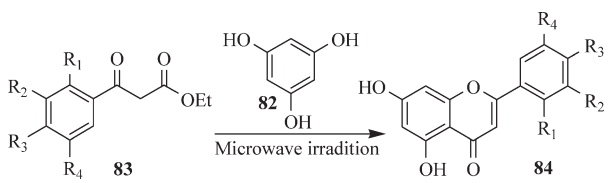
**Chromone ring closure via solid-support.** In recent years, solid-phase chemical reaction has appeared many advantages including good selectivity, high yield, simple operation, and no pollution, and some researcher has applied this method in chromone synthesis.

***Via solid-support catalysts.*** In 2002, Blanco and coworkers [78] studied the catalytic performance of MPA ($(H_3PMo_{12}O_{40}\cdot nH_2O)$ and TPA ($H_3PW_{12}O_{40}\cdot nH_2O$) (Scheme 24), both bulk or supported on silica (S), to obtain flavones and substituted chromones **96** from 1-(2-hydroxyphenyl)-3-aryl-1,3-propanediones **95**, using glacial acetic acid as solvent at 90°C. The result showed that the conversion to flavones and substituted chromones was in general higher in homogeneous phase than that observed for the supported catalysts. Nevertheless, the use of the supported catalysts enabled an easy separation and recovery of the catalyst for its immediate reuse without any important decrease of the catalytic activity. In addition, the unchanged starting material may be recycled to the reactor because it was almost quantitatively recovered and secondary products were not practically formed.

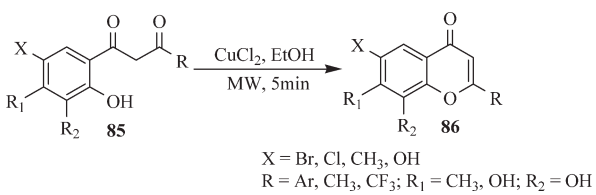
In 2005, van Lier and coworkers [79] explored silica gel-supported $InBr_3$ or $InCl_3$ (15–20 mol %) as a new solid-support catalysts for the facile and efficient oxidation, under solvent free conditions (Scheme 25), of 2′-hydroxychalcones **97** to yield the corresponding flavones **98** in >80% yield. The catalysts were easily prepared, stable, and efficient under mild reaction conditions.

Trifluoromethanesulfonic acid (TFMS) is known to be a strong acid, and it is used in many organic reactions such as Friedel Crafts reactions, polymerization, Koch carbonylation, among others [80]. However, the recovery of the triflic acid from the reaction mixture results in the formation of large amounts of waste [80]. So, in 2007, Romanelli and coworkers described the synthesis and characterization of TFMS supported on mesoporous titania [81] using urea as a low-cost, pore-forming agent (Scheme 26), via HCl catalyzed sol–gel reactions. The acidic characteristics of the solids were determined by potentiometric titration with *n*-butylamine. The use of these solid catalysts provided interesting yields in the cyclization reaction of 1-(2-hydroxyphenyl)-3-aryl-1,3-

**Scheme 21**

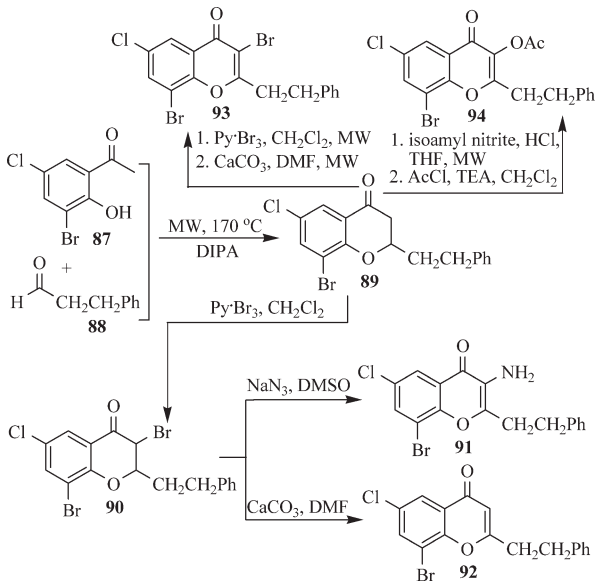


**Scheme 22**



X = Br, Cl, $CH_3$, OH
R = Ar, $CH_3$, $CF_3$; $R_1 = CH_3$, OH; $R_2$ = OH

**Scheme 23**

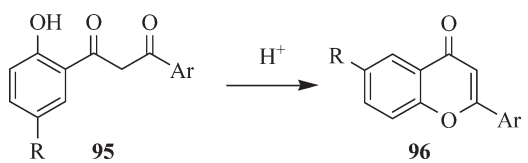


propanediones **99** to flavone **100**, also leading to an easy separation and recovering of the catalysts for further use.

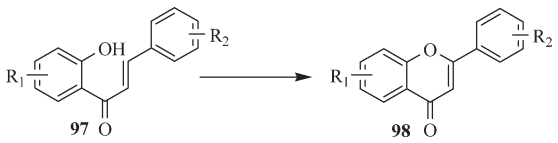
In 2009, Romanelli and coworkers [82] also prepared the $TFMSC_1$ and $TFMSC_2$ catalysts by adsorption of TFMS on two activated carbons with different textural properties used as supports (Scheme 27). The $TFMSC_2$ catalyst used as solid catalyst provided interesting yields in the cyclization reaction of 1-(2-hydroxyphenyl)-3-aryl-1,3-propanediones **101** to flavones and chromones **102**, also leading to an easy separation and recovery of the catalysts for further use. Moreover, as a significant decrease of the catalytic activity was not observed, they can be recycled without any activity loss.

***Solid-supported synthesis.*** In 2001, Borrell *et al*. [83] developed procedures for the synthesis of the solid-supported synthetic equivalents of chromones (Scheme 28). Treatment of the Wang chloro resin in DMA with 3 equiv of *o*-hydroxyacetophenone **103** and 3 equiv of NaOMe at 80°C overnight quantitatively afforded **104**. Compound **104** was then treated with DMF and $POCl_3$ under Vilsmeier–Haack reaction conditions affording chromone **105** as the major product. In this way, heterocyclic libraries could be effectively and rapidly synthesized.

**Scheme 24**

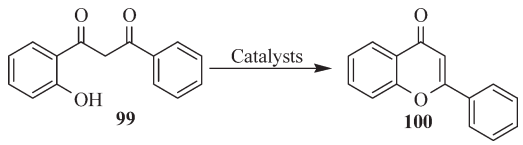


**Scheme 25**

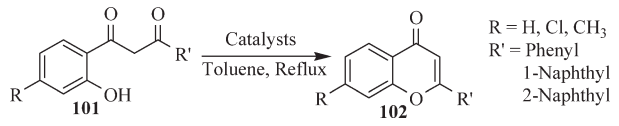


In 2004, Albericio and coworkers [84] described an effective solid-phase preparation of the pharmaceutically interesting 4*H*-2-(3-hydroxy-4-methoxyphenyl)-naphtho [1,2-*b*]pyran-1-one system from an anchored bisarylacetylene (Scheme 29). The coupling reaction between the resin **107** and acetylene **106** with $PdCl_2(PPh_3)_2$, CuI as catalyst, $Et_3N$ as base, and THF as solvent cleanly afforded the resin **108**. Then *O*-silylation of the MOM methoxy group with $Me_3SiBr$ followed by demethylation via nucleophilic attack of bromide gave the *O*-trimethylsilyl derivative. This compound was susceptible to further electrophilic addition by the triple bond and trapping of the resulting carbocation intermediate by atmospheric $H_2O$ then generated the keto group. Further oxidation gave the anchored compound **109**. Final cleavage with $AlCl_3$ rendered **110**. Through this solid-phase strategy, the quite rare 2-(aryl)naphtho[1,2-*b*]pyran-1-one was effectively synthesized. These compounds, like other polycondensed heterocyclic systems bearing electrondonating substituents, are of undoubted pharmaceutical interest. This solid-phase synthetic strategy will facilitate the preparation of libraries with applications in drug discovery.

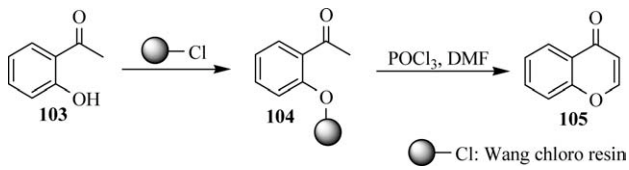
**Scheme 26**



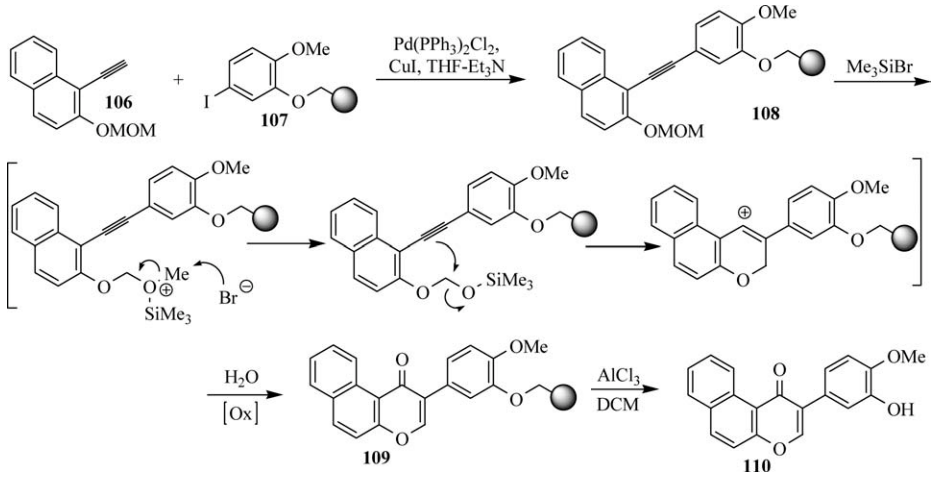
**Scheme 27**



**Scheme 28**



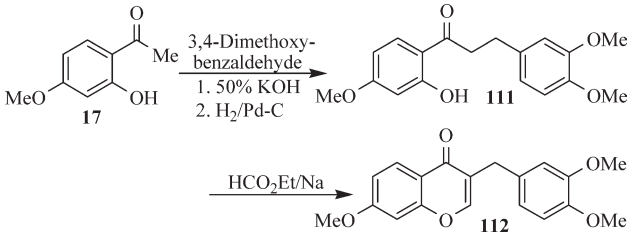
**Scheme 29**



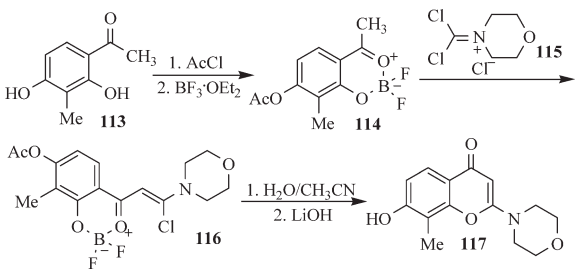
**Chromone ring closure through other methods.** Besides the above acid catalyst, base catalyst, microwave irradiation, and solid-supported synthesis in ring closure, there are many other catalysts and reaction conditions in this chromone construction.

***Sodium as a catalyst.*** In 1993, Davis and Chen [85] synthesized the chromone through a highly efficient procedure catalysted by sodium sand (Scheme 30). Heating 2-hydroxy-4-methoxyacetophenone (**17**) with 3,4-dimethoxybenzaldehyde in methanol using 50% aqueous KOH followed by hydrogenation over 10% palladium on activated carbon gave 2′-hydroxy-4′,3,4-trimethoxydihydrochalcone (**111**) in 89% overall yield. Treatment of **111** in ethyl formate with sodium sand at 0°C afforded chromone **112** in high yield. However, this reaction was not practical because the hot sodium sand was very dangerous during the reaction.

**Scheme 30**



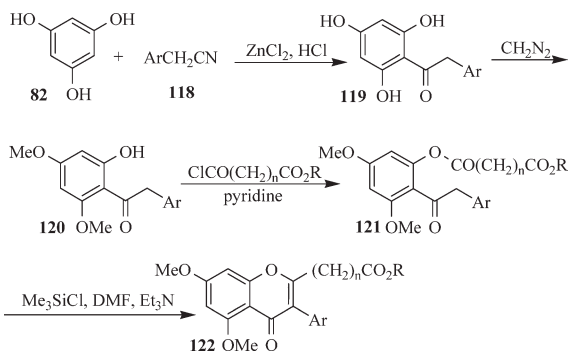
**Scheme 31**



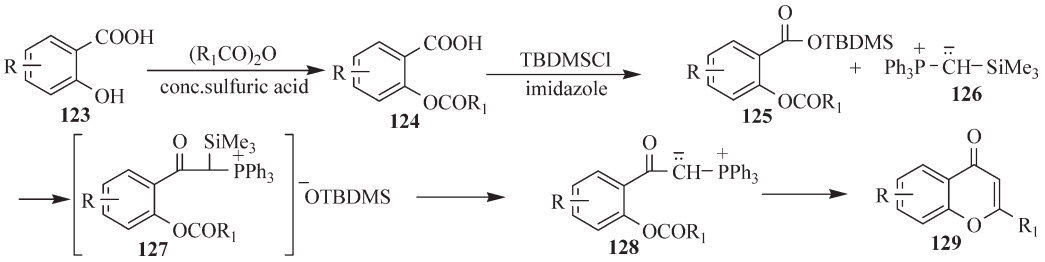
***Through basic hydrolysis.*** In 1993, Morris *et al*. [86] accomplished the preparation of chromone utilizing a novel synthesis of 2-aminochromones **117** via the condensation of $BF_2$ complexes of 2'-hydroxyacetophenones with phosgeniminium salts [87] (Scheme 31). Acetylation of **113** followed by treatment with $BF_3{\cdot}OEt_2$ afforded the $BF_2$ complex **114** in 76% overall yield. Reaction of **114** with 4-(dichloromethylene)morpholinium chloride (**115**) (65°C, 24 h) produced **116**. Liberation of the $BF_2$ complex ($H_2O$, $CH_3CN$) promoted cyclization to afford chromone **117** upon basic hydrolysis of the acetate protecting group (67% from **114**). Through this method, a side chain containing nitrogen atoms could be introduced into the chromone ring.

***$Me_3SiCl$ as a catalyst.*** In 1999, Pelter *et al*. [88] reported the synthesis of chromone ring via $Me_3SiCl$/DMF/$Et_3N$ (Scheme 32). Phloroglucinol **82** was reacted with 4-methoxybenzyl cyanide **118** by a modified procedure using catalytic $ZnCl_2$ to give **119** in 91% yield. Methylation of **119** with diazomethane in methanol readily gave **120** in which only the 2-hydroxyl group

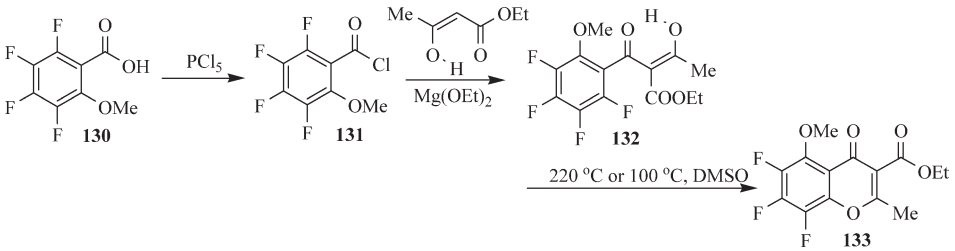
**Scheme 32**



**Scheme 33**



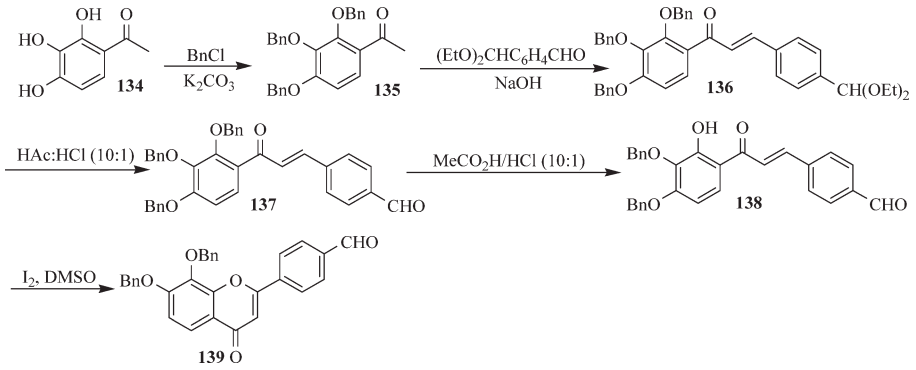
**Scheme 34**



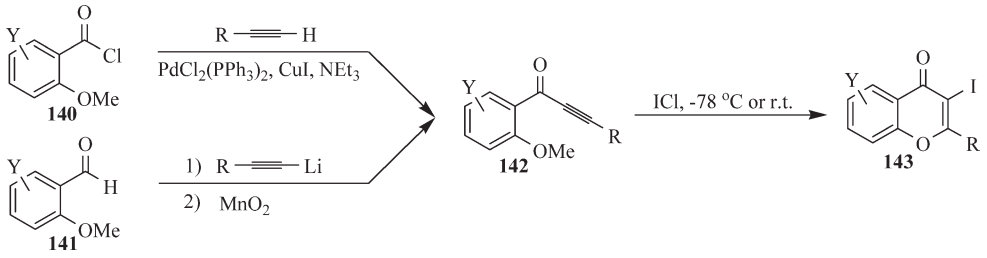
was free. Acylation of **120** gave the required esters **121**. A simple modification using $Me_3SiCl/DMF/Et_3N$ converted **121** to **122** in high yield.

***Via intramolecular ester carbonyl olefination.*** In 2000, Kumar and Bodas [89] reported a new and simple route to 4*H*-chromen-4-ones via intramolecular ester carbonyl olefination using (trimethylsilyl)methylenetriphenylphosphorane (Scheme 33). Salicylic acid or its substituted derivative **123** was converted into its *O*-acyl(aroyl) derivatives **124** by reaction with the corresponding anhydride. Compound **124** was then treated with *tert*-butyldimethylsilyl chloride in the presence of imidazole to furnish the corresponding silyl ester **125** in excellent yields. When a mixture of compound **125** and

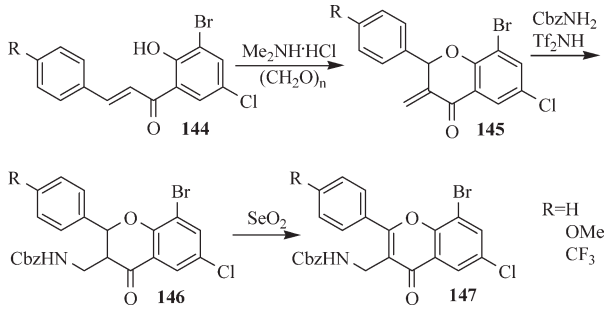
**Scheme 35**



**Scheme 36**



**Scheme 37**



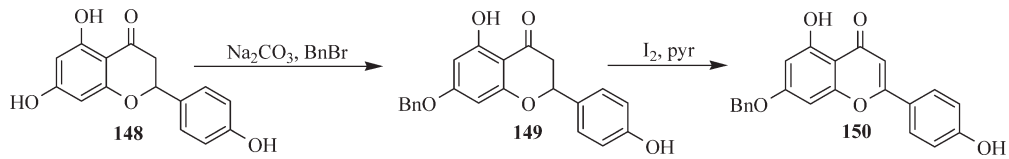
(trimethylsilyl)methylenetriphenylphosphorane **126** was heated in refluxing THF, the desired chromones **129** was obtained in 55–80% yields. This is the first report of chromone synthesis via intramolecular Wittig ester carbonyl olefination using (trimethylsilyl) methylenetriphenyl-phosphorane.

***Via heating.*** In 2001, Saloutin and coworkers [90] described the acylation of ethyl acetoacetate by the fluorobenzoyl chloride and synthesis of novel flurobenzopyran-2(4)-one (Scheme 34). 2-Dimethoxy-3,4,5,6-tetrafluorobenzoyl chloride **131** was obtained by heating the corresponding acid **130** with an excess of phosphorus pentachloride. Then, the interaction of fluorobenzoyl chloride **131** with ethyl acetoacetate in the presence of magnesium ethoxide resulted in β,β′-dioxaester **132**, which readily cyclized into chromone **133** on heating in the absence of solvents or in DMSO. The cyclization proceeded through intramolecular substitution of the *o*-fluorine atom in the fluorophenyl substituent.

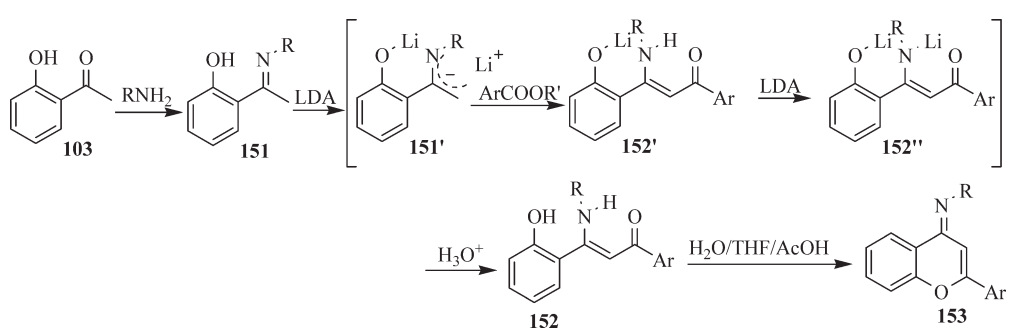
***Iodine as a catalyst.*** In 2004, Tomé and coworkers [91] reported the synthesis of chromone through iodine as a catalyst (Scheme 35). Benzylation of 2′,3′,4′-trihydroxyacetophenone **134** with benzyl chloride in the presence of potassium carbonate afforded the corresponding 2′,3′,4′-tribenzyloxy-acetophenone **135** in 90% yield. This compound was condensed with terephthalaldehyde mono(diethyl acetal) to give chalcone **136**. Hydrolysis of the acetal group furnished the formylchalcone **137**. Selective debenzylation of the 2-benzyloxy group was achieved by the treatment of **137** with a mixture of acetic acid and concentrated hydrochloric acid (10:1) for 1 h at 40°C. Finally, formylflavone **139** was obtained by oxidative cyclization of **138** in refluxing dimethylsulfoxide with a catalytic amount of iodine. This approach was widely used in chromone ring closure, and many synthesis have adopted this approach [92–95].

***Via ICl-induced cyclization.*** In 2006, Larock and coworkers [96] described the ICl-induced cyclization of heteroatom-substituted alkynones **142** (Scheme 36); this method provided a simple, highly efficient approach to various 3-iodochromones **143**. The 2-methoxyaryl-containing alkynones required were readily prepared in one or two steps by two complementary methods: (1) the palladium/copper-catalyzed Sonogashira coupling of an acid chloride **140** with a terminal acetylene at room temperature or 50°C [97] or (2) the addition of a lithium acetylide to an aldehyde **141**, followed by oxidation of the resulted secondary alcohol by activated $MnO_2$ [98]. This process was run under mild conditions, tolerated various functional groups, and generally provided chromones in good to excellent yields.

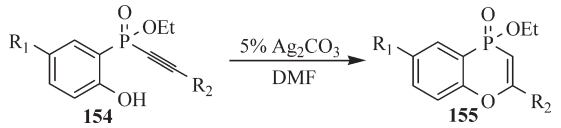
**Scheme 38**



**Scheme 39**



**Scheme 40**



***Under Mannich conditions.*** In 2007, Luthman and coworkers [99] developed an efficient synthetic route to Cbz-protected 3-aminomethyl-2-aryl-8-bromo-6-chlorochromones **147** (Scheme 37). In their synthetic route, 3-Aryl-1-(3-bromo-5-chloro-2-hydroxyphenyl)-2-propen-1-one **144** was reacted under Mannich conditions yielding 2-aryl-8-bromo-6-chloro-3-methylenechroman-4-one **145**, which was further converted to the target compound **147** via an aza-Michael reaction followed by an $SeO_2$ oxidation [100–103]. This procedure represented a new method to introduce a primary aminomethyl group at the 3-position of a 2-arylchromone scaffold.

***Through base-induced elimination.*** In 2009, Rizzacasa and coworkers [104] described the synthesis of chromone through Iodination of naringenin followed by base-induced elimination (Scheme 38). This began with selective benzylation of naringenin (**148**) on the more acidic C7 phenol to afford benzyl ether **149**. Iodination followed by base-induced elimination gave the flavone **150** in a reasonable yield for the two steps.

**Synthesis of heterocycle analog of chromone.** The chromones have gained considerable synthetic and pharmacological interest for a long time because of their diverse biological activities, and recent studies have indicated that a lot of natural heterocycle analog containing phosphorus, sulphur, and nitrogen also show the expected bioactivity, so many synthesis of heterocycle analog of chromone have been reported with high regioselectivity and good yields.

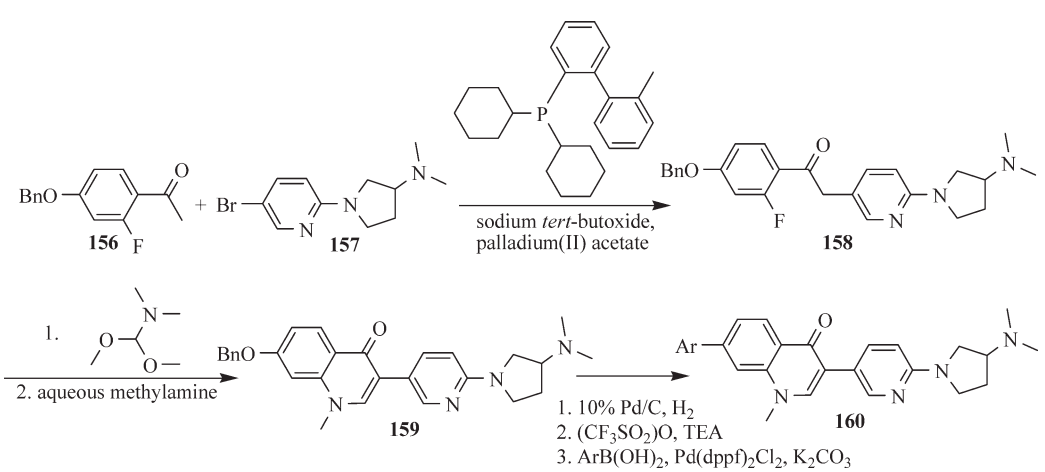
***Synthesis of 4H-Chromen-4-ylidenamines.*** 4*H*-Chromen-4-ylidenamines **153** were derivatives of chromones, that have awakened new interest because the simplest of them (2-phenyl-*4H*-chromen-4-imine), has been used [105] for treatment of cell proliferative diseases and for its antihypoxic, hypotensive, and antiallergic properties. So, in 2000, Palmieri's group [106] described a method to obtain 4*H*-chromen-4-ylidenamines **153** (Scheme 39). The reaction of *o*-imidoyl phenol dianions **151′** with aromatic esters and subsequent acid cyclization of the 3-(2-hydroxyphenyl)-3-(amino)-1-phenylprop-2-en-1-ones **152** afforded *4H*-chromen-4-ylidenamines **153** in satisfactory yields, a class of compounds of renewed interest.

***Synthesis of phosphachromones.*** Because there was a remarkable similarity in reactivity and bioactivities between the carbon species and their phosphorus counterparts [107,108], one can anticipate that the phosphachromone analog of chromone would have potential bioactivities similar to those of chromones, so in 2008, Ding and coworkers [109] reported a novel $Ag_2CO_3$-catalyzed cyclization reaction of *O*-hydroxyphenylethynylphosphinates **154** to phosphachromones **155** with high regioselectivity and good yields (Scheme 40), which provided an effective approach to synthesize the new kind of phosphorus heterocycles.

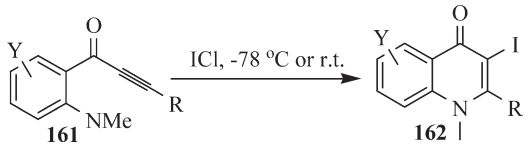
***Synthesis of quinolones.*** In 2006, Dyck and coworkers [110] reported the synthesis of the quinolone derivatives (Scheme 41). Bromopyridine **157** was coupled to 4′-benzyloxy-2′-fluoroacetophenone **156** to provide **158**. Aminomethylenation with dimethylformamide dimethyl acetal provided the precyclization intermediate which, upon reaction with methylamine, provided the quinolone core (**159**). Removal of the benzyl protecting group gave the phenol, which was converted to the triflate and coupled with aryl boronic acids to provide the target quinolones **160**.

In 2006, Larock and coworkers [96] described the ICl-induced cyclization of nitrogen-substituted alkynones **161** to afford the quinolones **162** in good to excellent yields (Scheme 42).

**Scheme 41**



**Scheme 42**



In 2008, Nam and coworkers [111] reported the synthesis of quinolinone as they designed and synthesized the 4-quinolinone 2-carboxamides as calpain inhibitors (Scheme 43). Diethyl oxalpropionate (**163**) was condensed with aniline in acetic acid to give anilino-maleate **164**. Compound **164** was heated at 250°C in mineral oil to form the cyclized product, quinolinone **165**.

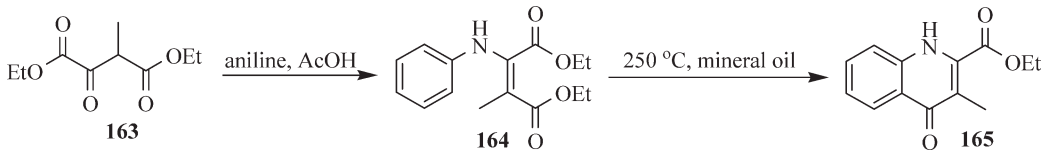
***Synthesis of thioflavones.*** In 2004, Kataoka *et al*. [112] reported the synthesis of thioflavones as they studied the SARs of thioflavone derivatives as specific inhibitors of the ERK-MAP kinase signaling pathway (Scheme 44). Condensation of benzaldehydes **166** with α-benzoyl sulfoxide **167** gave α-sulfinyl enones **168** in good yields. Cyclization of **168** followed by debenzylation was performed by the treatment with formic acid at 5°C to give 3-(methylsulfinyl)-2,3-dihydro-4*H*-1-benzothiopyran-4-ones **169** as a mixture of diastereoisomers. Refluxing the diastereomer mixtures of **169** in benzene caused the elimination of methanesulfenic acid to form thioflavones **170**.

In 2006, Larock and coworkers [96] described the ICl-induced cyclization of sulphur-substituted alkynones **171** to give various 3-iodo-thiochromones **172** in good to excellent yields (Scheme 45).

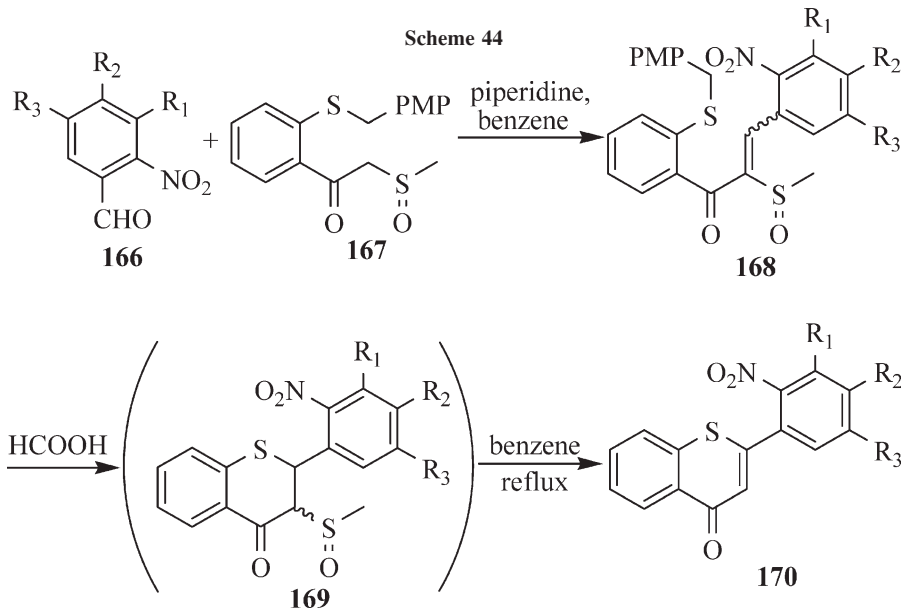
## CONCLUSIONS

Chromone derivatives have high potential in drug discovery. Synthesis of large compound libraries is a general trend in a modern drug discovery process. Furthermore, computer-aided drug design can be used to perform virtual screening before the compounds are synthesized. Both methodologies require rapid synthesis of the compounds preferably from a limited number of starting materials. So, in recent years, a lot of synthetic method to construct the chromone ring appeared. In this review, some recent improvements of the classical synthetic methods and of some nonclassical methods to obtain simple oxygenated chromones have been reported, which includes acid as catalyst, base as catalyst, microwave irradiation assisted synthesis, solid-supported synthesis, and other methods. Furthermore, recent studies have indicated that a lot of natural heterocycle analog containing phosphorus, sulphur, and nitrogen also show the expected bioactivity, so many synthesis of heterocycle analog of chromone have been reported with high regioselectivity

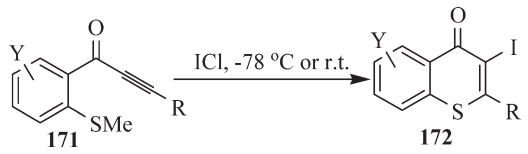
**Scheme 43**



**Scheme 44**



**Scheme 45**



and good yields. So, the strategies for synthesis of heterocycle analog containing phosphorus, nitrogen, and sulfur are also summarized in this review. We hope this review will stimulate interest in the synthesis of chromone with biological activities in the near future.

The interaction of both 2-iminocoumarin-3-carbonitriles and 2-iminocoumarin-3-carbothioamides with 2-aminothiophen-3-carboxamides lead to formation of 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins in two steps. The simplicity of the procedure, as well as the high yields of the target products make this method to be a good alternative of Knoevenagel condensation for the synthesis of 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins.

*J. Heterocyclic Chem.*, **47**, 800 (2010).

## INTRODUCTION

3-Substituted-2-iminocoumarins are known not only due to their versatile biological activity, such as anti-inflammatory [1,2], antimicrobial, antifungal [3,4], and antitumor [5–9], but also as luminescent indicators [10] and laser dyes [11–13]. They can also be useful as effective reagents for 2-substituted 2*H*-1-benzopyrans syntheses [14]. Therefore, the development of a simple methodology for synthesis 2-iminocoumarins substituted with heterocyclic moiety at position 3 is important problem of benzopyrans chemisrty.

With regard to the pharmacological potential of thieno[2,3-*d*]pyrimidines [15–24] as the part of our research work on the synthesis of 3-heteryl-2-iminocoumarins [25,26], we focused our efforts on the synthesis of 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins.

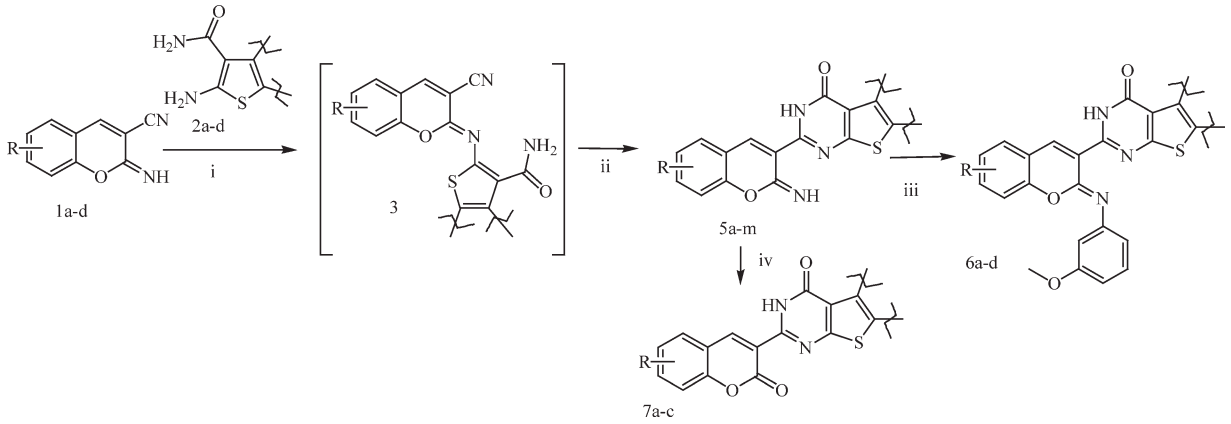
The most commonly used method for synthesis of 3-heteryl-2-iminocoumarins is the Knoevenagel condensation of salicylic aldehydes with nitriles of heterylacetic acids [27–30]. However, for synthesis of 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins this approach is not convenient enough due to the difficulties in the starting building-blocks, the corresponding 2-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)acetonitriles, preparation [31]. With the aim to develop more suitable method, we tested the alternative route for synthesis of 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins based on intramolecular rearrangement of 2-iminocoumarins, so-called ''recyclization'' approach.

Recently it was shown that ''recyclization'' of 2-iminocoumarin-3-carboxamides under the action of binucleophlic reagents results in various 3-heterylcoumarins [25,26,32–37]. According to the proposed mechanism of these reactions the carboxamide group of 2-iminocoumarin-3-carboxamide serves as precursor of lactone C=O group of the resulting 3-heterylcoumarin. Thus, it was worthy to assume that utilization of 2-iminocoumarin-3-carbonitriles in a similar rearrangement would lead to the formation of products with the C=NH moiety in the 2 position of benzopyran ring. Therefore, we studied the interaction between 2-iminocoumarin-3-carbonitriles and 2-aminothiophen-3-carboxamides as the possible convenient approach for synthesis of desired 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins.

## RESULTS AND DISCUSSION

It is known that the interaction of 2-iminocoumarin-3-carboxamides with arylamines in the glacial acetic acid leads to formation of 2-*N*-aryliminocoumarin-3-carboxamides [34–38]. We applied a similar reaction to obtain the key-intermediates, which apparently were 2-(3-carbamoyl-2-thienylimino)-coumarin-3-carbonitriles **3** by interaction between 2-iminocoumarin-3-carbonitriles 1

**Scheme 1**



and 2-aminothiophen-3-carboxamides 2. The compounds **3** were isolated from glacial acetic acid as red solids and used without any additional purification.

The ''recyclization'' of 2-(3-carbamoyl-2-thienylimino)coumarin-3-carbonitriles **3** was performed by heating in DMF. The anhydrous solvent was used to avoid hydrolysis of the imino group of product **5** formed (Scheme 1). The proposed mechanism of ''recyclization'' reaction is depicted on the Scheme 2.

The compounds **5a–m** were obtained in the high yields (65–89%) (Method A).

In the $^1$H NMR spectra of the compounds **5a–m**, the signal of proton in the position 4 of coumarin resonate in the range δ 8.66–8.83 ppm, as well as the signal of imino group proton (δ 9.31–9.51 ppm) and aromatic protons (δ 7.20–7.94 ppm) are present. All these spectra also contain signal of thieno[2,3-*d*]pyrimidine fragment NH (14.08–14.50 ppm). Though the LC/MS spectra for compound **5** show their high purity, in most cases the $^1$H NMR spectra of derivatives **5** in DMSO-$d_6$ contain some additional signals, possibly from the open form of the iminolactone ring.

The IR-spectra (KBr) of the compounds **5a–m** have the strong absorption bands of υ C=O and υ C=N at 1700–1621 cm$^{-1}$, the broad band of υ N—H (pyrimidine and imino-group) at 3500–3150 cm$^{-1}$. In the spectra of the products **5**, the signal of υ CN is absent comparatively with the spectra of intermediates 3 (2240–2220 cm$^{-1}$).

Unfortunately the compounds **5** appeared to be slightly soluble in the suitable solvents to measure $^{13}$C NMR spectra. Thus with the aim to prove the presence of imino-group in the molecule of these derivatives we performed their acidic hydrolysis (HCl) in 2-propanol-water mixture. The obtained products appeared to be the same as previously reported 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)coumarins **7a–c** [34–36] (Table 1).

Also the presence of the imino group in the structure of **5** allowed us to obtain 2-*N*-aryliminoproducts **6** (using reaction of **5** with *m*-anisidine in glacial acetic acid) as crystalline substances.

In the $^1$H NMR spectra of the compounds **6a–d** the signals of methoxygroup (3.76–3.78 ppm) and aromatic protons (6.73–7.53 ppm) of 3-methoxyphenyl substituent appear.

The crystals of compound **6a** appeared to be suitable for X-ray diffraction analysis after the crystallization from DMF. In the crystal phase of the compound **6** was observed as hemisolvate with DMF.

According to X-ray diffraction data the 2-minocoumarin fragment and 4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin fragment are coplanar within 0.04 Å (Fig. 1). Such arrangement of these fragments relatively each other is stabilized by the formation of the N(2)—H(2N)...N(3) intramolecular hydrogen bond (H...N 1.96 Å N—H...N 138°) and the H(19)...N(1) attractive interaction (2.39 Å when compared with the van der Waals radii sum [39] 2.67 Å). The

[a] Isolated yields of **5** based on **1** used (Method A); Isolated yields of **6** and **7** based on **5** used.

tetrahydrocycle is disordered over two half-chair conformation (A and B) with population 75:25%. Deviations of the C(4) and C(5) atoms from the mean plane of the remaining atoms of the ring are −0.50 and 0.19 Å, respectively for conformer A and 0.31 and −0.47 Å, respectively for B. The methoxyphenyl substituent is located in the cis-conformation relatively the C(12)—O(2) bond [the C(20)—N(3)—C(12)—O(2) torsion angle is 1.7(5)°] and it adopts –sc conformation relatively the C(12)—N(3) bond [the C(12)—N(3)—C(20)—C(25) torsion angle is -43.4(5)°]. The methoxy group is coplanar to the plane of the aromatic ring [the C(26)—O(3)—C(24)—C(25) torsion angle is 2.0(6)°].

The structures of the products 6 have been also confirmed using elemental analyses, IR, and LC/MS-spectra.

Following the mechanism of ''recyclization'' reaction, we tested whether the 2-iminocoumarin-3-carbothioamides were suitable precursors for 2-thiocoumarins synthesis. We obtained the intermediate 2-(3-carbamoyl-2-thienylimino)-coumarin-3-carbothioamides **9** by reaction of 2-iminocoumarin-3-carbothioamides **8** [40] with 2-aminothiophen-3-carboxamides **2** in glacial acetic acid. Further ''recyclization'' have been performed by heating compounds **9** in DMF. Though instead of the desired 2-(2-thiocoumarin-3-yl)thieno[2,3-*d*]pyrimidin-4-ones **10** 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins **5** were isolated (Scheme 3). Thus it can be deduced that in this case the hydrogen sulfide cleavage is preferable way for recyclization the 2-iminocoumarin-3-carbothioamides (Scheme 4) (Method B).

## CONCLUSION

It was established that interaction of both 2-iminocoumarin-3-carbonitriles and 2-iminocoumarin-3-carbothioamides with 2-aminothiophen-3-carboxamides after the rearrangement of arylimino intermediates lead to formation of 3-(4-oxo-3,4-dihydrothieno[2,3-*d*]pyrimidin-2-yl)-2-iminocoumarins. The simplicity of the proposed procedure as well as the high yields of the target products make this method to be a good alternative of Knoevenagel condensation for the synthesis of derivatives **5**. The further reaction of **5** with *m*-anisidine allowed us to obtain 2-(2-(3-methoxyphenylimino)-coumarin-3-yl)thieno[2,3-*d*]pyrimidin-4-ones **6**.

## EXPERIMENTAL

Melting points were measured with a Buchi B-520 melting point apparatus and were not corrected. Elemental analyses were within ± 0.4% of the theoretical value. IR spectra were recorded on Specord M80 spectrometers in KBr. $^1$H NMR spectra were recorded on Varian Mercury-200 spectrometer in DMSO-$d_6$ and $CDCl_3$ using TMS as an internal standard. Mass spectral analyses were obtained on a PE SCIEX API 150EX mass spectrometer.

**X-ray study.** The colourless crystals of 6a ($C_{26}H_{20}N_3O_3SCl$ 0.5 $C_3H_7NO$) are triclinic. At 293 K, $a$ = 8.760(1), $b$ = 11.321(1), $c$ = 13.895(1) Å, α = 86.85(1)°, β = 83.36(1)°, γ = 85.46(1)°, $V$ = 1363.0(3) Å$^3$, $M_r$ = 562.0, $Z$ = 2, space

group $P\bar{1}$, $d_{calc}$ = 1.282 g/cm$^3$, μ(MoK$_\alpha$) = 0.253 mm$^{-1}$, $F(000)$ = 547. Intensities of 7751 reflections (4600 independent, $R_{int}$ = 0.038) were measured using the ''Xcalibur-3'' diffractometer (graphite monochromated MoK$_\alpha$ radiation, CCD detector, ω-scanning, $2T_{max}$ = 50°). The structure was solved by direct method using SHELXTL package [41]. The restrains for bond lengths in the disordered fragment were applied during refinement ($Csp^2$—$Csp^3$ 1.51 Å, $Csp^3$—$Csp^3$ 1.54 Å). Positions of the hydrogen atoms were located from electron density difference maps and refined by ''riding'' model with $U_{iso}$ = $nU_{eq}$ of the carrier atom ($n$ = 1.5 for methyl group and $n$ = 1.2 for other hydrogen atoms). Full-matrix least-squares refinement against $F^2$ in anisotropic approximation for nonhydrogen atoms using 4517 reflections was converged to $wR_2$ = 0.191 ($R_1$ = 0.063 for 2815 reflections with F > 4σ($F$), $S$ = 1.156). The final atomic coordinates, and crystallographic data for molecule 6a have been deposited to with the Cambridge Crystallographic Data Centre, 12 Union Road, CB2 1EZ, UK and are available on request quoting the deposition numbers CCDC 705029.

**2-Iminocoumarin-3-carbonitriles.** 1a–d were obtained starting of malononitrile by interaction with corresponding salicylic aldehydes [42]. 2-Iminocoumarin-3-carbothioamides **8a-c** were synthesized by interaction of salicylic aldehydes of 2-cyanoethanethioamide [40].

**2-Iminocoumarin-3-carbonitrile (1a).** This compound was obtained in 65% yield as a yellow solid, mp 160–162°C; IR (cm$^{-1}$): 3293, 3038, 2228, 1651, 1601, 1450; $^1$H NMR ($CDCl_3$): δ 7.12 (m, 2 H), 7.32 (d, $J$ = 6.41 Hz, 1 H), 7.46 (t, $J$ = 7.63 Hz, 1 H), 7.64 (br.s, 1 H), 7.70 (br.s, 1 H); Anal. calcd. for $C_{10}H_6N_2O$: H, 3.34; C, 55.36; N, 10.33. Found: H, 3.20; C, 55.08; N, 10.14.

**6-Chloro-2-Iminocoumarin-3-carbonitrile (1b).** This compound was obtained in 72% yield as a yellow solid, mp 172–174°C; IR (cm$^{-1}$): 3307, 3046, 2233, 1649, 1599, 1478; $^1$H NMR ($CDCl_3$): δ 7.09 (d, $J$ = 8.85 Hz, 1 H), 7.37 (d, $J$ = 2.14 Hz, 1 H), 7.47 (dd, $J$ = 8.85, 2.44 Hz, 1 H), 7.69 (br.s, 1 H), 7.80 (br.s, 1 H); Anal. calcd. for $C_{10}H_5ClN_2O$: H, 3.15; C, 53.66; N, 10.01. Found: H, 3.22; C, 53.33; N, 9.77.

**2-Imino-8-methoxy-coumarin-3-carbonitrile (1c).** This compound was obtained in 70% yield as a yellow solid, mp 165–167°C; IR (cm$^{-1}$): 3287, 3054, 2226, 1651, 1607, 1477; $^1$H NMR ($CDCl_3$): δ 3.84 (s, 3 H), 6.89 (d, $J$ = 6.71 Hz, 1 H), 7.05 (m, 2 H), 7.67 (br.s, 1 H), 7.78 (br.s, 1 H); Anal. calcd. for $C_{11}H_8N_2O_2$: H, 3.44; C, 54.95; N, 10.05. Found: H, 3.40; C, 54.70; N, 9.82.

**8-Ethoxy-2-iminocoumarin-3-carbonitrile (1d).** This compound was obtained in 78% yield as a yellow solid, mp 161–163°C; IR (cm$^{-1}$): 3320, 3036, 2228, 1655, 1604, 1467; $^1$H NMR ($CDCl_3$): δ 1.36 (t, $J$ = 6.71 Hz, 3 H), 4.03 (q, $J$ = 6.71 Hz, 2 H), 6.84 (m, 1 H), 6.98 (m, 2 H), 7.61 (br.s, 1 H) 7.71 (br.s, 1 H); Anal. calcd. for $C_{12}H_{10}N_2O_2$: H, 3.57; C, 55.33; N, 9.93. Found: H, 3.31; C, 55.25; N, 9.67.

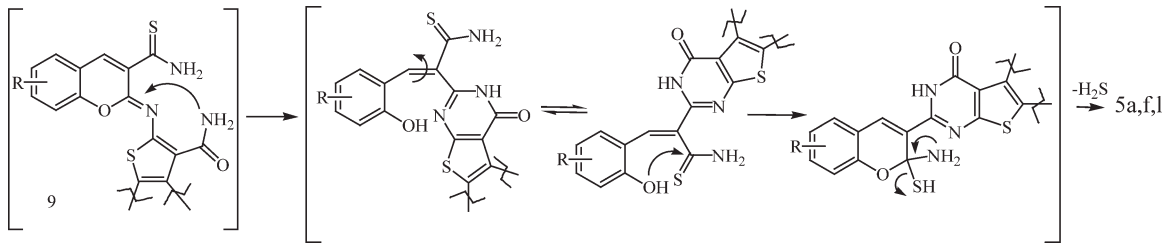
**2-Aminothiophene-3-carboxamides.** 2a–d were obtained from cyclohexanone, 4-methyl-cyclohexanone, and *N*-substituted piperidin-4-ones according to the Gewald procedure [43–45].

**2-Amino-6-methyl-4,5,6,7-tetrahydro-1-benzothiophene-3-carboxamide 2(b).** This compound was obtained in 62% yield as a colorless solid, mp 187–189°C; IR (cm$^{-1}$): 3400, 3259, 3180, 2944, 1632, 1584, 1561, 1499; $^1$H NMR (DMSO-$d_6$): δ 0.97 (t, $J$ = 6.22 Hz, 3 H), 1.25 (m, 1 H), 1.74 (m, 2 H), 2.05 (m, 1 H), 2.58 (m, 2 H), 3.31 (br.s, 1 H), 6.49 (br.s, 2 H), 6.87 (s, 2 H).

**6-Acetyl-2-amino-4,5,6,7-tetrahydrothieno[2,3-*c*]pyridine-3-carboxamide 2(c).** This compound was obtained in 65% yield as a colorless solid, mp 250–252°C; IR (cm$^{-1}$): 3497, 3394, 3280, 3159, 1651, 1563, 1480; $^1$H NMR (DMSO-$d_6$): δ 2.01, 2.05 (s, 3 H), 2.63 (br.s, 2 H), 2.73 (br.s, 2 H), 3.57 (br.s, 2 H), 4.35, 4.39 (s, 2 H), 6.56 (br.s, 2 H), 6.92 (s, 1 H), 6.98 (s, 1 H).

**Ethyl 2-amino-3-(aminocarbonyl)-4,7-dihydrothieno[2,3-*c*] pyridine-6(5*H*)-carboxylate 2(d).** This compound was obtained in 60% yield as a colorless solid, mp 185–187°C; IR

**Scheme 4**



($cm^{-1}$): 3431, 3365, 3319, 3172, 1690, 1638, 1572, 1427; $^1H$ NMR (DMSO-$d_6$): δ 1.18 (t, $J$ = 7.32 Hz, 3 H), 2.68 (t, $J$ = 5.49 Hz, 2 H), 3.55 (t, $J$ = 5.49 Hz, 2 H), 4.06 (q, $J$ = 7.32 Hz, 2 H), 4.29 (s, 2 H), 6.48 (s, 2 H), 6.88 (s, 2 H).

**General procedure for the preparation of 2-(2-iminocoumarin-3-yl)thieno[2,3-*d*]pyrimidin-4-ones 5a–m.** To the warm (40–50°C) solution of 2-aminothiophene-3-carboxamide 2 (2 mmol) in glacial acetic acid (3 mL) the solution of either 2-iminocoumarine-carbonitrile 1 (Method A) or 2-iminocoumarine-3-carbothioamide 8 (Method B) (2 mmol) in glacial acetic acid (3 mL) was added and the mixture was heated at 70–80°C for 30 min. Then the reaction mixture was cooled. The precipitate that formed was collected by filtration and dried. The product **3** (Method A) or **9** (Method B) was dissolved in DMF (5 mL) at 140–150°C and heated for 3 h. The precipitate of **5** formed after cooling was filtered out, washed with 2-propanol and dried.

**2-(2-Iminocoumarin-3-yl)-5,6,7,8-tetrahydro-benzo[4,5]-thieno[2,3-*d*]pyrimidin-4-one (5a).** This compound was obtained in 74% yield (Method A) and 72% (Method B) as a red solid, mp 280–282°C; IR ($cm^{-1}$): 3451, 3156, 2932, 2846, 1654, 1615, 1535, 1473; $^1H$ NMR (DMSO-$d_6$): δ 1.72 (br.s, 4 H), 2.63 (br.s, 2 H), 2.79 (br.s, 2 H), 7.21 (m, 2 H), 7.53 (t, $J$ = 6.7 Hz, 1 H), 7.79 (d, $J$ = 6.4 Hz, 1 H), 8.71 (s, 1H, H-4), 9.31 (br.s, 1H, =NH), 14.17 (br.s, 1H, -NHCO); lcms: m/z ($MH^+$) 350. Published online 4 June 2010 in Wiley InterScience (www.interscience.wiley.com).

Tetrahydrocarbazoles **4** obtained from phenylhydrazines and cyclohexanones gave by cyclocondensation with 2-substituted malonates **5** in all cases 4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1-*jk*]carbazol-6-ones **6** by attack at the nitrogen and the aromatic ring of tetrahydrocarbazoles **4**; the direction of the cyclization was not dependent on substituents either in the aromatic or the saturated ring; isomeric pyridocarbazoles could not be isolated. Electrophilic substitutions of pyridocarbazoles **6** under mild conditions took place exclusively at the 5-position and gave pyridocarbazolediones **9**-**11** with 5-nitro-, 5-hydroxy or 5-chloro-substituents. Exchange of the chloro substituent in **11** gave 5-azido- and 5-amino products **12**, **14** or **16**. Reactions at the aromatic ring were not observed. Chlorination of 4-hydroxypyridocarbazoles **6** with phosphoryl chloride by nucleophilic substitution took place exclusively at the 4-position and gave 4-chloropyridocarbazolones **17**, which were further reacted to azides and amines **18, 19**.

*J. Heterocyclic Chem.,* **47**, 807 (2010).

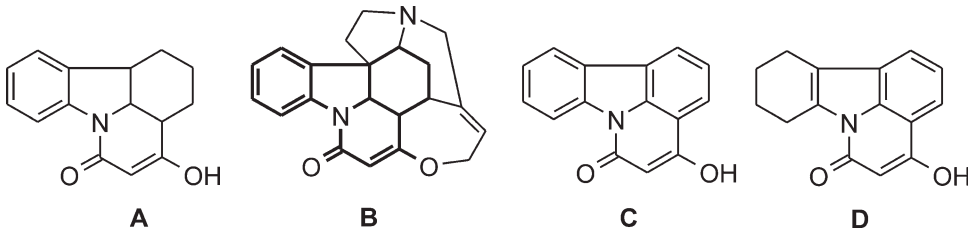
## INTRODUCTION

Tetrahydropyrido[3,2,1-*jk*]carbazol-6-one **A** is part of the heterocyclic skeleton of many natural products (*e.g.* strychnos alkaloids such as strychninolones **B** [1] and derivatives such as brucinolones [2] and vomicin [3]). It possesses the biologically interesting combination of an indole and a 2-pyridone structure. Moreover, some derivatives have found interest in pharmacological investigations [4]. Recently, we published the synthesis and reactions of pyrido[3,2,1-*jk*]carbazol-6-ones **C** with two aromatic rings [5]. In this article, we report about the synthesis and reactions of tetrahydropyrido [3,2,1-*jk*]carbazol-6-ones **D** having partial structures more similar to the natural products (Scheme 1).

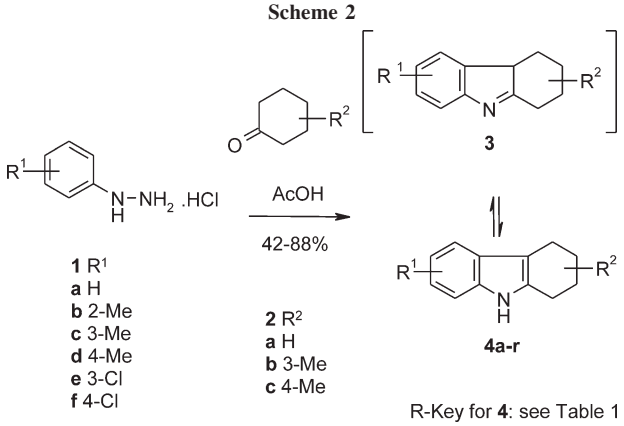
## RESULTS AND DISCUSSION

Our approach to the tetrahydro-pyridocarbazole system started with the synthesis of 2,3,4,5-tetrahydro-1*H*-carbazoles **4** with suitable substituents at the desired positions. Despite numerous reactions and catalysts described in the literature, such as the cyclization of cyclohexanone phenylhydrazones [6] or 2-phenylcyclohexanone oxime [7], the reaction of 2-chlorocyclohexanone [8] or 2-hydroxycyclohexanone with aniline [9], or the hydrogenation of carbazole [10], we found that an adapted version of a long-known procedure from Ref. [11] gave the best and simplest approach. Our synthetic approach started from phenylhydrazines **1** and cyclohexanones **2** in acetic acid as solvent without isolation of

**Scheme 1**



**Scheme 2**



phenylhydrazones, and we combined this reaction with a one-pot release of chloro- and methyl substituted phenylhydrazines **1**, which are commercially available only as hydrochlorides. The cumbersome release of oily and sensitive free phenylhydrazine bases could be skipped, when sodium acetate was added to the reaction mixture which gave *in situ* the desired phenylhydrazines. Excess sodium acetate and formed sodium chloride was removed at the end of the reaction during work-up by precipitation with diethyl ether.

To study the influence of substituents at the aromatic ring, chloro- and methyl-phenylhydrazines **1** were reacted with cyclohexanones **2** to synthesize a series of

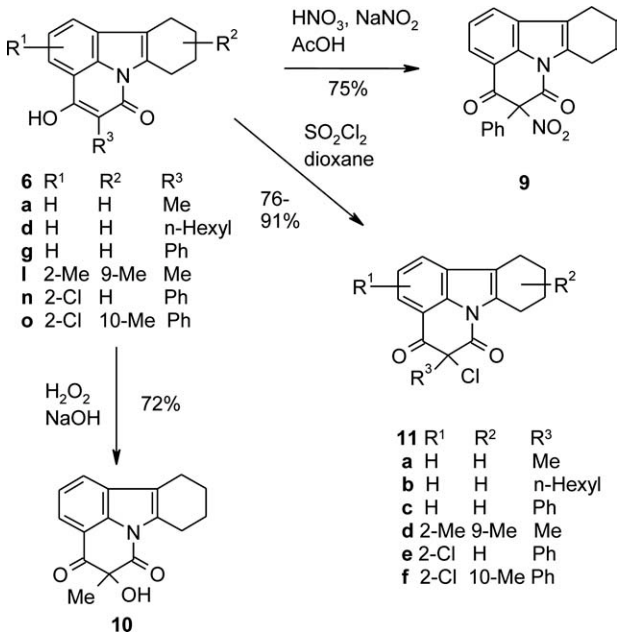
**Scheme 4**



tetrahydrocarbazoles with methyl- and chloro substituents in the aromatic ring and methyl substituents in the saturated ring. The structure could be assigned to **4**, as evident from $^1$H NMR spectra with clear 9-NH signals ranging between 10.4 and 10.8 ppm, and no hydrogen signal of a 4a-proton present in the possibly formed isomeric structure **3**. 2-Methylcyclohexanone (**2**, $R^2$ = 2-Me) gives, depending on the reaction conditions, a mixture of both isomers of **3** and **4**, 1- or 4a-methyl-tetrahydrocarbazole [12]; the work on these topics is in progress [13]. 3-Methylcyclohexanone (**2b**) gave 2-methyl-tetrahydrocarbazoles **4e, h, i, k, n, q**, as evident from the $^1$H NMR signal of 4-$CH_2$ at ~2.6 ppm and of the 2-CH at ~1.4 ppm; the corresponding 4-methyl isomer could not be isolated. From 3-methylphenylhydrazine (**1c**) we isolated both isomers, 7-methyl-tetrahydrocarbazoles **4f,h** and 5-methyl derivatives **4g,i** in a ratio of about 10:1 (Scheme 2).

The cyclocondensation reaction of **4** was performed with ethyl 2-alkyl- and 2-phenylmalonates **5a-h**. $^1$H NMR spectral data revealed that in all cases the ring closure was directed to the aromatic ring to produce 4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1-*jk*]carbazol-6-ones **6** as evident from the ratio of aromatic: aliphatic protons and unaffected $CH_2$ groups in position 8. 6-Chloro-tetrahydrocarbazoles **4m-o** did not show significant influence on the synthesis and gave 2-chloro-pyridocarbazoles **6n-p**. 7-Chloro-tetrahydrocarbazoles **4p-r** gave, probably by deactivation of the aromatic nucleus, very low yields or unseparable mixtures which did not allow the isolation of pure 3-chloro-pyridocarbazoles **6**; the isolation of possibly formed isomers **7/8** was not achieved.

6-Methyl-tetrahydrocarbazoles **4c-e** formed in reasonable yields 2-methyl-pyridocarbazoles **6k-m**. 8-Methyl-tetrahydrocarbazoles **4j-l** prevented the formation of pyridocarbazoles **6** by steric hindrance, but gave again no reaction to isomeric pyridocarbazoles **7/8**.

The yields of pyridocarbazoles **6a-j** without substituents in the aromatic carbazole nucleus were ranging from 20 to 80%. The cyclization reaction proceeds in two steps via an initial malono-monoamide followed by formation of a thermally produced ketene derivative which cyclizes in an electrophilic substitution towards the aromatic carbazole ring [14]. The differing yields can be explained by both a competing malono-diamide formation and side-reactions during the ketene reaction.

There are some other reaction sequences known using highly reactive malonic acid derivatives, which avoid the high temperatures of the second ketene forming step: one of these derivatives is the well established *bis*(2,4,6-trichlorophenyl) malonate (active malonate, magic malonate) [15], another one is (chlorocarbonyl)ethylketene (chlorocarbonylketene, in older literature also named as malonyldichloride) [16]. We compared the reactions of *bis*(2,4,6-trichlorophenyl) 2-benzylmalonate (**5i**) and 2-benzyl-2-(chlorocarbonyl)ethylketene (**5j**) with tetrahydrocarbazole **4a** to 5-benzyl-4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1:*jk*]carbazol-6-one (**6h**). Both reactions gave the desired product **6h**, trichlorophenylester **5i** in 30% and chlorocarbonylketene **5j** in 55% yield, which is better than the yield of the thermal method, but does not counterbalance the disadvantages of time-consuming and expensive syntheses of **5i** and **5j** (Scheme 3; Table 1).

Tetrahydro-pyridocarbazoles **6** possess besides the biologically interesting indole structure a 4-hydroxy-pyridone structure element, which is susceptible for many reactions. It can exist in tautomeric structures: the 4-hydroxy-6-oxo-structure as drawn in **6** is the predominant structure as evident in all spectroscopic investigations (*e.g.* shown by the hydroxy signal at 10.6–10.9 ppm in the $^1$H NMR spectra, and a single IR signal for the amide-CO at position 6 at about 1650 $cm^{-1}$). A reversed 4-oxo-6-hydroxy structure can be excluded because of its missing 4-pyridone signal in IR spectra [17]. However, during reactions with suitable reagents, the molecule can react from its 4,6-dioxo tautomer giving fixed dioxo-derivatives. The carbon at position 5 behaves due to the neighborship of two carbonyl groups as reactive CH acidic moiety, and electrophilic reactions such as nitration are directed first to this position. Therefore, it is possible to nitrate **6a** in position 5 by a gentle reaction with concentrated nitric acid in the presence of sodium nitrite as catalyst in glacial acetic acid already

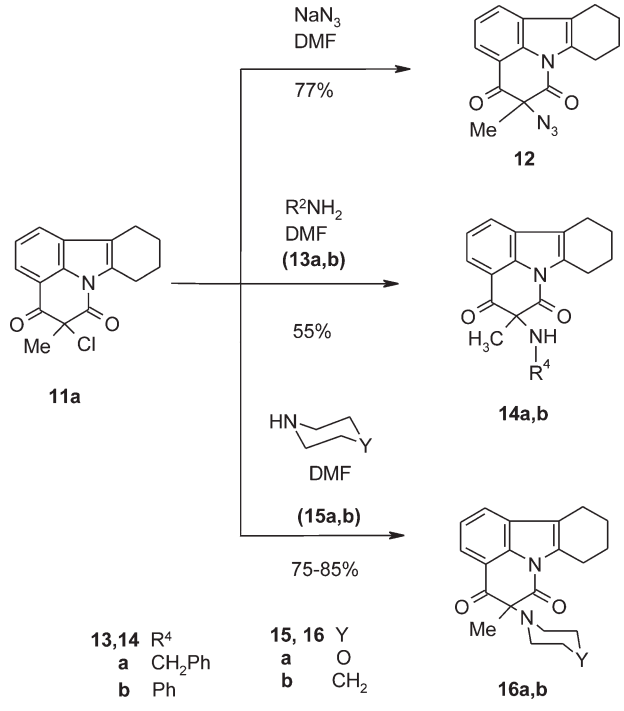
[b]Methods C and D for 6h are described in the experimental part.

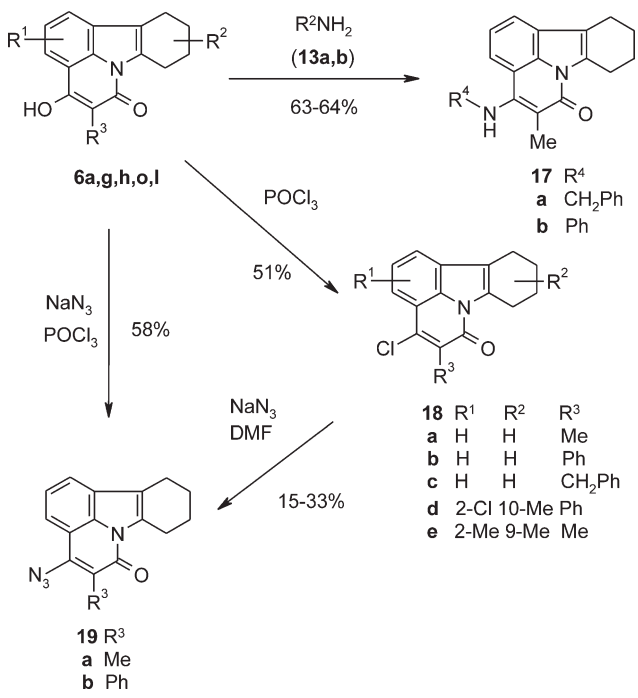
at room temperature. All other aromatic positions (1,2, and 3) remain unaffected, and 5-nitro-pyridocarbazoledione **9** is obtained in 75% yield. Hydroxylation of **6a** with hydrogenperoxide in buffered slightly alkaline aqueous solution gives in good yields 5-hydroxy-pyridocarbazoledione **10**, which contains the 3-hydroxy-2,4-dioxoquinoline structure element present in contents of some *Pseudomonas* bacteria (Scheme 4; Table 2) [18].

Electrophilic chlorination of **6** in position 5 could be performed with sulfuryl chloride. Because of the reactivity of this reagent, 2,5-dimethyl- and 2,5,9-trimethyl derivatives **6a** and **6k** had to be brought to reaction at room temperature, otherwise polychlorinated by-products were formed. The formed 5-chloro-pyridocarbazolediones **11**, which were obtained in excellent yields, serve as starting material for further substitution reactions: as examples an azidation and aminations are shown. The azidation of **11a** proceeds by simple halogen exchange at the aliphatic C-5 position at 50°C and gives in excellent yields 5-azido-pyridocarbazoledione **12**. Amination was performed with primary and secondary amines: **11a** gave with benzylamine (**13a**) the corresponding 5-benzylamino-pyridocarbazoledione **14a** in excellent yields; with aniline (**13b**) as the amino component, the yield of the corresponding 5-phenylamino-pyridocarbazoledione **14b** was slightly lower. Reaction of **1a** with secondary amines such as morpholine (**15a**) or piperidine (**15b**) gave in excellent yields 5-morpholino- and 5-piperidino-pyridocarbazolediones **16a**,**b** (Scheme 5).

**Scheme 5**



**Scheme 6**



In contrast to the electrophilic reactions shown above, a nucleophilic displacement takes place at the 4-position of the pyridocarbazolone. The 4-hydroxy group of **6** can be easily displaced by a chloro function, using phosphoryl chloride as reagent, or by substituted amino groups. Amination of **6a** at position 4 can be achieved by reaction of the reactive 4-hydroxy group with benzylamine (**13a**) and gives 4-benzylamino-pyridocarbazolones **17a** in excellent yield. The amination of **6a** with aniline (**13b**) needed the addition of aniline hydrochloride as acidic catalyst and gave in exellent yields 4-anilinopyridocarbazolone **17b**. Chlorination with phosphoryl chloride gave 4-chloropyridocarbazolones **18** in moderate to excellent yields. The nucleophilic exchange of the chloro substituent in 4-chloro-5-methylpyridocarbazolone **18a** against the azide group gave 4-azidopyrido[3,2,1-*jk*]carbazolones **19a** in only 15% yield. 4-Chloro-5-phenylpyridocarbazolone **18b** gave slightly better yields of 33% of the corresponding 4-azidopyrido[3,2,1-*jk*]carbazolone **19b**. To improve the yield, we used our recently developed one-pot synthesis [5] starting from 4-hydroxypyridocarbazolone **6a**, which reacted with a mixture of sodium azide and phosphoryl chloride (probably via reactive phosphoric esters) in dimethylformamide to obtain in this one-pot reaction **19a** in 58% yield (Scheme 6).

## CONCLUSION

Our results show that cyclization reactions of 2,3,4,5-tetrahydro-1*H*-carbazoles **1** with malonic acid derivatives give solely the 8,9,10,11-pyrido[3,2,1-*jk*]carbazole system **6**. Attempts to force a cyclization to 1,2,3,3a-tetrahydro-pyrido[3,2,1-jk]carbazole or its tautomeric ring system (**7/8**) by deactivation of the aromatic nucleus by electronic or steric influences failed. Electrophilic and nucleophilic substitution reactions with suitable reagents and conditions took place exclusively at the fused pyridone ring at position 5 or 4, respectively.

## EXPERIMENTAL

**General.** Melting points were determined using a Stuart SMP3 Melting Point Apparatus in open capillary tubes. IR spectra were recorded using a Mattson Galaxy Series FTIR 7020 instrument with potassium bromide discs. NMR spectra were recorded on a Bruker AMX 360 instrument (360 MHz $^1$H, 90 MHz $^{13}$C) or on a Bruker Avance DRX 500 instrument (500 MHz $^1$H, 125 MHz $^{13}$C). Chemical shifts are given in ppm (δ) from the internal TMS standard. Elemental analyses were performed at the Microanalytical Laboratory of the University of Vienna, Austria. Mass spectra were obtained from a HP 1100 LC/MSD mass spectral instrument (positive or negative APCI ion source, 50–200 V, nitrogen). Dry column flash chromatography [19] was carried out on Merck Kieselgel 60 H (5–40 μm). All reactions were monitored by thin layer chromatography on 0.2 mm silica gel F 254 (Merck, Darmstadt, Germany) plates using UV light (254 and 366 nm) for detection. Analytical HPLC was performed on a Shimadzu LC 20 system equipped with a diode array detector (215 and 254 nm) on a Pathfinder AS reversed phase (4.6150 mm, 5 μm) column, running an acetonitrile/water gradient (30–100% acetonitrile). Common reagent-grade chemicals are either commercially available and were used without further purification or prepared by standard literature procedures.

***General methods for the Fischer indole synthesis of 2,3,4,9-tetrahydro-1H-carbazoles (4).*** *Method A (one pot procedure).* To a mixture of anhydrous sodium acetate (2.46 g, 30 mmol) in glacial acetic acid (40 mL) the appropriate cyclohexanone **2** (30 mmol) was added at 90°C, then the corresponding phenylhydrazine hydrochloride **1.HCl** (25 mmol) was added in small portions during 1 h. The reaction mixture was further heated under reflux for 1 h, cooled to room temperature and diluted with diethyl ether (100 mL). The precipitated solid (inorganic salts) was separated by suction filtration and washed with diethyl ether. The combined filtrates were taken to dryness in vacuo, the residue diluted with a mixture of ethanol/water (7:3, 100 mL) and after standing for 3 h, the precipitated product isolated by suction filtration. The product was dried in vacuo at room temperature, then recrystallized from the appropriate solvent using charcoal.

*Method B (2-step procedure).* The corresponding phenylhydrazine hydrochloride **1.HCl** (27 mmol) was suspended in 0.5*M* aqueous sodium hydroxide (100 mL) and stirred at 70°C for 30 min. After cooling the precipitated oil was separated (loss ~5–10%) and added without further purification to a solution of the appropriate cyclohexanone **2** (30 mmol) in glacial acetic acid (70 mL) in small portions during 1 h. The reaction mixture was then heated under reflux for 1 h and cooled to room temperature under stirring until a solid precipitated. The

mixture was cooled to 5°C, the precipitated solid isolated by suction filtration and the filtrate cooled again to isolate a second crop. The combined solids were washed with water (100 mL) and ethanol/water (7:3, 100 mL), air-dried and then recrystallized from the appropriate solvent using charcoal.

R-key and data of **4a-r**: Table 1.

***General Methods for the cyclization of tetrahydrocarbazoles 4 to 4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1-jk]carbazol-6-ones (6).*** *Method A (thermal neat method).* A mixture of the appropriate diethyl malonate **5** (30 mmol) and the corresponding tetrahydrocarbazole **4** (25 mmol) was heated for 2–3 h to 280–300°C in a metal bath using a Vigreux column equipped with a distillation bridge. During this time the first equivalent of ethanol (25 mmol, about 0.9 mL) was liberated. When the liberation of ethanol had stopped, the reaction mixture was heated for about 30 min to a bath temperature of 330–350°C; during this time the second equivalent of ethanol (0.9 mL, 25 mmol) was liberated. The reaction mixture was cooled to about 80°C, methanol (30 mL) was added, the mixture cooled to room temperature and filtered by suction. The solid was taken up in aqueous sodium hydroxide solution (0.25*M*, 100 mL) and extracted with toluene (100 mL). The aqueous layer was decolorized with charcoal at 50 to 80°C and filtered. Concentrated hydrochloric acid was added to the filtrate until pH ~3, the precipitate filtered by suction, washed acid-free with water, dried and recrystallized from the appropriate solvent.

*Method B (thermal solution method).* A solution of the appropriate diethyl malonate **5** (30 mmol) and the corresponding tetrahydrocarbazole **4** (25 mmol) in diphenylether (25 mL) was heated under reflux at 250°C in a metal bath using a Vigreux column equipped with a distillation bridge for about 12 h. During this time, 2 equivalents of ethanol were liberated (50 mmol, about 1.8 mL). After cooling to room temperature, diethyl ether (50 mL) was added, and the solid which precipitated was filtered by suction, washed with diethyl ether and dried. The collected solid was taken up in aqueous sodium hydroxide solution (0.25*M*, 100 mL) and filtered by suction. Concentrated hydrochloric acid was added to the filtrate until pH ~3, the precipitate filtered by suction, washed acid-free with water, dried and recrystallized from the appropriate solvent.

R-key and data of **6a-p**: Table 2.

***5-Benzyl-4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1-jk]carbazol-6-one (6h).*** From tetrahydrocarbazole **4a** and *bis*(2,4,6-trichlorophenyl) 2-benzylmalonate (**5i**) (Method C, ''active malonate'' method [15]):

Bis*(2,4,6-trichlorophenyl) 2-benzylmalonate (**5i**).* A mixture of dry 2-benzylmalonic acid (**5**, $R^3 = CH_2Ph$, X = OH) (38.8 g, 0.2 mol), 2,4,6-trichlorophenol (63.2 g, 0.32 mol) and phosphoryl chloride (64.4 g, 0.42 mol) was heated under reflux until the evolution of hydrogen chloride gas had stopped (about 4–6 h). The reaction mixture was then poured onto crushed ice (600 mL), filtered by suction, the solid washed with ice-water, dissolved in toluene (400 mL) and washed with aqueous sodium hydrogencarbonate solution (5%) and water. The organic layer was dried with sodium sulfate and the solvent removed under reduced pressure. The residue was triturated with hexane, filtered and dried at room temperature. The yield was 44.6 g (50%), light yellowish prisms, mp 104°C (lit. mp 106–107°C [15a]).

*5-Benzyl-4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1:jk]carbazol-6-one (**6h**).* An intimate mixture of tetrahydrocarbazole **4a** (3.75 g, 22 mmol) and *bis*(2,4,6-trichlorophenyl) 2-benzylmalonate (**5i**) (12.1 g, 22 mmol) was heated without solvent for 60 min to 250°C. The 2,4,6-trichlorophenol vapors were removed *via* a funnel into the water pump. After cooling the dark reaction mixture was washed with hexane until the product became semi-solid. Then the product was stirred overnight with aqueous sodium hydroxide solution (0.5*M*, 500 mL), filtered, the filtrate extracted with toluene (2 × 100 mL) and the aqueous phase acidified with concentrated hydrochloric acid. The precipitate was washed with water, recrystallized from glacial acetic acid/water and dried. The yield was 2.17 g (30%).

***From tetrahydrocarbazole 4a and 2-benzyl-2-(chlorocarbonyl)ethylketene (5j) (Method D, ''(chlorocarbonyl)ethylketene''-method [16]).*** *2-Benzyl-2-(chlorocarbonyl)ethylketene (5j).* To a solution of 2-benzylmalonic acid (**5**, $R^3 = CH_2Ph$, X = OH) (38.8 g, 0.2 mol) in toluene (50 mL), thionyl chloride (59.5 g, 0.6 mol) was added dropwise under stirring in a nitrogen atmosphere. The mixture was heated for 24 h under reflux, then toluene and excess thionyl chloride were removed by distillation under reduced pressure (60°C, 130 mm Hg). The residue was distilled under reduced pressure (134–140°C, 15 mm Hg). The yield was 27.2 g (70%) yellowish oil; lit. bp 110–112°C (1.5 mm Hg) [16b].

*5-Benzyl-4-hydroxy-8,9,10,11-tetrahydropyrido[3,2,1:jk]carbazol-6-one (6h).* To a solution of tetrahydrocarbazole **4a** (5.12 g, 30 mmol) in dry ethyl acetate (150 mL), 2-benzyl-2-(chlorocarbonyl)ketene (**5j**) (6.5 g, 33 mmol) and dry triethylamine (4.5 mL) was added at 40–50°C. The yellow reaction mixture turned red and viscous and a small amount of a dark solid precipitated. The reaction mixture was kept for 30 min at room temperature, then the precipitate was filtered off, the filtrate taken to dryness under reduced pressure and triturated with xylene. The resulting precipitate was filtered by suction and dried. The yield was 5.42 g (55%), yellowish prisms. Data of **6h**: Table 2.

***5-Nitro-5-phenyl-8,9,10,11-tetrahydropyrido[3,2,1-jk]carbazole-4,6-dione (9).*** A solution of 4-hydroxy-pyridocarbazole **6a** (2.00 g, 6.3 mmol) in glacial acetic acid (12 mL) was treated with concentrated nitric acid (1.2 mL) and sodium nitrite (0.03 g). The mixture was stirred for 30 min at room temperature, then diluted with ice/water (45 mL), the formed yellow precipitate separated by suction filtration and washed with water until acid-free. The yield was 1.70 g (75%), yellow prisms, mp 164°C (methanol). IR: 2960–2860 w, 1730 s (4-C=O), 1695 s (6-C=O), 1660 sh, 1625 w, 1590 w, 1570 s $cm^{-1}$; $^1H$ NMR ($CF_3COOH$): δ 1.80–2.10 (m, 4 H, 9-$CH_2$, 10-$CH_2$), 2.70 (t, $J = 7.0$ Hz, 2 H, 11-$CH_2$), 3.15 (t, $J = 7.0$ Hz, 2 H, 8-$CH_2$), 7.25 (t, $J = 7.1$ Hz, 1 H, 2-H), 7.35–7.50 (m, 3 H, PhH), 7.55–7.60 (m, 2 H, PhH), 7.70 (d, $J = 7.1$ Hz, 1-H), 7.90 (d, $J = 7.1$ Hz, 1 H, 8-H). Anal. calcd. for $C_{21}H_{16}N_2O_4$ (360.37): C, 69.99; H, 4.48; N, 7.77. Found: C, 70.34; H, 4.71; N, 7.45.

***5-Hydroxy-5-methyl-8,9,10,11-tetrahydropyrido[3,2,1-jk]carbazol-4,6-dione (10).*** A solution of 4-hydroxy-pyridocarbazole **6a** (0.68 g, 2.7 mmol) in aqueous sodium hydroxide solution (0.25*M*, 60 mL) was slowly brought to pH ~8 with aqueous potassium dihydrogenphosphate solution (1*M*, ~10 mL), then hydrogenperoxide (30%, 20 mL) was added. The reaction mixture was stirred for 6 h at 40°C. After cooling to room temperature, the mixture was poured onto crushed ice/water (100

mL), the solid filtered by suction and washed with water. The yield was 0.52 g (72%), yellow prisms, mp 189°C (ethanol). IR: 3395 s, 2945 m, 1711 s (4-C=O), 1684 s (6-C=O), 1630 w, 1593 m $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$): δ 1.49 (s, 3 H, 5-Me), 1.82–1.88 (m, 4 H, 9-$CH_2$, 10-$CH_2$), 2.68 (t, $J$ = 7.0 Hz, 2 H, 11-$CH_2$), 3.06 (t, $J$ = 7.0 Hz, 2 H, 8-$CH_2$), 6.15 (s, 1 H, 5-OH), 7.41 (t, $J$ = 7.6 Hz, 1 H, 2-H), 7.69 (d, $J$ = 7.6 Hz, 1 H, 1-H), 7.82 (d, $J$ = 7.6 Hz, 1 H, 3-H); MS [APCI, pos]: m/e (%) = 271 (11), 270 (M, 100). Published online 4 June 2010 in Wiley InterScience (www.interscience.wiley.com).

A new class of bis heterocycles having two different heterocyclic rings *viz*., pyrroles in combination with pyrazolines and isoxazolines were synthesized. All the compounds were characterized by elemental and spectral analysis.

*J. Heterocyclic Chem.,* **47**, 825 (2010).

## INTRODUCTION

Heterocyclic chemistry has attracted a lot of interest during recent years as many useful drugs have emerged in this branch. In fact, the development of simple, facile, and efficient synthetic methodologies for the development of five membered heterocycles has been a challenging task in organic synthesis. Amongst five membered heterocycles, pyrroles, pyrazoles, and isoxazoles have gained importance because of their varied physiological activities. As constituents of cytotoxic drugs, such as netrospin and distamycin, 4-aminopyrrole-2-carboxylates, have been used as the main compounds in the construction of a diverse series of DNA-binding ligands exhibiting antibiotic, antiviral, and oncolytic properties [1]. The related 3-amino pyrroles also exhibit anticonvulsant activity by blocking sodium channels [2]. In addition, pyrazolines and isoxazolines have gained importance due to their various chemotherapeutic properties. In fact, Celecoxib, a pyrazole derivative and Valdecoxib, an isoxazole derivative, have been widely used in the market as anti-inflammatory drugs [3]. Hence, it was considered worthwhile to prepare molecules having both pyrrole and pyrazole/isoxazole rings. In the literature, 3,4-disubstituted pyrroles were reported either by coupling imines and nitroalkanes or by using Friedel-Craft's acylation in the presence of an electron-withdrawing group on the pyrrole nitrogen or on 3,4-silylated precursors [4]. However, these synthetic routes were often complicated and limited to only some substituents. Previously, 3,4-disubstituted pyrroles were synthesized from Michael acceptors and tosylmethyl isocyanide (TosMIC) [5]. Following this synthetic methodology, we have reported recently a new regioselective one step procedure using phenyl vinyl sulfone, aryl styryl sulfones, benzyl styryl sulfones and TosMIC, leading to a series of 3,4-disubstituted pyrroles in good yields [6]. Similarly, pyrazolines and isoxazolines were prepared by 1,3-dipolar cycloaddition of an ylide to an alkene involving the 3+2 cycloaddition principle [7]. Among the ylides, diazomethane, nitrile imines, and nitrile oxides were used extensively as reactive intermediates. These nitrile imines and nitrile oxides can be generated by the dehydrogenation of araldehyde phenylhydrazones and araldoximes with lead tetraacetate [8], mercury acetate [9], 1-chlorobenzotriazole [10], chloramine-T [11] etc. Use of the latter for *in situ* generation of dipolar reagents has enthused many organic chemists. In fact, we have reported the 1,3-dipolar cycloaddition reaction of Chloramine-T catalysed dipolar reagents with variety of activated mono and bis(olefins) [12]. Apart from these, bis heterocycles, bis pyrroles and pyrrolyl pyrazoles were prepared from 1-arylsulfonyl-2-styrylsulfonyl ethenes by 1,3-dipolar cycloaddition methodology [13]. The present communication deals with the synthesis of hitherto unknown sulfonelinked bis (heterocycles) having pyrrole together with pyrazole or

isoxazole units, from 1,3-dipolar cycloaddition of TosMIC, nitrile imines and nitrile oxides to sulfonyl activated olefins.

## RESULTS AND DISCUSSION

The synthetic scheme was based on the reactivity of *E*,*E*-bis(styryl)sulfone (**1**) towards 1,3-dipolar reagents *viz*., TosMIC, diazomethane, nitrile imines and nitrile oxides. When **1** was treated with TosMIC in the presence of sodium hydride in a mixture of ether and dimethylsulfoxide, a solid was obtained which was identified as 4-aryl-3-(2′-arylethenesulfonyl)-1*H*-pyrrole (**2**) by spectral studies (Scheme 1; Table 1). Compound **2a** exhibited two singlets at δ 6.85 and 7.48 ppm, assigned to $C_2$-H and $C_5$-H of pyrrole ring protons. Two doublets were observed at δ 6.96 and 7.63 ppm corresponding to olefinic protons, in addition to the signals of aromatic protons (Table 3). The $^{13}C$ nuclear mass spectroscopy (NMR) spectra of **2a** showed signals at δ 119.8, 125.7, 125.9, and 127.3 for pyrrole ring carbons, C-4, C-3, C-5, C-2 and at δ 124.2, 141.3 ppm for olefinic carbons, C-1′, C-2′ (Table 3). Thus the formation of **2** indicates that the reaction was regiospecific. Attempts to prepare bis (4-aryl-1*H*-pyrrol-3-yl)sulfone (**3**) by treating **1** with

| **9a** | 287–289 | 68 | $C_6H_5$ | $C_6H_5$ | $C_{25}H_{18}N_2O_3S$ (426.50) | 70.40 | 4.25 | 6.57 |
| | | | | | | 70.52 | 4.28 | 6.51 |

two equivalents of TosMIC were not successful. However, **3** was obtained by treating **2** with one equivalent of TosMIC, as confirmed by NMR spectroscopy. Compound **3a** exhibited two sharp singlets at δ 6.84 and 7.08 ppm corresponding to $C_{2,2'}$-H and $C_{5,5'}$-H. The $^{13}C$ NMR spectra of **3a** exhibited signals at 119.2 (C-4,4′), 122.6 (C-3,3′), 126.2 (C-5,5′), 127.4 (C-2,2′). This indicates that the molecule was highly symmetrical.

The olefin in **2** was utilized in the synthesis of pyrazolines and isoxazolines. When **2** was subjected to 1,3-dipolar cycloaddition reaction with diazomethane, (4′-aryl-4′,5′-dihydro-1′*H*-pyrazol-3′-yl)-(4-aryl-1*H*-pyrrol-3-yl)-sulfone (**4**) was obtained (Scheme 1; Table 1). The $^1H$ NMR spectra of **4a** showed an *AMX* splitting pattern of the pyrazoline ring protons at δ 4.48 ($H_A$), 3.86 ($H_M$) and 3.48 ppm ($H_X$) respectively, in addition to the signals of the pyrrole ring protons. The observed coupling constant values $J_{AM} = 12.6$, $J_{AX} = 5.5$ and $J_{MX} = 10.0$ Hz indicated that $H_A$ and $H_M$ were *cis*, $H_A$ and $H_X$ were *trans* and $H_M$ and $H_X$ were *geminal*. The $^{13}C$ NMR spectrum of **4a** exhibited signals at δ 46.9, 57.2, 119.4, 120.3, 124.8, 125.6 and 152.3 ppm for the carbons C-4′, C-5′, C-4, C-3, C-5, C-2, and C-3′, respectively (Table 2).

In addition, the reaction of **2** with nitrile imines and nitrile oxides generated from araldehyde phenylhydrazones and araldoximes in the presence of chloramine-T resulted in (1′,3′,5′-triaryl-4′,5′-dihydro-1′*H*-pyrazol-4′-yl)-(4-aryl-1*H*-pyrrol-3-yl)-sulfones (**5**) and (3′,5′-diaryl-

4′,5′-dihydroisoxazol-4′-yl)-(4-aryl-1*H*-pyrrol-3-yl)-sulfone (**6**), respectively (Scheme 1; Table 1). The $^1$H NMR spectrum of **5a** and **6a** displayed two doublets at δ 5.25, 5.19 and 5.63, 5.67 ppm, respectively, which were assigned to $C_{4'}$-H and $C_{5'}$-H, the two methine protons of the pyrazoline and isoxazoline rings. The *J* values indicated that they were in *trans* geometry (Table 3). The $^{13}$C NMR spectra of **5a** and **6a** displayed signals at 63.0, 64.9 (C-4′), 87.4, 83.7 (C-5′), 119.2, 119.4 (C-4), 121.0, 121.9 (C-3), 124.4, 124.3 (C-5), 126.8, 126.3 (C-2) and 154.9, 151.7 (C-3′), respectively (Table 3). Compounds **4a**, **5a** and **6a** on oxidation with chloranil in xylene, gave the corresponding pyrazoles and isoxazoles **7a**, **8a** and **9a**. The disappearance of two doublets corresponding to pyrazoline/isoxazoline ring protons in the $^1$H NMR spectra confirmed their formation.

## CONCLUSION

A simple dipolarophile, bis(styryl)sulfone was exploited to get a new and novel sulfone-linked bis(heterocycles) containing two different heterocyclic rings adopting simple and versatile 1,3-dipolar cycloaddition methodology.

## EXPERIMENTAL

Melting points were determined in open capillaries on a Mel-Temp apparatus and are uncorrected. The purity of the compounds was checked by thin layer chromatography (Silica gel H, BDH, ethyl acetate-hexane, 1:3). The infrared (IR) spectra were recorded on a Thermo Nicolet IR 200 FT-IR in KBr pellets and the wave numbers were given in $cm^{-1}$. The $^1$H NMR spectra were recorded in $CDCl_3$/DMSO-$d_6$ on a Jeol JNM λ-300 MHz. The $^{13}$C NMR spectra were recorded in $CDCl_3$/DMSO-$d_6$ on a Jeol JNM spectrometer operating at 75.5 MHz. All chemical shifts are reported in δ (ppm) using TMS as an internal standard. Elemental analyses were performed using Perkin-Elmer 240C elemental analyser. The starting substrates *E,E*-bis(styryl)sulfones were prepared according to the literature procedure [14]. Araldehyde phenylhydrazones and araldoximes were prepared by standard procedures [15].

**4-Aryl-3-(2-arylethenesulfonyl)-1*H*-pyrroles (2).** ***General procedure.*** A mixture of TosMIC (5 mmol) and **1** (5 mmol) in $Et_2O$/DMSO (2:1) was added dropwise under stirring to a suspension of NaH (50 mg) in $Et_2O$ (10 mL) at room temperature. Stirring was continued for about 6 h. Then it was diluted with $H_2O$ and extracted with $Et_2O$. The ethereal layer was dried over anhydrous $Na_2SO_4$. The solvent was removed *in vacuo*. The resultant solid was purified by recrystallization from MeOH.

**Bis(4-aryl-1*H*-pyrrol-3yl)-sulfones (3).** ***General procedure.*** A mixture of TosMIC (5 mmol) and **2** (5 mmol) in $Et_2O$/DMSO (2:1) was added dropwise under stirring to a suspension of NaH (50 mg) in $Et_2O$ (10 mL) at room temperature. Stirring was continued for about 7 h. Then, $H_2O$ was added and the product was extracted with $Et_2O$ and dried over anhydrous $Na_2SO_4$. The solvent was removed *in vacuo*. The resultant solid was purified by column chromatography [Silica gel, hexane-ethyl acetate (1:4)].

**(4′-Aryl-4′,5′-dihydro-1′*H*-pyrazol-3′-yl)-(4-aryl-1*H*-pyrrol-3-yl)-sulfones (4).** ***General procedure.*** To a cooled solution of **2** (5 mmol) in $CH_2Cl_2$ (20 mL), an ethereal solution of diazomethane (40 mL, 0.4*M*) and triethylamine (0.12 g) were added. The reaction mixture was kept at −20 to −15°C for 48–56 h. The solvent was removed under reduced pressure. The resultant solid was purified by recrystallization from MeOH.

**(1′,3′,5′-Triaryl-4′,5′-dihydro-1′*H*-pyrazol-4′-yl)-(4-aryl-1*H*-pyrrol-3-yl)-sulfones (5).** ***General procedure.*** A mixture of **2** (1 mmol), araldehyde phenylhydrazone (2 mmol) and chloramine-T (2 mmol) in MeOH (20 mL) was refluxed for 20–22 h. over a water bath. The precipitated inorganic salts were filtered off. The filtrate was concentrated and the residue was extracted with $CH_2Cl_2$. The organic phase was washed with water, brine and dried over anhydrous $Na_2SO_4$. The solvent was removed under reduced pressure. Recrystallization of the crude product from ethanol resulted in pure **5**.

**(3′,5′-Diaryl-4′,5′-dihydro-isoxazol-4′-yl)-(4-aryl-1*H*-pyrrol-3-yl)-sulfones (6).** ***General procedure.*** A mixture of **2** (1 mmol), araldoxime (2 mmol) and chloramine-T (2 mmol) in MeOH (20 mL) was refluxed for 16–18 h. over a water bath. The precipitated inorganic salts were filtered off. The filtrate was concentrated and the residue was extracted with $CH_2Cl_2$. The organic phase was washed with water, brine and dried over anhydrous $Na_2SO_4$. The solvent was removed under reduced pressure. Recrystallization of the crude product from ethanol resulted in pure **6**.

**(4′-Phenyl-1′*H*-pyrazol-3′-yl)-(4-phenyl-1*H*-pyrrol-3-yl)-sulfone (7a)/(4-phenyl-1*H*-pyrrol-3-yl)-(1′,3′,5′-triphenyl-1′*H*-pyrazol-4′-yl)-sulfone (8a)/(3′,5′-diphenyl-isoxazol-4′-yl)-(4-phenyl-1*H*-pyrrol-3-yl)-sulfone (9a).** ***General procedure.*** A solution of **4a/5a/6a** (1 mmol) and chloranil (1.04 mmol) in

xylene (10 mL) was refluxed for 30–35 h. Then it was treated with 5% sodium hydroxide solution. The organic layer was separated and repeatedly washed with water, dried over anhydrous $Na_2SO_4$ and was removed on a rotary evaporator. The solid obtained was purified by recrystallization in isopropanol to give pure **7a/8a/9a** respectively.

**Acknowledgment.** The authors are thankful to DST, New Delhi, India for the financial assistance under major research project.

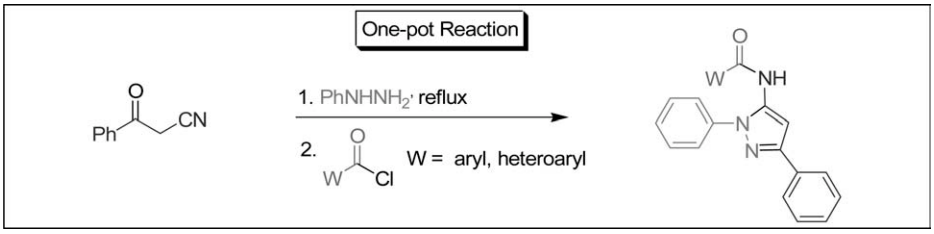
Published online 4 June 2010 in Wiley InterScience (www.interscience.wiley.com).



A ''one-pot'' method for the synthesis of *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amides was developed by cyclization of benzoylacetonitrile (**1**) and phenylhydrazine in neat condition followed by acylation. The corresponding *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amides were provided in good to excellent yields (70–90%). The significant advantages of the new synthetic method are excellent yields and simple work-up procedure without isolation and purification of intermediary 5-amino-1,3-diphenyl pyrazol (**2**).

*J. Heterocyclic Chem.,* **47**, 831 (2010).

## INTRODUCTION

Pyrazole compounds have aroused great interest in recent years because of their wide spectrum of biological activities, including anti-inflammatory, antipyretic, gastric secretion stimulatory, antidepressant, antibacterial, anticonvulsant, antifilarial agents, and as analytical reagents [1–4].

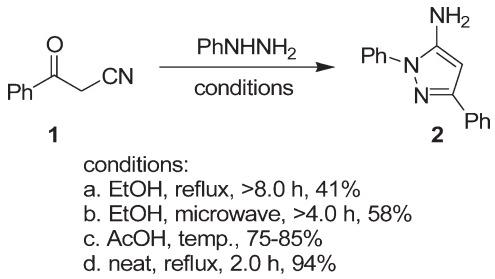
A recently reported pyrazole, 3-cyano-*N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)benzamide (**16**, CDPPB), was developed as the first centrally active positive allosteric modulator of rat and human metabotropic glutamate receptor $mGluR_5$ subtype [5–7]. The receptors play an important role in controlling neuronal excitability and synaptic transmission in the central nervous system of the mammalian brain [8,9]. *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amide derivatives are also considered as potential targets for therapeutic intervention in a variety of neurological and psychiatric illnesses [10]. The detailed structure–activity relationship studies of CDPPB analogs were reported by de Paulis *et al*. in 2006 [11]. Herein, we provided an efficient and convenient one-pot method to synthesize *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amides for the large-scale preparation.

## RESULTS AND DISCUSSION

The traditional method for the synthesis of analog **2** [12,13] was the reaction of benzoylacetonitrile (**1**) with phenylhydrazine under different conditions to provide the key intermediate 5-amino-1,3-diphenyl pyrazole (**2**). The conditions include: (1) heated in EtOH [14], (2) microwave radiation [15], and (3) heated in acetic acid (Scheme 1) [15]. Compound **2** was then subjected to acylation to provide model compound **5** [*N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)benzamide]. These methods all involve two steps, and it is necessary to purify aminopyrazole **2**. To develop a better synthetic methodology for expanding the structural variation of compound **5**, we developed an efficient and convenient ''one-pot'' method for their syntheses. Benzoylacetonitrile (**1**) was allowed to react with neat phenylhydrazine. The resultant **2**, needless to be purified, was subjected to acylation to generate model compound **5** in good to excellent yields (Scheme 1).

We first tried to prepare 5-amino-1,3-diphenyl pyrazole (**2**) by traditional methods to study their feasibility for one-pot reaction of *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)benzamide derivatives. The first method was refluxing benzoylacetonitrile (**1**) with the same equivalent of

**Scheme 1**



phenylhydrazine in EtOH for >8.0 h (see Scheme 1, path a) [14]. Compound **2** was generated in only 41% yield *via* tandem condensation and thermal cyclization. Another method was the use of microwave irradiation of 1 with hydrazine in EtOH solution for >4.0 h to provide compound **2** in 58% yield (see Scheme 1, path b) [15]. The two literature-reported methods did not provide compound **2** in satisfactory yield, as a result, not suitable for direct acylation for a one-pot preparation. Use of acetic acid as the solvent could provide **2** in 75–85% yield (see Scheme 1, path c). However, the residual acetic acid should be distilled before acylation. Those methods were troublesome for removing EtOH or acetic acid, especially in large-scale preparation.

We then carried out the reaction in neat condition. Benzoylacetonitrile (**1**) was allowed to react with phenylhydrazine in neat condition at reflux for 2.0 h (see Scheme 1, path d). The desired 5-amino-pyrazole **2** was successfully generated in 94% yield. Compound **2** was fully characterized by spectroscopic method, and the results were consistent with the reported data of previous literature [14,15]. This method is able to promote the cyclization yield and provide the one-pot approach for *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amide derivatives.

For searching a better acylation agent to generate **3**, compound **2** was treated with various acylation agents, including acetyl chloride, acetic anhydride, and ethyl acetate (EtOAc) at room temperature or at reflux for 3.0–4.0 h in THF (see Table 1). The corresponding acylated products were obtained in 85%, 83%, and trace yields, respectively. When compound **2** was reacted with ethyl benzoate or ethyl phenylacetate, the reaction gave the corresponding compounds **4** and **5** in 89% and 93% yields (see Table 1).

We then tried to combine the two-step process into a one-pot reaction. Compound **1** was refluxed with the same equivalent amount of phenylhydrazine in neat condition for 2 h. After the reaction was completed, the resultant compound **2** was dissolved in $CH_2Cl_2$ and stirred in ice-bath. The acylation agents, including acetyl chloride, benzoyl chloride, and phenylacetyl chloride, were diluted with anhydrous $CH_2Cl_2$, and THF was slowly added to the reaction mixture at 0–10°C. The reaction was stirred for 3–4 h from 0–10°C to the room temperature under $N_2$, and the corresponding acylation products *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amide **3–5** were successfully provided in 78–90% yields in the one-pot reaction (see Table 1).

We then tried to apply this new method to synthesize *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)benzamide derivatives by use of different monosubstituted benzoyl halides containing Cl, F, $CH_3$, $CF_3$, OMe, CN, and $NO_2$ functionalities as the acylation agents (Scheme 2 and Table 2). The corresponding *N*-(1,3-diphenyl-1-*H*-pyrazol-5-yl)benzamide **6–19**, which were reported as a novel class of positive allosteric modulation of $mGluR_5$ [5,11], could be obtained in 70–90% yields (Table 2). Use of 2,4-difluorobenzoyl chloride also provided the corresponding product **15** in 88% yields. Compounds **6–19** were fully characterized by spectroscopic methods, and the data were consistent with reported [5,11]. For example, the pyrazole ring in compound **16** presented a peak at δ 6.79 ppm for NH—C=C—$^1$H and a peak at δ 95.7 ppm for NH—$^{13}$C=C in NMR. Its IR spectrum showed absorption at 2232 $cm^{-1}$ for —CN stretching and 3308 $cm^{-1}$ for —N—H stretching [14]. Being the first centrally active positive allosteric modulator of $mGluR_5$, compound **16** was synthesized by this one-pot method in 73% yield.

The method can also be applied to the synthesis of quinoline-8-sulfonyl and heteroarylaminopyrazoles. Use of quinoline-8-sulfonyl chloride, 2-benzofurancarbonyl chloride, 2-furoyl chloride, isoxazole-5-carbonyl chloride, 2-thiophenecarbonyl chloride, and trimellitic anhydride chloride could successfully provide the corresponding *N*-(1,3-diphenyl-1*H*-pyrazol-5yl)amide **20–25** in 70–90% yields (see Scheme 3 and Table 3).

In conclusion, we have successfully developed a newly one-pot method by treating benzoylacetonitrile (**1**) and phenylhydrazine with various acylation agents,

**Table 1**

The results of *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amide derivatives **3–5** *via* step-by-step and one-pot synthesis.

including acetyl chloride, aryl chloride, heteroaryl chloride, quinoline-8-sulfonyl chloride, and trimellic anhydride chloride to give *N*-(1,3-diphenyl-1*H*-pyrazol-5-yl)amides **3–25** in 70–90% yields. The new strategy has been demonstrated to substantially promote the productive yields in the generation of substituted *N*-(1,3-diphenyl-1-*H*-pyrazol-5-yl)benzamides **6–19** compounds.

## EXPERIMENTAL

**General procedure.** All chemicals were reagent grade and used as purchased. All reactions were carried out under nitrogen atmosphere and monitored by TLC analysis. Flash column chromatography was carried out on silica gel (230–400 mesh). Commercially available reagents were used without further purification unless otherwise noted. Dichloromethane, ethyl acetate, hexanes, and methanol were purchased from ECHO Chemical (USA). Dry tetrahydrofuran (reagent grade) and 3-fluorobenzoyl chloride were purchased from Aldrich (USA). The following compounds were purchased from Acoros Chemical (Japan): acetyl chloride, benzoyl chloride, 3-cyanobenzoic acid, 2,4-difluorobenzoyl chloride, 4-fluorobenzoyl chloride, 3-methylbenzoyl chloride, and 4-methylbenzoyl chloride. Benzoylacetonitrile, 2-chlorobenzoyl chloride, 3-chlorobenzoyl chloride, 4-cyanobenzoyl chloride, 3-methoxylbenzoyl chloride, phenylhydrazine, and quinoline-8-sulfonyl chloride were purchased from TCI Chemical (Japan). Isoxazole-5-carbonyl chloride 2-nitrobenzoyl chloride, 4-(trifluoromethyl)benzoyl chloride, and trimellitic anhydride chloride were purchased from Alfa Chemical. 2-Furoyl chloride was purchased from Merck Chemical (Germany). Purification by gravity column chromatography was carried out by use of Merck Reagents Silica Gel 60 (particle size 0.063–0.200 mm, 70–230 mesh ASTM). Infrared (IR) spectra were measured on a Bomem Michelson Series FT-IR spectrometer. The wavenumbers reported are referenced to the polystyrene 1601 $cm^{-1}$ absorption. Absorption intensities are recorded by the following abbreviations: s, strong; m, medium; w, weak. Proton NMR spectra were obtained on a Bruker (200 MHz) spectrometer by use of $CDCl_3$ and $d_6$-DMSO as solvent. Carbon-13 NMR spectra were obtained on a Bruker (50 MHz) spectrometer by the use of $CDCl_3$ as solvent. Carbon-13 chemical shifts are referenced to the center of the $CDCl_3$ triplet (δ 77.0 ppm). Multiplicities are recorded by the following abbreviations: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; *J*, coupling constant (Hz). Elemental analyses were carried out on a Heraeus CHN–O RAPID element analyzer.

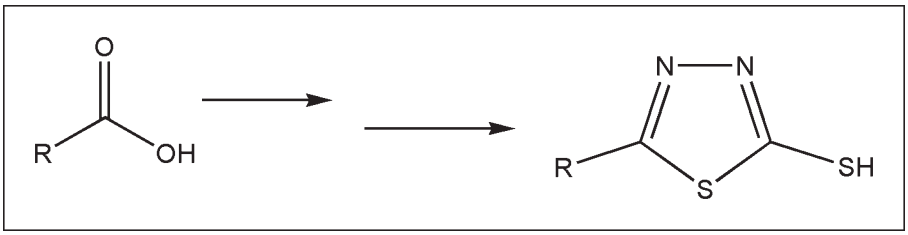
Published online 4 June 2010 in Wiley InterScience (www.interscience.wiley.com).



A fast, efficient synthesis of 5-substituted-1,3,4-thiadiazole-2-thiols was successfully developed, assessed using green chemistry matrices, and compounds were screened for their *in vitro* nitrification inhibitory activity. The greener method was superior with higher energy efficiency, E(nvironmental) factor, atom economy, atom efficiency, carbon efficiency, and reaction mass efficiency.

## INTRODUCTION

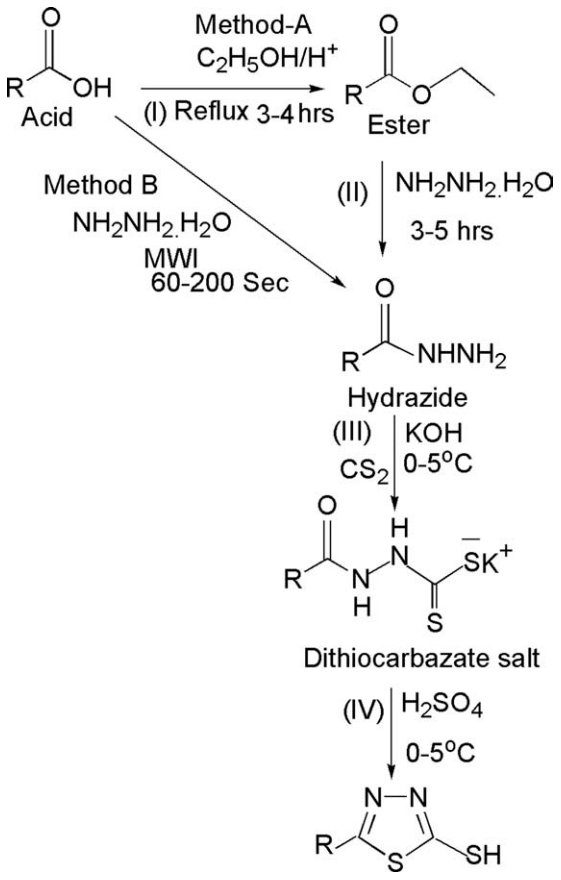
With increasing global population, demands have been increased to meet the requirements and consequently the industrial pollution. To control this detrimental phenomenon, the term ''green chemistry'' has come into existence [2]. Green chemistry is a package of technologies, design principles, and tools to reduce toxicity, resource energy use, and pollution of chemicals [2,3]. Due to environmental awareness [4], chemists have focused their attention to examine bioactive products such as heterocycles and processes in terms of environment friendliness. The 1,3,4-thiadiazoles are important bioactive heterocyclic moieties and have been reported to have wide range of bioactivities [5] such as neuroprotective, antibacterial, antidepressant, and antituberculour. One of the title compound, 5-methyl-1,3,4-thiadiazole-2-thiol is the side chain at C-3 position of a well known antibiotic Cefazolin sodium [6].

The low nitrogen use efficiency accounts to US$ 17 Billion annual nitrogen losses worldwide along with environmental and health hazards [7,8]. There is, thus, an urgent call for improving the efficiency of N-fertilizer use to achieve higher food production for catering the ever increasing population and also to minimize fertilizer related pollution of the environment [9]. Despite a great interest in the development and use of nitrification inhibitors to date, only a few compounds have been adopted for agricultural use [10]. The main problems associated with these inhibitors are the high cost involved in the development, subsequent registration of effective nitrification inhibitors, and the economics of their use in field conditions [11]. Various heterocyclics being an important bioactive class are used as nitrification inhibitors [12], but their use is restrained because of the complex synthetic procedures involving hazardous chemicals and subsequent cost. This problem can be solved by synthesizing potential nitrification inhibiting heterocyclics with minimum cost in an environment friendly manner. Keeping in view the aforementioned consideration, this study was taken up to design and synthesize 5-substituted-1,3,4-thiadiazole-2-thiols in a greener and cost effective way as potential nitrification inhibitors.

## RESULTS AND DISCUSSION

5-Substituted-1,3,4-thiadiazole-2-thiols have been synthesized starting from carboxylic acids following the conventional (protocol 1) and improved greener synthetic protocol (protocol 2). Reaction pathway is depicted in Scheme 1. In protocol 1, carboxylic acids were esterified by refluxing with ethyl alcohol for 3–4 h in the presence of sulfuric acid. These ester yielded corresponding hydrazide on refluxing with hydrazine hydrate for 3–5 h [13]. The analytical and spectral data of hydrazides were in complete agreement with those given in literature [13–17]. Hydrazides on reaction with carbon disulphide and potassium hydroxide afforded thiocarbazate salts, which are cyclized in the presence of concentrated sulfuric acid to afford 5-substituted-1,3,4-

**Scheme 1.** Synthesis of 5-substituted-1,3,4-thiadiazole-2-thiols.



thiadiazole-2-thiols. In protocol 2, our new greener one-pot method was used for the synthesis of acid hydrazides [18], and hydrazides were further processed similarly as in protocol 1 to yield 5-substituted-1,3,4-thiadiazole-2-thiols. This innovation improved the overall synthetic protocol for 5-substituted-1,3,4-thiadiazole-2-thiols in terms of yield, time, energy, atom economy and efficiency, number of steps, and other green chemistry measures (Table 3). All these compounds were characterized by analytical and spectral data (Tables 1 and 2).

The structures of 5-substituted-1,3,4-thiadiazole-2-thiols were established on the basis of their IR, $^1$H-NMR, $^{13}$C-NMR, CHNS data. The analytical and spectral data of 5-substituted-1,3,4-thiadiazole-2-thiols are given in Tables 1 and 2. The structure was supported by the absence of IR bands at 3200–3300, 1650–1670 $cm^{-1}$ due to $NHNH_2$ and CONH groups, respectively, and appearance of 1550–1590 $cm^{-1}$ due to C=N groups. It was also supported by the $^1$H-NMR data showing signals at δ 11.0–14.2 due to SH and $^{13}$C-NMR data showing signals at δ 160.0–174.0 and 176–192 due to 5 C—N and 2 C—N, respectively.

Both conventional and greener synthetic protocols for 5-substituted-1,3,4-thiadiazole-2-thiols were assessed using various green chemistry measures [19–21]. The developed greener protocol showed 4.7–11.4% increase in overall yield (Table 1). 5-Phenyl-1,3,4-thiadiazole-2-thiol was taken as a case for all calculations and related data for both the protocols (1 and 2) are described in Table 3.

The overall yield, *i.e.*, starting from benzoic acid to 5-phenyl-1,3,4-thiadiazole-2-thiol, following protocol 2 was 69.3% as compared with 59.6% from conventional protocol. There was 9.7% increase in the yield. The number of steps was also reduced to three as compared with four in protocol 1. This resulted in the higher energy efficiency and reduction of time, as total heating time was just 60–200 s under microwaves in protocol 2 as compared with 6–9 h in protocol 1. Among the various green chemistry matrices, *E*-factor values for protocols 1 and 2 were 20.1 and 14.8 kg waste/kg product, respectively, showing the reduction of 26.4% in the waste produced over the production of 1 kg of the product. Atom economy was increased by 5% as it was 43.3 and 48.3% for protocols 1 and 2, respectively. Atom efficiency, which considers both atom economy and yield parameters, showed an improvement of 7.7%. Carbon efficiency was found to be 28.5 and 34.7% for protocols 1 and 2, respectively, and it was improved by 6.2%. Reaction mass efficiency possessed the values of 31.5 (protocol 1) and 36.1 (protocol 2) as well as an increase of 4.6% was observed.

Results obtained in the *in vitro* soil incubation study are described in the Table 4. All the test compounds showed significantly higher ammonium-N and lower nitrate-N content as compared with urea alone The nitrite-N content remained insignificant (<0.5 mg/kg) in all the samples on all the sampling days.

All the compounds have been found to be effective nitrification inhibitors showing 49.5–79.7%, 36.8–78.8%, 42.4–78.5%, and 24.6–76.85% nitrification inhibition (NI) at 7th, 14th, 21st, and 28th days, respectively (Table 4). 4-Amino-1,2-4-triazole (ATC), the reference inhibitor at 10% dose, showed 75.3%, 75.7%, 77.2%, and 73.7% inhibitory activity on 7th, 14th, 21st, and 28th days, respectively, whereas the corresponding data on 5% dose were 65.9%, 65.5%, 65.3%, and 59.2% as well as at 1% dose were 60.9%, 57.4%, 54.6%, and 39.0% on 7th, 14th, 21st, and 28th days, respectively.

Among the series, 5-heptyl-1,3,4-thiadiazole-2-thiol (**ii**), 5-(2-chloro phenyl)-1,3,4-thiadiazole-2-thiol (**vi**), 5-(2,4,-dichloro phenyl)-1,3,4-thiadiazole-2-thiol (**vii**), 5-(2-methyl phenyl)-1,3,4-thiadiazole-2-thiol (**viii**), 5-(3-methyl phenyl)-1,3,4-thiadiazole-2-thiol (**ix**), 5-(3,4,-dimethoxy phenyl)-1,3,4-thiadiazole-2-thiol (**xii**), 5-(2-hydroxy phenyl)-1,3,4-thiadiazole-2-thiol (**xiii**), and 5-(4-hydroxy-3-methoxy phenyl)-1,3,4-thiadiazole-2-thiol

(**xiv**) were found to be the promising nitrification inhibitors.

Among the active series, 5-(3-methyl phenyl)-1,3,4-thiadiazole-2-thiol (**ix**) was most active at 10% dose with NI 78.2%, 77.1%, 77.3%, and 76.8% on 7th, 14th, 21st, and 28th days, respectively. The next active compound was 5-(2-chloro phenyl)-1,3,4-thiadiazole-2-thiol (**vi**) with activity at 10% was 79.7%,78.8%, 77.7%, and 75.1% on 7th, 14th, 21st and 28th days, respectively (Table 4).

Other active compounds (**vii**), (**xii**), (**xiii**), (**viii**), (**ii**), and (**xiv**) were statistically at par with ATC as evident from least significant difference (LSD) values. Compound (**xv**) showed 77.3%, 76.6%, 78.5%, and 68.4% NI on 7th, 14th, 21st, and 28th days, respectively. It performed statistically at par with ATC on 7th, 14th, 21st, but its activity was lower on 28th day. Rest of the compounds was less active at 10% doses than the reference inhibitor ATC. Among them, least active was compound (**iv**) with activity of 58% on the 28th day at 10% dose.

Among the active series compound (**vi**) was most active at 5% dose with NI 74.1, 73.5, 72.3, and 65.4 on 7th, 14th, 21st, and 28th days, respectively (Table 4). It performed better than ATC (5%) and statistically at par with ATC (10%) on 7th and 14th day. The next active compound was (**vii**) at 5% dose with NI 72.5%, 71.5%, 72.1%, and 63.1% on 7th, 14th, 21st, and 28th days, respectively. Other active compounds showed NI in the range of 56.1–73.8% during the entire period of incubation. All these compounds were statistically similar to ATC (5%). Remaining compounds were found to be inferior to reference inhibitor ATC (5%).

Compound (**vi**) at 5% dose performed best with NI 66.3%, 62.9%, 54.4%, and 41.4% on 7th, 14th, 21st, and 28th days, respectively. The next in performance were (**x**), (**xiv**), (**viii**), (**vii**), (**ii**), and (**xii**). All these

**Table 3**

Comparative assessment of protocols 1 and 2 using green chemistry measures.

| Matrix | Protocol 1 (Conventional) | Protocol 2 (Greener) | Improvement |
|---|---|---|---|
| Overall yield (%) | 59.6 | 69.3 | 9.7% increase |
| Number of steps | Four | Three | 25% reduction |
| Heating time | 6–9 h | 60–200 s | 162–360 times decrease |
| Energy consumption (KWh) | 6–9 | 0.015–0.050 | 180–400 times reduction |
| E(nvironmental) factor (Kg waste/Kg product) | 20.1 | 14.8 | 26.4% reduction |
| Atom economy (%) | 43.3 | 48.3 | 5% increase |
| Atom efficiency (%) | 25.8 | 33.5 | 7.7% increase |
| Carbon efficiency (%) | 28.5 | 34.7 | 6.2% increase |
| Reaction mass efficiency (%) | 31.5 | 36.1 | 4.6% increase |

compounds were statistically at per with each other (Table 4). All the compounds showed an increase in NI with the increase in dose. Enhancement in NI is more from 1 to 5% increases in dose as compared with 5 to 10%.

**Structure-activity relationship.** In general, aryl substituted thiadiazoles performed better than the alkyl substituted 1,3,4-thiadiazole-2-thiols at all the doses. The 5-substitution in the 1,3,4-thiadiazole with aliphatic chains of 1, 7, 9, and 11 carbon atoms were used. The chain aliphatic seven of carbon atoms performed the best as evident from their performance on 28th day of incubation. The overall effect in minimizing NI was significantly higher with seven carbon atoms with 69.8 and 63.1% as compared with 58.1–64.4% and 52.9–56.2% with others at 10 and 5% doses, respectively (Fig. 1). At 1% dose, maximum NI, 36.2%, was observed with seven carbon atoms, but it was superior to NI with one carbon atom, 25.7% only and performed at par with others.

5-Aryl substitution in the 1,3,4-thiadiazole ring with chloro atoms in phenyl ring was used. Introduction of chlorine atoms in the phenyl ring resulted in the increase of activity and found to be significantly superior to phenyl substitution with no chlorine atom (Fig. 2). Their effect on NI was similar for both mono and dichloro phenyl derivatives (Fig. 2), which were superior to phenyl derivative. Both chloro derivative showed 36.2–41.4%, 63.8–65.4%, and 73.6–75.1% NI at 1, 5, and 10% dose, respectively. The phenyl derivative showed 24.6%, 43.6%, and 60.8% NI at respective 1, 5 and 10% doses.

5-(3-Methyl phenyl)-1,3,4-thiadiazole-2-thiol, 5-(4-chloro phenyl)-1,3,4-thiadiazole-2-thiol and 5-(2,4-dichlorophenyl)-1,3,4-thiadiazole-2-thiol emerged as potent nitrification inhibitors. The study revealed the cost effective and environment friendly synthesis of the potent 1,3,4-thiadizole-2-thiols. These compounds hold promise to be used as nitrification inhibitors and also as prototypes for the discovery of potent analogues through the process of compound library design and screening.

## EXPERIMENTAL

Thin layer chromatography was performed on 200-μm thick aluminum sheets having silica gel 60 $F_{254}$ as adsorbent. Different solvent systems were used for developing the TLC plates. Spots were visualized either by UV-light or iodine vapors. Melting points were determined by using electro thermal melting point apparatus and are uncorrected. Microwave irradiation was carried out by using Samsung microwave oven model CE118KF operating at 2450 MHz. A Christ Lypholizer model Alpha 1-2 LD was used for lyophilizing purpose. Nuclear magnetic resonance (NMR) spectra were recorded on a Brucker Abamce, 400 MHz instrument, after dissolving the samples in $CDCl_3$/DMSO($d_6$) using tetramethylsilane (TMS) as an internal standard. Chemical shifts were reported in δ values relative to TMS and the notations used are s-singlet, d-doublet, t-triplet, m-multiplet, and brs-broad singlet. Infrared (IR) spectra were recorded on a Nicolet Fourier Transform Infrared Spectrophotometer, Model Impact 400 (FTIR) in either nujol mull or KBr disc. A Varian, Series 634, UV–Vis double beam spectrophotometer was used. Elemental analysis was carried out using EuroVector CHNS analyzer. All the chemicals and reagents were purchased from S D Fine Chemicals, Qualigens Fine Chemicals, and Merck India.

**Synthesis of test chemicals.** 5-Substituted-1,3,4-thiadiazole-2-thiols were synthesized following the Scheme 1 using the both conventional (protocol 1) and greener synthesis (protocol 2). Protocol 2 used the new greener method [18] for synthesizing the intermediate hydrazides which otherwise required 6–9 h heating under protocol 1 [13].

***Conventional method of synthesis of carboxylic acid hydrazides (Method-A).*** The organic acids were esterified in the presence of ethyl alcohol and catalytic amount of sulfuric acid. The resulted esters were hydrazinolysed with hydrazine hydrate to afford the hydrazides [13].

***Greener method for synthesis of carboxylic acid hydrazides (Method B).*** Carboxylic acid (0.01 mol) and hydrazine hydrate (0.012 mol) were irradiated under microwaves for 60–200 s at 900 W. Then, the reaction mixture was cooled to −20°C and lyophilized at −50°C. The product obtained was recrystallized from methyl alcohol. The hydrazides were characterized on the basis of physical and spectral data [13–17].

**Preparation of 5-substituted-1,3,4-thiadiazole-2-thiols.** Potassium hydroxide (0.11 mol) was dissolved in minimum amount of ethanol, and hydrazide (0.1 mol) was added to it. The reaction mixture was cooled to 0–5°C followed by

drop wise addition of carbon disulphide (0.11 mol). After addition, the reaction mixture was stirred for 30 min to afford solid potassium dithiocarbazate salt. It was filtered, washed with chilled acetone, dried, and used as such for further reaction. Potassium dithiocarbazate salt (0.1 mol) was added slowly in small lots to conc sulfuric acid (2.5 times of salt) at 5°C with constant stirring. The reaction mixture was stirred for 30 min, and the resulting viscous liquid was poured over crushed ice slowly. The solid obtained was filtered and washed with excess of water till the filtrate become neutral to litmus paper. The wet solid was suspended in water at 40°C and 25% sodium hydroxide solution was added slowly with stirring to adjust the pH of the solution in the range of 8.0–9.0. The resulting solution was filtered through a charcoal bed, and pH was adjusted

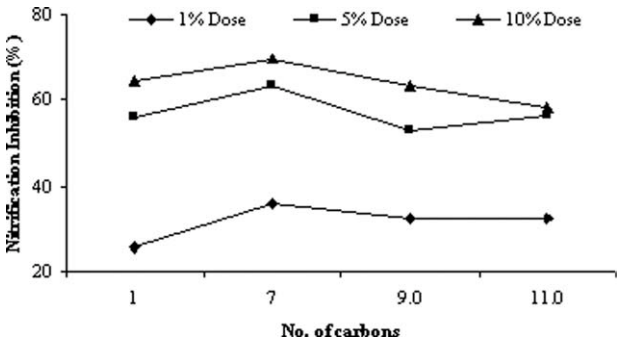

**Figure 1.** Effect of number of aliphatic C-atoms at 5-position of 1,3,4-thiadiazole-2-thiol on nitrification inhibition.

to 3.0–5.0 by drop wise addition of 50% hydrochloric acid. White solid obtained was filtered, washed with water, and dried. All the compounds were characterized on the basis of physical and spectral data as depicted in Tables 1 and 2.

**Assessment by green chemistry matrices.** The developed synthetic protocol for 5-substituted-1,3,4-thiadiazole-2-thiols was assessed by following green chemistry matrices, which were calculated as reported [19–21].

**Nitrification inhibitory activity.** The soil with following properties was collected from the farm of the institute for *in vitro* incubation experiments. Sand 60.8%, silt 18.7%, clay 20.5%, water holding capacity 35.5%, bulk density 1.51 mg/kg, organic C 0.5%, available N 553.72%, ammonium-N 3.2 mg/kg, nitrite-N traces, nitrate-N 8.54 mg/kg, pH (soil: water::1:2.5) 7.9, and EC at 25°C 0.35 $dSm^{-1}$.

The test chemicals (5-substituted-1,3,4-thiadiazole-2-thiols) and reference inhibitor, ATC, were tested at three doses (1, 5 and 10% of applied urea-N) along with urea alone control.

The experiments were laid following completely randomized design with three replicates. Fifty grams of air dried, finely ground, and sieved (10 mesh) soil was taken in 100 mL capacity plastic beakers. Calculated amount of the test chemical (0.1, 0.5, and 1.0 mg for 1, 5, and 10% dose of applied urea-N, respectively) in acetone was added to each beaker and mixed thoroughly. In all the treatments including control, same volume of acetone was added. After mixing, 10 mg urea-N (200 mg urea-N per kg of soil) in aqueous solution was added, mixed thoroughly, and distilled water was added to each beaker for maintaining the moisture at 50% of water holding capacity [25] of the soil. The experiment was conducted in triplicate with concomitant controls. For ATC, the soil was prepared in similar way. All the beakers were accurately weighed, labeled, and incubated in a BOD incubator at 28 ± 1°C, and 98% relative humidity. Soil moisture was maintained by adding distilled water every alternate day (if required) after taking the difference of weight. Samples (5 g) were drawn on 7th, 14th, 21st, and 28th day of incubation. Before sampling, distilled water was added to make up for the loss in weight because of evaporation of water and mixed thoroughly. Ammonium, nitrite, and nitrate-N were extracted in 50 mL 2*M* aqueous sodium sulfate solution. The soil with extracting solution was shaken for an hour on a reciprocal shaker and filtered. Ammonium, nitrite, and nitrate-N were estimated following Indophenol blue, sulfanilic acid, and phenol disulfonic acid method, respectively [26,27].

The contents of ammonium nitrate and nitrite-N were obtained from the standard curves and expressed in mg $kg^{-1}$. The nitrification rate for a constant period of incubation was calculated using Sahrawat's [28] formula. The data were statistically analyzed following the procedure laid out by Gomez and Gomez [29]. The analysis of variance was computed using Statistical Package for Social Services (SPSS version 10.0), and treatment means were compared by LSD at 5% levels.

The novel hydroperoxy sultams, 2,3-dihydro-3-hydroperoxy-2-aryl-4,5-diphenylisothiazole 1,1-dioxides, were synthesized by the oxidation of the 2-aryl-4,5-diphenyl substituted isothiazolium salts with $H_2O_2$. These hydroperoxy sultams were investigated as epoxidation agents in the epoxidation reaction of *cis*-cyclooctene catalyzed by MoB. 2-(2-Chlorophenyl)-2,3-dihydro-3-hydroperoxy-4,5-diphenylisothiazole 1,1-dioxide was found to have the highest epoxidation ability.

*J. Heterocyclic Chem.,* **47**, 846 (2010).

## INTRODUCTION

The cyclic sulfonamides (sultams) have been shown to be highly useful heterocycles for medicinal chemistry [1,2] as well as for chemical methodology [3,4]. They show biological activities such as antibacterial [5,6], anticonvulsant [7,8], sedative-hypnotic [9], and peptidomimetic [10,11]. Sultams have found application as chiral auxiliaries in several asymmetric processes such as Diels-Alder reactions [12,13], alkylation [14], and dihydroxylation [15] and are used in enantioselective catalysis [16]. Hydroperoxy sultams can also serve as oxidants in oxidation of heteroatoms (N, S, P) [17,18] and in epoxidation of double bonds [19].

We now report the synthesis of novel hydroperoxy sultams, 2,3-dihydro-3-hydroperoxy-2-aryl-4,5-diphenylisothiazole 1,1-dioxides, and studies of their epoxidation ability in the epoxidation reaction of *cis*-cyclooctene catalyzed by molybdenum boride MoB.

## RESULTS AND DISCUSSION

Our approach to hydroperoxy sultams started from isothiazolium salts (1) (Scheme 1) which were prepared for the first time by intramolecular cyclocondensation of β-thiocyanatovinyl aldehydes and the suitably substituted anilines in the presence of perchloric acid in acetic acid in moderate-to-good yields: 1a (61%), 1b (62%), and 1c (51%) according to already reported synthesis [20,21]. The oxidation of the 2-aryl-4,5-diphenyl substituted isothiazolium salts in glacial acetic acid with 30% $H_2O_2$ at r.t. gave stable 3-hydroperoxysultams (2) in good yields: 2-(2-chlorophenyl)-2,3-dihydro-3-hydroperoxy-4,5-diphenylisothiazole 1,1-dioxide (2a) (70%), 2-(2,6-dichlorophenyl)-2,3-dihydro-3-hydroperoxy-4,5-diphenylisothiazole 1,1-dioxide (2b) (70%) and 2-(2,6-dichloro-4-nitrophenyl)-2,3-dihydro-3-hydroperoxy-4,5-diphenylisothiazole 1,1-dioxide (2c) (72%) after 72, 72 and 96 h stirring, respectively.

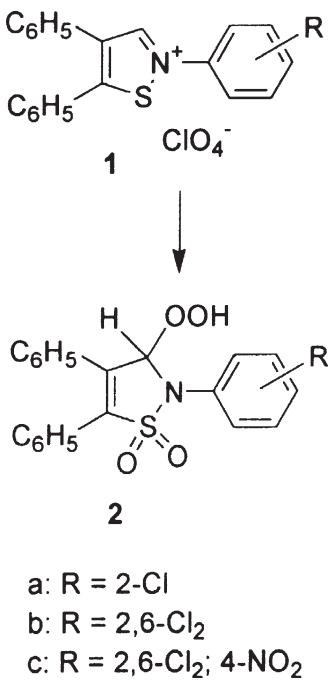
The structures of the 3-hydroperoxysultams 2a, 2b, and 2c were established by IR and NMR spectroscopy and composition was confirmed by mass spectrometry and elemental analysis.

The IR spectra of compounds 2 show two absorption bands at 1302–1316 and 1146–1160 $cm^{-1}$ for the $SO_2$ groups which are characteristic for the antisymmetric and symmetric vibrations of the 1,1-dioxides, respectively. The two absorption bands for the $NO_2$ group are observed at 1335 and 1537 $cm^{-1}$ in the spectrum of compound 2c.

In $^1H$ NMR spectra of 3-hydroperoxysultams 2, the typical absorption of the 3-H atom appears at 6.49–6.60 ppm. The $^{13}C$ NMR signals for C-3 at 92.5–95.0 ppm are characteristic for compounds 2.

The 2 were investigated as epoxidation agents in the epoxidation reaction of cyclooctene in the presence of molybdenum boride. The kinetic curves of 2 consumption and 1,2-epoxycyclooctane accumulation in the

**Scheme 1**



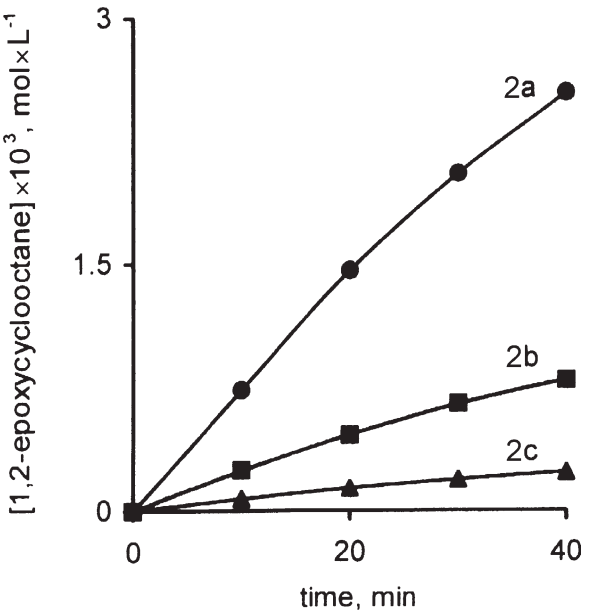


**Figure 2.** The kinetic curves of the 1,2-epoxycyclooctane accumulation in the catalytic epoxidation reaction of cyclooctene by **2**.

epoxidation process are presented in Figures 1 and 2, respectively. It is evident that epoxidation ability of investigated 2 is different and is defined by the nature of the substituents on the aromatic ring connected at nitrogen atom of hydroperoxide molecule.

The highest value of hydroperoxy sultam consumption in the catalytic epoxidation process was observed for 2a containing only one *ortho*-chlorine atom and conversion of this hydroperoxide was equal to 73% after 40 min of reaction. In the case of 2b with two chlorine atoms in ortho-position to bond of nitrogen with aromatic ring, the hydroperoxide consumption was the lowest and hydroperoxide conversion was 41%. The value of hydroperoxide conversion for 2c which contains three substituents—two chlorine atoms and one $NO_2$ group—is 47% so it is between 2a and 2b.

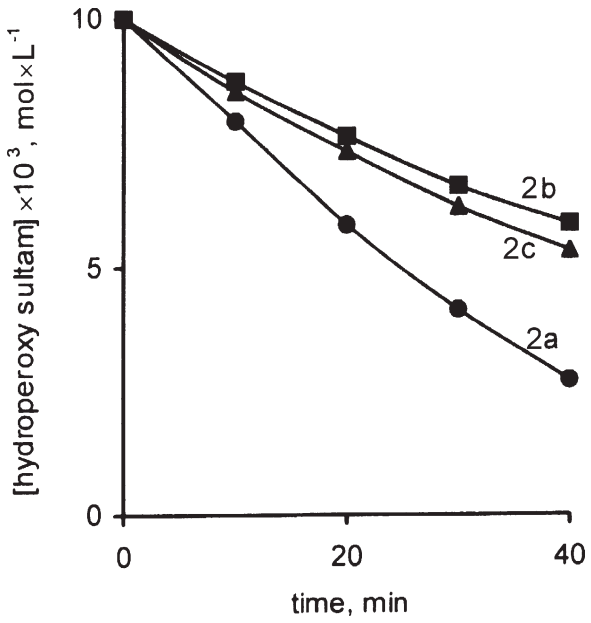

**Figure 1.** The kinetic curves of the consumption of **2** in the catalytic epoxidation reaction of cyclooctene.

The epoxide is formed in the presence of all investigated hydroperoxy sultams. This fact indicates on possibility of their application as epoxidation agents in the catalytic reaction with cyclooctene. The highest epoxidation ability exhibits 2a, the selectivity of epoxide formation (calculated as ratio of formed epoxide quantity to consumed hydroperoxide quantity) in its presence is 35%. The lowest epoxidation ability demonstrates 2c in the case of which the selectivity of epoxide formation is only 5%. 2b shows intermediate selectivity 19%.

From the obtained results, one can conclude that the most effective oxidant in the catalytic epoxidation reaction of cyclooctene is 2a, which molecule contains only one substituent—chlorine atom in α-position to bond of nitrogen with aromatic ring. Introduction of another one chlorine atom and especially $NO_2$ group leads to decrease of the parameters of the epoxidation reaction. It is probably caused by dominant influence of a steric factor. The increase in quantity of substituents complicates possibility of the simultaneous coordination of hydroperoxy sultam and cyclooctene on catalyst and formation of intermediate triple complex which is

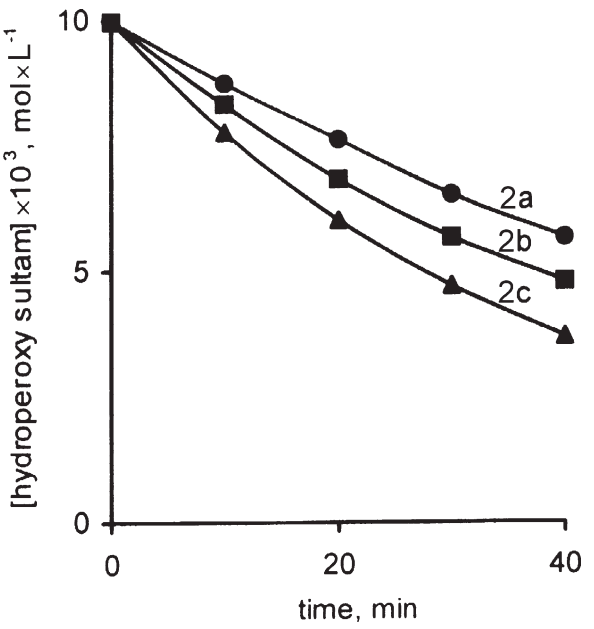

**Figure 3.** The kinetic curves of the consumption of **2** in the catalytic decomposition reaction.

responsible for epoxide formation [22–24]. Accordingly, the efficiency of the epoxidation reaction decreases.

Taking into account the significant contribution of unproductive 2 consumption into overall process of the cyclooctene epoxidation, it is reasonable to study the decomposition process of investigated hydroperoxy sultams catalyzed by MoB at the same reaction conditions in the absence of cyclooctene in the reaction system. Figure 3 shows the kinetic curves of 3-hydroperoxysultams consumption in the process of catalytic decomposition. One can see that the decomposition process most actively occurs in the case of 2c with hydroperoxide conversion 63%. One may suggest that presence of $NO_2$ group in a para-position to bond of nitrogen with aromatic ring favors the proceeding of the catalytic decomposition process. The values of conversions of 2b and 2a are smaller and are equal to 52% and 43%, correspondingly.

Comparing the data of the decomposition process with the data of the epoxidation process, it is possible to conclude that the highest epoxidation ability in the epoxidation process has 2a which is the least active in the decomposition reaction. At the same time, the 2c, which is the most actively consumed in the decomposition process, has the lowest epoxidation ability in the reaction with cyclooctene.

In summary, we have described the synthesis of novel 2,3-dihydro-3-hydroperoxy-2-aryl-4,5-diphenylisothiazole 1,1-dioxides by oxidation of the 2-aryl-4,5-diphenyl substituted isothiazolium salts with $H_2O_2$. We have shown that these hydroperoxy sultams can act as epoxidation agent in the epoxidation reaction of cyclooctene catalyzed by MoB.

## EXPERIMENTAL

Melting points were determined on Boetius micro-melting-point apparatus and are corrected. IR spectra are expressed in $cm^{-1}$ and were recorded on Genisis FTIR Unicam Analytical System (ATI Mattson) using KBr pellets. $^1H$ NMR spectra were recorded on 200- (Varian Gemini-200) and 300-MHz (Varian Gemini-300). Chemical shifts are reported in δ (ppm) relative to tetramethylsilane (TMS) as internal standard. $^{13}C$ NMR spectra were received on the named spectrometers. Electron impact mass spectra (EI-MS) were recorded on a Quadrupol-MS VG 12-250 at an ionizing voltage of 70 eV. Elemental analysis was determined on Heraeus CHNO Rapid Analyzer.

**Synthesis of 2,3-dihydro-3-hydroperoxy-2-aryl-4,5-diphenylisothiazole 1,1-dioxides (2).** $H_2O_2$ (0.7 mL, 30%) was added to a stirred suspension of **1** (0.26 mmol) in AcOH (0.7 mL) at room temperature. After dissolution of salts **1**, colorless precipitates of **2** were obtained after 72–96 h and isolated. The crude products were washed with water.

**General experimental procedure for the catalytic epoxidation of cyclooctene by 2.** The epoxidation process was carried out in a thermostated glass reactor fitted with a reflux condenser and a magnetic stirrer under an argon atmosphere at temperature 23°C. The reactor was loaded with 0.01 g of MoB (Alfa Aesar) as a heterogeneous catalyst, 0.3 mL of *cis*-cyclooctene (Acros Organics), 3.5 mL chloroform as solvent, and 0.01 mol $L^{-1}$ of **2**. It is established that **2** does not decompose in the absence of catalyst in the reaction system and 1,2-epoxycyclooctane is not formed under the reaction conditions. The concentration of **2** was determined by iodometric titration [25]. The reaction mixtures were analyzed by using a Hewlett Packard HP 6890 N chromatograph, a capillary column DB-1 (60 m × 0.32 mm × 0.5 μm) packed with dimethylsiloxane. The

column temperature was changed from 50 up to 250°C with rate of 10° in 1 min.

**Acknowledgments.** The work was partly supported by the Deutscher Akademischer Austauschdienst (DAAD) and by the Graduiertenkolleg 378 ''Mechanistische und Anwendungsaspekte nichtkonventioneller Oxidationsreaktionen.''

New *N*-[(1,3-diphenylpyrazol-4-yl)methyl]α-amino acids (**1a–i**) have been synthesized and tested *in vitro* for their antiproliferative activity against human myelogenous leukemia K562, colon adenocarcinoma HT-29, cervix carcinoma HeLa, and normal fetal lung fibroblasts, MRC-5. Compounds derived from both phenylalanine enantiomer precursors appeared to be the most active against myelogenous leukemia K562 cell lines with a high cytotoxic potential.

## INTRODUCTION

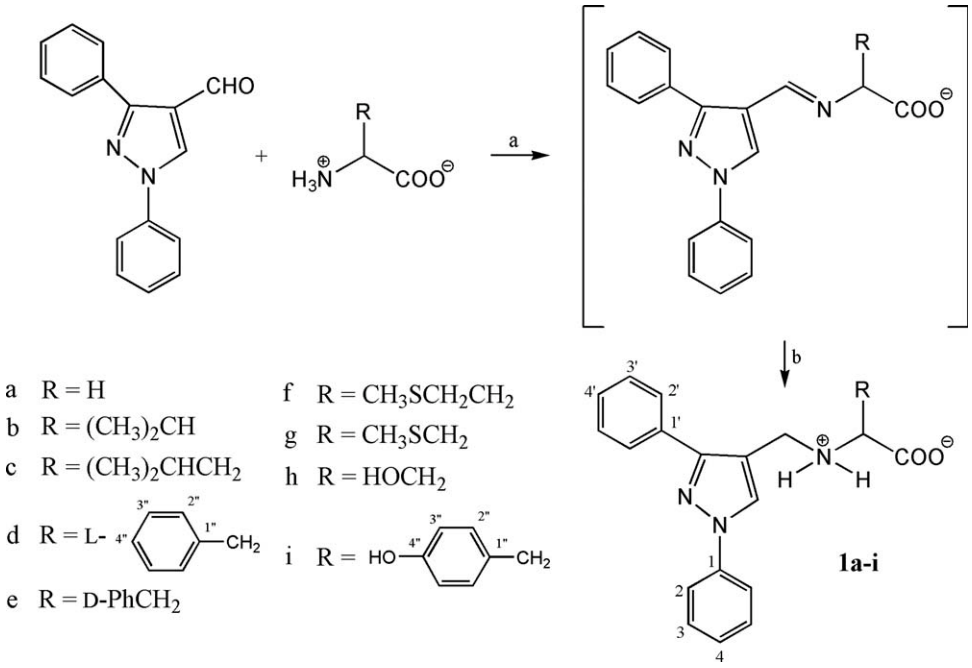
Arylpyrazole derivatives play an important role in biologically active compounds and therefore represent an interesting template for medicinal chemistry. These compounds displayed diverse biological properties such as antiparasitic [1], antifungal [2], antibacterial [3], and antidiabetic [4]. Moreover, arylpyrazole derivatives have shown several biological activities as seen in cyclooxygenase-2 [5], p38 MAP kinase [6], and nonnucleoside HIV-1 reverse transcriptase inhibitors [7]. In the research for antitumor agents, arylpyrazole derivatives exhibited promising antiproliferative properties against several kinds of human tumor cell lines [8–10].

The cytotoxic drugs, such as doxorubicin, 5-fluorouracil, and camptothecins, can damage DNA or affect cellular metabolic pathways causing indirect block of the cell cycle. Unfortunately, these agents produce an irreversible damage to both normal and tumor cells, resulting in a significant toxicity and side effects [11–13]. In this respect, it is desirable to synthesize new highly specific antitumor agents with comparable efficacy and reduced toxicity than the currently available drugs. In view of these observations and as a continuation of our interest toward synthesis and biological activity of arylpyrazole derivatives [14,15], some new *N*-[(1,3-diphenylpyrazol-4-yl)methyl] α-amino acids were prepared with the aim to have promising antiproliferative properties against several kinds of human tumor cell lines.

## RESULTS AND DISCUSSION

In this work, condensation of the optically active L- and D-amino acids (except **1a**) with 1,3-diphenylpyrazole-4-carboxaldehyde in the presence of NaOH led to the formation of Schiff base intermediates. As α-amino acids are sparingly soluble in alcoholic solvents, the Schiff base formation takes long time, and the reaction gives lower yields even under reflux conditions. Thus, the condensation reaction was accelerated using solventless method [16] combining aldehyde, α-amino acids, and NaOH in a porcelain mortar with pestle and aggregating the dry solid mixture until a white powder was formed. The condensation was completed by an additional heating at reflux for 2 h in dry methanol (Scheme 1).

**Scheme 1.** Reagents and conditions: (a) NaOH, continuous aggregating at rt, then MeOH, reflux, 2 h; (b) $NaBH_4$, 0–5°C, then rt, 12 h, AcOH.



The stability of the formed Schiff base products depends on several factors such as amino acid side chain polarity [17], the metal, pH, solvent, and temperature [18]. The problem with Schiff base instability can be overcome by their reduction to give a more flexible amine and not constrained compounds. In the light of these facts, we have performed out the reduction with an excess of $NaBH_4$ without isolation of Schiff base to afford the novel *N*-[(1,3-diphenylpyrazol-4-yl)methyl] α-amino acids.

The structures of the new compounds were confirmed using different spectral data (IR, $^1H$, and $^{13}C$ NMR) and elemental analysis. The IR spectra revealed the presence of $NH_2^+$ stretching frequencies between 2650 and 2300 $cm^{-1}$ in the form of broad band with multiple peaks on the low frequency wing, which continue until about 2200 $cm^{-1}$, confirming their zwitterionic nature. The $\nu_{as}$ (COO) was related to the strong absorption band appearing in the spectra between 1619 and 1601 $cm^{-1}$, whereas the symmetric carboxylate stretches $\nu_s$ (COO) correspond to the medium–strong peaks about 1410 $cm^{-1}$ [19]. The other characteristic very strong absorption bands in the IR spectra were those attributed to the pyrazole ring: ν (C=C) and ν (C=N) between 1601 and 1547 $cm^{-1}$ as well as δ (C=C) about 1505 $cm^{-1}$ [20].

The $^1H$ NMR spectra of all compounds exhibited a characteristic AB system except **1a** and ABX system for **1d**, **1e**, **1g**, **1h**, and **1i**. The $^1H$ NMR spectra revealed the presence of characteristic singlet peak attributed to pyrazole ring proton appeared between 7.97 and 8.67 depending on the applied solvent system. The complete assignment of all reported signals ($^1H$ and $^{13}C$) in the experimental part was carried out by means of 1D and 2D homo- and heteronuclear correlated NMR spectroscopy.

The newly synthesized compounds **1a–i** were evaluated *in vitro* for their antiproliferative activity against human myelogenous leukemia K562, colon adenocarcinoma HT-29, cervix carcinoma HeLa, and normal fetal lung fibroblasts, MRC-5 using sulforhodamine B (SRB) assay [21] and doxorubicin (Dox) as reference drug. The results are presented in Table 1.

The malignant cell line K562 was the most sensitive, where the pronounced cytotoxicity was achieved by seven of nine tested samples. The compounds with benzyl group **1d** and **1e** showed the most potent cytotoxic activity against human myelogenous leukemia K562 cell lines. The replacement of the benzyl group in **1d** by a hydrophobic isobutyl group leading to **1c** would retain potential hydrophobic bonding while creating spatial property differences between the benzyl and isobutyl group. The comparison of the cytotoxicity of **1d** or **1e** with **1c** indicates that **1d** and **1e** are more active in inhibition of these cells. When the side chain was replaced with an isopropyl group **1b**, a complete inactivity against K562 was observed. The moderate activity was achieved when an additional heteroatom was

[a] $IC_{50}$ is the concentration of compound required to inhibit the cell growth by 50% compared to an untreated control.

incorporated into the side chain **1f**. These differences in cytotoxicity could be related to their conformation and size of the substitutes. The bulky isopropyl group **1b** and voluminous sulfur atom **1g** closely to aminocarboxylate skeleton induce the decrease of cytotoxic activity, probably preventing the formation of intermolecular interaction with cell receptors. Comparison of the cytotoxicity of compounds derived from different enantiomers of phenylalanine indicates that D-phenylalanine demonstrated similar activity with respect to L-phenylalanine analog. We could also suggest that **1d** and **1e** are the most cytotoxic compounds because of their planarity and hydrophobic properties. These results indicate that spatial effects and side chain length should be an important factor in the design of future molecules. It is interesting to note that the compounds **1h** and **1i** having polar hydroxyl groups proved to be less active than **1d** and **1e**, suggesting that electronic character could be diminished in comparison with hydrophobic requirements of amino acid part of molecule. Compounds **1g** and **1e** were also active against HeLa and HT29 cell lines, respectively, but their activity was significantly lower compared with doxorubicin. On the other hand, all compounds were devoid of any cytotoxicity against the normal fetal lung fibroblasts MRC-5. Generally, the hydrophobic character and steric effects in amino acid moiety appear to be the main factors for the growth suppressing potential against K562 cell lines. Further modification of compounds **1d** and **1e**, especially the transformation of carboxylate group and identification of its molecular target, is under investigation.

**Thermal analysis.** Thermal analysis of pharmaceutical compounds is a very reliable method for purity control, and it is a necessary part of the characterization of new compounds with potential bioactivity [22,23]. As amino acid–water–protein interface interactions are very important in biological systems [24]; the thermal properties of these new amino acid derivatives may be of special interest.

In the series of nine new compounds, two of them are pure N-substituted amino acids, whereas the others crystallize with different number of water molecules.

Thermal measurements reveal that the stability of N-substituted amino acids **1a** and **1b** is rather high in both atmospheres (in $N_2$ 200 and 205°C, respectively). Most probably as a consequence of some sensitivity toward oxidation, in air the thermal stability of the compounds is somewhat less. The decomposition mechanism in inert and oxidative atmosphere also differs (see Fig. 1).

The dehydration pattern of the hydrates does not depend on the atmosphere. The dehydrated compounds **1c**, **1g**, **1h**, and **1i** are stable to above 200°C, with the previous remark: their stability in air is less with about 5°C. Compounds **1d**, **1e**, and **1f** decompose further after dehydration, without giving a stable anhydrous intermediate.

The decomposition of all samples was accompanied by melting, observed visually. The decomposition mechanism of the first decomposition step of dry compounds is proposed only on the basis of the mass loss. The fragmentation begins with that of the side chain, *e.g.*, the mass loss to the minimum in DTG curve of **1a** amounts 14.5% in $N_2$ that agrees well with the loss of $CO_2$ molecule (calcd. 14.32%). The valine **1b** derivative most probably decomposes by the loss of the methyl groups. However, it is pointless to give a decomposition mechanism in lack of coupled measurements. It is more important to have a closer look to the dehydration process of the hydrates from both the theoretical and practical point of view. The mass loss with the corresponding temperature of the dehydration is given in Table 2 together with the decomposition temperature of the anhydrous compound.

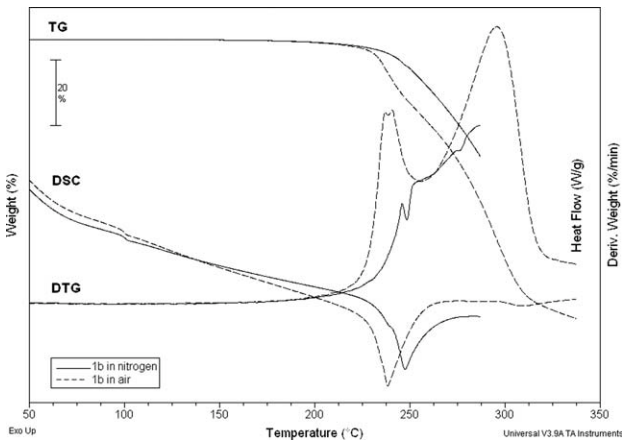

**Figure 1.** Thermal decomposition curves of **1b** in air and nitrogen.

**Table 2**

Mass loss of the dehydration, the dehydration temperature, and the onset temperature of the decomposition of the anhydrous compound in $N_2$.

| Compound | Dehydration, $\Delta m$ (%) | | $t_{DEHYD.}$ (°C) | $t_{DECOMP.}$ (°C) | Comments |
|---|---|---|---|---|---|
| | Exp. | Calcd. | | | |
| **1c** | 4.2 | 4.72 | <105 | 215 | Stable anhydrous compound |
| **1d, 1e** | 7.3 | 8.31 | <130 | – | Stepwise dehydration, continuous decomposition |
| **1f** | 10.4 | 10.17 | <135 | – | Stepwise dehydration, continuous decomposition |
| **1g** | 1.3 | 4.67 | <50 | 203 | Crystal water |
| **1h** | 2.2 | 5.34 | <150 | 225 | Structural water |
| **1i** | 0.5 | 4.36 | <30 | 235 | Loosely bond crystal water |

As the decomposition of the compounds **1d**, **1e**, and **1f** is continuous to obtain better separated decomposition steps, quasi-isothermal [25] (SWI) measurement was carried out. Figure 2 illustrates SWI curve of the compound **1f**. The five water molecules evaporate to 150°C (exp. 15.8%, calcd. 16.95%) in five clearly distinguished steps, not one by one, but through a complex process governed by macroscopic properties of the sample (*e.g.*, the rate of the diffusion) as well as by their different bonding energy. The dehydration of this compound is most probable followed by the evaporation of $CH_3COOH$ molecule. The difference in experimentally determined mass loss and the theoretical one is most probable because of the evaporation of the crystal water at room temperature. The dehydration of **1d** and **1e** derivatives shows similar complexity of the dehydration. Derivative **1h**, according to elemental analysis data, contains both crystal and structural water, belonging to more than one molecule. By TA only the structural water is detected, because in air the compound lost its crystal water completely. Compound **1i** has some crystal water left, while most of it has evaporated during the storage time.

Taking into account the importance of the interactions in the relation of amino acid–water–protein, the cytotoxicity of the compounds might be related to H-bond-forming capability in the molecules. This, indirectly, may be investigated using TA data of hydrates. However, the correlation is not straightforward. TA data may refer only to the preferences of an amino acid to bind water molecules and the strength of the bond between them [26].

## CONCLUSIONS

In summary, a new class of *N*-[(1,3-diphenylpyrazol-4-yl)methyl] α-amino acids were synthesized, and their antiproliferative activity against human myelogenous leukemia K562, colon adenocarcinoma HT-29, cervix carcinoma HeLa, and normal fetal lung fibroblasts, MRC-5 was evaluated. The nature, spatial effects and the distance of bulky substitutes from aminocarboxylate part of molecule appeared to play an important role in antiproliferative activity against different malignant cell lines. The dehydration temperature is related to the water bond energy and might be connected with the active sites of some bioactive molecules.

## EXPERIMENTAL

All chemicals were obtained from commercial sources (Aldrich) and used as supplied. 1,3-Diphenylpyrazole-4-carboxaldehyde was synthesized by Vilsmeier-Haack reaction [27].

Melting points were determined on a Mel-Temp capillary melting points apparatus, model 1001, and are uncorrected. Optical rotations were measured on a Rudolph Research Analytical automatic polarimeter Autopol IV. Elemental (C, H, N, and S) analysis of the samples was carried out by standard micromethods in the Center for Instrumental Analysis, Faculty of Chemistry, Belgrade. IR spectra were recorded on a Perkin Elmer Spectrum One FTIR spectrometer with a KBr disc. $^1H$ and $^{13}C$ NMR spectra were recorded on a Varian Gemini 200 (200 MHz) and a Bruker Avance III spectrometer operating at 500 MHz. As a consequence of the poor solubility in DMSO-$d_6$, the NMR spectra were recorded in pyridine-$d_5$/$D_2O$ and NaOD/$D_2O$ solvent system for **1h** and **1i**. Thermal measurements were conducted using SDT Q600 TA Instruments'

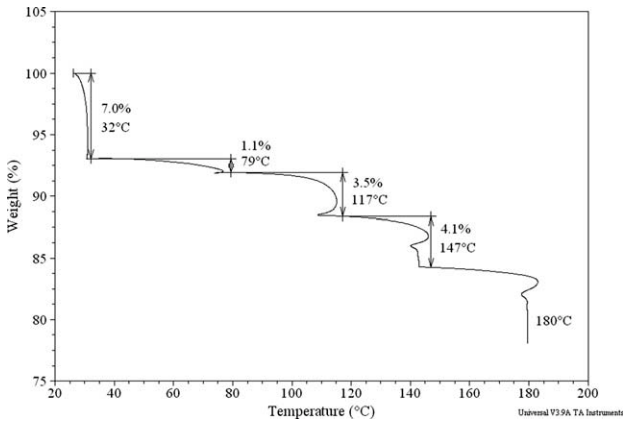

**Figure 2.** SWI decomposition curve of **1g**, illustrating the complexness of its dehydration.

thermal analyzer with about 2 mg sample masses and a heating rate of 20°C/min in air and nitrogen atmospheres. The sample holder and the reference cells were made of alumina.

**General procedure for the preparation of 1a–i.** 1,3-Diphenylpyrazole-4-carboxaldehyde (0.62 g, 2.5 mmol), α-amino acid (2.75 mmol), and NaOH (0.11 g, 2.75 mmol, for **1i** 0.22g, 5.50 mmol) were milled using a porcelain mortar and pestle to obtain a homogenous white powder until the release of water was observed. This mixture was transferred into 50 $cm^3$ of dry methanol and heated to reflux for 2 h. After cooling in an ice bath, sodium borohydride (0.11 g, 3 mmol) was added in several portions with stirring. The solution was stirred for additional 2 h at room temperature, then diluted with 50 $cm^3$ of deionized water, and left for 12 h, after which time the white precipitate had formed by addition of glacial acetic acid. The crude product was purified by dissolving in 1*M* NaOH and precipitation with glacial acetic acid. Recrystallized compound was collected by filtration, washed with plenty of water, and dried over anhydrous $CaCl_2$.

Calcd. for $C_{25}H_{25}N_3O_4$ (431.48 g/mol): C, 69.59; H, 5.84; N, 9.74; Found: C, 69.69; H, 5.82; N, 9.74.

**Biological evaluation.** Three human tumor cell lines and one human nontumor cell line were used in this study: K562 (chronic myelogenous leukemia), HeLa (epitheloid carcinoma of cervix), HT-29 (colon adenocarcinoma), and MRC5 (lung fetal fibroblasts). The cells were grown in RPMI 1640 (K562 cells) or Dulbecco's modified Eagle's medium (DMEM) with 4.5% of glucose (HeLa, HT-29, and MRC5 cells). Media were supplemented with 10% of fetal calf serum (FCS, NIVNS) and antibiotics: 100 IU/mL of penicillin and 100 μg/mL of streptomycin (ICN Galenika). All cell lines were cultured in flasks (Costar, 25 cm$^2$) at 37°C in the 100% humidity atmosphere and 5% of $CO_2$. Only viable cells were used in the assay. Viability was determined by dye exclusion assay with Trypan blue.

Cytotoxicity was evaluated by colorimetric SRB assay as described by Skehan et al. [21]. Briefly, single cell suspension was plated into 96-well microtiter plates (Costar, flat bottom): $1 \times 10^4$ of K562 and $5 \times 10^3$ of HeLa, HT29, and MRC5 cells, per 180 mL of medium. Plates were preincubated for 24 h at 37°C, 5% $CO_2$. Tested substances at concentration ranging from $10^{-8}$ to $10^{-4}M$ were added to all wells except to the control ones. After incubation period (48 h/37°C/5% $CO_2$), SRB assay was carried out as follows: 50 μL of 80% trichloroacetic acide (TCA) was added to all wells; an hour later, plates were washed with distillate water, and 75 μL of 0.4% SRB was added to all wells; half an hour later, plates were washed with citric acid (1%) and dried at room temperature. Finally, 200 μL of 10 mmol TRIS (pH = 10.5) basis was added to all wells. Absorbance was measured on the microplate reader (Multiscan MCC340, Labsystems) at 540/690 nm. The wells without cells, containing compete medium only, acted as blank.

Cytotoxicity was calculated according to the formula:

$$(1 - A_{TEST}/A_{CONTROL}) \times 100$$

and expressed as a percent of cytotoxicity (CI %).

**Acknowledgment.** The work was financed by the Ministry for Science of the Republic of Serbia (Grant N° 142028) and the Provincial Secretariat for Science and Technological Development of Vojvodina.

Cyclohexyl isocyanides react with dialkyl acetylenedicarboxylates in the presence of CH-acids such as cyclohexane-1,3-dione or *N*,*N*′-dimethylbarbituric acid in one-pot to afford 4*H*-pyran annulated heterocyclic systems in fairly high yields.

*J. Heterocyclic Chem.*, **47**, 857 (2010).

## INTRODUCTION

In the meantime multicomponent reactions are well established as a powerful tool for the rapid construction of complex and structurally diverse compounds from relatively simple building blocks [1]. High atom-economy, chemical efficiency, and convergence are typical features of such one-pot condensations of at least three different starting materials. Because of the remarkable high purity of libraries, multicomponent reactions are well-suited for both combinatorial chemistry [2] and high-speed parallel synthesis and therefore possess high exploratory power [3]. Amongst the known multicomponent reactions, isocyanide based MCRs such as the versatile Ugi and Passerini reactions are especially valuable [4]. Especially isocyanide-based [5] and asymmetric [6] multicomponent reactions have been emerging fields of interest in the last decade, but the construction of heterocycles via multicomponent reactions was also in the focus recently [7]. However, there are only a few applications of multicomponent reactions in dihydroindeno[1,2-b]pyran so far [8]. In our Laboratory, isocyanide-based multicomponent reactions of CH-acids have just recently been key instruments for the rapid synthesis of the novel pyran ring systems of pyrimidine, indeno, and 4*H*-chromene. Herein we report how such reactions contributed significantly to the synthesis of the novel heterocyclic compounds.

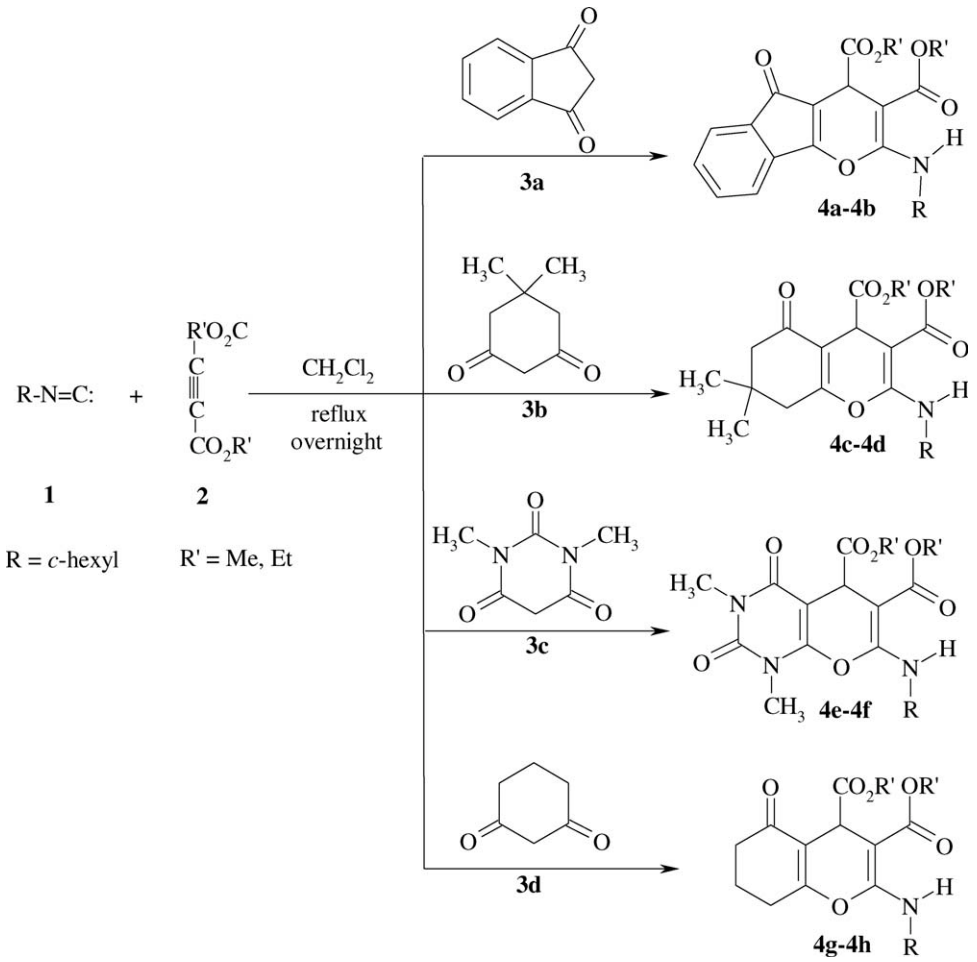
## RESULTS AND DISCUSSION

The one-pot three component condensation reactions of alkyl isocyanides **1** with electron-deficient acetylenic esters **2** in the presence of CH-acids **3a–d** proceeded in anhydrous dichloromethane and was completed after 12 h to afford corresponding heterocyclic systems **4a–h**, in moderate to good yields (65–90%). $^1$H NMR and $^{13}$C NMR spectra of the crude products clearly indicated the formation of heterocyclic compounds **4a–h**. The structures of the products **4a–h** were deduced from their elemental analyses, IR, $^1$H NMR, and $^{13}$C NMR spectra. The mass spectra of compounds **4a–h** displayed molecular ion peak at appropriate *m*/*z* values. Initial fragmentations involved loss from or complete loss of the side chains and scission of heterocyclic system.

The $^1$H NMR spectrum of **4a** consisted of a multiplet of signals for the cyclohexyl ring ($\delta$ = 1.13–1.90 ppm) and two single sharp lines for methoxy groups ($\delta$ = 3.70 and 3.73 ppm). A multiplet resonance is observed for the N—CH group ($\delta$ = 3.82 ppm), and a single sharp line for methine proton ($\delta$ = 4.38 ppm). A fairly broad singlet ($\delta$ = 8.90 ppm) was observed for the NH group. The presence of an amine proton was confirmed by exchange with $D_2O$. The chemical shift of the N—H group indicates that this moiety must have participated in a six-member intramolecular hydrogen bond formation with the vicinal carbonyl group as shown in Scheme 1.

The $^1$H decoupled $^{13}$C NMR spectrum of **4a** showed 20 sharp signals in agreement with proposed structure. Compound **4a** possesses a highly polarized carbon-carbon double bond. The β-carbon of this enaminone system appears about 72–77 ppm. These signals along with the downfield shift of the NH proton, support the enaminone structure **4**. The $^1$H NMR and $^{13}$C NMR spectra of

**Scheme 1**

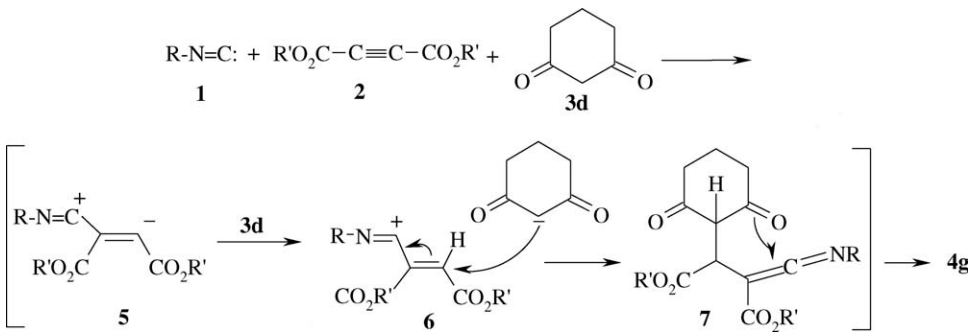


**4b–h** are similar to those of **4a**, except for the CH-acids and ester moieties. Partial assignments of these resonances are given in the experimental section.

The structural assignments made on the basis of the $^{1}H$ NMR and $^{13}C$ NMR spectra of **4a** was supported by measurement of its IR spectra. The IR spectrum of **4a** showed strong absorption at 3420, 1737, and 1678 $cm^{-1}$ due to the N—H and carbonyls groups.

A plausible mechanism for formation of **4g** is shown in Scheme 2. On the basis of the well established chemistry of isocynides [4] it is reasonable to assume that compound **4g** results from initial addition of alkyl isocyanide **1** to the acetylenic ester to form intermediate **5**. Protonation of **5** by **3d** and subsequent attack of the resulting nucleophile generated to the positively charged ion **6** afforded ketenimine **7** (Scheme 2). Such an

**Scheme 2**



addition product may tautomerize and cyclize, under the reaction conditions employed, to produce **4g**.

In conclusion, the three-component reaction of alkyl isocyanides with electron-deficient acetylenic esters in the presence of CH-acids provides a simple entry into the synthesis of 4*H*-pyran annulated heterocyclic systems of potential synthetic interest. The present procedure carries the advantage that, not only is the reaction performed under neutral conditions, but also the substances can be mixed without any activation or modification.

## EXPERIMENTAL

Dialkyl acetylenedicarboxylates, alkyl isocyanides, and other reagents and solvents used in this work were obtained from Fluka (Buchs, Switzerland) and used without further purification. NMR spectra were recorded with a Bruker DRX-300 AVANCE instrument (299.9 MHz for $^1$H and 75.4 MHz. for $^{13}$C) with $CDCl_3$ as solvent. Chemical shifts are given in ppm (δ) relative to internal TMS, and coupling constant (*J*) are reported in hertz (Hz). Melting points were measured with an electrotherma1 9100 apparatus. Elemental analyses for C, H, and N were performed using a Heraeus CHN-O-Rapid analyzer. These results agreed favorably with the calculated values. Mass spectra were recorded with a Shimadzu QP-GC Mass 5050 spectrometer operating at an ionization potential of 70 eV. IR spectra were measured with Bruker Tensor 27 spectrometer.

**Typical procedure for preparation of compounds 4a–h.** To a stirred solution of 0.145 g indan-1,3-dione (1 mmol) and 0.142 g dimethyl acetylendicarboxylate (1 mmol) in 10 mL dichloromethane, was added, 0.109 g *c*-hexyl isocyanide (1 mmol) in 2 mL dichloromethane at room temperature over 4 min via a syringe. The reaction mixture was heated at reflux for 12 h. The solvent was removed and the residue was purified by silica gel (Merck silica gel 60, 70–230 mesh) column chromatography using hexane/ethyl acetate (8:2) as eluent.

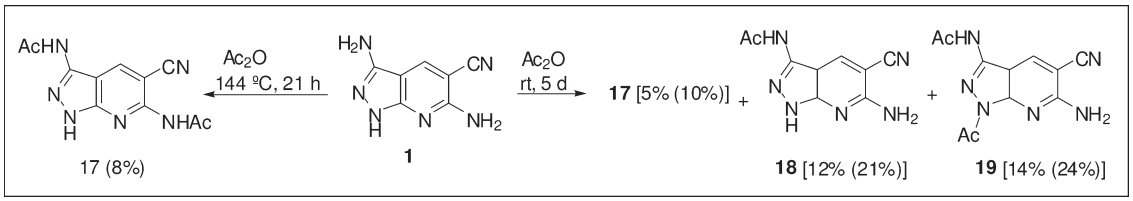
Published online 8 June 2010 in Wiley InterScience (www.interscience.wiley.com).



The acetylation reaction of the differently substituted 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile derivatives **1**–**6** is reported. The structure of the resulting acetamides has been investigated and confirmed by analytical, spectroscopic, and chemical transformations. From these studies, we conclude that, in general, under mild conditions, and using acetic anhydride, when free, the *N*(1)H moiety is a more reactive center respect to the C(3)$NH_2$ and C(6)$NH_2$ groups. This trend is reversed when no steric hindrance due to presence of a phenyl group at C4 drives the preferred acetylation to C(3)$NH_2$, as it is evident by comparing the observed results from precursor **1** with **3**. When N1 is blocked, the (C3)$NH_2$ group undergoes preferential acetylation over the (C6)$NH_2$ site, which only has been mono (or diacetylated) at reflux. Computational analyses based on DFT studies have been extensively used to explain the observed reactivities.

*J. Heterocyclic Chem.*, **47**, 861 (2010).

## INTRODUCTION

The pyrazolo[3,4-*b*]pyridine ring system [1] is present in a number of pharmaceutically important compounds targeted to inhibit VEGFR/PDGFR kinases [2] or GSK-3 [3]. In a current project aimed at the synthesis, design, and biological evaluation of new GSK-3 inhibitors, we have recently synthesized a series of known and new 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridines [4] (**A**) (Chart 1). To carry out basic SAR studies, we decided to explore the acylation reaction of 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridines (**1**–**6**) (Chart 2) to get presumably more potent inhibitors as previously demonstrated by other authors [3].

In this context, previous reports from other laboratories have described that the acylation ($C_3H_7COCl$, pyridine, reflux) of precursor **7** gave the C(3)$NH_2$ acetylated derivative **8** in 80% yield (Chart 3). Note, however, that the carbamoylation of the free amino groups on the fused pyrazole ring system in compound **9** showed a reversed regioselectivity, providing compound **10** (Chart 3) [5]. In addition, it has been also shown that under mild conditions, 5-substituted 3-aminopyrazoles are almost simultaneously acylated at N1 and at C(3)$NH_2$ to give diacylated derivatives [6]. Substituted 3-amino-1*H*-pyrazolo[3,4-*b*]quinoxalines have been selectively N-acylated at N1 [7]. Compound **2** has been reported to give exclusively the C(3)-*N*-formyl derivative **11** or the acetamide **13** from related amide **12** (Chart 3) [8]. Finally, a more complex situation was described for 4,5-diphenyl-1*H*-pyrazolo[3,4-*c*]pyridazine (**14**) [9] when using acetyl chloride. Depending on the base used, the acetylation goes to C(3)$NH_2$ to give compound **15** (for triethylamine as base) or to **16** (for pyridine as base) (Chart 3) [9]. Note also that the position of the acetyl residue at N1 was not unambiguously confirmed by X-ray analysis neither discussed in depth; however, 4,5-diphenyl-1*H*-pyrazolo[3,4-*c*]pyridazines have been regioselectively N-alkylated at N1 [9], a result that is in good agreement with similar reaction on 3-amino-1*H*-pyrazolo[3,4-*b*]quinoxalines [7].

In summary, all these data confirm that a simple reaction such as the acetylation in a complex, polyfunctionalized, heterocyclic framework can be more complicated than presumed at first glance [10]. This is in fact what we have observed in the acetylation of 3,6-diamino-pyrazolopyridines **1**–**6** (Chart 2), and in this work, we report our results.

## RESULTS AND DISCUSSION

**Synthesis, structural analysis, and reactivity.** The synthesis of 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (**1**) (Chart 2) proceeded uneventually as described by reacting 2-amino-6-chloropyridine-3,5-

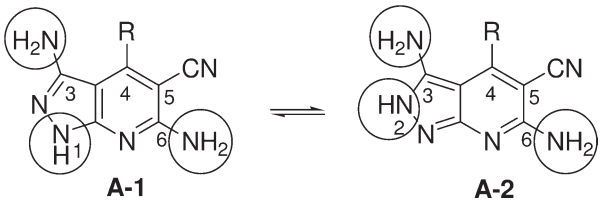


**Chart 1.** 3-6 Diamino-1*H*-pyrazolo[3,4-*b*]pyridines.

dicarbonitrile with hydrazine hydrate [8]. In the HMBC experiment of pyrazolopyridine **1**, we assigned the chemical shifts for the protons at C(3)N$H_2$ and C(6)N$H_2$, at δ 5.56 and 6.70, as cross-peaks were observed with the signals at δ 99.8 (C3a) and 83.0 (C5), respectively; in agreement with this, the signal at 99.8 ppm (C3a) showed a cross-peak with the signal at δ 11.60, corresponding to N(1)H. Similar chemical shifts and effects have been observed for protons in the other related compounds described here, and this trend [δ C(6)N$H_2$ >> δ C(3)N$H_2$] has served as diagnostic for proton assignments and structure determination (see later).

The reaction of compound **1** [8] with acetic anhydride, after 21 h, at 144°C, was complete, but extensive decomposition was observed by TLC analysis, and only *N*,*N*′-(5-cyano-3a,7a-dihydro-1*H*-pyrazolo[3,4-*b*]pyridine-3,6-diyl)diacetamide (**17**) could be isolated in 8% yield (Chart 4). Based on the analytical (MS/elemental analysis) and the NMR spectra, compound **17** was clearly a diacetamide derivative of precursor **1**, showing in its $^1$H NMR spectrum two acetyl groups integrating for six protons (2xNHCOC$H_3$), as a singlet at δ 2.12; the singlet at δ 10.96 was assigned to C(3)N*H*COCH$_3$ as it showed cross-peaks in the HMBC spectrum with C3a (δ 104.7) and NH*C*OCH$_3$ (δ 169.2); consequently, the singlet at δ 10.79 corresponded to the proton at C(6)N*H*COCH$_3$; finally, the singlet for one proton at δ 13.62 was assigned to N(1)*H*. In this reaction, we detected traces of a second compound that was identical to the compound isolated when the reaction was carried at out at room temperature for 5 days and identified as *N*-(6-amino-5-cyano-1*H*-pyrazolo[3,4-*b*]pyridin-3-yl)acetamide (**18**), isolated in 12% yield (21% taking into account the recovered starting material); in this reaction, we also isolated diacetamide **19** [14% (24%)] and compound **17** [5% (10%)] (Chart 4). In the $^1$H NMR spectrum of monoacetamide **18**, we could analyzed only one singlet for two protons at δ 6.95, indicating that the only free $NH_2$ group was at C6, leaving free the N(1)H (δ 12.66), the acetamido group being thus at C3, as in the $^1$H NMR spectrum the signals for NHCOCH$_3$ appeared at δ (NH) 10.69 and δ (COCH$_3$) 2.12. These assignments were confirmed in the HMBC experiment, as the signal at δ 12.66 showed cross-peaks with C3a, C3, and C7a, while the singlet at δ 10.69 showed cross-peaks with C3a and NH*C*OCH$_3$. In the $^1$H NMR spectrum of compound **19**, in addition to similar signals to those described for compound **18** (see Experimental), no N(1)H resonance was observed at low field, but a new singlet appeared for three protons at 2.77 ppm, characteristic for N(1)COCH$_3$ (see compound **16** in Chart 3) [9]. In summary, we conclude that the acetylation of 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (**1**) is relatively complex, and a number of differently substituted acetamido derivatives were isolated and characterized. Under mild reaction conditions, preferent acetylation at C(3)$NH_2$ followed at N(1) positions was observed; the acetylation at C(6)$NH_2$ being also possible, at reflux, to give diacetamide **17** (Chart 4), as the only detected, in a poor chemical yield. Overall, these facts are in good agreement with the previous results [5–7] on the acylation of related substrates (see Chart 3) and strongly point to the absence of a substituent at C4, the key to favor the acetylation at C(3)$NH_2$ (see later).

The acetylation of 3,6-diamino-1-methyl-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (**2**) [8], under mild conditions, gave only monoacetamide **20** in good yield (Chart 4). In the $^1$H MNMR of this compound, we could

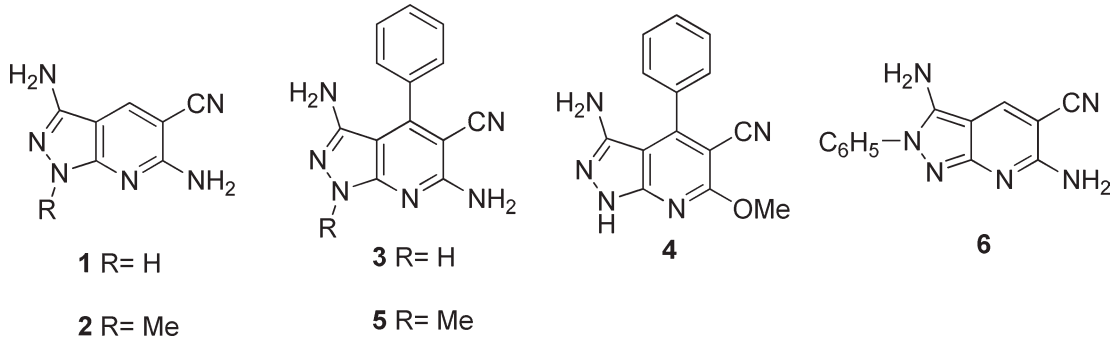

**Chart 2.** Structure of compounds **1–6**.

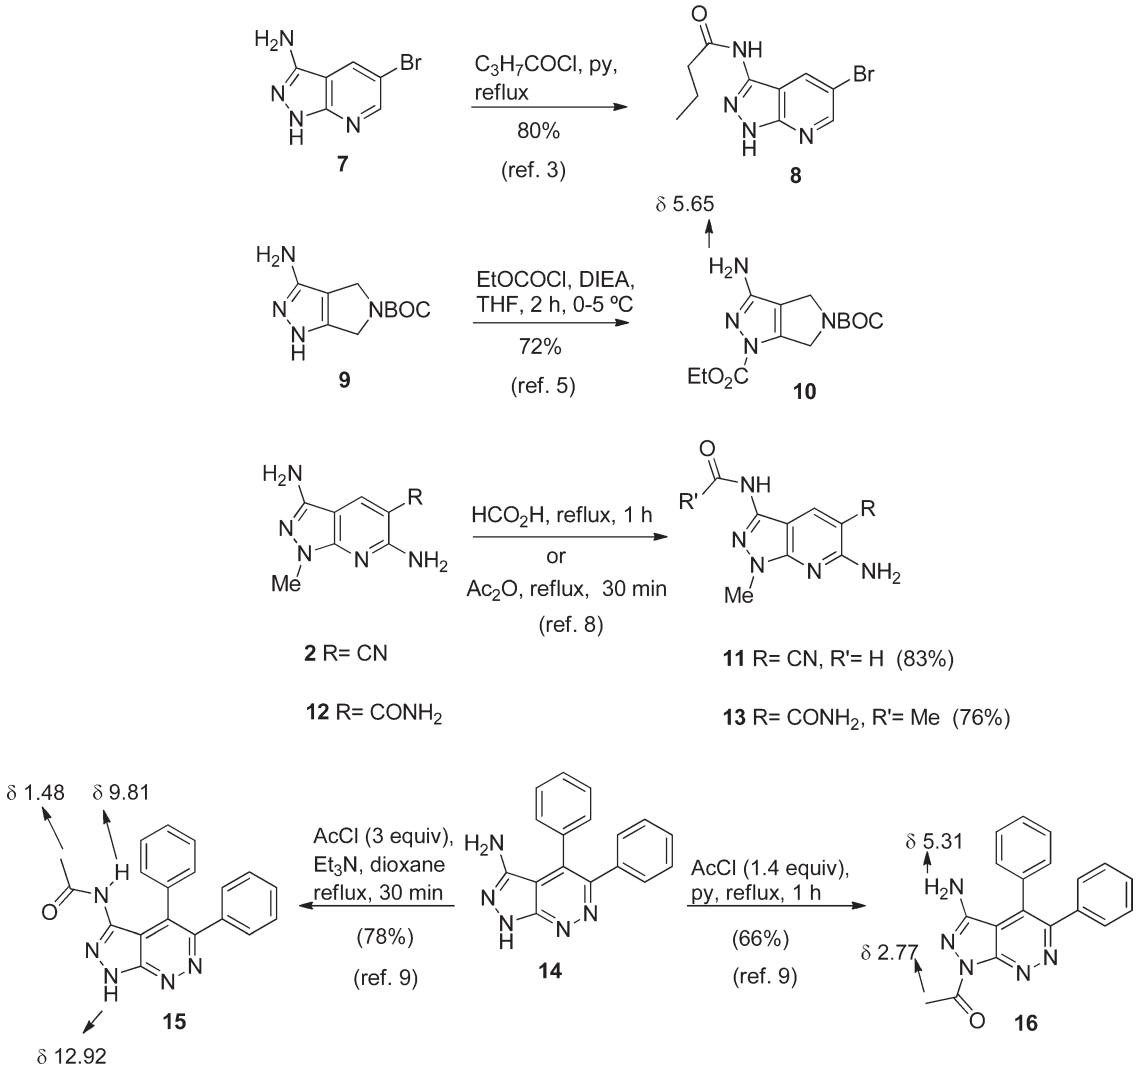

**Chart 3.** Transformation of compounds **2**, **7**, **8**, **12**, and **14**.

analyze two singlets for proton at δ 10.74 and for two protons at δ 7.08, corresponding to (C3)N*H*COCH$_3$ and (C6)NH$_2$ protons, respectively. In agreement with this assignment, in the HMBC-NMR experiment of this pyrazolopyridine, the NH proton at C(3)N*H*COCH$_3$ resonated at δ 10.74 and showed cross-peaks with C3a (100.3 ppm) and NH*C*OCH$_3$ (168.1 ppm), whereas for the proton at C(6)NH$_2$ (δ 7.08) cross-peaks appeared with the signals at δ 86.4 (C5), 158.3 (C6), and 150.7 (C7a). In addition, a small but evident selective nOe experiments between the NH proton at δ 10.74 [(C3)N*H*COCH$_3$] and H4 (δ 8.57) confirmed the position of the acetyl group on the nitrogen at C3. This result and reactivity is thus also in good agreement with the reported reactivity of precursor **2** in the formylation reaction (Chart 3) [8].

The small nOe observed between both protons in the N*H*COC*H*$_3$ group and H4 in compound **20** could be rationalized after computational analysis, which showed that, in fact, rotamer **20b** was 7.0 kcal/mol more stable than conformer **20a** (Fig. 1), possibly because of the lone pair–lone pair electronic repulsion between the carbonylic oxygen and the N2 present in conformer **20a**. On the other hand, the calculated chemical shifts for protons in NHCOC*H*$_3$ are in good agreement with the experimental values.

The reaction of 2-amino-6-chloro-4-phenylpyridine-3,5-dicarbonitrile [11] with hydrazine hydrate [4] gave 3,6-diamino-4-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (**3**) (Chart 2) [12]. In the acetylation of compound **3** with Ac$_2$O, at 0°C, for 20 h (Method A, see Experimental), a solid was formed; it was filtered, washed with cold water/EtOH, and recrystallized from ethanol to give compound **21** in 25% yield (Chart 4). The analytical and spectroscopic data of this molecule

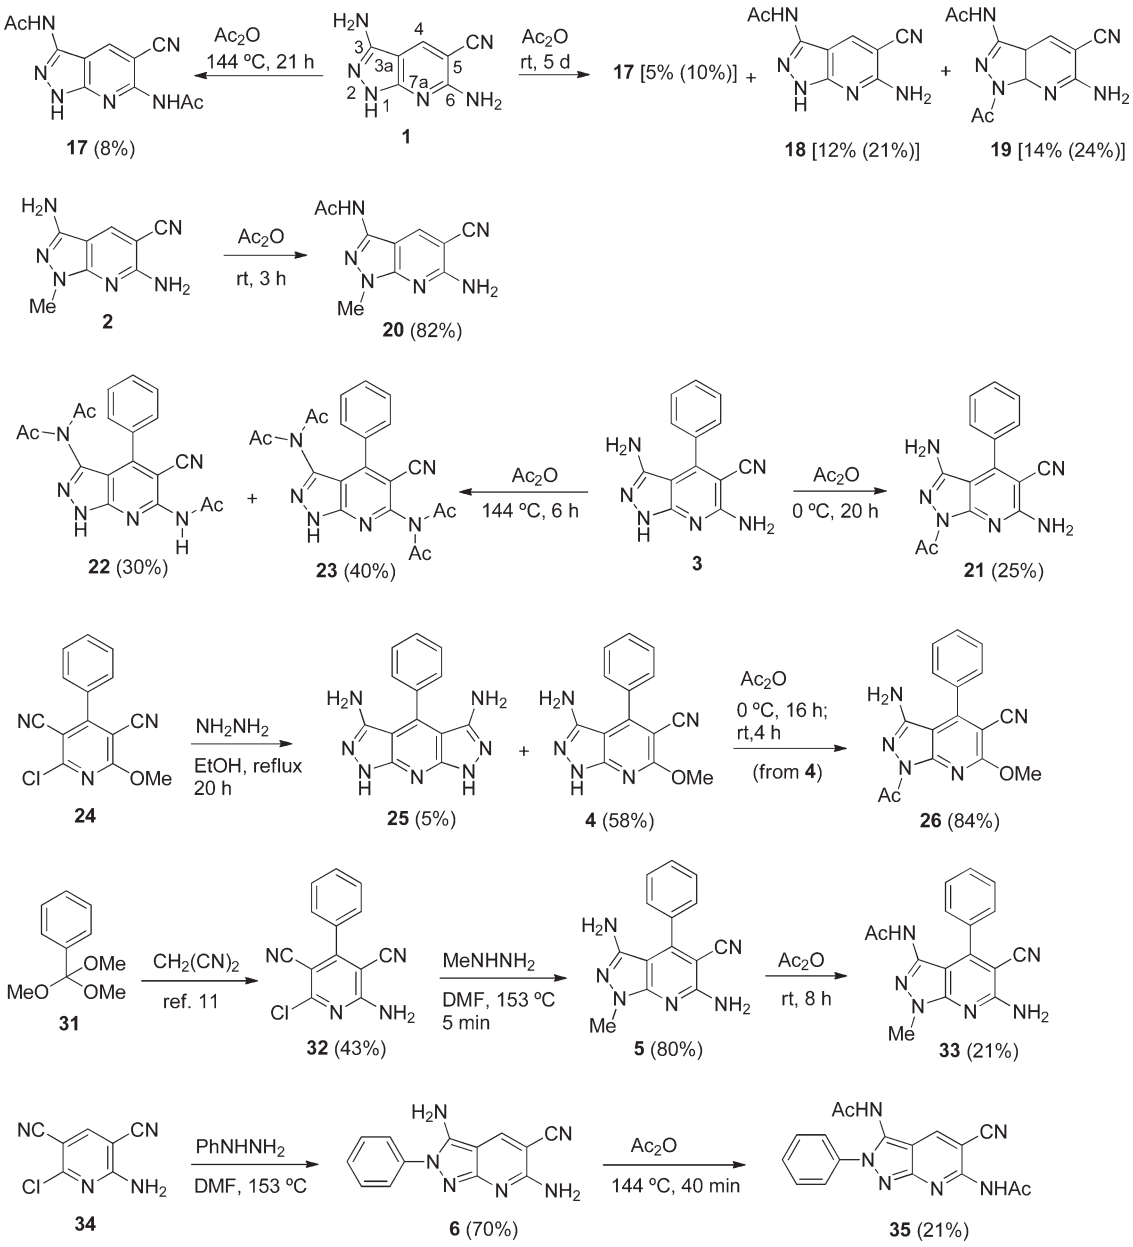

**Chart 4.** The acetylation reaction of compounds **1**–**6**.

clearly showed that **21** was a monoacetamide, as in the $^1$H NMR, a methyl group was observed at an anomalous low field (δ 2.58) and two broad singlets (7.40 and 4.82 ppm) for two protons, each one corresponding to the $NH_2$ groups at carbons C6 and C3, respectively. These data along with the absence of a free NH, or a NH resonance for a N*H*COCH$_3$ moiety, clearly supported the structure of **21** as 1-acetyl-3,6-diamino-4-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile.This structure has also been confirmed by the data obtained in the $^{13}$C NMR, HMQC, and HMBC experiments.

To improve the chemical yield, the acetylation reaction was carried out with $Ac_2O$ at rt for 5 h or with AcCl, in pyridine, at 0°C for 5 days, but the yields (21 and 24%, respectively) of compound **21** were not better. Finally, the acetylation reaction was performed with $Ac_2O$ at reflux for 6 h; after work-up and purification, peracetylated derivatives **22** (30%) and **23** (40%) were isolated (Chart 4). The structure of compound **22** was established as a triacetamide derivative of precursor **3** by its analytical and spectroscopic data. As in the $^1$H NMR spectrum, we observed a broad singlet for one

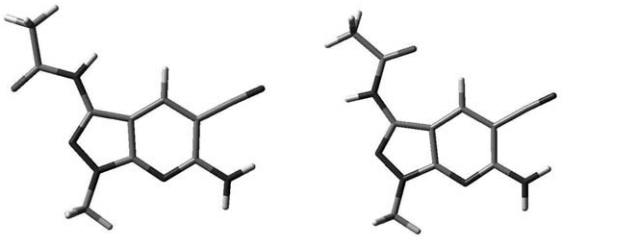

**Figure 1.** Conformers for compound **20**.

proton at 14.45 ppm, and three acetyl groups [δ 2.15 (singlet, one acetyl) and 1.91 (singlet, two acetyl groups)]; we concluded that N(1) was free, the only structural problem that remained to be established was to determine if the $NHCOCH_3$ group was at C3 or at C6. In the HMBC spectrum, the signal al δ 10.98 (N*H*$COCH_3$) showed cross-peaks with signals at 100.0, 152.3, and 169.5 (N*C*$OCH_3$). In the case that the group $NHCOCH_3$ was at C6, the signals at 100.0 and 152.3 should be assigned to C5 and C6, respectively, the signal appearing at 106.5 ppm corresponding thus to C3a, an assignment that seems reasonable, as we have routinely observed in the compounds investigated here that in the $^{13}C$ NMR spectrum δ C3a >> C5. To prove this hypothesis, a series of nOe experiments were carry out. When the N*H*$COCH_3$ was irradiated, only the singlet at 2.15 ppm showed a weak effect; the irradiation of this signal also showed only a weak effect at 10.98 ppm. However, the irradiation of the singlet at 1.91 ppm integrating for six protons (two $NHCOCH_3$ groups) produced a sharp effect on the aromatic protons; the reverse irradiation also produced the same effect. From these experiments, we conclude that the two acetamido groups should be in the same carbon (C3). For compound **23**, as in the $^1H$ MNR spectrum, we observed a broad singlet at δ 14.93 for one proton, clearly assigned to N(1)H, the location of the four acetamido groups present in the molecule at C3 and C6 was evident.

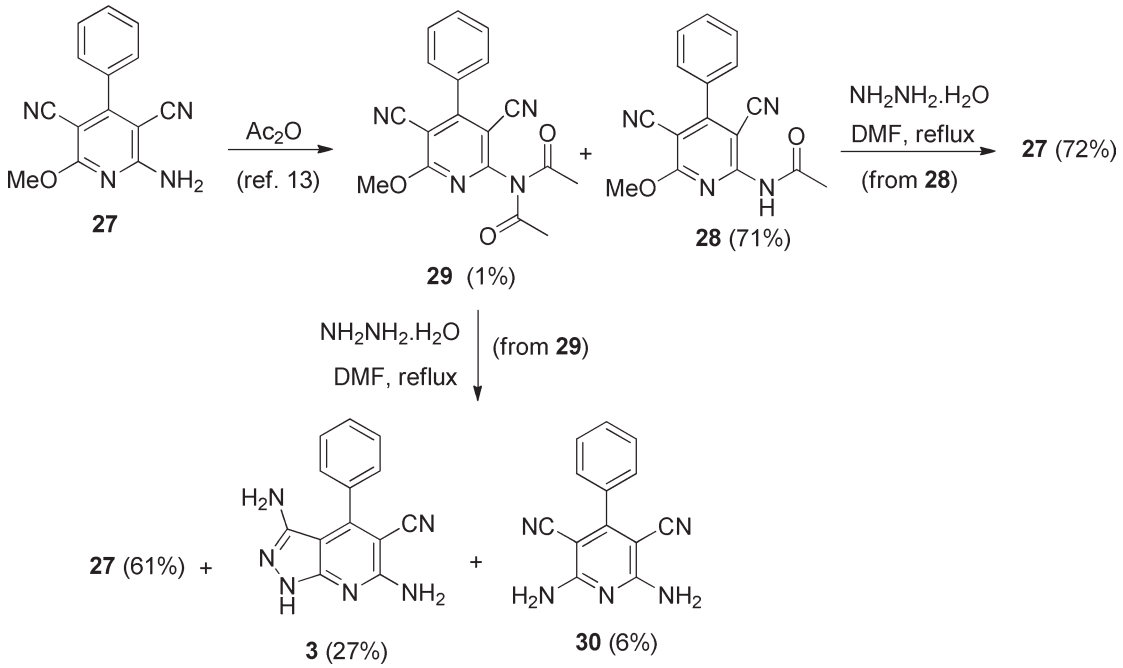
The regioselective acetylation at N1 in compound **3**, respect to both $NH_2$ groups at C3 and C6, under mild conditions, prompted us to investigate the same reaction on precursor **4**, where only two positions at N1 and C(3)$NH_2$ were available for the acetylation. This compound has been prepared from readily available 2-chloro-6-methoxy-4-phenylpyridine-3,5-dicarbonitrile (**24**) [13] after reaction with hydrazine hydrate; in this reaction, we isolated also traces of the bis-pyrazolopyridine **25** (Chart 4). When compound **4** was acetylated with $Ac_2O$ (see Experimental) compound **26** was isolated in good yield (84%) (Chart 4). The analytical and spectroscopic data clearly showed that compound **26** is a monoacetamide bearing the acetyl group at N1, as a broad singlet appeared at 5.10 ppm integrating for two protons [C(6)$NH_2$], and the singlet for the acetyl groups integrating for three protons resonated at δ 2.69, a value that we have found in compound **21** (see earlier) and in compound **16** [9] (Chart 3).

In view of these results, and as we were interested in the synthesis of the monoacetamide at C6 in these pyrazolopyridines, we considered an alternative synthetic route based on the acetylation of 2-amino-6-methoxy-4-phenylpyridine-3,5-dicarbonitrile (**27**) [13] (Scheme 1). Carrying out the reaction as reported [13], we obtained a mixture of monoacetamide **28** (71%) and imide **29** (1%) (Scheme 1) that were easily separated by column chromatography and submitted to reaction with hydrazine hydrate, in DMF at reflux, aiming at the ''one-pot'' methoxy displacement and simultaneous pyrazolopyridine formation. For compound **28**, we obtained compound **27** in 72% yield (Scheme 1). For compound **29**, we isolated and characterized compounds **27**, **30**, and **3** (Scheme 1). The formation of these compounds is the result of a series of deacetylation reactions followed by pyrazolo formation. The structure of compound **30** has been unequivocally established by comparison of the reported data in literature [11] and with an authentic sample prepared in the reaction of DMF [14] with 6-amino-2-chloro-4-phenylpyridine-3,5-dicarbonitrile (**32**) [11,15] (see Experimental), obtained from the reaction of trimethylorthobenzoate (**31**) with malononitrile [11] (see Experimental) (Chart 4).

Next, we have investigated the acetylation of precursor **5**, prepared as usual from compound 6-amino-2-chloro-4-phenylpyridine-3,5-dicarbonitrile (**32**) [11] and *N*-methylhydrazine (Chart 4). As expected, in the $^1H$ NMR spectrum of compound **5**, a positive nOe effect between the broad singlet at δ 4.36 and the aromatic protons allowed us to assign this chemical shift for protons at C(3)$NH_2$, the signal at 6.90 ppm corresponding to C(6)$NH_2$. The acetylation of pyrazolopyridine **5** ($Ac_2O$, rt, 8 h) provided compound **33** in low yield (Chart 4). Not unexpectedly, in the $^1H$ NMR of compound **33**, the singlet for two protons at δ 7.12 [(C6)$NH_2$] clearly demonstrated that the acetylation has taken place in the C(3)$NH_2$ group. Selective nOe experiments also showed the small but evident effect between the protons at the acetamide group (CON*H*$CH_3$).

For compound **33** (Fig. 2), rotamer **b** is 1.8 kcal/mol more stable than **a**, possibly because of the electronic repulsion between the carbonylic oxygen and the N2 present in conformer **a**, as previously shown for compound **20**, although the effect here should be less strong, because the presence of the phenyl ring prevents a coplanar arrangement between the amide group and the azole plane, being rotated with a dihedral angle of 58°.

**Scheme 1.** Synthesis of compounds **28** and **29** and their reaction with hydrazine hydrate.



This fact increases the energy of conformer **b** and reduces the energy difference between the two possible conformers. On the other hand, the calculated and the experimental chemical shifts for the methyl groups in NHCOC$H_3$ are in good agreement; the low δ chemical shift observed for this methyl group possibly due to the shielding effect of the aromatic ring at C4.

Finally, we have prepared precursor **6** in good yield in the reaction of 2-amino-6-chloropyridine-3,5-dicarbonitrile (**34**) with *N*-phenylhydrazine (Chart 4). After selective nOe experiments in the $^1$H NMR spectrum of this compound, the resonance at δ 6.97 was assigned to the amino group at C3, while the singlet integrating for two protons at δ 6.48 corresponded to (C6)$NH_2$. This analysis is the reverse that we have observed in the other precursors investigated in this work and must ascribed to the presence of a phenyl ring at N2. In fact, it is well known that the reaction of 2-halogeno-3-cyanopyridines with *N*-arylhydrazines respect to *N*-alkylhydrazines provides 2-aryl-2*H*-pyrazolo[3,4-*b*]pyridines instead of 1-alkyl-4-phenyl-1*H*-pyrazolo[3,4-*b*]pyridines [16]. The acetylation of compound **6** at reflux for 40 min gave the diacetylated derivative **35** in 21% yield (Chart 4), which showed spectroscopic and analytical data in good agreement with this structure (see Experimental).

**Computational studies.** In view of the results obtained for pyrazolopyridine **3** (Chart 4), we next addressed the reaction mechanisms to explain the observed regioselectivities during the acetylation reactions.

All calculations were carried out with Gaussian03 package [17]. All the minima and transition states involving were fully optimized with the B3LYP hybrid functional [18]. As the key aspect to account for reactivity and regioselectivity concerns atoms bearing lone-pair electrons, we have applied the extended 6-31+G(d,p) basis set to get reliable structures and energy values. Then, to optimize computational resources, we have selected AcCl as acetylated agent instead of $Ac_2O$. Treatment of precursor **1** with both electrophiles has shown similar results (see main text). Zero-point energies and thermal contributions to thermodynamic functions and activation parameters, as well as harmonic frequencies to assess the nature of the stationary points, were computed at the same level of theory on the

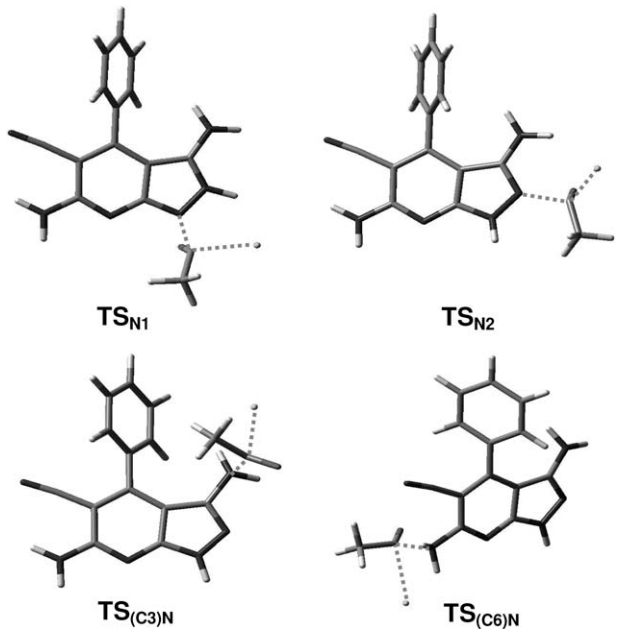

**Figure 3.** Transition structures for the N-acetylation of **3**.

optimized structures. To test the influence of solvation effects, we have calculated solvation free energies in solution $\Delta G_{solv}$ for the ground state and transition structures at the PCM/UAHF/B3LYP/6-31G(d) level [19] using the previously optimized gas-phase structures. Combination of these solvation free energies with gas-phase free energies obtained at B3LYP/6-31+G(d,p) level yields the relative free energy in solution $\Delta G^{\ddagger}_{sol}$ compiled in Table 2 in column 4 and Figure 3. Natural bond orbital (NBO) analyses [20] have been performed by the module NBO v.3.1 implemented in Gaussian 03 to evaluate the NPA charges at the optimization level.

We have initially carried out the study of the tautomeric equilibrium for compound **3**. We have focused on the prototropy tautomerism between the **3**-1*H* and **3**-2*H* forms involving the azole moiety (Scheme 2) as the structure with the hydrogen atom attached to the pyridine nitrogen at the position 7 is energetically unfavorable, as was expected from valence bond resonance considerations and verified by calculations on this [our calculations (B3LYP/6-31+G(d,p) reveal a structure 24.5 kcal mol$^{-1}$ less stable than **3**-1*H*] and related structures [21].

Both structures **3**-1*H* and **3**-2*H* have in common that the amino groups are partially planarized (out-of-plane deviation of (C3)N/(C6)N: 29.4°/10.8° and 28.9°/14.2° in **3**-1*H* and **3**-2*H*, respectively) as the N electron pairs are part of the aromatic system, and that the aromatic ring attached to the C4 position is rotated with respect to the pyridine plane (with dihedral angles of 57.5 and 59.7°, respectively) to avoid steric repulsions with substituents at C3 and C5.

At the B3LYP/6-31+G(d,p) level, the tautomer **3**-2*H* is predicted to be less stable than **3**-1*H* by 9.5 and 4.0 kcal/mol in the gas phase and in DMSO, respectively. According to the Boltzmann distribution, at a temperature of 298 K, this difference in energy corresponds to a **3**-1*H*:**3**-2*H* ratio of >99:<1, with the population of the minor tautomer below the limit of detection for conventional NMR spectroscopy. Thus, according to the calculations, tautomer **3**-2*H* is unlikely to coexist with the other tautomer.

This preference of the 1*H* tautomer in pyrazolopyridines agrees with structural analysis of 4-aryl-5-cyano-pyrazolo[3,4-*b*]pyridines [22], theoretical studies of pyrazolo[3,4-*b*]pyridines bearing a variety of substituents [23], and crystallographic data of protein–ligand complexes [24], which indeed confirm that in this class of compounds, the (N1)H forms key H-bonds with the enzymes (cyclin-dependent kinases).

This picture contrasts with that for the related structures pyrano[2,3-c]pyrazoles (6-amino-5-cyano-3-methyl-4-aryl/heteroaryl-2*H*,4*H*-dihydropyrano[2,3-*c*]pyrazoles) as they exist predominantly in the 2*H* tautomeric form [25]. To confirm the reliability of our calculations in the prediction of tautomeric equilibria, we have performed further computations on the 6-amino-5-cyano-3-methyl-4-phenyl-dihydropyrano[2,3-*c*]pyrazole ring system [25–27]. Our results indicate that the 2*H* tautomer is 3.7 kcal mol$^{-1}$ more stable than the 1*H* form in the gas phase. These data are in agreement with the crystallographic results [25–27], thus supporting our theoretical protocol in the estimation of the tautomeric equilibrium.

The reactivity of the 3,6-diamino-pyrazolo[3,4-b]pyridines against acetylation merits a careful analysis as four nucleophilic positions can undergo acetylation: besides both amino moieties [(C3)N and (C6)N], the piridinic- and pyrrole-type N of the pyrazole (N1, N2). The electron pair of the pyridinic-type N makes this position more nucleophilic than the pyrrole-type N, whose electron pair is part of the aromatic system.

In an attempt to rationalize the regioselectivity, DFT calculations were performed to determine both the atomic charges and the HOMO of **3**. In general, reactions with hard (high-lying LUMOs) electrophiles are charged

**Scheme 2.** Tautomer equilibrium in compound **3**.

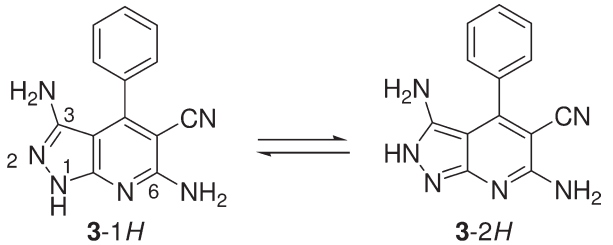

**Table 1**

Calculated NPA charges and HOMO coefficients for the N atoms of **3** prone to undergo attack by the acylating agent.

| | NPA charges | | HOMO coefficients | |
|---|---|---|---|---|
| | **3**-1*H* | **3**-2*H* | **3**-1*H* | **3**-2*H* |
| N1 | −0.397 | −0.327 | 0.47 | 0.73 |
| N2 | −0.340 | −0.380 | 0.64 | 0.34 |
| (C3)N | −0.861 | −0.861 | 0.58 | 0.46 |
| (C6)N | −0.829 | −0.837 | 0.30 | 0.36 |

controlled, whereas reactions with soft (low-lying LUMOs) electrophiles are under frontier molecular orbital (FMO) control. The calculated atomic charges are not consistent with the experimentally determined regioselectivity. Thus, the greatest amount of negative charge is found at the (C3)N position (atomic charge = −0.861, Table 1), while reaction occurs selectively at the azole moiety. On the other hand, the observed selectivity fits well with the computed HOMO coefficients on both tautomers **3**-1*H* and **3**-2*H* (Table 1) as the largest value, and hence providing better overlapping orbital with the electrophile, is situated at the pyridinic-type nitrogen.

Although orbital properties can account only for the electronic factors, the steric effects (if exist) are included in the free energy of activation for the reaction. From a mechanistic point of view, when the reaction is carried out in the absence of a deprotonating agent, it should be expected that the N—H of the azole becomes acidic enough to be deprotonated only when the pyridinic-type N has been attacked by the acylated agent [28]. According to this assumption, we have considered the attack on every N of the neutral structure and have selected acetyl chloride (see Experimental) as electrophile to simulate the acetylation reaction.

The calculated transition structures (Fig. 3) provide free energy differences that suggest a kinetically favored attack on the azole ($\mathbf{TS_{N1}}$ and $\mathbf{TS_{N2}}$) rather than on the amino moieties ($\mathbf{TS_{(C3)N}}$ and $\mathbf{TS_{(C6)N}}$) in the gas phase and in solution (Table 2). In fact, as has been described earlier, these groups are rather planarized as the lone pair is partially delocalized in the aromatic system, thus being less nucleophilic groups than expected. This observation agrees with the experimental selectivity shown earlier (Chart 4). In the azole, the kinetically preferred site for the acetylation, in the gas phase and in solution, is N2 in the **3**-1*H* form (Table 2), which indeed is the proposed predominant tautomer. Also, according to these results, a small amount of the regioisomeric product could be formed by attacking at N1 in the **3**-2*H* form (estimation of the Boltzmann distribution N2:N1 93:7). In summary, these results suggest that **21** should be mostly the N2-substituted structure that results from N-acetylation of the major tautomer of **3** (**3**-1*H*). In view of these theoretical results and to support the position of the acetyl group at N1/N2, we tried to crystallize compound **21** as a free base or as its hydrochloride, but without success; consequently, the location of the acetyl groups at N1 is a tentative hypothesis that still needs to be experimentally confirmed.

Bases on these data, if the azole positions are blocked to undergo reaction, the (C3)N should be the preferred reactive site. This hypothesis agrees with the experimental observations as (C3)N is the acetylation site found in **20**. To further shed light on this result, we have performed calculations for the formation of **20** from the pyrazolopyridine **2**. The HOMO coefficients are parallel to those found for **3**-1*H*: (C3)N = 0.62, (C6)N = 0.27. Likewise, the calculated transition structure for the attacking on the amino group at C3 is 8.3 kcal $mol^{-1}$ more stable than on the amino at C6 (Fig. 4). Accordingly, **20** is acetylated at (C3)N, which is supported by the experimental evidence.

In conclusion, in this work, we have described the acetylation of differently substituted 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile derivatives (**1**–**6**. The structure of the resulting acetamides has been investigated and confirmed by analytical, spectroscopic, and chemical transformations. From these studies, we conclude that, in general, under mild conditions, and using acetic anhydride, when free, the *N*(1)H moiety is the more reactive center respect to the C(3)$N$H$_2$ and C(6)$N$H$_2$ groups. This trend is reversed when no steric hindrance due to presence of a phenyl group at C4 drives the preferred acetylation to C(3)NH$_2$, as it is evident by comparing the observed results from precursor **1** with **3**. When N1 is blocked, the (C3)$N$H$_2$ group undergoes preferential acetylation over the (C6)$N$H$_2$ site, which only has been mono (or diacetylated) at reflux.

On the basis of these data, we have also undertaken a computational analysis to explain the observed selectivities during the acetylation reactions. The calculations of frontier orbital coefficients on the reactants pyrazolopyridines and activation barriers agree with the regiochemistry observed. The regioselectivity on the acetylation of the amino groups can be explained by the availability of

**Table 2**

Thermodynamic data (in kcal $mol^{-1}$) in gas phase and in solution for the potential transition structures for the N-acetylation of **3**.

| Transition structures | $\Delta H^{\ddagger}_{gas}$ | $\Delta G^{\ddagger}_{gas}$ | $\Delta G^{\ddagger}_{sol}$ |
|---|---|---|---|
| $TS_{N1}$ | 1.7 | 1.6 | 1.6 |
| $TS_{N2}$ | 0.0 | 0.0 | 0.0 |
| $TS_{(C3)N}$ | 6.2 | 6.5 | 3.2 |
| $TS_{(C6)N}$ | 11.2 | 11.1 | 7.3 |

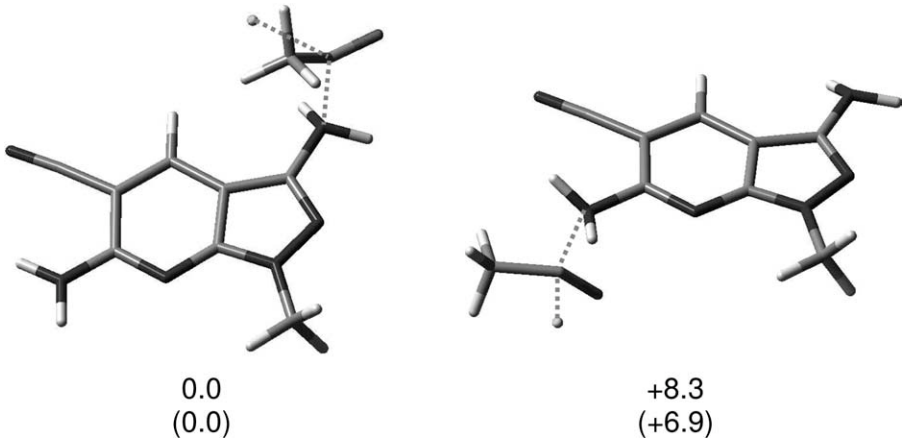

**Figure 4.** Transition structures for the acetylation of **2** at (C3)N (left) and (C6)N (right). Free-energy differences (in kcal $mol^{-1}$) are shown in the gas phase and in solution (in parenthesis).

the N lone pair. A NBO analysis on **2**, **3**-1*H* and the unsubstituted pyrazole[3,4-*b*]pyridine (Chart 5, values in blue) reveals that for the cyano derivatives the lone-pair orbital at (C6)N is less populated, and hence less prone to act as nucleophile, than (C3)N because of a higher delocation on the aromatic system. This induces a higher planarization of the amino group at C6 (Chart 5, values in parenthesis). Conversely, the absence of the electron-withdrawing nitrile substituent allows a more populated lone-pair orbital at (C6)N, in accordance with a decreased *N*-planarization. Therefore, the regioselectivity could be modulated by a careful choice of substituents [29].

## EXPERIMENTAL

Melting points were determined on a microscope type apparatus and are uncorrected. $^1$H NMR and $^{13}$C NMR spectra were recorded at rt at 300, 400, or 500 MHz and at 75, 100, or 125 MHz. The assignment of chemical shifts is based on standard NMR experiments ($^1$H, $^{13}$C-DEPT, $^1$H,$^1$H-COSY, HSQC, HMBC). In the NMR spectra, values with (*) can be interchanged. Two-dimensional [$^1$H, $^1$H] NMR experiments (NOESY) were carried out with the following parameters: a delay time of 1 s, a spectral width of 3000 Hz in both dimensions, 4096 complex points in t2 and 4 transients for each of 256 time increments, and linear prediction to 512. The data were zero-filled to 4096 × 4096 real points. NOESY experiments were acquired with a mix time of 300 ms. Mass spectra were recorded on a GC/MS spectrometer with an API-ES ionization source. Elemental analyses were performed at CQO (CSIC, Spain). TLC was performed on silica F254 and detection by UV light at 254 nm or by charring with ninhydrin, anisaldehyde, or phosphomolybdic-$H_2SO_4$ dyeing reagents. Where anhydrous solvents were needed, they were purified following the usual procedures. Column chromatography was performed on silica gel 60 (230 mesh).

**Acetylation of 3,6-diamino-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (1)**

***Method A.*** A solution of compound **1** [8] (100 mg, 0.57 mmol) in $Ac_2O$ (4 mL, 26.52 mmol, 70 equiv) was heated at 144°C for 21 h. The $Ac_2O$ in excess was removed, and the crude submitted to flash chromatography eluting with mixtures of $CH_2Cl_2$/MeOH from 1 to 4% to give *N*,*N*′-(5-cyano-3a,7a-dihydro-1*H*-pyrazolo[3,4-*b*]pyridine-3,6-diyl)diacetamide (**17**) (13 mg, 8%) [mp 294–296°C; IR (KBr) ν 3434, 3306, 32470, 2928, 1685, 1673, 1611, 1584, 1517, 1430, 1395, 1246, 1011 $cm^{-1}$; $^1$H NMR (DMSO-$d_6$, 300 MHz): δ 13.62 (s, 1H, N1H), 10.96 (s, 1H, C3NHAc), 10.79 (s, 1H, C6NHAc), 8.89 (s, 1H, H4), 2.12 (s, 6H, 2xCOCH$_3$); $^{13}$C NMR (DMSO-$d_6$, 125 MHz): δ 169.2 (2xN*C*OCH3), 168.4 (C6), 150.8 (C7a), 141.5 (C3),* 141.1 (C4),* 116.9 (CN), 104.7 (C3a), 97.2 (C5), 23.0

**1-Acetyl-3-amino-6-methoxy-4-phenyl-1*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (26).** A solution of **4** (80 mg, 0.3 mmol) in $Ac_2O$ (4 mL, 3.9 mmol, 13 equiv) was stirred at 0°C for 16 h and at rt for 4 h. Alter evaporation of the excess of $Ac_2O$, the crude was purified by column chromatography, eluting with $CH_2Cl_2$/MeOH 1% to afford compound **26** (63 mg, 84%): mp 236–238°C; IR (KBr) ν 3485, 3265, 3181, 2225, 1715, 1624, 1589, 1571, 1393, 1349, 1153 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$, 300 MHz): δ 7.65–7.57 (m, 5H, Ph), 5.10 (s, 2H, $NH_2$), 4.10 (s, 3H, $OCH_3$), 2.69 (s, 3H, $NCOCH_3$); $^{13}C$ NMR (DMSO-$d_6$,75 MHz): δ 167.8, 164.9, 153.4, 151.0, 150.7, 132.7, 131.2, 129.8, 129.0 (aromatic, $C_6H_5$), 115.4 (CN), 104.8 (C3a), 92.5 (C5), 55.6 ($OCH_3$), 25.3 ($NCOCH_3$); MS (ES): $[M + 1]^+$ 308.3, $[M + Na]^+$ 370.2, $[2M + Na]^+$ 637.5. Anal. Calcd. for $C_{16}H_{13}N_5O.1/2H_2O$: C, 60.75; H, 4.46; N, 22.14; found: C, 60.59; H, 4.21; N, 22.07.

**Reaction of *N*-acetyl-*N*-(3,5-dicyano-6-methoxy-4-phenylpyridin-2-yl)acetamide (29) with hydrazine hydrate.** A solution of compound **29** (50 mg, 0.15 mmol) and hydrazine hydrate (20 μL, 0.22 mmol, 1.5 equiv) in DMF (5 mL) was refluxed (153°C) for 30 min until complete reaction. Then, the excess of DMF was removed, AcOEt was added, and washed with water. The organic phase was dried, filtered, and evaporated to give a solid that was submitted to chromatography eluting with (hexane/EtOAc, from 8/2 to 1/1) to give compounds **27** (23 mg, 61%), **30** [11] (2 mg, 6%), and **3** (10 mg, 27%).

**2,6-Diamino-4-phenylpyridine-3,5-dicarbonitrile (30).** In a 30-mL glass tube equipped with septa was placed a solution of 6-amino-2-chloro-4-phenylpyridine-3,5-dicarbonitrile (**32**) (0.382 g, 1.5 mmol) in 10 mL of DMF. The reaction mixture was stirred for 30 s before the irradiation to homogenize the solution and then exposed to MWI 250W at 180°C during 3 min. After completion showed by TLC (hexane/AcOEt, 3/2), the reaction mixture was diluted with water, and the precipitate was filtered and washed with water. The residue was purified by column chromatography ($CH_2Cl_2$/MeOH, 25/1 to 10/1, v/v) to yield product **30** (155 mg, 44%), which showed spectroscopic data in good accord with those reported in literature [11].

**6-Amino-2-chloro-4-phenylpyridine-3,5-dicarbonitrile (32).** To a solution of trimethylorthobenzoate (**31**) (1.82 g, 0.01 mol) in pyridine (5 mL) was added malononitrile (1.32 g, 0.02 mol, 2 equiv). The mixture was heated at 110°C for 7 h. After cooling, concentrated aqueous hydrochloric acid (10 mL) was added, and the mixture was heated at 100°C for 2.5 h. After cooling to rt, the mixture was diluted with water and filtered to afford compound **32** (1.0 g, 40%), which showed spectroscopic data in agreement with those reported in literature [11].

**3,6-Diamino-1-methyl-4-phenyl-1H-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (5).** A mixture of 6-amino-2-chloro-4-phenylpyridine-3,5-dicarbonitrile (**32**) (254 mg, 1 mmol) and methylhydrazine (0.11 mL, 1.1 mmol, 1.1 equiv) in DMF (10 mL) was warmed at 153°C for 5 min. The mixture was cooled at rt; the solid was filtered and recrystallized from ethanol to give precursor **5** (211 mg, 80%): mp 279–281°C; IR (KBr) ν 3477, 3427, 3379, 3323, 3191, 2201, 1654, 1589, 1573, 1561, 1405, 1204 $cm^{-1}$; $^1H$ NMR (DMSO, 300 MHz): δ 7.58–7.48 (m, 5H, $C_6H_5$), 6.90 [s, 2H, C(6)$NH_2$], 4.36 [s, 2H, C(3)$NH_2$], 3.59 (s, 3H, $NCH_3$); $^{13}C$ NMR (DMSO, 75 MHz): δ 158.2 (C6), 151.7 (C4), 150.5 (C7a), 147.5 (C3), 133.8 (C1′), 129.7 (C4′), 128.8 [2C (C2′,C6′)], 128.2 [2C (C3′,C5′)], 117.3 (CN), 98.0 (C3a), 84.3 (C5), 32.4 ($NCH_3$); MS (ES): $[2M]^+$ 528.7, $[2M - 1]^+$ 527.7. Anal. Calcd. for $C_{14}H_{12}N_6$: C, 63.62; H, 4.58; N, 31.80; found C, 63.60; H, 4.65; N, 32.04.

***N*-(6-Amino-5-cyano-1-methyl-4-phenyl-1*H*-pyrazolo[3,4-*b*]pyridin-3-yl)acetamide (33).** A solution of compound **5** (100 mg, 0.38 mmol) in $Ac_2O$ (2.5 mL, 26.52 mmol, 70 equiv) was stirred at rt for 8 h. The crude was cooled at 0°C, and the precipitate was filtered, washed with EtOH, and submitted to chromatography (AcOEt) to give compound **33** (24 mg, 21%): mp 249–251°C; IR (KBr) ν 3489, 3414, 3330, 3263, 3052, 2218, 1664, 1625, 1590, 1571, 1518, 1444, 1399, 1379, 1259, 1196 $cm^{-1}$; $^1H$ NMR (DMSO-$d_6$, 300 MHz): δ 9.49 (s, 1H, NH), 7.58–7.48 (m, 5H, $C_6H_5$), 7.12 (s, 2H, $NH_2$), 3.78 (s, 3H, $NCH_3$), 1.42 (s, 3H, $COCH_3$); $^{13}C$ NMR (DMSO-$d_6$, 75 MHz): δ 169.1 ($NCOCH_3$), 159.8 (C6), 152.7 (C4), 151.7 (C7a), 139.0 (C3), 133.9 (C1′), 129.9 (C4′), 129.3 (2C, C2′,C6′), 128.6 (2C, C3′,C5′), 117.5 (CN), 102.9 (C3a), 88.3 (C5), 33.8 ($NCH_3$), 22.51 ($NCOCH_3$); MS (ES): $[M + 1]^+$ 307.1. Anal. Calcd. for $C_{14}H_{12}N_6$: C, 62.74; H, 4.61; N, 27.44; found C, 62.96; H, 4.68; N, 27.31.

**3,6-Diamino-2-phenyl-2*H*-pyrazolo[3,4-*b*]pyridine-5-carbonitrile (6).** A solution of precursor **34** [8] (100 mg, 0.56 mmol) and *N*-phenylhydrazine (82 μL, 0.84 mmol, 1.5 equiv) in DMF (2 mL, 5mL/mmol) was warmed at 153°C for 1 h until complete reaction (TLC analysis). The mixture was cooled at 0°C; the solid was recovered and submitted to chromatography eluting with $CH_2Cl_2$/MeOH (from 0.5 to 2%) to give product **6** (91 mg, 70%): mp 306–308°C; IR (KBr) ν 3467, 3353, 3299, 3154, 2211, 1620, 1596, 1455, 1343 $cm^{-1}$; $^1H$ NMR (DMSO, 300 MHz): δ 8.36 [s, 1H, H4), 7.57–7.37 (m, 5H, aromatic), 6.95 [s, 2H, (C3)$NH_2$], 6.47 [s, 2H, (C6)$NH_2$]; $^{13}C$ NMR (DMSO, 75 MHz): δ 157.9 (C6)*, 156.5 (C7a)*, 143.0 (C3), 140.0 (C4), 138.2 (C1′), 129.3 (C3′,C5′), 127.4 (C4′), 123.9 (C2′,C6′), 118.5 (CN), 96.9 (C3a), 84.6 (C5); MS (CI): *m/z* 251 [$M^+$, 100], 234 [$M^+$-$NH_2$, 8], 92 (14), 77(21). Published online 8 June 2010 in Wiley InterScience (www.interscience.wiley.com).

A mild, efficient and highly selective approach to the synthesis of cryptotackiene derivatives via three-component reactions of 3-amino-9-ethylcarbazole and aromatic aldehydes with electron-rich alkenes, such as 2,3-dihydrofuran, or 3,4-dihydro-2*H*-pyran catalyzed by iodine in THF is reported. It is worth to note that only *trans*-products were obtained with high selectivity in good to high yields, which confirmed by X-ray diffraction analysis.

*J. Heterocyclic Chem.*, **47**, 873 (2010).

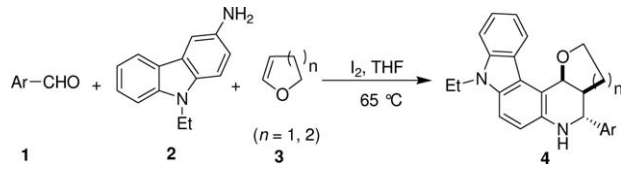
## INTRODUCTION

Cryptotackiene, a linear 5-*N*-methyl-5*H*-indolo[2,3-*b*]quinoline alkaloid isolated from the West African shrub *Cryptolepis sanguinolenta*, has been reported to exhibit strong antiplasmodial activity [1]. A few of cryptotackiene derivatives are found to display strong antimicrobial and cytotoxic activities *in vitro* and significant antitumor properties *in vivo* [2]. In addition, its isomeric moiety, named ellipticine (5,11-dimethyl-6*H*-indolo[2,3-*g*]isoquinoline), also exhibits promising results in the treatment of osteolytic breast cancer metastases, brain tumors, kidney sarcoma, and myeloblastic leukemia [3]. More recent studies have also indicated that they possessed a good activity against HIV [4]. Accordingly, a wide variety of strategies [5–7] have been reported to construct these aforementioned active moieties for their important biological activities.

The imino Diels–Alder [4+2] cyclo-addition reaction presents a powerful synthetic tool to the construction of the polycyclic cryptotackiene ring systems. Of which the imines derived from aromatic amines and aldehyde, act as heterodienes and undergo Diels–Alder reaction with various dienophiles in the presence of acidic catalysts [8–11]. The multicomponent reactions (MCRs) involving 3-amino-9-ethylcarbazole, which reported by Gaddam and Nagarajan, represent an effective synthetic pathway toward cryptotackiene derivatives [12]. However, the known methods suffer from some disadvantages. For instance, these procedures often require harsh reaction conditions, multistep reaction, metal catalysts, expensive reagents or no stereo-selectivity. Especially for the stereo-selectivity, they always give *cis*- and *trans*-isomers using 2,3-dihydrofuran, 3,4-dihydro-2*H*-pyran as starting materials.

As an inexpensive, efficient, and environmentally benign catalyst, iodine has been used extensively in organic synthesis. More and more organic transformations [13] promoted by molecular iodine have been documented in recent years. In our previous paper, we have synthesized series of benzo[*f*]quinoline derivatives via three-component reactions of aromatic aldehyde, naphthalen-2-amine, and various ketones [14] induced by iodine. As a continuation of our research devoted to this iodine-catalyzed reaction, 3-amino-9-ethylcarbazole was selected as similar amine to react with aromatic aldehyde, and 2,3-dihydrofuran or 3,4-dihydro-2*H*-pyran for the challenge of its stereo-selectivity. It was noteworthy that only *trans*-4-aryl-8-ethyl-3,3*a*,4,5,8,12*d*-hexahydro-2*H*-furo[3,2-*c*]indolo[3,2-*f*]quinoline or *trans*-5-aryl- 9-

**Scheme 1.** Reaction of **1**, **2**, and **3**.



ethyl-2,3,4,4*a*,5,6,9,13*d*-hexahydropyrano[3,2-*c*]indolo [3,2-*f*]quinoline derivatives were obtained with high selectivity in good to high yields.

## RESULTS AND DISCUSSION

Treatment of aromatic aldehyde **1**, 3-amino-9-ethylcarbazole **2**, and 2,3-dihydrofuran **3** in THF in the presence of 5 mol % iodine at reflux condition afforded the corresponding *trans*-4-aryl-8-ethyl-3,3*a*,4,5,8,12*d*-hexahydro-2*H*-furo[3,2-*c*]indolo[3,2-*f*]quinoline derivatives **4** in good to high yields with high stereo-selectivity (Scheme 1). Obviously, these results were different from *trans*- to *cis*-isomers catalyzed by $InCl_3$ in ionic liquid [12].

In our initial study, the reaction of 4-nitrobenzaldehyde **1d**, 3-amino-9-ethylcarbazole **2**, and 2,3-dihydrofuran **3** was used as a model reaction to optimize the reaction conditions. The reaction was first carried out in THF in the absence of $I_2$. It was found that no reaction occurred at room temperature or reflux condition (Table 1, entries 1 and 2). Similar reactions were attempted in the presence of 5, 10, and 20 mol % of $I_2$. The results from Table 1 (entries 5-7) show that 5 mol % $I_2$ at reflux in THF is sufficient to initiate the reaction. Higher loading of the catalyst had no significant influence on the reaction yield. To find the optimum reaction temperature, the reaction was carried out with 5 mol % of $I_2$ at room temperature, 50°C and reflux temperature, resulting in the isolation of **4d** in trace amount, 68% and 88% yields (Table 1, entries 3-5), respectively. Thus, 5 mol % of $I_2$ and a reaction temperature at reflux were optimal conditions. In addition, $CH_3CN$, benzene, DMF, and $CHCl_3$ (Table 1, entries 8-11) were also tested as the solvents. In these cases, product **4d** was formed in slightly lower yields (Table 1, entries 8-11).

According to the optimized conditions, various aromatic aldehydes **1** were then subjected to react with 3-amino-9-ethylcarbazole **2** and **3** to generate a library of **4** (Table 2, entries 1 to 8). For aldehyde **1**, the yields of **4** were not sensitive to the electronic properties of the aromatic ring in the presence of electron-withdrawing groups (such as halide and nitro) or electron-donating groups (such as alkoxyl group) (Table 2). The *trans*-structure of **4g** was further confirmed by X-ray diffraction analysis, and the crystal structure was shown in Figure 1. The 2,3-dihydrofuran could be expended to other electron-rich alkenes, such as 3,4-dihydro-2*H*-pyran was also chosen as reactant to react with **1** and **2**, giving corresponding *trans*-5-aryl-9-ethyl-2,3,4,4*a*,5,6,9,13*d*-hexahydropyrano[3,2-*c*]indolo[3,2-*f*]quinoline with good yields and stereo-selectivity (Table 2, entries 9 to 12).

According to the literatures [15], we think that iodine catalyzes the reaction as a mild Lewis acid. The mechanism was tentatively proposed as shown in Scheme 2. The Schiff base **I** may be formed first by the reaction of aromatic aldehyde and 3-amino-9-ethylcarbazole. Then imino-Diels–Alder reaction between the iodine-activated Schiff base **II** and 2,3-dihydrofuran takes place

**Table 1**

Synthetic results of **4d** under different reaction conditions.[a]
