$$V_{(i)} \cdot V_{(j)} = \delta_{ij}, \tag{10}$$

i.e.,

$$V^a_{(i)} V^a_{(j)} = \delta_{ij},$$

where $V_{(i)} \cdot V_{(j)}$ is the Clifford scalar product defined by[19]

$$V_{(i)} \cdot V_{(j)} = \tfrac{1}{2}(V_{(i)} V_{(j)} + V_{(j)} V_{(i)}). \tag{11}$$

Since the potential A is also a SU(2) Clifford vector, we have the projection formula

$$A = (A \cdot V_{(i)}) V_{(i)}. \tag{12}$$

Substituting this formula into (3), we obtain

$$DV_{(i)} = dV_{(i)} - (A \cdot V_{(j)})[V_{(j)}, V_{(i)}]. \tag{13}$$

Using (10), (11) and (13), and considering that

$$[V_{(j)}, V_{(i)}] = 2V_{(j)} V_{(i)} - 2V_{(i)} \cdot V_{(j)}, \tag{14}$$

we can rewrite A as

$$A = 1/4 dV_{(i)} V_{(i)} - 1/4 DV_{(i)} V_{(i)}. \tag{15}$$

According to (7), we define that

$$a = \tfrac{1}{4} dV_{(i)} V_{(i)}, \tag{16}$$

and

$$b = \tfrac{1}{4} DV_{(i)} V_{(i)}. \tag{17}$$

It is easy to prove that the decomposition formula above satisfies the requirement in (6), even has global property, and is independent from the local coordinates.

Let a family $\{W, V, U, \ldots\}$ be an open cover of M and S_{uv} be the transition matrix function which satisfy the following condition:[21]

$$S_{uu=1}, \quad S^{-1}_{vu} = S_{uv}, \quad S_{wv} S_{vu} S_{uw} = I; \quad W \cap V \cap U \neq \varnothing. \tag{18}$$

For any two open neighborhoods V and U, if $V \cap U \neq \varnothing$, then

$$V_{(i)v} = S_{vu} V_{(i)} S^{-1}_{vu}, \tag{19}$$

where the subscripts ''$_u$'' and ''$_v$'' represent the open covers U and V correspondingly, and we know that the gauge potential A undergoes the gauge transformation

$$A_v = S_{vu} A_u S^{-1}_{vu} + dS_{vu} S^{-1}_{vu}, \tag{20}$$

which is the fundamental condition for the existence of the gauge potential on the principal $P(\pi, M, \mathrm{SU}(2))$. In the physics terminology S_{vu} is just the gauge transformation (6) in the gauge theory. In the following, for abbreviation, we shall use the notation $S_{vu} = S$. According to (19), we deduce that

$$dV_{(i)v} V_{(i)v} = S dV_{(i)u} V_{(i)u} S^{-1} + dSS^{-1} - V_{(i)v} dSS^{-1} V_{(i)v}. \tag{21}$$

Considering that A is a vector of Clifford algebra, we can see that dSS^{-1} is a vector of the Clifford algebra. Also, then, there exists the following formula:[19]

$$V_{(i)v} dSS^{-1} V_{(i)v} = -3 dSS^{-1}. \tag{22}$$

Noticing that

$$DV_{(i)v}=SDV_{(i)u}S^{-1},$$

from (15), and making use of (19), (21) and (22), one can easily obtain

$$A_v-\tfrac{1}{4}(dV_{(i)v}V_{(i)v}-DV_{(i)v}V_{(i)v})=S[A_u-\tfrac{1}{4}(DV_{(i)u}V_{(i)u}-DV_{(i)u}V_{(i)u})]S^{-1}. \tag{23}$$

The expression above shows that if the decomposition formula on the open neighborhood U,

$$A_v=\tfrac{1}{4}(dV_{(i)v}V_{(i)v}-DV_{(i)v}V_{(i)v}),$$

holds true, the decomposition formula on the open neighborhood U,

$$A_u=\tfrac{1}{4}(dV_{(i)u}V_{(i)u}-DV_{(i)u}V_{(i)u}),$$

must hold true, too. This means that the general decomposition formula (15) has a global property and is independent from the choice of the local coordinates.

We know that the characteristic class is the fundamental topological property, and it is independent of the gauge potential.[22] So, to discuss the Chern class, we can take A as

$$A=\tfrac{1}{4}dU_{(i)}U_{(i)}. \tag{24}$$

One can regard it as a special gauge. By use of this formula, the magnetic monopole can be studied as in Refs. 6–8. In this paper we want to discuss the topological properties of a four-dimensional manifold, a decomposition formula in terms of the sphere bundle over the manifold will be convenient.

Now, let us return to discuss the decomposition theory on the sphere bundle of a compact and oriented four-dimensional manifold. Let M be a compact and oriented four-dimensional manifold and $P(\pi,M,G)$ be a principal bundle with the structure group $G=\mathrm{SU}(2)$. A smooth vector field ϕ^A $(A=0,1,2,3)$ can be found on the base manifold M. We define a unit vector field on M as

$$\begin{gathered} n^A=\phi^A/\|\phi\|, \quad A=0,1,2,3, \\ \|\phi\|=\sqrt{\phi^A\phi^A}, \end{gathered} \tag{25}$$

in which the superscripts ''A'' are the local orthonormal frame index.

In fact, **n** is identified as a section of the sphere bundle over M (or a partial section of the vector bundle over M).[5] We see that the zeros of $\boldsymbol{\phi}$ are just the singular points of **n**. Since the global property of a manifold has close relation with zeros of a smooth vector fields on it, this expression of the unit vector **n** is a very powerful tool in the discussion of the global topology. It naturally guarantees the constraint

$$n^An^A=1. \tag{26}$$

We can express the unit vector **n** in terms of the Clifford algebra[23] as

$$n=n^As_A, \quad A=0,1,2,3, \tag{27}$$

where

$$s=(I,i\boldsymbol{\sigma}), \quad s^\dagger=(I,-i\boldsymbol{\sigma}). \tag{28}$$

We know that n is just an element of Spin(3) in terms of geometric algebra.[19] We can rewrite (26) as

$$nn^\dagger=1. \tag{29}$$

It is easy to see that n has three independent components. Since the orthonormal basis of the SU(2) Clifford one-vectors just have three independent components, we can express $U_{(i)}$ in terms

of an element of Spin(3). From gauge transformations of the orthonormal basis given in Ref. 24, and the spinorial transformation given in Ref. 25, one can expand $U_{(i)}$ in terms of an element of Spin(3) as

$$U^a_{(i)}=2(n^0)^2\delta^{ia}+2n^0n^b\in^{iba}+2n^in^a-\delta^{ia}. \tag{30}$$

It is easy to prove

$$U^a_{(i)}U^a_{(j)}=\delta_{ij}. \tag{31}$$

Using (30) and (24), as a result, the gauge potential A will be expressed as

$$A=dnn^\dagger. \tag{32}$$

Because n is a unit element of the sphere bundle over M, we will discuss the topological property of the principle $P(\pi,M,\mathrm{SU}(2))$ directly by using this formula.

III. THE SU(2) CHERN DENSITY AND ITS INNER STRUCTURE

It is well known that gauge potential (connection) and gauge field (curvature) play essential roles in discussing the topological properties of a manifold. For the principal $P(\pi,M,\mathrm{SU}(2))$ the SU(2) Chern density is an important topological characteristic. In this section we will discuss the SU(2) Chern density by using the decomposition formula (32), which we have just given in the last section.

We know that the second Chern class is the fundamental characteristic of the principal $P(\pi,M,\mathrm{SU}(2))$. It is denoted as

$$C_2(P)=\frac{1}{8\pi^2}\mathrm{Tr}(F\wedge F). \tag{33}$$

The curvature F is defined as

$$F=dA-A\wedge A. \tag{34}$$

One can show that the gauge field F is a generalized function when there exist m singular points z_i $(i=1,2,\ldots,m)$ in the unit vector field n. Let us substitute the formula (32) into (34). Then

$$F\begin{cases}=0 & \text{when } x\neq z_i,\\ \neq 0 & \text{when } x=z_i,\end{cases} \tag{35}$$

where z_i are the singular points of n. This means that the gauge field F vanishes at the region where n has no singular points, but at the singular points of n the gauge field F does not vanish. This feature we will show soon is due to the nontriviality property of the principal $P(\pi,M,\mathrm{SU}(2))$, and is essential to study some physical problem.

The second SU(2) Chern class can be rewrite in terms of Chern Simon:[22,26]

$$C_2(P)=\frac{1}{8\pi^2}d\Omega \tag{36}$$

and

$$\Omega=\frac{1}{8\pi^2}\mathrm{Tr}\left(A\wedge dA-\frac{2}{3}A\wedge A\wedge A\right), \tag{37}$$

which is known as the Chern–Simon form.[27]

Substituting (32) into (36) and considering (29), we obtain

$$C_2(P)=\frac{1}{24\pi^2}\mathrm{Tr}(dn\wedge dn^\dagger\wedge dn\wedge dn^\dagger). \tag{38}$$

In detail, substituting (27) into the formula above,

$$C_2(P)=\frac{1}{24\pi^2}\in^{\mu\nu\lambda\rho}\partial_\mu n^A\partial_\nu n^B\partial_\lambda n^C\partial\rho n^D Tr(s_A s_B^\dagger s_C s_D^\dagger)dx^4$$

$$=\frac{1}{12\pi^2}\in^{\mu\nu\lambda\rho}\in_{ABCD}\partial_\mu n^A\partial_\nu n^B\partial_\lambda n^C\partial_\rho n^D dx^4. \tag{39}$$

By substituting (25) into (39), considering

$$dn^A=\frac{d\phi^A}{\|\phi\|}+\phi^A d\left(\frac{1}{\|\phi\|}\right), \tag{40}$$

we have

$$C_2(P)=-\frac{1}{4\pi^2}\frac{\partial^2}{\partial\phi^A\partial\phi^A}\left(\frac{1}{\|\phi\|^2}\right)D(\phi/x)d^4x, \tag{41}$$

where $D(\phi/x)$ is the Jacobian defined as

$$\epsilon^{ABCD}D(\phi/x)=\epsilon^{\mu\nu\lambda\rho}\partial_\mu\phi^A\partial\nu\phi^B\partial_\lambda\phi^C\partial_\rho\phi^D. \tag{42}$$

By means of the general Green's function formula

$$\frac{\partial^2}{\partial\phi^A\partial\phi^A}\left(\frac{1}{\|\phi\|^2}\right)=-4\pi\delta^4(\boldsymbol{\phi}), \tag{43}$$

we have

$$C_2(P)=\delta^4(\boldsymbol{\phi})D(\phi/x)d^4x. \tag{44}$$

Suppose $\phi^A(x)$ $(A=0,1,2,3)$ have m isolated zeros at $x_\mu=z_\mu^i$ $(i=1,2,\ldots,m)$. According to the δ-function theory,[28] $\delta(\boldsymbol{\phi})$ can be expressed by

$$\delta(\boldsymbol{\phi})=\sum_{i=1}^{m}\frac{\beta_i\delta(\mathbf{x}-\mathbf{z}_i)}{|D(\phi/x)|_{\mathbf{x}=\mathbf{z}_i}}, \tag{45}$$

and one then obtains

$$C_2(P)=\sum_{i=1}^{m}\eta_i\beta_i\delta^4(x-z_i)d^4x, \tag{46}$$

where β_i is a positive integer (the Hopf index of the ith zeros) and η_i is the Brouwer degree:[29]

$$\eta_i=\frac{D(\phi/x)}{|D(\phi/x)|}=\mathrm{sgn}[D(\phi/x)]\big|_{x=z_i}=\pm 1. \tag{47}$$

The meaning of the Hopf index β_i is that the vector field function $\boldsymbol{\phi}$ covers the corresponding region β_i times while $\mathbf{x}$ covers the region of the neighborhood of zero z_i once. From the above discussion, the Chern density $\rho(M)$ is defined as

$$\rho(M)=\sum_{i=1}^{m}\eta_i\beta_i\delta^4(x-z_i), \tag{48}$$

which shows that the topological structure of Chern density ρ is labeled by the Brouwer degrees and the Hopf index. The integration of $\rho(M)$ on M,

$$C_2=\int_M \rho(M)d^4x=\sum_{i=1}^{m}\eta_i\beta_i, \tag{49}$$

is an integer called the Chern number, which is a topological invariant of M.

The result (49) suggests that the zero points of the smooth vector $\boldsymbol{\phi}$ are essential to the topological properties of the base manifold M. On the other hand, the density (48) can be regarded as the density of a system of k classical pointlike particles with topological invariant charges $g_i=\eta_i\beta_i$ on the four-dimensional manifold.

IV. THE BIFURCATION OF CHERN DENSITY

As discussed before, the zeros of the smooth vector $\boldsymbol{\phi}$ play important roles in studying the Chern class of the manifold M. In this section, we will study the properties of the zero points, in other words, the properties of the following equation solutions

$$\begin{aligned}&\phi^0(x^0,x^1,x^2,x^3)=0,\quad \phi^1(x^0,x^1,x^2,x^3)=0,\\ &\phi^2(x^0,x^1,x^2,x^3)=0,\quad \phi^3(x^0,x^1,x^2,x^3)=0.\end{aligned} \tag{50}$$

As we knew before, if the Jacobian determinant

$$D\left(\frac{\phi}{x}\right)=\frac{\partial(\phi^0,\phi^1,\phi^2,\phi^3)}{\partial(x^0,x^1,x^2,x^3)}\neq 0,$$

we will have the isolated solutions of (50). The isolated solutions are called regular points. It is easy to see that the result in Sec. III is based on this condition. However, when this condition fails, the above results will change in some way, and will lead to the branch process of topological density and give rise to the bifurcation.

In order to show this case easily, we want to have some suppose. It is convenient to let $x^0=t$, and suppose $\phi^0=\phi^0(t)$. We denote one of the zero points as $(t^*,\mathbf{z}_i)$. We know that if

$$D\left(\frac{\boldsymbol{\phi}}{\mathbf{x}}\right)\Big|_{(t^*,\mathbf{z}_i)}=\frac{\partial(\phi^1,\phi^2,\phi^3)}{\partial(x^1,x^2,x^3)}\Big|_{(t^*,\mathbf{z}_i)}=0,$$

the Jacobian $D(\phi/x)|_{(t^*,\mathbf{z}_i)}=0$ will be obtained automatically. We will show that this case will lead to the branch process of topological density. In this case, Eqs. (50) will be rewritten as

$$\phi^0(t)=0, \tag{51}$$

and

$$\phi^1(t,x^1,x^2,x^3)=0,\quad \phi^2(t,x^1,x^2,x^3)=0,\quad \phi^3(t,x^1,x^2,x^3)=0. \tag{52}$$

It is well known that when the Jacobian $D(\boldsymbol{\phi}/\mathbf{x})|_{(t^*,\mathbf{z}_i)}=0$, the usual implicit function theorem is of no use. However, if the Jacobian

$$D^1\left(\frac{\boldsymbol{\phi}}{x}\right)\Big|_{(t^*,\mathbf{z}_i)}=\frac{\partial(\phi^1,\phi^2,\phi^3)}{\partial(t,x^2,x^3)}\Big|_{(t^*,\mathbf{z}_i)}\neq 0,$$

we can use the Jacobian $D^1(\boldsymbol{\phi}/x)|_{(t^*,\mathbf{z}_i)}$ instead of $D(\boldsymbol{\phi}/\mathbf{x})|_{(t^*,\mathbf{z}_i)}=0$, for the purpose of using the implicit function theorem.[30] Then we have a unique solution of Eqs. (52) in the neighborhood of the points $(t^*,\mathbf{z}_i)$:

$$t=t(x^1),\quad x^i=x^i(x^1),\quad i=2,3, \tag{53}$$

with $t^*=t(x^1)$. We call the critical points $(t^*,\mathbf{z}_i)$ the limit points. In the present case, it is easy to know that

$$\left.\frac{dx^1}{dt}\right|_{(t^*,\mathbf{z}_i)} = \frac{D^1(\boldsymbol{\phi}/x)|_{(t^*,\mathbf{z}_i)}}{D(\boldsymbol{\phi}/x)|_{(t^*,\mathbf{z}_i)}} = \infty,$$

i.e.,

$$\left.\frac{dt}{dx^1}\right|_{(t^*,\mathbf{z}_i)} = 0.$$

Then we have the Taylor expansion of (53) at the point $(t^*,\mathbf{z}_i)$:

$$t = t^* + \left.\frac{dt}{dx^1}\right|_{(t^*,\mathbf{z}_i)} (x^1 - z_i^1) + \frac{1}{2}\left.\frac{d^2t}{(dx^1)^2}\right|_{(t^*,\mathbf{z}_i)} (x^1 - z_i^1)^2 = t^* + \frac{1}{2}\left.\frac{d^2t}{(dx^1)^2}\right|_{(t^*,\mathbf{z}_i)} (x^1 - z_i^1)^2.$$

Therefore,

$$t - t^* = \frac{1}{2}\left.\frac{d^2t}{(dx^1)^2}\right|_{(t^*,\mathbf{z}_i)} (x^1 - z_i^1)^2, \tag{54}$$

which is a parabola in the x^1-t plane. From (54), we can obtain the two solutions $x_1^1(t)$ and $x_2^1(t)$, which give the branch solutions of the system (50). If $d^2t/(dx^1)^2|_{(t^*,\mathbf{z}_i)} > 0$, we have the branch solutions for $t > t^*$; otherwise, we have the branch solutions for $t > t^*$. These two condition are related to the origin and annihilation of topological charges.[31] Since the Chern number (49) is a topological invariant, the topological numbers of these two must be opposite at the zero point, i.e.,

$$\beta_{i1}\eta_{i1} = -\beta_{i2}\eta_{i2}.$$

For a limit point, it also requires the $D^1(\boldsymbol{\phi}/x)|_{(t^*,\mathbf{z}_i)} \neq 0$. As for a bifurcation point,[32] it must satisfy a more complete condition. This case will be discussed in the following subsections in detail.

A. The branch process at the bifurcation point

In this subsection, we have the restrictions of the system (50) at the bifurcation point $(t^*,\mathbf{z}_i)$:

$$\left.D\left(\frac{\boldsymbol{\phi}}{\mathbf{x}}\right)\right|_{(t^*,\mathbf{z}_i)} = 0, \quad \left.D^1\left(\frac{\boldsymbol{\phi}}{x}\right)\right|_{(t^*,\mathbf{z}_i)} = 0. \tag{55}$$

These will lead to an important fact that the function relationship between t and x^1 is not unique in the neighborhood of the bifurcation point $(\mathbf{z}_i, t^*)$. It is easy to see from the equation

$$\left.\frac{dx^1}{dt}\right|_{(t^*,\mathbf{z}_i)} = \frac{D^1(\boldsymbol{\phi}/x)|_{(t^*,\mathbf{z}_i)}}{D(\boldsymbol{\phi}/x)|_{(t^*,\mathbf{z}_i)}}, \tag{56}$$

which, under the restraint (55), directly shows that the direction of the integral curve of Eq. (56) is indefinite at the point $(\mathbf{z}_i, t^*)$. This is why the very point $(\mathbf{z}_i, t^*)$ is called a bifurcation point of the system (50).

Next, we will find a simple way to search for the different directions of all branch curves at the bifurcation point. Assume that the bifurcation point $(\mathbf{z}_i, t^*)$ has been found from (52). We know that, at the bifurcation point $(\mathbf{z}_i, t^*)$, the rank of the Jacobian matrix $[\partial\boldsymbol{\phi}/\partial x]$ is smaller than 3. First, we suppose the rank of the Jacobian matrix $[\partial\boldsymbol{\phi}/\partial x]$ is 2 (the case of a more smaller rank will be discussed later). Suppose that the 2×2 submatrix $J_1(\phi/x)$ is

$$J_1\left(\frac{\phi}{x}\right)=\begin{pmatrix} \frac{\partial\phi^1}{\partial x^2} & \frac{\partial\phi^1}{\partial x^3} \\ \frac{\partial\phi^2}{\partial x^2} & \frac{\partial\phi^2}{\partial x^3} \end{pmatrix}, \tag{57}$$

and its determinant $D_1(\phi/x)$ does not vanish. The implicit function theorem says that there exists one and only one function relation

$$x^i=f^i(x^1,t), \quad i=2,3. \tag{58}$$

We denoted the partial derivatives as

$$f^i_1=\frac{\partial f^i}{\partial x^1}; \quad f^i_t=\frac{\partial f^i}{\partial t}; \quad f^i_{11}=\frac{\partial^2 f^i}{\partial x^1\partial x^1}; \quad f^i_{1t}=\frac{\partial^2 f^i}{\partial x^1\partial x^t}; \quad f^i_{tt}=\frac{\partial f^i}{\partial x^t\partial x^t}.$$

From (50) and (58) we have, for $a=1,2,3$,

$$\phi^a=\phi^a(x^1,f^2(x^1,t),f^3(x^1,t),t)=0, \tag{59}$$

which give

$$\frac{\partial\phi^a}{\partial x^1}=\phi^a_1+\sum_{j=2}^{3}\frac{\partial\phi^a}{\partial f^j}\frac{\partial f^j}{\partial x^1}=0, \tag{60}$$

$$\frac{\partial\phi^a}{\partial t}=\phi^a_t+\sum_{j=2}^{3}\frac{\partial\phi^a}{\partial f^j}\frac{\partial f^j}{\partial t}=0, \tag{61}$$

from which we can get the first-order derivatives of f^i: f^i_1 and f^i_t. Differentiating (60) with respect to x^1 and t, respectively, we get

$$\sum_{j=2}^{3}\phi^a_j f^j_{11}=-\sum_{j=2}^{3}\left[2\phi^a_{j1}f^j_1+\sum_{k=2}^{3}(\phi^a_{jk}f^k_1)f^j_1\right]-\phi^a_{11}, \quad a=1,2,3, \tag{62}$$

$$\sum_{j=2}^{3}\phi^a_j f^j_{1t}=-\sum_{j=2}^{3}\left[\phi^a_{jt}f^j_1+\phi^a_{j1}f^j_t+\sum_{k=2}^{3}(\phi^a_{jk}f^k_t)f^j_1\right]-\phi^a_{1t}, \quad a=1,2,3. \tag{63}$$

The differentiation of (61) with respect to t gives

$$\sum_{j=2}^{3}\phi^a_j f^j_{tt}=-\sum_{j=2}^{3}\left[2\phi^a_{jt}f^j_t+\sum_{k=2}^{3}(\phi^a_{jk}f^k_t)f^j_t\right]-\phi^a_{tt}, \quad a=1,2,3, \tag{64}$$

where

$$\phi^a_{jk}=\frac{\partial^2\phi^a}{\partial x^j\partial x^k}, \quad \phi^a_{jt}=\frac{\partial^2\phi^a}{\partial x^j\partial t}. \tag{65}$$

The differentiation of (61) with respect to x^1 gives the same expression as (63). By making use of the Gaussian elimination method to (62), (63) and (64) we can find the second-order derivatives f^i_{11}, f^i_{1t} and f^i_{tt}. The above discussion does not matter to the last component $\phi^3(\mathbf{x},t)$. In order to find the different values of dx^1/dt at the bifurcation point $(\mathbf{z}_i,t^*)$, let us investigate the Taylor expansion of $\phi^3(\mathbf{x},t)$ in the neighborhood of $(\mathbf{z}_i,t^*)$. Substituting (58) into $\phi^3(\mathbf{x},t)$ we have the function of two variables x^1 and t,

$$F(x^1,t)=\phi^3(x^1,f^2(x^1,t),f^3(x^1,t),t), \tag{66}$$

which, according to (52), must vanish at the bifurcation point

$$F(z_i^1, t^*) = 0. \tag{67}$$

From (66) we have the first-order partial derivatives of $F(x^1,t)$:

$$\frac{\partial F}{\partial x^1} = \phi_1^3 + \sum_{j=2}^{3} \phi_j^3 f_1^j, \quad \frac{\partial F}{\partial t} = \phi_t^3 + \sum_{j=2}^{3} \phi_j^3 f_t^j. \tag{68}$$

Using (60) and (61), the first equation of (55) is expressed as

$$D\left(\frac{\boldsymbol{\phi}}{x}\right)\Big|_{(\mathbf{z}_i, t^*)} = \begin{vmatrix} -\sum_{j=2}^{3} \phi_j^1 f_1^j & \phi_2^1 & \phi_3^1 \\ -\sum_{j=2}^{3} \phi_j^2 f_1^j & \phi_2^2 & \phi_3^2 \\ \phi_1^3 & \phi_2^3 & \phi_3^3 \end{vmatrix}_{(\mathbf{z}_i, t^*)} = 0, \tag{69}$$

which, by Cramer's rule, can be written as

$$D\left(\frac{\boldsymbol{\phi}}{x}\right)\Big|_{(\mathbf{z}_i, t^*)} = \frac{\partial F}{\partial x^1} \det J_1\left(\frac{\phi}{x}\right)\Big|_{(\mathbf{z}_i, t^*)} = 0.$$

Since $\det J_1(\phi/x)|_{(\mathbf{z}_i, t^*)} \neq 0$, the above equation gives

$$\frac{\partial F}{\partial x^1}\Big|_{(\mathbf{z}_i, t^*)} = 0. \tag{70}$$

With the same reasons, we have

$$\frac{\partial F}{\partial t}\Big|_{(\mathbf{z}_i, t^*)} = 0. \tag{71}$$

The second-order partial derivatives of the function F are easily found to be

$$\frac{\partial^2 F}{(\partial x^1)^2} = \phi_{11}^3 + \sum_{j=2}^{3} \left[2\phi_{1j}^3 f_1^j + \phi_j^3 f_{11}^j + \sum_{k=2}^{3} (\phi_{kj}^3 f_1^k) f_1^j \right], \tag{72}$$

$$\frac{\partial^2 F}{\partial x^1 \partial t} = \phi_{1t}^3 + \sum_{j=2}^{3} \left[\phi_{1j}^3 f_t^j + \phi_{tj}^3 f_1^j + \phi_j^3 f_{1t}^j + \sum_{k=2}^{3} (\phi_{jk}^3 f_t^k) f_1^j \right], \tag{73}$$

$$\frac{\partial^2 F}{\partial t^2} = \phi_{tt}^3 + \sum_{j=2}^{3} \left[2\phi_{jt}^3 f_t^j + \phi_j^3 f_{tt}^j + \sum_{k=2}^{3} (\phi_{jk}^3 f_t^k) f_t^j \right], \tag{74}$$

which at $(\mathbf{z}_i, t^*)$ are denoted by

$$A = \frac{\partial^2 F}{(\partial x^1)^2}\Big|_{(\mathbf{z}_i, t^*)}, \quad B = \frac{\partial^2 F}{\partial x^1 \partial t}\Big|_{(\mathbf{z}_i, t^*)}, \quad C = \frac{\partial^2 F}{\partial t^2}\Big|_{(\mathbf{z}_i, t^*)}. \tag{75}$$

Then taking notice of (67), (70), (71) and (75), the Taylor expansion of $F(x^1,t)$ in the neighborhood of the bifurcation point $(\mathbf{z}_i, t^*)$ can be expressed as

$$F(x^1,t) = \tfrac{1}{2}A(x^1 - z_i^1)^2 + B(x^1 - z_i^1)(t - t^*) + \tfrac{1}{2}C(t - t^*)^2, \tag{76}$$

which by (66) is the expression of $\phi^3(\mathbf{x},t)$ in the neighborhood of $(\mathbf{z}_i,t^*)$. The expression (76) is reasonable, which shows that at the bifurcation point $(\mathbf{z}_i,t^*)$ one of the equations (50), $\phi^3(\mathbf{x},t)=0$, is satisfied, i.e.,

$$A(x^1-z_i^1)^2+2B(x^1-z_i^1)(t-t^*)+C(t-t^*)^2=0. \tag{77}$$

Dividing (77) by $(t-t^*)^2$ and taking the limit $t\to t^*$ as well as $x^1\to z_i^1$, we get

$$A\left(\frac{dx^1}{dt}\right)^2+2B\frac{dx^1}{dt}+C=0. \tag{78}$$

In the same way we have

$$C\left(\frac{dt}{dx^1}\right)^2+2B\frac{dt}{dx^1}+A=0. \tag{79}$$

The different directions of the branch curves at the bifurcation point are determined by (78) or (79). It is easy to see that there are at most two different branches.

B. The branch process at a higher degenerated point

In Sec. IV A we have studied the case that the rank of the Jacobian matrix $[\partial\phi/\partial x]$ of Eqs. (50) is $2=3-1$. In this subsection, we consider the case that the rank of the Jacobian matrix is $1=3-2$. Let the $J_2(\boldsymbol{\phi}/x)=\partial\phi^1/\partial x^1$ and suppose that $\det J_2\neq 0$. With the same reasons as when obtaining (58), we can have the function relations

$$x^3=f^3(x^1,x^2,t). \tag{80}$$

Substituting the relations (80) into the last two equations of (50), we have the following two equations with three arguments x^1,x^2,t:

$$\begin{aligned} F_1(x^1,x^2,t)&=\phi^2(x^1,x^2,f^3(x^1,x^2,t),t)=0,\\ F_2(x^1,x^2,t)&=\phi^3(x^1,x^2,f^3(x^1,x^2,t),t)=0. \end{aligned} \tag{81}$$

Calculating the partial derivatives of the function F_1 and F_2 with respect to x^1, x^2 and t, taking notice of (80) and using six similar expressions to (70) and (71), i.e.,

$$\left.\frac{\partial F_j}{\partial x^1}\right|_{(\mathbf{z}_i,t^*)}=0,\quad \left.\frac{\partial F_j}{\partial x^2}\right|_{(\mathbf{z}_i,t^*)}=0,\quad \left.\frac{\partial F_j}{\partial t}\right|_{(\mathbf{z}_i,t^*)}=0,\quad j=1,2, \tag{82}$$

we have the following forms of Taylor expressions of F_1 and F_2 in the neighborhood of $(\mathbf{z}_i,t^*)$:

$$\begin{aligned} F_j(x^1,x^2,t)\approx{}&A_{j1}(x^1-z_i^1)^2+A_{j2}(x^1-z_i^1)(x^2-z_i^2)+A_{j3}(x^1-z_i^1)\\ &\times(t-t^*)+A_{j4}(x^2-z_i^2)^2+A_{j5}(x^2-z_i^2)(t-t^*)+A_{j6}(t-t^*)^2=0,\quad j=1,2. \end{aligned} \tag{83}$$

In the case of $A_{j1}\neq 0, A_{j4}\neq 0$, dividing (83) by $(t-t^*)^2$ and taking the limit $t\to t^*$, we obtain two quadratic equations of dx^1/dt and dx^2/dt:

$$A_{j1}\left(\frac{dx^1}{dt}\right)^2+A_{j2}\frac{dx^1}{dt}\frac{dx^2}{dt}+A_{j3}\frac{dx^1}{dt}+A_{j4}\left(\frac{dx^2}{dt}\right)^2+A_{j5}\frac{dx^2}{dt}+A_{j6}=0,\quad j=1,2. \tag{84}$$

Eliminating the variable dx^1/dt, we obtain an equation of dx^2/dt in the form of a determinant,

$$\begin{vmatrix} A_{11} & A_{12}v+A_{23} & A_{14}v^2+A_{15}v+A_{16} & 0 \\ 0 & A_{11} & A_{12}v+A_{13} & A_{14}v^2+A_{15}v+A_{16} \\ A_{21} & A_{22}v+A_{23} & A_{24}v^2+A_{25}v+A_{26} & 0 \\ 0 & A_{21} & A_{22}v+A_{23} & A_{24}v^2+A_{25}v+A_{26} \end{vmatrix} = 0, \tag{85}$$

where $v=dx^2/dt$, that is a fourth-order equation of dx^2/dt:

$$a_0\left(\frac{dx^2}{dt}\right)^4+a_1\left(\frac{dx^2}{dt}\right)^3+a_2\left(\frac{dx^2}{dt}\right)^2+a_3\left(\frac{dx^2}{dt}\right)+a_4=0. \tag{86}$$

Therefore, we get different directions at the bifurcation point corresponding to different branch curves. The number of different branch curves is at most four. At the end of this section, we conclude that in our theory of topological density there exists the crucial case of branch process. This means that a normal point-like topological charge, which moves through the bifurcation point, may split into several point-like topological charges moving along different branch curves. Since the topological density is invariant, the total charge of the splitting topological particles must be precisely equal to the topological charge of the original particle.

Since the Chern density is identically conserved, the sum of the topological charges of these split topological densities must be equal to that of the original current at the bifurcation point. We suppose that there exist l different branches. Then the topological density of Chern class $\rho(M)$ changes in the following form:

$$\rho(M)=\sum_{i=1}^{k}\rho_i=\sum_{i=1}^{k}\sum_{j=1}^{l}\rho_{ij},$$

where

$$\rho_i=g_i\delta^4(x-z_i), \quad \rho_{ij}=g_{ij}\delta^4(x-z_{ij}), \quad 1\leqslant j\leqslant l. \tag{87}$$

With the same reason, the sum of the topological charges at the bifurcation points will have the following form:

$$g_i=\sum_{i=1}^{l}g_{ij}.$$

for fixed i.

V. CONCLUSION

We have explicitly constructed the gauge potential decomposition theory of SU(2) gauge theory in terms of the sphere bundle on a four-dimensional manifold. An important observation of the application of this theory is that the SU(2) Chern density takes the form of a general function. We also find that the Chern density has the bifurcation process. It is shown that the topological charges are split under this case, and the total charges are conserved. Those features are very important in discussing the topological problems on a four-manifold. Since many problems, not only in theoretical physics but also in differential geometry, are associated with the SU(2) gauge theory, the theory of SU(2) gauge potential decomposition, the inner structure of the SU(2) Chern density will provide important and powerful methods in those fields.

(Received 21 November 1997; accepted for publication 5 March 1998)

We extend the work of Foda *et al.* and propose an elliptic quantum algebra $A_{q,p}(\widehat{sl_n})$. Similar to the case of $A_{q,p}(\widehat{sl_2})$, our presentation of the algebra is based on the relation $RLL=LLR^*$, where R and R^* are Z_n symmetric R matrices with the elliptic moduli chosen differently, and a scalar factor is also involved. With the help of the results obtained by Asai *et al.*, we realize type I and type II vertex operators in terms of bosonic free fields for the Z_n symmetric Belavin model. We also give a bosonization for the elliptic quantum algebra $A_{q,p}(\widehat{sl_n})$ at level one.

I. INTRODUCTION

The investigation of the symmetries in quantum integrable models has been attracting a great deal of interest. Recently, the quantum affine algebra $U_q(\widehat{sl_2})$ has been studied extensively and applied successfully to the XXZ model in the antiferromagnetic regime: see Ref. 1 and the references therein. The R matrix associated with the XXZ model is the six-vertex model which is a trigonometric vertex model. Using the approach of free boson realization of the vertex operators, Jimbo *et al.* obtained integral formulas for the correlation functions and the form factors for the XXZ model.

It is well known that we can obtain the six-vertex model from the Baxter's eight-vertex model[2] by taking a special limit. And we know that the XYZ model, the spin chain equivalent of the eight-vertex model, is a generalization of the XXZ model. Foda *et al.*[3] proposed an elliptic extention of the quantum affine algebra $A_{q,p}(\widehat{sl_2})$ as an algebra of symmetries for the eight-vertex model. The Kyoto group also conjecture that type I and type II vertex operators for the elliptic algebra $A_{q,p}(\widehat{sl_2})$ can be found. So, it is an open problem to give a bosonic free fields realization for vertex operators of the elliptic algebra $A_{q,p}(\widehat{sl_2})$. It is also an interesting problem to extend the elliptic algebra $A_{q,p}(\widehat{sl_2})$ to a more general case $A_{q,p}(\widehat{sl_n})$ which would play the role of the symmetry algebra in the Z_n Belavin model. In this paper, we will study these problems.

It is now believed that the vertex operator approach[1,4] and the method of bosonization are very powerful to study correlation functions of solvable lattice models. It is first formulated for vertex models, and then extended to incorporate face models.[5,6] Lukyanov and Pugai[6] successfully give a bosonic realization of the vertex operators for the ABF model.[7] This result is developed to a more general case by Asai *et al.*[8] They give a bosonization of vertex operators for the $A^{(1)}_{n-1}$ face model,[9] the ABF model being the case $n=2$ with a restricted condition. We know there is a face–vertex correspondence between the $A^{(1)}_{n-1}$ face model and the Z_n Belavin[10] vertex model. When $n=2$, the Z_n symmetric Belavin model reduces to the Baxter's eight-vertex model. In our former work,[11] we used the intertwiners of face–vertex correspondence, and obtained type I vertex operators for the Z_n Belavin vertex model with the help of the results obtained by Asai *et al.*[8] In the present paper, continuing to extend the results in Ref. 8 and our former work in Ref. 11, we give a bosonization of type II vertex operators for the Z_n Belavin model. Using the Miki's

construction,[12] we obtain a bosonic realization for the elliptic algebra $A_{q,p}(\widehat{sl_n})$ (which is first proposed in this paper) at level one. As a special case of $n=2$, this will give the bosonization for $A_{q,p}(\widehat{sl_2})$ algebra at level one.

The paper is organized as follows. In Sec. II we introduce the Z_n symmetric Belavin vertex model and give a definition for the elliptic algebra $A_{q,p}(\widehat{sl_n})$. In Sec. III we define the vertex operators for the algebra $A_{q,p}(\widehat{sl_n})$ at level one. Section IV is devoted to the main results of this paper. Extending the work of Asai *et al.*, we introduce another set of boson oscillators and obtain a bosonization of type II vertex operators for the $A_{n-1}^{(1)}$ face model. Using face–vertex correspondence, we give a free boson realization of type I and type II vertex operators for the Z_n Belavin model. This gives a bosonization of the elliptic algebra $A_{q,p}(\widehat{sl_n})$ at level one. Finally, we give a summary and discussions in Sec. V. The Appendix contains some detailed calculations.

II. THE MODEL AND THE ELLIPTIC ALGEBRA $A_{q,p}(\widehat{sl_n})$

We first introduce some notations. Let $n\in Z^+$ and $n\geqslant 2$, $w\in C$ and $\mathrm{Im}\, w\geqslant 0$, $r\geqslant n+2$ and take real value, $\tau\in C$ with $\mathrm{Im}\,\tau>0$.

Define matrix g,h,I_α with elements taking the values

$$g_{ij}=\omega^i\delta_{ij},\quad \omega=\exp\left\{\frac{2\pi i}{n}\right\},$$

$$h_{jk}=\delta_{j+1,k},\quad I_\alpha=I_{(\alpha_1,\alpha_2)}=g^{\alpha_2}h^{\alpha_1}.$$

The elliptic functions are defined as

$$\theta\begin{bmatrix}a\\ b\end{bmatrix}(z,\tau)=\sum_{m\in Z}\exp\{\pi i[(m+a)^2\tau+2(m+a)(z+b)]\},$$

$$\sigma_\alpha(z,\tau)=\sigma_{(\alpha_1,\alpha_2)}(z,\tau)=\theta\begin{bmatrix}\frac{1}{2}+\frac{\alpha_1}{n}\\ \frac{1}{2}+\frac{\alpha_2}{n}\end{bmatrix}(z,\tau).$$

Redefine $z\equiv vw$, $\tau\equiv rw$. The R matrix of the Z_n symmetric R matrix can be defined as

$$\bar{R}(vw,rw)=\frac{\sigma_0(w,rw)}{\sigma_0(vw+w,rw)}\sum_\alpha W_\alpha(vw,rw)I_\alpha\otimes I_\alpha^{-1}, \tag{1}$$

where

$$W_\alpha(wv,rw)=\frac{\sigma_\alpha\left(vw+\frac{w}{n},rw\right)}{n\sigma_\alpha\left(\frac{w}{n},rw\right)}. \tag{2}$$

It is necessary to introduce other notations,

$$R(v)\equiv R(vw,rw)=x^{2v(1/n-1)}\frac{g_1(v)}{g_1(-v)}\bar{R}(vw,rw), \tag{3}$$

where $x=e^{\pi iw}$ and

$$g_1(v)=\frac{\{x^{2v}x^2\}\{x^{2n+2r-2}x^{2v}\}}{\{x^{2n}x^{2v}\}\{x^{2r}x^{2v}\}}, \tag{4}$$

where $\{z\}=(z;x^{2r},x^{2n})$ and $(z;p_1,\ldots,p_n)\equiv\Pi_{\{n_i\}=0}^{\infty}(1-zp_1^{n_1}\cdots p_m^{n_m})$.

The R matrix $R(v,rw)$ has the following properties:

$$\text{Yang–Baxter equation: } R_{12}(v_1-v_2)R_{13}(v_1-v_3)R_{23}(v_2-v_3)$$
$$=R_{23}(v_2-v_3)R_{13}(v_1-v_3)R_{12}(v_1-v_2);$$
$$\text{unitary: } R_{12}(v)R_{21}(-v)=1; \tag{5}$$
$$\text{cross-unitarity: } \sum_{jl} R_{kj}^{li}(v)R_{i'l}^{jk'}(-v-n)=\delta_{ii'}\delta_{kk'}.$$

The parameters v,w,r in our parametrization for the Z_n symmetric R matrix in Eq. (3) are related to that of Foda *et al.*[8] as follows: $q=e^{i\pi w}=x$, $\xi=x^v$, $p=x^{2r}$.

Define

$$R^*(v)=\Delta_n^2(v)R(vw,(r-c)w),$$
$$\Delta_n(v)=-x[2(n-2)/n]v\,\frac{(x^{2n-2+2v};x^{2n})(x^{2-2v};x^{2n})}{(x^{2+2v};x^{2n})(x^{2n-2-2v};x^{2n})}. \tag{6}$$

Definition: The algebra $A_{q,p}(\widehat{gl_n})$ is generated by $L_{ij}(v)$, satisfying the relation

$$R^+(v_1-v_2)L_1(v_1)L_2(v_2)=L_2(v_2)L_1(v_1)R^{*+}(v_1-v_2), \tag{7}$$

where

$$R^+(v)=R(v)\tau^{-1}(-v+\tfrac{1}{2}),\quad R^{*+}(v)=R^*(v)\tau^{-1}(-v+\tfrac{1}{2}),$$
$$\tau(v)=x^{[2(1-n)/n]v}\,\frac{(x^{1+2v};x^{2n})(x^{2n-1-2v};x^{2n})}{(x^{2n-1+2v};x^{2n})(x^{1-2v};x^{2n})}. \tag{8}$$

By a standard argument based on the antisymmetric fusion for the Z_n symmetry R matrix,[10] we find that the following quantum determinant belongs to the center of $A_{q,p}(\widehat{gl_n})$:

$$q-\det L(v)=\sum_{\sigma\in S_n}\ \operatorname{sign}(\sigma)L_{1,\sigma(1)}(v-n)L_{2,\sigma(2)}(v-n+1)\cdots L_{n,\sigma(n)}(v-1). \tag{9}$$

Therefore, we can impose the further relation $q-\det L(v)=q^{c/2}$ and define the quotient algebra

$$A_{q,p}(\widehat{sl_n})=A_{q,p}(\widehat{gl_n})/(q-\det L(v)-q^{c/2}). \tag{10}$$

Remark: For the case $n=2$, we have $\Delta_n(v)=-1$. The algebra $A_{q,p}(\widehat{sl_n})$ reduces to the original elliptic algebra $A_{q,p}(\widehat{sl_2})$ proposed by Foda et al.[3]

III. BOSONIZATION OF THE ALGEBRA $A_{q,p}(\widehat{sl_n})$ AT LEVEL ONE

In the following, we will mainly restrict our attention to the level one case, and we have $c=1$. The $R^*(v)$ now becomes

$$R^*(v)=\Delta_n^2(v)R(v,(r-1)w). \tag{11}$$

The algebra relation remains as

$$R^+(v_1-v_2)L_1(v_1)L_2(v_2)=L_2(v_2)L_1(v_1)R^{*+}(v_1-v_2). \tag{12}$$

We first introduce a type I vertex operator corresponding to the half-column transfer matrix of the Z_n Belavin model,[5,11,13] and a type II vertex operator of the Z_n Belavin model which is

expected to create the eigenstates of the transfer matrix. We denote the two types of vertex operators as

(i) the vertex operator of type I: $\Phi_i(v)$;

(ii) the vertex operator of type II: $\Psi_i^*(v)$.

These Vertex operators satisfy the Faddeev–Zamolodchikov (ZF) algebra,

$$\Phi_j(v_2)\Phi_i(v_1)=\sum_{lk} R_{lk}^{ij}(v_1-v_2)\Phi_l(v_1)\Phi_k(v_2), \tag{13}$$

$$\Psi_i^*(v_1)\Psi_j^*(v_2)=\sum_{lk} \Psi_k^*(v_2)\Psi_l^*(v_1)R_{ij}^{*lk}(v_1-v_2)\Delta_n^{-1}(v_1-v_2), \tag{14}$$

$$\Phi_i(v_1)\Psi_j^*(v_2)=\tau^{-1}(v_1-v_2)\Psi_j^*(v_2)\Phi_i(v_1). \tag{15}$$

In the next section, we will give a q-boson free field realization of the type I and type II vertex operators listed above.

Introduce Miki's construction,[12]

$$L_{ij}(v)=\Phi_i(v)\Psi_j^*(v-\tfrac{1}{2}). \tag{16}$$

Using relations of the ZF algebra Eq. (13)–Eq. (15), one can prove that the operator matrix L constructed above satisfies the defining relation of the elliptic quantum algebra, Eq. (7). Here the relation $\tau(v+\frac{1}{2})/\tau(-v+\frac{1}{2})=\Delta_n^{-1}(v)$ has been used.

Thus, if the bosonization of the type I and type II vertex operators at level one satisfying Eq. (13)–Eq. (15) can be found, we can find a free boson realization of the elliptic algebra $A_{q,p}(\widehat{sl_n})$ at level one. Moreover, the elliptic algebra $A_{q,p}(\widehat{sl_n})$ and its vertex operators $\Phi_i(v),\Phi_j^*(v)$ at level one have the following relations, which is the generalized relations of Frenkel *et al.* in studying the q-affine algebra:[14]

$$\Phi_2(v_2)L_1(v_1)=R_{12}^{+}(v_1-v_2)L_1(v_1)\Phi_2(v_2),$$

$$L_1(v_1)\Psi_2^*(v_2-\tfrac{1}{2})=\Psi_2^*(v_2-\tfrac{1}{2})L_1(v_1)R_{12}^{*+}(v_1-v_2).$$

IV. BOSONIZATION FOR VERTEX OPERATORS

In this section, we will use a face–vertex correspondence relation to obtain a bosonization of vertex operators for the Z_n Belavin model satisfying Eq. (13)–Eq. (15).

A. Bosonization for the $A_{n-1}^{(1)}$ face model

We first give a brief review of the bosonization of type I vertex operators for the $A_{n-1}^{(1)}$ face model,[8] and then similarly construct the bosonization of type II vertex operators for the $A_{n-1}^{(1)}$ face model.

Let $\epsilon_\mu(1\leqslant\mu\leqslant n)$ be the orthonormal bases in R^n, which are supplied with the inner product $\langle\epsilon_\mu,\epsilon_\nu\rangle=\delta_{\mu\nu}$. Set

$$\overline{\epsilon}_\mu=\epsilon_\mu-\epsilon,\quad \epsilon=\frac{1}{n}\sum_{\mu=1}^{n}\epsilon_\mu.$$

The type $A_{n-1}^{(1)}$ weight Lattice is the linear span of the $\overline{\epsilon}_\mu$: $P=\Sigma_{\mu=1}^{n}Z\overline{\epsilon}_\mu$. Let ω_μ $(1\leqslant\mu\leqslant n-1)$ be the fundamental weights and $\alpha_\mu(1\leqslant\mu\leqslant n-1)$ be the simple roots: $\omega_\mu=\Sigma_{\nu=1}^{\mu}\overline{\epsilon}_\nu$, $\alpha_\mu=\epsilon_\mu-\epsilon_{\mu+1}$.

An ordered pair $(b,a)\in P^2$ is called admissible if and only if there exists μ $(1\leqslant\mu\leqslant n)$ such that $b-a=\overline{\epsilon}_\mu$. An ordered set of four weights $\binom{cd}{ba}\in P^4$ is called an admissible configuration around a face if and only if the pairs (b,a), (c,b), (d,a), and (c,d) are admissible. To each admissible configuration around a face, one can associate the Boltzmann weight for it.[2,7,9]

We introduce the zero mode operators $q_\mu,p_\mu(1\leqslant\mu\leqslant n)$, which satisfy

$$[p_\mu, iq_\nu] = \langle \epsilon_\mu, \epsilon_\nu \rangle = \delta_{\mu\nu}.$$

Set

$$Q_{\overline{\epsilon}_\mu} = q_\mu - \frac{1}{n}\sum_{l=1}^{n} q_l, \quad P_{\overline{\epsilon}_\mu} = p_\mu - \frac{1}{n}\sum_{l=1}^{n} p_l + \frac{1}{\sqrt{r(r-1)}} w_\mu,$$

where $\{w_j\}$ are generic complex numbers, which ensures that the intertwiners $\tilde{\varphi}(v)^{(k)}_{\mu,a}$ and $\overline{\varphi}(v)^{(k)}_{a,\mu}$ (see the following section) could exist. We can also reconstruct the zero mode operators P_α, Q_α (Ref. 8) indexed by $\alpha \in P$, which are Z linear in α and satisfy

$$[P_\alpha, iQ_\beta] = \langle \alpha, \beta \rangle \quad (\alpha, \beta \in P).$$

Now we consider the oscillator part. Define free bosonic oscillators β^j_m $(1 \leqslant j \leqslant n, m \in Z/\{0\})$ satisfying the relations

$$[\beta^j_m, \beta^k_n] = \begin{cases} m \dfrac{[(n-1)m]_x[(r-1)m]_x}{[nm]_x[rm]_x} \delta_{n+m,0}, & j=k, \\ -mx^{sign(j-k)nm} \dfrac{[m]_x[(r-1)m]_x}{[nm]_x[rm]_x} \delta_{n+m,0}, & j \neq k. \end{cases} \tag{17}$$

Here we have used the standard notation $[a]_x = (x^a - x^{-a})/(x - x^{-1})$. The bosonic oscillators should satisfy the constraint $\Sigma_{j=1}^{n} x^{-2jm}\beta^j_m = 0$. One can check that the above constraint is compatible with the commutation relations, Eq. (18). Similarly, we can also introduce another set of bosonic oscillators β'^j_m $(1 \leqslant j \leqslant n,\ m \in Z/\{0\})$ which will be used to construct the type II vertex operators and are related to the original bosons by $\beta'^j_m = \{[rm]_x/[(r-1)m]_x\}\beta^j_m$. Using β^j_m, β'^j_m, we define the operators,

$$S^j_m = (\beta^j_m - \beta^{j+1}_m)x^{-jm}, \quad \Omega^j_m = \sum_{k=1}^{j} x^{(j-2k+1)m}\beta^k_m, \tag{18}$$

$$S'^j_m = (\beta'^j_m - \beta'^{j+1}_m)x^{-jm}, \quad \Omega'^j_m = \sum_{k=1}^{j} x^{(j-2k+1)m}\beta'^k_m. \tag{19}$$

Define the bosonic Fock spaces $\mathscr{F}_{l,k} = c[\{\beta^j_{-1}, \beta^j_{-2}, \ldots\}_{1 \leqslant j \leqslant n}]|l,k\rangle$ and the vacuum vector,

$$|l,k\rangle = e^{i\sqrt{r/(r-1)}Q_l - i\sqrt{(r-1)/r}Q_k}|0,0\rangle. \tag{20}$$

In the following part of this paper, we will construct the bosonic realization of the vertex operators defined in Eq. (13)–Eq. (15) on the space $\Sigma_{l,k\in P} \oplus F_{l,k}$. For the generic r (e.g., an irrational number), we can introduce two types of independent operators $\hat{K}$ and $\hat{L}$ with $\hat{K} = \Sigma_\mu \hat{k}_\mu \overline{\epsilon}_\mu$, $\hat{L} = \Sigma_\mu \hat{l}_\mu \overline{\epsilon}_\mu$, which act on the space $\Sigma_{l,k\in P} \oplus F_{l,k}$ as

$$\hat{k}_\mu F_{l,k} = (w_\mu + k_\mu)F_{l,k}, \quad \text{if } k = \sum_\mu k_\mu \overline{\epsilon}_\mu,$$

$$\hat{l}_\mu F_{l,k} = (w_\mu + l_\mu)F_{l,k}, \quad \text{if } l = \sum_\mu l_\mu \overline{\epsilon}_\mu.$$

Let us introduce some basic operators acting on the space $\Sigma_{l,k\in P} \oplus F_{l,k}$:

$$\eta_j(v) = e^{-i\sqrt{(r-1)/r}(Q_{\omega_j} - i2v \ln x P_{\omega_j})} : e^{-\Sigma_{m\neq 0}(l/m)\Omega^j_m x^{-2vm}} :,$$

$$\xi_j(v) = e^{i\sqrt{(r-1)/r}(Q_{\alpha_j} - i2v \ln x P_{\alpha_j})} : e^{\Sigma_{m\neq 0}(1/m)S^j_m x^{-2vm}} :, \tag{21}$$

$$\eta_j'(v)=e^{i\sqrt{r/(r-1)}(Q_{\omega_j}-i2v\ \ln xP_{w_j})}{:}e^{\Sigma_{m\neq 0}(1/m)\Omega_m'^j x^{-2vm}}{:},$$

$$\xi_j'(v)=e^{-i\sqrt{r/(r-1)}(Q_{\alpha_j}-i2v\ \ln xP_{\alpha_j})}{:}e^{-\Sigma_{m\neq 0}(1/m)S_m'^j x^{-2vm}}{:}.$$

We can obtain the normal order relations which will be presented in the Appendix. From those results, we have the following commutation relations:

$$\xi_j(v_1)\xi_{j+1}(v_2)=-\frac{[v_1-v_2+\frac{1}{2}]}{[v_1-v_2-\frac{1}{2}]}\,\xi_{j+1}(v_2)\xi_j(v_1),$$

$$\xi_j(v_1)\,\eta_j(v_2)=-\frac{[v_1-v_2+\frac{1}{2}]}{[v_1-v_2-\frac{1}{2}]}\,\eta_j(v_2)\xi_j(v_1), \tag{22}$$

$$\xi_j(v_1)\xi_j(v_2)=\frac{[v_1-v_2-1]}{[v_1-v_2+1]}\,\xi_j(v_2)\xi_j(v_1),$$

where

$$[v]=x^{v^2/r-v}(x^{2v};x^{2r})(x^{2r}x^{-2v};x^{2r})(x^{2r};x^{2r})=\sigma\left(\frac{v}{r},-\frac{1}{rw}\right)\times\text{const.} \tag{23}$$

The bosonization of the type I vertex operator in the $A_{n-1}^{(1)}$ face model was given by Asai *et al.*,[8]

$$\phi_\mu(v)=\oint\prod_{j=1}^{\mu-1}\frac{dx^{2v_j}}{2\pi i x^{2v_j}}\,\eta_1(v)\xi_1(v_1)\cdots\xi_{\mu-1}(v_{\mu-1})\prod_{j=1}^{\mu-1}f(v_j-v_{j-1},\pi_{j\mu}), \tag{24}$$

$$\pi_\mu=\sqrt{r(r-1)}P_{\bar{\epsilon}_\mu},\quad \pi_{\mu\nu}=\pi_\mu-\pi_\nu,\quad v_0=v,\quad f(v,w)=\frac{[v+\frac{1}{2}-w]}{[v-\frac{1}{2}]}. \tag{25}$$

The integration contours are simple closed curves around the origin, satisfying

$$x|x^{2v_{j-1}}|<|x^{2v_j}|<x^{-1}|x^{2v_{j-1}}|.$$

We also have another set of relations,

$$\xi_j'(v_1)\xi_{j+1}'(v_2)=-\frac{[v_1-v_2-\frac{1}{2}]'}{[v_1-v_2+\frac{1}{2}]'}\,\xi_{j+1}'(v_2)\xi_j'(v_1),$$

$$\xi_j'(v_1)\,\eta_j'(v_2)=-\frac{[v_1-v_2-\frac{1}{2}]'}{[v_1-v_2+\frac{1}{2}]'}\,\eta_j'(v_2)\xi_j'(v_1), \tag{26}$$

$$\xi_j'(v_1)\xi_j(v_2)=\frac{[v_1-v_2+1]'}{[v_1-v_2-1]'}\,\xi_j'(v_2)\xi_j'(v_1),$$

where

$$[v]'=x^{v^2/(r-1)-v}(x^{2v};x^{2r-2})(x^{2r-2}x^{-2v};x^{2r-2})(x^{2r-2};x^{2r-2})=\sigma\left(\frac{v}{r-1},-\frac{1}{(r-1)w}\right)\times\text{const}'. \tag{27}$$

Construct type II vertex operators in the $A_{n-1}^{(1)}$ face model as

$$\phi'_\mu(v)=\oint\prod_{j=1}^{\mu-1}\frac{dx^{2v_j}}{2\pi i x^{2v_j}}\,\eta'_1(v)\xi'_1(v_1)\cdots\xi'_{\mu-1}(v_{\mu-1})\prod_{j=1}^{\mu-1}f'(v_j-v_{j-1},\pi_{j\mu}),\tag{28}$$

$$f'(v,w)=\frac{[v-\frac{1}{2}+w]'}{[v+\frac{1}{2}]'}.\tag{29}$$

Here the integration contours are simple closed curves around the origin satisfying

$$x|x^{2v_{j-1}}|<|x^{2v_j}|<x^{-1}|x^{2v_{j-1}}|.$$

Define the face Boltzmann weights for admissible configurations around a face,

$$\overline{W}\left(\begin{matrix}a+2\overline{\epsilon}_\mu & a+\overline{\epsilon}_\mu\\ a+\overline{\epsilon}_\mu & a\end{matrix}\middle|v\right)\equiv\overline{W}(a|v)^{\mu\mu}_{\mu\mu}=1,$$

$$\overline{W}\left(\begin{matrix}a+\overline{\epsilon}_\mu+\overline{\epsilon}_\nu & a+\overline{\epsilon}_\nu\\ a+\overline{\epsilon}_\nu & a\end{matrix}\middle|v\right)\equiv\overline{W}(a|v)^{\mu\nu}_{\nu\mu}=\frac{[v+a_{\mu\nu}][1]}{[v+1][a_{\mu\nu}]},\quad \mu\neq\nu,\tag{30}$$

$$\overline{W}\left(\begin{matrix}a+\overline{\epsilon}_\mu+\overline{\epsilon}_\nu & a+\overline{\epsilon}_\mu\\ a+\epsilon_\nu & a\end{matrix}\middle|v\right)\equiv\overline{W}(a|v)^{\mu\nu}_{\mu\nu}=\frac{[v][a_{\mu\nu}-1]}{[v+1][a_{\mu\nu}]},\quad \mu\neq\nu.$$

We also define another Boltzmann weight,

$$\overline{W}'\left(\begin{matrix}a+2\overline{\epsilon}_\mu & a+\overline{\epsilon}_\mu\\ a+\overline{\epsilon}_\mu & a\end{matrix}\middle|v\right)\equiv\overline{W}'(a|v)^{\mu\mu}_{\mu\mu}=1,$$

$$\overline{W}'\left(\begin{matrix}a+\overline{\epsilon}_\mu+\overline{\epsilon}_\nu & a+\overline{\epsilon}_\nu\\ a+\overline{\epsilon}_\nu & a\end{matrix}\middle|v\right)\equiv\overline{W}'(a|v)^{\mu\nu}_{\nu\mu}=\frac{[v+a_{\mu\nu}]'[1]'}{[v+1]'[a_{\mu\nu}]'},\quad \mu\neq\nu,\tag{31}$$

$$\overline{W}'\left(\begin{matrix}a+\overline{\epsilon}_\mu+\overline{\epsilon}_\nu & a+\overline{\epsilon}_\mu\\ a+\epsilon_\nu & a\end{matrix}\middle|v\right)\equiv\overline{W}'(a|v)^{\mu\nu}_{\mu\nu}=\frac{[v]'[a_{\mu\nu}-1]'}{[v+1]'[a_{\mu\nu}]'},\quad \mu\neq\nu.$$

Following the results obtained by Asai *et al.* in Ref. 8, we have

$$\phi_\mu(v_2)\phi_\nu(v_1)=r_1(v_2-v_1)\sum_{\mu',\nu'}\phi_{\mu'}(v_1)\phi_{\nu'}(v_2)\overline{W}(\hat{\pi}/v_1-v_2)^{\mu\nu}_{\nu'\mu'}.\tag{32}$$

Using the method introduced by Asai *et al.* in Ref. 8, and noting that

$$f'(v,\pi_{j\mu}-r)=\frac{[v-\frac{1}{2}+\pi_{j\mu}-r]'}{[v+\frac{1}{2}]'}=-\frac{[v-\frac{1}{2}+\pi_{j\mu}-1]'}{[v+\frac{1}{2}]'}$$

$$=-\frac{[-v+\frac{1}{2}-\pi_{j\mu}+1]'}{[-v-\frac{1}{2}]'}=-f(-v,\pi_{j\mu}-1)|_{r\to r-1},$$

$$f'(v,\pi_{\mu\nu}+r)=-f(-v,\pi_{\mu\nu}+1)|_{r\to r-1},$$

we can derive the following commutation relations:

$$\phi'_\mu(v_1)\phi'_\nu(v_2)=r'_1(v_1-v_2)\sum_{\mu',\nu'}\phi'_{\mu'}(v_2)\phi'_{\nu'}(v_1)\overline{W}'(\hat{\pi}|v_1-v_2)^{\mu\nu}_{\nu'\mu'},\tag{33}$$

$$\phi_\mu(v_1)\phi'_\nu(v_2)=\tau(v_1-v_2)\phi'_\nu(v_2)\phi_\mu(v_1),\tag{34}$$

where

$$r_1(v)=x^{2(r-1)(n-1)v/nr}\frac{g_1(-v)}{g_1(v)},\quad r_1'(v)=x^{2r(n-1)v/n(r-1)}\frac{g_1'(-v)}{g_1'(v)}.$$

One can see that ϕ_μ,ϕ_μ' are the intertwiners between the Fock space,

$$\phi_\mu(v):\ F_{l,k}\to F_{l,k+\bar{\epsilon}_\mu},$$

$$\phi_\mu'(v):\ F_{l,k}\to F_{l+\bar{\epsilon}_\mu,k}.$$

B. Face–vertex correspondence and modular transformation

It is convenient to introduce some notations. Define

$$\bar{R}^{(1)}(v)=\frac{\sigma_0\left(\frac{1}{r},-\frac{1}{rw}\right)}{\sigma_0\left(\frac{v+1}{r},-\frac{1}{rw}\right)}\sum_\alpha\frac{\sigma_\alpha\left(\frac{v}{r}+\frac{1}{nr},-\frac{1}{rw}\right)}{n\sigma_\alpha\left(\frac{1}{nr},-\frac{1}{rw}\right)}I_\alpha\otimes I_\alpha^{-1},$$

$$\bar{R}'^{(1)}(v)=\frac{\sigma_0\left(\frac{1}{r-1},-\frac{1}{(r-1)w}\right)}{\sigma_0\left(\frac{v+1}{r-1},-\frac{1}{(r-1)w}\right)}\sum_\alpha\frac{\sigma_\alpha\left(\frac{v}{r-1}+\frac{1}{n(r-1)},-\frac{1}{(r-1)w}\right)}{n\sigma_\alpha\left(\frac{1}{n(r-1)},-\frac{1}{(r-1)w}\right)}I_\alpha\otimes I_\alpha^{-1},$$

$$\varphi_{\mu,\hat{K}}^{(k)}(v)=\theta^{(k)}\left(\frac{v+n\langle\hat{K},\epsilon_\mu\rangle}{r}+\frac{(n-1)}{r},-\frac{1}{rw}\right),\tag{35}$$

$$\varphi_{\hat{L},\mu}'^{(k)}(v)=\theta^{(k)}\left(\frac{v+n\langle\hat{L},\epsilon_\mu\rangle}{r-1}+P_0,-\frac{1}{(r-1)w}\right),$$

$$\theta^{(k)}(z,\tau)=\theta\begin{bmatrix}-\frac{k}{n}\\ 0\end{bmatrix}(z,n\tau).$$

Although we choose the different function $\theta^{(k)}(v)$ from the ordinary one,[15] the face–vertex correspondence relation is still survived,

$$\sum_{k,l}\bar{R}^{(1)}(v_1-v_2)_{ij}^{kl}\varphi_{\nu,\hat{K}+\bar{\epsilon}_\mu}^{(k)}(v_1)\varphi_{\mu,\hat{K}}^{(l)}(v_2)=\sum_{\mu',\nu'}\bar{W}(\hat{K}|v_1-v_2)_{\nu'\mu'}^{\nu\mu}\varphi_{\nu',\hat{K}}^{(i)}(v_1)\varphi_{\mu',\hat{K}+\bar{\epsilon}_\nu}^{(j)}(v_2),$$

$$\sum_{k,l}\bar{R}'^{(1)}(v_1-v_2)_{ij}^{kl}\varphi_{\hat{L},\mu}'^{(k)}(v_1)\varphi_{\hat{L}-\bar{\epsilon}_\mu,\nu}'^{(l)}(v_2)=\sum_{\mu',\nu'}\bar{W}'(\hat{L}|v_1-v_2)_{\mu'\nu'}^{\mu\nu}\varphi_{\hat{L}-\bar{\epsilon}_{\nu'},\mu'}'^{(i)}(v_1)\varphi_{\hat{L},\nu'}'^{(j)}(v_2).$$

For the generic number $\{w_j\}$, we can introduce intertwiners $\tilde{\varphi}_{\mu,\hat{K}}(v)$ and $\tilde{\varphi}_{\hat{L},\mu}'(v)$, satisfying relations[15]

$$\sum_k\tilde{\varphi}_{\mu\hat{K}}^{(k)}(v)\varphi_{\nu,\hat{K}}^{(k)}(v)=\delta_{\mu\nu},\quad\sum_k\bar{\varphi}_{\hat{L},\nu}'^{(k)}(v)\varphi_{\hat{L},\nu}'^{(k)}(v)=\delta_{\mu\nu}.$$

So it is easy to find the following face–vertex correspondence relations,

$$\sum_{k,l}\bar{R}^{(1)}(v_1-v_2)_{kl}^{ij}\tilde{\varphi}_{\mu,\hat{K}}^{(k)}(v_1)\tilde{\varphi}_{\nu,\hat{K}+\bar{\epsilon}_\mu}^{(l)}(v_2)=\sum_{\mu',\nu'}\bar{W}(\hat{K}|v_1-v_2)_{\mu\nu}^{\mu'\nu'}\tilde{\varphi}_{\mu',\hat{K}+\bar{\epsilon}_{\nu'}}^{(i)}(v_1)\tilde{\varphi}_{\nu',\hat{K}}^{(j)}(v_2),\tag{36}$$

$$\sum_{k,l} \overline{R'}^{(1)}(v_1-v_2)_{kl}^{ij}\overline{\varphi}^{\prime(k)}_{\hat{L}-\overline{\epsilon}_{\nu,\mu}}(v_1)\overline{\varphi}^{\prime(l)}_{\hat{L},\nu}(v_2)=\sum_{\mu',\nu'} \overline{W}'(\hat{L}|v_1-v_2)_{\mu\nu}^{\nu'\mu'}\overline{\varphi}^{(i)}_{\hat{L},\nu'}(v_1)\overline{\varphi}^{(j)}_{\hat{L}-\overline{\epsilon}_{\nu',\mu'}}(v_2). \tag{37}$$

Introduce the modular transformation,

$$\theta\begin{bmatrix}\frac{1}{2}+a\\ \frac{1}{2}+b\end{bmatrix}\left(\frac{z}{\tau},-\frac{1}{\tau}\right)=\theta\begin{bmatrix}\frac{1}{2}+b\\ \frac{1}{2}-a\end{bmatrix}(z,\tau)\exp\ \pi i\left\{\frac{z^2}{\tau}+a-b+2ab\right\}\times\text{const}, \tag{38}$$

where the const only depends on τ. Therefore, we can derive the following relations for Z_n symmetry R matrices $\overline{R}^{(1)}(v)$ and $\overline{R'}^{(1)}(v)$,

$$(M\otimes M)\overline{R}^{(1)}(v)(M^{-1}\otimes M^{-1})=x^{[2v(1-n)/nr]}P\overline{R}(vw,rw)P, \tag{39}$$

$$(M\otimes M)\overline{R'}^{(1)}(v)(M^{-1}\otimes M^{-1})=x^{2v(1-n)/n(r-1)}P\overline{R}(vw,(r-1)w)P, \tag{40}$$

where P is the permutation operator acting on the tensor space $V\otimes V$ as $P(e_i\otimes e_j)=e_j\otimes e_i$, and the matrix $(M)_{lk}=\omega^{-lk}=\exp\{(-2i\pi/n)lk\}$ which have the following properties:

$$MgM^{-1}=h^{-1},\quad MhM^{-1}=g.$$

C. Bosonization for the Z_n Belavin model

Based on the bosonization for the $A_n^{(1)}$ face model and the face–vertex correspondence, we will construct the bosonization of two types of vertex operators for the Z_n Belavin model.

First, define

$$\Phi_j(v)=\sum_{i=1}^{n}\sum_{\mu=1}^{n} M_{ji}\phi_\mu(v)\tilde{\varphi}^{(i)}_{\mu,\hat{K}}(-v), \tag{41}$$

$$\Psi_j(v)=\sum_{i=1}^{n}\sum_{\mu=1}^{n} M_{ji}\phi'_\mu(v)\overline{\varphi}^{(i)}_{-\hat{L},\mu}(-v), \tag{42}$$

which satisfy the commutation relations on the space $\Sigma_{l,k\in P}\oplus F_{l,k}$,

$$\Phi_j(v_2)\Phi_i(v_1)=\sum_{ij} R_{lk}^{ij}(v_1-v_2)\Phi_l(v_1)\Phi_k(v_2), \tag{43}$$

$$\Psi_i(v_1)\Psi_j(v_2)=\sum_{lk} \Psi_k(v_2)\Psi_l(v_1)R_{lk}^{*ij}(v_1-v_2)\Delta_n^{-1}(v_1-v_2), \tag{44}$$

$$\Phi_i(v_1)\Psi_j(v_2)=\tau(v_1-v_2)\Psi_j(v_2)\Phi_i(v_1). \tag{45}$$

Based on the antisymmetric fusion for the Z_n symmetric R matrix,[10,15] we can define

$$\Psi_j^*(v)=\Psi_{(1,\ldots,j-1,j+1,\ldots,n)}(v)$$

$$\equiv\sum_{\sigma\in S_{n-1}} \text{sign}(\sigma)\Psi_{\sigma(1)}(v+n-1)\Psi_{\sigma(2)}(v+n-2)\cdots\Psi_{\sigma(n)}(v+1),$$

and derive the following relations:

$$\Phi_j(v_2)\Phi_i(v_1)=\sum_{lk} R_{lk}^{ij}(v_1-v_2)\Phi_l(v_1)\Phi_k(v_2), \tag{46}$$

$$\Psi_i^*(v_1)\Psi_j^*(v_2)=\sum_{lk}\ \Psi_k^*(v_2)\Psi_l^*(v_1)R_{ij}^{*lk}(v_1-v_2)\Delta_n^{-1}(v_1-v_2), \tag{47}$$

$$\Phi_i(v_1)\Psi_j^*(v_2)=\tau^{-1}(v_1-v_2)\Psi_j^*(v_2)\Phi_i(v_1). \tag{48}$$

Therefore, we obtain the bosonic realization of vertex operators $\Phi_i(v)$ and $\Psi_i^*(v)$ defined in Sec. II. Moreover, we obtain the bosonic realization for $A_{q,p}(\widehat{sl_n})$ algebra at level one through Miki construction, Eq. (16). Thus, this algebra is self-consistent.

Remark: For the case $n=2$ $(\Delta_2=-1)$, the bosonic operators $\Phi_i(v)$ and $\Psi_i^*(v)$ become the type I and type II vertex operators of $A_{q,p}(\widehat{sl_2})$ at level one proposed by Foda *et al.*[3]

Although we have constructed the bosonization of $A_{q,p}(\widehat{sl_n})$ at level one, we have still not found the scaling element which is related to the corner transfer matrix.[1–3] But, for the $A_{n-1}^{(1)}$ face type model, we could construct such a scaling element.[11] Unfortunately, the intertwiners $\tilde{\varphi}_{\mu,\hat{K}}^{(i)}(v)$ and $\tilde{\varphi}_{-\hat{L},\mu}^{(i)}(v)$ break the shift properties of vertex operators $\Phi_i(v)$ and $\Psi_i^*(v)$ in the vertex type model. So, the scaling element D of the elliptic algebra $A_{q,p}(\widehat{sl_n})$ is still an open problem.

V. DISCUSSION

For $n=2$, the algebra $A_{q,p}(\widehat{sl_n})$ reduces to the original $A_{q,p}(\widehat{sl_2})$ algebra which was first proposed by Foda *et al.*[3] The quantum affine algebra $U_q(\widehat{sl_2})$ is a degeneration algebra of $A_{q,p}(\widehat{sl_2})$ with $p=0$.[3] Unfortunately, due to the nontrivial scalar factor $\Delta_n(v)$ when $2<n$, the relation between the elliptic algebra $A_{q,p}(\widehat{sl_n})$ and $U_q(\widehat{sl_n})$ is still an open problem.

Some elliptic algebras were proposed by Felder[16] and its central extension was constructed by Enriquez *et al.*[17] However, our elliptic algebra is quite different from the algebra given by Felder or by Enriquez *et al.* This is a result of the fact that the $A_{q,p}(\widehat{sl_n})$ algebra is based on the relation ''$RLL=LLR^*$'' and $R.R^*$ are chosen with the different elliptic moduli. Moreover, the Drinfeld currents of the dynamically twisted algebra of our elliptic algebra[18] is quite different from that of Felder's algebra and from that of the Enriquez *et al.* algebra.

As discussed in Ref. 8, vertex operators $\phi_\mu(v)$ in the $A_{n-1}^{(1)}$ face model was the q analog of the chiral primary fields of q-deformed W algebras.[16] However, the vertex operators $\Phi_i(v)$ and $\Psi_j^*(v)$ in the Z_n Belavin model are reconstructed by the vertex operators of the $A_{n-1}^{(1)}$ face model through the face–vertex correspondence relations. Moreover, the elliptic algebra $A_{q,p}(\widehat{sl_n})$ at level one can be constructed by Miki construction. So, there exist some relations between the algebra $A_{q,p}(\widehat{sl_n})$ and q-deformed W algebras.[19]

Besides the degenerate algebra $A_{q,0}(\widehat{sl_n})$, there exists another degenerate algebra $A_{\hbar,\eta}(\widehat{sl_n})$,[20] which can be obtained by the scaling limit $(v=u/\hbar,\ q=x,\ p=x^\eta,\ x\to 1)$ of the elliptic algebra $A_{q,p}(\widehat{sl_n})$. The resulting algebra $A_{\hbar,\eta}(\widehat{sl_n})$ is some deformation of the Yangian double $DY(\widehat{sl_n})$.[20,21] In the scaling limit case the R matrix entering the $\Psi^*\Psi^*$ commutation relation would be interpreted as the S matrix for a soliton of the affine Toda theory. (In the case of $n=2$, it is related to sine-Gordon theory.[21]) Moreover, the $\hbar$-deformed W algebra[22] would be related to the degenerate algebra $A_{\hbar,\eta}(\widehat{sl_n})$ in some way.

In our formulation, the algebra $A_{q,p}(\widehat{sl_n})$ is formulated in the framework of the ''RLL'' approach in terms of the L operator. It would be of great importance to find an analogic Drinfeld current for the algebra $A_{q,p}(\widehat{sl_n})$. For a special case $A_{q,p}(\widehat{sl_2})$ with the scaling limit, the Drinfeld currents for the algebra $A_{\hbar,\eta}(\widehat{sl_2})$ were found to be the Gauss coordinates of the L operator.[20] We expect that the same relation would exist for the elliptic algebra $A_{q,p}(\widehat{sl_n})$.

APPENDIX: SOME DETAILED CALCULATIONS

1. The normal order relation for the basic operator

We list the relations as three series: Type I,

$$\eta_1(v_1)\,\eta_1(v_2)=x^{2(r-1)(n-1)v_1/nr}g_1(v_2-v_1):\eta_1(v_1)\,\eta_1(v_2):,$$

$$\begin{aligned}
&\eta_j(v_1)\xi_j(v_2)=x^{[2(1-r)/r]v_1}s(v_2-v_1):\eta_j(v_1)\xi_j(v_2):,\\
&\xi_j(v_2)\,\eta_j(v_1)=x^{[2(1-r)/r]v_2}s(v_1-v_2):\xi_j(v_2)\,\eta_j(v_1):,\\
&\xi_j(v_1)\xi_{j+1}(v_2)=x^{[2(1-r)/r]v_1}s(v_2-v_1):\xi_j(v_1)\xi_{j+1}(v_2):,\\
&\xi_{j+1}(v_2)\xi_j(v_1)=x^{[2(1-r)/r]v_2}s(v_1-v_2):\xi_j(v_1)\xi_{j+1}(v_2):,\\
&\xi_j(v_1)\xi_j(v_2)=x^{[4(r-1)/r]v_1}t(v_2-v_1):\xi_j(v_1)\xi_j(v_2):,\\
&\xi_j(v_1)\xi_l(v_2)=:\xi_j(v_1)\xi_l(v_2): \quad \text{if } |l-j|>1,\\
&\eta_j(v_1)\xi_l(v_2)=:\eta_j(v_1)\xi_l(v_2): \quad \text{if } l\neq j;
\end{aligned} \tag{A1}$$

Type II,

$$\begin{aligned}
&\eta_1'(v_1)\,\eta_1'(v_2)=x^{2r(n-1)v_1/(r-1)n}g_1'(v_2-v_1):\eta_1'(v_1)\,\eta_1'(v_2):,\\
&\xi_j'(v_1)\,\eta_j'(v_2)=x^{[-2r/(r-1)]}s'(v_2-v_1):\xi_j'(v_1)\,\eta_j'(v_2):,\\
&\eta_j'(v_2)\xi_j'(v_1)=x^{[-2r/(r-1)]v_2}s'(v_1-v_2):\eta_j'(v_2)\xi_j'(v_1):,\\
&\xi_j'(v_1)\xi_{j+1}'(v_2)=x^{[-2r/(r-1)]v_1}s'(v_2-v_1):\xi_j'(v_1)\xi_{j+1}'(v_2):,\\
&\xi_{j+1}'(v_2)\xi_j'(v_1)=x^{[-2r/(r-1)]v_2}s'(v_1-v_2):\xi_j'(v_1)\xi_{j+1}'(v_2):,\\
&\xi_j'(v_1)\xi_j'(v_2)=x^{[4r/(r-1)]v_1}t'(v_2-v_1):\xi_j'(v_1)\xi_j'(v_2):,\\
&\xi_j'(v_1)\xi_l'(v_2)=:\xi_j'(v_1)\xi_l'(v_2): \quad \text{if } |l-j|>1,\\
&\eta_j'(v_1)\xi_l'(v_2)=:\eta_j'(v_1)\xi_l'(v_2): \quad \text{if } l\neq j;
\end{aligned} \tag{A2}$$

Type I with type II:

$$\begin{aligned}
&\eta_j(v_1)\xi_j'(v_2)=(x^{2v_1}-x^{2v_2}):\xi_j'(v_2)\,\eta_j(v_1):,\\
&\xi_j'(v_2)\,\eta_j(v_1)=(x^{2v_2}-x^{2v_1}):\eta_j(v_1)\xi_j'(v_2):,\\
&\xi_j(v_1)\,\eta_j'(v_2)=(x^{2v_1}-x^{2v_2}):\xi_j(v_1)\,\eta_j'(v_2):,\\
&\eta_j'(v_2)\xi_j(v_1)=(x^{2v_2}-x^{2v_1}):\eta_j'(v_2)\xi_j(v_1):,\\
&\eta_l(v_1)\xi_j'(v_2)=:\eta_l(v_1)\xi_j'(v_2)=:\xi_j'(v_2)\,\eta_l(v_1), \quad \text{if } l\neq j,\\
&\eta_l'(v_1)\xi_j(v_2)=:\eta_l'(v_1)\xi_j(v_2)=:\xi_j(v_2)\,\eta_l'(v_1), \quad \text{if } l\neq j,\\
&\xi_j(v_1)\xi_{j+1}'(v_2)=(x^{2v_1}-x^{2v_2}):\xi_j(v_1)\xi_{j+1}'(v_2):,\\
&\xi_{j+1}'(v_2)\xi_j(v_1)=(x^{2v_2}-x^{2v_1}):\xi_{j+1}'(v_2)\xi_j(v_1):,
\end{aligned} \tag{A3}$$

$$\xi_j(v_1)\xi_j'(v_2)=x^{-4v_1}\,\frac{1}{(1-xx^{2(v_2-v_1)})(1-x^{-1}x^{2(v_2-v_1)})}:\xi_j(v_1)\xi_j'(v_2):,$$

$$\xi_j'(v_2)\xi_j(v_1)=x^{-4v_2}\,\frac{1}{(1-xx^{2(v_1-v_2)})(1-x^{-1}x^{2(v_1-v_2)})}:\xi_j'(v_2)\xi_j(v_1):,$$

$$\xi_j(v_1)\xi'_l(v_2)=:\xi_j(v_1)\xi'_l(v_2): \quad \text{if } |j-l|>1,$$

$$\xi'_l(v_2)\xi_j(v_1)=:\xi'_l(v_2)\xi_j(v_1): \quad \text{if } |j-l|>1,$$

$$\eta_1(v_1)\eta'_j(v_2)=x^{2v_1[(j-n)/n]}\frac{(x^{2n-j}x^{2(v_2-v_1)};x^{2n})}{(x^jx^{2(v_2-v_1)};x^{2n})}:\eta_1(v_1)\eta'_j(v_2):,$$

$$\eta'_j(v_2)\eta_1(v_1)=x^{2v_2[(j-n)/n]}\frac{(x^{2n-j}x^{2(v_1-v_2)};x^{2n})}{(x^jx^{2(v_1-v_2)};x^{2n})}:\eta'_j(v_2)\eta_1(v_1):,$$

where

$$g_1(v)=\frac{\{x^2x^{2v}\}\{x^{2n+2r-2}x^{2v}\}}{\{x^{2n}x^{2v}\}\{x^{2r}x^{2v}\}}, \quad s(v)=\frac{(x^{2r-1}x^{2v};x^{2r})}{(xx^{2v};x^{2r})},$$

$$t(v)=(1-x^{2v})\frac{(x^2x^{2v};x^{2r})}{(x^{2r-2}x^{2v};x^{2r})},$$

$$g'_1(v)=\frac{\{x^{2v}\}'\{x^{2n+2r-2}x^{2v}\}'}{\{x^{2r}x^{2v}\}'\{x^{2n-2}x^{2v}\}'}, \quad \{z\}'=(z;x^{2r-2},x^{2n}),$$

$$s'(v)=\frac{(x^{2r-1}x^{2v};x^{2r-2})}{(x^{-1}x^{2v};x^{2r-2})}, \quad t'(v)=(1-x^{2v})\frac{(x^{-2}x^{2v};x^{2r-2})}{(x^{2r}x^{2v};x^{2r-2})}. \tag{A4}$$

2. Proof of the commutation relations, Eq. (43)–Eq. (45)

Notice that with the commutation relation for zero mode operators, we have

$$\phi_\nu(v_1)\tilde{\varphi}^{(k)}_{\mu,\hat{K}}(v_2)=\tilde{\varphi}^{(k)}_{\mu,\hat{K}-\bar{\epsilon}_\nu}(v_2)\phi_\nu(v_1), \quad \phi'_\nu(v_1)\tilde{\varphi}^{(k)}_{\mu,\hat{K}}(v_2)=\tilde{\varphi}^{(k)}_{\mu,\hat{K}}(v_2)\phi'_\nu(v_1),$$

$$\phi_\nu(v_1)\overline{\varphi}'^{(k)}_{\hat{L},\mu}(v_2)=\overline{\varphi}'^{(k)}_{\hat{L},\mu}(v_2)\phi_\nu(v_1), \quad \phi'_\nu(v_1)\overline{\varphi}'^{(k)}_{\hat{L},\mu}(v_2)=\overline{\varphi}'^{(k)}_{\hat{L}-\bar{\epsilon}_{\nu,\mu}}(v_2)\phi'_\nu(v_1).$$

Define

$$Z_j(v)=\sum_{\mu=1}^{n}\phi_\mu(v)\tilde{\varphi}^{(i)}_{\mu,\hat{K}}(-v), \quad Z'_j(v)=\sum_{\mu=1}^{n}\phi'_\mu(v)\overline{\varphi}'^{(i)}_{-\hat{L},\mu}(-v).$$

Notice that

$$\overline{W}(\hat{\pi}|v)^{\nu'\mu'}_{\nu\mu}|_{F_{l,k}}=\overline{W}(\hat{K}|v)^{\nu'\mu'}_{\nu\mu}|_{F_{l,k}},$$

using the exchange relation of $\phi_\mu(v)$ in Eq. (32) and the face–vertex correspondence by $\tilde{\varphi}^{(k)}_{\mu,\hat{K}}(v)$ in Eq. (36), we have

$$Z_j(v_2)Z_i(v_1)=\sum_{l,k}r_1(v_2-v_1)(P\overline{R}^{(1)}(v_1-v_2)P)^{ij}_{lk}Z_l(v_1)Z_k(v_2).$$

Notice the properties of the Z_n symmetry R matrix under the modular transformation, Eq. (39), we obtain

$$Z_j(v_2)Z_i(v_1)=\sum_{l,k}(M^{-1}\otimes M^{-1}R(v_1-v_2)M\otimes M)^{ij}_{lk}Z_l(v_1)Z_k(v_2).$$

Due to $\Phi_j(v)=\Sigma_{i=1}^{n}M_{ji}Z_i(v)$, one can obtain Eq. (43). Using the same method and noticing that

$$\overline{W}'(\hat{L}|v)^{\mu\nu}_{\nu'\mu'}=\overline{W}'(-\hat{L}|v)^{\nu\mu}_{\mu'\nu'}, \quad \frac{r_1'(v)}{r_1(-v)|_{r\to r-1}}=\Delta_n(v),$$

$$\overline{W}'(\hat{\pi}|v)^{\nu'\mu'}_{\nu\mu}|_{F_{l,k}}=\overline{W}'(\hat{L}|v)^{\nu'\mu'}_{\nu\mu}|_{F_{l,k}},$$

we can obtain Eq. (44) and Eq. (45).

Coupling constant thresholds of perturbed periodic Hamiltonians

Silvestro Fassari and Martin Klaus[a)]
Department of Mathematics, Virginia Tech, Blacksburg, Virginia 24061

(Received 6 March 1998; accepted for publication 24 March 1998)

We consider Schrödinger operators of the form $H_\lambda = -\Delta + V + \lambda W$ on $L^2(\mathbf{R}^\nu)$ ($\nu = 1$, 2, or 3) with V periodic, W short range, and λ a real non-negative parameter. Then the continuous spectrum of H_λ has the typical band structure consisting of intervals, separated by gaps. In the gaps there may be discrete eigenvalues of H_λ that are functions of the parameter λ. Let (a,b) be a gap and $E(\lambda) \in (a,b)$ an eigenvalue of H_λ. We study the asymptotic behavior of $E(\lambda)$ as λ approaches a critical value λ_0, called a coupling constant threshold, at which the eigenvalue either emerges from or is absorbed into the continuous spectrum. A typical question is the following: Assuming $E(\lambda) \downarrow a$ as $\lambda \downarrow \lambda_0$, is $E(\lambda) - a \sim c(\lambda - \lambda_0)^\alpha$ for some $\alpha > 0$ and $c \neq 0$, or is there an expansion in some other quantity? As one expects from previous work in the case $V = 0$, the answer strongly depends on ν. © *1998 American Institute of Physics.* [S0022-2488(98)03007-2]

I. INTRODUCTION

We consider the family of Schrödinger operators,

$$H_\lambda = H_0 + \lambda W, \tag{1.1}$$

on $L^2(\mathbf{R}^\nu)$, $\nu = 1,2,3$, where

$$H_0 = -\Delta + V, \tag{1.2}$$

V is periodic and W is a short-range perturbation. The parameter λ, called the coupling constant, is assumed to be real and non-negative. Specific conditions will be placed on V and W below; they will guarantee that the spectra of H_0 and H_λ exhibit the qualitative behavior described in this Introduction. One important restriction on V that we should mention at the outset is that in two and three dimensions we assume V to be of a form which allows us to solve the eigenvalue problem for H_0 by separation of variables. As is typical for Schrödinger operators with a periodic potential, the spectrum $\sigma(H_0)$ of H_0 consists of bands separated by gaps, where in one dimension the generic situation is that there are infinitely many gaps, while in two and three dimensions the number of gaps is finite. By a gap in $\sigma(H_0)$ we mean an interval (a,b) such that $a,b \in \sigma(H_0)$ and $(a,b) \cap \sigma(H_0) = \varnothing$. For $\lambda > 0$, the spectrum of H_λ is made up of a continuous part which coincides with the spectrum of H_0 and a discrete part consisting of at most a finite number of eigenvalues (counting multiplicities) in every gap. Since there are no eigenvalues when $\lambda = 0$, by general results from perturbation theory, eigenvalues of H_λ can appear in a gap only by emerging from one of its endpoints as λ is varied. Likewise, eigenvalues can disappear from a gap only by converging to an endpoint. A value λ_0 is called a coupling constant threshold (henceforth abbreviated as c.c.th.) for the family H_λ at the endpoint a, resp. b, of a gap (a,b), if there is an eigenvalue branch $E(\lambda)$ of H_λ such that $E(\lambda) \downarrow a$, resp. $E(\lambda) \uparrow b$, as $\lambda \downarrow \lambda_0$ or $\lambda \uparrow \lambda_0$. The case where $E(\lambda) \downarrow a$ as $\lambda \uparrow \lambda_0$ describes an eigenvalue that approaches the endpoint a from the right and is absorbed into the continuous spectrum at $\lambda = \lambda_0$. The case where $E(\lambda) \downarrow a$ as $\lambda \downarrow \lambda_0$ corresponds to the situation where an eigenvalue appears at a as $\lambda \uparrow \lambda_0 + \epsilon$ ($\epsilon > 0$). The third possibility is that

a)Electronic mail: klaus@math.vt.edu

 © 1998 American Institute of Physics

there is an eigenvalue converging to a both as $\lambda \uparrow \lambda_0$ and as $\lambda \downarrow \lambda_0$. In other words, an eigenvalue comes in from the right and ''turns around'' at a as λ is increased. Of course, analogous possibilities exist at the endpoint b.

The main object of this paper is to study the analytic behavior of $E(\lambda)$ when λ is near a c.c.th. λ_0. Our analysis rests on the Birman–Schwinger principle which allows us to recast the eigenvalue problem for H_λ as an eigenvalue problem for a compact integral operator. Depending on the dimension we will employ slightly different versions of the Birman–Schwinger principle. For any fixed $\lambda \geqslant 0$ we introduce the operators

$$K_{\lambda,E} = W^{1/2}(H_\lambda - E)^{-1}|W|^{1/2}, \quad W^{1/2} = |W|^{1/2}\mathrm{sgn}\ W, \tag{1.3}$$

where sgn denotes the sign function, and call them Birman–Schwinger kernels, since in the applications these operators will be represented by explicit integral kernels. In one dimension the relevant kernel will be $K_{\lambda_0,E}$, where λ_0 is a c.c.th.; in two and three dimensions it will be $K_{0,E}$. The Birman–Schwinger principle says that

$$H_\lambda \psi = E\psi, \tag{1.4}$$

with $E \in (a,b)$ and $\psi \in L^2(\mathbf{R}^\nu)$ if and only if

$$(a)\ \ (\lambda - \lambda_0)K_{\lambda_0,E} f = -f, \quad \nu = 1,$$

$$(b)\ \ \lambda K_{0,E} f = -f, \quad \nu = 2,3,$$

where f and ψ are related by $f = W^{1/2}\psi$ and $\psi = -[\lambda - \lambda_0](H_{\lambda_0} - E)^{-1}|W|^{1/2} f$ in case (a), resp. $\psi = -\lambda(H_0 - E)^{-1}|W|^{1/2} f$, in case (b). Moreover, the multiplicity of E as an eigenvalue of H_λ is the same as the (geometric) multiplicity of -1 as an eigenvalue of $(\lambda - \lambda_0)K_{\lambda_0,E}$, resp. $\lambda K_{0,E}$. Note that the Birman–Schwinger kernel is not self-adjoint unless W has constant sign, so that in general one has to distinguish between the algebraic and geometric multiplicity of an eigenvalue.

The main reason for using different kernels depending on the dimension is that in one dimension it is useful to think of $(\lambda - \lambda_0)W$ as a perturbation of H_{λ_0} because the solutions to $H_{\lambda_0}\psi = E\psi$ can be constructed using familiar techniques from the theory of integral equations and $K_{\lambda_0,E}$ can be expressed in terms of these solutions. One could also use $K_{0,E}$ in one dimension, but we were able to obtain stronger results by using $K_{\lambda_0,E}$. In two and three dimensions it is more convenient to view λW as a perturbation of H_0 because our assumptions on V will allow us to get detailed information about the resolvent $(H_0 - E)^{-1}$ and, therefore, about $K_{0,E}$.

For later use we give some more details of our approach when $\nu = 1$ or 2. We choose the notation appropriate for the one-dimensional case but keep it sufficiently general so that the two-dimensional case is included by setting $\lambda_0 = 0$. Consider the specific situation where $E(\lambda) \uparrow b$ as $\lambda \downarrow \lambda_0$. It turns out that as in the case $V = 0$, the kernel $K_{\lambda_0,E}$ can be decomposed into two parts: a singular part and a regular part. The singular part is of finite rank (rank one if $\nu = 1$) and diverges as $E \uparrow b$, while the regular part has a limit (in Hilbert–Schmidt norm) as $E \uparrow b$. The general form of this decomposition is

$$K_{\lambda_0,E} = Q_{\lambda_0,E} + R_{\lambda_0,E}, \tag{1.5}$$

$$Q_{\lambda_0,E} = \sum_{j=1}^{N} d_{\lambda_0;j}(E) L_{\lambda_0,E;j}, \quad L_{\lambda_0,E;j}\cdot = \omega_{\lambda_0,E;j}(\tilde{\omega}_{\lambda_0 E;j}, \cdot). \tag{1.6}$$

Here and in the sequel $(,)$ denotes the inner product in $L^2(\mathbf{R}^\nu)$ such that $(f,g) = \int_{\mathbf{R}^\nu} \overline{f(x)} g(x) d^\nu x$. The sets of vectors $\{\omega_{\lambda_0,E;j}\}_{j=1}^N$ and $\{\tilde{\omega}_{\lambda_0,E;j}\}_{j=1}^N$ are separately linearly independent and $\lim_{E\uparrow b}\ \omega_{\lambda_0,E;j}$ and $\lim_{E\uparrow b}\ \omega_{\lambda_0,E;j}$ exist in the L^2-norm. The coefficients $d_{\lambda_0;j}(E)$ are real and diverge as $E \uparrow b$ in a specific manner depending on ν. So, in (1.5), $Q_{\lambda_0,E}$ is the singular part and $R_{\lambda_0,E}$ is the regular part. In one dimension $N = 1$, but in two dimensions any $N > 1$ is possible. Note that for $|\lambda - \lambda_0|$ small enough,

$$(\lambda-\lambda_0)K_{\lambda_0,E}f=-f\Leftrightarrow[\lambda-\lambda_0](1+[\lambda-\lambda_0]R_{\lambda_0,E})^{-1}Q_{\lambda_0,E}f=-f.$$

By using (1.6), the right-hand is seen to be equivalent to

$$(\mathbf{I}_N+\mathbf{A})\mathbf{v}=0, \tag{1.7}$$

where $\mathbf{I}_N$ denotes the identity matrix in $\mathbf{C}^N$, $\mathbf{A}$ is the $N\times N$ matrix with entries

$$A_{i,j}=(\lambda-\lambda_0)d_{\lambda_0;j}(E)(\tilde{\omega}_{\lambda_0,E;i},(1+[\lambda-\lambda_0]R_{\lambda_0,E})^{-1}\omega_{\lambda_0,E;j}),$$

and $\mathbf{v}$ is the vector with components $v_j=(\tilde{\omega}_{\lambda_0,E;j},f)$, $j=1,...,N$. If $\mathbf{v}$ is known, then f is given by

$$f=-(\lambda-\lambda_0)\sum_{j=1}^{N} d_{\lambda_0;j}(E)(1+[\lambda-\lambda_0]R_{\lambda_0,E})^{-1}\omega_{\lambda_0,E;j}v_j.$$

From (1.7) we conclude that a nontrivial solution $\mathbf{v}$ exists if and only if $\det[\mathbf{I}_N+\mathbf{A}]=0$, that is,

$$\det[\,\delta_{ij}+(\lambda-\lambda_0)d_{\lambda_0;j}(E)(\tilde{\omega}_{\lambda_0,E;i},(1+[\lambda-\lambda_0]R_{\lambda_0,E})^{-1}\omega_{\lambda_0,E;j})]_{i,j=1}^{N}=0, \tag{1.8}$$

where δ_{ij} is the Kronecker delta. This is the equation which we will use to investigate $E(\lambda)$.

We remark that a similar approach has been used by Simon[1] and Holden[2] when $V=0$ and $\nu=2$. An alternative method to study $E(\lambda)$ is based on eigenvalue perturbation theory. The reader is referred to Refs. 1 and 3–5, and, in the special case when V is a Kronig–Penney potential, to Ref. 6. The eigenvalue perturbation method has the drawback that in some cases, when certain integrals involving W are zero, it becomes rather cumbersome and causes complications because $K_{\lambda_0,E}$ is in general not self-adjoint. At this point we should mention that for most results in this paper we do not require W to have constant sign. It is mainly for these reasons that we have decided not to use eigenvalue perturbation theory in one and two dimensions in this paper.

In three dimensions the situation is different in that the operator $K_{0,E}$ converges to a limit, $K_{0,b}$, as $E\uparrow b$, where $K_{0,b}$ is compact. Then an eigenvalue $E(\lambda)$ is associated with an eigenvalue branch $\tau(E)$ of $K_{0,E}$ such that $\lim_{E\uparrow b}\tau(E)$ exists and is finite, and the eigenvalue $E(\lambda)$ is found by solving $\lambda\tau(E)=-1$ for $E(\lambda)$. Moreover, the c.c.th.'s are given by $-1/\tau_j(b)$, where $\tau_j(b)$ $(j=1,2,...)$ denotes the negative eigenvalues of $K_{0,b}$. Thus, in three dimensions, $\lambda_0=0$ is never a c.c.th. at b (under our assumptions on V and W). Similarly, $\lambda_0=0$ is never a c.c.th. at a and hence, if λ is sufficiently small, H_λ has no eigenvalues in the gap (a,b).

We would like to mention that part of our motivation for studying the c.c.th. behavior of perturbed periodic Hamiltonians came from seminars given by two of our colleagues, Chris Beattie and George Hagedorn, on spectral properties of operators of the type considered here. Both of these individuals have also done numerical calculations of eigenvalue branches in dimensions one and two.[7,8] Further motivation came from earlier work on the subject in the case $V=0$,[1–5] the Kronig–Penney case,[6] and from related work on c.c.th.'s[9,10] and on eigenvalues in spectral gaps.[11–15]

This paper is organized as follows. Section II is devoted to the one-dimensional case. We describe the various threshold behaviors that can occur and find the leading order asymptotics of the eigenvalues. In some cases we also find higher order corrections to the leading term. We will see that generally $E(\lambda)-b\sim -c(\lambda-\lambda_0)^{2m}$ as $\lambda\downarrow\lambda_0$ or $\lambda\uparrow\lambda_0$, with $c>0$ and m a positive integer. Similar results hold at a. However, there are various situations where we can say more. For example, if $b=\inf\sigma(H_0)$ and $\lambda_0=0$, then only $m=1$ and 2 can occur, while if $\lambda_0>0$, then only $m=1$ is possible (Theorems 2.11 and 2.12). If b (or a) is the endpoint of a finite gap, then a similar result holds provided the support of W is suitably restricted (Theorem 2.16). Without such a restriction any m seems to be possible. For an eigenvalue that ''turns around'' we always have $m\geqslant 2$ with m even [Theorem 2.12(ii) and (v)]. Because we have made an effort to keep the

assumptions on W as weak as possible, there are technical details that require a careful discussion and which have caused this section to become larger than originally intended. In order to avoid extensive digressions we have moved the proofs of five technical lemmas to an Appendix.

In Section III we consider some special cases and extensions of the results of Section II, and compare them with similar results in the literature. In particular, we present an example illustrating the case $\lambda_0=0$, $E(\lambda)-a\sim c\lambda^8 (c>0)$, and we briefly discuss the case when $W(x)$ is of the form $\pm\delta(x-x_0)$.

In Section IV we consider the two-dimensional case. In view of the length of Section II we content ourselves with a discussion of the case $\lambda_0=0$. The typical leading behavior at the right endpoint of a gap in two dimensions is $E(\lambda)-b\sim -c_1 e^{-c_2/\lambda^s}$ as $\lambda\downarrow 0$, with c_1, $c_2>0$, and s a positive integer. If $b=\inf\sigma(H_0)$, then generally $s=1$, but $s=2$ is also possible if a certain integral involving W vanishes. At other endpoints any s seems to be possible, but $s=1$ is the generic situation. There is also the possibility that more than one distinct eigenvalue approaches an endpoint as $\lambda\downarrow 0$, or that an eigenvalue is degenerate.

Finally, in Section V we briefly consider the three-dimensional case, restricting ourselves to c.c.th.'s at the bottom of the essential spectrum which we assume to be at zero. The main result, Theorem 5.3, shows that there are two possible behaviors: either $E(\lambda)\sim -c(\lambda-\lambda_0)^2$ or $E(\lambda)\sim -c(\lambda-\lambda_0)$ as $\lambda\downarrow\lambda_0$, with $c>0$, where the second possibility can only occur if zero is an eigenvalue of H_{λ_0}. This type of result was to be expected in light of previous work on the subject.[9]

II. ONE DIMENSION: GENERAL RESULTS

In this section we consider the operator family (1.1) on $L^2(\mathbf{R})$ under the assumptions that V and W are real-valued,

$$V\in L^1_{loc}(\mathbf{R}),\quad V(x+p)=V(x),\quad \text{for some } p>0, \tag{2.1}$$

and that W satisfies one of the following conditions:

$$\int_{-\infty}^{\infty}(1+|x|)|W(x)|dx<\infty, \tag{H1}$$

$$\int_{-\infty}^{\infty}(1+x^2)|W(x)|dx<\infty, \tag{H2}$$

$$\int_{-\infty}^{\infty}e^{c|x|}|W(x)|dx<\infty,\quad c>0. \tag{H3}$$

Condition (2.1) implies that V is $-d^2/dx^2$-form bounded with relative bound zero (see Ref. 16, p. 8). Thus $H_0=-d^2/dx^2+V$ can be defined as a self-adjoint, semi-bounded operator by means of the KLMN theorem (see Ref. 17, Theorem VI.2.1; Ref. 18, Theorem X.17). Alternatively, the differential operator defined by H_0 is limit-point at $\pm\infty$. Hence H_0 can be interpreted as the unique self-adjoint extension of the minimal operator $H_{0,\min}$ with domain $D(H_{0,\min})=\{\psi\in L^2:\psi,\psi'\in AC_{loc}$, supp ψ compact, $H_0\psi\in L^2\}$ (see Ref. 19, p. 41). Here AC_{loc} denotes the set of locally absolutely continuous functions on $\mathbf{R}$. If (H1) holds, then the multiplication operator W is a relatively form compact perturbation of H_0 (cf. Ref. 20, pp. 114 and 369) and this is equivalent to the compactness of the Birman–Schwinger kernel. It is well-known that the spectrum of H_0 is absolutely continuous and of the form

$$\sigma(H_0)=\bigcup_{n=0}^{\infty}[E_{2n},E_{2n+1}],$$

where $-\infty<E_0<E_1\leqslant E_2<E_3\leqslant E_4\cdots$. So the intervals $[E_{2n},E_{2n+1}]$ are the bands and the intervals (E_{2n-1},E_n) (with $E_{-1}=-\infty$) are the gaps. In general a gap may be empty (E_{2n-1}

$=E_n$), but in this paper we will only be concerned with nonempty gaps. The spectral parameter E will always be assumed to lie in a gap or at an endpoint of a gap. We first summarize some well-known facts about the equation

$$H_0\psi = E\psi. \tag{2.2}$$

This equation has the two solutions (also known as Floquet solutions or Bloch waves),

$$\psi_0^{(\pm)}(x,E) = \theta_0(x,E) + m_0^{(\pm)}(E)\,\phi_0(x,E), \tag{2.3}$$

where $\theta_0(x,E)$ and $\phi_0(x,E)$ are solutions of (2.2) satisfying for all E the initial conditions $\theta_0(0,E) = \phi_0'(0,E) = 1$, $\theta_0'(0,E) = \phi_0(0,E) = 0$, and $m_0^{(\pm)}(E)$ are the Titchmarsh–Weyl m-functions associated with the intervals $\mathbf{R}_+ = [0,\infty)$ and $\mathbf{R}_- = (-\infty,0]$, respectively. Explicitly,

$$m_0^{(\pm)}(E) = \frac{\phi_0'(p,E) - \theta_0(p,E)}{2\phi_0(p,E)} \pm i\,\frac{\sin[q(E)]}{\phi_0(p,E)}, \tag{2.4}$$

$$q(E) = \cos^{-1}[\Delta(E)], \quad \Delta(E) = \frac{1}{2}\,[\phi_0'(p,E) + \theta_0(p,E)]. \tag{2.5}$$

Here $\Delta(E)$ is the Floquet determinant which is related to the spectrum of H_0 by $\sigma(H_0) = \{E : |\Delta(E)| \leqslant 1\}$. The branch of $\cos^{-1}$ in (2.5) is chosen such that $q(E)$ is continuous, $\mathrm{Im}[q(E)] > 0$ for $E < E_0$, and $q(E_0) = 0$. The solutions (2.3) are linearly independent for E inside a gap and satisfy

$$[\psi_0^{(+)}(\cdot,E); \psi_0^{(-)}(\cdot,E)] = -\frac{2i\,\sin[q(E)]}{\phi_0(p,E)}, \tag{2.6}$$

where $[f;g]$ denotes the Wronskian of f and g. Moreover, $\psi_0^{(\pm)}(x,E)$ can alternatively be written in the form

$$\psi_0^{(\pm)}(x,E) = e^{\pm ikx}\xi_0^{(\pm)}(x,E), \tag{2.7}$$

where $k = k(E) = q(E)/p$ is called the quasi-momentum, $\xi_0^{(\pm)}(x,E)$ have period p and $\xi_0^{(\pm)}(0,E) = 1$ [since $\psi_0^{(\pm)}(0,E) = 1$]. We further introduce the notation

$$\mathscr{G}_n = (E_{2n-1}, E_{2n}), \quad n = 0,1,2,\ldots,$$

$$\mathscr{B}_n = [E_{2n-2}, E_{2n-1}], \quad n = 1,2,\ldots,$$

so that $\mathscr{G}_n$ denotes the nth gap starting with the zeroth gap $(-\infty, E_0)$, and $\mathscr{B}_n$ denotes the nth band. The function $k(E)$ maps[21,22] $\mathscr{B}_n$ onto the interval $[(n-1)\pi/p, n\pi/p]$ in the k-plane, and it maps $\mathscr{G}_0$ onto the positive imaginary axis, and each $\mathscr{G}_n$ $(n = 1,2,\ldots)$ onto a segment of the form $\mathscr{S}_n = \{k : k = n\pi/p + i\mu, 0 < \mu \leqslant \delta_n\}$ for some $\delta_n > 0$, where $\mu = \mu(E) = \mathrm{Im}[k(E)]$. Here $\delta_n > 0$ is determined by the equation $k(\widetilde{E}_n) = n\pi/p + i\delta_n$, where $\widetilde{E}_n$ is the unique point (cf. Ref. 23, p. 295) in $\mathscr{G}_n$ such that $\Delta'(\widetilde{E}_n) = 0$. The two intervals $(E_{2n-1}, \widetilde{E}_n]$ and $[\widetilde{E}_n, E_{2n})$ are both mapped onto the segment $\mathscr{S}_n$ and hence the function $\mu \mapsto E(n\pi/p + i\mu)$ has two branches, $E^{(1)}(n\pi/p + i\mu)$ and $E^{(2)}(n\pi/p + i\mu)$, such that $E^{(1)}(n\pi/p + i\mu) \to E_{2n-1}$ and $E^{(2)}(n\pi/p + i\mu) \to E_{2n}$ as $\mu \downarrow 0$. Moreover, the functions $\mu \mapsto E^{(j)}(n\pi/p + i\mu)$ $(j = 1,2)$ are analytic, even and satisfy

$$E^{(j)}(n\pi/p + i\mu) - E_{2n-2+j} = \frac{(-1)^n p^2}{2\Delta'(E_{2n-2+j})}\,\mu^2 + O(\mu^4), \quad \mu \downarrow 0. \tag{2.8}$$

This follows from (2.5) by expanding $\Delta(E)$ about the point E_{2n-2+j}, using $\Delta(E_{2n-2+j}) = (-1)^n$ and the fact that $\phi_0(x,E)$ and $\theta_0(x,E)$ are analytic functions of E, hence even functions of μ. From now on we assume that

$$\phi_0(p,E_n) \neq 0, \tag{2.9}$$

at the endpoint under consideration. The case $\phi_0(p,E_n)=0$ will be discussed separately, since it requires special arguments. Note that for $n=0$, (2.9) is automatically satisfied because E_0 is the lowest point of $\sigma(H_0)$. In fact, $\phi_0(p,E_0)=0$ implies that $\phi_0(x,E_0)$ is periodic (with period p) and hence has infinitely many zeros, contradicting that E_0 is the lowest point of $\sigma(H_0)$. Moreover, the solution $\psi_0^{(+)}(x,E_0)$, which is well-defined because $\phi_0(p,E_0)\neq 0$, is periodic and thus has no zeros. Hence, by the Sturm separation theorem, $\phi_0(x,E_0)$ has exactly one zero (at $x=0$). There are two solutions, $F_\lambda^{(\pm)}(x,E)$, of (1.4) which are defined as solutions of the integral equations

$$F_\lambda^{(\pm)}(x,E)=\psi_0^{(\pm)}(x,E)-\lambda\int_x^{\pm\infty}A_0(x,y;E)W(y)F_\lambda^{(\pm)}(y,E)dy, \tag{2.10}$$

$$A_0(x,y;E)=-\frac{i\phi_0(p,E)}{2\sin[q(E)]}\left[\psi_0^{(+)}(x,E)\psi_0^{(-)}(y,E)-\psi_0^{(-)}(x,E)\psi_0^{(+)}(y,E)\right]. \tag{2.11}$$

The solutions $F_\lambda^{(\pm)}(x,E)$ correspond to the standard Jost solutions in the case when $V=0$ and, as usual, (2.10)–(2.11) are obtained by applying the variation of constants formula to (1.4) and using (2.6). For reasons given below, the relevant case for us will be that in which for a fixed $\lambda\geqslant 0$, $F_\lambda^{(+)}(x,E_n)$ and $F_\lambda^{(-)}(x,E_n)$ are linearly dependent. This case will also be called the exceptional case and we will call λ an exceptional value (at a given endpoint E_n) if $[F_\lambda^{(+)}(\cdot,E_n);F_\lambda^{(-)}(\cdot,E_n)]=0$. In the exceptional case we define the constant a_n by

$$F_\lambda^{(+)}(x,E_n)=a_n\,F_\lambda^{(-)}(x,E_n). \tag{2.12}$$

The case when $[F_\lambda^{(+)}(\cdot,E_n);F_\lambda^{(-)}(\cdot,E_n)]\neq 0$ will be called the generic case.

Next we introduce the transmission coefficient $T_\lambda(E)$ associated with (1.4),

$$T_\lambda(E)=-\frac{2i\,\sin[q(E)]}{[F_\lambda^{(+)}(\cdot,E);F_\lambda^{(-)}(\cdot,E)]\phi_0(p,E)}. \tag{2.13}$$

The transmission coefficient will enter naturally into our analysis and bring the advantage that we can draw on recent work on its asymptotic properties.[24] We remark that usually $T_\lambda(E)$ is first defined for $E\in\sigma(H_0)$ and then analytically continued into the gaps. The results of Ref. 24 were shown to be valid when E lies in a gap.

It will sometimes be convenient to number the gaps by using the symbol

$$\tilde{n}=\left[\frac{n+1}{2}\right], \tag{2.14}$$

where $[x]$ denotes the largest integer less than or equal to x. Then E_n is the left (right) endpoint of the gap $\mathscr{G}_{\tilde{n}}$ if n is odd (even). The statement $E\to E_n$ is understood to mean that E approaches E_n from within the gap $\mathscr{G}_{\tilde{n}}$, where E_n may be either endpoint of $\mathscr{G}_{\tilde{n}}$. In terms of μ this can be simply stated as $\mu\downarrow 0$, with the understanding that E is viewed as a function of μ, namely, $E=E^{(j)}(\tilde{n}\pi/p+i\mu)$, with the proper branch labeled by j ($j=n+2-2\tilde{n}$).

The following theorem was proved in Ref. 24 (Theorem 3.3).

Theorem 2.1: Suppose that (H1) and (2.9) hold. Fix $\lambda\geqslant 0$. Then $T_\lambda(E)$ is continuous at every E_n and there are two possible asymptotic behaviors of $T_\lambda(E)$ as $\mu\downarrow 0$ ($E\in\mathscr{G}_{\tilde{n}}$):

(i) In the generic case,

$$T_\lambda(E)=\beta_n\mu+o(\mu), \tag{2.15}$$

with β_n real and nonzero.

(ii) In the exceptional case,

$$T_\lambda(E)=T_\lambda(0)+o(1),\quad T_\lambda(0)=\frac{2a_n}{1+a_n^2}. \tag{2.16}$$

Of course, (2.15) follows immediately from (2.13), along with the fact that $F_\lambda^{(\pm)}(x,E_n)$ are real and

$$\sin[q(E)]=i(-1)^{\tilde{n}}\sinh \mu p, \quad E\in\mathscr{G}_{\tilde{n}}. \tag{2.17}$$

The proof of (2.16) is more involved. Note that if $\lambda=0$, then $F_0^{(\pm)}(x,E)=\psi_0^{(\pm)}(x,E)$, so $T_0(E)=1$ for all E, and we are in case (ii) with $a_n=1$.

Lemma 2.2: Suppose that (H1) and (2.9) hold. Then $[F_\lambda^{(+)}(\cdot,E_n);F_\lambda^{(-)}(\cdot,E_n)]=0$ if and only if

$$\int_{-\infty}^{\infty}\psi_0^{(+)}(x,E_n)W(x)F_\lambda^{(+)}(x,E_n)dx=0. \tag{2.18}$$

Proof: This result was proved in Ref. 24 as a consequence of Lemma 2.1 there. We briefly sketch the argument here, since we will use one formula from the proof later. For $E=E_n$ the integral equation (2.10) for $F_\lambda^{(+)}(x,E_n)$ becomes

$$F_\lambda^{(+)}(x,E_n)=\psi_0^{(+)}(x,E_n)-\lambda\int_x^{\infty}A_0(x,y;E_n)W(y)F_\lambda^{(+)}(y,E_n)dy, \tag{2.19}$$

$$A_0(x,y;E_n)=\lim_{E\to E_n}A_0(x,y;E)=\phi_0(x,E_n)\psi_0^{(+)}(y,E_n)-\psi_0^{(+)}(x,E_n)\phi_0(y,E_n). \tag{2.20}$$

Since $[F_\lambda^{(+)}(\cdot,E_n);F_\lambda^{(-)}(\cdot,E_n)]=0$ if and only if $H_\lambda\psi=E_n\psi$ has a bounded (nontrivial) solution, the assertion (2.18) follows on letting $x\to-\infty$ in (2.19) and using standard estimates (see Ref. 24, or Lemma 2.3 below). ∎

For the following it is convenient to normalize the solutions $F_\lambda^{(\pm)}(x,E)$ by introducing

$$\psi_\lambda^{(\pm)}(x,E)=\frac{F_\lambda^{(\pm)}(x,E)}{F_\lambda^{(\pm)}(0,E)}, \tag{2.21}$$

so that $\psi_\lambda^{(\pm)}(0,E)=1$. Therefore, in addition to (2.9), we make the assumption

$$F_\lambda^{(\pm)}(0,E_n)\neq 0, \tag{2.22}$$

so that by continuity $F_\lambda^{(\pm)}(0,E)\neq 0$ for E near E_n. It turns out that (2.22) is not a serious restriction, since by shifting the origin if necessary, we can always make sure that it holds. This point will be discussed in more detail later when we remove condition (2.9) by the same method.

The integral kernel of the resolvent $(H_\lambda-E)^{-1}$, i.e., the Green's function of H_λ, will be denoted by $G_{\lambda,E}(x,y)$. It is given by

$$G_{\lambda,E}(x,y)=\frac{1}{[\psi_\lambda^{(+)}(\cdot,E);\psi_\lambda^{(-)}(\cdot,E)]}\begin{cases}\psi_\lambda^{(+)}(x,E)\psi_\lambda^{(-)}(y,E), & y<x,\\ \psi_\lambda^{(-)}(x,E)\psi_\lambda^{(+)}(y,E), & y>x.\end{cases} \tag{2.23}$$

For fixed λ and E inside a gap, the Wronskian in the denominator of (2.23) vanishes exactly when E is an eigenvalue of H_λ, and so it is nonzero for E near but different from an endpoint E_n. The Birman–Schwinger kernel (1.3) is given by

$$K_{\lambda,E}(x,y)=W(x)^{1/2}G_{\lambda,E}(x,y)|W(y)|^{1/2}, \quad W(x)^{1/2}=|W(x)|^{1/2}\operatorname{sgn}W(x).$$

In order to split $K_{\lambda,E}$ into a singular and a regular part we write

$$G_{\lambda,E}(x,y)=\frac{1}{G_{\lambda,E}(0,0)}G_{\lambda,E}(x,0)G_{\lambda,E}(0,y)+G^D_{\lambda,E}(x,y). \tag{2.24}$$

where $G^D_{\lambda,E}(x,y)$ is the Green's function of H_λ with an additional Dirichlet condition at the origin. The decomposition (2.24) was used in Ref. 15 to study the number of eigenvalues in $\mathscr{G}_n$ for n large. Then the corresponding decomposition of $K_{\lambda,E}$ is

$$K_{\lambda,E}=d_\lambda(E)L_{\lambda,E}+R_{\lambda,E}, \tag{2.25}$$

where $L_{\lambda,E}$ and $R_{\lambda,E}$ are integral operators with kernels $L_{\lambda,E}(x,y)$ and $R_{\lambda,E}(x,y)$, respectively, given by

$$\begin{aligned} L_{\lambda,E}(x,y)&=\omega_\lambda(x,E)\tilde{\omega}_\lambda(y,E),\\ R_{\lambda,E}(x,y)&=W(x)^{1/2}G^D_{\lambda,E}(x,y)|W(y)|^{1/2}, \end{aligned} \tag{2.26}$$

$$\begin{aligned} \omega_\lambda(x,E)&=\begin{cases} W(x)^{1/2}\psi^{(+)}_\lambda(x,E), & x>0,\\ W(x)^{1/2}\psi^{(-)}_\lambda(x,E), & x<0, \end{cases}\\ \tilde{\omega}_\lambda(y,E)&=\omega_\lambda(y,E)\operatorname{sgn} W(y), \end{aligned} \tag{2.27}$$

$$G^D_{\lambda,E}(x,y)=\begin{cases} \phi_\lambda(x,E)\psi^{(+)}_\lambda(y,E), & 0<x<y,\\ \psi^{(+)}_\lambda(x,E)\phi_\lambda(y,E), & 0<y<x,\\ -\phi_\lambda(x,E)\psi^{(-)}_\lambda(y,E), & y<x<0,\\ -\psi^{(-)}_\lambda(x,E)\phi_\lambda(y,E), & x<y<0,\\ 0, \quad \text{otherwise.} \end{cases} \tag{2.28}$$

Moreover,

$$d_\lambda(E)=G_{\lambda,E}(0,0)=\frac{1}{[\psi^{(+)}_\lambda(\cdot,E);\psi^{(-)}_\lambda(\cdot,E)]}, \tag{2.29}$$

so that, by (2.6) and (2.17),

$$d_0(E)=\frac{(-1)^{\tilde{n}}\phi_0(p,E)}{2\sinh\,\mu p}, \quad E\in\mathscr{G}_{\tilde{n}}. \tag{2.30}$$

Another useful expression for $d_\lambda(E)$ follows from (2.13), (2.17), (2.21), and (2.29), namely,

$$d_\lambda(E)=\frac{(-1)^{\tilde{n}}\phi_0(p,E)T_\lambda(E)F^{(+)}_\lambda(0,E)F^{(-)}_\lambda(0,E)}{2\sinh\,\mu p}, \quad E\in\mathscr{G}_{\tilde{n}}. \tag{2.31}$$

The implicit equation (1.8) for $E(\lambda)$ can be written as

$$[\lambda-\lambda_0](\tilde{\omega}_{\lambda_0,E},(1+[\lambda-\lambda_0]R_{\lambda_0,E})^{-1}\omega_{\lambda_0,E})=-\frac{1}{d_{\lambda_0}(E)}, \tag{2.32}$$

where λ_0 is a c.c.th. and $\omega_{\lambda,E}$ (resp., $\tilde{\omega}_{\lambda,E}$) denotes the function $\omega_\lambda(x,E)$ [resp., $\tilde{\omega}_\lambda(x,E)$] defined in (2.27). Notice that the decomposition (2.25) is of the form (1.5), (1.6) with $N=1$ if we set $\lambda=\lambda_0$, $d_{\lambda_0;1}(E)=d_{\lambda_0}(E)$, $L_{\lambda_0,E;1}=L_{\lambda_0,E}$, $\omega_{\lambda_0,E;1}=\omega_{\lambda_0,E}$, etc.

Our goal now is to find solutions $E=E(\lambda)$ of (2.32) such that $E(\lambda)\to E_n$ as $\lambda\to\lambda_0$. We do this by first finding the solutions in the form $\mu(\lambda)$ and then using (2.8) to obtain $E(\lambda)$. Expanding the left-hand side of (2.32) in powers of $\lambda-\lambda_0$ yields

$$\sum_{j=0}^{\infty}(-1)^j[\lambda-\lambda_0]^{j+1}(\tilde{\omega}_{\lambda_0,E},R^j_{\lambda_0,E}\omega_{\lambda_0,E})=-\frac{1}{d_{\lambda_0}(E)}. \tag{2.33}$$

Now we would like to expand the coefficients $(\tilde{\omega}_{\lambda_0,E}, R^j_{\lambda_0,E}\omega_{\lambda_0,E})$ and the right-hand side of (2.33) in powers of μ and then obtain an expansion of $\mu(\lambda)$ in powers of $\lambda-\lambda_0$. It is not hard to see that a full expansion will generally not be possible under assumptions (H1) or (H2); one needs stronger assumptions like (H3) to do this. Under (H1) or (H2) one can only expect to find a few terms in an expansion of $\mu(\lambda)$. In particular, since the right-hand side of (2.33) vanishes linearly in μ, it will be easy to obtain the leading order term of $\mu(\lambda)$ provided the coefficient with $j=0$, $(\tilde{\omega}_{\lambda_0,E_n}, \omega_{\lambda_0,E_n})$, is nonzero. However, we are also interested in the case when $(\tilde{\omega}_{\lambda_0,E_n}, \omega_{\lambda_0,E_n}) = 0$, and, more generally, in the case when $(\tilde{\omega}_{\lambda_0,E_n}, R^j_{\lambda_0,E_n}\omega_{\lambda_0,E_n}) = 0$ for $j=0,1,\ldots,M-1$ and $(\tilde{\omega}_{\lambda,E_n}, R^M_{\lambda_0,E_n}\omega_{\lambda_0,E_n}) \neq 0$ for some M. Or, what if $(\tilde{\omega}_{\lambda_0,E_n}, R^j_{\lambda_0,E_n}\omega_{\lambda_0,E_n}) = 0$ for all j, if this is possible? In order to answer these questions we need some technical lemmas. Since the proofs of these lemmas are somewhat lengthy but mostly standard and do not contribute much to the understanding of our main results, they have all been consigned to the Appendix. In the following we will always think of E as a function of μ [as explained below (2.14)]. The phrase ''for E near E_n'' shall mean that there is a $\mu_0>0$ sufficiently small, so that the given statement holds for $0 \leqslant \mu \leqslant \mu_0$. The letter C will be used to denote various constants that may depend on μ_0 (but not on μ) and are not necessarily the same at each appearance. Differentiation with respect to μ will be denoted by a dot.

Lemma 2.3: Assume (H1), (2.9), (2.22), and fix $\lambda \geqslant 0$. Then for E near E_n we have the estimates

(i) $|\psi^{(\pm)}_\lambda(x,E)| \leqslant Ce^{\mp\mu x}$, $x \in \mathbf{R}_\pm$,

(ii) $|\phi_\lambda(x,E)| \leqslant C(1+|x|)e^{\mu|x|}$,

(iii) $|\dot{\phi}_\lambda(x,E)| \leqslant C[\mu(1+|x|)^3/(1+\mu|x|)^2]e^{\mu|x|}$.

Furthermore, if $\lambda=0$ and (H1) holds, or if $\lambda>0$ and (H2) holds, then

(iv) $|\dot{\psi}^{(\pm)}_\lambda(x,E)| \leqslant C(1+|x|)e^{\mp\mu x}$, $x \in \mathbf{R}_\pm$.

Proof: See the Appendix. ■

It is true that for E near but different from E_n, the function $\psi^{(\pm)}_\lambda(x,E)$ is differentiable with respect to μ under condition (H1) alone, for any $\lambda \geqslant 0$. However, if $\lambda>0$ and (H2) is not satisfied, then $\dot{\psi}_\lambda(x,E)$ will in general not remain bounded as $\mu \downarrow 0$. In other words, estimate (iv) no longer holds. The evidence for this conclusion comes from a result in Ref. 25 (Theorem 3.1) where, in the case $V=0$, it was proved that for a certain class of potentials that satisfy (H1) but violate (H2), the Jost solutions are in general not differentiable with respect to k $(k=\sqrt{-E})$ at $k=0$.

Lemma 2.4: Assume (H1), (2.9), (2.22) and fix $\lambda \geqslant 0$. Then for E near E_n we have

(i) $G^D_{\lambda,E}(x,y) \leqslant C[1+\min\{|x|,|y|\}]$,

(ii) $R_{\lambda,E} \to R_{\lambda,E_n}$ in Hilbert–Schmidt norm as $E \to E_n$,

(iii) Assume $\lambda=0$ and (H1), or $\lambda>0$ and (H2). Then

$$|\dot{G}^D_{\lambda,E}(x,y)| \leqslant C(1+|x|)(1+|y|). \tag{2.34}$$

Proof: See the Appendix. ■

We note that (i) implies

$$|G^D_{\lambda,E}(x,y)| \leqslant C(1+|x|)^{1/2}(1+|y|)^{1/2}.$$

When $\lambda=0$ a bound of this type was used in Ref. 15. Under condition (H1) all we can say in general is that $\|R_{\lambda,E}-R_{\lambda,E_n}\|_{H.S.}=o(1)$ as $E \to E_n$. However, if (H2) holds, then (2.34) implies that $\dot{R}_{\lambda,E}(x,y)$ is Hilbert–Schmidt and hence $\|R_{\lambda,E}-R_{\lambda,E_n}\|_{H.S.}=O(\mu)$.

Lemma 2.5: In addition to (2.9) and (2.22) assume $\lambda=0$ and (H1), or $\lambda>0$ and (H2). Then, for E near E_n, the functions $\mu \to (\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})$, $s=0,1,2,\ldots$, are continuously differentiable and obey

(i) $|(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})| \leqslant \tilde{C}r^s$,

(ii) $|d(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})/d\mu| \leqslant \tilde{C}r^s$,

for some $\tilde{C}>0$ and $r>0$.

Proof: See the Appendix. ■

The next two lemmas are essential for our study of (2.33). They are variants of the inverse function theorem tailored to our needs.

Lemma 2.6: Suppose $a_j(\mu)$, $j=1,2,...$, and $c(\mu)$ are continuous real-valued functions defined for $0\leqslant\mu\leqslant\mu_0$, satisfying

(a) $|a_j(\mu)|\leqslant Dr^j$, $j=1,2,3,...$, for some $D>0$, $r>0$, and $0\leqslant\mu\leqslant\mu_0$,

(b) $a_j(\mu)=O(\mu)$ as $\mu\to 0$, for $j=1,2,...N-1$, and $a_N(0)\neq 0$ for some $N\geqslant 1$,

(c) $c(\mu)=\dot{c}(0)\mu+o(\mu)$, with $\dot{c}(0)>0$, as $\mu\to 0$,

and consider the equation

$$\sum_{j=1}^{\infty} a_j(\mu)z^j=c(\mu). \tag{2.35}$$

Then the following occur:

(i) If N is odd and $a_N(0)>0$, then there is a unique, real, continuous solution $z(\mu)$ of (2.35) such that $z(\mu)=[\dot{c}(0)/a_N(0)]^{1/N}\mu^{1/N}+o(\mu^{1/N})$ as $\mu\downarrow 0$.

(ii) If N is odd and $a_N(0)<0$, then there is a unique, real, continuous solution $z(\mu)$ such that $z(\mu)=-[-\dot{c}(0)/a_N(0)]^{1/N}\mu^{1/N}+o(\mu^{1/N})$ as $\mu\downarrow 0$.

(iii) If N is even and $a_N(0)>0$, then there are exactly two real, continuous solutions $z_{\pm}(\mu)$ such that $z_{\pm}(\mu)=\pm[\dot{c}(0)/a_N(0)]^{1/N}\mu^{1/N}+o(\mu^{1/N})$ as $\mu\downarrow 0$.

(iv) If N is even and $a_N(0)<0$, then (2.35) has no real solution converging to zero as $\mu\downarrow 0$.

(v) If $a_j(0)=0$ for all j and $|a_j(\mu)|\leqslant C_1 r_1^j\mu$ for some $C_1>0$ and $r_1>0$, then there is no real solution converging to zero as $\mu\downarrow 0$.

Proof: See the Appendix. ■

Lemma 2.7: Suppose that, in addition to (a)–(c) of Lemma 2.6, $a_j(\mu)$ ($j=1,2,...$) and $c(\mu)$ are continuously differentiable, and $|\dot{a}_j(\mu)|\leqslant C_2 r_2^j$, for some $C_2>0$ and $r_2>0$. Then we have the following:

(i) If N is even and $a_N(0)>0$, then (2.35) has a unique solution $\mu(z)$ such that

$$\mu(z)=\frac{a_N(0)}{\dot{c}(0)}\,z^N+o(z^N), \quad z\to 0. \tag{2.36}$$

(ii) If N is odd and $a_N(0)>0$, resp. $a_N(0)<0$, then (2.35) has a solution obeying (2.36) as $z\downarrow 0$, resp. $z\uparrow 0$.

(iii) Suppose that $c(\mu)=\dot{c}(0)\mu+c_2\mu^2+o(\mu^2)$ with $\dot{c}(0)>0$. Then, under the same assumptions on $a_N(0)$ as in (i) and (ii) and with z approaching zero in the same manner as there, we have that

$$\mu(z)=\frac{a_N(0)}{\dot{c}(0)}\,z^N+\left[\frac{a_{N+1}(0)}{\dot{c}(0)}+\frac{a_N(0)\dot{a}_1(0)}{\dot{c}(0)^2}-\frac{c_2 a_1(0)^2}{\dot{c}(0)^3}\,\delta_{N,1}\right]z^{N+1}+o(z^{N+1}). \tag{2.37}$$

In (2.37) the Kronecker symbol $\delta_{N,1}$ has been added only for clarity. It follows from assumption (b) of Lemma 2.6 that $a_1(0)=0$ when $N>1$; thus the coefficient c_2 has no effect on (2.37) when $N>1$. Note that if $a_N(0)=0$, then (2.37) just reduces to (2.36) but with $N+1$ in place of N.

Proof: See the Appendix. ■

Some technical comments on Lemmas 2.6 and 2.7 may be in order. In assumption (c) of Lemma 2.6 we do not intend to imply that $c(\mu)$ is continuously differentiable on $[0,\mu_0]$, only that besides being continuous, it is also differentiable at $\mu=0$. In the application of Lemma 2.6 we will actually need the inverse function $\mu(z)$ of $z(\mu)$ [in case (iii) we need the inverse of each of the two functions $z_{\pm}(\mu)$]. Lemma 2.6 does not guarantee the existence of these inverse functions. For example, the solution $z(\mu)$ of the equation $[1+2\mu\,\sin(1/\mu)]z=\mu(0<\mu\leqslant\mu_0)$ does not have an inverse on $(0,\mu_0]$, no matter how small μ_0. However, in the applications we will have additional information on $\mu(z)$ which will allow us to argue that the inverse function exists. It may be also useful to give a short illustration of what can happen if $a_j(\mu)$ and $c(\mu)$ violate some of the conditions placed on them in Lemmas 2.6 and 2.7. Consider, for example, the equation $z+z^2=\mu+\mu^{1+\epsilon}$ with $1/2<\epsilon<1$, i.e., $a_1(\mu)=a_2(\mu)=1$, $c(\mu)=\mu+\mu^{1+\epsilon}$, and so $\dot{c}(0)=1$. Thus $c(\mu)$ does not fulfill condition (iii) of Lemma 2.7. Then $\mu(z)=z-z^{1+\epsilon}+z^2+o(z^2)$ and we see that a term, $-z^{1+\epsilon}$, has slipped between the linear and quadratic terms so that (2.37) no longer holds. Now replace $a_1(\mu)$ by μ, so that the equation becomes $\mu z+z^2=\mu+\mu^{1+\epsilon}$. Then $\mu(z)$

$=z^2-z^{2(1+\epsilon)}+O(z^3)$ which shows that the ϵ has no effect on the leading term. This is in agreement with Lemma 2.6. Furthermore, if $a_1(\mu)$ does not vanish linearly, uniqueness or existence may break down. For example, the equation $5\sqrt{\mu}z-4z^2=\mu$ has two solutions $\mu(z)=z^2$ and $\mu(z)=16z^2$, and the equation $\mu^{2/3}z-z^2=\mu$ has no real non-negative solution $\mu(z)$ that converges to zero as $z\to 0$.

Theorem 2.8: Assume (2.9) and (2.22). If $\lambda_0>0$ is a c.c.th. at E_n, then λ_0 is an exceptional value. The exceptional values and the c.c.th.'s each form a discrete set with no finite accumulation points.

Proof: Suppose that $[F^{(+)}_{\lambda_0}(\cdot,E_n);F^{(-)}_{\lambda_0}(\cdot,E_n)]\neq 0$. Then, by (2.15) and (2.31), the right-hand side of (2.33) approaches a finite nonzero limit as $E\to E_n$, whereas, by Lemma 2.5, the left-hand side goes to zero as $\lambda\to\lambda_0$, uniformly in E for E near E_n. Therefore, a solution $\mu(\lambda)$ of (2.33) satisfying $\mu(\lambda)\to 0$ as $\lambda\to\lambda_0$ does not exist and hence λ_0 cannot be a c.c.th. This proves the first part. For the second part we allow λ to be complex. Solving (2.19) by iteration, we see that for each x, the functions $\lambda\mapsto F^{(\pm)}_{\lambda}(x,E_n)$ and $\lambda\mapsto F^{(\pm)'}_{\lambda}(x,E_n)$ are entire functions of λ. Hence $\lambda\mapsto[F^{(+)}_{\lambda}(\cdot,E_n);F^{(-)}_{\lambda}(\cdot,E_n)]$ is entire and the conclusion follows. ■

In connection with Theorem 2.8 we remind the reader that $\lambda_0=0$ is always an exceptional value, but, as we will see below, it need not always be a c.c.th. [Theorem 2.11(i)]. Moreover, the restrictions (2.9) and (2.22) can be removed and the first assertion of Theorem 2.8 has a converse if $n=0$ and, under further assumptions, also when $n\geqslant 1$. This will be shown in Theorems 2.14(iii) and 2.16(i).

From now on we will always assume that we are in the exceptional case. In order to determine the threshold behavior of the eigenvalues we have to identify (2.33) with (2.35). Since $\dot{c}(0)$ in Lemma 2.6 must be positive, we need to know the sign of the derivative of $-1/d_{\lambda_0}(E)$ with respect to μ. To this end, we first note that by (2.12), (2.16), and (2.31),

$$-\frac{1}{d_{\lambda_0}(E)}=\frac{(-1)^{\tilde{n}+1}(1+a_n^2)p}{\phi_0(p,E_n)F^{(+)}_{\lambda_0}(0,E_n)^2}\,\mu+o(\mu). \tag{2.38}$$

Now it is known[14] that if (2.9) holds, then

$$\phi_0(p,E_n)>0, \quad n=4j \quad \text{and} \quad n=4j+1,$$

$$\phi_0(p,E_n)<0, \quad n=4j+2 \quad \text{and} \quad n=4j+3, \ j=0,1,\ldots .$$

Therefore,

$$\operatorname{sgn}[(-1)^{\tilde{n}+1}\phi_0(p,E_n)]=(-1)^{n+1},$$

and if we set

$$c_{\lambda_0}(\mu)=\frac{(-1)^n}{d_{\lambda_0}(E)}, \tag{2.39}$$

then

$$\dot{c}_{\lambda_0}(0)=\frac{(-1)^{\tilde{n}+n}(1+a_n^2)p}{\phi_0(p,E_n)F^{(+)}_{\lambda_0}(0,E_n)^2}>0. \tag{2.40}$$

In order to achieve some computational simplications later, we introduce the kernel

$$M_{\lambda,E}(x,y)=d_{\lambda}(E)W(x)^{1/2}|W(y)|^{1/2}\cdot\begin{cases}B_{\lambda}(x,y;E), & y<x,\\ B_{\lambda}(y,x;E), & y>x,\end{cases}$$
$$B_{\lambda}(x,y;E)=\psi^{(+)}_{\lambda}(x,E)\psi^{(-)}_{\lambda}(y,E)-\psi^{(+)}_{\lambda}(x,E_n)\psi^{(+)}_{\lambda}(y,E_n), \tag{2.41}$$

and denote the associated integral operator by $M_{\lambda,E}$. We remark that the integral operator $M_{\lambda,E}$ satisfies

$$K_{\lambda,E}=d_\lambda(E)L_{\lambda,E_n}+M_{\lambda,E}, \tag{2.42}$$

and thus is associated with a decomposition of $K_{\lambda,E}$ slightly different from that in (2.25). When $V=0$ this decomposition corresponds to that used in Refs. 1 and 5. If we assume (H2), then Lemma 2.4(ii) also holds for $M_{\lambda,E}$, namely $M_{\lambda,E}\to M_{\lambda,E_n}$ in the Hilbert–Schmidt norm. Then we could use the implicit equation

$$[\lambda-\lambda_0](\tilde{\omega}_{\lambda_0,E_n},(1+[\lambda-\lambda_0]M_{\lambda_0,E})^{-1}\omega_{\lambda_0,E_n})=-\frac{1}{d_{\lambda_0}(E)},$$

instead of (2.32). In this paper we need (2.41) only when $E=E_0$ and $\lambda=0$. Then we have

$$M_{0,E_0}(x,y)=\frac{-W(x)^{1/2}|W(y)|^{1/2}}{2}\cdot\begin{cases}A_0(x,y;E_0), & y<x,\\ A_0(y,x;E_0), & y>x,\end{cases} \tag{2.43}$$

where $A_0(x,y;E_0)$ is defined in (2.20). If only (H1) is assumed, then the kernel (2.43) will in general not represent a bounded operator. However, here we will only need certain matrix elements like $(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0})$. This matrix element exists as an integral over $\mathbf{R}^2$ and is equal to $\lim_{E\to E_0}(\tilde{\omega}_{0,E_0},M_{0,E}\omega_{0,E_0})$, where this limit exists by the estimates in Lemma 2.3.

In preparation of our next theorem we first prove two lemmas. Let λ_0 be an exceptional value and define

$$I_{\lambda_0,j}(E)=(\tilde{\omega}_{\lambda_0,E},R^j_{\lambda_0,E}\omega_{\lambda_0,E}),\quad j=0,1,2,...; \tag{2.44}$$

in particular,

$$I_{\lambda_0,0}(E_n)=(\tilde{\omega}_{\lambda_0,E_n},\omega_{\lambda_0,E_n})=\int_{-\infty}^{\infty}W(x)\psi^{(+)}_{\lambda_0}(x,E_n)^2dx. \tag{2.45}$$

Lemma 2.9: Assume (H1), (2.9), $n=0$, and $\lambda_0=0$. Then

$$(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0})=(\tilde{\omega}_{0,E_0},R_{0,E_0}\omega_{0,E_0})+\frac{1}{\dot{c}_0(0)}I_{0,0}(E_0)\dot{I}_{0,0}(E_0). \tag{2.46}$$

Proof: By (2.25), (2.39), (2.42), and (2.44), we have

$$\begin{aligned}(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0})-(\tilde{\omega}_{0,E_0},R_{0,E_0}\omega_{0,E_0})&=\lim_{E\to E_0}d_0(E)(\tilde{\omega}_{0,E_0},[L_{0,E}-L_{0,E_0}]\omega_{0,E_0})\\&=2\frac{1}{\dot{c}_0(0)}(\tilde{\omega}_{0,E_0},\omega_{0,E_0})(\tilde{\omega}_{0,E_0},\dot{\omega}_{0,E_0})\\&=\frac{1}{\dot{c}_0(0)}I_{0,0}(E_0)\dot{I}_{0,0}(E_0),\end{aligned}$$

proving (2.46). In the last equation we have used $\dot{I}_{0,0}(E)=2(\tilde{\omega}_{0,E},\dot{\omega}_{0,E})$. Note that, by Lemma 2.3(iv), $\dot{I}_{0,0}(E_0)$ exists under condition (H1). ■

Lemma 2.10: Assume (H1), $W\neq 0$, and $n=0$. Then the following are true:

(i) If $\lambda_0>0$, $[F^{(+)}_{\lambda_0}(\cdot,E_0);F^{(-)}_{\lambda_0}(\cdot,E_0)]=0$, and (2.22) holds, then $I_{\lambda_0,0}(E_0)<0$.

(ii) If $\lambda_0=0$ and $I_{0,0}(E_0)=0$, then $I_{0,1}(E_0)=(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0})>0$.

As we shall see later, in (i) it is not really necessary to assume (2.22). The only purpose of this assumption is to ensure that $\psi^{(+)}_{\lambda_0}(x,E_0)$ is defined by (2.21).

Proof: (i) Since $F^{(\pm)}_{\lambda_0}(x,E_0)$ are linearly dependent, (2.18) holds with $n=0$ and $\lambda=\lambda_0$. Multiplying (2.19) for $n=0$ by $W(x)F^{(+)}_{\lambda_0}(x,E_0)$, integrating over $\mathbf{R}$ using an integration by parts and Lemma 2.2, and using (2.21) and (2.45) yields

$$F^{(+)}_{\lambda_0}(0,E_0)^2 I_{\lambda_0,0}(E_0)=\int_{-\infty}^{\infty} W(x)F^{(+)}_{\lambda_0}(x,E_0)^2 dx$$

$$=-2\lambda_0\int_{-\infty}^{\infty} W(x)F^{(+)}_{\lambda_0}(x,E_0)\phi_0(x,E_0)$$

$$\times\left(\int_x^{\infty} W(y)\psi_0^{(+)}(y,E_0)F^{(+)}_{\lambda_0}(y,E_0)dy\right)dx. \tag{2.47}$$

Now the relation $[\phi_0(x,E_0)/\psi_0^{(+)}(x,E_0)]'=1/\psi_0^{(+)}(x,E_0)^2$ [recall that $\psi_0^{(+)}(x,E_0)$ has no zeros] together with an integration by parts yields

$$F^{(+)}_{\lambda_0}(0,E_0)^2 I_{\lambda_0,0}(E_0)=-\lambda_0\int_{-\infty}^{\infty}\frac{1}{\psi_0^{(+)}(x,E_0)^2}$$

$$\times\left(\int_x^{\infty} W(y)\psi_0^{(+)}(y,E_0)F^{(+)}_{\lambda_0}(y,E_0)dy\right)^2 dx<0. \tag{2.48}$$

The boundary terms from the integration by parts vanish on account of Lemma 2.3 and (H1). Hence $I_{\lambda_0,0}(E_0)<0$, proving (i).

(ii) By (2.45) and (2.46), since $I_{0,0}(E_0)=0$, we have that $I_{0,1}(E_0)=(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0})$. Then, from (2.43), by an integration by parts and using that $\psi_0^{(+)}(x,E_0)=\psi_0^{(-)}(x,E_0)$, we obtain

$$I_{0,1}(E_0)=2\int_{-\infty}^{\infty} W(x)\psi_0^{(+)}(x,E_0)\phi_0(x,E_0)\left(\int_x^{\infty} W(y)\psi_0^{(+)}(y,E_0)^2 dy\right)dx. \tag{2.49}$$

Proceeding with (2.49) as with (2.47), we obtain

$$I_{0,1}(E_0)=\int_{-\infty}^{\infty}\frac{1}{\psi_0^{(+)}(x,E_0)^2}\left(\int_x^{\infty} W(y)\psi_0^{(+)}(y,E_0)^2 dy\right)^2 dx>0,$$

and (ii) is proved. ∎

In the following the constant

$$\nu_n=\frac{|\phi_0(p,E_n)|F^{(+)}_{\lambda_0}(0,E_n)^2}{(1+a_n^2)\sqrt{2|\Delta'(E_n)|}} \tag{2.50}$$

will frequently appear. We do not explicitly indicate the dependence on λ_0 of this and similar constants.

Theorem 2.11: Assume (H1), $W\neq 0$, and $n=0$. Then we have the following:

(i) $\lambda_0=0$ is a c.c.th. at E_0 if and only if $I_{0,0}(E_0)\leqslant 0$. If this is the case, then there exists a unique eigenvalue $E(\lambda)$ such that

$$\sqrt{E_0-E(\lambda)}=-\nu_0 I_{0,0}(E_0)\lambda+\nu_0(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0})\lambda^2+o(\lambda^2),\quad \lambda\downarrow 0. \tag{2.51}$$

(ii) Suppose that $\lambda_0>0$, $[F^{(+)}_{\lambda_0}(\cdot,E_0);F^{(-)}_{\lambda_0}(\cdot,E_0)]=0$, and that (2.22) holds. Then λ_0 is a c.c.th., $I_{\lambda_0,0}(E_0)<0$, and there is a unique eigenvalue given by

$$\sqrt{E_0-E(\lambda)}=-\nu_0 I_{\lambda_0,0}(E_0)(\lambda-\lambda_0)+o(\lambda-\lambda_0),\quad \lambda\downarrow\lambda_0. \tag{2.52}$$

Proof: Suppose λ_0 is a c.c.th. at E_0. Then we identify (2.33) with (2.35) by means of the substitutions $1/d_{\lambda_0}(E_0)=c_{\lambda_0}(\mu)\to c(\mu)$ [cf. (2.39) with $n=0$], $\lambda-\lambda_0\to z$, and $(-1)^{j+1}(\tilde{\omega}_{\lambda_0,E},R^j_{\lambda_0,E}\omega_{\lambda_0,E})=(-1)^{j+1}I_{\lambda_0,j}(E)\to a_{j+1}(\mu)$ $(j=0,1,...)$. To prove (i), first note that, since $\psi_0^{(+)}(x,E_0)=\psi_0^{(-)}(x,E_0)$, $\lambda_0=0$ is an exceptional value at each E_0. By Lemma 2.6(ii), if $a_1(0)<0$, then (2.35) does not have an acceptable (i.e. positive) solution $z(\mu)$. Hence $a_1(0)=-I_{0,0}(E_0)\geqslant 0$ is necessary for $\lambda_0=0$ to be a c.c.th. To show the sufficiency of the condition $I_{0,0}(E_0)\leqslant 0$ we note that by Lemma 2.10(ii), if $I_{0,0}(E_0)=0$, then $I_{0,1}(E_0)=a_2(0)>0$. So either $a_1(0)>0$ or $a_1(0)=0$ and $a_2(0)>0$. Moreover, Lemma 2.5(ii) guarantees that the coefficients $a_k(\mu)$ are continuously differentiable, and from (2.29) and (2.39) it follows that $c(\mu)$ is continuously differentiable, $\dot{c}(0)>0$ [cf. (2.40)] and $c_2=0$ [because $\phi_0(p,E)$ is an even function of μ]. Hence Lemma 2.7(iii) applies and $\mu(z)$ is given by (2.37). This shows that $\lambda_0=0$ is a c.c.th. It remains to convert (2.37) to (2.51). Considering the bracketed term in (2.37), using (2.46), we have

$$\frac{a_2(0)}{\dot{c}(0)}+\frac{a_1(0)\dot{a}_1(0)}{\dot{c}(0)^2}=\frac{I_{0,1}(E_0)}{\dot{c}(0)}+\frac{I_{0,0}(E_0)\dot{I}_{0,0}(E_0)}{\dot{c}(0)^2}=\frac{1}{\dot{c}(0)}\,(\tilde{\omega}_{0,E_0},M_{0,E_0}\omega_{0,E_0}). \tag{2.53}$$

Now (2.51) follows from (2.37), (2.53), and using (2.8) to relate μ to $\sqrt{E_0-E(\lambda)}$. This proves (i).

(ii) When $\lambda_0>0$, then $a_1(0)=-I_{\lambda_0,0}(E_0)>0$ by Lemma 2.10(i), and hence $z(\mu)=[\dot{c}(0)/a_1(0)]\mu+o(\mu)$ by Lemma 2.6(ii). Note that Lemma 2.7 is not applicable, since $a_k(\mu)$ and $c(\mu)$ are not necessarily continuously differentiable at $\mu=0$. Now we show that the function $z(\mu)$ is invertible for small enough μ. We argue by contradiction. Suppose that $z(\mu_1)=z(\mu_2)$ for $0<\mu_1<\mu_2$. Then $z(\mu)$ assumes an extremum at an interior point of this interval, say at μ^*. If $z(\mu^*)$ is a strict extremum, then there are two sequences $\{\mu_{n,\pm}\}$ such that $\mu_{n,+}\downarrow\mu^*$, $\mu_{n,-}\uparrow\mu^*$, $z(\mu_{n,+})=z(\mu_{n,-})$, and $z(\mu_{n,\pm})\to z(\mu^*)$ as $\mu_{n,\pm}\to\mu^*$. This means that, as $\lambda\to\lambda_0+z(\mu^*)$, two eigenvalue sequences $\{E(i\mu_{n,\pm})\}$ belonging to H_{λ_n} with $\lambda_n=\lambda_0+z(\mu_{n,+})=\lambda_0+z(\mu_{n,-})$ converge to the eigenvalue $E(i\mu^*)$ of $H_{\lambda_0+z(\mu^*)}$. Consequently, by standard results from perturbation theory, $H_{\lambda_0+z(\mu^*)}$ has a discrete eigenvalue of multiplicity two. But this is impossible; hence $z(\mu)$ cannot have a strict minimum at μ^*. If the extremum at μ^* is not strict, then there exists a sequence $\{\mu_n\}$ such that $\mu_n\to\mu^*$ and $z(\mu_n)=z(\mu^*)$. This implies that the values $E(i\mu^*)$ and $E(i\mu_n)$ are all eigenvalues of $H_{\lambda_0+z(\mu^*)}$ and that $E(i\mu^*)$ is an accumulation point of these eigenvalues. Again, this is impossible. Hence $z(\mu)$ is a monotone function. Inverting it we get $\mu(z)=[a_1(0)/\dot{c}(0)]z+o(z)$ and (2.52) follows from (2.8). ■

In the statement of the next theorem, in order to reduce the number of case distinctions, we temporarily lift the restriction $\lambda\geqslant 0$ to the extent that we allow λ to approach 0 from below if the c.c.th. is $\lambda_0=0$.

Theorem 2.12: Suppose that $\lambda_0=0$ or $\lambda_0>0$ and $[F^{(+)}_{\lambda_0}(\cdot,E_n);F^{(-)}_{\lambda_0}(\cdot,E_n)]=0$, $n\geqslant 1$, and that (2.9) and (2.22) hold. Also, suppose that for some $M\geqslant 0$,

$$I_{\lambda_0,j}(E_n)=0,\quad j=0,...,M-1,\quad I_{\lambda_0,M}(E_n)\neq 0. \tag{2.54}$$

Further, assume one of the following:

(a) $\lambda_0=0$ and (H1),

(b) $\lambda_0>0$, $M=0$, and (H1),

(c) $\lambda_0>0$, $M\geqslant 1$, and (H2).

Then the following holds:

(i) If n is odd, M is even, and $I_{\lambda_0,M}(E_n)>0$ [resp., $I_{\lambda_0,M}(E_n)<0$], then there is a unique eigenvalue $E(\lambda)$ of H_λ obeying

$$\sqrt{E(\lambda)-E_n}=\nu_n I_{\lambda_0,M}(E_n)(\lambda-\lambda_0)^{M+1}[1+o(1)],\quad \lambda\downarrow\lambda_0\quad(\text{resp. }\lambda\uparrow\lambda_0). \tag{2.55}$$

(ii) If n is odd, M is odd, and $I_{\lambda_0,M}(E_n)<0$, then there is an eigenvalue obeying

$$\sqrt{E(\lambda)-E_n}=-\nu_n I_{\lambda_0,M}(E_n)(\lambda-\lambda_0)^{M+1}[1+o(1)],\quad \lambda\downarrow\lambda_0\quad\text{and}\quad\lambda\uparrow\lambda_0. \tag{2.56}$$

(iii) If n is odd, M is odd, and $I_{\lambda_0,M}(E_n)>0$, then there is no eigenvalue converging to E_n as either $\lambda\downarrow\lambda_0$ or $\lambda\uparrow\lambda_0$.

(iv) If n is even, M is even, and $I_{\lambda_0,M}(E_n)<0$ [resp. $I_{\lambda_0,M}(E_n)>0$], then there is a unique eigenvalue $E(\lambda)$ of H_λ obeying

$$\sqrt{E_n-E(\lambda)}=-\nu_n I_{\lambda_0,M}(E_n)(\lambda-\lambda_0)^{M+1}[1+o(1)],\quad \lambda\downarrow\lambda_0\quad (\text{resp. } \lambda\uparrow\lambda_0). \tag{2.57}$$

(v) If n is even, M is odd and $I_{\lambda_0,M}(E_n)>0$, then there is an eigenvalue obeying

$$\sqrt{E_n-E(\lambda)}=\nu_n I_{\lambda_0,M}(E_n)(\lambda-\lambda_0)^{M+1}[1+o(1)],\quad \lambda\downarrow\lambda_0\quad \text{and}\quad \lambda\uparrow\lambda_0. \tag{2.58}$$

(vi) If n is even, M is odd, and $I_{\lambda_0,M}(E_n)<0$, then there is no eigenvalue converging to E_n as either $\lambda\downarrow\lambda_0$ or $\lambda\uparrow\lambda_0$.

Proof: Apply Lemma 2.7 if (a) or (c) are assumed and use Lemma 2.6, together with the argument about inverting $z(\mu)$ used in the proof of Theorem 2.11, when (b) is assumed. In identifying (2.33) with (2.35) use (2.39) and the correspondence $(-1)^{j+n+1}I_{\lambda_0,j}(E)\to a_{j+1}(\mu)$; further details are omitted. ■

Some comments about Theorems 2.11 and 2.12 may be in order. According to (2.51) and (2.52) eigenvalues can approach E_0 only as $\lambda\downarrow\lambda_0$. In other words, eigenvalues that appear at E_0 can only move to the left as λ increases. This is well-known and not only true for λ near λ_0 but for all $\lambda>\lambda_0$ (Ref. 20, p. 79; Ref. 26, footnote on p. 89). For an endpoint E_n with n odd, i.e., the left endpoint of a gap, part (i) of Theorem 2.12 describes the two situations where an eigenvalue either appears at E_n as $\lambda\uparrow\lambda_0+\epsilon$ [if $I_{\lambda_0,M}(E_n)>0$] or where an eigenvalue comes in from the right and gets absorbed into the continuous spectrum at E_n [if $I_{\lambda_0,M}(E_n)<0$]. Case (ii) describes the situation where an eigenvalue ''turns around'' at E_n. Note that $M+1$ is even and hence $M+1\geqslant 2$, so that $E(\lambda)-E_n=O(\lambda^4)$ at least. In case (iii), λ_0 is an exceptional value, but there is no eigenvalue converging to E_n as $\lambda\downarrow\lambda_0$ or $\lambda\uparrow\lambda_0$. In other words, λ_0 is an exceptional value but not a c.c.th. For n even, the possibilities are similar as can be seen from (iv)–(vi).

Theorem 2.13: Suppose that W satisfies (H3). Then $\sqrt{E(\lambda)-E_n}$ is given by a convergent power series in $\lambda-\lambda_0$.

Proof: Both sides of (2.32) can be analytically continued, as functions of μ, to a complex neighborhood of $\mu=0$. This follows by generalizing the estimates in Lemmas 2.3 and 2.4 to the case when μ (resp., E) is complex. We omit a detailed discussion and only sketch a few steps. The estimates $|\phi_{\lambda_0}(x,E)|\leqslant C(1+|x|)e^{|\mathrm{Re}\,\mu||x|}$ and $|\psi^{(\pm)}_{\lambda_0}(x,E)|\leqslant Ce^{\mp(\mathrm{Re}\,\mu)x}$ for $x\in\mathbf{R}_\pm$ imply that $|G^D_{\lambda_0,E}(x,y)|\leqslant C[1+\min\{|x|,|y|\}]e^{|\mathrm{Re}\,\mu|(|x|+|y|)}$. The exponential factor appearing here will be absorbed by the decay of W when used in the expressions for $R_{\lambda_0,E}$ and $\omega_{\lambda_0,E}$, provided $2|\mathrm{Re}\,\mu|<c$, where c is the constant in (H3). As a result, the function $h(\mu,z)$ in (A30) (see the Appendix) is jointly analytic in μ and z near $\mu=z=0$, $h(0,0)=0$, and $h_\mu(0,0)\neq 0$. Therefore, by the implicit function theorem for analytic functions, the equation $h(\mu,z)=0$ has, for small z, a unique analytic solution $\mu(z)$. ■

Next we discuss how the above results have to be modified when (2.9) or (2.22) are not satisfied, that is, when $\phi_0(p,E_n)=0$, or $\phi_0(p,E_n)\neq 0$ but $F^{(\pm)}_{\lambda_0}(0,E_n)=0$. These special situations may easily occur for reasons of symmetry. For example, if V and W are even, then the subspaces of odd and even parity, respectively, are reducing subspaces for H_λ. Hence on the subspace of odd parity we have $F^{(\pm)}_{\lambda_0}(0,E_n)=0$ at the threshold. Moreover, either E_1 or E_2 is the first Dirichlet eigenvalue for the eigenvalue problem (2.2) on the interval $[0,p]$ and thus $\phi_0(p,E_j)=0$ for $j=1$ or 2. That our approach breaks down when $\phi_0(p,E_n)=0$ is evident from (2.4) which shows that the Titchmarsh–Weyl coefficient $m_0^{(+)}(E)$ [or $m_0^{(-)}(E)$] becomes singular as $E\to E_n$; the imaginary part of $m_0^{(+)}(E)$ blows up, while the real part approaches a finite limit. Note that $\phi_0(p,E)$ vanishes quadratically in μ as $\mu\downarrow 0$, while $\sin[q(E)]$ only vanishes linearly. This implies that the decomposition (2.25) is no longer useful. One way to deal with this situation would be to choose a different decomposition of the Green's function, and this is also necessary if one wants to give a complete treatment of the case $\phi_0(p,E_n)=0$. However, here we are interested only in

obtaining the leading terms of some of the eigenvalue expansions, and so we choose a different approach. We perform a shift of the origin so that for the shifted problem conditions (2.9) and (2.22) are satisfied. Then we relate the expressions for the shifted problem back to the original problem. We will often refer to Ref. 24, where some details of this method have already been worked out.

Let $b \in \mathbf{R}$, and replace $V(x)$ and $W(x)$ in (1.1) and (1.2) by $V(x+b)$ and $W(x+b)$. Clearly, the spectrum of H_λ is invariant under the shift. We denote the various solutions associated with the shifted problem by means of an additional argument or subscript b, e.g., $\psi_\lambda^{(+)}(x,E;b)$, $\phi_\lambda(x,E;b)$, $\nu_{n;b}$, etc. From (2.45) and (2.50) we have

$$\nu_{n;b} I_{\lambda_0,0}(E_n;b) = \frac{|\phi_0(p,E_n;b)|}{(1+a_n^2)\sqrt{2|\Delta'(E_n)|}} \int_{-\infty}^{\infty} W(x+b) F_{\lambda_0}^{(+)}(x,E_n;b)^2 dx, \tag{2.59}$$

where we used (2.21) for the shifted problem and the fact that the constant a_n [defined in (2.12)] and the discriminant $\Delta(E)$ are invariant under the shift. We now distinguish between two cases.

Case 1: $F_{\lambda_0}^{(\pm)}(0,E_n)=0$ and $\phi_0(p,E_n)\neq 0$: Since

$$\psi_0^{(\pm)}(x,E;b) = \frac{\psi_0^{(\pm)}(x+b,E)}{\psi_0^{(\pm)}(b,E)},$$

$$F_{\lambda_0}^{(\pm)}(x,E;b) = \psi_0^{(\pm)}(x,E;b) + o(1), \quad x \to \pm\infty,$$

it follows that

$$F_{\lambda_0}^{(\pm)}(x,E;b) = \frac{F_{\lambda_0}^{(\pm)}(x+b,E)}{\psi_0^{(\pm)}(b,E)}. \tag{2.60}$$

So we can choose b such that $\psi_0^{(\pm)}(b,E_n)\neq 0$ and $F_{\lambda_0}^{(\pm)}(b,E_n)\neq 0$, and hence

$$F_{\lambda_0}^{(\pm)}(0,E_n;b) = \frac{F_{\lambda_0}^{(\pm)}(b,E_n)}{\psi_0^{(\pm)}(b,E_n)} \neq 0.$$

Furthermore, we have [cf. Ref. 24, Eqs. (3.37)–(3.38)]

$$\phi_0(p,E_n;b) = \psi_0^{(+)}(b,E_n)^2 \phi_0(p,E_n) \neq 0, \tag{2.61}$$

so that (2.9) and (2.22) are both satisfied for the shifted problem. Since $F_{\lambda_0}^{(\pm)}(0,E_n)=0$, we have

$$F_{\lambda_0}^{(\pm)}(x,E_n) = F_{\lambda_0}^{(\pm)'}(0,E_n)\,\phi_{\lambda_0}(x,E_n), \tag{2.62}$$

and so (2.59) can be written as

$$\nu_{n;b} I_{\lambda_0,0}(E_n;b) = \tilde{\nu}_n \tilde{I}_{\lambda_0,0}(E_n), \tag{2.63}$$

$$\tilde{\nu}_n = \frac{|\phi_0(p,E_n)| F_{\lambda_0}^{(+)'}(0,E_n)^2}{(1+a_n^2)\sqrt{2|\Delta'(E_n)|}}, \quad \tilde{I}_{\lambda_0,0}(E_n) = \int_{-\infty}^{\infty} W(x)\,\phi_{\lambda_0}(x,E_n)^2 dx. \tag{2.64}$$

Finally, we find an expression for $I_{\lambda_0,1}(E_n;b) = (\tilde{\omega}_{\lambda_0,E_n;b}, R_{\lambda_0,E_n;b}\omega_{\lambda_0,E_n;b})$ under the assumption that $\tilde{I}_{\lambda_0,0}(E_n)=0$, so that we can also determine the leading order term in the eigenvalue expansion when $\tilde{I}_{\lambda_0,0}(E_n)=0$. By using (2.26) and $\tilde{I}_{\lambda_0,0}(E_n)=0=I_{\lambda_0,0}(E_n;b)$, we obtain

$$I_{\lambda_0,1}(E_n;b)=2\int_{-\infty}^{\infty}W(x+b)\,\phi_{\lambda_0}(x,E_n;b)\,\psi_{\lambda_0}^{(+)}(x,E_n;b)\left(\int_x^{\infty}W(y+b)\,\psi_{\lambda_0}^{(+)}(y,E_n;b)^2dy\right)dx. \tag{2.65}$$

Now using

$$\phi_{\lambda_0}(x,E_n;b)=\theta_{\lambda_0}(b,E_n)\,\phi_{\lambda_0}(x+b,E_n)-\phi_{\lambda_0}(b,E_n)\,\theta_{\lambda_0}(x+b,E_n), \tag{2.66}$$

along with (2.60), (2.61), (2.62) for $x=b$, and $\tilde{I}_{\lambda_0,0}(E_n)=0$, we get

$$\begin{aligned}\nu_{n;b}I_{\lambda_0,1}(E_n;b)&=\tilde{\nu}_n\tilde{I}_{\lambda_0,1}(E),\\ \tilde{I}_{\lambda_0,1}(E_n)&=-2\int_{-\infty}^{\infty}W(x)\,\phi_{\lambda_0}(x,E_n)\,\theta_{\lambda_0}(x,E_n)\left(\int_x^{\infty}W(y)\,\phi_{\lambda_0}(y,E_n)^2dy\right)dx.\end{aligned} \tag{2.67}$$

Case 2: $\phi_0(p,E_n)=0 (n\geqslant 1)$: In place of (2.61) we now have [cf. Ref. 24, Eq. (3.37)]

$$\phi_0(p,E_n;b)=-\phi_0(b,E_n)^2\theta_0'(p,E_n), \tag{2.68}$$

and we see that by choosing b such that $\phi_0(b,E_n)\neq 0$ we can make sure that $\phi_0(p,E_n;b)\neq 0$. The exceptional case is now characterized by the property that $H_{\lambda_0}\psi=E_n\psi$ has a unique (up to constant factors) nontrivial solution. This is the same as saying that the shifted problem is exceptional in the sense defined below Theorem 2.1. Assuming we are in the exceptional case, following Ref. 24 we introduce the solutions

$$\eta_{\lambda_0}^{(\pm)}(x,E)=\frac{F_{\lambda_0}^{(\pm)}(x,E)}{m_0^{(\pm)}(E)}, \tag{2.69}$$

of $H_{\lambda_0}\psi=E\psi$, and note that

$$\eta_{\lambda_0}^{(\pm)}(x,E_n)=\lim_{E\to E_n}\eta_{\lambda_0}^{(\pm)}(x,E) \tag{2.70}$$

exist, and that $\eta_{\lambda_0}^{(\pm)}(x,E_n)$ represent bounded nontrivial solutions of $H_{\lambda_0}\psi=E_n\psi$. Moreover, $\eta_{\lambda_0}^{(+)}(x,E_n)=b_n\eta_{\lambda_0}^{(-)}(x,E_n)$ for some constant b_n, analogous to (2.12), and $\eta_0^{(\pm)}(x,E_n)=\phi_0(x,E_n)$ if $\lambda_0=0$ and $\eta_{\lambda_0}^{(\pm)}(x,E_n)=\phi_0(x,E_n)+o(1)$ as $x\to\pm\infty$ if $\lambda_0>0$. These asymptotics follow from the integral equation that $\eta_{\lambda_0}^{(\pm)}(x,E_n)$ satisfy and which can be obtained from (2.69) and (2.10):

$$\eta_{\lambda_0}^{(\pm)}(x,E_n)=\phi_0(x,E_n)-\lambda_0\int_x^{\pm\infty}\tilde{A}_0(x,y;E_n)W(y)\,\eta_{\lambda_0}^{(\pm)}(y,E_n)dy, \tag{2.71}$$

where $\tilde{A}_0(x,y;E_n)=\phi_0(x,E_n)\,\theta_0(y,E_n)-\theta_0(x,E_n)\,\phi_0(y,E_n)$. Note that $\tilde{A}_0(x,y;E_n)=\lim_{E\to E_n}A_0(x,y;E)$, where $A_0(x,y;E)$ is defined in (2.11), as can be seen by inserting (2.3) and (2.4) in (2.11). $\tilde{A}_0(x,y;E_n)$ replaces the kernel in (2.20) which becomes formally undefined because $\phi_0(p,E_n)=0$. Since $\psi_0^{(\pm)}(b,E)/m_0^{(\pm)}(E)\to\phi_0(b,E_n)$ as $E\to E_n$, by (2.60), (2.69), and (2.70) we obtain

$$F_{\lambda_0}^{(\pm)}(x,E_n;b)=\frac{\eta_{\lambda_0}^{(\pm)}(x+b,E_n)}{\phi_0(b,E_n)},\quad \psi_{\lambda_0}^{(+)}(x,E_n;b)=\frac{\eta_{\lambda_0}^{(+)}(x+b,E_n)}{\eta_{\lambda_0}^{(+)}(b,E_n)}, \tag{2.72}$$

and hence

$$F_{\lambda_0}^{(+)}(x,E_n;b)=b_nF_{\lambda_0}^{(-)}(x,E_n;b). \tag{2.73}$$

Upon inserting (2.68), (2.72), and (2.73) in (2.59), we find that

$$\nu_{n;b} I_{\lambda_0,0}(E_n;b) = \kappa_n J_{\lambda_0,0}(E_n), \tag{2.74}$$

$$\kappa_n = \frac{|\theta_0'(p,E_n)|}{(1+b_n^2)\sqrt{2|\Delta'(E_n)|}}, \quad J_{\lambda_0,0}(E_n) = \int_{-\infty}^{\infty} W(x)\,\eta_{\lambda_0}^{(+)}(x,E_n)^2 dx. \tag{2.75}$$

As in Case 1, by assuming $J_{\lambda_0,0}(E_n)=0$, we can obtain an expression for the product $\nu_{n;b} I_{\lambda_0,1}(E_n;b)$ which we state without a detailed derivation:

$$\nu_{n;b} I_{\lambda_0,1}(E_n;b) = \kappa_n J_{\lambda_0,1}(E_n), \tag{2.76}$$

$$J_{\lambda_0,1}(E_n) = 2\int_{-\infty}^{\infty} W(x) h_{\lambda_0}(x,E_n)\,\eta_{\lambda_0}^{(+)}(x,E_n)\left(\int_x^{\infty} W(y)\,\eta_{\lambda_0}^{(+)}(y,E_n)^2 dy\right) dx. \tag{2.77}$$

Here $h_{\lambda_0}(x,E_n)$ is any solution of $H_{\lambda_0}\psi = E_n\psi$ such that $[\eta_{\lambda_0}(\cdot,E_n); h_{\lambda_0}(\cdot,E_n)]=1$. This concludes our discussion of Case 2.

The expressions on the right-hand sides of (2.63) and (2.74) can be written in a common form that involves an arbitrary bounded, nontrivial solution $\tilde{\psi}_{\lambda_0}(x,E_n)$ of $H_{\lambda_0}\psi = E_n\psi$. If $\phi_0(p,E_n) \neq 0$, we have that $\tilde{\psi}_{\lambda_0}(x,E_n) = \tilde{\psi}_{\pm}\psi_0^{(\pm)}(x,E_n) + o(1)$ as $x \to \pm\infty$ for some nonzero constants $\tilde{\psi}_{\pm}$. Similarly, if $\phi_0(p,E_n)=0$, since $\tilde{\psi}_{\lambda_0}(x,E_n)$ is a multiple of $\eta_{\lambda_0}^{(+)}(x,E_n)$, there are constants $\tilde{\psi}_{\pm}$ such that $\tilde{\psi}_{\lambda_0}(x,E_n) = \tilde{\psi}_{\pm}\phi_0(x,E_n) + o(1)$ as $x \to \pm\infty$. If $\phi_0(p,E_n) \neq 0$, it follows that

$$\nu_n I_{\lambda_0,0}(E_n), \text{ resp. } \tilde{\nu}_n \tilde{I}_{\lambda_0,0}(E_n) = \frac{|\phi_0(p,E_n)|}{\sqrt{2|\Delta'(E_n)|}}\left[\frac{\int_{-\infty}^{\infty} W(x)\tilde{\psi}_{\lambda_0}(x,E_n)^2 dx}{\tilde{\psi}_+^2 + \tilde{\psi}_-^2}\right], \tag{2.78}$$

and, if $\phi_0(p,E_n)=0$, then

$$\kappa_n J_{\lambda_0,0}(E_n) = \frac{|\theta_0'(p,E_n)|}{\sqrt{2|\Delta'(E_n)|}}\left[\frac{\int_{-\infty}^{\infty} W(x)\tilde{\psi}_{\lambda_0}(x,E_n)^2 dx}{\tilde{\psi}_+^2 + \tilde{\psi}_-^2}\right]. \tag{2.79}$$

When $\lambda_0=0$, the right-hand sides of (2.78) and (2.79) can be expressed in yet another form, one that involves the effective mass. Recall [see Ref. 27 and (2.8)] that at the endpoint E_n the effective mass m_n^* is given by

$$m_n^* = \frac{|\Delta'(E_n)|}{p^2}. \tag{2.80}$$

Furthermore, as a consequence of the variation of constants formula [see (2.3.7) and (2.3.9) in Ref. 28] we have

$$\Delta'(E_n) = \begin{cases} -\dfrac{1}{2}\,\phi_0(p,E_n)\displaystyle\int_0^p \psi_0^{(+)}(x,E_n)^2 dx, & \phi_0(p,E_n)\neq 0, \\ \dfrac{1}{2}\,\theta_0'(p,E_n)\displaystyle\int_0^p \phi_0(x,E_n)^2 dx, & \phi_0(p,E_n)=0 \end{cases}. \tag{2.81}$$

If $\lambda_0=0$, then $\tilde{\psi}_0(x,E_n) = \tilde{\psi}_+\psi_0^{(+)}(x,E_n)$ [resp., $\tilde{\psi}_0(x,E_n) = \tilde{\psi}_+\phi_0^{(+)}(x,E_n)$] and $\tilde{\psi}_+ = \tilde{\psi}_-$. Therefore, from (2.78)–(2.81) it follows that

$$\nu_n I_{0,0}(E_n), \ \tilde{\nu}_n \tilde{I}_{0,0}(E_n), \text{ resp. } \kappa_n J_{0,0}(E_n) = \frac{\sqrt{m_n^*}\,p}{\sqrt{2}}\left[\frac{\int_{-\infty}^{\infty} W(x)\tilde{\psi}_0(x,E_n)^2 dx}{\int_0^p \tilde{\psi}_0(x,E_n)^2 dx}\right].$$

In the next theorem we specialize some of the results contained in Lemma 2.10, Theorem 2.11, and Theorem 2.12 to the situations described in Cases 1 and 2. We confine ourselves to the cases $M=0$ and $M=1$ [cf. (2.54)], where, in the present context, the case $M=0$ corresponds to either $\tilde{I}_{\lambda_0,0}(E_n)\neq 0$ or $J_{\lambda_0,0}(E_n)\neq 0$, and the case $M=1$ corresponds to either $\tilde{I}_{\lambda_0,0}(E_n)=0$ and $\tilde{I}_{\lambda_0,1}(E_n)\neq 0$, or $J_{\lambda_0,0}(E_n)=0$ and $J_{\lambda_0,1}(E_n)\neq 0$.

Theorem 2.14: Assume (H1), $W\neq 0$, and $\lambda\geqslant 0$.

(i) If $F^{(\pm)}_{\lambda_0}(0,E_0)=0$, then $\lambda_0>0$, $\tilde{I}_{\lambda_0,0}(E_0)<0$, and there exists a unique eigenvalue obeying

$$\sqrt{E_0-E(\lambda)}=-\tilde{\nu}_0\tilde{I}_{\lambda_0,0}(E_0)(\lambda-\lambda_0)+o(\lambda-\lambda_0),\quad \lambda\downarrow\lambda_0. \tag{2.82}$$

(ii) Suppose that either $\phi_0(p,E_n)\neq 0$, $n\geqslant 1$, $\lambda_0>0$, and $F^{(\pm)}_{\lambda_0}(0,E_n)=0$, or $\phi_0(p,E_n)=0$ and λ_0 is an exceptional value. Also assume (H2) if $M=1$. If $M=0$ or 1, then Theorem 2.12 applies with $I_{\lambda_0,M}(E_n)$ replaced by $\tilde{I}_{\lambda_0,M}(E_n)$ [resp., $J_{\lambda_0,M}(E_n)$], and the constants ν_n replaced by $\tilde{\nu}_n$ (resp., κ_n).

(iii) $\lambda_0>0$ is a c.c.th. at E_0 if and only if λ_0 is an exceptional value. If $\lambda_0>0$ is a c.c.th. at E_n with $n\geqslant 1$, then λ_0 is an exceptional value.

Proof: (i) Since $F^{(\pm)}_0(0,E_0)=1$, it follows that $\lambda_0>0$ and that λ_0 is an exceptional value. The rest follows from Lemma 2.10(i) and Theorem 2.11(ii) by applying a shift and using (2.63). (ii) follows from Theorem 2.12, along with (2.63), (2.67), (2.74), and (2.76). The assertion in (iii) concerning E_0 is a direct consequence of Theorems 2.8 and 2.11, and, in Case 1, of (i) and (ii). The statement concerning E_n with $n\geqslant 1$ has been proved in Theorem 2.8 when $\phi_0(p,E_n)\neq 0$ and $F^{(\pm)}_{\lambda_0}(0,E_n)\neq 0$. If one of these restrictions is dropped, then the result follows by using a shift as above and following the proof of Theorem 2.8. Note that the Wronskian $[F^{(+)}_{\lambda_0}(\cdot,E_n;b);\ F^{(-)}_{\lambda_0}(\cdot,E_n;b)]$ is independent of b by (2.60) and (2.72). ■

We remark that there are connections between some of our results concerning eigenvalue absorption at E_0 and earlier work by Gesztesy and Zhao.[29] In Ref. 29 the concepts of criticality, subcriticality, and supercriticality were defined for general second order linear differential operators. Without going into details, we note that in our context H_λ is critical if and only if $\lambda=0$ or $\lambda=\lambda_{0,\min}$, where $\lambda_{0,\min}=\min\{\lambda_0:\lambda_0$ is a c.c.th. at $E_0\}$. Moreover, assuming $\lambda_{0,\min}>0$, H_λ is subcritical if $0<\lambda<\lambda_{0,\min}$ and supercritical if $\lambda>\lambda_{0,\min}$. This follows (after some arguments) from Lemma 2.10 and Theorems 2.11 and 2.14 here, and Definition 3.2 and Theorem 3.6 in Ref. 29. Also, Lemma 3.18 in Ref. 29 and our Lemma 2.10(i) correspond to each other (ignoring the differences in the assumptions on V).

One may ask whether Lemma 2.10, Theorem 2.11, and Theorem 2.14 [(i) and (iii)] can be extended to endpoints other than E_0. It turns out that for compactly supported W, under some further assumptions on the location of the support of W relative to the zeros of the bounded (nontrivial) solution of $H_0\psi=E_n\psi$, this is possible. The fact that zeros of solutions play a role in threshold problems has been noted earlier (see Ref. 10, Theorem 3.2) and in a related context in Ref. 30 (Theorem 8.2).

Note that when $n\geqslant 1$, then any nontrivial solution of $H_0\psi=E_n\psi$ has infinitely many zeros. If $\phi_0(p,E_n)\neq 0$, let ζ_k, $k\in\mathbf{Z}$, denote the zeros of $\psi^{(+)}_0(x,E_n)$ arranged in ascending order, i.e., $\cdots<\zeta_{-1}<\zeta_0<\zeta_1<\cdots$. Similarly, if $\phi_0(p,E_n)=0$, let η_k denote the zeros of $\phi_0(x,E_n)$ arranged in ascending order.

Lemma 2.15: Assume (H1), $W\neq 0$, and $n\geqslant 1$. Let $\lambda_0\geqslant 0$ be an exceptional value at the endpoint E_n.

(i) Suppose $\phi_0(p,E_n)\neq 0$, $\lambda_0>0$, and supp $W\subset[\zeta_k,\zeta_{k+1}]$ for some fixed $k\in\mathbf{Z}$. Then $I_{\lambda_0,0}(E_n)<0$ [resp., $\tilde{I}_{\lambda_0,0}(E_n)<0$ if $F^{(\pm)}_{\lambda_0}(0,E_n)=0$]. If $\phi_0(p,E_n)=0$ and supp $W\subset[\eta_k,\eta_{k+1}]$ for some fixed $k\in\mathbf{Z}$, then $J_{\lambda_0,0}(E_n)<0$.

(ii) Suppose that $\lambda_0=0$. If $\phi_0(p,E_n)\neq 0$ and

$$\int_{\zeta_k}^{\zeta_{k+1}} W(x)\,\psi^{(+)}_0(x,E_n)^2\,dx=0, \tag{2.83}$$

for all $k \in \mathbf{Z}$, then $I_{0,0}(E_n)=0$ and $I_{0,1}(E_n)>0$.

If $\phi_0(p,E_n)=0$ and

$$\int_{\eta_k}^{\eta_{k+1}} W(x)\,\phi_0(x,E_n)^2 dx=0,$$

for all $k \in \mathbf{Z}$, then $J_{0,0}(E_n)=0$ and $J_{0,1}(E_n)>0$.

Proof: (i) If $\phi_0(p,E_n)\neq 0$, we can mimic the proof of Lemma 2.10(i) except that the relevant integrals now only involve $x \in [\zeta_k,\zeta_{k+1}]$. As in (2.47) and (2.49) we now get

$$\int_{\zeta_k}^{\zeta_{k+1}} W(x) F_{\lambda_0}^{(+)}(x,E_n)^2 dx<0,$$

so that $I_{\lambda_0,0}(E_n)<0$, resp., $\widetilde{I}_{\lambda_0,0}(E_n)<0$ [see (2.62) and (2.64)]. When $\phi_0(p,E_n)=0$, we use (2.71), the relation $[\theta_0(x,E_n)/\phi_0(x,E_n)]'=-1/\phi_0(x,E_n)^2$, and the analog of Lemma 2.2, namely, the fact that

$$\int_{\eta_k}^{\eta_{k+1}} \phi_0(x,E_n)\,W(x)\,\eta_{\lambda_0}^{(+)}(x,E_n)dx=0,$$

to derive

$$J_{\lambda_0,0}(E_n)=-\lambda_0\int_{\eta_k}^{\eta_{k+1}} \frac{1}{\phi_0(x,E_n)^2}\left(\int_x^{\eta_{k+1}} \phi_0(y,E_n)\,W(y)\,\eta_{\lambda_0}^{(+)}(y,E_n)dy\right)^2 dx<0.$$

This proves (i). Considering (ii), it is obvious by summing over all intervals $[\zeta_k,\zeta_{k+1}]$ that $I_{0,0}(E_n)=0$ [resp., $J_{0,0}(E_n)=0$]. If $\phi_0(p,E_n)\neq 0$ and (2.83) holds, then (2.49) becomes

$$I_{0,1}(E_n)=2\sum_{k\in\mathbf{Z}}\int_{\zeta_k}^{\zeta_{k+1}} W(x)\,\psi_0^{(+)}(x,E_n)\,\phi_0(x,E_n)\left(\int_x^{\zeta_{k+1}} W(y)\,\psi_0^{(+)}(y,E_n)^2 dy\right)dx.$$

Using $[\phi_0(x,E_n)/\psi_0^{(+)}(x,E_n)]'=1/\psi_0^{(+)}(x,E_n)^2$ on each interval $[\zeta_k,\zeta_{k+1}]$, along with an integration by parts, we obtain

$$I_{0,1}(E_n)=\sum_{k\in\mathbf{Z}}\int_{\zeta_k}^{\zeta_{k+1}} \frac{1}{\psi_0^{(+)}(x,E_n)^2}\left(\int_x^{\zeta_{k+1}} W(y)\,\psi_0^{(+)}(y,E_n)^2 dy\right)^2 dx>0. \quad \blacksquare$$

If $\phi_0(p,E_n)=0$, then we argue similarly by using (2.77) with $\lambda_0=0$, $\eta_0^{(+)}(x,E_n)=\phi_0(x,E_n)$, and $[h_0(x,E_n)/\phi_0(x,E_n)]'=1/\phi_0(x,E_n)^2$; thus $J_{0,1}(E_n)>0$. $\blacksquare$

Theorem 2.16: Suppose supp $W\subset[\zeta_k,\zeta_{k+1}]$, resp., supp $W\subset[\eta_k,\eta_{k+1}]$ if $\phi_0(p,E_n)=0$, for some $k \in \mathbf{Z}$ and $W\neq 0$. Then the following holds:

(i) $\lambda_0>0$ is a c.c.th. at E_n if and only if λ_0 is an exceptional value. Then $I_{\lambda_0,0}(E_n)<0$ [resp., $\widetilde{I}_{\lambda_0,0}(E_n)<0$, resp., $J_{\lambda_0,0}(E_n)<0$] and the corresponding eigenvalue obeys (2.55) as $\lambda\uparrow\lambda_0$, with $M=0$, if n is odd, and it obeys (2.57) as $\lambda\downarrow\lambda_0$, with $M=0$, if n is even.

(ii) If n is even, then $\lambda_0=0$ is a c.c.th. at E_n if and only if $I_{0,0}(E_n)\leqslant 0$ [resp., $J_{0,0}(E_n)\leqslant 0$]. The corresponding eigenvalue obeys (2.57) as $\lambda\downarrow\lambda_0$, with $M=0$, if $I_{0,0}(E_n)<0$, and it obeys (2.58) as $\lambda\downarrow\lambda_0$ and $\lambda\uparrow\lambda_0$, with $M=1$, if $I_{0,0}(E_n)=0$.

(iii) If n is odd, then $\lambda_0=0$ is a c.c.th. at E_n if and only if $I_{0,0}(E_n)>0$ [resp., $J_{0,0}(E_n)>0$]. The corresponding eigenvalue obeys (2.55) as $\lambda\downarrow\lambda_0$, with $M=0$.

Proof: (i) If $n=0$, then the result has already been established in Theorem 2.14(iii) together with Theorem 2.11(ii) and Theorem 2.14(i). If $n\geqslant 1$ and $\lambda_0>0$ is a c.c.th., then Theorem 2.14(iii) implies that λ_0 is an exceptional value. The converse follows from Lemma 2.15(i), Theorem 2.14(ii), and parts (i) and (iv) of Theorem 2.12. Note that Lemma 2.15(i) implies $I_{\lambda_0,0}(E_n)<0$ [resp., $\widetilde{I}_{\lambda_0,0}(E_n)<0$, resp., $J_{\lambda_0,0}(E_n)<0$], and so $M=0$. This proves (i). To prove (ii), suppose that $\lambda_0=0$ is a c.c.th. and that $I_{0,0}(E_n)>0$ [resp., $J_{0,0}(E_n)>0$]. Then, by Theorem 2.12(iv), an eigen-

value converging to E_n as $\lambda \downarrow 0$ cannot exist. Hence $I_{0,0}(E_n) \leqslant 0$ [resp., $J_{0,0}(E_n) \leqslant 0$]. The converse follows from Theorem 2.12(iv) if $I_{0,0}(E_n) < 0$ [resp., $J_{0,0}(E_n) < 0$], and from Lemma 2.15(ii) combined with Theorem 2.12(v) if $I_{0,0}(E_n) = 0$ [resp., $J_{0,0}(E_n) = 0$]. In (iii), if $I_{0,0}(E_n) > 0$ [resp., $J_{0,0}(E_n) > 0$], then $\lambda_0 = 0$ is a c.c.th. by Theorem 2.12(i). Conversely, if $\lambda_0 = 0$ is a c.c.th., then necessarily $I_{0,0}(E_n) \geqslant 0$ [resp., $J_{0,0}(E_n) \geqslant 0$]. However, if $I_{0,0}(E_n) = 0$ [resp., $J_{0,0}(E_n) = 0$], then Lemma 2.15(ii) implies that we are in case (iii) of Theorem 2.12 with $M = 1$. Hence $\lambda_0 = 0$ is not a c.c.th. This is a contradiction and thus $I_{0,0}(E_n) > 0$ [resp., $J_{0,0}(E_n) > 0$]. ■

Theorem 2.16(i) implies that, under the stated restrictions on the support of W, at the right endpoint of a gap an eigenvalue can only appear as $\lambda \uparrow \lambda_0 + \epsilon$; it cannot get absorbed as $\lambda \uparrow \lambda_0$. Similarly, at the left endpoint an eigenvalue can only get absorbed as $\lambda \uparrow \lambda_0$; there is no eigenvalue near the endpoint for λ slightly larger than λ_0.

Note that the points ζ_k (resp., η_k) are the zeros of the unique (up to constant multiples) bounded, nontrivial solution of $H_0\psi = E_n\psi$. Let $\tilde{\psi}_0(x, E_n)$ denote any such solution. It turns out that if we assume W to be non-negative, then the results of Theorem 2.16 can be strengthened as follows.

Theorem 2.17: Suppose that the support of W lies between two consecutive zeros of $\tilde{\psi}_0(x, E_n)$ and that $W \geqslant 0$ $(W \neq 0)$. If n is even, then there are no c.c.th.'s at E_n. If n is odd, then $\lambda_0 = 0$ is the only c.c.th. at E_n.

Proof: For any c.c.th. $\lambda_0 \geqslant 0$ we have $I_{\lambda_0,0}(E_n) > 0$ [resp., $\tilde{I}_{\lambda_0,0}(E_n) > 0$, resp., $J_{\lambda_0,0}(E_n) > 0$], by (2.45), (2.64), (2.75), and the assumption on W. Now the assertions follow from Theorem 2.16. ■

The final theorem of this section tells us what happens if W satisfies the support condition of Theorem 2.17 at both endpoints of a gap.

Theorem 2.18: Suppose that at each endpoint of the gap (E_n, E_{n+1}) (n odd) the support of W satisfies the condition of Theorem 2.17, and that $W \geqslant 0$ $(W \neq 0)$. Then there is a unique eigenvalue $E(\lambda)$ such that $\lim_{\lambda \downarrow 0} E(\lambda) = E_n$, $E(\lambda)$ is strictly increasing for $\lambda > 0$, $\lim_{\lambda \uparrow \infty} E(\lambda) = E_\infty$ exists, and $E_\infty \in (E_n, E_{n+1}]$.

Proof: By Theorem 2.17, $\lambda_0 = 0$ is the only c.c.th. at E_n. Moreover, by perturbation theory, since W is non-negative (and nontrivial), $E'(\lambda) > 0$ for $\lambda > 0$. Furthermore, the eigenvalue cannot get absorbed at E_{n+1} by Theorem 2.17. Thus $E(\lambda)$ has to converge to a limit as $\lambda \to +\infty$, and this limit must lie in $(E_n, E_{n+1}]$ (it may be the point E_{n+1}). ■

Theorem 2.18 describes the situation where an eigenvalue $E(\lambda)$ is ''trapped.'' The trapping phenomenon has been discussed in detail, and in greater generality, in Ref. 13. There, an interpretation of E_∞ as a Dirichlet eigenvalue of H_0 on $\mathbf{R} \backslash \operatorname{supp} W$ was given. Theorems 2.17 and 2.18 also fit together with more general results obtained in Ref. 11 (see, e.g., Corollary 3.2) which, in the present context, imply that the number of c.c.th.'s at a left endpoint of a gap is always finite, provided W has compact support and is non-negative. Some further results along these lines will appear elsewhere.

III. ONE DIMENSION: FURTHER RESULTS AND SPECIAL CASES

In this section we discuss some special aspects of the results of Section II and we establish the connection with related results that have appeared in the literature.

In Lemma 2.10(ii) and Lemma 2.15(ii), we were able to conclude that $I_{\lambda_0,1}(E_n) > 0$ provided that $I_{\lambda_0,0}(E_n) = 0$. So it is natural to ask whether it is possible that $I_{\lambda_0,0}(E_n) = I_{\lambda_0,1}(E_n) = 0$ ($W \neq 0$, of course). As the following example shows the answer is in the affirmative, at least when $\lambda_0 = 0$. We give the construction for the case when $\phi_0(p, E_n) \neq 0$, but it will be obvious that similar examples can be constructed if $\phi_0(p, E_n) = 0$, showing that $J_{0,0}(E_n) = J_{0,1}(E_n) = 0$ is possible. The construction of an example with $\lambda_0 > 0$ will not be attempted here. Suppose that V is even and W is odd. Then $\psi_0^{(+)}(x, E_n)$ is even, in fact $\psi_0^{(+)}(x, E_n) = \theta_0(x, E_n)$, $\phi_0(x, E_n)$ is odd, and hence $I_{0,0}(E_n) = 0$ by symmetry and (2.45). Furthermore, symmetry implies that $I_{0,j}(E_n) = 0$ for j even. Consider now a specific W of the form

$$W(x)=\begin{cases}1, & x\in[c,c+\epsilon],\\ -1, & x\in[-c-\epsilon,-c],\\ 0, & \text{otherwise},\end{cases}$$

where $c>0$ and $\epsilon>0$ are parameters. The function $h(x)=\int_x^\infty W(y)\psi_0^{(+)}(y,E_n)^2dy$ is even and non-negative. Hence, by symmetry, we can write (2.49) as

$$I_{0,1}(E_n)=4\int_c^{c+\epsilon}W(x)\psi_0^{(+)}(x,E_n)\phi_0(x,E_n)\left(\int_x^{c+\epsilon}W(y)\psi_0^{(+)}(y,E_n)^2dy\right)dx. \tag{3.1}$$

Now let ζ_1 denote the smallest positive zero of $\psi_0^{(+)}(x,E_n)$ and let η_1 denote the smallest positive zero of $\phi_0(x,E_n)$. Then $\zeta_1<\eta_1$ by the interlacing property of zeros. On $(0,\zeta_1)$ we have $\psi_0^{(+)}(x,E_n)>0$ and $\phi_0(x,E_n)>0$, and on (ζ_1,η_1) we have $\psi_0^{(+)}(x,E_n)<0$ and $\phi_0(x,E_n)>0$. Let $\epsilon<\min\{\zeta_1/2,(\eta_1-\zeta_1)/2\}$ and choose $c=\zeta_1/2$. Then $I_{0,1}(E_n)>0$. On the other hand, choosing $c=(\zeta_1+\eta_1)/2$ we get $I_{0,1}(E_n)<0$. So if we vary c from $\zeta_1/2$ to $(\zeta_1+\eta_1)/2$, then there exists a value c for which $I_{0,1}(E_n)=0$. Hence $I_{0,0}(E_n)=I_{0,1}(E_n)=0$ for this value of c. From the above argument we also see that for every sufficiently small $\epsilon>0$ there is a $c=c(\epsilon)$ such that $I_{0,1}(E_n)=0$ and that $c(\epsilon)\to\zeta_1$ as $\epsilon\to0$. The asymptotic behavior of the function $c(\epsilon)$ as $\epsilon\to0$ can be obtained by expanding the right-hand side of (3.1) in powers of ϵ and $c-\zeta_1$ using the approximations $\psi_0^{(+)}(x,E_n)=\psi_0^{(+)'}(\zeta_1,E_n)(x-\zeta_1)+o(x-\zeta_1)$ and $\phi_0(x,E_n)=\phi_0(\zeta_1,E_n)+o(1)$, and setting $I_{0,1}(E_n)=0$. Introducing variables r and φ such that $c-\zeta_1=r\cos\varphi$ and $\epsilon=r\sin\varphi$, it follows that

$$I_{0,1}(E_n)=\frac{[\psi_0^{(+)'}(\zeta_1,E_n)]^3\phi_0(\zeta_1,E_n)}{15}\cdot r^5f(\varphi)\sin^2\varphi+o(r^5),$$

$$f(\varphi)=30\cos\varphi+17\sin\varphi+11\sin3\varphi.$$

The relevant zero of $f(\varphi)$ is $\varphi_0=1.96784...$ which gives $c(\epsilon)=\zeta_1+\epsilon\cot\varphi_0+o(\epsilon)$, where $\cot\varphi_0=-0.41932...$. So $c(\epsilon)<\zeta_1$ and $c(\epsilon)+\epsilon>\zeta_1$ as it should be, since the support of W must contain the point ζ_1 in its interior. We have already mentioned that $I_{0,2}(E_n)=0$ by symmetry. We want to show that $I_{0,3}(E_n)<0$ for ϵ small and $c=c(\epsilon)$. This follows by writing

$$I_{0,3}(E_n)=4\int_c^{c+\epsilon}\phi_0(x,E_n)u(x,E_n)\left(\int_x^{c+\epsilon}\psi_0^{(+)}(y,E_n)u(y,E_n)dy\right)dx,$$

where $u(x,E_n)=[G_0^DW\psi_0^{(+)}](x,E_n)$, and expanding the right-hand side as in the case of $I_{0,1}(E_n)$. The result is

$$I_{0,3}(E_n)=\frac{[\psi_0^{(+)'}(\zeta_1,E_n)]^5\phi_0(\zeta_1,E_n)^3}{11340}\cdot r^9g(\varphi)\sin^4\varphi+o(r^9),$$

$$g(\varphi)=26838\cos\varphi-1386\cos3\varphi-2772\cos5\varphi+16556\sin\varphi+15383\sin3\varphi+1067\sin5\varphi.$$

Since $g(\varphi_0)=9.31172...>0$, $\psi_0^{(+)'}(\zeta_1,E_n)<0$, and $\phi_0(\zeta_1,E_n)>0$, we conclude that $I_{0,3}(E_n)<0$ for small enough r, resp., small enough $\epsilon(r,\epsilon>0)$. By Theorem 2.12, if n is odd, then there is an eigenvalue obeying (2.56) with $\lambda_0=0$ and $M=3$, i.e., $\sqrt{E(\lambda)-E_n}=-\nu_nI_{0,3}(E_n)\lambda^4+o(\lambda^4)$ as $\lambda\downarrow0$. On the other hand, if n is even, then case (vi) of Theorem 2.12 occurs and there is no eigenvalue approaching zero as $\lambda_0\downarrow0$ (or as $\lambda_0\uparrow0$).

Next we specialize Theorems 2.11 and 2.12 and compare them with some known results in the literature. Suppose that $V\neq0$, so that $E_0=0$ and $[0,\infty)$ is the only band. If (H1) holds and $\int_{-\infty}^\infty W(x)dx\leqslant0$, then $\lambda_0=0$ is a c.c.th. and (2.51) reduces to

$$\sqrt{-E(\lambda)}=-\frac{\lambda}{2}\int_{-\infty}^\infty W(x)dx-\frac{\lambda^2}{4}\int_{-\infty}^\infty W(x)|x-y|W(y)dxdy+o(\lambda^2),\quad \lambda\downarrow0, \tag{3.2}$$

which is a well-known result.[1,4,5] If $\lambda_0>0$, we can compare our results with a result in Ref. 10 (Theorem 3.2), although the operators considered there were of a somewhat different form, namely, $-d^2/dx^2+V+\lambda W$ with $V,W\in C_0^\infty(\mathbf{R})$, and the method used there was also different. For simplicity we set $V=0$ and assume that $\lambda_0>0$ is a c.c.th. for $H_\lambda=-d^2/dx^2+\lambda W$ at $E_0=0$. In accordance with the notation established above (2.78), we let $\tilde{\psi}_{\lambda_0}(x,0)$ be any bounded nontrivial solution of $H_{\lambda_0}\psi=0$. Then the limits $\lim_{x\to\pm\infty}\tilde{\psi}_{\lambda_0}(x,0)=\tilde{\psi}_\pm$ exist and are nonzero. Using (2.78) and the appropriate expansion for $E(\lambda)$ [(2.52), (2.82), or Theorem 2.14(ii)] gives

$$E(\lambda)=-\left[\frac{\int_{-\infty}^{\infty}W(x)\tilde{\psi}_{\lambda_0}(x,0)^2dx}{\tilde{\psi}_+^2+\tilde{\psi}_-^2}\right]^2(\lambda-\lambda_0)^2+o([\lambda-\lambda_0]^2),\quad \lambda\downarrow\lambda_0. \tag{3.3}$$

This result agrees with (3.8) in Ref. 10. Furthermore, (3.3) is easily extended to the case $V\neq 0$ with V and W obeying (2.1) and (H1), respectively. The problem where $V(x)=l_\pm/x^2$ for large $\pm x$, with constants $l_\pm$, was studied recently by Engländer and Pinsky.[31]

Our results extend to the case when V and W contain delta functions. To be specific, suppose that $W(x)=\pm\delta(x-x_0)$ and that V still obeys (2.1). We show how this example fits into the context of the present paper. We give details only for the case $W(x)=+\delta(x-x_0)$. Suppose that E is an eigenvalue of H_λ in a certain gap with eigenfunction $\tilde{\psi}_\lambda(x,E)$. Then we can assume that $\tilde{\psi}_\lambda(x,E)=\psi_0^{(+)}(x,E)$ for $x>x_0$ and $\tilde{\psi}_\lambda(x,E)=c\,\psi_0^{(-)}(x,E_n)$ for $x<x_0$ with some constant c. At x_0, the following matching conditions are satisfied:

$$\psi_0^{(+)}(x_0,E)=c\,\psi_0^{(-)}(x_0,E),\quad \psi_0^{(+)'}(x_0,E)-c\,\psi_0^{(-)'}(x_0,E)=\lambda\,\psi_0^{(+)}(x_0,E). \tag{3.4}$$

It is immediately clear that E can be an eigenvalue only when $\psi_0^{(\pm)}(x_0,E)\neq 0$. The equation determining the eigenvalues follows from (3.4) and (2.29):

$$\lambda\,\psi_0^{(+)}(x_0,E)\,\psi_0^{(-)}(x_0,E)=-\frac{1}{d_0(E)}. \tag{3.5}$$

This equation is equivalent to (2.33) with $\lambda_0=0$ as can be seen by inserting W in (2.44) which gives

$$I_{0,j}(E)=\begin{cases}\phi_0(x_0,E)^j\psi_0^{(+)}(x_0,E)^{j+2}, & x_0\geqslant 0,\\ (-1)^j\phi_0(x_0,E)^j\psi_0^{(-)}(x_0,E)^{j+2}, & x_0<0.\end{cases} \tag{3.6}$$

Summing the geometric series in (2.33) yields

$$\frac{\lambda\,\psi_0^{(+)}(x_0,E)^2}{1+\lambda\,\phi_0(x_0,E)\,\psi_0^{(+)}(x_0,E)}=-\frac{1}{d_0(E)},\quad x_0\geqslant 0, \tag{3.7}$$

$$\frac{\lambda\,\psi_0^{(-)}(x_0,E)^2}{1-\lambda\,\phi_0(x_0,E)\,\psi_0^{(-)}(x_0,E)}=-\frac{1}{d_0(E)},\quad x_0<0. \tag{3.8}$$

With the help of (A1) (see the Appendix) it is easy to see that (3.7) and (3.8) are equivalent to (3.5). If $\phi_0(p,E_n)\neq 0$ and λ_0 is a c.c.th., then from (2.3), (2.38), and (3.5) we conclude that $\lambda_0\psi_0^{(+)}(x_0,E_n)^2=0$, so $\lambda_0=0$ or $\psi_0^{(+)}(x_0,E_n)=0$. In the latter case we have $\psi_0^{(\pm)}(x_0,E)=O(\mu)$ as $E\to E_n$. So, in view of (2.38) this means that in the limit $\mu\to 0$ the two sides of (3.5) are incompatible regardless of what c.c.th. λ is converging to. Thus, if $\psi_0^{(+)}(x_0,E_n)=0$, then (3.5) has no solution $E(\lambda)$ such that $E(\lambda)\to E_n$ and so there are no c.c.th.'s in this case. This is in agreement with case (v) of Lemma 2.6, since then, by (3.6), $I_{0,j}(E_n)=0$ for all j. If $\psi_0^{(+)}(x_0,E_n)\neq 0$, then $\lambda_0=0$ is the only c.c.th. Further analysis then shows that n has to be odd, which is in agreement with the fact that W is non-negative, and that (2.55) applies with $M=0$ and $I_{0,0}(E_n)=\psi_0^{(+)}(x_0,E_n)^2$. The case $\phi_0(p,E_n)=0$ and $\psi_0^{(+)}(x_0,E_n)=0$, can be handled similarly, or by a shift as in Section II. The result is that $\lambda_0=0$ is the sole c.c.th. provided $\phi_0(x_0,E_n)\neq 0$ and n is odd. Then Theorem 2.14(ii) applies. In sum we see that at E_n with n odd an eigenvalue

enters the gap as $\lambda \uparrow \lambda + \epsilon$ if and only if x_0 does not coincide with a zero of the bounded solution of $H_0\psi = E_n\psi$. An analogous result holds when $W(x) = -\delta(x - x_0)$ and n is even. Without going into detail we mention that the above results can be further specialized by taking H_0 to be a Kronig-Penney Hamiltonian of the form $V(x) = \Sigma_{m=-\infty}^{\infty} \delta(x - [2m-1]a)$, with $a > 0$, so that $p = 2a$. The reader is referred to Ref. 32 for detailed information about such Hamiltonians. Theorems 2.6.4–2.6.6 (Section III.2.6) of Ref. 32 deal with the existence of eigenvalues when W represents a substitutional or interstitial delta-type impurity and those results are direct consequences of the results presented above.

IV. TWO DIMENSIONS

In two dimensions we assume that V is given by

$$V(x) = V^{(1)}(x_1) + V^{(2)}(x_2), \quad x = (x_1, x_2), \tag{4.1}$$

with $V^{(j)}$ real-valued, $V^{(j)} \in L^1_{loc}(\mathbf{R})$, and

$$V^{(j)}(x_j + p_j) = V^{(j)}(x_j), \quad p_j > 0, \quad j = 1,2. \tag{4.2}$$

Moreover, W is real-valued and satisfies

$$\int_{\mathbf{R}^2} |W(x)|^{1+\gamma} d^2x < \infty, \quad \int_{\mathbf{R}^2} |W(x)|(1+|x|)^{\gamma} d^2x < \infty, \tag{4.3}$$

for some $\gamma > 0$. Here and below the symbol $|\ |$ denotes the Euclidean norm in $\mathbf{R}^{\nu}$. The assumptions (4.1)–(4.2) guarantee that V is relatively $-\Delta$-form bounded with relative bound zero so that $H_0 = -\Delta + V$ can be defined by the method of forms. This follows from the corresponding one-dimensional result. Alternatively, H_0 is the unique self-adjoint extension of the minimal operator $H_{0,\min} = H^{(1)}_{0,\min} \otimes \mathbf{I} + \mathbf{I} \otimes H^{(2)}_{0,\min}$, where $H^{(j)}_{0,\min}$ is the minimal operator associated with the one-dimensional operator,

$$H_0^{(j)} = -\frac{d^2}{dx_j^2} + V^{(j)}(x_j),$$

on $L^2(\mathbf{R})$. Since each $H^{(j)}_{0,\min}$ is essentially self-adjoint, $H_{0,\min}$ is also essentially self-adjoint (Ref. 33, Theorem 8.33), and so $H_0 = \overline{H_{0,\min}}$. The conditions (4.3) imply[1] that $|W|^{1/2}(-\Delta + 1)^{-1}|W|^{1/2}$ is Hilbert–Schmidt. Hence $|W|^{1/2}(-\Delta + 1)^{-1/2} \in \mathscr{T}_4$, where $\mathscr{T}_p$ $(1 \leqslant p \leqslant \infty)$ denotes the usual trace ideals.[34] Let $E < \inf\sigma(H_0)$. Since $(-\Delta + 1)^{1/2}(H_0 - E)^{-1/2}$ is bounded, we conclude that $|W|^{1/2}(H_0 - E)^{-1/2} = [|W|^{1/2}(-\Delta + 1)^{-1/2}][(-\Delta + 1)^{1/2}(H_0 - E)^{-1/2}] \in \mathscr{T}_4$. Thus $|W|^{1/2}(H_0 - E)^{-1}|W|^{1/2}$ is Hilbert–Schmidt, and so W is a relatively form compact perturbation of H_0.

The spectrum of H_0 coincides with the set

$$\bigcup_{n,m=0}^{\infty} \{E_n^{(1)}(\theta_1) + E_m^{(2)}(\theta_2) : \theta_1 \in [0,2\pi], \theta_2 \in [0,2\pi]\}, \tag{4.4}$$

where $E_n^{(j)}(\theta_j)$, $n = 0,1,2,...$, are the eigenvalues, arranged in increasing order, of the spectral problem

$$\begin{gathered} H_0^{(j)}(\theta_j)\phi = \left[-\frac{d^2}{dx_j^2} + V^{(j)}(x_j)\right]\phi = E\phi, \quad j = 1,2, \\ \phi(p_j) = e^{i\theta_j}\phi(0), \quad \phi'(p_j) = e^{i\theta_j}\phi'(0), \quad \theta_j \in [0,2\pi]. \end{gathered} \tag{4.5}$$

The spectrum of $H_0^{(j)}$ consists of the bands $[E_0^{(j)}(0), E_0^{(j)}(\pi)]$, $[E_1^{(j)}(\pi), E_1^{(j)}(0)]$, etc. The sums $E_n^{(1)}(\theta_1) + E_m^{(2)}(\theta_2)$ $(n,m = 0,1,...)$ are the eigenvalues of the closure of the operator $H_0^{(1)}(\theta_1) \otimes \mathbf{I} + \mathbf{I} \otimes H_0^{(2)}(\theta_2)$, and the corresponding normalized eigenfunctions are products of the form

$\psi_n^{(1)}(x_1,\theta_1)\psi_m^{(2)}(x_2,\theta_2)$, where $\psi_n^{(j)}(x_j,\theta_j)$ is the normalized eigenfunction for the eigenvalue problem (4.5). We extend these eigenfunctions to all of $\mathbf{R}$ by using the boundary conditions in (4.5). We also note that

$$\psi_n^{(j)}(x,\theta_j)=\overline{\psi_n^{(j)}(x,2\pi-\theta_j)}, \tag{4.6}$$

$$E_n^{(j)}(2\pi-\theta_j)=E_n^{(j)}(\theta_j), \tag{4.7}$$

and that for n even (resp., n odd) the functions $E_n^{(j)}(\theta_j)$ are strictly monotone increasing (resp., decreasing) on $[0,\pi]$ (Ref. 20, Theorem XIII.89). Moreover, near the edges of a gap in $\sigma(H_0^{(j)})$ we have [cf. (2.8)]

$$E_n^{(j)}(\theta_j)=E_n^{(j)}(0)+c_n^{(j)}\theta_j^2+O(\theta_j^4), \quad \theta_j\to 0, \tag{4.8}$$

$$E_n^{(j)}(\theta_j)=E_n^{(j)}(\pi)+d_n^{(j)}(\theta_j-\pi)^2+O([\theta_j-\pi]^4), \quad \theta_j\to\pi, \tag{4.9}$$

where $(-1)^n c_n^{(j)}>0$ and $(-1)^n d_n^{(j)}<0$. Without loss of generality we may assume that

$$E_0^{(1)}(0)=E_0^{(2)}(0)=0, \tag{4.10}$$

so that the first spectral band is given by $[0, E_0^{(1)}(\pi)+E_0^{(2)}(\pi)]$. We first consider absorption of an eigenvalue at the bottom of the spectrum, that is, at energy zero. For the Birman–Schwinger kernel we use $K_{0,E}$ as defined in (1.3), but to simplify the notation we omit the subscript 0 and just write K_E. For any interval Δ, let P^{Δ} denote the corresponding spectral projection for H_0. We first decompose K_E as follows: Pick $\delta>0$ and write

$$K_E=K_E^{[0,\delta]}+K_E^{(\delta,\infty)}, \tag{4.11}$$

where

$$K_E^{[0,\delta]}=W^{1/2}P^{[0,\delta]}(H_0-E)^{-1}P^{[0,\delta]}|W|^{1/2}, \tag{4.12}$$

$$K_E^{(\delta,\infty)}=W^{1/2}P^{(\delta,\infty)}(H_0-E)^{-1}P^{(\delta,\infty)}|W|^{1/2}. \tag{4.13}$$

Lemma 4.1: If $E<0$ and $\delta>0$, then $K_E^{(\delta,\infty)}$ is Hilbert–Schmidt and has an analytic continuation in the Hilbert–Schmidt norm to a complex neighborhood of $E=0$.

Proof: For $E<0$ write $K_E^{(\delta,\infty)}=ABC$ with $A=W^{1/2}(H_0+1)^{-1/2}$, $B=P^{(\delta,\infty)}(H_0+1)^{1/2}(H_0-E)^{-1}(H_0+1)^{1/2}P^{(\delta,\infty)}$, and $C=(H_0+1)^{-1/2}|W|^{1/2}$. Then A and C both lie in $\mathscr{T}_4$ and B is norm-analytic near $E=0$. Hence the product ABC is analytic in the Hilbert-Schmidt norm for E near 0. ∎

In order to analyze the operator $K_E^{[0,\delta]}$ in (4.12) we use the representation of Ref. 20 (see Theorem XIII.98) which allows us to express the integral kernel of $K_E^{[0,\delta]}$ as

$$K_E^{[0,\delta]}(x,y)=W(x)^{1/2}\int_{\mathscr{D}_\delta}\left[\frac{\psi_0^{(1)}(x_1,\theta_1)\psi_0^{(2)}(x_2,\theta_2)\overline{\psi_0^{(1)}(y_1,\theta_1)\psi_0^{(2)}(y_2,\theta_2)}}{E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E}\,\frac{d^2\theta}{(2\pi)^2}\right]|W(y)|^{1/2}, \tag{4.14}$$

where $\theta=(\theta_1,\theta_2)$ and

$$\mathscr{D}_\delta=\{\theta\in[0,2\pi]^2: E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)\leqslant\delta\}. \tag{4.15}$$

Let

$$S(x_1,x_2,y_1,y_2;\theta)=\psi_0^{(1)}(x_1,\theta_1)\psi_0^{(2)}(x_2,\theta_2)\overline{\psi_0^{(1)}(y_1,\theta_1)\psi_0^{(2)}(y_2,\theta_2)}, \tag{4.16}$$

$$G(x,y;\theta)=S(x_1,x_2,y_1,y_2;\theta)+S(y_1,x_2,x_1,y_2;\theta)+S(x_1,y_2,y_1,x_2;\theta)+S(y_1,y_2,x_1,x_2;\theta), \tag{4.17}$$

$$H(x,y;\theta)=G(x,y;\theta)-G(x,y;0). \tag{4.18}$$

Note that because $\psi_0^{(j)}(x_j,0)$ is real, we have

$$G(x,y;0)=4\psi_0^{(1)}(x_1,0)\psi_0^{(2)}(x_2,0)\psi_0^{(1)}(y_1,0)\psi_0^{(2)}(y_2,0). \tag{4.19}$$

Moreover, $G(x,y;\theta)$ can be written as

$$\begin{aligned}G(x,y;\theta)=4[&\mathrm{Re}(\psi_0^{(1)}(x_1,\theta_1))\mathrm{Re}(\psi_0^{(1)}(y_1,\theta_1))+\mathrm{Im}(\psi_0^{(1)}(x_1,\theta_1))\mathrm{Im}(\psi_0^{(1)}(y_1,\theta_1))]\\ &\times[\mathrm{Re}(\psi_0^{(2)}(x_2,\theta_2))\mathrm{Re}(\psi_0^{(2)}(y_2,\theta_2))+\mathrm{Im}(\psi_0^{(2)}(x_2,\theta_2))\mathrm{Im}(\psi_0^{(2)}(y_2,\theta_2))].\end{aligned} \tag{4.20}$$

Lemma 4.2: For δ small enough, $K_E^{[0,\delta]}$ can be decomposed as

$$K_E^{[0,\delta]}=b(E;\delta)L+R_E^{[0,\delta]}, \tag{4.21}$$

where

$$b(E;\delta)=\frac{1}{\pi^2}\int_{\mathscr{E}_\delta}\frac{d^2\theta}{E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E},$$

$$\mathscr{E}_\delta=\{\theta\in[0,\pi]^2:E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)\leqslant\delta\},$$

$$L\cdot=\omega(\tilde{\omega},\cdot),$$

$$\omega(x)=W(x)^{1/2}\psi_0^{(1)}(x_1,0)\psi_0^{(2)}(x_2,0),\quad \tilde{\omega}=\omega\ \mathrm{sgn}\ W, \tag{4.22}$$

and $R_E^{[0,\delta]}$ is the integral operator with kernel

$$R_E^{[0,\delta]}(x,y)=W(x)^{1/2}\left[\int_{\mathscr{E}_\delta}\frac{H(x,y;\theta)}{E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E}\frac{d^2\theta}{(2\pi)^2}\right]|W(y)|^{1/2}. \tag{4.23}$$

Proof: We first notice that for δ sufficiently small, the set $\mathscr{D}_\delta$ in (4.15) consists of four disjoint pieces which are located near the corners of the square $[0,2\pi]^2$. The set $\mathscr{E}_\delta$ is that portion of $\mathscr{D}_\delta$ which contains the origin. By using (4.6), (4.7), (4.16), and (4.17), we can reduce the integral over $\mathscr{D}_\delta$ to one over $\mathscr{E}_\delta$, so that (4.14) becomes

$$K_E^{[0,\delta]}(x,y)=W(x)^{1/2}\left[\int_{\mathscr{E}_\delta}\frac{G(x,y;\theta)}{E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E}\frac{d^2\theta}{(2\pi)^2}\right]|W(y)|^{1/2}. \tag{4.24}$$

Inserting $G(x,y;\theta)=G(x,y;0)+H(x,y;\theta)$ in (4.24) and using (4.19) yields (4.21). Note that (4.3) implies $\omega\in L^2(\mathbf{R}^2)$ so that L is a rank-one operator on $L^2(\mathbf{R}^2)$. ■

Theorem 4.3: For $-\delta<E<0$ with $\delta>0$ sufficiently small we have the convergent expansion

$$\begin{aligned}b(E;\delta)=&-\frac{1}{2\pi^2}\left(\sum_{m=0}^{\infty}a_{2m}E^m\right)\ln(-E)+\frac{1}{2\pi^2}\left(\sum_{m=0}^{\infty}a_{2m}E^m\right)\ln(\delta-E)\\ &+\frac{1}{2\pi^2}\sum_{k=1}^{\infty}\delta^{-k}\left(\sum_{m=k}^{\infty}\frac{a_{2m}\delta^{m+1}}{m-k+1}\right)E^{k-1},\end{aligned} \tag{4.25}$$

with suitable coefficients a_{2m} (to be defined below).

Proof: Define new variables v_1 and v_2 $(v_1,v_2\geqslant 0)$ by

$$v_1=\sqrt{E_0^{(1)}(\theta_1)},\quad v_2=\sqrt{E_0^{(2)}(\theta_2)}. \tag{4.26}$$

For sufficiently small v_1 and v_2 the inverse functions

$$\theta_1 = h_1(v_1), \quad \theta_2 = h_2(v_2), \tag{4.27}$$

exist and, by (4.8) and (4.10), are odd, analytic functions of v_1 and v_2, respectively. By means of the polar coordinates

$$r = \sqrt{v_1^2 + v_2^2}, \quad v_1 = r\cos\varphi, \quad v_2 = r\sin\varphi,$$

we can express $b(E;\delta)$ as

$$b(E;\delta) = \frac{1}{\pi^2}\int_0^{\sqrt{\delta}}\int_0^{\pi/2} \frac{h_1'(r\cos\varphi)h_2'(r\sin\varphi)}{r^2 - E}\, r\,dr\,d\varphi = \frac{1}{\pi^2}\int_0^{\sqrt{\delta}} \frac{u(r)r}{r^2 - E}\, dr, \tag{4.28}$$

$$u(r) = \int_0^{\pi/2} h_1'(r\cos\varphi)h_2'(r\sin\varphi)\,d\varphi. \tag{4.29}$$

The functions $h_1'(r\cos\varphi)$ and $h_2'(r\sin\varphi)$ are even functions of r and hence $u(r)$ can be expanded as

$$u(r) = \sum_{m=0}^{\infty} a_{2m} r^{2m}, \tag{4.30}$$

for $r < r_0$, where $r_0 > 0$ is less than the minimum of the radii of convergence for h_1 and h_2. Inserting (4.30) in (4.28) gives

$$b(E;\delta) = \frac{1}{\pi^2}\sum_{m=0}^{\infty} a_{2m} I_m(E;\delta),$$

$$I_m(E;\delta) = \int_0^{\sqrt{\delta}} \frac{r^{2m+1}}{r^2 - E}\, dr, \quad m = 0,1,2,\ldots . \tag{4.31}$$

Then

$$I_0(E;\delta) = -\tfrac{1}{2}\ln(-E) + \tfrac{1}{2}\ln(\delta - E),$$

and $I_m(E;\delta)$ is given recursively by

$$I_m(E;\delta) - E I_{m-1}(E;\delta) = \frac{\delta^m}{2m}, \quad m = 1,2,\ldots .$$

Thus

$$I_m(E;\delta) = -\frac{1}{2}E^m \ln(-E) + \frac{1}{2}E^m \ln(\delta - E) + \frac{1}{2}\sum_{k=1}^{m} \frac{\delta^{m-k+1}}{m-k+1} E^{k-1}, \tag{4.32}$$

as can be verified by induction on m or, alternately, by differentiation with respect to δ. Inserting (4.32) in (4.31) yields (4.25). It is easy to see that choosing $\delta < r_0^2$ ensures convergence of the various series on the right-hand side of (4.25) for $-\delta < E < 0$. ■

From (4.25) we infer that

$$b(E;\delta) = -\frac{a_0}{2\pi^2}\ln(-E) + c(\delta) - \frac{a_2}{2\pi^2} E \ln(-E) + O(E),$$

where

$$c(\delta) = \frac{1}{2\pi^2}\left[a_0 \ln\delta + \sum_{m=1}^{\infty} \frac{a_{2m}\delta^m}{m}\right].$$

By using (4.8), (4.26), and (4.27), we find $h_j'(0)=1/\sqrt{c_0^{(j)}}$ $(j=1,2)$ and thus, by (4.29) and (4.30),

$$a_0=\frac{\pi}{2\sqrt{c_0^{(1)}c_0^{(2)}}}. \tag{4.33}$$

We let

$$R_{E;\delta}=R_E^{[0,\delta]}+K_E^{(\delta,\infty)}=K_E-b(E;\delta)L, \tag{4.34}$$

and define the operator M_E by

$$K_E=-\frac{a_0}{2\pi^2}\ln(-E)L+M_E, \tag{4.35}$$

so that

$$M_E=\left[c(\delta)-\frac{a_2}{2\pi^2}E\ln(-E)+O(E)\right]L+R_{E;\delta}. \tag{4.36}$$

We now study the behavior of M_E as $E\to 0$. Note that, by (4.35), M_E is independent of δ. Also, note that the representation (4.35) is of the form (1.5) with $N=1$, $\lambda_0=0$, $d_{0;1}(E)=-a_0/(2\pi^2)$, $\omega_{0,E;1}=\omega$ as given by (4.22), and $R_{0,E}=M_E$. We remark that for two-dimensional perturbed periodic Schrödinger operators it has been noted earlier[35] that the Birman-Schwinger kernel diverges as $E\uparrow 0$, and this fact has been discussed in connection with the criticality of such operators.

Lemma 4.4: For every $\alpha\in(0,1]$ and $\theta_j\geqslant 0$ sufficiently small there is a constant C_j such that

$$|\psi_0^{(j)}(x_j,\theta_j)-\psi_0^{(j)}(x_j,0)|\leqslant C_j\,(1+|x_j|)^{\alpha}\theta_j^{\alpha},\quad j=1,2. \tag{4.37}$$

Proof: Let $\psi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))$ denote the solutions defined in (2.7) associated with the potential $V^{(j)}$ for $E=E_0^{(j)}(\theta_j)$. Thus

$$\psi_0^{(j)}(x_j,\theta_j)=\frac{\psi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))}{N_0^{(j,+)}(\theta_j)}=\frac{e^{i\theta_j x_j/p_j}\xi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))}{N_0^{(j,+)}(\theta_j)}, \tag{4.38}$$

where

$$N_0^{(j,+)}(\theta_j)=\left(\int_0^{p_j}|\xi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))|^2dx_j\right)^{1/2}. \tag{4.39}$$

Recall that the functions $\psi_0^{(j)}(x_j,\theta_j)$ are normalized over one period. In the following estimates $\tilde{C}_j$ denotes a suitable constant. Similarly to (i) and (iv) of Lemma 2.3 we have

$$|\psi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))|\leqslant\tilde{C}_j$$

and thus

$$|\psi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))-\psi_0^{(j,+)}(x_j,0)|\leqslant 2\tilde{C}_j.$$

Moreover,

$$|\dot{\psi}_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))|\leqslant\tilde{C}_j(1+|x_j|),$$

where now the dot denotes differentiation with respect to θ_j. Therefore,

$$|\psi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))-\psi_0^{(j,+)}(x_j,0)|\leqslant\tilde{C}_j\theta_j(1+|x_j|)$$

and hence, by interpolation,

$$|\psi_0^{(j,+)}(x_j,E_0^{(j)}(\theta_j))-\psi_0^{(j,+)}(x_j,0)|\leqslant 2^{1-\alpha}\tilde{C}_j\theta_j^{\alpha}(1+|x_j|)^{\alpha}$$

for any $\alpha\in(0,1]$. Furthermore,

$$|N_0^{(j,+)}(\theta_j)-N_0^{(j,+)}(0)|=O(\theta_j)$$

by (4.39). Now (4.37) follows from (4.38). ■

Theorem 4.5: There is a Hilbert–Schmidt operator M_0 and $\beta>0$ such that $\|M_E-M_0\|_{H.S.}=O(|E|^{\beta})$ as $E\uparrow 0$.

Proof: In view of Lemma 4.1, (4.34), and (4.36), it suffices to show that $R_E^{[0,\delta]}$ converges in Hilbert–Schmidt norm to a limit $R_0^{[0,\delta]}$ as $E\uparrow 0$, and that $\|R_E^{[0,\delta]}-R_0^{[0,\delta]}\|_{H.S.}=O(|E|^{\beta})$. We write

$$H(x,y;\theta)=[S(x_1,x_2,y_1,y_2;\theta)-\psi_0^{(1)}(x_1,0)\psi_0^{(2)}(x_2,0)\psi_0^{(1)}(y_1,0)\psi_0^{(2)}(y_2,0)]+\cdots, \quad (4.40)$$

where the right-hand side consists of four obvious terms coming from subtracting (4.19) from (4.17). Each of these terms can again be written as a sum of four terms, namely

$$\begin{aligned}&S(x_1,x_2,y_1,y_2;\theta)-\psi_0^{(1)}(x_1,0)\psi_0^{(2)}(x_2,0)\psi_0^{(1)}(y_1,0)\psi_0^{(2)}(y_2,0)\\&\quad=[\psi_0^{(1)}(x_1,\theta_1)-\psi_0^{(1)}(x_1,0)]\psi_0^{(2)}(x_2,\theta_2)\overline{\psi_0^{(1)}(y_1,\theta_1)\psi_0^{(2)}(y_2,\theta_2)}+\cdots, \quad (4.41)\end{aligned}$$

where it is clear how the right-hand side is obtained. Applying Lemma 4.4 to each term on the right-hand side of (4.41) and then using the result in (4.40) gives

$$|H(x,y;\theta)|\leqslant C(1+|x|)^{\alpha}(1+|y|)^{\alpha}|\theta|^{\alpha}, \quad \alpha\in(0,1]. \quad (4.42)$$

Substituting (4.42) in (4.23) leads to θ-integrals that are bounded independently of E, since by using polar coordinates (ignoring irrelevant factors) we have

$$\int_{\mathscr{C}_\delta}\frac{|\theta|^{\alpha}}{E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E}\,d^2\theta\leqslant C\int_0^{\sqrt{\delta}}\frac{r^{\alpha+1}}{r^2-E}\,dr\leqslant C\,\frac{\delta^{\alpha/2}}{\alpha}.$$

Consequently,

$$|R_E^{[0,\delta]}(x,y)|\leqslant C|W(x)|^{1/2}(1+|x|)^{\alpha}(1+|y|)^{\alpha}|W(y)|^{1/2}. \quad (4.43)$$

So if we take α so that $0<\alpha\leqslant\min\{1,\gamma/2\}$, where γ is the constant in (4.3), then (4.43) provides us with the required uniform bound on $|R_E^{[0,\delta]}(x,y)|$ that allows us to conclude, as in the proof of Lemma 2.4(ii), that $R_E^{[0,\delta]}\to R_0^{[0,\delta]}$ in Hilbert–Schmidt norm as $E\uparrow 0$. Taking the derivative of $R_E^{[0,\delta]}$ with respect to E and using the estimate

$$\int_{\mathscr{C}_\delta}\frac{|\theta|^{\alpha}}{[E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E]^2}\,d^2\theta\leqslant C\int_0^{\sqrt{\delta}}\frac{r^{\alpha+1}}{(r^2-E)^2}\,dr\leqslant C|E|^{-1+\alpha/2}\int_0^{\infty}\frac{u^{\alpha+1}}{(u^2+1)^2}\,du,$$

we get

$$\left|\frac{dR_E^{[0,\delta]}}{dE}(x,y)\right|\leqslant C|E|^{-1+\alpha/2}|W(x)|^{1/2}(1+|x|)^{\alpha}(1+|y|)^{\alpha}|W(y)|^{1/2}. \quad (4.44)$$

Thus an integration gives $\|R_E^{[0,\delta]}-R_0^{[0,\delta]}\|_{H.S.}=O(|E|^{\alpha/2})$, and so we can choose any $\beta\leqslant\min\{1/2,\gamma/4\}$ to reach the conclusion of the theorem. ■

According to (1.8) and (4.35) the equation for the bound state reads

$$\lambda(\tilde{\omega},[1+\lambda M_E]^{-1}\omega)=\frac{2\pi^2}{a_0\ln(-E)}, \quad (4.45)$$

and we are looking for solutions obeying $E(\lambda)\uparrow 0$ as $\lambda\downarrow 0$. Since for $|E|$ small, the right-hand side of (4.45) is negative, such solutions can exist only if

$$(\tilde{\omega},\omega)=\int_{\mathbf{R}^2} W(x)\psi_0^{(1)}(x_1,0)^2\psi_0^{(2)}(x_2,0)^2 d^2x\leqslant 0.$$

The next lemma is the analog of Lemma 2.10(ii) in two dimensions.

Lemma 4.6: If $(\tilde{\omega},\omega)=0$ and $W\neq 0$, then $(\tilde{\omega},M_0\omega)>0$.

Proof: $(\tilde{\omega},\omega)=0$ is equivalent to $L\omega=0$, and so, by (4.35) and Theorem 4.5,

$$\lim_{E\uparrow 0}(\tilde{\omega},K_E\omega)=(\tilde{\omega},M_0\omega). \tag{4.46}$$

Let

$$\hat{K}_E=(\operatorname{sgn} W)K_E=|W|^{1/2}(H_0-E)^{-1}|W|^{1/2},\quad E<0.$$

Then $\hat{K}_E$ is an increasing family of positive self-adjoint operators. So

$$(\tilde{\omega},K_E\omega)=(\omega,\hat{K}_E\omega)\geqslant 0,$$

and hence, by (4.46), $(\tilde{\omega},M_0\omega)\geqslant 0$. Furthermore, by (4.46), $(\tilde{\omega},M_0\omega)=0$ implies $(\omega,\hat{K}_E\omega)=0$ for all $E<0$. So $(H_0-E)^{-1/2}|W|^{1/2}\omega=0$ for all $E<0$; in particular,

$$(H_0+1)^{-1/2}|W|^{1/2}\omega=0, \tag{4.47}$$

and thus $|W|^{1/2}\omega=0$. Since $|W|^{1/2}\omega$ is generally not in $L^2(\mathbf{R}^2)$, the last conclusion requires an explanation. If we consider the scale of Hilbert spaces $\mathscr{H}_{+1}\subset L^2(\mathbf{R}^2)\subset\mathscr{H}_{-1}$, where $\mathscr{H}_{+1}=D([H_0+1]^{1/2})$ with the norm $\|f\|_{+1}=\|(H_0+1)^{1/2}f\|$ and $\mathscr{H}_{-1}$ is the completion of $L^2(\mathbf{R})$ in the norm $\|f\|_{-1}=\|(H_0+1)^{-1/2}f\|$, then $|W|^{1/2}\omega\in\mathscr{H}_{-1}$. Moreover, $(H_0+1)^{-1/2}$ maps $\mathscr{H}_{-1}$ to $L^2(\mathbf{R}^2)$ and has a trivial kernel. Since H_0+1 and $-\Delta+1$ have the same form domain, or, equivalently, by multiplying (4.47) from the left by $(-\Delta+1)^{-1/2}(H_0+1)^{1/2}$, we conclude that $(-\Delta+1)^{-1/2}|W|^{1/2}\omega=0$. Then, by using a Fourier transform, we obtain $W(x)=0$, a.e. Since this is not the case, $(\tilde{\omega},M_0\omega)>0$. ■

In the next theorem, $E_0(\lambda)$ denotes the lowest eigenvalue (ground state) of H_λ. Moreover, a_0 is the constant defined in (4.33) and β is as in Theorem 4.5.

Theorem 4.7: Assume (4.1)–(4.3). Then there is an eigenvalue $E_0(\lambda)$ of H_λ satisfying the following:

(i) $E_0(\lambda)$ is simple and the only eigenvalue converging to zero as $\lambda\downarrow 0$.

(ii) If $(\tilde{\omega},\omega)<0$, then

$$E_0(\lambda)=-e^{-h_1(\lambda)}[1+O(e^{-\rho_1/\lambda})],\quad \lambda\downarrow 0, \tag{4.48}$$

where $\rho_1=2\pi^2\gamma_{-1}\beta a_0^{-1}$ and

$$h_1(\lambda)=\frac{2\pi^2}{a_0}\left[\frac{\gamma_{-1}}{\lambda}+\gamma_0+\sum_{n=1}^{\infty}\gamma_n\lambda^n\right],$$

$$\gamma_{-1}=-\frac{1}{(\tilde{\omega},\omega)},\quad \gamma_0=-\frac{(\tilde{\omega},M_0\omega)}{(\tilde{\omega},\omega)^2}, \tag{4.49}$$

with the series in (4.49) being convergent for λ small enough.

(iii) If $(\tilde{\omega},\omega)=0$, then

$$E_0(\lambda)=-e^{-h_2(\lambda)}[1+O(\lambda^{-2}e^{-\rho_2/\lambda^2})],\quad \lambda\downarrow 0, \tag{4.50}$$

where ρ_2 is any constant such that $0<\rho_2<2\pi^2\nu_{-2}\beta a_0^{-1}$, and

$$h_2(\lambda)=\frac{2\pi^2}{a_0}\left[\frac{\nu_{-2}}{\lambda^2}+\frac{\nu_{-1}}{\lambda}+\nu_0+\sum_{n=1}^{\infty}\nu_n\lambda^n\right],$$

$$\nu_{-2}=\frac{1}{(\tilde{\omega},M_0\omega)},\quad \nu_{-1}=\frac{(\tilde{\omega},M_0^2\omega)}{(\tilde{\omega},M_0\omega)^2},\quad \nu_0=\frac{(\tilde{\omega},M_0^2\omega)^2}{(\tilde{\omega},M_0\omega)^3}-\frac{(\tilde{\omega},M_0^3\omega)}{(\tilde{\omega},M_0\omega)^2}. \tag{4.51}$$

(iv) If $(\tilde{\omega},\omega)>0$, then λ_0 is not a c.c.th.

We remark that in the case $V\neq 0$ the coefficients γ_{-1}, γ_0, ν_{-2}, ν_{-1}, and ν_0 reduce to those given by Holden.[2]

Proof: (i) The existence and uniqueness of $E_0(\lambda)$ are obvious if we recall the approach based on eigenvalue perturbation theory.[1,3] However, for later use it is useful to have an independent argument based solely on (4.45). First, existence is obvious from (4.45), Theorem 4.5, and the intermediate value theorem. Uniqueness follows by taking the derivative with respect to E and showing that $[d/dE](\tilde{\omega},[1+\lambda M_E]^{-1}\omega)=O(|E|)^{-1+\alpha/2}$ as $E\uparrow 0$, uniformly in λ, with $0<\alpha\leqslant\min\{1,\gamma/2\}$. This follows from (4.44), which remains valid if we replace $R_E^{[0,\delta]}$ by M_E, and estimates similar to those used in the proof of Lemma 2.5. The restriction on α comes from the fact that the integral $\int_{\mathbf{R}^2}(1+|x|)^{2\alpha}|W(x)|d^2x$ must be finite. Further details are omitted. Since the derivative of the right-hand side of (4.45) is equal to $2\pi^2 a_0^{-1}E^{-1}[\ln(-E)]^{-2}$, and thus dominates for small E, uniqueness follows.

To prove (ii) note that, by (4.45),

$$\ln(-E)=-\frac{2\pi^2}{a_0}\left[\frac{\gamma_{-1}}{\lambda}+\gamma_0+o(1)\right], \tag{4.52}$$

and so, by Theorem 4.5,

$$\|(1+\lambda M_E)^{-1}-(1+\lambda M_0)^{-1}\|_{H.S.}\leqslant C_1\lambda|E|^{\beta}\leqslant C_2\lambda e^{-\rho_1/\lambda}, \tag{4.53}$$

where $\rho_1=2\pi^2\gamma_{-1}\beta a_0^{-1}$. Hence we can write (4.45) as

$$\lambda(\tilde{\omega},(1+\lambda M_0)^{-1}\omega)+O(\lambda^2 e^{-\rho_1/\lambda})=\frac{2\pi^2}{a_0\ln(-E)}. \tag{4.54}$$

Let

$$h_1(\lambda)=-\frac{2\pi^2}{a_0}\frac{1}{\lambda(\tilde{\omega},[1+\lambda M_0]^{-1}\omega)}. \tag{4.55}$$

Then (4.48) and (4.49) follow from (4.54) and (4.55) by expanding $(1+\lambda M_0)^{-1}$.

The proof of (iii) is similar. Instead of (4.52) we now have

$$\ln(-E)=-\frac{2\pi^2}{a_0}\left[\frac{\nu_{-2}}{\lambda^2}+\frac{\nu_{-1}}{\lambda}+\nu_0+o(1)\right],$$

and thus

$$\|(1+\lambda M_E)^{-1}-(1+\lambda M_0)^{-1}\|\leqslant C_1\lambda|E|^{\beta}\leqslant C_2\lambda e^{-\rho_2/\lambda^2},$$

with $0<\rho_2<2\pi^2\nu_{-2}\beta a_0^{-1}$, taking into account the possibility that ν_{-1} may be negative. Since $(\tilde{\omega},\omega)=0$, the function $h_1(\lambda)$ can be rewritten as

$$h_2(\lambda)=\frac{2\pi^2}{a_0}\frac{1}{\lambda^2(\tilde{\omega},M_0[1+\lambda M_0]^{-1}\omega)}.$$

Expanding the denominator leads to (4.51). In place of (4.54) we have from (4.45),

$$-\lambda^2(\tilde{\omega},M_0[1+\lambda M_0]^{-1}\omega)+O(\lambda^2 e^{-\rho_2/\lambda^2})=\frac{2\pi^2}{a_0\ln(-E)}. \tag{4.56}$$

So, by solving (4.56) for E and putting $E=E_0(\lambda)$, we obtain (4.50).

Conclusion (iv) is obvious from (4.45) because the two sides have opposite signs when λ and E are small. ■

If we assume

$$\int_{\mathbf{R}^2} e^{c|x|}|W(x)|d^2x<\infty, \quad c>0, \tag{4.57}$$

then $E_0(\lambda)$ has a convergent expansion in terms of quantities containing factors of the form $e^{-d/\lambda}$ $(d>0)$ and powers of λ. First, note that from (2.3), (2.4), and (2.7), it follows that the normalization constants $N_0^{(j,+)}(\theta_j)$ $(j=1,2)$ in (4.39), originally defined for real θ_j, can be analytically continued to a complex neighborhood of zero and that $N_0^{(j,+)}(\theta_j)$ are even functions of θ_j. Consequently, the real part of $\psi_0^{(j)}(x_j,\theta_j)$ is an even function of θ_j and the imaginary part is an odd function of θ_j. Thus there is a $\tilde{\theta}>0$ such that for $|\theta_j|<\tilde{\theta}$ $(j=1,2)$ we have the convergent expansions

$$\psi_0^{(j)}(x_j,\theta_j)=\alpha_0^{(j)}(x_j)+i\beta_1^{(j)}(x_j)\theta_j+\alpha_2^{(j)}(x_j)\theta_j^2+i\beta_3^{(j)}(x_j)\theta_j^3+\ldots, \tag{4.58}$$

where

$$\alpha_0^{(j)}(x_j)=\frac{\psi_0^{(j,+)}(x_j,0)}{N_0^{(j,+)}(0)}, \quad \beta_1^{(j)}(x_j)=\frac{\phi_0^{(j)}(x_j,0)}{\phi_0^{(j)}(p_j,0)N_0^{(j,+)}(0)},$$

and $\alpha_n^{(j)}(x_j)$ and $\beta_n^{(j)}(x_j)$ are real. Also, recall that $\phi_0^{(j)}(p_j,0)\neq 0$, since $E_0^{(j)}(0)=0=\inf\sigma(H_0^{(j)})$. Equation (4.58) follows from (4.38), (2.3), and (2.4) with $q(E)=q(E_0^{(j)}(\theta_j))=\theta_j$, by expanding $\psi_0^{(j)}(x_j,\theta_j)$ in powers of θ_j. In view of (4.20) and (4.58) the function $H(x,y;\theta)$ in (4.18) is even in θ_1 and θ_2 separately, and hence can be expanded as

$$H(x,y;\theta)=\sum_{n,m=0}^{\infty} A_{nm}(x,y)\theta_1^{2n}\theta_2^{2m}, \tag{4.59}$$

where $A_{00}(x,y)=0$ because $H(x,y;0)=0$. From (4.16), (4.18), and (4.38) we obtain the inequality

$$|H(x,y;\theta)|\leq Ce^{|\theta_1||x_1|/p_1+|\theta_2||x_2|/p_2+|\theta_1||y_1|/p_1+|\theta_2||y_2|/p_2}. \tag{4.60}$$

Let $\tilde{p}=(p_1^{-2}+p_2^{-2})^{1/2}$ and assume $|\theta_j|<\tilde{\theta}(j=1,2)$. Using the Schwarz inequality gives

$$|H(x,y;\theta)|\leq Ce^{\tilde{\theta}\,\tilde{p}(|x|+|y|)}.$$

Thus, by Cauchy's inequality, we obtain

$$|A_{nm}(x,y)|\leq C\,\frac{e^{\tilde{\theta}\,\tilde{p}(|x|+|y|)}}{\tilde{\theta}^{2(n+m)}}. \tag{4.61}$$

Inserting (4.59) in (4.23) and using polar coordinates according to (4.26) and (4.27) gives rise to integrals of the form

$$\rho_{nm}(r)=\int_0^{\pi/2} h_1'(r\,\cos\,\varphi)h_2'(r\,\sin\,\varphi)\cos^{2n}\,\varphi\,\sin^{2m}\,\varphi d\varphi.$$

The functions $\rho_{nm}(r)$ can be expanded as

$$\rho_{nm}(r)=\sum_{s=0}^{\infty} c_{nm;2s}\,r^{2s},$$

where the series converges for $r<r_0$ with r_0 being the same as in (4.30). Again, by Cauchy's inequality, there is a constant $M_{r_0}>0$ (independent of n and m) such that

$$|c_{nm;2s}| \leqslant \frac{M_{r_0}}{r_0^{2s}}. \tag{4.62}$$

Assuming δ to be so small that $\delta < \min\{\tilde{\theta}^2, r_0^2\}$ and $\mathscr{E}_\delta \subset \{\theta \in [0,\pi]^2 : |\theta_j| < \tilde{\theta}, j=1,2\}$, for $-\delta < E < 0$ we have

$$R_E^{[0,\delta]}(x,y) = \frac{W(x)^{1/2}}{4\pi^2}\left[\sum_{n,m,s=0}^{\infty} c_{nm;2s} A_{nm}(x,y) I_{n+m+s}(E;\delta)\right]|W(y)|^{1/2}, \tag{4.63}$$

where $I_{n+m+s}(E;\delta)$ is given by (4.32). Inserting (4.32) in (4.63) gives

$$R_E^{[0,\delta]}(x,y) = \left[\sum_{n=0}^{\infty} D_n^{(1)}(x,y) E^n\right] E \ln(-E) + \sum_{n=0}^{\infty} D_n^{(2)}(x,y) E^n, \tag{4.64}$$

where the coefficients $D_n^{(1)}(x,y)$ and $D_n^{(2)}(x,y)$ obey

$$|D_n^{(j)}(x,y)| \leqslant C|W(x)|^{1/2} e^{\tilde{\theta}\tilde{p}(|x|+|y|)}|W(y)|^{1/2}, \quad j=1,2.$$

Hence the kernels $D_n^{(j)}(x,y)$ are Hilbert–Schmidt if we assume that $\tilde{\theta} \leqslant c/(2\tilde{p})$, where c is the constant in (4.57). By (4.36), and since $K_E^{(\delta,\infty)}$ is analytic at $E=0$, the expansion (4.64) carries over to $R_{E;\delta}$ and to M_E. As a result, (4.45) can be written in the form

$$\ln(-E) = \begin{cases} -\dfrac{2\pi^2}{a_0}\left[\dfrac{\gamma_{-1}}{\lambda} + \gamma_0 + \displaystyle\sum_{\substack{n,m,s=0 \\ n+m+s \geqslant 1}} e_{nms} E^n [E \ln(-E)]^m \lambda^s\right], & (\tilde{\omega},\omega) < 0, \\ -\dfrac{2\pi^2}{a_0}\left[\dfrac{\nu_2}{\lambda^2} + \dfrac{\nu_{-1}}{\lambda} + \nu_0 + \displaystyle\sum_{\substack{n,m=0 \\ s \geqslant -2}} f_{nms} E^n [E \ln(-E)]^m \lambda^s\right], & (\tilde{\omega},\omega) = 0, \end{cases} \tag{4.65}$$

where $f_{00-2} = f_{00-1} = f_{000} = 0$. Let

$$v = \lambda^{-1} e^{-2\pi^2 \gamma_{-1}/(a_0\lambda)}, \quad w = \lambda^{-4} e^{-(2\pi^2/a_0)[\nu_{-2}/\lambda^2 + \nu_{-1}/\lambda]}. \tag{4.66}$$

Theorem 4.8: Assume (4.57). Then the following holds.

(i) If $(\tilde{\omega},\omega) < 0$, then for λ sufficiently small, $E_0(\lambda)$ has the uniformly and absolutely convergent expansion

$$E_0(\lambda) = \sum_{n,m=1}^{\infty} c_{nm} v^n \lambda^m, \tag{4.67}$$

where $c_{11} = -e^{-2\pi^2 \gamma_0/a_0}$.

(ii) If $(\tilde{\omega},\omega) = 0$, then

$$E_0(\lambda) = \sum_{\substack{n=1 \\ m=4}}^{\infty} c_{nm} w^n \lambda^m, \tag{4.68}$$

where $c_{14} = -e^{-2\pi^2 \nu_0/a_0}$.

Proof: (i) Write

$$E_0(\lambda) = e^{-(2\pi^2/a_0)[\gamma_{-1}/\lambda + \gamma_0]}[1+\eta],$$

and substitute it in the first equation in (4.65). After some simplifications we get an equation of the form

$$F(\eta,v,\lambda)=0, \tag{4.69}$$

where F is analytic in all three variables in a neighborhood of zero, $F(0,0,0)=0$, and $[\partial F/\partial\eta](0,0,0)\neq 0$. Thus, by the implicit function theorem for analytic functions, (4.69) has a unique solution $\eta=\eta(v,\lambda)$ given by a convergent power series in the variables v and λ; this implies (4.67). The proof of (ii) is similar: We insert

$$E_0(\lambda)=e^{-(2\pi^2/a_0)[\nu_{-2}/\lambda^2+\nu_{-1}/\lambda+\nu_0]}[1+\eta]$$

in the second equation in (4.65) to obtain an equation of the form $F(\eta,w,\lambda)=0$ whose solution $\eta=\eta(w,\lambda)$ is analytic in both variables for $|w|$ and $|\lambda|$ small. Thus (4.68) follows. ■

There is a slight discrepancy between our expansion for $E_0(\lambda)$ and the corresponding expansion of Ref. 2 in the case $V=0$ in that the quantity w used here contains the factor λ^{-4} in contrast to the factor λ^{-3} in Ref. 2. The reason for having the factors λ^{-1} and λ^{-4} in front of the exponentials in (4.66) is due to the terms $e_{010}\,E\,\ln(-E)$ and $f_{01-2}E\,\ln(-E)\lambda^{-2}$ in (4.65), respectively. These terms arise from expanding $(\tilde{\omega},M_E\omega)$ for E small [cf. (4.45)].

This concludes our discussion of the behavior of the ground state. We now investigate what happens in the first gap, that is in the interval

$$(E_0^{(1)}(\pi)+E_0^{(2)}(\pi),\min\{E_1^{(1)}(\pi),E_1^{(2)}(\pi)\}),$$

provided

$$\min\{E_1^{(1)}(\pi),E_1^{(2)}(\pi)\}>E_0^{(1)}(\pi)+E_0^{(2)}(\pi). \tag{4.70}$$

We only consider the case $\lambda_0=0$ and content ourselves with obtaining the leading terms in the expansion of the eigenvalues. For this purpose we divide our analysis into two parts.

Case 1: Absorption at $E^*=E_0^{(1)}(\pi)+E_0^{(2)}(\pi)$. In this case we decompose K_E as follows:

$$K_E=K_E^{[E^*-\delta,E^*]}+K_E^{\mathbf{R}\setminus[E^*-\delta,E^*]},$$

where the notation [cf. (4.11)–(4.13)] is self-explanatory. The integral associated with $K_E^{[E^*-\delta,E^*]}$ [i.e., the analog of (4.14)] extends over the region $\{\theta\in[0,2\pi]^2: E^*-\delta\leqslant E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)\leqslant E^*\}$. It contains the point (π,π) and is symmetric with respect to the lines $\theta_1=\pi$ and $\theta_2=\pi$. Using this symmetry and (4.6) and (4.7), the integration can be reduced to one over that portion of the region on which $\theta_1\leqslant\pi$ and $\theta_2\leqslant\pi$. It follows that we can write

$$K_E=\frac{b_0}{2\pi^2}\ln|E-E^*|L+M_E^{(1)}, \tag{4.71}$$

where now $b_0=2^{-1}\pi[d_0^{(1)}d_0^{(2)}]^{-1/2}$, with $d_0^{(1)}$ and $d_0^{(2)}$ being the constants in (4.9), $L\cdot=\omega(\tilde{\omega},\cdot)$, and $\tilde{\omega}=\omega\ \mathrm{sgn}\ W$, where

$$\omega(x)=W(x)^{1/2}\psi_0^{(1)}(x_1,\pi)\psi_0^{(2)}(x_2,\pi).$$

As in Theorem 4.5 one shows that $M_E^{(1)}\to M_{E^*}^{(1)}$ in the Hilbert–Schmidt norm as $E\downarrow E^*$. Note the sign change in the first term in (4.71) as compared to (4.35). Therefore, an eigenvalue can get absorbed at E^* only if

$$(\tilde{\omega},\omega)=\int_{\mathbf{R}^2}W(x)\psi_0^{(1)}(x_1,\pi)^2\psi_0^{(2)}(x_2,\pi)^2d^2x\geqslant 0.$$

Theorem 4.9: Suppose (4.1)–(4.3) and (4.70) hold. Then the following holds:
(i) If $(\tilde{\omega},\omega)>0$, then there is a unique, simple eigenvalue $E(\lambda)$ such that

$$E(\lambda)-E^*=e^{-(2\pi^2/b_0)[\mu_{-1}/\lambda+\mu_0+o(1)]},\quad \lambda\downarrow 0. \tag{4.72}$$

(ii) If $(\tilde{\omega},[M_{E*}^{(1)}]^k\omega)=0$ for $k=0,1,...,n-1$ and $(-1)^n(\tilde{\omega},[M_{E*}^{(1)}]^n\omega)>0$, then there are constants $c_0,\ldots,c_{n+1}$ such that

$$E(\lambda)-E^*=e^{c_0/\lambda^{n+1}+c_1/\lambda^n+\cdots+c_{n+1}+o(1)},\quad \lambda\downarrow 0,$$

where

$$c_0=\frac{2\pi^2(-1)^{n+1}}{b_0(\tilde{\omega},[M_{E*}^{(1)}]^n\omega)}<0.$$

(iii) If $(\tilde{\omega},[M_{E*}^{(1)}]^k\omega)=0$ for $k=0,1,...,n-1$ and $(-1)^n(\tilde{\omega},[M_{E*}^{(1)}]^n\omega)<0$, then λ_0 is not a c.c.th.

Proof: (i) is a special case of (ii). In analogy to (4.45), the equation for $E(\lambda)$ now reads

$$-\lambda(\tilde{\omega},[1+\lambda M_E^{(1)}]^{-1}\omega)=\frac{2\pi^2}{b_0\,\ln|E-E^*|}. \tag{4.73}$$

Then (ii) follows from (4.73) by proceeding as in the proof of Theorem 4.7(ii). The coefficients c_n are obtained by expanding $[1+\lambda M_{E*}^{(1)}]^{-1}$, noting that the difference $[1+\lambda M_E^{(1)}]^{-1}-[1+\lambda M_{E*}^{(1)}]^{-1}$ has no effect on these coefficients because it is controlled by an estimate similar to that in (4.53). Uniqueness and simplicity of the eigenvalue follow as in the proof of Theorem 4.7. ■

Of course, we could be more explicit about the remainder terms in (4.72) and write it in a form like (4.48). If $(\tilde{\omega},\omega)=0$, then in general nothing can be said about the sign of $(\tilde{\omega},M_{E*}^{(1)}\omega)$; that is, there is no analog of Lemma 4.6. The reason is that the proof of Lemma 4.6 uses in an essential way the fact that we are at the bottom of the spectrum.

Case 2: Absorption at $E^*=\min\{E_1^{(1)}(\pi),E_1^{(2)}(\pi)\}$. This case will be divided further into three cases. As we will see, in one of these cases it is possible that two eigenvalues approach E^* as $\lambda\downarrow 0$. We first describe the decompositions of K_E that characterize each case. Then, in Theorem 4.10, we collect the information about the behavior of the eigenvalues that converge to E^* as $\lambda\downarrow 0$.

(a) $E^*=E_1^{(1)}(\pi)$ and $E_1^{(2)}(\pi)>E^*$: In this case, for sufficiently small δ, the relevant region for the θ-integration is given by $\{\theta\in[0,2\pi]^2: E^*\leqslant E_1^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)\leqslant E^*+\delta\}$. This region has two components containing the points $(\pi,0)$ and $(\pi,2\pi)$, respectively. The singular contribution to K_E again has rank one and we have the decomposition

$$K_E=-\frac{e_0}{2\pi^2}\ln|E-E^*|L+M_E^{(2)},$$

where $e_0=2^{-1}\pi[d_1^{(1)}c_0^{(2)}]^{-1/2}$, $L\cdot=\omega(\tilde{\omega},\cdot)$, $\tilde{\omega}=\omega\ \mathrm{sgn}\ W$, and

$$\omega(x)=W(x)^{1/2}\psi_1^{(1)}(x_1,\pi)\psi_0^{(2)}(x_2,0).$$

Moreover, $M_E^{(2)}\to M_{E*}^{(2)}$ in the Hilbert–Schmidt norm as $E\uparrow E^*$.

(b) $E^*=E_1^{(2)}(\pi)$ and $E_1^{(1)}(\pi)>E^*$: This case is analogous to case (a). We have

$$K_E=-\frac{f_0}{2\pi^2}\ln|E-E^*|L+M_E^{(3)},$$

where $f_0=2^{-1}\pi[d_1^{(2)}c_0^{(1)}]^{-1/2}$, $L\cdot=\omega(\tilde{\omega},\cdot)$, $\tilde{\omega}=\omega\ \mathrm{sgn}\ W$, and

$$\omega(x)=W(x)^{1/2}\psi_0^{(1)}(x_1,0)\psi_1^{(2)}(x_2,\pi).$$

Moreover, $M_E^{(3)}\to M_{E*}^{(3)}$ in the Hilbert–Schmidt norm as $E\uparrow E^*$.

(c) $E^*=E_1^{(1)}(\pi)=E_1^{(2)}(\pi)$: In this case the critical region of integration is $\{\theta\in[0,2\pi]^2: E^* \leqslant E_0^{(1)}(\theta_1)+E_1^{(2)}(\theta_2)\leqslant E^*+\delta\}\cup\{\theta\in[0,2\pi]^2: E^*\leqslant E_1^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)\leqslant E^*+\delta\}$ and thus has four components located near $(\pi,0)$, $(2\pi,\pi)$, $(\pi,2\pi)$, and $(0,\pi)$. Let

$$\omega_1=W(x)^{1/2}\psi_0^{(1)}(x_1,0)\,\psi_1^{(2)}(x_2,\pi),\quad \omega_2=W(x)^{1/2}\psi_1^{(1)}(x_1,\pi)\,\psi_0^{(2)}(x_2,0). \tag{4.74}$$

Then K_E is of the form

$$K_E=d_1(E)\,\omega_1(\tilde{\omega}_1,\cdot)+d_2(E)\,\omega_2(\tilde{\omega}_2,\cdot)+R_E,$$

where

$$d_1(E)=\frac{1}{\pi^2}\int_{\mathscr{E}_{1,\delta}}\frac{d^2\theta}{E_0^{(1)}(\theta_1)+E_1^{(2)}(\theta_2)-E},$$

$$\mathscr{E}_{1,\delta}=\{\theta\in[0,\pi]^2: E^*\leqslant E_0^{(1)}(\theta_1)+E_1^{(2)}(\theta_2)\leqslant E^*+\delta\},$$

$$d_2(E)=\frac{1}{\pi^2}\int_{\mathscr{E}_{2,\delta}}\frac{d^2\theta}{E_1^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)-E},$$

$$\mathscr{E}_{2,\delta}=\{\theta\in[0,\pi]^2: E^*\leqslant E_1^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)\leqslant E^*+\delta\}.$$

Also, $R_E\to R_{E*}$ in the Hilbert–Schmidt norm as $E\uparrow E^*$. Since ω_1 and ω_2 are linearly independent, the operator $d_1(E)\,\omega_1(\tilde{\omega}_1,\cdot)+d_2(E)\,\omega_2(\tilde{\omega}_2,\cdot)$ has rank two. The coefficients $d_1(E)$ and $d_2(E)$ diverge as $E\uparrow E^*$ according to

$$d_1(E)=-\beta_1\,\ln|E-E^*|+O(1),$$

$$d_2(E)=-\beta_2\,\ln|E-E^*|+O(1),$$

where $\beta_1=(4\pi)^{-1}[d_1^{(2)}c_0^{(1)}]^{-1/2}$, $\beta_2=(4\pi)^{-1}[d_1^{(1)}c_0^{(2)}]^{-1/2}$. This follows from a result analogous to (4.25). Thus (1.8) reads

$$\det\begin{bmatrix}1+\lambda d_1(E)(\tilde{w}_1,[1+\lambda R_E]^{-1}w_1) & \lambda d_2(E)(\tilde{w}_1,[1+\lambda R_E]^{-1}w_2)\\ \lambda d_1(E)(\tilde{w}_2,[1+\lambda R_E]^{-1}w_1) & 1+\lambda d_2(E)(\tilde{w}_2,[1+\lambda R_E]^{-1}w_2)\end{bmatrix}=0. \tag{4.75}$$

The next theorem gives information about the behavior of the eigenvalues for each of the above situations.

Theorem 4.10: Suppose (4.1)–(4.3) and (4.70) hold. Then we have the following:

(a) Suppose $E^*=E_1^{(1)}(\pi)$ and $E_1^{(2)}(\pi)>E^*$: If $(\tilde{\omega},\omega)<0$, then there is a unique, simple eigenvalue obeying

$$E^*-E(\lambda)=e^{-(2\pi^2/e_0)[\sigma_{-1}/\lambda+\sigma_0+o(1)]},\quad \lambda\downarrow 0,$$

where

$$\sigma_{-1}=-\frac{1}{(\tilde{\omega},\omega)},\quad \sigma_0=-\frac{(\tilde{\omega},M_{E^*}^{(2)}\omega)}{(\tilde{\omega},\omega)^2}.$$

If $(\tilde{\omega},\omega)=0$, then a result analogous to Theorem 4.9(ii) holds. If $(\tilde{\omega},\omega)>0$, then $\lambda_0=0$ is not a c.c.th.

(b) Suppose $E^*=E_1^{(2)}(\pi)$ and $E_1^{(1)}(\pi)>E^*$: If $(\tilde{\omega},\omega)<0$, then there is a unique, simple eigenvalue obeying

$$E^*-E(\lambda)=e^{-(2\pi^2/f_0)[\rho_{-1}/\lambda+\rho_0+o(1)]},\quad \lambda\downarrow 0,$$

where

$$\rho_{-1} = -\frac{1}{(\tilde{\omega},\omega)}, \quad \rho_0 = -\frac{(\tilde{\omega},M^{(3)}_{E^*}\omega)}{(\tilde{\omega},\omega)^2}.$$

If $(\tilde{\omega},\omega)=0$, then a result analogous to Theorem 4.9(ii) holds. If $(\tilde{\omega},\omega)>0$, then $\lambda_0=0$ is not a c.c.th.

(c) Suppose $E^*=E_1^{(1)}(\pi)=E_1^{(2)}(\pi)$: Let

$$c_\pm = -\beta_1(\tilde{\omega}_1,\omega_1)-\beta_2(\tilde{\omega}_2,\omega_2)\pm\sqrt{[\beta_1(\tilde{\omega}_1,\omega_1)-\beta_2(\tilde{\omega}_2,\omega_2)]^2+4\beta_1\beta_2(\tilde{\omega}_1,\omega_2)^2}.$$

If $c_\pm>0$, then there are two eigenvalues (counting multiplicities) approaching E^* as $\lambda\downarrow 0$ given by

$$E^*-E(\lambda)=e^{-2/(c_\pm\lambda)+O(1)}, \quad \lambda\downarrow 0. \tag{4.76}$$

If $c_\pm$ are nonzero and of opposite signs, then there is only one eigenvalue, the one corresponding to c_+, that converges to E^* as $\lambda\downarrow 0$, and for it (4.76) holds.

Proof: The proofs in cases (a) and (b) are by now familiar. The result in case (c) follows by expanding the left-hand side of (4.75) for λ small and E near E^*, and using an estimate like (4.53). Further details are omitted. ■

We see from (4.75) that if $W\leqslant 0 (W\neq 0)$, then $c_\pm>0$ by the Schwarz inequality, $(\tilde{\omega}_1,\omega_2)^2 \leqslant (\tilde{\omega}_1,\omega_1)^2(\tilde{\omega}_2,\omega_2)^2$. Thus there are two eigenvalues (counting multiplicities) that converge to E^* as $\lambda\downarrow 0$. As one would expect, if V and W have certain symmetry properties, then the two eigenvalues may degenerate into one eigenvalue of multiplicity two. For example, this happens if $V^{(1)}$ and $V^{(2)}$ in (4.1) are given by identical functions, $V^{(1)}(\xi)=V^{(2)}(\xi)$ $(\xi\in\mathbf{R})$, W is symmetric, $W(x_1,x_2)=W(x_2,x_1)$, and even in x_1 and x_2 separately, and $E_1^{(1)}(\pi)$ is the first Dirichlet eigenvalue of the operator $H_0^{(1)}$ on the interval $[0,p]$. To see this, let $\mathscr{U}$ be the unitary operator $(\mathscr{U}\psi)(x_1,x_2)=\psi(x_2,x_1)$ and let $\mathscr{M}_1=\{\psi\in L^2(\mathbf{R}^2):\psi(x_1,x_2)=\psi(-x_1,x_2)=-\psi(x_1,-x_2)\}$ and $\mathscr{M}_2=\{\psi\in L^2(\mathbf{R}^2):\psi(x_1,x_2)=\psi(x_1,-x_2)=-\psi(-x_1,x_2)\}$. Then $\mathscr{M}_1$ and $\mathscr{M}_2$ are orthogonal, invariant subspaces for H_λ (for any $\lambda\geqslant 0$) such that $\mathscr{U}\mathscr{M}_1=\mathscr{M}_2$ and $\mathscr{U}\mathscr{M}_2=\mathscr{M}_1$. Moreover, $\mathscr{M}_1$ and $\mathscr{M}_2$ are invariant subspaces for K_E. By (4.74) and because of the symmetries of the potentials,

$$\omega_1=W(x)^{1/2}\psi_0^{(1)}(x_1,0)\psi_1^{(1)}(x_2,\pi), \quad \omega_2=W(x)^{1/2}\psi_1^{(1)}(x_1,\pi)\psi_0^{(1)}(x_2,0).$$

Since $\psi_0^{(1)}(\cdot,0)$ is even and $\psi_1^{(1)}(\cdot,\pi)$ is odd, $\omega_1\in\mathscr{M}_1$ and $\omega_2\in\mathscr{M}_2$. It follows that the restrictions of K_E to the invariant subspaces $\mathscr{M}_1$ and $\mathscr{M}_2$ are unitarily equivalent; in fact $K_E\restriction\mathscr{M}_1 = \mathscr{U}(K_E\restriction\mathscr{M}_2)\mathscr{U}$. Thus the eigenvalue in (4.76) is degenerate and of multiplicity two. Furthermore, $(\tilde{\omega}_1,\omega_2)=0$, $(\tilde{\omega}_1,\omega_1)=(\tilde{\omega}_2,\omega_2)$, $\beta_1=\beta_2$, and thus $c_+=c_-=-2\beta_1(\tilde{\omega}_1,\omega_1)$.

If $W\geqslant 0 (W\neq 0)$, then $c_\pm<0$, and there are no eigenvalues that converge to E^* as $\lambda\downarrow 0$. If one or both of $c_\pm$ are zero, then a more detailed investigation is necessary.

We do not discuss here in detail eigenvalues in higher gaps. We only remark that the singular part of K_E can have any rank. The following example shows how rank three might arise. Assume that $E_0^{(1)}=E_0^{(2)}(0)=0$, $E_0^{(1)}(\pi)=E_0^{(2)}(\pi)=1$, $E_1^{(1)}(\pi)=E_1^{(2)}(\pi)=5$, $E_1^{(1)}(0)=E_1^{(2)}(0)=6$, $E_2^{(1)}(0)=E_2^{(2)}(0)=7$, $E_2^{(1)}(\pi)=E_2^{(2)}(\pi)=8$, and $E_3^{(1)}(\pi)=E_3^{(2)}(\pi)=10$. Then the lowest two (open) gaps of the two-dimensional problem are (2,5) and (9,10) (the point {7} represents a closed gap). The singular part of K_E has rank 1 at $E=2$, rank 2 at $E=5$, rank 1 at $E=9$, and rank 3 at $E=10$. In the last instance we have $\omega_1(x)=W(x)^{1/2}\psi_0^{(1)}(x_1,0)\psi_3^{(2)}(x_2,\pi)$ $\omega_2(x)=W(x)^{1/2}\psi_3^{(1)}(x_1,\pi)\psi_0^{(2)}(x_2,0)$, and $\omega_3(x)=W(x)^{1/2}\psi_2^{(1)}(x_1,\pi)\psi_2^{(2)}(x_2,\pi)$ because $E_0^{(1)}(0)+E_3^{(2)}(\pi)=E_3^{(1)}(\pi)+E_0^{(2)}(0)=E_1^{(1)}(\pi)+E_1^{(2)}(\pi)=10$.

V. THREE DIMENSIONS

We briefly discuss the three-dimensional problem under the assumptions that

$$V(x)=V^{(1)}(x_1)+V^{(2)}(x_2)+V^{(3)}(x_3), \quad x=(x_1,x_2,x_3), \tag{5.1}$$

with W, $V^{(j)}$ real-valued, $V^{(j)}\in L^1_{loc}(\mathbf{R})$, and

$$V^{(j)}(x_j+p_j)=V(x_j), \quad p_j>0, \quad j=1,2,3, \tag{5.2}$$

$$W\in L^{3/2}(\mathbf{R}^3), \quad \int_{\mathbf{R}^3}(1+|x|)^{\gamma}|W(x)|d^3x, \tag{5.3}$$

for a suitable $\gamma>0$. As in one and two dimensions, H_0 can be defined by the forms method or as the closure of a suitable minimal operator (cf. Section IV). The condition $W\in L^{3/2}(\mathbf{R}^3)$ implies that $W\in\mathscr{R}$, the class of Rollnick potentials (Ref. 18, p. 170; Ref. 26). Such potentials are relatively form compact with respect to $-\Delta$ and so also with respect to H_0. We only consider eigenvalue absorption at the bottom of the continuous spectrum which we assume to be at $E=0$. As in the two-dimensional case we may suppose that the spectrum of each $H_0^{(j)}$ also begins at zero. The Birman–Schwinger kernel is given by

$$K_E=W^{1/2}(H_0-E)^{-1}|W|^{1/2}, \quad E<0,$$

and K_E is Hilbert–Schmidt because $W\in\mathscr{R}$. To shorten the notation we will write

$$\Psi_0(x,\theta)=\psi_0^{(1)}(x_1,\theta_1)\psi_0^{(2)}(x_2,\theta_2)\psi_0^{(3)}(x_3,\theta_3), \quad \theta=(\theta_1,\theta_2,\theta_3).$$

We also let

$$G(x,y;\theta)=\Psi_0(x,\theta)\overline{\Psi_0(y,\theta)}+\cdots, \tag{5.4}$$

where the dots indicate terms that are obtained from the first one by interchanging any number of elements between the ordered triples $\{x_1,x_2,x_3\}$ and $\{y_1,y_2,y_3\}$, respecting the order of the elements as in (4.17).

Theorem 5.1: Suppose (5.1)–(5.3) hold. Then K_E has the expansion

$$K_E=K_0+(-E)^{1/2}B+o(|E|^{1/2}), \quad E\uparrow 0, \tag{5.5}$$

where the symbol o refers to the Hilbert-Schmidt norm and B is a rank-one operator with kernel

$$B(x,y)=-\frac{1}{4\pi\sqrt{c_0^{(1)}c_0^{(2)}c_0^{(3)}}}W(x)^{1/2}\Psi_0(x,0)\Psi_0(y,0)|W(y)|^{1/2}. \tag{5.6}$$

We remark that if $V=0$, then $E_0^{(k)}(\theta_k)=\theta_k^2/p_k^2$, where the periods p_k are arbitrary positive numbers, so that $c_0^{(k)}=1/p_k^2$, $\Psi_0(x,0)=1/\sqrt{p_1p_2p_3}$. Hence

$$B(x,y)=-\frac{1}{4\pi}W(x)^{1/2}|W(y)|^{1/2},$$

which is a familiar result [see, e.g., Ref. 3, Eq. (2.7)].

Proof: In order to shorten the notation we define

$$E_0(\theta)=E_0^{(1)}(\theta_1)+E_0^{(2)}(\theta_2)+E_0^{(3)}(\theta_3).$$

(i) In place of (4.24) we now have

$$K_E^{[0,\delta]}(x,y)=W(x)^{1/2}\left[\int_{\mathscr{E}_\delta}\frac{G(x,y;\theta)}{E_0(\theta)-E}\frac{d^3\theta}{(2\pi)^3}\right]|W(y)|^{1/2}, \tag{5.7}$$

where $\mathscr{E}_\delta=\{\theta\in[0,\pi]^3:E_0(\theta)\leqslant\delta\}$. We now write (5.7) as

$$K_E^{[0,\delta]}(x,y)=X_E^{[0,\delta]}(x,y)+Y_E^{[0,\delta]}(x,y), \tag{5.8}$$

$$X_E^{[0,\delta]}(x,y)=W(x)^{1/2}G(x,y;0)|W(y)|^{1/2}\left[\int_{\mathscr{E}_\delta}\frac{d^3\theta}{(2\pi)^3[E_0(\theta)-E]}\right], \tag{5.9}$$

$$Y_E^{[0,\delta]}(x,y)=W(x)^{1/2}\left[\int_{\mathscr{E}_\delta}\frac{H(x,y;\theta)}{E_0(\theta)-E}\,\frac{d^3\theta}{(2\pi)^3}\right]|W(y)|^{1/2}, \tag{5.10}$$

$$H(x,y;\theta)=G(x,y;\theta)-G(x,y;0). \tag{5.11}$$

First consider the integral on the right-hand side of (5.9). Following (4.26) and (4.27) we set $v_j=\sqrt{E_0^{(j)}(\theta_j)}$, $\theta_j=h_j(v_j)$, for $j=1,2,3$, and $r=\sqrt{v_1^2+v_2^2+v_3^2}$, $v_1=r\sin\chi\cos\varphi$, $v_2=r\sin\chi\sin\varphi$, $v_3=r\cos\chi$. Note that the domain of integration lies in the first octant. By using these spherical coordinates we obtain

$$\int_{\mathscr{E}_\delta}\frac{d^3\theta}{E_0(\theta)-E}=\int_0^{\sqrt{\delta}}\frac{g(r)r^2}{r^2-E}\,dr, \tag{5.12}$$

where

$$g(r)=\int_0^{\pi/2}\left(\int_0^{\pi/2}h_1'(r\sin\chi\cos\varphi)h_2'(r\sin\chi\sin\varphi)d\varphi\right)h_3'(r\cos\chi)\sin\chi\,d\chi.$$

For $r<r_1$ with $r_1>0$ sufficiently small, we can expand $g(r)$ as

$$g(r)=\sum_{m=0}^{\infty}b_{2m}r^{2m},$$

and insert it in (5.12). Note that [cf. (4.33)]

$$b_0=\frac{\pi}{2\sqrt{c_0^{(1)}c_0^{(2)}c_0^{(3)}}}. \tag{5.13}$$

This gives

$$\int_{\mathscr{E}_\delta}\frac{d^3\theta}{E_0(\theta)-E}=\sum_{m=0}^{\infty}b_{2m}J_m(E;\delta), \tag{5.14}$$

where

$$J_m(E;\delta)=\int_0^{\sqrt{\delta}}\frac{r^{2m+2}}{r^2-E}\,dr=(-1)^m(-E)^{m+1/2}\left[-\frac{\pi}{2}+\arctan\sqrt{-\frac{E}{\delta}}\right]+\sum_{k=1}^{m+1}\frac{\delta^{m-k+3/2}}{2m-2k+3}E^{k-1}. \tag{5.15}$$

Note that in contrast to (4.32) the right-hand side of (5.15) does not contain any logarithmic terms. From (5.14), (5.15), and (5.9), we see that the term $(-E)^{1/2}B$ in (5.5) comes from the first term on the right-hand side of (5.15) for $m=0$ and by using (5.13) and $G(x,y;0)=8\Psi_0(x,0)\Psi_0(y,0)$ which follows from (5.4) and the reality of $\Psi_0(x,0)$. The other terms on the right-hand side of (5.15) only affect either the term $X_0^{[0,\delta]}(x,y)$ or the corrections of order $O(|E|)$. Thus

$$X_E^{[0,\delta]}(x,y)=X_0^{[0,\delta]}(x,y)+(-E)^{1/2}B(x,y)+O(|E|). \tag{5.16}$$

Note that $X_E^{[0,\delta]}(x,y)$ is a Hilbert–Schmidt kernel because $W\in L^1(\mathbf{R}^3)$. Now we turn to the term $Y_E^{[0,\delta]}(x,y)$ in (5.10) which we write as $Y_E^{[0,\delta]}(x,y)=Y_0^{[0,\delta]}(x,y)+[Y_E^{[0,\delta]}(x,y)-Y_0^{[0,\delta]}(x,y)]$, and note that

$$Y_E^{[0,\delta]}(x,y)-Y_0^{[0,\delta]}(x,y)=EW(x)^{1/2}\left[\int_{\mathscr{E}_\delta}\frac{H(x,y;\theta)}{[E_0(\theta)-E]E_0(\theta)}\,\frac{d^3\theta}{(2\pi)^3}\right]|W(y)|^{1/2}. \tag{5.17}$$

As in (4.42) we have the estimate $|H(x,y;\theta)|\leq C(1+|x|)^\alpha(1+|y|)^\alpha|\theta|^\alpha(\alpha\in(0,1])$ which we insert in (5.17). From the θ-integration we get

$$\int_0^{\sqrt{\delta}} \frac{r^\alpha}{r^2-E}\,dr = |E|^{(\alpha-1)/2}\int_0^{\sqrt{\delta/|E|}} \frac{u^\alpha}{u^2+1}\,du.$$

If we pick any $\alpha\in(0,1)$, then the integral on the right-hand side stays bounded as $E\uparrow 0$ and thus the right-hand side is $O(|E|^{(\alpha-1)/2})$. Hence, by (5.17),

$$|Y_E^{[0,\delta]}(x,y)-Y_0^{[0,\delta]}(x,y)|\leqslant C|E|^{(\alpha+1)/2}|W(x)|^{1/2}(1+|x|)^\alpha(1+|y|)^\alpha|W(y)|^{1/2}. \tag{5.18}$$

So, by (5.3), if we choose α such that $0<\alpha<\min\{1,\gamma/2\}$, then $(1+|x|)^\alpha|W(x)|^{1/2}\in L^2(\mathbf{R}^3)$, which says that the right-hand side of (5.18) is Hilbert–Schmidt and of order $o(|E|^{1/2})$. Thus

$$Y_E^{[0,\delta]}(x,y)=Y_0^{[0,\delta]}(x,y)+o(|E|^{1/2}). \tag{5.19}$$

Since $K_E^{(\delta,\infty)}=K_0^{(\delta,\infty)}+O(|E|)$, by adding (5.16) and (5.19) and using $K_0=X_0^{[0,\delta]}(x,y)+Y_0^{[0,\delta]}(x,y)+K_0^{(\delta,\infty)}$, we obtain (5.5). ∎

Recall that λ_0 is a c.c.th. at $E=0$ if and only $\lambda_0 K_0$ has eigenvalue -1, resp., K_0 has eigenvalue $-\lambda_0^{-1}$. Hence $\lambda_0=0$ cannot be a c.c.th. in three dimensions for the class of potentials considered here. The following lemma will help us classify the possible behaviors of the eigenvalues $E(\lambda)$ that converge to zero as $\lambda\downarrow 0$.

Lemma 5.2: Assume (5.1), (5.2), and (5.3) with $\gamma>1$. Suppose that $K_0 f_0=-\lambda_0^{-1}f_0$, $f_0\in L^2(\mathbf{R}^3)$, $f_0\neq 0$, and $Bf_0=0$. Then zero is an eigenvalue of H_{λ_0}. If $-\lambda_0^{-1}$ is an eigenvalue of K_0 of geometric multiplicity k with geometric eigenspace $\mathcal{N}_0$ and $Bf=0$ for all $f\in\mathcal{N}_0$, then zero is an eigenvalue of H_{λ_0} of multiplicity k.

Proof: We will show that

$$\chi_0=H_0^{-1}|W|^{1/2}f_0 := s-\lim_{E\uparrow 0}(H_0-E)^{-1}|W|^{1/2}f_0 \tag{5.20}$$

is an eigenfunction of H_{λ_0} for the eigenvalue zero. To do this we start from the decomposition

$$(H_0-E)^{-1}|W|^{1/2}f_0=(H_0-E)^{-1}P^{[0,\delta]}|W|^{1/2}f_0+(H_0-E)^{-1}P^{(\delta,\infty)}|W|^{1/2}f_0, \tag{5.21}$$

and first establish the strong convergence as $E\uparrow 0$ of each term on the right-hand side. For the second term on the right-hand side of (5.21) this is clear from

$$(H_0-E)^{-1}P^{(\delta,\infty)}|W|^{1/2}f_0=[(H_0-E)^{-1}(H_0+1)^{1/2}P^{(\delta,\infty)}][(H_0+1)^{-1/2}|W|^{1/2}f_0],$$

since $(H_0+1)^{-1/2}|W|^{1/2}$ is a bounded operator and $\lim_{E\uparrow 0}(H_0-E)^{-1}(H_0+1)^{1/2}P^{(\delta,\infty)}$ exists in norm by the spectral theorem. As for the first term on the right-hand side of (5.21), our task is to show that

$$s-\lim_{E\uparrow 0}\int_{\mathbf{R}^3}\left[\int_{\mathscr{E}_\delta}\frac{G(x,y;\theta)}{E_0(\theta)-E}\frac{d^3\theta}{(2\pi)^3}\right]|W(y)|^{1/2}f_0(y)\,d^3y\in L^2(\mathbf{R}^3). \tag{5.22}$$

To do this we split the terms that make up $G(x,y;\theta)$ as follows; we indicate it for the first term on the right-hand side of (5.7):

$$\Psi_0(x,\theta)\overline{\Psi_0(y,\theta)}=\Psi_0(x,\theta)\Psi_0(y,0)+\Psi_0(x,\theta)[\overline{\Psi_0(y,\theta)}-\Psi_0(y,0)]. \tag{5.23}$$

Notice that when (5.23) is substituted in (5.22), the first term in (5.23) gives no contribution because of the assumption $Bf_0=0$ and (5.6). The integral arising from the second term is dealt with as follows. We set $\hat{x}=(x_1/p_1,x_2/p_2,x_3/p_3)$ so that

$$\Psi_0(x,\theta)=e^{i\theta\cdot\hat{x}}\frac{\xi_0^{(1,+)}(x_1,E_0^{(1)}(\theta_1))}{N_0^{(1,+)}(\theta_1)}\frac{\xi_0^{(2,+)}(x_2,E_0^{(2)}(\theta_2))}{N_0^{(2,+)}(\theta_2)}\frac{\xi_0^{(3,+)}(x_3,E_0^{(3)}(\theta_3))}{N_0^{(3,+)}(\theta_3)}, \tag{5.24}$$

from which, by expanding the functions $\xi_0^{(+)}(x_j,E_0^{(j)}(\theta_j))$ in powers of θ_j, we obtain

$$\Psi_0(x,\theta)=\sum_{m,n,s=0}^{\infty} a_{mns}(x)\,\theta_1^m\theta_2^n\theta_3^s, \tag{5.25}$$

where the coefficients $a_{mns}(x)$ obey

$$|a_{mns}(x)|\leqslant M\tilde{\theta}^{-m-n-s}, \tag{5.26}$$

for some $M>0$ and $\tilde{\theta}>0$, and where $|\theta_j|<\tilde{\theta}$. As a result, from (5.22)–(5.25) we obtain

$$\int_{\mathbf{R}^3}\left[\int_{\mathscr{E}_\delta}\frac{G(x,y;\theta)}{E_0(\theta)-E}\frac{d^3\theta}{(2\pi)^3}\right]|W(y)|^{1/2}f_0(y)d^3y=\sum_{m,n,s=0}^{\infty}a_{mns}(x)\int_{\mathscr{E}_\delta}e^{i\theta\cdot\hat{x}}g_{mns}(\theta,E)d^3\theta+\cdots, \tag{5.27}$$

where

$$g_{mns}(\theta,E)=\frac{\theta_1^m\theta_2^n\theta_3^s}{(2\pi)^3[E_0(\theta)-E]}\int_{\mathbf{R}^3}\Delta(y;\theta)|W(y)|^{1/2}f_0(y)d^3y,$$

$$\Delta(y;\theta)=\overline{\Psi_0(y;\theta)}-\Psi_0(y;0),$$

and where the dots in (5.27) indicate further terms similar to the one displayed [cf. (5.4)]. By Lemma 4.4,

$$|\Delta(y;\theta)|\leqslant C(1+|y|)^{\alpha}|\theta|^{\alpha},\quad \alpha\in(0,1],$$

and thus using the Schwarz inequality gives

$$\left|\int_{\mathbf{R}^3}\Delta(y;\theta)|W(y)|^{1/2}f_0(y)d^3y\right|\leqslant C|\theta|^{\alpha}\|W\|_{2\alpha}^{1/2}\ \|f_0\|,$$

where $\|W\|_{2\alpha}=\int_{\mathbf{R}^3}(1+|y|)^{2\alpha}|W(y)|d^3y$. Now, since (5.3) holds with $\gamma>1$, we may choose α such that $1/2<\alpha<\min\{1,\gamma/2\}$. This guarantees that

$$\frac{|\theta|^{m+n+s+\alpha}}{E_0(\theta)-E}\in L^2(\mathscr{E}_\delta),$$

for all $E\leqslant 0$ with the L^2-norm being bounded independently of E. Therefore

$$\|g_{mns}(\theta,E)\|_{L^2(\mathscr{E}_\delta)}\leqslant C\delta^{(m+n+s+\alpha)/2-1/4}\|W\|_{2\alpha}^{1/2}\|f_0\|,$$

for all $E\leqslant 0$. By the Plancherel theorem and (5.26), we conclude that

$$\left\|a_{mns}(x)\int_{\mathscr{E}_\delta}e^{i\theta\cdot\hat{x}}g_{mns}(\theta,E)d^3\theta\right\|_{L^2(\mathbf{R}^s)}\leqslant\tilde{C}\delta^{\alpha/2-1/4}\left(\frac{\sqrt{\delta}}{\tilde{\theta}}\right)^{m+n+s}\|W\|_{2\alpha}^{1/2}\|f_0\|.$$

Thus, if we choose $\sqrt{\delta}<\tilde{\theta}$, then the series on the right-hand side of (5.27) converges absolutely in the L^2-norm. This implies that $\|(H_0-E)^{-1}P^{[0,\delta]}|W|^{1/2}f_0\|$ is bounded independently of E for $E<0$. Moreover, this norm is increasing in E and hence converges as $E\uparrow 0$. In addition, $(H_0-E)^{-1}P^{[0,\delta]}|W|^{1/2}f_0$ converges weakly as $E\uparrow 0$ because $(\varphi,(H_0-E)^{-1}P^{[0,\delta]}|W|^{1/2}f_0)$ converges for any φ from the dense set $\{\varphi\in L^2:\ \varphi\in\mathrm{Ran}\ P^{[\epsilon,\infty)}$ for some $\epsilon>0\}$. These facts imply (5.22), and hence we have shown that $\chi_0=H_0^{-1}|W|^{1/2}f_0\in L^2(\mathbf{R}^3)$. It remains to show that $H_{\lambda_0}\chi_0=0$. We argue as follows. Let $\psi\in\mathscr{D}(H_{\lambda_0})$. Thus $\psi\in\mathscr{D}(H_0^{1/2})$ and so

$$
\begin{aligned}
(\chi_0, H_{\lambda_0}\psi) &= (H_0^{-1}|W|^{1/2}f_0, H_{\lambda_0}\psi) \\
&= \lim_{E\uparrow 0}([H_0-E]^{-1}|W|^{1/2}f_0, H_{\lambda_0}\psi) \\
&= \lim_{E\uparrow 0}([H_0+1]^{-1/2}H_{\lambda_0}[H_0-E]^{-1}|W|^{1/2}f_0, [H_0+1]^{1/2}\psi) \\
&= \lim_{E\uparrow 0}([H_0+1]^{-1/2}|W|^{1/2}(1+\lambda_0 K_E)f_0, [H_0+1]^{1/2}\psi) = 0,
\end{aligned}
$$

because $K_E \to K_0$ in norm and $-\lambda_0^{-1}$ is an eigenvalue of K_0 with eigenvector f_0. Thus $\chi_0 \in \mathscr{D}(H_{\lambda_0}^*) = \mathscr{D}(H_{\lambda_0})$ and $H_{\lambda_0}\chi_0 = 0$. To prove the last assertion, suppose that $f_1, \ldots, f_k$ are linearly independent eigenvectors of K_0 for the eigenvalue $-\lambda_0^{-1}$. Multiplying the equation $c_1 H_0^{-1}|W|^{1/2}f_1 + \cdots + c_k H_0^{-1}|W|^{1/2}f_k = 0$ from the left by $W^{1/2}$ and using that $\lambda_0 W^{1/2}H_0^{-1}|W|^{1/2}f_j = -f_j$ $(j=1,\ldots,k)$ implies $c_1 = \cdots = c_k = 0$. ■

From now on we assume

$$
W(x) \leqslant 0 \quad \text{a.e.}, \tag{5.28}
$$

which implies that $K_E = -|W|^{1/2}(H_0 - E)^{-1}|W|^{1/2}$ is self-adjoint. Assumption (5.28) is made here only for convenience, in order to avoid discussion of certain technical points that arise when we apply perturbation theory to K_E. The case where W changes sign has been discussed in Ref. 3 (Section 8). The next theorem is similar to Theorem 2.3 in Ref. 3 and to Theorem 2.1 in Ref. 9.

Theorem 5.3: Suppose V and W satisfy (5.1), (5.2), (5.3) with $\gamma > 1$, and (5.28). Let λ_0 be a c.c.th. at $E=0$. Suppose that m $(m \geqslant 1)$ eigenvalues approach zero as $\lambda \downarrow \lambda_0$. Then we have the alternatives:

(i) 0 is not an eigenvalue of H_{λ_0}, $m=1$, and there is a unique eigenvalue obeying $E(\lambda) = -c(\lambda-\lambda_0)^2 + o([\lambda-\lambda_0]^2)$ with $c \neq 0$.

(ii) 0 is an eigenvalue of H_{λ_0} in which case at most one eigenvalue is in case (i) while the other eigenvalues obey $E(\lambda) = -c(\lambda-\lambda_0) + o(\lambda-\lambda_0)$ with $c \neq 0$. Moreover, 0 is either an eigenvalue of H_{λ_0} of multiplicity $m-1$ or m, depending on whether or not there is an eigenvalue in case (i).

Proof: By the Birman–Schwinger principle, $-\lambda_0^{-1}$ is an eigenvalue of K_0 of multiplicity m. Let $\mathscr{N}_0$ denote the corresponding eigenspace. For $E<0$ there are m eigenvalues $\tau_j(E)$ $(j=1,\ldots,m)$ of K_E converging to $-\lambda_0^{-1}$ and the $\tau_j(E)$ are strictly decreasing functions of E. We can obtain $\tau_j(E)$ from (5.5) by using eigenvalue perturbation theory and then solve $\lambda\tau_j(E) = -1$ for $E(\lambda)$ to get the eigenvalue branch $E_j(\lambda)$.

Considering (i), since 0 is not an eigenvalue of H_{λ_0}, by Lemma 5.2, we have that $Bf \neq 0$ for all nonzero $f \in \mathscr{N}_0$. However, since B has rank one, this can only happen if $m=1$. Let $f_0 \in \mathscr{N}_0$ with $\|f_0\| = 1$. Then, by (5.6) and (5.28), $(f_0, Bf_0) > 0$. From perturbation theory[17] and (5.5), we infer that

$$
\tau(E) = -\lambda_0^{-1} + (f_0, Bf_0)(-E)^{1/2} + o(|E|^{1/2}),
$$

which leads to $E(\lambda) = -c(\lambda-\lambda_0)^2 + o([\lambda-\lambda_0]^2)$ with $c = \lambda_0^{-4}(f_0, Bf_0)^{-2}$; so (i) is proved.

To prove (ii), notice that B either vanishes on all of $\mathscr{N}_0$ or on a subspace of dimension $m-1$ of $\mathscr{N}_0$. Thus, by Lemma 5.2, 0 is an eigenvalue of H_{λ_0} of multiplicity m or $m-1$, respectively. Now the number of eigenvalues that behave like $-c(\lambda-\lambda_0) + o(\lambda-\lambda_0)$ with $c>0$ as $\lambda \downarrow \lambda_0$ is equal to the multiplicity of 0 as eigenvalue of H_{λ_0}. To see this, let P_0 denote the orthogonal projection onto the kernel of H_{λ_0}. Then

$$
P_0 W P_0 = -\lambda_0^{-1} P_0 H_0 P_0 \leqslant 0,
$$

so that, since H_0 has a trivial kernel, $P_0 W P_0$ also has a trivial kernel on Ran P_0. Thus $P_0 W P_0$, which is self-adjoint and negative, has $p = \dim[\text{Ran } P_0]$ strictly negative eigenvalues, and

$p=m-1$ or m. Then Theorem 2.4(ii) in Ref. 10 implies that the number of eigenvalues that approach 0 as $\lambda\downarrow\lambda_0$ and which, for λ sufficiently close to λ_0, obey an estimate of the form

$$-a(\lambda-\lambda_0)<E(\lambda)<-b(\lambda-\lambda_0), \tag{5.29}$$

with $a>b>0$, is equal to p. However, from the proof of that theorem one also infers that there is a $c>0$ such that for any $\epsilon>0$ we can choose a and b such that $c-\epsilon<b<a<c+\epsilon$ and so that (5.29) is satisfied as $\lambda\downarrow\lambda_0$ ($-c$ is just one of the p nonzero eigenvalues of P_0WP_0). Since $\epsilon>0$ is arbitrary, it follows that we can replace (5.29) by the stronger statement

$$E(\lambda)=-c(\lambda-\lambda_0)+o(\lambda-\lambda_0), \quad \lambda\downarrow\lambda_0. \tag{5.30}$$

If $p=m$, then all m eigenvalues obey (5.30), with the coefficient c depending on the eigenvalue, of course. If $p=m-1$, then there is exactly one eigenvalue that does not obey (5.29). Then B does not vanish on all of $\mathscr{N}_0$ and so, by perturbation theory, there is one eigenvalue that is in case (i), and this must be the eigenvalue that does not obey (5.29). ■

APPENDIX: PROOFS OF LEMMAS 2.3–2.7

1. Proof of Lemma 2.3

We first prove the entire lemma when $\lambda=0$. Obviously, (i) and (iv) immediately follow from (2.7). To prove (ii) and (iii) we note that from (2.3), (2.4), (2.17), and (2.30), we have

$$\phi_0(x,E)=-d_0(E)[\psi_0^{(+)}(x,E)-\psi_0^{(-)}(x,E)]. \tag{A1}$$

In order to simplify the notation we define

$$g(x,\mu)=\xi_0^{(+)}(x,E(\tilde{n}\pi/p+i\mu)), \tag{A2}$$

where we now assume that an endpoint E_n of the gap $\mathscr{G}_{\tilde{n}}$, together with the proper branch of $E(\tilde{n}\pi/p+i\mu)$, have been selected. We temporarily use the shorthand notation $\tilde{\psi}_0^{(\pm)}(x,\mu)=\psi_0^{(\pm)}(x,E(\tilde{n}\pi/p+i\mu))$ and note that, by (2.3), (2.4), and (2.17),

$$\tilde{\psi}_0^{(+)}(x,\mu)=\tilde{\psi}_0^{(-)}(x,-\mu).$$

This implies, by (2.7),

$$\xi_0^{(-)}(x,E(\tilde{n}\pi/p+i\mu))=e^{2i\tilde{n}\pi x/p}g(x,-\mu), \tag{A3}$$

and thus

$$\tilde{\psi}_0^{(\pm)}(x,\mu)=e^{i\tilde{n}\pi x/p}e^{\mp\mu z}g(x,\pm\mu). \tag{A4}$$

Thus, from (A2)–(A4) it follows that [again using $E=E(\tilde{n}\pi/p+i\mu)$]

$$\begin{aligned}\psi_0^{(+)}(x,E)-\psi_0^{(-)}(x,E)=e^{i\tilde{n}\pi x/p}[e^{-\mu x}g(x,\mu)-e^{\mu x}g(x,-\mu)]-e^{i\tilde{n}\pi x/p}\sinh\mu x[g(x,\mu)\\ +g(x,-\mu)]+e^{i\tilde{n}\pi x/p}\cosh\mu x[g(x,\mu)-g(x,-\mu)].\end{aligned} \tag{A5}$$

Next we note that, by (2.30),

$$d_0(E)=\frac{\alpha}{\mu}+\beta\mu+O(\mu^3), \tag{A6}$$

where α and β are constants; in particular,

$$\alpha=\frac{(-1)^{\tilde{n}}\phi_0(p,E_n)}{2p}.$$

Moreover, $d_0(E)$ is an odd function of μ. Furthermore (a dot means $d/d\mu$),

$$g(x,\mu)+g(x,-\mu)=2\xi_0^{(+)}(x,E_n)+O(\mu^2), \tag{A7}$$

$$g(x,\mu)-g(x,-\mu)=2\dot{\xi}_0^{(+)}(x,E_n)\mu+O(\mu^3). \tag{A8}$$

Therefore, on inserting (A5)–(A8) in (A1) we get

$$\phi_0(x,E)=2\alpha\xi_0^{(+)}(x,E_n)e^{i\tilde{n}\pi x/p}\mu^{-1}\sinh\mu x-2\alpha\dot{\xi}_0^{(+)}(x,E_n)e^{i\tilde{n}\pi x/p}\cosh\mu x+O(\mu)\sinh\mu x$$
$$+O(\mu^2)\cosh\mu x. \tag{A9}$$

Now (ii) follows from (A9) and the estimates

$$|\sinh\mu x|\leqslant C\,\frac{\mu|x|}{1+\mu|x|}\,e^{\mu|x|},\quad \cosh\mu x\leqslant Ce^{\mu|x|}. \tag{A10}$$

Similarly, on differentiating (A9) with respect to μ and using (A10), along with the estimate

$$|\sinh\mu x-\mu x\cosh\mu x|\leqslant C\,\frac{\mu^3|x|^3}{(1+\mu|x|)^2}\,e^{\mu|x|}, \tag{A11}$$

and assuming $\mu<1$, we obtain (iii). Thus the lemma has been proved when $\lambda=0$. Now suppose that $\lambda>0$. In view of (2.19) and (2.21) it suffices to prove (i) and (iv) for $F_\lambda^{(\pm)}(x,E)$ instead of $\psi_\lambda^{(\pm)}(x,E)$. By using (2.11), (2.17), (A2), and (A4), we obtain

$$A_0(x,y;E)=2\alpha e^{(i\tilde{n}\pi/p)(x+y)}\xi_0^{(+)}(x,E_n)\xi_0^{(+)}(y,E_n)\mu^{-1}\sinh\mu(x-y)-2\alpha e^{(i\tilde{n}\pi/p)(x+y)}[\dot{\xi}_0^{(+)}$$
$$\times(x,E_n)\xi_0^{(+)}(y,E_n)-\xi_0^{(+)}(x,E_n)\dot{\xi}_0^{(+)}(y,E_n)]\cosh\mu(x-y)+O(\mu)\sinh\mu(x-y)$$
$$+O(\mu^2)\cosh\mu(x-y).$$

Thus, by using (A10), (A11), and obvious variants of them, we obtain the bounds

$$|A_0(x,y;E)|\leqslant C(1+|x-y|)e^{\mu|x-y|}, \tag{A12}$$

$$|\dot{A}_0(x,y;E)|\leqslant C\,\frac{\mu(1+|y-x|)^3}{(1+\mu|y-x|)^2}\,e^{\mu|y-x|}, \tag{A13}$$

To prove (i), use (A12) and (i) with $\lambda=0$ in (2.10). This yields, for $x>0$,

$$|F_\lambda^{(+)}(x,E)|\leqslant Ce^{-\mu x}+C\lambda e^{-\mu x}\int_x^\infty(1+y)|W(y)|e^{\mu y}|F_\lambda^{(+)}(y,E)|dy. \tag{A14}$$

Multiplying (A14) by $e^{\mu x}$ and applying Gronwall's inequality proves (i) for $F_\lambda^{(+)}(x,E)$. The proof for $F_\lambda^{(-)}(x,E)$ is similar. Considering (iv) we start from

$$\dot{F}_\lambda^{(+)}(x,E)=\dot{\psi}_0(x,E)-\lambda\int_x^\infty\dot{A}_0(x,y;E)W(y)F_\lambda^{(+)}(y,E)dy-\lambda\int_x^\infty A_0(x,y;E)W(y)\dot{F}_\lambda^{(+)}(y,E)dy.$$

Thus, by (A12), (A13), and (i) for $\lambda=0$, we conclude that

$$|\dot{F}_\lambda^{(+)}(x,E)|\leqslant C(1+x)e^{-\mu x}+C\lambda e^{-\mu x}\int_x^\infty\frac{\mu(1+y)}{(1+\mu y)^2}\,(1+y)^2|W(y)|dy+C\lambda e^{-\mu x}$$
$$\times\int_x^\infty|W(y)|(1+y)^2\,\frac{e^{\mu y}|\dot{F}_\lambda^{(+)}(y,E)|}{1+y}\,dy. \tag{A15}$$

Dividing both sides by $(1+x)e^{-\mu x}$ and applying Gronwall's inequality yields (iv). Note that condition (H2) enters through the second and third term on the right-hand side of (A15). To prove (ii) we use the fact that $\phi_\lambda(x,E)$ is a solution of the integral equation

$$\phi_\lambda(x,E)=\phi_0(x,E)+\lambda\int_0^x A_0(x,y;E)W(y)\phi_\lambda(y,E)dy. \tag{A16}$$

By using (ii) with $\lambda=0$ and (A12) we obtain (assuming $x>0$)

$$|\phi_\lambda(x,E)|=C(1+x)e^{\mu x}+C(1+x)e^{\mu x}\int_0^x e^{-\mu y}W(y)|\phi_\lambda(y,E)|dy. \tag{A17}$$

Dividing (A17) by $(1+x)e^{\mu x}$ and using Gronwall's inequality yields (ii) for $x>0$. When $x<0$, the argument is similar, so (ii) is proved. The proof of (iii) is similar to the proof of (iv). We differentiate (A16) with respect to μ and use (ii) and (iii) for $\lambda=0$, together with (A12), (A13), and the monotonicity of the function $y\to\mu(1+y)^2/[1+\mu y]^2$ (assuming $\mu<1$). This gives (for $x>0$)

$$\frac{e^{-\mu x}(1+\mu x)^2|\dot\phi_\lambda(x,E)|}{\mu(1+x)^3}\leq C+C\int_0^x(1+y)|W(y)|\,\frac{e^{-\mu y}(1+\mu y)^2|\dot\phi_\lambda(x,E)|}{\mu(1+y)^3}\,dy.$$

An application of Gronwall's inequality yields the desired estimate when $x>0$, and an analogous estimate holds when $x<0$. Note that only condition (H1) is needed here. ■

2. Proof of Lemma 2.4

(i) The bound immediately follows from Lemma 2.3(i), (ii), and (2.28). To prove (ii) use (2.26), (2.28), part (i), and the dominated convergence theorem, to conclude that

$$\|R_{\lambda,E}-R_{\lambda,E_n}\|_{H.S.}^2=\int_{\mathbf{R}^2}|W(x)||G^D_{\lambda,E}(x,y)-G^D_{\lambda,E_n}(x,y)|^2|W(y)|dxdy\to 0,$$

as $E\to E_n$. Finally, (iii) follows by differentiating (2.28) and applying Lemma 2.3. ■

3. Proof of Lemma 2.5

Let $C_1>0$ be a constant such that

$$|\omega_\lambda(x,E)|\leq C_1|W(x)|^{1/2},\quad |\dot\psi_\lambda(x,E)|\leq C_1|W(x)|^{1/2}(1+|x|). \tag{A18}$$

These estimates follow from Lemma 2.3(i), (iv), and (2.27). Let

$$\sigma=\int_{-\infty}^{\infty}|W(x)|(1+|x|)dx.$$

Then using (2.27), Lemma 2.4(i), and

$$\int_{-\infty}^{\infty}(1+\min\{|x|,|z|\})|W(z)|(1+\min\{|z|,|y|\})dz\leq\sigma(1+\min\{|x|,|y|\}),$$

we deduce by induction that

$$|(R^s_{\lambda,E})(x,y)|\leq C^s\sigma^{s-1}|W(x)|^{1/2}[1+\min\{|x|,|y|\}]|W(y)|^{1/2},\quad s=1,2,...,$$

and thus, by using (A18),

$$|(R^s_{\lambda,E}\omega_{\lambda,E})(x)|\leq C_1C^s\sigma^s|W(x)|^{1/2},\quad s=0,1,2,.... \tag{A19}$$

Now (i) follows from (A18) and (A19) which give

$$|(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})| \leq C_1^2 C^s \sigma^{s+1}. \tag{A20}$$

So choosing $\tilde{C} = C_1^2\sigma$, $r = C\sigma$ proves estimate (i). To prove (ii) we formally differentiate $(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})$:

$$\frac{d(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})}{d\mu} = (\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\dot{\omega}_{\lambda,E}) + (\dot{\tilde{\omega}}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E}) + \sum_{j=0}^{s-1} (\tilde{\omega}_{\lambda,E}, R^j_{\lambda,E}\dot{R}_{\lambda,E}R^{s-j-1}_{\lambda,E}\omega_{\lambda,E}). \tag{A21}$$

Then we note that

$$|(R^{*s}_{\lambda,E}\tilde{\omega}_{\lambda,E})(x)| \leq C_1 C^s \sigma^s |W(x)|^{1/2}, \tag{A22}$$

where the * denotes the adjoint, and so

$$|\dot{\tilde{\omega}}(x,E)(R^s_{\lambda,E}\omega_{\lambda,E})(x)| \leq C_1^2 C^s \sigma^s |W(x)|(1+|x|), \tag{A23}$$

$$|\dot{\omega}_\lambda(x,E)(R^{*s}_{\lambda,E}\tilde{\omega}_{\lambda,E})(x)| \leq C_1^2 C^s \sigma^s |W(x)|(1+|x|), \tag{A24}$$

$$|(R^{*j}_{\lambda,E}\tilde{\omega}_{\lambda,E})(x)\dot{R}_{\lambda,E}(x,y)(R^{s-j-1}_{\lambda,E}\omega_{\lambda,E})(y)| \leq C_1^2 C^s \sigma^{s-1} |W(x)|(1+|x|)(1+|y|)|W(y)|. \tag{A25}$$

For the last inequality we used (A20), (A22), and (2.34). Since the various scalar products in (A25) are multiple integrals involving the functions $R_{\lambda,E}(x,y)$, $\omega_\lambda(x,E)$, $\tilde{\omega}_\lambda(x,E)$, and their derivatives with respect to μ, the estimates (A22)–(A25) provide us with the necessary L^1-bounds on the integrands to justify the formal differentiation leading to (A21) (see, e.g., Ref. 36, Theorem 16.8). From (A23)–(A25) we obtain

$$|(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\dot{\omega}_{\lambda,E})| \leq C_1^2 C^s \sigma^{s+1}, \quad |(\dot{\tilde{\omega}}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})| \leq C_1^2 C^s \sigma^{s+1}, \tag{A26}$$

$$|(\tilde{\omega}_{\lambda,E}, R^j_{\lambda,E}\dot{R}_{\lambda,E}R^{s-j-1}_{\lambda,E}\omega_{\lambda,E}| \leq C_1^2 C^s \sigma^{s+1}. \tag{A27}$$

Inserting (A26) and (A27) in (A21) gives

$$\left|\frac{d(\tilde{\omega}_{\lambda,E}, R^s_{\lambda,E}\omega_{\lambda,E})}{d\mu}\right| \leq (2+s) C_1^2 C^s \sigma^{s+1},$$

and so assertion (ii) follows on setting $r = C\sigma$, $\tilde{C} = (2+s)C_1^2\sigma$. ■

4. Proof of Lemma 2.6

In proving (i)–(iii) it suffices to consider the case $a_N(0) > 0$ and, in (iii), to find the solution $z_+(\mu)$; the modifications needed in the other cases are obvious. We always assume that $0 \leq \mu \leq \mu_0$ and $0 \leq z < r^{-1}$ so that the series on the left-hand side of (2.35) converges absolutely, and uniformly in μ. We begin by writing (2.35) in the form

$$a_N(\mu) z^N \left(1 + \sum_{j=1}^{\infty} \frac{a_{N+j}(\mu)}{a_N(\mu)} z^j\right) = \dot{c}(0)\mu \left(1 - \sum_{j=1}^{N-1} \frac{a_j(\mu)}{\mu \dot{c}(0)} z^j + o(1)\right), \tag{A28}$$

where the $o(1)$-term is a function of μ and comes from $c(\mu) = \dot{c}(0)\mu[1+o(1)]$. Note that the infinite sum on the left of (A28) is $O(z)$ uniformly in μ and that the finite sum on the right is also $O(z)$ uniformly in μ because $\mu^{-1}a_j(\mu)$ is bounded by assumption (b). Therefore, for any $\delta \in (0,1)$ there is $z_1 > 0$ and $\mu_1 > 0$ $(z_1 < r^{-1}, \mu_1 \leq \mu_0)$ such that

$$\begin{aligned} a_N(\mu) z^N (1-\delta) &\leq \dot{c}(0)\mu(1+\delta), \\ a_N(\mu) z^N (1+\delta) &\geq \dot{c}(0)\mu(1-\delta), \end{aligned} \tag{A29}$$

for $0 \leqslant z \leqslant z_1$ and $0 \leqslant \mu \leqslant \mu_1$. Define

$$h(\mu,z) = \sum_{j=1}^{\infty} a_j(\mu) z^j - c(\mu), \tag{A30}$$

so that (2.35) becomes

$$h(\mu,z) = 0. \tag{A31}$$

Now choose any two numbers b_1 and b_2 such that $0 < b_1 < [\dot{c}(0)/a_N(0)]^{1/N} < b_2$. Since δ in (A29) is arbitrary, we conclude that for μ_1 and z_1 sufficiently small, every pair $\{\mu,z\}$ satisfying (A31), $0 \leqslant \mu \leqslant \mu_1$, and $0 < z \leqslant z_1$, also satisfies $b_1 \mu^{1/N} < z < b_2 \mu^{1/N}$. Moreover, a simple calculation using (b) and (c) gives

$$\lim_{\mu \to 0} \mu^{-1} h(\mu, b_1 \mu^{1/N}) = a_N(0) b_1^N - \dot{c}(0) < 0,$$

$$\lim_{\mu \to 0} \mu^{-1} h(\mu, b_2 \mu^{1/N}) = a_N(0) b_2^N - \dot{c}(0) > 0.$$

Therefore, if μ is sufficiently small, the function $z \mapsto h(\mu,z)$ has a zero $z(\mu)$ in the interval $[b_1 \mu^{1/N}, b_2 \mu^{1/N}]$. This proves the existence of solutions to (2.35). To prove uniqueness we consider the partial derivative $h_z(\mu,z)$ for fixed μ and $z \in [b_1 \mu^{1/N}, b_2 \mu^{1/N}]$. We have

$$h_z(\mu,z) = \sum_{j=1}^{N-1} j a_j(\mu) z^{j-1} + N a_N(\mu) z^{N-1} + \sum_{j=N+1}^{\infty} j a_j(\mu) z^{j-1}.$$

The first sum is $O(\mu)$ by assumption (b), the term in the middle is bounded from below by $N[a_N(0)/2] b_1^{N-1} \mu^{1-1/N}$ for μ small, and the last sum is $O(\mu)$. Hence the middle term dominates as $\mu \to 0$, and so $h_z(\mu,z) > 0$ on $[b_1 \mu^{1/N}, b_2 \mu^{1/N}]$. Thus the solution $z(\mu)$ is unique. The continuity of $z(\mu)$ follows from the continuity of $h(\mu,z)$ in both variables.

Assertions (iv) and (v) follow directly from (2.35) which becomes inconsistent. First, if N is even and $a_N(0) < 0$, then the two sides of (2.35) have different signs for μ and z small enough. The sign of z does not matter. Secondly, if $a_j(0) = 0$ for all j with the specified bound on $|a_j(\mu)|$, the left-hand side of (2.35) is bounded by $C_1 r_1 (1 - r_1 |z|)^{-1} |z| \mu$ provided $|z| < \min\{r^{-1}, r_1^{-1}\}$. This bound is incompatible with the right-hand side and the assumption that $\dot{c}(0) > 0$. Thus Lemma 2.6 is proved. ■

5. Proof of Lemma 2.7

(i) The existence of a solution $\mu(z)$ follows from (A28) arguing similarly as in the proof of Lemma 2.6. Considering only the case where $a_N(0) > 0$ and assuming $z \geqslant 0$, we see that the solution $\mu(z)$ is located in an interval of the form $[\tilde{b}_1 z^N, \tilde{b}_2 z^N]$, where $0 < \tilde{b}_1 < a_N(0)/\dot{c}(0) < \tilde{b}_2$. The uniqueness is a consequence of the fact that $h(\mu,z)$ is differentiable with respect to μ if $|z| < \min\{r^{-1}, r_2^{-1}\}$ and $h_\mu(\mu,z) = -\dot{c}(0) + o(1)$ on the interval $[\tilde{b}_1 z^N, \tilde{b}_2 z^N]$. The proof of (iii) proceeds by substituting $\mu(z) = [a_N(0)/\dot{c}(0)] z^N [1 + \varphi(z)]$ in (2.35) and using $a_j(\mu) = \dot{a}_j(0)\mu + o(\mu)$ for $j = 1,\ldots,N-1$, and the given expansion for $c(\mu)$, to find the leading contribution of order $O(z)$ to $\varphi(z)$. The result is (2.37). ■

JWKB connection-formula problem revisited again via Borel summation

Nanny Fröman and Per Olof Fröman
Department of Theoretical Physics, University of Uppsala, Box 803, S-751 08 Uppsala, Sweden

(Received 12 December 1997; accepted for publication 27 April 1998)

Silverstone [Phys. Rev. Lett. **55**, 2523–2526 (1985)] has expressed the opinion that the traditional version of the JWKB connection formulas associated with a classical turning point is incorrect and that the correct version follows from the Borel-based summability of the asymptotic expansions for the Airy functions. In the present paper we show that this assertion is incorrect. After the Borel summation of the asymptotic expressions for the Airy functions has actually been performed explicitly, there are no connection problems, and thus no connection formulas, but *exact* relations expressing the functions $\mathrm{Ai}(z)$ and $\mathrm{Bi}(z)$ in terms of the Whittaker function, although with two defects: Due to the derivation there appear false restrictions on $\arg z$, and there is an artificial cut that coincides with the Stokes line along the real z-axis. We also show that these *exact* relations can be obtained more appropriately in a direct way with the aid of standard formulas available in handbooks, whereby the defects mentioned do not appear. On the other hand, when one uses truncated asymptotic series, the Stokes phenomenon gives rise to connection problems, and the connection formulas, which one uses for handling these connection problems, are inherently one-directional. This property of the connection formulas is demonstrated and discussed anew, in general terms as well as with special regard to the Airy functions. © *1998 American Institute of Physics.*
[S0022-2488(98)00609-4]

I. INTRODUCTION

The properties of the JWKB connection formulas have been the subject of much discussion during several decades in the past. Misconceptions, apparently due to lack of clarity and precision in the formulation of the connection problem, have given rise to controversies. The discussion between Langer[1] and Jeffreys[2] is well known. Both claimed that the connection formulas are one-directional, but Langer misunderstood Jeffreys and thus objected against Jeffreys who was, however, quite right. In Fröman and Fröman[3] and Olver[4] connection formulas associated with a simple turning point were derived, and rigorous upper bounds for the errors were given. Fröman and Fröman[3] demonstrated anew the one-directional nature of the connection formulas. A still more detailed analysis of the connection formulas, with numerical confirmation of their one-directional nature, was given by N. Fröman.[5] Thus, with the connection problem clearly formulated, the correctness as well as the one-directional nature of the connection formulas has long since been clarified. According to Olver (Ref. 6, p. 517) absences of explicit boundary conditions for the solutions and bounds for the error terms could be regarded as contributory causes of the misunderstandings of the meaning of the connection formulas that have occurred frequently in the literature.

In opposition to the results quoted above, Silverstone[7] claims that the traditional version of the JWKB connection formulas associated with a classical turning point is incorrect and that the correct version follows from the Borel summability of the asymptotic expansions for the Airy functions. To analyze this recipe it is thus sufficient to consider the Airy differential equation,

$$\frac{d^2\psi}{dz^2} - z\psi = 0, \tag{1.1}$$

 © 1998 American Institute of Physics

and to investigate what the result of the Borel summation of the asymptotic expansions for the Airy functions really is.

In Sec. II we write down the asymptotic expansions of the Airy functions, and in Sec. III we perform the Borel summation of these asymptotic expansions. This results in *exact* relations that express the Airy functions in terms of the Whittaker function, although with the defects that there are false restrictions on $\arg z$ and that there is an artificial cut that coincides with the Stokes line along the real z-axis. In Sec. IV we derive the exact formulas expressing the Airy functions in terms of the Whittaker function in a more appropriate, direct way with the aid of standard formulas available in handbooks. This direct procedure yields formulas that correctly reproduce the single-valuedness of the Airy functions, and hence there appear no artificial restrictions on $\arg z$ and no artificial cut. For the differential equation $d^2\psi/dx^2+x\psi=0$ and the first order of the JWKB approximation, we show in Sec. V in a concrete way that Silverstone's[7] Eqs. (24) and (25) are not correct connection formulas. In Sec. VI we reconsider the connection formulas and demonstrate again in an alternative way their one-directional nature. We summarize our conclusions in Sec. VII.

II. ASYMPTOTIC EXPANSIONS OF THE AIRY FUNCTIONS

According to 10.4.59 in Abramowitz and Stegun (Ref. 8, p. 448) we have

$$\mathrm{Ai}(z)\sim\frac{1}{2\sqrt{\pi}}\,z^{-1/4}e^{-\zeta}\sum_{k=0}^{\infty}\frac{c_k}{(-\zeta)^k},\quad z\to\infty,\quad |\arg z|<\pi, \tag{2.1}$$

with

$$\zeta=\tfrac{2}{3}z^{3/2}, \tag{2.2}$$

$$c_k=\frac{\Gamma(3(k+1/6))}{2^k3^{3k}\Gamma(k+1/2)\Gamma(k+1)} \tag{2.3a}$$

$$=\frac{\Gamma(k+1/6)\Gamma(k+5/6)}{2^k\Gamma(k+1)\Gamma(1/6)\Gamma(5/6)}, \tag{2.3b}$$

where the last member has been obtained with the aid of 6.1.19 and 6.1.17 in Abramowitz and Stegun (Ref. 8, p. 256). Using Eq. (5) in Luke (Ref. 9, p. 32), we obtain from (2.3a) the asymptotic formula

$$c_k\sim\frac{(2\pi)^{1/2}[(k-1/2)/e]^{k-1/2}}{2\pi2^k}\sim\frac{\Gamma(k)}{2\pi2^k},\quad k\to\infty. \tag{2.4}$$

Recalling that the Airy function Ai is single-valued, and using 10.4.7 in Abramowitz and Stegun (Ref. 8, p. 446), we obtain

$$\mathrm{Ai}(-z)=e^{+i\pi/3}\mathrm{Ai}(ze^{+i\pi/3})+e^{-i\pi/3}\mathrm{Ai}(ze^{-i\pi/3}). \tag{2.5}$$

With the aid of (2.1) we obtain from (2.5) the formula

$$\mathrm{Ai}(-z)\sim\frac{1}{2\sqrt{\pi}}\,z^{-1/4}\left[e^{+i(\zeta-\pi/4)}\sum_{k=0}^{\infty}\frac{c_k}{(i\zeta)^k}+e^{-i(\zeta-\pi/4)}\sum_{k=0}^{\infty}\frac{c_k}{(-i\zeta)^k}\right],\quad |\arg z|<2\pi/3, \tag{2.6}$$

which we can also obtain by rewriting 10.4.60 in Abramowitz and Stegun (Ref. 8, p. 448).

According to 10.4.9 in Abramowitz and Stegun (Ref. 8, p. 446) we have

$$\mathrm{Bi}(z)=\pm2ie^{\mp i\pi/3}\,\mathrm{Ai}(ze^{\pm2\pi i/3})\mp i\,\mathrm{Ai}(z), \tag{2.7}$$

and with the aid of (2.1) we obtain from (2.7)

$$\mathrm{Bi}(z)\sim\frac{1}{\sqrt{\pi}}\,z^{-1/4}\left[e^{\zeta}\sum_{k=0}^{\infty}\ \frac{c_k}{\zeta^k}\mp\frac{1}{2}\,ie^{-\zeta}\sum_{k=0}^{\infty}\ \frac{c_k}{(-\zeta)^k}\right],$$

$$-\pi<\arg z<\pi/3(\text{upper sign}),\quad -\pi/3<\arg z<\pi(\text{lower sign}). \tag{2.8}$$

From 10.4.9 in Abramowitz and Stegun (Ref. 8, p. 446) we obtain

$$\mathrm{Bi}(-z)=2e^{\pm i\pi/6}\,\mathrm{Ai}(ze^{\mp i\pi/3})\mp i\,\mathrm{Ai}(-z), \tag{2.9}$$

and with the aid of (2.1) we obtain from (2.9) the formula

$$\mathrm{Bi}(-z)\sim\frac{1}{2\sqrt{\pi}}\,z^{-1/4}\left[e^{+i(\zeta+\pi/4)}\sum_{k=0}^{\infty}\ \frac{c_k}{(i\zeta)^k}+e^{-i(\zeta+\pi/4)}\sum_{k=0}^{\infty}\ \frac{c_k}{(-i\zeta)^k}\right],$$

$$|\arg z|<2\pi/3, \tag{2.10}$$

which we can also obtain by rewriting 10.4.64 in Abramowitz and Stegun (Ref. 8, p. 449).

In Sec. III we shall explicitly perform the Borel summation of the asymptotic expansions (2.1), (2.6), (2.8), and (2.10).

III. BOREL SUMMATION OF THE ASYMPTOTIC SERIES

Since

$$\frac{1}{k!}\int_0^{\infty}e^{-t}t^k\,dt=1, \tag{3.1}$$

one can in each term of a divergent, infinite series introduce the left-hand member of (3.1) as a factor. When one then interchanges the summation and the integration, the infinite series in the integrand may be convergent, and the integral may also be convergent. The result of this procedure is called Borel summation of the original divergent series.

Recalling (3.1), one can write (2.1) as

$$\mathrm{Ai}(z)\sim\frac{1}{2\sqrt{\pi}}\,z^{-1/4}e^{-\zeta}\sum_{k=0}^{\infty}\ \frac{c_k}{(-\zeta)^k}\,\frac{1}{k!}\int_0^{\infty}e^{-t}t^k\,dt,\quad |\arg z|<\pi. \tag{3.2}$$

Inserting the expression for c_k according to (2.3b) into (3.2), and interchanging the order of summation and integration, and writing $=$ instead of $\sim$, since at the end we do not get an asymptotic but an *exact* formula, we obtain

$$\mathrm{Ai}(z)=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}e^{-\zeta}\int_0^{\infty}dt\ e^{-t}\,\frac{\Gamma(1)}{\Gamma(1/6)\Gamma(5/6)}\sum_{k=0}^{\infty}\ \frac{\Gamma(k+1/6)\Gamma(k+5/6)}{\Gamma(k+1)}\,\frac{1}{k!}\left(-\frac{t}{2\zeta}\right)^k,$$

$$|\arg z|<\pi. \tag{3.3}$$

Recalling (2.3b) and (2.4), we see that the infinite series in (3.3) is convergent when $|-t/(2\zeta)|<1$. Its sum (with the constant factor in front of the summation sign included) is equal to ${}_2F_1(1/6,5/6;1;-t/(2\zeta))$ according to 15.1.1 in Abramowitz and Stegun (Ref. 8, p. 556). Therefore we can write (3.3) as

$$\mathrm{Ai}(z)=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}e^{-\zeta}\int_0^{\infty}dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta)),\quad |\arg z|<\pi. \tag{3.4}$$

Using in Buchholz Eqs. (30) and (19) (Ref. 10, pp. 78 and 19, respectively), we obtain

$$\int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta))=e^{\zeta}W_{0,-1/3}(2\zeta)=e^{\zeta}W_{0,1/3}(2\zeta),$$

$$|\arg\ \zeta|<\pi,\ \text{ i.e., }\ |\arg\ z|<2\pi/3. \tag{3.5}$$

Inserting (3.5) into (3.4), we obtain

$$\mathrm{Ai}(z)=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}W_{0,-1/3}(2\zeta)=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}W_{0,1/3}(2\zeta),\quad |\arg\ z|<2\pi/3. \tag{3.6}$$

Proceeding analogously as above, we shall from (2.6), (2.8), and (2.10) now obtain the functions $\mathrm{Ai}(-z)$, $\mathrm{Bi}(z)$, and $\mathrm{Bi}(-z)$ expressed in terms of the Whittaker function.

We obtain from (2.6),

$$\mathrm{Ai}(-z)=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}\Big[e^{i(\zeta-\pi/4)}\int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta e^{-i\pi/2}))$$
$$+e^{-i(\zeta-\pi/4)}\int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta e^{i\pi/2}))\Big],\quad |\arg\ z|<2\pi/3, \tag{3.7}$$

and then from (3.7),

$$\mathrm{Ai}(-z)=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}[e^{-i\pi/4}W_{0,-1/3}(2\zeta e^{-i\pi/2})+e^{+i\pi/4}W_{0,-1/3}(2\zeta e^{i\pi/2})]$$
$$=\frac{1}{2\sqrt{\pi}}\,z^{-1/4}[e^{-i\pi/4}W_{0,1/3}(2\zeta e^{-i\pi/2})+e^{+i\pi/4}W_{0,1/3}(2\zeta e^{i\pi/2})],\quad |\arg\ z|<\pi/3. \tag{3.8}$$

Formula (2.8) yields

$$\mathrm{Bi}(z)=\frac{1}{\sqrt{\pi}}\,z^{-1/4}\Big[e^{\zeta}\int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta e^{\pm i\pi}))$$
$$\mp\frac{1}{2}\,ie^{-\zeta}\int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta))\Big],$$

$$-\pi<\arg\ z<\pi/3(\text{upper sign}),\quad -\pi/3<\arg\ z<\pi(\text{lower sign}), \tag{3.9}$$

where in the first hypergeometric function we have written $-t/(2\zeta e^{\pm i\pi})$ in order to make the formula to be derived below valid in the largest possible region of $\arg z$. From (3.9) we obtain

$$\mathrm{Bi}(z)=\frac{1}{\sqrt{\pi}}\,z^{-1/4}\Big[W_{0,-1/3}(2\zeta e^{\pm i\pi})\mp\frac{1}{2}\,iW_{0,-1/3}(2\zeta)\Big]$$
$$=\frac{1}{\sqrt{\pi}}\,z^{-1/4}\Big[W_{0,1/3}(2\zeta e^{\pm i\pi})\mp\frac{1}{2}\,iW_{0,1/3}(2\zeta)\Big],$$

$$-2\pi/3<\arg\ z<0(\text{upper sign}),\quad 0<\arg\ z<2\pi/3(\text{lower sign}). \tag{3.10}$$

Putting in Eq. (21b) in Buchholz (Ref. 10, p. 20) $\kappa=0$ and $\mu=\pm 2/3$, and replacing z by 2ζ, and using the reflection formula for the Γ-function, we obtain

$$W_{0,\pm 1/3}(2\zeta) = -i[W_{0,\pm 1/3}(2\zeta e^{+i\pi}) - W_{0,\pm 1/3}(2\zeta e^{-i\pi})]. \tag{3.11}$$

With the aid of this formula it is easily seen that from (3.10) one obtains the same formula when one uses the upper signs as when one uses the lower signs, viz.

$$\mathrm{Bi}(z) = \frac{1}{2\sqrt{\pi}}\, z^{-1/4}[W_{0,\pm 1/3}(2\zeta e^{+i\pi}) + W_{0,\pm 1/3}(2\zeta e^{-i\pi})], \quad |\arg z| < 2\pi/3, \tag{3.12}$$

where the region of $\arg z$ has been obtained with the use of both the upper and the lower signs in (3.10).

From (2.10) we obtain

$$\begin{aligned}\mathrm{Bi}(-z) = \frac{1}{2\sqrt{\pi}}\, z^{-1/4}\Bigg[& e^{+i(\zeta+\pi/4)} \int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta e^{-i\pi/2})) \\ & + e^{-i(\zeta+\pi/4)} \int_0^\infty dt\ e^{-t}\ {}_2F_1(1/6,5/6;1;-t/(2\zeta e^{+i\pi/2}))\Bigg], \quad |\arg z| < 2\pi/3,\end{aligned} \tag{3.13}$$

and then from (3.13),

$$\begin{aligned}\mathrm{Bi}(-z) &= \frac{1}{2\sqrt{\pi}}\, z^{-1/4}[e^{+i\pi/4} W_{0,-1/3}(2\zeta e^{-i\pi/2}) + e^{-i\pi/4} W_{0,-1/3}(2\zeta e^{i\pi/2})] \\ &= \frac{1}{2\sqrt{\pi}}\, z^{-1/4}[e^{+i\pi/4} W_{0,1/3}(2\zeta e^{-i\pi/2}) + e^{-i\pi/4} W_{0,1/3}(2\zeta e^{i\pi/2})], \quad |\arg z| < \pi/3.\end{aligned} \tag{3.14}$$

IV. DIRECT DERIVATION OF THE FORMULAS OBTAINED BY BOREL SUMMATION

We have according to 10.4.14 in Abramowitz and Stegun (Ref. 8, p. 447)

$$\mathrm{Ai}(z) = \frac{1}{\pi}\,(z/3)^{1/2} K_{1/3}(\zeta) \tag{4.1}$$

and according to Eq. (8) in Luke (Ref. 9, p. 213)

$$K_{1/3}(\zeta) = \left(\frac{\pi}{2\zeta}\right)^{1/2} W_{0,1/3}(2\zeta). \tag{4.2}$$

Inserting (4.2) into (4.1) and using (2.2), we obtain (3.6), but without the restriction $|\arg z| < 2\pi/3$.

We have according to 10.4.15 in Abramowitz and Stegun (Ref. 8, p. 447)

$$\mathrm{Ai}(-z) = \tfrac{1}{2}(z/3)^{1/2}[e^{+i\pi/6} H^{(1)}_{1/3}(\zeta) + e^{-i\pi/6} H^{(2)}_{1/3}(\zeta)] \tag{4.3}$$

and according to Eqs. (2a) and (2b) in Buchholz (Ref. 10, p. 207)

$$e^{-i\pi/6} H^{(2)}_{1/3}(\zeta) = \left(\frac{2}{\pi\zeta}\right)^{1/2} e^{+i\pi/4} W_{0,1/3}(2\zeta e^{i\pi/2}), \tag{4.4a}$$

$$e^{+i\pi/6} H^{(1)}_{1/3}(\zeta) = \left(\frac{2}{\pi\zeta}\right)^{1/2} e^{-i\pi/4} W_{0,1/3}(2\zeta e^{-i\pi/2}). \tag{4.4b}$$

Inserting (4.4a) and (4.4b) into (4.3) and using (2.2), we obtain (3.8), but without the restriction $|\arg z| < 2\pi/3$.

With the aid of 10.4.14 in Abramowitz and Stegun (Ref. 8, p. 447) and (2.2) we obtain from (2.7)

$$\mathrm{Bi}(z)=\pm\frac{2i}{\pi}\,(z/3)^{1/2}K_{1/3}(\zeta e^{\pm i\pi})\mp\frac{i}{\pi}\,(z/3)^{1/2}K_{1/3}(\zeta). \tag{4.5}$$

When we use Eq. (2c) in Buchholz (Ref. 10, p. 207) we obtain from (4.5) the expressions for $\mathrm{Bi}(z)$ in the last member of (3.10), but without the restrictions on $\arg z$. When we then use Eq. (19) in Buchholz (Ref. 10, p. 19), we obtain the first expressions for $\mathrm{Bi}(z)$ in (3.10), but without the restrictions on $\arg z$.

We have according to 10.4.19 in Abramowitz and Stegun (Ref. 8, p. 447)

$$\mathrm{Bi}(-z)=\tfrac{1}{2}i(z/3)^{1/2}[e^{+i\pi/6}H^{(1)}_{1/3}(\zeta)-e^{-i\pi/6}H^{(2)}_{1/3}(\zeta)]. \tag{4.6}$$

Inserting (4.4a) and (4.4b) into (4.6) and using (2.2), we obtain (3.14), but without the restriction $|\arg z|<\pi/3$.

With the aid of general formulas for special functions we have above in a direct way derived (3.6), (3.8), (3.10), and (3.14), but without obtaining the restrictions on $\arg z$ that appear when these formulas are derived by means of Borel summation. We shall now illuminate the nature of these formulas further by deriving (3.8) from (3.6) and (3.14) from (3.10), still without obtaining any restrictions on $\arg z$. To this purpose it is convenient to use (2.2) to rewrite (3.6), (3.8), (3.10), and (3.14) as

$$\mathrm{Ai}(z)=\frac{(2/3)^{1/6}}{2\sqrt{\pi}}\,\zeta^{-1/6}W_{0,1/3}(2\zeta), \tag{4.7a}$$

$$\mathrm{Ai}(-z)=\frac{(2/3)^{1/6}}{2\sqrt{\pi}}\,\zeta^{-1/6}[e^{-i\pi/4}W_{0,1/3}(2\zeta e^{-i\pi/2})+e^{+i\pi/4}W_{0,1/3}(2\zeta e^{i\pi/2})], \tag{4.7b}$$

$$\mathrm{Bi}(z)=\frac{(2/3)^{1/6}}{\sqrt{\pi}}\,\zeta^{-1/6}\left[W_{0,1/3}(2\zeta e^{\pm i\pi})\mp\frac{1}{2}\,iW_{0,1/3}(2\zeta)\right], \tag{4.8a}$$

$$\mathrm{Bi}(-z)=\frac{(2/3)^{1/6}}{2\sqrt{\pi}}\,\zeta^{-1/6}[e^{+i\pi/4}W_{0,1/3}(2\zeta e^{-i\pi/2})+e^{-i\pi/4}W_{0,1/3}(2\zeta e^{i\pi/2})], \tag{4.8b}$$

respectively. When in (4.7a) we replace z by $-z$ and ζ by $\zeta e^{\pm 3i\pi/2}$ according to (2.2), we obtain (4.7b) by using (3.11) with ζ replaced by $\zeta e^{\pm i\pi/2}$. According to the conclusion in connection with (3.11) and (3.12) in Sec. III, it is clear that one obtains the same function when one uses the upper signs as when one uses the lower signs in (4.8a), and we can therefore use the upper signs when they are most convenient and the lower signs when they are most convenient. When in (4.8a) we replace z by $-z$ and ζ by $\zeta e^{\mp 3i\pi/2}$, where the upper and lower sign belongs together with the upper and lower signs in (4.8a), we obtain (4.8b) with the aid of (3.11) when we there replace ζ by $\zeta e^{\pm i\pi/2}$.

V. DEMONSTRATION OF THE FACT THAT SILVERSTONE'S EQS. (24) AND (25) ARE NOT CORRECT CONNECTION FORMULAS

Silverstone (Ref. 7) claims that the correct connection formulas are expressed by his Eqs. (24) and (25), which, with $\hbar=1$ and the turning point denoted by t, and on noting that $S=|S|$, $dS/dx=|dS/dx|$, $Q=|Q|$, $-dQ/dx=|dQ/dx|$, we can write as

$$\psi\sim 2b|dS/dx|^{-1/2}\cos(|S|+\pi/4)+2a|dS/dx|^{-1/2}\cos(|S|-\pi/4),\quad \arg(x-t)\approx 0, \tag{5.1a}$$

$$\psi\sim 2b|dQ/dx|^{-1/2}\exp(+|Q|)+(a\pm ib)|dQ/dx|^{-1/2}\exp(-|Q|),\quad \arg(t-x)\approx 0,\quad \mp\,\mathrm{Im}\;x>0. \tag{5.1b}$$

In (5.1a) and (5.1b), which are thus equivalent to Silverstone's (Ref. 7) Eqs. (24) and (25), respectively, S and Q are Silverstone's notations for phase-integrals in the classically allowed and the classically forbidden region, respectively. In each one of these phase-integrals the limits of integration are t and x, and the integrand is assigned to an arbitrary order of the JWKB-approximation and is thus a sum in which each term is characterized by the summation index n. In the discussion in the present section we shall, instead of the notations of the previous sections, use the same notations as in (5.1a) and (5.1b), and we shall assume that the differential equation is $d^2\psi/dx^2+x\psi=0$. For the function ψ in (5.1a) and (5.1b) we then have [see Silverstone's (Ref. 7) Eq. (4)]

$$\psi=2\pi^{1/2}[a\ \mathrm{Ai}(-x)+b\ \mathrm{Bi}(-x)]. \tag{5.2}$$

If one retains the whole sum from $n=0$ to $n=\infty$ in the expressions for S and Q in (5.1a) and (5.1b), expands the phase-integral functions to obtain functions corresponding to those in Sec. II, and performs Borel summation, one obtains *exact* expressions for the Airy functions in terms of the Whittaker function, and thus there appear no connection problems and no connection formulas; see Sec. II. However, when the sums in the expressions for S and Q are truncated, the formulas (5.1a) and (5.1b) are *not correct connection formulas*. Below we shall verify this fact for the first order of the JWKB-approximation.

We decompose the function (5.2) into pure phase-integral functions by defining in the classically allowed region complex conjugate, x-dependent coefficients $A(x)$ and $B(x)=A^*(x)$ such that we have *exactly*

$$\psi(x)=A|dS/dx|^{-1/2}\exp(+i|S|)+B|dS/dx|^{-1/2}\exp(-i|S|),\quad x>t, \tag{5.3a}$$

$$\frac{d\psi(x)}{dx}=A\frac{d}{dx}\{|dS/dx|^{-1/2}\exp(+i|S|)\}+B\frac{d}{dx}\{|dS/dx|^{-1/2}\exp(-i|S|)\},\quad x>t, \tag{5.3b}$$

and by defining in the classically forbidden region real, x-dependent coefficients $C(x)$ and $D(x)$ such that we have *exactly*

$$\psi(x)=C|dQ/dx|^{-1/2}\exp(+|Q|)+D|dQ/dx|^{-1/2}\exp(-|Q|),\quad x<t, \tag{5.4a}$$

$$\frac{d\psi(x)}{dx}=C\frac{d}{dx}\{|dQ/dx|^{-1/2}\exp(+|Q|)\}+D\frac{d}{dx}\{|dQ/dx|^{-1/2}\exp(-|Q|)\},\quad x<t. \tag{5.4b}$$

From (5.2), (5.3a), (5.3b), (5.4a), and (5.4b), with the *first-order* JWKB-expressions for S and Q, we obtain with the use of asymptotic formulas for the Airy functions the following approximate expressions for the coefficients in (5.3a) and (5.3b) and (5.4a) and (5.4b):

$$A=a\ \exp(-i\pi/4)+b\ \exp(+i\pi/4), \tag{5.5a}$$

$$B=a\ \exp(+i\pi/4)+b\ \exp(-i\pi/4), \tag{5.5b}$$

$$C=\frac{5a\ \exp(-2|Q|)}{144|Q|^2}+2b, \tag{5.6a}$$

$$D=a+\frac{b\ \exp(+2|Q|)}{27|Q|^2}. \tag{5.6b}$$

Inserting (5.5a) and (5.5b) into (5.3a) and (5.3b) and (5.6a) and (5.6b) into (5.4a) and (5.4b), we obtain approximately

$$\psi(x)=2b|dS/dx|^{-1/2}\cos(|S|+\pi/4)+2a|dS/dx|^{-1/2}\cos(|S|-\pi/4),\quad x>t, \tag{5.7a}$$

$$\psi(x)=\left(\frac{5a\ \exp(-2|Q|)}{144|Q|^2}+2b\right)|dQ/dx|^{-1/2}\ \exp(+|Q|)$$
$$+\left(a+\frac{b\ \exp(+2|Q|)}{27|Q|^2}\right)|dQ/dx|^{-1/2}\ \exp(-|Q|),\quad x<t, \tag{5.7b}$$

and corresponding formulas for $d\psi(x)/dx$; see (5.3b) and (5.4b). It is seen that (5.1a) agrees with (5.7a), and [since $\exp(-2Q)\ll 1$] that the coefficient of the exponentially large phase-integral function in (5.1b) is in satisfactory agreement with (5.7b) unless $|a/b|$ is too large. However, there is an essential disagreement between the coefficient of the exponentially small phase-integral function in (5.1b) and (5.7b) when $b\neq 0$. In the classically forbidden region the function $2\pi^{1/2}\ \mathrm{Bi}(-x)$ does not represent the *pure,* exponentially large phase-integral function but contains a strong admixture of the exponentially small phase-integral function, as displayed in (5.2) and (5.7b). This is the reason why the coefficient of the exponentially small phase-integral function in (5.7b) is very large, and thus differs strongly from the corresponding coefficient in (5.1b), when $b\neq 0$. The above discussion explains why (5.1a) and (5.1b), i.e., Silverstone's (Ref. 7) Eqs. (24) and (25), are not correct connection formulas.

VI. ONE-DIRECTIONAL NATURE OF THE CONNECTION FORMULAS

In every discussion of the connection problem for asymptotic approximations it is of crucial importance to adhere to the rigorous formulation of this problem: Given the asymptotic approximation of a wave function and its derivative at, or in the immediate neighborhood of, a given initial point (without any *further* knowledge of the wave function), what is the asymptotic approximation of the same wave function and its derivative in another region of the complex plane?

Although, as mentioned in Sec. I, the one-directional nature of the connection formulas has already long ago been proved and clarified in differing ways, we shall in this section demonstrate this property again but in an alternative way, whereby we adhere to Silverstone's[7] notations, but with the simplification that we put $\hbar=1$, and with the difference that we denote the turning point by t, while we let x_1 be a *given* point in the classically forbidden region. Thus we consider an *unspecified,* one-dimensional differential equation of the Schrödinger type with one simple classical turning point t on the real x-axis, but with no other transition point close to that axis, and we assume that to the right of t there is a classically allowed region extending to $+\infty$ and to the left of t there is a classically forbidden region extending to $-\infty$.

We shall first discuss the connection formula

$$|dQ/dx|^{-1/2}\ \exp(-|Q|)\rightarrow 2|dS/dx|^{-1/2}\ \cos(|S|-\pi/4), \tag{6.1}$$

and we consider the connection between $-\infty$ and $+\infty$. The *exact* solution of the differential equation that, as $x\rightarrow-\infty$, tends to the function in the left-hand member of (6.1) increases in the classically forbidden region in the direction toward the turning point, and as $x\rightarrow+\infty$ it tends to the function $\Omega|dS/dx|^{-1/2}\cos(|S|-\pi/4+\delta)$, where Ω and δ are constants, Ω being approximately equal to 2, and δ, although in general different from zero, being to its absolute value small compared to unity. When one makes the connection in the direction of the arrow in (6.1), one is thus allowed to put approximately $\Omega=2$ and $\delta=0$, which yields the connection formula (6.1). On the other hand, the *exact* solutions with the phase equal to, or close to, the phase of the cosine in the right-hand member of (6.1) as $x\rightarrow+\infty$, are in the classically forbidden region extremely sensitive to small deviations of the phase from $|S|-\pi/4+\delta$. In fact, the *exact* solution that tends to the function in the right-hand member of (6.1) as $x\rightarrow+\infty$, will tend to infinity as $x\rightarrow-\infty$, unless δ is *exactly* equal to zero, which occurs only in very exceptional situations. When $\delta\neq 0$, although small, the phase of the wave function in the right-hand member of (6.1) is not *exactly* equal to the phase that corresponds to the solution that decreases exponentially when x tends to $-\infty$, and, because of the sensitivity of the solution to small changes of the phase, there will in the classically forbidden region be an admixture of the function $|dQ/dx|^{-1/2}\exp(+|Q|)$, which tends to infinity as x tends to $-\infty$, and hence the connection formula (6.1) is one-directional. This is illustrated in Fig. 6 in N. Fröman (Ref. 5), which is based on numerical results.

For the particular case of the differential equation $d^2\psi/dx^2+x\psi=0$ one has the exceptional situation that $\delta=0$ for the special connection between $-\infty$ and $+\infty$, and therefore the connection formula (6.1) is bidirectional in that special case, but it is one-directional for connection between $-\infty$ and points in the classically allowed region lying at a *finite* distance from the turning point *t*. This can be verified directly by means of the asymptotic formulas for the Airy functions.

We shall now discuss the connection formula

$$|dS/dx|^{-1/2}\cos(|S|+\pi/4)\rightarrow|dQ/dx|^{-1/2}\exp(+|Q|). \tag{6.2}$$

Let $\psi_1(x)$ and $\psi_2(x)$ be the two real, linearly independent *exact* solutions of the differential equation that fulfill the conditions that

$$\psi_1(x) \text{ is represented by } |dQ/dx|^{-1/2}\exp(-|Q|) \text{ when } x\rightarrow-\infty, \tag{6.3}$$

$$\psi_2(x) \text{ is represented by } |dS/dx|^{-1/2}\cos(|S|+\pi/4) \text{ when } x\rightarrow+\infty. \tag{6.4}$$

We define complex conjugate, *x*-dependent coefficients $A_k(x)$ and $B_k(x)=A_k^*(x)$, where $k=1$ or $k=2$, such that in the classically allowed region we have *exactly*

$$\psi_k(x)=A_k|dS/dx|^{-1/2}\exp(+i|S|)+B_k|dS/dx|^{-1/2}\exp(-i|S|), \quad k=1,2, \tag{6.5a}$$

$$\frac{d\psi_k(x)}{dx}=A_k\frac{d}{dx}\{|dS/dx|^{-1/2}\exp(+i|S|)\}+B_k\frac{d}{dx}\{|dS/dx|^{-1/2}\exp(-i|S|)\}, \quad k=1,2, \tag{6.5b}$$

and we define real, *x*-dependent coefficients $C_k(x)$ and $D_k(x)$, where $k=1$ or $k=2$, such that in the classically forbidden region we have *exactly*

$$\psi_k(x)=C_k|dQ/dx|^{-1/2}\exp(+|Q|)+D_k|dQ/dx|^{-1/2}\exp(-|Q|), \quad k=1,2, \tag{6.6a}$$

$$\frac{d\psi_k(x)}{dx}=C_k\frac{d}{dx}\{|dQ/dx|^{-1/2}\exp(+|Q|)\}+D_k\frac{d}{dx}\{|dQ/dx|^{-1/2}\exp(-|Q|)\}, \quad k=1,2. \tag{6.6b}$$

The precise meaning of (6.3) and (6.4) is then that

$$C_1(-\infty)=0, \tag{6.3a$'$}$$

$$D_1(-\infty)=1, \tag{6.3b$'$}$$

$$A_2(+\infty)=\tfrac{1}{2}\exp(+i\pi/4), \tag{6.4a$'$}$$

$$B_2(+\infty)=\tfrac{1}{2}\exp(-i\pi/4). \tag{6.4b$'$}$$

It is known[3] that, apart from the immediate neighborhood of the turning point *t*, we have

$$A_1(x)\approx\exp(-i\pi/4) \quad \text{classically allowed region,} \tag{6.7a}$$

$$B_1(x)\approx\exp(+i\pi/4) \quad \text{classically allowed region,} \tag{6.7b}$$

$$A_2(x)\approx\tfrac{1}{2}\exp(+i\pi/4) \quad \text{classically allowed region,} \tag{6.7c}$$

$$B_2(x)\approx\tfrac{1}{2}\exp(-i\pi/4) \quad \text{classically allowed region,} \tag{6.7d}$$

$$|C_1(x)|\ll\exp[-2|Q(x)|] \quad \text{classically forbidden region,} \tag{6.8a}$$

$$D_1(x)\approx1 \quad \text{classically forbidden region,} \tag{6.8b}$$

$$C_2(x)\approx1 \quad \text{classically forbidden region,} \tag{6.8c}$$

$$|D_2(x)| \ll \exp[2|Q(x)|] \quad \text{classically forbidden region,} \tag{6.8d}$$

and that in general

$$|D_2(x)| \gg 1 \quad \text{classically forbidden region,} \tag{6.8e}$$

although $D_2(x)$ may change sign in the region considered, so that there may exist an *exceptional* point in the classically forbidden region where $D_2(x)$ is equal to zero. In that case the absolute value of $D_2(x)$ is at the most of the order of magnitude unity in a very small interval containing the exceptional point; see Eq. (44b) and Fig. 8 in N. Fröman (Ref. 5). From (6.5a), (6.5b) and (6.7a)–(6.7d) it follows that *approximately*

$$\psi_1(x) = 2|dS/dx|^{-1/2} \cos(|S| - \pi/4) \quad \text{classically allowed region,} \tag{6.9a}$$

$$\psi_2(x) = |dS/dx|^{-1/2} \cos(|S| + \pi/4) \quad \text{classically allowed region.} \tag{6.9b}$$

From (6.6a) and (6.6b) it follows that in the classically forbidden region

$$|dQ(x)/dx|^{-1/2} \exp[|Q(x)|] = \frac{D_2(x)\psi_1(x) - D_1(x)\psi_2(x)}{C_1(x)D_2(x) - C_2(x)D_1(x)}, \tag{6.10a}$$

$$\frac{d}{dx}\{|dQ(x)/dx|^{-1/2} \exp[|Q(x)|]\} = \frac{D_2(x)d\psi_1(x)/dx - D_1(x)d\psi_2(x)/dx}{C_1(x)D_2(x) - C_2(x)D_1(x)}, \tag{6.10b}$$

and with the aid of (6.10a) and (6.10b) we realize that the *exact* solution $\psi(x)$ of the differential equation that at the *fixed* point x_1 in the classically forbidden region fulfills the conditions

$$\psi(x_1) = \{|dQ/dx|^{-1/2} \exp(+|Q|)\}_{x=x_1}, \tag{6.11a}$$

$$\psi'(x_1) = \left\{\frac{d}{dx}[|dQ/dx|^{-1/2} \exp(+|Q|)]\right\}_{x=x_1}, \tag{6.11b}$$

is given by the *exact* formula

$$\psi(x) = \frac{D_2(x_1)\psi_1(x) - D_1(x_1)\psi_2(x)}{C_1(x_1)D_2(x_1) - C_2(x_1)D_1(x_1)}, \quad -\infty < x < +\infty, \tag{6.12}$$

which, with the aid of (6.8a)–(6.8d) can be written *approximately* as

$$\psi(x) = \psi_2(x) - D_2(x_1)\psi_1(x), \quad -\infty < x < +\infty. \tag{6.12'}$$

Using (6.9a) and (6.9b) we can in the classically allowed region write (6.12′) approximately as

$$\psi(x) = |dS(x)/dx|^{-1/2} \cos(|S(x)| + \pi/4) - 2D_2(x_1)|dS(x)/dx|^{-1/2} \cos(|S(x)| - \pi/4). \tag{6.13}$$

If x_1 does not lie very close to a possibly existing *exceptional* point where $D_2(x) = 0$, we have $|D_2(x_1)| \gg 1$ according to (6.8e), and (6.13) can *approximately* be written as

$$\psi(x) = 2|D_2(x_1)||dS(x)/dx|^{-1/2} \cos(|S(x)| + 3\pi/4) \quad \text{when} \quad D_2(x_1) > 0, \tag{6.14a}$$

$$\psi(x) = 2|D_2(x_1)||dS(x)/dx|^{-1/2} \cos(|S(x)| - \pi/4) \quad \text{when} \quad D_2(x_1) < 0. \tag{6.14b}$$

Under the assumption introduced immediately before (6.14a), the amplitude $2|D_2(x_1)|$ in (6.14a) and (6.14b) is large compared to unity, and for an unspecified differential equation we cannot give a general, approximate analytical expression for it. Comparing (6.14a) and (6.14b) with the left-hand member of the connection formula (6.2), we see that this connection formula is one-directional.

The above demonstration of the one-directional nature of the connection formula (6.2) can be summarized in a concrete way as follows. The solution $\psi_2(x)$ that is represented by the left-hand member of (6.2) in the classically allowed region, is in the classically forbidden region approximately given by $|dQ/dx|^{-1/2}\exp(+|Q|)$ with an admixture of $|dQ/dx|^{-1/2}\exp(-|Q|)$ that is insignificant, although the coefficient $D_2(x)$ of the latter phase-integral function in general is much larger than unity to its absolute value. The connection formula (6.2) can thus be used in the direction of the arrow. On the other hand, the solution $\psi(x)$ that at the *fixed* point x_1 in the classically forbidden region is represented by $|dQ/dx|^{-1/2}\exp(+|Q|)$ without any admixture of $|dQ/dx|^{-1/2}\exp(-|Q|)$, is approximately $\psi(x)=\psi_2(x)-D_2(x_1)\psi_1(x)$, and for this solution one obtains in the classically allowed region the approximate formula (6.13), from which one then obtains (6.14a) and (6.14b), unless $|D_2(x)|$ is accidentally at most of the order of magnitude unity. The connection formula (6.2) thus *can not* be used in the direction opposite to the arrow.

The analysis of the connection formula (6.2) performed above is an alternative to the analysis by N. Fröman[5] which was performed entirely within the framework of the *F*-matrix method.[3] The results of these alternative analyses are, of course, equivalent. Figure 8 in N. Fröman (Ref. 5) provides a numerical illustration of a case (involving a Coulomb potential) in which there exists an exceptional point such that, in accordance with (6.14a) and (6.14b), the phase changes abruptly from $3\pi/4$ to $-\pi/4$, and the amplitude goes through a narrow and deep minimum, as x_1 passes through the exceptional point. For another special case, viz. the differential equation $d^2\psi/dx^2+x\psi=0$, one can by straightforward, although somewhat tedious, analytical calculations, in which the asymptotic formulas for the Airy functions are used, show that the wave function $\psi(x)$ that at the *fixed* point x_1 in the classically forbidden region fulfills the initial conditions (6.11a) and (6.11b), is in the classically allowed region given by the approximate formula

$$\psi(x)=\frac{\exp(2|Q(x_1)|)}{27|Q(x_1)|^2}\,|dQ(x)/dx|^{-1/2}\cos[+|Q(x)|+3\pi/4]. \tag{6.15}$$

In this particular case there does not exist an exceptional point in the classically forbidden region, and (6.14a) is valid for every choice of x_1 (not too close to t) in the classically forbidden region.

VII. CONCLUSIONS

The Borel summation of the asymptotic series for the Airy functions, with *infinitely many terms retained*, yields *exact* relations which express the Airy functions in terms of the Whittaker function, and hence there remain no connection problems and no connection formulas after the Borel summation has been performed. Since the Borel summation is not the appropriate method for obtaining these exact relations, there appear false restrictions on $\arg z$ and an artificial cut that coincides with the Stokes line along the real z-axis; see Sec. III. One can derive these exact relations in a more appropriate, direct way with the aid of standard formulas available in handbooks, and then there appear no false restrictions on $\arg z$ and no artificial cut along the Stokes line; see Sec. IV.

On the other hand, when *truncated* asymptotic series are used, the Stokes phenomenon gives rise to connection problems, and the connection formulas for the handling of these problems are inherently one-directional; see Sec. VI.

When a wave function is well defined in the whole complex plane, and its asymptotic series is Borel summable, the accuracy of a truncated Borel sum will increase indefinitely as the number of terms is increased, and on a Stokes line, where the asymptotic series is not Borel summable, it is possible to calculate the wave function via analytic continuation of the result obtained in the region outside the Stokes line. This provides an efficient method for numerically exact calculation on the Stokes line of *a wave function that is well defined in the whole complex plane*,[11] but not of a wave function that is defined only approximately at a point in the classically allowed region, and thus it does not result in a connection formula. In particular, the fact that, by implementing the Borel procedure numerically, one can obtain the sum of an asymptotic series, representing a wave function that is well defined in the whole complex plane, to a much higher accuracy than is possible by partial summation of the original asymptotic series[11] is not relevant for the connection problem, formulated in the beginning of Sec. VI.

Across the Stokes line there is a cut *as regards the Borel summability*. However, the coefficient of the exponentially small term in the asymptotic series does not change discontinuously as z crosses the Stokes line, but is a continuous function of z. This follows in an obvious way from the continuity of the F-matrix in the method for solving connection problems developed by Fröman and Fröman.[3]

In every discussion of the connection formulas it is of primary importance to define clearly what one means by saying that a solution $\psi(x)$ of the differential equation in question at a given point x_0 is represented by a single phase-integral function, $f_1(x)$ or $f_2(x)$, respectively, without any admixture of the other phase-integral function, $f_2(x)$ or $f_1(x)$, respectively, and the only reasonable definition is obviously the requirement that $\psi(x_0)=f_k(x_0)$ and $\psi'(x_0)=f_k'(x_0)$, where $k=1$ or $k=2$, respectively. Adhering to this definition, we have considered the differential equation $d^2\psi/dx^2+x\psi=0$ and the first order of the JWKB-approximation and shown that Silverstone's (Ref. 7) ''correct connection formula,'' given by his Eqs. (24) and (25), is erroneous; see Sec. V.

Silverstone[7] has considered the Borel summation of the asymptotic series for the Airy functions, but not the connection problem for asymptotic approximations, formulated rigorously as in the beginning of Sec. VI. For points in the classically allowed and classically forbidden regions on opposite sides of a simple turning point, the solution of the connection problem is in a correct and satisfactory way given by the one-directional connection formulas (6.1) and (6.2).

As regards transmission through a potential barrier, also discussed by Silverstone,[7] a rigorous treatment by Fröman, Fröman, and Lundborg (Chap. 5 in Ref. 12), in which the barrier is considered as a whole, resulted in a new, very accurate connection formula for a barrier. In particular, this formula accounts in a completely correct way for terms in the transmission coefficient that for a superdense potential barrier are of the order of magnitude $\exp[-4|Q|]$ in Silverstone's[7] notation and with $\hbar=1$. Barrier penetration formulas obtained in treatments, where the connection of the wave function across each one of the two classical turning points of the barrier is treated separately, can sometimes be used, but there are important cases in which they are unsatisfactory, e.g., for energies in the neighborhood of the top of a barrier and for energies in the neighborhood of a resonance.

It is very important to make a clear distinction between the situation when one knows the wave function perfectly well in a certain region of the complex z-plane and the situation when one knows the wave function only approximately in that region. In the former situation one can obtain the wave function in another region be means of *bidirectional* analytic continuation (for instance with the use of Borel summation), while in the latter situation one has only *one-directional* connection formulas. The long dispute concerning the one-directional nature of the connection formulas seems in some cases to be due to an unclear distinction between these two situations.

We can very briefly summarize our conclusions as follows. When one uses Borel summation of infinite asymptotic series, one obtains exact formulas, and thus there remain no connection problems. To use the term connection formulas, when one is referring to exact solutions, is inadequate and gives rise to confusion. When one uses truncated asymptotic series, one is left with the Stokes phenomenon and the inherently one-directional connection formulas.

ACKNOWLEDGMENTS

The present investigation was initiated during the time 6 February–31 March 1995, when the authors were invited to participate in the program *Exponential Asymptotics* at the Isaac Newton Institute for Mathematical Sciences in Cambridge, England. We wish to express our gratitude to the Isaac Newton Institute for a most fruitful time in an extremely stimulating scientific atmosphere. We are also much indebted to Professor Michael Berry for the invitation to participate in the program *Exponential Asymptotics*. We would also like to thank Professor Harris J. Silverstone, who participated in the same program, for interesting and valuable discussions.

Derivative expansion of one-loop effective actions for Yang-Mills fields

T. D. Gargett[a] and I. N. McArthur[b]
Physics Department, The University of Western Australia, Nedlands, Western Australia 6907, Australia

(Received 31 December 1997; accepted for publication 24 April 1998)

Low energy effective actions are computed by integrating out degrees of freedom heavier than some energy scale of physical interest. At the one-loop level, the low energy effective action can be computed in terms of the functional trace of the heat kernel associated with the operator appearing in the part of the action quadratic in the heavy fields. Here, a technique for computing this functional trace is illustrated in the case of heavy scalar fields coupled to a Yang-Mills background. It makes use of the similarity of the functional trace of the heat kernel expressed in momentum space to a Gaussian integral. An explicit computation of the piece of the low energy effective action for the Yang-Mills fields quadratic in derivatives of the field strength is carried out, extending previously known results on the form of the long wavelength limit of the low energy effective action. © *1998 American Institute of Physics.* [S0022-2488(98)02209-9]

I. INTRODUCTION

The study of perturbative low energy effective actions has been very important for phenomenological applications of quantum field theory, where one is often interested in physics at an energy scale small compared with some of the mass scales in an underlying renormalizable quantum field theory. Although particles with masses larger than the energy scale of interest cannot be observed directly, they do contribute to interactions of the ''light'' degrees of freedom as virtual intermediate states. These contributions are summarized in the low energy effective action for the light degrees of freedom, which is obtained by summing Feynman diagrams with heavy degrees of freedom in loops.

In this paper, the case of massless gauge fields interacting with massive matter fields is considered. There has been much work on the computation of the one-loop low energy effective action for the gauge bosons in this case, with the principle focus being on the ''long wavelength limit.'' This is the lowest order term in an expansion of the effective action in derivatives of the field strength, and involves integrating out the massive matter fields in the presence of a *constant* gauge field background. Schwinger[1] used canonical methods to determine the complete form of the effective action in the long wavelength limit for the case of $U(1)$ gauge fields, reproducing earlier results of Heisenberg and Euler.[2] This result has since been rederived by a variety of other methods,[3–5] including extension to non-Abelian gauge groups. Here, the complete form of the first nontrivial correction to Schwinger's result will be computed, namely the term in the effective action involving two derivatives of the field strength.

This calculation is presented as an application of an approach to computing one-loop low energy effective actions developed by the authors in the context of supersymmetric Yang-Mills theories.[6] Using Schwinger proper time regularization, or the closely related zeta function regularization, the one-loop effective action can be computed in terms of the functional trace of the heat kernel for the operator in the piece of the original action quadratic in the quantum fields. The approach of Ref. 6 was to exploit the similarity of the functional trace of the heat kernel expressed in momentum space to a Gaussian integral, which allows Schwinger's result to be derived very efficiently. Here, we show that this method extends naturally to allow computation of the expan-

sion of the one-loop effective action in terms of covariant derivatives of the field strength of the background gauge fields. This is equivalent to the computation of corrections to the long wavelength limit of the effective action.

The plan of the paper is as follows. In the next section, we review the derivative expansion of the effective action. The technique introduced in Ref. 6 for computing the low energy effective action in the presence of covariantly constant background gauge fields is described in Sec. III, and its extension to nonconstant background gauge fields is discussed in Sec. IV. This is illustrated in Sec. V, where the terms in the effective action linear in the momenta of the gauge bosons are shown to vanish. The main results of the paper are presented in Sec. VI, where the full second order term in the derivative expansion of the effective action is computed. A short discussion follows. Details of computations have been relegated to appendices.

II. DERIVATIVE EXPANSION OF THE EFFECTIVE ACTION

For definiteness, the case of a free massive scalar field coupled to a Yang-Mills background is considered, although the technique readily generalizes to the inclusion of light scalars interacting with the heavy scalars, or to massive fields of different spin. In four-dimensional Euclidean space, the action is

$$S[\phi,A_\mu]=\int d^4x\ \phi^\dagger(-D_\mu D_\mu+m^2)\phi,$$

where D_μ is the covariant derivative in the representation R of the gauge group to which the scalar fields belong. (Since the metric is Euclidean, contracted space–time indices will be written with both indices lowered.) The heat kernel associated with the operator $(-D_\mu D_\mu+m^2)$ is $e^{-tm^2}K(x,x';t)$, where $K(x,x';t)$ is the heat kernel for massless scalars, defined formally as

$$K(x,x';t)=e^{tD_\mu D_\mu}\delta^{(4)}(x,x'). \tag{1}$$

The one-loop effective action for the gauge fields obtained by ''integrating out'' the heavy scalar fields is $\Gamma_{\rm eff}[A_\mu]=-\ln Z[A_\mu]$, with $Z[A_\mu]=\int[d\bar{\phi}][d\phi]e^{-S[\phi,A_\mu]}$. Using the zeta function regularization, $\Gamma_{\rm eff}[A_\mu]=-\zeta'(0)$, where the zeta function is

$$\zeta(s)=\frac{1}{\Gamma(s)}\int_0^\infty dt t^{s-1}e^{-tm^2/\mu^2}\ {\rm Tr}\int d^4x\ \lim_{x\to x'}K(x,x';t/\mu^2). \tag{2}$$

Here, Tr is a trace over gauge indices, and μ is a parameter with dimensions of mass introduced to make t dimensionless.

Thus the problem reduces to that of computing the functional trace

$$\int d^4x\ \lim_{x\to x'}K(x,x';t)\equiv\int d^4x\ K(t)$$

of the massless heat kernel. To do this, it is convenient to introduce a plane wave representation $\delta^{(4)}(x,x')=\int(d^4k/(2\pi)^4)\,e^{ik.(x-x')}$ for the delta function in expression (1) for the kernel. Then

$$K(t)=\lim_{x\to x'}\int\frac{d^4k}{(2\pi)^4}e^{ik.(x-x')}(e^{-ik.(x-x')}e^{tD_\mu D_\mu}e^{ik.(x-x')})=\int\frac{d^4k}{(2\pi)^4}e^{tX_\mu X_\mu}, \tag{3}$$

where

$$X_\mu=D_\mu+ik_\mu. \tag{4}$$

The effective action is a functional of the field strength $F_{\mu\nu}=[D_\mu,D_\nu]$ and its covariant derivatives as a result of gauge invariance (there is no anomaly for a scalar field). In the $U(1)$ case (or background electromagnetic field), the covariant derivatives are ordinary derivatives. The piece of the effective action independent of derivatives of the background field strength is its long

wavelength limit, corresponding to the limit of zero momentum gauge bosons. It is the first term in the expansion of the effective action in derivatives of the field strength, which translates in momentum space to an expansion in powers of momenta of the gauge bosons. Equivalently, this can be viewed as an expansion of the effective action in commutators of covariant derivatives, with the long wavelength limit being a truncation with only single commutators of the covariant derivatives, and corrections to the effective action corresponding to the inclusion of higher order commutators.

As emphasized by Avramidi,[5] the covariant generalization of this in the case of non-Abelian gauge groups is then an expansion of the effective action in commutators of the appropriate covariant derivatives

$$\Gamma_{\text{eff}}[A_\mu]=\int d^4x(\Phi(F)+(DF)\Psi(F)(DF)+\cdots)$$

(where space–time indices have been suppressed). The first term is the long wavelength limit of the effective action, and is computed by integrating out the scalar fields in the presence of a gauge field background with covariantly constant field strength. The aim of this paper is to demonstrate an algorithm for the computation of $K(t)$ in (3) which is well adapted to this expansion of the effective action in covariant derivatives of the background gauge field.

Note that although $K(t)$ as defined by (3) is x-dependent via the covariant derivatives, this will be suppressed for notational convenience. The quantities $X_\mu=D_\mu+ik_\mu\mathbf{1}$ are considered as matrices in the representation R of the Lie algebra of the gauge group.

III. COVARIANTLY CONSTANT BACKGROUND GAUGE FIELDS

We begin by outlining the technique developed in Ref. 6 for computing the functional trace of the heat kernel for the case of covariantly constant background gauge field strength, $D_\mu F_{\nu\rho}=0$. From (3), it follows that $K(t)$ satisfies the linear differential equation

$$\frac{dK(t)}{dt}=K_{\mu\mu}(t), \tag{5}$$

with the notation

$$K_{\mu_1\mu_2\cdots\mu_n}(t)=\int\frac{d^4k}{(2\pi)^4}X_{\mu_1}X_{\mu_2}\cdots X_{\mu_n}e^{tX.X}. \tag{6}$$

Here, $X.X=X_\mu X_\mu$ with X_μ defined by (4). The aim is then to determine $K_{\mu\nu}(t)$ in terms of $K(t)$ to allow this differential equation to be solved for $K(t)$, from which the effective action is computed via (2). The method for doing this introduced in Ref. 6 is to exploit the similarity of expressions of the form (6) to moments of an ordinary Gaussian. To compute

$$\int\frac{d^4k}{(2\pi)^4}k_{\mu_1}k_{\mu_2}\cdots k_{\mu_n}e^{-tk.k},$$

one can use the identity

$$0=\int\frac{d^4k}{(2\pi)^4}\frac{\partial}{\partial k^{\mu_n}}(k_{\mu_1}k_{\mu_2}\cdots k_{\mu_{n-1}}e^{-tk.k})$$

repeatedly to obtain an expression in terms of the ordinary Gaussian $\int[d^4k/(2\pi)^4]e^{-tk.k}$. Similarly, to compute $K_{\mu\nu}(t)$, we use the fact that

$$0=\int\frac{d^4k}{(2\pi)^4}\frac{\partial}{\partial k^{\nu}}(X_\mu e^{tX.X}),$$

as the factor e^{-tk^2} in the integrand ensures that the boundary terms vanish. However, this is now a very nontrivial statement, because the X_μ defined by (4) are not commuting objects; in fact, $[X_\mu, X_\nu] = F_{\mu\nu}$. Doing the derivative with respect to k^ν yields

$$0 = i\delta_{\mu\nu} K(t) + 2it \int \frac{d^4k}{(2\pi)^4} X_\mu \int_0^1 ds (e^{stX.X} X_\nu e^{-stX.X}) e^{tX.X}. \tag{7}$$

The quantity

$$\int_0^1 ds\ e^{stX.X} X_\nu e^{-stX.X} = \sum_{m=0}^{\infty} \frac{t^m}{(m+1)!} ad^{(m)}(X.X)(X_\nu) \tag{8}$$

is readily computed in the case where $F_{\mu\nu} = [X_\mu, X_\nu]$ is covariantly constant; one simply ignores $[X_\mu, [X_\nu, X_\rho]]$ and higher order commutators in the computation of the terms in the series. The result is

$$\int_0^1 ds e^{stX.X} X_\nu e^{-stX.X} = B_{\nu\rho}(t) X_\rho, \tag{9}$$

where

$$B_{\nu\rho}(t) = \sum_{m=0}^{\infty} \frac{(-2t)^m}{(m+1)!} (F^m)_{\nu\rho} = \left[\frac{1 - e^{-2tF}}{2tF} \right]_{\nu\rho}. \tag{10}$$

This expression contains two different matrix products, one over gauge indices and one over space–time indices. The gauge indices on $F_{\mu\nu}$ and on $B_{\mu\nu}(t)$ have been suppressed, but it should not be forgotten that like $K(t)$ itself, they are matrices in the representation R of the gauge group.

Substituting (10) and (9) into (7) and using the fact that the matrix $B_{\nu\rho}(t)$ can be moved through X_μ because the commutators $[X_\mu, F_{\nu\rho}]$ are being set to zero, one finds that

$$0 = \delta_{\mu\nu} K(t) + 2t B_{\nu\rho}(t) K_{\mu\rho}(t).$$

Multiplying both sides by the inverse matrix $B^{-1}_{\lambda\nu}(t)$ gives

$$K_{\mu\nu}(t) = \left[\frac{F}{e^{-2tF} - 1} \right]_{\nu\mu} K(t),$$

so that (5) becomes

$$\frac{dK(t)}{dt} = \mathrm{tr} \left[\frac{F}{e^{-2tF} - 1} \right] K(t), \tag{11}$$

where the trace tr is over space–time indices (but *not* over gauge indices; $K(t)$ is still a matrix with respect to the gauge indices). An essential point here is that because the power series (17) begins with **1**, the inverse matrix $B^{-1}_{\mu\nu}(t)$ does not involve inverse powers of $F_{\mu\nu}$; *so there is never a need to invert the matrix* $F_{\mu\nu}$. Remembering that $K(t)$ is a matrix and using $\mathrm{tr}(F/e^{-2tF} - 1) = \mathrm{tr}(Fe^{2tF}/1 - e^{2tF}) = -\frac{1}{2}\mathrm{tr}[C^{-1}(1 - e^{2tF})^{-1}(d/dt)(1 - e^{2tF})C]$, with C a matrix independent of t, the solution of the differential equation is easily seen to be

$$K(t) = \det[(1 - e^{2tF})C]^{-1/2}.$$

It remains to compute the integration constant C. This is done by requiring that this expression reduces to $\int d^4k/(2\pi)^4 e^{-tk^2} = (16\pi^2 t^2)^{-1}$ in the limit $F \to 0$, from which it follows that $C = 2\pi/F$. Using $\det A = (\det AA^T)^{1/2}$ and $F^T = -F$, this can be symmetrized to give

$$K(t)=\frac{1}{8\pi^2}\det\left[\frac{F^2}{\cosh(2tF)-1}\right]^{1/4}=\frac{1}{16\pi^2t^2}\det\left[\frac{tF}{\sinh\ tF}\right]^{1/2} \tag{12}$$

as obtained by many other authors.[3–5]

For later reference, we make the following point. If expression (12) for $K(t)$ is substituted into (2), it is not possible to perform the t integration in closed form to determine the zeta function and hence the low energy effective action. *Rather, one has to expand $K(t)$ as a power series in t and perform the t integration in (2) order by order in this expansion.* The term of order t^n in the expansion of $K(t)$ gives rise to a contribution to the effective action involving $(n+2)$ factors of the field strength, and so, in the case of a $U(1)$ gauge field, represents an effective vertex for the interaction of $(n+2)$ gauge bosons. So one has to evaluate the low energy effective action as a sum of effective vertices. This is no serious loss, as physically, it is the effective vertices which are of interest. As such, there is really no need to solve the differential equation (11) in closed form; *it suffices to solve for $K(t)$ as a power series expansion in t*. [Indeed, in the paper of Ritz and Delbourgo[7] on the effective n-photon interactions in the low energy effective action for scalar QED, the power series expansion they obtain for $\ln K(t)$ can be obtained by integrating Eq. (11),

$$\frac{dK(t)}{dt}=-\frac{1}{2t}\sum_{m=0}^{\infty}\frac{(-2t)^m}{m!}B_m tr(F^m)K(t),$$

where the definition $z/(e^z-1)=\Sigma_{m=0}^{\infty}(1/m!)\,B_m z^m$ of the Bernoulli numbers B_m is used.] This point will be important later when we examine corrections to the low energy effective action; we will obtain a differential equation for $K(t)$ which is difficult to solve in closed form but which is easily integrated term by term to determine the corrections to $K(t)$ as a power series in t. For later reference, the power series expansion of $K(t)$ in the long wavelength limit, which we denote by $K^{(0)}(t)$, begins

$$K^{(0)}(t)=\frac{1}{16\pi^2t^2}\left[1-\frac{t^2}{12}\text{tr}\ F^2+\frac{t^4}{360}\left(\text{tr}\ F^4+\frac{5}{4}(\text{tr}\ F^2)^2\right)+\cdots\right], \tag{13}$$

where the traces are over space–time indices but not gauge indices. It will be seen later that traces of odd powers of F arise only in corrections to the long wavelength limit, as they can be expressed in terms of covariant derivatives of the field strength.

IV. CORRECTIONS TO THE LONG WAVELENGTH LIMIT

The above procedure for establishing a linear differential equation satisfied by $K(t)$ is easily extended to the case where higher order commutators are included, corresponding to corrections to the long wavelength limit of the effective action, or higher order terms in the (covariant) derivative expansion of the full effective action. The cost is greater complexity. However, all the steps involved are purely combinatoric and algebraic, and as such, have the potential to be implemented using a symbolic computational language. It should be stressed that the procedure outlined below does not allow computation of the kernel itself, but only its functional trace; therefore it can be used to determine the effective action, but not Green's functions in the presence of the background gauge field.

Before explaining the method, it is necessary to introduce some terminology to be adopted, namely the *order* of the approximation to the effective action. The long wavelength limit will be termed *zeroth order* because it involves no covariant derivatives of the field strength $F_{\mu\nu}$. In terms of the computation in the previous section it means including commutators $[X_\mu,X_\nu]$, but setting all higher order commutators to zero. An *nth order* contribution to the effective action will mean one with n covariant derivatives of the field strength; they can all be acting on one field strength, they can all be acting on different field strengths, or anything in between, as all these possibilities are related using integration by parts in x-space in the effective action. In terms of the computation of $K(t)$, the nth order contribution contains n commutators of X_μ with the zeroth order commutators $[X_\nu,X_\rho]=F_{\nu\rho}$, either all acting one $[X_\nu,X_\rho]$, or all on different ones, or anything between.

The equation $dK(t)/dt = K_{\mu\mu}(t)$ is the starting point for an order n computation of $K(t)$, and requires the determination of $K_{\mu\nu}(t)$ to the required order. As above, this is achieved using the identity

$$0 = \int \frac{d^4k}{(2\pi)^4} \frac{\partial}{\partial k^\nu}(X_\mu e^{tX.X}) = i\delta_{\mu\nu}K(t) + 2it\int \frac{d^4k}{(2\pi)^4} X_\mu \left(\int_0^1 ds\ e^{stX.X} X_\nu e^{-stX.X} \right) e^{tX.X}. \tag{14}$$

The computation of the integral over s via the power series expansion (8) cannot be done exactly, and it is at this point that a truncation to a given order n must be made. The result of summing the power series with this truncation can be expressed in the form

$$\int_0^1 ds e^{-stX.X} X_\nu e^{stX.X} = A_\nu(t) + B_{\nu\rho}(t)X_\rho + C_{\nu\rho\sigma}(t)X_\rho X_\sigma + D_{\nu\rho\sigma\lambda}(t)X_\rho X_\sigma X_\lambda + \cdots. \tag{15}$$

The tensors $A_\nu(t), B_{\nu\rho}(t), \ldots$ are independent of X_μ by definition (but not of its commutators). The series on the right hand side will only have a finite number of terms depending on the order of the computation; in fact at order n there are terms with at most $(n+1)$ free X's. This is established by referring back to (8). If $ad^{(m)}(X.X)(X_\nu)$ contains p free X's, then $ad^{(m+1)}(X.X)(X_\nu)$ contains an additional free X only if it also contains an extra higher order commutator. Given that $ad^{(0)}(X.X)(X_\nu) = X_\nu$ and that there are at most n higher order commutators to the order we are considering, the required conclusion easily follows. The computation of the tensors $A_\nu(t), B_{\nu\rho}(t), \ldots$ to the required order is the only nontrivial step in the procedure, as will be seen in Secs. V and VI.

Substitution of the result (15) into (14) yields

$$\begin{aligned} 0 = {} & \frac{1}{2t}\delta_{\mu\nu}K(t) + A_\nu(t)K_\mu(t) + [X_\mu, A_\nu(t)]K(t) + B_{\nu\rho}(t)K_{\mu\rho}(t) \\ & + [X_\mu, B_{\nu\rho}(t)]K_\rho(t) + C_{\nu\rho\sigma}(t)K_{\mu\rho\sigma}(t) + [X_\mu, C_{\nu\rho\sigma}(t)]K_{\rho\sigma}(t) + \cdots. \end{aligned} \tag{16}$$

Now, as was seen in the previous section, $B_{\nu\rho}(t)$ contains a zeroth order contribution; this will be denoted $B^{(0)}_{\nu\rho}(t)$, and

$$B^{(0)}_{\nu\rho}(t) = \sum_{m=0}^{\infty} \frac{(-2t)^m}{(m+1)!}(F^m)_{\nu\rho} = \left[\frac{1 - e^{-2tF}}{2tF} \right]_{\nu\rho}. \tag{17}$$

Recall also that the power series begins with **1**, so that $B^{(0)}_{\nu\rho}(t)$ can be inverted without introducing negative powers of $F_{\mu\nu}$. So, denoting any higher order contribution to $B_{\nu\rho}(t)$ by $\tilde{B}_{\nu\rho}(t)$, one can rearrange Eq. (16) in the form:

$$\begin{aligned} K_{\mu\nu}(t) = {} & -(B^{(0)})^{-1}_{\nu\rho}(t)\{ (1/2t)\, K(t)\, \delta_{\rho\mu} + A_\rho(t)K_\mu(t) + [X_\mu, A_\rho(t)]K(t) + \tilde{B}_{\rho\sigma}(t)K_{\mu\sigma}(t) \\ & + [X_\mu, B_{\rho\sigma}(t)]K_\sigma(t) + C_{\rho\sigma\lambda}(t)K_{\mu\sigma\lambda}(t) + [X_\mu, C_{\rho\sigma\lambda}(t)]K_{\sigma\lambda}(t) + \cdots\}. \end{aligned} \tag{18}$$

We now show by an inductive type of argument that this equation allows the computation of $K_{\mu\nu}(t)$ in terms of $K(t)$ to order n. Since all the tensors $K_{\mu_1\cdots\mu_m}(t)$ are multiplied by objects of at least order 1, it is only necessary to compute these tensors to order $(n-1)$. They are computed in a similar manner to $K_{\mu\nu}(t)$ itself; start this time with the identity

$$0 = \int \frac{d^4k}{(2\pi)^4} \frac{\partial}{\partial k^{\mu_m}}(X_{\mu_1}\cdots X_{\mu_{m-1}} e^{tX.X}) \tag{19}$$

and repeat the steps which led to Eq. (18). To compute $K_{\mu_1\cdots\mu_m}(t)$ to order $(n-1)$ requires a knowledge of the tensors to at most order $(n-2)$ by the same argument as for $K_{\mu\nu}(t)$. Repeating this argument, one finds that it is only necessary to have knowledge of the tensors $K_{\mu_1\cdots\mu_m}(t)$ to order zero.

To complete the argument, we need to determine the tensors $K_{\mu_1\cdots\mu_m}(t)$ to order zero. Beginning with the identity (19), one obtains

$$0 = i\delta_{\mu_m\mu_1}K_{\mu_2\cdots\mu_{m-1}}(t) + \cdots + i\delta_{\mu_m\mu_{m-1}}K_{\mu_1\cdots\mu_{m-2}}(t) + 2it\int\frac{d^4k}{(2\pi)^4}X_{\mu_1}\cdots X_{\mu_{m-1}}\left(\int_0^1 ds e^{stX.X}X_{\mu_m}e^{-stX.X}\right)e^{tX.X}.$$

Substituting the zeroth order result for the integral over s and using the fact that $(B^{(0)})^{-1}_{\nu\rho}(t)$ commutes with X_μ at this order,

$$K_{\mu_1\cdots\mu_m}(t) = -\frac{1}{2t}(B^{(0)})^{-1}_{\mu_m\mu_1}(t)K_{\mu_2\cdots\mu_{m-1}}(t) - \frac{1}{2t}(B^{(0)})^{-1}_{\mu_m\mu_2}(t)K_{\mu_1\mu_3\cdots\mu_{m-1}}(t) - \cdots\frac{1}{2t}(B^{(0)})^{-1}_{\mu_m\mu_{m-1}}(t)K_{\mu_1\cdots\mu_{m-2}}(t).$$

Iterating this using the zeroth order expressions $K^{(0)}_\mu(t)=0$ (as easily established from the identity (19) in the case $m=1$) and

$$K_{\mu\nu}(t) = -\frac{1}{2t}(B^{(0)})^{-1}_{\nu\mu}(t)K(t),$$

it then follows that at zeroth order $K_{\mu_1\cdots\mu_{2m+1}}(t)$ vanishes and

$$K_{\mu_1\cdots\mu_{2m}}(t) = \frac{1}{(-2t)^m}\sum_{perm.}{}' (B^{(0)})^{-1}_{\mu_{i_1}\mu_{i_2}}(t)\cdots(B^{(0)})^{-1}_{\mu_{i_{2m-1}}\mu_{i_{2m}}}K(t), \tag{20}$$

where the prime on the sum indicates the sum over all permutations

$$\{\mu_{i_1},\mu_{i_2},\ldots,\mu_{i_{2m-1}},\mu_{i_{2m}}\}$$

of $\{\mu_1,\mu_2,\ldots,\mu_{2m}\}$ with $i_1>i_2$, $i_3>i_4,\ldots,i_{2m-1}>i_{2m}$. This then completes the argument that $K_{\mu\nu}(t)$ can be consistently computed in terms of $K(t)$ at a given order, thus allowing $K(t)$ to be found via solution of (5).

In the following sections, the above procedure for computing the functional trace of the kernel will be carried out at order 1 and order 2. Before doing so, we make the following comment. Except for the need to order indices because $(B^{(0)})^{-1}_{\mu\nu}(t)$ is not symmetric in μ and ν, the zeroth order expressions for $K_{\mu_1\cdots\mu_m}(t)$ have a ''Wick-type'' appearance, with the role of the free field propagator played by $(B^{(0)})^{-1}_{\mu\nu}(t)$. This analogy is entirely apt, as the Wick expansion for a free field can be derived (see, for example, Ref. 8) from the following identity which is the analog of (19):

$$0 = \int[d\phi]\frac{\delta}{\delta\phi(x_m)}(\phi(x_1)\phi(x_2)\cdots\phi(x_{m-1})e^{-S[\phi]}).$$

However, since the integral in $K(t)$ is an ordinary integral and not a functional integral, the tensors $K_{\mu_1\cdots\mu_m}(t)$ might better be considered as non-Abelian analogs of the usual Gaussian integrals $\int[d^4k/(2\pi)^4]k_{\mu_1}\cdots k_{\mu_m}e^{-tk^2}$, whose values, as pointed out earlier, can also be deduced from the identity

$$0=\int \frac{d^4k}{(2\pi)^4}\frac{\partial}{\partial k^{\mu_m}}(k_{\mu_1}\cdots k_{\mu_{m-1}}e^{-tk^2}).$$

V. THE FIRST ORDER CORRECTION

The first order correction to the effective action vanishes. This is because it is linear in the three index tensor $D_\mu F_{\nu\rho}$, and it is not possible to make a Lorentz invariant expression by contraction with $F_{\mu\nu}$'s. Nevertheless it is instructive to see how this arises in the procedure outlined above before proceeding to calculate the first nontrivial correction.

The only nontrivial step is the computation of

$$\int_0^1 ds e^{stX.X}X_\mu e^{-stX.X}=\sum_{m=0}^{\infty}\frac{t^m}{(m+1)!}ad^{(m)}(X.X)(X_\mu)$$

to first order, i.e., truncated to contain at most one higher order commutator of the form $[X_\mu,[X_\nu,X_\rho]]=(D_\mu F_{\nu\rho})$. The actual computation is described in the next section, and for the current purposes it is only necessary to note that the result is of the form

$$\int_0^1 ds e^{stX.X}X_\mu e^{-stX.X}=A^{(1)}_\mu(t)+B^{(0)}_{\mu\nu}(t)X_\nu+C^{(1)}_{\mu\nu\rho}(t)X_\nu X_\rho,$$

where $B^{(0)}_{\mu\nu}(t)$ is the zeroth order matrix (17), and $A^{(1)}_\mu(t)$ and $C^{(1)}_{\mu\nu\rho}(t)$ are first order, i.e., are linear in $(D_\mu F_{\nu\rho})$. So, substituting into (18), we find that to first order

$$K_{\mu\nu}(t)=-\frac{1}{2t}(B^{(0)})^{-1}_{\nu\mu}(t)K(t)-(B^{(0)})^{-1}_{\nu\rho}(t)A^{(1)}_\rho(t)K_\mu(t)-(B^{(0)})^{-1}_{\nu\rho}(t)C^{(1)}_{\rho\sigma\lambda}(t)K_{\mu\sigma\lambda}(t),$$

where $[X_\mu,A^{(1)}_\rho(t)]$ and $[X_\mu,C^{(1)}_{\rho\sigma\lambda}(t)]$ are omitted because they are of second order. Because their coefficients are first order, $K_\mu(t)$ and $K_{\mu\sigma\lambda}(t)$ are only required to zeroth order, and it was shown in the previous section that the tensors $K_{\mu_1\cdots\mu_{2m+1}}(t)$ all vanish at zeroth order. Thus there is no correction to the zeroth order result $K_{\mu\nu}(t)=-(1/2t)(B^{(0)})^{-1}_{\nu\mu}(t)K(t)$, as expected.

VI. THE SECOND ORDER CORRECTION

The first nontrivial correction to $K(t)$ contains terms which are quadratic in the tensor $(D_\mu F_{\nu\rho})$ and terms which are linear in $(D_\mu D_\nu F_{\rho\sigma})$. Both of these types of terms are required by consistency, as contributions of the second type are related in the effective action to those of the first type by integration by parts in x-space. As mentioned in Sec. IV, the only nontrivial step is the computation of $\int_0^1 ds e^{stX.X}X_\mu e^{-stX.X}$ in the form (15) to second order. This is done in Appendix A, where a diagrammatic technique is developed to aid in the manipulation of the third and fourth rank tensors involved. These diagrammatic techniques allow the determination of the individual terms in the power series (8). In the zeroth order case, this power series could be written compactly in the matrix (with respect to space–time indices) form (17). However, when higher rank tensors are present, this is not always possible. For example, expressions like

$$\sum_{p=0}^{m}\binom{n}{p}(F^p)_{\nu\lambda}(D_\mu F_{\lambda\sigma})(F^{n-p})_{\sigma\rho}$$

are encountered. There is no compact way to write it as a function of the matrix $F_{\mu\nu}$. To allow sums such as this to be written in a compact form, it is necessary to introduce an appropriate notation. First, note that to the order that we are working, the matrices $F_{\mu\nu}$ and $(D_\rho F_{\sigma\lambda})$, considered as matrices in the representation R of the gauge group, commute. This is because $F_{\mu\nu}=[X_\mu,X_\nu]$, so that using the Jacobi identity,

$$[F_{\mu\nu},(D_\rho F_{\sigma\lambda})]=-[[(D_\rho F_{\sigma\lambda}),X_\mu],X_\nu]-[[X_\nu,(D_\rho F_{\sigma\lambda})],X_\mu].$$

Since $(D_\rho F_{\sigma\lambda})$ is itself a commutator, the terms on the right hand side are seen to be third order and so can be dropped. Thus the sum can be rewritten

$$\sum_{p=0}^{m} \binom{n}{p} (-1)^{n-p} (F^p)_{\nu\lambda} (F^{n-p})_{\rho\sigma} (D_\mu F_{\lambda\sigma})$$

using the antisymmetry of $F_{\mu\nu}$ in its space–time indices. We write this as:

$$(F_2 - F_3)^n (D_1 F_{23}).$$

Here, F_2 and F_3 are shorthand for (antisymmetric) matrices in their space–time indices. The ''2'' and ''3'' on $(D_1 F_{23})$ mean that the right-hand indices on the space–time matrices F_2 and F_3 are contracted with space–time indices in the positions represented by ''2'' and ''3'' respectively on the three index tensor $(D_\mu F_{\nu\rho})$. The index ''1'' which is not repeated stands for a free space–time index. The only potential ambiguity is in the ordering of the matrices F_2 and F_3, this time considered as matrices in the representation R of the gauge group, when $(F_2+F_3)^n$ is expanded out. However, the commutator $[F_2, F_3]$ is second order, and since F_2 and F_3 multiply the first order object $(D_1 F_{23})$, their ordering is irrelevant. (In fact, using the Jacobi identity, $[F_{\mu\nu}, F_{\rho\sigma}] = -(D_\nu D_\mu F_{\rho\sigma}) - (D_\mu D_\nu F_{\rho\sigma})$. This means that care must be exercised in using the zeroth order results in Sec. III in the second order computation, as any reordering of the field strengths made in deriving zeroth order results will be invalid if used in the second order calculation. However, no such reorderings were made at zeroth order.) Alternatively, using the antisymmetry of $F_{\mu\nu}$, the expression can also be written as $(D_1 F_{23})(F_3 - F_2)^n$, where it is now the left-hand indices on the space–time matrices F_2 and F_3 which are contracted with $(D_1 F_{23})$. With a little practice, it is easy to become quite adept at translating back and forth between tensor expressions and this notation.

An alternative notation based on differential operators which retains the tensor structure explicitly can also be used. We can write, for example,

$$\sum_{p=0}^{m} \binom{n}{p} (F^p)_{\nu\lambda} (D_\mu F_{\lambda\sigma}) (F^{n-p})_{\sigma\rho} = \frac{d^n}{dz^n} [e^{zF}]_{\nu\lambda} (D_\mu F_{\lambda\sigma}) [e^{zF}]_{\sigma\rho}\big|_{z=0}. \tag{21}$$

The sums in Appendix A can also be done explicitly using this notation.

Returning to the computation of the right hand side of (15) to order 2, the result is

$$\int_0^1 ds e^{stX.X} X_\mu e^{-stX.X} = A_\mu^{(1)}(t) + (B_{\mu\nu}^{(0)}(t) + B_{\mu\nu}^{(2)}(t)) X_\nu + C_{\mu\nu\rho}^{(1)}(t) X_\nu X_\rho + D_{\mu\nu\rho\sigma}^{(2)}(t) X_\nu X_\rho X_\sigma, \tag{22}$$

where the superscript ''(n)'' denotes a contribution of order n to a tensor. The tensors $A_\mu^{(1)}(t)$, etc. are computed in Appendix A using the shorthand notation for tensors introduced above, and the results are given in Eqs. (A5), (A6), (A7) and (A8).

With these results, the rest of the procedure for determining the second order contribution $K^{(2)}(t)$ to $K(t)$ is purely algebraic, as outlined in Sec. IV. The steps are detailed in Appendix B. The result is that

$$K^{(2)}(t) = K^{(0)}(t) M^{(2)}(t), \tag{23}$$

where $M^{(2)}(t)$ satisfies the differential equation

$$\begin{aligned} \frac{dM^{(2)}(t)}{dt} = -(B^{(0)})^{-1}_{\mu\nu}(t) \{ & [X_\mu, A_\nu^{(1)}(t)] K^{(0)}(t) + A_\nu^{(1)}(t) K_\mu^{(1)}(t) \\ & + [X_\mu, B_{\nu\rho}^{(0)}(t)] K_\rho^{(1)}(t) + B_{\nu\rho}^{(2)}(t) K_{\mu\rho}^{(0)}(t) + [X_\mu, C_{\nu\rho\sigma}^{(1)}(t)] K_{\rho\sigma}^{(0)}(t) \\ & + C_{\nu\rho\sigma}^{(1)}(t) K_{\mu\rho\sigma}^{(1)}(t) + D_{\nu\rho\sigma\lambda}^{(2)}(t) K_{\mu\rho\sigma\lambda}^{(0)}(t) \} / K^{(0)}(t). \end{aligned} \tag{24}$$

Although the right hand side of Eq. (24) has been computed in closed form in Appendix B, we have been unable to integrate this equation in closed form. This is *not* because it is not integrable. The power series expansion (see below) of the right hand side begins at order t^2, and involves only positive powers of the field strength $F_{\mu\nu}$. This can be integrated to determine $M^{(2)}(t)$ to any required order in t. [The integration constant clearly vanishes, as $K^{(2)}(t)$ vanishes when DF is set to zero.] However, the complexity of the closed form expression is such that solving the differential Eq. (24) in closed form is a formidable task. As mentioned at the end of Sec. III, the inability to solve in closed form is not seen as a major difficulty in applying these results. In a given physical situation, one is usually interested in a particular effective n-point interaction for the gauge bosons. This requires finding the piece of the effective action with n powers of the field strength, and so, via (2), one is interested in the piece of the functional trace of the heat kernel with n powers of the field strength. A power series expansion of the functional trace of the heat kernel is therefore necessary anyway.

Power series expansion of the right hand side of (24) using the results derived in Appendices A and B is readily achieved order using Mathematica.[9] Although seven different tensor structures appear in the result, some are related by Jacobi identities, and only three of them are independent. The rules for converting the tensor structures into these three forms are given in Appendix C. Applying these, $K^{(2)}(t)$ is given by (23) with $K^{(0)}$ as in (13) and

$$M^{(2)}(t)=\sum_{p,q,r} c_1^{(p,q,r)}(t)(D_\alpha F_{\beta\gamma})(F^p)_{\gamma\rho}(F^q)_{\beta\alpha}(F^r)_{\nu\mu}(D_\mu F_{\nu\rho})+\sum_{p,q,r} c_2^{(p,q,r)}(t)(D_\alpha F_{\beta\gamma})$$
$$\times(F^p)_{\alpha\rho}(F^q)_{\beta\nu}(F^r)_{\gamma\mu}(D_\mu F_{\nu\rho})+\sum_{p,q} c_3^{(p,q)}(t)(D_\alpha D_\beta F_{\gamma\delta})(F^p)_{\gamma\alpha}(F^q)_{\delta\beta}. \qquad (25)$$

We present the expansions to order t^{11} (but stressing the fact that Appendix B contains all the ingredients to compute the right hand side of (24) in closed form and hence allowing the computation of $M^{(2)}(t)$ to any desired order):

$$\sum_{p,q,r} c_1^{(p,q,r)}(t)x^p y^q z^r$$
$$=\frac{t^3}{180}+\frac{t^5}{3780}(-2x^2-4z^2-18xz+51yz)+\frac{t^7}{56700}(3x^4+6z^4-110yz^3+3y^2z^2+26x^3z$$

$$\times(4146x^9-10078x^8z+2360x^7z^2-6745x^6z^3+2121x^5z^4-6363x^4z^5+2025x^3z^6$$

$$-6410x^2z^7+1786xz^8-7718z^9)+O(t^{12}).$$

As a check on these results, they can be compared with the known results for the heat kernel $K(t)$. In the limit $t\to 0$, the heat kernel has the asymptotic expansion

$$K(t)=\frac{1}{16\pi^2 t^2}\sum_{n=0}^{\infty} a_n t^n.$$

The coefficients a_n have been computed *exactly* for a small number of values of n by a variety of means: a_3 by Gilkey,[10] a_4 by van de Ven[12] and Avramidi,[11] a_5 by van de Ven[12] and Bel'kov *et al.*,[13] and very recently, a_6 by Fliegner *et al.*[14] and van de Ven.[15] The reduction of a_n to second order (which means neglecting terms with more than two covariant derivatives of the field strength) must coincide with coefficient of t^n in the expansion of $16\pi^2 t^2 K(t)$ to second order via (23) and the power series (13) and (25).

For example, a_3 as computed by Gilkey is

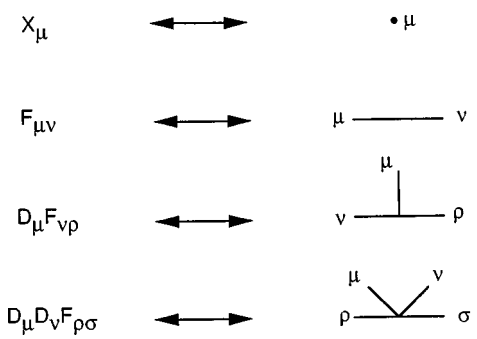

DIAGRAM 1. Representation of the basic tensor structures.

$$a_3=\tfrac{1}{180}(D_\alpha F_{\alpha\gamma})(D_\beta F_{\beta\gamma})+\tfrac{1}{45}(D_\alpha F_{\beta\gamma})(D_\alpha F_{\beta\gamma})-\tfrac{1}{30}F_{\alpha\beta}F_{\beta\gamma}F_{\gamma\alpha}+\tfrac{1}{30}(D_\alpha D_\alpha F_{\beta\gamma})F_{\beta\gamma}. \tag{26}$$

For comparison, the expansions (13) and (25) show that, *to second order*,

$$a_3=\tfrac{1}{180}(D_\alpha F_{\alpha\gamma})(D_\beta F_{\beta\gamma})+\tfrac{2}{45}(D_\alpha F_{\beta\gamma})(D_\gamma F_{\beta\alpha})-\tfrac{1}{20}(D_\alpha D_\beta F_{\alpha\gamma})F_{\gamma\beta}+\tfrac{1}{60}(D_\alpha D_\beta F_{\gamma\beta})F_{\gamma\alpha}. \tag{27}$$

The first terms of (26) and (27) are obviously the same, and the second terms are equivalent after the application of one of the Jacobi identities in Appendix C used to convert tensor structures to one of the three standard forms. The last two terms of (26) are also equivalent to the last two terms in (27); this requires recognition of the fact that despite appearances, $F_{\alpha\beta}F_{\beta\gamma}F_{\gamma\alpha}$ is actually a second order term, as it can be expressed as $\frac{1}{2}[F_{\alpha\beta},F_{\beta\gamma}]F_{\gamma\alpha}$. Application of the Jacobi identity

$$[F_{\alpha\beta},F_{\gamma\delta}]=(D_\alpha D_\beta F_{\gamma\delta})-(D_\beta D_\alpha F_{\gamma\delta})$$

then yields the required equivalence. Note that in the case of a_3, there are no terms higher than second order in the exact expression; this is no longer true for a_n for $n\geqslant 4$.

The coefficients of t^4 and t^5 in the second order expression (23) for $K(t)$ obtained in this paper agree with the reduction to second order of the a_4 and a_5 obtained in Refs. 12, 11, and 14. [These authors actually compute $\int d^4x\ a_n$, so that the expressions obtained for a_n are ambiguous up to total derivatives; this must be borne in mind when making comparison with the results of this paper (and in fact when comparing the exact results for a_n found by different authors).]

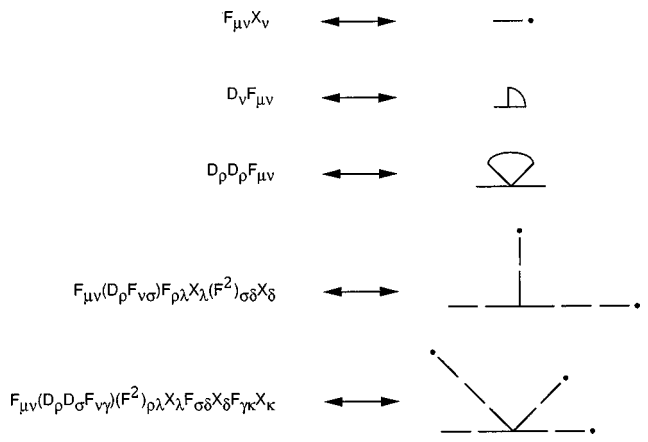

DIAGRAM 2. Examples of more complicated tensor structures.

This is a highly nontrivial check; for example, the expression for a_5 in Ref. 14 contains 36 terms. Comparison with the recently computed a_6 (Refs. 14 and 15) has not been attempted, as the exact expression in Ref. 14 contains 304 terms. Expressions for a_n with $n \geqslant 6$ have not been computed; the results of this paper are equivalent to the computation of a_n to second order for *all* n.

VII. CONCLUSION

The aim of this paper has been to show that the approach to computing the long wavelength limit of one-loop low energy effective actions developed in Ref. 6 is also well adapted to the problem of computing corrections to the long wavelength limit, corresponding to higher order terms in the derivative expansion of the effective action. This has been demonstrated by an explicit computation which yields the complete form for the first nontrivial correction to long wavelength limit of the low energy effective action when massive scalar fields are integrated out in the presence of a Yang-Mills background. The technique readily generalizes to the case where the heavy fields are of different spin, or where there are also light scalars coupled to the heavy fields.

Note added in proof: In a recent preprint (hep-th/9804143), V. P. Gusynin and I. A. Shovkovy present details of computations of higher derivative terms in the effective actions for scalar and spinor QED based on a different method, namely, the worldline (or string-inspired) formalism. This extends their previous work presented in Can. J. Phys. **74**, 282 (1996), where they computed the terms in the effective action for four-dimensional QED up to two derivatives in the field strength.

ACKNOWLEDGMENTS

Both authors are grateful to Professor J. Wess for his hospitality at the University of Munich, where this work was commenced. I.N.M. is also grateful to the Alexander von Humboldt-Stiftung for a Research Fellowship during that period.

APPENDIX A: EVALUATING COMMUTATORS TO SECOND ORDER

In this Appendix, details of the calculation of

$$\int_0^1 ds\; e^{stX.X} X_\mu e^{-stX.X} = \sum_{m=0}^{\infty} \frac{t^m}{(m+1)!} ad^{(m)}(X.X)(X_\mu) \tag{A1}$$

up to order two are presented. It was found convenient to introduce a diagrammatic method for generating the series of commutators $ad^{(m)}(X.X)(X_\mu)$. For a given m, the expression for $ad^{(m)}(X.X)(X_\mu)$ will consist of terms constructed from X_μ, $F_{\mu\nu}$, $(D_\mu F_{\nu\rho})$ and $(D_\mu D_\nu F_{\rho\sigma})$. So, to proceed to the $(m+1)$st commutator with $X.X$, it suffices to know the commutator of $X.X$ with these four quantities. The commutator with $(D_\mu D_\nu F_{\rho\sigma})$ produces terms of order 3 and so need not be considered. To order 2, the other commutators are:

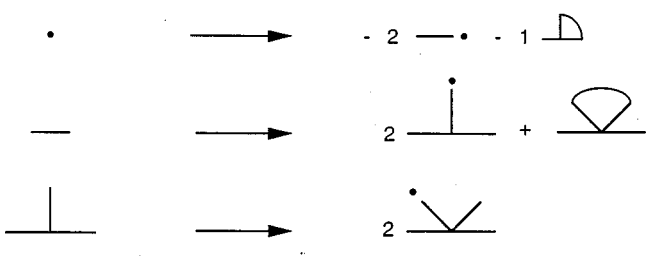

DIAGRAM 3. Rules for constructing commutators.

$$[X.X,X_\mu]=-2F_{\mu\nu}X_\nu-(D_\nu F_{\mu\nu}),$$

$$[X.X,F_{\mu\nu}]=2(D_\rho F_{\mu\nu})X_\rho+(D_\rho D_\rho F_{\mu\nu}), \tag{A2}$$

$$[X.X,D_\mu F_{\nu\rho}]=2(D_\sigma D_\mu F_{\nu\rho})X_\sigma.$$

The diagrammatic method consists of introducing symbols for the tensors X_μ, $F_{\mu\nu}$, $(D_\mu F_{\nu\rho})$ and $(D_\mu D_\nu F_{\rho\sigma})$ which can be assembled in a way which codes the contractions of their space–time indices. In this way, given the diagrams representing $ad^{(m)}(X.X)(X_\mu)$, the diagrams representing the $(m+1)$st commutator are generated by replacing the symbols in the diagrams one at a time by the combinations of symbols dictated by (A2).

The symbols for the tensors X_μ, $F_{\mu\nu}$, $(D_\mu F_{\nu\rho})$ and $(D_\mu D_\nu F_{\rho\sigma})$ are shown in Diagram 1. Contraction of indices is represented by joining the ends of the line segments on the diagrammatic elements appropriately: some examples are illustrated in Diagram 2. Diagram 3 shows the rules (A2) for going from the diagram for $ad^{(m)}(X.X)(X_\mu)$ to that for the $(m+1)$st commutator. The diagrams generated in this manner for $ad^{(m)}(X.X)(X_\mu)$ with $m=0,1,2$ and 3 are shown in Diagram 4. Using this approach, the contributions to $ad^{(m)}(X.X)(X_\mu)$ and their multiplicities are shown in Diagram 5. Although the combinatoric factor associated with a given diagram was initially established by inspection, it is relatively easy to prove by induction that they are correct.

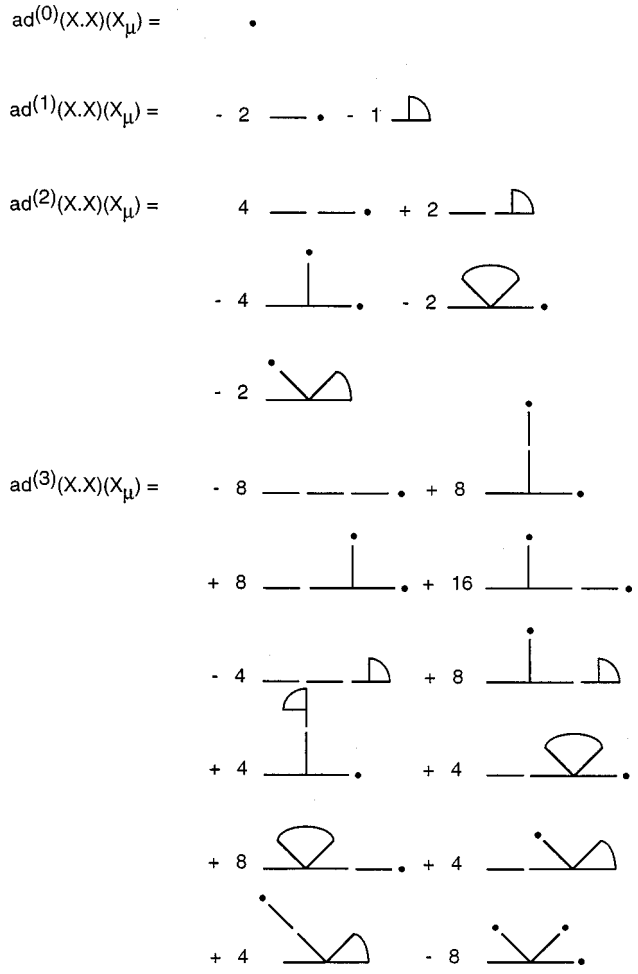

DIAGRAM 4. Representation of $ad^{(m)}(x\cdot x)(x_\mu)$ for $m=0$, 1, 2, 3.

Thus the tensors which appear in (22) corresponding to the expansion of the right hand side of (A1) to order 2 are:

$$A^{(1)}_{\mu}(t) = -\frac{1}{2}\sum_{n=1}^{\infty}\frac{(-2t)^n}{(n+1)!}(F^{n-1})_{\mu\nu}(D_\rho F_{\rho\nu}),$$

$$C^{(1)}_{\mu\nu\rho}(t) = -\sum_{n=2}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-2}\sum_{q=0}^{n-p-2}\binom{p+q+1}{q+1}(F^{n-p-q-2})_{\mu\sigma}(D_\lambda F_{\sigma\gamma})(F^q)_{\lambda\nu}(F^p)_{\gamma\rho},$$

$$\begin{aligned}
B^{(2)}_{\mu\nu}(t) = {} & \frac{1}{2}\sum_{n=3}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-3}\sum_{q=0}^{n-3-p}\left\{\binom{p+q+2}{q+2}(F^{n-3-p-q})_{\mu\rho}(D_\sigma F_{\rho\lambda})(F^q)_{\sigma\gamma}(D_\delta F_{\delta\gamma})(F^p)_{\lambda\nu}\right. \\
& \left.+\binom{p+q+2}{q+1}(F^{n-3-p-q})_{\mu\lambda}(D_\rho F_{\lambda\sigma})(F^q)_{\rho\nu}(F^p)_{\sigma\gamma}(D_\delta F_{\delta\gamma})\right\} \\
& -\frac{1}{2}\sum_{n=2}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-2}(F^{n-2-p})_{\mu\rho}(D_\sigma D_\gamma F_{\rho\gamma})(F^p)_{\sigma\nu}-\frac{1}{2}\sum_{n=2}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-2}(p+1) \\
& \times(F^{n-2-p})_{\mu\rho}(D_\gamma D_\gamma F_{\rho\sigma})(F^p)_{\sigma\nu}-\sum_{n=3}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=1}^{n-2}\sum_{q=0}^{n-p-2}\sum_{r=0}^{p-1}\binom{p+q+1}{q+1} \\
& \times(F^{n-p-q-2})_{\mu\sigma}(D_\lambda F_{\sigma\gamma})(F^q)_{\lambda\rho}(F^r)_{\gamma\alpha}(D_\rho F_{\alpha\beta})(F^{p-r-1})_{\beta\nu}
\end{aligned}$$

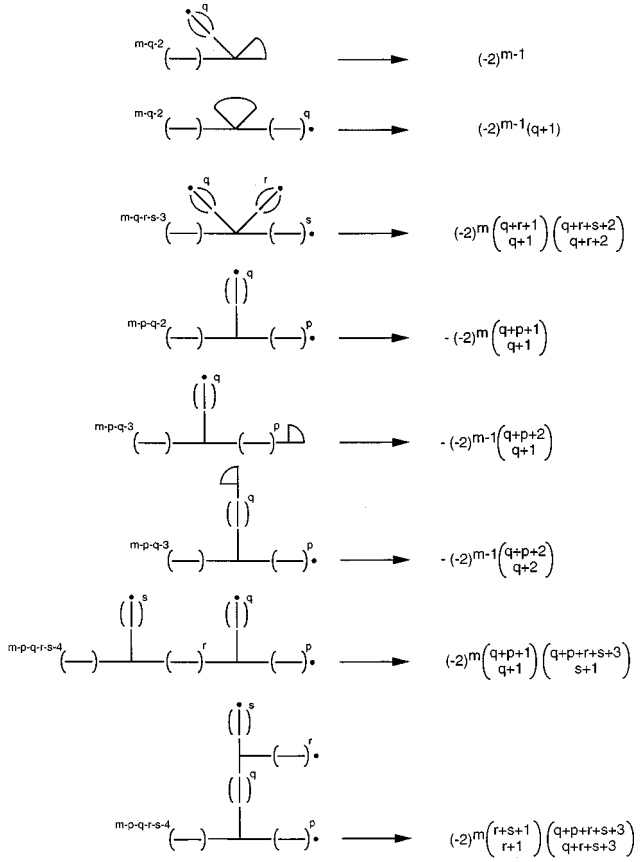

DIAGRAM 5. Contributions to $ad^{(m)}(x\cdot x)(x_\mu)$ and their multiplicities.

$$D^{(2)}_{\mu\nu\rho\sigma}(t)=\sum_{n=4}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-4}\sum_{q=0}^{n-4-p}\sum_{r=0}^{n-4-p-q}\sum_{s=0}^{n-4-p-q-r}\binom{r+s+1}{s+1}\Bigg\{\binom{n-p-1}{q+1}$$
$$\times(F^p)_{\mu\lambda}(D_\gamma F_{\lambda\delta})(F^q)_{\gamma\nu}(F^{n-p-q-r-s-4})_{\delta\alpha}(D_\beta F_{\alpha\epsilon})(F^s)_{\beta\rho}(F^r)_{\epsilon\sigma}+\binom{n-p-1}{q}$$
$$\times(F^p)_{\mu\lambda}(D_\gamma F_{\lambda\delta})(F^{n-4-p-q-r-s})_{\gamma\alpha}(D_\beta F_{\alpha\epsilon})(F^s)_{\beta\nu}(F^r)_{\epsilon\rho}(F^q)_{\delta\sigma}\Bigg\}$$
$$+\sum_{n=3}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-3}\sum_{q=0}^{n-3-p}\sum_{r=0}^{n-3-p-q}\binom{p+q+1}{p+1}\binom{p+q+r+2}{p+q+2}(F^{n-3-p-q-r})_{\mu\gamma}$$
$$\times(D_\delta D_\epsilon F_{\gamma\alpha})(F^p)_{\delta\nu}(F^q)_{\epsilon\rho}(F^r)_{\alpha\sigma}.$$

There is a subtlety associated with the fourth sum in the expression for $B^{(2)}_{\mu\nu}(t)X_\nu$. It actually arises from

$$-\sum_{n=2}^{\infty}\frac{(-2t)^n}{(n+1)!}\sum_{p=0}^{n-2}\sum_{q=0}^{n-p-2}\binom{p+q+1}{q+1}(F^{n-p-q-2})_{\mu\sigma}(D_\lambda F_{\sigma\gamma})(F^q)_{\lambda\nu}X_\nu(F^p)_{\gamma\rho}X_\rho, \quad \text{(A3)}$$

which, upon moving the X_ν to the right through $(F^p)_{\gamma\rho}$, gives $C^{(1)}_{\mu\nu\rho}(t)X_\nu X_\rho$. The commutators induced in this process give rise to a contribution to $B^{(2)}_{\mu\nu}(t)X_\nu$ which is contained in the fourth sum.

The sums in this expression can be carried out explicitly. Using the notation introduced in Sec. VI for tensor contractions, and introducing the quantities

$$E(F)=\frac{e^{2tF}-1}{F},$$

$$H_{p,q}(F_1,F_2,F_3)=\frac{(F_1+F_2)^p}{(F_1+F_2-F_3)}\left[\frac{E(F_1+F_2)}{(F_1+F_2)^q}-\frac{E(F_3)}{F_3^q}\right]-\frac{F_2^p}{(F_2-F_3)}\left[\frac{E(F_2)}{F_2^q}-\frac{E(F_3)}{F_3^q}\right], \quad \text{(A4)}$$

we find

$$A^{(1)}_1(t)=-\frac{1}{4tF_1}\{E(-F_1)-2t\}(D_2F_{21}), \quad \text{(A5)}$$

$$C^{(1)}_{123}(t)=-\frac{1}{2tF_2}H_{1,1}(F_2,F_3,-F_1)(D_2F_{13}), \quad \text{(A6)}$$

$$B^{(2)}_{12}(t)=\frac{1}{4t}(D_3F_{12})\frac{1}{F_3^2}\Bigg\{(F_2+F_3)H_{1,2}(-F_3,-F_2,F_1)+\frac{F_2F_3}{(F_1+F_2)^2}\left[\frac{E(-F_2)}{F_2}+\frac{E(F_1)}{F_1}\right]$$
$$+\frac{2F_3E(-F_2)}{F_2(F_1+F_2)}+\frac{2tF_3E(-F_2)}{(F_1+F_2)}-\frac{2tF_3}{F_2(F_1+F_2)}\Bigg\}(D_4F_{43})+\frac{1}{4t}(D_2F_{13})\frac{1}{F_2F_3}$$
$$\times\left\{\frac{2t}{F_1}-H_{2,2}(-F_3,-F_2,F_1)+\frac{F_3^2}{(F_1+F_3)}\left[\frac{E(F_1)}{F_1^2}-\frac{E(-F_3)}{F_3^2}\right]\right\}(D_4F_{43})$$
$$+\frac{1}{4t}(D_2D_3F_{13})\left\{\frac{1}{(F_1+F_2)}\left[-\frac{E(-F_2)}{F_2}-\frac{E(F_1)}{F_1}\right]+\frac{2t}{F_1F_2}\right\}+\frac{1}{4t}(D_3D_3F_{12})$$
$$\times\left\{\frac{1}{(F_1+F_2)^2}\left[-E(F_1)+\frac{(F_1+2F_2)E(-F_2)}{F_2}\right]+\frac{2tE(-F_2)}{(F_1+F_2)}-\frac{2t}{F_2(F_1+F_2)}\right\}$$
$$-\frac{1}{2t}(D_3F_{14})\frac{1}{F_3(F_2+F_4)}\{H_{1,1}(-F_3,F_2,F_1)-H_{1,1}(-F_3,-F_4,F_1)\}(D_3F_{42}), \quad \text{(A7)}$$

$$D^{(2)}_{1234}(t)=\frac{1}{2t}(D_2F_{15})\,\frac{1}{F_2F_3}\Bigg\{\frac{(F_3+F_4)}{(F_3+F_4+F_5)}\Bigg[\frac{1}{(-F_5)}H_{3,3}(-F_2,-F_5,F_1)-\frac{1}{(F_3+F_4)}H_{3,3}$$
$$(-F_2,F_3+F_4,F_1)\Bigg]+\frac{F_4}{(F_4+F_5)}\Bigg[\frac{1}{F_4}H_{3,3}(-F_2,F_4,F_1)$$
$$-\frac{1}{(-F_5)}H_{3,3}(-F_2,-F_5,F_1)\Bigg]\Bigg\}(D_3F_{54})+\frac{1}{2t}(D_5F_{14})$$
$$\times\Bigg\{\frac{(F_2+F_3)}{F_2(F_2+F_3+F_5)}\Bigg[\frac{1}{(F_2+F_3)^2}H_{3,3}(F_2+F_3,-F_4,F_1)-\frac{1}{F_5^2}H_{3,3}(-F_5,-F_4,F_1)\Bigg]$$
$$+\frac{F_3}{F_2(F_3+F_5)}\Bigg[\frac{1}{F_5^2}H_{3,3}(-F_5,-F_4,F_1)-\frac{1}{F_3^2}H_{3,3}(F_3,-F_4,F_1)\Bigg]\Bigg\}(D_2F_{53})$$
$$-\frac{1}{2t}(D_2D_3F_{14})\frac{1}{F_2}\Bigg\{\frac{1}{(F_2+F_3)}H_{2,2}(-F_2-F_3,-F_4,F_1)$$
$$-\frac{1}{F_3}H_{2,2}(-F_3,-F_4,F_1)\Bigg\}. \tag{A8}$$

It should be noted that in some of the above expressions, several different terms involving a particular $E(F_i)$ appear and could be combined into a single term. However, we have chosen to leave the expression in an unsimplified form involving the combinations $H_{p,q}(F_1,F_2,F_3)$ defined in (A4). This is because such a structure is responsible for many cancellations which occur to ensure that, as power series in t, these expressions involve no negative powers of the field strengths F.

APPENDIX B: *K(t)* TO SECOND ORDER

Here we give details of the determination of the second order contribution $K^{(2)}(t)$ to $K(t)$ using the procedure outlined in Sec. IV. As explained there, it is necessary to determine $K_{\mu\nu}(t)$ to second order via Eq. (18). Using the results $K^{(0)}_{\mu}(t)=0$ and $K^{(0)}_{\mu\nu\rho}(t)=0$ from Sec. IV and $K^{(1)}(t)=0$ from Sec. V, we find

$$K^{(2)}_{\mu\nu}(t)=-(B^{(0)})^{-1}_{\nu\rho}(t)\{(1/2t)\,\delta_{\rho\mu}K^{(2)}(t)+[X_\mu,A^{(1)}_\rho(t)]K^{(0)}(t)$$
$$+A^{(1)}_\rho(t)K^{(1)}_\mu(t)+[X_\mu,B^{(0)}_{\rho\sigma}(t)]K^{(1)}_\sigma(t)+B^{(2)}_{\rho\sigma}(t)K^{(0)}_{\mu\sigma}(t)$$
$$+[X_\mu,C^{(1)}_{\rho\sigma\lambda}(t)]K^{(1)}_{\sigma\lambda}(t)+C^{(1)}_{\rho\sigma\lambda}(t)K^{(1)}_{\mu\sigma\lambda}(t)+D^{(2)}_{\rho\sigma\lambda\delta}(t)K^{(0)}_{\mu\sigma\lambda\delta}(t)\}.$$

This result is to be substituted into the differential equation $dK^{(2)}(t)/dt=K^{(2)}_{\mu\mu}(t)$. By writing

$$K^{(2)}(t)=K^{(0)}(t)M^{(2)}(t),$$

the differential equation for $M^{(2)}(t)$ becomes:

$$\frac{dM^{(2)}(t)}{dt}=-(B^{(0)})^{-1}_{\mu\rho}(t)\{[X_\mu,A^{(1)}_\rho(t)]K^{(0)}(t)+A^{(1)}_\rho(t)K^{(1)}_\mu(t)$$
$$+[X_\mu,B^{(0)}_{\rho\sigma}(t)]K^{(1)}_\sigma(t)+B^{(2)}_{\rho\sigma}(t)K^{(0)}_{\mu\sigma}(t)+[X_\mu,C^{(1)}_{\rho\sigma\lambda}(t)]K^{(0)}_{\sigma\lambda}(t)$$
$$+C^{(1)}_{\rho\sigma\lambda}(t)K^{(1)}_{\mu\sigma\lambda}(t)+D^{(2)}_{\rho\sigma\lambda\delta}(t)K^{(0)}_{\mu\sigma\lambda\delta}(t)\}/K^{(0)}(t). \tag{B1}$$

It remains to determine $K^{(1)}_{\mu}(t)$ and $K^{(1)}_{\mu\nu\rho}(t)$ in terms of $K^{(0)}(t)$, as $K^{(0)}_{\mu\nu}(t)$ and $K^{(0)}_{\mu\nu\rho\sigma}(t)$ have already been expressed in terms of $K^{(0)}(t)$ in Eq. (20). As explained in Sec. IV, this is done via the generalization of the expression (18) to higher order tensors, and the results are:

$$\frac{K^{(1)}_{\mu}(t)}{K^{(0)}(t)} = -(B^{(0)})^{-1}_{\mu\nu}(t)\{A^{(1)}_{\nu}(t) + (1/2t)(B^{(0)})^{-1}_{\rho\sigma}(t)C^{(1)}_{\nu\rho\sigma}(t)\},$$

$$\begin{aligned}\frac{K^{(1)}_{\mu\nu\rho}(t)}{K^{(0)}(t)} = &-(1/2t)(B^{(0)})^{-1}_{\rho\sigma}(t)\{\delta_{\sigma\mu}K^{(1)}_{\nu}(t)/K^{(0)}(t) + \delta_{\sigma\nu}K^{(1)}_{\mu}(t)/K^{(0)}(t)\\ &-\{A^{(1)}_{\sigma}(t)(B^{(0)})^{-1}_{\nu\mu}(t) + [X_{\mu}, B^{(0)}_{\sigma\lambda}(t)](B^{(0)})^{-1}_{\lambda\nu}(t)\\ &+[X_{\nu}, B^{(0)}_{\sigma\lambda}(t)](B^{(0)})^{-1}_{\lambda\mu}(t)\} + 2tC^{(1)}_{\sigma\lambda\delta}(t)K^{(0)}_{\mu\nu\lambda\delta}(t)/K^{(0)}(t)\}.\end{aligned}$$

Assembling the above ingredients, the right hand side of the differential equation (B1) for $M^{(2)}(t)$ can be evaluated by inserting the expressions (A5), (A6), (A7) and (A8) for the tensors $A^{(1)}_{\mu}(t)$, etc. We have done this to obtain a closed form expression for the right hand side of (B1). For the sake of brevity, the expression is not reproduced here, but it can easily be derived using the above information. The integrated power series expansion of this expression is reproduced in Sec. VI to order t^{11}.

APPENDIX C: THE INDEPENDENT TENSOR STRUCTURES

In this Appendix, rules for manipulating the terms in the second order contribution to $K(t)$ into three independent tensor structures are given. The tensor structures which appear in $M^{(2)}(t)$ are of the following forms:

(i) $\lim_{\substack{2\to3\\4\to5}}(D_1F_{23})f(F_1,F_3,F_4)(D_4F_{51})$

(ii) $\lim_{\substack{2\to3\\4\to5}}(D_2F_{31})f(F_1,F_3,F_4)(D_4F_{51})$

(iii) $(D_1F_{23})f(F_1,F_2,F_3)(D_1F_{23})$

(iv) $(D_1F_{23})f(F_1,F_2,F_3)(D_3F_{21})$,

(v) $\lim_{\substack{1\to2\\3\to4}}(D_1D_2F_{34})f(F_2,F_4)$,

(vi) $\lim_{\substack{1\to3\\2\to4}}(D_1D_2F_{34})f(F_3,F_4)$,

where f denotes some functional of the field strengths (which is different for the different tensor structures).

These six tensor structures are not independent. Application of the Jacobi identity allows them all to be expressed in terms of the three tensor structures (ii), (iv) and (vi). The rules for putting the remaining tensor structures in these standard forms by use of the Jacobi identity are:

$$\lim_{\substack{2\to3\\4\to5}}(D_1F_{23})f(F_1,F_3,F_4)(D_4F_{51}) = \lim_{\substack{2\to3\\4\to5}}(D_2F_{31})[f(F_1,-F_3,F_4)-f(F_1,F_3,F_4)](D_4F_{51}),$$

$$(D_1F_{23})f(F_1,F_2,F_3)(D_1F_{23}) = (D_1F_{23})[f(F_1,F_2,F_3)+f(F_1,F_3,F_2)](D_3F_{21}),$$

$$\lim_{\substack{1\to2\\3\to4}}(D_1D_2F_{34})f(F_2,F_4) = \lim_{\substack{1\to3\\2\to4}}(D_1D_2F_{34})[f(F_3,F_4)-f(F_3,-F_4)].$$

The standard tensor structures also satisfy a number of identities as a result of the Jacobi identity and the ability to transpose expressions containing contracted space–time indices. These are

$$0=\lim_{\substack{2\to 3\\4\to 5}}(D_2F_{31})(f(F_1,F_3,F_4)-f(-F_1,F_4,F_3))(D_4F_{51}),$$

$$0=(D_1F_{23})(f(F_1,F_2,F_3)-f(-F_3,-F_2,-F_1))(D_3F_{21}),$$

$$0=(D_1F_{23})(f(F_1,F_2,F_3)-f(F_3,F_2,F_1)$$

$$-f(F_3,F_1,F_2)+f(F_1,F_3,F_2))(D_3F_{21}),$$

$$0=\lim_{\substack{1\to 3\\2\to 4}}(D_1D_2F_{34})(f(F_3,F_4)+f(F_4,F_3)+f(-F_3,-F_4)+f(-F_4,-F_3)).$$

These identities have been applied to reduce the power series (25) for $M^{(2)}(t)$ to its most economical form.

(Received 7 October 1997; accepted for publication 20 April 1998)

Chiral U(1) anomaly is derived with mathematical rigor for a Euclidean fermion coupled to a smooth external U(1) gauge field on an even dimensional torus as a continuum limit of lattice regularized fermion field theory with the Wilson term in the action. The present work rigorously proves for the first time that the Wilson term correctly reproduces the chiral anomaly. © *1998 American Institute of Physics.* [S0022-2488(98)03609-3]

I. INTRODUCTION

It is widely believed that the continuum limit of a lattice regularized theory of quantized fermion gives the correct chiral anomaly[1–3] if we have Wilson terms in the lattice fermion action.[4] Since Karsten and Smit[5] observed this fact by a perturbative argument, there appeared mathematically more careful analyses,[6,7] in which it was claimed that the Wilson fermion has the expected continuum limit and gives the correct chiral anomaly under some mathematical ansatz on perturbative expansions. However, a further investigation on the validity of the ansatz has not been published so far, and from a mathematical view point, a proof that Wilson's formalism for a lattice fermion is a correct scheme giving the expected anomaly, has not been completed.

On the other hand, in modern physics, the Wilson fermion provides not only a mathematical basis for analytic investigations but also a practical scheme for numerical studies on Euclidean quantum field theories including fermions. In view of this, we cannot help asking for a mathematically rigorous proof that the Wilson term correctly reproduces the chiral anomaly in the continuum limit.

In the present paper, we study Wilson's formalism for a Euclidean lattice fermion coupled to a smooth external U(1) gauge field defined on an even dimensional torus and derive the expected chiral anomaly in the continuum limit with mathematical rigor. The present work rigorously proves for the first time that the Wilson term correctly reproduces the chiral anomaly.

We summarize below three essential mathematical problems in the present study and the strategies to solve the problems.

(1) Chiral oscillation. Let $\mathbb{T}_a^d=(a\mathbb{Z}/L\mathbb{Z})^d$ be a discrete torus with period L and lattice spacing a, where L/a is a positive integer. We denote by $\mathbb{V}_a^d$ the vector space consisting of all functions $u:\mathbb{T}_a^d\to\mathbb{C}^{2^{d/2}}$ defined on $\mathbb{T}_a^d$ with values in the ''fiber'' $\mathbb{C}^{2^{d/2}}$. The vacuum expectation of divergence of chiral current, which is our main quantity of interest, is written in the form of $\mathrm{Tr}(K\gamma_{d+1})$, where K is an operator acting on $\mathbb{V}_a^d$, and γ_{d+1} is the chirality in d dimensions [see (3.1)]. [Note that γ_{d+1} is regarded as an operator acting on $\mathbb{V}_a^d$ instead of the fiber $\mathbb{C}^{2^{d/2}}$ and therefore the multiplicities of the eigenvalues ±1 are not uniformly bounded in the lattice spacing a.]

To take the trace, we choose, as in Refs. 6 and 7, the ''planewave basis,'' i.e., the set of eigenfunctions of the (free) translations on the lattice [see (4.4)]. Though this choice may be standard, it should be underlined because the Wilson term is too weak to make the *trace norm* of

b)Electronic mail: d34335@m-unix.cc.u-tokyo.ac.jp

 © 1998 American Institute of Physics

$K\gamma_{d+1}$ uniformly bounded in the lattice spacing a. In other words, it is essential to ''cancel'' [see, e.g., (6.9)] the highly degenerate positive and negative eigenvalues of γ_{d+1} (the ''chiral oscillation'') before taking the continuum limit. The planewave basis is convenient for this purpose.

Strategy 1: Take the trace with respect to the planewave basis in order to explicitly cancel the chiral oscillation.

It may be illustrative to compare the situation with a previous related work by one of the authors (H.W.).[8–10] There, the chiral oscillation is controlled by introducing an additional heat-kernel regularization, with which the operator in question lies in the trace class, and the continuum limit can be taken without explicit cancellation of chiral oscillation. As a result, the index of the continuum Dirac operator appears, which is equal to the Chern class by the index theorem,[11] hence the proof is completed.

(2) Perturbative expansion. After performing the fermion integration, we have a formula with inverse of operators [see (3.9)]. If we try to expand the inverse operators perturbatively, the convergence of the expansion becomes a problem, as is usual with formal perturbation series. For example, the operator C defined in (3.8) is decomposed as

$$C = C_0 + C_1 \tag{1.1}$$

into a *free part* C_0 (for vanishing gauge potentials) and an *interaction part* C_1, but the Neumann series

$$C^{-1} = \sum_{\ell=0}^{\infty} (-C_0^{-1}C_1)^{\ell} C_0^{-1} \tag{1.2}$$

is not absolutely convergent, unless the gauge field is sufficiently small. The following idea was suggested in Ref. 7 without details:

Strategy 2: Terminate a perturbative expansion of inverse operator up to a finite order, and use ''positivity'' to control the remainder terms.

Namely, we use an identity

$$C^{-1} = C_0^{-1} + \sum_{j=1}^{m-1} (-C_0^{-1}C_1)^j C_0^{-1} + (-C_0^{-1}C_1)^m C^{-1}, \quad m = 1,2,..., \tag{1.3}$$

for a sufficiently large m. What we need is the power-counting property of the operator $(-C_0^{-1}C_1)^j$, and an *a priori bound* arising from positivity of C, to control the remainder terms. See Secs. IV and V for details. It may be suggestive to note that remainder estimates based on *positivity* are used in the convergence proof of cluster expansions in constructive field theory.

(3) Power counting. Strategy 2 should be accompanied by a rigorous power-counting argument. Furthermore, we need asymptotic estimates of operators, when we take the continuum limit. Our last point is to employ the power-counting arguments with mathematical rigor in order to extract the asymptotic behaviors.

Strategy 3: Show and use the fact that the operators in question are ''quasidiagonal'' with respect to the planewave basis.

The class of *quasidiagonal operators* defined in Sec. IV is closed with respect to the summation and the product, and, under a simple assumption, it is also closed with respect to the inverse operation. This calculus, which is a systematic arrangement of the asymptotic analysis of lattice operators in the spirit of power counting, fits our analysis in this paper well. The smoothness assumption on the gauge fields is of relevance here. See Sec. IV for details.

According to the above strategies, we take the continuum limit of $\mathrm{Tr}(K\gamma_{d+1})$ and confirm that the Wilson fermion gives the correct chiral anomaly.

This paper is organized as follows. We describe the model and state the result (Theorem 2.1) in Sec. II. Theorem 2.1 is proved in the subsequent sections. In Sec. III, we derive the expression of chiral anomaly in the form of chiral oscillation. Section IV is devoted to the calculus of quasidiagonal operators. In Sec. V, we apply the framework of Sec. IV to several operators and determine their orders. The proof of Theorem 2.1 is completed in Sec. VI.

The propositions in Secs. III and VI may guide readers who wish to have an overview of our argument.

II. PROBLEM AND RESULT

In this section, we formulate the problem and then state the result in Theorem 2.1.

A. Notation

Let $\mathbb{T}_a^d$ be a discrete torus with lattice spacing a and period L. Throughout this paper, we assume that $0<a<1/2$, $L/a\in\mathbb{Z}$. Let $\mathbb{V}_a^d$ be the set of all mappings

$$u=(u_s)_{s=1,2,\ldots,2^{d/2}}:\quad \mathbb{T}_a^d\to\mathbb{C}^{2^{d/2}}. \tag{2.1}$$

We impose the antiperiodic boundary condition for definiteness, though boundary conditions play no essential roles in this paper. (The antiperiodic boundary condition is required in the proof of the reflection positivity.[12])

Let $(\ ,\ )$ be the inner product on $\mathbb{V}_a^d$ defined by

$$(v,u)=a^d\sum_{x\in\mathbb{T}_a^d}(v(x),u(x))_x, \tag{2.2}$$

where $(\ ,\ )_x$ is the (standard) inner product on $\mathbb{C}^{2^{d/2}}$:

$$(v(x),u(x))_x=\sum_{s=1}^{2^{d/2}}\overline{v_s}(x)u_s(x).$$

Let $A_\mu(x)$, $\mu=1,2,\ldots,d$, be a fixed smooth U(1) gauge field on the continuum torus $\mathbb{T}^d=(\mathbb{R}/L\mathbb{Z})^d$. Using A_μ, we assign the gauge group element

$$U_\mu(x)=\exp\left(-iQ\int_0^a A_\mu(x+se_\mu)ds\right) \tag{2.3}$$

to a directed link $(x,x+e_\mu)$, $x\in\mathbb{T}_a^d$, $\mu=1,2,\ldots,d$, where $Q\in\mathbb{R}$ is a charge and e_μ is a unit vector along the μth axis for $\mu=1,2,\ldots,d$. Denote the free and the covariant translations by $T_{\mu 0}$ and T_μ, respectively:

$$T_{\mu 0}u(x)=u(x+ae_\mu),\quad \mu=1,2,\ldots,d,\quad x\in\mathbb{T}_a^d,\quad u\in\mathbb{V}_a^d, \tag{2.4}$$

$$T_\mu=U_\mu T_{\mu 0},\quad \mu=1,2,\ldots,d, \tag{2.5}$$

where U_μ denotes the multiplication operator defined by

$$U_\mu u(x)=U_\mu(x)u(x),\quad \mu=1,2,\ldots,d,\quad x\in\mathbb{T}_a^d,\quad u\in\mathbb{V}_a^d. \tag{2.6}$$

Note that $T_\mu^*=T_\mu^{-1}$ holds, where T_μ^* is the adjoint with respect to the inner product $(\ ,\ )$. Put

$$D_\mu=\frac{1}{2a}(T_\mu-T_\mu^*),\quad \mu=1,2,\ldots,d, \tag{2.7}$$

and let γ_μ, $\mu=1,2,\ldots,d$, be the d dimensional anti-Hermitian Dirac matrices. Namely,

$$\gamma_\mu\gamma_\nu+\gamma_\nu\gamma_\mu=-2\delta_{\mu\nu}I_{2^{d/2}},\quad \mu,\nu=1,2,\ldots,d, \tag{2.8}$$

where I_ℓ denotes the unit matrix of order ℓ. In what follows, we abbreviate $\gamma_\mu\otimes\dot{I}$ to γ_μ, where $\dot{I}$ denotes the identity operator on the space $\dot{\mathbb{V}}_a^d=\{\varphi:\mathbb{T}_a^d\to\mathbb{C}\}$. Then, the lattice Dirac operator on the discrete torus $\mathbb{T}_a^d$ is by definition

$$\not{D} = \sum_{\mu=1}^{d} \gamma_\mu D_\mu . \tag{2.9}$$

B. Lattice fermion

As is well-known, the operator $\not{D}$ has eigenfunctions called *doublers* which do not approximate any eigenfunctions of the continuum Dirac operator. In order to suppress the contributions of doublers to vacuum expectation values, we introduce the Wilson term:

$$W = -\sum_{\mu=1}^{d} (2I - T_\mu - T_\mu^*), \tag{2.10}$$

where I denotes the identity operator on $\mathbb{V}_a^d$. Then our lattice fermion action is written as

$$S(\overline{\psi}, \psi) = \left(\overline{\psi}, \left(i\not{D} + MI - \frac{r}{2a} W \right) \psi \right), \tag{2.11}$$

where $M > 0$ is the fermion mass and r is a positive constant. (Our analysis allows any $r > 0$, but the proof of reflection positivity[12] requires $0 < r \leqslant 1$.) Using the action S, we define the vacuum expectation by

$$\langle \Phi(\overline{\psi}, \psi) \rangle = \frac{1}{Z(A)} \int \prod_{x \in \mathbb{T}_a^d} d\overline{\psi}(x) d\psi(x) \exp(-S(\overline{\psi}, \psi)) \Phi(\overline{\psi}, \psi), \tag{2.12}$$

where the integrations with respect to $\overline{\psi}$ and ψ are the Grassmann integrations[12,13] and the partition function $Z(A)$ is defined by

$$Z(A) = \int \prod_{x \in \mathbb{T}_a^d} d\overline{\psi}(x) d\psi(x) \exp(-S(\overline{\psi}, \psi)) = \det\left(i\not{D} + MI - \frac{r}{2a} W \right). \tag{2.13}$$

Note that the semipositivity of $-W$,

$$(u, -Wu) = \sum_{\mu=1}^{d} \| (I - T_\mu) u \|^2 \geqslant 0, \tag{2.14}$$

implies

$$\left(u, \left(i\not{D} + MI - \frac{r}{2a} W \right) u \right) \neq 0, \quad u \neq 0, \tag{2.15}$$

hence $Z(A) \neq 0$.

C. Lattice chiral current

We define the lattice chiral current by

$$J_\mu(x) = \tfrac{1}{2}(\overline{\psi}(x), \gamma_{d+1}\gamma_\mu (T_\mu \psi)(x))_x + \tfrac{1}{2}((T_\mu \overline{\psi})(x), \gamma_{d+1}\gamma_\mu \psi(x))_x, \quad \mu = 1,2,...,d, \tag{2.16}$$

where the chirality γ_{d+1} is by definition

$$\gamma_{d+1} = i^{d/2} \gamma_1 \gamma_2 \cdots \gamma_d . \tag{2.17}$$

Put

$$Y(x) = \frac{1}{a} \sum_{\mu=1}^{d} (J_\mu(x) - J_\mu(x - a e_\mu)) - 2M_i(\overline{\psi}(x), \gamma_{d+1}\psi(x))_x, \quad x \in \mathbb{T}_a^d, \tag{2.18}$$

and smear it as

$$Y(\xi)=a^d\sum_{x\in\mathbb{T}_a^d}\xi(x)Y(x) \tag{2.19}$$

by an arbitrary real-valued smooth function ξ defined on the continuum torus. The functional $Y(x)$ is the ''divergence'' of lattice chiral current with a mass correction. Our problem is to calculate $\lim_{a\to 0}\langle Y(\xi)\rangle$.

D. Result

Let us state our result.

Theorem 2.1: For an arbitrary smooth gauge field $A=(A_\mu)$ and for an arbitrary smooth function ξ both defined on the continuum torus $\mathbb{T}^d$, it holds that

$$\lim_{a\to 0}\langle Y(\xi)\rangle=\frac{-2iQ^{d/2}}{(4\pi)^{d/2}(d/2)!}\int_{\mathbb{T}^d}dx\xi(x)\sum_{\mu_1,\mu_2,\ldots,\mu_d=1}^{d}\epsilon_{\mu_1\mu_2\cdots\mu_d}F_{\mu_1\mu_2}(x)F_{\mu_3\mu_4}(x)\cdots F_{\mu_{d-1}\mu_d}(x), \tag{2.20}$$

where $\epsilon_{\mu_1\mu_2\cdots\mu_d}$ is the totally antisymmetric tensor and

$$F_{\mu\nu}(x)=\partial_\mu A_\nu(x)-\partial_\nu A_\mu(x). \tag{2.21}$$

Namely, $\langle Y(x)\rangle$ weakly converges to the Chern class in the continuum limit. In the subsequent sections, we prove this fact with mathematical rigor.

III. CHIRAL OSCILLATION

In this section, we carry out the Grassmann integrations, and write the chiral anomaly as a trace of an operator on $\mathbb{V}_a^d$.

Proposition 3.1: (Refs. 6 and 7) *It holds that*

$$\langle Y(\xi)\rangle=-2i\ \mathrm{Tr}_{\mathbb{V}_a^d}[\Lambda\xi\gamma_{d+1}], \tag{3.1}$$

where

$$\Lambda=\frac{1}{2}\left(i\not{D}+MI-\frac{r}{2a}W\right)^{-1}(i\not{D}+MI)+\frac{1}{2}(i\not{D}+MI)\left(i\not{D}+MI-\frac{r}{2a}W\right)^{-1}. \tag{3.2}$$

Proof: It is easy to see that

$$Y(\xi)=a^d\sum_{x\in\mathbb{T}_a^d}\xi(x)Y(x) \tag{3.3}$$

$$=(\overline{\psi},\xi\gamma_{d+1}i\not{D}\psi)+(i\not{D}\overline{\psi},\xi\gamma_{d+1}\psi)-2Mi(\overline{\psi},\xi\gamma_{d+1}\psi), \tag{3.4}$$

where in (3.4) we used the same symbol ξ for the multiplication operator given by $(\xi u)(x)=\xi(x)u(x)$, $x\in\mathbb{T}_a^d$. Using (3.4) and manipulating the Grassmann integrations, we obtain (3.1). Here, (2.15) ensures the existence of the inverse of $i\not{D}+MI-(r/2a)W$. □

Taking into account the behavior of the Wilson term $-(r/2a)W$ for doublers, one may intuitively see that the Λ works as a ''projection'' to decouple doublers, and according to this picture, one can write the scenario that when the doublers go out of the continuum world, they take away a part of lattice chiral current and produce the chiral unbalance in the continuum world. One may say that this is the origin of chiral anomaly and nonzero index of the Dirac operator.

Put

$$L=MI-\frac{r}{2a}W, \tag{3.5}$$

$$X_{\mu\nu}=D_\mu L^{-1}D_\nu-D_\nu L^{-1}D_\mu, \quad \mu,\nu=1,2,...,d, \tag{3.6}$$

$$B=\frac{1}{2}\sum_{\mu,\nu=1}^{d}\gamma_\mu\gamma_\nu X_{\mu\nu}, \tag{3.7}$$

$$C=L-\sum_{\mu=1}^{d}D_\mu L^{-1}D_\mu. \tag{3.8}$$

Proposition 3.2: (Refs. 6 and 7) *It holds that*

$$\langle Y(\xi)\rangle=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\frac{r}{2a}(\xi W+W\xi)(C+B)^{-1}\gamma_{d+1}\right]. \tag{3.9}$$

Proof: Put

$$H_0=i\not{D}+MI, \tag{3.10}$$

$$H_1=i\not{D}+L, \tag{3.11}$$

and rewrite (3.1) as

$$\langle Y(\xi)\rangle=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}[\gamma_{d+1}(H_0H_1^{-1}+H_1^{-1}H_0)\xi]. \tag{3.12}$$

Since $H_0=H_1+(r/2a)W$ and $\mathrm{Tr}_{\mathbb{V}_a^d}[\xi\gamma_{d+1}]=0$, it holds that

$$\langle Y(\xi)\rangle=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\gamma_{d+1}\frac{r}{2a}(WH_1^{-1}+H_1^{-1}W)\xi\right]. \tag{3.13}$$

Note that

$$H_1L^{-1}H_1^*=L+\not{D}L^{-1}\not{D}=C+B \tag{3.14}$$

implies

$$H_1^{-1}=L^{-1}H_1^*(C+B)^{-1}. \tag{3.15}$$

Furthermore,

$$H_1\gamma_{d+1}=\gamma_{d+1}H_1^* \tag{3.16}$$

holds, while L, $\xi W+W\xi$, and $(C+B)^{-1}$ commute with γ_{d+1}. Then we have

$$\begin{aligned}\langle Y(\xi)\rangle&=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\frac{r}{2a}(\xi W+W\xi)L^{-1}H_1^*(C+B)^{-1}\gamma_{d+1}\right]\\&=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\frac{r}{2a}(\xi W+W\xi)L^{-1}\frac{H_1+H_1^*}{2}(C+B)^{-1}\gamma_{d+1}\right]\\&=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\frac{r}{2a}(\xi W+W\xi)(C+B)^{-1}\gamma_{d+1}\right].\end{aligned} \tag{3.17}$$

□

IV. QUASIDIAGONAL OPERATORS

All the lattice operators appearing in this paper are ''quasidiagonal'' with respect to the plane wave basis. In this section, we define the class of quasidiagonal operators, give a few examples (Lemmas 4.1, 4.2), and prove basic properties (Lemmas 4.3, 4.4).

A. Definition of quasidiagonal operators

We first fix an orthonormal basis of $\mathbb{V}_a^d$. Put

$$\mathbb{T}_a^{d*}=\left\{p=(p_\mu)\in\mathbb{R}^d \middle| p_\mu=\frac{2k_\mu+1}{L}\pi, k_\mu\in\mathbb{Z}, |p_\mu|<\frac{2}{a}\,\pi\right\}. \tag{4.1}$$

We regard $\mathbb{T}_a^{d*}$ as a discrete torus with period $(2/a)\pi$ and spacing $2\pi/L$ and denote by $\langle p\rangle$ the periodic distance on $\mathbb{T}_a^{d*}$:

$$\langle p\rangle=\max_{\mu=1,2,\ldots,d}\langle p_\mu\rangle=\max_{\mu=1,2,\ldots,d}\min_{n\in\mathbb{Z}}\left|p_\mu-\frac{2n}{a}\,\pi\right|. \tag{4.2}$$

For $p\in\mathbb{T}_a^{d*}$, define the antiperiodic plane wave u_p on $\mathbb{T}_a^d$ with a momentum p by

$$u_p(x)=L^{-d/2}\exp(ipx),\quad x\in\mathbb{T}_a^d. \tag{4.3}$$

Furthermore, let χ_α, $\alpha=1,2,\ldots,2^{d/2}$, be the canonical orthonormal basis of $\mathbb{C}^{2^{d/2}}$ with respect to the standard inner product. Then,

$$u_{\alpha p}=\chi_\alpha\otimes u_p\in\mathbb{V}_a^d,\quad \alpha=1,2,\ldots,2^{d/2},\quad p\in\mathbb{T}_a^{d*}, \tag{4.4}$$

constitute an orthonormal basis of $\mathbb{V}_a^d$:

$$(u_{\alpha p},u_{\beta q})=\delta_{\alpha\beta}\delta_{pq},\quad \alpha,\beta=1,2,\ldots,2^{d/2},\quad p,q\in\mathbb{T}_a^{d*}, \tag{4.5}$$

where the inner product $(\ ,\ )$ is the one defined by (2.2).

Let us formulate the class of quasidiagonal operators. Operators such as T_μ or C acting on $\mathbb{V}_a^d$ have dependencies on the lattice spacing a, so that when we define such operators, we in fact define families of operators $T_\mu=T_\mu^{(a)}$, $a>0$, or $C=C^{(a)}$, $a>0$.

Definition: Let $k=k(a,p)$, $p\in\mathbb{T}_a^{d*}$, be a non-negative function satisfying

$$k(a,p)\leqslant c(1+\langle p-q\rangle)^\tau k(a,q),\quad p,q\in\mathbb{T}_a^{d*}, \tag{4.6}$$

for some constants c and τ independent of a, p, and q. Then, for a family of linear operators $K^{(a)}$ on $\mathbb{V}_a^d$, we say that $K^{(a)}$ is *a quasidiagonal operator of the order k* and write $K^{(a)}=\mathscr{O}(k)$, if

$$|(u_{\alpha p},K^{(a)}u_{\beta q})|\leqslant c_\sigma\frac{k(a,p)}{(1+\langle p-q\rangle)^\sigma}, \tag{4.7}$$

holds for all $\sigma\geqslant 0, p,q\in\mathbb{T}_a^{d*}$, and $\alpha,\beta=1,2,\ldots,2^{d/2}$. Here the constant c_σ may depend on σ but not on a, p, q, α, β.

Note that (4.6) and (4.7) imply

$$|(u_{\alpha p},K^{(a)}u_{\beta q})|\leqslant c'_\sigma\frac{k(a,q)}{(1+\langle p-q\rangle)^\sigma} \tag{4.8}$$

for another constant c'_σ. In other words,

$$K^{(a)}=\mathscr{O}(k)\Rightarrow K^{(a)*}=\mathscr{O}(k). \tag{4.9}$$

In the following, we often suppress writing a dependencies of operators explicitly and write K instead of $K^{(a)}$. Then we will simply say that K is quasidiagonal and write $K=\mathscr{O}(k)$.

B. Free parts and multiplication operators

Define the ''free parts'' of D_μ, W, L, and C by

$$D_{\mu 0}=\frac{1}{2a}\,(T_{\mu 0}-T_{\mu 0}^{*}), \tag{4.10}$$

$$W_0=-\sum_{\mu=1}^{d}\,(2-T_{\mu 0}-T_{\mu 0}^{*}), \tag{4.11}$$

$$L_0=MI-\frac{r}{2a}\,W_0, \tag{4.12}$$

$$C_0=L_0-\sum_{\mu=1}^{d}\,L_0^{-1}D_{\mu 0}^{2}, \tag{4.13}$$

respectively. A free part of an operator is equal to the operator when the gauge potentials A_μ, $\mu=1,2,...,d$, vanish. The free part of B vanishes. Since $-W_0$ is semipositive [see (2.14)], L_0 and C_0 are positive definite and therefore invertible.

These operators are *exactly diagonal* with respect to the planewave basis and are the first examples of quasidiagonal operators.

Lemma 4.1: We have the following.

$$T_{\mu 0}=\mathcal{O}(1), \tag{4.14}$$

$$T_{\mu 0}-I=\mathcal{O}(a(1+\langle p\rangle)), \tag{4.15}$$

$$D_{\mu 0}=\mathcal{O}(1+\langle p\rangle), \tag{4.16}$$

$$W_0=\mathcal{O}(a^2(1+\langle p\rangle^2)), \tag{4.17}$$

$$L_0=\mathcal{O}(1+a\langle p\rangle^2), \tag{4.18}$$

$$L_0^{-1}=\mathcal{O}\left(\frac{1}{1+a\langle p\rangle^2}\right), \tag{4.19}$$

$$C_0=\mathcal{O}\left(\frac{1+\langle p\rangle^2}{1+a\langle p\rangle^2}\right), \tag{4.20}$$

$$C_0^{-1}=\mathcal{O}\left(\frac{1+a\langle p\rangle^2}{1+\langle p\rangle^2}\right). \tag{4.21}$$

Proof: (4.14)–(4.17) follow from

$$T_{\mu 0}u_{\alpha p}=e^{iap_\mu}u_{\alpha p}, \tag{4.22}$$

$$D_{\mu 0}u_{\alpha p}=\frac{i}{a}\,\sin(ap_\mu)u_{\alpha p}, \tag{4.23}$$

$$W_{\mu 0}u_{\alpha p}=-2\sum_{\mu=1}^{d}\,(1-\cos(ap_\mu))u_{\alpha p}. \tag{4.24}$$

For example, if $K=T_{\mu 0}-I$, then (4.7) is satisfied by putting $k(a,p)=a\langle p\rangle$. We add an extra ''1'' in (4.15) in order to ensure (4.6): the function $k(a,p)=a(1+\langle p\rangle)$ satisfies (4.6), because

$$1+\langle q+r\rangle\leqslant 1+\langle q\rangle+\langle r\rangle\leqslant(1+\langle r\rangle)(1+\langle q\rangle),\quad q,r\in\mathbb{T}_a^{d*}. \tag{4.25}$$

For the case $K=W_0$, we need

$$1+\langle q+r\rangle^2 \leqslant 1+2(\langle q\rangle^2+\langle r\rangle^2) \leqslant 2(1+\langle r\rangle^2)(1+\langle q\rangle^2), \quad q,r\in\mathbb{T}_a^{d*}. \tag{4.26}$$

The other bounds are shown by using

$$L_0 u_{\alpha p}=\left(M+\frac{r}{2a}\sum_{\mu=1}^{d}(1-\cos ap_\mu)\right)u_{\alpha p}, \tag{4.27}$$

$$C_0 u_{\alpha p}=\left(M+\frac{r}{2a}\sum_{\mu=1}^{d}(1-\cos ap_\mu)+\frac{\Sigma_{\mu=1}^{d}(1/a^2)\sin^2 ap_\mu}{M+(r/2a)\,\Sigma_{\mu=1}^{d}(1-\cos ap_\mu)}\right)u_{\alpha p}. \tag{4.28}$$

□

A multiplication operator determined by a smooth function on $\mathbb{T}^d$ is another example of quasi diagonal operators.

Lemma 4.2: Let ϕ be a multiplication operator defined by

$$\phi u(x)=\varphi(x)u(x); \quad x\in\mathbb{T}_a^d, \quad u\in\mathbb{V}_a^d, \tag{4.29}$$

for a complex valued smooth (periodic) function $\varphi(x)$ on the continuum torus $\mathbb{T}^d$. Then, we have $\phi=\mathcal{O}(1)$.

Furthermore, $\phi=\mathcal{O}(1)$ holds, if ϕ is defined by

$$\phi u(x)=\varphi_a(x)u(x), \quad x\in\mathbb{T}_a^d, \quad u\in\mathbb{V}_a^d, \tag{4.30}$$

for a family of functions $\varphi_a(x)$ on $\mathbb{T}^d$ that are ''uniformly smooth,'' i.e.,

$$\sup_{x\in\mathbb{T}^d}|\partial^\alpha\varphi_a(x)|<c^{(\alpha)}, \quad \alpha=(\alpha_1,\ldots,\alpha_d)\in\{0,1,2,...\}^d, \tag{4.31}$$

where $\{c^{(\alpha)}|\alpha\in\{0,1,...\}^d\}$ is a family of constants independent of a, and ∂^α stands for $\Pi_{k=1}^d\partial_k^{\alpha_k}$.

Proof: We show the first part of the lemma. Since $\varphi(x)$ is smooth and satisfies

$$(u_{\alpha p},\phi u_{\beta q})=\delta_{\alpha\beta}a^d\sum_{x\in\mathbb{T}_a^d}e^{i(q-p)x}\varphi(x), \quad \alpha,\beta=1,2,...,2^{d/2}, \quad p,q\in\mathbb{T}_a^{d*}, \tag{4.32}$$

there exists c_σ such that

$$|(u_{\alpha p},\phi u_{\beta q})|\leqslant\frac{c_\sigma}{(1+\langle p-q\rangle)^\sigma}, \quad \sigma\geqslant 0 \tag{4.33}$$

for $p,q\in\mathbb{T}_a^{d*}$ and for $\alpha,\beta=1,2,...,2^{d/2}$. Then, $K_a=\phi$ and $k(a,p)=1$ satisfy (4.6) and (4.7). The other part of the lemma can be proved in a similar way. □

C. Basic properties

The class of quasidiagonal operators is closed with respect to summation, product, and the inverse operation in the following sense.

Lemma 4.3: Let $K_j=\mathcal{O}(k_j)$, $j=1,2$. Then, we have $K_1+K_2=\mathcal{O}(k_1+k_2)$ and $K_1K_2=\mathcal{O}(k_1k_2)$.

The proof is given in Sec. IV D. Note that, when we say $K=\mathcal{O}(k)$, it is implied that k has the property (4.6) with some constants c, τ.

*Lemma 4.4: Suppose that $K=K_0+K_1$ satisfies the following, where ''*const.*'' stands for some positive constant independent of a and p:*

(1) There exists k_0 satisfying

$$k_0(p)\leqslant\text{const.}(1+\langle p\rangle)^\nu, \quad p\in\mathbb{T}_a^{d*}, \tag{4.34}$$

for some constant ν independent of a and p, such that K_0 is exactly of the order k_0 in the sense that $K_0=\mathcal{O}(k_0)$ and $K_0^{-1}=\mathcal{O}(1/k_0)$ hold.

(2) K_1 is of a lower order than K_0 in the sense that $K_1=\mathcal{O}(k_1)$ and

$$\frac{k_1(p)}{k_0(p)}\leqslant \text{const.}(1+\langle p\rangle)^{-\delta}, \quad p\in \mathbb{T}_a^{d*}, \tag{4.35}$$

for some constant $\delta>0$ independent of a and p.

(3) K^{-1} exists and is uniformly bounded, i.e.,

$$\|K^{-1}\|=\sup_{\substack{u\in \mathbb{V}_a^d \\ u\neq 0}} \frac{\|K^{-1}u\|}{\|u\|}\leqslant c \tag{4.36}$$

for some constant c independent of a.

Then we have $K^{-1}=\mathcal{O}(1/k_0)$.

The proof is given in Sec. IV F.

By means of Lemmas 4.3 and 4.4, we can estimate traces on $\mathbb{V}_a^d$ using the order of operators. As may be seen explicitly from Lemma 4.1, such estimates provide a mathematical justification of the power counting argument.

D. Proof of Lemma 4.3

Let us first show $K_1+K_2=\mathcal{O}(k_1+k_2)$. Assume

$$k_1(a,p)\leqslant c_1(1+\langle p-q\rangle)^{\tau_1}k_1(a,q), \tag{4.37}$$

$$k_2(a,p)\leqslant c_2(1+\langle p-q\rangle)^{\tau_2}k_2(a,q), \tag{4.38}$$

$$|(u_{\alpha p},K_1u_{\beta q})|\leqslant c_{1\sigma}\frac{k_1(a,p)}{(1+\langle p-q\rangle)^{\sigma}}, \tag{4.39}$$

$$|(u_{\alpha p},K_2u_{\beta q})|\leqslant c_{2\sigma}\frac{k_2(a,p)}{(1+\langle p-q\rangle)^{\sigma}}, \tag{4.40}$$

for $\sigma\geqslant 0$, $p,q\in\mathbb{T}_a^{d*}$, and for $\alpha,\beta=1,2,...,2^{d/2}$. Then, putting $K=K_1+K_2$, $k=k_1+k_2$, $\tau=\max(\tau_1,\tau_2)$, $c=\max(c_1,c_2)$, and $c_\sigma=\max(c_{1\sigma},c_{2\sigma})$, we have (4.6) and (4.7), and consequently, $K_1+K_2=\mathcal{O}(k_1+k_2)$.

Let us show $K=K_1K_2=\mathcal{O}(k_1k_2)$. Put $k=k_1k_2$. Then, for $c=c_1c_2$ and for $\tau=\tau_1+\tau_2$, (4.6) holds. In order to show (4.7), we need the following lemma.

Lemma 4.5: If $0\leqslant\rho\leqslant\min\{\sigma,\tau\}$ and $\sigma+\tau-\rho\geqslant d+1$ hold, we have

$$\sum_{r\in\mathbb{T}_a^{d*}}(1+\langle p-r\rangle)^{-\sigma}(1+\langle r-q\rangle)^{-\tau}\leqslant\text{const.}(1+\langle p-q\rangle)^{-\rho}, \tag{4.41}$$

*where ''*const.*'' is independent of p, q, and a.*

Proof: Decompose the summation on the left-hand side of (4.41) as

$$\begin{aligned}&\sum_{r\in\mathbb{T}_a^{d*}}(1+\langle p-r\rangle)^{-\sigma}(1+\langle r-q\rangle)^{-\tau}\\ &\quad=\left(\sum_{\substack{r\in\mathbb{T}_a^{d*}\\ \langle p-r\rangle\geqslant\langle r-q\rangle}}+\sum_{\substack{r\in\mathbb{T}_a^{d*}\\ \langle p-r\rangle<\langle r-q\rangle}}\right)(1+\langle p-r\rangle)^{-\sigma}(1+\langle r-q\rangle)^{-\tau}.\end{aligned} \tag{4.42}$$

Let us estimate the first sum. If $\langle p-r\rangle\geqslant\langle r-q\rangle$, then it holds that

$$2\langle p-r\rangle \geqslant \langle p-r\rangle + \langle r-q\rangle \geqslant \langle p-q\rangle, \tag{4.43}$$

hence

$$\begin{aligned}
&\sum_{\substack{r\in \mathbb{T}_a^{d*}\\ \langle p-r\rangle \geqslant \langle r-q\rangle}} (1+\langle p-r\rangle)^{-\sigma}(1+\langle r-q\rangle)^{-\tau} \\
&\quad \leqslant \sum_{\substack{r\in \mathbb{T}_a^{d*}\\ \langle p-r\rangle \geqslant \langle r-q\rangle}} (1+\langle p-r\rangle)^{-\rho}(1+\langle p-r\rangle)^{-\sigma+\rho}(1+\langle r-q\rangle)^{-\tau} \\
&\quad \leqslant \sum_{r\in \mathbb{T}_a^{d*}} \left(1+\frac{1}{2}\langle p-q\rangle\right)^{-\rho}(1+\langle r-q\rangle)^{-\tau-\sigma+\rho} \leqslant \text{const.}\left(1+\frac{1}{2}\langle p-q\rangle\right)^{-\rho},
\end{aligned} \tag{4.44}$$

where we also used the assumptions $0\leqslant\rho\leqslant\sigma$ and $\tau+\sigma-\rho\geqslant d+1$. The second sum on the right-hand side of (4.42) can be estimated in a similar way. □

Using (4.39), (4.40), (4.38), and (4.41), we have

$$\begin{aligned}
|(u_{\alpha p}, K_1K_2u_{\beta q})| &\leqslant \sum_{\gamma=1}^{2^{d/2}} \sum_{r\in \mathbb{T}_a^{d*}} |(u_{\alpha p}, K_1u_{\gamma r})||(u_{\gamma r}, K_2u_{\beta q})| \\
&\leqslant \sum_{\gamma=1}^{2^{d/2}} \sum_{r\in \mathbb{T}_a^{d*}} \frac{c_{1\sigma}c_{2r}k_1(a,p)k_2(a,r)}{(1+\langle p-r\rangle)^{\sigma}(1+\langle r-q\rangle)^{\tau}} \\
&\leqslant \sum_{\gamma=1}^{2^{d/2}} \sum_{r\in \mathbb{T}_a^{d*}} \frac{c_{1\sigma}c_{2\tau}c_2k_1(a,p)k_2(a,p)}{(1+\langle p-r\rangle)^{\sigma-\tau_2}(1+\langle r-q\rangle)^{\tau}} \leqslant \text{const.}\ \frac{c_{1\sigma}c_{2\tau}c_2k_1(a,p)k_2(a,p)}{(1+\langle p-q\rangle)^{\rho}}
\end{aligned} \tag{4.45}$$

by choosing sufficiently large σ and τ for each ρ. This implies (4.7) for $K=K_1K_2$, hence a proof of Lemma 4.3 is completed.

E. Preparation for a proof of Lemma 4.4

In this section, we prepare Lemmas 4.6, 4.7, and 4.8 for the proof of Lemma 4.4.

The idea of the proof of Lemma 4.4 is to estimate the right-hand side of the identity

$$K^{-1} = \sum_{j=0}^{n-1} J^jK_0^{-1} + J^nK^{-1}, \quad n=1,2,..., \tag{4.46}$$

where

$$J = -K_0^{-1}K_1. \tag{4.47}$$

Lemma 4.3 implies that the first term on the right-hand side of (4.46) is quasidiagonal. For the second term, as we shall see later, J^nK^{-1} for a sufficiently large n has a good power-counting property in spite of the poor information (4.36) on K^{-1}. The key point is that the order of J is strictly lower than 1:

Lemma 4.6: It holds that

$$J = \mathcal{O}((1+\langle p\rangle)^{-\delta}). \tag{4.48}$$

Furthermore, for $n\geqslant \nu/\delta$,

$$J^n = \mathcal{O}(1/k_0) \tag{4.49}$$

holds.

Proof: The assumption (4.35) and Lemma 4.3 imply (4.48). Then we have

$$J^n = \mathcal{O}((1+\langle p\rangle)^{-n\delta}), \quad n = 1,2,\ldots . \tag{4.50}$$

In view of (4.34), we can bound the order of J^n as follows:

$$(1+\langle p\rangle)^{-n\delta} \leqslant \text{const.}\ \frac{(1+\langle p\rangle)^{\nu-n\delta}}{k_0(p)}. \tag{4.51}$$

Choosing $n \geqslant \nu/\delta$, we obtain (4.49). □

The above lemma implies that multiplying by J improves the power-counting properties of operators.

In order to determine the order of the second term on the right-hand side of (4.46), we have to bound

$$\langle p_\mu - q_\mu\rangle^\rho |(u_{\alpha p}, J^n K^{-1} u_{\beta q})| \tag{4.52}$$

for $\rho \geqslant 0, p, q \in \mathbb{T}_a^{d*}$, and for $\alpha, \beta = 1,2,\ldots,2^{d/2}$. To this end, we use commutators with $(1/a)T_{\mu 0}$. Let us write

$$\mathrm{ad}_\mu(R) = \left[\frac{1}{a}\, T_{\mu 0}, R\right] \tag{4.53}$$

for an operator R on $\mathbb{V}_a^d$.

Lemma 4.7: For an operator R on $\mathbb{V}_a^d$, it holds that

$$|(u_{\alpha p}, \mathrm{ad}_\mu(R) u_{\beta q})| \begin{cases} \leqslant \langle p_\mu - q_\mu\rangle |(u_{\alpha p}, R u_{\beta q})| \\ \geqslant \dfrac{1}{\pi}\, \langle p_\mu - q_\mu\rangle |(u_{\alpha p}, R u_{\beta q})|, \end{cases}$$

$$p, q \in \mathbb{T}_a^{d*}, \quad \alpha, \beta = 1,2,\ldots,2^{d/2}, \quad \mu = 1,2,\ldots,d. \tag{4.54}$$

Furthermore, if $R = \mathcal{O}(r)$, then $\mathrm{ad}_\mu(R) = \mathcal{O}(r)$.

Proof: The bounds (4.54) follow from

$$\begin{aligned} |(u_{\alpha p}, \mathrm{ad}_\mu(R) u_{\beta q})| &= \frac{1}{a}\, |(\exp(i p_\mu a) - \exp(i q_\mu a))| |(u_{\alpha p}, R u_{\beta q})| \\ &= \frac{2}{a} \left| \sin\left(\frac{1}{2}\,(p_\mu - q_\mu)a\right)\right| |(u_{\alpha p}, R u_{\beta q})|. \end{aligned} \tag{4.55}$$

The estimate $\mathrm{ad}_\mu(R) = \mathcal{O}(r)$ follows from (4.54) and (4.7). □

Lemma 4.8. (1) For $R = \mathcal{O}(r)$, we have

$$|(u_{\alpha p}, R K^{-1} u_{\beta q})| \leqslant \text{const.}\ r(p), \quad p, q \in \mathbb{T}_a^{d*}, \quad \alpha, \beta = 1,2,\ldots,2^{d/2}, \tag{4.56}$$

where ''const.'' *is a constant independent of a, p, and q.*

(2) Assume that $R = \mathcal{O}(r)$ is at most of the same order as K, i.e.,

$$r(p) \leqslant k_0(p), \quad p \in \mathbb{T}_a^{d*}. \tag{4.57}$$

Then, we have

$$\sum_{s' \in \mathbb{T}_a^{d*}} |(u_{\alpha s'}, RK^{-1}u_{\beta s})| \leqslant \text{const.}, \quad s \in \mathbb{T}_a^{d*}, \quad \alpha, \beta = 1,2,...,2^{d/2}, \tag{4.58}$$

where ''const.'' *is a constant independent of a and s.*

Proof: (1) (4.7) and (4.36) imply

$$|(u_{\alpha p}, Ru_{\gamma s})| \leqslant \frac{\text{const. } r(p)}{(1+\langle p-s\rangle)^{d+1}}, \tag{4.59}$$

$$|(u_{\gamma s}, K^{-1}u_{\beta p})| \leqslant c, \tag{4.60}$$

for $p, s \in \mathbb{T}_a^{d*}$ and for $\alpha, \beta, \gamma = 1,2,...,2^{d/2}$. Then, we have

$$\begin{aligned} |(u_{\alpha p}, RK^{-1}u_{\beta q})| &\leqslant \sum_{s \in \mathbb{T}_a^{d*}} |(u_{\alpha p}, Ru_{\gamma s})||(u_{\gamma s}, K^{-1}u_{\beta q})| \\ &\leqslant \sum_{s \in \mathbb{T}_a^{d*}} \frac{\text{const. } r(p)}{(1+\langle p-s\rangle)^{d+1}} \leqslant \text{const. } r(p), \end{aligned} \tag{4.61}$$

where we used

$$\sum_{s \in \mathbb{T}_a^{d*}} (1+\langle s\rangle)^{-d-1} \leqslant \text{const.} \tag{4.62}$$

(2) Using (4.46), we have

$$\begin{aligned} \sum_{s' \in \mathbb{T}_a^{d*}} |(u_{\alpha s'}, RK^{-1}u_{\beta s})| &\leqslant \sum_{s' \in \mathbb{T}_a^{d*}} \sum_{j=0}^{n-1} |(u_{\alpha s'}, RJ^j K_0^{-1} u_{\beta s})| \\ &\quad + \sum_{s' \in \mathbb{T}_a^{d*}} |(u_{\alpha, s'}, RJ^n K^{-1} u_{\beta s})|. \end{aligned} \tag{4.63}$$

Let us bound the right-hand side of the above inequality. For the first term, (4.48) implies

$$J = \mathcal{O}(1), \tag{4.64}$$

hence

$$RJ^j K_0^{-1} = \mathcal{O}\left(\frac{r}{k_0}\right) \tag{4.65}$$

holds. Then, from (4.65), (4.8), and (4.57), we obtain

$$\begin{aligned} \sum_{s' \in \mathbb{T}_a^{d*}} \sum_{j=0}^{n-1} |(u_{\alpha s'}, RJ^j K_0^{-1} u_{\beta s})| &\leqslant \text{const. } \frac{r(s)}{k_0(s)} \sum_{s' \in \mathbb{T}_a^{d*}} (1+\langle s'-s\rangle)^{-d-1} \\ &\leqslant \text{const.}, \quad s \in \mathbb{T}_a^{d*}, \end{aligned} \tag{4.66}$$

for a ''const.'' independent of a and s. For the second term, note that (4.34) and $r(p) \leqslant k_0(p)$ imply that by choosing a sufficiently large n, we can make the order $r(p)(1+\langle p\rangle)^{-n\delta}$ of RJ^n lower than $(1+\langle p\rangle)^{-d-1}$. Then, using (4.36) for K^{-1} and (4.6) for RJ^n with $\sigma = d+1$, we have

$$\sum_{s' \in \mathbb{T}_a^{d*}} |(u_{\alpha s'}, RJ^n K^{-1} u_{\beta s})| \leqslant \sum_{s', s'' \in \mathbb{T}_a^{d*}} \sum_{\gamma=1}^{2^{d/2}} |(u_{\alpha s'}, RJ^n u_{\gamma s''})||(u_{\alpha s''}, K^{-1} u_{\beta s})|$$

$$\leqslant \sum_{s', s'' \in \mathbb{T}_a^{d*}} \sum_{\gamma=1}^{2^{d/2}} \text{const.} (1+\langle s' \rangle)^{-d-1} (1+\langle s'-s'' \rangle)^{-d-1} \leqslant \text{const.} \tag{4.67}$$

□

F. Proof of Lemma 4.4

In order to show Lemma 4.4, it suffices to estimate the right-hand side of (4.46). For the first term, using (4.64), we have the following bound:

$$\sum_{j=0}^{n-1} J^j K_0^{-1} = \mathcal{O}(1/k_0). \tag{4.68}$$

For the second term, we have to estimate

$$\langle p_\mu - q_\mu \rangle^\rho |(u_{\alpha p}, J^n K^{-1} u_{\beta q})| \tag{4.69}$$

for $\rho \geqslant 0$, $p,q \in \mathbb{T}_a^{d*}$, and for $\alpha, \beta = 1,2,...,2^{d/2}$.

If $\rho = 0$, (4.49) and (4.56) yield

$$|(u_{\alpha p}, J^n K^{-1} u_{\beta p})| \leqslant \frac{\text{const.}}{k_0(p)}, \quad p,q \in \mathbb{T}_a^{d*}, \quad \alpha, \beta = 1,2,...,2^{d/2}. \tag{4.70}$$

Now assume $\rho > 0$. Then Lemma 4.7 implies

$$\langle p_\mu - q_\mu \rangle^\rho |(u_{\alpha p}, J^n K^{-1} u_{\beta q})| \leqslant \pi^\rho |(u_{\alpha p}, \text{ad}_\mu^\rho (J^n K^{-1}) u_{\beta q})|, \quad p,q \in \mathbb{T}_q^{d*}, \quad \alpha, \beta = 1,2,...,2^{d/2}. \tag{4.71}$$

Here we note the equalities

$$\text{ad}_\mu^\rho (J^n K^{-1}) = \sum_{m=0}^{\rho} \binom{\rho}{m} \text{ad}_\mu^{\rho-m}(J^n) \text{ad}_\mu^m (K^{-1}) \tag{4.72}$$

and

$$\text{ad}_\mu^m (K^{-1}) = \sum_{\ell=1}^{m} \sum_{(m_1, m_2, ..., m_\ell)} \frac{(-1)^\ell m!}{m_1! m_2 \cdots m_\ell!} K^{-1} \text{ad}_\mu^{m_1}(K) K^{-1} \text{ad}_\mu^{m_2}(K) K^{-1} \cdots \text{ad}_\mu^{m_\ell}(K) K^{-1},$$

$$m = 1,2,..., \tag{4.73}$$

where the summation $\Sigma_{(m_1, m_2, ..., m_\ell)}$ is taken over all $(m_1, m_2, ..., m_\ell)$'s such that

$$m_1 + m_2 + \cdots + m_\ell = m, \tag{4.74}$$

$$m_1, m_2, ..., m_\ell \geqslant 1. \tag{4.75}$$

Combining them, we obtain

$$\mathrm{ad}_\mu^\rho(J^nK^{-1})=\mathrm{ad}_\mu^\rho(J^n)K^{-1}+\sum_{m=1}^{\rho}\binom{\rho}{m}\sum_{\ell=1}^{m}\sum_{(m_1,m_2,\ldots,m_\ell)}\frac{(-1)^\ell m!}{m_1!m_2!\cdots m_\ell!}$$
$$\times\mathrm{ad}_\mu^{\rho-m}(J^n)K^{-1}\mathrm{ad}_\mu^{m_1}(K)K^{-1}\mathrm{ad}_\mu^{m_2}(K)K^{-1}\cdots\mathrm{ad}_\mu^{m_\ell}(K)K^{-1}. \tag{4.76}$$

Then, it suffices to bound $\mathrm{ad}_\mu^{m'}(J^n)K^{-1}$ and $\mathrm{ad}_\mu^m(K)K^{-1}$.

Note that (4.49) and the latter part of Lemma 4.7 imply $\mathrm{ad}_\mu^{m'}(J^n)=\mathcal{O}(1/k_0)$ for sufficiently large n. Then, using (4.56), we have

$$|(u_{\alpha p},\mathrm{ad}_\mu^{m'}(J^n)K^{-1}u_{\beta s})|\leqslant\frac{\text{const.}}{k_0(p)},\quad p,s\in\mathbb{T}_a^{d*},\quad \alpha,\beta=1,2,\ldots,2^{d/2}. \tag{4.77}$$

Furthermore, the assumptions on the orders of K_0 and K_1 imply $K=\mathcal{O}(k_0)$. This fact and Lemma 4.7 and (4.58) imply

$$\sum_{s\in\mathbb{T}_a^{d*}}\sum_{\beta=1}^{2^{d/2}}|(u_{\beta s},\mathrm{ad}_\mu^m(K)K^{-1}u_{\gamma s'})|\leqslant\text{const.},\quad s'\in\mathbb{T}_a^{d*},\quad \gamma=1,2,\ldots,2^{d/2}. \tag{4.78}$$

Then, (4.71), (4.76), (4.77), and (4.78) imply

$$\langle p_\mu-q_\mu\rangle^\rho|(u_{\alpha p},J^nK^{-1}u_{\beta q})|\leqslant\frac{\text{const.}}{k_0(p)},$$
$$\rho>0,\quad p,q\in\mathbb{T}_a^{d*},\quad \alpha,\beta=1,2,\ldots,2^{d/2}. \tag{4.79}$$

This together with (4.70) yields $J^nK^{-1}=\mathcal{O}(1/k_0)$, which concludes the analysis on the second term on the right-hand side of (4.46), hence the proof of Lemma 4.4.

V. ORDERS OF OPERATORS

Using the framework of quasidiagonal operators, we determine the orders of lattice operators.

A. Orders of interaction parts

Interaction parts of the operators T_μ, D_μ, W, L, and C are by definition

$$T_{\mu 1}=T_\mu-T_{\mu 0}, \tag{5.1}$$
$$D_{\mu 1}=D_\mu-D_{\mu 0}, \tag{5.2}$$
$$W_1=W-W_0, \tag{5.3}$$
$$L_1=L-L_0, \tag{5.4}$$
$$C_1=C-C_0. \tag{5.5}$$

Namely,

$$T_{\mu 1}=(U_\mu-I)T_{\mu 0}, \tag{5.6}$$
$$D_{\mu 1}=\frac{1}{2a}(T_{\mu 1}-T_{\mu 1}^*), \tag{5.7}$$
$$W_1=\sum_{\mu=1}^{d}((U_\mu-I)(T_{\mu 0}-I)+(T_{\mu 0}^*-I)(U_\mu^*-I)+(U_\mu+U_\mu^*-2I)), \tag{5.8}$$

$$L_1 = -\frac{r}{2a} W_1, \tag{5.9}$$

$$C_1 = L_1 - \sum_{\mu=1}^{d} (D_\mu (L^{-1} - L_0^{-1}) D_\mu + D_{\mu 1} L_0^{-1} D_\mu + D_{\mu 0} L_0^{-1} D_{\mu 1}). \tag{5.10}$$

Lemma 5.1: We have the following order estimates.
(1) The orders of the interaction parts:

$$T_{\mu 1} = \mathcal{O}(a), \tag{5.11}$$

$$D_{\mu 1} = \mathcal{O}(1), \tag{5.12}$$

$$W_1 = \mathcal{O}(a^2(1 + \langle p \rangle)), \tag{5.13}$$

$$L_1 = \mathcal{O}(a(1 + \langle p \rangle)). \tag{5.14}$$

(2) The orders of the full operators:

$$T_\mu = \mathcal{O}(1), \tag{5.15}$$

$$D_\mu = \mathcal{O}(1 + \langle p \rangle), \tag{5.16}$$

$$W = \mathcal{O}(a^2(1 + \langle p \rangle^2)), \tag{5.17}$$

$$L = \mathcal{O}(1 + a\langle p \rangle^2). \tag{5.18}$$

Proof: (1) follows from (5.6) to (5.9) and Lemma 4.3 together with Lemma 4.1 and

$$U_\mu - I, U_\mu^* - I = \mathcal{O}(a), \tag{5.19}$$

$$U_\mu + U_\mu^* - 2I = \mathcal{O}(a^2). \tag{5.20}$$

(2) follows from (1) and Lemma 4.1. □

B. Orders of L^{-1} and C^{-1}

Lemma 5.2: The operator L is positive definite and satisfies

$$(u, Lu) \geqslant M \|u\|^2, \tag{5.21}$$

$$\|L^{-1}\| \leqslant M^{-1}. \tag{5.22}$$

Furthermore, it holds that

$$L^{-1} = \mathcal{O}\left(\frac{1}{1 + a\langle p \rangle^2}\right), \tag{5.23}$$

$$L^{-1} - L_0^{-1} = \mathcal{O}\left(\frac{a(1 + \langle p \rangle)}{(1 + a\langle p \rangle^2)^2}\right). \tag{5.24}$$

Proof: The semipositivity of $-W$ [see (2.14)] yields (5.21), from which (5.22) follows. Furthermore, we have (5.23) from (4.18), (4.19), (5.14), and Lemma 4.4, because

$$\frac{a(1 + \langle p \rangle)}{1 + a\langle p \rangle^2} \leqslant \frac{2}{1 + \langle p \rangle}. \tag{5.25}$$

Finally, estimating the right-hand side of

$$L^{-1}-L_0^{-1}=-L^{-1}L_1L_0^{-1}, \tag{5.26}$$

we obtain (5.24). □

Lemma 5.3: The operator C is positive definite and satisfies

$$(u,Cu)\geqslant M\|u\|^2, \tag{5.27}$$

$$\|C^{-1}\|\leqslant M^{-1}. \tag{5.28}$$

Furthermore, it holds that

$$C_1=\mathcal{O}\left(\frac{1+\langle p\rangle}{1+a\langle p\rangle^2}\right), \tag{5.29}$$

$$C=\mathcal{O}\left(\frac{1+\langle p\rangle^2}{1+a\langle p\rangle^2}\right), \tag{5.30}$$

$$C^{-1}=\mathcal{O}\left(\frac{1+a\langle p\rangle^2}{1+\langle p\rangle^2}\right). \tag{5.31}$$

Proof: In the right-hand side of (3.8), L is positive definite (Lemma 5.2) and

$$D_\mu^*=-D_\mu, \quad \mu=1,2,...,d. \tag{5.32}$$

Then, (5.27) and (5.28) hold. Applying Lemmas 4.1, 5.1, and 5.2 to operators on the right-hand side of (5.10), we have (5.29), which, with (4.20), implies (5.30). Finally, we obtain (5.31) from (4.20), (4.21), and (5.28). □

C. Order of $X_{\mu\nu}$

We begin with the following.

Lemma 5.4: If ϕ is a multiplication operator which satisfies (4.30) and (4.31), we have, for $\mu=1,2,...,d$,

$$[T_{\mu 0},\phi]=\mathcal{O}(a), \tag{5.33}$$

$$[T_{\mu 0}^*,\phi]=\mathcal{O}(a), \tag{5.34}$$

$$[T_{\mu 0}+T_{\mu 0}^*,\phi]=\mathcal{O}(a^2(1+\langle p\rangle)). \tag{5.35}$$

Proof: We bound the right-hand side of

$$[T_{\mu 0},\phi]=(T_{\mu 0}\phi T_{\mu 0}^*-\phi)T_{\mu 0}. \tag{5.36}$$

Since $T_{\mu 0}\phi T_{\mu 0}^*$ is a multiplication operator determined by the translation of φ, it holds that

$$T_{\mu 0}\phi T_{\mu 0}^*-\phi=\mathcal{O}(a). \tag{5.37}$$

This proves (5.33). The estimate (5.34) is obtained in a similar way. The estimate (5.35) follows from

$$[T_{\mu 0}+T_{\mu 0}^*,\phi]T_{\mu 0}=2a(T_{\mu 0}\phi T_{\mu 0}^*-\phi)D_{\mu 0}+(T_{\mu 0}\phi T_{\mu 0}^*+T_{\mu 0}^*\phi T_{\mu 0}-2\phi)T_{\mu 0}^* \tag{5.38}$$

with the help of

$$T_{\mu 0}\phi T_{\mu 0}^*+T_{\mu 0}^*\phi T_{\mu 0}-2\phi=\mathcal{O}(a^2). \tag{5.39}$$

□

The refined bound (5.35) due to the cancellation between $T_{\mu 0}$ and $T^*_{\mu 0}$ is essential in the proof of Proposition 6.1.

Lemma 5.5: We have the following order estimates:

$$[D_{\mu 1}, D_{\nu 0}] = \mathcal{O}(1), \tag{5.40}$$

$$[D_{\mu 1}, D_{\nu 1}] = \mathcal{O}(a), \tag{5.41}$$

$$[D_{\mu}, D_{\nu}] = \mathcal{O}(1), \tag{5.42}$$

$$[L_0, D_{\nu 1}] = \mathcal{O}(a(1+\langle p\rangle)), \tag{5.43}$$

$$[L_1, D_{\nu 0}] = \mathcal{O}(a(1+\langle p\rangle)), \tag{5.44}$$

$$[L_1, D_{\nu 1}] = \mathcal{O}(a), \tag{5.45}$$

$$[L, D_{\nu}] = \mathcal{O}(a(1+\langle p\rangle)), \tag{5.46}$$

$$X_{\mu\nu} = \mathcal{O}\left(\frac{a(1+\langle p\rangle^2)}{(1+a\langle p\rangle^2)^2}\right), \tag{5.47}$$

where $\mu, \nu = 1,2,...,d$.

Proof: Put $\eta_\mu = U_\mu - I$. Then, $\eta_\mu = \mathcal{O}(a)$ and

$$[T_{\mu 1}, T_{\nu 0}] = [\eta_\mu, T_{\nu 0}] T_{\mu 0} \tag{5.48}$$

hold. Using (5.33) for $\phi = (1/a)\eta_\mu$ [the functions $U_\mu(x)$ and $\eta_\mu(x)$ can be extended on the whole $\mathbb{T}^d$], we obtain

$$[T_{\mu 1}, T_{\nu 0}] = \mathcal{O}(a^2). \tag{5.49}$$

Similarly, we have

$$[T^*_{\mu 1}, T_{\nu 0}], [T_{\mu 1}, T^*_{\nu 0}], [T^*_{\mu 1}, T^*_{\nu 0}] = \mathcal{O}(a^2). \tag{5.50}$$

Then, (5.40) holds. The estimates

$$[T_{\mu 1}, T_{\nu 1}] = -\eta_\mu [\eta_\nu, T_{\mu 0}] T_{\nu 0} + \eta_\nu [\eta_\mu, T_{\nu 0}] T_{\mu 0} = \mathcal{O}(a^3), \tag{5.51}$$

$$[T^*_{\mu 1}, T_{\nu 1}], [T_{\mu 1}, T^*_{\nu 1}], [T^*_{\mu 1}, T^*_{\nu 1}] = \mathcal{O}(a^3), \tag{5.52}$$

are obtained similarly, from which we have (5.41). The estimate (5.42) follows from (5.40) and (5.41), because $D_{\mu 0}$ and $D_{\nu 0}$ commutes.

Next, using

$$[T_{\mu 0} + T^*_{\mu 0}, T_{\nu 1}] = [T_{\mu 0} + T^*_{\mu 0}, \eta_\nu] T_{\nu 0}, \tag{5.53}$$

$$[T_{\mu 0}, T_{\nu 1} + T^*_{\nu 1}] = T_{\nu 0} [T_{\mu 0}, \eta_\nu + \eta^*_\nu] - 2aD_{\nu 0} [T_{\mu 0}, \eta^*_\nu], \tag{5.54}$$

and Lemma 5.4, and the fact that $\eta_\nu + \eta^*_\nu = \mathcal{O}(a^2)$, we have

$$[T_{\mu 0} + T^*_{\mu 0}, T_{\nu 1}] = \mathcal{O}(a^3(1+\langle p\rangle)), \tag{5.55}$$

$$[T_{\mu 0}, T_{\nu 1} + T^*_{\nu 1}] = \mathcal{O}(a^3(1+\langle p\rangle)). \tag{5.56}$$

Similarly,

$$[T_{\mu 0} + T^*_{\mu 0}, T^*_{\nu 1}] = \mathcal{O}(a^3(1+\langle p\rangle)), \tag{5.57}$$

$$[T^*_{\mu 0}, T_{\nu 1} + T^*_{\nu 1}] = \mathcal{O}(a^3(1+\langle p\rangle)) \tag{5.58}$$

hold and we obtain (5.43) and (5.44). Furthermore, (5.45) is shown by estimating the right-hand sides of

$$[T_{\mu 1} + T^*_{\mu 1}, T_{\nu 1}] = \eta_\mu [T_{\mu 0}, \eta_\nu] T_{\nu 0} + \eta_\nu [\eta_\mu, T_{\nu 0}] T_{\mu 0} + [T^*_{\mu 0}, \eta_\nu] \eta^*_\mu T_{\nu 0} + \eta_\nu T^*_{\mu 0} [\eta^*_\mu, T_{\nu 0}] \tag{5.59}$$

and its adjoint. The estimate (5.46) follows from (5.43) to (5.45). Finally, note that

$$X_{\mu\nu} = D_\mu L^{-1} [D_\nu, L] L^{-1} - D_\nu L^{-1} [D_\mu, L] L^{-1} + [D_\mu, D_\nu] L^{-1}. \tag{5.60}$$

Estimating the right-hand side of (5.60) by means of (5.16), (5.23), (5.42), and (5.46), we obtain (5.47). □

Lemma 5.6: The operator $C+B$ is positive definite and satisfies

$$(u, (C+B)u) \geqslant M \|u\|^2, \tag{5.61}$$

$$\|(C+B)^{-1}\| \leqslant M^{-1}. \tag{5.62}$$

Furthermore, it holds that

$$B = \mathcal{O}\left(\frac{a(1+\langle p\rangle^2)}{(1+a\langle p\rangle^2)^2} \right), \tag{5.63}$$

$$BC^{-1} = \mathcal{O}\left(\frac{a}{1+a\langle p\rangle^2} \right), \tag{5.64}$$

$$(C+B)^{-1} = \mathcal{O}\left(\frac{1+a\langle p\rangle^2}{1+\langle p\rangle^2} \right). \tag{5.65}$$

Proof: (5.61) and (5.62) are obtained from

$$(u, (C+B)u) = (u, Lu) + \sum_{\mu=1}^{d} (D_\mu u, L^{-1} D_\mu u) \tag{5.66}$$

and (5.21). (5.63) is a consequence of (3.7) and (5.47). (5.64) follows from (5.63) and (5.31). Lemma 4.4 then yields (5.65). □

D. Leading term of $X_{\mu\nu}$

We extract the leading term of $X_{\mu\nu}$ and bound the remainder. Put

$$E_{\mu 0} = \tfrac{1}{2}(T_{\mu 0} + T^*_{\mu 0}), \quad \mu = 1,2,...,d. \tag{5.67}$$

Lemma 5.7: For $\mu, \nu = 1,2,...,d$, we have

$$[D_\mu, D_\nu] + iQF_{\mu\nu} E_{\mu 0} E_{\nu 0} = \mathcal{O}(a), \tag{5.68}$$

$$[L, D_\mu] + iarQ \sum_{\rho=1}^{d} F_{\mu\rho} D_{\rho 0} E_{\mu 0} = \mathcal{O}(a), \tag{5.69}$$

where Q is the charge and $F_{\mu\nu}$ is the field strength defined by (2.21).

Proof: Put $\eta_\mu = U_\mu - I$. Recalling (2.3), we have

$$\eta_\mu - T_{\nu 0} \eta_\mu T^*_{\nu 0} = -a\partial_\nu \eta_\mu + \mathcal{O}(a^3) = -ia^2 Q \partial_\nu A_\mu + \mathcal{O}(a^3). \tag{5.70}$$

Then, (5.48) and (5.36) yield

$$[T_{\mu 1}, T_{\nu 0}] = ia^2 Q(_\nu A_\mu) T_{\mu 0} T_{\nu 0} + \mathcal{O}(a^3). \tag{5.71}$$

Similarly, we have

$$[T_{\mu 1}, T^*_{\nu 0}] = -ia^2 Q(\partial_\nu A_\mu) T_{\mu 0} T^*_{\nu 0} + \mathcal{O}(a^3), \tag{5.72}$$

$$[T^*_{\mu 1}, T_{\nu 0}] = -ia^2 Q(\partial_\nu A_\mu) T^*_{\mu 0} T_{\nu 0} + \mathcal{O}(a^3), \tag{5.73}$$

$$[T^*_{\mu 1}, T^*_{\nu 0}] = ia^2 Q(\partial_\nu A_\mu) T^*_{\mu 0} T^*_{\nu 0} + \mathcal{O}(a^3), \tag{5.74}$$

hence

$$[D_{\mu 1}, D_{\nu 0}] = iQ(\partial_\nu A_\mu) E_{\mu 0} E_{\nu 0} + \mathcal{O}(a). \tag{5.75}$$

This together with (5.41) yields (5.68). Let us show (5.69). (5.38) and (5.53) yield

$$[T_{\rho 0} + T^*_{\rho 0}, T_{\mu 1}] = -2ia^3 Q(\partial_\rho A_\mu) D_{\rho 0} T_{\mu 0} + \mathcal{O}(a^3). \tag{5.76}$$

Similarly, we have

$$[T_{\rho 0} + T^*_{\rho 0}, T^*_{\mu 1}] = 2ia^3 Q(\partial_\rho A_\mu) D_{\rho 0} T^*_{\mu 0} + \mathcal{O}(a^3). \tag{5.77}$$

Then,

$$[L_0, D_{\mu 1}] = iarQ \sum_{\rho=1}^{d} (\partial_\rho A_\mu) D_{\rho 0} E_{\mu 0} + \mathcal{O}(a) \tag{5.78}$$

follows. Furthermore, (5.54) implies

$$[L_1, D_{\mu 0}] = -iarQ \sum_{\rho=1}^{d} (\partial_\mu A_\rho) D_{\rho 0} E_{\mu 0} + \mathcal{O}(a). \tag{5.79}$$

Then, (5.69) follows from (5.78), (5.79), and (5.45). □

Lemma 5.8: It holds that

$$X_{\mu\nu} + iQ\left(F_{\mu\nu} E_{\mu 0} E_{\nu 0} L_0^{-1} + ar \sum_{\rho-1}^{d} F_{\rho\nu} L_0^{-2} D_{\rho 0} D_{\mu 0} E_{\nu 0} - ar \sum_{\rho=1}^{d} F_{\rho\mu} L_0^{-2} D_{\rho 0} D_{\nu 0} E_{\mu 0} \right)$$
$$= \mathcal{O}\left(\frac{a(1+\langle p \rangle)}{(1+a\langle p \rangle^2)^2} \right) \tag{5.80}$$

for $\mu, \nu = 1,2,...,d$.

Proof: We extract the leading term from the right-hand side of (5.60). First, (5.68) and (5.24) imply

$$[D_\mu, D_\nu] L^{-1} = -iQF_{\mu\nu} E_{\mu 0} E_{\nu 0} L_0^{-1} + \mathcal{O}\left(\frac{a(1+\langle p \rangle)}{(1+a\langle p \rangle^2)^2} \right). \tag{5.81}$$

Similarly, from (5.69), we have

$$D_\mu L^{-1} [D_\nu, L] L^{-1} = -iarQ \sum_{\rho} D_{\mu 0} L_0^{-1} F_{\rho\nu} D_{\rho 0} D_{\rho 0} E_{\nu 0} L_0^{-1} + \mathcal{O}\left(\frac{a(1+\langle p \rangle)}{(1+a\langle p \rangle^2)^2} \right). \tag{5.82}$$

In the right-hand side of the above equality, we may move $F_{\rho\nu}$ to the front of the term by using the following lemma. [The difference is absorbed in the second term on the right-hand side of (5.82).] Thus we have the desired result. □

Lemma 5.9: If ϕ *is a multiplication operator which satisfies (4.30) and (4.31), we have, for* $\mu = 1,2,...,d$,

$$[D_{\mu 0},\phi]=\mathcal{O}(1), \tag{5.83}$$

$$[E_{\mu 0},\phi]=\mathcal{O}(a), \tag{5.84}$$

$$[W_0,\phi]=\mathcal{O}(a^2(1+\langle p\rangle)), \tag{5.85}$$

$$[L_0^{-1},\phi]=\mathcal{O}\left(\frac{1}{(1+a\langle p\rangle^2)(1+\langle p\rangle)}\right), \tag{5.86}$$

$$[C_0^{-1},\phi]=\mathcal{O}\left(\frac{1+a\langle p\rangle^2}{(1+\langle p\rangle^3)}\right). \tag{5.87}$$

Proof: The estimates (5.83)–(5.85) follow from (5.33) to (5.35). The commutators with L_0^{-1} and with C_0^{-1} are estimated using commutators with L_0 and with C_0, respectively. □

VI. PROOF OF THEOREM 2.1

A. Irrelevant terms

If we formally expand $(C+B)^{-1}$ on the right-hand side of (3.9), we have

$$\langle Y(\xi)\rangle \overset{\text{formally}}{=} \sum_{j=0}^{\infty} z^{(j)}, \tag{6.1}$$

where

$$z^{(j)}=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\frac{r}{2a}\,(\xi W+W\xi)C^{-1}(-BC^{-1})^j\gamma_{d+1}\right],\quad j=0,1,2,\ldots. \tag{6.2}$$

The following proposition is a consequence of the order estimates in Sec. V.

Proposition 6.1: For $j>d/2$, $z^{(j)}$ is irrelevant, i.e.,

$$\lim_{a\to 0}\left(\langle Y(\xi)\rangle-\sum_{j=0}^{d/2} z^{(j)}\right)=0. \tag{6.3}$$

Proof: It suffices to bound the right-hand side of

$$\langle Y(\xi)\rangle-\sum_{j=0}^{d/2} z^{(j)}=-i\ \mathrm{Tr}_{\mathbb{V}_a^d}\left[\frac{r}{2a}\,(\xi W+W\xi)(C+B)^{-1}(-BC^{-1})^{d/2+1}\gamma_{d+1}\right]. \tag{6.4}$$

The order estimates (5.17), (5.65), and (5.64) imply

$$\frac{r}{2a}\,(\xi W+W\xi)(C+B)^{-1}(-BC^{-1})^{d/2+1}\gamma_{d+1}=\mathcal{O}\left(\frac{a^{d/2+2}}{(1+a\langle p\rangle^2)^{d/2}}\right), \tag{6.5}$$

with the help of Lemmas 4.2 and 4.3. Let us take the trace on $\mathbb{V}_a^d$ by means of the planewave basis (4.4). Then, we have from (4.7) with $q=p$,

$$\left|\langle Y(\xi)\rangle-\sum_{j=0}^{d/2} z^{(j)}\right|\leqslant \text{const.}\ \sum p\in\mathbb{T}_a^{d*}\ \frac{a^{d/2+2}}{(1+a\langle p\rangle^2)^{d/2}}\leqslant \text{const.}\ a^2\ \log(1/a)\to 0, a\to 0, \tag{6.6}$$

where we used

$$\sum_{p\in\mathbb{T}_a^{d*}}\ \frac{a^{\ell}}{(1+a\langle p\rangle^2)^{\ell}}\leqslant \text{const.}\begin{cases} a^{\ell-d/2}, & l>d/2\\ \log(1/a), & \ell=d/2.\end{cases} \tag{6.7}$$

□

B. Spin properties

Next we take into account the ''spin properties'' of operators. We classify operators on $\mathbb{V}_a^d$ with respect to the homogeneous degrees in γ matrices. For example, C and B have 0 and 2 homogeneous degrees, respectively. An operator with homogeneous degree 0 is regarded as an operator on $\dot{\mathbb{V}}_a^d=\{\varphi:\mathbb{T}_a^d\to\mathbb{C}\}$. Since $\mathbb{V}_a^d=\mathbb{C}^{2^{d/2}}\otimes\dot{\mathbb{V}}_a^d$, the trace is factorized as:

$$\mathrm{Tr}_{\mathbb{V}_a^d}=\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}\,\mathrm{Tr}_{\mathbb{C}^{2^{d/2}}}. \tag{6.8}$$

Proposition 6.2: It holds that

$$z^{(j)}=0, \quad j=0,2,...,d/2-1, \tag{6.9}$$

$$z^{(d/2)}=-i^{d/2+1}\sum_{\mu_1,\mu_2,\ldots,\mu_d=1}^{d}\epsilon_{\mu_1\mu_2\cdots\mu_d}\,\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}\left[\frac{r}{2a}\,(\xi W+W\xi)\right.$$
$$\left.\times C^{-1}X_{\mu_1\mu_2}C^{-1}X_{\mu_3\mu_4}C^{-1}\cdots X_{\mu_{d-1}\mu_d}C^{-1}\right], \tag{6.10}$$

where $\epsilon_{\mu_1\mu_2\cdots\mu_d}$ denotes the totally antisymmetric tensor, and all the operators, having homogeneous degree 0, are regarded as defined on the space $\dot{\mathbb{V}}_a^d$.

Proof: The operator $(\xi W+W\xi)C^{-1}(-BC^{-1})^j$ has homogeneous degree $2j$ in γ's. Then, (6.9) is obvious from

$$\mathrm{Tr}_{\mathbb{C}^{2^{d/2}}}(\gamma_{\mu_1}\gamma_{\mu_2}\cdots\gamma_{\mu_\ell}\gamma_{d+1})=0, \quad 0\leqslant\ell<d, \quad \mu_1,\mu_2,\ldots,\mu_\ell=1,2,...,d. \tag{6.11}$$

On the other hand, (6.10) follows from (3.7) and

$$\mathrm{Tr}_{\mathbb{C}^{2^{d/2}}}(\gamma_{\mu_1}\gamma_{\mu_2}\cdots\gamma_{\mu_d}\gamma_{d+1})=(-2i)^{d/2}\epsilon_{\mu_1\mu_2\cdots\mu_d}, \quad \mu_1,\mu_2,\ldots,\mu_d=1,2,...,d. \tag{6.12}$$

□

C. Leading terms

We extract the leading terms from (6.10). Let us introduce the ''normal product'' $:\ :$ that moves multiplication operators to front, e.g.,

$$:\xi W_0+W_0\xi:=2\xi W_0, \tag{6.13}$$

$$:F_{\mu\nu}E_{\mu0}E_{\nu0}L_0^{-1}F_{\mu'\nu'}E_{\mu'0}E_{\nu'0}L_0^{-1}:=F_{\mu\nu}F_{\mu'\nu'}E_{\mu0}E_{\nu0}L_0^{-1}E_{\mu'0}E_{\nu'0}L_0^{-1}. \tag{6.14}$$

Proposition 6.3: Put, for $\mu,\nu=1,2,...,d$,

$$\overline{X}_{\mu\nu}=-iQ\left(F_{\mu\nu}E_{\mu0}E_{\nu0}L_0^{-1}+2ar\sum_{\rho=1}^{d}F_{\rho\nu}L_0^{-2}D_{\rho0}D_{\mu0}E_{\nu0}\right) \tag{6.15}$$

and

$$z_0=-i^{d/2+1}\sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d}\ \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}}^{d}\epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}}$$
$$\times\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}\left[:\frac{r}{a}\,\xi W_0C_0^{-1}\overline{X}_{\mu_1\nu_1}C_0^{-1}\overline{X}_{\mu_2\nu_2}C_0^{-1}\cdots\overline{X}_{\mu_{d/2}\nu_{d/2}}C_0^{-1}:\right], \tag{6.16}$$

Then, we have

$$\lim_{a\to0}(z^{(d/2)}-z_0)=0. \tag{6.17}$$

Proof: Insert

$$C^{-1}=C_0^{-1}-C_0^{-1}C_1C^{-1} \tag{6.18}$$

into the right-hand side of (6.10) and expand it with respect to C_1. Lemma 4.1 and Lemma 5.3 imply that C_0^{-1} has the same order as C^{-1} and

$$C_0^{-1}C_1C^{-1}=\mathcal{O}\left(\frac{1}{1+\langle p\rangle}\,\frac{1+a\langle p\rangle^2}{1+\langle p\rangle^2}\right) \tag{6.19}$$

is of lower order than C^{-1} by the factor $1/(1+\langle p\rangle)$. Then, terms containing C_1 vanish in the continuum limit in a similar way as in the proof of Proposition 6.1. By the same reason, we can replace W by W_0 [see (5.13), (5.17), and (4.17)]. Furthermore, we can replace $X_{\mu\nu}$ by

$$-iQ\left(F_{\mu\nu}E_{\mu 0}E_{\nu 0}L_0^{-1}+ar\sum_{\rho=1}^{d}F_{\rho\nu}L_0^{-2}D_{\rho 0}D_{\mu 0}E_{\nu 0}-ar\sum_{\rho=1}^{d}F_{\rho\mu}L_0^{-2}D_{\rho 0}D_{\nu 0}E_{\mu 0}\right) \tag{6.20}$$

[see (5.80)]. Here, the second and third terms of (6.20) give the same contributions to $z^{(d/2)}$ when (5.80) is inserted into the right-hand side of (6.10). Then, we can replace $X_{\mu\nu}$ by $\overline{X}_{\mu\nu}$. Finally in order to replace $\xi W_0+W_0\xi$ by $2\xi W_0$ and to take the normal product, it suffices to bound commutators $[W_0,\xi]$, $[C_0^{-1},F_{\mu\nu}]$, $[E_{\mu' 0}E_{\nu' 0}L_0^{-1},F_{\mu\nu}]$, etc. Those commutators are estimated using Lemma 5.9: By taking a commutator with a multiplication operator, the order of the free part of an operator (with the suffix 0 like $D_{\mu 0}$) is reduced by the factor $1/(1+\langle p\rangle)$, hence the trace containing at least one commutators vanishes in the continuum limit. □

D. Symmetry arguments

In view of (6.15) and (6.16), we see that z_0 is a polynomial in r of order $d/2+1$ if we ignore the r dependencies of L_0^{-1} and C_0^{-1}. The following proposition claims that the cubic and higher order terms vanish.

Proposition 6.4: Put

$$z_1=-iQ^{d/2}\sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d}\ \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}=1}^{d}\epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}}\frac{r}{a}$$
$$\times\mathrm{Tr}_a^{\wedge d}\left[:\xi W_0C_0^{-(d/2+1)}L_0^{-d/2}\prod_{j=1}^{d/2}(F_{\mu_j\nu_j}E_{\mu_j 0}E_{\nu_j 0}):\right], \tag{6.21}$$

$$z_2=-iQ^{d/2}\sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d}\ \sum_{\nu_1,\nu_2,..,\nu_{d/2}}^{d}\epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}}2r^2$$
$$\times\mathrm{Tr}_a^{\wedge d}\left[:\xi W_0C_0^{-(d/2+1)}L_0^{-(d/2+1)}\sum_{\ell=1}^{d/2}\sum_{\rho=1}^{d}F_{\rho\nu_\ell}D_{\rho 0}D_{\mu_\ell 0}E_{\nu_\ell 0}\prod_{\substack{j=1\\ j\neq\ell}}^{d/2}(F_{\mu_j\nu_j}E_{\mu_j 0}E_{\nu_j 0}):\right]. \tag{6.22}$$

Then, we have

$$z_0=z_1+z_2. \tag{6.23}$$

Moreover, in the right-hand side of (6.22), we can fix the value of ρ to μ_ℓ, i.e.,

$$z_2 = -iQ^{d/2} \sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d} \sum_{\nu_1,\nu_2,\ldots,\mu_{d/2}=1}^{d} \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}=1}^{d} \epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}} 2r^2$$
$$\times \mathrm{Tr}_a^{\dot{\vee}d}\left[:\xi W_0 C_0^{-(d/2+1)} L_0^{-(d/2+1)} \sum_{\ell=1}^{d/2} F_{\mu_\ell\nu_\ell} D_{\mu_\ell 0}^2 E_{\nu_\ell 0} \prod_{\substack{j=1 \\ j\neq\ell}}^{d/2} (F_{\mu_j\nu_j} E_{\mu_j 0} E_{\nu_j 0}) : \right]. \quad (6.24)$$

Proof: Insert (6.15) into the summand on the right-hand side of (6.16) and expand it. Let us look at a term generated by the expansion that contains at least two factors of the form $2ar\Sigma_{\rho=1}^{d} F_{\rho\nu} L_0^{-2} D_{\rho 0} D_{\mu 0} E_{\nu 0}$ [the second term of the right-hand side of (6.15)]. Such a term has the form

$$:\cdots 2ar \sum_{\rho_\ell=1}^{d} F_{\rho_\ell\nu_\ell} L_0^{-2} D_{\rho_\ell 0} D_{\mu_\ell 0} E_{\nu_\ell 0} \cdots 2ar \sum_{\rho_{\ell'}=1}^{d} F_{\rho_{\ell'}\nu_{\ell'}} L_0^{-2} D_{\rho_{\ell'} 0} D_{\mu_{\ell'} 0} E_{\nu_{\ell'} 0} \cdots :. \quad (6.25)$$

Then, it is symmetric with respect to μ_ℓ and $\mu_{\ell'}$ hence it vanishes when it is summed up with respect to μ_ℓ and $\mu_{\ell'}$ under the presence of the totally antisymmetric tensor. This gives (6.23).

Next, note that $\mu_1,\nu_1,\ldots,\mu_{d/2},\nu_{d/2}$ are mutually distinct because of the totally antisymmetric tensor. Then, the sum (6.22) is decomposed into partial sums in which ρ is fixed to μ_j or ν_j for $j=1,2,\ldots,d/2$. If $\rho=\nu_\ell$, $F_{\rho\nu_\ell}$ vanishes. It therefore suffices to consider the case $\rho=\mu_j,\nu_j$ for some $j\neq\ell$. Assume $\rho=\mu_j$. In this case, the summand has the form

$$:\cdots F_{\mu_j\nu_\ell} D_{\mu_j 0} D_{\mu_\ell 0} E_{\nu_\ell 0} \cdots F_{\mu_j\nu_j} E_{\mu_j 0} E_{\nu_j 0} \cdots : \quad (6.26)$$

Then, it is symmetric with respect to ν_ℓ and ν_j, hence it vanishes when it is summed up with respect to ν_ℓ and ν_j. The term for $\rho=\nu_j$ similarly vanishes. Thus we have (6.24). □

Combining Propositions 6.1, 6.2, 6.3, and 6.4, we obtain:

Proposition 6.5: Put

$$G = \frac{r}{a} W_0 C_0^{-(d/2+1)} L_0^{-(d/2+1)} \left(L_0 + ar \sum_{\ell=1}^{d} \frac{D_{\ell 0}^2}{E_{\ell 0}} \right) \prod_{j=1}^{d} E_{j0}, \quad (6.27)$$

where we write (with a slight abuse of notation)

$$\frac{D_{\ell 0}^2}{E_{\ell 0}} \prod_{j=1}^{d} E_{j0} = D_{\ell 0}^2 \prod_{\substack{j=1 \\ j\neq\ell}}^{d} E_{j0}. \quad (6.28)$$

Then we have

$$\lim_{a\to 0} (\langle Y(\xi)\rangle + iQ^{d/2} \mathrm{Tr}_a^{\dot{\vee}d}(\xi \epsilon F^{d/2} G)) = 0, \quad (6.29)$$

where

$$\epsilon F^{d/2} = \sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d} \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}=1}^{d} \epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}} \prod_{j=1}^{d/2} F_{\mu_j\nu_j}. \quad (6.30)$$

Proof: Rewrite the right-hand sides of (6.21) and (6.24) as:

$$z_1 = -iQ^{d/2} \mathrm{Tr}_a^{\dot{\vee}d}\left(\xi \epsilon F^{d/2} \frac{r}{a} W_0 C_0^{-(d/2+1)} L_0^{-d/2} \prod_{j=1}^{d} E_{j0} \right), \quad (6.31)$$

$$z_2 = -iQ^{d/2}\,\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}\Bigg(\xi \sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d} \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}=1}^{d} \epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}} \prod_{j=1}^{d/2} F_{\mu_j\nu_j} \times 2r^2 W_0 C_0^{-(d/2+1)} L_0^{-(d/2+1)} \sum_{\ell=1}^{d/2} \frac{D_{\mu_\ell 0}^2}{E_{\mu_\ell 0}} \prod_{j=1}^{d} E_{j0}\Bigg)$$

$$= -iQ^{d/2}\,\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}\Bigg(\xi \sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d} \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}=1}^{d} \epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}} \prod_{j=1}^{d/2} F_{\mu_j\nu_j} \times 2r^2 W_0 C_0^{-(d/2+1)} L_0^{-(d/2+1)} \frac{1}{2} \sum_{\ell=1}^{d/2} \left(\frac{D_{\mu_\ell 0}^2}{E_{\mu_\ell 0}} + \frac{D_{\nu_\ell 0}^2}{E_{\nu_\ell 0}}\right) \prod_{j=1}^{d} E_{j0}\Bigg)$$

$$= -iQ^{d/2}\,\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}\Bigg(\xi \epsilon F^{d/2} 2r^2 W_0 C_0^{-(d/2+1)} L_0^{-(d/2+1)} \frac{1}{2} \sum_{\ell=1}^{d/2} \frac{D_{\ell 0}^2}{E_{\ell 0}} \prod_{j=1}^{d} E_{j0}\Bigg). \tag{6.32}$$

Then, the proposition follows from (6.3), (6.9), (6.17), (6.23), (6.31), and (6.32). □

E. Coefficients

We take the trace of the left-hand side of (6.29) with respect to the (spinless) planewave basis $u_p, p \in \mathbb{T}_a^{d*}$, defined by (4.3). In the following proposition, $G(p)$ is the eigenvalue of G, i.e., $Gu_p = G(p)u_p$ (see the proof of Lemma 4.1).

Proposition 6.6: Put

$$G(p) = -2r^2 a^d \sum_{\mu=1}^{d} (1-\cos ap_\mu) \prod_{\lambda=1}^{d} \cos ap_\lambda \times \frac{\dfrac{Ma}{r} + \sum_{\nu=1}^{d} (1-\cos ap_\nu) - \sum_{\nu=1}^{d} \dfrac{\sin^2 ap_\nu}{\cos ap_\nu}}{[(Ma + r\Sigma_{\nu=1}^{d}(1-\cos ap_\nu))^2 + \Sigma_{\nu=1}^{d} \sin^2 ap_\nu]^{d/2+1}}, \tag{6.33}$$

$$\kappa_a = \frac{1}{L^d} \sum_{p \in \mathbb{T}_a^{d*}} G(p). \tag{6.34}$$

Then, we have

$$\lim_{a\to 0}\left(\langle Y(\xi)\rangle + i\kappa_a Q^{d/2} a^d \sum_{x \in \mathbb{T}_a^d} \xi(x) \epsilon F^{d/2}(x)\right) = 0, \tag{6.35}$$

where

$$\epsilon F^{d/2}(x) = \sum_{\mu_1,\mu_2,\ldots,\mu_{d/2}=1}^{d} \sum_{\nu_1,\nu_2,\ldots,\nu_{d/2}=1}^{d} \epsilon_{\mu_1\nu_1\cdots\mu_{d/2}\nu_{d/2}} \prod_{j=1}^{d/2} F_{\mu_j\nu_j}(x), \quad x \in \mathbb{T}_a^d. \tag{6.36}$$

Proof: Let ϕ be a multiplication operator determined by a function φ which satisfies (4.30) and (4.31), and let K_0 be a free operator on $\dot{\mathbb{V}}_a^d$, i.e., an operator with u_p, $p \in \mathbb{T}_a^{d*}$ as the set of eigenfunctions. We denote the eigenvalue by $K_0(p)$, i.e., $K_0 u_p = K_0(p)u_p$. Then we see that

$$\mathrm{Tr}_{\dot{\mathbb{V}}_a^d}(\phi K_0) = \sum_{p \in \mathbb{T}_a^{d*}} (u_p, \phi K_0 u_p) = \sum_{p \in \mathbb{T}_a^{d*}} K_0(p)(u_p, \phi u_p) = \sum_{p \in \mathbb{T}_a^{d*}} K_0(p) \frac{a^d}{L^d} \sum_{x \in \mathbb{T}_a^d} \varphi(x). \tag{6.37}$$

The proposition is a consequence of (6.29) and (6.37). □

Now, the proof of Theorem 2.1 is completed if we confirm the following.

Proposition 6.7: (Ref. 7) *It holds that*

$$\lim_{a\to 0} \kappa_a = \frac{2}{(4\pi)^{d/2}(d/2)!}. \tag{6.38}$$

Proof: Put

$$g(a,q) = a^{-d} G(q/a) = -2r^2 \sum_{\mu=1}^{d} (1-\cos q_\mu) \prod_{\lambda=1}^{d} \cos q_\lambda \times \frac{\dfrac{Ma}{r} + \sum_{\nu=1}^{d} (1-\cos q_\nu) - \sum_{\nu=1}^{d} \dfrac{\sin^2 q_\nu}{\cos q_\nu}}{[(Ma + r\Sigma_{\nu=1}^{d}(1-\cos q_\nu))^2 + \Sigma_{\nu=1}^{d} \sin^2 q_\nu]^{d/2+1}} \tag{6.39}$$

for $a>0$, and

$$g(0,q) = \lim_{a\downarrow 0} g(a,q). \tag{6.40}$$

Using the function g, we write

$$\kappa_a = \left(\frac{a}{L}\right)^d \sum_{q\in a\mathbb{T}_a^{d*}} g(a,q). \tag{6.41}$$

For $q\in\mathbb{T}^{d*}=[-\pi,\pi]^d$, let $[q]$ denote the point in $a\mathbb{T}_a^{d*}$ nearest to q. $[q]$ is defined almost everywhere in $\mathbb{T}^{d*}$. Then, it holds that

$$\kappa_a = \frac{1}{(2\pi)^d} \int_{\mathbb{T}^{d*}} dq g(a,[q]). \tag{6.42}$$

Note that, for an arbitrarily small $\epsilon>0$, we can choose $\delta>0$ such that

$$\frac{1}{(2\pi)^d} \int_{B_\delta} dq |g(a,[q])| < \epsilon, \tag{6.43}$$

hold for any $a\geqslant 0$, where $B_\delta=\{q\in\mathbb{R}^d \,|\, |q|<\delta\}$. Removing the small ball B_δ from the hypercube $\mathbb{T}^{d*}$, we can take the continuum limit:

$$\lim_{a\to 0} \frac{1}{(2\pi)^d} \int_{\mathbb{T}^{d*}\setminus B_\delta} dq g(a,[q]) = \frac{1}{(2\pi)^d} \int_{\mathbb{T}^{d*}\setminus B_\delta} dq g(0,q). \tag{6.44}$$

Then, it holds that

$$\lim_{a\to 0} \kappa_a = \frac{1}{(2\pi)^d} \int_{\mathbb{T}^{d*}} dq g(0,q). \tag{6.45}$$

It therefore suffices to show

$$\int_{\mathbb{T}^{d*}} dq g(0,q) = \frac{2}{d}\,\Omega_d, \tag{6.46}$$

where Ω_d stands for the area of the d-dimensional unit sphere, i.e., $\Omega_d=(2\pi)^{d/2}/(d-2)!!$. This fact is proved for $d=4$ in Ref. 5 and for all d and all r in Ref. 7. □

(To be strict, our conclusion is consistent with that of Ref. 7, if we include $\Pi_\mu \epsilon_\mu$ and replace s^d-1 by s^{d-1} in the integrand of (A20) in Ref. 7.)

APPENDIX: OPERATORS

We list up the operators that are (globally) used in this paper.

$$T_{\mu 0}u(x)=u(x+ae_{\mu}), \tag{2.4}$$

$$T_{\mu}=U_{\mu}T_{\mu 0}, \tag{2.5}$$

$$D_{\mu}=\frac{1}{2a}\,(T_{\mu}-T_{\mu}^{*}), \tag{2.7}$$

$$\not{D}=\sum_{\mu=1}^{d}\gamma_{\mu}D_{\mu}, \tag{2.9}$$

$$W=-\sum_{\mu=1}^{d}\,(2I-T_{\mu}-T_{\mu}^{*}), \tag{2.10}$$

$$L=MI-\frac{r}{2a}\,W, \tag{3.5}$$

$$X_{\mu\nu}=D_{\mu}L^{-1}D_{\nu}-D_{\nu}L^{-1}D_{\mu}, \tag{3.6}$$

$$B=\frac{1}{2}\sum_{\mu,\nu=1}^{d}\,\gamma_{\mu}\gamma_{\nu}X_{\mu\nu}, \tag{3.7}$$

$$C=L-\sum_{\mu=1}^{d}\,D_{\mu}L^{-1}D_{\mu}, \tag{3.8}$$

$$E_{\mu 0}=\tfrac{1}{2}(T_{\mu 0}+T_{\mu 0}^{*}). \tag{5.67}$$

We construct the Feynman integrands for a class of exponentially growing time-dependent potentials as white noise functionals. We show that they solve the Schrödinger equation. The Morse potential is considered as a special case. © *1998 American Institute of Physics.* [S0022-2488(98)03909-7]

I. INTRODUCTION

As an alternative approach to quantum mechanics Feynman introduced the concept of path integrals,[1] which developed into an extremely useful tool in many branches of theoretical physics.

Unfortunately, Feynman's intuitive idea of averaging over some set of paths is mathematically meaningful only for the heat equation where the underlying structure for the free motion is based on the Brownian paths with Wiener measure. This is stated by the famous Feynman–Kac formula. To write down solutions of the Schrödinger equation as path integrals is much more involved and often less direct. A measure does not exist for the Feynman integral as in the Euclidean case.[2] We do not give a full list of references, but we would like to refer to Ref. 3, their method using infinite dimensional Fresnel integrals and their extensive list of references to further approaches to Feynman integrals. Furthermore, we want to mention one of the most widely used methods, analytic continuation. The calculation itself takes place on the Euclidean side, where we have the whole machinery of probabilistic theory at our disposal. The final step is to perform an analytic continuation in some parameter such as time or mass to get solutions of the Schrödinger equation. In Sec. IV D we will prove that continuation in the mass is incompatible with perturbation theory in the case we are considering. Additionally, we want to mention the method of Doss,[4] using the Feynman–Kac formula and complex scaling. The method of Doss can also be used in the framework of white noise analysis.[5,6]

White noise analysis,[5,7,8] is a framework which offers various generalizations of concepts known from finite dimensional analysis to the infinite dimensional case, among them are differential operators and Fourier transform.

The underlying random variable is not Brownian motion but rather its velocity, white noise. Being independent at each time, white noise provides a suitable infinite dimensional coordinate system. The ''integral'' is understood as the dual pairing of a distribution with a test function, so that the Feynman integrand itself has meaning as a distribution. This allows us to calculate not only the propagator but, more generally, time ordered expectation values. Important for the usefulness of any approach to Feynman integrals is the class of potentials we are able to handle. In white noise analysis Feynman integrals have been constructed for different classes of potentials. The first were proposed by Ref. 9 and by Khandekar and Streit.[10] The latter construction was generalized in Refs. 11 and 12 to a wider class, also allowing time-dependent interactions. Potentials there were given as superpositions of δ functions. Unfortunately, this is restricted to one space dimension. In Ref. 6 another set was considered, the so-called Albeverio–Høegh–Krohn class[3] of potentials that are Fourier transforms of measures. Here the space dimension is arbitrary, on the other hand, the potentials are smooth and bounded. We shall instead consider Laplace transforms of measures, again for arbitrary finite space dimension. In Sec. IV we construct the

 © 1998 American Institute of Physics

Feynman integrand as a white noise distribution and show that the corresponding propagator solves the Schrödinger equation. The potentials are smooth but they grow, in general, exponentially at $\pm\infty$. They are too singular to be handled by Kato–Rellich perturbation theory. Nevertheless we show that the propagator is analytic in the coupling constant and we write it as a Dyson series. In Sec. V we consider the special case of Morse potentials $V(x)=g(e^{-2ax}-2\gamma e^{ax})$ for illustration and for more explicit calculations. This problem is solvable in closed form.[13–16] There the authors derive the Green function, the spectrum, and the eigenfunctions. These quantities are in general not analytic in g. If we change from positive to negative g we also lose the essential self-adjointness of the corresponding Hamilton operator. This dramatic change, however, does not destroy the analyticity of the propagator.

II. WHITE NOISE ANALYSIS

In this section we give a brief overview of concepts and theorems of white noise analysis which we use.[5,8,7]

The starting point of d-dimensional white noise analysis is the real separable Hilbert space

$$L_d^2 := L^2(\mathbb{R})\otimes\mathbb{R}^d, \quad d\in\mathbb{N}, \tag{1}$$

which is unitary isomorphic to a direct sum of d identical copies of $L^2(\mathbb{R})$—the space of real valued square-integrable functions with respect to Lebesgue measure. The norm in L_d^2 is given by

$$|f|_0 := \sum_{j=1}^{d} \int_{\mathbb{R}} f_j^2(s)ds, \quad f\in L_d^2. \tag{2}$$

In this space we choose the densely imbedded nuclear space

$$S_d := S(\mathbb{R})\otimes\mathbb{R}^d. \tag{3}$$

A typical element $\xi\in S_d$ is a d-dimensional vector where each component is a Schwartz test function. By $\{|\cdot|_p\}_{p\in\mathbb{N}}$ we denote a family of Hilbert norms topologizing S_d. Together with the dual space

$$S_d' := S'(\mathbb{R})\otimes\mathbb{R}^d, \tag{4}$$

we obtain the basic nuclear triple

$$S_d \subset L_d^2 \subset S_d'. \tag{5}$$

Let $\mathscr{B}$ be the σ-algebra generated by cylinder sets on S_d'. Using Minlos's theorem we construct a measure space on $(S_d',\mathscr{B})$ by fixing the characteristic function,

$$\int_{S_d'} \exp(i\langle\omega,\xi\rangle)d\mu(\omega) = \exp\left(-\frac{1}{2}|\xi|_0^2\right), \quad \xi\in S_d, \tag{6}$$

where $\langle\cdot,\cdot\rangle$ denotes the dual pairing between S_d' and S_d. The space $(S_d',\mathscr{B},\mu)$ is called the vector valued white noise space. Within this formalism a version of d-dimensional Wiener's Brownian motion is given by

$$B(\tau) := \langle\omega,\mathbb{1}_{[0,\tau)}\rangle := (\langle\omega,\mathbb{1}_{[0,\tau)}\otimes e_1\rangle,\ldots,\langle\omega,\mathbb{1}_{[0,\tau)}\otimes e_d\rangle), \quad \omega\in S_d', \tag{7}$$

where $\{e_1,\ldots,e_d\}$ denotes the canonical basis of $\mathbb{R}^d$. We shall construct a Gel'fand triple with smooth and generalized functions of white noise around the complex Hilbert space

$$L^2(\mu) := L^2(S_d',\mathscr{B},\mu) \tag{8}$$

and we denote the scalar product in this space by

$$((f,g))=\int_{S_d'}\overline{f}(\omega)g(\omega)d\mu(\omega),\quad f,g\in L^2(\mu). \tag{9}$$

We proceed by choosing first a special subspace $(S_d)^1$ of test functionals. Then we construct the Gel'fand triple

$$(S_d)^1\subset L^2(\mu)\subset(S_d)^{-1}. \tag{10}$$

Elements of the space $(S_d)^{-1}$ are called Kondratiev distributions, the well-known Hida distributions form a subspace. Instead of reproducing the explicit construction here,[17,18] we shall characterize the distributions by their T-transforms in Theorem 2 below. Let $\Phi\in(S_d)^{-1}$, then there exist $p,q\in\mathbb{N}_0$ such that we can define for every

$$\xi\in U_{p,q}:=\{\xi\in S_d\,|\,|\xi|_p^2<2^{-q}\} \tag{11}$$

the T-transform by

$$T\Phi(\xi):=\langle\langle\Phi,\exp(i\langle\cdot,\xi\rangle)\rangle\rangle, \tag{12}$$

where $\langle\langle\cdot,\cdot\rangle\rangle$ denotes the bilinear extension of the scalar product of $L^2(\mu)$. The definition of the T-transform can be extended via analytic continuation to the complexification of S_d, which we denote by $S_{d,\mathbb{C}}$. Further, we need the definition of holomorphy in a nuclear space.[19]

Definition 1: A function $F:U\to\mathbb{C}$ is holomorphic on an open set $U\subseteq S_{d,\mathbb{C}}$ iff for all $\theta_0\in U$

1. *for any $\theta\in S_{d,\mathbb{C}}$ the mapping $\lambda\mapsto F(\theta_0+\lambda\theta)$ is holomorphic in some neighborhood of 0 in $\mathbb{C}$,*
2. *there exists an open neighborhood U' of θ_0 such that F is bounded on U'.*

F is holomorphic at 0 iff F is holomorphic in a neighborhood of 0.

Now we can give the above-mentioned characterization theorem, which is in the case of Hida distributions due to Refs. 20 and 21, and for Kondratiev distributions to Ref. 18.

Theorem 2: *Let $U\subseteq S_{d,\mathbb{C}}$ be open and $F:U\to\mathbb{C}$ be holomorphic at zero, then there exists a unique $\Phi\in(S_d)^{-1}$ such that $T\Phi=F$. Conversely, let $\Phi\in(S_d)^{-1}$ then $T\Phi$ is holomorphic at zero. The correspondence between F and Φ is a bijection if we identify holomorphic functions which coincide on an open neighborhood of zero.*

As a consequence of the characterization we also have a criterion for sequences and integrals with respect to an additional parameter.

Theorem 3: *Let $(\Phi_n)_{n\in\mathbb{N}}$ be a sequence in $(S_d)^{-1}$, such that there exists $U_{p,q}$, $p,q\in\mathbb{N}_0$, so that*

1. *all $T\Phi_n$ are holomorphic on $U_{p,q}$,*
2. *there exists $C>0$ such that $|T\Phi_n(\theta)|\leq C$ for all $\theta\in U_{p,q}$ and all $n\in\mathbb{N}$,*
3. *$(T\Phi_n(\theta))_{n\in\mathbb{N}}$ is a Cauchy sequence in $\mathbb{C}$ for all $\theta\in U_{p,q}$.*

Then $(\Phi_n)_{n\in\mathbb{N}}$ converges strongly in $(S_d)^{-1}$.

Theorem 4: *Let $(\Lambda,\mathscr{A},\nu)$ be a measure space and $\lambda\mapsto\Phi_\lambda$ a mapping from Λ to $(S_d)^{-1}$. We assume that there exists $U_{p,q}$, $p,q\in\mathbb{N}_0$, such that*

1. *$T\Phi_\lambda$ is holomorphic on $U_{p,q}$ for every $\lambda\in\Lambda$,*
2. *the mapping $\lambda\mapsto T\Phi_\lambda(\theta)$ is measurable for every $\theta\in U_{p,q}$,*
3. *there exists $C\in L^1(\Lambda,\nu)$ such that*

$$|T\Phi_\lambda(\theta)|\leq C(\lambda) \tag{13}$$

for all $\theta\in U_{p,q}$ and for ν-almost all $\lambda\in\Lambda$.

Then there exist $p',q'\in\mathbb{N}_0$, which only depend on p,q, such that Φ_λ is Bochner integrable. In particular,

$$\int_\Lambda\Phi_\lambda d\nu(\lambda)\in(S_d)^{-1} \tag{14}$$

and $T[\int_\Lambda \Phi_\lambda d\nu(\lambda)]$ *is holomorphic on* $U_{p',q'}$. *We may interchange dual pairing and integration*

$$\left\langle\left\langle \int_\Lambda \Phi_\lambda d\nu(\lambda), \varphi \right\rangle\right\rangle = \int_\Lambda \langle\langle \Phi_\lambda, \varphi\rangle\rangle d\nu(\lambda), \quad \varphi \in (S_d)^1. \tag{15}$$

At the end of this section we want to give some examples of distributions.[5]

Example 5: To define the kinetic energy factor in the path integrals one would like to give a meaning to the formal expression

$$\exp\left(c \int_{\mathbb{R}} \omega(t)^2 dt \right),$$

where c is a complex constant. We define the normalized exponential

$$N\exp\left(c \int_{\mathbb{R}} \omega(t)^2 dt \right)$$

as a distribution via the following T-transform:

$$T\left[N\exp\left(c \int_{\mathbb{R}} \omega(t)^2 dt \right)\right](\xi) = \exp\left(\frac{1}{4c-2} \int_{\mathbb{R}} \xi^2(\tau) d\tau \right), \quad c \neq \frac{1}{2}.$$

Example 6: Donsker's delta function. In order to ''pin'' Brownian motion at a point $a \in \mathbb{R}^d$ we want to consider the formal composition of the Dirac delta distribution with Brownian motion: $\delta(B(t)-a)$. This can be given a precise meaning as a Hida distribution.[22] Its T-transform is given by

$$T[\delta(B(t)-a)](\xi) = \frac{1}{(2\pi t)^{d/2}} \exp\left(-\frac{1}{2t} \left(\int_0^t i\xi(s) ds + x_0 - a \right)^2 - \frac{1}{2} |\xi|_0^2 \right).$$

III. THE FREE FEYNMAN INTEGRAND

We follow Refs. 9 and 23 in viewing the Feynman integral as a weighted average over Brownian paths. We use a slight change in the definition of the paths, which are here modeled by

$$x(\tau) = x - \sqrt{\frac{\hbar}{m}} \int_\tau^t \omega(\sigma) d\sigma =: x - \sqrt{\frac{\hbar}{m}} \langle \omega, \mathbb{1}_{(\tau,t]} \rangle. \tag{16}$$

In the sequel we set $\hbar = m = 1$ unless otherwise stated. Correspondingly, we define the Feynman integrand for the free motion by[11]

$$I_0(x,t|x_0,t_0) = N\exp\left(\frac{i+1}{2} \int_{\mathbb{R}} \omega^2(\tau) d\tau \right) \delta(x(t_0) - x_0). \tag{17}$$

We recall that the delta distribution $\delta(x(t_0)-x_0)$ is used to fix the starting point and plays the role of an initial distribution. In the sequel instead of $I_0(x,t|x_0,t_0)$ we will often use the shorthand I_0. Thus we get for the T-transform,

$$TI_0(\xi) = \frac{1}{(2\pi i|t-t_0|)^{d/2}} \exp\left[-\frac{i}{2} \int_{\mathbb{R}} \xi^2(\tau) d\tau - \frac{1}{2i|t-t_0|} \left(\int_{t_0}^t \xi(\tau) d\tau + x - x_0 \right)^2 \right]. \tag{18}$$

Not only the expectation ($\xi=0$) but also the T-transform has a physical meaning. Integrating formally by parts we find

$$TI_0(\xi)=\int_{\mathscr{S}_d'} I_0(\omega)\exp\left(-i\int_{t_0}^{t} x(\tau)\cdot\dot{\xi}(\tau)d\tau\right)d\mu(\omega)\exp\left(-\frac{i}{2}\int_{[t_0,t]^c}\xi^2(\tau)d\tau\right)$$
$$\times\exp[ix\cdot\xi(t)-ix_0\cdot\xi(t_0)]. \tag{19}$$

The multiplication denoted by a dot is just the scalar product in $\mathbb{R}^d$. Indeed it is straightforward to verify that

$$K_0^{(\xi)}(x,t|x_0,t_0)=TI_0(\xi)\exp\left(\frac{i}{2}\int_{[t_0,t]^c}\xi^2(\tau)d\tau\right)\exp[ix_0\cdot\xi(t_0)-ix\cdot\xi(t)] \tag{20}$$

is the propagator corresponding to the potential $W=\dot{\xi}(t)\cdot x$, i.e., it obeys the Schrödinger equation

$$(i\partial_t+\tfrac{1}{2}\Delta_d-\dot{\xi}(t)\cdot x)K_0^{(\xi)}(x,t|x_0,t_0)=0 \tag{21}$$

with the initial condition

$$\lim_{t\searrow t_0} K_0^{(\xi)}(x,t|x_0,t_0)=\delta(x-x_0).$$

IV. THE FEYNMAN INTEGRAND FOR A NEW CLASS OF UNBOUNDED POTENTIALS

Now we construct the Feynman integrand for a new class of potentials and calculate the propagators. In Sec. IV C we show that the propagators solve the corresponding Schrödinger equation and in Sec. IV E we generalize to time-dependent potentials.

A. The interactions

Definition 7: Let m be a complex measure on the Borel sets on $\mathbb{R}^d, d\geqslant 1$ *fulfilling the following condition:*

$$\int_{\mathbb{R}^d} e^{C|\alpha|}d|m|(\alpha)<\infty,\quad \forall C>0. \tag{22}$$

We define a potential V on $\mathbb{R}^d$ *by*

$$V(x)=\int_{\mathbb{R}^d} e^{\alpha\cdot x}dm(\alpha). \tag{23}$$

Remark 8: A consequence of the above condition (22) is that the measure *m* is finite. By Lebesgue's dominated convergence theorem we obtain that the potentials are restrictions to the real line of entire functions. In particular, they are locally bounded and without singularities. However, they are in general unbounded at $\pm\infty$.

Remark 9: The time-dependent case will be considered in Sec. IV E.

Example 10: Every finite measure with compact support fulfills the above condition (22).

Example 11: The simplest example is the Dirac measure in one dimension $m:=g\delta_a$ for $a>0$ and $g\in\mathbb{R}$. The associated potential is $V(x)=ge^{ax}$. Obviously all polynomials of exponential functions of the above kind are also in our class, too, e.g., $\sinh(ax)$, $\cosh(ax)$.

Example 12: In particular, the well known Morse potential $V(x):=g(e^{-2ax}-2\gamma e^{-ax})$ with $g,a,x\in\mathbb{R}$ and $\gamma>0$ is included in the above class. We will discuss this potential in Sec. V in more detail.

Example 13: If we choose a Gaussian density, we get potentials of the form $V(x)=ge^{bx^2}$ with $b,x\in\mathbb{R}$.

Example 14: Further entire functions of arbitrary high order of growth are inside the aforementioned class. More explicitly, the measures $d/m(\alpha):=\Theta(\alpha)\exp(-k\alpha^{1+b})d\alpha$ with $b,k>0$ and $x\in\mathbb{R}$ fulfill the condition (22). The corresponding potentials are entire functions of order $1+1/b$, see Ref. 24, Lemma 7.2.1.

B. The Feynman integrand as a generalized white noise functional

In order to handle potentials of the form given above

$$V(x)=\int_{\mathbb{R}^d} e^{\alpha\cdot x}dm(\alpha)$$

within our approach we must give a meaning to the following pointwise multiplication:

$$I=I_0\cdot\exp\left(-i\int_{t_0}^{t}V(x(\tau))d\tau\right), \tag{24}$$

where

$$x(\tau)=x-\int_{\tau}^{t}\omega(s)ds$$

is a path, as in Sec. III. For convenience we assume $t_0<t$ in the sequel. As a first step we formally expand the exponential

$$I=\sum_{n=0}^{\infty}\frac{(-i)^n}{n!}\int_{[t_0,t^n]}\int_{\mathbb{R}^{dn}} I_0\cdot\prod_{j=1}^{n}e^{\alpha_j\cdot x(\tau_j)}\prod_{j=1}^{n}dm(\alpha_j)d^n\tau \tag{25}$$

into a perturbation series. In Theorem 16 we will show the existence of the integrals and the series. However, first we have to give a definition for the product

$$I_0\cdot\prod_{j=1}^{n}e^{\alpha_j\cdot x(\tau_j)}. \tag{26}$$

Products of this type have already been considered, see, e.g., Example 6. In view of the Characterization Theorem 2 it is enough to define the product via its T-transform. Arguing formally we obtain

$$\begin{aligned}T\left(I_0\cdot\prod_{j=1}^{n}e^{\alpha_j\cdot x(\tau_j)}\right)(\xi)&=\int_{S_d'}I_0\cdot\prod_{j=1}^{n}e^{\alpha_j\cdot x(\tau_j)}\exp(i\langle\omega,\xi\rangle)d\mu(\omega)\\&=TI_0\left(\xi+i\sum_{j=1}^{n}\alpha_j\mathbb{1}_{[\tau_j,t)}\right)\exp\left(\sum_{j=1}^{n}\alpha_j\cdot x\right).\end{aligned} \tag{27}$$

We only need to verify that TI_0 is extendable to $\xi+i\Sigma_{j=1}^{n}\alpha_j\mathbb{1}_{(\tau_j,t]}$. This is clearly fulfilled, since the explicit formula (18) extends continuously to all $\xi\in L_d^2$.

Hence we may define the product in this way:

Proposition 15: Let $\tau_j\in[t_0,t]$ for $j=1,\ldots,n$; $t_0<t$ and $\alpha_j\in\mathbb{R}^d$. Then the pointwise product

$$\Phi_n=I_0\cdot\prod_{j=1}^{n}e^{\alpha_j\cdot x(\tau_j)} \tag{28}$$

defined by

$$\begin{aligned}T\Phi_n(\xi)&=TI_0\left(\xi+i\sum_{j=1}^{n}\alpha_j\mathbb{1}_{(\tau_j,t]}\right)\exp\left(\sum_{j=1}^{n}\alpha_j\cdot x\right)\\&=(2\pi i(t-t_0))^{-d/2}\exp\left[-\frac{i}{2}\int_{\mathbb{R}}\left(\xi(s)+i\sum_{j=1}^{n}\alpha_j\mathbb{1}_{(\tau_j,t]}(s)\right)^2ds\right]\\&\quad\times\exp\left\{-\frac{1}{2i(t-t_0)}\left[\int_{t_0}^{t}\xi(s)ds+i\sum_{j=1}^{n}\alpha_j(t-\tau_j)+(x-x_0)\right]^2\right\}\exp\left(\sum_{j=1}^{n}\alpha_j\cdot x\right)\end{aligned}$$

is a Kondratiev distribution.

Proof: Obviously this has an extension in $\xi \in \mathcal{S}_d(\mathbb{R})$ to all $\theta \in \mathcal{S}_{d,\mathbb{C}}(\mathbb{R})$ and fulfills the first part of Definition 1. In order to prove that $\Phi_n \in (\mathcal{S}_d)^{-1}$ by applying Theorem 2, we need a bound

$$
\begin{aligned}
|T\Phi_n(\theta)| &\leqslant (2\pi(t-t_0))^{-d/2} \exp\left\{ \frac{1}{2}|\theta|_0^2 + \int_{\mathbb{R}} \left| \theta(s) \sum_{j=1}^n \alpha_j \mathbb{1}_{(\tau_j,t]}(s) \right| ds \right\} \\
&\quad \times \exp\left\{ \frac{1}{2(t-t_0)} \left[2 \left| \left((x-x_0) + i \sum_{j=1}^n \alpha_j (t-\tau_j) \right) \int_{t_0}^t \theta(s) ds \right| + (t-t_0)|\theta|_0^2 \right. \right. \\
&\quad \left. \left. + 2 \left| (x-x_0) \cdot \sum_{j=1}^n \alpha_j (t-\tau_j) \right| \right] \right\} \exp\left(\sum_{j=1}^n \alpha_j \cdot x \right) \\
&\leqslant (2\pi(t-t_0))^{-d/2} \exp\left(\sum_{j=1}^n |\alpha_j||x-x_0| + \sum_{j=1}^n |\alpha_j||x_0| \right) \\
&\quad \times \exp\left[|\theta|_0^2 + \left(2\sqrt{t-t_0} \sum_{j=1}^n |\alpha_j| + \frac{|x-x_0|}{\sqrt{t-t_0}} \right) |\theta|_0 \right] \\
&=: C_n(\alpha_1, \ldots, \alpha_j, \theta).
\end{aligned} \tag{29}
$$

Thus Φ_n is a Kondratiev distribution, in fact by the above bound it is also a Hida distribution.[21] ■

Now we are able to prove the existence of the integrand.

Theorem 16: *Let V be as in Definition 7. Then*

$$
I := \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \int_{[t_0,t]^n} \int_{\mathbb{R}^{dn}} I_0 \cdot \prod_{j=1}^n e^{\alpha_j \cdot x(\tau_j)} \prod_{j=1}^n dm(\alpha_j) d^n\tau \tag{30}
$$

exists as a generalized white noise functional. The series converges in the strong topology of $(\mathcal{S}_d)^{-1}$. *The integrals exist in the sense of Bochner integrals. Therefore we can express the T-transform by*

$$
TI(\theta) = \sum_{n=0}^{\infty} \frac{(-i)^n}{n!} \int_{[t_0,t]^n} \int_{\mathbb{R}^{dn}} T\left(I_0 \cdot \prod_{j=1}^n e^{\alpha_j \cdot x(\tau_j)} \right)(\theta) \prod_{j=1}^n dm(\alpha_j) d^n\tau \tag{31}
$$

for all θ *in a neighborhood of zero*

$$
U_{p,q} := \{ \theta \in S_{d,\mathbb{C}} | 2^q |\theta|_p < 1 \} \tag{32}
$$

for some $p,q \in \mathbb{N}_0$.

Proof: We have already shown in Proposition 15 that the product

$$
\Phi_n := I_0 \cdot \prod_{j=1}^n e^{\alpha_j \cdot x(\tau_j)}
$$

is a Kondratiev distribution, moreover, we derived the estimate (29). In order to see that the integrals exist in the sense of Bochner we want to apply Theorem 4. As the *T*-transform of Φ_n is entire in $\xi \in \mathcal{S}_{d,\mathbb{C}}(\mathbb{R})$ and measurable, it remains only to derive a suitable bound

$$\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}} C_n(\alpha_1,\ldots,\alpha_j,\theta)\prod_{j=1}^{n} d|m|(\alpha_j)d^n\tau$$

$$\leqslant (2\pi(t-t_0))^{-d/2}(t-t_0)^n \exp\left(|\theta|_0^2+\frac{|x-x_0|}{\sqrt{t-t_0}}|\theta|_0\right)$$

$$\times\left\{\int_{\mathbb{R}^d}\exp([|x-x_0|+|x_0|+2\sqrt{t-t_0}|\theta|_0]|\alpha|)d|m|(\alpha)\right\}^n, \tag{33}$$

which is finite since the measure satisfies condition (22). Due to Theorem 4 there exists an open neighborhood U independent of n and

$$I_n := \int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}}\Phi_n\prod_{j=1}^{n} dm(\alpha_j)d^n\tau \in (\mathscr{S}_d)^{-1}, \quad \forall n\in\mathbb{N}$$

with TI_n holomorphic on U. To finish the proof we must show that the series converges in $(\mathscr{S}_d)^{-1}$ in the strong sense. For that we apply Theorem 3. We know that TI_n is holomorphic on U and we can bound it by

$$|TI(\theta)|\leqslant\sum_{n=0}^{\infty}\frac{1}{n!}|TI_n(\theta)|$$

$$\leqslant(2\pi(t-t_0))^{-d/2}\exp\left(|\theta|_0^2+\frac{|x-x_0|}{\sqrt{t-t_0}}|\theta|_0\right)$$

$$\times\exp\left\{(t-t_0)\int_{\mathbb{R}^d}\exp[(|x|+2|x_0|+2\sqrt{t-t_0}|\theta|_0)|\alpha|]d|m|(\alpha)\right\}<\infty \tag{34}$$

for $\theta\in U$, so that we prove $I\in(\mathscr{S}_d)^{-1}$. ■

Remark 17: The bound established in the proof above has a trivial, but rather surprising consequence. For the forthcoming discussion it is convenient to show the dependence on the coupling constant explicitly, so that we get

$$TI(\theta)=\sum_{n=0}^{\infty}\frac{(-ig)^n}{n!}\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}} T\left(I_0\cdot\prod_{j=1}^{n} e^{\alpha_j\cdot x(\tau_j)}\right)(\theta)\prod_{j=1}^{n} dm(\alpha_j)d^n\tau, \tag{35}$$

which is a perturbation series in the coupling constant. Recall the bound we have already calculated; we obtain that

$$|TI(\theta)|\leqslant\sum_{n=0}^{\infty}\frac{|g|^n}{n!}|TI_n(\theta)|$$

$$\leqslant(2\pi(t-t_0))^{-d/2}\exp\left(|\theta|_0^2+\frac{|x-x_0|}{\sqrt{t-t_0}}|\theta|_0\right)$$

$$\times\exp\left\{|g|(t-t_0)\int_{\mathbb{R}^d}\exp([|x-x_0|+|x_0|+2\sqrt{t-t_0}|\theta|_0]|\alpha|)d|m|(\alpha)\right\} \tag{36}$$

and hence $TI(\theta)$ is entire in the coupling constant g for all fixed x, x_0, $t_0<t$ and $\theta\in U_{p,q}$. This is surprising, since the corresponding Hamilton operators, even if they are essentially self-adjoint for $g>0$, lose this property for $g<0$ in general. Quantities such as eigenvalues and eigenvectors will not be analytic in the coupling constant. [On the other hand under a stronger condition than (22), Albeverio *et al.*[25] have shown that the solution of the Schrödinger equation $\Psi_t(x)$ is analytic in the coupling constant if the initial wave function Ψ_0 as a function of x is from a certain class of analytic functions.]

C. Schrödinger equation

Our aim is to prove that the propagator constructed above indeed solves the Schrödinger equation. We are able to show that for $t_0<t$ the propagator does not only solve it in the sense of distributions, but also in the sense of ordinary functions. Similar to the free case, see Eq. (20), we can also give the test function in the T-transform a physical meaning corresponding to a time-dependent homogeneous external small force in the sense of (32). To compensate the extra factors appearing in the formal integration by parts, see again (20), we consider

$$TI(\theta)\cdot\exp\left[\frac{i}{2}\int_{[t_0,t]^c}\theta^2(s)ds+ix_0\cdot\theta(t_0)-ix\cdot\theta(t)\right]. \tag{37}$$

This then produces the Schrödinger propagator as follows:

Theorem 18: *Let V be as in Definition* 7. *Then*

$$\begin{aligned}K^{(\theta)}(x,t|x_0,t_0)=&\sum_{n=0}^{\infty}\frac{(-ig)^n}{n!}(2\pi i(t-t_0))^{-d/2}\\&\times\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}}\exp\left\{-\frac{i}{2}\int_{t_0}^{t}\left(\theta(s)+i\sum_{j=1}^{n}\alpha_j\mathbb{1}_{(\tau_j,t]}(s)\right)^2ds\right\}\\&\times\exp\left\{-\frac{1}{2i(t-t_0)}\left[\int_{t_0}^{t}\theta(s)ds+i\sum_{j=1}^{n}\alpha_j(t-\tau_j)+(x-x_0)\right]^2\right\}\\&\times\exp\left(\sum_{j=1}^{n}\alpha_j\cdot x\right)\exp(ix_0\cdot\theta(t_0)-ix\cdot\theta(t))\prod_{j=1}^{n}dm(\alpha_j)d^n\tau\end{aligned} \tag{38}$$

solves the Schrödinger equation for all $x,x_0,t_0<t$,

$$\left(i\frac{\partial}{\partial t}+\frac{1}{2}\Delta_d-gV(x)-x\cdot\dot{\theta}(t)\right)K^{(\theta)}(x,t|x_0,t_0)=0 \tag{39}$$

with initial condition

$$\lim_{t\searrow t_0}K^{(\theta)}(x,t|x_0,t_0)=\delta(x-x_0). \tag{40}$$

Remark 19: We may also write the propagator as a product of the free propagator with a perturbation series

$$\begin{aligned}K^{(\theta)}(x,t|x_0,t_0)=&K_0^{(\theta)}(x,t|x_0,t_0)\cdot\sum_{n=0}^{\infty}\frac{(-ig)^n}{n!}(t-t_0)^n\int_{[0,1]^n}\int_{\mathbb{R}^{dn}}\prod_{j=1}^{n}dm(\alpha_j)d^n\sigma\\&\times\exp\left\{-\frac{i}{2}(t-t_0)\left[\sum_{j=1}^{n}\sum_{k=1}^{n}\alpha_j\cdot\alpha_k(\sigma_j\sigma_k-\sigma_j\wedge\sigma_k)\right]\right\}\exp\left\{\sum_{j=1}^{n}\alpha_j\cdot\left[\sigma_jx\right.\right.\\&\left.\left.+(1-\sigma_j)x_0+\sigma_j\int_{(t-t_0)\sigma_j+t_0}^{t}\theta(s)ds-(1-\sigma_j)\int_{t_0}^{(t-t_0)\sigma_j+t_0}\theta(s)ds\right]\right\}.\end{aligned} \tag{41}$$

Remark 20: The bounds in the following proof also yield that for fixed $\theta\in U_{p,q}$ the above series as a function of x, t, x_0, t_0 is C^∞ and that we are allowed to interchange integration and summation with differentiation.

Proof: It is easy to see that $T\Phi_n(\theta)$ is C^∞ in the variables x, x_0, t_0, t if $t<t_0$. For simplification we introduce the following abbreviation:

$$K^{(\theta)}(x,t|x_0,t_0)=\sum_{n=0}^{\infty}\frac{(-ig)^n}{n!}K_n^{(\theta)}(x,t|x_0,t_0), \tag{42}$$

where

$$K_n^{(\theta)}(x,t|x_0,t_0)=\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}} T\Phi_n(\theta)\exp\left(\frac{i}{2}\int_{[t_0,t]^c}\theta^2(s)ds+ix_0\cdot\theta(t_0)-ix\cdot\theta(t)\right)\times\prod_{j=1}^{n} dm(\alpha_j)d^n\tau. \tag{43}$$

By direct computation we obtain

$$\left(i\frac{\partial}{\partial t}+\frac{1}{2}\Delta_d\right)\left[T\Phi_n(\theta)\exp\left(\frac{i}{2}\int_{[t_0,t]^c}\theta^2(s)ds+ix_0\cdot\theta(t_0)-ix\cdot\theta(t)\right)\right]=x\cdot\dot{\theta}(t)\left[T\Phi_n(\theta)\exp\left(\frac{i}{2}\int_{[t_0,t]^c}\theta^2(s)ds+ix_0\cdot\theta(t_0)-ix\cdot\theta(t)\right)\right]. \tag{44}$$

Thus the above product alone solves already the free Schrödinger equation with an extra small external force. The next step is to calculate the derivatives of $K_n^{(\theta)}$. We interchange them with the integrals. Since the domain of the τ-integrals depends on t, we get an extra term compared to (44) if we differentiate with respect to t. Using the theorem of Fubini we recognize that this term corresponds to the potential $V(x)$,

$$\left(i\frac{\partial}{\partial t}+\frac{1}{2}\Delta_d\right)K_n^{(\theta)}(x,t|x_0,t_0)=x\cdot\dot{\theta}(t)K_n^{(\theta)}(x,t|x_0,t_0)+\frac{in}{g}V(x)K_{n-1}^{(\theta)}(x,t|x_0,t_0), \tag{45}$$

which is a typical recursion formula driven by the potential. By summing up we see that $K^{(\theta)}(x,t|x_0,t_0)$ solves formally the Schrödinger equation. It remains to justify the operations above. This can be done similarly to the proof of Theorem 16 if we bound the derivatives of $T\Phi_n(\theta)$ as follows. The derivatives of $T\Phi_n(\theta)$ have the form

$$\left\{a_0(\tau_1,\ldots,\tau_n,\theta)+a_1(\tau_1,\ldots,\tau_n,\theta)\cdot\left(\sum_{j=1}^{n}\alpha_j\right)+a_2(\tau_1,\ldots,\tau_n,\theta)\cdot\left(\sum_{j=1}^{n}\alpha_j\right)^2\right\}\cdot T\Phi_n(\theta), \tag{46}$$

where a_i are continuous in the τ_j. As the τ_j varies only in a compact domain we can bound the derivatives by

$$\{b_0(\theta)+b_1(\theta)+2b_2(\theta)\}\cdot\exp\left(\sum_{j=1}^{n}|\alpha_j|\right)\cdot C_n(\alpha_1,\ldots,\alpha_j,\theta), \tag{47}$$

where C_n is the bound in the proof of Proposition 15 and

$$b_i(\theta):=\sup_{\tau_j\in[t_0,t]}|a_i(\tau_1,\ldots,\tau_n,\theta)|. \tag{48}$$

The rest of the proof can be done as before. ■

D. Continuation to imaginary mass

Using continuation to imaginary mass we obtain a formal perturbation series for the propagator of the heat equation. If the measure in Definition 7 is positive we show that this perturbation series diverges. In the following discussion we need the explicit dependence of the propagator on $\hbar$ and m. For simplification we put $\theta=0$. $K^{(0)}$ is abbreviated as K. Using (41) we obtain

$$K(x,t|x_0,t_0)=K_0(x,t|x_0,t_0)\cdot\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{-ig(t-t_0)}{\hbar}\right)^n\int_{[0,1]^n}\int_{\mathbb{R}^{dn}}\prod_{j=1}^{n}dm(\alpha_j)d^n\sigma$$
$$\times\exp\left\{-\frac{i\hbar}{2m}(t-t_0)\left[\sum_{j=1}^{n}\sum_{k=1}^{n}\alpha_j\cdot\alpha_k(\sigma_j\sigma_k-\sigma_j\wedge\sigma_k)\right]\right\}$$
$$\times\exp\left\{\sum_{j=1}^{n}\alpha_j\cdot[\sigma_j x+(1-\sigma_j)x_0]\right\}. \tag{49}$$

If we perform a formal analytic continuation in the mass from m to im we get

$$K^H(x,t|x_0,t_0)=K_0^H(x,t|x_0,t_0)\cdot\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{-ig(t-t_0)}{\hbar}\right)^n\int_{[0,1]^n}\int_{\mathbb{R}^{dn}}\prod_{j=1}^{n}dm(\alpha_j)d^n\sigma$$
$$\times\exp\left\{-\frac{\hbar}{2m}(t-t_0)\left[\sum_{j=1}^{n}\sum_{k=1}^{n}\alpha_j\cdot\alpha_k(\sigma_j\sigma_k-\sigma_j\wedge\sigma_k)\right]\right\}$$
$$\times\exp\left\{\sum_{j=1}^{n}\alpha_j\cdot[\sigma_j x+(1-\sigma_j)x_0]\right\}. \tag{50}$$

This solves formally the heat equation with potential $-igV(x)$. Usually, convergence properties are easier to handle for the heat equation than for the Schrödinger equation. However, in our case it is the other way around.

Theorem 21: *Let $d=1$ and let m be a positive measure on the Borel sets of $\mathbb{R}$ fulfilling condition (22). If $m(\mathbb{R}\setminus\{0\})>0$ then the power series in g*

$$\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{-ig(t-t_0)}{\hbar}\right)^n\int_{[0,1]^n}\int_{\mathbb{R}^n}\prod_{j=1}^{n}dm(\alpha_j)d^n\sigma\,\exp\left\{-\frac{\hbar}{2m}(t-t_0)\right.$$
$$\left.\times\left[\sum_{j=1}^{n}\sum_{k=1}^{n}\alpha_j\cdot\alpha_k(\sigma_j\sigma_k-\sigma_j\wedge\sigma_k)\right]\right\}\exp\left\{\sum_{j=1}^{n}\alpha_j\cdot[\sigma_j x+(1-\sigma_j)x_0]\right\} \tag{51}$$

diverges for every $g\neq 0$ for any fixed $x_0,x,t_0<t$.

Remark: Analogously we can handle the continuation in $\hbar$ and time.

Proof: Either there exists $a_0>0$ with $m([a_0,\infty))>0$ or $a_0<0$ with $m((-\infty,a_0])>0$. Without loss of generality we assume $a_0>0$. We use the shorthand

$$F(\alpha_1,\ldots,\alpha_n,\sigma_1,\ldots,\sigma_n):=\exp\left\{-\frac{\hbar}{2m}(t-t_0)\left[\sum_{j=1}^{n}\sum_{k=1}^{n}\alpha_j\cdot\alpha_k(\sigma_j\sigma_k-\sigma_j\wedge\sigma_k)\right]\right\}$$
$$\times\exp\left\{\sum_{j=1}^{n}\alpha_j\cdot[\sigma_j x+(1-\sigma_j)x_0]\right\}. \tag{52}$$

For $\frac{3}{16}\leqslant\sigma_j,\sigma_k\leqslant\frac{4}{16}$ we have

$$\sigma_j\sigma_k-\sigma_j\wedge\sigma_k\leqslant-\tfrac{1}{16}. \tag{53}$$

Since the integrand is positive we get

$$\left|\int_{[0,1]^n}\int_{\mathbb{R}^n} F(\alpha_1,\ldots,\alpha_n,\sigma_1,\ldots,\sigma_n)\prod_{j=1}^n dm(\alpha_j)d^n\sigma\right|$$

$$\geqslant \int_{[3/16,4/16]^n}\int_{[a_0,\infty)^n} F(\alpha_1,\ldots,\alpha_n,\sigma_1,\ldots,\sigma_n)\prod_{j=1}^n dm(\alpha_j)d^n\sigma$$

$$\geqslant \int_{[3/16,4/16]^n}\int_{[a_0,\infty)^n} \exp\left\{\frac{\hbar}{2m}(t-t_0)\frac{1}{16}n^2a_0^2\right\}$$

$$\times\exp\left\{-\sum_{j=1}^n |\alpha_j|(|x_0|+|x|)\right\}\prod_{j=1}^n dm(\alpha_j)d^n\sigma$$

$$\geqslant\left(\frac{1}{16}\right)^n \exp\left\{\frac{\hbar}{32m}(t-t_0)a_0^2n^2\right\}\left(\int_{a_0}^\infty \exp\{-|\alpha|(|x_0|+|x|)\}dm(\alpha)\right)^n. \tag{54}$$

By the above assumption for a_0 the last factor does not vanish. Thus we get for the series

$$\sum_{n=0}^\infty \left|\frac{1}{n!}\left(\frac{-ig(t-t_0)}{\hbar}\right)^n\int_{[0,1]^n}\int_{\mathbb{R}^n} F(\alpha_1,\ldots,\alpha_n,\sigma_1,\ldots,\sigma_n)\prod_{j=1}^n dm(\alpha_j)d^n\sigma\right|$$

$$\geqslant\sum_{n=0}^\infty \frac{1}{n!}\left(\frac{|g|(t-t_0)}{16\hbar}\int_{a_0}^\infty \exp\{-|\alpha|(|x_0|+|x|)\}dm(\alpha)\right)^n \exp\left(\frac{\hbar}{32m}(t-t_0)a_0^2n^2\right)=\infty.$$

■

E. Time-dependent potentials

One of the advantages of the Feynman integral is that it can be easily extended to time-dependent potentials.

Theorem 22: *Let m denote a complex measure on the Borel sets of* $\mathbb{R}^d\times[t_0',t']$; $d\geqslant 1$, *such that*

$$\int_{\mathbb{R}^d}\int_{t_0'}^{t'} e^{C|\alpha|}d|m|(\alpha,\tau)<\infty,\quad \forall C>0. \tag{55}$$

Then for $t_0'\leqslant t_0<t\leqslant t'$,

$$I:=\sum_{n=0}^\infty \frac{(-i)^n}{n!}\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}} I_0\cdot\prod_{j=1}^n e^{\alpha_j\cdot x(\tau_j)}\prod_{j=1}^n dm(\alpha_j,\tau_j) \tag{56}$$

exists as a generalized white noise functional in $(\mathcal{S}_d)^{-1}$. *The T-transform fulfills the following equation:*

$$TI(\theta)=\sum_{n=0}^\infty \frac{(-i)^n}{n!}\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}} T\left(I_0\cdot\prod_{j=1}^n e^{\alpha_j\cdot x(\tau_j)}\right)(\theta)\prod_{j=1}^n dm(\alpha_j,\tau_j) \tag{57}$$

for all θ *in a neighborhood of zero.*

Remark 23: If we consider the Schrödinger equation for the whole class defined in the above theorem, the potential becomes a distribution in the time variable. This causes technical difficulties; we only use the special forms given below.

Theorem 24: *Let m be as in Theorem 22. If additionally m has either the special form*

$$dm(\alpha,\tau)=\sum_{j=1}^k dm_j(\alpha)\rho_j(\tau)d\tau \tag{58}$$

with $k\in\mathbb{N}$, m_j complex measures on the Borel sets of $\mathbb{R}^d$ and $\rho_j\in C^0(\mathbb{R},\mathbb{C})$ for all $j=1,...,k$; or the special form

$$dm(\alpha,\tau)=\rho(\alpha,\tau)\ \ d^d\alpha\ \ d\tau \tag{59}$$

where $\rho:\mathbb{R}^d\times[t_0',t']\to\mathbb{C}$ with $\rho(\alpha,\cdot)$ continuous on $[t_0',t']$ for all $\alpha\in\mathbb{R}^d$ and $\sup_{\tau\in[t_0',t']}|\rho(\alpha,\tau)|e^{C|\alpha|}$ in $L^1(\mathbb{R},d^d\alpha)$ for all $C>0$.
Then the propagator

$$\begin{aligned}K^{(\theta)}(x,t|x_0,t_0)=&\sum_{n=0}^{\infty}\frac{(-ig)^n}{n!}(2\pi i(t-t_0))^{-d/2}\exp(ix_0\cdot\theta(t_0)-ix\cdot\theta(t))\\&\times\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}}\exp\left\{-\frac{i}{2}\int_{t_0}^{t}\left(\theta(s)+i\sum_{j=1}^{n}\alpha_j\mathbb{1}_{(\tau_j,t]}(s)\right)^2ds\right\}\exp\left\{-\frac{1}{2i(t-t_0)}\right.\\&\times\left.\left[\int_{t_0}^{t}\theta(s)ds+i\sum_{j=1}^{n}\alpha_j(t-\tau_j)+(x-x_0)\right]^2\right\}\exp\left(\sum_{j=1}^{n}\alpha_j\cdot x\right)\prod_{j=1}^{n}dm(\alpha_j,\tau_j)\end{aligned} \tag{60}$$

solves the Schrödinger equation with potential $x\cdot\dot{\theta}(t)+V(x,t)$ for all $t_0'<t_0<t<t'$, where

$$V(x,t):=\sum_{j=1}^{k}\int_{\mathbb{R}^d}e^{\alpha\cdot x}dm_j(\alpha)\rho_j(t) \tag{61}$$

or respectively

$$V(x,t):=\int_{\mathbb{R}^d}e^{\alpha\cdot x}\rho(\alpha,t)d^d\alpha. \tag{62}$$

Proof of Theorems 22 and 24: The proof can be done in a similar way as in the previous subsection. Only the measure $dm(\alpha_j)d\tau_j$ has to be replaced by $dm(\alpha_j,\tau_j)$. More explicitly, we then get instead of bound (33) the following

$$\begin{aligned}&\int_{[t_0,t]^n}\int_{\mathbb{R}^{dn}}C_n(\alpha_1,\ldots,\alpha_j,\theta)\prod_{j=1}^{n}d|m|(\alpha_j,\tau_j)\\&\leqslant(2\pi(t-t_0))^{-d/2}\exp\left(|\theta|_0^2+\frac{|x-x_0|}{\sqrt{t-t_0}}|\theta|_0\right)\\&\quad\times\left\{\int_{\mathbb{R}^d}\int_{t_0}^{t}\exp([|x-x_0|+|x_0|+2\sqrt{t-t_0}|\theta|_0]|\alpha|)d|m|(\alpha,\tau)\right\}^n.\end{aligned} \tag{63}$$

To complete the proof of Theorem 24 we have to justify the interchange of the time derivative with the α-integrals. For this we use an extra condition as, e.g., in the second special form the integrability of $\sup_{\tau\in[t_0',t']}|\rho(\alpha,\tau)|\exp(|\alpha|\,|x|)$. ■

V. A SPECIAL CASE: THE MORSE POTENTIAL

In order to illustrate the remarkable fact that the propagator is analytic in the coupling constant we discuss the Morse potential as a special case of the class of potentials we studied in Sec. IV. This potential has been very useful in molecular and nuclear physics, see, e.g., Ref. 26.

Definition 25: In $L^2(\mathbb{R},\mathbb{C})$ we consider the Hamilton operator

$$H:=-\tfrac{1}{2}\Delta+g(e^{-2ax}-2\gamma e^{-ax}) \tag{64}$$

with $\gamma,g,a\in\mathbb{R}$. As domain we choose

$$D(H) := C_0^\infty(\mathbb{R},\mathbb{C}), \tag{65}$$

the set of infinite differentiable functions with compact support. For $g>0$ *and* $\gamma>0$ *this is called the Morse potential.*

We now collect some well-known results from operator theory.[27,28]

Proposition 26: H is symmetric and

$$D(H^*)=\left\{ f\in L^2(\mathbb{R},\mathbb{C})\cap C^1(\mathbb{R},\mathbb{C}) \,\middle|\, \begin{array}{c} f' \text{ is absolutely continuous} \\ \text{on each compact interval of } \mathbb{R} \text{ and } Hf\in L^2(\mathbb{R},\mathbb{C}) \end{array} \right\}.$$

Since we have a real potential the deficiency indices are equal and thus there exists a self-adjoint extension, which is not necessarily unique.

From Theorems X.8 and X.9 in Ref. 28 we can derive the following proposition:

Proposition 27: H is essentially self-adjoint for $g\geqslant 0$ *and it is not essentially self-adjoint for* $g<0$.

For the Morse potential ($g>0$) there exist treatments by algebraic,[29] and by operator methods.[30] Furthermore, path integral techniques have been applied.[13–15] One uses path-dependent space-time transformation to convert the path integral for the Morse potential into the radial path integral for the harmonic oscillator in three dimensions which is well known. Further refinements were done in Refs. 16 and 31. Using the latter technique one calculates the Green function, the kernel of the resolvent; moreover, one derives the spectrum and the eigenfunctions. Originally the method of path-dependent space-time transformation was applied to calculate the Feynman integral of the hydrogen atom.[32,33] The following formulas are taken from Ref. 16. First we will have a look at the Green function.

$$\begin{aligned} G(x',x;E) &:= \langle x'|(E-H)^{-1}|x\rangle \\ &= -\frac{\Gamma((1+\nu-\gamma\omega)/2)}{\omega|a|/2\Gamma(\nu+1)}\exp\left(\frac{a}{2}(x+x')\right) \\ &\quad\times\{\Theta(a(x-x'))W_{\gamma\omega/2,\nu/2}(\omega e^{-ax'})M_{\gamma\omega/2,\nu/2}(\omega e^{-ax}) \\ &\quad+\Theta(a(x'-x))M_{\gamma\omega/2,\nu/2}(\omega e^{-ax'})W_{\gamma\omega/2,\nu/2}(\omega e^{-ax})\} \end{aligned} \tag{66}$$

with $x',x\in\mathbb{R}$. Θ denotes the Heaviside function with the convention $\Theta(0)=1/2$, Γ is Euler's gamma function, $M_{\varkappa,\mu/2}$ and $W_{\varkappa,\mu/2}$ Whittaker's functions,[34] $\omega := 2\sqrt{2g}/|a|$ and $\nu := 2\sqrt{-2E}/|a|$. The $\sqrt{\cdot}$ denotes the principal branch of the square root with the cut along the negative real half line. Then we get for the spectrum

$$\sigma(H)=[0,\infty)\cup\left\{ -\frac{1}{8}a^2\left(\frac{2\gamma}{|a|}\sqrt{2g}-2n-1\right)^2 \,\middle|\, n\in\mathbb{N}_0 \text{ with } \frac{2\gamma}{|a|}\sqrt{2g}-2n-1>0 \right\} \tag{67}$$

and for the eigenvectors of the discrete eigenvalues

$$\begin{aligned} \Psi_n(x) &= \sqrt{\frac{|a|(\gamma\omega-2n-1)\Gamma(n+1)}{\Gamma(\gamma\omega-n)}}\,\omega^{\gamma\omega/2-(2n+1)/2}\exp\left(-\frac{a}{2}(\gamma\omega-(2n+1))x\right) \\ &\quad\times\exp\left(-\frac{\omega}{2}e^{-ax}\right)L_n^{(\gamma\omega-2n-1)}(\omega e^{-ax}) \end{aligned} \tag{68}$$

where $L_n^{(\mu)}$ is a generalized Laguerre polynomial.[34]

Proposition 28: The Green function (66), the eigenvectors, and the discrete eigenvalues are not analytic in g.

Proof: For the discrete eigenvalues the above statement is obvious. The Green function is not even analytic in $\omega=2\sqrt{2g}/|a|$. Using Ref. 35 we can rewrite (66) as

$$
\begin{aligned}
G(x',x;E) = &-\frac{2\pi}{|a|\sin(\nu\pi)}\exp\left(-\frac{\omega}{2}(e^{-ax'}+e^{-ax})\right)\\
&\times\Bigg\{\Theta(a(x-x'))\frac{{}_1F_1((1+\nu-\gamma\omega)/2;1+\nu,\omega e^{-ax})}{\Gamma(1+\nu)}\\
&\times\Bigg[-\omega^{\nu}e^{-\nu a(x+x')/2}\frac{\Gamma((1+\nu-\gamma\omega)/2)}{\Gamma((1-\nu-\gamma\omega)/2)}\frac{{}_1F_1((1+\nu-\gamma\omega)/2;1+\nu,\omega e^{-ax'})}{\Gamma(1+\nu)}\\
&+e^{\nu a(x'-x)/2}\frac{{}_1F_1((1-\nu-\gamma\omega)/2;1-\nu,\omega e^{-ax'})}{\Gamma(1-\nu)}\Bigg]\\
&+\Theta(a(x'-x))\frac{{}_1F_1((1+\nu-\gamma\omega)/2;1+\nu,\omega e^{-ax'})}{\Gamma(1+\nu)}\\
&\times\Bigg[-\omega^{\nu}e^{-\nu a(x+x')/2}\frac{\Gamma((1+\nu-\gamma\omega)/2)}{\Gamma((1-\nu-\gamma\omega)/2)}\frac{{}_1F_1((1+\nu-\gamma\omega)/2;1+\nu,\omega e^{-ax})}{\Gamma(1+\nu)}\\
&+e^{\nu a(x-x')/2}\frac{{}_1F_1((1-\nu-\gamma\omega)/2;1-\nu,\omega e^{-ax})}{\Gamma(1-\nu)}\Bigg]\Bigg\}
\end{aligned}
$$

with $\nu=2\sqrt{-2E}/|a|$ and ${}_1F_1$ denotes a generalized hypergeometric function.[34] The function

$$
\frac{{}_1F_1(a;b,x)}{\Gamma(b)} \tag{69}
$$

is entire in a, b, x. Thus we only have to investigate $\Gamma((1+\nu-\gamma\omega)/2)\omega^{\nu}$. This is obviously not analytic in ω near $\omega=0$. For the eigenvectors we can proceed along the same line. ■

Although the Green function, the discrete eigenvalues, and the eigenfunctions are not analytic, the propagator has a perturbation series which is uniformly absolutely convergent in the coupling constant for every compact set in the variables x, t, x_0, t_0. For the Morse potential we obtain an expansion for the propagator from (41). Putting $\theta=0$ and doing the $dm(\alpha_j)$ integrations we get

$$
\begin{aligned}
K(x,t|x_0,t_0) = K_0(x,t|x_0,t_0)\cdot\sum_{n=0}^{\infty}\frac{(-ig)^n}{n!}(t-t_0)^n\sum_{j_1,\ldots,j_n=1}^{2}(-2\gamma)^{2n-\sum_{k=1}^{n}j_k}\\
\times\int_{[0,1]^n}\exp\left\{-a\sum_{l=1}^{n}j_l(\sigma_l x+(1-\sigma_l)x_0)\right\}\\
\times\exp\left\{-\frac{i}{2}(t-t_0)a^2\sum_{l=1}^{n}\sum_{k=1}^{n}j_k j_l[\sigma_j\sigma_k-\sigma_j\wedge\sigma_k]\right\}d^n\sigma.
\end{aligned} \tag{70}
$$

In the sum over n the coefficient of g^n is bounded by

$$
\frac{1}{n!}|t-t_0|^n(1+2|\gamma|)^n e^{2n|a|(|x-x_0|+|x_0|)}.
$$

(Received 18 December 1997; accepted for publication 21 February 1998)

The interconnection between quantum mechanics and probabilistic classical mechanics for a free relativistic particle is derived in terms of Wigner functions (WF) for both Dirac and Klein-Gordon (K-G) equations. Construction of WF is achieved by first defining a bilocal 4-current and then taking its Fourier transform w.r.t. the relative 4-coordinate. The K-G and Proca cases also lend themselves to a closely parallel treatment *provided* the Kemmer-Duffin β-matrix formalism is employed for the former. Calculation of WF is carried out in a Lorentz-covariant fashion by standard ''trace'' techniques. The results are compared with a recent derivation due to Bosanac. © *1998 American Institute of Physics.* [S0022-2488(98)02907-7]

I. INTRODUCTION: WIGNER FUNCTION AS LINK BETWEEN QM AND CM

Since the advent of Quantum Mechanics (QM), there have been several investigations aimed at understanding Schrödinger equations and their relativistic counterparts from stochastic/statistical premises in classical mechanics, epitomized by Focker-Planck[1,2] and Liouville equations.[3–6] In the process most such investigations have had to resort at some stage to some sort of ansatz designed to introduce the ''square-root'' of a probability function,[1–4] or make a more direct use of the wave function from the outset.[5,6] This of course does not address the core issue of the foundations of quantum physics, viz., the existence of complex probability amplitudes obeying the ''superposition principle,'' and the need to invoke the ''collapse hypothesis'' to explain the outcome of a quantum measurement. Even without any commitment to resolve this central mystery of conventional quantum physics, it is both interesting and illuminating to explore the classical roots of quantum mechanics by comparing and relating their respective mathematical structures as in several contemporary investigations.[3–6]

Among the several approaches to an alternative ''derivation'' of QM, we would like to pick out for explicit scrutiny, a recent formulation due to Bosanac[4] in which the author makes essential use of the probabilistic (instead of ''trajectory-oriented'') approach to Classical Mechanics (CM) via the Liouville equation, wherein the Uncertainty Principle is sought to be incorporated at the outset, as a means of capturing a good chunk of QM. Our purpose in this regard is more in the nature of an ''inverse'' (to Ref. 4) approach, which stems from a desire to give a more direct role to the QM wave function borne out of its ''being already there,'' thereby according it a more open role in the construction of the Wigner Function,[7] as in other orthodox approaches.[5,6] As we shall see, this approach has the advantage of presenting the treatment of different types of relativistic equations (Dirac, Klein-Gordon, Proca, etc.) within a unified framework.

The central quantity that satisfies the Liouville equation is the Wigner-function[7] which in itself was conceived within the QM framework, as a bilinear in the ''wave function.'' Granting the existence of the wave function in turn implies the existence of its Fourier transform which represents its momentum space counterpart, and the two together guarantee a built-in effect of the Uncertainty Principle, as clearly recognized in Ref. 4. Using such a (hybrid) approach in which the prior existence of the wave function is implicit in the structure of the Wigner function,[7] Bosanac[4] claims to derive the Schrödinger equation from the Liouville equation, consistently with current conservation, apparently as an inverse (?) problem. An extension to the corresponding relativistic

 © 1998 American Institute of Physics

problem, rather surprisingly, seemed to yield only the Dirac equation (spinor), but not the Klein-Gordon (K-G) equation (scalar), a result whose mystery we seek to clarify in this paper and (hopefully) pave the way to a generalization (see below).

Specifically, we have been actuated by a desire to re-examine the issue of Dirac versus K-G,[4] but with a more conscious recognition of an active role of the ''wave function'' at the outset, and in the process we find that the Liouville and current conservation equations for both the Dirac and K-G cases follow from identical premises, *provided* one has no qualms about the free use of *multi-component* wave functions in both Dirac and K-G cases, and not (selectively) for the Dirac case only.[4] Indeed it is easily seen from a detailed perusal of the steps in Ref. 4 that the author's success in deriving the Dirac equation is crucial to his *ansatz* of a 4-component spinor, without which the necessary consistency checks would not be forth-coming. On the other hand he did not seem to consider a similar possibility for the K-G case, viz., the existence of the less familiar Kemmer-Duffin equations for integral spins,[8] wherein the multicomponent structure of the corresponding wave function satisfying a first order equation as in the Dirac case seems to be the right form for putting the K-G and Proca cases on parallel footing with Dirac. Of course the question of whether, in spite of a multicomponent ansatz for the K-G wave function, a bosanac-like treatment[4] of working backwards from the Liouville-cum-current-conservation equations to the K-G equation would have succeeded, is still open, since the Kemmer-Duffin β-matrices are singular, unlike the Dirac matrices which are not (see Sec. IV).

In carrying out this exercise we have been guided solely by the orthodox (Dyson[9]) philosophy that a relativistic quantization of a *single* particle has inherent problems of consistency, whose resolution hinges on the simultaneous existence of an infinite number of particles, i.e., on a *field* concept. Indeed, Dirac's postulation of the infinite sea (of negative energy particles) in the vacuum was enough ground for Pauli-Weisskopf[10] to reinterpret the single particle density from the K-G equation as an average charge density (which could ''locally'' have either sign).[9] Of course from a practical point of view, a single particle interpretation has considerable appeal, but it requires the ''protective cover'' of Feynman's positron theory[11] which mandates $\pm$ time directions to be associated with $\pm$ energy propagations, respectively.

In what follows, we shall keep in the forefront, the results of Ref. 4 for pointwise comparison with the derivation to be presented here under the orthodox ''field'' paradigm[9] which is routinely available in any standard text.[12] In Sec. II, we give a ''direct'' derivation of the Wigner function for the Dirac equation and thence the corresponding Liouville plus current conservation equations, a procedure whose steps are roughly in ''inverse'' order to those of Ref. 4. In Sec. III, we do the corresponding exercise for the K-G and Proca cases via the Kemmer-Duffin[8] formulation,[13] and in so doing, bring out the strong similarity of the two systems. Section IV concludes with a short discussion, including a comparison with Ref. 4.

II. WIGNER FUNCTION FOR THE DIRAC EQUATION

We begin by writing the Dirac equation for a free field $\psi(x)$ in the ''Euclidean'' covariant notation as[13]

$$(\gamma_\mu \partial_\mu + m)\psi(x) = 0; \quad \overline{\psi}(x)(m - \partial_\mu \gamma_\mu) = 0. \tag{2.1}$$

Now define a bilocal current $j_\mu(x_1, x_2)$ as

$$j_\mu(x_1, x_2) = \overline{\psi}(x_1) i \gamma_\mu \psi(x_2). \tag{2.2}$$

Next put $x_1 = x - q$ and $x_2 = x + q$ as in Ref. 4, and define a 4-vector $V_\mu(x,p)$ as

$$V_\mu(x,p) = \pi^{-4} \int d^4q e^{2ip.q} \overline{\psi}(x+q) i \gamma_\mu \psi(x-q). \tag{2.3}$$

The fourth component of V_μ may be identified with the standard WF ρ. As a check on this quantity, its integral w.r.t. d^4p yields the usual 4-current $J_\mu(x)$ as

$$J_\mu(x)=\int d^4p\,V_\mu(x,p)=\overline{\psi}(x)i\gamma_\mu\psi(x), \tag{2.4}$$

from which the standard current conservation equation is recovered as

$$\partial_\mu J_\mu(x)=0. \tag{2.5}$$

Next we make a Gordon reduction of V_μ [always possible for a free field $\psi(x)$] so as to bring out the separate contributions V^c_μ and V^s_μ arising from the ''convective'' and ''spin'' currents, respectively:

$$V^c_\mu(x,p)=\pi^{-4}\int d^4q e^{2ip.q}\overline{\psi}(x+q)\frac{p_\mu}{m}\psi(x-q); \tag{2.6}$$

$$V^s_\mu(x,p)=\pi^{-4}\partial^{(x)}_\nu\int d^4q e^{2ip.q}\overline{\psi}(x+q)\frac{\sigma_{\mu\nu}}{2m}\psi(x-q). \tag{2.7}$$

We check from these that *two* separate conservation equations follow:

$$\partial_\mu V^c_\mu(x,p)=\partial_\mu V^s_\mu(x,p)=0, \tag{2.8}$$

the former being a consequence of the K-G equation for each component of $\psi(x)$ and $\overline{\psi}(x)$, and the latter being identically satisfied.

We now seek to use the Gordon reduction as a key element for deriving the Liouville equation á lá Ref. 4, and in so doing bring out its role in putting our procedure in closer correspondence to Ref. 4. For the central issue is one of demonstrating that the density function $\rho(x,p)$ and the current function $V_i(x,p)$ are related by the ''classical'' velocity factor v_i, so as to ensure the ''correct'' structure of the Liouville equation.[4] To that end we note from (2.3), (2.6), and (2.7) that the effect of Gordon reduction in (3) may be expressed in operator form sandwiched between ψ and $\overline{\psi}$:

$$i\gamma_\mu=\frac{p_\mu}{m}+\frac{1}{2m}\partial^{(x)}_\nu\sigma_{\mu\nu}. \tag{2.9}$$

The spatial part of this equation is seen as the precise counterpart of Eq. (27) of Ref. 4 (after integration w.r.t. d^4pd^4q), with the following identifications: The convective term p_μ in (2.9) has a space part p_i which corresponds to the j_i term of Ref. 4, since it bears the ratio v_i to the time component p_0, as the correct factor connecting the current function $V_i(x,p)$ to the density function $V_0(x,p)$. The space part of the full γ_μ term collectively represents the two terms a_id and $a_i\epsilon$ in Eq. (27) of Ref. 4. Finally the last (derivative) term in (2.9) corresponds to the $\nabla\times\Phi$ term in Eq. (27) of Ref. 4 since it has a zero divergence by itself, as seen from the second part of Eq. (2.8), and therefore has no separate influence on the equation of continuity. Therefore, following the logic of Ref. 4, this term has no effect on the anatomy of the Liouville equation which is thus entirely contained in the first (convective) part of Eq. (2.8). To reveal this structure more explicitly, the $\rho(x,p)$ function of Ref. 4 reads, in our 4×4 Dirac matrix notation, as follows:

$$\rho(x,p)\equiv V_0(x,p)=\pi^{-4}\int d^4q e^{2ip.q}\overline{\psi}(x+q)\gamma_4\psi(x-q), \tag{2.10}$$

which satisfies the Liouville equation

$$\partial_0\rho(x,p)+v_i\partial_i\rho(x,p)=0, \tag{2.11}$$

that is merely a paraphrase of the first part of Eq. (2.8) representing the conservation of the *convective* part of the V_μ function.

To end this section, we outline a construction for the ρ function analogously to Eqs. (51)–(53) of Ref. 4, using a fully covariant procedure. To that end, we write down Fourier representations for the Dirac spinors on the lines of Ref. 12, but adapted to the Euclidean phase convention:[13]

$$\psi(x_1)=(2\pi)^{-3/2}\int d^3p_1(m/E_1)^{1/2}[b_{p_1r_1}u^{r_1}(p_1)e^{ix_1\cdot p_1}+d^*_{p_1r_1}v^{r_1}(p_1)e^{-ix_1\cdot p_1}]; \quad (2.12)$$

$$\overline{\psi}(x_2)=(2\pi)^{-3/2}\int d^3p_2(m/E_2)^{1/2}[b^*_{p_2r_2}\overline{u^{r_2}}(p_2)e^{-ix_2\cdot p_2}+d_{p_2r_2}\overline{v^{r_2}}(p_2)e^{ix_2\cdot p_2}]; \quad (2.13)$$

where b and d are (c-number) electron and positron amplitudes, respectively, and u and v are the corresponding positive and negative energy spinors. The latter are more conveniently expressed in terms of Lorentz boost operators as follows:[12]

$$u^{r_1}(p_1)=[(m-i\gamma\cdot p_1)/(2\sqrt{m(m+E_1)})]u^{r_1}(0); \quad (2.14)$$

$$v^{r_1}(p_1)=[(m+i\gamma\cdot p_1)/(2\sqrt{m(m+E_1)})]v^{r_1}(0). \quad (2.15)$$

These Lorentz boost factors are proportional to energy projection operators for the corresponding spinors. To specify their spin states, we can further multiply these quantities by the spin projection operators P_n,[12]

$$P_n=[1+i\gamma\cdot\hat{n}\gamma_5]/2, \quad (2.16)$$

where $\hat{n}$ is a unit 4-vector representing the direction of spin.[12] After these manipulations on the spinors through the sequence of Eqs. (2.10)–(2.16), and their substitution in the defining Eq. (2.3) for V_μ, the spinor dependence can be totally removed by ''tracing.'' To simplify these expressions note that only the b^*b and d^*d terms will survive, while the cross terms will drop out of the traces, since the $\pm$ energy spinors at a given momentum (zero) are orthogonal to each other. The rest of the simplification is routine and the result can be compactly expressed in terms of two quantities $Tr^{\pm}_{\mu}$ defined as follows:

$$Tr^{\pm}_{\mu}=\frac{\pm m(p_1+p_2)_\mu+\epsilon_{\mu\lambda\rho\sigma}p_{1\lambda}p_{2\rho}\hat{n}_\sigma}{2\sqrt{E_1(m+E_1)E_2(m+E_2)}}. \quad (2.17)$$

Before substituting these quantities in Eq. (2.3) for $V_\mu(x,p)$, note that of the two terms on the right, the first (convective) term has the desired structure for the ''Liouville form,'' Eq. (2.11), but the second (spin) term has not. However, in accordance with the discussion immediately following Eq. (2.9), in line with Ref. 4, one need not insist on the ''Liouville connection'' separately for both the terms since the ''spin'' term (proportional to $\hat{n}$) can be traced back to the ''derivative'' term of (2.9) which has no separate effect on the equation of continuity. Therefore we need only the $\mu=4$ component in Eq. (2.17) above to extract the ρ-function fully, whence the corresponding ''current'' function V_i can be generated by multiplying with $v_i=p_i/p_0$ only.

To proceed further, integration over d^3p_1 and d^3p_2 may be simplified via the transformations $p_{1,2}=p'\pm k/2$, remembering that $x_{2,1}=x\pm q$. Further, the 3D integrals may be converted to 4D integrations over p' and k via the identity

$$d^3p_1d^3p_2=2E_12E_2d^4p'd^4k\delta(p'^2+m^2+k^2/4)\delta(2p'\cdot k), \quad (2.18)$$

making use of the result $\delta(a)\delta(b)=\delta((a+b)/2)\delta(a-b)$. Integration over d^4q now gives $\delta^4(p'\mp p)$ for the terms b^*b and d^*d, respectively; subsequent integration over d^4p' gives $p'=\pm p$. Collecting all these results and substituting in (2.10) gives

$$\rho(x,p)=\pi^{-3}\int d^4k\,\delta(p^2+m^2+k^2/4)\,\delta(2p\cdot k)[b^*(\mathbf{p}+\mathbf{k}/2)b(\mathbf{p}-\mathbf{k}/2)e^{ik.x}$$
$$+d^*(\mathbf{p}+\mathbf{k}/2)d(\mathbf{p}-\mathbf{k}/2)e^{-ik\cdot x}](2mp_0+2i\hat{n}.(\mathbf{p}\times\mathbf{k}))\sqrt{\frac{E_1E_2}{(m+E_1)(m+E_2)}}. \tag{2.19}$$

This expression corresponds to Eqs. (51)–(53) of Ref. 4, after taking due account of the difference in the choice of the respective basis functions (Dirac versus Pauli types), as well as the covariant versus non-covariant notations. Note that the integration in (2.19) is basically angular $d\Omega_k$ in content, like in Ref. 4, since the four-dimensional (4D) integration d^4k is also multiplied by the two δ-functions which take care of the magnitudes of both $\mathbf{k}$ and k_0. Our 3-vector $\mathbf{k}$ is $2\mathbf{k}$ of Ref. 4, and $\hat{n}$ is $\hat{\omega}$ of Ref. 4. Finally, our expression for ρ compactly covers both $\pm$ energy components.

We next turn to the K-G and Proca cases via Kemmer-Duffin equations.

III. WIGNER FUNCTION FOR INTEGRAL SPIN

Because of the relative lack of exposure of the Kemmer-Duffin equations[8] in the contemporary literature, it will first be useful to recall some basic results which are summarized in Roman[13] in the Euclidean phase convention, from which we shall freely draw on several results without much comment. The first order differential equation for integral spin is expressible in β-matrix notation as[13]

$$(\beta_\mu\partial_\mu+m)\psi(x)=0;\overline{\psi}(m-\partial_\mu\beta_\mu)=0, \tag{3.1}$$

where $\psi(x)$ is a multi-component field, each of whose components ψ_i satisfies the K-G equation, and $\overline{\psi}=\psi^\dagger\eta_4$ and $\eta_4=2\beta_4^2-1$. The spin-0 and spin-1 cases correspond to 5- and 10-component irreducible representations, respectively. These components are

$$\begin{aligned}&\text{Spin}-0:\psi_i(i=1-4)=-\partial_\mu\phi(x)/m;\quad \psi_5=\phi,\\ &\text{Spin}-1:\psi_i(i=1-6)=-F_{\mu\nu}/m;\quad \psi_i(i=1-4)=\phi_\mu.\end{aligned} \tag{3.2}$$

The various quantities like bilocal 4-current $j_\mu(x_1,x_2)$, phase space 4-current $V_\mu(x,p)$, and local 4-current $J_\mu(x)$ follow very closely the corresponding constructions (1.2)–(1.5) for the Dirac case, with the replacements: γ_μ by β_μ; γ_4 by η_4. Thus the phase space 4-current is given by

$$V_\mu(x,p)=\pi^{-4}\int d^4q e^{2ip.q}\overline{\psi}(x+q)i\beta_\mu\psi(x-q), \tag{3.3}$$

and its break-up into convective and spin components is achieved via ''Gordon reduction'' analogously to the Dirac case. However the algebra of the β matrices is a bit more involved than that of the γ matrices because the former are singular. Thus[8,13]

$$\beta_\lambda\beta_\mu\beta_\nu+\beta_\nu\beta_\mu\beta_\lambda=\beta_\lambda\delta_{\mu\nu}+\beta_\nu\delta_{\mu\lambda};\quad \eta_4^2=1. \tag{3.4}$$

The ''spin'' operator $S_{\mu\nu}$ is given by

$$iS_{\mu\nu}=\beta_\mu\beta_\nu-\beta_\nu\beta_\mu, \tag{3.5}$$

and, except for a factor of $\frac{1}{2}$, has exactly the same role as that of $\sigma_{\mu\nu}$, including its antisymmetry property. For writing down the counterpart of Gordon reduction, the following equations are needed:

$$(\partial_\mu-\beta_\nu\beta_\mu\partial_\nu)\psi(x)=0;\quad \overline{\psi}(x)(\partial_\mu-\beta_\nu\beta_\mu\partial_\nu)=0. \tag{3.6}$$

With the help of (3.1) and (3.6), and making use of the definition (3.5) for the ''spin,'' the matrix β_μ in (3.3) may be written in a form analogous to (2.9) as

$$i\beta_\mu = \frac{p_\mu}{m} + \partial_\nu^{(x)} \frac{S_{\mu\nu}}{m}, \tag{3.7}$$

which shows a clear division between the convective and spin parts, with the latter having a ''derivative'' structure whose divergence vanishes by itself, as in the second part of Eq. (2.8). Therefore this term has no direct role in the Liouville equation like in the Dirac case, exactly as in Ref. 4.

So far this β-formalism for integral spin covers both spin-0 (K-G) and spin-1 (Proca) cases, and one may wonder why for the former there should be a spin term $S_{\mu\nu}$ at all, in the Gordon reduction (3.7). Actually this term is effectively *zero* for the spin-0 case since, as has been explained in Roman,[13] for the 5×5 representation the eigenvalues of $S_3 = S_{12}$ are nonmeasurable. Indeed the probability density,[13]

$$\rho = -i(\psi_4^*\psi_5 + \psi_5^*\psi_4) = -i(\partial_0\phi^*\phi - \phi^*\partial_0\phi)/m, \tag{3.8}$$

vanishes in the eigenstates that correspond to $S_3 = \pm 1$, so that the presence of the $S_{\mu\nu}$-term in the spin-0 case is purely symbolic. Substituting this information in (3.3), and noting from (3.8) that only the components $\psi_{4,5}$ survive for the phase space density function $\rho(x,p)$ for the K-G case, the final result works out as

$$\rho(x,p) = \frac{1}{m}\pi^{-4} i \int d^4q e^{2ip.q}[\partial_0\phi^*(x+q)\phi(x-q) - \phi^*(x+q)\partial_0\phi(x-q)], \tag{3.9}$$

while Eq. (3.7) ensures that the phase space current function $\mathbf{V}(x,p)$ is related to $\rho(x,p)$ by the factor $\mathbf{p}/p_0 = \mathbf{v}$, so that the structure of the Liouville equation is preserved. As a further check, the integration of (3.9) over d^4p reproduces the K-G density function $\rho(x)$ of (3.8) exactly. The last quantity is of course not positive definite, as expected[13] for the K-G case. Again as in the Dirac case, it is possible to write down an expression for $\rho(x,p)$ closely analogous to (2.19), except for the absence of the ''spin'' term, in the third line. We omit this routine step for brevity.

For the Proca case, the ''spin'' term in the Gordon reduction (3.7) will now contribute to the $\rho(x,p)$ function, while the Liouville connection is again maintained via the convective p_μ term only. From the structure of $\rho(x,p)$, which corresponds to $\mu = 4$, it is seen quite clearly that the ''spin'' contribution arising from the second term of Eq. (3.7) in the Proca case is proportional to $\mathbf{S}\cdot\mathbf{E}\times\mathbf{H}$, where $\mathbf{E}$ and $\mathbf{H}$ are the ''electric'' and ''magnetic'' components of $F_{\mu\nu}$, respectively. Again we skip the Fourier representation (2.19) for the full $\rho(x,p)$ function, as this step will not illuminate the structure any further beyond the above demonstration of a close parallelism between the spin-1/2 and integral spin (0,1) cases.

IV. DISCUSSION AND CONCLUSION

This study was motivated by a desire to understand some results due to Bosanac[4] in which he claims to derive the Dirac equation, starting from the (classical) premises of the Liouville equation. What intrigued us was the assertion[4] that the ''derivation'' leads to the Dirac equation, instead of to the Klein-Gordon equation. To examine this question more closely, we were led to start from the *opposite* direction to Ref. 4, viz., a ''direct'' derivation of the Liouville equation through an explicit construction of the Wigner Functions[7] themselves, as in more orthodox approaches,[5,6] with a view to throwing some light on this apparent asymmetry between the Dirac and the K-G cases. Rather surprisingly, our result indicates a close parallelism between both spin-1/2 and spin-(0,1) cases, brought about by the Kemmer-Duffin[8] formalism[13] for integral spin as a natural counterpart to the Dirac equation for spin-1/2. In both cases, we have made essential use of the Gordon reduction into ''convective'' and ''spin'' contributions to the 4-current, wherein the convective part gives the desired ''Liouville ratio'' p_0:$\mathbf{p}$ between the density and current functions in phase space, but the spin part does not. However the latter has a derivative structure by virtue of which its 4-divergence vanishes identically, so as to yield a ''spin'' current conser-

vation by itself [Eq. (2.8)], and hence has no direct effect on the dynamics of the Liouville equation as such, which is entirely governed by the convective term only. This result seems to accord rather well with the corresponding result of Bosanac,[4] viz., his Eq. (27), despite a vast difference in the respective procedures. In particular, since the Gordon reduction in our derivation has proved crucial for a neat identification of the origin of these two terms as convective and spin contributions, respectively, it may be safely assumed that the same mechanism underlies the derivation in Ref. 4 as well, irrespective of the manner of the derivation.

Without going into the philosophical aspects of the classical foundations of Quantum Mechanics, it is pertinent to ask why only the Dirac equation has been amenable to the Bosanac derivation.[4] For it will be rather naive to argue that no substantial quantum mechanical input has gone into the latter approach, since the very structure of the Wigner Function as a bilinear in the (quantum mechanical) wave function is a tacit acknowledgement of the existence of the latter, with the Uncertainty Principle as a built-in corollary of the same. Further, the structure of the Dirac equation is implicit in the ansatz,[4] Eq. (16), in terms of Pauli spinors F_1, F_2, with anticommutation relations (23)–(25) characteristic of Dirac matrices in the Pauli 2-component form, all of which ingredients have been crucial to the (indirect) derivation of the main Eq. (27). Indeed the entire exercise[4] is a fine example of how to work backwards from the (bilinear) Liouville equation to the (linear) Dirac equation, albeit in the Pauli 2-component form. Yet it goes without saying that the ansatz of a 4-component spinor [satisfying a Dirac-type equation (16)[4]] has been very much of an input in the derivation.

A comparison with our ''direct'' derivation would suggest that a possible reason why the K-G equation was not amenable to the Bosanac derivation was the missing element of a multi-component wave function in his formulation of the K-G problem, something we have sought to rectify through the Kemmer-Duffin β-matrix formalism[8] which restores the formal analogy to the Dirac case. However, and this may be important, even if the Bosanac formalism had included a multi-component wave function for the integral (including zero) spin field, it is doubtful if working backwards from the Liouville to the K-G equation would have proved successful in this case, since the β-matrices are *singular*, unlike the Dirac matrices, so that a routine inversion of steps on the lines of 4 might well not have been possible (we did not succeed in this effort). But there seems to be no problem in the ''forward'' steps (from QM equation to Liouville) going through in the K-G and Proca cases with equal ease, as the above derivation indicates.

The foregoing comparison would suggest that the structure of Quantum Mechanics is probably richer and more varied than can be fully captured in one go, through alternative formulations. And yet the basically indeterministic nature of QM poses a continuous challenge to innovative ideas designed to capture its full flavor from ''objective-realist'' premises, so as to provide a more ''classical'' approach to its uncanny predictions. Reference 4 may be regarded as one more effort in this direction, as part of an ongoing movement[14] for resolving the foundational paradoxes of orthodox QM which has acquired fresh momentum with heavyweights for and against the Copenhagen Interpretation arrayed in comparable strengths on both sides of the Great Divide.[15]

(Received 30 January 1997; accepted for publication 27 April 1998)

The Wheeler–DeWitt equation for the minimally coupled Friedman–Robertson–Walker-massive-scalar-field minisuperspace is written as a two-component Schrödinger equation with an explicitly ''time''-dependent Hamiltonian. This reduces the solution of the Wheeler–DeWitt equation to the eigenvalue problem for a nonrelativistic one-dimensional harmonic oscillator and an infinite series of trivial algebraic equations whose iterative solution is easily found. The solution of these equations yields a mode expansion of the solution of the original Wheeler–DeWitt equation. Further analysis of the mode expansion shows that in general the solutions of the Wheeler–DeWitt equation for this model are doubly graded, i.e., every solution is a superposition of two definite-parity solutions. Moreover, it is shown that the mode expansion of both even- and odd-parity solutions is always infinite. It may be terminated artificially to construct approximate solutions. This is demonstrated by working out an explicit example which turns out to satisfy DeWitt's boundary condition at initial singularity. © *1998 American Institute of Physics.* [S0022-2488(98)01209-2]

I. INTRODUCTION

It is well-known that the Wheeler–DeWitt equation for the minimally coupled Friedman–Robertson–Walker (FRW)-massive-scalar-field (the scalar field is assumed to be homogeneous) minisuperspace can be written in the form of the Klein–Gordon equation (this equation corresponds to simplest choice of factor ordering) in $(1+1)$ dimensions,[1]

$$\left[-\frac{\partial^2}{\partial\alpha^2}+\frac{\partial^2}{\partial\phi^2}+\kappa e^{4\alpha}-m^2e^{6\alpha}\phi^2\right]\psi(\alpha,\phi)=0, \tag{1}$$

where $\alpha=\ln a$, a is the scale factor of the FRW metric

$$ds^2=-dt^2+a^2(t)[dr^2+S_\kappa(r)(d\theta^2+\sin^2\theta d\varphi^2)],$$

$$S_\kappa:=\begin{cases}\sinh r & \text{for } \kappa=-1: \text{ open universe}\\ r & \text{for } \kappa=0: \text{ flat universe}\\ \sin r & \text{for } \kappa=1: \text{ closed universe,}\end{cases}$$

and ϕ is a real scalar field of mass m. It is also well-known that unlike the massless case[2] exact solutions of this equation are not known. The approximate solutions are usually obtained using the semiclassical Wentzel–Kramers–Brillouin (WKB) methods.[3]

Recently, I have used a two-component formulation of the Klein–Gordon equation to study the geometrical phases induced on a Klein–Gordon field due to a dynamical background spacetime geometry and electromagnetic or scalar interactions.[4] In the present article, I shall try to apply the same approach for the treatment of the Wheeler–DeWitt equation (1).

II. TWO-COMPONENT FORM OF THE WHEELER–DEWITT EQUATION

The idea of the two-component formalism[5] is to transform the Klein–Gordon equation which is of second order in time-derivative, into a system of two coupled differential equations which are first order in the time-derivative. The latter may be viewed as a Schrödinger equation. In this way one can apply the well-developed techniques of solving the Schrödinger equation to obtain solutions of the Klein–Gordon equation. The application of the two-component formalism for the Klein–Gordon equation is described in detail in Ref. 4. Here I only include the results which are relevant for the solution of Eq. (1).

Equation (1) can be expressed in the form:

$$\left[\eta^{\mu\nu}\frac{\partial}{\partial X^{\mu}}\frac{\partial}{\partial X^{\nu}}+V(X)\right]\psi=0, \tag{2}$$

where $\mu,\ \nu=0,\ 1,\ (\eta^{\mu\nu}):=\mathrm{diag}(-1,1),\ X^0:=\alpha,\ X^1:=\phi,$ and

$$V(X):=\kappa e^{4X^0}-m^2e^{6X^0}(X^1)^2=\kappa e^{4\alpha}-m^2e^{6\alpha}\phi^2=\kappa a^4-m^2a^6\phi^2. \tag{3}$$

Hence, α plays the role of ''time.'' Furthermore, defining

$$\Psi:=\frac{1}{\sqrt{2}}\begin{pmatrix}\psi+i\dot{\psi}\\ \psi-i\dot{\psi}\end{pmatrix}, \tag{4}$$

one can easily check that Eq. (2) is equivalent to the Schrödinger equation

$$i\dot{\Psi}=H\Psi, \tag{5}$$

with the explicitly time-dependent Hamiltonian:

$$H=\frac{1}{2}\begin{pmatrix}1+D & -1+D\\ 1-D & -1-D\end{pmatrix}, \tag{6}$$

where a dot represents differentiation with respect to $X^0=\alpha$ and

$$D:=-\frac{\partial^2}{\partial(X^1)^2}-V=-\frac{\partial^2}{\partial\phi^2}-V. \tag{7}$$

The two-component Hamiltonian (6) has the following remarkable properties.

(1) It belongs to the (dynamical) Lie algebra $\mathrm{su}_s(1,1)\otimes\mathrm{su}_u(1,1)$. Here $\mathrm{su}_s(1,1)$ is the standard representation of su(1,1) with the basis

$$K_3=J_3=\frac{1}{2}\sigma_3,\quad K_a=iJ_{\alpha}=\frac{i}{2}\sigma_a\quad (a=1,2),$$

where σ_i are Pauli matrices, and $\mathrm{su}_u(1,1)$ denotes the unitary representation of su(1,1) constructed out of the position x and momentum p operators of the one-dimensional quantum mechanics, with the basis $\{(x^2-p^2)/4,(x^2+p^2)/4,(xp+px)/4\}$.[6] This is easily seen, by writing H in the form $H=K_-+K_+D$, where $K_{\pm}:=K_3\pm K_2$, and observing that the operator D belongs to $\mathrm{su}_u(1,1)$.

(2) It is the square root of the operator D, in the sense that it satisfies

$$H^2=\begin{pmatrix}D & 0\\ 0 & D\end{pmatrix}=D. \tag{8}$$

This is reminiscent of Dirac's treatment of the noninteracting Klein–Gordon equation in $(3+1)$-dimensional Minkowski space, where the Dirac operator plays the role of the square root of the Klein–Gordon operator.

Next let us examine the eigenvalues E_n and eigenvectors Ψ_n of the Hamiltonian H. In order to have a well-posed eigenvalue problem for H, one should discuss the properties of the space of

two-component wave functions $\mathscr{H}$. This will be done in Sec. III. Here we suffice to note that as a vector space $\mathscr{H}$ is the inner sum of two vector subspaces each of which is isomorphic (as Hilbert spaces) to $L^2(\mathbb{R})$. In view of this observation and the particular form of the Hamiltonian H, the formal solution of the eigenvalue equation

$$H\Psi_n=E_n\Psi_n, \tag{9}$$

for H is given by

$$\Psi_n=\frac{1}{\sqrt{2}}\begin{pmatrix}1+E_n\\1-E_n\end{pmatrix}\Phi_n, \quad D\Phi_n=E_n^2\Phi_n. \tag{10}$$

This shows that the eigenvalue equation (9) for $H:\mathscr{H}\to\mathscr{H}$ is in fact equivalent to the eigenvalue equation (10) for $D:L^2(\mathbb{R})\to L^2(\mathbb{R})$. Since the latter is a a well-posed eigenvalue equation in the Hilbert space $L^2(\mathbb{R})$, so is the former. In particular, the eigenvectors Ψ_n do belong to $\mathscr{H}$.

Next let use substitute Eq. (7) in the second equation in (10). This yields

$$\left[-\frac{1}{2}\frac{\partial^2}{\partial\phi^2}+\frac{1}{2}\omega^2\phi^2\right]\Phi_n=\mathscr{E}_n\Phi_n, \tag{11}$$

where $\omega:=me^{3\alpha}=ma^3$ and $\mathscr{E}_n:=(E_n^2+\kappa e^{4\alpha})/2=(E_n^2+\kappa a^4)/2$. Equation (11) is the eigenvalue equation for a simple harmonic oscillator with frequency ω and unit mass. Hence:

$$\mathscr{E}_n=\omega(n+\tfrac{1}{2})=ma^3(n+\tfrac{1}{2}), \tag{12}$$

$$\Phi_n=N_nH_n(\sqrt{\omega}\phi)e^{-\frac{1}{2}\omega\phi^2}=N_nH_m(\sqrt{ma^3}\phi)e^{-\frac{1}{2}ma^3\phi^2}, \tag{13}$$

where H_n are Hermite polynomials and N_n are normalization constants. The latter are determined by the requirement that Φ_n be normalized with the usual $L^2(\mathbb{R})$ norm. This leads to

$$N_n=\left[\frac{\omega}{\pi(2^nn!)^2}\right]^{1/4}=\left[\frac{ma^3}{\pi(2^nn!)^2}\right]^{1/4}.$$

Note that Φ_n and consequently Ψ_n tend to zero as $a\to0$ or $a\to\infty$.

Substituting Eq. (12) in the expression for $\mathscr{E}_n$, one has

$$E_{\pm n}=\pm\sqrt{\omega(2n+1)-\kappa e^{4\alpha}}=\pm\sqrt{me^{3\alpha}(2n+1)-\kappa e^{4\alpha}}=\pm a\sqrt{ma(2n+1)-\kappa a^2}. \tag{14}$$

Thus, for $\kappa=-1$ or 0, $E_{\pm n}$ are real, whereas for $\kappa=1$ and $a>m$, there are eigenvectors $\Psi_{\pm n}$ with imaginary eigenvalue. They correspond to the integers n satisfying $m(2n+1)<a$.

So far, I have given the solution for the eigenvalue problem for the Hamiltonian H. The eigenvectors of H, however, do not solve the Schrödinger equation. This is mainly because H is explicitly time dependent. The general solution of the Schrödinger equation for an arbitrary explicitly time-dependent Hamiltonian is not known. However, in the cases where the eigenvalue problem for the Hamiltonian is solvable, there are techniques based on the adiabatic approximation[7–9] which may be used to obtain approximate and occasionally exact solutions. These techniques can be employed if the Hamiltonian is self-adjoint. In order to examine the self-adjointness of the Hamiltonian H, one first needs a notion of an inner product on the space $\mathscr{H}$ of two-component wave functions Ψ.

III. HILBERT SPACE STRUCTURE OF $\mathscr{H}$

As a vector space, the space $\mathscr{H}$ of two-component wave functions is isomorphic to $L^2(\mathbb{R})\oplus L^2(\mathbb{R})$. Here by the vector space $L^2(\mathbb{R})\oplus L^2(\mathbb{R})$, I mean the vector space inner sum of two copies of $L^2(\mathbb{R})$, not the Hilbert space inner sum of these spaces where the sum is also endowed with a canonical inner product. Furthermore, in what follows I allow for negative norms and the terms ''inner product'' and ''Hilbert space'' refer to a Hermitian bilinear (sesquilinear) form and

a vector space endowed with such a form, respectively. [A Hermitian bilinear or sesquilinear form on a complex vector space V is a function $\mu: V\times V\to\mathbb{C}$ which is linear in its second variable and satisfies $\mu(v_1,v_2)=\mu(v_2,v_1)^*$ where* denotes complex conjugation.]

The relation $\mathscr{H}=L^2(\mathbb{R})\oplus L^2(\mathbb{R})$ may be viewed as a restriction on the solutions of the Wheeler–DeWitt equation, since for finite α the elements of $L^2(\mathbb{R})\oplus L^2(\mathbb{R})$ vanish at ''spatial'' infinity, i.e., $\phi=\pm\infty$. This choice seems, however, to be a natural and at the same time a rather general one. It is only restrictive as far as the boundary condition at spatial infinity is concerned. It is still quite general, for it does not correspond to any fixed boundary conditions at $\alpha=\pm\infty$. Furthermore, although $\mathscr{H}$ has two vector subspaces with L^2 inner products, an inner product on $\mathscr{H}$ is not *a priori* fixed.

An inner product (sesquilinear form) on $\mathscr{H}$ may be given by the inner product on $L^2(\mathbb{R})$ and a Hermitian two-by-two matrix h. A particularly advantageous choice for h is $h=\sigma^3=\mathrm{diag}(1,-1)$, i.e.,

$$(\Psi,\tilde{\Psi}):=\langle\Psi^1|\tilde{\Psi}^1\rangle-\langle\Psi^2|\tilde{\Psi}^2\rangle, \tag{15}$$

where $\langle\ |\ \rangle$ denotes the inner product on $L^2(\mathbb{R})$. This choice, on the one hand, renders H ''self-adjoint'' in the sense that for all Ψ, $\tilde{\Psi}\in\mathscr{H}$,

$$(\Psi,H\tilde{\Psi})=(H\Psi,\tilde{\Psi}). \tag{16}$$

[Note that the adjoint of a linear operator is well-defined if one has an inner product which defines a positive definite norm. This is because in the definition of the adjoint of a linear operator one uses the Riesz lemma whose proof makes use of the positive definiteness of the norm.[10] Here the term ''self-adjoint'' refers to the validity of Eq. (16).] On the other hand, it reduces to the Klein–Gordon inner product (for more details see Ref. 4) for the solutions (4) of the Schrödinger equation (5).

Adopting this inner product on $\mathscr{H}$, one can compute

$$(\Psi_{\pm m},\Psi_{\pm n})=(E^*_{\pm m}+E_{\pm n})\,\delta_{mn}\,. \tag{17}$$

Here I have used (10) and the fact that Φ_n are orthonormal. In particular, $(\Psi_{\pm n},\Psi_{\pm n})=2\,\mathrm{Re}(E_{\pm n})=\pm 2|\mathrm{Re}(E_n)|$. Hence, the eigenvectors $\Psi_{\pm n}$ with imaginary eigenvalues (if they exist) have zero norm; they are null vectors. This is of course to be expected since the Hamiltonian satisfies Eq. (16). (Note that it is the nonpositive definiteness of the corresponding norm that allows for imaginary eigenvalues and null eigenvectors to exist.) Furthermore, note that the null eigenvectors are only present for the $\kappa=1$ case.

Another interesting consequence of Eq. (17) is that

$$(\Psi_{\pm n},\Psi_{\mp n})=\begin{cases}0 & \text{for } E_n \text{ real}\\ E_{\mp n} & \text{for } E_n \text{ imaginary.}\end{cases} \tag{18}$$

Hence, if we view $\mathscr{H}$ as the linear span of $\Psi_{\pm n}$, it can be orthogonally decomposed as

$$\mathscr{H}=\mathscr{H}^{(-)}\oplus\mathscr{H}^{(0)}\oplus\mathscr{H}^{(+)}, \tag{19}$$

where $\mathscr{H}^{(-)}$, $\mathscr{H}^{(0)}$, and $\mathscr{H}^{(+)}$ are the linear span of the negative-norm, null, and positive-norm eigenvectors. Note that this decomposition is time dependent (it depends on $a=e^\alpha$), and not every null vector belongs to $\mathscr{H}^{(0)}$. Furthermore, Eq. (18) implies that the basis $\{\Psi_n\}$ (respectively, $\{\Psi_{-n}\}$) of $\mathscr{H}^{(+)}$ (respectively, $\mathscr{H}^{(-)}$) is orthogonal, whereas $\mathscr{H}_0$ can be orthogonally decomposed into the sum of two-dimensional subspaces $\mathscr{H}^{(0)}_n=\mathrm{Span}(\Psi_n\oplus\Psi_{-n})$ with $n\leqslant(a/m-1)/2$, namely

$$\mathscr{H}^{(0)}=\bigoplus_{n=1}^{N}\mathscr{H}^{(0)}_n, \tag{20}$$

where $N:=[(a/m-1)/2]$ is the largest integer part of $(a/m-1)/2$.

Although the inner product (15) has a number of interesting properties, in the remainder of this article I shall not assume that $\mathscr{H}$ is endowed with this inner product. In fact, the results presented in the following sections are independent of the choice of the 2×2 matrix h which determines the inner product on $\mathscr{H}$. I shall only use the well-known Hilbert space properties of the space $L^2(\mathbb{R})$.

IV. ADIABATIC APPROXIMATION

Consider the ansatz

$$\Psi = e^{i\zeta_{\mathscr{N}}}\Psi_{\mathscr{N}}, \tag{21}$$

for the solution of the Schrödinger equation (5), where $\zeta_{\mathscr{N}}$ is a complex-valued function of α, and $\mathscr{N}=\pm n\in\mathbb{Z}$. Plugging (21) in (5) and making use of the eigenvalue equation (9) and the form (10) of the eigenvectors $\Psi_{\mathscr{N}}$, one has:

$$[-(\dot{\zeta}_{\mathscr{N}}+E_{\mathscr{N}})(1+E_{\mathscr{N}})+i\dot{E}_{\mathscr{N}}]\Phi_n+i(1+E_{\mathscr{N}})\dot{\Phi}_n=0,$$

$$[-(\dot{\zeta}_{\mathscr{N}}+E_{\mathscr{N}})(1-E_{\mathscr{N}})-i\dot{E}_{\mathscr{N}}]\Phi_n+i(1-E_{\mathscr{N}})\dot{\Phi}_n=0.$$

Adding and subtracting both sides of these equations, one finds:

$$(\dot{\zeta}_{\mathscr{N}}+E_{\mathscr{N}})\Phi_n-i\dot{\Phi}_n=0,\quad \dot{E}_{\mathscr{N}}=0. \tag{22}$$

Here the first equation implies that for $\tilde{n}\neq n$, $A_{\tilde{n}n}:=i\langle\Phi_{\tilde{n}}|\dot{\Phi}_n\rangle=0$. This requirement together with the second relation in (22) signify the conditions under which the adiabatic approximation would yield an exact solution of the Schrödinger equation. Clearly, $\dot{E}_{\mathscr{N}}\neq 0$ for the case under consideration. Thus the adiabatic approximation cannot be exact. However, approximate solutions may be sought if $\dot{E}_{\mathscr{N}}$ and $A_{\tilde{n}n}$ are small.

Performing the necessary calculations, one can show that for arbitrary non-negative integers $\tilde{n}$ and n:

$$A_{\tilde{n}n}:=i\langle\Phi_{\tilde{n}}|\dot{\Phi}_n\rangle=\frac{3i}{4}\,[\sqrt{n(n-1)}\,\delta_{\tilde{n},n-2}-\sqrt{(\tilde{n})(\tilde{n}-1)}\,\delta_{\tilde{n},n+2}], \tag{23}$$

$$\dot{E}_{\mathscr{N}}=\pm\frac{3\left[n+\frac{1}{2}-\frac{2\kappa a}{3m}\right]\sqrt{m}a^{3/2}}{\sqrt{2n+1-\frac{\kappa a}{m}}}\quad\text{where } \mathscr{N}=\pm n. \tag{24}$$

Equation (23) indicates that the adiabatic approximation is not valid, i.e., the solutions of the form (21) do not exist.

Another consequence of Eq. (23) is that in a mode expansion of a solution Ψ of Eq. (5), the even modes $\Psi_{2\mathscr{N}}$ and the odd modes $\Psi_{2\mathscr{N}+1}$ do not mix in the course of evolution. This suggests the existence of a double grading of the set of solutions. In particular one has the *even* and *odd* solutions:

$$\Psi_{\text{even}}=\sum_{\mathscr{N}=-\infty}^{\infty}Z_{2\mathscr{N}}\Psi_{2\mathscr{N}},\quad \Psi_{\text{odd}}=\sum_{\mathscr{N}=-\infty}^{\infty}Z_{2\mathscr{N}+1}\Psi_{2\mathscr{N}+1}. \tag{25}$$

V. MODE EXPANSION OF THE SOLUTIONS

Consider expressing the solution Ψ of the two-component Wheeler–DeWitt equation (5) as a linear combination of the eigenfunctions $\Psi_{\mathscr{N}}$ of the Hamiltonian:

$$\Psi=\sum_{\mathcal{N}=-\infty}^{\infty} Z_{\mathcal{N}}\Psi_{\mathcal{N}},\quad Z_{\mathcal{N}}=Z_{\mathcal{N}}(\alpha). \tag{26}$$

Substituting this equation in (5) and using Eqs. (9) and (10) to simplify the result, one finds

$$\sum_{n=0}^{\infty}\left[(\dot{\sigma}_n+i\sigma_{-n}E_n)\Phi_n+\sigma_n\dot{\Phi}_n\right]=0, \tag{27}$$

$$\sum_{n=0}^{\infty}\left[(\dot{\sigma}_{-n}E_n+i\sigma_nE_n^2+\sigma_{-n}\dot{E}_n)\Phi_n+\sigma_{-n}E_n\dot{\Phi}_n\right]=0, \tag{28}$$

where

$$\sigma_{\pm n}=\sigma_{\pm n}(\alpha):=Z_n\pm Z_{-n},\quad n=0,1,2,\ldots .$$

Note that in general $Z_{-0}\neq Z_0$ and $\sigma_{-0}\neq\sigma_0$.

Next take the inner product of both sides of Eqs. (27) and (28) with $\Phi_{\tilde{n}}$. Making use of Eq. (23) and orthonormality of Φ_n, one has:

$$\dot{\sigma}_n+iE_n\sigma_{-n}+\tfrac{3}{4}\sqrt{(n+1)(n+2)}\sigma_{n+2}-\tfrac{3}{4}\sqrt{n(n-1)}\sigma_{n-2}=0, \tag{29}$$

$$E_n\dot{\sigma}_{-n}+iE_n^2\sigma_n+\dot{E}_n\sigma_{-n}+\tfrac{3}{4}\sqrt{(n+1)(n+2)}E_{n+2}\sigma_{-(n+2)}-\tfrac{3}{4}\sqrt{n(n-1)}E_{n-2}\sigma_{-(n-2)}=0, \tag{30}$$

where $\sigma_{-(0)}=\sigma_{-0}$.

In order to analyze these equations further, let us solve for σ_{-n} from (29) and substitute the result in (30). Doing the same for $\sigma_{-(n\pm2)}$, one obtains:

$$\sigma_{-n}=\frac{i}{E_n}\left[\dot{\sigma}_n+\frac{3}{4}\sqrt{(n+1)(n+2)}\sigma_{n+2}-\frac{3}{4}\sqrt{n(n-1)}\sigma_{n-2}\right], \tag{31}$$

$$\begin{aligned}\ddot{\sigma}_n+[E_n^2-\tfrac{3}{2}(n^2+n+1)]\sigma_n+\tfrac{3}{2}\sqrt{(n+1)(n+2)}\dot{\sigma}_{n+2}-\tfrac{3}{2}\sqrt{n(n-1)}\dot{\sigma}_{n-2}\\ +(\tfrac{3}{4})^2\sqrt{(n+1)(n+2)(n+3)(n+4)}\sigma_{n+4}+(\tfrac{3}{4})^2\sqrt{n(n-1)(n-2)(n-3)}\sigma_{n-4}=0.\end{aligned} \tag{32}$$

Note that Eq. (32) links only σ_{2n}'s, with $n=0,1,\ldots$, thus making the analysis of the coefficients of non-negative modes independent of those of the negative modes.

Equations (31) and (32) clearly display the splitting of the solutions of the Wheeler–DeWitt equation into even and odd solutions. Since these equations are linear and there is no correlation between the even and odd solutions, every solution is a linear combination of an even and an odd solution. Hence without loss of generality, one can restrict to the analysis of Ψ_{even} and Ψ_{odd}.

Before engaging in this analysis, however, I would like to note that the mode expansion (26) for the two-component wave function Ψ, translates into

$$\psi=\sum_{n=0}^{\infty}\sigma_n\Phi_n, \tag{33}$$

for the one-component wave function. Thus, it is the coefficients of the zero and positive modes that determine the solution of the Wheeler–DeWitt equation (1). The negative modes are related to the derivative of ψ with respect to α. Hence, they are also uniquely determined once the zero and positive modes are given.

In the following sections, I shall show that the mode expansion of the solution of the Wheeler–DeWitt equation (1) is always infinite. This is another way of demonstrating the fact that the adiabatic approximation, which corresponds to including only a single mode in this expansion, always fails. Nevertheless, if one tries to blindly apply the adiabatic approximation or a slightly

improved version of it in which one sets all $\sigma_{\pm n}$ to zero, except $\sigma_{\pm n_*}$ for some n_*, then Eqs. (29) and (30) yield $\ddot{\sigma}_{n*}+E_n^2\sigma_{n*}=0$. This corresponds to the eigenvalue equation for a one-dimensional quantum particle of mass 1/2 and potential $\mathscr{V}(\alpha):=-E_n^2=\kappa e^{4\alpha}-(2n+1)me^{3\alpha}$. Specifically, σ_{n*} is the zero-energy eigenfunction. For $\kappa=1$, $\mathscr{V}$ vanishes at $\alpha=-\infty$. It decreases to attain a negative minimum as α increases, and then monotonically increases to $+\infty$ as $\alpha\to+\infty$. Hence, if one requires the zero-energy eigenfunction to vanish at $\alpha=+\infty$ where $\mathscr{V}=+\infty$, then the mass m must satisfy a peculiar quantization condition. This is analogous to the mass quantization advocated in Ref. 11. However, note that the basic hypothesis of this argument, namely the validity of the adiabatic approximation or alternatively the presence of only a single mode in the mode expansion (33), is never satisfied. Hence, the argument leading to the quantization of mass does not apply.

VI. EVEN SOLUTIONS

Let us first prove:

Lemma 1: An even solution $\Psi_{\rm even}=\Sigma_{\mathscr{N}}Z_{2\mathscr{N}}\Psi_{2\mathscr{N}}$ *is nontrivial, i.e.,* $\Psi_{\rm even}\neq 0$, *if and only if* $\sigma_{\pm 0}\neq 0$.

In order to prove this statement, one sets $n=0$ in Eqs. (29) and (30). This leads to

$$\dot{\sigma}_0+iE_0\sigma_{-0}+\frac{3\sqrt{2}}{4}\,\sigma_2=0, \tag{34}$$

$$E_0\dot{\sigma}_{-0}+\dot{E}_0\sigma_{-0}+iE_0^2\sigma_0+\frac{3\sqrt{2}}{4}\,E_2\sigma_{-2}=0. \tag{35}$$

Therefore, if $\sigma_{\pm 0}=0$, both σ_2 and σ_{-2} must vanish. However, by virtue of Eqs. (32) and (31), this is sufficient to conclude that $\sigma_{2\mathscr{N}}=0$, for all $\mathscr{N}\in\mathbb{Z}$. This completes the proof of Lemma 1. Furthermore, one can prove

Lemma 2: Every nontrivial even solution has an infinite mode expansion.

The even solutions may nevertheless be constructed inductively in terms of $\sigma_{\pm 0}$. This is done by noting that Eqs. (31) and (32) yield trivial algebraic equations for $\sigma_{\pm 2(n+1)}$ in terms of $\sigma_{\pm 2n}$. Performing an induction on n, one can express the coefficients of all the modes as linear combinations of $\sigma_{\pm 0}$ and its derivatives. For example, one has

$$\sigma_2=-\frac{1}{\sqrt{2}}\left(\frac{4}{3}\right)(\dot{\sigma}_0+iE_0\sigma_{-0}), \tag{36}$$

$$\sigma_4=\frac{1}{\sqrt{4!}}\left(\frac{4}{3}\right)^2\left[\ddot{\sigma}_0+2iE_0\dot{\sigma}_{-0}+\left(\frac{3}{2}-E_0^2\right)\sigma_0+2i\dot{E}_0\sigma_{-0}\right]. \tag{37}$$

It is easily seen that as a result of this construction σ_{2n} involves the first n derivatives of σ_0, first $n-1$ derivatives of σ_{-0}, and the first $n-1-j$ derivatives of E_{2j}, for $j=0,1,\ldots,n-1$.

Since according to Eq. (24), $\dot{E}_n$ diverges at the zero of E_n, demanding regularity of σ_n would impose certain conditions on $\sigma_{\pm 0}$. In fact, in view of the appearance of E_n^2 in Eq. (32), which is analytic for every α, one can easily show that the only source of possible singularity is the term proportional to E_0 in the expression for σ_2. Thus, in order to ensure the regularity of σ_{2n}, one must require that at the zero of E_0, i.e., $\alpha=\ln(m/\kappa)$, $\sigma_{-0}E_0$ and all its derivatives must vanish. In other words there must be an open neighborhood $\mathscr{O}$ of $\alpha=\ln(m/\kappa)$, in which $\sigma_{-0}(\alpha)$ is of the form $E_0(\alpha)f(\alpha)$ for some smooth (C^∞) function f. In particular $\sigma_{-0}(\ln(m/\kappa))$ must vanish. Note that for the flat ($\kappa=0$) and open ($\kappa=-1$) cases, this condition is void and σ_{2n} are regular if and only if $\sigma_{\pm 0}$ are regular.

Finally note that termination of the mode expansion for a nontrivial even solution is equivalent to vanishing of at least three consecutive σ_{2n}'s. This would impose three functional conditions on $\sigma_{\pm 0}$ which are in general incompatible. This proves Lemma 2.

VII. ODD SOLUTIONS

The structure of the odd solutions is similar to that of the even solutions. The role of $\sigma_{\pm 0}$ is played by $\sigma_{\pm 1}$. In particular, one has

Lemma 3: An odd solution $\Psi_{\rm odd}=\Sigma_{\mathcal{N}} Z_{2\mathcal{N}+1}\Psi_{2\mathcal{N}+1}$ *is nontrivial, if and only if* $\sigma_{\pm 1}:=Z_1 \pm Z_{-1}\neq 0$.

This is a direct consequence of Eqs. (29) and (32) which also provide an inductive construction of the mode coefficients $\sigma_{\pm(2n+1)}$ in terms of $\sigma_{\pm 1}$. For example one has:

$$\sigma_3=-\frac{1}{\sqrt{3!}}\left(\frac{4}{3}\right)(\dot{\sigma}_1+iE_1\sigma_{-1}), \tag{38}$$

$$\sigma_5=\frac{1}{\sqrt{5!}}\left(\frac{4}{3}\right)^2\left[\ddot{\sigma}_1+2iE_1\dot{\sigma}_{-1}+\left(\frac{9}{2}-E_1^2\right)\sigma_1+2i\dot{E}_1\sigma_{-1}\right]. \tag{39}$$

A natural consequence of this inductive construction is

Lemma 4: Every nontrivial odd solution has an infinite mode expansion.

The regularity condition on the odd solutions is analogous to the even case. One can again show that the only source of possible singularity is the term $E_1\sigma_{-1}$ in the expression for σ_3. Hence the regularity of σ_{2n+1} and therefore ψ is ensured by requiring that in the vicinity of the zero of E_1, namely $\alpha=\ln(3m/\kappa)$, σ_{-1} must be of the form $E_1(\alpha)g(\alpha)$, for some smooth function g.

The occurrence of two free functions of α in the construction of even and odd solutions is in complete agreement with the general structure of the Wheeler–DeWitt/Klein–Gordon equation (1) whose solutions depend on two boundary or two initial conditions. The latter are given by two functions of α which in the above procedure can be used to determine $\sigma_{\pm 0}$ or $\sigma_{\pm 1}$ depending on whether the solution is even or odd. In general the solution will be the sum of an even and an odd part. In this case the boundary (initial) conditions would determine both $\sigma_{\pm 0}$ and $\sigma_{\pm 1}$. Once these functions are determined the above iterative construction yields the mode expansion of the general solution.

VIII. REAL SOLUTIONS

Probably the best-known proposal for the solution of the Wheeler–DeWitt equation is that of Hartle and Hawking[12] who suggested the path integral expression $\psi\propto\int \exp(-I)$ for the ground state wave function. Here I stands for the Euclidean action. The Hartle–Hawking wave function is by construction real.

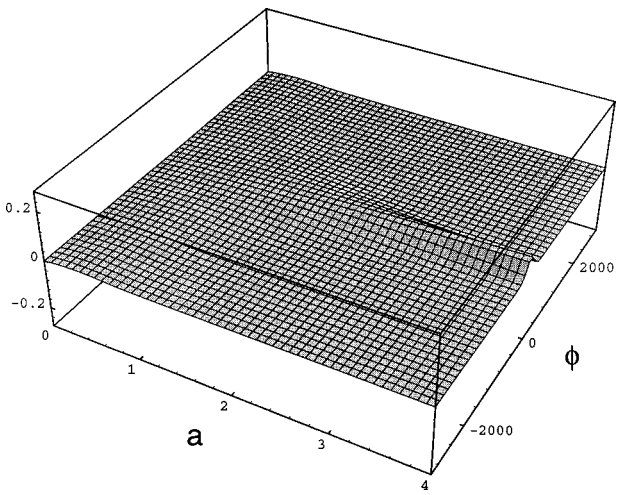

FIG. 1. Plot of $\psi_0=\psi_2=\Sigma_{n=0}^{2}\,\sigma_n\Phi_n$, for $\sigma_{\pm 1}=\sigma_{-0}=0$, $\sigma_0=1$, and $m=10^{-6}$.

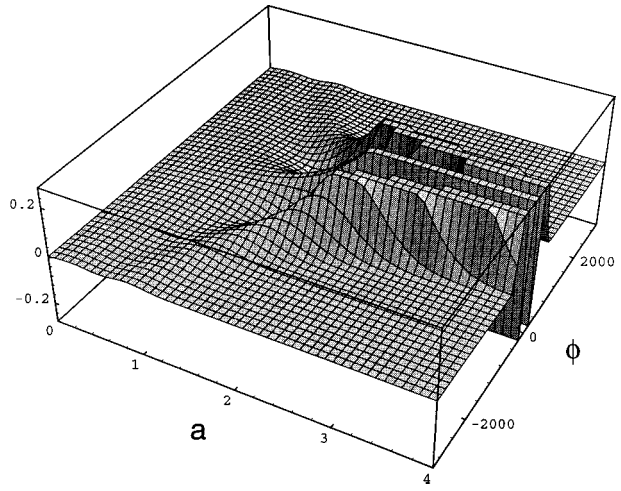

FIG. 2. Plot of $\psi_4:=\Sigma_{n=0}^{4}\ \sigma_n\Phi_n$, for $\sigma_{\pm 1}=\sigma_{-0}=0$, $\sigma_0=1$, and $m=10^{-6}$.

It is not difficult to see that the reality of the one-component solution of the Wheeler–DeWitt equation implies the reality of the coefficient functions σ_n in its mode expansion (33). This is because Φ_n are already real. In view of this observation and Eq. (29), $E_n\sigma_{-n}$ must be imaginary. However, as discussed in Sec. II for the open and flat universes ($\kappa=-1,0$), E_n is always real so that σ_{-n} must be imaginary. For the close universe ($\kappa=1$) E_n is real for $a\leqslant m(2n+1)$ and imaginary otherwise. Hence in this case ($\kappa=1$) the opposite holds for σ_{-n}, i.e., it is imaginary for $a<m(2n+1)$ and real for $a>m(2n+1)$.

These conditions can also be stated as the reality condition on σ_0, σ_1, σ_2, and σ_3 which also generate the solutions. Therefore, they are rather trivial.

IX. APPROXIMATE SOLUTIONS

As shown in the preceding sections, the mode expansion of the solutions never terminates. Therefore, one cannot use it to construct an exact solution unless one can actually find the generic expression for the mode coefficients and sum the series. This is an almost impossible task. However, one can terminate the mode expansion artificially and obtain an infinite class of approximate solutions. $\psi\approx\psi_{n_*}:=\Sigma_{n=0}^{n_*}\ \sigma_n\Phi_n$. The domain of reliability of this solution will in general depend on the boundary (initial) conditions, alternatively the functions $\sigma_{\pm 0}$ and $\sigma_{\pm 1}$.

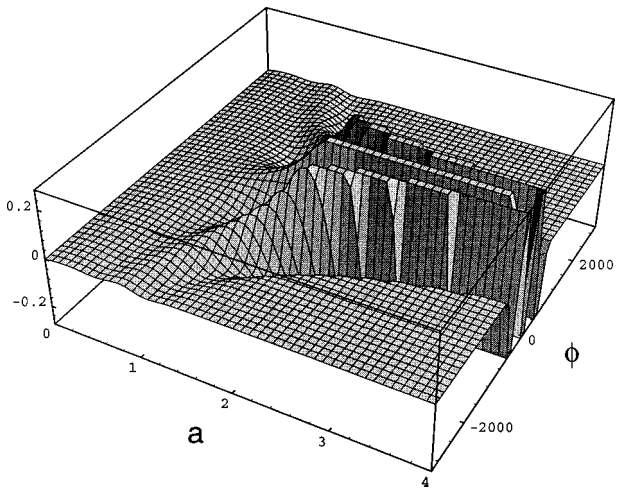

FIG. 3. Plot of $\psi_6:=\Sigma_{n=0}^{6}\ \sigma_n\Phi_n$, for $\sigma_{\pm 1}=\sigma_{-0}=0$, $\sigma_0=1$, and $m=10^{-6}$.

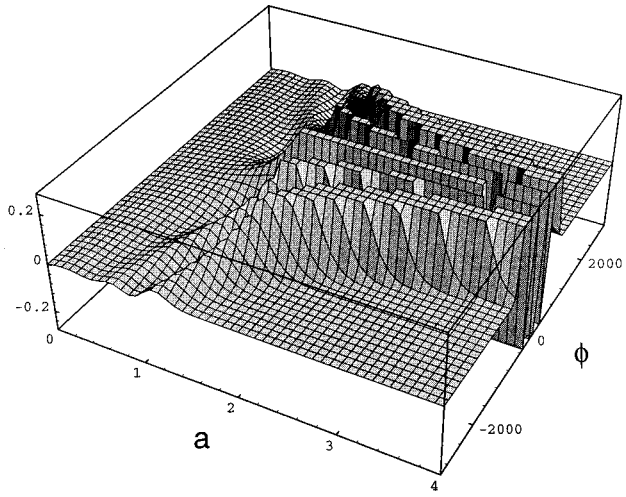

FIG. 4. Plot of $\psi_8 := \Sigma_{n=0}^{8}\ \sigma_n \Phi_n$, for $\sigma_{\pm 1} = \sigma_{-0} = 0$, $\sigma_0 = 1$, and $m = 10^{-6}$.

In this section, I shall examine the simple choice $\sigma_{-0} = \sigma_{\pm 1} = 0$ and $\sigma_0 = 1$. Clearly, this corresponds to a real even solution whose mode coefficients can be obtained using Eq. (32). For example for the closed FRW case where $\kappa = 1$, one has

$$\sigma_2 = 0, \quad \sigma_4 = (\tfrac{2}{3})^{5/2}(\tfrac{3}{2} + a^4 - ma^3), \quad \sigma_6 = \left(\frac{32a^3}{81\sqrt{5}}\right)(3m - 4a),$$

$$\sigma_8 = \frac{4}{243}\sqrt{\frac{2}{35}}\,(4a^8 - 40ma^7 + 36m^2a^6 + 324a^4 - 288ma^3 + 189),$$

$$\sigma_{10} = -\frac{16}{10935\sqrt{7}}\,(96a^5 - 1000ma^4 + 744m^2a^3 + 3604a - 2655m)a^3.$$

Substituting these relations in the expression for ψ_n and making use of the identity[13]

$$H_n(x) = 2^n x^n + \sum_{i=1}^{[n/2]} (-1)^i 2^{n-i}(2i-1)!!\binom{n}{2i} x^{n-2i},$$

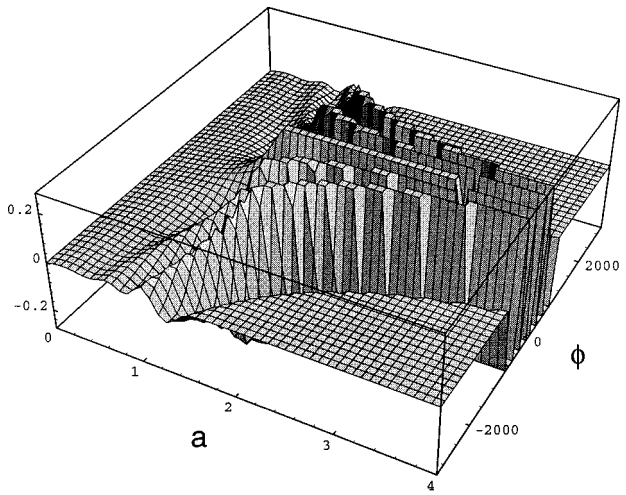

FIG. 5. Plot of $\psi_{10} := \Sigma_{n=0}^{10}\ \sigma_n \Phi_n$, for $\sigma_{\pm 1} = \sigma_{-0} = 0$, $\sigma_0 = 1$, and $m = 10^{-6}$.

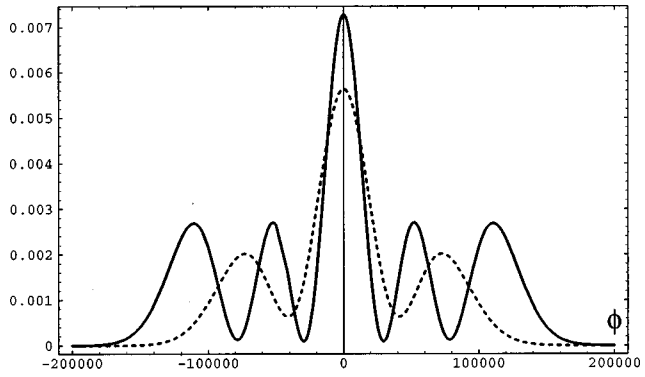

FIG. 6. Plot of the restriction of ψ_6 (dotted line), ψ_8 (dashed line), and ψ_{10} (full line) to the $a=0.1$ line. Note that the graphs of ψ_8 and ψ_{10} coincide for this value of a. This shows the reliability of the finite mode approximation. Note also the range of the values of ϕ over which ψ_n are nonzero.

to calculate the mode functions Φ_n, one can compute $\psi_0=\psi_2$, ψ_4, ψ_6, ψ_8 and ψ_{10}. Figures 1–5 illustrate three-dimensional plots of these functions. Figures 6–9 are plots of the restriction of ψ_6, ψ_8, and ψ_{10} to the lines $a=0.1,1,10,100$. These figures show that for small a the finite mode approximation is quite reliable. In fact, as depicted in Fig. 6, for $a=0.1$, the graphs of ψ_8 and ψ_{10} coincide. For larger a one may improve the approximation by including the contribution of higher modes.

Note also that initially ψ_n are nonzero for a wide range of values of ϕ. However, as a increases the width of this region, which is symmetric with respect to the line $\phi=0$, shrinks. This is easily seen from Figs. 6–9. Note also that for large a, the solutions picks about $\phi=0$ and the approximate solutions become less reliable. As $a\to\infty$, all the approximate solutions seem to vanish except at $\phi=0$.

X. DISCUSSION AND CONCLUSION

Probably the most important aspect of the two-component formulation of the Wheeler–DeWitt equation is the fact that the construction of the solutions in this formulation does not, *a priori*, require fixing a particular inner product or boundary conditions. The freedom in the choice of the inner product is reflected as the independence of the mode expansion from the choice of the Hermitian matrix h which together with the L^2 inner product on $L^2(\mathbb{R})$ determines the inner product on $\mathscr{H}=L^2(\mathbb{R})\oplus L^2(\mathbb{R})$. As far as the boundary conditions are concerned, besides the implicit restriction of vanishing boundary condition at ''spatial'' infinity, the analysis presented here applies generally.

An interesting consequence of the application of the two-component formalism is a specific double grading of the solutions of the Wheeler–DeWitt equation. This allows one to write down

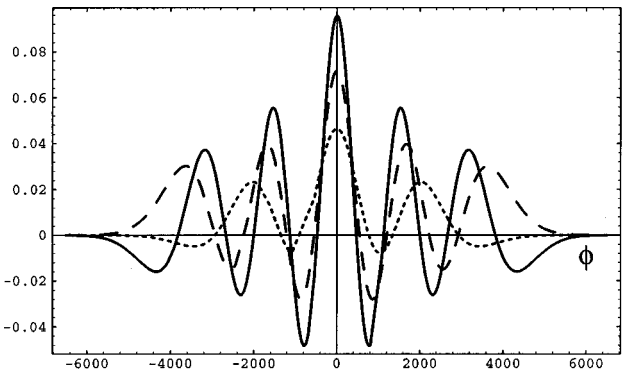

FIG. 7. Plot of the restriction of ψ_6 (dotted line), ψ_8 (dashed line), and ψ_{10} (full line) to the $a=1$ line. Note the range of the values of ϕ over which ψ_n are nonzero.

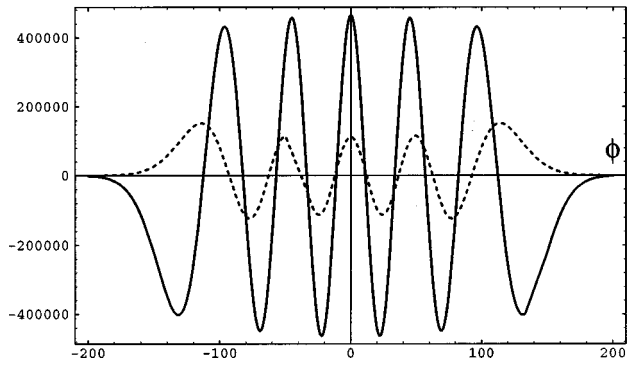

FIG. 8. Plot of the restriction of ψ_8 (dotted line), and ψ_{10} (full line) to the $a=10$ line. Note the range of the values of ϕ over which ψ_n are nonzero.

the most general solution of this equation as a sum of definite-parity (even and odd) solutions whose structure can be easily understood. The two definite-parity parts of the solution do not mix during the evolution. In particular, if the initial wave function has definite parity, its parity remains intact throughout the evolution.

Unfortunately, the mode expansion of the solutions never terminates. Thus, a closed expression for an exact solution cannot be found in this way. However, approximate solutions can be constructed by artificially terminating the mode expansion. The domain of applicability of such approximations depend generally on the boundary (initial) conditions.

An alternative approximation is the adiabatic approximation which is, however, not valid. The ansatz of the adiabatic approximation, i.e., $\psi\approx\sigma_n(\alpha)\Phi_n(\alpha,\phi)$, is reminiscent of the application of the Born–Oppenheimer approximation in quantum cosmology originally advocated by Banks.[14] In this approach one views the gravitational degrees of freedom as the ''slow'' variables and the matter degrees of freedom as the ''fast'' variables and considers solutions of the form $\psi=\psi_{\text{gravity}}(\alpha)\psi_{\text{matter}}(\alpha,\phi)$. The results of this article indicate that for $\psi_{\text{matter}}=\Phi_n$ such an approximation cannot be valid.

Another notable implication of the results of this article is regarding the implicit boundary condition at the initial singularity $a=0$. If one assumes that the coefficient functions σ_n are regular at $a=0$, then as a consequence of the appearance of $a^{3/4}$ in the expression for Φ_n, the one-component wave-function ψ vanishes at $a=0$. This is much in the spirit of an argument of DeWitt.[15] Here it follows as a direct consequence of a regularity condition (which may or may not hold). As seen from Figs. 1 to 5, the choice $\sigma_{-0}=\sigma_{\pm1}=0$ and $\sigma_0=1$ leads to approximate solutions which are regular at $a=0$. They clearly satisfy DeWitt's boundary conditions.

A problem which is not addressed in this article is that of the convergence of the mode expansion in $\mathscr{H}$. This is a difficult problem and I have not been able to find the necessary and sufficient conditions under which the mode expansion converges. In fact, a rigorous convergence

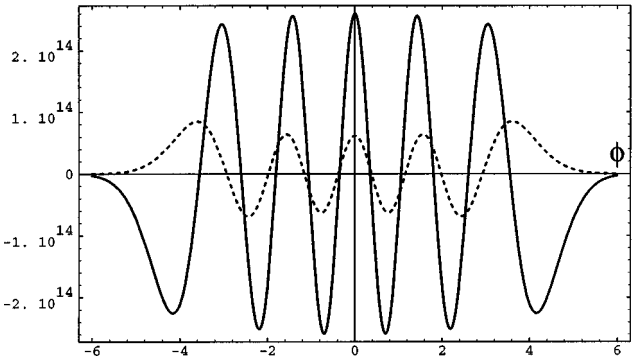

FIG. 9. Plot of the restriction of ψ_8 (dotted line), and ψ_{10} (full line) to the $a=100$ line. Note the range of the values of ϕ over which ψ_n are nonzero.

analysis requires a choice of a positive-definite inner product (norm) on $\mathscr{H}$. However, as demonstrated in Sec. IX, there are regions of the minisuperspace in which the contribution from the higher order modes is small. This may be viewed as an indication of possible pointwise asymptotic convergence of the mode expansion in this regions. This argument is however far from being satisfactory and further investigation of this point is necessary.

Finally, I wish to emphasize the following points.

(1) The fact that the two-component Hamiltonian (6) belongs to the dynamical Lie algebra $\mathrm{su}_s(1,1)\otimes\mathrm{su}_u(1,1)$ suggests a further investigation of the solution of the corresponding Schrödinger equation using the group theoretical methods such as those employed in solving the Schrödinger equation for time-dependent harmonic oscillators.[16] Recall that the Hamiltonian for a time-dependent harmonic oscillator belongs to $\mathrm{su}_u(1,1)$.[6]

(2) The two-component approach to Wheeler–DeWitt equation has a wider domain of applicability than the simple minisuperspace model studied in this article. For example, the addition of an interaction potential for the scalar field would only complicate the defining equation for Φ_n and the inductive construction of the mode expansion. The general structure of the method would however remain intact. In particular, the ϕ-dependence of the solutions would still be given by Φ_n. More generally, for any other minisuperspace, in the gauge in which the shift vector corresponding to DeWitt's supermetric[15] vanishes, the two-component Hamiltonian is of the form (6), where D is some second-order elliptic operator. Therefore, even in this case the developments reported in this article are essentially applicable.

Note added in proof: After the completion of this work, Refs. 17, 18 were brought to my attention where the authors use two different two-component formulations of the Wheeler–DeWitt equation. The methods described in these articles differ substantially from the present article's. I have also noticed a recent paper by Embacher[19] who defines the operator D of Eq. (7) as the (matter) energy operator and obtains the mode expansion (33) in the context of the one-component Wheeler–DeWitt equation. He does not, however, obtain the equations satisfied by the mode coefficients. Instead, he focuses on the semiclassical and adiabatic approximations. The two-component approach developed in this paper justifies the choice of the mode functions made by Embacher in a very natural way. It also makes it possible to obtain the structure of the mode expansion by iteratively solving for the mode coefficients.

(Received 13 March 1998; accepted for publication 23 April 1998)

A quantum version is presented for the Anosov system defined by the time evolution implemented by the geodesic coflow on the cotangent bundle of any compact quotient manifold obtained from the Poincaré half-plane. While the canonical Weyl algebra does not close under time evolution, the symplectic structure of these classical systems can be exploited to produce objects akin to the CCR algebras encountered in quantum field theory. This construction allows one to lift both the geodesic and the horocyclic flows to a Weyl algebra describing the quantum dynamics corresponding to the systems under consideration. The Anosov relations as proposed in Ref. 1 are found to be valid for these models. A quantum version of the classical ergodicity of these systems is discussed in the last section. © *1998 American Institute of Physics.* [S0022-2488(98)02109-4]

I. INTRODUCTION: THE CLASSICAL ARCHETYPE

The classical theory of Anosov systems describes a class of unstable dynamical systems. Recently a general axiomatic framework for a possible noncommutative extension of the Anosov theory to the quantum realm has been proposed and developed in this Journal;[1] see also Ref. 2. However, up to now, the only existing examples of quantum Anosov systems are the quantum version of the ''Arnold Cat'' and the modular action of the Lorentz group on a Rindler wedge. Moreover, it is argued in Ref. 1 that the usual, or canonical, quantization of the archetype of classical Anosov systems—namely free motion of a particle moving on a compact Riemannian manifold of constant negative curvature—cannot carry over the Anosov structure: The spectrum of the Laplace–Beltrami operator is discrete, so that the resulting quantum system is not even ergodic. The purpose of the present paper is to propose an alternative quantization scheme that carries over the full Anosov structure.

The classical situation can be summarized as follows. The exponential sensitivity to initial conditions of the geodesic flow in Lobatchevski hyperbolic geometry was noticed already by the end of the last century,[3] and it can be regarded as the prototype for the study of Anosov structures.[4]

Specifically, three flows are defined, first on the cotangent bundle T^*M of the Poincaré half-plane, i.e., the two-dimensional, simply connected Riemannian manifold (M,g) of constant negative curvature $\kappa=-\rho^2$. These flows are the geodesic flows $\mathrm{Fl}_t^{X_H}$ and the two horocyclic flows $\mathrm{Fl}_s^{E_\pm}$. They satisfy the Anosov relations

$$\mathrm{Fl}_{-t}^{X_H}\circ\mathrm{Fl}_s^{E_\pm}\circ\mathrm{Fl}_t^{X_H}=\mathrm{Fl}_{\mathrm{e}^{\pm\rho t}s}^{E_\pm}, \tag{1.1}$$

where the corresponding vector fields X_H and $E_\pm$—for details, see Lemma A4 and Remark A5—will be subsequently normalized by $r^2=g(G_\pm,G_\pm)=g(H_\pm,H_\pm)$; for transparency, we simply chose in this section the usual normalization $r=1$. These complete vector fields then satisfy the Anosov commutation relations (ACRs)

$$[X_\pm,E_\pm]=\pm\rho\,E_\pm\,. \tag{1.2}$$

Suffice it to say here that: (i) the vector field X_H is the Hamiltonian vector field for the Hamiltonian

 © 1998 American Institute of Physics

$$H(x^i,p_i):=\tfrac{1}{2}g^{\sharp}((x^i,p_i),(x^i,p_i))=\tfrac{1}{2}(p_1^2+p_2^2); \tag{1.3}$$

(ii) the vector fields $E_{\pm}$ are the expanding (respectively, contracting) *horocyclic vector fields*; (iii) the constants $\pm\rho$ appearing in these ACRs are to be interpreted as the *Lyapunov coefficients* for this dynamical system; and (iv) while the geodesic flow is a symplectic action, this is *emphatically not* the case for the horocyclic flows (see Proposition A9).

In order to obtain a probability measure invariant under the dynamics, one finally restricts the above flows to the unit cotangent bundle of certain compact quotients Γ/M of the Poincaré half-plane M by co-compact, discrete subgroups Γ of the symmetry group $\mathrm{SL}(2,R)$ of M. It is the resulting dynamical system that is the classical archetype for the quantum structures we want to construct: it is indeed a C-flow, and thus satisfies in particular the following properties (listed in descending strength): it is a K-flow, it is mixing with uniform Lebesgue spectrum, and it is ergodic.[4]

Appendix A presents a fuller, self-contained treatment of this classical model, together with further bibliographical references. The presentation is made in a notation that covers a two-parameter family of models. This is done with two purposes in mind. The first is to facilitate quantization; the second is to allow, at some ulterior stage, a smooth passage to the flat limit where the ergodic behavior disappears. This notation is therefore systematically used in the main body of the paper.

In *Appendix B*, we discuss a no-go theorem showing why the canonical quantum realization of the Weyl algebra does not allow one to implement the time evolution as a geometric action by automorphisms.

In *Sec. II*, we show how to enlarge the quantum algebra to obtain a dynamics implemented by a group of automorphisms; this new Weyl C*-algebra is described in detail.

In *Sec. III*, we construct quantum versions of the horocyclic actions on this algebra implementing the Anosov relations.

Section IV describes how to restrict the quantum hyperbolic systems, when the Poincaré half-plane is replaced by any compact, complete, connected two-dimensional manifolds of constant negative curvature, so that the full quantum Anosov structure can be displayed.

Section V specifically addresses the ergodicity of the quantum systems so obtained, in terms of the existence of states that are invariant under geodesic and horocyclic actions.

II. QUANTUM DYNAMICS

When naturally extended[5,6] to curved configuration spaces, the usual construction of the quantum Weyl group is known to allow a proper description of the kinematics. However, it may fail to sustain a self-contained description of the dynamics. We show in Appendix B that, indeed, this is already the case for the geodesic flow on the Poincaré half-plane.

Consequently, we propose in this section an alternative Weyl algebra, built directly on a class of smooth functions on the *phase space*. The idea in the background is that, classically, the algebra of (exponentiated) observables is given by essentially bounded functions $L^{\infty}(T^*M,\mathbb{C})$ on the phase space. Our definition has the advantage that time evolution can be defined. The first step in this direction is to find a reasonable symplectic structure on the space of smooth functions with compact support $C_c^{\infty}(T^*M,\mathbb{R})$ on the phase space T^*M of our classical models.

Definition 2.1: With the notations introduced in Appendix A, let $C_c^{\infty}(T^*M_{\mu,\lambda},\mathbb{R})$ denote the space of smooth functions of compact support on the cotangent bundle $T^*M_{\mu,\lambda}$. Let H denote the Hamiltonian, and $\{\,.\,,\,.\,\}$ the Poisson bracket. We define a degenerate skew-symmetric bilinear form on $C_c^{\infty}(T^*M_{\mu,\lambda},\mathbb{R})$ by

$$\sigma(f,g):=\int_{T^*M_{\mu,\lambda}} H\{f,g\}\quad \omega\wedge\omega \qquad \forall f,g\in C_c^{\infty}(T^*M_{\mu,\lambda},\mathbb{R}). \tag{2.1}$$

We denote by (V,σ) the degenerate symplectic vector space $(C_c^{\infty}(T^*M_{\mu,\lambda},\mathbb{R}),\sigma)$.

Remark 2.2: In Proposition 2.5 below, we will compute the ''kernel'' of the symplectic form σ and obtain a nondegenerate symplectic vector space. The construction of Weyl algebras with degenerate symplectic vector spaces has been examined in Ref. 7.

Lemma 2.3: The skew-symmetric form σ may also be written equivalently as

$$(a)\quad \sigma(f,g)=\int_{T^*M_{\mu,\lambda}}(fdg-gdf)\wedge dH\wedge\omega,$$

$$(b)\quad \sigma(f,g)=\frac{1}{2}\int_{T^*M_{\mu,\lambda}}(f\{g,H\}-g\{f,H\})\ \omega\wedge\omega,$$

where $f,g\in V$ and H is the Hamiltonian.

Proof: We compute

$$\begin{aligned}(fdg-gdf)\wedge dH\wedge\omega&=-d(H(fdg-gdf)\wedge\omega)+2Hdf\wedge dg\wedge\omega\\&=-d(H(fdg-gdf)\wedge\omega)+H\ i_{X_g}df\ \omega\wedge\omega\\&=-d(H(fdg-gdf)\wedge\omega)+H\{f,g\}\ \omega\wedge\omega.\end{aligned}\tag{2.2}$$

Finally using Stoke's theorem yields (a). In order to show the equality (b), we compute

$$\begin{aligned}(fdg-gdf)\wedge dH\wedge\omega&=(fdg-gdf)\wedge i_{X_H}\omega\wedge\omega\\&=\tfrac{1}{2}(fdg-gdf)\wedge i_{X_H}(\omega\wedge\omega)\\&=\tfrac{1}{2}(i_{X_H}(fdg-gdf))\ \omega\wedge\omega\\&=\tfrac{1}{2}(f\ i_{X_H}dg-g\ i_{X_H}df)\ \omega\wedge\omega\\&=\tfrac{1}{2}(f\{g,H\}-g\{f,H\})\ \omega\wedge\omega.\end{aligned}\tag{2.3}$$

□

Remark 2.4: The naive candidate $\int\{f,g\}\ \omega\wedge\omega$ does not work as a symplectic form, since the integrand is exact. Indeed, for any $f,g\in C_c^\infty(T^*M_{\mu,\lambda},\mathsf{R})$, we have:

$$\begin{aligned}\{f,g\}\ \omega\wedge\omega&=(i_{X_g}df)\ \omega\wedge\omega\\&=df\wedge i_{X_g}(\omega\wedge\omega)\\&=2df\wedge dg\wedge\omega=d((fdg-gdf)\wedge\omega).\end{aligned}\tag{2.4}$$

Proposition 2.5: Let V_0 be the ''kernel'' V_0 of σ defined as

$$V_0:=\cap_{f\in V}\{g\in V|\sigma(f,g)=0\}.$$

Then

$$V_0=\{g\in V|\{g,H\}=0\},$$

i.e., V_0 coincides with the constants of motion. $V_0\subset V$ is an algebra. The symplectic form σ factors to a nondegenerate symplectic form $\tilde{\sigma}:\tilde{V}\times\tilde{V}\to\mathsf{R}$ on the vector space $\tilde{V}:=V/V_0$: $\tilde{\sigma}([f],[g]):=\sigma(f,g)$ for $f,g\in V$, where $[.]:V\to\tilde{V}$ denotes the quotient mapping.

Proof: From Lemma 2.3, we know that $g\in V_0$ iff we have for all $f\in V$:

$$\int_{T^*M_{\mu,\lambda}}f\{g,H\}\ \omega\wedge\omega=\int_{T^*M_{\mu,\lambda}}g\{f,H\}\ \omega\wedge\omega\tag{2.5}$$

and therefore

$$2\int_{T^*M_{\mu,\lambda}} f\{g,H\}\ \omega\wedge\omega=\int_{T^*M_{\mu,\lambda}} (f\{g,H\}+g\{f,H\})\ \omega\wedge\omega$$
$$=\int_{T^*M_{\mu,\lambda}} \{fg,H\}\ \omega\wedge\omega. \tag{2.6}$$

By Remark 2.4 the second line in the above expression vanishes. Hence

$$\int_{T^*M_{\mu,\lambda}} f\{g,H\}\ \omega\wedge\omega=0 \quad \forall f\in V \tag{2.7}$$

and thus $\{g,H\}=0$. □

Remark 2.6: Let us choose a coordinate system on the cotangent bundle $T^*M_{\mu,\lambda}$ where $r=|p|$ is singled out; the Hamiltonian then takes the form $H=H(r)=\frac{1}{2}r^2$, and the corresponding Hamiltonian vector field reads:

$$X_H(x^1,x^2,r,\psi)=r\ \cos\ \psi\cdot s^1+r\ \sin\ \psi\cdot s^2+\frac{2\lambda r}{\mu}\ \sin\ \psi\ \partial_\psi. \tag{2.8}$$

Whence we get the following explicit condition for g to belong to the kernel V_0:

$$0=\{g,H\}=X_H(g)$$
$$=\frac{1}{\mu}r\ \cos\ \psi\ (\partial_{x^1}g)+re^{-2\lambda x^1}\ \sin\ \psi\ (\partial_{x_2}g)+\frac{2\lambda r}{\mu}\ \sin\ \psi(\partial_\psi g). \tag{2.9}$$

Any function $g=g(r)$ depending only on the variable r, which is essentially energy, satisfies this relation. The absence of other constants of the motion is the statement that the classical system is ergodic as long as long as the curvature does not vanish. As the flat situation is reached in the limit where $(\mu,\lambda)=(1,0)$, (2.9) reduces to

$$0=\cos\ \psi\ (\partial_{x^1}g)+\sin\ \psi\ (\partial_{x^2}g) \tag{2.10}$$

from which we read that new constants of the motion do appear in this limit: functions depending not only on r, but also on ψ (i.e., not only the energy, but the angular momentum as well). Thus, the vector space $\tilde{V}:=V/V_0$ can be considered as a space of functions ''living'' on the configuration space, *only* in the flat limit: This fact prompted our formulation—one of the main objects of this paper—of the solution to the quantization problem for the curved case.

Lemma 2.7: Let $\Phi:T^*M_{\mu,\lambda}\to T^*M_{\mu,\lambda}$ be a diffeomorphism, that is ω-symplectic and leaves the Hamiltonian H invariant. Then σ is invariant under

$$\Phi^*: f\in V\mapsto f\circ\Phi\in V.$$

Proof:

$$\sigma(\Phi^*f,\Phi^*g)=\int_{T^*M_{\mu,\lambda}} H\{\Phi^*f,\Phi^*g\}\ \omega\wedge\omega$$
$$=\int_{T^*M_{\mu,\lambda}} H\Phi^*\{f,g\}\ \omega\wedge\omega$$
$$=\int_{T^*M_{\mu,\lambda}} \Phi^*(H\{f,g\}\ \omega\wedge\omega)$$
$$=\int_{T^*M_{\mu,\lambda}} H\{f,g\}\ \omega\wedge\omega=\sigma(f,g), \tag{2.11}$$

where we used that symplectomorphisms may be passed through Poisson bracket, H and ω are

invariant under Φ by hypothesis. □

Definition 2.8: For $[f]\in\widetilde{V}$ consider the *-algebra $\Delta(\widetilde{V},\widetilde{\sigma})$ C-generated by elements $W([f])$ with multiplication law

$$W([f])W([g]):=e^{-i\hbar\sigma([f],[g])}W([f+g]) \quad \forall [f],[g]\in\widetilde{V}$$

and an involution defined by $W([f])^*:=W([-f])$. Note that $\Delta(\widetilde{V},\widetilde{\sigma})$ is linearly generated by the $W([f])$. The elements $W([f])$ become unitaries, the unit of the algebra is $W([0])=:\mathsf{I}$. An arbitrary element $R\in\Delta(\widetilde{V},\widetilde{\sigma})$ may thus be written as a finite sum $R=\Sigma_{i=1}^{N}\beta_i W([f_i])$ for $f_i\in\widetilde{V}$ and $\beta_i\in\mathsf{C}$. One knows[7] that there exists a unique C*-norm on this *-algebra, such that its completion with respect to this norm is a C*-algebra: we denote this C*-algebra by $\mathcal{W}:=\overline{\Delta(\widetilde{V},\widetilde{\sigma})}$, and call it the Weyl C*-algebra of our system.[8,9]

Remarks 2.9: (1) At this level, $\hbar$ is merely a parameter which, if put to zero, makes the Weyl algebra Abelian. In fact, if $\hbar=0$ the map

$$\mathcal{W}\ni W([f])\mapsto \mathrm{e}^{if}\in L^{\infty}(T^*M_{\mu,\lambda},\mathsf{C})$$

provides an isomorphism from the Weyl algebra $\mathcal{W}$ to the classical Abelian algebra of observables $L^{\infty}(T^*M_{\mu,\lambda},\mathsf{C})$. (2) The *-algebra $\Delta(\widetilde{V},\widetilde{\sigma})$ has the following locality property: if $f,g\in V$ such that $\mathrm{supp}(f)\cap\mathrm{supp}(g)=\varnothing$, then $W([f])$ commutes with $W([g])$.

Proposition 2.10: Let Fl^{X_H} be the classical geodesic flow. Then

$$\tau_t W([f]):=W([(\mathrm{Fl}_t^{X_H})^*f])\equiv W([f_t])$$

defines a one-parameter group $\tau:\mathsf{R}\to\mathrm{Aut}(\mathcal{W})$ of *-automorphisms of the Weyl algebra $\mathcal{W}$.

In the sequel, the τ_t will be referred to as *the geodesic automorphisms*.

Proof: Let $\Phi:T^*M_{\mu,\lambda}\to T^*M_{\mu,\lambda}$ be a symplectomorphism on the cotangent bundle, that leaves the Hamiltonian invariant, let $\tau_\Phi W([f]):=W([\Phi^*f])$; this is well-defined. Indeed, if $\{H,f\}=0$, then

$$\{H,\Phi^*f\}=\{H,f\circ\Phi\}=\{H\circ\Phi,f\circ\Phi\}=\{H,f\}\circ\Phi=0. \tag{2.12}$$

Further

$$\begin{aligned}\tau_\Phi W(f)\tau_\Phi W(g)&=W(\Phi^*f)W(\Phi^*g)\\&=W(\Phi^*(f+g))\exp(-i\hbar\sigma(\Phi^*f,\Phi^*g))\\&=W(\Phi^*(f+g))\exp(-i\hbar\sigma(f,g)\\&=\tau_\Phi W(f+g)\exp(-i\hbar\sigma(f,g))\\&=\tau_\Phi(W(f)W(g))\end{aligned} \tag{2.13}$$

shows that τ_Φ defines indeed an automorphism of the Weyl algebra. The one-parameter group property is trivial. Finally observe that the lifted geodesic flow $\mathrm{geo}(.;t):T^*M_{\mu,\lambda}\to T^*M_{\mu,\lambda}$ satisfies all demanded requirements: It is symplectic due to Proposition A.9.1 and leaves the Hamiltonian invariant, as it is contained in the r-sphere bundle $T_r^*M_{\mu,\lambda}$. □

III. EXPANDING AND CONTRACTING AUTOMORPHISMS

We know from Proposition A.9 that, while the geodesic flow is implemented by symplectomorphisms of the cotangent bundle, this is *not* the case for the horocyclic flows, thus making more difficult the quantization of the latter. To achieve this is the task of the present section. The following consideration is motivated by Ref. 10.

Lemma 3.1: Let $[f]\in\widetilde{V}$, $Q:\widetilde{V}\to\mathsf{R}$ be a linear functional (without any specified regularity conditions) on the vector space $\widetilde{V}$ and $S_s:\widetilde{V}\to\widetilde{V}$ be a one-parameter group of linear operators, $s\in\mathsf{R}$. Let

$$\beta_s W([f]) := e^{is\langle Q,[f]\rangle} W(S_s[f]).$$

(1) Then $(\beta_s)_{s\in\mathsf{R}}$ defines a one-parameter group of *-automorphisms of the Weyl algebra $\mathcal{W}$ if and only if $(S_s)_{s\in\mathsf{R}}$ is a one-parameter group of symplectic transformations of the vector space $\tilde{V}$ which satisfies $\langle Q,S_s[f]\rangle = \langle Q,[f]\rangle$.

(2) Moreover, one gains the Anosov commutation relations

$$\tau_{-t}\circ\beta_s\circ\tau_t = \beta_{e^{\rho t}s}$$

if and only if $\langle Q,[f_t]\rangle = e^{\rho t}\langle Q,[f]\rangle$ and $(\mathrm{Fl}_{-t}^{X_H})^* S_s (\mathrm{Fl}_t^{X_H})^* = S_{e^{\rho t}s}$.

Proof: Ad (1): Upon imposing the conditions $\langle Q,[f]\rangle = \langle Q,S_s[f]\rangle$ for all $[f]\in\tilde{V}$ and $s\in\mathsf{R}$ we compute

$$\begin{aligned}
\beta_{s_2}\beta_{s_1}(W([f]) &= \beta_{s_2}(\exp(is_1\langle Q,[f]\rangle)W(S_{s_1}[f])) \\
&= \exp(is_2\langle Q,S_{s_1}[f]\rangle)\exp(is_1\langle Q,[f]\rangle)W(S_{s_1+s_2}[f]) \\
&= \exp(is_1\langle Q,[f]\rangle + is_2\langle Q,S_{s_1}[f]\rangle)W(S_{s_1+s_2}[f]) \\
&= \exp(i(s_1+s_2)\langle Q,[f]\rangle)W(S_{s_1+s_2}[f]) \\
&= \beta_{s_1+s_2}W([f]), \qquad (3.1)
\end{aligned}$$

which shows sufficiency and also necessity of $\langle Q,S_s[f]\rangle = \langle Q,[f]\rangle$. The requirement for $S_s:\tilde{V}\to\tilde{V}$ to be symplectic is necessary and sufficient for $\beta_s:\mathcal{W}\to\mathcal{W}$ to be an automorphism; see, in particular (2.13).

Ad (2): We assume the conditions in part (2) of the statement are valid and get

$$\begin{aligned}
\tau_{-t}\circ\beta_s\circ\tau_t(W([f]) &= \tau_{-t}\circ\beta_s(W([f_t])) \\
&= \tau_{-t}(\exp(is\langle Q,[f_t]\rangle)W(S_s[f_t])) \\
&= \exp(ise^{\rho t}\langle Q,[f]\rangle)W((\mathrm{Fl}_{-t}^{X_H})^* S_s(\mathrm{Fl}_t^{X_H})^*[f]) \\
&= \exp(ise^{\rho t}\langle Q,[f]\rangle)W(S_{e^{\rho t}s}[f]) \\
&= \beta_{e^{\rho t}s}W([f]). \qquad (3.2)
\end{aligned}$$

To see the necessity of the condition follows also from these lines with a spectral argument: It is not possible, if $[f]\neq[g]$, that $W([f]) = e^{i\varphi}W([g])$ for some $\varphi\in[0;2\pi]$ because all $W([f])$ with $[f]\neq 0$ have spectrum the unit circle S^1 whereas the spectrum of $e^{i\varphi}$ clearly consists of a single point. □

Remarks 3.2: (1) Since by Proposition A.9 the horocyclic flows $h_\pm$ are not symplectic we must stress that the above lemma makes it definitely impossible to define q-horocyclic flows as $\beta_s^\pm(W([f])) = W([h_\pm(s)^* f])$ and therefore, after having clarified the nature of Q, we will set $S_s = \mathsf{I}$ in Theorem 3.7 below.

(2) A second idea would be to make use of the vector fields $E_\pm$ defined in Corollary A.8 and the relation $E_\pm(f_t)\circ\mathrm{Fl}_{-t}^{X_H} = \exp(\mp 2\lambda r\mu t)E_\pm(f)$. A naive candidate for the linear functional Q would then be an expression like

$$\langle Q^{(\pm,r)},[f]\rangle = \int_{T_r^* M_{\mu,\lambda}} E_\mp(f)\ \Omega_r .$$

However, this does not work either because $L_{E_\pm}\Omega_r = 0$ by Proposition A.9.2, and therefore

$$\int_{T_r^* M_{\mu,\lambda}} E_\mp(f)\ \Omega_r = -\int_{T_r^* M_{\mu,\lambda}} f\ L_{E_\mp}\Omega_r = 0.$$

The following lemma will show that the linear functional $Q:\tilde{V}\to\mathsf{R}$ may indeed be realized as

a measure on some suitably adapted function subspace of $C^\infty(T^*M_{\mu,\lambda},\mathsf{R})$.

Lemma 3.3: There exist nonzero functions $q_\pm \in C^\infty(U,\mathsf{R})$ such that

$$q_\pm \circ \mathrm{Fl}_t^{X_H} = \exp(\mp(2\lambda r/\mu)\, t) q_\pm .$$

Here $U \subset T^*M_{\mu,\lambda}$ is an open subset of the phase space.

Proof: The functions $q_\pm$ must satisfy the differential equation

$$L_{X_H} q_\pm = \mp \frac{2\lambda r}{\mu} \cdot q_\pm , \tag{3.3}$$

where X_H is the Hamiltonian vector field that generates the geodesic flow. The convenient choice of coordinates used in Remark 2.6 suggests the ansatz $q_\pm = q_\pm(\psi)$ (although it is *not* the most general one). In Lemma 4.2 we will get a whole family of further solutions. The differential equations (3.3) reduce then to

$$\sin\psi \cdot \partial_\psi q_\pm = \mp q_\pm . \tag{3.4}$$

The solutions of these equations are

$$q_-(\psi) = \tan\left(\frac{\psi}{2}\right), \quad q_+(\psi) = \cot\left(\frac{\psi}{2}\right). \tag{3.5}$$

□

Since these solutions do not depend on r, they can be used without modification in the following discussion restricted to $T_r^*M_{\mu,\lambda}$.

Proposition 3.4: Let

$$V^{(r)} := \left\{ f \in C_c^\infty(T^*M_{\mu,\lambda},\mathsf{R}) \,\middle|\, \int_{T_r^*M_{\mu,\lambda}} f q_\pm \, \Omega_r < \infty \right\}. \tag{3.6}$$

Then, for $f \in V^{(r)}$, the functional

$$\langle Q^{(\pm,r)}, [f] \rangle := \int_{T_r^*M_{\mu,\lambda}} f q_\pm \, \Omega_r \tag{3.7}$$

satisfies the conditions of Lemma 3.1.2. Moreover, the space $V^{(r)}$ of functions is invariant under the geodesic flow, namely $(\mathrm{Fl}_{\mathsf{R}}^{X_H})^* V^{(r)} = V^{(r)}$. Equivalence classes of functions modulo constants of motion are written as in Proposition 2.5: $\tilde{V}^{(r)}$. Both spaces $V^{(r)}$ and $\tilde{V}^{(r)}$ are symplectic vector spaces.

Proof: Assume $\{H,f\} = 0$, then

$$\begin{aligned} 0 &= \int_{T_r^*M_{\mu,\lambda}} \{f,H\} q_\pm \, \Omega_r \\ &= \int_{T_r^*M_{\mu,\lambda}} L_{X_H}(f) q_\pm \, \Omega_r \\ &= -\int_{T_r^*M_{\mu,\lambda}} f L_{X_H}(q_\pm) \, \Omega_r = \pm \frac{2\lambda r}{\mu} \int_{T_r^*M_{\mu,\lambda}} f q_\pm \, \Omega_r , \end{aligned}$$

which shows that (in case $\lambda > 0$) the expression $\langle Q^{(\pm,r)}, [f] \rangle$ and also $\tilde{V}^{(r)}$ are well-defined. The two assertions on invariance under geodesic flow and Anosov relations are proved in one step: For $f \in V^{(r)}$ we compute

$$\begin{aligned}\langle Q^{(\pm,r)},[f\circ \mathrm{Fl}_t^{X_H}]\rangle &= \int_{T_r^* M_{\mu,\lambda}} (f\circ \mathrm{Fl}_t^{X_H}) q_\pm \ \Omega_r \\ &= \int_{T_r^* M_{\mu,\lambda}} f(q_\pm \circ \mathrm{Fl}_{-t}^{X_H}) \ \Omega_r \\ &= \exp\left[\pm\left(\frac{2\lambda r}{\mu}\right) t\right] \int_{T_r^* M_{\mu,\lambda}} f q_\pm \ \Omega_r \\ &= \exp\left[\pm\left(\frac{2\lambda r}{\mu}\right) t\right] \langle Q^{(\pm,r)},[f]\rangle.\end{aligned}$$

This shows that with $\langle Q^{(\pm,r)},[f]\rangle<\infty$ one has also $\langle Q^{(\pm,r)},[f_t]\rangle<\infty$ for all $t\in \mathsf{R}$. □

Remarks 3.5: (1) The reader will have noticed that in contrast to Lemma 3.1 the linear functional $Q^{(\pm,r)}$ is not defined on the whole of $\tilde{V}$ but we had to restrict to $\tilde{V}^{(r)}$ in order for (3.7) to make sense.

(2) That $\tilde{V}^{(r)}$ is invariant under the geodesic flow may be understood geometrically, because it can be shown that the loci where $q_\pm$ are not defined, namely $\psi=0$ or $=\pi$, are the trajectories of geodesic flow lines on the cotangent bundle. More precisely, they correspond to geodesics perpendicular to the real axis in the $\mathsf{C}^\uparrow$-picture of the Poincaré half-plane described in A2.

Definition 3.6: The Weyl algebra generated by the Weyl operators $W([f])$ for $f\in V^{(r)}$ will be referred to as *restricted Weyl algebra* and be denoted by $\mathcal{W}^{(r)}$.

Summarizing the above discussions we arrive at the main theorem of this section:

Theorem 3.7: Let $f\in V^{(r)}$, then

$$\chi_s^{(\pm,r)}(W([f])=\exp\left(i\ s\int_{T_r^* M_{\mu,\lambda}} f q_\pm \ \Omega_r\right)\cdot W([f]) \tag{3.8}$$

defines a one-parameter family of *-automorphisms of the restricted Weyl algebra $\mathcal{W}^{(r)}$ such that for all $t,s\in \mathsf{R}$ the Anosov relations hold:

$$\tau_{-t}\circ\chi_s^{(\pm,r)}\circ\tau_t=\chi^{(\pm,r)}_{\exp(\pm(2\lambda/\mu)\,rt)_s}. \tag{3.9}$$

In the sequel, the automorphisms $\chi^{(\pm,r)}:\mathsf{R}\to \mathrm{Aut}(\mathcal{W}^{(r)})$ will be referred as the *expanding*, respectively, *contracting automorphisms* or, simply, the *horocyclic automorphisms*. □

Proposition 3.8: The derivation generating the horocyclic automorphisms is given by

$$\delta^{(\pm,r)}(W([f]))=i\int_{T_r^* M_{\mu,\lambda}} f q_\pm \ \Omega_r\cdot W([f]) \tag{3.10}$$

for $f\in V^{(r)}$. The Weyl operators $W([f])$ such that $f\in V^{(r)}$ provide a dense domain (in the restricted Weyl algebra $\mathcal{W}^{(r)}$) of definition for $\delta^{(\pm,r)}$. We have the commutation relations

$$\tau_{-t}\circ\delta^{(\pm,r)}\circ\tau_t=\exp\left(\pm\frac{2\lambda r}{\mu}t\right)\delta^{(\pm,r)} \tag{3.11}$$

and, upon denoting by δ_τ the derivation generating the one-parameter group of geodesic automorphisms:

$$\delta_\tau\circ\delta^{(\pm,r)}-\delta^{(\pm,r)}\circ\delta_\tau=\frac{2\lambda r}{\mu}\delta^{(\pm,r)}. \tag{3.12}$$

Proof: Everything here follows by differentiation of the corresponding assertions in Theorem 3.7. □

IV. QUANTUM ANOSOV SYSTEMS ON COMPACT QUOTIENT MANIFOLDS

This section describes how to translate geodesic and horocyclic automorphisms defined in the previous sections on $M_{\mu,\lambda}$ to a compact quotient $\Gamma\backslash M_{\mu,\lambda}$. This will be needed in the next section where we will construct states.

Definition 4.1: We choose a fundamental domain F_Γ as described in A.14 with associated cotangent fundamental domain $T^*\check{F}_\Gamma$. $\check{F}_\Gamma$ shall denote the open interior of the (compact) fundamental domain F_Γ. We restrict the space of smooth functions on the cotangent bundle to the space of smooth Γ-periodic functions, i.e.,

$$V_\Gamma := \cap_{\gamma\in\Gamma}\{f\in C_c^\infty(T^*M_{\mu,\lambda},\mathsf{R})\,|\,f\circ U_*(\gamma)=f\}, \tag{4.1}$$

where U_* is defined in A.12. Proposition A.15 states that both the geodesic and horocyclic flows may be restricted to T^*F_Γ in a consistent way. Finally we will need the counterpart of the space of functions defined in Proposition 3.4 which shall be

$$V_{F_\Gamma}^{(r)} := \left\{ f\in V_\Gamma \,\middle|\, \int_{T_r^*F_\Gamma} f q_\pm\ \Omega_r < \infty \right\}. \tag{4.2}$$

These function spaces are endowed with a (degenerate) symplectic form $\sigma_{F_\Gamma}: V_{F_\Gamma}^{(r)}\times V_{F_\Gamma}^{(r)}\to\mathsf{R}$ by setting

$$\sigma_{F_\Gamma}(f,g) := \int_{T^*F_\Gamma} H\{f,g\}\ \omega\wedge\omega \tag{4.3}$$

for $f,g\in V_{F_\Gamma}^{(r)}$. Again, there are the nondegenerate versions $\tilde{V}_{F_\Gamma}^{(r)}$ and $\tilde{\sigma}_{F_\Gamma}$ when we factor out the constants of motion, as we did in Proposition 2.5. The Weyl algebra generated by $W([f])$ for $[f]\in\tilde{V}_{F_\Gamma}^{(r)}$ will be denoted by $\mathcal{W}_{F_\Gamma}^{(r)}$. Since, given a discrete co-compact subgroup Γ of SL(2,R), there are many choices for associated fundamental domains F_Γ, at first sight this could lead to some annoying ambiguity. The following results show that the Weyl algebra does in fact not depend on the choice of F_Γ.

Lemma 4.2: Let $g\in\mathrm{SL}(2,\mathsf{R})$ and $q_\pm$ be the functions computed in Lemma 3.3. Then $U_*(g)^*q_\pm$ also solves the equation $L_{X_H}q_\pm = \mp(2\lambda r/\mu)\,q_\pm$.

Proof: We compute

$$\begin{aligned}
L_{X_H}(U_*(g)^*q_\pm) &= X_H(q_\pm\circ U_*(g))\\
&= \{q_\pm\circ U_*(g), H\}\\
&= \{q_\pm\circ U_*(g), H\circ U_*(g)\}\\
&= \{q_\pm, H\}\circ U_*(g)\\
&= L_{X_H}q_\pm\circ U_*(g)\\
&= \mp\frac{2\lambda r}{\mu}q_\pm\circ U_*(g) = \mp\frac{2\lambda r}{\mu}U_*(g)^*q_\pm .
\end{aligned} \tag{4.4}$$

We used the fact that $U_*(g)$ acts symplectically and leaves the r-sphere bundle $T_r^*M_{\mu,\lambda}$ invariant. □

In order to accomplish a clean passage to the quotient $\Gamma\backslash M_{\mu,\lambda}$ we introduce the following notion:

Definition 4.3: Let F_Γ be an arbitrary (compact) fundamental domain with open interior $\check{F}_\Gamma$. We define the periodic extension $\mathrm{Per}_{F_\Gamma}q_\pm$ of $q_\pm$ with respect to the fundamental domain F_Γ by

$$\mathrm{Per}_{F_\Gamma}q_\pm(U_*(\gamma)\overline{x}) := q_\pm(\overline{x}) \tag{4.5}$$

for all $\gamma\in\Gamma$ and $\overline{x}\in T_r^*\check{F}_\Gamma$.

Proposition 4.4: The F_Γ-periodic extension $\mathrm{Per}_{F_\Gamma}q_\pm$ of $q_\pm$ is well-defined up to a set of measure zero in $T_r^*M_{\mu,\lambda}$. $\mathrm{Per}_{F_\Gamma}q_\pm$ is Γ-periodic and may thus be factorized to the quotient $T_r^*(\Gamma\backslash M_{\mu,\lambda})$ which shall again be denoted by $\mathrm{Per}_{F_\Gamma}q_\pm$. Let $\gamma\in\Gamma$, then there exists a diffeomorphism $R(\gamma):T_r^*(\Gamma\backslash M_{\mu,\lambda})\to T_r^*(\Gamma\backslash M_{\mu,\lambda})$ such that

$$\mathrm{Per}_{U(\gamma)F_\Gamma}q_\pm = R(\gamma)^*\mathrm{Per}_{F_\Gamma}q_\pm \tag{4.6}$$

and

$$R(\gamma)^*\mathrm{Per}_{F_\Gamma}q_\pm\circ\mathrm{Fl}_t^{X_H} = \exp\left(\mp\frac{2\lambda r}{\mu}t\right)R(\gamma)^*\mathrm{Per}_{F_\Gamma}q_\pm \tag{4.7}$$

for all $t\in\mathbb{R}$ and $\gamma\in\Gamma$. The diffeomorphism $R(\gamma):T_r^*(\Gamma\backslash M_{\mu,\lambda})\to T_r^*(\Gamma\backslash M_{\mu,\lambda})$ has the following properties:

(1) $\Pi\circ R(\gamma)=\mathrm{Id}$ where $\Pi:T_r^*(\Gamma\backslash M_{\mu,\lambda})\to\Gamma\backslash M_{\mu,\lambda}$ is the footpoint projection.
(2) $R(\gamma\gamma')=R(\gamma)R(\gamma')$ for all $\gamma,\gamma'\in\mathrm{SL}(2,\mathbb{R})$.
(3) $R(\gamma)$ keeps the volume Ω_r invariant, but is not σ_{F_Γ}-symplectic.

Proof: We may assume that F_Γ is a compact geodesic polygon and therefore $T_r^*\check{F}_\Gamma\cong\check{F}_\Gamma\times S^1$. One has

$$T_r^*M_{\mu,\lambda}\cong\cup_{\gamma\in\Gamma}(U(\gamma)F_\Gamma\times S^1)=\cup_{\gamma\in\Gamma}U(\gamma)F_\Gamma\times S^1.$$

Then the F_Γ-periodic extension $\mathrm{Per}_{F_\Gamma}q_\pm$ is well defined apart from the set

$$N_\pm:=(\cup_{\gamma\in\Gamma}U(\gamma)\partial F_\Gamma\times S^1)\cup(\cup_{\gamma\in\Gamma}U(\gamma)F_\Gamma\times U_*(\gamma).(F_\Gamma,\psi_\pm)),$$

where $\psi_+=0$ and $\psi_-=\pi$ are, in the chart of Lemma 3.3, the angles where $|q_\pm|=\infty$. ∂F_Γ denotes the boundary of the fundamental domain F_Γ. However, the set $N_\pm\subset T_r^*M_{\mu,\lambda}$ has measure zero. For $\gamma,\gamma'\in\Gamma$ and $\overline{x_0}\in T_r^*\check{F}_\Gamma$, $\overline{x}:=U_*(\gamma')\overline{x_0}\in U_*(\gamma')T_r^*\check{F}_\Gamma$ we conclude from

$$\begin{aligned}(\mathrm{Per}_{F_\Gamma}q_\pm\circ U_*(\gamma))(\overline{x}) &= \mathrm{Per}_{F_\Gamma}q_\pm(U_*(\gamma)U_*(\gamma')\overline{x_0})\\ &= \mathrm{Per}_{F_\Gamma}q_\pm(U_*(\gamma\gamma')\overline{x_0})\\ &= q_\pm(\overline{x_0})\\ &= \mathrm{Per}_{F_\Gamma}q_\pm(U_*(\gamma')\overline{x_0})\\ &= \mathrm{Per}_{F_\Gamma}q_\pm(\overline{x})\end{aligned}$$

that $\mathrm{Per}_{F_\Gamma}q_\pm\circ U_*(\gamma)=\mathrm{Per}_{F_\Gamma}q_\pm$, whence $\mathrm{Per}_{F_\Gamma}q_\pm$ is Γ-periodic. Let $F_\Gamma{}'=U(\gamma)F_\Gamma$ be another fundamental domain in the tiling defined by F_Γ. Our aim is to compare $\mathrm{Per}_{F_\Gamma}q_\pm$ and $\mathrm{Per}_{F_\Gamma{}'}q_\pm$. Since it has already been shown that both $\mathrm{Per}_{F_\Gamma}q_\pm$ and $\mathrm{Per}_{F_\Gamma{}'}q_\pm$ are Γ-periodic, we restrict to $T_r^*\check{F}_\Gamma$. With $\overline{x}\in T_r^*\check{F}_\Gamma$ we see from

$$\mathrm{Per}_{F_\Gamma{}'}q_\pm(\overline{x})=q_\pm(U_*(\gamma)\overline{x})=U_*(\gamma)^*q_\pm(\overline{x}) \tag{4.8}$$

that, restricted to $T_r^*\check{F}_\Gamma$, $\mathrm{Per}_{F_\Gamma{}'}q_\pm$ equals $U_*(\gamma)^*q_\pm$. Upon using the chart with $\overline{x}=(x,\psi)$ and

$$
\begin{aligned}
(U_*(\gamma)^* q_\pm)(x,\psi) &= q_\pm(U_*(\gamma).(x,\psi)) \\
&= q_\pm(U(\gamma).x, T_x^* U(\gamma).\psi) \\
&= (\cot,\tan)(\tfrac{1}{2}T_x^*)U(\gamma)\cdot\psi) \\
&= q_\pm(x, T_x^* U(\gamma).\psi)
\end{aligned}
$$

we conclude, again if restricted to $T_r^*\check{F}_\Gamma$, that $U_*(\gamma)^* q_\pm = R(\gamma)^* q_\pm$ with $R(\gamma).(x,\psi) := (x, T_x^* U(\gamma).\psi)$ and further

$$
\mathrm{Per}_{F_{\Gamma'}} q_\pm = \mathrm{Per}_{U(\gamma)F_\Gamma} q_\pm = R(\gamma)^* \mathrm{Per}_{F_\Gamma} q_\pm .
$$

These lines, with the definition of $R(\gamma)$, also imply that $R(\gamma\gamma') = R(\gamma)R(\gamma')$ and with Lemma 4.2 that

$$
R(\gamma)^* \mathrm{Per}_{F_\Gamma} q_\pm \circ \mathrm{Fl}_t^{X_H} = \exp\left(\mp \frac{2\lambda r}{\mu} t \right) R(\gamma)^* \mathrm{Per}_{F_\Gamma} q_\pm .
$$

We used that $U_*(\gamma)$ leaves the r-sphere bundles invariant; the explicit shape of $R(\gamma)$ shows that $\Pi \circ R(\gamma) = \mathrm{Id}$ and also that $R(\gamma)$ factors to a nontrivial diffeomorphism of the quotient $T_r^*(\Gamma\backslash M_{\mu,\lambda})$. $R(\gamma): T_r^*(\Gamma\backslash M_{\mu,\lambda}) \to T_r^*(\Gamma\backslash M_{\mu,\lambda})$ may be interpreted as a base point dependent fiber rotation of the r-sphere bundle $T_r^*(\Gamma\backslash M_{\mu,\lambda})$ over the identity on $\Gamma\backslash M_{\mu,\lambda}$ whence $R(\gamma)^* \Omega_r = \Omega_r$, i.e., $R(\gamma)$ leaves the volume Ω_r invariant, but it is not σ_{F_Γ}-symplectic. □

Remarks 4.5: (1) One has to actually consider the functions $q_\pm$ in the sense of distributions: As they occur in our computations only below the integral their definition only up to a set of measure zero does not harm either.

(2) Our strategy was to compare the function spaces $V_{F_\Gamma}^{(r)}$ over different fundamental domains F_Γ in terms of the functions $q_\pm$ occurring in their definition. To reduce the study of these functions, which are not Γ-periodic, to a fundamental domain $T_r^*\check{F}_\Gamma$ without losing information, is made easier by the very special shape of $q_\pm$: they do not depend on F_Γ but only on the angle ψ which is part of the information already contained in $\check{F}_\Gamma \times S^1 \cong T_r^*\check{F}_\Gamma$.

Proposition 4.6: Let $\gamma \in \Gamma$ and F_Γ, $F_{\Gamma'} = U(\gamma)F_\Gamma$ be two fundamental domains. Then the symplectic vector spaces of functions $V_{F_\Gamma}^{(r)}$ and $V_{F_{\Gamma'}}^{(r)}$ are symplectomorphic.

Proof: We compute

$$
\begin{aligned}
\int_{T_r^* F_{\Gamma'}} f q_\pm \, \Omega_r &= \int_{T_r^*(\Gamma\backslash M_{\mu,\lambda})} f \cdot \mathrm{Per}_{F_{\Gamma'}} q_\pm \, \Omega_r \\
&= \int_{T_r^*(\Gamma\backslash M_{\mu,\lambda})} f \cdot R(\gamma)^* \mathrm{Per}_{F_\Gamma} q_\pm \, \Omega_r \\
&= \int_{T_r^*(\Gamma\backslash M_{\mu,\lambda})} R(\gamma^{-1})^* f \cdot \mathrm{Per}_{F_\Gamma} q_\pm \, \Omega_r = \int_{T_r^* F_\Gamma} R(\gamma^{-1})^* f \cdot q_\pm \, \Omega_r
\end{aligned}
$$

from which we see that $f \in V_{F_\Gamma}^{(r)}$ if and only if $R(\gamma)^* f \in V_{F_{\Gamma'}}$. We rewrite the definition of $V_{F_\Gamma}^{(r)}$ as it was given in Definition 4.1 in terms of an arbitrary but fixed fundamental domain F_Γ:

$$
V_{U(\gamma)F_\Gamma}^{(r)} = \left\{ f \in V_\Gamma \,\middle|\, \int_{T_r^* F_\Gamma} R(\gamma^{-1})^* f \cdot q_\pm \, \Omega_r < \infty \right\}. \tag{4.9}
$$

We note that the symplectic form $\sigma_{F_{\Gamma'}}$ on $V_{U(\gamma)F_\Gamma}^{(r)}$—expressed in terms of the fundamental domain F_Γ—has to be arranged via

$$
\sigma_{U(\gamma)F_\Gamma}(f,g) = \int_{T^* F_\Gamma} H\{f,g\}_\gamma \, \omega \wedge \omega \tag{4.10}
$$

where $\{\,.\,,.\,\}_\gamma$ shall indicate that this Poisson bracket has to be formed with respect to the symplectic form $R(\gamma)^*\omega$; i.e., if $f,g\in V^{(r)}_{U(\gamma)F_\Gamma}$, then $\{f,g\}_\gamma:=(R(\gamma)^*\omega)(X_f,X_g)$ and $i_{X_f}R(\gamma)^*\omega:=df$. Finally we have

$$\{R(\gamma)^*f,R(\gamma)^*g\}_\gamma=\{f,g\}\circ R(\gamma).$$

Then one observes immediately, that the map

$$R(\gamma)^*:V^{(r)}_{F_\Gamma}\to V^{(r)}_{U(\gamma)F_\Gamma},f\mapsto R(\gamma)^*f$$

is a symplectomorphism, i.e.,

$$\begin{aligned}\sigma_{U(\gamma)F_\Gamma}(R(\gamma)f,R(\gamma)g)&=\int_{T^*F_\Gamma}H\{R(\gamma)^*f,R(\gamma)^*g\}_\gamma\ \omega\wedge\omega\\&=\int_{T^*F_\Gamma}(H\{f,g\}\circ R(\gamma))\ \omega\wedge\omega\\&=\int_{T^*F_\Gamma}H\{f,g\}\ \omega\wedge\omega=\sigma_{F_\Gamma}(f,g)\end{aligned}\tag{4.11}$$

for all $\gamma\in\Gamma$. Thereby we had to use the fact that the Hamiltonian H is $R(\gamma)$-invariant, namely $H\circ R(\gamma)=H$, and that $R(\gamma)^*(\omega\wedge\omega)=\omega\wedge\omega$, Proposition 4.4.3. □

Theorem 4.7: Let F_Γ and F'_Γ be two fundamental domains associated to a discrete cocompact subgroup Γ of SL(2,R). Then the Weyl algebras $\mathcal{W}^{(r)}_{F_\Gamma}$ and $\mathcal{W}^{(r)}_{F'_\Gamma}$ are isomorphic and will from now on be written $\mathcal{W}^{(r)}_\Gamma$. Hence the Weyl algebra $\mathcal{W}^{(r)}_\Gamma$ is uniquely determined up to an isomorphism by the subgroup $\Gamma\subset\mathrm{SL}(2,\mathsf{R})$.

Proof: We know from the discussion above that the function spaces $V^{(r)}_{F_\Gamma}$ and $V^{(r)}_{F'_\Gamma}$ are symplectomorphic. Then we give the argument that $R(\gamma)$ makes also sense on the quotient $\tilde{V}^{(r)}_{F_\Gamma}$. Suppose that $\{f,H\}=0$. Then

$$\{R(\gamma)^*f,H\}_\gamma=\{R(\gamma)^*f,R(\gamma)^*H\}_\gamma=\{f,H\}\circ R(\gamma)=0.$$

Therefore the extension of $W([f])\mapsto W([R(\gamma)^*f])$ to $\mathcal{W}^{(r)}_{V_{F_\Gamma}}$ makes sense and defines a *-isomorphism $\mathcal{F}:\mathcal{W}^{(r)}_{F_\Gamma}\to\mathcal{W}^{(r)}_{F_\Gamma'}$ from the same argument as in Proposition 2.10. □

Remark 4.8: In the sequel and in particular in Sec.V we will sometimes refer to the symplectic function spaces $(V^{(r)}_\Gamma,\sigma_\Gamma)$, respectively $(\tilde{V}^{(r)}_\Gamma,\tilde{\sigma}_\Gamma)$. This shall mean that we choose a specific fundamental domain F_Γ with function spaces $(V^{(r)}_{F_\Gamma},\sigma_{F_\Gamma})$ respectively $(\tilde{V}^{(r)}_{F_\Gamma},\tilde{\sigma}_\Gamma)$ as given in Definition 4.1, and we work with the isomorphic copy $\mathcal{W}^{(r)}_{F_\Gamma}$ of the Weyl algebra $\mathcal{W}^{(r)}_\Gamma$.

Finally we come to the main theorem in this section stating the analog of Theorem 3.7 for compact quotients $\Gamma\backslash M_{\mu,\lambda}$.

Theorem 4.9: Let F_Γ and F'_Γ be two fundamental domains with associated function spaces $V^{(r)}_{F_\Gamma}$ and $V^{(r)}_{F'_\Gamma}$ such that $F'_\Gamma=U(\gamma)F_\Gamma$ for some $\gamma\in\Gamma$. We set $\mathcal{F}:\mathcal{W}^{(r)}_{F_\Gamma}\to\mathcal{W}^{(r)}_{F'_\Gamma}$ for the induced isomorphism of Weyl algebras as described in the proof of Theorem 4.7. The geodesic automorphisms on the Weyl algebra $\mathcal{W}^{(r)}_\Gamma$ are in any case well-defined by $\tau_t W([f]):=W([f_t])$. For any $\gamma\in\Gamma$ we define the horocyclic automorphisms for $W([f])\in\mathcal{W}^{(r)}_{U(\gamma)F_\Gamma}$ as

$$\chi^{(\pm,r)}_s W([f]):=\exp\left(is\int_{T^*_rF_\Gamma}R(\gamma^{-1})^*f\cdot q_\pm\ \Omega_r\right)\cdot W([f]).\tag{4.12}$$

Then the following diagram commutes:

$$\begin{array}{ccc} \mathcal{W}^{(r)}_{F_\Gamma} & \chi_s^{(\pm,r)}_{\rightarrow} & \mathcal{W}^{(r)}_{F_\Gamma} \\ \mathcal{F}\downarrow & & \downarrow\mathcal{F} \\ \mathcal{W}^{(r)}_{F'_\Gamma} & \chi_s^{(\pm,r)}_{\rightarrow} & \mathcal{W}^{(r)}_{F'_\Gamma} \end{array}$$

Consequently the horocyclic automorphisms can unambiguously be defined on the Weyl algebra $\mathcal{W}^{(r)}_\Gamma$. Moreover, the Anosov commutation relations

$$\tau_{-t}\circ\chi_s^{(\pm,r)}\circ\tau_t=\chi^{(\pm,r)}_{\exp(\pm(2\lambda r/\mu)\,t)s}$$

also hold on $\mathcal{W}^{(r)}_\Gamma$.

Proof: Let $F'_\Gamma=U(\gamma)F_\Gamma$ and $V^{(r)}_{F'_\Gamma}=R(\gamma)^*V^{(r)}_{F_\Gamma}$. Then

$$\begin{aligned}\mathcal{F}\chi_s^{(\pm,r)}W([f])&=\exp\left(is\int_{T^*_rF_\Gamma}fq_\pm\,\Omega_r\right)\cdot W([R(\gamma)^*f])\\&=\exp\left(is\int_{T^*_rF_\Gamma}R(\gamma)^*f\cdot R(\gamma)^*q_\pm\,\Omega_r\right)\cdot W([R(\gamma)^*f])\\&=\chi_s^{(\pm,r)}W([R(\gamma)^*f])=\chi_s^{(\pm,r)}\mathcal{F}W([f]).\end{aligned}\tag{4.13}$$

In order to see the statement concerning the ACR we observe that the crucial relation occurring in the proof of Proposition 3.4 is

$$\begin{aligned}\int_{T^*_rF_\Gamma}f_t\cdot R(\gamma)^*q_\pm\,\Omega_r&=\int_{T^*_rF_\Gamma}f(R(\gamma)^*q_\pm\circ\mathrm{Fl}^{X_H}_{-t})\,\Omega_r\\&=\exp\left(\pm\frac{2\lambda r}{\mu}t\right)\int_{T^*_rF_\Gamma}f\cdot R(\gamma)^*q_\pm\,\Omega_r.\end{aligned}\tag{4.14}$$

This still holds after passing to the quotient because of Proposition 4.4. □

Remark 4.10: In the spirit of Proposition 3.4 we abbreviate the expression occurring in (4.12) by

$$\int_{T^*_rF_\Gamma}R(\gamma^{-1})^*f\cdot q_\pm\,\Omega_r=\int_{T^*_rF_\Gamma}f\cdot R(\gamma)^*q_\pm\,\Omega_r=:\langle Q^{(\pm,r)}_{U(\gamma)F_\Gamma},[f]\rangle\tag{4.15}$$

where $[f]\in\widetilde{V}^{(r)}_{U(\gamma)F_\Gamma}$. Since this is obviously independent from the choice of the fundamental domain F_Γ, namely

$$\langle Q^{(\pm,r)}_{F_\Gamma},[f]\rangle=\langle Q^{(\pm,r)}_{U(\gamma)F_\Gamma},[R(\gamma)^*f]\rangle$$

we write from now on in the same vein as in Remark 4.8 simply $Q^{(\pm,r)}_\Gamma$. Equation (4.14) then shows that

$$\langle Q^{(\pm,r)}_\Gamma,[f_t]\rangle=\exp\left(\pm\frac{2\lambda r}{\mu}t\right)\langle Q^{(\pm,r)}_\Gamma,[f]\rangle.\tag{4.16}$$

The one-parameter group of horocyclic automorphisms on the Weyl algebra $\mathcal{W}^{(r)}_\Gamma$ may now be rewritten as

$$\chi_s^{(\pm,r)}W([f])=e^{is\langle Q^{(\pm,r)}_\Gamma,[f]\rangle}\cdot W([f]).\tag{4.17}$$

Remark 4.11: We want to mention that the analysis presented above can be adapted to a slightly more general case: While we considered explicitly only fundamental domains sitting in

the same tiling as a given fundamental domain, it is actually possible to allow $F_{\Gamma'}=U(g)F_\Gamma$ for any $g\in \mathrm{SL}(2,\mathsf{R})$ instead of $g\in\Gamma$; and also to take into account ambiguities arising from Lemma 4.2, namely to consider distinct solutions of Lemma 3.3. A straightforward check shows how the arguments, essentially those in Proposition 4.4, go through in the general situation; this mostly involves tracking the effects of the conjugations $\Gamma\to g^{-1}\Gamma g$ with $g\in \mathrm{SL}(2,\mathsf{R})$.

V. INVARIANT STATES AND ERGODICITY

The aim of this section is to construct a state on the Weyl C*-algebra $\mathcal{W}$ which is invariant under the geodesic and the horocyclic automorphisms. We also investigate whether this state can be chosen to be regular in order not to lose field operators; recall that a state Φ on the Weyl algebra $\mathcal{W}$ is regular, if $\mathsf{R}\ni t\mapsto\Phi(W(t[f]))$ is continuous. To illustrate that this requirement is genuine, consider the state $\Phi_0(W([f])):=\delta_{f0}$ where δ_{f0} is the Kronecker symbol; this state is invariant under all possible flows, but it is not regular. The following proposition shows that in fact one cannot expect a state to be both regular and invariant under the horocyclic automorphism group.

Proposition 5.1: Let $\Phi:\mathcal{W}_\Gamma^{(r)}\to\mathsf{C}$ be a state on the Weyl algebra $\mathcal{W}_\Gamma^{(r)}$, which is invariant under the horocyclic automorphism group $\chi^{(\pm,r)}$. Then—if $\chi^{(\pm,r)}$ acts nontrivially—Φ cannot be a regular state.

Proof: Invariance of the state Φ under the horocyclic automorphisms implies

$$\Phi(\chi_s^{(\pm,r)}W([f]))=e^{is\langle Q_\Gamma^{(\pm,r)},[f]\rangle}\Phi(W([f]))=\Phi(W([f])) \tag{5.1}$$

for all $f\in V_\Gamma^{(r)}$. We see that either $\Phi(W([f]))=0$ or $\langle Q_\Gamma^{(\pm,r)},[f]\rangle=0$. Since we assume that the horocyclic automorphisms are nontrivial, there exists an $f\in V_\Gamma^{(r)}$ such that $\langle Q_\Gamma^{(\pm,r)},[f]\rangle\neq 0$, but then $\Phi(W([f]))=0$ and therefore $\lim_{\epsilon\to 0}\Phi(W(\epsilon[f]))=0$ whereas $\Phi(W([0]))=1$. We conclude that Φ cannot be regular. □

Definition 5.2: Let $\tilde{V}_\Gamma^{(r)}$ be the real symplectic vector space as it was described in Remark 4.8. Then for any $[f],[g]\in\tilde{V}_\Gamma^{(r)}$ with H the Hamiltonian

$$\langle[f],[g]\rangle:=\int_{T^*(\Gamma\backslash M_{\mu,\lambda})}\{f,H\}\{g,H\}\ \omega\wedge\omega \tag{5.2}$$

defines a positive definite inner product on $\tilde{V}_\Gamma^{(r)}$. The completion with respect to the norm $\|[f]\|:=\sqrt{\langle[f],[f]\rangle}$ is a Hilbert space and will be denoted by $\mathcal{V}$.

Lemma 5.3: The symplectic form $\tilde{\sigma}_\Gamma:\tilde{V}_\Gamma^{(r)}\times\tilde{V}_\Gamma^{(r)}\to\mathsf{R}$ may be separately extended to the Hilbert space $\mathcal{V}$. More precisely, for any $[f]\in\tilde{V}_\Gamma^{(r)}$ and $h\in\mathcal{V}$ the expression $\tilde{\sigma}_\Gamma([f],h)$ can be uniquely defined.

Proof: For $[f],[g]\in\tilde{V}_\Gamma^{(r)}$ we compute

$$\begin{aligned}\tilde{\sigma}_\Gamma([f],[g])&=\int_{T^*(\Gamma\backslash M_{\mu,\lambda})}H\{f,g\}\ \omega\wedge\omega\\&=\int_{T^*(\Gamma\backslash M_{\mu,\lambda})}(H\{f,g\}-\{f,gH\})\ \omega\wedge\omega\\&=-\int_{T^*(\Gamma\backslash M_{\mu,\lambda})}g\{f,H\}\ \omega\wedge\omega\end{aligned} \tag{5.3}$$

with Remark 2.4. From this we get

$$
\begin{aligned}
|\tilde{\sigma}_\Gamma([f],[g])|^2 &= \Big| \int_{T^*(\Gamma\setminus M_{\mu,\lambda})} H\{f,g\}\ \omega\wedge\omega \Big|^2 \\
&= \left| \int_{T^*(\Gamma\setminus M_{\mu,\lambda})} g\{f,H\}\ \omega\wedge\omega \right|^2 \\
&\leqslant \left(\int_{T^*(\Gamma\setminus M_{\mu,\lambda})} |g\{f,H\}|\ \omega\wedge\omega \right)^2 \\
&\leqslant \int_{T^*(\Gamma\setminus M_{\mu,\lambda})} |g|^2\ \omega\wedge\omega \cdot \int_{T^*(\Gamma\setminus M_{\mu,\lambda})} |\{f,H\}|^2\ \omega\wedge\omega \\
&= \int_{T^*(\Gamma\setminus M_{\mu,\lambda})} |g|^2\ \omega\wedge\omega \cdot \langle [f],[f]\rangle
\end{aligned} \tag{5.4}
$$

which shows, that for fixed $[g]\in\tilde{V}_\Gamma^{(r)}$ the expression $\tilde{\sigma}_\Gamma([f],[g])$ is $\|.\|$-continuous in $[f]$, hence can be extended to $\mathcal{V}$ in one entry. □

Proposition 5.4: There exists a complex structure $J:\mathcal{V}\to\mathcal{V}$ and a real positive inner product $\alpha:\mathcal{V}\times\mathcal{V}\to\mathsf{R}$ such that

$$
\alpha([f],[g]) = -\tilde{\sigma}_\Gamma(J[f],[g]) \Leftrightarrow \alpha(J[f],[g]) = \tilde{\sigma}_\Gamma([f],[g])
$$

for all $[f],[g]\in\tilde{V}_\Gamma^{(r)}$. The completion of $\tilde{V}_\Gamma^{(r)}$ with respect to α will be denoted by $\mathcal{V}^\alpha$. The inner product α is invariant under the geodesic evolution.

Proof: From Lemma 5.3 $\tilde{\sigma}([f],.)$ is a bounded linear functional on the Hilbert space $\mathcal{V}$ for all $[f]\in\tilde{V}_\Gamma^{(r)}$, therefore we may set

$$
\tilde{\sigma}_\Gamma([f],[g]) = \langle A[f],[g]\rangle \tag{5.5}
$$

for a possibly unbounded linear operator A on the Hilbert space $\mathcal{V}$ by Riesz representation theorem. A is densely defined, namely on $\tilde{V}_\Gamma^{(r)}\subset\mathcal{V}$. Skew symmetry of $\tilde{\sigma}_\Gamma$ yields $-A\subseteq A^*$, whence A is closable. W.l.o.g., let A be closed. Closed densely defined operators allow polar decomposition $A=JP$ for a partial isometry J and a positive (unbounded) operator P which is given by $P=\sqrt{A^*A}=\sqrt{-A^2}$ and therefore $A=JP=PJ$. Since the symplectic form $\tilde{\sigma}_\Gamma$ is nondegenerate, the linear operator A is injective, and the same holds for J and P. Uniqueness of polar decomposition gives finally $J^2=-\mathsf{I}$ and $J=-J^*=J^{-1}$. It is also easily checked that $\tilde{\sigma}_\Gamma$ is J-orthogonal:

$$
\begin{aligned}
\tilde{\sigma}_\Gamma(J[f],J[g]) &= \langle AJ[f],J[g]\rangle \\
&= \langle PJ^2[f],J[g]\rangle = -\langle P[f],J[g]\rangle = \langle JP[f],[g]\rangle \\
&= \langle A[f],[g]\rangle = \tilde{\sigma}_\Gamma([f],[g]).
\end{aligned} \tag{5.6}
$$

The next step defines

$$
\alpha([f],[g]) := -\tilde{\sigma}_\Gamma(J[f],[g]) \tag{5.7}
$$

and one checks that α is a positive inner product on the vector space $\tilde{V}_\Gamma^{(r)}$ which is also J-orthogonal:

$$
\alpha(J[f],J[g]) = \tilde{\sigma}_\Gamma([f],J[g]) = -\tilde{\sigma}_\Gamma(J[f],[g]) = \alpha([f],[g]). \tag{5.8}
$$

To see the invariance of α under the automorphism group generated by the geodesic flow we compute

$$
\langle A[f],[g]\rangle = \tilde{\sigma}_\Gamma([f],[g]) = \tilde{\sigma}_\Gamma([f_t],[g_t]) = \langle A[f_t],[g_t]\rangle = \langle (A[f_t])_{-t},[g]\rangle \tag{5.9}
$$

for all $g \in \mathcal{V}$, hence $(\mathrm{Fl}_t^{X_H})^* \circ A = A \circ (\mathrm{Fl}_t^{X_H})^*$ for all $t \in \mathbb{R}$, the linear operator A commutes with time evolution on the dense subspace $\tilde{V}_\Gamma^{(r)}$. Upon setting $J = A\sqrt{-A^2}$ it remains to argue that the square root $\sqrt{-A^2}$ commutes with the time flow, which is done by writing the spectral resolution of the positive operator $-A^2 = \int_0^\infty u \, dE_u$ and observation that $\sqrt{-A^2} = \int_0^\infty \sqrt{u} \, dE_u$. □

Corollary 5.5: The real inner product α and the symplectic form $\tilde{\sigma}_\Gamma$ satisfy the following relation:

$$|\tilde{\sigma}_\Gamma([f],[g])|^2 \leqslant \alpha([f],[f]) \cdot \alpha([g],[g]) \quad \forall [f],[g] \in \tilde{V}_\Gamma^{(r)}.$$

Therefore $\tilde{\sigma}_\Gamma$ may continuously be extended to the Hilbert space $\mathcal{V}^\alpha$.

Proof: For any $[f],[g] \in \tilde{V}_\Gamma^{(r)}$ we have

$$|\tilde{\sigma}_\Gamma([f],[g])|^2 = |\alpha(J[f],[g])|^2 \leqslant \alpha(J[f],J[f]) \cdot \alpha([g],[g]) = \alpha([f],[f]) \cdot \alpha([g],[g]). \tag{5.10}$$

This shows continuity of $\tilde{\sigma}_\Gamma$ with respect to the norm induced by the inner product α on the Hilbert space $\mathcal{V}^\alpha$. □

Corollary 5.6: Let $[f] \in \tilde{V}_\Gamma^{(r)}$, then for any $W([f]) \in \Delta(\tilde{V}_\Gamma^{(r)}, \tilde{\sigma}_\Gamma)$

$$W([f]) \mapsto \Phi(W([f])) := \exp(-\tfrac{1}{2}\alpha([f],[f]))$$

defines a pure quasifree, regular state on the Weyl C*-algebra $\mathcal{W}_\Gamma^{(r)}$. Further the state Φ is invariant with respect to the geodesic automorphism group: $\Phi \circ \tau_t = \Phi$ for $t \in \mathbb{R}$.

Proof: Corollary 5.5 ensures that Φ is a positive linear functional on $\Delta(\tilde{V}_\Gamma^{(r)}, \tilde{\sigma}_\Gamma)$ such that $\Phi(\mathbb{1}) = 1$; thus it can be extended to a state on $\mathcal{W}_\Gamma^{(r)}$. The general theory[8,9] implies that Φ is in fact a pure and regular state. Invariance under τ follows from Proposition 5.4, since α is invariant under the geodesic flow $\mathrm{Fl}_t^{X_H} : \tilde{V}_\Gamma^{(r)} \to \tilde{V}_\Gamma^{(r)}$. □

Remark 5.7: From the proof of Proposition 5.4 we observe that

$$\alpha([f],[g]) = -\tilde{\sigma}_\Gamma(J[f],[g]) = \langle AJ[f],[g] \rangle = \langle P[f],[g] \rangle \tag{5.11}$$

for some positive (unbounded) operator P. Corollary 5.5 states the crucial relation in order that Corollary 5.6 defines a state, in fact Corollary 5.5 ensures positivity. This leads to the conclusion that for any other positive linear operator P' such that $P \leqslant P'$ the expression

$$W([f]) \mapsto \exp\left(-\frac{\hbar}{2} \langle P'[f],[f] \rangle \right) \tag{5.12}$$

will also define a quasifree state on the Weyl algebra $\mathcal{W}_\Gamma^{(r)}$. It is known that these states are pure if and only if $P = P'$, in which case the corresponding GNS representation is equivalent to the Fock representation.[9]

Up to now we succeeded in the construction of a state on the Weyl C*-algebra $\mathcal{W}_\Gamma^{(r)}$ which is invariant under the geodesic automorphisms. The aim of the final step is to produce a state which is also invariant under the group of horocyclic automorphisms. From Lemma 5.1 we know that the following averaging procedure will destroy the regularity of the state constructed in Corollary 5.6.

Proposition 5.8: Let $\Phi : \mathcal{W}_\Gamma^{(r)} \to \mathbb{C}$ be the state constructed in Corollary 5.6; let further $Q_\Gamma^{(\pm,r)}$ be the linear functional on the vector space $\tilde{V}_\Gamma^{(r)}$ as it was explained in Remark 4.10. Then

$$\overline{\Phi}_r(W([f]) := \begin{cases} 0 & \text{if } \langle Q_\Gamma^{(\pm,r)}, [f] \rangle \neq 0 \\ \Phi(W([f]) & \text{otherwise} \end{cases}$$

is a state invariant both under the automorphism groups corresponding to the geodesic flow τ and the horocyclic flows $\chi^{(\pm,r)}$. However $\overline{\Phi}_r$ is not regular.

Proof: We denote by $\mathcal{S}(\mathcal{W}_\Gamma^{(r)})$ the set of states of $\mathcal{W}_\Gamma^{(r)}$. From (4.16) and Corollary 5.6 it follows that $\overline{\Phi}_r \in \mathcal{S}(\mathcal{W}_\Gamma^{(r)})$ is invariant under the geodesic automorphism group τ_t. Further from Theorem 4.9, one sees that, for any $\Phi \in \mathcal{S}(\mathcal{W}_\Gamma^{(r)})$:

$$\Phi(\chi_s^{(\pm,r)} W([f])) = \Phi(e^{is\langle Q_\Gamma^{(\pm,r)},[f]\rangle} W([f])) = e^{is\langle Q_\Gamma^{(\pm,r)},[f]\rangle} \Phi(W([f])). \tag{5.13}$$

One possible averaging procedure is given by

$$\begin{aligned} \overline{\Phi}_r(W([f])) &:= \lim_{s\to\infty} \frac{1}{2s} \int_{-s}^{s} \Phi(\chi_u^{(\pm,r)} W([f]))\, du \\ &= \lim_{s\to\infty} \frac{1}{2s} \int_{-s}^{s} e^{iu\langle Q_\Gamma^{(\pm,r)},[f]\rangle}\, du \cdot \Phi(W([f])) \\ &= \begin{cases} 0 & \text{if } \langle Q_\Gamma^{(\pm,r)},[f]\rangle \neq 0 \\ \Phi(W([f])) & \text{otherwise}. \end{cases} \end{aligned} \tag{5.14}$$

By construction $\overline{\Phi}_r \in \mathcal{S}(\mathcal{W}_\Gamma^{(r)})$ is an invariant state under the horocyclic automorphisms $\chi_s^{(\pm,r)}$. □

Remark 5.9: We want to stress the fact, that for any $r>0$ we constructed a Weyl algebra $\mathcal{W}_\Gamma^{(r)}$ and a state $\overline{\Phi}_r$ which is invariant with respect to *both* the horocyclic automorphisms $\chi_s^{(\pm,r)}$ *and* the dynamics τ_t. Hence, the models described in this paper do satisfy all the defining conditions that lead to the very strong ergodic properties obtained in Ref. 1: they are quantum Anosov flows.

VI. CONCLUSIONS AND OUTLOOK

While the usual irreducible representations—of the system of imprimitivity based on configuration space—led to the impasse already noted in Ref. 1, and discussed more specifically in Appendix B here, our extension to the larger Weyl algebras $\mathcal{W}^{(r)}$ and $\mathcal{W}_\Gamma^{(r)}$ (see Definitions 3.6 and 4.1; and Theorem 4.7) now makes it possible to implement quantum versions of *both* the geodesic *and* the horocyclic flows (see Propositions 2.10 and 3.4; and Theorems 3.7 and 4.9); in particular, these groups of automorphisms satisfy the Anosov commutation relation proposed in Ref. 1, [see here Eq. (3.9) of Theorem 3.7].

As for future extensions of the present work, we think it could be interesting to investigate in more details the properties of the Weyl algebras we constructed here, explore their full physical interpretation, and in the flat case ($\lambda = 0$), to relate them to one of the known Weyl algebras.[11] In view of our Proposition 3.8 and of the general classical structures,[4] it might also be reasonable to try and extend the work of Ref. 1 in terms of relations between *derivations*: compare to the relations (3.11) and (3.12) obtained here for the derivations generating our geodesic and horocyclic automorphisms.

ACKNOWLEDGMENTS

I.P. wishes to thank the Mathematics Department at the University of Florida, Gainesville, for the hospitality he enjoyed during the academic year 1996–1997. Both authors are grateful to Georg Peter, Director of the Sonderpädagogisches Zentrum, Rankweil-Vorderland, Austria for the Zentrum's hospitality in July 1997. I.P. also wants to acknowledge here the partial support of the Land Government of Vorarlberg, Austria.

APPENDIX A: CLASSICAL ANOSOV STRUCTURES FOR THE HYPERBOLIC GEODESIC FLOW

The main purpose of this Appendix is to fix the notation for the classical objects we want to quantize. It may also serve two ancillary functions: to provide an essentially self-contained presentation of the classical structures; and to have a notation flexible enough to show readily how these structures collapse in the limit where the curvature of the configuration space vanishes.

1. Flows on the configuration spaces $M_{\mu,\lambda}$

Definitions A.1: $(M_{\mu,\lambda},g)$ (or simply $M_{\mu,\lambda}$) denotes the Riemannian manifold $\mathbb{R}^2$, with Cartesian coordinates (x^1,x^2), and metric

$$g(x^1,x^2)=\mu^2\ dx^1\otimes dx^1+e^{-4\lambda x^1}dx^2\otimes dx^2 \tag{A1}$$

where $\mu>\lambda\geqslant 0$ are left arbitrary. Upon passing to an orthonormal coframe $\{\sigma^1,\sigma^2\}$ given by

$$\sigma^1(x^1,x^2)=\mu\ dx^1,\sigma^2(x^1,x^2)=e^{-2\lambda x^1}dx^2 \tag{A2}$$

and its dual orthonormal frame field $\{s_1,s_2\}$ defined via $\langle\sigma^i,s_j\rangle:=\delta^i_j$ we write $g^\sharp=s_1\otimes s_1+s_2\otimes s_2$ for the cometric. The cotangent bundle $T^*M_{\mu,\lambda}$ (respectively, the tangent bundle $TM_{\mu,\lambda}$) shall be parametrized as

$$\begin{aligned} T^*M_{\mu,\lambda}\ni(x^i,p_i)\equiv(x^1,x^2,p_1,p_2)\equiv p_1\sigma^1(x^1,x^2)+p_2\sigma^2(x^1,x^2),\\ TM_{\mu,\lambda}\ni(x^i,v^i)\equiv(x^1,x^2,v^1,v^2)\equiv v^1s_1(x^1,x^2)+v^2s_2(x^1,x^2). \end{aligned} \tag{A3}$$

Thus p_i (respectively, v^i) appear as coordinates with respect to the chosen orthonormal coframe $\{\sigma^1,\sigma^2\}$ (respectively, the frame $\{s_1,s_2\}$). The identification of $TM_{\mu,\lambda}$ and $T^*M_{\mu,\lambda}$ via the metric g is now written as $(\Sigma p_i\sigma^i)^\sharp=\Sigma p_is_i$ and conversely $(\Sigma v^is_i)^\flat=\Sigma v^i\sigma^i$. For the ''length'' of covectors (respectively, vectors), we introduce the notations:

$$\begin{aligned} |(x^1,x^2,p_1,p_2)|:=\sqrt{g^\sharp((x^i,p_i),(x^i,p_i))}(=\sqrt{{p_1}^2+{p_2}^2}),\\ |(x^1,x^2,v^1,v^2)|:=\sqrt{g((x^i,v^i),(x^i,v^i))}(=\sqrt{(v^1)^2+(v^2)^2}). \end{aligned} \tag{A4}$$

Proposition A.2: $(M_{\mu,\lambda},g)$ is a two-dimensional, simply connected Riemannian manifold of constant negative (sectional) curvature $\kappa=-4\lambda^2/\mu^2$. For $\mu=2\lambda$

$$\Phi:M_{\mu,\lambda}\to\mathbb{C}^\uparrow,(x^1,x^2)\mapsto x^2+ie^{2\lambda x^1}$$

establishes an isometry from $M_{\mu,\lambda}$ onto Poincaré half-plane $\mathbb{C}^\uparrow:=\{z\in\mathbb{C}\mid \mathrm{Im}\ z>0\}$. In the case $(\mu,\lambda)=(1,0)$, the model becomes the flat $\mathbb{R}^2$.

Proof: Upon using Cartan's structure equations

$$d\sigma^i=-\sum_k\ \omega^i{}_k\wedge\sigma^k,\quad \Omega^i{}_k=d\omega^i{}_k+\sum_j\ \omega^i{}_j\wedge\omega^j{}_k \tag{A5}$$

one readily computes the connection one-form $\omega^1{}_2=(2\lambda/\mu)\ \sigma^2$ and the curvature two-form $\Omega^1{}_2=-(4\lambda^2/\mu^2)\ \sigma^1\wedge\sigma^2$. From these expressions one gets for the (sectional) curvature κ,

$$\kappa(s_1,s_2)=-g(\Omega^2{}_1(s_1,s_2)s_2,s_2)=-\frac{4\lambda^2}{\mu^2}(\sigma^1\wedge\sigma^2)(s_1,s_2)g(s_2,s_2)=-\frac{4\lambda^2}{\mu^2}. \tag{A6}$$

In order to see that Φ is the required isometry one observes that

$$\Phi^*\left(-4\frac{dz\otimes d\bar{z}}{(z-\bar{z})^2}\right)=g \tag{A7}$$

where the expression in the bracket on the left-hand side is the metric of Poincaré half-plane. □

Remark A.3: The advantage of this model for Lobatchevski hyperbolic geometry over Poincaré half-plane or the open-unit-disk model in $\mathbb{C}$ is that it allows one to follow immediately the effect of the ''flattening'' $(\mu,\lambda)\to(1,0)$ since the underlying manifold is already $\mathbb{R}^2$.

Lemma A.4: Let $(x^i,v^i)\in TM_{\mu,\lambda}$ with $0<|(x^i,v^i)|=r=\mathrm{const}$, then:

(1) There exist two vector fields $G_\pm \in \mathcal{X}(M_{\mu,\lambda})$ such that $\nabla_{G_\pm} G_\pm = 0$ and $G_\pm(x^1,x^2) = v^1 s_1(x^1,x^2) + v^2 s_2(x^1,x^2)$: $G_\pm$ are geodesic vector fields having the geodesic through (x^1,x^2) with initial tangent vector (x^i,v^i) as a flow line. The vector fields $G_\pm$ may be chosen such that $g(G_\pm,G_\pm) = r^2 = \text{const}$, and the $G_\pm$ are complete.
(2) For these geodesic vector fields $G_\pm \in \mathcal{X}(M_{\mu,\lambda})$, there exist vector fields $H_\pm \in \mathcal{X}(M_{\mu,\lambda})$ such that $g(G_\pm,H_\pm) = 0$ and $g(H_\pm,H_\pm) = r^2$. The vector fields $H_\pm$ are complete.
(3) The above vector fields satisfy the relations $[G_\pm,H_\pm] = \pm(2\lambda r/\mu) H_\pm$. The integral version of this relation in terms of the respective flows reads

$$\mathrm{Fl}_{-t}^{G_\pm} \circ \mathrm{Fl}_s^{H_\pm} \circ \mathrm{Fl}_t^{G_\pm} = \mathrm{Fl}^{H_\pm}_{\exp(\pm(2\lambda/\mu) rt)_s}. \quad (*)$$

Proof: Choose $(x^1,x^2,v^1,v^2) \in TM_{\mu,\lambda}$ and set $v^1 = r \cos\psi$, $v^2 = r \sin\psi$. We first treat the case $\cos\psi \neq \pm 1$. For $(y^1,y^2) \equiv y \in \mathbb{R}^2$ consider the functions

$$z^\pm(y^1,y^2) = \pm \frac{2\lambda}{\mu} \mathrm{e}^{-2\lambda y^1}(K_\pm - y^2), \quad \text{(A8)}$$

where

$$K_\pm := x^2 \pm \frac{\mu}{2\lambda} e^{2\lambda x^1} \frac{\sin\psi}{1 \mp \cos\psi} \quad \text{(A9)}$$

are determined by the chosen (x^i,v^i). Upon setting

$$G_\pm(y) = \mp r \frac{1 - z_\pm(y)^2}{1 + z_\pm(y)^2} s_1 + r \frac{2 z_\pm(y)}{1 + z_\pm(y)^2} s_2 \quad \text{(A10)}$$

one checks that the vector fields $G_\pm$ are geodesic vector fields indeed. For the vector fields $H_\pm$ we set

$$H_\pm(y) = -r \frac{2 z_\pm(y)}{1 + z_\pm(y)^2} s_1 \mp r \frac{1 - z_\pm(y)^2}{1 + z_\pm(y)^2} s_2. \quad \text{(A11)}$$

From this construction we observe that in case $\cos\psi = 1$ the vector fields G_- and H_- can also be defined: we set $G_+ := rs^1$ and $H_+ := rs^2$. The same applies in the case $\cos\psi = -1$ for G_+ and H_+, where we define $G_- := -rs^1$ and $H_- := -rs^2$. Then $g(G_\pm,H_\pm) = 0$ by construction. A straightforward computation shows that these vector fields also satisfy $[G_\pm,H_\pm] = \pm(2\lambda r/\mu) H_\pm$. As $M_{\mu,\lambda}$ is a complete Riemannian manifold, we conclude from the Hopf–Riemann theorem that maximal geodesics are defined on $\mathbb{R}$ and hence the vector fields $G_\pm$ and also $H_\pm$ are complete. The commutation relation for the flows can be shown generally: assume the flows of two vector fields $X,Y \in \mathcal{X}(M)$ on a manifold M satisfy

$$\mathrm{Fl}_{-t}^X \circ \mathrm{Fl}_s^Y \circ \mathrm{Fl}_t^X = \mathrm{Fl}^Y_{e^{\rho t} s} \quad \text{(A12)}$$

for some $\rho \in \mathbb{R}$. Taking the derivative with respect to s at $s = 0$ of the left-hand side ($x \in M$) yields

$$\frac{d}{ds}\Big|_{s=0} (\mathrm{Fl}_{-t}^X \circ \mathrm{Fl}_s^Y \circ \mathrm{Fl}_t^X)(x) = T(\mathrm{Fl}_{-t}^X).Y(\mathrm{Fl}_t^X(x)) = (\mathrm{Fl}_t^X)^* Y(x) \quad \text{(A13)}$$

and for the right-hand side

$$\frac{d}{ds}\Big|_{s=0} \mathrm{Fl}^Y_{e^{\rho t} s}(x) = e^{\rho t} Y(x) \Rightarrow (\mathrm{Fl}_t^X)^* Y = e^{\rho t} Y. \quad \text{(A14)}$$

Finally upon taking the derivative with respect to t at $t = 0$ we obtain $L_X Y = [X,Y] = \rho Y$ which completes the proof. □

Remark A.5: (1) The vector fields $G_\pm, H_\pm \in \mathcal{X}(M_{\mu,\lambda})$ described in the above lemma (or more precisely their liftings to the vector fields $X_H, E_\pm \in \mathcal{X}(T^*M_{\mu,\lambda})$ defined in Corollary A.8 below) are a special case of a *(classical) Anosov system*. The commutation relations (*) of Lemma A.4 shall be referred to as *Anosov commutation relations* (ACR). The constants $\pm(2\lambda/\mu)\,r$ appearing in the ACR are the *Lyapunov coefficients* for this system. The vector fields $H_\pm$ are the expanding, respectively, contracting *horocyclic vector field*.

(2) The geodesic through (x^1,x^2) with initial tangent vector (x^i,v^i) is an integral curve of both vector fields $G_\pm$.

(3) In two dimensions the vector fields $H_\pm$ are determined by $G_\pm$ uniquely (up to a nonzero function) because the metric is nondegenerate. The vector fields $G_\pm$ and $H_\pm$ depend on the chosen point (x^i,v^i).

(4) Concerning property (3) in Lemma A.4, one can generally conclude that

$$[G,H]=fH \tag{A15}$$

where f is a function. To be more precise, assume

$$\nabla_G G=0, \qquad g(G,H)=0, \quad g(G,G)=\text{const} \tag{A16}$$

then

$$\begin{gathered} g(\nabla_G H,G)=\nabla_G(g(H,G))-g(H,\nabla_G G)=0, \\ g(\nabla_H G,G)=\nabla_H(g(G,G))-g(G,\nabla_H G), \\ g(\nabla_H G,G)=0, \end{gathered} \tag{A17}$$

and therefore, since $g([H,G],G)=g(\nabla_H G,G)-g(\nabla_G H,G)$,

$$g([H,G],G)=0 \tag{A18}$$

and, since the manifold is two dimensional, one concludes that $[H,G]=fH$ for some function f. Note that the conditions on G and H listed at the beginning of this remark would be too weak to conclude that the ''Lyapunov coefficient'' is a constant indeed: Pick a point in $M_{\mu,\lambda}$ and consider all geodesics emanating from this point. After removing the point, this family of geodesics determines a geodesic vector field as well as a vector field that is perpendicular to the geodesic vector field; this is in fact an example where the Lyapunov coefficient is not a constant but a function. However, in this case, the vector fields are not complete either.

(5) A similar situation occurs in deSitter space–time, where one may also implement an Anosov system, however here the ''Lyapunov coefficients'' are only constant on the horizons.[12]

2. Flows on the phase spaces $T^*M_{\mu,\lambda}$

Proposition A.6: The flows $\mathrm{Fl}_t^{G_\pm}$, respectively, $\mathrm{Fl}_s^{H_\pm}$ of the geodesic, respectively, horocyclic vector fields are lifted to the cotangent bundle in the following manner:

$$\mathrm{geo}((x^i,p_i);t):=G_\pm^\flat(\mathrm{Fl}_t^{G_\pm}(x^i)), \qquad h_\pm((x^i,p_i);s):=G_\pm^\flat(\mathrm{Fl}_s^{H_\pm}(x^i)),$$

where the geodesic vector fields $G_\pm$ depend on the point (x^i,p_i) and have to be chosen such that $G_\pm^\flat(x^i)=(x^i,p_i)$. The actions geo and $h_\pm$ mapping $T^*M_{\mu,\lambda}\times\mathsf{R}$ to $T^*M_{\mu,\lambda}$ will be referred to as geodesic coflow and (cotangent) horocyclic flows. The flows geo and $h_\pm$ leave the r-sphere bundle $T_r^*M_{\mu,\lambda}$ invariant, where $T_r^*M_{\mu,\lambda}:=\{(x^i,p_i)\in T^*M_{\mu,\lambda} \mid |(x^i,p_i)|=r\}$. They again satisfy the ACR with the same Lyapunov coefficients:

$$\mathrm{geo}(h_\pm(\mathrm{geo}(x^i,p_i;t);s);-t)=h_\pm\left(x^i,p_i;\exp\left(\pm\frac{2\lambda}{\mu}rt\right)s\right).$$

Proof: $\mathrm{geo}: T^*M_{\mu,\lambda}\times \mathbb{R} \to T^*M_{\mu,\lambda}$ coincides with the common geodesic coflow through (x^i,p_i) and does not depend on which of the two $G_\pm$'s we choose. That $h_\pm : \mathbb{R}\times T^*M_{\mu,\lambda}\times \mathbb{R} \to T^*M_{\mu,\lambda}$ is actually a flow may be seen from

$$h_\pm((x^i,p_i);0) = G_\pm^\flat(\mathrm{Fl}_0^{H_\pm}(x^i)) = G_\pm^\flat(x^i) = (x^i,p_i) \tag{A19}$$

and

$$\begin{aligned} h_\pm(h_\pm((x^i,p_i);s_1);s_2) &= h_\pm(G_\pm^\flat(\mathrm{Fl}_{s_1}^{H_\pm}(x^i));s_2) \\ &= G_\pm^\flat(\mathrm{Fl}_{s_2}^{H_\pm}(\mathrm{Fl}_{s_1}^{H_\pm}(x^i))) \\ &= G_\pm^\flat(\mathrm{Fl}_{s_1+s_2}^{H_\pm}(x^i)) = h_\pm((x^i,p_i);s_1+s_2). \end{aligned} \tag{A20}$$

From the same lines one concludes that the ACR are fulfilled:

$$\begin{aligned} \mathrm{geo}(h_\pm(\mathrm{geo}(x^i,p_i;t);s);-t) &= \mathrm{geo}(h_\pm(G_\pm^\flat(\mathrm{Fl}^{G_\pm}(x^i));s);-t) \\ &= \mathrm{geo}(G_\pm^\flat(\mathrm{Fl}_s^{H_\pm}\circ \mathrm{Fl}_t^{G_\pm}(x^i));-t) \\ &= G_\pm^\flat(\mathrm{Fl}_{-t}^{G_\pm}\circ \mathrm{Fl}_s^{H_\pm}\circ \mathrm{Fl}_t^{G_\pm}(x^i)) \\ &= G_\pm^\flat\left(\mathrm{Fl}^{H_\pm}_{\exp\left(\pm\frac{2\lambda}{\mu}rt\right)s}(x^i)\right) = h_\pm\left(x^i,p_i;\exp\left(\pm\frac{2\lambda}{\mu}rt\right)s\right). \end{aligned} \tag{A21}$$

Since $g^\sharp(G_\pm^\flat,G_\pm^\flat)=r^2=\mathrm{const}$, the flows geo and $h_\pm$ are contained in $T_r^*M_{\mu,\lambda}$ by construction and Lemma A.4.1 and 2. □

3. Symplectic structures

So far we have given an explicit description of an Anosov system on the r-sphere bundle $T_r^*M_{\mu,\lambda}$ of Poincaré half-plane. We still need to state some properties of the geodesic and horocyclic flows which we will use in the quantization carried out in the body of the paper.

Any cotangent bundle carries the structure of a symplectic manifold in a natural manner; in our case the (nondegenerate) symplectic two-form $\omega\in\Omega^2(T^*M_{\mu,\lambda})$ is given at the point $(x^i,p_i)\in T^*M_{\mu,\lambda}$ by

$$\omega_{(x^i,p_i)} = \sum_{j=1}^{2}(\sigma^j\wedge dp_j - p_j d\sigma^j) = \sigma^1\wedge dp_1 + \sigma^2\wedge dp_2 + \frac{2\lambda}{\mu}p_2\ \sigma^1\wedge\sigma^2. \tag{A22}$$

A smooth function $f\in C^\infty(T^*M_{\mu,\lambda},\mathbb{R})$ determines a Hamiltonian vector field $X_f\in\mathcal{X}(T^*M_{\mu,\lambda})$ via $i_{X_f}\omega = df$. Moreover in the sequel we will need a Poisson bracket which is defined as $\{f,g\} := \omega(X_f,X_g)$ for $f,g\in C^\infty(T^*M_{\mu,\lambda},\mathbb{R})$. $\omega\wedge\omega$ will serve as the volume on phase space $T^*M_{\mu,\lambda}$.

Remark A.7: The Hamiltonian flow on the cotangent bundle $T^*M_{\mu,\lambda}$ determined by the Hamiltonian

$$H(x^i,p_i) := \tfrac{1}{2}g^\sharp((x^i,p_i),(x^i,p_i)) = \tfrac{1}{2}(p_1^2+p_2^2) \tag{A23}$$

coincides with the geodesic coflow as given in Proposition A.6.[13] Therefore the corresponding Hamiltonian vector field X_H is in turn the geodesic cospray on the cotangent bundle. The r-sphere bundle may now also be defined as $H^{-1}(r^2/2)$ for $r>0$. Moreover there exists a unique volume Ω_r on $T_r^*(M_{\mu,\lambda})$ such that $\omega\wedge\omega = \Omega_r\wedge dH$.

Corollary A.8: Upon using the notation of Proposition A.6 and Remark A.7, we may define the vector fields $X_H, E_\pm\in\mathcal{X}(T^*M_{\mu,\lambda})$

$$\mathrm{geo}((x^i,p_i);t) = \mathrm{Fl}_t^{X_H}(x^i,p_i) \quad \text{and} \quad h_\pm((x^i,p_i);s) =: \mathrm{Fl}_s^{E_\pm}(x^i,p_i),$$

where $X_H, E_\pm \in \mathcal{X}(T^*M_{\mu,\lambda})$ denote the vector fields generating the geodesic flow and the horocyclic flows on $T^*M_{\mu,\lambda}$. Once restricted to $T_r^*M_{\mu,\lambda}$, they satisfy

$$[X_H, E_\pm] = \pm \frac{2\lambda r}{\mu} E_\pm .$$

Proof: This follows immediately from Lemma A.4.3 and the conclusion of Proposition A.6, with the ACR rewritten as:

$$\mathrm{Fl}_{-t}^{X_H} \circ \mathrm{Fl}_s^{E_\pm} \circ \mathrm{Fl}_t^{X_H} = \mathrm{Fl}_{\exp(\pm(2\lambda/\mu) rt)s}^{E_\pm}. \tag{A24}$$

□

Proposition A.9:

(1) The geodesic co-flow geo: $T_r^*M_{\mu,\lambda} \times \mathbb{R} \to T_r^*M_{\mu,\lambda}$ is a one-parameter group of symplectomorphisms.
(2) The horocyclic flows $h_\pm : T_r^*M_{\mu,\lambda} \times \mathbb{R} \to T_r^*M_{\mu,\lambda}$ do not consist of symplectomorphisms; nevertheless $h_\pm$ leave the volume Ω_r on $T_r^*(M_{\mu,\lambda})$ invariant.

Proof: Ad (1): From the definition of geo, we see that

$$\mathrm{geo}((x^i, p_i); t) := G_\pm^\flat(\mathrm{Fl}_t^{G_\pm}(x^i)) = T_{x^i}^* \mathrm{Fl}_t^{G_\pm} . G_\pm^\flat(x^i)$$

whence the geodesic coflow arises as lift of the diffeomorphisms $\{\mathrm{Fl}_t^{G_\pm} | t \in \mathbb{R}\} \subset \mathrm{Diff}(M_{\mu,\lambda})$ and is therefore symplectic.[13] (An alternate argument would be that the geodesic coflow arises as a Hamiltonian flow). *Ad* (2): Since $h_\pm(T_r^*M_{\mu,\lambda}; s) \subset T_r^*M_{\mu,\lambda}$ $\forall s \in \mathbb{R}$ we have $L_{E_\pm} H = 0$. Assume $\mathrm{Fl}_s^{E_\pm}$ are symplectic $\Leftrightarrow L_{E_\pm}\omega = 0$, then

$$0 = dL_{E_\pm} H = L_{E_\pm} dH = L_{E_\pm} i_{X_H}\omega = i_{[E_\pm, X_H]}\omega + i_{X_H} L_{E_\pm}\omega = \mp \frac{2\lambda r}{\mu} \cdot i_{E_\pm}\omega$$

which yields $E_\pm = 0$, a contradiction if $\lambda > 0$. If $\lambda = 0$ we arrive in the flat case, where the statement may be checked by explicit computation. In order to see that $h_\pm(s)^*\Omega_r = \Omega_r$, it suffices to check that $h_\pm(s)^*(\omega \wedge \omega) = \omega \wedge \omega$; this again is done by explicit computation. □

4. Flows on the unit cotangent bundle of compact quotients $\Gamma \backslash M_{\mu,\lambda}$

Finally, we review in this subsection a family of classical hyperbolic flows that admit a natural invariant probability measure. We recall first[14] that a Riemannian manifold M of dimension $n \geqslant 2$ is complete, connected, and of constant negative curvature $\kappa < 0$, if and only if it is isometric to a quotient $\Gamma \backslash H_\kappa^{(n)}$, where $H_\kappa^{(n)}$ is *the* simply connected n-dimensional hyperbolic space of curvature κ ; and Γ is a group of isometries of $H_\kappa^{(n)}$ acting: (i) freely (i.e., for every $x \in H_\kappa^{(n)}$: $\Gamma_x \equiv \{\gamma \in \Gamma | \gamma[x] = x\}$ is trivial); and (ii) properly discontinuously (i.e., for every $x \in H_\kappa^{(n)}$: there exists a neighborhood U of x such that $\Gamma_U \equiv \{\gamma \in \Gamma | \gamma[U] \cap U \neq \varnothing\}$ is finite; the latter condition implying that the orbit space is Hausdorff. In order to exploit the detailed information gathered on the geodesic flow on the universal covering space $H_\kappa^{(n)}$, we restrict our attention to the case of two-dimensional manifolds. This, however, still allows for spectral pathologies of the type exemplified by the Selberg trace formula[15] where $\Gamma (= \mathrm{SL}(2,\mathbb{Z}))$ acts freely and even properly discontinuously on the Poincaré half-plane, with nevertheless $\Gamma \backslash H_\kappa^{(2)}$ *not* compact, although it is of finite volume. To obtain a good ergodic behavior, based on a natural invariant probability measure, we will henceforth assume that Γ is co-compact. The literature on these manifolds is extensive: see, e.g., Refs. 16–19; for a concrete example of a compact (i.e., not just finite-volume) fundamental domain, see e.g., Ref. 20.

Proposition A.10: If $\lambda > 0$ the symmetry group of $M_{\mu,\lambda}$ is $\mathrm{SL}(2,\mathbb{R})$. Since $\dim M_{\mu,\lambda} = 2$ and $\dim \mathrm{SL}(2,\mathbb{R}) = 3$, the Riemannian manifold $M_{\mu,\lambda}$ is a maximally symmetric space. The isotropy groups are all isomorphic to $\mathrm{SO}(2,\mathbb{R})$. The group H_2 occurring in the Iwasawa decomposition $\mathrm{SL}(2,\mathbb{R}) = H_2 \cdot \mathrm{SO}(2,\mathbb{R})$ acts freely and transitively on $M_{\mu,\lambda}$.

Proof: Solving Killing equation $L_K g = 0$ provides us with three linear independent Killing vector fields $K_i \in \mathcal{X}(M_{\mu,\lambda}), i \in \{1,2,3\}$,

$$K_1(x^1,x^2) = \mu s^1 + 2\lambda x^2 e^{-2\lambda x^1} s^2,$$

$$K_2(x^1,x^2) = e^{-2\lambda x^1} s^2, \tag{A25}$$

$$K_3(x^1,x^2) = -\mu x^2 s^1 + \left(\frac{\mu^2}{2\lambda} \sinh(2\lambda x^1) - \lambda (x^2)^2 e^{-2\lambda x^1} \right) s^2.$$

We remark that for $(\mu,\lambda) = (1,0)$ these Killing vector fields generate the Euclidean group $E_2 = \mathrm{SO}(2,\mathbb{R}) \cdot \mathbb{R}^2$. In general, the Lie brackets are given by

$$[K_1,K_2] = -2\lambda K_2, \quad [K_1,K_3] = \mu^2 K_2 + 2\lambda K_3, \quad [K_2,K_3] = -K_1. \tag{A26}$$

If $\lambda > 0$ the applications

$$\hat{K}_1 := \frac{1}{\lambda} K_1 \mapsto \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

$$\hat{K}_2 := \frac{1}{\sqrt{\lambda}} K_2 \mapsto \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \tag{A27}$$

$$\hat{K}_3 := \frac{1}{\sqrt{\lambda}} \left(\frac{\mu^2}{4\lambda} K_2 + K_3 \right) \mapsto \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$$

provide a Lie algebra (anti-) isomorphism of the Lie algebra of Killing vector fields onto the Lie algebra $\mathsf{sl}(2,\mathbb{R})$ of the special linear group $\mathrm{SL}(2,\mathbb{R})$. $K_3(0,0) = 0$ and therefore generates the isotropy group at the point $(0,0) \in M_{\mu,\lambda}$, which is one-dimensional and has to be compact, whence is $\mathrm{SO}(2,\mathbb{R})$. Since $M_{\mu,\lambda}$ is connected, the isotropy groups at different points are all isomorphic via conjugation. The vector fields K_1 and K_2 have no zeros on $M_{\mu,\lambda}$, hence the group H_2 generated by their flows acts effectively; a dimension argument shows transitivity. □

Lemma A.11: Let $U: \mathrm{SL}(2,\mathbb{R}) \to \mathrm{Isom}(M_{\mu,\lambda}), \gamma \mapsto U(\gamma)$ denote the representation of $\mathrm{SL}(2,\mathbb{R})$ as isometries on $M_{\mu,\lambda}$. Then we have:

(1) $\Phi \circ \mathrm{Fl}_t^X = \mathrm{Fl}_t^{\Phi_* X} \circ \Phi$ for $\Phi \in \mathrm{Diff}(M_{\mu,\lambda})$ and $X \in \mathcal{X}(M_{\mu,\lambda})$.
(2) $U(\gamma)_* G_\pm$ are again geodesic vector fields.
(3) $g(U(\gamma)_* G_\pm, U(\gamma)_* H_\pm) = 0$ for all $\gamma \in \mathrm{SL}(2,\mathbb{R})$.

Proof: *Ad* (1) $\Phi_* X := T\Phi \circ X \circ \Phi^{-1}$, consider

$$\frac{d}{dt}(\Phi \circ \mathrm{Fl}_t^X) = T\Phi . \frac{d}{dt} \mathrm{Fl}_t^X = T\Phi \circ X \circ \mathrm{Fl}_t^X = \Phi_* X (\Phi \circ \mathrm{Fl}_t^X) \tag{A28}$$

and

$$\Phi(\mathrm{Fl}_0^X(x)) = \Phi(x). \tag{A29}$$

This shows (1). *Ad* (2): Remember that isometries map geodesics to geodesics, then use (1). *Ad* (3): This is clear. □

Definition A.12: We define the induced action $U_*: \mathrm{SL}(2,\mathbb{R}) \to \mathrm{Diff}(T_r^* M_{\mu,\lambda})$ of the group $\mathrm{SL}(2,\mathbb{R})$ on the r-sphere bundle $T_r^* M_{\mu,\lambda}$ by

$$U_*: \mathrm{SL}(2,\mathbb{R}) \to \mathrm{Diff}(T_r^* M_{\mu,\lambda}), \gamma \mapsto U_*(\gamma) := ((x^i,p_i) \mapsto (U(\gamma).x^i, T^*_{x^i} U(\gamma).p_i)) \tag{A30}$$

where $U: \mathrm{SL}(2,\mathbb{R}) \to \mathrm{Diff}(M_{\mu,\lambda})$ is the action on the configuration space $M_{\mu,\lambda}$.

Theorem A.13: Let $U_*:\mathrm{SL}(2,\mathbb{R}) \to \mathrm{Diff}(T_r^* M_{\mu,\lambda})$ be the representation of $\mathrm{SL}(2,\mathbb{R})$ on the r-sphere bundle as defined in A.12. Then $U_*(\gamma)$ commutes with both the geodesic and horocyclic flows:

$$U_*(\gamma)\mathrm{geo}(.,t) = \mathrm{geo}(.,t)U_*(\gamma) \quad \text{and} \quad U_*(\gamma)h_\pm(.,s) = h_\pm(.,s)U_*(\gamma) \tag{A31}$$

for all $t,s \in \mathbb{R}$ and $\gamma \in \mathrm{SL}(2,\mathbb{R})$. Moreover, $U_*(\gamma)$ are symplectomorphisms for all $\gamma \in \Gamma$.

Proof: Taking into account $U_*(\gamma).X^\flat = (U(\gamma)_* X)^\flat$ and Lemma A.11, we consider the ''raised'' flows on $TM_{\mu,\lambda}$:

$$\begin{aligned} TU(\gamma).G_\pm(\mathrm{Fl}_t^{G_\pm}(x^i)) &= TU(\gamma).G_\pm(U(\gamma^{-1})U(\gamma).\mathrm{Fl}_t^{G_\pm}(x^i)) \\ &= (U_*(\gamma)G_\pm)(U(\gamma).\mathrm{Fl}_t^{G_\pm}(x^i)) \\ &= (U(\gamma)_* G_\pm)(\mathrm{Fl}_t^{U(\gamma)^* G_\pm}(U(\gamma).x^i)) \end{aligned} \tag{A32}$$

which shows that U_* commutes with geo; the proof for $H_\pm$ follows the same lines. Finally $U_*(\gamma)$ are symplectomorphisms as lifts of diffeomorphisms of the configuration space $M_{\mu,\lambda}$. □

We are now in position to describe the dynamics on *smooth quotients manifolds* $\Gamma\backslash M_{\mu,\lambda}$ where $\Gamma \subset \mathrm{SL}(2,\mathbb{R})$ is a discrete *co-compact* subgroup of the symmetry group $\mathrm{SL}(2,\mathbb{R})$ of the model $M_{\mu,\lambda}$.

Definition A.14: Let $\Gamma \subset \mathrm{SL}(2,\mathbb{R})$ be a discrete co-compact subgroup of $\mathrm{SL}(2,\mathbb{R})$ acting on $M_{\mu,\lambda}$ via a representation U. There exists a compact subset $F_\Gamma \subset M_{\mu,\lambda}$ such that $\cup_{\gamma\in\Gamma} U(\gamma).F_\Gamma = M_{\mu,\lambda}$, and there are no two Γ-equivalent points in the interior of F_Γ. The boundary of F_Γ consists of geodesic arcs. F_Γ is called *fundamental domain* for the discrete co-compact group $\Gamma \subset \mathrm{SL}(2,\mathbb{R})$. We recall (see the beginning of Appendix A 4) that the compact quotients considered in this paper are smooth manifolds.

Proposition A.15: $\mathrm{Fl}_t^{X_H}$, $\mathrm{Fl}_s^{E_\pm}: T^*M_{\mu,\lambda} \to T^*M_{\mu,\lambda}$, the geodesic and horocyclic flows on the cotangent bundle $T^*M_{\mu,\lambda}$, factor to the corresponding flows—again denoted by $\mathrm{Fl}_t^{X_H}$, respectively, $\mathrm{Fl}_s^{E_\pm}$—on the cotangent bundle $T^*(\Gamma\backslash M_{\mu,\lambda})$ of the quotient $\Gamma\backslash M_{\mu,\lambda}$. Moreover, the flows on the quotient cotangent bundle $T^*(\Gamma\backslash M_{\mu,\lambda})$ again satisfy the ACR. Furthermore, the quotient sphere bundles $T_r^*(\Gamma\backslash M_{\mu,\lambda})$ admit a probability measure ν that is invariant under both of these flows.

Proof: It follows from Theorem A.13 that the factorization is well-defined and satisfies the ACR. The projections of geodesics are indeed the geodesics on $\Gamma\backslash M_{\mu,\lambda}$ since $\pi: M_{\mu,\lambda} \to \Gamma\backslash M_{\mu,\lambda}$ is a Riemannian covering. Finally, the images of the horocycles are the corresponding horocycles on $\Gamma\backslash M_{\mu,\lambda}$, because they remain perpendicular to the geodesics. The probability measure ν is obtained by normalizing the measure Ω_r on the quotient determined by $\omega \wedge \omega = \Omega_r \wedge dH$; thereby $\omega \in \Omega^2(T^*(\Gamma\backslash M_{\mu,\lambda}))$ is the canonical symplectic form on the cotangent bundle of the quotient $\Gamma\backslash M_{\mu,\lambda}$, see Remark A.7 (and also Remark A.17 below). Proposition A.9 implies that this measure is invariant under both the geodesic and the horocyclic flows. □

This concludes our review of the main ingredients of the classical system, the quantization of which is the purpose of the body of this paper. While our review emphasized the structures we shall actually rely on, the singular importance of this system is that it provides a model for some of the strongest ergodic property one can expect from a classical Hamiltonian dynamical system. These properties are summarized in the following result.

Theorem A.16: The geodesic flow on the unit cotangent bundle $T_1^* M_{\mu,\lambda}$ is a C-flow. It thus satisfies in particular the following properties in the ergodic hierarchy: it is a K-flow, it is mixing with uniform Lebesgue spectrum, and it is ergodic.

This result is textbook staple; it is referred to in Ref. 4 as the Lobatchevski–Hadamard Theorem; see their Theorem 14.3, and its proof in their Appendix 21; see also Refs. 21 and 22. The metric transitivity itself had been known already for more than sixty years,[23] while the group theoretical approach which we shall exploit in our quantization has been pioneered, for the classical version of the model, in Ref. 24.

Remark A.17: In the body of the paper, we deal with the Anosov system on some compact quotient $\Gamma\backslash M_{\mu,\lambda}$ of Lobatchevski hyperbolic geometry $M_{\mu,\lambda}$. There, we use on the quotient only

the system of flows as given in (A.15), and from these we produce all the further objects we need, e.g., the corresponding vector fields. Neither do we intend to factor the symplectic form of $T^*M_{\mu,\lambda}$ to $T^*(\Gamma\backslash M_{\mu,\lambda})$; indeed, $T^*(\Gamma\backslash M_{\mu,\lambda})$ is a cotangent bundle on its own right, and therefore carries its own symplectic structure.

APPENDIX B: A NO-GO DYNAMICAL THEOREM

1. The Weyl group

To find the appropriate Weyl group for a physical system described by the cotangent bundle of some configuration space (i.e., systems with finitely many degrees of freedom) one usually looks for a group acting transitively, effectively and symplectically on the phase space under consideration, Ref. 5. In our case, the phase space is the cotangent bundle $T^*M_{\mu,\lambda}$ of Poincaré half-plane, and the group may be chosen, Ref. 6, to be $G^4_\lambda := H^2_\lambda \oslash \mathbb{R}^2$ with group multiplication law

$$(a^1,a^2,b_1,b_2)(c^1,c^2,d_1,d_2)=(a^1+c^1,a^2+\mathrm{e}^{2\lambda a^1}c^2,b_1+d_1,b_2+\mathrm{e}^{-2\lambda a^1}d_2) \tag{B1}$$

which leads to the Lie algebra $\mathfrak{g}^4_\lambda$:

$$[K_1,K_3]=[K_2,K_3]=[K_2,K_4]=[K_3,K_4]=0, \tag{B2}$$

$$[K_1,K_2]=2\lambda K_2,[K_1,K_4]=-2\lambda K_4. \tag{B2}$$

Moreover one has to make a transition to a central extension W^5_λ

$$0\to S^1\to W^5_\lambda\to G^4_\lambda\to 0 \tag{B3}$$

determined by the cocycle $c: G^4_\lambda\times G^4_\lambda\to S^1$:

$$c((a^1,a^2,b_1,b_2),(c^1,c^2,d_1,d_2))=\exp(i(a_1d_1+a_2d_2e^{-2\lambda a^1})). \tag{B4}$$

The Lie algebra $\mathfrak{w}^5_\lambda$ of W^5_λ is then given by

$$\begin{gathered}[K_2,K_3]=[K_3,K_4]=0,\\ [K_1,K_2]=2\lambda K_2,[K_1,K_4]=-2\lambda K_4,\\ [K_1,K_3]=[K_2,K_4]=K_5,\\ [K_i,K_5]=0 \quad \text{for } i=1,\ldots,4.\end{gathered} \tag{B5}$$

2. Action of G^4_λ on $T^*M_{\mu,\lambda}$.

Take $(x^1,x^2,p_1,p_2)\in T^*M_{\mu,\lambda}$, then

$$(a^1,a^2,b_1,b_2).(x^1,x^2,p_1,p_2)=\left(a^1+x^1,a^2+e^{2\lambda a^1}x^2,p_1+\frac{b_1}{\mu},p_2+e^{2\lambda(a^1+x^1)}b_2\right) \tag{B6}$$

One also defines an action of the central extension W^5_λ on $T^*M_{\mu,\lambda}$ by letting S^1 act trivially. This action determines corresponding fundamental vector fields $\zeta_{K_i}\in\mathfrak{X}(T^*M_{\mu,\lambda})$ which are given by:

$$\begin{gathered}\zeta_{K_1}(x^i,p_i)=\partial_{x^1}+2\lambda x^2\partial_{x^2},\\ \zeta_{K_2}(x^i,p_i)=\partial_{x^2},\\ \zeta_{K_3}(x^i,p_i)=\frac{1}{\mu}\partial_{p_1},\end{gathered} \tag{B7}$$

$$\zeta_{K_4}(x^i,p_i)=\mathrm{e}^{2\lambda x^1}\partial_{p_2},$$

$$\zeta_{K_5}(x^i,p_i)=0.$$

One checks that this is a symplectic action on the phase space $T^*M_{\mu,\lambda}$.

3. Behavior under the geodesic flow

B.1. The No-go theorem: The Weyl algebra is not closed under the action of the geodesic flow, unless the configuration space is flat.

Proof: The theorem asserts that, in case $\lambda\neq 0$, the vector space generated by the functions f_j, which in turn are determined up to a constant by $i_{\zeta_{K_j}}\omega=df_j$, is not closed under time evolution. This is equivalent to the statement that the vector space generated by the fundamental vector fields $\{\zeta_{K_j}|1\leqslant j\leqslant 4\}$ is not closed under the geodesic flow, i.e., that $[X_H,\zeta_{K_j}]$ is not a linear combination of the ζ_{K_j}'s with *constant* coefficients. Upon recalling that the action of the geodesic flow is generated by the vector field

$$X_H(x^i,p_i)=\frac{p_1}{\mu}\partial_{x^1}+p_2e^{2\lambda x^1}\partial_{x^2}-\frac{2\lambda}{\mu}p_2^2\partial_{p_1}+\frac{2\lambda}{\mu}p_1p_2\partial_{p_2} \tag{B8}$$

we find indeed:

$$[X_H,\zeta_{K_j}](x^i,p_i)=\begin{pmatrix} 0 & 2\lambda p_2e^{2\lambda x^1} & 0 & 0\\ 0 & 0 & 0 & 0\\ -\dfrac{1}{\mu^2} & \dfrac{2\lambda}{\mu^2}x^2 & 0 & -\dfrac{2\lambda}{\mu^2}p_2e^{-2\lambda x^1}\\ 0 & -e^{4\lambda x^1} & \lambda e^{2\lambda x^1}p_2 & 0 \end{pmatrix}\cdot(\zeta_{K_j}(x^i,p_i)). \tag{B9}$$

For $(\mu,\lambda)=(1,0)$ this matrix of coefficients becomes independent from (x^i,p_i). This is exactly the reduction to the situation as one knows it from ''flat'' quantum mechanics, Ref. 5. □

Note that the above no-go theorem is lurking behind the negative result of Sec. V in Ref. 1. It is thus to circumvent this theorem that we devised the quantization scheme presented in Sec. II of the present paper.

The one-loop effective potential of a thermodynamic fermion loop in a constant magnetic field is studied. As expected, it can be interpreted literally as a discretized sum of $(D-2)$-dimensional energy density above the Dirac sea. Large/small mass expansions of the potential are also examined. © *1998 American Institute of Physics.* [S0022-2488(98)04109-7]

I. INTRODUCTION

Recently, effects of the magnetic field on the chiral symmetry breaking have been intensively studied.[1–3] In the paper,[4] we obtained a simple analytic form of the thermodynamic effective potential for a fermion loop coupled to constant magnetic field in D dimensions. On the contrary, the corresponding (D-dimensional) effective potential for the electric field case[5–9] cannot easily be organized into a concise form like the magnetic case due to a number of singularities; in other words, possessing an imaginary part.[10] Nevertheless we derived a few analytic expressions for the real parts of the effective potential and its gap equation in the simplest (zero temperature) case through the electromagnetic dual transformation; i.e., rotating a magnetic parameter $\xi=eB$ into a pure imaginary number $\xi=i\rho=ieE$.[4] This rotation procedure cannot always be applied to an intermediate process of calculation, depending on whether or not the potential can be regarded as a complex analytic function of ξ. It is expected to be valid, when the potential is written in terms of a special analytic function. In this way, a compact form of D-dimensional thermodynamic effective potential for the electric case might be obtained.

However, in the nonzero temperature case, there is no useful analytic expression suitable for that purpose; in other words, the electromagnetic dual symmetry becomes unclear. Thus, it is certainly important to know some behaviors of the potential in a constant magnetic field for finding or examining a behavior of thermodynamic potential in a constant electric field. Associated with this strategy, here we present some more analytic representations (in terms of special functions) of the thermodynamic effective potential for a Fermion loop coupled to a constant magnetic field.

The paper is organized as follows. In Sec. II, we discuss a physical interpretation of the effective potential. As is well known, effective potentials possess the meaning of energy density, and can actually be derived from the traces over energy spectra.[11,12] However, the derivation of our potential is *not* based on such a trace computation, and we would like to clarify that a mathematical expression of the (finite temperature) potential indicates the physical meaning exactly. There is also a dimensional reduction from D to $D-2$ in the presence of a magnetic field, and we hence expect that the structure should be $D-2$-dimensional energy density averaged by the Fermi–Dirac state density.

We then present, in Secs. III and IV, large/small mass expansions of the thermodynamic effective potential with keeping β *finite* (One should note that this is certainly a different argument from Ref. 4, which mainly concentrated on an infinite β limit). In order to see a validity for the present results, we shall reproduce a zero temperature potential (with $\mu\neq 0$) from those expansions. Namely, applying a low-temperature expansion to each mass expansion, we shall see that the leading terms of the low-temperature expansions coincide with the zero-temperature potential obtained in Ref. 4, where none of these (mass and temperature) expansions were used and its T

$=0$ situation was rather direct. In this sense, in this paper another proof of the zero-temperature potential of finite density is provided.

II. STRUCTURE OF THE EFFECTIVE POTENTIAL

The basic parts of the model Lagrangian are

$$\mathscr{L}=\bar{\psi}i\gamma^{\mu}(\partial_{\mu}-ieA_{\mu})\psi-m\bar{\psi}\psi, \tag{1}$$

and the D-dimensional thermodynamic effective potential is derived at one loop,[4]

$$V_{\beta,\mu}(m;\xi)=-\frac{\mathrm{tr}[1]}{2\beta}\int_0^{\infty}\frac{ds}{s}\frac{\Theta_2\left(s\,\frac{2\mu}{\beta},is\,\frac{4\pi}{\beta^2}\right)}{(4\pi s)^{(D-1)/2}}\,s\xi\,\coth(s\xi)e^{-s(m^2-\mu^2)}, \tag{2}$$

where Θ_2 is the elliptic theta function of the second kind and tr[1] stands for the trace of the gamma matrix unit. This can also be rewritten in the form

$$V_{\beta,\mu}(m;\xi)=V_R(m;\xi)+\tilde{V}_{\beta,\mu}(m;\xi), \tag{3}$$

where the first term V_R is a renormalized effective potential for the original Lagrangian (1), or one may add a four-Fermi interaction to the Lagrangian (1) if necessary. However, such a Fermion interaction does not contribute to the second term $\tilde{V}_{\beta,\mu}$, which is the pure thermodynamic part of the effective potential (2) and is renormalization free. Since our present interest is the thermodynamic part, which possesses a model-independent structure, we focus on the latter potential, and its explicit form is given by[4]

$$\tilde{V}_{\beta,\mu}(m;\xi)=\frac{\mathrm{tr}[1]\xi}{(4\pi)^{D/2}}\left[\frac{1}{2}\,\mathscr{O}_{\beta}(m)+\sum_{l=1}^{\infty}\mathscr{O}_{\beta}(\sqrt{m^2+2l\xi})\right], \tag{4}$$

where

$$\mathscr{O}_{\beta}(\sigma)=4\sum_{n=1}^{\infty}(-1)^n\cosh(n\beta\mu)\left(\frac{\beta n}{2\sigma}\right)^{1-D/2}K_{D/2-1}(n\beta\sigma). \tag{5}$$

Note that Eq. (4) is composed of the sum over a discrete energy spectrum $\epsilon_n=\pm\sqrt{m^2+2n\xi}$ due to the presence of a magnetic field. Since ξ possesses the mass dimension 2, the fundamental object $\mathscr{O}_{\beta}(\sigma)$ in the pure thermal effective potential possesses mass dimension $D-2$. Hence Eq. (5) can be interpreted as an effective potential in $D-2$ dimensions. We can regard this fact as an example of the dimensional reduction from D to $D-2$. Furthermore, here we suggest one more interesting feature: From this specific potential form, we can read clearly the common fact that the effective potential is understood as an energy density. Although this statement is very natural, however, the above potential forms, Eqs. (2) and (5), do not explain this structure explicitly.

Let us reveal here the desired structure, introducing another expression for Eq. (5),

$$\mathscr{O}_{\beta}(\sigma)=\frac{-2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\left[\int_0^{\infty}\frac{(t^2+2\sigma t)^{(D-3)/2}}{1+e^{\beta(t+\sigma+\mu)}}\,dt+(\mu\to-\mu)\right], \tag{6}$$

where we have used an integral representation for K_{ν} and then performed the sum on n. Changing the integration variable with $\epsilon=t+\sigma$, we obtain

$$\mathscr{O}_{\beta}(\sigma)=\frac{-2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\left[\int_{\sigma}^{\infty}\frac{(\epsilon^2-\sigma^2)^{(D-3)/2}}{1+e^{\beta(\epsilon-\mu)}}\,d\epsilon+(\mu\to-\mu)\right]. \tag{7}$$

The RHS of this equation can be interpreted as follows. The denominator of the integrand is related to the state density $N(\epsilon)$ averaged by the Fermi–Dirac statistics,

$$N(\epsilon)=\frac{1}{1+e^{\beta(\epsilon-\mu)}}, \tag{8}$$

and the numerator with integration measure carrying the mass dimension $D-2$ (the same as $\mathcal{O}_\beta$),

$$f(\epsilon)d\epsilon=(\epsilon^2-\sigma^2)^{(D-3)/2}\,d\epsilon, \tag{9}$$

is understood as an energy density for the infinitesimal interval $d\epsilon$. The integration means nothing but a total sum of this energy density over the whole state density $N(\epsilon)$, and the lower bound of the integration is restricted by the Dirac sea of the fermion mass σ. In addition, in the case of zero temperature, $N(\epsilon)$ takes 1 or 0, and the Fermi energy is given at the point $\epsilon=\mu$. Thus we have

$$\mathcal{O}_\infty(\sigma)\equiv\lim_{\beta\to\infty}\mathcal{O}_\beta(\sigma)=\int_\sigma^\mu f(\epsilon)d\epsilon, \tag{10}$$

and this is exactly the result given in Ref. 4,

$$\mathcal{O}_\infty(\sigma)=-\frac{2\sqrt{\pi}}{\Gamma\left(\frac{D+1}{2}\right)}(2\sigma)^{(D-3)/2}(\mu-\sigma)^{(D-1)/2}F\left(\frac{3-D}{2},\frac{D-1}{2};\frac{D+1}{2};\frac{\sigma-\mu}{2\sigma}\right)\theta(\mu-\sigma). \tag{11}$$

Next, we consider the further details of $\mathcal{O}_\beta(\sigma)$ (for finite β), which we did not get through in the previous paper.[4] We present below its large/small mass expansions at finite β. Obviously, in Eq. (6), there are two ways of performing a binomial expansion for the quantity $f(\epsilon)$; i.e., for $(t^2+2\sigma t)^\nu$, where $\nu=(D-3)/2$.

III. THE LARGE MASS EXPANSION

First, let us consider the large σ case (σ^{-1} expansion). After changing $\beta t\to t$ and expanding around $\sigma=\infty$, we can perform the integration seen in Eq. (6) for each expansion mode,

$$\mathcal{O}_\beta(\sigma)=\frac{-2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\beta^{2-D}\sum_{k=0}^{\infty}\binom{\frac{D-3}{2}}{k}(2\beta\sigma)^{(D-3)/2-k}\Gamma\left(\frac{D-1}{2}+k\right)$$
$$\times\exp[-\beta(\sigma+\mu)]\Phi\left(\frac{D-1}{2}+k;\frac{1}{2}+\frac{i\beta}{2\pi}(\sigma+\mu),1\right)+(\mu\to-\mu), \tag{12}$$

where $\Phi(z;s,a)$ is the Lerch transcendental function, defined by

$$\Phi(z;s,a)=\sum_{n=0}^{\infty}\frac{e^{2\pi ins}}{(n+a)^z}=\frac{1}{\Gamma(z)}\int_0^\infty\frac{e^{-at}t^{z-1}}{1-e^{-t+2\pi is}}\,dt\quad(\mathrm{Re}\,z>1,\ 0<a\leqslant 1). \tag{13}$$

Since the Lerch function is transformed into the generalized zeta function by the relation

$$e^{2\pi is}\Phi(1-z;s,1)=(2\pi)^{-z}\Gamma(z)[e^{(\pi i/2)z}\zeta(z,s)+e^{-(\pi i/2)z}\zeta(z,1-s)], \tag{14}$$

we can transform Eq. (12) into another representation,

$$\mathcal{O}_\beta(\sigma)=\frac{2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\sum_{k=0}^{\infty}\binom{\frac{D-3}{2}}{k}(2\sigma)^{[(D-3)/2]-k}(2\pi)^{[(D-3)/2]+k}\Gamma\left(\frac{D-1}{2}+k\right)\Gamma\left(\frac{3-D}{2}-k\right)$$
$$\times 2\beta^{[(1-D)/2]-k}\,\mathrm{Re}\left[e^{(\pi i/2)[(3-D)/2-k]}\zeta\left(\frac{3-D}{2}-k,\ \frac{1}{2}+\frac{i\beta}{2\pi}(\sigma+\mu)\right)+(\mu\to-\mu)\right]. \tag{15}$$

When $D=3$, the above summations in Eqs. (12) and (15) consist of only the $k=0$ term, and the latter expression (15) contains superficial divergence (in the gamma function). In this sense, the former (12) may rather be a fundamental expression. Anyway, both expressions coincide with the following in $D=3$ (see also the first literature of Ref. 1),

$$\mathcal{O}_\beta(\sigma)=-2\frac{\sqrt{\pi}}{\beta}\ln[(1+e^{-\beta(\sigma+\mu)})(1+e^{-\beta(\sigma-\mu)})]. \tag{16}$$

Nevertheless, the latter representation (15) is convenient to consider the low-temperature expansion (β^{-1} expansion). Let us find that the leading term of the expansion reproduces the previous result (11). The β^{-1} expansion can be performed through the asymptotic formula for the zeta function,

$$\zeta(z,a)\sim\frac{1}{z-1}\,a^{1-z},\quad |a|\to\infty. \tag{17}$$

For example, the highest power of β is calculated as follows:

$$\mathrm{Re}\left[e^{(\pi i/2)[(3-D)/2-k]}\zeta\left(\frac{3-D}{2}-k,\ \frac{1}{2}+\frac{i\beta}{2\pi}(\sigma\pm\mu)\right)\right]$$
$$=\frac{1}{\frac{1-D}{2}-k}\left(\frac{\beta}{2\pi}|\sigma\pm\mu|\right)^{[(D-1)/2]+k}\mathrm{Re}[e^{(\pi i/2)[(3-D)/2-k]}e^{(\pi i/2)[k+(D-1)/2]\mathrm{sign}(\sigma\pm\mu)}]+\cdots$$
$$=\frac{(\beta/2\pi)^{[(D-1)/2]+k}}{\frac{1-D}{2}-k}\times\begin{cases}0, & \text{for } +,\\ \cos\left[\left(1-k-\frac{D}{2}\right)\pi\right]|\mu-\sigma|^{(D-1)/2+k}\theta(\mu-\sigma), & \text{for } -,\end{cases}$$
$$+\cdots. \tag{18}$$

Substituting this result onto the RHS of Eq. (15), we derive

$$\mathcal{O}_\beta(\sigma)=\frac{2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\sum_{k=0}^{\infty}\binom{\frac{D-3}{2}}{k}\frac{(2\sigma)^{[(D-3)/2]-k}}{\frac{1-D}{2}-k}(\mu-\sigma)^{[(D-1)/2]+k}\theta(\mu-\sigma)+\mathcal{O}(\beta^{-1}), \tag{19}$$

where we have applied the following relation to eliminate the cosine factor seen in Eq. (18):

$$\Gamma\left(\frac{1}{2}+z\right)\Gamma\left(\frac{1}{2}-z\right)=\frac{\pi}{\cos\,\pi z},\quad \text{for } z=1-k-\frac{D}{2}. \tag{20}$$

Furthermore, using

$$\frac{1}{\frac{1-D}{2}-k}=\frac{\Gamma\left(\frac{1-D}{2}-k\right)}{\Gamma\left(\frac{3-D}{2}-k\right)}=\frac{(-1)^k\pi}{\cos\left(D\,\frac{\pi}{2}\right)\Gamma\left(\frac{3-D}{2}-k\right)\Gamma\left(\frac{1+D}{2}+k\right)}, \tag{21}$$

and

$$F(\alpha,\beta;\gamma;z)=\sum_{n=0}^{\infty}\frac{z^n}{n!}\,\frac{\Gamma(1-\alpha)\Gamma(1-\beta)\Gamma(\gamma)}{\Gamma(1-\alpha-n)\Gamma(1-\beta-n)\Gamma(\gamma+n)}, \tag{22}$$

we find

$$\mathcal{O}_\beta(\sigma)=\frac{2\pi^{3/2}(2\sigma)^{(D-3)/2}(\mu-\sigma)^{(D-1)/2}}{\cos\left(D\,\frac{\pi}{2}\right)\Gamma\left(\frac{3-D}{2}\right)\Gamma\left(\frac{D-1}{2}\right)\Gamma\left(\frac{D+1}{2}\right)}$$
$$\times F\left(\frac{3-D}{2},\,\frac{D-1}{2};\,\frac{D+1}{2};\,\frac{\sigma-\mu}{2\sigma}\right)\theta(\mu-\sigma)+\mathcal{O}(\beta^{-1}). \tag{23}$$

The leading term is now identified with the quantity (11) through the formula (20) for $z=(D-2)/2$.

IV. THE SMALL MASS EXPANSION

Second, let us compute the small mass expansion. The calculation is parallel to the above σ^{-1} expansion. Expanding $(t^2+2\sigma t)^\nu$ for small σ and integrating each mode, we obtain the following two representations:

$$\mathcal{O}_\beta(\sigma)=\frac{-2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\,\beta^{2-D}\sum_{k=0}^{\infty}\binom{\frac{D-3}{2}}{k}(2\beta\sigma)^k\Gamma(D-2-k)$$
$$\times\exp[-\beta(\sigma+\mu)]\Phi\left(D-2-k;\,\frac{1}{2}+\frac{i\beta}{2\pi}\,(\sigma+\mu),1\right)+(\mu\to-\mu), \tag{24}$$

and

$$\mathcal{O}_\beta(\sigma)=\frac{2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\sum_{k=0}^{\infty}\binom{\frac{D-3}{2}}{k}(2\sigma)^k(2\pi)^{D-3-k}\,\frac{\Gamma\left(\frac{D-1-k}{2}\right)\Gamma\left(\frac{3-D+k}{2}\right)}{\cos\left[\frac{\pi}{2}\,(3-D+k)\right]}$$
$$\times\beta^{2-D+k}\,\mathrm{Re}\left[e^{(\pi i/2)(3-D+k)}\zeta\left(3-D+k,\,\frac{1}{2}+\frac{i\beta}{2\pi}\,(\sigma+\mu)\right)+(\mu\to-\mu)\right], \tag{25}$$

where the Lerch transformation (14) and the following formula are applied:

$$\Gamma(D-2-k)\Gamma(3-D+k)=\frac{\Gamma\left(\frac{D-1-k}{2}\right)\Gamma\left(\frac{3-D+k}{2}\right)}{\cos\left[\frac{\pi}{2}\,(3-D+k)\right]}. \tag{26}$$

Again, let us perform the β^{-1} expansion in Eq. (25) and sum up the leading contribution similarly to the former case. The resulting equation is

$$\mathcal{O}_\beta(\sigma)=\frac{-2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\frac{(\mu-\sigma)^{D-2}}{D-2}F\left(\frac{D-1}{2},D-1;3-D;\frac{-2\sigma}{\mu-\sigma}\right)\theta(\mu-\sigma)+\mathcal{O}(\beta^{-1}). \quad (27)$$

The value of $\mathcal{O}_\beta$ at the origin $\sigma=0$ for finite β can be obtained by putting $\sigma=0$ into (25). The $k=0$ term is only nonzero, and we get $\mathcal{O}_\beta(0)$;

$$\mathcal{O}_\beta(0)=\frac{2}{\sqrt{\pi}}\left(\frac{2\pi}{\beta}\right)^{D-2}\Gamma\left(\frac{3-D}{2}\right)\mathrm{Re}\ \zeta\left(3-D,\frac{1}{2}+i\frac{\beta\mu}{2\pi}\right). \quad (28)$$

For infinite β, we just put $\sigma=0$ in (27), and only the leading term survives;

$$\mathcal{O}_\infty(0)=-\frac{2\sqrt{\pi}}{\Gamma\left(\frac{D-1}{2}\right)}\frac{\mu^{D-2}}{D-2}. \quad (29)$$

V. CONCLUDING REMARKS

In closing this paper, we make two interesting remarks on Eq. (29). The first one is that we can see that Eq. (29) is exactly a dimensionally reduced potential by $D\to D-2$ up to a normalization constant factor. It can be seen by comparison with the potential of the continuum theory (i.e., $\xi=0$ case):[13]

$$\lim_{\beta\to\infty}\tilde{V}_{\beta,\mu}(0)=-2\frac{\mathrm{tr}[1]}{(4\pi)^{D/2}}\frac{2\sqrt{\pi}}{\Gamma\left(\frac{D+1}{2}\right)}\frac{\mu^D}{D}. \quad (30)$$

Second, Eq. (29) is divergent if we take the limit $D\to 2$. This *is* an interesting point, although a magnetic analysis in $D=2$ *per se* is meaningless. The reason is as follows: As pointed out in the Introduction as well as in Ref. 4, we can obtain an effective potential for the electric case at $T=0$ from the present case through rotating $\xi\to i\rho$. This rotation makes the quantity (29) purely imaginary, and it certainly means that the imaginary part of the (electric case) potential is divergent in $D=2$.[6]

Amplitude equations for electrostatic waves: Multiple species

John David Crawford[a] and Anandhan Jayaraman[b]
Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260

(Received 16 June 1997; accepted for publication 20 April 1998)

The amplitude equation for an unstable electrostatic wave is analyzed using an expansion in the mode amplitude $A(t)$. In the limit of weak instability, i.e., $\gamma \to 0^+$ where γ is the linear growth rate, the nonlinear coefficients are singular and their singularities predict the dependence of $A(t)$ on γ. Generically the scaling $|A(t)| = \gamma^{5/2} r(\gamma t)$ as $\gamma \to 0^+$ is required to cancel the coefficient singularities to all orders. This result predicts the electric field scaling $|E_k| \sim \gamma^{5/2}$ will hold universally for these instabilities (including beam-plasma and two-stream configurations) throughout the dynamical evolution and in the time-asymptotic state. In exceptional cases, such as infinitely massive ions, the coefficients are less singular and the more familiar trapping scaling $|E_k| \sim \gamma^2$ is recovered. © *1998 American Institute of Physics.* [S0022-2488(98)03009-6]

I. INTRODUCTION

A. Overview and background

We recently presented a detailed analysis of the amplitude equation for an unstable electrostatic mode in an unmagnetized Vlasov plasma [henceforth (I)].[1] In that work, the amplitude equation was studied using an expansion in the wave amplitude, and only the electron motion was considered with the ions treated as a fixed neutralizing background. In this paper we study the effect of including mobile ions and investigate the mode amplitude equation for an electrostatic wave in a multispecies unmagnetized plasma. As in (I), we focus on the regime of weak instability and carefully analyze the structure of the amplitude equation in the limit $\gamma \to 0^+$ where γ is the linear growth rate for the unstable wave.

Incorporating the effects of finite ion inertia is a significant step for several reasons. With finite mass, the ion motion occurs on a finite time scale $T_i < \infty$ and in the limit of very weak growth rates this will be a fast time scale, i.e., $T_i \ll \gamma^{-1}$ as $\gamma \to 0^+$. Over the duration of the instability, the ions can readily respond to the electric field of the wave especially resonant ions near the phase velocity. This ion response is always present even for high frequency modes such as plasma waves since at the phase velocity the wave frequency is Doppler-shifted to zero. In addition, there are modes such as ion-acoustic waves that depend on ion density oscillations and are suppressed when the ions are treated as fixed. Allowing for mobile ions is a prerequisite, if we seek the amplitude equation for an unstable ion-acoustic mode.

This paper can be read independently, but the reader is referred to (I) for a discussion of the history of the problem and additional introductory material. An essential difference between our approach and previous work lies in the choice of unperturbed state. Earlier theories assumed an equilibrium with a neutrally stable mode and obtained ill-defined expansion coefficients.[2–6] This can be avoided by taking the weakly unstable equilibrium as the unperturbed state; a choice that naturally leads one to work with the unstable manifold. A brief summary of our results on the multispecies case has appeared elsewhere.[7]

In the limit $\gamma \to 0^+$, the amplitude equation defines a kind of singular perturbation problem whose detailed features reveal asymptotic scaling behavior of the nonlinear wave. This is a key idea behind our approach and it can be formulated more precisely as follows. The mode eigen-

[b]Electronic mail: anand@merlin.phyast.pitt.edu

 © 1998 American Institute of Physics

value $\lambda=\gamma-i\omega$ can be complex (beam-plasma) or real (two-stream), but in either case the equations for the mode amplitude $A(t)=\rho(t)e^{-i\theta(t)}$ have the form

$$\dot{\rho}=\gamma\rho+a_1\rho^3+a_2\rho^5+\mathcal{O}(\rho^7), \tag{1}$$

$$\dot{\theta}=\omega+a_1'\rho^2+a_2'\rho^4+\mathcal{O}(\rho^6). \tag{2}$$

Since the Vlasov equilibrium is assumed to be spatially homogeneous, the evolution of $\rho(t)$ decouples from the phase $\theta(t)$. Suppose for simplicity that the coefficients a_j are constant (ignoring their dependence on γ), then we may view (1) as a singular perturbation problem with the linear term $\gamma\rho$ representing the perturbation. If $\gamma>0$, then there is always a neighborhood of the equilibrium $\rho=0$ where the perturbation dominates the unperturbed system and can completely change the dynamics.

As in other such singular problems, a possible strategy is to seek a (singular) change of variables which transforms (1) into a regular perturbation problem. Thus it is natural to define a new amplitude $r(\tau)$ by

$$\rho(t)=\gamma^{\beta}r(\gamma^{\delta}t) \tag{3}$$

and rewrite (1) in terms of $r(\tau)$

$$\frac{dr}{d\tau}=\gamma^{1-\delta}r(\tau)+\gamma^{2\beta-\delta}a_1(\gamma)r^3+\gamma^{4\beta-\delta}a_2(\gamma)r^5+\cdots. \tag{4}$$

If possible, the choice of β and δ should be made so that (i) each term in (4) is well behaved as $\gamma\to 0^+$ and (ii) the effect of $\gamma>0$ is a regular perturbation of the system at $\gamma=0$. The latter condition requires $\delta=1$; otherwise the linear term will continue to be a singular perturbation. The exponent β then needs to be chosen (if possible) to achieve a balance between the nonlinear terms and the linear term. In the simplest situation, when the coefficients $a_1,a_2,\ldots$ have well-defined *finite* limits as $\gamma\to 0$, then one has the exponent $\beta=1/2$ and this yields

$$\frac{dr}{d\tau}=r(\tau)+a_1(\gamma)r^3+\gamma a_2(\gamma)r^5+\cdots. \tag{5}$$

The unperturbed system $\dot{r}=r+a_1(0)r^3$ now includes the linear term and near $r=0$ the effect of small γ is unimportant. The change of variables (3) is singular at $\gamma=0$ as expected, but nevertheless we have determined the overall scaling $\beta=1/2$ for nonlinear solutions near the equilibrium in the regime of weak instability. In addition, since terms in (4) at fifth order or higher are at least of order $\mathcal{O}(\gamma)$, the unperturbed problem truncates to a simple balance between the linear instability and the dominant nonlinear term.

For an unstable electrostatic wave, the situation is quite different because the nonlinear coefficients a_j blow up as $\gamma\to 0$ and the exponent $\beta=1/2$ does not yield a well-behaved equation for $r(\tau)$. We attack the problem of finding a satisfactory value for β in two steps. First, we determine what choice for β will control the singularity of the cubic coefficient a_1 in (1), and then we investigate whether this choice will also remove the singularities of the higher order nonlinear terms. Typically, the cubic coefficient diverges asymptotically like γ^{-4} in which case we must choose $\beta\geqslant 5/2$ in order to obtain a finite cubic term in the rescaled amplitude equation (4).

Our analysis shows that setting $\beta=5/2$ yields a theory that is finite to all orders as $\gamma\to 0$ at $\gamma=0$ retains (rescaled) nonlinear terms that balance the linear instability. Choosing a larger exponent $\beta=5/2+\epsilon$ would also yield a finite theory to all orders, but now the cubic term is of order $\mathcal{O}(\gamma^{2\epsilon})$ and all the higher order terms ($j>1$) are of order $\mathcal{O}(\gamma^{2\epsilon j})$; there is no balance between the linear and nonlinear terms at $\gamma=0$. For $\epsilon>0$, the larger exponent suppresses nonlinear effects too strongly. In this sense, the scaling

$$\rho(t)=\gamma^{5/2}r(\gamma t) \tag{6}$$

is uniquely determined. Of the two steps, the second is by far the most difficult; it is relatively straightforward to compute a_1 and determine its divergence (Sec. III). Verifying that a given choice of β works to all orders requires a detailed study of the recursion relations of the theory and the final theorem is proved by induction (Sec. IV).

In special cases, the cubic coefficient is less singular, diverging like γ^{-3} instead of γ^{-4}. The limit of infinitely massive ions is the best known example of this situation, and in (I) we found that $\beta=2$ was the scaling needed to make the nonlinear amplitude equation finite to all orders. In this paper, we identify two additional examples where the cubic coefficient has a γ^{-3} singularity: if the effects of the resonant ions are negligible (in a sense we make precise in Sec. III D) or if the electron and ion masses are equal, i.e., for an electron-positron plasma. In the former case we prove that the exponent $\beta=2$ is correct, but the precise value of β for the electron-positron system is not unambiguously determined due to special complications in the singularity structure of the amplitude expansion.

B. Notation

Our model is a one-dimensional, multispecies Vlasov plasma defined by

$$\frac{\partial F^{(s)}}{\partial t}+v\frac{\partial F^{(s)}}{\partial x}+\kappa^{(s)}E\,\frac{\partial F^{(s)}}{\partial v}=0, \tag{7}$$

$$\frac{\partial E}{\partial x}=\sum_s\int_{-\infty}^{\infty}dv F^{(s)}(x,v,t). \tag{8}$$

Here x, t and v are measured in units of u/ω_e, ω_e^{-1} and u, respectively, where u is a chosen velocity scale and $\omega_e^2=4\pi e^2 n_e/m_e$. The plasma length is L with periodic boundary conditions and we adopt the normalization

$$\int_{-L/2}^{L/2}dx\int_{-\infty}^{\infty}dv F^{(s)}(x,v,t)=\left(\frac{z_s n_s}{n_e}\right)L, \tag{9}$$

where $q_s=ez_s$ is the charge of species s and $\kappa^{(s)}\equiv q_s m_e/em_s$. Note that $\kappa^{(e)}=-1$ for electrons and that the normalization (9) for negative species makes the distribution function negative.

Let $F_0(v)$ and $f(x,v,t)$ denote the multicomponent fields for the equilibrium and perturbation, respectively, and κ the matrix of mass ratios,

$$f\equiv\begin{pmatrix} f^{(s_1)}\\ f^{(s_2)}\\ \vdots\end{pmatrix},\quad F_0\equiv\begin{pmatrix} F_0^{(s_1)}\\ F_0^{(s_2)}\\ \vdots\end{pmatrix},\quad \kappa\equiv\begin{pmatrix} \kappa^{(s_1)} & 0 & 0 & \cdots\\ 0 & \kappa^{(s_2)} & 0 & \cdots\\ \vdots & \vdots & \vdots & \end{pmatrix}, \tag{10}$$

then the system (7) and (8) can be concisely expressed as

$$\frac{\partial f}{\partial t}=\mathscr{L}f+\mathscr{N}(f), \tag{11}$$

where the linear operator is defined by

$$\mathscr{L}f=\sum_{l=-\infty}^{\infty}e^{ilx}(L_l f_l)(v), \tag{12}$$

$$(L_l f_l)(v)=\begin{cases}0 & l=0\\ -il[v f_l(v)+\kappa\cdot\eta_l(v)\Sigma_{s'}\int_{-\infty}^{\infty}dv' f_l^{(s')}(v')] & l\neq 0,\end{cases} \tag{13}$$

with $\eta_l(v)\equiv-\partial_v F_0/l^2$, and the nonlinear operator $\mathscr{N}$ is

$$\mathcal{N}(f)=\sum_{m=-\infty}^{\infty} e^{imx}\sum_{l=-\infty}^{\infty}{}' \frac{i}{l}\left(\kappa\cdot\frac{\partial f_{m-l}}{\partial v}\right)\sum_{s'}\int_{-\infty}^{\infty}dv' f_l^{(s')}(v'). \tag{14}$$

In the spatial Fourier expansion (12), l denotes an integer multiple of the basic wave number $2\pi/L$, and a primed summation as in (14) omits the $l=0$ term. The notation $\kappa\cdot\eta_l(v)$ or $\kappa\cdot\partial_v f_{m-l}$ denotes matrix multiplication.

An equilibrium $F_0(v)$ depends on parameters such as the densities or temperatures of the various species, but this dependence will be suppressed unless it is explicitly needed.

Symmetries of the model (11) and the equilibrium $F_0(v)$ are important qualitative features of the problem, and play a significant role in Sec. II when we formulate the amplitude expansions. Spatial translation, $\mathcal{T}_a:(x,v)\to(x+a,v)$, and reflection, $\mathcal{R}:(x,v)\to(-x,-v)$, act as operators on $f(x,v,t)$ in the usual way: if α denotes an arbitrary transformation then $(\alpha f)(x,v)\equiv f(\alpha^{-1}(x,v))$ where $(\alpha f)(x,v)$ denotes the transformed distribution function. The operators $\mathcal{L}$ and $\mathcal{N}$ commute with $\mathcal{T}_a$ due to the spatial homogeneity of F_0, and if $F_0(v)=F_0(-v)$, then $\mathcal{L}$ and $\mathcal{N}$ also commute with the reflection operator $\mathcal{R}$. With periodic boundary conditions, x is a periodic coordinate so $\mathcal{T}_a$ and $\mathcal{R}$ generate O(2), the symmetry group of the circle. If only the translation symmetry is present, then the group is SO(2).

An inner product is needed in Sec. II to derive the amplitude equation. For two multicomponent fields of (x,v), e.g., $B=(B^{(s_1)},B^{(s_2)},B^{(s_3)},\ldots)$ and $D=(D^{(s_1)},D^{(s_2)},D^{(s_3)},\ldots)$, we define their inner product by

$$(B,D)\equiv\sum_s\int_{-L/2}^{L/2}dx\int_{-\infty}^{\infty}dv B^{(s)}(x,v)^*D^{(s)}(x,v)=\int_{-L/2}^{L/2}dx\langle B,D\rangle, \tag{15}$$

where

$$\langle B,D\rangle\equiv\sum_s\int_{-\infty}^{\infty}dv B^{(s)}(x,v)^*D^{(s)}(x,v). \tag{16}$$

C. Summary of linear theory

The spectral theory for $\mathcal{L}$ is well established, and the needed results are simply recalled to establish our notation.[8–10] The eigenvalues $\lambda=-ilz$ of $\mathcal{L}$ are determined by the roots $\Lambda_l(z)=0$ of the ''spectral function,''

$$\Lambda_l(z)\equiv 1+\int_{-\infty}^{\infty}dv\,\frac{\Sigma_s\kappa^{(s)}\eta_l^{(s)}(v)}{v-z}. \tag{17}$$

If the contour in (17) is replaced by the Landau contour for $\mathrm{Im}(z)<0$ then we have the linear dielectric $\epsilon_l(z)$; for $\mathrm{Im}(z)>0$, $\Lambda_l(z)$ and $\epsilon_l(z)$ are the same function. For SO(2) symmetry, the eigenvalues are generically complex; for O(2) symmetry, when the equilibrium is also reflection-symmetric, then real eigenvalues can occur as in a two-stream instability; see, for example, Ref. 11.

Associated with an eigenvalue $\lambda=-ilz$ is the multicomponent eigenfunction $\Psi(x,v)=e^{ilx}\psi(v)$ where

$$\psi(v)=-\frac{\kappa\cdot\eta_l}{v-z}. \tag{18}$$

There is also an associated adjoint eigenfunction $\tilde{\Psi}(x,v)=e^{ilx}\tilde{\psi}(v)/L$ satisfying $(\tilde{\Psi},\Psi)=1$ with

$$\tilde{\psi}(v)=-\frac{1}{\Lambda_l'(z)^*(v-z^*)}. \tag{19}$$

Note that all components of $\tilde{\psi}(v)$ are the same. The normalization in (19) assumes that the root of $\Lambda_l(z)$ is simple and is chosen so that $\langle \tilde{\psi}, \psi \rangle = 1$. The adjoint determines the projection of $f(x,v,t)$ onto the eigenvector, and this projection defines the time-dependent amplitude of Ψ, i.e., $A(t) \equiv (\tilde{\Psi}, f)$.

II. AMPLITUDE EQUATION ON THE UNSTABLE MANIFOLD

A. Unstable linear modes

The equilibrium $F_0(v)$ is assumed to support a ''single'' unstable mode in the following sense. We shall assume that E^u, the unstable subspace for $\mathscr{L}$, is two dimensional. With translation symmetry and periodic boundary conditions, this is the simplest instability problem that can be posed.

Henceforth, let k denote the wave number of this unstable mode that is associated with the root $\Lambda_k(z_0) = 0$ which we assume to be simple, i.e., $\Lambda_k'(z_0) \neq 0$. The corresponding eigenvector is

$$\Psi_1(x,v) = e^{ikx}\psi(v) = e^{ikx}\left(- \frac{\kappa \cdot \eta_k}{v - z_0} \right). \tag{20}$$

The root $z_0 = v_p + i\gamma/k$ determines the phase velocity $v_p = \omega/k$ and the growth rate γ of the linear mode as the real and imaginary parts of the eigenvalue $\lambda = -ikz_0 = \gamma - i\omega$. From (17) and $\Lambda_k(z_0) = 0$, we obtain

$$\Lambda_l(z_0) = (l^2 - k^2)/l^2; \tag{21}$$

this identity will be useful shortly.

When $F_0(v)$ lacks reflection symmetry, then Ψ_1 typically has a nonzero phase velocity and λ is complex. In this case, the identities $\Lambda_k(z) = \Lambda_{-k}(z)$ and $\Lambda_k(z)^* = \Lambda_k(z^*)$ imply three additional modes: Ψ_1^*, Ψ_2, and Ψ_2^* where

$$\Psi_2(x,v) = e^{ikx}\psi(v)^*. \tag{22}$$

These eigenfunctions correspond to eigenvalues λ^*, $-\lambda^*$, and $-\lambda$, respectively, and fill out the eigenvalue quartet characteristic of Hamiltonian systems. In the absence of reflection symmetry, the eigenvalues are typically simple and the unstable subspace is two dimensional.

When $F_0(v)$ is reflection-symmetric, the eigenvalues may be either real or complex. In either case Ψ_j and $\mathscr{R} \cdot \Psi_j$ are linearly independent so the eigenvalues have multiplicity two. Now E^u is two dimensional only in the case of a real eigenvalue since a multiplicity-two complex conjugate pair implies a four-dimensional unstable subspace; this latter possibility is not considered further.

The components of the distribution function along the unstable eigenvectors Ψ_1 and Ψ_1^* are identified by writing

$$f(x,v,t) = [A(t)\Psi(x,v) + \text{c.c.}] + S(x,v,t), \tag{23}$$

where $A(t) = (\tilde{\Psi}, f)$ is the mode amplitude for Ψ and $(\tilde{\Psi}, S) = 0$. In (23), the subscript on Ψ_1 has been dropped, and $\tilde{\Psi} = \exp(ikx)\tilde{\psi}/L$ is the adjoint function for z_0 from (19).

The action of translation $\mathscr{T}_a$ and reflection $\mathscr{R}$ on $f(x,v,t)$ implies an action by these operators on the variables (A,S). From (23) we note that $\mathscr{T}_a f(x,v,t) = f(x-a,v,t)$ is equivalent to

$$\mathscr{T}_a(A, S(x,v)) = (e^{-ika}A, S(x-a,v)), \tag{24}$$

and reflection $\mathscr{R} f(x,v,t) = f(-x,-v,t)$ yields

$$\mathscr{R}(A, S(x,v)) = (A^*, S(-x,-v)). \tag{25}$$

When these transformations are symmetries, these relations are important for organizing the amplitude expansions introduced in Sec. III.

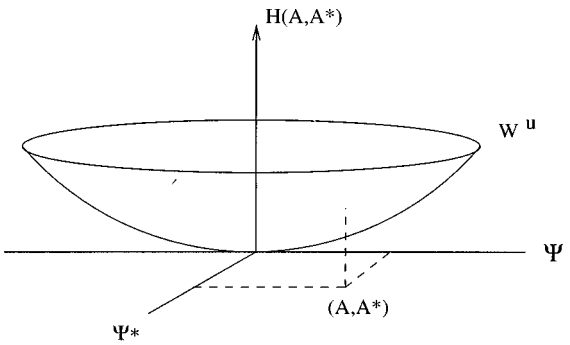

FIG. 1. Schematic representation of the unstable manifold.

B. Derivation of the amplitude equation

In the (A,S) variables, the Vlasov equation (11) becomes:

$$\dot{A}=\lambda A+(\tilde{\Psi},\mathcal{N}(f)), \tag{26}$$

$$\frac{\partial S}{\partial t}=\mathcal{L}S+\mathcal{N}(f)-[(\tilde{\Psi},\mathcal{N}(f))\Psi+\text{c.c.}], \tag{27}$$

where

$$(\tilde{\Psi},\mathcal{N}(f))=-i\sum_{l=-\infty}^{\infty}{}' \frac{1}{l}\langle\partial_v\tilde{\psi},\kappa\cdot f_{k-l}\rangle\sum_{s'}\int_{-\infty}^{\infty}dv' f_l^{(s')}(v'). \tag{28}$$

In writing (26) we have used the adjoint relationship $(\tilde{\Psi},\mathcal{L}S)=(\mathcal{L}^{\dagger}\tilde{\Psi},S)=\lambda(\tilde{\Psi},S)=0$ and in (28) an integration by parts shifts the velocity derivative onto $\tilde{\psi}$. These coupled equations are equivalent to (11); however, by restricting them to the unstable manifold we obtain an autonomous equation for $A(t)$. This procedure is briefly summarized; a more detailed description is provided in (I).

The unstable subspace E^u is invariant under the linear dynamics $\partial_t f=\mathcal{L}f$, but this no longer holds once the nonlinear terms $\mathcal{N}(f)$ are included. Instead we assume there is a two-dimensional invariant surface, the unstable manifold W^u, that represents the nonlinear deformation of E^u. The unstable manifold is tangent to E^u at the equilibrium, and near F_0 it can be described by a function $H(x,v,A,A^*)$ which locates the manifold ''above'' the point $[A\Psi+A^*\Psi^*]$ in E^u; the geometry is illustrated in Fig. 1.

Thus

$$f^u(x,v,t)=[A(t)\Psi(x,v)+\text{c.c.}]+H(x,v,A(t),A^*(t)) \tag{29}$$

represents a distribution function on W^u. In this expression, the evolution of S can be determined from H, i.e.,

$$S(x,v,t)=H(x,v,A(t),A^*(t))=\begin{pmatrix} H^{(s_1)}(x,v,A(t),A^*(t)) \\ H^{(s_2)}(x,v,A(t),A^*(t)) \\ \vdots \end{pmatrix}. \tag{30}$$

When this representation is substituted into (26) and (27) we obtain

$$\dot{A}=\lambda A+(\tilde{\Psi},\mathcal{N}(f^u)), \tag{31}$$

$$\left.\frac{\partial S}{\partial t}\right|_{f^u}=\mathcal{L}H+\mathcal{N}(f^u)-[(\tilde{\Psi},\mathcal{N}(f^u))\Psi+\text{c.c.}]. \tag{32}$$

Note that (31) defines an *autonomous* two-dimensional flow describing the self-consistent nonlinear evolution of the unstable mode; this is the amplitude equation we shall study.

Certain general features of the amplitude equation follow from the transformations (24) and (25) when these are symmetries of the Vlasov equation (11). For our problem, the amplitude equation always has translation symmetry (24) and we can apply standard results on the form of such symmetric equations. In particular, a two-dimensional vector field $\dot{A}=V(A,A^*)$ that is symmetric with respect to $A\to Ae^{-ika}$ can be written as $V(A,A^*)=Ap(\sigma)$ where $\sigma=|A|^2$ and $p(\sigma)$ is a smooth function determined from V.[12] Hence we know the right hand side of (31) takes the general form,

$$Ap(\sigma)=\lambda A+(\tilde{\Psi},\mathcal{N}(f^u)), \tag{33}$$

where the function $p(\sigma)$ must be determined from the Vlasov equation. Typically $p(\sigma)$ is complex-valued, however, when F_0 is reflection-symmetric then $p(\sigma)$ is forced to be real.

C. Analysis of $H(x,v,A,A^*)$

An equation for H follows by requiring consistency between (30) and (32). Equating the time derivative of (30) with the right hand side of (32) gives

$$\frac{\partial H}{\partial A}\dot{A}+\frac{\partial H}{\partial A^*}\dot{A}^*=\mathcal{L}H+\mathcal{N}(f^u)-[(\tilde{\Psi},\mathcal{N}(f^u))\Psi+\text{c.c.}], \tag{34}$$

which is to be solved for H subject to (35). Since the manifold is tangent to E^u at the equilibrium, H must satisfy

$$0=H(x,v,0,0)=\frac{\partial H}{\partial A}(x,v,0,0)=\frac{\partial H}{\partial A^*}(x,v,0,0). \tag{35}$$

The symmetries of the problem impose general restrictions on H because the unstable manifold is mapped onto itself by a symmetry transformation. For a translation this invariance means that $f^u(x-a,v,t)$ corresponds to a point on the manifold and thus can be written as,

$$(\mathcal{T}_a f^u)(x,v)=[A\Psi(x-a,v)+\text{c.c.}]+H(x-a,v,A,A^*) \tag{36}$$

$$=[A'\Psi(x,v)+\text{c.c.}]+H(x,v,A',A'^*). \tag{37}$$

Consistency between these two expressions requires that the transformed amplitude A' is related to the initial amplitude A by $A'=e^{-ika}A$ [cf. (24)], and this implies that H satisfies

$$H(x-a,v,A,A^*)=H(x,v,e^{ika}A,e^{-ika}A^*). \tag{38}$$

If, in addition, the system (26) and (27) has reflection symmetry, then similar reasoning yields

$$H(-x,-v,A,A^*)=H(x,v,A^*,A). \tag{39}$$

These general symmetry properties of H usefully constrain the form of the Fourier expansion

$$H(x,v,A,A^*)=\sum_{l=-\infty}^{\infty}e^{ilx}H_l(v,A,A^*)=\sum_{l=-\infty}^{\infty}e^{ilx}\begin{pmatrix}H_l^{(s_1)}(v,A,A^*)\\ H_l^{(s_2)}(v,A,A^*)\\ \vdots\end{pmatrix}. \tag{40}$$

Applying (38) shows that the components H_l must vanish unless l is an integer multiple of k and that the nonzero components have the general form

$$H_0(v,A,A^*)=\sigma h_0(v,\sigma),\quad H_k(v,A,A^*)=A\sigma h_1(v,\sigma),$$

$$H_{mk}(v,A,A^*)=A^m h_m(v,\sigma)\quad \text{for}\quad m\geqslant 2, \tag{41}$$

where $H_{-l}=H_l^*$. The functions h_m are not determined by symmetry; however, if reflection symmetry also holds, then

$$h_m(-v,\sigma)=h_m(v,\sigma)^*. \tag{42}$$

The reasoning leading to these symmetry results can be briefly outlined. The translation symmetry (38) requires

$$e^{-ila}H_l(v,A,A^*)=H_l(v,Ae^{-ika},A^*e^{ika}). \tag{43}$$

By choosing $a=2\pi/k$, this implies we find $H_l=0$ unless $\exp(2\pi i(l/k))=1$, hence the nonzero components satisfy $l=mk$ for integer m. Now recall that a function $G(v,A,A^*)$ which is invariant under $A\to Ae^{-ika}$ has the form $G(v,A,A^*)=g(v,\sigma)$ where $\sigma=|A|^2$ and $g(v,\sigma)$ is a smooth function determined by G. The relation in (43) implies that $G(v,A,A^*)=(A^*)^mH_{mk}(v,A,A^*)$ is such an invariant function. The factor $(A^*)^m$ in G requires that the corresponding $g(v,\sigma)$ contain an overall factor of σ^m; hence we set $g(v,\sigma)=\sigma^m h(v,\sigma)$. The resulting expression, $(A^*)^mH_{mk}=\sigma^m h(v,\sigma)$, then implies $H_{mk}=A^m h(v,\sigma)$. This general form, together with the requirement (35), leads to general expressions for the Fourier components of H in (41).

D. Equations for $p(\sigma)$ and $h_m(v,\sigma)$

The calculation of the amplitude equation (31) reduces to a determination of the function $p(\sigma)$ in (33); this requires the evaluation of $(\tilde{\Psi},\mathcal{N}(f^u))$ from (28) and involves the Fourier components of f^u

$$f_l^u=[A\psi(v)\delta_{l,k}+A^*\psi(v)^*\delta_{l,-k}]+H_l(v,A,A^*). \tag{44}$$

Combining (28) with (41) and (44) yields

$$\begin{aligned}(\tilde{\Psi},\mathcal{N}(f^u))=\frac{-iA\sigma}{k}\Bigg\{&\langle\partial_v\tilde{\psi},\kappa\cdot(h_0-h_2)\rangle+\frac{\Gamma_2}{2}\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle\\&+\sigma\Big[\Gamma_1\langle\partial_v\tilde{\psi},\kappa\cdot h_0\rangle-\Gamma_1^*\langle\partial_v\tilde{\psi},\kappa\cdot h_2\rangle+\frac{\Gamma_2}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_1^*\rangle-\frac{\Gamma_2^*}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_3\rangle\Big]\\&+\sum_{l=3}^{\infty}\frac{\sigma^{l-2}}{l}[\Gamma_l\langle\partial_v\tilde{\psi},\kappa\cdot h_{l-1}^*\rangle-\sigma\Gamma_l^*\langle\partial_v\tilde{\psi},\kappa\cdot h_{l+1}\rangle]\Bigg\}.\end{aligned} \tag{45}$$

In this expression, sum over the velocity integrals of $h_m^{(s)}$ is denoted by

$$\Gamma_m(\sigma)\equiv\sum_s\int_{-\infty}^{\infty}dv\,h_m^{(s)}(v,\sigma). \tag{46}$$

Now comparing (33) and (45) provides the desired expression for p

$$\begin{aligned}p(\sigma)=\lambda-\frac{i\sigma}{k}\Bigg\{&\langle\partial_v\tilde{\psi},\kappa\cdot(h_0-h_2)\rangle+\frac{\Gamma_2}{2}\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle+\sigma\Big[\Gamma_1\langle\partial_v\tilde{\psi},\kappa\cdot h_0\rangle-\Gamma_1^*\langle\partial_v\tilde{\psi},\kappa\cdot h_2\rangle\\&+\frac{\Gamma_2}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_1^*\rangle-\frac{\Gamma_2^*}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_3\rangle\Big]+\sum_{l=3}^{\infty}\frac{\sigma^{l-2}}{l}[\Gamma_l\langle\partial_v\tilde{\psi},\kappa\cdot h_{l-1}^*\rangle\\&-\sigma\Gamma_l^*\langle\partial_v\tilde{\psi},\kappa\cdot h_{l+1}\rangle]\Bigg\}.\end{aligned} \tag{47}$$

This expression for p involves the functions $h_m(v,\sigma)$ which define H. The equations that determine $h_m(v,\sigma)$ follow from the general equation for H in (34). In presenting these relations we shall use $\mathscr{P}_\perp$, the orthogonal projection defined by the unstable mode. Let $\mathscr{P}$ denote the projection operator onto $\psi(v)$ of a multicomponent function $g(v)$,

$$(\mathscr{P}g)(v) \equiv \langle \tilde{\psi}, g \rangle \psi(v), \tag{48}$$

with the orthogonal projection $\mathscr{P}_\perp \equiv I - \mathscr{P}$ given by

$$(\mathscr{P}_\perp g)(v) = g(v) - \psi(v)\langle \tilde{\psi}, g \rangle. \tag{49}$$

With the previous expression for $(\tilde{\Psi}, \mathscr{N}(f^u))$ in (45) and the notation in (41) for the Fourier components of H, the components of (34) take the form:

$$(p+p^*)\left[h_0 + \sigma \frac{\partial h_0}{\partial \sigma}\right] = \frac{i}{k}\frac{\partial}{\partial v}\kappa \cdot \left\{\left[\psi^* + \sigma(h_1^* - \psi\Gamma_1^*) + \sigma^2 h_1^*\Gamma_1 + \sum_{l=2}^{\infty} \frac{\sigma^{l-1}}{l} h_l^*\Gamma_l\right] - \text{c.c.}\right\}, \tag{50}$$

$$\begin{aligned}\left[(2p+p^*)h_1 - (L_k h_1) + (p+p^*)\sigma\frac{\partial h_1}{\partial \sigma}\right] &= \frac{i}{k}\mathscr{P}_\perp \frac{\partial}{\partial v}\kappa \cdot \left\{h_0 - h_2 + \frac{1}{2}\psi^*\Gamma_2 + \sigma\left[h_0\Gamma_1 - h_2\Gamma_1^* f + \frac{1}{2}h_1^*\Gamma_2 - \frac{1}{2}h_3\Gamma_2^*\right]\right. \\ &\left. + \sum_{l=3}^{\infty} \frac{\sigma^{l-2}}{l}[h_{l-1}^*\Gamma_l - \sigma h_{l+1}\Gamma_l^*]\right\},\end{aligned} \tag{51}$$

$$\begin{aligned}\left[2ph_2 - L_{2k}h_2 + (p+p^*)\sigma\frac{\partial h_2}{\partial \sigma}\right] &= \frac{i}{k}\frac{\partial}{\partial v}\kappa \cdot \left\{\psi + \sigma\left[h_1 + \psi\Gamma_1 - h_3 + \frac{1}{2}h_0\Gamma_2 + \frac{1}{3}\psi^*\Gamma_3\right]\right. \\ &\left. \times\sigma^2\left[h_1\Gamma_1 - h_3\Gamma_1^* - \frac{1}{2}h_4\Gamma_2^* + \frac{1}{3}h_1^*\Gamma_3\right] - \frac{\sigma^3}{3}h_5\Gamma_3^* + \sum_{l=4}^{\infty}\frac{\sigma^{l-2}}{l}[h_{l-2}^*\Gamma_l - \sigma^2 h_{l+2}\Gamma_l^*]\right\},\end{aligned} \tag{52}$$

and

$$\begin{aligned}\left[mph_m - L_{mk}h_m + (p+p^*)\sigma\frac{\partial h_m}{\partial \sigma}\right] &= \frac{i}{k}\frac{\partial}{\partial v}\kappa \cdot \left\{h_{m-1} + \frac{\psi}{m-1}\Gamma_{m-1} + \sum_{l=2}^{m-2}\frac{h_{m-l}}{l}\Gamma_l + \sigma\left[h_{m-1}\Gamma_1\right.\right. \\ &\left. - h_{m+1} + \frac{h_1}{m-1}\Gamma_{m-1} + \frac{h_0}{m}\,amma_m + \frac{\psi^*}{m+1}\Gamma_{m+1}\right] + \sigma^2\left[-h_{m+1}\Gamma_1^* + \frac{h_1^*}{m+1}\Gamma_{m+1}\right] \\ &\left. + \sum_{l=m+2}^{\infty}\frac{\sigma^{l-m}}{l}h_{l-m}^*\Gamma_l - \sum_{l=2}^{\infty}\frac{\sigma^l}{l}h_{m+l}\Gamma_l^*\right\}\end{aligned} \tag{53}$$

for $m=0,1,2$, and $m>2$, respectively.

Together with (47) these component equations determine the functions $p(\sigma)$ and $\{h_m(\sigma)\}_{m=0}^{\infty}$; however, they cannot be solved except using the expansions introduced in the next section. From a practical standpoint, we have achieved a reduction of the problem to the analysis of functions of a *single* real variable, i.e., σ. In the study of the amplitude equation (31) this reduction represents a very useful simplification.

III. EXPANSIONS, RECURSION RELATIONS, AND PINCHING SINGULARITIES

The amplitude equation on the unstable manifold,

$$\dot{A}=Ap(\sigma), \tag{54}$$

is analyzed by expressing $p(\sigma)$, $h_m(v,\sigma)$, and $\Gamma_m(\sigma)$ as power series in σ:

$$p(\sigma)=\sum_{j=0}^{\infty} p_j\sigma^j, \quad h_m(v,\sigma)=\sum_{j=0}^{\infty} h_{m,j}(v)\sigma^j, \quad \Gamma_m(\sigma)=\sum_{j=0}^{\infty} \Gamma_{m,j}\sigma^j, \tag{55}$$

where $\Gamma_{m,j}=\int dv\,\Sigma_s h_{m,j}^{(s)}(v)$.

The coefficients p_j and $h_{m,j}(v)$ are calculated by recursively solving (47) and (50)–(53). A recursion relation for p_j follows from (47) by inserting the expansions above and solving at each order in σ; this calculation yields

$$p_0=\lambda, \tag{56}$$

$$p_j=\frac{i}{k}[\mathscr{A}_j+\mathscr{B}_j] \quad \text{for} \quad j\geqslant 1, \tag{57}$$

where

$$\mathscr{A}_j=-\langle\partial_v\tilde{\psi},\kappa\cdot(h_{0,j-1}-h_{2,j-1})\rangle-\frac{1}{2}\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle\Gamma_{2,j-1}-\sum_{l=0}^{j-2}[\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,j-l-2}\rangle\Gamma_{1,l}$$
$$-\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,j-l-2}\rangle\Gamma_{1,l}^*], \tag{58}$$

$$\mathscr{B}_j=-\sum_{l=0}^{j-2}\left\{\frac{1}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_{1,j-l-2}^*\rangle\Gamma_{2,l}+\sum_{m=0}^{l}\left[\frac{\Gamma_{j-l+1,m}}{j-l+1}\langle\partial_v\tilde{\psi},\kappa\cdot h_{j-l,l-m}^*\rangle\right.\right.$$
$$\left.\left.-\frac{\Gamma_{j-l,m}^*}{j-l}\langle\partial_v\tilde{\psi},\kappa\cdot h_{j-l+1,l-m}\rangle\right]\right\}. \tag{59}$$

Here and below, a summation is understood to be omitted if the lower limit exceeds the upper limit. This organization of the terms in (58) and (59) will turn out to distinguish to different singular behaviors: $\mathscr{A}_j\sim\gamma^{-(5j-1)}$ and $\mathscr{B}_j\sim\gamma^{-(5j-2)}$.

The corresponding relations for $h_{m,j}(v)$ are determined similarly by applying the expansions (55) to the general equations (50)–(53); the resulting equations are solved for $h_{m,j}(v)$. Our results are conveniently stated in terms of the resolvent operator $R_l(w)\equiv(w-L_l)^{-1}$ and certain auxiliary functions $I_{m,j}(v)$ whose detailed expressions are provided below. For $m=0$, $h_{0,j}$ is simply

$$h_{0,j}(v)=\frac{I_{0,j}(v)}{(1+j)(\lambda+\lambda^*)}, \tag{60}$$

and the coefficients $h_{m,j}$ for $m>0$ require the resolvent

$$h_{m,j}(v)=R_{mk}(w_{m,j})I_{m,j} \tag{61}$$

with the complex numbers $w_{m,j}$ defined by

$$w_{m,j} \equiv (j+\delta_{m,1})(\lambda+\lambda^*)+m\lambda = 2(j+\delta_{m,1})\gamma + m\lambda. \tag{62}$$

A general expression for $R_l(w)$ follows from (13) by solving $(w-L_l)f=g$ for f.[10,13] Here both $g(v)=(g^{(s_1)}(v),g^{(s_2)}(v),\ldots)$ and f are multicomponent fields, and $R_l(w)$ acts by

$$R_l(w)g = \begin{pmatrix} (R_l(w)g)^{(s_1)}(v) \\ (R_l(w)g)^{(s_2)}(v) \\ \vdots \end{pmatrix}, \tag{63}$$

where

$$(R_l(w)g)^{(s)}(v) = \frac{1}{il(v-iw/l)}\left[g^{(s)}(v) - \frac{\kappa^{(s)}\eta_l^{(s)}}{\Lambda_l(iw/l)} \sum_{s'} \int_{-\infty}^{\infty} dv' \, \frac{g^{(s')}(v')}{v'-iw/l} \right]. \tag{64}$$

Note the following significant feature: the arguments $w_{m,j}$ of the resolvent in (61) determine *poles* of $h_{m,j}(v)$ located at $v=z_{m,j}$ where $z_{m,j} \equiv iw_{m,j}/mk$. For $m \geqslant 1$, these poles always fall in the upper half-plane above the phase velocity v_p:

$$z_{m,j} = z_0 + \frac{i\gamma d_{m,j}}{k} = v_p + \frac{i\gamma(1+d_{m,j})}{k}, \tag{65}$$

where $d_{m,j} \equiv 2(j+\delta_{m,1})/m$.

A. Recursion relations for $I_{m,j}$

The auxiliary functions $I_{0,j}(v)$ are defined by

$$I_{0,0}(v) = \frac{i}{k}\frac{\partial}{\partial v}\kappa\cdot(\psi^*-\psi) \tag{66}$$

for $j=0$, and for $j \geqslant 1$

$$I_{0,j}(v) = -\sum_{n=0}^{j-1}(1+n)(p_{j-n}+p_{j-n}^*)h_{0,n}(v) + \frac{i}{k}\frac{\partial}{\partial v}\kappa\cdot\left\{ \left[h_{1,j-1}^* - \psi\Gamma_{1,j-1}^* + \sum_{n=0}^{j-2} h_{1,n}^*\Gamma_{1,j-n-2} + \sum_{n=0}^{j-1}\sum_{l=0}^{n} \frac{h_{j-n+1,l}^*}{j-n+1}\Gamma_{j-n+1,n-l} \right] - \text{c.c.} \right\}. \tag{67}$$

For $m=1$, the functions $I_{1,j}(v)$ are given by

$$\begin{aligned} I_{1,j}(v) = &-\sum_{n=0}^{j-1}[(2+n)p_{j-n}+(1+n)p_{j-n}^*]h_{1,n} + \frac{i}{k}\mathscr{P}_\perp\frac{\partial}{\partial v}\kappa\cdot\Bigg\{ h_{0,j} - h_{2,j} + \frac{1}{2}\psi^*\Gamma_{2,j} \\ &+ \sum_{n=0}^{j-1}\Bigg[h_{0,n}\Gamma_{1,j-n-1} - h_{2,n}\Gamma_{1,j-n-1}^* + \frac{1}{2}h_{1,n}^*\Gamma_{2,j-n-1} - \frac{1}{2}h_{3,n}\Gamma_{2,j-n-1}^* \\ &+ \sum_{m=0}^{n}\left(\frac{h_{j-n+1,m}^*}{j-n+2}\Gamma_{j-n+2,n-m} \right)\Bigg] - \sum_{n=0}^{j-2}\sum_{m=0}^{n}\left[\frac{h_{j-n+2,m}}{j-n+1}\Gamma_{j-n+1,n-m}^* \right]\Bigg\}. \end{aligned} \tag{68}$$

The notation $\mathscr{P}_\perp g(v)$ was defined in (49): $\mathscr{P}_\perp g(v) = g(v) - \psi(v)\langle\tilde{\psi},g\rangle$.

For $m=2$ the functions $I_{2,j}(v)$ are given by

$$I_{2,0}(v) = \frac{i}{k}\frac{\partial}{\partial v}\kappa\cdot\psi \tag{69}$$

for $j=0$, and for $j \geqslant 1$

$$I_{2,j}(v)=-\sum_{n=0}^{j-1}[(2+n)p_{j-n}+np_{j-n}^{*}]h_{2,n}+\frac{i}{k}\frac{\partial}{\partial v}\kappa\cdot\Bigg\{h_{1,j-1}+\psi\Gamma_{1,j-1}-h_{3,j-1}+\frac{1}{3}\psi^{*}\Gamma_{3,j-1}$$
$$+\frac{1}{2}\sum_{n=0}^{j-1}h_{0,n}\Gamma_{2,j-n-1}+\sum_{n=0}^{j-2}\Bigg[h_{1,n}\Gamma_{1,j-n-2}-h_{3,n}\Gamma_{1,j-n-2}^{*}-\frac{1}{2}h_{4,n}\Gamma_{2,j-n-2}^{*}$$
$$+\frac{1}{3}h_{1,n}^{*}\Gamma_{3,j-n-2}+\sum_{m=0}^{n}\frac{h_{j-n,m}^{*}}{j-n+2}\Gamma_{j-n+2,n-m}\Bigg]-\sum_{n=0}^{j-3}\frac{h_{5,n}}{3}\Gamma_{3,j-n-3}^{*}$$
$$-\sum_{n=0}^{j-4}\sum_{m=0}^{n}\frac{h_{j-n+2,m}}{j-n}\Gamma_{j-n,n-m}^{*}\Bigg\}. \tag{70}$$

For $m>2$, the functions $I_{m,j}(v)$ are given by

$$I_{m,j}(v)=-\sum_{n=0}^{j-1}[(m+n)p_{j-n}+np_{j-n}^{*}]h_{m,n}(v)+\frac{i}{k}\frac{\partial}{\partial v}\kappa\cdot\Bigg\{h_{m-1,j}+\frac{\psi}{m-1}\Gamma_{m-1,j}$$
$$+\sum_{l=2}^{m-2}\sum_{n=0}^{j}\frac{h_{m-l,n}}{l}\Gamma_{l,j-n}-h_{m+1,j-1}+\frac{\psi^{*}}{m+1}\Gamma_{m+1,j-1}+\sum_{n=0}^{j-1}\Bigg[h_{m-1,n}\Gamma_{1,j-n-1}$$
$$+\frac{h_{1,n}}{m-1}\Gamma_{m-1,j-n-1}+\frac{h_{0,n}}{m}\Gamma_{m,j-n-1}\Bigg]+\sum_{n=0}^{j-2}\Bigg[-h_{m+1,n}\Gamma_{1,j-n-2}^{*}+\frac{h_{1,n}^{*}}{m+1}\Gamma_{m+1,j-n-2}$$
$$+\sum_{l=0}^{n}\left(\frac{h_{j-n,l}^{*}}{j+m-n}\Gamma_{j+m-n,n-l}-\frac{h_{m+j-n,l}}{j-n}\Gamma_{j-n,n-l}^{*}\right)\Bigg]\Bigg\}; \tag{71}$$

in this last expression, if a subscript is negative the term is understood to be omitted, e.g., for $j=0$, $h_{m+1,j-1}$ is omitted.

B. Useful identities

The relations (57), (60) and (61), and (66)–(71) can be applied systematically to calculate p_j and $h_{m,j}$ to any order. The leading coefficient p_0 is determined by linear theory (56) and from the linear eigenfunction ψ one can also calculate $h_{0,0}$ and $h_{2,0}$, c.f. (66) and (69), respectively. These two coefficients then suffice to calculate p_1 from (57). From $\{p_1,h_{0,0},h_{2,0}\}$, the coefficients $h_{1,0}$ and $h_{3,0}$ can be determined and then $h_{0,1}$ and $h_{2,1}$. This provides the input to calculate p_2, and from this point on the structure of the calculation to all orders falls into the simple pattern summarized in Table I.

For the remainder of the paper, our analysis of the expansion (55) is facilitated by several identities which we summarize here. These relations allow $\Gamma_{m,j},h_{m,j}$, and certain important integrals to be obtained very simply from the auxiliary functions $I_{m,j}$.

If $m=0$ we note that (60) and (66) and (67) imply $\Gamma_{0,j}=0$. For $m>0$, by substituting (61) into $\Gamma_{m,j}=\int dv\,\Sigma_s h_{m,j}^{(s)}$ and rearranging, we obtain

$$\Gamma_{m,j}=\frac{-i/mk}{\Lambda_{mk}(z_{m,j})}\sum_s\int_{-\infty}^{\infty}dv\,\frac{I_{m,j}^{(s)}(v)}{v-z_{m,j}}\quad(m>0). \tag{72}$$

With (72) for $\Gamma_{m,j}$, the general form for $h_{m,j}$ in (61) can be reexpressed as

$$h_{m,j}(v)=\left(\frac{-i}{mk}\right)\frac{I_{m,j}(v)}{v-z_{m,j}}-\left(\frac{\kappa\cdot\eta_{mk}}{v-z_{m,j}}\right)\Gamma_{m,j}\quad(m>0). \tag{73}$$

In this way $\Gamma_{m,j}$ and $h_{m,j}$ are written explicitly in terms of $I_{m,j}$.

The coefficients p_j depend on integrals of the form $\langle\partial_v\tilde{\psi},\kappa\cdot h_{m,j}\rangle$, and it is helpful to express these integrals directly in terms of $I_{m,j}$ also. From (60) we obtain the identity

TABLE I. Order of calculation of $h_{m,j}(v)$ and p_j from $\psi(v)$. The flow of calculation of the $h_{m,j}(v)$ is indicated by moving downward. From $\psi(v)$, $h_{0,0}$ and $h_{2,0}$ can be calculated and then p_1 determined; $h_{1,0}$ and $h_{3,0}$ are calculated next from $\{p_1, h_{0,0}, h_{2,0}\}$ and then $h_{0,1}$ and $h_{2,1}$ can be evaluated. This then determines p_2, and so forth. For $j_1 \geqslant 2$, p_{j_1} requires prior calculation of $h_{m,j}$ for $0 \leqslant m \leqslant j_1+1$ and $0 \leqslant j \leqslant j_1 - m + 1 - 2(\delta_{m,0}+\delta_{m,1})$.

	$m=0$	$m=1$	$m=2$	$m=3$	$m=4$	$m=5$	$m=6$	$\cdots$
p_0		$\psi(v)$						
p_1	$h_{0,0}$	–	$h_{2,0}$					
		$h_{1,0}$		$h_{3,0}$				
p_2	$h_{0,1}$		$h_{2,1}$					
		$h_{1,1}$			$h_{4,0}$			
p_3	$h_{0,2}$		$h_{2,2}$	$h_{3,1}$				
		$h_{1,2}$				$h_{5,0}$		
p_4	$h_{0,3}$		$h_{2,3}$	$h_{3,2}$	$h_{4,1}$			
		$h_{1,3}$					$h_{6,0}$	
p_5	$h_{0,4}$		$h_{2,4}$	$h_{3,3}$	$h_{4,2}$	$h_{5,1}$		
$\vdots$								

$$\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa}\cdot h_{0,j}\rangle = \frac{1}{2\gamma(1+j)\Lambda_k'(z_0)} \int_{-\infty}^{\infty} dv\ \frac{\Sigma_s \boldsymbol{\kappa}^{(s)} I_{0,j}^{(s)}}{(v-z_0)^2}; \tag{74}$$

similarly, by integrating (73) we find

$$\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa}\cdot h_{m,j}\rangle = \left(\frac{-i}{mk\Lambda_k'(z_0)}\right)\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s \boldsymbol{\kappa}^{(s)} I_{m,j}^{(s)}}{(v-z_0)^2(v-z_{m,j})} - \left(\frac{\Gamma_{m,j}}{\Lambda_k'(z_0)}\right)\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s (\boldsymbol{\kappa}^{(s)})^2 \boldsymbol{\eta}_{mk}^{(s)}}{(v-z_0)^2(v-z_{m,j})}. \tag{75}$$

C. Analysis of the cubic coefficient

It is instructive at this point to evaluate and examine the cubic coefficient p_1 in detail. This coefficient illustrates the occurrence of pinching singularities and the procedures needed to evaluate such singular integrals.

From (57) we have

$$p_1 = -\frac{i}{k}\left[\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa}\cdot(h_{0,0}-h_{2,0})\rangle + \frac{\Gamma_{2,0}}{2}\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa}\cdot\psi^*\rangle\right] \tag{76}$$

so $h_{0,0}(v)$, $h_{2,0}(v)$ and $\Gamma_{2,0}$ are needed to calculate p_1. From (60) and (66) we have

$$h_{0,0}(v) = -\frac{1}{k^2}\frac{\partial}{\partial v}\left[\frac{\boldsymbol{\kappa}^2\cdot\boldsymbol{\eta}_k}{(v-z_0)(v-z_0^*)}\right], \tag{77}$$

where $\boldsymbol{\kappa}^2$ denotes the square of the mass matrix. From (21), (69) and (72) we obtain

$$\Gamma_{2,0} = -\frac{2}{3k^2}\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\boldsymbol{\kappa}^2\cdot\boldsymbol{\eta}_k)^{(s)}}{(v-z_0)^3}, \tag{78}$$

and inserting (69) into (73) yields

$$h_{2,0}(v) = \frac{1}{2k^2}\left(\frac{\boldsymbol{\kappa}\cdot\partial_v\psi}{v-z_0}\right) - \frac{\Gamma_{2,0}}{4}\left(\frac{\boldsymbol{\kappa}\cdot\boldsymbol{\eta}_k}{v-z_0}\right). \tag{79}$$

Here we have made the substitution $\boldsymbol{\eta}_{2k} = \boldsymbol{\eta}_k/4$.

We are concerned with the form of the various integrals in p_1 in the asymptotic regime of small growth rate $\gamma \to 0^+$. The behavior of these integrals is determined by any complex singularities of the integrand that approach the real velocity axis as $\gamma \to 0^+$. We shall always assume that whatever complex analytic structure characterizes F_0 there are never any singularities that move to the real axis in this limit and therefore the singularities in η_k can be regarded as irrelevant in analyzing a given integral.

The singularities of interest are associated with the explicit poles in the denominator of a given integrand. For example, $\Gamma_{2,0}$ has a third-order pole at $v = z_0$ which approaches the real axis from above as $\gamma \to 0^+$. In this case, there are no corresponding poles in the lower half-plane, and consequently no pinching singularity develops; therefore $\Gamma_{2,0}$ has a finite limit as the growth rate goes to zero. Similarly, we see by inspection that $h_{2,0}$ has a third-order pole at $v = z_0$ and consequently the integrand of $\langle \partial_v \tilde{\psi}, \kappa \cdot h_{2,0} \rangle$ has a fifth-order pole at $v = z_0$. However, again there is no pinching singularity and this integral also has a finite limit as $\gamma \to 0^+$.

The remaining integrals, $\langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle$ and $\langle \partial_v \tilde{\psi}, \kappa \cdot h_{0,0} \rangle$, are more interesting. The simplest example is $\langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle$ whose integrand has a double pole at $v = z_0$ and a simple pole at $v = z_0^*$:

$$\langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle = -\frac{1}{\Lambda_k'(z_0)} \sum_s \int_{-\infty}^{\infty} \frac{dv (\kappa^2 \cdot \eta_k)^{(s)}}{(v - z_0)^2 (v - z_0^*)}. \tag{80}$$

As $\gamma \to 0^+$, these poles approach the real axis from above and below; this creates a pinching singularity and the integral has a singular limit. We analyze this integral in two steps that can be applied to all such singular integrals: a partial fraction expansion extracts the singularity and the dispersion relation is applied to eliminate integrals over the electron distribution function. The motivation for the second step is to incorporate the one relation between the different distribution functions and to expose the effect of treating the ions as mobile.

The partial fraction expansion of the integrand yields

$$\frac{1}{(v - z_0)^2 (v - z_0^*)} = \left(\frac{ik}{2\gamma} \right)^2 \left[\frac{1}{v - z_0^*} - \frac{1}{v - z_0} \right] - \left(\frac{ik}{2\gamma} \right) \frac{1}{(v - z_0)^2} \tag{81}$$

so that our integral becomes

$$\sum_s \int_{-\infty}^{\infty} \frac{dv (\kappa^2 \cdot \eta_k)^{(s)}}{(v - z_0)^2 (v - z_0^*)} = \left(\frac{ik}{2\gamma} \right)^2 \left[\sum_s \int_{-\infty}^{\infty} \frac{dv (\kappa^2 \cdot \eta_k)^{(s)}}{v - z_0^*} - \sum_s \int_{-\infty}^{\infty} \frac{dv (\kappa^2 \cdot \eta_k)^{(s)}}{v - z_0} \right] - \left(\frac{ik}{2\gamma} \right) \sum_s \int_{-\infty}^{\infty} \frac{dv (\kappa^2 \cdot \eta_k)^{(s)}}{(v - z_0)^2}. \tag{82}$$

On the right hand side of this expression all the integrals are free of pinching singularities and therefore have finite limits as $\gamma \to 0^+$. The singularities of the original integral are now explicitly shown in the factors γ^{-2} and γ^{-1}.

The dispersion relation for the unstable mode $\Lambda_k(z_0) = 0$ implies the identities

$$\int_{-\infty}^{\infty} dv \, \frac{\eta_k^{(e)}(v)}{v - z_0} = 1 + \int_{-\infty}^{\infty} dv \, \frac{\Sigma_s' \kappa^{(s)} \eta_k^{(s)}(v)}{v - z_0}, \tag{83}$$

$$\int_{-\infty}^{\infty} dv \, \frac{\eta_k^{(e)}(v)}{(v - z_0)^2} = -\Lambda_k'(z_0) - \int_{-\infty}^{\infty} dv \, \frac{\Sigma_s^* \kappa^{(s)} \eta_k^{(s)}(v)}{(v - z_0)^2}, \tag{84}$$

where we have used $\kappa^{(e)} = -1$ and the primed sum indicates that the electron term is omitted. Substitution of (83) and (84) for the electron integrals in (82) yields

$$\sum_s \int_{-\infty}^{\infty} \frac{dv (\kappa^2 \cdot \eta_k)^{(s)}}{(v - z_0)^2 (v - z_0^*)} = \left(\frac{ik}{2\gamma} \right)^2 \left[-2i \sum_s{}' \kappa^{(s)} (1 + \kappa^{(s)}) \mathrm{Im} \int_{-\infty}^{\infty} \frac{dv \, \eta_k^{(s)}}{v - z_0} \right]$$

$$+\left(\frac{ik}{2\gamma}\right)\left[\Lambda_k'(z_0)+\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)})\int_{-\infty}^{\infty}\frac{dv\,\eta_k^{(s)}}{(v-z_0)^2}\right]. \quad (85)$$

Combining this with (80) we conclude that $\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle$ typically diverges like γ^{-2} in the small growth rate limit. There are exceptions, however; for example, in the limit of fixed ions, $\kappa^{(s)}\to 0$ for $s\neq e$, then we are left with

$$\sum_s\int_{-\infty}^{\infty}\frac{dv(\kappa^2\cdot\eta_k)^{(s)}}{(v-z_0)^2(v-z_0^*)}\to\left(\frac{ik}{2\gamma}\right)\Lambda_k'(z_0), \quad (86)$$

and the divergence is merely γ^{-1}.

We treat the remaining integral $\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle$ in the same fashion. This integrand now has a fourth-order pole at $v=z_0$ and a simple pole at $v=z_0^*$:

$$\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle=-\frac{2}{k^2\Lambda_k'(z_0)}\sum_s\int_{-\infty}^{\infty}\frac{dv(\kappa^3\cdot\eta_k)^{(s)}}{(v-z_0)^4(v-z_0^*)}. \quad (87)$$

Again we make a partial fraction expansion

$$\frac{1}{(v-z_0)^4(v-z_0^*)}=\left(\frac{ik}{2\gamma}\right)^4\left[\frac{1}{v-z_0^*}-\frac{1}{v-z_0}\right]-\left(\frac{ik}{2\gamma}\right)^3\frac{1}{(v-z_0)^2}-\left(\frac{ik}{2\gamma}\right)^2\frac{1}{(v-z_0)^3}$$
$$-\left(\frac{ik}{2\gamma}\right)\frac{1}{(v-z_0)^4}, \quad (88)$$

and eliminate the electron integrals to find

$$\sum_s\int_{-\infty}^{\infty}\frac{dv(\kappa^3\cdot\eta_k)^{(s)}}{(v-z_0)^4(v-z_0^*)}=\left(\frac{ik}{2\gamma}\right)^4\left[+2i\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)2})\,\mathrm{Im}\int_{-\infty}^{\infty}\frac{dv\,\eta_k^{(s)}}{v-z_0}\right]$$
$$+\left(\frac{ik}{2\gamma}\right)^3\left[-\Lambda_k'(z_0)+\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)2})\int_{-\infty}^{\infty}\frac{dv\,\eta_k^{(s)}}{(v-z_0)^2}\right]$$
$$+\left(\frac{ik}{2\gamma}\right)^2\left[-\frac{\Lambda_k''(z_0)}{2}+\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)2})\int_{-\infty}^{\infty}\frac{dv\,\eta_k^{(s)}}{(v-z_0)^3}\right]$$
$$+\left(\frac{ik}{2\gamma}\right)\left[-\frac{\Lambda_k'''(z_0)}{6}+\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)2})\int_{-\infty}^{\infty}\frac{dv\,\eta_k^{(s)}}{(v-z_0)^4}\right]. \quad (89)$$

Thus for $\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle$ the typical divergence is γ^{-4}.

Combining these results with p_1 in (76), we obtain the asymptotic form of the cubic coefficient as $\gamma\to 0^+$

$$p_1=\frac{1}{\gamma^4}[c_1(\gamma)-\gamma d_1(\gamma)+\mathcal{O}(\gamma^2)], \quad (90)$$

where c_1 and d_1 are nonsingular functions of γ defined by

$$c_1(\gamma)=-\frac{k}{4\Lambda_k'(z_0)}\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)2})\,\mathrm{Im}\left(\int_{-\infty}^{\infty}dv\,\frac{\eta_k^{(s)}}{v-z_0}\right), \quad (91)$$

$$d_1(\gamma)=\frac{1}{4}-\frac{1}{4\Lambda_k'(z_0)}\sum_s{}'\kappa^{(s)}(1-\kappa^{(s)2})\int_{-\infty}^{\infty}dv\,\frac{\eta_k^{(s)}}{(v-z_0)^2}; \quad (92)$$

this result was briefly presented without derivation in an earlier paper.[7] When the leading term is nonzero at $\gamma=0$ [i.e., $c_1(0)\neq 0$], then p_1 diverges like γ^{-4} as a result of the divergence in $\langle \partial_v \tilde{\psi}, \kappa\cdot h_{0,0}\rangle$.

The significance of this result is best understood in light of our earlier discussion of scaling the amplitude $A(t)$ to obtain an amplitude equation free of singular features at small growth rates. With our expression for p_1, the amplitude equation for the unstable mode is

$$\dot{A}=A\left[\lambda+\frac{[c_1(0)+\mathcal{O}(\gamma)]}{\gamma^4}\left|A\right|^2+p_2(\gamma)\left|A\right|^4+\cdots\right], \tag{93}$$

which we rewrite using polar variables $A=\rho e^{-i\theta}$ as

$$\dot{\rho}=\gamma\rho+\frac{1}{\gamma^4}[\mathrm{Re}(c_1(0))+\mathcal{O}(\gamma)]\rho^3+\mathrm{Re}(p_2)\rho^5+\cdots, \tag{94}$$

$$\dot{\theta}=\omega-\frac{1}{\gamma^4}[\mathrm{Im}(c_1(0))+\mathcal{O}(\gamma)]\rho^2-\mathrm{Im}(p_2)\rho^4+\cdots. \tag{95}$$

Now we introduce a scaled amplitude $\rho(t)=\gamma^\beta r(\gamma t)$ following (3) and anticipate that $\delta=1$ is required to remove the singular effect of the linear term:

$$\frac{dr}{d\tau}=r+\frac{\gamma^{2\beta-1}}{\gamma^4}[\mathrm{Re}(c_1(0))+\mathcal{O}(\gamma)]r^3+\gamma^{4\beta-1}\ \mathrm{Re}(p_2)r^5+\cdots, \tag{96}$$

$$\dot{\theta}=\omega-\frac{\gamma^{2\beta}}{\gamma^4}[\mathrm{Im}(c_1(0))+\mathcal{O}(\gamma)]r^2-\gamma^{4\beta}\ \mathrm{Im}(p_2)r^4+\cdots. \tag{97}$$

The exponent β should be chosen so that the nonlinear coefficients have finite limits as $\gamma\to 0^+$. The most stringent requirements on β arise from the coefficients in the $dr/d\tau$ equation, and the cubic term requires $2\beta\geqslant 5$ to absorb the γ^{-4} singularity. Setting $\beta=5/2$ suffices to cancel the singularities in p_1 and allow the cubic nonlinearity to formally balance with the linear term at small γ:

$$\frac{dr}{d\tau}=r+[\mathrm{Re}(c_1(0))+\mathcal{O}(\gamma)]r^3+\gamma^9\ \mathrm{Re}(p_2)r^5+\cdots, \tag{98}$$

$$\dot{\theta}=\omega-\gamma[\mathrm{Im}(c_1(0))+\mathcal{O}(\gamma)]r^2-\gamma^{10}\ \mathrm{Im}(p_2)r^4+\cdots. \tag{99}$$

This choice for β assumes that $\mathrm{Re}(c_1(0))\neq 0$ and that the singularities at fifth (and higher) order are also removed by the same scaling that absorbs the cubic singularity. Typically the condition $\mathrm{Re}(c_1(0))\neq 0$ is satisfied, but there are interesting exceptions and they are discussed next. The adequacy of the $\beta=5/2$ scaling in controlling higher-order singularities is studied in Sec. IV.

D. Special cases: $c_1(0)=0$

Evaluating $c_1(0)$ as $\gamma\to 0^+$ yields

$$c_1(0)=-\frac{\pi k}{4\Lambda_k'(v_p+i0)}\sum_s{}'\,\kappa^{(s)}(1-\kappa^{(s)2})\,\eta_k^{(s)}(v_p(0)), \tag{100}$$

where $v_p(0)$ denotes the linear phase velocity at zero growth rate. Since the first factor $(\pi k/4\Lambda_k')$ cannot vanish, the special case $c_1(0)=0$ will only arise if the species sum (which excludes the electrons) vanishes. By carefully adjusting the parameters of a given model, one can presumably arrange for exact cancellations between different terms in this sum, but there is little motivation to study such artificial situations.

However, there are three natural circumstances in which $c_1(0)=0$ because every term in the sum vanishes independently, and the cubic coefficient is clearly less singular:

(a) Infinitely massive ions: $\kappa^{(s)}=0$ for all $s\neq e$.
(b) Zero slope for the resonant ions: $\eta_k^{(s)}(v_p(0))=0$ for all $s\neq e$.
(c) An electron-positron plasma: $\kappa^{(p)2}=1$ for positrons.
In all three cases, the cubic coefficient has the asymptotic form

$$p_1=-\frac{1}{\gamma^3}[d_1(0)+\mathcal{O}(\gamma)] \tag{101}$$

with $d_1(0)$ given by the full formula (92) for the second case and $d_1(0)=1/4$ in the first and third cases.

In the rescaled equation (96), this weakened singularity requires only that $2\beta\geqslant 4$, and setting $\beta=2$ yields

$$\frac{dr}{d\tau}=r+[\mathrm{Re}(d_1(0))+\mathcal{O}(\gamma)]r^3+\gamma^7\ \mathrm{Re}(p_2)r^5+\cdots, \tag{102}$$

$$\dot{\theta}=\omega-[\mathrm{Im}(d_1(0))+\mathcal{O}(\gamma)]r^2-\gamma^8\ \mathrm{Im}(p_2)r^4+\cdots. \tag{103}$$

In (I), we have shown that the exponent $\beta=2$ suffices to absorb the singularities in (102) and (103) to *all* orders for a plasma with fixed ions; this exponent corresponds to the relatively familiar trapping scaling for the electric field of an unstable mode. In Sec. V, we provide a new proof of this result and also establish the same conclusion for the case (b) where each ion distribution is flat at the phase velocity: $\eta_k^{(s)}(v_p)=0$ for all $s\neq e$. This will occur, for example, if the ions are sufficiently cold and do not populate the resonant region in velocity space. On the other hand, when there is an exact reflection symmetry $F_0(v)=F_0(-v)$, we can have an unstable mode with $v_p=0$ and $\eta_k^{(s)}(0)=0$ holds even though the ion distribution function is nonzero at $v=0$. This latter situation arises for instabilities of reflection-symmetric equilibria due to real eigenvalues, e.g., a reflection-symmetric two-stream instability.

Our understanding of the third example, an electron-positron plasma, is less complete. In Sec. V B we obtain by explicit calculation $\mathrm{Re}(p_2)\sim\gamma^{-8}$ so the rescaled fifth-order term in (102) remains singular unless $\beta\geqslant 9/4$. However, the singularity structure of the full expansion is more complicated and we have not determined the effects of singularities at higher order.

IV. SINGULARITY STRUCTURE OF THE EXPANSION

Our goal is a systematic analysis of the singularities of p_j to all orders in the amplitude equation (54). The detailed calculation of p_j rapidly becomes prohibitively laborious, but the recursion relations (57)–(59) determining the higher order coefficients in terms of lower order quantities (cf. Table I) can be analyzed to determine the properties of p_j. This study requires an accurate estimate of the pinching singularities in the integrals found in p_j. For this purpose we introduce an ''index'' which allows the divergence of a given integral to be assessed by a simple counting procedure. As in our discussion of the cubic coefficient, we assume the analytic singularities of F_0 do not affect the divergence behavior; the precise assumption on F_0 is given in (108) below.

A. Definition of the index

At every order in the expansion, the pinching singularities have a common structure. For $n>0$, define

$$D_n(\alpha,v)\equiv\frac{1}{(v-\alpha_1)(v-\alpha_2)\cdots(v-\alpha_n)}, \tag{104}$$

where $\alpha\equiv(\alpha_1,\ldots,\alpha_n)$ and also define $D_0(\alpha,v)\equiv 1$. Evaluating p_j for $j\geqslant 1$ involves integrands of the form

$$\mathcal{I}(v)=D_m(\beta,v)*D_n(\alpha,v)\sum_s{}'\ (\kappa^{(s)})^{m'}\frac{\partial^q\eta_l^{(s)}}{\partial v^q} \tag{105}$$

with $m+n\geqslant 1$, $m'\geqslant 1$ and $q\geqslant 0$. The poles in $\mathcal{G}(v)$ may be written as

$$\alpha_j = z_0 + i\gamma\nu_j/k, \quad j=1,\ldots,n, \tag{106}$$

$$\beta_j^* = z_0^* - i\gamma\zeta_j/k, \quad j=1,\ldots,m; \tag{107}$$

since they always lie along the vertical line $\mathrm{Re}(v)=v_p(\gamma)$. The specific pole locations are given by the numbers $\nu_j\geqslant 0$ and $\zeta_j\geqslant 0$ which vary depending on the integral. In all cases, these numbers are independent of F_0; in particular ν_j and ζ_j are independent of γ.

The complex-analytic singularities of F_0 are assumed to be unimportant for the amplitude expansions in the following sense. For any $n\geqslant 1$ and $q\geqslant 0$, we assume that

$$\lim_{\gamma\to 0^+}\left|\int_{-\infty}^{\infty} dv\, D_n(\alpha,v)\,\frac{\partial^q \eta_l^{(s)}}{\partial v^q}\right| < \infty \tag{108}$$

holds for each species and arbitrary choices of ν_j in (106). For example, it is sufficient for each distribution function $F_0^{(s)}(v)$ to be analytic on a neighborhood of $v_p(0)$, the linear phase velocity at zero growth rate; in this case the limit in (108) can be evaluated by the Plemej formulas for Cauchy integrals.[14]

The *index* of $\mathcal{G}(v)$ in (105) is defined by

$$\mathrm{Ind}[\mathcal{G}] \equiv m+n+q-1, \tag{109}$$

and $\mathrm{Ind}[\mathcal{G}]\geqslant 0$ since we assume $m+n\geqslant 1$. For example, for ψ in (20), the integrand of $\Gamma_{2,0}$ in (78) and the integrand of $\langle \partial_v\tilde{\psi}, \kappa\cdot\psi^*\rangle$ in (80), we obtain the indices

$$\mathrm{Ind}\left[\sum_s \kappa^{(s)}\psi^{(s)}\right]=0, \quad \mathrm{Ind}\left[\frac{\Sigma_s(\kappa^2\cdot\eta_k)^{(s)}}{(v-z_0)^3}\right]=2, \quad \mathrm{Ind}\left[\frac{\Sigma_s(\kappa^2\cdot\eta_k)^{(s)}}{(v-z_0)^2(v-z_0^*)}\right]=2. \tag{110}$$

If $mn=0$, our assumption (108) ensures that $\int dv\,\mathcal{G}(v)$ is nonsingular, but when $mn\neq 0$, then as $\gamma\to 0^+$, the integral of $\mathcal{G}$ develops a pinching singularity at the phase velocity $v_p(0)$. The index of $\mathcal{G}$ estimates the worst possible divergence of $\int dv\,\mathcal{G}$ due to this singularity.

Lemma IV.1: For $\mathcal{G}(v)$ *in* (105) *with* $mn\neq 0$, *the integral of* $\mathcal{G}$ *satisfies*

$$\lim_{\gamma\to 0^+}\gamma^J\left|\int_{-\infty}^{\infty} dv\,\mathcal{G}(v)\right| < \infty \tag{111}$$

with $J=\mathrm{Ind}[\mathcal{G}]$. *However, if*

$$\sum_s{}' \kappa^{(s)}[(-1)^{m'}+(\kappa^{(s)})^{m'-1}]\,\eta_k^{(s)}(v_p(0))=0, \tag{112}$$

then the integral of $\mathcal{G}$ *is less singular and* (111) *holds with* $J=\mathrm{Ind}[\mathcal{G}]-1$. *In* (112) *the prime on the summation indicates that the sum omits the electron species.*

Proof: By integrating by parts q times we can reduce to the case with $q=0$. With $q=0$, consider the simplest possibility $m+n=2$, and make a partial fraction expansion of the integrand

$$\int_{-\infty}^{\infty} dv\,\frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_1)(v-\beta_1^*)} = \frac{(-ik/\gamma)}{(2+\nu_1+\zeta_1)}\left[\int_{-\infty}^{\infty} dv\,\frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_1)} - \int_{-\infty}^{\infty} dv\,\frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\beta_1^*)}\right]. \tag{113}$$

The integrals on the right are nonsingular with limits at $\gamma=0$ given by the Plemej formula

$$\lim_{\gamma\to 0^+}\left[\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_1)}-\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\beta_1^*)}\right]=2\pi i\sum_s\ (\kappa^{(s)})^{m'}\eta_l^{(s)}(v_p(0)). \tag{114}$$

From the limit $\gamma\to 0^+$ of the dispersion relation $\Lambda_k(z_0)=0$, we obtain $\Sigma_s(\kappa^{(s)})\,\eta_k^{(s)}(v_p(0))=0$ for the imaginary part. Since $\kappa^{(e)}=-1$, this can be rewritten as $\eta_k^{(e)}=\Sigma_s'(\kappa^{(s)})\,\eta_k^{(s)}(v_p(0))$, and used to eliminate $\eta_k^{(e)}$ from (114):

$$\lim_{\gamma\to 0^+}\left[\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_1)}-\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\beta_1^*)}\right]$$
$$=2\pi i\left(\frac{k^2}{l^2}\right)\sum_s{}'\,\kappa^{(s)}[(-1)^{m'}+(\kappa^{(s)})^{m'-1}]\,\eta_k^{(s)}(v_p(0)). \tag{115}$$

This proves the lemma for $m+n=2$. It is important that the limit in (115) is independent of the parameters ν_1 and ζ_1 that locate the poles α_1 and β_1 for $\gamma>0$.

For integrals with $m+n>2$, by expanding the integrand in partial fractions, they can be reexpressed in terms of integrals with $m+n-1$ multiplied by a factor of γ^{-1}. A simple induction argument then establishes (111) for general $mn\neq 0$. (Recall that if $mn=0$ then the integrals are nonsingular.)

The general significance of the condition in (112) becomes clear from the form of the partial fraction expansion. For example, consider the expansion for $(m,n)=(2,1)$:

$$\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_1)(v-\alpha_2)(v-\beta_1^*)}=\frac{(-ik/\gamma)}{(2+\nu_1+\zeta_1)}\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_1)(v-\alpha_2)}$$
$$-\frac{(-ik/\gamma)^2}{(2+\nu_1+\zeta_1)(2+\nu_2+\zeta_1)}\left[\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_2)}\right.$$
$$\left.-\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\beta_1^*)}\right]. \tag{116}$$

The second term is the dominant singularity γ^{-2} and at $\gamma=0$ the bracketed integrals yield the same factor obtained previously in (115). When this factor is zero, the singularity of the $(m,n)=(2,1)$ integral is reduced from 2 to 1.

In the partial fraction expansion of the general case, the most singular terms that diverge according to (111) will always be proportional to the difference of two nonsingular integrals:

$$\left[\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\alpha_j)}-\int_{-\infty}^{\infty} dv\ \frac{\Sigma_s(\kappa^{(s)})^{m'}\eta_l^{(s)}}{(v-\beta_{j'}^*)}\right] \tag{117}$$

whose limit at $\gamma=0$ is given by (115). Thus when this limit is zero, the singularity of the term must drop by 1. This proves the second part of the lemma. □

The exceptional situation defined by the condition in (112) is a generalization of the feature noted previously in our analysis of the cubic coefficient. Setting $m'=3$ in (112) yields $c_1(0)=0$ from (100); the special circumstance that corresponded to a less singular integral at third order.

Our application of Lemma IV.1 to the recursion relations for $I_{m,j}$ requires generalization of the index to allow for sums of functions with well-defined indices and products of $\mathcal{G}$ with singular functions of γ. In each case, the generalized index is defined so that Eq. (111) remains true, i.e., the index for the composite function gives the *maximal* possible divergence of its integral.

First, if $\mathcal{G}_1(v)$ and $\mathcal{G}_2(v)$ have indices satisfying $\mathrm{Ind}[\mathcal{G}_1]\geqslant\mathrm{Ind}[\mathcal{G}_2]$ then we define the index of the sum to be the larger index:

$$\mathrm{Ind}[\mathscr{G}_1+\mathscr{G}_2]\equiv\mathrm{Ind}[\mathscr{G}_1]. \tag{118}$$

Clearly, $\mathrm{Ind}[\mathscr{G}_1]$ gives the maximal possible divergence of $\int dv(\mathscr{G}_1+\mathscr{G}_2)$. Second, if $q(\gamma)$ is a function of γ with the asymptotic behavior $q(\gamma)\sim\gamma^{-\nu}$ as $\gamma\to 0^+$, then we define the index of $q(\gamma)\mathscr{G}(v)$ to be

$$\mathrm{Ind}[q\mathscr{G}]\equiv\mathrm{Ind}[\mathscr{G}]+\nu. \tag{119}$$

Estimates of the form (111) still hold for $q\mathscr{G}$ with $J=\mathrm{Ind}[q\mathscr{G}]$. This completes the definition of the index.

By applying (118) and (119), the indices of $I_{m,j}$ and $h_{m,j}$ may be determined. For example, from (66) and (69) we have the indices

$$\mathrm{Ind}\left[\sum_s \kappa^{(s)}I_{0,0}^{(s)}\right]=1,\quad \mathrm{Ind}\left[\sum_s \kappa^{(s)}I_{2,0}^{(s)}\right]=1, \tag{120}$$

and from (77) and (79)

$$\mathrm{Ind}\left[\sum_s \kappa^{(s)}h_{0,0}^{(s)}\right]=2,\quad \mathrm{Ind}\left[\sum_s \kappa^{(s)}h_{2,0}^{(s)}\right]=2. \tag{121}$$

The index for $h_{2,0}^{(s)}$ is correct provided $\Gamma_{2,0}$ does not diverge more strongly than γ^{-2}. We can confirm this immediately from the index in (110); in fact, $\Gamma_{2,0}$ is nonsingular, as noted already in Sec. III C. In Sec. IV B, these indices are applied to determine the singularity of p_1. We stress again that when applied to a composite function $\mathscr{G}(v)$ the estimate in (111) does not necessarily determine the true singularity, but only an upper bound on the possible divergence of the integral.

There are several immediate consequences of the index definition worth stating. First, complex conjugation does not alter the index, $\mathrm{Ind}[\mathscr{G}]=\mathrm{Ind}[\mathscr{G}^*]$; second, if $G(v)$ has a well-defined index, then dividing G by $(v-\alpha)$ or $(v-\beta^*)$ simply increases the index of G by one:

$$\mathrm{Ind}[\mathscr{G}/(v-\alpha)]=\mathrm{Ind}[\mathscr{G}/(v-\beta^*)]=\mathrm{Ind}[\mathscr{G}]+1. \tag{122}$$

Here α,β are defined as in (106) and (107) and thereby increase the index of every term in G by one; this implies (122). Finally, from (105), differentiating $\mathscr{G}$ also raises the index by one, $\mathrm{Ind}[\partial_v\mathscr{G}]=1+\mathrm{Ind}[\mathscr{G}]$.

B. Analysis of p_1 using the index

The above relations along with recursion relations determine the indices of $I_{m,j}$ and $h_{m,j}$ to all orders. This information permits an estimate of the singularities of the coefficients p_j for $j\geqslant 1$. In practice, this must be done recursively following the organization of the amplitude expansions in Table I. The procedure is illustrated here for the first level of Table I; more general results on the index to all orders are provided in Secs. IV C and V.

Table I begins with ψ, $h_{0,0}$ and $h_{2,0}$ whose indices were evaluated in (110) and (121). From this information, we can estimate the integrals required to evaluate p_1 in (76). The integrand of $\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle$ has index 2, and the integrands of $\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle$ and $\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}\rangle$ have index 4. In each case, the factor $\partial_v\tilde{\psi}^{(s)*}$ increases the index by two from the values obtained in (110) and (121). Now Lemma IV.1 tells us that $\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle$ cannot diverge more strongly than γ^{-2}, and $\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle$ and $\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}\rangle$ cannot diverge more strongly than γ^{-4}.

These conclusions imply that the singularity of p_1 cannot be worse than γ^{-4}; this was found in Sec. III C by an explicit calculation of p_1. The explicit evaluation, of course, provided the important additional result that the γ^{-4} singularity actually occurs unless one of the exceptional cases corresponding to $c_1(0)=0$ is considered. The foregoing index analysis is easier but yields less complete information.

C. The main result

The main result on the singularity structure of the amplitude expansions can now be proved.

Theorem IV.1: *For $j \geqslant 1$, the coefficients in the expansion of the amplitude equation* (54) *satisfy*

$$\lim_{\gamma \to 0^+} \gamma^{5j-1} |p_j| < \infty. \tag{123}$$

Let $J_{m,j} \equiv (2m+5j-3)+4\delta_{m,0}+5\delta_{m,1}$, then for $j \geqslant 0$, $m \geqslant 0$ and $m' \geqslant 0$, the indices of $I^{(s)}_{m,j}$ and $h^{(s)}_{m,j}$ obey

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} I^{(s)}_{m,j}\right] \leqslant J_{m,j}. \tag{124}$$

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{m,j}\right] \leqslant J_{m,j}+1, \tag{125}$$

and the integrals in (72) *and* (75) *satisfy*

$$\lim_{\gamma \to 0^+} \gamma^{J_{m,j}+1} |\Gamma_{m,j}| < \infty, \tag{126}$$

$$\lim_{\gamma \to 0^+} \gamma^{J_{m,j}+3-\delta_{m,1}} |\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa} \cdot h_{m,j} \rangle| < \infty. \tag{127}$$

In addition, integrals over $I^{(s)}_{1,j}(v)$ satisfy

$$\lim_{\gamma \to 0^+} \gamma^{J_{1,j}+n-1} \left| \int_{-\infty}^{\infty} dv D_n(\alpha, v) \sum_s (\kappa^{(s)})^{m'} I^{(s)}_{1,j}(v) \right| < \infty \tag{128}$$

for $n \geqslant 1$ where $D_n(\alpha, v)$ is defined in (104) *with upper half-plane poles $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n)$ of the form* (106) *but otherwise arbitrary.*

The relations in (124)–(128) are of interest chiefly for their utility in proving (123). We are able to prove (124) and (125) as upper bounds, but we expect them to hold as equalities in most cases. For $m=1$, the bounds in (126) and (127) give stronger estimates on the integrals than one would obtain simply from the index of the integrand calculated using (124) and (125). Similarly, the bounds in (128) are needed because they provide sharper estimates for the $m=1$ case than are available using the index information (124) and (125) alone.

Even though $h_{1,j}$ and $h^*_{1,j}$ have the same index, it is very important to recognize that the conclusion in (127) may not hold for $\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa} \cdot h^*_{1,j} \rangle$. The most singular terms in $\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa} \cdot h_{1,j} \rangle$ are not in general the most singular terms in $\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa} \cdot h^*_{1,j} \rangle$; for $\langle \partial_v \tilde{\psi}, \boldsymbol{\kappa} \cdot h^*_{1,j} \rangle$, if we wish to avoid explicitly evaluating the integral, our only means of estimating the divergence is by calculating the index of the integrand from (125).

Proof: (1) The proof is by induction using the organization of Table I. In Secs. IV A and IV B, the relations in (123)–(127) have been explicitly verified for $I_{0,0}$, $I_{2,0}$, $h_{0,0}$, $h_{2,0}$, $\Gamma_{0,0}$, $\Gamma_{2,0}$, and p_1. This proves the theorem for the first level of Table I, but does not establish the validity of (128) for the initial case $j=0$ which enters in the second level of Table I. By substituting the recursion relation (68) for $I_{1,0}$ into (128) we obtain

$$\gamma^{3+n}\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} I_{1,0}^{(s)}(v)$$

$$= \gamma^{3+n}\left(\frac{i}{k}\right)\int_{-\infty}^{\infty} dv D_n(\alpha,v)\partial_v\left(\kappa\cdot\left[h_{0,0}-h_{2,0}+\frac{1}{2}\psi^*\Gamma_{2,0}\right]\right)$$

$$+ \gamma^{3+n}\left(\frac{i}{k}\right)\left\langle \partial_v\tilde{\psi},\kappa\cdot\left[h_{0,0}-h_{2,0}+\frac{1}{2}\psi^*\Gamma_{2,0}\right]\right\rangle\int_{-\infty}^{\infty} dv D_n(\alpha,v)\psi(v). \quad (129)$$

On the right hand side, the index of the first integrand is $(n+3)$ so the factor of γ^{n+3} ensures a finite limit. In the second term, the integral over $D_n\psi$ is nonsingular since all poles are in the upper half-plane, but the coefficient $\langle\partial_v\tilde{\psi},\kappa\cdot[h_{0,0}-h_{2,0}+\frac{1}{2}\psi^*\Gamma_{2,0}]\rangle$ diverges like γ^{-4} (cf. Sec. III C). Thus for $n\geqslant 1$ the second term will also have a finite limit; this verifies (128) for $I_{1,0}$.

(2) The relations (123)–(128) are extended by induction to all coefficients $I_{m,j}$, $h_{m,j}$, and p_j using the recursion relations (57)–(59) and (66)–(71). Assume that (123)–(128) are valid down to some arbitrary level of Table I, and consider what the recursion relations imply for the coefficients evaluated at the next level. We use (m_1,j_1) to denote subscripts of coefficients such as I_{m_1,j_1}, h_{m_1,j_1} and p_{j_1} that are to be evaluated from lower order quantities assumed to satisfy (123)–(128).

The induction argument has three parts. First, we show that the properties (125)–(127) must hold for h_{m_1,j_1} and Γ_{m_1,j_1} if I_{m_1,j_1} satisfies two relations, namely the index identity (124)

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} I_{m_1,j_1}^{(s)}\right]\leqslant J_{m_1,j_1}, \quad (130)$$

and the $m_1=1$ estimate (128)

$$\lim_{\gamma\to 0^+}\gamma^{J_{1,j_1}+n-1}\left|\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} I_{1,j_1}^{(s)}(v)\right|<\infty. \quad (131)$$

In the second part of the proof, we verify that (130) and (131) do hold for I_{m_1,j_1}. Finally, in the third part of the proof, we verify that (125)–(127) imply (123) for p_{j_1}. It is important to note from Table I that the quantities h_{m_1,j_1} depend on p_j for $j<j_1$, but are independent of p_{j_1} so the reasoning is not circular.

(3) **(Part 1):** Suppose that (130) and (131) hold, then the three relations (125)–(127) are easily obtained as follows. First, consider (126) which holds trivially for $m_1=0$ since $\Gamma_{0,j_1}=0$. For $m_1\geqslant 2$, (126) follows from (130) and the identity (72). For $m_1=1$, we have to allow for the fact that $\Lambda_k(z_{1,j_1})\sim\gamma$ as $\gamma\to 0^+$, and apply (131) to estimate the integral in (72). Next (125) follows by applying (130) and (126) to the identity (73). Each term in (73) separately has a maximum index of $(J_{m_1,j_1}+1)$ so this must bound the index of the sum.

Finally consider (127). For $m_1\neq 1$, this relation follows from (125), and for $m_1=1$ we evaluate (127) using the identity in (73):

$$\gamma^{J_{1,j_1}+2}\langle\partial_v\tilde{\psi},\kappa\cdot h_{1,j_1}\rangle = -\gamma^{5j_1+6}\left(\frac{i}{k}\right)\langle\partial_v\tilde{\psi},\kappa\cdot I_{1,j_1}/(v-z_{1,j_1})\rangle$$

$$-\gamma^{5j_1+6}\Gamma_{1,j_1}\langle\partial_v\tilde{\psi},\kappa^2\cdot\eta_k/(v-z_{1,j_1})\rangle. \quad (132)$$

The first term on the right is nonsingular by virtue of (131), and the second term is also nonsingular by virtue of (126).

(4) **(Part 2):** Thus the crux of the matter is to verify (130) and (131) from the recursion relations for $I_{m_1,j_1}^{(s)}$, i.e., from (66)–(71). In this step, we assume (123)–(128) apply to the quantities appearing on the right hand side of these recursion relations, then the properties in (130) and (131) are verified term by term.

Verification of (130)*—the index of* I_{m_1,j_1}: The index of each term on the right hand side of the recursion relations for $I^{(s)}_{m_1,j_1}(v)$ can be evaluated by applying (123)–(127); this exercise shows that all of these terms have an index less than or equal to J_{m_1,j_1} which establishes (130) for $I^{(s)}_{m_1,j_1}$. A few examples from (68), the recursion relation for $(m_1,j_1)=(1,j_1)$, illustrate these index calculations; note that in these examples $J_{1,j_1}=5j_1+4$.

(a) The terms in (68) that depend on p_j have the form $[(2+n)p_{j_1-n}+(1+n)p^*_{j_1-n}]h^{(s)}_{1,n}$; from (125) we have

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{1,n}\right] \leqslant J_{1,n}+1=5n+5, \tag{133}$$

and from (123) the singularity of p_{j_1-n} is determined, hence

$$\mathrm{Ind}\left[p_{j_1-n}\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{1,n}\right] \leqslant 5(j_1-n)-1+(5n+5)=5j_1+4 \tag{134}$$

which is consistent with (130) for $(m_1,j_1)=(1,j_1)$.

(b) Next consider the term $\mathscr{P}_\perp \kappa\cdot\partial_v h_{0,j_1}$ in (68); from the definition (49) we have that the index of $\mathscr{P}_\perp \kappa\cdot\partial_v h_{0,j_1}$ is equal to the largest index obtained from the two terms $\kappa\cdot\partial_v h_{0,j_1}$ and $\psi(v)\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,j_1}\rangle$. These terms have individual indices

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} \partial_v h^{(s)}_{0,j_1}\right] \leqslant 5j_1+3, \tag{135}$$

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} \psi^{(s)}(v)\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,j_1}\rangle\right] \leqslant 5j_1+4, \tag{136}$$

where the first index (135) comes from (125) and the second follows from (127). Hence

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} (\mathscr{P}_\perp \kappa\cdot\partial_v h_{0,j_1})^{(s)}\right] \leqslant 5j_1+4 \tag{137}$$

which is consistent with (130) for $(m_1,j_1)=(1,j_1)$.

(c) A more subtle example is the term $\mathscr{P}_\perp \kappa\cdot\partial_v h^*_{1,n}\Gamma_{2,j_1-n-1}$ in (68) which expands to

$$\mathscr{P}_\perp \kappa\cdot\partial_v h^*_{1,n}\Gamma_{2,j_1-n-1}=\kappa\cdot\partial_v h^*_{1,n}\Gamma_{2,j_1-n-1}+\Gamma_{2,j_1-n-1}\psi(v)\langle\partial_v\tilde{\psi},\kappa\cdot h^*_{1,n}\rangle. \tag{138}$$

Now the index of each term can be evaluated to give

$$\mathrm{Ind}\left[\Gamma_{2,j_1-n-1}\sum_s (\kappa^{(s)})^{m'} \partial_v h^{(s)*}_{1,n}\right] \leqslant 5j_1+2, \tag{139}$$

$$\mathrm{Ind}\left[\Gamma_{2,j_1-n-1}\sum_s (\kappa^{(s)})^{m'} \psi^{(s)}\langle\partial_v\tilde{\psi},\kappa\cdot h^*_{1,n}\rangle\right] \leqslant 5j_1+4; \tag{140}$$

thus

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} (\mathscr{P}_\perp \kappa\cdot\partial_v h^*_{1,n})^{(s)}\Gamma_{2,j_1-n-1}\right] \leqslant 5j_1+4 \tag{141}$$

which is consistent with (130) for $(m_1,j_1)=(1,j_1)$. In this last example, (139) is obtained from (125) and (126); the second result (140) differs from (136) since (127) cannot be applied and the

singularity of $\langle \partial_v \tilde{\psi}, \kappa \cdot h^*_{1,n} \rangle$ must be estimated from the index in (125). In a similar way the index of each term appearing on the right in the recursion relations (66)–(71) for $I_{m_1,j_1}(v)$ can be estimated with the final result in (130).

(5) *Verification of* (131): We integrate the recursion relation for $I_{1,j_1}(v)$ and examine the resulting expression to establish (131). When (68), the recursion for I_{1,j_1}, is inserted into (131) we obtain

$$\begin{aligned}
&\gamma^{J_{1,j_1}+n-1}\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} I^{(s)}_{1,j_1}(v) \\
&\quad = -\gamma^{5j_1+n+3}\sum_{l=0}^{j_1-1}[(2+l)p_{j_1-l}+(1+l)p^*_{j_1-l}]\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{1,l}(v) \\
&\qquad + \gamma^{5j_1+n+3}\left(\frac{i}{k}\right)\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'+1} G^{(s)}(v) \\
&\qquad + \gamma^{5j_1+n+3}\left(\frac{i}{k}\right)\langle \partial_v \tilde{\psi}, \kappa \cdot G\rangle \int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} \psi^{(s)}(v),
\end{aligned} \tag{142}$$

where $G(v)=h_{0,j_1}-h_{2,j_1}+\cdots$ denotes the collection of terms enclosed by brackets in (68). The relations (124)–(127) hold for these terms by assumption, and it is straightforward to verify that $\mathrm{Ind}[G]\leqslant 5j_1+2$; this immediately implies that the terms in (142) involving G are finite as $\gamma\to 0^+$. For the remaining terms in (142) we have $p_{j_1-l}\sim\gamma^{-5(j_1-l)+1}$ from (123), hence we need to prove

$$\lim_{\gamma\to 0^+}\gamma^{5l+4+n}\left|\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{1,l}(v)\right| < \infty \quad (n\geqslant 1) \tag{143}$$

to establish (131). The formula in (125) bounds the index of the integrand in (143) by only $(5l+n+5)$ which is not sufficient. Instead, we evaluate (143) using the identity (73)

$$\begin{aligned}
\int_{-\infty}^{\infty} dv D_n(\alpha,v)\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{1,l}(v) &= -\left(\frac{i}{k}\right)\int_{-\infty}^{\infty} dv D_n(\alpha,v)\,\frac{\Sigma_s(\kappa^{(s)})^{m'} I^{(s)}_{1,l}(v)}{(v-z_{1,l})} \\
&\quad -\Gamma_{1,l}\int_{-\infty}^{\infty} dv D_n(\alpha,v)\,\frac{\Sigma_s(\kappa^{(s)})^{m'+1}\eta^{(s)}_k}{(v-z_{1,l})}.
\end{aligned} \tag{144}$$

The integral in the second term is nonsingular and $\Gamma_{1,l}\sim\gamma^{-5l-5}$ from (126), thus the desired estimate in (143) holds for the second term. It remains to verify

$$\lim_{\gamma\to 0^+}\gamma^{5l+4+n}\left|\int_{-\infty}^{\infty} dv D_n(\alpha,v)\,\frac{\Sigma_s(\kappa^{(s)})^{m'} I^{(s)}_{1,l}(v)}{(v-z_{1,l})}\right| < \infty \quad (n\geqslant 1) \tag{145}$$

for the first term in (144); this follows from (128) with $j\to l$ and $D_n\to D_n/(v-z_{1,l})$.
The proof of (143) establishes (131) for I_{1,j_1}.

(6) **(Part 3):** *Verification of* (123) *for* p_{j_1}: It is straightforward to check that application of (125)–(127) to the right hand side of the recursion relations (57)–(59) yields the estimate in (123). A few examples from (58) and (59) suffice to illustrate how this is carried out.

(a) Consider the term $\langle \partial_v \tilde{\psi}, \kappa \cdot h_{0,j_1-1}\rangle$ in (58); from (127) the singularity of this integral is at most

$$|\langle \partial_v \tilde{\psi}, \kappa \cdot h_{0,j_1-1}\rangle| \sim \left(\frac{1}{\gamma}\right)^{3+J_{0,j_1-1}} = \left(\frac{1}{\gamma}\right)^{5j_1-1} \tag{146}$$

which is consistent with (123).

(b) Other terms will involve products of integrals; for example, $\Gamma_{2,j_1-1}\langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle$ in (58). Using (82) and (126) we determine that the singularity of this product is at most

$$|\Gamma_{2,j_1-1}\langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle| \sim \left(\frac{1}{\gamma}\right)^{1+J_{2,j_1-1}} \left(\frac{1}{\gamma}\right)^2 = \left(\frac{1}{\gamma}\right)^{5j_1-1} \tag{147}$$

which again is consistent with (123).

(c) A final example is the product $\Gamma_{2,l}\langle \partial_v \tilde{\psi}, \kappa \cdot h^*_{1,j_1-l-2} \rangle$ with $0 \leqslant l \leqslant j_1 - 2$ from (59); applying (125) and (126) to this shows a maximum singularity of

$$|\Gamma_{2,l}\langle \partial_v \tilde{\psi}, \kappa \cdot h^*_{1,j_1-l-2} \rangle| \sim \left(\frac{1}{\gamma}\right)^{1+J_{2,l}} \left(\frac{1}{\gamma}\right)^{3+J_{1,j_1-l-2}} = \left(\frac{1}{\gamma}\right)^{5j_1-1} \tag{148}$$

which is consistent with (123).

This completes the proof. □

D. Implications of the main result

Theorem IV.1 allows us to evaluate the $\gamma \to 0^+$ limit of the theory. Rewriting the amplitude equation (54) using polar variables $A(t) = \rho(t)\exp(-i\theta(t))$, and the scaling

$$\rho(t) = \gamma^{5/2} r(\gamma t) \tag{149}$$

from Sec. III C, yields

$$\frac{dr}{d\tau} = r + \sum_{j=1}^{\infty} [\gamma^{5j-1} \operatorname{Re}(p_j)] r^{2j+1}, \tag{150}$$

$$\frac{d\theta}{dt} = \omega - \gamma \sum_{j=1}^{\infty} [\gamma^{5j-1} \operatorname{Im}(p_j)] r^{2j}, \tag{151}$$

where $\tau = \gamma t$. The result (123) on the divergence of the coefficients p_j ensures that the terms in (150) and (151) are now finite as $\gamma \to 0^+$. Introducing the asymptotic coefficients

$$c_j(0) = \lim_{\gamma \to 0^+} [\gamma^{5j-1} p_j] \quad (j \geqslant 1) \tag{152}$$

the amplitude equation for a weakly unstable wave becomes

$$\frac{dr}{d\tau} = r + \sum_{j=1}^{\infty} [\operatorname{Re}(c_j(0)) + \mathcal{O}(\gamma)] r^{2j+1}. \tag{153}$$

Unless $\operatorname{Re}(c_j(0)) = 0$ in each term, the scaling in (149) is required to obtain a finite theory. The circumstances that could force $c_1(0) = 0$ were discussed in Sec. III C, and will be analyzed more completely in Sec. V.

The electric field is obtained from Poisson's equation $(imk)E_{mk}(t) = \Sigma_s \int_{-\infty}^{\infty} dv\, f^{u\,(s)}_{mk}$ using the form of f^u_{mk} in (44)

$$E_{mk}(t) = \begin{cases} -iA(1 + \sigma\Gamma_1(\sigma))/k, & m = 1 \\ -iA^m \Gamma_m(\sigma)/mk, & m > 1. \end{cases} \tag{154}$$

The small growth rate behavior of $\Gamma_m(\sigma)$ can be inferred from (126) and the expansion $\Gamma_m(\sigma) = \Sigma_j \Gamma_{m,j} \sigma^j$. Using $\sigma^j = \gamma^{5j} r^{2j}$, we find an expansion of Γ_m with a nonsingular limit

$$\gamma^{2m-2+5\delta_{m,1}} \Gamma_m = \sum_{j=0}^{\infty} \gamma^{J_{m,j}+1} \Gamma_{m,j} r^{2j}, \tag{155}$$

and this motivates our definition of Γ^c_m

$$\Gamma_m^c = \lim_{\gamma\to 0^+} \gamma^{2m-2+5\delta_{m,1}}\Gamma_m = \sum_{j=0}^{\infty} b_{m,j}(0) r^{2j}, \tag{156}$$

where

$$b_{m,j}(0) \equiv \lim_{\gamma\to 0^+} [\gamma^{J_{m,j}+1}\Gamma_{m,j}]. \tag{157}$$

With this notation, the asymptotic form of the Fourier expansion $E(x,t)=\Sigma_m E_{mk}(t)\exp(imkx)$ of the field can be evaluated

$$E(x,t) = -\frac{i\gamma^{5/2}}{k}\Bigg[r(\tau)(1+\Gamma_1^c r(\tau)^2 + \mathcal{O}(\gamma)) e^{i(kx-\theta(t))} + \sum_{m=2}^{\infty} \gamma^{(m-1)/2} \frac{(\Gamma_m^c r(\tau)^m + \mathcal{O}(\gamma))}{m} e^{im(kx-\theta(t))} \Bigg] + \text{c.c.} \tag{158}$$

The asymptotic form may be rewritten more simply as

$$\frac{iE(x,t)}{\gamma^{5/2}} = \left[\frac{r(\tau)}{k}(1+\Gamma_1^c r(\tau)^2) e^{i(kx-\theta(t))} + \text{c.c.} \right] + \mathcal{O}(\sqrt{\gamma}); \tag{159}$$

this describes an electric field comprised of a single Fourier component whose coefficient scales like $\gamma^{5/2}$ and evolves nonlinearly according to the asymptotic amplitude equation (153). The $\gamma^{5/2}$ scaling yields a dramatically smaller field than would be expected from the trapping scaling γ^2 characteristic of a model with infinitely massive ions.

An analogous discussion of the asymptotic distribution function $f(x,v,t)$ is substantially more complicated because of singularities in v that emerge as $\gamma\to 0^+$. This issue is briefly treated in Sec. VI, but we defer a full analysis to a companion paper.[15]

V. SPECIAL CASES

Section III D identified three settings for which $c_1(0)=0$ and the γ^{-4} singularity of p_1 is replaced by a γ^{-3} divergence:

(a) Infinitely massive ions: $\kappa^{(s)}=0$ for all $s\neq e$,
(b) zero slope for the resonant ions: $\eta_k^{(s)}(v_p(0))=0$ for all $s\neq e$,
(c) an electron-positron plasma: $\kappa^{(p)^2}=1$ for positrons $(s=p)$.

From the partial fraction expansion in Lemma IV.1, we found the general condition required to reduce the singularity of a standard integral,

$$\int_{-\infty}^{\infty} dv\, \mathcal{G}(v) = \int_{-\infty}^{\infty} dv\, D_m(\beta,v)^* D_n(\alpha,v) \sum_s (\kappa^{(s)})^{m'} \frac{\partial^q \eta_l^{(s)}}{\partial v^q} \quad (mn>0) \tag{160}$$

from $\gamma^{-m-n-q+1}$ to $\gamma^{-m-n-q+2}$; namely,

$$\sum_s{}' \kappa^{(s)}[(-1)^{m'} + (\kappa^{(s)})^{m'-1}] \eta_k^{(s)}(v_p(0)) = 0, \tag{161}$$

where the primed sum omits the electrons. The specific instance of (161) that yields $c_1(0)=0$ corresponds to $m'=3$.

The validity of this general condition varies between the three settings listed above. For both (a) and (b), (161) holds quite generally for all integers $m'\geqslant 0$; however, for the third setting (c), the condition reduces to

$$[(-1)^{m'}+1]\eta_k^{(p)}(v_p(0)) = 0, \tag{162}$$

and this will be generally satisfied only for m' odd.

A. Cases (a) and (b)

It is relatively simple to adapt Theorem IV.1 to accommodate the first two settings where (161) holds uniformly. The following result restates Theorem IV.1 of (I) under more general assumptions [note that the definition of the index in this paper differs from (I)].[1]

Theorem V.1: *Assume that* (161) *holds for all* $m' \geqslant 0$; *then for* $j \geqslant 1$, *the coefficients in the expansion of the amplitude equation* (54) *satisfy*

$$\lim_{\gamma \to 0^+} \gamma^{4j-1} |p_j| < \infty. \tag{163}$$

Let $J_{m,j} \equiv (2m+5j-3)+4\delta_{m,0}+5\delta_{m,1}$, *then for* $j \geqslant 0$, $m \geqslant 0$ *and* $m' \geqslant 0$, *the indices of* $I^{(s)}_{m,j}$ *and* $h^{(s)}_{m,j}$ *obey*

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} I^{(s)}_{m,j}\right] \leqslant J_{m,j} - j - \delta_{m,1}. \tag{164}$$

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} h^{(s)}_{m,j}\right] \leqslant J_{m,j} + 1 - j - \delta_{m,1}, \tag{165}$$

and the integrals in (72) *and* (75) *satisfy*

$$\lim_{\gamma \to 0^+} \gamma^{J_{m,j}-j} |\Gamma_{m,j}| < \infty, \tag{166}$$

$$\lim_{\gamma \to 0^+} \gamma^{J_{m,j}+2-j-\delta_{m,1}} |\langle \partial_v \tilde{\psi}, \kappa \cdot h_{m,j} \rangle| < \infty. \tag{167}$$

The proof is simpler since (165)–(167) follow directly from (164) and there is no need for special estimates such as (128) in the $m=1$ case.

Proof: (1) The induction proof follows that for Theorem IV.1, and we only highlight the new features brought in by (161). The recursion relations for $I_{m,j}$ are finite sums; each term of which has the form $q(\gamma)\mathcal{G}(v)$ where $\mathrm{Ind}[\mathcal{G}(v)] \geqslant 1$ and the coefficient $q(\gamma)$ may be singular as $\gamma \to 0^+$. According to Lemma IV.1, with (161) in force, if $J = \mathrm{Ind}[q(\gamma)\mathcal{G}(v)]$, then $\gamma^{J-1} q(\gamma) \int dv\, \mathcal{G}(v)$ remains finite as $\gamma \to 0^+$.

(2) We have already shown that (161) implies (163) for $j=1$ so the theorem has been proved for the first level of Table I. As before, we assume that (163)–(167) are valid down to some arbitrary level of Table I, and consider what the recursion relations imply for the coefficients evaluated at the next level. Again, we use (m_1, j_1) to denote subscripts of coefficients such as I_{m_1,j_1}, h_{m_1,j_1} and p_{j_1} that are to be evaluated from lower order quantities assumed to satisfy (163)–(167). Following the organization of the previous proof, we first check that (164) for $I^{(s)}_{m_1,j_1}$ implies (165)–(167) for $h^{(s)}_{m_1,j_1}$, Γ_{m_1,j_1}, and $\langle \partial_v \tilde{\psi}, \kappa \cdot h_{m_1,j_1} \rangle$, respectively. Then (164) is verified from the recursion relation for $I^{(s)}_{m_1,j_1}$, and finally (163) is shown to follow from (165)–(167).

(3) **(Part 1):** Assume that (164) holds for $I^{(s)}_{m_1,j_1}$:

$$\mathrm{Ind}\left[\sum_s (\kappa^{(s)})^{m'} I^{(s)}_{m_1,j_1}\right] \leqslant J_{m_1,j_1} - j_1 - \delta_{m_1,1}, \tag{168}$$

then the properties (165)–(167) are easily obtained as follows. First, the integrand of Γ_{m_1,j_1} in (72) has index

$$\mathrm{Ind}\left[\sum_s I^{(s)}_{m_1,j_1} \Big/ (v - z_{m,j})\right] \leqslant J_{m_1,j_1} - j_1 - \delta_{m_1,1} + 1 \tag{169}$$

from (164) so the expression

$$\gamma^{J_{m_1,j_1}-j_1-\delta_{m_1,1}}\int_{-\infty}^{\infty} dv\,\frac{\Sigma_s I_{m,j}^{(s)}(v)}{v-z_{m,j}} \tag{170}$$

remains finite as $\gamma\to 0^+$; this proves (166) since the $\delta_{m_1,1}$ in the exponent compensates for the added singularity of $\Lambda_k(z_{1,j_1})$ in (72). Next, (165) follows by applying (168) and (166) to the identity (73). Finally, the integrand in (167) has index

$$\mathrm{Ind}\left[\sum_s \partial_v\tilde{\psi}^{(s)}\kappa^{(s)}h_{m,j}^{(s)}\right]\leqslant J_{m_1,j_1}-j_1-\delta_{m_1,1}+3 \tag{171}$$

from (165) so the bound in (167) follows from (161) and Lemma IV.1.

(4) **(Part 2):** *Verification of* (168)*—the index of* I_{m_1,j_1}: The consequences of (161) for the index calculation are incorporated in (163)–(166). The index of each term on the right hand side of the recursion relations for $I_{m_1,j_1}^{(s)}(v)$ can be evaluated by applying these conclusions regarding the lower order coefficients; this is done exactly as in the proof of (130) in Theorem IV.1. The bound in (168) follows as before.

(5) **(Part 3):** *Verification of* (163) *for* p_{j_1}: It is straightforward to check that application of (165)–(167) to the right hand side of the recursion relations (57)–(59) yields the estimate in (163) just as in the proof of Theorem IV.1. □

In light of the discussion in Sec. IV D, the theorem tells us that the scaling in (149) is replaced by

$$\rho(t)=\gamma^2 r(\gamma t) \tag{172}$$

for the special cases (a) and (b). This modification in turn implies an electric field characterized by the ''trapping scaling'' $E_k\sim\gamma^2$; the discussion in (I) provides detailed expressions for the asymptotic form of $E(x,t)$ and $f^{(e)}(x,v,t)$ in the limit $\gamma\to 0^+$ when the ions are fixed.[1]

B. An electron-positron plasma

The result $p_j\sim\gamma^{-4j+1}$ for the two special cases just considered is not correct for the electron-positron system with $\kappa^{(p)}=-\kappa^{(e)}=1$. Although $p_1\sim\gamma^{-3}$ does hold, we find at fifth order $p_2\sim\gamma^{-8}$ instead of $p_2\sim\gamma^{-7}$. Thus the trapping scaling of the amplitude in (172) is not sufficient to obtain a finite expansion. We summarize the evaluation of p_2 from (57)–(59), but leave the comprehensive analysis of this case as an open problem.

The exact recursion relation for p_2 is

$$\begin{aligned}-ikp_2=&-\langle\partial_v\tilde{\psi},\kappa\cdot(h_{0,1}-h_{2,1})\rangle-\tfrac{1}{2}\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle\Gamma_{2,1}-\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle\Gamma_{1,0}+\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}\rangle\Gamma_{1,0}^*\\&-\left\{\frac{1}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_{1,0}^*\rangle\Gamma_{2,0}+\frac{\Gamma_{3,0}}{3}\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}^*\rangle-\frac{\Gamma_{2,0}^*}{2}\langle\partial_v\tilde{\psi},\kappa\cdot h_{3,0}\rangle\right\},\end{aligned} \tag{173}$$

and, in the bracketed terms, $\Gamma_{2,0}$ and $\Gamma_{3,0}$ are nonsingular so Theorem IV.1 ensures the divergence of these terms cannot exceed γ^{-4}; hence they are subdominant:

$$\begin{aligned}-ikp_2=&-\langle\partial_v\tilde{\psi},\kappa\cdot(h_{0,1}-h_{2,1})\rangle-\tfrac{1}{2}\langle\partial_v\tilde{\psi},\kappa\cdot\psi^*\rangle\Gamma_{2,1}-\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle\Gamma_{1,0}\\&+\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}\rangle\Gamma_{1,0}^*+\mathcal{O}(\gamma^{-4}).\end{aligned} \tag{174}$$

Here consider the two terms involving $\Gamma_{1,0}$. In the general case, Theorem IV.1 gives $\Gamma_{1,0}\sim\gamma^{-5}$, but this drops to γ^{-4} when we take (161) into account for m' odd. The integral $\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}\rangle$ is nonsingular so $\langle\partial_v\tilde{\psi},\kappa\cdot h_{2,0}\rangle\Gamma_{1,0}^*\sim\gamma^{-4}$ and we neglect this term also. Next $\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle$ is written out to find

$$\langle\partial_v\tilde{\psi},\kappa\cdot h_{0,0}\rangle=\frac{i}{2k\gamma}\langle\partial_v\tilde{\psi},\kappa^2\cdot\partial_v(\psi^*-\psi)\rangle; \tag{175}$$

this integrand has index equal to 3, but contains an odd power of κ so (161) holds and the divergence cannot exceed γ^{-2}. Overall, $\langle \partial_v \tilde{\psi}, \kappa \cdot h_{0,0} \rangle \Gamma_{1,0}$ has a maximum singularity of γ^{-7}. A careful examination of the first term in (174) yields the same estimate $\langle \partial_v \tilde{\psi}, \kappa \cdot (h_{0,1} - h_{2,1}) \rangle \sim \gamma^{-7}$.

The dominant singularity in p_2 arises from the remaining term

$$p_2 = -\frac{i\Gamma_{2,1}}{2k} \langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle + \mathcal{O}(\gamma^{-7}), \tag{176}$$

and from (85) and (115), we obtain

$$\langle \partial_v \tilde{\psi}, \kappa \cdot \psi^* \rangle = -\left(\frac{k}{\gamma}\right)^2 \left[\frac{i\pi \eta_k^{(p)}(v_p(0))}{\Lambda_k'(v_p + i0)} + \mathcal{O}(\gamma) \right]. \tag{177}$$

The evaluation of $\Gamma_{2,1}$ starts from (72)

$$\Gamma_{2,1} = \frac{-i/2k}{\Lambda_{2k}(z_{2,1})} \sum_s \int_{-\infty}^{\infty} dv \, \frac{I_{2,1}^{(s)}(v)}{v - z_{2,1}}, \tag{178}$$

and the recursion relation (70) for $I_{2,1}$

$$I_{2,1}(v) = -2p_1 h_{2,0} + \frac{i}{k} \frac{\partial}{\partial v} \kappa \cdot \left\{ h_{1,0} + \psi \Gamma_{1,0} - h_{3,0} + \frac{1}{3} \psi^* \Gamma_{3,0} + \frac{1}{2} h_{0,0} \Gamma_{2,0} \right\}. \tag{179}$$

Note that $\Lambda_{2k}(z_{2,1}) = 3/4 + \mathcal{O}(\gamma)$ from (21) so any singularities arise from the integral

$$\int_{-\infty}^{\infty} dv \, \frac{\Sigma_s I_{2,1}^{(s)}(v)}{v - z_{2,1}} = -2p_1 \int_{-\infty}^{\infty} dv \, \frac{\Sigma_s h_{2,0}^{(s)}(v)}{v - z_{2,1}} + \frac{i}{k} \int_{-\infty}^{\infty} \frac{dv}{(v - z_{2,1})^2} \sum_s \kappa^{(s)} \left[h_{1,0}^{(s)} + \psi^{(s)} \Gamma_{1,0} - h_{3,0}^{(s)} + \frac{1}{3} \psi^{(s)*} \Gamma_{3,0} + \frac{1}{2} h_{0,0}^{(s)} \Gamma_{2,0} \right]. \tag{180}$$

The strongest singularity here occurs in the integral over $h_{1,0}^{(s)}$, and all other terms in (180) are subdominant; thus we can focus attention on the expression

$$\int_{-\infty}^{\infty} dv \, \frac{\Sigma_s I_{2,1}^{(s)}(v)}{v - z_{2,1}} = \frac{i}{k} \int_{-\infty}^{\infty} dv \, \frac{\Sigma_s \kappa^{(s)} h_{1,0}^{(s)}}{(v - z_{2,1})^2} + \mathcal{O}(\gamma^{-4}). \tag{181}$$

When $h_{1,0}^{(s)}$ is evaluated using (73) we obtain

$$\int_{-\infty}^{\infty} dv \, \frac{\Sigma_s I_{2,1}^{(s)}(v)}{v - z_{2,1}} = \frac{1}{k^2} \int_{-\infty}^{\infty} dv \, \frac{\Sigma_s \kappa^{(s)} I_{1,0}^{(s)}}{(v - z_{2,1})^2 (v - z_{1,0})} + \mathcal{O}(\gamma^{-4}). \tag{182}$$

Now the recursion relation (68) for $I_{1,0}^{(s)}$ is applied, and examination of the various terms shows that the dominant singularity arises from the occurrence of ψ^* in $h_{0,0}$ so that (178) can be reduced to

$$\Gamma_{2,1} = \left(\frac{i[1 + \mathcal{O}(\gamma)]}{3\gamma k^5} \right) \int_{-\infty}^{\infty} dv \, \frac{\Sigma_s (\kappa^{(s)})^3 \partial_v^2 \psi^{(s)}(v)^*}{(v - z_{2,1})^2 (v - z_{1,0})} + \mathcal{O}(\gamma^{-5}). \tag{183}$$

Finally a partial fraction expansion of the remaining integral yields a γ^{-5} singularity

$$\int_{-\infty}^{\infty} dv \, \frac{\Sigma_s (\kappa^{(s)})^3 \partial_v^2 \psi^{(s)}(v)^*}{(v - z_{2,1})^2 (v - z_{1,0})} = \frac{1}{\gamma^5} \left[-\left(\frac{\pi}{8}\right) k^5 \eta_k^{(p)}(v_p(0)) + \mathcal{O}(\gamma) \right], \tag{184}$$

and leads to the asymptotic form of p_2 from (176)

TABLE II. Summary of the exponent β obtained from the amplitude equation. The cases (a), (b) and (c) are the exceptional cases discussed in Sec. V.

System	β	Comment
$c_1(0)\neq 0$	$\frac{5}{2}$	generic result for multiple mobile species
(a) $c_1(0)=0$	2	infinitely massive ions
(b) $c_1(0)=0$	2	$\eta_k^{(s)}(v_p)=0$ for each ion species
(c) $c_1(0)=0$	$\frac{9}{4}\leqslant\beta\leqslant\frac{5}{2}$	an electron-positron plasma

$$p_2=\frac{1}{\gamma^8}\left[\left(\frac{i\pi^2 k}{48}\right)\frac{\eta_k^{(p)}(v_p)^2}{\Lambda_k'(v_p+i0)}+\mathcal{O}(\gamma)\right]+\mathcal{O}(\gamma^{-7}). \tag{185}$$

Since $\mathrm{Im}\,\Lambda_k'(v_p+i0)$ is typically nonzero, this shows that $\mathrm{Re}(p_2)\sim\gamma^{-8}$ and implies that the trapping scaling (172) leaves a residual singularity at fifth order. With $\rho(t)=\gamma^\beta r(\gamma t)$ the rescaled equation becomes

$$\frac{dr}{d\tau}=r+\gamma^{2\beta-1}\,\mathrm{Re}(p_1)r^3+\gamma^{4\beta-1}\,\mathrm{Re}(p_2)r^5+\cdots \tag{186}$$

so $\beta\geqslant 9/4$ is required to overcome the γ^{-8} divergence in p_2.

VI. DISCUSSION

Our analysis of an unstable electrostatic wave expresses the Vlasov distribution function $f(x,v,t)$ in terms of the wave amplitude, i.e.,

$$f(x,v,t)=[A(t)e^{ikx}\psi(v)+\mathrm{c.c.}]+\sum_{m=-\infty}^{\infty}e^{imkx}H_{mk}(v,A,A^*), \tag{187}$$

where $A(t)$ evolves according to an amplitude equation,

$$\dot{A}(t)=Ap(|A^2|). \tag{188}$$

In the small growth rate limit, the eigenvalue of the unstable mode approaches the imaginary axis and, at $\gamma=0$, merges with a neutrally stable continuous spectrum on the axis.[1,10] This ''interaction'' between the unstable mode and the neutrally stable continuum leads to singular features in the asymptotic form of the amplitude equation (188).[16]

These singularities are physically significant since they reflect the very strong nonlinear interaction between the wave and the resonant particles at the linear phase velocity. Remarkably, the quantitative form of the singularities can be consistently interpreted as fixing overall scalings of the nonlinear solution with the linear growth rate in the asymptotic limit $\gamma\to 0^+$. This interpretation is achieved through a singular transformation $|A(t)|=\gamma^\beta r(\gamma t)$ of the mode amplitude in which the exponent β is fixed by the criterion that the rescaled dynamics,

$$\frac{dr}{d\tau}=r(\tau)\frac{\mathrm{Re}(p(\gamma^{2\beta}r(\tau)^2))}{\gamma}, \tag{189}$$

is free of singularities as $\gamma\to 0^+$. Our conclusions are summarized in Table II; with the notable exception of the electron-positron system, we can rigorously establish an exact value of $\beta=5/2$ in the typical instability and $\beta=2$ for certain exceptional models. In the electron-positron case, we have fixed only a range of possible β values from the explicit calculation of $p(|A|^2)$ through fourth order in $|A|$; the complexity of the recursion relations in this case prevents the iterative determination of the dominant singularities at each order.

The shift from $\beta=2$ to $\beta=5/2$ as the true asymptotic scaling due to finite mass ions at the phase velocity of the wave is our most significant conclusion regarding the physical character of the nonlinear wave. Since previous studies of the asymptotic scaling of single wave instabilities

have focused primarily on plasma waves and assumed fixed ions, this shift was not anticipated and was discovered purely as a consequence of the singularities in the amplitude equation (188). Numerical simulations of unstable ion-acoustic waves or unstable plasma waves in systems with finite mass ratios would be of considerable interest in this connection. In particular, for plasma waves one expects a crossover in the asymptotic scaling from the trapping scaling ($\beta=2$) to $\beta=5/2$ at sufficiently small growth rates. Predictions of this crossover have been made elsewhere based on the competition between the γ^{-4} and γ^{-3} singularities in the cubic coefficient.[7]

In this paper we have not analyzed the asymptotic form of $f(x,v,t)$, but it is clear from the expansions for $H(x,v,A,A^*)$ that this is an interesting question. For example, consider the leading coefficient in $h_0(v)$ from (77),

$$h_{0,0}(v)=-\frac{1}{k^2}\frac{\partial}{\partial v}\left[\frac{\kappa^2\cdot\eta_k}{(v-z_0)(v-z_0^*)}\right]; \tag{190}$$

there are poles in the complex-velocity plane at z_0 and z_0^* that approach the real velocity axis at v_p in the limit $\gamma\to 0^+$. Thus the coefficient becomes a singular function at the phase velocity when $\gamma=0$; on the other hand, for $v\neq v_p$, the coefficient is well-behaved at small growth rates. In the distribution function (187) this particular coefficient is multiplied by $|A|^2$ so that after rescaling the amplitude we have a term of the form $r^2\gamma^{2\beta}h_{0,0}(v)$. Now the emerging singularity in velocity space is weighted by a factor of $\gamma^{2\beta}$, and one would like to understand whether the resulting product is finite or singular at $\gamma=0$. A detailed analysis of this problem will be presented in a forthcoming paper, but the primary conclusion can be simply summarized.[15] Inside a neighborhood of width $\mathcal{O}(\gamma)$, and centered on $v=v_p$, the singularities in the coefficients of H are balanced by the factors of γ introduced by the rescaling of $|A|$ and one can obtain finite, nonzero limits for the weighted coefficients. Outside this small neighborhood of the phase velocity, the factors of γ force the weighted coefficients to vanish at $\gamma=0$.

The connection between coefficient singularities and nonlinear scalings that is studied in this paper is relevant in other settings. As mentioned above, a key feature of our instabilities is the emergence of the critical eigenvalues from a neutrally stable continuous spectrum. It has been appreciated recently that this characteristic is shared by a diverse set of additional examples which include the onset of linear instability in fluid shear flows,[17–20] instabilities of solitary waves,[21–23] synchronization of large systems of coupled oscillators,[24] and bifurcations in ''mean field'' descriptions of the dynamics of bubble clouds in fluids.[25] In the phase-dynamical models of coupled oscillators, the amplitude equations of the weakly unstable modes have been analyzed in the $\gamma\to 0^+$ limit.[26,27] In these studies, the coefficients can be singular or nonsingular depending on how the oscillators are coupled, but when singularities occur in the limit of small growth they can be absorbed by singular rescalings of the amplitude in a procedure analogous to the method used in this paper. The specific values of the scaling exponents are different, but yield predictions for the emergence of the nonlinear synchronized state.

It seems likely that the analysis of singular amplitude equations provides a general means to determine scaling exponents for weakly unstable systems. The exponents in turn provide a quantitative measure of the strong nonlinear interaction between the neutrally stable modes and the weakly unstable modes.

The integrability of multivector fields in a differentiable manifold is studied. Then, given a jet bundle $J^1E \to E \to M$, it is shown that integrable multivector fields in E are equivalent to integrable connections in the bundle $E \to M$ (that is, integrable jet fields in J^1E). This result is applied to the particular case of multivector fields in the manifold J^1E and connections in the bundle $J^1E \to M$ (that is, jet fields in the repeated jet bundle J^1J^1E), in order to characterize integrable multivector fields and connections whose integral manifolds are canonical lifting of sections. These results allow us to set the Lagrangian evolution equations for first-order classical field theories in three equivalent geometrical ways (in a form similar to that in which the Lagrangian dynamical equations of nonautonomous mechanical systems are usually given). Then, using multivector fields, we discuss several aspects of these evolution equations (both for the regular and singular cases); namely, the existence and nonuniqueness of solutions, the integrability problem and Noether's theorem, giving insights into the differences between mechanics and field theories.

I. INTRODUCTION

The theory of *multisymplectic manifolds* (that is, differentiable manifolds endowed with a closed nondegenerate k-form, with $k \geqslant 2$) has been revealed as a powerful tool for geometrically describing some problems in physics. In particular, jet bundles and their duals, equipped with specific multisymplectic forms, are the suitable geometrical frameworks for describing the Lagrangian and Hamiltonian formalisms of first-order classical field theories (a nonexhaustive list of references is Refs. 1–9).

As a consequence of this fact, the study of multisymplectic manifolds and their properties has increased lately;[10–12] in particular, those concerning the behavior of *multisymplectic Hamiltonian systems*, which are the generalization of the corresponding symplectic case. This generalization requires the use of *multivector fields* as a fundamental tool, and their contraction with differential forms, which is the intrinsic formulation of the systems of partial differential equations locally describing the field. Hence, the study of the integrability of such equations (that is, of the corresponding multivector fields), is of considerable interest and constitutes the first aim in this paper.

A particular situation of special relevance arises when multivector fields in fiber bundles are considered. In these cases, a result on the equivalence of integrable multivector fields and jet fields, or connections in the corresponding first-order jet bundles, can be stated.

Furthermore, in the jet bundle description of classical field theories, the evolution equations are usually obtained using the multisymplectic form in order to characterize the critical sections which are solutions of the problem. Nevertheless, in mechanics we can write the evolution equations in a more geometric–algebraic manner using vector fields, and then obtain the critical sections as integral curves of these vector fields. Different attempts have been made to achieve the same goal with the evolution equations of field theories. So, for the Lagrangian formalism, this is done in two different ways: by using *Ehresmann connections* in a jet bundle[13,14] or, what is

[a)]Electronic mail: MATMCML@MAT.UPC.ES
[b)]Electronic mail: MATNRR@MAT.UPC.ES

equivalent, their associated *jet fields*.[4] Moreover, in Refs. 15–18, the evolution equations in the Hamiltonian formalism and generalized Poisson brackets are stated (mainly in local coordinate terms) using multivector fields (although, as far as we know, the first use of multivector fields in the realm of field theories can be found in Ref. 6). A further goal of this work is to carry out a deeper and pure geometrical analysis of these procedures for the Lagrangian formalism, showing that all these ways are, in fact, equivalent.

Thus, the aims of this paper are the following.

(1) To study the integrability of multivector fields in differentiable manifolds in general.
(2) To set the equivalence between jet fields in the jet bundle J^1E and a certain kind of multivector fields in E. This equivalence will in fact be used for jet fields in the ''repeated'' jet bundle J^1J^1E and the corresponding multivector fields in the jet bundle J^1E.
(3) To use these results to state the Lagrangian evolution equations for first-order classical field theories using multivector fields; and to prove this formalism is equivalent to the above mentioned ways of setting these equations.
(4) To use, in particular, this *multivector field formalism* to study some features of Lagrangian field theories; namely, the existence and nonuniqueness of solutions, the problem of the integrability and Noether's theorem. In this way the differences between mechanics and field theories will be made evident.

The structure of the paper is the following.

The first part is devoted to an analysis of the first two items. In particular, the following.

In Sec. II A we introduce the notion and characterization of *integrable multivector fields* in a manifold, as well as several properties for them.

Section II B is devoted to the presentation of an algorithm for finding the submanifold (if it exists) where a nonintegrable multivector field is integrable. This algorithm is applied to solve a particular system of partial differential equations in Sec. II C.

In Secs. II D and II E, we study the integrability of jet fields, connections and special kinds of multivector fields in jet bundles; and their equivalence. This equivalence is considered for the particular case of jet fields in J^1J^1E, and the suitable multivector fields in J^1E.

In Sec. II F, after giving different geometrical characterizations for *semi-holonomic* and *holonomic* multivector fields, they are finally related with semi-holonomic and holonomic jet fields.

In the second part, the applications to Lagrangian first-order field theories are considered. Thus we have the following.

Section III A is a short background on Lagrangian first-order classical field theory.

Section III B is devoted to establishing the evolution equations for classical field theories (the *Euler–Lagrange equations*) using multivector fields in J^1E, showing that this is equivalent to using jet fields in J^1J^1E or their associated connections in $J^1E\to M$.

In Secs. III C and III D, the analysis of the evolution equations is made for regular and singular Lagrangian field theories, using multivector fields. In particular, we show that the existence of integrable multivector fields solution of the equations is not guaranteed (even in the regular case). The nonuniqueness of solutions is also discussed, as well as the integrability of these solutions. Furthermore, algorithmic procedures for finding multivector fields solutions in the singular case is outlined in Sec. III D.

In Sec. III E we deal with the *generalized symmetries* of a Lagrangian system, and a version of *Noether's theorem* using the multivector field formalism is proved.

An example, which is a quite general version of many typical models in field theories, is analyzed in Sec. III F.

Finally, a summary with the main results in the work is given.

An appendix is included as a remainder of the definitions and main properties of the canonical structures in a jet bundle, which are used in some parts of the work.

All manifolds are real, paracompact, connected and C^∞. All maps are C^∞. The sum over crossed repeated indices is understood.

II. MULTIVECTOR FIELDS AND CONNECTIONS

We begin this work by studying the integrability of multivector fields in differentiable manifolds in general; and setting the equivalence between jet fields and multivector fields in jet bundles.

A. Multivector fields in differentiable manifolds

Let E be an n-dimensional differentiable manifold. Sections of $\Lambda^m(TE)$ are called *m-multivector fields* in E. We will denote by $\mathcal{X}^m(E)$ the set of m-multivector fields in E. In general, given a m-multivector field $Y\in\mathcal{X}^m(E)$, for every $p\in E$, there exists an open neighborhood $U_p\subset E$ and $Y_1,\ldots,Y_r\in\mathcal{X}(U_p)$ such that

$$Y=\sum_{U_p 1\leqslant i_1<\cdots<i_m\leqslant r} f^{i_1\cdots i_m}Y_{i_1}\wedge\cdots\wedge Y_{i_m}\,, \tag{1}$$

with $f^{i_1\cdots i_m}\in C^\infty(U_p)$ and $m\leqslant r\leqslant \dim E$. The situation we are interested in is when, for every $p\in E$, we can take $r=m$; therefore[19,20] we have the following.

Definition 1: An m-multivector field $Y\in\mathcal{X}^m(E)$ *is said to be* decomposable *iff there are* $Y_1,\ldots,Y_m\in\mathcal{X}(E)$ *such that* $Y=Y_1\wedge\cdots\wedge Y_m$.

The multivector field $Y\in\mathcal{X}^m(E)$ *is said to be* locally decomposable *iff, for every* $p\in E$, *there exists an open neighborhood* $U_p\subset E$ *and* $Y_1,\ldots,Y_m\in\mathcal{X}(U_p)$ *such that* $Y=_{U_p} Y_1\wedge\cdots\wedge Y_m$.

Every multivector field $Y\in\mathcal{X}^m(E)$ defines an operation $i(Y)$ of degree $-m$ in the algebra of differential forms $\Omega(E)$. If $\Omega\in\Omega^k(E)$ is a differentiable k-form in E; using (1), this is

$$i(Y)\Omega=\sum_{U_p 1\leqslant i_1<\cdots<i_m\leqslant r} f^{i_1\cdots i_m}i(Y_{i_1}\wedge\cdots\wedge Y_{i_m})\Omega=\sum_{1\leqslant i_1<\cdots<i_m\leqslant r} f^{i_1\cdots i_m}i(Y_{i_1})\cdots i(Y_{i_m})\Omega,$$

if $k\geqslant m$, and it is obviously equal to zero if $k<m$. The k-form Ω is said to be *j-nondegenerate* (for $1\leqslant j\leqslant k-1$) iff, for every $p\in E$ and $Y\in\mathcal{X}^j(E)$, $i(Y_p)\Omega_p=0\Leftrightarrow Y_p=0$ (see Refs. 10 and 11 for more information on these topics).

Let D be an m-dimensional distribution in E; that is, an m-dimensional subbundle of TE. Obviously sections of $\Lambda^m D$ are m-multivector fields in E. The existence of a nonvanishing global section of $\Lambda^m D$ is equivalent to the orientability of D. We are interested in the relation between nonvanishing m-multivector fields in E and m-dimensional distributions in TE. So we set the following.

Definition 2: A nonvanishing m-multivector field $Y\in\mathcal{X}^m(E)$ *and an m-dimensional distribution* $D\subset TE$ *are* locally associated *iff there exists a connected open set* $U\subseteq E$ *such that* $Y|_U$ *is a section of* $\Lambda^m D|_U$.

As a consequence of this definition, if $Y,Y'\in\mathcal{X}^m(E)$ are nonvanishing multivector fields locally associated, on the same connected open set U, with the same distribution D, then there exists a nonvanishing function $f\in C^\infty(U)$ such that $Y'=_U fY$. This fact defines an equivalence relation in the set of nonvanishing m-multivector fields in E, whose equivalence classes will be denoted by $\{Y\}_U$. Therefore we can state the following.

Theorem 1: *There is a bijective correspondence between the set of m-dimensional orientable distributions D in TE and the set of the equivalence classes* $\{Y\}_E$ *of nonvanishing, locally decomposable m-multivector fields in E.*

Proof: Let $\omega\in\Omega^m(E)$ be an orientation form for D. If $p\in E$ there exists an open neighborhood $U_p\subset E$ and $Y_1,\ldots,Y_m\in\mathcal{X}(U_p)$, with $i(Y_1\wedge\cdots\wedge Y_m)\omega>0$, such that $D|_{U_p}=\mathrm{span}\{Y_1,\ldots,Y_m\}$. Then $Y_1\wedge\cdots\wedge Y_m$ is a representative of a class of m-multivector fields associated with D in U_p. But the family $\{U_p;p\in E\}$ is a covering of E; let $\{U_\alpha;\alpha\in A\}$ be a locally finite refinement and $\{\rho_\alpha;\alpha\in A\}$ a subordinate partition of unity. If $Y_1^\alpha,\ldots,Y_m^\alpha$ is a local basis of D in U_α, with $i(Y_1^\alpha\wedge\cdots\wedge Y_m^\alpha)\omega>0$, then $Y=\Sigma_\alpha\rho_\alpha Y_1^\alpha\wedge\cdots\wedge Y_m^\alpha$ is a global representative of the class of nonvanishing m-multivector fields associated with D in E.

The converse is trivial because if $Y|_U=Y_1^1\wedge\cdots\wedge Y_m^1=Y_1^2\wedge\cdots\wedge Y_m^2$, for different sets $\{Y_1^1,\ldots,Y_m^1\}$, $\{Y_1^2,\ldots,Y_m^2\}$, then $span\ \{Y_1^1,\ldots,Y_m^1\}=span\ \{Y_1^2,\ldots,Y_m^2\}$. ■

Comments:

- If $Y \in \mathcal{X}^m(E)$ is a nonvanishing m-multivector field and $U \subseteq E$ is a connected open set, the distribution associated with the class $\{Y\}_U$ will be denoted by $\mathcal{D}_U(Y)$. If $U=E$ we will write simply $\mathcal{D}(Y)$.
- If D is a nonorientable m-dimensional distribution in TE, for every $p \in E$, there exists an open neighborhood $U_p \subset E$ and a nonvanishing multivector field $Y \in \mathcal{X}^m(U)$ such that $D|_{U_p} = \mathcal{D}_U(Y)$.

Definition 3: Let $Y \in \mathcal{X}^m(E)$ be a multivector field.

1. *A submanifold $S \hookrightarrow E$, with $dim\ S = m$, is said to be an* integral manifold *of Y iff, for every $p \in S$, Y_p spans $\Lambda^m T_p S$.*
2. *Y is said to be an* integrable multivector field *on an open set $U \subseteq E$ iff, for every $p \in U$, there exists an integral manifold $S \hookrightarrow U$ of Y, with $p \in S$.*
3. *Y is said to be* integrable *iff it is integrable in E.*

Obviously, every integrable multivector field is nonvanishing.

Now, bearing in mind the statement in theorem II A, we can define the following.

Definition 4: Let $Y \in \mathcal{X}^m(E)$ be a multivector field.

1. *Y is said to be* involutive *on a connected open set $U \subseteq E$ iff it is locally decomposable in U and its associated distribution $\mathcal{D}_U(Y)$ is involutive.*
2. *Y is said to be* involutive *iff it is involutive on E.*
3. *Y is said to be* locally involutive *around $p \in E$ iff there is a connected open neighborhood $U_p \ni p$ such that Y is involutive on U_p.*

Note that if Y is locally involutive around every $p \in E$, then it is involutive.

Now, the classical *Frobenius' theorem* can be reformulated in this context as follows.

Proposition 1: A nonvanishing and locally decomposable multivector field $Y \in \mathcal{X}^m(E)$ is integrable on a connected open set $U \subseteq E$ if, and only if, it is involutive on U.

Note that if a multivector field Y is integrable, then so is every other in its equivalence class $\{Y\}$, and all of them have the same integral manifolds.

As is well known, an m-dimensional distribution D is integrable if, and only if, it is locally spanned by a set of vector fields $(Y_1, \ldots, Y_m)$ such that $[Y_\mu, Y_\nu] = 0$, for every pair Y_μ, Y_ν. Thus a multivector field $Y \in \mathcal{X}^m(E)$ is integrable if, and only if, for every $p \in E$, there exists an open neighborhood $U_p \subset E$ and $Y_1, \ldots, Y_m \in \mathcal{X}(U_p)$ such that

1. $Y_1, \ldots, Y_m$ span $\mathcal{D}_{U_p}(Y)$.
2. $[Y_\mu, Y_\nu] = 0$, for every pair Y_μ, Y_ν.

Then there is a nonvanishing function $f \in C^\infty(U_p)$ such that $Y|_{U_p} = f Y_1 \wedge \cdots \wedge Y_m$.

Now, let $\{\tau^\mu\}$ be the local one-parameter groups of diffeomorphisms of Y_μ around p (for $\mu = 1, \ldots, m$). The second condition above implies that $\tau^\mu \circ \tau^\nu = \tau^\nu \circ \tau^\mu$, for every μ, ν. Then, if S_p is the integral manifold of Y through p, there exist open neighborhoods $V(0) \subset \mathbf{R}^m$ and $W_p \subset U_p \subset E$, and a map

$$\tau : V(0) \times W_p \to U_p$$

$$(t,q) \mapsto \tau_t(q) := (\tau^1_{t_1} \circ \ldots \circ \tau^m_{t_m})(q) \quad (t = (t_1, \ldots, t_m)),$$

verifying that

1. τ is injective.
2. $\tau_{t+s} = \tau_t \circ \tau_s$, for $t, s, t+s \in V(0)$.
3. For every $q \in W_p$, the set $\{\tau_t(q); t \in V(0)\}$ is an open neighborhood of q in S_q.

The map τ is called the m-flow associated with the multivector field Y (see Ref. 21 for the terminology and notation). Therefore we can define the following.

Definition 5: A multivector field $Y \in \mathcal{X}^m(E)$ is said to be a dynamical multivector field *iff*

1. *Y is integrable.*
2. *For every* $p \in E$, *there exists an open neighborhood* $U_p \subset E$ *and* $Y_1, \ldots, Y_m \in \mathcal{X}(U_p)$ *such that* $[Y_\mu, Y_\nu] = 0$, *for every pair* Y_μ, Y_ν, *and* $Y|_{U_p} = Y_1 \wedge \cdots \wedge Y_m$.

Thus, as a consequence of all these comments we have the following.

Proposition 2: Let $\{Y\}$ *be a class of integrable m-multivector fields. Then there is a representative Y of the class which is a dynamical multivector field.*

B. Integrability algorithm for locally decomposable multivector fields

Every locally decomposable multivector field $Y \in \mathcal{X}^m(E)$ defines a system of (first-order) partial differential equations, whose solutions (if they exist) give locally the integral manifolds of Y.

Nevertheless, in many applications, we have a locally decomposable multivector field which is not integrable in E, but integrable in a submanifold of E. What this means is that the corresponding system of partial differential equations has no solution everywhere in E, but only on the points of that submanifold. For instance, this problem arises when we look for solutions of evolution equations in field theories (as we will see later).

Next we present an algorithm which allows us to find this submanifold. Although we will maintain the global notation (E for the manifold), this is a local algorithm; that is, we are in fact working on suitable open sets in E. Hence, let $Y \equiv \wedge_{\mu=1}^{m} Y_\mu$.

• *Integrability condition*:

The condition for Y to be integrable is equivalent to demanding that the distribution spanned by $Y_1, \ldots, Y_m$ is involutive. Then, let $Z_1, \ldots, Z_{n-m} \in \mathcal{X}(E)$, such that $Y_1, \ldots, Y_m$, $Z_1, \ldots, Z_{n-m}$ are a local basis of $\mathcal{X}(E)$. Therefore, for every couple Y_μ, Y_ν $(1 \leqslant \mu, \nu \leqslant m)$ we have

$$[Y_\mu, Y_\nu] = \xi^\rho_{\mu\nu} Y_\rho + \zeta^l_{\mu\nu} Z_l,$$

for some functions $\xi^\rho_{\mu\nu}, \zeta^l_{\mu\nu}$. Consider the system $\zeta^l_{\mu\nu} = 0$ and let

$$E_1 = \{p \in E;\ \zeta^l_{\mu\nu}(p) = 0,\ \forall \mu, \nu, l\};$$

we have three options.

1. $E_1 = E$.
   Then the distribution spanned by $Y_1, \ldots, Y_m$ is involutive, and the multivector field Y is integrable in E. If, in addition, all the functions $\xi^\rho_{\mu\nu}$ are zero everywhere, then Y is also a dynamical multivector field.
2. $E_1 = \varnothing$.
   Then the distribution spanned by $Y_1, \ldots, Y_m$ is not involutive at any point in E, and hence the multivector field Y is not integrable.
3. E_1 is a proper subset of E.
   In this case we assume that E_1 is a closed submanifold of E and the functions $\zeta^l_{\mu\nu}$ are the constraints locally defining E_1. The distribution spanned by $Y_1, \ldots, Y_m$ is involutive on E_1; that is, the multivector field Y is involutive on E_1. Moreover, if all the functions $\xi^\rho_{\mu\nu}$ are zero everywhere in E_1, then Y is also a dynamical multivector field in E_1.
   Obviously, $Y : E_1 \to \Lambda^m TE|_{E_1}$. If, in addition, $Y : E_1 \to \Lambda^m TE_1$, then Y is an integrable multivector field tangent to E_1. Nevertheless, this is not the case in general, so we need the following.

• *Tangency condition*:

Consider the set

$$E_2 := \{p \in E_1;\ Y(p) \in \Lambda^m T_p E_1\}.$$

For E_2 we have the same problem, so we define inductively, for $i > 1$,

$$E_i := \{p \in E_{i-1};\ Y(p) \in \Lambda^m T_p E_{i-1}\},$$

and assume that we obtain a sequence of nonempty (closed) submanifolds $\cdots \subset E_i \subset \cdots \subset E_1 \subset E$.

Observe that the necessary and sufficient condition for a locally decomposable multivector field $Y=Y_1\wedge\cdots\wedge Y_m$ to be tangent to E_i is that Y_μ is tangent to E_i, for every μ. Hence, if $E_f:=\cap_{1\geqslant 1}E_i$, and assuming that E_f is a nonempty (closed) submanifold of E with $\dim E_f\geqslant m$, we have that $Y:E_f\to\Lambda^m TE_f$; this is involutive and therefore integrable on the manifold E_f.

Using the constraints, we have that, if $\{\zeta_{\alpha_i}^{(i)}\}$ is a basis of constraints defining locally E_i in E_{i-1}, the tangency condition is

$$0\underset{E_i}{=}Y_\mu(\zeta_{\alpha_i}^{(i)})\ ,\quad \forall\mu,\alpha_i\,,$$

that is, we have

$$E_{i+1}:=\{p\in E_i\,;Y_\mu(\zeta_{\alpha_i}^{(i)})(p)=0,\forall\mu,\alpha_i\},$$

and again we have the same situation as in the case of $E_1\subset E$.

This algorithm ends in one of the following two options.

1. We obtain a submanifold $E_f\hookrightarrow E$, with $\dim E_f\geqslant m$, where Y is an integrable multivector field (and, maybe, dynamical).
2. We obtain a submanifold E_f with $\dim E_f<m$, or the empty set. Then the problem has no solution in E.

We will call this procedure the *integrability algorithm* for multivector fields.

Remark: As is clear, although we have developed this algorithm for locally decomposable multivector fields, the procedure is obviously applicable for distributions in general.

C. An example

In order to show how the above algorithm of integrability is applied we take the following example of a system of partial differential equations which does not verify the integrability condition (see Ref. 22),

$$\frac{\partial y_1}{\partial x_1}=y_1-x_1-x_2\,,\quad \frac{\partial y_1}{\partial x_2}=y_1{}^2-x_1{}^2-x_2{}^2-2x_1-2x_2-2x_1x_2\,,$$

$$\frac{\partial y_2}{\partial x_1}=-y_2+x_1+x_2\,,\quad \frac{\partial y_2}{\partial x_2}=1.$$

For this system we have $E\equiv\mathbf{R}^4$, with local coordinates (x_1,x_2,y_1,y_2). The associated distribution is locally spanned by the vector fields

$$Y_1=\frac{\partial}{\partial x_1}+(y_1-x_1-x_2)\frac{\partial}{\partial y_1}+(-y_2+x_1+x_2)\frac{\partial}{\partial y_2}\,,$$

$$Y_2=\frac{\partial}{\partial x_2}+(y_1{}^2-x_1{}^2-x_2{}^2-2x_1-2x_2-2x_1x_2)\frac{\partial}{\partial y_1}+\frac{\partial}{\partial y_2}\,,$$

and a representative of the corresponding class of locally decomposable multivector fields $\{Y\}\subset\mathcal{X}^2(E)$ is $Y=Y_1\wedge Y_2$.

• *Integrability condition*:

As local basis of $\mathcal{X}(E)$ we take the set $(Y_1,Y_2,\partial/\partial y_1,\partial/\partial y_2)$. Then the condition of involutivity of the above distribution leads to

$$[Y_1,Y_2]=((x_1+x_2-y_1)^2-1)\frac{\partial}{\partial y_1}=0,$$

which gives the constraint $\zeta^{(1)}\equiv(x_1+x_2-y_1)^2-1=(x_1+x_2-y_1-1)(x_1+x_2-y_1+1)\equiv\zeta_a^{(1)}\zeta_b^{(1)}$; and we have the two disjoint submanifolds,

$$E_1^a := \{(x_1, x_2, y_1, y_2) | x_1 + x_2 - y_1 - 1 = 0\},$$

$$E_1^b := \{(x_1, x_2, y_1, y_2) | x_1 + x_2 - y_1 + 1 = 0\},$$

and the tangency condition must hold separately for each one of them.

• *Tangency condition*:

1. *Tangency condition for* E_1^a: We obtain that $Y_1(\zeta_a^{(1)}) \underset{E_1^a}{=} 2$; then Y_1 is not tangent to E_1^a at any point, and the system has no solution on E_1^a.
2. *Tangency condition for* E_1^b: In this case we have that $Y_1(\zeta_a^{(1)}) \underset{E_1^b}{=} 0$ and $Y_2(\zeta_a^{(1)}) \underset{E_1^b}{=} 0$. Then $Y|_{E_1^b} \in \mathcal{X}^2(E_1^b)$ and it is integrable on E_1^b.

• *Integration of the system on* E_1^b:

The general solution of the system on E_1^b is

$$y_1 = x_1 + x_2 + 1, \quad y_2 = x_1 + x_2 - 1 + ce^{-x_1} \quad (c \in \mathbf{R}),$$

and there exists an integral manifold through every point on E_1^b. (Compare with Ref. 22, pp. 47, 53.)

D. Multivector fields in fiber bundles

The particular situation in which we are interested is the study of multivector fields in fiber bundles and, in particular, in jet bundles. Bearing this in mind, first we state some results concerning multivector fields in fiber bundles in general.

Let $\tau: E \to M$ be a fiber bundle with $\dim M = m$. We denote by $\mathrm{V}(\tau)$ the vertical bundle associated with τ [that is, $\mathrm{V}(\tau) = \mathrm{Ker}\, T\tau$], and by $\mathcal{X}^{\mathrm{V}(\tau)}(E)$ the corresponding sections or vertical vector fields.

We are interested in the case that the integral manifolds of multivector fields are sections of the projection τ. In order to characterize this kind of multivector fields we set the following.

Definition 6: A multivector field $Y \in \mathcal{X}^m(E)$ *is said to be* transverse to the projection τ *(or* τ-transverse*) iff, at every point* $y \in E$, $(i(Y)(\tau^* \omega))_y \neq 0$, *for every* $\omega \in \Omega^m(M)$ *with* $\omega(\tau(y)) = 0$.

Comments:

• This condition is equivalent to $(\Lambda^m T\tau \circ Y)(y) \neq 0$, for every $y \in E$.

• If $Y \in \mathcal{X}^m(E)$ is locally decomposable, then Y is τ-transverse if, and only if, $T_y\tau(\mathcal{D}(Y)) = T_{\tau(y)}M$, for every $y \in E$. [Remember that $\mathcal{D}(Y)$ is the m-distribution associated to Y.]

Then we can state the following.

Theorem 2: *Let* $Y \in \mathcal{X}^m(E)$ *be integrable. Then* Y *is* τ*-transverse if, and only if, its integral manifolds are local sections of* $\tau: E \to M$.

Proof: Consider $y \in E$, with $\tau(y) = x$. In a neighborhood of y there exists $Y_1, \ldots, Y_m \in \mathcal{X}(E)$ such that $Y_1, \ldots, Y_m$ span $\mathcal{D}(Y)$ and $Y = Y_1 \wedge \cdots \wedge Y_m$. But, as Y is τ-transverse, $(i(Y) \times (\tau^* \omega))_y \neq 0$, for every $\omega \in \Omega^m(M)$ with $\omega(x) \neq 0$. Thus, taking into account the second comment above, $\mathcal{D}(Y)$ is a τ-transverse distribution and $Y_\mu \notin \mathcal{X}^{\mathrm{V}(\tau)}(E)$ at any point, for every Y_μ. Now, let $S \hookrightarrow E$ be the integral manifold of $\mathcal{D}(Y)$ passing through y then $T_y S = \mathrm{span}\{(Y_1)_y, \ldots, (Y_m)_y\}$. As a consequence of all of this, and again taking into account the second comment above, for every point $y \in S$, $T_y\tau(\mathcal{D}(Y)) = T_{\tau(y)}M$, then $\tau|_S$ is a local diffeomorphism and S is a local section of τ.

The converse is obvious. ■

Observe that, in this case, if $\phi: U \subset M \to E$ is a local section with $\phi(x) = y$ and $\phi(U)$ is the integral manifold of Y through y, then $T_y(\mathrm{Im}\ \phi)$ is $\mathcal{D}_y(Y)$.

Now, considering the diagram

$$\begin{array}{ccc} \Lambda^m\mathrm{T}(\pi^{-1}(U)) & \overset{\Lambda^m\mathrm{T}\pi}{\underset{\Lambda^m\mathrm{T}\phi}{\rightleftarrows}} & \Lambda^m\mathrm{T}U \\ \Lambda^m\tau_E \big\downarrow\big\uparrow & Y & \big\downarrow \Lambda^m\tau_U \\ \pi^{-1}(U) & \underset{\pi}{\overset{\phi}{\rightleftarrows}} & U\subset M \end{array}$$

we have the following.

Proposition 3: $Y\in\mathcal{X}^m(E)$ is integrable and π-transverse if, and only if, for every point $y\in E$, there exists a local section $\phi:U\subset M\to E$ such that $\phi(\pi(y))=y$; and a nonvanishing function $f\in C^\infty(E)$ such that $\Lambda^m T\phi = fY\circ\phi\circ\Lambda^m\tau_U$.

Proof: If Y is integrable and π-transverse, then by theorem 2, for every $y\in E$, with $\pi(y)=x$, there is an integral local section $\phi:U\subset M\to E$ of Y at y such that $\phi(x)=y$. Then, by definition 3, Y_y spans $\Lambda^m T_y\phi$, and hence the relation in the statement holds and the above diagram becomes commutative on the open set U.

Conversely, if the relation holds, then Im ϕ is an integral manifold of Y at y; then Y is integrable and, as ϕ is a section of π, Y is necessarily π-transverse. ■

E. Multivector fields and connections in jet bundles

Next we are going to establish the relation between multivector fields and connections in jet bundles. Let $\pi:E\to M$ be a fiber bundle, $\pi^1:J^1E\to E$ the corresponding first-order jet bundle of local sections of π, and $\overline{\pi^1}=\pi\circ\pi^1:J^1E\to M$. If (x^μ,y^A) is a local system of coordinates adapted to the projection π ($\mu=1,\ldots,m$, $A=1,\ldots,N$), let (x^μ,y^A,v^A_μ) be the induced local system of coordinates in J^1E.

With the aim of relating the elements in $\mathcal{X}^m(E)$ to connections in $\pi:E\to M$, we briefly recall several ways of giving a connection (see Ref. 14).

Definition 7: A connection in $\pi:E\to M$ *is one of the following equivalent elements.*

1. *A global section of* $\pi^1:J^1E\to E$ *(that is, a mapping* $\Psi:E\to J^1E$ *such that* $\pi^1\circ\Psi=\mathrm{Id}_E$*). It is called a* jet field.
2. *A subbundle* $H(E)$ *of* TE *such that* $TE=V(\pi)\oplus H(E)$*. It is called a* horizontal subbundle.
3. *A* π*-semibasic* 1*-form* $\boldsymbol{\nabla}$ *on* E *with values in* TE*, such that* $\boldsymbol{\nabla}^*\alpha=\alpha$*, for every* π*-semibasic form* $\alpha\in\Omega^1(E)$*. It is called the* connection form *or* Ehresmann connection.

The equivalence among these elements can be seen in Ref. 14, or it suffices to observe their local expressions. In a natural chart (x^μ,y^A,v^A_μ) we have

$$\Psi=(x^\mu,y^A,\Gamma^A_\rho(x^\mu,y^A)),$$

$$\boldsymbol{\nabla}=dx^\mu\otimes\left(\frac{\partial}{\partial x^\mu}+\Gamma^A_\mu(x^\mu,y^A)\frac{\partial}{\partial y^A}\right), \tag{2}$$

$$H(E)=\mathrm{span}\left\{\frac{\partial}{\partial x^\mu}+\Gamma^A_\mu(x^\mu,y^A)\frac{\partial}{\partial y^A}\right\}.$$

Comments:

- The horizontal subbundle $H(E)$ is also denoted $\mathcal{D}(\Psi)$ when it is considered as the distribution associated with Ψ.
- A jet field $\Psi:E\to J^1E$ (resp., an Ehresmann connection $\boldsymbol{\nabla}$) is said to be orientable iff $\mathcal{D}(\Psi)$ is an orientable distribution on E.
- If M is orientable, then every connection is also orientable.

Let $\Psi:E\to J^1E$ be a jet field. A section $\phi:M\to E$ is said to be an *integral section* of Ψ iff $\Psi\circ\phi=j^1\phi$ (where $j^1\phi:M\to J^1E$ denotes the canonical lifting of ϕ). Ψ is said to be an *integrable*

jet field iff it admits integral sections through every point of E or, what is equivalent, if, and only if, $\mathcal{D}(\Psi)$ is an involutive distribution [that is, $\mathcal{D}(\Psi)$ is integrable]. Locally, if $\phi=(x^\mu,f^A(x^\nu))$, then ϕ is an integral section of Ψ if, and only if, ϕ is a solution of the following system of partial differential equations:

$$\frac{\partial f^A}{\partial x^\mu}=\Gamma^A_\mu\circ\phi. \tag{3}$$

As is well known, a jet field Ψ is integrable if, and only if, the curvature of the connection form $\mathbf{\nabla}$ associated with Ψ vanishes identically; where the *curvature* of a connection $\mathbf{\nabla}$ is the (2,1)-tensor field defined by

$$\mathcal{R}(Z_1,Z_2):=(\mathrm{Id}-\mathbf{\nabla})([\mathbf{\nabla}(Z_1),\mathbf{\nabla}(Z_2)])=i([\mathbf{\nabla}(Z_1),\mathbf{\nabla}(Z_2)])(\mathrm{Id}-\mathbf{\nabla}),$$

for every $Z_1,Z_2\in\mathcal{X}(E)$. Using the coordinate expressions of the connection form $\mathbf{\nabla}$ and the 1-jet field Ψ, a simple calculation leads to

$$\mathcal{R}=\frac{1}{2}\left(\frac{\partial\Gamma^B_\eta}{\partial x^\mu}-\frac{\partial\Gamma^B_\mu}{\partial x^\eta}+\Gamma^A_\mu\frac{\partial\Gamma^B_\eta}{\partial y^A}-\Gamma^A_\eta\frac{\partial\Gamma^B_\mu}{\partial y^A}\right)(dx^\mu\wedge dx^\eta)\otimes\frac{\partial}{\partial y^B}\,.$$

Hence, from this local expression of $\mathcal{R}$ we obtain the local integrability conditions of the equations (3).

Now, the relation between multivector fields and connections (jet fields) is given as a particular case of theorem 1.

Theorem 3: *There is a bijective correspondence between the set of orientable jet fields* $\Psi:E\to J^1E$ *(that is, the set of orientable connections* $\mathbf{\nabla}$ *in* $\pi:E\to M$*) and the set of the equivalence classes of locally decomposable and* π*-transverse multivector fields* $\{Y\}\subset\mathcal{X}^m(E)$*. They are characterized by the fact that* $\mathcal{D}(\Psi)=\mathcal{D}(Y)$.

In addition, the orientable jet field Ψ *is integrable if, and only if, so is Y, for every* $Y\in\{Y\}$.

Proof: If Ψ is an orientable jet field in J^1E, let $\mathcal{D}(\Psi)$ be its horizontal distribution. Then, taking $D\equiv\mathcal{D}(\Psi)$, we construct $\{Y\}$ by applying theorem 1 and, since the distribution $\mathcal{D}(\Psi)$ is π-transverse, the result follows immediately. The proof of the converse statement is similar.

Moreover, Ψ is integrable if, and only if, $\mathcal{D}(\Psi)=\mathcal{D}(Y)$ also is. Therefore it follows that Y is also integrable, for $Y\in\{Y\}$, and conversely. ■

As is obvious, recalling the local expression (2), we obtain the following local expression for a particular representative multivector field Y of the class $\{Y\}$ associated with the jet field Ψ:

$$Y\equiv\bigwedge_{\mu=1}^{m}Y_\mu=\bigwedge_{\mu=1}^{m}\left(\frac{\partial}{\partial x^\mu}+\Gamma^A_\mu\frac{\partial}{\partial y^A}\right),$$

and $\phi=(x^\mu,f^A(x^\nu))$ is an integral section of Y if, and only if, ϕ is a solution of the system of partial differential equations (3).

Remarks:

- If M is an orientable manifold and $\omega\in\Omega^m(M)$ is the volume form in M, then the above representative can be obtained from the relation $i(Y)(\pi^*\omega)=i(\partial/\partial x^1\wedge\cdots\wedge\partial/\partial x^m)\times(\pi^*\omega)$.
- It is interesting to point out that, if we consider the integrability algorithm described in Sec. II B for this kind of multivector fields, then the integrability condition (given by the involutivity condition for the associated distribution) is equivalent now to the condition $\mathcal{R}=0$ ($\mathcal{R}$ being the curvature of the associated jet field). Furthermore, in this case, at the end of the algorithm, we will obtain directly a *dynamical multivector field* as the representative of the class of integrable multivector fields.

In Lagrangian classical field theory we are interested in multivector fields in the bundle $\overline{\pi}^1:J^1E\to M$. Hence, all the above considerations must be adapted to the bundle projections $J^1J^1E\xrightarrow{\pi^1_1}J^1E\xrightarrow{\overline{\pi}^1}M$. In this way we have the following.

1. Let $X \in \mathcal{X}^m(J^1E)$ be integrable. Then X is $\overline{\pi}^1$-transverse if, and only if, its integral manifolds are local sections of $\overline{\pi}^1 : J^1E \to M$ (theorem 2).
2. $X \in \mathcal{X}^m(J^1E)$ is integrable and $\overline{\pi}^1$-transverse if, and only if, for every point $\overline{y} \in J^1E$, there exists a local section $\psi : U \subset M \to J^1E$ such that $\psi(\overline{\pi}^1(\overline{y})) = \overline{y}$; and a nonvanishing function $f \in \mathrm{C}^\infty(J^1E)$ such that $\Lambda^m T\psi = fX \circ \psi \circ \Lambda^m \tau_U$ (proposition 3).
3. In order to relate multivector fields in J^1E with connections in $\overline{\pi}^1 : J^1E \to M$, let $\mathcal{Y} : J^1E \to J^1J^1E$ be a jet field, and $\boldsymbol{\nabla}$ and $H(J^1E)$ its associated connection form and horizontal subbundle, respectively. If (x^μ, y^A, v^A_μ) is a natural local chart in J^1E, then the induced chart in J^1J^1E is denoted $(x^\mu, y^A, v^A_\mu, a^A_\rho, b^A_{\rho\mu})$. We have the following local expressions for these elements:

$$\mathcal{Y} = (x^\mu, y^A, v^A_\mu, F^A_\rho(x,y,v), G^A_{\mu\rho}(x,y,v)),$$

$$\boldsymbol{\nabla} = dx^\mu \otimes \left(\frac{\partial}{\partial x^\mu} + F^A_\mu \frac{\partial}{\partial y^A} + G^A_{\mu\rho} \frac{\partial}{\partial v^A_\rho} \right),$$

$$H(J^1E) = \mathrm{span} \left\{ \frac{\partial}{\partial x^\mu} + F^A_\mu \frac{\partial}{\partial y^A} + G^A_{\mu\rho} \frac{\partial}{\partial v^A_\rho} \right\}.$$

4. Let $\psi = (x^\mu, f^A(x), g^A_\mu(x))$ be a local section of $\overline{\pi}^1$. It is an integral section of $\mathcal{Y}$ if, and only if, ψ is a solution of the following system of partial differential equations:

$$\frac{\partial f^A}{\partial x^\mu} = F^A_\mu \circ \psi\,, \quad \frac{\partial g^A_\rho}{\partial x^\mu} = G^A_{\rho\mu} \circ \psi, \tag{4}$$

and the necessary and sufficient condition for this system to be integrable is that the curvature $\mathcal{R}$ of $\mathcal{Y}$ vanishes everywhere; that is, in coordinates,

$$\begin{aligned} 0 = & \left(\frac{\partial F^B_\eta}{\partial x^\mu} + F^A_\mu \frac{\partial F^B_\eta}{\partial y^A} + G^A_{\gamma\mu} \frac{\partial F^B_\eta}{\partial v^A_\gamma} - \frac{\partial F^B_\mu}{\partial x^\eta} - F^A_\eta \frac{\partial F^B_\mu}{\partial y^A} - G^A_{\rho\eta} \frac{\partial F^B_\mu}{\partial v^A_\rho} \right) (dx^\mu \wedge dx^\eta) \otimes \frac{\partial}{\partial y^B} \\ & + \left(\frac{\partial G^B_{\rho\eta}}{\partial x^\mu} + F^A_\mu \frac{\partial G^B_{\rho\eta}}{\partial y^A} + G^A_{\gamma\mu} \frac{\partial G^B_{\rho\eta}}{\partial v^A_\gamma} - \frac{\partial G^B_{\rho\mu}}{\partial x^\eta} - F^A_\eta \frac{\partial G^B_{\rho\mu}}{\partial y^A} - G^A_{\gamma\eta} \frac{\partial G^B_{\rho\mu}}{\partial v^A_\gamma} \right) (dx^\mu \wedge dx^\eta) \otimes \frac{\partial}{\partial v^B_\rho}\,. \end{aligned} \tag{5}$$

5. From the above local expressions we obtain for a representative multivector field X of the class $\{X\}$ associated with the jet field $\mathcal{Y}$, the expression

$$X \equiv \bigwedge_{\mu=1}^{m} X_\mu = \bigwedge_{\mu=1}^{m} \left(\frac{\partial}{\partial x^\mu} + F^A_\mu \frac{\partial}{\partial y^A} + G^A_{\mu\rho} \frac{\partial}{\partial v^A_\rho} \right). \tag{6}$$

Moreover, as in the case of the bundle E, if M is an orientable manifold and $\omega \in \Omega^m(M)$ is the volume form in M, then the above representative can be obtained from the relation

$$i(Y)(\overline{\pi}^{1*}\omega) = i\left(\frac{\partial}{\partial x^1} \wedge \cdots \wedge \frac{\partial}{\partial x^m} \right)(\overline{\pi}^{1*}\omega).$$

F. Holonomic multivector fields and holonomic jet fields

We wish to characterize the integrable multivector fields in J^1E whose integral manifolds are canonical prolongations of sections of π. In order to achieve this we first recall the same situation for jet fields.[4,14]

Definition 8: A jet field $\mathcal{Y}$ is said to be *holonomic* iff it is integrable and its integral sections $\psi: M \to J^1E$ are holonomic; that is, they are canonical liftings of sections $\phi: M \to E$.

Let $\mathbf{y} \in J^1J^1E$ with $\mathbf{y} \overset{\pi_1^1}{\mapsto} y \overset{\overline{\pi}^1}{\mapsto} y \overset{\pi}{\mapsto} x$, and $\psi: M \to J^1E$ a representative of $\mathbf{y}$; that is, $\mathbf{y} = T_x\psi$. Consider the section $\phi = \pi^1 \circ \psi: M \to E$, and let $j^1\phi$ be its canonical prolongation. Then we are able to define another natural projection,

$$\begin{array}{rccc} j^1\pi^1 & : & J^1J^1E & \mapsto & J^1E \\ & & \mathbf{y} & \mapsto & j^1(\pi^1 \circ \psi)(\overline{\pi}_1^1(\mathbf{y})). \\ & & (x^\mu, y^A, v^A_\mu, a^A_\rho, b^A_{\mu\rho}) & \mapsto & (x^\mu, y^A, a^A_\rho) \end{array}$$

Definition 9: A jet field $\mathcal{Y}: J^1E \to J^1J^1E$ *is said to be a* Second Order Partial Differential Equation (SOPDE) *or a* semi-holonomic *jet field (or also that it verifies the* SOPDE condition), *iff it is also a section of the projection* $j^1\pi^1$*; that is,* $j^1\pi^1 \circ \mathcal{Y} = \mathrm{Id}_{J^1E}$.

This is equivalent to saying that $\mathcal{Y}$ *is a section of the projection* $\hat{J}^2E \to J^1E$*, where* $\hat{J}^2E$ *denotes the* semi-holonomic 2-jet manifold *(see Ref. 14, p. 173).*

The relation among integrable, holonomic and SOPDE jet fields (connections) is the following.

Theorem 4: A jet field $\mathcal{Y}: J^1E \to J^1J^1E$ is holonomic if, and only if, it is integrable and SOPDE.

The condition $j^1\pi^1 \circ \mathcal{Y} = \mathrm{Id}_{J^1E}$ is locally expressed as follows: $\mathcal{Y} = (x^\mu, y^A, v^A_\mu, F^A_\rho, G^A_{\nu\rho})$ is a SOPDE if, and only if, $F^A_\rho = v^A_\rho$.

For multivector fields in J^1E, first we define the following.

Definition 10: A multivector field $X \in \mathcal{X}^m(J^1E)$ is said to be holonomic iff

1. X is integrable.
2. X is $\overline{\pi}^1$-transverse.
3. The integral sections $\psi: M \to J^1E$ of X are holonomic.

In order to study the SOPDE question for multivector fields, we adopt two different approaches: The first one, which is similar to the characterization of *second order* (that is, holonomic) vector fields in time-dependent mechanics, is based on the study of the two different bundle structures of TJ^1E over TE. The second one uses the *structure canonical form* $\theta \in \Omega^1(J^1E, \pi^{1*}V(\pi))$ (see the Appendix).

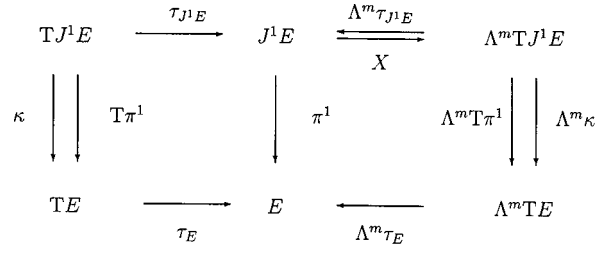
In the first approach, we have a natural vector bundle projection $T\pi^1: TJ^1E \to TE$ and another one $\kappa: TJ^1E \to TE$ defined by

$$\kappa(\overline{y,u}) := T_{\overline{\pi}^1(\overline{y})}\phi(T_{\overline{y}}\overline{\pi}^1(\overline{u})),$$

where $(\overline{y,u}) \in TJ^1E$ and $\phi \in \overline{y}$. If $(W; x^\mu, y^A, v^A_\mu)$ is a local natural chart in J^1E and $\overline{y} \in J^1E$ with $\overline{y} \overset{\overline{\pi}^1}{\to} y \overset{\pi}{\to} x$, then

$$\kappa\left(\alpha^\mu \frac{\partial}{\partial x^\mu}\bigg|_{\overline{y}} + \beta^A \frac{\partial}{\partial y^A}\bigg|_{\overline{y}} + \lambda^A_\mu \frac{\partial}{\partial v^A_\mu}\bigg|_{\overline{y}}\right) = \alpha^\mu \frac{\partial}{\partial x^\mu}\bigg|_y + v^A_\mu(\overline{y})\alpha^\mu \frac{\partial}{\partial y^A}\bigg|_y.$$

This projection is extended in a natural way to $\Lambda^m TJ^1E$, and so we have the following diagram:



and we can define the following.

Definition 11: A $\overline{\pi^1}$*-transverse multivector field* $X \in \mathcal{X}^m(J^1E)$ *verifies the* SOPDE condition *(we also say that it is a* SOPDE *or a* semi-holonomic multivector field*) iff* $\Lambda^m\kappa \circ X = \Lambda^m T\pi^1 \circ X$.

The condition for X to be $\overline{\pi^1}$-transverse is necessary in order to relate this definition to the fact that, if X is integrable, then its integral sections are canonical prolongations of sections of π (as will be seen later).

With regard to the second approach, observe that for every $X \in \mathcal{X}(J^1E)$, we obtain that $\theta(X) \equiv i(\theta)X$ is a section of the bundle $\pi^{1*}V(\pi) \to J^1E$ [that is, an element of $\Gamma(\pi^{1*}V(\pi))$]. Then we have a natural extension of the action of θ to every $X \in \mathcal{X}^m(J^1E)$. Furthermore, denoting $V^m(\pi) := \ker \Lambda^m T\pi$ and recalling the definition of θ (see definition A in the Appendix) we can define the following.

Definition 12: The structure canonical *m*-form *of* J^1E *is the m-form* θ^m *in* J^1E *with values on* $\pi^{1*}V^m(\pi)$, *which is defined by*

$$(\theta^m(X))(\overline{y}) \equiv (i(\theta^m)X)(\overline{y}) := (\Lambda^m T_{\overline{y}}\overline{\pi}^1 - \Lambda^m T_{\overline{y}}(\phi \circ \overline{\pi^1}))(X_{\overline{y}}),$$

where $X \in \mathcal{X}^m(J^1E)$, $\overline{y} \in J^1E$ and ϕ is a representative of $\overline{y}$.

Observe that $\theta^m \in \Omega^m(J^1E, \pi^{1*}V^m(\pi))$ and that $\theta^m \neq \overbrace{\theta \wedge \cdots \wedge \theta}^{m}$.

Now we can state the following.

Proposition 4: Let $X \in \mathcal{X}^m(J^1E)$ *be* $\overline{\pi^1}$*-transverse and locally decomposable. Then the following conditions are equivalent.*

1. *X is a SOPDE.*
2. $i(\theta^m)X = 0$.
3. $i(\theta)X = 0$.
4. $(W; x^\mu, y^A, v^A_\mu)$ *is a natural chart in* J^1E, *then the local expression of X* is

$$X \equiv \bigwedge_{\mu=1}^{m} X_\mu = \bigwedge_{\mu=1}^{m} f_\mu \left(\frac{\partial}{\partial x^\mu} + v^A_\mu \frac{\partial}{\partial y^A} + G^A_{\mu\rho} \frac{\partial}{\partial v^A_\rho} \right), \tag{7}$$

where f_μ *are nonvanishing functions.*

5. $i(\alpha)X = 0$, *for every* $\alpha \in \mathcal{M}_c$; *where* $\mathcal{M}_c$ *denotes the contact module* in J^1E *(see the Appendix).*

Proof: Let $(W; x^\mu, y^A, v^A_\mu)$ be a natural chart in J^1E. Suppose that $X \in \mathcal{X}^m(J^1E)$ is $\overline{\pi^1}$-transverse and locally decomposable; then in this chart we have

$$X = \bigwedge_{\mu=1}^{m} f_\mu \left(\frac{\partial}{\partial x^\mu} + F^A_\mu \frac{\partial}{\partial y^A} + G^A_{\mu\rho} \frac{\partial}{\partial v^A_\rho} \right),$$

with f_μ nonvanishing functions:

$(1 \Leftrightarrow 2)$ It is obvious.

$(2 \Leftrightarrow 4)$ If $\overline{y} \in U \subset J^1E$ and $\phi \in \overline{y}$, then

$$\begin{aligned}(\theta^m(X))(\overline{y}) &= (\Lambda^m T_{\overline{y}}\overline{\pi}^1 - \Lambda^m T_{\overline{y}}(\phi \circ \overline{\pi^1}))(X_{\overline{y}}) \\ &= \bigwedge_{\mu=1}^{m} f_\mu(\overline{y}) \left(\frac{\partial}{\partial x^\mu} + F^A_\mu(\overline{y}) \frac{\partial}{\partial y^A} \right)_y - \bigwedge_{\mu=1}^{m} f_\mu(\overline{y}) \left(\frac{\partial}{\partial x^\mu} + v^A_\mu(\overline{y}) \frac{\partial}{\partial y^A} \right)_y,\end{aligned}$$

therefore $\theta^m(X) = 0 \Leftrightarrow F^A_\mu = v^A_\mu$, for every A, μ,

$(3 \Leftrightarrow 4)$ Since $\theta = (dy^B - v^B_\rho\, dx^\rho) \otimes \dfrac{\partial}{\partial y^B}$, we have that

$$i(\theta)X=\Bigg[f^1(F_1^B-v_1^B)\wedge\bigwedge_{\mu\neq 1} f_\mu\Bigg(\frac{\partial}{\partial x^\mu}+F_\mu^A\frac{\partial}{\partial y^A}+G_{\mu\rho}^A\frac{\partial}{\partial v_\rho^A}\Bigg)$$
$$-f^2(F_2^B-v_2^B)\wedge\bigwedge_{\mu\neq 2} f_\mu\Bigg(\frac{\partial}{\partial x^\mu}+F_\mu^A\frac{\partial}{\partial y^A}+G_{\mu\rho}^A\frac{\partial}{\partial v_\rho^A}\Bigg)+\ \dots\ \Bigg]\otimes\frac{\partial}{\partial y^B};$$

therefore $i(X)\theta=0 \Leftrightarrow F_\mu^A=v_\mu^A$, for every A,μ.

($4 \Leftrightarrow 5$) It is immediate from item 4, and bearing in mind the local expressions given in the Appendix. ■

The relation between integrable, holonomic and SOPDE multivector fields in J^1E is the following.

Theorem 5: *A multivector field $X\in\mathcal{X}^m(J^1E)$ is holonomic if, and only if, it is integrable and SOPDE.*

Proof: Let $\overline{y}\in J^1E$ be and $\psi:M\to J^1E$ an integral section of X at $\overline{y}$, with $\psi(x)=\overline{y}$. For $Z\in\Lambda^m T_xM$ with $Z_x\neq 0$, as ψ is an integral section, there exists $\lambda\in\mathbf{R}$ with $\lambda\neq 0$ such that $\Lambda^m T_x\psi(Z_x)=\lambda X_{\overline{y}}$ and hence

$$(i(\theta)X)(\overline{y})=\frac{1}{\lambda}i(\theta)(\Lambda^m T_x\psi(Z_x))=\frac{1}{\lambda}i(\psi^*\theta)Z_x=0;$$

therefore $i(X)\theta=0 \Leftrightarrow \psi^*\theta=0$, which is the necessary and sufficient condition for ψ to be holonomic (see proposition A in the Appendix). ■

Finally, as a consequence of theorems 3, 4 and 5 we have the following theorem.

Theorem 6: There is a bijective correspondence between the set of orientable jet fields $\mathcal{Y}:J^1E\to J^1J^1E$ (i.e., the set of orientable connections $\boldsymbol{\nabla}$ in $\overline{\pi}^1:J^1E\to M$) and the set of the equivalence classes of locally decomposable and $\overline{\pi}^1$-transverse multivector fields $\{X\}\subset\mathcal{X}^m(J^1E)$. They are characterized by the fact that $\mathcal{D}(\mathcal{Y})=\mathcal{D}(X)$. In addition we have the following.

1. The jet field $\mathcal{Y}$ is integrable if, and only if, so is X, for every $X\in\{X\}$.
2. The jet field $\mathcal{Y}$ is a SOPDE if, and only if, so is X, for every $X\in\{X\}$.
3. The jet field $\mathcal{Y}$ is holonomic if, and only if, so is X, for every $X\in\{X\}$.

If $\mathcal{Y}$ is a SOPDE, then we can choose [see the local expressions (6) and (7)]

$$X\equiv\bigwedge_{\mu=1}^m\Bigg(\frac{\partial}{\partial x^\mu}+v_\mu^A\frac{\partial}{\partial y^A}+G_{\mu\rho}^A\frac{\partial}{\partial v_\rho^A}\Bigg), \tag{8}$$

as a representative multivector field of $\{X\}$. For a SOPDE multivector field or jet field, on the other hand, if a section $j^1\phi=(x^\mu,f^A,\partial f^A/\partial x^\mu)$ has to be an integral section of such a field, the necessary and sufficient condition is that ϕ is the solution of the following system of (second-order) partial differential equations:

$$G_{\nu\rho}^A\Bigg(x^\mu,f^A,\frac{\partial f^A}{\partial x^\mu}\Bigg)=\frac{\partial^2 f^A}{\partial x^\rho\ \partial x^\nu}\,, \tag{9}$$

which justifies the nomenclature. It is important to remark that, since the integrability of a class of multivector fields is equivalent to demanding that the curvature $\mathcal{R}$ of the connection associated with this class vanishes everywhere; the system (9) has solution if, and only if, the following additional system of equations [which arise from the condition (5) for a SOPDE] holds (for every $B,\ \mu,\ \rho,\ \eta$):

$$\begin{aligned}0&=G_{\eta\mu}^B-G_{\mu\eta}^B,\\ 0&=\frac{\partial G_{\eta\rho}^B}{\partial x^\mu}+v_\mu^A\frac{\partial G_{\eta\rho}^B}{\partial y^A}+G_{\mu\gamma}^A\frac{\partial G_{\eta\rho}^B}{\partial v_\gamma^A}-\frac{\partial G_{\mu\rho}^B}{\partial x^\eta}-v_\eta^A\frac{\partial G_{\mu\rho}^B}{\partial y^A}-G_{\eta\gamma}^A\frac{\partial G_{\mu\rho}^B}{\partial v_\gamma^A}\,.\end{aligned} \tag{10}$$

Observe that this is a system of $\frac{1}{2}Nm(m-1)$ linear relations (the first group of equations) and $\frac{1}{2}Nm^2(m-1)$ partial differential equations (the second group).

III. APPLICATION TO LAGRANGIAN CLASSICAL FIELD THEORIES

At this point, our goal is to show that the Lagrangian formalism for field theories can also be established using jet fields in J^1J^1E, their associated connections in J^1E or, equivalently, multivector fields in J^1E. Then, we use multivector fields for discussing the main features of the evolution equations.

A. Background on Lagrangian field theories

Henceforth we assume that M is an m-dimensional oriented manifold and $\omega \in \Omega^m(M)$ is the volume m-form on M.

A *classical field theory* is described by its *configuration bundle* $\pi: E \to M$ (where M is an oriented manifold with volume form ω), and a *Lagrangian density* which is a $\overline{\pi^1}$-semibasic m-form on J^1E. A Lagrangian density is usually written as $\mathcal{L} = \pounds(\overline{\pi^1}^* \omega)$, where $\pounds \in C^\infty(J^1E)$ is the *Lagrangian function* associated with $\mathcal{L}$ and ω. In a natural system of coordinates this expression is $\mathcal{L} = \pounds(x^\mu, y^A, v^A_\mu) dx^1 \wedge \cdots \wedge dx^m$. Then a *Lagrangian system* is a couple $((E,M;\pi),\mathcal{L})$. The states of the field are the sections of π which are critical for the functional,

$$\begin{aligned} \mathbf{L} \quad : \quad & \Gamma_c(M,E) \to \mathbf{R}, \\ & \phi \quad \to \int_M (j^1\phi)^* \mathcal{L}, \end{aligned}$$

where $\Gamma_c(M,E)$ is the set of compact supported sections of π.

In order to characterize these critical sections, and using the *vertical endomorphism* $\mathcal{V}$ of the bundle J^1E (see the Appendix), we construct the differentiable forms

$$\Theta_{\mathcal{L}} := i(\mathcal{V})\mathcal{L} + \mathcal{L} \in \Omega^m(J^1E) \; ; \quad \Omega_{\mathcal{L}} := -d\Theta_{\mathcal{L}} \in \Omega^{m+1}(J^1E),$$

which are called the *Poincaré–Cartan m* and $(m+1)$-forms associated with the Lagrangian density $\mathcal{L}$. The Lagrangian system is said to be *regular* iff $\Omega_{\mathcal{L}}$ is 1-nondegenerate and, as a consequence, $(J^1E, \Omega_{\mathcal{L}})$ is a multisymplectic manifold.[10]

In a natural chart (x^μ, y^A, v^A_μ) in J^1E, the expressions of the above forms are

$$\begin{aligned} \Theta_{\mathcal{L}} &= \frac{\partial \pounds}{\partial v^A_\mu} dy^A \wedge d^{m-1}x_\mu - \left(\frac{\partial \pounds}{\partial v^A_\mu} v^A_\mu - \pounds \right) d^m x, \\ \Omega_{\mathcal{L}} &= -\frac{\partial^2 \pounds}{\partial v^B_\nu \, \partial v^A_\mu} dv^B_\nu \wedge dy^A \wedge d^{m-1}x_\mu - \frac{\partial^2 \pounds}{\partial y^B \, \partial v^A_\mu} dy^B \wedge dy^A \wedge d^{m-1}x_\mu \\ &\quad + \frac{\partial^2 \pounds}{\partial v^B_\nu \, \partial v^A_\mu} v^A_\mu dv^B_\nu \wedge d^m x + \left(\frac{\partial^2 \pounds}{\partial y^B \, \partial v^A_\mu} v^A_\mu - \frac{\partial \pounds}{\partial y^B} + \frac{\partial^2 \pounds}{\partial x^\mu \, \partial v^B_\mu} \right) dy^B \wedge d^m x \end{aligned} \tag{11}$$

[where $d^{m-1}x_\mu \equiv i(\partial/\partial x^\mu) d^m x$] and the condition of regularity is equivalent to demanding that $\det(\partial^2 \pounds / \partial v^A_\mu \partial v^B_\nu)(\overline{y}) \neq 0$, for every $\overline{y} \in J^1E$.

Then, the (compact-supported) critical sections $\phi: M \to E$ of the variational problem can be characterized as follows.

Proposition 5: Let $((E,M;\pi),\mathcal{L})$ *be a Lagrangian system. The critical sections of the variational problem posed by* $\mathcal{L}$ *are those which satisfy the following equivalent conditions.*

1. $d/dt|_{t=0} \int_M (j^1\phi_t)^* \mathcal{L} = 0$, being $\phi_t = \tau_t \circ \phi$, *where* $\{\tau_t\}$ *is a local one-parameter group of any* π*-vertical and compact supported vector field* $Z \in \mathcal{X}(E)$.
2. $(j^1\phi)^* i(X)\Omega_{\mathcal{L}} = 0$, *for every* $X \in \mathcal{X}(J^1E)$.
3. *The local components of* ϕ *satisfy the Euler–Lagrange equations*:

$$\left(\frac{\partial \pounds}{\partial y^A}\right)_{j^1\phi} - \frac{\partial}{\partial x^\mu}\left(\frac{\partial \pounds}{\partial v^A_\mu}\right)_{j^1\phi} = 0.$$

(See, for instance, Ref. 4 for the proof, and also Refs. 1, 5, 8, 9 as complementary references on all these topics.)

B. The evolution equations in terms of connections and multivector fields

As is well known, the evolution equations in analytical mechanics can be written in a geometric–algebraic manner using vector fields, and then the solutions of the variational problem can be obtained as integral curves of these vector fields. Now we wish to do the same with the evolution equations of field theories, using jet fields (connections) and their equivalent multivector fields, and then obtaining the critical sections as integral sections of these elements.

As a previous step, we must define the action of jet fields on differential forms (see Ref. 4).

Let $\mathcal{Y}: J^1E \to J^1J^1E$ be a jet field. A map $\overline{\mathcal{Y}}: \mathcal{X}(M) \to \mathcal{X}(J^1E)$ can be defined in the following way: let $Z \in \mathcal{X}(M)$, then $\overline{\mathcal{Y}}(Z) \in \mathcal{X}(J^1E)$ is the vector field defined as

$$\overline{\mathcal{Y}}(Z)(\overline{y}) := (T_{\overline{\pi}^1(\overline{y})}\psi)(Z_{\overline{\pi}^1(\overline{y})}),$$

for every $\overline{y} \in J^1E$ and $\psi \in \mathcal{Y}(\overline{y})$. This map is an element of $\Omega^1(M) \otimes_M \mathcal{X}(J^1E)$ and its local expression is

$$\overline{\mathcal{Y}}\left(f^\mu \frac{\partial}{\partial x^\mu}\right) = f^\mu\left(\frac{\partial}{\partial x^\mu} + F^A_\mu \frac{\partial}{\partial y^A} + G^A_{\rho\mu}\frac{\partial}{\partial v^A_\rho}\right).$$

This map induces an action of $\mathcal{Y}$ on $\Omega(J^1E)$. In fact, let $\xi \in \Omega^{m+j}(J^1E)$, and with $j \geqslant 0$, we define $i(\mathcal{Y})\xi: \mathcal{X}(M) \times \overset{(m)}{\ldots} \times \mathcal{X}(M) \to \Omega^j(J^1E)$ given by

$$((i(\mathcal{Y})\xi)(Z_1, \ldots, Z_m))(\overline{y}; X_1, \ldots, X_j) := \xi(\overline{y}; \overline{\mathcal{Y}}(Z_1), \ldots, \overline{\mathcal{Y}}(Z_m), X_1, \ldots, X_j),$$

for $Z_1, \ldots, Z_m \in \mathcal{X}(M)$ and $X_1, \ldots, X_j \in \mathcal{X}(J^1E)$. This is a $C^\infty(M)$-linear and alternate map on the vector fields $Z_1, \ldots, Z_m$. This map $i(\mathcal{Y})\xi$ so-defined, extended by zero to forms of degree $p < m$, is called the *inner contraction* of the jet field $\mathcal{Y}$ and the differential form ξ.

The following result characterizes the action of integrable jet fields on forms (see Ref. 4 for the proof).

Proposition 6: Let $\mathcal{Y}$ be an integrable jet field and $\xi \in \Omega^p(J^1E)$ with $p \geqslant m$. The necessary and sufficient condition for the integral sections of $\mathcal{Y}$, $\psi: M \to J^1E$, to verify the relation $\psi^* i(X)\xi = 0$, for every $X \in \mathcal{X}(J^1E)$, is $i(\mathcal{Y})\xi = 0$.

At this point the following theorem gives the characterization of the critical sections of a Lagrangian field theory in terms of connections (jet fields) and multivector fields.

Theorem 7: *Let $((E, M; \pi), \mathcal{L})$ be a Lagrangian system. The critical sections of the variational problem posed by $\mathcal{L}$ satisfy the following equivalent conditions.*

1. *They are the integral sections of a holonomic jet field $\mathcal{Y}_\mathcal{L}: J^1E \to J^1J^1E$, such that*

$$i(\mathcal{Y}_\mathcal{L})\Omega_\mathcal{L} = 0.$$

2. *They are the integral sections of a holonomic jet field $\mathcal{Y}_\mathcal{L}: J^1E \to J^1J^1E$, such that*

$$i(\mathbf{\nabla}_\mathcal{L})\Omega_\mathcal{L} = (m-1)\Omega_\mathcal{L},$$

   where $\mathbf{\nabla}_\mathcal{L}$ is the associated connection form.

3. *They are the integral sections of a class of holonomic multivector fields $\{X_\mathcal{L}\} \subset \mathcal{X}^m(J^1E)$, such that*

$$i(X_\mathcal{L})\Omega_\mathcal{L} = 0.$$

Proof: These results are consequences of all the above results. In particular, the following holds.

1. It follows from the second item in proposition 5 and proposition 6.
2. See Refs. 13 and 9 for this proof.
3. It is a consequence of the first item and theorem 6.

■

The conditions in this theorem are the version of the Euler–Lagrange equations in terms of jet fields, connection forms and multivector fields, respectively.

C. Analysis of the evolution equations for regular Lagrangians

Using these formulations and, in particular, the multivector fields formalism, it is possible to explore some important properties of the evolution equations in field theories, specifically the existence and multiplicity of solutions. As a first situation, we can consider the case of regular Lagrangian systems.

First, let us recall that the equivalent problem in (time-dependent) mechanics consists in finding vector fields $X_{\mathcal{L}} \in \mathcal{X}(TQ \times \mathbf{R})$ [where TQ is the velocity phase space of the system), such that they verify the dynamical equation $i(X_{\mathcal{L}})\Omega_{\mathcal{L}} = 0$, and they are holonomic vector fields [their integral curves are canonical lifting of curves in Q; that is, sections of the projection $Q \times \mathbf{R} \to \mathbf{R}$]. In this case, the regularity of the Lagrangian function assures the existence and uniqueness of a holonomic vector field which is the solution of the intrinsic equation of motion, with the additional condition $i(X_{\mathcal{L}})dt = 1$.

In field theories we search for (classes of) nonvanishing and locally decomposable multivector fields $X_{\mathcal{L}} \in \mathcal{X}^m(J^1E)$ such that the following occurs.

$$\begin{aligned} &1.\ \text{The equation } i(X_{\mathcal{L}})\Omega_{\mathcal{L}} = 0 \text{ holds.} \\ &2.\ X_{\mathcal{L}} \text{ are SOPDE.} \\ &3.\ X_{\mathcal{L}} \text{ are integrable.} \end{aligned} \tag{12}$$

Remarks:

- If a multivector field satisfies condition 2 and also verifies that $i(X_{\mathcal{L}})(\overline{\pi}^1{}^*\omega) = 1$, then its local expression is (6).
- Let us recall that, if $\{X_{\mathcal{L}}\} \subset \mathcal{X}^m(J^1E)$ is a class of locally decomposable and $\overline{\pi}^1$-transverse multivector fields, then condition 3 is equivalent to demanding that the curvature $\mathcal{R}$ of the connection associated with this class vanishes everywhere.

Following the terminology introduced in Refs. 13 and 14 for connections, we define the following.

Definition 13: $X_{\mathcal{L}} \in \mathcal{X}^m(J^1E)$ is said to be an Euler–Lagrange multivector field *for $\mathcal{L}$ iff it is locally decomposable and verifies conditions 1 and 2 of definition 12.*

Regularity of Lagrangians assures the existence of Euler–Lagrange multivector fields (or connections). In fact we have the following.

Theorem 8: (Existence and local multiplicity of Euler–Lagrange solutions). *Let $((E,M;\pi),\mathcal{L})$ be a regular Lagrangian system.*

1. *There exist classes of locally decomposable and $\overline{\pi}^1$-transverse multivector fields $\{X_{\mathcal{L}}\} \subset \mathcal{X}^m(J^1E)$ (and hence equivalent jet fields $\mathcal{Y}_{\mathcal{L}} : J^1E \to J^1J^1E$ with associated connection forms $\boldsymbol{\nabla}_{\mathcal{L}}$), such that*
2. *(a) the following equivalent conditions hold:*

$$i(X_{\mathcal{L}})\Omega_{\mathcal{L}} = 0\,, \quad i(\mathcal{Y}_{\mathcal{L}})\Omega_{\mathcal{L}} = 0\,, \quad i(\boldsymbol{\nabla}_{\mathcal{L}})\Omega_{\mathcal{L}} = (m-1)\Omega_{\mathcal{L}}\,. \tag{13}$$

(b) $X_{\mathcal{L}} \in \{X_{\mathcal{L}}\}$ are SOPDE (and therefore so is the corresponding $\mathcal{Y}_{\mathcal{L}}$).

In a local system the above solutions depend on $N(m^2-1)$ arbitrary functions.

Proof: In order to prove this, we use the multivector field formalism (for another proof of these statements using the Ehresmann connection formalism see Refs. 13 and 14).

1. First we analyze the local existence of solutions and then their global extension.

In a chart of natural coordinates in J^1E, the expression of $\Omega_{\mathcal{L}}$ is (11), and taking the multi-

vector field given in (6) as the representative of the class $\{X_{\mathcal{L}}\}$, from the relation $i(X_{\mathcal{L}})\Omega_{\mathcal{L}}=0$ we obtain the following conditions.

• The coefficients on dv^A_μ must vanish:

$$0=(F^B_\mu-v^B_\mu)\frac{\partial^2 \pounds}{\partial v^A_\nu\ \partial v^B_\mu} \quad (\text{for every } B,\nu). \tag{14}$$

But, if $\mathcal{L}$ is regular, the matrix $(\partial^2\pounds/\partial v^A_\nu\ \partial v^B_\mu)$ is regular. Therefore $F^B_\mu=v^B_\mu$ (for every B,μ); which proves that if $X_{\mathcal{L}}$ exists it is a SOPDE.

• The coefficients on dy^A must vanish:

$$0=\frac{\partial \pounds}{\partial y^A}-\frac{\partial^2 \pounds}{\partial x^\mu\ \partial v^A_\mu}-\frac{\partial^2 \pounds}{\partial y^B\ \partial v^A_\mu}F^B_\mu-\frac{\partial^2 \pounds}{\partial v^B_\nu\ \partial v^A_\mu}G^B_{\nu\mu}+\frac{\partial^2 \pounds}{\partial y^A\ \partial v^B_\mu}(F^B_\mu-v^B_\mu) \quad (A,B=1,\dots,N), \tag{15}$$

and taking into account that we have obtained $F^B_\mu=v^B_\mu$, these relations lead to

$$\frac{\partial^2 \pounds}{\partial v^B_\nu\ \partial v^A_\mu}G^B_{\nu\mu}=\frac{\partial \pounds}{\partial y^A}-\frac{\partial^2 \pounds}{\partial x^\mu\ \partial v^A_\mu}-\frac{\partial^2 \pounds}{\partial y^B\ \partial v^A_\mu}v^B_\mu \quad (A,B=1,\dots,N), \tag{16}$$

which is a system of N linear equations on the functions $G^B_{\nu\mu}$. This is a compatible system as a consequence of the regularity of $\mathcal{L}$, since the matrix of the coefficients has (constant) rank equal to N (observe that the matrix of this system is obtained as a rearrangement of rows of the Hessian matrix).

• Finally, from the above conditions, we obtain that the coefficients on dx^μ vanish identically.

These results allow us to assure the local existence of (classes of) multivector fields satisfying the desired conditions. The corresponding global solutions are then obtained using a partition of unity subordinated to a covering of J^1E made of local natural charts.

[Observe that, if $j^1\phi=(x^\mu,f^A,\partial f^A/\partial x^\mu)$ is an integral section of $X_{\mathcal{L}}$, then $v^A_\mu=\partial f^A/\partial x^\mu$ and $G^A_{\nu\mu}=\partial^2 f^A/\partial x^\nu\ \partial x^\mu$, and therefore Eqs. (16) are the Euler–Lagrange equations for the section ϕ.]

2. In a chart of natural coordinates in J^1E, the expression of a SOPDE multivector field $X_{\mathcal{L}}\in\{X_{\mathcal{L}}\}$ is given by (8). So, it is determined by the Nm^2 coefficients $G^B_{\nu\mu}$, which are related by the N independent equations (16). Therefore, there are $N(m^2-1)$ arbitrary functions.

■

Comments:

- If, in addition, $\{X_{\mathcal{L}}\}$ is integrable; then every $X_{\mathcal{L}}\in\{X_{\mathcal{L}}\}$ is a holonomic multivector field (and, therefore, $\mathcal{Y}_{\mathcal{L}}$ is also a holonomic jet field).
- As additional conditions on the functions $G^A_{\rho\mu}$ must be imposed in order to assure that $X_{\mathcal{L}}$ is integrable; hence the number of arbitrary functions will be in general less than $N(m^2-1)$.

The last problem consists in studying if it is possible to find a class of integrable Euler–Lagrange multivector fields. This question is posed in the following terms: taking the suitable representatives in each class, the set of Euler–Lagrange multivector fields $X_{\mathcal{L}}$ can be locally written in the form (8), where the coefficients $G^A_{\mu\nu}$ verify Eqs. (16). This is a linear system and, then, if $\mathcal{G}^A_{\mu\nu}$ is a particular solution of this system, we can write

$$X_{\mathcal{L}}=\bigwedge_{\mu=1}^{m}\left(\frac{\partial}{\partial x^\mu}+v^A_\mu\frac{\partial}{\partial y^A}+\mathcal{G}^B_{\mu\gamma}\frac{\partial}{\partial v^B_\gamma}+g^C_{\mu\eta}\frac{\partial}{\partial v^C_\eta}\right),$$

where $g^C_{\eta\mu}$ satisfy the homogeneous linear system,

$$\frac{\partial^2 \pounds}{\partial v^C_\eta\ \partial v^A_\mu}g^C_{\eta\mu}=0 \quad (A=1,\dots,N).$$

As the problem now is to select the integrable Euler–Lagrange multivector fields, from the solutions of this system we can choose those that make the corresponding multivector field $X_{\mathcal{L}}$ verify the integrability condition; that is, the curvature of the associated connection $\nabla_{\mathcal{L}}$ vanishes [Eqs. (10)].

As far as we know, since we have a system of partial differential equations with linear restrictions, there is no way for assuring the existence of an integrable solution, or how to select it; observe that, considering the Euler–Lagrange equations for the coefficients $G^A_{\mu\nu}$ [Eqs. (16)], together with the integrability conditions [Eqs. (10)], we have $N+\frac{1}{2}Nm(m-1)$ linear equations and $\frac{1}{2}Nm^2(m-1)$ partial differential equations. Then, if the set of linear restrictions [made of the Eqs. (16) and the first group of Eqs. (10)] allow us to isolate $N+\frac{1}{2}Nm(m-1)$ coefficients $G^A_{\mu\nu}$ as functions on the remaining ones; and the set of $\frac{1}{2}Nm^2(m-1)$ partial differential equations [the second group of equations (10)] on these remaining coefficients satisfies the conditions on the *Cauchy–Kowalewska theorem*,[23] then the existence of integrable Euler–Lagrange multivector fields is assured (see the example in Sec. III F).

On the other hand, if we can eventually select some particular Euler–Lagrange multivector field solution, then the integrability algorithm developed in Sec. II B can be applied in order to find a submanifold where this multivector field is integrable (if it exists).

D. Discussion on the evolution equations for singular Lagrangian field theories

Next we discuss the case of singular Lagrangian systems ($\Omega_{\mathcal{L}}$ is 1-degenerate). As in the regular case, the existence of multivector fields (or connections) verifying conditions (12) is not assured. The difference with the regular case lies in the following facts.

1. A locally decomposable and $\overline{\pi^1}$-transverse multivector field $X\in\mathcal{X}^m(J^1E)$ verifying condition 1 on J^1E (the evolution equation) does not necessarily exist.
2. If such a multivector field exists, it does not necessarily hold condition 2 (the SOPDE condition).

As in the regular case, the existence of Euler–Lagrange multivector fields does not imply their integrability. Nevertheless, it is possible for these integrable multivector fields to exist on a submanifold of J^1E. So we can state the following problem: to look for a submanifold $S\hookrightarrow J^1E$ where integrable Euler–Lagrange multivector fields $X_{\mathcal{L}}\in\mathcal{X}^m(J^1E)$ exist; and then their integral sections are contained in S. Observe that these conditions imply that $\overline{\pi^1}|_S:S\to M$ is onto on M, because $X_{\mathcal{L}}$ is SOPDE.

As a first step, we do not consider the integrability condition. [In this way, the situation is quite analogous to that in (time-dependent) mechanics.[24,25]]

The procedure is algorithmic (from now on we suppose that all the multivector fields are locally decomposable).

- First, let S_1 be the set of points of J^1E where Euler–Lagrange multivector fields do exist; that is,

$$S_1:=\left\{\overline{y}\in J^1E;\ \exists X_{\mathcal{L}}\in\mathcal{X}^m(J^1E)\ \text{ such that }\left\{\begin{array}{c}(i(X_{\mathcal{L}})\Omega_{\mathcal{L}})(\overline{y})=0\\(i(X_{\mathcal{L}})(\overline{\pi^1}{}^*\omega))(\overline{y})=1\\X_{\mathcal{L}}\ \text{is a SOPDE at}\ \overline{y}\end{array}\right\}\right\}.$$

We assume that S_1 is a nonempty (closed) submanifold of J^1E.

This is the *compatibility condition*.

- Now, denote by $\mathcal{X}^m_{\mathcal{L}}(J^1E,S_1)$ the set of multivector fields in J^1E which are Euler–Lagrange on S_1. Let $X_{\mathcal{L}}:S_1\to\Lambda^m TJ^1E|_{S_1}$ be in $\mathcal{X}^m_{\mathcal{L}}(J^1E,S_1)$. If, in addition, $X_{\mathcal{L}}:S_1\to\Lambda^m TS_1$; that is, $X_{\mathcal{L}}\in\mathcal{X}^m(S_1)$, then we say that $X_{\mathcal{L}}$ is a solution on S_1. Nevertheless, this last condition is not assured except perhaps in a set of points $S_2\subset S_1\subset J^1E$, which we will assume to be a (closed) submanifold, and which is defined by

$$S_2:=\{\overline{y}\in S_1;\ \exists X_{\mathcal{L}}\in\mathcal{X}^m_{\mathcal{L}}(J^1E,S_1)\ \text{ such that }\ X_{\mathcal{L}}(\overline{y})\in\Lambda^m T_{\overline{y}}S_1\}.$$

This is the so-called *consistency* or *tangency condition*.

- In this way, a sequence of (closed) submanifolds, $\ldots \subset S_i \subset \cdots \subset S_1 \subset J^1E$, is assumed to be obtained, each one of them being defined as

$$S_i := \{\overline{y} \in S_{i-1};\ \exists X_{\mathcal{L}} \in \mathcal{X}^m_{\mathcal{L}}(J^1E, S_{i-1}) \ \text{ such that } \ X_{\mathcal{L}}(\overline{y}) \in \Lambda^m T_{\overline{y}} S_{i-1}\}.$$

It is important to point out that, for every submanifold S_i of this sequence, $\overline{\pi}^1|_{S_i}: S_i \to M$ must be on M.

- There are two possible options for the final step of this algorithm, namely the following.

1. The algorithm ends by giving a submanifold $S_f \hookrightarrow J^1E$, with $\dim S_f \geqslant m$ (where $S_f = \cap_{i \geqslant 1} S_i$) and Euler–Lagrange multivector fields $X_{\mathcal{L}} \in \mathcal{X}^m(S_f)$. S_f is then called the *final constraint submanifold*.
2. The algorithm ends by giving a submanifold S_f with $\dim S_f < m$, or the empty set. Then there is no Euler–Lagrange multivector fields $X_{\mathcal{L}} \in \mathcal{X}^m(S_f)$. In this case the Lagrangian system has no solution.

Comment:

The problem considered here can also be treated in an alternative manner by splitting the procedure into two steps (see Ref. 13 for a more detailed discussion on this method, using Ehresmann connections).

1. First, searching for a submanifold P_f of J^1E and locally decomposable multivector fields $X_{\mathcal{L}} \in \mathcal{X}^m(J^1E)$, such that

(a) $(i(X_{\mathcal{L}})\Omega_{\mathcal{L}})|_{P_f} = 0$.

(b) $(i(X_{\mathcal{L}})(\overline{\pi}^{1*}\omega))|_{P_f} = 1$.

(c) $X_{\mathcal{L}}: P_f \to \Lambda^m T P_f$.

This procedure is called the *constraint algorithm*.

2. Second, searching for a submanifold S_f of P_f and locally decomposable multivector fields $X_{\mathcal{L}} \in \mathcal{X}^m(J^1E)$, such that

(a) $(i(X_{\mathcal{L}})\Omega_{\mathcal{L}})|_{S_f} = 0$.

(b) $X_{\mathcal{L}}$ is a SOPDE on S_f.

(c) $X_{\mathcal{L}}: S_f \to \Lambda^m T S_f$.

It is then clear that, in some particular cases, locally decomposable and $\overline{\pi}^1$-transverse multivector fields, solutions of the evolution equations on some submanifold P_f, can exist, but none of them being SOPDE at any point belonging to P_f.

The local treatment of the singular case shows significant differences to the regular one. In fact, although the starting equations are the same in both cases [Eqs. (14) and (15)]; since the matrix $(\partial^2 \pounds / \partial v^A_\nu \, \partial v^B_\mu)$ is not regular, the first group does not imply the SOPDE condition. Nevertheless, we can impose this condition by making $F^A_\mu = v^A_\mu$, for every A, μ. Therefore, we have the system of equations for the coefficients $G^A_{\mu\nu}$ which is (16) again. As we have stated, this system is not compatible in general, and S_1 is the closed submanifold where the system is compatible. Then, there are Euler–Lagrange multivector fields on S_1, but the number of arbitrary functions on which they depend is not the same as in the regular case, since it depends on the dimension of S_1 and the rank of the Hessian matrix of $\pounds$. Now the tangency condition must be analyzed in the same way as in the algorithm of Sec. II B.

Finally, the question of integrability must be considered. We make the same remarks as at the end of the above section, but for the submanifold S_f instead of J^1E.

E. Noether's theorem for multivector fields

Next we recover the idea of *conserved quantity* and state Noether's theorem in terms of multivector fields. First we need a previous lemma.

Lemma 1: Let $Y \in \mathcal{X}^m(J^1E)$ be a holonomic multivector field. If $\zeta \in \Omega^m(J^1E)$ belongs to the ideal generated by the contact module [this ideal is denoted $\mathcal{I}(\mathcal{M}_c)$], then $i(Y)\zeta = 0$.

Proof: Consider $\overline{y}\in J^1E$, with $\overline{\pi}^1(\overline{y})=x$, and a section $\phi:M\to E$ such that $j^1\phi$ is an integral section of Y passing through $\overline{y}$; that is $j^1\phi(x)=\overline{y}$. Then, as Y is SOPDE, there exists $f\in C^\infty(J^1E)$ with

$$(\Lambda^m T_x j^1\phi)\left(\frac{\partial}{\partial x^1}\wedge\cdots\wedge\frac{\partial}{\partial x^m}\right)=(fY)\overline{_{y}},$$

and therefore

$$\begin{aligned}(i(Y)\zeta)(\overline{y})&=(i(Y)\zeta)(j^1\phi(x))\\&=i(Y_{j^1\phi(x)})(\zeta(j^1\phi(x)))\\&=\frac{1}{f(\overline{y})}i\left((\Lambda^m T_x j^1\phi)\left(\frac{\partial}{\partial x^1}\wedge\cdots\wedge\frac{\partial}{\partial x^m}\right)\right)(\zeta(j^1\phi(x)))\\&=\frac{1}{f(\overline{y})}i\left(\frac{\partial}{\partial x^1}\wedge\cdots\wedge\frac{\partial}{\partial x^m}\right)((j^1\phi)^*\zeta)(x))=0,\end{aligned}$$

because ζ belongs to the ideal generated by the contact module and then $(j^1\phi)^*\zeta=0$. ■

Now we are able to prove the following.

Theorem 9 (Noether): *Let $((E,M;\pi),\mathcal{L})$ be a Lagrangian system and $X_{\mathcal{L}}\in\mathcal{X}^m(J^1E)$ an integrable Euler–Lagrange multivector field. Let $X\in\mathcal{X}(J^1E)$ be a vector field satisfying the following conditions.*

1. *X* preserves the contact module: $L(X)\mathcal{M}_c\subset\mathcal{M}_c$.
2. There exist $\xi\in\Omega^{m-1}(J^1E)$, and $\alpha\in\mathcal{I}(\mathcal{M}_c)\cap\Omega^m(J^1E)$ such that $L(X)\mathcal{L}=d\xi+\alpha$.

Then $i(X_{\mathcal{L}})d(\xi-i(X)\Theta_{\mathcal{L}})=0$.

Proof: First we have that

$$L(X)\Theta_{\mathcal{L}}=i(X)d\Theta_{\mathcal{L}}+di(X)\Theta_{\mathcal{L}},$$

however, as $\Theta_{\mathcal{L}}:=i(\mathcal{V})\mathcal{L}+\mathcal{L}\equiv\vartheta_{\mathcal{L}}+\mathcal{L}$,

$$L(X)\Theta_{\mathcal{L}}=L(X)(\vartheta_{\mathcal{L}}+\mathcal{L})=L(X)\vartheta_{\mathcal{L}}+d\xi+\alpha\ ,$$

and $L(X)\vartheta_{\mathcal{L}}\in\mathcal{I}(\mathcal{M}_c)$, because $\vartheta_{\mathcal{L}}\in\mathcal{I}(\mathcal{M}_c)$. So we obtain

$$i(X)d\Theta_{\mathcal{L}}+di(X)\Theta_{\mathcal{L}}=d\xi+\zeta,$$

with $\zeta=\alpha+L(X)\vartheta_{\mathcal{L}}\in\mathcal{I}(\mathcal{M}_c)$. Then

$$d(\xi-i(X)\Theta_{\mathcal{L}})=i(X)d\Theta_{\mathcal{L}}-\zeta,$$

and therefore

$$i(X_{\mathcal{L}})d(\xi-i(X)\Theta_{\mathcal{L}})=i(X_{\mathcal{L}})i(X)d\Theta_{\mathcal{L}}+i(X_{\mathcal{L}})\zeta=0,$$

since $i(X_{\mathcal{L}})i(X)\Omega_{\mathcal{L}}=0$, for every $X\in\mathcal{X}(J^1E)$, because $X_{\mathcal{L}}$ is a solution of the Euler–Lagrange equations, and $i(X_{\mathcal{L}})\zeta=0$, by the previous lemma. ■

*Definition 14: Let $((E,M;\pi),\mathcal{L})$ be a Lagrangian system. An (*infinitesimal) generalized symmetry *of the Lagrangian system is a vector field $X\in\mathcal{X}(J^1E)$ such that it verifies conditions 1 and 2 of the above theorem.*

In particular, X is said to be an infinitesimal natural symmetry *if it is the canonical prolongation of a vector field $Z\in\mathcal{X}(E)$.*

Remark: As a special case, if $L(X)\mathcal{L}=0$, then $i(X_{\mathcal{L}})di(X)\Theta_{\mathcal{L}}=0$. These are the so-called *symmetries of the Lagrangian*.

An immediate consequence of the above theorem is the following fact: if $\alpha=\xi-i(X)\Theta_{\mathcal{L}} \in \Omega^{m-1}(J^1E)$, then $i(X_{\mathcal{L}})\alpha=0$, and hence, if $J:N\hookrightarrow J^1E$ is an integral submanifold of $X_{\mathcal{L}}$, we have $J^*d\alpha=0$ and then $dJ^*\alpha=0$. But the integral submanifolds of $X_{\mathcal{L}}$ are images of canonical lifting of sections, $j^1\phi:M\to J^1E$; therefore $0=(j^1\phi)^*d\alpha=d(j^1\phi)^*\alpha$; that is the following.

Theorem 10 (Noether): *Let X be an infinitesimal generalized symmetry of the system $((E,M;\pi),\mathcal{L})$. Then, the $(m-1)$-form $\xi-i(X)\Theta_{\mathcal{L}}$ is closed on the critical sections of the variational problem posed by $\mathcal{L}$.*

F. Example

(See also Ref. 26.)

Most of the (quadratic) Lagrangian systems in field theories can be modeled as follows: $\pi:E\to M$ is a trivial bundle (usually $E=M\times\mathbf{R}^N$) and then $\pi^1:J^1E\to E$ is a vector bundle. g is a metric in this vector bundle, Γ is a connection of the projection π^1 and $f\in C^\infty(E)$ is a potential function. Then the Lagrangian function is

$$\pounds(\overline{y})=\tfrac{1}{2}g(\overline{y}-\Gamma(\pi^1(\overline{y})),\overline{y}-\Gamma(\pi^1(\overline{y})))+\pi^{1*}f(\overline{y}),$$

and in natural coordinates takes the form[26]

$$\pounds=\tfrac{1}{2}a^{\mu\nu}_{AB}(y)(v^A_\mu-\Gamma^A_\mu(x))(v^B_\nu-\Gamma^B_\nu(x))+f(y).$$

In order to apply the formalism which has been developed in this work, we consider a model where the matrix of the coefficients $a^{\mu\nu}_{AB}$ is regular and symmetric at every point [that is, $a^{\mu\nu}_{AB}(y)=a^{\nu\mu}_{BA}(y)$]. This fact is equivalent to the nondegeneracy of the metric g.

The associated Poincaré–Cartan $(m+1)$-form is then

$$\begin{aligned}\Omega_{\mathcal{L}}=&-a^{\nu\mu}_{BA}\,dv^B_\nu\wedge dy^A\wedge d^{m-1}x_\mu\\&-\frac{\partial a^{\nu\mu}_{CA}}{\partial y^B}(v^C_\nu-\Gamma^C_\nu)dy^B\wedge dy^A\wedge d^{m-1}x_\mu+a^{\nu\mu}_{BA}v^A_\mu\,dv^B_\nu\wedge d^mx\\&+\left(\frac{\partial a^{\nu\mu}_{CA}}{\partial y^B}(v^C_\nu-\Gamma^C_\nu)v^A_\mu-\frac{\partial a^{\nu\mu}_{CA}}{\partial y^B}(v^C_\nu-\Gamma^C_\nu)-\frac{\partial f}{\partial y^B}-a^{\mu\nu}_{AB}\frac{\partial\Gamma^A_\nu}{\partial x^\mu}\right)dy^B\wedge d^mx,\end{aligned}$$

and the system is obviously regular. Then, taking (8) as the local expression for representatives of the corresponding classes of Euler–Lagrange multivector fields $\{X_{\mathcal{L}}\}\subset\mathcal{X}^m(J^1E)$, their components $G_{\mu\nu}$ are related by Eqs. (16), which in this case are

$$a^{\nu\mu}_{BA}G^B_{\nu\mu}=\frac{1}{2}\frac{\partial a^{\nu\mu}_{CB}}{\partial y^A}(v^C_\nu-\Gamma^C_\nu)(v^B_\mu-\Gamma^B_\mu)+\frac{\partial f}{\partial y^A}+a^{\mu\nu}_{BA}\frac{\partial\Gamma^B_\nu}{\partial x^\mu}-\frac{\partial a^{\nu\mu}_{CA}}{\partial y^B}v^B_\mu(v^C_\nu-\Gamma^C_\nu).\tag{17}$$

This system allows us to isolate N of these components as functions of the remaining $N(m^2-1)$; and then it determines a family of (classes of) Euler–Lagrange multivector fields. In order to obtain an integrable class, the condition of integrability $\mathcal{R}=0$ (where $\mathcal{R}$ is the curvature of the associated connection) must hold; that is, Eqs. (10) must be added to the last system.

A simpler case is obtained when Γ is an integrable connection. Then there exist local natural charts in J^1E such that $\Gamma^A_\mu=0$;[3] and then $\pounds=\frac{1}{2}a^{\mu\nu}_{AB}(y)v^A_\mu v^B_\nu+f(y)$. If, in addition, we consider that the matrix of coefficients is $a^{\mu\nu}_{AB}(y)=\delta_{AB}\delta^{\mu\nu}$ (that is, we take an orthonormal frame for the metric g), then we have that

$$\pounds=\tfrac{1}{2}\,\delta_{AB}\delta^{\mu\nu}v^A_\mu v^B_\nu+f(y).$$

In this case Eqs. (17) reduce to

$$\delta_{BA}\delta^{\nu\mu}G^B_{\nu\mu}=\frac{\partial f}{\partial y^A}\,.$$

From this system we can isolate N of the coefficients $G^A_{\mu\nu}$; for instance, if $\mu,\nu=0,1,\ldots,m-1$, those for which $\mu=\nu=0$: Thus

$$\delta_{AB}G^B_{00}=\frac{\partial f}{\partial y^A}-\sum_{\mu=1}^{m-1}\delta_{AB}G^B_{\mu\mu}.$$

Therefore the Euler–Lagrange multivector fields are

$$X_{\mathcal{L}}=\bigwedge_{\mu=0}^{m-1}\left(\frac{\partial}{\partial x^\mu}+v^A_\mu\frac{\partial}{\partial y^A}+\delta^0_\mu\left[\frac{\partial f}{\partial y^A}-\sum_{\nu=1}^{m-1}\delta_{AB}G^B_{\nu\nu}\right]\frac{\partial}{\partial v^A_0}+\sum_{\mu=\gamma\neq 0}G^B_{\mu\gamma}\frac{\partial}{\partial v^B_\gamma}+\sum_{\mu\neq\gamma}G^C_{\mu\gamma}\frac{\partial}{\partial v^C_\gamma}\right).$$

Now, if we look for integrable Euler–Lagrange multivector fields, the integrability conditions (10) must be imposed.

As a particular case, we can consider this last model with dim $M=2$. Equations (16) are

$$\delta^{BA}\frac{\partial f}{\partial y^A}-G^B_{00}-G^B_{11}=0,$$

and the expression of the Euler–Lagrange multivector fields will then be

$$X_{\mathcal{L}}=\left(\frac{\partial}{\partial x^0}+v^A_0\frac{\partial}{\partial y^A}+G^A_{00}\frac{\partial}{\partial v^A_0}+G^A_{01}\frac{\partial}{\partial v^A_1}\right)$$
$$\wedge\left(\frac{\partial}{\partial x^1}+v^A_1\frac{\partial}{\partial y^A}+G^A_{10}\frac{\partial}{\partial v^A_0}+\left[G^A_{00}-\delta^{AB}\frac{\partial f}{\partial y^B}\right]\frac{\partial}{\partial v^A_1}\right).$$

The integrability conditions (10) are

$$0=G^B_{01}-G^B_{10},$$

$$0=\frac{\partial G^B_{10}}{\partial x^0}+v^A_0\frac{\partial G^B_{10}}{\partial y^A}+G^A_{00}\frac{\partial G^B_{10}}{\partial v^A_0}+G^A_{01}\frac{\partial G^B_{10}}{\partial v^A_1}$$
$$-\frac{\partial G^B_{00}}{\partial x^1}-v^A_1\frac{\partial G^B_{00}}{\partial y^A}-G^A_{10}\frac{\partial G^B_{00}}{\partial v^A_0}-\left(G^A_{00}-\delta^{AC}\frac{\partial f}{\partial y^C}\right)\frac{\partial G^B_{00}}{\partial v^A_1},$$

$$0=\frac{\partial G^B_{00}}{\partial x^0}+v^A_0\frac{\partial G^B_{00}}{\partial y^A}-v^A_0\frac{\partial^2 f}{\partial y^{A2}}+G^A_{00}\frac{\partial G^B_{00}}{\partial v^A_0}+G^A_{01}\frac{\partial G^B_{00}}{\partial v^A_1}$$
$$-\frac{\partial G^B_{01}}{\partial x^1}-v^A_1\frac{\partial G^B_{01}}{\partial y^A}-G^A_{10}\frac{\partial G^B_{01}}{\partial v^A_0}-\left(G^A_{00}-\delta^{AC}\frac{\partial f}{\partial y^C}\right)\frac{\partial G^B_{01}}{\partial v^A_1}.$$

The first relation imposes $G^B_{01}=G^B_{10}$, and then the others are a system of $2N$ partial differential equations on the functions G^B_{00} and G^B_{01}. For this system the hypothesis of the Cauchy–Kowalewska theorem holds,[23] and hence there exist integrable multivector fields solutions of the Euler–Lagrange equations for $\mathcal{L}$.

IV. CONCLUSIONS AND OUTLOOK

We have studied the integrability of multivector fields in a differentiable manifold and the relation between integrable jet fields and multivector fields in jet bundles, using this to give alternative geometric formulations of the Lagrangian formalism of classical field theories (of first order). In particular we have the following.

• We have introduced the notion of *integrable multivector fields* in a manifold E, first proving that every orientable distribution in E is equivalent to a class of *nonvanishing, locally decomposable* multivector fields, and then demanding that this distribution be integrable. The idea of *multiflow* for a certain kind of integrable multivector fields (which we call *dynamical*) is studied, showing in addition that from every class of integrable multivector fields we can select a representative which is dynamical.

In addition, an algorithmic procedure for finding the (maximal) submanifold of E where a locally decomposable multivector field is integrable (if it exists) is also developed.

The results obtained can be summarized in the following table:

$$\begin{array}{ccccc} \text{Integrable} & & \text{Integrable m.v.f.} & & \left\{\begin{array}{l}\left\{\begin{array}{l}\text{Non}-\text{van. m.v.f.}\\ \text{Loc. dec. m.v.f.}\end{array}\right\}(class)\\ \text{Involutive m.v.f. } (class)\end{array}\right. \\ \text{Orientable} & \Leftrightarrow & (class) & \Leftrightarrow & \text{Orientable} \\ \text{distribution} & & \downarrow & & \text{distribution} \\ & & \text{Dynamical m.v.f.} & & \\ & & (representative) & & \end{array}$$

• We have established the relation between integrable jet fields in J^1E and a certain kind of integrable m-multivector fields in E, by proving that every orientable jet field Ψ is equivalent to a class of nonvanishing m-multivector fields $\{Y\}$, and conversely, in such a way that their associated distributions $\mathcal{D}(\Psi)$ and $\mathcal{D}(Y)$ are the same. Of course, in order to make this equivalence consistent, it is necessary for the distribution $\mathcal{D}(Y)$ to be transverse to the projection $\pi: E \to M$. So we have

$$\left.\begin{array}{c}\text{Transverse m.v.f.}\\ \text{Locally decomp. m.v.f.}\end{array}\right\}(class) \Leftrightarrow \text{Orientable j.f.}$$

• We have applied these ideas to prove that every orientable jet field $\mathcal{Y}$ in J^1J^1E is equivalent to a class of locally decomposable and nonvanishing m-multivector fields $\{X\}$ in J^1E, and conversely. In this case, the consistency of this equivalence requires the distribution $\mathcal{D}(X)$ to be transverse to the projection $\overline{\pi}^1: J^1E \to M$.

The integrability and the SOPDE condition for multivector fields in this framework are then discussed, giving several equivalent characterizations for SOPDE multivector fields, which lead finally to establishing the equivalence between classes of holonomic multivector fields and orientable, holonomic jet fields. So we have the following summarizing scheme:

$$\begin{array}{ccccc} \text{Holonomic m.v.f} & & \left\{\begin{array}{l}\left\{\begin{array}{c}\overline{\pi}^1-\text{Transverse m.v.f.}\\ \text{Involutive m.v.f.}\end{array}\right\}(class) \quad \Leftrightarrow \quad \left\{\begin{array}{l}\text{Orientable j.f.}\\ \text{Integrable j.f.}\end{array}\right.\\ \left\{\begin{array}{c}\text{Loc. decom. m.v.f.}\\ \text{SOPDE m.v.f.}\end{array}\right\}(class) \quad \Leftrightarrow \quad \left\{\begin{array}{l}\text{SOPDE j.f.}\\ \text{Orientable j.f.}\end{array}\right.\end{array}\right\} \text{Holonomic} \\ (class) & & & & \text{j.f.} \end{array}$$

• We prove that the evolution equations for first-order classical field theories in the Lagrangian formalism (*Euler–Lagrange equations*) can be written in three equivalent geometric ways: using multivector fields in J^1E, jet fields in J^1J^1E or their associated Ehresmann connections in J^1E. These descriptions allow us to write the evolution equations for field theories in an analogous way to the dynamical equations for (time-dependent) mechanical systems.

• Using the formalism with multivector fields, we show that the evolution equations can have no integrable solutions in J^1E, for neither regular nor singular Lagrangian systems.

In the regular case, Euler–Lagrange multivector fields (that is, SOPDE and the solution of the Lagrangian evolution equations) always exist; but they are not necessarily integrable. In the singular case, not even the existence of such an Euler–Lagrange multivector field is assured. In both cases, the multivector field solution (if it exists) is not unique. These features are significant differences in relation to the analogous situation in mechanics.

• With regard to these facts, for the singular case we outline an algorithmic procedure in order to obtain the submanifold of J^1E where Euler–Lagrange multivector fields exist.

Further research on these latter topics will be carried out in the future.

• A version of Noether's theorem using multivector fields is also proved.

In a forthcoming paper devoted to the Hamiltonian formalism of field theories, we will extend these results to the dual bundle of J^1E.

ACKNOWLEDGMENTS

We wish to thank Mr. Jeff Palmer for his assistance in preparing the English version of the manuscript. We thank Prof. I. V. Kanatchikov for his helpful comments. We are also grateful for the financial support of the CICYT TAP97-0969-C03-01.

APPENDIX: CANONICAL STRUCTURES OF A JET BUNDLE

(Following Ref. 5. See also Ref. 4.)

Consider a first-order jet bundle $J^1E \overset{\pi^1}{\to} E \overset{\pi}{\to} M$. Let $\phi: M \to E$ be a section of π, $x \in M$ and $y = \phi(x)$. The *vertical differential* of the section ϕ at the point $y \in E$ is the map

$$\begin{aligned} d^v_y\phi \quad &: T_yE \to \quad V_y(\pi), \\ &\quad u \ \to u - T_y(\phi \circ \pi)u. \end{aligned}$$

If (x^μ, y^A) is a natural local system of E and $\phi = (x^\mu, \phi^A(x^\mu))$, then

$$d^v_y\phi\left(\frac{\partial}{\partial x^\mu}\right)_y = -\left(\frac{\partial \phi^A}{\partial x^\mu}\right)_y \left(\frac{\partial}{\partial y^A}\right)_y, \quad d^v_y\phi\left(\frac{\partial}{\partial y^A}\right)_y = \left(\frac{\partial}{\partial y^A}\right)_y.$$

Observe that the vertical differential splits T_yE into a vertical component and another which is tangent to the image of ϕ at the point y. In addition, $d^v_y\phi(u)$ is the projection of u on the vertical part of this splitting.

Definition 15: Consider $\overline{y} \in J^1E$ *with* $\overline{y} \overset{\overline{\pi^1}}{\mapsto} y \mapsto {}^{\pi}x$ *and* $\overline{u} \in T_{\overline{y}}J^1E$. *The* structure canonical form *of* J^1E *is a* 1*-form* θ *in* J^1E *with values on* ${\pi^1}^*V(\pi)$ *which is defined by*

$$\theta(\overline{y};\overline{u}) := (d^v_y\phi)(T_{\overline{y}}\pi^1(\overline{u})) = (T_{\overline{y}}\pi^1 - T_{\overline{y}}(\phi \circ \overline{\pi^1}))(\overline{u}),$$

where the section ϕ *is a representative of* $\overline{y}$.

Definition 16: Let θ *be the structure canonical form of* J^1E. *It can be considered as a* $C^\infty(J^1E)$*-linear map* $\theta: \Gamma(J^1E, {\pi^1}^*V(\pi))^* \to \Omega^1(J^1E)$. *The image of this map is called the* contact module *or* Cartan distribution *of* J^1E. *It is denoted by* $\mathcal{M}_c$.

The expression of θ in a natural local system of J^1E is $\theta = (dy^A - v^A_\mu\, dx^\mu) \otimes \partial/\partial y^A$. Then $\mathcal{M}_c$ is generated by the forms $\theta^A = dy^A - v^A_\mu\, dx^\mu$ in this open set.

If $\phi: M \to E$ is a section of π, we denote by $j^1\phi: M \to J^1E$ its canonical prolongation. Then, a section $\psi: M \to J^1E$ is said to be *holonomic* iff $\psi = j^1\phi$, for some ϕ. Holonomic sections can be characterized using the structure canonical form or, equivalently, the contact module, as follows.

Proposition 7: Let $\psi: M \to J^1E$ *be a section of* $\overline{\pi^1}$. *The following assertions are equivalent.*

1. ψ *is a holonomic section.*
2. $\psi^*\theta = 0$.
3. $\psi^*\alpha = 0$, *for every* $\alpha \in \mathcal{M}_c$.

Definition 17: 1. For every $\overline{y} \in J^1E$, *consider the canonical isomorphism,*

$$\mathcal{S}_{\overline{y}}: T^*_{\overline{\pi^1}(\overline{y})}M \otimes V_{\pi^1(\overline{y})}(\pi) \to V_{\overline{y}}(\pi^1),$$

which consists of associating with an element $\alpha \otimes v \in T^*_{\overline{\pi^1}(\overline{y})}M \otimes V_{\pi^1(\overline{y})}(\pi)$ *the directional derivative in* $\overline{y}$ *with respect to* $\alpha \otimes v$. *Taking into account that* $\alpha \otimes v$ *acts in* $J^1_{\overline{y}}E$ *by translation,*

$$\mathcal{S}_{\overline{y}}(\alpha\otimes v):=D_{\alpha\otimes v}(\overline{y}):f\mapsto\lim_{t\to 0}\frac{f(\overline{y}+t(\alpha\otimes v))-f(\overline{y})}{t},$$

for $f\in \mathrm{C}^\infty(J^1_yE)$. *Then we have the following isomorphism of* $C^\infty(J^1E)$*-modules:*

$$\mathcal{S}:\Gamma(J^1E,\overline{\pi^1}^*T^*M)\otimes\Gamma(J^1E,\pi^{1*}V(\pi))\to\Gamma(J^1E,V(\pi^1)),$$

which is called the vertical endomorphism $\mathcal{S}$.

2. *As* $\mathcal{S}\in\Gamma(J^1E,(\pi^{1*}V(\pi))^*)\otimes\Gamma(J^1E,V(\pi^1))\otimes\Gamma(J^1E,\overline{\pi^1}^*TM)$ [*where all the tensor products are on* $\mathrm{C}^\infty(J^1E)$]*; the* vertical endomorphism $\mathcal{V}$ *arises from the natural contraction between the factors* $\Gamma(J^1E,(\pi^{1*}V(\pi))^*)$ *of* $\mathcal{S}$ *and* $\Gamma(J^1E,\pi^{1*}V(\pi))$ *of* θ*; that is*

$$\mathcal{V}=i(\mathcal{S})\theta\in\Omega^1(J^1E)\otimes\Gamma(J^1E,V(\pi^1))\otimes\Gamma(J^1E,\overline{\pi^1}^*TM).$$

If (x^μ,y^A,v^A_μ) is a natural system of coordinates, the local expression of $\mathcal{S}$ and $\mathcal{V}$ are given in this local system by

$$\mathcal{S}=\xi^A\otimes\frac{\partial}{\partial v^A_\mu}\otimes\frac{\partial}{\partial x^\mu};\quad \mathcal{V}=(dy^A-v^A_\mu\,dx^\mu)\otimes\frac{\partial}{\partial v^A_\nu}\otimes\frac{\partial}{\partial x^\nu},$$

where $\{\xi^A\}$ is the local basis of $\Gamma(J^1E,\pi^{1*}V(\pi))^*$ which is dual of $\{\partial/\partial y^A\}$.

(Received 1 December 1997; accepted for publication 5 May 1998)

In this paper we address the problem of the reflection coefficient limit in a periodic stratified structure when the number of periods tends to infinity. We show that the graph of the reflected energy admits a superior envelope and we exhibit an explicit formula. © *1998 American Institute of Physics.* [S0022-2488(98)00809-3]

I. INTRODUCTION

The study of multilayered structures is an old one,[1] and has generated a tremendous amount of literature. Nevertheless it continues to be studied since it is a good laboratory for the general study of periodic structures, e.g., photonic crystals. Besides, modern technology allows its realization and there is a need for theoretical works, for instance, in the optimization of Bragg mirrors. In this paper we address the problem of reflection coefficient behavior when the number of periods tends to infinity. In the very simple case of a symmetric slab, it is known that when the thickness of the slab tends to infinity, the reflection coefficient oscillates and does not converge towards that of a diopter. As could be expected, the same happens for general periodic structure, provided that the concerned wavelength does not belong to a forbidden band. Nevertheless, it is possible to exhibit a weaker result: We show in this paper that when the number of periods tends to infinity, the graph of the reflection coefficient admits a superior envelope, whose explicit expression is derived.

II. SETTING OF THE PROBLEM

We consider in $\mathbb{R}^3$, endowed with a triaxial Cartesian coordinate system $(0,x,y,z)$, a periodic obstacle C, with period h in the x direction (cf. Fig. 1). C is enlightened by a monochromatic plane wave, polarized parallel to (Oz), under the incidence θ

$$\mathbf{U}^i=\exp(ik(x\ \cos\ \theta-y\ \sin(\theta))\exp(-i\omega t))\mathbf{z}, \tag{1}$$

with $k=\omega\sqrt{\varepsilon_0\mu_0}$. C is characterized by its relative permittivity ε, which is assumed to be real and piecewise continuous. The discontinuity points of ε over one period are labeled by $\{x_l\}, l \in\{0,\ldots,p-1\}$. We assume that C is made of N periods. Besides, we set

$$\beta:]0,Nh[\to\mathbb{R}^+ x\mapsto k\sqrt{\varepsilon(x)-\sin^2(\theta)} \tag{2}$$

and $\beta_0=k\ \cos\ \theta$.

Under these conditions, the electromagnetic field is described by a function $U(x)$ and $U(x)\exp(iky\ \sin\ \theta)$ represents the z-component of the electric field (E// polarization), resp. magnetic field (H// polarization). Maxwell equations lead to the following problem, where

$$F=\begin{pmatrix} U \\ p^{-1}\dot{U}\end{pmatrix}\quad 0\leqslant x\leqslant Nh:\frac{dF}{dx}=\begin{pmatrix} 0 & p \\ -p^{-1}\beta^2 & 0\end{pmatrix}F, \tag{3}$$

$$x\leqslant 0:U(x)=\exp(i\beta_0 x)+r_N(k)\exp(-i\beta_0 x), \tag{4}$$

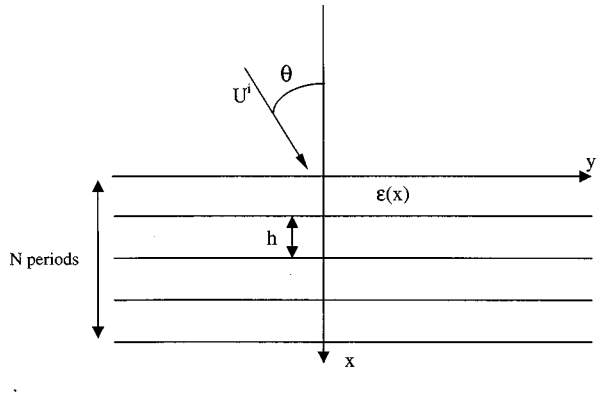

FIG. 1. Scheme of the diffraction problem.

$$x \geqslant Nh: U(x) = t_N(k)\exp(i\beta_0 x),$$

with $p \equiv 1$ for the E// polarization, $p \equiv \varepsilon$ for the H// polarization and $U \in C(\mathbb{R}), p^{-1}\dot{U} \in C(\mathbb{R})$. In order to get a useful representation of the field, we will need the following result.

Lemma 1: There exists $\mathbf{T} = (\mathrm{T}_{ij}) \in C(\mathbb{R}^+, S\mathbb{L}_2(\mathbb{R}))$, *such that* $F((n+1)h) = \mathbf{T}F(nh)$. $\mathbf{T}$ *is called the monodromy matrix of (3).*

Proof: The regularity of ε implies that

$$F = \begin{pmatrix} U \\ p^{-1}\dot{U} \end{pmatrix}$$

verifies an equality of the following type: $F(x_{l+1}) = T_l F(x_l)$ where $T_l \in C(\mathbb{R}^+, S\mathbb{L}_2(\mathbb{R}))$ (cf. Ref. 2). Consequently, the same kind of relation holds for one period; $\mathbf{T}$ is defined by setting

$$\mathbf{T}: \mathbb{R}^+ \to \mathrm{S}\mathbb{L}_2(\mathbb{R}), \quad k \mapsto \prod_{l=0}^{p-1} T_l(k). \tag{5}$$

For the entire structure, we deduce a global relation:

$$\mathbf{T}^N \begin{pmatrix} 1 + r_N(k) \\ i\beta_0(1 - r_N(k)) \end{pmatrix} = t_N(k) \begin{pmatrix} 1 \\ i\beta_0 \end{pmatrix}. \tag{6}$$

We are interested in the behavior of the reflected field when the number of periods tends to infinity. In that case, the relevant quantity seems to be the reflected energy, which is the square modulus of the reflection coefficient. The aim of this paper is, therefore, to study the limit of $R_N := k \mapsto |r_N(k)|^2$ when $N \to +\infty$.

III. STATEMENT OF THE RESULTS

As we are interested in the behavior of the graph of the reflected energy, we use the concept of Γ-convergence, whose meaning is recalled:

Definition 2: *A sequence of functions* (f_N), *defined on a compact subset* Ω *of* $\mathbb{R}$, Γ*-converges towards* f *if, by definition, the two following propositions hold:*

($\star$) $\forall (x_N) \to x$, $liminf\ f_N(x_N) \geqslant f(x)$

($\star\star$) *For all* $x \in \Omega$, *there exists a sequence* (x_N) *verifying* $(x_N) \to k$ *and limsup* $f_N(x_N) \leqslant f(x)$.

Our main result is:

Theorem 3: *(1) We assume that* $\frac{1}{2}|Tr(\mathbf{T})| > 1$, *and we denote by* μ *the eigenvalue of* $\mathbf{T}$ *of smallest modulus.*

When $N \to \infty$ (R_N) *converges pointwise towards 1,* (F_N) *converges pointwise towards* F_∞ *verifying* $\mathbf{T}F_\infty = \mu F_\infty$.

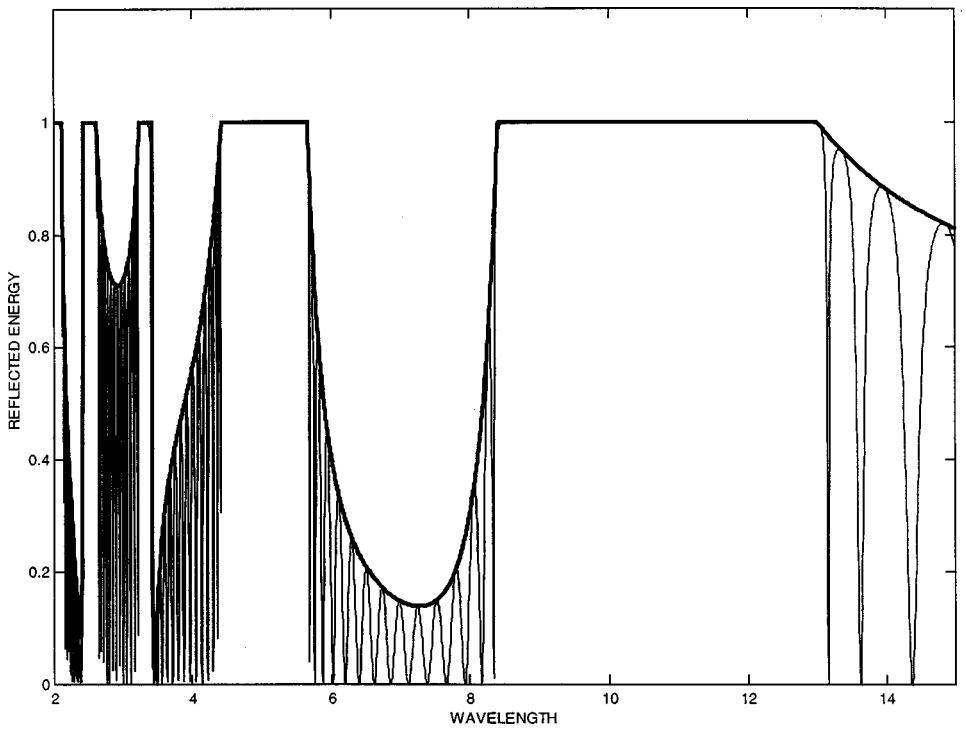

FIG. 2. Reflected energy and gamma-limit for a periodic structure with two layers: $h_1=1$, $h_2=1$,$\varepsilon_1=12.25$, $\varepsilon_2=2.25$. The thick line corresponds to the graph of (8).

(2) We assume that $\frac{1}{2}|Tr(\mathbf{T})|<1$.
When $N\to\infty$, $(1-R_N)$ Γ*-converges towards*

$$k\mapsto(1-\tfrac{1}{4}Tr(\mathbf{T})^2)(\mathrm{T}_{12}\beta_0-\mathrm{T}_{21}\beta_0^{-1})^{-2}. \tag{7}$$

The limit of the superior envelope of the graph of R_N *is, therefore, the graph of:*

$$R_\Gamma : k\mapsto 1-(1-\tfrac{1}{4}Tr(\mathbf{T})^2)(\mathrm{T}_{12}\beta_0-\mathrm{T}_{21}\beta_0^{-1})^{-2}. \tag{8}$$

Numerical Example: We give in Fig. 2 the square modulus of the reflection coefficient of a Bragg mirror (i.e., two layers in one period), with permittivities 12.25 and 2.25 and thicknesses 1 enlightens under normal incidence by a plane wave. The thick line corresponds to the superior limit.

Remark: The case $\frac{1}{2}|Tr(\mathbf{T})|=1$ is a peculiar one, as it may correspond to a transparent medium, i.e., $\mathbf{T}$ is the identity, or to a nondiagonalizable matrix $\mathbf{T}$. Indeed, 1 is then the only eigenvalue. In the first case, (8) admits a discontinuity point, while in the second, R_Γ is equal to 1 and (8) is continuous.

IV. PROOFS

(1) We assume that $\frac{1}{2}|Tr(\mathbf{T})|>1$. The eigenvalues of $\mathbf{T}$ are distinct and real, we denote by μ the smallest one ($|\mu|<1$). $\mathbf{T}$ can be put in diagonal form

$$\mathbf{T}=\mathbf{P}\begin{pmatrix}\mu & 0\\ 0 & \mu^{-1}\end{pmatrix}\mathbf{P}^{-1},\mathbf{P}=\begin{pmatrix}a & c\\ b & d\end{pmatrix}\in S\mathbb{L}_2(\mathbb{R}).$$

Let us denote

$$F_N(0)=\begin{pmatrix}\zeta_N\\ \xi_N\end{pmatrix}.$$

The condition (6) gives

$$\frac{\zeta_N}{\xi_N}=\frac{iac\beta_0\mu^{2N}-iac\beta_0-bc\mu^{2N}+ad}{iad\beta_0\mu^{2N}-ibc\beta_0-bd\mu^{2N}+bd}. \tag{9}$$

Going to the limit, we get: $\lim_{N\to+\infty}\zeta_N/\xi_N=a/b$, which proves that $F_N(0)$ tends towards an eigenvector associated to μ. Moreover, the equalities $\zeta_N=1+r_N, \xi_N=i\beta_0(1-r_N)$ imply that

$$r=\lim_{M\to\infty} r_N=\frac{i\beta_0 a-b}{i\beta_0 a+b}. \tag{10}$$

Finally: $|r|=1$.

(2) We now assume that $\frac{1}{2}|Tr(\mathbf{T})|<1$. We set $\Phi: k\mapsto \arccos(\frac{1}{2}Tr(\mathbf{T}))$.

It can easily be shown (cf. Ref. 3) that

$$\mathbf{T}^N=\begin{pmatrix} T_{11}S_N-S_{N-1} & T_{12}S_N \\ T_{21}S_N & T_{22}S_N-S_{N-1}\end{pmatrix},$$

with $S_N=\sin(N\Phi)\sin(\Phi)^{-1}$. Equation (6) allows us to write: $R_N=1-4f_N$ where

$$\begin{aligned} f_N&: k\mapsto\{4+\sin^2(N\Phi)[g(k)-4]\}^{-1},\\ g&: k\mapsto(T_{12}\beta_0-T_{21}\beta_0^{-1})^2\sin(\Phi)^{-2}.\end{aligned} \tag{11}$$

Our aim is to show the Γ-convergence of (f_N) towards $1/g$, that is, the two following propositions:

($\star$) $\forall(k_N)\to k$, *liminf* $f_N(k_N)\geqslant 1/g(k)$

($\star\star$) *For all* k *such that* $\frac{1}{2}|Tr(\mathbf{T})|<1$, *there exists a sequence* (k_N) *verifying* $(k_N)\to k$ *and limsup* $f_N(k_N)\leqslant 1/g(k)$.

First we note that $R_N\geqslant 0$ implying $g(k)-4\geqslant 0$. As a consequence, we deduce $f_N(k)\geqslant 1/g(k)$, for all k such that $\frac{1}{2}|Tr(\mathbf{T})|<1$. Which proves ($\star$).

For ($\star\star$), we first prove:

Lemma 4: *For* $\Phi\in[0,\pi]$, *there exists* $(\Phi_N)\to\Phi$, *such that* $\sin(N\Phi_N)\to 1$. This lemma is obvious by choosing $\Phi_N=\Phi+(\pi/2-u_N)/(N)$, where $u_N\equiv N\Phi[2\pi]$.

Let us now consider an open interval U verifying: $\forall k\in U, \frac{1}{2}|Tr(\mathbf{T})|<1$ and choose $k_0\in U$. We set $\Phi_0=\Phi(k_0)$ and $V=\Phi(U)$. From the above lemma, there exists $(\Phi_N)\to\Phi_0$ such that $\sin(N\Phi_N)\to 1$. As Φ is continuous, we deduce: $W:=\Phi^{-1}(\{\overline{\Phi_N}\})\cap U\neq\varnothing$ ($\overline{A}$ denotes the closure of the set A). Noticing that $k_0\in\overline{W}$, we conclude that there exists $k_N\to k_0$ such that $f_N(k_N)\to 1/g(k_0)$.

V. CONCLUSION

For a general multilayered periodic structure, we have shown that, when the number of periods tends to infinity, the superior envelope of the reflectivity admits a limit. This result gives a regularization of the reflection coefficient and could be of use for the optimization of such structures.

Black hole thermodynamics and spectral analysis

F. Belgiorno[a)]
Dipartimento di Fisica, Università di Milano, 20133 Milano, Italy

(Received 5 January 1998; accepted for publication 6 April 1998)

We deal with some problems concerning quantum matter fields thermodynamics on static spherosymmetric black hole backgrounds. By means of variable separation, we study the self-adjointness of the Euclidean wave operators relevant in the calculation of the partition function and of the thermal Green functions for the case of scalar quantum fields in thermal equilibrium with a Schwarzschild black hole. In this respect, the role of the horizon surface is analyzed. An approach to this topic, related to completeness of the Euclidean manifold, is also discussed. It is found that, if the horizon surface is not included in the Euclidean manifold (or if it cannot be included, as in the case of a temperature different from the black hole one), essential self-adjointness is missing and boundary conditions on the horizon are required. We also analyze some qualitative spectral properties of the given wave operators after introducing an infrared regularization by means of a spherical box. We find that in the standard Euclidean path integral approach the spectrum is purely discrete. The same analysis is carried out for the noncovariant choice of the functional measure in the Euclidean path integral. An analogous study is carried for an extremal Reissner–Nordström black hole and it is sketched in the nonextremal one. The latter is completely analogous to the Schwarzschild case, whereas in the extremal case it is found that the corresponding Riemannian manifold is complete for every choice of the temperature and that at finite four volume there is a nonvoid continuous spectrum. Physical implications of our results are discussed. © *1998 American Institute of Physics.* [S0022-2488(98)03509-9]

I. INTRODUCTION

In the framework of the Euclidean approach to black hole thermodynamics it is postulated that the partition function for scalar quantum matter fields in thermal equilibrium with a black hole is given by[1]

$$Z=\int_{P(\beta)}[D\phi]\exp(-S[\phi]), \tag{1}$$

where $S[\phi]$ is the classical action for the free field ϕ,

$$S[\phi]=\frac{1}{2}\int d^4x\sqrt{g}\phi(-\Delta+M^2+\xi R)\phi,$$

and Δ is the Laplacian on functions; M is the mass of the field and ξ is an arbitrary coupling constant of the field with the Ricci scalar R. $P(\beta)$ indicates that periodic boundary conditions on the Euclidean time are imposed and $[D\phi]$ is generally chosen to be the covariant functional measure,

$$[D\phi]=\prod_x g(x)^{1/4}\,d\phi(x),$$

where $g(x)\equiv\det(g_{ab}(x))$. In the configuration space, a possible choice for the measure is the noncovariant one:

a)Electronic mail: belgiorno@mi.infn.it

 © 1998 American Institute of Physics

$$[D\phi]_{NC}=\prod_x \sqrt{g^{00}(x)}g(x)^{1/4}\, d\phi(x).$$

This measure is the one, e.g., derived by choosing a Liouville measure in phase space.[2] For the sake of completeness, we will also treat this case, although it is not the standard choice. A criticism about the validity of the noncovariant choice is found in Ref. 3 and a further discussion is given in Ref. 2. In any case, results relative to the noncovariant measure are equivalent to the ones that can be obtained by working on the so called optical manifold, as it will result from the following section.

In (1) one has to specify the background metric and the manifold; a necessary condition in order to give a physical meaning to a partition function is that the metric is stationary or static, unless some adiabatic expansion in the time dependence of the manifold is considered. In the following, we will deal with static spherosymmetric asymptotically flat black hole manifolds. Their metric for the external Euclidean region can be written as

$$ds^2=g_{00}(r)d\tau^2+\frac{1}{g_{00}(r)}dr^2+r^2\, d\Omega^2. \tag{2}$$

The function $g_{00}(r)$ is characterized by one or more zeros, the greatest of which, say r_{bh}, identifies the event horizon. The corresponding manifold (in the above coordinates) is diffeomorphic to $\mathscr{M}=S^1\times(r_{bh},\infty)\times S^2$. Actually, as it is generally accepted, at the Hawking temperature the thermodynamical manifold in the case of the Schwarzschild nondegenerate Killing horizon and for the covariant measure, also encloses the point $r=r_{bh}$, so that the above metric corresponds only to an incomplete chart partially covering the actual thermodynamical manifold $\mathscr{M}_E$. A detailed discussion on this topic is found in Sec. III. A spherical boundary at $r=R>r_{bh}$ is also introduced as a natural infrared regulator necessary in order to obtain finiteness for global quantities like the partition function, free energy, entropy and internal energy. In every case, such a regularization corresponds to a finite four-volume.

In the case of free scalar fields, for the covariant functional measure, equation (1) becomes

$$Z=\frac{1}{\sqrt{\mathrm{Det}(-\Delta+m^2+\xi R)}}, \tag{3}$$

so in the free field case the calculation of the partition function reduces to the calculation of a functional determinant of the wave operator,

$$A\equiv-\Delta+M^2+\xi R.$$

If the noncovariant choice is made, one gets

$$Z=\frac{1}{\sqrt{\mathrm{Det}[g_{00}(-\Delta+m^2+\xi R)]}}; \tag{4}$$

the operator involved in the functional determinant is then[4]

$$A_{NC}\equiv g_{00}A.$$

The operators A and A_{NC} also determine the thermal Green functions.[4]

The zeta function approach is the most useful tool in order to perform partition function calculations, but we will not pursue it in this paper. Our work consists mainly in the analysis of essential self-adjointness and of some qualitative spectral properties of the above wave operators on black hole manifold $\mathscr{M}$ and its relations, if it is possible, with the analysis on $\mathscr{M}_E$. In particular, the role of the horizon is analyzed in relation to the deficiency indices of the wave operators; essential self-adjointness (in the absence of the box) is regarded as a property ensuring that physics, i.e., thermodynamical features of the system, is well defined without any necessity of introducing boundary conditions on the horizon.

We will also discuss the case in which a conical defect γ is present in the manifold (see also Sec. III), i.e., when $\gamma \equiv \beta/\beta_h \neq 1$, where β is the inverse temperature and β_h is the inverse of the Hawking temperature. As usual, the case $\gamma=1$ will be called ''on shell,'' whereas the case $\gamma \neq 1$ will be called ''off shell.'' We recall that, although thermal equilibrium with the black hole can be obtained only at the Hawking temperature, going off shell appears as an intermediate computational tool in some approaches to black hole thermodynamics. For a general discussion on these topics see, e.g., Refs. 5, 6 and references therein.

The results we will obtain will be inferred by the analysis of the partial wave operators (p.w.o.) arising by variable separation on the black hole manifold. Other tools, particularly in the case of qualitative spectral analysis, could be used, but we prefer variable separation as it allows us to treat straightforwardly all cases. Finally, some results about qualitative spectral properties of the p.w.o. we will obtain overlap partially with the ones contained in Ref. 4 as far as the Schwarzschild on shell case is considered.

II. VARIABLE SEPARATION

The minimal domain for the wave operator A is $C_0^\infty(\mathscr{M})$,[7,8] which is dense in $L^2(\mathscr{M}, d^4x\sqrt{g})$. We can write

$$L^2(\mathscr{M}, d^4x\sqrt{g}) = L^2(S^1, d\tau) \otimes L^2(I, dr') \otimes L^2(S^2, d\Omega),$$

where I is the ''radial'' interval and dr' is the suitable measure on it. We denote by K_n the eigenspace corresponding to the eigenvalue n^2, $n \in \mathbb{Z}$ of the operator $-\partial_\tau^2$ with a periodic boundary condition on τ and by S_l the eigenspace corresponding to the eigenvalue $l \in \mathbb{N}$ of the Laplace–Beltrami operator $-\Delta_\Omega$ on S^2; then one gets

$$L^2(S^1, d\tau) \otimes L^2(I, dr') \otimes L^2(S^2, d\Omega) = \sum_{n,l \in \mathbb{N}}^{\oplus} V_{nl},$$

where

$$V_{nl} = L^2(I, dr') \otimes K_n \otimes S_l;$$

cf. also Ref. 9, chapter X, Example 4. The subspaces V_{nl} are reducing subspaces for A. We so obtain the orthogonal decomposition of the operator A in the direct sum of partial wave operators A_{nl} defined by restricting A to $D(A) \cap V_{nl}$; such restrictions will be called the V_{nl}-parts of A. We get

$$A = \sum_{n,l \in \mathbb{N}}^{\oplus} A_{nl} \otimes \mathrm{Id}_n \otimes \mathrm{Id}_l, \tag{5}$$

where $\mathrm{Id}_n, \mathrm{Id}_l$ are the identity operators on K_n, S_l, respectively. The direct sum in (5) is defined on the linear hull $L\{C_0^\infty(I) \otimes K_n \otimes S_l : n,l \in \mathbb{N}\}$ that is also a core for its closure. Moreover, the closures of A restricted to $L\{C_0^\infty(I) \otimes K_n \otimes S_l : n,l \in \mathbb{N}\}$ and of A defined on $C_0^\infty(\mathscr{M})$ are identical.

Indeed, let us consider the closure $\overline{A}$ of A on $C_0^\infty(\mathscr{M})$. We will show that $L\{C_0^\infty(I) \otimes K_n \otimes S_l : n,l \in \mathbb{N}\}$ is a core for $\overline{A}$. It is known[10] that a subspace reduces a closable operator if and only if it reduces its closure; in our case we have an orthogonal decomposition of the whole Hilbert space into the orthogonal sum of reducing subspaces for the operator A and for its closure $\overline{A}$. Then in the latter case, it holds that

$$\overline{A} = \sum_{n,l \in \mathbb{N}}^{\oplus} \overline{A}_{nl} \otimes \mathrm{Id}_n \otimes \mathrm{Id}_l. \tag{6}$$

We recall that, if X is a reducing subspace for a closable (closed) operator A, the X-part of A is closable (closed) and the closure of the X-part of A is the X-part of the closure of A.[10] This means that the closure of the V_{nl}-parts of A coincide with the V_{nl}-parts of $\overline{A}$. Moreover, from the

corollary to theorem 4.4.5 of Ref. 10 one can conclude that the closure of the direct sum (5) of closable operators A_{nl} is the direct sum of the closures $\overline{A_{nl}}$. The thesis then follows from the equality between the closure of the direct sum in (5) and the orthogonal decomposition of $\overline{A}$ in (6).

This means that problems of self-adjointness of the operator A on $C_0^\infty(\mathscr{M})$ are reduced to the analogous problems for the p.w.o., A_{nl}. Particularly, the following relation between the deficiency indices $(N_+(\overline{A}),N_-(\overline{A}))$ of $\overline{A}$ and the ones of the p.w.o. (cf. also Ref. 9, chapter X, Problem 1a) holds:

$$N_+(\overline{A})=\sum_{n,l\in\mathbb{N}} N_+(\overline{A_{nl}})\cdot \dim K_n\cdot \dim S_l,$$
$$N_-(\overline{A})=\sum_{n,l\in\mathbb{N}} N_-(\overline{A_{nl}})\cdot \dim K_n\cdot \dim S_l. \tag{7}$$

We will assume the commutativity of the self-adjoint extension of the wave operator A with the operators $-\partial_\tau^2$ and $-\Delta_\Omega$ in any case in which this property is not automatically given. This means that we will consider only those self-adjoint extensions of A having the same reducing subspaces V_{nl} as A; these extensions are obtained by extending the partial wave operators A_{nl} in $L^2(I,dr')$. Then the relevant spectral problem,

$$A\psi_N=\lambda_N\psi_N,$$

by means of the factorization of the eigenfunctions,

$$\psi(\tau,r,\theta,\phi)=\zeta(r)f(\tau)Y_{lm}(\theta,\phi) \tag{8}$$

[$Y_{lm}(\theta,\phi)$ are the spherical harmonics], becomes a spectral problem for a family of one-dimensional Schrödinger-like operators defined on an interval (the radial one). Indeed, given the suitable domain for A_{nl} to be self-adjoint, the above eigenvalue problem reduces to

$$A_{nl}\zeta_{\alpha nl}=\lambda_{\alpha nl}\zeta_{\alpha nl}. \tag{9}$$

We also recall the following formula, relating the spectrum of the above selected self-adjoint extension of the operator A with the spectrum of the self-adjoint extensions of the p.w.o.:

$$\sigma(A)=\overline{\bigcup_{n,l\in\mathbb{N}}\sigma(A_{nl})}. \tag{10}$$

The noncovariant operator A_{NC} is treated in an analogous way. The only difference is in the Hilbert space measure. Indeed, A_{NC} becomes formally self-adjoint in the Hilbert space $L^2(\mathscr{M},d^4x(\sqrt{g}/g_{00}))$.

We recall also that the following (unitary) transformation[11] on the field $\phi=\overline{\phi}/\sqrt{g_{00}}$ from $L^2(\mathscr{M},d^4x(\sqrt{g}/g_{00}))$ to $L^2(\mathscr{M},d^4x(\sqrt{g}/g_{00}^2))$ carries the eigenvalue problem for A_{NC} into the eigenvalue problem for

$$A_{opt}\equiv-\Delta_h+q(x), \tag{11}$$

where Δ_h is the Laplacian on scalar functions for the so called optical metric $h_{\mu\nu}$

$$ds_{opt}^2=d\tau^2+\frac{1}{g_{00}^2(r)}dr^2+\frac{r^2}{g_{00}(r)}d\Omega^2, \tag{12}$$

and the potential $q(x)$ is

$$q(x)=\frac{1}{\sqrt{g_{00}}}(\Delta_h\sqrt{g_{00}})+g_{00}(M^2+\xi R).$$

About this equivalence, cf. also Ref. 7, chapter 3. The p.w.o. analysis is sufficient in order to establish self-adjointness properties of A_{NC}. Nevertheless, a ''direct'' approach is possible and it is found in Appendix C.

III. SCHWARZSCHILD BLACK HOLE

The function $g_{00}(r)$ in (2) is given by

$$g_{00}(r)=1-\frac{r_{bh}}{r},$$

where r_{bh} is the black hole radius, associated with the black hole mass m by $r_{bh}=2m$. (We use natural units $\hbar=c=G=k_B=1$.) We will start by treating the case of generic γ on the manifold $\mathscr{M}$. It is useful to pass to rescaled coordinates:

$$\tau\to\frac{\tau}{2r_{bh}\gamma}\in[0,2\pi);\quad r\to\frac{r}{2r_{bh}}\in\left(\frac{1}{2},\infty\right).$$

We will call these rescaled coordinates again τ, r, unless explicitly remarked. So one gets

$$ds^2=(2r_{bh})^2\left(\left(1-\frac{1}{2r}\right)\gamma^2d\tau^2+\frac{1}{\left(1-\frac{1}{2r}\right)}dr^2+r^2d\Omega^2\right).$$

By means of the new variable

$$y=\sqrt{2}\sqrt{r-\tfrac{1}{2}}\in(0,\infty),$$

the metric becomes

$$ds^2=(2r_{bh})^2\left(\frac{y^2}{(1+y^2)}\,\gamma^2d\tau^2+(1+y^2)dy^2+\frac{1}{4}(1+y^2)^2d\Omega^2\right). \tag{13}$$

This choice of the ''radial'' variable is particularly suitable in order to explore the behavior of the metric near the horizon, that is, for $y\to0^+$; indeed, as it is well known, near the horizon the manifold has a conical structure:

$$ds^2\sim(2r_{bh})^2\left(y^2\gamma^2d\tau^2+dy^2+\frac{1}{4}d\Omega^2\right), \tag{14}$$

that is, it is equivalent to $C_\gamma\times S^2$, where C_γ is a two-dimensional cone that degenerates to a punctured plane if $\gamma=1$. In the presence of a conical defect $\gamma\neq1$, a careful analysis has to be done in order to take into account curvature distributional contributions[12] at the tip of the cone.

If $\gamma=1$, then the Riemannian manifold can be extended smoothly up to include the surface $y=0$. In fact, in the framework of the so called Euclidean path integral approach,[1] the thermodynamical manifold is required to be the one representing the so called Euclidean section of the maximal extension of the Schwarzschild spacetime, characterized by $\gamma=1$ and $R=0$ and including $y=0$, that is $r=r_{bh}$. Note that the metric in (2) is related with a coordinate chart not covering the value $r=r_{bh}$. This value corresponds to a set of fixed points for the Killing vector ∂_τ and can be covered, e.g., by means of the Kruskal Euclidean coordinates T, X,[1]

$$ds^2=\frac{4r_{bh}^3}{r}\exp\left(-\frac{r}{r_{bh}}\right)(dT^2+dX^2)+r^2d\Omega^2.$$

The relation with the incomplete chart is

$$T^2+X^2=\left(\frac{r}{r_{bh}}-1\right)\exp\left(\frac{r}{r_{bh}}\right),\quad \frac{T}{X}=\tan\left(\frac{\tau}{2r_{bh}}\right).$$

The manifold covered by the given Kruskal chart corresponds to the Euclidean section, that is $\mathscr{M}_E=\mathbb{R}^2\times S^2$. Note that its fundamental group is trivial, i.e., $\mathscr{M}_E$ is simply connected, whereas $\Pi_1(\mathscr{M})=\mathbb{Z}$. Note also the relation between T, X and ''conical'' coordinates:

$$T=\exp\left(\frac{y^2+1}{2}\right)y\ \sin(\tau),\quad X=\exp\left(\frac{y^2+1}{2}\right)y\ \cos(\tau). \tag{15}$$

It is evident that the manifold $\mathscr{M}_E$ is not compatible with the choice of the noncovariant functional measure and with the introduction of a conical defect. Both these cases require us to consider a manifold $\mathscr{M}=S^1\times(0,\infty)\times S^2$, that is, the manifold cannot include the bifurcation surface $y=0$. So a modification in topology of the manifold is required w.r.t. the Euclidean path integral approach (cf. also Ref. 4).

We will start by discussing the on shell case for the covariant measure choice; a comparison between the case in which the manifold is $\mathscr{M}$ and the case in which the manifold is $\mathscr{M}_E$ will be carried out. (As it is known,[4] this choice for the manifold cannot allow a tree level gravitational entropy contribution.) Then an analysis of the off shell case and of the noncovariant one, both necessarily defined only on $\mathscr{M}$, will be made.

As a final remark of this section, we stress that in the following we will deal with operators defined on metrics of the form

$$ds^2=c^2(G(y)d\tau^2+F(y)dy^2+H^2(y)d\Omega^2),$$

where c is a constant with the dimensions of length. We will carry our analysis about p.w.o. on the rescaled metric,

$$ds^2_{\text{rescaled}}=G(y)d\tau^2+F(y)dy^2+H^2(y)d\Omega^2.$$

It is evident that

$$A=\frac{1}{c^2}A_{\text{rescaled}}.$$

A. p.w.o. analysis on shell

The wave operator A in the metric (13) with $\gamma=1$ can be written as

$$A=\frac{1}{yf(y)^2}(-\partial_y(yf(y)\partial_y))-\frac{f(y)}{y^2}\partial_\tau^2-\frac{4}{f(y)^2}\Delta_\Omega+M^2+\xi R,$$

where

$$f(y)=1+y^2.$$

We recall that the Euclidean section is Ricci-flat, so $R=0$. The (rescaled) p.w.o. operators in the metric (13) are

$$A_{nl}=\frac{1}{yf(y)^2}(-\partial_y(yf(y)\partial_y)+V_{nl}(y)), \tag{16}$$

where

$$V_{nl}(y)=yf(y)^2R_{nl}(y),$$

$$R_{nl}(y)=\frac{f(y)}{y^2}n^2+\frac{4l(l+1)}{f(y)^2}+M^2,$$

$$y \in (0,\infty).$$

The p.w.o. obtained has a Sturm–Liouville form and the powerful theorems concerning Sturmian operators can be used.

The p.w.o. A_{nl} in (16) defines a singular Sturm–Liouville operator on an interval $I \subset \mathbb{R}$. Indeed, it is an operator of the form

$$L\varphi(y) = \frac{1}{k(y)}\left(-\frac{d}{dy}\left(p(y)\frac{d\varphi(y)}{dy}\right) + q(y)\varphi(y)\right).$$

Conditions to be satisfied by $k(y)$, $p(y)$, $q(y)$ are, e.g., found in Refs. 13, 14. In our case we get $k(y) = yf(y)^2 > 0$, $p(y) = yf(y)$, $q(y) = V_{nl}(y)$ that are all smooth functions for $y \in (0,\infty)$. Note that $y = 0$ is a singular point for L. One can define the maximal and the minimal operators[13] induced by our p.w.o. In our case the minimal operator $T_0(A_{nl})$ can be defined as follows:

$$D(T_0(A_{nl})) = C_0^\infty(I) \cap L^2(I, k(y)dy),$$

$$T_0(A_{nl})\varphi = A_{nl}\varphi \quad \text{for} \quad \varphi \in D(T_0(A_{nl}));$$

the maximal operator $T(A_{nl})$ can be defined as (cf. Ref. 7)

$$D(T(A_{nl})) = \{\varphi \in C^\infty(I) \,|\, \varphi, A_{nl}\varphi \in L^2(I, k(y)dy)\} = D(T_0^*(A_{nl})) \cap C^\infty(I),$$

$$T(A_{nl})\varphi = A_{nl}\varphi \quad \text{for} \quad \varphi \in D(T(A_{nl})).$$

$L \equiv A_{nl}$ is a formal elliptic differential operator formally self-adjoint. Ellipticity implies that a weak solution of the equation $(L - \lambda)\varphi = 0$ for $\lambda \in \mathbb{C}$ is also a strong solution and a smooth solution of the same equation.[7] So deficiency subspaces of the minimal operator are necessarily subspaces of $C^\infty(I) \cap L^2(I, k(y)dy)$, and are spanned by ordinary (i.e., nondistributional) solutions of the given differential equation.

1. Deficiency indices of A

We now study the behavior of the solution of the differential equation

$$A_{nl}\varphi = \lambda\varphi, \tag{17}$$

near $y = 0$. We want to determine if, according to Weyl's alternative, in a right neighbor of 0, all the solutions of (17) are square integrable for every $\lambda \in \mathbb{C}$, that is, $\varphi \in L^2((0,c], k(y)dy)$, $0 < c < \infty$ for every $\lambda \in \mathbb{C}$; or if, for every $\lambda \in \mathbb{C}$ it exists a solution not square integrable. In the former case, one gets the so called limit circle case (LCC); in the second one the so called limit point case (LPC) is verified.

Equation (17) is equivalent to the following one:

$$\left(-\partial_y^2 - \frac{1+3y^2}{y(1+y^2)}\partial_y + (1+y^2)(R_{nl}(y) - \lambda)\right)\varphi(y) = 0,$$

and it is a second order differential equation with rational coefficients. Near $y = 0$ one gets

$$\left(-\partial_y^2 - \left(\frac{1}{y} + O(y)\right)\partial_y + \left(\frac{n^2}{y^2} + 2n^2 + 4l(l+1) + M^2 - \lambda + O(y^2)\right)\right)\varphi(y) = 0,$$

and the following root for the indicial equation:

$$\alpha_1 = |n|, \quad \alpha_2 = -|n|.$$

A fundamental system for $y \to 0^+$ is given by

$$\zeta_+(y)=y^{|n|}\sum_{k=0}^{\infty}a_k y^k,\quad \zeta_-(y)=y^{-|n|}\sum_{k=0}^{\infty}b_k y^k+\zeta_+(y)\log(y).$$

For $n\neq 0$, we get the LPC: there are for every choice of λ solutions not belonging to $L^2((0,c],y(1+y^2)^2dy)$, where $(0,c]$ represents a right neighbor of 0. For $n=0$ one has the LCC: both the independent solutions of our equation are square integrable in a right neighbor of 0. Moreover, it is easy to show that the LPC is verified at infinity for every p.w.o.

For a real formal differential operator of order 2 one can find straightforwardly the deficiency indices of T_0 from the knowledge of the behavior of τ according to Weyl's alternative. Indeed, according to theorem 5.7 of Ref. 14, the deficiency indices are (0,0) if one gets the LPC at both the extremes; (1,1) if one finds the LPC at one extreme and the LCC at the other; (2,2) if LCC is verified at both the extremes.

Summarizing our results, we have that the partial wave operators with $n\neq 0$ are characterized by the limit point case at 0 and at infinity, so they have deficiency indices (0,0); the partial wave operators with $n=0$ are characterized by the limit circle case at 0 and have deficiency indices (1,1).

This means that for $n\neq 0$ in this case the p.w.o. are essentially self-adjoint, whereas for $n=0$ there is a one parameter family of self-adjoint extensions for each p.w.o.

The deficiency indices of A are given by the formula (7) and they are evidently equal and infinite. Indeed, even if there is only a value of n contributing nonzero deficiency indices, namely $n=0$, we have

$$N_+(\overline{A})=\sum_{l\in\mathbb{N}}(2l+1)N_+(\overline{A}_{0l})=\infty,\quad N_-(\overline{A})=\sum_{l\in\mathbb{N}}(2l+1)N_-(\overline{A}_{0l})=\infty$$

due to the fact that one has to sum over $l\in\mathbb{N}$. This means that the wave operator A is not essentially self-adjoint on $\mathscr{M}$ and that boundary conditions on the horizon have to be defined. We postpone a discussion about suitable boundary conditions to subsection III B.

2. Spectral analysis

We limit ourselves at first at the case in which a spherical boundary surrounds the black hole. This means $y\in(0,y_b]$. Note that $y=y_b$ is a regular point for the p.w.o. and the LCC is verified there. Deficiency indices then become (2,2) in the $n=0$ case and (1,1) in the $n\neq 0$ one. Moreover, and a Dirichlet boundary condition is assumed at $y=y_b$. Deficiency indices of A are (∞,∞).

Let us analyze some qualitative properties of the spectrum. In order to study the spectral properties of the p.w.o. it is useful to introduce the variable z defined by

$$\frac{dz}{dy}=\sqrt{1+y^2};\tag{18}$$

the transformation (18) is smooth and one obtains

$$z(y)=\tfrac{1}{2}(y\sqrt{1+y^2}+\log(y+\sqrt{1+y^2})),\quad z\in(0,z_b].\tag{19}$$

The metric becomes

$$ds^2=(2r_{bh})^2\left(\frac{y(z)^2}{f(y(z))}d\tau^2+dz^2+\frac{1}{4}f(y(z))^2d\Omega^2\right),\tag{20}$$

where $f(y(z))=1+y(z)^2$.

The wave operator on shell on the basis (8) gives rise to the following p.w.o.:

$$A_{nl}=-\frac{1}{P(z)}\partial_z(P(z)\partial_z)+V_{nl}(z),$$

$$P(z)=y(z)(1+y(z)^2)^{3/2},$$

$$V_{nl}(z)=n^2\frac{(1+y(z)^2)}{y(z)^2}+4l(l+1)\frac{1}{(1+y(z)^2)^2}+M^2.$$

The following Liouville unitary transformation:

$$U:L^2((0,z_b],P(z)dz)\to L^2((0,z_b],dz),$$

$$(U\varphi)(z)=\sqrt{P(z)}\varphi(z)\equiv u(z),$$

carries (17) into $B_{nl}u(z)=\lambda u(z)$, where

$$B_{nl}=-\frac{d^2}{dz^2}+Q_{nl}(z),$$

$$Q_{nl}(z)=V_{nl}(z)+\frac{1}{2}\left(\frac{dG(z)}{dz}+\frac{G(z)^2}{2}\right),$$

$$G(z)=\frac{d\ \log(P(z))}{dz};$$

it holds that $A_{nl}=U^{-1}B_{nl}U$ and also $\varphi\in L^2((0,z_b],P(z)dz)\Leftrightarrow u\in L^2((0,z_b],dz)$. The potential term is given by

$$Q_{nl}(z)=\left(n^2-\frac{1}{4}\right)\frac{1}{z^2}\frac{z^2}{y(z)^2}+W_{nl}(z),$$

$$W_{nl}(z)=n^2+M^2+\frac{4l(l+1)}{(1+y(z)^2)^2}+\frac{1}{4(1+y(z)^2)^3}(11+3y(z)^2+y(z)^4);$$

$W_{nl}(z)$ is a bounded smooth function in $(0,z_b]$. For $z\sim 0^+$, that is for $y\sim 0^+$, one gets a singular behavior of the operators B_{nl}. Note that our B_{nl}, for $I=(0,\infty)$, represents a particular case of the Schrödinger-like operators studied in Ref. 15.

The $n\neq 0$ case does not require the definition of a boundary condition at $z=0$. The choice of the Dirichlet boundary condition at $z=z_b$ defines a self-adjoint extension of the p.w.o. Then we can apply criterion (25) of Ref. 16, p. 1598, in order to determine if the essential spectrum σ_e of our self-adjoint extension is void. We recall that all the self-adjoint extensions of our minimal operators have the same essential spectrum, because they have finite deficiency indices. The above criterion requires that, given an operator of the form

$$B=-\frac{d^2}{dz^2}+Q(z),\quad z\in(0,z_b],$$

where $Q(z)$ is real and continuous function, if

$$\liminf_{z\to 0} z^2Q(z)>-\tfrac{1}{4},$$

then $\sigma_e(B)=\varnothing$ and B is bounded from below. Our $Q_{nl}(z)$ satisfies the request to be a real continuous function and it holds that

$$\lim_{z\to 0^+} z^2Q_{nl}(z)=n^2-\tfrac{1}{4}>-\tfrac{1}{4},$$

so the essential spectrum is void. [We used $\lim_{z\to 0^+}[z^2/y(z)^2]=1$.] This means that for $n\neq 0$ there is only a discrete spectrum for our operators.

In the $n=0$ case, from Ref. 16 (corollary 12, p. 1402), one infers that the essential spectrum is again void: indeed each A_{0l} is a formally self-adjoint differential operator of order 2 having

deficiency indices (2,2). Note that this is true for every choice of the boundary condition at $z=0$ as far as the resulting operator is self-adjoint. Moreover, the p.w.o. A_{0l} are bounded from below, as it can be inferred from Sturmian oscillation theory.[16,14]

Summarizing, we found that the p.w.o. have a purely discrete spectrum for all n,l and for every value of the mass M (due to the fact that the Schwarzschild solution is Ricci-flat; the other coupling ξ is irrelevant).

As expected, the presence of a box discretizes the spectrum of the wave operator A, and this is expected to be on physical grounds a necessary condition in order to get a finite partition function.

3. No box case

We will adopt the so called ''decomposition method.'' See also Ref. 14, chapter 11. Our analysis is based on Ref. 16, theorem 4, p. 1438.

Let L be a formal differential operator defined on an interval I with end points a,b and let $I=I_1\cup I_2$, where I_1,I_2 are subintervals of I. Let L_1 and L_2 be the restrictions of L to I_1 and I_2, respectively. Then

$$\sigma_e(L)=\sigma_e(L_1)\cup\sigma_e(L_2).$$

In our case we choose

$$I_1=(0,z_b], \quad I_2=[z_b,\infty).$$

Let us analyze the essential spectrum of the operators $B_{nl}|_{[z_b,\infty)}$. Given

$$\lim_{z\to\infty} Q_{nl}(z)=M^2+n^2,$$

according to theorem 16, p. 1448 of Ref. 16, it results in

$$\sigma_e(B_{nl}|_{[z_b,\infty)})=\{\lambda|\lambda\geqslant M^2+n^2\}. \tag{21}$$

Summarizing, in the absence of the box, the essential spectrum is nonvoid for every value of n and for every value of M.

B. Boundary conditions at $y=0$ and analysis on $\mathscr{M}_E$

We have to choose a boundary condition for our operators at the singular point $y=0$. In the case $y\in(0,\infty)$ there is no boundary condition to choose at infinity (LPC); we have a one parameter family of self-adjoint extensions of the p.w.o., A_{0l}. In the case $y\in(0,y_b]$, *a priori* one could choose mixed boundary conditions, i.e., periodic boundary conditions. *A priori*, the given family of p.w.o. with $n=0$ admits a four-parameter family of self-adjoint extensions. We are not interested in the general case and we limit ourselves to selecting a Dirichlet boundary condition at $y=y_b$ and to choosing separated boundary conditions for $y=0$ and $y=y_b$. In fact, the presence of a spherical box should not modify the boundary condition one has at $y=0$ when there is no box. This amounts necessarily to choosing a separated boundary condition. With a fixed boundary condition at $y=y_b$ and separated boundary conditions, we have *a priori* also in the case with a spherical box a one-parameter family of self-adjoint extensions for the p.w.o., A_{0l}. Note that, A_{nl} being bounded from below, we can choose the Friedrichs extension that would require a separated set of boundary conditions too, as it results from Ref. 16, remark $(D5)$, p. 1545. At the regular point $y=y_b$, this amounts to selecting just a Dirichlet boundary condition $\zeta(y_b)=0$.

When the point $y=0$ is characterized by the LCC, the boundary condition, i.e., the self-adjoint extension, is selected according to the following physical criterion: If the thermal manifold is chosen to be $\mathscr{M}$, then the singularity appearing at $y=0$ is due to incompleteness (but not to a singularity; no singularity arises in the curvature invariants as $y=0$, as far as the on shell case is considered) in the manifold. A natural choice for the boundary condition in $y=0$ can be the one not introducing ''extra-sources'' at the singularity itself (cf. the appendix of Ref. 17 and the discussion of the off shell case).

In a certain sense, the singularity is a removable one. In our case, the natural choice is the boundary condition corresponding to Friedrichs' ''ausgezeichnete Randbedingung,'' [18] which in the case in which $y \in (0,\infty)$ corresponds to the choice of the Friedrichs extension for A_{0l}. This boundary condition at $y=0$ and the Dirichlet one at $y=y_b$ define the Friedrichs extension for A_{0l} in the $y \in (0,y_b]$ case.

We note that our choice corresponds in fact to the choice of the Friedrichs extension for A. Indeed, in general the Friedrichs extension of a direct sum $C=\Sigma_k^{\oplus} C_k$, $k \in \mathbb{N}$ of operators C_k bounded from below is equal to the direct sum of the Friedrichs extensions of the operators C_k (cf. Ref. 13, exercise 5.43). This fact implies in our case that the Friedrichs extension of C has the same reducing subspaces as C.

It is interesting to see what happens if the thermal manifold is the whole Euclidean section $\mathscr{M}_E$. We get that *the wave operator A is essentially self-adjoint* on $C_0^{\infty}(\mathscr{M}_E)$. Indeed, $(\mathscr{M}_E, g_{\mu\nu})$, where $g_{\mu\nu}$ is the metric given in Kruskal coordinates, is a complete Riemannian manifold and, given a complete Riemannian manifold $\mathscr{M}_R$, the wave operator $A=-\Delta+M^2$ defined on $C_0^{\infty}(\mathscr{M}_R)$ is essentially self-adjoint.[7,8] For the completeness of the Euclidean section, see, e.g., Ref. 19, example (a), p. 271 and see also Appendix B herein. So the wave operator A on $\mathscr{M}_E$ gets $(N_+(\overline{A}),N_-(\overline{A}))=(0,0)$. Moreover, A is also bounded from below,[8] and both these conditions imply that its unique self-adjoint extension is the Friedrichs extension.[9] The introduction of a spherical boundary in $\mathscr{M}_E$ gives rise to a manifold like $D\times S^2$, where D is a 2D disk. A becomes not essentially self-adjoint, and a self-adjoint extension is obtained if, e.g., a Dirichlet boundary condition is imposed. Then it is known that the spectrum of A is purely discrete and that Friedrichs extension of the minimal operator corresponds to a Dirichlet boundary condition.[7]

A question that could be raised concerns which relation exists (for simplicity we consider the case of no spherical box) between the Friedrichs extension $\overline{A}$ of the essentially self-adjoint wave operator A on $C_0^{\infty}(\mathscr{M}_E)$, and the Friedrichs extension A^F of the direct sum of p.w.o. It is easy to show that they actually coincide. For a demonstration see Appendix D. This means that, according to the above reasoning, the only possible choice for the boundary condition at $y=0$ for A_{0l} is the one implementing the Friedrichs extension in the absence of the box, which is the ''ausgezeichnete Randbedingung.'' See also the conclusions. [In the case of $\mathscr{M}_E$, one has that $y=0$ is a coordinate singularity due to a bad choice of the chart. In the given chart for the Euclidean section, the problem is analogous to the one related to the use of a polar coordinate chart in the plane, where the origin cannot be covered by the given chart and the wave equation becomes singular there. This singularity is only a coordinate singularity. This analogy can be easily realized by means of the relations (15).]

An explicit implementation of the ''ausgezeichnete Randbedingung'' is given in Ref. 18, sec. 3. One has to deal with an operator A_{nl} semibounded at $y=0$. A real fundamental system of solutions ψ,ω of the equation $A_{nl}u=\mu u$ exists such that they do not vanish in $0<y\leqslant s<y_b$ (s generic) and that

$$\lim_{y\to 0} \frac{\omega}{\psi}=0.$$

Then the ''ausgezeichnete Randbedingung'' is

$$\lim_{y\to 0} \frac{u}{\psi}=0,$$

and it is not dependent on μ, ψ, ω. Such a real fundamental system in our case $n=0,l$ near $y=0$ can be chosen as

$$\omega=1+a_1 y+O(y^2),$$

$$\psi=b_1 y+(1+a_1 y)\log(y)+O(y^2),$$

so Friedrichs' boundary condition is

$$\lim_{y\to 0}\frac{\zeta(y)}{\log(y)}=0.$$

C. Off shell case

If one chooses an inverse temperature β not equal to β_h, then distributional curvature singularities develop near $y=0$ in (13).[12] One can show that the Ricci scalar is given by

$$R=2(1-\gamma)\,\frac{\delta(y)}{y}.$$

We will start by treating simply the case of minimal coupling $\xi=0$. The $\xi\neq 0$ case is shortly discussed at the end of this subsection. The minimal coupling case is somehow special, because no curvature singularity appears in the wave equation, the only term having distributional nature being the coupling to the Ricci scalar curvature. It is evident that the only change in the on shell case formulas consists in the following substitution:

$$n^2\to\frac{n^2}{\gamma^2}.$$

1. Deficiency indices of A

The eigenvalue equation is

$$\left(-\partial_y^2-\frac{1+3y^2}{y(1+y^2)}\partial_y+(1+y^2)\left(\frac{(1+y^2)}{y^2}\,\frac{n^2}{\gamma^2}+\frac{4l(l+1)}{(1+y^2)^2}+M^2-\lambda\right)\right)\varphi(y)=0,$$

and near $y=0$ one gets

$$\left(-\partial_y^2-\left(\frac{1}{y}+O(y)\right)\partial_y+\left(\frac{n^2}{\gamma^2}\frac{1}{y^2}+2\,\frac{n^2}{\gamma^2}+4l(l+1)+M^2-\lambda+O(y^2)\right)\right)\varphi(y)=0. \qquad (22)$$

The corresponding indicial equation has the following roots:

$$\alpha_1=\frac{|n|}{\gamma},\quad \alpha_2=-\frac{|n|}{\gamma}.$$

The presence of the conical defect affects the characterization of the Weyl's alternative. Both the solutions belong to $L^2((0,c],y(1+y^2)^2dy)$, where $(0,c]$ represents a right neighbor of 0, if

$$\frac{|n|}{\gamma}<1.$$

This means that, if we fix a value of $\gamma<1$, for $n\neq 0$, we get the LPC; for $n=0$ one has the LCC. The choice $\gamma<1$ gives the same qualitative properties as the on shell case, and it is natural if one considers a high temperature off shell limit ($\beta\to 0^+\Leftrightarrow\gamma\to 0^+$).

If we fix $\gamma>1$, i.e., if we fix a temperature lower that the black hole one, then the LCC holds for every n such that $|n|<\gamma$. LPC is verified definitively. Indeed, by posing $\gamma=[\gamma]+\epsilon$, $\epsilon\in[0,1)$, one gets

$$\epsilon>0\Rightarrow \text{LPC},\forall n,\quad \text{such that } |n|\geqslant\bar{n}\equiv[\gamma]+1;$$

$$\epsilon=0\Rightarrow \text{LPC},\forall n,\quad \text{such that } |n|\geqslant\bar{n}\equiv[\gamma].$$

The LPC holds at infinity. Then all the p.w.o. with $|n|<\bar{n}$ have deficiency indices (1,1), whereas all the p.w.o. with $|n|\geqslant\bar{n}$ have deficiency indices (0,0).

The deficiency indices of the wave operator A result to be (∞,∞) also in the off shell case, for every choice of γ. Indeed it holds that

$$N_+(\bar{A}) = \sum_{l\in\mathbb{N}} (2l+1) N_+(\bar{A}_{0l}) + 2\sum_{n=1}^{\bar{n}-1} \sum_{l\in\mathbb{N}} (2l+1) N_+(\bar{A}_{nl}) = \infty,$$

$$N_-(\bar{A}) = \sum_{l\in\mathbb{N}} (2l+1) N_-(\bar{A}_{0l}) + 2\sum_{n=1}^{\bar{n}-1} \sum_{l\in\mathbb{N}} (2l+1) N_-(\bar{A}_{nl}) = \infty.$$

From this point of view, there is a remarkable difference w.r.t. Laplacian operators defined on metric cones like

$$ds^2 = dy^2 + y^2 g_{M_k},$$

where $y \in (0,\infty)$ and g_{M_k} is the (y independent) metric on a k-dimensional compact manifold.[20] Indeed, in the latter case, with self-evident notation, we get

$$\Delta = \frac{1}{y^k}\partial_y(y^k\partial_y) + \frac{1}{y^2}\Delta_k, \tag{23}$$

and only a finite number of eigenvalues of the elliptic operator Δ_k, defined on a compact manifold, can contribute to the deficiency indices of the laplacian Δ, that, as a consequence, gets finite deficiency indices. Moreover, as shown in Ref. 20, the wave operator in (23) is not essentially self-adjoint only for $k=1,2$. The case $k=1$ is extensively discussed in Ref. 21.

Note that for $\gamma>1$ one gets, w.r.t. the $\gamma\leqslant 1$ case, a number of further self-adjoint extensions to define: For each value of l, there are $2[\gamma]$ further self-adjoint extensions to define for $\epsilon>0$ and $2([\gamma]-1)$ for $\epsilon=0$. An analogous problem exists for quantum mechanics on cones with conical defect $\gamma>1$.[21]

The lack of essential self-adjointness of the wave operators can be interpreted in terms of incompleteness of the conical metric. See also Appendix B. The corresponding Riemannian manifold is also nonextendible (cf. Ref. 20 for the metric cone case), so one cannot ''remove'' the singularity in a different chart. The choice of the boundary condition at $y=0$ is then less straightforward in the off shell case, because it lacks the possibility to interpretate the singularity at $y=0$ as a coordinate one. The ''ausgezeichnete Randbedingung'' could be naively privileged as the most directly connected to the on shell case (no conical defect).

Actually, a more careful analysis should be done. We limit ourselves to propose the following conjecture. It is known[22] that a delta-like model potential in a Schrödinger-like equation can be implemented by means of a suitable boundary condition on the Schrödinger operator (bounded from below) without the delta-like potential on a suitable domain. Choices of self-adjoint extensions different from Friedrichs' one correspond to such delta-like potentials. The same could be expected to be true also in this case, so boundary conditions other than the ''ausgezeichnete'' one could be reasonably related to distributional potentials on the two-dimensional surface $y=0$. Then one could also expect that the nonminimal case, characterized by the presence of a ''delta'' potential on $y=0$, can be dealt with by means of the same self-adjoint extensions techniques as for analogous problems in ordinary flat space quantum mechanics.[22,15] If the above hypothesis is right, that is, if it is possible to define the model potential via the self-adjoint extension method, then boundary conditions at $y=0$ different from Friedrichs' one could be sufficient for implementing the nonminimal coupling case. (If this is true, it is reasonable to conjecture that suitable self-adjoint extensions of the $n=0$ case are enough also for the case $\gamma>1$. The other cases could define other distributional interactions we are not interested in. For $n\neq 0$ such that $|n|<\bar{n}$ it would seem natural in this framework to impose Friedrichs boundary condition at $y=0$.)

In the given purely conjectural framework, the coupling ξ, that on shell is irrelevant, becomes a bare coupling related via the renormalization group[22] to the self-adjoint extension parameters and the naive approach to privilege the Friedrichs' boundary condition also in the case $\xi\neq 0$ should be better justified.

Before a discussion about qualitative spectral properties, we characterize the self-adjoint extensions of the p.w.o., A_{nl}, in the presence of a spherical boundary at $y=y_b$. Obviously, defi-

ciency indices become (2,2) for $|n|<\overline{n}$ and (1,1) for $|n|\geqslant\overline{n}$. Taking into account that we will limit ourselves to consider a Dirichlet separated boundary condition at $y=y_b$, it holds for the essential self-adjointness domain on $\mathscr{U}_{nl}$ for the self-adjoint extensions of A_{nl},

$$\mathscr{U}_{nl}=\{\zeta|\zeta\in C^{\infty}(0,y_b]\cap L^2((0,y_b],y(1+y^2)^2\ dy),$$

$$A_{nl}\zeta\in L^2((0,y_b],y(1+y^2)^2\ dy),[\zeta,\zeta_1](y=0)=0;\quad \zeta(y=y_b)=0\},$$

where $[u,v]\equiv p(y)(u(dv/dy)-(du/dy)v)$; $\zeta_1\not\equiv 0$ satisfies Eq. (17) for Im $\lambda\neq 0$ and is such that $[\zeta_1,\zeta_1](0)=0$.[23]

Given the general structure of the equation near the regular singular point $y=0$ [cf. equation (22)], we can express the condition at that point by following Ref. 23, chapter 8 or, equivalently, Ref. 24. As a preliminary step, we give some definitions. Let $\alpha_1\geqslant\alpha_2$ be the roots of the indicial equation. Moreover, define the following fundamental system:

$$\zeta_+(y)=y^{\alpha_1}\sum_{k=0}^{\infty}\ \omega_k y^k,$$

$$\zeta_-(y)=y^{\alpha_2}\sum_{k=0}^{\infty}\ \psi_k y^k+c\zeta_+(y)\log(y);$$

the coefficients ω_k, ψ_k, c are uniquely determined. (Particularly, it holds that $\omega_0=1$ and $\psi_0=1$ and $c=0$ for $\alpha_1-\alpha_2\neq 0,1,2,\ldots$; $\psi_0=0$ and $c=1$ for $\alpha_1-\alpha_2=0$; $\psi_0=1$ and $\psi_n=0$ for $\alpha_1-\alpha_2=n$, $n=1,2,\ldots$.) Then let us suitably define

$$\omega_2(y)=\omega_0+\omega_1 y,$$

$$\psi_2(y)=\psi_0+\psi_1 y,\quad \zeta_{1,2}(y)=y^{\alpha_1}\omega_2(y),$$

$$\zeta_{2,2}(y)=y^{\alpha_2}\psi_2(y)+c\zeta_{1,2}(y)\log(y).$$

(It is easy to show that the parameter σ appearing in Ref. 23 is equal to 2 in our case. For further details, see Ref. 23.) Then, define for $\zeta(y)\in\mathscr{U}_{nl}$,

$$a_0=\lim_{y\to 0}\frac{\zeta(y)}{y^{\alpha_2}},\quad a_1=\lim_{y\to 0}\frac{\zeta(y)-a_0\zeta_{2,2}(y)}{y^{\alpha_1}},$$

for real $\alpha_1\neq\alpha_2$ and

$$a_0=\lim_{y\to 0}\frac{\zeta(y)}{y^{\alpha_1}\log(y)},\quad a_1=\lim_{y\to 0}\frac{(\zeta(y)-a_0\zeta_{2,2}(y)}{y^{\alpha_1}},$$

for real $\alpha_1=\alpha_2$. The above numbers a_0,a_1 satisfy the conditions to be the so called *Rellich initial numbers*[23] and eventually this means that $\mathscr{U}_{nl}$ can be written as

$$\mathscr{U}_{nl}=\{\zeta|\zeta\in C^{\infty}(0,y_b]\cap L^2((0,y_b],y(1+y^2)^2dy),$$

$$A_{nl}\zeta\in L^2((0,y_b],y(1+y^2)^2dy),\ \zeta(y=y_b)=0;\quad a_0\cos(s)+a_1\sin(s)=0,\ s\in[0,\pi)\}.$$

The equivalence between the condition $a_0\cos(s)+a_1\sin(s)=0$ and a condition like

$$\nu a_0=a_1;\quad \nu\in(-\infty,+\infty]$$

is trivial. The ''ausgezeichnete Randbedingung'' at $y=0$ is equivalent to

$$a_0=0,$$

that is, $s=0$ or $\nu=\infty$. We recall that in our case $\alpha_1=|n|/\gamma>\alpha_2=-|n|/\gamma$ if $n\neq 0$ and $\alpha_1=\alpha_2=0$ for $n=0$.

The above characterization is general and it holds for every choice of γ.

2. Spectral analysis

All results about qualitative properties of the spectrum remain unaltered w.r.t. the on shell case. All the p.w.o. with deficiency indices (2,2) have, from Ref. 16 (corollary 12, p. 1402), a void essential spectrum. The same is true in the case of deficiency indices (1,1): the same choice of the variable z and of the Liouville transformation as in the on shell case carries (17) into $B_{nl}u(z)=\lambda u(z)$, where

$$B_{nl}=-\frac{d^2}{dz^2}+Q_{nl}(z),\quad Q_{nl}(z)=\left(\frac{n^2}{\gamma^2}-\frac{1}{4}\right)\frac{1}{z^2}\frac{z^2}{y(z)^2}+W_{nl}(z),$$

$$W_{nl}(z)=\frac{n^2}{\gamma^2}+M^2+\frac{4l(l+1)}{(1+y(z)^2)^2}+\frac{1}{4(1+y(z)^2)^3}(11+3y(z)^2+y(z)^4).$$

From

$$\lim_{z\to 0^+} z^2Q_{nl}(z)=\frac{n^2}{\gamma^2}-\frac{1}{4}>-\frac{1}{4},$$

and from criterion (25) of Ref. 16, p. 1598, it is proven that the essential spectrum of any self-adjoint extension is void. If $y\in(0,\infty)$, then every p.w.o. gets an essential spectrum contribution, and a completely analogous approach to the one for the $\gamma=1$ case gives

$$\sigma_e(A_{nl})=\left\{\lambda\,\middle|\,\lambda\geqslant\frac{n^2}{\gamma^2}+M^2\right\}.$$

D. Noncovariant measure

In the case when one chooses the noncovariant measure, essential self-adjointness properties and qualitative properties of the spectrum of the wave operator change remarkably. The following discussion will hold both for the on shell case $\gamma=1$ and for the off shell case with minimal coupling $\xi=0$.

The partial wave operators are

$$A_{nl}=\frac{y}{f(y)^3}(-\partial_y(yf(y)\partial_y)+V_{nl}(y)),\quad V_{nl}(y)=\frac{f(y)^3}{y}v_{nl}(y),$$

$$v_{nl}(y)=\frac{4y^2}{f(y)^3}l(l+1)+M^2\frac{y^2}{f(y)}+\frac{n^2}{\gamma^2},\quad f(y)=1+y^2.$$

The Hilbert space containing the domain is $L^2(I,[f(y)^3/y]dy)$, where $I=(0,\infty)$ if no spherical box is introduced. For $y\to 0^+$ the asymptotic form of the differential equation (17),

$$\left(-\partial_y^2-\frac{1}{y}\partial_y+\frac{1}{y^2}\left(\frac{n^2}{\gamma^2}-\lambda\right)\right)\zeta(y)=0,$$

gives the following secular roots:

$$\alpha_+=\sqrt{\frac{n^2}{\gamma^2}-\lambda},\quad \alpha_-=-\sqrt{\frac{n^2}{\gamma^2}-\lambda}.$$

By choosing, e.g., $\lambda=0$ it is straightforward to realize that at $y=0$ the LPC is verified as well as at infinity (cf. also Ref. 23, theorem 1, p. 251). The deficiency indices are then (0,0) for each A_{nl}. So for A_{NC} one obtains $(N_+,N_-)=(0,0)$.

The introduction of a spherical box restricts the y-interval to $(0,y_b]$. The point $y=y_b$ is a regular point for each p.w.o., so that the LCC is verified there.

Qualitative spectral properties can be inferred by means of the following variable transformation (tortoise-like),

$$z=-\log(y)-\frac{y^2}{2}, \quad z\in[-z_b,\infty),$$

such that the rescaled metric becomes

$$ds^2=\frac{y(z)^2}{(1+y(z)^2)}(d\tau^2+dz^2)+\frac{1}{4}(1+y(z)^2)^2\, d\Omega^2; \tag{24}$$

the Liouville transformation,

$$\varphi=\frac{\zeta(y(z))}{f(y(z))},$$

then carries Eq. (17) into an eigenvalue equation for the operator,

$$B_{nl}=-\partial_z^2+Q_{nl}(z),$$

$$Q_{nl}(z)=\frac{4y(z)^2}{f(y(z))^3}l(l+1)+M^2\frac{y(z)^2}{f(y(z))}+\frac{n^2}{\gamma^2}+\frac{4y(z)^2}{f(y(z))^4}.$$

It holds

$$\lim_{z\to\infty} Q_{nl}(y(z))=\lim_{y\to 0^+} Q_{nl}(y)=\frac{n^2}{\gamma^2},$$

so, according to theorem 3, p. 1448, of Ref. 16, one has

$$\sigma_e(A_{nl})=\left\{\lambda\,\middle|\,\lambda\geqslant\frac{n^2}{\gamma^2}\right\}.$$

A noncovariant measure, that is, the choice of a noncovariant scalar product, gives rise to a nonvoid essential spectrum for every n. This means that spectral properties of the p.w.o. are deeply modified by the choice of the measure.

By means of the decomposition method, we can also see what happens if there is no spherical box, i.e., for $y\in(0,+\infty)=(0,y_b]\cup[y_b,+\infty)$. The analysis on the latter interval is completely analogous to the one on the former and one gets

$$\sigma_e(A_{nl}|_{[y_b,+\infty)})=\left\{\lambda\,\middle|\,\lambda\geqslant\frac{n^2}{\gamma^2}+M^2\right\}.$$

[The variable to choose is $z=\log(y)+y^2/2\in[c,\infty)$; the Liouville transformation and the potential $Q_{nl}(y)$ are the same as in the first interval.] Then the essential spectrum of the p.w.o. in the absence of the box proves to be the same as if there is the box.

Regarding the nonminimally coupled off shell case, we limit ourselves to note that there is a distributional contribute to the potential given by

$$\xi R=\xi 2(1-\gamma)\frac{y\,\delta(y)}{f(y)},$$

and that, for noncovariant measure, the problem of studying the nonminimal case appears to be even more difficult than for a covariant choice of the measure. Indeed, as it is clear for $y\in(0,\infty)$, there is no possibility to define distributional contributions by means of the self-adjoint

extension technique: The $\xi=0$ wave operator A is essentially self-adjoint, so that there is no freedom to define self-adjoint extensions.

IV. EXTREMAL BLACK HOLES

Reissner–Nordström electrically charged black holes are the most direct black hole spherosymmetrical extensions of the Schwarzschild solution. They are characterized by two geometrical hair, the mass m and the charge e and by a Ricci scalar $R=0$ (but they are not Ricci flat). We will consider only uncharged scalar matter fields on these charged black hole backgrounds. Then a discussion of the nonextreme case is entirely analogous to the one for the Schwarzschild case, and for sake of completeness it is sketched in Appendix A. Here we will focus our study on the degenerate black hole case: when $e^2=m^2$ the event horizon is not a bifurcate Killing horizon and near the horizon there is no conical singularity. In the Schwarzschild gauge the metric in (2) has

$$g_{00}(r)=\frac{(r-r_{bh})^2}{r^2},$$

and we can choose an arbitrary value for the period β of the imaginary time τ due to the fact that there is no conical structure near the horizon. Rescaling by r_{bh} the variables τ,r (we will still call them τ,r) and introducing the variable $y=r-1\in(0,y_b]$ one obtains

$$ds^2=(r_{bh})^2\left(\frac{y^2}{(y+1)^2}d\tau^2+\frac{(y+1)^2}{y^2}dy^2+(y+1)^2d\Omega^2\right).$$

We stress that in this case no thermodynamical manifold is defined as different from $\mathscr{M}=S^1\times(0,\infty)\times S^2$. So we will work exclusively on $\mathscr{M}$. The Riemannian manifold $(\mathscr{M},g_{\mu\nu})$ results to be complete, as it is shown in Appendix B. So the wave operator A has to be essentially self-adjoint in the absence of a spherical box. This fact will result also from the p.w.o. analysis. Note that completeness of the given Riemannian manifold implies that it is nonextendible.

The partial wave operators are

$$A_{nl}=\frac{1}{(y+1)^2}(-\partial_y(y^2\partial_y)+Q_{nl}(y)),$$

$$Q_{nl}(y)=(y+1)^2q_{nl}(y),$$

$$q_{nl}(y)=\frac{(y+1)^2}{y^2}n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2+\frac{l(l+1)}{(y+1)^2}+M^2,$$

and the Hilbert space containing the domain is $L^2(I,(1+y)^2dy)$, where $I=(0,\infty)$ in the absence of the box.

A. Deficiency indices of *A*

Equation (17) is

$$\left(-\partial_y^2-\frac{2}{y}\partial_y+\frac{(1+y)^2}{y^2}(q_{nl}(y)-\lambda)\right)\varphi(y)=0. \tag{25}$$

Then for $y\to0^+$ one gets

$$\left(-\partial_y^2-\frac{2}{y}\partial_y+\left(\left(\frac{n^2}{y^4}+\frac{4n^2}{y^3}\right)\left(\frac{2\pi r_{bh}}{\beta}\right)^2+\frac{6n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2+l(l+1)+M^2-\lambda}{y^2}+O\left(\frac{1}{y}\right)\right)\right)\varphi(y)=0. \tag{26}$$

For $n\neq0$ there is an irregular singularity for $y\to0$ and at the leading order the solutions are (cf. Ref. 16, p. 1432)

$$\varphi_1 = \exp\left(\frac{|n|\left(\frac{2\pi r_{bh}}{\beta}\right)}{y} \right) y^{-2|n|(2\pi r_{bh}/\beta)}(1+O(y)),$$

$$\varphi_2 = \exp\left(\frac{-|n|\left(\frac{2\pi r_{bh}}{\beta}\right)}{y} \right) y^{2|n|(2\pi r_{bh}/\beta)}(1+O(y)).$$

They are characterized by an essential singularity at $y=0$ and, existing for every λ a solution not square integrable near the origin, one gets the limit point case.

If $n=0$, then the singularity in (26) becomes a regular one and the corresponding indicial equation admits the following roots:

$$\alpha_1 = \tfrac{1}{2}(-1+c_\lambda), \quad \alpha_2 = \tfrac{1}{2}(-1-c_\lambda),$$

$$c_\lambda = \sqrt{1+4l(l+1)+4M^2-4\lambda}.$$

It is easy to see that, for every choice of λ, l, M one finds the LPC. (If $M>0$ one can choose, e.g., $\lambda=0$ and verify for every l the LPC according to Weyl's alternative (cf. Ref. 13). The same value $\lambda=0$ is suitable for $M=0$, $l>0$. If $M=0$, $l=0$ then a suitable choice in order to see that one has LPC could be $\lambda=1/4$. See also theorem 1, p. 251, of Ref. 23.)

The LPC is verified also at infinity. Then the p.w.o. have deficiency indices (0,0) and there is no boundary condition to choose at $y=0$ in the extremal case.

B. Spectral properties

In the following, $I=(0,y_b]$. We define the new variable z,

$$\frac{dz}{dy} = -\left(1+\frac{1}{y}\right), \quad z(y) = -y-\log(y), \quad z\in[z_b,\infty),$$

in such a way as to get the following rescaled metric:

$$ds^2 = \frac{y(z)^2}{(y(z)+1)^2} d\tau^2 + dz^2 + (y(z)+1)^2\, d\Omega^2;$$

by posing

$$\varphi = \frac{g(y)}{s(y)}, \quad s(y) = \sqrt{y(y+1)},$$

Eq. (25) becomes

$$[\partial_z^2 + (\lambda - R_{nl}(z))]g(z) = 0,$$

where

$$R_{nl}(z) = \frac{\partial_z^2 s(y(z))}{s(y(z))} + \frac{Q_{nl}(y(z))}{(y(z)+1)^2}$$
$$= \frac{1}{4}\frac{(4y(z)+1)}{(y(z)+1)^4} + \frac{(y(z)+1)^2}{y(z)^2} n^2 \left(\frac{2\pi r_{bh}}{\beta}\right)^2 + \frac{l(l+1)}{(y(z)+1)^2} + M^2.$$

[We note that these coordinates allow us to determine very easily if the LPC is verified at $y=0 \Leftrightarrow z=\infty$. Indeed, being $R_{nl}(z)$ is a positive function, conditions for LPC at $z=\infty$ according to

the corollary to theorem 6.3 of Ref. 14 are easily verified.] We can determine if the essential spectrum is void or not according to Ref. 16, theorem 16, p. 1448. We have to find $\lim_{z\to+\infty} R_{nl}(z)$, which is equivalent to $\lim_{y\to 0^+} R_{nl}(y)$. We get

$$n\neq 0 \Rightarrow \lim_{z\to+\infty} R_{nl}(z)=+\infty \Leftrightarrow \sigma_e(A_{nl})=\varnothing,$$

$$n=0 \Rightarrow \lim_{z\to+\infty} R_{0l}(z)=\tfrac{1}{4}+l(l+1)+M^2 \Leftrightarrow \sigma_e(A_{0l})=\{\lambda\,|\,\lambda\geqslant \tfrac{1}{4}+l(l+1)+M^2\}.$$

Due to the nonvoid essential spectrum contribution of the partial wave operators with $n=0$, one finds that $\sigma_e(A)\neq\varnothing$. Physical implications of this very interesting result are briefly discussed in the conclusions.

It is simple to show that, in the absence of the box, i.e., when $y\in(0,+\infty)\Leftrightarrow z\in(-\infty,+\infty)$, the essential spectrum is nonvoid for every value of n, and $\sigma_e(A_{nl})=\{\lambda\,|\,\lambda\geqslant M^2+n^2(2\pi r_{bh}/\beta)^2\}$.

C. Noncovariant measure

The noncovariant choice of the measure leads to the following partial wave operators:

$$A_{nl}=\frac{y^2}{(y+1)^4}(-\partial_y(y^2\partial_y)+S_{nl}(y)),$$

$$S_{nl}(y)=\frac{(y+1)^4}{y^2}n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2+l(l+1)+M^2(1+y)^2.$$

The domain of the p.w.o. is contained in $L^2((0,\infty),[(y+1)^4/y^2]dy)$. The study of Weyl's alternative amounts to determining if near $y=0$ either the LPC or the LCC holds for the solutions of the equation

$$\left(-\partial_y^2-\frac{2}{y}\partial_y+\frac{\left(n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2-\lambda\right)(1+y)^4}{y^4}+\frac{l(l+1)}{y^2}+\frac{M^2(1+y)^2}{y^2}\right)\zeta=0.$$

For all the possible values of the parameters, the LPC holds and so the deficiency indices of the p.w.o. are (0,0) (cf. also corollary of theorem 6.3 of Ref. 14 in the following coordinate choice). Then the wave operator A is essentially self-adjoint.

Qualitative spectral properties in the spherical box are easily found by means of the following variable transformation:

$$z(y)=\frac{1}{y}-2\log(y)-y;\quad z\in[z_b,\infty), \tag{27}$$

such that the rescaled metric becomes

$$ds^2=\frac{y^2}{(y+1)^2}(d\tau^2+dz^2)+(y+1)^2\,d\Omega^2.$$

Then the following Liouville transformation:

$$\zeta(y(z))=\frac{\varphi(y(z))}{1+y(z)},$$

allows us to get the eigenvalue equation

$$(-\partial_z^2+Q_{nl}(z))\varphi=\lambda\varphi,$$

where

$$Q_{nl}(z)=n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2+M^2\,\frac{y(z)^2}{(1+y(z))^2}+\frac{y(z)^2}{(1+y(z))^4}l(l+1)+\frac{2y(z)^3}{(1+y(z))^6}.$$

According to theorem 16, p. 1448 of Ref. 16, given

$$\lim_{z\to\infty} Q_{nl}(y(z))=\lim_{y\to 0} Q_{nl}(y)=n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2,$$

we find that the essential spectrum is the set

$$\sigma_e(A_{nl})=\left\{\lambda\,\middle|\,\lambda\geqslant n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2\right\}, \tag{28}$$

and it is nonvoid for all the p.w.o.

The essential spectrum contribution arising from the p.w.o. restricted to the interval $y\in[y_b,+\infty)$ is given by

$$\sigma_e(A_{nl}|_{[y_b,\infty)})=\left\{\lambda\,\middle|\,\lambda\geqslant n^2\left(\frac{2\pi r_{bh}}{\beta}\right)^2+M^2\right\},$$

so that the essential spectrum of the p.w.o. is the same as in (28).

V. CONCLUSIONS

The analysis of scalar field wave operators on the Euclidean section of a Schwarzschild black hole has been carried in the so called on shell case and in the off shell one for minimal coupling to the curvature. In the case of the covariant choice of the functional measure, the properties of the physical self-adjoint extension of the wave operators to be chosen show that on shell the natural choice for the thermal manifold is $\mathscr{M}_E$ because of the nature of the ''singularity'' at the horizon to be only a coordinate one. Indeed, even if one starts with $\mathscr{M}$, the boundary condition to be chosen is such that the corresponding self-adjoint extension coincides with the one calculated on $\mathscr{M}_E$. The off shell case is different from the on shell one, because going off shell means being forced to work on an incomplete Riemannian manifold and to impose a boundary condition at $r=r_{bh}$ that cannot be selected on firm physical grounds (the shift from the equilibrium temperature being unphysical) and whose choice is also nontrivial from a mathematical point of view.

By posing a spherical box around the black hole, corresponding in all cases to a finite Euclidean four-volume V_4, we have found that the essential spectrum is void only if the covariant measure for the path integral is chosen.

In the case of the noncovariant choice, one finds that A_{NC} is essentially self-adjoint on $C_0^\infty(\mathscr{M})$ and has a nonvoid essential spectrum in a finite volume (cf. also Ref. 4) unless another infrared regularization is introduced near the horizon. The equivalence of the spectral problem of A_{NC} with the spectral problem of A_{opt} on the optical manifold gives a qualitative insight about spectral properties; indeed, the corresponding four-volume $V_{4\,optical}$ is divergent unless a further infrared regularization is introduced near the ''radial'' coordinate $r=r_{bh}$.

An analogous study has been generalized to the case of electrically neutral scalar fields on nondegenerate Reissner–Nordström black hole manifolds and analogous results have been obtained.

The extremal case has revealed some very peculiar features. First of all, the corresponding Riemannian manifold is complete for any β-periodicity of the Euclidean time τ, and so it lacks the possibility to define in this way a preferred geometric temperature for the thermal equilibrium of the quantum field on the extremal black hole background. Any choice of β ensures essential self-adjointness of the wave operator on $C_0^\infty(\mathscr{M})$. From this point of view thermal quantum field theory on the extremal background is not different from, e.g., thermal quantum field theory in flat space and there is no apparent contradiction in interpreting this fact as a lack of thermal effects associated with the given black hole background, at least as far as the Euclidean path integral

approach is pursued. A second relevant feature is the presence of a nonvoid essential spectrum, whichever choice of the measure one makes. So in the extremal case it is not possible to get a discretization of physical states by posing a spherical box with reflecting boundary conditions at a fixed distance from the event horizon. Only by also introducing a further boundary near the degenerate horizon can one get a discrete spectrum. Anyway, it has to be noted that for the covariant choice the only contribution to the essential spectrum of the wave operator comes from the p.w.o. with $n=0$ and that the subspace $n=0$ in the Euclidean approach to ''standard'' finite temperature quantum field theory corresponds to a zero temperature contribution (vacuum contribution);[25] so it does not seem to affect the thermal properties of the system.

Further investigations on these topics will be the subject of future works.

ACKNOWLEDGMENTS

The author wishes to thank especially F. Valz-Gris for his very helpful remarks and his careful bibliographic suggestions. Thanks are also addressed to A. S. Cattaneo, S. Desantis, A. Santambrogio, and M. Spreafico for some discussions about differential geometry.

APPENDIX A: NONEXTREMAL REISSNER–NORDSTRÖM BLACK HOLES

The nondegenerate Reissner–Nordström black hole is characterized by a mass m and by an electric charge e, with $m^2<e^2$. A conical structure near the event horizon is again present and this gives rise qualitatively to the same analysis as in the Schwarzschild case. The metric in the external region has the same form as in (2) with

$$g_{00}(r)=\frac{(r-r_{bh})(r-r_c)}{r^2},$$

where r_{bh} is the event horizon radius and r_c is the Cauchy horizon radius, with $r_c<r_{bh}$. The conical defect is avoided if the period β is fixed at the following value:

$$\beta_h=\frac{2\pi}{k}=4\pi\frac{r_{bh}^2}{r_{bh}-r_c}, \quad k=\frac{r_{bh}-r_c}{2r_{bh}^2}.$$

We define the rescaled variables $\tau\to k\tau\in[0,2\pi)$; $r\to kr\in(kr_{bh},\infty)$ (if a spherical box at $r=R>r_{bh}$ is introduced then $r\to kr\in(kr_{bh},kR]$). By means of the change of variable,

$$z=\sqrt{2}\sqrt{r-kr_{bh}}\in(0,\infty),$$

one finds

$$ds^2=\frac{1}{k^2}\left(z^2\frac{h(z)}{f(z)}d\tau^2+\frac{f(z)}{h(z)}dz^2+\frac{1}{4}f(z)d\Omega^2\right),$$

$$f(z)=(\delta+z^2)^2, \quad h(z)=\delta^2+z^2,$$

$$\delta=2kr_{bh}=1-\frac{r_c}{r_{bh}}\in(0,1).$$

Note that the value $\delta=0$ corresponds to the extremal case, whereas $\delta=1$ is the Schwarzschild one. We will consider only noncharged scalar matter, so there is no need to introduce a chemical potential and a grand canonical partition function.

1. Deficiency indices of *A*

Also in this case it is possible to show that the Euclidean manifold $\mathcal{M}=S^1\times(0,\infty)\times S^2$ can be extended to a complete Riemannian manifold $\mathcal{M}_E$. The principle is the same as in the Schwarzschild case. See also Appendix B. Then the wave operator A is essentially self-adjoint on $C_0^\infty(\mathcal{M}_E)$.

The partial wave operators become in this case

$$A_{nl}=-\frac{1}{zf(z)}\partial_z(zh(z)\partial_z)+V_{nl}(z),$$

$$V_{nl}(z)=\frac{n^2}{z^2}\frac{f(z)}{h(z)}+\frac{4l(l+1)}{f(z)}+M^2.$$

The differential equation (17) is equivalent to

$$\left(-\partial_z^2-\frac{3z^2+\delta^2}{z(z^2+\delta^2)}\partial_z+\frac{(z^2+\delta)^2}{z^2+\delta^2}(V_{nl}(z)-\lambda)\right)\zeta=0,$$

and its asymptotic expansion for $z\to 0^+$ is

$$\left(-\partial_z^2-\frac{1}{z}\partial_z+\frac{n^2}{z^2}\right)\zeta=0.$$

The indicial equation is the same as in the Schwarzschild case, and one finds the LCC for all the p.w.o. with $n=0$ and the LPC for all the p.w.o. with $n\neq 0$.

2. Spectral analysis

In the case of the p.w.o. with $n=0$, one has the LCC at both the extremes of the interval $(0,z_b]$ and the deficiency indices are (2,2), so one can conclude that the spectrum is purely discrete. In order to study the case with $n\neq 0$, it is useful to introduce the following variable:

$$\frac{dx}{dz}=\frac{z^2+\delta}{\sqrt{z^2+\delta^2}},$$

$$x(z)=\frac{1}{2}z\sqrt{z^2+\delta^2}+\delta\left(1-\frac{\delta}{2}\right)\log|z+\sqrt{z^2+\delta^2}|+C\in(0,x_b],$$

$$C=-\delta\left(1-\frac{\delta}{2}\right)\log|\delta|,$$

in such a way that the metric becomes

$$ds^2=\frac{1}{k^2}\left(z(x)^2\frac{\delta^2+z(x)^2}{(\delta+z(x)^2)^2}d\tau^2+dx^2+\frac{1}{4}(\delta+z(x)^2)^2d\Omega^2\right). \tag{29}$$

The Liouville transformation,

$$\zeta(x)=\frac{1}{\sqrt{z(x)(\delta+z(x)^2)(\delta^2+z(x)^2)^{1/2}}}\phi(x),$$

carries the p.w.o.,

$$A_{nl}=-\partial_x^2-(\partial_x\log(z(x)(\delta+z(x)^2)(\delta^2+z(x)^2)^{1/2})\partial_x+V_{nl}(z(x)),$$

into a form suitable for applying theorems and criteria of Ref. 16,

$$B_{nl}=-\partial_x^2+V_{nl}(z(x))+G(z(x)),$$

$$G=\tfrac{1}{2}\left(\partial_x H+\tfrac{1}{2}H^2\right),$$

$$H=\partial_x\log(z(x)(\delta+z(x)^2)(\delta^2+z(x)^2)^{1/2}),$$

where

$$G=-\frac{\delta^6-2\delta^4 z(x)^2(2+\delta)-\delta^2 z(x)^4(4+20\delta-9\delta^2)-8z(x)^6\delta(2-\delta)}{4z(x)^2(\delta+z(x)^2)^4(\delta^2+z(x)^2)}.$$

We have then

$$B_{nl}=-\partial_x^2+v_{nl}(z(x)),$$

$$v_{nl}(z(x))=\left(n^2-\frac{1}{4}\right)\frac{1}{z(x)^2}+w_{nl}(z(x)),$$

$$w_{nl}=\text{smooth bounded function},$$

and according to criterion (25), p. 1598 of Ref. 16, given

$$\lim_{x\to 0^+} x^2 v_{nl}(z(x))=n^2-\tfrac{1}{4}>-\tfrac{1}{4},$$

one can conclude that the essential spectrum of all the p.w.o. with $n\neq 0$ is empty. Summarizing, one gets a purely discrete spectrum for all the p.w.o.

The off shell case is entirely analogous to the one discussed in the Schwarzschild case; also analogous is the study of the noncovariant measure spectrum.

APPENDIX B: COMPLETENESS OF THE EUCLIDEAN MANIFOLDS

In order to show that the Euclidean manifold in the on shell case $(\mathscr{M}_E, g_{\mu\nu})$ is a complete Riemannian manifold one can proceed as follows. $(\mathscr{M}_E, g_{\mu\nu})$ can be seen as the warped product[26] of the 2D Riemannian manifold $(\mathbb{R}^2, g_{ab})$, where the metric g_{ab} is diagonal (with entries, e.g., in the Schwarzschild case both equal to $(4r_{bh}^3/r)\exp(-r/r_{bh})$), with the 2D sphere S^2 (canonical metric). The warping function[26] is $r^2>0$. In general, a warped product $(A, g_{\mu\nu}(A)) \times_h (B, g_{\mu\nu}(B))$ of two Riemannian manifolds with warping function $h>0$ is complete if and only if $(A, g_{\mu\nu}(A))$ and $(B, g_{\mu\nu}(B))$ are complete Riemannian manifolds.[26] The 2D sphere is compact and then is complete. In order to show that $(\mathbb{R}^2, g_{ab})$ is complete we note that in the ''conical'' chart (29) $\tau\in[0,2\pi); x\in(0,\infty)$ the metric is written in polar coordinates originating at 0, so one can refer to sec. 4 of Ref. 27.

One can equivalently use the following trick, which allows us to give a unified treatment also for studying completeness of the Riemannian manifold in the off shell case and in the extremal one. Define[28] a divergent curve on a manifold $\mathscr{M}$ as a differentiable mapping $\alpha:[0,\infty)\to\mathscr{M}$ such that for any compact set $K\subset\mathscr{M}$ there exists $t_0\in(0,\infty)$ with $\alpha(t)\notin K$, $\forall t>t_0$. The length of the divergent curve is defined by

$$\lim_{t\to\infty}\int_0^t dt|\alpha'(t)|.$$

$(\mathscr{M}, g_{\mu\nu})$ is complete if and only if the length of any divergent curve is unbounded.[28] In all cases the metric gets the form

$$ds_2^2=\eta^2(x)d\tau^2+dx^2,$$

with $\tau\in[0,2\pi)$, $\eta(x)$ a suitable function and $x\in I$. The interval I is equal to $(0,\infty)$ in the nondegenerate case and if $\gamma=1$ can become $[0,\infty)$; it is $(-\infty,+\infty)$ in the extremal case. For such a metric all lines $\tau=\text{const}$ are geodesics. If $I=(0,\infty)$, then the ''radial'' geodesics $\tau=\text{const}$ starting from a given K and ''going towards'' the point $x=0$ are divergent curves of finite length, so the manifold is necessarily incomplete. The same is not true if $I=[0,\infty)$ because in this case all divergent curves have to ''point towards'' $x=\infty$ and so they have to be unbounded.

If $I=\mathbb{R}$ one can use the fact that the divergent curves given by the ''radial'' geodesics have to diverge (in length) at $x=+\infty$ and/or at $x=-\infty$. Indeed, one can, e.g., consider (without loss of generality) compact sets of the type $K=S^1\times[x_0,x_1]$ with $-\infty<x_0<x_1<\infty$. Given a divergent curve ending, say, at $x_d>x_1$ one has that

$$\int_0^{t_d} dt|\alpha'(t)| = \int_0^{t_d} dt \sqrt{\left(\frac{dx}{dt}\right)^2 + \eta^2(x)\left(\frac{d\tau}{dt}\right)^2} \geqslant \int_0^{t_d} dt \left|\frac{dx}{dt}\right|;$$

the last term above can be assumed to represent the length of a purely radial geodesic (suitably reparametrized) having the same starting point and with an end point having the same radial coordinate as the given divergent curve. It is evident that such a radial geodesic is a divergent curve too and that its length is unbounded. Then also the extremal manifold is complete.

Concerning the optical Riemannian manifold $(\mathscr{M},h_{\mu\nu})$, the optical metric is a warped product of a 2D metric,

$$ds_2^2 = d\tau^2 + \frac{1}{g_{00}^2(r)} dr^2,$$

with the canonical metric on S^2. The warping function is $r^2/g_{00}(r)$. Also in this case one can limit showing the completeness of the above 2D metric, but this proves to be an easy task. Indeed, the given metric is a metric on a product manifold $S^1\times I$, where $I=(r_{bh},\infty)$, and it is complete if each factor is complete.[29] A tortoise-like change of radial coordinate carries the above metric into

$$ds_2^2 = d\tau^2 + dx^2,$$

where $x\in\mathbb{R}$. Then each factor is complete.

APPENDIX C: ESSENTIAL SELFADJOINTNESS OF A_{NC}

In this section we show that the noncovariant wave operator (for minimal coupling $\xi=0$ in the conical case) is essentially self-adjoint on $C_0^\infty(\mathscr{M})$ without involving a p.w.o. analysis. The starting point is the well known equivalence between A_{NC} and $A_{opt}\equiv-\Delta_h+q(x)$ given in (11). We can then translate the problem of self-adjointness properties of A_{NC} into the analogous one for A_{opt} on the optical manifold. We know that the optical manifold is a complete Riemannian manifold, so surely the optical Laplacian $-\Delta_h$ is essentially self-adjoint on $C_0^\infty(\mathscr{M})\cap L^2(\mathscr{M},d^4x\sqrt{h})$. We can show that the sum $-\Delta_h+q(x)$ is essentially self-adjoint on the same domain. Indeed, we have, e.g. using the tortoise ''radial'' coordinate x, that

$$q(y(x)) = M^2 \frac{y(x)^2}{(1+y(x)^2)} - \frac{1}{(1+y(x)^2)^4}$$

in the Schwarzschild case (if $\gamma\neq1$ then $\xi=0$); in the extremal case it holds that

$$q(y(x)) = M^2 \frac{y(x)^2}{(1+y(x))^2} + 2\frac{y(x)^3}{(1+y(x))^6}.$$

The above potentials are smooth bounded functions on $\mathscr{M}$. As operators in $L^2(\mathscr{M},d^4x\sqrt{h})$; they are self-adjoint bounded multiplication operators Q_q having domain $D(Q_q)=\{\phi|q\phi\in L^2(\mathscr{M},d^4x\sqrt{h})\}=L^2(\mathscr{M},d^4x\sqrt{h})$. In particular, we get trivially $C_0^\infty(\mathscr{M})\subset D(Q_q)$. Then we can use the Rellich–Kato theorem[13] because Q_q, being bounded, is also $(-\Delta_h)$-bounded with $(-\Delta_h)$-bound 0.

We can conclude that A_{NC} is essentially self-adjoint on $C_0^\infty(\mathscr{M})\cap L^2(\mathscr{M},d^4x(\sqrt{g}/g_{00}))$.

APPENDIX D: FRIEDRICHS EXTENSION FOR THE ON SHELL CASE

We want to show that the Friedrichs extension A^F of the direct sum of the p.w.o. coincides with the closure $\overline{A}$ of the essentially self-adjoint operator A defined on $C_0^\infty(\mathscr{M}_E)$.

The first step is to show that a core $D(A^F)$ of A^F is contained in the core $C_0^\infty(\mathscr{M}_E)$ of $\overline{A}$. We have that $D(A^F)$ is given by

$$D(A^F)=L\{D_{nl}\otimes K_n\otimes S_l : n,l\in\mathbb{N}\},$$

$$D_{nl}=C_0^\infty(0,\infty) \quad \forall n\neq 0,$$

$$D_{0l}=C_0^\infty(0,\infty)+L\{w_F\},$$

where w_F, as it will result from the following, is a smooth function such that the Friedrichs boundary condition is implemented. This core is contained in $C_0^\infty(\mathscr{M}_E)$ and the given boundary condition is the only one allowing such an inclusion. For analogous discussions in the case of Schrödinger operators in quantum mechanics, see Ref. 14, sec. 17.F.

In fact, one can obtain a core for a general self-adjoint extension of A_{0l} as follows:

$$D_{0l}=C_0^\infty(0,\infty)+L\{\cos(s)w_1+\sin(s)w_2\},$$

where w_1, w_2 are smooth functions such that[14]

$$w_i=\begin{cases} u_i(y), & \text{for } y \text{ close to } 0,\\ 0, & \text{for } y \text{ close to } \infty,\end{cases}$$

and u_1, u_2 are a fundamental system for the equation $(A_{0l}-\lambda)u=0$. In our case a fundamental system has the following leading order behavior near $y=0$:

$$u_1(y)\sim 1, \quad u_2(y)\sim \log(y).$$

We want to see for which value of s the function

$$\varphi_s(y)\equiv\cos(s)w_1(y)+\sin(s)w_2(y)$$

is in $C_0^\infty(\mathscr{M}_E)$. By taking the limit $\lim_{y\to 0}\varphi_s(y)$ it results that the only value of s allowing us to get a finite limit in 0 and so to include D_{0l} in $C_0^\infty(\mathscr{M}_E)$ is $s=0$ and it corresponds to the Friedrichs extension.

We have obtained that the restriction A^F_{core} of A^F to its core is such that $A^F_{core}\subset A$. Note that A^F_{core} is obviously essentially self-adjoint. This implies that $(A^F_{core})^*=A^F\supset A^*=\overline{A}$. But both the operators $(A^F_{core})^*$ and $\overline{A}$ are self-adjoint. The equality $A^F=\overline{A}$ follows.

(Received 8 October 1997; accepted for publication 14 May 1998)

The semiconductor Boltzmann equation is considered within a material with a space-dependent band characteristic. Its fluid limit under strong elastic collisions leads to the so-called spherical harmonics expansion (SHE) model. For this model, the influence of smoothly space-dependent or abruptly discontinuous band characteristics is analyzed. For the latter case which occurs at heterojunction interfaces, kinetic boundary layers are analyzed and higher order transmission conditions are derived. In a further step, transmission conditions through heterojunctions for the energy-transport and drift-diffusion models (which are obtained as moments of the SHE model) are constructed. © *1998 American Institute of Physics.* [S0022-2488(98)02409-8]

I. INTRODUCTION

The drift-diffusion (DD) model of semiconductors is, by far, the most simple and widely used macroscopic semiconductor model.[1,2] Its derivation from the more fundamental kinetic model, the semiconductor Boltzmann equation, has been made mathematically rigorous in Refs. 3 and 4.

However, the search for more accurate descriptions of carrier transport in semiconductors has been motivated by the recent developments in microelectronics technology. Several models have been proposed to improve the DD model, including the hydrodynamic (HD) model,[5] the energy-transport (ET) model,[6] and the spherical harmonic expansion (SHE) model.[7,8] Among these, the SHE and ET models have been proved to derive from a diffusion approximation of the Boltzmann transport equation,[9,10,7,11] while this question still remains open for the HD model. The diffusion approximation naturally provides consistent closure relations to the SHE and ET models while phenomenological arguments must be invoked to close the HD model. For this reason, in the present paper, we shall concentrate on the SHE and ET models, and on the DD model which stands as a submodel of the ET model.

The available derivations of the SHE and ET models concern materials with homogeneous crystalline structure.[7,10,9] The goal of the present paper is to extend them to materials with smoothly space-dependent band diagrams and to abrupt heterojunctions. Smoothly space-dependent band diagrams appear in materials with graded stoechiometry (like $Al_xGa_xAs_{1-x}$) which are used in certain microelectronics components. Heterojunctions are now widely used in various applications. The DD model has been extended to smoothly space-dependent band diagrams in Ref. 12 and to heterojunctions in Ref. 13.

In Sec. II, we show that the SHE model for smoothly space-dependent band diagrams is structurally identical as for space independent band diagrams, provided that an adequate set of variables and unknowns are used. Similar conclusions are drawn for the ET and DD models in Sec. VI.

For abrupt heterojunctions, the problem is more complicated. We start with the interface problem at the level of the Boltzmann equation. Interface conditions at the band discontinuity are set up in terms of reflection-transmission matrices which take into account carrier scattering by the irregularities of the potential at the interface. Various properties of these interface conditions are reviewed in Sec. III, together with a few practical examples.

In Sec. IV, we proceed to the diffusion approximation of the Boltzmann equation complemented with the interface conditions at the heterojunction. Transmission conditions for the SHE

 © 1998 American Institute of Physics

model are naturally derived from this procedure. As usual, the order of accuracy of the diffusion approximation is measured in terms of the dimensionless mean free path, ratio of the mean free path (associated with elastic collisions) to the typical size of the device. If the first order of accuracy is retained, two natural continuity relations are derived, one relating the values of the SHE-distribution function on each side, the other one relating its fluxes on each side. At the second order of accuracy, the continuity condition on the SHE distribution function is replaced by a condition which links its jump at the interface to the common value of its fluxes on each side of the interface. The coefficient in this combination is similar to the ''extrapolation length'' originating from the presence of kinetic boundary layers[14,15] and introduced in the semiconductor context in Refs. 16 and 17. It is obtained as the equilibrium limit of two half space stationary kinetic problems connected with the interface conditions, which will later be referred to as a ''two-sided Milne problem,'' in reference to the Milne problem of kinetic theory.[14] In Sec. V, it is shown that the two-sided Milne problem is solvable under reasonable assumptions on the solution of one-sided Milne problems with inflow boundary conditions. For special cases these assumptions can be verified. An approximation procedure in the spirit of, e.g., Ref. 15, is carried out leading (for rotationally invariant models) to explicit formulas for the above-mentioned coefficient in the second-order transmission condition.

Transmission conditions at heterojunction interfaces are then derived for the ET and the DD models by a moment expansion of the corresponding transmission conditions for the SHE model (Sec. VI). This procedure supposes that there is no boundary layer in the ET or DD limit of the SHE model, or at least, that the influence of this boundary layer is negligible. This point will be discussed in detail in future work. The obtained first-order transmission condition for the DD model reduces to the classical one.[13] For the DD model, transmission conditions of the form of the second-order conditions have been derived in Ref. 18. They correspond to a very rough approximation of the solution of the two-sided Milne problem.

We believe that the use of these second-order transmission conditions will significantly improve the accuracy of the numerical treatment of heterojunction interfaces. Future work will be devoted to the numerical implementation of these conditions and their validation against experimental and numerical data.

II. THE SPHERICAL HARMONIC EXPANSION (SHE) MODEL

The SHE model is derived from the semiconductor Boltzmann equation through a diffusion approximation procedure using elastic collisions as the dominant scattering mechanism. We refer to Ref. 9 for a discussion of the validity of the elastic approximation of the phonon collision operator. Here, our starting point will be the following Boltzmann equation:

$$\frac{\partial f^\alpha}{\partial t}+\frac{1}{\alpha}\,(\nabla_k\epsilon\cdot\nabla_x f^\alpha-\nabla_x\epsilon\cdot\nabla_k f^\alpha)=\frac{1}{\alpha^2}\,Q(f^\alpha)+S(f^\alpha), \tag{II.1}$$

where $f^\alpha=f^\alpha(x,k,t)$ is the electron distribution function depending on the position $x\in\mathbf{R}^3$, the momentum $k\in B$, and the time $t>0$. The Brillouin zone B is the elementary cell of the dual lattice L^* and is identified with the torus $B=\mathbf{R}^3/L^*$. We suppose that B does not depend on x, which means that the interatomic distances remain the same as the material changes. This hypothesis is reasonable because abrupt heterojunctions or materials with graded stoechiometry are based on materials which share almost the same lattice characteristics.

The function $\epsilon=\epsilon(x,k,t)$ is the total particle energy of an electron in the lattice. It can be decomposed in the following way:

$$\epsilon(x,k,t)=e(x,k)-V(x,t)=e(x,k)-\chi(x)-\phi(x,t), \tag{II.2}$$

with $e(x,0)=0$. The function $e(x,k)$ is the kinetic energy measured from the bottom of the conduction band, while $-V(x,t)$ is the energy of the bottom of the conduction band measured from an arbitrary fixed origin.[19] The potential $V(x,t)$ can itself be decomposed into the Coulomb potential $\phi(x,t)$ arising from the electron space-charge, the doping and the applied bias, which is smooth and may depend upon t, and the electron affinity $\chi(x)$, which only depends on the material and is therefore independent of t. In the present section, we shall first suppose that $\chi(x)$

and $e(x,k)$ are smooth. The space-dependent kinetic energy $e(x,k)$ takes into account the variations of the band diagram as the material smoothly changes. A typical form of $e(x,k)$ is that of a parabolic band diagram with a space-dependent effective mass:

$$e(x,k)=\frac{k^2}{2m_*(x)}. \tag{II.3}$$

However, in the remainder of this section, any smooth C^1 function e: $(x,k)\in\mathbf{R}^3\times B\to\mathbf{R}$ will be admissible. We denote by $v(x,k)=\nabla_k\epsilon(x,k,t)=\nabla_k e(x,k)$ the particle velocity.

The collision operator $Q(f)$ takes into account both impurity scattering and phonon scattering in its elastic limit.[9,7] It is written:

$$Q(f)(k)=\int_B \Phi(x,k,k')\,\delta(\epsilon(k')-\epsilon(k))(f(k')-f(k))dk', \tag{II.4}$$

where the (x,t) dependence of ϵ, f, and $Q(f)$ has been omitted for brevity. The δ function in (II.4) expresses the elastic character of the interaction. $\Phi(x,k,k')$ is the transition matrix associated with the considered interactions. We shall not specify it (see Ref. 20), assuming only its positivity and invariance under exchange of k and k'.

The collision operator $S(f)$ takes into account all the other interactions, these being considered as weaker than the elastic interaction: The inelastic correction to the phonon collisions, the electron–electron collisions, and possibly, other interaction mechanisms. Their exact expression will not be needed here and we refer to Ref. 9 for more details.

Equation (II.1) is already written in scaled form. The scaling is detailed in Ref. 9. Let us just recall that the energy scale is that of the applied bias, and not that of the thermal energy associated with the lattice temperature, and consequently, to some extent, high field effects are included. The parameter α represents the scaled mean free path, i.e., the ratio of the mean free path for elastic interactions to the typical size of the phenomena under consideration. It is supposed small ($\alpha\ll 1$).

The SHE model is obtained as the formal limit of (II.1) when α tends to zero,[9,7,21] by means of the Hilbert expansion:

$$f^\alpha=f^0+\alpha f^1+\alpha^2 f^2+\cdots. \tag{II.5}$$

After inserting the ansatz (II.5) in (II.1), terms of equal powers of α at the left- and right-hand sides of (II.1) are identified. This formal expansion procedure will be carried out in the following, and a rigorous justification is left as the subject for future work. This means in particular that the occurring functions will be assumed sufficiently smooth such that the computations are justified.

Before proceeding, we recall the coarea formula[22]

$$\int_B \psi(k)dk=\int_{-\infty}^{\infty}\int_{\mathcal{S}_{(x,\epsilon,t)}} \psi(k)\,\frac{dS_{(x,\epsilon,t)}(k)}{|\nabla_k\epsilon(x,k,t)|}\,d\epsilon, \tag{II.6}$$

where $\mathcal{S}_{(x,\epsilon,t)}$ is the ((x,t) dependent) manifold

$$\mathcal{S}_{(x,\epsilon,t)}=\{k\in B,\epsilon(x,k,t)=\epsilon\},$$

in k-space and $dS_{(x,\epsilon,t)}(k)$ is the Euclidean surface element on $\mathcal{S}_{(x,\epsilon,t)}$. We denote by $dN_{(x,\epsilon,t)}(k)$ the coarea and by $N(x,\epsilon,t)$ the energy density of states:

$$dN_{(x,\epsilon,t)}(k)=\frac{dS_{(x,\epsilon,t)}(k)}{|\nabla_k\epsilon(x,k,t)|},\quad N(x,\epsilon,t)=\int_{\mathcal{S}_{(x,\epsilon,t)}} dN_{(x,\epsilon,t)}(k). \tag{II.7}$$

The coarea formula (II.6) is valid for every $\psi\in C(\overline{B})$, if

$$N(x,\epsilon,t)<\infty\quad \forall(x,\epsilon,t)\in\mathbf{R}^3\times\mathbf{R}\times\mathbf{R}^+ \tag{II.8}$$

holds. This is an assumption on the set where $\nabla_k\epsilon$ vanishes and on its behavior close to this set.

The collisions modeled by the operator Q do not change the energy of a particle. Therefore, we can consider Q as an operator acting on $L^2(\mathscr{S}_{(x,\epsilon,t)}, dN_{(x,\epsilon,t)})$ for every fixed (x,ϵ,t). From Ref. 9, we have

Lemma II.1: (i) The null space of Q consists of the constants only.
(ii) The equation $Q(f)=g$ is solvable if and only if

$$\int_{\mathscr{S}_{(x,\epsilon,t)}} g(k)\,dN_{(x,\epsilon,t)}(k)=0, \tag{II.9}$$

and its solution f is unique provided that

$$\int_{\mathscr{S}_{(x,\epsilon,t)}} f(k)\,dN_{(x,\epsilon,t)}(k)=0. \tag{II.10}$$

(iii) Q is a nonpositive self-adjoint operator, i.e.,

$$\int_{\mathscr{S}_{(x,\epsilon,t)}} Q(f)g\,dN_{(x,\epsilon,t)}=\int_{\mathscr{S}_{(x,\epsilon,t)}} fQ(g)\,dN_{(x,\epsilon,t)},$$

$$\int_{\mathscr{S}_{(x,\epsilon,t)}} Q(f)f\,dN_{(x,\epsilon,t)}\leqslant 0,$$

with equality implying that f is in the null space of Q.

A more precise functional setting and additional properties of Q can be found in Ref. 9 or Ref. 21. A consequence of point (i) is that if $Q(f)=0$ holds for a function $f(x,k,t)$, then $f(x,k,t)=F(x,\epsilon(x,k,t),t)$ for a function F of position, energy, and time.

The Hilbert procedure leads to the following sequence of equations for f^i, $i=0,1,2$:

$$Q(f^0)=0, \tag{II.11}$$

$$Q(f^1)=\nabla_k\epsilon\cdot\nabla_x f^0-\nabla_x\epsilon\cdot\nabla_k f^0, \tag{II.12}$$

$$Q(f^2)=\nabla_k\epsilon\cdot\nabla_x f^1-\nabla_x\epsilon\cdot\nabla_k f^1+\frac{\partial f^0}{\partial t}-S(f^0). \tag{II.13}$$

From (II.11) and Lemma II.1 (i), it follows that there exists $F=F(x,\epsilon,t)$, such that

$$f^0(x,k,t)=F(x,\epsilon(x,k,t),t). \tag{II.14}$$

The function $F(x,\epsilon,t)$ cannot be specified further by using Eq. (II.11) alone. To derive the equation for F that we are looking for, we must solve the next order equations (II.12) and (II.13). Equation (II.12) reduces to

$$Q(f^1)=\nabla_k\epsilon\cdot\nabla_x F.$$

Since $\nabla_x F$ only depends on the energy, f^1 can be written as

$$f^1=-\lambda(x,k,t)\cdot\nabla_x F+F^1(x,\epsilon(x,k,t),t), \tag{II.15}$$

where F^1 is arbitrary and λ is the solution of

$$-Q(\lambda)=\nabla_k\epsilon, \quad \int_{\mathscr{S}_{(x,\epsilon,t)}} \lambda\,dN_{(x,\epsilon,t)}=0. \tag{II.16}$$

Existence and uniqueness of solutions of (II.16) are guaranteed by Lemma II.1 (ii), since $\int_{\mathscr{S}}\nabla_k\epsilon\,dN=0$. Note that (II.16) must be understood componentwise. Then we have the

Theorem II.2: Let f^0 and f^1 be given by (II.14) and (II.15). Then, a solution f^2 of (II.13) exists if and only if $F(x,\epsilon,t)$ satisfies

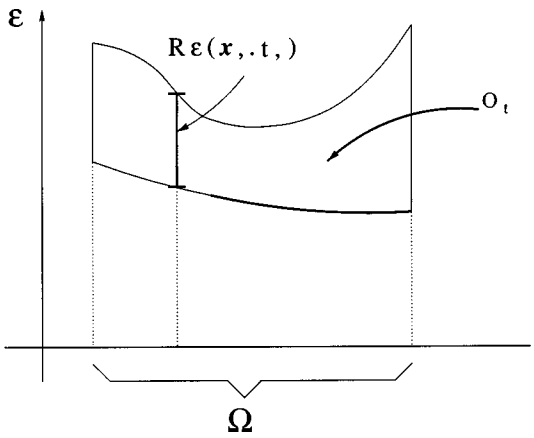

FIG. 1. Domain of definition of F: Case of a smooth band diagram.

$$N(x,\epsilon,t)\left(\frac{\partial F}{\partial t}-\frac{\partial \phi}{\partial t}\frac{\partial F}{\partial \epsilon}\right)-\nabla_x\cdot(D(x,\epsilon,t)\nabla_x F)=\overline{S}(F), \tag{II.17}$$

with the diffusion matrix $D(x,\epsilon,t)$ given by

$$D(x,\epsilon,t)=\int_{\mathscr{S}_{(x,\epsilon,t)}}\nabla_k\epsilon\otimes\lambda\, dN_{(x,\epsilon,t)}, \tag{II.18}$$

where $\otimes$ denotes the tensor product, and

$$\overline{S}(F)=\int_{\mathscr{S}_{(x,\epsilon,t)}}S(F)dN_{(x,\epsilon,t)}.$$

Proof: With (II.15), (II.13) is written as

$$Q(f^2)=\nabla_k\epsilon\cdot\nabla_x F^1-\nabla_x\cdot(\nabla_k\epsilon(\lambda\cdot\nabla_x F))+\nabla_k\cdot(\nabla_x\epsilon(\lambda\cdot\nabla_x F))+\frac{\partial F}{\partial t}+\frac{\partial F}{\partial\epsilon}\frac{\partial\epsilon}{\partial t}-S(F).$$

Then, the solvability condition (II.9), together with the identities [valid for any smooth function $u(x,k,t)$, denoting for short, $\mathscr{S}_\epsilon:=\mathscr{S}_{(x,\epsilon,t)}$, $dN_\epsilon:=dN_{(x,\epsilon,t)}$]:

$$\nabla_x\left(\int_{\mathscr{S}_\epsilon}u\ dN_\epsilon\right)=\int_{\mathscr{S}_\epsilon}\nabla_x u\ dN_\epsilon-\frac{\partial}{\partial\epsilon}\left(\int_{\mathscr{S}_\epsilon}u\nabla_x\epsilon\ dN_\epsilon\right),$$

$$\int_{\mathscr{S}_\epsilon}\nabla_k u\ dN_\epsilon=\frac{\partial}{\partial\epsilon}\int_{\mathscr{S}_\epsilon}\nabla_k\epsilon\ u\ dN_\epsilon,$$

leads to the result. Here, we have used (II.2) to ensure that $\partial\epsilon/\partial t=-\partial\phi/\partial t$ is independent of k.■

Remark II.3: The SHE model (11.17) with an x-dependent band diagram is identical to the standard SHE model expressed in terms of the total energy variable (compare to Ref. 9, Eqs. (III.23), (III.24)). The only difference lies in the position-dependent density of states N and diffusivity D. We also note that, following Ref. 9, the diffusivity is a symmetric non negative matrix, which satisfies

$$D\geqslant\frac{C}{N}\int_{\mathscr{S}_\epsilon}\nabla_k\epsilon\otimes\nabla_k\epsilon\, dN_\epsilon,$$

where $C>0$ is a constant related to the coercivity constant of Q and $(\nabla_k\epsilon\nabla_k\epsilon)$ is the tensor square of $\nabla_k\epsilon$. We shall not detail this point here. ■

Remark II.4: $F(x,\epsilon,t)$ is defined on the (time-dependent) domain (*see Fig. 1*)

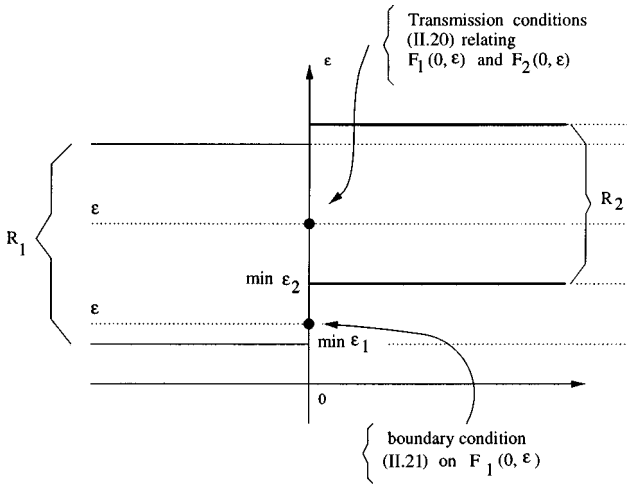

FIG. 2. Domain of definition of F: Case of an abrupt heterojunction at Σ.

$$\mathcal{O}_t=\{(x,\epsilon)\in\Omega\times\mathbf{R}|N(x,\epsilon,t)>0\}=\{(x,\epsilon)\in\Omega\times\mathbf{R}|\,\epsilon\in\mathcal{R}\epsilon(x,\cdot,t)\},\tag{II.19}$$

where Ω is the device domain in x-space and $\mathcal{R}\epsilon(x,\cdot,t)$ is the numerical range of the energy function $k\in B\to\epsilon(x,k,t)$. Therefore, boundary conditions must be prescribed for $x\in\partial\Omega$ or $\epsilon\in\partial\mathcal{R}\epsilon(x,\cdot,t)$. For $x\in\partial\Omega$, we refer to Ref. 16 where this question is addressed in detail. For $\epsilon\in\partial\mathcal{R}\epsilon(x,\cdot,t)$, it is enough to note that the diffusion constant D (see (II.18)) vanishes, because the density of states vanishes. Thus, the parabolic problem (II.17) degenerates (see Ref. 9 for details) and no boundary condition needs to be prescribed. ■

Now, instead of a smoothly x-dependent band diagram, we consider a heterojunction, modeled as an abrupt interface Σ separating two media Ω_1 and Ω_2 which have different band diagram characteristics. Let us denote by $e_i(k)$ and χ_i, $i=1,2$, the kinetic energy and the affinity of each material. For simplicity, we now assume that e_i and χ_i do not vary within Ω_i. Therefore

$$\epsilon(x,k,t)=e_i(k)-\chi_i-\phi(x,t),\quad x\in\Omega_i,\quad k\in B,\quad t>0.$$

For $x\in\Sigma$, let

$$\epsilon_i(x,k,t)=\lim_{y\to x,y\in\Omega_i}\epsilon(y,k,t).$$

The jump discontinuity of the band diagram characteristics across Σ results in similar jump discontinuities of the coefficients $N(x,\epsilon,t)$ and $D(x,\epsilon,t)$ [see formulas (II.7) and (II.18)]. In a weak formulation of (II.17) this does not cause any problem, and the resulting interface conditions are continuity of F and of the normal flux $\nu^T D\nabla_x F$ across Σ:

$$F_1=F_2,\quad \nu^T D_1\nabla_x F_1=\nu^T D_2\nabla_x F_2,\quad x\in\Sigma.\tag{II.20}$$

Here, $\nu(x)$ denotes the normal vector to Σ at a given point x oriented say from 1 to 2, ν^T, the transpose of ν, and

$$\nu^T D\nabla_x F=\sum_{i,j}\nu_i D_{ij}\frac{\partial F}{\partial x_j}.$$

Remark II.5: For $x\in\Sigma$, conditions (II.20) are only valid for the values of ϵ such that $(x,\epsilon)\notin\partial\mathcal{O}_t$, where $\mathcal{O}_t$ is the domain of definition of F (II.19). When $(x,\epsilon)\in\partial\mathcal{O}_t$, for instance, if $\min\epsilon_1(x,\cdot,t)<\epsilon<\min\epsilon_2(x,\cdot,t)$, a boundary condition must be assigned to F_1 instead (see Fig. 2). But since electrons of energy ϵ are totally reflected by the potential barrier, there is no net flux across the heterojunction, and the boundary condition is naturally the zero flux condition:

$$\nu^T D_1 \nabla_x F_1(x,\epsilon,t) = 0. \tag{II.21}$$

At variance with Remark 2.3, D_1 is not necessarily degenerate because ϵ is not an extremal value of $\epsilon_1(x,\cdot,t)$. A similar condition must of course be assigned to F_2 when (x,ϵ) is an end point of the domain of definition of F_2. ■

Transmission conditions (II.20) and (II.21) may be justified by successively performing a diffusion limit of the Boltzmann equation for a smoothed band diagram and then letting the smoothing parameter go to zero. A natural question is whether these two procedures commute, or equivalently, does the diffusion limit of a kinetic model with discontinuous band diagram lead to transmission conditions (II.20), (II.21)? In Sec. III, we set up the heterojunction transmission problem at the kinetic level. Then, in Sec. IV, we show that conditions (II.20) and (II.21) are deduced from a first-order diffusion approximation of this problem. We then derive more accurate conditions from a second-order diffusion approximation.

III. THE KINETIC TRANSMISSION PROBLEM AT A HETEROJUNCTION

We focus on a transmission problem which describes a one-dimensional heterojunction. We let $\Omega_1=(-\infty,0)$, $\Omega_2=(0,\infty)$ and we denote by $f_i^\alpha(x,k,t)$, $x\in\Omega_i$, $k\in B$, $t\geqslant 0$, the distribution function in Ω_i, which solves (with obvious notations)

$$\frac{\partial f_i^\alpha}{\partial t}+\frac{1}{\alpha}\left(v_{i,x}\frac{\partial f_i^\alpha}{\partial x}+\frac{\partial \phi}{\partial x}\frac{\partial f_i^\alpha}{\partial k_x}\right)=\frac{1}{\alpha^2}Q_i(f_i^\alpha)+S_i(f_i^\alpha), \tag{III.1}$$

where $e_i(k)$, $i=1,2$, is the kinetic energy in each domain Ω_i and $v_{i,x}(k)=(\partial e_i/\partial k_x)(k)$ is the associated velocity in the x-direction. We recall that the affinity χ_i is constant over Ω_i and that the total energy is given by

$$\epsilon(x,k,t)=e_i(k)-\chi_i-\phi(x,t), \quad x\in\Omega_i.$$

For simplicity, we set $\phi(0,t)=0$ and we denote by $\epsilon_i(k)$ the right and left limits of ϵ at 0:

$$\epsilon_i(k)=e_i(k)-\chi_i. \tag{III.2}$$

The numerical range of ϵ_i is denoted by $\mathscr{R}_i$.

In the following, we shall assume (which is satisfied in practice[20]) a reflection symmetry of the model. As a consequence, the functions $e_i(k)$, $i=1,2$ are even and the collision operators are even in the sense that for any arbitrary smooth function $f(k)$, we have:

$$Q_i(f(-k))=Q_i(f)(-k), \quad S_i(f(-k))=S_i(f)(-k). \tag{III.3}$$

We now set up boundary conditions for f_i at $x=0$. Particle scattering by the interface is due to the localized potential which sits at the heterojunction because of the change in crystalline structure. It may be described at the kinetic level by scattering operators mutually relating the incoming and outgoing parts (relative to Ω_i) of the two distribution functions f_i, $i=1,2$ at the interface. The spirit is similar to gas–surface interaction operators.[23] However, here we assume the scattering to be of purely elastic nature and the theory of Ref. 23 must be slightly adapted.

We respectively denote by f_i^+ and f_i^- the outgoing and incoming parts of the distribution function f_i at $x=0$:

$$f_i^\pm = f_i|_{\{k\in B,\pm\sigma_i v_{i,x}(k)>0\}} \quad \text{with} \quad \sigma_1=+1 \quad \text{and} \quad \sigma_2=-1. \tag{III.4}$$

The reflection-transmission problem for f_i at $x=0$ is written as

$$f_i^- = \mathscr{T}_i(f_1^+, f_2^+), \quad i=1,2, \tag{III.5}$$

with, for $k\in B$ such that $\sigma_i v_{i,x}(k)<0$:

$$\mathcal{T}_i(f_1^+, f_2^+)(k) = \int_{\{k' \in B, \sigma_i v_{i,x}(k') > 0\}} R_i(k' \to k)\, \delta(\epsilon_i(k) - \epsilon_i(k'))\, f_i(k')\, dk' + \int_{\{k' \in B, \sigma_j v_{j,x}(k') > 0\}} T_{j \to i}(k' \to k)\, \delta(\epsilon_i(k) - \epsilon_j(k'))\, f_j(k')\, dk'. \quad \text{(III.6)}$$

In (III.6), the first integral accounts for the reflection of particles of Ω_i by the interface, while the second one describes their transmission from Ω_j into Ω_i. The delta functions express that reflection as well as transmission occur with conservation of total particle energy. The coefficients $R_i(k' \to k)$ and $T_{i \to j}(k' \to k)$ are non-negative measures derived from the scattering operator of the underlying microscopic dynamics.[24]

For $\epsilon \in \mathbf{R}$, we introduce

$$\mathcal{S}_\epsilon^i = \{k \in B, \epsilon_i(k) = \epsilon\}, \quad dN_\epsilon^i(k) = \frac{dS_\epsilon^i(k)}{|\nabla_k \epsilon_i(k)|}, \quad \text{(III.7)}$$

$dS_\epsilon^i(k)$ being the Euclidean surface element on $\mathcal{S}_\epsilon^i$. Also, we introduce

$$\mathcal{S}_\epsilon^{i,\pm} = \{k \in \mathcal{S}_\epsilon^i, \quad \pm \sigma_i v_{i,x}(k) > 0\}$$

and σ_i given by (III.4). Then, using the coarea formula (II.6), relation (III.6) can be rewritten for $k \in B$ such that $\sigma_i v_{i,x}(k) < 0$:

$$\mathcal{T}_i(f_1^+, f_2^+)(k) = \int_{\mathcal{S}^{i,+}_{\epsilon_i(k)}} R_i(k' \to k) f_i(k')\, dN^i_{\epsilon_i(k)}(k') + \int_{\mathcal{S}^{j,+}_{\epsilon_i(k)}} T_{j \to i}(k' \to k) f_j(k')\, dN^j_{\epsilon_i(k)}(k'), \quad \text{(III.8)}$$

with the convention that $j \neq i$ in (III.8). In particular, we note that, if $\epsilon_i(k) \notin \mathcal{R}_j$ [where we recall that $\mathcal{R}_i$ denotes the numerical range of $\epsilon_i(k)$], the second integral in (III.8) is identically zero (because $\mathcal{S}^j_{\epsilon_i(k)} = \emptyset$). Thus, for such particle energies, only reflection occurs, as expressed by the first integral in (III.8).

We now set up conditions for the reflection-transmission operators $\mathcal{T}_i$ to provide a physically sound description of electron scattering by the interface.

Hypothesis 1: Current conservation.

$$|v_{i,x}(k)| = \int_{\mathcal{S}^{i,-}_{\epsilon_i(k)}} |v_{i,x}(k')| R_i(k \to k') dN^i_{\epsilon_i(k)}(k') + \int_{\mathcal{S}^{j,-}_{\epsilon_i(k)}} |v_{j,x}(k')| T_{i \to j}(k \to k') dN^j_{\epsilon_i(k)}(k'), \quad \text{(III.9)}$$

holds for all $k \in B$ such that $\sigma_i v_{i,x}(k) > 0$, with again $j \neq i$ in (III.9).

With property (III.9), the flux of particles of given energy ϵ is continuous through the interface, as asserted by the following Lemma, the proof of which is a simple computation:

Lemma III.1: Let $f_i(k)$, $i = 1,2$, be connected through relation (III.5) with R_i and $T_{i \to j}$ satisfying Hypothesis 1. Then, we have,

$$\int_{\mathcal{S}^1_\epsilon} v_{1,x} f_1 dN^1_\epsilon = \int_{\mathcal{S}^2_\epsilon} v_{2,x} f_2 dN^2_\epsilon, \quad \forall \epsilon \in \mathcal{R}_1 \cap \mathcal{R}_2, \quad \text{(III.10)}$$

$$\int_{\mathcal{S}^i_\epsilon} v_{i,x} f_i dN^i_\epsilon = 0, \quad \forall \epsilon \in \mathcal{R}_i \backslash \mathcal{R}_j. \quad \text{(III.11)}$$

Conversely, for (III.10) and (III.11) to be satisfied for any pair (f_1, f_2) connected by (III.5), R_i and $T_{i\to j}$ must satisfy (III.9).

Hypothesis 2: Reciprocity: For all k, k' in B such that $\epsilon_i(k)=\epsilon_i(k')$ and $\sigma_i v_{i,x}(k)>0$, $\sigma_i v_{i,x}(k')<0$, we assume

$$|v_{i,x}(k')|R_i(k\to k')=|v_{i,x}(-k)|R_i(-k'\to -k). \tag{III.12}$$

Similarly, for all k, k' in B such that $\epsilon_i(k)=\epsilon_j(k')$ and $\sigma_i v_{i,x}(k)>0, \sigma_j v_{j,x}(k')<0$, we assume

$$|v_{j,x}(k')|T_{i\to j}(k\to k')=|v_{i,x}(-k)|T_{j\to i}(-k'\to -k), \tag{III.13}$$

where σ_i is given by (III.4).

Relations (III.12) and (III.13) result from the time reversibility (and thus, the unitarity of the scattering matrix) of the microscopic particle dynamics at the interface (see, e.g., Ref. 24). The validity of the reciprocity relation is discussed in Ref. 23 for gas–surface interaction.

Combining (III.9) with (III.12) and (III.13), and using the evenness of $e_i(k)$, we obtain:

$$1=\int_{\mathscr{S}^{i,+}_{\epsilon_i(k)}} R_i(k'\to k)\,dN^i_{\epsilon_i(k)}(k')+\int_{\mathscr{S}^{j,+}_{\epsilon_i(k)}} T_{j\to i}(k'\to k)\,dN^j_{\epsilon_i(k)}(k'), \tag{III.14}$$

for all k such that $\sigma_i v_{i,x}(k)<0$. It follows that the constant function equal to 1 is a particular solution of the interface condition (III.5).

Hypothesis 3: Transmittivity. Some transmission occurs whenever it is energetically possible:

$$\overline{T}_{j\to i}(k,\epsilon):=\int_{\mathscr{S}^{j,+}_{\epsilon}} T_{j\to i}(k'\to k)\,dN^j_{\epsilon}(k')>0 \tag{III.15}$$

for every $\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2$ and for k in a subset of $\mathscr{S}^{i,-}_{\epsilon}$ with positive measure.

Note that by the reciprocity relation (III.13), (III.15) holds for both $T_{1\to 2}$ and $T_{2\to 1}$, even if it is only required for one of them. As mentioned above, only reflection occurs for particle energies not in the common range of ϵ_1 and ϵ_2:

$$\overline{T}_{j\to i}(\cdot,\epsilon)=0, \quad \epsilon\in\mathscr{R}_i\backslash\mathscr{R}_j. \tag{III.16}$$

Lemma III.2: Let R_i and $T_{i\to j}$ satisfy Hypotheses 1–3. Assume, in addition, that the functions $e_i(k)$ are even. Then, two functions $F_1(\epsilon_1(k))$ and $F_2(\epsilon_2(k))$ of the energy satisfy the transmission condition (III.5) if and only if

$$F_1(\epsilon)=F_2(\epsilon) \quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2. \tag{III.17}$$

Proof: Using (III.14), the transmission conditions for F_1 and F_2 can be written as

$$\overline{T}_{j\to i}(k,\epsilon)(F_1(\epsilon)-F_2(\epsilon))=0. \tag{III.18}$$

The result follows immediately from (III.15) and (III.16). ■

With (III.14), relation (III.8) expresses that f_i^- is a convex combination of f_1^+ and f_2^+. We deduce the following version of the Darrozes–Guiraud inequality[23] for our particular transmission process:

Lemma III.3: Let f_i satisfy the transmission condition (III.5), with reflection-transmission matrices satisfying Hypotheses 1 and 2 and with even functions $e_i(k)$. Then, we have [with σ_i given by (III.4)]:

$$\int_{\mathscr{S}^2_{\epsilon}} v_{2,x}|f_2|^2\,dN^2_{\epsilon}\leqslant\int_{\mathscr{S}^1_{\epsilon}} v_{1,x}|f_1|^2\,dN^1_{\epsilon}, \quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2, \tag{III.19}$$

$$\sigma_i\int_{\mathscr{S}^i_{\epsilon}} v_{i,x}|f_i|^2\,dN^i_{\epsilon}\geqslant 0, \quad \forall\,\epsilon\in\mathscr{R}_i\backslash\mathscr{R}_j. \tag{III.20}$$

Proof: Using Jensen's inequality on (III.8), assuming $\epsilon \in \mathscr{R}_1 \cap \mathscr{R}_2$, and $\epsilon_i(k) = \epsilon$, we get

$$|f_i^-(k)|^2 \leqslant \int_{\mathscr{S}_\epsilon^{i,+}} R_i(k' \to k) |f_i(k')|^2 dN_\epsilon^i(k') + \int_{\mathscr{S}_\epsilon^{j,+}} T_{j\to i}(k' \to k) |f_j(k')|^2 dN_\epsilon^j(k'). \tag{III.21}$$

Then, multiplying (III.21) by $v_{i,x}(k)$, integrating over $\mathscr{S}_\epsilon^{i,-}$, summing up the contributions of f_1 and f_2 and using (III.9) we obtain (III.19). The inequality (III.20) can be proven in a similar way. ■

We now give two examples of transmission operators $\mathscr{T}_i$ which satisfy the above Hypotheses 1–3.

Example 1: Semiclassical transmission of particles between media with spherically symmetric band diagrams across a perfectly plane interface. From Hamiltonian mechanics, we know that the transmission of a particle across a perfectly plane interface occurs with conservation of parallel momentum and total energy. We assume that transmission of a particle with momentum k from side i to side j produces a particle with momentum k'. Denoting by y and z the coordinates parallel to the heterojunction, the transmission process can be written as:

$$k_y' = k_y, \quad k_z' = k_z, \quad \epsilon_j(k') = \epsilon_i(k) \tag{III.22}$$

with ϵ_i given by (III.2). We suppose that e_i is spherically symmetric: $e_i(k) = \overline{e_i}(|k|)$, with a strictly monotone $\overline{e_i}$ [parabolic band diagrams (II.3) being obviously covered by this assumption]. Relation $\epsilon = \overline{e_i}(|k|) - \chi_i$ can be inverted and we denote by $|k| = \kappa_i(\epsilon)$ the inverse relation. From the first two relations in (III.22), we deduce that

$$|k'|^2 - k_x'^2 = |k|^2 - k_x^2,$$

and, with the last relation (III.22) and the definition of κ_i, we obtain that the transverse momentum is transmitted according to

$$k_x' = \sigma_i \psi_i(k)^{1/2}, \quad \psi_i(k) = k_x^2 - |k|^2 + \kappa_j(\epsilon_i(k))^2, \tag{III.23}$$

if $\psi_i(k) > 0$, the particle being reflected (with $k_x' = -k_x$) otherwise.

Now, we define the reflection-transmission operator $\mathscr{T}_i$ according to:

$$\mathscr{T}_i(f_1^+, f_2^+)(k) = (1 - \overline{T}_{j\to i}(k)) f_i^+(rk) + \overline{T}_{j\to i}(k) f_j^+(t_{j\to i}k), \tag{III.24}$$

with $i = 1,2$, $j \neq i$, $k \in B$, such that $\sigma_i k_x \leqslant 0$ and with $\overline{T}_{j\to i}(k)$ being the transmission probability of the semiclassical transmission process, satisfying:

$$0 \leqslant \overline{T}_{j\to i}(k) \leqslant 1, \quad \overline{T}_{j\to i}(k) = 0 \quad \text{if } \psi_i(k) < 0. \tag{III.25}$$

The case of a purely classical transmission is covered with $\overline{T}_{j\to i}(k) = 1$ when $\psi_i(k) > 0$ and $\overline{T}_{j\to i}(k) = 0$ otherwise.

In (III.24), r and $t_{j\to i}$ are particle reflection and transmission operators defined by inverting (III.23):

$$t_{j\to i}k = (-\sigma_i \psi_i(k)^{1/2}, k_y, k_z) \quad \text{if } \psi_i(k) > 0, \tag{III.26}$$

$$rk = (-k_x, k_y, k_z), \tag{III.27}$$

for $k \in B$, such that $\sigma_i k_x \leqslant 0$.

The reflection and transmission matrices associated with (III.24) can be determined from:

$$T_{j\to i}(k' \to k)\, \delta(\epsilon_i(k) - \epsilon_j(k')) = \overline{T}_{j\to i}(k)\, \delta(k' - t_{j\to i}k), \tag{III.28}$$

$$R_i(k' \to k)\, \delta(\epsilon_i(k) - \epsilon_i(k')) = (1 - \overline{T}_{j\to i}(k))\, \delta(k' - rk). \tag{III.29}$$

We easily deduce that Hypotheses 1 and 2 hold if and only if $\overline{T}_{j\to i}$ satisfy the following properties:

$$\overline{T}_{j\to i}(k_x,-k_y,-k_z)=\overline{T}_{j\to i}(k_x,k_y,k_z),\quad \overline{T}_{j\to i}(k)=\overline{T}_{i\to j}(rt_{j\to i}k). \tag{III.30}$$

The last property is the usual quantum-mechanical reciprocity relation.[25] A simple computation using (III.28) shows that the notation $\overline{T}_{j\to i}$ for the transmission probabilities is compatible with its definition in (III.15). Thus, the assumption

$$\overline{T}_{j\to i}(k)>0 \quad \text{for } \psi_i(k)>0,$$

is sufficient for Hypothesis 3 to be satisfied.

Semiclassical transmission probabilities $\overline{T}_{j\to i}$ can be deduced from a scattering analysis of a one-dimensional Schrödinger model of the heterojunction. A simple example is the formula[18]

$$\overline{T}_{j\to i}(k)=\frac{4k_x(t_{j\to i}k)_x m_i m_j}{(k_x m_j+(t_{j\to i}k)_x m_i)^2}$$

for the case of a step barrier and parabolic bands $e_i(k)=k^2/(2m_i)$ on both sides. ■

Example 2: Purely isotropic reflection-transmission operators: Here we assume that the reflection-transmission coefficients are such that the incoming distributions f_i^- only depend on $\epsilon_i(k)$. This implies that $R_i(k\to k')$ and $T_{i\to j}(k\to k')$ only depend on k. Then, Hypothesis 2 implies that R_i and $T_{i\to j}$ are of the form

$$R_i(k\to k')=\hat{R}_i(\epsilon_i(k))|v_{i,x}(k)|,\quad T_{i\to j}(k\to k')=\hat{T}(\epsilon_i(k))|v_{i,x}(k)|.$$

Moreover, by Hypothesis 1, we deduce that $\hat{R}_i$ and $\hat{T}$ must satisfy the relations

$$1=\alpha_i(\epsilon)\hat{R}_i(\epsilon)+\alpha_j(\epsilon)\hat{T}(\epsilon),\quad i\neq j,$$

for $\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2$ with

$$\alpha_i(\epsilon)=\int_{\mathscr{S}_\epsilon^{i,-}}|v_{i,x}|dN_\epsilon^i. \tag{III.31}$$

Therefore, R_i and $T_{i\to j}$ are given in terms of the single arbitrary function $\hat{T}(\epsilon)$:

$$R_i(k\to k')=|v_{i,x}(k)|\,\frac{1-\alpha_j\hat{T}}{\alpha_i}\,(\epsilon_i(k)),\quad T_{i\to j}(k\to k')=|v_{i,x}(k)|\hat{T}(\epsilon_i(k)), \tag{III.32}$$

with $0\leqslant\hat{T}(\epsilon)\leqslant\min(1/\alpha_1(\epsilon),1/\alpha_2(\epsilon))$ for $\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2$ and $\hat{T}(\epsilon)=0$ otherwise. By $\overline{T}_{i\to j}=\alpha_i\hat{T}$, the assumption $\hat{T}(\epsilon)>0$ for $\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2$ is sufficient for Hypothesis 3 to be satisfied. ■

IV. DIFFUSION APPROXIMATION OF THE HETEROJUNCTION MODEL

In this section we assume that the transmission operator is given by (III.6) and satisfies Hypotheses 1–3. We start with the definition of an order k approximate solution:

Definition IV.1: f_i^α is an order k approximate solution of the Boltzmann transmission problem (III.1) and (III.5) if

(i) f_i^α solves the Boltzmann equation (III.1) up to order α^k terms in each domain Ω_i:

$$\frac{\partial f_i^\alpha}{\partial t}+\frac{1}{\alpha}\left(v_{i,x}\frac{\partial f_i^\alpha}{\partial x}+\frac{\partial\phi}{\partial x}\frac{\partial f_i^\alpha}{\partial k_x}\right)-\frac{1}{\alpha^2}\,Q_i(f_i^\alpha)-S_i(f_i^\alpha)=\mathscr{O}(\alpha^k), \tag{IV.1}$$

(ii) f_i^α satisfies the transmission condition (III.5) up to order α^k terms:

$$f_i^\alpha(0,\cdot,t)^-=\mathscr{T}_i(f_1^\alpha(0,\cdot,t)^+,\ f_2^\alpha(0,\cdot,t)^+)+\mathscr{O}(\alpha^k). \tag{IV.2}$$

(iii) The flux of particles of given energy ϵ given by

$$J_i^\alpha(x,\epsilon,t)=\frac{1}{\alpha}\int_{\mathscr{S}_{(x,\epsilon,t)}} v_{i,x}(k) f_i^\alpha(x,k,t)\,dN_{(x,\epsilon,t)}(k),$$

is continuous through the interface up to order α^k terms, i.e.,

$$J_1^\alpha(0,\epsilon,t)-J_2^\alpha(0,\epsilon,t)=\mathscr{O}(\alpha^k),\quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2, \tag{IV.3}$$

$$J_i^\alpha(0,\epsilon,t)=\mathscr{O}(\alpha^k),\quad \forall\,\epsilon\in\mathscr{R}_i\backslash\mathscr{R}_j. \tag{IV.4}$$

Condition (iii) needs some explanation: On first glance it seems superfluous, since flux conservation is already included in the transmission conditions. However, the analysis below shows that (iii) is needed both to completely specify an order k approximate solution and to enable the construction of an order $k+1$ approximation.

In this section, we are concerned with the derivation of interface conditions for the SHE distribution function $F(x,\epsilon,t)$ across the heterojunction at $x=0$. We shall successively derive first- and second-order transmission conditions, by respectively constructing order 1 and order 2 approximate solutions of the Boltzmann transmission problem (III.1), (III.5). We start with the first-order transmission conditions. Following Sec. II, the Hilbert expansion (II.5) of f_i^α in each domain Ω_i leads to an approximate solution of the form

$$f_i^\alpha(x,k,t)=F_i^0(x,\epsilon(x,k,t),t)+\alpha\left(F_i^1(x,\epsilon(x,k,t),t)-\lambda_{i,x}(x,k,t)\,\frac{\partial F_i^0}{\partial x}\,(x,\epsilon(x,k,t),t)\right)$$
$$+\alpha^2 f_i^2(x,k,t), \tag{IV.5}$$

where F_i^0 is a solution of the SHE equation in Ω_i:

$$N_i(x,\epsilon,t)\left(\frac{\partial F_i^0}{\partial t}-\frac{\partial\phi}{\partial t}\,\frac{\partial F_i^0}{\partial\epsilon}\right)-\frac{\partial}{\partial x}\left(D_i(x,\epsilon,t)\,\frac{\partial F_i^0}{\partial x}\right)=\overline{S}_i(F_i^0). \tag{IV.6}$$

Here, $N_i(x,\epsilon,t)$ is the density of states (II.7) in each domain Ω_i, and $D_i(x,\epsilon,t)$ is the scalar which corresponds to the $x-x$ entry of the diffusion matrix (II.18) in Ω_i:

$$D_i(x,\epsilon,t)=\int_{\mathscr{S}_{(x,\epsilon,t)}}\lambda_{i,x}(x,k,t)v_{i,x}(k)\,dN_{(x,\epsilon,t)}(k). \tag{IV.7}$$

The following theorem states that the first-order interface conditions coincide with those established in Sec. II.

Theorem IV.2: Let f_i^α be defined by (IV.5) with F_i^0 solving (IV.6). Then, f_i^α is an order 1 approximate solution of the Boltzmann transmission problem (III.1), (III.5) if and only if F_i^0 verifies the following continuity relations:

$$F_1^0(0,\epsilon,t)=F_2^0(0,\epsilon,t),\quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2, \tag{IV.8}$$

$$D_1\,\frac{\partial F_1^0}{\partial x}\,(0,\epsilon,t)=D_2\,\frac{\partial F_2^0}{\partial x}\,(0,\epsilon,t),\quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2, \tag{IV.9}$$

$$D_i\,\frac{\partial F_i^0}{\partial x}\,(0,\epsilon,t)=0,\quad \forall\,\epsilon\in\mathscr{R}_i\backslash\mathscr{R}_j. \tag{IV.10}$$

Proof: By construction, f_i^α is an order 1 approximate solution of the Boltzmann equation (III.1) inside each Ω_i. Now, inserting ansatz (IV.5) into the transmission condition (III.5), we get

$$(f_i^\alpha)^- - \mathscr{T}_i((f_1^\alpha)^+,(f_2^\alpha)^+)=[F_i^{0-}-\mathscr{T}_i(F_1^{0+},F_2^{0+})]+\mathscr{O}(\alpha).$$

By Lemma (III.2), imposing (IV.8) is necessary and sufficient to guarantee that

$$F_i^{0-} - \mathcal{T}_i(F_1^{0+}, F_2^{0+}) = 0,$$

and thus to ensure (IV.2) with $k=1$. Finally, the flux of particles of energy ϵ associated with (IV.5) is given at $x=0$ by

$$J_i^\alpha(0,\epsilon,t) = -\left(D_i \frac{\partial F_i^0}{\partial x} \right)(0,\epsilon,t) + \mathcal{O}(\alpha).$$

Therefore condition (IV.3) requires (IV.9) while (IV.4) requires (IV.10). ■

We now proceed to the derivation of second-order transmission conditions. The forthcoming procedure is inspired from the now classical method of Ref. 14, already applied to semiconductors in Refs. 16 and 26, to derive higher order boundary conditions and kinetic-fluid coupling algorithms. We start again with the Hilbert expansion (away from the heterojunction), like in (II.5), but retaining an additional term:

$$f_i^\alpha = F_i^0 + \alpha\left(F_i^1 - \lambda_{i,x} \frac{\partial F_i^0}{\partial x} \right) + \alpha^2 f_i^2 + \alpha^3 f_i^3. \tag{IV.11}$$

Inserting ansatz (IV.11) in (IV.1) and identifying terms of equal powers of α yields the equations (II.13) for the determination of f_i^2 and

$$Q_i(f_i^3) = \frac{\partial \epsilon}{\partial k_x}\frac{\partial f_i^2}{\partial x} - \frac{\partial \epsilon}{\partial x}\frac{\partial f_i^2}{\partial k_x} + \frac{\partial f_i^1}{\partial t} - S_i(f_i^1). \tag{IV.12}$$

Here, we suppose that S_i is linear (a nonlinear S_i would just result in slightly more complicated calculations). The first step of the procedure is to look for conditions which ensure the solvability of system (II.11)–(II.13), (IV.12), and thus, the existence of the terms involved in expansion (IV.11). This guarantees that ansatz (IV.11) satisfies (IV.1) with $k=2$.

Recall that the solution of (II.11) and (II.12) is given by:

$$f_i^0(x,k,t) = F_i^0(x,\epsilon_i(k),t), \tag{IV.13}$$

$$f_i^1(x,k,t) = -\lambda_{i,x}(k) \frac{\partial F_i^0}{\partial x}(x,\epsilon_i(k),t) + F_i^1(x,\epsilon_i(k),t). \tag{IV.14}$$

Proposition IV.3: Let f_i^0 and f_i^1 be respectively given by (IV.13) and (IV.14). Then, there exist f_i^2 and f_i^3, respectively solutions of (II.13), (IV.12), if and only if F_i^0 and F_i^1 both satisfy the SHE equation (IV.6).

Proof: That the SHE-equation for F_i^0 is necessary for the existence of f_i^2, has already been verified in Sec. II.

To find the solvability condition for (IV.12), we need an explicit expression of f_i^2. For that purpose, let h_i^2 be the unique solution of (II.13) in which F_i^1 is set to zero, and satisfying (II.10). With hypothesis (III.3) and the uniqueness statement of Lemma II.1 (ii), we deduce that h_i^2 is an even function with respect to k. Then, the most general solution f_i^2 of (II.13) is

$$f_i^2 = h_i^2 - \lambda_{i,x}\frac{\partial F_i^1}{\partial x} + F_i^2, \tag{IV.15}$$

where $F_i^2 = F_i^2(x,\epsilon,t)$ is arbitrary. Inserting (IV.15) in (IV.12) yields

$$\begin{aligned} Q_i^0(f_i^3) = &\left(\frac{\partial \epsilon}{\partial k_x}\frac{\partial}{\partial x} - \frac{\partial \epsilon}{\partial x}\frac{\partial}{\partial k_x} \right)\left(-\lambda_{i,x}\frac{\partial (F_i^1)}{\partial x} \right) + \frac{\partial (F_i^1)}{\partial t} - S_i(F_i^1) \\ &+ \left(\frac{\partial \epsilon}{\partial k_x}\frac{\partial}{\partial x} - \frac{\partial \epsilon}{\partial x}\frac{\partial}{\partial k_x} \right)(h_i^2 + (F_i^2)) + \frac{\partial}{\partial t}\left(-\lambda_{ix}\frac{\partial (F_i^0)}{\partial x} \right) - S_i\left(-\lambda_{i,x}\frac{\partial (F_i^0)}{\partial x} \right). \end{aligned}$$

Here the notation (F_i^m), $m=0,1$ is a shorthand for $F_i^m(x,\epsilon_i(x,k,t),t)$.

The last line consists of odd terms in k which vanish after integration over $\mathscr{S}_{(x,\epsilon,t)}$. Therefore, the solvability condition (II.9) reduces to the integration of the first line, which obviously yields the SHE equation (IV.6) for F_i^1. ■

With Proposition IV.3, ansatz (IV.11) satisfies condition (IV.1) with $k=2$. We must now find transmission conditions on F_i^0 and F_i^1 which guarantee that (IV.11) is also of order 2 at the interface, i.e., satisfies (IV.2), (IV.3), (IV.4) with $k=2$. Conditions (IV.8)–(IV.10) must be imposed on F_i^0 because they are necessary to guarantee the order 1 approximation (Theorem IV.2). However, whatever transmission conditions are prescribed to F_i^1, it is impossible to make ansatz (IV.11) an order 2 approximate solution at the interface. Indeed, if this were the case, the first-order term f_i^1 given by (IV.14) would have to satisfy the transmission condition (III.5). But f_i^1 involves $\lambda_{i,x}(k)$, which is not a function of the energy only and which cannot be canceled at the interface by just a suitable choice of F_i^1. Therefore, we need to modify ansatz (IV.11) by introducing a transmission layer term, which is exponentially small inside each domain Ω_i, but which cancels the first-order term f_i^1 at the interface. The definition of this transmission layer term is the second step of the procedure.

To derive the transmission layer term, we start from the kinetic problem (III.1) and we stretch the position variable in the direction normal to the boundary. Letting

$$E(x,t)=\frac{\partial \phi}{\partial x}(x,t), \quad \theta_i^\alpha(\xi,k,t)=f_i^\alpha(\alpha\xi,k,t),$$

we get:

$$\frac{\partial \theta_i^\alpha}{\partial t}+\frac{1}{\alpha^2}\,v_{i,x}\,\frac{\partial \theta_i^\alpha}{\partial \xi}-\frac{1}{\alpha}\,E(\alpha x,t)\,\frac{\partial \theta_i^\alpha}{\partial k_x}=\frac{1}{\alpha^2}\,Q_i(\theta_i^\alpha)+S_i(\theta_i^\alpha). \tag{IV.16}$$

We suppose that $E(\alpha x,t)=\mathscr{O}(1)$ as $\alpha\to 0$, which implies that there exists no sharp transition layer in the electrostatic potential. Keeping only the leading order terms of (IV.16), we obtain the following kinetic layer equation with unknown $\theta_i(\xi,k)$, $\sigma_i\xi<0$, $k\in B$, $i=1,2$:

$$v_{i,x}(k)\,\frac{\partial \theta_i}{\partial \xi}=Q_i(\theta_i). \tag{IV.17}$$

Since the transmission layer term θ_i must cancel the first-order term f_i^1 at the interface, we need to consider inhomogeneous transmission conditions at the interface. Namely, given two functions $\ell_i(k)$, $i=1,2$, for $k\in B$, we impose

$$(\theta_i(0,\cdot)-\ell_i)^-=\mathscr{T}_i((\theta_1(0,\cdot)-\ell_1)^+,(\theta_2(0,\cdot)-\ell_2)^+). \tag{IV.18}$$

Layer terms need to have limits as $|\xi|\to\infty$. At least, we look for bounded solutions of problem (IV.17), (IV.18). Integrating (IV.17) over $\mathscr{S}_\epsilon^i$ [see (III.7) for the definition of $\mathscr{S}_\epsilon^i$], we get

$$\frac{\partial}{\partial \xi}J_i(\xi,\epsilon)=0, \quad J_i(\xi,\epsilon)=\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,\theta_i(\xi,k)\,dN_\epsilon^i(k).$$

Therefore, $J_i(\xi,\epsilon)=J_i(\epsilon)$ is constant with respect to ξ. Then, we multiply (IV.17) by $\lambda_{i,x}(k)$, integrate over $\mathscr{S}_\epsilon^i$, use the self-adjointness of Q_i [property (iii) of Lemma II.1] and get:

$$\frac{\partial}{\partial \xi}K_i(\xi,\epsilon)+J_i(\epsilon)=0, \quad K_i(\xi,\epsilon)=\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\lambda_{i,x}(k)\,\theta_i(\xi,k)\,dN_\epsilon^i(k), \tag{IV.19}$$

or

$$K_i(\xi,\epsilon)=-J_i(\epsilon)\xi+K_i(0,\epsilon). \tag{IV.20}$$

Bounded solutions θ_i (leading to bounded K_i) therefore satisfy the zero flux condition:

$$J_i(\epsilon)=\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,\theta_i(\xi,k)\,dN_\epsilon^i(k)=0,\quad \epsilon\in\mathscr{R}_i. \tag{IV.21}$$

The transmission condition (IV.18) and Lemma III.1 imply that the flux produced by $\theta_1(0,\cdot)-\ell_1$ is equal to the flux produced by $\theta_2(0,\cdot)-\ell_2$. Since by (IV.21) the fluxes produced by the $\theta_i(0,\cdot)$ vanish, a necessary condition for the existence of a bounded solution of (IV.17), (IV.18) is given by the flux continuity condition

$$\int_{\mathscr{S}_\epsilon^1} v_{1,x}\ell_1\,dN_\epsilon^1=\int_{\mathscr{S}_\epsilon^2} v_{2,x}\ell_2\,dN_\epsilon^2,\quad \forall\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2, \tag{IV.22}$$

$$\int_{\mathscr{S}_\epsilon^i} v_{i,x}\ell_i\,dN_\epsilon^i=0,\quad \forall\epsilon\in\mathscr{R}_i\backslash\mathscr{R}_j. \tag{IV.23}$$

For the homogeneous version of (IV.17) and (IV.18) ($\ell_1=\ell_2=0$) an easy computation shows that bounded solutions are given by

$$\theta_i(\xi,k)=\Theta(\epsilon_i(k)),\quad i=1,2, \tag{IV.24}$$

where Θ is an arbitrary bounded function of ϵ.

Problem (IV.17), (IV.18) belongs to the class of Milne problems, which are widely used in many areas of kinetic theory.[14,27,16,15,17] In the present paper is the first occurrence (to our knowledge) of a ''two-sided'' Milne problem. In Sec. V an existence theorem will be proved under strong assumptions on the solutions of the corresponding one-sided Milne problems for $\xi>0$ and $\xi<0$ with inflow boundary conditions. For rotationally symmetric band diagrams $e_i(k)$ and collision operators Q_i these assumptions can be verified (see Sec. V). For more general band diagrams, they are conjectures which will be dealt with in future work.

In the rest of this section, we shall assume the results of the existence theorem: Under conditions (IV.22), (IV.23), problem (IV.17), (IV.18) has a bounded solution, which is unique up to the addition of a function of the type (IV.24) with arbitrary Θ. For $|\xi|\to\infty$, $\theta_i(\xi,k)$ converges exponentially to an element $\theta_i^\infty(\epsilon_i(k))$ of the kernel of Q_i.

Finally, a simple computation shows that when θ_i is a bounded solution corresponding to the inhomogeneities ℓ_i, then $A(\epsilon_i(k))\,\theta_i(\xi,k)$ is a bounded solution corresponding to the inhomogeneities $A(\epsilon_i(k))\ell_i(k)$ for arbitrary functions $A(\epsilon)$.

Once the transmission layer problem is set up, the third step of the procedure is to find a modified ansatz (IV.11) which provides a true order 2 approximate solution of the Boltzmann transmission problems (III.1) and (III.5). We introduce the following modified Hilbert expansion:

$$f_i^\alpha=F_i^0(x,\epsilon,t)+\alpha\Bigg[-\lambda_{i,x}(k)\,\frac{\partial F_i^0}{\partial x}(x,\epsilon,t)+F_i^1(x,\epsilon,t)+\left(\theta_i\left(\frac{x}{\alpha},k\right)-\theta_i^\infty(\epsilon_i(k))\right)J_{\mathrm{int}}^0(\epsilon_i(k),t)\Bigg]+\alpha^2 f_i^2+\alpha^3 f_i^3. \tag{IV.25}$$

We recall that F_i^0 and F_i^1 satisfy the SHE-equation and that F_i^0 satisfies the first-order transmission conditions (IV.8), (IV.9), and (IV.10). We denote by $J_{\mathrm{int}}^0(\epsilon,t)$, the common value in expression (IV.9), i.e.,

$$J_{\mathrm{int}}^0(\epsilon,t)=\left(D_i\,\frac{\partial F_i^0}{\partial x}\right)(0,\epsilon,t),\quad \epsilon\in\mathscr{R}_1\cap\mathscr{R}_2. \tag{IV.26}$$

J_{int}^0 is the (leading order) flux of particles of energy ϵ at the interface. The transmission layer corrector term θ_i is a solution of the two-sided Milne problem (IV.17), (IV.18) with $\ell_i(k)$ given by

$$\ell_i(k)=D_i^{-1}(0,\epsilon_i(k))\lambda_{i,x}(k),$$

if $\epsilon_i(k)$ belongs to $\mathscr{R}_1 \cap \mathscr{R}_2$ and $\ell_i(k) = 0$ otherwise. From the definition (IV.7) of D_i, we have for $\epsilon \in \mathscr{R}_1 \cap \mathscr{R}_2$:

$$\int_{\mathscr{S}^i_\epsilon} v_{i,x} \ell_i dN^i_\epsilon = D_i(0,\epsilon,t)^{-1} \int_{\mathscr{S}^i_\epsilon} v_{i,x}(k) \lambda_{i,x}(k) dN^i_\epsilon(k) = 1,$$

so that the flux continuity conditions (IV.22), (IV.23) are satisfied. With our assumptions on the two-sided Milne problem, the layer term θ_i exists and the difference

$$\theta(\epsilon) = \theta_2^\infty(\epsilon) - \theta_1^\infty(\epsilon) \tag{IV.27}$$

of its asymptotic values when $|\xi| \to \infty$ is determined uniquely. The next theorem provides interface conditions on F_i^1, necessary for an ansatz of the form (IV.25) to be an order 2 approximate solution of the Boltzmann transmission problem.

Theorem IV.4: Let $F_i^0(x,\epsilon,t)$ and $F_i^1(x,\epsilon,t)$ satisfy the SHE equation (IV.6), and let F_i^0 satisfy the transmission conditions (IV.8), (IV.9), (IV.10). Then, for f_i^α given by ansatz (IV.25) to be an order 2 approximate solution of the Boltzmann transmission problem (III.1), (III.5), it is necessary that F_i^1 satisfies:

$$F_2^1(0,\epsilon,t) - F_1^1(0,\epsilon,t) = \theta(\epsilon) J^0_{\mathrm{int}}(\epsilon,t), \quad \forall \epsilon \in \mathscr{R}_1 \cap \mathscr{R}_2, \tag{IV.28}$$

together with the current relations (IV.9) and (IV.10).

Proof: Inserting ansatz (IV.25) into the transmission condition (III.5), we get, at $x = 0$:

$$\begin{aligned}
&(f_i^\alpha)^- - \mathscr{T}_i((f_1^\alpha)^+, (f_2^\alpha)^+) \\
&\quad = (F_i^0(\epsilon_i)^- - \mathscr{T}_i(F_1^0(\epsilon_1)^+, F_2^0(\epsilon_2)^+) + \alpha \Bigg[\left(\theta_i J^0_{\mathrm{int}} - \lambda_{i,x} \frac{\partial F_i^0}{\partial x} \right)^- \\
&\qquad - \mathscr{T}_i \left(\left(\theta_1 J^0_{\mathrm{int}} - \lambda_{1,x} \frac{\partial F_1^0}{\partial x} \right)^+, \left(\theta_2 J^0_{\mathrm{int}} - \lambda_{2,x} \frac{\partial F_2^0}{\partial x} \right)^+ \right) \\
&\qquad + \alpha [(F_i^1 - \theta_i^\infty J^0_{\mathrm{int}})^- - \mathscr{T}_i((F_1^1 - \theta_1^\infty J^0_{\mathrm{int}})^+, (F_2^1 - \theta_2^\infty J^0_{\mathrm{int}})^+)] + \mathscr{O}(\alpha^2)
\end{aligned} \tag{IV.29}$$

The order α^0 term at the right-hand side of (IV.29) is zero because F_i^0 satisfies (IV.8) and because of Lemma III.2. The second one of the order α terms is also zero by a similar application of Lemma III.2 as soon as transmission condition (IV.28) is imposed to F_i^1. For the first one of the order α terms, we use the fact that $\theta_i J^0_{\mathrm{int}}(\epsilon_i)$ is a solution of the two-sided Milne problem (IV.17), (IV.18), and (IV.21) associated with

$$\ell_i(k) = D_i(\epsilon_i)^{-1} \lambda_{i,x}(k) J^0_{\mathrm{int}}(\epsilon_i) = \lambda_{i,x}(k) \frac{\partial F_i^0}{\partial x}(\epsilon_i).$$

Therefore $\theta_i J^0_{\mathrm{int}}(\epsilon_i) - \lambda_{i,x} \partial F_i^0 / \partial x(\epsilon_i)$ satisfies the interface condition (III.5), which shows that the first one of the order α terms in (IV.29) also vanishes. We deduce that ansatz (IV.25) satisfies the transmission condition (III.5) up to order α^2 terms.

Finally, we turn to the flux condition (IV.3). Inserting ansatz (IV.25) into (IV.3) and recalling that fluxes of functions of ϵ only vanish, that the flux of θ_i is zero by definition [condition (IV.21)], and that condition (IV.9) holds for F_i^0, we get for $\epsilon \in \mathscr{R}_1 \cap \mathscr{R}_2$:

$$J_1^\alpha(0,\epsilon,t) - J_2^\alpha(0,\epsilon,t) = \alpha \left[\int_{\mathscr{S}^1_\epsilon} v_{1,x}(k) f_1^2(0,k,t) dN^1_\epsilon(k) - \int_{\mathscr{S}^2_\epsilon} v_{2,x}(k) f_2^2(0,k,t) dN^2_\epsilon(k) \right] + \mathscr{O}(\alpha^2). \tag{IV.30}$$

But, with (IV.15), given that F_i^2 is a function of ϵ only and that h_i^2 is an even function of k, the order α term in (IV.30) reduces to

$$-\left(\int_{\mathscr{S}_\epsilon^1} v_{1,x}(k)\lambda_{1,x}(k)dN_\epsilon^1(k)\right)\frac{\partial F_1^1}{\partial x}(\epsilon)+\left(\int_{\mathscr{S}_\epsilon^2} v_{2,x}(k)\lambda_{2,x}(k)dN_\epsilon^2(k)\right)\frac{\partial F_2^1}{\partial x}(\epsilon).$$

The integral terms in the above expressions are nothing else than $D_i(\epsilon)(=D_i(0,\epsilon,t))$ according to (IV.7). Thus, condition (IV.9) for F_i^1 ensures that the order α term in (IV.30) is identically zero and that relation (IV.3) holds with $k=2$. The same arguments can be used to derive relation (IV.4) with $k=2$, which completes the proof of Theorem IV.4. ■

The construction of a complete $O(\alpha^2)$-approximation would require $O(\alpha^2)$ and $O(\alpha^3)$ layer terms. Let instead f_i^2 and f_i^3 be outer approximations given by Proposition IV.3. Inserting ansatz (IV.25) into the Boltzmann equation (III.1) and using the proof of Proposition IV.3, we obtain:

$$\begin{aligned}
&\partial_t f_i^\alpha+\frac{1}{\alpha}\left(v_{i,x}\frac{\partial f_i^\alpha}{\partial x}+\frac{\partial\phi}{\partial x}\frac{\partial f_i^\alpha}{\partial k_x}\right)-\frac{1}{\alpha^2}Q_i(f_i^\alpha)-S_i(f_i^\alpha)\\
&\quad=\alpha^2\left[\partial_t f_i^2+\alpha\partial_t f_i^3-S_i(f_i^2)-\alpha S_i(f_i^3)+\left(v_{i,x}\frac{\partial}{\partial x}+\frac{\partial\phi}{\partial x}\frac{\partial}{\partial k_x}\right)f_i^3\right]\\
&\qquad+\left(\alpha\partial_t+\frac{\partial\phi}{\partial x}\frac{\partial}{\partial k_x}-\alpha S_i\right)\left(\left(\theta_i\left(\frac{x}{\alpha},k\right)-\theta_i^\infty(\epsilon_i(k))\right)J_0^{\mathrm{int}}(\epsilon_i(k),t)\right).
\end{aligned}\tag{IV.31}$$

The first line of the right-hand side of (IV.31) is $O(\alpha^2)$ while the last line of (IV.31) is exponentially small away from $x=0$. Therefore, f_i^α is a formal approximate solution of order 2 to the Boltzmann equation (III.1), in domains of the form $\{|x|\geqslant x_0\}$.

The last step of the procedure is to combine F_i^0 and F_i^1 into a single SHE distribution function:

$$F_i^\alpha=F_i^0+\alpha F_i^1,$$

which satisfies the SHE equation (IV.6) in each Ω_i, the flux conditions (IV.9) and (IV.10) and the jump relation [deduced from (IV.8) for F_i^0 and from (IV.28) for F_i^1]:

$$F_2^\alpha(0,\epsilon,t)-F_1^\alpha(0,\epsilon,t)=\alpha\theta(\epsilon)J_{\mathrm{int}}^0(\epsilon,t).\tag{IV.32}$$

However, in (IV.32), J_{int}^0 is the flux of F_i^0 and not that of F_i^α. It would thus be desirable to replace it by J_{int}^α [with J_{int}^α being defined by (IV.26) with F_i^0 replaced by F_i^α], in order to obtain a self-contained transmission problem for F_i^α. But first, we must check if this problem would be well-posed.

Lemma IV.5: We have

$$\theta(\epsilon)\geqslant 0,\quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2.\tag{IV.33}$$

Proof: We apply the Darrozes–Guiraud inequality (III.19) to the transmission condition

$$(\theta_i-D_i^{-1}\lambda_{i,x})^-=\mathscr{T}_i((\theta_1-D_1^{-1}\lambda_{1,x})^+,(\theta_2-D_2^-\lambda_{2,x})^+),$$

and obtain for $\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2$,

$$\begin{aligned}
&\int_{\mathscr{S}_\epsilon^2} v_{2,x}(k)\left|\theta_2(0,k)-\lambda_{2,x}(k)D_2(\epsilon)^{-1}\right|^2dN_\epsilon^2(k)\\
&\qquad\leqslant\int_{\mathscr{S}_\epsilon^1} v_{1,x}(k)\left|\theta_1(0,k)-\lambda_{1,x}(k)D_1(\epsilon)^{-1}\right|^2dN_\epsilon^1(k).
\end{aligned}\tag{IV.34}$$

We develop:

$$\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,|\theta_i(0,k)-\lambda_{i,x}(k)D_i(\epsilon)^{-1}|^2 dN_\epsilon^i(k)$$

$$= \int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,|\theta_i(0,k)|^2 dN_\epsilon^i(k) + \left(\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)|\lambda_{i,x}(k)|^2 dN_\epsilon^i(k)\right) D_i(\epsilon)^{-2}$$

$$-2\left(\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\lambda_{i,x}(k)\,\theta_i(0,k) dN_\epsilon^i(k)\right) D_i(\epsilon)^{-1}. \tag{IV.35}$$

Multiplying Eq. (IV.17) by $\theta_i(\xi,k)$, integrating over k, and using property (iii) of Lemma II.1, we get

$$\frac{1}{2}\frac{\partial}{\partial\xi}\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,|\theta_i(\xi,k)|^2 dN_\epsilon^i(k) = \int_{\mathscr{S}_\epsilon^i} Q_i(\theta_i)\,\theta_i dN_\epsilon^i(k) \leqslant 0.$$

Moreover, since $\lim_{|\xi|\to\infty}\theta_i(\xi,k)=\theta_i^\infty(\epsilon_i(k))$ is an even function of k, we have

$$\lim_{|\xi|\to\infty}\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,|\theta_i(\xi,k)|^2 dN_\epsilon^i(k)=0.$$

We deduce

$$\sigma_i\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\,|\theta_i(0,k)|^2 dN_\epsilon^i(k)\leqslant 0, \quad \sigma_1=1,\sigma_2=-1. \tag{IV.36}$$

Then, using that $\lambda_{i,x}(k)$ is an odd function of k, we obtain:

$$\int_{\mathscr{S}_\epsilon^i} v_{i,x}|\lambda_{i,x}|^2 dN_\epsilon^i=0. \tag{IV.37}$$

Finally, we have

$$\int_{\mathscr{S}_\epsilon^i} v_{i,x}(k)\lambda_{i,x}(k)\,\theta_i(0,k) dN_\epsilon^i(k)=K_i(0,\epsilon),$$

where the K-integral $K_i(\xi,\epsilon)$ has been defined at (IV.19) and is constant with respect to ξ [because of (IV.20) and because $J_i=0$]. Thus, using (IV.7):

$$K_i(0,\epsilon)=\lim_{|\xi|\to\infty} K_i(\xi,\epsilon)=D_i(\epsilon)\,\theta_i^\infty(\epsilon). \tag{IV.38}$$

Inserting (IV.35), (IV.36), (IV.37) and (IV.38) into (IV.34) leads to the result. ■

We may now introduce $\tilde{F}_i^\alpha$, a solution of the SHE equation (IV.6) in each domain Ω_i, with the flux relations (IV.9) and (IV.10) at $x=0$ and the jump relation

$$\tilde{F}_2^\alpha-\tilde{F}_1^\alpha-\alpha\theta\tilde{J}_\alpha^{\text{int}}=0, \quad \forall\,\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2, \tag{IV.39}$$

where $\tilde{J}_\alpha^{\text{int}}$ is the common value of the current at the interface [formula (IV.26) with F_i^0 replaced by $\tilde{F}_i^\alpha$]. Relation (IV.39) is the final form of the order 2 transmission condition for the SHE distribution, that we are looking for. We note that $\theta\geqslant 0$ is a sufficient condition for the SHE equation with transmission conditions (IV.9), (IV.10), and (IV.39) to be well-posed. As a matter of example, we look at the following model problem.

Lemma IV.6: The stationary one-dimensional transmission problem for $F(x)$, $x\in(-1,1)$ given by

$$-(DF')'+F=S, \quad x\in(-1,1), \tag{IV.40}$$

$$F(-1)=F(1)=0, \tag{IV.41}$$

$$D_1F_1'=D_2F_2':=J^{\text{int}}, \quad F_1'=\lim_{x\to 0^-}F'(x), \quad F_2'=\lim_{x\to 0^+}F(x), \tag{IV.42}$$

$$F_2-F_1-\theta J^{\text{int}}=0 \quad F_1=\lim_{x\to 0^-}F(x), \quad F_2=\lim_{x\to 0^+}F(x), \tag{IV.43}$$

with $D(x)=D_1$ for $x\in(-1,0)$, $D(x)=D_2$ for $x\in(0,1)$, is well-posed for $\theta\geqslant 0$.

Proof: Multiplying (IV.40) by F, integrating by parts and using (IV.41), (IV.42), and (IV.43), leads to the following variational formulation:

$$\int_{-1}^{1} D|F'|^2\,dx+\int_{-1}^{1}|F|^2\,dx+\theta^{-1}|F_2-F_1|^2=\int_{-1}^{1}FS\,dx. \tag{IV.44}$$

If $\theta=0$, the term $\theta^{-1}|F_2-F_1|^2$ must be replaced by 0. From (IV.44), it is easy to prove existence of solution by Lax–Milgram theory. ■

The difference $F_i^\alpha-\tilde{F}_i^\alpha$ satisfies the same SHE problem (IV.6), (IV.9), (IV.10), but with an inhomogeneous transmission condition (IV.39) where the right-hand side is of order α^2 [use (IV.32)]. A stability theory derived from the existence theory of Lemma IV.6 then shows that $\tilde{F}_i^\alpha-F_i^\alpha$ is of order α^2. By virtue of (IV.25) and of evenness considerations, we have, away from $x=0$:

$$\frac{1}{N_i(x,\epsilon,t)}\int_{\mathscr{S}_{(x,\epsilon,t)}} f_i^\alpha(k)\,dN_\epsilon^i(k)=F_i^\alpha(x,\epsilon,t)+\mathscr{O}(\alpha^2).$$

Therefore, as a final theorem we can state:

Theorem IV.7: Let $\tilde{F}_i^\alpha$ be the solution of the transmission problem for the SHE equation (IV.6) with transmission conditions (IV.9), (IV.10), (IV.39). Then $\tilde{F}_i^\alpha(\epsilon)$ is formally an order 2 approximation of the energy-shell average of f_i^α, away from the interface.

V. THE KINETIC TRANSMISSION LAYER PROBLEM

In this section, we are concerned with the existence and uniqueness theory of the transmission layer problem (IV.17), (IV.18). In particular, rotationally symmetric models will be treated in detail. We shall start, however, dealing with the general case.

Our analysis will be based on assumptions on the one-sided Milne problems

$$v_{i,x}\frac{\partial\theta_i}{\partial\xi}=Q_i(\theta_i), \quad \xi\in I_i=\sigma_i(-\infty,0], \quad k\in\mathscr{S}_\epsilon^i, \tag{V.1}$$

$$\theta_i^- \text{ given on } \mathscr{S}_\epsilon^{i,-}, \tag{V.2}$$

for $\epsilon\in\mathscr{R}_i$, where the abbreviation $\theta_i^\pm=\theta_i(0,\cdot)^\pm$ is used. Note that we use the fact that the Milne problem is decoupled in the energy direction.

Hypothesis 4: For $i=1$ or 2, $\epsilon\in\mathscr{R}_i$ and arbitrary $\theta_i^-\in L^2(\mathscr{S}_\epsilon^{i,-},dN_\epsilon^i)$ the problem (V.1), (V.2) has a unique solution in $L^\infty(I_i,L^2(\mathscr{S}_\epsilon^i,dN_\epsilon^i))$ such that the Albedo operator $\mathscr{A}_i$, determined from $\theta_i^+=\mathscr{A}_i\theta_i^-$ is compact from $L^2(\mathscr{S}_\epsilon^{i,-},dN_\epsilon^i)$ to $L^2(\mathscr{S}_\epsilon^{i,+},dN_\epsilon^i)$. Furthermore, as $|\xi|\to\infty$, θ_i converges exponentially to a constant.

It will be shown below that this assumption can be verified for rotationally symmetric models. Its verification for more general cases remains the subject of future work.

Theorem V.1: Assume the hypotheses 1–4. Then the two-sided Milne problem (IV.17), (IV.18) has a bounded solution iff $\mathscr{C}_1$ and $\mathscr{C}_2$ satisfy the solvability conditions (IV.22), (IV.23). In this case, the solution is unique up to the addition of a solution of the form (IV.24) of the homogeneous problem.

Proof: With the help of the Albedo operators, the transmission conditions (IV.18) can be written as

$$\theta_i^- - \mathcal{T}_i(\mathcal{A}_1\theta_1^-, \mathcal{A}_2\theta_2^-) = \ell_i^- - \mathcal{T}_i(\ell_1^+, \ell_2^+),$$

reducing the problem to a fixed point problem for the θ_i^-:

$$\begin{pmatrix} \theta_1^- \\ \theta_2^- \end{pmatrix} - K\begin{pmatrix} \theta_1^- \\ \theta_2^- \end{pmatrix} = \begin{pmatrix} \ell_1^- \\ \ell_2^- \end{pmatrix} - \begin{pmatrix} \mathcal{T}_1(\ell_1^+, \ell_2^+) \\ \mathcal{T}_2(\ell_1^+, \ell_2^+) \end{pmatrix}, \tag{V.3}$$

with

$$K\begin{pmatrix} \theta_1^- \\ \theta_2^- \end{pmatrix} = \begin{pmatrix} \mathcal{T}_1(\mathcal{A}_1\theta_1^-, \mathcal{A}_2\theta_2^-) \\ \mathcal{T}_2(\mathcal{A}_1\theta_1^-, \mathcal{A}_2\theta_2^-) \end{pmatrix}. \tag{V.4}$$

An application of Jensen's inequality as in the proof of Lemma III.3 and an integration with respect to k shows that $\mathcal{T}_i$ is a continuous operator from $L^2(\mathcal{S}_\epsilon^{1,+}, dN_\epsilon^1) \times L^2(\mathcal{S}_\epsilon^{2,+}, dN_\epsilon^2)$ to $L^2(\mathcal{S}_\epsilon^{i,-}, dN_\epsilon^i)$. Therefore, by Hypothesis 4, K is a compact operator on $L^2(\mathcal{S}_\epsilon^{1,-}, dN_\epsilon^1) \times L^2(\mathcal{S}_\epsilon^{2,-}, dN_\epsilon^2)$.

Let now $\ell_i = 0$, $i = 1,2$. Multiplying (IV.17) by θ_i, integrating it with respect to k, and using Lemma II.1 (iii) yields

$$\frac{1}{2}\frac{\partial}{\partial \xi}\int_{\mathcal{S}_\epsilon^i} v_{i,x}\theta_i^2 dN_\epsilon^i = \int_{\mathcal{S}_\epsilon^i} Q_i(\theta_i)\theta_i dN_\epsilon^i \leqslant 0. \tag{V.5}$$

By Hypothesis 4, θ_i tends to a constant independent of $k \in \mathcal{S}_\epsilon^i$ as $|\xi|$ tends to infinity. Therefore, integrating (V.5) with respect to ξ over I_i and using the oddness of $v_{i,x}$ leads to

$$\int_{\mathcal{S}_\epsilon^1} v_{1,x}(k)\theta_1(0,k)^2 dN_\epsilon^1(k) \leqslant 0 \leqslant \int_{\mathcal{S}_\epsilon^2} v_{2,x}(k)\theta_2(0,k)^2 dN_\epsilon^2(k).$$

Combined with the Darrozes–Guiraud inequality (Lemma III.3), this implies that

$$\int_{\mathcal{S}_\epsilon^i} v_{i,x}(k)\theta_i(0,k)^2 dN_\epsilon^i(k) = 0, \quad i = 1,2.$$

Therefore, we have:

$$\int_{I_i}\int_{\mathcal{S}_\epsilon^i} Q_i(\theta_i)\theta_i dN_\epsilon^i d\xi = 0,$$

which implies, with Lemma II.1 (iii) that θ_i is constant on $\mathcal{S}_\epsilon^i$: $\theta_i = \theta_i(\xi, \epsilon)$. Then using Eq. (IV.17), we see that θ_i is also independent of ξ: $\theta_i = \theta_i(\epsilon)$. Finally, Lemma III.2 implies

$$\theta_1(\epsilon) = \theta_2(\epsilon),$$

completing the proof for the homogeneous case.

We now turn to the inhomogeneous case. It has already been observed in Sec. IV that (IV.22) and (IV.23) are necessary solvability conditions. Since $I - K$ (where I is the identity operator) is a Fredholm operator on $L^2(\mathcal{S}_\epsilon^{1,-}, dN_\epsilon^1) \times L^2(\mathcal{S}_\epsilon^{2,-}, dN_\epsilon^2)$ whose kernel is the one-dimensional vector space spanned by the constants, its range is closed and of codimension 1, and (IV.22) and (IV.23) are thus also sufficient for the existence of a solution. ■

We now specialize to a spherically symmetric model and, thus, consider a spherically symmetric band diagram

$$e_i(k) = \overline{e_i}(|k|) \tag{V.6}$$

with a strictly monotone $\overline{e_i}$, and rotationally symmetric collision and transmission operators. The parabolic band diagram (II.3) is a particular case of (V.6).

Because of the monotonicity hypothesis on $\overline{e_i}$, there exists a one-to-one correspondence between $|k|$ and $\epsilon=\epsilon_i(k)=\overline{e_i}(|k|)-\chi_i$. We denote the inverse relation by $|k|=\kappa_i(\epsilon)$. It will be convenient to introduce a new set of variables $\epsilon\in\mathscr{R}_i$, $\mu\in[-1,1]$, $\varphi\in[0,2\pi)$ such that

$$k=\kappa_i(\epsilon)(\mu,\sqrt{1-\mu^2}\cos\varphi,\sqrt{1-\mu^2}\sin\varphi). \tag{V.7}$$

The measure $dN^i_\epsilon(k)$ is given in these coordinates by

$$dN^i_\epsilon(k)=\overline{v_i}(\epsilon)^{-1}\kappa_i^2(\epsilon)d\mu d\varphi \quad \text{with } \overline{v_i}(\epsilon)=\frac{\partial\overline{e_i}}{\partial|k|}(\kappa_i(\epsilon)). \tag{V.8}$$

The hypothesis of rotational symmetry for Q_i implies that the matrix element $\Phi_i(k,k')$ [see (II.4)] is invariant under all orthogonal transformations of $\mathbf{R}^3$, i.e., $\Phi_i(Rk,Rk')=\Phi(k,k')$, for all R in the orthogonal group $O_3(\mathbf{R})$. Therefore, Φ_i is of the form

$$\Phi_i(k,k')=\tilde{\Phi}_i\left(\epsilon,\frac{k}{|k|}\cdot\frac{k'}{|k'|}\right) \tag{V.9}$$

[since Φ_i needs to be defined only when $\epsilon_i(k)=\epsilon_i(k')=\epsilon$]. A special case is the relaxation time model

$$\Phi_i=\Phi_i(\epsilon)=\frac{\overline{v_i}(\epsilon)}{4\pi\kappa_i(\epsilon)^2\tau_i(\epsilon)}, \tag{V.10}$$

where the collision operator takes the form

$$Q_i(f)=\frac{1}{\tau_i(\epsilon)}\left(\frac{1}{4\pi}\int_{-1}^{1}\int_0^{2\pi}f(\epsilon,\mu',\varphi')d\varphi'd\mu'-f(\epsilon,\mu,\varphi)\right). \tag{V.11}$$

The hypothesis of rotational symmetry for the transmission operator $\mathscr{T}_i$ is that R_i and $T_{i\to j}$ are invariant under all the orthogonal transformations that leave the interface Σ globally invariant. Therefore, $R_i(k\to k')$ for $\epsilon_i(k)=\epsilon_i(k')=\epsilon\in\mathscr{R}_i$ and $T_{i\to j}(k\to k')$ for $\epsilon_i(k)=\epsilon_j(k')=\epsilon$ are of the form:

$$\begin{aligned}
R_i(k\to k')&=\tilde{R}_i\left(\epsilon,\frac{k_yk_y'+k_zk_z'}{\sqrt{k_y^2+k_z^2}\sqrt{k_y'^2+k_z'^2}};\frac{k_x}{|k_x|}\to\frac{k_x'}{|k_x'|}\right),\\
T_{i\to j}(k\to k')&=\tilde{T}_{i\to j}\left(\epsilon,\frac{k_yk_y'+k_zk_z'}{\sqrt{k_y^2+k_z^2}\sqrt{k_y'^2+k_z'^2}};\frac{k_x}{|k_x|}\to\frac{k_x'}{|k_x'|}\right).
\end{aligned} \tag{V.12}$$

With the spherical symmetry assumption and the relaxation time model for the collision operator, Hypothesis 4 can be verified:

Lemma V.2: Assume (V.6) and (V.10). Then Hypothesis 4 holds.

Proof: We have to analyze the one-sided Milne problem

$$\overline{v_i}\mu\frac{\partial\theta_i}{\partial\xi}=Q_i(\theta_i),\quad \xi\in I_i,\quad \mu\in[-1,1],\quad \varphi\in[0,2\pi), \tag{V.13}$$

$$\theta_i(0,\mu,\varphi)=\theta_B(\mu,\varphi),\quad \sigma_i\mu<0, \tag{V.14}$$

where Q_i is given by (V.11). Here and in the following we skip the dependencies on ϵ since it is only a parameter. For the solution we make the ansatz

$$\theta_i(\xi,\mu,\varphi)=\overline{\theta_i}(\xi,\mu)+\begin{cases}e^{-\xi/|\mu|}(\theta_B(\mu,\varphi)-\overline{\theta_B}(\mu)) & \sigma_i\mu<0\\ 0 & \sigma_i\mu>0,\end{cases} \tag{V.15}$$

where $\overline{\theta_B}$ is the average with respect to φ of θ_B:

$$\overline{\theta_B}(\mu)=\frac{1}{2\pi}\int_0^{2\pi}\theta_B(\mu,\varphi)d\varphi.$$

It is easily checked that (V.15) is a solution of (V.13), (V.14) if $\overline{\theta_i}$ satisfies the φ-averaged problem

$$\overline{v}_i\mu\,\frac{\partial\overline{\theta_i}}{\partial\xi}=\frac{1}{\tau_i}\left(\frac{1}{2}\int_{-1}^{1}\overline{\theta_i}(\xi,\mu')d\mu'-\overline{\theta_i}(\xi,\mu)\right),\quad \xi\in I_i,\quad \mu\in[-1,1] \tag{V.16}$$

$$\overline{\theta_i}(0,\mu)=\overline{\theta_B}(\mu),\quad \sigma_i\mu<0. \tag{V.17}$$

Now the proof can be completed by references to the literature. The φ-averaged problem is a version of the Milne problem of neutron transport. Results on existence, uniqueness, and exponential decay to an equilibrium state can be found in Ref. 14. This provides existence for the full problem (V.13), (V.14). Uniqueness can be shown analogously to the corresponding result for (V.16) and (V.17) in Ref. 14. By (V.15), the Albedo operator for the full problem is the composition of the φ-average and the Albedo operator for the averaged problem. The compactness of the latter follows from its representation in terms of the Chandrasekhar H-function.[27] Compactness of the full Albedo operator is then obvious. ■

We now return to the general problem without symmetry assumptions and investigate a scheme which, in the spirit of those reviewed in Ref. 15, approximately solves the two-sided Milne problem and provides approximate values of the parameter θ (IV.27). In the following, a fixed value of $\epsilon\in\mathscr{R}_1\cap\mathscr{R}_2$ is considered. We start by applying the Albedo operators to the rows of (V.3) and obtaining a fixed point problem for the θ_i^+:

$$\theta_i^+=\mathscr{A}_i(\mathscr{T}_i(\theta_1^+,\theta_2^+)+\varphi_i^-),\quad i=1,2. \tag{V.18}$$

Now the Albedo operators are approximated by $\tilde{\mathscr{A}}_i$, $i=1,2$, defined by the requirements that a constant function is returned and that the vanishing flux property of the full problem is preserved:

$$f^+=\tilde{\mathscr{A}}_i f^-\Leftrightarrow f^+=f^+(\epsilon)\quad\text{and}\quad\int_{\mathscr{S}_\epsilon^i}v_{i,x}f\,dN_\epsilon^i=0.$$

The approximating Albedo operators are explicitly given by

$$\tilde{\mathscr{A}}_i f^-=\frac{1}{\alpha_i}\int_{\mathscr{S}_\epsilon^{i,-}}|v_{i,x}|f^-dN_\epsilon^i,$$

with α_i defined in (III.31). When (V.18) is approximated by

$$\theta_i^+=\tilde{\mathscr{A}}_i(\mathscr{T}_i(\theta_1^+,\theta_2^+)+\varphi_i^-),\quad i=1,2 \tag{V.19}$$

the θ_i^+ are constant on $\mathscr{S}_\epsilon^{i,+}$. Application of the transmission operator to constant data gives

$$\mathscr{T}_i(\theta_1^+,\theta_2^+)=\theta_i^++(\theta_j^+-\theta_i^+)\overline{T}_{j\to i}, \tag{V.20}$$

where $\overline{T}_{j\to i}$ has been defined in (III.15) and (III.14) has been used. Substitution in (V.19) gives

$$\theta_i^+-\theta_j^+=\frac{\tilde{\mathscr{A}}_i\varphi_i^-}{\tilde{\mathscr{A}}_i\overline{T}_{j\to i}}, \tag{V.21}$$

where we have used that constant factors can be taken out of $\tilde{\mathscr{A}}_i$ and that $\tilde{\mathscr{A}}_i$ reduces to the identity when applied to constants. The positivity of the denominator in the right-hand side of (V.21) is a consequence of the transmittivity Hypothesis 3.

Of course, the question arises if the result for $\theta_1^+ - \theta_2^+$ is the same for the two formulas ($i=1$, $j=2$ and $i=2$, $j=1$) contained in (V.21). With the help of the reciprocity relation (III.13) it is easy to show that

$$\alpha_1 \tilde{\mathscr{A}}_1 \overline{T}_{2\to 1} = \alpha_2 \tilde{\mathscr{A}}_2 \overline{T}_{1\to 2}$$

holds. On the other hand, a straightforward computation using the flux conservation property of the transmission operator (Lemma III.1) shows that

$$\alpha_1 \tilde{\mathscr{A}}_1 \varphi_1^- = -\alpha_2 \tilde{\mathscr{A}}_2 \varphi_2^-$$

holds iff the ℓ_i satisfy the solvability condition (IV.22). The approximating problem requires the same solvability condition as the original one.

The *K*-integral (IV.19)

$$K_i = \int_{\mathscr{S}_\epsilon^i} v_{i,x} \lambda_{i,x} \theta_i \, dN_\epsilon^i$$

is constant in each Ω_i. Evaluation at $|\xi| = \infty$ gives

$$K_i = D_i \theta_i^\infty .$$

With the transmission conditions (IV.18) and with (V.20), $\theta_i(\xi = 0)$ can be expressed in terms of the θ_i^+:

$$K_i = \int_{\mathscr{S}_\epsilon^{i,-}} v_{i,x} \lambda_{i,x} \varphi_i^- \, dN_\epsilon^i + D_i(\theta_i^+ + \beta_i(\theta_j^+ - \theta_i^+)),$$

with

$$\beta_i = \frac{1}{D_i} \int_{\mathscr{S}_\epsilon^{i,-}} v_{i,x} \lambda_{i,x} \overline{T}_{j\to i} \, dN_\epsilon^i .$$

Note that $\overline{T}_{j\to i} \leqslant 1$ (III.14) and the oddness of $v_{i,x}$ and $\lambda_{i,x}$ imply

$$\beta_i \leqslant \tfrac{1}{2}.$$

By elimination of K_i, θ_i^∞ can be computed. Taking the difference gives

$$\theta = \theta_2^\infty - \theta_1^\infty = (1-\beta_1-\beta_2)(\theta_2^+ - \theta_1^+) + \frac{1}{D_2} \int_{\mathscr{S}_\epsilon^{2,-}} v_{2,x} \lambda_{2,x} \varphi_2^- \, dN_\epsilon^2 - \frac{1}{D_1} \int_{\mathscr{S}_\epsilon^{1,-}} v_{1,x} \lambda_{1,x} \varphi_1^- \, dN_\epsilon^1 . \tag{V.22}$$

The formulation of the second-order transmission conditions for the SHE-model requires the value of θ for the choice $\ell_i = \lambda_{i,x}/D_i$ of the inhomogeneities. In this case, our result can be simplified.

Lemma V.3: Assume $\ell_i = \lambda_{i,x}/D_i$. Then

$$\alpha_i \tilde{\mathscr{A}}_i \varphi_i^- = \sigma_i (1-\beta_1-\beta_2).$$

Proof: With

$$\varphi_i^- = \frac{\lambda_{i,x}}{D_i} - \mathscr{T}_i\left(\frac{\lambda_{1,x}^+}{D_1}, \frac{\lambda_{2,x}^+}{D_2}\right)$$

we obtain $\alpha_i \tilde{\mathscr{A}}_i \varphi_i^- = A + B + C$ with

$$A=\frac{1}{D_i}\int_{\mathscr{S}_\epsilon^{i,-}}|v_{i,x}|\lambda_{i,x}dN_\epsilon^i=\frac{\sigma_i}{2},$$

as well as

$$B=-\frac{1}{D_i}\int_{\mathscr{S}_\epsilon^{i,-}}\int_{\mathscr{S}_\epsilon^{i,+}}R_i(k'\to k)|v_{i,x}(k)|\lambda_{i,x}(k')dN_\epsilon^i(k')dN_\epsilon^i(k)=\sigma_i(\tfrac{1}{2}-\beta_i) \qquad \text{(V.23)}$$

by the reciprocity relation (III.12) and by (III.14). Similarly we show

$$C=-\frac{1}{D_j}\int_{\mathscr{S}_\epsilon^{i,-}}\int_{\mathscr{S}_\epsilon^{j,+}}T_{j\to i}(k'\to k)|v_{i,x}(k)|\lambda_{j,x}(k')dN_\epsilon^j(k')dN_\epsilon^i(k)=\sigma_j\beta_j, \qquad \text{(V.24)}$$

completing the proof. ■

After substitution of (V.21), (V.22) becomes

$$\theta=\frac{(1-\beta_1-\beta_2)^2}{\alpha_i\tilde{\mathscr{K}}_i\overline{T}_{j\to i}}-\sum_{i=1}^{2}\frac{\sigma_i}{D_i}\int_{\mathscr{S}_\epsilon^{i,-}}v_{i,x}\lambda_{i,x}\varphi_i^-dN_\epsilon^i, \qquad \text{(V.25)}$$

which is explicit up to the computation of $\lambda_{i,x}$.

A simplification can be achieved by returning to the assumptions (V.6), (V.10), and (V.12) of spherical symmetry and the relaxation time model for the collision operator. In this case, $\lambda_{i,x}$ can be computed explicitly:

$$\lambda_{i,x}=\tau_i v_{i,x}=\tau_i\overline{v}_i\mu.$$

The quantities needed in (V.25) are

$$\beta_i=\frac{3}{2}\int_{\sigma_i\mu<0}\mu^2\overline{T}_{j\to i}(\epsilon,\mu)d\mu,$$

$$\alpha_i\tilde{\mathscr{K}}_i\overline{T}_{j\to i}=2\pi\kappa_i^2\int_{\sigma_i\mu<0}|\mu|\overline{T}_{j\to i}(\epsilon,\mu)d\mu,$$

with

$$\overline{T}_{j\to i}(\epsilon,\mu)=\frac{\kappa_j^2}{\overline{v}_j}\int_{\sigma_j\mu'>0}\int_0^{2\pi}\tilde{T}_{j\to i}(\epsilon,\cos\varphi;\mu'\to\mu)d\varphi d\mu',$$

as well as

$$\frac{1}{D_i}\int_{\mathscr{S}_\epsilon^{i,-}}v_{i,x}\lambda_{i,x}\varphi_i^-dN_\epsilon^i=\frac{3}{2}\int_{\sigma_i\mu<0}\mu^2\varphi_i^-(\epsilon,\mu)d\mu,$$

with

$$\varphi_i^-(\epsilon,\mu)=\frac{3\mu}{4\pi\kappa_i^2}-\frac{3}{4\pi\overline{v}_i}\int_{\sigma_i\mu'>0}\int_0^{2\pi}\mu'\tilde{R}_i(\epsilon,\cos\varphi;\mu'\to\mu)d\varphi d\mu'$$
$$-\frac{3}{4\pi\overline{v}_j}\int_{\sigma_j\mu'>0}\int_0^{2\pi}\mu'\tilde{T}_{j\to i}(\epsilon,\cos\varphi;\mu'\to\mu)d\varphi d\mu'.$$

We conclude this section by applying our results to the examples of transmission operators from Sec. III.

Example 1: Semiclassical transmission conditions (III.24). Let k_1, k_2 be such that $k_2 = t_{2\to 1} k_1$ or $k_1 = t_{1\to 2} k_2$ [see (III.26)]. Relation (III.23) translates to the (ϵ,μ) geometry into $\epsilon_1 = \epsilon_2 = \epsilon$ and:

$$\kappa_1^2(\epsilon)(1-\mu_1^2) = \kappa_2^2(\epsilon)(1-\mu_2^2). \tag{V.26}$$

We now suppose, without loss of generality, that $\kappa_1^2(\epsilon)/\kappa_2^2(\epsilon) > 1$ and define $\mu_0 \in (0,1)$ by $\kappa_2^2(\epsilon) = (1-\mu_0^2)\kappa_1^2(\epsilon)$. Equation (V.26) is then written

$$1-\mu_1^2 = (1-\mu_0^2)(1-\mu_2^2). \tag{V.27}$$

It allows us to define the particle transmission process $t_{j\to i}$ in the (ϵ,μ) system of coordinates by $\mu_j = t_{j\to i}\mu_i$ with, for all $\mu_2 > 0$ and $\mu_1 < -\mu_0$:

$$t_{1\to 2}\mu_2 = \sqrt{1-(1-\mu_0^2)(1-\mu_2^2)}, \quad t_{2\to 1}\mu_1 = -\sqrt{1-\frac{1-\mu_1^2}{1-\mu_0^2}}. \tag{V.28}$$

If $-\mu_0 < \mu_1 < 0$, $t_{2\to 1}\mu_1$ is not defined. The reflection operator r is simply defined by $r\mu_i = -\mu_i$. Rotational symmetry for R_i and $T_{i\to j}$ respectively, given by (III.28) and (III.29) simply means that the transmission probability $T_{j\to i}$ satisfies: $T_{j\to i} = T_{j\to i}(\epsilon_i, \mu_i)$ for all $\sigma_i\mu_i < 0$, $i = 1,2$, and with $0 \leqslant \overline{T}_{j\to i} \leqslant 1$. The reciprocity relation (III.30) gives:

$$\overline{T}_{2\to 1}(\epsilon,\mu) = \begin{cases} \overline{T}_{1\to 2}(\epsilon, r t_{2\to 1}\mu), & \mu < -\mu_0 \\ 0 \quad \text{else.} \end{cases} \tag{V.29}$$

The transmission and reflection rates (V.12) are now given by

$$\tilde{R}_i(\epsilon;\mu\to\mu') = \frac{\overline{v}_i}{2\pi\kappa_i^2}\,(1-\overline{T}_{j\to i}(\epsilon,\mu'))\,\delta(\mu+\mu'),$$

$$\tilde{T}_{i\to j}(\epsilon;\mu\to\mu') = \frac{\overline{v}_i}{2\pi\kappa_i^2}\,\overline{T}_{j\to i}(\epsilon,\mu')\,\delta(\mu - t_{i\to j}\mu').$$

Of course, purely classical transmission is described within this framework with $\overline{T}_{1\to 2}(\mu) = 1$, for $\mu \in [0,1]$. Now we substitute into the above formulas for the spherically symmetric case and compute

$$\beta_1 + \beta_2 = \frac{3\kappa_2^2}{2}\int_0^1 \mu\left(\frac{t_{1\to 2}\mu}{\kappa_1^2} + \frac{\mu}{\kappa_2^2}\right)\overline{T}_{1\to 2}(\epsilon,\mu)\,d\mu,$$

$$\alpha_i \tilde{\mathscr{B}}_i \overline{T}_{j\to i} = 2\pi\kappa_2^2 \int_0^1 \mu\,\overline{T}_{1\to 2}(\epsilon,\mu)\,d\mu,$$

$$-\sum_{i=1}^{2}\frac{\sigma_i}{D_i}\int_{\mathscr{S}_\epsilon^{i,-}} v_{i,x}\lambda_{i,x}\varphi_i^- dN_\epsilon^i = \frac{9}{16\pi}\left[\frac{1}{\kappa_1^2} + \frac{1}{\kappa_2^2} - 2\kappa_2^2\int_0^1 \mu\left(\frac{t_{1\to 2}\mu}{\kappa_1^2} + \frac{\mu}{\kappa_2^2}\right)^2 \overline{T}_{1\to 2}(\epsilon,\mu)\,d\mu\right].$$

Note that these results apply to the case $\kappa_2^2/\kappa_1^2 < 1$. In the converse situation $\kappa_2^2/\kappa_1^2 > 1$, the roles of 1 and 2 must be exchanged. The above formulas cannot be simplified further without specifying the values of the transmission coefficients. In the case of purely classical transmission ($\overline{T}_{1\to 2} = 1$) we substitute in (V.25) and obtain

$$\theta = \frac{9}{32\pi\kappa_1^2}\,\mu_0^4\left[1 + \frac{8}{9}\frac{\mu_0^2}{1-\mu_0^2} + \frac{1}{2(1-\mu_0^2)^{3/2}}\ln\left(\frac{1+\sqrt{1-\mu_0^2}}{1-\sqrt{1-\mu_0^2}}\right)\right]. \tag{V.30}$$

We note that $\theta=0$ when $\kappa_1=\kappa_2$ ($\mu_0^2=1-\kappa_2^2/\kappa_1^2=0$), i.e., when there is no heterojunction at all. On the other hand, $\theta\to\infty$ when $\kappa_2\to 0$, i.e., when ϵ tends to the boundary of the region $\mathscr{R}_1\cap\mathscr{R}_2$. Thanks to that, when ϵ crosses the boundary between $\mathscr{R}_1\cap\mathscr{R}_2$ and $\mathscr{R}_1\setminus\mathscr{R}_2$, there is a continuous shift from the transmission conditions (IV.39), (IV.9), to the Neumann condition (IV.10). ■

Example 2: Isotropic reflection-transmission conditions. We consider the reflection-transmission rates (III.32). Clearly, the corresponding transmission operator is rotationally symmetric and the reflection and transmission rates (V.12) are

$$\tilde{R}_i(\epsilon;\mu\to\mu')=\frac{\overline{v_i}(\epsilon)}{\pi\kappa_i(\epsilon)^2}\,(1-\pi\kappa_j(\epsilon)^2\hat{T}(\epsilon))|\mu|,$$

$$\tilde{T}_{i\to j}(\epsilon;\mu\to\mu')=\overline{v_i}(\epsilon)\hat{T}(\epsilon)|\mu|$$

with $\hat{T}$ being the transmission coefficient from (III.32), satisfying $0\leqslant\hat{T}\pi\kappa_i^2\leqslant 1$, $i=1,2$. If, in addition, relaxation time collision operators are considered, the above formulas yield, after some easy computations:

$$\theta=\frac{1}{\pi^2\kappa_1^2\kappa_2^2}\left(\frac{1}{\hat{T}}-\frac{15\pi}{32}\,(\kappa_1^2+\kappa_2^2)\right)\geqslant 0.$$

■

VI. APPLICATION TO THE ENERGY-TRANSPORT AND DRIFT-DIFFUSION MODELS

The energy-transport (ET) and drift-diffusion (DD) models are usually directly derived from the semiconductor Boltzmann equation (II.1) by a diffusion approximation using appropriate assumptions on the dominant scattering (see Refs. 10 and 13). However, using the knowledge that the equilibrium distribution of electrons is a Fermi–Dirac distribution, they can also be derived from the SHE model by the moment method, using a Fermi–Dirac ansatz to compute the fluxes. We shall use this method to derive the ET and DD models for an x-dependent band diagram, and their associated transmission conditions at a heterojunction interface.

We first consider a band diagram which depends smoothly on x and define the macroscopic density n, total energy $\mathscr{E}_{\rm tot}$, particle current j_n and total energy current $j_{\mathscr{E}_{\rm tot}}$ according to

$$\begin{pmatrix} n \\ n\mathscr{E}_{\rm tot}\end{pmatrix}=\int_{\mathbf{R}} F\begin{pmatrix}1\\ \epsilon\end{pmatrix}N d\epsilon,\quad \begin{pmatrix} j_n \\ j_{\mathscr{E}_{\rm tot}}\end{pmatrix}=-\int_{\mathbf{R}} D\nabla_x F\begin{pmatrix}1\\ \epsilon\end{pmatrix}d\epsilon, \tag{VI.1}$$

where F is a solution of the SHE equation (II.17). We also let q_n and $q_{\mathscr{E}_{\rm tot}}$ the particle and total energy gain rates due to the collisions modeled by $S(F)$:

$$\begin{pmatrix} q_n \\ q_{\mathscr{E}_{\rm tot}}\end{pmatrix}=\int_{\mathbf{R}} S(F)\begin{pmatrix}1\\ \epsilon\end{pmatrix}d\epsilon.$$

Then, multiplying (II.17) by 1 and ϵ and integrating over ϵ leads to the particle and total energy conservation equations:

$$\frac{\partial n}{\partial t}+\nabla_x\cdot j_n=q_n, \tag{VI.2}$$

$$\frac{\partial}{\partial t}\,(n\mathscr{E}_{\rm tot})+n\,\frac{\partial\phi}{\partial t}+\nabla_x\cdot j_{\mathscr{E}_{\rm tot}}=q_{\mathscr{E}_{\rm tot}}. \tag{VI.3}$$

The ET model is obtained by closing these equations assuming that F is a Fermi–Dirac distribution:

$$F(x,\epsilon,t)=\mathscr{F}_{\epsilon_F,T}(\epsilon):=\frac{1}{\exp\left(\frac{\epsilon-\epsilon_F}{T}\right)+1}, \tag{VI.4}$$

where $\epsilon_F=\epsilon_F(x,t)$ and $T=T(x,t)$ are, respectively, the scaled Fermi energy and temperature. We define the functions $n(\epsilon_F,T;x,t)$ and $n\mathscr{E}_{\rm tot}(\epsilon_F,T;x,t)$ by:

$$\begin{pmatrix} n \\ n\mathscr{E}_{\rm tot}\end{pmatrix}(\epsilon_F,T;x,t)=\int_{\mathbf{R}}\mathscr{F}_{\epsilon_F,T}(\epsilon)\begin{pmatrix}1\\ \epsilon\end{pmatrix}N(x,\epsilon,t)\,d\epsilon, \tag{VI.5}$$

where the (x,t) dependence of n and $n\mathscr{E}_{\rm tot}$ comes from the dependence of the band diagram characteristics upon (x,t). We also define the diffusion matrices $D_{ij}=D_{ij}(\epsilon_F,T;x,t)$, $i=1,2$, $j=1,2$, by

$$D_{ij}(\epsilon_F,T;x,t)=\int_{\mathbf{R}}\mathscr{F}_{\epsilon_F,T}(\epsilon)(1-\mathscr{F}_{\epsilon_F,T}(\epsilon))D(x,\epsilon,t)\,\epsilon^{i+j-2}d\epsilon. \tag{VI.6}$$

We note that each D_{ij} is a non-negative symmetric 3×3 matrix, that $D_{12}=D_{21}$, and that under weak geometric assumptions on $e(x,k)$, the 6×6 matrix

$$D=\begin{pmatrix}D_{11} & D_{12}\\ D_{21} & D_{22}\end{pmatrix}$$

is symmetric positive definite (see Ref. 9 for details). With these definitions, inserting (VI.4) in (VI.1) leads to

$$j_n=-D_{11}\nabla_x\left(\frac{\epsilon_F}{T}\right)-D_{12}\nabla_x\left(-\frac{1}{T}\right), \tag{VI.7}$$

$$j_{\mathscr{E}_{\rm tot}}=-D_{21}\nabla_x\left(\frac{\epsilon_F}{T}\right)-D_{22}\nabla_x\left(-\frac{1}{T}\right). \tag{VI.8}$$

The ET model written in terms of the Fermi energy-temperature variables consists in equations (VI.2), (VI.3), (VI.7), (VI.8) together with the closure relation (VI.5). The DD model is just the ET model in which the temperature is kept constant equal to the lattice temperature. If the lattice temperature is uniform, its formulation in terms of the Fermi-energy variable consists of (VI.2) and (VI.7) in which $\nabla_x(-1/T)=0$. The ET and DD models are sometimes more conveniently expressed in terms of the chemical potential ϵ_F+V rather than in terms of the Fermi energy ϵ_F.[10]

Now, we turn toward discontinuous band diagrams. We shall use the results of Secs. IV and V to derive appropriate transmission conditions for the ET and DD models. We begin with the first-order transmission conditions (IV.8), (IV.9), (IV.10). First, inserting the Fermi–Dirac ansatz (VI.4) into relation (IV.8) leads to the continuity of the temperatures and of the Fermi levels, i.e., with obvious notations:

$$\epsilon_{F_1}=\epsilon_{F_2},\quad T_1=T_2. \tag{VI.9}$$

Then, inserting the Fermi–Dirac ansatz (VI.4) and taking the first two moments (in ϵ) of relations (IV.9), (IV.10) leads to:

$$\left[\int_{\mathscr{R}_1\cap\mathscr{R}_2}D_i(\epsilon)(\mathscr{F}_i(1-\mathscr{F}_i))(\epsilon)\left(\nabla\left(\frac{\epsilon_{F_i}}{T_i}\right)+\epsilon\nabla\left(-\frac{1}{T_i}\right)\right)\begin{pmatrix}1\\ \epsilon\end{pmatrix}d\epsilon\right]=0, \tag{VI.10}$$

$$\int_{\mathscr{R}_i\setminus\mathscr{R}_j}D_i(\epsilon)(\mathscr{F}_i(1-\mathscr{F}_i))(\epsilon)\left(\nabla\left(\frac{\epsilon_{F_i}}{T_i}\right)+\epsilon\nabla\left(-\frac{1}{T_i}\right)\right)\begin{pmatrix}1\\ \epsilon\end{pmatrix}d\epsilon=0,\quad i=1,2, \tag{VI.11}$$

where $\mathscr{F}_i := \mathscr{F}_{\epsilon_{F_i},T_i}$ and where, for a quantity A, we denote by $[A]$ its jump across the heterojunction: $[A_i] = A_2 - A_1$. But (VI.11) can be added to the corresponding term of (VI.10) to give the flux continuity condition [using (VI.6)–(VI.8)]:

$$j_{n_1} = j_{n_2} := j_n^{\text{int}}, \quad (j_{\mathscr{E}_{\text{tot}}})_1 = (j_{\mathscr{E}_{\text{tot}}})_2 := j_{\mathscr{E}_{\text{tot}}}^{\text{int}}. \tag{VI.12}$$

The first-order transmission conditions for the ET model at a heterojunction interface thus consist in (VI.9), (VI.12). Only the continuity of ϵ_F and j_n needs to be retained for the DD model. These conditions are classical for the DD model, and are derived or used by many authors (see, e.g., Ref. 13).

We now turn toward the second-order transmission condition (IV.39). Of course, the continuity of the fluxes (VI.12) remains unchanged in the second-order conditions. Now, taking the moments of (IV.39), we get:

$$\int_{\mathscr{R}_1 \cap \mathscr{R}_2} \frac{1}{\theta(\epsilon)} (F_2^\alpha - F_1^\alpha) \begin{pmatrix} 1 \\ \epsilon \end{pmatrix} d\epsilon = \alpha \int_{\mathscr{R}_1 \cap \mathscr{R}_2} J_\alpha^{\text{int}} \begin{pmatrix} 1 \\ \epsilon \end{pmatrix} d\epsilon. \tag{VI.13}$$

Inserting the Fermi–Dirac ansatz (VI.4) in the right-hand side of (VI.13) and using (VI.10)–(VI.12), we obtain:

$$\int_{\mathscr{R}_1 \cap \mathscr{R}_2} J_\alpha^{\text{int}} \begin{pmatrix} 1 \\ \epsilon \end{pmatrix} d\epsilon = \begin{pmatrix} j_n^{\text{int}} \\ j_{\mathscr{E}_{\text{tot}}}^{\text{int}} \end{pmatrix}. \tag{VI.14}$$

Now, the Fermi–Dirac ansatz (VI.4) and Taylor's formula lead to:

$$F_2^\alpha - F_1^\alpha = \mathscr{F}_{\epsilon_{F_2},T_2} - \mathscr{F}_{\epsilon_{F_1},T_1} = \mathscr{G}(\epsilon) \left(\left[\frac{\epsilon_F}{T} \right] + \epsilon \left[-\frac{1}{T} \right] \right), \tag{VI.15}$$

with

$$\mathscr{G}(\epsilon) = \int_0^1 \mathscr{F}_s(\epsilon)(1 - \mathscr{F}_s(\epsilon)) ds = \mathscr{G}(\epsilon; \epsilon_{F_1}, T_1, \epsilon_{F_2}, T_2),$$

$$\mathscr{F}_s(\epsilon) = \left(\exp\left((1-s) \frac{\epsilon - \epsilon_{F_1}}{T_1} + s \frac{\epsilon - \epsilon_{F_2}}{T_2} \right) + 1 \right)^{-1},$$

$$\left[\frac{\epsilon_F}{T} \right] = \frac{\epsilon_{F_2}}{T_2} - \frac{\epsilon_{F_1}}{T_1}, \quad \left[-\frac{1}{T} \right] = -\left(\frac{1}{T_2} - \frac{1}{T_1} \right).$$

Inserting (VI.15) into the left-hand side of (VI.13), we are led to

$$\int_{\mathscr{R}_1 \cap \mathscr{R}_2} \frac{1}{\theta(\epsilon)} (F_2^\alpha - F_1^\alpha) \begin{pmatrix} 1 \\ \epsilon \end{pmatrix} d\epsilon = \Lambda \begin{pmatrix} \left[\frac{\epsilon_F}{T} \right] \\ \left[-\frac{1}{T} \right] \end{pmatrix}, \tag{VI.16}$$

where $\Lambda = (\Lambda_{ij})_{i=1,2;j=1,2} = \Lambda(\epsilon_{F_1}, T_1, \epsilon_{F_2}, T_2)$ is the 2×2 matrix given by:

$$\Lambda_{k\ell} = \int_{\mathscr{R}_1 \cap \mathscr{R}_2} \frac{1}{\theta(\epsilon)} \mathscr{G}(\epsilon) \epsilon^{k+\ell-2} d\epsilon, \quad k = 1,2; \ell = 1,2. \tag{VI.17}$$

Following (VI.13), equating (VI.16) and (VI.14) leads to the following transmission condition for the ET model:

$$\Lambda(\epsilon_{F_1}, T_1, \epsilon_{F_2}, T_2)\begin{pmatrix} \left[\dfrac{\epsilon_F}{T}\right] \\ \left[-\dfrac{1}{T}\right] \end{pmatrix} = \alpha \begin{pmatrix} j_n^{\text{int}} \\ j_{\mathscr{E}_{\text{tot}}}^{\text{int}} \end{pmatrix}. \tag{VI.18}$$

For Λ to be finite, we need $1/\theta(\epsilon)$ to be integrable. This is an additional requirement to be imposed on the reflection-transmission operators R_i, $T_{i\to j}$. This requirement is satisfied for classical reflection-transmission across a plane interface (V.30), see the last discussion of example 1, Sec. V. When θ^{-1} is integrable, it is an easy matter to check that Λ is a symmetric positive-definite matrix.

Therefore, second-order transmission conditions for the ET model consist of the flux continuity conditions (VI.12), and the jump conditions (VI.18). The symmetry and positive definiteness of Λ is a sufficient condition for formal well-posedness of the problem, as can be viewed from an easy extension of Lemma IV.6 to vector valued functions (left to the reader). Second-order transmission conditions for the DD model are simply obtained by taking the first condition (VI.12) and the first component of (VI.18), (with $[-1/T]=0$). At the level of the DD model, interface conditions of this form have been considered in Ref. 18. There the computation of Λ_{11} corresponds to using the crude approximation $\theta_2^+ - \theta_1^+$ from (V.21) for the value of θ.

Clearly, at equilibrium, when the currents j_n^{int} and $j_{\mathscr{E}_{\text{tot}}}^{\text{int}}$ are zero, condition (VI.18) reduces to the continuity of the Fermi energy and temperature (VI.9). In spite of their apparent complexity, the second-order transmission conditions can easily be implemented in the framework of finite element codes or box method codes by means of weak formulations. This point will be developed in future work.

(Received 8 May 1998; accepted for publication 18 May 1998)

Using successive approximations, we derive a hierarchical set of integro-differential equations for the evolution of the statistical moments of a wave propagating through non-Gaussian longitudinally correlated media. A closure procedure in the spirit of the Ornstein–Uhlenbeck process produces the most general set of equations currently available. The procedure can be applied to a large class of Cauchy problems in mathematical physics. © *1998 American Institute of Physics.* [S0022-2488(98)02509-2]

I. INTRODUCTION

This paper extends previous formulations[1–4] of classical wave propagation through random media to account for the evolution of statistical moments of a wave propagating through longitudinally correlated non-Gaussian medium. Mathematically, this problem is described by a stochastic Schrödinger equation whose potential is the random refractivity. Therefore, we look for equations that govern the evolution of the statistical moments of the wave fields. Our formulation addresses the closure problem of an infinite hierarchy of coupled equations. Thus, it shares common features with other branches of mathematical physics, e.g., the Schrödinger wave equation with random potentials,[5] the Bogoliobov–Born–Green–Kirkwood–Yvon (BBGKY) hierarchy in statistical physics,[6] and the hierarchical set of equations due to Keller and Friedmann in statistical turbulence theory.[7]

The motivation for this problem emerged from laser-propagation experiments through the atmosphere, where the random refractivity due to the turbulent temperature and humidity induce fluctuations on the light waves. When dealing with turbulence, the notion of intermittency is necessarily introduced. The intermittency is a type of nonstationarity of the turbulence due to bursts of thermal plumes. These waveforms often have a ramplike shape on which the small-scale random process is superimposed (e.g., Refs. 8 and 9). Actually, except for the scales, there is no distinction between the small and the large processes; they are part of the complete turbulent process. Thus, the turbulent process is admittedly non-Gaussian, and additionally large-scale boundary effects, e.g., orography, introduce a large-scale correlation along the propagation path. To obtain stable results, averaging over the intermittency is a must. However, one may speculate that it is possible to measure the intermittency of turbulence using laser scintillometry, and, for this, excessive averaging is detrimental.

Although its motivation came from atmospheric optics and from turbulence theory, nonstationary statistics is of great concern to all theories that intend to interpret an experiment. One remedy that is often used is applying a conditional sampling. Here, the experiment is used to examine a theory, which is partial, but otherwise well defined. A second remedy is to randomize the locally well-established partial theory. This can lead to flexibility in interpreting experiments by introducing more parameters. We caution, however, that unless the physical model of the large-scale variability is well understood, this procedure can lead to superfluous flexibility and incorrect interpretations.

In the case of wave propagation, the nonstationarity along the path introduces a longitudinal correlation that prevents the closing of the differential equations, thus path integrals must be used.[10] Additionally, the departure from the Gaussian model means that the tail of the distribution

[a)]Electronic mail: gozani@colorado.edu

has a non-negligible effect, and a second-order description of the medium does not apply.[11] In both cases, the current theory is too limited to be practically useful.[12] The present paper addresses both deviations from the regular random process.

We note that whereas, conceptually, our procedure is simple, the complexity due to dimensionality and hierarchy is quite large. We could handle the excessive bookkeeping only by using multi-index notation, where we treated arrays symbolically as if they were scalars. Eventually, we can close the hierarchy at any level we like and choose a manageable difficulty. Completing the formulation would require a proof of convergence that currently we do not have. We content ourselves by noting that many elements of this procedure were already proven correct in previous studies. Finally, we introduce preparatory steps that seem to be required for a proof of convergence.

The paper is based on four prior journal articles that handled only one aspect of the problem we solve. The formulation is rather complicated; therefore, we summarize their contributions and relationship to the present formulation. Reference 1 obtained the hierarchical statistical moment equations for a Gaussian longitudinally-correlated medium. Reference 2 proved the convergence of this hierarchy as the order of the hierarchy is increased. Reference 3 obtained the statistical closure for a non-Gaussian δ-correlated medium; in this case, no hierarchy was involved and the results can be derived by other methods. Reference 4 suggested an asymptotic expansion based on the hierarchy for a non-Gaussian medium with the inner scale of turbulence as a small parameter. This is its closure assumption, but note that the asymptotic expansion was applied to the entire hierarchy of integro-differential equations.

The present paper extends Refs. 1–3 to account for the evolution of statistical moments of wave propagating through longitudinally correlated non-Gaussian medium. It is different from Ref. 4 in two major respects: (a) the formulation in nonasymptotic, and (b) it uses the δ-correlated model as a closure assumption only for the highest-order equation. The latter model is given a meaning by an asymptotic expansion of the integral term of the integro-differential equation. One may note that our equations are in the configuration domain, whereas Ref. 4 provides a partial Laplace transform on the timelike variable. This is, of course, only a minor difference that depended on the goal of the analysis.

Let us portray the plan of the paper. Section II is the main thrust of the paper. It defines the mathematical problem and provides all the necessary steps of the derivation toward a statistical closure. It also gives a simple example that helps to clarify how to use the method. In Sec. III we suggest an approximation of the δ-correlated process that is meaningful in the context of this closure. In Sec. IV we discuss extensions of the present closure for the sake of proving convergence to the genuine solution. Finally, in Sec. V we summarize the paper and suggest future directions.

II. MATHEMATICAL FORMULATION

A. Definitions

We begin with the well-established Schrödinger-type equation (e.g., Ref. 13):

$$[2ik\partial_z+\boldsymbol{\Delta}_{\mathbf{x}}-\boldsymbol{\Delta}_{\mathbf{y}}+k^2\nu(z,\mathbf{x},\mathbf{y})]\,\gamma(z,\mathbf{x},\mathbf{y})=0, \tag{1}$$

$$\gamma(z=0,\mathbf{x},\mathbf{y})=\gamma_0(\mathbf{x},\mathbf{y})\in L_2(\mathbb{R}^{2(N+M)}),\quad \mathbf{x}\in\mathbb{R}^{2N},\quad \mathbf{y}\in\mathbb{R}^{2M}. \tag{2}$$

This equation describes the stochastic evolution of the product of multiple scalar fields:

$$\gamma(z,\mathbf{x},\mathbf{y})=\prod_{n=1}^{N}\psi(z,x_n)\prod_{m=1}^{M}\psi^*(z,y_n) \tag{3}$$

scattered forward under the narrow-angle approximation. Here $\psi(z,x_n)$ is the complex field envelope, the symbol* denotes complex conjugation, z is the propagation range, $x_n\in\mathbb{R}^2$ and $y_m\in\mathbb{R}^2$ are two-dimensional position vectors transverse to the propagation direction, and k is the reference wave number. In (1) and (2), $\mathbf{x}\equiv(x_1,\ldots,x_N)$ and $\mathbf{y}\equiv(y_1,\ldots,y_M)$ are multi-vectors and $\boldsymbol{\Delta}_{\mathbf{v}}\equiv(\Delta_1+\cdots+\Delta_s)$ is a multi-Laplacian operator with $\mathbf{v}=\mathbf{x}$ or $\mathbf{v}=\mathbf{y}$ and $s=N$ or $s=M$, respectively.

Equations (1) and (2) comprise a Cauchy problem. The timelike variable $z \in [0, Z]$ denotes the propagation range. The spacelike variables are $\mathbf{x}$ and $\mathbf{y}$. Solutions of this equation are well posed in $L([0, Z], H)$, where $H = L_2[\mathbb{R}^{2(N+M)}]$, a separable complex Hilbert space.

The last term in (1), $\nu(z,\mathbf{x},\mathbf{y})$, is the *random scattering potential* that accounts for parametric fluctuations defined over an appropriate probability space. It is defined as

$$\nu(z,\mathbf{x},\mathbf{y}) = \sum_{n=1}^{N} \mu(z,x_n) - \sum_{m=1}^{M} \mu(z,y_m) = \int d^2x' \ \alpha(x')\mu(z,x'), \tag{4}$$

where

$$\alpha(x') = \sum_{n=1}^{N} \delta(x'-x_n) - \sum_{m=1}^{M} \delta(x'-y_m), \tag{5}$$

and $\mu(z,x)$ is a random electric susceptibility. A stochastic process is fully characterized by the *characteristic functional*

$$\Phi_\mu[\omega] \equiv \left\langle \exp\left[i \int dz' \int dx' \ \omega(z',x')\mu(z',x') \right] \right\rangle, \tag{6}$$

and the *cumulant-generating functional* $\Theta_\mu[\omega] \equiv \ln \Phi_\mu[\omega]$. In (6), $\langle \cdot \rangle$ denotes an ensemble average. Here, the subscript μ identifies the process. However, whereas all our derivations could be worked out with $\mu(z,x)$ leading to lengthy expressions, we prefer to formulate all in terms of $\nu(z,\mathbf{x},\mathbf{y})$ that produces shorter, albeit equivalent, expressions. Therefore, we will subsequently omit the subscript of the characteristic functionals that identify the random process, in an understanding it means Φ_ν and Θ_ν.

The characteristic functional of $\nu(z,\mathbf{x},\mathbf{y})$ reads

$$\begin{aligned}\Phi_z[w(z,\mathbf{x},\mathbf{y})] &\equiv \left\langle \exp\left[i \int_0^z dz' \int d\mathbf{x}' \ d\mathbf{y}' \ w(z',\mathbf{x}',\mathbf{y}')\nu(z',\mathbf{x}',\mathbf{y}') \right] \right\rangle \\ &\equiv \exp\{\Theta_z[w(z,\mathbf{x},\mathbf{y})]\} = \exp\left[\sum_{m=1}^{\infty} \frac{1}{m!} \int_0^z dz_1' \int d\mathbf{x}_1' \ d\mathbf{y}_1' \cdots \int_0^z dz_m' \int d\mathbf{x}_m' \ d\mathbf{y}_m' \right. \\ &\quad \left. \times K_\nu^{(m)}(z_1',\ldots,z_m';\mathbf{x}_m',\mathbf{y}_m',\ldots,\mathbf{x}_m',\mathbf{y}_m') w(z_1',\mathbf{x}_1',\mathbf{y}_1') \cdots w(z_m',\mathbf{x}_m',\mathbf{y}_m') \right],\end{aligned} \tag{7}$$

where

$$K_\nu^{(m)}(z_1,\ldots,z_m;\mathbf{x}_1,\mathbf{y}_1,\ldots,\mathbf{x}_m,\mathbf{y}_m) = \langle \nu(z_1,\mathbf{x}_1,\mathbf{y}_1) \cdots \nu(z_m,\mathbf{x}_m,\mathbf{y}_m) \rangle_c \tag{8}$$

are the cumulants (semi-invariants) of order m, with $\langle \cdot \rangle_c$ denoting the cumulant average. In (7), the subscript z of Φ_z and Θ_z signifies dependency on z through the upper limit of the integral as the process is limited to $[0, z]$. From (7),

$$K_\nu^{(m)}(z_1,\ldots,z_m;\mathbf{x}_1,\mathbf{y}_1,\ldots,\mathbf{x}_m,\mathbf{y}_m) \equiv \left. \frac{\delta^m \Theta_z[w(z',\mathbf{x}',\mathbf{y}')]}{\delta w(z_1',\mathbf{x}_1',\mathbf{y}_1') \cdots \delta w(z_m',\mathbf{x}_m',\mathbf{x}_m',\mathbf{y}_m')} \right|_{[w]=0}. \tag{9}$$

For quasi-homogeneity in z, the cumulants of $\nu(z,\mathbf{x},\mathbf{y})$ assume the form

$$\langle \nu(z_1,\mathbf{x}_1,\mathbf{y}_1) \cdots \nu(z_m,\mathbf{x}_m,\mathbf{y}_m) \rangle_c = K_\nu^{(m)}(z_1, z_2 - z_1, \ldots, z_n - z_1; \mathbf{x}_1,\mathbf{y}_1,\ldots,\mathbf{x}_m,\mathbf{y}_m), \tag{10}$$

with a peak dependency of the differences. In this case, the dependency on z_1 expresses the large-scale variability along the path.

Subsequently, we denote $\mathbf{r} = (\mathbf{x},\mathbf{y}) \in \mathbb{R}^{2(N+M)}$, where $\mathbf{r}$ is an array of $(N+M)$ two-dimensional transverse position vectors. Similarly, $\gamma(z,\mathbf{r}) \equiv \gamma(z,\mathbf{x},\mathbf{y})$, $\nu(z,\mathbf{r}) \equiv \nu(z,\mathbf{x},\mathbf{y})$, $w(z,\mathbf{r}) \equiv w(z,\mathbf{x},\mathbf{y})$, and $\mathscr{L}_\mathbf{r} \equiv \boldsymbol{\Delta}_\mathbf{x} - \boldsymbol{\Delta}_\mathbf{y}$ is an ultrahyperbolic operator. This notation simplifies the descrip-

tion because most of the analysis is done with respect to the timelike variable, z, and not with respect to the spacelike variables $\mathbf{x}$ and $\mathbf{y}$. Finally we note that our derivation has a broader context than atmospheric optics, because it applies as well to a Cauchy problem with a more general linear, although deterministic operator $\mathscr{L}_{\mathbf{r}}$.

For the sake of brevity, we define additional multi-vectors. Let ${}^m\boldsymbol{\rho}$ and ${}^m\mathbf{r}$ be $1\times m$ arrays of spacelike multi-vectors describing the cluster of points on the plane transverse to the propagation direction:

$$\begin{gathered} {}^m\boldsymbol{\rho}\equiv(\mathbf{r}_1,\ldots,\mathbf{r}_m), \quad \mathbf{r}_s=(\mathbf{x}_s,\mathbf{y}_s), \quad s=1,\ldots,m, \\ {}^m\mathbf{r}\equiv(\mathbf{r}_1,\ldots,\mathbf{r}_m), \quad \mathbf{r}_1=\mathbf{r}_2=\cdots=\mathbf{r}_m=\mathbf{r}. \end{gathered} \tag{11}$$

Similarly, the timelike $1\times m$ vectors are

$$\begin{gathered} {}^m\boldsymbol{\tau}\equiv(z_1,\ldots,z_m), \\ {}^m\mathbf{z}\equiv(z_1,\ldots,z_m), \quad z_1=z_2=\cdots=z_m=z, \\ {}^m\mathbf{0}\equiv(z_1,\ldots,z_m), \quad z_1=z_2=\cdots=z_m=0, \\ \pm{}^m\boldsymbol{\infty}\equiv(z_1,\ldots,z_m), \quad z_1\to\pm\infty, \quad z_2\to\pm\infty,\ldots, \quad z_m\to\pm\infty. \end{gathered} \tag{12}$$

The left-superscript m is required constantly because multi-vectors of different lengths are used in the same expressions. Finally, we define a multi-index variational derivative

$$\mathbf{D}^n({}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})=\frac{\delta^n}{\delta\nu(z_1,\mathbf{r}_1)\cdots\delta\nu(z_n,\mathbf{r}_n)}. \tag{13}$$

B. Derivation

First we average (1) and (2):

$$[2ik\partial_z+\mathscr{L}_{\mathbf{r}}]\langle\gamma(z,\mathbf{r})\rangle=-k^2\langle\nu(z,\mathbf{r})\gamma(z,\mathbf{r})\rangle, \tag{14}$$

$$\langle\gamma(z=0,\mathbf{r})\rangle=\gamma_0(\mathbf{r}). \tag{15}$$

The term on the right-hand side of (14) is yet statistically unclosed. Contrary to the tractable situation when a δ-correlated process or a Gaussian process is assumed, the term $\langle\nu(z,\mathbf{r})\gamma[\nu(\cdot)]\rangle$ cannot be closed in an exact form, hence a purely partial differential equation is unavailable. On the other hand, it is possible to obtain a set of integro-differential equations by successive approximations. To close this average, we use the expansion derived by Klyatskin[14] using operators with variational derivatives,

$$\begin{aligned} \langle\nu(z,\mathbf{r})\gamma[\nu(\cdot)]\rangle &\equiv\left\langle\frac{1}{i(\delta/i\,\delta\nu(z',\mathbf{r}'))}\,\frac{\partial}{\partial z}\,\Theta_z\left[\frac{\delta}{i\,\delta\nu(z',\mathbf{r}')}\right]\gamma[\nu(\cdot)]\right\rangle \\ &=\sum_{m=0}^{\infty}\frac{1}{m!}\int_{{}^m\mathbf{0}}^{{}^m\mathbf{z}}d^m\boldsymbol{\tau}'\int d^m\boldsymbol{\rho}'\,K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')\left\langle\frac{\delta^m\gamma(z,\mathbf{r})}{\delta\nu(z_1',\mathbf{r}_1')\cdots\delta\nu(z_m',\mathbf{r}_m')}\right\rangle, \end{aligned} \tag{16}$$

where

$$K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau},{}^m\boldsymbol{\rho})=\langle\nu(z,\mathbf{r})\nu(z_1,\mathbf{r}_1)\cdots\nu(z_m,\mathbf{r}_m)\rangle_c. \tag{17}$$

In (16), $\delta/\delta\nu(z_m,\mathbf{r}_m)$, $m\in\mathbb{N}$, denotes a variational derivative, where $\delta\nu(z_n,\mathbf{r}_n)$ is a surface differing from zero only in the vicinity of $(z_m,\mathbf{r}_m)\in([0,z],\mathbb{R}^{2(N+M)})$. The index $m=0$ means that no integration is involved on the right-hand side of (16), and, therefore, there in no need for multi-vectors for this term.

Let us take the nth variational derivative of (1) and average the result. Upon applying the variational derivatives as indicated in (16) for $z_1,\ldots,z_n<z$, we find that $\langle \mathbf{D}^n({}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle$ follows an integro-differential equation similar to (14), i.e.,

$$[2ik\partial_z+\mathscr{L}_{\mathbf{r}}]\langle \mathbf{D}^n({}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle=-k^2\sum_{m=0}^{\infty}\frac{1}{m!}\int_{m_0}^{m\mathbf{z}}d^m\boldsymbol{\tau}'\int d^m\boldsymbol{\rho}'\,K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')\times\langle \mathbf{D}^{m+n}({}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}',{}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle, \tag{18}$$

where

$$\begin{aligned}\mathbf{D}^{m+n}({}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}',{}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})&\equiv\mathbf{D}^m({}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')\mathbf{D}^n({}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\\&=\mathbf{D}^{m+n}(({}^n\boldsymbol{\tau},{}^m\boldsymbol{\tau}'),({}^n\boldsymbol{\rho},{}^m\boldsymbol{\rho}'))\\&=\mathbf{D}^{m+n}({}^{m+n}\boldsymbol{\tau},{}^{m+n}\boldsymbol{\rho}).\end{aligned} \tag{19}$$

Note that in (18), $\mathbf{D}^n({}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})(\nu(z,\mathbf{r})\,\gamma(z,\mathbf{r}))$ produces terms that contain

$$\frac{\delta\nu(z,\mathbf{r})}{\delta\nu(z_n,\mathbf{r}_n)}=\delta(\mathbf{r}-\mathbf{r}_n)\,\delta(z-z_n)=0,\quad z_n<z, \tag{20}$$

hence are dropped.

We seek the related initial conditions for this hierarchical set. The initial condition for $\langle\gamma\rangle$ at $z=0$ is γ_0, which is deterministic. The initial condition for $\langle \mathbf{D}^n({}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle$ is found using the integro-differential equation:

$$2ik\gamma(z,\mathbf{r})=2ik\gamma_0(\mathbf{r})-\int_0^z dz'\;\mathscr{L}_{\mathbf{r}}\gamma(z',\mathbf{r})-k^2\int_0^z dz'\;\nu(z',\mathbf{r})\,\gamma(z',\mathbf{r}). \tag{21}$$

Applying $\delta/\delta\nu(z_1,\mathbf{r}_1)$ for $z_1<z$ we obtain

$$\begin{aligned}2ik\,\frac{\delta\gamma(z,\mathbf{r})}{\delta\nu(z_1,\mathbf{r}_1)}&=-\int_{z_1}^z dz'\;\mathscr{L}_{\mathbf{r}}\,\frac{\gamma(z',\mathbf{r})}{\delta\nu(z_1,\mathbf{r}_1)}\\&\quad-k^2\int_{z_1}^z dz'\,\nu(z',\mathbf{r})\,\frac{\gamma(z',\mathbf{r})}{\delta\nu(z_1,\mathbf{r}_1)}-k^2\,\delta(\mathbf{r}-\mathbf{r}_1)\,\delta(z-z_1)\,\gamma(z_1,\mathbf{r}_1).\end{aligned} \tag{22}$$

Because causality implies that $\delta/\delta\nu(z_1,\mathbf{r}_1)\equiv 0$ for $z_1>z$, we seek a boundary condition for $z_1\uparrow z$. In this limit we obtain

$$\frac{\delta\gamma(z,\mathbf{r})}{\delta\nu(z_1,\mathbf{r}_1)}=i\,\frac{k}{2}\,\delta(\mathbf{r}-\mathbf{r}_1)\,\gamma(z_1,\mathbf{r}_1). \tag{23}$$

Averaging (23) we obtain the initial condition for the first derivative

$$\left\langle\frac{\delta\gamma(z,\mathbf{r})}{\delta\nu(z_1,\mathbf{r}_1)}\right\rangle=i\,\frac{k}{2}\,\delta(\mathbf{r}-\mathbf{r}_1)\langle\gamma(z_1,\mathbf{r}_1)\rangle, \tag{24}$$

which is shown to depend on a lower element of the hierarchy. We use (23) to get the initial condition for higher elements by applying the variational derivative successively and averaging:

$$\begin{aligned}\langle \mathbf{D}^m({}^m\boldsymbol{\tau},{}^m\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle&\equiv\langle \mathbf{D}^m(z_1,\mathbf{r}_1;\ldots;z_m,\mathbf{r}_m)\,\gamma(z,\mathbf{r})\rangle\\&=i\,\frac{k}{2}\,\delta(\mathbf{r}-\mathbf{r}_m)\langle \mathbf{D}^{m-1}({}^{m-1}\boldsymbol{\tau},{}^{m-1}\boldsymbol{\rho})\,\gamma(z,\mathbf{r}_m)\rangle,\end{aligned} \tag{25}$$

where $0\leqslant z_m\leqslant\cdots\leqslant z_2\leqslant z_1\leqslant z$.

C. δ-correlation closure

A δ-correlated process with respect only to z at the hierarchy-order $m=M$ immediately closes the hierarchical set. In this case, all the cumulants are δ-correlated in z, i.e.,

$$K_{\nu}^{(m)}({}^{m}\boldsymbol{\tau},{}^{m}\boldsymbol{\rho})=K_{\mathrm{eff}}^{(m)}(z,{}^{m}\boldsymbol{\rho})\,\delta(z_1-z_2)\cdots\delta(z_{m-1}-z_m). \tag{26}$$

The cumulant-generating functional in this case assumes the form

$$\begin{aligned}\Theta_z^{\mathrm{eff}}[w(z,\mathbf{r})]&=\sum_{m=1}^{\infty}\frac{i^m}{m!}\int_{-{}^{m}\boldsymbol{\infty}}^{{}^{m}\boldsymbol{\infty}}d^m\boldsymbol{\tau}'\int d^m\boldsymbol{\rho}'K_{\nu}^{(m)}({}^{m}\boldsymbol{\tau}',{}^{m}\boldsymbol{\rho})w(z_1',\mathbf{r}_1')\cdots w(z_m',\mathbf{r}_m')\\&\quad\times\theta(z_1)\cdots\theta(z_m)\,\theta(z-z_1)\cdots\theta(z-z_m)\\&=\sum_{m=1}^{\infty}\frac{i^m}{m!}\int_0^z dz'\int d^m\boldsymbol{\rho}'K_{\mathrm{eff}}^{(m)}(z',{}^{m}\boldsymbol{\rho}')w(z',\mathbf{r}_1')\cdots w(z',\mathbf{r}_m'),\end{aligned} \tag{27}$$

where $\pm{}^{m}\boldsymbol{\infty}$ is defined in (12), and we used the step function defined as $\theta(z<0)\equiv 0;\ \theta(z\geqslant 0)\equiv 1$.

In the case of the δ-correlated process, the closure formula admits a jump discontinuity as $\langle\nu(z'\to z,\mathbf{r})\,\gamma[\,\cdot\,]\rangle$. The result is[14]

$$\begin{aligned}\langle\nu(z,\mathbf{r})\,\gamma[\,\nu(\cdot)\,]\rangle&\equiv\left\langle\frac{1}{i(\delta/i\,\delta\nu_z(\mathbf{r}))}\,\frac{\partial}{\partial z}\,\Theta_z^{\mathrm{eff}}\left[\frac{\delta}{i\,\delta\nu_z(\mathbf{r})}\right]\gamma[\,\nu(\cdot)\,]\right\rangle\\&=\sum_{m=0}^{\infty}\frac{1}{(m+1)!}\int d^m\boldsymbol{\rho}'K_{\mathrm{eff}}^{(m+1)}(z,\mathbf{r};{}^{m}\boldsymbol{\rho}')\langle\mathbf{D}^m({}^{m}\mathbf{z},{}^{m}\boldsymbol{\rho}')\,\gamma(z,\mathbf{r})\rangle,\end{aligned} \tag{28}$$

where

$$\mathbf{D}^m({}^{m}\mathbf{z},{}^{m}\boldsymbol{\rho}')\,\gamma(z,\mathbf{r})\equiv\frac{\delta^m\gamma(z,\mathbf{r})}{\delta\nu_z(\mathbf{r}_1')\cdots\delta\nu_z(\mathbf{r}_m')}, \tag{29}$$

and we note that in (29), $\delta/\delta\nu_z(\mathbf{r}_n')$, $n\in\mathbb{N}$, means a *partial variational derivative* with a fixed z plane, i.e., $\delta\nu_z(\mathbf{r}_n')$ is a surface differing from zero only in the vicinity of $\mathbf{r}_n'\in\mathbb{R}^{2(N+M)}$.

Thus, the equation of the Mth-order successive approximation reads

$$\begin{aligned}[2ik\partial_z+\mathscr{L}_{\mathbf{r}}]\langle\mathbf{D}^M({}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle&=-k^2\sum_{m=0}^{\infty}\frac{1}{(m+1)!}\left(i\,\frac{k}{2}\right)^m\int d^m\boldsymbol{\rho}'\;K_{\mathrm{eff}}^{(m+1)}(z,\mathbf{r};{}^{m}\boldsymbol{\rho}')\\&\quad\times\langle\mathbf{D}^{m+M}({}^{m}\mathbf{z},{}^{m}\boldsymbol{\rho}',{}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle.\end{aligned} \tag{30}$$

Now we have to find $\langle\mathbf{D}^{m+M}({}^{m}\mathbf{z},{}^{m}\boldsymbol{\rho}',{}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle$. Using (23) and letting ${}^{m}\boldsymbol{\tau}\uparrow{}^{m}\mathbf{z}$, we obtain

$$\langle\mathbf{D}^{m+M}({}^{m}\mathbf{z},{}^{m}\boldsymbol{\rho}',{}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle=\left(i\,\frac{k}{2}\right)^m\delta({}^{m}\mathbf{r}-{}^{m}\boldsymbol{\rho}')\langle\mathbf{D}^M({}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle. \tag{31}$$

Because $\langle\mathbf{D}^M({}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle$ is known from the initial condition, we obtain

$$\begin{aligned}[2ik\partial_z+\mathscr{L}_{\mathbf{r}}]\langle\mathbf{D}^M({}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle&=-k^2\sum_{m=0}^{\infty}\frac{1}{(m+1)!}\left(i\,\frac{k}{2}\right)^m K_{\mathrm{eff}}^{(m+1)}(z,\mathbf{r};{}^{m}\mathbf{r})\\&\quad\times\langle\mathbf{D}^M({}^{M}\boldsymbol{\tau},{}^{M}\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle,\end{aligned} \tag{32}$$

where the integral over ${}^{m}\boldsymbol{\rho}'$ collapsed because of the $\delta({}^{m}\mathbf{r}-{}^{m}\boldsymbol{\rho}')$ in (31). In (32), the functional

$$\sum_{m=0}^{\infty} \frac{i^m}{(m+1)!} K_{\rm eff}^{(m+1)}(z,\mathbf{r};{}^m\mathbf{r})\beta^m(z)\Big|_{\beta(z)=k/2} = \frac{1}{i\beta(z)}\,\partial_z \ln \Phi_z^{\rm eff}[\beta(z')\delta(\mathbf{r}-\mathbf{r}')]\Big|_{\beta(z')=k/2}$$

$$\equiv \frac{1}{i\beta(z)}\,\partial_z \Theta_z^{\rm eff}[\beta(z')\delta(\mathbf{r}-\mathbf{r}')]\Big|_{\beta(z')=k/2}. \quad (33)$$

Here we remind the reader that for $w(z',\mathbf{r}')=\beta(z')\delta(\mathbf{r}-\mathbf{r}')$, the characteristic functionals of a process that is δ-correlated in z read

$$\Phi_z^{\rm eff}[\beta(z')\delta(\mathbf{r}-\mathbf{r}')] \equiv \left\langle \exp\left[i\int_0^z dz'\ \nu(z',\mathbf{r})\beta(z')\right]\right\rangle$$

$$\Theta_z^{\rm eff}[\beta(z')\delta(\mathbf{r}-\mathbf{r}')] \equiv \sum_{m=1}^{\infty}\ \frac{i^m}{m!}\ \int_0^z dz'\ K_{\rm eff}^{(m)}(z';{}^m\mathbf{r})\beta^m(z'). \quad (34)$$

Note that because $\beta(z)=k/2$ is a constant,

$$\frac{\delta}{i\,\delta\beta(z)} = \frac{1}{i\beta(z)}\,\partial_z = -i\,\frac{2}{k}\,\partial_z. \quad (35)$$

Accordingly, the effective cumulants are obtained from

$$K_{\rm eff}^{(m)}(z;{}^m\mathbf{r}) = \frac{\delta^m \Theta_z^{\rm eff}[\beta(z')\delta(\mathbf{r}-\mathbf{r}')]}{\delta\beta(z_1)\cdots\delta\beta(z_m)}\Big|_{\beta(z)=k/2} = \left(-i\,\frac{2}{k}\right)^m \partial_z^m \Theta_z^{\rm eff}\left[\frac{k}{2}\,\delta(\mathbf{r}-\mathbf{r}')\right], \quad (36)$$

where ∂_z^m operates only on the limits of the integral in (34).

Thus, we finally obtain a set of M equations, $M-1$ of which are in (18) with a boundary condition in (25), and the Mth equation is

$$[2ik\partial_z + \mathscr{L}_{\mathbf{r}}]\langle \mathbf{D}^M({}^M\boldsymbol{\tau},{}^M\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle = \partial_z \Theta_z^{\rm eff}\left[\frac{k}{2}\,\delta(\mathbf{r}-\mathbf{r}')\right]\langle \mathbf{D}^M({}^M\boldsymbol{\tau},{}^M\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle, \quad (37)$$

with the boundary condition

$$\langle \mathbf{D}^M({}^M\boldsymbol{\tau},{}^M\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle = i\,\frac{k}{2}\,\delta(\mathbf{r}-\mathbf{r}_1)\langle \mathbf{D}^{M-1}({}^{M-1}\boldsymbol{\tau},{}^{M-1}\boldsymbol{\rho})\,\gamma(z,\mathbf{r}_1)\rangle. \quad (38)$$

By truncating the order of the hierarchy at $m=M$, we also determine the number of cumulants involved in the approximation. Thus, although we do not need to approximate $\Theta_z^{\rm eff}$ in (37), we can decide upon its truncation order, i.e., $m=M$ according to the accuracy in comparison with $\Theta_z^{\rm eff}$. A schematic array, where the cumulants involved are truncated at $M=4$, is

$$\begin{bmatrix} K^{(1)} & K^{(2)} & K^{(3)} & K^{(4)} & \searrow_0 \\ K^{(1)} & K^{(2)} & K^{(3)} & \searrow_0 & \searrow_0 \\ K^{(1)} & K^{(2)} & \searrow_0 & \searrow_0 & \searrow_0 \\ K_{\rm eff}^{(1)} & K_{\rm eff}^{(2)} & K_{\rm eff}^{(3)} & K_{\rm eff}^{(4)} & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix}. \quad (39)$$

In (39), the rows represent the order of the hierarchy, the $\{\searrow_0\}$ indicates discarded cumulants and the ellipsis a continuation of a possibly truncated $\Theta_z^{\rm eff}$ of the δ-correlated process indicated by the effective cumulants defined in (36). The vertical dots beyond $M=4$ indicate that the governing equations are the same and, hence, can be ignored.

A truncation of $M=1$ leads readily to the moment equations for a non-Gaussian δ-correlated medium determined already by Klyatskin.[3,14]

D. Example

To exemplify the procedure and bring down to earth the multi-dimensional multi-vector notations let us analyze a simple example. We discard the operator $\mathscr{S}_{\mathbf{r}}$ because it does not alter the principle steps of the procedure and simplifies the explanation considerably. Consider the ordinary differential equation

$$\begin{aligned} &\frac{d\psi(z)}{dz} = i\,\frac{k}{2}\,\mu(z)\psi(z), \\ &\psi(0) = \psi_0, \quad 0 \leqslant z \leqslant Z. \end{aligned} \tag{40}$$

In (40), the medium is represented by $\mu(z)$, which is a zero-mean stationary non-Gaussian process. We would like to obtain an approximate closed set of integro-differential equations for its average $\langle\psi\rangle$, taking into account a finite correlation length. A zero-mean process has a vanishing first cumulant, i.e., $K^{(1)}(z)\equiv 0$. Additionally stationarity means that the cumulants $K^{(m+1)}(z,\tau_1',\ldots,\tau_m') = K^{(m+1)}(z-\tau_1',\ldots,z-\tau_m')$, and that $\partial_z K_{\text{eff}}^{(m)}(z)=0$, $\forall m$. Denoting the effective cumulants by the constants $\kappa_m \equiv K_{\text{eff}}^{(m)}$ we present the effective characteristic functional as

$$\Phi_z^{\text{eff}}\left[\frac{k}{2}\right] = \exp\left[z\sum_{m=1}^{\infty}\frac{1}{m!}\left(\frac{ik}{2}\right)^m \kappa_m\right] \equiv \exp\left(z\,\frac{d}{dz}\,\Theta_z^{\text{eff}}\left[\frac{k}{2}\right]\right). \tag{41}$$

Let us choose a truncation order of $M=3$ that leads to a hierarchy of three equations. The first equation reads

$$\begin{aligned} \frac{d\langle\psi(z)\rangle}{dz} &= i\,\frac{k}{2}\int_0^z d\tau_1\, K^{(2)}(z-\tau_1)\left\langle\frac{\delta\psi(z)}{\delta\mu(\tau_1)}\right\rangle \\ &\quad + i\,\frac{k}{2}\,\frac{1}{2!}\int_0^z d\tau_1\int_0^z d\tau_2\, K^{(3)}(z-\tau_1,z-\tau_2)\left\langle\frac{\delta^2\psi(z)}{\delta\mu(\tau_1)\delta\mu(\tau_2)}\right\rangle, \end{aligned} \tag{42}$$

subject to the initial condition

$$\langle\psi(0)\rangle = \psi_0. \tag{43}$$

The second equation reads

$$\frac{d}{dz}\left\langle\frac{\delta\psi(z)}{\delta\mu(\tau_1)}\right\rangle = i\,\frac{k}{2}\int_0^z d\tau_2\, K^{(2)}(z-\tau_2)\left\langle\frac{\delta^2\psi(z)}{\delta\mu(\tau_2)\delta\mu(\tau_1)}\right\rangle, \quad 0\leqslant\tau_1\leqslant z, \tag{44}$$

subject to the initial condition

$$\left\langle\frac{\delta\psi(z)}{\delta\mu(\tau_1)}\right\rangle\Bigg|_{z=\tau_1} = i\,\frac{k}{2}\,\langle\psi(\tau_1)\rangle. \tag{45}$$

The third equation, on which we apply the δ-correlation ansatz, reads

$$\frac{d}{dz}\left\langle\frac{\delta^2\psi(z)}{\delta\mu(\tau_2)\delta\mu(\tau_1)}\right\rangle = \frac{d}{dz}\,\Theta_z^{\text{eff}}\left[\frac{k}{2}\right]\left\langle\frac{\delta^2\psi(z)}{\delta\mu(\tau_2)\delta\mu(\tau_1)}\right\rangle, \quad 0\leqslant\tau_2,\ \ \tau_1\leqslant z, \tag{46}$$

subject to the initial condition

$$\left\langle\frac{\delta^2\psi(z)}{\delta\mu(\tau_2)\delta\mu(\tau_1)}\right\rangle\Bigg|_{z=\tau_1} = i\,\frac{k}{2}\left\langle\frac{\delta\psi(\tau_1)}{\delta\mu(\tau_2)}\right\rangle. \tag{47}$$

A Gaussian $\mu(z)$ in (42) implies $K^{(n)}(\cdot)\equiv 0$ for $n>2$, hence the obvious distinction between ours and the Gaussian case. Choosing $M=2$ leads to a *practically Gaussian* case, thus to show any

improvement of the proposed procedure, we need at least $M=3$. The distinction between our formulation and the non-Gaussian δ-correlation version becomes clear if we note that all the equations in the hierarchy of the δ-correlation formulation follow the same partial differential equation (37) and, in particular, (46), whereas our formulation follows this partial differential equation only from $M=3$ onward.

In general, the set of three equations must be solved numerically. Sometimes the last equation can be solved analytically. Then, this solution is inserted in the lower-order equations of the hierarchy. Often, the resulting integro-differential equations cannot be solved analytically.

In the present case we can solve the last equation, whose solution is

$$\left\langle \frac{\delta^2\psi(z)}{\delta\mu(\tau_1)\delta\mu(\tau_2)}\right\rangle = i\,\frac{k}{2}\exp\left[(z-\tau_1)\,\frac{d}{dz}\,\Theta_z^{\mathrm{eff}}\left[\frac{k}{2}\right]\right]\left\langle \frac{\delta\psi(\tau_1)}{\delta\mu(\tau_2)}\right\rangle. \tag{48}$$

Inserting (48) into the second-order equation (44) gives

$$\frac{d}{dz}\left\langle \frac{\delta\psi(z)}{\delta\mu(\tau_1)}\right\rangle = \left(i\,\frac{k}{2}\right)^2\,\frac{1}{2!}\int_0^z d\tau_2\,K^{(2)}(z-\tau_2)\,\exp\left[(z-\tau_1)\,\frac{d}{dz}\,\Theta_z^{\mathrm{eff}}\left[\frac{k}{2}\right]\right]\left\langle \frac{\delta\psi(\tau_1)}{\delta\mu(\tau_2)}\right\rangle, \tag{49}$$

and inserting (49) into the first equation (42) gives

$$\begin{aligned}\frac{d\langle\psi(z)\rangle}{dz} &= i\,\frac{k}{2}\int_0^z d\tau_1\,K^{(2)}(z-\tau_1)\left\langle \frac{\delta\psi(z)}{\delta\mu(\tau_1)}\right\rangle + i\left(\frac{k}{2}\right)^2\,\frac{1}{2!}\int_0^z d\tau_1\int_0^z d\tau_2\,K^{(3)}(z-\tau_1,z-\tau_2)\\ &\quad\times\exp\left[(z-\tau_1)\,\frac{d}{dz}\,\Theta_z^{\mathrm{eff}}\left[\frac{k}{2}\right]\right]\left\langle \frac{\delta\psi(\tau_1)}{\delta\mu(\tau_2)}\right\rangle.\end{aligned} \tag{50}$$

Integrating both (49) and (50) with respect to z and incorporating the initial condition (43) and (45) the set of two coupled equations to be solved is

$$\begin{aligned}\langle\psi(z)\rangle &= \psi_0 + i\,\frac{k}{2}\int_0^z dz'\int_0^{z'} d\tau_1\,K^{(2)}(z'-\tau_1)\left\langle \frac{\delta\psi(z')}{\delta\mu(\tau_1)}\right\rangle\\ &\quad + i\left(\frac{k}{2}\right)^2\,\frac{1}{2!}\int_0^z dz'\int_0^{z'} d\tau_1\int_0^{z'} d\tau_2\,K^{(3)}(z'-\tau_1,z'-\tau_2)\\ &\quad\times\exp\left[(z-\tau_1)\,\frac{d}{dz}\,\Theta_z^{\mathrm{eff}}\left[\frac{k}{2}\right]\right]\left\langle \frac{\delta\psi(\tau_1)}{\delta\mu(\tau_2)}\right\rangle,\end{aligned} \tag{51}$$

and

$$\begin{aligned}\left\langle \frac{\delta\psi(z)}{\delta\mu(\tau_1)}\right\rangle &= i\,\frac{k}{2}\,\langle\psi(\tau_1)\rangle + \left(i\,\frac{k}{2}\right)^3\,\frac{1}{2!}\int_0^z d\tau_1\int_0^z d\tau_2\,K^{(2)}(z-\tau_2)\\ &\quad\times\exp\left[(z-\tau_1)\,\frac{d}{dz}\,\Theta_z^{\mathrm{eff}}\left[\frac{k}{2}\right]\right]\left\langle \frac{\delta\psi(\tau_1)}{\delta\mu(\tau_2)}\right\rangle.\end{aligned} \tag{52}$$

The Gaussian case is obtained by setting $K^{(3)}(\cdot)=0$, and $d\Theta_z^{\mathrm{eff}}/dz=(ik/2)^2\kappa_2/2!$.

III. THE δ-CORRELATION LIMIT

The δ-correlated process does not occur in nature, thus it should be given a physical meaning. We invoked a δ-correlated process only in the last equation, whereas in the lower-order equations, the full cumulant is used. Other closure techniques involve the assumption that either a high-order cumulant (moment) depends on the lower order cumulants (moments), or at the $(n-1)$th level the nth cumulant (moment) vanishes or is asymptotically small. To assign a physical meaning to the effective cumulant defined in (26) and (27), we note that a δ-correlated process can be considered

the limit of the Ornstein–Uhlenbeck process,[5] i.e., white Gaussian noise. This process and its δ-correlated limit are both phenomenologically convenient forms to write the partial integral on the right-hand side of (18) as

$$\mathscr{I} \equiv \int_{{}^m\mathbf{0}}^{{}^m\mathbf{z}} d\,{}^m\boldsymbol{\tau}'\; K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')\langle \mathbf{D}^{m+n}({}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}',{}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle$$

$$\simeq \langle \mathbf{D}^{m+n}({}^m\mathbf{z},{}^m\boldsymbol{\rho}',{}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle \int_{{}^m\mathbf{0}}^{{}^m\mathbf{z}} d\,{}^m\boldsymbol{\tau}'\, K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}'), \tag{53}$$

where ${}^m\mathbf{0}$ and ${}^m\mathbf{z}$ are defined in (12), and the final step that follows (30) is immediately applicable. This means that $\langle \mathbf{D}^{m+n}(\cdot)\,\gamma(z,\mathbf{r})\rangle$ is supposed to have longer timelike scales than $K_\nu^{(m+1)}(\cdot)$. In this case the integro-differential formulation leads to a single partial differential equation. We term this case the *stochastic limit*. In fact, we expect in many cases that the timelike correlation length of $\langle \mathbf{D}^{m+n}(\cdot)(z,\mathbf{r})\rangle$ is of the order of the propagation length, whereas the scale of the $K_\nu^{(m+1)}(\cdot)$ is of the order of $L<(m+1)l$, where l is the largest correlation scale of the medium. Thus, $z\gg L$ is an intuitive definition of the δ-correlated approximation, and $l/z\to 0$ must hold uniformly for an arbitrary $m\leqslant M$.

We stress that in the *coherent limit*, which is opposite to the stochastic limit mentioned above, a partial differential equation cannot be obtained. In this case, and in the intermediate coherent-stochastic case, we have to use the proposed successive approximations to obtain a set of statistically closed, albeit integro-differential equations.

The closure procedure can be filled with content, if we define the characteristic scale to be

$$l_j(z,{}^m\mathbf{z},{}^m\boldsymbol{\rho}') \equiv \lim_{{}^m\boldsymbol{\tau}'\uparrow{}^m\mathbf{z}} \left| \frac{K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')}{\partial_{z_j'} K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')} \right|, \quad j=1,\ldots,m. \tag{54}$$

Then, we assume that $K_\nu^{(m+1)}(\cdot)$ attains its maximum as ${}^m\boldsymbol{\tau}\uparrow{}^m\mathbf{z}$, but this point is not a stationary point. We evaluate the integral $\mathscr{I}$ using a Laplace-type expansion in z/l_j and integrate the exponential integrand by parts;

$$\mathscr{I} \equiv \int_{{}^m\mathbf{0}}^{{}^m\mathbf{z}} d\,{}^m\boldsymbol{\tau}'\; K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}')\langle \mathbf{D}^{m+n}({}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}',{}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle$$

$$\sim \langle \mathbf{D}^{m+n}({}^m\mathbf{z},{}^m\boldsymbol{\rho}',{}^n\boldsymbol{\tau},{}^n\boldsymbol{\rho})\,\gamma(z,\mathbf{r})\rangle K_\nu^{(m+1)}(z,\mathbf{r};{}^m\mathbf{z},{}^m\boldsymbol{\rho}') \prod_{j=1}^{m} l_j(z,{}^m\mathbf{z},{}^m\boldsymbol{\rho}')(1-e^{-z/l_j}), \tag{55}$$

where $z\gg l_j$ leads to the stochastic limit, i.e., the δ-correlated case. Comparing (55) and (26) and (27), the effective cumulant can be found if we note that $K_\nu^{(m+1)}(z,\mathbf{r};{}^m\mathbf{z},{}^m\boldsymbol{\rho}')$ is a function of z/l_j for $j=1,\ldots,m$. Thus,

$$K_{\mathrm{eff}}^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\rho}') = \int_{{}^m\mathbf{0}}^{{}^m\infty} d\,{}^m\boldsymbol{\tau}'\; K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}) \sim K_\nu^{(m+1)}(z,\mathbf{r};{}^m\mathbf{z},{}^m\boldsymbol{\rho}') \prod_{j=1}^{m} l_j(z,{}^m\mathbf{z},{}^m\boldsymbol{\rho}'). \tag{56}$$

Finally, if ${}^m\boldsymbol{\tau}={}^m\mathbf{z}$ happened to be a stationary point, then using a scale related to the square root of the normalized determinant of the Hessian of $K_\nu^{(m+1)}(\cdot)$ leads to a similar result with a Gaussian integral.

IV. DISCUSSION: A CONSISTENT δ-CORRELATION CLOSURE

Although outside the scope of this paper, predicting how a convergence proof might evolve, we note that the cumulant discard does not represent systematically the cumulants of our closure device, i.e., the δ-correlation model. Thus, we propose another closure procedure that is best summarized by the schematic array, where, for example, the δ-correlation assumption is applied at the hierarchy order $M=3$. In this case the array is

$$\begin{bmatrix} K^{(1)} & K^{(2)} & K^{(3)} & K_3^{(4)} & \cdots \\ K^{(1)} & K^{(2)} & K_3^{(3)} & K_3^{(4)} & \cdots \\ K_{\text{eff}}^{(1)} & K_{\text{eff}}^{(2)} & K_{\text{eff}}^{(3)} & K_{\text{eff}}^{(4)} & \cdots \\ K_{\text{eff}}^{(1)} & K_{\text{eff}}^{(2)} & K_{\text{eff}}^{(3)} & K_{\text{eff}}^{(4)} & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix}, \tag{57}$$

where effective cumulants $\{K_{\text{eff}}^{(m)}\}$ can be readily obtained by using (26) or (56), and the $\{K_M^{(m)}\}$ may be the effective cumulants or hybrids defined as the regular cumulants up to the order M and δ-correlated onward:

$$K_M^{(m+1)}(z,\mathbf{r};{}^M\boldsymbol{\tau},{}^m\boldsymbol{\rho}) \simeq \int_0^\infty dz'_{M+1} \cdots \int_0^\infty dz'_m \; K_\nu^{(m+1)}(z,\mathbf{r};{}^m\boldsymbol{\tau}',{}^m\boldsymbol{\rho}). \tag{58}$$

Regarding this infinite system, we note that once we applied a δ-correlation closure, hierarchy orders higher than M follow the same integro-differential equation. In the example above with $M=3$, this is expressed in (57) by identical rows three and four, etc. Finally, the hybrid cumulant $K_M^{(m)}$ seems to be the best option although its use must be justified. The complete representation of all the cumulants, albeit partly in an approximated effective form, seems to be required for a proof of convergence to a genuine solution, which we intend to explore in the future.

V. CONCLUSIONS

We presented here a hierarchy of integro-differential equations that can be used to obtain the governing equations for a general Cauchy problem with random parametric fluctuations. To the best of our knowledge, this is the most general formulation that has been presented in this context. As we mentioned previously, currently there is no proof of convergence of this procedure, although limiting cases are known to be correct. To this end, we suggested also an alternative closure procedure that seems to be required for a proof of convergence.

The formulation is rather complicated, but in a few cases, e.g., the second-statistical moment [$N=M=1$ in (2)], or when $\mathscr{L}_{\mathbf{r}}$ is a first-order differential operator, it is possible to obtain tractable equations. In the future, we intend to show these equations for simple physical cases that clarify the difference between the Gaussian and the non-Gaussian cases and to prove the convergence of the procedure to the genuine solution.

(Received 9 June 1997; accepted for publication 1 May 1998)

By extending the formalism of maximally even sets to the one-dimensional antiferromagnetic Ising model with arbitrary-range interaction in an applied magnetic field it is shown that the system exhibits a devil's-staircase magnetic phase diagram. A ''generalized'' similarity dimension (a generalization for nonuniform fractals) of the phase diagram is calculated and compared to previous results. It is shown that previous estimates of the dimension of the phase diagram for this system differs from this ''generalized'' similarity dimension. © *1998 American Institute of Physics.* [S0022-2488(98)00509-X]

I. INTRODUCTION

The role the one-dimensional Ising model plays in the analysis of various physical systems has been discussed previously by Bak and Bruinsma.[1,2] They show that, in the infinite limit, the magnetic phase diagram for a one-dimensional array of Ising spins with a $1/x^{\alpha}$ $(\alpha>1)$ antiferromagnetic interaction is a complete devil's staircase with an estimated ''average'' fractal dimension of $2/(1+\alpha)$.

Recently, Douthett and Krantz[3] investigated the one-dimensional antiferromagnetic spin-1/2 Ising model at zero temperature and zero applied field using the formalism of maximally/minimally even sets.[4,5] Assuming periodic boundary conditions, they show that the configurational energy, for a given density of down (up) spins, $\rho=N_-/N(\rho=N_+/N)$ where N is the number of lattice sites and $N_-(N_+)$ are the numbers of down (up) spins, interacting via a strictly convex interaction is minimized by a maximally even distribution of up and down spins where the maximally even distribution is given by the following algorithm.[4]

> Let i be a fixed integer such that $0\leqslant i\leqslant N-1$, and assign down-spins (up-spins) to sites $\lfloor (Nk+i)/N_{\pm}\rfloor$ where $k=0,1,...,N_{\pm}-1$. Assign up-spins (down-spins) to the remaining sites. Then each down- and up-spin spectrum consists of one or two consecutive integers. Conversely, if each down-spin (up-spin) spectrum consists of one or two consecutive integers, then there exists an i, $0\leqslant i\leqslant N-1$, such that the down-spins (up-spins) occupy the sites $\lfloor (Nk+i)/N_{\pm}\rfloor$, $k=0,1,...,N_{\pm}-1$, and the up-spins (down-spins) occupy the rest.

A restricted form of this algorithm has been discussed by Clough and Myerson.[6,7] The kth spectrum of down (up) spins is defined to be the set of distinct, clockwise distances between down (up) spin pairs that have $k-1$ down (up) spins between them. Previously, Hubbard[8] observed that, for a given down-spin density, the minimum configurational energy occurs when each spectrum consists of one or two consecutive integers. Douthett and Krantz[3] proceeded to apply their formalism to a discrete system of one-dimensional spin-1/2 Ising spins with an exponentially de-

 © 1998 American Institute of Physics

creasing antiferromagnetic pairwise interaction. Then, they extended the results to describe the configurational energy in the limit of large N. In this paper the theory is generalized to include the effects of an applied magnetic field.

II. FIELD DEPENDENCE

We start with the antiferromagnetic Hamiltonian:

$$H_{\text{anti}}=\sum_{\substack{i,j=0\\ i\neq j}}^{N-1} J(|i-j|)\sigma_i\sigma_j-\sum_{i=0}^{N-1}\sigma_i h, \tag{1}$$

where $J(|i-j|)$ is the absolute value of the ''reduced'' pairwise interaction (where we have absorbed the usual constant factors) between the spins at lattice sites i and j, the σ's represent the orientations of the spins $(+1$ or $-1)$ on the ith and jth sites relative to the axis defined by the reduced applied field, h, and N is the number of lattice sites. As shown in Ref. 3 the configurational energy for a given fraction of down spins $(\rho=N_-/N)$ is minimized by a maximally even distribution of up and down spins where the ρ's are given by ratios in the Farey series. The minimum energy per spin is given by

$$U_{\min}(\rho)=\begin{cases}\displaystyle\sum_{k=1}^{\infty} J(k) & \text{if } \rho=0\\ \displaystyle\sum_{k=0}^{\infty} f_k(\rho) & \text{otherwise,}\end{cases} \tag{2a}$$

where

$$f_k(\rho)=\begin{cases}(1-4\rho)\displaystyle\sum_{j=1}^{\infty} J(j) & \text{if } k=0\\ 4\rho[(1-\{k/\rho\})J(\lfloor k/\rho\rfloor)+\{k/\rho\}J(\lceil k/\rho\rceil)] & \text{otherwise}\end{cases} \tag{2b}$$

and $\{x\}$ represents the fractional part of x, $\lfloor x\rfloor$ is the floor function of x, and $\lceil x\rceil$ is the ceiling function of x. For a given n, the sum $\Sigma_{k=0}^{n} f_k(\rho)$ calculates the energy for the $\lceil n/\rho\rceil$th near neighbors $(\rho\leqslant 1/2)$. This function is strictly convex, differentiable almost everywhere (ae), and is symmetric about $\rho=1/2$ on the interval $[0,1]$. Note that $\rho=0$ corresponds to all up spins (no down spins) and $\rho=1$ corresponds to all down spins. In an applied field, h, the average energy per spin as a function of the down-spin density, ρ, is

$$U_h(\rho)=U_{\min}(\rho)-(1-2\rho)h. \tag{3}$$

In order to describe the phase diagram, the values of ρ that minimize $U_h(\rho)$ are plotted versus h. The result is the so-called devil's-staircase phase diagram which will be described in more detail below. Similar results for this model have been obtained by other means (see Aubry[9,10] and Ishimura[11]).

It is possible to find the left and right end points (h_l and h_r) of the field intervals for a given rational fraction, ρ, by taking the right and left derivatives of $U_h(\rho)$, setting each to zero, and solving for the fields. Then for $0<\rho<1$,

$$h_l=-(1/2)D^+U_{\min}(\rho)=2\left[\sum_{k=1}^{\infty} J(k)-\sum_{k=1}^{\infty} g(\lceil k/\rho\rceil-1)\right], \tag{4a}$$

$$h_r=-(1/2)D^-U_{\min}(\rho)=2\left[\sum_{k=1}^{\infty} J(k)-\sum_{k=1}^{\infty} g(\lfloor k/\rho\rfloor)\right], \tag{4b}$$

where $g(m)=(m+1)J(m)-mJ(m+1)$ and the symbols D^- and D^+ represent the left- and right-hand derivatives, respectively.

Letting $\rho = p/q$, where p and q are coprime, the second sums in each of the field terms may be rearranged to express the field end points for a given p and q as

$$h_l(p/q) = 2\left[\sum_{k=1}^{\infty} J(k) - \sum_{j=1}^{p}\sum_{k=1}^{\infty} g(q(k-1)+\lceil qj/p\rceil - 1)\right] \tag{5a}$$

and

$$h_r(p/q) = 2\left[\sum_{k=1}^{\infty} J(k) - \sum_{j=1}^{p}\sum_{k=1}^{\infty} g(q(k-1)+\lfloor qj/p\rfloor)\right]. \tag{5b}$$

Taking the difference between $h_l(p/q)$ and $h_r(p/q)$ gives the length of the field step in the devil's-staircase phase diagram:

$$\Delta h(q) = h_r(p/q) - h_l(p/q) = 2q\sum_{k=1}^{\infty} [k(J(qk-1) - 2J(qk) + J(qk+1))]. \tag{6}$$

Note that Δh depends only on the denominator q. This expression is equivalent to Eq. (5) of Ref. 1 which was arrived at by calculating the configurational energy cost to flip one down-spin up, rearranging the spins in a new minimum configuration, and solving for one field end point when the energy cost was equal to zero, indicating that this configuration was a stable state. Similarly, the other field end point was determined by calculating the energy cost to flip one up-spin down, rearranging the spins, setting the energy change to zero, and solving for the field.

III. EXPONENTIAL INTERACTION

We have chosen an antiferromagnetic interaction of the form:

$$\mathscr{J}(k) = -J_0 \exp(-\alpha k), \tag{7}$$

where α and J_0 are positive constants. Then, $J(k) = J_0 e^{-\alpha k}$ where, $k = 1,2,3,...$ denotes near-neighbor, next-near-neighbor, next-next-near-neighbor pairs, etc., respectively.[3] Shown in Fig. 1 is the reduced configurational energy per spin ($U_h/J_0 h_T$) versus the down-spin density, ρ, for several (reduced) applied fields ($h/J_0 h_T$) assuming an exponentially decreasing antiferromagnetic interaction with $\alpha = 0.5$. In the denominator of the reduced quantities, h_T is the field at which a down-spin density of zero occurs. As the applied field is increased the down-spin density that minimizes the configurational energy decreases as more spins align along the field. The reduced applied field ranges from zero, where the minimum configurational energy occurs when $\rho = 0.5$ and the up and down spins alternate on the lattice, to unity, where the minimum configurational energy occurs when $\rho = 0.0$ and all the spins are up.

For convenience, the configurational energy, in Fig. 1, has been calculated for fractional densities that occur in the Farey series $F_8 = \{0,1/8,1/7,1/6,1/5,1/4,2/7,1/3,3/8,2/5,3/7,1/2\}$. The origin of the devil's-staircase phase diagram becomes clearer when one examines the details of Fig. 1 (see the insert). For each rational ρ, $U_h(\rho)$ has a corner with different right and left derivatives. For a given ρ, the right derivative is zero when the field is h_l. As the field is increased that ρ minimizes U_h until the field reaches h_r at which point the left derivative is zero. This occurs at every rational density. For example, for a reduced field near 0.2 a down-spin density of 2/5 minimizes the configurational energy (see Fig. 1). As the field is increased, a down-spin density of 2/5 still minimizes the energy until the configurational energy is decreased enough such that the next (smallest) down-spin density minimizes the configurational energy. For the applied fields in between, the down-spin density of 2/5 minimizes the configurational energy and a step in the phase diagram occurs.

A similar behavior is seen in the insert of Fig. 1 for a value of the down-spin density near 1/3. This type of behavior occurs in the limit of large N as well, yielding a devil's-staircase phase diagram with the field width of each step given by Eq. (6). The explicit form of the field width at each step for our example interaction is given below.

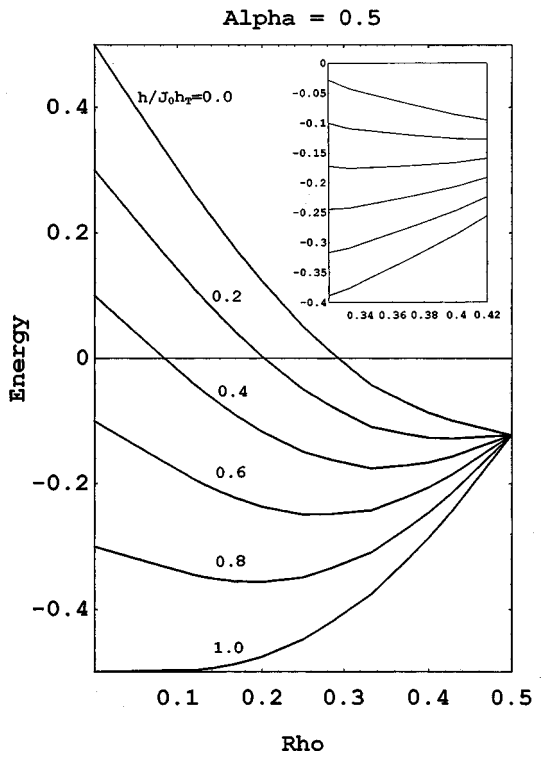

FIG. 1. Reduced configurational energy (U_h/J_0h_T) vs down-spin density (ρ) for various reduced applied fields (h/J_0h_T). The insert shows a portion of the plot for down-spin densities between 0.32 and 0.42. See the text for details.

For the exponentially decreasing antiferromagnetic interaction the equations that describe the applied field end points [Eqs. (5a) and (5b)] may be simplified:

$$h_l=\begin{cases} 2J_0 r/(1-r) & \text{if } \rho=0 \\ 2J_0\left[r/(1-r)-\sum_{k=1}^{p} G(q,\lceil qk/p\rceil-1)\right] & \text{otherwise} \end{cases} \tag{8a}$$

and

$$h_r=\begin{cases} -2J_0 r/(1-r) & \text{if } \rho=0 \\ 2J_0\left[r/(1-r)-\sum_{k=1}^{p} G(q,\lfloor qk/p\rfloor)\right] & \text{otherwise,} \end{cases} \tag{8b}$$

where $r=e^{-\alpha}$ and $G(q,m)=[g(m)-r^{2q}g(m-q)]/(1-r^q)^2$.

The applied field step width as a function of q, only, becomes

$$\Delta h(q)=2qr^{q-1}(1-r)^2/(1-r^q)^2, \quad q\geqslant 2. \tag{9}$$

Thus, for exponential interactions, the infinite sums in Eqs. (5a), (5b), and (6) can be expressed in closed form.

IV. THE DEVIL'S STAIRCASE

Shown in Fig. 2, is the resulting devil's-staircase magnetic phase diagram for the exponentially decreasing antiferromagnetic interaction with $\alpha=0.5$. As described in Eqs. (6) and (9), the applied field step widths depend only on the denominator of the rational fraction of the appropriate down-spin density. As expected, the phase diagram shows symmetry about zero applied field and a down-spin density of one-half. Equivalently, the system can be described either by down-spin or up-spin density versus applied field.

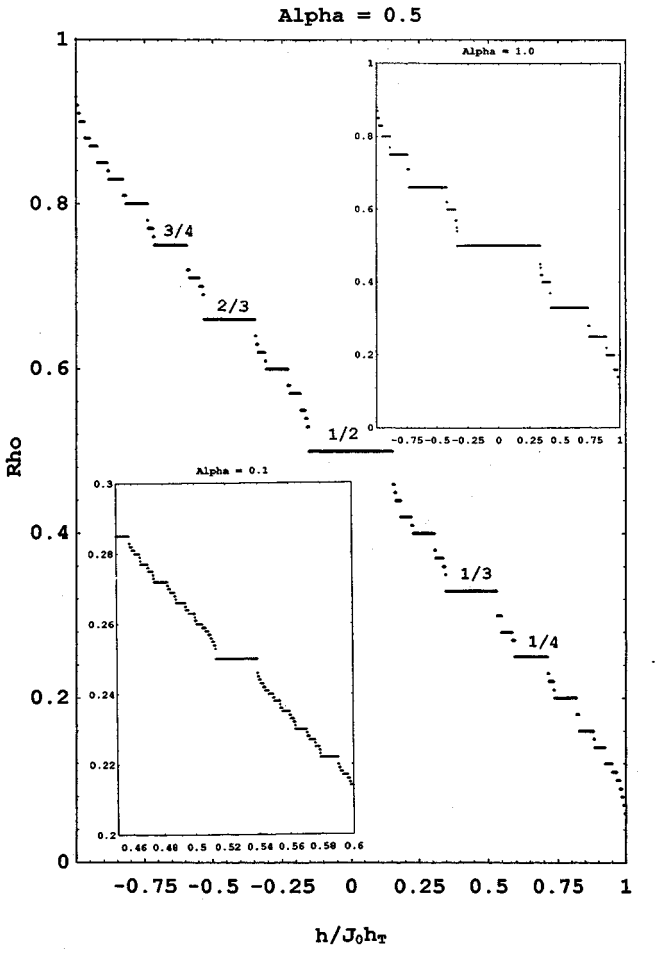

FIG. 2. Devil's-staircase phase diagram, Down-spin density (ρ) vs reduced applied field (h/J_0h_T) for the exponentially decreasing antiferromagnetic interaction with $\alpha=0.5$. [Upper Insert: Phase diagram with $\alpha=1.0$. Lower Insert: Phase diagram with $\alpha=0.1$.]

For comparison, the upper insert of Fig. 2 shows the resulting devil's staircase for a shorter range interaction, $\alpha=1.0$. The reduced field step widths for a given q are wider, relatively, as h_T, the field at which a down-spin density of zero occurs $[h_T=2e^{-\alpha}/(1-e^{-\alpha})]$, decreases with increasing α. As α increases further, i.e., the interaction becomes of shorter and shorter range and the spins become more and more independent, the $\rho=1/2$ reduced field step width approaches 2 (from -1 at the left-hand side to $+1$ at the right-hand side). In absolute terms the field interval from $-h_T$ to h_T is getting smaller. At these end points the density switches discontinuously to 0 or 1 depending on the direction of the applied field. For further comparison, the devil's-staircase phase diagram for longer ranged interactions, $\alpha=0.1$ is shown in the lower insert of Fig. 2, where for convenience, we have shown only a limited portion of the phase diagram.

V. DIMENSIONS

Previously, Bruinsma and Bak[2] estimated the ''average'' fractal dimension of a devil's-staircase magnetic phase diagram for a one-dimensional antiferromagnetic Ising model with a $1/x^{\alpha}$ interaction. They find a dimension by counting the number of phase transitions, $N(q)$, that one could measure with a precision of $\Delta h(q)$ and use

$$D_F=\lim_{q\to\infty}\ln(N(q))/\ln(H_T/\Delta h(q)),$$

TABLE I. ''Generalized'' similarity dimension of the devil's-staircase phase diagram for an exponentially decreasing antiferromagnetic interaction with different ranges, α, in the large q limit.

$J=J_0\exp(-\alpha k)$	$\alpha=0.01$	$\alpha=0.05$	$\alpha=0.10$	$\alpha=0.50$
''Generalized'' similarity dimension	0.3983	0.3255	0.2849	0.1851

where H_T is the range of the applied field. Because the allowed densities are rational fractions contained in the Farey series, the number of phases that will occur, $N(q)$, is just equal to the sum of Euler phi functions up to q, $\Phi(q)$. In the limit of large q this sum behaves like $3q^2/\pi^2$.[12] For a $1/x^\alpha$ interaction the ratio $H_T/\Delta h(q)$ can be shown to approach $q^{1+\alpha}$ in the limit of large q. Therefore, Bruinsma and Bak[2] estimate the fractal dimension as $2/(1+\alpha)$ in the limit of large q. For our exponential interaction D_F is zero for all $\alpha>0$.

The simple form of this dimension is appealing, however, this dimension is nonstandard and as such cannot be compared to fractal dimensions in general. In particular, it is easy to show that D_F differs from the capacity/box dimension for two-scale Cantor sets. Let Δ_1 and Δ_2 be the ratios to scale down the lengths to construct the two-scale Cantor set. If for the two scale ratios, Δ_1 and Δ_2, $\Delta_1<\Delta_2$ then D_F is dominated by the smaller scale factor:

$$D_F=-\log 2/\log \Delta_1. \tag{10}$$

On the other hand, the capacity dimension for this two-scale Cantor set is the solution to

$$\Delta_1^{D_c}+\Delta_2^{D_c}=1. \tag{11}$$

These two dimensions are equal if and only if $\Delta_1=\Delta_2$.

Jackson[13] generalizes Eq. (11) for an n-scale Cantor set. In the case of a Farey series Cantor set, there are an infinite number of scales; so we calculate the similarity dimension for nonuniform fractals (a generalization of the capacity dimension for nonuniform cantor sets) as described by Hilborn.[14] This generalization accounts for the changing scale factor at each level. For the purposes of our calculation this reduces to numerically finding the similarity dimension for nonuniform fractals, D_s, thus:

$$\sum_{k=1}^{\Phi(q)}(\Delta L_q(k))^{D_s}=\left(4\sum_{k=1}^{\infty}J(k)\right)^{D_s}, \tag{12}$$

where $\Delta L_q(k)$ denote the difference between the left and right field end points of subsequent stable phases, i.e., the ΔL_q's represent the ''gaps'' in the phase diagram. The fact that the ΔL_q's are different at each level accounts for the changing scale at each level mentioned above for nonuniform fractals—to which this ''generalized'' similarity dimension applies, as pointed out by Hillborn.[14] For exponential interactions the right-hand side of Eq. (12) becomes $(4J_0r/(1-r))^{D_s}$. The right-hand side of Eq. (12) is just $2h_T$, the length of the horizontal axis—from the field at which the spins are all up to the field at which the spins are all down.

Shown in Table I are the ''generalized'' similarity dimensions for the phase diagrams for exponentially decreasing antiferromagnetic interactions with varying ranges. As seen in this table the ''generalized'' fractal dimension depends on the range of the interaction. The longer the range, the larger the ''generalized'' similarity dimension. The approach of the value of the generalized similarity dimension in the large denominator limit is shown in Fig. 3 for the four values of the range, α, given in Table I. The horizontal axis is the largest denominator, q, occurring in the Farey series which generates the rational fractions representing the down-spin densities, ρ. For large q the number of allowable phases is $3\,q^2/\pi^2$ as mentioned above. This means that for a denominator of 3700 the distinct number of terms in Eq. (12) required to calculate the dimension is some 2.1 million. (If the phase diagram were not symmetric about $\rho=0$ such a calculation would require some 4.2 million terms.)

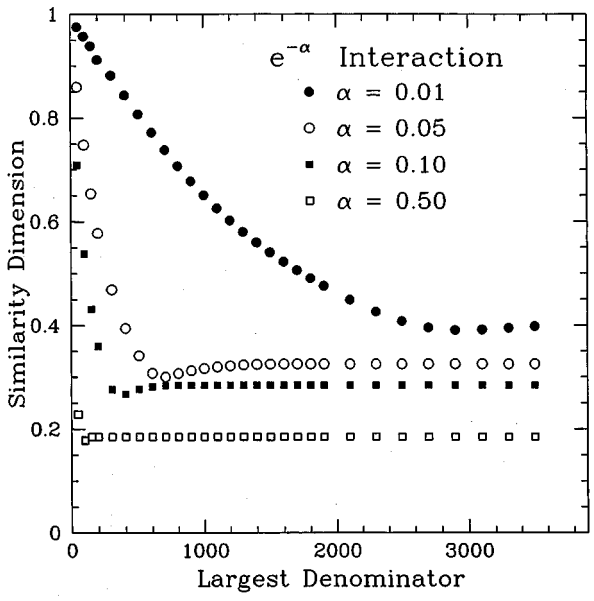

FIG. 3. ''Generalized'' similarity dimension as a function of the largest denominator in the Farey series.

Shown in Fig. 3 is the dependence of the generalized similarity dimension on q, which indicates that the fractal phase diagram is not self-similar at all levels, which is to be expected for nonuniform fractals.

Similar observations have been made by Bruinsma and Bak[2] with respect to their ''average'' dimension and the $1/x^2$ interaction. The ''average'' fractal dimension calculated by these researchers approaches $2/(1+\alpha)$, or 2/3 in this case, in the limit of large q, and approaches this limit from below as self similar subsets each with dimension $1/(1+\alpha)$, or 1/3 are combined.[2] In Table II we show the generalized similarity dimension calculated for the $1/x^2$ interaction. The generalized similarity dimension for this interaction approaches a limit of 0.645 which is different than the 2/3 ''average'' dimension calculated by Bruinsma and Bak.[2] As there is no formal connection between the average dimension of Bruinsma and Bak[2] and the generalized similarity dimension, we can only note that such a difference occurs.

VI. SUMMARY

The analysis of the one-dimensional antiferromagnetic spin- 1/2 Ising model with an arbitrary-range exponential interaction using the formalism of maximally even sets[3] has been extended to

TABLE II. ''Generalized'' similarity dimension of the devil's-staircase phase diagram for a $1/x^2$ antiferromagnetic interaction as q, the largest denominator in the Farey series (which determines the allowable down-spin densities) increases.

$J \propto 1/x^{\alpha}$	$\alpha = 2.0$
q	D_s
5	0.603
10	0.619
15	0.627
20	0.631

include the effect of an applied magnetic field. It is shown that the magnetic phase diagram is a complete devil's staircase in which the field step width can be expressed in closed form.

The resulting fractal is shown to be a nonuniform Cantor set. The generalized similarity dimension[14] for this case is calculated numerically and compared to a previous closed form estimate of the fractal dimension.[2] Our results suggest that the generalized similarity dimension for this system differs from the closed form estimate.

Analytic-bilinear approach to integrable hierarchies. I. Generalized KP hierarchy

L. V. Bogdanov[a] and B. G. Konopelchenko
Consortium EINSTEIN,[b] Dipartimento di Fisica dell'Università di Lecce and Sezione INFN, 73100 Lecce, Italy

(Received 9 June 1997; accepted for publication 18 May 1998)

An analytic-bilinear approach for construction and study of integrable hierarchies, in particular, the KP hierarchy is proposed. It starts with the generalized Hirota identity for the Cauchy–Baker–Akhiezer (CBA) function and leads to a generalized KP hierarchy in the form of compact functional equations containing a special shift operator. A generalized KP hierarchy incorporates the basic KP hierarchy, modified KP hierarchy, KP singularity manifold equation hierarchy, and corresponding hierarchies of linear problems. Different ''vertical'' levels of the generalized KP hierarchy are connected via invariants of the Combescure symmetry group. The resolution of functional equations also gives rise to the τ function and the addition formulas for it. © *1998 American Institute of Physics.* [S0022-2488(98)03209-5]

I. INTRODUCTION

The Kadomtsev–Petviashvili (KP) equation and the whole KP hierarchy of equations are significant parts of the theory of integrable equations. They arise in various fields of physics from hydrodynamics to string theory. They are also the tools to solve several problems in mathematics from the differential geometry of surfaces to an algebraic geometry.

The KP hierarchy has been described and studied within the framework of different approaches. The Sato approach[1] (see also Refs. 2–6) and the $\bar{\partial}$-dressing method[7–10] are, perhaps, the most beautiful and powerful among them. The infinite-dimensional Grassmannian, pseudodifferential operators, Hirota bilinear identity, and τ function are the basic ingredients of the Sato approach, which is, in essence, algebraic. In contrast, the $\bar{\partial}$ method, based on the nonlocal $\bar{\partial}$ problem for the wave function, mostly uses the analytic properties of the wave function. These two approaches look completely different. On the other hand, each of them has its own advantages. So one could expect that their marriage could be rather profitable.

A bridge between the Sato approach and the $\bar{\partial}$-dressing method has been established by the observation that the Hirota bilinear identity can be derived from the $\bar{\partial}$-dressing method.[10,11] Elements of the approach which combine the characteristic features of both methods, namely, the Hirota bilinear identity from the Sato approach and the analytic properties of solutions from the $\bar{\partial}$-dressing method, have been considered in Refs. 12, 13.

In this paper we are devoted to the analytic-bilinear approach to integrable hierarchies. It is based on the generalized Hirota bilinear identity for the wave function with simple analytic properties [the Cauchy–Baker–Akhiezer (CBA) function]. This approach allows us to derive generalized hierarchies of integrable equations in terms of the CBA function $\psi(\lambda,\mu,\mathbf{x})$ in a compact, finite form. Such generalized equations contain integrable equations in their usual form, their modified partners, and corresponding linear problems.

The generalized Hirota bilinear identity provides various functional equations for the CBA function. The resolution of some of them leads to the introduction of the τ function, while others give rise to the addition theorems for the τ function. The properties of the τ function, such as the associated closed 1-form and its global definition, also arise in a simple manner within the ap-

 © 1998 American Institute of Physics

proach under consideration. Generic discrete transformations of the CBA function and of the τ function are presented in the determinant form. These transformations are the generalized forms of the usual iterated Darboux transformations.

The generalized KP hierarchy is presented also in the ''moving'' frame, depending on the parameter. This generalized KP hierarchy written in the different ''moving'' frames contains the Darboux system of equations.

In addition to the usual infinite-dimensional symmetries, the generalized KP hierarchy possesses the symmetries given by the Combescure transformations. The invariants of these symmetry transformations have the compact forms in terms of the CBA function. The generalized KP hierarchy written in terms of these invariants coincide with the usual KP hierarchy, mKP hierarchy, and SM-KP hierarchy.

In this paper we make an emphasis of the concepts of generalized hierarchy and Combescure symmetry transformation invariants. We tried to derive and present a generalized KP hierarchy in a rather elementary manner.

The second part of the paper is devoted to the generalized multicomponent KP and two-dimensional Toda lattice hierarchies. In that paper we present more general and sophisticated forms of generalized integrable hierarchies.

The paper is organized as follows. The generalized Hirota identity is introduced in Sec. II. The generalized KP hierarchy is derived in Sec. III. Combescure symmetry transformations are discussed in Sec. IV. The generalized KP hierarchy in the ''moving'' frame is considered in Sec. V. The τ function is introduced in Sec. VI. The addition formulas for the τ function are also obtained here. Transformations of the CBA function and the τ function given by the determinant formulas and the Darboux transformations are discussed in Sec. VII. Closed one-form variational formulas for the τ function are presented in Sec. VIII.

II. GENERALIZED HIROTA IDENTITY

The famous Hirota bilinear identity provides us with a condensed and compact form of the integrable hierarchies. Here we will derive the generalized Hirota bilinear identity in the frame of the $\overline{\partial}$-dressing method.

The $\overline{\partial}$-dressing method (see Refs. 7–10) is based on the nonlocal $\overline{\partial}$ problem of the form

$$\overline{\partial}_\lambda(\chi(\lambda,\mathbf{x})-\eta(\lambda,\mathbf{x}))=\int\int_{\mathbb{C}} d\mu\wedge d\overline{\mu}\ \chi(\mu,\mathbf{x})g^{-1}(\mu,\mathbf{x})R(\mu,\lambda)g(\lambda,\mathbf{x}),$$
$$(\chi(\lambda,\mathbf{x})-\eta(\lambda,\mathbf{x}))_{|\lambda|\to\infty}\to 0, \tag{1}$$

where $\lambda\in\mathbb{C}$, $\mathbf{x}$ is some set of dynamical variables, $\overline{\partial}_\lambda=\partial/\partial\overline{\lambda}$, $\eta(\lambda,\mathbf{x})$ is a rational function of λ (normalization). In a general case, the function $\chi(\lambda,\mathbf{x})$ and the kernel $R(\lambda,\mu)$ are matrix-valued functions.

The dependence of the solution $\chi(\lambda,\mathbf{x})$ of the problem (1) on the dynamical variables is hidden in the function $g(\lambda,\mathbf{x})$. For the case of continuous variables, g is a product of the functions $g_i=\exp(K_i x_i)$, where $K_i(\lambda)$ are, in general, commuting matrix meromorphic functions.

It is assumed that the problem (1) is uniquely solvable. The $\overline{\partial}$-dressing method allows us to construct and solve wide classes of nonlinear partial differential equations (PDEs) which correspond to the different choice of the functions $K_i(\lambda)$.

Here we will assume that the kernel $R(\lambda,\mu)$ is equal to zero in some open subset G of the complex plane with respect to λ and to μ. This subset should typically include all zeros and poles of the considered class of functions $g(\lambda)$ and a neighborhood of infinity.

In this case the solution of the problem (1) normalized by η is the function

$$\chi(\mathbf{x},\lambda)=\eta(\mathbf{x},\lambda)+\varphi(\mathbf{x},\lambda),$$

where $\eta(\lambda)$ is a rational function of λ (normalization), all poles of $\eta(\lambda)$ belong to G, and $\varphi(\lambda)$ decreases as $\lambda\to\infty$ and is *analytic* in G.

The special class of solutions of the $\bar{\partial}$ problem (1) normalized by $(\lambda-\mu)^{-1}$ [$\eta(\lambda)=(\lambda-\mu)^{-1}$, $\mu\in G$] is of particular importance for the whole $\bar{\partial}$-dressing method.[8] Let us consider the $\bar{\partial}$ problem (1) for such solutions and the corresponding dual problem for the dual function $\chi^*(\lambda,\mu,\mathbf{x}')$:

$$\bar{\partial}_\lambda\chi(\lambda,\mu;g_1)=2\pi i\delta(\lambda-\mu)+\int\int_{\mathbb{C}} d\nu\wedge d\bar{\nu}\,\chi(\nu,\mu;g_1)g_1(\nu)R(\nu,\lambda)g_1(\lambda)^{-1},$$
$$\bar{\partial}_\lambda\chi^*(\lambda,\mu;g_2)=-2\pi i\delta(\lambda-\mu)-\int\int_{\mathbb{C}} d\nu\wedge d\bar{\nu}\,g_2(\nu)R(\lambda,\nu)g_2(\lambda)^{-1}\chi^*(\nu,\mu;g_2), \tag{2}$$

where $g_1=g(\lambda,\mathbf{x})$, $g_2=g(\lambda,\mathbf{x}')$, functions $\chi(\lambda,\mu;g_1)$ and $\chi^*(\lambda,\mu;g_2)$ are treated as functionals of the functions g_1, g_2, or, if the parametrization of g_1 and g_2 in terms of the variables $\mathbf{x}$, $\mathbf{x}'$ is given, just as functions of the variables $\mathbf{x}$, $\mathbf{x}'$.

After simple calculations, one gets

$$\int\int_G d\nu\wedge d\bar{\nu}\,\frac{\partial}{\partial\nu}(\chi(\nu,\lambda;g_1)g_1(\nu)g_2(\nu)^{-1}\chi^*(\nu,\mu;g_2))$$
$$=\int_{\partial G}\chi(\nu,\lambda;g_1)g_1(\nu)g_2(\nu)^{-1}\chi^*(\nu,\mu;g_2)d\nu=0. \tag{3}$$

In the particular case $g_1=g_2$ from (3), it follows that in $\bar{G}$ the function $\chi(\lambda,\mu)$ is equal to $-\chi^*(\mu,\lambda)$ (see also Ref. 14). So, finally, we have

$$\int_{\partial G}\chi(\nu,\mu;g_1)g_1(\nu)g_2^{-1}(\nu)\chi(\lambda,\nu;g_2)d\nu=0. \tag{4}$$

Here the function $\chi(\lambda,\mu)$ possesses the following analytical properties:

$$\bar{\partial}_\lambda\chi(\lambda,\mu)=2\pi\mathrm{i}\delta(\lambda-\mu),\quad -\bar{\partial}_\mu\chi(\lambda,\mu)=2\pi\mathrm{i}\delta(\lambda-\mu),$$

where $\delta(\lambda-\mu)$ is a δ function, or, in other words, $\chi\to(\lambda-\mu)^{-1}$ as $\lambda\to\mu$ and $\chi(\lambda,\mu)$ is an analytic function of both variables λ,μ for $\lambda\neq\mu$.

In the particular case $\lambda=\mu=0$, the relation (4) is nothing but the usual Hirota identity for the KP wave function $\chi(\nu,0,\mathbf{x})$ and the dual KP wave function $\chi^*(\nu,0,\mathbf{x}')$ (see, e.g., Refs. 1–4). Just in this case (for $\lambda=\mu=\infty$), the Hirota bilinear identity has been derived from the $\bar{\partial}$ problem in Ref. 11.

The identity (4) represents itself as the generalization of the Hirota identity which is bilocal with respect to the dynamical variables $\mathbf{x}$ and the spectral variables (λ,μ). It can be considered as the point of departure without any reference to the $\bar{\partial}$-dressing method. Namely, the generalized Hirota bilinear relation (4) is the starting point of the analytic-bilinear approach which we will consider in this paper. The double bilocality (with respect to $\mathbf{x}$ and (λ,μ)) provides us an additional freedom which will allow us to represent integrable hierarchies in a unified and condensed form.

Introducing the function $\psi(\lambda,\mu,\mathbf{x})$ via

$$\psi(\lambda,\mu;g)=g^{-1}(\mu)\chi(\lambda,\mu;g)g(\lambda), \tag{5}$$

one gets another form of the generalized Hirota equation,

$$\int_{\partial G}\psi(\nu,\mu;g_1)\psi(\lambda,\nu;g_2)d\nu=0. \tag{6}$$

Note that in the framework of the algebro-geometric technique, the function $\psi(\lambda,\mu)$ corresponds to the Cauchy–Baker–Akhiezer kernel on the Riemann surface (see Ref. 15). We will refer to the function $\psi(\lambda,\mu)$ as the Cauchy–Baker–Akhiezer (CBA) function.

We will assume in what follows that we are able to find solutions for the relation (4) somehow. In particular, it can be done by the $\bar{\partial}$-dressing method.

The general setting of the problem of solving (4) requires some modification of the Segal–Wilson Grassmannian approach.[4] Let us consider two linear spaces, $W(g)$ and $\tilde{W}(g)$, defined by the function $\chi(\lambda,\mu)$ [satisfying (4)] via equations connected with Eq. (4),

$$\int_{\partial G} f(\nu;g)\chi(\lambda,\nu;g)d\nu=0, \tag{7}$$

$$\int_{\partial G} \chi(\nu,\mu;g)h(\nu;g)d\nu=0; \tag{8}$$

here $f(\lambda)\in W$, $h(\lambda)\in\tilde{W}$; $f(\lambda)$, $h(\lambda)$ are defined in $\bar{G}$.

It follows from the definition of linear spaces $W,\tilde{W}$ that

$$\begin{aligned} f(\lambda)&=2\pi\mathrm{i}\int\int_G \eta(\nu)\chi(\lambda,\nu)d\nu\wedge d\bar{\nu}, \quad \eta(\nu)=\left(\frac{\partial}{\partial\bar{\nu}}f(\nu)\right),\\ h(\mu)&=-2\pi\mathrm{i}\int\int_G \chi(\nu,\mu)\tilde{\eta}(\nu)d\nu\wedge d\bar{\nu}, \quad \tilde{\eta}(\nu)=\left(\frac{\partial}{\partial\bar{\nu}}h(\nu)\right). \end{aligned} \tag{9}$$

These formulas, in some sense, provide an expansion of the functions f,h in terms of the basic function $\chi(\lambda,\mu)$. The formulas (9) readily imply that linear spaces $W,\tilde{W}$ are transversal to the space of holomorphic functions in G (the transversality property).

From the other point of view, these formulas define a map of the space of functions (distributions) on $\bar{G}$ $\eta,\tilde{\eta}$ to the spaces $W,\tilde{W}$. We will call $\eta(\tilde{\eta})$ a *normalization* of the corresponding function belonging to $W(\tilde{W})$.

The dynamics of linear spaces $W,\tilde{W}$ looks very simple:

$$W(g)=W_0g^{-1}; \quad \tilde{W}(g)=g\tilde{W}_0; \tag{10}$$

here $W_0=W(g=1)$, $\tilde{W}_0=\tilde{W}(g=1)$ [the formulas (10) follow from identity (4) and the formulas (9)].

To introduce a dependence on several variables (maybe of a different type), one should consider a product of corresponding functions $g(\lambda)$ (all of them commute).

The formula (4) is a basic tool for our construction. Analytic properties of the CBA kernel accompanied with the different choices of the functions g_1 and g_2 will provide us with various compact and useful relations.

III. GENERALIZED KP HIERARCHY

In the present paper we will consider the scalar KP hierarchy. It is generated by the generalized Hirota formula (4) where G is a unit disk and

$$g(\lambda,\mathbf{x})=\exp\left(\sum_{i=1}^{\infty} x_i\lambda^{-i}\right). \tag{11}$$

Let us consider the formula (4) with

$$g_1g_2^{-1}=g(\nu,\mathbf{x})g^{-1}(\nu,\mathbf{x}')=\exp\left(\sum_{i=1}^{\infty}(x_i-x_i')\nu^{-i}\right)=\frac{\nu-a}{\nu-b}, \tag{12}$$

where a and b are arbitrary complex parameters, $a,b\in G$. Since $\ln(1-\epsilon)=-\sum_{i=1}^{\infty}\epsilon^i/i$, one has

$$x_i' - x_i = \frac{1}{i}a^i - \frac{1}{i}b^i.$$

Substituting the expression (12) into (4), one gets

$$\left(\frac{\mu-a}{\mu-b}\right)\chi(\lambda,\mu,\mathbf{x}+[a]) - \left(\frac{\lambda-a}{\lambda-b}\right)\chi(\lambda,\mu,\mathbf{x}+[b])$$
$$+(b-a)\chi(\lambda,b,\mathbf{x}+[a])\chi(b,\mu,\mathbf{x}+[b]) = 0, \quad \lambda \neq \mu, \tag{13}$$

where $\mathbf{x}+[a]=x_i+[a]_i$, $0 \leqslant i < \infty$, $[a]_i=(1/i)a^i$. Equation (13) is the simplest functional equation for $\chi(\lambda,\mu,\mathbf{x})$ which follows from the generalized Hirota equation (4).

Residues of the LHS of (13) at the poles $\mu=b$ and $\lambda=b$ vanish identically. Evaluating the LHS of (13) at $\mu=a$ and $\lambda=a$, one gets the equations

$$\left(\frac{\lambda-a}{\lambda-b}\right)\chi(\lambda,a,\mathbf{x}+[b]) = (b-a)\chi(\lambda,b,\mathbf{x}+[a])\chi(b,a,\mathbf{x}+[b]), \tag{14}$$

$$\left(\frac{\mu-a}{\mu-b}\right)\chi(a,\mu,\mathbf{x}+[a]) = (a-b)\chi(a,b,\mathbf{x}+[a])\chi(b,\mu,\mathbf{x}+[b]). \tag{15}$$
$$a \neq b.$$

Equations (14) and (15) imply that

$$(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x}) = \frac{(\lambda-a)\chi(\lambda,a,\mathbf{x}-[a]+[\mu])}{(\mu-a)\chi(\mu,a,\mathbf{x}-[a]+[\mu])} = \frac{(a-\mu)\chi(a,\mu,\mathbf{x}+[a]-[\lambda])}{(a-\lambda)\chi(a,\lambda,\mathbf{x}+[a]-[\lambda])}. \tag{16}$$

Since $(\mu-a)\chi(\mu,a)\to 1$ as $\mu-a\to 0$, one gets from (16),

$$(\lambda-\mu)^2\chi(\lambda,\mu,\mathbf{x}+[\lambda])\chi(\mu,\lambda,\mathbf{x}+[\mu]) = -1. \tag{17}$$

We will solve the equations (14)–(17) in the next section. Now, let us consider the particular form of Eq. (13) for $b=0$. In terms of the CBA function, it reads as

$$\psi(\lambda,\mu,\mathbf{x}+[a]) - \psi(\lambda,\mu,\mathbf{x}) = a\psi(\lambda,\mathbf{x}+[a])\tilde{\psi}(\mu,\mathbf{x}); \quad x_i' - x_i = \frac{1}{i}a^i, \tag{18}$$

where we have introduced the Baker–Akhiezer and dual Baker–Akhiezer functions $\psi(\lambda,\mathbf{x}) = g(\lambda)\chi(\lambda,0,\mathbf{x})$, $\tilde{\psi}(\mu,\mathbf{x})=g(\mu)^{-1}\chi(0,\mu,\mathbf{x})$. This equation is a condensed finite form of the whole KP-mKP hierarchy. The expansion of this relation over a generates the KP-mKP hierarchies (and dual hierarchies) and linear problems for them. Indeed, Eq. (18) is equivalent to the infinite system of equations,

$$p_{i+1}(\tilde{\partial})\psi(\lambda,\mu,\mathbf{x}) = \tilde{\psi}(\mu,\mathbf{x})p_i(\tilde{\partial})\psi(\lambda,\mathbf{x}), \tag{19}$$

where p_i are Schur polynomials and $\tilde{\partial}=(\partial/\partial x_1,(1/2)(\partial/\partial x_2),\ldots,(1/n)(\partial/\partial x_n),\ldots)$. The first three equations from (19) are (we are using the equivalent symmetric form)

$$\psi(\lambda,\mu,\mathbf{x})_x = \psi(\lambda,\mathbf{x})\tilde{\psi}(\mu,\mathbf{x}), \tag{20}$$

$$\psi(\lambda,\mu,\mathbf{x})_y = \psi(\lambda,\mathbf{x})_x\tilde{\psi}(\mu,\mathbf{x}) - \psi(\lambda,\mathbf{x})\tilde{\psi}(\mu,\mathbf{x})_x, \tag{21}$$

$$\psi(\lambda,\mu,\mathbf{x})_t = \tfrac{1}{4}\psi(\lambda,\mu,\mathbf{x})_{xxx} - \tfrac{3}{4}\psi(\lambda,\mathbf{x})_x\tilde{\psi}(\mu,\mathbf{x})_x$$
$$+\tfrac{3}{4}(\psi(\lambda,\mathbf{x})_y\tilde{\psi}(\mu,\mathbf{x}) - \psi(\lambda,\mathbf{x})\tilde{\psi}(\mu,\mathbf{x})_y), \tag{22}$$

$$x=x_1; \quad y=x_2; \quad t=x_3.$$

A combination of the first two equations gives equivalently the equations

$$\psi(\lambda,\mu,\mathbf{x})_y-\psi(\lambda,\mu,\mathbf{x})_{xx}=-2\psi(\lambda,\mathbf{x})\tilde{\psi}(\mu,\mathbf{x})_x, \tag{23}$$

$$\psi(\lambda,\mu,\mathbf{x})_y+\psi(\lambda,\mu,\mathbf{x})_{xx}=2\psi(\lambda,\mathbf{x})_x\tilde{\psi}(\mu,\mathbf{x}). \tag{24}$$

Evaluating the first equation at $\mu=0$, the second at $\lambda=0$ (it is easier to do it rewriting the equation in terms of the function χ), one gets

$$f(\mathbf{x})_y-f(\mathbf{x})_{xx}=u(\mathbf{x})f(\mathbf{x}), \tag{25}$$

$$\tilde{f}(\mathbf{x})_y+\tilde{f}(\mathbf{x})_{xx}=-u(\mathbf{x})\tilde{f}(\mathbf{x}), \tag{26}$$

where $u(\mathbf{x})=-2\chi(0,0)_x$ and

$$f=\int \psi(\lambda,0)\rho(\lambda)d\lambda,$$

$$\tilde{f}=\int \tilde{\rho}(\mu)\psi(0,\mu)d\mu;$$

$\rho(\lambda)$ and $\tilde{\rho}(\mu)$ are some arbitrary functions.

In a similar manner, one obtains from (20)–(22) the equations

$$f_t-f_{xxx}=\tfrac{3}{2}uf_x+\tfrac{3}{4}(u_x+\partial_x^{-1}u_y)f, \tag{27}$$

$$\tilde{f}_t-\tilde{f}_{xxx}=\tfrac{3}{2}u\tilde{f}_x+\tfrac{3}{4}(u_x-\partial_x^{-1}u_y)\tilde{f}. \tag{28}$$

Both the linear system (25), (27) for the wave function f and the linear system (26), (28) for the wave function $\tilde{f}$ give rise to the same KP equation,

$$u_t=\tfrac{1}{4}u_{xxx}+\tfrac{3}{2}uu_x+\tfrac{3}{4}\partial_x^{-1}u_{yy}. \tag{29}$$

To derive linear problems for the mKP and dual mKP equations, we integrate Eqs. (20), (23), (24), and (22) with the two arbitrary functions $\rho(\lambda)$, $\tilde{\rho}(\mu)$,

$$\Phi(\mathbf{x})_x=f(\mathbf{x})\tilde{f}(\mathbf{x}), \tag{30}$$

$$\Phi(\mathbf{x})_y-\Phi(\mathbf{x})_{xx}=-2f(\mathbf{x})\tilde{f}(\mathbf{x})_x, \tag{31}$$

$$\Phi(\mathbf{x})_y+\Phi(\mathbf{x})_{xx}=2f(\mathbf{x})_x\tilde{f}(\mathbf{x}), \tag{32}$$

$$\Phi(\mathbf{x})_t-\Phi(\mathbf{x})_{xxx}=-\tfrac{3}{2}f(\mathbf{x})_x\tilde{f}(\mathbf{x})_x-\tfrac{3}{4}(f(\mathbf{x})\tilde{f}(\mathbf{x})_y-f(\mathbf{x})_y\tilde{f}(\mathbf{x})), \tag{33}$$

where

$$\Phi=\int\int \tilde{\rho}(\mu)\psi(\lambda,\mu)\rho(\lambda)d\lambda\, d\mu.$$

Using the first equation to exclude f from the second (and $\tilde{f}$ from the third), we obtain

$$\Phi_y-\Phi_{xx}=v(\mathbf{x})\Phi_x, \tag{34}$$

$$\Phi_y+\Phi_{xx}=-\tilde{v}(\mathbf{x})\Phi_x, \tag{35}$$

where $v=-2[\tilde{f}(\mathbf{x})_x/\tilde{f}(\mathbf{x})]$, $\tilde{v}=2[f(\mathbf{x})_x/f(\mathbf{x})]$.

Similarly, one gets from (22),

$$\Phi_t-\Phi_{xxx}=\tfrac{3}{2}v(\mathbf{x})\Phi_{xx}+\tfrac{3}{4}(v_x+\tfrac{1}{2}v^2+\partial_x^{-1}v_y)\Phi_x, \tag{36}$$

$$\Phi_t-\Phi_{xxx}=\tfrac{3}{2}\tilde{v}(\mathbf{x})\Phi_{xx}+\tfrac{3}{4}(\tilde{v}_x+\tfrac{1}{2}\tilde{v}^2-\partial_x^{-1}\tilde{v}_y)\Phi_x. \tag{37}$$

The system (34), (36) gives rise to the mKP equation,

$$v_t=\tfrac{1}{4}v_{xxx}-\tfrac{3}{8}v^2v_x+\tfrac{3}{4}v_x\partial_x^{-1}v_y+\tfrac{3}{4}\partial_x^{-1}v_{yy}, \tag{38}$$

while the system (35), (37) leads to the dual mKP equation, which is obtained from (38) by the substitution $v\to\tilde{v}$, $t\to -t$, $y\to -y$, $x\to -x$.

So the function Φ is simultaneously a wave function for the mKP and dual mKP linear problems with different potentials, defined by the dual KP (KP) wave functions.

Using the equation (22) and relations (34) and (35), one also obtains an equation for the function Φ,

$$\Phi_t=\tfrac{1}{4}\Phi_{xxx}+\tfrac{3}{8}\frac{\Phi_y^2-\Phi_{xx}^2}{\Phi_x}+\tfrac{3}{4}\Phi_xW_y, \quad W_x=\frac{\Phi_y}{\Phi_x}. \tag{39}$$

This equation first arose in the Painlève analysis of the KP equation as a singularity manifold equation.[16]

It is a tedious but absolutely straightforward check that the expansion of (18) in higher orders of a generates (**1**) the whole hierarchy of KP singularity manifold equations for $\psi(\lambda,\mu)$ [or $\Phi(\mathbf{x})$]; (**2**) the hierarchy of linear problems for the mKP and dual mKP equations, where $\psi(\lambda,\mu)$ [or $\Phi(\mathbf{x})$] is the common wave function and $v=-2(\ln\tilde{\psi}(\mu,\mathbf{x}))_x$, $\tilde{v}=-2(\ln\psi(\lambda,\mathbf{x}))_x$ are the potentials; (**3**) the mKP hierarchy for v and the dual mKP hierarchy for $\tilde{v}$; (**4**) the hierarchies of the KP linear problems for $\psi(\lambda,\mathbf{x})$ and the dual KP linear problems for $\tilde{\psi}(\mu,\mathbf{x})$ and; finally, (**5**) the KP hierarchy of equations for $u=-2\chi(0,0)_x$.

Note also one interesting consequence of the formula (17),

$$\chi(0,\lambda,\mathbf{x})=-\frac{1}{\lambda^2}\chi^{-1}(\lambda,0,\mathbf{x}+[\lambda]). \tag{40}$$

IV. KP HIERARCHY IN THE "MOVING FRAME." DARBOUX EQUATIONS AS THE HORIZONTAL SUBHIERARCHY

Now let us consider the expansion of the LHS of (13) over $\epsilon=a-b$, where $\epsilon\to 0$. In the first order in ϵ, one gets

$$\Delta_1(b)\psi(\lambda,\mu,\mathbf{x})=\psi(b,\mu,\mathbf{x})\psi(\lambda,b,\mathbf{x}), \tag{41}$$

where

$$\Delta_1(b)=\sum_{n=1}^{\infty}b^{n-1}\frac{\partial}{\partial x_n}.$$

In the higher orders in ϵ one obtains the hierarchy of equations of the form (20)–(22) and their higher analogs with the substitution $\psi(\lambda,0,\mathbf{x})\to\psi(\lambda,b,\mathbf{x})$, $\psi(0,\mu,\mathbf{x})\to\psi(b,\mu,\mathbf{x})$ and

$$\frac{\partial}{\partial x_i}\to\Delta_i(b)=\sum_{n=i}^{\infty}\frac{n!}{n(n-i)!i!}b^{n-i}\frac{\partial}{\partial x_i}.$$

Such a substitution is, in fact, nothing but the change of dynamical variables (or the coordinates on the group of functions g). Indeed, it is not difficult to show that $\Delta_i(b)=\partial/\partial x_i(b)$, where the dynamical variables $x_i(b)$ are defined by the relation

$$\sum_{i=1}^{\infty} \frac{x_i(b)}{(\lambda-b)^i}=\sum_{i=1}^{\infty} \frac{x_i}{(\lambda)^i}. \tag{42}$$

It is clear that

$$\left[\frac{\partial}{\partial x_i(\lambda')},\frac{\partial}{\partial x_i(\lambda)}\right]=0. \tag{43}$$

Note one interesting property of the derivatives $\partial/\partial x_i(b)$, namely,

$$\left[\frac{\partial}{\partial \lambda},\frac{\partial}{\partial x_i(\lambda)}\right]=(i+1)\frac{\partial}{\partial x_{i+1}(\lambda)}. \tag{44}$$

So the operator $\partial/\partial\lambda$ is a ''master symmetry'' for all vector fields $\partial/\partial x_i(\lambda)$.

The expansion of Eq. (13) up to the third order in ϵ gives the equations

$$\frac{\partial}{\partial x_1(b)}\psi(\lambda,\mu,\mathbf{x}(b))=\psi(b,\mu,\mathbf{x}(b))\psi(\lambda,b,\mathbf{x}(b)), \tag{45}$$

$$\frac{\partial}{\partial x_2(b)}\psi(\lambda,\mu,\mathbf{x}(b))=\frac{\partial}{\partial x_1(b)}\psi(\lambda,b,\mathbf{x}(b))\cdot\psi(b,\mu,\mathbf{x}(b)) - \psi(\lambda,b,\mathbf{x}(b))\cdot\frac{\partial}{\partial x_1(b)}\psi(b,\mu,\mathbf{x}(b)), \tag{46}$$

$$\begin{aligned}&\frac{\partial}{\partial x_3(b)}\psi(\lambda,\mu,x(b))\\ &=\frac{1}{4}\frac{\partial^3}{\partial x_1(b)^3}\psi(\lambda,\mu,\mathbf{x}(b))-\frac{3}{4}\frac{\partial}{\partial x_1(b)}\psi(\lambda,b,\mathbf{x}(b))\cdot\frac{\partial}{\partial x_1(b)}\psi(b,\mu,\mathbf{x}(b))\\ &\quad+\frac{3}{4}\left(\frac{\partial}{\partial x_2(b)}\psi(\lambda,b,\mathbf{x}(b))\cdot\psi(b,\mu)-\psi(\lambda,b,\mathbf{x}(b))\cdot\frac{\partial}{\partial x_2(b)}\psi(b,\mu,\mathbf{x}(b))\right).\end{aligned} \tag{47}$$

The analogs of Eqs. (23) and (24) have the form

$$\frac{\partial}{\partial x_2(b)}\psi(\lambda,\mu,\mathbf{x}(b))-\frac{\partial^2}{\partial x_1(b)^2}\psi(\lambda,\mu,\mathbf{x}(b))+2\psi(\lambda,b)\frac{\partial}{\partial x_1(b)}\psi(b,\mu,\mathbf{x}(b))=0, \tag{48}$$

$$\frac{\partial}{\partial x_2(b)}\psi(\lambda,\mu,\mathbf{x}(b))+\frac{\partial^2}{\partial x_1(b)^2}\psi(\lambda,\mu,\mathbf{x}(b))-2\frac{\partial}{\partial x_1(b)}\psi(\lambda,b)\cdot\psi(b,\mu,\mathbf{x}(b))=0. \tag{49}$$

Equations (45)–(47) and higher equations again give rise to the generalized KP hierarchy, but now in coordinates $x_i(b), i=1,2,3,\ldots$. For such a KP hierarchy written in the ''moving'' frame, the parameter b is an arbitrary one, but fixed.

Let us consider now equations of the type (45) written for several values of b. We denote $x_1(b_\alpha)=\xi_\alpha$, $\alpha=1,2,\ldots,n$. Equations (45), taken for $b=b_\alpha$, $\lambda=b_\beta$, $\mu=b_\gamma(\alpha\neq\beta\neq\gamma)$, look like

$$\frac{\partial}{\partial \xi_\alpha}\psi_{\beta\gamma}=\psi_{\beta\alpha}\psi_{\alpha\gamma},\quad \alpha\neq\beta\neq\gamma, \tag{50}$$

where $\psi_{\alpha\beta}=\psi(b_\alpha,b_\beta,\mathbf{x})$. The system (50) is just a well-known system of N^2-N resonantly interacting waves.

Integrating Eqs. (45) over μ with the function $\rho(\mu)$ and evaluating the result at $b=b_\alpha$, $\gamma=b_\beta$, one gets

$$\frac{\partial f_\beta}{\partial \xi_\alpha} = \psi_{\beta\alpha} f_\alpha \quad (\alpha \neq \beta), \tag{51}$$

where $f_\beta = \int d\mu \psi(b_\beta, \mu)\rho(\mu)$. Analogously, one gets

$$\frac{\partial f^*_\beta}{\partial \xi_\alpha} = \psi_{\alpha\beta} f^*_\alpha \quad (\alpha \neq \beta), \tag{52}$$

where $f^*_\beta = \int d\lambda \psi(\lambda, b_\beta)\rho^*(\lambda)$ and $\rho^*(\lambda)$ is an arbitrary function. The systems (51) and (52) are the linear problem and dual linear problem for Eqs. (50), respectively.

Expressing $\psi_{\alpha\beta}$ via f_α and f^*_α, one gets from (51) and (52) [using (50)] the same system for f_α and f^*_α,

$$\frac{\partial^2 H_\alpha}{\partial \xi_\beta \partial \xi_\gamma} = \frac{1}{H_\beta}\frac{\partial H_\beta}{\partial \xi_\gamma}\frac{\partial H_\alpha}{\partial \xi_\beta} + \frac{1}{H_\gamma}\frac{\partial H_\gamma}{\partial \xi_\beta}\frac{\partial H_\alpha}{\partial \xi_\gamma} \quad (\alpha \neq \beta \neq \gamma \neq \alpha). \tag{53}$$

The system (53) is the Darboux system which was introduced for the first time in the differential geometry of surfaces[14] and then was rediscovered in the matrix form within the ∂-dressing method in the paper.[5] Note that the Darboux equations in the variables of the type $x_1(b_\alpha)$ have also appeared in the paper[17] within completely different approach.

One can treat the Darboux equations (53) with different n as the horizontal subhierarchy of the whole generalized KP hierarchy. Note that Eqs. (45)–(47) and their higher analogs give rise to the higher resonantly interacting waves equations.

V. COMBESCURE SYMMETRY TRANSFORMATIONS FOR THE GENERALIZED KP HIERARCHY

Let us consider now the symmetries of the equations derived above. All the higher equations of the hierarchy are, as usual, the symmetries of each member of the hierarchy. Here we will discuss another type of symmetry.

Since $\rho(\lambda)$ and $\tilde{\rho}(\mu)$ are arbitrary functions, Eqs. (39) and the hierarchy (18) possess the symmetry transformation

$$\Phi(\rho(\lambda), \tilde{\rho}(\mu)) \to \Phi' = \Phi(\rho'(\lambda), \tilde{\rho}'(\mu)).$$

This transformation is, in fact, the transformation which changes the normalization of the wave functions. The fact that such transformations are connected with the so-called Combescure transformations, known for a long time in differential geometry, was pointed out in Ref. 12.

The Combescure transformation was introduced last century within the study of the transformation properties of surfaces (see, e.g., Refs. 18, 19). It is a transformation of surface such that the tangent vector at a given point of the surface remains parallel. The Combescure transformation is essentially different from the well-known Bäcklund and Darboux transformations. The Combescure transformation plays an important role in the theory of the systems of a hydrodynamical type.[20] It is also of great interest for the theory of $(2+1)$-dimensional integrable systems.[21] Combescure symmetry transformations are an essential part of the analytic-bilinear approach.

The Combescure transformation can be characterized in terms of the corresponding invariants. The simplest of these invariants for the mKP equation is just the potential of the KP equation L operator expressed through the wave function

$$u = \frac{f(\mathbf{x})_y - f(\mathbf{x})_{xx}}{f(\mathbf{x})}, \tag{54}$$

$$u = \frac{\tilde{f}(\mathbf{x})_y - \tilde{f}(\mathbf{x})_{xx}}{\tilde{f}(\mathbf{x})}, \tag{55}$$

or, in terms of the solution for the mKP (dual mKP) equation,

$$v'_y+v'_{xx}-\tfrac{1}{2}((v')^2)_x=v_y+v_{xx}-\tfrac{1}{2}(v^2)_x, \tag{56}$$

$$\tilde{v}'_y-\tilde{v}'_{xx}-\tfrac{1}{2}((\tilde{v}')^2)_x=\tilde{v}_y-\tilde{v}_{xx}-\tfrac{1}{2}(\tilde{v}^2)_x. \tag{57}$$

The solutions of the mKP equations are transformed only by a subgroup of the Combescure symmetry group corresponding to the change of the weight function $\tilde{\rho}(\mu)$ (left subgroup), and they are invariant under the action of the subgroup corresponding to $\rho(\lambda)$ (vice versa for the dual mKP).

All the hierarchy of the Combescure transformation invariants is given by the expansion over ϵ near the point $\mathbf{x}$ of the relation (18), rewritten in the form

$$\frac{\partial}{\partial\epsilon}\left(\frac{\tilde{f}(\mathbf{x}')-\tilde{f}(\mathbf{x})}{\epsilon\tilde{f}(\mathbf{x})}\right)=-\frac{1}{2}\frac{\partial}{\partial\epsilon}\partial_{x'}^{-1}u(\mathbf{x}'),\quad x'_i-x_i=\frac{1}{i}\epsilon^i; \tag{58}$$

$$\frac{\partial}{\partial\epsilon}\left(\frac{f(\mathbf{x})-f(\mathbf{x}')}{\epsilon f(\mathbf{x})}\right)=\frac{1}{2}\frac{\partial}{\partial\epsilon}\partial_{x'}^{-1}u(\mathbf{x}'),\quad x'_i-x_i=-\frac{1}{i}\epsilon^i. \tag{59}$$

The expansion of the left part of these relations gives the Combescure transformation invariants in terms of the wave functions $\tilde{f}$, f. To express them in terms of the mKP equation (the dual mKP equation) solution, one should use the formulas

$$v=-2\frac{\tilde{f}_x}{\tilde{f}},\quad \tilde{f}=\exp\left(-\frac{1}{2}\partial_x^{-1}v\right); \tag{60}$$

$$\tilde{v}=2\frac{f_x}{f},\quad f=\exp\left(\frac{1}{2}\partial_x^{-1}\tilde{v}\right). \tag{61}$$

It is also possible to consider special Combescure transformations, keeping invariant the KP equation (the dual KP equation) wave functions [i.e., solutions for the dual mKP (mKP) equations]. The first invariants of this type are

$$\frac{\Phi'_x(\mathbf{x})}{\tilde{f}'(\mathbf{x})}=\frac{\Phi_x(\mathbf{x})}{\tilde{f}(\mathbf{x})}, \tag{62}$$

$$\frac{\Phi'_x(\mathbf{x})}{f'(\mathbf{x})}=\frac{\Phi_x(\mathbf{x})}{f(\mathbf{x})}. \tag{63}$$

All the hierarchies of the invariants of this type are generated by the expansion of the left part of the following relations over ϵ:

$$\left(\frac{\Phi(\mathbf{x}')-\Phi(\mathbf{x})}{\tilde{f}(\mathbf{x})}\right)=\epsilon f(\mathbf{x}'),\quad x'_i-x_i=\frac{1}{i}\epsilon^i; \tag{64}$$

$$\left(\frac{\Phi(\mathbf{x})-\Phi(\mathbf{x}')}{f(\mathbf{x})}\right)=\epsilon\tilde{f}(\mathbf{x}'),\quad x'_i-x_i=-\frac{1}{i}\epsilon^i. \tag{65}$$

Now let us consider the equation (39) and all the hierarchies given by the relation (18). This equation admits the Combescure group of symmetry transformations $\Phi(\rho(\lambda),\tilde{\rho}(\mu))\to\Phi'=\Phi(\rho'(\lambda),\tilde{\rho}'(\mu))$ consisting of two subgroups (the right and left Combescure transformations). These subgroups have the following invariants:

$$v=\frac{\Phi_y-\Phi_{xx}}{\Phi_x} \tag{66}$$

and

$$\tilde{v}=\frac{\Phi_y+\Phi_{xx}}{\Phi_x}. \tag{67}$$

From (34), (35) it follows that they just obey the mKP and dual mKP equation, respectively. The invariant for the full Combescure transformation can be obtained by the substitution of the expression for v via Φ (66) to the formula (56). It reads as

$$u=\partial_x^{-1}\left(\frac{\Phi_y}{\Phi_x}\right)_y-\frac{\Phi_{xxx}}{\Phi_x}+\frac{\Phi_{xx}^2-\Phi_y^2}{2\Phi_x^2}. \tag{68}$$

From (25), (26), (54), (55), (56), and (57) it follows that u solves the KP equation.

So there is an interesting connection between Eq. (39), mKP–dual mKP equations, and the KP equation. Equation (39) is the unifying equation. It possesses a Combescure symmetry transformations group. After the factorization of Eq. (39) with respect to one of the subgroups (right or left), one gets the mKP or dual mKP equation in terms of the invariants for the subgroup (66), (67). The factorization of Eq. (39) with respect to the full Combescure transformations group gives rise to the KP equation in terms of the invariant of group (68).

In other words, the invariant of Eq. (39) under the full Combescure group is described by the KP equation, while the invariants under the action of its right and left subgroups are described by the mKP or dual mKP equations.

VI. τ FUNCTION AND ADDITION FORMULAS

Now we will analyze the functional equations (13)–(17). Evaluating (16) at $a=0$, one gets

$$\chi(\lambda,\mu,\mathbf{x})=\frac{1}{\lambda-\mu}\,\frac{\lambda\chi(\lambda,0,\mathbf{x}+[\mu])}{\mu\chi(\mu,0,\mathbf{x}+[\mu])}, \tag{69}$$

and the relation

$$\frac{\lambda\chi(\lambda,0,\mathbf{x}+[\mu])}{\mu\chi(\mu,0,\mathbf{x}+[\mu])}=\frac{\mu\chi(0,\mu,\mathbf{x}-[\lambda])}{\lambda\chi(0,\lambda,\mathbf{x}-[\lambda])}. \tag{70}$$

Using the relation (40), one obtains from the above equation the relation which contains the function $\chi(\lambda,0,\mathbf{x})$ only. It is of the form

$$\chi(\lambda,0,\mathbf{x})\chi(\mu,0,\mathbf{x}-[\lambda])=\chi(\mu,0,\mathbf{x})\chi(\lambda,0,\mathbf{x}-[\mu]), \tag{71}$$

or, equivalently,

$$\frac{\chi(\lambda,0,\mathbf{x}-[\mu])}{\chi(\lambda,0,\mathbf{x})}=\frac{\chi(\mu,0,\mathbf{x}-[\lambda])}{\chi(\mu,0,\mathbf{x})}. \tag{72}$$

It is straightforward to check that Eqs. (14)–(17) are satisfied identically due to the formulas (69) and (71) or (72). So the problem is reduced to resolution of the functional equation (71) or (72).

Introducing the function $\phi(\lambda,\mu,\mathbf{x})=(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x})$ analytic in the unit disk we get

$$\chi(\lambda,\mu,\mathbf{x})=\frac{1}{\lambda-\mu}\,\frac{\phi(\lambda,0,\mathbf{x}+[\mu])}{\phi(\mu,0,\mathbf{x}+[\mu])}, \tag{73}$$

and the equation

$$\frac{T_\mu\phi(\lambda,0,\mathbf{x})}{\phi(\lambda,0,\mathbf{x})}=\frac{T_\lambda\phi(\mu,0,\mathbf{x})}{\phi(\mu,0,\mathbf{x})}, \tag{74}$$

where $T_\lambda f(\mathbf{x})=f(\mathbf{x}-[\lambda])$.

Remark: Note that for the function $R(a,b,\mathbf{x})=\phi(a,0,\mathbf{x}+[a]+[b])$, Eq. (15) implies

$$R(a,\lambda)R(\lambda,b)R(b,a)=R(a,b)R(b,\lambda)R(\lambda,a).$$

So the problem of resolution of Eqs. (14) and (15) is connected also with the functional equation which is of the form of the triangle (Yang–Baxter) equation, well known in the theory of quantum solvable models (see, e.g., Ref. 22).

A symmetric structure of Eq. (74) clearly suggests a substitution resolving it,

$$\phi(\lambda,0,\mathbf{x})=\frac{T_\lambda \tau(\mathbf{x})}{\tau(\mathbf{x})}=\frac{\tau(\mathbf{x}-[\lambda])}{\tau(\mathbf{x})}, \tag{75}$$

where $\tau(\mathbf{x})$ is an arbitrary function.

Using (69), we get

$$\chi(\lambda,\mu,\mathbf{x})=\frac{1}{(\lambda-\mu)}\frac{\tau(\mathbf{x}-[\lambda]+[\mu])}{\tau(\mathbf{x})}. \tag{76}$$

We would like to emphasize here that the functions $\phi(\lambda,0,\mathbf{x})$, $\phi(0,\mu,\mathbf{x})$ define, in fact, Baker–Akhiezer and dual (adjoint) Baker–Akhiezer functions which satisfy a standard Hirota bilinear identity [it follows directly from (4); the only minor difference with the common approach is that we work in the neighborhood of zero, not in the neighborhood of infinity]. The formula (75) for the Baker–Akhiezer function is well known (see Refs. 1–4). We have shown that expression (75) for the BA function implies expression (76) for the CBA function. So this point gives a connection to the standard technique. Expression (76) could serve as a definition to introduce the CBA function to the context of the Grassmannian technique (see also Refs. 15, 13). And we could refer to the known results, considering the question of the existence of the τ function providing a substitution (75) for the arbitrary BA function. But we prefer to give an independent proof here, because the use of functional equations for the CBA function makes this proof quite simple and elegant, and it also provides a new expression for the closed one-form defining the τ function.

To prove the existence of the τ function, we use Eq. (41) taken at $\lambda\to\mu$. Equation (41), in terms of the function χ, reads as

$$\Delta_1(b)\chi(\lambda,\mu,\mathbf{x})+\left(\frac{1}{\lambda-b}-\frac{1}{\mu-b}\right)\chi(\lambda,\mu,\mathbf{x})=\chi(\lambda,b,\mathbf{x})\chi(b,\mu,\mathbf{x}). \tag{77}$$

Taking $\lambda\to\mu$, we get

$$\Delta_1(\mu)\chi_{\mathrm{r}}(\lambda,\lambda,\mathbf{x})=\Delta_1(\lambda)\chi_{\mathrm{r}}(\mu,\mu,\mathbf{x})=\chi(\lambda,\mu,\mathbf{x})\chi(\mu,\lambda,\mathbf{x})+(\lambda-\mu)^{-2}, \tag{78}$$

where $\chi_{\mathrm{r}}(\lambda,\mu,\mathbf{x})=\chi(\lambda,\mu,\mathbf{x})-(\lambda-\mu)^{-1}$. This equation implies that there exists a function $\tau(\mathbf{x})$, such that

$$\Delta_1(\lambda)\ln\ \tau(\mathbf{x})=-\chi_{\mathrm{r}}(\lambda,\lambda,\mathbf{x}), \tag{79}$$

or, using the expansion in λ,

$$d\ \ln\ \tau(\mathbf{x})=-\sum_{n=1}^{\infty}\ \frac{\partial^{n-1}}{\partial\lambda^{n-1}}\chi_{\mathrm{r}}(\lambda,\lambda,\mathbf{x})\Big|_{\lambda=0}dx_n. \tag{80}$$

[(78) guarantees that the cross-derivatives are equal, or, in other words, that the form (80), defining the τ function, is closed].

Moreover, using (41), it is also possible to express the function $\chi(\lambda,\mu,\mathbf{x})$ through the τ function. Taking the limit $b\to\lambda$, one obtains

$$\Delta_1(\lambda)\chi(\lambda,\mu,\mathbf{x})+\left(\frac{\partial}{\partial\lambda}-\frac{1}{\mu-\lambda}\right)\chi(\lambda,\mu,\mathbf{x})=\chi_{\mathrm{r}}(\lambda,\lambda,\mathbf{x})\chi(\lambda,\mu,\mathbf{x}), \tag{81}$$

or, for the function $\phi(\lambda,\mu,\mathbf{x})=(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x})$, using the definition of the τ function (80),

$$\left(\Delta_1(\lambda)+\frac{\partial}{\partial\lambda}\right)\ln\ \phi(\lambda,\mu,\mathbf{x})=-\Delta_1(\lambda)\ln\ \tau(\mathbf{x}). \tag{82}$$

Equation (82) is a nonhomogeneous infinite-dimensional wave equation. A general solution for it is a sum of the general solution of a homogeneous equation and the special solution of a nonhomogeneous equation, it can be written as

$$\ln\ \phi(\lambda,\mu,\mathbf{x})=F(\mu,\mathbf{x}-[\lambda])-\ln\ \tau(\mathbf{x}). \tag{83}$$

Then, using the condition $\phi(0,0,\mathbf{x})=1$, one obtains

$$\phi(\lambda,0,\mathbf{x})=\frac{\tau(\mathbf{x}-[\lambda])}{\tau(\mathbf{x})}, \tag{84}$$

Q.E.D.

A similar argument leads to the formula

$$\phi(0,\mu,\mathbf{x})=\frac{\tau(\mathbf{x}+[\mu])}{\tau(\mathbf{x})}. \tag{85}$$

So the τ function that we have introduced by the definition (80) is a usual τ function of the KP hierarchy. The next step is to find the formula expressing the CBA function through the τ function; given the formula (84), we already have done it in the beginning of the section. So we have proved that there exists a τ function such that the CBA function is expressed through it by the formula (76).

Now we will use the general equation (13). Substituting (76) into (13), one gets

$$\begin{aligned}&(a-\mu)(\lambda-b)\tau(\mathbf{x}+[a]+[\mu])\tau(\mathbf{x}+[\lambda]+[b])+(\lambda-a)(\mu-b)\tau(\mathbf{x}+[\lambda]+[a])\tau(\mathbf{x}+[b]+[\mu])\\&\quad+(b-a)(\lambda-\mu)\tau(\mathbf{x}+[b]+[a])\tau(\mathbf{x}+[\lambda]+[\mu])=0.\end{aligned} \tag{86}$$

It is nothing but the simplest addition formula for the τ function derived in Ref. 1, which is closely connected with the Fay's trisecant formula.[23]

The generalized Hirota identity gives rise also to other addition formulas from Ref. 1. Indeed, let us choose in (4),

$$g(\mathbf{x})g^{-1}(\mathbf{x}')=\prod_{\alpha=1}^{n}\ \frac{\nu-a_\alpha}{\nu-b_\alpha}, \tag{87}$$

where n is an arbitrary integer and $\mathbf{x}'-\mathbf{x}=\Sigma_{\alpha=1}^{n}[a_\alpha]-[b_\alpha]$. In this case, Eq. (4) gives

$$\begin{aligned}&\prod_{\alpha=1}^{n}\ \frac{\mu-a_\alpha}{\mu-b_\alpha}\chi\left(\lambda,\mu,\mathbf{x}+\sum_{\alpha=1}^{n}\ [a_\alpha]\right)-\prod_{\alpha=1}^{n}\ \frac{\lambda-a_\alpha}{\lambda-b_\alpha}\chi\left(\lambda,\mu,\mathbf{x}+\sum_{\alpha=1}^{n}\ [b_\alpha]\right)+\sum_{\alpha=1}^{n}\ (b_\alpha-a_\alpha)\\&\times\prod_{\gamma,\gamma\neq\alpha}\ \frac{b_\alpha-a_\gamma}{b_\alpha-b_\gamma}\chi\left(\lambda,b_\alpha,\mathbf{x}+\sum_{\delta=1}^{n}\ [a_\delta]\right)\chi\left(b_\alpha,\mu,\mathbf{x}+\sum_{\delta=1}^{n}\ [b_\delta]\right)=0.\end{aligned} \tag{88}$$

Substituting the expression (76) into (88) and shifting $\mathbf{x}\to\mathbf{x}+[\lambda]$, one gets

$$\prod_{\alpha=1}^{n} \frac{(\mu-a_\alpha)}{(\mu-b_\alpha)(\mu-\lambda)} \tau\left(\mathbf{x}+[\mu]+\sum_{\gamma=1}^{n}[a_\gamma]\right)\tau\left(\mathbf{x}+[\lambda]+\sum_{\gamma=1}^{n}[b_\gamma]\right)$$

$$-\prod_{\alpha=1}^{n} \frac{(\lambda-a_\alpha)}{(\lambda-b_\alpha)(\lambda-\mu)} \tau\left(\mathbf{x}+[\mu]+\sum_{\gamma=1}^{n}[b_\gamma]\right)\tau\left(\mathbf{x}+[\lambda]+\sum_{\gamma=1}^{n}[a_\gamma]\right)$$

$$+\sum_{\alpha=1}^{n} \frac{(b_\alpha-a_\alpha)}{(b_\alpha-\mu)(\lambda-b_\alpha)} \prod_{\gamma,\gamma\neq\alpha} \frac{b_\alpha-a_\gamma}{b_\alpha-b_\gamma} \tau\left(\mathbf{x}+[b_\alpha]+\sum_{\beta=1}^{n}[a_\beta]\right)$$

$$\times\tau\left(\mathbf{x}+[\lambda]+[\mu]+\sum_{\beta,\beta\neq\alpha}[b_\beta]\right)=0. \tag{89}$$

It is not difficult to check (after some renotations) that Eq. (89) coincides with the Plücker's relations for a universal Grassmannian manifold (see Theorem 3 of Ref. 1). That means, according to Theorems 1–3 of the paper,[1] that τ is the τ function of the KP hierarchy. Note that the formulas (76), (89) provide solutions simultaneously for the KP, mKP (dual mKP), and SM-KP hierarchies.

VII. DETERMINANT FORMULAS FOR TRANSFORMATIONS

The analytic-bilinear approach allows us to represent in a compact form, not only the integrable hierarchies but also rather general transformations acting in the space of solutions.

We will consider here the transformations which are equivalent to the action of an arbitrary meromorphic function $g(\lambda)$ on the CBA function $\chi(\lambda,\mu,x)$. Let $g(\lambda)$ be a meromorphic function in G which has simple poles at the points a_i $(i=1,2,\ldots,n)$ and simple zeros at the points b_i $(i=1,2,\ldots,n)$, i.e., $g(\lambda)=\Pi_{i=1}^{n}(\lambda-a_i)/(\lambda-b_i)$. To construct the transformed CBA function $\chi^\dagger(\lambda,\mu)$, it is sufficient to find a solution of the equation

$$\int_{\partial G}\chi(\nu,\mu)g(\nu)\chi^\dagger(\lambda,\nu)d\nu=0,$$

where $\chi^\dagger$ has the same normalization $((\lambda-\mu)^{-1})$ as χ.

The simplest way to find $\chi^\dagger$ consists in using the following consequence of Eq. (4),

$$\int_{\partial G}\int_{\partial G} d\nu\, d\rho\ \chi(\nu,\mu)g(\nu)\chi^\dagger(\rho,\nu,g)g^{-1}(\rho)\chi(\lambda,\rho)=0.$$

Using this formula, one finds

$$\chi^\dagger(\lambda,\mu)=g^{-1}(\lambda)g(\mu)\frac{\det\Delta_{n+1}}{\det\Delta_n}, \tag{90}$$

where

$$\Delta_{m,\alpha\beta}=\chi(a_\alpha,b_\beta),\quad \alpha,\beta=1,2,\ldots,m,$$

and $a_{n+1}=\lambda$, $b_{n+1}=\mu$.

The formula (90) defines the generic discrete transformation of χ. In terms of the τ function, this transformation has the form

$$\frac{\tau^\dagger(\mathbf{x}-[\lambda]+[\mu])}{\tau^\dagger(\mathbf{x})}=(\lambda-\mu)g^{-1}(\lambda)g(\mu)\frac{\det F_{n+1}}{\tau(\mathbf{x})\det F_n},$$

where

$$F_{n,\alpha\beta}=\frac{\tau(\mathbf{x}-[a_\alpha]+[b_\beta])}{a_\alpha-b_\beta}.$$

In the simplest case $n=1$, we have ($b_1=b$, $a_1=a$)

$$\chi^{\dagger}(\lambda,\mu)=\frac{(\lambda-b)(\mu-a)}{(\lambda-a)(\mu-b)}\frac{\begin{vmatrix}\chi(a,b) & \chi(a,\mu)\\ \chi(\lambda,b) & \chi(\lambda,\mu)\end{vmatrix}}{\chi(a,b)} \tag{91}$$

and

$$\frac{\tau^{\dagger}(\mathbf{x}-[\lambda]+[\mu])}{\tau^{\dagger}(\mathbf{x})}=\frac{(\lambda-\mu)(a-b)(\lambda-b)(\mu-a)}{(\lambda-a)(\mu-b)}\frac{\begin{vmatrix}\dfrac{\tau(\mathbf{x}-[a]+[b])}{a-b} & \dfrac{\tau(\mathbf{x}-[a]+[\mu])}{a-\mu}\\ \dfrac{\tau(\mathbf{x}-[\lambda]+[b])}{\lambda-b} & \dfrac{\tau(\mathbf{x}-[\lambda]+[\mu])}{\lambda-\mu}\end{vmatrix}}{\tau(\mathbf{x})\,\tau(\mathbf{x}-[a]+[b])},$$

where $|A|=\det A$. One can represent the transformations (90) also in terms of the function $\psi(\lambda,\mu)$. In that form the determinant formulas (90) taken at $\lambda=0$ or $\mu=0$ are very similar to the determinant formulas for the iterated Darboux transformations (see, e.g., Ref. 24). The formulas (90) give us the Darboux transformations for all subhierarchies (KP, mKP, dual mKP, SM-KP hierarchies) of the generalized KP hierarchy.

The determinant formulas (90) provide us also the multilinear relations for the τ function. Since $\tau^{\dagger}(\mathbf{x})=\tau(\mathbf{x}+\Sigma_{i=1}^{n}(-[a_i]+[b_i]))$, the formula (90) is the n-linear relation for the τ function. It is easy to check that in the simplest case $n=1$ this formula gives the simplest addition formula (86). At $n=2$ the formula looks like

$$\tau(\mathbf{x})\,\tau(\mathbf{x}-[\lambda]+[\mu]+[b_1]-[a_1]+[b_2]-[a_2])\times\begin{vmatrix}\dfrac{\tau(\mathbf{x}-[a_1]+[b_1])}{a_1-b_1} & \dfrac{\tau(\mathbf{x}-[a_1]+[b_2])}{a_1-b_2}\\ \dfrac{\tau(\mathbf{x}-[a_2]+[b_1])}{a_2-b_1} & \dfrac{\tau(\mathbf{x}-[a_2]+[b_2])}{a_2-b_2}\end{vmatrix}$$

$$=\frac{(\lambda-\mu)(\mu-a_1)(\mu-a_2)(\lambda-b_1)(\lambda-b_2)}{(\mu-b_1)(\mu-b_2)(\lambda-a_1)(\lambda-a_2)}\,\tau(\mathbf{x}+[b_1]-[a_1]+[b_2]-[a_2])$$

$$\times\begin{vmatrix}\dfrac{\tau(\mathbf{x}-[\lambda]+[\mu])}{\lambda-\mu} & \dfrac{\tau(\mathbf{x}-[\lambda]+[b_1])}{\lambda-b_1} & \dfrac{\tau(\mathbf{x}-[\lambda]+[b_2])}{\lambda-b_2}\\ \dfrac{\tau(\mathbf{x}-[a_1]+[\mu])}{a_1-\mu} & \dfrac{\tau(\mathbf{x}-[a_1]+[b_1])}{a_1-b_1} & \dfrac{\tau(\mathbf{x}-[a_1]+[b_2])}{a_1-b_2}\\ \dfrac{\tau(\mathbf{x}-[a_2]+[\mu])}{a_2-\mu} & \dfrac{\tau(\mathbf{x}-[a_2]+[b_1])}{a_2-b_1} & \dfrac{\tau(\mathbf{x}-[a_2]+[b_2])}{a_2-b_2}\end{vmatrix}. \tag{92}$$

It is cumbersome but straightforward to check that the relation (92) is satisfied due to the higher addition formulas (89) with $n=2$.

VIII. τ FUNCTION AS A FUNCTIONAL

The formula (76) can be written both for the variables $\mathbf{x}$ and in terms of the function g (g is defined on the unit circle); in the second case the τ function is treated as a functional of the function g,

$$\chi(\lambda,\mu;g)=\frac{\tau(g\times g_{(\lambda,\mu)})}{\tau(g)(\lambda-\mu)} \tag{93}$$

(see Ref. 13), where $g_{(\lambda,\mu)}(\nu)=(\nu-\lambda)/(\nu-\mu)$. The expression in terms of g will be important for the second part of our paper to transfer the notion of the τ function to the multicomponent case. So in this section we will give independent proof of the unique existence of the τ function, providing an expression (93) for an arbitrary CBA function (in the class of g analytic and having

no zeros outside the unit circle, normalized by 1 at infinity). A definition of the τ function in terms of a closed variational one-form arises in this context. The second part of the proof (existence) could be conducted similar to the proof in Sec. VI, but here we prefer to give a straightforward calculation to demonstrate some peculiar features of the direct derivation (especially the use of a determinant formula).

Differentiating (93) with respect to λ, one obtains

$$-\frac{1}{\tau(g)} \oint \frac{\delta\tau(g\times g_{(\lambda,\mu)})}{\delta \ln g(\nu)} \frac{1}{\nu-\lambda} d\nu = \frac{\partial}{\partial\lambda}(\lambda-\mu)\chi(\lambda,\mu;g), \tag{94}$$

or for $\lambda=\mu$

$$-\frac{1}{\tau(g)} \oint \frac{\delta\tau(g)}{\delta \ln g(\nu)} \frac{1}{\nu-\lambda} d\nu = \chi_{\mathrm{r}}(\lambda,\lambda;g), \tag{95}$$

where $\chi_{\mathrm{r}}(\lambda,\mu;g)=\chi(\lambda,\mu;g)-(\lambda-\mu)^{-1}$. This equation can be rewritten in the form

$$-\frac{1}{\tau(g)} \oint \frac{\delta\tau(g)}{\delta \ln g(\nu)} \frac{1}{\nu-\lambda} d\nu = \oint \chi_{\mathrm{r}}(\nu,\nu;g) \frac{1}{\nu-\lambda} d\nu. \tag{96}$$

Relation (96) implies that the functionals $-[1/\tau(g)][\delta\tau(g)/\delta \ln g(\nu)]$ and $\chi_{\mathrm{r}}(\nu,\nu;g)$ are identical for the class of functions analytic outside the unit circle and decreasing at infinity. Thus, for $\delta g/g$ belonging to this class, one has

$$-\delta \ln \tau(g) = \oint \chi_{\mathrm{r}}(\nu,\nu;g) \frac{\delta g(\nu)}{g(\nu)} d\nu. \tag{97}$$

This expression gives a variational 1-form defining the τ function. It is easy to prove using the identity (4) that this form is *closed*. Indeed, according to (4),

$$\delta\chi(\lambda,\mu;g) = \oint \chi(\nu,\mu;g) \frac{\delta g(\nu)}{g(\nu)} \chi(\lambda,\nu;g) d\nu,$$

$$\delta\chi_{\mathrm{r}}(\lambda,\lambda;g) = \oint \chi_{\mathrm{r}}(\nu,\lambda;g) \frac{\delta g(\nu)}{g(\nu)} \chi_{\mathrm{r}}(\lambda,\nu;g) d\nu. \tag{98}$$

So the variation of (97) gives

$$-\delta^2 \ln \tau(g) = \oint \oint \chi_{\mathrm{r}}(\nu,\lambda;g)\chi_{\mathrm{r}}(\lambda,\nu;g) \frac{\delta' g(\nu)}{g(\nu)} \frac{\delta g(\lambda)}{g(\lambda)} d\nu\, d\lambda. \tag{99}$$

The symmetry of the kernel of second variation with respect to λ, ν implies that the form (97) is closed.

So the formula (97) gives the definition of the τ function in terms of the closed 1-form (and also proves the uniqueness of the τ function satisfying the formula (93)].

For the standard KP coordinates,

$$\frac{\delta g(\lambda)}{g(\lambda)} = \sum_{n=1}^{\infty} \frac{dx_n}{\lambda^n}.$$

This formula allows us to obtain a closed 1-form in terms of dx_n,

$$-\delta \ln \tau(\mathbf{x}) = \sum_{n=1}^{\infty} \frac{\partial^{n-1}}{\partial\nu^{n-1}} \chi_{\mathrm{r}}(\nu,\nu;\mathbf{x})\Big|_{\nu=0} dx_n, \tag{100}$$

which coincides with the expression (80). For $x=x_1$ this formula immediately gives the standard formula

$$\frac{\partial^2}{\partial x^2}\ln\,\tau=\frac{1}{2}u,$$

where u is a solution for the KP equation.

It is possible to prove that the function τ defined as the solution of the relation (97) satisfies the global formula (93) (existence). To do this, we will show, using the formula (97), that the derivatives of the difference of logarithms of the LHS and the RHS of the expression (93) with respect to $\lambda,\mu,\bar{\lambda},\bar{\mu},$ and the variation with respect to $g,$ are equal to zero for arbitrary λ,μ,g. That means that the LHS and RHS of (76) could differ only by the factor, and the normalization of the function χ implies that this factor is equal to 1.

First we will calculate the derivative with respect to λ,

$$\begin{aligned}&\frac{\partial}{\partial\lambda}(\ln\,\chi(\lambda,\mu)(\lambda-\mu)-\ln\,\tau(g\times g_{(\lambda,\mu)})+\ln\,\tau(g))\\&\quad=\frac{\partial}{\partial\lambda}\ln\,\chi(\lambda,\mu)(\lambda-\mu)+\oint\chi_{\mathrm{r}}(\nu,\nu;g\times g_{(\lambda,\mu)})\,\frac{1}{\lambda-\nu}d\nu\\&\quad=\frac{\partial}{\partial\lambda}\ln\,\chi(\lambda,\mu)(\lambda-\mu)+\chi_{\mathrm{r}}(\lambda,\lambda;g\times g_{(\lambda,\mu)}).\end{aligned}\tag{101}$$

The second term can be found in terms of $\chi(\lambda,\mu;g)$ using the determinant formula (91). The formula (91) gives

$$\chi(\lambda,\mu;g\times g_{(\lambda,\mu')})=\frac{(\lambda-\mu')(\mu-\lambda)}{\mu-\mu'}\,\frac{\det\begin{pmatrix}\chi(\lambda,\mu;g) & \chi(\lambda,\mu';g)\\ \frac{\partial}{\partial\lambda}\chi(\lambda,\mu;g) & \frac{\partial}{\partial\lambda}\chi(\lambda,\mu';g)\end{pmatrix}}{\chi(\lambda,\mu';g)}.\tag{102}$$

Taking the regular part of this formula at $\mu=\lambda$, one immediately obtains that the expression (101) is equal to zero.

The case with the derivative over μ is analogous; derivatives over $\bar{\lambda}$ and $\bar{\mu}$ immediately give zero. So now we proceed to the calculation of variation,

$$\begin{aligned}&\delta(\ln\,\chi(\lambda,\mu)(\lambda-\mu)-\ln\,\tau(g\times g_{(\lambda,\mu)})+\ln\,\tau(g))\\&\quad=\frac{1}{\chi(\lambda,\mu)}\oint\chi(\nu,\mu;g)\frac{\delta g(\nu)}{g(\nu)}\chi(\lambda,\nu;g)d\nu\\&\qquad-\oint\chi_{\mathrm{r}}(\nu,\nu;g\times g_{(\lambda,\mu)})\,\frac{\delta g(\nu)}{g(\nu)}d\nu+\oint\chi(\nu,\nu;g)\frac{\delta g(\nu)}{g(\nu)}d\nu\end{aligned}\tag{103}$$

[we have used (98) and (97)]. Using the determinant formula (90) to transform the second term, one concludes that the variation is equal to zero.

Below we will give a brief sketch of the derivation of a 1-form in terms of the Baker–Akhiezer function. Differentiation of (76) (with shifted arguments) with respect to λ and μ gives

$$\left(\frac{\partial}{\partial\lambda}+\frac{\partial}{\partial x_1(\lambda)}\right)\ln[(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x})]=-\frac{\partial}{\partial x_1(\lambda)}\ln\,\tau(\mathbf{x}),\tag{104}$$

$$\left(\frac{\partial}{\partial\mu}-\frac{\partial}{\partial x_1(\mu)}\right)\ln[(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x})]=\frac{\partial}{\partial x_1(\mu)}\ln\,\tau(\mathbf{x}),\tag{105}$$

where $\partial/\partial x_1(\lambda)=\Sigma_{n=1}^{\infty}\lambda^{n-1}(\partial/\partial x_n)$. Equation (104) implies that

$$\frac{\partial}{\partial x_n}\ln\ \tau(\mathbf{x}) = -\frac{1}{(n-1)!}\frac{\partial^{n-1}}{\partial\lambda^{n-1}}\left(\left(\frac{\partial}{\partial\lambda}+\frac{\partial}{\partial x_1(\lambda)}\right)\ln[(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x})]\right)\Bigg|_{\lambda=0}.$$

Hence, we have the closed 1-form ω,

$$\omega(\mathbf{x},d\mathbf{x}) = -\sum_{n=1}^{\infty}\ \frac{1}{(n-1)!}\frac{\partial^{n-1}}{\partial\lambda^{n-1}}\left(\left(\frac{\partial}{\partial\lambda}+\frac{\partial}{\partial x_1(\lambda)}\right)\ln[(\lambda-\mu)\chi(\lambda,\mu,\mathbf{x})]\right)\Bigg|_{\lambda=0} dx_n, \quad (106)$$

and $\omega = d\ \ln\ \tau$. A similar expression for ω can be obtained using (105). At $\mu = 0$ the formula (106) is equivalent to the formula found in Ref. 3.

(Received 9 June 1997; accepted for publication 4 September 1997)

An analytic-bilinear approach for the construction and study of integrable hierarchies is discussed. Generalized multicomponent KP and 2D Toda lattice hierarchies are considered. This approach allows us to represent generalized hierarchies of integrable equations in a condensed form of finite functional equations. A generalized hierarchy incorporates basic hierarchy, modified hierarchy, singularity manifold equation hierarchy, and corresponding linear problems. Different levels of generalized hierarchy are connected via invariants of Combescure symmetry transformation. The resolution of functional equations also leads to the τ function and addition formulas to it. © *1998 American Institute of Physics.*

I. INTRODUCTION

The Kadomtsev–Petviashvili (KP) equation and the whole KP hierarchy as well as the multicomponent KP and two-dimensional Toda lattice hierarchies are among the most important ingredients of the theory of integrable partial differential equations. They arise in various fields of physics from hydrodynamics to string theory.

Integrable hierarchies have been described and studied within the framework of different approaches. The Sato approach[1–6] and the $\bar{\partial}$-dressing method (see Refs. 7–9 and a review[10]) are among the most beautiful and powerful among them. These two approaches look completely different. The Sato approach is in essence algebraic with its infinite-dimensional Grassmannian, pseudodifferential operators, the Hirota bilinear identity, and the τ function. In contrast, the $\bar{\partial}$-dressing method, based on the nonlocal $\bar{\partial}$ problem, mostly uses the technique of the complex variable theory.

Recently we proposed (Refs. 11, 12) an approach which combines the characteristic features of both these methods, namely, the Hirota bilinear identity from the Sato approach and analytic properties of the wave functions from the $\bar{\partial}$-dressing method. This analytic-bilinear approach is based on the generalized Hirota bilinear identity for the wave function $\psi(\lambda,\mu)$ with simple analytic properties [the Cauchy–Baker–Akhiezer (CBA) function]. The CBA function [or, to be more precise, its ''nonsingular part'' $\chi(\lambda,\mu)$] is defined in some region G of the complex plane and it is characterized by the generalized Hirota bilinear identity on the boundary of this region.[13] The CBA function arises both in the $\bar{\partial}$-dressing method[8] and in the finite gap integration method,[14] and it can be introduced also in the context of the general Grassmannian approach.[1,6]

According to the generalized Hirota bilinear identity, the CBA function is a functional of the function g defined on the boundary of G (in fact, g is a map of ∂G to $\mathbb{C}^{\times}$ (i.e., $\mathbb{C}-0$), or, in other words, it is an element of the loop group). One can choose some special subgroups of the generic loop group parametrized by a finite number of variables (''times'') to get particular examples of integrable equations. This is a standard approach in the $\bar{\partial}$-dressing method. One may also try to use some generic loop group and extract a full infinite set of equations. So the notion of the hierarchy arises. The dependence of the CBA function on g encodes the dynamics of the system. The hierarchy can be written down in variational form, i.e., as equations describing variations of

the objects of theory under the arbitrary variation of group element g. To get a hierarchy in terms of times, one should introduce a parametrization of the loop group.

The distinctive feature of an analytic-bilinear approach is that our primary object is the CBA function and hierarchies are written in the form of equations for the CBA function (we call these equations *generalized* hierarchies). The analytic-bilinear approach allows us to describe generalized hierarchies in a compact finite form. Such a generalized hierarchy contains a basic integrable hierarchy, a hierarchy of equations for wave functions (modified hierarchy), and a hierarchy of equations for CBA-type wave functions (we call it the singularity manifold equations (SM) hierarchy, because in the scalar KP case it coincides with the singularity manifold equations obtained from the Painleve analysis of KP; however, our context is completely different), and corresponding linear problems. The relation between three hierarchies of equations can be described in terms of invariants of the Combescure symmetry group (Refs. 11, 12).

The generalized Hirota bilinear identity provides various functional equations for the CBA function. The resolution of some of them leads to the introduction of the τ function, while others give rise to the addition theorems for the τ function. The properties of the τ function, such as the associated closed 1-form and its global definition also arise in a simple manner within the analytic-bilinear approach.

The first part of this paper[12] was devoted to the scalar KP hierarchy. In this case G is just a domain of the complex plane. Without the loss of generality, we choose G as a unit disc. The group element g is defined on the unit circle and can be represented in a form

$$g(\lambda)=\lambda^n g_{\text{in}}\times g_{\text{out}},$$

where n is the index of the function, g_{in} and g_{out} are functions analytic and having no zeros, respectively, inside (outside) the unit circle on the complex plane (i.e., elements of the loop groups Γ_- and Γ_+). In the scalar KP hierarchy case, we have no opportunity to treat the index variable without some additional construction, so we put the index to zero. The functions g_{out} and g_{in} are parametrized in a standard way by infinite sets of ''positive'' and ''negative'' times. But it appears that in the scalar KP hierarchy case the dependence of the objects of theory on g_{in} (i.e., on negative times in our notations) is trivial, so the scalar KP hierarchy is defined effectively by the subgroup Γ_+ of the loop group Γ.

In the second part of this paper we consider the generalized multicomponent KP hierarchy and the two-dimensional Toda lattice hierarchy (for other approaches to the usual multicomponent KP hierarchy and 2D Toda lattice hierarchy see Refs. 1, 2, 4, 5, 15, 16).

There are two equivalent approaches to investigating a multicomponent hierarchy. One could start with the generalized Hirota identity for the matrix-valued CBA function. In this case G is again a unit disc, and g is a diagonal matrix function on the unit circle (i.e., a set of N functions g_n). Another way is to start with the scalar CBA function defined in the region G consisting of N disconnected domains (unit discs for simplicity). In this case the dynamics is also defined by the set of N functions g_n, and the CBA function consists, in fact, of $N\times N$ disconnected components. These two representations are exactly equivalent and are associated with the multicomponent loop group Γ^N. In our paper we will use both of them.

As in the scalar case, the objects of multicomponent KP theory depend trivially on the subgroup Γ_-^N. The difference with the scalar case consists of the presence of discrete variables (indices), though only the lattice vectors with a zero general index are admissible.

Since the generalized Hirota bilinear identity is our primary object, it is quite natural to proceed from the hierarchy corresponding to the simplest choice of G—the unit disk—to the hierarchies corresponding to G consisting of several unit discs, i.e., from the scalar KP hierarchy to the multicomponent KP hierarchy. But on the other hand, the loop group is also a fundamental object of the theory, so one would like to find a hierarchy with a full-scale action of the generic loop group on the objects of theory. This hierarchy is known as the Toda lattice hierarchy. In our approach it can be introduced as a two-component KP hierarchy with the special choice of G consisting of two discs with the common boundary (the unit circle): one disc around the origin and one disc around infinity. In this case, up to some trivial dynamics, one can glue two special loops defining the two-component KP hierarchy to obtain a generic loop. In the case of a Toda lattice

hierarchy the discrete index variable, positive and negative time variables, get their natural interpretation.

We first consider the multicomponent KP hierarchy. We start with the generalized Hirota identity for the matrix-valued CBA function and derive various finite functional equations for this function. Part of these functional equations present the compact form of the generalized multicomponent KP hierarchy which includes equations for potentials (the standard multicomponent KP hierarchy), equations for the wave functions (the modified multicomponent KP hierarchy), equations for CBA-type wave functions (singularity manifold equation hierarchy), and corresponding linear problems.

Resolution of functional equations introduces the set of τ functions. We discuss also the associated closed 1-form and its global definition. The simplest integrable systems are given by the resonantly interacting wave equations and by the scalar Darboux system which is its modified partner.

We present a compact form of *equations* of multicomponent KP hierarchy, the modified KP hierarchy, and the singularity manifold equation hierarchy, using shift operators. Similar formulas for the first two cases can be found in Ref. 17.

The two-component case which corresponds to the generalized Davey–Stewartson (DS) hierarchy is considered in detail.

The description of the generalized Toda lattice hierarchy within the analytic-bilinear approach requires minor modifications of the multicomponent KP case. For simplicity we consider here only the Abelian Toda lattice hierarchy. It appears that a modified Toda lattice equation (i.e., the equation for the Toda lattice wave functions) coincides with the 2D Volterra system,[18] which was recently discussed in the literature in different contexts.[19,20] We derive a 2D Toda lattice singularity manifold equation, which was also discussed in Ref. 21. The invariants of the Combescure transformations group (Refs. 11, 12) are found. We also present the hierarchies of equations using shift operators.

The paper is organized as follows. The generalized Hirota bilinear identity and some basic formulas are discussed in Sec. II. A generalized multicomponent KP hierarchy is considered in Sec. III. Compact forms of equations of generalized multicomponent KP hierarchy are presented in Sec. IV. Section V is devoted to the generalized DS hierarchy. The τ function for the DS hierarchy is introduced in Sec. VI. The τ function and corresponding addition formulas for the multicomponent KP hierarchy are considered in Sec. VII. A closed variational 1-form and the global definition for the τ function are given in Sec. VIII. The basic equations for the generalized 2D Toda lattice hierarchy are derived in Sec. IX. Concrete equations associated with the generalized 2DTL hierarchy are presented in Sec. X. Addition formulas for the 2DTL hierarchy are given in Sec. XI.

II. GENERALIZED HIROTA IDENTITY, FUNCTIONAL EQUATIONS, AND GENERALIZED MULTICOMPONENT KP HIERARCHY

The analytic-bilinear approach starts with the generalized Hirota bilinear identity,

$$\int_{\partial G}\chi(\nu,\mu;g_1)g_1(\nu)g_2^{-1}(\nu)\chi(\lambda,\nu;g_2)d\nu=0, \tag{1}$$

where $\chi(\lambda,\mu;g)$ is the CBA function normalized by the condition $\chi\to(\lambda-\mu)^{-1}$ as $\lambda\to\mu$ and $\chi(\lambda,\mu)$ is an analytic function of both variables λ,μ for $\lambda\neq\mu$ in the domain G with the boundary ∂G. The quantity $g=g(\lambda,\boldsymbol{x})$ specifies the dependence on the infinite set of dynamical variables $\boldsymbol{x}=(x_1,x_2,\dots)$. In terms of the wave function $\psi(\lambda,\mu;g)$ defined via

$$\psi(\lambda,\mu;g)=g^{-1}(\mu)\chi(\lambda,\mu;g)g(\lambda), \tag{2}$$

the generalized Hirota bilinear identity looks like

$$\int_{\partial G}\psi(\nu,\mu;g_1)\psi(\lambda,\nu;g_2)d\nu=0. \tag{3}$$

Note that the generalized Hirota bilinear identity is bilocal both in dynamical and spectral variables.

In this paper we consider the case for which χ and ψ take their value in the full linear group $\mathrm{GL}(N,\mathbb{C})$, G is a unit disc with a center $\lambda=0$. Elements $g(\lambda,\boldsymbol{x})$ belong to maximal Abelian subgroup of $\mathrm{GL}(N,\mathbb{C})$.

It is important to note that there is an alternative way to treat the matrix problem (1), starting from the *scalar* identity but with the region G consisting of several disconnected domains. In this case one has to choose domain G consisting of N unit discs D_α with the center at $\lambda=0$. Now the scalar CBA function effectively consists of $N\times N$ disconnected components and can be interpreted as a matrix function defined on the unit disc:

$$\chi_{\alpha\beta}(\lambda,\mu)=\chi(\lambda,\mu),\quad \lambda\in D_\beta,\quad \mu\in D_\alpha. \tag{4}$$

The function g in this framework is a set of N functions defined on the unit circle. Thus, rewriting the scalar identity in matrix notations, we get *exactly* the same matrix generalized Hirota identity, where g is a diagonal matrix.

So the matrix structure in the scalar case is hidden in the multicomponent domain of the definition of the CBA function. The advantage of the scalar treatment is the opportunity to preserve most of the structure of the one-component KP hierarchy case almost intact and to use geometric intuition in the matrix case. We will use both representations of the generalized Hirota identity in the paper.

The dependence on dynamical variables is hidden in the set of N functions g defined on the unit circle. The most natural choice would be to treat sets of arbitrary functions on the circle having no zeros, forming the group by multiplication. Arbitrary g can be represented in the form

$$g(\lambda)=\lambda^n g_{\mathrm{in}}\times g_{\mathrm{out}},$$

where discrete variable n is the index of the function, g_{in} and g_{out} are functions analytic and having no zeros, respectively, inside (outside) the unit circle on the complex plane. We will use the following parametrization for g_{in} and g_{out}:

$$g_{\alpha\ \mathrm{out}}=\exp\left(\sum_{n=1}^{\infty} x_{(\alpha)n}\lambda^{-n}\right), \tag{5}$$

$$g_{\alpha\ \mathrm{in}}=\exp\left(\sum_{-\infty}^{n=-1} x_{(\alpha)n}\lambda^{-n}\right). \tag{6}$$

In these formulas we have omitted ''the zero time'' x_0, that defines simply some constant factor in front of g and, according to (1), it does not change the function χ.

So, in the general case the set of functions g_α can be parametrized by N discrete times n_α and N infinite sets of continuous variables $x_{(\alpha)n}$, $n\in\mathbb{Z}$. But in the case of the KP hierarchy the dependence of the function $\chi(\lambda,\mu;g)$ on g_{in} (in other words, on the ''negative times'') is trivial; according to (1) (the ''scalar'' form), we get

$$\chi(\lambda,\mu;g\times g_{\mathrm{in}})=g_{\mathrm{in}}^{-1}(\mu)\chi(\lambda,\mu;g)g_{\mathrm{in}}(\lambda). \tag{7}$$

It occurs that other important objects (KP solution, τ function) also depend on negative times trivially. Thus, for simplicity, from the very beginning we omit the dependence on the negative times.

As for discrete times, we will see that the case of multicomponent KP hierarchy allows only sets of discrete times with the zero general index ($\sum_{\alpha=1}^{N} n_\alpha=0$).

So the case of multicomponent KP hierarchy seems a bit asymmetric with respect to positive and negative times, and it also does not allow us to consider arbitrary lattice vectors of discrete times. The most natural way to resolve these problems is to consider the multicomponent Toda-lattice hierarchy (see below). The objects of the Toda lattice hierarchy have a natural dependence on positive, negative, and discrete times.

To find special solutions for (1), one may use some additional construction (e.g., a $\bar{\partial}$-dressing method or algebro-geometric technique). But it is possible to develop a procedure of solving (1) in terms of (1) itself. In this case the function $\chi(\lambda,\mu,g=1)=\chi_0(\lambda,\mu)$ should be treated as initial data, and one can start from arbitrary $\chi_0(\lambda,\mu)$ possessing the necessary analytical properties. Then the dynamics of the function $\chi(\lambda,\mu)$ can be defined via the variational form of identity (1),

$$\delta\chi(\lambda,\mu;g)=\oint \chi(\nu,\mu;g)\frac{\delta g(\nu)}{g(\nu)}\chi(\lambda,\nu;g)d\nu. \tag{8}$$

So the problem of solving (1) is reduced to (infinite number in terms of variables x_n) differential equations with an initial condition. Taking the second variation in $\delta(\ln g)$, it is easy to prove that this system is self-consistent (i.e., the cross-derivatives are equal), and it is a correctly defined variational equation for the function $\chi(\lambda,\mu,g)$. Going further, one could take higher variational derivatives (all of them have a very simple form) and represent a formal solution in terms of a Taylor-type series.

Another approach to solving (1) is to extract from it some linear integral equations. Indeed, let us choose some initial condition $\chi_0(\lambda,\mu)$. Then for the function $\chi(\lambda,\mu,g)$ from (1) we have a pair of equations,

$$\int_{\partial G}\chi(\nu,\mu;g)g(\nu)\chi_0(\lambda,\nu)d\nu=0, \tag{9}$$

$$\int_{\partial G}\chi_0(\nu,\mu)g^{-1}(\nu)\chi(\lambda,\nu;g)d\nu=0. \tag{10}$$

These relations can be interpreted as linear integral equations for the function $\chi(\lambda,\mu;g)$; integral equations of such a type arise in the context of a nonlocal Riemann problem. Using the technique developed in Ref. 13, one may show that if both of these equations are solvable [in the class of functions $\chi(\lambda,\mu)$ with the analytical properties specified above, here they play a role of *normalization*], then the solution for both equations is the same and it is unique.

There is a very important class of functions g corresponding to some special discrete transformations—meromorphic functions—for which the dynamics can be found explicitly. Namely, the solution for both equations (9), (10) exists (and it is unique), if and only if the meromorphic function g has an equal number of zeros and poles in G (taking into account the multiplicity), and it is given by the determinant formula.[13] This statement means that the dependence of χ on discrete (index) variables is correctly defined for the *zero general index case* and, moreover, it can be represented in explicit form.[13]

III. GENERALIZED MULTICOMPONENT KP HIERARCHY

Proceeding with the multicomponent KP case, we choose the following parametrization for g_{out} (matrix representation):

$$g(\lambda,\boldsymbol{x})=\exp\left[\sum_{\alpha=1}^{N}\sum_{n=1}^{\infty}\frac{E_\alpha}{\lambda^n}x_{(\alpha)n}\right], \tag{11}$$

where the matrices E_α form a basis of the commutative subalgebra of diagonal matrices: $(E_\alpha)_{\beta\gamma}=\delta_{\alpha\beta}\delta_{\beta\gamma}$ $(\alpha,\beta,\gamma=1,\ldots,N)$. So we have an N infinite series of dynamical variables $x_{(\alpha)n}$.

Equations (1) or (3) with g of the form (11) generically define the multicomponent KP hierarchy. To extract from them finite functional equations similar to the scalar case we consider the Hirota identity (1) for the dynamical variables $x'_{(\alpha)n}$ and $x_{(\alpha)n}$ related in a special way, namely,

$$x'_{(\alpha)n}-x_{(\alpha)n}=\frac{1}{n}a_\alpha^n-\frac{1}{n}b_\alpha^n, \tag{12}$$

where a_α, b_α $(0\geqslant\alpha\geqslant N)$ are arbitrary parameters. We will also use vector notations $\boldsymbol{x}=(\boldsymbol{x}_{(1)},\ldots,\boldsymbol{x}_{(N)})$, $\boldsymbol{x}_{(\alpha)}=(x_{(\alpha)1},x_{(\alpha)2},\ldots)$. In these terms the preceding formula looks like

$$\boldsymbol{x}'_{(\alpha)}-\boldsymbol{x}_{(\alpha)}=[a_\alpha]-[b_\alpha], \tag{13}$$

or

$$\boldsymbol{x}'-\boldsymbol{x}=[\boldsymbol{a}]-[\mathbf{b}], \tag{14}$$

where $[\boldsymbol{a}]_{(\alpha)i}=(1/i)\,a_\alpha^i$. For such x and x' due to the formula $\log(1-\epsilon)=-\Sigma_{n=1}^{\infty}(\epsilon^n/n)$ one has

$$(g_1(\nu)g_2^{-1}(\nu))_{\alpha\beta}=\delta_{\alpha\beta}\frac{\nu-a_\alpha}{\nu-b_\alpha},\quad 0\geqslant\alpha,\quad \beta\geqslant N. \tag{15}$$

Substitution of the expression (15) into (1) gives

$$\left(\frac{\mu-a_\alpha}{\mu-b_\alpha}\right)\chi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\left(\frac{\lambda-a_\beta}{\lambda-b_\beta}\right)\chi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{b}])$$
$$+\sum_{\gamma=1}^{N}(b_\gamma-a_\gamma)\chi_{\gamma\beta}(\lambda,b_\gamma,\boldsymbol{x}+[\boldsymbol{a}])\chi_{\alpha\gamma}(b_\gamma,\mu,\boldsymbol{x}+[\boldsymbol{b}])=0. \tag{16}$$

Equation (16) represents the final functional form of the generalized multicomponent KP hierarchy. It encodes the usual multicomponent KP hierarchy and its modified version together with their linear problems. To demonstrate this fact we, similar to the scalar case,[12] consider the particular form of equation (16) with $b_\alpha=0$, $0\geqslant\alpha\geqslant N$,

$$\left(1-\frac{a_\alpha}{\mu}\right)\chi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\left(1-\frac{a_\beta}{\lambda}\right)\chi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x})=\sum_{\gamma=1}^{N}a_\gamma\chi_{\gamma\beta}(\lambda,0,\boldsymbol{x}+[\boldsymbol{a}])\chi_{\alpha\gamma}(0,\mu,\boldsymbol{x})=0, \tag{17}$$

or, in terms of the CBA and Baker–Akhiezer functions,

$$\psi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\psi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x})=\sum_{\gamma=1}^{N}a_\gamma\psi_{\gamma\beta}(\lambda,\boldsymbol{x}+[\boldsymbol{a}])\tilde{\psi}_{\alpha\gamma}(\mu,\boldsymbol{x}), \tag{18}$$

where $\psi_{\gamma\beta}(\lambda,\boldsymbol{x})=\chi(\lambda,0,\boldsymbol{x})g_\beta(\lambda)$, $\tilde{\psi}_{\gamma\beta}(\mu,\boldsymbol{x})=\chi(0,\mu,\boldsymbol{x})g_\gamma^{-1}(\mu)$. The expansion of (18) in the Taylor series in $a_{(\gamma)}$ gives rise in the first order to the following equation:

$$\frac{\partial\psi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x})}{\partial x_{(\gamma)1}}=\psi_{\gamma\beta}(\lambda,\boldsymbol{x})\tilde{\psi}_{\alpha\gamma}(\mu,\boldsymbol{x}). \tag{19}$$

Evaluating the equation (17) with $\alpha\neq\beta\neq\gamma\neq\alpha$ at $\lambda=\mu=0$, one obtains the system

$$\frac{\partial P_{\alpha\beta}}{\partial\xi_\gamma}=P_{\alpha\gamma}P_{\gamma\beta}, \tag{20}$$

where $P_{\alpha\beta}=\chi_{\alpha\beta}(0,0,\boldsymbol{x})$, $\xi_\gamma=x_{(\gamma)1}$, which is nothing but the Darboux system in terms of rotation coefficients[22] or resonantly interacting waves equation.[7] Equation (17) with $\alpha\neq\gamma$ and $\mu=0$ gives the system

$$\frac{\partial\Psi_\alpha}{\partial\xi_\gamma}=P_{\alpha\gamma}\Psi_\gamma, \tag{21}$$

where

$$\Psi_\alpha = \sum_{\beta=1}^{N} \oint d\lambda \; f_\beta(\lambda)\psi_{\alpha\beta}(\lambda, \boldsymbol{x}), \tag{22}$$

and $f_\beta(\lambda)$ are arbitrary functions. The system (21) is a well-known linear problem for equations (20).

Equation (17) with $\beta \neq \gamma$ and $\lambda = 0$ gives the adjoint linear problem for the system (20),

$$\frac{\partial \tilde{\Psi}_\beta}{\partial \xi_\gamma} = P_{\gamma\beta}\tilde{\Psi}_\gamma, \tag{23}$$

where $\tilde{\Psi}_\beta = \Sigma_{\alpha=1}^{N} \oint d\mu \tilde{f}_\alpha(\mu)\tilde{\psi}_{\alpha\beta}(\mu, \boldsymbol{x})$ and $\tilde{f}_\alpha(\mu)$ are arbitrary functions.

Further, (21) implies that $P_{\alpha\gamma} = (1/\Psi_\gamma)(\partial\Psi_\alpha/\partial\xi_\gamma)$. Substituting this expression into (20), one gets

$$\partial_\beta\partial_\gamma\Psi_\alpha = \Psi_\beta^{-1}(\partial_\gamma\Psi_\beta)(\partial_\beta\Psi_\alpha) + \Psi_\gamma^{-1}(\partial_\beta\Psi_\gamma)(\partial_\gamma\Psi_\alpha), \tag{24}$$

where $\partial_\beta = \partial/\partial\xi_\beta$. This is a well-known Darboux–Zakharov–Manakov system which has been discovered in the theory of systems of conjugate surfaces first[22] and then has been rediscovered within the $\bar{\partial}$-dressing method in Ref. 7. This system is a modified partner of the system (20). To get the linear problem for it, it is sufficient to substitute the expression $P_{\alpha\gamma} = (1/\Psi_\gamma)(\partial\Psi_\alpha/\partial\xi_\gamma)$ into (23).

Thus the system (17) contains the equation (20), its modified partner (24), and their linear problems.

The higher order terms in the expansion of (17) in a_γ give rise to the higher analogs of equation (19). It is a straightforward check that these equations contain the higher order equations (20), their modified analogs, and corresponding linear problems.

The generalized multicomponent KP hierarchy described by functional equation (16) has a rather special structure. In particular, it contains N independent generalized scalar KP hierarchies. They are obviously given by equations (16) with $\alpha = \beta$ and $b_\gamma = a_\gamma$ for all γ except $\gamma = \alpha$. It is also quite clear that the number of effective independent dynamical variables is equal to three. For instance, the systems (20) and (24) are overdetermined and represent a collection of commuting closed systems defined for every triad of dynamical variables.

Note also that one can get the multicomponent KP hierarchy starting with the scalar generalized Hirota identity (1). In this case one has to choose a disconnected domain G consisting of N unit discs D_α with the center at $\lambda = 0$. In this case the scalar CBA function effectively consists of $N \times N$ disconnected components and can be interpreted as a matrix function. So the matrix structure in the scalar case is hidden in the multicomponent domain of definition of the CBA function. The function $g(\lambda)$ is defined on the set of N unit circles S_α and consists in fact of N components g_α defined on a unit circle.

The advantage of the scalar treatment is the opportunity to preserve most of the structure of the one-component KP hierarchy case almost without modification.

Using the parametrization (5), we represent the function $g(\lambda)$ (defined on the set of N unit circles S_α) as

$$g(\boldsymbol{x}, \lambda) = \prod_{\alpha=1}^{N} \exp\left(\sum_{i=1}^{\infty} x_{(\alpha)i} K_\alpha^i \right), \tag{25}$$

where

$$K_\alpha(\lambda) = \frac{1}{\lambda}, \quad \lambda \in D_\alpha;$$

$$K_\alpha(\lambda) = 0, \quad \lambda \notin D_\alpha.$$

In this case the transformation group element g_0 providing just the same shift of the $\boldsymbol{x}$ variables takes the form

$$g_0(\nu)=(g_1(\nu)g_2^{-1}(\nu))=\frac{\nu-a_\alpha}{\nu-b_\alpha},\quad \nu\in D_\alpha. \tag{26}$$

The analog of equation (16) reads as

$$g_0(\mu)\chi(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-g_0(\lambda)\chi(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{b}])$$
$$+\sum_{\gamma=1}^{N}(b_\gamma-a_\gamma)\chi(\lambda,b_{(\gamma)},\boldsymbol{x}+[\boldsymbol{a}])\chi(b_\gamma,\mu,\boldsymbol{x}+[\boldsymbol{b}])=0. \tag{27}$$

It seems to be a scalar equation, but if we take into account that the function χ consists of a set of disconnected components and denote $\chi_{\alpha\beta}(\lambda,\mu)=\chi(\lambda,\mu)$, $\lambda\in D_\beta$, $\mu\in D_\alpha$, then this equation gives rise exactly to the system (16).

The analog of equation (17) is, respectively,

$$\prod_{\alpha=1}^{N}(1-a_\alpha K_\alpha(\mu))\chi(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\prod_{\alpha=1}^{N}(1-a_\alpha K_\alpha(\lambda))\chi(\lambda,\mu,\boldsymbol{x})$$
$$=\sum_{\gamma=1}^{N}a_{(\gamma)}\chi_\gamma(\lambda,\boldsymbol{x}+[\boldsymbol{a}])\tilde{\chi}_\gamma(\mu,\boldsymbol{x})=0, \tag{28}$$

and in terms of CBA and BA functions one gets

$$\psi(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\psi(\lambda,\mu,\boldsymbol{x})=\sum_{\gamma=1}^{N}a_\gamma\psi_\gamma(\lambda,\boldsymbol{x}+[\boldsymbol{a}])\tilde{\psi}_\gamma(\mu,\boldsymbol{x}), \tag{29}$$

where we have introduced the notations

$$\begin{aligned}
\chi_\gamma(\lambda,\boldsymbol{x})&=\chi(\lambda,0_\gamma,\boldsymbol{x}),\\
\tilde{\chi}_\gamma(\mu,\boldsymbol{x})&=\chi(0_\gamma,\mu,\boldsymbol{x}),\\
\psi_\alpha(\lambda,\boldsymbol{x})&=g(\lambda)\chi_\alpha(\lambda,\boldsymbol{x}),\\
\tilde{\psi}_\alpha(\mu,\boldsymbol{x})&=g^{-1}(\mu)\tilde{\chi}_\alpha(\mu,\boldsymbol{x});
\end{aligned} \tag{30}$$

0_α denotes the center point of the disc D_α.

We will also use the following notations, most of them exactly corresponding to notations introduced in the frame of matrix representation: for potentials,

$$\chi_{\alpha\beta}(\boldsymbol{x})=\chi_{\mathrm{r}}(0_\beta,0_\alpha,\boldsymbol{x}),$$

$$\chi_{\mathrm{r}}(\lambda,\mu,\boldsymbol{x})=\chi(\lambda,\mu,\boldsymbol{x})-\delta_{\alpha\beta}\frac{1}{\lambda-\mu},\quad \lambda\in D_\alpha,\quad \mu\in D_\beta;$$

for wave functions,

$$\begin{aligned}
\Phi(\boldsymbol{x})&=\int\int_{\partial G}d\lambda\ d\mu\ f(\lambda)\tilde{f}(\mu)\psi(\lambda,\mu,\boldsymbol{x}),\\
\Psi_\alpha(\boldsymbol{x})&=\int_{\partial G}d\lambda\ f(\lambda)\psi_\alpha(\lambda,\boldsymbol{x}),\\
\tilde{\Psi}_\alpha(\boldsymbol{x})&=\int_{\partial G}d\mu\ \tilde{f}(\mu)\tilde{\psi}_\alpha(\mu,\boldsymbol{x}),
\end{aligned} \tag{31}$$

where $f(\lambda),\tilde{f}(\mu)$ are arbitrary functions defined on the boundary of G (i.e., on N unit circles).

IV. EQUATIONS OF GENERALIZED KP HIERARCHY IN COMPACT FORM

The basic equation of the multicomponent KP hierarchy (17) looks very simple and contains all the information about generalized hierarchy—the hierarchy of linear problems and the hierarchy of equations. However, sometimes this information could be excessive and one would prefer to have a compact form of the *equations* of the hierarchy. It is possible to extract all the hierarchies of equations from (17) in terms of shift operators. To derive the equations of the KP hierarchy, we will use generic shifts of times. For each triad of different shifts (i.e., shifts with different parameters) it is possible to derive a closed system of equations, representing, in fact, the multicomponent KP hierarchy.

As we will see later, the multicomponent KP hierarchy in a general case incorporates also discrete times not reducible to the shifts of continuous times. So equations of a multicomponent KP hierarchy can also contain these essentially discrete times. It is possible to include them to equations of this section, but now we will derive the equations of KP hierarchy containing only continuous times. Discrete times will be discussed later in the context of the Toda lattice hierarchy.

Thus, we will derive a compact form of the equation of the multicomponent KP hierarchy, the modified KP hierarchy, and the singularity manifold equation hierarchy. It is interesting to note that these equations are obtained in fact in the form of lattice equations, and all the hierarchies are given by the expansion of these lattice equations with respect to the parameters of the lattice.

In this section we will use the matrix form of the equation (17), i.e.,

$$\Delta\chi(\lambda,\mu)+\frac{1}{\lambda}\chi(\lambda,\mu)A-\frac{1}{\mu}A\cdot T\chi(\lambda,\mu)=\chi(0,\mu)AT\chi(\lambda,0). \tag{32}$$

Here the common argument $\boldsymbol{x}$ is omitted, the function $\chi(\lambda,\mu,\boldsymbol{x})$ is $N\times N$ matrix-valued function, A is a diagonal matrix, $A_{pq}=\delta_{pq}a_q$, and we have introduced the shift operator and difference operator,

$$T\chi(\lambda,\mu,\boldsymbol{x})=\chi(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}]),\quad \boldsymbol{a}=(a_1,\ldots,a_N),$$

$$\Delta\chi(\lambda,\mu,\boldsymbol{x})=(T-1)\chi(\lambda,\mu,\boldsymbol{x}).$$

If one takes the first term of expansion of the relation (32) at $\lambda=0$, $\mu=0$, one obtains an identity containing the potential $u=\chi_{\mathrm{r}}(0,0,\boldsymbol{x})$ and two higher terms of expansion of $\chi_{\mathrm{r}}(\lambda,\mu,\boldsymbol{x})$. It is possible to cancel these terms by combining three equations (32) with different matrices A_k, $k\in\{1,2,3\}$ and get an equation for the potential u.

First, it is easy to cancel the terms containing A_i/λ combining pairs of equations,

$$\Delta_i\chi(\lambda,\mu)A_j-\Delta_j\chi(\lambda,\mu)A_i+\frac{1}{\mu}\left(A_iT_i\chi(\lambda,\mu)A_j-A_jT_j\chi(\lambda,\mu)A_i\right)$$
$$=\chi(0,\mu)A_iT_i\chi(\lambda,0)A_j-\chi(0,\mu)A_jT_j\chi(\lambda,0)A_i. \tag{33}$$

And then, multiplying this equation by the operator A_kT_k from the left, taking the sum by different permutations of indices i,j,k, and using the first term of expansion by λ,μ at $\lambda=0$, $\mu=0$, one obtains the equation

$$\sum_{(ijk)}\epsilon_{ijk}A_kT_k(\Delta_iu-uA_iT_iu)A_j=0, \tag{34}$$

where $u=\chi_{\mathrm{r}}(0,0,\boldsymbol{x})$, and the summation goes over different permutations of indices. This extremely simple equation generates all equations of multicomponent KP hierarchy (not containing essentially discrete variables). A similar equation can be found in Ref. 17.

The scalar case of (34) represents a scalar KP hierarchy in the form of the superposition formula for three Bäcklund transformations. To simplify the derivation of equations of the KP

hierarchy from this equation, it is possible to take the first order of expansion in terms of the parameter a_1, performing, in fact, a transition $\Delta_1 \to \partial/\partial x_1$, $T_1 \to 1$ and thus distinguishing the continuous variable $x := x_1$ (obtaining, in fact, the superposition formula for *two* Bäcklund transformations).

It is easy to check that the choice of three elementary shifts $T_i : \boldsymbol{x}_{(i)} \to \boldsymbol{x}_{(i)} + [a_i]$ (only the variables $\boldsymbol{x}_{(i)}$ are shifted) in the formula (34) in the first nontrivial order of expansion $(a_i a_j a_k)$ leads to the standard form of the three waves interaction equation.

Using cross-differences of equations (32), it is possible to obtain equations for the wave functions (''modified equations''),

$$\sum_{(ijk)} \epsilon_{ijk} A_k T_k(\tilde{\Psi}^{-1} \cdot (T_i \tilde{\Psi})) A_j = 0. \tag{35}$$

Equations of this type for the DS case and N-wave equations case were derived in Ref. 23; see also the lattice form in Ref. 17.

And finally, it is easy to check using (32) that Φ satisfies the equation

$$(T_1\Delta_3\Phi)\cdot(T_3\Delta_1\Phi)^{-1}\cdot(T_3\Delta_2\Phi)\cdot(T_2\Delta_3\Phi)^{-1}\cdot(T_2\Delta_1\Phi)\cdot(T_1\Delta_2\Phi)^{-1} = 1. \tag{36}$$

This symmetric equation represents a multicomponent singularity manifold equation hierarchy. In the scalar case it reads as

$$(T_2\Delta_1\Phi)(T_3\Delta_2\Phi)(T_1\Delta_3\Phi) = (T_2\Delta_3\Phi)(T_3\Delta_1\Phi)(T_1\Delta_2\Phi). \tag{37}$$

We would like to remind the reader here of the main points of the concept of the Combescure symmetry transformation. The term Combescure symmetry transformation originates from geometry, where it is used for the transformation of surface, keeping all tangent vectors parallel.[22] For the integrable Darboux system describing triply conjugate systems of surfaces this transformation has a very simple interpretation in the contexts of theory of integrable systems, and in fact a general class of integrable equations (''modified'' equations) possesses this type of transformation (though the geometrical interpretation in this case may be missing). Our concept of the Combescure transformation is inspired mainly by integrability, not geometry (see Ref. 11).

Integrable equations for the wave functions (i.e., modified equations and singularity manifold type equations) possess the symmetry transformations corresponding to the freedom of choice of the wave function for the same CBA function. In spectral terms this symmetry is described by the change of weight functions $\rho(\lambda)$, $\eta(\mu)$. In terms of equations themselves this symmetry is represented using the Combescure invariants. The solutions are connected by the Combescure symmetry transformation, if Combescure invariants for them are the same. The Combescure symmetry group consists of two subgroups (''left'' and ''right''), corresponding to the change of one weight function [$f(\lambda)$ or $\tilde{f}(\mu)$; see notations (31); in our case $f(\lambda)$ and $\tilde{f}(\mu)$ are matrix-valued functions, multiplication by $f(\lambda)$ is from the right, by $\tilde{f}(\mu)$ is from the left, and here we will use the terms ''left'' and ''right'' Combescure invariants according to the rules of matrix multiplication]. Singularity manifold-type equations possess three types of invariants: left, right, and complete invariants. Modified equations possess only one type of invariant (left or right) and are invariant under an opposite Combescure subgroup. In this sense the basic hierarchy is invariant under the action of the full Combescure group.

We will write down some of the Combescure invariants of equations (35), (36). Combescure invariants for the equation (35) read as

$$C_{ij} = (\tilde{\Psi})^{-1}(\Delta_i \tilde{\Psi} A_j - \Delta_j \tilde{\Psi} A_i). \tag{38}$$

The left Combescure invariants for the equation (36) are given by

$$C'_{ij} = (\Delta_i \Phi)(\Delta_j \Phi)^{-1}. \tag{39}$$

V. GENERALIZED DS HIERARCHY

Now we will consider the 2-component case of the multicomponent KP hierarchy in more detail. In this section we derive the DS hierarchy and the hierarchy of corresponding linear problems, the mDS hierarchy and linear problems, and in the end we present the compact form of the hierarchy of Combescure transformation invariants for the mDS hierarchy. To perform all the derivations in terms of hierarchy, we use the formulas containing two continuous times ($x_1 := x_{(1)1}$ and $x_2 := x_{(2)1}$ and discrete shifts $[a_1]$ and $[a_2]$, the first acting on $\boldsymbol{x}_{(1)}$, the second on $\boldsymbol{x}_{(2)}$). These shifts change all the times of the hierarchy, and the expansion in a_1, a_2 will generate the hierarchy in terms of partial differential equations.

To derive DS hierarchy and linear problems, we will use the following special cases of the formula (28):

$$\frac{1}{a_1}\Delta_1\chi(\lambda,\mu,\boldsymbol{x})+K_1(\lambda)\chi(\lambda,\mu,\boldsymbol{x})-K_1(\mu)T_1\chi(\lambda,\mu,\boldsymbol{x})=\tilde{\chi}_1(\mu,\boldsymbol{x})T_1\chi_1(\lambda,\boldsymbol{x}), \tag{40}$$

$$\frac{1}{a_2}\Delta_2\chi(\lambda,\mu,\boldsymbol{x})+K_2(\lambda)\chi(\lambda,\mu,\boldsymbol{x})-K_2(\mu)T_2\chi(\lambda,\mu,\boldsymbol{x})=\tilde{\chi}_2(\mu,\boldsymbol{x})T_2\chi_2(\lambda,\boldsymbol{x}), \tag{41}$$

$$\partial_1\chi(\lambda,\mu,\boldsymbol{x})+(K_1(\lambda)-K_1(\mu))\chi(\lambda,\mu,\boldsymbol{x})=\tilde{\chi}_1(\mu,\boldsymbol{x})\chi_1(\lambda,\boldsymbol{x}), \tag{42}$$

$$\partial_2\chi(\lambda,\mu,\boldsymbol{x})+(K_2(\lambda)-K_2(\mu))\chi(\lambda,\mu,\boldsymbol{x})=\tilde{\chi}_2(\mu,\boldsymbol{x})\chi_2(\lambda,\boldsymbol{x}), \tag{43}$$

where we have introduced shift operators and difference operators,

$$T_1\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})=\chi(\lambda,\mu,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}),$$

$$T_2\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})=\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}+[a_2]),$$

$$\Delta_1\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})=(T_1-1)\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}),$$

$$\Delta_2\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})=(T_2-1)\chi(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}).$$

These operators can also be represented as differential operators,

$$T_1=\exp\left(\sum_{n=1}^{\infty}\frac{a_1^n}{n}\partial_{(1)n}\right),$$

$$T_2=\exp\left(\sum_{n=1}^{\infty}\frac{a_2^n}{n}\partial_{(2)n}\right).$$

The coefficient of expansion of T_1 in a_1, T_2 in a_2 are given explicitly in terms of Schur's polynomials $p_N(\partial_{(1)1}/1,\ldots,\partial_{(1)N}/N)$, $p_N(\partial_{(2)1}/1,\ldots,\partial_{(2)N}/N)$.

The L operator for the DS hierarchy is obtained by taking (42) at $\lambda=0_2$, (43) at $\lambda=0_1$ [and then passing on to the wave functions (31)],

$$\begin{aligned}&\partial_1\Psi_2=u\Psi_1,\quad u=\chi_{21}(\boldsymbol{x}),\quad \partial_1=\frac{\partial}{\partial x_1},\quad x_1=x_{(1)1};\\ &\partial_2\Psi_1=v\Psi_2,\quad v=\chi_{12}(\boldsymbol{x}),\quad \partial_2=\frac{\partial}{\partial x_2},\quad x_2=x_{(2)1};\end{aligned} \tag{44}$$

while the hierarchy of A operators is obtained by taking, respectively, (40) at $\mu=0_2$, (41) at $\mu=0_1$,

$$\frac{\Delta_1}{a_1}\Psi_2 = uT_1\Psi_1,$$
$$\frac{\Delta_2}{a_2}\Psi_1 = vT_2\Psi_2. \tag{45}$$

One can also obtain dual L and A operators, taking (40), (42) at $\mu = 0_2$, (41), (43) at $\lambda = 0_1$.

It is possible to get the DS hierarchy through compatibility conditions, but we prefer to extract it directly from the basic formulas (40), (41), (42), (43).

Taking the difference of equations (40), (42) at $\lambda = 0_1$, $\mu = 0_2$, and also using similar combinations, one obtains the system of equations

$$\begin{gathered}
(1/a_1(T_1-1)-\partial_1)u = (T_1-1)\chi_{11}u,\\
(1/a_1(1-T_1^{-1})-\partial_1)v = (T_1^{-1}-1)\chi_{11}v,\\
(1/a_2(T_2-1)-\partial_2)v = (T_2-1)\chi_{22}v,\\
(1/a_2(1-T_2^{-1})-\partial_2)u = (T_2^{-1}-1)\chi_{22}u,\\
\partial_1\chi_{22} = uv,\\
\partial_2\chi_{11} = uv.
\end{gathered} \tag{46}$$

This system of equations represents a compact form of the DS hierarchy. The expansion of this system in a_1, a_2 generates the DS equation and higher equations of the hierarchy. It is useful to note that this expansion has the structure of recursion relations, expressing the derivatives in higher times through derivatives in lower times.

It is possible to obtain a DS hierarchy from the formula (34). One could start with the three shifts $T_1: \boldsymbol{x}_{(1)} \to \boldsymbol{x}_{(1)} + [a_1]$, $T_2: \boldsymbol{x}_{(2)} \to \boldsymbol{x}_{(2)} + [a_2]$, $T_3: \boldsymbol{x}_{(1)} \to \boldsymbol{x}_{(1)} + [a_3]$ (or $T_3: \boldsymbol{x}_{(2)} \to \boldsymbol{x}_{(2)} + [a_3]$ for the part of the hierarchy with higher times connected with the disc D_2). Then, taking the first order of expansion in a_1, a_2 and thus performing a transition from two difference operators to derivatives $\Delta_1 \to \partial/\partial x_1$, $T_1 \to 1$, $\Delta_2 \to \partial/\partial x_2$, $T_2 \to 1$, and finally writing down matrix components of equation (34), one obtains the DS hierarchy exactly in the form (46).

The zeroth order of expansion just gives trivial identities. The first order of expansion of the first pair of equations in a_1 and the second pair in a_2 gives the DS system

$$\begin{gathered}
\tfrac{1}{2}(\partial_{(1)2} + \partial_1^2)u = u\partial_1\chi_{11},\\
\tfrac{1}{2}(\partial_{(1)2} - \partial_1^2)v = -v\partial_1\chi_{11},\\
\tfrac{1}{2}(\partial_{(2)2} + \partial_2^2)v = v\partial_2\chi_{22},\\
\tfrac{1}{2}(\partial_{(2)2} - \partial_2^2)u = -u\partial_2\chi_{22},\\
\partial_1\chi_{22} = uv,\\
\partial_2\chi_{11} = uv,
\end{gathered} \tag{47}$$

where $\partial_{(1)2} = \partial/\partial x_{(1)2}$, $\partial_{(2)2} = \partial/\partial x_{(2)2}$. The usual form of the DS system (see, e.g., Ref. 24) is a closed subsystem of (47) written in terms of the time t defined as $\partial_t = \partial_{(1)2} + \partial_{(2)2}$.

The second order of expansion, with the use of the DS equations (47), gives

$$\begin{gathered}
\tfrac{1}{3}(\partial_{(1)3} - \partial_1^3)u = u\partial_2^{-1}\partial_1(u\partial_1 v) - \partial_1(u\partial_2^{-1}\partial_1 uv),\\
\tfrac{1}{3}(\partial_{(1)3} - \partial_1^3)v = v\partial_2^{-1}\partial_1(v\partial_1 u) - \partial_1(v\partial_2^{-1}\partial_1 uv),
\end{gathered} \tag{48}$$

$$\begin{aligned}
&\tfrac{1}{3}(\partial_{(2)3}-\partial_2^3)v = v\partial_1^{-1}\partial_2(v\partial_2 u)-\partial_2(v\partial_1^{-1}\partial_2 uv),\\
&\tfrac{1}{3}(\partial_{(2)3}-\partial_2^3)u = u\partial_1^{-1}\partial_2(u\partial_2 v)-\partial_2(u\partial_1^{-1}\partial_2 uv),
\end{aligned} \tag{49}$$

which is the higher DS system (Ref. 25). The reduction $u=1$ gives rise to the split Nizhnik–Veselov–Novikov equation for v,[26,27] while the reduction $u=v$ leads to the modified Nizhnik–Veselov–Novikov equation.[25]

To proceed to the modified DS hierarchy case, we integrate equations (40), (41), (42), (43) over λ,μ with some weight functions and obtain equations for wave functions,

$$\begin{aligned}
&\frac{\Delta_1}{a_1}\Phi = \tilde{\Psi}_1 T_1 \Psi_1,\\
&\frac{\Delta_2}{a_2}\Phi = \tilde{\Psi}_2 T_2 \Psi_2,\\
&\partial_1\Phi = \tilde{\Psi}_1\Psi_1,\\
&\partial_2\Phi = \tilde{\Psi}_2\Psi_2.
\end{aligned} \tag{50}$$

The L operator for a modified DS hierarchy can be obtained from the last pair of equations, using equations (44) and a dual DS L operator,

$$\partial_1\partial_2\Phi = (\partial_2 U)\partial_1\Phi + (\partial_1 V)\partial_2\Phi, \tag{51}$$

where $U=\ln\Psi_1$, $V=\ln\Psi_2$. The hierarchy of A operators arises if one uses the second pair of equations (50) to exclude $\tilde{\Psi}_1,\tilde{\Psi}_2$ from the first pair,

$$\begin{aligned}
&\frac{\Delta_1}{a_1}\Phi = W_1\partial_1\Phi, \quad W_1 = \frac{T_1\Psi_1}{\Psi_1};\\
&\frac{\Delta_2}{a_2}\Phi = W_2\partial_2\Phi, \quad W_2 = \frac{T_2\Psi_2}{\Psi_2}.
\end{aligned} \tag{52}$$

The compatibility condition for (51), (52) gives the modified DS hierarchy,

$$\frac{1}{a_1}\Delta_1\partial_2 U + (T_1\partial_2 U)(\partial_1 W_1) + (T_1\partial_1 V)(\partial_2 W_1) + W_1(\partial_2 U)\Delta_1\partial_1 V = \partial_1\partial_2 W_1 + \partial_1(W_1\partial_2 U), \tag{53}$$

$$\frac{1}{a_1}\Delta_1\partial_1 V + W_1(\Delta_1\partial_1 V)(\partial_1 V) - \partial_1(W_1\partial_1 V) = 0,$$

$$W_1 = \exp(\Delta_1 U),$$

and for times with the subscript (2),

$$\frac{1}{a_2}\Delta_2\partial_1 V + (T_2\partial_1 V)(\partial_2 W_2) + (T_2\partial_2 U)(\partial_1 W_2) + W_2(\partial_1 V)\Delta_2\partial_2 U = \partial_2\partial_1 W_2 + \partial_2(W_2\partial_1 V), \tag{54}$$

$$\frac{1}{a_2}\Delta_2\partial_2 U + W_2(\Delta_2\partial_2 U)(\partial_2 U) - \partial_2(W_2\partial_2 U) = 0,$$

$$W_2 = \exp(\Delta_2 V).$$

The zeroth order of expansion of these equations in a_1,a_2 gives a modified DS equation,[23]

$$\tfrac{1}{2}\partial_2(\partial_{(1)2}U-\partial_1^2U-(\partial_1U)^2)+\partial_1(\partial_2U\cdot\partial_1V)=0,$$
$$\partial_{(1)2}V+\partial_1^2V+(\partial_1V)=\partial_1V\cdot\partial_1U, \tag{55}$$

$$\tfrac{1}{2}\partial_1(\partial_{(2)2}V-\partial_2^2V-(\partial_2V)^2)+\partial_2(\partial_2U\cdot\partial_1V)=0,$$
$$\partial_{(2)2}U+\partial_2^2U+(\partial_2U)^2=\partial_2V\cdot\partial_2U. \tag{56}$$

The hierarchy of Combescure invariants (Ref. 11) for the modified DS hierarchy is obtained by a representation of the DS solutions u,v through the mDS solutions U,V,

$$u=\exp(-T_1U)\frac{\Delta_1}{a_1}\exp(V),$$
$$v=\exp(-T_2V)\frac{\Delta_2}{a_2}\exp(U). \tag{57}$$

VI. τ FUNCTION FOR THE GENERALIZED DS HIERARCHY

Now we will analyze the functional equations (16) for the case $N=2$. For convenience we present them here explicitly:

$$\left(\frac{\mu-a_1}{\mu-b_1}\right)\chi_{11}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\left(\frac{\lambda-a_1}{\lambda-b_1}\right)\chi_{11}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_1-a_1)\chi_{11}(\lambda,b_1,\boldsymbol{x}+[\boldsymbol{a}])$$
$$\times\chi_{11}(b_1,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_2-a_2)\chi_{21}(\lambda,b_2,\boldsymbol{x}+[\boldsymbol{a}])\chi_{12}(b_2,\mu,\boldsymbol{x}+[\boldsymbol{b}])=0, \tag{58}$$

$$\left(\frac{\mu-a_2}{\mu-b_2}\right)\chi_{22}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\left(\frac{\lambda-a_2}{\lambda-b_2}\right)\chi_{22}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_1-a_1)\chi_{12}(\lambda,b_1,\boldsymbol{x}+[\boldsymbol{a}])$$
$$\times\chi_{21}(b_1,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_2-a_2)\chi_{22}(\lambda,b_2,\boldsymbol{x}+[\boldsymbol{a}])\chi_{22}(b_2,\mu,\boldsymbol{x}+[\boldsymbol{b}])=0, \tag{59}$$

$$\left(\frac{\mu-a_1}{\mu-b_1}\right)\chi_{12}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\left(\frac{\lambda-a_2}{\lambda-b_2}\right)\chi_{12}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_1-a_1)\chi_{12}(\lambda,b_1,\boldsymbol{x}+[\boldsymbol{a}])$$
$$\times\chi_{11}(b_1,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_2-a_2)\chi_{22}(\lambda,b_2,\boldsymbol{x}+[\boldsymbol{a}])\chi_{12}(b_2,\mu,\boldsymbol{x}+[\boldsymbol{b}])=0, \tag{60}$$

$$\left(\frac{\mu-a_2}{\mu-b_2}\right)\chi_{21}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{a}])-\left(\frac{\lambda-a_1}{\lambda-b_1}\right)\chi_{21}(\lambda,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_1-a_1)\chi_{11}(\lambda,b_1,\boldsymbol{x}+[\boldsymbol{a}])$$
$$\times\chi_{21}(b_1,\mu,\boldsymbol{x}+[\boldsymbol{b}])+(b_2-a_2)\chi_{21}(\lambda,b_2,\boldsymbol{x}+[\boldsymbol{a}])\chi_{22}(b_2,\mu,\boldsymbol{x}+[\boldsymbol{b}])=0. \tag{61}$$

First it is clear that equations (58) with $a_2=b_2$ and (59) with $a_1=b_1$ which coincide with those for scalar KP hierarchy give rise to the following expressions for χ_{11} and χ_{22} (see Ref. 12),

$$\chi_{11}(\lambda,\mu,\boldsymbol{x})=\frac{1}{(\lambda-\mu)}\frac{\tau_1(\boldsymbol{x}_{(1)}-[\lambda]+[\mu],\boldsymbol{x}_{(2)})}{\tau_1(\boldsymbol{x})}, \tag{62}$$

$$\chi_{22}(\lambda,\mu,\boldsymbol{x})=\frac{1}{(\lambda-\mu)}\frac{\tau_2(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}-[\lambda]+[\mu])}{\tau_2(\boldsymbol{x})}, \tag{63}$$

where τ_1 and τ_2 are the components of the τ function which depend on the variables $\boldsymbol{x}=(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})$.

Let us consider now equation (59) at $\mu=a_1$ and $a_2=b_2$. Substituting the expression (62) into this equation, we obtain

$$\tau_1(\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)}+[a_2])\chi_{12}(\lambda,a_1,\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)}+[a_2])$$

$$= \tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[a_2])\chi_{12}(\lambda,a_1,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[a_2]). \tag{64}$$

For $b_1=0$ after the change $\boldsymbol{x}_{(2)}+[a_2]\to\boldsymbol{x}_{(2)}$, one gets

$$\tau_1(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})\chi_{12}(\lambda,a_1,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}) = \tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)})\chi_{12}(\lambda,0,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}). \tag{65}$$

Denoting the RHS of this equation as $\tilde{\tau}_{12}(\lambda,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)})$, we rewrite it as

$$\chi_{12}(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}) = \frac{\tilde{\tau}_{12}(\lambda,\boldsymbol{x}_{(1)}+[\mu],\boldsymbol{x}_{(2)})}{\tau_1(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})}. \tag{66}$$

Then the substitution of (66) into equation (64) with $\mu=a_1$ and $\lambda=a_2$ gives rise to

$$\tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[b_2])\ \frac{\tilde{\tau}_{12}(a_2,\boldsymbol{x}_{(1)}+[a_1]+[b_1],\boldsymbol{x}_{(2)}+[a_2])}{\tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[a_2])}, \tag{67}$$

$$= \tau_2(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[b_2])\ \frac{\tilde{\tau}_{12}(b_2,\boldsymbol{x}_{(1)}+[a_1]+[b_1],\boldsymbol{x}_{(2)}+[b_2])}{\tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[a_2])}. \tag{68}$$

This equation implies that

$$\tilde{\tau}_{12}(a,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}) = \frac{\tau_{12}(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}-[a])}{\rho(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})} \tag{69}$$

and

$$\rho(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}) = \frac{\tau_2(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})}{\tau_1(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})}, \tag{70}$$

where τ_{12} is an arbitrary function. Substitution of (69) into (66) gives

$$\chi_{12}(\lambda,\mu,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}) = \frac{\tau_{12}(\lambda,\boldsymbol{x}_{(1)}+[\mu],\boldsymbol{x}_{(2)}-[\lambda])}{\tau_2(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})}. \tag{71}$$

Now we proceed with equation (61). Substitution of the expression (63) into this equation with $\mu=a_2$, $a_1=b_1$ gives

$$\chi_{21}(\lambda,a_2,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[b_2]) = \frac{\tau_2(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[a_2])}{\tau_2(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[b_2])}\chi_{21}(\lambda,b_2,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}+[a_2]). \tag{72}$$

After the change $\boldsymbol{x}_{(1)}+[a_1]\to\boldsymbol{x}_{(1)}$ and the choice $b_2=0$ one gets

$$\tau_2(\boldsymbol{x})\chi_{21}(\lambda,a_2,\boldsymbol{x}) = \tau_2(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}+[a_2])\chi_{21}(\lambda,0,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}+[a_2]). \tag{73}$$

From this equation one concludes that

$$\chi_{21}(\lambda,\mu,\boldsymbol{x}) = \frac{\tilde{\tau}_{21}(\lambda,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}+[\mu])}{\tau_2(\boldsymbol{x})}, \tag{74}$$

where $\tilde{\tau}_{21}(\lambda,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}) = \tau_2(\boldsymbol{x})\chi_{21}(\lambda,0,\boldsymbol{x})$.

Substituting now with $\mu=a_2$, $\lambda=a_1$, $b_2=0$ we obtain

$$\frac{\tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)})}{\tau_2(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)})}\ \tilde{\tau}_{21}(a_1,\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)}) = \frac{\tau_1(\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)})}{\tau_2(\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)})}\ \tilde{\tau}_{21}(b_1,\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)}). \tag{75}$$

Hence

$$\tilde{\tau}_{21}(a_1,\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)})=\frac{\tau_{21}(\boldsymbol{x}_{(1)}-[a_1],\boldsymbol{x}_{(2)})}{\tilde{\rho}(\boldsymbol{x})} \tag{76}$$

and

$$\tilde{\rho}(\boldsymbol{x})=\frac{\tau_1(\boldsymbol{x})}{\tau_2(\boldsymbol{x})}. \tag{77}$$

Substitution of (76) and (77) into (74) gives

$$\chi_{21}(\lambda,\mu,\boldsymbol{x})=\frac{\tau_{21}(\boldsymbol{x}_{(1)}-[\lambda],\boldsymbol{x}_{(2)}+[\mu])}{\tau_1(\boldsymbol{x})}. \tag{78}$$

To establish the relation between τ_1 and τ_2 we consider again equation (75). Due to (76) one gets

$$\frac{\tau_1(\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)})}{\tau_2(\boldsymbol{x}_{(1)}+[b_1],\boldsymbol{x}_{(2)})}=\frac{\tau_1(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)})}{\tau_2(\boldsymbol{x}_{(1)}+[a_1],\boldsymbol{x}_{(2)})}. \tag{79}$$

Since a_1 and b_1 are arbitrary parameters, one concludes that

$$\frac{\tau_1(\boldsymbol{x})}{\tau_2(\boldsymbol{x})}=f(\boldsymbol{x}_{(2)}). \tag{80}$$

In the same way, it follows from (60) that

$$\frac{\tau_1(\boldsymbol{x})}{\tau_2(\boldsymbol{x})}=f(\boldsymbol{x}_{(1)}). \tag{81}$$

Thus

$$\frac{\tau_1(\boldsymbol{x})}{\tau_2(\boldsymbol{x})}=\text{const}. \tag{82}$$

Having in mind the formulas (62) and (63), one can put $\tau_1=\tau_2$ without the loss of generality.

So for the 2-component KP hierarchy one has

$$\chi_{11}(\lambda,\mu,\boldsymbol{x})=\frac{1}{(\lambda-\mu)}\,\frac{\tau(\boldsymbol{x}_{(1)}-[\lambda]+[\mu],\boldsymbol{x}_{(2)})}{\tau(\boldsymbol{x})}, \tag{83}$$

$$\chi_{22}(\lambda,\mu,\boldsymbol{x})=\frac{1}{(\lambda-\mu)}\,\frac{\tau(\boldsymbol{x}_{(1)},\boldsymbol{x}_{(2)}-[\lambda]+[\mu])}{\tau(\boldsymbol{x})}, \tag{84}$$

$$\chi_{12}(\lambda,\mu,\boldsymbol{x})=\frac{\tau_{12}(\boldsymbol{x}_{(1)}+[\mu],\boldsymbol{x}_{(2)}-[\lambda])}{\tau(\boldsymbol{x})}, \tag{85}$$

$$\chi_{21}(\lambda,\mu,\boldsymbol{x})=\frac{\tau_{21}(\boldsymbol{x}_{(1)}-[\lambda],\boldsymbol{x}_{(2)}+[\mu])}{\tau(\boldsymbol{x})}. \tag{86}$$

At this step τ, τ_{12}, and τ_{21} are arbitrary functions. Substitution of the expressions (83)–(86) into the general functional equations (58)–(61) gives rise to the four bilinear functional equations for these functions which represent themselves with the addition formulas. We will write them down explicitly for the multicomponent case later.

VII. τ FUNCTION AND ADDITION FORMULAS FOR THE *N*-COMPONENT KP HIERARCHY

It will be shown in the next section that the objects of multicomponent KP hierarchy depend not only on continuous times, but also on discrete times (indices). The addition formulas arising from the discrete dynamics will be considered in the context of the Toda lattice hierarchy. Here we derive only the addition formulas following from the basic formula (16) defining the dynamics for continuous variables.

For the general multicomponent KP hierarchy the system (16) looks rather complicated. But its analysis is simplified considerably due to the special structure of equations (16). It is not difficult to see that for two fixed values of α and β, taking $a_\gamma = b_\gamma$, $\gamma \neq \alpha$, $\gamma \neq \beta$, the system reduces to four equations of the DS hierarchy (58)–(61) for the variables $\boldsymbol{x}_{(\alpha)}$ and $\boldsymbol{x}_{(\beta)}$. Hence, in these variables we have the formulas

$$\chi_{\alpha\alpha}(\lambda,\mu,\boldsymbol{x}) = \frac{1}{(\lambda-\mu)} \frac{\tau(\boldsymbol{x}_{(1)},\ldots,\boldsymbol{x}_{(\alpha)}-[\lambda]+[\mu],\ldots,\boldsymbol{x}_{(N)})}{\tau(\boldsymbol{x})},$$
$$\chi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x}) = \frac{\tau_{\alpha\beta}(\boldsymbol{x}_{(1)},\ldots,\boldsymbol{x}_{(\alpha)}+[\mu],\ldots,\boldsymbol{x}_{(\beta)}-[\lambda],\ldots,\boldsymbol{x}_{(N)})}{\tau(\boldsymbol{x})} \quad (\alpha \neq \beta). \tag{87}$$

Here indices α and β are arbitrary. Therefore the formulas (87) take place for all α and β.

To compactify these formulas we will introduce the shift operator $T_\alpha(\lambda)$ $(\alpha = 1,\ldots,N)$,

$$T_\alpha(\lambda) f(\boldsymbol{x}) = f(\boldsymbol{x}_{(1)},\ldots,\boldsymbol{x}_{(\alpha)}+[\lambda],\ldots,\boldsymbol{x}_{(N)}). \tag{88}$$

Using such operators, one can present the formulas (87) in the form

$$\chi_{\alpha\alpha}(\lambda,\mu,\boldsymbol{x}) = \frac{1}{\lambda-\mu} \frac{T_\alpha(\mu)T_\alpha^{-1}(\lambda)\tau(\boldsymbol{x})}{\tau(\boldsymbol{x})}, \quad \alpha = 1,\ldots,N,$$
$$\chi_{\alpha\beta}(\lambda,\mu,\boldsymbol{x}) = \frac{T_\alpha(\mu)T_\beta^{-1}(\lambda)\tau_{\alpha\beta}(\boldsymbol{x})}{\tau(\boldsymbol{x})}, \quad \alpha \neq \beta. \tag{89}$$

In the special cases $\lambda = 0$ or $\mu = 0$ these formulas reduce to the standard formulas for the Baker–Akhiezer function.[3,14,16] Separating the diagonal case $\alpha = \beta$ and the off diagonal one, one gets

$$\begin{aligned}
&(a_\alpha-\mu)(\lambda-b_\alpha)\tau(\boldsymbol{x}+[\boldsymbol{b}])T_\alpha(\mu)T_\alpha^{-1}(\lambda)\tau(\boldsymbol{x}+[\boldsymbol{a}]) + (b_\alpha-\mu)(\lambda-a_\alpha)\tau(\boldsymbol{x}+[\boldsymbol{a}])\\
&\quad\times T_\alpha(\mu)T_\alpha^{-1}(\lambda)\tau(\boldsymbol{x}+[\boldsymbol{b}]) + (b_\alpha-a_\alpha)(\lambda-\mu)T_\alpha(\mu)T_\alpha^{-1}(b_\alpha)\tau(\boldsymbol{x}+[\boldsymbol{b}])T_\alpha(b_\alpha)\\
&\quad\times T_\alpha^{-1}(\lambda)\tau(\boldsymbol{x}+[\boldsymbol{a}]) + (\mu-\lambda)(\mu-b_\alpha)(\lambda-b_\alpha)\sum_{\gamma\neq\alpha}(b_\gamma-a_\gamma)T_\alpha(\mu)\\
&\quad\times T_\gamma^{-1}(b_\gamma)\tau_{\alpha\gamma}(\boldsymbol{x}+[\boldsymbol{b}])T_\gamma(b_\gamma)T_\beta^{-1}(\lambda)\tau_{\gamma\beta}(\boldsymbol{x}+[\boldsymbol{a}]) = 0
\end{aligned} \tag{90}$$

and

$$\begin{aligned}
&(\mu-a_\alpha)(\lambda-b_\beta)\tau(\boldsymbol{x}+[\boldsymbol{b}])T_\alpha(\mu)T_\beta^{-1}(\lambda)\tau_{\alpha\beta}(\boldsymbol{x}+[\boldsymbol{a}]) + (\mu-b_\alpha)(\lambda-a_\beta)\tau(\boldsymbol{x}+[\boldsymbol{a}])\\
&\quad\times T_\alpha(\mu)T_\beta^{-1}(\lambda)\tau_{\alpha\beta}(\boldsymbol{x}+[\boldsymbol{b}]) + (b_\alpha-a_\alpha)(\lambda-b_\beta)T_\alpha(\mu)T_\alpha^{-1}(b_\alpha)\tau(\boldsymbol{x}+[\boldsymbol{b}])T_\alpha(b_\alpha)\\
&\quad\times T_\beta^{-1}(\lambda)\tau_{\alpha\beta}(\boldsymbol{x}+[\boldsymbol{a}]) + (\mu-b_\alpha)(\lambda-b_\beta)\sum_{\gamma\neq\alpha,\beta}(b_\gamma-a_\gamma)T_\alpha(\mu)T_\gamma^{-1}(b_\gamma)\tau_{\alpha\gamma}(\boldsymbol{x}\\
&\quad+[\boldsymbol{b}])T_\gamma(b_\gamma)T_\beta^{-1}(\lambda)\tau_{\gamma\beta}(\boldsymbol{x}+[\boldsymbol{a}]) = 0.
\end{aligned} \tag{91}$$

Equations (90) and (91) represent the extension of the simplest addition formula for the τ function in the scalar case (see Ref. 12) to the multicomponent case. They are related to the generalization

of the bilinear relations for the Plücker coordinates to the multicomponent case. On the other hand they could be connected with the possible multidimensional extensions of the Fay's trisecant formula.[28]

More general addition formulas for the τ function follow from the general functional equation for the function $\chi_{\alpha\beta}$ which corresponds to the choice

$$(g_1(\boldsymbol{x})g_2^{-1}(\boldsymbol{x}))_{\alpha\beta}=\delta_{\alpha\beta}\prod_{k=1}^{N}\frac{\nu-a_{\alpha k}}{\nu-b_{\alpha k}}. \tag{92}$$

VIII. τ-FUNCTIONAL SUBSTITUTION AND CLOSED 1-FORM

The formulas (83), (84), (85), (86) indicate that it is possible to preserve in the multicomponent case the general formula connecting the τ function and the CBA function in the scalar case. It would be more consistent first to define the τ function through the CBA function in terms of the closed one-form, and then to prove that this definition implies the general formula. On the other hand, one may treat the general formula as the definition and then prove the correctness of this definition reducing it to closed 1-form and showing the equivalence of ''local'' and ''global'' formulas (that implies the unique existence of the τ function, at least in some neighborhood of $g=1$). In this paper we would rather follow the second way.

So we define the τ function by the relation

$$\chi(\lambda,\mu,g)=\chi_0(\lambda,\mu)\frac{\tau(g_{(\lambda,\mu)}g)}{\tau(g)}. \tag{93}$$

Here $\chi_0(\lambda,\mu)$ is just the function $(\lambda-\mu)^{-1}$ extended as 1 for λ, μ in different D_i, and the function $g_{(\lambda,\mu)}$ is an extension of the function $(\nu-\lambda)/(\nu-\mu)$ to the case of disconnected G,

$$\chi_0(\lambda,\mu)=\begin{cases}\dfrac{1}{\lambda-\mu}, & \text{for } \lambda\in D_i, \quad \mu\in D_i,\\ 1, & \text{for } \lambda\in D_i, \quad \mu\in D_j, \quad i\neq j.\end{cases} \tag{94}$$

The function $g_{(\lambda,\mu)}$ [in fact, it is a set of N loop group elements $g_i(\nu)$ depending on the parameters λ,μ] is the ratio of two terms,

$$\begin{gathered}g_{(\lambda,\mu)}=\frac{g_{(\lambda)}}{g_{(\mu)}},\\ g_{(\lambda)i}(\nu)=\begin{cases}\nu-\lambda, & \text{for } \lambda\in D_i,\\ 1, & \text{for } \lambda\notin D_i.\end{cases}\end{gathered} \tag{95}$$

To extract the formulas (83), (84), (85), (86) from the formula (93), one should recall that the loop group defining the multicomponent KP hierarchy can be decomposed in the following way:

$$g_i(\nu)=g_{i\mathrm{out}}(\nu)\times\nu^{n_i}, \quad \sum_{i=1}^{N}n_i=0, \tag{96}$$

where the first term defines the dependence on continuous times and the second—on the discrete times (indices). If λ,μ belong to the same D_i, using explicit parametrization of the loop group elements, we obtain exactly the formulas (83), (84). For $\lambda\in D_k$, $\mu\in D_p$, $k\neq p$, $g_{(\lambda,\mu)}$ has a factorization,

$$\begin{gathered}g_{(\lambda,\mu)k}(\nu)=\frac{\nu-\lambda}{\nu}\times\nu,\\ g_{(\lambda,\mu)p}(\nu)=\frac{\nu}{\nu-\mu}\times\nu^{-1},\end{gathered} \tag{97}$$

$$g_{(\lambda,\mu)i}(\nu)=1, \quad i\neq k, \quad i\neq p.$$

Using these formulas, we obtain the formulas (85), (86), with the components of the τ function interpreted as a τ function with shifted index variables (the general index zero is preserved). For example, in the two-component case the function τ_{12} corresponds to $\tau(n_1-1,n_2+1)$. To express the CBA function with zero indices, we need to know the set of functions τ, τ_{ij}, $i\neq j$. Then for other admissible index vectors the CBA function and the τ function can be found explicitly through the determinant formulas.[13] Thus, the discrete dynamics is exactly solvable in terms of initial data (CBA function with zero indices or the set of τ functions τ, τ_{ij}, $i\neq j$).

Returning to our original purpose, we will extract the definition of the τ function in terms of the closed 1-form from (2) and then prove that both definitions are equivalent. Our derivation will mostly repeat the derivation in the scalar case given in Ref. 12, but we would like to mention it due to the importance for the following consideration.

Differentiating (93) with respect to λ, one obtains

$$-\frac{1}{\tau(g)}\oint \frac{\delta\tau(g\times g_{(\lambda,\mu)})}{\delta \ln g_\alpha(\nu)}\frac{1}{\nu-\lambda}d\nu=\frac{\partial}{\partial\lambda}(\lambda-\mu)\chi_{\alpha\alpha}(\lambda,\mu;g), \tag{98}$$

or for $\lambda=\mu$,

$$-\frac{1}{\tau(g)}\oint \frac{\delta\tau(g)}{\delta \ln g_\alpha(\nu)}\frac{1}{\nu-\lambda}d\nu=\chi_{r\alpha\alpha}(\lambda,\lambda;g), \tag{99}$$

where $\chi_{r\alpha\beta}(\lambda,\mu;g)=\chi_{\alpha\beta}(\lambda,\mu;g)-\delta_{\alpha\beta}(\lambda-\mu)^{-1}$, ''$r$'' is for ''regularized.'' This equation can be rewritten in the form

$$-\frac{1}{\tau(g)}\oint \frac{\delta\tau(g)}{\delta \ln g_\alpha(\nu)}\frac{1}{\nu-\lambda}d\nu=\oint \chi_{r\alpha\alpha}(\nu,\nu;g)\frac{1}{\nu-\lambda}d\nu. \tag{100}$$

Relation (100) implies that the linear functionals $-[1/\tau(g)][\delta\tau(g(\nu))/\delta \ln g]$ and $\chi_r(\nu,\nu;g)$ are identical for arbitrary variations $\delta g/g$ analytic outside each D_i and decreasing at infinity. Thus for $\delta g/g$ belonging to this class of functions the variation of the τ function is given by

$$-\delta \ln \tau(g)=\sum_{\alpha=1}^{N}\oint \chi_{r\alpha\alpha}(\nu,\nu;g)\frac{\delta g_\alpha(\nu)}{g_\alpha(\nu)}d\nu. \tag{101}$$

This expression defines a variational 1-form defining the τ function. It is easy to prove using the identity (1) that this form is *closed*. Indeed, according to (1) [here we are using scalar notations, it is not difficult to extract equations in terms of components $\chi_{\alpha\beta}(\lambda,\mu;g)$],

$$\begin{aligned}\delta\chi(\lambda,\mu;g)&=\int_{\partial G}\chi(\nu,\mu;g)\frac{\delta g(\nu)}{g(\nu)}\chi(\lambda,\nu;g)d\nu,\\ \delta\chi_r(\lambda,\lambda;g)&=\int_{\partial G}\chi_r(\nu,\lambda;g)\frac{\delta g(\nu)}{g(\nu)}\chi_r(\lambda,\nu;g)d\nu.\end{aligned} \tag{102}$$

So the variation of (101) gives

$$-\delta^2 \ln \tau(g)=\int_{\partial G}\int_{\partial G}\chi_r(\nu,\lambda;g)\chi_r(\lambda,\nu;g)\frac{\delta' g(\nu)}{g(\nu)}\frac{\delta g(\lambda)}{g(\lambda)}d\nu d\lambda. \tag{103}$$

The symmetry of the kernel of second variation with respect to λ,ν implies that the form (101) is closed.

So the formula (101) gives the definition of the τ function in terms of the closed 1-form. For the standard KP coordinates,

$$\frac{\delta g_\alpha(\lambda)}{g_\alpha(\lambda)} = \sum_{n=1}^{\infty} \frac{dx_{(\alpha)n}}{\lambda^n}.$$

This formula allows us to obtain a closed 1-form in terms of $dx_{\alpha n}$,

$$-d\ \ln\ \tau(\boldsymbol{k},\boldsymbol{x}) = \sum_{\alpha=1}^{N}\sum_{n=0}^{\infty} \frac{\partial^n}{\partial \nu^n}\,\chi_{r\alpha\alpha}(\nu,\nu,\boldsymbol{k},\boldsymbol{x})\Big|_{\nu=0} dx_{(\alpha)n}. \tag{104}$$

To prove that the ''local'' definition in terms of the closed 1-form implies the global definition (93), it is sufficient to show that logarithmic derivatives of the LHS and the RHS of (93) with respect to λ,μ and variational logarithmic derivatives with respect to $\delta g_\alpha / g_\alpha$ are equal in virtue to (101) and generalized Hirota bilinear identity (1). Then the lhs and the rhs of (93) could differ only by the factor, and the normalization of the function χ implies that this factor is equal to 1.

Here we will prove only the equality of logarithmic variations; the proof for derivatives is analogous (see Ref. 12).

The logarithmic variation of (93) gives

$$\begin{aligned}
&\delta(\ln\ \chi(\lambda,\mu;g)(\lambda-\mu) - \ln\ \tau(g\times g_{(\lambda,\mu)}) + \ln\ \tau(g)) \\
&\quad = \frac{1}{\chi(\lambda,\mu)} \int_{\partial G} \chi(\nu,\mu;g)\,\frac{\delta g(\nu)}{g(\nu)}\,\chi(\lambda,\nu;g)\,d\nu \\
&\qquad - \int_{\partial G} (\chi_r(\nu,\nu;g\times g_{(\lambda,\mu)}) - \chi_r(\nu,\nu;g))\,\frac{\delta g(\nu)}{g(\nu)}\,d\nu
\end{aligned} \tag{105}$$

[we have used (102) and (101)]. After the use of the determinant formula,[13]

$$\chi(\lambda,\mu;g\times g_{(\lambda',\mu')}) = g^{-1}_{(\lambda',\mu')}(\lambda)\,g_{(\lambda',\mu')}(\mu)\,\frac{\begin{vmatrix}\chi(\lambda',\mu') & \chi(\lambda',\mu)\\ \chi(\lambda,\mu') & \chi(\lambda,\mu)\end{vmatrix}}{\chi(\lambda',\mu')}, \tag{106}$$

to transform the second term, one concludes that the variation is equal to zero.

IX. GENERALIZED 2D TODA LATTICE HIERARCHY. BASIC EQUATIONS

We will consider here for simplicity only scalar 2D Toda lattice hierarchy. It is generated by the generalized Hirota identity with the domain G which consists of two disconnected regions, i.e., in some sense it is a two-point KP hierarchy. But it also possess some fundamental special features and can be treated as a primary object with respect to the scalar KP hierarchy.

Without loss of generality one can choose G as

$$G = D_0 \cup D_\infty,$$

where D_0 and D_∞ are unit discs around the origin and infinity, respectively. The two-component KP hierarchy is generated by the pair of functions $g_{\rm in}$, $g_{\rm out}$ defined on the boundary of D_0, D_∞, respectively, having a zero general index (let their individual indices be $n,-n$), $g_{\rm out}$ is analytic and has no zeros outside the unit circle, and $g_{\rm in}$ inside the unit circle. It is easy to see, that dynamics defined by the pair of these functions coincides with the dynamics defined by one function for both boundaries,

$$g = \lambda^n g_{\rm in} g_{\rm out}, \tag{107}$$

up to some trivial dynamics, defined by a function analytic in $G = D_0 \cup D_\infty$ ($g = g_{\rm in}$, $\lambda \in D_0$; $g = g_{\rm out}$, $\lambda \in D_\infty$).

As we know, an *arbitrary* function on the circle having no zeros (arbitrary loop) can be represented in the form (107). So in the case of the Toda lattice hierarchy the objects of the theory nontrivially depend on the whole loop group (i.e., on discrete time, positive, and negative con-

tinuous times); the τ function in this case is a functional of arbitrary g on the circle. Discrete dynamics is correctly defined, because in this case λ^n is a function having in G an equal number of zeros and poles.

The explicit parametrization of the loop group element g in terms of times is given by

$$g(n,\boldsymbol{x},\nu)=g(n,\boldsymbol{x}_+,\boldsymbol{x}_-,\nu)=\nu^n\exp\left(\sum_{k=1}^{\infty}x_{(+)k}\nu^{-k}+x_{(-)k}\nu^k\right). \tag{108}$$

The compact form of the 2D Toda lattice hierarchy in terms of the function $\chi(\lambda,\mu,k,\boldsymbol{x})$ can be obtained from (1) using special combinations of group elements $g_1g_2^{-1}$ with simple analytical properties. To define dynamics with respect to continuous times, let us take

$$g_0(\nu):=g_1(\nu)g_2^{-1}(\nu)=\frac{\nu-a_+}{\nu-b_+}\frac{\nu-a_-}{\nu-b_-},$$

$$a_+,b_+\in D_0,\quad a_-,b_-\in D_\infty, \tag{109}$$

$$g_0(\nu)=g_+\times(g_-)^{-1},\quad g_+=\frac{\nu-a_+}{\nu-b_+},\quad g_-=\frac{\nu-b_-}{\nu-a_-}.$$

Substituting the expression for $g_1g_2^{-1}$ into the generalized Hirota bilinear identity (1), one obtains

$$\begin{aligned}&g_0(\mu)\chi(\lambda,\mu,g\times g_+)-g_0(\lambda)\chi(\lambda,\mu,g\times g_-)+\mathrm{Res}(g_0)|_{b_+}\chi(\lambda,b_+,g\times g_+)\chi(b_+,\mu,g\times g_-)\\&\quad+\mathrm{Res}(g_0)|_{b_-}\chi(\lambda,b_-,g\times g_+)\chi(b_-,\mu,g\times g_-)=0.\end{aligned} \tag{110}$$

The equations of the Toda lattice hierarchy are generated by equation (110) with $b_+=0$, $b_-=\infty$, or, in terms of g_0,

$$\begin{aligned}g_0(\nu)=g_1(\nu)g_2^{-1}(\nu)=\left(1-\frac{\nu}{a_-}\right)\left(1-\frac{a_+}{\nu}\right)=\exp\left(\sum_{i=1}^{\infty}\frac{1}{i}\left(\left(\frac{\nu}{a_-}\right)^i+\left(\frac{a_+}{\nu}\right)^i\right)\right),\\|a_+|<1,\quad |a_-|>1.\end{aligned} \tag{111}$$

Substituting into equation (110) parametrization of loop group elements in terms of times, we obtain

$$\begin{aligned}&\left(1-\frac{\mu}{a_-}\right)\left(1-\frac{a_+}{\mu}\right)\chi(\lambda,\mu,n,\boldsymbol{x}_++[\boldsymbol{a}_+],\boldsymbol{x}_-)-\left(1-\frac{\lambda}{a_-}\right)\left(1-\frac{a_+}{\lambda}\right)\\&\times\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_--[\boldsymbol{a}_-])+-a_+\chi(\lambda,0,n,\boldsymbol{x}_++[\boldsymbol{a}_+],\boldsymbol{x}_-)\chi(0,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_--[\boldsymbol{a}_-])\\&-\frac{1}{a_-}\chi(\lambda,\infty,n,\boldsymbol{x}_++[\boldsymbol{a}_+],\boldsymbol{x}_-)\chi(\infty,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_--[\boldsymbol{a}_-])=0,\end{aligned} \tag{112}$$

where $\chi(\lambda,\infty)=\chi(\lambda,\mu)\times\mu|_{\mu=\infty}$. In terms of CBA and BA functions $\psi(\lambda,\mu)$ and $\psi_0(\lambda)$, $\tilde{\psi}_0(\mu)$ $\psi_\infty(\lambda)$, $\tilde{\psi}_\infty(\mu)$ we have

$$\begin{aligned}&\psi(\lambda,\mu,n,\boldsymbol{x}_++[\boldsymbol{a}_+],\boldsymbol{x}_-)-\psi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_--[\boldsymbol{a}_-])\\&\quad=a_+\psi_0(\lambda,n,\boldsymbol{x}_++[\boldsymbol{a}_+],\boldsymbol{x}_-)\tilde{\psi}_0(\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_--[\boldsymbol{a}_-])\\&\qquad+\frac{1}{a_-}\psi_\infty(\lambda,n,\boldsymbol{x}_++[\boldsymbol{a}_+],\boldsymbol{x}_-)\tilde{\psi}_\infty(\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_--[\boldsymbol{a}_-]).\end{aligned} \tag{113}$$

To get equations defining the discrete dynamics, we take

$$g_0(\nu)=g_1(\nu)g_2^{-1}(\nu)=\frac{1}{\lambda} \tag{114}$$

or

$$g_0(\nu)=g_1(\nu)g_2^{-1}(\nu)=\lambda. \tag{115}$$

In the first case the equation for the function χ reads as

$$\frac{1}{\mu}\chi(\lambda,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)-\frac{1}{\lambda}\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)=\chi(\lambda,0,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)\chi(0,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-), \tag{116}$$

and in the second case,

$$\mu\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)-\lambda\chi(\lambda,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)=\chi(\lambda,\infty,n,\boldsymbol{x}_+,\boldsymbol{x}_-)\chi(\infty,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-). \tag{117}$$

In terms of CBA and BA functions one gets

$$\psi(\lambda,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)-\psi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)=\psi_0(\lambda,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)\tilde{\psi}_0(\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$

$$\psi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)-\psi(\lambda,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)=\psi_\infty(\lambda,n,\boldsymbol{x}_+,\boldsymbol{x}_-)\tilde{\psi}(\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-). \tag{118}$$

Equations (113), (118) define the generalized 2D Toda lattice hierarchy. The discrete dynamics can be resolved in both directions explicitly [i.e., $\chi(n+1)$, $\chi(n-1)$ can be expressed through $\chi(n)$] using the determinant formula.[13]

X. TODA LATTICE HIERARCHY: 2DTL, 2D VOLTERRA CHAIN, 2DTL SINGULARITY MANIFOLD EQUATION

At this point we would like to derive the simplest equations of the generalized 2D Toda lattice hierarchy. They contain three variables: one discrete variable n and two continuous variables $x_{(+)1}$, $x_{(-)1}$ (we will denote them x_+ and x_-). We will derive three different equations corresponding to different levels of the tower of equations of the generalized hierarchy: the main equation (the standard two-dimensional Toda lattice equation), the modified equation (i.e., the equation for the Baker–Akhiezer function), and the singularity manifold-type equation (arising here as an equation for the CBA function). It is interesting to note that the second and the third equations (not to mention the first) are already known in literature in different contexts (see Refs. 18–21).

The basic equations for our derivation are equations (116), (117) and the zeroth order terms of expansion of (112) in a_+, $1/a_-$, i.e.,

$$\left(\frac{\partial}{\partial x_+}+\frac{1}{\lambda}-\frac{1}{\mu}\right)\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)=\chi(\lambda,0,n,\boldsymbol{x}_+,\boldsymbol{x}_-)\chi(0,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$

$$\left(\frac{\partial}{\partial x_-}+\lambda-\mu\right)\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)=\chi(\lambda,\infty,n,\boldsymbol{x}_+,\boldsymbol{x}_-)\chi(\infty,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-). \tag{119}$$

In terms of CBA and BA functions instead of (119) we have

$$\frac{\partial}{\partial x_+}\psi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)=\psi_0(\lambda,n,\boldsymbol{x}_+,\boldsymbol{x}_-)\tilde{\psi}_0(\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$

$$\frac{\partial}{\partial x_-}\psi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)=\psi_\infty(\lambda,n,\boldsymbol{x}_+,\boldsymbol{x}_-)\tilde{\psi}_\infty(\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-). \tag{120}$$

Combining (116), (117), and (119), one obtains

$$\left(\frac{\partial}{\partial x_+}+\frac{1}{\lambda}\right)\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)-\frac{1}{\lambda}\,\chi(\lambda,\mu,n-1,\boldsymbol{x}_+,\boldsymbol{x}_-)=\chi(\lambda,0,n,\boldsymbol{x}_+,\boldsymbol{x}_-)(\chi(0,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)$$
$$-\chi(0,\mu,n-1,\boldsymbol{x}_+,\boldsymbol{x}_-)),$$
$$\left(\frac{\partial}{\partial x_-}+\lambda\right)\chi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)-\lambda\chi(\lambda,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)=\chi(\lambda,\infty,n,\boldsymbol{x}_+,\boldsymbol{x}_-)(\chi(\infty,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)$$
$$-\chi(\infty,\mu,n+1,\boldsymbol{x}_+,\boldsymbol{x}_-)). \tag{121}$$

Taking the first equation at $\lambda=\infty$, $\mu=0$, the second at $\lambda=0$, $\mu=\infty$, one obtains the following equations:

$$\partial_+u(n)=(U(n)-U(n-1))u(n),$$
$$\partial_-v(n)=(V(n)-V(n+1))v(n). \tag{122}$$

Here we have introduced the notations

$$u(n)=\chi(\infty,0,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$
$$v(n)=\chi(0,\infty,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$
$$U(n)=\chi_r(0,0,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$
$$V(n)=\chi_r(\infty,\infty,n,\boldsymbol{x}_+,\boldsymbol{x}_-),$$

and we omit arguments $\boldsymbol{x}_+,\boldsymbol{x}_-$ common for all functions.

Equations (119) taken, respectively, at $\lambda=\infty$, $\mu=\infty$; $\lambda=0$, $\mu=0$ give rise to the following relations:

$$\partial_+V(n)=u(n)v(n)-1,$$
$$\partial_-U(n)=u(n)v(n)-1, \tag{123}$$

which together with (122) form a closed system of equations.

There is also an additional relation implied by (116), (117):

$$u(n+1)v(n)=1. \tag{124}$$

This formula shows that the functions $u(n)$ and $v(n)$ are not independent.

The system of equations (122), (123), (124) represent some special form of classical 2D Toda lattice equations. To show it, let us derive more standard forms of the Toda lattice from this system. First, it is easy to show that

$$\partial_+\partial_-\ln u(n)=u(n)v(n)-u(n-1)v(n-1),$$
$$\partial_+\partial_-\ln v(n)=u(n)v(n)-u(n+1)v(n+1). \tag{125}$$

Thus, for the function $h(n)=u(n)v(n)$ we have an equation,

$$\partial_+\partial_-\ln h(n)=2h(n)-h(n-1)-h(n+1), \tag{126}$$

which is the 2D Toda lattice equation in the Darboux form.

Since, according to (124), the functions $u(n)$ and $v(n)$ are not independent, we can write an equation for one function,

$$\partial_+\partial_-\ln u(n)=\frac{u(n)}{u(n+1)}-\frac{u(n-1)}{u(n)}. \tag{127}$$

In terms of $\theta(n)=\ln u(n)$ we have

$$\partial_+\partial_-\theta(n)=\exp(\theta(n)-\theta(n+1))-\exp(\theta(n-1)-\theta(n)). \tag{128}$$

This is just a standard form of the 2D Toda lattice equation. An original bilinear form, introduced by Toda, follows from addition formulas for the τ function, which will be given in the next section.

Now we proceed to the modified Toda lattice equation. In this case we will use the equations for generic wave functions, which are given by (118) and (120) integrated over λ and μ with some weight functions $\rho(\lambda)$ and $\eta(\mu)$ [in fact, each of them in the matrix notations is a pair of functions defined as an ''in'' unit circle and an ''out'' unit circle; see also (31)]:

$$\begin{aligned}\Phi(n)-\Phi(n+1)&=\Psi_0(n+1)\tilde{\Psi}_0(n),\\ \Phi(n)-\Phi(n-1)&=\Psi_\infty(n-1)\tilde{\Psi}_\infty(n)\end{aligned} \tag{129}$$

(we have omitted common arguments $\boldsymbol{x}_+,\boldsymbol{x}_-$).

Combining these equations, one obtains a linear problem for the modified Toda lattice equation,

$$\begin{aligned}\partial_+\Phi&=W_+(1-T)\Phi,\quad W_+=\frac{\psi_0}{T\psi_0},\\ \partial_-\Phi&=W_-(1-T^{-1})\Phi,\quad W_-=\frac{\psi_\infty}{T^{-1}\psi_\infty}.\end{aligned} \tag{130}$$

The compatibility condition gives the modified Toda lattice equations,

$$\begin{aligned}\partial_-W_+&=W_+(1-T)W_-,\\ \partial_+W_-&=W_-(1-T^{-1})W_+.\end{aligned} \tag{131}$$

These equations appeared in the literature[18] under the name of a two-dimensional Volterra chain; they were discussed quite recently in Refs. 19, 20. It is interesting to note that in Ref. 19 they arose in the geometrical context.

Proceeding further, one can obtain an equation for the function Φ, using linear operators of a modified Toda lattice to express the functions W_+, W_- via the function Φ and then substituting the final result into equations (131). Both equations give rise to the same equation,

$$\partial_+\partial_-\Phi+\partial_+\Phi\cdot\partial_-\Phi\left(\frac{1}{T\Phi-\Phi}+\frac{1}{T^{-1}\Phi-\Phi}\right)=0. \tag{132}$$

This equation was also introduced in different contexts in Refs. 19, 20. Another interesting feature of equation (132) could be its connection with the Painleve analysis of the 2DTL. Making a comparison with the one-dimensional Toda lattice case,[21] and recalling the analogous equation for the scalar KP case, it is natural to suggest that the equation (132) represents a singularity manifold equation for the 2DTL.

Equation (132) generates 2DTL and a two-dimensional Volterra chain in different ways: first, in terms of Combescure invariants, and second, in terms of expansion in λ,μ of the function $\psi(\lambda,\mu,n,\boldsymbol{x}_+,\boldsymbol{x}_-)$ which satisfies equation (132).

The Combescure invariants for (132) are given by the formulas

$$\begin{aligned}W_+&=-\frac{\partial_+\Phi}{\Delta\Phi},\\ W_-&=\frac{\partial_-T\Phi}{\Delta\Phi},\end{aligned} \tag{133}$$

(we have written down only ''left'' invariants). For a two-dimensional Volterra chain the Combescure invariants look like

$$u = W_- \exp(-\Delta^{-1}(W_- + TW_+)),$$
$$v = W_+ \exp(\Delta^{-1}(W_- + TW_+)). \tag{134}$$

Substituting (133) in (134), one obtains expressions of the full Combescure group invariants for singularity manifold equation (132).

At last, we present the formulas for the hierarchies of the two-dimensional Toda, Volterra, and 2D Toda singularity manifold equations. The derivation is very similar to the case of DS hierarchy, so we will omit it.

The 2DTL hierarchy can be represented as an equation,

$$T_+ T_-^{-1} u + \frac{a_+}{a_-} Tu = T_+ u T_-^{-1} u \left(\frac{1}{u} + \frac{a_+}{a_-} \frac{1}{T_+ T_-^{-1} T^{-1} u} \right), \tag{135}$$

where a convention for shift and difference operators is standard,

$$T_+ : \boldsymbol{x}_+ \to \boldsymbol{x}_+ + [a_+],$$
$$T_- : \boldsymbol{x}_- \to \boldsymbol{x}_+ + [a_-^{-1}],$$
$$\Delta_+ = T_+ - 1, \tag{136}$$
$$\Delta_- = (T_- - 1).$$

The 2D Volterra hierarchy reads as

$$a_- \Delta_- W_+ + (T_- W_+)(TW_-) - (T_+ W_-) W_+ = 0,$$
$$1/a_+ \Delta_+ W_- + (T_+ W_-)(T^{-1} W_+) - (T_- W_+) W_- = 0, \tag{137}$$

where $W_+ = T_+ \Psi_0 / T\Psi_0$, $W_- = T_- \Psi_\infty / T^{-1} \Psi_\infty$.

Finally, the 2DTL singularity manifold equation hierarchy looks like

$$\{T_-(T_+ - 1)\Phi\}\{T(T_- - T^{-1})\Phi\}\{T_+(1 - T^{-1})\Phi\} = \{(T_+ - 1)\Phi\}\{T_+(T_- - T^{-1})\Phi\} \times \{T_-(T - 1)\Phi\}. \tag{138}$$

This equation possesses a symmetry $T_+ \to T_-$, $T_- \to T_+$, $T \to T^{-1}$. Though this symmetry is not obvious it can be easily verified.

XI. ADDITION FORMULAS FOR TODA-LATTICE HIERARCHY

The τ-functional substitution,

$$\chi(\lambda, \mu, g) = \frac{1}{\lambda - \mu} \frac{\tau(g_{(\lambda,\mu)} g)}{\tau(g)},$$
$$g_{(\lambda,\mu)} = \frac{\lambda - \nu}{\mu - \nu}, \tag{139}$$

to (110), (118) leads to addition formulas for the τ function, the expansion of which gives the equations of the Toda lattice hierarchy in terms of the τ function.

The simplest addition formulas follow from (118),

$$\frac{1}{\mu(\lambda-\mu)}\,\tau(g\times g_d g_{(\lambda,\mu)})\tau(g)-\frac{1}{\lambda(\lambda-\mu)}\tau(g\times g_{(\lambda,\mu)})\tau(g\times g_d)$$
$$+\frac{1}{\lambda\mu}\tau(g\times g_d g_{(\lambda,0)})\tau(g\times g_{(0,\mu)})=0,\quad g_d(\nu)=\nu. \tag{140}$$

This is a functional form of addition formulas, containing four components characterized by the position of λ,μ with respect to the unit circle. Using parametrization of loop group elements in terms of times, we obtain a standard form of addition formulas. It is convenient to write down first the factorization formulas for the function $g_{(\lambda,\mu)}$, representing it as a product of functions analytic inside and outside the unit circle for different positions of λ and μ. For λ,μ both belonging to D_0 (D_∞) the factorization is trivial, because $g_{(\lambda,\mu)}$ is analytic outside (inside) the unit circle. For λ,μ in different domains it is given by

$$g_{(\lambda_+,\mu_-)}=g_d g_{(\lambda_+,0)}g_{(\infty,\mu_-)},$$
$$g_{(\lambda_-,\mu_+)}=g_d^{-1}g_{(\lambda_-,\infty)}g_{(0,\mu_+)}; \tag{141}$$

here the subscript $+,-$ just indicates the position inside or outside the unit circle.

In terms of time variables, the action of loop group elements represented in the formula (140) (taking into account the factorization formulas) looks like

$$g_{(\lambda_+,\mu_+)}\to \boldsymbol{x}_+ +[\mu_+]-[\lambda_+],$$
$$g_{(\lambda_-,\mu_-)}\to \boldsymbol{x}_- +[\mu_-^{-1}]-[\lambda_-^{-1}],$$
$$g_{(\lambda_+,\mu_-)}\to n+1,\boldsymbol{x}_+ -[\lambda_+],\boldsymbol{x}_- +[\mu_-^{-1}], \tag{142}$$
$$g_{(\lambda_-,\mu_+)}\to n-1,\boldsymbol{x}_+ +[\mu_+],\boldsymbol{x}_- -[\lambda_-^{-1}].$$

Substituting these formulas in (140), we obtain a standard form of addition formulas for the Toda lattice hierarchy. It occurs that off-diagonal components of (140) give the same formula with interchanged λ,μ, so we have three addition formulas,

$$\lambda\,\tau_n^{(\boldsymbol{x}_+ +[\mu],\boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\lambda^{-1}])}-\mu\,\tau_{n-1}^{(\boldsymbol{x}_+ +[\mu],\boldsymbol{x}_-)}\tau_{n+1}^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\lambda^{-1}])}=(\lambda-\mu)\,\tau_n^{(\boldsymbol{x}_+,\boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+ +[\mu],\boldsymbol{x}_- +[\lambda^{-1}])}, \tag{143}$$
$$|\lambda|>1,\quad |\mu|<1,$$

$$\lambda\,\tau_{n+1}^{(\boldsymbol{x}_+ +[\mu],\boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+ +[\lambda],\boldsymbol{x}_-)}-\mu\,\tau_n^{(\boldsymbol{x}_+ +[\mu],\boldsymbol{x}_-)}\tau_{n+1}^{(\boldsymbol{x}_+ +[\lambda],\boldsymbol{x}_-)}=(\lambda-\mu)\,\tau_{n+1}^{(\boldsymbol{x}_+,\boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+ +[\mu]+[\lambda],\boldsymbol{x}_-)}, \tag{144}$$
$$|\lambda|<1,\quad |\mu|<1,$$

$$\lambda\,\tau_n^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\mu^{-1}])}\tau_{n-1}^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\lambda^{-1}])}-\mu\,\tau_{n-1}^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\mu^{-1}])}\tau_n^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\lambda^{-1}])}$$
$$=(\lambda-\mu)\,\tau_{n-1}^{(\boldsymbol{x}_+,\boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+,\boldsymbol{x}_- +[\mu^{-1}]+[\lambda^{-1}])},\quad |\lambda|>1,\quad |\mu|>1. \tag{145}$$

In fact, we have used only the first equation of the pair of equations (118), but the second equation gives exactly the same set of addition formulas.

The formula (143) is a well-known simplest addition formula for the Toda lattice hierarchy. The formulas (144), (145) do not shift negative (positive) times and it is connected with the Bäcklund transformations for the KP equation.

To get more generic addition formulas, one could use the formula (110). To get more symmetric expressions, we will use a special version of this formula corresponding to the choice

$$g_0(\nu) := g_1(\nu) g_2^{-1}(\nu) = \frac{\nu-\xi}{\nu-\eta}, \tag{146}$$

where we do not specify from the beginning the position of the points λ_1, μ_1. This choice leads to the following functional form of the addition formula:

$$\begin{aligned}(\mu-\eta)(\lambda-\xi)\tau(gg_{(\xi,\eta)}g_{(\lambda,\mu)})\tau(g) - (\lambda-\eta)(\mu-\xi)\tau(gg_{(\lambda,\mu)})\tau(gg_{(\xi,\eta)}) \\ +(\lambda-\mu)(\eta-\xi)\tau(gg_{(\xi,\mu)})\tau(gg_{(\lambda,\eta)}) = 0.\end{aligned} \tag{147}$$

The formula (147) contains 16 components depending on the position of four parameters with respect to the unit circle. It is convenient to introduce the function showing the position of each parameter,

$$i_\lambda = \begin{cases} \frac{1}{2}, & |\lambda|<1, \\ -\frac{1}{2}, & |\lambda|>1. \end{cases} \tag{148}$$

Then the addition formulas take the form

$$\begin{aligned}(\mu-\eta)(\lambda-\xi)\tau_{n-i_\eta-i_\mu}^{(\boldsymbol{x}+[[\eta]]+[[\mu]])}\tau_{n-i_\lambda-i\xi}^{(\boldsymbol{x}+[[\lambda]]+[[\xi]])} - (\lambda-\eta)(\mu-\xi)\tau_{n-i_\mu-i_\xi}^{(\boldsymbol{x}+[[\xi]]+[[\mu]])}\tau_{n-i_\lambda-i_\eta}^{(\boldsymbol{x}+[[\lambda]]+[[\eta]])} \\ +(\lambda-\mu)(\eta-\xi)\tau_{n-i_\lambda-i_\mu}^{(\boldsymbol{x}+[[\mu]]+[[\lambda]])}\tau_{n-i_\eta-i_\xi}^{(\boldsymbol{x}+[[\eta]]+[[\xi]])} = 0,\end{aligned} \tag{149}$$

where

$$(\boldsymbol{x}+[[\lambda]]) = \begin{cases} (\boldsymbol{x}_+ + [\lambda], \boldsymbol{x}_-) & |\lambda|<1, \\ (\boldsymbol{x}_+, \boldsymbol{x}_- + [\lambda^{-1}]), & |\lambda|>1. \end{cases}$$

Due to its symmetric form, the formula (149) contains only five different addition formulas corresponding to all four parameters inside the unit circle: one parameter outside, two parameters outside, three parameters outside, all four parameters outside. The first and the last case just give the KP addition formulas, so we will consider only the remaining three cases. First we write down the addition formulas for the case when two variables (say, λ and μ) are inside the unit circle:

$$\begin{aligned}(\mu-\eta)(\lambda-\xi)\tau_n^{(\boldsymbol{x}_+ + [\mu], \boldsymbol{x}_- + [\eta^{-1}])}\tau_n^{(\boldsymbol{x}_+ + [\lambda], \boldsymbol{x}_- + [\xi^{-1}])} \\ -(\lambda-\eta)(\mu-\xi)\tau_n^{(\boldsymbol{x}_+ + [\mu], \boldsymbol{x}_- + [\xi^{-1}])}\tau_n^{(\boldsymbol{x}_+ + [\lambda], \boldsymbol{x}_- + [\eta^{-1}])} \\ +(\lambda-\mu)(\eta-\xi)\tau_{n-1}^{(\boldsymbol{x}_+ + [\mu]+[\lambda], \boldsymbol{x}_-)}\tau_{n+1}^{(\boldsymbol{x}_+, \boldsymbol{x}_- + [\eta^{-1}]+[\xi^{-1}])} = 0.\end{aligned} \tag{150}$$

The structure of this addition formula is similar to the formula (143), and in fact (150) is a generalized version of (143).

When one parameter (say, λ) is inside the unit circle, we obtain the following addition formula:

$$\begin{aligned}(\mu-\eta)(\lambda-\xi)\tau_{n+1}^{(\boldsymbol{x}_+, \boldsymbol{x}_- + [\eta^{-1}]+[\mu^{-1}])}\tau_n^{(\boldsymbol{x}_+ + [\lambda], \boldsymbol{x}_- + [\xi^{-1}])} \\ \times(\lambda-\eta)(\mu-\xi)\tau_{n+1}^{(\boldsymbol{x}_+, \boldsymbol{x}_- + [\xi^{-1}]+[\mu^{-1}])}\tau_n^{(\boldsymbol{x}_+ + [\lambda], \boldsymbol{x}_- + [\eta^{-1}])} \\ +(\lambda-\mu)(\eta-\xi)\tau_n^{(\boldsymbol{x}_+ + [\lambda], \boldsymbol{x}_- + [\mu^{-1}])}\tau_{n+1}^{(\boldsymbol{x}_+, \boldsymbol{x}_- + [\eta^{-1}]+[\xi^{-1}])} = 0.\end{aligned} \tag{151}$$

And the last case (λ outside the unit circle) gives

$$\begin{aligned}(\mu-\eta)(\lambda-\xi)\tau_{n-1}^{(\boldsymbol{x}_+ + [\eta]+[\mu], \boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+ + [\xi], \boldsymbol{x}_- + [\lambda^{-1}])} - (\lambda-\eta)(\mu \\ -\xi)\tau_{n-1}^{(\boldsymbol{x}_+ + [\xi]+[\mu], \boldsymbol{x}_-)}\tau_n^{(\boldsymbol{x}_+ + [\eta], \boldsymbol{x}_- + [\lambda^{-1}])}\end{aligned}$$

$$+(\lambda-\mu)(\eta-\xi)\tau_n^{(\boldsymbol{x}_+ +[\mu],\boldsymbol{x}_- +[\lambda^{-1}])}\tau_{n-1}^{(\boldsymbol{x}_+ +[\eta]+[\xi],\boldsymbol{x}_-)}=0. \tag{152}$$

The formulas (151), (152) generalize the formulas (144), (145).

Supersymmetric Drinfeld–Sokolov reduction

F. Delduc and L. Gallot
Laboratoire de Physique, ENS Lyon, 46 Allée d'Italie, 69364 Lyon, France

(Received 25 February 1998; accepted for publication 2 April 1998)

The Drinfeld–Sokolov construction of integrable hierarchies, as well as its generalizations, may be extended to the case of loop superalgebras. A sufficient condition on the algebraic data for the resulting hierarchy to be invariant under supersymmetry transformation is given. The method used is a construction of the hierarchies in superspace, where supersymmetry is manifest. Several examples are discussed. © *1998 American Institute of Physics.* [S0022-2488(98)01009-3]

I. INTRODUCTION

One can find in the literature many examples of supersymmetric hierarchies (see, e.g., Refs. 1–7) but a general discussion of these hierarchies in the Drinfeld–Sokolov (DS) reduction framework is still lacking. The construction of a hierarchy in the Drinfeld–Sokolov approach relies on some algebraic data.[8–11] In particular, one needs to introduce a loop algebra, together with an integer grading of this algebra, and a semisimple positively graded element Λ in the loop algebra. One may simply replace everywhere the words ''loop algebra'' by ''loop superalgebra,'' and the construction carries through without major difficulties. The hierarchy which will be obtained in this way contains both commuting and anticommuting (Grassmann odd) fields. However, in general it will not be supersymmetric, that is to say it will not contain an odd conserved charge whose Poisson bracket with itself is the charge associated with translation invariance. Another way to put it is that it will not admit a symmetry transformation relating commuting to anticommuting fields in such a way that the commutator of two such transformations is a space translation. The simplest example of such a hierarchy will be given in Sec. III.[12,13]

Suppose now that we wish to construct supersymmetric hierarchies. It turns out that a very simple additional requirement on the input data is sufficient to ensure that the hierarchy will possess supersymmetry. Namely, the semisimple element Λ, necessarily an even element of the superalgebra, should be the square of an odd graded element Ψ of the superalgebra. This will be shown in Sec. II by constructing the hierarchy from the input data directly in superspace, where supersymmetry is manifest at all steps of the procedure.

Several examples of the general construction are gathered in Sec. III. In particular, we shall give the Drinfeld–Sokolov formulations for the supersymmetric hierarchies studied in the Gelfand–Dickey approach in Ref. 14. Some examples of supersymmetric extensions of the homogeneous hierarchies, which require the use of a twisted loop superalgebra, are also studied.

II. DS REDUCTION

In this section, we shall recapitulate the Drinfeld–Sokolov construction for the supersymmetric Korteweg–de Vries (KdV) type hierarchies in $N=1$ superspace. As a generalization of the construction in Ref. 4, we shall give the supersymmetric version of the construction given in Ref. 11. Some details, common to both the bosonic and the supersymmetric cases will be omitted and we refer to the literature[8–11] for details.

A. Superspace

We shall consider an $N=1$ superspace with one space coordinate x and one Grassmann coordinate θ. The pair of coordinates (x,θ) will be denoted by $\tilde{x}$. The supersymmetric covariant derivative is defined by

TABLE I. The symmetry properties.

$[A,B\}=$	$A\in{}_+\mathcal{G}$	$A\in{}_-\mathcal{G}$
$B\in{}_+\mathcal{G}$	$-[B,A\}$	$-[\hat{B},A\}$
$B\in{}_-\mathcal{G}$	$-[B,\hat{A}\}$	$[\hat{B},\hat{A}\}$

$$D=\frac{\partial}{\partial\theta}+\theta\partial,\quad D^2=\partial\equiv\frac{\partial}{\partial x}. \tag{1}$$

We define the integration of a superfield $H(\tilde{x})$ over the $N=1$ superspace to be

$$\int d\tilde{x}\ H(\tilde{x})=\int dx\ DH|_{\theta=0}. \tag{2}$$

A superalgebra $\mathcal{G}$[15] is a Z_2 graded algebra $\mathcal{G}=\mathcal{G}_{\bar{0}}\oplus\mathcal{G}_{\bar{1}}$ with the product law $[\ ,\}$ satisfying for any $a\in\mathcal{G}_\alpha$ and $b\in\mathcal{G}_\beta$,

$$[a,b\}=-(-)^{\alpha\beta}[b,a\},\quad [a,[b,c\}\}=[[a,b\},c\}+(-)^{\alpha\beta}[b,[a,c\}\}. \tag{3}$$

We shall denote by a caret the automorphism of $\mathcal{G}$ that reverses the sign of odd elements,

$$M\in\mathcal{G},\quad M=M_{\bar{0}}+M_{\bar{1}}\to\hat{M}=M_{\bar{0}}-M_{\bar{1}}. \tag{4}$$

We shall only consider classical superalgebras[15] equipped with a bilinear invariant form denoted by $\langle\ ,\rangle$.

In the following, we shall use superfields taking values in the tensor product $\underline{\mathcal{G}}$ of a superalgebra $\mathcal{G}$ with some Grassmann algebra $\mathcal{G}r=\mathcal{G}r_{\bar{0}}\oplus\mathcal{G}r_{\bar{1}}$. An element in this space is called ''even'' if it belongs to ${}_+\underline{\mathcal{G}}=\mathcal{G}_{\bar{0}}\otimes\mathcal{G}r_{\bar{0}}\oplus\mathcal{G}_{\bar{1}}\otimes\mathcal{G}r_{\bar{1}}$ and ''odd'' if it belongs to ${}_-\underline{\mathcal{G}}=\mathcal{G}_{\bar{0}}\otimes\mathcal{G}r_{\bar{1}}\oplus\mathcal{G}_{\bar{1}}\otimes\mathcal{G}r_{\bar{0}}$. If we denote by T^a a basis vector of $\mathcal{G}$, an element A in $\underline{\mathcal{G}}$ may be expanded as

$$A=\sum_a A_aT^a,\quad A_a\in\mathcal{G}r. \tag{5}$$

The supercommutator of two elements A and B in $\underline{\mathcal{G}}$ will be defined as

$$[A,B\}=\sum_{a,b}A_aB_b[T^a,T^b\}. \tag{6}$$

With this definition, the supercommutator satisfies the symmetry properties listed in Table I.
If $A(\tilde{x})$ is a superfield taking values in ${}_+\underline{\mathcal{G}}$ or ${}_-\underline{\mathcal{G}}$, we extend the definition of the supercommutator in order to include the derivatives

$$[D,A(\tilde{x})\}=\Sigma_a(DA_a(\tilde{x}))T^a,$$

$$[D,A(\tilde{x})\}=\mp[\hat{A}(\tilde{x}),D\}\quad\text{if } A\in{}_\pm\underline{\mathcal{G}}.$$

We denote by $\mathcal{F}[J]\in\mathcal{G}r$ a functional of the superfield $J(\tilde{x})$ which takes values in ${}_+\underline{\mathcal{G}}$ or ${}_-\underline{\mathcal{G}}$. The functional derivative of $\mathcal{F}[J]$ with respect to $J(\tilde{x})$, denoted by $\delta\mathcal{F}/[\delta J(\tilde{x})]$, is defined by

$$\frac{d}{d\epsilon}\mathcal{F}[J+\epsilon r]|_{\epsilon=0}=\int d\tilde{x}\left\langle\frac{\delta\mathcal{F}}{\delta J(\tilde{x})},r(\tilde{x})\right\rangle, \tag{7}$$

where $r(\tilde{x})$ is any superfield with the same parity as $J(\tilde{x})$, and ϵ is a real parameter. Notice that the functional derivative of $\mathcal{F}$ has the same parity as $\mathcal{F}$ if J is odd, and the opposite one if J is even.

Following the lines of Ref. 11, a supersymmetric KdV system and its modified system will be associated with the choice of a sextuplet $(\mathscr{A}, d_1, d_0, \Psi; \alpha^0, \beta^0)$. $\mathscr{A}$ is an affine superalgebra (we shall not restrict ourselves to affine superalgebras possessing a purely odd root system) with vanishing center, that is a twisted loop superalgebra

$$\mathscr{A} = \mathscr{L}(\mathscr{G}, \tau) \subset \mathscr{G} \otimes C[\lambda, \lambda^{-1}] \tag{8}$$

attached to a finite dimensional classical superalgebra $\mathscr{G}$ with an automorphism τ of finite order. d_1 and d_0 are two compatible integer gradations of $\mathscr{A}$ ($[d_1, d_0] = 0$). The subsets $\mathscr{A}_m^n = \mathscr{A}^n \cap \mathscr{A}_m$ with $\mathscr{A}^n = \{X \in \mathscr{A} | d_1(X) = nX\}$, $\mathscr{A}_m = \{X \in \mathscr{A} | d_0(X) = mX\}$ define a bigrading of $\mathscr{A}$. We also assume that

$$\mathscr{A}^{>0} \subset \mathscr{A}_{\geqslant 0}, \quad \mathscr{A}^{<0} \subset \mathscr{A}_{\leqslant 0}. \tag{9}$$

In the sextuplet, Ψ is supposed to be an odd element of $\mathscr{A}$ with positive d_1-grade, $d_1(\Psi) = k\Psi$ with $k > 0$, whose square $\Lambda = \frac{1}{2}[\Psi, \Psi]$ is semisimple,

$$\mathscr{A} = \mathrm{Ker}(\mathrm{ad}\ \Lambda) \oplus \mathrm{Im}(\mathrm{ad}\ \Lambda). \tag{10}$$

We denote by $\mathscr{Z}$ the center of the kernel $\mathscr{K} = \mathrm{Ker}(\mathrm{ad}\ \Lambda)$. $\mathscr{Z}$ contains only even elements of $\mathscr{A}$.

We finally assume that $\mathscr{A}^0$ can be decomposed into the direct sum of two of its subalgebras as

$$\mathscr{A}^0 = \alpha^0 \oplus \beta^0 \quad \text{with} \quad \alpha^0 = \mathscr{A}^0_{\geqslant 0}, \quad \beta^0 \subset \mathscr{Z}^0. \tag{11}$$

The superalgebra $\mathscr{A}$ is then decomposed into $\mathscr{A} = \alpha \oplus \beta$, where $\alpha = \mathscr{A}^{>0} \oplus \alpha^0$ and $\beta = \beta^0 \oplus \mathscr{A}^{<0}$ are subalgebras. The usual decomposition[4] is recovered if one requires the supplementary condition

$$\mathscr{A}^0 \subset \mathscr{A}_0, \tag{12}$$

which implies $\alpha^0 = \mathscr{A}^0$, $\beta^0 = \{0\}$.

We introduce the odd Lax operator

$$\mathscr{L} = D + q(\tilde{x}) + \Psi, \tag{13}$$

where the odd superfield $q(\tilde{x})$ takes values in ${}_-\mathscr{A}$. We shall write evolution equations on $\mathscr{L}$ of the zero curvature type

$$\frac{\partial}{\partial t}\mathscr{L} = [A, \mathscr{L}], \tag{14}$$

where the even superfield $A(\tilde{x})$ takes values in ${}_+\mathscr{A}$. From the odd Lax operator $\mathscr{L}$ we may obtain an even operator by

$$\mathscr{L}_x = \tfrac{1}{2}[\hat{\mathscr{L}}, \mathscr{L}] = \partial + Q - \Lambda, \tag{15}$$

where the even superfield $Q(\tilde{x}) = Dq + \frac{1}{2}[\hat{q}, q\} - [\psi, q\}$ takes values in ${}_+\mathscr{A}$. It will evolve as

$$\frac{\partial}{\partial t}\mathscr{L}_x = [\hat{A}, \mathscr{L}_x]. \tag{16}$$

The phase space

$$\Theta = \{\mathscr{L} = D + q + \Psi | q \in {}_-\mathscr{A}^{<k} \cap {}_-\mathscr{A}^{\geqslant 0} \cap {}_-\mathscr{A}_{\geqslant 0}\} \tag{17}$$

will define a modified KdV type system, while a KdV type system will be obtained from

$$\mathscr{Q} = \{\mathscr{L} = D + q + \Psi | q \in {}_-\mathscr{A}^{\leqslant k} \cap {}_-\mathscr{A}_{\geqslant 0}\}. \tag{18}$$

In both cases, the construction relies on the following version of the formal dressing procedure. For any $q \in {}_-\mathscr{A}^{<k}$, there exists a unique $F(q(\tilde{x})) \in {}_+(\mathrm{Im}(\mathrm{ad}\ \Lambda))^{<0}$ such that

$$\mathscr{L}_0 = e^{\hat{F}} \mathscr{L} e^{-F} = D + H + \Psi, \tag{19}$$

where $H \in {}_-(\mathrm{Ker}(\mathrm{ad}\ \Lambda))^{<k}$. At any finite grade, the components of both F and H are differential polynomials in terms of those of q. By this we mean that the graded components of F and H are polynomials in the components of q and of a finite number of its derivatives Dq, ∂q, etc. Suppose that this is true up to grade $-n+k$ for H and $-n$ for F, then, at the next grade, Eq. (19) reduces to

$$H^{k-n-1} = P(H^{k-1},\ldots,H^{k-n},F^{-1},\ldots,F^{-n}) + [\hat{F}^{-n-1},\Psi\}. \tag{20}$$

It is not hard to show that the transformation ad Ψ may be restricted to the image Im (ad Λ), and that this restriction is an isomorphism. In other words, there is a unique element G^{-n-1-k} in ${}_+\mathrm{Im}(\mathrm{ad}\ \Lambda)$ such that

$$F^{-n-1} = [\hat{G}^{-n-1-k},\Psi\}.$$

Then Eq. (20) may be written as

$$H^{k-n-1} = P(H^{k-1},\ldots,H^{k-n},F^{-1},\ldots,F^{-n}) + [\Lambda,G^{-n-1-k}]. \tag{21}$$

From the fact that Λ is semisimple, see Eq. (10), we conclude that there exists one and only one choice for $G^{-n-1-k} \in \mathrm{Im}(\mathrm{ad}\ \Lambda)$ such that this equation holds at this grade. For later purposes, we define for any constant $b \in \mathscr{Z}^{\geqslant 0}$ the functional

$$\mathscr{H}_b(q) = \int d\tilde{x} \langle b, H(q) \rangle. \tag{22}$$

and the even superfield

$$B_b(q) = e^{-\hat{F}} b e^{\hat{F}}. \tag{23}$$

The graded components of $B_b(q)$ are differential polynomials in the components of q. Moreover, we have the property

$$[b,\mathscr{L}_0] = 0 \Rightarrow [B_b(q),\mathscr{L}] = 0. \tag{24}$$

According to a standard calculation, the functional derivative of $\mathscr{H}_b(q)$ is

$$\frac{\delta}{\delta q} \mathscr{H}_b(q) = B_b(q). \tag{25}$$

B. The modified system

The formal dressing procedure may in particular be applied to the phase space Θ defined in Eq. (17). We shall construct on this phase space an integrable system of the modified KdV type. The splitting of $\mathscr{A}$,

$$\mathscr{A} = \alpha + \beta, \tag{26}$$

yields an r-matrix,

$$\mathscr{R} = \tfrac{1}{2}(\mathscr{P}_\alpha - \mathscr{P}_\beta), \tag{27}$$

where $\mathscr{P}_\alpha$, $\mathscr{P}_\beta$ are the projectors on the respective subalgebras α, β along the subalgebras β, α. $\mathscr{R}$ satisfies the (super) classical modified Yang–Baxter equation

$$\mathscr{R}([X,\mathscr{R}(Y)\}+[\mathscr{R}(X),Y\}) = [\mathscr{R}(X),\mathscr{R}(Y)\}+\tfrac{1}{4}[X,Y\}, \tag{28}$$

which is a sufficient condition for the r-bracket $[\ ,\ \}_{\mathscr{R}}$ defined by

$$[X,Y\}_{\mathscr{R}} = [X,\mathscr{R}(Y)\}+[\mathscr{R}(X),Y\}, \tag{29}$$

to satisfy the super Jacobi identity. The evolution equation for the modified system, associated with the constant element $b \in \mathscr{Z}^{\geqslant 0}$, is given by

$$\frac{\partial}{\partial t_b} q = [\mathscr{R}(B_b(q)),\mathscr{L}\}. \tag{30}$$

Using Eq. (24), this evolution equation may be written as

$$\frac{\partial}{\partial t_b} q = [\mathscr{P}_\alpha(B_b(q)),\mathscr{L}\} = -[\mathscr{P}_\beta(B_b(q)),\mathscr{L}\}, \tag{31}$$

from which one easily checks that (30) is a consistent evolution equation. Using that $[B_a(\theta),B_b(\theta)]=0$ for all $a,b \in \mathscr{Z}^{\geqslant 0}$ and that, as a consequence of (30), $(\partial/\partial t_a)B_b(\theta) = [\mathscr{R}(B_a(\theta)),B_b(\theta)\}$, together with the modified classical Yang–Baxter equation (28) for $\mathscr{R}$, it can be shown that the flows associated with different elements of $\mathscr{Z}^{\geqslant 0}$ commute:

$$\left[\frac{\partial}{\partial t_a}, \frac{\partial}{\partial t_b}\right] q = 0, \quad \forall a,b \in \mathscr{Z}^{\geqslant 0}. \tag{32}$$

Finally, the functionals $\mathscr{H}_a(q)$ are conserved quantities for this evolution equation

$$\frac{\partial}{\partial t_b} \mathscr{H}_a(q) = 0. \tag{33}$$

We shall now describe the Hamiltonian formalism for this hierarchy of evolution equations. For this, it will be convenient to introduce a Poisson bracket on the local functionals of the fields in the space

$$\mathscr{M} = \{\mathscr{L} = D + q + \Psi \,|\, q \in _\mathscr{A}^{<k}\}, \tag{34}$$

which contains as subsets both Θ and $\mathscr{Q}$. The Poisson bracket is inferred from the existence of the r-bracket $[\ ,\ \}_{\mathscr{R}}$ and reads

$$\{f,g\}_{\mathscr{R}} = \int d\tilde{x} \left\langle \left[\frac{\delta f}{\delta q}, \frac{\delta g}{\delta q}\right]_{\mathscr{R}}, q + \Psi \right\rangle + (-1)^{[g]+1} \left\langle \mathscr{R}\,\frac{\delta f}{\delta q}, D\,\frac{\hat{\delta} g}{\delta q} \right\rangle + (-1)^{[g]+1} \left\langle \frac{\delta f}{\delta q}, D\mathscr{R}\,\frac{\hat{\delta} q}{\delta q} \right\rangle, \tag{35}$$

where $[g]=0$ if g is an even functional, and $[g]=1$ if g is odd. The important fact here is that $\Theta \subset \mathscr{M}$ is a Poisson submanifold, so that we may restrict the Poisson bracket to Θ. The evolution equation (30) may be written in the following Hamiltonian form:

$$\frac{\partial}{\partial t_b} f = \{f,\mathscr{H}_b(q)\}_{\mathscr{R}}, \tag{36}$$

and the Hamiltonians are in involution with respect to the Poisson bracket

$$\{\mathscr{H}_a(q),\mathscr{H}_b(q)\}_{\mathscr{R}} = 0. \tag{37}$$

C. The KdV type system

We shall describe here the construction of a KdV type system and its relation with the modified system. We shall require the nondegeneracy condition

$$\mathrm{Ker}(\mathrm{ad}(\Lambda)) \cap \mathscr{A}_0^{<0} = \{0\}. \tag{38}$$

The phase space of the KdV type system is the factor space $\mathscr{Q}/\mathscr{N}$ where $\mathscr{N}$ is the group of gauge transformations e^{γ} acting on $\mathscr{Q}$ as

$$e^{\gamma}: \mathscr{L} \mapsto e^{\gamma} \mathscr{L} e^{-\gamma} \quad \gamma(\tilde{x}) \in {}_+\mathscr{A}_0^{<0}. \tag{39}$$

Let us define a subspace $\mathscr{Q}_V$ of the phase space $\mathscr{Q}$ by

$$\mathscr{Q}_V = \{\mathscr{L} = D + q_V + \Psi \,|\, q_V(\tilde{x}) \in {}_-V\}, \tag{40}$$

where V is a vector space such that

$$\mathscr{A}^{<k} \cap \mathscr{A}_{\geqslant 0} = [\Psi, \mathscr{A}_0^{<0}] \oplus V. \tag{41}$$

Due to the nondegeneracy condition (38), for any field configuration q in $\mathscr{Q}$, there is a unique field-dependent gauge transformation such that the image is $\mathscr{Q}_V$. In other words, $\mathscr{Q}_V$ is a model for $\mathscr{Q}/\mathscr{N}$. When regarded as functions on $\mathscr{Q}$, the components of $q_V(q)$ are differential polynomials which freely generate the set of gauge invariant differential polynomials on $\mathscr{Q}$. We shall refer to $\mathscr{Q}_V$ as a Drinfeld–Sokolov gauge.

To construct an integrable hierarchy on $\mathscr{Q}/\mathscr{N}$, we shall first exhibit commuting flows on $\mathscr{Q}$ by means of the formal dressing procedure. Similar to the modified case, we define commuting flows on $\mathscr{Q}$ by

$$\frac{\partial}{\partial t_b} q = [\mathscr{R}(B_b(q)), \mathscr{L}], \tag{42}$$

for any $b \in \mathbb{Z}^{\geqslant 0}$. It is not a difficult task to verify that the conditions on the sextuplet $(\mathscr{A}, d_1, d_0, \Psi; \alpha^0, \beta^0)$ ensure that (42) gives a consistent evolution equation on $\mathscr{Q}$. This equation has a gauge invariant meaning, which is to say that the evolution of gauge invariant quantities is given by gauge invariant differential polynomials. This is a consequence of the uniqueness of the formal dressing procedure.[11] If we use $\mathscr{Q}_V$ as a model for $\mathscr{Q}/\mathscr{N}$, then the evolution equation (42) on $\mathscr{Q}_V$ takes the form

$$\frac{\partial}{\partial t_b} q_V = [\mathscr{R}(B_b(q_V)) + \eta_b(q_V), D + q_V + \Psi], \tag{43}$$

where $\eta_b(q_V) \in {}_+\mathscr{A}_0^{<0}$ is a uniquely determined differential polynomial in q_V. The flows thus defined on $\mathscr{Q}_V$ commute.

The Hamiltonian interpretation of these flows is as follows. Notice first that $\mathscr{Q} \subset \mathscr{M}$ is a Poisson submanifold with respect to the Poisson bracket $\{\ ,\ \}_{\mathscr{R}}$, hence the evolution equation (42) can be put in the Hamiltonian form

$$\frac{\partial}{\partial t_b} f = \{f, \mathscr{H}_b\}_{\mathscr{R}}, \tag{44}$$

where $\mathscr{H}_b$ is obtained from the formal dressing procedure. We know that if f is gauge invariant then the right-hand side of (44) is gauge invariant. Since $\mathscr{H}_b$ is a gauge invariant functional of $\mathscr{Q}$, by the uniqueness property, we are then led to suspect that the Poisson bracket $\{f, g\}_{\mathscr{R}}$ of any two gauge invariant functionals on $\mathscr{Q}$ is again gauge invariant. Close inspection of the Poisson bracket shows that this is indeed the case. As a consequence, a nonlinear Poisson bracket is defined on $\mathscr{Q}/\mathscr{N}$ by identifying the local functionals on $\mathscr{Q}/\mathscr{N}$ with gauge invariant functionals on $\mathscr{Q}$. The KdV type hierarchy on $\mathscr{Q}/\mathscr{N}$ is generated by the Hamiltonians $\mathscr{H}_b$ and this induced bracket. The evolution equations of this hierarchy (43) hence take the form (44) where f is a gauge invariant functional.

The modified type system is related to the KdV type system by a Miura map. One can first check that $\Theta \in \mathscr{Q}$ and $\mathscr{Q}/\mathscr{N}$ have the same dimension

$$\dim(\mathscr{A}^{<k}\cap\mathscr{A}^{\geqslant 0}\cap\mathscr{A}_{\geqslant 0})=\dim(\mathscr{A}^{<k}\cap\mathscr{A}_{\geqslant 0})-\dim(\mathscr{A}^{<0}\cap\mathscr{A}_{0}), \tag{45}$$

which means that the two systems have the same number of independent fields. The map

$$\mu:\Theta\to\mathscr{Q}/\mathscr{N} \tag{46}$$

induced by the projection $\mathscr{Q}\to\mathscr{Q}/\mathscr{N}$ is the Miura map. μ maps the flows of the modified system onto those of the KdV type system. From the Hamiltonian point of view, μ is a Poisson map from the linear Poisson bracket $\{\ ,\ \}_{\mathscr{R}}$ on Θ to the nonlinear Poisson bracket on $\mathscr{Q}/\mathscr{N}$ induced by the Poisson bracket $\{\ ,\ \}_{\mathscr{R}}$ on $\mathscr{Q}$.

Remark: In this construction, the Hamiltonians are associated with the elements in $\mathscr{Z}$, the center of Ker (ad Λ). Inami and Kanno[4] associated the Hamiltonians with the elements in a vector space $\tilde{\mathscr{K}}$ such that the following decomposition of Ker (ad Λ) holds

$$\mathscr{K}=[\mathscr{K},\mathscr{K}\}\oplus\tilde{\mathscr{K}}. \tag{47}$$

$[\mathscr{K},\mathscr{K}\}$ is the commutant of $\mathscr{K}$. Indeed, an evolution equation of the hierarchy may be written on the dressed operator $\mathscr{L}_0$ and reads

$$\partial_{t_b}\mathscr{L}_0=[A_b,\mathscr{L}_0\}, \tag{48}$$

where $A_b\in\mathscr{K}$. If one decomposes the dressed operator into $\mathscr{L}_0=D+H_{[\mathscr{K},\mathscr{K}\}}+H_{\tilde{\mathscr{K}}}+\Psi$, then one obtains the conservation law

$$\partial_{t_b}H_{\tilde{\mathscr{K}}}=-D(\hat{A}_b)_{\tilde{\mathscr{K}}}\Rightarrow\partial_{t_b}\int d\tilde{x}H_{\tilde{\mathscr{K}}}=0. \tag{49}$$

In the examples that we shall look at hereafter, the set of conserved quantities associated with $\tilde{\mathscr{K}}$ is identified with the one associated with $\mathscr{Z}$. This is a consequence of the fact that $\tilde{\mathscr{K}}$ may be chosen in a way such that $\mathscr{Z}$ and $\tilde{\mathscr{K}}$ are isotropic and conjugated with respect to the invariant bilinear form $\langle\ ,\ \rangle$ on $\mathscr{A}$.

III. EXAMPLES

A. A reminder of the scalar formalism

In this section, we wish to study the matrix Lax formulation for the two series of $N=2$ KdV hierarchies described in Ref. 14. Before starting, we recall some basic facts about the $N=1$ scalar Lax formulation of these hierarchies.

This formalism, which is an analog of the Gelfand–Dickey formalism, is based on the use of the algebra $\mathscr{C}$ of even $N=1$ pseudo-differential operators (Ψ DOs) of the form

$$L=\sum_{i<M}u_iD^i. \tag{50}$$

The coefficient functions u_i are $N=1$ superfields. We define the residue of the pseudodifferential operator L by res $L=u_{-1}$. The trace of L is the integral of the residue

$$\mathrm{Tr}\ L=\int d\tilde{x}\ \mathrm{res}\ L,\quad \mathrm{Tr}[L,L']=0. \tag{51}$$

The algebra $\mathscr{C}$ can be decomposed into the direct sum of two associative subalgebras $\mathscr{C}=\mathscr{C}_{\geqslant 1}\oplus\mathscr{C}_{\leqslant 0}$ where $L=L_{\geqslant 1}$ is in $\mathscr{C}_{\geqslant 1}$ if it is a differential operator containing only strictly positive powers of D, and $L=L_{\leqslant 0}$ is in $\mathscr{C}_{\leqslant 0}$ if it is a pseudodifferential operator containing only negative or zero powers of D. We denote by $\mathscr{R}$ the classical r-matrix associated with this splitting:

$$\mathscr{R}(L)=\tfrac{1}{2}(L_{\geqslant 1}-L_{\leqslant 0}). \tag{52}$$

Then the commuting flows of an $N=2$ KP hierarchy, for an operator L of the form

$$L=D^{2n}+\sum_{i=1}^{\infty} U_i D^{2n-i-1}, \tag{53}$$

are defined by

$$\partial_{t_k} L=[.\mathscr{R}(L^{k/n}),L]. \tag{54}$$

This $N=2$ KP hierarchy is the so-called nonstandard supersymmetric KP hierarchy.[16,17] Due to the fact that the r-matrix $\mathscr{R}$ is not skew symmetric, these flows are Hamiltonian with respect to a linear and two quadratic Poisson brackets. We introduce these Poisson structures on the linear functionals of L of the type $l_X(L)=\mathrm{Tr}(LX)$, X being some element in $\mathscr{C}$ which does not depend on the phase space fields $\{U_i\}$. The linear structure is

$$\{l_X,l_Y\}_{(1)}(L)=\mathrm{Tr}(L[X,Y]_{\mathscr{R}}), \tag{55}$$

and the two quadratic ones[18,14] are

$$\{l_X,l_Y\}^a_{(2)}(L)=\mathrm{Tr}(LX(LY)_{\geqslant 0}-XL(YL)_{\geqslant 0})+\int d^2\tilde{x}(-\psi_Y\ \mathrm{res}[L,X] + \mathrm{res}[L,Y]\mathrm{res}(XLD^{-1})-\mathrm{res}[L,X]\mathrm{res}(YLD^{-1})), \tag{56}$$

$$\{l_X,l_Y\}^b_{(2)}(L)=\mathrm{Tr}(LX(LY)_{\geqslant 0}-XL(YL)_{\geqslant 0})+\int d^2\tilde{x}(\psi_Y\ \mathrm{res}[L,X] + \mathrm{res}[L,Y]\mathrm{res}(LXD^{-1})-\mathrm{res}[L,X]\mathrm{res}(LYD^{-1})), \tag{57}$$

where the quantity ψ_X is defined up to a constant by $D\psi_X=\mathrm{res}[L,X]$. The two quadratic brackets are of the $abcd$ type.[19] Introducing the Hamiltonians $\mathscr{H}_k=(n/k)\mathrm{Tr}(L^{k/n})$, the $N=2$ KP evolution equations (54) may be written in the Hamiltonian form

$$\partial_{t_k} l_X(L)=\{l_X,\mathscr{H}_{k+n}\}_{(1)}(L)=\{l_X,\mathscr{H}_k\}^{a,b}_{(2)}(L). \tag{58}$$

The Hamiltonians form a family of quantities in involution with respect to any of these three brackets. The two quadratic brackets are related to each other by an invertible Poisson map p of $\mathscr{C}$ defined by

$$p(L)=\partial^{-1}L^t, \tag{59}$$

where L^t is the operator adjoint to L. One has the relation

$$\{l_X\circ p,l_Y\circ p\}^a_{(2)}=-\{l_X,l_Y\}^b_{(2)}\circ p, \tag{60}$$

which gives an equivalence between the two quadratic structures. However, there is no relation between the Hamiltonians $\mathrm{Tr}(L^{k/n})$ and $\mathrm{Tr}(p(L)^{k/(n-1)})$.

As in the bosonic case, $N=2$ KdV hierarchies are consistent reductions of the KP hierarchy. Indeed, a first series of KdV hierarchies[3,4] is obtained by considering the restriction $L=L_{\geqslant 1}$, that is to say

$$L=D^{2n}+\sum_{i=1}^{2n-2} w_i D^{2n-i-1}, \tag{61}$$

which defines a Poisson submanifold of the quadratic bracket $\{\ ,\ \}^a_{(2)}$. The Poisson algebra on the fields w_i is the $N=2\mathscr{W}_n$ algebra. The restriction

$$L=D^{2n-2}+\sum_{i=1}^{2n-3} w_i D^{2n-i-3}+D^{-1}w_{2n-2} \tag{62}$$

defines a Poisson submanifold of both the quadratic bracket $\{\ ,\ \}^b_{(2)}$ and the linear one $\{\ ,\ \}_{(1)}$ and then gives a second series of KdV hierarchies. The two series of KdV hierarchies are related to each other by the Poisson map p.

The two series of $N=2$ KdV hierarchies correspond to two series of $N=2$ modified KdV hierarchies as we shall now explain.

Let us write first the operator (61) in the factorized form

$$\begin{aligned} L=&(D+\theta_{2n-2})(D+\theta_{2n-2}+\theta_{n-1})(D+\theta_{2n-3}+\theta_{n-1})\cdots \\ &\times(D+\theta_n+\theta_2)(D+\theta_n+\theta_1)(D+\theta_1)D, \end{aligned} \tag{63}$$

where the Miura fields θ_k satisfy the following Poisson algebra of the Gardner type:

$$\{f,g\}=-\int d\tilde{x}\sum_{i,j=1}^{2n-2} C_{ij}D\left(\frac{\delta f}{\delta\theta_i}\right)\frac{\delta g}{\delta\theta_j}. \tag{64}$$

The symmetric invertible matrix C is

$$C=\begin{pmatrix} 0 & A \\ A^t & 0 \end{pmatrix}, \tag{65}$$

where the $(n-1)\times(n-1)$ upper triangular matrix A has ones on the diagonal and above the diagonal: $A_{ij}=0$ if $j>i$ and $A_{ij}=1$ if $j\leqslant i$. The comparison between Eqs. (61) and (63) yields the Miura transformation which gives the KdV fields in terms of the Miura fields. A standard calculation[20] shows that the Miura transformation is a Poisson map from the Gardner type bracket (64) to the first quadratic bracket $\{\ ,\ \}^a_{(2)}$.

A similar statement for the second series of KdV hierarchies is the following. Let us write the operator (62) in the factorized form

$$\begin{aligned} L=&D^{-1}(D+\theta_1)(D+\theta_n+\theta_1)(D+\theta_n+\theta_2)\cdots \\ &\times(D+\theta_{2n-3}+\theta_{n-1})(D+\theta_{2n-2}+\theta_{n-1})(D+\theta_{2n-2}), \end{aligned} \tag{66}$$

which yields the Miura transformation by comparison with (62). The Miura fields satisfy the Gardner Poisson algebra (64). Then, the Miura transformation is an (anti) Poisson map from the Gardner type bracket (64) to the second quadratic bracket $\{\ ,\ \}^b_{(2)}$.

B. A matrix formulation for the first series

The first series of $N=2$ KdV hierarchies has been studied in Refs. 3 and 4. It can be described within the usual Drinfeld–Sokolov formalism with an appropriate choice of the sextuplet $(\mathscr{A},d_1,d_0,\Psi;\alpha^0,\beta^0)$ such that $\beta^0=\{0\}$.

We consider $\mathscr{A}=sl(n|n)\otimes\mathbf{C}[\lambda,\lambda^{-1}]$. A $2n\times 2n$ matrix in $sl(n|n)$ has vanishing supertrace

$$\mathrm{str}\ M=\sum_{i=1}^{2n}(-1)^{i+1}M_{ii}.$$

The center of the superalgebra $\mathscr{A}$ is spanned by the matrices $\lambda^k I$ where I is the $2n\times 2n$ identity matrix. $\mathscr{A}$ is endowed with the two compatible gradations

$$d_1=2n\lambda\partial_\lambda+\mathrm{ad}\ \mathscr{K}_I,\quad \mathscr{K}_I=\Sigma_{k=1}^{2n}\frac{2n+1-2k}{2}e_{k,k}, \tag{67}$$

$$d_0=2\lambda\partial_\lambda+\mathrm{ad}\ \mathscr{K},\quad \mathscr{K}=\Sigma_{k=1}^{2n-1}e_{k,k}. \tag{68}$$

Here d_1 is the principal gradation but d_0 is not the homogeneous gradation. Notice that this choice for d_0 is the only point where our formalism differs from that of Refs. 3 and 4. We have made this

choice in order to be able to define a Drinfeld–Sokolov gauge. The end result, though, is the same as in Refs. 3 and 4. The assumptions in (9) are satisfied, as well as the supplementary condition $\mathscr{A}^0 \subset \mathscr{A}_0$. We choose for Ψ the odd element of d_1-grade one

$$\Psi = \sum_{k=1}^{2n-1} e_{k,k+1} + \lambda e_{2n,1} \tag{69}$$

whose square Λ is semisimple.

1. The modified system

We shall first identify the modified system defined by the above choice of algebraic data with the system characterized by the factorized Lax operator (63). We parametrize the phase space Θ in (17) by

$$q(\tilde{x}) = \sum_{k=1}^{n-1} \theta_k (e_{2k-1,2k-1} + e_{2k,2k}) + \sum_{k=n}^{2n-2} \theta_k (e_{2k-2n+2,2k-2n+2} + e_{2k-2n+3,2k-2n+3}). \tag{70}$$

We have fixed the gauge freedom induced by the center of $\mathscr{A}$ by setting the coefficient of $e_{2n,2n}$ in q to zero. The explicit evaluation of the Poisson bracket (35) on Θ yields exactly the bracket given in (64). The linear problem $\mathscr{L}\Psi = 0$, where $\Psi = (\psi_1, \psi_2, \ldots, \psi_{2n})^t$, leads to the eigenvalue equation

$$\begin{aligned} L\psi_{2n} = &(D + \theta_{2n-2})(D + \theta_{2n-2} + \theta_{n-1})(D + \theta_{2n-3} + \theta_{n-1}) \cdots \\ &\times (D + \theta_n + \theta_2)(D + \theta_n + \theta_1)(D + \theta_1) D \psi_{2n} = \lambda \psi_{2n}. \end{aligned} \tag{71}$$

This allows us to identify the Hamiltonians of both systems and finally the two modified systems themselves.

2. The KdV type system

It is easily checked that the nondegeneracy condition (38) is satisfied in this case at hand. In order to identify the KdV type system associated with the above algebraic data as the nth $N = 2$ KdV hierarchy of the first series, we parametrize the phase space $\mathscr{Q}/\mathscr{N}$ by a convenient DS gauge $\mathscr{Q}_V$ whose general element is

$$q_V(\tilde{x}) = \sum_{k=1}^{2n-2} (-)^k U_k e_{2n-1,k}. \tag{72}$$

From the linear problem $\mathscr{L}\Psi = 0$, we obtain the eigenvalue equation on ψ_{2n},

$$L\psi_{2n} = (D^{2n} + U_1 D^{2n-2} + U_2 D^{2n-3} + \cdots + U_{2n-2} D)\psi_{2n} = \lambda \psi_{2n}. \tag{73}$$

The correspondence between the two parametrizations of L in (71) and (73) provides the Miura map μ: $\Theta \to \mathscr{Q}/\mathscr{N} = \mathscr{Q}_V$ which is a Poisson map when Θ is equipped with the linear bracket (35) and $\mathscr{Q}/\mathscr{N}$ is equipped with the nonlinear bracket obtained as the reduction of the linear bracket on $\mathscr{Q}$. Using the identification between the linear bracket on Θ with the Gardner type bracket in (64), we conclude that the nonlinear bracket on $\mathscr{Q}/\mathscr{N}$ coincides with the bracket $\{\ ,\ \}^a_{(2)}$ on the operator L. The identification with the nth $N = 2$ KdV hierarchy is then established.

C. A matrix formulation for the second series

The second series of $N = 2$ KdV hierarchies can be recovered within the generalized Drinfeld–Sokolov formalism with an appropriate choice of the sextuplet $(\mathscr{A}, d_1, d_0, \Psi; \alpha^0, \beta^0)$.

We consider $\mathscr{A} = sl(n|n-1) \otimes \mathbf{C}[\lambda, \lambda^{-1}]$. A $2n-1 \times 2n-1$ matrix in $sl(n|n-1)$ has vanishing supertrace

$$\mathrm{str}\, M = \sum_{i=1}^{2n-1} (-1)^{i+1} M_{ii}\,.$$

$\mathscr{A}$ is endowed with the two compatible gradations

$$d_1 = (2n-2)\lambda\partial_\lambda + \mathrm{ad}\, \mathscr{K}_{\mathrm{II}}, \quad \mathscr{K}_{\mathrm{II}} = \Sigma_{k=1}^{2n-1}(n-k)e_{k,k}\,, \tag{74}$$

$$d_0 = \lambda\partial_\lambda\,, \tag{75}$$

satisfying the assumptions in (9), but not the supplementary condition (12). Here d_0 is the homogeneous gradation but d_1 is not the principal gradation. We choose for Ψ the odd element of d_1-grade one

$$\Psi = \sum_{k=1}^{2n-2} e_{k,k+1} + \lambda(e_{2n-1,1} + e_{2n,2}) \tag{76}$$

whose square Λ is semisimple. The d_1-grade zero part of the center $\mathscr{Z}$ of the kernel is spanned by the matrix

$$\Lambda_0 = \lambda e_{2n-1,1} + e_{1,1} + 2\sum_{k=2}^{2n-2} e_{k,k} + e_{2n-1,2n-1} + \lambda^{-1} e_{1,2n-1}\,, \tag{77}$$

and we take $\beta^0 = \mathrm{span}\{\Lambda_0\}$, so that the decomposition (11) holds.

1. The modified system

We wish to identify the modified system defined by the above choice of algebraic data with the system belonging to the factorized Lax operator (66). For this we now parametrize the phase space Θ in (17) by

$$\begin{aligned} q(\tilde{x}) = {} & \xi H + \Sigma_{k=1}^{n-1}\theta_k(e_{2n-2k,2n-2k} + e_{2n-2k+1,2n-2k+1}) \\ & + \Sigma_{k=n}^{2n-2}\theta_k(e_{4n-3-2k,4n-3-2k} + e_{4n-2-2k,4n-2-2k}) + \lambda(\theta_1 + \theta_{2n-2})e_{2n-1,1}\,, \end{aligned} \tag{78}$$

where $H = (n-1)(\Sigma_{k=0}^{n-1} e_{2k+1,2k+1}) + n(\Sigma_{k=1}^{n-1} e_{2k,2k})$ is an element in $\mathscr{K}^0$ which has the property that it cannot be written as the commutator of two elements in $\mathscr{K}$. H is also dual to Λ_0 since $\langle H, \Lambda_0\rangle = 2(1-n) \neq 0$. Let us define the linear functional of q,

$$\mathscr{I}[q] \equiv \int d\tilde{x} f(\tilde{x})\langle \Lambda_0, q\rangle = 2(1-n)\int d\tilde{x} f(\tilde{x})\xi. \tag{79}$$

Using the property that Λ_0 is an element of β^0 and the expression of the Poisson structure (35), it is not difficult to show that the functional $\mathscr{I}[q]$ has vanishing Poisson bracket with any other functional $\mathscr{G}[q]$. Hence ξ can be set to zero. The explicit evaluation of the Poisson bracket (35) on Θ then yields exactly the bracket given in (64). The linear problem $\mathscr{L}\Psi = 0$ leads to the eigenvalue equation

$$\begin{aligned} L\psi_1 = {} & D^{-1}(D+\theta_1)(D+\theta_1+\theta_n)(D+\theta_2+\theta_n)\cdots \\ & \times(D+\theta_{2n-3}+\theta_{n-1})(D+\theta_{2n-2}+\theta_{n-1})(D+\theta_{2n-2})\psi_1 = 2\lambda\psi_1\,. \end{aligned} \tag{80}$$

This allows us to identify the Hamiltonians of both systems and finally the two modified systems themselves.

2. The KdV type system

In order to identify the KdV type system associated with the above algebraic data as the nth $N=2$ KdV hierarchy of the second series, we parametrize the phase space $\mathscr{Q}/\mathscr{N}$ by a convenient DS gauge $\mathscr{Q}_V$ whose general element is

$$q_V(\tilde{x}) = \sum_{k=1}^{2n-2} (-)^k U_k e_{2n-1,2n-1-k} + \xi H. \tag{81}$$

The field ξ can be set to zero by identical considerations as in the modified case. From the linear problem $\mathscr{L}\Psi = 0$, we obtain the eigenvalue equation on ψ_1,

$$L\psi_1 = D^{-1}(D^{2n-1} + U_1 D^{2n-3} + \cdots U_{2n-3} D + U_{2n-2})\psi_1 = 2\lambda\psi_1. \tag{82}$$

The correspondence between the two parametrizations of L in (80) and (82) provides the Miura map $\mu: \Theta \to \mathscr{Q}/\mathscr{N} = \mathscr{Q}_V$. The identification with the nth $N=2$ KdV hierarchy is then established by the same arguments as in the case of the first series.

IV. OTHER EXAMPLES

In this section we shall give the Drinfeld–Sokolov reduction procedure for some interesting, supersymmetric or not, integrable systems.

A. Fermionic extension of KdV

The fermionic extension of KdV[12,13] is a nonsupersymmetric bi-Hamiltonian integrable hierarchy. Its second Hamiltonian structure is the $N=1$ superconformal algebra. The evolution equations of the hierarchy are

$$\partial_{t_k} L = [L_{\geqslant 0}^{(2k+1)/n}, L], \tag{83}$$

where the Lax operator L is

$$L = \partial^2 - u - \xi\partial^{-1}\xi, \tag{84}$$

where $\xi(x)$ is a Grassmann odd field. This hierarchy can be recovered within the usual (nonsupersymmetric) Drinfeld–Sokolov formalism based on a superalgebra rather than a Lie algebra. We consider the loop superalgebra $\mathscr{A} = \mathrm{osp}(1|2) \otimes C[\lambda, \lambda^{-1}]$. The supertrace of the 3×3 matrix M is defined by

$$\mathrm{str}(M) = M_{1,1} - M_{2,2} + M_{3,3} \tag{85}$$

and a matrix in osp$(1|2)$ may be parametrized as

$$M = \begin{pmatrix} a & \alpha & b \\ \beta & 0 & \alpha \\ c & -\beta & -a \end{pmatrix}. \tag{86}$$

$\mathscr{A}$ is equipped with the two compatible gradations

$$d_1 = 4\lambda\partial_\lambda + \mathrm{ad}(e_{11} - e_{33}), \tag{87}$$

$$d_0 = \lambda\partial_\lambda. \tag{88}$$

d_1 is the principal gradation and d_0 is the homogeneous one. They satisfy the conditions (9) as well as (12). Finally, we choose for Λ the even d_1-grade two element

$$\Lambda = e_{1,3} + \lambda e_{3,1}. \tag{89}$$

Λ is semisimple. Notice that Λ cannot be written as the square of an odd element in $\mathscr{A}$. This is the reason why the system associated with this choice of Λ is not supersymmetric. The lax operator is

$$\mathscr{L} = \partial + Q + \Lambda \tag{90}$$

with $Q \in \mathscr{A}^{\leqslant 1} \cap \mathscr{A}_{\geqslant 0}$. The gauge algebra is the set of λ independent lower triangular matrices and a convenient DS gauge is

$$Q_V=\begin{pmatrix} 0 & 0 & 0 \\ \xi & 0 & 0 \\ u & -\xi & 0 \end{pmatrix}. \tag{91}$$

The linear problem $\mathscr{L}\Psi=0$ where $\Psi=(\psi_1,\psi_2,\psi_3)^t$ leads to the eigenvalue equation

$$L\psi_1=(\partial^2-u-\xi\partial^{-1}\xi)\psi_1=\lambda\psi_1. \tag{92}$$

The relation with the fermionic extension of KdV is then obtained by using standard arguments.

B. $N=4$ KdV, extensions of $N=2$ KdV

1. $N=4$ KdV

The $N=4$ KdV hierarchy[21,22,14] can be viewed as a reduction of the $N=2$ KP hierarchy[14] for which the scalar Lax operator in $N=1$ superspace is

$$L=\partial-W_1+D^{-1}W_2+D^{-1}\bar{\phi}D^{-1}\phi, \tag{93}$$

where W_1, ϕ, and $\bar{\phi}$ are even superfields, while W_2 is an odd superfield. This hierarchy can be recovered within the generalized DS formalism. We consider the algebra $\mathscr{A}=sl(2|2)\otimes C[\lambda,\lambda^{-1}]$. The supertrace of a 4×4 matrix M is

$$\mathrm{str}\ M=M_{11}-M_{22}-M_{33}+M_{44}.$$

This superalgebra is equipped with the two compatible gradations

$$d_1=2\lambda\partial_\lambda+\mathrm{ad\ Diag}(1,0,0,-1), \tag{94}$$

$$d_0=\lambda\partial_\lambda. \tag{95}$$

We choose the d_1-grade one odd element Ψ to be

$$\Psi=e_{1,2}+e_{2,4}+\lambda e_{2,1}+\lambda e_{4,2}. \tag{96}$$

$\Lambda=\Psi^2$ is semisimple. We then define

$$\beta^0=\mathscr{Z}^0=\mathrm{span}(\Lambda_0), \tag{97}$$

where $\Lambda_0=\lambda e_{4,1}+e_{1,1}+2e_{2,2}+e_{4,4}+\lambda^{-1}e_{1,4}$. The decomposition (11) holds. A convenient DS gauge for this system is then

$$\mathscr{L}=D+\begin{pmatrix} u+\xi & 1 & 0 & 0 \\ \lambda+W_1 & u-\xi & 0 & 1 \\ \phi & 0 & u-\xi & 0 \\ W_2 & \lambda & \bar{\phi} & u+\xi \end{pmatrix}. \tag{98}$$

The superfield u is the coefficient of the center of $sl(2|2)$, hence it can be set consistently to zero. The superfield ξ is the coefficient of an element H which belongs to $\mathscr{K}^0$, dual to Λ_0. Hence ξ is central in the Poisson algebra and can be set consistently to zero. The linear problem $\mathscr{L}\Psi=0$ then leads to the eigenvalue equation

$$L\psi_1=(\partial-W_1+D^{-1}W_2+D^{-1}\bar{\phi}D^{-1}\phi)\psi_1=2\lambda\psi_1, \tag{99}$$

leading to the identification of this matrix hierarchy with the $N=4$ KdV hierarchy. One can find in Ref. 14 an infinite series of hierarchies where the $N=1$ scalar Lax operator has the same pseudo-differential part as in Eq. (93), but where the differential part is more general. A matrix Lax formulation for these hierarchies is found by generalizing the above scheme to the superalgebra $sl(n|n)$.

2. Fermionic extension of the $N=2$ $a=4$ KdV hierarchy

The fermionic extension of the $N=2$ $a=4$ KdV hierarchy is very similar to the $N=4$ KdV hierarchy just discussed. It is a reduction of the $N=2$ KP hierarchy and its scalar lax operator[14] is

$$L=\partial-W_1+D^{-1}W_2+D^{-1}\bar{\phi}D^{-1}\phi, \tag{100}$$

where W_1 is an even superfield while W_2, ϕ, and $\bar{\phi}$ are odd superfields.

Its matrix interpretation is also very similar to the one of the $N=4$ KdV hierarchy as we shall see now. We choose the loop superalgebra $\mathscr{A}=sl(3|1)\otimes C[\lambda,\lambda^{-1}]$. The supertrace of a 4×4 matrix M is

$$\text{str } M=M_{11}-M_{22}+M_{33}+M_{44}.$$

$\mathscr{A}$ is equipped with the two compatible gradations

$$d_1=2\lambda\partial_\lambda+\text{ad Diag}(1,0,0,-1), \tag{101}$$

$$d_0=\lambda\partial_\lambda. \tag{102}$$

We choose the d_1-grade one odd element Ψ to be

$$\Psi=e_{1,2}+e_{2,4}+\lambda e_{2,1}+\lambda e_{4,2}. \tag{103}$$

The even element $\Lambda=\Psi^2$ is semisimple. We then take

$$\beta^0=\mathscr{Z}^0=\text{span}(\Lambda_0), \tag{104}$$

where $\Lambda_0=\lambda e_{4,1}+e_{1,1}+2e_{2,2}+e_{4,4}+\lambda^{-1}e_{1,4}$. The decomposition (11) holds.

A convenient DS gauge for this system is then

$$\mathscr{L}=D+\begin{pmatrix} u+\xi & 1 & 0 & 0 \\ \lambda+W_1 & u+2\xi & 0 & 1 \\ \phi & 0 & -u & 0 \\ W_2 & \lambda & \bar{\phi} & u+\xi \end{pmatrix}. \tag{105}$$

The element $H=e_{1,1}+2e_{2,2}+e_{4,4}$ belongs to $\mathscr{K}^0$ and is dual to Λ_0. Hence ξ is central in the Poisson algebra and can be set consistently to zero. The Abelian gauge invariance generated by the grade zero element $K=e_{1,1}+e_{2,2}-e_{3,3}+e_{4,4}$ which commutes with Ψ can be used to set u to zero. The linear problem $\mathscr{L}\Psi=0$ then leads to the eigenvalue equation

$$L\psi_1=(\partial-W_1+D^{-1}W_2+D^{-1}\bar{\phi}D^{-1}\phi)\psi_1=2\lambda\psi_1. \tag{106}$$

This scheme can be generalized to $sl(n+1|n-1)$ without difficulty, giving a matrix Lax formulation for some hierarchies described in Ref. 14.

C. $N=2$ homogeneous hierarchies

Homogeneous bosonic hierarchies[8–10] are associated with a loop algebra $\mathscr{A}=\mathscr{G}\otimes C[\lambda,\lambda^{-1}]$ for which one takes $d_1=d_0$ to be the homogeneous gradation. As a consequence, in this case there exists only an analog of the modified KdV type equations. The simplest such hierarchies have a Lax operator of the type

$$\mathscr{L}=\partial+q+\Lambda, \tag{107}$$

where the semisimple grade one element $\Lambda=\lambda H$ is such that H belongs to the Cartan subalgebra of $\mathscr{G}$. In this case q takes its values in $\mathscr{A}_0=\mathscr{G}$. The flows of the hierarchy take the particular form

$$\partial_{t_b}q=[(B_b[q])_{-1},\lambda H], \tag{108}$$

which means that only the components of q in $(\mathrm{Im}(\mathrm{ad}\,\Lambda))_0$ have nontrivial evolution equations. The components of q in $(\mathrm{Ker}(\mathrm{ad}\,\Lambda)_0)$ can be consistently set to zero at the level of evolution equations. If H is regular, $(\mathrm{Ker}(\mathrm{ad}\,\Lambda)_0)$ is the Cartan subalgebra of $\mathcal{G}$ but if H is not regular, $(\mathrm{Ker}(\mathrm{ad}\,\Lambda)_0)$ is a bigger subalgebra of $\mathcal{G}$.

The simplest examples are associated with $\mathcal{G}=sl(2)$ or $sl(3)$. When $\mathcal{G}=sl(2)$, the above construction leads to the nonlinear Schrödinger (NLS) hierarchy with the Lax operator

$$\mathcal{L}=\partial+\begin{pmatrix}0 & \phi\\ \bar{\phi} & 0\end{pmatrix}+\lambda\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{109}$$

When $\mathcal{G}$ is the rank two Lie algebra $sl(3)$, there exists a one parameter family of such integrable hierarchies. Each hierarchy is associated with a Cartan element

$$H_t=\mathrm{Diag}(1,-2t,2t-1). \tag{110}$$

In the generic case, H_t is regular. The phase space contains six fields associated with the roots of $sl(3)$. In the particular cases when $t=-\frac{1}{2}$, $\frac{1}{4}$ or 1, H_t is not regular and the phase space contains only four fields.

In the following, we shall study two examples of $N=2$ supersymmetric extensions of the homogeneous hierarchies. We consider the twisted loop superalgebra

$$\mathcal{A}=\bigoplus_{k\in Z}\lambda^{2k}\mathcal{G}_0\oplus\lambda^{2k+1}\mathcal{G}_1, \tag{111}$$

where $\mathcal{G}$ is a classical superalgebra, and $d_1=d_0$ is the homogeneous gradation. The choice $\mathcal{G}=sl(2|1)$ will lead to the $N=2$ NLS hierarchy. In the case when $\mathcal{G}=sl(3|1)$, there are only three possible choices of the odd element Ψ. They lead to generalizations of the $sl(3)$ hierarchies associated with the particular values $t=-\frac{1}{2},\frac{1}{4},1$.

1. The N=2 NLS hierarchy

The $N=2$ NLS hierarchy[23] can be viewed as a reduction of the $N=2$ KP hierarchy[14] associated with the $N=1$ scalar Lax operator

$$L=\partial-\phi D^{-1}\bar{\phi}D, \tag{112}$$

where ϕ and $\bar{\phi}$ are fermionic fields. It can be obtained in the DS formalism as a homogeneous hierarchy for which $\mathcal{G}=sl(2|1)$. We choose the supertrace of a 3×3 matrix M to be

$$\mathrm{str}\,M=M_{11}-M_{22}+M_{33}.$$

We choose the grade one odd element Ψ to be

$$\Psi=\lambda(e_{1,2}+e_{2,1}). \tag{113}$$

$\Lambda=\Psi^2=\lambda^2(e_{1,1}+e_{2,2})$ is a semisimple element of $\mathcal{A}$. Notice that $e_{1,1}+e_{2,2}$ is not the Cartan element appearing in the bosonic operator (109). It differs from it by $\frac{1}{2}(e_{1,1}+2e_{2,2}+e_{3,3})$, which is an element of the center of $\mathcal{G}_0$. Since Ψ has grade one, the phase space belongs to the grade zero part of the superalgebra, so that the matrix Lax operator $\mathcal{L}$ contains only odd superfields

$$\mathcal{L}=D+\begin{pmatrix}u_0 & \lambda & \phi\\ \lambda & u_0+u_1 & 0\\ \bar{\phi} & 0 & u_1\end{pmatrix}. \tag{114}$$

The grade zero element $H=e_{1,1}+e_{2,2}$ which belongs to the center of the kernel $\mathcal{Z}$ generates an Abelian gauge invariance. A consequence of this gauge invariance is that the field u_1 has trivial equations of evolution

$$\partial_{t_b}u_1=-\partial_{t_b}\,\mathrm{str}(Hq)=-\mathrm{str}(H[(B_b(q))_{-1},\Psi\})=0 \tag{115}$$

for any b in $\mathcal{Z}(\mathcal{K})^{>0}$. Hence u_1 can be set consistently to zero in the evolution equations. The gauge invariance can also be used to set $u_0=0$. The linear problem $\mathcal{L}\Psi=0$ then leads to the eigenvalue equation

$$L\psi_2=(\partial-\phi D^{-1}\bar{\phi}D)\psi_2=\lambda^2\psi_2 \tag{116}$$

and the hierarchy thus obtained is the $N=2$ NLS hierarchy.

2. The $sl(3|1)$ example

We choose here $\mathcal{G}=sl(3|1)$. We choose the supertrace of a 4×4 matrix M to be

$$\mathrm{str}\ M=M_{11}+M_{22}+M_{33}-M_{44}.$$

The only three possible choices of the element Ψ are

$$\Psi_i=\lambda(e_{i,4}+e_{4,i}),\quad i=1,2,3. \tag{117}$$

The semisimple element $\Lambda=\Psi^2$ is then

$$\Lambda_i=\frac{\lambda^2}{3}\,(U+(3\delta_{i,1}-1)H_{t_i}),\quad i=1,2,3. \tag{118}$$

where $U=\mathrm{Diag}(1,1,1,3)$ belongs to the center of $\mathcal{G}_0^-$ and $t_1=\frac{1}{4}$, $t_2=1$, $t_3=-\frac{1}{2}$. The $N=2$ hierarchies thus considered are generalizations of the particular bosonic $sl(3)$ hierarchies. With similar arguments as used previously, it can be shown that the phase space may be reduced to four odd superfields. For example, in the case $i=1$, the Lax operator $\mathcal{L}$ takes the form

$$\mathcal{L}=D+\begin{pmatrix} 0 & \phi_1 & \phi_2 & \lambda \\ \bar{\phi}_1 & 0 & 0 & 0 \\ \bar{\phi}_2 & 0 & 0 & 0 \\ \lambda & 0 & 0 & 0 \end{pmatrix}. \tag{119}$$

The linear problem $\mathcal{L}\Psi=0$ then leads to the eigenvalue equation

$$L\psi_4=\left(\partial-\sum_{k=1}^{2}\phi_i D^{-1}\bar{\phi}_i D\right)\psi_4=\lambda^2\psi_4 \tag{120}$$

where one recognizes the $N=1$ scalar Lax operator of the two components $N=2$ KP hierarchy. The generalization to $sl(n|1)$ is *a priori* straightforward.

(Received 2 December 1997; accepted for publication 25 March 1998)

We use a factorized L operator to construct an integrable model with open boundary conditions. By taking the trigonometric ($\tau \to \sqrt{-1}\infty$) and scaling limits ($w \to 0$), we get a Hamiltonian of a classical integrable system. It shows that this integrable system is similar to those found by Calogero *et al.* [J. Math. Phys. **10**, 2191 (1969); **12**, 419 (1971)]. © *1998 American Institute of Physics.* [S0022-2488(98)01709-5]

I. INTRODUCTION

In recent decades, a series of one-dimensional integrable many-body systems has been found.[1–6] One effective method to prove the integrability of the many-body systems is the Lax representation, which means that we can construct the complete set of integrals of the motion. The Lax representation for the elliptic Calogero–Moser model was found by Krichever,[7] and the Ruijsenaars–Macdonald commuting difference operators can also prove the integrability of the many-body systems.[5,6,8,9]

It is known that there are many two-dimensional exactly solved models in statistical mechanics.[10–15] The integrability is proved by the commuting transfer matrix. Recently, some relations between the one-dimensional many-body systems and the two-dimensional solvable models were found (see Refs. 16–19 and the references therein). Hasegawa[16] found that the L operator[20–22] for the two-dimensional Z_n Belavin model can be related to the Krichever's Lax matrix[7] and the commuting difference operators given by the L operators are similar to the Ruijsenaars–Macdonald difference operators. Hasegawa studied the Z_n Belavin model by imposing the periodic boundary conditions. We will study the Z_n Belavin model by imposing the open boundary conditions for the case of open boundary conditions (see Refs. 23 and 24 and the references therein). Using the factorized L operators and one solution of the reflection equation, we can construct commuting difference operators which should be equivalent to the Ruijsenaars–Macdonald difference operators. By taking a special limit, we find a trigonometric integrable model which is similar to the trigonometric model found by Calogero *et al.*[2–4] Principally, we can obtain a classical integrable system if we can find a solution to the reflection equation.

The paper is organized as follows: In Sec. II, we will introduce the Z_n symmetric Belavin model. The factorized L operator will be given in Sec. III. The commuting difference operators connected with the transfer matrix with open boundary conditions will be given in Sec. IV. The special limit is taken in Sec. V and the integrable model is found in this section. Section VI containes a summary and discussions.

II. THE Z_n SYMMETRIC BELAVIN R MATRIX

The Z_n symmetric Belavin R matrix[14,15] is given as

$$R_{12}=\frac{1}{n}\sum_{\alpha\in Z_n^2} W_\alpha(z) I_\alpha\otimes I_\alpha^{-1}, \tag{1}$$

with

$$\begin{gathered} W_\alpha(z)=\frac{\sigma_\alpha(z+\eta)}{\sigma_\alpha(\eta)}, \quad I_\alpha=g^{\alpha_2}h^{\alpha_1}, \quad h_{ij}=\delta_{i+1,j}, \\ g_{ij}=\omega^i\delta_{i,j}, \quad \omega=e^{2\pi\sqrt{-1}/n}, \quad i,j\in Z_n, \\ \sigma_\alpha(z)\equiv\theta\begin{bmatrix}\frac{1}{2}+\frac{\alpha_1}{n}\\ \frac{1}{2}+\frac{\alpha_2}{n}\end{bmatrix}\quad(z,\tau), \\ \theta\begin{bmatrix}a\\ b\end{bmatrix}(z,\tau)\equiv\sum_{m\in Z} e^{\pi\sqrt{-1}(m+a)^2\tau+2\pi\sqrt{-1}(m+a)(z+b)}. \end{gathered} \tag{2}$$

This R matrix satisfies the Yang–Baxter equation (YBE),[10,11]

$$R_{12}(z_1-z_2)R_{13}(z_1-z_3)R_{23}(z_2-z_3)=R_{23}(z_2-z_3)R_{13}(z_1-z_3)R_{12}(z_1-z_2), \tag{3}$$

where $R_{12}(z)$, $R_{13}(z)$, and $R_{23}(z)$ act in $C^n\otimes C^n\otimes C^n$ with $R_{12}(z)=R(z)\otimes 1$, $R_{23}(z)=1\otimes R(z)$, etc. One can find that the R matrix also satisfies the following unitary and cross-unitary properties:

$$R_{12}(z_1-z_2)R_{21}(z_2-z_1)=\rho(z_1-z_2)\cdot\mathrm{id}, \tag{4}$$

$$R_{21}^{t_2}(z_2-z_1-nw)R_{12}^{t_2}(z_1-z_2)=\tilde{\rho}(z_1-z_2)\cdot\mathrm{id}, \tag{5}$$

where

$$\rho(z)=\frac{h(z+w)h(-z+w)}{h^2(w)}, \tag{6}$$

$$\tilde{\rho}(z)=\frac{h(z)h(-z-nw)}{h^2(w)}, \tag{7}$$

w is defined by $w\equiv n\eta$, $h(z)\equiv\sigma_0(z)$, and t_i means the transposition in the ith space.

Assume an operator matrix $L(z)$ satisfies the Yang–Baxter relation (YBR)

$$R_{12}(z_1-z_2)L_1(z_1)L_2(z_2)=L_2(z_2)L_1(z_1)R_{12}(z_1-z_2), \tag{8}$$

with $L_1(z_1)=L(z_1)\otimes 1$ and $L_2(z_2)=1\otimes L(Z_2)$. For the periodic boundary conditions, its transfer matrix is defined by $t(z)=\mathrm{tr}\,L(z)$. We can prove that these transfer matrices with different spectra commute with each other $\{[t(z_1),t(z_2)]=0\}$. For the open boundary conditions, Sklyanin[23] proposed a systematic approach to handle the problems which involve the reflection equation (RE)

$$R_{12}(z_1-z_2)K_1(z_1)R_{21}(z_1+z_2)K_2(z_2)=K_2(z_2)R_{12}(z_1+z_2)K_1(z_1)R_{21}(z_2-z_1), \tag{9}$$

where the reflecting K matrix is a solution of the RE. In order to construct the integrable models, we also need a dual reflection equation (DRE) which is associated with the cross-unitary relation of the R matrix. For Z_n Belavin model, the dual RE takes the form[24]

$$R_{12}(z_1-z_2)\tilde{K}_1(z_1)R_{21}(-z_1-z_2-nw)\tilde{K}_2(z_2)=\tilde{K}_2(z_2)R_{12}(-z_1-z_2-nw)\tilde{K}_1(z_1)R_{21}(z_2-z_1). \tag{10}$$

If we define the transfer matrix as $t(z)=\mathrm{tr}\,[\tilde{K}(z)L(z)K(z)L^{-1}(-z)]$, with the help of unitary and cross-unitary relations, one can prove that $[t(z_1),t(z_2)]=0$, which means the model under consideration is integrable.

Additionally, there is an isomorphism between $K(z)$ and $\tilde{K}(z)$:

$$\Phi: K(z)\to\tilde{K}(z)=K\left(-z-\frac{nw}{2}\right). \tag{11}$$

Given a solution $K(z)$ of the RE, we can find a solution $\tilde{K}(z)$ of the DRE. For Z_n Belavin model, a solution $K(z)$ to the RE is as follows:[24]

$$K(z)=K_0(z)K_0(0), \tag{12}$$

where

$$K_0(z)=\sum_{\alpha\in Z_n^2} U_{2\alpha}(z)\omega^{2\alpha_1\alpha_2}I_{2\alpha}, \tag{13}$$

$$U_{2\alpha}(z)=\frac{\sigma_{2\alpha}(z+c)}{\sigma_{2\alpha}(c)}, \tag{14}$$

where c is an arbitrary constant.

III. THE FACTORIZED *L* MATRIX

Jimbo *et al.*[25] defined the intertwiner of the Z_n model as an n-element column vector $\phi_{a,a+\hat{\mu}}(z)$ whose jth element is

$$\phi^{(j)}_{a,a+\hat{\mu}}(z)=\theta^{(j)}(z-nw\overline{a}_\mu,n\tau), \tag{15}$$

$$\theta^{(j)}(z-nw\overline{a}_\mu,n\tau)=\theta\begin{bmatrix}\frac{1}{2}-\frac{j}{n}\\ \frac{1}{2}\end{bmatrix}(z-nw\overline{a}_\mu,n\tau), \tag{16}$$

where $\overline{a}_\mu=a_\mu-(1/n)\Sigma_\nu a_\nu+\delta_\mu$, $a\in Z^n$, and δ_μ are some generic numbers. Using the intertwiner, the face–vertex correspondence can be written as

$$R_{12}(z_1-z_2)^{i'j'}_{ij}\phi^{(i')}_{a-\hat{\mu}-\hat{\nu},\alpha-\hat{\mu}}(z_1)\phi^{(j')}_{a-\hat{\mu},a}(z_2)=\sum_\kappa W\begin{bmatrix}a-\hat{\mu}-\hat{\nu} & a-\hat{\mu}\\ a-\hat{\kappa} & a\end{bmatrix}(z_1-z_2)\times\phi^{(j)}_{a-\hat{\mu}-\hat{\nu},a-\hat{\kappa}}(z_2)\phi^{(i)}_{a-\hat{\kappa},a}(z_1), \tag{17}$$

where

$$W\begin{bmatrix}a-\hat{\mu}-\hat{\nu} & a-\hat{\mu}\\ a-\hat{\kappa} & a\end{bmatrix}(z)$$

is the face Boltzmann weight of $A^{(1)}_{n-1}$ interaction-round-a-face (IRF) model.[25] It is defined as

$$W\begin{bmatrix} a-2\hat{\mu} & a-\hat{\mu} \\ a-\hat{\mu} & a \end{bmatrix}(z)=\frac{h(z+w)}{h(w)},$$

$$W\begin{bmatrix} a-\hat{\mu}-\hat{\nu} & a-\hat{\mu} \\ a-\hat{\mu} & a \end{bmatrix}(z)=\frac{h(z-a_{\mu\nu}w)}{h(-a_{\mu\nu}w)}, \tag{18}$$

$$W\begin{bmatrix} a-\hat{\mu}-\hat{\nu} & a-\hat{\nu} \\ a-\hat{\mu} & a \end{bmatrix}(z)=\frac{h(z)h((a_{\mu\nu}+1)w)}{h(w)h(a_{\mu\nu}w)}. \tag{19}$$

The other face Boltzmann weights are defined as zeroes where $a_{\mu\nu}=\overline{a}_{\mu}-\overline{a}_{\nu}$. At the same time, we can also find the n-element row vectors $\tilde{\phi}$ and $\overline{\phi}$ which satisfy the following relations[20–22,25]

$$\tilde{\phi}^{(k)}_{a-\hat{\mu},a}(z)\,\phi^{(k)}_{a-\hat{\nu},a}(z)=\delta_{\mu\nu}, \tag{20}$$

$$\overline{\phi}^{(k)}_{a,a+\hat{\mu}}(z)\,\phi^{(k)}_{a,a+\hat{\nu}}(z)=\delta_{\mu\nu}. \tag{21}$$

The above equation can also be written as

$$\sum_{\mu}\ \phi_{a-\hat{\mu},a}(z)\,\tilde{\phi}_{a-\hat{\mu},a}(z)=I, \tag{22}$$

$$\sum_{\mu}\ \phi_{a,a+\hat{\mu}}(z)\,\overline{\phi}_{a,a+\hat{\mu}}(z)=I. \tag{23}$$

Using those results, the face–vertex correspondence can be written in other forms:

$$\tilde{\phi}^{(i)}_{a-\hat{\mu},a}(z_1)R_{12}(z_1-z_2)^{i'j'}_{ij}\,\phi^{(j')}_{a-\hat{\nu},a}(z_2)=\sum_{\kappa}\ W\begin{bmatrix} a-\hat{\mu}-\hat{\kappa} & a-\hat{\nu} \\ a-\hat{\mu} & a \end{bmatrix}(z_1-z_2)$$
$$\times\,\phi^{(j)}_{a-\hat{\mu}-\hat{\kappa},a-\hat{\mu}}(z_2)\,\tilde{\phi}^{(i')}_{a-\hat{\mu}-\hat{\kappa},a-\hat{\nu}}(z_1), \tag{24}$$

$$\overline{\phi}^{(j)}_{a,a+\hat{\mu}}(z_2)R_{12}(z_1-z_2)^{i'j'}_{ij}\,\phi^{(i')}_{a-\hat{\nu}-\hat{\kappa},a-\hat{\mu}}(z_1)=\sum_{\kappa}\ W\begin{bmatrix} a & a+\hat{\nu} \\ a+\hat{\mu} & a+\hat{\mu}+\hat{\kappa} \end{bmatrix}(z_1-z_2)$$
$$\times\,\phi^{(i)}_{a+\hat{\mu},a+\hat{\mu}+\hat{\kappa}}(z_1)\,\overline{\phi}^{(j')}_{a+\hat{\nu},a+\hat{\mu}+\hat{\kappa}}(z_2), \tag{25}$$

$$\tilde{\phi}^{(i)}_{a-\hat{\mu},a}(z_1)\,\tilde{\phi}^{(j)}_{a-\hat{\mu}-\hat{\nu},a-\hat{\mu}}(z_2)R_{12}(z_1-z_2)^{i'j'}_{ij}=\sum_{\kappa}\ W\begin{bmatrix} a-\hat{\mu}-\hat{\nu} & a-\hat{\kappa} \\ a-\hat{\mu} & a \end{bmatrix}(z_1-z_2)$$
$$\times\,\tilde{\phi}^{(j')}_{a-\hat{\kappa},a}(z_2)\,\tilde{\phi}^{(i')}_{a-\hat{\mu}-\hat{\nu},a-\hat{\kappa}}(z_1), \tag{26}$$

$$\overline{\phi}^{(i)}_{a+\hat{\mu},a+\hat{\mu}+\hat{\nu}}(z_1)\,\overline{\phi}^{(j)}_{a,a+\hat{\mu}}(z_2)R_{12}(z_1-z_2)^{i'j'}_{ij}=\sum_{\kappa}\ W\begin{bmatrix} a & a+\hat{\kappa} \\ a+\hat{\mu} & a+\hat{\mu}+\hat{\nu} \end{bmatrix}(z_1-z_2)$$
$$\times\,\overline{\phi}^{(j')}_{a+\hat{\kappa},a+\hat{\mu}+\hat{\nu}}(z_2)\,\overline{\phi}^{(i')}_{a,a+\hat{\kappa}}(z_1). \tag{27}$$

With the help of those face–vertex correspondence relations, we then can construct the $L(z)$ matrix[20–22] which meet the YBR. Let

$$f(a,\mu,z)^{j}_{i}=\phi^{(i)}_{a-\hat{\mu},a}(z+\xi_1)\,\tilde{\phi}^{(j)}_{a-\hat{\mu},a}(z+\xi_2), \tag{28}$$

where ξ_1 and ξ_2 are arbitrary complex numbers. Then from the face–vertex correspondence relations (17) and (26), we have

$$R(z_1-z_2)_{ij}^{i'j'}f(a-\hat{\mu},\nu,z_1)_{i'}^{i''}f(a,\nu,z_2)_{j'}^{j''}+\mu\rightleftarrows\nu$$
$$=f(a-\hat{\mu},\nu,z_2)_{j}^{j'}f(a,\nu,z_1)_{i}^{i'}R(z_1-z_2)_{i'j'}^{i''j''}+\mu\rightleftarrows\nu, \tag{29}$$

where $\mu\leftrightarrow\nu$ means the same form as the term before them, while the μ and ν exchange with each other. We introduce the difference operator Γ_μ,

$$\Gamma_\mu f(a)=f(a+\hat{\mu})\Gamma_\mu, \tag{30}$$

and we have

$$R(z_1-z_2)_{ij}^{i'j'}\Gamma_\nu f(a,\nu,z_1)_{i'}^{i''}\Gamma_\mu f(a,\nu,z_2)_{j'}^{j''}+\mu\leftrightarrow\nu$$
$$=\Gamma_\nu f(a,\nu,z_2)_{j}^{j'}\Gamma_\mu f(a,\nu,z_1)_{i}^{i'}R(z_1-z_2)_{i'j'}^{i''j''}+\mu\leftrightarrow\nu. \tag{31}$$

We can find that the above equation is sufficient to prove the following YBR:

$$R(z_1-z_2)_{ij}^{i'j'}L(a,z_1)_{i'}^{i''}L(a,z_2)_{j'}^{j''}=L(a,z_2)_{j}^{j'}L(a,z_1)_{i}^{i'}R(z_1-z_2)_{i'j'}^{i''j''}, \tag{32}$$

where $L(a,z_k)=\Sigma_\mu\Gamma_\mu f(a,\mu,z_k)$. Let

$$g(a,\mu,z)_i^j=\phi_{a,a+\hat{\mu}}^{(i)}(z+\xi_2)\overline{\phi}_{a,a+\hat{\mu}}^{(j)}(z+\xi_1). \tag{33}$$

There is

$$\sum_\nu\Gamma_\nu f(a,\nu,z)_i^j\sum_\mu\Gamma_{-\mu}g(a,\mu,z)_j^k=\delta_{ik}. \tag{34}$$

It shows that $L^{-1}(a,z)=\Sigma_\mu\Gamma_{-\mu}g(a,\mu,z)$. Then the transfer matrix with open boundary conditions is

$$t(z)=\mathrm{tr}\,\tilde{K}(z)L(a,z)K(z)L^{-1}(a,-z)$$
$$=\mathrm{tr}\,\tilde{K}(z)\sum_\nu\Gamma_\nu f(a,\nu,z)K(z)\sum_\mu\Gamma_{-\mu}g(a,\mu,-z)$$
$$=\sum_{\mu\nu}\Gamma_{-\mu}\Gamma_\nu F_{\mu\nu}^{(1)}(a,z)F_{\mu\nu}^{(2)}(a,z)=\sum_{\mu\nu}\Gamma_{-\mu}\Gamma_\nu G_{\mu\nu}(a,z), \tag{35}$$

with

$$F_{\mu\nu}^{(1)}(a,z)=\tilde{\phi}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}^{(i)}(z+\xi_2)K(z)_i^j\phi_{a,a+\hat{\mu}}^{(j)}(-z+\xi_2), \tag{36}$$

$$F_{\mu\nu}^{(2)}(a,z)=\overline{\phi}_{a,a+\hat{\mu}}^{(k)}(-z+\xi_1)\tilde{K}(z)_k^l\phi_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}^{(l)}(z+\xi_1), \tag{37}$$

$$G_{\mu\nu}(a,z)=F_{\mu\nu}^{(1)}(a,z)F_{\mu\nu}^{(2)}(a,z). \tag{38}$$

IV. THE CALCULATION OF TRANSFER MATRIX $t(z)$

Substituting the $K(z)$ (12) into Eq. (36), we obtain

$$F_{\mu\nu}^{(1)}(a,z)=\tilde{\phi}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}^{(i)}(z)\sum_{\gamma\in Z_n^2}U_{2\gamma}(z)\omega^{2\gamma_1\gamma_2}[g^{2\gamma_2}h^{2\gamma_1}K_0(0)]_i^j\phi_{a,a+\hat{\mu}}^{(j)}(-z). \tag{39}$$

Here we let $\xi_1=\xi_2=0$. We can prove that

$$g^{\beta-1}h^{\alpha}K_0(0)\phi_{a,a+\hat{\mu}}(z)=(-1)^{\beta-1}e^{2\pi\sqrt{-1}(\alpha/n)(\alpha\tau/2+z-nw\overline{a}_\mu+1/2)}\phi_{a,a+\hat{\mu}}(-z+2nw\overline{a}_\mu-\alpha\tau-\beta) \tag{40}$$

(see Appendix). The above equation (39) can be written as

$$F^1_{\mu\nu}(a,z)=\sum_{\gamma\in Z_n^2}U_{2\gamma}(z)e^{2\pi\sqrt{-1}2\gamma_1\gamma_2/n}e^{2\pi\sqrt{-1}(2\gamma_1/n)(2\gamma_1\tau/2-z-nw\overline{a}_\mu+1/2)}\tilde{\phi}^{(i)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(z)$$
$$\times\phi^{(i)}_{a,a+\hat{\mu}}(z+2nw\overline{a}_\mu-2\gamma_1\tau-2\gamma_2-1). \tag{41}$$

From Eq. (23) we know $\tilde{\phi}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(z)$ can be obtained from the inverse of the matrix $\tilde{M}$ whose elements are

$$\tilde{M}_{i\lambda}(z)=\phi^{(i)}_{a+\hat{\mu}-\hat{\lambda},a+\hat{\mu}}(z)=\theta^{(i)}(z-nw(\overline{a}_\lambda+\delta_{\mu\lambda}-1)). \tag{42}$$

So we get

$$\tilde{\phi}^{(i)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(z)\phi^{(i)}_{a,a+\hat{\mu}}(z+2nw\overline{a}_\mu-2\gamma_1\tau-(2\gamma_2+1))=\frac{\det\tilde{M}}{\det\tilde{M}}. \tag{43}$$

Substituting the ν column elements of matrix $\tilde{M}$ with the corresponding elements of column vector $\phi_{a,a+\hat{\mu}}(z+2nw\overline{a}_\mu-2\gamma_1\tau-(2\gamma_2+1))$ while keeping other matrix elements unchanged, we obtain the matrix $\tilde{M}'$.

Suppose the elements of a matrix A are defined as $A_{ij}=\theta^{(i)}(nz_j)$. One can prove that the determinant of the matrix A has the results[20–22]

$$\det A=C(\tau)h\left(\sum_i z_i-\frac{n-1}{2}\right)\prod_{i<k}h(z_i-z_k). \tag{44}$$

Using this result, we obtain

$$\tilde{\phi}^{(i)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(z)\phi^{(i)}_{a,a+\hat{\mu}}(z+2nw\overline{a}_\mu-2\gamma_1\tau-(2\gamma_2+1))$$
$$=\frac{h\left(-z+w\delta+w(1-n)+\frac{n-1}{2}-w(\overline{a}_\nu+\delta_{\mu\nu}-1+\overline{a}_\mu)+\frac{1}{n}(2\gamma_1\tau+2\gamma_2+1)\right)}{h\left(-z+w\delta+w(1-n)+\frac{n-1}{2}\right)}$$
$$\times\prod_{j\neq\nu}\frac{h\left(-w(\overline{a}_j+\delta_{\mu j}-1+\overline{a}_\mu)+\frac{1}{n}(2\gamma_1\tau+2\gamma_2+1)\right)}{h(-w(\overline{a}_j+\delta_{\mu j}-\overline{a}_\nu-\delta_{\mu\nu}))} \tag{45}$$

($\delta=\Sigma_i\delta_i$). With the help of the formula

$$\sigma_0\left(z+\frac{1}{n}(\alpha\tau+\beta)\right)=e^{-2\pi\sqrt{-1}(\alpha/n)(\alpha\tau/2n+z+1/2+\beta/n)}\sigma_{\alpha,\beta}(z,\tau), \tag{46}$$

finally we obtain

$$F^{(1)}_{\mu\nu}(a,z)=\sum_{\gamma\in Z_n^2}U_{2\gamma}(z)e^{-2\pi\sqrt{-1}(2\gamma_1\gamma_2/n)}e^{2\pi\sqrt{-1}(2\gamma_1/n)}$$
$$\times\frac{\sigma_{2\gamma_1,2\gamma_2+1}(-z+w\delta+w(1-n)+(n-1)/2-w(\overline{a}_\nu+\delta_{\mu\nu}-1+\overline{a}_\mu))}{\sigma_0(-z+w\delta+w(1-n)+(n-1)/2)}$$

$$\prod_{j\neq\nu}\frac{\sigma_{2\gamma_1,2\gamma_2+1}(-w(\overline{a}_j+\delta_{\mu j}-1+\overline{a}_\mu))}{\sigma_0(-w(\overline{a}_j+\delta_{\mu j}-\overline{a}_\nu-\delta_{\mu\nu}))}. \tag{47}$$

Substituting the $\tilde{K}(z)$ into Eq. (37), considering the isomorphism relation between $\tilde{K}(z)$ and $K(z)$(11), we obtain

$$F^{(2)}_{\mu\nu}(a,z)=\overline{\phi}^{(k)}_{a,a+\hat{\mu}}(-z)\sum_{\gamma\in Z_n^2}U_{2\gamma}\left(-z-\frac{nw}{2}\right)\omega^{2\gamma_1\gamma_2}[g^{2\gamma_2}h^{2\gamma_1}K_0(0)]^l_k\phi^{(l)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(z). \tag{48}$$

Using Eq. (40), we have

$$\begin{aligned}F^{(2)}_{\mu\nu}(a,z)=&\sum_{\gamma\in Z_n^2}U_{2\gamma}\left(-z-\frac{nw}{2}\right)e^{2\pi\sqrt{-1}(2\gamma_1\gamma_2/n)}e^{2\pi\sqrt{-1}(2\gamma_1/n)(2\gamma_1\tau/2+z-nw(\overline{a}_\nu+\delta_{\mu\nu}-1)+1/2)}\\&\times\overline{\phi}^{(k)}_{a,a+\hat{\mu}}(-z)\phi^{(k)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(-z+2nw(\overline{a}_\nu+\delta_{\mu\nu}-1)-2\gamma_1\tau-2\gamma_2-1).\end{aligned} \tag{49}$$

From Eq. (23), we also know $\overline{\phi}_{a,a+\hat{\mu}}(-z)$ can be obtained from the inverse of the matrix $\overline{M}$ whose elements are

$$\overline{M}_{i\lambda}(-z)=\phi^{(i)}_{a,a+\hat{\lambda}}(-z)=\theta^{(i)}(-z-nw\overline{a}_\lambda). \tag{50}$$

So, we obtain

$$\overline{\phi}^{(k)}_{a,a+\hat{\mu}}(-z)\phi^{(k)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(-z+2nw(\overline{a}_\nu+\delta_{\mu\nu}-1)-2\gamma_1\tau-2\gamma_2-1)=\frac{\det\overline{M}'}{\det\overline{M}}. \tag{51}$$

Substituting the μ column elements of matrix $\overline{M}$ with the corresponding elements of column vector $\phi_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(-z+2nw(\overline{a}_\nu+\delta_{\mu\nu}-1)-2\gamma_1\tau-2\gamma_2-1)$, holding other matrix elements unchanged, we get the matrix M'. Using this result of (44), we obtain

$$\begin{aligned}&\overline{\phi}^{(k)}_{a,a+\hat{\mu}}(-z)\phi^{(k)}_{a+\hat{\mu}-\hat{\nu},a+\hat{\mu}}(-z+2nw(\overline{a}_\nu+\delta_{\mu\nu}-1)-2\gamma_1\tau-2\gamma_2-1)\\&\quad=\frac{h(z+w\delta+(n-1)/2-w(\overline{a}_\mu+\delta_{\mu\nu}-1+\overline{a}_\nu)+(1/n)(2\gamma_1\tau+2\gamma_2+1))}{h(z+w\delta+(n-1)/2)}\\&\qquad\times\prod_{j\neq\mu}\frac{h(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\nu)+(1/n)(2\gamma_1\tau+2\gamma_2+1))}{h(-w(\overline{a}_j-\overline{a}_\mu))}.\end{aligned} \tag{52}$$

Similarly, with the help of Eq. (46), we get

$$\begin{aligned}F^{(2)}_{\mu\nu}(a,z)=&\sum_{\gamma\in Z_n^2}U_{2\gamma}\left(-z-\frac{nw}{2}\right)e^{-2\pi\sqrt{-1}(2\gamma_1\gamma_2/n)}e^{2\pi\sqrt{-1}(2\gamma_1/n)}\\&\times\frac{\sigma_{2\gamma_1,2\gamma_2+1}(z+w\delta+(n-1)/2-w(\overline{a}_\mu+\delta_{\mu\nu}-1+\overline{a}_\nu))}{\sigma_0(z+w\delta+(n-1)/2)}\\&\times\prod_{j\neq\mu}\frac{\sigma_{2\gamma_1,2\gamma_2+1}(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\nu))}{\sigma_0(-w(\overline{a}_j-\overline{a}_\mu))}.\end{aligned} \tag{53}$$

V. TAKING THE TRIGONOMETRIC AND SCALING LIMITS

When $\tau\to\sqrt{-1}\infty$, considering $2\gamma_1/n\neq m$ (m is an integer number), we can find that

$$\theta\begin{bmatrix}\frac{1}{2}+\frac{2\gamma_1}{n}\\ \frac{1}{2}+\frac{2\gamma_2+1}{n}\end{bmatrix}(z,\tau)\to f(\tau)e^{2\pi\sqrt{-1}(2\gamma_1/n+1/2+m)(z+1/2+(2\gamma_2+1)/n)}. \tag{54}$$

Then,

$$U_{2\gamma}(z)\to e^{2\pi\sqrt{-1}(2\gamma_1/n+1/2+m)z} \tag{55}$$

$$\begin{aligned}F^{(1)}_{\mu\nu}(a,z)\to&\sum_{\gamma_1}\frac{e^{2\pi\sqrt{-1}(2\gamma_1/n+1/2+m)z}e^{2\pi\sqrt{-1}(2\gamma_1/n)}}{\sin\pi(-z+w\delta+w(1-n)+(n-1)/2)}\prod_{j\neq\nu}\frac{1}{\sin\pi(\bar{a}_j+\delta_{\mu j}-\bar{a}_\nu-\delta_{\mu\nu})}\\&\times\sum_{\gamma_2}e^{-2\pi\sqrt{-1}(2\gamma_1\gamma_2/n)}f^n(\tau)e^{2\pi\sqrt{-1}(2\gamma_1/n+1/2+m)(-z+n-1/2-nw\bar{a}_\mu+2\gamma_2)}\\&\times\sum_{\gamma_2}e^{2\pi\sqrt{-1}(2\gamma_1\gamma_2/n)}=\sum_{\gamma_2}(e^{2\pi\sqrt{-1}(2\gamma_1/n)})^{\gamma_2}=0.\end{aligned} \tag{56}$$

We can see that from $F^{(2)}_{\mu\nu}(a,z)$, we can obtain the same result. So we only pay attention to the case where $2\gamma_1/n=m$. The next step is to consider this case.

We know there is an arbitrary parameter c in $U_{2\gamma}(z)$. Let $c=\epsilon\tau+c'$ with $\epsilon<1/n$. We have

$$\theta\begin{bmatrix}\frac{1}{2}+\frac{2\gamma_1}{n}\\ \frac{1}{2}+\frac{2\gamma_2}{n}\end{bmatrix}(z+c,\tau)=e^{-2\pi\sqrt{-1}\epsilon(2\epsilon\tau/n+z+c'+1/2+2\gamma_2/n)}\theta\begin{bmatrix}\frac{1}{2}+\frac{2\gamma_1}{n}+\epsilon\\ \frac{1}{2}+\frac{2\gamma_2}{n}\end{bmatrix}(z+c',\tau). \tag{57}$$

Then

$$\begin{aligned}U_{2\gamma}(z)=&e^{-2\pi\sqrt{-1}\epsilon z}\frac{\theta\begin{bmatrix}\frac{1}{2}+\frac{2\gamma_1}{n}+\epsilon\\ \frac{1}{2}+\frac{2\gamma_2}{n}\end{bmatrix}(z+c',\tau)}{\theta\begin{bmatrix}\frac{1}{2}+\frac{2\gamma_1}{n}+\epsilon\\ \frac{1}{2}+\frac{2\gamma_2}{n}\end{bmatrix}(c',\tau)},\\&\to e^{-2\pi\sqrt{-1}\epsilon z}e^{2\pi\sqrt{-1}(1/2+2\gamma_1/n+\epsilon+m)z},\end{aligned} \tag{58}$$

which have no relation to γ_2 and do not include any dynamics variables like $\bar{a}_\mu$, so we handle it as an irrelevant constant when taking the trigonometric limit. The conclusion (56) still holds when $c=\epsilon\tau+c'$. Now, we can obtain ($2\gamma_1/n=m$)

$$\begin{aligned}F^{(1)}_{\mu\nu}(a,z)=&\sum_{\gamma_2}\frac{\sin\pi(-z+w\delta+w(1-n)+(n-1)/2-w(\bar{a}_\nu+\delta_{\mu\nu}-1+\bar{a}_\mu)+(2\gamma_2+1)/n)}{\sin\pi(-z+w\delta+w(1-n)+(n-1)/2)}\\&\times\prod_{j\neq\nu}\frac{\sin\pi(-w(\bar{a}_j+\delta_{\mu j}-1+\bar{a}_\mu)+(2\gamma_2+1)/n)}{\sin\pi(-w(\bar{a}_j+\delta_{\mu j}-\bar{a}_\nu-\delta_{\mu\nu}))},\end{aligned} \tag{59}$$

$$F^{(2)}_{\mu\nu}(a,z)=\sum_{\gamma_2}\ \frac{\sin\ \pi(z+w\delta+(n-1)/2-w(\overline{a}_\nu+\delta_{\mu\nu}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}{\sin\ \pi\left(z+w\delta+\dfrac{n-1}{2}\right)}$$

$$\times\prod_{j\neq\mu}\ \frac{\sin\ \pi(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\nu)+(2\gamma_2+1)/n)}{\sin\ \pi(-w(\overline{a}_j-\overline{a}_\mu))}. \tag{60}$$

For the n conservations that do not depend on the spectrum parameter z, when $z\to-\sqrt{-1}\infty$, we can get the integrable Hamiltonian of the system. So there are

$$F^{(1)}_{\mu\nu}(a,z)=\sum_{\gamma_2}\ e^{\pi\sqrt{-1}(-w(\overline{a}_\nu+\delta_{\mu\nu}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}$$

$$\times\prod_{j\neq\nu}\ \frac{\sin\ \pi(-w(\overline{a}_j+\delta_{\mu j}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}{\sin\ \pi(-w(\overline{a}_j+\delta_{\mu j}-\overline{a}_\nu-\delta_{\mu\nu}))}, \tag{61}$$

$$F^{(2)}_{\mu\nu}(a,z)=\sum_{\gamma_2}\ e^{-\pi\sqrt{-1}(-w(\overline{a}_\nu+\delta_{\mu\nu}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}$$

$$\times\prod_{j\neq\mu}\ \frac{\sin\ \pi(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}{\sin\ \pi(-w(\overline{a}_j+\overline{a}_\mu))}. \tag{62}$$

Expanding $\sin\ \pi(-w(\overline{a}_j+\delta_{\mu j}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)$ in $F^{(1)}_{\mu\nu}(a,z)$ and $\sin\ \pi(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\nu)+(2\gamma_2'+1)/n)$ in $F^{(2)}_{\mu\nu}(a,z)$ respectively as follows,

$$\frac{1}{2\sqrt{-1}}\left[e^{\pi\sqrt{-1}(-w(\overline{a}_j+\delta_{\mu j}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}-e^{-\pi\sqrt{-1}(-w(\overline{a}_j+\delta_{\mu j}-1+\overline{a}_\mu)+(2\gamma_2+1)/n)}\right], \tag{63}$$

$$\frac{1}{2\sqrt{-1}}\left[e^{\pi\sqrt{-1}(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\nu)+(2\gamma_2+1)/n)}-e^{-\pi\sqrt{-1}(-w(\overline{a}_j+\delta_{\mu\nu}-1+\overline{a}_\nu)+(2\gamma_2+1)/n)}\right], \tag{64}$$

and summing over γ_2 and γ_2' we can find that all the terms of $F^{(1)}_{\mu\nu}(a,z)$ and $F^{(2)}_{\mu\nu}(a,z)$ have the forms

$$\sum_{\gamma_2}\ e^{(2\pi\sqrt{-1}/n)m\gamma_2},\quad m=\underbrace{1\pm1\pm\cdots\pm1}_{n-1}=n,n-2,n-4,\ldots,-n+2, \tag{65}$$

and

$$\sum_{\gamma_2'}\ e^{(2\pi\sqrt{-1}/n)m\gamma_2'},\quad m=\underbrace{1\pm1\pm\cdots\pm1}_{n-1}=n,n-2,n-4,\ldots,-n+2. \tag{66}$$

Only for the case $m=\pm n,0$ are the above summations not equal to zeroes. When $n=$even, m can take n or 0, but it is rather complex to calculate the case $m=0$. For simplicity, we only consider $n=$odd, so m can only take n. We have

$$F^{(1)}_{\mu\nu}(a,z)\rightsquigarrow e^{\pi\sqrt{-1}\Sigma_i(-w(\overline{a}_i+\delta_{\mu i}-1+\overline{a}_\mu)+1/n)}\prod_{j\neq\nu}\ \frac{1}{\sin\ \pi(-w(\overline{a}_j+\delta_{\mu j}-\overline{a}_\nu-\delta_{\mu\nu}))}, \tag{67}$$

$$F^{(2)}_{\mu\nu}(a,z)\rightsquigarrow e^{-\pi\sqrt{-1}\Sigma_i(-w(\overline{a}_i+\delta_{\mu\nu}-1+\overline{a}_\nu)+1/n)}\prod_{j\neq\mu}\ \frac{1}{\sin\ \pi(-w(\overline{a}_j-\overline{a}_\mu))}, \tag{68}$$

$$G_{\mu\nu}(a,z)\rightsquigarrow e^{\pi\sqrt{-1}(nw(\bar{a}_\nu-\bar{a}_\mu)+nw\delta_{\mu\nu}-w)}\prod_{j\neq\nu}\frac{1}{\sin\pi(-w(\bar{a}_j+\delta_{\mu j}-\bar{a}_\nu-\delta_{\mu\nu}))}$$

$$\times\prod_{k\neq\mu}\frac{1}{\sin\pi(-w(\bar{a}_k-\bar{a}_\mu))}. \tag{69}$$

For $\bar{a}_j-\bar{a}_k=a_j-a_k+\delta_j-\delta_k$, and $H=\Sigma_{\mu\nu}\Gamma_{-\mu}\Gamma_\nu G_{\mu\nu}(a,z)$, in which $\Gamma_\mu f(a)=f(a+\hat{\mu})\Gamma_\mu$, we obtain,

$$H=\sum_{\mu\nu}\Gamma_\nu\left[e^{\pi\sqrt{-1}(nw(a_\nu+\delta\nu))}\prod_{j\neq\nu}\frac{1}{\sin\pi(-w(a_j-a_\nu+\delta_j-\delta_\nu))}\right]\Gamma_{-\mu}\left[e^{-\pi\sqrt{-1}(nw(a_\mu+\delta_\mu))}\right.$$

$$\left.\times\prod_{k\neq\mu}\frac{1}{\sin\pi(-w(a_k-a_\mu+\delta_k-\delta_\mu))}\right]. \tag{70}$$

In quantum theory, one can set $\hat{p}_\mu=(\hbar/\sqrt{-1})(\partial/\partial x_\mu)$,

$$e^{(\hbar/\sqrt{-1})(\partial/\partial x_\mu)}f(x)=f\left(x+\frac{\hbar}{\sqrt{-1}}\hat{\mu}\right)e^{(\hbar/\sqrt{-1})(\partial/\partial x_\mu)}. \tag{71}$$

Compared with $\Gamma_\mu f(a)=f(a+\hat{\mu})\Gamma_\mu$, let $\Gamma_\mu\rightsquigarrow e(\hbar/\sqrt{-1})(\partial/\partial x_\mu)$, $-\sqrt{-1}w(a_\mu+\delta_\mu)\rightsquigarrow x_\mu$, and $w\rightsquigarrow\hbar$. There is

$$H\rightsquigarrow\sum_{\mu\nu}e^{\hat{p}_\nu}\left[e^{-n\pi x_\nu}\prod_{j\neq\nu}\frac{1}{\sinh\pi(x_j-x_\nu)}\right]e^{-\hat{p}_\mu}\left[e^{n\pi x_\mu}\prod_{k\neq\mu}\frac{1}{\sinh\pi(x_k-x_\mu)}\right]. \tag{72}$$

When $\hat{p}_\lambda\rightsquigarrow p_\lambda$, it becomes a Hamiltonian of a classical integrable system.

We also can begin directly from Eqs. (59) and (60). According to the expanding method used for getting the results (67) and (68), we have

$$F^{(1)}_{\mu\nu}(a,z)\rightsquigarrow[e^{\pi\sqrt{-1}(-z+(n-1)/2+1-nw\bar{a}_\mu)}-e^{-\pi\sqrt{-1}(-z+(n-1)/2+1-nw\bar{a}_\mu)}]$$

$$\times\prod_{j\neq\nu}\frac{1}{\sin\pi(-w(\bar{a}_j-\bar{a}_\nu+\delta_{\mu j}-\delta_{\mu\nu}))}, \tag{73}$$

$$F^{(2)}_{\mu\nu}(a,z)\rightsquigarrow[e^{\pi\sqrt{-1}(z+(n-1)/2+1-nw(\bar{a}_\nu+\delta_{\mu\nu}-1))}-e^{-\pi\sqrt{-1}(z+(n-1)/2+1-nw(\bar{a}_\nu+\delta_{\mu\nu}-1))}]$$

$$\times\prod_{j\neq\mu}\frac{1}{\sin\pi(-w(\bar{a}_j-\bar{a}_\mu))}, \tag{74}$$

while ignoring those sine functions which have no any dynamics variables. Let

$$g_{\mu\nu}=\prod_{j\neq\nu}\frac{1}{\sin\pi(-w(\bar{a}_j+\delta_{\mu j}-\bar{a}_\nu-\delta_{\mu\nu}))}\prod_{k\neq\mu}\frac{1}{\sin\pi(-w(\bar{a}_k-\bar{a}_\mu))}. \tag{75}$$

Then we have

$$G_{\mu\nu}(a,z)=\{e^{\pi\sqrt{-1}(n+1-nw(\bar{a}_\mu+\bar{a}_\nu+\delta_{\mu\nu}-1))}+e^{-\pi\sqrt{-1}(n+1-nw(\bar{a}_\mu+\bar{a}_\nu+\delta_{\mu\nu}-1))}$$

$$-e^{\pi\sqrt{-1}(-2z-nw(\bar{a}_\nu+1-\bar{a}_\nu-\delta_{\mu\nu}))}-e^{-\pi\sqrt{-1}(-2z-nw(\bar{a}_\mu+1-\bar{a}_\nu-\delta_{\mu\nu}))}\}g_{\mu\nu}. \tag{76}$$

For different z, $H(z)$ commute with each other, so we can obtain three commutable Hamiltonians H^i from H

$$H^i=\sum_{\mu\nu}\Gamma_{-\mu}\Gamma_\nu G^i_{\mu\nu},\quad i=1,2,3, \tag{77}$$

with

$$G^1_{\mu\nu}=\{e^{\pi\sqrt{-1}(n+1-nw(\bar{a}_\mu+\bar{a}_\nu+\delta_{\mu\nu}-1))}+e^{-\pi\sqrt{-1}(n+1-nw(\bar{a}_\mu+\bar{a}_\nu+\delta_{\mu\nu}-1))}\}g_{\mu\nu}, \tag{78}$$

$$G^2_{\mu\nu}=e^{\pi\sqrt{-1}(-2z-nw(\bar{a}_\mu+1-\bar{a}_\nu-\delta_{\mu\nu}))}g_{\mu\nu}, \tag{79}$$

$$G^3_{\mu\nu}=e^{-\pi\sqrt{-1}(-2z-nw(\bar{a}_\mu+1-\bar{a}_\nu-\delta_{\mu\nu}))}g_{\mu\nu}. \tag{80}$$

In $G^1_{\mu\nu}$, if we have $\delta_\mu\to\delta_\mu+\rho$, where ρ is commutable, we may still get two integrable Hamiltonians

$$H^{11}=\sum_{\mu\nu}\Gamma_{-\mu}\Gamma_\nu G^{11}_{\mu\nu}, \tag{81}$$

$$H^{12}=\sum_{\mu\nu}\Gamma_{-\mu}\Gamma_\nu G^{12}_{\mu\nu}, \tag{82}$$

with

$$G^{11}_{\mu\nu}=e^{\pi\sqrt{-1}(n+1-nw(\bar{a}_\mu+\bar{a}_\nu+\delta_{\mu\nu}-1))}g_{\mu\nu}, \tag{83}$$

$$G^{12}_{\mu\nu}=e^{-\pi\sqrt{-1}(n+1-nw(\bar{a}_\mu+\bar{a}_\nu+\delta_{\mu\nu}-1))}g_{\mu\nu}. \tag{84}$$

Here H^{11} and H^{12} all can commute with H^2 and H^3, but they may not commute with each other.

An integrable system requires its Poisson bracket $H=f_1,f_2,\ldots,f_n$ satisfies

$$\{f_i,f_j\}=\sum_{lm}\left(\frac{\partial f_i}{\partial p_l}\frac{\partial f_j}{\partial q_m}-\frac{\partial f_i}{\partial q_l}\frac{\partial f_j}{\partial p_m}\right)=0. \tag{85}$$

When we take variables as changed, i.e., $q_i\to q_i'=\chi q_i+\rho_i$, p_i remain unchanged. In the new variable set $\{q_i',p_i\}$, the above equation (85) still holds, so the system is still integrable. Taking some kind of limit after the variable substitution, we may achieve a new integrable system, i.e., in Eq. (72), let $x_j\to x_j'=\chi x_j$. Then there is

$$H'=\sum_{\mu\nu}e^{p_\nu}\left[e^{-n\pi(1/\chi)x'_\nu}\prod_{j\neq\nu}\frac{1}{\sinh(\pi/\chi)(x_j'-x_\nu')}\right]e^{-p_\mu}\left[e^{n\pi(1/\chi)x'_\mu}\prod_{k\neq\mu}\frac{1}{\sinh(\pi/\chi)(x_k'-x_\mu')}\right]. \tag{86}$$

When $\chi\to\infty$, take the lowest order term. Then we obtain

$$H''=\sum_{\mu\nu}e^{p_\nu-p_\mu}\prod_{j\neq\nu}\frac{1}{x_j-x_\nu}\prod_{k\neq\mu}\frac{1}{x_k-x_\mu}. \tag{87}$$

This may be an integrable Hamiltonian.

Additionally, we can let $x_0\to x_0+\rho_0$ with others unchanged in H, and let $\sinh(\pi(x_0-x_i))$ become $\frac{1}{2}e^{\pi(x_0-x_i)}$ to obtain a new Hamiltonian. We also can change two variables or more to get a new Hamiltonian, i.e., let $\delta_0\gg\delta_1\gg\cdots\gg\delta_{n-1}\gg1\to\infty$, $x_i\to x_i+\delta_i$. There are $\sinh\pi(x_i-x_j)\to\frac{1}{2}e^{\pi(x_i-x_j+\delta_i-\delta_j)}$ $(i<j)$. Then

$$H\to\sum_{\mu\nu}e^{p_\nu-p_\mu}e^{-n\pi(x_\mu-x_\nu)}\prod_{j<\nu}e^{-\pi(x_j-x_\nu)}\prod_{j>\nu}e^{-\pi(x_\nu-x_j)}\prod_{k<\mu}e^{-\pi(x_k-x_\nu)}\prod_{k>\mu}e^{-\pi(x_\nu-x_k)}. \tag{88}$$

Like this, we can get the number of integrable Hamiltonians.

VI. SUMMARY AND DISCUSSIONS

We study the Z_n Belavin model with the open boundary conditions. By the factorized L operators, we constructed the commuting difference operators which are similar to the Ruijsenaars–Macdonald difference operators. We obtained a one-dimensional many-body integrable model from these commuting difference operators. By taking the special limit, this model is similar to the Calogero model.

The one-dimensional integrable models presented in this paper are obtained from the transfer matrix operators with open boundary conditions. Generally, for different solutions of the reflection equations, we can define different transfer matrices. Thus, to some extent, we give a systematic approach to obtain one-dimensional many-body integrable models. Besides the Z_n Belavin model, there are many two-dimensional exactly solvable models in statistical mechanics. It is interesting to find relations between those models with some one-dimensional many-body systems.

APPENDIX

$$
\begin{aligned}
[g^{\beta}h^{\alpha}K_0(0)\phi_{a,a+\hat{\mu}}(z)]^{(i)} &= \omega^{\beta i}\delta_{ij}\delta_{j+\alpha,k}\overline{\delta}_{k+l,0}\theta^{(l)}(z-nw\overline{a}_{\mu},n\tau)\\
&= \omega^{\beta i}\theta\begin{bmatrix}\dfrac{1}{2}+\dfrac{i+\alpha}{n}\\ \dfrac{1}{2}\end{bmatrix}(z-nw\overline{a}_{\mu},n\tau)\\
&= \omega^{\beta i}\theta\begin{bmatrix}-\dfrac{1}{2}-\dfrac{i+\alpha}{n}\\ -\dfrac{1}{2}\end{bmatrix}(-z+nw\overline{a}_{\mu},n\tau)\\
&= (-1)\omega^{\beta i}e^{2\pi\sqrt{-1}(1/2-(i-\alpha)/n\beta}\theta\begin{bmatrix}\dfrac{1}{2}-\dfrac{i+\alpha}{n}\\ \dfrac{1}{2}\end{bmatrix}(-z+nw\overline{a}_{\mu},n\tau).
\end{aligned}
$$

Using the formula

$$
\theta^{(i)}(z+\alpha\tau+\beta,n\tau)=e^{-2\pi\sqrt{-1}(\alpha/2)(\alpha\tau/2+z+1/2+\beta)}e^{2\pi\sqrt{-1}(1/2-i(i-2)/n)\beta}\theta\begin{bmatrix}\dfrac{1}{2}-\dfrac{i-\alpha}{n}\\ \dfrac{1}{2}\end{bmatrix}(z,n\tau), \tag{A1}
$$

there is

$$
\begin{aligned}
\cdots &= (-1)^{(\beta-1)}e^{2\pi\sqrt{-1}(\alpha/n)(\alpha\tau/2+z-nw\overline{a}_{\mu}+1/2)}\omega^{i}\theta\begin{bmatrix}\dfrac{1}{2}-\dfrac{i}{n}\\ \dfrac{1}{2}\end{bmatrix}(-z+nw\overline{a}_{\mu}-\alpha\tau-\beta,n\tau)\\
&= (-1)^{(\beta-1)}e^{2\pi\sqrt{-1}(\alpha/n)(\alpha\tau/2+z-nw\overline{a}_{\mu}+1/2)}\omega^{i}\phi^{(i)}_{a,a+\hat{\mu}}(-z+2nw\overline{a}_{\mu}-\alpha\tau-\beta,n\tau)\\
&= (-1)^{(\beta-1)}e^{2\pi\sqrt{-1}(\alpha/n)(\alpha\tau/2+z-nw\overline{a}_{\mu}+1/2)}[g\phi_{a,a+\hat{\mu}}(-z+2nw\overline{a}_{\mu}-\alpha\tau-\beta,n\tau)]^{(i)}.
\end{aligned} \tag{A2}
$$

By moving the g from the right-hand side of the equation to the left-hand side, we obtain the conclusion (40).

(Received 13 August 1997; accepted for publication 3 April 1998)

The straightforward proof of involutiveness of the set of integrals of motion for the general Calogero–Moser model is given for the classical as well as the quantum case. © *1998 American Institute of Physics.* [S0022-2488(98)01307-3]

I. INTRODUCTION

The Calogero–Moser–Sutherland (CMS) model,[1–3] perhaps a paradigm of solvable finite-dimensional Hamiltonian systems,[4] although discovered more than a quarter century ago, still attracts much attention. It has been observed to have interesting connections and physical applications in various fields like fractional statistics,[5] the quantum Hall effect,[6] spin chains,[7] two-dimensional gravity,[8] and QCD[9] or higher spin theories.[10] Apart from its relevance in these or other branches of theoretical physics, it provides a theoretical laboratory for studying diverse techniques commonly used in mathematical physics; the R-matrix method,[11] the inverse scattering method,[12] the collective field methods,[13] and the W algebras.[14] Paraphrasing the famous Lenin statement about an electron, one can say that the CMS model is inexhaustible.

The classical and quantum integrability of the CMS model has been proven by different methods in numerous papers. The most tedious step is a demonstration that the set of functionally independent conserved quantities is in involution. This may be achieved by arguments based on asymptotics,[15] Lax matrix techniques,[16] a recursion procedure,[17] or by more recent and rather advanced R-matrix procedures.[11]

Our aim in this article is to give direct formal proof of classical and quantum integrability of the CMS model (without a harmonic oscillator term) using only elementary methods, mainly the normal ordering procedure. The proof is valid for most general potential given by the Weierstrass function (which, in special cases, reduces to well-known rational, trigonometric, and hyperbolic potentials). The starting point is the expression for integrals of motion given by Sawada and Kotera[18] and Wojciechowski.[17] The involutivity appears then to be guaranteed by the set of identities obeyed by Weierstrass functions which generalize the well-known addition formula; a similar phenomenon appears in the relativistic case.[19] Given this formula and the notion of normal ordering the proof becomes quite easy.

II. PROOF OF INTEGRABILITY

The Calogero–Moser model[1–3] is defined by the following choice of Hamiltonian:

$$H=\frac{1}{2}\sum_{i=1}^{N} p_i^2+\frac{g}{2}\sum_{i,j=1}^{N}{}' V(x_i-x_j), \tag{1}$$

where Σ' denotes summation over $i\neq j$ and V is the Weierstrass function (which, in particular cases, reduces to rational, trigonometric, or hyperbolic functions).

The classical integrals of motion can be conveniently defined as follows:[18] one starts with the quantity

$$J_N=\exp\left(-\frac{g}{2}\sum_{i,j=1}^{N}{}' V(x_i-x_j)\,\frac{\partial^2}{\partial p_i \partial p_j}\right)\prod_{k=1}^{N} p_k\,. \tag{2}$$

[a)]Electronic mail: cgonera@krysia.uni.odz.pl

 © 1998 American Institute of Physics

Obviously, J_N is a completely symmetric polynomial of the Nth order in p's. In fact, it is simply the determinant of the Lax matrix.[4] Other integrals of motion are defined recursively:

$$J_{N-1}=\left\{\sum_{k=1}^{N} x_k, J_N\right\}, \tag{3}$$

where $\{,\}$ is a standard Poisson bracket. These integrals can be compactly written as follows. Define

$$J(\alpha)=\exp\left(\frac{g}{2}\sum_{i,j=1}^{N}{}' V(x_i-x_j)\,\frac{\partial^2}{\partial p_i \partial p_j}\right)\prod_{k=1}^{N}(p_k+\alpha). \tag{4}$$

Then, Eq. (3) implies

$$J(\alpha)=\sum_{n=0}^{N}\frac{\alpha^n}{n!}J_{N-n}. \tag{5}$$

It follows from Eq. (4) that $J(\alpha)$ is the determinant of the Lax matrix with diagonal elements p_k replaced by $p_k+\alpha$. Therefore, J_n are, up to a constant, the coefficients of the characteristic equation for the Lax matrix. It can be shown that the Poisson brackets $\{J_n, J_{n'}\}$ all vanish. Moreover, the Hamiltonian (1) is expressible in terms of J_n's. Therefore, they are involutive integrals of motion for the classical Calogero–Moser model.

As was noticed by Calogero, Marchioro, and Ragnisco,[20] there are no ordering ambiguities in defining $\hat{J}_n$'s in quantum theory. Therefore we expect the quantum Calogero–Moser model to also be integrable with $\hat{J}_n$'s providing the complete set of commuting integrals of motion. Our aim here is to give a simple formal proof of this statement.

Before entering into details let us stress that although it is true that there is no ordering problem with the definition of quantum counterparts of classical integrals of motion J_n's (actually, this is exactly why these integrals were chosen as a starting point; it would be much more troublesome if one would like to start with traces of powers of the Lax matrix, where ordering problems are significant), it does not imply that there are no ordering problems when one considers the commutators of such integrals. On the contrary, these ordering ambiguities are very relevant because even the product of ''harmless'' operators contains many terms for which the ordering problem is nontrivial. In fact, the cancellations among higher-order terms in $\hbar$ are nontrivial and result from identities (15) below those valid for elliptic functions; the point is that in the reordering of x's and p's in such a way that the classical result for the Poisson bracket can be used, one gets extra terms which cancel only because of Eq. (15). This is just the main point of the proof.

Let us first note that it is sufficient to prove that

$$[\hat{J}_N, \hat{J}(\alpha)]=0, \tag{6}$$

for any α. To see this the following reasoning is sufficient. The involutiveness of the $\hat{J}_n$'s is equivalent to the equation

$$[\hat{J}(\alpha), \hat{J}(\beta)]=0, \tag{7}$$

for all $\alpha,\beta\in\mathbb{R}$. However, the transformation $\hat{x}_i\to\hat{x}_i$, $\hat{p}_i\to\hat{p}_i+\text{const}$ is a unitary transformation, so due to $\hat{J}_N=\hat{J}(0)$, Eq. (7) is implied by

$$[\hat{J}_N, \hat{J}(\beta-\alpha)]=0, \tag{8}$$

i.e., by Eq. (6).

The product of $\hat{x}$ and $\hat{p}_i$ operators will be called normally ordered if all $\hat{p}_i$ factors stand rightmost. With such a definition to any polynomial function $f(x,p)$ defined on classical phase space (which can be explicitly $\hbar$ dependent), there corresponds a unique operator,

$$\hat{f}=:f(\hat{x},\hat{p}):, \tag{9}$$

where ''$:\cdots:$'' means normal ordering defined above. In order to simplify the notation, Eq. (9) will be written henceforth as

$$\hat{f}=:f(x,p):, \tag{10}$$

and it is understood that $:\cdots:$ means the operation of replacing the classical x, p variables by corresponding operators followed by normal ordering. It is obvious that our definition can be extended to include a nonpolynomial function (using, for example, the coordinate representation or formal power expansions).

The following important formulas hold:

$$:f(x,p)::g(x,p):=:f\left(x,p-i\hbar\,\frac{\partial}{\partial y}\right)g(y,p)|_{x=y}:, \tag{11a}$$

$$:f(x,p)::g(x,p):=:g\left(x-i\hbar\,\frac{\partial}{\partial q},p\right)f(x,q)|_{p=q}:. \tag{11b}$$

One can prove the above relations by starting with polynomials in x and p and generalizing accordingly. We shall use the notion of normal ordering to prove Eq. (6).

Due to the fact that there are no ordering ambiguities in quantizing $\hat{J}_n$'s, the classical expressions can be taken as symbols of their quantum counterparts. Using the formulas (11) it is straightforward to write the symbol of the commutator $[\hat{J}(\alpha),\hat{J}_N]$:

$$[\hat{J}(\alpha),\hat{J}_N]=:\exp\left(\frac{-g}{2}\sum_{i,j=1}{}'\left(V(x_i-x_j-i\hbar)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\right)\frac{\partial^2}{\partial p_i\partial p_j}-\frac{g}{2}\sum_{i,j}{}'\,V(x_i-x_j)\frac{\partial^2}{\partial q_i\partial q_j}\right)$$
$$\cdot\left(\prod_k\,(p_k+\alpha)q_k-\prod_k\,p_k(q_k+\alpha)\right):|_{p=q}. \tag{12}$$

Therefore it is sufficient to prove that

$$\exp\left(\frac{-g}{2}\sum_{i,j=1}{}'\left(V(x_i-x_j-i\hbar)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\right)\frac{\partial^2}{\partial p_i\partial p_j}-\frac{g}{2}\sum_{i,j}{}'\,V(x_i-x_j)\frac{\partial^2}{\partial q_i\partial q_j}\right)$$
$$\times\left(\prod_k\,(p_k+\alpha)q_k-\prod_k\,p_k(q_k+\alpha)\right):|_{p=q}=0. \tag{13}$$

For further convenience let us define the objects:

$$X_A(p,q,\alpha)\equiv\prod_{i\notin A}\,(p_i+\alpha)q_i-\prod_{i\notin A}\,p_i(q_i+\alpha)\equiv:Y_A(p,q,\alpha)-Y_A(q,p,\alpha), \tag{14}$$

for any subset $A\subset(1,...,N)$. The following useful properties are immediate consequences of the above definitions:

(i) If $F(q,\partial/\partial q;p,\partial/\partial p)=F(p,\partial/\partial p;q,\partial/\partial q)$, then $F(p,\partial/\partial p;q,\partial/\partial q)X_A(p,q,\alpha)|_{p=q}=0$;

(ii) $\partial^2X_A/\partial p_i^2=\partial^2X_A/\partial q_i^2=0$;

(iii)

$$\prod_{j\in\beta}\,\frac{\partial^2}{\partial p_j\partial q_j}\,X_A=\begin{cases}0, & A\cap B\neq\varnothing,\\ X_{A\cup B}, & A\cap B=\varnothing;\end{cases}$$

(iv)

$$\frac{\partial X_A(p,q,\alpha)}{\partial p_i}=\begin{cases}0, & i\in A,\\ q_i X_{A\cup\{i\}}-\alpha Y_{A\cup\{i\}}(q,p,\alpha), & i\in A,\end{cases}$$

$$\frac{\partial X_A(p,q,\alpha)}{\partial q_i}=\begin{cases}0, & i\in A;\\ p_i X_{A\cup\{i\}}+\alpha Y_{A\cup\{i\}}(p,q,\alpha), & i\notin A;\end{cases}$$

(v)

$$\frac{\partial Y_A}{\partial q_i}=\begin{cases}0, & i\in A\\ (p_i+\alpha)Y_{A\cup\{i\}} & i\notin A,\end{cases}$$

$$\frac{\partial Y_A}{\partial p_i}=\begin{cases}0, & i\in A\\ q_i Y_{A\cup\{i\}}, & i\notin A,\end{cases}$$

Note that

$$X_\varnothing=\prod_k (p_k+\alpha)q_k-\prod_k p_k(q_k+\alpha).$$

Our proof is based on the following identity proven in the Appendix:

$$\sum_{i_1,\ldots,i_N} P(x_{i_1}-x_{i_2})P(x_{i_2}-x_{i_3})\cdots P(x_{i_{N-2}}-x_{i_{N-1}})P'(x_{i_{N-1}}-x_{i_N})=0, \tag{15}$$

where $P(x)$ is the Weierstrass function, $P'(x)$ its derivative, and the sum extends over all permutations of numbers $(1,\ldots,N)$.

In order to prove Eq. (13), we expand $V(x_i-x_j-i\hbar(\partial/\partial q_i-\partial/\partial q_j))$ in powers of $i\hbar(\partial/\partial q_i-\partial/\partial q_j)$. Let us note that due to property (ii) above,

$$\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)^n X_A=0, \tag{16}$$

for any A and $n>2$. Hence, we have only to show that

$$\exp\left(\frac{-g}{2}\sum_{i,j}{}' V(x_i-x_j)\left(\frac{\partial^2}{\partial p_i\partial p_j}+\frac{\partial^2}{\partial q_i\partial q_j}\right)+\frac{i\hbar g}{2}\sum_{i,j}{}' V(x_i-x_j)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\frac{\partial^2}{\partial p_i\partial p_j}\right)$$
$$\cdot\exp\left(\frac{g\hbar^2}{4}\sum_{i,j}{}' V''(x_i-x_j)\frac{\partial^2}{\partial p_i\partial p_j}\frac{\partial^2}{\partial q_i\partial q_j}\right)X_\varnothing|_{p=q}=0. \tag{17}$$

Now, (iii) above implies that

$$\exp\left(\frac{g\hbar^2}{4}\sum_{i,j}{}' V''(x_i-x_j)\frac{\partial^2}{\partial p_i\partial p_j}\frac{\partial^2}{\partial q_i\partial q_j}\right)X_\varnothing$$

can be written as a linear combination (with coefficients depending only on x's) of the quantities X_A, $A=\varnothing$, $\{i,j\}$, etc. Moreover, it is easy to see that

$$\exp\left(\frac{-g}{2}\sum_{i,j}{}' V(x_i-x_j)\frac{\partial^2}{\partial p_i\partial p_j}+\frac{\partial^2}{\partial q_i\partial q_j}\right)\exp\left(\frac{i\hbar g}{2}\sum_{i,j}{}' V'(x_i-x_j)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\frac{\partial^2}{\partial p_i\partial p_j}\right)X_A$$
$$=\exp\left(\frac{-g}{2}\sum_{i,j\notin A}{}' V(x_i-x_j)\left(\frac{\partial^2}{\partial p_i\partial p_j}+\frac{\partial^2}{\partial q_i\partial q_j}\right)\right)\exp\left(\frac{i\hbar g}{2}\sum_{i,j\notin A}{}' V'(x_i-x_j)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\frac{\partial^2}{\partial p_i\partial p_j}\right)X_A,$$

which implies that it is sufficient to show

$$\exp\left(\frac{-g}{2}\sum_{i,j}{}'\ V(x_i-x_j)\left(\frac{\partial^2}{\partial p_i\partial p_j}+\frac{\partial^2}{\partial q_i\partial q_j}\right)\right)$$
$$\times\exp\left(\frac{i\hbar g}{2}\sum_{i,j}{}'\ V'(x_i-x_j)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\frac{\partial^2}{\partial p_i\partial p_j}\right)X_A|_{p=q}=0, \tag{18}$$

for any number of degrees of freedom. Let us denote

$$D\equiv-\frac{g}{2}\sum_{i,j}{}'\ V(x_i-x_j)\left(\frac{\partial^2}{\partial p_i\partial p_j}+\frac{\partial^2}{\partial q_i\partial q_j}\right),$$
$$C\equiv\frac{i\hbar g}{2}\sum_{i,j}{}'\ V(x_i-x_j)\left(\frac{\partial}{\partial q_i}-\frac{\partial}{\partial q_j}\right)\frac{\partial^2}{\partial p_i\partial p_j}. \tag{19}$$

Equation (18) reads now as

$$e^De^CX_\varnothing|_{p=q}=0, \tag{20}$$

and the expansion in powers of C is equivalent to the one in powers of $\hbar$. Obviously, this expansion has a finite number of terms.

In order to prove Eq. (20) we use the induction with respect to the powers of C. In zeroth order in $\hbar$ Eq. (20) follows immediately from the property (i) and expresses the trivial fact that classical dynamical variables commute.

Now, by the induction hypothesis we assume that

$$e^DC^nX_\varnothing|_{p=q}=0, \tag{21a}$$

for any number of particles, i.e. (as explained above) that

$$e^DC^nX_A|_{p=q}=0, \tag{21b}$$

for any subset A. Due to the properties (iii)–(v) we have

$$e^DC^{n+1}X_\varnothing=-\frac{g}{2}\,e^DC^n\sum_{i,j}{}'\ V'(x_i-x_j)(q_j-q_i)X_{\{i,j\}}$$
$$=-\frac{g}{2}\,e^D\sum_{i,j}{}'\ V'(x_i-x_j)(q_j-q_i)C^nX_{\{i,j\}}. \tag{22}$$

The last equality follows from the observation that the commutator $[C,q_j-q_i]$ acting on $X_{\{i,j\}}$ gives zero, by property (iv). Therefore we have to show that

$$e^D\sum_{i,j}{}'\ V'(x_i-x_j)(q_j-q_i)C^nX_{\{i,j\}}|_{p=q}=0. \tag{23}$$

Writing

$$e^D(q_j-q_i)=((q_j-q_i)+[D,q_j-q_i])e^D, \tag{24}$$

one obtains

$$e^D\sum_{ij}{}'\ V'(x_i-x_j)(q_j-q_i)C^nX_{\{ij\}}|_{p=q}=\sum_{ij}{}'\ V'(x_i-x_j)(q_j-q_i)e^DC^nX_{\{ij\}}|_{p=q}$$
$$-2g\sum_{i_1,i_2,i_3}{}'\ V'(x_{i_1}-x_{i_2})V(x_{i_2}-x_{i_3})e^DC^n\left.\frac{\partial X_{\{ij\}}}{\partial q_{i_3}}\right|_{p=q}. \tag{25}$$

The first term on the right-hand side of Eq. (25) vanishes by the induction hypothesis. As for the second one, we shall show that

$$\sum_{i_1,i_2,i_3}{}' V'(x_{i_1}-x_{i_2})V(x_{i_2}-x_{i_3})e^D C^n \frac{\partial X_{\{ij\}}}{\partial q_{i_3}}$$

$$\approx (-g)^{m-3}\sum_{i_1,\ldots,i_m}{}' V'(x_{i_1}-x_{i_2})V(x_{i_2}-x_{i_3})\cdots V(x_{m-1}-x_{i_m})e^D\cdot C^n \frac{\partial X_{\{i_1\ldots i_{m-1}\}}}{\partial \eta_{i_m}}, \tag{26}$$

where $\eta=p$ or q and ''$\approx$'' stands for equality up to the terms which vanish when $p=q$.

Let us assume that $\eta=p$ (for $\eta=q$ the proof goes along the same lines). It follows from the property (iv) that

$$\frac{\partial X_{\{i_1\ldots i_{m-1}\}}}{\partial p_{i_m}} = q_{i_m} X_{\{i_1\ldots i_m\}}(p,q,\alpha) - \alpha Y_{\{i_1\ldots i_m\}}(q,p,\alpha). \tag{27}$$

Inserting (27) onto the right-hand side of Eq. (26) we get two terms. The one including the function $Y_{\{i_1\cdots i_m\}}$ vanishes due to the identity (15) because $C^n Y_{\{i_1\cdots i_m\}}$ does not depend on the permutation of indices $i_1,\ldots,i_m$. As for the remaining term, we write it as

$$e^D q_{i_m} C^n X_{\{i_1\cdots i_m\}} = (q_{i_m}+[D,q_{i_m}])e^D C^n X_{\{i_1\ldots i_m\}}$$

$$= q_{i_m} e^D C^n X_{\{i_1\cdots i_m\}} - g\sum_{i_{m+1}}{}' V(x_{i_m}-x_{i_{m+1}})e^D C^n \frac{\partial X\{i_1\cdots i_m\}}{\partial q_{i_{m+1}}}. \tag{28}$$

By the induction hypothesis (with respect to n) the first term on the right-hand side gives no contribution for $p=q$ while the second one yields Eq. (26) for $m+1$; induction with respect to m (with n fixed) therefore yields Eq. (26).

Putting $m=N$ in Eq. (26), using (iv), and taking into account our basic identity (15), we get

$$\sum_{i_1,i_2,i_3}{}' V'(x_{i_1}-x_{i_2})v(x_{i_2}-x_{i_3})e^D C^n \left.\frac{\partial X\{i,j\}}{\partial q_{i_3}}\right|_{p=q} = 0,$$

which concludes the proof of Eq. (21) for $n\to n+1$.

So the proof of integrability is completed.

APPENDIX: PROOF OF THE IDENTITY (15)

Below we sketch the proof of the basic identity (15).

Let, for any $n\geqslant 3$,

$$K_n(x_1,\ldots,x_n) \equiv \sum_{(i_1,\ldots,i_n)\subset(1,\ldots,n)} P(x_{i_1}-x_{i_2})\cdots P(x_{i_{n-2}}-x_{i_{n-1}})P'(x_{i_{n-1}}-x_{i_n}), \tag{A1}$$

where $P(x)$ is the Weierstrass function, $P'(x)$ is its derivative, and the sum on the right-hand side extends over all permutations of numbers 1,...,n.

We claim that

$$K_n(x_1,\ldots,x_n)=0, \tag{A2}$$

for any $n\geqslant 3$.

The proof is by induction. For $n=3$, (A2) reduces to well-known addition theorem for the Weierstrass function.[21]

Let us assume that (A2) holds for some n. Define

$$\Delta \equiv \{n\omega_1 + m\omega_2 \in \mathbb{C} | n,m \in \mathbb{Z}\},$$

where ω_1, ω_2 are periods of P.

Let us single out one of the x variables, say x_1, and consider K_{n+1} as a function of this variable. Assume that $x_i - x_j \notin \Delta$ for any $2 \leqslant i \neq j \leqslant n+1$. Then K_{n+1}, viewed as a function of x_1, is double periodic and analytic except possible poles of, at most, third order coming from single factors on the right-hand side of Eq. (A1) and located at the points $x_1 - x_k \in \Delta$, $k = 2,...,n+1$. We claim that K_{n+1} is analytic on the whole x_1-complex plane. Obviously, it is sufficient to consider the poles appearing due to $x_1 - x_2 \in \Delta$; moreover, due to double periodicity in x_1 we can restrict ourselves to the case $x_1 \to x_2$. Let us call $z \equiv x_1 - x_2$ and select the singular terms of K_{n+1}. A careful but easy analysis gives

$$K_{n+1}(x_1,\ldots,x_{n+1}) = \frac{2}{z^2} K_n(x_2,\ldots,x_n) - \frac{1}{z} \frac{\partial K_n(x_2,\ldots,x_{n+1})}{\partial x_2} + O(1). \tag{A3}$$

By the induction assumption the singular term vanishes. Therefore $K_{n+1}(x_1,x_2,\ldots,x_{n+1})$, considered as a function of x_1, is doubly periodic and analytic provided $x_i - x_j \notin \Delta$, $2 \leqslant i \neq j \leqslant n+1$. Consequently, it is a constant. This reasoning can be, of course, repeated for any variable x_i. We conclude that K_{n+1} is constant on the open connected set,

$$\Lambda = \{(x_1,\ldots,x_{n+1}) \in \mathbb{C}^{n+1} | x_i - x_j \notin \Delta, 1 \leqslant 1, j \leqslant n+1\} \tag{A4}$$

But K_{n+1} is meromorphic on $\mathbb{C}^{n+1}$ and $\overline{\Lambda} = \mathbb{C}^{n+1}$; hence K_{n+1} is constant. Now, K_{n+1} is odd under the inversion $x_i \to -x_i$, $i = 1,...,n+1$, so it vanishes.

(Received 21 January 1998; accepted for publication 8 April 1998)

The so-called Blaszak–Marciniak lattice is considered. By the dependent variable transformation, the Blaszak–Marciniak lattice is transformed into a quart-linear form. By introducing an auxiliary variable, we further transform it into the bilinear form. A corresponding Bäcklund transformation is obtained. Furthermore, a nonlinear superposition formula is proved rigorously. As an application of the obtained results, soliton solutions are derived. © *1998 American Institute of Physics.* [S0022-2488(98)01409-1]

I. INTRODUCTION

The so-called Blaszak–Marciniak (BM) lattice is[1,2]

$$\begin{aligned}\frac{d}{dt}a(n)&=c(n+1)-c(n-1),\\ \frac{d}{dt}b(n)&=a(n-1)c(n-1)-a(n)c(n),\\ \frac{d}{dt}c(n)&=c(n)(b(n)-b(n+1)),\end{aligned}\tag{1}$$

which was first derived as an application of *r*-matrix formalism to the algebra of shifts operators. Some research on the BM lattice has been conducted. For examples, Blaszak and Marciniak established the bi-Hamiltonian structure of this system.[1] An integrable symplectic map connected with the BM lattice and its hierarchy was obtained by Wu and Geng.[2] The purpose of this paper is to derive a Bäcklund transformation for the BM lattice and establish a nonlinear superposition formula for it. As a result, multisoliton solutions are derived step by step.

We now consider the system (1). By the dependent variable transformation

$$a(n)=\frac{D_t^2 f(n+1)\cdot f(n+1)}{2f(n)f(n+2)},\quad b(n)=\left(\ln\frac{f(n)}{f(n+1)}\right)_t,\quad c(n)=\frac{f(n)f(n+2)}{f^2(n+1)},$$

(1) can be transformed into the following form:

$$\frac{1}{2}\left[\frac{D_t^2 f(n+1)\cdot f(n+1)}{f(n)f(n+2)}\right]_t=\frac{f(n+1)f(n+3)}{f^2(n+2)}-\frac{f(n+1)f(n-1)}{f^2(n)},\tag{2}$$

or equivalently

$$\tfrac{1}{2}D_t(D_t^2 f(n)\cdot f(n))\cdot(e^{D_n}f(n)\cdot f(n))=f^2(n-1)f(n)f(n+2)-f(n)f(n-2)f^2(n+1),\tag{3}$$

 © 1998 American Institute of Physics

where the bilinear operators are defined as follows:[3–5]

$$D_x^m D_t^n a\cdot b\equiv\left(\frac{\partial}{\partial x}-\frac{\partial}{\partial x'}\right)^m\left(\frac{\partial}{\partial t}-\frac{\partial}{\partial t'}\right)^n a(x,t)b(x',t')|_{x'=x,t'=t}.$$

$$\exp(\delta D_n)a(n)\cdot b(n)\equiv\exp\left[\delta\left(\frac{\partial}{\partial n}-\frac{\partial}{\partial n'}\right)\right]a(n)b(n')|_{n'=n}=a(n+\delta)b(n-\delta).$$

By introducing an auxiliary variable z and using (A1), we can decouple (3) into the following bilinear form:

$$(D_t^2-2D_z e^{D_n})f(n)\cdot f(n)=0, \tag{4}$$

$$(D_z D_t-4\sinh^2(\tfrac{1}{2}D_n))f(n)\cdot f(n)=0. \tag{5}$$

The paper is organized as follows. In Sec. II we give a Bäcklund transformation for Eqs. (4) and (5). Then in Sec. III, we give a brief proof of a nonlinear superposition formula. Some particular solutions of Eqs. (4) and (5) are then found through this formula. Finally, Sec. IV summarizes the obtained results. Appendix A lists some bilinear operator identities made use of in this paper. In Appendix B, a detailed deduction of relation (17) is given.

II. A BÄCKLUND TRANSFORMATION FOR THE BM LATTICE

In this section, we derive a Bäcklund transformation for Eqs. (4) and (5). The result obtained is

Proposition 1: A Bäcklund transformation for (4) and (5) is

$$(D_t+\lambda^{-1}e^{-D_n}+\mu)f(n)\cdot g(n)=0, \tag{6}$$

$$(D_z e^{-(1/2)D_n}-\lambda e^{(1/2)D_n}+\gamma e^{-(1/2)D_n})f(n)\cdot g(n)=0, \tag{7}$$

$$[\lambda^{-1}D_t e^{-(1/2)D_n}-D_z e^{(1/2)D_n}-\gamma e^{(1/2)D_n}+\omega e^{-(1/2)D_n}]f(n)\cdot g(n)=0, \tag{8}$$

where λ, μ, γ, and ω are arbitrary constants.

Proof: Let $f(n)$ be a solution of Eqs. (4) and (5). If we can show that Eqs. (6)–(8) guarantee that the following two relations:

$$P_1\equiv(D_t^2-2D_z e^{D_n})g(n)\cdot g(n)=0,$$

$$P_2\equiv(D_z D_t-4\sinh^2(\tfrac{1}{2}D_n))g(n)\cdot g(n)=0,$$

hold, then Eqs. (6)–(8) form a Bäcklund transformation.

Note that (5) is just the bilinear form for the two-dimensional Toda lattice. From Ref. 6 we know that (6) and (7) guarantee $P_2=0$. Therefore, we only need to prove $P_1=0$. By use of (A2)–(A6) and (6)–(8), we have

$$\begin{aligned}-f^2(n)P_1=&\,2D_t(D_t f(n)\cdot g(n))\cdot f(n)g(n)-4\sinh(\tfrac{1}{2}D_n)\\&\times\{[D_z e^{(1/2)D_n}f(n)\cdot g(n)]\cdot[e^{-(1/2)D_n}f(n)\cdot g(n)]\\&-[e^{(1/2)D_n}f(n)\cdot g(n)]\cdot[D_z e^{-(1/2)D_n}f(n)\cdot g(n)]\}\\=&-2\lambda^{-1}D_t[e^{-D_n}f(n)\cdot g(n)]\cdot f(n)g(n)-4\sinh(\tfrac{1}{2}D_n)\\&\times[D_z e^{(1/2)D_n}f(n)\cdot g(n)]\cdot[e^{-(1/2)D_n}f(n)\cdot g(n)]-4\gamma\sinh(\tfrac{1}{2}D_n)\\&\times[e^{(1/2)D_n}f(n)\cdot g(n)]\cdot[e^{-(1/2)D_n}f(n)\cdot g(n)]\end{aligned}$$

$$
\begin{aligned}
&= 4\lambda^{-1}\sinh(\tfrac{1}{2}D_n)[D_t e^{-(1/2)D_n} f(n)\cdot g(n)]\cdot[e^{-(1/2)D_n} f(n)\cdot g(n)] - 4\sinh(\tfrac{1}{2}D_n)\\
&\times[D_z e^{(1/2)D_n} f(n)\cdot g(n)]\cdot[e^{-(1/2)D_n} f(n)\cdot g(n)] - 4\gamma\sinh(\tfrac{1}{2}D_n)\\
&\times[e^{(1/2)D_n} f(n)\cdot g(n)]\cdot[e^{-(1/2)D_n} f(n)\cdot g(n)] = 0.
\end{aligned}
$$

Thus we have completed the proof of proposition 1.

By use of (6)–(8), we can easily obtain the following solutions from the trivial solution $f(n)=1$:

$$g(n) = 1 + \exp(\eta)$$

with

$$\lambda = \left(\frac{e^{2p}}{1+e^{p}}\right)^{(1/3)}, \quad \mu = -\lambda^{-1}, \quad \gamma = \lambda, \omega = \lambda,$$

where $\eta = pn + qz + rt + \eta^0$, $q = \lambda(1-e^{-p})$, $r = \lambda^{-1}(e^{p}-1)$.

III. A NONLINEAR SUPERPOSITION FORMULA

In the following, we shall simply denote, without confusion, $f(n,t)=f(n)$ or f. The result reached is

Proposition 2: Let f_0 be a solution of Eqs. (4) and (5) and suppose that $f_i (i=1,2)$ are solutions of (4) and (5) which are related to f_0 under the BT Eqs. (6)–(8) with parameters $(\lambda_i,\mu_i,\gamma_i,\omega_i)$, i.e., $f_0 \overset{(\lambda_i,\mu_i,\gamma_i,\omega_i)}{\longrightarrow} f_i (i=1,2)$, $\lambda_1\lambda_2 \neq 0$, $f_j \neq 0$ $(j=0,1,2)$. Then f_{12} defined by

$$\exp(-\tfrac{1}{2}D_n) f_0\cdot f_{12} = c[\lambda_1 \exp(-\tfrac{1}{2}D_n) - \lambda_2 \exp(\tfrac{1}{2}D_n)] f_1\cdot f_2 \quad (c \text{ is a nonzero constant}), \tag{9}$$

is a new solution which is related to f_1 and f_2 under the BT (6)–(8) with parameters $(\lambda_2,\mu_2,\gamma_2,\omega_2)$, $(\lambda_1,\mu_1,\gamma_1,\omega_1)$, respectively.

Proof: Same as the deduction in Ref. 6, we can show that

$$(D_t + \lambda_2^{-1} e^{-D_n} + \mu_2) f_1\cdot f_{12} = 0, \tag{10}$$

$$(D_t + \lambda_1^{-1} e^{-D_n} + \mu_1) f_2\cdot f_{12} = 0, \tag{11}$$

$$(D_z e^{-(1/2)D_n} - \lambda_2 e^{(1/2)D_n} + \gamma_2 e^{-(1/2)D_n}) f_1\cdot f_{12} = 0, \tag{12}$$

$$(D_z e^{-(1/2)D_n} - \lambda_1 e^{(1/2)D_n} + \gamma_1 e^{-(1/2)D_n}) f_2\cdot f_{12} = 0, \tag{13}$$

and

$$-D_t f_1\cdot f_2 + (\mu_1-\mu_2) f_1 f_2 - \frac{1}{c\lambda_1\lambda_2} e^{-D_n} f_0\cdot f_{12} = 0. \tag{14}$$

Therefore, in order to prove proposition 2, it suffices to show that

$$[\lambda_2^{-1} D_t e^{-(1/2)D_n} - D_z e^{(1/2)D_n} - \gamma_2 e^{(1/2)D_n} + \omega_2 e^{-(1/2)D_n}] f_1\cdot f_{12} = 0, \tag{15}$$

$$[\lambda_1^{-1} D_t e^{-(1/2)D_n} - D_z e^{(1/2)D_n} - \gamma_1 e^{(1/2)D_n} + \omega_1 e^{-(1/2)D_n}] f_2\cdot f_{12} = 0. \tag{16}$$

From

$$\frac{1}{\lambda_1}[(D_z e^{-(1/2)D_n}-\lambda_1 e^{(1/2)D_n}+\gamma_1 e^{-(1/2)D_n})f_0(n)\cdot f_1(n)]f_2\left(n-\tfrac{1}{2}\right),$$

$$-\frac{1}{\lambda_2}[(D_z e^{-(1/2)D_n}-\lambda_2 e^{(1/2)D_n}+\gamma_2 e^{-(1/2)D_n})f_0(n)\cdot f_2(n)]f_1(n-\tfrac{1}{2})=0,$$

we can deduce that (for detail, see Appendix B)

$$[\lambda_2 D_z e^{(1/2)D_n}+\lambda_1 D_z e^{-(1/2)D_n}-2\lambda_2\gamma_1 e^{(1/2)D_n}+2\lambda_1\gamma_2 e^{-(1/2)D_n}]f_1(n)\cdot f_2(n)$$
$$+\frac{1}{c}D_z e^{-(1/2)D_n}f_0(n)\cdot f_{12}(n)=0. \tag{17}$$

Since f_1 and f_2 are two solutions of Eq. (4), we have, by use of (A2)–(A9), (9), (10), (12), (17), and $f_0 \underset{(\lambda_2,\mu_2,\gamma_2,\omega_2)}{\rightarrow} f_2$, that

$$0=[(D_t^2-2D_z e^{D_n})f_1\cdot f_1]f_2^2-f_1^2[(D_t^2-2D_z e^{D_n})f_2\cdot f_2],$$

$$=2D_t(D_t f_1\cdot f_2)\cdot f_1 f_2-4\sinh(\tfrac{1}{2}D_n)\{[D_z e^{(1/2)D_n}f_1\cdot f_2]\cdot[e^{-(1/2)D_n}f_1\cdot f_2]$$
$$-[e^{(1/2)D_n}f_1\cdot f_2]\cdot[D_z e^{-(1/2)D_n}f_1\cdot f_2]\}$$

$$=-2D_t\left[\frac{1}{c\lambda_1\lambda_2}e^{-D_n}f_0\cdot f_{12}\right]\cdot f_1 f_2-\frac{4}{\lambda_1}\sinh\left(\frac{1}{2}D_n\right)\{[(\lambda_1 D_z e^{-(1/2)D_n}$$
$$+\lambda_2 D_z e^{(1/2)D_n})f_1\cdot f_2]\cdot[e^{(1/2)D_n}f_1\cdot f_2]-[(\lambda_1 e^{-(1/2)D_n}-\lambda_2 e^{(1/2)D_n})f_1\cdot f_2]\cdot[D_z e^{(1/2)D_n}f_1\cdot f_2]\}$$

$$=-\frac{2}{c\lambda_1\lambda_2}e^{-(1/2)D_n}\{[D_t e^{-(1/2)D_n}f_0\cdot f_2]\cdot[e^{-(1/2)D_n}f_1\cdot f_{12}]$$
$$-[e^{-(1/2)D_n}f_0\cdot f_2]\cdot[D_t e^{-(1/2)D_n}f_1\cdot f_{12}]\}-\frac{4}{\lambda_1}\sinh\left(\frac{1}{2}D_n\right)\left\{\left[-\frac{1}{c}D_z e^{-(1/2)D_n}f_0\cdot f_{12}\right.\right.$$
$$\left.\left.-2\gamma_2\lambda_1 e^{-(1/2)D_n}f_1\cdot f_2\right]\cdot[e^{(1/2)D_n}f_1\cdot f_2]-\frac{1}{c}[e^{-(1/2)D_n}f_0\cdot f_{12}]\cdot[D_z e^{(1/2)D_n}f_1\cdot f_2]\right\}$$

$$=-\frac{2}{c\lambda_1\lambda_2}e^{-(1/2)D_n}\{[D_t e^{-(1/2)D_n}f_0\cdot f_2]\cdot[e^{-(1/2)D_n}f_1\cdot f_{12}]$$
$$-[e^{-(1/2)D_n}f_0\cdot f_2]\cdot[D_t e^{-(1/2)D_n}f_1\cdot f_{12}]\}+\frac{2}{c\lambda_1}e^{-(1/2)D_n}\{[D_z e^{(1/2)D_n}f_0\cdot f_2]\cdot[e^{-(1/2)D_n}f_1$$
$$\cdot f_{12}]-[e^{-(1/2)D_n}f_0\cdot f_2]\cdot[D_z e^{(1/2)D_n}f_1\cdot f_{12}]+[e^{(1/2)D_n}f_0\cdot f_2]\cdot[D_z e^{-(1/2)D_n}f_1\cdot f_{12}]$$
$$-[D_z e^{-(1/2)D_n}f_0\cdot f_2]\cdot[e^{(1/2)D_n}f_1\cdot f_{12}]\}+\frac{8\gamma_2}{\lambda_1}\sinh\left(\frac{1}{2}D_n\right)[(\lambda_1 e^{-(1/2)D_n}$$
$$-\lambda_2 e^{(1/2)D_n})f_1\cdot f_2]\cdot[e^{(1/2)D_n}f_1\cdot f_2]$$

$$=-\frac{2}{c\lambda_1\lambda_2}e^{-(1/2)D_n}\{[D_t e^{-(1/2)D_n}f_0\cdot f_2]\cdot[e^{-(1/2)D_n}f_1\cdot f_{12}]$$
$$-[e^{-(1/2)D_n}f_0\cdot f_2]\cdot[D_t e^{-(1/2)D_n}f_1\cdot f_{12}]\}+\frac{2}{c\lambda_1}e^{-(1/2)D_n}\{[D_z e^{(1/2)D_n}f_0\cdot f_2]\cdot[e^{-(1/2)D_n}f_1\cdot 12]$$
$$-[e^{-(1/2)D_n}f_0\cdot f_2]\cdot[D_z e^{1/2D_n}f_1\cdot f_{12}]-[e^{(1/2)D_n}f_0\cdot f_2]\cdot[\gamma_2 e^{-(1/2)D_n}f_1\cdot f_{12}]$$

$$+[\gamma_2 e^{-(1/2)D_n} f_0 \cdot f_2]\cdot[e^{(1/2)D_n} f_1 \cdot f_{12}]\} + \frac{8\gamma_2}{\lambda_1 c}\sinh\left(\frac{1}{2}D_n\right)[e^{-(1/2)D_n} f_0 \cdot f_{12}]\cdot[e^{(1/2)D_n} f_1 \cdot f_2]$$

$$= -\frac{2}{c\lambda_1} e^{-(1/2)D_n}\{[(\lambda_2^{-1} D_t e^{-(1/2)D_n} - D_z e^{(1/2)D_n} + \gamma_2 e^{(1/2)D_n}) f_0 \cdot f_2]\cdot[e^{-(1/2)D_n} f_1 \cdot f_{12}]$$

$$-[e^{-(1/2)D_n} f_0 \cdot f_2]\cdot[(\lambda_2^{-1} D_t e^{-(1/2)D_n} - D_z e^{(1/2)D_n} + \gamma_2 e^{(1/2)D_n}) f_1 \cdot f_{12}]\}$$

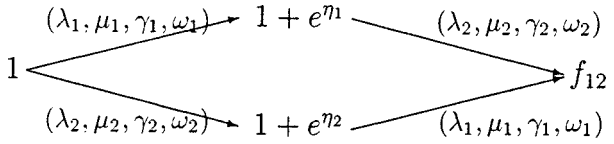
$$+\frac{4\gamma_2}{\lambda_1 c} e^{-(1/2)D_n}\{[e^{(1/2)D_n} f_0 \cdot f_2]\cdot[e^{-(1/2)D_n} f_1 \cdot f_{12}] - [e^{-(1/2)D_n} f_0 \cdot f_2]\cdot[e^{(1/2)D_n} f_1 \cdot f_{12}]\}$$

$$= \frac{2}{c\lambda_1} e^{-(1/2)D_n}[e^{-(1/2)D_n} f_0 \cdot f_2]\cdot[(\lambda_2^{-1} D_t e^{-(1/2)D_n} - D_z e^{(1/2)D_n} - \gamma_2 e^{(1/2)D_n}$$

$$+\omega_2 e^{-(1/2)D_n}) f_1 \cdot f_{12}]\},$$

which implies that (15) holds. Similarly we can prove (16) also holds. Therefore we have completed the proof of the proposition 2.

As an application of the result, we can construct soliton solutions of the BM lattice. Choose for example $f_0 = 1$, $c = 1/(\lambda_1 - \lambda_2)$. It is easily verified that



where

$$f_{12} = 1 + \frac{\lambda_1 e^{-p_1/2} - \lambda_2 e^{p_1/2}}{\lambda_1 - \lambda_2} e^{\eta_1} + \frac{\lambda_1 e^{p_2/2} - \lambda_2 e^{-p_2/2}}{\lambda_1 - \lambda_2} e^{\eta_2} + \frac{\lambda_1 e^{(p_2 - p_1)/2} - \lambda_2 e^{(p_1 - p_2)/2}}{\lambda_1 - \lambda_2} e^{\eta_1 + \eta_2}$$

with

$$\eta_i = p_i n + q_i z + r_i t + \eta_i^0, \quad q_i = \lambda_i(1 - e^{-p_i}), \quad r_i = \lambda_i^{-1}(e^{p_i} - 1)$$

and

$$\lambda_i = \left(\frac{e^{2p_i}}{1 + e^{p_i}}\right)^{1/3}, \quad \mu_i = -\lambda_i^{-1}, \quad \gamma_i = \lambda_i, \quad \omega_i = \lambda_i.$$

In general, along this line, we can obtain multisoliton solutions for the BM lattice (4) and (5) step by step.

IV. SUMMARY

The so-called Blaszak–Marciniak lattice has been considered. By the dependent variable transformation, the BM lattice is transformed into a quart-linear form. By introducing an auxiliary variable, we further transform it into the bilinear form. We have given a Bäcklund transformation for the BM lattice as well as a nonlinear superposition formula for it. As an application of the obtained results, soliton solutions are derived.

APPENDIX A: HIROTA BILINEAR OPERATOR IDENTITIES

The following bilinear operator identities hold for arbitrary functions a, b, c, and d.

$$2D_t[D_z e^{D_n} a(n)\cdot(n)]\cdot[e^{D_n} a(n)\cdot a(n)] = a^2(n-1)D_t D_z a(n+1)\cdot a(n+1) - a^2(n+1)D_t D_z a(n-1)\cdot a(n-1), \tag{A1}$$

$$(D_t^2 a\cdot a)b^2 - a^2 D_t^2 b\cdot b = 2D_t(D_t a\cdot b)\cdot ab, \tag{A2}$$

$$[D_z e^{D_n} a\cdot a]b^2 - a^2[D_z e^{D_n} b\cdot b] = 2\sinh(\tfrac{1}{2}D_n)\{[D_z e^{(1/2)D_n} a\cdot b]\cdot[e^{-(1/2)D_n} a\cdot b] - [e^{(1/2)D_n} a\cdot b]\cdot[D_z e^{-(1/2)D_n} a\cdot b]\}, \tag{A3}$$

$$D_t(e^{-D_n} a\cdot b)\cdot ab = -2\sinh(\tfrac{1}{2}D_n)[D_t e^{-(1/2)D_n} a\cdot b]\cdot[e^{-(1/2)D_n} a\cdot b], \tag{A4}$$

$$D_t a\cdot a = 0, \tag{A5}$$

$$\sinh(\tfrac{1}{2}D_n)a\cdot a = 0, \tag{A6}$$

$$D_t(e^{-D_n} a\cdot b)\cdot cd = e^{-(1/2)D_n}\{[D_t e^{-(1/2)D_n} a\cdot d]\cdot[e^{-(1/2)D_n} c\cdot b] - [e^{-(1/2)D_n} a\cdot d]\cdot[D_t e^{-(1/2)D_n} c\cdot b]\}, \tag{A7}$$

$$\begin{aligned} &2\sinh(\tfrac{1}{2}D_n)\{[D_t e^{-(1/2)D_n} a\cdot b]\cdot[e^{(1/2)D_n} c\cdot d] + [e^{-(1/2)D_n} a\cdot b]\cdot[D_t e^{(1/2)D_n} c\cdot d]\} \\ &= e^{-(1/2)D_n}\{[D_t e^{(1/2)D_n} a\cdot d]\cdot[e^{-(1/2)D_n} c\cdot b] + [e^{(1/2)D_n} a\cdot d]\cdot[D_t e^{-(1/2)D_n} c\cdot b] \\ &\quad - [D_t e^{-(1/2)D_n} a\cdot d]\cdot[e^{(1/2)D_n} c\cdot b] - [e^{-(1/2)D_n} a\cdot d]\cdot[D_t e^{(1/2)D_n} c\cdot b]\}, \end{aligned} \tag{A8}$$

$$\begin{aligned} &2\sinh(\tfrac{1}{2}D_n)[e^{-(1/2)D_n} a\cdot b]\cdot[e^{(1/2)D_n} c\cdot d] \\ &= e^{-(1/2)D_n}\{[e^{(1/2)D_n} a\cdot d]\cdot[e^{-(1/2)D_n} c\cdot b] - [e^{-(1/2)D_n} a\cdot d]\cdot[e^{(1/2)D_n} c\cdot b]\}. \end{aligned} \tag{A9}$$

APPENDIX B: DEDUCTION OF (17)

By use of (9), we have

$$\begin{aligned} 0 &= \frac{1}{\lambda_1}\left[D_z f_0\left(n-\frac{1}{2}\right)\cdot f_1\left(n+\frac{1}{2}\right) - \lambda_1 f_0\left(n+\frac{1}{2}\right) f_1\left(n-\frac{1}{2}\right) + \gamma_1 f_0\left(n-\frac{1}{2}\right) f_1\left(n+\frac{1}{2}\right)\right] f_2\left(n-\frac{1}{2}\right) \\ &\quad - \frac{1}{\lambda_2}\left[D_z f_0\left(n-\frac{1}{2}\right)\cdot f_2\left(n+\frac{1}{2}\right) - \lambda_2 f_0\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)\right. \\ &\quad \left. + \gamma_2 f_0\left(n-\frac{1}{2}\right) f_2\left(n+\frac{1}{2}\right)\right] f_1\left(n-\frac{1}{2}\right) \\ &= -\frac{1}{c\lambda_1\lambda_2} f_{0z}\left(n-\frac{1}{2}\right)[c(\lambda_1 e^{-(1/2)D_n} - \lambda_2 e^{(1/2)D_n}) f_1(n)\cdot f_2(n)] \\ &\quad + f_0\left(n-\frac{1}{2}\right)\left[-\lambda_1^{-1} f_{1z}\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right) + \lambda_2^{-1} f_1\left(n-\frac{1}{2}\right) f_{2z}\left(n+\frac{1}{2}\right)\right. \\ &\quad \left. + \frac{\gamma_1}{\lambda_1} f_1\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right) - \frac{\gamma_2}{\lambda_2} f_1\left(n-\frac{1}{2}\right) f_2\left(n+\frac{1}{2}\right)\right] \\ &= f_0\left(n-\frac{1}{2}\right)\left[-\frac{1}{c\lambda_1\lambda_2} f_{0z}\left(n-\frac{1}{2}\right) f_{12}\left(n+\frac{1}{2}\right) - \lambda_1^{-1} f_{1z}\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)\right. \end{aligned}$$

$$+\lambda_2^{-1} f_1\left(n-\frac{1}{2}\right) f_{2z}\left(n+\frac{1}{2}\right)+\frac{\gamma_1}{\lambda_1} f_1\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)-\frac{\gamma_2}{\lambda_2} f_1\left(n-\frac{1}{2}\right) f_2\left(n+\frac{1}{2}\right)\Bigg]$$

$$=f_0\left(n-\frac{1}{2}\right)\Bigg[-\frac{1}{2c\lambda_1\lambda_2} D_z f_0\left(n-\frac{1}{2}\right)\cdot f_{12}\left(n+\frac{1}{2}\right)-\frac{1}{2c\lambda_1\lambda_2}[e^{-(1/2)D_n} f_0(n)\cdot f_{12}(n)]_z$$

$$-\lambda_1^{-1} f_{1z}\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)+\lambda_2^{-1} f_1\left(n-\frac{1}{2}\right) f_{2z}\left(n+\frac{1}{2}\right)+\frac{\gamma_1}{\lambda_1} f_1\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)$$

$$-\frac{\gamma_2}{\lambda_2} f_1\left(n-\frac{1}{2}\right) f_2\left(n+\frac{1}{2}\right)\Bigg]$$

$$=f_0\left(n-\frac{1}{2}\right)\Bigg\{-\frac{1}{2c\lambda_1\lambda_2} D_z e^{-(1/2)D_n} f_0(n)\cdot f_{12}(n)-\frac{1}{2\lambda_1\lambda_2}\Bigg[\lambda_1 f_1\left(n-\frac{1}{2}\right) f_2\left(n+\frac{1}{2}\right)$$

$$-\lambda_2 f_1\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)\Bigg]_z-\lambda_1^{-1} f_{1z}\left(n+\frac{1}{2}\right) f_2\left(n-\frac{1}{2}\right)+\lambda_2^{-1} f_1\left(n-\frac{1}{2}\right) f_{2z}\left(n+\frac{1}{2}\right)$$

$$+\frac{\gamma_1}{\lambda_1} e^{(1/2)D_n} f_1(n)\cdot f_2(n)-\frac{\gamma_2}{\lambda_2} e^{-(1/2)D_n} f_1(n)\cdot f_2(n)\Bigg\}$$

$$=f_0\left(n-\frac{1}{2}\right)\Bigg\{-\frac{1}{2c\lambda_1\lambda_2} D_z e^{-(1/2)D_n} f_0(n)\cdot f_{12}(n)-\frac{1}{2\lambda_1} D_z e^{(1/2)D_n} f_1(n)\cdot f_2(n)$$

$$-\frac{1}{2\lambda_2} D_z e^{-(1/2)D_n} f_1(n)\cdot f_2(n)+\frac{\gamma_1}{\lambda_1} e^{(1/2)D_n} f_1(n)\cdot f_2(n)-\frac{\gamma_2}{\lambda_2} e^{-(1/2)D_n} f_1(n)\cdot f_2(n)\Bigg\}$$

$$=0,$$

which implies that (17) holds.

(Received 27 October 1997; accepted for publication 17 April 1998)

We construct the supersymmetric extensions of the Darboux–Bäcklund transformations (DBTs) for the Manin–Radul super Korteweg–de Vries (KdV) hierarchy using the super-pseudo-differential operators. The elementary DBTs are triggered by the gauge operators constructed from the wave functions and adjoint wave functions of the hierarchy. Iterating these elementary DBTs, we obtain not only Wronskian-type but also binary-type superdeterminant representations of the solutions. © *1998 American Institute of Physics.* [S0022-2488(98)00109-1]

I. INTRODUCTION

In the past few decades, the Darboux–Bäcklund transformations (DBTs) have been shown to be an efficient method to obtain the soliton solutions of the nonlinear integrable systems including Korteweg–de Vries (KdV), Kadomtsev–Petviashili (KP), sine–Gordon, and nonlinear Schrödinger equations (see, for example, Ref. 1), etc. In contrast to these results, the application of the DBTs to superintegrable systems is quite limited. The reasons are partly due to the complexity of the supersymmetric formulation of superintegrable systems. However, as far as the supersoliton solutions are concerned, the supersymmetric generalization of the DBTs is urgently needed.

Recently, Liu[2] proposed a DBT for the Manin–Radul super KdV (MR sKdV) equation.[3] The DBT is triggered by a gauge operator which is a first-order superdifferential operator (SDO) parametrized by a wave function of the associated linear system. By iterating such a DBT, Liu and Mañas[4] obtained the supersymmetric version of the Crum transformation for the MR sKdV equation and showed that the solutions can be expressed in terms of Wronskian superdeterminants.

In this paper, we will investigate the DBTs for the MR sKdV hierarchy from a super-pseudo-differential operator (SΨDO) point of view. Motivated by the non-supersymmetric cases[1,5–12] and the works described above, we introduce the adjoint DBT which is triggered by an adjoint wave function of the system. This adjoint DBT in combination with the previous one forms a binary DBT which is constructed from a wave function and an adjoint wave function. Iterating these elementary DBTs, we obtain not only Wronskian-type but also binary-type superdeterminant representations for the solutions of the MR sKdV hierarchy which have not been obtained previously.

Our paper is organized as follows: In Sec. II, some basic facts about SΨDO are recalled and the MR sKdV hierarchy is defined. In Sec. III, we introduce the elementary DBTs which are triggered by the gauge operators constructed from the wave functions and the adjoint wave functions of the MR sKdV system. In Sec. IV, we iterate these DBTs to obtain the solutions of the MR sKdV hierarchy. Concluding remarks are presented in Sec. V.

II. PRELIMINARIES

Before considering a specific superintegrable system, let us recall some basic facts of the SΨDO which is defined by

[a)]Electronic mail: shaw@math.nctu.edu.tw
[b)]Electronic mail: mhtu@phys.nthu.edu.tw

 © 1998 American Institute of Physics

$$\Lambda = D^N + \sum_{i=-\infty}^{N-1} U_i D^i, \quad N \in \mathbf{Z}, \tag{2.1}$$

where the supercovariant derivative $D \equiv \partial_\theta + \theta\partial$ satisfies $D^2 = \partial$ and θ is the Grassmann variable ($\theta^2 = 0$) which, together with the even variable $x \equiv t_1$, defines the $(1|1)$ superspace with coordinate (x, θ). The formal inverse of D is introduced by $D^{-1} = \theta + \partial_\theta \partial^{-1}$, which satisfies $DD^{-1} = D^{-1}D = 1$. The coefficients U_i are superfields that depend on the variables x, θ, and t_i and can be represented by $U_i = u_i(t) + \theta v_i(t)$. Since the SΨDO is assumed to be homogeneous under Z_2 grading, the grading of the superfield U_i is $|U_i| = N + i \pmod 2$. Here we refer the parity of U_i to be even if $|U_i| = 0$ and odd if $|U_i| = 1$. The supercovariant derivative D satisfies the supersymmetric version of the Leibniz rule:[3]

$$D^i U = \sum_{k=0}^{\infty} (-1)^{|U|(i-k)} \begin{bmatrix} i \\ k \end{bmatrix} (D^k U) D^{i-k}, \tag{2.2}$$

where the superbinomial coefficients $\left[\begin{smallmatrix} i \\ k \end{smallmatrix}\right]$ are defined by

$$\begin{bmatrix} i \\ k \end{bmatrix} = \begin{cases} \begin{pmatrix} [i/2] \\ [k/2] \end{pmatrix} & \text{for } 0 \leqslant k \leqslant i \quad \text{and } (i,k) \neq (0,1) \mod 2 \\ (-1)^{[k/2]} \begin{bmatrix} -i+k-1 \\ k \end{bmatrix} & \text{for } i < 0, \\ 0 & \text{otherwise.} \end{cases} \tag{2.3}$$

It is convenient to separate Λ into the positive and negative parts as follows:

$$\Lambda_+ = \sum_{i \geqslant 0} U_i D^i, \quad \Lambda_- = \sum_{i \leqslant -1} U_i D^i. \tag{2.4}$$

The superresidue (sres) of Λ is defined by

$$\text{sres}\,(\Lambda) = U_{-1}, \tag{2.5}$$

and the conjugate operation ''*'' for SΨDOs can be defined as follows

$$(PQ)^* = (-1)^{|P||Q|} Q^* P^*, \tag{2.6}$$

which implies that $U^* = U$ for arbitrary superfield U and

$$(\partial^i)^* = (-1)^i \partial^i, \quad (D^i)^* = (-1)^{i(i+1)/2} D^i. \tag{2.7}$$

A simple calculation shows that

$$\Lambda^* = \sum_i (-1)^N (-1)^{i(i-1)/2} D^i U_i. \tag{2.8}$$

With these definitions in hand, let us provide some useful identities which will simplify the computations involving compositions of SΨDOs.

Lemma 1:

$$(\Lambda^*)_+ = (\Lambda_+)^*, \quad (\Lambda^*)_- = (\Lambda_-)^*, \tag{2.9}$$

$$(D^{-1}\Lambda)_- = D^{-1}(\Lambda^*)_0 + D^{-1}(\Lambda)_-, \tag{2.10}$$

$$(\Lambda D^{-1})_- = (\Lambda)_0 D^{-1} + \Lambda_- D^{-1}, \tag{2.11}$$

$$\text{sres}\,(\Lambda) = \text{sres}\,(\Lambda^*), \quad (D\ \text{sres}\,(\Lambda)) = \text{sres}\,(D\Lambda - (-1)^{|\Lambda|}\Lambda D), \tag{2.12}$$

$$\text{sres}\,(\Lambda D^{-1})=(\Lambda)_0, \quad \text{sres}\,(D^{-1}\Lambda)=(-1)^{|\Lambda|}(\Lambda^*)_0, \tag{2.13}$$

$$\text{sres}\,(D^{-1}\Lambda_1\Lambda_2 D^{-1})=\text{sres}\,(D^{-1}(\Lambda_1^*)_0\Lambda_2 D^{-1})+\text{sres}\,(D^{-1}\Lambda_1(\Lambda_2)_0 D^{-1}), \tag{2.14}$$

where $\Lambda_1=(\Lambda_1)_+$ and $\Lambda_2=(\Lambda_2)_+$.

Proof: The proofs for these identities are straightforward. Here we only give the proof for the second identity. From the left-hand side, we have

$$(D^{-1}\Lambda)_-=(D^{-1}\Lambda_+)_-+D^{-1}\Lambda_-. \tag{2.15}$$

Then using (2.2), we obtain

$$\begin{aligned}(D^{-1}\Lambda_+)_- &= \left(\sum_{k=0}^{\infty}\sum_{i=0}^{N}(-1)^{(N+i)(1+k)}\begin{bmatrix}-1\\ k\end{bmatrix}(D^k U_i)D^{-1-k+i}\right)_- \\ &= \sum_{l=0}^{\infty}\sum_{i=0}^{N}(-1)^{(N+i)(1+i+l)}(-1)^{[(i+l)/2]}(D^{i+l}U_i)D^{-1-l} \\ &= \sum_{l=0}^{\infty}(-1)^{N(1+l)}(-1)^{[l/2]}(D^l(\Lambda^*)_0)D^{-1-l}=D^{-1}(\Lambda^*)_0. \end{aligned}\tag{2.16}$$

Here the relation $(-1)^{[i/2]}=(-1)^{i(i-1)/2}$ has been used to reach the third line of (2.16). □

The MR sKdV hierarchy is defined, in Lax form, as

$$\partial_{t_n}L=[P_n,\,L], \quad n=1,3,5,..., \tag{2.17}$$

with

$$L=\partial^2+v_1D+v_0, \tag{2.18}$$

$$P_n=L_+^{n/2}, \tag{2.19}$$

where the coefficients v_1 and v_0 are superfields depending on the variables $(\theta,x,t_3,t_5,\ldots)$ with grading $|v_i|=i \pmod 2$. We can rewrite the hierarchy equations (2.17) as follows:

$$\partial_{t_m}P_n-\partial_{t_n}P_m+[P_n,\,P_m]=0, \tag{2.20}$$

which is called the zero-curvature condition and is equivalent to the whole set of equations of (2.17). If we can find a set of superfields $\{v_1,v_0\}$ and hence a corresponding set of superdifferential operators (SDO) $\{P_n\}$ satisfying (2.20), then we have a solution to the MR sKdV hierarchy. In fact, the MR sKdV hierarchy was constructed originally from the MR sKP hierarchy[3] associated with the odd SΨDO: $\Lambda_{\text{MR}}=D+\Sigma_{i=0}^{\infty}U_{-i}D^{-i}$ by the reduction $L=(\Lambda_{\text{MR}}^4)_+$ and has been shown to be bi-Hamiltonian.[13,14] Substituting (2.18) and (2.19) into the Lax equation (2.17) for $n=3$, one obtains

$$\partial_{t_3}v_0=\tfrac{1}{4}\partial_x(v_{0xx}+3v_0^2+3v_1(Dv_0)), \tag{2.21}$$

$$\partial_{t_3}v_1=\tfrac{1}{4}\partial_x(v_{1xx}+3v_1(Dv_1)+6v_1v_0), \tag{2.22}$$

which is the MR sKdV equation. By setting $v_1=0$, Eqs. (2.21) and (2.22) reduce to the KdV equation. The Lax equation (2.17) can be viewed as the compatibility condition of the linear system

$$L\phi=\lambda\phi, \quad \partial_{t_n}\phi=(P_n\phi)_0, \tag{2.23}$$

where ϕ and λ are called wave function and spectral parameter of the hierarchy, respectively. On the other hand, we can also introduce adjoint wave function ψ which satisfies the linear system

$$L^*\psi=\eta\psi, \quad \partial_{t_n}\psi=-((P_n)^*\psi)_0. \tag{2.24}$$

For convenience, throughout this paper, ϕ and ψ will stand for wave function and adjoint wave function, respectively. Of course, it should be realized that both ϕ and ψ are superfields in this formalism. In next section, we will use these (adjoint) wave functions to construct the DBTs for the MR sKdV hierarchy.

III. THE ELEMENTARY DB TRANSFORMATIONS

We consider the following transformation:

$$L\to\hat{L}=TLT^{-1}, \tag{3.1}$$

where $T=T(\theta,x,t_3,t_5,\ldots)$ is any reasonable SΨDO. To guarantee that such transformations can generate new solutions of the MR sKdV hierarchy, the transformed Lax operator $\hat{L}$ should preserve the form of (2.18) and satisfy the Lax equation (2.17). It is easy to show that under the transformation (3.1), the operator P_n then is transformed as

$$P_n\to\hat{P}_n=TP_nT^{-1}+\partial_{t_n}TT^{-1}, \tag{3.2}$$

which preserves the zero curvature condition (2.20). Note that although P_n is a SDO, the right-hand side of (3.2) will, in general, not be a purely SDO. However, if we suitably choose the gauge operator T such that $\hat{P}_n$, as defined by (3.2), is also a purely SDO, then $\{\hat{L},\hat{P}_n\}$ represents a valid new solution to the MR sKdV hierarchy. To formulate the DBTs of the MR sKdV hierarchy, let us introduce a superfield Ω called bilinear potential[6] (or squared eigenfunction potential) which is constructed from a wave function and an adjoint wave function and will be useful later on.

Lemma 2: For any pair of ϕ and ψ, there exists a bilinear potential $\Omega(\psi,\phi)$ satisfying

$$(D\Omega(\psi,\phi))=\psi\phi, \tag{3.3}$$

$$\partial_{t_n}\Omega(\psi,\phi)=\operatorname{sres}\,(D^{-1}\psi P_n\phi D^{-1}). \tag{3.4}$$

Proof: To prove the existence of the bilinear potential Ω, we have to show that Eqs. (3.3) and (3.4) are compatible. First, we note that (3.3) is consistent with (3.4) for $n=1$. Since

$$\Omega_x=\operatorname{sres}\,(D^{-1}\psi P_1\phi D^{-1})=\operatorname{sres}\,(D^{-1}\psi D^2\phi D^{-1})=(D\psi)\phi+(-1)^{|\psi|}\psi(D\phi)=(D(D\Omega)), \tag{3.5}$$

this implies that

$$(D\Omega)_x=(D(D(D\Omega)))=(D\Omega_x). \tag{3.6}$$

In general, from (3.3) and (3.4) we have

$$\begin{aligned}(D\partial_{t_n}\Omega)&=(D\,\operatorname{sres}\,(D^{-1}\psi P_n\phi D^{-1}))\\&=\operatorname{sres}\,(\psi P_n\phi D^{-1}-(-1)^{|\psi||\phi|}D^{-1}\psi P_n\phi)\\&=\psi(P_n\phi)-(-1)^{|\psi||\phi|}\phi(P_n^*\psi)\\&=\psi\phi_{t_n}+\psi_{t_n}\phi\\&=\partial_{t_n}(D\Omega).\end{aligned} \tag{3.7}$$

Second, from (3.4) and (2.14), we have

$$\begin{aligned}\partial_{t_m}(\partial_{t_n}\Omega)-\partial_{t_n}(\partial_{t_m}\Omega)&=\operatorname{sres}\,\partial_{t_m}(D^{-1}\psi P_n\phi D^{-1})-\operatorname{sres}\,\partial_{t_n}(D^{-1}\psi P_m\phi D^{-1})\\&=\operatorname{sres}\,(D^{-1}\psi(\partial_{t_m}P_n-\partial_{t_n}P_m)\phi D^{-1})\end{aligned}$$

$$
\begin{aligned}
&-\operatorname{sres}\,(D^{-1}\psi(P_m^*\psi)P_n\phi D^{-1})+\operatorname{sres}\,(D^{-1}\psi P_n(P_m\phi)D^{-1})\\
&+\operatorname{sres}\,(D^{-1}\psi(P_n^*\psi)P_m\phi D^{-1})-\operatorname{sres}\,(D^{-1}\psi P_m(P_n\phi)D^{-1})\\
&=\operatorname{sres}\,(D^{-1}\psi(\partial_{t_m}P_n-\partial_{t_n}P_m+[P_n,\,P_m])\phi D^{-1})=0. \qquad (3.8)
\end{aligned}
$$

Here the zero-curvature condition of the MR sKdV hierarchy has been used in the last line. □

Remarks: $\Omega(\psi,\phi)$ is a superfield with parity $(-1)^{|\psi||\phi|+1}$ and can be represented by $\Omega(\psi,\phi)=\int^x \psi_2\phi_1+(-1)^{|\psi|}\int^x \psi_1\phi_2+\theta\psi_1\phi_1$, where $\phi=\phi_1+\theta\phi_2$ and $\psi=\psi_1+\theta\psi_2$.

Proposition 1:[2] Let χ be an even wave function of the linear system. Then the gauge operator

$$T=\chi D\chi^{-1}=D+\alpha,\quad \alpha\equiv-\frac{(D\chi)}{\chi}, \qquad (3.9)$$

triggers the following DBT:

$$\hat{L}=TLT^{-1}=\partial^2+\hat{v}_1D+\hat{v}_0, \qquad (3.10)$$

$$\hat{\phi}=(T\phi)=\chi(D\chi^{-1}\phi), \qquad (3.11)$$

$$\hat{\psi}=((T^{-1})^*\psi)=\chi^{-1}\Omega(\psi,\chi), \qquad (3.12)$$

where the transformed coefficients are given by

$$\hat{v}_1=-v_1-2\alpha_x, \qquad (3.13)$$

$$\hat{v}_0=v_0+(Dv_1)+2\alpha(v_1+\alpha_x). \qquad (3.14)$$

Proof: We first show that $\hat{L}$ has the same form as L. From (3.10) we have

$$\hat{L}_-=(\chi D\chi^{-1}L\chi D^{-1}\chi^{-1})_-=\chi(D\chi^{-1}(L\chi))D^{-1}\chi^{-1}=0, \qquad (3.15)$$

which implies that $\hat{L}$ is a SDO. A simple calculation shows that the transformed coefficients $\hat{v}_1$ and $\hat{v}_0$ are given by (3.13) and (3.14), respectively. Furthermore, the hierarchy equation for $\hat{L}$ is given by

$$\partial_{t_n}\hat{L}=[TP_nT^{-1}+\partial_{t_n}TT^{-1},\,\hat{L}]. \qquad (3.16)$$

Using the identity

$$\chi D\chi^{-1}\Lambda_+\chi D^{-1}\chi^{-1}=(\chi D\chi^{-1}\Lambda\chi D^{-1}\chi^{-1})_+ +\chi(D\chi^{-1}(\Lambda_+\chi)_0)D^{-1}\chi^{-1} \qquad (3.17)$$

and then substituting $\Lambda=L^{n/2}$ (n odd), we obtain

$$\hat{P}_n=TP_nT^{-1}+\partial_{t_n}TT^{-1}=(TL^{n/2}T^{-1})_+ +\chi(D\chi^{-1}\partial_{t_n}\chi)D^{-1}\chi^{-1}+\partial_{t_n}TT^{-1}=\hat{L}_+^{n/2}. \qquad (3.18)$$

Hence

$$\partial_{t_n}\hat{L}=[\hat{L}_+^{n/2},\,\hat{L}]. \qquad (3.19)$$

The evolution equations for $\hat{\phi}$ and $\hat{\psi}$ can be verified in a similar way. From (3.11), we have

$$\partial_{t_n}\hat{\phi}=\partial_{t_n}T\phi+T\partial_{t_n}\phi=\partial_{t_n}TT^{-1}\hat{\phi}+TP_nT^{-1}\hat{\phi}=(\hat{P}_n\hat{\phi})_0. \qquad (3.20)$$

Similarly,

$$\partial_{t_n}\hat{\psi}=\partial_{t_n}(T^{-1})^*\psi+(T^{-1})^*\partial_{t_n}\psi=((T^{-1})^*(\partial_{t_n}T)^*+(T^{-1})^*P_n^*T^*)\hat{\psi}=-(\hat{P}_n^*\hat{\psi})_0. \qquad (3.21)$$

□

Having described the first construction of the DBT, we now turn to another construction using the adjoint wave function.

Proposition 2: Let μ be an even adjoint wave function of the linear system (2.24). Then the gauge operator

$$S=\mu^{-1}D^{-1}\mu=(D-\beta)^{-1},\quad \beta\equiv-\frac{(D\mu)}{\mu}, \tag{3.22}$$

triggers the following adjoint DB transformation:

$$\hat{L}=SLS^{-1}=\partial^2+\hat{v}_1D+\hat{v}_0, \tag{3.23}$$

$$\hat{\phi}=(S\phi)=\mu^{-1}\Omega(\mu,\phi), \tag{3.24}$$

$$\hat{\psi}=((S^{-1})^*\psi)=-\mu(D\mu^{-1}\psi), \tag{3.25}$$

where

$$\hat{v}_1=-v_1+2\beta_x, \tag{3.26}$$

$$\hat{v}_0=v_0+(Dv_1)-2(D\beta)_x-2\beta(v_1-\beta_x). \tag{3.27}$$

Proof: The proof is similar to the Proposition 1. Here we only mention that Eq. (3.19) can be verified easily by using the identity

$$(\mu^{-1}D^{-1}\mu\Lambda\mu^{-1}D\mu)_-=\mu^{-1}D^{-1}\mu\Lambda_-\mu^{-1}D\mu-(-1)^{|\Lambda|}\mu^{-1}D^{-1}(D\mu^{-1}(\Lambda_+^*\mu)_0)\mu \tag{3.28}$$

instead of (3.17). □

Proposition 3: For any pair of even wave function χ and odd adjoint wave function μ, the gauge operator

$$R=1-\chi\Omega(\mu,\chi)^{-1}D^{-1}\mu \tag{3.29}$$

triggers the following binary DB transformation:

$$\hat{L}=RLR^{-1}=\partial^2+\hat{v}_1D+\hat{v}_0, \tag{3.30}$$

$$\hat{\phi}=(R\phi)=\phi-\chi\Omega(\mu,\chi)^{-1}\Omega(\mu,\phi), \tag{3.31}$$

$$\hat{\psi}=((R^{-1})^*\psi)=\psi-\mu\Omega(\mu,\chi)^{-1}\Omega(\psi,\chi), \tag{3.32}$$

where

$$\hat{v}_1=v_1-2\Gamma_x,\quad \Gamma\equiv\frac{(D\Omega)}{\Omega}, \tag{3.33}$$

$$\hat{v}_0=v_0+2(D\Gamma)_x+2v_1\Gamma-2\Gamma\alpha_x+2\alpha\Gamma_x+2\Gamma\Gamma_x. \tag{3.34}$$

Proof: The gauge operator R is just a composition of the DB transformation T and the adjoint DB transformation S. To see this, let us first perform a DB transformation triggered by the wave function χ. The odd adjoint wave function μ is thus transformed to $\hat{\mu}=\chi^{-1}\Omega(\mu,\chi)$ which is an even one. Then a subsequent adjoint DB transformation S triggered by $\hat{\mu}$ is performed and the composition of these two transformations is given by $R=\hat{\mu}^{-1}D^{-1}\hat{\mu}\chi D\chi^{-1}$ $=\chi\Omega^{-1}D^{-1}\Omega D\chi^{-1}=1-\chi\Omega^{-1}D^{-1}\mu$. Therefore, the remaining part of the proof is just a corollary of the Propositions 1 and 2. □

Remarks: The binary DB transformation can also be constructed from a pair of χ and μ with $|\chi|=1$ and $|\mu|=0$. A direct calculation shows that $R=\hat{\chi}D\hat{\chi}^{-1}\mu^{-1}D^{-1}\mu=1-\chi\Omega^{-1}D^{-1}\mu$, which has the same form as (3.29). We also note that the transformed coefficients (3.33) and (3.34) are just the ones in Ref. 2 where a different approach was presented.

IV. ITERATION OF THE DB TRANSFORMATIONS

We have introduced the elementary DBTs which contain the DBT, the adjoint DBT, and the binary DBT triggered by the gauge operators *T*, *S*, and *R*, respectively. Using these elementary transformations as the building blocks, the more complicated transformations can be constructed from the compositions of these gauge operators. In Ref. 4, by iterating the DB transformation *T*, the so-called Crum transformation for the MR sKdV equation was constructed and the Wronskian superdeterminant representations for the solutions were obtained. This construction starts with *n* wave functions χ_i, $i=0,...,n-1$ of the linear system (2.23) with parity $(-1)^i$. Using χ_0, say, to perform the first DBT of Proposition 1, then χ_i are transformed to $\hat{\chi}_i$. It is obvious that $\hat{\chi}_0=0$. The next step is to perform a subsequent DBT triggered by $\hat{\chi}_1$, say, which leads to the new wave functions $\hat{\hat{\chi}}_i$ with $\hat{\hat{\chi}}_1=0$. Iterating this process such that all the wave functions are used up, then an *n*-step DBT with gauge operator T_n is obtained.

Proposition 4:[4] Let χ_i, $i=0,...,n-1$ be wave functions of the linear system (2.23) with parity $(-1)^i$. Then after *n* iterations of the DBT of Proposition 1, the transformed Lax operator becomes

$$\hat{L}=T_nLT_n^{-1},\quad T_n=D^n+\sum_{i=0}^{n-1}a_iD^i, \tag{4.1}$$

$$=\partial^2+\hat{v}_1D+\hat{v}_0, \tag{4.2}$$

where the coefficients a_i are defined by

$$T_n\chi_j=0,\quad j=0,...,n-1, \tag{4.3}$$

and

$$\hat{v}_1=(-1)^nv_1-2(a_{n-1})_x, \tag{4.4}$$

$$\hat{v}_0=v_0-2(a_{n-2})_x-a_{n-1}((-1)^nv_1+\hat{v}_1)+\frac{1-(-1)^n}{2}(Dv_1). \tag{4.5}$$

Remarks: Due to the fact that the parity of the gauge operator T_n depends on *n*, the cases for *n* being even or odd are rather different. In Ref. 4, the coefficients a_i for both cases have been obtained separately by solving the linear equation (4.3) and the transformed fields $\hat{v}_1$ and $\hat{v}_0$ can be expressed in a compact form in terms of the superdeterminant. We will present such a calculation in a more general case involving the binary DBTs.

Now let us turn to a similar construction using the adjoint wave functions.

Proposition 5: Let μ_i, $i=0,...,n-1$ be adjoint wave functions of the linear system (2.24) with parity $(-1)^i$. Then after *n* iterations of the adjoint DBT of Proposition 2, the transformed Lax operator becomes

$$\hat{L}=S_nLS_n^{-1},\quad (S_n^{-1})^*=(-1)^{[n/2]}\left(D^n+\sum_{i=0}^{n-1}b_iD^i\right) \tag{4.6}$$

$$=\partial^2+\hat{v}_1D+\hat{v}_0, \tag{4.7}$$

where the coefficients b_i are defined by

$$(S_n^{-1})^*\mu_j=0,\quad j=0,...,n-1, \tag{4.8}$$

and

$$\hat{v}_1=(-1)^n v_1+2(b_{n-1})_x, \tag{4.9}$$

$$\hat{v}_0=v_0-2(b_{n-2})_x+b_{n-1}((-1)^n v_1+\hat{v}_1)+\frac{1+(-1)^n}{2}(Dv_1)-(D\hat{v}_1). \tag{4.10}$$

Proof: Essentially, the proof is exactly the same as Proposition 4. □

Proposition 6: Let $\chi_0,\ldots,\chi_{n-1}$ be even wave functions of the linear system (2.23) and $\mu_0,\ldots,\mu_{n-1}$ be odd adjoint wave functions of the linear system (2.24). Then after n iterations of the binary DBT of Proposition 3, the transformed Lax operator becomes

$$\hat{L}=R_n L R_n^{-1}, \quad R_n=1-\sum_{i=0}^{n-1} c_i D^{-1}\mu_i, \tag{4.11}$$

$$=\partial^2+\hat{v}_1 D+\hat{v}_0, \tag{4.12}$$

where the coefficient c_i are defined by

$$R_n\chi_j=0, \quad j=0,\ldots,n-1, \tag{4.13}$$

and

$$\hat{v}_1=v_1-2\sum_{i=0}^{n-1}(c_i\mu_i)_x, \tag{4.14}$$

$$\hat{v}_0=v_0+(v_1+\hat{v}_1)\sum_{i=0}^{n-1} c_i\mu_i+2\sum_{i=0}^{n-1}(c_i(D\mu_i))_x. \tag{4.15}$$

Proof: A straightforward calculation. We only remark that the form of the gauge operator R_n can be verified by induction. □

Proposition 7: The transformed coefficients, $\hat{v}_1$ and $\hat{v}_0$, in Eqs. (4.14) and (4.15) can be expressed as

$$\hat{v}_1=v_1-2(D^3 \ln\det\Omega), \tag{4.16}$$

$$\hat{v}_0=v_0+(v_1+\hat{v}_1)(D\ln\det\Omega)+2\sum_{i=0}^{n-1}\left(D^2\left(\frac{\det\Omega^{(i)}}{\det\Omega}(D\mu_i)\right)\right), \tag{4.17}$$

where $\Omega_{ij}\equiv\Omega(\mu_i,\chi_j)$ and $\Omega^{(i)}$ is constructed from Ω with its ith row replaced by $(\chi_0,\ldots,\chi_{n-1})$.

Proof: The proof follows easily from the Cramer's formula. □

Remarks: The expressions of the transformed fields $\hat{v}_1$ and $\hat{v}_0$ show that they are unchanged under the interchange of any two wave functions χ_i and χ_j with $i\neq j$. Hence the permutability of DBTs is still maintained in this supersymmetric formalism. We also note that the case for $|\chi_i|=1$ and $|\mu_i|=0$ gives the same result.

Finally let us discuss a more general DBT in which the numbers of wave functions and adjoint wave functions are unequal.

Proposition 8: Suppose there are n adjoint wave functions $\mu_0,\ldots,\mu_{n-1}$ and $n+m$ wave functions $\chi_0,\ldots,\chi_{n+m-1}$ of the MR sKdV system. Assume the parities of μ_i are all odd, whereas among χ_i, $\chi_0,\ldots,\chi_{n+[m+1/2]-1}$ are even and $\chi_{n+[m+1/2]},\ldots,\chi_{n+m-1}$ are odd. Then after performing the DB transformations triggered by these (adjoint) wave functions, the transformed Lax operator reads

$$\hat{L}=Q_{(n,m)}LQ_{(n,m)}^{-1}, \quad Q_{(n,m)}=D^m+\sum_{i=0}^{m-1} d_i D^i+\sum_{i=0}^{n-1} e_i D^{-1}\mu_i, \tag{4.18}$$

$$=\partial^2+\hat{v}_1 D+\hat{v}_0, \tag{4.19}$$

where the coefficients d_i and e_i are defined by

$$Q_{(n,m)}\chi_i=0, \quad i=0,...,n+m-1, \tag{4.20}$$

and

$$\hat{v}_1=(-1)^m v_1-2(d_{m-1})_x, \tag{4.21}$$

$$\hat{v}_0=v_0-2(d_{m-2})_x-d_{m-1}((-1)^m v_1+\hat{v}_1)+\frac{1-(-1)^m}{2}(Dv_1). \tag{4.22}$$

Proof: The gauge operator $Q_{(n,m)}$ can be realized easily as follows: since the number of wave functions is larger than that of the adjoint wave functions, thus part of the even wave functions, say, $\chi_0,\ldots,\chi_{n-1}$, would be paired with odd adjoint wave functions $\mu_0,\ldots,\mu_{n-1}$ to form the binary DB transformation R_n of Proposition 7 and the residual wave functions $\chi_n,\ldots,\chi_{n+m-1}$ will form the DB transformation T_m of Proposition 4. Hence $Q_{(n,m)}=T_m R_n$ and its expression in (4.18) can be verified by induction. □

Notice that the parity of the gauge operator $Q_{(n,m)}$ depends on m, therefore the case for m being even or odd should be discussed separately.

For $m=2k$, it is convenient to define the following row vectors:

$$\boldsymbol{\chi}^{[0]}=(\chi_0,\chi_1,\ldots,\chi_{n+k-1}), \quad \boldsymbol{\chi}^{[1]}=(\chi_{n+k},\ldots,\chi_{n+2k-1}), \tag{4.23}$$

$$\mathbf{p}^{[0]}=(e_0,e_1,\ldots,e_{n-1},d_0,d_2,\ldots,d_{2k-2}), \quad \mathbf{p}^{[1]}=(d_1,d_3,\ldots,d_{2k-1}), \tag{4.24}$$

$$\mathbf{q}^{[i]}=\partial_x^k\boldsymbol{\chi}^{[i]}, \quad i=0,1, \tag{4.25}$$

and matrices

$$\Omega_{ij}^{[0]}=\Omega(\mu_i,\chi_j), \quad i=0,...,n-1; j=0,...,n+k-1, \tag{4.26}$$

$$\Omega_{ij}^{[1]}=\Omega(\mu_i,\chi_{n+k+j}), \quad i=0,...,n-1; j=0,...,k-1, \tag{4.27}$$

$$\Xi^{[i]}=\begin{pmatrix} \boldsymbol{\chi}^{[i]} \\ \partial_x\boldsymbol{\chi}^{[i]} \\ \vdots \\ \partial_x^{k-1}\boldsymbol{\chi}^{[i]} \end{pmatrix}, \quad i=0,1, \tag{4.28}$$

where the superscript in brackets stands for the parity of the corresponding vector or matrix.

Proposition 9: After solving the linear equation (4.20) for $m=2k$, the transformed coefficients, $\hat{v}_1$ and $\hat{v}_0$ in Eqs. (4.21) and (4.22) can be expressed as

$$\hat{v}_1=v_1+2\left(\frac{\det(\hat{D}-\hat{C}A^{-1}B)}{\det(D-CA^{-1}B)}\right)_x, \tag{4.29}$$

$$\hat{v}_0=v_0+2\left(\frac{\operatorname{sdet}\hat{\mathbf{M}}}{\operatorname{sdet}\mathbf{M}}\right)_x-(v_1+\hat{v}_1)\left(\frac{\det(\hat{D}-\hat{C}A^{-1}B)}{\det(D-CA^{-1}B)}\right), \tag{4.30}$$

where the supermatrix

$$\mathbf{M}=\begin{pmatrix} A & B \\ C & D \end{pmatrix}$$

with

$$A=\begin{pmatrix} \Omega^{[0]} \\ \Xi^{[0]} \end{pmatrix}, \quad B=\begin{pmatrix} \Omega^{[1]} \\ \Xi^{[1]} \end{pmatrix}, \tag{4.31}$$

$$C=(D\Xi^{[0]}),\quad D=(D\Xi^{[1]}),$$

and its superdeterminant is defined by[15]

$$\text{sdet }\mathbf{M}=\frac{\det(A-BD^{-1}C)}{\det D}=\frac{\det A}{\det(D-CA^{-1}B)}. \tag{4.32}$$

The matrix $\hat{\mathbf{M}}$ is constructed from $\mathbf{M}$ with its $(n+k)$th row replaced by its ∂_x derivation, whereas $\hat{D}$ and $\hat{C}$ are constructed from D and C with their last rows replaced by their D derivation.

Proof: For $m=2k$, the transformed coefficients $\hat{v}_1$ and $\hat{v}_0$ are expressed as

$$\hat{v}_1=v_1-2(d_{2k-1})_x, \tag{4.33}$$

$$\hat{v}_0=v_0-2(d_{2k-2})_x+(v_1+\hat{v}_1)d_{2k-1}. \tag{4.34}$$

Since the parity of the operator $Q_{(n,2k)}$ is even, we can rewrite the linear equation (4.20) as follows:

$$(\mathbf{p}^{[0]},\mathbf{p}^{[1]})\mathbf{M}=-(\mathbf{q}^{[0]},\mathbf{q}^{[1]}). \tag{4.35}$$

Now multiplying $\mathbf{M}^{-1}$ to the right of (4.35), we have

$$(\mathbf{p}^{[0]},\mathbf{p}^{[1]})=-(\mathbf{q}^{[0]},\mathbf{q}^{[1]})\begin{pmatrix}(A-BD^{-1}C)^{-1} & -AB^{-1}(D-CA^{-1}B)\\ -D^{-1}C(A-BD^{-1}C)^{-1} & (D-CA^{-1}B)^{-1}\end{pmatrix}, \tag{4.36}$$

which implies

$$\mathbf{p}^{[0]}(A-BD^{-1}C)=-(\mathbf{q}^{[0]}-\mathbf{q}^{[1]}D^{-1}C), \tag{4.37}$$

$$\mathbf{p}^{[1]}(D-CA^{-1}B)=-(\mathbf{q}^{[1]}-\mathbf{q}^{[0]}A^{-1}B). \tag{4.38}$$

Using Cramer's rule, we obtain

$$d_{2k-2}=\mathbf{P}^{[0]}_{n+k}=-\frac{\text{sdet }\hat{\mathbf{M}}}{\text{sdet }\mathbf{M}}, \tag{4.39}$$

$$d_{2k-1}=\mathbf{P}^{[1]}_{k}=-\frac{\det(\hat{D}-\hat{C}A^{-1}B)}{\det(D-CA^{-1}B)}, \tag{4.40}$$

which lead to the results (4.29) and (4.30). □

For $m=2k+1$, some notations in Eqs. (4.23)–(4.28) should be modified to

$$\boldsymbol{\chi}^{[0]}=(\chi_0,\chi_1,\ldots,\chi_{n+k}),\quad \boldsymbol{\chi}^{[1]}=(\chi_{n+k+1},\ldots,\chi_{n+2k}), \tag{4.41}$$

$$\mathbf{p}^{[0]}=(d_1,d_3,\ldots,d_{2k-1}),\quad \mathbf{p}^{[1]}=(e_0,e_1,\ldots,e_{n-1},d_0,d_2,\ldots,d_{2k}), \tag{4.42}$$

$$\mathbf{q}^{[i]}=(D^{2k+1}\boldsymbol{\chi}^{[i]}),\quad i=0,1, \tag{4.43}$$

$$\Omega^{[0]}_{ij}=\Omega(\mu_i,\chi_j),\quad i=0,\ldots,n-1,\quad j=0,\ldots,n+k, \tag{4.44}$$

$$\Omega^{[1]}_{ij}=\Omega(\mu_i,\chi_{n+k+j+1}),\quad i=0,\ldots,n-1,\quad j=0,\ldots,k-1, \tag{4.45}$$

$$\Xi^{[i]}=\begin{pmatrix}\boldsymbol{\chi}^{[0]}\\ \partial_x\boldsymbol{\chi}^{[0]}\\ \vdots\\ \partial_x^k\boldsymbol{\chi}^{[0]}\end{pmatrix},\qquad i=0,1. \tag{4.46}$$

Then we can define another supermatrix

$$\mathbf{N}=\begin{pmatrix} \breve{A} & \breve{B} \\ \breve{C} & D \end{pmatrix}$$

where the matrices $\breve{A}$ and $\breve{B}$ are constructed from the matrices A and B by taking into account the replacements (4.41)–(4.46), whereas $\breve{C}$ does the same thing in addition to removing the last row.

Proposition 10: Solving the linear equation (4.20) for $m=2k+1$, the transformed coefficients, $\hat{v}_1$ and $\hat{v}_0$, in Eqs. (4.21) and (4.22) can be expressed as

$$\hat{v}_1=-v_1+2\left(\frac{\det(\tilde{A}-\tilde{B}D^{-1}\breve{C})}{\det(\breve{A}-\breve{B}D^{-1}\breve{C})}\right)_x, \tag{4.47}$$

$$\hat{v}_0=v_0+(Dv_1)+2\left(\frac{\operatorname{sdet}\mathbf{N}}{\operatorname{sdet}\tilde{\mathbf{N}}}\right)_x+(v_1-\hat{v}_1)\left(\frac{\det(\tilde{A}-\tilde{B}D^{-1}\breve{C})}{\det(\breve{A}-\breve{B}D^{-1}\breve{C})}\right), \tag{4.48}$$

where $\tilde{\mathbf{N}}$ is constructed from $\mathbf{N}$ with its last row replaced by its ∂_x derivation, whereas $\tilde{A}$ and $\tilde{B}$ are constructed from $\breve{A}$ and $\breve{B}$ with their last rows replaced by their D derivation.

Proof: For $m=2k+1$, the linear equation (4.20) now becomes

$$(\mathbf{p}^{[1]},\mathbf{p}^{[0]})\mathbf{N}=-(\mathbf{q}^{[1]},\mathbf{q}^{[0]}). \tag{4.49}$$

Following the procedures for the case of $m=2k$, it is easy to show that

$$d_{2k}=\mathbf{p}^{[1]}_{n+k+1}=\frac{\det(\tilde{A}-\tilde{B}D^{-1}\breve{C})}{\det(\breve{A}-\breve{B}D^{-1}\breve{C})}, \tag{4.50}$$

$$d_{2k-1}=\mathbf{p}^{[0]}_{k}=-\frac{\operatorname{sdet}\mathbf{N}}{\operatorname{sdet}\tilde{\mathbf{N}}}, \tag{4.51}$$

which imply that the transformed coefficients $\hat{v}_1$ and $\hat{v}_0$ are given by (4.47) and (4.48), respectively. □

Remarks: (1) In both cases ($m=2k$ or $2k+1$), the expressions for $\hat{v}_1$ and $\hat{v}_0$ are, indeed, independent of the order of the even wave functions as well as the odd ones. (2) For the case that the number of the adjoint wave functions is larger than that of the wave functions in a DBT, we can get a similar result just by exchanging the roles played by them. (3) When we set $n=0$, the binary type expressions for $\hat{v}_1$ and $\hat{v}_0$ then reduce to the Wronskian-type ones obtained in Ref. 4. Especially in the $m=2k$ case, it is possible to write d_{2k-1} in terms of superdeterminant.

V. CONCLUDING REMARKS

We have studied the solutions of the MR sKdV hierarchy by using DBTs. In addition to the previously known DBT,[2,4] we provide the adjoint DBT which can be combined with the former one to form the binary DBT. Using these elementary DBTs, we obtain not only Wronskian-type but also binary-type solutions for the MR sKdV hierarchy. The super soliton solutions then can be constructed from the trivial one which corresponds to $v_1=v_0=0$ by using the formulas derived in Sec. IV. Finally, we would like to remark that our approach involves only the algebra of SΨDOs, hence the formulation is general enough to extend to the other cases such as super KP hierarchies and their reductions. We will leave these discussions to another publication.

Note added in proof: After submission of this manuscript for publication we were informed by Q. P. Liu that Propositions 6 and 7 were also obtained in Ref. 16 by using the vectorial Darboux transformation.

Integrable semi-discretization of the coupled modified KdV equations

Takayuki Tsuchida,[a] Hideaki Ujino, and Miki Wadati
Department of Physics, Graduate School of Science, University of Tokyo, Hongo 7-3-1, Bunkyo-ku,

(Received 3 February 1998; accepted for publication 13 May 1998)

The discrete version of the inverse scattering method proposed by Ablowitz and Ladik is extended to solve multi-component systems. The extension enables one to solve the initial value problem, which proves directly the complete integrability of a semi-discrete version of the coupled modified Korteweg–de Vries (KdV) equations and their hierarchy. It also provides a procedure to obtain conservation laws and multi-soliton solutions of the hierarchy. © *1998 American Institute of Physics.* [S0022-2488(98)01909-4]

I. INTRODUCTION

In the theory of solitons, the inverse scattering method (ISM) is known to be one of the most useful tools to analyze various integrable models.[1] The ISM has been widely applied to models with continuous coordinates such as the KdV equation,[2] the modified KdV (mKdV) equation,[3–5] and the nonlinear Schrödinger (NLS) equation.[6] The class of Lax pairs to perform the ISM has been extended from the 2×2 AKNS formulation[7] to 3×3 (Refs. 8–10) and, more generally, $N\times N$ matrix formulations[11,12] so as to solve multi-component integrable models including the three-wave interaction equations[8] and the coupled NLS equations (Manakov system).[9] Recently the authors[13] proposed a new extension of the ISM to solve the coupled modified KdV (cmKdV) equations,

$$\frac{\partial u_i}{\partial t}+6\left(\sum_{j,k=0}^{M-1} C_{jk}u_j u_k\right)\frac{\partial u_i}{\partial x}+\frac{\partial^3 u_i}{\partial x^3}=0, \quad i=0,1,...,M-1, \tag{1.1}$$

which was shown to have an infinite number of local conservation laws by Svinolupov.[14] Iwao and Hirota obtained soliton solutions by the direct method (Hirota's method).[15]

On the other hand, Flaschka,[16] Manakov,[17] and Ablowitz and Ladik[18,19] showed that the discrete version of the ISM formulation is also applicable to discrete integrable models such as the Toda lattice, the Volterra model, the discrete mKdV equation, and the discrete NLS equation. However, the class of discrete models which are integrable by the ISM is not large enough compared with that of continuous models.

In the present paper, we propose a matrix generalization of the Ablowitz–Ladik hierarchy and we solve the semi-discrete coupled modified KdV (sd-cmKdV) equations, or the coupled modified Volterra equations,[20]

$$\frac{\partial u_n^{(i)}}{\partial t}=\left(1+\sum_{j,k=0}^{M-1} C_{jk}u_n^{(j)}u_n^{(k)}\right)(u_{n+1}^{(i)}-u_{n-1}^{(i)}), \quad i=0,1,...,M-1, \tag{1.2}$$

and the higher flows in the hierarchy. This model reduces to the cmKdV equations (1.1) in the continuum limit by some variable transformations. Hisakado[20] revealed the connection between the sd-cmKdV equations and the 2-D Toda lattice. Ohta[21] obtained an N-soliton solution for the model which is equivalent to the sd-cmKdV equations by the Hirota's method. Hirota[22] studied a similar model,

[a]Electronic mail: tsuchida@monet.phys.s.u-tokyo.ac.jp

 © 1998 American Institute of Physics

$$\frac{\partial u_n^{(i)}}{\partial t}=\sum_{j,k=0}^{M-1} C_{jk}u_n^{(j)}u_n^{(k)}\cdot(u_{n+1}^{(i)}-u_{n-1}^{(i)}),\quad i=0,1,...,M-1, \tag{1.3}$$

in the open-end case and obtained the so-called molecule solutions. However, for the first time, in the present paper the initial value problem of the sd-cmKdV equations is solved and the most general soliton solutions are given.

The paper is organized as follows. In Sec. II, we introduce a Lax formulation for the sd-cmKdV equations and prove that the model has an infinite number of conservation laws. In Sec. III, we perform the ISM for the sd-cmKdV equations. As a result, the initial value problem is solved and the *N*-soliton solution is obtained. The last section, Sec. IV, is devoted to the summary and discussions.

II. GENERAL FORMULATION

In this section, we propose a Lax formulation for the sd-cmKdV equations, which is a new extension of the formulation by Ablowitz and Ladik.[1,18,19] The Lax formulation gives us an infinite number of conservation laws.

A. Normalization

We introduce an M-component vector $\mathbf{u}_n(t)$ and a constant $M\times M$ matrix G,

$$\mathbf{u}_n=(u_n^{(0)},u_n^{(1)},\ldots,u_n^{(M-1)})^T,\quad G=(-C_{ij}),$$

where the superscript T means the transposition. In this notation, the sd-cmKdV equations (1.2) are rewritten as

$$\mathbf{u}_{n,t}=(1-\mathbf{u}_n^TG\mathbf{u}_n)(\mathbf{u}_{n+1}-\mathbf{u}_{n-1}). \tag{2.1}$$

In the following, we assume that G is a real symmetric regular matrix and thus may set

$$G=P^T\Lambda P,$$

$$\Lambda=\mathrm{diag}(\lambda_0,\ldots,\lambda_{M-1}),\quad \lambda_j\neq 0\quad \text{for all } j.$$

Here P is a real orthogonal matrix,

$$P^TP=PP^T=I.$$

In terms of a new set of dependent variables $\mathbf{v}_n=(v_n^{(0)},v_n^{(1)},\ldots,v_n^{(M-1)})^T$ defined by

$$\mathbf{v}_n\equiv P\mathbf{u}_n,$$

Eq. (2.1) is cast into

$$\mathbf{v}_{n,t}=(1-\mathbf{v}_n^T\Lambda\mathbf{v}_n)(\mathbf{v}_{n+1}-\mathbf{v}_{n-1}), \tag{2.2}$$

or more explicitly

$$\frac{\partial v_n^{(i)}}{\partial t}=\left(1-\sum_{j=0}^{M-1}\lambda_jv_n^{(j)2}\right)(v_{n+1}^{(i)}-v_{n-1}^{(i)}),\quad \lambda_j\neq 0,\quad i=0,1,...,M-1. \tag{2.3}$$

Changing a scale of v_i by $\sqrt{|\lambda_i|}\cdot v_n^{(i)}\to v_n^{(i)}$, we obtain normalized sd-cmKdV equations,

$$\frac{\partial v_n^{(i)}}{\partial t}=\left(1-\sum_{j=0}^{M-1}\varepsilon_jv_n^{(j)2}\right)(v_{n+1}^{(i)}-v_{n-1}^{(i)}),\quad \varepsilon_j=\mathrm{sgn}(\lambda_j)=\pm 1,\quad i=0,1,...,M-1. \tag{2.4}$$

The above expression of the sd-cmKdV equations is more convenient than Eq. (1.2) to perform the ISM. Thus, we mainly deal with Eq. (2.4) as the sd-cmKdV equations in what follows. Further, the dependent variables $\{v_n^{(i)}\}$ are assumed to be real.

B. Lax pair

We introduce a set of auxiliary linear equations

$$\Psi_{n+1}=L_n\Psi_n, \quad \Psi_{n,t}=M_n\Psi_n. \tag{2.5}$$

Here Ψ_n is a $(p+q)$-component vector and L_n, M_n are $(p+q)\times(p+q)$ matrices. The compatibility condition of Eq. (2.5) is given by

$$L_{n,t}+L_nM_n-M_{n+1}L_n=O. \tag{2.6}$$

We call L_n, M_n the Lax pair and Eq. (2.6) (a semi-discrete version of) the zero-curvature condition or, simply, the Lax equation. We employ the following form of the Lax pair,

$$L_n=z\begin{bmatrix} I_1 & O \\ O & O \end{bmatrix}+\begin{bmatrix} O & Q_n \\ R_n & O \end{bmatrix}+\frac{1}{z}\begin{bmatrix} O & O \\ O & I_2 \end{bmatrix}=\begin{bmatrix} zI_1 & Q_n \\ R_n & \dfrac{1}{z}I_2 \end{bmatrix}, \tag{2.7}$$

$$\begin{aligned} M_n&=z^2\begin{bmatrix} aI_1 & O \\ O & O \end{bmatrix}+z\begin{bmatrix} O & aQ_n \\ aR_{n-1} & O \end{bmatrix}+\begin{bmatrix} -aQ_nR_{n-1}+c_1I_1 & O \\ O & bR_nQ_{n-1}+c_2I_2 \end{bmatrix} \\ &\quad+\frac{1}{z}\begin{bmatrix} O & -bQ_{n-1} \\ -bR_n & O \end{bmatrix}+\frac{1}{z^2}\begin{bmatrix} O & O \\ O & -bI_2 \end{bmatrix} \\ &=\begin{bmatrix} z^2aI_1-aQ_nR_{n-1}+c_1I_1 & zaQ_n-\dfrac{1}{z}bQ_{n-1} \\ zaR_{n-1}-\dfrac{1}{z}bR_n & -\dfrac{1}{z^2}bI_2+bR_nQ_{n-1}+c_2I_2 \end{bmatrix}, \end{aligned} \tag{2.8}$$

where z is the spectral parameter which satisfies $z_t=0$. Here I_1 and I_2 are respectively the $p\times p$ and $q\times q$ unit matrices, Q_n is a $p\times q$ matrix, and R_n is a $q\times p$ matrix.

Substituting Eqs. (2.7) and (2.8) into Eq. (2.6), we obtain a set of matrix equations

$$Q_{n,t}-aQ_{n+1}-bQ_{n-1}+(c_2-c_1)Q_n+aQ_{n+1}R_nQ_n+bQ_nR_nQ_{n-1}=O, \tag{2.9a}$$

$$R_{n,t}+bR_{n+1}+aR_{n-1}+(c_1-c_2)R_n-bR_{n+1}Q_nR_n-aR_nQ_nR_{n-1}=O. \tag{2.9b}$$

Choosing the constants as

$$a=-b=1, \quad c_1=c_2(=0),$$

we obtain

$$Q_{n,t}-(Q_{n+1}-Q_{n-1})+(Q_{n+1}R_nQ_n-Q_nR_nQ_{n-1})=O, \tag{2.10a}$$

$$R_{n,t}-(R_{n+1}-R_{n-1})+(R_{n+1}Q_nR_n-R_nQ_nR_{n-1})=O. \tag{2.10b}$$

We call this model (2.10) the semi-discrete (sd-) matrix mKdV equation.[13] If we set

$$R_n=-I, \quad Q_n=W_n-I, \tag{2.11}$$

we obtain a matrix version of the Lotka–Volterra equation,

$$W_{n,t}=W_{n+1}W_n-W_nW_{n-1}, \tag{2.12}$$

where W_n is a square matrix.

When we take an alternative choice

$$a=b=i, \quad c_2-c_1=2i,$$

we obtain

$$iQ_{n,t}+(Q_{n+1}+Q_{n-1}-2Q_n)-(Q_{n+1}R_nQ_n+Q_nR_nQ_{n-1})=O, \tag{2.13a}$$

$$iR_{n,t}-(R_{n+1}+R_{n-1}-2R_n)+(R_{n+1}Q_nR_n+R_nQ_nR_{n-1})=O. \tag{2.13b}$$

We call this model the semi-discrete (sd-) matrix nonlinear Schrödinger (NLS) equation. The integrable model (2.13) or, more generally, (2.9) was found by D. Trubatch and M. J. Ablowitz, as far as the authors know.

C. Conservation laws

In this subsection, we present a systematic method to construct local conservation laws for the system (2.9) which includes the sd-matrix mKdV equation and the sd-matrix NLS equation as its reductions. We start from a special class, $p=q=l$, of Eq. (2.5),

$$\begin{bmatrix}\Psi_{1n+1}\\ \Psi_{2n+1}\end{bmatrix}=\begin{bmatrix}F_{1n} & Q_n\\ R_n & F_{2n}\end{bmatrix}\begin{bmatrix}\Psi_{1n}\\ \Psi_{2n}\end{bmatrix}, \tag{2.14}$$

$$\begin{bmatrix}\Psi_{1n}\\ \Psi_{2n}\end{bmatrix}_t=\begin{bmatrix}A_n & B_n\\ C_n & D_n\end{bmatrix}\begin{bmatrix}\Psi_{1n}\\ \Psi_{2n}\end{bmatrix}, \tag{2.15}$$

where all the entries in Eqs. (2.14) and (2.15) are assumed to be $l\times l$ square matrices. The following is a discrete version of the method for continuous systems.[13,23] The zero-curvature condition (2.6) gives

$$F_{1n,t}+F_{1n}A_n+Q_nC_n-A_{n+1}F_{1n}-B_{n+1}R_n=O, \tag{2.16a}$$

$$F_{2n,t}+F_{2n}D_n+R_nB_n-D_{n+1}F_{2n}-C_{n+1}Q_n=O, \tag{2.16b}$$

$$Q_{n,t}+F_{1n}B_n+Q_nD_n-A_{n+1}Q_n-B_{n+1}F_{2n}=O, \tag{2.16c}$$

$$R_{n,t}+F_{2n}C_n+R_nA_n-D_{n+1}R_n-C_{n+1}F_{1n}=O. \tag{2.16d}$$

Defining an $l\times l$ square matrix Γ_n by

$$\Gamma_n\equiv\Psi_{2n}\Psi_{1n}^{-1}, \tag{2.17}$$

we can prove the following relations from Eqs. (2.14) and (2.15):

$$\Gamma_{n+1}=(R_n+F_{2n}\Gamma_n)(F_{1n}+Q_n\Gamma_n)^{-1}, \tag{2.18}$$

$$\Gamma_{n,t}=C_n+D_n\Gamma_n-\Gamma_nA_n-\Gamma_nB_n\Gamma_n. \tag{2.19}$$

Equation (2.19) can be interpreted as a matrix version of the Ricatti equation. Using Eqs. (2.16) and (2.18), we can rewrite Eq. (2.19) as

$$\begin{aligned}(Q_n\Gamma_n+F_{1n})_t(Q_n\Gamma_n+F_{1n})^{-1}=&A_{n+1}-(Q_n\Gamma_n+F_{1n})A_n(Q_n\Gamma_n+F_{1n})^{-1}\\ &+B_{n+1}\Gamma_{n+1}-(Q_n\Gamma_n+F_{1n})B_n\Gamma_n(Q_n\Gamma_n+F_{1n})^{-1}.\end{aligned} \tag{2.20}$$

Taking the trace of Eq. (2.20), we get

$$\mathrm{tr}\{\log(Q_n\Gamma_n+F_{1n})\}_t=\mathrm{tr}(A_{n+1}+B_{n+1}\Gamma_{n+1})-\mathrm{tr}(A_n+B_n\Gamma_n). \tag{2.21}$$

Assuming that L_n is expressed as Eq. (2.7), we have

$$F_{1n}=zI, \quad F_{2n}=\frac{1}{z}\,I. \tag{2.22}$$

The matrices Q_n and R_n are square matrices in this case. Then Eqs. (2.21) and (2.18) are cast into

$$\left\{\mathrm{tr}\,\log\left(I+\frac{1}{z}\,Q_n\Gamma_n\right)\right\}_t=\mathrm{tr}(A_{n+1}+B_{n+1}\Gamma_{n+1})-\mathrm{tr}(A_n+B_n\Gamma_n), \tag{2.23}$$

$$zQ_n\Gamma_n=Q_nR_{n-1}+\frac{1}{z}\,Q_nQ_{n-1}^{-1}(Q_{n-1}\Gamma_{n-1})-(Q_n\Gamma_n)(Q_{n-1}\Gamma_{n-1}). \tag{2.24}$$

Equation (2.23) has the form of the local conservation law. It shows that $\mathrm{tr}\{\log(I+Q_n\Gamma_n/z)\}$ is a generating function of the conserved densities for Eq. (2.9). We expand $Q_n\Gamma_n$ with respect to the inverse of the spectral parameter z in the following form:

$$Q_n\Gamma_n=\sum_{j=1}^{\infty}\frac{1}{z^{2j-1}}\,f_n^{(j)}. \tag{2.25}$$

Substituting Eq. (2.25) into Eq. (2.24), we obtain a recursion formula for $f_n^{(j)}$:

$$f_n^{(j)}=Q_nR_{n-1}\delta_{j,1}+Q_nQ_{n-1}^{-1}f_{n-1}^{(j-1)}-\sum_{k=1}^{j-1}f_n^{(k)}f_{n-1}^{(j-k)}, \quad j=1,2,\ldots. \tag{2.26}$$

The formula (2.26) yields $f_n^{(j)}$; for instance,

$$f_n^{(1)}=Q_nR_{n-1},$$

$$f_n^{(2)}=Q_nR_{n-2}-Q_nR_{n-1}Q_{n-1}R_{n-2},$$

$$\begin{aligned}f_n^{(3)}=&Q_nR_{n-3}-Q_nR_{n-2}Q_{n-2}R_{n-3}-Q_nR_{n-1}Q_{n-1}R_{n-3}-Q_nR_{n-2}Q_{n-1}R_{n-2}\\&+Q_nR_{n-1}Q_{n-1}R_{n-2}Q_{n-2}R_{n-3}+Q_nR_{n-1}Q_{n-1}R_{n-2}Q_{n-1}R_{n-2}.\end{aligned}$$

We put Eq. (2.25) into $\mathrm{tr}\{\log(I+Q_n\Gamma_n/z)\}$ and expand it with respect to $1/z$:

$$\mathrm{tr}\left\{\log\left(I+\frac{1}{z^2}\,f_n^{(1)}+\frac{1}{z^4}\,f_n^{(2)}+\frac{1}{z^6}\,f_n^{(3)}+\cdots\right)\right\}=\mathrm{tr}\left\{\frac{1}{z^2}\,f_n^{(1)}+\frac{1}{z^4}\left(f_n^{(2)}-\frac{1}{2}\,f_n^{(1)2}\right)+\cdots\right\}.$$

Thus, the first two conserved densities given by this expansion are

$$J_n^{(-1)}=f_n^{(1)}=Q_nR_{n-1}, \tag{2.27a}$$

$$J_n^{(-2)}=\mathrm{tr}\{f_n^{(2)}-\tfrac{1}{2}\,(f_n^{(1)})^2\}=\mathrm{tr}\{Q_nR_{n-2}-Q_nR_{n-1}Q_{n-1}R_{n-2}-\tfrac{1}{2}\,(Q_nR_{n-1})^2\}. \tag{2.27b}$$

Next we expand $Q_n\Gamma_n$ with respect to z. For this purpose, we rewrite Eq. (2.24) as

$$Q_n\Gamma_n=-zQ_nR_n+zQ_nQ_{n+1}^{-1}(Q_{n+1}\Gamma_{n+1})(Q_n\Gamma_n+zI). \tag{2.28}$$

We substitute the following expansion,

$$Q_n\Gamma_n=\sum_{j=1}^{\infty}z^{2j-1}g_n^{(j)}, \tag{2.29}$$

into Eq. (2.28) and obtain a recursion formula,

$$g_n^{(j)} = -Q_n R_n \delta_{j,1} + Q_n Q_{n+1}^{-1} g_{n+1}^{(j-1)} + Q_n Q_{n+1}^{-1} \sum_{k=1}^{j-1} g_{n+1}^{(k)} g_n^{(j-k)}. \tag{2.30}$$

By use of the formula (2.30), the first three of the coefficients $g_n^{(j)}$ are given by

$$g_n^{(1)} = -Q_n R_n,$$

$$g_n^{(2)} = -Q_n R_{n+1}(I - Q_n R_n),$$

$$g_n^{(3)} = -Q_n R_{n+2}(I - Q_n R_n) + Q_n R_{n+1} Q_n R_{n+1}(I - Q_n R_n) + Q_n R_{n+2} Q_{n+1} R_{n+1}(I - Q_n R_n).$$

We put Eq. (2.29) into $\mathrm{tr}\{\log(I + Q_n \Gamma_n / z)\}$ and expand it with respect to z. Then we obtain

$$\begin{aligned}\mathrm{tr}\,\{\log(I + g_n^{(1)} + z^2 g_n^{(2)} + z^4 g_n^{(3)} + \cdots)\} = \mathrm{tr}\{&\log(I + g_n^{(1)}) + z^2 g_n^{(2)}(I + g_n^{(1)})^{-1} \\ &+ z^4[g_n^{(3)}(I + g_n^{(1)})^{-1} - \tfrac{1}{2}\{g_n^{(2)}(I + g_n^{(1)})^{-1}\}^2] + \cdots\}.\end{aligned}$$

Thus, the first three conserved densities given by this expansion are

$$J_n^{(0)} = \mathrm{tr}\{\log(I + g_n^{(1)})\} = \mathrm{tr}\{\log(I - Q_n R_n)\}, \tag{2.31a}$$

$$J_n^{(1)} = Q_n^{-1} g_n^{(2)}(I + g_n^{(1)})^{-1} Q_n = -R_{n+1} Q_n, \tag{2.31b}$$

$$\begin{aligned}J_n^{(2)} &= \mathrm{tr}[g_n^{(3)}(I + g_n^{(1)})^{-1} - \tfrac{1}{2}\{g_n^{(2)}(I + g_n^{(1)})^{-1}\}^2] \\ &= \mathrm{tr}\{-Q_n R_{n+2} + Q_n R_{n+2} Q_{n+1} R_{n+1} + \tfrac{1}{2}(Q_n R_{n+1})^2\}.\end{aligned} \tag{2.31c}$$

We should pay attention to the fact that all the entries of matrices $J_n^{(-1)}$ and $J_n^{(1)}$ are conserved densities for Eq. (2.9). We can prove it by a straightforward calculation. That is the reason why we dropped tr in Eqs. (2.27a) and (2.31b).

D. Reduction of the Lax pair for the semi-discrete coupled modified KdV equations

In this subsection, we show a reduction of the sd-matrix mKdV equation to the sd-cmKdV equations. We recursively define $2^{m-1} \times 2^{m-1}$ matrices $Q_n^{(m)}$ and $R_n^{(m)}$ by

$$Q_n^{(1)} = \mu_0 v_n^{(0)} + i v_n^{(1)}, \quad R_n^{(1)} = \varepsilon_1(\mu_0 v_n^{(0)} - i v_n^{(1)}), \tag{2.32}$$

$$Q_n^{(m+1)} = \begin{bmatrix} Q_n^{(m)} & -\varepsilon_{2m+1}(\mu_{2m} v_n^{(2m)} + i v_n^{(2m+1)}) I_{2^{m-1}} \\ -(\mu_{2m} v_n^{(2m)} - i v_n^{(2m+1)}) I_{2^{m-1}} & -R_n^{(m)} \end{bmatrix}, \tag{2.33}$$

$$R_n^{(m+1)} = \begin{bmatrix} R_n^{(m)} & -\varepsilon_{2m+1}(\mu_{2m} v_n^{(2m)} + i v_n^{(2m+1)}) I_{2^{m-1}} \\ -(\mu_{2m} v_n^{(2m)} - i v_n^{(2m+1)}) I_{2^{m-1}} & -Q_n^{(m)} \end{bmatrix}. \tag{2.34}$$

Here $I_{2^{m-1}}$ is the $2^{m-1} \times 2^{m-1}$ unit matrix, each ε_i is a constant which is either 1 or -1, and μ_{2m} is a constant that satisfies

$$\mu_{2m}^2 = \frac{\varepsilon_{2m}}{\varepsilon_{2m+1}} = \varepsilon_{2m} \varepsilon_{2m+1}.$$

For $Q_n^{(m)}$ and $R_n^{(m)}$ defined by Eqs. (2.32)–(2.34), we can prove a simple relation,

$$Q_n^{(m)} R_n^{(m)} = R_n^{(m)} Q_n^{(m)} = \sum_{j=0}^{2m-1} \varepsilon_j v_n^{(j)2} \cdot I_{2^{m-1}}, \tag{2.35}$$

by induction. Then substituting $Q_n^{(m)}$ and $R_n^{(m)}$ for Q_n and R_n in the sd-matrix mKdV equation (2.10), we obtain

$$v_{n,t}^{(i)}-(v_{n+1}^{(i)}-v_{n-1}^{(i)})+\left(\sum_{j=0}^{M-1}\varepsilon_j v_n^{(j)2}\right)(v_{n+1}^{(i)}-v_{n-1}^{(i)})=0,\quad \varepsilon_j=\pm 1,\quad i=0,1,...,M-1, \tag{2.36}$$

where we set $M=2m$. Setting

$$\mu_{2j}=1,\quad j=0,1,...,m-1,$$

and

$$q_n^{(j)}=v_n^{(2j)}+iv_n^{(2j+1)},$$

we get an alternative representation of the sd-cmKdV equations in terms of complex variables,

$$q_{n,t}^{(i)}-(q_{n+1}^{(i)}-q_{n-1}^{(i)})+\left(\sum_{j=0}^{m-1}\varepsilon_{2j}|q_n^{(j)}|^2\right)(q_{n+1}^{(i)}-q_{n-1}^{(i)})=0,\quad i=0,1,...,m-1. \tag{2.37}$$

In the following, we choose

$$\varepsilon_i=-1,\quad i=0,1,...,2m-1,$$

$$\mu_{2j}=1,\quad j=0,1,...,m-1,$$

and consider a self-focusing type of the sd-cmKdV equations (2.4), that is,

$$\frac{\partial v_n^{(i)}}{\partial t}=\left(1+\sum_{j=0}^{M-1}v_n^{(j)2}\right)(v_{n+1}^{(i)}-v_{n-1}^{(i)}),\quad i=0,1,...,M-1. \tag{2.38}$$

In this case, the recursion relations of $Q_n^{(m)}$ and $R_n^{(m)}$ are given by

$$Q_n^{(1)}=v_n^{(0)}+iv_n^{(1)},\quad R_n^{(1)}=-v_n^{(0)}+iv_n^{(1)}, \tag{2.39}$$

$$Q_n^{(m+1)}=\begin{bmatrix} Q_n^{(m)} & (v_n^{(2m)}+iv_n^{(2m+1)})I_{2^{m-1}} \\ -(v_n^{(2m)}-iv_n^{(2m+1)})I_{2^{m-1}} & -R_n^{(m)} \end{bmatrix}, \tag{2.40}$$

$$R_n^{(m+1)}=\begin{bmatrix} R_n^{(m)} & (v_n^{(2m)}+iv_n^{(2m+1)})I_{2^{m-1}} \\ -(v_n^{(2m)}-iv_n^{(2m+1)})I_{2^{m-1}} & -Q_n^{(m)} \end{bmatrix}. \tag{2.41}$$

For example, the Lax matrix L_n for the four-component sd-cmKdV equations (2.38) is given by

$$L_n=\begin{bmatrix} z & 0 & v_n^{(0)}+iv_n^{(1)} & v_n^{(2)}+iv_n^{(3)} \\ 0 & z & -v_n^{(2)}+iv_n^{(3)} & v_n^{(0)}-iv_n^{(1)} \\ -v_n^{(0)}+iv_n^{(1)} & v_n^{(2)}+iv_n^{(3)} & \frac{1}{z} & 0 \\ -v_n^{(2)}+iv_n^{(3)} & -v_n^{(0)}-iv_n^{(1)} & 0 & \frac{1}{z} \end{bmatrix}. \tag{2.42}$$

The relation (2.35) for the above $Q_n^{(m)}$ and $R_n^{(m)}$ is

$$Q_n^{(m)}R_n^{(m)}=R_n^{(m)}Q_n^{(m)}=-\sum_{j=0}^{2m-1}v_n^{(j)2}\cdot I_{2^{m-1}}. \tag{2.43}$$

This relation plays a crucial role in performing the ISM. In addition, a simple relation between $Q_n^{(m)}$ and $R_n^{(m)}$ holds,

$$R_n = -Q_n^{\dagger}, \tag{2.44}$$

where the symbol † denotes the Hermitian conjugate.

Because the sd-cmKdV equations are given as a reduction of the sd-matrix mKdV equation, the results in Sec. II C assure that the sd-cmKdV equations have an infinite number of local conservation laws. Explicit forms of the first four conserved densities for the original sd-cmKdV equations (1.2) are given by

$$\log\left(1+\sum_{j,k} C_{jk}u_n^{(j)}u_n^{(k)}\right), \tag{2.45}$$

$$\begin{gathered} u_{n+1}^{(j)}u_n^{(k)}-u_n^{(j)}u_{n+1}^{(k)} \quad \text{for all } j,k(j\neq k), \\ \sum_{j,k} C_{jk}u_{n+1}^{(j)}u_n^{(k)}, \end{gathered} \tag{2.46}$$

$$\begin{aligned} &\left(1+\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_{n+1}^{(k)}\right)\cdot\sum_{j,k} C_{jk}u_{n+2}^{(j)}u_n^{(k)}+\left(\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_n^{(k)}\right)^2 \\ &\quad -\frac{1}{2}\sum_{j,k} C_{jk}u_n^{(j)}u_n^{(k)}\cdot\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_{n+1}^{(k)}, \end{aligned} \tag{2.47}$$

$$\begin{aligned} &\left(1+\sum_{j,k} C_{jk}u_{n+2}^{(j)}u_{n+2}^{(k)}\right)\left(1+\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_{n+1}^{(k)}\right)\cdot\sum_{j,k} C_{jk}u_{n+3}^{(j)}u_n^{(k)} \\ &\quad +2\sum_{j,k} C_{jk}u_{n+2}^{(j)}u_n^{(k)}\cdot\left(1+\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_{n+1}^{(k)}\right)\left(\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_n^{(k)}+\sum_{j,k} C_{jk}u_{n+2}^{(j)}u_{n+1}^{(k)}\right) \\ &\quad -\left(\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_n^{(k)}\cdot\sum_{j,k} C_{jk}u_{n+2}^{(j)}u_{n+2}^{(k)}+\sum_{j,k} C_{jk}u_{n+2}^{(j)}u_{n+1}^{(k)}\cdot\sum_{j,k} C_{jk}u_n^{(j)}u_n^{(k)}\right) \\ &\quad \cdot\left(1+\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_{n+1}^{(k)}\right)+\frac{4}{3}\left(\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_n^{(k)}\right)^3 \\ &\quad -\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_n^{(k)}\cdot\sum_{j,k} C_{jk}u_n^{(j)}u_n^{(k)}\cdot\sum_{j,k} C_{jk}u_{n+1}^{(j)}u_{n+1}^{(k)}. \end{aligned} \tag{2.48}$$

III. INVERSE SCATTERING METHOD

In this section we consider the scattering and inverse scattering problems associated with the $2l\times 2l$ ($l=2^{m-1}$) matrix (2.7),

$$\Psi_{n+1}=L_n\Psi_n, \quad L_n=\begin{bmatrix} zI & Q_n \\ R_n & \dfrac{1}{z}I \end{bmatrix}, \tag{3.1}$$

under the constraints (2.43) and (2.44),

$$R_n=-Q_n^{\dagger}, \quad Q_nR_n=-\sum_{j=0}^{2m-1} v_n^{(j)2}\cdot I\equiv-\sigma_nI. \tag{3.2}$$

The rapidly decreasing boundary conditions are assumed,

$$Q_n, R_n\to O \quad \text{as} \quad n\to\pm\infty. \tag{3.3}$$

Considering time dependence of the scattering data, we can solve the initial value problem of the sd-cmKdV equations (2.38). Some of the main ideas in what follows are an extension and a modification of the analyses in Refs. 13, 24, and 25 for the matrix KdV equation and the matrix mKdV equation in the continuous theory. The notation used in this section follows the one in Ref. 1.

A. Scattering problem

Let $\Psi_n(z)$ and $\Phi_n(z)$ be solutions of Eq. (3.1) composed by $2l(=2^m)$ rows and $l(=2^{m-1})$ columns. We can show that

$$\Psi_{n+1}^{\dagger}\left(\frac{1}{z^*}\right)\Phi_{n+1}(z)=(I-Q_nR_n)\Psi_n^{\dagger}\left(\frac{1}{z^*}\right)\Phi_n(z)=\rho_n\Psi_n^{\dagger}\left(\frac{1}{z^*}\right)\Phi_n(z).$$

Here $*$ denotes the complex conjugate and ρ_n is defined by

$$\rho_n\equiv 1+\sigma_n=1+\sum_{j=0}^{2m-1} v_n^{(j)2}. \tag{3.4}$$

We employ the following definition of the matrix Wronskian $W_n[\Psi,\ \Phi]$,

$$W_n[\Psi,\ \Phi]\equiv\Psi_n^{\dagger}\left(\frac{1}{z^*}\right)\Phi_n(z), \tag{3.5}$$

which satisfies

$$W_{n+1}[\Psi,\ \Phi]=(I-Q_nR_n)W_n[\Psi,\ \Phi]=\rho_nW_n[\Psi,\ \Phi]. \tag{3.6}$$

Using Eq. (3.6) repeatedly, we get

$$W_{\infty}[\Psi,\ \Phi]=\tau W_{-\infty}[\Psi,\ \Phi], \tag{3.7}$$

where τ is defined by

$$\tau\equiv\prod_{n=-\infty}^{\infty}\rho_n=\prod_{n=-\infty}^{\infty}\left(1+\sum_{j=0}^{2m-1} v_n^{(j)2}\right), \tag{3.8}$$

and assumed to be finite. It should be noticed that τ is a conserved quantity [see Eq. (2.45)].

We introduce Jost functions $\phi_n,\bar{\phi}_n$ and $\psi_n,\bar{\psi}_n$ which satisfy the boundary conditions,

$$\phi_n\sim\begin{bmatrix} I \\ O \end{bmatrix}z^n \qquad \text{as} \quad n\to-\infty, \tag{3.9a}$$

$$\bar{\phi}_n\sim\begin{bmatrix} O \\ -I \end{bmatrix}z^{-n} \quad \text{as} \quad n\to-\infty, \tag{3.9b}$$

and

$$\psi_n\sim\begin{bmatrix} O \\ I \end{bmatrix}z^{-n} \qquad \text{as} \quad n\to+\infty, \tag{3.9c}$$

$$\bar{\psi}_n\sim\begin{bmatrix} I \\ O \end{bmatrix}z^{n} \qquad \text{as} \quad n\to+\infty. \tag{3.9d}$$

Here O and I respectively stand for the $l\times l$ zero matrix and the $l\times l$ unit matrix. It can be shown that ϕ_nz^{-n},ψ_nz^n are analytic outside the unit circle ($|z|>1$) on the complex z plane, and that

$\overline{\phi}_n z^n, \overline{\psi}_n z^{-n}$ are analytic inside the unit circle ($|z|<1$) on the z plane, when Q_n, R_n go to O sufficiently rapidly as $n \to \pm\infty$. We assume the following summation representation of the Jost functions ψ_n and $\overline{\psi}_n$:

$$\psi_n = \sum_{n'=n}^{\infty} z^{-n'} K(n,n'), \tag{3.10a}$$

$$\overline{\psi}_n = \sum_{n'=n}^{\infty} z^{n'} \overline{K}(n,n'), \tag{3.10b}$$

where $K(n,n')$ and $\overline{K}(n,n')$ are column vectors which consist of two $l \times l$ square matrices,

$$K(n,n') = \begin{bmatrix} K_1(n,n') \\ K_2(n,n') \end{bmatrix}, \quad \overline{K}(n,n') = \begin{bmatrix} \overline{K_1}(n,n') \\ \overline{K_2}(n,n') \end{bmatrix}.$$

We substitute Eq. (3.10) into Eq. (3.1). Equating the terms with the same power of z, we get the relations for K_1 and K_2,

$$K_1(n,n) = O, \tag{3.11a}$$

$$Q_n K_2(n,n) = -K_1(n,n+1), \tag{3.11b}$$

$$K_1(n,n+j+1) = K_1(n+1,n+j) - Q_n K_2(n,n+j) \quad (j \geqslant 1), \tag{3.11c}$$

$$R_n K_1(n,n+j) = K_2(n+1,n+j) - K_2(n,n+j-1) \quad (j \geqslant 1), \tag{3.11d}$$

and for $\overline{K}_1$ and $\overline{K}_2$,

$$\overline{K}_2(n,n) = O, \tag{3.12a}$$

$$R_n \overline{K}_1(n,n) = -\overline{K}_2(n,n+1), \tag{3.12b}$$

$$Q_n \overline{K}_2(n,n+j) = \overline{K}_1(n+1,n+j) - \overline{K}_1(n,n+j-1) \quad (j \geqslant 1), \tag{3.12c}$$

$$\overline{K}_2(n,n+j+1) = \overline{K}_2(n+1,n+j) - R_n \overline{K}_1(n,n+j) \quad (j \geqslant 1). \tag{3.12d}$$

Because a pair of the Jost functions ϕ_n and $\overline{\phi}_n$, or ψ_n and $\overline{\psi}_n$, forms a fundamental system of the solutions of the scattering problem (3.1), we can set

$$\phi_n(z) = \overline{\psi}_n(z) A(z) + \psi_n(z) B(z), \tag{3.13a}$$

$$\overline{\phi}_n(z) = \overline{\psi}_n(z) \overline{B}(z) - \psi_n(z) \overline{A}(z). \tag{3.13b}$$

Here the coefficients $\{A(z), \overline{A}(z), B(z), \overline{B}(z)\}$ are n-independent $l \times l$ matrices which are called scattering data.

To derive the formula of the ISM rigorously and concisely, we assume that Q_n and R_n are on compact support. The result is, however, applicable to larger classes of potentials Q_n and R_n. According to the asymptotic behaviors of the Jost functions (3.9a)–(3.9d), we obtain

$$W_{-\infty}[\phi,\ \phi] = W_{-\infty}[\overline{\phi},\ \overline{\phi}] = W_{\infty}[\psi,\ \psi] = W_{\infty}[\overline{\psi},\ \overline{\psi}] = I, \tag{3.14a}$$

$$W_n[\phi,\ \overline{\phi}] = W_n[\psi,\ \overline{\psi}] = O, \tag{3.14b}$$

$$A(z) = W_{\infty}[\overline{\psi},\ \phi], \tag{3.14c}$$

$$\overline{A}(z) = -W_{\infty}[\psi,\ \overline{\phi}], \tag{3.14d}$$

$$B(z)=W_\infty[\psi,\ \phi], \tag{3.14e}$$

$$\overline{B}(z)=W_\infty[\overline{\psi},\ \overline{\phi}]. \tag{3.14f}$$

The expressions (3.14c) and (3.14d) show that $A(z)$ and $\overline{A}(z)$ are respectively analytic outside the unit circle ($|z|>1$) and inside the unit circle ($|z|<1$). Using the relations (3.14), we obtain the following relations among $A(z)$, $\overline{A}(z)$, $B(z)$, and $\overline{B}(z)$:

$$A^\dagger\left(\frac{1}{z^*}\right)A(z)+B^\dagger\left(\frac{1}{z^*}\right)B(z)=\tau\, I, \tag{3.15a}$$

$$\overline{A}^\dagger\left(\frac{1}{z^*}\right)\overline{A}(z)+\overline{B}^\dagger\left(\frac{1}{z^*}\right)\overline{B}(z)=\tau\, I, \tag{3.15b}$$

$$A^\dagger\left(\frac{1}{z^*}\right)\overline{B}(z)-B^\dagger\left(\frac{1}{z^*}\right)\overline{A}(z)=O. \tag{3.15c}$$

These relations are written in a matrix form as

$$\begin{bmatrix} A^\dagger(1/z^*) & B^\dagger(1/z^*) \\ \overline{B}^\dagger(1/z^*) & -\overline{A}^\dagger(1/z^*) \end{bmatrix}\begin{bmatrix} A(z) & \overline{B}(z) \\ B(z) & -\overline{A}(z) \end{bmatrix}=\tau\begin{bmatrix} I & O \\ O & I \end{bmatrix},$$

which leads to the inversion of Eq. (3.13),

$$\tau\overline{\psi}_n(z)=\phi_n(z)A^\dagger\left(\frac{1}{z^*}\right)+\overline{\phi}_n(z)\overline{B}^\dagger\left(\frac{1}{z^*}\right), \tag{3.16a}$$

$$\tau\psi_n(z)=\phi_n(z)B^\dagger\left(\frac{1}{z^*}\right)-\overline{\phi}_n(z)\overline{A}^\dagger\left(\frac{1}{z^*}\right). \tag{3.16b}$$

Equation (3.16a) is used in Appendix A.

B. Gel'fand–Levitan–Marchenko equations

Multiplying $A(z)^{-1}$ and $\overline{A}(z)^{-1}$ from the right to Eqs. (3.13a) and (3.13b), respectively, we obtain

$$\phi_n(z)A(z)^{-1}=\overline{\psi}_n(z)+\psi_n(z)B(z)A(z)^{-1}, \tag{3.17a}$$

$$\overline{\phi}_n(z)\overline{A}(z)^{-1}=-\psi_n(z)+\overline{\psi}_n(z)\overline{B}(z)\overline{A}(z)^{-1}. \tag{3.17b}$$

We substitute Eq. (3.10) into the right side of Eq. (3.17a) and operate

$$\frac{1}{2\pi i}\oint_C dz\ z^{-m-1}\quad (m\geqslant n),$$

where C denotes a contour along the unit circle $|z|=1$. Then we obtain

$$J=\overline{K}(n,m)+\sum_{n'=n}^{\infty}K(n,n')F_C(n'+m),$$

where F_C and J are defined by

$$F_C(n'+m)\equiv\frac{1}{2\pi i}\oint_C B(z)A(z)^{-1}z^{-(n'+m)-1}\,dz,$$

$$J \equiv \frac{1}{2\pi i} \oint_C \phi_n z^{-n} A(z)^{-1} z^{n-m-1}\, dz. \tag{3.18}$$

We notice that $\phi_n z^{-n}$ and $A(z)$ are analytic outside the unit circle C, $|z|>1$. The inverse of $A(z)$, i.e., $A(z)^{-1}$, is given by

$$A(z)^{-1} = \frac{1}{\det A(z)} \tilde{A}(z),$$

where $\tilde{A}$ is the cofactor matrix of A. Thus the singularities of the integrand of Eq. (3.18) in $|z|>1$ come from the zeros of $\det A(z)$. We assume that $1/\det A(z)$ has $2N$ isolated simple poles $\{z_1, z_2, \ldots, z_{2N}\}$ and is regular on the unit circle C [see Eq. (3.35) for the reason why we set the number of poles $2N$]. We set

$$J_{\infty,n} = \lim_{z\to\infty} \phi_n z^{-n} A(z)^{-1},$$

and use the residue theorem. Then the integral J is computed as

$$J = -\sum_{j=1}^{2N} \psi_n(z_j) C_j z_j^{-m-1} + J_{\infty,n}\delta_{n,m} = -\sum_{j=1}^{2N} \sum_{n'=n}^{\infty} K(n,n') C_j z_j^{-(n'+m)-1} + J_{\infty,n}\delta_{n,m},$$

where C_j is the residue matrix of $B(z)A(z)^{-1}$ at $z=z_j$. Defining

$$F_D(n'+m) \equiv \sum_{j=1}^{2N} C_j z_j^{-(n'+m)-1},$$

we arrive at the discrete version of the Gel'fand–Levitan–Marchenko equation,

$$\overline{K}(n,m) + \sum_{n'=n}^{\infty} K(n,n') F(n'+m) = J_{\infty,n}\delta_{n,m} \quad (m \geqslant n). \tag{3.19}$$

Here $F(n'+m)$ is defined by

$$\begin{aligned} F(n'+m) &\equiv F_C(n'+m) + F_D(n'+m) \\ &= \frac{1}{2\pi i} \oint_C B(z)A(z)^{-1} z^{-(n'+m)-1} dz + \sum_{j=1}^{2N} C_j z_j^{-(n'+m)-1}. \end{aligned} \tag{3.20}$$

Similarly, we operate

$$\frac{1}{2\pi i} \oint_C dz\, z^{m-1} \quad (m \geqslant n)$$

on Eq. (3.17b). Then we obtain

$$\overline{J} = -K(n,m) + \sum_{n'=n}^{\infty} \overline{K}(n,n') \overline{F}_C(n'+m),$$

where

$$\overline{F}_C(n'+m) = \frac{1}{2\pi i} \oint_C \overline{B}(z)\overline{A}(z)^{-1} z^{n'+m-1}\, dz,$$

$$\overline{J} = \frac{1}{2\pi i} \oint_C \overline{\phi}_n z^n \overline{A}(z)^{-1} z^{-n+m-1}\, dz.$$

We notice that $\overline{\phi}_n z^n$ and $\overline{A}(z)$ are analytic inside the unit circle C, $|z|<1$. We assume that $1/\det \overline{A}(z)$ has $2N$ isolated simple poles $\{\overline{z}_1,\overline{z}_2,\ldots,\overline{z}_{2N}\}$ and is regular on the unit circle C. We set

$$\overline{J}_{0,n}=\lim_{z\to 0}\ \overline{\phi}_n z^n \overline{A}(z)^{-1},$$

and use the residue theorem. The integral $\overline{J}$ is given by

$$\overline{J}=\sum_{k=1}^{2\overline{N}} z^{-(n'+m)-1}\ \overline{\psi}_n(\overline{z}_k)\overline{C}_k\overline{z}_k^{m-1}+\overline{J}_{0,n}\delta_{n,m}=\sum_{k=1}^{2\overline{N}}\sum_{n'=n}^{\infty}\overline{K}(n,n')\overline{C}_k\overline{z}_k^{n'+m-1}+\overline{J}_{0,n}\delta_{n,m},$$

where $\overline{C}_k$ is the residue matrix of $\overline{B}(z)\overline{A}(z)^{-1}$ at $z=\overline{z}_k$. Defining

$$\overline{F}_D(n'+m)\equiv-\sum_{k=1}^{2\overline{N}}\ \overline{C}_k\overline{z}_k^{n'+m-1},$$

we obtain the counterpart of the discrete Gel'fand–Levitan–Marchenko equation,

$$K(n,m)-\sum_{n'=n}^{\infty}\ \overline{K}(n,n')\overline{F}(n'+m)=-\overline{J}_{0,n}\delta_{n,m}\quad(m\geqslant n).\tag{3.21}$$

Here $\overline{F}(n'+m)$ is defined by

$$\begin{aligned}\overline{F}(n'+m)&\equiv\overline{F}_C(n'+m)+\overline{F}_D(n'+m)\\&=\frac{1}{2\pi i}\ \oint_C\overline{B}(z)\overline{A}(z)^{-1}z^{n'+m-1}\,dz-\sum_{k=1}^{2\overline{N}}\ \overline{C}_k\overline{z}_k^{n'+m-1}.\end{aligned}\tag{3.22}$$

From Eqs. (3.11b) and (3.11d), we obtain

$$\begin{aligned}K_2(n,n)&=(I-R_nQ_n)^{-1}K_2(n+1,n+1)\\&=(I-R_nQ_n)^{-1}(I-R_{n+1}Q_{n+1})^{-1}K_2(n+2,\ n+2)\\&\vdots\\&=\prod_{i=n}^{\infty}\ (I-R_iQ_i)^{-1}=\prod_{i=n}^{\infty}\ \rho_i^{-1}\cdot I,\end{aligned}$$

where $\lim_{n\to\infty} K_2(n,n)=I$ is used. Similarly, from Eqs. (3.12b) and (3.12c) with $\lim_{n\to\infty}\overline{K}_1(n,n)=I$, we obtain

$$\begin{aligned}\overline{K}_1(n,n)&=(I-Q_nR_n)^{-1}\overline{K}_1(n+1,\ n+1)\\&=(I-Q_nR_n)^{-1}(I-Q_{n+1}R_{n+1})^{-1}\overline{K}_1(n+2,\ n+2)\\&\vdots\\&=\prod_{i=n}^{\infty}\ (I-Q_iR_i)^{-1}=\prod_{i=n}^{\infty}\ \rho_i^{-1}\cdot I.\end{aligned}$$

Thus, it is natural to set

$$K(n,m)=\kappa(n,m)\prod_{i=n}^{\infty}\ (I-R_iQ_i)^{-1}=\kappa(n,m)\prod_{i=n}^{\infty}\ \rho_i^{-1}\quad(m\geqslant n),\tag{3.23}$$

$$\overline{K}(n,m)=\overline{\kappa}(n,m)\prod_{i=n}^{\infty}\ (I-Q_iR_i)^{-1}=\overline{\kappa}(n,m)\prod_{i=n}^{\infty}\ \rho_i^{-1}\quad(m\geqslant n).\tag{3.24}$$

Here $\kappa(n,m)$ and $\overline{\kappa}(n,m)$ are column vectors whose elements are $l\times l$ square matrices:

$$\kappa(n,m)=\begin{bmatrix}\kappa_1(n,m)\\ \kappa_2(n,m)\end{bmatrix},\quad \overline{\kappa}(n,m)=\begin{bmatrix}\overline{\kappa}_1(n,m)\\ \overline{\kappa}_2(n,m)\end{bmatrix}.$$

In particular, $\kappa(n,n)$ and $\overline{\kappa}(n,n)$ are given by

$$\kappa(n,n)=\begin{bmatrix} O \\ I \end{bmatrix}, \tag{3.25}$$

$$\overline{\kappa}(n,n)=\begin{bmatrix} I \\ O \end{bmatrix}. \tag{3.26}$$

Putting Eq. (3.23) with (3.25) and Eq. (3.24) with (3.26) into Eq. (3.11) and Eq. (3.12), respectively, we obtain the relations for κ_1, κ_2, $\overline{\kappa}_1$, and $\overline{\kappa}_2$,

$$-\kappa_1(n,n+1)=Q_n, \tag{3.27}$$

$$-\overline{\kappa}_2(n,n+1)=R_n, \tag{3.28}$$

$$\kappa_1(n,n+j+1)=\rho_n\kappa_1(n+1,n+j)-Q_n\kappa_2(n,n+j) \quad (j\geqslant 1), \tag{3.29}$$

$$R_n\kappa_1(n,n+j)=\rho_n\kappa_2(n+1,n+j)-\kappa_2(n,n+j-1) \quad (j\geqslant 1), \tag{3.30}$$

$$Q_n\overline{\kappa}_2(n,n+j)=\rho_n\overline{\kappa}_1(n+1,n+j)-\overline{\kappa}_1(n,n+j-1) \quad (j\geqslant 1), \tag{3.31}$$

$$\overline{\kappa}_2(n,n+j+1)=\rho_n\overline{\kappa}_2(n+1,n+j)-R_n\overline{\kappa}_1(n,n+j) \quad (j\geqslant 1). \tag{3.32}$$

In terms of κ and $\overline{\kappa}$, the Gel'fand–Levitan–Marchenko equations (3.19) and (3.21) for $m>n$ are expressed as

$$\overline{\kappa}(n,m)+\begin{bmatrix} O \\ I \end{bmatrix}F(n+m)+\sum_{n'=n+1}^{\infty}\kappa(n,n')F(n'+m)=\begin{bmatrix} O \\ O \end{bmatrix} \quad (m>n), \tag{3.33}$$

$$\kappa(n,m)-\begin{bmatrix} I \\ O \end{bmatrix}\overline{F}(n+m)-\sum_{n'=n+1}^{\infty}\overline{\kappa}(n,n')\overline{F}(n'+m)=\begin{bmatrix} O \\ O \end{bmatrix} \quad (m>n). \tag{3.34}$$

It should be noted that the scattering problem (3.1) gives the symmetry properties of the scattering data. Iterating Eq. (3.1), we can prove that $A(z),\overline{A}(z)$ are polynomials in z of even degree and $B(z),\overline{B}(z)$ are polynomials in z of odd degree. This fact leads to

$$\det A(z)=\det A(-z), \tag{3.35}$$

$$\det \overline{A}(z)=\det \overline{A}(-z), \tag{3.36}$$

which mean the eigenvalues $z_j,\overline{z_k}$ should appear as positive–negative pairs. Further, we have

$$B(z)A(z)^{-1}=-B(-z)A(-z)^{-1}, \tag{3.37}$$

$$\overline{B}(z)\overline{A}(z)^{-1}=-\overline{B}(-z)\overline{A}(-z)^{-1}. \tag{3.38}$$

Therefore, we can simplify the forms of F and $\overline{F}$ as

$$F(n+m)=\begin{cases} 2F_R(n+m), & m=n+2j-1, \\ O, & m=n+2j, \end{cases} \quad j\geqslant 1, \tag{3.39a}$$

$$F_R(n+m)=\frac{1}{2\pi i}\int_{C_R}B(z)A(z)^{-1}z^{-(n+m)-1}\,dz+\sum_{j=1}^{N}C_jz_j^{-(n+m)-1}, \tag{3.39b}$$

and

$$\overline{F}(n+m)=\begin{cases} 2\overline{F}_R(n+m), & m=n+2j-1, \\ 0, & m=n+2j, \end{cases} \quad j\geqslant 1, \tag{3.40a}$$

$$\overline{F}_R(n+m)=\frac{1}{2\pi i}\int_{C_R}\overline{B}(z)\overline{A}(z)^{-1}z^{n+m-1}\,dz-\sum_{k=1}^{\overline{N}}\overline{C}_k\overline{z}_k^{n+m-1}. \tag{3.40b}$$

Here C_R denotes a contour along the right-half portion of the unit circle C.

The symmetry properties of F and $\overline{F}$ give rise to those of κ and $\overline{\kappa}$. From Eqs. (3.33) and (3.34), we obtain

$$\kappa_1(n,m)=\begin{cases} \kappa_{1R}(n,m), & m=n+2j-1, \\ 0, & m=n+2j, \end{cases} \quad j\geqslant 1, \tag{3.41a}$$

$$\kappa_2(n,m)=\begin{cases} \kappa_{2R}(n,m), & m=n+2j, \\ 0, & m=n+2j-1, \end{cases} \quad j\geqslant 1, \tag{3.41b}$$

$$\overline{\kappa}_1(n,m)=\begin{cases} \overline{\kappa}_{1R}(n,m), & m=n+2j, \\ 0, & m=n+2j-1, \end{cases} \quad j\geqslant 1, \tag{3.41c}$$

$$\overline{\kappa}_2(n,m)=\begin{cases} \overline{\kappa}_{2R}(n,m), & m=n+2j-1, \\ 0, & m=n+2j, \end{cases} \quad j\geqslant 1. \tag{3.41d}$$

Considering the above symmetry properties, we obtain the simplified Gel'fand–Levitan–Marchenko equations for κ_{1R} and $\overline{\kappa}_{2R}$:

$\kappa_{1R}(n,m)$ $(m>n, m-n=\text{odd})$

$$=2\overline{F}_R(n+m)-4\sum_{\substack{n'=n+2 \\ n'-n=\text{even}}}^{\infty}\sum_{\substack{n''=n+1 \\ n''-n=\text{odd}}}^{\infty}\kappa_{1R}(n,n'')F_R(n''+n')\overline{F}_R(n'+m), \tag{3.42}$$

$\overline{\kappa}_{2R}(n,m)$ $(m>n, m-n=\text{odd})$

$$=-2F_R(n+m)-4\sum_{\substack{n'=n+2 \\ n'-n=\text{even}}}^{\infty}\sum_{\substack{n''=n+1 \\ n''-n=\text{odd}}}^{\infty}\overline{\kappa}_{2R}(n,n'')\overline{F}_R(n''+n')F_R(n'+m). \tag{3.43}$$

C. Time dependence of the scattering data

Under the rapidly decreasing boundary conditions (3.3), the asymptotic form of the Lax matrix M_n for the sd-matrix mKdV equation (2.10) is given by

$$M_n\to\begin{bmatrix} z^2 I & O \\ O & \dfrac{1}{z^2}I \end{bmatrix} \quad \text{as} \quad n\to\pm\infty. \tag{3.44}$$

We define time-dependent Jost functions by

$$\phi_n^{(t)} \equiv \phi_n e^{z^2 t} \sim \begin{bmatrix} I \\ O \end{bmatrix} z^n e^{z^2 t} \qquad \text{as} \quad n \to -\infty,$$

$$\overline{\phi}_n^{(t)} \equiv \overline{\phi}_n e^{(1/z^2)t} \sim \begin{bmatrix} O \\ -I \end{bmatrix} z^{-n} e^{(1/z^2)t} \quad \text{as} \quad n \to -\infty,$$

$$\psi_n^{(t)} \equiv \psi_n e^{(1/z^2)t} \sim \begin{bmatrix} O \\ I \end{bmatrix} z^{-n} e^{(1/z^2)t} \quad \text{as} \quad n \to +\infty,$$

$$\overline{\psi}_n^{(t)} \equiv \overline{\psi}_n e^{z^2 t} \sim \begin{bmatrix} I \\ O \end{bmatrix} z^n e^{z^2 t} \qquad \text{as} \quad n \to +\infty.$$

From the relations

$$\frac{\partial \phi_n^{(t)}}{\partial t} = M_n \phi_n^{(t)}, \quad \frac{\partial \overline{\phi}_n^{(t)}}{\partial t} = M_n \overline{\phi}_n^{(t)},$$

we obtain

$$\frac{\partial \phi_n}{\partial t} = (M_n - z^2 I)\phi_n, \quad \frac{\partial \overline{\phi}_n}{\partial t} = \left(M_n - \frac{1}{z^2} I \right) \overline{\phi}_n. \tag{3.45}$$

We put the definitions of the scattering data,

$$\phi_n(z) = \overline{\psi}_n(z) A(z,t) + \psi_n(z) B(z,t), \tag{3.46a}$$

$$\overline{\phi}_n(z) = \overline{\psi}_n(z) \overline{B}(z,t) - \psi_n(z) \overline{A}(z,t), \tag{3.46b}$$

into Eq. (3.45). Then taking the limit $n \to +\infty$, we obtain

$$A_t(z,t) = O, \tag{3.47a}$$

$$B_t(z,t) = -\left(z^2 - \frac{1}{z^2} \right) B(z,t), \tag{3.47b}$$

and

$$\overline{A}_t(z,t) = O, \tag{3.47c}$$

$$\overline{B}_t(z,t) = \left(z^2 - \frac{1}{z^2} \right) \overline{B}(z,t). \tag{3.47d}$$

From Eq. (3.47), the time dependences of BA^{-1}, C_j and $\overline{BA}^{-1}, \overline{C}_k$, are respectively concluded as

$$B(z,t)A(z,t)^{-1} = B(z,0)A(z,0)^{-1} e^{-(z^2 - 1/z^2)t}, \tag{3.48}$$

$$C_j(t) = C_j(0) e^{-(z_j^2 - 1/z_j^2)t}, \tag{3.49}$$

and

$$\overline{B}(z,t)\overline{A}(z,t)^{-1} = \overline{B}(z,0)\overline{A}(z,0)^{-1} e^{(z^2 - 1/z^2)t}, \tag{3.50}$$

$$\overline{C}_k(t) = \overline{C}_k(0) e^{(\overline{z}_k^2 - 1/\overline{z}_k^2)t}. \tag{3.51}$$

The above result gives explicitly time-dependent forms of $F_R(n,t)$ and $\overline{F}_R(n,t)$ for odd n,

$$F_R(n,t)=\frac{1}{2\pi i}\int_{C_R} B(z,0)A(z,0)^{-1}z^{-n-1}e^{-(z^2-1/z^2)t}\,dz+\sum_{j=1}^{N} C_j(0)z_j^{-n-1}e^{-(z_j^2-1/z_j^2)t}, \tag{3.52}$$

$$\overline{F}_R(n,t)=\frac{1}{2\pi i}\int_{C_R} \overline{B}(z,0)\overline{A}(z,0)^{-1}z^{n-1}e^{(z^2-1/z^2)t}dz-\sum_{k=1}^{\overline{N}} \overline{C}_k(0)\overline{z}_k^{n-1}e^{(\overline{z}_k^2-1/\overline{z}_k^2)t}. \tag{3.53}$$

D. Initial value problem

According to the constraints $R_n=-Q_n^{\dagger}$ and $Q_nR_n=-\sigma_nI$, we have some additional relations besides Eqs. (3.35)–(3.38), which make the further analysis simple.

The first additional relation is

$$\det \overline{A}(z)=\left\{\det A\left(\frac{1}{z^*}\right)\right\}^*, \tag{3.54}$$

which is proved in Appendix A. This relation gives us useful information about the numbers and the positions of the poles of $A(z)^{-1}$ and $\overline{A}(z)^{-1}$. That is,

$$\overline{N}=N, \quad \overline{z_k}=\frac{1}{z_k^*}. \tag{3.55}$$

Due to Eq. (3.15c), we have the second additional relation,

$$\overline{B}(z)\overline{A}(z)^{-1}=\left\{B\left(\frac{1}{z^*}\right)A\left(\frac{1}{z^*}\right)^{-1}\right\}^{\dagger}, \tag{3.56}$$

which leads to

$$\overline{B}(z)\overline{A}(z)^{-1}=\{B(z)A(z)^{-1}\}^{\dagger} \quad (\text{on } |z|=1), \tag{3.57a}$$

$$\overline{C_k}=-\frac{1}{z_k^{*2}}C_k^{\dagger}. \tag{3.57b}$$

The relations (3.55) and (3.57) give a relation between $\overline{F_R}(n,t)$ and $F_R(n,t)$,

$$\overline{F_R}(n,t)=F_R(n,t)^{\dagger}. \tag{3.58}$$

So as to make the ISM applicable to the sd-cmKdV equations, we have to take account of the internal symmetries of Q_n and R_n defined by Eqs. (2.39)–(2.41).

If we set $Q_n^{(m)}$ and $R_n^{(m)}$ for $m\geqslant 2$ as

$$Q_n^{(m)}=v_n^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1} v_n^{(k)}e_k, \quad R_n^{(m)}=-v_n^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1} v_n^{(k)}e_k, \tag{3.59}$$

the following important relations for $2^{m-1}\times 2^{m-1}$ matrices $\{e_i\}$ hold:

$$\{e_i,e_j\}_+=-2\delta_{ij}\mathbb{1}, \tag{3.60}$$

$$e_k^{\dagger}=-e_k, \tag{3.61}$$

$$\text{tr } e_k=0. \tag{3.62}$$

Here $\{\cdot,\cdot\}_+$ means the anticommutator and $\mathbb{1}$ is the $2^{m-1}\times 2^{m-1}$ unit matrix, which has been denoted as $I_{2^{m-1}}$ so far. From Eq. (3.60), we have

$$\text{tr}(e_ie_j)=-2^{m-1}\delta_{ij}. \tag{3.63}$$

Now, we discuss the initial value problem of the sd-cmKdV equations. Considering the scattering problem (3.1) with the potentials $Q_n^{(m)}$ and $R_n^{(m)}$ for $m \geqslant 2$, we can show the following conditions on the scattering data.

Proposition III.D.1: (1) The determinant of $A(z)$ satisfies

$$\det A(z) = \{\det A(z^*)\}^*, \tag{3.64}$$

as a function of z. Thus the poles of $1/\det A(z)$ outside the unit circle should appear as pairs which are situated symmetric with respect to the real axis. Therefore, we replace N in Sec. III B with $2N$ and can set the values of $2N$ poles in the right portion outside the unit circle C as

$$z_{2j-1} = \xi_j + i\eta_j = a_j e^{i\theta_j}, \quad j = 1,2,...,N, \tag{3.65a}$$

$$z_{2j} = z_{2j-1}^* = \xi_j - i\eta_j = a_j e^{-i\theta_j}, \quad j = 1,2,...,N, \tag{3.65b}$$

where

$$a_j > 1, \quad 0 < \theta_j \leqslant \frac{\pi}{2},$$

for $\theta_j \neq 0$. The condition (3.65) should be interpreted as follows. If $\theta_j = 0$, it does not need its counterpart. The values of the remaining $2N$ poles in the left portion outside the unit circle are given by

$$z_{2N+k} = -z_k, \quad k = 1,2,...,2N.$$

(2) The reflection coefficient $B(z)A(z)^{-1}$ on $|z| = 1$ should be expressed as

$$B(z)A(z)^{-1} = r^{(0)}\mathbb{1} + \sum_{k=1}^{2m-1} r^{(k)} e_k. \tag{3.66}$$

Here $r^{(0)}$ and $r^{(k)}$ are complex functions of z and t which satisfy

$$r^{(0)}(z^*) = r^{(0)}\left(\frac{1}{z}\right) = r^{(0)}(z)^*, \quad r^{(k)}(z^*) = r^{(k)}\left(\frac{1}{z}\right) = r^{(k)}(z)^*, \tag{3.67}$$

for $|z| = 1$.

(3) The residue matrices $\{C_1, C_2, \ldots, C_{2N-1}, C_{2N}\}$ should be expressed as

$$C_{2j-1} = c_j^{(0)}\mathbb{1} + \sum_{k=1}^{2m-1} c_j^{(k)} e_k, \quad j = 1,2,...,N, \tag{3.68a}$$

$$C_{2j} = c_j^{(0)*}\mathbb{1} + \sum_{k=1}^{2m-1} c_j^{(k)*} e_k, \quad j = 1,2,...,N, \tag{3.68b}$$

where $c_j^{(0)}$ and $c_j^{(k)}$ are complex functions of t. For example, $\{C_1, C_2, \ldots, C_{2N}\}$ for the four-component $(m = 2)$ sd-cmKdV equations are given by

$$C_{2j-1} = \begin{bmatrix} \alpha_j & \beta_j \\ -\gamma_j & \delta_j \end{bmatrix}, \quad j = 1,2,...,N,$$

$$C_{2j} = \begin{bmatrix} \delta_j^* & \gamma_j^* \\ -\beta_j^* & \alpha_j^* \end{bmatrix}, \quad j = 1,2,...,N,$$

in a different notation.

A proof of the statements is given in Appendix B.

Considering the above conditions, we get explicit expressions of $F_R(n,t)$ and $\overline{F_R}(n,t)$ for odd n:

$$
\begin{aligned}
F_R(n,t) &= \frac{1}{2\pi i}\int_{C_R} B(z)A(z)^{-1}z^{-n-1}\,dz + \sum_{j=1}^{2N} C_j z_j^{-n-1} \\
&= \frac{1}{2\pi i}\int_{C_R}\left(r^{(0)}\mathbb{1} + \sum_{k=1}^{2m-1} r^{(k)}e_k\right)z^{-n-1}\,dz + \sum_{j=1}^{2N} C_j z_j^{-n-1} \\
&= \frac{1}{2\pi i}\int_{C_{UR}}\left\{(r^{(0)}z^{-n-1} + r^{(0)*}z^{*-n+1})\mathbb{1} + \sum_{k=1}^{2m-1}(r^{(k)}z^{-n-1} + r^{(k)*}z^{*-n+1})e_k\right\}dz \\
&\quad + \sum_{j=1}^{N}\left\{(c_j^{(0)}z_j^{-n-1} + c_j^{(0)*}z_j^{*-n-1})\mathbb{1} + \sum_{k=1}^{2m-1}(c_j^{(k)}z_j^{-n-1} + c_j^{(k)*}z_j^{*-n-1})e_k\right\}, \\
&= \frac{1}{2\pi i}\int_{C_{UR}}\left\{(r^{(0)}z^{-n-1} + r^{(0)*}z^{n-1})\mathbb{1} + \sum_{k=1}^{2m-1}(r^{(k)}z^{-n-1} + r^{(k)*}z^{n-1})e_k\right\}dz \\
&\quad + \sum_{j=1}^{N}\left\{(c_j^{(0)}z_j^{-n-1} + c_j^{(0)*}z_j^{*-n-1})\mathbb{1} + \sum_{k=1}^{2m-1}(c_j^{(k)}z_j^{-n-1} + c_j^{(k)*}z_j^{*-n-1})e_k\right\}, \qquad (3.69)
\end{aligned}
$$

$$
\begin{aligned}
\overline{F_R}(n,t) &= F_R(n,t)^\dagger \\
&= \frac{1}{2\pi i}\int_{C_R}\left(r^{(0)*}\mathbb{1} - \sum_{k=1}^{2m-1} r^{(k)*}e_k\right)z^{n-1}\,dz + \sum_{j=1}^{2N} C_j^\dagger z_j^{*-n-1} \\
&= \frac{1}{2\pi i}\int_{C_{UR}}\left\{(r^{(0)}z^{-n-1} + r^{(0)*}z^{n-1})\mathbb{1} - \sum_{k=1}^{2m-1}(r^{(k)}z^{-n-1} + r^{(k)*}z^{n-1})e_k\right\}dz \\
&\quad + \sum_{j=1}^{N}\left\{(c_j^{(0)}z_j^{-n-1} + c_j^{(0)*}z_j^{*-n-1})\mathbb{1} - \sum_{k=1}^{2m-1}(c_j^{(k)}z_j^{-n-1} + c_j^{(k)*}z_j^{*-n-1})e_k\right\}, \qquad (3.70)
\end{aligned}
$$

where C_{UR} denotes the quadrant (upper-right portion) of the unit circle contour C. Because $B(z)A(z)^{-1}$ and C_j depend on t as Eqs. (3.48) and (3.49), the time dependences of $r^{(0)}, r^{(k)}$ and $c_j^{(0)}, c_j^{(k)}$ are given by

$$
r^{(0)}(z,t) = r^{(0)}(z,0)e^{-(z^2-1/z^2)t}, \quad r^{(k)}(z,t) = r^{(k)}(z,0)e^{-(z^2-1/z^2)t}, \qquad (3.71)
$$

$$
c_j^{(0)}(t) = c_j^{(0)}(0)e^{-(z_j^2-1/z_j^2)t}, \quad c_j^{(k)}(t) = c_j^{(k)}(0)e^{-(z_j^2-1/z_j^2)t}. \qquad (3.72)
$$

It should be noted that $F_R(n,t)$ and $\overline{F_R}(n,t)$ for odd n are expressed as

$$
F_R(n,t) = f^{(0)}(n,t)\mathbb{1} + \sum_{k=1}^{2m-1} f^{(k)}(n,t)e_k,
$$

$$
\overline{F_R}(n,t) = f^{(0)}(n,t)\mathbb{1} - \sum_{k=1}^{2m-1} f^{(k)}(n,t)e_k,
$$

where the real functions $f^{(0)}(n,t)$ and $f^{(k)}(n,t)$ satisfy

$$
\partial_t f^{(0)}(2n+1,t) - f^{(0)}(2n+3,t) + f^{(0)}(2n-1,t) = 0,
$$

$$
\partial_t f^{(k)}(2n+1,t) - f^{(k)}(2n+3,t) + f^{(k)}(2n-1,t) = 0.
$$

Considering the relation (3.58), we get the time-dependent Gel'fand–Levitan–Marchenko equations,

$$\kappa_{1R}(n,m;t) \quad (m>n, m-n=\text{odd})$$

$$=2F_R(n+m,t)^\dagger-4\sum_{\substack{n_1=n+2\\ n_1-n=\text{even}}}^{\infty}\sum_{\substack{n_2=n+1\\ n_2-n=\text{odd}}}^{\infty}\kappa_{1R}(n,n_2;t)F_R(n_2+n_1,t)F_R(n_1+m,t)^\dagger, \tag{3.73}$$

$$\overline{\kappa}_{2R}(n,m;t) \quad (m>n, m-n=\text{odd})$$

$$=-2F_R(n+m,t)-4\sum_{\substack{n_1=n+2\\ n_1-n=\text{even}}}^{\infty}\sum_{\substack{n_2=n+1\\ n_2-n=\text{odd}}}^{\infty}\overline{\kappa}_{2R}(n,n_2;t)F_R(n_2+n_1,t)^\dagger F_R(n_1+m,t), \tag{3.74}$$

where $F_R(n,t)$ for odd n is given by Eq. (3.69).

We can solve the initial value problem of the sd-cmKdV equations as follows.

(1) For given potentials at $t=0$, $Q_n(0)$ and $R_n(0)$ which are expressed as Eq. (3.59), we solve the scattering problem (3.1), and obtain scattering data $\{B(z)A(z)^{-1}, z_j, C_j\}$ or, more concretely, $\{r^{(0)}, r^{(k)}, z_j, c_j^{(0)}, c_j^{(k)}\}$.
(2) The time dependence of the scattering data is given by Eqs. (3.48) and (3.49) [or (3.71) and (3.72)].
(3) We substitute the time-dependent scattering data into the Gel'fand–Levitan–Marchenko equations (3.73) and (3.74). Solving the equations, we reconstruct the time-dependent potentials

$$Q_n(t)=-\kappa_{1R}(n,n+1;t), \tag{3.75}$$

$$R_n(t)=-\overline{\kappa}_{2R}(n,n+1;t). \tag{3.76}$$

This directly proves the complete integrability of the sd-cmKdV equations (2.38). The same procedure is applicable to solve the initial value problem of the higher flows of the sd-cmKdV hierarchy. For instance, we can consider the Lax equation (2.6) with the L_n-matrix (3.1) whose time derivative is replaced with the second flow of the sd-cmKdV hierarchy. As a solution of such a Lax equation, we get an M_n-matrix which contains from z^4 to $1/z^4$ terms. Correspondingly, the time dependences of the scattering data (3.48)–(3.51) should be replaced by, for instance,

$$B(z,t)A(z,t)^{-1}=B(z,0)A(z,0)^{-1}e^{-(z^4-1/z^4)t}, \tag{3.77}$$

$$C_j(t)=C_j(0)e^{-(z_j^4-1/z_j^4)t}, \tag{3.78}$$

and

$$\overline{B}(z,t)\overline{A}(z,t)^{-1}=\overline{B}(z,0)\overline{A}(z,0)^{-1}e^{(z^4-1/z^4)t}, \tag{3.79}$$

$$\overline{C}_k(t)=\overline{C}_k(0)e^{(\overline{z}_k^4-1/\overline{z}_k^4)t}. \tag{3.80}$$

Employing the above time dependences, we can solve the initial value problem of the second flow of the sd-cmKdV hierarchy:

$$\frac{\partial v_n^{(i)}}{\partial t}=\left(1+\sum_{j=0}^{M-1}v_n^{(j)2}\right)\left\{\left(1+\sum_{k=0}^{M-1}v_{n+1}^{(k)2}\right)v_{n+2}^{(i)}-\left(1+\sum_{k=0}^{M-1}v_{n-1}^{(k)2}\right)v_{n-2}^{(i)}\right.$$
$$\left.-\left(\sum_{k=0}^{M-1}v_{n+1}^{(k)2}-\sum_{k=0}^{M-1}v_{n-1}^{(k)2}\right)v_n^{(i)}+2\left(\sum_{k=0}^{M-1}v_{n+1}^{(k)}v_n^{(k)}+\sum_{k=0}^{M-1}v_n^{(k)}v_{n-1}^{(k)}\right)(v_{n+1}^{(i)}-v_{n-1}^{(i)})\right\},$$
$$i=0,1,\ldots,M-1. \tag{3.81}$$

E. Soliton solutions

Assuming the reflection-free potentials which satisfy for z on $|z|=1$,

$$B(z)=\overline{B}(z)=O,$$

we can construct soliton solutions of the sd-cmKdV equations. In this case, $F_R(n,t)$ and $\overline{F}_R(n,t)$ for odd n are given by

$$F_R(n,t)=\sum_{j=1}^{2N} C_j(t)z_j^{-n-1}, \quad C_j(t)=C_j(0)e^{-(z_j^2-1/z_j^2)t}, \tag{3.82}$$

$$\overline{F}_R(n,t)=-\sum_{k=1}^{2N} \overline{C}_k(t)\overline{z}_k^{n-1}, \quad \overline{C}_k(t)=\overline{C}_k(0)e^{(\overline{z}_k^2-1/\overline{z}_k^2)t}. \tag{3.83}$$

To solve Eq. (3.42) [or Eq. (3.73)] with Eqs. (3.82) and (3.83), we set

$$\kappa_{1R}(n,m)=\sum_{k=1}^{2N} P_k(n)\overline{C}_k(t)\overline{z}_k^{n+m-1} \quad (m-n=\text{odd}). \tag{3.84}$$

Substituting Eq. (3.84) into Eq. (3.42) or Eq. (3.73), we have

$$P_k(n)-4\sum_{l=1}^{2N}\sum_{j=1}^{2N}\left(\frac{\overline{z}_l}{z_j}\right)^{2n}\frac{\overline{z}_k^2}{(z_j^2-\overline{z}_k^2)(z_j^2-\overline{z}_l^2)}P_l(n)\overline{C}_l(t)C_j(t)=-2I. \tag{3.85}$$

We introduce a matrix S defined by

$$\begin{aligned} S_{lk}&\equiv\delta_{lk}I-4\sum_{j=1}^{2N}\left(\frac{\overline{z}_l}{z_j}\right)^{2n}\frac{\overline{z}_k^2}{(z_j^2-\overline{z}_k^2)(z_j^2-\overline{z}_l^2)}\overline{C}_l(t)C_j(t)\\ &=\delta_{lk}I+4\sum_{j=1}^{2N}\frac{1}{z_j^{2n}z_l^{*2n}(z_j^2z_k^{*2}-1)(z_j^2z_l^{*2}-1)}C_l(t)^{\dagger}C_j(t), \quad 1\leqslant l,k\leqslant 2N. \end{aligned} \tag{3.86}$$

Then Eq. (3.85) is expressed by

$$(\,P_1\,P_2\cdots P_{2N}\,)\begin{pmatrix} S_{11} & \cdots & S_{1\,2N}\\ \vdots & \ddots & \vdots\\ S_{2N1} & \cdots & S_{2N\,2N}\end{pmatrix}=-2(\underbrace{I\,I\cdots I}_{2N}).$$

Similarly, to solve Eq. (3.43) [or Eq. (3.74)] with Eqs. (3.82) and (3.83), we set

$$\overline{\kappa}_{2R}(n,m)=\sum_{j=1}^{2N}\overline{P}_j(n)C_j(t)z_j^{-(n+m)-1} \quad (m-n=\text{odd}). \tag{3.87}$$

Substituting Eq. (3.87) into Eq. (3.43) or Eq. (3.74), we have

$$\overline{P}_j(n)-4\sum_{l=1}^{2N}\sum_{k=1}^{2N}\frac{\overline{z}_k^{2n+2}}{z_l^{2n}}\frac{1}{(z_l^2-\overline{z}_k^2)(z_j^2-\overline{z}_k^2)}\overline{P}_l(n)C_l(t)\overline{C}_k(t)=-2I. \tag{3.88}$$

In terms of a matrix $\overline{S}$,

$$\bar{S}_{lk} \equiv \delta_{lk} I - 4 \sum_{j=1}^{2N} \frac{\bar{z}_j^{2n+2}}{z_l^{2n}} \frac{1}{(z_l^2 - \bar{z}_j^2)(z_k^2 - \bar{z}_j^2)} C_l(t) \bar{C}_j(t)$$

$$= \delta_{lk} I + 4 \sum_{j=1}^{2N} \frac{1}{z_l^{2n} z_j^{*2n} (z_l^2 z_j^{*2} - 1)(z_k^2 z_j^{*2} - 1)} C_l(t) C_j(t)^\dagger, \quad 1 \leqslant l,k \leqslant 2N, \tag{3.89}$$

we rewrite Eq. (3.88) as

$$(\bar{P}_1 \bar{P}_2 \cdots \bar{P}_{2N}) \begin{pmatrix} \bar{S}_{11} & \cdots & \bar{S}_{1\,2N} \\ \vdots & \ddots & \vdots \\ \bar{S}_{2N1} & \cdots & \bar{S}_{2N\,2N} \end{pmatrix} = -2(\underbrace{I\, I \cdots I}_{2N}).$$

Thus the N-soliton solution of the sd-cmKdV equations (2.38) is given by

$$Q_n^{(m)}(t) = -\kappa_{1R}(n, n+1; t)$$

$$= -\sum_{k=1}^{2N} P_k(n) \bar{C}_k(t) \frac{1}{z_k^{*2n}} = -2(\underbrace{I\, I \cdots I}_{2N}) S^{-1} \begin{pmatrix} C_1(t)^\dagger \dfrac{1}{z_1^{*2n+2}} \\ C_2(t)^\dagger \dfrac{1}{z_2^{*2n+2}} \\ \vdots \\ C_{2N}(t)^\dagger \dfrac{1}{z_{2N}^{*2n+2}} \end{pmatrix}, \tag{3.90a}$$

$$R_n^{(m)}(t) = -\bar{\kappa}_{2R}(n, n+1; t)$$

$$= -\sum_{j=1}^{2N} \bar{P}_j(n) C_j(t) \frac{1}{z_j^{2n+2}} = 2(\underbrace{I\, I \cdots I}_{2N}) \bar{S}^{-1} \begin{pmatrix} C_1(t) \dfrac{1}{z_1^{2n+2}} \\ C_2(t) \dfrac{1}{z_2^{2n+2}} \\ \vdots \\ C_{2N}(t) \dfrac{1}{z_{2N}^{2n+2}} \end{pmatrix}. \tag{3.90b}$$

Rigorously, Eq. (3.90) includes solitons, breathers, and their coexistence. To extract soliton solutions, we should impose appropriate conditions on the residue matrices $\{C_j\}, \{\bar{C}_k\}$. As a criterion of soliton, we employ the condition that each solitary wave observed in the first conserved density,

$$\log\left\{1 + \sum_{j=0}^{2m-1} (v_n^{(j)}(t))^2\right\}, \tag{3.91}$$

has a time-independent shape. Calculating an asymptotic form of (3.91) at $n \to +\infty$, we find that the criterion gives necessary conditions

$$C_{2j-1}\bar{C}_{2j} = \bar{C}_{2j} C_{2j-1} = C_{2j}\bar{C}_{2j-1} = \bar{C}_{2j-1} C_{2j} = O, \quad j = 1,2,...,N. \tag{3.92}$$

Equation (3.92) is simplified to

$$\sum_{i=0}^{2m-1} (c_j^{(i)})^2 = 0, \quad j = 1,2,...,N. \tag{3.93}$$

To check the sufficiency of the conditions (3.92) or (3.93), we consider the $N=1$ case. For this purpose, we set

$$\begin{aligned}\overline{C_1} &= -\frac{1}{z_1^{*2}}\, C_1^\dagger \\ &= -\frac{1}{z_1^{*2}}\left(c_1^{(0)} * \mathbb{1} - \sum_{k=1}^{2m-1} c_1^{(k)} * e_k \right) \\ &\equiv \overline{c}_1^{(0)} \mathbb{1} + \sum_{k=1}^{2m-1} \overline{c}_1^{(k)} e_k , \end{aligned} \tag{3.94}$$

$$\overline{C_2} = \overline{c}_1^{(0)} * \mathbb{1} + \sum_{k=1}^{2m-1} \overline{c}_1^{(k)} * e_k , \tag{3.95}$$

$$\overline{z_1} = \frac{1}{z_1^*} = e^{-W+i\theta}, \quad W>0, \tag{3.96}$$

$$e^{\phi_0} = \frac{\sinh 2W}{\sqrt{2 \sum_{j=0}^{2m-1} |\overline{c}_1^{(j)}(0)|^2}}. \tag{3.97}$$

Here Eq. (3.93) for $N=1$ is rewritten as

$$\sum_{j=0}^{2m-1} (\overline{c}_1^{(j)}(0))^2 = 0. \tag{3.98}$$

With the help of the conditions (3.92), Eq. (3.90) for $N=1$ yields

$$\begin{aligned} Q_n^{(m)}(t) &= \operatorname{sech}\left\{ 2nW + \frac{1}{2}\left(z_1^2 + z_1^{*2} - \frac{1}{z_1^2} - \frac{1}{z_1^{*2}} \right) t + \phi_0 \right\} \frac{\sinh 2W}{\sqrt{2 \sum_{j=0}^{2m-1} |\overline{c}_1^{(j)}(0)|^2}} \\ &\quad \cdot \left\{ \left(\frac{z_1}{z_1^*} \right)^n \overline{C}_1(0) e^{(1/2)(z_1^2 - z_1^{*2} - 1/z_1^2 + 1/z_1^{*2})t} + \left(\frac{z_1^*}{z_1} \right)^n \overline{C}_2(0) e^{-(1/2)(z_1^2 - z_1^{*2} - 1/z_1^2 + 1/z_1^{*2})t} \right\} \\ &= \operatorname{sech}\{2nW + 2(\sinh 2W \cos 2\theta)t + \phi_0\} \frac{\sinh 2W}{\sqrt{2 \sum_{j=0}^{2m-1} |\overline{c}_1^{(j)}(0)|^2}} \\ &\quad \cdot \{ \overline{C}_1(0) e^{2i\{n\theta + (\cosh 2W \sin 2\theta)t\}} + \overline{C}_2(0) e^{-2i\{n\theta + (\cosh 2W \sin 2\theta)t\}} \}, \end{aligned} \tag{3.99a}$$

$$R_n^{(m)}(t) = -Q_n^{(m)}(t)^\dagger. \tag{3.99b}$$

Equation (3.99) can be expressed explicitly for each component as

$$\begin{aligned} v_n^{(i)}(t) &= \operatorname{sech}\{2nW + 2(\sinh 2W \cos 2\theta)t + \phi_0\} \frac{\sinh 2W}{\sqrt{2 \sum_{j=0}^{2m-1} |\overline{c}_1^{(j)}(0)|^2}} \\ &\quad \cdot \{ \overline{c}_1^{(i)}(0) e^{2i\{n\theta + (\cosh 2W \sin 2\theta)t\}} + \overline{c}_1^{(i)} * (0) e^{-2i\{n\theta + (\cosh 2W \sin 2\theta)t\}} \}, \quad i = 0,1,\ldots,2m-1. \end{aligned} \tag{3.100}$$

For the above solution, we have

$$\sum_{i=0}^{2m-1} (v_n^{(i)}(t))^2 = \sinh^2 2W \operatorname{sech}^2\{2nW + 2(\sinh 2W \cos 2\theta)t + \phi_0\}, \tag{3.101}$$

which satisfies the criterion given before. Thus, Eq. (3.100) with (3.98) is interpreted as a one-soliton solution for the sd-cmKdV equations (2.38) with $M=2m$. The structure of the one-soliton solution is essentially the same as that for the continuous cmKdV equations (1.1).[13]

This result shows that the conditions (3.92) are necessary and sufficient for Eq. (3.90) to be the pure N-soliton solution. It is noted that the number of the arbitrary parameters is larger than that of the continuous coupled NLS equations.

A comment is in order. Ohta[21] obtained an N-soliton solution for semi-discrete coupled NLS equations, which can be cast into the sd-cmKdV equations by a simple transformation. The above N-soliton solution (3.90) with the constraints (3.92) contains more parameters for general $M=2m$ than that of Ohta's. We conjecture that Ohta's result coincides with ours by a particular choice of those parameters.

It is not evident whether Eqs. (3.90a) and (3.90b) can be expressed as

$$Q_n^{(m)}(t)=v_n^{(0)}(t)\mathbb{1}+\sum_{k=1}^{2m-1} v_n^{(k)}(t)e_k, \tag{3.102a}$$

$$R_n^{(m)}(t)=-v_n^{(0)}(t)\mathbb{1}+\sum_{k=1}^{2m-1} v_n^{(k)}(t)e_k, \tag{3.102b}$$

without using the products of e_i such as $e_ie_j, e_ie_je_k$. Further, $v_n^{(0)}, v_n^{(k)}$ should be real in Eqs. (3.102a) and (3.102b). Noting the fact that summations and products of real quaternions are real quaternions, either Eq. (3.102a) or (3.102b) can be proved for $m=2$ (four-component sd-cmKdV equations) by using the Neumann–Liouville expansion (see Appendix C). It is left for a future problem to prove both Eqs. (3.102a) and (3.102b) for $M=2m\geqslant 4$ rigorously.

IV. SUMMARY AND DISCUSSIONS

In this paper, we have studied the semi-discrete version of the coupled mKdV equations (sd-cmKdV equations). To solve the model, we have presented a new extension of the discrete version of the ISM proposed by Ablowitz and Ladik.[18,19] By this extension, we have shown for the first time that the initial value problem of the sd-cmKdV equations is solvable by the ISM. We remark that both of the constraints (3.2) play an important role in the process of the ISM, while only the former constraint is necessary for the continuous theory. Further, the extension enables us to solve semi-discrete coupled NLS equations or, more generally, semi-discrete coupled Hirota equations[26] by the ISM. The details will be reported in separate papers.

The sd-cmKdV equations can be transformed into other completely integrable models. If we take new dependent variables as

$$v_{2n}^{(i)}=V_n^{(i)}, \quad v_{2n-1}^{(i)}=-I_n^{(i)},$$

the sd-cmKdV equations (2.4) are cast into a new coupled version of the self-dual network equations,[18,27]

$$\frac{1}{1-\sum_{j=0}^{M-1}\varepsilon_j V_n^{(j)2}}\frac{\partial V_n^{(i)}}{\partial t}=I_n^{(i)}-I_{n+1}^{(i)}, \tag{4.1a}$$

$$\frac{1}{1-\sum_{j=0}^{M-1}\varepsilon_j I_n^{(j)2}}\frac{\partial I_n^{(i)}}{\partial t}=V_{n-1}^{(i)}-V_n^{(i)}, \tag{4.1b}$$

with $\varepsilon_j=\pm 1$.

If we set one variable to be a constant in Eq. (2.4), for instance,

$$\varepsilon_0 v_n^{(0)2}=1 \quad \text{for all } n,$$

the sd-cmKdV equations are cast into

$$\frac{\partial v_n^{(i)}}{\partial t} = -\left(\sum_{j=1}^{M-1} \varepsilon_j v_n^{(j)2} \right)(v_{n+1}^{(i)} - v_{n-1}^{(i)}), \quad i = 1,2,...,M-1. \tag{4.2}$$

This system was studied by Hirota, who gave its molecule solutions.[22]

Shifting the variables $v_n^{(i)}$ by $v_n^{(i)} \to a_i v_n^{(i)} + b_i$, we obtain a coupled version of the generalized Volterra model:[27]

$$\frac{\partial v_n^{(i)}}{\partial t} = \left(\alpha + \sum_j \beta_j v_n^{(j)} + \sum_j \gamma_j v_n^{(j)2} \right)(v_{n+1}^{(i)} - v_{n-1}^{(i)}). \tag{4.3}$$

We believe that our extensions of the Ablowitz–Ladik hierarchy will be useful in the study of the discrete multi-component integrable models.

ACKNOWLEDGMENTS

One of the authors (TT) would like to express his hearty thanks to Professor K. Sogo, Dr. N. Sasa, Dr. M. Hisakado, and Dr. M. Shiroishi for many useful comments and fruitful discussions. While writing the paper, the authors were informed by Dr. Hisakado that the similar Lax formulation in terms of the Clifford algebra was used in the work of Eichenherr and Pohlmeyer.[28] The authors are grateful to Dr. Y. Ohta, D. Trubatch, and Professor M. J. Ablowitz for informing their results prior to publication.

In order to check the conservation laws of the semi-discrete coupled mKdV equations, the authors partly utilized profitable *Mathematica* algorithm coded by Ü. Göktaş, W. Hereman, and G. Erdmann.[29]

APPENDIX A: PROOF OF EQ. (3.54)

We start from a counterpart of the linear equations (2.5),

$$\Psi_{n+1} = L_n \Psi_n, \tag{A1}$$

where Ψ_n is assumed to be a square matrix. Then, we get a chain of identities,

$$\Psi_{n+1}\Psi_n^{-1} = L_n, \quad \frac{\det \Psi_{n+1}}{\det \Psi_n} = \det L_n,$$

$$\det \Psi_\infty = \det \Psi_{-\infty} \cdot \prod_{n=-\infty}^{\infty} \det L_n. \tag{A2}$$

We consider the case that L_n is given by

$$L_n = \begin{bmatrix} zI & Q_n \\ R_n & \dfrac{1}{z} I \end{bmatrix}, \tag{A3}$$

with $l \times l$ square matrices I, Q_n, and R_n, which satisfy the constraints (3.2). Equation (A2) gives

$$\det \Psi_\infty = \det \Psi_{-\infty} \cdot \left(\prod_{n=-\infty}^{\infty} \rho_n \right)^l = \tau^l \cdot \det \Psi_{-\infty},$$

where ρ_n and τ are defined by Eqs. (3.4) and (3.8),

$$\rho_n=(\det L_n)^{1/l}=1+\sigma_n=1+\sum_{j=0}^{2m-1} v_n^{(j)2},$$

$$\tau=\prod_{n=-\infty}^{\infty}\rho_n.$$

It should be noted that τ is a conserved quantity, which is proved by the zero-curvature condition (2.6) [see also Eq. (2.45)].

If we take $[\phi_n\ \psi_n]$ as Ψ_n, we get

$$\lim_{n\to-\infty}\det[\overline{\phi}_n\ \overline{\psi}_n]=\frac{1}{\tau^l}\cdot\det A^{\dagger}\left(\frac{1}{z^*}\right),$$

$$\lim_{n\to+\infty}\det[\overline{\phi}_n\ \overline{\psi}_n]=\det\overline{A}(z),$$

which lead to the formula to be proved,

$$\det\overline{A}(z)=\left\{\det A\left(\frac{1}{z^*}\right)\right\}^*. \tag{A4}$$

APPENDIX B: PROOF OF PROPOSITION III.D.1

Let us recall $\Gamma_n=\Psi_{2n}\Psi_{1n}^{-1}$ defined in Sec. II C. We assume

$$\lim_{|z|\to\infty}\Gamma_n=O. \tag{B1}$$

Then the relation (2.18) with Eq. (2.22) becomes

$$\begin{aligned}\Gamma_{n+1}&=\left(R_n+\frac{1}{z}\Gamma_n\right)(zI+Q_n\Gamma_n)^{-1}\\&=\left(R_n+\frac{1}{z}\Gamma_n\right)z^{-1}\sum_{j=0}^{\infty}(-1)^j\left(\frac{1}{z}Q_n\Gamma_n\right)^j\\&=\sum_{j=0}^{\infty}\frac{(-1)^j}{z^{j+1}}R_nQ_n\cdot\Gamma_n(Q_n\Gamma_n)^{j-1}+\sum_{j=0}^{\infty}\frac{(-1)^j}{z^{j+2}}\Gamma_n(Q_n\Gamma_n)^j.\end{aligned} \tag{B2}$$

Here Q_n and R_n for the $2m$-component sd-cmKdV equations (2.38) ($m\geqslant 2$) are given by

$$Q_n^{(m)}=v_n^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}v_n^{(k)}e_k,\quad R_n^{(m)}=-v_n^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}v_n^{(k)}e_k, \tag{B3}$$

which lead to

$$Q_n^{(m)}R_n^{(m)}=-\sum_{j=0}^{2m-1}v_n^{(j)2}\cdot\mathbb{1}, \tag{B4}$$

as is mentioned in (2.43).

We first show the following theorem and corollary.

Theorem B.1: Let X,Y,Z be $2^{m-1}\times 2^{m-1}$ matrices given by

$$X=x^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}x^{(k)}e_k,\quad Y=y^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}y^{(k)}e_k,\quad Z=z^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}z^{(k)}e_k,$$

where the coefficients $x^{(0)},x^{(k)}$; $y^{(0)},y^{(k)}$; $z^{(0)},z^{(k)}$ are real. Then there exist real numbers $w^{(0)},w^{(k)}$ that satisfy

$$W\equiv XYZ+ZYX=w^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}w^{(k)}e_k. \tag{B5}$$

A proof is given in Ref. 13. □

Corollary B.2: Let X,Y be $2^{m-1}\times 2^{m-1}$ matrices given by

$$X=x^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}x^{(k)}e_k,\quad Y=y^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}y^{(k)}e_k,$$

where the coefficients $x^{(0)},x^{(k)}$; $y^{(0)},y^{(k)}$ are real. Then there exist real numbers $s_j^{(0)},s_j^{(k)}$ that satisfy

$$\begin{aligned}S_j&\equiv(XY)^{j-1}X=X(YX)^{j-1}\\&=s_j^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}s_j^{(k)}e_k.\end{aligned} \tag{B6}$$

The statement can be proved from Theorem B.1, by induction. □

Using Corollary B.2, we can prove by induction that Γ_n is expressed by

$$\Gamma_n=\gamma_n^{(0)}\mathbb{1}+\sum_{k=1}^{2m-1}\gamma_n^{(k)}e_k, \tag{B7}$$

where the coefficients $\gamma_n^{(0)}$ and $\gamma_n^{(k)}$ satisfy

$$\gamma_n^{(0)}(z)=\{\gamma_n^{(0)}(z^*)\}^*,\quad \gamma_n^{(k)}(z)=\{\gamma_n^{(k)}(z^*)\}^*. \tag{B8}$$

In other words, $\gamma_n^{(0)}(z)$ and $\gamma_n^{(k)}(z)$ are polynomials in $1/z$ with real coefficients. This fact is particularly easy to understand when the potentials Q_n and R_n are on compact support.

We recall the asymptotic behavior of the Jost function ϕ_n at $n\to\pm\infty$,

$$\phi_n\equiv\begin{bmatrix}\phi_{1n}\\ \phi_{2n}\end{bmatrix}\sim\begin{bmatrix}I\\ O\end{bmatrix}z^n \qquad \text{as } n\to-\infty,$$

$$\sim\begin{bmatrix}A(z)z^n\\ B(z)z^{-n}\end{bmatrix} \quad \text{as } n\to+\infty.$$

These relations yield

$$\lim_{n\to-\infty}\phi_{1n}z^{-n}=I,\quad \lim_{n\to+\infty}\phi_{1n}z^{-n}=A(z). \tag{B9}$$

We see that

$$\lim_{|z|\to\infty}\phi_{2n}\phi_{1n}^{-1}=O.$$

Then we can replace Γ_n in Eq. (B7) with $\phi_{2n}\phi_{1n}^{-1}$. Thus $\det A(z)$ is expressed as

$$\begin{aligned}
\det A(z) &= \exp\{\mathrm{tr}\ \log A(z)\} \\
&= \exp\left\{ \mathrm{tr} \sum_{n=-\infty}^{\infty} [\log(\phi_{1n+1}z^{-n-1}) - \log(\phi_{1n}z^{-n})] \right\} \\
&= \exp\left\{ \mathrm{tr} \sum_{n=-\infty}^{\infty} \log[\phi_{1n+1}\phi_{1n}^{-1}z^{-1}] \right\} \\
&= \exp\left\{ \mathrm{tr} \sum_{n=-\infty}^{\infty} \log\left[I + \frac{1}{z} Q_n^{(m)}\phi_{2n}\phi_{1n}^{-1} \right] \right\} \\
&= \exp\left\{ \mathrm{tr} \sum_{n=-\infty}^{\infty} \sum_{j=1}^{\infty} \frac{(-1)^{j-1}}{j} \left(\frac{1}{z} Q_n^{(m)}\Gamma_n \right)^j \right\} \\
&= \exp\left\{ \mathrm{tr} \sum_{n=-\infty}^{\infty} \sum_{j=1}^{\infty} \frac{(-1)^{j-1}}{j\cdot z^j} Q_n^{(m)} \cdot (\Gamma_n Q_n^{(m)})^{j-1}\Gamma_n \right\} \\
&= \exp\left\{ \mathrm{tr} \sum_{n=-\infty}^{\infty} \sum_{j=1}^{\infty} \frac{(-1)^{j-1}}{j\cdot z^j} Q_n^{(m)} \left(s_{j,n}^{(0)}\mathbb{1} + \sum_{k=1}^{2m-1} s_{j,n}^{(k)} e_k \right) \right\} \\
&= \exp\left\{ 2^{m-1} \sum_{n=-\infty}^{\infty} \sum_{j=1}^{\infty} \frac{(-1)^{j-1}}{j\cdot z^j} \left(v_n^{(0)} s_{j,n}^{(0)} - \sum_{k=1}^{2m-1} v_n^{(k)} s_{j,n}^{(k)} \right) \right\}. \qquad \text{(B10)}
\end{aligned}$$

At the last equality, we have used Eqs. (3.62) and (3.63). Due to Eq. (B8), $\det A(z)$, as a function of z, satisfies

$$\det A(z) = \{\det A(z^*)\}^*. \qquad \text{(B11)}$$

This is a proof of Proposition III.D.1 (1).

Further, we obtain

$$\begin{aligned}
B(z)A(z)^{-1} &= \lim_{n\to+\infty} \phi_{2n}\phi_{1n}^{-1}\cdot z^{2n} \\
&= \lim_{n\to+\infty} \left[\gamma_n^{(0)}(z) z^{2n}\mathbb{1} + \sum_{k=1}^{2m-1} \gamma_n^{(k)}(z) z^{2n} e_k \right] \\
&= r^{(0)}(z)\mathbb{1} + \sum_{k=1}^{2m-1} r^{(k)}(z) e_k, \qquad \text{(B12)}
\end{aligned}$$

with conditions

$$r^{(0)}(z) = \{r^{(0)}(z^*)\}^*, \quad r^{(k)}(z) = \{r^{(k)}(z^*)\}^*. \qquad \text{(B13)}$$

Using Eqs. (B12) and (B13), we can straightforwardly prove Proposition III.D.1 (2) and (3).

APPENDIX C: NEUMANN–LIOUVILLE EXPANSION

We begin with the Gel'fand–Levitan–Marchenko equations (3.42) and (3.43),

$$\begin{aligned}
&\kappa_{1R}(n,m) \quad (m>n, m-n = \text{odd}) \\
&= 2\overline{F}_R(n+m) - 4\sum_{l_1=1}^{\infty}\sum_{l_2=1}^{\infty} \kappa_{1R}(n, n+2l_2-1) F_R(2n+2l_2+2l_1-1)\overline{F}_R(n+2l_1+m),
\end{aligned} \qquad \text{(C1)}$$

$$\overline{\kappa}_{2R}(n,m) \quad (m>n, m-n=\text{odd})$$
$$= -2F_R(n+m) - 4\sum_{l_1=1}^{\infty}\sum_{l_2=1}^{\infty} \overline{\kappa}_{2R}(n,n+2l_2-1)\overline{F}_R(2n+2l_2+2l_1-1)F_R(n+2l_1+m). \tag{C2}$$

By successive approximations, we obtain the Neumann–Liouville expansion for κ_{1R} and $\overline{\kappa}_{2R}$,

$$\kappa_{1R}(n,n+1)$$
$$= 2\overline{F}_R(2n+1) - 8\sum_{l_1=1}^{\infty}\sum_{l_2=1}^{\infty} \overline{F}_R(2n+2l_2-1)F_R(2n+2l_2+2l_1-1)\overline{F}_R(2n+2l_1+1)+\cdots$$
$$+2\cdot(-4)^j\sum_{l_1=1}^{\infty}\sum_{l_2=1}^{\infty}\cdots\sum_{l_{2j}=1}^{\infty} \overline{F}_R(2n+2l_{2j}-1)F_R(2n+2l_{2j}+2l_{2j-1}-1)$$
$$\cdot\overline{F}_R(2n+2l_{2j-1}+2l_{2j-2}-1)\cdots\overline{F}_R(2n+2l_3+2l_2-1)F_R(2n+2l_2+2l_1-1)$$
$$\cdot\overline{F}_R(2n+2l_1+1)+\cdots, \tag{C3}$$

$$\overline{\kappa}_{2R}(n,n+1)$$
$$= -2F_R(2n+1) + 8\sum_{l_1=1}^{\infty}\sum_{l_2=1}^{\infty} F_R(2n+2l_2-1)\overline{F}_R(2n+2l_2+2l_1-1)F_R(2n+2l_1+1)+\cdots$$
$$-2\cdot(-4)^j\sum_{l_1=1}^{\infty}\sum_{l_2=1}^{\infty}\cdots\sum_{l_{2j}=1}^{\infty} F_R(2n+2l_{2j}-1)\overline{F}_R(2n+2l_{2j}+2l_{2j-1}-1)$$
$$\cdot F_R(2n+2l_{2j-1}+2l_{2j-2}-1)\cdots F_R(2n+2l_3+2l_2-1)\overline{F}_R(2n+2l_2+2l_1-1)$$
$$\cdot F_R(2n+2l_1+1)+\cdots. \tag{C4}$$

Possibly degenerate tetrad gravity and Maxwell–Dirac fields

Daniel Canarutto[a)]
Dipartimento di Matematica Applicata ''G. Sansone,'' Via S. Marta 3, 50139 Firenze, Italia

(Received 20 November 1997; accepted for publication 19 May 1998)

I present an integrated approach to tetrad gravity and Maxwell–Dirac fields, which is not singular in the case when the tetrad is degenerate. All field equations are linear. The geometric data consist only of a complex vector bundle $\mathbf{S}\to\mathbf{M}$ with two-dimensional fibers, where $\mathbf{M}$ is a real 4-manifold. All needed structures are functorially derived from $\mathbf{S}$. Any considered object which is not a functorial construction is assumed to be a dynamical field. © *1998 American Institute of Physics.* [S0022-2488(98)03809-2]

I. INTRODUCTION

In the classical two-spinor formalism[1,2] the correspondence $v^a \leftrightarrow v^{AA\cdot}$ between spacetime and spinor indices is usually considered as ''adapted'' to the spacetime metric, which represents the gravitational field, according to $g_{ab}\leftrightarrow \boldsymbol{\epsilon}_{AB}\boldsymbol{\epsilon}_{A\cdot B\cdot}$. A somewhat different attitude consists in viewing that correspondence as the gravitational field itself. Namely, if $\mathbf{S}$ is a complex vector bundle with two-dimensional fibers, one can formulate a ''tetrad-gravity'' approach in which the tetrad is valued in the Hermitian subspace $\mathbf{H}$ of $\mathbf{S}\otimes\overline{\mathbf{S}}$. We obtain an integrated formulation of Einstein–Cartan–Maxwell–Dirac fields by assuming *minimal geometric data*: All the needed geometric structures are derived functorially from $\mathbf{S}$, without fixing any extra background field; if we consider an object which is not functorially determined from $\mathbf{S}$, then it is a dynamical field of the theory. So, the tetrad is a map $\Theta: T\mathbf{M}\to\mathbf{H}$; a linear connection $\mathrm{\Gamma}$ on $\mathbf{S}$ naturally splits into the gravitational and electromagnetic parts; the Dirac field ψ is a section of $\mathbf{W}:=\mathbf{S}\oplus\overline{\mathbf{S}}^{\bigstar}$ (there is a natural Clifford map $\mathbf{H}\to\mathrm{End}\mathbf{W}$). Even coupling factors naturally arise as covariantly constant sections of (tensor) powers of a real line bundle $\mathbf{L}$, where $\mathbf{L}^2:=\mathbf{L}\otimes\mathbf{L}$ is defined to be the Hermitian subbundle of $\wedge^2\mathbf{S}\otimes\wedge^2\overline{\mathbf{S}}$. This $\mathbf{L}$ can be seen as the ''space of length units'' (a spacetime object tensorialized by some power of $\mathbf{L}$ might be called a ''conformal density'' [1]). In general I will not assume a given $\boldsymbol{\epsilon}\in\wedge^2\mathbf{S}^{\bigstar}$, or a given Hermitian metric on the fibers of $\mathbf{S}$ (a global fixed $\boldsymbol{\epsilon}$ implies that $\wedge^2\mathbf{S}$ is a trivializable bundle, thus excluding the possibility of describing topological effects).

If we translate *directly* the standard Einstein–Cartan–Maxwell–Dirac theory in terms of the above said fields Θ, $\mathrm{\Gamma}$, and ψ, then we are forced to use Θ^{-1} (in the standard formulation, the inverse $g^{\#}$ of the spacetime metric is essential). However, it has been suggested[3] that a theory which remains nonsingular also when Θ is degenerate may be interesting in view of quantization: it would allow metric signature change, and the degenerate case could be seen as a geometrical basis for a stochastical approach to quantum theory. From the mathematical point of view, the nonsingularity requirement constitutes a selection criterion which leads to a particularly simple formulation.

The novelties of this paper, with respect to the previous one,[4] are essentially the following: now, also the treatment of the electromagnetic field satisfies the nonsingularity criterion and is well integrated with the rest—as a consequence, all Lagrangians and equations are first order; the study of the electromagnetic gauge in this context (Sec. VII) is new; the description of two-spinor connections is improved, leading to simpler expressions of the field equations, and in particular of the generalized Dirac equation; some conventions have been changed in order to have a description more consistent and readily comparable with standard approaches.

II. TWO-SPINORS REVISITED

A. Complex spaces

If X is any set and $f:X\to\mathbb{C}$ then we denote by $\overline{f}$ the conjugate map, $\overline{f}(x):=\overline{f(x)}$.

If $\mathbf{V}$ is a finite-dimensional complex vector space then we shall denote by $\mathbf{V}^\star$ and $\mathbf{V}^*$ its complex and real dual spaces, respectively. Moreover we shall denote by $\overline{\mathbf{V}}^\star$ the antidual space (i.e., the space of all antilinear maps $\mathbf{V}\to\mathbb{C}$), and by $\overline{\mathbf{V}}:=(\mathbf{V}^\star)^\star$ the conjugate space (then $\overline{\mathbf{V}}^\star\cong\mathbf{V}^\star$). We have the conjugation anti-isomorphisms $\mathbf{V}^\star\to\overline{\mathbf{V}}^\star$ and $\mathbf{V}\to\overline{\mathbf{V}}$.

Let (ζ_a) be a basis of $\mathbf{V}$, $a=1,\ldots,n$, and (z^a) the dual basis of $\mathbf{V}^\star$. Then we have the conjugate bases $(\overline{\zeta}_{a\cdot}):=(\overline{\zeta_a})$ of $\overline{\mathbf{V}}$ and $(\overline{z}^{\overline{a}}):=(\overline{z^a})$ of $\overline{\mathbf{V}}^\star$. If $v=v^a\zeta_a$ and $\lambda=\lambda_a z^a$ then $\overline{v}=\overline{v}^{\overline{a}}\overline{\zeta}_{a\cdot}$ and $\overline{\lambda}=\overline{\lambda}_{a\cdot}\overline{z}^{\overline{a}}$ with $\overline{v}^{\overline{a}}=\overline{v^a}$, $\overline{\lambda}_{a\cdot}=\overline{\lambda_a}$.

Conjugation can be naturally extended to tensor products of the above spaces with any number of factors. If τ is a tensor then $\overline{\tau}$ has dotted indices in the place of nondotted indices of τ, and vice-versa. A tensor $w\in\mathbf{V}\otimes\overline{\mathbf{V}}$ is said to be Hermitian if $\overline{w}=w^T$, where the superscript T denotes transposition. In coordinates this means $\overline{w}^{b\cdot a}=w^{ab\cdot}$. We have the *real* decomposition $\mathbf{V}\otimes\overline{\mathbf{V}}=H\mathbf{V}\oplus iH\mathbf{V}$ into Hermitian and anti-Hermitian subspaces.

If $\mathbf{V}$ is one-dimensional then $\mathbf{V}\cong\mathbf{V}^{1/2}\otimes\mathbf{V}^{1/2}$ where $\mathbf{V}^{1/2}$ is its *square root* space, which is unique up to an isomorphism. Similarly one defines $\mathbf{V}^{1/p}$ for $p\in\mathbb{N}$, hence also $\mathbf{V}^{q/p}$ for $p,q\in\mathbb{N}$. If we set $\mathbf{V}^{-1}:=\mathbf{V}^\star$, the power of a one-dimensional complex vector space is naturally defined for all rational exponents.

B. Two-spinor space

Let $\mathbf{S}$ be a two-dimensional complex vector space. We set $\mathbf{\Lambda}^2:=\wedge^2\mathbf{S}$ and identify $\mathbf{\Lambda}^{-2}:=\mathbf{\Lambda}^{2\star}$ with $\wedge^2\mathbf{S}^\star$ through the rule[5] $\omega(s\wedge s'):=\frac{1}{2}\omega(s,s')$, $\forall\,\omega\in\wedge^2\mathbf{S}^\star$, $s,\,s'\in\mathbf{S}$, where $s\wedge s':=\frac{1}{2}(s\otimes s'-s'\otimes s)$. If $\omega\neq 0$ then it has a unique ''inverse'' or ''dual'' element $\omega^{-1}\equiv\omega^\star$ such that $\omega(\omega^{-1})=1$.

The Hermitian subspace of $\mathbf{\Lambda}^2\otimes\overline{\mathbf{\Lambda}^2}$ is a real vector space with a distinguished orientation; its positive semispace will be indicated by $\mathbf{L}^2$, thus $\mathbf{\Lambda}^2\otimes\overline{\mathbf{\Lambda}^2}=\mathbb{C}\otimes\mathbf{L}^2$. Moreover we have the square root semispace $\mathbf{L}$, characterized by $\mathbf{L}^2\cong\mathbf{L}\otimes\mathbf{L}$. If r is any rational number then we define $\mathbf{\Lambda}^r:=(\mathbf{\Lambda}^2)^{r/2}$, hence $\mathbf{\Lambda}^r\otimes\overline{\mathbf{\Lambda}^r}=\mathbb{C}\otimes\mathbf{L}^r$. In particular we obtain $(r=1)$ the square root $\mathbf{\Lambda}$ of $\mathbf{\Lambda}^2$.

Next, consider the complex two-dimensional space

$$\mathbf{U}:=\mathbf{L}^{-1/2}\otimes\mathbf{S},$$

and observe that the one-dimensional space $\wedge^2\mathbf{U}=\mathbf{L}^*\otimes\wedge^2\mathbf{S}$ has a natural Hermitian metric; hence there is the distinguished set of normalized symplectic forms on $\mathbf{U}$, differing by a phase factor. This is our 2-*spinor space*. We say that elements of $\mathbf{U}$ and of its tensor algebra are ''conformally invariant,'' while tensorializing by $\mathbf{L}^r$ we obtain ''conformal densities'' of weight r.

Any basis (ξ_A) of $\mathbf{S}$ determines the basis $w:=\boldsymbol{\epsilon}^{AB}\xi_A\wedge\xi_B$ of $\mathbf{\Lambda}^2$, where $\boldsymbol{\epsilon}^{AB}$ is the antisymmetric Ricci matrix, and the basis $l:=\sqrt{w\otimes\overline{w}}$ of $\mathbf{L}$. Then we also have the induced *normalized* basis $(\zeta_A):=(l^{-1/2}\otimes\xi_A)$ of $\mathbf{U}$ and its dual basis (z^A); the induced (mutually dual) bases $\boldsymbol{\epsilon}:=\boldsymbol{\epsilon}_{AB}z^A\wedge z^B\in\wedge^2\mathbf{U}^\star$ and $\boldsymbol{\epsilon}^*\equiv\boldsymbol{\epsilon}^{-1}=\boldsymbol{\epsilon}^{AB}\zeta_A\wedge\zeta_B\in\wedge^2\mathbf{U}$ are then normalized too.

Note that, in contrast to the usual 2-spinor formalism, no ''symplectic'' 2-form $\boldsymbol{\epsilon}$ is fixed in general. Two-spinor indices may be lowered and raised by $\boldsymbol{\epsilon}_{AB}$ and its inverse $\boldsymbol{\epsilon}^{AB}$, but this operation is not intrinsic. However, $\boldsymbol{\epsilon}\otimes\overline{\boldsymbol{\epsilon}}$ is an intrinsic object (Sec. II C). Also, one has a distinguished symplectic 2-form on the space $\mathbf{U}':=(\wedge^2\mathbf{U})^{-1/2}\otimes\mathbf{U}=\mathbf{\Lambda}^{-1}\otimes\mathbf{S}$.

C. Lorentz structure

There is a natural bilinear form $\tilde{g}$ on $\mathbf{U}\otimes\overline{\mathbf{U}}$, given for decomposable elements by

$$\tilde{g}(p\otimes\overline{q},r\otimes\overline{s})=\boldsymbol{\epsilon}(p,r)\overline{\boldsymbol{\epsilon}}(\overline{q},\overline{s}),$$

where $\boldsymbol{\epsilon}$ is any normalized symplectic form. If we consider the decomposition of $\mathbf{U}\otimes\overline{\mathbf{U}}$ into its Hermitian and anti-Hermitian real subspaces, namely

$$\mathbf{U}\otimes\overline{\mathbf{U}}=\mathbf{H}\oplus i\mathbf{H},$$

then it turns out that the restriction of $\tilde{g}$ to $\mathbf{H}$ is a Lorentz metric with signature $(+,-,-,-)$; in fact a normalized basis (ζ_A) induces the basis $(\tau_\lambda := \tau_\lambda^{AB'}\zeta_A\otimes\overline{\zeta_{B'}})$ of $\mathbf{H}$ (where the $(\tau_\lambda^{AB'})$'s are the Pauli matrices divided by $\sqrt{2}$) which turns out to be a $\tilde{g}$-orthonormal basis, i.e., $\tilde{g}(\tau_\lambda,\tau_\mu)=\eta_{\lambda\mu}$. Moreover $\tilde{g}$ determines, up to sign, a normalized volume form $\tilde{\eta}$ on $\mathbf{H}$.

Next we observe that an element of $\mathbf{U}\otimes\overline{\mathbf{U}}$ can be seen as a linear map $\mathbf{U}^\star\to\mathbf{U}$, while an element of $\mathbf{U}^\star\otimes\mathbf{U}^\star$ can be seen as a linear map $\mathbf{U}\to\overline{\mathbf{U}}^\star$. Then we define the map

$$\tilde{\gamma}:\mathbf{U}\otimes\overline{\mathbf{U}}\to\mathrm{End}(\mathbf{U}\oplus\overline{\mathbf{U}}^\star):y\mapsto\tilde{\gamma}(y):=\sqrt{2}(y+\overline{y^b}),$$

where y^b is the element of $\mathbf{U}^\star\otimes\overline{\mathbf{U}}^\star$ corresponding to y via the ''index lowering'' isomorphism induced by $\tilde{g}$.

The restriction of $\tilde{\gamma}$ to $\mathbf{H}$ turns out to be a Clifford map. Thus we are led to regard $\mathbf{W}:=\mathbf{U}\oplus\overline{\mathbf{U}}^\star$ as the space of Dirac spinors, decomposed into its Weyl subspaces. Given $\psi=u+\chi\in\mathbf{W}$, its ''Dirac adjoint'' is $\overline{\psi}=\overline{\chi}+\overline{u}\in\mathbf{U}^\star\oplus\overline{\mathbf{U}}\equiv\mathbf{W}^\star$.

III. TWO-SPINOR CONNECTIONS

We consider any manifold $\mathbf{M}$ and a complex vector bundle $\mathbf{S}\to\mathbf{M}$ with two-dimensional fibers. Base coordinates are indicated by (x^a). According to the constructions of the Sec. II, we now have the bundles $\mathbf{\Lambda}^2$, $\mathbf{L}$, $\mathbf{U}$, $\mathbf{H}$ over $\mathbf{M}$, with smooth natural structures. Moreover we have the semivector bundles $\mathbf{L}^r$, with r rational. But observe that, for given r, according to the bundle topology we may have no $\mathbf{\Lambda}^r=(\mathbf{\Lambda}^2)^{r/2}$, or we may have one or more (not isomorphic) such bundles. We always obtain a unique $\mathbf{\Lambda}^r$ by a suitable restriction of the base manifold; in particular, locally we obtain a bundle $\mathbf{\Lambda}=(\wedge^2\mathbf{S})^{1/2}$.

A complex-linear connection $\mathrm{Б}$ on $\mathbf{S}\to\mathbf{M}$ induces connections on each of the above bundles. Consider a frame (ξ_A) of $\mathbf{S}$ and the induced frames l of $\mathbf{L}$ and (ξ_A) of $\mathbf{U}$ (Sec. II B). Denote by $\mathrm{Б}_a{}^A{}_B$ the coefficients of $\mathrm{Б}$ in the frame (ξ_A). Then one finds

$$\nabla l=-G_a\mathrm{d}x^a\otimes l,\quad \nabla\epsilon=2iA_a\mathrm{d}x_a\otimes\epsilon,$$

where

$$A_a=\frac{1}{4i}(\mathrm{Б}_a{}^A{}_A-\overline{\mathrm{Б}}_a{}^{A'}{}_{A'}),\quad G_a=\tfrac{1}{4}(\mathrm{Б}_a{}^A{}_A+\overline{\mathrm{Б}}_a{}^{A'}{}_{A'}).$$

Since G_a and A_a are real, we see that $\mathrm{Б}$ actually yields a linear connection on $\mathbf{L}$, and that the induced linear connection on $\wedge^2\mathbf{U}$ is Hermitian.

Next consider the linear connection $\tilde{\Gamma}$ induced by $\mathrm{Б}$ on $\mathbf{U}\otimes\overline{\mathbf{U}}$; a calculation shows that its coefficients $\tilde{\Gamma}^\mu_{a\lambda}$ in the Hermitian frame (τ_λ) are real, hence $\tilde{\Gamma}$ is reducible to a real linear connection on the Hermitian subbundle $\mathbf{H}$. Moreover $\tilde{\Gamma}$ is metric, i.e., $\nabla\tilde{g}=0$.

A basic result (see also Ref. 4) is now that, conversely, $\mathrm{Б}$ can be unically expressed in terms of the induced connections $\tilde{\Gamma}$, G, and A by

$$\mathrm{Б}_a{}^A{}_B=(G_a+iA_a)\delta^A{}_B+\tfrac{1}{2}\tilde{\Gamma}_a{}^{AA'}{}_{BA'},$$

where $\tilde{\Gamma}_a{}^{AA'}{}_{BB'}:=\tilde{\Gamma}^\lambda_{a\mu}\tau_\lambda{}^{AA'}\tau^\mu{}_{BB'}$. A similar relation holds among the curvature tensors of the considered connections, namely

$$R_{ab}{}^A{}_B=-(dG+i\mathrm{d}A)_{ab}\delta^A{}_B+\tfrac{1}{2}\tilde{R}_{ab}{}^{AA'}{}_{BA'}.$$

IV. GAUGE TRANSFORMATIONS

The principal bundle of all frames of $\mathbf{S}$ has the structure group $\mathrm{Gl}(2,\mathbb{C})$. For $K\in\mathrm{Gl}(2,\mathbb{C})$, consider the transformations induced on $\wedge^2\mathbf{S}$, $\mathbf{L}$, $\mathbf{U}$, $\wedge^2\mathbf{U}$, and $\mathbf{H}$:

$$K_{\wedge^2\mathbf{S}} = \det K, \qquad K_{\mathbf{L}} = |\det K|, \qquad K_{\mathbf{U}} = |\det K|^{-1/2} K,$$

$$K_{\wedge^2\mathbf{U}} = |\det K|^{-1} \det K = \exp(i \arg\det K),$$

$$\widetilde{K}^{\mu}_{\lambda} := (K_{\mathbf{H}})^{\mu}_{\lambda} = |\det K|^{-1} \tau_{\lambda}{}^{AA\cdot} K^{B}_{A} \overline{K}^{B\cdot}_{A\cdot} \tau^{\mu}{}_{BB\cdot}.$$

Since $\mathrm{Gl}(2,\mathbb{C})$ is connected we see that $K_{\mathbf{H}}$ preserves orientation, namely we have a way of selecting ''positive'' orientations on **H**: those orientations for which the ''Pauli basis'' (τ_λ) induced by any basis of **S** is positively oriented.

In this paper I will assume that the curvature of the connection G on **L** vanishes, $dG = 0$. This amounts to gauging away the conformal (''dilaton'') symmetry, so that the fundamental bundle is $\mathbf{U} \to \mathbf{M}$. The gauge group now reduces to transformations of the form $|\det K|^{-1/2} K$, with $K \in \mathrm{Gl}(2,\mathbb{C})$. Namely the gauge group is constituted by all complex 2×2 matrices having the module of the determinant equal to 1. This group is

$$\widetilde{\mathrm{Sl}}(2,\mathbb{C}) := (\mathrm{U}(1) \times \mathrm{Sl}(2,\mathbb{C}))/\mathbb{Z}_2,$$

where $\mathbb{Z}_2$ is identified with the normal subgroup of $\mathrm{U}(1)\times\mathrm{Sl}(2,\mathbb{C})$ generated by $(-1, -\mathbf{1})$.

V. TWO-SPINOR TETRAD

A. Tetrad and related fields

From now on I assume that **M** is a real four-dimensional manifold. Consider a linear morphism

$$\Theta : T\mathbf{M} \to \mathbf{S} \otimes \overline{\mathbf{S}} = \mathbb{C} \otimes \mathbf{L} \otimes \mathbf{H},$$

i.e., a section

$$\Theta : \mathbf{M} \to \mathbb{C} \otimes \mathbf{L} \otimes \mathbf{H} \otimes T^*\mathbf{M}$$

(all tensor products are over **M**). Its coordinate expression is

$$\Theta = \Theta^{\lambda}_{a}\, l \otimes \tau_{\lambda} \otimes \mathrm{d}x^a = \Theta^{AA\cdot}_{a}\, l \otimes \zeta_A \otimes \overline{\zeta}_{A\cdot} \otimes \mathrm{d}x^a,$$

with Θ^{λ}_{a}, $\Theta^{AA\cdot}_{a} : \mathbf{M} \to \mathbb{C}$. If we restrict our attention to the case when Θ is nondegenerate and valued in the Hermitian subspace $\mathbf{L}\otimes\mathbf{H} \subset \mathbf{S}\otimes\overline{\mathbf{S}}$, then we can view Θ as a ''scaled'' *tetrad* (or *soldering form*, or *vierbein*). In that case the coefficients Θ^{λ}_{a} are real while $\Theta^{AA\cdot}_{a}$ are Hermitian, $\overline{\Theta}^{A\cdot A}_{a} = \Theta^{AA\cdot}_{a}$. By abuse of language we shall call any Θ a (possibly degenerate) tetrad.

From Θ we obtain the following objects (in general, an object ''living'' in **H** will be distinguished by a tilde from its corresponding—via Θ—spacetime object):

$$g := \Theta^* \tilde{g} : \mathbf{M} \to \mathbb{C} \otimes \mathbf{L}^2 \otimes T^*\mathbf{M} \otimes T^*\mathbf{M},$$

$$\eta := \Theta^* \tilde{\eta} : \mathbf{M} \to \mathbb{C} \otimes \mathbf{L}^4 \otimes \wedge^4 T^*\mathbf{M},$$

$$\gamma := \tilde{\gamma} \circ \Theta : T\mathbf{M} \to \mathbb{C} \otimes \mathbf{L} \otimes \mathrm{End}(\mathbf{W}).$$

We have the coordinate expressions:

$$g = \eta_{\lambda\mu} \Theta^{\lambda}_{a} \Theta^{\mu}_{b}\, l^2 \otimes \mathrm{d}x^a \otimes \mathrm{d}x^b = \epsilon_{AB} \epsilon_{A\cdot B\cdot} \Theta^{AA\cdot}_{a} \Theta^{BB\cdot}_{b}\, l^2 \otimes \mathrm{d}x^a \otimes \mathrm{d}x^b,$$

$$\eta = \det(\Theta)\, l^4 \otimes \mathrm{d}x^0 \wedge \mathrm{d}x^1 \wedge \mathrm{d}x^2 \wedge \mathrm{d}x^3,$$

$$\gamma = \sqrt{2}\, \Theta^{AA\cdot}_{a}\, l \otimes (\zeta_A \otimes \overline{\zeta}_{A\cdot} + \epsilon_{AB}\epsilon_{A\cdot B\cdot} \overline{z}^{B\cdot} \otimes z^B) \otimes \mathrm{d}x^a.$$

If and only if Θ is real and nondegenerate, the above objects turn out to be a conformal Lorentz metric, the corresponding (up to sign, unique) conformal volume form and a conformal Clifford map.

B. Cotetrad

The following construction holds for any (possibly degenerate) Θ. For $p=0,1,2,3,4$ consider the map

$$\check{\Theta}^{(p)}:\wedge^p(\mathbf{S}\otimes\overline{\mathbf{S}})\otimes(\wedge^p T^*\mathbf{M})\to\mathbb{C}\otimes\mathbf{L}^4\otimes\wedge^4 T^*\mathbf{M}$$

defined by

$$\check{\Theta}^{(p)}(\xi):=\frac{1}{(4-p)!}\circ\tilde{*}[\xi\wedge(\wedge^{4-p}\Theta)],$$

where $\tilde{*}$ is the Hodge operator, in the exterior algebra $\wedge(\mathbf{H})$, determined by $\tilde{\eta}$. In particular, we shall be concerned with $\check{\Theta}^{(2)}$ and $\check{\Theta}:=\check{\Theta}^{(1)}$, which I call the *co-tetrad* (it may be seen as a kind of ''pseudoinverse'' of Θ, defined even if Θ is degenerate). We have the coordinate expression

$$\check{\Theta}(\xi)=\check{\Theta}^a_\lambda\xi^\lambda_a l^4\otimes\mathrm{d}^4x:=\frac{1}{3!}\,\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}\Theta^\mu_b\Theta^\nu_c\Theta^\rho_d\xi^\lambda_a l^4\otimes\mathrm{d}^4x.$$

Clearly $\check{\Theta}$ can also be seen as a linear map $\mathbf{S}\otimes\overline{\mathbf{S}}\to\mathbb{C}\otimes\mathbf{L}^4\otimes T\mathbf{M}\otimes\wedge^4 T^*\mathbf{M}$ over $\mathbf{M}$. Using this point of view, in the nondegenerate case we can write $\check{\Theta}=\Theta^{-1}\otimes\eta$.

C. Tetrad and connections

A further point about the nondegenerate case deals with connections, and will turn out to be essential for recovering the standard interpretation: if $\mathbb{B}$ is a complex-linear connection on $\mathbf{S}$, and G and $\tilde{\Gamma}$ are the induced connections on $\mathbf{L}$ and $\mathbf{H}$, then a nondegenerate tetrad $\Theta:T\mathbf{M}\to\mathbf{L}\otimes\mathbf{H}$ yields a unique connection Γ on $T\mathbf{M}$, characterized by the condition

$$\nabla[\Gamma\otimes\tilde{\Gamma}]\Theta=0.$$

Moreover Γ is metric, i.e., $\nabla[\Gamma]g=0$. Denoting by ${\Gamma_a}^\lambda{}_\mu$ the coefficients of Γ in the frame $\Theta_\lambda:=\Theta^{-1}(l\otimes\tau_\lambda)$ we obtain

$${\Gamma_a}^\lambda{}_\mu={\tilde{\Gamma}_a}^\lambda{}_\mu+2G_a\delta^\lambda{}_\mu.$$

In general, the connection Γ will have nonvanishing torsion, with coordinate expression

$$\Theta^\lambda_c T^c{}_{ab}=\partial_{[a}\Theta^\lambda_{b]}+\Theta^\mu_{[a}{\tilde{\Gamma}_{b]}}^\lambda{}_\mu+2\Theta^\lambda_{[a}G_{b]}.$$

The curvature tensors of Γ and $\tilde{\Gamma}$ are related by ${R_{ab}}^\lambda{}_\mu={\tilde{R}_{ab}}^\lambda{}_\mu$, or

$${R_{ab}}^c{}_d={\tilde{R}_{ab}}^\lambda{}_\mu\Theta^c_\lambda\Theta^\mu_d.$$

Remark: In the degenerate case there is no induced spacetime connection Γ, but one still has the two-spinor connection $\mathbb{B}$ and its decomposition.

VI. FIELDS AND FIELD EQUATIONS

I am going to present an approach to Einstein–Cartan–Maxwell–Dirac fields, in which the fundamental fields are Θ, $\mathbb{B}$, F, and ψ; in Sec. VI E. I will add to these the neutrino field. All objects and equations are nonsingular even if Θ is degenerate. For simplicity, henceforth I will take Θ to be Hermitian-valued, but extension to the more general complexified case is straightforward. I will make the further assumption $\mathrm{d}G=0$ (vanishing of the curvature tensor of the connection induced on $\mathbf{L}$), so that the G-part of $\mathbb{B}$ can be gauged away.

I'll define Lagrangian 4-forms by means of the co-tetrad $\breve{\Theta}$; these can be translated into the usual Lagrangians in the nondegenerate case. Coupling constants arise naturally, as covariantly constant sections of **L**, from the requirement that the Lagrangian be conformally invariant. I will get first-order Lagrangians and equations. In Sec. VII I will examine some extensions of the present formulation, related to the electromagnetic gauge.

A. Gravitational Lagrangian

The gravitational field is represented by Θ (which can be viewed as a ''square root'' of the metric) and the traceless part of B, namely $\widetilde{\Gamma}$. We set

$$\mathscr{L}_g := \tfrac{1}{4}\boldsymbol{\kappa}^{-1}\breve{\Theta}^{(2)}(\widetilde{R}^{\#}) = \tfrac{1}{8}\boldsymbol{\kappa}^{-1}\widetilde{*}\circ(\widetilde{R}^{\#}\wedge\Theta\wedge\Theta):\mathbf{M}\to\wedge^4 T^*\mathbf{M},$$

where $\widetilde{R}^{\#}:\mathbf{M}\to\wedge^2 T^*\mathbf{M}\otimes\wedge^2\mathbf{H}$ is the curvature tensor of $\widetilde{\Gamma}$ with one index raised via $\tilde{g}$, and $\boldsymbol{\kappa}:\mathbf{M}\to\mathbf{L}^2$ is a covariantly constant section called the *gravitational coupling factor*. Note how this is necessary in order to obtain a true 4-form on **M**. Setting $\boldsymbol{\kappa}=\kappa l^2$ one has the coordinate expression $\mathscr{L}_g=\ell_g \mathrm{d}^4x$ with

$$\ell_g = \tfrac{1}{8}\kappa^{-1}\boldsymbol{\epsilon}_{\lambda\mu\nu\rho}\boldsymbol{\epsilon}^{abcd}\widetilde{R}_{ab}{}^{\lambda\mu}\Theta_c{}^{\nu}\Theta_d{}^{\rho},$$

which in the nondegenerate case equals $-(1/2\kappa)R\ \det\Theta$.

B. Electromagnetic Lagrangian

The electromagnetic potential and the electromagnetic field are considered independent fields. These are the connection A induced by B on $\wedge^2 U$ and a spinor field

$$\widetilde{F}:\mathbf{M}\to\mathbf{L}^{-2}\otimes\Lambda^2\mathbf{H}^*.$$

The Lagrangian density is the sum of two terms[6]

$$\mathscr{L}_{\mathrm{em}} = -\tfrac{1}{2}\Theta^{(2)}(\mathrm{d}A\otimes\widetilde{F}) + \tfrac{1}{4}(\widetilde{F}\cdot\widetilde{F})\,\eta;$$

its coordinate expression is $\mathscr{L}_{\mathrm{em}}=\ell_{\mathrm{em}}\mathrm{d}^4x$ with

$$\ell_{\mathrm{em}} = -\tfrac{1}{4}\boldsymbol{\epsilon}^{abcd}\boldsymbol{\epsilon}_{\lambda\mu\nu\rho}\partial_a A_b\widetilde{F}^{\lambda\mu}\Theta_c{}^{\nu}\Theta_d{}^{\rho} + \tfrac{1}{4}\widetilde{F}^{\alpha\beta}\widetilde{F}_{\alpha\beta}\ \det\Theta.$$

Since $\widetilde{F}$ does not appear in the other terms of the total Lagrangian, the $\widetilde{F}$ component of the field equations is immediately seen to yield

$$-\tfrac{1}{2}\boldsymbol{\epsilon}^{abcd}\boldsymbol{\epsilon}_{\lambda\mu\nu\rho}\partial_a A_b\Theta_c{}^{\nu}\Theta_d{}^{\rho} + \widetilde{F}_{\lambda\mu}\ \det\Theta = 0,$$

which in the nondegenerate case gives $F := \Theta^*\widetilde{F} = 2\,\mathrm{d}A \Rightarrow \mathscr{L}_{\mathrm{em}} = -\tfrac{1}{4}F^2\,\eta$.

C. Dirac Lagrangian

Recall that the Dirac spinor field and its ''adjoint'' are the fields

$$\psi = u+\chi:\mathbf{M}\to\mathbf{L}^{-3/2}\otimes\mathbf{W} = \mathbf{L}^{-3/2}\otimes(\mathbf{U}\oplus\overline{\mathbf{U}}^{\bigstar}),$$

$$\overline{\psi} = \overline{\chi}+\overline{u}:\mathbf{M}\to\mathbf{L}^{-3/2}\otimes(\mathbf{U}^{\bigstar}\oplus\overline{\mathbf{U}}) = \mathbf{L}^{-3/2}\otimes\mathbf{W}^{\bigstar},$$

so that if $\psi'=u'+\chi'$ then $\langle\overline{\psi},\psi'\rangle = \langle\overline{\chi},u'\rangle + \langle\chi',\overline{u}\rangle$ is valued in $\mathbb{C}\otimes\mathbf{L}^{-3}$. We set

$$\mathscr{L}_D = \frac{i}{\sqrt{2}}\,\breve{\Theta}(\nabla u\otimes\overline{u} - u\otimes\nabla\overline{u} + \tilde{g}^{\#}(\overline{\chi}\otimes\nabla\chi - \nabla\overline{\chi}\otimes\chi)) - m(\langle\chi,\overline{u}\rangle + \langle\overline{\chi},u\rangle)\,\eta,$$

where m: $\mathbf{M}\to\mathbf{L}^{-1}$ is a covariantly constant section. Note how we replaced the combination $mc/\hbar$ with m only, which is essentially the usual setting $\hbar=c=1$. Actually, in the present context, the particle's mass and the Planck constant appear only in this combination. We have the coordinate expression $\mathscr{L}_D=\ell_D d^4x$ with

$$\ell_D=\frac{i}{\sqrt{2}}\,\breve{\Theta}^a_{AA\cdot}(\nabla_a u^A\overline{u}^{A\cdot}-u^A\nabla_a\overline{u}^{A\cdot}+\epsilon^{AB}\overline{\epsilon}^{A\cdot B\cdot}(\overline{\chi}_B\nabla_a\chi_{B\cdot}-\nabla_a\overline{\chi}_B\chi_{B\cdot}))$$
$$-m(\overline{\chi}_A u^A+\chi_{A\cdot}\overline{u}^{A\cdot})\det\Theta.$$

D. Field equations

The Θ component of the field equations reads

$$\tfrac{1}{2}\,\kappa^{-1}\epsilon_{\lambda\mu\nu\rho}\epsilon^{abcd}R_{ab}{}^{\lambda\mu}\theta^\rho_d=\tfrac{1}{2}\,\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}\partial_a A_b\widetilde{F}^{\lambda\mu}\Theta^\rho_d-\tfrac{1}{4}\,\widetilde{F}^2\breve{\Theta}^c_\nu$$
$$-\frac{i}{4}\,\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}\Theta^\mu_b\Theta^\rho_d(\overline{\psi}\widetilde{\gamma}^\lambda\nabla_a\psi-\overline{\widetilde{\gamma}^\lambda\nabla_a\psi}\psi)+m\overline{\psi}\psi\breve{\Theta}^c_\nu.$$

In the nondegenerate case, the left-hand side amounts essentially to the Einstein tensor, and the right-hand side can be viewed as the sum of the energy-momentum tensors of the electromagnetic field and of the Dirac field. The $\widetilde{\Gamma}$ component gives the equation for torsion

$$\tfrac{1}{2}\kappa^{-1}\epsilon_{\lambda\mu\nu\rho}\epsilon^{abcd}(\partial_b\Theta^\nu_c+\Theta^\sigma_b\widetilde{\Gamma}_c{}^\nu{}_\sigma)\Theta^\rho_d=\frac{i}{4\sqrt{2}}\,[(\breve{\Theta}^a_{AC\cdot}\tau_{[\lambda}{}^{DC\cdot}\tau_{\mu]DA\cdot}-\breve{\Theta}^a_{CA\cdot}\tau_{[\lambda}{}^{CD\cdot}\tau_{\mu]AD\cdot})u^A\overline{u}^{A\cdot}$$
$$+(\breve{\Theta}^{aBC\cdot}\tau_{[\lambda}{}^{DB\cdot}\tau_{\mu]DC\cdot}-\breve{\Theta}^{aCB\cdot}\tau_{[\lambda}{}^{BD\cdot}\tau_{\mu]CD\cdot})\overline{\chi}_B\chi_{B\cdot}].$$

From this we see that the spinor field is a source for torsion, and that in this context we cannot formulate a torsion-free theory.

The A-component is

$$\epsilon^{abcd}(\mathrm{d}*F)_{bcd}+\breve{\Theta}^a_\lambda(\overline{\psi}\widetilde{\gamma}^\lambda\psi)=0.$$

In the nondegenerate case this gives the (second) Maxwell equation $\frac{1}{2}*\mathrm{d}*F=j$, where $j^a:=\Theta^a_\lambda(\overline{\psi}\widetilde{\gamma}^\lambda\psi)$ is the Dirac current.

The ψ component, namely the $\overline{u}$ and $\overline{\chi}$ components, give the following modified form of the Dirac equation

$$\begin{cases}\sqrt{2}i\breve{\Theta}^a_{AA\cdot}\nabla_a u^A-m\chi_{A\cdot}\det\Theta+\mathscr{B}_{AA\cdot}u^A=0,\\ \sqrt{2}i\breve{\Theta}^{aAA\cdot}\nabla_a\chi_{A\cdot}-mu^A\det\Theta+\mathscr{B}^{AA\cdot}\chi_{A\cdot}=0,\end{cases}$$

where

$$\mathscr{B}_{AA\cdot}=\frac{i}{\sqrt{2}}\left[\partial_a\breve{\Theta}^a_{AA\cdot}+\frac{1}{2}\,(\breve{\Theta}^a_{BA\cdot}\widetilde{\Gamma}_a{}^{BC\cdot}{}_{AC\cdot}+\breve{\Theta}^a_{AB\cdot}\widetilde{\Gamma}_a{}^{CB\cdot}{}_{CA\cdot})\right]$$

(in the nondegenerate case just divide by $\det\Theta$ and take into account $\breve{\Theta}=\Theta^{-1}\det\Theta$; dropping the $\mathscr{B}$ terms, this is essentially the usual 2-spinor form of the Dirac equation[1]). The ψ-component gives the conjugate equation.

Finally note that we can express $\partial_a\Theta^\mu_b$ algebraically in terms of $\widetilde{\Gamma}$ and ψ via the torsion equation, and replace for this derivative in $\mathscr{B}_{AA\cdot}$ and $\mathscr{B}^{AA\cdot}$. These kind of torsion-related nonlinearities are known to arise in the context of Einstein–Cartan–Dirac fields.[7–11] Their possible physical meaning is an argument under discussion.

E. Neutrino field

Dropping the mass term in the Dirac Lagrangian poses no mathematical problem, and one obtains two decoupled Weyl equations (with an extra term related to the torsion). How do we ''turn off'' the electromagnetic interaction? Since A, being a connection, is not a section of a vector bundle, apparently it makes no sense to let it be zero. However, if $\mathbf{\Lambda}^2 := \wedge^2\mathbf{S}$ has a root $\mathbf{\Lambda}$ (Secs. II B, III), then we can take the neutrino bundle to be

$$\mathbf{U}' := (\wedge^2\mathbf{U})^{-1/2} \otimes \mathbf{U} = \mathbf{\Lambda}^{-1} \otimes \mathbf{S}.$$

I said that $\mathbf{U}'$ has a natural symplectic structure; moreover any two-spinor connection on $\mathbf{S}$ is easily seen to yield a flat connection on $\wedge^2\mathbf{U}'$. By the way, tensorializing $\mathbf{U}$ by powers of $\mathbf{\Lambda}$ is a natural way of introducing particles with different electric charges interacting with the same electromagnetic potential.

VII. ELECTROMAGNETIC GAUGE

The standard 2-spinor formalism considers certain decompositions of *world-tensors*—we may say elements in the tensor algebra $\otimes\mathbf{H}$—which are important for various reasons. In particular, the reduced forms of the fields are useful in the study of the Cauchy problem.

The decomposition procedure is essentially based on fixing a normalized 2-form $\boldsymbol{\epsilon}$: $\mathbf{M} \to \wedge^2\mathbf{U}^\star$. However, a choice of $\boldsymbol{\epsilon}$ is equivalent to that of an electromagnetic gauge, because the connection A is made into a true 1-form $A_a = -i/4\langle \nabla_a \boldsymbol{\epsilon}, \boldsymbol{\epsilon}^{-1} \rangle$. In the usual setting $\boldsymbol{\epsilon}$ is assumed to be a covariantly constant, fixed object, and the electromagnetic gauge is associated with the choice of a *different* normalized 2-form α (Ref. 1, Sec. V A).

In order to recover that setting, without assuming extra background structure, one might take the neutrino bundle $\mathbf{U}'$ as the fundamental 2-spinor bundle. Then one might reintroduce A as a *new* connection on $\wedge^2\mathbf{U}'$ (possibly flat in the neutrino case). I'll consider the above said decompositions only in relation to the choice of a gauge, allowing $\nabla\boldsymbol{\epsilon} \neq 0$ in general. Locally, we may view the condition $\nabla\boldsymbol{\epsilon} = 0$ as referring to the flat connection determined by the gauge on $\wedge^2\mathbf{U}^\star$; then A becomes a true 1-form as the difference between two connections.[12]

A. Fixing a gauge

In this section and in the next one I assume a fixed gauge. Then, locally, one can find normalized frames of $\mathbf{U}$ such that $\boldsymbol{\epsilon} = \boldsymbol{\epsilon}_{AB} z^A \wedge z^B$. Consider now a new field Φ: $\mathbf{M} \to \mathbf{L}^{-2} \otimes \vee^2\mathbf{U}$ (symmetrized tensor product) defined as the contraction between $\overline{F}$ and $\boldsymbol{\epsilon}$, in coordinates $\Phi_{AB} = \frac{1}{2}\overline{\boldsymbol{\epsilon}}^{A\cdot B\cdot}\widetilde{F}_{AA\cdot BB\cdot}$. We can take Φ instead of $\widetilde{F}$ as dynamic object of the theory; as far as the calculation of the field equations is concerned, we find no essential differences. An interesting fact, however, is that—by expressing $d{*}F$ in terms of $\nabla{*}F$ antisymmetrized—the two (groups of) Maxwell equations can now be written as the single equation

$$j^{AA\cdot} \det \Theta = 2\check{\Theta}^{aBA\cdot}(\nabla_a \Phi_{BC} + 2iA_a \Phi_{BC})\boldsymbol{\epsilon}^{AC} - i\boldsymbol{\epsilon}^{abcd}\boldsymbol{\epsilon}_{\lambda\mu\nu\rho}\Theta_a^{AA\cdot}\Theta_b^{BB\cdot}T^h{}_{cd}\Theta_h^{CC\cdot}\Phi_{BC}\overline{\boldsymbol{\epsilon}}_{B\cdot C\cdot}.$$

If the torsion vanishes and $\nabla\boldsymbol{\epsilon} = 0$, then we recover the usual two-spinor form of the Maxwell equations (Ref. 1, formula 5.1.52).

Consider the relation between Φ and A derived as one as the field equations. In the nondegenerate case it can be written

$$\Phi_{AB} = \tfrac{1}{2}\nabla_a A_b \overline{\boldsymbol{\epsilon}}^{A\cdot B\cdot}(\Theta^a_{AA\cdot}\Theta^b_{BB\cdot} + \Theta^a_{BA\cdot}\Theta^b_{AB\cdot}) + \tfrac{1}{2}T^c{}_{ab}A_c\overline{\boldsymbol{\epsilon}}^{A\cdot B\cdot}\Theta^a_{AA\cdot}\Theta^b_{BB\cdot}.$$

Assuming the Lorenz gauge

$$\nabla_a A_b \overline{\boldsymbol{\epsilon}}^{A\cdot B\cdot}\boldsymbol{\epsilon}^{AB}\Theta^a_{AA\cdot}\Theta^b_{BB\cdot} = 0$$

this becomes

$$\Phi_{AB} = \overline{\boldsymbol{\epsilon}}^{A\cdot B\cdot}\Theta^a_{AA\cdot}\Theta^b_{BB\cdot}(\nabla_a A_b + \tfrac{1}{2}T^c{}_{ab}A_c).$$

B. Schwinger Lagrangian

When a gauge is fixed, and A is made into a true 1-form, one can modify $\mathscr{L}_{\text{em}}$ into a general relativistic ''Schwinger'' Lagrangian:

$$\mathscr{L}_S = -\tfrac{1}{4}\Theta^{(2)}(A\wedge\nabla\widetilde{F} + dA\otimes\widetilde{F}) + \tfrac{1}{4}\widetilde{F}\cdot\widetilde{F}\,\eta,$$

or

$$\mathscr{L}_S = \tfrac{1}{8}\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}\Theta^{\nu}_{c}\Theta^{\rho}_{d}(\nabla_a\widetilde{F}^{\lambda\mu}A_b - \partial_a A_b\widetilde{F}^{\lambda\mu}) + \tfrac{1}{4}\widetilde{F}^{\alpha\beta}\widetilde{F}_{\alpha\beta}\ \det\Theta.$$

As before, the $\widetilde{F}$ component of the field equations gives the equation relating $\widetilde{F}$ to A,

$$2\widetilde{F}_{\lambda\mu}\ \det\Theta - (\partial_a A_b + \tfrac{1}{2}A_h T^h{}_{ab})\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}\Theta^{\nu}_{c}\Theta^{\rho}_{d} = 0.$$

So, in the nondegenerate case, $F = 2dA + A\lrcorner T$. The A component, coupling to the Dirac current, is

$$\tfrac{1}{8}\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}[\nabla_b\widetilde{F}^{\lambda\mu}\Theta^{\nu}_{c}\Theta^{\rho}_{d} + \partial_a(\widetilde{F}^{\lambda\mu}\Theta^{\nu}_{c}\Theta^{\rho}_{d})].$$

In the nondegenerate case this reads

$$-\tfrac{1}{2}(\nabla_h F^{ah} + \partial_b F_{cd}\epsilon^{abcd})\det\Theta,$$

which is different from the usual divergence of F because of the torsion. Also, we have the $\widetilde{\Gamma}$ component

$$(\mathscr{E}_S)^{a}_{\lambda\mu} = \tfrac{1}{8}\epsilon^{abcd}A_b\Theta^{\nu}_{c}\Theta^{\rho}_{d}\widetilde{F}^{\alpha}{}_{[\lambda}\epsilon_{\mu]\alpha\nu\rho},$$

which enters the torsion equation, and the Θ component

$$(\mathscr{E}_S)^{c}_{\nu} = \tfrac{1}{4}\epsilon^{abcd}\epsilon_{\lambda\mu\nu\rho}\Theta^{\rho}_{d}(\nabla_a\widetilde{F}^{\lambda\mu}A_b - \partial_a A_b\widetilde{F}^{\lambda\mu}) + \tfrac{1}{4}\widetilde{F}^{\alpha\beta}\widetilde{F}_{\alpha\beta}\breve{\Theta}^{c}_{\nu},$$

which enters the gravitational equation.

C. The gauge as a dynamical object

Rather than fixing a gauge, we might assume that the gauge itself is a field of the theory. We denote it by ω and write its local expression as $\omega = e^{-2it}\epsilon$; locally we may regard the function t: $\mathbf{M}\to\mathbb{R}$ as the dynamical gauge field. Moreover we consider a further field

$$X:\mathbf{M}\to\mathbf{L}^{-3}\otimes\mathbf{H},$$

whose meaning will result from the field equations. Write the Lagrangian in terms of $w := \omega^{-1}$ as

$$\mathscr{L}_{\text{gauge}} = -\frac{i}{2}\,\breve{\Theta}[X\lrcorner(\nabla w\otimes\overline{w} - \nabla\overline{w}\otimes w)] + qX^2\eta,$$

where the (covariantly) constant $q\in\mathbf{L}^2$ is needed in order to have a conformally invariant form. The coordinate expression is

$$\mathscr{L}_{\text{gauge}} = 2(\partial_a t - A_a)X^{\lambda}\breve{\Theta}^{a}_{\lambda} + q\,\eta_{\lambda\mu}X^{\lambda}X^{\mu}\ \det\Theta.$$

The X and t components of the field equations are, respectively,

$$qX_{\lambda}\ \det\Theta + (\partial_a t - A_a)\breve{\Theta}^{a}_{\lambda} = 0, \qquad \partial_a(X^{\lambda}\breve{\Theta}^{a}_{\lambda}) = 0.$$

In the nondegenerate case these become

$$qX_{\lambda} = A'_a\Theta^{a}_{\lambda}, \quad A' := A - \mathrm{d}t,$$

$$(\nabla_a X^\lambda + T^b{}_{ab} X^\lambda)\,\breve{\Theta}^a_\lambda = 0.$$

The first equation then determines qX as the spinor representative of A', the 1-form determined by the gauge ω, while the second is the Lorenz condition modified by the torsion.

The Lagrangian $\mathscr{L}_{\text{gauge}}$ contributes also to the A and Θ components of the total field equations, so we have also a ''gauge current'' and a ''gauge stress-energy tensor,'' whose possible physical meanings are to be discussed.

Group-theoretical quantization of 2+1 gravity in the metric-torus sector

P. Hájíček
Institute for Theoretical Physics, University of Bern, Sidlerstrasse 5, CH-3012 Bern, Switzerland

(Received 17 June 1997; accepted for publication 5 August 1997)

A symmetry based quantization method of reparametrization invariant systems is described; it will work for all systems that possess complete sets of perennials whose Lie algebras close and those that generate sufficiently large symmetry groups. The construction leads to a quantum theory including a Hilbert space, a complete system of operator observables, and a unitary time evolution. The method is applied to the $2+1$ gravity. The paper is restricted to the metric-torus sector, zero cosmological constant Λ and it makes strong use of the so-called homogeneous gauge; the chosen algebra of perennials is that of Martin. Two frequent problems are tackled. First, the Lie algebra of perennials does not generate a group of symmetries. The notion of group completion of a reparametrization invariant system is introduced so that the group does act; the group completion of the physical phase space of our model is shown to add only some limit points to it so that the ranges of observables are not unduly changed. Second, a relatively large number of relations between observables exists; they are transferred to the quantum theory by the well-known methods of Kostant and Kirillov. In this way, a uniqueness of the physical representation of some extension of Martin's algebra is shown. The Hamiltonian is defined by a systematic procedure due to Dirac; for the torus sector, the result coincides with that by Moncrief. The construction may be extended to higher genera and nonzero Λ of the $2+1$ gravity, because some complete sets of perennials are well-known and there are no obstructions to the closure of the algebra. © *1998 American Institute of Physics.* [S0022-2488(98)00409-5]

I. INTRODUCTION

The $(2+1)$-dimensional gravity is a popular model. It has been utilized as a laboratory for studies of specific problems in quantum gravity (for reviews, see Refs. 1 and 2). Our aim is to illustrate a symmetry based method of quantization of the so-called *reparametrization invariant systems* (RIS); a RIS is a constrained system whose dynamics is completely determined by its constraints (the value of the Hamiltonian is zero). For this purpose, $2+1$ gravity seems particularly interesting, because it is a generally covariant RIS and the structure of its constraints is very similar to that of the general relativity.

The (technical) starting point of the method is a choice of a set of functions on the phase space that satisfy three conditions. First, they should have vanishing Poisson brackets with all constraints. Such quantities have been called ''first-class'' by Dirac[3] and they are often called ''observables'' today. The name ''observables'' is, however, not justified in the case of RIS's. This difficulty, which is connected to the problem of time, has been first noticed by Kuchař,[4] who has introduced a special name, *perennials*, for the first-class quantities of RIS's. An attempt at a mathematical formulation of Kuchař's ideas can be found in Ref. 5, where a construction of observables from perennials is described that necessarily makes use of some additional (time) structures (cf. Sec. II). The second condition on the set is that it separates the classical solutions. This means that for two different solutions there is at least one function from the set that takes on different values at these solutions. This property is called *completeness*: it was first introduced by Bergmann[6] and it was later used by Ashtekar[7] as one of the basic properties within the algebraic quantization method. The third condition on the set is that it forms a closed algebra with respect to linear combinations and Poisson brackets. Thus, it will be a Lie algebra **g**.

 © 1998 American Institute of Physics

However, availability of perennials in the general relativity, or even their existence, has been questioned.[4] Indeed, one *can* invent RIS's that possess no perennials. However, these are mathematical constructs whose physics is strange; they cannot be reduced, even locally, and their physical phase spaces are not manifolds. It turns out that physically reasonable systems do possess complete systems of perennials (for proof, see Ref. 5). True, perennials of a special kind, for example those that are linear in momenta or are local in certain sense are already shown to be absent in the general relativity.[8,9] We shall show, however, how these proofs are transcended for the $2+1$ gravity model (to which the proof methods of Kuchař, Anderson, and Torre may be applicable). The third condition, that the perennials form a Lie algebra, might also be a source of problems; there are finite dimensional symplectic manifolds that do not admit a complete finite set of perennials whose algebra closes. However, it seems that such systems are again rather artificial with strange physics and that they also would be very difficult to quantize by any existing method.

The complete algebra of perennials plays a twofold role in the theory. First, as already mentioned, observables can be constructed from them. We assume that these observables comprise the most important and directly measurable properties of the system—this condition, although a little vague from the mathematical point of view, should influence the choice of the algebra **g**. Second, a group G of symmetries is generated by **g**, if some conditions are satisfied. Such a group, if it exists, can strongly simplify the task of finding suitable representation of the algebra **g** (that is, quantizing the system). The corresponding methods are those of the so-called *group quantization* (see Ref. 10 for a review); a modification of the methods suitable for the RIS's has been suggested by Rovelli.[11] The existence of the group G can however also help to solve the problem of time that afflicts the quantization of RIS's. The idea of this use for G stems from an old paper by Dirac;[12] in this paper, a time evolution has been constructed for a system of relativistic particles on the Minkowski spacetime. Dirac's ideas have been extended to general RIS's and developed to a coherent theory in Refs. 5 and 13. Although already published, this theory is far from being well known. We give, therefore, a short pedagogic exposition in Sec. II to make the paper self-contained.

The group G of symmetries is obtained from the algebra **g** in two steps. First, each Lie algebra determines a unique (simply connected) abstract Lie group G. Second, the Hamiltonian vector fields of the elements of the algebra determine an action of G on the phase space, if the vector fields are complete—we shall meet a prominent example of incomplete Hamiltonian vector fields in the $2+1$ gravity model. The action is then unique; let us call it *Hamiltonian action* of G. In some cases, the center of G will contain a nontrivial subgroup G_c, whose elements act trivially. Two cases must be distinguished: isolated elements of G in G_c and Lie subgroups of G in G_c. One can simplify G by taking the quotient with respect to the isolated elements, but not with respect to the Lie part of G_c.[10]

The $2+1$ gravity model can be considered as a dynamics of an ISO(1,2) affine connection of a three-dimensional manifold M.[14] If some conditions are satisfied, then the affine connection defines a Lorentzian metric on M and this property is preserved by the dynamics (we shall cut out the singularities!). We assume that Cauchy surface Σ is the torus $(S^1\times S^1)$ and that the metric is well-defined; in such a case, we speak of the *metric-torus sector*. This sector alone gives a solvable but unexpectedly interesting model so that all the general points above can be illustrated in a rather nontrivial way. We shall limit ourselves to this sector and we will work in a particular gauge, the so-called homogeneous gauge, in which the three-metric depends only on the time coordinate. Let us remark that there is no reason why our method should not work for higher genera. One can try to use the loop variables described in Refs. 15 or 16; the topology of the physical phase spaces for all higher genera is contractible and there are global Darboux coordinates; thus, there are no obstructions to the existence of a complete system of functions with a closed algebra.

In the present paper, we will choose the complete set of perennials that has been published by Martin.[15] The perennials are directly related to the topological degrees of freedom of the system and can be expressed as a kind of Wilson loop variable. For the metric-torus sector, Moncrief observed that Martin's perennials form the six-dimensional algebra **g** isomorph to iso(1,2). We shall introduce new canonical coordinates that are adapted to Martin's perennials; the constraint becomes formally the mass-shell condition for a rest-mass-zero relativistic particle. Thus, further four perennials can be immediately written down; together with the old ones, they form a ten-

dimensional algebra so(2,3). The corresponding group G is the conformal group of three-dimensional flat spacetime; G is isomorph to SO(2,3).

The problem of existence of the Hamiltonian action for G is nontrivial. Our calculation will reveal that only a subgroup $G_0 \subset G$ with the structure of $\mathrm{SO}(1,2)\times\mathbf{R}$ acts on the phase space of the system. It is easy to observe, however, that the phase space can be extended so that the whole group G has the Hamiltonian action on the extended space. We call such extensions *group completions*. A minimal group completion is unique under some quite general conditions. It turns out that the minimal group completion of the physical phase space consists, in our case, of adding ''relatively few points'' in such a way that the ranges of observables are not changed except for adding some boundary points to them.

The metric-torus sector has two degrees of freedom. Thus, a ten-dimensional algebra like $\mathbf{g}$ will exhibit six independent relations. Using the Kostant-Kirillov method, we find that the group G does not possess any physical representation. This has to do with Van Hove theorem: the physical phase space is too small and the algebra $\mathbf{g}$ of functions is too large to be represented without deformation. We find, however, that one of its maximal subgroups, G_1, which is seven-dimensional, and isomorph to $(\mathrm{SO}(1,2)\times\mathbf{R})\otimes_s\mathbf{R}^3$, possesses a unique physical representation and we calculate the form of the operators representing $\mathbf{g}_1$. Here, ''$\otimes_s$'' denotes the semidirect product of groups. Three independent classical relations for G_1 can be written down in terms of (generalized) Casimir operators.

For the construction of time evolution à la Dirac, we can use only the four-dimensional subgroup G_0; then the Hamiltonian action of G_0 on the constraint surface (and so on the classical spacetimes) provides the interpretation of the corresponding unitary transformations in the Hilbert space. It turns out that this action ''goes in time direction'' and so a time evolution can be constructed. The candidates for the Hamiltonian that generates everywhere time evolution towards future form a three-dimensional family. Most of these operators are unbounded from below. Thus, the condition that an operator generates time evolution towards the future does not necessarily guarantee that the operator has a non-negative spectrum. However, there is exactly one Hamiltonian that *is* bounded from below (and it is even nonnegative). The positive Hamiltonian coincides with the Hamiltonian written down by Moncrief[17] and the time coincides with the constant mean external curvature.

Some surprise is that the quantum mechanics we have constructed are not equivalent to the ''ordinary'' quantum mechanics of the rest-mass-zero free particle in three-dimensional Minkowski spacetime, in spite of the fact that the algebra of observables is so(2,3)-like for the particle, and that we managed to introduce new variables in which the constraint coincides with the ordinary mass-shell condition for such a particle. The explanation is that the global structure of the torus configuration space is very different from that of the particle (which is the three-dimensional Minkowski spacetime): the former is only a subset of the latter, namely, the inside of the light cone of the origin. The points outside of the light cone correspond to timelike two-surfaces evolving in a spacelike direction (the signature of the spacetime remains $+1$).

The plan of the paper is as follows. In Sec. II, we briefly describe the mathematical apparatus that has turned out advantageous for the study of RIS's, their observable properties, and their time evolution. No detail and proofs are given, because these can be found in already published papers.[5,13] In Sec. III, we list our starting assumptions and equations concerning the $2+1$ gravity model. They are mostly taken over from Refs. 17 and 18, where more detail can be found. One nontrivial but plausible assumption is that the so-called homogeneous gauge can be chosen in which the model becomes finite-dimensional.[18,19]

In Sec. IV, we study the problem of action of the group, define the group completion of a RIS and the weak action of the group. We derive the group completion of the model and prove that the group completed physical phase space contains the original one as an open dense subset. We define the action of G on the completed physical phase space, give the form of all observables obtained from the algebra $\mathbf{g}$ on the physical phase space and list all independent relations.

Section V describes an application of Dirac's time evolution idea to our model. We find that the dynamics is much more unique than in the case of free relativistic particle studied by Dirac (who found three inequivalent ''forms of relativistic dynamics''); we find only one ''form.'' Finally, in Sec. VI, after a brief description of the Kostant-Kirillov method, we derive the physical representation.

II. EXAMPLE: THE RELATIVISTIC PARTICLE

We consider a free relativistic particle of mass $m>0$ on the four-dimensional Minkowski space–time with coordinates x^μ and the metric $\eta_{\mu\nu}=\mathrm{diag}(-1,1,1,1)$. This is one of the systems studied originally by Dirac.[12] Let the conjugate momenta be p_μ and the constraint be $\mathscr{H}=(1/2)\times(p\cdot p+m^2)$. We shall use the abbreviation $A\cdot B:=\eta_{\mu\nu}A^\mu B^\nu$ throughout the paper.

The manifold $\mathbf{R}^8$ with the coordinates x^μ and p_μ, and with the symplectic form $\tilde{\Omega}=dp_\mu\wedge dx^\mu$ will be called extended phase space and denoted by $\tilde{\Gamma}$. The submanifold Γ of $\tilde{\Gamma}$ defined by $\mathscr{H}=0$ and $p_0<0$ is the *constraint surface*. The function $\mathscr{H}$ is the so-called *super-Hamiltonian*. It defines Γ, generates reparametrizations along the particle trajectories, and generates the dynamics,

$$\dot{x}^\mu=\mathscr{N}\{x^\mu,\mathscr{H}\},\quad \dot{p}_\mu=\mathscr{N}\{p_\mu,\mathscr{H}\}, \tag{1}$$

where $\mathscr{N}$ is an arbitrary function, the so-called *lapse*. The arcs that are determined by maximal solutions of Eqs. (1) will be called *c-orbits*. A *c*-orbit will be typically denoted by γ. *c*-orbits represent classical solutions. The quotient space $\bar{\Gamma}=\Gamma/\gamma$ will be called *physical phase space*; we will assume that $\bar{\Gamma}$ is a manifold. In this case, there is a symplectic form $\bar{\Omega}$ on $\bar{\Gamma}$ that is uniquely determined by $\tilde{\Omega}$. In our example, Γ is seven-dimensional, *c*-orbits are one-dimensional, so $\bar{\Gamma}$ is six-dimensional. The dimension of the physical space is the double of the physical degrees of freedom.

An important notion is that of *transversal surface*. This is any submanifold Γ_i of Γ such that each *c*-orbit intersects Γ_i exactly once and in a transversal direction (any vector at an intersection point that is simultaneously tangential to the *c*-orbit and to the transversal surface is necessarily the zero vector). The importance of transversal surfaces for the description of time evolution in relativistic theories has been recognized by Dirac.[12] Each transversal surface Γ_i carries a unique symplectic form Ω_i, the pull back of $\tilde{\Omega}$ to Γ_i. The symplectic space (Γ_i,Ω_i) can be identified with $(\bar{\Gamma},\bar{\Omega})$ by the map that sends each *c*-orbit γ from $\bar{\Gamma}$ to the intersection point of γ with Γ_i. An example of transversal surface, which we denote by Γ_0, is given by the equations $x^0=0$ and $\mathscr{H}=0$. As coordinates on Γ_0, the functions x^1, x^2, x^3, p_1, p_2, and p_3 can be chosen; in these coordinates, $\Omega_0=dp_k\wedge dx^k$. As we can see, Γ_0 defines a particular *time instant*, namely $x^0=0$. This is a general property of transversal surfaces; for example, in the general relativity, a transversal surface defines a unique Cauchy surface in any generic space–time solution (i.e., the solution that admits no symmetry).

The Poincaré group (in fact, only the componet of identity thereof) ISO (1,3) acts on $\tilde{\Gamma}$ in the usual way, leaving both $\tilde{\Omega}$ and Γ invariant. Such transformations in $\tilde{\Gamma}$ are called *symmetries*. The action is generated by ten functions p_μ, $J_k:=\epsilon_{klm}x_l p_m$ and $K_k:=x_k p_0-x_0 p_k$, $k=1,2,3$ (the indices are lowered and raised by the metric). The functions have vanishing Poisson brackets with $\mathscr{H}$ (as $\mathscr{H}$ is an invariant), so they are perennials. They form a Lie algebra that is isomorphic to iso(1,3) with respect to linear combinations and Poisson brackets, and the set separates *c*-orbits. Thus, we have an example of a complete Lie algebra $\mathbf{g}$ of perennials.

In this case, the group that is determined by $\mathbf{g}$ is $\mathrm{Sl}(2,\mathbf{C})\otimes_S\mathbf{R}^4$. The Hamiltonian action of the group is just the above action of ISO(1,3): The center of Sl(2,**C**) contains only one element that is different from identity, which acts trivially, so we can restrict ourselves to the group ISO(1,3).

Important general properties of symmetries are (see Refs. 11 and 13) (a) a symmetry sends *c*-orbits onto *c*-orbits and (b) it sends transversal surfaces onto transversal surfaces. The property (b) is crucial to the construction of dynamics á la Dirac;[12] by the transformations of the group G, a time instant is sent into another time instant. Dirac also proposed to choose maximally symmetric (with respect to G) transversal surfaces. Such a choice not only minimizes the number of ''different time instants,'' but also simplifies the operator observables.[12] There are three inequivalent maximally symmetric transversal surfaces for the relativistic particle; (a) the spacelike plane $x^0=0$, (b) the pair of hyperboloids $x\cdot x=1$, and (c) the null plane $x^0-x^1=0$. This leads to Dirac's ''three forms of dynamics.''

At first sight, it seems that perennials *are* observables. Thus, p_k are the momenta and J_k are the angular momenta of the particle. Such an association is, however, more difficult for p_0 and K_k. It is clearly not reasonable to put $-p_0$ equal to the energy, because only $\sqrt{\mathbf{p}^2+m^2}$ will lead

to the observed spectrum of the particle. Of course, $\sqrt{\mathbf{p}^2+m^2}$ is the value of $-p_0$ at the constraint surface Γ. More problems are encountered, if we try to interpret K_k as an observable. We can utilize p_μ together with K_k to form the functions

$$X_t^k := \frac{K_k}{p_0} + \frac{p_k}{p_0}\, t$$

for any constant t: as functions of perennials, X_t^k are themselves perennials. They can be interpreted as coordinates of the particle at the time $x^0=t$. It turns out, that this is a quite general way of forming observables from perennials; for it to work, some ''time structure'' is necessary. Here, we have used the (standard) family of transversal surfaces Γ_t defined by the equations $x^0=t$, as well as the family of maps generated by p_0 and sending Γ_t to $\Gamma_{t'}$ for each pair (t,t'). One easily verifies that

$$\frac{\partial X_t^k}{\partial t} + \{X_t^k, p_0\} = 0.$$

The class $\{X_t^k | t \in \mathbf{R}\}$ can, therefore, be considered as a Heisenberg observable, and so an observable turns out to be a class of perennials. The apparently trivial relation between perennials and observables for the particular perennials p_k and J_k in this case (the functions in the class are t-independent and coincide in form with the original perennials) is due to the fact that these perennials are connected in a special way to the standard time structure (represented by Γ_t and p_0) that is determined in the phase space by an inertial frame; p_k and J_k have vanishing Poisson brackets with p_0 and they leave (via Poisson bracket) each time instant Γ_t invariant. A systematic theory is given in Ref. 5.

An important technical tool for the present paper will be *projection to a transversal surface*. One can project perennials and symmetries. The projection o_1 of a perennial o to the transversal surface Γ_1 is a function on Γ_1 defined as the pullback of o to Γ_1: $o_1 := o|_{\Gamma_1}$. This projection preserves three operations: linear combinations, multiplications of functions, and Poisson brackets (of perennials). In particular, for the Poisson brackets, we have $\{o_1, o_1'\}_1 = \{o, o'\}$, where $\{\cdot,\cdot\}_1$ is the Poisson bracket in (Γ_1, Ω_1), $\{\cdot,\cdot\}$ that of $(\tilde{\Gamma}, \tilde{\Omega})$, o_1 the projection of o and o_1' that of o' to Γ_1 (for the proof, see Ref. 13). Projections of perennials to a given transversal surface can (sometimes!) be considered as Schrödinger observables (for more detail, see Ref. 5).

Similar to perennials, symmetries can also be projected. Let ϕ be a symmetry and $p \in \Gamma_1$. Then, the projection $\phi_1 : \Gamma_1 \to \Gamma_1$ of ϕ to Γ_1 is defined by $\{\phi_1(p)\} := \gamma_{\phi(p)} \cap \Gamma_1$, where $\{a\}$ is the set with the element a and γ_q is the c-orbit through the point q. One can show that ϕ_1 preserves Ω_1 as well as the group multiplication of symmetries; thus, the projection of a group of symmetries is a group of symplectic maps.[5] Moreover, if o generates a one-dimensional group of symmetries ϕ_t, then o_1 generates a one-dimensional group of symplectic maps ψ_t and it holds that $\psi_t = \phi_{t1}$ for all t, where ϕ_{t1} is the projection of ϕ_t to Γ_1.[13]

Finally, let Γ_1 and Γ_2 be two transversal surfaces, $p \in \Gamma_1$ and ρ: $\Gamma_1 \to \Gamma_2$ defined by $\{\rho(p)\} := \gamma_p \cap \Gamma_2$. Then, the pull back of Ω_2 by ρ is Ω_1 and the pull back of o_2 is o_1 for any perennial o with projection o_1 to Γ_1 and o_2 to Γ_2. Thus, ρ realizes the equivalence of all Γ_i's.[13]

Another important notion that we can illustrate with the relativistic particle model is that of *relation*. The projections of the ten perennials p_μ, J_k, and K_k to the transversal surface Γ_0 are linearly independent. However, there must be four functional relations between them, because Γ_0 is only six-dimensional. There cannot be more independent relations, as the functions form a complete system. The relations can be written as

$$\mathbf{p}^2 = -m^2, \quad \epsilon^{\mu\nu\rho\sigma} p_\nu J_{\rho\sigma} = 0,$$

where $J_{\rho\sigma} := \epsilon_{\rho\sigma\mu\nu} x^\mu p^\nu$. These relations have a close connection to the values of Casimir elements for this particular representation of the Poincaré group. Pohlmayer[20] has discussed the general case.

In the quantum version, we shall try to preserve these relations so that they become similar relations between operators (that may be deformed: some additional terms proportional to $\hbar$ may

appear). There also can be spectral conditions like $p_0<0$, that should be satisfied in the quantum theory. A unitary representation of the group G that preserves the relations between its generators and that satisfies the spectral condition is called *physical representation*.

III. THE HOMOGENEOUS GAUGE

In this section, we return to the $2+1$ gravity and briefly summarize our starting assumptions and equations. More detail can be found in Refs. 17 and 18. We shall consider only the metric-torus sector of the $2+1$ gravity system. In arbitrary coordinates x^1 and x^2 on arbitrary spacelike surfaces $t=\text{const}$ with the manifold structure Σ, the metric of the spacetime M has the form

$$ds^2=-N^2dt^2+g_{ab}(dx^a-N^adt)(dx^b-N^bdt)$$

and the ADM action for the model reads

$$S=\int_{\mathbf{R}}dt\int_{\Sigma}d^2x\left(\pi^{ab}\frac{\partial g_{ab}}{\partial t}-\mathcal{N}\mathcal{H}-\mathcal{N}^a\mathcal{H}_a\right),$$

where

$$\mathcal{H}=-\frac{1}{\sqrt{g}}[\pi^{ab}\pi_{ab}-(\pi^a_a)^2]+\sqrt{g}\mathcal{R},$$

$$\mathcal{H}_a=-2\nabla_b\pi^b_a.$$

∇_a is the covariant derivative associated with the metric g_{ab} and $\mathcal{R}$ is the curvature scalar of the two-surfaces $t=\text{const}$.

The analysis of the model simplifies enormously, if one can choose the so-called ''homogeneous gauge.'' It is the choice of coordinates such that the fields g_{ab} and π^{ab} are independent of x^1 and x^2.[17,19] A rigorous proof that such coordinates exist for each classical solution of the model has not yet been published. If each solution, however, admits at least one Cauchy surface of constant mean curvature (CMC), which seems to be a very plausible conjecture, then the existence can be shown.[18] The existence of the CMC surface has been proven by Andersson for genera higher than 1 and there are some ideas even for genus 1.[21] We will assume, that there is such a Cauchy surface; in any case, one can consider this as a part of the definition of the system, and if the conjecture is invalid, then this system will not be completely equivalent to the $2+1$ gravity.

In the homogeneous gauge, the metric can be taken in the form[17]

$$ds^2=-N(t)^2dt^2+e^{2\mu(t)}(dx^1)^2+e^{2\nu(t)}(dx^2+\beta(t)dx^1)^2. \tag{2}$$

A straightforward calculation then leads to the action

$$S=\int dt(p_\mu\dot{\mu}+p_\nu\dot{\nu}+p_\beta\dot{\beta}-\mathcal{N}\mathcal{H}),$$

where

$$\mathcal{H}=\tfrac{1}{2}(e^{-\mu-\nu}p_\mu p_\nu-e^{\mu-3\nu}p_\beta^2).$$

Moncrief then performs two canonical transformations; the first is

$$q^1=\nu-\mu,\quad q^2=\beta,\quad q^3=\nu+\mu,$$

$$p_\mu=-p_1+p_3,\quad p_\nu=p_1+p_3,\quad p_\beta=p_2,$$

so that the super-Hamiltonian becomes

$$\mathcal{H}=\tfrac{1}{2}e^{-q^3}(p_3^2-p_1^2-e^{-2q^1}p_2^2).$$

These coordinates are advantageous for visualization of the geometry of the system. The extended phase space is $\tilde{\Gamma}=T^*\mathbf{R}^3$ with the canonical coordinates q^1, q^2, q^3, p_1, p_2, and p_3; the meaning of q^3 and p_3 is

$$q^3=\log\sqrt{g},\quad p_3=\frac{\sqrt{g}}{\mathscr{N}}\frac{\partial q^3}{\partial t}.$$

The constraint surface Γ is the light cone in the momentum space

$$p_3^2-p_1^2-e^{-2q^1}p_2^2=0.$$

The $p_3>0$ half of the cone represents expanding, the $p_3<0$ half contracting, and the cusp $p_3=0$ represents the static tori—solutions with higher symmetry. We shall adhere to the convention that the coordinate t on the tori spacetimes is future oriented for $\mathscr{N}>0$.

The structure of the constraint surface Γ and of the physical phase space $\overline{\Gamma}=\Gamma/\gamma$ is spoilt by the points of higher symmetry.[22] The c-orbits with $p_3\neq 0$ are curves, those with $p_3=0$ are just points. As the static solutions form a set of measure zero, we can cut them away. Thus, we consider only that part of the system that satisfies the condition

$$p_3\neq 0.$$

The new system will have a disconnected phase space $\tilde{\Gamma}'=\tilde{\Gamma}'_+\cup\tilde{\Gamma}'_-$, a constraint surface $\Gamma'=\Gamma'_+\cup\Gamma'_-$ and a physical phase space $\overline{\Gamma}'=\overline{\Gamma}'_+\cup\overline{\Gamma}'_-$, where $\tilde{\Gamma}'_+:=\{x\in\tilde{\Gamma}|p_3>0\}$, $\Gamma'_+:=\Gamma\cap\tilde{\Gamma}'_+$, and $\overline{\Gamma}'_+:=\Gamma'_+/\gamma$ (similarly for $p_3<0$).

After this truncation, Moncrief performs the second transformation,

$$T=\ln|p_3|-q^3,\quad p_T=-p_3,$$

the other variables remaining the same; the super-Hamiltonian then reads

$$\mathscr{H}=-\frac{e^T}{2p_T}(p_T^2-p_1^2-e^{-2q^1}p_2^2). \tag{3}$$

The meaning of the variable T is given by

$$g^{ab}K_{ab}=\frac{1}{2\mathscr{N}}g^{ab}\frac{\partial g_{ab}}{\partial t}=\epsilon e^T,$$

where $\epsilon=\pm 1$ and the sign is determined by $\epsilon=\text{sign } p_3=-\text{sign } p_T$. Thus, ϵ is just the sign of the CMC of the surface $t=\text{const}$.

Martin's[15] constants of motion (perennials) are in these coordinates given by[17]

$$C_1=-(\epsilon/2)e^T\{[e^{-q^1}+(q^2)^2e^{q^1}](p_T+p_1)-2e^{-q^1}p_1+2q^2e^{-q^1}p_2\}, \tag{4}$$

$$C_2=-(\epsilon/2)e^T[e^{q^1}(p_T+p_1)], \tag{5}$$

$$C_3=-(\epsilon/2)e^T[q^2e^{q^1}(p_T+p_1)+e^{-q^1}p_2], \tag{6}$$

$$C_4=\tfrac{1}{2}\{[e^{-2q^1}-(q^2)^2]p_2+2q^2p_1\}, \tag{7}$$

$$C_5=\tfrac{1}{2}p_2, \tag{8}$$

$$C_6=p_1-q^2p_2. \tag{9}$$

They can be expressed as a kind of loop integrals by means of the original fields $g_{ab}(x)$ and $\pi^{ab}(x)$.[15]

Moncrief observed that the Poisson brackets of the variables P_μ and J^μ defined by

$$P_0 := \tfrac{1}{2}(C_1 + C_2), \quad P_1 := \tfrac{1}{2}(C_1 - C_2), \quad P_2 := C_3, \tag{10}$$

and

$$J^0 := -C_4 + C_5, \quad J^1 := -C_4 - C_5, \quad J_2 = -C_6,$$

form a Lie algebra isomorphic to iso(1,2). If we introduce the abbreviations

$$A := A^\mu P_\mu, \quad C := C_\mu J^\mu,$$

then

$$\{A, A'\} = 0, \quad \{A, C\} = (\varepsilon^{\rho\mu\nu} A_\mu C_\nu) P_\rho, \quad \{C, C'\} = (\varepsilon_{\rho\mu\nu} C^\mu C^\nu) J^\rho. \tag{11}$$

Here, we raise and lower the indices of X^μ and P_μ by the Minkowskian three-metric diag$(-1,1,1)$, $\varepsilon^{\rho\mu\nu}$ and $\varepsilon_{\rho\mu\nu}$ are the usual antisymmetric symbols ($\varepsilon_{\rho\mu\nu}$ is not $\varepsilon^{\rho\mu\nu}$ with lowered indices).

Formulas (4)–(9) imply the following four equations:

$$C_1 C_2 - C_3^2 = \tfrac{1}{4} e^{2T} (p_T^2 - p_1^2 - e^{-2q^1} p_2^2), \tag{12}$$

$$\{C_4, \mathscr{H}'\} = \{C_5, \mathscr{H}'\} = \{C_6, \mathscr{H}'\} = 0,$$

where

$$\mathscr{H}' = p_T^2 - p_1^2 - e^{-2q^1} p_2^2.$$

Thus, all C's are perennials.

There also are some discrete symmetries that originate from the nonuniqueness of the metric (2) for a given torus geometry (class group transformations, see e.g., Ref. 23). We shall not discuss the question whether these transformations are to be considered as symmetries or as gauge transformations. If $\mathbf{X}_1$ and $\mathbf{X}_2$ form a basis of a lattice in $\mathbf{E}^2$ defining the torus, then the metric has the form

$$g_{11} = \mathbf{X}_1 \cdot \mathbf{X}_1, \quad g_{12} = \mathbf{X}_1 \cdot \mathbf{X}_2, \quad g_{22} = \mathbf{X}_2 \cdot \mathbf{X}_2,$$

where $\mathbf{a} \cdot \mathbf{b}$ denotes the scalar product of the vectors $\mathbf{a}$ and $\mathbf{b}$ in $\mathbf{E}^2$. The following two transformations of the basis generate the whole group of the discrete transformations (''large diffeomorphisms''):

$$\mathbf{X}_1' = \mathbf{X}_2, \quad \mathbf{X}_2' = \mathbf{X}_1,$$

so that

$$g_{11}' = g_{22}, \quad g_{12}' = g_{12}, \quad g_{22}' = g_{11}, \tag{13}$$

and

$$\mathbf{X}_1' = \mathbf{X}_1, \quad \mathbf{X}_2' = \mathbf{X}_1 + \mathbf{X}_2,$$

so that

$$g_{11}' = g_{11}, \quad g_{12}' = g_{11} + g_{12}, \quad g_{22}' = g_{11} + 2g_{12} + g_{22}. \tag{14}$$

Using Eq. (2), we obtain from Eq. (13) for μ, ν, and β,

$$e^{2\mu'} = \frac{e^{2(\mu+\nu)}}{e^{2\mu} + \beta^2 e^{2\nu}}, \quad e^{2\nu'} = e^{2\mu} + \beta^2 e^{2\nu},$$

$$\beta' = \beta \frac{e^{2\nu}}{e^{2\mu} + \beta^2 e^{2\nu}}.$$

The corresponding transformation of q^1, q^2, and q^3 is

$$e^{q'^1} = e^{q^1}[(q^2)^2 + e^{-2q^1}], \tag{15}$$

$$q'^2 = \frac{q^2}{(q^2)^2 + e^{-2q^1}}, \tag{16}$$

$$q'^3 = q^3. \tag{17}$$

This gives for the momenta

$$p_1' = \frac{(q^2)^2 - e^{-2q^1}}{(q^2)^2 + e^{-2q^1}} p_1 + \frac{2q^2 e^{-2q^1}}{(q^2)^2 + e^{-2q^1}} p_2,$$

$$p_2' = 2q^2 p_1 - [(q^2)^2 - e^{-2q^1}] p_2.$$

One can then easily verify that

$$p_1'^2 + e^{-2q'^1} p_2'^2 = p_1^2 + e^{-2q^1} p_2^2,$$

so that the super-Hamiltonian (3) is invariant.

The transformation (14) gives

$$\mu' = \mu, \quad \nu' = \nu, \quad \beta' = 1 + \beta.$$

Thus,

$$q'^1 = q^1, \quad q'^2 = 1 + q^2, \quad q'^3 = q^3, \tag{18}$$

and

$$p_1' = p_1, \quad p_2' = p_2, \quad p_3' = p_3.$$

Again, $\mathscr{H}$ is conserved.

The transformations (15)–(17) imply

$$C_1' = C_2, \quad C_2' = C_1, \quad C_3' = C_3,$$

and (18) implies

$$C_1' = C_1 + C_2 + 2C_3, \quad C_2' = C_2, \quad C_3' = C_2 + C_3.$$

These are both integral transformations with determinant 1 as one expects for loop variables, if the loops are just permuted or linearly combined.

IV. GROUP COMPLETION OF THE PHASE SPACE

A. Completion by ISO(1,2)

In this section, we will investigate which transformations are generated by the perennials P_μ and J^μ in the phase space of the system. This task will be simplified, if we use coordinates that are adapted to the perennials in the following sense. C_1, C_2, and C_3 action via Poisson brackets in the phase space can be projected to the configuration space spanned by T, q^1, and q^2, and the projections are the vector fields $\hat{C}_1$, $\hat{C}_2$, and $\hat{C}_3$ given by replacing p_T, p_1, and p_2 by $\partial/\partial T$, $\partial/\partial q^1$, and $\partial/\partial q^2$ in expressions (4)–(6). The perennials C_1, C_2, and C_3 have vanishing Poisson

brackets with each other, so $\hat{C}_1$, $\hat{C}_2$, and $\hat{C}_3$ will define a holonomous frame; the corresponding coordinates are the desired ones. Let us first simplify these vectors by the transformation

$$u=T, \quad v=q^1-T, \quad y=q^2,$$

so that

$$\hat{C}_1=-(\epsilon/2)e^{-v}[(1+y^2e^{2u+2v})\partial_u+2y\partial_y-2\partial_v],$$

$$\hat{C}_2=-(\epsilon/2)e^{2u+v}\partial_u,$$

$$\hat{C}_3=-(\epsilon/2)e^{2u+v}(y\partial_u+e^{-2u-2v}\partial_y).$$

Now, we look for pairs of independent functions that are annihilated by each of these differential operators. The method of characteristics suggests that we study integral curves of the vector fields. The integral curve of $\hat{C}_1$ is defined by

$$\dot{u}=A(1+y^2e^{2u+2v}), \quad \dot{y}=A(2y), \quad \dot{v}=A(-2),$$

where $A=-\epsilon e^{-v}/2$. Thus,

$$(1/y)\dot{y}+\dot{v}=0,$$

$$-2e^{-2u-v}\dot{u}+2ye^{v}\dot{y}+(-e^{-2u-v}+y^2e^{v})\dot{v}=0,$$

and we have

$$\hat{C}_1(ye^{v})=0, \quad \hat{C}_1(e^{-2u-v}+y^2e^{v})=0.$$

The integral curve of $\hat{C}_2$ satisfies

$$\dot{u}=-\tfrac{1}{2}e^{2u+v}, \quad \dot{y}=0, \quad \dot{v}=0,$$

hence,

$$\hat{C}_2v=0, \quad \hat{C}_2y=0.$$

Similarly for $\hat{C}_3$,

$$\dot{u}=By, \quad \dot{y}=Be^{-2u-2v}, \quad \dot{v}=0,$$

where $B=-(\epsilon/2)e^{2u+v}$. Thus,

$$-e^{-2u-2v}\dot{u}+y\dot{y}=0,$$

and

$$\hat{C}_3v=0, \quad \hat{C}_3(e^{-2u-2v}+y^2)=0.$$

The pair of independent functions we have found for each vector field determines all functions that are annihilated by the field. We can easily find three independent functions such that each vector field annihilates exactly two of them. The results can be summarized in the following table:

$\hat{C}_1$		ye^{v},	$e^{-2u-v}+y^2e^{v}$,
$\hat{C}_2$	v,	ye^{v},	
$\hat{C}_3$	v,		$e^{-2u-v}+y^2e^{v}$.

Hence, the following transformation will simplify the vector fields:

$$\xi = e^{-2u-v} + y^2 e^v, \quad \eta = v, \quad \zeta = y e^v.$$

Indeed, we obtain that

$$\hat{C}_1 = \epsilon e^{-\eta} \partial_\eta, \quad \hat{C}_2 = \epsilon \partial_\xi, \quad \hat{C}_3 = -(\epsilon/2) \partial_\zeta.$$

Finally, the transformation

$$X^0 = \epsilon(e^\eta + \xi), \quad X^1 = \epsilon(e^\eta - \xi), \quad X^2 = -2\epsilon\zeta,$$

gives

$$\hat{P}_\rho = \frac{\partial}{\partial X^\rho}, \quad \rho = 0,1,2.$$

Composing all the transformations, we express X^ρ by means of the original variables T, q^1, and q^2,

$$X^0 = \epsilon e^{-T}[e^{q^1} + e^{-q^1} + (q^2)^2 e^{q^1}], \tag{19}$$

$$X^1 = \epsilon e^{-T}[e^{q^1} - e^{-q^1} - (q^2)^2 e^{q^1}], \tag{20}$$

$$X^2 = \epsilon e^{-T}[-2q^2 e^{q^1}]. \tag{21}$$

The class group transformations in terms of the coordinates X read

$$X'^0 = (3/2)X^0 + (1/2)X^1 - X^2,$$

$$X'^1 = -(1/2)X^0 + (1/2)X^1 + X^2,$$

$$X'^2 = -X^0 - X^1 + X^2,$$

which is an element of SO(1,2), and

$$X'^0 = X^0, \quad X'^1 = -X^1, \quad X'^2 = X^2.$$

The relations (19)–(21) together with (4)–(6) and (10) define a symplectic embedding ι: $\tilde{\Gamma}' \mapsto T^*M^3$ of the phase space $\tilde{\Gamma}'$ of our system, each component of which is spanned by the coordinates T, q^1, q^2, p_t, p_1, and p_2, into the cotangent bundle $T^*\mathbf{M}^3$ of the three-dimensional Minkowski space $\mathbf{M}^3$ with the coordinates (X^μ, P_μ). A very important point is that the image $\iota(\tilde{\Gamma}')$ is only a proper subset of $T^*\mathbf{M}^3$, namely the cotangent bundle of the inside of the light cone of the origin. Indeed, calculating $X \cdot X$ from (19)–(21), we obtain the identity

$$X \cdot X = -4e^{-2T} = -(4/\tau^2).$$

At the points of the light cone, the CMC is infinite; this surface represents the singularity of the torus dynamics. For the CMC τ, we obtain

$$\tau = \frac{2\epsilon}{\sqrt{-X \cdot X}}. \tag{22}$$

From Eq. (19), it follows that $\epsilon X^0 > 0$. Thus $\tilde{\Gamma}'_+ (\tilde{\Gamma}'_-)$ is mapped on the inside of the future (past) light cone. Moreover, Eqs. (4)–(6) and (10) yield

$$P_0 = (\epsilon e^T/4)(V_T p_T - V_1 p_1 - e^{-2q^1} V_2 p_2),$$

where

$$V_T=e^{q^1}+e^{-q^1}+(q^2)^2e^{q^1},\quad V_1=e^{q^1}-e^{-q^1}+(q^2)^2e^{q^1},\quad V_2=2q^2e^{q^1}.$$

We easily verify the identity

$$-V_T^2+V_1^2+e^{-2q^1}V_2^2=-4.$$

Thus, (V_T,V_1,V_2) is a ''timelike vector'' oriented towards the future ($V_T>0$) and (p_T,p_1,p_2) is a ''null vector'' (at the constraint surface, see (3)). Their ''scalar product'' $-V_Tp_T+V_1p_1+e^{-2q^1}V_2p_2$ is, therefore, negative (positive) if $p_T>0$ ($p_T<0$). As the sign of p_T and of ϵ are correlated, it follows that

$$P_0<0$$

everywhere at the constraint surface. This, together with Eqs. (10) and (12) imply that the points of the constraint surface satisfy the conditions

$$P\cdot P=0,\quad P_0<0 \tag{23}$$

with respect to the new variables (X^μ,P_μ). Let us denote by $\mathscr{P}$ the set of points in the momentum space with the coordinates P_μ that satisfy Eq. (23).

The transformation inverse to (19)–(21) is well-defined only inside the light cone, and can be written with respect to the coordinates as follows:

$$e^T=\frac{2}{\sqrt{-X\cdot X}},\quad e^{q^1}=\epsilon\,\frac{X^0+X^1}{\sqrt{-X\cdot X}},\ q^2=-\frac{X^2}{X^0+X^1}.$$

As X^0+X^1 is positive (negative) inside the future (past) half cone, e^{q^1} will be always positive. If we try to extend the transformation to the whole of $\mathbf{M}^3$, then we discover the meaning of the points lying outside the light cone. A simple calculation leads to the following complex transformation of the original variables,

$$t=it',\quad \nu=\nu'+(i\pi/2),$$

μ and β remaining unchanged, where t' and ν' are real. Then, all new momenta are real, but

$$e^{2T}=-p_3^2e^{-2\mu-2\nu'},\quad e^{2q^1}=-e^{-2\mu+2\nu'},$$

so that e^{2T} and e^{2q^1} become negative as necessary. Thus, we obtain space–times with the metric

$$ds^2=\mathscr{N}^2(t')dt'^2+e^2\mu(t')(dx^1)^2-e^{2\nu'(t')}[dx^2+\beta(t')dx^1]^2,$$

which have the Lorentz signature, but are acausal. A complete null geodesic crossing from the inside to the outside of the light cone represents an analytic three-dimensional space–time analogous to the Taub-NUT solution (see e.g., Ref. 24) with a Cauchy horizon and the Taub-NUT-like incompleteness at the cross point, if the singularity is viewed as a lightlike torus.

Martin's perennials are push-forwarded by ι just into the usual generators of the Poincaré group in the three-dimensional Minkowski spacetime $\mathbf{M}^3$: P_ρ and $J^\rho=\epsilon^{\rho\mu\nu}X_\mu P_\nu$. The corresponding group action is not transitive on $T^*\mathbf{M}^3$; the orbits are classified by the well-known invariants $P\cdot P$ and sign P_0, if $P\cdot P\leqslant 0$. However, each orbit of the group ISO(1,2) intersects $\iota(\tilde{\Gamma}')$, so no superfluous orbit has been added. Inside of the light cone, only the subgroup SO(1,2) acts; P's do not define any group acion on $\iota(\tilde{\Gamma}')$, because the corresponding vector fields are badly incomplete there. We can interpret our construction as follows.

The system of six Martin's functions form a complete algebra perennials; only three of them, the generators of SO(1,2), can be integrated to give a group action on the phase space $\tilde{\Gamma}'$; the three Hamiltonian vector fields corresponding to the perennials P_ρ are incomplete in $\tilde{\Gamma}'$. However, the Lie algebra generated by the six perennials defines a group, ISO(1,2). With the standard symplectic form, $\Omega_{\mathrm{ISO}}=dP_\mu\wedge dX^\mu$ of cotangent bundles, $T^*\mathbf{M}^3$ is a phase space, on which this group

does act. There is a map, ι, that sends $\tilde{\Gamma}'$ in $T^*\mathbf{M}^3$; ι is a symplectic imbedding and it pushes forward Martin's perennials into the generators of the action of ISO(1,2) on $T^*\mathbf{M}^3$. Thus, the map ι is equivariant for the two actions of the subgroup SO(1,2) of ISO(1,2). Such a space $T^*\mathbf{M}^3$ together with such a map ι can be called *minimal group completion of the phase space* $\tilde{\Gamma}'$ *corresponding to the complete Lie algebra of Martin's perennials*. The completion is minimal in the sense that there is no smaller completion (subspace of $T^*\mathbf{M}^3$), because each orbit of ISO(1,2) in $T^*\mathbf{M}^3$ intersects $\iota(\tilde{\Gamma}')$.

The constraint surface Γ' will be mapped to the subset of $T^*\mathbf{M}^3$ given by $X\cdot X<0$ and Eq. (23). The group ISO(1,2) does not act on $\iota(\Gamma')$ even if the generators of the group are tangential to $\iota(\Gamma')$: again, the translations are incomplete within this surface. However, there is a unique completion of $\iota(\Gamma')$ in $T^*\mathbf{M}^3$ on which the group acts, which we call $\Gamma_{\rm ISO}$. This surface is determined just by Eq. (23). Clearly, $(T^*\mathbf{M}^3, \Omega_{\rm ISO}, \Gamma_{\rm ISO})$ is a reparametrization invariant system that defines the corresponding c-orbits; they coincide with the maximal null geodesics in $\mathbf{M}^3$. Moreover, the image $\iota(\gamma)$ of each c-orbit γ in Γ' lies completely within some of the c-orbits of $(T^*\mathbf{M}^3, \Omega_{\rm ISO}, \Gamma_{\rm ISO})$—namely, in that null geodesic that extends $\iota(\gamma)$. Thus, we also have a well-defined map, $\bar{\iota}$: $\Gamma'\mapsto\Gamma_{\rm ISO}$, where $\Gamma_{\rm ISO}$ is the physical phase space of $(T^*\mathbf{M}^3, \Omega_{\rm ISO}, \Gamma_{\rm ISO})$.

In this sense, we can speak about a *group completion of the reparametrization invariant system*.

The completion constructed above has an important property which makes them interesting for physics. Let (M,Ω) be a symplectic manifold and let a set $\mathbf{g}$ of functions form a Lie algebra with respect to linear combinations and Poisson brackets. Let G be the (abstract) simply connected group that is determined by $\mathbf{g}$. Let (M_G,Ω_G,ι) be a minimal group completion of (M,Ω) by G. Thus, G acts on (M_G,Ω_G) as a group of symplectic diffeomorphisms. Let the image $\iota(M)$ be an open dense subset of M_G. Then, we say that the group G has a *weak action* on (M,Ω). For the above construction, we shall show the theorem:

Theorem 1: *The group ISO(1,2) has a weak action on the physical phase space* $\tilde{\Gamma}'$.

Proof: Consider the two surfaces $\Sigma_\pm$ defined by $X\cdot X=1$ and $\pm X^0>0$, respectively, inside the light cone of the origin in $\mathbf{M}^3$; the manifolds $\Sigma_\pm\times\mathscr{P}$ are global transversal surfaces in $\iota(\Gamma'_+)$ and $\iota(\Gamma'_-)$, as they are intersected by all null geodesics inside of the light cone. Thus, $\bar{\Gamma}'$ can be identified with $(\Sigma_+\times\mathscr{P})\cup(\Sigma_-\times\mathscr{P})$. Next consider the surface Σ in $\mathbf{M}^3$ defined by $X^0=0$. Clearly, the manifold $\Sigma\times\mathscr{P}$ is a global transversal surface for the group completed system, because it is intersected by any null geodesic at exactly one point; we can identify $\Gamma_{\rm ISO}$ with $\Sigma\times\mathscr{P}$.

Every point of $\Sigma_\pm\times\mathscr{P}$ defines a unique null geodesic; this geodesic intersects $\Sigma\times\mathscr{P}$ at precisely one point. Thus we have a well-defined map ρ: $(\Sigma_+\times\mathscr{P})\cup(\Sigma_-\times\mathscr{P})\mapsto\Sigma\times\mathscr{P}$ (the map ρ and its properties have been described in Sec. II). It is easy to see that $\bar{\iota}$ can be identified with ρ and so we have to show that $\rho(\Sigma_+\times\mathscr{P})\cup(\Sigma_-\times\mathscr{P})$ is open and dense in $\Sigma\times\mathscr{P}$.

Let us introduce the coordinates u and v at the surfaces Σ_ϵ by

$$X^0=\epsilon\sqrt{1+u_1^2+u_2^2},\quad X^1=u_1,\quad X^2=u_2,$$

and the coordinates x_1 and x_2 at Σ by $X^1=x_1$ and $X^2=x_2$. Let us consider null geodesics with a definite three-momenta of the form

$$P_\mu=p(1,\cos\alpha,\sin\alpha),\tag{24}$$

where p is a (negative) number. The null geodesic with the momenta (24) starting at the point (x_1,x_2) of Σ will intersect Σ_ϵ at the point

$$t=\epsilon\sqrt{1+u_1^2+u_2^2},\quad u_1=x_1+\epsilon\cos\alpha\sqrt{1+u_1^2+u_2^2},$$

$$u_2=x_2+\epsilon\sin\alpha\sqrt{1+u_1^2+u_2^2}.$$

Solving for (x_1,x_2), we obtain a description of ρ in terms of the coordinates u_1, u_2, ϵ, x_1, and x_2,

$$x_1 = u_1 - \epsilon \cos \alpha \sqrt{1+u_1^2+u_2^2}, \tag{25}$$

$$x_2 = u_2 - \epsilon \sin \alpha \sqrt{1+u_1^2+u_2^2}. \tag{26}$$

To see which part of Σ is hit, we introduce new variables,

$$x_1' = x_1 \cos \alpha + x_2 \sin \alpha, \quad x_2' = -x_1 \sin \alpha + x_2 \cos \alpha,$$

$$u_1' = u_1 \cos \alpha + u_2 \sin \alpha, \quad u_2' = -u_1 \sin \alpha + u_2 \cos \alpha,$$

and observe that

$$u_1^2 + u_2^2 = u_1'^2 + u_2'^2.$$

Then, Eqs. (25) and (26) are equivalent to

$$x_1' = u_1' - \epsilon \sqrt{1+u_1'^2+u_2'^2}, \quad x_2' = u_2'. \tag{27}$$

Thus, as u_2' runs through $\mathbf{R}$, so does x_2'. For a fixed x_2',

$$x_1' = u_1' - \epsilon \sqrt{1+u_1'^2+x_2'^2},$$

hence

$$\frac{dx_1'}{du_1'} = 1 - \epsilon \frac{u_1'}{\sqrt{1+u_1'^2+x_2'^2}} > 0, \quad \epsilon = \pm 1.$$

For $\epsilon = +1$, $x_1' \to -\infty$ as $u_1' \to -\infty$. On the other side, we obtain

$$\lim_{u_1'=\infty} x_1' = \lim_{u_1'=\infty} \frac{-1-x_2'^2}{u_1' + \sqrt{1+u_1'^2+x_2'^2}} = 0.$$

For $\epsilon = -1$, $x_1' \to \infty$ as $u_1' \to \infty$. On the other side, we obtain

$$\lim_{u_1'=-\infty} x_1' = \lim_{u_1'=-\infty} \frac{1+x_2'^2}{|u_1'| + \sqrt{1+u_1'^2+x_2'^2}} = 0.$$

Thus, Σ_+ is mapped to $x_1 \cos \alpha + x_2 \sin \alpha < 0$ and Σ_- is mapped to $x_1 \cos \alpha + x_2 \sin \alpha > 0$. Only the straight line $x_1 \cos \alpha + x_2 \sin \alpha = 0$ is missing from each surface $P_1 = \text{const}$, $P_2 = \text{const}$. It follows that $\rho(\tilde{\Gamma}')$ is open and dense. Q.E.D.

There is a standard way of construction of group completions, if the Lie algebra of observables is complete. Let (M, Ω) be a symplectic manifold and let $\mathbf{g}$ be a Lie algebra generated by a complete system of functions on M. Let G be the unique simply connected group whose Lie algebra coincides with $\mathbf{g}$. Let $\mathbf{g}^*$ be the dual linear space to $\mathbf{g}$ and let ad* be the coadjoint representation of G on $\mathbf{g}^*$. The orbits of the action ad* of G in $\mathbf{g}^*$ are homogeneous symplectic spaces of the group G according to a beautiful result of Kirillov.[25] Moreover, from a basis of $\mathbf{g}$, a (basis-independent) map Π: $M \mapsto \omega$ of M into an orbit ω can be constructed; Π is the so-called momentum map. Then, the manifold ω with Kirillov's symplectic structure and with Π as ι is the desired (minimal) completion.

As an example consider the manifold M with the coordinates q and p given by $q^2 + p^2 < 1$, equipped with the symplectic form $\Omega = dp \wedge dq$. Let the algebra $\mathbf{g}$ be generated by the functions q, p, and 1 (constant function). The corresponding group is the three-dimensional Heisenberg group defined on $\mathbf{R}^3$ with group law

$$(a_1,b_1,r_1)\cdot(a_2,b_2,r_2)=\left(a_1+a_2,b_1+b_2,r_1+r_2+\frac{b_1a_2-b_2a_1}{2}\right).$$

The space dual to the algebra is $\mathbf{R}^3$ with the coordinates A, B, and R, the orbits of the group are the planes $R=\text{const}$ and the momentum map is

$$A=q, \quad B=p, \quad R=1.$$

Thus, the orbit ω on which M is mapped is given by the equation $R=1$. The image of M is the disk $A^2+B^2<1$, and the group does not act even weakly.

B. SO(2,3) completion

There is a motivation to look for further symmetries; the subgroup SO(1,2) that acts on $\tilde{\Gamma}'$ is too small to define a time evolution à la Dirac. The simple form of the reparametrization invariant system $(T^*\mathbf{M}^3, \Omega_{\mathrm{ISO}}, \Gamma_{\mathrm{ISO}})$ allows us to see immediately that there are more perennials than just the generators of the three-dimensional Poincaré group; we have also the conformal isometries. The so-called dilatation is generated by

$$D:=X^\mu P_\mu, \tag{28}$$

and the so-called conformal accelerations are generated by

$$Q_0:=(X\cdot X)P_0+2X^0(X\cdot P), \tag{29}$$

$$Q_1:=(X\cdot X)P_1-2X^1(X\cdot P), \tag{30}$$

$$Q_2:=(X\cdot X)P_2-2X^2(X\cdot P). \tag{31}$$

It is easy to verify that the Poisson brackets of these variables with $P\cdot P$ weakly vanish. Let us denote $B^\mu Q_\mu$ by B. Then, the Lie algebra of A, B, C, and D is given by Eqs. (11) and

$$\{A,B\}=2(A\cdot B)D-2(\varepsilon_{\rho\mu\nu}A^\mu B^\nu)J^\rho, \quad \{B,C\}=(\varepsilon^{\rho\mu\nu}B_\mu C_\nu)Q_\rho, \tag{32}$$

$$\{A,D\}=-A, \quad \{B,B'\}=0, \quad \{B,D\}=B, \quad \{C,D\}=0. \tag{33}$$

This is the Lie algebra of the group SO(2,3). Indeed, let Z^0, Z^1, Z^3, W^0, and W^1 be coordinates in $\mathbf{R}^5$ with the metric

$$dS^2=-(dZ^0)^2-(dW^0)^2+(dZ^1)^2+(dZ^2)^2+(dW^1)^2; \tag{34}$$

to obtain the algebra (11), (32), and (33), we have to just identify

$$J^\rho\mapsto\varepsilon^{\rho\mu\nu}Z_\mu\frac{\partial}{\partial Z^\nu}, \quad D\mapsto W_0\frac{\partial}{\partial W^1}-W_1\frac{\partial}{\partial W^0},$$

$$P_\rho\mapsto\left(Z_\rho\frac{\partial}{\partial W^0}-W_0\frac{\partial}{\partial Z^\rho}\right)-\left(Z_\rho\frac{\partial}{\partial W^1}-W_1\frac{\partial}{\partial Z^\rho}\right),$$

$$Q_\rho\mapsto\left(Z_\rho\frac{\partial}{\partial W^0}-W_0\frac{\partial}{\partial Z^\rho}\right)+\left(Z_\rho\frac{\partial}{\partial W^1}-W_1\frac{\partial}{\partial Z^\rho}\right),$$

where the indices are lowered by the metric (34).

The Hamiltonian vector field corresponding to the dilatation is complete not only within $T^*\mathbf{M}^3$, but even within $\iota(\tilde{\Gamma}')$. The Hamiltonian vector fields corresponding to Q's are incomplete within $T^*\mathbf{M}^3$; however, there is still a chance to construct additional observables from Q's, so we

have to construct the next completion. This completion is well-known; it is the cotangent bundle $T^*\overline{\mathbf{M}}^3$ of the compactified Minkowski space–time $\overline{\mathbf{M}}^3$.[26] Let us briefly describe the construction, because we shall need some details of it.

Consider the three-dimensional Einstein cosmology space–time $\mathbf{M}_E^3$ with the coordinates τ, ϑ, and φ and the metric

$$ds^2 = -d\tau^2 + d\vartheta^2 + \sin^2\vartheta d\varphi^2.$$

The null geogesics that start at the point $\tau = \tau_0$, $\vartheta = 0$, are given by

$$\tau = \tau_0 + \lambda, \quad \vartheta = \lambda, \quad \varphi = \text{const}.$$

These geodesic form a null cone that refocuses at the point $\tau = \tau_0 + \pi$, $\vartheta = \pi$. Similarly, all null geodesics through the point $\tau = \tau_0$, $\vartheta = \pi$, have the form

$$\tau = \tau_0 + \lambda, \quad \vartheta = \pi - \lambda, \quad \varphi = \text{const},$$

and they refocus at $\tau = \tau_0 + \pi$, $\vartheta = 0$. As it is well-known, (e.g., Ref. 26), the compactified Minkowski space–time $\overline{\mathbf{M}}^3$ is obtained from $\mathbf{M}_E^3$ by the identification of each point $(\tau, \vartheta, \varphi)$ with the point $(\tau + \pi, \pi - \vartheta, \varphi + \pi)$. There is a conformal isometry ϕ that sends $\mathbf{M}^3$ into $\overline{\mathbf{M}}^3$ such that the set $\phi(\mathbf{M}^3)$ lies in the future of the null cone between the points $(\tau = -\pi, \vartheta = 0)$ and $(\tau = 0, \vartheta = \pi)$, and in the past of the null cone between $(\tau = 0, \vartheta = \pi)$ and $(\tau = \pi, \vartheta = 0)$.

Another copy of Minkowski space–time lies between the points $(\tau = -\pi, \vartheta = \pi)$, $(\tau = 0, \vartheta = 0)$, and $(\tau = \pi, \vartheta = \pi)$. By the above identification and the two conformal isometries, the point X^μ of the first Minkowski space–time will be mapped to the point Y^μ of the second one given by

$$Y^\mu = \frac{X^\mu}{X \cdot X}, \tag{35}$$

if the inertial coordinates X^μ and Y^μ are chosen properly. We will make some use of these two patches of $\overline{\mathbf{M}}^3$; the fact that they do not cover $\overline{\mathbf{M}}^3$ will not be important. Let us call them U and V.

The map ϕ is a diffeomorphism of three-dimensional manifolds and it can be extended to an isomorphism ϕ_{cot} of the cotangent bundles of these manifolds. As the conformal group SO(2,3) acts transitively in $T^*\overline{\mathbf{M}}^3$, the triad $(T^*\overline{\mathbf{M}}^3, \Omega_{\text{SO}}, \phi_{\text{cot}})$ is the desired minimal SO(2,3) completion; the form Ω_{SO} is the standard symplectic form of cotangent bundles; observe that it is exact. The set $\phi_{\text{cot}}(T^*\mathbf{M}^3)$ is equal to T^*U, and so it is open and dense in $T^*\overline{\mathbf{M}}^3$. Thus, SO(2,3) *acts weakly* on $T^*\overline{\mathbf{M}}^3$.

Let the canonical coordinates in the cotangent bundles T^*U and T^*V be X^μ, P_μ, and Y^μ, Q_μ, respectively. Then the transformation (35) between X^μ and Y^μ leads to the following transformation between P_μ and Q_μ:

$$Q_\mu = (X \cdot X) P_\mu - 2(X \cdot P) X_\mu. \tag{36}$$

The inverse map is

$$X^\mu = \frac{Y^\mu}{Y \cdot Y}, \quad P_\mu = (X \cdot X) Q_\mu - 2(X \cdot Q) Y_\mu. \tag{37}$$

Comparison with Eqs. (29)–(31) shows that the use of the letter Q for this coordinate will not lead to any confusion with the notation for the generators of conformal accelerations. From the transformation formulas (36) and (37), we easily verify that the symplectic form Ω_{SO} at the points where the patches overlap satisfies

$$dP_\mu \wedge dX^\mu = dQ_\mu \wedge dY^\mu.$$

The SO(2,3) completion of the RIS $(T^*\mathbf{M}^3, \Omega_{\text{ISO}}, \Gamma_{\text{ISO}})$ is $(T^*\overline{\mathbf{M}}^3, \Omega_{\text{SO}}, \Gamma_{\text{SO}})$, where Γ_{SO} is given by the equations

$$g_i^{\mu\nu}P_\mu^i P_\nu^i=0, \quad P_0^i<0,$$

within each chart T^*U_i, where the metric $g_i^{\mu\nu}$ is the metric of the conformal chart U_i, P_μ^i the canonical coordinate in the fibers of T^*U_i, and we allow only charts that have the same time orientation.

It follows that the projection of the *c*-orbits to the configuration space $T^*\overline{\mathbf{M}}^3$ are complete null geodesics; they are closed curves (topologically S^1). The ϕ-images of the *c*-orbits of the system $(T^*\underline{\mathbf{M}}^3,\Omega_{\mathrm{ISO}},\Gamma_{\mathrm{ISO}})$ are the null geodesics in the chart U; each of them is completed by one point in $\mathbf{M}^3$. The null geodesics in $\mathbf{M}^3$ that do not contain any ϕ-images form the light cone of the origin of the chart V $(Y^\mu=0)$. Hence, the surface Γ_0 given by the equations $X^0=0$, $P_0=-\sqrt{P_1^2+P_2^2}$ within the chart T^*U, and by $Y^0=0$, $Q_0=-\sqrt{Q_1^2+Q_2^2}$ within the chart T^*V is a global transversal surface. We can introduce coordinates $(x_1,x_2)\in\mathbf{R}^2$, $(p_1,p_2)\in\mathbf{R}^2\backslash\{0\}$ in $\Gamma_0\cap T^*U$ and $(y_1,y_2)\in\mathbf{R}^2$, $(q_1,q_2)\in\mathbf{R}^2\backslash\{0\}$ in $\Gamma_0\cap T^*V$ such that the imbedding equations are

$$\left.\begin{array}{lll} X^0=0, & X^1=x_1, & X^2=x_2, \\ P_0=-\sqrt{p_1^2+p_2^2}, & P_1=p_1, & P_2=p_2, \end{array}\right\} \tag{38}$$

and

$$Y^0=0, \quad Y^1=y_1, \quad Y^2=y_2,$$

$$Q_0=-\sqrt{q_1^2+q_2^2}, Q_1=q_1, \quad Q_2=q_2.$$

One easily verifies that Γ_0 defined in this way is a smooth surface and that the transformation formulas (35), (36), and (37) imply the relations

$$x_k=\frac{y_k}{y_1^2+y_2^2}, \quad p_k=(y_1^2+y_2^2)q_k-2(y_1q_1+y_2q_2)y_k. \tag{39}$$

In particular, Eq. (36) implies that $Q_0<0$ if $P_0<0$. The pullback Ω_0 of the symplectic form Ω_{SO} to Γ_0 is given in these coordinates by

$$\Omega_0=dp_k\wedge dx_k=dq_k\wedge dy_k,$$

the last inequality following from Eqs. (39). Ω_0 is exact.

The manifold Γ_0 is a bundle with the fiber $\mathscr{P}\cong S^1\times\mathbf{R}$ given by $x_k=\mathrm{const}$ or $y_k=\mathrm{const}$. The base space is S^2, and the coordinates (x_1,x_2) and (y_1,y_2) are nothing but the two stereographic projection charts of S^2. The symplectic space (Γ_0,Ω_0) is a homogeneous symplectic space of the group SO(2,3), which acts on Γ_0 by the projection of symmetries (see Sec. II); each element of the conformal group maps null geodesics in null geodesics. $(\underline{\Gamma}_0,\Omega_0)$ can be identified with the group completed physical phase space $\overline{\Gamma}_{\mathrm{SO}}$. The composition $\phi\circ\overline{\iota}$ of the ISO(1,2)-completion and the SO(2,3)-completion gives the image $\phi(\overline{\iota}(\overline{\Gamma}'))$ as an open dense subspace of Γ_0; thus, the conformal group SO(2,3) acts weakly (and transitively) on $\overline{\Gamma}'$.

The generators of the action of SO(2,3) on Γ_0 are Hamiltonian vector fields of the projections of the perennials P_μ, Q_μ, J^μ, and D from $T^*\mathbf{M}^3$ to Γ_0 (see Sec. II). In the patch (x_k,p_k), the projections coincide with the functions

$$\left.\begin{array}{lll} \overline{P}_0:=-\sqrt{\mathbf{p}\cdot\mathbf{p}}, & \overline{Q}_0:=-(\mathbf{x}\cdot\mathbf{x})\sqrt{\mathbf{p}\cdot\mathbf{p}}, & \overline{J}^0:=x_1p_2-x_2p_1, \\ \overline{P}_1:=p_1, & \overline{Q}_1:=(\mathbf{x}\cdot\mathbf{x})p_1-2(\mathbf{x}\cdot\mathbf{p})x_1, & \overline{J}^1:=-x_2\sqrt{\mathbf{p}\cdot\mathbf{p}}, \\ \overline{P}_2:=p_2, & \overline{Q}_2:=(\mathbf{x}\cdot\mathbf{x})p_2-2(\mathbf{x}\cdot\mathbf{p})x_2, & \overline{J}^2:=x_1\sqrt{\mathbf{p}\cdot\mathbf{p}}, \\ & & \overline{D}:=\mathbf{x}\cdot\mathbf{p}. \end{array}\right\} \tag{40}$$

These functions will be considered as observables. Here, we have used the abbreviation $\mathbf{u}\cdot\mathbf{v}:=u_1v_1+u_2v_2$. The expressions within the other patch, (y_k,q_k), are analogous, one just has to exchange P's and Q's, write y for x and q for p. Via Poisson brackets, the functions generate the

Lie algebra of SO(2,3). They are ten functions of four variables; thus, there will be six relations. These relations can be systematically written down, if we solve the definitions of $\overline{P_1}$, $\overline{P^2}$, $\overline{J^1}$, and $\overline{J^2}$ for p_1, p_2, x_1, and x_2 and substitute the results into the other definitions,

$$\overline{P_0^2}=\overline{P_1^2}+\overline{P_2^2}, \quad \overline{J^0}\,\overline{P_0}+\overline{J^1}\,\overline{P_1}+\overline{J^2}\,\overline{P_2}=0, \tag{41}$$

$$\overline{Q_0^2}=\overline{Q_1^2}+\overline{Q_2^2}, \quad \overline{D}=\frac{\overline{P_1}\,\overline{J^2}-\overline{P_2}\,\overline{J^1}}{\sqrt{\overline{\mathbf{P}}\cdot\overline{\mathbf{P}}}}, \tag{42}$$

$$\overline{Q_1}=\frac{\overline{P_1}}{\overline{\mathbf{P}}\cdot\overline{\mathbf{P}}}[(\overline{J^1})^2-(\overline{J^2})^2]+\frac{\overline{P_2}}{\overline{\mathbf{P}}\cdot\overline{\mathbf{P}}}[2\overline{J^1}\,\overline{J^2}], \tag{43}$$

$$\overline{Q_2}=\frac{\overline{P_1}}{\overline{\mathbf{P}}\cdot\overline{\mathbf{P}}}[2\overline{J^1}\,\overline{J^2}]-\frac{\overline{P_2}}{\overline{\mathbf{P}}\cdot\overline{\mathbf{P}}}[(\overline{J^1})^2-(\overline{J^2})^2]. \tag{44}$$

The two Eqs. (41) are relations concerning also ISO(1,2) alone and the four relations (42)–(44) can be used to calculate the remaining generators of SO(2,3). A quadratic relation follows:

$$-(\overline{J^0})^2+(\overline{J^1})^2+(\overline{J^2})^2=\overline{D^2}. \tag{45}$$

The Poisson brackets of the four quadratic expressions $P\cdot P$, $Q\cdot Q$, $J\cdot P$, and $-D^2+J\cdot J$ with the generators P_μ, Q_μ, J^μ, and D are mostly vanishing or proportional to $P\cdot P$; they are (generalized) Casimirs of some subgroups.

As it was explained in Sec. II, the action of SO(2,3) on Γ_0 is generated by the Hamiltonian vector fields of the observables (40). This defines a linear map from the Lie algebra so(2,3) into vector fields on Γ_0. We can describe the map, if we choose a basis of so(2,3) and list the images of the elements of the basis. Let the basis be

$$(\mathscr{P}_0,\mathscr{P}_1,\mathscr{P}_2,\mathscr{Q}_0,\mathscr{Q}_1,\mathscr{Q}_2,\mathscr{T}^0,\mathscr{T}^1,\mathscr{T}^2,\mathscr{D}). \tag{46}$$

Here, we denote the abstract elements of the Lie algebra by upper case calligraphic letters to distinguish them from the corresponding perennials or vector fields. The association with the vector fields is

$$\mathscr{P}_0\mapsto-\frac{p_k}{\sqrt{\mathbf{p}\cdot\mathbf{p}}}\frac{\partial}{\partial x_k}, \quad \mathscr{P}_k\mapsto\frac{\partial}{\partial x_k}, \tag{47}$$

$$\mathscr{Q}_0\mapsto-\frac{\mathbf{x}\cdot\mathbf{x}}{\sqrt{\mathbf{p}\cdot\mathbf{p}}}p_k\frac{\partial}{\partial x_k}+2\sqrt{\mathbf{p}\cdot\mathbf{p}}x_k\frac{\partial}{\partial p_k}, \tag{48}$$

$$\mathscr{Q}_k\mapsto[(\mathbf{x}\cdot\mathbf{x})\delta_{kl}-2x_kx_l]\frac{\partial}{\partial x_l}+[(\mathbf{x}\cdot\mathbf{p})\delta_{kl}+x_kp_l-x_lp_k]\frac{\partial}{\partial p_l}, \tag{49}$$

$$\mathscr{T}^0\mapsto-x_2\frac{\partial}{\partial x_1}+x_1\frac{\partial}{\partial x_2}-p_2\frac{\partial}{\partial p_1}+p_1\frac{\partial}{\partial p_2}, \tag{50}$$

$$\mathscr{T}^1\mapsto-\frac{x_2p_k}{\sqrt{\mathbf{p}\cdot\mathbf{p}}}\frac{\partial}{\partial x_k}+\sqrt{\mathbf{p}\cdot\mathbf{p}}\frac{\partial}{\partial p_2}, \tag{51}$$

$$\mathscr{T}^2\mapsto\frac{x_1p_k}{\sqrt{\mathbf{p}\cdot\mathbf{p}}}\frac{\partial}{\partial x_k}-\sqrt{\mathbf{p}\cdot\mathbf{p}}\frac{\partial}{\partial p_1}, \tag{52}$$

$$\mathscr{D} \mapsto x_1 \frac{\partial}{\partial x_1} + x_2 \frac{\partial}{\partial x_2} - p_1 \frac{\partial}{\partial p_1} - p_2 \frac{\partial}{\partial p_2}. \tag{53}$$

We shall need the form of these vector fields for the construction of the physical representation of the group in Sec. VI.

V. THE HAMILTONIAN

In this section, we study the time evolution of the $2+1$ gravity model. We are going to apply Dirac's idea; a choice of transversal surfaces of maximal symmetry, and a comparison of different time levels using symmetry operations.

There are two problems that prevent a straightforward application. First, the group SO(2,3) is too large to have a representation that satisfies all conditions on *physical* representation (see the next section). Second, only a four-dimensional subgroup of SO(2,3) has the *action* on the phase space of the system that is associated with the corresponding Lie algebra of perennials.

The largest subgroups that have physical representations are G_1 and G_2 with the structure $(\mathrm{SO}(1,2)\times\mathbf{R})\otimes_S\mathbf{R}^3$. G_1 is generated by $\mathscr{T}^0$, $\mathscr{T}^1$, $\mathscr{T}^2$, $\mathscr{D}$, $\mathscr{P}_0$, $\mathscr{P}_1$, and $\mathscr{P}_2$ and G_2 by $\mathscr{T}^0$, $\mathscr{T}^1$, $\mathscr{T}^2$, $\mathscr{D}$, $\mathscr{Q}_0$, $\mathscr{Q}_1$, and $\mathscr{Q}_2$. Consider G_1. The corresponding group completion of the $2+1$ gravity coincides with the ISO(1,2)-completion that was constructed in the previous section, because the only additional element, the dilatation $\mathscr{D}$, acts on $\tilde{\Gamma}'$. Let us, therefore, restrict ourselves to G_1.

The group G_1 acts weakly on the physical phase space Γ'. This is important for the quantum generators of the group to have suitable spectra. On the other hand, the weak action is not sufficient for the construction of a time evolution according to Dirac. Let us explain these two points.

Consider the two-dimensional disk example described at the end of the previous section. The Heisenberg group did not act even weakly. On the disk, the values of the classical observables q and p are bounded; $q^2+p^2<1$. On the group completion, which is a whole plain, the values of q fill up the interval $(-\infty,\infty)$ and similarly for p. This follows from the structure of the Lie algebra (see, e.g., Ref. 10). If we represent q and p by self-adjoint operators satisfying the canonical commutation relations, then this structure forces the spectra again to fill up the whole real axis. The corresponding quantum mechanics contains semiclassical wave packets with average values of $\hat{q}$ and $\hat{p}$ that lie far away from possible classical values. Let us call this the *problem of ranges*. On the other hand, if a group acts weakly, then the only change of the range of classical values that is motivated is an addition of some limit points. This would happen in any case in the quantum mechanics, because the spectrum of any self-adjoint operator is a closed subset of **R**. In this respect, the weak action does not differ from an ordinary action.

However, for Dirac's idea to work, we have to find a family of maximally symmetric transversal surfaces and a sufficiently large subset of the symmetry group so that all such surfaces can be obtained from one by the action of the subset. We emphasize that this has to work within the constraint surface of the classical theory so that we can interpret the transformations. Clearly, for these purposes, the weak action is not adequate. First, the maximally symmetric surfaces will lie in the group completed constraint surface, but not, in general, inside that of the system; the intersection of such surfaces with the constraint surface of the system will not be, in general, globally transversal. Second, an image of a globally transversal surface by an element of the group that has only a weak action will not, in general, lie inside the constraint surface. It is easy to construct examples of this kind for the action of G_1. This means that only the subgroup G_0 is at our disposal for Dirac's construction.

The group $G_0=\mathrm{SO}(1,2)\times\mathbf{R}$ generated by $\mathscr{T}^0$, $\mathscr{T}^1$, $\mathscr{T}^2$, and $\mathscr{D}$ is a Cartesian product of two simple groups. Its three-dimensional subgroups are of two types:

(1) SO (1,2), which is the *unique* subgroup of this type, because it is a normal subgroup;
(2) Subgroups that leave a null plane invariant; an example is the subgroup of the plane $X^0+X^1=0$, which is generated by $\mathscr{T}^0+\mathscr{T}^1$, $\mathscr{T}^2$ and $\mathscr{D}$. All other subgroups of this type are (group-) similar to this one.

The surfaces in Γ' symmetric with respect to SO (1,2) satisfy $-(X^0)^2+(X^1)^2+(X^2)^2=\mathrm{const}(\mathrm{const}<0)$, have two components (with $X^0>0$ and $X^0<0$), and form a one-dimensional

family. The components coincide with the CMC surfaces, and the union of both components is globally transversal. On the other hand, the projection of the surfaces to $\mathbf{M}^3$ that are invariant with respect to the null plane groups are of course these null planes; the surfaces do not lie inside the null cone $\iota(\tilde{\Gamma}')$ and their intersections with $\iota(\tilde{\Gamma}')$ are not transversal. We summarize the results:

Theorem 2: *The* $2+1$ *gravity model possesses a unique one-dimensional family of maximally symmetric globally transversal surfaces. Each such surface has two components that are CMC surfaces with opposite values of the CMC.*

The second step of the construction is to find a subgroup that would carry us along the family of the CMC surfaces. Thus, it must be a subgroup whose elements are representatives of all classes of $G_0/\mathrm{SO}(1,2)$. However, $G_0/\mathrm{SO}(1,2)=\mathbf{R}$, so the desired subgroup is generated by just one element, which must have the form $\mathscr{D}+a\mathscr{T}^0+b\mathscr{T}^1+c\mathscr{T}^2$, where a, b, and c are three arbitrary reals. We can normalize the generator in this way, as the overall factor does not change the subgroup, and the factor in front of $\mathscr{D}$ must be nonzero; a nontrivial motion of the CMC surface is generated just by the $\mathscr{D}$ term. Let us study how it acts on the CMC τ. Using Eqs. (22) and (28), we find that

$$\{\tau,D\}=-\frac{2\epsilon}{\sqrt{-X\cdot X}}.$$

Thus, for $\epsilon>0$, the action of D diminishes τ, and for $\epsilon<0$, it enlarges τ. $\epsilon>0$ ($\epsilon<0$) means that we are in the future (past) light cone of the origin. In the future light cone, we have expanding tori ($\tau>0$) and they expand from the ''big bang'' $\tau=\infty$ to the maximal expansion state $\tau=0$. Thus, D generates evolution towards future here. In the past light cone ($\tau<0$), we have contracting tori that start at the maximal expansion state $\tau=0$ and finish at the ''big crunch'' $\tau=-\infty$. Thus D generates an evolution towards past. Luckily enough, there is a smooth Hamiltonian H that evolves everything towards the future; $H=D$ inside the future light cone and $H=-D$ inside the past light cone. Let us calculate the corresponding perennial $\overline{H}$ on the physical phase space $\overline{\Gamma}_{\mathrm{ISO}}$. From the proof of theorem 1, it follows that the portion $\overline{\Gamma}'_+$ of the physical phase space that corresponds to the future half of the light cone is given by $x_1\cos\alpha+x_2\sin\alpha<0$ and that $\overline{\Gamma}'_-$ corresponding to the past one by $x_1\cos\alpha+x_2\sin\alpha>0$. However, Eq. (24) implies that

$$p_1=p\cos\alpha,\quad p_2=p\sin\alpha,$$

where $p<0$. Here x_1, x_2, p_1, and p_2 are the coordinates that we have chosen in the physical phase space $\overline{\Gamma}$ (cf. Eq. (38)). Then, from the last of Eq. (40) it follows that $\overline{D}$ is positive for the expanding tori and negative for the contracting ones, or

$$\overline{H}=|\overline{D}|. \tag{54}$$

In the general case, we start from the function

$$\overline{D}+a\overline{J^0}+b\overline{J^1}+c\overline{J^2}.$$

As it is only the D-part which leads to changes in τ, the Hamiltonian that evolves towards the future corresponding to the above function is

$$\overline{H}=\mathrm{sign}(\overline{D})(\overline{D}+a\overline{J^0}+b\overline{J^1}+c\overline{J^2}).$$

Equations (40) lead to

$$\overline{H}=\mathrm{sign}(\mathbf{x}\cdot\mathbf{p})[\mathbf{x}\cdot\mathbf{p}+a(x_1p_2-x_2p_1)+bx_2\sqrt{\mathbf{p}\cdot\mathbf{p}}-cx_1\sqrt{\mathbf{p}\cdot\mathbf{p}}].$$

Let us change the variables x_1, x_2, p_1, and p_2 to $\overline{D}$, $\overline{J^0}$, p, α; we obtain

$$\overline{H}=|\overline{D}|(1+b\sin\alpha-c\cos\alpha)+\mathrm{sign}(\overline{D})\overline{J^0}(a+b\cos\alpha+c\sin\alpha). \tag{55}$$

We can see that $\overline{H}$ is unbounded from below except for the case that $a=b=c=0$, because $\overline{J^0}$ can take on arbitrary values independent of $\overline{D}$ and α. Hence, (54) is the only one from the three-dimensional family of possible candidates for a Hamiltonian that is bounded from below (and even positive). This is, of course, nothing but an intriguing observation; there is no *a priori* reason for the generator of the time evolution, even if it evolves towards the future, to be bounded from below or positive, unless it plays simultaneously another role, for example that of the total energy of the system. We also observe that the dynamics simplifies strongly if we choose (54) in comparison with all other candidates; $\overline{J^\mu}$ becomes time independent, and P_μ just scales with time. The next comment is that the choice (54) leads to the dynamics that has been obtained by Moncrief.[17] Finally, it is easy to see that there will be no problem to define the quantum mechanical operator $\hat{H}$ from H, if the operators $\hat{D}$ and $\hat{J}^\mu$ are given, because $\hat{D}$ will commute with all $\hat{J}$'s. The corresponding problem of ranges will be automatically solved, if we define $|\hat{H}|$ by the spectral theorem.

VI. THE PHYSICAL REPRESENTATION

The physical representation of the algebra so(2,3) would map each element of the algebra to a linear operator on a common invariant dense domain $\mathscr{K}_0$ in a Hilbert space $\mathscr{K}$; the map R must satisfy the following conditions:

(1) R is linear, $R(1)=id$, and
$$(i/\hbar)R(\{X,Y\})=R(X)R(Y)-R(Y)R(X)$$
for all X, $Y\in$ so(2,3) on $\mathscr{K}_0$;
(2) the operators $R(X)$ for all $X\in$ so(2,3) are essentially self-adjoint on $\mathscr{K}_0$;
(3) the problem of ranges is satisfactorily solved;
(4) the operators $R(X)$ for all $X\in$ so(2,3) satisfy algebraic relations that go over to (41)–(44) in the classical limit.

In general, the group method of quantization of an algebra $\mathbf{g}$ of observables on a symplectic manifold (M,Ω) is to find a unitary representation on a Hilbert space $\mathscr{K}$ of the group G corresponding to the algebra. Then, the generators of the group action on $\mathscr{K}$ satisfy automatically the conditions (1) and (2), but a part of condition (3) $(P_0<0)$ and condition (4) can pose problems.

In this section, we are going to use an old idea of finding the physical representation by the group way; the Kostant–Kirillov method of orbits. This method works quite generally for finite systems. Let us briefly describe the steps of the method (for more detail see Refs. 25 and 27).

The method of orbits is based on the momentum map Π determined by the algebra of observables $\mathbf{g}$ (in this way, the relations and ranges are encoded). $\Pi(M)$ is a particular orbit ω of G in the linear space $\mathbf{g}^*$ dual to the Lie algebra $\mathbf{g}$, where the group acts via the coadjoint representation.

The method starts with a choice of a point $F\in\omega$ and with calculating the stabilizer $G_F\subset G$ of F. Then, the subalgebra $\mathbf{n}_F$ called subordinate to F must be found satisfying the conditions

(1) $\langle F,[X,Y]\rangle=0 \quad \forall X,Y\in\mathbf{n}_F$,
(2) $\mathrm{codim}_{\mathbf{g}}\mathbf{n}_F=(1/2)\dim\ \omega$,
(3) Pukanszky's condition; let $\mathbf{n}_F^\perp$ be the subspace of $\mathbf{g}^*$ that annihilates $\mathbf{n}_F$, then, $F+\mathbf{n}_F^\perp\subset\omega$.

One can show that $\mathbf{g}_F\subset\mathbf{n}_F$. The subalgebra $\mathbf{n}_F$ generates a subgroup N_F of G and one must find a one-dimensional unitary representation $R_{\mathbf{n}}$ of N_F such that

$$R_{\mathbf{n}}(\exp\ X)=\exp(\langle F,X\rangle)$$

in a neighborhood of the identity of N_F. Such a representation will exist, if Kirillov's symplectic form of ω is integral (its integral over any two-cycle is an integer). The physical representation is then just the unitary representation of G induced by N_F (see Refs. 25 and 28).

In our case, $M=\Gamma_0$ and as the group we first take SO(2,3). The momentum map Π will be described in terms of a coordinate system in $\mathbf{g}^*$; the coordinate system will be associated with the basis that is dual to (46); let the corresponding coordinates be $(\xi_\mu,\zeta_\mu,\theta^\mu,\delta)$. Then, the momentum map is given by

$$\left.\begin{array}{lll} \xi_0=-\sqrt{\mathbf{p}\cdot\mathbf{p}}, & \zeta_0=-(\mathbf{x}\cdot\mathbf{x})\sqrt{\mathbf{p}\cdot\mathbf{p}}, & \theta^0=x_1p_2-x_2p_1, \\ \xi_1=p_1, & \zeta_1=(\mathbf{x}\cdot\mathbf{x})p_1-2(\mathbf{x}\cdot\mathbf{p})x_1, & \theta^1=-x_2\sqrt{\mathbf{p}\cdot\mathbf{p}}, \\ \xi_2=p_2, & \zeta_2=(\mathbf{x}\cdot\mathbf{x})p_2-2(\mathbf{x}\cdot\mathbf{p})x_2, & \theta^2=x_1\sqrt{\mathbf{p}\cdot\mathbf{p}}, \\ & & \delta=\mathbf{x}\cdot\mathbf{p}. \end{array}\right\} \tag{56}$$

As the group SO(2,3) has a trivial center, the momentum map is a symplectic isomorphism and the homogeneous symplectic space (Γ_0,Ω_0) of G can be identified with the orbit ω. Then, the Kirillov symplectic form Ω_0 is exact and so it is trivially integral.

Let us choose the point F corresponding to the point $u\in\Gamma_0$ that is given by the values of coordinates $x_1=x_2=0$, $p_1=1$, and $p_2=0$. From Eqs. (56), we calculate the coordinates of F to be $(-1,1,0,0,0,0,0,0,0,0)$. The map of $\mathbf{g}$ into $T_F\omega$ is given by the values of the vector fields (47)–(53) at the point u,

$$\mathscr{P}_0\mapsto-\frac{\partial}{\partial x_1},\quad \mathscr{P}_k\mapsto\frac{\partial}{\partial x_k}, \tag{57}$$

$$\mathscr{Q}_0\mapsto 0,\quad \mathscr{Q}_k\mapsto 0, \tag{58}$$

$$\mathscr{T}^0\mapsto\frac{\partial}{\partial p_2},\quad \mathscr{T}^1\mapsto\frac{\partial}{\partial p_2},\quad \mathscr{T}^2\mapsto-\frac{\partial}{\partial p_1}, \tag{59}$$

$$\mathscr{D}\mapsto-\frac{\partial}{\partial p_1}. \tag{60}$$

The kernel of the map is, therefore, the subalgebra $\mathbf{g}_F$ generated by $\mathscr{P}_0+\mathscr{P}_1$, $\mathscr{T}^0-\mathscr{T}^1$, $\mathscr{D}-\mathscr{T}^2$, and $\mathscr{Q}_\mu$, $\mu=0,1,2$. The algebra $\mathbf{g}_F$ has to be extended to $\mathbf{n}_F$. Thus, we have to find a two-dimensional subspace of $\mathbf{g}/\mathbf{g}_F$ which is invariant with respect to $\mathbf{g}_F$. $\mathbf{g}/\mathbf{g}_F$ is four-dimensional; we choose $[\mathscr{P}_1]$, $[\mathscr{P}_2]$, $[\mathscr{T}^1]$, and $[\mathscr{T}^2]$ as its basis. The action of $Y\in\mathbf{g}_F$ on $\mathbf{g}/\mathbf{g}_F$ is given by $[X]\mapsto\pi([X,Y])$, where X is a representation of an element of the basis of $\mathbf{g}/\mathbf{g}_F$, $[X]$ is the corresponding class, and π is the projector from $\mathbf{g}$ to $\mathbf{g}/\mathbf{g}_F$. A straightforward calculation gives

	$\mathscr{P}_0+\mathscr{P}_1$	$\mathscr{T}^0-\mathscr{T}^1$	$\mathscr{D}-\mathscr{T}^2$	$\mathscr{Q}_0$	$\mathscr{Q}_1$	$\mathscr{Q}_2$
$[\mathscr{P}_1]$	0	$[-\mathscr{P}_2]$	0	$[2.\mathscr{T}^2]$	$[2.\mathscr{T}^2]$	$[-2.\mathscr{T}^1]$
$[\mathscr{P}_2]$	0	0	$[-\mathscr{P}_2]$	$[-2.\mathscr{T}^1]$	$[2.\mathscr{T}^1]$	$[2.\mathscr{T}^2]$
$[\mathscr{T}^1]$	$[\mathscr{P}_2]$	$[\mathscr{T}^2]$	$[-\mathscr{T}^1]$	0	0	0
$[\mathscr{T}^2]$	0	0	0	0	0	0

Our task is to find a two-dimensional (in general complex) common invariant subspace of all six transformations. The Abelian subalgebra generated by $\mathscr{Q}_0$, $\mathscr{Q}_1$, and $\mathscr{Q}_2$ is represented by triangular matrices. They have a common invariant subspace T spanned by $[\mathscr{T}^1]$ and $[\mathscr{T}^2]$; there is no complex linear combination $[a\mathscr{P}_1+b\mathscr{P}_2]$ that would be mapped by all $\mathscr{Q}_\mu$, $\mu=0,1,2$, to a one-dimensional subspace of T. Thus, T is the only two-dimensional invariant subspace of all $\mathscr{Q}_\mu$, $\mu=0,1,2$. However, this subspace is not invariant with respect to $\mathscr{P}_0+\mathscr{P}_1$. Hence, no subordinate algebra $\mathbf{n}_F$ exists for the whole group SO(2,3).

In fact, if we just want to have a unitary representation of SO(2,3) by complex functions on a two-dimensional manifold M (this reflects the fact that we have two physical degrees of freedom), then such a representation will determine a definite action of SO(2,3) on M that will be transitive, or else the representation will not be irreducible. Then, $M=\mathrm{SO}(2,3)/G_M$, where G_M is a stabilizer of a point of M. Thus, SO(2,3) had to admit an eight-dimensional subgroup. However, there is no such subgroup.[28]

There is, however, $\mathbf{n}_F$, if we restrict ourselves to some subgroup of SO(2,3); the largest are G_1, generated by $(\mathscr{P}_0,\mathscr{P}_1,\mathscr{P}_2,\mathscr{T}^0,\mathscr{T}^1,\mathscr{T}^2,\mathscr{D})$ and G_2 generated by $(\mathscr{Q}_0,\mathscr{Q}_1,\mathscr{Q}_2,\mathscr{T}^0,\mathscr{T}^1,\mathscr{T}^2,\mathscr{D})$. Γ_0 is still a space where G_1 or G_2 act; they do not act transitively, however: the points with $x_1=x_2=0$ are invariant with respect to G_2 and those with $y_1=y_2=0$

with respect to G_1. These points have to be cut out in respective cases. Thus, the coordinate patch (x_k,p_k) is a homogeneous space of G_1 and (y_k,q_k) that of G_2. The action of the group G_1 on T^*U is the same as that of G_2 on T^*V in the respective coordinates. Let us consider G_1 and $T^*\mathbf{M}^3$ only. In fact, only this case is a group extension of our original system, namely a G_1-extension.

From the corresponding part of the table, we can see immediately that there are two different invariant subspaces; T_1 spanned by $[\mathscr{P}_1]$ and $[\mathscr{P}_2]$ and T_2 spanned by $[\mathscr{P}_2]$ and $[\mathscr{T}^2]$. It is easy to see that there are no others. From T_2, we obtain the subalgebra $\mathbf{n}_{2F}$ generated by $\mathscr{P}_0+\mathscr{P}_1$, $\mathscr{P}_2$, $\mathscr{T}^0-\mathscr{T}^1$, $\mathscr{T}^2$ and $\mathscr{D}$; $\mathbf{n}_{2F}$ satisfies the conditions (1) and (2), but it does not satisfy Pukanszky's condition. Indeed, the subspace $\mathbf{n}_{2F}^{\perp}$ that annihilates it has the form $(a,-a,0,b,b,0,0)$ where $(a,b)\in\mathbf{R}^2$. The subset $F+\mathbf{n}_{2F}^{\perp}$ is given by $(-1+a,1-a,0,b,b,0,0)$. This will lie in ω if the equations

$$-\sqrt{\mathbf{p}\cdot\mathbf{p}}=-1+a,\quad p_1=1-a,\quad p_2=0,$$

$$x_1p_2-x_2p_1=b,\quad -x_2\sqrt{\mathbf{p}\cdot\mathbf{p}}=b,\quad x_1\sqrt{\mathbf{p}\cdot\mathbf{p}}=0,$$

$$x\cdot\mathbf{p}=0,$$

have solutions for any a and b. However, the first equation implies that $a<1$. Thus, this algebra is not admissible. Similar calculation for T_1 shows that the corresponding algebra $\mathbf{n}_{1F}$ satisfies all three conditions and so it is the only possibility. Let us concentrate on $\mathbf{n}_{1F}$, which is generated by $\mathscr{P}_0$, $\mathscr{P}_1$, $\mathscr{P}_2$, $\mathscr{T}^0-\mathscr{T}^1$, and $\mathscr{D}-\mathscr{T}^2$.

The map of the Lie algebra $\mathbf{g}_1$ of the group G_1 into $T_F\omega$ given by Eqs. (47) and (50)–(53) sends $\mathbf{n}_{1F}$ on the subspace $E_F\in T_F\omega$ spanned by the vectors

$$\frac{\partial}{\partial x_1},\quad \frac{\partial}{\partial x_2}. \tag{61}$$

We can use the action ad* of the group G_1 to bring the subspace from the point F to any other point of ω; this is a well-defined procedure, because $\mathbf{n}_{1F}$ is invariant with respect to the stabilizer G_{1F} of F. The result is the subspace spanned by (61) at any point (x_1,x_2,p_1,p_2) of ω. Indeed, we can use the four one-dimensional subgroups of G_1 generated by $\mathscr{P}_1$, $\mathscr{P}_2$, $\mathscr{T}^0$, and $\mathscr{T}^2$. The corresponding vector fields given by Eqs. (47), (50), and (52) describe the action of these generators on ω; their projections to the submanifold $x_1=x_1^0$, $x_2=x_2^0$ for any constant x_1^0 and x_2^0 is independent of x_1^0 and x_2^0. Thus, the curve defined by

$$x_1=\gamma_1(t),\quad x_2=\gamma_2(t),\quad p_1=p_1^0,\quad p_2=p_2^0, \tag{62}$$

with the real constants p_1^0 and p_2^0 will be mapped onto a curve of the form

$$x_1=\gamma_1'(t),\quad x_2=\gamma_2'(t),\quad p_1=p_1'^0,\quad p_2=p_2'^0$$

by any element of the group. Hence, the subspace E_F will be mapped to the subspace $E_{F'}$ spanned by the vectors (61) at any point F' of ω with $x_1=x_2=0$ and p_1 and p_2 arbitrary. The vector fields (61) (which are now used in their role of the action of $\mathscr{P}_1$ and $\mathscr{P}_2$) can easily be integrated; they generate the maps

$$(x_1,x_2,p_1,p_2)\mapsto(x_1+a,x_2+b,p_1,p_2)$$

with arbitrary a and b. Thus, curves of the form (62) are mapped to

$$x_1=\gamma_1(t)+a,\quad x_2=\gamma_2(t)+b,\quad p_1=p_1^0,\quad p_2=p_2^0.$$

Hence, $E_{F'}$ goes over to $E_{F''}$ spanned again by (61) in an arbitrary point F'' of ω. The resulting subbundle of the tangent bundle is called *polarization*. It is an integrable subbundle, its integral manifolds $\mathscr{E}$ being given by $p_1=\text{const}$, $p_2=\text{const}$.

At this stage, it is much quicker to guess the form of the operators representing the Lie algebra than to calculate the representation according to the general procedure by Kostant–Kirillov. The unitary representation of G_1 that we are going to construct is induced by the representation $R_{\mathbf{n}}$ of the subgroup N_{1F} that is generated by the subalgebra $\mathbf{n}_{1F}$. Thus, the Hilbert space will be built from complex functions on the homogeneous space G_1/N_{1F}. This may be identified with the manifold $\Gamma_{\mathrm{ISO}}/\mathscr{E}$ that is just $\mathbf{R}^2\backslash\{0\}$ with the coordinates p_1 and p_2 and which we have denoted by $\mathscr{P}$ in Sec. IV A. If we look at the formula for the induced representation [see e.g., Ref. 28, p. 479, formula (15)], we can see that there will be three kinds of terms in the operators representing the Lie algebra of G_1. From the representation of N_{1F}, multiplicative terms will come; they must clearly be multiplications by $-\sqrt{\mathbf{p}\cdot\mathbf{p}}$, p_1, and p_2 for the operators $\hat{P}_0$, $\hat{P}_1$, and $\hat{P}_2$. From the action of G_1 on the classes G_1/N_{1F}, differential operators come; they must be projections of the vector fields (47), (50)–(53) to the space $\mathscr{P}$ multiplied by $-i$,

$$J^0_{\mathrm{diff}}=ip_2\frac{\partial}{\partial p_1}-ip_1\frac{\partial}{\partial p_2},$$

$$J^1_{\mathrm{diff}}=-i\sqrt{\mathbf{p}\cdot\mathbf{p}}\,\frac{\partial}{\partial p_2},\quad J^2_{\mathrm{diff}}=i\sqrt{\mathbf{p}\cdot\mathbf{p}}\,\frac{\partial}{\partial p_1},$$

$$D_{\mathrm{diff}}=ip_1\frac{\partial}{\partial p_1}+ip_2\frac{\partial}{\partial p_2}.$$

Finally, there will be terms coming from the Radon–Nikodym derivative that will correct the differential operators. Such terms have the general form

$$\frac{i}{2\sigma}\,(\xi_{\mathrm{diff}}\sigma),$$

where σ is a quasi-invariant measure on G_1/N_{1F}. Different but equivalent measures will lead to unitarily equivalent representations. A choice that strongly simplifies the correction terms is

$$\sigma=\frac{1}{\sqrt{\mathbf{p}\cdot\mathbf{p}}}.$$

Then, finally, the operators must have the form

$$\hat{P}_0\psi(p)=-\sqrt{\mathbf{p}\cdot\mathbf{p}}\psi(p),\quad \hat{P}_k\psi(p)=p_k\psi(p), \tag{63}$$

$$\hat{J}^0\psi(p)=ip_2\frac{\partial\psi(p)}{\partial p_1}-ip_1\frac{\partial\psi(p)}{\partial p_2}, \tag{64}$$

$$\hat{J}^1\psi(p)=-i\sqrt{\mathbf{p}\cdot\mathbf{p}}\,\frac{\partial\psi(p)}{\partial p_2},\quad \hat{J}^2=i\sqrt{\mathbf{p}\cdot\mathbf{p}}\,\frac{\partial\psi(p)}{\partial p_1}, \tag{65}$$

$$\hat{D}=ip_1\frac{\partial\psi}{\partial p_1}+ip_2\frac{\partial\psi}{\partial p_2}+\frac{i}{2}\,\psi. \tag{66}$$

It is straightforward but tedious to verify that this guessed operators coincide with those that would follow from the full general construction of the representation.

An interesting question is: What happened with the relations? For the group G_1, we have only three relations, and we can take Eqs. (41) and (45). Composing the corresponding operators on a common invariant domain [say, $C^\infty_0(\mathscr{P})$], we obtain easily,

$$-\hat{P}_0^2+\hat{P}_1^2+\hat{P}_2^2=0, \tag{67}$$

$$\hat{J}^0\hat{P}_0+\hat{J}^1\hat{P}_1+\hat{J}^2\hat{P}_2=0, \tag{68}$$

$$-\hat{D}^2-(\hat{J}^0)^2+(\hat{J}^1)^2+(\hat{J}^2)^2=\tfrac{1}{4}. \tag{69}$$

Thus only the last relation has been deformed (of course, there will be $\hbar^2/4$ at the right-hand side, if $\hbar$, which has been set equal 1, is restored). The left-hand sides of Eqs. (67)–(69) are generalized Casimirs of the group G_1 in the following sense. Let $E(\mathbf{g}_1)$ be the envelopping algebra of $\mathbf{g}_1$, let $\mathscr{H}=-\mathscr{P}_0^2+\mathscr{P}_1^2+\mathscr{P}_2^2$ represent the constraint and let $\mathscr{I}(\mathscr{H})$ be the ideal in $E(\mathbf{g}_1)$ generated by $\mathscr{H}$. Then, the classes of the left-hand sides of Eqs. (67)–(69) in $E(\mathbf{g}_1)/\mathscr{I}(\mathscr{H})$ commute with all elements of $E(\mathbf{g}_1)/\mathscr{I}(\mathscr{H})$.

It is interesting to observe that each state ψ of the Hilbert space $\mathscr{K}$ of the physical representation must satisfy the equation

$$(-\hat{P}_0^2+\hat{P}_1^2+\hat{P}_2^2)\psi=0, \tag{70}$$

which follows from Eq. (67). This is a point where the group method touches the operator constraint method of quantization, because Eq. (70) has the form of the operator constraint equation of our system (for more detail, see Ref. 20).

Existence theorems for hairy black holes in $\mathfrak{su}(N)$ Einstein–Yang–Mills theories

N. E. Mavromatos and E. Winstanley[a)]
University of Oxford, Theoretical Physics, 1 Keble Road OX1 3NP, United Kingdom

(Received 15 December 1997; accepted for publication 13 April 1998)

We establish the existence of hairy black holes in $\mathfrak{su}(N)$ Einstein–Yang–Mills theories, described by $N-1$ parameters, corresponding to the nodes of the gauge field functions. © *1998 American Institute of Physics.* [S0022-2488(98)01807-6]

I. INTRODUCTION

Interest in non-Abelian Einstein–Yang–Mills theories was sparked by the discovery of particlelike[1] and non-Reissner–Nordström (''hairy'') black hole[2] solutions when the gauge group is $\mathfrak{su}(2)$. Since then a plethora of hairy black holes, possessing nontrivial geometry and a field structure outside the event horizon, have been found (see, for example, Ref. 3), including colored black holes in $\mathfrak{su}(N)$ Einstein–Yang–Mills theories.[4,5] Many of these objects have as a fundamental requirement for the existence of hair, a non-Abelian gauge field, often coupled to other fields, such as a Higgs field.[6] As in Ref. 6 the existence of gauge hair is not surprising in itself, since the gauge field force is long range. However, the non-Abelian nature of the field is important for evading the no-hair theorem, for example, for scalar fields coupled to the gauge field. The vast majority of these solutions have been found only numerically, with analytic work in this area at present being limited to an extensive study of the $\mathfrak{su}(2)$ case,[7–9] and some analysis of the field equations for general N.[10,11]

In this paper we continue this analysis of the coupled Einstein–Yang–Mills equations for an $\mathfrak{su}(N)$ gauge field, and prove analytically the existence of ''genuine'' hairy black hole solutions for every N. By a ''genuine'' $\mathfrak{su}(N)$ black hole, we mean a solution which is not simply the result of embedding a smaller gauge group in $\mathfrak{su}(N)$. As in the $\mathfrak{su}(2)$ case, the solutions are labeled by the number of nodes of each of the $N-1$ nonzero functions required to describe the gauge field. We shall prove that for each integer n_1, there are an infinite number of sequences of integers $n_{N-1} \geqslant n_{N-2} \geqslant \cdots \geqslant n_1$ corresponding to black hole solutions. It is to be expected that, in fact, *every* such sequence corresponds to a black hole solution, but unfortunately we are unable to prove this analytically, although we shall present a numerically based argument for $\mathfrak{su}(3)$ and numerical investigations [such as that done for $\mathfrak{su}(5)$ in Ref. 4] for higher dimension groups which indicate that this is, in fact, the case. The method used to prove the main theorem of this paper is remarkably simple, drawing only on elementary topological ideas.

The structure of the paper is as follows. In Sec. II we review briefly the $\mathfrak{su}(N)$ Einstein–Yang–Mills field equations and the ansatz and notations we shall employ in the rest of the paper. Next, we state some elementary properties of these equations, including results from Ref. 11. The remainder of the paper has a similar progression of ideas as in Ref. 7, and we continue by first analyzing the behavior of solutions to the field equations in the two asymptotic regimes, at infinity and close to the event horizon. Although these forms were discussed in Ref. 11, we present here a shorter proof. Section V is devoted to a discussion of the flat space solutions, which will be important for later propositions. The results here are somewhat weaker than in Ref. 7 due to the fact that for $\mathfrak{su}(N)$, we have $N-1$ variables and therefore have a $2(N-1)$-dimensional phase space rather than a phase plane as in the $\mathfrak{su}(2)$ case, so the powerful Poincaré–Bendixson theory no longer applies. We now consider integrating the field equations outward from the event horizon and consider the various possible behaviors of the resulting solutions. As in Ref. 7 there are three types of solutions: the regular black holes we are seeking, singular solutions (in which the lapse function vanishes outside the event horizon), and oscillating solutions in which the geometry is not

asymptotically flat. The main results of this paper are in Secs. VII and VIII. An inductive argument is used to prove the existence of solutions for $\mathfrak{su}(N)$, assuming existence for $\mathfrak{su}(N-1)$ [since we have rigorous theorems for $\mathfrak{su}(2)$[7,8]]. The argument is presented in detail for $\mathfrak{su}(3)$ in Sec. VII and a brief outline of the extension to general N in Sec. VIII. Finally, a summary and our conclusions are presented in Sec. IX.

II. ANSATZ AND FIELD EQUATIONS

In this section we first describe the ansatz we are using and outline the field equations.

The field equations for an $\mathfrak{su}(N)$ Yang–Mills gauge field coupled to gravity have been derived in Ref. 10 for a spherically symmetric geometry. We take the line element, in the usual Schwarzschild coordinates, to be

$$ds^2=-S^2\mu dt^2+\mu^{-1}dr^2+r^2d\theta^2+r^2\sin^2\theta d\phi^2, \tag{1}$$

where the metric functions μ and S are functions of r alone and

$$\mu(r)=1-\frac{2m(r)}{r}. \tag{2}$$

A spherically symmetric $\mathfrak{su}(N)$ gauge potential may be written in the form[10]

$$\mathcal{A}=\mathcal{A}dt+Bdr+\frac{1}{2}(C-C^H)d\theta-\frac{i}{2}[(C+C^{\mathrm{H}})\sin\theta+D\cos\theta]d\phi, \tag{3}$$

where $D=\mathrm{Diag}\{k_1,k_2,\ldots,k_N\}$ with $k_1\geqslant k_2\geqslant\cdots\geqslant k_N$ integers whose sum is zero. In addition, C is a strictly upper triangular complex matrix such that $C_{ij}\neq 0$ only if $k_i=k_j+2$ and C^{H} its Hermitian conjugate, and A, B are anti-Hermitian matrices that commute with D. An irreducible representation of $\mathfrak{su}(N)$ can be constructed by taking[10]

$$D=\mathrm{Diag}\{N-1,N-3,\ldots,-N+3,-N+1\}. \tag{4}$$

In this case A, B have trace zero and can be written as

$$A_{jj}=i\left\{-\frac{1}{N}\sum_{k=1}^{j-1}k\mathcal{A}_k+\sum_{k=j}^{N-1}\left(1-\frac{k}{N}\right)\mathcal{A}_k\right\}, \tag{5}$$

for real functions $\mathcal{A}_k$, and similarly for B. The only nonvanishing entries of C are

$$C_{j,j+1}=\omega_j e^{i\gamma}, \tag{6}$$

where ω_j and γ_j are real functions. All the functions in this ansatz depend only on r. Now we make the following simplifying assumption:[10]

$$\mathcal{A}_j=0,\quad \mathcal{B}_j+\gamma_j'=0,\quad \forall_j. \tag{7}$$

The remaining gauge freedom can then be used to set $B=0$,[12] which implies that the γ_j are constants, which we choose to be zero for simplicity.

The gauge field equations for the ω_j then take the form[10,11] (where we have set $\kappa=2$ in Ref. 10)

$$r^2\mu\omega_j''+(2m-2r^3p_\theta)\omega_j'+[1-\omega_j^2+\tfrac{1}{2}(\omega_{j-1}^2+\omega_{j+1}^2)]\omega_j=0, \tag{8}$$

where

$$p_\theta=\frac{1}{4r^4}\sum_{j=1}^{N}[\omega_j^2-\omega_{j-1}^2-N-1+2j]^2, \tag{9}$$

and the Einstein equations can be simplified to

$$m' = \mu G + r^2 p_\theta, \quad \frac{S'}{S} = \frac{2G}{r}, \tag{10}$$

where

$$G = \sum_{j=1}^{N-1} \omega_j'^2. \tag{11}$$

Note that $\omega_0 \equiv 0 \equiv \omega_N$, so that these are the usual equations[2] in the $\mathfrak{su}(2)$ case, and have a very similar, but slightly coupled, structure for general N. The equations (8)–(11) possess two symmetries.[11] First, the substitution $\omega_j \to -\omega_j$ for any fixed j leaves the equations invariant, exactly as in the $\mathfrak{su}(2)$ case. Second, there is an additional symmetry under the transformation $j \to N-j$ for all j. We will not assume that this symmetry is respected by the solutions of the field equations, so that the $\mathfrak{su}(3)$ case is not necessarily trivial.

We are concerned in this paper with black holes, which will have a regular event horizon at $r = r_h$, where $\mu = 0$. The equations in their present form are singular at r_h, so in order to produce a set of equations which are regular as $\mu \to 0$, we define a new independent variable τ by[7]

$$\frac{dr}{d\tau} = r\sqrt{\mu}, \tag{12}$$

denote $d/d\tau$ by; and define new dependent variables κ, U_j, and Ψ as follows:[7]

$$\Psi = \sqrt{\mu}, \quad U_j = \Psi \omega_j', \quad \kappa = \frac{1}{2\Psi}\,(1 + \Psi^2 + 2\mu G - 2r^2 p_\theta). \tag{13}$$

Then the field equations take the form[7]

$$\dot{r} = r\Psi, \tag{14}$$

$$\dot{\omega}_j = r U_j, \tag{15}$$

$$\dot{\Psi} = (\kappa - \Psi)\Psi - 2\mu G, \tag{16}$$

$$(S\Psi)^{\cdot} = S(\kappa - \Psi)\Psi, \tag{17}$$

$$\dot{U}_j = -(\kappa - \Psi)U_j - \frac{1}{r}\left[1 - \omega_j^2 + \frac{1}{2}\,(\omega_{j+1}^2 + \omega_{j-1}^2)\right]\omega_j, \tag{18}$$

$$\dot{\kappa} = -\kappa^2 + 1 + 2\mu G. \tag{19}$$

The main thrust of this article is to prove the existence of regular, black hole solutions of the field equations for general N with $N-1$ degrees of freedom. In other words, we begin with a regular event horizon at $r = r_h$, where $\mu = 0$, and integrate outward with increasing r. Later we shall classify the possible behavior of the solutions as r increases. We are interested primarily in those solutions which possess the physical properties of a black hole geometry, namely, for which $\mu > 0$ for all $r > r_h$, the ω_j and their derivatives are finite for all $r > r_h$ and the spacetime becomes flat in the limit $r \to \infty$. We shall refer to such solutions as *regular black hole solutions*.

III. ELEMENTARY RESULTS

In this section we state a few elementary results, which will prove useful in a later analysis. First, two lemmas which are proved in the $\mathfrak{su}(N)$ case exactly as in the $\mathfrak{su}(2)$ case; see Ref. 7.

Lemma III.1: If $\mu(r_0) < 1$ *for some* r_0 *then* $\mu(r) < 1$ *for all* $r \geqslant r_0$.

Lemma III.2: As long as $0 < \mu < 1$ *all field variables are regular functions of* r.

These two lemmas show that for a regular event horizon at $r=r_h$, where $\mu=0$, then $\mu<1$ for all $r>r_h$ and the field variables are regular functions as long as $\mu>0$. The black hole solutions we seek approach the Schwarzschild geometry as $r\to\infty$, so we may assume that all ω_j are bounded for all r (from Lemma III.2 each ω_j is bounded on every closed interval $[r_h, r_1]$, so we are simply assuming that ω_j remains bounded as $r\to\infty$). It will be proved in Sec. VI that this assumption is, in fact, valid for solutions having $\mu>0$ for all r. Define a quantity M_j for each j to be the lowest upper bound on ω_j^2, i.e.,

$$\omega_j^2\leqslant M_j, \quad \forall_j=1,2,...,N-1. \tag{20}$$

It has been shown in Ref. 8 that the following result is true for $N=2$, and proved, in general, with the assumption that all ω_j are bounded via an elegant method in Ref. 11.

Theorem III.3 $M_j\leqslant j(N-j)$:

Part of the proof of this theorem in Ref. 11 involves a knowledge of where ω_j may have maxima or minima. The result following is less powerful than in the $\mathfrak{su}(2)$ case due to the coupling in the gauge field equation (8).

Proposition III.4: As long as $\mu(r)>0$, the function $\omega_j(r)$ cannot have maxima in the regions

$$\omega_j>\sqrt{1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)} \quad \textit{and} \quad 0>\omega_j>-\sqrt{1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)}, \tag{21}$$

or minima in the regions

$$\omega_j<-\sqrt{1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)} \quad \textit{and} \quad 0<\omega_j<\sqrt{1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)}. \tag{22}$$

Proof: When $\omega_j'=0$, from (8),

$$\mu\omega_j''=-\frac{1}{r^2}\left[1-\omega_j^2+\frac{1}{2}\,(\omega_{j+1}^2+\omega_{j-1}^2)\right]\omega_j, \tag{23}$$

so that ω_j will have a maximum if

$$\omega_j>0 \quad \text{and} \quad \omega_j^2<1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2), \tag{24}$$

or

$$\omega_j<0 \quad \text{and} \quad \omega_j^2>1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2). \tag{25}$$

Similarly, ω_j will have a minimum if

$$\omega_j>0 \quad \text{and} \quad \omega_j^2>1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2), \tag{26}$$

or

$$\omega_j<0 \quad \text{and} \quad \omega_j^2<1+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2). \tag{27}$$

□

IV. ASYMPTOTIC BEHAVIOR OF SOLUTIONS

We seek solutions to the above field equations representing black holes with a regular event horizon at $r=r_h$ and finite total energy density. In order to prove the local existence of solutions of the field equations with the desired asymptotic behavior, we shall apply the following theorem.[7]

Theorem IV.1: *Consider a system of differential equations for $n+m$ functions* $\mathbf{a}=(a_1,a_2,\ldots,a_n)$ *and* $\mathbf{b}=(b_1,b_2,\ldots,b_m)$ *of the form*

$$x\,\frac{da_i}{dx}=x^{p_i}f_i(x,\mathbf{a},\mathbf{b}), \quad x\,\frac{db_i}{dx}=-\lambda_i b_i+x^{q_i}g_i(x,\mathbf{a},\mathbf{b}), \tag{28}$$

with constants $\lambda_i > 0$ *and integers* p_i, $q_i \geqslant 1$ *and let* $\mathscr{C}$ *be an open subset of* $\mathbb{R}^n$ *such that the functions* f_i *and* g_i *are analytic in a neighborhood of* $x=0$, $\mathbf{a}=\mathbf{c}$, $\mathbf{b}=\mathbf{0}$, *for all* $\mathbf{c} \in \mathscr{C}$. *Then there exists an n-parameter family of solutions of the system (28) such that*

$$a_i(x) = c_i + O(x^{p_i}), \quad b_i(x) = O(x^{q_i}), \tag{29}$$

where $a_i(x)$ *and* $b_i(x)$ *are defined for* $\mathbf{c} \in \mathscr{C}$, *and* $|x| < x_0(\mathbf{c})$ *and are analytic in* x *and* $\mathbf{c}$.

In this section we consider only the equations for μ and the ω_j. The equation for S (10) is independent of the others and hence can be integrated immediately once we have the other field variables, with an additional parameter. This procedure gives a finite answer on any closed, bounded interval on which the remaining variables are finite. Results similar to Propositions IV.2 and IV.3 were proved in Ref. 11, but here we are using a more straightforward approach.

A. Behavior at infinity

As $r \to \infty$, in order to have finite total energy density, the geometry must approach the Schwarzschild solution, that is,

$$m \to M = \text{const}, \quad G \to 0, \quad p_\theta \to 0. \tag{30}$$

Hence each ω_j must approach a constant value, which is fixed by (30) to be

$$\omega_j^2 \to j(N-j). \tag{31}$$

The equations for the ω_j are then automatically satisfied in the limit as $r \to \infty$.

Proposition IV.2: There exists an N-parameter family of local solutions of (8)–(11) near $r = \infty$ *analytic in* c_j, M, *and* r^{-1} *such that*

$$\mu(r) = 1 - \frac{2M}{r} + O\left(\frac{1}{r^4}\right), \quad \omega_j(r) = \sqrt{j(N-j)} - \frac{c_j}{r} + O\left(\frac{1}{r^2}\right). \tag{32}$$

Proof: Introduce new variables,

$$x = \frac{1}{4}, \quad \psi_j = r(\sqrt{j(N-j)} - \omega_j), \quad \xi_j = r^2 \mu \omega_j', \quad \lambda = r(1-\mu). \tag{33}$$

Then

$$x \frac{d\lambda}{dx} = -\frac{2}{x}(\mu G + r^2 p_\theta), \tag{34}$$

where

$$G = x^4 \sum_{j=1}^{N-1} \frac{\xi_j^2}{\mu^2} \tag{35}$$

and

$$p_\theta = \frac{x^4}{4} \sum_{j=1}^{N} [x^2 \psi_j^2 - x^2 \psi_{j-1}^2 - 2x\psi_j \sqrt{j(N-j)} + 2x\psi_{j-1}\sqrt{(j-1)(N-j+1)}]^2, \tag{36}$$

that is,

$$x \frac{d\lambda}{dx} = -x^3 f_\lambda, \tag{37}$$

where f_λ is a polynomial in x, μ^{-1}, ξ's, and ψ's. Similarly,

$$x\frac{d\psi_j}{dx}=-\psi_j+\frac{1}{\mu}\xi_j=-\psi_j+\xi_j+xf_{\psi_j}, \tag{38}$$

where f_{ψ_j} is analytic in x, λ, ψ's, and ξ's in a neighborhood of $x=0$. Using the field equations, we also have

$$\begin{aligned}x\frac{d\xi_j}{dx}=&-2\xi_j+2\psi_j[j(N-j)]-\psi_{j-1}\sqrt{j(j-1)(N-j)(N-j+1)}\\&-\psi_{j+1}\sqrt{j(j+1)(N-j)(N-j-1)}+xf_{\xi_j},\end{aligned} \tag{39}$$

where f_{ξ_j} is a polynomial in x, μ^{-1}, ψ's, and ξ's. The algebra simplifies if we define new functions α_j, β_j such that

$$\psi_j=\alpha_j+\beta_j, \quad \xi_j=\alpha_j+\Lambda\beta_j, \tag{40}$$

where Λ is a real constant not equal to unity. The equations for α_j and β_j then read as

$$\begin{aligned}(\Lambda-1)x\frac{d\alpha_j}{dx}=&2\alpha_j-2[j(N-j)]\alpha_j+\sqrt{j(j-1)(N-j)(N-j+1)}\alpha_{j-1}\\&+\sqrt{j(j+1)(N-j)(N-j-1)}\alpha_{j+1}+(\Lambda^2+\Lambda)\beta_j-2[j(N-j)]\beta_j\\&+\sqrt{j(j-1)(N-j)(N-j+1)}\beta_{j-1}+\sqrt{j(j+1)(N-j)(N-j-1)}\beta_{j+1}+xf_{\alpha_j},\end{aligned} \tag{41}$$

$$\begin{aligned}(\Lambda-1)x\frac{d\beta_j}{dx}=&-2\alpha_j+2[j(N-j)]\alpha_j-\sqrt{j(j-1)(N-j)(N-j+1)}\alpha_{j-1}\\&-\sqrt{j(j+1)(N-j)(N-j-1)}\alpha_{j+1}+(1-3\Lambda)\beta_j+2[j(N-j)]\beta_j\\&-\sqrt{j(j-1)(N-j)(N-j+1)}\beta_{j-1}-\sqrt{j(j+1)(N-j)(N-j-1)}\beta_{j+1}+xf_{\beta_j},\end{aligned}$$

where the f_{α_j} and f_{β_j} are analytic functions of x, μ^{-1}, α's, and β's. Consider the matrix $\mathscr{M}_{N-1}$ whose entries are

$$\begin{pmatrix}2(N-1) & -\sqrt{(N-1)2(N-2)} & \cdots\\ -\sqrt{(N-1)2(N-2)} & 2.2(N-2) & \cdots\\ 0 & -\sqrt{2(N-2)3(N-3)} & \cdots\\ \vdots & \vdots & \vdots\end{pmatrix}. \tag{42}$$

For a vector $\mathbf{q}=(q_1,\ldots,q_{N-1})$, let $p_j=\sqrt{j(N-j)}q_j$ for $j=1,\ldots,N-1$. Then

$$\mathbf{q}^T\mathscr{M}_{N-1}\mathbf{q}=p_1^2+p_{N-1}^2+(p_1-p^2)^2+\cdots(p_{N-2}-p_{N-1})^2. \tag{43}$$

Hence, the matrix $\mathscr{M}_{N-1}$ is real, symmetric, and positive definite, and will have positive real eigenvalues $\mathscr{E}_i$, and corresponding eigenvectors $\mathbf{v}_i$. We may expand our variable vectors in terms of eigenvectors of $\mathscr{M}_{N-1}$ as follows:

$$\boldsymbol{\alpha}=\sum_{i=1}^{N-1}A_i(x)\mathbf{v}_i, \quad \boldsymbol{\beta}=\sum_{i=1}^{N-1}B_i(x)\mathbf{v}_i, \tag{44}$$

$$\mathbf{f}_\alpha=\sum_{i=1}^{N-1}F_i(x)\mathbf{v}_i, \quad \mathbf{f}_\beta=\sum_{i=1}^{N-1}G_i(x)\mathbf{v}_i, \tag{45}$$

in terms of which the equations (41) now become

$$(\Lambda-1)x\,\frac{dA_i}{dx}=(2-\mathscr{E}_i)A_i+(\Lambda^2+\Lambda-\mathscr{E}_i)B_i+xF_i\,,$$
$$(\Lambda-1)x\,\frac{dB_i}{dx}=(\mathscr{E}_i-2)A_i+(1-3\Lambda+\mathscr{E}_i)B_i+xG_i\,. \tag{46}$$

This transformation has removed the coupling between the j's, but the A's and B's are still coupled. Repeating the procedure with the matrix $\mathscr{P}_i$ will decouple these equations, where

$$\mathscr{P}_i=\begin{pmatrix} 2-\mathscr{E}_i & \Lambda^2+\Lambda-\mathscr{E}_i \\ -2+\mathscr{E}_i & 1-3\Lambda+\mathscr{E}_i \end{pmatrix}. \tag{47}$$

This matrix has eigenvalues

$$\mu_\pm=\tfrac{1}{2}(1-\Lambda)(3\pm\sqrt{1+4\mathscr{E}_i}), \tag{48}$$

and corresponding eigenvectors $\mathbf{V}_\pm$. Writing

$$\begin{pmatrix} A_i \\ B_i \end{pmatrix}=C_+(x)\mathbf{V}_++C_-(x)\mathbf{V}_-\,,\quad \begin{pmatrix} F_i \\ G_i \end{pmatrix}=D_+(x)\mathbf{V}_++D_-(x)\mathbf{V}_-\,, \tag{49}$$

the equations are now

$$(\Lambda-1)x\,\frac{dC_\pm}{dx}=\mu_\pm C_\pm+xD_\pm\,. \tag{50}$$

In the case where $\mu_-<0$, Theorem IV.1 applies directly, and we have

$$C_-=O(x); \tag{51}$$

when $\mu_-=0$ (corresponding to $\mathscr{E}_i=2$),

$$C_-=K_-+O(x), \tag{52}$$

for some constant K_-. The other eigenvalue μ_+ is always strictly positive, and in this situation Theorem IV.1 does not apply. However, Eq. (50) can be integrated using the standard Picard method (see, for example, Ref. 13) to give an analytic solution,

$$C_+=K_++O(x). \tag{53}$$

Both $C_\pm$ will be analytic in $K_\pm$ and x in some neighborhood of $x=0$ and substituting back through Eqs. (44) and (49) gives solutions of the form (32), as required. □

B. Behavior at the event horizon

We assume that at $r=r_h$ there is a nondegenerate event horizon, namely, $\mu(r_h)=0$, but $\mu'(r_h)>0$ is finite.

Proposition IV.3: There exists an N-parameter family of local solutions of (8)–(11) near $r=r_h$, *analytic in* r_h, $\omega_{j,h}$ *and* r *such that*

$$\mu(r_h+\rho)=\mu'(r_h)+O(\rho),$$
$$\omega_j(r_h+\rho)=\omega_{j,h}+w_j'(r_h)+O(\rho^2), \tag{54}$$

where $\mu'(r_h)$ *and* $\omega_j'(r_h)$ *are functions of the* $\omega_{j,h}$.

Proof: Let $\rho=r-r_h$ be the new independent variable, and define

$$x=r,\quad \lambda=\frac{\mu}{\rho},\quad \psi_j=\omega_j\,,\quad \xi_j=\frac{\mu\omega_j'}{\rho}. \tag{55}$$

Then the field equations take the form

$$\rho \frac{dx}{d\rho} = \rho, \tag{56}$$

$$\rho \frac{d\lambda}{d\rho} = -\lambda + \left[\frac{1}{x} - 2xp_\theta\right] + \rho \frac{\lambda}{x}[1-2G] = -\lambda + \rho H_\lambda + F_\Lambda, \tag{57}$$

$$\rho \frac{d\psi_j}{d\rho} = \frac{\rho \xi_j}{\lambda}, \tag{58}$$

$$\rho \frac{d\xi_j}{d\rho} = -\xi_j + \rho H_j + F_j, \tag{59}$$

where the F's and H's are polynomials in x^{-1}, λ^{-1}, and the other variables, and the F's depend only on x and ψ_j's. Next, define

$$\tilde{\xi}_j = \xi_j - F_j, \quad \tilde{\lambda} = \lambda - F_\lambda, \tag{60}$$

whose derivatives are given by

$$\rho \frac{d\tilde{\xi}_j}{d\rho} = -\tilde{\xi}_j + \rho G_j, \tag{61}$$

$$\rho \frac{d\tilde{\lambda}}{d\rho} = -\tilde{\lambda} + \rho G_\lambda. \tag{62}$$

Here the G's are analytic in $x^{-1}, \lambda^{-1}, \lambda, x, \tilde{\lambda}, \psi_j, \tilde{\xi}_j$. Applying Theorem IV.1, there exist solutions of the form

$$x = r_h + \rho, \quad \psi_j = \omega_{j,h} + O(\rho), \quad \tilde{\lambda}, \tilde{\xi}_y = O(\rho), \tag{63}$$

which gives the behavior (54), together with the required analyticity. From the field equations (8)–(11), setting $\mu(r_h) = 0$, gives the following relations:

$$\mu'(r_h) = \tfrac{1}{2} r_h^2 p_\theta(r_h), \tag{64}$$

$$\omega_j'(r_h) = -\frac{[1 - \omega_{j,h}^2 + \frac{1}{2}(\omega_{j-1,h}^2 + \omega_{j+1,h}^2)\omega_{j,h}]}{r_h - r_h^3 \rho_\theta(r_h)}, \tag{65}$$

where

$$p_\theta(r_h) = \frac{1}{4r_h^4} \sum_{j=1}^{N} [\omega_{j,h}^2 - \omega_{j-1,h}^2 - N - 1 + 2j]^2. \tag{66}$$

□

V. FLAT SPACE SOLUTIONS

The behavior of the gauge field equations in the flat space limit will be useful later in Sec. VI, when we come to examine the properties of regular solutions. We are not concerned here with the global existence of flat space solutions, but only the local properties pertinent to the curved space problem.

The analysis here is similar to that in Ref. 7, but note that for general N there will be $N-1$ coupled gauge field equations. The powerful Poincaré–Bendixson theory of autonomous systems is not applicable when $N > 2$, and so we will be able to derive only correspondingly weaker results,

and cannot draw a phase portrait. Fortunately, the theorems later require only a knowledge of the nature of the critical points and the local behavior close to these points, which is the subject of this section.

In flat space the gauge field equations reduce to

$$r^2\omega_j''+[1-\omega_j^2+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)]\omega_j=0. \tag{67}$$

These equations can be made autonomous by changing variables to $\tau=\log r$, and denoting $d/d\tau$ by

$$\ddot{\omega}_j-\dot{\omega}_j+[1-\omega_j^2+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)]\omega_j=0. \tag{68}$$

This system of $N-1$ coupled equations has critical points when

$$[1-\omega_j^2+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)]\omega_j=0, \quad \forall j=1,2,...,N-1. \tag{69}$$

If $\omega_j\neq 0$ for all j, then

$$\omega_j=\sqrt{j(N-j)}. \tag{70}$$

There is also a critical point when $\omega_j=0$ for all j.

The other critical points can be described as follows. Suppose that $\omega_i=0$ and $\omega_{i+k}=0$, but that $\omega_{i+m}\neq 0$ for $m=1,...,k-1$ (where $k\geqslant 2$). The critical point is then described by the equations

$$\begin{aligned} 0&=\omega_i\,,\\ 0&=1-\omega_{i+1}^2+\tfrac{1}{2}(\omega_i^2+\omega_{i+2}^2),\\ &\vdots\\ 0&=1-\omega_{i+k-1}^2+\tfrac{1}{2}(\omega_{i+k-2}^2+\omega_{i+k}^2),\\ 0&=\omega_{i+k}\,, \end{aligned} \tag{71}$$

which have the solution

$$\omega_{i+m}=\sqrt{m(k-m)}, \quad \text{for } m=1,...,k-1. \tag{72}$$

In other words, if we have a run of k nonzero ω's with zero ω_i at each end, then the solution for the nonzero ω's is the same as the $N=k$ case with no zero ω's. We can also put together a run of as many zero ω's as we like in the critical point.

In order to classify the critical points, we linearize the field equations. Let

$$\omega_j(\tau)=\omega_j^{(0)}+\epsilon_j(\tau), \tag{73}$$

where $\omega_j^{(0)}$ is the value of ω_j at the critical point and ϵ_j is a small perturbation. The equation for ϵ_j is, to first order.

$$0=\ddot{\epsilon}_j-\dot{\epsilon}_j+\epsilon_j[1-\omega_j^{(0)2}+\tfrac{1}{2}(\omega_{j+1}^{(0)2}+\omega_{j-1}^{(0)2})]+\omega_j^{(0)}[-2\epsilon_j\omega_j^{(0)}+\epsilon_{j+1}\omega_{j+1}^{(0)}+\epsilon_{j-1}\omega_{j-1}^{(0)}]. \tag{74}$$

We shall take the two cases we need to consider in turn.

First, the case where $\omega_j^{(0)}=0$, when the equation for ϵ_j reduces to

$$\ddot{\epsilon}_j-\dot{\epsilon}_j+\epsilon_j[1+\tfrac{1}{2}(\omega_{j+1}^{(0)2}+\omega_{j-1}^{(0)2})]=0. \tag{75}$$

In order to find the nature of the critical point, let

$$\epsilon_j=e^{\lambda\tau}; \tag{76}$$

then λ satisfies the equation

$$\lambda^2-\lambda+[1+\tfrac{1}{2}(\omega_{j+1}^{(0)2}+\omega_{j-1}^{(0)2})]=0. \tag{77}$$

This implies that

$$\lambda=\tfrac{1}{2}\pm\tfrac{1}{2}i\alpha, \tag{78}$$

where α is the positive real number given by

$$\alpha^2=3+2\omega_{j+l}^{(0)2}+2\omega_{j-1}^{(0)2}. \tag{79}$$

We conclude that, in the $(\epsilon_j,\dot{\epsilon}_j)$ plane, we have an unstable focal point, as found in the $\mathfrak{su}(2)$ case in Ref. 7.

Second, we consider the situation in which there is at least one $\omega_j^{(0)}$ which is nonzero. Suppose that $\omega_i^{(0)}=0$, and $\omega_{i+k}^{(0)}=0$, but $\omega_{i+m}^{(0)}\neq 0$ for $m=1,...,k-1$, where we include the case that $i=0$ and $k=N$. Then we have a series of coupled perturbation equations:

$$\begin{aligned}
0&=\ddot{\epsilon}_{i+1}-\dot{\epsilon}_{i+1}-2\epsilon_{i+1}\omega_{i+1}^{(0)2}+\epsilon_{i+2}\omega_{i+2}^{(0)}\omega_{i+1}^{(0)},\\
0&=\ddot{\epsilon}_{i+2}-\dot{\epsilon}_{i+2}-2\epsilon_{i+2}\omega_{i+2}^{(0)2}+\epsilon_{i+3}\omega_{i+3}^{(0)}\omega_{i+2}^{(0)}+\epsilon_{i+1}\omega_{i+1}^{(0)}\omega_{i+2}^{(0)},\\
&\vdots\\
0&=\ddot{\epsilon}_{i+k-1}-\dot{\epsilon}_{i+k-1}-2\epsilon_{i+k-1}\omega_{i+k-1}^{(0)2}+\epsilon_{i+k-2}\omega_{i+k-2}^{(0)}\omega_{i+k-1}^{(0)}.
\end{aligned} \tag{80}$$

Define a vector $\boldsymbol{\epsilon}$ by

$$\boldsymbol{\epsilon}=(\epsilon_{i+1},\ldots,\epsilon_{i+k-1})^T, \tag{81}$$

and consider solutions of the form

$$\boldsymbol{\epsilon}=\boldsymbol{\epsilon}^{\lambda r}\mathbf{q}, \tag{82}$$

where $\mathbf{q}$ is a constant vector. Then $\lambda^2-\lambda$ are eigenvalues of the matrix $\mathscr{M}_{k-1}$ given by (42). As discussed in Sec. IV, the matrix $\mathscr{M}_{k-1}$ has positive real eigenvalues $\mathscr{E}_j$. Then

$$\lambda=\frac{1\pm\sqrt{1+4\mathscr{E}_j}}{2}=j+1,-j \tag{83}$$

will have positive and negative real values, and there is a saddle point. Again this is in direct analogy with the $\mathfrak{su}(2)$ case.[7]

VI. GLOBAL BEHAVIOR OF THE SOLUTIONS

In this section we investigate the behavior of solutions of the regular field equations (14)–(19) as functions of τ. From Sec. IV, we know that, given any starting values $\omega_{j,h}$ for the gauge field functions, then there is a local solution of the field equations in a neighborhood of the regular event horizon at $r=r_h$, $\tau=0$, which is analytic in τ and the initial parameters. Furthermore, from Lemma III.2, as long as $0<\Psi<1$ the solutions remain regular. Therefore, as we integrate out in τ from the event horizon there are only three possibilities.

(1) There is a $\tau_0>0$ such that $\Psi(\tau_0)=0$.
(2) For all $\tau>0$, we have $\Psi(\tau)>0$ and $r(\tau)$ remains bounded as $\tau\to\infty$.
(3) For all $\tau>0$, we have $\Psi(\tau)>0$ and $r(\tau)\to\infty$ as $\tau\to\infty$.

We refer to solutions of the first type as *singular* solutions. Those of type (2) are known as *oscillating* solutions in Ref. 7, and we retain their terminology. It will be shown below (Proposition VI.4), that there is a maximum value $r_{\max}$ of r for oscillating solutions. Finally, we denote by S_∞ solutions of the first type for which $r(\tau_0)<r_{\max}$. Our first task is to show that solutions of type

(3) are precisely the black hole solutions we are seeking. We begin by proving the assumption made at the end of Sec. II, namely, that for solutions of type (3), each ω_j is bounded for all r.

Lemma VI.1: If $\Psi(\tau)>0$ *for all* τ *and* $\lim_{\tau\to\infty} r(\tau)=\infty$ *then all the* ω_j *remain bounded as* $r\to\infty$.

Proof: From the local existence Propositions IV.3 and IV.2 and Lemma III.2, each ω_j is an analytic function of r as long as $\mu>0$. Introduce a new variable $x=r^{-1}$; then each ω_j is an analytic function of x in a neighborhood of $x=0$, except possibly at $x=0$, and can be written as a Laurent series:

$$\omega_j(x)=\sum_{n=-\infty}^{\infty} a_n^j x^n. \tag{84}$$

In order for $\mu>0$ for all r, it must be the case that $2mr^{-1}=2mx<1$, although m itself need not necessarily remain bounded. Hence $2mx$ is bounded in a neighborhood of $x=0$, and, in particular, is analytic at $x=0$. Therefore we can write

$$2mx=\sum_{n=0}^{\infty} b_n x^n. \tag{85}$$

Thus

$$m=\frac{1}{2}\sum_{n=0}^{\infty} b_n x^{n-1}, \quad \frac{dm}{dr}=-x^2\frac{dm}{dx}=-\frac{1}{2}\sum_{n=0}^{\infty} b_n(n-1)x^n, \tag{86}$$

so that dm/dr is analytic in a neighborhood of $x=0$. From the field equations,

$$\frac{dm}{dr}=\mu G+r^2 p_\theta, \tag{87}$$

where

$$G=\sum_{j=1}^{N-1}\left(\frac{d\omega_j}{dr}\right)^2, \quad r^2 p_\theta=\frac{x^2}{4}\sum_{j=1}^{N}[\omega_j^2-\omega_{j-1}^2-N-1+2j]^2. \tag{88}$$

Since both G and $r^2 p_\theta$ are positive, they must each be analytic in a neighborhood of $x=0$. Consider G first, using

$$\frac{d\omega_j}{dr}=-x^2\frac{d\omega_j}{dx}=-\sum_{n=-\infty}^{\infty} a_n^j n x^{n+1}, \tag{89}$$

and since $(d\omega_j/dr)^2$ must be analytic near $x=0$, it must be the case that

$$a_n^j=0, \quad \forall n<-1. \tag{90}$$

Then

$$\omega_j^2=\frac{a_{-1}^{j2}}{x^2}+\sum_{n=-1}^{\infty} c_n^j x^n, \tag{91}$$

for constants c_n^j and hence

$$\omega_j^2-\omega_{j-1}^2-N-1+2j=\frac{1}{x^2}[a_{-1}^{j2}-a_{-1}^{(j-1)2}]+\sum_{n=-1}^{\infty} d_n^j x^n. \tag{92}$$

Since $r^2 p_\theta$ is analytic,

$$a^{j}_{-1} = \pm a^{j-1}_{-1}, \quad \forall j. \tag{93}$$

But $\omega_0 \equiv 0$, so $a^{0}_{-1} = 0$, and thus $a^{j}_{-1} = 0$ for all j. We conclude that ω_j is analytic at $x = 0$, and therefore finite as $x = 0$. Therefore ω_j is bounded for all $r \in [r_h, \infty)$. □

Proposition VI.2: If $\Psi(\tau) > 0$ *for all* τ *and* $\lim_{\tau\to\infty} r(\tau) = \infty$, *then the solution tends to one of the flat space critical points, with the exception of the origin.*

The proof of this proposition closely follows Proposition 14 of Ref. 7, the main thrust of which is the following lemma.

Lemma VI.3: If $\Psi(\tau) > 0$ *for all* τ *and* $\lim_{\tau\to\infty} r(\tau) = \infty$ *then*

$$\lim_{\tau\to\infty} \Psi(\tau) = 1. \tag{94}$$

Proof: There are two cases to consider.

(1) There is at least one ω_j which has zeros for arbitrarily large r.
(2) All ω_j have only a finite number of zeros.

Case 1: The proof in this situation follows exactly that of Proposition 14 of Ref. 7 [Eqs. (74)–(76)] since all the ω_j's are bounded (Lemma VI.1).

Case 2: In this case there is a $T_1 > 0$ such that for all $\tau > T_1$ no ω_j has a zero. However, since the equations governing the ω_j are coupled, the ω_j do not necessarily have to be monotonic, provided Proposition III.4 is satisfied.

Suppose, initially, that there is a $T_2 > T_1$ such that for all $\tau > T_2$ every ω_j is monotonic. In this situation each ω_j has a limit and so $\lim_{\tau\to\infty} U_j = 0$ for all j. Then the proof of Proposition 14 of Ref. 7 carries over directly to show that $m(\tau)$ is bounded and $\lim_{\tau\to\infty} \Psi(\tau) = 1$. The proof proceeds as follows. First, in analogy to Eq. (74) of Ref. 7, integrating the field equations (14)–(19) gives, for each j,

$$|\Psi U_j(\tau_2) - \Psi U_j(\tau_1)| \leqslant \frac{c_j}{r(\tau_1)}, \tag{95}$$

for all $\tau_2 > \tau_1 > T_2$, and some constant c_j, since all the ω_j are bounded. Fix τ_1 for the moment; then for all $\tau_3 > \tau_1$,

$$\int_{\tau_1}^{\tau_3} r \Psi U_j^2 d\tau' \leqslant c_j' \int_{\tau_1}^{\tau_3} \dot{\omega}_j d\tau' \leqslant c_j'', \tag{96}$$

for constants c_j' and c_j'', since ω_j has a limit. Hence

$$m(\tau_3) - m(\tau_1) \leqslant \frac{1}{2} \sum_{j=1}^{N-1} c_j'', \tag{97}$$

which is bounded.

Next, turn to the other extreme situation, where ω_j^2 has minima for arbitrarily large r, for every j. If ω_j^2 has a minimum at $r = r_0$, then by Proposition III.4,

$$\omega_j^2(r_0) \geqslant 1 + \tfrac{1}{2}(\omega_{j+1}^2(r_0) + \omega_{j-1}^2(r_0)). \tag{98}$$

Define N_j to be the greatest lower bound of the set of minimum values of ω_j^2 for $\tau > T_1$, where N_j can be zero (although ω_j^2 cannot). Then we have

$$N_j \geqslant 1 + \tfrac{1}{2}(N_{j+1} + N_{j-1}). \tag{99}$$

These inequalities may be solved to give

$$N_j \geqslant j(N - j), \quad \forall j. \tag{100}$$

However, since $\omega_j^2 \leqslant j(N-j)$ for all j from Theorem III.3, it follows that $\omega_j^2(\tau) = j(N-j)$ for sufficiently large τ and all j. Therefore $U_j(\tau)$ is zero for sufficiently large τ; hence $m(\tau)$ is bounded as $\tau \to \infty$ and $\lim_{\tau\to\infty} \Psi(\tau) = 1$.

The remaining intermediate case is where ω_j and ω_{j+l}, where $l > 1$, are monotonic for all sufficiently large τ, while ω_{j+i}^2, $i = 1,...,l-1$ have minima for arbitrarily large τ. We include the possibility that $j = 0$, to cover the case where there is only one ω_i which has a limit. Define L_1 and L_2 by

$$\omega_j^2 \to L_1, \quad \omega_{j+l}^2 \to L_2, \tag{101}$$

as $\tau \to \infty$. Given $\epsilon > 0$, there is a T_1 such that

$$|\omega_j^2 - L_1| < \epsilon, \quad |\omega_{j+l}^2 - L_2| < \epsilon, \quad \forall\, \tau > T_1. \tag{102}$$

If ω_{j+1}^2 has a minimum at $\tau_0 > T_1$, then

$$\omega_{j+1}^2(\tau_0) \geqslant 1 + \tfrac{1}{2}(\omega_{j+2}^2(\tau_0) + \omega_j^2(\tau_0)) \geqslant 1 + \tfrac{1}{2}(\omega_{j+2}^2(\tau_0) + L_1 - \epsilon). \tag{103}$$

With N_{j+1} as before, then

$$N_{j+1} \geqslant 1 + \tfrac{1}{2} N_{j+2} + K_1, \tag{104}$$

where $K_1 = \frac{1}{2}(L_1 - \epsilon)$. Similarly,

$$N_{j+l-1} \geqslant 1 + \tfrac{1}{2} N_{j+l-2} + K_2, \tag{105}$$

where $K_2 = \frac{1}{2}(L_2 - \epsilon)$. The remaining inequalities for $N_{j+2},\ldots, N_{j+l-2}$ are exactly as before (99). The previous method can be repeated to give

$$N_{j+i} \geqslant i(l-i) + K_1 + K_2, \quad i = i,\ldots,l-1. \tag{106}$$

Now define $\check{N}_i$ to be the lowest upper bound of the set of maximum values of ω_i^2 (which exists since ω_i^2 is bounded). If ω_{j+1}^2 has a maximum at $\tau_0 > T_1$, then

$$\omega_{j+1}^2(\tau_0) \geqslant 1 + \tfrac{1}{2}(\omega_{j+2}^2(\tau_0) + \omega_j^2(\tau_0)) \geqslant 1 + \tfrac{1}{2}(\omega_{j+2}^2 + L_1 + \epsilon). \tag{107}$$

The analysis now proceeds exactly as in the previous paragraph and yields

$$\tilde{N}_{j+i} \leqslant i(l-i) + \tilde{K}_1 + \tilde{K}_2, \quad i = 1,...,l-1, \tag{108}$$

where $\tilde{K}_i = \frac{1}{2}(L_i + \epsilon)$ for $i = 1,2$. In addition, by definition it must be the case that

$$\tilde{N}_{j+i} \geqslant N_{j+i}, \tag{109}$$

which means that

$$i(l-i) + \tfrac{1}{2}(L_1 + L_2) - \epsilon \leqslant N_{j+i} \leqslant \tilde{N}_{j+i} \leqslant i(l-i) + \tfrac{1}{2}(L_1 + L_2) + \epsilon, \tag{110}$$

for all $\epsilon > 0$, whence $\tilde{N}_{j+i} = N_{j+i}$ for all i and

$$\omega_{j+i}^2 = i(l-i) + \tfrac{1}{2}(L_1 + L_2), \tag{111}$$

for sufficiently large τ.

In conclusion, then, we have shown that the intermediate case has some ω_j's which are monotonic for sufficiently large τ, with the remaining ω_j's being constant for sufficiently large τ. Hence, in this case also m is bounded as $\tau \to \infty$ and $\lim_{\tau\to\infty} \Psi(\tau) = 1$. □

Proof of Proposition VI.2: In order to show that the geometry becomes flat as $\tau \to \infty$, it remains to show that $S \to 1$ as $\tau \to \infty$. From the proof of Lemma VI.3, for ω_j having a limit as $\tau \to \infty$, we have

$$rU_i = \dot{\omega}_i \to 0, \tag{112}$$

as $\tau \to \infty$. In case 1 of the proof of Lemma VI.3, the proof of Ref. 7 carries straight over to show that $U_i \to 0$ as $\tau \to \infty$ also in this situation. Now

$$\frac{\dot{S}}{S} = \Psi G = \frac{1}{\Psi} \sum_{i=1}^{N-1} U_i^2 \leqslant \frac{C}{\Psi r^2}, \tag{113}$$

for some constant C and sufficiently large τ. Therefore

$$\frac{S'}{S} = \frac{\dot{S}}{S} \frac{1}{r\Psi} \leqslant \frac{C}{\mu r^3} \leqslant \frac{\tilde{C}}{r^3}, \tag{114}$$

for some constant $\tilde{C}$ and sufficiently large τ, as $\mu \to 1$ as $\tau \to \infty$. This means that S has a finite limit as $\tau \to \infty$.

The field equations only involve S'/S rather than just S itself. Therefore S is defined only up to a multiplicative constant, and without loss of generality we may therefore take the finite limit of S as $\tau \to \infty$ to be 1, so that the space–time is asymptotically flat.

Let $\delta(\tau) = 2\Psi - \kappa - 1$ be a small perturbation; then the equation for ω_j reads as

$$\ddot{\omega}_j + [1 - \omega_j^2 + \tfrac{1}{2}(\omega_{j+1}^2 + \omega_{j-1}^2)]\omega_j = (1 + \delta(\tau))\dot{\omega}_j, \tag{115}$$

as $\tau \to \infty$. Since δ is small. it does not alter the position or nature of the critical points as compared with the exactly flat space case. Lemma VI.3 showed that each $\dot{\omega}_j$, $\ddot{\omega}_j \to 0$ as $\tau \to \infty$. Hence, ω_j must approach one of the critical points whose nature was elucidated in Sec. V. The flat space analysis showed that, if $\omega_j = 0$, then there is an unstable focal point in the $(\omega_j, \dot{\omega}_j)$ plane. Hence our solution cannot approach this value, unless $\omega_j \equiv 0$. The solution has to tend to one of the saddle points along a stable direction, and, in direct analogy with the $\mathfrak{su}(2)$ case,[14] there are no solutions where $\omega_j \to 0$ as $\tau \to \infty$. The solution must therefore be a member of the family found in the local existence theorem IV.2. □

The power of proposition VI.2 lies in that, if we can prove the existence of solutions for which $\Psi > 0$ for all $\tau > 0$ and $r \to \infty$, then these solutions are automatically the regular black holes (and, if $r_h \to 0$, soliton solutions[1]) we seek. We close this section by determining the asymptotic behavior of solutions of type (2).

Proposition VI.4: If $\Psi(\tau) > 0$ for all $\tau > 0$ and $r(\tau)$ remains bounded, then $\Psi \to 0$ and $\kappa \to 1$ as $\tau \to \infty$. In addition, there is at least one j for which $\omega_j \to 0$ as $\tau \to \infty$. and this ω_j has infinitely many zeros.

Proof: Since r is monotonic increasing and bounded, it has a limit r_0. In addition, m is monotonic increasing and bounded since the positivity of μ implies that

$$m < \frac{r}{2} \leqslant \frac{r_0}{2}. \tag{116}$$

As $\tau \to \infty$, $\dot{r} \to 0$ and hence $\Psi \to 0$ from (14). Consider the quantity

$$E = -\frac{r^2}{4}(1 + \Psi^2 - 2\kappa\Psi) = -\frac{r^2}{2}(-\mu G + r^2 p_\theta). \tag{117}$$

Then

$$\dot{E} = 2r^2\mu G\Psi - r^2\kappa\mu G < r^2\mu G(1 - \kappa) < 0, \tag{118}$$

for sufficiently large τ for which $\Psi < 1/2$, and since $\kappa > 1$.[7] Hence

$$E \to -\frac{r_0^2}{4}, \tag{119}$$

as $\tau\to\infty$, since E is monotonically decreasing for sufficiently large τ. Then, following Ref. 7 we have $\kappa\to 1$ as $\tau\to\infty$.

Let $\delta(\tau)=\kappa-2\Psi-1$ be small: then the equation for ω_j reads as

$$\ddot{\omega}_j=\dot{\omega}_j(-1-\delta)-\omega_j[1-\omega_j^2+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)]. \tag{120}$$

Replacing τ by $-\tau$ yields the equation

$$\ddot{\omega}_j=\dot{\omega}_j(1+\delta)-\omega_j[1-\omega_j^2+\tfrac{1}{2}(\omega_{j+1}^2+\omega_{j-1}^2)], \tag{121}$$

which is the equation for flat space solutions, so that ω_j must approach one of the critical points. The fact that $E\neq 0$ means that p_θ cannot tend to zero as $\tau\to\infty$ because μG does vanish in the limit. Hence, at least one of the ω_j's must be zero as $\tau\to\infty$. Since δ is small it alters neither the position nor the characteristics of the critical points, and hence this ω_j will go into the focus at zero. Therefore it oscillates infinitely many times before it hits zero. □

We may determine the value of r_0 as follows. Since κ is finite and we have (119), it follows that $r^2 p_\theta\to 1/2$ as $\tau\to\infty$. Hence

$$r_0^2=\frac{1}{2}\lim_{\tau\to\infty}\sum_{j=1}^{N}(\omega_j^2-\omega_{j-1}^2-N-1+2j)^2. \tag{122}$$

The maximum possible value of r_0^2 is when all $\omega_j\to 0$ as $\tau\to\infty$. In this case,

$$r_{0,\max}^2=\frac{1}{2}\sum_{j=1}^{N}(-N-1+2j)^2=\frac{1}{6}N(N-1)(N+1). \tag{123}$$

The minimum possible value of r_0^2 is when only one $\omega_j\to 0$ as $\tau\to\infty$, when

$$r_0^2=j^2(N-j)^2, \tag{124}$$

which has a minimum when $j=1$ or $N-1$, and

$$r_0^2=(N-1)^2. \tag{125}$$

With this value of r_0, we follow Ref. 7 and denote by S_∞ singular solutions for which μ vanishes outside the event horizon when $r<r_{0,\max}$.

VII. $\mathfrak{su}(3)$ BLACK HOLES

We are now in a position to prove the existence of regular black holes. We begin in this section with $\mathfrak{su}(3)$, which we shall study in some detail, before proceeding to the general case in the next section. The method in general is exactly the same as in this section, but it is hoped that by doing the simplest specific case, where we have just two gauge field degrees of freedom, explicitly, the proof will be more transparent.

Genuine $\mathfrak{su}(3)$ solutions [as opposed to embedded $\mathfrak{su}(2)$ solutions which are discussed below] have been found numerically in Ref. 11. There it was conjectured that, analogous to the $\mathfrak{su}(2)$ case, black hole solutions exist for an infinite, but discrete, set of points in the parameter space given by the values at the event horizon of the functions describing the gauge degrees of freedom.

First, we review briefly the way in which $\mathfrak{su}(2)$ solutions may be embedded in $\mathfrak{su}(3)$. For neutral black holes, numerical solutions are discussed in Ref. 5, where both $\mathfrak{su}(2)$ and $\mathfrak{so}(3)$ embeddings are discussed. The $\mathfrak{so}(3)$ embedding contains scaled $\mathfrak{su}(2)$ black holes as well as genuine $\mathfrak{so}(3)$ solutions possessing two degrees of freedom, which are indexed by the number of nodes of each of the gauge field functions. The method for embedding charged black holes can be found in Ref. 4, where the various possible embeddings are described in detail and numerical solutions presented for the various embeddings in $\mathfrak{su}(5)$. Such solutions possess Coulomb charge arising from one or more of the gauge degrees of freedom. The remaining gauge field functions do not contribute to the charge and have structures similar to the neutral solutions. The black holes are once again indexed by the number of nodes of the gauge functions.

Neutral black holes. Let $\omega_1(r)=\sqrt{2}\omega(r)$ and $\omega_2(r)=\sqrt{2}\omega(r)$. Then the field equations (8)–(11) become

$$r^2\mu\omega''=-(2m-2r^3p_\theta)\omega'-(1-\omega^2)\omega, \tag{126}$$

$$m'=(\mu G+r^2p_\theta), \tag{127}$$

$$\frac{S'}{S}=\frac{2G}{r}, \tag{128}$$

where

$$\mu=1-\frac{2m}{r}, \quad G=4\omega'^2, \quad p_\theta=\frac{2}{r^4}(\omega^2-1)^2. \tag{129}$$

In order to extract the precise form of the $\mathfrak{su}(2)$ equations, define a new independent variable R and a new dependent variable M by

$$R=\tfrac{1}{2}r, \quad M=\tfrac{1}{2}m, \tag{130}$$

with the other field variables remaining unchanged. Then the equations are

$$R^2\mu\frac{d^2\omega}{dR^2}=-\left[2M-\frac{(\omega^2-1)^2}{2R}\right]\frac{d\omega}{dR}-(1-\omega^2)\omega, \tag{131}$$

$$\frac{dM}{dR}=\left[\mu\left(\frac{d\omega}{dR}\right)^2+\frac{1}{2R^2}(\omega^2-1)^2\right], \tag{132}$$

$$\frac{1}{S}\frac{dS}{dR}=\frac{2}{R}\left(\frac{d\omega}{dR}\right)^2. \tag{133}$$

These are now exactly the $\mathfrak{su}(2)$ field equations, and the existence of regular black hole solutions has been proved in Refs. 7 and 9.

Charged black holes. Suppose $\omega_2(r)\equiv 0$ [the case $\omega_1(r)\equiv 0$ is identical]. Then

$$r^2\mu\omega_1''=-(2m-2r^3p_\theta)\omega_1'-(1-\omega_1^2)\omega_1, \tag{134}$$

$$m'=\left[\omega_1'^2+\frac{1}{2r^2}(\omega_1^2-1)^2+\frac{3}{2r^2}\right], \tag{135}$$

$$\frac{S'}{S}=\frac{2\omega_1'^2}{r}. \tag{136}$$

While these equations are *not* the same as those for $\mathfrak{su}(2)$ neutral black holes, the equations for κ, Ψ, U, ω_1, r, and S as functions of τ are identical. Hence the analysis of Ref. 7 carries over immediately to prove the existence of black hole solutions of this form.

Our first existence proposition states the existence of genuine $\mathfrak{su}(3)$ black holes, that is, black holes which do not belong to one of the two families outlined above. The proof is remarkably simple once we have set up our notation suitably.

Proposition VII.1: There exist regular black hole solutions of the $\mathfrak{su}(3)$ *Einstein–Yang–Mills equations which do not correspond to embedded* $\mathfrak{su}(2)$ *charged or neutral black holes.*

The strategy in proving this proposition is very similar to that used in Ref. 7. Generic values of the starting parameters $(\omega_{1,h},\omega_{2,h})$ lead to a singular solution, but we will prove that there must be some values of the starting parameters which do not lead to a singular solution. First, we rule out the possibility of solutions of type (2). From Sec. VI, any solution for which $\mu(\tau)>0$ for all τ and $r(\tau)$ remains bounded as $\tau\to\infty$, has $r\to r_0$ as $\tau\to\infty$, where

$$(N-1)^2 \leqslant r_0^2 \leqslant \tfrac{1}{6}N(N+1)(N-1). \tag{137}$$

For $N=3$, therefore, $r_0=2$. Fixing $r_h>2$ will therefore rule out the possibility of such solutions. This is analogous to the value $r_h>1$ which rules out such solutions in the $\mathfrak{su}(2)$ case. At the end of this section we shall return to the existence proof for $r_h \leqslant 2$.

For every pair of starting values $(\omega_{1,h},\omega_{2,h})$ there are then just two possibilities.

(1) $\mu(\tau)>0$ for all τ and we have a regular black hole solution.
(2) There is a $\tau_0>0$ such that $\mu(\tau_0)=0$, and we have a singular solution.

Define a new variable R by

$$R=\frac{r-r_h}{r}, \tag{138}$$

and R_m by the maximum value of R for each solution, that is, in case one $R_m=1$ (corresponding to $r\to\infty$), and in case two $R_m=R(\tau_0)$. For each solution we define n_i to be the number of zeros of the function ω_i between $\tau=0$ and $\tau=\infty$ in case 1 and $\tau=\tau_0$ in case (2), where n_i can be infinite. Defining new variables N_i by

$$N_i=\frac{n_i}{1+n_i}, \tag{139}$$

we allow the possibility that $N_i=1$.

Each pair of nonzero starting values $(\omega_{1,h},\omega_{2,h})$ can then be mapped to the three quantities (R_m,N_1,N_2) for the corresponding solution, giving rise to a map from $\mathbb{R}^2$ [$(\omega_{1,h},\omega_{2,h})$ space] to $\mathbb{B}^2\times[0,1]$ [(R_m,N_1,N_2) space], where $\mathbb{B}$ is the discrete set $\{0,\frac{1}{2},\frac{2}{3},\frac{3}{4},\ldots,1\}$. Call this map f. Figures 1–3 sketch the nature of $(\omega_{1,h},\omega_{2,h})$ space, $\mathbb{B}\times[0,1]$, and $\mathbb{B}^2$, respectively. Note that this map will not be 1–1 for $N=3$, although it was conjectured in Ref. 7 that for $N=2$ the map is 1–1.

Note that since we know the nature of the solution space when one of the $\omega_{i,h}$ vanishes (since in this case $\omega_i\equiv 0$), we do not need to extend the map f to the coordinate axes in $(\omega_{1,h},\omega_{2,h})$ space. With this notation, we are ready to prove Proposition VII.1, once we have the following lemma.

Lemma VII.2: Suppose that for starting values $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ *there is a singular solution with* $\mu(\overline{\tau}_0)=0$ *and the gauge field functions having node structure* $(\overline{n}_1,\overline{n}_2)$. *Then the map* f *is continuous at* $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$.

Proof: From Proposition IV.3, the field variables are continuous in τ and the starting parameters. Thus, all starting values $(\omega_{1,h},\omega_{2,h})$ in a sufficiently small neighborhood of $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ will give rise to a singular solution with $\mu(\tau_0)=0$ where τ_0 is close to $\overline{\tau}_0$, the values of the field variables at τ_0 will be close to those at $\overline{\tau}_0$ in the original solution, and the node structure will be $(\overline{n}_1,\overline{n}_2)$ since the gauge field functions cannot have double zeros (Proposition III.4). In other words, f is continuous at $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$. □

Proof of Proposition VII.1: Consider the open subset of the $(\omega_{1,h},\omega_{2,h})$ plane given by

$$D=\{(\omega_{1,h},\omega_{2,h}):0<\omega_{1,h}<\omega_{2,h}\}. \tag{140}$$

The subset $D'=\{(\omega_{1,h},\omega_{2,h}):0<\omega_{2,h}<\omega_{1,h}\}$ can be treated similarly. The symmetries of the field equations (8)–(11) mean that it is sufficient to consider only the first quadrant of the $(\omega_{1,h},\omega_{2,h})$ plane. From Ref. 7 we know that along the line $\omega_{1,h}=\omega_{2,h}$ there are singular solutions with node structure (n_1,n_1) for all $n_1=1,2,\ldots$. Therefore there are neighborhoods of D corresponding to singular solutions with node structure (n_1,n_1) for all $n_1=1,2,\ldots$. Hence $f(D)$ contains points corresponding to (R_m,N_1,N_1) for all $N_1\in\mathbb{B}$. Therefore $f(D)$ is not a connected set. Therefore f cannot be continuous everywhere on D because D is connected. Hence, we conclude that there exists at least one $(\omega_{1,h},\omega_{2,h})\in D$ corresponding to a black hole solution because f is continuous for all $(\omega_{1,h},\omega_{2,h})$ corresponding to singular solutions. □

This approach allows us to see quite simply how the transversality property conjectured in Ref. 7 arises in the $\mathfrak{su}(2)$ case. Along the lien of values of ω_h, singular solutions having different

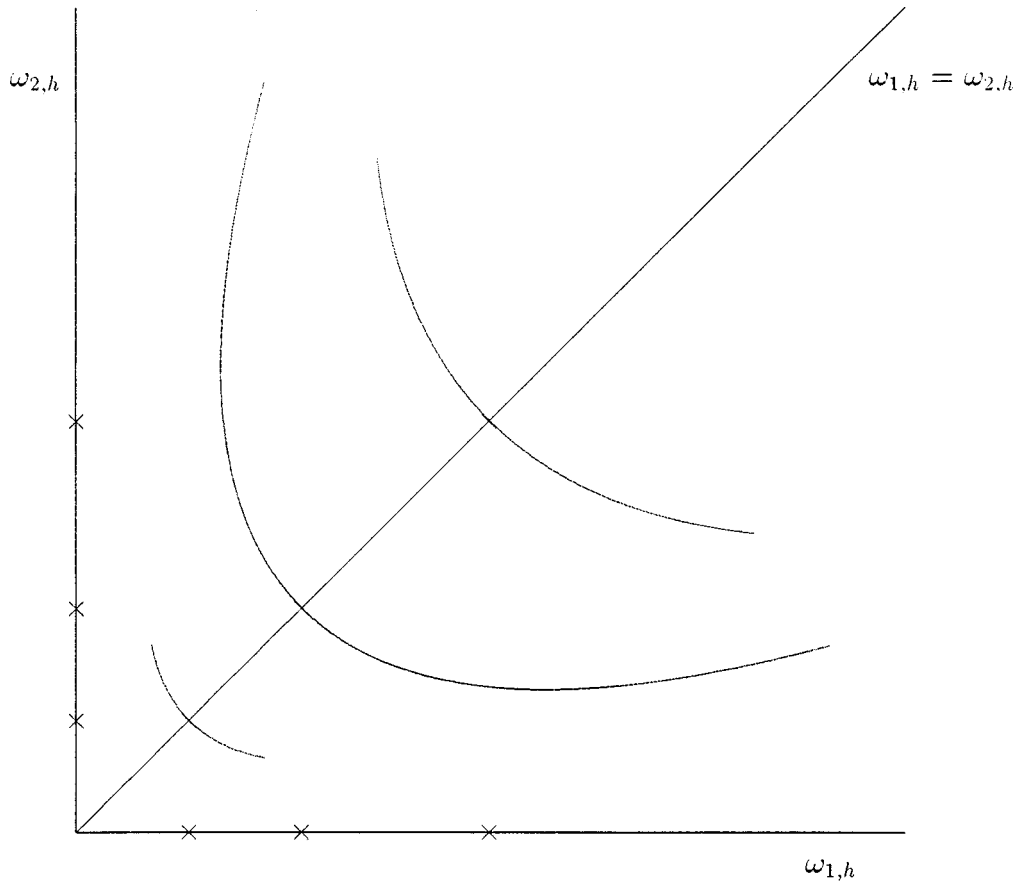

FIG. 1. The $(\omega_{1,h},\omega_{2,h})$ plane, with a schematic representation of the lines representing regular black hole solutions, which are also denoted by crosses.

numbers of nodes must be separated by at least one regular solution. For $\mathfrak{su}(2)$, it is known that values of ω_h sufficiently close to 1 correspond to singular solutions with ω having one node, while sufficiently small ω_h correspond to solutions having as many nodes as we like. In addition, if we have a regular solution with n nodes, then all singular solutions with ω_h sufficiently close have either n or $n+1$ nodes. Starting with the singular solutions with one node, and decreasing ω_h, we first hit a regular solution with one node (there being only the trivial solution with no nodes). Then there may be more singular solutions with one node or two nodes. In the former case there must be another regular solution with one node; in the latter case there will next be a regular solution with two nodes. Either way, there must be a regular solution with two nodes before we can move on to singular solutions with $n>2$ nodes. The process continues for all n.

Having shown that there exist genuine $\mathfrak{su}(3)$ black holes, the main result of this section is the following theorem, which we prove at the moment for the case $r_h>2$, returning to the case $r_h \leqslant 2$ at the end of the section.

Theorem VII.3: *Given* $\overline{n_1}=0,1,\ldots$ *. then there exist regular black hole solutions of the* $\mathfrak{su}(3)$ *Einstein–Yang–Mills equations with* $\omega_1(r)$ *having* $\overline{n_1}$ *nodes and* $\omega_2(r)$ *having* n_2 *nodes, for infinitely many* $n_2 \geqslant \overline{n_1}$.

A similar result holds with the roles of ω_1 and ω_2 reversed. Note that this result is slightly weaker than the corresponding theorem for $\mathfrak{su}(2)$, since we cannot guarantee that every combination of (n_1,n_2) is the node structure of the gauge fields for some black hole solution, only that an infinite number of such combinations does occur for each n_1. At the end of this section we shall give an argument, based on a numerical analysis, that, in fact, black holes exist for all (n_1,n_2), although we are not able to prove this analytically. The proof of Theorem VII.3 will proceed via a series of lemmas.

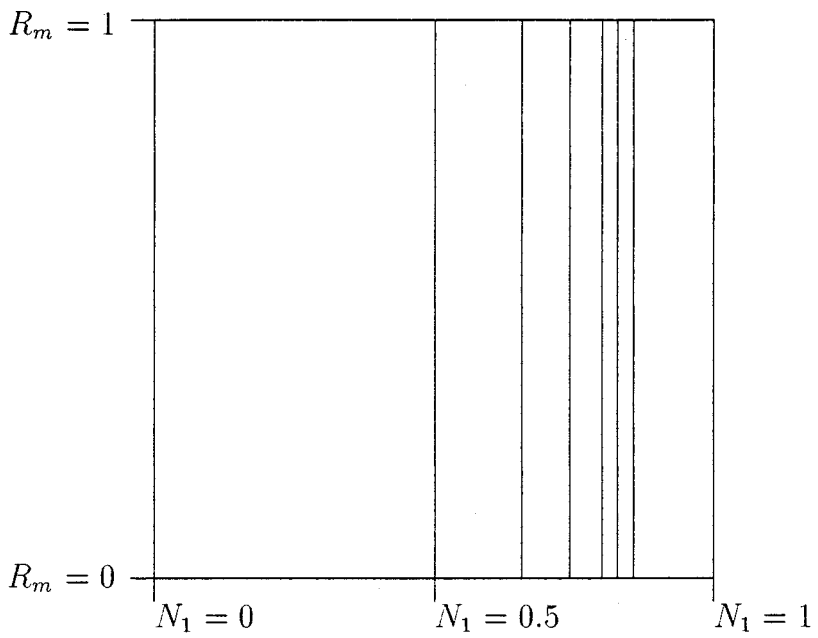

FIG. 2. Schematic representation of the set $\mathbb{B}\times[0,1]$, corresponding to the space of parameters of the $\mathfrak{su}(3)$ solutions in Sec. VII. The horizontal axis represents N_1, the number of nodes of the gauge function ω_1, and the vertical axis R_m, which characterizes the maximum value of the radial coordinate r for each solution.

Lemma VII.4: Suppose that the starting parameters $(0,\overline{\omega}_{2,h})$ *correspond to a charged regular black hole solution in which* $\omega_2(r)$ *has* $\overline{n}_2$ *zeros. Then, given* n_0, *for all sufficiently small* $\omega_{1,h}$ *and* $\omega_{2,h}$ *sufficiently close to* $\overline{\omega}_{2,h}$, *the solutions are regular or singular solutions with* $n_1 \geqslant n_0$ *and* $n_2 \geqslant \overline{n}_2$.

Proof: By continuity, all field variables will remain close to the original charged solution until $r \gg 1$ and the geometry is approximately flat. At this point ω_1 will be very small and ω_2 will be

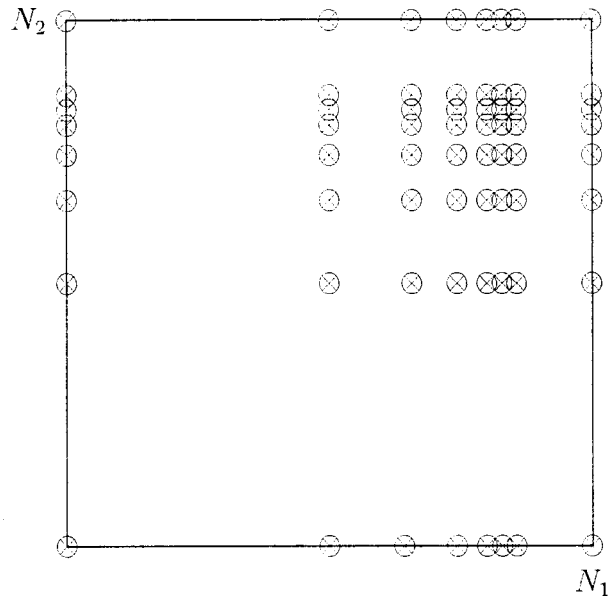

FIG. 3. The projection of the parameter space of solutions onto the set $\mathbb{B}\times\mathbb{B}$. The axes are N_1 and N_2, the number of nodes of the respective gauge functions ω_1 and ω_2. The crosses indicate schematically the points in this set.

close to 1. The equations for $\epsilon_1=\omega_1$ and $\epsilon_2=\omega_2-1$ as functions of τ are, in this regime, to first order,

$$0=\ddot{\epsilon}_1-\dot{\epsilon}_1+\tfrac{3}{2}\epsilon_1, \quad 0=\ddot{\epsilon}_2-\dot{\epsilon}_2-2\epsilon_2. \tag{141}$$

This corresponds to a focus in the $(\omega_1,\dot{\omega}_1)$ plane, and hence with $\omega_{1,h}$ sufficiently small, ϵ_1 will have at least n_0 zeros. □

Lemma VII.5: If $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ *leads to a regular black hole solution with* ω_1 *having* $\overline{n}_1$ *nodes and* ω_2 *having* $\overline{n}_2$ *nodes, then all* $(\omega_{1,h},\omega_{2,h})$ *sufficiently close to* $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ *lead to regular or singular solutions with* ω_1 *having at least* $\overline{n}_1$ *zeros and* ω_2 *having at least* $\overline{n}_2$ *zeros.*

Proof: Since the solutions are continuous in the starting parameters and r, for $(\omega_{1,h},\omega_{2,h})$ sufficiently close to $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$, the gauge function ω_1 will have $\overline{n}_1$ zeros and ω_2 will have $\overline{n}_2$ zeros for $r<r_1$ for some r_1 and $\omega_i(r_1)$ will be close to their asymptotic values. □

From the proof of Proposition VII.1, it is expected that the $(\omega_{1,h},\omega_{2,h})$ plane will be partitioned into open sets containing singular solutions with (n_1,n_2) nodes by lines of regular solutions. These lines of regular solutions will occur as the horizon radius, r_h, is varied. Numerical investigations[4,5,11] indicate that for fixed r_h regular solutions exist at discrete points in the $(\omega_{1,h},\omega_{2,h})$ plane, the positions of these discrete points varying as r_h is varied. Lemma VII.5 shows that lines corresponding to regular solutions with different numbers of nodes must be disjoint, and, furthermore, that the region corresponding to singular solutions with $(\overline{n}_1,\overline{n}_2)$ nodes will be bounded by lines of regular solutions having (n_1,n_2) nodes, where $n_1\leqslant\overline{n}_1$ and $n_2\leqslant\overline{n}_2$. Lemma VII.5 is somewhat weaker than the corresponding result for $\mathfrak{su}(2)$,[7] since the coupling between the ω's means that we cannot bound from above the number of zeros of the gauge field functions by analytic arguments. Below we shall address this question further by numerical investigations. This leads directly to our existence theorem VII.3 being slightly weaker than for $N=2$.

Lemma VII.6: Suppose $(0,\overline{\omega}_{2,h})$ *corresponds to a charged regular solution, where* ω_2 *has* $\overline{n}_2$ *nodes. Given* n_0, *let* D_0 *be the largest neighborhood of* $(0,\overline{\omega}_{2,h})$ *for which* $(\omega_{1,h},\omega_{2,h})$ *correspond to regular or singular solutions with* $n_1\geqslant n_0$ *and* $n_2\geqslant\overline{n}_2$. *Suppose, in addition, that there is* $(\hat{\omega}_{1,h},\hat{\omega}_{2,h})\in D_0$ *corresponding to a singular solution with* $n_1=n_0$ *and* $n_2=\overline{n}_2$. *Then there is* $(\omega^R_{1,h},\omega^R_{2,h})\in D_0$ *corresponding to a regular solution with* $n_1=n_0$ *and* $n_2=\overline{n}_2$.

Proof: Let $\check{n}_0>n_0$. Then there is a neighborhood $\tilde{D}_0\subset D_0$, $\tilde{D}_0\neq D_0$ for which all solutions are regular or singular solutions with $n_1\geqslant\tilde{n}_0$ and $n_2\geqslant\overline{n}_2$. In $\tilde{D}_0$ there must be at least one singular solution having $n_1\geqslant\tilde{n}_0$ and $n_2\geqslant\overline{n}_2$, by Lemma VII.5, corresponding to starting values $(\tilde{\omega}_{1,h},\tilde{\omega}_{2,h})$. Consider a curve joining $(\tilde{\omega}_{1,h},\tilde{\omega}_{2,h})$ and $(\hat{\omega}_{1,h},\hat{\omega}_{2,h})$ and lying in D_0. Then there must be at least one regular solution along this curve. Let $(\omega^R_{1,h},\omega^R_{2,h})$ be the regular solution closest to $(\hat{\omega}_{1,h},\hat{\omega}_{2,h})$, having $n_1=n^R_1$ and $n_2=n^R_2$. Since $(\omega^R_{1,h},\omega^R_{2,h})\in D_0$, it follows that $n^R_1\geqslant n_0$ and $n^R_2\geqslant\overline{n}_2$. Also, from Lemma VII.5, $n^R_1\leqslant n_0$ and $n^R_2\leqslant\overline{n}_2$, since sufficiently close to $(\omega^R_{1,h},\omega^R_{2,h})$ there are singular solutions having $n_1=n_0$ and $n_2=\overline{n}_2$. Therefore $n^R_1=n_0$ and $n^R_2=\overline{n}_2$. □

Lemma VII.7: Given $\overline{n}_2$ *and* $n_0>\overline{n}_2$, *then there exist regular and singular solutions with* $n_2=\overline{n}_2$ *and* $n_1\geqslant n_0$.

Proof: Consider the point $(0,\overline{\omega}_{2,h})$ which corresponds to the charged regular solution with $n_2=\overline{n}_2$. Then all $(\omega_{1,h},\omega_{2,h})$ sufficiently close to $(0,\overline{\omega}_{2,h})$ are regular or singular solutions with $n_1\geqslant n_0$ and $n_2\geqslant\overline{n}_2$. Let all such $(\omega_{1,h},\omega_{2,h})$ form a neighborhood D_0 of $(0,\overline{\omega}_{2,h})$. From Ref. 7, there exist $(0,\hat{\omega}_{2,h})\in D_0$ corresponding to singular solutions having $\omega_1\equiv 0$ and $n_2=\overline{n}_2$. By continuity, all $(\omega_{1,h},\omega_{2,h})$ sufficiently close to $(0,\hat{\omega}_{2,h})$ correspond to singular solutions having $n_1\geqslant n_0$ and $n_2=\overline{n}_2$. Hence, by Lemma VII.6, there are also in this neighborhood regular black hole solutions having $n_1\geqslant n_0$ and $n_2=\overline{n}_2$. □

Proof of Theorem VII.3: Fix $\overline{n}_2$. Then we have regular solutions with node structure $(\overline{n}_2,\overline{n}_2)$. Now let $n_0=\overline{n}_2+1$, then from Lemma VII.7 there are regular solutions having $n_2=\overline{n}_2$ and $n_1\geqslant n_0$. Let n_0' be the smallest such n_1. Now set $n_0=n_0'+1$ and repeat the process. □

In order to guarantee the existence of black hole solutions having node structure $(\overline{n}_1,\overline{n}_2)$ for every pair of integers $(\overline{n}_1,\overline{n}_2)$, we would require the following lemma in addition to Lemma VII.7.

Lemma VII.8: Suppose $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ *corresponds to a regular black hole solution in which* ω_1 *has* $\overline{n_1}$ *nodes and* ω_2 *has* $\overline{n_2}$ *nodes. Then, for* $(\omega_{1,h},\omega_{2,h})$ *sufficiently close to* $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$*, solutions for which* ω_2 *still has* $\overline{n_2}$ *nodes are such that* ω_1 *has either* $\overline{n_1}$ *or* $\overline{n_1}+1$ *nodes.*

The argument we now give for Lemma VII.8 is not an analytic proof because we require a numerical analysis.

Proof: By continuity, we know that for $(\omega_{1,h},\omega_{2,h})$ sufficiently close to $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$, the gauge function ω_1 has $\overline{n_1}$ zeros and ω_2 has $\overline{n_2}$ zeros for $r<r_1$ for some r_1, and $\omega_i(r_1)$ will be close to their asymptotic values. Since we are considering only solutions for which ω_2 has $\overline{n_2}$ nodes, for $r>r_1$, then ω_2 will be of one sign. Therefore we may consider the new dependent variable

$$\psi=\frac{\omega_1}{\omega_2}, \tag{142}$$

which will have the same number of zeros as $\omega_1(r)$ for $r>r_1$. Then the equation satisfied by ψ is

$$r^2\mu\psi''+(2m-2r^3p_\theta)\psi'+2r^2\mu\,\frac{\omega_2'}{\omega_2}\,\psi'+\tfrac{3}{2}\omega_2^2\psi(1-\psi^2)=0. \tag{143}$$

On some interval, $r_1<r<r_2$, the geometry will be very nearly flat, and it will remain flat until one of ω_1, ω_2 or their derivatives approach $O(\sqrt{r})$. Next, consider the flat space equations for ψ and ω_2, which have the autonomous form (where $\tau=\log r$)

$$\begin{aligned} 0&=\ddot{\omega}_2-\dot{\omega}_2+(1-\omega_2^2+\tfrac{1}{2}\psi^2\omega_2^2)\omega_2,\\ 0&=\ddot{\psi}-\dot{\psi}+\frac{2\dot{\omega}_2}{\omega_2}\,\dot{\psi}+\frac{3}{2}\,\omega_2^2\psi(1-\psi^2). \end{aligned} \tag{144}$$

Without loss of generality, we may assume that we are close to the critical point where $\psi=1$ and $\omega_2=\sqrt{2}$. Using the substitution

$$\psi=1+\epsilon_1,\quad \omega_2=\sqrt{2}(1+\epsilon_2), \tag{145}$$

the linearized equations close to this critical point are

$$0=\ddot{\epsilon}_1-\dot{\epsilon}_1-6\epsilon_1,\quad 0=\ddot{\epsilon}_2-\dot{\epsilon}_2+2\epsilon_1-2\epsilon_2. \tag{146}$$

The analysis of Sec. V has already shown that we have a saddle point here; this notation is convenient merely because the perturbation in ψ decouples from that of ω_2 in the linear approximation. From the form of the equation (143), it is clear that $|\psi|$ will be monotonic, increasing for $|\psi|>1$. In other words, for $\epsilon_1>0$ initially, $\epsilon_1>0$ always and ω_1 will have no additional zeros for $r>r_1$. Hence, we need only consider the case where $\epsilon_1<0$ initially. Unfortunately, the nonlinear perturbation equations cannot be integrated analytically, and so we present a numerical argument. For initial ϵ_1, ϵ_2 sufficiently small, the values of ϵ_1 and ϵ_2 will remain close to those on the unstable manifold for all $\tau<\tau_1$ for some τ_1, where τ_1 can be taken to be as large as we like by making the initial perturbations sufficiently small. Numerical integration of the nonlinear equations with the initial point on the unstable manifold and $\epsilon_1<0$ shows that ϵ_2 increases monotonically and ϵ_1 decreases monotonically with just one zero, and cuts through $\epsilon_1=-2$ (corresponding to $\psi=-1$), from whence ψ must be monotonically decreasing (see Figs. 4 and 5). Hence, in this case ω_1 has $\overline{n_1}+1$ zeros. □

Lemma VII.8 allows us to prove that every combination of integers (n_1,n_2) must correspond to a black hole solution. In the proof of Theorem VII.3, we begin with regular solutions with node structure $(\overline{n_2},\overline{n_2})$, and then from Lemma VII.8 there are either regular or singular solutions with node structure $(\overline{n_2}+1,\overline{n_2})$. Using Lemma VII.6, there are then regular solutions having this node structure, and the proof of Theorem VII.3 follows as before.

So far we have proved the existence of infinitely many $\mathfrak{su}(3)$ black holes only for $r_h>2$. The remainder of this section will be spent proving the result for $r_h\leqslant 2$. In this case, the points at

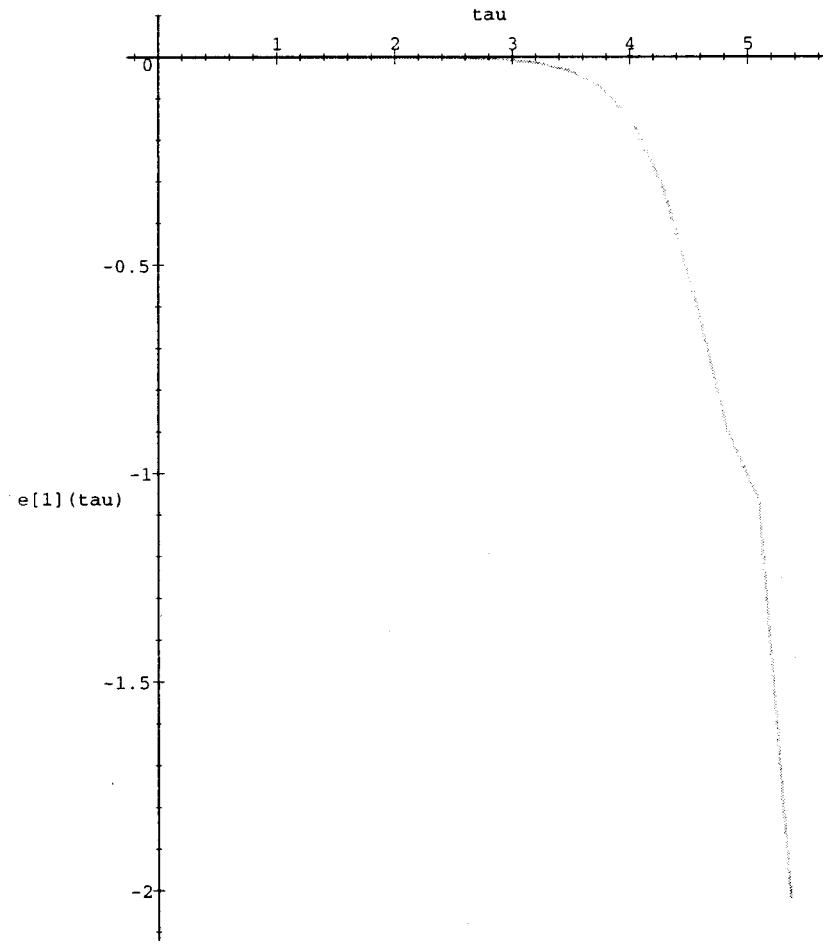

FIG. 4. The su(3) perturbation $\epsilon_1(\tau)$ along the unstable manifold. The value $\tau=0$ corresponds to the critical point. Note that $\psi=1+\epsilon_1$ monotonically decreases through 0 and -1, from which point it will continue to monotonically decrease.

which the map f is not continuous (which must still exist by the argument used in proving Proposition VII.1) do not necessarily correspond to regular black hole solutions: they could also be oscillating solutions. A couple of lemmas concerning oscillating solutions are required before the proofs of Proposition VII.1 and Theorem VII.3 can be extended.

Lemma VII.9: If $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ *leads to an oscillating solution with* $\omega_1(\tau)\to 0$ *and* $\omega_2(\tau)\to 1$ *as* $\tau\to\infty$, *and* ω_2 *has* $\overline{n}_2$ *zeros, then all* $(\omega_{1,h},\omega_{2,h})$ *sufficiently close to* $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ *lead to one of the following types of solution.*

(1) *An oscillating solution in which* $\omega_1(\tau)\to 0$ *and* $\omega_2(\tau)\to 1$ *as* $\tau\to\infty$, *with* ω_2 *having at least* $\overline{n}_2$ *zeros.*

(2) *Given* n_0, *either a regular or a singular solution with* $n_1\geqslant n_0$ *and* $n_2\geqslant\overline{n}_2$.

(3) *An* S_∞ *solution.*

Proof: Since in the original solution ω_1 has infinitely many zeros and the solutions are analytic in τ and the starting values, there is some τ_1 such that all solutions with $(\omega_{1,h},\omega_{2,h})$ sufficiently close to $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})$ must have at least n_0 zeros of ω_1 and $\overline{n}_2$ zeros of ω_2 for $\tau<\tau_1$, and all variables will be close to their asymptotic values. □

Lemma VII.10: There exists $(\overline{\omega}_{1,h},\overline{\omega}_{2,h})\in D$ *corresponding to an oscillating solution.*

Proof: From Ref. 7 we know that there are points on the line $\omega_{1,h}=\omega_{2,h}$ corresponding to S_∞ solutions. By continuity, there is a neighborhood D_0 of the line $\omega_{1,h}=\omega_{2,h}$ corresponding to S_∞ solutions. However, Lemma VII.5 still applies in this case, so that the regular solutions on the line $\omega_{1,h}=\omega_{2,h}$ will have singular solutions in D sufficiently close to them for which $r(\tau_0)>2$. Therefore, by Lemma VII.9, there must be points in D which correspond to oscillating solutions. □

The proofs of Proposition VII.1 and Theorem VII.3 are now exactly the same as for $r_h>2$.

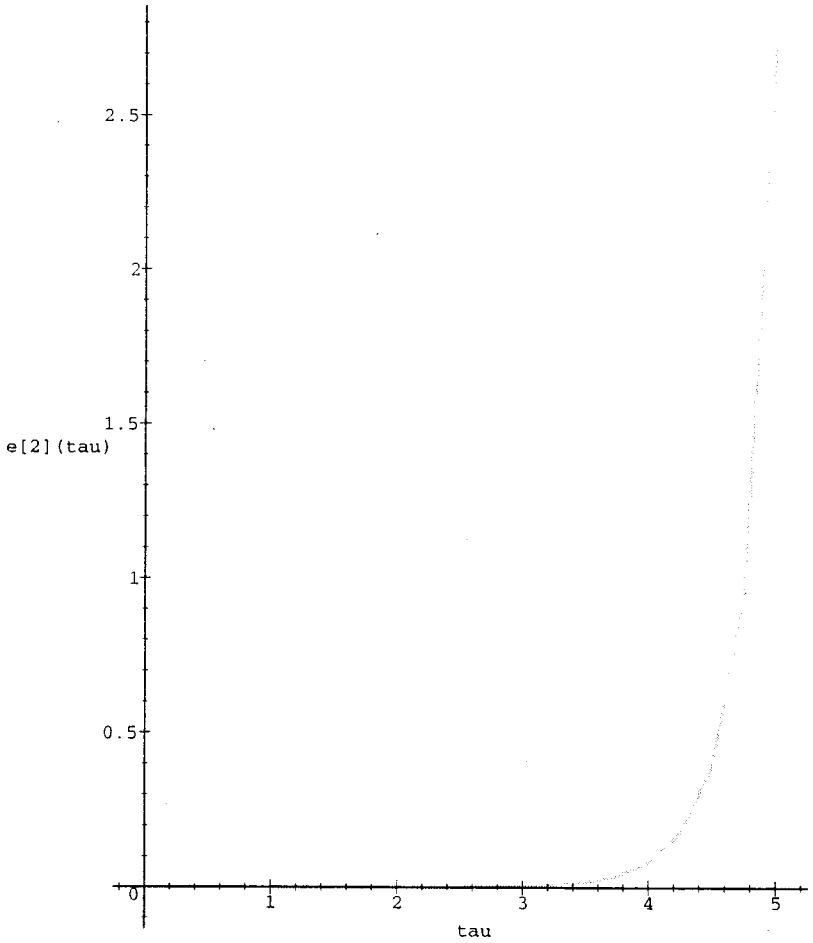

FIG. 5. The $\mathfrak{su}(3)$ perturbation ϵ_2 along the unstable manifold. Note that this is a monotonically increasing function, which is in accordance with the gauge function ω_2 having no further zeros.

Since oscillating solutions have an infinite number of zeros for at least one of the gauge field functions, and using Lemma VII.9, regular solutions are still needed to separate singular solutions having different node structures.

VIII. $\mathfrak{su}(N)$ BLACK HOLES

The detailed discussion of the previous section now enables us to proceed quite swiftly to the analogs of Proposition VII.1 and Theorem VII.3 for general N. The method of proof will be by induction, which was the basic idea used in the previous section, where we proved existence for $\mathfrak{su}(3)$ exploiting known results about $\mathfrak{su}(2)$.

The first step is to illustrate how solutions which are from $\mathfrak{su}(n)$, where $n<N$ may be embedded in the $\mathfrak{su}(N)$ framework. First, exactly as in the $N=3$ case, we may embed neutral $\mathfrak{su}(2)$ solutions.[11] We set $\omega_j(r)=\sqrt{j(N-j)}\omega(r)$ and introduce a scaled variable $R=\lambda_N r$, where

$$\lambda_N=(\tfrac{1}{6}N(N+1)(N-1))^{1/2}. \tag{147}$$

Then the field equations are exactly the same as the $\mathfrak{su}(2)$ ones, and the existence of solutions follows directly.[11] Second, charged, effectively $\mathfrak{su}(N-1)$ solutions can be generated by setting $\omega_1\equiv 0$ (or $\omega_{N-1}\equiv 0$).[4] Although the equation for m' in this situation is not the same as for neutral $\mathfrak{su}(N-1)$ black holes, due to the charge, the regular equations discussed in Sec. II are unchanged, so the proof of existence of neutral $\mathfrak{su}(N-1)$ black holes extends naturally to this case.

For $N>3$, there are additional embeddings which arise from setting at least one of $\omega_2,\ldots,\omega_{N-2}\equiv 0$, so that the gauge field equations decouple into two or more sets of coupled

components, the sets being coupled to each other only through the metric. Solutions of this form have been found numerically in Ref. 4. We illustrate how the existence of black holes of this type may be proved by considering the simplest case, which arises when $N=4$. In this case, we have three nonzero gauge field functions, ω_1, ω_2, ω_3. If we set $\omega_2\equiv 0$, then the field equations take the form

$$r^2\mu\omega_1''=-(2m-2r^3p_\theta)\omega_1'-(1-\omega_1^2)\omega_1, \tag{148}$$

$$r^2\mu\omega_3''=-(2m-2r^3p_\theta)\omega_3'-(1-\omega_3^2)\omega_3, \tag{149}$$

$$m'=(\mu G+r^2p_\theta), \tag{150}$$

$$\frac{S'}{S}=\frac{2G}{r}, \tag{151}$$

where

$$G=\omega_1'^2+\omega_3'^2, \quad p_\theta=\frac{1}{2r^4}([\omega_1^2-1]^2+[\omega_3^2-1]^2+8). \tag{152}$$

These equations look very much like two uncoupled $\mathfrak{su}(2)$ degrees of freedom, however, the two ω's are (albeit weakly) coupled. The fact that we have two gauge field functions here means that we can use the methods of Sec. VII to prove the existence of regular black hole solutions. In fact, all the results of that section carry directly over to this situation on replacing ω_2 there by ω_3 here. There is one exception. The equations (148), (149) are slightly different from those in Sec. VII, and this enables us to strengthen Lemma VII.5.

Lemma VIII.1: If $(\overline{\omega}_{1,h},\overline{\omega}_{3,h})$ *leads to a regular black hole solution with* ω_1 *having* $\overline{n}_1$ *nodes and* ω_3 *having* $\overline{n}_3$ *nodes, then all* $(\omega_{1,h},\omega_{3,h})$ *sufficiently close to* $(\overline{\omega}_{1,h},\overline{\omega}_{3,h})$ *lead to regular or singular solutions with* ω_1 *having either* $\overline{n}_1$ *or* $\overline{n}_1+1$ *zeros and* ω_3 *having either* $\overline{n}_3$ *or* $\overline{n}_3+1$ *zeros.*

Proof: Since the solutions are continuous in the starting parameters and r, for $(\omega_{1,h},\omega_{3,h})$ sufficiently close to $(\overline{\omega}_{1,h},\overline{\omega}_{3,h})$, there is some r_1 such that ω_1 will have $\overline{n}_1$ zeros and ω_3 will have $\overline{n}_3$ zeros for $r<r_1$. There will also be an $r_2>r_1$ such that all field variables are close to their asymptotic values for $r\in[r_1,r_2]$. The flat space field equations (see Sec. V) decouple completely since $\omega_2\equiv 0$, and so the phase plane analysis of Ref. 7 is valid in this case. The phase plane analysis enables us to be more precise about the number of zeros of the perturbed gauge field functions, unlike the more general case where the phase space had more than two coupled dimensions. Therefore the conclusions of Ref. 7 can be applied directly here and each gauge field function can have, at most, one zero for $r>r_2$. □

With this more powerful lemma, the analysis of Sec. VII reaches the conclusion that there are regular black hole solutions of the required form for each r_h and node structure (n_1,n_3).

For general N, similar embeddings of the form of two or more $\mathfrak{su}(n)$ $(n<N)$ type solutions separated by at least one $\omega_j\equiv 0$ are possible, and the existence proof follows the lines outlined above for $\mathfrak{su}(4)$, using the existence of solutions for the various $\mathfrak{su}(n)$. The allowed node structures will be exactly the same as those for the constituent $\mathfrak{su}(n)$ components. We refer the reader to Ref. 4 for further details of the construction of solutions of this form.

The remainder of this section will be spent outlining briefly the proof of the following theorem. By ''types'' in the statement of the theorem we mean the node structures of the gauge field functions.

Theorem VIII.2: *There exist infinitely many types of regular black hole solutions of the* $\mathfrak{su}(N)$ *Einstein–Yang–Mills equations including genuine* $\mathfrak{su}(N)$ *solutions and embedded solutions.*

All that remains to prove this theorem is to show the existence of genuine $\mathfrak{su}(N)$ solutions in which the node structures of the gauge field functions are not all the same. We assume for an inductive hypothesis that the theorem holds for all $n<N$. The situation is slightly complicated by the fact that our parameter space consisting of the $\omega_{j,h}$'s is now $N-1$ dimensional. We consider the $\omega_{1,h}=0$ hyperplane, on which we know the solution space by the inductive hypothesis. The

map $\int$ (see sec. VII) now takes $\mathbb{R}^{N-1}$ to $\mathbb{B}^{N-1}\times[0,1]$. Again, we need only consider the action of f on those parts of $\mathbb{R}^{N-1}$ in which no $\omega_{j,h}$ vanishes. We restrict attention to one of the disjoint spaces so generated without loss of generality. Lemma VII.2 and the proof of the $\mathfrak{su}(N)$ equivalent of proposition VII.1 now carry over to prove the existence of genuine $\mathfrak{su}(N)$ black holes. Lemmas VII.4, VII.6, and VII.7 now hold for a point $(0,\overline{\omega}_{2,h},\ldots,\overline{\omega}_{N-1,h})$ corresponding to a charged solution, and Lemmas VII.5 and VII.9 carry straight over to a point $(\overline{\omega}_{1,h},\overline{\omega}_{2,h},\ldots,\overline{\omega}_{N-1,h})$ which leads to a regular black hole solution or oscillating solution, respectively. These are the ingredients necessary for the simple argument which leads to the proof of Theorem VII.3 and hence Theorem VIII.2 for both $r_h^2>\frac{1}{6}N(N+1)(N-1)$ (in which case no oscillating solutions exist), and $r_h^2\leqslant\frac{1}{6}N(N+1)(N-1)$. Note that, as in the $\mathfrak{su}(3)$ case, we are not able to prove analytically that every sequence of integers $(n_1,n_2,\ldots,n_{N-1})$ corresponds to a black hole solution whose gauge functions have this node structure, although it might reasonably be expected that this is indeed the case.

IX. RESULTS AND CONCLUSIONS

In this paper we have proved the existence of a vast number of hairy black holes in $\mathfrak{su}(N)$ Einstein–Yang–Mills theories. The solutions are described by $N-1$ parameters, corresponding to the number of nodes of the gauge field functions. The result of Ref. 12 tells us that each of these solutions will have a topological instability, similar to the flat-space ''sphaleron,'' as was the case for $\mathfrak{su}(2)$ black holes. This instability does not necessarily diminish the physical importance of these objects, as they may have an important role in processes such as cosmological particle creation.[15]

We now briefly mention another important reason for studying $\mathfrak{su}(N)$ black holes, namely the behavior of the solutions as $N\to\infty$. Black holes in $\mathfrak{su}(\infty)$ Einstein–Yang–Mills theory would possess an infinite amount of hair, requiring an infinite number of parameters to describe their geometry. This might be analogous to the ''W-hair'' found in noncritical string theory,[16] and have drastic consequences for the Hawking radiation, information loss, and quantum decoherence processes associated with black holes. The existence of infinite amounts of hair might also render such objects stable. It is already known that the $\mathfrak{su}(\infty)$ Lie algebra is simply that of the diffeomorphisms of the sphere.[17] This means that the limit as $N\to\infty$ cannot be taken smoothly, in particular, the results of the present paper are only valid when N is finite. We hope to return to this matter in a subsequent publication.

Covariant spin structure

Gennadi A. Sardanashvily
Department of Theoretical Physics, Moscow State University, 117234 Moscow, Russia

(Received 5 December 1997; accepted for publication 29 April 1998)

Dirac fermion fields associated with different tetrad gravitational fields and under general covariant transformations are described by sections of the composite bundle $S\to\Sigma\to X^4$, which is both the Dirac spinor bundle over the tetrad bundle Σ and the natural one over X^4. As a natural bundle, $S\to X^4$ admits general covariant transformations which are those of Dirac spin structures. A different way is to consider a background spin structure. We find gauge transformations which preserve this spin structure, but act on effective tetrad fields as general covariant transformations.

I. INTRODUCTION

Metric and metric-affine theories of gravity in the absence of fermion fields are formulated on the natural bundles over a world manifold X^4 such that there exist canonical lifts of diffeomorphisms of X^4 onto these bundles. These lifts are general covariant transformations. The invariance of gravitational Lagrangians under general covariant transformations leads to the energy-momentum conservation laws in these gravitation theories.[1–5] A problem arises because of Dirac fermion fields.

Remark: Manifolds throughout are real, finite-dimensional, Hausdorff, second-countable and connected. By a world manifold X^4 is meant a four-dimensional noncompact oriented manifold which is parallelizable. Such a manifold admits a Dirac spin structure which module isomorphisms is unique.[6,7] This property remains true for all spin structures on X^4 which are generated by the twofold universal covering groups.[8]

Recall that a Dirac spin structure on a world manifold X^4 is said to be a pair (P^h,z_h) of a principal spin bundle $P^h\to X^4$ with the structure spin group $L_s=SL(2,\mathbf{C})$ and a principal bundle morphism

$$z_h: P^h\to LX, \tag{1}$$

over X^4 from P^h to the principal bundle $LX\to X^4$ of oriented linear frames in the tangent bundle TX of X^4.[9–11] The structure group of LX is $GL_4=GL^+(4,\mathbf{R})$. Every Dirac spin structure factorizes through the morphism

$$z_h: P^h\to L^hX\subset LX,$$

where L^hX, called a reduced Lorentz structure, is a principal Lorentz sub-bundle of the frame bundle LX whose structure group is the proper Lorentz group $L=SO^0(1,3)$. Note that a reduced Lorentz structure is not preserved under general covariant transformations of the frame bundle LX. From the physical viewpoint, it means that a Dirac spin structure provides spontaneous breaking of world symmetries.[12,13]

By the well-known theorem,[14] there is one-to-one correspondence between the reduced Lorentz sub-bundles L^hX of the frame bundle LX and the global sections of the quotient bundle

$$\Sigma=LX/L\to X^4, \tag{2}$$

called the tetrad bundle. Its elements are oriented frames in TX module Lorentz transformations. The bundle Σ is the twofold covering of the bundle Σ_g of pseudo-Euclidean bilinear forms in TX, whose global sections are pseudo-Riemannian metrics on X^4. Global sections h of $\Sigma\to X^4$ are tetrad fields on X^4. Accordingly, a Dirac spin structure P^h which factorizes through L^hX is said to be associated with the tetrad field h.

 © 1998 American Institute of Physics

Following the standard terminology of gauge theory,[15–18] one may say that tetrad fields, associated with reduced Lorentz structures, are Higgs fields corresponding to spontaneous breaking of world symmetries.[12,13,15]

Dirac fermion fields in the presence of a tetrad field h are described by sections of the P^h-associated spinor bundle

$$S^h=(P^h\times V)/L_s\to X^4, \tag{3}$$

whose typical fiber V carries the spinor representation of the spin group L_s. To describe Dirac fermion fields and, in particular, to be provided with the Dirac operator, the spinor bundle S^h (3) must be represented as a sub-bundle of the bundle of Clifford algebras, that is, as a spinor structure on the cotangent bundle T^*X in the terminology of Lawson and Michelson.[9] The crucial point is that, for different S^h and $S^{h'}$, these representations are not equivalent though the spin structures P^h and $P^{h'}$ are isomorphic (see Sec. IV). Roughly speaking, for different tetrad fields h, the Clifford representations

$$\gamma_h(dx^\lambda)=h^\lambda_a\gamma^a,$$

of co-frames dx^λ by Dirac's matrices are not equivalent.[12,13]

It follows that every Dirac fermion field must be described in a pair (s_h,h) with a certain tetrad field h, and Dirac fermion fields in the presence of different tetrad fields fail to be given by sections of the same spinor bundle. This fact exhibits the physical nature of gravity as a Higgs field.

There are two ways to describe Dirac fermion fields in the presence of different gravitational fields and under general covariant transformations.

(i) Gravitational fields are identified with different tetrad fields on a world manifold X^4, and the totality of fermion-gravitation pairs (s_h,h) is examined. The goal is to construct a bundle over X^4 whose sections exhaust all these pairs.

(ii) A background spin structure (defined, e.g., by the whole fermion matter of the Universe) and the associated tetrad field on a world manifold X^4 are considered, while different gravitational fields lead to different effective tetrad (or metric) fields, which do not change the background spin structure. The key point is to find gauge transformations over diffeomorphisms of X^4 which both keep the background geometry and act on effective tetrad fields as general covariant transformations.

It should be emphasized that, in both variants, the equations of motion are equivalent at least locally, and so are the equations for a gravitational field if a Lagrangian is independent of a background field.

Following the first variant, let us consider the universal twofold covering group $\widetilde{GL}_4$ of the group GL_4 and the corresponding twofold covering bundle $\widetilde{LX}$ of the frame bundle LX.[9,19–21] The bundle $\widetilde{LX}\to X^4$ inherits the general covariant transformations of the frame bundle LX. However, the spinor representation of the group $\widetilde{GL}_4$ is infinite dimensional. Therefore, the $\widetilde{LX}$-associated spinor bundle describes infinite-dimensional ''world'' spinor fields, but not the Dirac ones. The theory of world spinors has been developed.[22]

In contrast with this world spinor model, our purpose here is to describe the totality of familiar Dirac fermion fields on a world manifold, without appealing to the spinor representation of the general linear group.

We use the fact that the frame bundle LX is the principal bundle $LX\to\Sigma$ over the tetrad bundle Σ (2) with the structure Lorentz group L. Since the diagram

$$\begin{array}{ccc} \widetilde{GL}_4 & \longrightarrow & GL_4 \\ \uparrow & & \uparrow \\ L_s & \xrightarrow{z_L} & L \end{array} \tag{4}$$

commutes (see Sec. V), the bundle $\widetilde{LX}$ is an L_s-principal bundle over the same tetrad bundle $\Sigma = \widetilde{LX}/L_s$. Then the commutative diagram

$$\begin{array}{ccc} \widetilde{LX} & \xrightarrow{\tilde{z}} & LX \\ & \searrow\swarrow & \\ & \Sigma & \end{array} \tag{5}$$

provides a Dirac spin structure on the tetrad bundle Σ. We will show that, for any tetrad field h, the restriction $h^*\widetilde{LX}$ of the L_s-principal bundle $\widetilde{LX}\to\Sigma$ to $h(X^4)\subset\Sigma$ is isomorphic to the L_s-principal sub-bundle P^h of the bundle $\widetilde{LX}\to X^4$ such that the diagram

$$\begin{array}{ccc} \widetilde{LX} & \xrightarrow{\tilde{z}} & LX \\ \uparrow & & \uparrow \\ P^h & \xrightarrow{z_h} & L^hX \end{array} \tag{6}$$

commutes. Then general covariant transformations of the bundle $\widetilde{LX}\to X^4$ take the form of automorphisms of the principal spin bundle $\widetilde{LX}\to\Sigma$ over general covariant transformations of the tetrad bundle Σ. These are desired general covariant transformations of Dirac spin structures (1) as the restrictions to $h(X)\subset\Sigma$ of the diagram (5), called the covariant spin structure.

Now let us consider the spinor bundle

$$S=(\widetilde{LX}\times V)/L_s\to\Sigma, \tag{7}$$

associated with the principal spin bundle $\widetilde{LX}\to\Sigma$. Its typical fiber is the Dirac spinor space V. Given a tetrad field h, the restriction h^*S of $S\to\Sigma$ to $h(X)\subset\Sigma$ is a sub-bundle of the composite bundle

$$S\to\Sigma\to X^4. \tag{8}$$

This sub-bundle is isomorphic to the P^h-associated spinor bundle S^h (3) whose sections s_h describe Dirac fermion fields in the presence of the tetrad field h (see Sec. II). It follows that sections of the composite bundle (8) projected onto different tetrad fields $h:X^4\to\Sigma$ exhaust the totality of pairs (s_h,h) of Dirac fermion fields and tetrad fields. The configuration space of this totality is the first order jet manifold J^1S of the composite bundle $S\to X^4$.[5,23] In this model, tetrad fields are dynamic. They are treated as gravitational fields. We will construct the total Dirac operator and the total Lagrangian on the configuration space J^1S whose restrictions to $h(X)\subset\Sigma$, for any tetrad field h, recover the familiar Dirac operator and the familiar Dirac's Lagrangian of fermion fields in the presence of the tetrad field h and a general linear connection K on X^4.

Note that the bundle $S\to X^4$ is not a spinor bundle. It is provided with the structure of the $\widetilde{LX}$-associated bundle with the structure group $\widetilde{GL}_4$ which acts on the typical fiber $(\widetilde{GL}_4\times V)/L_s$ by the induced representation (see Sec. II). Therefore, general covariant transformations of $\widetilde{LX}$ yield the corresponding automorphisms of the bundle $S\to X^4$, which takes the form of automorphisms of the spinor bundle $S\to\Sigma$ over the general covariant transformations of the tetrad bundle $\Sigma\to X^4$. We will construct the canonical lift onto S of vector fields on X^4 which is the generator of these transformations. Then the energy-momentum conservation law can be derived.[5,23]

Following the variant (ii), we consider a background spin structure P^h associated with a background tetrad field h. In this model, gravitational fields are identified with the sections of the LX-associated group bundle $Q\to X$. The canonical morphism $Q\times\Sigma\to\Sigma$ restricted to $h(X)\subset\Sigma$

defines effective tetrad fields.[24] We will construct automorphisms of LX over diffeomorphisms of X which both preserve the background spin structure $P^h \to LX$ and act on effective tetrad fields as general covariant transformations.

II. REDUCED STRUCTURE

The reduced structure language provides the adequate mathematical formulation of gauge models with broken symmetries.[15–18]

Let $\pi_{PX}: P \to X$ be a principal bundle with a structure group G, which acts freely and transitively

$$R_g: p \mapsto pg, \quad p \in P, \quad g \in G, \tag{9}$$

on P on the right. Let

$$Y = (P \times V)/G, \tag{10}$$

be a P-associated bundle with a typical fiber V on which the structure group G acts on the left. Recall that the quotient (10) is defined by identification of elements (p,v) and $(pg, g^{-1}v)$ for all $g \in G$. Its elements will be denoted by $(p,v)\cdot G$. To say more exactly, the bundle Y (10) is canonically associated with P. In particular, every automorphism Φ of a principal bundle P [which, by definition, is equivariant $R_g \circ \Phi = \Phi \circ R_g$, $\forall g \in G$, under the canonical action (9)] yields the corresponding automorphism

$$\Phi_Y: (P \times V)/G \to (\Phi(P) \times V)/G,$$

of the P-associated bundle Y (10). Recall that every vertical automorphism Φ of P takes the form $p \to p\phi(p)$ where ϕ is a G-valued equivariant function on P, i.e., $\phi(pg) = g^{-1}\phi(p)g$, $\forall g \in G$.

Let H be a Lie subgroup of G. We have the composite bundle

$$P \to P/H \to X,$$

where $\pi_{\Sigma X}: P/H \to X$ is a P-associated bundle, denoted by Σ, with the typical fiber G/H, and $\pi_{P\Sigma}: P \to P/H$ is a principal bundle with the structure group H. A H-principal sub-bundle P^h of P is called a reduced structure.[25,26] By the well-known theorem,[14] there is one-to-one correspondence between the global sections h of the quotient bundle $\Sigma \to X$ and the H-principal sub-bundles P^h of P. Such a sub-bundle P^h is isomorphic to the pull-back $h^*P = \pi_{P\Sigma}^{-1}(h(X))$ over X of the bundle $P \to \Sigma$ by h. The following assertion takes place.[5,26]

Proposition 1: Every vertical automorphism Φ of the principal bundle $P \to X$ sends a reduced sub-bundle P^h onto a reduced sub-bundle $P^{h'}$ which is isomorphic to P^h as a H-principal bundle. Conversely, let two reduced sub-bundles P^h and $P^{h'}$ of a principal bundle P be isomorphic to each other as H-principal bundles. Then every isomorphism $\Phi: P^h \to P^{h'}$ over X can be extended to a vertical automorphism of P.

If the quotient G/H is homeomorphic to an Euclidean space, all H-principal sub-bundles of P are isomorphic to each other as H-principal bundles.[27] This also takes place if P is a trivial bundle.

Given a reduced sub-bundle P^h of a principal bundle P, let

$$Y^h = (P^h \times V)/H, \tag{11}$$

be the P^h-associated bundle with a typical fiber V. If $P^{h'}$ is another reduced sub-bundle of P which is isomorphic to P^h, the bundles Y^h and $Y^{h'}$ are isomorphic, but not canonically isomorphic in general.

Proposition 2: Let P^h be a H-principal sub-bundle of a G-principal bundle P. Let Y^h be the P^h-associated bundle (11) with a typical fiber V. If V carries a representation of the whole group G, the fiber bundle Y^h is canonically isomorphic to the P-associated fiber bundle (10).

Proof: Every element of Y can be represented as $(p,v)\cdot G$, $p \in P^h$. Then the desired isomorphism is

$$Y^h \ni (p,v)\cdot H \mapsto (p,v)\cdot G \in Y.$$

It follows that, given a H-principal sub-bundle P^h of P, any P-associated bundle Y with the structure group G is canonically equipped with a structure of the P^h-associated fiber bundle Y^h with the structure group H. Briefly, we will write

$$Y=(P\times V)/G\cong(P^h\times V)/H=Y^h.$$

However, P^h- and $P^{h'}$-associated bundle structures on Y are not equivalent because, given bundle atlases Ψ^h of P^h and $\Psi^{h'}$ of $P^{h'}$, the union of the associated atlases of Y has necessarily G-valued transition functions between the charts from Ψ^h and $\Psi^{h'}$.

In gauge theory on the principal bundle P, sections h of the quotient bundle Σ are treated as Higgs fields, while sections s_h of the P^h-associated bundle Y^h (11) describe matter fields in the presence of the Higgs fields h. From the physical viewpoint, the structure group G of P is said to be the group of broken symmetries because matter fields carries only a representation of its subgroup H, and a reduced structure $P^h\subset P$ which is not preserved under automorphisms of P.

In general, Y^h is not associated or canonically associated with other H-principal sub-bundles of P. It follows that matter fields can be represented only by pairs with Higgs fields.

To describe the totality of these pairs (s_h,h) for all Higgs fields, let us consider the composite bundle

$$Y \xrightarrow{\pi_{Y\Sigma}} \Sigma \xrightarrow{\pi_{\Sigma X}} X, \tag{12}$$

where $Y\to\Sigma$ is the bundle

$$Y_\Sigma=(P\times V)/H,$$

associated with the H-principal bundle $P\to\Sigma$.[5,28] There is the canonical isomorphism $i_h: Y^h \to h^*Y$ of the P^h-associated bundle Y^h to the sub-bundle of $Y\to X$ which is the restriction

$$h^*Y=(h^*P\times V)/H\cong(P^h\times V)/H=Y^h,$$

of the bundle Y_Σ to $h(X)\subset\Sigma$, i.e.,

$$i_h(Y^h)=\pi_{Y\Sigma}^{-1}(h(X)). \tag{13}$$

Then every global section s_h of Y^h corresponds to the global section $i_h\circ s_h$ of the composite bundle (12). Conversely, every global section s of the composite bundle (12) which projects onto a section $h=\pi_{Y\Sigma}\circ s$ of the bundle $\Sigma\to X$ takes its values into the sub-bundle $i_h(Y^h)\subset Y$ in accordance with the relation (13). Hence, there is one-to-one correspondence between the sections of the bundle Y^h and the sections of the composite bundle (12) which cover h.

Remark: The total space of the composite bundle $Y\to X$ (12) has the structure of the P-associated bundle

$$Y=(P\times(G\times V)/H)/G,$$

where the elements (p,g,v) and $(pab,b^{-1}g,a^{-1}v)$ for all $a\in H$ and $b\in G$ are identified. Its typical fiber is the quotient $(G\times V)/H$ of the product $G\times V$ by identification of the elements (g,v) and $(ag,a^{-1}v)$ for all $a\in H$. The group G act on this typical fiber by the rule

$$G\ni b: (g,v)\cdot H\to(bg,v)\cdot H,$$

which is the induced representation of G by the identic representation of H. In particular, if the typical fiber V of the composite bundle $Y\to X$ admits the action of the group G, these two bundle structures on Y are equivalent.

The feature of the dynamics of field systems on composite bundles consists in the following.[5,28] Let the composite bundle Y (12) be coordinated by $(x^\lambda, \sigma^m, y^i)$, where (x^λ, σ^m) are bundle coordinates on $\Sigma \to X$. Its first order jet manifold is provided with the adapted coordinates $(x^\lambda, \sigma^m, y^i, \sigma^m_\lambda, y^i_\lambda)$. Let

$$A = dx^\lambda \otimes (\partial_\lambda + A^i_\lambda \partial_i) + d\sigma^m \otimes (\partial_m + A^i_m \partial_i), \tag{14}$$

be a principal connection on the bundle $Y \to \Sigma$. This connection defines the splitting

$$VY = VY_\Sigma \underset{Y}{\oplus} (Y \underset{\Sigma}{\times} V\Sigma),$$

$$\dot{y}^i \partial_i + \dot{\sigma}^m \partial_m = (\dot{y}^i - A^i_m \dot{\sigma}^m)\partial_i + \dot{\sigma}^m (\partial_m + A^i_m \partial_i),$$

of vertical tangent bundles. Using this splitting, one can construct the first-order differential operator

$$\begin{aligned} &\widetilde{D}: J^1 Y \to T^*X \underset{Y}{\otimes} VY_\Sigma, \\ &\widetilde{D} = dx^\lambda \otimes (y^i_\lambda - A^i_\lambda - A^i_m \sigma^m_\lambda)\partial_i, \end{aligned} \tag{15}$$

on the composite bundle Y. The operator (15) possesses the following important property. Given a global section h of Σ, its restriction

$$\begin{aligned} &\widetilde{D}_h = \widetilde{D} \circ J^1 i_h : J^1 Y^h \to T^*X \otimes VY^h, \\ &\widetilde{D}_h = dx^\lambda \otimes (y^i_\lambda - A^i_\lambda - A^i_m \partial_\lambda h^m)\partial_i, \end{aligned} \tag{16}$$

to Y^h is exactly the familiar covariant differential relative to the principal connection

$$A_h = dx^\lambda \otimes [\partial_\lambda + (A^i_m \partial_\lambda h^m + A^i_\lambda)\partial_i],$$

on the bundle $Y^h \to X$, which is induced by the principal connection (14) on the bundle $Y \to \Sigma$ by the imbedding i_h.

III. LORENTZ STRUCTURE

An example of a reduced structure is a Lorentz reduced structure in gravitation theories which is deduced from the equivalence principle,[15] and accompanies a Dirac fermion matter.[12,13]

Let $\pi_{LX}: LX \to X^4$ be the frame bundle. Given the holonomic frames $\{\partial_\mu\}$ in the tangent bundle TX, every element $\{H_a\}$ of LX takes the form $H_a = H^\mu_a \partial_\mu$, where H^μ_a is a matrix element of the group GL_4. The frame bundle LX is provided with the bundle coordinates (x^λ, H^μ_a). In these coordinates, the canonical action of the structure group GL_4 on LX reads

$$R_g : H^\mu_a \mapsto H^\mu_b g^b_a, \quad g \in GL_4.$$

As is well-known, the frame bundle LX is equipped with the canonical $\mathbf{R}^4$-valued one-form, which is given by the coordinate expression

$$\theta_{LX} = H^a_\mu dx^\mu \otimes t_a, \tag{17}$$

where $\{t_a\}$ is a fixed basis for $\mathbf{R}^4$ and H^b_μ is the inverse matrix of H^μ_a.

Since a world manifold is parallelizable, the structure group GL_4 of the frame bundle LX is reducible to the Lorentz group L. The corresponding L-principal sub-bundle L^hX is a reduced Lorentz structure. Since LX is trivial, any two Lorentz sub-bundles L^hX and $L^{h'}X$ are isomorphic to each other. By virtue of Proposition 1, there exists a vertical bundle automorphism Φ of LX which sends L^hX onto $L^{h'}X$.

As was mentioned above, there is one-to-one correspondence between the Lorentz sub-bundles L^hX of LX and the global sections h of the tetrad bundle Σ (2) with the typical fiber GL_4/L.

Every tetrad field h defines an associated Lorentz atlas $\Psi^h=\{U_\zeta, z^h_\zeta\}$ of the frame bundle LX where the corresponding local sections z^h_ζ of LX take their values into the Lorentz sub-bundle L^hX. Given a Lorentz atlas Ψ^h, the pull-back

$$z^{h*}_\zeta \theta_{LX}=h^a\otimes t_a=h^a_\lambda dx^\lambda\otimes t_a, \tag{18}$$

of the canonical form θ_{LX} (17) by a local section z^h_ζ is said to be a (local) tetrad form. It determines the tetrad coframes $\{h^a\}$ in the cotangent bundle $T^*X\to X^4$. Their coefficients h^a_μ and the inverse matrix elements $h^\mu_a=H^\mu_a\circ z^h_\zeta$ are called tetrad functions.

Given a Lorentz sub-bundle L^hX, let us consider the associated bundle of Minkowski spaces

$$M^hX=(L^hX\times M)/L, \tag{19}$$

where M is provided with the Minkowski metric η. By virtue of Proposition 2, this bundle is isomorphic to the cotangent bundle T^*X. However, the Minkowski structures M^hX and $M^{h'}X$ on T^*X for different tetrad fields h and h' are not equivalent.

IV. DIRAC SPIN STRUCTURE

Every bundle of Minkowski spaces M^hX (19) over a world manifold is extended to the bundle of Clifford algebras C^hX with the fibers generated by the fibers of M^hX.[10] This bundle C^hX has the structure group $\mathrm{Aut}(\mathbf{C}_{1,3})$ of inner automorphisms of the Clifford algebra $\mathbf{C}_{1,3}$. In general, C^hX does not contain a spinor sub-bundle because a spinor subspace V (a minimal left ideal) of $\mathbf{C}_{1,3}$ is not stable under inner automorphisms of $\mathbf{C}_{1,3}$. As was shown,[29,30] a spinor sub-bundle of C^hX exists if the transition functions of C^hX can be lifted from $\mathrm{Aut}(\mathbf{C}_{1,3})$ to the Clifford group $G_{1,3}$. This agrees with the usual condition of existence of a spin structure which holds for X^4. Such a spinor sub-bundle is the bundle S^h (3) associated with the universal twofold covering

$$z_h: P^h\to L^hX, \quad z_h\circ R_g=R_{z_{L(g)}}, \quad \forall g\in L_s,$$

of L^hX. This is the h-associated Dirac spin structure on a world manifold.

There exists the bundle morphism

$$\gamma_h: T^*X\otimes S^h=(P^h\times(M\otimes V))/L_s\to(P^h\times\gamma(M\otimes V))/L_s=S^h, \tag{20}$$

whereby γ is meant the left action of $M\subset\mathbf{C}_{1,3}$ on $V\subset\mathbf{C}_{1,3}$.[12,13] One can think of (20) as being the representation of covectors to X^4 by the Dirac γ-matrices on elements of the spinor bundle S^h. Relative to an atlas $\{z_\zeta\}$ of P^h and to the associated Lorentz atlas $\{z_h\circ z_\zeta\}$ of LX, the representation (20) reads

$$y^A(\gamma_h(h^a(x)\otimes v))=\gamma^{aA}{}_B y^B(v), \quad v\in S^h_x,$$

where y^A are the corresponding bundle coordinates of S^h, and h^a are the tetrad coframes (18). For brevity, we will write

$$\hat h^a=\gamma_h(h^a)=\gamma^a, \quad \hat d x^\lambda=\gamma_h(dx^\lambda)=h^\lambda_a(x)\gamma^a.$$

Let A_h be a principal connection on S^h, and let

$$D: J^1S^h\to T^*X\underset{S^h}{\otimes}S^h,$$

$$D=(y^A_\lambda-A^{ab}{}_\lambda L_{ab}{}^A{}_B y^B)dx^\lambda\otimes\partial_A$$

where

$$L_{ab}=\tfrac{1}{4}[\gamma_a,\gamma_b], \tag{21}$$

be the corresponding covariant differential. The first-order differential Dirac operator is defined on S^h by the composition

$$\begin{aligned}&\Delta_h=\gamma_h\circ D: J^1S^h\to T^*X\otimes S^h\to S^h,\\ &y^A\circ\Delta_h=h^\lambda_a\gamma^{aA}{}_B(y^B_\lambda-\tfrac{1}{2}A^{ab}{}_\lambda L_{ab}{}^A{}_B y^B).\end{aligned} \tag{22}$$

The h-associated spinor bundle S^h is equipped with the fiber spinor metric

$$a_h(v,v')=\tfrac{1}{2}(v^+\gamma^0 v'+v'^+\gamma^0 v),\quad v,v'\in S^h.$$

Using this metric and the Dirac operator (22), one can define Dirac's Lagrangian

$$\begin{aligned}L_h=\Bigg\{\frac{i}{2}h^\lambda_q\Bigg[y^+_A(\gamma^0\gamma^q)^A{}_B\left(y^B_\lambda-\frac{1}{2}A_\lambda{}^{ab}L_{ab}{}^B{}_C y^C\right)\\ -\left(y^+_{\lambda A}-\frac{1}{2}A_\lambda{}^{ab}y^+_C L^+_{ab}\right)(\gamma^0\gamma^q)^A{}_B y^B\Bigg]-m y^+_A(\gamma^0)^A{}_B y^B\Bigg\}\det(h^a_\mu),\end{aligned} \tag{23}$$

on J^1S^h which describes Dirac fermion fields in the presence of a tetrad field h and a principal connection A_h on S_h.

We consider the general case of a principal connection A_h on S_h generated by a general linear connection on a world manifold as follows. Let ω_K be a connection form on LX of a general linear connection

$$K=dx^\lambda\otimes\left(\partial_\lambda+K_\lambda{}^\mu{}_\nu\dot{x}^\nu\frac{\partial}{\partial\dot{x}^\mu}\right), \tag{24}$$

on X^4, called a world connection. By virtue of the well-known theorem,[14] the pull-back $z^*_h\omega_L$ over P^h of the Lorentz part ω_L of ω_K is the connection form of the spin connection

$$K_h=dx^\lambda\otimes[\partial_\lambda+\tfrac{1}{4}(\eta^{kb}h^a_\mu-\eta^{ka}h^b_\mu)(\partial_\lambda h^\mu_k-h^\nu_k K_\lambda{}^\mu{}_\nu)L_{ab}{}^A{}_B y^B\partial_A], \tag{25}$$

on S^h, where L_{ab} are the generators (21).[23,31–33]

Remark: There is one-to-one correspondence between the world connections and the sections of the quotient bundle

$$C_K=J^1LX/GL_4, \tag{26}$$

whereby J^1LX implies the first-order jet manifold of the frame bundle $LX\to X^4$. With respect to the holonomic frames in TX, the bundle C_K is coordinated by $(x^\lambda,k_\lambda{}^\nu{}_\alpha)$ so that, for any section K of $C_K\to X^4$,

$$k_\lambda{}^\nu{}_\alpha\circ K=K_\lambda{}^\nu{}_\alpha,$$

are the coefficients of the world connection K (24).

Motivated by the connection (25), one can obtain the canonical lift

$$\widetilde{\tau}=\tau^\lambda\partial_\lambda+\tfrac{1}{4}(\eta^{kb}h^a_\mu-\eta^{ka}h^b_\mu)(\tau^\lambda\partial_\lambda h^\mu_k-h^\nu_k\partial_\nu\tau^\mu)L_{ab}{}^A{}_B y^B\partial_A, \tag{27}$$

of vector fields τ on X onto the spinor bundle S^h.[5,23] The lift (27) is brought into the form

$$\widetilde{\tau}=\tau_{\{\}}-\tfrac{1}{4}(\eta^{kb}h^a_\mu-\eta^{ka}h^b_\mu)h^\nu_k\nabla_\nu\tau^\mu L_{ab}{}^A{}_B y^B\partial_A,$$

where $\tau_{\{\}}$ is the horizontal lift of τ by means of the spin Levi-Civita connection for the tetrad field h, and $\nabla_\nu\tau^\mu$ are the covariant derivatives of τ relative to the Levi-Civita connection.[34,35]

The canonical lift (27) fails to be a generator of general covariant transformations because it does not involve transformations of tetrad fields. To define general covariant transformations, one must consider spinor structures associated with different tetrad fields. The difficulty arises because, though the principal spinor bundles P^h and $P^{h'}$ are isomorphic, the associated structures of the bundles of Minkowski spaces M^hX and $M^{h'}X$ (19) on the cotangent bundle T^*X are not equivalent, and so are the representations γ_h and $\gamma_{h'}$ (20).[12,13] Indeed, let

$$t^* = t_\mu dx^\mu = t_a h^a = t'_a h'^a,$$

be an element of T^*X. Its representations γ_h and $\gamma_{h'}$ (20) read

$$\gamma_h(t^*) = t_a \gamma^a = t_\mu h^\mu_a \gamma^a, \quad \gamma_{h'}(t^*) = t'_a \gamma^a = t_\mu h'^\mu_a \gamma^a.$$

There is no isomorphism Φ_s of S^h onto $S^{h'}$ which can obey the condition

$$\gamma_{h'}(t^*) = \Phi_s \gamma_h(t^*) \Phi_s^{-1}, \quad \forall t^* \in T^*X.$$

We thus observe the phenomenon of symmetry breaking in gravitation theory which exhibits the physical nature of gravity as a Higgs field.

V. COVARIANT SPIN STRUCTURE

We start from the following two facts.

Remark: The L-principal bundle

$$P_L := GL_4 \to GL_4/L, \tag{28}$$

is trivial. In accordance with the classification theorem,[27] a G-principal bundle over an n-dimensional sphere S^n is trivial if the homotopy group $\pi_{n-1}(G)$ is trivial. The base GL_4/L is homeomorphic to $S^3 \times \mathbf{R}^7$. Let us consider the morphism f_1 of S^3 into GL_4/L, $f_1(p) = (p,0)$, and the pull-back L-principal bundle $f_1^* P_L \to S^3$. Since L is homeomorphic to $RP^3 \times \mathbf{R}^3$ and $\pi_2(L) = 0$, this bundle is trivial. Let f_2 be the projection of GL_4/L onto S^3. Then the pull-back L-principal bundle $f_2^*(f_1^* P_L) \to GL_4/L$ is also trivial. Since the composition $f_1 \circ f_2$ of GL_4/L into GL_4/L is homotopic to the identity morphism of GL_4/L, the bundle $f_2^*(f_1^* P_L) \to GL_4/L$ is equivalent to the bundle P_L.[27] It follows that the bundle (28) is also trivial.

Remark: The diagram (4) commutes. The restriction of the universal covering group $\widetilde{GL}_4 \to GL_4$ to the Lorentz group L is obviously a covering space of L. Let us show that this is the universal covering space. Indeed, any noncontractible cycle in GL_4 belongs to some subgroup $SO(3) \subset GL_4$ and the restriction of the covering bundle $\widetilde{GL}_4 \to GL_4$ to $SO(3)$ is the universal covering of $SO(3)$. Since the L is homotopic to its maximal compact subgroup $SO(3)$, its universal covering space belongs to $\widetilde{GL}_4$.

As a consequence, we have the commutative diagram (6)[36] and the covariant spin structure (5).

The covariant spin structure is unique. Since the bundle $\Sigma \to X^4$ is trivial, the set of nonequivalent spin structures on Σ is in bijective correspondence with the cohomology group $H^1(S^3 \times \mathbf{R}^7 \times X^4; \mathbf{Z}_2)$. Since the cohomology group $H^1(S^3; \mathbf{Z}_2)$ is trivial and a spin structure on S^3 is unique,[37] one can show that nonequivalent spin structures on Σ are in bijective correspondence with those on X^4.

Let us consider the composite spinor bundle S (8) where $S \to \Sigma$ is the spinor bundle (7) associated with the L_s-principal bundle $\widetilde{LX} \to \Sigma$. Given a tetrad field h, there is the canonical isomorphism

$$i_h : S^h = (P^h \times V)/L_s \to (h^* \widetilde{LX} \times V)/L_s,$$

of the h-associated spinor bundle S^h (3) onto the restriction h^*S of the spinor bundle $S \to \Sigma$ to $h(X) \subset \Sigma$. Thence, every global section s_h of the spinor bundle S^h corresponds to the global

section $i_h \circ s_h$ of the composite spinor bundle (3). Conversely, every global section s of the composite spinor bundle (8), which projects onto a tetrad field h, takes its values into the sub-bundle $i_h(S^h) \subset S$.

Let the frame bundle $LX \to X^4$ be provided with a holonomic atlas $\{U_\zeta, T\phi_\zeta\}$, and let the principal bundles $\widetilde{LX} \to \Sigma$ and $LX \to \Sigma$ have the associated atlases $\{U_\epsilon, z^s_\epsilon\}$ and $\{U_\epsilon, z_\epsilon = \widetilde{z} \circ z^s_\epsilon\}$, respectively. With these atlases, the composite spinor bundle S is equipped with the bundle coordinates $(x^\lambda, \sigma^\mu_a, y^A)$, where $(x^\lambda, \sigma^\mu_a)$ are coordinates on Σ such that σ^μ_a are the matrix components of the group element $(T\phi_\zeta \circ z_\epsilon)(\sigma)$, $\sigma \in U_\epsilon$, $\pi_{\Sigma X}(\sigma) \in U_\zeta$. For any tetrad field h, we have $(\sigma^\lambda_a \circ h)(x) = h^\lambda_a(x)$ where $h^\lambda_a(x) = H^\lambda_a \circ z_\epsilon \circ h$ are the tetrad functions with respect to the Lorentz atlas $\{z_\epsilon \circ h\}$ of $L^h X$.

The spinor bundle $S \to \Sigma$ is the sub-bundle of the bundle of Clifford algebras which is generated by the bundle of Minkowski spaces

$$E_M = (LX \times M)/L \to \Sigma,$$

associated with the L-principal bundle $LX \to \Sigma$. Since the bundles LX and P_L (28) are trivial, so is the bundle $E_M \to \Sigma$. Hence, it is isomorphic to the product $\Sigma \times_X T^*X$. Then there exists the representation

$$\gamma_\Sigma : T^*X \otimes_\Sigma S = (\widetilde{LX} \times (M \otimes V))/L_s \to (\widetilde{LX} \times \gamma(M \otimes V))/L_s = S, \tag{29}$$

given by the coordinate expression

$$\hat{d}x^\lambda = \gamma_\Sigma(dx^\lambda) = \sigma^\lambda_a \gamma^a.$$

Restricted to $h(X) \subset \Sigma_T$, this representation recovers the morphism γ_h (20).

Using this representation, one can construct the total Dirac operator on the composite spinor bundle S as follows. Since the bundles $\widetilde{LX} \to \Sigma$ and $\Sigma \to X^4$ are trivial, let us consider a principal connection A (14) on the L_s-principal bundle $\widetilde{LX} \to \Sigma$ given by the local connection form

$$A = (A_\lambda{}^{ab} dx^\lambda + A^{kab}_\mu d\sigma^\mu_k) \otimes L_{ab}, \tag{30}$$

$$\begin{aligned} A_\lambda{}^{ab} &= -\tfrac{1}{2}(\eta^{kb}\sigma^a_\mu - \eta^{ka}\sigma^b_\mu)\sigma^\nu_k K_\lambda{}^\mu{}_\nu, \\ A^{kab}_\mu &= \tfrac{1}{2}(\eta^{kb}\sigma^a_\mu - \eta^{ka}\sigma^b_\mu), \end{aligned} \tag{31}$$

where K is a world connection on X^4. This connection defines the associated spin connection

$$A_S = dx^\lambda \otimes (\partial_\lambda + \tfrac{1}{2} A_\lambda{}^{ab} L_{ab}{}^A{}_B y^B \partial_A) + d\sigma^\mu_k \otimes (\partial^k_\mu + \tfrac{1}{2} A^{kab}_\mu L_{ab}{}^A{}_B y^B \partial_A), \tag{32}$$

on the spinor bundle $S \to \Sigma$. The choice of the connection (30) is motivated by the fact that, given a tetrad field h, the restriction of the spin connection (32) to S^h is exactly the spin connection (25).

The connection (32) yields the first order differential operator $\widetilde{D}$ (15) on the composite spinor bundle $S \to X^4$ which reads

$$\widetilde{D} : J^1 S \to T^*X \otimes_\Sigma S,$$

$$\begin{aligned} \widetilde{D} &= dx^\lambda \otimes [y^A_\lambda - \tfrac{1}{2}(A_\lambda{}^{ab} + A^{kab}_\mu \sigma^\mu_{\lambda k}) L_{ab}{}^A{}_B y^B] \partial_A \\ &= dx^\lambda \otimes [y^A_\lambda - \tfrac{1}{4}(\eta^{kb}\sigma^a_\mu - \eta^{ka}\sigma^b_\mu)(\sigma^\mu_{\lambda k} - \sigma^\nu_k K_\lambda{}^\mu{}_\nu) L_{ab}{}^A{}_B y^B] \partial_A. \end{aligned} \tag{33}$$

The corresponding restriction $\widetilde{D}_h$ (16) of the operator $\widetilde{D}$ (33) to $J^1 S^h \subset J^1 S$ recovers the familiar covariant differential on the h-associated spinor bundle $S^h \to X^4$ relative to the spin connection (27).

Combining (29) and (33), we obtain the first-order differential operator

$$\Delta=\gamma_\Sigma\circ\widetilde{D}: J^1S\to T^*X\underset{\Sigma}{\otimes}S\to S,$$

$$y^B\circ\Delta=\sigma_a^\lambda\gamma^{aB}{}_A[y^A_\lambda-\tfrac{1}{4}(\eta^{kb}\sigma^a_\mu-\eta^{ka}\sigma^b_\mu)(\sigma^\mu_{\lambda k}-\sigma^\nu_k K_\lambda{}^\mu{}_\nu)L_{ab}{}^A{}_B y^B], \tag{34}$$

on the composite spinor bundle $S\to X^4$. One can think of Δ as being the total Dirac operator on S since, for every tetrad field h, the restriction of Δ to $J^1S^h\subset J^1S$ is exactly the Dirac operator Δ_h (22) on the spinor bundle S^h in the presence of the tetrad field h and the spin connection (25).

Thus, we come to the model of metric-affine gravity and Dirac fermion fields. The total configuration space of this model is the jet manifold J^1Y of the bundle product

$$Y=C_K\underset{\Sigma}{\times}S, \tag{35}$$

where C_K is the bundle of world connections (26). It is coordinated by $(x^\mu,\sigma^\mu_a,k_\mu{}^\alpha{}_\beta,y^A)$, and J^1Y is provided with the adapted coordinates

$$(x^\mu,\sigma^\mu_a,k_\mu{}^\alpha{}_\beta,y^A,\sigma^\mu_{\lambda a},k_{\lambda\mu}{}^\alpha{}_\beta,y^A_\lambda).$$

The bundle (35) can be endowed with the spin connection

$$A_Y=dx^\lambda\otimes(\partial_\lambda+\widetilde{A}_\lambda{}^{ab}L_{ab}{}^A{}_B y^B\partial_A)+d\sigma^\mu_k\otimes(\partial^k_\mu+A^{kab}_\mu L_{ab}{}^A{}_B y^B\partial_A), \tag{36}$$

where A^{kab}_μ is given by the expression (31), and

$$\widetilde{A}_\lambda{}^{ab}=-\tfrac{1}{2}(\eta^{kb}\sigma^a_\mu-\eta^{ka}\sigma^b_\mu)\sigma^\nu_k k_\lambda{}^\mu{}_\nu.$$

Using the connection (36), we obtain the first-order differential operator

$$\widetilde{D}_Y: J^1Y\to T^*X\underset{\Sigma}{\otimes}S,$$

$$\widetilde{D}_Y=dx^\lambda\otimes[y^A_\lambda-\tfrac{1}{4}(\eta^{kb}\sigma^a_\mu-\eta^{ka}\sigma^b_\mu)(\sigma^\mu_{\lambda k}-\sigma^\nu_k k_\lambda{}^\mu{}_\nu)L_{ab}{}^A{}_B y^B]\partial_A, \tag{37}$$

and the total Dirac operator

$$\Delta_Y=\gamma_\Sigma\circ\widetilde{D}: J^1Y\to T^*X\underset{\Sigma}{\otimes}S\to S,$$

$$y^B\circ\Delta_Y=\sigma_a^\lambda\gamma^{aB}{}_A[y^A_\lambda-\tfrac{1}{4}(\eta^{kb}\sigma^a_\mu-\eta^{ka}\sigma^b_\mu)(\sigma^\mu_{\lambda k}-\sigma^\nu_k k_\lambda{}^\mu{}_\nu)L_{ab}{}^A{}_B y^B], \tag{38}$$

on the bundle $Y\to X^4$. Given a section $K: X\to C_K$, the restrictions of the spin connection A_Y (36), the operator $\widetilde{D}_Y$ (37) and the Dirac operator Δ_Y (38) to K^*Y are exactly the spin connection (32) and the operators (33) and (34), respectively.

The total Lagrangian on the configuration space J^1Y of metric-affine gravity and fermion fields is the sum

$$L=L_{MA}+L_D. \tag{39}$$

A metric-affine Lagrangian L_{MA} depends on the metric coordinates

$$\sigma_{\mu\nu}=\sigma^a_\mu\sigma^b_\nu\eta_{ab} \tag{40}$$

and the curvature

$$R_{\lambda\mu}{}^\alpha{}_\beta=k_{\lambda\mu}{}^\alpha{}_\beta-k_{\mu\lambda}{}^\alpha{}_\beta+k_\mu{}^\alpha{}_\epsilon k_\lambda{}^\epsilon{}_\beta-k_\lambda{}^\alpha{}_\epsilon k_\mu{}^\epsilon{}_\beta.$$

Dirac's Lagrangian is

$$L_D=\left\{\frac{i}{2}\,\sigma_q^{\lambda}\left[y_A^+(\gamma^0\gamma^q)^A{}_B\left(y_\lambda^B-\frac{1}{4}\,(\eta^{kb}\sigma_\mu^a-\eta^{ka}\sigma_\mu^b)(\sigma_{\lambda k}^{\mu}-\sigma_k^{\nu}k_\lambda{}^\mu{}_\nu)L_{ab}{}^B{}_C y^C\right)\right.\right.$$
$$\left.-\left(y_{\lambda A}^+-\frac{1}{4}\,(\eta^{kb}\sigma_\mu^a-\eta^{ka}\sigma_\mu^b)(\sigma_{\lambda k}^{\mu}-\sigma_k^{\nu}k_\lambda{}^\mu{}_\nu)y_C^+L_{ab}^+{}^C{}_A\right)(\gamma^0\gamma^q)^A{}_B y^B\right]$$
$$\left.-my_A^+(\gamma^0)^A{}_B y^B\right\}\sqrt{|\sigma|},\quad \sigma=\det(\sigma_{\mu\nu}). \tag{41}$$

By construction, it is Hermitian. Note that, in fact, the Lagrangian L_D depends only on the torsion $k_\lambda{}^\mu{}_\nu-k_\nu{}^\mu_\lambda$ of a world connection, while the pseudo-Riemannian part is given by the derivative coordinates $\sigma_{\lambda k}^{\mu}$.

VI. GENERAL COVARIANT TRANSFORMATIONS

The frame bundle $LX\to X^4$ belongs to the category of natural bundles. Every diffeomorphism f of X^4 gives rise canonically to the automorphism

$$\widetilde{f}:(x^\lambda,H^\lambda{}_a)\mapsto(f^\lambda(x),\partial_\mu f^\lambda H^\mu{}_a), \tag{42}$$

of LX and to the corresponding automorphisms (general covariant transformations)

$$\widetilde{f}:T=(LX\times W)/GL_4\to(\widetilde{f}(LX)\times W)/GL_4,$$

of any LX-associated bundle T. In particular, if $T=TX$, the lift $\widetilde{f}=Tf$ is the familiar tangent morphism to f.

The lift (42) yields the canonical horizontal lift $\widetilde{\tau}$ of every vector field τ on X^4 onto LX-associated bundles. For instance, such a lift onto a tensor bundle $(\overset{m}{\otimes}TX)\otimes(\overset{k}{\otimes}T^*X)$ reads

$$\widetilde{\tau}=\tau^\mu\partial_\mu+[\partial_\nu\tau^{\alpha_1}\dot{x}_{\beta_1\cdots\beta_k}^{\nu\alpha_2\cdots\alpha_m}+\cdots-\partial_{\beta_1}\tau^\nu\dot{x}_{\nu\beta_2\cdots\beta_k}^{\alpha_1\cdots\alpha_m}-\cdots]\,\frac{\partial}{\partial\dot{x}_{\beta_1\cdots\beta_k}^{\alpha_1\cdots\alpha_m}}.$$

There also exists the canonical lift

$$\widetilde{\tau}_K=\tau^\mu\partial_\mu+[\partial_\nu\tau^\alpha k_\mu{}^\nu{}_\beta-\partial_\beta\tau^\nu k_\mu{}^\alpha{}_\nu-\partial_\mu\tau^\nu k_\nu{}^\alpha{}_\beta+\partial_{\mu\beta}\tau^\alpha]\,\frac{2}{\partial k_\mu{}^\alpha{}_\beta}, \tag{43}$$

of τ onto the bundle of world connections C_K (26), though this is not a LX-associated bundle.

Since the covariant spin structure is unique, the $\widetilde{GL}_4$-principal bundle $\widetilde{LX}\to X^4$ as well as the frame bundle LX admits the lift of any diffeomorphism f of the base X^4.[19]

This lift is defined by the commutative diagram

$$\begin{array}{ccc}\widetilde{LX} & \xrightarrow{\widetilde{f}} & \widetilde{LX}\\ {\scriptstyle\widetilde{z}}\downarrow & & \downarrow{\scriptstyle\widetilde{z}}\\ LX & \xrightarrow{\widetilde{f}} & LX\\ \downarrow & & \downarrow\\ X & \xrightarrow{f} & X\end{array}$$

The associated morphism of the spinor bundle $S\to\Sigma$ is given by the relation

$$\widetilde{f}_S:(p,v)\cdot L_s\to(\widetilde{f}(p),v)\cdot L_s,\quad p\in\widetilde{LX},\quad v\in S.$$

Because $\widetilde{f}$ is equivarient, this is a fiber-to-fiber automorphism of the bundle $S\to\Sigma$ over the automorphism $\widetilde{f}_\Sigma$ of the tetrad bundle $\Sigma\to X^4$ induced by the diffeomorphism f of X^4. Thus, we have the commutative diagram

$$\begin{array}{ccc} S & \xrightarrow{\widetilde{f}_S} & S \\ \downarrow & & \downarrow \\ \Sigma & \xrightarrow{\widetilde{f}_\Sigma} & \Sigma \\ \downarrow & & \downarrow \\ X^4 & \xrightarrow{f} & X^4 \end{array}$$

of general covariant transformations of the spinor bundle S.

Accordingly, there exists a canonical lift $\widetilde{\tau}_S$ onto S of every vector field τ on X^4. The goal is to find its coordinate expression. Difficulties arise because the tetrad coordinates σ_a^μ of Σ depend on the choice of an atlas of the bundle $LX\to\Sigma$. Therefore, noncanonical vertical components appear in the coordinate expression of $\widetilde{\tau}_S$.

The lift τ_Σ of a vector field τ on X^4 onto the tetrad bundle Σ can be derived from the relation (40) and the canonical lift

$$\widetilde{\tau}=\tau^\lambda\partial_\lambda+(\partial_\nu\tau^\alpha\sigma^{\nu\beta}+\partial_\nu\tau^\beta\sigma^{\nu\alpha})\frac{\partial}{\partial\sigma^{\alpha\beta}}, \tag{44}$$

of τ onto the bundle of pseudo-Riemannian metric Σ_g identified with an open sub-bundle of the tensor bundle $\overset{2}{\vee}TX$, and provided with coordinates $(x^\lambda,\sigma^{\mu\nu})$. We have

$$\tau_\Sigma=\tau^\lambda\partial_\lambda+\partial_\nu\tau^\mu\sigma_c^\nu\frac{\partial}{\partial\sigma_c^\mu}+Q_c^\mu\frac{\partial}{\partial\sigma_c^\mu},$$

where the terms Q_c^μ obey the condition

$$(Q_a^\mu\sigma_b^\nu+Q_a^\nu\sigma_b^\mu)\eta^{ab}=0.$$

Let us consider a horizontal lift of the vector field τ_Σ onto the spinor bundle $S\to\Sigma$ by means of the spin connection (32). It reads

$$\begin{aligned} A_S\widetilde{\tau}_\Sigma=\tau^\lambda\partial_\lambda+\partial_\nu\tau^\mu\sigma_c^\nu\frac{\partial}{\partial\sigma_c^\mu}+\frac{1}{4}(\eta^{kb}\sigma_\mu^a-\eta^{ka}\sigma_\mu^b)\sigma_k^\nu(\partial_\nu\tau^\mu-K_\lambda{}^\mu{}_\nu\tau^\nu)(L_{ab}{}^A{}_By^B\partial_A+L_{ab}^+{}^A{}_By_A^+\partial^B)\\ +Q_c^\mu\frac{\partial}{\partial\sigma_c^\mu}+\frac{1}{4}Q_k^\mu(\eta^{kb}\sigma_\mu^a-\eta^{ka}\sigma_\mu^b)(L_{ab}{}^A{}_By^B\partial_A+L_{ab}^+{}^A{}_By_A^+\partial^B). \end{aligned}$$

This leads us to the desired canonical lift of τ onto S:

$$\widetilde{\tau}_S=\tau^\lambda\partial_\lambda+\partial_\nu\tau^\mu\sigma_c^\nu\frac{\partial}{\partial\sigma_c^\mu}+Q_c^\mu\frac{\partial}{\partial\sigma_c^\mu}+\frac{1}{4}Q_k^\mu(\eta^{kb}\sigma_\mu^a-\eta^{ka}\sigma_\mu^b)(L_{ab}{}^A{}_By^B\partial_A+L_{ab}^+{}^A{}_By_A^+\partial^B),$$

which can be brought into the form

$$\widetilde{\tau}_S=\tau^\lambda\partial_\lambda+\partial_\nu\tau^\mu\sigma_c^\nu\frac{\partial}{\partial\sigma_c^\mu}+\vartheta,$$

$$\vartheta = \tfrac{1}{4} Q_k^\mu (\eta^{kb}\sigma_\mu^a - \eta^{ka}\sigma_\mu^b)\left[-L_{ab}{}^d{}_c \sigma_d^\nu \frac{\partial}{\partial \sigma_c^\nu} + L_{ab}{}^A{}_B y^B \partial_A + L^+_{ab}{}^A{}_B y^+_A \partial^B \right],$$

where $L_{ab}{}^d{}_c$ are generators of the Lorentz group in the Minkowski space. The term ϑ is the above-mentioned noncanonical part of this lift. The corresponding total vector field on the fibred product Y (35) reads

$$\widetilde{\tau}_Y = \widetilde{\tau} + \vartheta,$$

$$\widetilde{\tau} = \tau^\lambda \partial_\lambda + \partial_\nu \tau^\mu \sigma_c^\nu \frac{\partial}{\partial \sigma_c^\mu} + \widetilde{\tau}_K, \tag{45}$$

where $\overline{\tau}_K$ is the canonical lift (43) onto C_K. Its canonical part $\overline{\tau}$ (45) is the generator of a local one-parameter group of general covariant transformations of the bundle Y, whereas the vertical vector field ϑ is the generator of a local one-parameter group of vertical Lorentz automorphisms of the bundle $S \to \Sigma$. By construction, the total Lagrangian L (39) obeys the relations

$$\mathbf{L}_{J^1\vartheta} L_D = 0, \tag{46}$$

$$\mathbf{L}_{J^1\widetilde{\tau}} L_{MA} = 0, \quad \mathbf{L}_{J^1\widetilde{\tau}} L_D = 0. \tag{47}$$

The relation (46) leads to the Nöther conservation law, while the equalities (47) lead to the energy-momentum one.[23]

VII. BACKGROUND SPIN STRUCTURE

Let us consider the case of a background spin structure and the corresponding background tetrad field h.

Given a tetrad field h, any general covariant transformation of the frame bundle LX can be written as the composition $\widetilde{f} = \Phi \circ \widetilde{f}_h$ of its automorphism $\widetilde{f}_h$ over f which preserves L^hX and some vertical automorphism

$$\Phi : p \mapsto p\,\phi(p), \quad p \in LX, \tag{48}$$

where ϕ is a GL_4-valued equivariant function on LX. Since LX is trivial, the automorphism $\widetilde{f}_h$ exists. Indeed, let z^h be a global section of L^hX. Put

$$\widetilde{f}_h : L_xX \ni p = z^h(x)g \mapsto z^h(f(x))g \in L_{f(x)}X.$$

The automorphism $\widetilde{f}_h$ restricted to L^hX induces an automorphism of the principal bundle P^h and the corresponding automorphism $\widetilde{f}_s$ of the spinor bundle S^h, which preserves the representation (20).

Turn now to the vertical automorphism Φ. Let us consider the group bundle $Q \to X$ associated with LX. Its typical fiber is the group GL_4 which acts on itself by the adjoint representation. Let $(x^\lambda, q^\lambda_\mu)$ be coordinates on Q. There exist the left and right canonical actions of Q on any LX-associated bundle T:

$$\rho_{l,r} : Q \underset{X}{\times} T \to T,$$

$$\rho_l : ((p,g)\cdot GL_4, (p,w)\cdot GL_4) \mapsto (p, gw)\cdot GL_4,$$

$$\rho_r : ((p,g)\cdot GL_4, (p,w)\cdot GL_4) \mapsto (p, g^{-1}w)\cdot GL_4.$$

Given a vertical automorphism Φ (48) of LX, the corresponding vertical automorphisms of an associated bundle T and the group bundle Q read

$$\Phi : (p,w)\cdot GL_4 \mapsto (p, \phi(p)w)\cdot GL_4,$$

$$\Phi:(p,g)\cdot GL_4\mapsto(p,\phi(p)g\phi^{-1}(p))\cdot GL_4.$$

For any Φ (48), there exists the fiber-to-fiber morphism

$$\overline{\Phi}:(p,q)\cdot GL_4\mapsto(p,\phi(p)q)\cdot GL_4,$$

of the group bundle Q such that

$$\rho_l(\overline{\Phi}(Q)\times T)=\Phi(\rho_l(Q\times T)), \tag{49}$$

$$\rho_r(\overline{\Phi}(Q)\times\Phi(T))=\rho_r(Q\times T). \tag{50}$$

For instance, if $T=T^*X$, the expressions (49) and (50) take the coordinate form

$$\rho_r:(x^\lambda,q^\lambda_\mu,\dot{x}_\mu)\mapsto(x^\lambda,\dot{x}_\lambda q^\lambda_\mu),$$

$$\overline{\Phi}:(x^\lambda,q^\lambda_\mu)\mapsto(x^\lambda,S^\lambda_\nu q^\nu_\mu),$$

$$\rho_r(x^\lambda,S^\lambda_\nu q^\nu_\mu,\dot{x}_\alpha(S^{-1})^\alpha_\lambda)=(x^\lambda,\dot{x}_\lambda q^\lambda_\mu).$$

Hence, we obtain the representation

$$\gamma_Q:(Q\times T^*X)\underset{Q}{\otimes}(Q\times S^h)\to(Q\times S^h),$$

$$\gamma_Q=\gamma_h\circ\rho_r:(q,t^*)\mapsto\dot{x}_\lambda q^\lambda_\mu\hat{d}x^\mu=\dot{x}_\lambda q^\lambda_\mu h^\mu_a\gamma^a, \tag{51}$$

on elements of the spinor bundle S^h. Let q_e be the canonical global section of the group bundle $Q\to X^4$ whose values are the unit elements of the fibers of Q. Then the representation γ_Q (51) restricted to $q_e(X^4)$ comes to the representation γ_h (20).

Let h be a background tetrad field, while sections $q(x)$ of the group bundle Q are dynamic variables treated as gravitational fields. There is the canonical morphism

$$\rho_l:Q\underset{X}{\times}\Sigma\to\Sigma,$$

$$\rho_l:((p,g)\cdot GL_4,(p,\sigma)\cdot GL_4)\mapsto(p,g\sigma)\cdot GL_4,\quad p\in LX,$$

$$\rho_l:(x^\lambda,q^\lambda_\mu,\sigma^\mu_a)\mapsto(x^\lambda,q^\lambda_\mu\sigma^\mu_a).$$

This morphism restricted to $h(X^4)\subset\Sigma$ takes the form

$$\rho_h:Q\to\Sigma,$$

$$\rho_h:((p,g)\cdot L,(p,\sigma_0)\cdot L)\to(p,g\sigma_0)\cdot L,\quad p\in L^hX,$$

$$\rho_h:(x^\lambda,q^\lambda_\mu)\mapsto(x^\lambda,q^\lambda_\mu h^\mu_a), \tag{52}$$

where σ_0 is the center of the quotient GL_4/L.

Let Σ_h, coordinated by $\overline{\sigma}^\mu_a$, be the quotient of the bundle Q by the kernel $\mathrm{Ker}_h\rho_h$ of the morphism (52) with respect to the section h. This is isomorphic to the tetrad bundle Σ provided with the Lorentz structure of a L^hX-associated bundle. Then the representation (51), which is constant on $\mathrm{Ker}_h\rho_h$, reduces to the representation

$$(\Sigma_h\times T^*X)\underset{\Sigma_h}{\otimes}(\Sigma_h\times S^h)\to(\Sigma_h\times S^h),$$

$$(\tilde{\sigma},t^*)\mapsto\dot{x}_\lambda\tilde{\sigma}^\lambda_a\gamma^a.$$

Thence, one can think of a section $\widetilde{h}\neq h$ of the bundle Σ_h as being an effective tetrad field, and can treat $\widetilde{g}^{\mu\nu}=\widetilde{h}^\mu_a\widetilde{h}^\nu_b\eta_{ab}$ as an effective metric. It should be emphasized that the Greek indices go down and go up by means of the background metric $g^{\mu\nu}=h^\mu_a h^\nu_b\eta_{ab}$.

Given a general covariant transformation $\widetilde{f}=\Phi\circ\widetilde{f}_h$ of the frame bundle LX, let us consider the morphism

$$\widetilde{f}_Q:\quad Q\to\overline{\Phi}\circ\widetilde{f}_h(Q),\quad S^h\to\widetilde{f}_s(S^h),\quad T^*X\to\widetilde{f}(T^*X). \tag{53}$$

This preserves the representation (51), i.e., $\gamma_Q\circ\widetilde{f}_Q=\widetilde{f}_s\circ\gamma_Q$, and yields the general covariant transformation $\widetilde{\sigma}^\lambda_a\mapsto\partial_\mu f^\lambda\widetilde{\sigma}^\mu_a$ of the bundle Σ_h.

Using a spin connection K_h (25) and the representation γ_Q (51), one can construct the Dirac operator

$$\Delta_Q=q^\lambda{}_\mu h^\mu_a\gamma^a D_\lambda.$$

Restricted to $q_e(X^4)$, this operator recovers the Dirac operator Δ_h (22) on the spinor bundle S^h in the presence of the background tetrad field h and the world connection K.

In particular, we come to the metric-affine generalization of Logunov's model[38] whose configuration space is the jet manifold J^1Y of the product

$$Y=Q\underset{X}{\times}C_K\underset{X}{\times}S^h. \tag{54}$$

It is coordinated by $(x^\mu,q^\mu_\nu,k_\alpha{}^\mu{}_\nu,y^A)$. A total Lagrangian on this configuration space is the sum

$$L=L_{MA}+L_D+L_q(q,g), \tag{55}$$

where L_{MA} is a metric-affine Lagrangian expressed into the effective metric $\widetilde{\sigma}^{\mu\nu}=\widetilde{\sigma}^\mu_a\widetilde{\sigma}^\nu_b\eta^{ab}$, L_D is Dirac's Lagrangian (41), expressed into the effective tetrad coordinates $\widetilde{\sigma}^\lambda_a=q^\lambda_\mu h^\mu_a$, while the Lagrangian L_q depends on gravitational fields q and the background metric g.

For the sake of simplicity, let us replace the bundle Q in the product (54) with the bundle Σ_h. There exists the canonical lift $\widetilde{\tau}_{Y'}$ onto $\Sigma_h\times C_K\times S^h$ of every vector field τ on X^4. It coincides with the vector field $\widetilde{\tau}_Y$ (45) where σ^λ_a are replaced with $\widetilde{\sigma}^\lambda_a$. This lift is the generator of gauge transformations induced by morphisms $\widetilde{f}_Q$ (53). Then using the standard procedure,[5,23] obtain the energy-momentum conservation law

$$\partial_\lambda(\tau^\lambda L_q)+(\partial_\alpha\tau^\mu\widetilde{g}^{\alpha\nu}+\partial_\alpha\tau^\nu\widetilde{g}^{\alpha\mu})\,\frac{\partial L_q}{\partial\widetilde{g}^{\mu\nu}}\approx d_\lambda\left(2\tau^\mu\widetilde{g}^{\lambda\alpha}\,\frac{\partial L_q}{\partial\widetilde{g}^{\alpha\mu}}+\tau^\lambda L_q-d_\mu U^{\mu\lambda}\right), \tag{56}$$

where

$$U=2\,\frac{\partial L_{AM}}{\partial R_{\mu\lambda}{}^\alpha{}_\nu}\,(\partial_\nu\tau^\alpha-k_\sigma{}^\alpha{}_\nu\tau^\sigma),$$

is the generalized Komar superpotential.[3,23] If $L_q=0$, we obtain exactly the energy-momentum conservation law of the metric-affine gravitation theory, but with an effective metric. In the case of the Logunov's Lagrangian

$$L_q=\lambda_3 g_{\mu\nu}\widetilde{\sigma}^{\mu\nu}\sqrt{|\widetilde{\sigma}|},$$

the equality (56) comes to the well-known condition

$$\nabla_\alpha(\widetilde{g}^{\alpha\mu}\sqrt{|\widetilde{g}|})\approx 0,$$

where ∇_α are covariant derivatives relative to the Levi-Civita connection of the background metric g.

New varieties of Gowdy space–times

Masayuki Tanimoto[a)]
Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto 606-8502, Japan

(Received 2 February 1998; accepted for publication 1 May 1998)

Gowdy space–times are generalized to admit two commuting spatial local Killing vectors, and some new varieties of them are presented, which are all closely related to Thurston's geometries. Explicit spatial compactifications, as well as the boundary conditions for the metrics, are given in a systematic way. A short comment on an implication of their dynamics toward the initial singularity is made. © *1998 American Institute of Physics.* [S0022-2488(98)00209-6]

I. INTRODUCTION

Spatially compact inhomogeneous space–times admitting two commuting spatial Killing vectors are known as Gowdy space–times,[1] which have recently been paid a great deal of attention as favorable models for studies of asymptotic behavior toward the cosmological initial singularity.[2–6] Since Gowdy space–times provide the simplest inhomogeneous cosmologies, it seems natural to use them in the kind of studies first developed based on Bianchi homogeneous cosmologies[7] by Belinski *et al.*[8] This article's aim is not, however, to elucidate the dynamics of Gowdy space–times, but to point out some new features pertaining to their varieties, which may open new windows for looking at the initial singularity.

As is well known, Bianchi homogeneous cosmologies are classified by the local structures of simply transitive three-dimensional groups, Bianchi I–IX groups. Spatially compact Bianchi cosmologies[9–11] are more diverse than the open ones, since possible compact topologies are in general very diverse for each Bianchi (universal covering) cosmology. Nevertheless, Gowdy space–times having lower symmetry than these homogeneous ones are known to have very limited varieties, i.e., only T^3, $S^2\times S^1$, S^3, and lens spaces as their possible spatial topologies. Why is their diversity so poor? In fact, all the Bianchi cosmologies except types VIII and IX admit two commuting Killing vectors, and, moreover, compactifications are possible except for types IV and $\mathrm{VI}_{a\neq 0}$.[12,9] Since these compact Bianchi models can be thought of as (if they exist) homogeneous limits of compact inhomogeneous models which admit two commuting Killing vectors, it seems that Gowdy models should be more diverse. The solution to this paradox lies in whether the Killing vectors are local or global. That is, the restriction for the possible topologies of Gowdy space–times is a consequence of the definition that the two commuting Killing vectors must be globally defined, while spatially compact Bianchi cosmologies admit in general only local Killing vectors.

If we consider Killing vectors for the simplification of Einstein's equation, which is local in nature, the imposition of the globality of the Killing vectors is evidently unnecessary. We therefore generalize Gowdy space–times in this article to admit two commuting local Killing vectors. (This type of generalization was also considered by Rendall[13] in a different approach from ours.) We will actually find that there exist rich (topologically infinitely many) varieties of Gowdy space–times.

As is well known in the theory of three-dimensional topology, Thurston[14] enumerated eight types of homogeneous three-manifolds, called model geometries, S^3, E^3, H^3, $S^2\times E^1$, $H^2\times E^1$, $\widetilde{SL}(2,\mathbf{R})$, nilgeometry (Nil), and solvegeometry (Sol), and proved in essence that any compact three-dimensional manifold which admits a locally homogeneous Riemannian metric is a compact quotient of one of these eight types of homogeneous manifold (see Sec. 3.8 of Ref. 14). We effectively utilize these model geometries as in the compact locally homogeneous cases.[9,10]

In the next section, we show how we can apply Thurston's theorem to find (generalized)

Gowdy space–times, and in the subsequent two sections present three new types of Gowdy space–times as examples. The final section is devoted to conclusions, including a comment on the dynamics of the three Gowdy space–times.

II. POSSIBLE TOPOLOGIES

To find possible topologies of Gowdy space–times, we consider a ''homogenization'' of a compact Riemannian three-manifold (M,h_{ab}) which admits two commuting local Killing vectors. Namely, suppose we can smoothly deform the metric h_{ab}, preserving the two local Killing vectors, and can take a locally homogeneous limit $(M,h^{\rm lh}_{ab})$ of the Gowdy space (M,h_{ab}). Since the universal cover $(\tilde{M},\tilde{h}^{\rm lh}_{ab})$ of $(M,h^{\rm lh}_{ab})$ is homogeneous, it must be one of the BKSN types, i.e., Bianchi homogeneous three-manifolds and the Kantowski-Sachs-Nariai (KSN) homogeneous three-manifold.[15,16] On the other hand, since the homogenization $(M,h^{\rm lh}_{ab})$ is compact, $(M,h^{\rm lh}_{ab})$ must be homeomorphic to a compact quotient of one of the eight Thurston model geometries.

A (model) *geometry* is the pair $(\tilde{M},G)$ of a manifold $\tilde{M}$ and a group G of diffeomorphisms on $\tilde{M}$, such that G acts transitively on $\tilde{M}$ with compact isotropy subgroups. Since G acts transitively on $\tilde{M}$, $(\tilde{M},G)$ can be thought of as an equivalence class of the homogeneous manifolds whose isometry group is isomorphic to (or includes a subgroup isomorphic to) G.[10] For convenience we call $(\tilde{M},G)$ a *subgeometry* of $(\tilde{M},G')$ if G is a subgroup of another transitive group G' with compact isotropy subgroups. Moreover, if geometry $(\tilde{M},G)$ is not a subgeometry of any geometry, then we call $(\tilde{M},G)$ a *maximal* geometry, and if $(\tilde{M},G)$ does not have any subgeometry, then we call $(\tilde{M},G)$ a *minimal* geometry. While the eight Thurston geometries are maximal geometries, all the BKSN types except Bianchi IV and $\mathrm{VI}_{a\neq 0}$ can be thought of as the minimal geometries of Thurston geometries.[9,12] This correspondence helps apply Thurston geometries to space–time models.

The group G of the geometry $(\tilde{M},G)$ which corresponds to $(\tilde{M},\tilde{h}^{\rm lh}_{ab})$ should include a subgroup isomorphic to one of $\mathbf{R}^2$, $\mathbf{R}\times\mathrm{U}(1)$, and $\mathrm{U}(1)\times\mathrm{U}(1)$, corresponding to the commuting two Killing vectors. All Thurston geometries satisfy this condition. More precisely, what include $\mathbf{R}^2$ are geometries E^3, H^3, $H^2\times E^1$, $\widetilde{\mathrm{SL}}(2,\mathbf{R})$, Nil, and Sol. Geometry $S^2\times E^1$ includes $\mathbf{R}\times\mathrm{U}(1)$, and S^3 includes $\mathrm{U}(1)\times\mathrm{U}(1)$. Moreover, all the minimal geometries of these Thurston geometries except Bianchi VIII ($\widetilde{\mathrm{SL}}(2,\mathbf{R})$ as the maximal one) and IX (S^3, similarly) also satisfy this condition. Any compact quotient for all the homogeneous three-manifolds except Bianchi VIII and IX can therefore be a homogenization of a Gowdy space. Even for Bianchi VIII and IX, there can be a homogenization when imposing a fourth Killing vector on them.

This observation tells what homogeneous manifold can be the universal cover of a homogeneous limit of a Gowdy space. Once such a homogenization with isometry group G is fixed, the universal cover of the corresponding Gowdy space can be determined as follows. That is, we may find the subgroup H of G such that the actions are smooth along the two commuting Killing vectors, but discrete along the third one. The H-invariant metric is the universal cover metric of the Gowdy space (or space–time), if the fundamental group can be represented in H. In fact, the H-invariance is a necessary condition for the universal cover to admit a (spatially) compact quotient, so we need to check that. As we will see, it is easy to write such an H-invariant metric if using the invariant one-forms for the corresponding Bianchi type. The KSN type has already been discussed in Ref. 1, so we do not consider it in this article.

In the following, we show how these ideas work by presenting three examples, which are all new.

III. GOWDY ON *NIL*×R

As a first example let us consider Nil, which possesses Bianchi II as its minimal geometry. Note that the Bianchi II homogeneous spaces are characterized by the following commutation relations for the three Killing vectors

$$[\xi_1,\xi_2]=-\xi_3,\quad [\xi_2,\xi_3]=0,\quad [\xi_3,\xi_1]=0. \tag{1}$$

In terms of coordinate basis they can be represented by

$$\xi_1=\frac{\partial}{\partial x}+y\,\frac{\partial}{\partial z},\quad \xi_2=\frac{\partial}{\partial y},\quad \xi_3=\frac{\partial}{\partial z}. \tag{2}$$

For future use, we take this opportunity to write the finite actions generated by these ξ_i's:

$$\begin{pmatrix} a\\ b\\ c\end{pmatrix}\begin{pmatrix} x\\ y\\ z\end{pmatrix}=\begin{pmatrix} a+x\\ b+y\\ c+z+ay\end{pmatrix}, \tag{3}$$

where the component vectors

$$\left\{\begin{pmatrix} a\\ b\\ c\end{pmatrix}\equiv e^{c\xi_3}e^{b\xi_2}e^{a\xi_1}\,|\,a,b,c\in\mathbf{R}\right\} \tag{4}$$

form the Bianchi II group G_{II}. ($e^{a\xi_i}$ denotes the one-parameter group of diffeomorphisms generated by ξ_i.) Note that the ''spatial point'' (x,y,z) is the image of the origin (0,0,0) by the ''group element'' (x,y,z), so that Eq. (3) itself gives the multiplication rule in the Bianchi II group.

From the commutation relations (1), we find two possible choices of obtaining a Gowdy space–time model, i.e., one (Type 1) is to keep ξ_2 and ξ_3 as the two commuting Killing vectors and consider inhomogeneity along ξ_1, and the other (Type 2) is to keep ξ_1 and ξ_3 as Killing vectors and consider inhomogeneity along ξ_2. We consider Type 1 first.

Note that the invariant one-forms of Bianchi II, given by

$$\sigma^1=dx,\quad \sigma^2=dy,\quad \sigma^3=dz-xdy, \tag{5}$$

are globally defined on $\tilde{M}=\mathbf{R}^3$, so that we can expand any metric on $\tilde{M}$ by these one-forms,

$$dl^2=h_{ij}\sigma^i\sigma^j, \tag{6}$$

with globally defined metric functions h_{ij}. Note also that the subgroup H_{II} of G_{II} of which action is discrete along ξ_1 is formed by

$$\left\{\begin{pmatrix} 2m\pi\\ b\\ c\end{pmatrix}\,\middle|\, m\in\mathbf{Z},b,c\in\mathbf{R}\right\}. \tag{7}$$

(The choice of the interval for the first component is arbitrary. Our choice of 2π is just for definiteness.) Since the invariant one-forms (5) are invariant under H_{II} (and G_{II} by definition), the metric (6) is invariant under H_{II} iff the metric functions h_{ij} are, too. This requirement is equivalent to h_{ij}'s depending only on x and being periodic with period 2π, i.e.,

$$h_{ij}=h_{ij}(x)=h_{ij}(x+2\pi). \tag{8}$$

The homogeneous limit can be achieved when $h_{ij}=$constants. So, we have found the inhomogeneous metric of (the universal cover of) a Gowdy space, given by Eq. (6) with the boundary condition (8).

Now, we can write down the ''appropriate'' space–time metric by[1] imposing the two-surface orthogonality and choosing the isothermal coordinates for the reference surface. After all, we obtain the space–time metric

$$ds^2=e^{-\lambda/2}t^{-1/2}(-dt^2+(\sigma^1)^2)+R[e^P(\sigma^2)^2+2e^PQ\sigma^2\sigma^3+(e^PQ^2+e^{-P})(\sigma^3)^2], \tag{9}$$

where P, Q, R, and λ are functions of t and x and are periodic in x with period 2π. We have followed the parametrization of a recent paper[6] to make comparisons easier. The isometry group for the space–time is unchanged, given by H_{II} [(7)].

This metric should be considered as the universal cover metric $\tilde{g}_{ab}$ of a Gowdy space–time $(M\times\mathbf{R},g_{ab})$. Any topology of M is possible if the fundamental group $\pi_1(M)$ can be represented

in H_{II}. One can choose such a $\pi_1(M)$ in the list of compact quotients modeled on Nil, presented in Ref. 9. For example, choose the manifold ''$b/1(n)$,'' characterized by

$$\pi_1(M_n)=\langle g_1,g_2,g_3;[g_1,g_2]=g_3^n,[g_1,g_3]=1,[g_2,g_3]=1\rangle, \tag{10}$$

where n is a positive integer parametrizing the family $b/1$ of topologies on Nil. Then, using the multiplication rule (3), we can find the representation up to conjugations

$$\Gamma_n=\{g_1,g_2,g_3\}=\left\{\begin{pmatrix}2p\pi\\ {g_1}^2\\ 0\end{pmatrix},\begin{pmatrix}2q\pi\\ {g_2}^2\\ {g_2}^3\end{pmatrix},\begin{pmatrix}0\\ 0\\ \frac{2\pi}{n}(p{g_2}^2-q{g_1}^2)\end{pmatrix}\right\}, \tag{11}$$

where $p,q\in Z$, and $g_1^2,g_2^2,g_2^3\in\mathbf{R}$. Thus, we have obtained the Gowdy space–time $(M_n\times\mathbf{R}, g_{ab})=(\tilde{M}_n\times\mathbf{R},\tilde{g}_{ab})/\Gamma_n$, where the action of Γ_n is defined by Eq. (3). We may think of the real parameters (g_1^2,g_2^2,g_2^3) as the moduli parameters for the space–time.

Type 2 can be obtained by interchanging the roles of σ^1 and σ^2. For example, the metric can be obtained from Eq. (9) by transforming $\sigma^1\to\sigma^2$, $\sigma^2\to\sigma^1$, $P(t,x)\to P(t,y)$, etc. The isometry group thereof is formed by the actions

$$\left\{\left.\begin{pmatrix}a\\ 2m\pi\\ c\end{pmatrix}\right| m\in Z,a,c\in\mathbf{R}\right\}. \tag{12}$$

As can be easily checked, we can represent the fundamental group (10) into this isometry group in a form similar to Eq. (11).

Let us consider the vacuum Einstein equations. To be specific, we consider the Type 1. (As for the final results, we will present for both Types 1 and 2.) Note that, if neglecting the boundary conditions, our metric (9) is essentially the same as the metric given in Ref. 1,

$$ds^2=e^{-\lambda/2}t^{-1/2}(-dt^2+dx^2)+R[e^P dy^2+2e^P Q dy dz+(e^P Q^2+e^{-P})dz^2], \tag{13}$$

where P, Q, R, and λ are functions of t and x. In fact, our metric (9) is obtained from this one by transforming

$$P\to P+\ln[(1-xQ)^2+x^2e^{-2P}],\quad Q\to\frac{Q(1-xQ)^2-xe^{-2P}}{(1-xQ)^2+x^2e^{-2P}} \tag{14}$$

(though this does not preserve the periodicity of P and Q). Moreover, the role of R as the area function of the group orbits, consisting of flat T^2's,[17] is the same for both metrics. This can be checked by noticing that the natural volume element of the second term in the metric (9) is given by $R dy\wedge dz$. As a result, the function R of our metric satisfies the same key equation as that of metric (13), i.e.,[1]

$$\partial_{tt}R-\partial_{xx}R=0. \tag{15}$$

This equation can also be checked by a direct substitution into the vacuum Einstein equation. Then, since the group orbits for our spatial manifold do not degenerate everywhere (except at the initial singularity), R can be taken as $t(\equiv e^{-\tau})$, as in the Gowdy model on $T^3\times\mathbf{R}$.[1] Here $t=0(\tau=+\infty)$ corresponds to the initial singularity. With this choice of R, the remaining independent Einstein's equations for our metric (9) are found by a direct calculation to be

$$\begin{aligned}&\ddot{P}-e^{-2\tau}P''-e^{2P}\dot{Q}^2+e^{-2\tau}[e^{2P}(Q^2\pm Q')^2\pm 2Q'-e^{-2P}]=0,\\ &\ddot{Q}-e^{-2\tau}Q''+2\dot{P}\dot{Q}-2e^{-2\tau}[P'Q'\pm(P'\mp Q)(Q^2+e^{-2P})]=0,\end{aligned} \tag{16}$$

and

$$\begin{aligned}&\lambda' - 2(P' \mp 2Q)\dot{P} \mp 2[e^{2P}(Q^2 \pm Q') - 1]\dot{Q} = 0,\\ &\dot{\lambda} - \dot{P}^2 - e^{2P}\dot{Q}^2 - e^{-2\tau}[e^{2P}(Q^2 \pm Q')^2 + P'^2 + 2Q^2 \mp 2(Q' + 2P'Q) + e^{-2P}] = 0,\end{aligned} \tag{17}$$

where dot and dash denote τ and x (or y for the Type 2) derivatives, respectively. The upper and lower signs are for Types 1 and 2, respectively. Note that P and Q are not constrained, since λ does not appear in Eqs. (16). This is one of the advantages of vacuum Gowdy models. The integrability condition for the constraint equations (17) for λ is automatically satisfied with Eqs. (16). The boundary conditions for P, Q, and λ are the spatially periodic ones. The Hamiltonian for the dynamical equations (16) can be guessed from straightforwardly reducing the Einstein–Hilbert action with the metric (9). It is given by

$$H = \frac{1}{2}\int_0^{2\pi} d\theta[\pi_P^2 + e^{-2P}\pi_Q^2] + e^{-2\tau}[(P' \mp 2Q)^2 - 2(Q^2 \pm Q') + e^{2P}(Q^2 \pm Q')^2 + e^{-2P}], \tag{18}$$

where π_P and π_Q are the conjugate momenta of P and Q, respectively. The integration measure θ is x for Type 1, or y for Type 2.

IV. GOWDY ON SOL×R AND VII$_0$×R

The next examples correspond to Bianchi VI$_0$ and VII$_0$ as minimal geometries. Their maximal geometries are Sol and E^3, respectively. Since the local structures for Bianchi VI$_0$ and VII$_0$ are similar, we treat them in parallel in this section. The basic procedure is the same as that of the previous section.

We first observe the commutation relations of the sets of the three Killing vectors of the Bianchi groups

$$[\xi_1, \xi_2] = 0, \quad [\xi_2, \xi_3] = -\xi_1, \quad [\xi_3, \xi_1] = \xi_2 : \ \mathrm{VI}_0, \tag{19}$$

$$[\xi_1, \xi_2] = 0, \quad [\xi_2, \xi_3] = -\xi_1, \quad [\xi_3, \xi_1] = -\xi_2 : \ \mathrm{VII}_0. \tag{20}$$

(We write ''tags'' to distinguish the two types as above.) In terms of coordinate basis,

$$\xi_1 = \frac{\partial}{\partial x} + \frac{\partial}{\partial y}, \quad \xi_2 = \frac{\partial}{\partial x} - \frac{\partial}{\partial y}, \quad \xi_3 = \frac{\partial}{\partial z} - x\frac{\partial}{\partial x} + y\frac{\partial}{\partial y} : \ \mathrm{VI}_0, \tag{21}$$

$$\xi_1 = \frac{\partial}{\partial x}, \quad \xi_2 = \frac{\partial}{\partial y}, \quad \xi_3 = \frac{\partial}{\partial z} - y\frac{\partial}{\partial x} + x\frac{\partial}{\partial y} : \ \mathrm{VII}_0. \tag{22}$$

The Bianchi groups are formed by the finite actions of ξ_i's, which we take as

$$G_{\mathrm{VI}_0} = \left\{ \begin{pmatrix} a \\ b \\ c \end{pmatrix} \equiv e^{(a/2)(\xi_1+\xi_2)} e^{(b/2)(\xi_1-\xi_2)} e^{c\xi_3} \middle| a, b, c \in \mathbf{R} \right\}, \tag{23}$$

$$G_{\mathrm{VII}_0} = \left\{ \begin{pmatrix} a \\ b \\ c \end{pmatrix} \equiv e^{a\xi_1} e^{b\xi_2} e^{c\xi_3} \middle| a, b, c \in \mathbf{R} \right\}. \tag{24}$$

The actions or multiplications are given by

$$\begin{pmatrix} a \\ b \\ c \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} a + e^{-c}x \\ b + e^{c}y \\ c + z \end{pmatrix} : \ \mathrm{VI}_0, \quad \begin{pmatrix} a \\ b \\ c \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix} + \mathscr{R}_c \begin{pmatrix} x \\ y \end{pmatrix} \\ c + z \end{pmatrix} : \ \mathrm{VII}_0, \tag{25}$$

where $\mathscr{R}_c$ is the rotation matrix by angle c.

From the commutation relations (19) and (20), we find sole possibility of obtaining the Gowdy spaces, the ones inhomogeneous along ξ_3. Using the invariant one-forms

$$\sigma^1=\frac{1}{\sqrt{2}}(e^z dx+e^{-z}dy),\quad \sigma^2=\frac{1}{\sqrt{2}}(-e^z dx+e^{-z}dy),\quad \sigma^3=dz:\ \mathrm{VI}_0, \tag{26}$$

$$\sigma^1=\cos z dx+\sin z dy,\quad \sigma^2=-\sin z dx+\cos z dy,\quad \sigma^3=dz:\ \mathrm{VII}_0, \tag{27}$$

and the periodic functions

$$P=P(\tau,z)=P(\tau,z+z_0),\quad Q=Q(\tau,z)=Q(\tau,z+z_0),$$
$$\lambda=\lambda(\tau,z)=\lambda(\tau,z+z_0), \tag{28}$$

we can immediately write the same space–time metric for the two types as

$$ds^2=e^{-\lambda/2}e^{\tau/2}(-e^{-2\tau}d\tau^2+(\sigma^3)^2)+e^{-\tau}[e^P(\sigma^1)^2+2e^P Q\sigma^1\sigma^2+(e^P Q^2+e^{-P})(\sigma^2)^2]. \tag{29}$$

As we will see later, the period z_0 is specified depending upon the topology. The isometry groups H_{VI_0} and H_{VII_0} for the space–time metric (29) is formed by the discrete actions along ξ_3 and can be written in the same form

$$\left\{\begin{pmatrix} a \\ b \\ mz_0 \end{pmatrix}\middle| a,b\in\mathbf{R},m\in\mathbf{Z}\right\}. \tag{30}$$

In the following, we consider the vacuum Einstein equations first, since the compactifications must be discussed separately for each universal cover.

In the metric (29), we wrote the area function of the group orbit as $e^{-\tau}=t$, since, as in the Nil case, the group orbits do not degenerate except at the initial singularity for both types. The remaining Einstein equations are then found to be

$$\ddot{P}-e^{-2\tau}P''-e^{2P}\dot{Q}^2+e^{-2\tau}[e^{2P}(Q'+Q^2\mp 1)^2+2Q'-e^{-2P}]=0,$$
$$\ddot{Q}-e^{-2\tau}Q''+2\dot{P}\dot{Q}-2e^{-2\tau}[P'Q'+(P'-Q)(e^{-2P}+Q^2\mp 1)]=0, \tag{31}$$

and

$$\lambda'-2(P'-2Q)\dot{P}-2[e^{2P}(Q'+Q^2\mp 1)-1]\dot{Q}=0,$$
$$\dot{\lambda}-\dot{P}^2-e^{2P}\dot{Q}^2-e^{-2\tau}[(P'-2Q)^2-2(Q'+Q^2\mp 1)+e^{2P}(Q'+Q^2\mp 1)^2+e^{-2P}]=0, \tag{32}$$

where dot and dash denote, respectively, τ and z derivatives. The upper and lower signs are for $\mathrm{Sol}(\mathrm{VI}_0)$ and VII_0, respectively. The integrability condition for the constraint equations (32) for λ is automatically satisfied with Eqs. (31). The Hamiltonian for the dynamical equations (31) is given by

$$H=\frac{1}{2}\int_0^{z_0}dz[\pi_P^2+e^{-2P}\pi_Q^2]+e^{-2\tau}[(P'-2Q)^2-2(Q'+Q^2)+e^{2P}(Q'+Q^2\mp 1)^2+e^{-2P}]. \tag{33}$$

A. Compactification for Gowdy on Sol×R

We can take any topology of M of the Gowdy space–time $(M\times\mathbf{R},g_{ab})$ on $\mathrm{Sol}\times\mathbf{R}$ if we can represent the fundamental group $\pi_1(M)$ into H_{VI_0} (30) together with, if needed, the disconnected components defined with the discrete isometry

$$h:(x,y,z)\to(-x,-y,z). \tag{34}$$

As an explicit example, we consider the major sequence of compact quotients presented in Ref. 9. The fundamental groups are parametrized by an integer n such that $|n|>2$, and given by

$$\pi_1(M_n)=\langle g_1,g_2,g_3;[g_1,g_2]=1,\quad g_3g_1g_3^{-1}=g_2,\quad g_3g_2g_3^{-1}=g_1^{-1}g_2^n\rangle. \tag{35}$$

(This does not, however, exhaust all the compact quotients.[18]) We find that the representations are, up to conjugations, given by

$$\Gamma_n=\left\{\begin{pmatrix}\alpha u_1\\ \beta u_2\\ 0\end{pmatrix},\begin{pmatrix}\alpha v_1\\ \beta v_2\\ 0\end{pmatrix},\begin{pmatrix}0\\ 0\\ z_0\end{pmatrix}\right\}, \tag{36}$$

for $n>2$, and

$$\Gamma_n=\left\{\begin{pmatrix}\alpha u_1\\ \beta u_2\\ 0\end{pmatrix},\begin{pmatrix}\alpha v_1\\ \beta v_2\\ 0\end{pmatrix},h\circ\begin{pmatrix}0\\ 0\\ z_0\end{pmatrix}\right\}, \tag{37}$$

for $n<-2$, with $\alpha,\beta\in\mathbf{R}$. In these representations, (u_1,v_1), (u_2,v_2), and z_0 are determined in such a way that $\mathrm{sign}(n)e^{-z_0}$ and $\mathrm{sign}(n)e^{z_0}$ are the eigenvalues of matrix $\left(\begin{smallmatrix}0 & 1\\ -1 & n\end{smallmatrix}\right)$, and the corresponding normalized eigenvectors are (u_1,v_1) and (u_2,v_2), respectively. In particular, $e^{z_0}=|n+\sqrt{n^2-4}|/2$. We thus have obtained the Gowdy space–time $(M_n\times\mathbf{R},g_{ab})=(\tilde{M}_n\times\mathbf{R},\tilde{g}_{ab})/\Gamma_n$, where the universal cover metric $\tilde{g}_{ab}$ is given by Eq. (29) with one-forms (26).

B. Compactification for Gowdy on $\mathrm{VII}_0\times\mathbf{R}$

The Gowdy model that is most frequently picked up in the literature is the one on $T^3\times\mathbf{R}$, which would have been obtained by our procedure starting from Bianchi I. However, another $T^3\times\mathbf{R}$ model can be obtained from Bianchi VII_0, which we pick up here.

The fundamental group of T^3 is the infinite group with three commuting generators:

$$\pi_1(T^3)=\langle g_1,g_2,g_3;[g_1,g_2]=1,\quad [g_2,g_3]=1,\quad [g_3,g_1]=1\rangle. \tag{38}$$

The general solution of the representation into ''G_{VII_0}'' has already given in Eq. (97) of Ref. 9:

$$\Gamma=\left\{\begin{pmatrix}{g_1}^1\\ {g_1}^2\\ 2l\pi\end{pmatrix},\begin{pmatrix}{g_2}^1\\ {g_2}^2\\ 2m\pi\end{pmatrix},\begin{pmatrix}{g_3}^1\\ {g_3}^2\\ 2n\pi\end{pmatrix}\right\}, \tag{39}$$

where $g_1^1,g_1^2,g_2^1,g_2^2,g_3^1,g_3^2\in\mathbf{R}$, and $l,m,n\in Z$. We immediately notice that this representation is effective even in ''H_{VII_0}'' if we choose the period z_0 to 2π. So, this representation with $z_0=2\pi$ is the general solution. The only difference from the locally homogeneous case is that there are no effective conjugations. The representation (39) therefore gives the final form of the covering group. Finally, we have obtained the Gowdy space–time $(T^3\times\mathbf{R},g_{ab})=(\mathbf{R}^4,\tilde{g}_{ab})/\Gamma$, where the universal cover metric $\tilde{g}_{ab}$ is given by Eq. (29) with one-forms (27).

V. CONCLUSIONS

We have generalized Gowdy space–times to admit two commuting local Killing vectors. By this generalization, we gained rich varieties of new Gowdy space–times, but any advantages the original has, e.g., the simplicity of the vacuum Einstein equations, have not been lost. In this sense, the original definition demanding global existence of the two commuting Killing vectors was too much restricted. Our generalization is natural and useful for physical applications.

We have presented three new Gowdy space–times, on $\mathrm{Nil}\times\mathbf{R}$, on $\mathrm{Sol}\times\mathbf{R}$, and on $\mathrm{VII}_0\times\mathbf{R}$, which are closely related to Thurston geometries, Nil, Sol, and E^3, respectively. We have given not only the vacuum Einstein equations with boundary conditions but also an explicit representation of the covering group for each case. These three new models and the one called $T^3\times\mathbf{R}$ model in the literature have common features like (1) the group orbits do not degenerate

everywhere except at the initial singularity, and (2) there are two dynamical variables (i.e., P and Q). These features make the four models very similar. In fact, the only essential difference is the boundary condition for the metric. Since we wrote the space–time metrics in a suitable way for each case, their Einstein equations look different from each other, but the boundary conditions for the metric functions are the same, simply periodic. We could have written the space–time metric in a common form, e.g., like Eq. (13), but in that case, the boundary conditions for the metric functions would have taken inconvenient forms, as we have seen in the case of Nil.

It is worth noting that we can interpret the difference of the boundary conditions for the metrics as the difference of the ''background metrics.'' For example, the spatial metric of the (conventional) $T^3\times\mathbf{R}$ model can be smoothly deformed locally flat, so that we can think that the background is flat, while, say, the spatial metric of the Nil$\times\mathbf{R}$ model cannot be deformed locally flat but locally Bianchi II, so that the background is the Bianchi II locally homogeneous curved space in this case.

Here, we comment on the dynamics near the initial singularity of our three models. The Gowdy space–time on $T^3\times\mathbf{R}$ is conjectured[3] to be asymptotically velocity term dominated (AVTD).[2] Recent investigation by Berger and Garfinkle[6] supports this, *except for* measure-zero nongeneric spatial points. They succeeded in explaining the phenomenon by a potential picture, showing the nongeneric points correspond to the points where $Q'=0$. In our new models, such points correspond to points such that $Q'\pm Q^2=0$ (for Types 1 and 2 of Nil) and $Q'+Q^2\mp 1=0$ (for Sol and VII$_0$). Note that the points where $Q'=0$ are inevitable, since Q is periodic, but our four conditions are not necessarily satisfied in any spatial point. One may therefore expect that the Gowdy Nil$\times\mathbf{R}$, Sol$\times\mathbf{R}$, and VII$_0\times\mathbf{R}$ models are AVTD *everywhere*, so the ''curved backgrounds'' improve the AVTD behavior.

As a final remark, an extension of our method to the so-called $U(1)$ models[19] and other similar ones would also be possible, which is now under development, as well as a complete classification and further study of Gowdy models.

Note after the completion of this work: Recently, Weaver, Isenberg, and Berger[20] applied a Gowdy model on Sol$\times\mathbf{R}$ with magnetic field to examine the Mixmaster behavior toward the initial singularity. The boundary conditions imposed there are consistent with ours, though they look different since they used a metric similar to Eq. (13).

(Received 3 January 1997; accepted for publication 12 January 1998)

We give a complete justification of the classification of inequivalent subalgebras of the conformal algebra with respect to the inner automorphisms of the conformal group, and we perform the classification of the subalgebras of the conformal algebra $AC(1,3)$. © *1998 American Institute of Physics.* [S0022-2488(98)02309-3]

I. INTRODUCTION

The necessity of classifying the subalgebras of the conformal algebra is motivated by many problems in mathematics and mathematical physics.[1,2] The conformal algebra $AC(1,n)$ of Minkowski space $\mathbf{R}_{1,n}$ contains the extended Poincaré algebra $A\tilde{P}(1,n)$ and the full Galilei algebra $AG_4(n-1)$ (also known as the optical algebra). The classification of the subalgebras of the conformal algebra $AC(1,n)$ is almost reducible to the classification of the subalgebras of the algebras $A\tilde{P}(1,n)$ and $AG_4(n-1)$.

Patera, Winternitz and Zassenhaus[1] have given a general method for the classification of the subalgebras of inhomogeneous transformations. Using this method, the classification of the subalgebras $AP(1,n)$, $A\tilde{P}(1,n)$, and $AG_4(n-1)$ was carried out in Refs. 1–9 for $n=2,3,4$. In Refs. 7–11, this general method was supplemented by many structural results which made possible the algorithmization of the classification of the subalgebras of the Euclidean, Galilean, and Poincaré algebras for spaces of arbitrary dimensions. Indeed, this was done in Refs. 9 and 10, where the subalgebras of $AC(1,n)$ were classified up to conjugation under the conformal group $C(1,n)$ for $n=2,3,4$.

In order to perform the symmetry reduction of differential equations, it is necessary to identify the subalgebras of the symmetry algebra (of the equation) which give the same systems of basic invariants. This observation has led to the introduction in Ref. 12 of the concept of *I*-maximal subalgebras: a subalgebra F is said to be *I*-maximal if it contains every subalgebra of the symmetry algebra with the same invariants as F. In Ref. 13, all *I*-maximal subalgebras of $AC(1,4)$, classified upto $C(1,4)$-conjugation, were found in the representation defined on the solutions of the eikonal equation. Using these subalgebras, reductions of the eikonal and Hamilton–Jacobi equations to differential equations of lower order were obtained in Refs. 9 and 12. We note that the list of *I*-maximal subalgebras for a given algebra can differ according to the equation being investigated.

In the above works, the question of the connection between conjugation of the subalgebras of the algebra $A\tilde{P}(1,n)$ under the group $\tilde{P}(1,n)$ (or the group $AdA\tilde{P}(1,n)$ of inner automorphisms of the algebra $A\tilde{P}(1,n)$) and the conjugacy of these subalgebras under the group $C(1,n)$ was not dealt with. This, and the same problem for subalgebras of the Galilei algebra $AG_4(n-1)$, is the problem we address in the present article.

Since the group analysis of differential equations is of a local nature, we concentrate on conjugacy of the subalgebras under the group of inner automorphisms of the algebra $AC(1,n)$. Going over to conjugacy under $C(1,n)$ is not complicated, and requires only a further identification of the subalgebras under the action of at most three discrete symmetries. The results of this

 © 1998 American Institute of Physics

paper allow us to obtain a full classification of the subalgebras of $AC(1,n)$ for low values of n. On the basis of these results, we give at the end of this paper a classification of the algebra $AC(1,3)$ with respect to its group of inner automorphisms. The list of subalgebras obtained in this way can be used for the symmetry reduction of any system of differential equations which are invariant under $AC(1,3)$.

II. MAXIMAL SUBALGEBRAS OF THE CONFORMAL ALGEBRA

We denote by AdL the group of inner automorphisms of the Lie algebra L. Unless otherwise stated, conjugacy of subalgebras of L means conjugacy with respect to the group AdL. We consider AdL_1 as a subgroup of AdL_2 whenever L_1 is a subalgebra of L_2. The connected identity component of a Lie group H is denoted by H_1.

Let $\mathbf{R}_{1,n}$, $(n\geqslant 2)$, be Minkowski space with metric $g_{\alpha\beta}$, where $(g_{\alpha\beta})=\mathrm{diag}[1,-1,...,-1]$ and $\alpha,\beta=0,1,...,n$. The transformation defined by the equations

$$x_\alpha=x_\alpha(y_0,y_1,\ldots,y_n),\quad \alpha=0,1,...,n$$

of a domain $U\subset\mathbf{R}_{1,n}$ into $\mathbf{R}_{1,n}$, is said to be conformal if

$$\frac{\partial x_\mu}{\partial y^\alpha}\frac{\partial x_\nu}{\partial y^\beta}\,g^{\mu\nu}=\lambda(x)g_{\alpha\beta},$$

where $\lambda(x)\neq 0$ and $x=(x_0,x_1,\ldots,n)$. The conformal transformations of $\mathbf{R}_{1,n}$ form a Lie group, the conformal group $C(1,n)$. The Lie algebra $AC(1,n)$ of the group $C(1,n)$ has as its basis the generators of pseudorotations $J_{\alpha\beta}$, the translations P_α, the nonlinear conformal translations K_α, and the dilatations D, where $\alpha,\beta=0,1,...,n$. These generators satisfy the following commutation relations:

$$\begin{aligned}
&[J_{\alpha\beta},J_{\gamma\delta}]=g_{\alpha\delta}J_{\beta\gamma}+g_{\beta\gamma}J_{ga\delta}-g_{\alpha\gamma}J_{\beta\delta}-g_{\beta\delta}J_{\alpha\gamma},\\
&[P_\alpha,J_{\beta\gamma}]=g_{\alpha\beta}P_\gamma-g_{\alpha\gamma}P_\beta,\quad [P_\alpha,P_\beta]=0,\\
&[K_\alpha,J_{\beta\gamma}]=g_{\alpha\beta}K_\gamma-g_{\alpha\gamma}K_\beta,\ [K_\alpha,K_\beta]=0,\\
&[D,P_\alpha]=P_\alpha,\ [D,K_\alpha]=-K_\alpha,\ [D,J_{\alpha\beta}]=0,\\
&[K_\alpha,P_\beta]=2(g_{\alpha\beta}D-J_{\alpha\beta}).
\end{aligned}\tag{1}$$

The pseudo-orthogonal group $O(2,n+1)$ is the multiplicative group of all $(n+3)\times(n+3)$ real matrices C satisfying $C^tE_{2,n+1}C=E_{2,n+1}$, where $E_{2,n+1}=\mathrm{diag}[1,1,-1,...,-1]$. We denote by I_{ab} the $(n+3)\times(n+3)$ matrix whose entries are zero except for 1 in the (a,b) position, with $a,b=1,2,...,n+3$. The Lie algebra $AO(2,n+1)$ of $O(2,n+1)$ has as its basis the following operators:

$$\Omega_{12}=I_{12}-I_{21},\ \Omega_{ab}=-I_{ab}+I_{ba}\ \ (a<b;a,b=3,...,n+3),$$

$$\Omega_{ia}=-I_{ia}-I_{ai}\quad (i=1,2;a=3,...,n+3),$$

which satisfy the commutation relations

$$[\Omega_{ab},\Omega_{cd}]=\rho_{ad}\Omega_{bc}+\rho_{bc}\Omega_{ad}-\rho_{ac}\Omega_{bd}-\rho_{bd}\Omega_{ac}\quad (a,b,c,d=1,2,...,n+3),$$

where $(\rho_{ab})=E_{2,n+1}$. Let us denote by $\mathbf{R}_{2,n+1}$ the pseudo-Euclidean space of $n+3$ dimensions with metric ρ_{ab}. The matrices of the group $O(2,n+1)$ and the algebra $AO(2,n+1)$ will be identified with operators acting on the left on $\mathbf{R}_{2,n+1}$. Then, with this convention, $O(2,n+1)$ is the group of isometries of $\mathbf{R}_{2,n+1}$.

It is known (see for instance Ref. 9) that there is a homomorphism Ψ; $O(2,n+1)\to C(1,n)$ with kernel $\{\pm E_{n+3}\}$, where $\{E_{n+3}\}$ is the unit $(n+3)\times(n+3)$ matrix. Thus we are able to

identify $O(2,n+1)$ with $C(1,n)$. This homomorphism of groups induces an isomorphism f of the corresponding Lie algebras, f: $AO(2,n+1)\to AC(1,n)$, which is given by

$$f(\Omega_{\alpha+2,\beta+2})=J_{\alpha\beta},\quad f(\Omega_{1,\alpha+2}-\Omega_{a+2,n+3})=P_{\alpha},$$

$$f(\Omega_{1,\alpha+2}+\Omega_{\alpha+2,n+3})=K_{\alpha},\quad f(\Omega_{1,n+3})=-D\quad(\alpha,\beta=0,1,...,n).$$

We shall in this article identify the two algebras, using this isomorphism, so that we can write the previous equations as

$$\Omega_{\alpha+2,\beta+2}=J_{\alpha\beta},\quad \Omega_{1,\alpha+2}-\Omega_{\alpha+2,n+3}=P_{\alpha},$$

$$\Omega_{1,\alpha+2}+\Omega_{\alpha+2,n+3}=K_{\alpha},\quad \Omega_{1,n+3}=-D\quad(\alpha<\beta;\alpha,\beta=0,1,...,n).$$

We shall use the matrix realization of the conformal algebra.

Each matrix C which belongs to the identity component $O_1(2,n+1)$ of the group $O(2,n+1)$ is a product of matrices which are rotations in the x_1x_2 and x_ax_b planes ($a<b$; $a,b=3,...,n+3$) and hyperbolic rotations in the x_ix_a planes ($i=1,2$; $a=3,...,n+3$). Thus each such matrix C can be given as a finite product of matrices of the form $\exp X$, where $X\in AO(2,n+1)$. From this, it follows that each inner automorphism of the algebra $AO(2,n+1)$ is a mapping

$$\varphi_C: Y\to CYC^{-1}, \tag{2}$$

where $Y\in AO(2,n+1)$ and $C\in O_1(2,n+1)$, and conversely each mapping of this type is an inner automorphism of the algebra $AO(2,n+1)$.

In the process of our investigation mappings of the above type (2) will occur for certain matrices $C\in O(2,n+1)$, so we call these types of mappings $O(2,n+1)$-automorphisms of the algebra $AO(2,n+1)$ corresponding to the matrix C.

If G is the group of $O(2,n+1)$-automorphisms of the algebra $AO(2,n+1)$, and H is the subgroup of G consisting of its inner automorphisms, then H is normal in G and $[G:H]\leqslant 4$. Representatives of the cosets of G/H different from the identity will be

$$C_1=\mathrm{diag}[-1,1,...,1,-1],\quad C_2=\mathrm{diag}[1,1,-1,1,...,1],$$
$$C_3=\mathrm{diag}[-1,1-1,1,...,1,-1], \tag{3}$$

or

$$C_1=\mathrm{diag}[1,-1,1,...,1,-1,1],\quad C_2=\mathrm{diag}[1,1,-1,1,...,1],$$
$$C_3=\mathrm{diag}[1,-1,-1,1...,1,-1,1]. \tag{4}$$

Given a subspace V of $\mathbf{R}_{2,n+1}$, there is a maximal subalgebra of $AO(2,n+1)$ which leaves V invariant. We call this algebra the normalizer in $AO(2,n+1)$ of the subspace V.

Let $Q_1,\ldots,Q_{n+3}$ be a system of unit vectors in $\mathbf{R}_{2,n+1}$. Then the normalizer in $AO(2,n+1)$ of the isotropic subspace $\langle Q_1+Q_{n+3}\rangle$ is the extended Poincaré algebra

$$\tilde{AP}(1,n)=\langle P_0,P_1,\ldots,P_n\rangle\uplus(AO(1,n)\oplus\langle D\rangle),$$

where $\uplus$ denotes semidirect sum, and $\oplus$ denotes direct sum of algebras; $AO(1,n)=\langle J_{\alpha\beta}:\alpha,\beta=0,1,...,n\rangle$. The normalizer in $AO(2,n+1)$ of the completely isotropic subspace $\langle Q_1+Q_{n+3},Q_2+Q_{n+2}\rangle$ is the full Galilei algebra

$$AG_4(n-1)=\langle M,P_1,\ldots,P_{n-1},G_1,\ldots,G_{n-1}\rangle\uplus(AO(n-1)\oplus\langle R,S,T\rangle\oplus\langle Z\rangle),$$

where

$$M=P_0+P_n,\quad G_a=J_{0a}-J_{an}\quad(a=1,...,n-1),\quad R=-(J_{0n}+D),$$

$$S=\tfrac{1}{2}(K_0+K_n),\quad T=\tfrac{1}{2}(P_0-P_n),\quad Z=J_{0n}-D.$$

The generators of the algebra $AG_4(n-1)$ satisfy the following commutation relations:

$$[J_{ab},J_{cd}]=g_{ad}J_{bc}+g_{bc}J_{ad}-g_{ac}J_{bd}-g_{bd}J_{ac},$$

$$[G_a,J_{bc}]=g_{ab}G_c-g_{ac}G_b;\ [P_a,J_{bc}]=g_{ab}P_c-g_{ac}P_b,$$

$$[G_a,G_b]=0;\ [P_a,G_b]=\delta_{ab}M;\ [G_a,M]=0;\ [P_a,M]=0,$$

$$[J_{ab},M]=0;\ [R,S]=2S;\ [R,T]=-2T;\ [T,S]=R,$$

$$[Z,R]=[Z,S]=[Z,T]=[Z,J_{ab}]=0,$$

$$[R,G_a]=G_a;\ [R,P_a]=-P_a;\ [R,M]=0;\ [R,J_{ab}]=0,$$

$$[S,G_a]=0;\ [S,P_a]=-G_a;\ [S,M]=0;\ [S,J_{ab}]=0,$$

$$[T,G_a]=P_a;\ [T,P_a]=0;\ [T,M]=0;\ [T,J_{ab}]=0,$$

$$[Z,G_a]=-G_a;\ [Z,P_a]=-P_a;\ [Z,M]=-2M,$$

with $a,b,c,d=1,...,n-1$.

From these commutation relations we find that

$$\langle R,S,T\rangle=ASL(2,\mathbf{R});\ \langle R,S,T\rangle\oplus\langle Z\rangle=AGL(2,\mathrm{R}),$$

where $\mathbf{R}$ denotes the field of real numbers.

Let F be a reducible subalgebra of $AO(2,n+1)$. That is, there exists in $\mathbf{R}_{2,n+1}$ a nontrivial subspace W which is invariant under F. If W is isotropic, then there exists a totally isotropic subspace $W_0\subset W$ which is invariant under F. Since dim W_0 is 1 or 2, then, by Witt's theorem,[14] there exists an isometry $C\in O(2,n+1)$ such that CW_0 is either $\langle Q_1+Q_{n+3}\rangle$ or $\langle Q_1+Q_{n+3},Q_2+Q_{n+2}\rangle$. Taking into account that the matrices (3) do not change these subspaces and represent all the components of the group $O(2,n+1)$ different from the identity component $O_1(2,n+1)$, then we may assume that the above C lies in $O_1(2,n+1)$, the identity component. Thus there exists an inner automorphism φ of the algebra $AO(2,n+1)$ such that either $\varphi(F)\subset A\tilde{P}(1,n)$ or $\varphi(F)\subset AG_4(n-1)$.

If W is a nondegenerate subspace, then, by Witt's theorem, it is isometric with one of the following subspaces: $\mathbf{R}_{1,k}(k\geqslant 2)$, $\mathbf{R}_{2,k}(k\geqslant 1)$, $\mathbf{R}_k(k\geqslant 1)$. Each of the isometries (3) leaves invariant each of these subspaces, so that we may assume that the isometry which maps W onto one of these subspaces belongs to $O_1(2,n+1)$. From this, it follows that a subalgebra F is conjugate under the group of inner automorphisms of the algebra $AO(2,n+1)$ to a subalgebra of one of the following algebras:

(1) $AO'(1,k)\oplus AO''(1,n-k+1)$, where $AO'(1,k)=\langle\Omega_{ab}:a,b=1,3,...,k+2\rangle$ and $AO''(1,n-k+1)=\langle\Omega_{ab}:a,b=2,k+3,...,n+3\rangle$ with $n\geqslant 3$ and $k=2,...,[(n+1)/2]$;
(2) $AO(2,k)\oplus AO(n-k+1)$, where $AO(n-k+1)=\langle\Omega_{ab}:a,b=k+3,...,n+3\rangle$ with $k=0,1,...,n$.

In order to classify the subalgebras of these direct sums it is necessary to know the irreducible subalgebras of algebras of the type $AO(1,m)$ $(m\geqslant 2)$ and $AO(2,m)$, $(m\geqslant 3)$. It has been shown in Ref. 15 that $AO(1,m)$ has no irreducible subalgebras different from $AO(1,m)$. In Refs. 16 and 17 it has been shown that every semisimple irreducible subalgebra of $AO(2,m)$ $(m\geqslant 3)$ can be mapped by an automorphism of this algebra onto one of the following algebras:

(1) $AO(2,m)$;
(2) $ASU[1,(m/2)]$ when m is even;
(3) $\langle\Omega_{14}+\sqrt{3}\Omega_{13}+\Omega_{25},-\Omega_{15}+\Omega_{24}-\sqrt{3}\Omega_{23},\Omega_{12}-2\Omega_{45}\rangle$ when $m=3$.

It follows then that when $m>3$ is odd, the algebra $AO(2,m)$ has no irreducible subalgebras other than $AO(2,m)$. If $m=2k$ and $k\geqslant 2$, then, up to inner automorphisms, $AO(2,m)$ has two nontrivial maximal irreducible subalgebras: $ASU(1,k)\oplus\langle Y\rangle$, and $ASU(1,k)'\oplus\langle Y'\rangle$, where

$$Y=\mathrm{diag}[J,\ldots,J],\quad Y'=\mathrm{diag}[J,-J,J,\ldots,J]$$

with

$$J=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}.$$

We note that a subalgebra L of $AG_4(n-1)$ is conjugate under $Ad\ AO(2,n+1)$ with a subalgebra the algebra $A\tilde{P}(1,n)$ if and only if the projection of L onto $AGL(2,\mathbf{R})=\langle R,S,T\rangle\oplus\langle Z\rangle$ is conjugate under $Ad\ AGL(2,\mathbf{R})$ with a subalgebra of the algebra $\langle R,T,Z\rangle$.

III. CONJUGACY UNDER *Ad AP*(1,*n*) OF SUBALGEBRAS OF THE POINCARÉ ALGEBRA *AP*(1,*n*)

The Poincaré group $P(1,n)$ is the multiplicative group of matrices

$$\begin{pmatrix}\Delta & Y\\ 0 & 1\end{pmatrix},$$

where $\Delta\in O(1,n)$ and $Y\in\mathbf{R}^{n+1}$. Let I'_{ab}, $a,b=0,1,...,n+1$ be the $(n+2)\times(n+2)$ matrix whose entries are all zero except for the ab-entry, which is unity. Then a basis for $AP(1,n)$ is given by the matrices

$$J_{0a}=-I'_{0a}-I'_{a0},\quad J_{ab}=-I'_{ab}+I'_{ba},$$

$$P_0=I'_{0,n+1},\quad P_a=I'_{a,n+1},$$

with $a<b;a,b=1,...,n$. These basis elements obey the commutation relations (1). It is sometimes useful in calculations to identify elements of $AO(1,n)$ with matrices of the form

$$X=\begin{pmatrix}0 & \beta_{01} & \beta_{02} & \ldots & \beta_{0n}\\ \beta_{01} & 0 & \beta_{12} & \ldots & \beta_{1n}\\ \beta_{02} & -\beta_{12} & 0 & \ldots & \beta_{2n}\\ . & . & . & . & .\\ \beta_{0n} & -\beta_{1n} & -\beta_{2n} & \ldots & 0\end{pmatrix}$$

and elements of the space $U=\langle P_0,\ldots,P_n\rangle$ are represented by $n+1$-dimensional columns Y. In this case, we take

$$P_0=\begin{pmatrix}1\\0\\.\\.\\.\\0\end{pmatrix},\quad P_1=\begin{pmatrix}0\\1\\.\\.\\.\\0\end{pmatrix},\quad \ldots,\quad P_n=\begin{pmatrix}0\\0\\.\\.\\.\\1\end{pmatrix}$$

and with this notation it is easy to see that $[X,Y]=XY$. We endow the space U with the metric of the pseudo-Euclidean space $\mathbf{R}_{1,n}$, so that the inner product of two vectors

$$\begin{pmatrix} x_0 \\ x_1 \\ \cdot \\ \cdot \\ \cdot \\ x_n \end{pmatrix}, \quad \begin{pmatrix} y_0 \\ y_1 \\ \cdot \\ \cdot \\ \cdot \\ y_n \end{pmatrix}$$

is $x_0y_0-x_1y_1-\cdots-x_ny_n$. The projection of $AP(1,n)$ onto $AO(1,n)$ is denoted by $\hat{\varepsilon}$. We also note that $AO(n)$, contained in $AO(1,n)$, is generated by J_{ab} $(a<b;\ a,b=1,...,n)$.

Let B be a Lie subalgebra of the algebra $AO(1,n)$ which has no invariant isotropic subspaces in $\mathbf{R}_{1,n}$. Then B is conjugate under $Ad\ AO(1,n)$ to a subalgebra of $AO(n)$ or to $AO(1,k)\oplus C$ where $k\geqslant 2$ and C is a subalgebra of the orthogonal algebra $AO'(n-k)$ generated by the matrices J_{ab} $(a,b=k+1,...,n)$. In the first case, B is not conjugate to any subalgebra of $AO(n-1)$.

Proposition 1: Let B be a subalgebra of $AO(n)$ which is not conjugate to a subalgebra of $AO(n-1)$. If L is a subalgebra of $AP(1,n)$ and $\hat{\varepsilon}(L)=B$, then L is conjugate to an algebra $W\uplus C$, where W is a subalgebra of $\langle P_1,...,P_n\rangle$, and C is a subalgebra of $B\oplus\langle P_0\rangle$. Two subalgebras $W_1\uplus C_1$ and $W_2\uplus C_2$ of this type are conjugate to each other under $Ad\ AP(1,n)$ if and only if they are conjugate under $Ad\ AO(n)$.

Proof: The algebra B is a completely reducible algebra of linear transformations of the space U and annuls only the subspace $\langle P_0\rangle$ (other than the null subspace itself). Thus, by Theorem 1.5.3,[9] the algebra L is conjugate to an algebra of the form $W\uplus C$ where $W\subset\langle P_1,...,P_n\rangle$ and $C\subset B\oplus\langle P_0\rangle$. Now let $W_1\uplus C_1$ and $W_2\uplus C_2$ be of this form, conjugate under $Ad\ AP(1,n)$. Then there exists a matrix $\Gamma\in P_1(1,n)$ such that $\varphi_\Gamma(W_1\uplus C_1)=W_2\uplus C_2$, and from this it follows that $\varphi_\Lambda(B_1)=B_2$ for some $\Lambda\in O_1(1,n)$. Let $V=\langle P_1,...,P_n\rangle$. Since $[B_1,V]=V$, then $[B_2,\varphi_\Lambda(V)]=\varphi_\Lambda(V)$ and $\varphi_\Lambda(V)=V$. Thus we can assume that $\Lambda=\mathrm{diag}[1,\Lambda_1]$ where $\Lambda_1\in SO(n)$, so that the given algebras are conjugate under $Ad\ AO(n)$. The converse is obvious.

Proposition 2: Let $B=AO(1,k)\oplus C$, where $k\geqslant 2$ and $C\subset AO'(n-k)$. If L is a subalgebra of $AP(1,n)$ and $\hat{\varepsilon}(L)=B$ then L is conjugate to $L_1\oplus L_2$ where $L_1=AO(1,k)$ or $L_1=AP(1,k)$, and L_2 is a subalgebra of the Euclidean algebra $AE'(n-k)$ with basis P_a,J_{ab}, $(a,b=k+1,...,n)$. Two subalgebras of this form, $L_1\oplus L_2$ and $L_1'\oplus L_2'$ are conjugate under $Ad\ AP(1,n)$ if and only if $L_1=L_1'$ and L_2 is conjugate to L_2' under the group of $E'(n-k)$-automorphisms.

Proof: The proof is as in the proof of Proposition 1.

Lemma 1: If $C\in O(1,n)$ and $C(P_0+P_n)=\lambda(P_0+P_n)$ then $\lambda\neq 0$ and

$$C=\begin{pmatrix} \dfrac{1+\lambda^2(1+\mathbf{v}^2)}{2\lambda} & \lambda\mathbf{v}^tB & \dfrac{-1+\lambda^2(1-\mathbf{v}^2)}{2\lambda} \\ \mathbf{v} & B & -\mathbf{v} \\ \dfrac{-1+\lambda^2(1+\mathbf{v}^2)}{2\lambda} & \lambda\mathbf{v}^tB & \dfrac{1+\lambda^2(1-\mathbf{v}^2)}{2\lambda} \end{pmatrix}, \tag{5}$$

where $B\in O(n-1)$, $\mathbf{v}$ is an $(n-1)$-dimensional column vector, $\mathbf{v}^2$ is the scalar square of $\mathbf{v}$ and $\mathbf{v}^t$ is the transpose of $\mathbf{v}$. Conversely, every matrix C of this form satisfies $C(P_0+P_n)=\lambda(P_0+P_n)$.

Proof: Proof is by direct calculation.

Lemma 2: Let $C\in O(1,n)$ have the form (5), with $\lambda>0$. Then

$$C=\mathrm{diag}[1,B,1]\exp[(-\ln\lambda)J_{0n}]\exp(-\beta_1G_1-\cdots-\beta_{n-1}G_{n-1}),$$

where $G_a=J_{0a}-J_{an}$ and

$$\begin{pmatrix} \beta_1 \\ \cdot \\ \cdot \\ \cdot \\ \beta_{n-1} \end{pmatrix}=B^{-1}\mathbf{v}.$$

Proof: Direct calculation gives us

$$\exp(-\theta J_{0n})=\begin{pmatrix}\cosh\theta & 0 & \sinh\theta\\ 0 & E_{n-1} & 0\\ \sinh\theta & 0 & \cosh\theta\end{pmatrix}$$

and

$$\exp(-\beta_1 G_1-\cdots-\beta_{n-1}G_{n-1})=\begin{pmatrix}1+\frac{\mathbf{b}^2}{2} & \mathbf{b}^t & \frac{\mathbf{b}^2}{2}\\ \mathbf{b} & E_{n-1} & -\mathbf{b}\\ \frac{\mathbf{b}^2}{2} & \mathbf{b}^t & 1-\frac{\mathbf{b}^2}{2}\end{pmatrix},$$

where $\mathbf{b}=(\beta_1,\ldots,\beta_{n-1})^t$. On putting $\lambda=\exp\theta$ we have

$$\cosh\theta=\frac{\lambda^2+1}{2\lambda},\quad \sinh\theta=\frac{\lambda^2-1}{2\lambda}.$$

Since we have

$$\begin{pmatrix}\frac{\lambda^2+1}{2\lambda} & 0 & \frac{\lambda^2-1}{2\lambda}\\ 0 & E_{n-1} & 0\\ \frac{\lambda^2-1}{2\lambda} & 0 & \frac{\lambda^2+1}{2\lambda}\end{pmatrix}\begin{pmatrix}1+\frac{\mathbf{b}^2}{2} & \mathbf{b}^t & -\frac{\mathbf{b}^2}{2}\\ \mathbf{b} & E_{n-1} & -\mathbf{b}\\ \frac{\mathbf{b}^2}{2} & \mathbf{b}^t & 1-\frac{\mathbf{b}^2}{2}\end{pmatrix}$$

$$=\begin{pmatrix}\frac{1+\lambda^2(1+\mathbf{b}^2)}{2\lambda} & \lambda\mathbf{b}^t & \frac{-1+\lambda^2(1-\mathbf{b}^2)}{2\lambda}\\ \mathbf{b} & E_{n-1} & -\mathbf{b}\\ \frac{-1+\lambda^2(1+\mathbf{b}^2)}{2\lambda} & \lambda\mathbf{b}^t & \frac{1+\lambda^2(1-\mathbf{b}^2)}{2\lambda}\end{pmatrix},$$

then

$$\exp(-\theta J_{0n})\exp(-\beta_1 G_1-\cdots-\beta_{n-1}G_{n-1})=\mathrm{diag}[1,\beta^{-1},1]C$$

from which it follows directly that

$$C=\mathrm{diag}[1,B,1]\exp[(-\ln\lambda)J_{0n}]\exp(-\beta_1 G_1-\cdots-\beta_{n-1}G_{n-1})$$

and the lemma is proved.

The set of F of matrices of the form (5) with $\lambda>0$ is a group under multiplication. The mapping

$$C\to\begin{pmatrix}\lambda B & \lambda\mathbf{v}\\ 0 & 1\end{pmatrix}$$

is an isomorphism of the group F onto the extended Euclidean group $\tilde{E}(n-1)$. Thus we shall mean the group F when talking of the extended Euclidean group, and the connected identity component $\tilde{E}_1(n-1)$ will be identified with the group of matrices of the form (5) with $\lambda>0$ and $B\in SO(n-1)$. From Lemma 2 it follows that the Lie algebra AF of the group F is generated by the basis elements J_{ab},G_a,J_{0n} $(a<b;\ a,b=1,\ldots,n-1)$.

Lemma 3: If $C\in O_1(1,n)$ and $C(P_0+P_n)=\lambda(P_0+P_n)$ then $\lambda>0$ and $B\in SO(n-1)$ in (5).

Proof: Since

$$\frac{1+\lambda^2(1+\mathbf{v}^2)}{2\lambda}>0,$$

then we have $\lambda>0$. From Lemma 2, $\mathrm{diag}[1,B,1]\in O_1(1,n)$, so that $\det B>0$. Thus $B\in SO(n-1)$ and the lemma is proved.

Lemma 4: If $C\in O(1,n)$ and $\pm C\notin\widetilde{E}(n-1)$ then $C=\pm A_1C'A_2$ where $A_1,A_2\in\widetilde{E}(n-1)$ and $C'=\mathrm{diag}[1,...,1,-1]$.

Proof: We can choose a matrix $\Lambda\in O(n-1)$ so that $\Lambda C(P_0+P_n)=\alpha P_0+\beta P_1+\gamma P_n$ where $\alpha^2-\beta^2-\gamma^2=0$. If $\beta\neq 0$ then $\alpha-\gamma\neq 0$. Let $\theta=\beta/(\alpha-\gamma)$. Then,

$$\exp(\theta G_1)(\alpha P_0+\beta P_1+\gamma P_n)=\frac{\alpha-\gamma}{2}\,(P_0-P_n)$$

and so there exists a matrix $\Gamma\in\widetilde{E}(n-1)$ such that $\Gamma C(P_0+P_n)=\lambda(P_0+P_n)$ or $\Gamma C(P_0+P_n)=\lambda(P_0-P_n)$. In the first case, $\pm\Gamma C\in\widetilde{E}(n-1)$ so that then we have $\pm C\in\widetilde{E}(n-1)$, which is impossible. In the second case, $C'\Gamma C(P_0+P_n)=\lambda(P_0+P_n)$. For $\lambda>0$ we find $C'\Gamma C\in\widetilde{E}(n-1)$. Put $C'\Gamma C=A_2$, $\Gamma=A_1^{-1}$. Then $C=A_1C'A_2$. If $\lambda<0$ then we put $-C'\Gamma C=A_2$, in which case $C=-A_1C'A_2$, and the lemma is proved.

Lemma 5: If $C\in O_1(1,n)$ and $C\notin\widetilde{E}_1(n-1)$, then $C=D_1QD_2$, where $D_1,D_2\in\widetilde{E}_1(n-1)$, and $Q=\mathrm{diag}[1,-1,1,...,1,-1]$.

Proof: If $\pm C\in\widetilde{E}(n-1)$, then $C(P_0+P_n)=\gamma(P_0+P_n)$. By Lemma 3, $\gamma>0$ and $C\in\widetilde{E}_1(n-1)$, which contradicts the assumption. Thus, $\pm C\notin\widetilde{E}(n-1)$. By Lemma 4, $C=\pm A_1C'A_2$. From this it follows that $C=D_1\Gamma D_2$, where $D_1,D_2\in\widetilde{E}_1(n-1)$, and Γ is one of the matrices $\pm C',\pm Q$. However, $\Gamma\in O_1(1,n)$, since $\Gamma=D_1^{-1}CD_2^{-1}$, find from this it follows that $\Gamma=Q$. The Lemma is proved.

Direct calculation shows that the normalizer of the space $\langle P_0+P_n\rangle$ in $AO(1,n)$ is generated by the matrices G_a,J_{ab},J_{0n} $(a,b=1,...,n-1)$, which satisfy the commutation relations

$$[G_a,J_{bc}]=g_{ab}G_c-g_{ac}G_b,\ [G_a,G_b]=0,\ [G_a,J_{0n}]=G_a.$$

This means that the normalizer of the space $\langle P_0+P_n\rangle$ in the algebra $AO(1,n)$ is the extended Euclidean algebra

$$A\widetilde{E}(n-1)=\langle G_1,\ldots,G_{n-1}\rangle\uplus(AO(n-1)\oplus\langle J_{0n}\rangle)$$

in an $(n-1)$-dimensional space, where the generators of translations are $G_1,\ldots,G_{n-1}$ and the generator of dilatations is the matrix J_{0n}.

Let K be a subalgebra of $AP(1,n)$ such that its projection onto $AO(1,n)$ has an invariant isotropic subspace in Minkowski space $\mathbf{R}_{1,n}$. The subalgebra K is conjugate under $AdAP(1,n)$ with a subalgebra of the algebra $\mathcal{A}=AG_1(n-1)\uplus\langle J_{0n}\rangle$ where $AG_1(n-1)$ is the usual Galilei algebra with basis M,T,P_a,G_a,J_{ab} $(a,b=1,...,n-1)$, and $M=P_0+P_n,T=\frac{1}{2}(P_0-P_n)$.

Proposition 3: Let L_1 and L_2 be subalgebras of $\mathcal{A}$, with L_1 not conjugate under $Ad\ \mathcal{A}$ to any subalgebra having zero projection onto $\langle G_1,\ldots,G_{n-1}\rangle$. If $\varphi(L_1)=L_2$ for some $\varphi\in AdAP(1,n)$, then there exists an inner automorphism ψ of the algebra $\mathcal{A}$ with $\psi(L_1)=L_2$.

Proof: Since $Ad\ \mathcal{A}$ contains automorphisms which correspond to matrices of the form

$$\exp\left(\sum_{\gamma=0}^{n}a_\gamma P_\gamma\right) \tag{6}$$

and since $P(1,n)$ is a semidirect product of the group of matrices of the form (6) and the group $O(1,n)$ of matrices of the form $\mathrm{diag}[\Delta,1]$, then we may assume that $\varphi=\varphi_C$ with $C\in O_1(1,n)$. If $C\notin\widetilde{E}_1(n-1)$, then by Lemma 5, $C=D_1QD_2$. In that case we find that

$$(D_1QD_2)\hat{\varepsilon}(L_1)(D_2^{-1}QD_1^{-1})=\hat{\varepsilon}(L_2),$$

whence

$$Q(D_2\hat{\varepsilon}(L_1)D_2^{-1})Q=D_1^{-1}\hat{\varepsilon}(L_2)D_1. \tag{7}$$

However,

$$QG_aQ=Q(J_{0a}-J_{an})Q=\begin{cases} J_{0a}+J_{an} & \text{when } a\neq 1 \\ -(J_{01}+J_{1n}) & \text{when } a=1 \end{cases}.$$

This means that $QG_aQ\notin\mathcal{A}$. Because of this, the left-hand side of (7) does not belong to $\mathcal{A}$, whereas the right-hand side of (7) is a subalgebra of $\mathcal{A}$. This then implies that we must have $C\in\tilde{E}_1(n-1)$ and thus we have $\psi(L_1)=L_2$ for some $\psi\in Ad\mathcal{A}$.

Proposition 4: Let $\tilde{\mathcal{A}}$ be a Lie algebra with basis $P_0,P_a,P_n,J_{ab},J_{0n}$ $(a,b=1,...,n-1)$ and let L_1,L_2 be subalgebras of $\tilde{\mathcal{A}}$ such that at least one of them has a nonzero projection onto $\langle J_{0n}\rangle$. If $\varphi(L_1)=L_2$ for some $\varphi\in AdAP(1,n)$, then there exists an inner automorphism $\psi\in\tilde{\mathcal{A}}$ so that either $\psi(L_1)=L_2$ or $\psi(L_1)=\varphi_Q(L_2)$ where $Q=\mathrm{diag}[1,-1,1,...,1,-1]$.

Proof: As in the proof of Proposition 3, we may assume that $\varphi=\varphi_C$ where $C\in O_1(1,n)$. We shall also assume that the projection of L_1 onto $\langle J_{0n}\rangle$ is nonzero. If $C\in\tilde{E}_1(n-1)$ and $C\notin\tilde{O}_1(n-1)$ then the projection of the algebra $\varphi(L_1)$ onto $\langle G_1,\ldots,G_{n-1}\rangle$ is nonzero, and hence the projection of L_2 onto $\langle G_1,\ldots,G_{n-1}\rangle$ is nonzero, which contradicts the assumptions of the proposition. Thus, if $C\in\tilde{E}_1(n-1)$ then $\varphi\in Ad\tilde{\mathcal{A}}$.

Let $C\notin\tilde{E}_1(n-1)$. By Lemma 5, $C=D_1QD_2$ where $D_1,D_2\in\tilde{E}_1(n-1)$. Then $\varphi(L_1)=L_2$ can be written as

$$\varphi_Q[\sigma_{D_2}(L_1)]=\varphi_{D_1^{-1}}(L_2).$$

If $D_2\notin\tilde{O}_1(n-1)$ then the projection of $\varphi_{D_2}(L_1)$ onto $\langle G_1,\ldots,G_{n-1}\rangle$ is nonzero and hence $\varphi_Q[\varphi_{D_2}(L_1)]$ does not belong to $\mathcal{A}$. But then $\varphi_{D_1^{-1}}(L_2)$ is also not in $\mathcal{A}$. This is a contradiction. Thus $D_1,D_2\in\tilde{O}_1(n-1)$. From this it follows that $\varphi_Q(\psi(L_1))=L_2$ where $\psi=\varphi_D$ is an inner automorphism of the algebra $\tilde{\mathcal{A}}$. This proves the proposition.

Proposition 5: Suppose $2\leqslant m\leqslant n-1$. Let F be a subalgebra of the algebra $AO(m)$ which is not conjugate under $AdAO(m)$ to a subalgebra of $AO(m-1)$, and let L be a subalgebra of $\langle P_0,P_1,\ldots,P_n\rangle\uplus F$ such that $\hat{\varepsilon}(L)=F$. Then L is conjugate to an algebra $W\uplus K$, where W is a subalgebra of $\langle P_1,\ldots,P_m\rangle$ and K is a subalgebra of $F\oplus\langle P_0,P_{m+1},\ldots,P_n\rangle$. Two subalgebras $W_1\uplus K_1$ and $W_2\uplus K_2$ of this type are conjugate under $AdAP(1,n)$ if and only if there exists an automorphism $\psi\in AdAO(m)\times AdAO(1,n-m)$ such that $\psi(W_1\uplus K_1)=W_2\uplus K_2$ or $\psi(W_1\uplus K_1)=Q(W_2\uplus K_2)Q$ where

$$AO(1,n-m)=\langle J_{\alpha\beta}:\alpha,\beta=0,m+1,...,n\rangle$$

and $Q=\mathrm{diag}[1,-1,1,...,1,-1]$.

IV. CONJUGACY OF SUBALGEBRAS OF THE EXTENDED POINCARÉ ALGEBRA $A\tilde{P}(1,n)$ UNDER $AdAC(1,n)$

Lemma 6: If $C\in O(2,n+1)$ and $C(Q_1+Q_{n+3})=\lambda(Q_1+Q_{n+3})$ then $\lambda\neq 0$ and

$$C=\begin{pmatrix} \dfrac{1+\lambda^2(1-\mathbf{v}^2)}{2\lambda} & -\lambda\mathbf{v}^tE_{1,n}B & \dfrac{-1+\lambda^2(1+\mathbf{v}^2)}{2\lambda} \\ \mathbf{v} & B & -\mathbf{v} \\ \dfrac{-1+\lambda^2(1-\mathbf{v}^2)}{2\lambda} & -\lambda\mathbf{v}^tE_{1,n}B & \dfrac{1+\lambda^2(1+\mathbf{v}^2)}{2\lambda} \end{pmatrix}, \tag{8}$$

where $B\in O(1,n)$, $E_{1,n}=\mathrm{diag}[1,-1,...,-1]$, $\mathbf{v}$ is an $(n+1)\times 1$ matrix and $\mathbf{v}^2$ is its scalar square in $\mathbf{R}_{1,n}$. Conversely, every matrix C of the form (8) satisfies the condition $C(Q_1+Q_{n+3})=\lambda(Q_1+Q_{n+3})$.

Proof: Direct calculation.

Lemma 7: Let $C\in O(2,n+1)$ have the form (8), with $\lambda>0$. Then

$$C=\mathrm{diag}[1,B,1]\exp[(\ln\lambda)D]\exp(-\beta_0P_0-\beta_1P_1-\cdots-\beta_nP_n),$$

where

$$\begin{pmatrix}\beta_0\\ \beta_1\\ \cdot\\ \cdot\\ \cdot\\ \beta_n\end{pmatrix}=B^{-1}\mathbf{v}.$$

Proof: The proof of Lemma 7 is similar to that of Lemma 2.

The mapping

$$f:C\to\begin{pmatrix}\lambda B & \lambda\mathbf{v}\\ 0 & 1\end{pmatrix}$$

is a homomorphism of the group of matrices (8) onto the extended Poincaré group $\tilde{P}(1,n)$. The kernel of this homomorphism is the group of order two, $\{-E_{n+3},E_{n+3}\}$. Let us denote by H the set of matrices of the form (8) with $\lambda>0$. Then f is an isomorphism of H onto $\tilde{P}(1,n)$. For this reason we shall, in the remainder of this article, mean the group H when referring to $\tilde{P}(1,n)$. Its Lie algebra is the extended Poincaré algebra $A\tilde{P}(1,n)$ given in Sec. II.

Lemma 8: Let $C\in O_1(2,n+1)$ and let it be of the form (8) with $\lambda>0$. Then $B\in O_1(1,n)$.

Remark 1: Note that when $\lambda<0$ it is possible that B does not belong to $O_1(2,n+1)$.

Lemma 9: If $C\in O(2,n+1)$ and $\pm C\notin\tilde{P}(1,n)$ then either $C=\pm A_1QA_2$ or $C=A_1F(\theta)A_2$, where $A_1,A_2\in\tilde{P}(1,n)$, $Q=\mathrm{diag}[1,\ldots,1,-1]$ and $F(\theta)=\exp[(\theta/2)(K_0+P_0+K_n-P_n)]$.

Proof: There exists a matrix $\Lambda\in\tilde{P}(1,n)$ such that

$$\Lambda C(Q_1+Q_{n+3})=\alpha_1Q_1+\alpha_2Q_2+\alpha_3Q_{n+2}+\alpha_4Q_{n+3},$$

where $\alpha_1^2+\alpha_2^2-\alpha_3^2-\alpha_4^2=0$ and $\alpha_2\alpha_3\geqslant 0$. If $\alpha_1\neq\alpha_4$ then, as in the proof of Lemma 4, we obtain that

$$\exp(\beta_0P_0+\beta_nP_n)\Lambda C(Q_1+Q_{n+3})=\gamma(Q_1\pm Q_{n+3})$$

for some real numbers β_0,β_n,γ. From this it follows that

$$\Gamma\ \exp(\beta_0P_0+\beta_nP_n)\Lambda C(Q_1+Q_{n+3})=\lambda(Q_1+Q_{n+3}),$$

where $\lambda>0$ and $\Gamma=\pm E_{n+3}$ or $\Gamma=\pm Q$. By Lemma 6 and Lemma 7, we obtain

$$\Gamma\ \exp(\beta_0P_0+\beta_nP_n)\Lambda C=\tilde{\Lambda},\ \ \tilde{\Lambda}\in\tilde{P}(1,n).$$

Since $\pm C\notin\tilde{P}(1,n)$, then $\Gamma=\pm Q$, and so $C=\pm A_1QA_2$, where $A_1=\Lambda^{-1}\exp(-\beta_0P_0-\beta_nP_n)$, $A_2=\tilde{\Lambda}$.

If $\alpha_1=\alpha_4$, then also $\alpha_2=\alpha_3$. It is easy to verify that

$$F(\theta)\Lambda C(Q_1+Q_{n+3})=(\alpha_1\cos\theta+\alpha_2\sin\theta)(Q_1+Q_{n+3})+(\alpha_2\cos\theta-\alpha_1\sin\theta)(Q_2+Q_{n+2}).$$

If $\alpha_1=0$ then we put $\theta=(\pi/2)$, when $\alpha_2>0$ and $\theta=-(\pi/2)$, when $\alpha_2<0$. If $\alpha_1\neq 0$ then we let $\alpha_2\cos\theta-\alpha_1\sin\theta=0$. In that case,

$$\tan\theta=\frac{\alpha_2}{\alpha_1},\ \ \alpha_1\cos\theta+\alpha_2\sin\theta=\alpha_1\cos\theta(1+\tan^2\theta).$$

We choose the value of θ so that $\alpha_1\cos\theta>0$. With this choice of θ we have

$$F(\theta)\Lambda C(Q_1+Q_{n+3})=\lambda(Q_1+Q_{n+3}),$$

where $\lambda>0$. But then, as a result of Lemma 6 and Lemma 7, $F(\theta)\Lambda C=\tilde{\Lambda}$, $\tilde{\Lambda}\in\tilde{P}(1,n)$, and so $C=A_1F(-\theta)A_2$, where $A_1=\Lambda^{-1}$, $A_2=\tilde{\Lambda}$. The result is proved.

Lemma 10: Let L_1 and L_2 be subalgebras of $A\tilde{P}(1,n)$ which are not conjugate under $A\tilde{P}(1,n)$ to subalgebras of $A\tilde{O}(1,n)=AO(1,n)\oplus\langle D\rangle$. Then L_1,L_2 are conjugate under $AdAC(1,n)$ if and only if they are conjugate under $AdA\tilde{P}(1,n)$ or if one of the following conditions holds:

(1) n is an odd number and there exists an automorphism $\psi\in AdA\tilde{P}(1,n)$ with $\psi(L_1)=C_2L_2C_2^{-1}$ (see Eq. (3) for notation);
(2) there exist automorphisms $\psi_1,\psi_2\in A\tilde{P}(1,n)$ with

$$\psi_1(L_1)=F(\theta)[\psi_2(L_2)]F(-\theta).$$

Proof: Let $CL_1C^{-1}=L_2$ for some $C\in O_1(2,n+1)$. By Lemma 9, we may assume that $\pm C\in\tilde{P}(1,n)$ or that C is one of the matrices $\pm A_1QA_2$, $A_1F(\theta)A_2$ (we use the notation of Lemma 9). If $C\in\tilde{P}(1,n)$ then, by Lemma 8, C belongs to the identity component of the group $\tilde{P}(1,n)$ and thus φ_C is an inner automorphism of the algebra $A\tilde{P}(1,n)$. Now suppose $-C\in\tilde{P}(1,n)$. Then by Lemma 7, $C=-\mathrm{diag}[1,B,1]\Delta$, where $B\in O(1,n)$ and $\Delta\in\tilde{P}_1(1,n)$. Thus we may assume that $C=-\mathrm{diag}[1,B,1]$. From this it follows that $B\in O_1(1,n)$ for odd n and we have

$$\mathrm{diag}[1,1,-1,1,...,1,1]B\in O_1(1,n).$$

For even n this means that the algebras L_1,L_2 are conjugate to each other under $AdA\tilde{P}(1,n)$ or that there exists an automorphism $\psi\in AdA\tilde{P}(1,n)$ such that $\psi(L_1)=C_2L_2C_2^{-1}$.

Let $C=\pm A_1QA_2$. Then $C=\Gamma_1\Delta\Gamma_2$ with $\Gamma_1,\Gamma_2\in\tilde{P}(1,n)$ and $\Delta=\pm\mathrm{diag}[1,\epsilon_1,1,...,1,\epsilon_2,-1]$ with ϵ_1, $\epsilon_2\in\{-1,1\}$. Clearly, $\Delta\in O_1(2,n+1)$. When $C=A_1QA_2$ we have $\epsilon_1=1$, $\epsilon_2=-1$ and when $C=-A_1QA_2$, $\epsilon_1=1$, $\epsilon_2=(-1)^n$. Since

$$\Delta P_n\Delta^{-1}=\pm K_n,\quad \Delta P_\alpha\Delta^{-1}=\pm K_\alpha$$

with $\alpha<n$, then from $\Gamma_1^{-1}L_2\Gamma_1=\Delta(\Gamma_2L_1\Gamma_2^{-1})\Delta^{-1}$ it follows that the algebra $\Gamma_1^{-1}L_2\Gamma_1$ has a nonzero projection onto $\langle K_0,K_1,\ldots,K_n\rangle$, which is impossible. Thus the matrix C is different from $\pm A_1QA_2$.

Now let $C=A_1F(\theta)A_2$. If Γ is one of the matrices (4), then $\Gamma F(\theta)\Gamma^{-1}=F(\pm\theta)$, so that

$$C=A_1'F(\theta)A_2'\Delta,$$

where A_1', $A_2'\in\tilde{P}_1(1,n)$ and $\Delta=E$ or Δ is one of the matrices (4). Since Δ can be represented as a product of matrices in $O_1(2,n)$, then the last case is impossible, and we have proved the Lemma.

Theorem 1: Let L_1 and L_2 be subalgebras of $A\tilde{P}(1,n)$ which are not conjugate under $A\tilde{P}(1,n)$ to subalgebras of $A\tilde{O}(1,n)$ and such that their projections onto $AO(1,n)$ have no invariant isotropic subspace in $\mathbf{R}_{1,n}$. The subalgebras L_1 and L_2 are conjugate under $AdAC(1,n)$ if and only if they are conjugate under $AdA\tilde{P}(1,n)$ or when there exists an automorphism $\psi\in AdA\tilde{P}(1,n)$ such that $\psi(L_1)=C_2L_2C_2^{-1}$, where $C_2=\mathrm{diag}[1,1,-1,1,...,1]$.

Proof: By Lemma 10 we may assume that $\psi_1(L_1)=F(\theta)[\psi_2(L_2)]F(-\theta)$ for some $\psi_1,\psi_2\in A\tilde{P}(1,n)$. Under the given assumptions, the projection of $\psi_2(L_2)$ onto $AO(1,n)$ contains an element of the form

$$X=\sum_{b=1}^{n-1}(\alpha_bJ_{0b}+\gamma_bJ_{bn})+\sum_{b,c=1}^{n-1}\sigma_{bc}J_{bc},$$

where $\alpha_q\neq-\gamma_q$ for some $q(1\leqslant q\leqslant n-1)$. Since

$$F(\theta)J_{0q}F(-\theta)=J_{0q}\cos\theta+\tfrac{1}{2}(K_q+P_q)\sin\theta$$

and

$$F(\theta)J_{qn}F(-\theta)=J_{qn}\cos\theta+\tfrac{1}{2}(K_q-P_q)\sin\theta$$

we have that $F(\theta)XF(-\theta)$ contains the term

$$F(\theta)[\alpha_q J_{0q}+\gamma_q J_{qn}]F(-\theta)=(\alpha_q J_{0q}+\gamma_q J_{qn})\cos\theta+\tfrac{1}{2}[\alpha_q(K_q+P_q)+\gamma_q(K_q-P_q)]\sin\theta$$

and from this it follows that $(\alpha_q+\gamma_q)\sin\theta=0$ so that $\sin\theta=0$. But then $\theta=m\pi$. When $m=2d$ we have $F(\theta)=E_{n+3}$. When $m=2d+1$ then $F(\theta)=\mathrm{diag}[-1,-1,E_{n-1},-1,-1]$. However,

$$F(\theta)[\psi_2(L_2)]F(-\theta)=(-F(\theta))[\psi_2(L_2)](-F(-\theta))$$

from which it follows that we may assume that $\psi_1(L_1)=C[\psi_2(L_2)]C^{-1}$ where $C=\mathrm{diag}[1,1,-E_{n-1},1,1]$. If n is odd, then φ_C is an inner automorphism of $A\tilde{P}(1,n)$. If n is even, then $\varphi_{C_2}\varphi_C$ is an inner automorphism of the algebra $A\tilde{P}(1,n)$. In the first case, $\psi_3(L_1)=L_2$ where $\psi_3=\psi_2^{-1}\varphi_C^{-1}\psi_1$ is an inner automorphism of the algebra $A\tilde{P}(1,n)$. In the second case, $\psi(L_1)=\varphi_{C_2}(L_2)$ for some $\psi\in AdA\tilde{P}(1,n)$. The theorem is proved.

Theorem 2: Let L_1 and L_2 be subalgebras of $A\tilde{O}(1,n)$ having no invariant isotropic subspaces in $\mathbf{R}_{1,n}$. The subalgebras L_1,L_2 are conjugate under $AdAC(1,n)$ if and only if they are conjugate under $AdA\tilde{O}(1,n)$ or when there exists an automorphism $\psi\in AdA\tilde{O}(1,n)$ such that $\psi(L_1)=CL_2C^{-1}$ where C is one of the $(n+3)\times(n+3)$ matrices

$$\mathrm{diag}[1,1,-1,1,...,1],\ \ \mathrm{diag}[1,...,1,-1],\ \ \mathrm{diag}[1,...,1,-1,-1].$$

We note that $A\tilde{O}(1,n)\subset AO(2,n+1)$ and that the matrix C is $(n+3)\times(n+3)$.

V. SUBALGEBRAS OF THE FULL GALILEI ALGEBRA

Lemma 11: Let $C\in O(2,n+1)$ and $W=\langle Q_1+Q_{n+3},Q_2+Q_{n+2}\rangle$. If $CW=W$, then

$$C=\exp[\theta(S+T)]\mathrm{diag}[1,\varepsilon,K,\varepsilon,1]\exp(\alpha R+\beta Z)\exp\left(\sum_{i=1}^{n-1}\gamma_i G_i\right)\exp\left(\delta M+\lambda T+\sum_{i=1}^{n-1}\mu_i P_i\right), \quad (9)$$

where $\varepsilon=\pm1$, $K\in O(n-1)$.

Proof: We have

$$C(Q_1+Q_{n+3})=\alpha_1(Q_1+Q_{n+3})+\alpha_2(Q_2+Q_{n+2})$$

and so

$$F(-\theta)C(Q_1+Q_{n+3})=(\alpha_1\cos\theta-\alpha_2\sin\theta)(Q_1+Q_{n+3})+(\alpha_2\cos\theta+\alpha_1\sin\theta)(Q_2+Q_{n+2}).$$

If $\alpha_1=0$ then we put $\theta=(3\pi/2)$ when $\alpha_2>0$ and $\theta=(\pi/2)$ when $\alpha_2<0$. If $\alpha_1\neq0$ then we put $\alpha_1\sin\theta+\alpha_2\cos\theta=0$ and then $\tan\theta=-\alpha_2/\alpha_1$ and $\alpha_1\cos\theta-\alpha_2\sin\theta=\alpha_1\cos\theta(1+\tan^2\theta)$. We choose θ so that $\alpha_1\cos\theta>0$. For this choice of θ we have $F(-\theta)C(Q_1+Q_{n+3})=\xi(Q_1+Q_{n+3})$, where $\xi>0$. Using Lemma 7, we obtain

$$F(-\theta)C=A=\mathrm{diag}[1,B,1]\exp([\ln\xi]D)\exp\left(-\sum_{i=0}^{n}\beta_i P_i\right)\in\tilde{P}(1,n),$$

where $B\in O(1,n)$. Then $C=F(\theta)A$. The matrix A has the form (8). Direct calculation gives

$$A(Q_2+Q_{n+2})=\alpha(Q_1+Q_{n+3})+\beta Q_2+\gamma Q_{n+2}+\sum_{i=3}^{n+1}\delta_i Q_i.$$

From this it follows that

$$F(\theta)A(Q_2+Q_{n+2})=(\alpha\cos\theta+\beta\sin\theta)Q_1+(-\alpha\sin\theta+\beta\cos\theta)Q_2+(\gamma\cos\theta-\alpha\sin\theta)Q_{n+2}+(\gamma\sin\theta+\alpha\cos\theta)Q_{n+3}+\sum_{i=3}^{n+1}\delta_i Q_i.$$

Now we have $F(\theta)A(Q_2+Q_{n+2})\in W$, from which we have

$$\alpha\cos\theta+\beta\sin\theta=\gamma\sin\theta+\alpha\cos\theta,\quad -\alpha\sin\theta+\beta\cos\theta=\gamma\cos\theta-\alpha\sin\theta$$

and so we conclude that $\beta=\gamma$ and $\delta_j=0$, $j=3,...,n+1$. But in that case we have

$$\mathrm{diag}[1,B,1](Q_2+Q_{n+2})=\beta(Q_2+Q_{n+2}).$$

By Lemma 2, we have

$$\pm B=\mathrm{diag}[1,K,1]\exp[(-\ln|\beta|)J_{0n}]\exp\left(\sum_{i=1}^{n-1}\gamma_i G_i\right),$$

where $K\in O(n-1)$. We note that

$$K_0+P_0-K_n-P_n=2(S+T),\quad J_{0n}=\tfrac{1}{2}(Z-R),\quad D=-\tfrac{1}{2}(Z+R),$$

$$P_0=\tfrac{1}{2}(M+2T),\quad P_n=\tfrac{1}{2}(M-2T),\quad [D,G_a]=0,\quad [D,J_{0n}]=0.$$

The lemma is proved.

Lemma 12: Let $C\in O_1(2,n+1)$ and $W=\langle Q_1+Q_{n+3},Q_2+Q_{n+2}\rangle$. If $CW=W$ then the matrix C has the form (9) with $\varepsilon=1$ and $K\in SO(n-1)$.

Proof: From the conditions of Lemma 11 and the fact that we ask for $C\in O_1(2,n+1)$, it follows that $\mathrm{diag}[1,\varepsilon,K,\varepsilon,1]\in O_1(2,n+1)$. It follows now that $\varepsilon>0$ and that

$$\begin{vmatrix} K & 0\\ 0 & \varepsilon\end{vmatrix}>0$$

and thus we have $\varepsilon=1$ and $|K|>0$, whence $K\in SO(n-1)$. This proves the lemma.

The matrices of the form (9) with $\varepsilon=1$ and $K\in SO(n-1)$ form a group under multiplication, which we denote by $G_4(n-1)$ since its Lie algebra is the full Galilei algebra $AG_4(n-1)$. It is easy to see that $G_4(n-1)\subset O_1(2,n+1)$.

Lemma 13: If $C\in O_1(2,n+1)$ but $C\notin G_4(n-1)$, then $C=A_1\Gamma A_2$, where $A_1,A_2\in G_4(n-1)$ and Γ is one of the matrices

$$\Gamma_1=\mathrm{diag}[1,...,1,-1],\quad \Gamma_2=\mathrm{diag}[1,1,-1,1...,1,-1,1]. \tag{10}$$

Proof: Let

$$C(Q_1+Q_{n+3})=\sum_{i=1}^{n+3}\alpha_i Q_i,\quad \alpha_1^2+\alpha_2^2-\alpha_3^2-\cdots-\alpha_{n+3}^2=0.$$

There exists a matrix $\Lambda=\mathrm{diag}[1,1,\Delta,1,1]$ with $\Delta\in SO(n-1)$ such that $\Lambda C(Q_1+Q_{n+3})$ does not contain $Q_4,\ldots,Q_{n+1}$. Hence we may assume $\alpha_1^2+\alpha_2^2-\alpha_3^2-\alpha_{n+2}^2-\alpha_{n+3}^2=0$.

Since

$$S+T=\tfrac{1}{2}(K_0+P_0+K_n-P_n)=\Omega_{12}+\Omega_{n+2,n+3},$$

then, up to a factor $\exp[\theta(S+T)]$, we may suppose that $\alpha_1\neq 0$, $\alpha_2=0$. If $\alpha_1^2=\alpha_{n+3}^2$ then $\alpha_3=0$, $\alpha_{n+2}=0$. Assume $\alpha_1\neq\alpha_{n+3}$. As in the proof of Lemma 4, we find that

$$\exp(\beta_1P_1+\beta_2P_2)(\alpha_1Q_1+\alpha_3Q_3+\alpha_{n+2}Q_{n+2}+\alpha_{n+3}Q_{n+3})=\alpha_1'Q_1+\alpha_{n+3}'Q_{n+3},$$

where $\alpha_1'^2-\alpha_{n+3}'^2=0$. Thus there exists a matrix $A_1\in G_4(n-1)$ such that

$$A_1^{-1}C(Q_1+Q_{n+3})=\gamma(Q_1\pm Q_{n+3}),$$
$$A_1^{-1}C(Q_2+Q_{n+2})=\delta_1Q_1+\delta_2Q_2+\delta_3Q_3+\delta_4Q_{n+2}+\delta_5Q_{n+3}. \tag{11}$$

Since the pseudo-orthogonal transformations preserve the scalar product, it follows that the right-hand sides in (11) are also orthogonal, which implies that $\gamma(\delta_1\mp\delta_5)=0$ so that $\delta_5=\pm\delta_1$. If $\delta_2\neq\delta_4$ then multiplying the left- and right-hand sides in (11) by $\exp(\theta G_1)$ does not change the right-hand side of the first equality, and allows us to eliminate δ_3 by transforming it into 0. If $\delta_2=\delta_4$, then one easily deduces that $\delta_3=0$. Thus we may assume that $\delta_3=0$. But then we have $\delta_4=\pm\delta_2$ because $\delta_5=\pm\delta_1$ and $\delta_1^2+\delta_2^2-\delta_4^2-\delta_5^2=0$.

Let $W=\langle Q_1+Q_{n+3},Q_2+Q_{n+2}\rangle$. The above reasoning implies that for some matrix $A_1\in G_4(n-1)$ we have $\Gamma A_1^{-1}CW=W$ where Γ is one of the matrices (10). The fact that $\Gamma A_1^{-1}C\in O_1(2,n+1)$ implies, using Lemma 12, $\Gamma A_1^{-1}C=A_2\in G_4(n-1)$. Thus $C=A_1\Gamma A_2$ and the lemma is proved.

Lemma 14: The subalgebras L_1 and L_2 of $AG_4(n-1)$ are conjugate under $AdAC(1,n)$ if and only if they are conjugate under $AdAG(n-1)$ or if there exist automorphisms ψ_1,ψ_2 in $AdAG_4(n-1)$ with $\psi_1(L_1)=\Gamma[\psi_2(L_2)]\Gamma^{-1}$, where Γ is one of the matrices (10).

Proof: The result follows immediately from Lemma 13.

In the following table we give the action on the full Galilei algebra $AG_4(n-1)$ of the automorphisms $\varphi_{\Gamma_1},\varphi_{\Gamma_2},\varphi_{C_1},\varphi_{C_4},\varphi_{C_5}$ where

$$C_4=\exp\left(\frac{\pi}{2}(S+T)\right),\quad C_5=\exp(\pi(S+T))$$

(see (3) and (10) for the notation).

Theorem 3: Let L_1 and L_2 be subalgebras of $AG_4(n-1)$ which are not conjugate under $AdAG_4(n-1)$ with subalgebras of

$$\langle M,T,P_1,\ldots,P_{n-1}\rangle\uplus(AO(n-1)\otimes\langle D,J_{0n}\rangle)$$

and

$$AO(n-1)\oplus\langle S+T,Z\rangle.$$

Then the subalgebras L_1 and L_2 are conjugate under $AdAC(1,n)$ if and only if they are conjugate under $AdAG_4(n-1)$.

Proof: If the subalgebras L_1 and L_2 are conjugate under $AdAG_4(n-1)$ then they are conjugate under $AdAC(1,n)$. Now suppose that they are conjugate under $AdAC(1,n)$. In order to prove their conjugacy under $AdAG_4(n-1)$ it is sufficient (by Lemma 14) to show that for an arbitrary $\psi\in AdAG_4(n-1)$ and for each matrix Γ of the form (10), the subalgebra $\Gamma\psi(L_1)\Gamma^{-1}$ either equals $\psi(L_1)$ or is not contained in $AG_4(n-1)$, for then the only possibility is that they are conjugate under $AdAG_4(n-1)$.

If the projection of $\psi(L_1)$ onto $\langle G_1,\ldots,G_{n-1}\rangle$ is nonzero, then, using Table I, the subalgebra $\Gamma\psi(L_1)\Gamma^{-1}$ contains an element Y whose projection for some a, $1\leqslant a\leqslant n-1$ onto $\langle J_{0a},J_{an}\rangle$ is of the form $\lambda(J_{0a}+J_{an})$ with $\lambda\neq0$. If $\Gamma\psi(L_1)\Gamma^{-1}\subset AG_4(n-1)$, then the projection of Y onto $\langle J_{0a},J_{an}\rangle$ would have the form $\mu(J_{0a}-J_{an})$, which would imply $\lambda=\mu=-\mu=0$, an obvious contradiction.

Now let the projection of $\psi(L_1)$ onto $\langle G_1,\ldots,G_{n-1}\rangle$ be zero. Denote by $\tau\psi(L_1)$ the projection of $\psi(L_1)$ onto $\langle R,S,T\rangle$ If $\tau\psi(L_1)=\langle R,S,T\rangle$, then $\langle R,S,T\rangle\subset\psi(L_1)$. From this it follows that $\Gamma_2\psi(L_1)\Gamma_2^{-1}$ is not a subset of $AG_4(n-1)$. If we assume that $\Gamma_1\psi(L_1)\Gamma_1^{-1}\subset AG_4(n-1)$, we obtain, from Table I, that the projection of $\psi(L_1)$ onto $\langle P_1,\ldots,P_n,M\rangle$ is zero, and consequently we have either $\psi(L_1)=\langle R,S,T\rangle$ or $\psi(L_1)=\langle R,S,T\rangle\oplus\langle Z\rangle$. In this case, $\Gamma_1\psi(L_1)\Gamma_1^{-1}=\psi(L_1)$. If $\tau\psi(L_1)=\langle R+\alpha S,T+\beta S\rangle$, with $\alpha\neq0$, then $\Gamma_2\psi(L_1)\Gamma_2^{-1}$ is not contained in $AG_4(n-1)$. If we had $\Gamma_1\psi(L_1)\Gamma_1^{-1}\subset AG_4(n-1)$, then the projection of $\psi(L_1)$ onto $\langle P_1,\ldots,P_n,M\rangle$ would be zero. But then $\psi(L_1)$ would be conjugate under $AdAG_4(n-1)$ with a subalgebra of $AO(n-1)\oplus\langle R,T,Z\rangle$, which contradicts the assumptions of the theorem. The theorem is proved.

Theorem 4: Let L_1 and L_2 be subalgebras of the algebra

Z	$-Z$	R	Z	Z	Z	

$$L=\langle M,T,P_1,\ldots,P_{n-1}\rangle \uplus (AO(n-1)\oplus\langle D,J_{0n}\rangle)$$

having nonzero projection on $\langle J_{0n}\rangle$ and $\langle D\rangle$ and are not conjugate under AdL with subalgebras of the algebra $\langle M,T\rangle \uplus (AO(n-1)\oplus\langle D,J_{0n}\rangle)$. Then L_1 and L_2 are conjugate under $AdAC(1,n)$ if and only if they are conjugate under AdL or if there exists an automorphism $\psi \in AdL$ such that $\psi(L_1)=\Lambda L_2 \Lambda^{-1}$ where Λ is one of the matrices $\Gamma_2, C_5, \Gamma_2 C_5$ (see Table I).

Proof: If $\psi \in AdAG_4(n-1)$, then $\psi=\varphi_C$ where C is a matrix of the form (9). By theorem IV.3.4 of Ref. 9, the subalgebra L_1 is, up to an automorphism of $AdAG_4(n-1)$, one of the following algebras:

(1) $(U_1+U_2+U_3)\uplus F$, where $U_1 \subset \langle M\rangle$, $U_2 \subset \langle T\rangle$, $U_3 \subset \langle P_1,\ldots,P_{n-1}\rangle$ and $F \subset AO(n-1)\oplus\langle D,J_{0n}\rangle$;
(2) $(U_1+U_2)\uplus F$, where $U_1 \subset \langle T\rangle$, $U_2 \subset \langle P_1,\ldots,P_{n-1}\rangle$ and F is a subalgebra of $AO(n-1)\oplus\langle R,M\rangle$;
(3) $(U_1+U_2)\uplus F$, where $U_1 \subset \langle M\rangle$, $U_2 \subset \langle P_1,\ldots,P_{n-1}\rangle$ and F is a subalgebra of $AO(n-1)\oplus\langle Z,T\rangle$.

By assumption, the projection of L_1 onto $\langle P_1,\ldots,P_{n-1}\rangle$ is nonzero.

If $\psi(L_1)=L_2$, then in formula (9) $\theta=0$ or $\theta=\pi$ because for other values of θ the projection of $\psi(L_1)$ onto $\langle G_1,\ldots,G_{n-1}\rangle$ is nonzero. For this reason, $\gamma_1=\cdots=\gamma_{n-1}=0$ and so $\psi \in AdL$ or $\varphi_{C_5}\psi \in AdL$. Let there be automorphisms $\psi_1,\psi_2 \in AdAG_4(n-1)$ with $\Gamma\psi_1(L_1)\Gamma=\psi_2(L_2)$ where Γ is one of the matrices (10). If AdL did not contain ψ_1 and $\varphi_{C_5}\psi_1$, then the projection of $\psi_1(L_1)$ on $\langle G_1,\ldots,G_{n-1}\rangle$ would be nonzero, and so, by Table I, $\psi_2(L_2)$ would not be in $AG_4(n-1)$. Thus ψ_j or $\varphi_{C_5}\psi_j$ belongs to AdL for each $j=1,2$. For $\Gamma=\Gamma_1$ the projection of $\Gamma\psi_1(L_1)\Gamma$ onto $\langle K_1,\ldots,K_{n-1}\rangle$ is nonzero, so we have $\Gamma=\Gamma_2$. In this case $\Gamma\psi_2(L_2)\Gamma=\psi_2'(\Gamma L_2\Gamma)$. Using Lemma 14, the theorem is proved.

In a similar way, one proves the following results.

Theorem 5: Let B be a subalgebra of the algebra

$$N=\langle M,P_1,\ldots,P_{n-1}\rangle \uplus (AO(n-1)\oplus\langle D,T\rangle$$

and let B have nonzero projection onto $\langle D\rangle$. Then B is conjugate under $AdAC(1,n)$ to the algebra

$$F=(W_1\oplus W_2)\uplus E, \tag{12}$$

where E is a subalgebra of the algebra $AO(n-1)\oplus\langle D\rangle$, $W_1 \subset \langle P_1,\ldots,P_{n-1}\rangle$ and W_2 is one of the algebras $0, \langle P_0\rangle, \langle P_n\rangle, \langle M\rangle, \langle P_0,P_n\rangle$. If $W_2=\langle P_n\rangle$ or $W_2=\langle P_0,P_n\rangle$ then the subalgebra $W_1\uplus E$ is not conjugate under $AdAO(n-1)$ with any subalgebra of $\langle P_1,\ldots,P_{n-2}\rangle \uplus (AO(n-2)\oplus\langle D\rangle)$. Subalgebras F_1, F_2 of the type (12) of the algebra N with nonzero projection onto $\langle D\rangle$, which are not conjugate under AdN to subalgebras of $\langle M,T\rangle \uplus (AO(n-1)\oplus\langle D\rangle)$, will be conjugate under

$AC(1,n)$ if and only if they are conjugate under AdL or when there exists an automorphism $\psi \in AdL$ with $\psi(F_1)=\Gamma_2 F_2 \Gamma_2^{-1}$ (see (10)), where $L=AO(n-1)$ (we consider $AdAO(n-1)$ to be a subgroup of $AdAC(1,n)$).

Theorem 6: Let B be a subalgebra of the algebra

$$N=\langle M,P_1,\ldots,P_{n-1}\rangle \uplus (AO(n-1)\oplus\langle J_{0n},T\rangle$$

and let B have nonzero projection onto $\langle J_{0n}\rangle$. Then B is conjugate under $AdAC(1,n)$ with the algebra

$$F=W\uplus E, \tag{13}$$

where E is a subalgebra of the algebra $\langle P_1,\ldots,P_{n-1}\rangle \uplus (AO(n-1)\oplus\langle J_{0n}\rangle)$ and W is one of the algebras 0, $\langle M\rangle$, $\langle P_0,P_n\rangle$. Let $L=N\uplus\langle D\rangle$. Subalgebras F_1,F_2 of the type (13) of the algebra N which are not conjugate under AdN with subalgebras of the algebra $\langle M\rangle\uplus(AO(n-1)\oplus\langle J_{0n},T\rangle$, will be conjugate under $AdAC(1,n)$ if and only if they are conjugate under AdL or if there exists an automorphism $\psi\in AdL$ with $\psi(F_1)=\Lambda F_2\Lambda^{-1}$ where Λ is one of the matrices $\Gamma_2, C_5, \Gamma_2 C_5$ (see Table I).

Theorem 7: Let L_1,L_2 be subalgebras of the algebra $L=\langle M,S+T,Z\rangle\oplus AO(n-1)$ which have nonzero projection onto $\langle S+T\rangle$. The algebras L_1 and L_2 are conjugate under $AdAC(1,n)$ if and only if they are conjugate under AdL or if there exists an automorphism $\psi\in AdL$ such that $\psi(L_1)=\Gamma_1 L_2 \Gamma_1^{-1}$ (see Table I).

VI. SUBALGEBRAS OF $AC(1,3)$

We recall that in this article the conformal algebra $AC(1,3)$ is realized as the pseudo-orthogonal algebra $AO(2,4)$. It turns out that it is convenient to divide the subalgebras of $AO(2,4)$ into seven classes:

(1) subalgebras not having invariant isotropic subspaces in $\mathbf{R}_{2,4}$;
(2) subalgebras conjugate to subalgebras of $AG_1(2)$;
(3) subalgebras conjugate to subalgebras of $AG_1(2)\uplus\langle J_{03}\rangle$ and having nonzero projection onto $\langle J_{03}\rangle$;
(4) subalgebras conjugate to subalgebras of $AP(1,3)$ but not conjugate to subalgebras of $AG_1(2)\uplus\langle J_{03}\rangle$;
(5) subalgebras conjugate to subalgebras of $AG_1(2)\uplus\langle J_{03},D\rangle$ but not conjugate to subalgebras of $AG_1(2)\uplus\langle J_{03}\rangle$;
(6) subalgebras conjugate to subalgebras of $A\tilde{P}(1,3)$ but not conjugate to subalgebras of $AG_1(2)\uplus\langle J_{03},D\rangle$;
(7) subalgebras conjugate to subalgebras of $AG_4(2)$ but not conjugate to subalgebras of $A\tilde{P}(1,3)$.

Since subalgebras conjugate under $AdAC(1,3)$ are identified, we omit mentioning conjugacy when referring to classes. So, for instance, we shall consider the second class as consisting of subalgebras of $AG_1(2)$. In order to have a better survey of subalgebras it is convenient to split the classes into subclasses corresponding to certain properties of the projections of the subalgebras of a class onto the homogeneous part of the algebra.

The division of the set of subalgebras of $AC(1,3)$ into the classes (1)–(7) allows us easily to construct the set of subalgebras of each of the algebras $AG_1(2), AP(1,3), A\tilde{P}(1,3), AG_4(2)$. Up to conjugacy under $AdAC(1,3)$ we have

(a) the set of subalgebras of $AG_1(2)$ coincides with class (2);
(b) the set of subalgebras of $AP(1,3)$ is the union of classes (2), (3) and (4);
(c) the set of subalgebras of $A\tilde{P}(1,3)$ coincides with the union of classes (2)–(6);
(d) the set of subalgebras of $AG_4(2)$ is the union of classes (2), (3), (5), and (7).

We use the notation $F:U_1,\ldots,U_m$ for $U_1\uplus F,\ldots,U_m\uplus F$.

A. Subalgebras not possessing invariant isotropic subspaces in $\mathbf{R}_{2,4}$

This class is divided into subclasses by the existence for the subalgebras of invariant irreducible subspaces of a particular kind in the space $\mathbf{R}_{2,4}$.

1. Irreducible subalgebras of $AO(2,4)$

$$AC(1,3);$$

$$ASU(1,2)=\langle P_0+K_0+2J_{12},P_0+K_0+K_3-P_3,P_1+K_1+2J_{02},P_3+K_3+K_0-P_0,K_2-P_2+2J_{13},P_2+K_2-2J_{01},D+J_{03},K_1-P_1-2J_{23}\rangle;$$

$$ASU'(1,2)=\langle P_0+K_0-2J_{12},P_0+K_0+K_3-P_3,P_1+K_1-2J_{02},P_3+K_3+K_0-P_0,K_2-P_2-2J_{13},P_2+K_2+2J_{01},D+J_{03},K_1-P_1+2J_{23}\rangle;$$

$$ASU(1,2)\oplus\langle P_0+K_0-2J_{12}-K_3+P_3\rangle;$$

$$ASU'(1,2)\oplus\langle P_0+K_0+2J_{12}-K_3+P_3\rangle;$$

$$\langle P_0+K_0-2J_{12}-K_3+P_3\rangle\oplus\langle P_1+K_1+2J_{02},P_3+K_3+K_0-P_0,K_2-P_2+2J_{13}\rangle;$$

$$\langle P_0+K_0+2J_{12}-K_3+P_3\rangle\oplus\langle P_1+K_1-2J_{02},P_3+K_3+K_0-P_0,K_2-P_2-2J_{13}\rangle.$$

2. Irreducible subalgebras of $AO(1,4):AC(3)$

3. Irreducible subalgebras of $AO(2,3)$

$$AC(1,2);$$

$$\langle P_2+K_2+\sqrt{3}(P_1+K_1)+K_0-P_0,D+J_{02}-\sqrt{3}J_{01},P_0+K_0-2(K_2-P_2)\rangle;$$

$$\langle P_2+K_2-\sqrt{3}(P_1+K_1)+K_0-P_0,D+J_{02}+\sqrt{3}J_{01},P_0+K_0-2(K_2-P_2)\rangle.$$

4. Subalgebras of $AO(2,2)\oplus AO(2)$ with irreducible projection onto $AO(2,2)$

$$\langle J_{01}-D,K_0-P_0-P_1-K_1,P_0+K_0-K_1+P_1\rangle\oplus\langle P_0+K_0+K_1-P_1\rangle\oplus F,$$

where $F=0$ or $F=\langle J_{23}\rangle$;

$$\langle J_{01}+D,K_0-P_0+P_1+K_1,P_0+K_0+K_1-P_1\rangle\oplus\langle P_0+K_0-K_1+P_1\rangle\oplus F,$$

where $F=0$ or $F=\langle J_{23}\rangle$;

$$AC(1,1),AC(1,1)\oplus\langle J_{23}\rangle,\quad \text{where } AC(1,1)=\langle P_0,P_1,K_0,K_1,J_{01},D\rangle;$$

$$\langle J_{01}-D,K_0-P_0-P_1-K_1,P_0+K_0-K_1+P_1\rangle\oplus\langle P_0+K_0+K_1-P_1+\alpha J_{23}\rangle(\alpha\neq 0);$$

$$\langle J_{01}+D,K_0-P_0+P_1+K_1,P_0+K_0+K_1-P_1\rangle\oplus\langle P_0+K_0-K_1+P_1+\alpha J_{23}\rangle(a\neq 0).$$

5. Subalgebras of the type $AO(2,1)\oplus F$ with $F\subset AO(3)$

$AC(1)\oplus L$, where $AC(1)=\langle D,P_0,K_0\rangle$, and L is one of the algebras: $0,\langle J_{12}\rangle,\langle J_{12},J_{13},J_{23}\rangle$.

6. Subalgebras of $AO(2)\oplus AO(4)$ having an irreducible projection

$$\langle P_0+K_0\rangle;\ \langle P_0+K_0\rangle\oplus\langle 2J_{12}+\alpha(K_3-P_3)\rangle(|\alpha|\leqslant 1);$$

$$\langle P_0+K_0\rangle\oplus\langle J_{12},K_3-P_3\rangle;\ \langle P_0+K_0\rangle\oplus\langle J_{12},J_{13},J_{23};$$

$$\langle P_0+K_0\rangle\oplus\langle 2J_{12}+\varepsilon(K_3-P_3),2J_{13}-\varepsilon(K_2-P_2),2J_{23}+\varepsilon(K_1-P_1)(\varepsilon=\pm 1)\rangle;$$

$$\langle P_0+K_0\rangle\oplus\langle 2J_{12}+\varepsilon(K_3-P_3),2J_{13}-\varepsilon(K_2-P_2),2J_{23}+\varepsilon(K_1-P_1)\rangle$$

$$\oplus\langle 2J_{12}-\varepsilon(K_3-P_3)\rangle(\varepsilon=\pm 1);$$

$$\langle P_0+K_0\rangle\oplus\langle K_1-P_1,K_2-P_2,K_3-P_3,J_{12},J_{13},J_{23}\rangle;$$

$$\langle P_0+K_0+2\alpha J_{12}\rangle(\alpha\neq 0,|\alpha|\neq 1);$$

$$\langle P_0+K_0+2\alpha J_{12}+\beta(K_3-P_3)\rangle(\alpha\neq 0,|\alpha|\neq 1,\beta\geqslant\alpha,\beta\neq 1);$$

$$\langle 2J_{12}+\alpha(P_0+K_0),K_3-P_3+\beta(P_0+K_0)\rangle(\alpha\neq 0,\beta\geqslant 0,\ \text{with}\ |\alpha|\neq 1\ \text{when}\ \beta=0);$$

$$\langle\alpha(P_0+K_0)+2\varepsilon J_{12}-K_3+P_3\rangle\oplus\langle 2\varepsilon J_{12}+K_3-P_3,2\varepsilon J_{13}-K_2+P_2,2\varepsilon J_{23}+K_1-P_1\rangle(\alpha\geqslant 0);$$

$$\langle 2\varepsilon J_{12}+K_3-P_3,2\varepsilon J_{13}-K_2+P_2,2\varepsilon J_{23}+K_1-P_1\rangle(\varepsilon=\pm 1);$$

$$\langle 2\varepsilon J_{12}+K_3-P_3,2\varepsilon J_{13}-K_2+P_2,2\varepsilon J_{23}+K_1-P_1\rangle\oplus\langle 2\varepsilon J_{12}-K_3+P_3\rangle(\varepsilon=\pm 1);$$

$$\langle K_1-P_1,K_2-P_2,K_3-P_3,J_{12},J_{13},J_{23}\rangle.$$

7. Subalgebras of $AO(1,2)\oplus AO(1,2)$

$$\langle P_1+K_1,P_2+K_2,J_{12}\rangle\oplus\langle K_0-P_0,K_3-P_3,J_{03}\rangle;$$

$$\langle P_1+K_1+2\varepsilon J_{03},P_2+K_2+K_0-P_0,2\varepsilon J_{12}+K_3-P_3\rangle(\varepsilon=\pm 1);$$

$$\langle P_1+K_1,P_2+K_2,J_{12}\rangle\oplus\langle K_3-P_3\rangle.$$

B. Subalgebras of $AG_1(2)$

The classical Galilei algebra $AG_1(2)$ is the semidirect sum of a solvable ideal, generated by $\langle P_1,P_2,M,T\rangle$, and the Euclidean algebra $AE(2)=\langle G_1,G_2,J_{12}\rangle$. The projection of $AG_1(2)$ onto $AO(1,3)$ coincides with $AE(2)$, which has, up to inner automorphisms, the subalgebras $0,\langle J_{12}\rangle,\langle G_1\rangle,\langle G_1,G_2\rangle,\langle G_1,G_2,J_{12}\rangle$. The first two subalgebras are completely reducible algebras of linear transformations of Minkowski space $\mathbf{R}_{1,3}$, whereas the others are not of this type. Thus we divide this class into two subclasses *A* and *B*.

1. Subalgebras with completely reducible projection onto $AO(1,3)$

$$0,\langle P_0\rangle,\langle P_1\rangle,\langle M\rangle,\langle P_0,P_3\rangle,\langle M,P_1\rangle,\langle P_1,P_2\rangle,\langle M,P_1,P_2\rangle,\langle P_0,P_1,P_2\rangle,$$

$$\langle P_1,P_2,P_3\rangle,\langle P_0,P_1,P_2,P_3\rangle;$$

$$\langle J_{12}\rangle:0,\langle P_0\rangle,\langle P_3\rangle,\langle M\rangle,\langle P_0,P_3\rangle,\langle P_1,P_2\rangle,\langle P_0,P_1,P_2\rangle,\langle M,P_1,P_2\rangle,$$

$$\langle P_1,P_2,P_3\rangle,\langle P_0,P_1,P_2,P_3\rangle;$$

$$\langle J_{12}+P_0\rangle:0,\langle P_3\rangle,\langle P_1,P_2\rangle,\langle P_1,P_2,P_3\rangle;$$

$$\langle J_{12}\pm P_3\rangle:0,\langle P_0\rangle,\langle P_1,P_2\rangle,\langle P_0,P_1,P_2\rangle;$$

$$\langle J_{12}\pm 2T\rangle:0,\langle M\rangle,\langle P_1,P_2\rangle,\langle M,P_1,P_2\rangle.$$

2. Subalgebras whose projection onto $AO(1,3)$ is not completely reducible

$$\langle G_1\rangle:\langle P_2\rangle,\langle M,P_1\rangle,\langle M,P_2\rangle,\langle M,P_1+\alpha P_2\rangle,\langle M,P_1,P_2\rangle,\langle P_0,P_1,P_3\rangle,$$

$$\langle P_0,P_1,P_2,P_3\rangle(\alpha\neq 0);$$

$$\langle G_1 \pm P_2\rangle : 0, \langle M\rangle, \langle M, P_1\rangle, \langle P_0, P_1, P_3\rangle;$$

$$\langle G_1 + 2T\rangle : 0, \langle P_2\rangle, \langle M\rangle, \langle M, P_1\rangle, \langle M, P_2\rangle, \langle M, P_1 + \alpha P_2\rangle (\alpha \neq 0), \langle M, P_1, P_2\rangle;$$

$$\langle G_1, G_2\rangle : \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1 + \varepsilon P_2, G_2 - \varepsilon P_1, M\rangle, \langle G_1 + \varepsilon P_2, G_2 - \varepsilon P_1 + \alpha P_2, M\rangle (\varepsilon = \pm 1, \alpha \neq 0);$$

$$\langle G_1 + \alpha P_2, G_2 + 2T, M, P_1\rangle (\alpha \in \mathbf{R});$$

$$\langle G_1 \pm P_2, G_2, M, P_1\rangle, \langle G_1, G_2 + 2T, M, P_1, P_2\rangle;$$

$$\langle G_1, G_2, J_{12}\rangle : \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1, G_2, J_{12} \pm 2T, M, P_1, P_2\rangle, \langle G_1 + \varepsilon P_2, G_2 - \varepsilon P_1, J_{12}, M\rangle (\varepsilon = \pm 1).$$

C. Subalgebras of $AG_1(2) \uplus \langle J_{03}\rangle$ with nonzero projection onto $\langle J_{03}\rangle$

We divide also this class into two subclasses which are distinguished by whether or not they have a completely reducible projection onto $AO(1,3)$.

1. Subalgebras with completely reducible projection onto $AO(1,3)$

$$\langle J_{03}\rangle : 0, \langle P_1\rangle, \langle M\rangle, \langle P_0, P_3\rangle, \langle M, P_1\rangle,$$
$$\langle P_1, P_2\rangle, \langle P_0, P_1, P_3\rangle, \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle J_{03} + P_1\rangle : 0, \langle P_2\rangle, \langle M\rangle, \langle P_0, P_3\rangle, \langle M, P_2\rangle, \langle P_0, P_2, P_3\rangle;$$

$$\langle J_{12} + \alpha J_{03}\rangle : 0, \langle M\rangle, \langle P_0, P_3\rangle, \langle P_1, P_2\rangle, \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle (\alpha \neq 0);$$

$$\langle J_{12}, J_{03}\rangle : 0, \langle M\rangle, \langle P_0, P_3\rangle, \langle P_1, P_2\rangle, \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle.$$

2. Subalgebras with projections onto $AO(1,3)$ which are not completely reducible

$$\langle G_1, J_{03}\rangle : 0, \langle M\rangle, \langle P_2\rangle, \langle M, P_1\rangle, \langle M, P_2\rangle, \langle M, P_1 + \alpha P_2\rangle (\alpha \neq 0),$$
$$\langle M, P_1, P_2\rangle, \langle P_0, P_1, P_3\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1, J_{03} + P_2\rangle : 0, \langle M\rangle, \langle M, P_1\rangle, \langle M, P_1 + \alpha P_2\rangle (\alpha \neq 0), \langle P_0, P_1, P_3\rangle;$$

$$\langle G_1, J_{03} + P_1\rangle : \langle M\rangle, \langle M, P_2\rangle;$$

$$\langle G_1, J_{03} + P_1 + \alpha P_2, M\rangle (\alpha \neq 0);$$

$$\langle G_1, G_2, J_{03}\rangle : 0, \langle M\rangle, \langle M, P_1\rangle, \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1, G_2, J_{03} + P_1, M\rangle, \langle G_1, G_2, J_{03} + P_2, M, P_1\rangle;$$

$$\langle G_1, G_2, J_{12} + \alpha J_{03}\rangle : 0, \langle M\rangle, \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle (\alpha \neq 0);$$

$$\langle G_1, G_2, J_{12}, J_{03}\rangle : 0, \langle M\rangle, \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle.$$

D. Subalgebras of $AP(1,3)$ which are not conjugate to subalgebras of $AG_1(2) \uplus \langle J_{03}\rangle$

This class consists of those subalgebras of the Poincaré algebra $AP(1,3)$ whose projection onto $AO(1,3)$ do not possess isotropic invariant subspaces in $\mathbf{R}_{1,3}$. Since the projections are simple algebras, then each subalgebra of the fourth class splits. The full list of such algebras is

$$AO(1,2):0,\langle P_3\rangle,\langle P_0,P_1,P_2\rangle,\langle P_0,P_1,P_2,P_3\rangle;$$

$$AO(3):0,\langle P_0\rangle,\langle P_1,P_2,P_3\rangle,\langle P_0,P_1,P_2,P_3\rangle;$$

$$AO(1,3):0,\langle P_0,P_1,P_2,P_3\rangle.$$

E. Subalgebras of $AG_1(2)\uplus\langle J_{03},D\rangle$ which are not conjugate to subalgebras of $AG_1(2)\uplus\langle J_{03}\rangle$

Let K be a subalgebra of $AG_1(2)\uplus\langle J_{03},D\rangle$ with nonzero projection onto $\langle D\rangle$, and let $\hat{\theta}$ be the projection of K onto $\langle J_{03},D\rangle$. By Propositions IV.2.3 and IV.2.5 in Ref. 9, the algebra K, as a subalgebra of $A\tilde{P}(1,3)$, is split whenever $\hat{\theta}(K)$ is one of the subalgebras 1) $\langle D\rangle$; 2) $\langle \gamma D - J_{03}\rangle$ $(\gamma\neq\pm 1,0,2)$; 3) $\langle D,J_{03}\rangle$. This leads us to dividing this class of subalgebras into two subclasses of nonsplittable subalgebras K of $A\tilde{P}(1,3)$, denoted by D and E, for which the projection onto $\langle G_1,G_2\rangle$ is non-zero, and for which $\hat{\theta}(K)$ is $\langle J_{03}\mp D\rangle$ and $\langle J_{03}-2D\rangle$ respectively. It is also useful to distinguish the subclass A of subalgebras having zero projection onto $\langle G_1,G_2\rangle$. The subalgebras in this subclass differ from the other subalgebras in that their projections onto $AO(1,3)$ are completely reducible algebras of linear transformations of Minkowski space $\mathbf{R}_{1,3}$. All the other subalgebras are split, and we divide them formally into subclasses B and C, depending on the dimension of their projection onto $\langle D,J_{03}\rangle$.

1. Subalgebras with zero projection on $\langle G_1,G_2\rangle$

$$\langle D\rangle:\langle P_0\rangle,\langle P_0,P_3\rangle,\langle P_0,P_1,P_2\rangle,\langle P_1,P_2,P_3\rangle,\langle P_0,P_1,P_2,P_3\rangle;$$

$$\langle J_{12}+\alpha D\rangle:\langle P_0\rangle,\langle P_3\rangle,\langle P_0,P_3\rangle,\langle P_0,P_1,P_2\rangle,\langle P_1,P_2,P_3\rangle,\langle P_0,P_1,P_2,P_3\rangle(\alpha>0);$$

$$\langle J_{12},D\rangle:\langle P_0\rangle,\langle P_3\rangle,\langle P_0,P_3\rangle,\langle P_0,P_1,P_2\rangle,\langle P_1,P_2,P_3\rangle,\langle P_0,P_1,P_2,P_3\rangle;$$

$$\langle G_1, G_2, J_{12}+\alpha J_{03}, D\rangle : \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle (\alpha\neq 0);$$

$$\langle G_1, G_2, J_{03}+\alpha D, J_{12}+\beta D, M, P_1, P_2\rangle (|\alpha|\leqslant 1, \beta\geqslant 0, |\alpha|+\beta\neq 0);$$

$$\langle G_1, G_2, J_{03}+\alpha D, J_{12}+\beta D, P_0, P_1, P_2, P_3\rangle (\alpha^2+\beta^2\neq 0);$$

$$\langle G_1, G_2, J_{03}, J_{12}, D\rangle : \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle.$$

3. Split subalgebras with one-dimensional projection onto $\langle J_{03}, D\rangle$ and nonzero projection onto $\langle G_1, G_2\rangle$

$$\langle G_1+D\rangle : \langle P_0, P_1, P_3\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1, D\rangle : \langle P_0, P_1, P_3\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1+D, G_2, P_0, P_1, P_2, P_3\rangle \langle G_1, G_2, D, P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1, J_{03}+\alpha D\rangle : \langle P_2\rangle, \langle M, P_1\rangle, \langle M, P_2\rangle, \langle M, P_1+\beta P_2\rangle (|\alpha|\leqslant 1, \alpha\neq 0, \beta\neq 0);$$

$$\langle G_1, J_{03}+\alpha D\rangle : \langle M, P_1, P_2\rangle, \langle P_0, P_1, P_3\rangle, \langle P_0, P_1, P_2, P_3\rangle (\alpha\neq 0);$$

$$\langle G_1, G_2, J_{03}+\alpha D, M, P_1, P_2\rangle (0<|\alpha|\leqslant 1);$$

$$\langle G_1, G_2, J_{03}+\alpha D, P_0, P_1, P_2, P_3\rangle (\alpha\neq 0);$$

$$\langle G_1, G_2, J_{12}+\alpha D, P_0, P_1, P_2, P_3\rangle (\alpha\neq 0);$$

$$\langle G_1, G_2, J_{12}, D, P_0, P_1, P_2, P_3\rangle;$$

$$\langle G_1, G_2, J_{12}+\alpha J_{03}+\beta D, M, P_1, P_2\rangle (0<|\alpha|\leqslant|\beta|);$$

$$\langle G_1, G_2, J_{12}+\alpha J_{03}+\beta D, P_0, P_1, P_2, P_3\rangle (\beta\neq 0).$$

4. Nonsplit subalgebras of $AG_1(2)\uplus\langle J_{03}\mp D\rangle$ with nonzero projection onto $\langle G_1, G_2\rangle$ and $\langle J_{03}\mp D\rangle$

$$\langle J_{03}-D, G_1\pm P_2\rangle : 0, \langle M\rangle, \langle M, P_1\rangle, \langle P_0, P_1, P_3\rangle;$$

$$\langle J_{03}-D\pm 2T, G_1+\alpha P_2, M, P_1\rangle;$$

$$\langle J_{03}-D\pm 2T, G_1, M, P_1, P_2\rangle, \langle J_{03}+D+M, G_1, P_2\rangle;$$

$$\langle J_{03}-D, G_1+\epsilon P_2, G_2-\epsilon P_1+\alpha P_2, M\rangle (\epsilon=\pm 1, \alpha\in\mathbf{R});$$

$$\langle J_{03}-D, G_1\pm P_2, G_2, M, P_1\rangle \langle J_{03}-D\pm 2T, G_1, G_2, P_1, P_2, M\rangle;$$

$$\langle J_{12}+\alpha(J_{03}-D), G_1+\epsilon P_2, G_2-\epsilon P_1, M\rangle (\epsilon=\pm 1, \alpha\neq 0);$$

$$\langle J_{12}+\alpha(J_{03}-D\pm 2T), G_1, G_2, M, P_1, P_2\rangle (\alpha\neq 0);$$

$$\langle J_{12}\pm 2T, J_{03}-D, G_1, G_2, M, P_1, P_2\rangle;$$

$$\langle J_{12}+2\alpha T, J_{03}-D\pm 2T, G_1, G_2, M, P_1, P_2\rangle (\alpha\in\mathbf{R});$$

$$\langle J_{12}, J_{03}-D, G_1+\epsilon P_2, G_2-\epsilon P_1, M\rangle (\epsilon=\pm 1).$$

5. Nonsplit subalgebras of $AG_1(2)\uplus\langle J_{03}-2D\rangle$ with nonzero projection onto $\langle G_1, G_2\rangle$ and $\langle J_{03}-2D\rangle$

$$\langle J_{03}-2D, G_1+2T\rangle : 0, \langle M\rangle, \langle P_2\rangle, \langle M, P_1\rangle, \langle M, P_2\rangle, \langle M, P_1+\alpha P_2\rangle, \langle M, P_1, P_2\rangle (\alpha\neq 0);$$

$$\langle J_{03}-2D, G_1, G_2+2T\rangle : \langle M, P_1\rangle, \langle M, P_1, P_2\rangle.$$

F. Subalgebras of $A\tilde{P}(1,3)$ not conjugate to subalgebras of $AP(1,3)$ and of $AG_1(2)\uplus\langle J_{03}, D\rangle$

This class consists of those subalgebras of $AP(1,3)$ whose projection onto $AO(1,3)$ do not have invariant isotropic subspaces in $\mathbf{R}_{1,3,}$ and with a nonzero projection onto $\langle D\rangle$. We have

$$AO(1,2)\oplus\langle D\rangle : 0, \langle P_3\rangle, \langle P_0, P_1, P_2\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$AO(3)\oplus\langle D\rangle : 0, \langle P_0\rangle, \langle P_1, P_2, P_3\rangle, \langle P_0, P_1, P_2, P_3\rangle;$$

$$AO(1,3)\oplus\langle D\rangle : 0, \langle P_0, P_1, P_2, P_3\rangle.$$

G. Subalgebras of $AG_4(2)$ which are not conjugate to subalgebras of $A\tilde{P}(1,3)$

Let K be a subalgebra of $AG_4(2)$ and $\tau(K)$ its projection onto $AGL(2,\mathbf{R})$. By Propositions V.2.1 and V.2.2 of Ref. 9, the algebra K belongs to this class if and only if $\tau(K)$ is conjugate to one of the following algebras: $\langle S+T\rangle$, $\langle S+T\rangle+\langle Z\rangle$ (subdirect sum), $ASL(2,\mathbf{R})=\langle R,S,T\rangle$, $AGL(2,\mathbf{R})=\langle R,S,T,Z\rangle$. Because of this, we divide this seventh class into three subclasses, each of which consists of subalgebras having a corresponding projection onto $AGL(2,\mathbf{R})$; those subalgebras whose projections are either $ASL(2,\mathbf{R})$ or $AGL(2,\mathbf{R})$ are put into the same subclass.

1. Subalgebras whose projection onto $AGL(2,R)$ is $\langle S+T\rangle$

$$\langle S+T\rangle : 0, \langle M\rangle, \langle G_1, P_1, M\rangle, \langle G_1-\alpha^{-1}P_2, G_2+\alpha P_1, M\rangle, \langle G_1, G_2, P_1, P_2, M\rangle (0<|\alpha|\leqslant 1);$$

$$\langle S+T\pm M\rangle, \langle S+T+\alpha J_{12}\pm M\rangle (\alpha\neq 0);$$

$$\langle S+T+\alpha J_{12}\rangle : 0, \langle M\rangle, \langle G_1+\epsilon P_2, G_2-\epsilon P_1, M\rangle, \langle G_1, G_2, P_1, P_2, M\rangle (\epsilon=\pm 1, \alpha\neq 0);$$

$$\langle S+T+\epsilon J_{12}\rangle : \langle G_1+\epsilon P_2\rangle, \langle G_1+\epsilon P_2, M\rangle, \langle G_1+\epsilon P_2, G_1-\epsilon P_2, G_2+\epsilon P_1, M\rangle (\epsilon=\pm 1);$$

$$\langle S+T+\epsilon J_{12}\pm M, G_1+\epsilon P_2\rangle (\epsilon=\pm 1);$$

$$\langle S+T+\epsilon J_{12}+\epsilon G_1+P_2\rangle : 0, \langle M\rangle, \langle G_2-\epsilon P_1, M\rangle,$$

$$\langle G_1-\epsilon P_2, G_2+\epsilon P_1, M\rangle \langle G_2-\epsilon P_1, G_1-\epsilon P_2, G_2+\epsilon P_1, M\rangle (\epsilon=\pm 1);$$

$$\langle J_{12}, S+T\rangle : 0, \langle M\rangle, \langle G_1+\epsilon P_2, G_2-\epsilon P_1, M\rangle, \langle G_1, G_2, P_1, P_2, M\rangle (\epsilon=\pm 1);$$

$$\langle J_{12}\pm M, S+T+\alpha M\rangle(\alpha\in\mathbf{R});$$

$$\langle J_{12}, S+T\pm M\rangle.$$

2. Subalgebras whose projection onto $AGL(2,\mathbf{R})$ is the subdirect sum $\langle S+T\rangle+\langle Z\rangle$

$$\langle S+T+\alpha Z\rangle:0,\langle M\rangle,\langle G_1,P_1,M\rangle,\langle G_1-\beta^{-1}P_2,G_2+\beta P_1,M\rangle,$$

$$\langle G_1,G_2,P_1,P_2,M\rangle(0<|\beta|\leqslant 1,\alpha\neq 0);$$

$$\langle S+T,Z\rangle:0,\langle M\rangle,\langle G_1,P_1,M\rangle,\langle G_1-\alpha^{-1}P_2,G_2+\alpha P_1,M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle(0<|\alpha|\leqslant 1);$$

$$\langle S+T+\alpha J_{12}+\beta Z\rangle:0,\langle M\rangle,\langle G_1+\epsilon P_2,G_2-\epsilon P_1,M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle(\epsilon=\pm 1,\alpha\neq 0,\beta>0);$$

$$\langle S+T+\alpha J_{12},Z\rangle:0,\langle M\rangle,\langle G_1+\epsilon P_2,G_2-\epsilon P_1,M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle(\epsilon=\pm 1,\alpha\neq 0);$$

$$\langle S+T+\epsilon J_{12}+\alpha Z\rangle:\langle G_1+\epsilon P_2\rangle,\langle G_1+\epsilon P_2,M\rangle,$$

$$\langle G_1+\epsilon P_2,G_1-\epsilon P_2,G_2+\epsilon P_1,M\rangle(\epsilon=\pm 1,\alpha\neq 0);$$

$$\langle S+T+\epsilon J_{12},Z\rangle:\langle G_1+\epsilon P_2\rangle,\langle G_1+\epsilon P_2,M\rangle,\langle G_1+\epsilon P_2,G_1-\epsilon P_2,G_2+\epsilon P_1,M\rangle(\epsilon=\pm 1);$$

$$\langle J_{12}+\alpha Z,S+T+\beta Z\rangle:0,\langle M\rangle,\langle G_1+\epsilon P_2,G_2-\epsilon P_1,M\rangle,$$

$$\langle G_1,G_2,P_1,P_2,M\rangle(\epsilon=\pm 1,|\alpha|+|\beta|\neq 0);$$

$$\langle J_{12},S+T,Z\rangle:0,\langle M\rangle,\langle G_1+\epsilon P_2,G_2-\epsilon P_1,M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle(\epsilon=\pm 1).$$

3. Subalgebras whose projection onto $AGL(2,\mathbf{R})$ contains $ASL(2,\mathbf{R})$

$$\langle R,S,T\rangle:0,\langle M\rangle,\langle G_1,P_1,M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle;$$

$$\langle J_{12}\rangle\oplus\langle R,S,T\rangle:0,\langle M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle;$$

$$\langle J_{12}\pm M\rangle\oplus\langle R,S,T\rangle;$$

$$\langle R,S,T,Z\rangle:0,\langle M\rangle,\langle G_1,P_1,M\rangle,\langle G_1,G_2,P_1,P_2M\rangle;$$

$$\langle R,S,T\rangle\oplus\langle J_{12}+\alpha Z\rangle:0,\langle M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle(\alpha\neq 0);$$

$$\langle R,S,T\rangle\oplus\langle J_{12},Z\rangle:0,\langle M\rangle,\langle G_1,G_2,P_1,P_2,M\rangle.$$

ACKNOWLEDGMENTS

This work was supported in part by INTAS and DKNT of Ukraine. P. Basarab-Horwath thanks the Wallenberg fund of Linköping University and the Magnusson Fund of the Swedish Academy of Sciences for travel grants, and the Mathematics Institute of the Ukrainian Academy of Sciences in Kyïv for its hospitality.

Professor Wilhelm Fuschych died on April 7, 1997, after a short illness. This is a great loss for his family, his many students, and for the scientific community. His many and deep contributions to the field of symmetry analysis of differential equations have made the Kyïv school of symmetries known throughout the world. We take this opportunity to express our deep sense of loss as well as our gratitude for all the encouragement in research that Wilhelm Fushchych gave during the years we knew him.

Quommutator deformations of spl(N,1)

Y. Brihaye
Department of Mathematical Physics, University of Mons, Av. Maistriau, B-7000 Mons, Belgium

(Received 22 August 1997; accepted for publication 23 April 1998)

We analyze the Witten-Woronowicz's type deformations of the Lie superalgebras spl(N,1) and obtain deformations parametrized by $N(N-1)/2$ independent parameters for $N>2$ and by three parameters for $N=2$. For some of these algebras, finite dimensional representations can be constructed in terms of finite difference operators, providing operators that are relevant for the classification of quasiexactly solvable, finite difference equations. © *1998 American Institute of Physics.* [S0022-2488(98)03207-1]

I. INTRODUCTION

The study of deformations of classical Lie algebras has attracted much attention in the last few years. Many types of deformations have been proposed. In some of them, the commutators of the generators are set equal to nonlinear (in fact transcendental) functions of some of the generators; they are the Drinfeld–Jimbo deformations.[1,2] Other types of deformations consist in keeping the right-hand sides of the structure relations linear in the generators while the commutators of the left-hand side are deformed into quommutators, such deformations are called Witten–Woronowicz type.[3,4] In this second approach, all the generators are treated on the same footing and the quommutator relations provide normal ordering rules which allow one to write the elements of the enveloping algebra in a canonical form. This last property is useful for the kind of applications that we have in mind, namely the study of the quasiexactly solvable (QES), finite difference operators. The QES (differential or finite difference) equations refer to a class of spectral equations for which a finite part of the spectrum can be obtained by solving a system of algebraic equations.[5,6] In this respect, the linear operators which preserve a finite dimensional vector space of smooth functions are naturally related to QES equations; such operators are also called quasiexactly solvable. The invariant space is typically a direct sum of modules of polynomials of given degrees.

The observation that QES operators possess hidden algebras[5,6] and that they can be related to some abstract algebras has motivated several tentatives to classify these operators and to study their properties in more detail (see Refs. 7 and 8 for recent reviews). The scalar QES operators of one variable, preserving the vector space of polynomials of degree at most n, are related to the enveloping algebra of the Lie algebra sl(2).[9] Choosing, more generically, V as a direct sum of modules of polynomials, it is likely[10–14] that a finite number of basic QES operators can be put in correspondence with the generators of an abstract algebra, suitably represented in terms of differential operators. The more general QES operators can then be obtained as the polynomials in the basic operators, in other words they are the elements of an enveloping algebra.

The present understanding of QES equations suggests that the scalar QES equations are related to the classical Lie algebras[10,11] while the systems of coupled QES equations are related to superalgebras.[10,12,14] For instance, the superalgebra osp(2,2) [or equivalently spl(2,1)] plays a crucial role[10,12] for the systems of two equations of one variable. In the case of systems of two equations of V variables, the underlying symmetry is related to the superalgebras spl($V+1$,1).[14]

On the other hand it seems that, if we want to describe the algebraic structure underlying the QES finite difference equations, the representations of some deformed algebra emerge in a natural way. For instance, the scalar, finite difference QES operators in one variable[9] are related to the Witten deformation of sl(2). Owing to this example and the results of Ref. 14 it is natural to try to classify the deformations of Witten–Woronowicz type of the Lie superalgebras spl(N,1). This is the object of this paper; Drinfeld–Jimbo type deformations of general Lie superalgebras are discussed in Ref. 15.

II. THE ALGEBRA spl(N,1)

The graded Lie algebra spl(N,1) is generated by N^2 bosonic generators, N fermionic and N antifermionic generators. We will denote them, respectively, by E_a^b, V_a and $\overline{V^a}$, $a,b=1,...,N$. The structure relations read as follows:

$$\{V_a, V_b\}=0, \tag{1}$$

$$\{\overline{V^a}, \overline{V^b}\}=0, \tag{2}$$

$$\{V_a, \overline{V^b}\}=E_a^b, \tag{3}$$

$$[E_a^b, V_c]=\delta_c^b V_a-\delta_a^b V_c, \tag{4}$$

$$[E_a^b, \overline{V^c}]=\delta_a^b \overline{V^c}-\delta_a^c \overline{V^b}, \tag{5}$$

$$[E_a^b, E_c^d]=\delta_c^b E_a^d-\delta_a^d E_c^b. \tag{6}$$

As indicated in (6), the generators E_a^b form a gl(N) subalgebra. Equations (4) [resp. (5)] show that the generators V_a's (resp. $\overline{V^b}$) form an N-dimensional representation of gl(N) under the adjoint action of the E_a^b.

We will consider the deformations of spl(N,1) obtained by replacing the commutators (4)–(6) and the anticommutators (1)–(3) respectively, by quommutators and antiquommutators:

$$[A,B]_q=AB-qBA, \quad \{A,B\}_q=AB+qBA, \tag{7}$$

where q represents a parameter of deformation. More specifically, we classify the deformations obeying the following conditions:

(i) Each commutator (resp. antiquommutator) (1)–(6) defining the classical algebra is replaced by a quommutator (resp. antiquommutator) (7) with its own parameter q.
(ii) The couples of generators which (anti-) commute are imposed to (anti-) quommute.
(iii) The right hand side of (3)–(5) is kept linear in the generators; on the right-hand side of (6) we allow additional terms of the form $V_f \overline{V^g}$.

III. DEFORMATIONS OF spl(N,1)

In order to present the deformations of spl(N,1) it is convenient to introduce a set of $N(N-1)/2$ arbitrary parameters labeled q_{ab} such that

$$q_{ba}=\frac{1}{q_{ab}}, \quad a,b=1,\ldots,N. \tag{8}$$

The deformations of spl(N,1) obeying the conditions above and compatible with the associativity conditions (i.e., the Jacobi identities) read as follows:

$$V_a V_b+q_{ab}V_b V_a=0, \tag{9}$$

$$\overline{V^a}\,\overline{V^b}+q_{ab}\overline{V^b}\,\overline{V^a}=0, \tag{10}$$

$$V_a \overline{V^b}+q_{ba}\overline{V^b}V_a=E_a^b, \tag{11}$$

$$E_a^b V_c-q_{ac}q_{cb}V_c E_a^b=\delta_c^b V_a-\delta_a^b V_c, \tag{12}$$

$$E_a^b \overline{V^c}-q_{bc}q_{ca}\overline{V^c}E_a^b=\delta_a^b \overline{V^c}-q_{ba}\delta_a^c \overline{V_b}, \tag{13}$$

$$E_a^b E_c^d-q_{ac}q_{cb}q_{bd}q_{da}E_c^d E_a^b=\delta_b^c E_a^d-q_{ba}q_{ac}q_{cb}\delta_a^d E_c^b. \tag{14}$$

The normalization of the generators has been chosen in such a way that the right-hand sides of (11) and (12) look as simple as possible. The bosonic generators close under the quommutators (14), leading to a deformation of the Lie algebra gl(N). It can be checked that the products of three and of four q's defining the structure constants in (14) depend effectively on $(N-1)(N-2)/2$ parameters among the whole set of the $N(N-1)/2$ parameters q_{ab}. In fact, the algebra (14) coincides with the deformation of gl(N) constructed in Ref. 16. It is amusing to note that the parameters q_{ab}, used to label the deformations in Ref. 16, appear here as defining the antiquommutators (9) and (10) of the fermionic operators. Note, however, that another quommutator is used in Ref. 16, it can be related to (14) by an appropriate renormalization of the generators.

IV. DEFORMATIONS OF spl(2,1)

The analysis of Ref. 16 reveals that the algebra gl(2) leads to a richer set of deformations than for the generic case gl(N) for $N>2$. A similar result holds for the deformations of spl(N,1). We now discuss the deformations of spl(2,1) which, remember, is equivalent to the (perhaps more popular) graded Lie algebra osp(2,2).

The most general deformation of spl(2,1) obeying the three restrictions above and compatible with associativity depends on three parameters, say p,r,s.

The different relations read as follows.

(1) For the fermionic–fermionic relations,

$$V_1V_1=V_2V_2=0, \quad \overline{V}^1\overline{V}^1=\overline{V}^2\overline{V}^2=0, \tag{15}$$

$$\{V_1,V_2\}_{(p/sr)}=0, \quad \{\overline{V}^1,\overline{V}^2\}_{(s/pr)}=0, \tag{16}$$

$$\{\overline{V}^j,V_j\}=E_j^j, \quad j=1,2, \tag{17}$$

$$\{\overline{V}^1,V_2\}_{psr}=E_2^1, \quad \{\overline{V}^2,V_1\}_{(ps/r)}=E_1^2. \tag{18}$$

(2) For the fermionic–bosonic relations,

$$\begin{gathered}
[E_1^1,V_1]=0, \quad [E_2^2,V_1]_{s^2}=V_1, \\
[E_1^2,V_1]_{ps/r}=0, \quad [E_2^1,V_1]_{sr/p}=-\frac{sr}{p}V_2, \\
[E_1^1,V_2]_{p^2}=V_2, \quad [E_2^2,V_2]=0, \\
[E_1^2,V_2]_{p/sr}=-\frac{p}{sr}V_1, \quad [E_2^1,V_2]_{psr}=0,
\end{gathered} \tag{19}$$

$$\begin{gathered}
[E_1^1,\overline{V}^1]=0, \quad [E_2^2,\overline{V}^1]_{1/s^2}=-\frac{1}{s^2}\overline{V}^1, \\
[E_1^2,\overline{V}^1]_{ps/r}=\overline{V}^2, \quad [E_2^2,\overline{V}^1]_{1/psr}=0, \\
[E_1^1,\overline{V}^2]_{1/p^2}=-\frac{1}{p^2}\overline{V}^2, \quad [E_2^2,\overline{V}^2]=0, \\
[E_1^2,\overline{V}^2]_{r/ps}=0, \quad [E_2^1,\overline{V}^2]_{s/pr}=\overline{V}^1.
\end{gathered} \tag{20}$$

(3) For the bosonic–bosonic operators,

$$[E_1^1,E_2^2]=0, \tag{21}$$

$$[E_1^1,E_1^2]_{1/p^2}=-\frac{1}{p^2}E_1^2,\quad [E_2^2,E_1^2]_{s^2}=E_1^2, \tag{22}$$

$$[E_1^1,E_2^1]_{p^2}=E_2^1,\quad [E_1^1,E_2^1]_{1/s^2}=-\frac{1}{s^2}E_2^1, \tag{23}$$

$$[E_1^2,E_2^1]_{s^2/p^2}=E_1^1-\frac{s^2}{p^2}E_2^2+(s^2-1)V_1\overline{V^1}-\frac{s^2}{p^2}(p^2-1)V_2\overline{V^2}. \tag{24}$$

The three parameters of the deformation, noted p,r,s, are intrinsic and cannot be eliminated by a rescaling of the generators. This is seen easily from the way these parameters enter in the different coefficients defining the quommutator. The undeformed osp(2,2) algebra is recovered by $p=s=r=1$. In the limit $s^2=p^2=1$, the generic case of the previous section is recovered: There is only one deforming parameter, noted r. The gl(2) subalgebra is undeformed.

Keeping r,s,p arbitrary and decoupling the fermionic generators from Eq. (24) leads, together with (21), (22) and (23), to the two parameter deformation of gl(2) obtained in Ref. 17 (a four-parameter deformation of gl(2) was further obtained in Ref. 16).

V. REPRESENTATIONS

Restricting the three parameters p,r,s in the algebra presented in Sec. IV to the case

$$p=s^{-1}=q^{1/2},\quad r=1 \tag{25}$$

leads to a one parameter deformation of osp(2,2) parametrized by q which we will refer to as $\mathrm{osp}(2,2)_q$. The following operator q-commutes with the eight generators of the algebra

$$C=V_1\overline{V^1}-qV_2\overline{V^2}-q^2E_2^1E_1^2+qE_1^1E_2^2-E_1^1. \tag{26}$$

As for the Witten type deformation of sl(2),[9] it is possible to construct some representations of $\mathrm{osp}(2,2)_q$ in terms of a finite difference operator D_q:

$$D_qf(x)=\frac{f(x)-f(qx)}{(1-q)x},\quad D_qx^n=[n]_qx^{n-1},\quad [n]_q\equiv\frac{1-q^n}{1-q}. \tag{27}$$

The representations we want to discuss act on the vector space $P(n-1)\oplus P(n)$ [where $P(n)$ denotes the module of polynomials of degree n in the variable x]. It is therefore of dimension $2n-1$. The fermionic generators are represented by

$$\begin{gathered} V_1=\sigma_-,\quad V_2=x\sigma_-,\\ \overline{V_1}=q^{-n}(xD_q-[n]_q)\sigma_+,\quad \overline{V_2}=q^{-1}D_q\sigma_+, \end{gathered} \tag{28}$$

where $\sigma_\pm=(\sigma_1\pm i\sigma_2)/2$. The operators E_j^i are easily constructed with (16) and (17). It appears that the operator (26) vanishes for these representations.

Since the representations above are irreducible, all 2×2 matrix finite difference operators preserving $P(n-1)\oplus P(n)$ are elements of the enveloping algebra generated by (28).[7] These operators are therefore quasiexactly solvable.

VI. DEFORMATIONS OF osp(1,2)

Recently, a Witten type deformation of the super Lie algebra osp(1,2) was constructed.[18] We showed that this deformation is the only one to fulfill the three requirements of Sec. II, its finite dimensional representations can be expressed in terms of the operator (27). Again, the space of the representation is $P(n-1)\oplus P(n)$ and the two fermionic generators of osp(1,2) are represented by 2×2 matrix operators. Using exactly the same notation as in Ref. 18 we find

$$V_- = \begin{pmatrix} 0 & D_{q^2} \\ 1 & 0 \end{pmatrix}, \quad V_+ = \begin{pmatrix} 0 & q^{-2n}(xD_{q^2} - [n]_{q^2}) \\ x & 0 \end{pmatrix}. \tag{29}$$

The three bosonic operators, H, J_-, J_+ can then be computed through the structure of osp(1,2), namely,

$$H = \{V_-, V_+\}_q, \quad J_- = \{V_-, V_-\}_q, \quad J_+ = \{V_+, V_+\}_q. \tag{30}$$

Correspondingly, the Casimir operator [Eq. (13) in Ref. 18] has a value $C = -\frac{1}{2}[-n-\frac{1}{2}]_{q^2}$.

VII. CONCLUDING REMARKS

The representations of spl(V+1,1) formulated in terms of differential operators provide the building blocks for the construction of the QES operators preserving more general polynomial spaces of V variables.[14] This result, and the fact that the quommutators deformations of super Lie algebras have not been studied systematically (at least to our knowledge), motivate a study of the deformations of the Lie superalgebras spl(N,1) by means of quommutators.

On the other hand, the most interesting examples of QES systems (e.g., the relativistic Coulomb problem,[19] the doubly periodic Lame equation and the stability of the sphaleron in the Abelian Higgs model[12]) are related to the algebra osp(2,2). Generalizations of this algebra, e.g., its deformations, and the corresponding realizations in terms of finite difference operators therefore deserve some attention. The operators (28) could be relevant for the study of some coupled problems arising in discrete quantum mechanics in Ref. 20.

On a more abstract level we mention that the operators (28) can be used to construct finite difference operators preserving the vector space $P(m) \oplus P(n)$. The algebraic structure underlying these operators is probably determined by a series of deformed, nonlinear superalgebras indexed by $|m-n|$. Finally, it would be interesting to relate the two-parameter deformation of osp(2,2) of Ref. 21 with our deformation. The occurrence of some mapping between the two structures would allow us to transport the Hopf structure to our case.

On an easy transition from operator dynamics to generating functionals by Clifford algebras

Bertfried Fauser[a)]
Eberhard-Karls-Universität, Institut für Theoretische Physik, Auf der Morgenstelle 14, 72072 Tübingen, Germany

(Received 22 December 1997; accepted for publication 14 April 1998)

Clifford geometric algebras of multivectors are treated in detail. These algebras are built over a graded space and exhibit a grading or multivector structure. The careful study of the endomorphisms of this space makes it clear that opposite Clifford algebras have to be used for obtaining all endomorphisms. Based on these mathematics, we give a fully Clifford algebraic account on generating functionals, which is thereby geometric. The field operators are shown to be Clifford and opposite Clifford maps. This picture, relying on geometry, does not need positivity in principle. Furthermore, we propose a transition from operator dynamics to generating functionals, which is based on the algebraic techniques. As a calculational benefit, this transition is considerably short compared to standard ones. The transition is not injective (unique) and depends additionally on the choice of an ordering. We obtain a direct and constructive connection between orderings and the explicit form of the functional Hamiltonian. These orderings depend on the propagator of the theory and thus on the ground state. This is invisible in path integral formulations. The method is demonstrated within two examples, a nonlinear spinor field theory and spinor QED. Antisymmetrized and normal-ordered functional equations are derived in both cases. © *1998 American Institute of Physics.* [S0022-2488(98)02207-5]

I. INTRODUCTION

Modern quantum field theory is treated currently by means of path integrals.[1,2] Path integrals provide formal solutions of functional differential equations. Such functional differential equations encode the matrix element hierarchies of Dyson–Schwinger–Freese.[3–6] Generating functionals describe in a condensed form an infinite set of vacuum or transition matrix elements with a single mathematical entity. They prove to be useful in manipulations of the whole hierarchy.

Since path integrals are very compact in their formulation, one does not actually have an access to their meaning. Moreover, one is troubled with convergence problems, which can be treated up to now only by heuristic methods or in trivial cases; see chapter 6 of Ref. 2.

It seems therefore to be a good idea to study generating functionals and functional differential equations in their own right. Furthermore, it is known from ordinary differential equations that one can achieve information about the solutions without being able to integrate the differential equations. We expect to be able to support the usage of path integrals, at least their algebraic properties, in studying operator dynamics with the help of functional differential equations.

The connection between Lie groups and spin groups was established in Ref. 7, where the authors employed the bi-vector space, which is closed under the commutator product. To be able to treat nonlinear Hamiltonians (see the examples) we extend the mechanism to the whole graded space, which turns all algebra elements into Lie group elements.

The paper is organized in three logical parts. First, in section II, we establish the mathematical apparatus necessary to treat generating functionals algebraically correct. This will be done in the case of antisymmetry (fermions), but might be equally well established for symmetric algebras (bosons); see Ref. 8. This part is mathematically rigorous.

In the second part, consisting of sections III and IV, the infinite dimensional case of QFT is treated formally, since the transition to infinite many generators causes serious convergence prob-

lems. We give an algebraic account on generating functionals based on the Clifford algebra of multivectors. Field operators are shown to be Clifford endomorphisms of the graded space underlying the Grassmann algebra built over the Schwinger sources. This opens for the first time an algebraically motivated approach to quantum field theoretic functionals. In section IV we use the Heisenberg equation to give a very simple transition from operator dynamics into the space of generating functionals. Once more, this can be achieved only if one admits the Clifford geometric point of view. A single operator dynamics might result in different functional equations. This peculiar observation is an essential insight to understanding the computational power of functional differential equations and path integrals. The different functional equations obtained are subjected to different orderings and ultimately to different vacua. The correct choice of this ordering by means of normal-ordering with the help of a specific propagator selects a unique vacuum encoded implicitly in the theory, as was shown in Ref. 9. The Clifford geometric approach given in this paper makes it possible to investigate these connections and to have a constructive tool to implement inequivalent vacua in QFT.

In the third part, sections V and VI, examples of the method are given. A nonlinear spinor field theory, e.g., a Hubbard or Nambu–Jona-Lasinio type model, and spinor QED as an example of a boson-fermion coupling theory are treated. Both examples are dealt with in the antisymmetric and normal-ordered case. Explicit calculations of the functional equations shows furthermore the efficiency of our method. The usually necessary vertex-regularization is no longer apparent, since the algebraic treatment accounts for this transition correctly. This was know earlier on the operator level.[10] It is novel that one can achieve the normal-ordered functional equation in one single step.

In the conclusion the results are summarized and the relevance to path integral calculations is discussed.

II. CLIFFORD GEOMETRIC ALGEBRA OF MULTIVECTORS

There are many possibilities to introduce Clifford algebras, each of them emphasize a different point of view. In our case, it is of utmost importance to have the Clifford algebra built over a graded linear space. This grading is obtained from the space underlying a Grassmann algebra. The Clifford algebra is then related to the endomorphism algebra of this space. This construction, the Chevalley deformation,[11] was originally invented to be able to treat Clifford algebras over fields of $char=2$; see the appendix of Ref. 12 by Lounesto and Ref. 13. However, we use this construction in an entirely different context. With the help of the construction of Riesz,[12] one is able to reconstruct the multivector structure and thereby a correspondence between the linear spaces underlying the Clifford algebra and the Grassmann algebra in use. This reconstruction depends on an automorphism J, which is arbitrary; see Ref. 14. In fact this is just the reversed direction of our construction following Chevalley given below.

Let $T(V)$ be the tensor algebra built over the $\mathbb{K}$-linear space V. The field $\mathbb{K}$ will be either $\mathbb{R}$ or $\mathbb{C}$. With $V^0 \simeq \mathbb{K}$ we have

$$T(V)=\mathbb{K}\oplus V\oplus V\otimes_{\mathbb{K}} V\oplus\cdots . \tag{2.1}$$

The tensor algebra is associative and unital. In $T(V)$ one has bilateral or two-sided ideals, which can be used to construct new algebras by factorization. As an example we define the Grassmann algebra in this way.

Definition 1: The Grassmann algebra $\bigwedge(V)$ is the factor algebra of the tensor algebra w.r.t. the bilateral ideal

$$\begin{aligned} I_{Gr}&=\{y\,|\,y=a\otimes x\otimes x\otimes b,\quad a,b\in T(V),x\in V\}\\ \bigwedge(V)&=\pi(T(V))=\frac{T(V)}{I_{Gr}}=\mathbb{K}\oplus V\oplus V\wedge V\oplus\cdots . \end{aligned} \tag{2.2}$$

The canonical projection π: $T(V)\mapsto\bigwedge(V)$ maps the tensor product $\otimes$ onto the exterior or wedge product denoted by $\wedge$. ■

One may note that the factorization preserves the grading naturally inherited by the tensor algebra, since the ideal I_{Gr} is homogeneous. Defining homogeneous parts of $T(V)$ and $\wedge(V)$ by $T^k(V)=V\otimes\cdots\otimes V$ and $\wedge^k(V)=V\wedge\cdots\wedge V$ k-factors, we obtain $\pi(T^k(V))=\wedge^k(V)$.

Proceeding to Clifford algebras requires a further structure, the quadratic form.

Definition 2: The map $Q:V\mapsto\mathbb{K}$, satisfying

$$\text{(i)}\quad Q(\alpha x)=\alpha^2 Q(x),\quad \alpha\in\mathbb{K},x\in V,$$

$$\text{(ii)}\quad B_p(x,y)=\tfrac{1}{2}\,(Q(x+y)-Q(x)-Q(y)), \tag{2.3}$$

where $B_p(x,y)$ is a symmetric bilinear form, is called a quadratic form. ■

It is tempting to introduce an ideal I_{Cl},

$$I_{Cl}=\{y|y=a\otimes(x\otimes x-Q(x)\mathbb{1})\otimes b,\quad a,b\in T(V),x\in V\}, \tag{2.4}$$

to obtain the Clifford algebra by a factorization procedure. However, since we are interested in arbitrary bilinear forms underlying a Clifford algebra, we will take another approach, which is wide enough for such a structure. Furthermore, the Clifford algebra does not have an intrinsic multivector structure, but is only $\mathbb{Z}_2$ graded, since the ideal I_{Cl} is inhomogeneous but $\mathbb{Z}_2$ graded.

Let V^* be the space of linear forms on V, i.e., $V^*\simeq\text{lin}[V,\mathbb{K}]$. Elements $\omega\in V^*$ act on elements $x\in V$; but there is no natural connection between V and V^*. However, we can find a set of x_i which span V and dual elements ω_k acting on the x_i in a canonical way,

$$\omega_k(x_i)=\delta_{ki}\,. \tag{2.5}$$

This allows us to introduce a map $*$: $V\mapsto V^*$, $x_i^*=\omega_i$ which may be called an Euclidean dual isomorphism.[15] The pair (V^*,V) is connected by this duality which constitutes a pairing $\langle\cdot|\cdot\rangle$: $V^*\times V\mapsto\mathbb{K}$. Since V^* is isomorphic to V in finite dimensions, it is natural to build a Grassmann algebra $\wedge(V^*)$ over it. This is the algebra of Grassmann multiforms.

It is further a natural thing to extend the pairing of the grade-one space and its dual to the whole algebras $\wedge(V)$ and $\wedge(V^*)$, as can be seen by its frequent occurrence in literature.[13,14,16–19] This can be done by the following.

Definition 3: Let $\tau,\eta\in\wedge(V^*)$, $\omega\in V^*$, $u,v\in\wedge(V)$ and $x\in V$; then we can define a canonical action of $\wedge(V^*)$ on $\wedge(V)$ requiring

$$\text{(i)}\quad \omega(x)=\langle\omega|x\rangle,$$

$$\text{(ii)}\quad \omega(u\wedge v)=w(u)\wedge v+\hat{u}\wedge\omega(v), \tag{2.6}$$

$$\text{(iii)}\quad (\tau\wedge\eta)(u)=\tau(\eta(u)),$$

where $\hat{u}$ is the main involution $\hat{V}=-V$ extended to $\wedge(V)$. ■

In fact we have given by definition 3 an isomorphism between the Grassmann algebra of multiforms $\wedge(V^*)$ and the dual Grassmann algebra $[\wedge(V)]^*$. This can be made much clearer by writing

$$y\lrcorner x=\omega_y(x)=\langle\omega_y|y\rangle=B(y,x), \tag{2.7}$$

where we have used the canonical identification of V and V^* via the Euclidean dual isomorphism. One should be very careful in the distinction of $\wedge(V^*)$ and $[\wedge(V)]^*$, since they are isomorphic but not equivalent. Furthermore, we emphasize that in writing $y\lrcorner$ we make explicit use of a special dual isomorphism encoded in the contraction,

$$.\lrcorner:V\mapsto V^*,\quad y\to y\lrcorner=\omega_y\,. \tag{2.8}$$

Since there is no natural, either is mathematically motivated or even better, functorial relation between V and V^*, we are called to seek physically motivated reasons to select a dual isomorphism.

Theorem 4: Let (V,Q) be a pair of a $\mathbb{K}$-linear space V and Q a quadratic form as in definition 2. There exists an injection γ called Clifford map from V into the associative unital algebra $Cl(V,Q)$ which satisfies

$$\gamma_x\gamma_x = Q(x)\mathbb{1}. \tag{2.9}$$

■

Definition 5: The (smallest) algebra $Cl(V,Q)$ generated by $\mathbb{1}$ and γ_x is called (the) Clifford algebra of Q over V. ■

By polarization of this relation we get the usual commutation relations; $x,y \in V$,

$$\gamma_x\gamma_y + \gamma_y\gamma_x = 2B_p(x,y), \tag{2.10}$$

where $B_p(x,y)$ is the symmetric polar form of Q as defined in (2.3).

Remarks: (i) We could have obtained this result directly factoring the tensor algebra with the ideal (2.4). (ii) There exists Clifford algebras which are universal, in this case it is convenient to speak from the Clifford algebra over (V,Q). (iii) If $V \simeq \mathbb{K}^n \simeq \mathbb{C}^n$ or $\mathbb{R}^n$, we denote $Cl(V,Q)$ also by $Cl(\mathbb{C}^n) \simeq Cl_n$ or $Cl(\mathbb{R}_{p,q})$ where the pair p,q enumerate the number of positive and negative eigenvalues of Q. We can also give the dimension n and signature $s=p-q$ to classify all quadratic forms over $\mathbb{R}$. In the case of the complex field, one remains with the dimension, as can be seen, e.g., from the Weyl unitary trick, letting $x_i \to ix_i$ which flips the sign. We do not use sesquilinear forms here, which could be included nevertheless. ■

We will now use Chevalley-deformations to construct the Clifford algebra of multivectors. The main idea is that we can decompose the Clifford map as

$$\gamma_x = x\lrcorner + x\wedge. \tag{2.11}$$

We have thus a natural action of γ_x on the space $F\bigwedge(V)$.

Theorem 6: (Chevalley) Let $F\bigwedge(V)$ be the space underlying the Grassmann algebra over V and $\gamma_x: V \mapsto \mathrm{End}(F\bigwedge(V))$, $x \in V$ be defined as in (2.11); then γ_x is a Clifford map. ■

We have shown that Cl is a subalgebra of the endomorphism algebra of $F\bigwedge(V)$,

$$Cl \subseteq \mathrm{End}(F\bigwedge(V)). \tag{2.12}$$

It is possible to interpret $x\lrcorner$ and $x\wedge$ as annihilating and creation operators (on the space underlying the Grassmann algebra).[8]

With help of the relations (2.6) we can then lift this Clifford map to multivector actions. No symmetry requirement has to be made on the contraction. This leads to the following.

Definition 7: (Clifford algebra of multivectors) Let $B: V\times V \mapsto \mathbb{K}$ be an arbitrary bilinear form. The Clifford algebra $Cl(V,B)$ obtained from lifting the Clifford map,

$$\gamma_x = x\lrcorner + x\wedge = \langle x|\cdot\rangle + x\wedge = B(x,\cdot) + x\wedge, \tag{2.13}$$

to $\mathrm{End}(F\bigwedge(V))$ using the relations (2.6) is called the Clifford algebra of multivectors. ■

Note that $B(x,\cdot)=\omega_x$ is a map from $V \to V^*$ and incorporates a dual isomorphism. It is clear from the construction that $Cl(V,B)$ has a multivector structure or say a $\mathbb{Z}_n$-grading inherited from the graded space $F\bigwedge(V)$.

B admits a decomposition into symmetric and antisymmetric parts $B=G+F$. The symmetric part $G=B_p$ corresponds to a quadratic form Q; see (2.3).

Theorem 8: The Clifford algebra $Cl(V,Q) \simeq Cl(V,G)$ is isomorphic as Clifford algebra to $Cl(V,B)$, if B admits a decomposition $B=G+F$, $G^T=G$, $F^T=-F$. ■

A proof can be found for low dimensions in Ref. 19 and in general in Ref. 20. However, this result was implicitly known to physicists; see Refs. 10, 18, 21. In fact, this is the old Wick rule of QFT. We will insist on the $\mathbb{Z}_n$-grading and therefore carefully distinguish Clifford algebras of multivectors with a common quadratic form Q but different contractions B.

Definition 9: The opposite algebra A^{op} of an algebra A with product $m(a,b)=ab$ is defined to be the same linear space FA underlying A endowed with the opposite or transposed product $m^{op}(a,b)=m(b,a)=ba$. ■

Theorem 10: (Chevalley) The opposite Clifford algebra $Cl^{op}(V,Q)$ of $Cl(V,Q)$ is isomorphic to $Cl(V,-Q)$,

$$Cl^{op}(V,Q)\simeq Cl(V,-Q). \tag{2.14}$$

■

We can generalize this theorem to Clifford algebras of multivectors as the following.

Theorem 11: For Clifford algebras of multivectors it holds that

$$Cl^{op}(V,B)\simeq Cl(V,-B^T), \tag{2.15}$$

where T denotes the transposition of the bilinear form $B(x,y)^T=B(y,x)$. ■

The most general linear transformation on $F\wedge(V)$ is achieved by left and right translations, we have

$$\begin{aligned}\mathrm{End}(F\wedge V)\simeq\wedge(V)\otimes[\wedge(V)]^*&\simeq Cl(V,B)\hat{\otimes}Cl^{op}(V,B)\\ &\simeq Cl(V,B)\hat{\otimes}Cl(V,-B^T)\simeq Cl(V\oplus V,B\oplus -B^T);\end{aligned} \tag{2.16}$$

see, e.g., Ref. 22 theorem 5.5 or Ref. 23. This is the algebra which will be used in the subsequent sections.

The fact that in the above construction one has the graded tensor product is reflected by the following formulas. Let

$$\gamma_x=x\lrcorner_B+x\wedge, \quad \gamma_x^{op}=x\lrcorner_{-B^T}+x\wedge, \tag{2.17}$$

be the Clifford maps into $Cl(V,B)$ and $Cl^{op}(V,B)\simeq Cl(V,-B^T)$; then we obtain the following commutation relations:

$$\begin{aligned}\gamma_x\gamma_y+\gamma_y\gamma_x&=+2G(x,y),\\ y_x^{op}\gamma_y^{op}+\gamma_y^{op}\gamma_x^{op}&=-2G(x,y),\\ \gamma_x\gamma_y^{op}+\gamma_y^{op}\gamma_x&=0.\end{aligned} \tag{2.18}$$

Remember the decompositions $B=G+F$ and $B^{op}=-B^T=-G+F$. If one wants to treat ordinary left and right translations,

$$L_ax=ax, \quad R_ax=xa, \tag{2.19}$$

one has to introduce a further involution which accounts for the grading in the above graded tensor product of Cl and Cl^{op}. One defines

$$L_x=\gamma_x, \quad R_x=\gamma_x^{op}(\hat{\cdot}), \tag{2.20}$$

where $(\hat{\cdot})$ indicates the grade involution operator acting to the right. We obtain in this case the commutation relations as

$$\begin{aligned}L_xL_y+L_yL_x&=\gamma_x\gamma_y+\gamma_y\gamma_x=2G(x,y),\\ R_xR_y+R_yR_x&=\gamma_x^{op}\hat{\gamma}_y^{op}(\hat{\cdot})+\gamma_y^{op}\hat{\gamma}_x^{op}(\hat{\cdot})=2G(x,y)(\hat{\cdot}),\\ L_xR_y-R_yL_x&=\gamma_x\gamma_y^{op}(\hat{\cdot})-\gamma_y^{op}\hat{\gamma}_x(\hat{\cdot})=0.\end{aligned} \tag{2.21}$$

We give some further notations. Let $\{j_i\}$ be a set of elements spanning $V\simeq\langle j_1,\ldots,j_n\rangle$ and $\{\partial_k\}$ be a set of dual elements. Building the Grassmann algebras $\wedge(V)$, $\wedge(V^*)$ and defining the action of the forms via (2.6), one obtains the relations

$$\text{(i)}\quad j_i\wedge j_i=0=\partial_i\wedge\partial_i, \tag{2.22}$$

$$\text{(ii)}\quad \partial_i j_k + j_k \partial_i = B_{ik} + B_{ki} = 2G_{ik}\,.$$

The space $\mathbf{V} = V \oplus V^*$ is thus spanned by (note the order of indices)

$$\{e_1,\ldots,e_{2n}\} = \{j_1,\ldots,j_n,\partial_1,\ldots,\partial_n\}. \tag{2.23}$$

Usually, the choice of the contraction is taken to be the canonical one, with $G_{ik} = \delta_{ik}$. This leads to the so-called quantum algebra.[24] The resulting algebra is $Cl(\mathbf{V}, B^{can})$, where

$$[B^{can}(e_i,e_j)] = [B^{can}_{ij}] = \begin{vmatrix} 0_{n\times n} & \frac{1}{2}\,\mathbb{1}_{n\times n} \\ \frac{1}{2}\,\mathbb{1}_{n\times n} & 0_{n\times n} \end{vmatrix}. \tag{2.24}$$

This leads to the far more restricted commutation relations of Sallers quantum algebra (which is in fact a CAR algebra),

$$\begin{aligned} &\text{(i)}\quad j_i j_k + j_k j_i = 0 = \partial_i \partial_k + \partial_k \partial_i\,, \\ &\text{(ii)}\quad \partial_i j_k + j_k \partial_i = \delta_{ik}\,. \end{aligned} \tag{2.25}$$

However, see Ref. 25 for the usefulness of a more general bilinear form B. We will employ the j_i sources and ∂_k duals to construct field operators. A more general bilinear form $B = G + F$ is then introduced explicitly via the quantization G and the propagator F in terms of j sources and ∂ duals.

III. GENERATING FUNCTIONALS

Generating functionals originated from two major considerations. The first arose from studying covariant formulated perturbation theory;[3] see also Refs. 26, 27, to be able to handle free-free transitions of particles via a scattering matrix. The main ingredients are vacuum expectation values of time-ordered products of field operators. Since in- and out-going states are assumed to be free, one can retain the Fock representation, which, however, is not valid in the interacting case. Path integrals originated out of this branch of physics.[28]

A second approach was developed to treat QFT in an axiomatic way.[29] The main tool are vacuum expectation values of ordinary operator products. But, beside some structural results, the most prominent of them, the Wightman reconstruction theorem, has not led to a computationally useful tool,[30] apart from low dimensional models.[1]

Both of the constructions assume the following.

(1) The existence of field operators, and operators built from them, the Hermitian of which constitute the observables of the theory.
(2) The existence of a positive, linear, normalized functional, a state which allows the calculation of vacuum expectation values and a statistical interpretation.

There are further requirements necessary, but even the given ones are questionable. It is well known from C^*-algebra theory, that representations exist in the thermodynamic limit, in which no field operators do exist, but only in some larger closure of the algebra.

We will remain with the first assumption, but it tends to weaken the second one. It is mainly positivity which might be questioned in this context. QFT deals already with indefinite structures in describing interactions, e.g., Faddeev–Popov ghosts. Additionally we know, that on orthogonal Clifford algebras, which are related to fermionic fields, there are no nonsingular forms in dimensions higher than two (generators).[22,31]

It is clear that a statistical interpretation breaks down without positivity. But such an interpretation is not called for in the interaction region. Only in- and out-going states, which should have a particle interpretation, have to bear this feature. This idea was already proposed by Heisenberg.

However, we will go a step further and propose a geometric notation, which is valid in positive, indefinite and even singular cases. This makes it possible to decide afterwards in which situations positivity may be obtained and a statistical interpretation is meaningful; see Ref. 9. The Dirac theory was already treated within this method.[32]

We will treat fermionic quantum fields, but give in section VI also an example for a boson-fermion coupling theory, which can be developed straightforwardly.

Our starting point is the quantization rule imposed on field operators,

$$\{\psi_{I_1},\psi_{I_2}\}_+ = A_{I_1 I_2}, \tag{3.1}$$

where ψ_I is a ''super field'' defined as

$$\psi_I = \psi_{\Lambda K} = \begin{cases} \psi_K & \Lambda = 1, \\ \psi_K^\alpha & \Lambda = 2. \end{cases} \tag{3.2}$$

The anti-involution α is taken, e.g., to be the Hermitian or charge conjugation. $A_{I_1 I_2}$ is a symmetric c-number function of space-time and algebraic freedoms which all together are summarized in the multi-index $I=\{\Lambda,\alpha,\ldots\}$.

The relation (3.1) can be seen as the defining relation of a Clifford algebra $Cl(\langle\psi\rangle,A)$, when we identify the field operators as generators. To be able to give an algebraic basis of this Clifford algebra, we need an ordering. Let $\mathscr{P}$ denote such an ordering, which acts on the indices of the field operators. Clifford monomials in the field operators are then given by

$$e_n := \mathscr{P}(\psi_{I_1},\ldots,\psi_{I_n}), \tag{3.3}$$

where $\mathscr{P}$ might be, e.g., time-ordering, antisymmetry for equal times or normal-ordering w.r.t. a vacuum state. The linear space underlying $Cl(\langle\psi_I\rangle,A)$ is thus the linear span of the e_n Clifford monomials,

$$FCl(\langle\psi_I\rangle,A) \simeq \langle e_n\rangle. \tag{3.4}$$

As we emphasized in section II, it is of the utmost importance to have a graded space underlying those algebras, which leads to the Clifford algebra of multivectors of definition 7. In quantum field theory this space is obtained from a Grassmann algebra by introducing the anticommuting Schwinger sources j.[4] Indeed, due to the relation $j_I^2=0$ these are Grassmann generators. Assuming that the indices are from the same set as in the case of the ψ_I's, we build the Grassmann algebra over V with $V=\langle j_I\rangle$,

$$\wedge(\langle j_I\rangle) = \wedge(V). \tag{3.5}$$

Of course, we can identify the spaces underlying $Cl(\langle\psi_I\rangle,A)$ and $\wedge(\langle j_I\rangle)$ by means of Chevalley's identification,

$$FCl(\langle\psi_I\rangle,A) \simeq F\wedge(\langle j_I\rangle); \tag{3.6}$$

see section II. This is the graded space physicists make actual use of in their calculations. This remains true for path integrals also, as can be seen by their functional derivatives and the explicit occurrence of Schwinger source terms $\psi_I j_I$ in the exponent. It is therefore convenient to relate all entities to this space.

We know from Chevalley deformation, that the Clifford map ψ_I constitutes an endomorphism of $F\wedge(\langle j_I\rangle)$ which does not respect the grading. ψ_I may be decomposed in a grade lowering or annihilation operator ∂_I and a grade rising or creation operator $1/2 A_{I_1 I_2} j_{I_2}\wedge$,

$$\psi_I = \partial_I + \tfrac{1}{2} A_{I I_1} j_{I_1}\wedge, \tag{3.7}$$

where we omitted some superfluous factors. The ∂_I's are the canonical duals w.r.t. the Euclidean dual isomorphism. We have thus the commutation relations

$$\{j_I, j_K\}_+ = 0 = \{\partial_I, \partial_K\}_+, \quad \{J_I, \partial_K\}_+ = \delta_{IK}, \tag{3.8}$$

which results with (3.7) in the quantization condition (3.1),

$$\{\psi_I, \psi_K\}_+ = A_{IK}. \tag{3.9}$$

The next step towards a QFT generating functional is to project the Clifford monomials $e_n = \mathscr{P}(\psi_{I_1}, \ldots, \psi_{I_n})$ onto the graded space $F\wedge(\langle j_I \rangle)$. This is in fact a representation of the Clifford morphism obtained by lifting the ψ_I action to the whole algebra, as was described in section II. We write this projection as π: $FCl(V,A) \mapsto F\wedge(V)$,

$$\begin{aligned}\pi(e_n) &= \pi(\mathscr{P}(\psi_{I'_1}, \ldots, \psi_{I'_n})) \\ &= \langle \partial_{I_n} \wedge \cdots \wedge \partial_{I_1} \mathscr{P}(\psi_{I'_1}, \ldots, \psi_{I'_n}) \rangle_\pi j_{I_1} \wedge \cdots \wedge j_{I_n} \\ &= \langle 0 | \mathscr{P}(\psi_{I_1}, \ldots, \psi_{I_n}) | p \rangle j_{I_1} \wedge \cdots \wedge j_{I_n} = \rho_n(I_1, \ldots, I_n | p) j_{I_1} \wedge \cdots \wedge j_{I_n}.\end{aligned} \tag{3.10}$$

The index π parameterizes the linear normed functionals on $FCl(V,A)$, which is thereafter encoded in the bra $\langle 0|$ and ket $|p\rangle$ of the notation common to physicists. Observe that

$$\langle \partial_{I_n} \wedge \cdots \wedge \partial_{I_1} \mathscr{P}(\psi_{I_1}, \ldots, \psi_{I_n}) \rangle_\pi = \langle 0 | \mathscr{P}(\psi_{I_1}, \ldots, \psi_{I_n}) | p \rangle = \rho_n(I_1, \ldots, I_n | p) \tag{3.11}$$

is a c-number transition matrix element. If $|p\rangle$ is set equal to $|0\rangle$ we obtain vacuum expectation values which are known to be sufficient to describe the theory.

If a general element of $F\wedge(\langle j_I \rangle)$ is written down, this reads as

$$\begin{gathered}|\mathscr{P}(j,p)\rangle_F = \sum_{i=0}^{n} \frac{i^n}{n!} \rho_n(I_1, \ldots, I_n | p) j_{I_1} \wedge \cdots \wedge j_{I_n} |0\rangle_F, \\ \rho_n(I_1, \ldots, I_n | p) = \langle 0 | \mathscr{P}(\psi_{I_1}, \ldots, \psi_{I_n}) | p \rangle,\end{gathered} \tag{3.12}$$

and is thus exactly the definition of a fermionic generating functional in quantum field theory.[6,33] To emphasize the ''vector''-state character, in fact the left linear structure, we have added a functional ket $|0\rangle_F$ which is usually subjected to the relations

$${}_F\langle 0 | j_I = 0 = \partial_I |0\rangle_F. \tag{3.13}$$

These writings mimic in fact a linear form imposed on the algebra. We have thus given a Clifford algebraic account on quantum field theoretic generating functionals. The Clifford algebra involved was shown to be a Clifford algebra of multivectors built over a graded space $F\wedge(\langle j_I \rangle)$.

One may note that due to the explicit introduction of a basis $\{j_I\}$ the functional is also basis dependent, especially the matrix elements $\rho_n(I_1, \ldots, I_n | p)$. However, from our general considerations it is clear that the functional ''state'' $|\mathscr{P}(j,p)\rangle_F \in \wedge(\langle j_I \rangle)$ is an invariant object and is basis independent.

IV. TRANSITION FROM OPERATOR DYNAMICS TO GENERATING FUNCTIONALS

The most common case in quantum field theory is that an operator dynamics is given *a priori*. Furthermore, quantization calls for the Hamiltonian picture which breaks explicitly covariance.[34] This is not a problem as long as exact calculations are performed, since one is able to return to the manifest covariant theory.

Given a Hamiltonian, we can use the Heisenberg equation to write down the dynamics

$$i\dot{\psi}_I = [\psi, H]_-, \quad H = H[\psi]. \tag{4.1}$$

H is assumed to generate a one parameter family of automorphisms by integrating (4.1) to

$$\psi_I(t) = e^{iHt} \psi_I(0) e^{-iHt}. \tag{4.2}$$

It can be shown under the restrictive conditions of C^*-theory, this is always possible.

We know that generating functionals are constructed by lifting the ψ_I-action to $F\wedge(\langle j_I\rangle)$, so it is a natural question to ask for a Clifford morphism extension of (4.1). This will be the desired functional equation.

Since it is not quite clear which $H[\psi]$ integrates to a group action, we assume this explicitly. However, the space underlying a Clifford algebra can easily be made into a Lie-algebra by introducing the commutator product as a Lie-product. This has not to be confused with the Lie-algebras obtained as bi-vector sub-algebras under the commutator product.

A straightforward method to obtain derivatives of generating functionals is the Baker–Campbell–Hausdorff formula. If one writes the generating functional formally as

$$e^{\psi(t)} \simeq |\mathscr{P}(j,p)\rangle_F , \tag{4.3}$$

one has to calculate

$$\begin{aligned} i\partial_0 e^{\psi(t)} &= \sum_{k=0}^{\infty} [\psi,H]_k , \\ [\psi,H]_k &:= [[\psi,H]_{k-1},H]_- , \quad k \geqslant 1, \\ i\partial_0\psi &= [\psi,H]_0 = [\psi,H], \end{aligned} \tag{4.4}$$

which is quite tedious. Furthermore, one has to apply the BCH formula a second time to eliminate the field operators, which prolongates the calculations enormously. The result is then the functional equation

$$i\partial_0 |\mathscr{P}(j,p)\rangle_F = H[j,\partial]^{\mathscr{P}} |\mathscr{P}(j,p)\rangle_F , \tag{4.5}$$

with the functional Hamiltonian $H[j,\partial]^{\mathscr{P}}$. This Hamiltonian depends in its explicit form on the ordering implicit in $|\mathscr{P}(j,p)\rangle_F$.

We will circumvent these lengthy calculations using the opposite algebra $Cl^{op}(\langle\psi_I\rangle,A)$. To account for generating functionals, we reinterpret the field operators as Clifford endomorphisms on the space $F\wedge(\langle j_I\rangle)$ spanned by the Grassmann sources. If we allow only a left action, we can not reach every endomorphism on this space. However, the algebra $\wedge(\langle j_I\rangle)\otimes\wedge(\langle j_I\rangle^*)$ was shown to be isomorphic to $\mathrm{End}(F\wedge(\langle j_I\rangle))$. We have therefore to construct the opposite Clifford algebra to handle right actions. In theorem 2.14 we obtained the isomorphism

$$Cl^{op}(\langle\psi_I\rangle,A) \simeq Cl(\langle\psi_I\rangle,-A). \tag{4.6}$$

The decomposition into the creation and annihilation part reads then for the antisymmetric ordering as

$$\psi_I = \partial_I + \tfrac{1}{2} A_{II'} j_{I'}\wedge , \quad \psi_I^{op} = \partial_I - \tfrac{1}{2} A_{II'} j_{I'}\wedge . \tag{4.7}$$

ψ^{op} acts as an operator of right action from the left on the space $F\wedge(\langle j_I\rangle)$. Indeed, one finds

$$\partial_I = \tfrac{1}{2}(\psi_I + \psi_i^{op}), \quad j_I = A_{II'}(\psi_{I'} - \psi_{I'}^{op}), \tag{4.8}$$

where we assumed $AA = \mathbb{1}$, according to the Euclidean dual isomorphism. It is now an easy task to find the desired lifting of the Clifford morphism.

Let $g_n = \pi(e_n) = \rho_n(I_1,\ldots,I_n|p) j_{I_1}\wedge\cdots\wedge j_{I_n}$ be the projected monomial. The action of $H[\psi]$ on this monomial g_n may be defined as

$$i\dot{g}_n = [g_n, H[\psi]]_- = g_n H[\psi] - H[\psi] g_n , \tag{4.9}$$

$$= H[\psi^{op}(\hat{\cdot})] g_n - H[\psi] g_n . \tag{4.10}$$

A detailed investigation of the grading properties should then follow. However, to reproduce the results in the literature, the grade involution is suppressed. The action of the Hamiltonian on multivectors is thus defined to be

$$i\dot{g}_n=(H[\psi^{op}]-H[\psi])g_n. \tag{4.11}$$

Summing up the monomials yields the functional equation

$$i\partial_0|\mathscr{P}(j,a)\rangle_F=(H[\psi^{op}]-H[\psi])|\mathscr{P}(j,a)\rangle_F=H[j,\partial]^{\mathscr{P}}|\mathscr{P}(j,a)\rangle_F, \tag{4.12}$$

where $H[j,\partial]^{\mathscr{P}}$ is the desired functional Hamiltonian acting on the whole Dyson–Schwinger–Freese hierarchy encoded in the generating functional.

Instead of tedious calculations by means of the BCH formula, we have simply to decompose ψ and ψ^{op} into j-∂-parts and sum up the terms. In the above case of an antisymmetric ordering we have

$$H[j,\partial]^{as}=H[\psi^{op}]-H[\psi]=H[\partial-1/2Aj]-H[\partial+1/2Aj]. \tag{4.13}$$

The antisymmetric ordering was introduced in the second line due to the special form of the decomposition of ψ_I into annihilating and creating parts. In the case of an arbitrary ordering, we have to use the Clifford algebra of multivectors with an arbitrary bilinear form $B=G+F=A+F$ (G and A are synonyms). The resulting decompositions are (without factors)

$$\psi=\partial+Aj+Fj, \quad \psi^{op}=\partial-Aj+Fj, \tag{4.14}$$

due to theorem 2.15. We obtain as F-ordered or say normal-ordered functional Hamiltonian

$$H[j,\partial]^{\mathscr{N}}=H[\psi^{op}]-H[\psi]=H[\partial-Aj+Fj]-H[\partial+Aj+Fj], \tag{4.15}$$

and the normal-ordered functional equation

$$i\partial_0|\mathscr{N}(j,a)\rangle_F=(H[\psi^{op}]-H[\psi])|\mathscr{N}(j,a)\rangle_F=H[j,\partial]^{\mathscr{N}}|\mathscr{N}(j,a)\rangle_F. \tag{4.16}$$

The usefulness of this approach will be shown in the following sections by explicit calculations. Bosons can be treated in an analogous way using symplectic Clifford algebras.[8] We have not accounted for all factors i and 1/2 occurring for historical reasons in the definition of generating functionals; this will be done in the examples.

V. NONLINEAR SPINOR FIELD MODEL

It will be illuminating to treat every model in two versions. First the pure antisymmetric case which is the one-time limit of the time-ordered functionals and afterwards the more general normal-ordered case, where F is either the correct propagator of the theory or taken as a parameter.

We use a compact notation, where spinor operators and charge conjugate spinor operators are united,

$$\psi_I=\psi_{\Lambda K}=\begin{cases}\psi_K, & \Lambda=1,\\ \psi_K^c, & \Lambda=2.\end{cases} \tag{5.1}$$

It is useful to work with charge conjugate field operators, since they allow a compact notation of the field equations. We define our model as (summation and integration over repeated indices implicitly assumed).

$$\begin{aligned} i\partial_0\psi_I&=D_{II_1}\psi_{I_1}+gV_I^{\{I_1I_2I_2\}_{as}}\psi_{I_1}\psi_{I_2}\psi_{I_3},\\ \{\psi_{I_1}\psi_{I_2}\}_+&=A_{I_1I_2}, \end{aligned} \tag{5.2}$$

where D_{II_1} is a kinetic term and $V_I^{\{I_1I_2I_3\}_{as}}$ a constant vertex. The anticommutator is denoted by $A_{I_1I_2}$ and we require the identity $A_{I_1I_2}A_{I_2I_3}=\delta_{I_1I_3}$. For explicit expressions see, e.g., (6.10). But it is our intention not to give explicit expressions for D, V and A, since we want to demonstrate the model independency of our method.

The antisymmetry of $V_I^{\{I_1I_2I_2\}_{as}}$ can be pushed over to the field operator products. In this case one has to be careful since there are relations of the type

$$:\psi_{I_2}\wedge\psi_{I_3}\wedge\psi_{I_4}:=\psi_{I_2}\dot\wedge\psi_{I_3}\dot\wedge\psi_{I_4}=\psi_{I_2}\wedge\psi_{I_3}\wedge\psi_{I_4}+F_{I_2I_3}\psi_{I_4}-F_{I_2I_4}\psi_{I_3}+F_{I_3I_4}\psi_{I_2}, \tag{5.3}$$

which result from the normal-ordering.[10] We have thus carefully to distinguish the different wedge products, which ultimately lead to different vacua.[9] Literally this is done by the $:\cdots:$ notations used by physicists, but there without an algebraic theory behind. From the dynamics (5.2) we obtain the Hamilton operators

$$H[\psi]^\wedge=\frac{1}{2}A_{I_1I_3}D_{I_3I_2}\psi_{I_1}\wedge\psi_{I_2}+\frac{g}{4}A_{I_1I_5}V_{I_1}^{I_2I_3I_4}\psi_{I_1}\wedge\psi_{I_2}\wedge\psi_{I_3}\wedge\psi_{I_4} \tag{5.4}$$

and

$$H[\psi]^{\dot\wedge}=\frac{1}{2}A_{I_1I_3}D_{I_3I_2}\psi_{I_1}\dot\wedge\psi_{I_2}+\frac{g}{4}A_{I_1I_5}V_{I_1}^{I_2I_3I_4}\psi_{I_1}\dot\wedge\psi_{I_2}\dot\wedge\psi_{I_3}\dot\wedge\psi_{I_4}, \tag{5.5}$$

where the superscript wedges indicate the usage of the wedge or dotted wedge products.

A. Antisymmetric case

The antisymmetric case is connected with the normal wedge. Furthermore, the field operators corresponding to this ordering are given as

$$\begin{aligned}\psi&=\frac{1}{i}\partial_i-\frac{i}{2}A_{II_1}j_{I_1}\wedge\simeq\partial-Aj,\\ \psi^{op}&=\frac{1}{i}\partial_i+\frac{i}{2}A_{II_1}j_{I_1}\wedge\simeq\partial+Aj.\end{aligned} \tag{5.6}$$

Using the functional Heisenberg equation (4.12), we have to calculate

$$i\partial_0|\mathscr{A}(j,a)\rangle_F=E_{0a}|\mathscr{A}(j,a)\rangle_F=(H[\partial+Aj]-H[\partial-Aj])|\mathscr{A}(j,a)\rangle_F, \tag{5.7}$$

where $|a\rangle$ is assumed to be an energy eigen-''state'' here and in the sequel. Hence, we have to decompose the Clifford map ψ and ψ^{op} into creation and annihilation parts w.r.t. the space $F\wedge(\langle j_I\rangle)$. The first term of (5.4) is given as

$$T_1[\psi]^\wedge=\tfrac{1}{2}A_{I_1I_3}D_{I_3I_2}\psi_{I_1}\wedge\psi_{I_2}, \tag{5.8}$$

which results in functional form as

$$\begin{aligned}T_1[j,\partial]^\wedge&=T_1[\partial+Aj]-T_1[\partial-Aj]\\ &=\frac{1}{2}A_{I_1I_3}D_{I_3I_2}\left(\frac{1}{i}\partial_{I_2}+\frac{i}{2}A_{I_2I_2'}j_{I_2'}\right)\left(\frac{1}{i}\partial_{I_1}+\frac{i}{2}A_{I_1I_1'}j_{I_1'}\right)\\ &\quad-\left(\frac{1}{i}\partial_{I_2}-\frac{i}{2}A_{I_2I_2'}j_{I_2'}\right)\left(\frac{1}{i}\partial_{I_1}-\frac{i}{2}A_{I_1I_1'}j_{I_1'}\right)\\ &=\frac{1}{2}A_{I_2I_3}D_{I_3I_2}\left(\frac{1}{i^2}\{\partial_{I_2},\partial_{I_1}\}_+ +\frac{i^2}{4}A_{I_2I_2'}A_{I_1I_1'}\{j_{I_2'},j_{I_1'}\}_+ +4\frac{i}{2i}A_{I_2I_2'}j_{I_2'}\partial_{I_1}\right).\end{aligned} \tag{5.9}$$

Using the commutation relations of the j,∂ generators and the antisymmetry of AD, we obtain

$$T_1[j,\partial]^\wedge = -\tfrac{1}{2} A_{I_2 I_3} D_{I_3 I_1} 2 A_{I_2 I_2'} j_{I_2'} \partial_{I_1} = -D_{I_2' I_1} j_{I_2'} \partial_{I_1} = -D_{I_1 I_2} j_{I_1} \partial_{I_2}. \tag{5.10}$$

The interaction term,

$$T_2[\psi]^\wedge = \frac{g}{4} A_{I_1 I_5} V_{I_5}^{I_2 I_3 I_4} \psi_{I_1} \wedge \psi_{I_2} \wedge \psi_{I_3} \wedge \psi_{I_4}, \tag{5.11}$$

is decomposed as

$$\begin{aligned} T_2[j,\partial]^\wedge &= T_2[\partial + Aj] - T_2[\partial - Aj] \\ &= \frac{g}{4} A_{I_1 I_5} V_{I_5}^{I_2 I_3 I_4} \Bigg\{ \left(\frac{1}{i} \partial_{I_4} + \frac{i}{2} A_{I_4 I_4'} j_{I_4'} \right) \left(\frac{1}{i} \partial_{I_3} + \frac{i}{2} A_{I_3 I_3'} j_{I_3'} \right) \\ &\quad \times \left(\frac{1}{i} \partial_{I_2} + \frac{i}{2} A_{I_2 I_2'} j_{I_2'} \right) \left(\frac{1}{i} \partial_{I_1} + \frac{i}{2} A_{I_1 I_1'} j_{I_1'} \right) - \left(\frac{1}{i} \partial_{I_4} - \frac{i}{2} A_{I_4 I_4'} j_{I_4'} \right) \\ &\quad \times \left(\frac{1}{i} \partial_{I_3} - \frac{i}{2} A_{I_3 I_3'} j_{I_3'} \right) \left(\frac{1}{i} \partial_{I_2} - \frac{i}{2} A_{I_2 I_2'} j_{I_2'} \right) \left(\frac{1}{i} \partial_{I_1} - \frac{i}{2} A_{I_1 I_1'} j_{I_1'} \right) \Bigg\}. \end{aligned} \tag{5.12}$$

Since $T_2[j,\partial]^\wedge$ is an even function of the generators, we remain with terms of an odd number of j and ∂ generators. Furthermore we use the binomial theorem. This can be done, since new commutator terms does not arise due to antisymmetry of AV in $I_1,\ldots,I_4$. Accounting finally for a factor 2 from the two commutator terms, the result is

$$\begin{aligned} T_2[j,\partial]^\wedge &= g A_{I_4 I_5} V_{I_5}^{I_1 I_2 I_3} A_{I_4 I_4'} j_{I_4'} \partial_{I_3} \partial_{I_2} \partial_{I_1} + \frac{g}{4} A_{I_4 I_5} V_{I_5}^{I_1 I_2 I_3} A_{I_4 I_4'} j_{I_4'} A_{I_3 I_3'} j_{I_3'} A_{I_2 I_2'} j_{I_2'} \partial_{I_1} \\ &= g j_{I_1} V_{I_1}^{I_2 I_3 I_4} \left(\partial_{I_4} \partial_{I_3} \partial_{I_2} + \frac{1}{4} A_{I_4 I_4'} A_{I_3 I_3'} j_{I_4'} j_{I_3'} \partial_{I_2} \right). \end{aligned} \tag{5.13}$$

The functional Hamiltonian $H[j,\partial]^\wedge$ is the sum of $T_1^\wedge$ and $T_2^\wedge$. Therefore, the functional energy equation reads as

$$E_{a0} | \mathscr{A}(j,a) \rangle_F = \{ D_{I_1 I_2} j_{I_1} \partial_{I_2} + g j_{I_1} V_{I_1}^{I_2 I_3 I_4} (\partial_{I_3} \partial_{I_2} \partial_{I_1} + \tfrac{1}{4} A_{I_4 I_4'} A_{I_3 I_3'} j_{I_4'} j_{I_3'} \partial_{I_2}) \} | \mathscr{A}(j,a) \rangle_F, \tag{5.14}$$

in accordance with formula (3.98) in Ref. 21.

B. Normal-ordered case

The normal-ordered functional equation is related to the dotted wedge. It contains explicitly the propagator. This results in another functional Hamiltonian $H[j,\partial]^\wedge$. The functional energy equation reads as

$$i \partial_0 | \mathscr{N}(j,a) \rangle_F = E_{a0} | \mathscr{N}(j,a) \rangle_F = (H[\psi^{op}] - H[\psi]) | \mathscr{N}(j,a) \rangle_F, \tag{5.15}$$

where

$$\begin{aligned} \psi^{op} &= \frac{1}{i} \partial + \frac{i}{2} A_j \dot{\wedge} = \frac{1}{i} \partial + \frac{i}{2} Aj \wedge + iFj \wedge \simeq \partial + Aj + Fj, \\ \psi &= \frac{1}{i} \partial - \frac{i}{2} Aj \dot{\wedge} = \frac{1}{i} \partial - \frac{i}{2} Aj \wedge + iFj \wedge \simeq \partial - Aj + Fj, \end{aligned} \tag{5.16}$$

TABLE I. Resulting terms from $T_2[j,\partial]$ of the normal-ordered nonlinear spinor field functional equation.

$(\#\partial,\#Aj,\#Fj)$	$P_{k_1\cdots k_n}$	Factor	Resulting term
(3,1,0)	$\frac{4!}{3!}=4$	$4\frac{i}{2i^3}=-2$	$-A_{I_4I_4'}j_{I_4'}\partial_{I_3}\partial_{I_2}\partial_{I_1}$
(2,1,1)	$\frac{4!}{2!}=12$	$12\frac{i^2}{2i^2}=6$	$6A_{I_4I_4'}F_{I_3I_3'}j_{I_4'}j_{I_3'}\partial_{I_2}\partial_{I_1}$
(1,3,0)	$\frac{4!}{3!}=4$	$4\frac{i^3}{2^3i}=-\frac{1}{2}$	$-\frac{1}{2}A_{I_4I_4'}A_{I_3I_3'}A_{I_2I_2'}j_{I_4'}j_{I_3'}j_{I_2'}\partial_{I_1}$
(1,1,2)	$\frac{4!}{2!}=12$	$12\frac{i^3}{2i}=-6$	$-6A_{I_4I_4'}F_{I_3I_3'}F_{I_2I_2'}j_{I_4'}j_{I_3'}j_{I_2'}\partial_{I_1}$
(0,3,1)	$\frac{4!}{3!}=4$	$4\frac{i^4}{2^3}=\frac{1}{2}$	$\frac{1}{2}A_{I_4I_4'}A_{I_3I_3'}A_{I_2I_2'}F_{I_1I_1'}j_{I_4'}j_{I_3'}j_{I_2'}j_{I_1'}$
(0,1,3)	$\frac{4!}{3!}=4$	$4\frac{ii^3}{2}=2$	$2A_{I_4I_4'}F_{I_3I_3'}F_{I_2I_2'}F_{I_1I_1'}j_{I_4'}j_{I_3'}j_{I_2'}j_{I_1'}.$

are the Clifford maps related to the dotted wedge, written in terms of the undotted ones. This allows us to use the same j and ∂ generators. Since the operator dynamics is formally the same, we have once more to calculate T_1 and T_2. Now

$$\begin{aligned}\dot{T_1[j,\partial]\hat{}} &= T_1[\partial+Aj+Fj]-T_1[\partial-Aj+Fj]\\ &= \frac{1}{2}A_{I_1I_3}D_{I_3I_2}\left\{\left(\frac{1}{i}\partial_{I_2}+\frac{i}{2}A_{I_2I_2'}j_{I_2'}+iF_{I_2I_2'}j_{I_2'}\right)\left(\frac{1}{i}\partial_{I_1}+\frac{i}{2}A_{I_1I_1'}j_{I_1'}+iF_{I_1I_1'}j_{I_1'}\right)-\left(\frac{1}{i}\partial_{I_2}\right.\right.\\ &\quad\left.\left.-\frac{i}{2}A_{I_2I_2'}j_{I_2'}+iF_{I_2I_2'}j_{I_2'}\right)\left(\frac{1}{i}\partial_{I_1}-\frac{i}{2}A_{I_1I_1'}j_{I_1'}+iF_{I_1I_1'}j_{I_1'}\right)\right\}\end{aligned}\tag{5.17}$$

is no longer odd or even in j,∂ and we can only use antisymmetry arguments. Inspection of the equations shows that only odd numbers of A's can occur. These are

$$\begin{aligned}Aj\partial:&\ 2\frac{i}{2i}A_{I_2I_2'}j_{I_2'}\partial_{I_1},\\ AFjj:&\ 2\frac{i^2}{2}A_{I_2I_2'}F_{I_1I_1'}j_{I_2'}j_{I_1'}.\end{aligned}\tag{5.18}$$

With the same considerations as above, we obtain

$$\dot{T_1[j,\partial]\hat{}}=-D_{I_1I_2}j_{I_1}\partial_{I_2}+D_{I_1I_3}F_{I_3I_2}j_{I_1}j_{I_2}.\tag{5.19}$$

The interaction term T_2 is treated along the same lines. We have to use the polynomial theorem and the polynomial coefficients,

$$P_{k_1\cdots k_n}:=\frac{k!}{k_1!\cdots k_n!},\quad k=\sum k_n.\tag{5.20}$$

The resulting six terms occurring twice are given in Table I.

After juggling the indices and summarizing we obtain

$$\begin{aligned}\dot{T_2[j,\partial]\hat{}}=gV_{I_1}^{I_2I_3I_4}[&-j_{I_1}\partial_{I_4}\partial_{I_3}\partial_{I_2}+3F_{I_2I_2'}j_{I_1}j_{I_2'}\partial_{I_3}\partial_{I_4}\\ &-(3F_{I_3I_3'}F_{I_2I_2'}+\tfrac{1}{4}A_{I_3I_3'}A_{I_2I_2'})j_{I_1}j_{I_3'}j_{I_2'}\partial_{I_4}\\ &-(3F_{I_3I_3'}F_{I_2I_2'}+\tfrac{1}{4}A_{I_3I_3'}A_{I_2I_2'})F_{I_1I_1'}j_{I_1}j_{I_3'}j_{I_2'}j_{I_1'}].\end{aligned}\tag{5.21}$$

The normal-ordered functional energy equation obtained directly from the operator dynamics in one single step reads then as

$$\begin{aligned}E_{a0}|\mathcal{N}(j,a)\rangle_F &= H[j,\partial]\dot{\wedge}|\mathcal{N}(j,a)\rangle_F \\ &= \{D_{I_1I_2}j_{I_1}\partial_{I_2} - D_{I_1I_3}F_{I_3I_2}j_{I_1}j_{I_2} \\ &\quad + gV_{I_1}^{I_2I_3I_4}[j_{I_1'}\partial_{I_4}\partial_{I_3}\partial_{I_2} - 3F_{I_2I_2'}j_{I_1}j_{I_2'}\partial_{I_3}\partial_{I_4} \\ &\quad + (3F_{I_3I_3'}F_{I_2I_2'} + \tfrac{1}{4}A_{I_3I_3'}A_{I_2I_2'})j_{I_1}j_{I_3'}j_{I_2'}\partial_{I_4} \\ &\quad + (3F_{I_3I_3'}F_{I_2I_2'} + \tfrac{1}{4}A_{I_3I_3'}A_{I_2I_2'})F_{I_1I_1'}j_{I_1}j_{I_3'}j_{I_2'}j_{I_1'}]|\mathcal{N}(j,a)\rangle_F. \end{aligned} \tag{5.22}$$

$H[j,\partial]\dot{\wedge}$ is the normal-ordered functional Hamiltonian. The result agrees with (3.106) in Ref. 21.

Remark: In QFT the normal-ordered functional equation is obtained in two steps. Only after deriving the antisymmetric functional equation normal-ordering is performed explicitly via the nonperturbative Wick transformation,

$$\begin{aligned}|\mathcal{A}(j,a)\rangle_F &= e^{-1/2jFj}|\mathcal{N}(j,a)\rangle_F, \\ H[j,\partial]\dot{\wedge} &= e^{-1/2jFj}H[j,\partial]\wedge e^{+1/2jFj}.\end{aligned} \tag{5.23}$$

Observe that j commutes with $\exp(-1/2jFj)$, but not ∂, so that the transition can be given in terms of generators also,

$$\begin{aligned}\partial e^{-1/2jFj} &= e^{-1/2jFj}(\partial - Fj), \\ d &:= \partial - Fj, \\ H[j,\partial]\dot{\wedge} &= H[j,d]\wedge;\end{aligned} \tag{5.24}$$

compare with Ref. 32. This method requires explicit vertex regularization if the products $\wedge$ and $\dot{\wedge}$ are not explicitly treated as distinct $j_{I_1}\dot{\wedge}j_{I_2} = j_{I_1}\wedge j_{I_2} + F_{I_1I_2}$, as was shown in Ref. 10.

VI. SPINOR QUANTUM ELECTRODYNAMICS

We give spinor QED as an example for a boson-fermion coupling theory. We have to deal with a constrained theory, since spinor QED is a gauge theory. Especially on the quantum level this is a difficult task.[35] Hence in a first step we will eliminate the gauge freedom classically and perform the quantization afterwards. This is only possible in QED, because of the simple Abelian gauge coupling. In non-Abelian Yang–Mills Theories as QCD one has a nonlinear term in the Gauss' law, and a classical elimination leads to difficulties. However, this can be done using functional techniques.[35,36]

We start with the equations of classical spinor ED,

$$\begin{aligned}&\text{(i)}\quad \partial_\nu F^{\mu\nu} + \frac{ie_0}{2}\,\Psi C\gamma^\mu\sigma^2\Psi = 0, \\ &\text{(ii)}\quad (i\gamma^\mu\partial_\mu - m_0)\Psi + e_0 A_\mu\gamma^\mu\sigma^3\Psi = 0, \\ &\text{(iii)}\quad F^{\mu\nu} := \partial^\mu A^\nu - \partial^\nu A^\mu,\end{aligned} \tag{6.1}$$

where we have used the definition

$$\Psi = \Psi_{\alpha\Lambda} = \begin{cases}\Psi_\alpha, & \Lambda = 1, \\ \Psi^c_\alpha = C_{\alpha\beta}\overline{\Psi}_\beta, & \Lambda = 2\end{cases} \tag{6.2}$$

and omit the matrix indices. By definition the sigma matrices act on the super index Λ distinguishing the field and its charge conjugated field, which has to be treated as an independent quantity. The gamma matrices and the charge conjugation matrix C act on the spinor index α of the Ψ field.

We use the Coulomb gauge and set

$$\partial_k A^k = 0. \tag{6.3}$$

Furthermore we split the ''bosonic'' fields A and E into longitudinal and transverse parts,

$$\begin{gathered} A_k \equiv A_k^{tr}, \quad \text{because of} \quad \partial_k A^k = 0, \\ E_k = E_k^{tr} + E_k^l, E_k := -F^{0k} = F_{0k}. \end{gathered} \tag{6.4}$$

Furthermore we decompose the field equations into dynamic ones and the remaining constraint, the Gauss' law. Looking at (i) of (6.1) yields

$$\begin{gathered} \nu = 0: \ i\partial_0 E_k = -\tfrac{1}{2} e_0 \Psi C \gamma^k \sigma^2 \Psi + i(\partial_j \partial^k A^j - \partial_j \partial^j A^k), \\ \nu = k: \ \partial^k E_k = -i \frac{e_0}{2} \Psi C \gamma_0 \sigma^2 \Psi, \end{gathered} \tag{6.5}$$

and from the definition of E^k,

$$i\partial_0 A^{tr,k} = iE^k - i\partial_k A^0. \tag{6.6}$$

With the help of the current conservation the Gauss' law, $\nu = k$ from (6.5), can now be used to yield an expression for the A_0 field in terms of spinors,

$$A_0 = -i \frac{e_0}{2} \Delta^{-1} \Psi C \gamma_0 \sigma^2 \Psi. \tag{6.7}$$

The Δ^{-1} symbol is used for the integral kernel of the inverse of the Laplacian. For a further compactification of the notation we introduce a ''super field'' B_η in the ''bosonic'' fields also,

$$B_k^\eta := \begin{cases} A_k^{tr}, & \eta = 1, \\ E_k^{tr}, & \eta = 2. \end{cases} \tag{6.8}$$

The equations of motion reads then as

$$\begin{gathered} i\partial_0 \Psi_{I_1} = D_{I_1 I_2} \Psi_{I_2} + W^k_{I_1 I_2} B_k \Psi_{I_2} + U^{I_2 I_3 I_4}_{I_1} \Psi_{I_2} \Psi_{I_3} \Psi_{I_4}, \\ i\partial B_{K_1} = L_{K_1 K_2} B_{K_2} + J^{I_1 I_2}_{K_1} \Psi_{I_1} \Psi_{I_2}, \end{gathered} \tag{6.9}$$

with the definitions

$$\begin{gathered} I := \{\alpha, \Lambda, \mathbf{r}\}, \quad K := \{k, \eta, \mathbf{z}\}, \quad P^{tr} := 1 - \Delta^{-1} \boldsymbol{\nabla} \otimes \boldsymbol{\nabla}, \\ D_{I_1 I_2} := -(i\gamma_0 \gamma^k \partial_k - \gamma_0 m)_{\alpha_1 \alpha_2} \delta_{\Lambda_1 \Lambda_2} \delta(\mathbf{r}_1 - \mathbf{r}_2), \\ W^K_{I_1 I_2} := e_0 (\gamma_0 \gamma^k)_{\alpha_1 \alpha_2} \delta(\mathbf{r}_1 - \mathbf{r}_2) \delta(\mathbf{r}_1 - \mathbf{z}) \delta_{1\eta} \sigma^3_{\Lambda_1 \Lambda_2}, \\ U^{I_2 I_3 I_4}_{I_1} := -\frac{i}{8\pi} e_0^2 \left[(C\gamma_0)_{\alpha_2 \alpha_3} \delta_{\alpha_1 \alpha_4} \sigma^2_{\Lambda_2 \Lambda_3} \sigma^2_{\Lambda_1 \Lambda_4} \frac{\delta(\mathbf{r}_2 - \mathbf{r}_3) \delta(\mathbf{r}_1 - \mathbf{r}_4)}{|\mathbf{r}_1 - \mathbf{r}_2|} \right]_{\alpha s\{I_2 I_3 I_4\}}, \\ L_{K_1 K_2} := i\delta(\mathbf{z}_2 - \mathbf{z}_1) \delta_{k_1 k_2} \delta_{\eta_1 1} \delta_{\eta_2 2} + i\Delta(\mathbf{z}_1) \delta(\mathbf{z}_1 - \mathbf{z}_2) \delta_{k_1 k_2} \delta_{\eta_1 2} \delta_{\eta_2 1}, \\ J^{I_1 I_2}_K := -\tfrac{1}{2} e_0 P^{tr}(\mathbf{z} - \mathbf{r}_1) \delta(\mathbf{r}_1 - \mathbf{r}_2) (C\gamma^k)_{\alpha_1 \alpha_2} \delta_{2\eta} \sigma^2_{\Lambda_1 \Lambda_2}. \end{gathered} \tag{6.10}$$

We impose commutation relations on the Ψ and B fields which become thereby operators acting on a suitable state space. These states should belong to a Hilbert space, if the theory would be renormalized. The renormalization was discussed in Ref. 37 in a perturbative manner. As a postulate we introduce the equal time commutation relations,

$$\begin{aligned}
&\text{(i)}\quad \{\Psi_{I_1},\Psi_{I_2}\}_+^t := A_{I_1I_2} = C\gamma_0\sigma^1\delta(\mathbf{r}_1-\mathbf{r}_2),\\
&\text{(ii)}\quad [B_K,\Psi_I]_-^t := 0,\\
&\text{(iii)}\quad [B_{K_1},B_{K_2}]_-^t := C_{K_1K_2}.
\end{aligned} \tag{6.11}$$

Equation (i) of (6.11) is the canonical commutation relation for Ψ_α and $\overline{\Psi}_\alpha$, the Dirac adjoint field. In our notation with charge conjugate spinor operators, the somehow unusual $A_{I_1I_2}$ occurs. Because of the super field notation we have all four commutators belonging to the Ψ_α and $\overline{\Psi}_\alpha$ integrated in this relation.

Equation (ii) of (6.11) states that the boson fields are looked at as elementary fields. B_K is not a function of the Ψ_I fields. Equation (ii) (6.11) is usually postulated in QED.

Relation (iii) of (6.11) specifies the boson commutator. The special form of the c-number function $C_{K_1K_2}$ can be calculated as a consequence of requiring a consistent quantum field theory;[37] see below (6.13).

The set of equations (6.9) and (6.11) are the defining relations of Coulomb gauged quantized spinor ED. All previous steps are classical and only for convenience state a somehow self-consistent QFT. If one would quantize first and then try to eliminate Gauss' law, one would yield another QFT! The functional Hamiltonians (see below) would then have infinitely many terms.[38]

We obtain the Hamiltonian corresponding to the equations (6.9) as

$$\begin{aligned}
H(\Psi,B) = {}& \tfrac{1}{2}A_{I_1I_3}D_{I_3I_2}\Psi_{I_1}\Psi_{I_2} + \tfrac{1}{2}A_{I_1I_3}W^K_{I_3I_2}B_K\Psi_{I_1}\Psi_{I_2}\\
&+ \tfrac{1}{4}A_{I_1I_5}U^{I_2I_3I_4}_{I_5}\Psi_{I_1}\Psi_{I_2}\Psi_{I_3}\Psi_{I_4} + \tfrac{1}{2}C_{K_1K_3}L_{K_3K_2}B_{K_1}B_{K_2}.
\end{aligned} \tag{6.12}$$

There is no term $J_K^{I_1I_2}$ in the Hamiltonian. This term was eliminated with help of the commutator, (ii) of (6.11). Taking the time derivative and using the dynamics, one gets

$$C_{K_1K}W^K_{I_1I_2}\Psi_{I_2} = 2A_{I_1I}J_K^{II_2}\Psi_{I_2}. \tag{6.13}$$

This sort of consistency relation may be motivated by the physical assumption, that there is no asymmetry in the boson-fermion and fermion-boson interaction (action equals reaction, Newton). Furthermore a consistency consideration leads to the above relation.[37]

A. Antisymmetric case

We give the definitions of generating functionals for spinor QED. We introduce b sources and ∂^b duals,

$$\begin{aligned}
[b_{K_1},b_{K_2}]_- = 0 = [\partial^b_{K_1},\partial^b_{K_2}]_-,\\
[\partial^b_{K_1},b_{K_2}]_- = \delta_{K_1K_2},
\end{aligned} \tag{6.14}$$

analogous to the Schwinger sources. Therewith we define

$$\begin{aligned}
|.\mathscr{A}(a,j,b)\rangle_F &= \sum_{m,n=0}^{\infty}\frac{i^n}{n!m!}\,\tau_{nm}(I_1,\ldots,I_n,K_1,\ldots,K_m|a),\\
&\quad j_{I_1}\wedge\cdots\wedge j_{I_n}b_{K_1}\circ\cdots\circ b_{K_m}|0\rangle_F,\\
\tau_{nm}(I_1,\ldots,I_n,K_1,\ldots,K_m|a) &:= \langle 0|.\mathscr{A}(\psi_{I_1\cdots\psi_{I_n}}).\mathscr{S}(B_{K_1}\cdots B_{K_m})|a\rangle
\end{aligned} \tag{6.15}$$

and

$$|\mathscr{N}(a,j,b)\rangle_F = \sum_{m,n=0}^{\infty} \frac{i^n}{n!m!}\, \phi_{nm}(I_1,\ldots,I_n,K_1,\ldots,K_m|a),$$

$$j_{I_1}\dot{\wedge}\cdots\dot{\wedge} j_{I_n} b_{K_1}\circ\cdots\circ b_{K_m}|0\rangle_F,$$

$$\phi_{nm}(I_1,\ldots,I_n,K_1,\ldots,K_m|a) := \langle 0|\mathscr{N}(\psi_{I_1}\cdots\psi_{I_n})\mathscr{S}(B_{K_1}\cdots B_{K_m})|a\rangle, \tag{6.16}$$

where $\circ$ denotes the symmetric product of the b_K's, $\mathscr{A}$ the antisymmetrizer, $\mathscr{S}$ the symmetrizer and $\mathscr{N}$ the normal-ordering and $|a\rangle$ an energy eigen-''state.'' We assume, furthermore, that the j,∂ and b,∂^b generators commute. We do not consider bosonic normal-ordering. The field operators in the antisymmetric case are given as

$$\begin{aligned} \psi_I &= \frac{1}{i}\,\partial_I - \frac{i}{2}\,A_{II'}J_{I'}\wedge, \quad \psi_I^{op} = \frac{1}{i}\,\partial_I + \frac{i}{2}\,A_{II'}j_{I'}\wedge, \\ B_K &= \partial_K^b - \tfrac{1}{2}\,C_{KK'}b_{K'}\circ, \quad B_K^{op}\partial_K^b + \tfrac{1}{2}\,C_{KK'}b_{K'}\circ. \end{aligned} \tag{6.17}$$

Inserting these operators into (4.12) with the Hamiltonian (6.12) yields

$$\begin{aligned} E_{0a}|\mathscr{A}(a,j,b)\rangle = \{ & D_{I_1I_2}j_{I_1}\partial_{I_2} + W^K_{I_1I_2}j_{I_1}\partial_{I_2}\partial^b_K + L_{K_1K_2}b_{K_1}\partial^b_{K_2} + U^{I_2I_3I_4}_{I_1}j_{I_1} \\ & \times(\partial_{I_2}\partial_{I_3}\partial_{I_4} - \tfrac{1}{4}\,A_{I_3I_3'}A_{I_2I_2'}j_{I_2'}j_{I_3'}j_{I_4}) \\ & + J_K^{I_1I_2}b_K(\partial_{I_1}\partial_{I_2} + \tfrac{1}{4}\,A_{I_1I_1'}A_{I_2I_2'}j_{I_1'}j_{I_2'})\}|\mathscr{A}(a,j,b)\rangle, \end{aligned} \tag{6.18}$$

where the $A_{I_nI_m}$ terms stem from the field quantization of the fermions. Boson quantization terms would again occur, if the $J_K^{I_1I_2}$ would be eliminated in the above mentioned way. This result can be obtained from the normal-ordered equation by setting $F\equiv 0$, so we treat that case in more detail.

B. Normal-ordered case

The (fermion) normal-ordered equation is obtained by using the normal-ordered fermions,

$$\begin{aligned} \psi_I &= \frac{1}{i}\,\partial_I - \frac{i}{2}\,A_{II'}j_{I'}\wedge + iF_{II'}j_{I'}\wedge, \\ \psi_I^{op} &= \frac{1}{i}\,\partial_I + \frac{i}{2}\,A_{II'}j_{I'}\wedge + iF_{II'}j_{I'}\wedge; \end{aligned} \tag{6.19}$$

the boson operators remain unchanged. Before we proceed, we give the commutators of the fields, not displayed commutators, vanish. The bosons obey

$$\begin{aligned} [\partial^b_{K_1} \pm \tfrac{1}{2}\,C_{K_1K_1'}b_{K_1'}, \partial^b_{K_2} \pm \tfrac{1}{2}\,C_{K_2K_2'}b_{K_2'}]_- &= \mp C_{K_1K_2}, \\ [\partial^b_{K_1} \pm \tfrac{1}{2}\,C_{K_1K_1'}b_{K_1'}, \partial^b_{K_2} \mp \tfrac{1}{2}\,C_{K_2K_2'}b_{K_2'}]_- &= 0, \end{aligned} \tag{6.20}$$

while we have for the normal-ordered fermions,

$$\begin{aligned} \left\{\frac{1}{i}\,\partial_{I_1} \pm \frac{i}{2}\,A_{I_1I_1'}j_{I_1'} + iF_{I_1I_1'}j_{I_1'},\ \frac{1}{i}\,\partial_{I_2} \pm \frac{i}{2}\,A_{I_2I_2'}j_{I_2'} + iF_{I_2I_2'}j_{I_2'}\right\}_+ &= \pm A_{I_1I_2}, \\ \left\{\frac{1}{i}\,\partial_{I_1} \pm \frac{i}{2}\,A_{I_1I_1'}j_{I_1'} + iF_{I_1I_1'}j_{I_1'},\ \frac{1}{i}\,\partial_{I_2} \mp \frac{i}{2}\,A_{I_2I_2'}j_{I_2'} + iF_{I_2I_2'}j_{I_2'}\right\}_+ &= 0. \end{aligned} \tag{6.21}$$

We calculate directly the (fermion) normal-ordered functional Hamiltonian from $\dot{H[\Psi,B]^{\wedge}}$. Therefore we have to build

$$\dot{H[j,b,\partial,\partial_b]^{\wedge}} = H\left[\frac{1}{i}\,\partial_I + \frac{i}{2}\,A_{II'}j_{I'} + iF_{II'}j_{I'}, \partial^b_K + \frac{1}{2}\,C_{KK'}b_{K'}\right] - H\left[\frac{1}{i}\,\partial_I - \frac{i}{2}\,A_{II'}j_{I'} + iF_{II'}j_{I'}, \partial^b_K - \frac{1}{2}\,C_{KK'}b_{K'}\right]. \tag{6.22}$$

We have according to (6.12) four terms T_i. The T_1 term is of the same form as in the nonlinear spinor field model,

$$\dot{T_1[j,\partial]^{\wedge}} = D_{I_1I_2}j_{I_1}\partial_{I_2} - D_{I_1I_3}F_{I_3I_2}j_{I_1}j_{I_2}, \tag{6.23}$$

where the renormalization was discussed in Ref. 37. The term $\dot{T_2^{\wedge}}$ is given as

$$\begin{aligned}\dot{T_2[j,\partial]^{\wedge}} &= \tfrac{1}{2}\,A_{I_1I_3}W^K_{I_3I_2}[(\partial^b_K + \tfrac{1}{2}\,C_{KK'}b_{K'})(\cdots)(\cdots) - \left(\partial^b_K - \tfrac{1}{2}\,C_{KK'}b_{K'}\right)(\cdots)(\cdots)] \\ &= \tfrac{1}{2}\,A_{I_1I_3}W^K_{I_3I_2}[\partial^b_K\{(\cdots)(\cdots) - (\cdots)(\cdots)\} + \tfrac{1}{2}\,C_{KK'}b_{K'}\{(\cdots)(\cdots) + (\cdots)(\cdots)\}].\end{aligned} \tag{6.24}$$

The first term is just the same as before, while the second yields

$$2.\ \text{brace}\ \{\ \} = -2\partial_{I_1}\partial_{I_2} - 2\,\tfrac{1}{4}\,A_{I_1I_1'}A_{I_2I_2'}j_{I_1'}j_{I_2'} + 4F_{I_1I_1'}j_{I_1'}\partial_{I_2} - 2F_{I_1I_1'}F_{I_2I_2'}j_{I_1'}j_{I_2'}. \tag{6.25}$$

We may use (6.13) to obtain

$$\begin{aligned}\tfrac{1}{4}\,A_{I_1I_3}W^K_{I_3I_2}C_{KK'}b_{K'} &= -\tfrac{1}{4}\,A_{I_1I_3}C_{K'K}b_{K'}W^K_{I_3I_2} \\ &= -\tfrac{1}{2}\,A_{I_1I_3}A_{I_3I_4}J^{I_4I_2}_{K'}b_{K'} \qquad (6.26)\\ &= -\tfrac{1}{2}\,J^{I_1I_2}_K b_K, \qquad (6.27)\end{aligned}$$

and finally the result

$$\begin{aligned}\dot{T_2[j,\partial]^{\wedge}} &= W^K_{I_1I_2}[j_{I_1}\partial_{I_2} - F_{I_2I_2'}j_{I_1}j_{I_2'}]\partial^b_K + J^{I_1I_2}_k b_K \\ &\quad\times[\partial_{I_1}\partial_{I_2} - 2F_{I_1I_1'}j_{I_1'}\partial_{I_2} + (F_{I_1I_1'}F_{I_2I_2'} + \tfrac{1}{4}\,A_{I_1I_1'}A_{I_2I_2'})j_{I_1'}j_{I_2'}].\end{aligned} \tag{6.28}$$

The third term will be omitted, as it has the same structure as T_2 in the nonlinear spinor model. The last term runs along the lines of T_1 and has not changed at all from (6.18). Our result is then

$$\begin{aligned}E_{0a}|\mathcal{N}(a,j,b)\rangle = \{&D_{I_1I_2}j_{I_1}\partial_{I_2} - D_{I_1I_3}F_{I_3I_2}j_{I_1}j_{I_2} + W^K_{I_1I_2}[j_{I_1}\partial_{I_2} - F_{I_2I_2'}j_{I_1}j_{I_2'}]\partial^b_K \\ &+ J^{I_1I_2}_k b_K[\partial_{I_1}\partial_{I_2} - 2F_{I_1I_1'}j_{I_1'}\partial_{I_2} + (F_{I_1I_1'}F_{I_2I_1'} + \tfrac{1}{4}\,A_{I_1I_1'}A_{I_2I_2'})j_{I_1'}j_{I_2'}] \\ &+ U^{I_1I_2I_3}_J j_J[\partial_{I_1}\partial_{I_2}\partial_{I_3} - 3F_{I_3I_4}j_{I_4}\partial_{I_2}\partial_{I_1} + (3F_{I_3I_4}F_{I_2I_5} + \tfrac{1}{4}\,A_{I_3I_4}A_{I_2I_5})j_{I_4}j_{I_5}\partial_{I_1} \\ &- (F_{I_3I_4}F_{I_2I_5}F_{I_1I_6} + \tfrac{1}{4}\,A_{I_3I_4}A_{I_2I_5}A_{I_1I_6})j_{I_4}j_{I_5}j_{I_6}] + L_{K_1K_2}b_{K_1}\partial^b_{K_2}\}|\mathcal{N}(a,j,b)\rangle,\end{aligned} \tag{6.29}$$

which coincides with (8.59) in Ref. 21 and (63) in Ref. 37. We have succeeded in deriving the normal-ordered functional equation in one single step by Clifford algebraic considerations. No normal-ordering problems, as a vertex normal ordering, was necessary. No singular intermediate equation has occurred. And as a benefit, the calculation was considerable short.

VII. CONCLUSION

We have identified Clifford geometric algebras of multivectors as the appropriate mathematical tool in modeling quantum field theoretic generating functions. These algebras were studied in section II. Great emphasis was made on the connection of the spaces underlying the Clifford and Grassmann algebras, which induce the multivector structure in a Clifford algebra. This structure is ubiquitously used in physics, but not inherent in an ordinary Clifford algebra. However, if a Clifford algebra is constructed from generators and relations, one has implicitly imposed an ordering, which results in the explicit multivector structure. Only the Clifford algebra of multivectors can sytematically account for these situations and uncover the role played by the propagator. The propagator or say antisymmetric part of the contraction directly parameterizes the vacua underlying the theory as was shown in Ref. 9.

The third section develops a complete algebraic approach to quantum field theoretic generating functionals by means of Clifford algebras of multivectors. It was shown that the field operators can be seen as Clifford maps acting on the Grassmann algebra built from the Schwinger source terms. The vacuum was shown to be involved in the definition of matrix elements. This result remains true for path integrals, which rely on the same generating functionals. However, in the very compact notation of path integrals no direct access to these structures is possible.

In section IV we gave the transition from operator dynamics to generating functionals. This transition was motivated by the Heisenberg equation. However, there is no unique lifting of such an expression. To be able to reproduce the results in literature, we chose the opposite action, not the right action. Further investigations on that topic seem to be necessary. The last sections, V and VI, gave examples, which showed the easiness and computational advantages of this method. A nonlinear spinor field was treated in the antisymmetric and the normal-ordered case. The same was done for spinor QED as an example for a boson-fermion coupling theory. The most remarkable result is that it was possible to derive normal-ordered generating functionals directly, that is in one single step, from the operator dynamics. Furthermore, this showed that the algebraic theory has full control over the involved orderings and thereby over the involved vacuum states. This was investigated in detail in Ref. 9. The method was already applied to Dirac theory with some success.[32]

ACKNOWLEDGMENTS

Two long e-mail letters from Professor Z. Oziewicz, which improved the semantics and clarity of section II, were a valuable help in preparing this work. The support of Mrs. Ursula Wieland is gratefully acknowledged. The author would like to thank the referee for pointing out the importance of Ref. 7 for this work.

(Received 15 October 1997; accepted for publication 10 April 1998)

We consider quasilinear parabolic equations with gradient diffusivity $u_t = \mathrm{div}(|\nabla u|^\sigma \nabla u) + f(u)$, $x \in \mathbf{R}^N$, $t>0$, where $\sigma \neq -1$ is a fixed constant and $f(u)$ is a given smooth function. We also study quasilinear parabolic equations with a gradient-dependent coefficient $u_t = h(|\nabla u|)\Delta u + f(u)$, with a smooth function $h(p)$. For both classes of equations we derive first-order sign-invariants, i.e., first-order operators preserving their signs on the evolution orbits $\{u(\cdot,t), t>0\}$. We give a complete description of (maximal) sign-invariants of prescribed structures. As a consequence, we construct new exact solutions of some quasilinear equations. © *1998 American Institute of Physics.* [S0022-2488(98)01609-0]

Dedicated to Professor S. Kurdyumov on his 70th birthday.

I. INTRODUCTION

We consider quasilinear parabolic equations with gradientlike diffusivity

$$u_t = \mathrm{div}(|\nabla u|^\sigma \nabla u) + f(u), \quad x \in \mathbf{R}^N, \quad t>0, \tag{1.1}$$

where $\sigma \neq -1$ is a fixed constant and $f(u)$ is a sufficiently smooth function to be prescribed later. It is well-known that such types of diffusionlike operators occur, for instance, in the theory of non-Newtonian liquids and in some turbulence problems, see Ref. 1, and references therein. We also study quasilinear parabolic equations with a general nonlinearity in the diffusion term of the gradient-dependent type

$$u_t = h(|\nabla u|)\Delta u + f(u), \tag{1.2}$$

with a sufficiently smooth function $h(p)>0$. Such nonlinearities are widely used in mean curvature flow equations related to differential geometry and to problems of motion of a closed hypersurface in $\mathbf{R}^N$ by its mean curvature, see Refs. 2 and 3. Such equations are important in phase transition phenomena.[4] The one-dimensional Eq. (1.1) ($N=1$) corresponds to the function $h(p) = (\sigma+1)p^\sigma$ in (1.2). As a typical example we consider the equation

$$u_t = \frac{u_{xx}}{1+(u_x)^2} - \frac{1}{u}, \quad x \in \mathbf{R}, \quad t>0, \tag{1.3}$$

which describes (after a suitable surface parametrization) the evolution of cylindrically symmetric hypersurfaces moving by mean curvature in $\mathbf{R}^3$, see Refs. 5 and 6. On the other hand, a one-dimensional quasilinear parabolic equation with both gradient-dependent coefficients

$$u_t = \frac{u_{xx}}{1+(u_x)^2} + f(u)(1+(u_x)^2)^{1/2},$$

is interpreted[7] as an equation of motion for the graph of u

$$\Gamma_t=\{(x,y):\quad y=u(x,t),\quad x\in\mathbf{R}\},$$

with the equation

$$V=k+f(y),$$

where $V=u_t/(1+(u_x)^2)^{1/2}$ denotes the upward velocity of Γ_t and $k=u_{xx}/(1+(u_x)^2)^{3/2}$ is the upward curvature of Γ_t. This is an example of a curve shortening equation with driving force term $f(y)$. Blow-up of the derivative u_x for a more general equation of such type

$$u_t=a(u_x)u_{xx}+f(u)g(u_x),$$

was studied in Ref. 7.

Let us describe the main techniques of the present paper. We introduce a general first-order Hamilton–Jacobi (HJ) operator of the form

$$H(u)=H(u_t,\nabla u,u),$$

where the function $H(\cdot)$ is assumed to be smooth enough.

We say that the operator (HJ) is a sign-invariant of the given nonlinear parabolic equation if it preserves both signs, $\geqslant 0$ and $\leqslant 0$, on its solutions $u(x,t)$. This means that

$$H(u)\geqslant 0(\leqslant 0)\ \text{ in }\ \mathbf{R}^N\quad \text{for } t=0\ \Rightarrow\ H(u)\geqslant 0(\leqslant 0)\ \text{ in }\ \mathbf{R}^N\quad \text{for } t>0. \tag{1.4}$$

These properties are understood in the sense of a formal application of the Maximum Principle for linear parabolic equations, see details in Ref. 8.

Some ideas of sign invariants were originated from the qualitative theory of nonlinear parabolic equations where similar barrier techniques (one-sided as usual) play a fundamental role in the study of existence, uniqueness, differential, and asymptotic properties of wide classes of solutions. We refer to Refs. 8 and 9 where these questions are discussed in detail for other classes of quasilinear parabolic equations, and necessary references are available.

In this paper we present the results on the structure of the first-order sign-invariants admitted by the equations with gradient diffusivity. We study **maximal** sign-invariants describing all possible sign-invariants of a prescribed structure. We also construct the corresponding sets of exact solutions (i.e., those which can be expressed in terms of finite-dimensional dynamical systems) using the zero-invariance property of sign-invariants. Namely, under assumption (1.4) the operator (HJ) is also a zero-invariant of the evolution equation, i.e., there holds

$$H(u)=0\quad \text{for } t=0\ \Rightarrow\ H(u)=0\quad \text{for } t>0. \tag{1.5}$$

This is a differential constraint, a well-known approach for constructing exact solutions of nonlinear evolution equations, see Ref. 8. We claim that under certain restrictions a consistent differential constraint for a quasilinear second-order parabolic equation can be extended to a sign-invariant which describes properties of a much wider (than purely exact ones) class of solutions $u(x,t)$.

In Sec. II we consider sign-invariants of the form $u_t-\psi(u)$ and the corresponding exact solutions. Sections III and IV are devoted to the sign-invariants of the form $u_r-g(r)F(u)$, $r=|x|$, in the class of spatially symmetric solutions $u=u(r,t)$.

Sign-invariants for quasilinear parabolic equations can give new exact finite-dimensional solutions.[8,9] On the other hand, the corresponding differential inequalities $H(u)\geqslant 0(\leqslant 0)$ can define a generalized property of B-convexity (concavity) of solutions preserved in time,[10] which is treated as convexity (concavity) relative to the corresponding family B of exact solutions. Under certain hypotheses on initial-boundary data and the coefficients of the equation, the differential inequalities can allow us to derive some *a priori* bounds on more general solutions of the parabolic equation under consideration.

II. NONSTATIONARY AUTONOMOUS MAXIMAL SIGN-INVARIANT

We are looking for a sign-invariant for the general Eq. (1.2) of the form

$$H(u)\equiv u_t-\psi(u), \tag{2.1}$$

with a smooth function $\psi(u)$ depending on the coefficients of the equation. The structure of operator (2.1) comes from the conditions of ψ-criticality of solutions to quasilinear parabolic equations.[11] Given the particular structure (2.1) of the sign-invariants depending on a single unknown function $\psi(u)$ we perform our further research in terms of the following.

Definition 2.1: The set

$$\mathscr{H}_{\max}=\{H:\ \exists\psi \text{ such that } (2.1) \text{ is a sign-invariant of } (1.2)\}$$

is said to be a maximal sign-invariant of equation (1.2) of the type (2.1).

We begin with a preliminary description of the maximal sign-invariant.

Proposition 2.2: (2.1) is a sign-invariant to (1.2) if and only if the functions $h(p)$ and $\psi(u)$ satisfy the identity for all $(u,p)\in\mathbf{R}\times\mathbf{R}_+$

$$\mathscr{T}(u,p)=f'\psi-f\psi'+\frac{h'(p)}{h(p)}\,p(\psi-f)\psi'+h(p)p^2\psi''\equiv 0. \tag{2.2}$$

Proof: It is not difficult to calculate that the function $J=u_t-\psi(u)$, assumed to be sufficiently smooth, solves a linear parabolic equation of the form

$$J_t=\mathscr{L}J+\mathscr{T}, \tag{2.3}$$

where $\mathscr{L}$ is a second-order elliptic operator and $\mathscr{T}$ is as given in (2.2). Therefore, by the Maximum Principle, the function $J(\cdot,t)$ preserves its sign (both the positive and negative ones) given on the parabolic boundary of the domain if $\mathscr{T}=0$. See details in Ref. 8.

Let us now prove that

$$\mathscr{H}_{\max}=\{H(u)=u_t-\psi(u):\ \psi \text{ solves Eq. } (2.2)\},$$

is the maximal sign-invariant for Eq. (1.2). Indeed, assume for contradiction that there exist constants $\mu\in\mathbf{R}$, $\nu\in\mathbf{R}_+$ such that $\mathscr{T}(\mu,\nu)\neq 0$ and, say, >0. Then one can construct a smooth initial function $u_0\equiv u(x,0)$ such that $J(x,0)\equiv h(|\nabla u_0|)\Delta u_0+f(u_0)-\psi(u_0)=0$ in a neighborhood of the origin $x=0$, and $u_0(0)=\mu$, $|\nabla u_0|(0)=\nu$. For instance, one can take a symmetric function $u_0(r)$, $r=|x-x_0|$, with an arbitrary fixed $x_0\in\mathbf{R}^N$, $x_0\neq 0$. Then $u_0(|x_0|)=\mu$, $u_0'(|x_0|)=\nu$ and the existence of such a function $u_0(r)$ follows from the standard theory of ordinary differential equations. As usual, for a formal application of the maximum principle we assume that such a u_0 can be continued beyond a neighborhood of the origin to provide us with a local-in-time solution $J(x,t)$ of Eq. (2.3). Then a standard formal application of the maximum principle, based on the interior regularity results for uniformly parabolic equations implies that $J(x,t)>0$ for all small $t>0$ and $x\approx 0$. Therefore, the negative sign, $J\leqslant 0$, is not preserved on all the evolution orbits.□

We now give a detailed complete description of the maximal sign-invariant and the corresponding exact solutions. It follows from (2.2) that the right-hand side, as a function of p only, belongs to the linear span

$$W=\mathscr{L}\left\{1,\frac{h'(p)}{h(p)}\,p,\ h(p)p^2\right\}. \tag{2.4}$$

Therefore we consider three cases.

Case 1: dim $W=3$. Then since all the three terms in (2.2) are linearly independent we arrive at the system

$$f'\psi-f\psi'=0,\quad (\psi-f)\psi'=0,\quad \psi''=0, \tag{2.5}$$

which is easily solved with respect to the function $\psi(u)$. We have

$$\psi(u)=au+b, \quad f(u)=\lambda(au+b), \tag{2.6}$$

where either $\lambda=1$ or $a=0$. In particular, if $\lambda=1$, i.e., $\psi(u)=f(u)=au+b$ we have that the equation

$$u_t=h(|\nabla u|)\Delta u+au+b \quad (a\neq 0),$$

admits the exact solution

$$u(x,t)=\frac{1}{a}\,[g(x)e^{at}-b],$$

where $g(x)$ is an arbitrary harmonic function. If $a=0$ then the equation

$$u_t=h(|\nabla u|)\Delta u+b,$$

has the exact solution

$$u(x,t)=g(x)+dt,$$

where g solves the elliptic equation

$$h(|\nabla g|)\Delta g+b-d=0 \ \text{ in } \mathbf{R}^N.$$

Case 2: dim $W=2$. Without loss of generality, we may assume that there exist constants $\alpha\neq 0$, $\beta\neq 0$ such that

$$\frac{h'}{h}\,p+\alpha hp^2+\beta=0. \tag{2.7}$$

Substituting $h'p/h$ from (2.7) into (2.2) we conclude that the functions $f(u)$ and $\psi(u)$ satisfy the following system of the ODE's (ordinary differential equation)

$$\psi''=\alpha(\psi-f\,)\psi', \quad \beta\psi\psi'=f'\psi+(\beta-1)f\psi'. \tag{2.8}$$

The second one is easily solved with respect to the function f:

$$f=A_0\psi^{1-\beta}+\psi. \tag{2.9}$$

Here and later on A_0, B_0,… denote free constants of integration.

Substituting (2.9) into the first equation and integrating once we get the first-order ODE

$$\psi'=B_0+\frac{\alpha A_0}{\beta-2}\,\psi^{2-\beta}, \quad \beta\neq 2, \tag{2.10}$$

$$\psi'=B_0-\alpha A_0\,\log\,\psi, \quad \beta=2. \tag{2.11}$$

The system (2.7), (2.9)–(2.11) defines a multidimensional set of Eq. (1.2) which admit sign-invariant (2.1). The structure of the corresponding exact solutions is calculated from the identity $u_t=\psi(u)$ so that it takes the form

$$u(x,t)=\Phi^{-1}(t+\rho(x)), \tag{2.12}$$

where Φ^{-1} is the inverse function to

$$\Phi(u)=\int_1^u dz/\psi(z), \tag{2.13}$$

and $\rho(x)$ is a smooth function to be determined later by substituting (2.12) into equation (1.2). We then arrive at the following result.

Theorem 2.3: *(i) If $\beta \neq 2$ in (2.7) then the equation*

$$u_t = \frac{(2-\beta)\Delta u}{C_0|\nabla u|^\beta + \alpha|\nabla u|^2} + A_0\psi^{1-\beta}(u) + \psi(u), \tag{2.14}$$

where ψ solves (2.10), admits sign-invariant (2.1) and the exact solution (2.12) where ρ solves an elliptic equation of the form

$$\Delta\rho + B_0|\nabla\rho|^2 + \frac{A_0C_0}{2-\beta}|\nabla\rho|^\beta = 0. \tag{2.15}$$

(ii) If $\beta = 2$ then the parabolic equation takes the form

$$u_t = \frac{\Delta u}{(C_0 + \alpha \log|\nabla u|)|\nabla u|^2} + \frac{A_0}{\psi(u)} + \psi(u), \tag{2.16}$$

with ψ satisfying (2.11), and ρ in (2.12) solves the semilinear elliptic equation

$$\Delta\rho + (\mu + \nu \log|\nabla\rho|)|\nabla\rho|^2 = 0, \quad \mu = B_0 + A_0C_0, \quad \nu = \alpha A_0. \tag{2.17}$$

We now begin to study properties of particular simpler solutions of such type.

Example 2.1: We consider the case $\alpha = 2$ and $\beta = 0$ in (2.7), where h solves

$$\frac{h'}{h}\, p = -2hp^2. \tag{2.18}$$

Then $h(p) = (1+p^2)^{-1}$ and (2.2) reads $\mathscr{T}(u,p) \equiv f'\psi - f\psi' + h(p)p^2[\psi'' - 2(\psi - f)\psi'] = 0$. This yields the system of the ODE's [cf. (2.8)]

$$f'\psi - f\psi' = 0, \quad \psi'' - 2(\psi - f\,)\psi' = 0.$$

The general solution of this system is $f(u) = \lambda\psi(u)$, $\lambda \in \mathbf{R}$, where ψ solves the ODE

$$\psi'' - 2(1-\lambda)\psi\psi' = 0.$$

This representation includes the equation with $f \equiv 0$, i.e., $\lambda = 0$, see a remark below.

We now consider the solution with $\lambda = 1/2$ so that $\psi(u) = 2f(u)$ where f solves $f'' - 2ff' = 0$ and hence

$$f'(u) - f^2(u) = \gamma, \tag{2.19}$$

γ being a free constant. We consider three cases.

(i) If $\gamma = 0$ in (2.19) then $f(u) = -1/u$. Integrating the ordinary differential equation

$$u_t = \psi(u) \equiv -\frac{2}{u},$$

we obtain the explicit solution [cf. (2.12)]

$$u_*(x,t) = (\tilde{\rho}(x) - 4t)^{1/2}. \tag{2.20}$$

Substituting (2.20) into the corresponding parabolic equation [which coincides with (1.3) in the one-dimensional case]

$$u_t = \frac{\Delta u}{1+|\nabla u|^2} - \frac{1}{u}, \tag{2.21}$$

we arrive at the following linear elliptic equation for $\tilde{\rho}$:

$$\Delta\widetilde{\rho}+2=0, \quad x\in\mathbf{R}^N. \tag{2.22}$$

Let us discuss a few properties of such symmetric explicit solutions, $u_*=u_*(r,t)$, $r=|x|$. Then (2.22) is easily integrated:

$$\begin{aligned}\widetilde{\rho}(r)&=-\frac{1}{N}\,r^2+\frac{c_0}{2-N}\,r^{2-N}+c_1, \quad N\geqslant 3,\\ \widetilde{\rho}(r)&=-\frac{r^2}{2}+c_0\,\log r+c_1, \quad N=2,\end{aligned} \tag{2.23}$$

where c_0 and c_1 are arbitrary constants. In the one-dimensional case $N=1$, (2.20) is obviously the exact self-similar solution ($c_0=c_1=0$ by translations in x and t)

$$u_*(x,t)=2\sqrt{-t}\left(1-\frac{\xi^2}{4}\right)^{1/2}, \quad \xi=\frac{x}{\sqrt{-t}}, \tag{2.24}$$

describing the disappearance (extinction) of the solution at the origin $x=0$ at the finite time $t=0$. One can see that (2.24) is defined in the shrinking domain $\{|x|<2\sqrt{-t},\ t<0\}$ and it is not a weak solution of the free boundary problem to (2.21) for $x\in\mathbf{R}$ in the standard sense of integration by parts.

On the other hand, if $N\neq 1$, then solution (2.20), (2.23) is not self-similar and has the form ($c_1=0$ by translation in t and $c_0=1$)

$$\begin{aligned}u_*(r,t)&=\left(-\frac{r^2}{N}-\frac{r^{2-N}}{N-2}-4t\right)^{1/2}, \quad N\geqslant 3,\\ u_*(r,t)&=\left(-\frac{r^2}{2}+\log r-4t\right)^{1/2}, \quad N=2.\end{aligned} \tag{2.25}$$

It describes extinction of the solution to the initial-boundary value problem (IBVP) on the sphere $\{|x|\equiv r_0=(N/2)^{1/N}\}$ at the moment

$$T=-\frac{1}{4(N-2)}\left(\frac{N}{2}\right)^{2/N}, \quad N\geqslant 3; \quad T=-\frac{1}{8}, \quad N=2. \tag{2.26}$$

The behavior as $t\to T^-$, $r\to r_0$, is asymptotically self-similar.

(ii) If $\gamma=1$ in (2.19) then $f(u)=\tan u$. By integrating the ODE $u_t=2\tan u$ we deduce that

$$u_*(x,t)=\arcsin(\widetilde{\rho}(x)e^{2t}), \quad \widetilde{\rho}=e^{2\rho}, \tag{2.27}$$

where ρ solves the elliptic Eq. (2.15) with $\beta=0$, $A_0'=-1/2$, $B_0=C_0=2$. By substituting into equation

$$u_t=\frac{\Delta u}{1+|\nabla u|^2}+\tan u, \tag{2.28}$$

we obtain that $\widetilde{\rho}(x)$ solves the elliptic equation

$$\Delta\widetilde{\rho}-\widetilde{\rho}=0, \quad x\in\mathbf{R}^N. \tag{2.29}$$

(iii) Consider now the last case $\gamma=-1$. Then, the parabolic equation takes the form

$$u_t=\frac{\Delta u}{1+|\nabla u|^2}+\frac{1+e^{2u}}{1-e^{2u}}, \tag{2.30}$$

which admits the exact solution

$$u(x,t)=\pm\log[\sqrt{e^{-4t}\widetilde{\rho}^2(x)-1}+e^{-2t}\widetilde{\rho}(x)],\quad \widetilde{\rho}=\tfrac{1}{2}e^{-2\rho}, \tag{2.31}$$

where ρ satisfies (2.15) and $\widetilde{\rho}(x)$ solves the elliptic equation

$$\Delta\widetilde{\rho}+\widetilde{\rho}=0. \tag{2.32}$$

Similarly, the equation

$$u_t=\frac{\Delta u}{1+|\nabla u|^2}+\frac{1-e^{2u}}{1+e^{2u}},$$

admits the exact solution

$$u(x,t)=\pm\log[\sqrt{e^{-4t}\widetilde{\rho}^2(x)+1}+e^{-2t}\widetilde{\rho}(x)],\quad \widetilde{\rho}=\tfrac{1}{2}e^{-2\rho},$$

and $\widetilde{\rho}$ satisfies (2.32). In particular, in the one-dimensional case we deduce the following 2π-periodic solution

$$u(x,t)=\pm\log[\sqrt{e^{-4t}\sin^2 x+1}+e^{-2t}\sin x].$$

Remark 1: In the case of Eq. (1.1), $N=1$, where $h'(p)p/h(p)=\sigma$, we obtain the following two independent ODE's

$$\psi''=0,\quad f'\psi-f\psi'+\sigma(\psi-f)\psi'=0.$$

This yields the linear sign invariant $u_t-(au+b)$ in the case $f(u)=c(au+b)^{\sigma+1}+(au+b)$. The corresponding heat Eq. (1.1) is well-known to admit an explicit solution in separate variables describing for $\sigma>0$ standing regionally localized blow-up patterns (the so-called *S*-regime of localization), see Ref. 12.

Remark 2: It follows from (2.8) that in the case of the pure gradient-diffusivity equation with $f\equiv 0$, there exists a nontrivial sign-invariant (2.1) provided that $\beta=0$. Then the system (2.8) reduces to a single ODE of the form $\psi''=\alpha\psi\psi'$. In particular, in the case (2.18), with $\alpha=2$, $\beta=0$ in (2.7), we obtain $\psi''-2\psi\psi'=0$ whence

$$\psi'-\psi^2=\gamma,\quad \gamma\in\mathbf{R}.$$

We then deduce that the equation

$$u_t=\frac{\Delta u}{1+|\nabla u|^2},$$

admits the exact solution (2.12) where $\rho(x)$ solves the elliptic equation [cf. (2.15)]

$$\Delta\rho+\gamma|\nabla\rho|^2-1=0.$$

In particular, there exist all the exact solutions (2.20), (2.24), (2.25), and (2.31) where t has to be replaced by $t/2$.

Case 3: dim $W=1$. It is easy to see that we can restrict out attention to the function $h(p)=p^{-2}$. Then identity (2.2) reduces to a single ODE of the form

$$(\psi'+f\psi-\psi^2)'=0. \tag{2.33}$$

Integrating it once we obtain

$$\psi'+f\psi-\psi^2=\gamma. \tag{2.34}$$

Given a smooth function $f(u)$ we fix an arbitrary solution $\psi(u)$ to (2.34). Then we obtain the structure (2.12) of the explicit solutions. Substituting into the parabolic equation

$$u_t=\frac{\Delta u}{|\nabla u|^2}+f(u), \tag{2.35}$$

and using (2.34) we deduce that $\rho(x)$ satisfies the following semilinear elliptic equation:

$$\Delta\rho+\gamma|\nabla\rho|^2=0, \quad x\in\mathbf{R}^N, \tag{2.36}$$

which reduces to the Laplace equation $\Delta p=0$ in $\mathbf{R}^N$ by setting $p(x)=e^{\gamma\rho(x)}$. Recall that due to the single Eq. (2.33) on the function ψ the above explicit solutions to (2.35) exist for arbitrary lower-order terms $f(u)$, i.e., the set of such quasilinear parabolic equations is *infinite-dimensional*. On the other hand, for $N=1$ via the well-known transformation[13] $x=\psi(y,t)$ where ψ is such that $u(\psi(y,t),t)\equiv y$, the one-dimensional Eq. (2.35) reduces to the linear heat equation with convection $\psi_t=\psi_{yy}-f(y)\psi_y$. In terms of ψ this implies a certain linear superposition property of solutions.

This completes the analysis of identity (2.2) on the subspace (2.4).

III. NONAUTONOMOUS STATIONARY SIGN-INVARIANT

In this section we consider sign-invariants of the stationary structure which is nonautonomous in the spatial variable $x\in\mathbf{R}^N$. We restrict our attention to a class of radial symmetric solutions $u=u(r,t)$, $r=|x|\geqslant 0$. In this class the first-order operator has the form

$$H_*(u)\equiv u_r-g(r)F(u) \quad \text{for } t>0, \tag{3.1}$$

with yet unknown smooth non-negative functions $g(r)\not\equiv$const and $F(u)\neq 0$ a.e. The idea of such sign-invariants goes to the gradient bounds introduced[14] for semilinear parabolic equations. Generalizations to the quasilinear gradient-dependent operators can be found in Ref. 15. We apply operator (3.1) to Eq. (1.1) written in the equivalent radially symmetric form (we suppose for convenience that $u_r>0$)

$$u_t=(u_r)^\sigma\left[(\sigma+1)u_{rr}+\frac{N-1}{r}\,u_r\right]+f(u), \tag{3.2}$$

with $\sigma\neq -1$.

Proposition 3.1: Operator (3.1) is a sign-invariant of (3.2) if and only if the functions $g(r)$ and $F(u)$ satisfy the identity

$$\begin{aligned}\frac{\mathscr{T}(r,u)}{(\sigma+1)F^{\sigma+1}}\equiv{}&(g^\sigma g')'(r)+2(\sigma+1)(g^{\sigma+1}g')(r)F'+g^{\sigma+3}(r)[FF''+\sigma(F')^2]\\&+g(r)\left(\frac{f}{F}\right)'\frac{F^{1-\sigma}}{(\sigma+1)}+g^\sigma(r)\,\frac{N-1}{r}\left[g'(r)+g^2(r)\,\frac{\sigma}{\sigma+1}\,F'-\frac{g(r)}{(\sigma+1)r}\right]\\&=0.\end{aligned} \tag{3.3}$$

Proof: The proof is straightforward, see the previous one in Sec. II. Indeed, direct computations lead to the parabolic Eq. (2.3) for the function $J=H_*(u)$ with an elliptic operator $\mathscr{L}$ and the lower order term $\mathscr{T}$ given in (3.3). □

We now give a description of the maximal sign-invariant $\mathscr{H}_{\max}$, i.e., the whole set of sign-invariants of the form (3.1) with nontrivial (see above) functions g and F.

3.1. Dimension: $N=1$. Here the Greek letters α,β,γ... denote arbitrary constants.

Theorem 3.2: *Let $N=1$. Then $\mathscr{H}_{\max}=\mathscr{H}_1\cup\mathscr{H}_2$ where the sets $\mathscr{H}_{1,2}$ are defined as follows: (i) $H_*\in\mathscr{H}_1$ if g satisfies the ODE*

$$(g^\sigma g')'=\beta g^{\sigma+1}g'+\gamma g^{\sigma+3}+\delta g, \quad \gamma=-\sigma\left[\frac{\beta}{2(\sigma+1)}\right]^2, \tag{3.4}$$

and F is a linear function

$$F(u)=-\frac{\beta u}{2(\sigma+1)}. \tag{3.5}$$

(ii) $H_*\in\mathscr{H}_2$ if g and F satisfy the ODE's

$$g^\sigma g'=\gamma g^{\sigma+2}+\delta, \tag{3.6}$$

$$(F^\sigma F')'+2\gamma(\sigma+1)F^{\sigma-1}F'+\gamma^2(\sigma+2)F^{\sigma-1}=0. \tag{3.7}$$

The corresponding function $f(u)$ is then given by

$$\text{(i)}\quad f(u)=\frac{2\delta(\sigma+1)^2}{\sigma\beta}\left(-\frac{\beta u}{2(\sigma+1)}\right)^{\sigma+1}, \tag{3.8}$$

$$\text{(ii)}\quad f(u)=\frac{\delta(\sigma+1)}{\gamma}F^{\sigma+1}F'+\rho F. \tag{3.9}$$

Proof of Theorem 3.2: For $N=1$, the right-hand side of (3.3), as a function of the space variable r, is a linear combination (with coefficients depending on u) of four terms which should be linearly dependent (otherwise no nontrivial sign-invariant exists). Therefore, we assume that

$$\alpha_1(g^\sigma g')'+\beta_1 g^{\sigma+1}g'+\gamma_1 g^{\sigma+3}+\delta_1 g=0. \tag{3.10}$$

We need to consider two cases

Case 1: $\alpha_1\neq 0$. Let $\alpha_1=-1$, i.e.

$$(g^\sigma g')'=\beta_1 g^{\sigma+1}g'+\gamma_1 g^{\sigma+3}+\delta_1 g. \tag{3.11}$$

Substituting (3.11) into (3.3) we obtain a linear combination of the form

$$I_1(u)g^{\sigma+1}g'+I_2(u)g^{\sigma+3}+I_3(u)g=0 \tag{3.12}$$

on the linear space $\mathscr{W}=\mathscr{L}\{g^{\sigma+1}g',\ g^{\sigma+3},\ g\}$. Then we have: (i) If $\dim\mathscr{W}=3$ then we get the system of ODE's for F and f

$$I_1\equiv\beta_1+2(\sigma+1)F'=0,\quad I_2\equiv\gamma_1+FF''+\sigma(F')^2=0,$$

$$I_3\equiv\delta_1+\left(\frac{f}{F}\right)'\frac{1}{(\sigma+1)F^{\sigma-1}}=0, \tag{3.13}$$

which corresponds to the case $H_*\in\mathscr{H}_1$.

(ii) If $\dim\mathscr{W}=2$ then there exist constants γ and δ such that

$$g^{\sigma+1}g'=\gamma g^{\sigma+3}+\delta g. \tag{3.14}$$

Dividing (3.14) over $g\not\equiv 0$, differentiating once and comparing with (3.11) we conclude that such a function g exists if and only if

$$\gamma_1=\gamma[\gamma(\sigma+2)-\beta_1],\quad \delta_1=\delta[\gamma(\sigma+2)-\beta_1]. \tag{3.15}$$

One can see that this corresponds to the case $H_*\in\mathscr{H}_2$. Any less dimensional reduction of $\mathscr{W}$ is impossible.

Case 2: $\alpha_1=0$. This reduces to (3.14) and to the same analysis. □

The sign-invariants from $\mathscr{H}_1$ and the corresponding exact solutions in separate variables are already known and studied in detail.[12,16] Observe that the ODE (3.7) always admits a linear solution $F(u)=Cu$ with either $C=-\gamma$ or $C=-\gamma(\sigma+2)/\sigma$, which corresponds, after the transformations $u=e^{\rho Ct}v$, to stationary or separate-variable solutions.

We now consider new exact solutions generated by sign-invariants from $\mathscr{H}_2$. These solutions are new even for the semilinear heat Eq. (1.1) with $\sigma=0$.

Theorem 3.3: *The one-dimensional equation*

$$u_t=(\sigma+1)(u_x)^\sigma u_{xx}+f(u), \tag{3.16}$$

where $f(u)$ *is given by (3.9) with F satisfying (3.7), admits the exact solution* $u(x,t)$ *given by*

$$\Phi(u)\equiv\int_1^u dz/F(z)=\int_0^x g(y)dy+C_0(t), \tag{3.17}$$

with $g(y)$ *being a solution to (3.6) with the boundary conditions*

$$g(0)=\alpha>0. \tag{3.18}$$

The function C_0 *solves the ODE*

$$\frac{dC_0}{dt}=(\sigma+1)\left(\alpha^{\sigma+2}+\frac{\delta}{\gamma}\right)F^\sigma(\Phi^{-1}(C_0))(F'(\Phi^{-1}(C_0))+\gamma)+\rho, \quad t>0. \tag{3.19}$$

Proof: Substituting (3.17) into (3.16) and using (3.14) we obtain the identity

$$\frac{dC_0}{dt}=(\sigma+1)\left(g^{\sigma+2}+\frac{\delta}{\gamma}\right)F^\sigma(F'+\gamma)+\rho\equiv G(x,t). \tag{3.20}$$

One can check that under the hypotheses of the theorem $G_x\equiv 0$. In order to prove this identity one can differentiate $G(x,\cdot)$ and substitute $g^{\sigma+1}g'$ from (3.14). Finally, (3.7) yields the result.

Hence (3.20) is equivalent to the equation $C_0'=G(0,t)$ and (3.19) follows. □

3.2 Dimensions: $N>1$. If $N\neq 1$ then, in general, (3.3) with $\sigma\neq 0$ is a linear combination in a five-dimensional space of the form

$$W_\sigma=\mathscr{L}\left\{\varphi,\ g^{\sigma+1}g',\ g,\ g^{\sigma+3},\ \frac{g^{\sigma+2}}{r}\right\}, \quad \varphi=\nabla\cdot(g^\sigma\nabla g)-\frac{N-1}{\sigma+1}\frac{g^{\sigma+1}}{r^2}. \tag{3.21}$$

If $\sigma=0$ then the space is four-dimensional

$$W_0=\mathscr{L}\{\varphi,\ gg',\ g,\ g^3\}, \quad \varphi=\Delta g-(N-1)\frac{g}{r^2}. \tag{3.22}$$

The semilinear case $\sigma=0$. We now prove the main result on completeness for the semilinear equation with $\sigma=0$.

Theorem 3.4: *Let* $\sigma=0$. *A sign-invariant of the form (3.1) exists in the two cases: (i) for the equation with a special logarithmic nonlinearity*

$$u_t=\Delta u+Au\ \log u+Bu, \tag{3.23}$$

and (ii) for a class of equations when H_* *contains the special functions* $g(r)=c/r$ *or* $g(r)=cr$.

Proof: Consider the space W_0. In view of (3.3) with $\sigma=0$ we have to have that [see (3.22)]

$$\varphi=\alpha gg'+\beta g+\gamma g^3. \tag{3.24}$$

If we assume that

$$gg',\ g,\ \text{and}\ g^3\ \text{are linearly independent}, \tag{3.25}$$

then substituting (3.24) into (3.3) we arrive at the system

$$2F'+\alpha=0, \quad FF''+\gamma=0, \quad F(f/F)'+\beta=0,$$

whence $\gamma=0$ and F is a linear function. After translation in u and necessary rescaling in the independent variables we get (3.23).

If (3.25) does not hold then g satisfies

$$g'=\varepsilon g^2+\delta, \quad \text{so that } g''=2\varepsilon^2 g^3+2\varepsilon\delta g. \tag{3.26}$$

Substituting (3.26) and (3.24) we arrive at a cubic algebraic equation for g

$$(2\varepsilon^2-\alpha\varepsilon-\gamma)g^3+\frac{\varepsilon(N-1)}{r}\,g^2+\left(2\varepsilon\delta-\frac{N-1}{r^2}-\alpha\delta-\beta\right)g+\frac{\delta(N-1)}{r}=0.$$

One can see that it matches with (3.26) if and only if $\varepsilon\delta=0$. Indeed, if $\varepsilon\delta\neq 0$ then by (3.26) the function $g(r)$ is given either by an exponential-like function or by the tan. Both functions do not satisfy the cubic equation. Therefore either $g'=\delta$ $(\varepsilon=0)$ or $g'=\varepsilon g^2$ $(\delta=0)$ completing the proof. □

In the case (ii) nontrivial exact solutions can be found in Sec. III in Ref. 8.

Equation (3.23) is well-known to admit separable solutions $u=M(t)\psi(x)$ and others. See p. 93 in Ref. 17. Exact solutions corresponding to the functions $g(r)=r$ or $1/r$ were constructed in Ref. 8. Observe that theorem 3.4 proves a kind of completeness of the results of Sec. III in Ref. 8.

The corresponding maximal sign-invariant is presented in the proof of the theorem.

The quasilinear case: $\sigma\neq 0$. The analysis presented below gives a complete study of the sign-invariants (3.1) in the quasilinear case. We stress our attention to some particular situations, which correspond to new types of exact solutions, and omit details of the study of the known types or trivial solutions.

Consider the space W_σ. First of all it follows from (3.3) that the function φ given in (3.21) must satisfy

$$\varphi=\alpha g^{\sigma+1}g'+\beta g+\gamma g^{\sigma+3}+\delta\,\frac{g^{\sigma+2}}{r}. \tag{3.27}$$

(i) Similar to the case $\sigma=0$ one can show that the assumption [cf. (3.25)]

$$g^{\sigma+1}g', \quad g, \quad g^{\sigma+3} \text{ and } g^{\sigma+2}/r \text{ are linearly independent,} \tag{3.28}$$

leads to the equation

$$u_t=\operatorname{div}(|\nabla u|^\sigma\nabla u)+Au^{\sigma+1}+Bu, \tag{3.29}$$

which admits separable solutions.[12]

(ii) Assume now that (3.28) is false so that

$$g^\sigma g'=\varepsilon g^{\sigma+2}+\nu+\mu\,\frac{g^{\sigma+1}}{r}. \tag{3.30}$$

We study compatibility conditions for the system (3.27), (3.30). Differentiating (3.30) and substituting $(g^\sigma g')'$ into (3.27), as in the semilinear case, we arrive at the algebraic equation

$$Ag^{\sigma+3}+Bg+C\,\frac{g^{\sigma+2}}{r}+D\,\frac{g^{\sigma+1}}{r^2}+E\,\frac{1}{r}=0, \tag{3.31}$$

with the coefficients

$$A=\varepsilon^2(\sigma+2)-\alpha\varepsilon-\gamma,\quad B=\varepsilon\nu(\sigma+2)-\alpha\nu-\beta,$$
$$C=\varepsilon[\mu(2\sigma+3)+N-1]-\alpha\mu-\delta,$$
$$D=(\sigma+1)\left(\mu-\frac{1}{\sigma+1}\right)\left(\mu-\frac{1-N}{\sigma+1}\right),\tag{3.32}$$
$$E=\nu(\sigma+1)\left(\mu-\frac{1-N}{\sigma+1}\right).$$

Setting $w=rg(r)$ we obtain the system

$$r^{\sigma+2}(Bw+E)=-(Aw^{\sigma+3}+Cw^{\sigma+2}+Dw^{\sigma+1}),\tag{3.33}$$

$$rw^{\sigma}w'=\varepsilon w^{\sigma+2}+(\mu+1)w^{\sigma+1}+\nu r^{\sigma+2}.\tag{3.34}$$

It follows from (3.33) that $\sigma=-2$ plays a special role.

A: Let $\sigma\neq-2$. Then we need to consider two possibilities.

A.1: It follows from (3.33), (3.34) that under a suitable choice of the parameters there exists a special solution $w=$const, i.e., the function

$$g(r)=\frac{1}{r},\tag{3.35}$$

which will be considered in detail in Sec. IV. Observe that the function (3.35) gives a consistent type of (3.1) sign-invariants (3.1) for a wide class of quasilinear parabolic equations, see Sec. III in Ref. 8.

A.2: We now look for a nontrivial solution

$$w\not\equiv\text{const}.\tag{3.36}$$

Consider first the special case of (3.33)

$$B=E=0\quad\text{and}\quad A=C=D=0.\tag{3.37}$$

Then from (3.32) we get two cases: either $\mu=1/(\sigma+1)$ or $\mu=(1-N)/(\sigma+1)$.

If $\mu=1/(\sigma+1)$ $(D=0)$ and $\nu=0$ $(E=0)$ then (3.34) is solved explicitly:

$$g(r)=\left[-\frac{\varepsilon(\sigma+1)}{\sigma+2}\,r+kr^{-1/(\sigma+1)}\right]^{-1},\quad k=\text{const}.\tag{3.38}$$

The identity (3.3) reads

$$g^{\sigma+3}[\alpha\varepsilon+\gamma+2(\sigma+1)\varepsilon F'+FF''+\sigma(F')^2]+\frac{g^{\sigma+2}}{r}\left[\alpha\mu+\delta+\left(2\mu(\sigma+1)+\frac{(N-1)\sigma}{\sigma+1}\right)F'\right]$$
$$+g\left[\alpha\nu+\beta+2(\sigma+1)\nu F'+\left(\frac{f}{F}\right)'\frac{F^{1-\sigma}}{\sigma+1}\right]\equiv0.\tag{3.39}$$

Then similarly to the case $N=1$, from (3.39) we obtain the parabolic equation (3.2) with a linear term $f(u=cu)$ (and $F(u)=cu$), which admits a separable solution.

If $\mu=(1-N)/(\sigma+1)$ $(D=E=0)$ then (3.3) leads to $F(u)=-\varepsilon u$ and $f(u)=-(\sigma+1)\nu(-\varepsilon u)^{\sigma+1}$. Moreover, the resulting exact solution is stationary.

Assume now that $BE\neq0$. Then substituting $r^{\sigma+2}$ from (3.33):

$$r^{\sigma+2}=-\frac{w^{\sigma}(Aw^3+Cw^2+Dw)}{Bw+E},$$

into Eq. (3.34) rewritten in the form

$$\frac{dr^{\sigma+2}}{dw}=\frac{(\sigma+2)r^{\sigma+2}w^{\sigma}}{\varepsilon w^{\sigma+2}+(\mu+1)w^{\sigma+1}+\nu r^{\sigma+2}},$$

we arrive at a fifth-order polynomial of the independent variable $w\in\mathbf{R}$ with the coefficients depending on the parameters introduced in (3.27) and in (3.30), which has to vanish identically. This gives extra five equations on the parameters. The sixth coefficient of $w^0=1$ is $DE[E(\mu-1/(\sigma+1))-D\nu]=0$ by (3.32). It can be shown that this case provides no new solutions.

B: Let $\sigma=-2$. Then (3.33) and (3.34) take the form

$$(A+B)w+(C+E)+Dw^{-1}=0, \tag{3.40}$$

$$rw^{-2}w'=\varepsilon+(\mu+1)w^{-1}+\nu. \tag{3.41}$$

B.1: There exists a special solution $w=\text{const}$, to be considered in Sec. IV.

B.2: Assume (3.36) holds. Then (3.40) implies that

$$A+B=0,\quad C+E=0,\quad D=0.$$

Since $D=-(\mu+1)(\mu-N+1)$ by (3.32), we consider two possibilities.

B.2.1: Let $\mu=N-1$. Then $D=E=0$ and hence $C=0$. From (3.30) we then get the function

$$g(r)=\left(-\frac{\rho}{N}\,r+kr^{1-N}\right)^{-1},\quad \rho=\varepsilon+\nu. \tag{3.42}$$

In this case the coefficients of the second term $1/r$ on the right-hand side of (3.39) vanish identically, $g^{\sigma+3}\equiv g$ for $\sigma=-2$, and (3.39) reduces to a single equation for two functions f and F:

$$FF''-2(F')^2-2\rho F'-\left(\frac{f}{F}\right)'F^3=0. \tag{3.43}$$

Integrating it once, we obtain

$$f(u)=\frac{1}{F(u)}\,[F'(u)+\rho]+MF(u),\quad M=\text{const}. \tag{3.44}$$

B.2.2: If $\mu=-1$ then (3.30) takes the form

$$g^{-2}g'=\rho-\frac{1}{gr},\quad \rho=\varepsilon+\nu,$$

and hence

$$g(r)=(kr-\rho r\,\log r)^{-1}\quad(\rho\neq 0). \tag{3.45}$$

Substituting the parameters into (3.39) we obtain a linear combination on the subspace $\mathscr{L}\{g,r^{-1}\}$ and hence two linearly independent differential equations on f and F which give separate-variable solutions.

IV. SIGN-INVARIANTS AND NEW SOLUTIONS FOR $N>1$

Using the results on the maximal sign-invariants in Sec. III we now construct new exact solutions of the quasilinear Eq. (3.2) with $N>1$. It follows from Theorem 3.4 ($\sigma=0$) and further results for $\sigma\neq 0$ that nontrivial solutions exist in two cases only: Either (3.35) or (3.42), $\sigma=-2$.

4.1. The case: $g=1/r$. For convenience and for further applications we first perform calculations of the sign-invariants for a power-like function

$$g(r)=r^l. \tag{4.1}$$

Then from (3.3) we arrive at the four term identity

$$\mathscr{T}\equiv r^{l(\sigma+3)}I_1(u)+r^{l(\sigma+2)-1}I_2(u)+r^{l(\sigma+1)-2}I_3(u)+r^lI_4(u), \tag{4.2}$$

with the coefficients (we suppose that $F>0$)

$$I_1=F^2(F^{\sigma+1})'', \quad I_2=[2l(\sigma+1)^2+\sigma(N-1)]F^{\sigma+1}F', \tag{4.3}$$

$$I_3=[l(\sigma+1)-1][N-1+(\sigma+1)l]F^{\sigma+1}, \quad I_4=f'F-fF'. \tag{4.4}$$

Therefore, identity $\mathscr{T}\equiv 0$ yields four differential equations on the two functions f and F which is inconsistent in general.

From (4.2) it is clear that the case $l=-1$ plays a special role (other critical exponents l will be discussed in the final remarks of this section). Namely, if $l=-1$ and $\sigma\neq -2$ then (4.2) reduces to a two term identity on the span $\mathscr{L}\{r^{-(\sigma+3)},r^{-1}\}$ which determines a system of two ODE's

$$F^2(F^{\sigma+1})''+aF^{\sigma+1}F'+bF^{\sigma+1}=0,$$

$$a=\sigma(N-1)-2(\sigma+1)^2, \quad b=(\sigma+2)(\sigma+2-N), \tag{4.5}$$

$$f'F-fF'=0. \tag{4.6}$$

The last equation yields

$$f(u)=\lambda F(u), \quad \lambda=\text{const}. \tag{4.7}$$

Thus, the quasilinear equation with gradient diffusivity

$$u_t=|u_r|^\sigma\left[(\sigma+1)u_{rr}+\frac{N-1}{r}\,u_r\right]+\lambda F(u), \tag{4.8}$$

where $F(u)$ is an arbitrary solution of the ODE (4.5) admits the sign-invariant

$$H(u)=u_r-\frac{1}{r}\,F(u). \tag{4.9}$$

We now construct the corresponding exact solution.

Theorem 4.1: *The parabolic Eq. (4.8), (4.5) admits the solution*

$$v(r,t)\equiv\int_1^{u(r,t)}\frac{dz}{F(z)}=\log r+C_0(t), \tag{4.10}$$

where

$$C_0(t)=-\frac{1}{\sigma+2}\log(1+C_1e^{(\sigma+2)\lambda t})+\lambda t+C_2, \tag{4.11}$$

and C_1,C_2 are arbitrary constants.

Proof: The function v satisfies the evolution equation

$$v_t=F^\sigma(v_r)^\sigma\left[(\sigma+1)(v_{rr}+(v_r)^2F')+\frac{N-1}{r}\,v_r\right]+\lambda. \tag{4.12}$$

Substituting (4.10), which directly follows from (4.9) ($H(u)=0$), we get the equation

$$C_0'=\frac{1}{r^{\sigma+2}}\,\Phi(v)+\lambda, \tag{4.13}$$

where

$$\Phi(v)=F^{\sigma}(u)[(\sigma+1)(F'(u)-1)+N-1].$$

One can see from the ODE (4.5) that $\Phi'=(\sigma+2)\Phi$ whence $\Phi(v)=de^{(\sigma+2)v}$, with $d=\Phi(0)$. Finally, substituting $\Phi(v)$ into (4.13) and using (4.10) we arrive at the ODE $C_0'=de^{(\sigma+2)C_0}$, $t>0$, which gives (4.11). □

Example 4.1: The exact solution (4.10) depends on the ODE (4.5). It is integrated two times if $\sigma=1$ when it takes the form

$$(F^2)''+aF'+b=0, \quad a=N-9, \quad b=3(3-N).$$

If $N=3$ then $b=0$ and the general solution is

$$F(u)-C\ \log(F(u)+C)=3u, \quad C=\text{const}.$$

If $N\neq 3$ then we get the following algebraic equation for F

$$(F(u)-3u)^3\left(F(u)+\frac{N-3}{2}\,u\right)^{(N-3)/2}=C.$$

4.2. The case: $\sigma=-2$, $\mu=N-1$. Recall that the function (3.42) satisfies equation (3.30)

$$g^{-2}g'=\rho+\frac{N-1}{rg(r)}. \tag{4.14}$$

Exact solutions, which follow from the zero-invariance of the operator (3.1) are given in the following statement, which gives exact solutions to an infinite-dimensional family of quasilinear solutions.

Theorem 4.2: *The quasilinear equation*

$$u_t=\frac{1}{(u_r)^2}\left(-u_{rr}+\frac{N-1}{r}\,u_r\right)+\frac{F'(u)+\rho}{F(u)}+MF(u), \tag{4.15}$$

where $F\not\equiv 0$ *is an arbitrary smooth function and* $M=\text{const}$, *admits the exact solution* $u(r,t)$ *given by*

$$\Phi(u)\equiv\int_1^u\frac{dz}{F(z)}=-\frac{1}{\rho}\log\left(1-\frac{\rho}{kN}\,r^N\right)+Mt. \tag{4.16}$$

Observe that (4.15) is a parabolic equation backward in time.

Proof: Note that $f(u)$ in (4.15) is given by (3.44) and the solution (4.16) takes the form

$$\Phi(u)=\int_0^{\tau}g(y)dy+C_0(t), \tag{4.16a}$$

where g is specified in (3.42). Therefore as in the proof of Theorem 3.3, from (4.16a) we deduce that $u_t=FC_0'$, $u_r=Fg$, $u_{rr}=FF'g^2+Fg'$, and substituting these expressions into (4.15) we obtain the equation

$$C_0'=\frac{1}{F^2}\left(-g^{-2}g'+\rho+\frac{N-1}{rg(r)}\right)+M.$$

In view of (4.14) we get:

$$C_0'=M, \tag{4.17}$$

and we arrive at the solution (4.16). □

Example 4.2: Setting e.g., $F(u)=u^2$ we obtain that the quasilinear equation

$$u_t=\frac{1}{(u_r)^2}\left(-u_{rr}+\frac{N-1}{r}\,u_r\right)+\frac{Mu^4+2u+\rho}{u^2}$$

admits the solution

$$u(r,t)=\left[\frac{1}{\rho}\log\left(1-\frac{\rho}{kN}\,r^N\right)-Mt\right]^{-1}.$$

Final Remarks: 1. As far as we know the sign-invariant (3.1), (3.42), (3.43) for Eq. (4.15) with $N>1$ is a unique example of such a sign-invariant with a nonpower function $g(r)$ given in (3.42) with $\rho k\neq 0$. If we set $k=0$ in (3.42) then $g(r)\sim 1/r$ coincides with (4.1) for $l=-1$. On the other hand, solution (4.16a) then coincides with (4.10) [cf. (4.11), $\sigma=-2$).

2. It follows from identity (4.2) that the case $l=N-1$, $\sigma=-2$ is also a special one for the existence of a sign-invariant. It corresponds to $\rho=0$ in (3.42) and in (4.14).

3. The last special exponent is $l=1/(\sigma+1)$. Note that the corresponding differential inequality with the negative sign, $u_r+r^{1/(\sigma+1)}F(u)\leqslant 0$, plays an important part in the analysis of blow-up of radial solutions of the quasilinear Eq. (3.2) with $f(u)\sim u^p$, $p>1$. See Ref. 15. Substituting $l=1/(\sigma+1)$ into (4.2) we get the following ODE's on the functions f and F

$$(F^{\sigma+1})''=0,\quad f'F-fF'+F^{\sigma+1}F'[2+\sigma(N+1)]=0. \tag{4.18}$$

This yields the functions

$$F(u)=(au+b)^{1/(\sigma+1)},\quad f(u)=-\frac{2+\sigma(N+1)}{\sigma}\,(au+b)+\alpha(au+b)^{1/(\sigma+1)}. \tag{4.19}$$

In this case operator (3.1) with $g(r)=r^{1/(\sigma+1)}$ is also zero-invariant of Eq. (1.1) and exact solutions exist. However, more general solutions can be constructed by another invariant approach.[16] For instance, using the transformation $u=v^{(\sigma+1)/\sigma}$ in the equation

$$u_t=\mathrm{div}(|\nabla u|^{\sigma}\nabla u)+\alpha u^{1/(\sigma+1)}+\beta u,$$

we obtain the equation

$$v_t=\mathscr{B}(v)\equiv\mu^{-\sigma}|v_r|^{\sigma}\left[(\sigma+1)\left(vv_{rr}+\frac{1}{\sigma}\,(v_r)^2\right)+\frac{N-1}{r}\,vv_r\right]+\mu(\alpha+\beta v),$$

where $\mu=\sigma/(\sigma+1)$. The operator $\mathscr{B}$ admits the two-dimensional invariant subspace $W_2=\mathscr{L}\{1,|x|^{\gamma}\}$, $\gamma=(\sigma+2)/(\sigma+1)$, i.e., $\mathscr{B}(W_2)\subseteq W_2$. Thus, there exist exact solutions of the form $v_*(x,t)=C_0(t)+C_1(t)|x|^{\gamma}\in W_2$, where the coefficients $\{C_0(t),C_1(t)\}$ solve a nonlinear dynamical system. See details and generalizations in Ref. 16.

4. The structure of the exact solution (4.16) [as well as (2.12)] shows that it can be treated as a solution on a one-dimensional subspace or on a set invariant under a nonlinear operator of the equation. See different examples in Refs. 8,9,18, and 19.

(Received 27 October 1997; accepted for publication 27 April 1998)

We give a classification of all irreducible representations of the Arik–Coon oscillator algebra without the assumption that the number operator has a discrete nondegenerate spectrum. © *1998 American Institute of Physics.* [S0022-2488(98)01509-6]

I. INTRODUCTION

In theoretical physics literature a great number of papers have been devoted to the description of various quantum oscillator algebras (see e.g., Refs. 1–6). Here we choose the one generated by elements a, a^+, N with the relations

$$[N,a^+]=a^+, \quad [N,a]=-a, \quad aa^+-qa^+a=1,$$

where q is a fixed strictly positive real number. This algebra is called Arik–Coon oscillator algebra and denoted by $\tilde{A}_0$ in Ref. 5; its irreducible representations are described in Refs. 4 and 5 under the assumption that the spectrum of N is discrete and nondegenerate.

The aim of this paper is, on the one hand, to prove that this condition is automatically fulfilled and, on the other hand, to relate this question with the construction of C^*-algebras ''à la Woronowicz'' and with the theory of crossed products of C^*-algebras by their automorphism groups.

In order to do this, we shall need definitions more precise than the above ones; we shall replace the (rather vague) notion of a representation of $\tilde{A}_0$ by that of a quadruple $\mathcal{T}=(E,T,V,N)$ where E is a complex Hilbert space; T and N are (generally unbounded) self-adjoint operators in E with domains D_T, D_N, T being moreover positive; V is a partially isometric operator in E satisfying

(1) $V(D_T)\subset D_T$, $V^*(D_T)\subset D_T$,
(2) $VV^*=I$, $V^*V=$orthogonal projection onto $(\mathrm{Ker}\ T)^\perp$,
(3) $VT=(qT+I)V$ on D_T,
(4) T and N commute, i.e., their spectral projections commute,
(5) $V(D_N)\subset D_N$, $V^*(D_N)\subset D_N$,
(6) $NV-VN=-V$ on D_N.

The formal link with the above definition is $T=a^+a$, $a=VT^{1/2}$ (polar decomposition).

We call commutant of such a quadruple $\mathcal{T}$ the von Neumann algebra M of all bounded operators in E commuting with V, V^* and with the spectral projections of T and N; we say that $\mathcal{T}$ is irreducible if M is reduced to the scalars. The equivalence between two quadruples is the unitary equivalence.

The paper is organized as follows. In Sec. II we classify all triples (E,T,V); in Sec. III we construct a C^*-algebra A whose representations are in bijective correspondance with these triples (a similar construction has been done in Ref. 7 for the quantum euclidean group in two dimensions); in Sec. IV we classify all quadruples $\mathcal{T}$ and show that the corresponding C^*-algebra is a crossed product of A by the group $\mathbf{R}$ of real numbers.

Here I would like to thank the referee for his useful suggestions.

II. CLASSIFICATION OF TRIPLES $\mathscr{S}=(E,T,V)$

Theorem 1: *Every irreducible triple $\mathscr{S}=(E,T,V)$ is equivalent to one and only one of the following list:*

(i) If $q\geqslant 1$, only one triple $\mathscr{S}_0$ where $E_0=1^2(N)$ with orthonormal basis (e_n), $n\geqslant 0$, $T_0(e_n)=[n]_q e_n$ where $[n]_q=(q^n-1)/(q-1)$, $V_0 e_n=e_{n-1}$ (equal to 0 if $n=0$).
(ii) If $q<1$.

(a) A one-parameter family $\mathscr{S}_\theta$ ($\theta\in\mathbf{U}$=set of complex numbers of modulus 1) where $E_\theta=\mathbf{C}$, $T_\theta=(1-q)^{-1}$, $V_\theta=\theta$.
(b) A one-parameter family $\mathscr{S}_\mu$ ($\mu\in]q,1]$) where $E_\mu=1^2(\mathbf{Z})$ with orthonormal basis (e_n), $n\in\mathbf{Z}$, $T_\mu e_n=(q^n\mu+(1-q)^{-1})e_n$, $V_\mu e_n=e_{n-1}$.
(c) One triple $\mathscr{S}_0$ with the same formulas as in (i).

Sketch of proof:

(1) We denote by ρ the function of a real variable defined by $\rho(x)=qx+1$; its iterated ρ^n, for $n\in\mathbf{Z}$, are given by $\rho^n(x)=q^n x+[n]_q$. Fix $x\geqslant 0$.
  (a) If $q>1$, the sequence $\rho^n(x)$ is strictly increasing from $(1-q)^{-1}<0$ to $+\infty$
  (b) If $q<1$ and $x>(1-q)^{-1}$, it is strictly decreasing from $+\infty$ to $(1-q)^{-1}>0$
  (c) If $q<1$ and $x=(1-q)^{-1}$, it is constant
  (d) If $q<1$ and $x<(1-q)^{-1}$, it is strictly increasing from $-\infty$ to $(1-q)^{-1}>0$.
  Moreover if $x\neq(1-q)^{-1}$, there exists a neighborhood V of x such that the sets $\rho^n(V)$, for $n\in\mathbf{Z}$, are mutually disjoint.
(2) Let $\mathscr{S}$ be a triple (E,T,V), f a real valued bounded borel function on $\mathbf{R}$; then the bounded operator $f(T)$ satisfies $Vf(T)=f(\rho(T))\,V$ (indeed this is true on the domain D_∞, intersection of the domains of all positive powers of T, for f a polynomial, and remains true for a general f by continuity). In particular, if $f\circ\rho=f$, $f(T)$ belongs to the commutant of $\mathscr{S}$.
(3) If $\mathscr{S}$ is irreducible, the spectrum spT is either reduced to the point $(1-q)^{-1}$, or is a collection of nondegenerate eigenvalues of the form $\rho^n(x)$ with x fixed and n variable. The proof of this fact is very similar to those of Proposition 3.2 in Ref. 8 and Proposition 6.3 in Ref. 3.
(4) At this point, the proof is well known (see e.g., Ref. 5).

Remark: (On domains of self-adjointness for $a+a^+$ and $i(a-a^+$.) We choose the triple $\mathscr{S}_0$ with $q>1$; setting $A_+=a+a^+$, $A_-=i(a-a^+)$, we have

$$A_+ e_n=[n]_q^{1/2}e_{n-1}+[n+1]_q^{1/2}e_{n+1},$$

$$A_- e_n=i[n]_q^{1/2}e_{n-1}-i[n+1]_q^{1/2}e_{n+1},$$

these operators have been studied in Ref. 9 where the following properties are established. Let D denote the set of all vectors in $1^2(\mathbf{N})$ having a finite number of nonzero coordinates; clearly A_+ and A_- are defined and symmetric on D; let $\overline{A_+}$ and $\overline{A_-}$ be their closures. Then

(a) each of $\overline{A_+}$ and $\overline{A_-}$ has a one parameter family of self-adjoint extensions which are obtained by adjoining one dimension to its domain;
(b) every such self-adjoint extension has a purely discrete spectrum;
(c) $\overline{A_+}$ and $\overline{A_-}$ have no common domain on which they are self-adjoint.

Theorem 2: *Every triple $\mathscr{S}$ is a direct integral of irreducible ones.* The proof is the same as in the theory of group representations: One diagonalizes a maximal commutative subalgebra in the commutant of $\mathscr{S}$.

III. CONSTRUCTION OF A C^*-ALGEBRA ASSOCIATED TO THE TRIPLES $\mathscr{S}$

We shall consider only the (most complicated) case where $q<1$; the idea is to introduce the direct integral of all irreducible triples $\mathscr{S}$ of theorem 1 (ii), and replace everywhere T by the bounded operator $S=e^{-T}$. Set

$$\tilde{E}=\int_{\theta\in\mathbf{U}}^{\oplus}E_\theta\,d\theta\oplus\int_{\mu\in]q,1]}^{\oplus}E_\mu\,d\mu\oplus E_0=L^2(\mathbf{U})\oplus L^2(]q,1];1^2(\mathbf{Z}))\oplus 1^2(\mathbf{N}),$$

$$\tilde{T}=(1-q)^{-1}\oplus\int^{\oplus}T_\mu\,d\mu\oplus T_0,$$

$$\tilde{V}=\int^{\oplus}\theta\,d\theta\oplus\int^{\oplus}V_\mu\,d\mu\oplus V_0,$$

$$\tilde{S}=e^{-\tilde{T}},$$

$$B=\text{sub-}C^*\text{-algebra of }\mathscr{L}(\tilde{E})\text{ generated by }\tilde{S}\text{ and }\tilde{V},$$

$$A=\text{closed two-sided ideal of }B\text{ generated by }\tilde{S}.$$

The following lemma is easily proved:

Lemma 1: (i) *For every positive number a, we have* $\tilde{S}^a\in B$ *and*

$$\tilde{V}\tilde{S}^a=e^{-a}\tilde{S}^{-qa}\tilde{V}.$$

(ii) *The linear combinations of monomials* $(\tilde{V}^*)^m\tilde{V}^r\tilde{S}^P$, *where m and r are positive integers and P is a nonzero polynomial with respect to q and* q^{-1} *with positive integral coefficients, form a sub-*-algebra everywhere dense in A, which we denote by* A^0.

Theorem 3: *There is a bijective correspondance between representations* (E,π) *of A and triples* $\mathscr{S}=(E,T,V)$ *given by* $T=\log\pi(\tilde{S})$, $V=\pi(\tilde{V})$.

Sketch of proof: By theorem 2 we can limit ourselves to irreducible representations and triples. If (E,π) is an irreducible representation of *A*, $\pi(\tilde{S})$ is nonzero, its kernel is invariant and distinct from *E*, hence null; $\pi(\tilde{S})$ is positive and injective, $\log\pi(\tilde{S})$ exists, and $(E,\log\pi(\tilde{S}),\pi(\tilde{V}))$ is a triple.

Conversely consider an irreducible triple $\mathscr{S}$, and take for instance $\mathscr{S}$ of the form $\mathscr{S}_{\mu_0}$; we can define a representation π of A^0 by setting, for every

$$X=\sum_{m,r,P}\lambda_{m,r,P}(\tilde{V}^*)^m\tilde{V}^r\tilde{S}^P\in A^0,$$

$$\pi(X)=\sum_{m,r,P}\lambda_{m,r,P}(V_{\mu_0}^*)^mV_{\mu_0}^rS_{\mu_0}^P.$$

Then we have only to prove that π is continuous. But *X* contains as a direct summand the direct integral of all

$$X_\mu=\sum_{m,r,P}\lambda_{m,r,P}(V_\mu^*)^mV_\mu^rS_\mu^P$$

whence

$$\|X\|\geqslant\|\int^{\oplus}X_\mu\,d\mu\|=\sup_\mu\|X_\mu\|\geqslant\|X_{\mu_0}\|=\|\pi(X)\|.$$

IV. CLASSIFICATION OF QUADRUPLES $\mathscr{T}$

Theorem 4: (i) *If* $q\geqslant 1$, *every irreducible quadruple* $\mathscr{T}=(E,T,V,N)$ *is equivalent to one and only one of the one-parameter family* $\mathscr{T}_\gamma(\gamma\in\mathbf{R})$ *where* $E_\gamma=1^2(\mathbf{N})$ *with orthonormal basis* $(e_n)(n\geqslant 0)$, $T_\gamma e_n=[n]_q e_n$, $V_\gamma e_n=e_{n-1}$ *(equal to 0 if* $n=0$*)*, $N_\gamma e_n=(n+\gamma)e_n$.
(ii) *If* $q<1$, *every irreducible quadruple* $\mathscr{T}=(E,T,V,N)$ *is equivalent to one and only one of the*

following list:
(a) *a two-parameter family* $\mathscr{T}_{\mu,\gamma}$ $(\mu\in]q,1]$, $\gamma\in\mathbf{R})$ *where* $E_{\mu,\gamma}=1^2(\mathbf{Z})$ *with orthonormal basis* $(e_n)(n\in\mathbf{Z})$, $T_{\mu,\gamma}e_n=(q^n\mu+(1-q)^{-1})e_n$, $V_{\mu,\gamma}e_n=e_{n-1}$, $N_{\mu,\gamma}e_n=(n+\gamma)e_n$,
(b) *a one-parameter family* $\mathscr{T}_{0,\gamma}(\gamma\in[0,1[$ *as in* (a) *but with* $\mu=0$,
(c) *a one-parameter family* $\mathscr{T}_{\gamma}(\gamma\in\mathbf{R})$ *with the same formulas as in* (i).

N.B.: This result is compatible with Ref. 5, 4.1.2 if one defines the numbers $\widetilde{v_0}$ and c of Ref. 5 by $\widetilde{v_0}=\gamma$, $c=q^{-\gamma}(q^{\gamma}-1)/(q-1)$ in case (i) or (iic), and by $\widetilde{v_0}=\gamma$, $c=(q-1)^{-1}-q^{-\gamma}\mu$ in cases (iia) and (iib).

Theorem 5: *Define an action* α *of the group* $\mathbf{R}$ *by automorphisms of the C*-algebra A by* $\alpha_t(\widetilde{S})=\widetilde{S}$, $\alpha_t(\widetilde{V})=e^{-it}\widetilde{V}$ *and form the corresponding crossed-product* $A\times\mathbf{R}$. *Then there exists a bijective correspondance between representations of* $A\times\mathbf{R}$ *and quadruples* $\mathscr{T}$.

Sketch of proofs of Theorems 4 and 5: (a) We can replace each quadruple $\mathscr{T}=(E,T,V,N)$ by the quadruple (E,T,V,U) where U is the one-parameter unitary group $U_t=e^{itN}$; conditions (4)–(6) then become

$$U_tTU_t^{-1}=T,\quad U_tVU_t^{-1}=e^{-it}V. \tag{7}$$

Theorem 3 implies that quadruples $\mathscr{T}$ are in bijective correspondence with covariant representations of the pair $(A,\mathbf{R})$ (for more on this notion, see for instance Ref. 10); then theorem 5 is a consequence of the very definition of $A\times\mathbf{R}$.
(b) We now have to classify the irreducible covariant representations (π,U) of the pair $(A,\mathbf{R})$. To do this we can use the method explained in Ref. 10, analogous to the Mackey machinery (or ''Bargmann's little group method''), well known to construct representations of group extensions: One chooses an orbit X of the action of $\mathbf{R}$ on the dual space $\hat{A}$ of A, then a point ζ in X, then a covariant representation of the pair $(A,\mathbf{R}_\zeta)$ where $\mathbf{R}_\zeta$ is the stabilizer of ζ in $\mathbf{R}$, and induces it to $(A,\mathbf{R})$.

In case $q\geqslant 1$, $\tilde{A}$ is reduced to one single point, described in theorem 1(i), hence $\mathbf{R}_\zeta=\mathbf{R}$; moreover we have a particular U satisfying (7), namely $U_t^0e_n=e^{itn}e_n$; if U is another solution of (7), $U_t\,(U_t^0)^{-1}$ commutes with T and V, hence is a scalar which we can write as $e^{it\gamma}$, $\gamma\in\mathbf{R}$.

Consider now the case $q<1$; the orbits of $\mathbf{R}$ in $\hat{A}$ are the set X of all $\mathscr{S}_\theta$ $(\theta\in\mathbf{U})$; the various points $\mathscr{S}_\mu$, the point $\mathscr{S}_0$.

In the last two cases the proof is similar to that of the case $q\geqslant 1$, and we get families $\mathscr{T}_{\mu,\gamma}$ and $\mathscr{T}_\gamma$. Take now the orbit X and the point $\zeta=\mathscr{S}_1$; we have $\mathbf{R}_\zeta=2\pi\mathbf{Z}$, so that U is induced by a character of $2\pi\mathbf{Z}$, of the form $2\pi k\to\lambda^k$, $\lambda\in\mathbf{U}$; the space E of U can be realized as the set of complex functions on $\mathbf{R}$ satisfying

$$f(t+2\pi k)=\lambda^k f(t),\quad \int_0^{2\pi}|f(t)|^2dt<+\infty,$$

with the action $(U_tf)(s)=f(t+s)$. Taking the orthonormal basis of E consisting of the functions $e_n(t)=(2\pi)^{-1/2}e^{i(\gamma+n)t}$ with $\gamma\in[0,1]$ and $e^{2\pi i\gamma}=\lambda$, we get the family $\mathscr{T}_{0,\gamma}$.

V. CONCLUDING REMARKS

The same method can be applied to other algebras, for instance to the algebra defined (formally) by the same generators N,a,a^+ as before but with the relations

$$[N,a^+]=a^+,\quad [N,a]=-a, aa^+-qa^+a=0,$$

which is a deformation of the enveloping algebra of the euclidean group $E(2)$. In this case, for $q\neq 1$, besides the trivial one dimensional representation, one finds a two-parameter family of irreducible quadruples $\mathscr{T}_{\mu,\gamma}$ $(\mu\in]1,q]$ or $]q,1]$ according as $q>1$ or $q<1$, $\gamma\in\mathbf{R})$ where $E_{\mu,\gamma}=1^2(\mathbf{Z})$ with orthonormal basis (e_n) $(n\in\mathbf{Z})$, $T_{\mu,\gamma}e_n=q^n\mu e_n$, $V_{\mu,\gamma}e_n=e_{n-1}$, $N_{\mu,\gamma}e_n=(n+\gamma)e_n$.
