$$\delta^i_j = \frac{\partial x^i}{\partial t}\frac{\partial \tau}{\partial x^j} + \frac{\partial x^i}{\partial \varphi^r}\frac{\partial \varphi^r}{\partial x^j},$$

contracting with $\zeta_{ik} n[x]^k$, and using Eq. (1) and the definition of the surface normal we get the second equation (10). This leads to

$$\dot{x} = \frac{\boldsymbol{\nabla}\tau}{|\boldsymbol{\nabla}\tau|^2}(x). \tag{14}$$

In order to obtain a differential equation for the time function τ in the case where the derivative of the function α never vanishes, we differentiate Eq. (10) with respect to time and use Eq. (14) to get rid of $\dot{x}$. Thereby the time derivative of the left-hand side of (10) can solely be expressed by second covariant derivatives of the time function. To do the same for the right-hand side we use the equation

$$\dot{\sqrt{g[x]}} = \tfrac{1}{2}\sqrt{g[x]}\, g^{rs}\dot{g}_{rs},$$

obtain by the chain rule,

$$\partial_r \dot{x}^i = \partial_j(\boldsymbol{\nabla}\tau^{\,i}/|\boldsymbol{\nabla}\tau|^2)\partial_r x^j,$$

observe that the orthogonal projection π onto the tangent spaces of the hypersurfaces can be expressed in two ways by

$$g^{rs}\ \partial_r x^i\ \partial_s x^j = \pi^{ij}(x) = \zeta^{ij}(x) - n[x]^i n[x]^j$$

(see e.g., Ref. 3), and replace the normal vectors by the normalized gradients of the time function (9), which gives the second-order equation (11).

2. Denote by Σ_0 the level surface $\tau = 0$ and by $i:\Sigma_0 \to \mathcal{M}$ the canonical inclusion. Let $\omega_{i^*\zeta}$ denote the volume form on Σ_0 induced by the metric ζ. Consider the modified volume form,

$$\frac{1}{\alpha^{-1}(1/|\boldsymbol{\nabla}\tau|(i))}\ \omega_{i^*\zeta},$$

on Σ_0. Let r be the unique positive real number such that the two following integrals are equal:

$$\int_\Sigma r\rho = \int_{\Sigma_0} \frac{1}{\alpha^{-1}(1/|\boldsymbol{\nabla}\tau|(i))}\ \omega_{i^*\zeta}.$$

By Moser's lemma (see Ref. 7) there is a diffeomorphism $x_0:\Sigma \to \Sigma_0$ such that the two volume forms are diffeomorphic, i.e.,

$$r\rho = x_0^*\left(\frac{1}{\alpha^{-1}(1/|\boldsymbol{\nabla}\tau|(i))}\ \omega_{i^*\zeta}\right) = \frac{1}{\alpha^{-1}(1/|\boldsymbol{\nabla}\tau|(x_0))}\ \omega_{x_0^*\zeta},$$

whence Eq. (10) is satisfied for $t = 0$ and $r\rho$.

Observe now that for all points $y \in \Sigma_0$ we have

$$\tau(\Phi_t(y)) = t,$$

which can be seen by differentiating the left-hand side with respect to t and showing it to be equal to 1. When we insert $y = x_0(\varphi)$ in this equation and differentiate with respect to φ^r we see that the

gradient of the time function is always orthogonal to the surfaces $\Phi_t(x_0(\Sigma))$. Hence, $\nabla\tau(x(t,\varphi))/|\nabla\tau(x(t,\varphi))|$ is equal to the hypersurface normal $n[x_t](\varphi)$ whence we have the differential equation

$$\dot{x}(t,\varphi)=\frac{\nabla\tau(x(t,\varphi))}{|\nabla\tau(x(t,\varphi))|^2}=\frac{1}{|\nabla\tau(x(t,\varphi))|}\,n[x_t](\varphi).$$

We have already shown above that the function (for fixed $\varphi\in\Sigma$)

$$f(t):=\alpha(\sqrt{g_{rs}(t,\varphi)}/(r\rho(\varphi)))|\nabla\tau(x(t,\varphi))|$$

equals 1 for $t=0$ by construction of x_0. Upon differentiating f with respect to t, eliminating $\dot{x}$ by the equation above, and using the second-order equation (11), we get the first-order time-dependent differential equation for f:

$$\dot{f}(t)=\frac{\tau_{;ij}\nabla\tau^i\,\nabla\tau^j\widetilde{\beta}(|\nabla\tau|)}{|\nabla\tau|^4}(x(t,\varphi))\left(\frac{1}{\widetilde{\beta}(|\nabla\tau|)(x(t,\varphi))}-\frac{1}{\widetilde{\beta}(|\nabla\tau|(x(t,\varphi))/f(t))}\right)f(t).$$

Since the right-hand side smoothly depends on f in a neighborhood of $f=1$ the obvious constant solution $f(t)=1$ is unique. This proves Eq. (10) for all t. Q.E.D.

In other words, the open neighborhood $\mathcal{N}_\epsilon$ will be foliated by the level sets of τ, which are nothing else but the surfaces of constant time. Equations (9) and (14) have also been considered in Refs. 8 and 9 and only use the fact that $\dot{x}$ is proportional to the unit normal.

Note that for nonconstant α the above surface motion is *not* reparametrization invariant, which is here reflected in the fact that the time function satisfies a second-order partial differential equation whose normal derivative at the zero level surface encodes the ''volume part'' of the parametrization, i.e., the induced volume form compared to a reference volume. On the other hand, for the Optical model (7) the function α is equal to unity: this model of surface motion is invariant under reparametrization, and the differential equation for the time function is first order, viz. Eq. (10) for $\alpha=1$, which is the eikonal equation $|\nabla\tau|^2=1$ known in optics.

The second-order equations for all the time functions dealt with in Theorem II.1 can be derived from a Lagrangian: define the real-valued smooth function F as any solution of the first-order differential equation:

$$F'(z)=\frac{C}{\alpha^{-1}(1/z)}, \tag{15}$$

where C is an arbitrary nonzero real number. Define the Lagrangian $\mathcal{L}$ for the time function τ as:

$$\mathcal{L}(\partial\tau):=\sqrt{\det(\zeta_{ij})}F(|\nabla\tau|). \tag{16}$$

A straightforward calculation shows that the Euler Lagrange equations produce (11) for all F solving (15).

For the model (6) we can choose the Lagrangian density $\mathcal{L}(\partial\tau)$ equal to $\sqrt{\det(\zeta_{ij})}1/2|\nabla\tau|^2$, and get the Laplace equation

$$\Delta\tau=0, \tag{17}$$

where Δ is the Laplacian operator $[1/\sqrt{\det(\zeta_{ij})}]\partial_i(\sqrt{\det(\zeta_{ij})}\zeta^{ij}\partial_j$. This means that—despite its complicated nonlinear appeal—the model (6) is integrable at least for all those Riemannian manifolds for which the Laplace equation can be solved in a sufficiently explicit way, e.g., for $\mathbb{R}^n$, the sphere S^n, and hyperbolic space H^n. We shall discuss the surface motion in $\mathbb{R}^3$ (for which a linearizability was already noted in Ref. 10 without using the time function) according to its harmonic time function in more detail in the next section.

In numerical relativity theory the foliation of a given space–time into spacelike hypersurfaces, which are level surfaces of a (Lorentz) harmonic time function, has been dealt with by Bona and Massó in Ref. 11. This method of ''harmonic slicing'' avoids the occurrence of space–time singularities on these surfaces.

For the Lorentzian membrane we can choose the Lagrangian equal to the function $\sqrt{\det(\zeta_{ij})}\sqrt{|\nabla\tau|^2-1}$ and get the Euler–Lagrange equations,

$$(1-|\nabla\tau|^2)\Delta\tau+\tau_{;ij}\,\nabla\tau^{\,i}\,\nabla\tau^{\,j}=0, \tag{18}$$

whereas for the Euclidean membrane we can choose $\mathscr{L}(\partial\tau)$ equal to the function $\sqrt{\det(\zeta_{ij})}\sqrt{1+|\nabla\tau|^2}$ and get the equation

$$(1+|\nabla\tau|^2)\Delta\tau-\tau_{;ij}\,\nabla\tau^{\,i}\,\nabla\tau^{\,j}=0. \tag{19}$$

Note that the global description of surface motion by parametrization may drastically differ from the description by the level sets of a time function: although being equivalent for short time intervals (and some technical assumptions, see Theorem (II.1) the former allows the membrane to be at the same position at different times, but fixes the topological type, whereas the latter allows for varying topological type, but every point in space is contained in at most one level surface. In both pictures one has to admit violations of the regularity of the mappings (i.e., points where the Jacobians cease to have maximal rank) in order to produce interesting situations.

III. HARMONIC TIME FLOW IN THREE-DIMENSIONAL EUCLIDEAN SPACE AND ELECTROSTATICS

In this section we should like to discuss some solutions of the model (6) in $\mathbb{R}^3$ in terms of its harmonic time function. A comparison with the Euclidean membrane model (5) shows that (6) is an approximation of the Euclidean membrane model in the regime where the induced spatial membrane area element $\sqrt{\det(g_{rs})}$ is large compared to a reference area element ρ.

The Laplace equation (17) for flat $\mathbb{R}^3$ can be treated by methods known in electrostatics (see, e.g., Ref. 12). For example, consider a piece of wire of length L that is uniformally charged with line charge $\lambda=q/L$ and that is lying along the z axis between $-p:=L/2$ and p: its electrostatic potential τ is given by

$$\tau(\mathbf{x})=\lambda\,\log\left(\frac{\sqrt{x^2+y^2+(z+p)^2}+z+p}{\sqrt{x^2+y^2+(z-p)^2}+z-p}\right). \tag{20}$$

This function is harmonic outside the interval $[-p,p]$ along the z axis on which it becomes $\pm\infty$ according to the sign of λ and tends to zero for large distances from the origin. It is known that all the equipotential surfaces of this function are axially symmetric ellipsoids whose focal points are the end points of the piece of wire. In case λ is negative we get the—at least in electrostatics—unusual picture of the equipotential surfaces as surfaces of constant time: for $\tau=-\infty$ it is a singular line that blows up into bigger and bigger ellipsoids, and at $\tau=0$ the level surface is the sphere at spatial infinity.

This situation can be generalized a bit: let

$$\mathbf{x}_i^-,\mathbf{x}_j^+:S^1\to\mathbb{R}^3,\quad 1\leqslant i\leqslant m,\quad 1\leqslant j\leqslant n \tag{21}$$

be closed curves in $\mathbb{R}^3$, which are either points or immersed with only a finite number of self-intersection points. Suppose furthermore that any two different curves do not intersect. Moreover, let $\lambda_i^-,\lambda_j^+:S^1\to\mathbb{R}$ be positive smooth functions where $1\leqslant i\leqslant m$, $1\leqslant j\leqslant n$. On $\mathbb{R}^3$ minus all the images of the closed curves, $\mathbf{x}_1^-(S^1),\ldots,\mathbf{x}_m^-(S^1),\mathbf{x}_1^+(S^1),\ldots,\mathbf{x}_n^+(S^1)$ we can define the following harmonic function τ:

$$\tau(\mathbf{x}):=-\sum_{i=1}^{m}\int_0^{2\pi}d\varphi\,\frac{\lambda_i^-(\varphi)}{|\mathbf{x}-\mathbf{x}_i^-(\varphi)|}+\sum_{j=1}^{n}\int_0^{2\pi}d\varphi\,\frac{\lambda_j^+(\varphi)}{|\mathbf{x}-\mathbf{x}_j^+(\varphi)|}. \tag{22}$$

(It is harmonic because $\mathbf{x}\mapsto 1/|\mathbf{x}-\mathbf{y}|$ is harmonic for all $\mathbf{x}\neq\mathbf{y}$.) From the point of view of electrostatics, this a finite collection of closed curves carrying either positive or negative line charges. Due to the presence of the denominators in the above formula for τ it is clear that there is a negative real number $-t_0$ of a very large absolute value such that the equipotential surface $\tau=-t_0$ breaks up into m connected surfaces located each in the vicinity of one of the ''incoming curves'' $x_i^-(S^1)$. The following intuitive argument shows that each connected piece is diffeomorphic to a Riemann surface of genus equal to the number of loops that are generated by the self-intersections. In other words: the level surface piece near such a curve looks like a two-sphere if the curve is just a point, like a two-torus if the curve is immersed with no self-intersection, like a surface of genus two if the curve looks like the numeral 8, and so forth. Indeed, since $x_i^-(S^1)$ is compact we can cover it by a finite number of balls of diameter L where L can be chosen arbitrarily small. Now suppose that the map x_i^- is well behaved enough so that we can approximate it by a sequence of straight pieces of wire, each carrying a constant line charge equal to the mean value of λ_i^- over the piece of the curve. Formula (20) gives an approximate solution of the potential τ. From this formula one can infer that if the distance of the point $\mathbf{x}$ to the curve is very small compared to L, the potential is approximately proportional to the natural logarithm of the distance. Hence, for ''very early'' values of τ, the connected components of the equipotential surface are approximated by surfaces of constant distance from a given curve that visibly have the required topology. One has the same argumentation for very large or ''very late'' values of τ: here the connected components of the equipotential surfaces are certain Riemann surfaces centered around the ''outgoing curves'' $x_j^+(S^1)$.

We can interpret this geometrical picture as a theory for propagating membranes with a prescribed change of topology: if the time equals $-\infty$ one has m incoming membranes shrunk to one-dimensional objects whose homotopy and initial ''shape'' are encoded in the curves $\mathbf{x}_i^-$ with line charge functions λ_i^-. These m membranes will grow bigger and possibly melt together (which can be interpreted as an interaction) and for large positive time values the surface of equal time decomposes again into n connected components that will eventually center around the outgoing curves $\mathbf{x}_j^+$ with the final ''shape'' described by λ_j^+ and will be equal to these curves for $t=+\infty$.

In order to get more general solutions one has to solve the Dirichlet problem for the potential τ outside m conducting Riemann surfaces held at value $-t_0$ and n conducting Riemann surfaces held at value $+t_0$ for a positive real number t_0 whose solution, in principle, exists and is unique.

In order to get explicit solutions for the model (6) in higher-dimensionsional Euclidean space $\mathbb{R}^{M+1}$ we can easily generalize the above construction (22): we have to replace the curves $\mathbf{x}_i^{\mp}(\varphi)$ and by (at most) $M-1$-dimensional surfaces $\mathbf{x}_i^{\mp}(\varphi^1,\ldots,\varphi^{M-1})$ equipped with higher-dimensional ''line charge'' functions and the line integral over $1/|\mathbf{x}-\mathbf{x}_i^-(\varphi)|$ by a surface integral (of codimension two) over $1/|\mathbf{x}-\mathbf{x}_i^-(\varphi^1,\ldots,\varphi^{M-1})|^{M-1}$. More generally, one has to explicitly solve the higher-dimensional analog of the above-mentioned Dirichlet problem whose solution in principle exists and is unique.

Finally, one should point out that (6) may also be written as

$$\dot{x}^i=\int_\Sigma d^M\widetilde{\varphi}\; H^{ij}(\varphi,\widetilde{\varphi})\;\frac{\delta W}{\delta x^j(\widetilde{\varphi})}\,[x], \tag{23}$$

with

$$H^{ij}(\varphi,\widetilde{\varphi}):=\frac{\delta^{ij}\delta^M(\varphi,\widetilde{\varphi})}{\rho(\varphi)}, \tag{24}$$

$$W[x]:=\frac{1}{M+1}\int_\Sigma d^M\varphi\; x^i(\varphi)\epsilon_{ii_1\cdots i_M}\epsilon^{r_1\cdots r_M}\frac{1}{M!}\,\partial_{r_1}x^{i_1}(\varphi)\cdots\partial_{r_M}x^{i_M}(\varphi), \tag{25}$$

in $\mathbb{R}^n$, i.e., are gradient flows with respect to the volume functional W and the metric $H^{ij}(\varphi,\widetilde{\varphi})$.

IV. HAMILTONIAN FORMULATION AND CONSERVED CHARGES

Consider now a Hamiltonian field theory with fields (x,p) from Σ into the cotangent bundle $T^*\mathscr{N}$ of $\mathscr{N}$, where the conjugate momentum field p is supposed to be densitized.[13] Let the Hamiltonian be of the form

$$H(x,p) := \int_\Sigma d^M\varphi \sqrt{g}[x] h\left(\frac{|p|}{\sqrt{g}[x]}\right), \tag{26}$$

where h is a smooth function of one variable, $\sqrt{g} := \sqrt{g}[x] := \sqrt{\det g_{rs}}$ is defined as in (2), $p^2 := p_i p_j \zeta^{ij}(x), |p| := \sqrt{p^2}$, and u will be short for $|p|/\sqrt{g}$.[14]

From the canonical Poisson structure,

$$\{F,G\} = \int_\Sigma d^M\varphi \left(\frac{\delta F}{\delta x^i(\varphi)} \frac{\delta G}{\delta p_i(\varphi)} - \frac{\delta G}{\delta x^i(\varphi)} \frac{\delta F}{\delta p_i(\varphi)}\right), \tag{27}$$

we obtain Hamiltonian equations of motion,

$$\frac{\partial x^i}{\partial t} = \zeta^{ij}(x) h' \frac{p_j}{|p|}, \tag{28}$$

$$\frac{\partial p_i}{\partial t} = \zeta_{ij}(x)\partial_r((h-uh')\sqrt{g}g^{rs}\,\partial_s x^j) + \zeta_{ij}(x)(h-uh') \times \sqrt{g}g^{rs}\,\partial_r x^k\,\partial_s x^l\,\Gamma^j_{kl}(x) - \frac{1}{2}\,\partial_i\zeta^{jk}(x)h'\frac{p_j p_k}{|p|}. \tag{29}$$

Defining

$$C_r(x,p) := p_i\,\partial_r x^i \tag{30}$$

(the infinitesimal generators of diffeomorphisms), it is easy to check that (28) and (29) imply

$$\frac{\partial C_r}{\partial t} = 0 \tag{31}$$

(H is invariant under diffeomorphisms ϕ: $\Sigma \to \Sigma$), as well as

$$\frac{\partial}{\partial t}(\sqrt{g}h) = \partial_r\left(\left(\frac{hh'}{u} - h'^2\right) g^{rs} C_s(x,p)\right). \tag{32}$$

For solutions $(x(t),p(t))$ of the equations of motion satisfying $C_r(x(0),p(0)) = 0$ the rhs of Eq. (32) vanishes identically [for all t due to (31)], hence (for such solutions)

$$\sqrt{g}[x(t)] h\left(\frac{|p|(t)}{\sqrt{g}[x(t)]}\right) =: \rho, \tag{33}$$

with ρ some *time-independent* density on Σ. Inverting (33) to obtain $|p|/\sqrt{g}$ as a function of $\sqrt{g}/\rho$, and noting that for $N-M=1$ the condition

$$C_r(x,p) = p_i\,\partial_r x^i = 0, \quad 1 \leqslant r \leqslant M, \tag{34}$$

for x an immersion means that $\zeta^{ij}p_j$ must lie in the direction normal to the hypersurface defined by $\varphi \mapsto x(t,\varphi)$, one sees that (28) can be rewritten in the form mentioned in Sec. II [see (1)],

$$\frac{\partial x}{\partial t} = \alpha\left(\frac{\sqrt{g}}{\rho}\right) n, \tag{35}$$

with the functions α and h being related via

$$\alpha(z)z^2\partial_z\left(h^{-1}\left(\frac{1}{z}\right)\right)=-1. \tag{36}$$

In particular, for $h(z)=\sqrt{2z}$ we get $\alpha(z)=z$ (6) and

$$H[x,p]=\int_\Sigma d^M\varphi(4g[x]p^2)^{1/4}. \tag{37}$$

For $h(z)=\sqrt{1+z^2}$, which corresponds to $\alpha(z)=\sqrt{1-z^2}$, we get the Hamiltonian,

$$H[x,p]=\int_\Sigma d^M\varphi\sqrt{p^2+g[x]}, \tag{38}$$

of the relativistic M-brane in $M+1$-dimensional Minkowski space. Here $h(z)=z$, implying $\alpha(z)=1$, gives the Hamiltonian

$$H[x,p]=\int_\Sigma d^M\varphi\sqrt{p^2}, \tag{39}$$

of the Optical model (7).

Let us for a moment concentrate on (37): Motivated by the fact that the equation for the time function is linear [see (17)] and the observation,[5] made for $N=3$, that a Lax pair formulation of $\partial\mathbf{x}/\partial t=\sqrt{g}\mathbf{n}$ implies the time independence of $\int Q(x(t,\varphi^1,\varphi^2)d\varphi^1\,d\varphi^2$ for harmonic polynomials $Q(x^1,x^2,x^3)$, one is led to the conjecture that for all $N=M+1$, ρ, and $Q(x)$ any harmonic function of x,

$$\mathsf{Q}[x]:=\int_\Sigma d^M\varphi\ \rho Q(x), \tag{40}$$

will be independent of time if the hypersurface $\Sigma_t=x_t(\Sigma)$ evolves according to (6). The proof is a trivial application of Gauss' Theorem: assuming that for all t the moving surface Σ_t is a boundary of some open set V_t of $\mathscr{N}$ and writing dS_t^i for the surface element, we get

$$\frac{\partial\mathsf{Q}[x(t)]}{\partial t}=\int_\Sigma d^M\varphi\ \rho\ \partial_iQ(x(t))\ \frac{\partial x^i}{\partial t}=\int_\Sigma d^M\varphi\sqrt{g}[x(t)]n^i[x(t)]\partial_iQ(x(t))=\int_{\Sigma_t}dS_t^i\ \partial_iQ(x(t))$$

$$=\int_{V_t}d^Nx\sqrt{\det(\zeta_{kl})}\partial_j(\zeta^{ji}\ \partial_iQ)=\int_{V_t}d^Nx\sqrt{\det(\zeta_{kl})}\Delta Q=0.$$

In the Hamiltonian formulation (37) the nondynamical density $\rho(\varphi)$ is simply replaced by the Hamiltonian density

$$\mathscr{H}[x,p](\varphi):=\sqrt{g}[x](\varphi)h\left(\frac{|p|(\varphi)}{\sqrt{g}[x](\varphi)}\right), \tag{41}$$

i.e., $\mathscr{H}[x,p]=(g[x]p^2)^{1/4}$ in the case of (37). Indeed, for any harmonic Q the following functionals on phase space,

$$\mathsf{Q}[x,p]:=\int_\Sigma d^M\varphi(gp^2)^{1/4}Q(x), \tag{42}$$

will be time independent for solutions $(x(t),p(t))$ satisfying (28), (29), and the constraint (34).

Do the quantities (42) Poisson commute (on the reduced space)? The answer is ''yes'' (in fact, they form an infinite, presumably complete set of Poisson commuting, reparametrization invariant charges, thus providing the solution of a nontrivial diffeomorphism-invariant field theory)—but let

us first make some observations valid for all theories of the general form (26), i.e. arbitrary h, N, M, and ζ: With the canonical Poisson structure (27) one has the following Poisson brackets, where $f,\widetilde{f}$ are arbitrary smooth real-valued functions on Σ and X,Y are arbitrary vector fields on Σ:

$$\left\{\int_\Sigma d^M\varphi\ X^r C_r, \int_\Sigma d^M\varphi\ Y^s C_s\right\} = \int_\Sigma d^M\varphi [X,Y]^r C_r, \tag{43}$$

$$\left\{\int_\Sigma d^M\varphi\ f\mathscr{H}, \int_\Sigma d^M\varphi\ \widetilde{f}\mathscr{H}\right\} = \int_\Sigma d^M\varphi\left(\frac{hh'}{u}-h'^2\right)\times g^{rs}(f\ \partial_s\widetilde{f}-\widetilde{f}\ \partial_s f)C_r, \tag{44}$$

$$\left\{\int_\Sigma d^M\varphi\ f\mathscr{H}, \int_\Sigma d^M\varphi\ Y^s C_s\right\} = -\int_\Sigma d^M\varphi\ Y^s\ \partial_s f\ \mathscr{H}, \tag{45}$$

where $[X,Y]^r$ denotes the Lie bracket $\partial_s Y^r\ X^s-\partial_s X^r\ Y^s$ of X and Y.

While (43), together with (31), imply that, in principle, the Hamiltonian theory (26) may be reduced to a Hamiltonian theory on a diffeomorphism-invariant phase space (involving only $N-M$ fields and $N-M$ momenta) one should note that on the reduced phase space the density $\mathscr{H}$ (41) can no longer be defined, unless integrated over particular functions. This explains that although $\dot{\mathscr{H}}=0$ (32) for solutions of (28) and (29), satisfying the constraint (31), the Dirac bracket of $\mathscr{H}$ with H [see, e.g., Ref. 4 for the case (38)] would not give zero, due to (45). In particular, $\mathscr{H}$ is *not* a conserved quantity in the Hamiltonian theory.

The charges Q (42), however, *are* conserved on the reduced phase space: $\mathsf{Q}[x,p]=\int_\Sigma d^M\ \varphi\ \mathscr{H}Q(x)$ commutes with C_r,

$$\left\{\int_\Sigma d^M\varphi\ \mathscr{H}Q(x), \int_\Sigma d^M\varphi\ Y^r C_r\right\} = -\int_\Sigma d^M\varphi\ Y^r\ \partial_r Q(x)\mathscr{H} + \int_\Sigma d^M\varphi\ \mathscr{H}\ \partial_i Q(x) Y^r\ \partial_r x^i = 0 \tag{46}$$

[irrespective of Q, h, and $N-M$; just use (45) with $\widetilde{f}=Q(x)$ for the first term on the rhs of (46)], as well as with H (provided $C_r=0$, $N=M+1$, and $hh'=\text{const}$). Moreover,

$$\begin{aligned}
&\left\{\int_\Sigma d^M\varphi\ \mathscr{H}Q(x), \int_\Sigma d^M\varphi\ \mathscr{H}\widetilde{Q}(x)\right\}\\
&\quad=\int_\Sigma d^M\varphi\left(\frac{hh'}{u}-h'^2\right)g^{rs}(Q(x)\partial_s\widetilde{Q}(x)-\widetilde{Q}(x)\partial_s Q(x))C_r\\
&\qquad-\int_\Sigma d^M\varphi\sqrt{g}[x]h'h\ \frac{p_i}{|p|}\ \zeta^{ij}(x)(Q(x)\partial_j\widetilde{Q}(x)-\widetilde{Q}(x)\partial_j Q(x))\\
&\quad=\text{const}\int_\Sigma d^M\varphi\sqrt{g}[x]n^j[x](Q(x)\partial_j\widetilde{Q}(x)-\widetilde{Q}(x)\partial_j Q(x))\\
&\quad=\text{const}\int_{V_t} d^N x\sqrt{\zeta kl}\,\partial_i(\zeta^{ij}(Q\partial_j\widetilde{Q}-\widetilde{Q}\partial_j Q))=0,
\end{aligned} \tag{47}$$

where again we have assumed that Σ_t is the boundary of V_t. In (47), the first equality is general [using (44), with $f=Q(x)$, $\widetilde{f}=\widetilde{Q}(x)$, for the first term], the second equality holds if $C_r=0$ ($1\leqslant r\leqslant M$) and $N=M+1$ (so that $\zeta^{ij}p_j$ is proportional to the surface normal), and the last equality holds if Q and $\widetilde{Q}$ are harmonic functions (it actually holds as long as $\widetilde{Q}\ \Delta Q-Q\ \Delta\widetilde{Q}=0$, which is a much weaker requirement).

The preceding observation has far-reaching consequences. It not only proves the Poisson commutativity of the conserved charges Q given in (42) hence the integrability of (37); the freedom of choosing $Q(x)$ in $\mathbb{R}^3$, e.g. as a superposition $\Sigma_{l=0,|m|\leqslant l}^{\infty}\ q_{lm}Y_{lm}(\mathbf{x})$ with $Y_{lm}(\mathbf{x})$ being the solid spherical harmonics, neatly matches the degrees of freedom to be expected from the one

single field that is left over after the Hamiltonian reduction] but—confirming that integrable theories come in hierarchies—shows that *any* of the charges (42) with $\Delta Q=0$ may be considered as the Hamiltonian of another diffeomorphism-invariant field theory [possessing (42) as commuting conserved charges].

Due to

$$\int_\Sigma d^M\varphi\ Q(x)(4g[x]p^2)^{1/4}=\int_\Sigma d^M\varphi(4\widetilde{g}[x]\widetilde{p}^2)^{1/4}=:\widetilde{H}[x,p], \tag{48}$$

corresponding to $\widetilde{Q}(x)=1$ for a Riemannian manifold $(\mathscr{N},\widetilde{\zeta})$ with a conformally equivalent metric,

$$\widetilde{\zeta}_{ij}(x):=(Q(x))^{4/(N-2)}\zeta_{ij}(x) \tag{49}$$

[implying that $\sqrt{\widetilde{g}}=(Q(x))^{2(N-1)/N-2)}\sqrt{g}$, $\widetilde{p}^{\,2}=\widetilde{p}_i\widetilde{p}_j\widetilde{\zeta}^{ij}=p_ip_j\zeta^{ij}Q^{-4/(N-2)}$; $N\neq 2$; the very special case $N=2$ can be dealt with separately], and the fact that under the conformal change (49) the scalar curvature changes according to

$$\widetilde{R}=Q^{-4/(N-2)}\left(R-4\frac{N-1}{N-2}\frac{\Delta Q}{Q}\right), \tag{50}$$

$$=Q^{-4/(N-2)}R, \tag{51}$$

one sees that each hierarchy (of integrable Hamiltonian systems, resp. harmonic time functions) consists of hypersurface motions in Riemannian manifolds having conformally equivalent metrics and satisfying

$$\widetilde{R}\widetilde{\zeta}_{ij}=R\zeta_{ij}\,. \tag{52}$$

This intriguing observation should have many important consequences. Taking, e.g., $\mathscr{N}=\mathbb{R}^3$ and $\zeta_{ij}=\delta_{ij}$, the above suggests that the solutions of the linear, but nontrivial, equation,

$$\boldsymbol{\nabla}\cdot(Q^2(\mathbf{x})\boldsymbol{\nabla}\tau(\mathbf{x}))=0, \tag{53}$$

resp., the corresponding nonlinear equations,

$$\frac{\partial\mathbf{x}}{\partial t}=Q^2(\mathbf{x})\ \frac{\sqrt{\det(\partial_r\mathbf{x}\cdot\partial_s\mathbf{x})}}{\rho}\ \mathbf{n}, \tag{54}$$

are related to

$$\nabla^2\tau(\mathbf{x})=0, \tag{55}$$

resp.,

$$\frac{\partial\mathbf{x}}{\partial t}=\frac{\sqrt{\det(\partial_r\mathbf{x}\cdot\partial_s\mathbf{x})}}{\rho}\ \mathbf{n}, \tag{56}$$

via some generalized Bäcklund transformation for all $Q(\mathbf{x})$ satisfying

$$\nabla^2Q(\mathbf{x})=0. \tag{57}$$

[13] Although we shall always be working in canonical x^i and p_i coordinates (a bundle chart) on $T^*\mathscr{N}$ this has a global meaning: consider the one-dimensional real vector bundle of contravariant densities, $|\Lambda|T\Sigma$, over Σ [its smooth sections can be regarded as smooth real-valued functions $\hat{\rho}$ on the bundle $L(\Sigma)$ of linear frames of Σ that are equivariant under the structure group $GL(n,\mathbb{R})$ in the sense $\hat{\rho}(vg)=|\det(g)|^{-1}\hat{\rho}(v)$ for all $v\in L(\Sigma)$ and $g\in GL(n,\mathbb{R})$], with bundle projection $|\Lambda|\tau_\Sigma:|\Lambda|T\Sigma\to\Sigma$. Let $\tau^*_{\mathscr{N}}:T^*\mathscr{N}\to\mathscr{N}$ denote the canonical bundle projection. The pair (x,p) can now be regarded as a smooth vector bundle homomorphism $|\Lambda|T\Sigma\to T^*\mathscr{N}$ over the map $x:\Sigma\to\mathscr{N}$, i.e. $x\circ|\Lambda|\tau_\Sigma=\tau^*_{\mathscr{N}}\circ(x,p)$. Alternatively, since the bundle of densities is trivializable we may choose a fixed covariant nonvanishing positive reference density ρ_0 on Σ (a section in the bundle dual to $|\Lambda|T\Sigma$ and that induces an integral over Σ) and write $(x,p)=(x,p')\rho_0$, where (x,p') is an arbitrary smooth map $\Sigma\to T^*\mathscr{N}$ such that $x=\tau^*_{\mathscr{N}}\circ(x,p')$. In this fashion we can establish a (noncanonical) one-one-correspondence between the set of ''densitized maps'' as defined above and all smooth maps $\Sigma\to T^*\mathscr{N}$.
[14] In order to avoid clumsy notation we shall henceforth suppress the arguments $\varphi\in\Sigma$ in the integrals, the field x and its derivatives in $\sqrt{g}[x]$ and $n[x]$, and the argument u of h and h' from time to time.

New integrable generalizations of Calogero–Moser quantum problem

A one-parameter deformation of Calogero–Moser quantum problem is introduced. It is shown that corresponding Schrödinger operator is integrable for any value of the parameter and algebraically integrable in case of integer value. © *1998 American Institute of Physics.* [S0022-2488(98)00902-5]

I. INTRODUCTION

Let's consider the following Schrödinger operator describing the one-dimensional $(N+1)$-body problem:

$$L=\sum_{j=1}^{N+1}\frac{\hat{p}_j^2}{2m_j}+m(m+1)\sum_{i<j}^{N+1}\frac{m_i m_j}{(q_i-q_j)^2}, \tag{1}$$

where all but one of the ''masses'' are equal, $m_1=\cdots=m_N=1$, $m_{N+1}=m^{-1}$, m is some real parameter, $\hat{p}_j=i(\partial/\partial q_j)$ $(j=1,\ldots,N+1)$.

When $m=1$ one has a particular case of the Calogero operator[1] considered in Ref. 2.

The aim of the present paper is to show that such a deformation of the Calogero problem is still integrable in the quantum (but not in the classical!) case.

Recall that a Schrödinger operator in $\mathbf{R}^n$ is called *integrable* if there are n commuting differential operators $L_1=L,L_2,\ldots,L_n$ with constant and independent highest symbols $P_i(k)$. If there exists at least one more commuting operator L_{N+1} with a constant highest symbol $P_{n+1}(k)$ such that it takes the different values at the solutions of the algebraic system $P_i(k)=c_i$ $(i=1,\ldots,n)$, then L is called *algebraically integrable* (see Refs. 3 and 4).

Our main result is the following:

Theorem: *The Schrödinger operator (1) is integrable for an arbitrary m and algebraically integrable for any integer m.*

We prove also that the same is true for the corresponding trigonometric version

$$L=\sum_{j=1}^{N+1}\frac{\hat{p}_j^2}{2m_j}+m(m+1)\sum_{i<j}^{N+1}\frac{m_i m_j\omega^2}{\sin^2\omega(q_i-q_j)}, \tag{2}$$

$m_1=\ldots=m_N=1$, $m_{N+1}=m^{-1}$, which is the deformation of the Sutherland operator.[5]

We conjecture that the same is true also for the elliptic version

$$L=\sum_{j=1}^{N+1}\frac{\hat{p}_j^2}{2m_j}+m(m+1)\sum_{i<j}^{N+1}m_i m_j\wp(q_i-q_j), \tag{3}$$

$m_1=\ldots=m_N=1$, $m_{N+1}=m^{-1}$.

It is known to be true for $m=1$ (integrability,[6] algebraic integrability[7,8] for $N=2$ and Refs. 9, 10, and 11 for any N). For $N=2$ and any m the integrability of (3) was proven in Ref. 8.

In the coordinates $x_1=q_1, \ldots, x_N=q_N, x_{N+1}=(1/\sqrt{m})\,q_{N+1}$ the operators (1), (2), (3) have the form

$$L=-\Delta+\sum_{i<j}^{N} 2m(m+1)u(x_i-x_j)+\sum_{i=1}^{N} 2(m+1)u(x_i-\sqrt{m}x_{N+1}) \tag{4}$$

with $u(x)=x^{-2}, \omega^2 \sin^{-2}\omega x$ or $\wp(x)$, $\Delta=\partial_1^2+\ldots+\partial_{N+1}^2, \partial_j=\partial/\partial x_j$.

Olshanetsky and Perelomov[6] proposed the generalizations of the Calogero–Moser system of the form

$$L=-\Delta+\sum_{\alpha\in\mathfrak{R}_+} m_\alpha(m_\alpha+1)(\alpha,\alpha)u((\alpha,x)), \tag{5}$$

related to any root system $\mathfrak{R}$. Our operator (4) is related to the set $\mathbf{A}_N(m)$ which consists of the vectors $\alpha=e_i-e_j$ $(i<j\leqslant N)$ with multiplicities $m_\alpha=m$ and $\alpha=e_i-\sqrt{m}e_{N+1}$ $(i=1,\ldots,N)$ with $m_\alpha=1$. We may consider this set as a deformation of the root system $\mathbf{A}_N$.

It turns out that such a deformation exists also for the root system $\mathbf{B}_2$. It depends on two parameters l,m and consists of the vectors $\alpha_1=\sqrt{2m+1}e_1$ with multiplicity l, $\alpha_2=\sqrt{2l+1}e_2$ with multiplicity m and two vectors $\alpha_{3,4}=\frac{1}{2}(\alpha_1\pm\alpha_2)$ with multiplicity 1. We denote this set as $\mathbf{B}_2(l,m)$. The corresponding Schrödinger operator has the form:

$$\begin{aligned} L=&-\Delta+l(l+1)(2m+1)u(\sqrt{2m+1}x_1)+m(m+1)(2l+1)u(\sqrt{2l+1}x_2)+(l+m+1)\\ &\times u(\tfrac{1}{2}\sqrt{2m+1}x_1+\tfrac{1}{2}\sqrt{2l+1}x_2)+(l+m+1)u(\tfrac{1}{2}\sqrt{2m+1}x_1-\tfrac{1}{2}\sqrt{2l+1}x_2). \end{aligned} \tag{6}$$

We prove that this operator is integrable in rational $u=x^{-2}$ and trigonometric $u=\omega^2\sin^{-2}\omega x$ cases.

All these deformations appeared in Ref. 12 within a construction of the multidimensional Baker–Akhiezer function related to a configuration of hyperplanes proposed in Refs. 2 and 4.

In the rational case we can add the quadratic term Ω^2x^2 to the potential without destroying integrability:

$$\begin{aligned} L=&\hat{p}_1^2+\ldots+\hat{p}_N^2+m\hat{p}_{N+1}^2+2m(m+1)\sum_{i<j}^{N}\frac{1}{(q_i-q_j)^2}+2(m+1)\\ &\times\sum_{i=1}^{N}\frac{1}{(q_i-q_{N+1})^2}+\Omega^2\left(q_1^2+\ldots+q_N^2+\frac{1}{m}q_{N+1}^2\right). \end{aligned}$$

II. INTERTWINING OPERATORS AND INTEGRABILITY OF THE DEFORMED CALOGERO OPERATOR

We start with the standard Calogero operator $\mathscr{L}$ in $\mathbf{R}^N$:

$$\mathscr{L}=-\Delta+\sum_{i<j}^{N} 2m(m+1)(x_i-x_j)^{-2}. \tag{7}$$

It is well known that the operator $\mathscr{L}$ is integrable for any m. Moreover, for the symmetric polynomials $s_i(k)=k_1^i+\cdots+k_N^i$ $(i=1,\ldots,N)$ there exist commuting differential operators $\mathscr{L}_i$ with the highest symbols $s_i(k)$.[13,6] In Ref. 4 it was proven that for any *integer m* the operator (7) is *algebraically integrable*.

We will prove now that the same is true for the deformed Calogero operator,

$$L=-\Delta+\sum_{i<j}^{N}\frac{2m(m+1)}{(x_i-x_j)^2}+\sum_{i=1}^{N}\frac{2(m+1)}{(x_i-\sqrt{m}x_{N+1})^2}. \tag{8}$$

The idea of the proof is similar to the one we used in Ref. 2: We present a differential operator D which intertwines the operator (8) and

$$\hat{\mathscr{L}} = -\partial_{N+1}^2 + \mathscr{L}. \tag{9}$$

Let's introduce a set of differential operators $D_n^{i_1,\dots,i_k}$ by the following recursive formulas:

$$D_n = 1,\ D_n^i = \partial_i - \sqrt{m}\partial_n - (m+1)(x_i - \sqrt{m}x_n)^{-1},$$

$$D_n^{i_1,\dots,i_k} = D_n^{i_1,\dots,i_{k-1}} \circ (\partial_{i_k} - \sqrt{m}\partial_n) - (m+1)(x_{i_k} - \sqrt{m}x_n)^{-1} D_n^{i_1,\dots,i_{k-1}} \tag{10}$$

$$+ \sum_{s=1}^{k-1} \frac{m(m+1)}{(x_{i_s} - x_{i_k})^2} D_n^{i_1,\dots,\hat{i}_s,\dots,i_{k-1}}.$$

Here $\partial_i = \partial/\partial x_i$, $i_1, \dots, i_k$ are different natural indices less than n and the symbol $\hat{i}_s$ means that the index i_s must be omitted.

Theorem 1: *The operator $D = D_{N+1}^{1,\dots,N}$ defined by the formulas (10) intertwines the operator (8) and Calogero operator $\hat{\mathscr{L}}$*:

$$L \circ D = D \circ \hat{\mathscr{L}}. \tag{11}$$

The theorem can be proved by repeating the arguments of Ref. 14 where the case $m = 1$ was considered.

Corollary: For any operator $\hat{A}$ commuting with Calogero operator $\hat{\mathscr{L}}$ the operator $A = D \circ \hat{A} \circ D^*$ commutes with L where D^* means the operator formally adjoint to D.

Indeed, since L and $\hat{\mathscr{L}}$ are self-adjoint, it follows from (11) that $D^* \circ L = \hat{\mathscr{L}} \circ D^*$ and therefore

$$AL = D\hat{A}D^*L = D\hat{A}\hat{\mathscr{L}}D^* = D\hat{\mathscr{L}}\hat{A}D^* = LD\hat{A}D^* = LA.$$

Now taking integrals for $\hat{\mathscr{L}}$ as $\hat{A}$ we obtain independent integrals for L. The same arguments as in Ref. 15 show that these integrals commute with each other.

Taking the symmetric integrals $\hat{A} = \mathscr{L}_i$ $(i = 1, \dots, N)$ and $\hat{A} = \partial_{N+1}$ we obtain $N+1$ commuting integrals and therefore the integrability for the deformed Calogero system (8). Using the extra integrals of the system (7) found in Ref. 4 for integer m we construct in such a way the extra integrals for the system (8) to prove its algebraic integrability.

In the trigonometric case (4) the intertwining operator D is determined by the recursion formulas (cf. Ref. 14):

$$D_n = 1,\ D_n^i = \partial_i - \sqrt{m}\partial_n - (m+1)\,\omega \cot \omega(x_i - \sqrt{m}x_n),$$

$$D_n^{i_1,\dots,i_k} = D_n^{i_1,\dots,i_{k-1}} \circ (\partial_{i_k} - \sqrt{m}\partial_n) - (m+1)\,\omega \cot \omega(x_{i_k} - \sqrt{m}x_n) D_n^{i_1,\dots,i_{k-1}}$$

$$+ \sum_{s=1}^{k-1} \frac{m(m+1)\omega^2}{\sin^2 \omega(x_{i_s} - x_{i_k})} D_n^{i_1,\dots,\hat{i}_s,\dots,i_{k-1}},$$

$$D = D_{N+1}^{1,\dots,N}.$$

It satisfies the relation

$$L \circ D = D \circ \hat{\mathscr{L}},$$

where

$$L=-\Delta+\sum_{i<j}^{N}\ 2m(m+1)\frac{\omega^2}{\sin^2\ \omega(x_i-x_j)}+\sum_{i=1}^{N}\ 2(m+1)\frac{\omega^2}{\sin^2\ \omega(x_i-\sqrt{m}x_{N+1})}, \tag{12}$$

and

$$\hat{\mathscr{L}}=-(\partial_1^2+\ \ldots\ +\partial_{N+1}^2)+\sum_{i<j}^{N}\ 2m(m+1)\frac{\omega^2}{\sin^2\ \omega(x_i-x_j)} \tag{13}$$

is the Sutherland operator[5].

Since the Sutherland system is integrable for any m (see Ref. 6) and algebraically integrable for integer m[4] we can use the above argument to prove the same property for the deformed Sutherland operator (12).

Theorem 2: *The deformed Calogero–Sutherland operators (8), (12) are integrable for any value of the parameter m and algebraically integrable when m is an integer.*

Notice that the existence of the intertwining operator D allows one to find the solutions of the corresponding Schrödinger equation $L\psi=\lambda\psi$ as $\psi=D\psi_0$ where ψ_0 is the solution of the equation $\hat{\mathscr{L}}\psi_0=\lambda\psi_0$. In particular, for integer m we have the eigenfunction for L of the form

$$\psi=P(k,x)e^{(k,x)}, \tag{14}$$

where $P(k,x)$ is some polynomial on k with the highest terms

$$P(k)=\prod_{i<j}^{N}\ (k_i-k_j)^m\prod_{i=1}^{N}\ (k_i-\sqrt{m}k_{N+1})$$

(cf. Refs. 4 and 12). This function satisfies certain properties in k-variables (multidimensional Baker–Akhiezer function, see Ref. 12).

The intertwining operator exists also for the Schrödinger operator $L+\Omega^2x^2=L_\Omega$:

$$L_\Omega=-\Delta+\sum_{i<j}^{N}\frac{2m(m+1)}{(x_i-x_j)^2}+\sum_{i=1}^{N}\frac{2(m+1)}{(x_i-\sqrt{m}x_{N+1})^2}+\Omega^2(x_1^2+\cdots+x_{N+1}^2). \tag{15}$$

It is defined by the following recursive formulas:

$$D_n=1,\ D_n^i=\partial_i-\sqrt{m}\partial_n-\left(\frac{m+1}{x_i-\sqrt{m}x_n}+\Omega(x_i-\sqrt{m}x_n)\right),$$

$$D_n^{i_1,\ldots,i_k}=D_n^{i_1,\ldots,i_{k-1}}\circ(\partial_{i_k}-\sqrt{m}\partial_n)-\left(\frac{m+1}{x_{i_k}-\sqrt{m}x_n}+\Omega(x_{i_k}-\sqrt{m}x_n)\right)D_n^{i_1,\ldots,i_{k-1}}$$

$$+\sum_{s=1}^{k-1}\left(\frac{m(m+1)}{(x_{i_s}-x_{i_k})^2}-m\Omega\right)D_n^{i_1,\ldots,\hat{i}_s,\ldots,i_{k-1}}.$$

The following result can be proven similar to Ref. 14.

Theorem 3: *For* $D_\Omega=D_{N+1}^{1,\ldots,N}$ *we have*:

$$D_\Omega\circ(\mathscr{L}_\Omega+2N\Omega)=L_\Omega\circ D_\Omega, \tag{16}$$

where

$$\mathscr{L}_\Omega=-\Delta+\sum_{i<j}^{N}\frac{2m(m+1)}{(x_i-x_j)^2}+\Omega^2(x_1^2+\cdots+x_{N+1}^2). \tag{17}$$

Corollary: L_Ω *is integrable for any* m.

Again, the integrals can be obtained as

$$L_i^{\Omega}=D_{\Omega}\mathscr{L}_i D_{\Omega}^{*}$$

where $\mathscr{L}_i$ $(i=1,\ldots,N+1)$ are the integrals for the Calogero operator (17).

We should note that not all the integrals have such a form. For example, we can prove using the results of Ref. 12 the following

Theorem 4: *For the deformed Calogero operator (8) there exist commuting integrals $L_s(m)$ with the highest symbols*

$$p_s(k)=k_1^s+\ldots+k_N^s+m^{\frac{s-2}{2}}k_{N+1}^s.$$

When $m=1$ these integrals coincide with the standard integrals L_s of the Calogero system,[13] so $L_s(m)$ can be considered as their deformation.

III. THREE-PARTICLE CASE

We consider now the deformed three-particle Sutherland operator (2):

$$L=-\partial_1^2-\partial_2^2-m\partial_3^2+2m(m+1)u(q_1-q_2)+2(m+1)u(q_1-q_3)+2(m+1)u(q_2-q_3), \tag{18}$$

where $u(x)=\omega^2\ \sin^{-2}\ \omega x$.

In this case the intertwining operator D has the following form:

$$\begin{aligned}D=&(\partial_1-m\partial_3)(\partial_2-m\partial_3)-(m+1)\omega\ \cot\ \omega(q_1-q_3)(\partial_2-m\partial_3)\\&-(m+1)\omega\ \cot\ \omega(q_2-q_3)(\partial_1-m\partial_3)+(m+1)^2\omega^2\ \cot\ \omega(q_1-q_3)\cot\ \omega(q_2-q_3)\\&+m(m+1)\omega^2\ \sin^{-2}\ \omega(q_1-q_2).\end{aligned}$$

We have $L\circ D=D\circ\mathscr{L}$ with

$$\mathscr{L}=-\partial_1^2-\partial_2^2-m\partial_3^2+2m(m+1)\omega^2\ \sin^{-2}\ \omega(q_1-q_2).$$

When m is an integer we can intertwine $\mathscr{L}$ with $-\Delta=-\partial_1^2-\partial_2^2-m\partial_3^2$ by the following operator S:

$$\mathscr{L}\circ S=S\circ(-\Delta),$$

$$\begin{aligned}S=&(\partial_1-\partial_2-2m\omega\ \cot\ \omega(q_1-q_2))\circ(\partial_1-\partial_2-2(m-1)\omega\ \cot\ \omega(q_1-q_2))\ldots\circ(\partial_1-\partial_2\\&-2\omega\ \cot\ \omega(q_1-q_2)).\end{aligned}$$

It follows from this that the operator $D\circ S$ intertwines L and $-\Delta$:

$$L\circ(D\circ S)=D\circ\mathscr{L}\circ S=(D\circ S)\circ(-\Delta).$$

The quantum integrals for L can be written explicitly:

$$L_1=\partial_1+\partial_2+\partial_3,\ L_2=L,$$

$$L_3=\partial_1\partial_2\partial_3+\frac{1-m}{2}(\partial_1+\partial_2)\partial_3^2+\frac{(1-m)(1-2m)}{6}\partial_3^3$$
$$+(m+1)u(q_2-q_3)\partial_1+(m+1)u(q_1-q_3)\partial_2+m(m+1)u(q_1-q_2)\partial_3$$
$$+\frac{1-m^2}{2}(u(q_1-q_3)\circ\partial_3+\partial_3\circ u(q_1-q_3))$$
$$+\frac{1-m^2}{2}(u(q_2-q_3)\circ\partial_3+\partial_3\circ u(q_2-q_3)),$$

where $u(x)=\omega^2\ \sin^{-2}\omega x$.

While $\omega\to 0$ we obtain the analogous formulas for the deformed Calogero operator. It can be checked that the above formulas work also for the elliptic version of the operator (18) with $u(x)=\wp(x)$. This provides the integrability of the deformed elliptic Calogero–Moser system of three particles for the quantum case.

IV. DEFORMATION OF B_2-CASE

Let's consider the following Schrödinger operator:

$$L=-(2m+1)\frac{\partial^2}{\partial x_1^2}-(2l+1)\frac{\partial^2}{\partial x_2^2}+\frac{l(l+1)(2m+1)}{\sin^2 x_1}+\frac{m(m+1)(2l+1)}{\sin^2 x_2}$$
$$+\frac{(l+m+1)}{\sin^2\frac{1}{2}(x_1+x_2)}+\frac{(l+m+1)}{\sin^2\frac{1}{2}(x_1-x_2)}, \tag{19}$$

which is a trigonometric version of (6) after the change of variables $x_1\to\sqrt{2m+1}x_1, x_2\to\sqrt{2l+1}x_2$. When $l=m$ it coincides with the special case of B_2-generalization of the Calogero–Sutherland system. It turned out that the integrability takes place also for any l and m. We prove this by constructing operator D intertwining L and

$$\mathscr{L}=-(2m+1)\frac{\partial^2}{\partial x_1^2}-(2l+1)\frac{\partial^2}{\partial x_2^2}+\frac{l(l+1)(2m+1)}{\sin^2 x_1}+\frac{m(m+1)(2l+1)}{\sin^2 x_2}. \tag{20}$$

The explicit form of the intertwining operator is the following:

$$D=(2m+1)^2\partial_1^2-(2l+1)^2\partial_2^2$$
$$-(m+l+1)\cot\tfrac{1}{2}(x_1+x_2)((2m+1)\partial_1-(2l+1)\partial_2)$$
$$-(m+l+1)\cot\tfrac{1}{2}(x_1-x_2)((2m+1)\partial_1+(2l+1)\partial_2)$$
$$+(m+l+1)^2\cot\tfrac{1}{2}(x_1+x_2)\cot\tfrac{1}{2}(x_1-x_2)$$
$$-\frac{l(l+1)(2m+1)^2}{\sin^2 x_1}+\frac{m(m+1)(2l+1)^2}{\sin^2 x_2}, \tag{21}$$

where ∂_i denotes $\partial/\partial x_i$.

Theorem 5: *The operator D given by formula (21) intertwines the Schrödinger operators (19) and (20):*

$$D\circ\mathscr{L}=L\circ D.$$

Corollary: The operator (19) is integrable for any l,m and algebraically integrable for integer l and m.

The integrals have the form $I_k=D\circ\mathscr{L}_k\circ D^*$ $(k=1,2)$,

$$\mathscr{L}_1=-\partial_1^2+\frac{l(l+1)}{\sin^2 x_1},\quad \mathscr{L}_2=-\partial_2^2+\frac{m(m+1)}{\sin^2 x_2},\quad \mathscr{L}_1+\mathscr{L}_2=\mathscr{L}.$$

For integer l,m the operator (19) can be intertwined with $\mathscr{L}_0=-(2m+1)\partial_1^2-(2l+1)\partial_2^2$ by means of the following operator $S=D\circ S_1\circ S_2$, $L\circ S=S\circ\mathscr{L}_0$ where

$$S_1=(\partial_1-l\ \cot x_1)\circ(\partial_1-(l-1)\cot x_1)\circ\cdots\circ(\partial_1-\cot x_1),$$

$$S_2=(\partial_2-m\ \cot x_2)\circ(\partial_2-(m-1)\cot x_2)\circ\cdots\circ(\partial_2-\cot x_2).$$

In this case we obtain the extra integrals A_1,A_2 by the same method, $A_k=S\circ\partial_k\circ S^*$, which supply the algebraic integrability for L.

In the rational limit we have the operator

$$L=-(2m+1)\partial_1^2-(2l+1)\partial_2^2+\frac{l(l+1)(2m+1)}{x_1^2}$$

$$+\frac{m(m+1)(2l+1)}{x_2^2}+\frac{4(l+m+1)}{(x_1+x_2)^2}+\frac{4(l+m+1)}{(x_1-x_2)^2}.$$

V. CONCLUDING REMARKS

The natural question is what happens with our system in the classical limit. To obtain such a limit we multiply the operator (4) by $\hbar^2$ and replace $i\hbar\,\partial/\partial x_k$ by p_k. We have the following result:

$$\sum_{k=1}^{N+1}p_k^2+\sum_{i<j}^{N}2\hbar^2m(m+1)u(x_i-x_j)+\sum_{i=1}^{N}2\hbar^2(m+1)u(x_i-\sqrt{m}x_{N+1}).$$

Then in the limit $\hbar\to 0$, $m\to\infty, m\hbar\to\mu$ we obtain formally the Hamiltonian of the classical N-body Calogero system with one additional non-interacting particle:

$$H=\sum_{k=1}^{N+1}p_k^2+\sum_{i<j}^{N}2\mu^2u(x_i-x_j).$$

Notice that the formal classical analogue of our problem, i.e., the Hamiltonian system with the Hamiltonian

$$\sum_{k=1}^{N+1}\frac{p_k^2}{2m_k}+\gamma\sum_{i<j}^{N}m_im_j(q_i-q_j)^{-2}$$

seems to be integrable only if all the masses are equal. At least, for the three-particle case with the Hamiltonian

$$H=p_1^2+p_2^2+mp_3^2+\gamma\left((q_1-q_2)^{-2}+\frac{1}{m}(q_1-q_3)^{-2}+\frac{1}{m}(q_2-q_3)^{-2}\right)$$

and $m\neq 1$ one can show that any integral I which is a polynomial of the third order in momenta can be expressed via H and the total momentum $p_1+p_2+p_3$. So only for the case $m=1$ we have independent integral of the third order.

It is interesting to note also that in the limit $\omega\to\infty, m+1\to 0, \omega(m+1)\to$const we formally have the following operator

$$L=-\Delta+\sum_{k<l}^{N}\mu\,\delta(x_k-x_l)-\sum_{k=1}^{N}\mu\,\delta(x_k-ix_{N+1}),$$

or, in the coordinates $q_1=x_1,\ldots,q_N=x_N,q_{N+1}=ix_{N+1}$,

$$L=-\partial_1^2-\ldots-\partial_N^2+\partial_{N+1}^2+\sum_{k<l}^{N}\mu\,\delta(q_k-q_l)-\sum_{k=1}^{N}\mu\,\delta(q_k-q_{N+1}).$$

Another remark is about the relation of our system (1) to Huygens' principle. It can be shown that our deformations of the Calogero operator correspond to new examples of Huygensian equations in Minkowsky' space similar to the Coxeter case considered in Ref. 16. More precisely, the equation

$$(\Box_{M,1}+u(x))\phi=0$$

where $\Box_{M,1}=\partial_t^2-\partial_1^2-\ldots-\partial_M^2$ is the D'Alembert operator in $\mathbf{R}^{M,1}$ and the potential $u=u(x_1,\ldots,x_{N+1})$ has the form

$$u(x)=\sum_{i<j}^{N}\frac{2m(m+1)}{(x_i-x_j)^2}+\sum_{i=1}^{N}\frac{2(m+1)}{(x_i-\sqrt{m}x_{N+1})^2}$$

and satisfies Huygens' principle (in the Hadamard sense) if the parameter m is any integer and the dimension M is any odd number greater than $mN(N-1)+2N+2$. A similar result is true for the deformed B_2-system.

The last remark is about a difference version of our system. Such a version of the Calogero–Moser quantum problem has been discovered by Ruijsenaars (see, e.g., Ref. 17). In the rational case Ruijsenaars's system can be described as a dual system in the ''bispectral sense'' to the trigonometric CMS problem (Sutherland system). One can show (see Ref. 18), that the same relation is valid for our generalizations of the Sutherland system (12) and the following difference operator, which can be considered as a deformation of Ruijsenaars's operator:

$$\mathscr{D}(m)=\sum_{i=1}^{N}\left(1-\frac{\omega}{k_i-\sqrt{m}k_{N+1}+\gamma}\right)\prod_{j\neq i}^{N}\left(1-\frac{m\omega}{k_i-k_j}\right)T_i^{\omega}+m^{-1}\prod_{i=1}^{N}\left(1+\frac{m\omega}{k_i-\sqrt{m}k_{N+1}+\gamma}\right)T_{N+1}^{\sqrt{m}\omega}. \tag{22}$$

Here $\gamma=(1-m)\omega/2$ and $T_i^{\omega}\phi(k_1,\ldots,k_i,\ldots,k_{N+1})=\phi(k_1,\ldots,k_i+\omega,\ldots,k_{N+1})$ is the ω-shift in the ith direction. When $m=1$ $\gamma=0$ and $\mathscr{D}(m)$ coincides with one of the Ruijsenaars operators.[17]

Augmented temporal logic formalism for histories-based generalized quantum mechanics

Tulsi Dass[a] and Yogesh Joglekar[b]
Department of Physics, Indian Institute of Technology, Kanpur 208016, India

(Received 22 May 1997; accepted for publication 24 October 1997)

An axiomatic development of dynamics of systems in the framework of histories is given which contains the history versions of classical and traditional quantum mechanics as special cases. We consider theories which admit a quasitemporal structure (a generalization of the concept of time using partial semigroups) and whose ''single time'' propositions have the mathematical structure of a logic; isomorphism of logics at different ''instants of time'' is not assumed. The concept of directed partial semigroup is introduced to incorporate the concept of direction of flow of time in quasitemporal theories. Starting with a few simple axioms, the space of history propositions is explicitly constructed and shown to be an orthoalgebra (as envisaged in the scheme of Isham and Linden [J. Math. Phys. **35**, 5452–5476 (1994)]); its subspace consisting of history filters (''homogeneous histories'') is a meet semilattice. The partial semigroups employed allow semi-infinite irreducible decompositions. © *1998 American Institute of Physics.*

I. INTRODUCTION

In the traditional formulation of quantum mechanics, all measurements/observations refer to external (classical) observers; such a formalism obviously cannot serve as a basis for quantum cosmology. The consistent histories approach to quantum mechanics[1–7] is an outcome of efforts to evolve a formalism for quantum mechanics applicable to closed systems, in particular, the Universe.

The first paper to employ objects analogous to what are now called histories was probably the one by Houtappel, Van Dam, and Wigner[8] (HVW) who employed, in their treatment of geometric invariance principles, conditional probabilities $\Pi(B|A)$ where $A=(\alpha,r_\alpha;\beta,r_\beta;\ldots;\varepsilon,r_\varepsilon)$ denotes a set of measurements α, β,..., ε (at times $t_\alpha,t_\beta,\ldots,t_\varepsilon$) with outcomes $r_\alpha,\ldots,r_\varepsilon$ and similarly $B=(\zeta,r_\zeta;\ldots;\nu,r_\nu)$; the quantity $\Pi(B|A)$ denotes the probability of the realization of the sequence B, given A. [We have changed HVW's notation $\Pi(A|B)$ to $\Pi(B|A)$ to bring it in line with standard usage in probability theory.] The ordering of the times $t_\alpha,\ldots,t_\varepsilon$, $t_\zeta,\ldots,t_\nu$ is arbitrary. The objects $\Pi(B|A)$ are quite general and can be employed in classical as well as quantum mechanics. The measurements refer to external observers.

The objects presently used in histories-based quantum theory are closely related to the Π functions. By a history one typically means a sequence of measurements/records for a system in given initial state. For a system S in the state represented by the density operator $\rho(t_0)$, the joint probability of the sequence of measurement outcomes

$$(P_1,t_1;P_2,t_2;\ldots;P_n,t_n);t_1<t_2<\ldots<t_n, \tag{1.1}$$

where $t_1>t_0$ and $P_1,\ldots,P_n$ are appropriate Schödinger picture projection operators, is

$$\mathrm{Prob}(P_1,t_1;\ldots;P_n,t_n|\rho(t_0))=\mathrm{Tr}(C_\alpha\rho(t_0)C_\alpha^\dagger). \tag{1.2}$$

Here α denoted the history (1.1) and

$$C_\alpha = P_n U(t_n, t_{n-1}) \cdots P_2 U(t_2, t_1) P_1 U(t_1, t_0), \tag{1.3}$$

where $U(t', t'') = \exp[-iH(t'-t'')/\hbar]$ is the unitary evolution operator. The main inputs in this derivation are (i) unitary evolution of the undisturbed system during the open time intervals (t_j, t_{j+1}) $(j=0,1,...,n-1)$, (ii) reduction of state vector at times $t_1, t_2, \ldots, t_{n-1}$, and (iii) transition probability formula employed at the final time $t=t_n$.

In the interpretive scheme of Griffith and Omnes,[2,3] the Hilbert space-based mathematical formalism is retained, the reduction postulate is discarded and (1.2) is proposed to be interpreted as the probability for the history (1.1) for the closed system S (no external observers) with the further stipulation that situations involving measurements by external observers are to be dealt with by treating the closed system (system+observer) as above.

Some restrictions need to be imposed on admissible histories if the formula (1.2) is to be used as a classical probability. This is because the classical addition of probabilities cannot hold in the presence of quantum mechanical interference. The desired ''consistency condition'' (or ''decoherence condition'') between two histories α and β [with $\beta = (P'_1, t'_1; \ldots; P'_m, t'_m)$, say] turns out to be

$$\mathrm{Re}[d(\alpha, \beta)] = 0, \tag{1.4}$$

where the so-called decoherence functional $d(\alpha, \beta)$ is given by

$$d(\alpha, \beta) = \mathrm{Tr}[C_\alpha \rho(t_0) C_\beta^+]. \tag{1.5}$$

Note that

$$\mathrm{Prob}(\alpha) = d(\alpha, \alpha). \tag{1.6}$$

Gell-Mann and Hartle[4–7] (GH) have pursued a program for evolving a framework for the quantum dynamics of the Universe as a whole. Within that framework, they aim at understanding the origin of the quasiclassical domain of familiar experience taking as basic inputs the action of elementary particles and the initial condition of the Universe. In the ''generalized quantum mechanics'' (of a closed system) evolved by them, the basic ingredients are a set of fine-grained histories [usually taken to be the paths $q^i(t)$ in configuration space], allowed coarse grainings, and a space of decoherence functional $d(\alpha, \beta)$ (complex-valued functionals defined on pairs of histories in coarse-grained sets) for which four conditions [hermiticity, positivity, additivity, and normalization; see Eqs. (3.62a)–(3.62d)], which are satisfied by the $d(.,.)$ of Eq. (1.5), are *postulated*. The decoherence functionals serve, as above, to define decoherence conditions and probabilities of decoherent histories. No reference is made to an underlying Hilbert space.

Isham[9] (see also Isham and Linden[10]) has proposed that the proper mathematical framework for the axiomatic development of a GH type scheme is that of temporal quantum logic, a multitime generalization of traditional quantum logic.[11–15] In his scheme a partial semigroup (for definition, see Sec. II) structure was introduced in a pair of spaces [a space $\mathscr{T}$ of temporal supports (replacing the space of time sequences $t_1, \ldots, t_n$ employed in the traditional description of histories) and a space $\mathscr{U}$ of history filters (homogeneous histories); our notations are slightly different from those of Refs. 9 and 10] to generalize the concept of time and to describe the composition of histories in appropriate temporal relation to form larger histories. A homomorphism σ of $\mathscr{U}$ onto $\mathscr{T}$ associates, with an element α of $\mathscr{U}$, the element $\sigma(\alpha)$ of $\mathscr{T}$ representing the ''sequence of times'' at which the propositions of the history α are specified. The space $\mathscr{U}$ was assumed to have, besides the partial semigroup structure, the structure of a meet semilattice[16] with the operations of partial order $\leqslant$ (coarse graining) and a meet operation $\wedge$ (simultaneous realization of two histories). To accommodate the operation of negation of a history, the space $\mathscr{U}$ was proposed to be embedded in a larger space Ω (denoted as $\mathscr{U}.\mathscr{P}$ in Refs. 9 and 10) of history propositions (''inhomogeneous'' histories); the structure of an orthocomplemented lattice was envisaged (but not derived) for Ω. The decoherence functionals (objects associating complex numbers with pairs of elements of Ω) were assumed to have the same properties as in the GH scheme. A formalism of this type has the generality required to accommodate in it history versions of field theories on general space times (which may not admit foliation in terms of spacelike surfaces).

In Ref. 10, a more general scheme was proposed in which the basic objects were the space Ω of history propositions and the space $\mathscr{D}$ of decoherence functionals. The space Ω (whose elements will be denoted as $\underline{\alpha}$, $\underline{\beta}$,...) was postulated to have the structure of an orthoalgebra,[17] a structure incorporating partial order$\leqslant$(coarse graining), disjointness$\perp$(mutual exclusion), and disjoint joint operation $\oplus$ ($\alpha\oplus\beta$, defined only when $\alpha\perp\beta$, is to mean ''α or β'') with the stipulation that $\alpha\leqslant\beta$ if and only if there exists a (unique) $\gamma\varepsilon\,\Omega$ such that $\beta=\alpha\oplus\gamma$. It has two distinguished elements 0 (the null history proposition which is impossible to realize) and 1 (the unit history proposition which is sure to be realized); one has $0\leqslant\alpha\leqslant 1$ for all $\alpha\varepsilon\,\Omega$. For every $\alpha\varepsilon\,\Omega$, the relation $\alpha\leqslant 1$ implies the existence of a unique element$\neg\alpha$ (the negation of α) of Ω such that $\alpha\oplus\neg\alpha=1$. History theories with quasitemporal structure (i.e., those covered by an Isham type scheme) constitute a subclass of theories covered by this more general scheme.

While histories, in principle, contain information about the structural features and dynamics of a system, the Isham–Linden formalism is not adequately equipped to bring it out in an autonomous framework. In the present work we present a more detailed formalism for quasitemporal theories with a view to fulfill this need. Our framework is defined by three axioms A_1–A_3. The first axiom A_1 introduces a quasitemporal structure in terms of a triple $(\mathscr{U},\mathscr{T},\sigma)$ as in the Isham scheme. The second is a causality axiom which forbids ''closed time loops.'' Our main new axiom is A_3 in which the spaces $\mathscr{U}_\tau=\sigma^{-1}(\tau)$ for nuclear elements in $\mathscr{T}$ (''points of time''), the spaces of ''single time propositions,'' are assumed to have the structure of a logic as defined in Ref. 14, a natural assumption to make in view of the fact that this structure was arrived at (in the 1960s) by very general considerations. (In any case, it is worth studying history theories with this structure assumed for the $\mathscr{U}_\tau$'s and generalizing the concept of time as described above.) We, however, do not assume isomorphism of $\mathscr{U}_\tau$'s for different τ's. This generality, we feel, must be kept in order that the formalism is applicable to systems whose structural properties undergo qualitative change with temporal evolution. Using these three axioms, the space Ω of history propositions (''inhomogeneous histories'') is explicitly constructed and shown to be an orthoalgebra as envisaged in the Isham–Linden scheme. The subspace $\widetilde{\mathscr{U}}$ of Ω consisting of ''homogeneous histories'' (obtained from $\mathscr{U}$ by removing some redundancies) is shown to be a meet-semilattice.

An important subclass of the theories covered by these axioms is the one in which $\mathscr{U}_\tau=\mathscr{P}(\mathscr{H}_\tau)$, the lattice of projection operators in a separable Hilbert space $\mathscr{H}_\tau$, the Hilbert spaces $\mathscr{H}_\tau$ for different τ's being not necessarily naturally isomorphic. We shall refer to these theories as Hilbert space-based theories. Traditional quantum mechanics (in history version) obviously belongs to this class of theories.

The space $\mathscr{D}$ of decoherence functionals in both the GH and Isham–Linden schemes is not properly integrated with the basic framework; it is, for example, not made clear as to what it is that distinguishes different elements of $\mathscr{D}$ and when is a particular element of $\mathscr{D}$ relevant. In traditional quantum mechanics, a decoherence functional is determined by the evolution operator and the initial state [see Eq. (1.5)]. In the Isham–Linden formalism there is no explicitly defined concept of state or of evolution; information about both of these is contained in the decoherence functionals. It is, however, not clear how to bring out and use this information.

In our formalism, the $\mathscr{U}_\tau$'s being logics, both the concepts can be introduced in the conventional manner. Our axiom A_4 introduces temporal evolution in terms of an appropriate class of mappings between the $\mathscr{U}_\tau$'s. The last axiom A_5 associates a decoherence function with a given law of temporal evolution and a given initial state. The formalism would be complete if an explicit expression for the decoherence functional [analogous to that in Eq. (1.5) in the case of traditional quantum mechanics] is given. We are able to do it only for the Hilbert space-based theories. The decoherence functional proposed for these theories [Eq. (3.77)] is an adaptation from Eq. (4.19) of Ref. 10; it is, expectedly, a straightforward generalization of the expression in Eq. (1.5) for traditional quantum mechanics.

An innovation introduced in the present work is that, in our axiomatic scheme, a general history is allowed to have countably semi-infinite temporal support; this means that (homogeneous) histories are generally taken to involve single ''time'' propositions at ''times'' $\tau_1,\tau_2,\ldots$ or $\ldots\tau_{-1},\tau_0$. Similarly, an inhomogeneous history is generally taken to include a countable infinity of mutually exclusive homogeneous histories. This, we believe, should be helpful in addressing questions relating to, for example, the long time behavior of the Universe (under suitable hypotheses) besides facilitating analytical work in the present setting.

The rest of the paper is organized as follows. Section II is devoted to the treatment of partial semigroups. Here, apart from recalling a few definitions from Ref. 9, an improved treatment of the so-called unit and absorbing elements in partial semigroups is given, some new definitions are introduced and a useful lemma is proved. In the last section an axiomatic development of our formalism is presented. (We call it the augmented temporal logic formalism.) After developing the formalism in the form indicated above in Secs. III A–III D, Hilbert space-based theories are treated in Sec. III E and (history version of) classical mechanics in Sec. III F.

II. PARTIAL SEMIGROUPS

In the treatment of histories in traditional quantum theory, the time sequences $(t_1,\ldots,t_n)$ are employed only for book keeping; the properties of time t as a real variable are not used. It was Isham's[9] observation that the relevant mathematical structure employed in the book keeping of histories is that of a partial semigroup.

We briefly recall a few definitions. A semigroup is a set with an associative composition rule (product) defined on it. A partial semigroup (psg) is a set on which a similar composition rule is defined but not necessarily for all pairs of elements. Denoting the composition in a psg $\mathscr{K}$ (with elements $s,t,u,\ldots$) by $\circ$ we have

$$(s\circ t)\circ u = s\circ(t\circ u) \tag{2.1}$$

whenever the two sides are defined.

A homomorphism of a psg $\mathscr{K}$ into another psg $\mathscr{K}'$ is a mapping $\sigma:\mathscr{K}\to\mathscr{K}'$ such that, for all $s,t\varepsilon\mathscr{K}$ with $s\circ t$ defined, we have $\sigma(s)\circ\sigma(t)$ defined and

$$\sigma(s\circ t)=\sigma(s)\circ\sigma(t). \tag{2.2}$$

If σ is bijective, then it is called an isomorphism,

There are two psg's (we call them $\mathscr{K}_1$ and $\mathscr{K}_2$) implicitly involved in the description of histories of the form (1.1). We have

$$\mathscr{K}_1=\{\text{ finite ordered subsets of } R,\ \text{the real line}\}.$$

A typical element of $\mathscr{K}_1$ is

$$t=\{t_1,t_2,\ldots,t_n\};\quad t_1<t_2<\cdots<t_n. \tag{2.3}$$

If $s=\{s_1,s_2,\ldots,s_m\}\ \varepsilon\mathscr{K}_1$ such that $s_m<t_1$, we have $s\circ t$ defined and

$$s\circ t=\{s_1,s_2,\ldots,s_m,t_1,\ldots,t_n\}=s\cup t. \tag{2.4}$$

It is useful to adopt the convention

$$\{t_1\}\circ\{t_1\}=\{t_1\}. \tag{2.5}$$

With this convention we have $s\circ t$ defined for $s_m\leqslant t_1$.

The other psg $\mathscr{K}_2$ has, as its elements, histories of the form (1.1). With

$$\begin{aligned}\alpha&=\{(P_1,s_1),\ (P_2,s_2),\ldots,(P_m,s_m)\};\ s_1<s_2<\cdots<s_m,\\ \beta&=\{(P'_1,t_1),\ (P'_2,t_2),\ldots,(P'_n,t_n)\};\ t_1<t_2<\cdots<t_n,\end{aligned} \tag{2.6}$$

and $s_m<t_1$, we have $\alpha\circ\beta$ defined and given by

$$\alpha\circ\beta=\{(P_1,s_1),\ (P_2,s_2),\ldots,(P_m,s_m),\ (P'_1,t_1),\ldots,(P'_n,t_n)\}. \tag{2.7}$$

There is a homomorphism σ from $\mathscr{K}_2$ onto $\mathscr{K}_1$ given by

$$\sigma(\alpha)=s,\ \ \sigma(\beta)=t,\ \ \sigma(\alpha\circ\beta)=s\circ t. \tag{2.8}$$

The triple $(\mathscr{K}_2,\mathscr{K}_1,\sigma)$ defines what Isham[9] calls a quasitemporal structure (a pair of psg's with a homomorphism from one onto the other).

A prototype of psg's employed in our work later is an ''elder brother'' of $\mathscr{K}_1$, namely

$\mathscr{K}_3$ = {ordered subsets of R which are at most countably semi-infinite}.

Typical elements of $\mathscr{K}_3$ are of the form

$$s=\{s_1,s_2,\ldots,s_m\} \quad \text{(finite)},$$

$$s=\{s_1,s_2,\ldots,\} \quad \text{(right infinite)},$$

$$s=\{\ldots,s_{-1},s_0\} \quad \text{(left infinite)}.$$

The product $s\circ t$ is defined if at least one of s and t is finite, s is right finite, t is left finite, and the largest entry in s is not greater than the smallest entry in t; then $s\circ t=s\cup t$.

A unit element in a psg $\mathscr{K}$ is an element e such that

$$e\circ s=s\circ e=s \quad \text{for all } s\varepsilon\mathscr{K}. \tag{2.9}$$

A psg may or may not have a unit element; when it has, it is unique. [*Proof:* $e'=e'\circ e=e$.]

The empty set [when formally considered as an element of the psg in question with composition rule analogous to that for e in Eq. (2.9)] serves as the unit element in $\mathscr{K}_1$ and $\mathscr{K}_3$ above. In $\mathscr{K}_2$, there is no unit element. However, if we introduce an equivalence relation in $\mathscr{K}_2$ such that histories differing by any number of entries of form (p_j,t_j) where $P_j=I$, the identity operator, are equivalent then, denoting the equivalence class of α as $[\alpha]$, the set $\tilde{\mathscr{K}}_2$ of equivalence classes in $\mathscr{K}_2$ has a psg structure defined by

$$[\alpha]\circ[\beta]=[\alpha\circ\beta]. \tag{2.10}$$

All histories having only identity operators in their entries from an equivalence class which serves as the unit element in $\tilde{\mathscr{K}}_2$.

An absorbing element in a psg $\mathscr{K}$ is an element a such that

$$a\circ s=s\circ a=a \quad \text{for all } s\varepsilon\mathscr{K}. \tag{2.11}$$

Such an element, if it exists, is unique. [*Proof:* $a'=a'\circ a=a$.]

The psg's $\mathscr{K}_1$ and $\mathscr{K}_3$ have no absorbing elements. The psg's $\mathscr{K}_2$ and $\tilde{\mathscr{K}}_2$ also have no absorbing elements but, if we allow the use of the null projection operator in defining histories and strengthen the equivalence relation defining $\tilde{\mathscr{K}}_2$ by the stipulation that all histories having $P_j=0$ as one or more entries are to be treated as equivalent, then the resulting equivalence class will serve as the absorbing element in $\tilde{\mathscr{K}}_2$.

In this connection we note here that, in the so-called HPO (history projection operator) version[9] of histories in standard quantum theory (see the Appendix for details), the space of homogeneous projection operators of the form (A4) forms a psg isomorphic to the final $\tilde{\mathscr{K}}_2$ above with the unit operator $\tilde{I}$ and the null operator $\tilde{0}$ on the tensor product space $\tilde{\mathscr{H}}$ serving, respectively, as the unit and absorbing elements.

Let $\mathscr{K}$ be a psg with unit and absorbing elements e, a as above and σ a homomorpism of $\mathscr{K}$ into $\mathscr{K}'$. We must have, for all $s\in\mathscr{K}$,

$$\sigma(e)\circ\sigma(s)=\sigma(s)\circ\sigma(e)=\sigma(e\circ s)=\sigma(s),$$

$$\sigma(a)\circ\sigma(s)=\sigma(s)\circ\sigma(a)=\sigma(a\circ s)=\sigma(a).$$

It follows that

(i) if $\mathscr{K}$ has a unit element e and/or an absorbing element a and σ is onto, then $\mathscr{K}'$ must correspondingly have a unit element e' and/or an absorbing element a' and we must have

$$\sigma(e)=e', \quad \sigma(a)=a'. \tag{2.12}$$

(ii) More generally, $\sigma(e)$ and $\sigma(a)$ act, respectively, as unit and absorbing elements in the homomorphic image $\sigma(\mathscr{K})$ of $\mathscr{K}$ in $\mathscr{K}'$.

In a psg, elements other than the unit and the absorbing element will be called typical.

A psg $\mathscr{K}$ will be called directed if, for any two different typical elements s, t in $\mathscr{K}$, if $s\circ t$ is defined, then $t\circ s$ is not defined. Note that, in this definition, the composition $s\circ s$ is allowed. All the psg's considered above are directed. This property appears to be appropriate for defining the direction of flow of time in theories with quasitemporal structure.

A useful concept relating to partial semigroups which serves to introduce the concept of ''point of time'' in the framework of histories-based theories is that of irreducible decompositions of typical elements of a psg. This means expressing a typical element of a psg as a composition of ''nuclear'' elements which cannot be expressed as nontrivial compositions. For example, general elements of $\mathscr{K}_1$, $\mathscr{K}_3$, and $\tilde{\mathscr{K}}_2$ have irreducible decompositions of the form [we use the HPO notation (A4) for $\tilde{\mathscr{K}}_2$]

$$\mathscr{K}_1: \quad \{t_1,t_2,\ldots,t_n\}=\{t_1\}\circ\{t_2\}\circ\cdots\circ\{t_n\}, \tag{2.13a}$$

$$\mathscr{K}_3: \quad \{t_1,t_2,\ldots\}=\{t_1\}\circ\{t_2\}\circ\cdots, \tag{2.13b}$$

$$\tilde{\mathscr{K}}_2: \quad \overline{\alpha}=\alpha_{t_1}\circ\alpha_{t_2}\circ\cdots\circ\alpha_{t_n}. \tag{2.13c}$$

In $\mathscr{K}_1$ and $\mathscr{K}_3$, the nuclear elements correspond to points of time and, in $\tilde{\mathscr{K}}_2$, to single time ''history'' propositions. The set of nuclear elements of a psg $\mathscr{K}$ will be denoted as $\mathscr{N}(\mathscr{K})$. For all the psg's introduced above, clearly $\mathscr{N}(\mathscr{K})=R$.

The term ''nontrivial'' employed in the definition of a nuclear element refers to the possibility of trivial compositions of the form $s\circ e=e\circ s=s$ or of the form (2.5).

Not all psg's admit irreducible decompositions. For example analogs of $\mathscr{K}_1$ and $\mathscr{K}_3$ with intervals as their elements do not admit such decompositions.

We shall employ psg's of the type of $\mathscr{K}_3$ above which admit semi-infinite irreducible decompositions and in which conventions of the type of Eq. (2.5) are incorporated. We shall call such psg's special. To formalize it, we shall call a psg $\mathscr{K}$ (which may or may not contain unit and/or absorbing elements) special if there exists a subset $\mathscr{N}(\mathscr{K})$ of typical elements of $\mathscr{K}$ (whose elements will be called nuclear elements of $\mathscr{K}$) such that

(i) for every $s\varepsilon\mathscr{N}(\mathscr{K})$, we have $s\circ s=s$;
(ii) every non-nuclear typical element s of $\mathscr{K}$ admits a unique irreducible decomposition into a composition of elements of $\mathscr{N}(\mathscr{K})$ which is at most semi-infinite, i.e.,

$$s=s_1\circ\cdots\circ s_n \quad \text{or} \quad s=s_1\circ s_2\circ\cdots \quad \text{or} \quad s=\cdots\circ s_{-1}\circ s_0,$$

where $s_j\varepsilon\mathscr{N}(\mathscr{K})$. The uniqueness of these decompositions must be understood as modulo trivial compositions of the form $s_k\circ s_k=s_k$.

A subset A (which is at most countable and whose elements are listed in some definite order) of a psg $\mathscr{K}$ will be called orientable if there exists a bijection π of A such that, in $\pi(A)$, the composition of every pair of consecutive elements is defined. An ordering of elements of A permitting such a composition [such as that given by $\pi(A)$ above] will be called an orientation of A. In a semigroup every countable subset is orientable and every ordering of such a subset gives an orientation. It is clear from the example of semigroups that, in a psg, orientations of orientable subsets need not be unique.

One might expect that, in a directed psg, the orientations of orientable subsets are unique. This need not be true. As a counterexample, consider the three element directed psg $\mathscr{K}=\{a,b,c\}$ with $a\circ b$, $b\circ c$, and $c\circ a$ defined. One can have $a\circ b\circ c$, $b\circ c\circ a$, and $c\circ a\circ b$ as possible orientations of $\mathscr{K}$.

The following lemma will be used in Sec. III B.

Lemma (2.1): Let $\mathscr{K}$ be a special psg which does not admit elements expressible as nontrivial closed chains of the form $s\circ\cdots\circ s$ for any $s\varepsilon\mathscr{N}(\mathscr{K})$. [Such a psg is directed and its orientable

subsets have unique orientations; see propositions (3.2) and (3.3) below.]. Let $E_1, E_2,\ldots,E_n$ be orientable subsets of $\mathcal{N}(\mathcal{K})$ such that $E_i \cup E_j$ is orientable for every pair (i,j). Then $E = \cup_i E_i$ is orientable.

Proof: Let $E_i = \{s_k^{(i)}, k \varepsilon A_i\}, \quad i = 1,...,n$, where A_i are some countable index sets. To show that E is orientable, we must show that we can construct, by composition of all elements of E, a single element, say s_E, of $\mathcal{K}$.

Let us pick up some element of E, say $s_{i_1}^{(1)}$. We must show that, starting with $s_{i_1}^{(1)}$, one can go on adjoining element of E on the right and/or on the left (to construct an element of $\mathcal{K}$) untill all members of E are used up. An element s in E will be called a potential successor of $s_{i_1}^{(1)}$ if there exists an orientable subset of E containing both $s_{i_1}^{(1)}$ and s such that its (unique) orientation is given by an ordering of the form $\{\ldots, s_{i_1}^{(1)}, \ldots, s, \ldots\}$; similarly we define a potential predecessor. Since $E_i \cup E_j$ is orientable for every pair (i,j), every element in E other than $s_{i_1}^{(1)}$ is either a potential successor or a potential predecessor of $s_{i_1}^{(1)}$ (but not both because $\mathcal{K}$ does not admit nontrivial closed chains).

It is adequate to show how the collection F of potential successors of $s_{i_1}^{(1)}$, if nonempty, is to be used up. For this, it is adequate to show that, in F (assumed nonempty), there is an ''earliest'' element s^1 (by this we mean that every other element in F is a potential successor of s^1).

In every E_i the collection F_i of potential successors of $s_{i_1}^{(1)}$ is either empty or has an earliest element. In E_1, it is $s_{i_1+1}^{(1)}$ (if it exists); in $E_j (j \neq 1)$, it is the first element of E_j on the right of $s_{i_1}^{(1)}$ in the ordering showing the orientation of $E_1 \cup E_j$. The possible successors of $s_{i_1}^{(1)}$ (in the construction of s_E) are, therefore, in the (unique) set

$$[F] = \{s_{i_1+1}^{(1)}, s_{j_1}^{(2)}, \ldots, s_{k_1}^{(n)}\}, \text{ say}$$

where some of the entries on the right may be vacuous. By assumption, $[F]$ is nonempty. If it has only one element, it is the unique successor of $s_{i_1}^{(1)}$. If there are more than one, note that every pair in $[F]$ has a definite orientation which implies that $[F]$ has an earliest element. This element is the successor of $s_{i_1}^{(1)}$. Similarly for the predecessor. Q.E.D.

III. THE AUGMENTED TEMPORAL LOGIC FORMALISM

In this section we shall present an axiomatic development of the dynamics of (closed) systems in the framework of histories. This, as we shall see, contains the history versions of classical mechanics and traditional quantum mechanics as special cases.

A. The basic ingredients

We shall denote our axioms as $A_1,\ldots,A_5$. In this section we shall take up the first three of them which define the basic structure.

1. A_1 (quasitemporal structure axiom)

Associated with every dynamical system is a *history system* which, by definition, is a triple $(\mathcal{U}, \mathcal{T}, \sigma)$ where $\mathcal{U}$ (called ''the space of history filters'') and $\mathcal{T}$ (called ''the space of temporal supports'') are special psg's and σ is a homomorphism of $\mathcal{U}$ onto $\mathcal{T}$ such that

$$\sigma[\mathcal{N}(\mathcal{U})] = \mathcal{N}(\mathcal{T}). \tag{3.1}$$

Elements of $\mathcal{U}$ (to be called history filters) will be denoted as $\alpha, \beta, \ldots$ and those of $\mathcal{T}$ (to be called temporal supports) as $\tau, \tau', \ldots$. If $\alpha \circ \beta$ and $\tau \circ \tau'$ are defined, we shall write $\alpha \lhd \beta$ (which means α precedes β) and $\tau \lhd \tau'$ (τ precedes τ'). We shall often refer to ''temporally ordered'' sequences of the form $\alpha \lhd \beta \lhd \ldots \lhd \gamma$ and $\tau \lhd \tau' \lhd \ldots \lhd \tau''$ as chains.

2. A_2 (causality axiom)

If $\alpha, \beta, ..., \gamma \varepsilon \mathcal{N}(\mathcal{U})$ are such that

$$\alpha \lhd \beta \lhd \ldots \lhd \gamma \quad \text{with} \quad \sigma(\alpha) = \sigma(\gamma) \tag{3.2}$$

then we must have

$$\alpha = \beta = \cdots = \gamma. \tag{3.3}$$

In essence, this axiom forbids histories corresponding to ''closed time loops.'' This is one of the weakest formulations of causality.

We collect, in the first proposition below, a few auxiliary results (easily derived from the above two axioms).

Proposition (3.1): (a) If $\tau, \tau', \ldots, \tau'' \varepsilon \mathcal{N}(\mathcal{T})$ are such that

$$\tau \lhd \tau' \lhd \cdots \lhd \tau'' \lhd \tau$$

then we must have

$$\tau = \tau' = \cdots = \tau''.$$

(b) If τ', $\tau'' \varepsilon \mathcal{N}(\mathcal{T})$ are such that (i) and/or (ii) below holds:

(i) $\tau' \lhd \tau$ for any $\tau \varepsilon \mathcal{N}(\mathcal{T})$ if and only if $\tau'' \lhd \tau$,
(ii) $\tau \lhd \tau'$ for any $\tau \varepsilon \mathcal{N}(\mathcal{T})$ if and only if $\tau \lhd \tau''$, then we must have $\tau' = \tau''$

(c) Analogue of (b) for $\mathcal{N}(\mathcal{U})$ also holds.
(d) If $\tau \varepsilon \mathcal{T}$ is non-nuclear, then $\tau \circ \tau$ is not allowed.
(e) If $\alpha \varepsilon \mathcal{U}$ is non-nuclear then $\alpha \circ \alpha$ is not allowed.

Proposition (3.2): The partial semigroups $\mathcal{T}$ and $\mathcal{U}$ are directed.

Proof: We prove it only for $\mathcal{T}$. Suppose it is not directed. Then there are typical elements $\tau, \tau' \varepsilon \mathcal{T}$, $\tau \neq \tau'$ such that $\tau \lhd \tau'$ and $\tau' \lhd \tau$. It τ, τ' are both nuclear then the chain $\tau \lhd \tau' \lhd \tau$ gives $\tau = \tau'$ (contradiction). If one or both of τ, τ' are non-nuclear, $\tau \circ \tau'$ and $\tau' \circ \tau$ both can be defined only if both have finite irreducible decompositions, say

$$\tau = \tau_1 \circ \tau_2 \circ \cdots \circ \tau_m, \quad \tau' = \tau_1' \circ \tau_2' \circ \cdots \circ \tau_n' (n \geq 1, m > 1).$$

The element $\tau \circ \tau' \circ \tau$ contains, in its irreducible decomposition, the element

$$\tau_1 \circ \cdots \circ \tau_m \circ \tau_1' \circ \cdots \circ \tau_n' \circ \tau_1$$

giving $\tau_1 = \tau_2 = \cdots = \tau_m = \tau_1' = \tau_2' = \cdots = \tau_n'$ which, in turn, given $\tau' = \tau = \tau_1 \varepsilon \mathcal{N}(\mathcal{T})$ (contradiction). Q.E.D.

Proposition (3.3): Orientations of orientable subsets of $\mathcal{N}(\mathcal{T})$ and $\mathcal{N}(\mathcal{U})$ are unique.

Proof: We prove it for $\mathcal{N}(\mathcal{T})$. Suppose the proposition is not true. Then there exists an orientable subset $A = \{\tau_1, \tau_2, \ldots\}$ of $\mathcal{N}(\mathcal{T})$ having (at least) two different orientations. This implies that, for some pair (j,k), $j \neq k$, we have τ_j appearing earlier than τ_k in one orientation and later in the other so that we can form the two chains

$$\tau_j \lhd \cdots \lhd \tau_k \quad \text{and} \quad \tau_k \lhd \cdots \lhd \tau_j$$

giving, in turn, the chain

$$\tau_j \lhd \cdots \lhd \tau_k \lhd \cdots \lhd \tau_j$$

which implies $\tau_j = \tau_k$ (contradiction). Q.E.D.

We next introduce an axiom relating to the spaces $\mathcal{U}_\tau = \sigma^{-1}(\tau)$ $[\tau \varepsilon \mathcal{N}(\mathcal{T})]$ of ''single-time propositions;'' we give them the same structure as one has for the analogous objects in the

traditional proposition calculus for quantum mechanics. Formulations of proposition calculus by different authors differ in some details; we find the one of Varadarajan[14] best suited for our needs.

3. A_3 (logic structure axiom)

Every $\mathscr{U}_\tau$ (for τ nuclear) has the structure of a *logic* as defined in Ref. 14. This means that the following operations are defined in $\mathscr{U}_\tau$ with the indicated interpretations. [Some (harmless) redundancy in the following description can be ignored.]

(a) Partial order ($\leqslant$). The relation $\alpha \leqslant \beta$ for $\alpha, \beta \in \mathscr{U}_\tau$ should mean that the proposition α implies β or α is finer than β.

(b) In each $\mathscr{U}_\tau$, there is a unique null proposition 0_τ (the absurd proposition which can never be true) and a unique unit proposition 1_τ (the trivial proposition which is always true) such that

$$0_\tau \leqslant \alpha \leqslant 1_\tau \quad \text{for all} \quad \alpha \in \mathscr{U}_\tau. \tag{3.4}$$

(c) For each subset $A=\{\alpha_1, \alpha_2, \ldots\}$ of $\mathscr{U}_\tau$ which is at most countable, the greatest lower bound (glb) of A denoted as $\bigwedge_i \alpha_i$ (it is the coarsest proposition finer than all propositions in A) and the least upper bound (lub) of A denoted as $\bigvee_i \alpha_i$ (it is the finest proposition coarser than all propositions in A) exist in $\mathscr{U}_\tau$. For $\alpha, \beta \in \mathscr{U}_\tau$ their glb (or ''meet'') $\alpha \wedge \beta$ stands for ''α and β'' and lub (or ''join'') $\alpha \vee \beta$ for ''α or β.''

(d) Negation ($\neg$) or orthocomplementation. It is a bijection $\neg: \mathscr{U}_\tau \to \mathscr{U}_\tau$ such that

$$\text{(i)} \quad \neg(\neg\alpha) = \alpha \quad \text{for all} \quad \alpha \in \mathscr{U}_\tau, \tag{3.5a}$$

$$\text{(ii)} \quad \alpha \leqslant \beta \quad \text{if and only if} \quad \neg\beta \leqslant \neg\alpha, \tag{3.5b}$$

$$\text{(iii)} \quad \alpha \wedge (\neg\alpha) = 0_\tau, \quad \text{for all} \quad \alpha \in \mathscr{U}_\tau, \tag{3.5c}$$

$$\text{(iv)} \quad \alpha \vee (\neg\alpha) = 1_\tau \quad \text{for all} \quad \alpha \in \mathscr{U}_\tau. \tag{3.5d}$$

The proposition $\neg\alpha$ is to be interpreted as the negation of α, i.e., α is realized if and only if $\neg\alpha$ is not realized. We have

$$\neg(0_\tau) = 1_\tau, \quad \neg(1_\tau) = 0_\tau, \tag{3.6}$$

(e) If $\alpha, \beta \in \mathscr{U}_\tau$, then $\alpha \leqslant \beta$ if and only if there exists an element γ in $\mathscr{U}_\tau$ such that

$$\gamma \leqslant (\neg\alpha) \quad \text{and} \quad \gamma \vee \alpha = \beta. \tag{3.7}$$

In fact,[11] γ is unique and given by

$$\gamma = (\neg\alpha) \wedge \beta; \tag{3.8}$$

it is often denoted as $\beta - \alpha$. Denoting the disjoint join operation in (3.7) by $\oplus$, we have

$$\beta = \alpha \oplus [(\neg\alpha) \wedge \beta]. \tag{3.9}$$

We do not assume isomorphism of $\mathscr{U}_\tau$'s (as logics) for different τ's; this is in contrast to the situation in the proposition calculus for traditional quantum mechanics where one assumes the logics at different instants of time to be isomorphic.

Given $\alpha, \beta \in \mathscr{U}_\tau$, we shall say that $\alpha \perp \beta$ if $\alpha \leqslant \neg\beta$ (which is equivalent to $\beta \leqslant \neg\alpha$). This is a disjointness relation implying that if α is realized, then β is ruled out and vice versa. It implies the relation $\alpha \wedge \beta = 0_\tau$ (simultaneous realization of α and β is impossible).

Recalling Eq. (3.1) and the definition of $\mathscr{U}_\tau$, we have

$$\mathscr{N}(\mathscr{U}) = \bigcup_{\tau \in \mathscr{N}(\mathscr{T})} \mathscr{U}_\tau. \tag{3.10}$$

For a typical $\alpha \in \mathscr{U}$, we define supp(α) (called the temporal support of α) as the unique collection of elements of $\mathscr{N}(\mathscr{T})$ appearing in the irreducible decomposition of $\sigma(\alpha)$. Clearly supp(α) is an

orientable subset of $\mathcal{N}(\mathcal{T})$ with the unique orientation provided by the unique irreducible decomposition of $\sigma(\alpha)$. For any $\tau\varepsilon\,\mathrm{supp}(\alpha)$, the nuclear element in the irreducible decomposition of α projecting to τ under σ will be denoted as α_τ.

An $\alpha\varepsilon\mathcal{U}$ will be called

(i) a null history filter if $\alpha_\tau = 0_\tau$ for at least one $\tau\,\varepsilon\,\mathrm{supp}(\alpha)$;
(ii) a unit (or trivial) history filter if $\alpha_\tau = 1_\tau$ for all $\tau\,\varepsilon\,\mathrm{supp}(\alpha)$.

All the null history filters are obviously physically equivalent (they represent absurd histories) as are all the unit history filters. It is desirable to remove the redundancy implied by the presence of more than one of each type. We do this by constructing from $\mathcal{U}$, a psg $\tilde{\mathcal{U}}$ imitating the construction of $\tilde{\mathcal{K}}_2$ from $\mathcal{K}_2$ in Sec. II. In $\tilde{\mathcal{U}}$ all the null history filters form a single null element $\tilde{0}$ and all the unit history filters from a single unit element $\tilde{1}$. A general element $\tilde{\alpha}$ of $\tilde{\mathcal{U}}$ is an equivalence class of elements $\{\alpha\}$ of $\mathcal{U}$ differing from each other by superfluous 1_τ's in their irreducible decompositions. The irreducible decomposition of a general element of $\mathcal{U}$ defines, in an obvious manner, the same for the corresponding element of $\tilde{\mathcal{U}}$. It is now easily seen that $\tilde{\mathcal{U}}$ is a directed special psg with unit element $\tilde{1}$ and absorbing element $\tilde{0}$.

We now construct a psg $\tilde{\mathcal{T}}$ which is in the same relation to $\tilde{\mathcal{U}}$ as $\mathcal{T}$ is to $\mathcal{U}$. The typical elements of $\tilde{\mathcal{T}}$ and the homomorphism $\tilde{\sigma}:\tilde{\mathcal{U}}\to\tilde{\mathcal{T}}$ (restricted to typical elements) can be obtained in a single step by defining $\tilde{\tau}=\tilde{\sigma}(\tilde{\alpha})$ to be the reduced object obtained from $\tau=\sigma(\alpha)$ (for any representative α of $\tilde{\alpha}$) by deleting the images under σ of the redundant 1_τ's in the irreducible decomposition of α. We augment $\tilde{\mathcal{T}}$ by defining its unit element $\tilde{e}$ and absorbing element $\tilde{a}$ as

$$\tilde{e}=\phi(\text{the empty set}), \tag{3.11a}$$

$$\tilde{a}=\mathcal{N}(\mathcal{T}) \tag{3.11b}$$

and augmenting the psg structure of $\tilde{\mathcal{T}}$ by the relations

$$\tilde{e}\circ\tilde{\tau}=\tilde{\tau}\circ\tilde{e}=\tilde{\tau}\quad\text{for all}\quad\tilde{\tau}\varepsilon\tilde{\mathcal{T}}, \tag{3.12a}$$

$$\tilde{a}\circ\tilde{\tau}=\tilde{\tau}\circ\tilde{a}=\tilde{a}\quad\text{for all}\quad\tilde{\tau}\varepsilon\tilde{\mathcal{T}}. \tag{3.12b}$$

The homomorphism $\tilde{\sigma}$ can now be extended to include the relations

$$\tilde{\sigma}(\tilde{1})=\tilde{e}, \tag{3.13a}$$

$$\tilde{\sigma}(\tilde{0})=\tilde{a}. \tag{3.13b}$$

Defining, for any $\tilde{\alpha}\varepsilon\tilde{\mathcal{U}}$ $\mathrm{supp}(\tilde{\alpha})=\tilde{\sigma}(\tilde{\alpha})$ [considered as a subset of $\mathcal{N}(\tilde{\mathcal{T}})$], we have

$$\mathrm{supp}(\tilde{1})=\phi, \tag{3.14a}$$

$$\mathrm{supp}(\tilde{0})=\mathcal{N}(\tilde{\mathcal{T}}). \tag{3.14b}$$

Intuitively Eq. (3.14a) is easily understood from the definitions of $\tilde{1}$ and $\mathrm{supp}(\tilde{\alpha})$. Equation (3.14b) may be understood as formalizing the position that, given a representative α of some $\tilde{\alpha}\neq\tilde{0}$, a representative β of $\tilde{0}$ can always be chosen such that $\mathrm{supp}\,\beta\supset\mathrm{supp}\,\alpha$. Whenever any of the equations (3.11b), (3.12b), (3.13b), and (3.14b) creates problems of consistency and/or interpretation, one must go back to the description of the relevant situation in terms of the null history filters in $\mathcal{U}$.

Temporal supports of typical elements of $\tilde{\mathcal{U}}$ are orientable subsets of $\mathcal{N}(\tilde{\mathcal{T}})$; however, since $\tilde{0}$ is only a formal construction, there is no compelling need to assume the whole of $\mathcal{N}(\tilde{\mathcal{T}})$ $[=\mathrm{supp}(\tilde{0})]$ to be orientable. Indeed, as we shall see below, the formalism can be consistently developed without this assumption.

We next consider some operations/relations in $\tilde{\mathcal{U}}$ which the rich structure on $\mathcal{U}_\tau$'s permits us to define.

a. *Partial Order* ($\preccurlyeq$). For $\tilde{\alpha},\tilde{\beta}\in\tilde{\mathscr{U}}$, we say that $\tilde{\alpha}\preccurlyeq\tilde{\beta}$ (to mean that $\tilde{\alpha}$ is finer than $\tilde{\beta}$) if supp $\tilde{\beta}\subset$supp $\tilde{\alpha}$ and (if supp $\tilde{\beta}$ is nonempty) there exist representatives α and β of $\tilde{\alpha}$ and $\tilde{\beta}$ in $\mathscr{U}$ (with supp $\beta\subset$supp α) such that $\alpha_\tau\preccurlyeq\beta_\tau$ for all $\tau\in$ supp β.

Proposition (3.4): The relation $\preccurlyeq$ defined above is a partial order.

Proof: Clearly $\tilde{\alpha}\preccurlyeq\tilde{\alpha}$. Transitivity is easily seen from the definition and transitivity of the partial order on $\mathscr{U}_\tau$'s. Now, if $\tilde{\alpha}\preccurlyeq\tilde{\beta}$ and $\tilde{\beta}\preccurlyeq\tilde{\alpha}$, we have supp $\tilde{\alpha}=$supp $\tilde{\beta}$ and (if these supports are nonempty) $\alpha_\tau\preccurlyeq\beta_\tau$ and $\beta_\tau\preccurlyeq\alpha_\tau$ for each τ implying $\tilde{\alpha}=\tilde{\beta}$. When supp $\tilde{\alpha}=$supp $\tilde{\beta}=\varphi$, we trivially have $\tilde{\alpha}=\tilde{\beta}(=\tilde{1})$. Q. E. D.

It immediately follows from the above definition that

$$\tilde{0}\preccurlyeq\tilde{\alpha}\preccurlyeq\tilde{1}\quad\text{for all}\quad\tilde{\alpha}\in\tilde{\mathscr{U}}. \tag{3.15}$$

b. *Disjointness* ($\perp$). For $\tilde{\alpha},\tilde{\beta}\in\tilde{\mathscr{U}}$ we say that $\tilde{\alpha}\perp\tilde{\beta}$ (i.e., $\tilde{\alpha}$ and $\tilde{\beta}$ are disjoint which is to mean that if one is realized, the other is ruled out) if they have representatives α and β in $\mathscr{U}$ such that $s_{\alpha\beta}\equiv(\text{supp }\alpha)\cap(\text{supp }\beta)$ is nonempty and $\alpha_\tau\perp\beta_\tau$ for at least one $\tau\in s_{\alpha\beta}$.

This definition has the following desirable implications:

(i) The null element $\tilde{0}$ is disjoint with all $\tilde{\alpha}$ in $\tilde{\mathscr{U}}$.

(ii) The only element of $\tilde{\mathscr{U}}$ disjoint with $\tilde{1}$ is $\tilde{0}$.

c. *Disjoint Joint Operation* ($\oplus$). This operation is defined between two typical elements $\tilde{\alpha}$ and $\tilde{\beta}$ of $\tilde{\mathscr{U}}$ if

(i) supp $\tilde{\alpha}=$supp $\tilde{\beta}$,

(ii) $\tilde{\alpha}_{\tau_0}\perp\tilde{\beta}_{\tau_0}$ for one element $\tau_0\in\text{supp}(\tilde{\alpha})$,

(iii) $\tilde{\alpha}_\tau=\tilde{\beta}_\tau$ for $\tau\in\text{supp}(\tilde{\alpha})-\{\tau_0\}$.

Given these conditions (which imply $\tilde{\alpha}\perp\tilde{\beta}$; this special case of disjointness will be referred to as weak disjointness), we define $\tilde{\alpha}\oplus\tilde{\beta}$ as follows:

$$\text{supp}(\tilde{\alpha}\oplus\tilde{\beta})=\text{supp }\tilde{\alpha}=\text{supp }\tilde{\beta}$$

$$(\tilde{\alpha}\oplus\tilde{\beta})_\tau=\begin{cases}\tilde{\alpha}_{\tau_0}\vee\tilde{\beta}_{\tau_0} & \text{for}\quad\tau=\tau_0\\ \tilde{\alpha}_\tau(=\tilde{\beta}_\tau) & \text{for}\quad\tau\in\text{supp}(\tilde{\alpha})-\{\tau_0\}\end{cases}. \tag{3.16}$$

It is easily verified that

$$\text{(i)}\quad\tilde{\alpha}\oplus\tilde{\beta}=\tilde{\beta}\oplus\tilde{\alpha}, \tag{3.17a}$$

$$\text{(ii)}\quad(\tilde{\alpha}\oplus\tilde{\beta})\oplus\tilde{\gamma}=\tilde{\alpha}\oplus(\tilde{\beta}\oplus\tilde{\gamma}). \tag{3.17b}$$

d. *Meet Operation* ($\wedge$). For general elements $\tilde{\alpha}$, $\tilde{\beta}\in\tilde{\mathscr{U}}$, we define $\tilde{\alpha}\wedge\tilde{\beta}$ as follows:

(i) If $\text{supp}(\tilde{\alpha})\cup\text{supp}(\tilde{\beta})$ is not orientable, we put $\tilde{\alpha}\wedge\tilde{\beta}=\tilde{0}$.

(ii) If supp $\tilde{\alpha}\cup$supp $\tilde{\beta}$ is orientable, we define

$$\text{supp}(\tilde{\alpha}\wedge\tilde{\beta})=\text{supp}(\tilde{\alpha})\cup\text{supp}(\tilde{\beta}), \tag{3.18a}$$

$$(\tilde{\alpha}\wedge\tilde{\beta})_\tau=\begin{cases}\tilde{\alpha}_\tau & \text{for}\quad\tau\in\text{supp }\tilde{\alpha}-\text{supp }\tilde{\beta}\\ \tilde{\beta}_\tau & \text{for}\quad\tau\in\text{supp }\tilde{\beta}-\text{supp }\tilde{\alpha}\\ \tilde{\alpha}_\tau\wedge\tilde{\beta}_\tau & \text{for}\quad\tau\in\text{supp }\tilde{\alpha}\cap\text{supp }\tilde{\beta}\end{cases}. \tag{3.18b}$$

The history filter $\tilde{\alpha}\wedge\tilde{\beta}$ is to mean "$\tilde{\alpha}$ and $\tilde{\beta}$" (i.e., it is realized if and only if both $\tilde{\alpha}$ and $\tilde{\beta}$ are realized).

Proposition (3.5): The following relations hold in $\tilde{\mathscr{U}}$ ($\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$ denote general elements of $\mathscr{U}$):

$$\text{(i)}\quad\tilde{\alpha}\wedge\tilde{\alpha}=\tilde{\alpha}, \tag{3.19a}$$

(ii) $\tilde{\alpha}\wedge\tilde{\beta}=\tilde{\beta}\wedge\tilde{\alpha}$, (3.19b)

(iii) $\tilde{\alpha}\wedge\tilde{1}=\tilde{\alpha}$, (3.20a)

(iv) $\tilde{\alpha}\wedge\tilde{0}=\tilde{0}$, (3.20b)

(v) $\tilde{\alpha}\perp\tilde{\beta}$ implies $\tilde{\alpha}\wedge\tilde{\beta}=\tilde{0}$. [(iv) is a special case of this.]

(vi) When $\tilde{\alpha}\circ\tilde{\beta}$ is defined, we have

$$\tilde{\alpha}\wedge\tilde{\beta}=\tilde{\alpha}\circ\tilde{\beta}. \tag{3.21}$$

(vii) $\tilde{\alpha}\wedge\tilde{\beta}\leqslant\tilde{\alpha}$, (3.22)

(viii) $\tilde{\alpha}\leqslant\tilde{\alpha}\wedge\tilde{\beta}$ if and only if $\tilde{\alpha}\leqslant\tilde{\beta}$. This, with (vii), implies that $\tilde{\alpha}=\tilde{\alpha}\wedge\tilde{\beta}$ if and only if $\tilde{\alpha}\leqslant\tilde{\beta}$.

(ix) If $\tilde{\gamma}\leqslant\tilde{\alpha}$ and $\tilde{\gamma}\leqslant\tilde{\beta}$, then $\tilde{\gamma}\leqslant(\tilde{\alpha}\wedge\tilde{\beta})$. (3.23)

(x) If $\tilde{\alpha}\perp\tilde{\beta}$, then $(\tilde{\alpha}\wedge\tilde{\gamma})\perp(\tilde{\beta}\wedge\tilde{\gamma})$ for all $\tilde{\gamma}\in\tilde{\mathscr{U}}$.

Proof: Items (i)–(iv) follow immediately from the definition given above. Item (v) which, in view of item (iv) and the result that $\tilde{\alpha}\perp\tilde{1}$ only if $\tilde{\alpha}=\tilde{0}$, need be proved only for generic $\tilde{\alpha}$ and $\tilde{\beta}$, follows easily from the definitions of $\perp$ and $\wedge$.

Item (vi) follows immediately by noting that, when $\tilde{\alpha}\circ\tilde{\beta}$ is defined, we have supp $\tilde{\alpha}\cap$ supp $\tilde{\beta}=\phi$.

Item (vii): When $\tilde{\alpha}$ and/or $\tilde{\beta}$ equals $\tilde{0}$ or $\tilde{1}$, it is easily seen to follow from items (iii), (iv), (i), and Eq. (3.15). For generic $\tilde{\alpha}$ and $\tilde{\beta}$, the required support condition is trivially satisfied and the required relation follows from the definition (3.18) and the relation $\tilde{\alpha}_\tau\wedge\tilde{\beta}_\tau\leqslant\tilde{\alpha}_\tau$.

Item (viii): Cases when $\tilde{\alpha}$ and/or $\tilde{\beta}$ equals $\tilde{0}$ or $\tilde{1}$ are easily handled. We, therefore, take $\tilde{\alpha}$ and $\tilde{\beta}$ to be generic.

Given $\tilde{\alpha}\leqslant\tilde{\alpha}\wedge\tilde{\beta}$ we have

$$\text{supp } \tilde{\alpha}\cup\text{supp } \tilde{\beta}=\text{supp}(\tilde{\alpha}\wedge\tilde{\beta})\subset\text{supp } \tilde{\alpha} \tag{A}$$

which implies

$$\text{supp } \tilde{\beta}\subset\text{supp } \tilde{\alpha}; \tag{B}$$

moreover,

$$\tilde{\alpha}_\tau\leqslant(\tilde{\alpha}\wedge\tilde{\beta})_\tau \quad \text{for all } \tau\in\text{supp } \tilde{\alpha}\cup\text{supp } \tilde{\beta}. \tag{C}$$

Now

$$(\tilde{\alpha}\wedge\tilde{\beta})_\tau=\tilde{\alpha}_\tau\wedge\tilde{\beta}_\tau \quad \text{for } \tau\in\text{supp } \tilde{\alpha}\cap\text{supp } \tilde{\beta}=\text{supp } \tilde{\beta}. \tag{D}$$

Equations (C) and (D) give

$$\tilde{\alpha}_\tau\leqslant\tilde{\alpha}_\tau\wedge\tilde{\beta}_\tau \quad \text{for all } \tau\in\text{supp } \tilde{\beta}. \tag{E}$$

But $\tilde{\alpha}_\tau\wedge\tilde{\beta}_\tau\leqslant\tilde{\beta}_\tau$. Hence (E) gives

$$\tilde{\alpha}_\tau\leqslant\tilde{\beta}_\tau \quad \text{for all } \tau\in\text{supp } \tilde{\beta}. \tag{F}$$

The relations (B) and (F) imply $\tilde{\alpha}\leqslant\tilde{\beta}$.

Conversely, given $\tilde{\alpha}\leqslant\tilde{\beta}$, we have (B) and (F). The relation (B) implies (A) whereas (F), along with the trivial condition $\tilde{\alpha}_\tau\leqslant\tilde{\alpha}_\tau$ implies (E) which, in turn, implies, with Eq. (3.18) and (B), the relation (C). The relations (A) and (C) then imply $\tilde{\alpha}\leqslant\tilde{\alpha}\wedge\tilde{\beta}$.

Item (ix): The case $\tilde{\gamma}=\tilde{0}$ is trivial; $\tilde{\gamma}=\tilde{1}$ is possible only if $\tilde{\alpha}=\tilde{\beta}=\tilde{1}$ which, with (iii) above, reduces the required relation to triviality. We can, therefore, take $\tilde{\gamma}$ to be generic. The cases when $\tilde{\alpha}$ and/or $\tilde{\beta}$ equals $\tilde{0}$ or $\tilde{1}$ are trivial. We can, therefore, take $\tilde{\alpha}$, $\tilde{\beta}$, and $\tilde{\gamma}$ to be generic.

The given conditions imply the following relations:

$$\text{supp}\ \tilde{\alpha}\subset\text{supp}\ \tilde{\gamma},\quad \tilde{\gamma}_\tau\leqslant\tilde{\alpha}_\tau\quad\text{for all}\quad\tau\in\text{supp}\ \tilde{\alpha},$$

$$\text{supp}\ \tilde{\beta}\subset\text{supp}\ \tilde{\gamma},\quad \tilde{\gamma}_\tau\leqslant\tilde{\beta}_\tau\quad\text{for all}\quad\tau\in\text{supp}\ \tilde{\beta}.$$

This implies that $\text{supp}\ \tilde{\alpha}\cup\text{supp}\ \tilde{\beta}\subset\text{supp}\ \tilde{\gamma}$ and

$$\tilde{\gamma}_\tau\leqslant\tilde{\alpha}_\tau\wedge\tilde{\beta}_\tau\quad\text{for all}\quad\tau\in\text{supp}\ \tilde{\alpha}\cap\text{supp}\ \tilde{\beta}.$$

These results, along with the given conditions and Eq. (3.18) imply $\tilde{\gamma}\leqslant\tilde{\alpha}\wedge\tilde{\beta}$.

Item (x): The given condition $\tilde{\alpha}\perp\tilde{\beta}$ implies that

$$\tilde{S}_{\alpha\beta}\equiv(\text{supp}\ \tilde{\alpha})\cap(\text{supp}\ \tilde{\beta})\neq\phi\quad\text{and}\quad\tilde{\alpha}_{\tau_0}\perp\tilde{\beta}_{\tau_0}\quad\text{for some}\quad\tau_0\in\tilde{S}_{\alpha\beta}.$$

Clearly, $\tau_0\in\text{supp}(\tilde{\alpha}\wedge\tilde{\gamma})\cap\text{supp}(\tilde{\beta}\wedge\tilde{\gamma})$.

Now, if $\tau_0\notin\text{supp}\ \tilde{\gamma}$ we have $(\tilde{\alpha}\wedge\tilde{\gamma})_{\tau_0}=\tilde{\alpha}_{\tau_0}$ and $(\tilde{\beta}\wedge\tilde{\gamma})_{\tau_0}=\tilde{\beta}_{\tau_0}$ which are disjoint. If $\tau_0\in\text{supp}\ \tilde{\gamma}$, we have $(\tilde{\alpha}\wedge\tilde{\gamma})_{\tau_0}=\tilde{\alpha}_{\tau_0}\wedge\tilde{\gamma}_{\tau_0}$ and $(\tilde{\beta}\wedge\tilde{\gamma})_{\tau_0}=\tilde{\beta}_{\tau_0}\wedge\tilde{\gamma}_{\tau_0}$. We have

$$\tilde{\alpha}_{\tau_0}\wedge\tilde{\gamma}_{\tau_0}\leqslant\tilde{\alpha}_{\tau_0}\leqslant(\neg\tilde{\beta}_{\tau_0})\leqslant(\neg\tilde{\beta}_{\tau_0})\vee(\neg\tilde{\gamma}_{\tau_0})=\neg(\tilde{\beta}_{\tau_0}\wedge\tilde{\gamma}_{\tau_0})$$

proving the desired disjointness. Q.E.D.

This proposition gives relations between various operations in $\tilde{\mathscr{U}}$. In particular, the collection $(\tilde{\mathscr{U}},\leqslant,\wedge,\tilde{0},\tilde{1})$ can now be seen to be a meet-semilattice. [For a well-organized treatment of lattices and semilattices see, for example, Ref. 16.] As mentioned in Sec. I, a meet-semilattice structure was envisaged for the space of history filters in the scheme of Isham[9] for quasitemporal theories. It is the triple $(\tilde{\mathscr{U}},\tilde{\mathscr{T}},\tilde{\sigma})$ [and not the original $(\mathscr{U},\mathscr{T},\sigma)$] which corresponds to the triple in Ref. 9.

B. The space $\Omega=\Omega(\tilde{\mathscr{U}},\tilde{\mathscr{T}})$

As was noted in Ref. 9, the space $\mathscr{U}$ (or its refined version $\tilde{\mathscr{U}}$) of history filters (''homogeneous histories'') is not adequate for a histories-based formalism of (generalized) quantum mechanics. An important ingredient which is present in $\mathscr{U}_\tau$'s (families of ''single time'' propositions) but absent in $\mathscr{U}$ or $\tilde{\mathscr{U}}$ is the concept of negation. To incorporate this, we shall now embed $\tilde{\mathscr{U}}$ in a larger space Ω of history propositions (''inhomogeneous histories''). To motivate the following constructions, it is useful to point out here that the spaces $\tilde{\mathscr{U}}$ and Ω are the analogues of, respectively, the spaces of homogeneous and inhomogeneous projection operators in the HPO space $\tilde{\mathscr{H}}$ (see the Appendix).

The elements of Ω (to be called history propositions), will be taken to be of the form

$$\underline{\alpha}=\{\tilde{\alpha}^{(1)},\tilde{\alpha}^{(2)},\ldots\},\tag{3.24}$$

where the entries on the right are at most a countable collection of elements of $\tilde{\mathscr{U}}$ such that

(i) the order of the entries on the right is immaterial;
(ii) $\tilde{\alpha}^{(j)}\perp\tilde{\alpha}^{(k)}$ for $j\neq k$;
(iii) inclusion of any number of $\tilde{0}$'s inside the braces leaves $\underline{\alpha}$ unchanged;
(iv) the union of temporal supports of every finite subcollection of non-null $\tilde{\alpha}^{(j)}$'s is orientable;

(v) if $\tilde{\alpha}$ and $\tilde{\beta}$ are weakly disjoint (as defined in Sec. III A) with $\tilde{\alpha}\oplus\tilde{\beta}=\tilde{\gamma}$, then

$$\{\tilde{\alpha},\tilde{\beta},...\}=\{\tilde{\gamma},...\}, \tag{3.25}$$

where entries represented by dots are identical on the two sides.

For consistency, we must check that, given $\tilde{\delta}\in\tilde{\mathscr{U}}$ in the collection represented by ... in Eq. (3.25), we have $\tilde{\delta}\perp\tilde{\gamma}$ if and only if $\tilde{\delta}\perp\tilde{\alpha}$ and $\tilde{\delta}\perp\tilde{\beta}$. To verify this, let τ_0 be the point of weak disjointness of $\tilde{\alpha}$ and $\tilde{\beta}$ and τ' a point of disjointness of $\tilde{\gamma}$ and $\tilde{\delta}$. Since $\tilde{\alpha}_\tau=\tilde{\beta}_\tau=\tilde{\gamma}_\tau$ for all $\tau\neq\tau_0$, the required consistency condition is trivially satisfied if $\tau'\neq\tau_0$. We need, therefore, only consider the case when the disjointness of $\tilde{\gamma}$ with $\tilde{\delta}$ holds only at $\tau'=\tau_0$. We have

$$\tilde{\alpha}_{\tau_0}\perp\tilde{\beta}_{\tau_0},\ \ \tilde{\gamma}_{\tau_0}=\tilde{\alpha}_{\tau_0}\vee\tilde{\beta}_{\tau_0},\ \ \neg\tilde{\gamma}_{\tau_0}=(\neg\tilde{\alpha}_{\tau_0})\wedge(\neg\tilde{\beta}_{\tau_0}).$$

Now (i) given $\tilde{\gamma}_{\tau_0}\perp\tilde{\delta}_{\tau_0}$ we have $\tilde{\delta}_{\tau_0}\leqslant\neg\tilde{\gamma}_{\tau_0}\leqslant\neg\tilde{\alpha}_{\tau_0}$ implying that $\tilde{\delta}\perp\tilde{\alpha}$ and similarly $\tilde{\delta}\perp\tilde{\beta}$. (ii) Given $\tilde{\delta}_{\tau_0}\perp\tilde{\alpha}_{\tau_0}$ and $\tilde{\delta}_{\tau_0}\perp\tilde{\beta}_{\tau_0}$, we have $\tilde{\delta}_{\tau_0}\leqslant\neg\tilde{\alpha}_{\tau_0}$ and $\tilde{\delta}_{\tau_0}\leqslant\neg\tilde{\beta}_{\tau_0}$ which gives

$$\tilde{\delta}_{\tau_0}\leqslant(\neg\tilde{\alpha}_{\tau_0})\wedge\neg\tilde{\beta}_{\tau_0}=\neg(\tilde{\alpha}_{\tau_0}\wedge\tilde{\beta}_{\tau_0})=\neg\tilde{\gamma}_{\tau_0}$$

implying $\tilde{\delta}\perp\tilde{\gamma}$. This completes the verification.

The object $\underline{\alpha}$ of Eq. (3.24) represents a history proposition whose realization means realization of any of the mutually exclusive $\tilde{\alpha}^{(j)}$'s [$\tilde{\alpha}^{(1)}$ or $\tilde{\alpha}^{(2)}$ or $\tilde{\alpha}^{(3)}$ or...]; it is analogous to a sum of mutually orthogonal homogeneous projection operators in the HPO space $\tilde{\mathscr{H}}$. [See Eq. (3.33) below.]

The mapping $\tilde{\alpha}\to\{\tilde{\alpha}\}$ defines an embedding of $\tilde{\mathscr{U}}$ in Ω.

An intuitively appealing representation of $\underline{\alpha}$, equivalent to that in (3.24), is as a formal disjoint join:

$$\underline{\alpha}=\tilde{\alpha}^{(1)}\oplus\tilde{\alpha}^{(2)}\oplus\cdots \tag{3.26}$$

[with stipulations analogous to those in (i)–(v) above]. Equation (3.25) then appears more natural in the form

$$\tilde{\alpha}\oplus\tilde{\beta}\oplus\cdots=\tilde{\gamma}\oplus\cdots. \tag{3.27}$$

We shall, in fact, introduce a $\oplus$ operation in Ω below and a representation of the form (3.26) will appear [see Eq. (3.33)] with $\tilde{\alpha}^{(j)}$'s replaced by $\{\tilde{\alpha}^{(j)}\}$'s and $\oplus$ as the genuine disjoint join operation between the entries. The representation (3.24), however, has its own conveniences and we shall retain it.

We define the null element $\underline{0}$ and the unit element $\underline{1}$ in Ω as

$$\underline{0}=\{\overline{0}\},\quad \underline{1}=\{\overline{1}\}. \tag{3.28}$$

Elements of Ω other than these two will be called generic.

It must be noted that representation of the form (3.24) for an $\underline{\alpha}\in\Omega$ is not unique, even after disposing off the redundant $\tilde{0}'$s and the weakly disjoint pairs. For example,

$$\underline{\alpha}=\{\neg\alpha_{\tau_1}\circ\alpha_{\tau_2},\ \ \alpha_{\tau_1}\circ\neg\alpha_{\tau_2},\ \ \neg\alpha_{\tau_1}\circ\neg\alpha_{\tau_2}\}$$

can be represented as $\{\neg\alpha_{\tau_1},\alpha_{\tau_1}\circ\neg\alpha_{\tau_2}\}$ and also as $\{\neg\alpha_{\tau_1}\circ\alpha_{\tau_2},\neg\alpha_{\tau_2}\}$. This point must be taken care of to ensure that the definitions of various operations/relations in Ω are unambiguous.

We now consider operations and relations in Ω. The interpretation of these objects must be obvious from the discussion so far.

a. *Partial Order* ($\leqslant$). Given $\underline{\alpha},\underline{\beta}\in\Omega$, we say that $\underline{\alpha}\leqslant\underline{\beta}$ if they admit representations $\underline{\alpha}=\{\tilde{\alpha}^{(j)};j\in A\}$, $\underline{\beta}=\{\tilde{\beta}^{(k)};k\in B\}$ where A and B are suitable index sets, such that, for every $j\in A$, there is a $k\in B$ such that $\tilde{\alpha}^{(j)}\leqslant\tilde{\beta}^{(k)}$.

Recalling Eq. (3.15), we have

$$\underline{0} \leqslant \underline{\alpha} \leqslant \underline{1} \quad \text{for all} \quad \underline{\alpha} \in \Omega. \tag{3.29}$$

Before introducing other operations in Ω, it is useful to introduce the concept of support-compatibility. We shall say that $\underline{\alpha}, \underline{\beta} \in \Omega$ are support-compatible if

(i) at least one of them is $\underline{0}$ or $\underline{1}$, or
(ii) both are generic satisfying the condition that, for any representation $\underline{\alpha} = \{\tilde{\alpha}^{(i)}; i \in A\}$, $\underline{\beta} = \{\tilde{\beta}^{(j)}; j \in B\}$, the joint collection $\{\tilde{\alpha}^{(i)}, \tilde{\beta}^{(j)}; i \in A, j \in B\}$ is such that the union of temporal supports of any finite subset is orientable.

b. *Disjointness* ($\perp$). Given $\underline{\alpha} = \{\tilde{\alpha}^{(1)}, \tilde{\alpha}^{(2)}, \ldots\}$ and $\underline{\beta} = \{\tilde{\beta}^{(1)}, \tilde{\beta}^{(2)}, \ldots\}$ we shall say that $\underline{\alpha} \perp \underline{\beta}$ if they are support-compatible and if $\tilde{\alpha}^{(i)} \perp \tilde{\alpha}^{(j)}$ for all i, j. In view of the discussion after Eq. (3.25), this definition suffers no ambiguity due to nonuniqueness of representation of elements of Ω.

It immediately follows from this definition that

$$\text{(i)} \quad \underline{0} \perp \underline{\alpha} \quad \text{for all} \quad \underline{\alpha} \ \text{in} \ \Omega, \tag{3.30a}$$

$$\text{(ii)} \quad \underline{\alpha} \perp \underline{1} \quad \text{if and only if} \quad \underline{\alpha} = \underline{0}. \tag{3.30b}$$

c. Disjoint Join Operation ($\oplus$) Given two disjoint elements $\underline{\alpha} = \{\tilde{\alpha}^{(i)}; i \in A\}$ and $\underline{\beta} = \{\tilde{\beta}^{(j)}; j \in B\}$ in Ω we define

$$\underline{\alpha} \oplus \underline{\beta} = \{\tilde{\alpha}^{(i)}, \tilde{\beta}^{(j)}, i \in A, j \in B\}. \tag{3.31}$$

Lemma (2.1) permits the construction of disjoint sums of a countable number of pairwise disjoint elements of Ω (note that only the union of temporal supports of any finite subset of the joint collection of history filters needs to be orientable).

It is easily verified that

$$\underline{\alpha} \oplus \underline{\beta} = \underline{\beta} \oplus \underline{\alpha}$$

$$(\underline{\alpha} \oplus \underline{\beta}) \oplus \underline{\gamma} = \underline{\alpha} \oplus (\underline{\beta} \oplus \underline{\gamma})$$

$$\underline{\alpha} \oplus \underline{0} = \underline{\alpha} \quad \text{for all} \quad \underline{\alpha} \in \Omega. \tag{3.32}$$

The $\underline{\alpha}$ of (3.24) can now be represented as

$$\underline{\alpha} = \{\tilde{\alpha}^{(1)}\} \oplus \{\tilde{\alpha}^{(2)}\} \oplus \ldots . \tag{3.33}$$

This representation makes clear the correspondence between Ω and the family $\mathscr{P}'$ of inhomogeneous projectors in the HPO space $\tilde{\mathscr{H}}$ expressible as countable orthogonal sums of homogeneous projectors.

The $\oplus$ operations in $\tilde{\mathscr{H}}$ and Ω are compatible. Indeed, if $\tilde{\alpha}$ and $\tilde{\beta}$ are weakly disjoint with $\tilde{\alpha} \oplus \tilde{\beta} = \tilde{\gamma}$ we have

$$\{\tilde{\alpha}\} \oplus \{\tilde{\beta}\} = \{\tilde{\alpha}, \tilde{\beta}\} = \{\tilde{\alpha} \oplus \tilde{\beta}\} = \{\tilde{\gamma}\}.$$

An (at most countable) set of mutually disjoint history propositions $\underline{\alpha}, \underline{\beta}, \ldots$ will be called *complete* (or *exhaustive*) if

$$\underline{\alpha} \oplus \underline{\beta} \oplus \cdots = \underline{1}. \tag{3.34}$$

Given $\underline{\alpha}, \underline{\beta} \in \Omega$ which are mutually disjoint, it is easily seen from the definitions given above that

$$\underline{\alpha} \leqslant (\underline{\alpha} \oplus \underline{\beta}). \tag{3.35}$$

Proposition (3.6): If $\underline{\alpha}$, $\underline{\beta}$, $\underline{\gamma}$ are elements of Ω, then

(i) $\underline{\alpha} \oplus \underline{\beta} \leqslant \underline{\alpha} \oplus \underline{\gamma}$ implies $\underline{\beta} \leqslant \underline{\gamma}$;

(ii) $\underline{\alpha}\oplus\underline{\beta}=\underline{\alpha}\oplus\underline{\gamma}$ implies $\underline{\beta}=\underline{\gamma}$.

Proof: (i) Let $\underline{\alpha}=\{\tilde{\alpha}^{(i)};i\in A\}$, $\underline{\beta}=\{\tilde{\beta}^{(j)};j\in B\}$, and $\underline{\gamma}=\{\tilde{\gamma}^{(k)};k\in C\}$. We have $\underline{\alpha}\oplus\underline{\beta}=\{\tilde{\alpha}^{(i)},\tilde{\beta}^{(j)};i\in A,j\in B\}$ and $\underline{\alpha}\oplus\underline{\gamma}=\{\tilde{\alpha}^{(i)},\tilde{\gamma}^{(k)};i\in A,k\in C\}$. The given condition $\underline{\alpha}\oplus\underline{\beta}\leqslant\underline{\alpha}\oplus\underline{\gamma}$ implies that, for every $\tilde{\beta}^{(j)}$, there exists either an $\tilde{\alpha}^{(i)}$ such that $\tilde{\beta}^{(j)}\leqslant\tilde{\alpha}^{(i)}$ or a $\tilde{\gamma}^{(k)}$ such that $\tilde{\beta}^{(j)}\leqslant\tilde{\gamma}^{(k)}$. The first possibility is ruled out because $\tilde{\alpha}^{(i)}\perp\tilde{\beta}^{(j)}$ for all $i\in A$, $j\in B$. The second condition implies $\underline{\beta}\leqslant\underline{\gamma}$.
(ii) The given condition $\underline{\alpha}\oplus\underline{\beta}=\underline{\alpha}\oplus\underline{\gamma}$ implies

$$\underline{\alpha}\oplus\underline{\beta}\leqslant\underline{\alpha}\oplus\underline{\gamma}\quad\text{and}\quad\underline{\alpha}\oplus\underline{\gamma}\leqslant\underline{\alpha}\oplus\underline{\beta}$$

which implies, respectively, $\underline{\beta}\leqslant\underline{\gamma}$ and $\underline{\gamma}\leqslant\underline{\beta}$ giving $\underline{\beta}=\underline{\gamma}$. Q.E.D.

We now move towards introducing a negation operation in Ω. The following theorem will play a crucial role.

Theorem (3.7): Given $\underline{\alpha},\underline{\beta}\in\Omega$, we have $\underline{\alpha}\leqslant\underline{\beta}$ if and only if there exists a $\underline{\gamma}\in\Omega$ such that $\underline{\beta}=\underline{\alpha}\oplus\underline{\gamma}$; the element $\underline{\gamma}$ is unique.

As the ''if'' part of the theorem is already implied by Eq. (3.35), we have only to consider the ''only if'' part.

In the main part of the proof below, we shall ignore possible complications arising from support considerations. Appropriate remarks relating to this will be made at the end of the proof.

For $\underline{\alpha}=\underline{0}$, the desired result follows trivially from the first of the order relations in (3.29) and Eq. (3.32). If $\underline{\alpha}=\underline{1}$, the second relation in (3.29) implies that $\underline{\alpha}\leqslant\underline{\beta}$ if and only if $\underline{\beta}=\underline{1}$; the desired result now holds trivially with $\underline{\gamma}=\underline{0}$. We therefore need consider only the case when $\underline{\alpha}$ is a generic element of Ω represented as in Eq. (3.24). In this case $\underline{\beta}$ is either generic or equals $\underline{1}$.

Let

$$\underline{\alpha}=\{\tilde{\alpha}^{(1)}\}\oplus\{\tilde{\alpha}^{(2)}\}\oplus\cdots\quad\underline{\beta}=\{\tilde{\beta}^{(1)}\}\oplus\{\tilde{\beta}^{(2)}\}\oplus\cdots.$$

When $\underline{\beta}=\underline{1}$, we have, say, $\tilde{\beta}^{(1)}=\tilde{1}$ and $\tilde{\beta}^{(k)}=\tilde{0}$ for $k>1$. As a representative of $\tilde{\beta}^{(1)}$, we may choose any $\beta\in\mathscr{U}$ with supp(β), any orientable subset of $\mathscr{N}(\mathscr{U})$, and $\beta_\tau=1_\tau$ for all $\tau\in$ supp(β).

The relation $\underline{\alpha}\leqslant\underline{\beta}$ means that, for every $\tilde{\alpha}^{(j)}$, there is a $\tilde{\beta}^{(k)}$ such that

$$\tilde{\alpha}^{(j)}\leqslant\tilde{\beta}^{(k)}. \tag{3.36}$$

In general, there may be more than one $\tilde{\alpha}^{(j)}$'s satisfying (3.36) with the same $\tilde{\beta}^{(k)}$. There may be some $\tilde{\beta}^{(k)}$'s not involved in any relation of the form (3.36); these will be called ''spectators'' and the remaining ones ''active.'' The spectator $\tilde{\beta}^{(k)}$ clearly go as ''summands'' in $\underline{\gamma}$.

To prove the theorem, it is clearly adequate to consider a general active $\tilde{\beta}^{(k)}$ such that

$$\{\tilde{\alpha}^{(p)}\}\leqslant\{\tilde{\beta}^{(k)}\}\quad\text{for } p=j,j',j'',\ldots \tag{3.37}$$

and show that

$$\{\tilde{\beta}^{(k)}\}=[\{\tilde{\alpha}^{(j)}\}\oplus\{\tilde{\alpha}^{(j')}\}\oplus\cdots]\oplus\rho(k), \tag{3.38}$$

where the entries in the parentheses are in one-to-one correspondence with the values of p in (3.37). To prove (3.38), it is, in turn, adequate to prove that

$$\{\tilde{\beta}^{(k)}\}=\{\tilde{\alpha}^{(j)}\}\oplus\underline{\lambda}^{(\cdots)} \tag{3.39}$$

with

$$\underline{\lambda}^{(\cdots)}=\{\tilde{\alpha}^{(q)}\}\oplus\cdots\quad\text{for } q=j',j'',\ldots\ . \tag{3.40}$$

When $\underline{\beta}$ is generic, the relation (3.37) implies that supp($\tilde{\beta}^{(k)}$)$\subset$supp($\tilde{\alpha}^{(p)}$) and

$$\tilde{\alpha}_\tau^{(p)} \leqslant \tilde{\beta}_\tau^{(k)} \quad \text{for all} \quad \tau \in \text{supp}(\tilde{\beta}^{(k)}). \tag{3.41}$$

Equation (3.9) now gives

$$\tilde{\beta}_\tau^{(k)} = \tilde{\alpha}_\tau^{(p)} \oplus \tilde{\in}_\tau^{(k,p)} \quad \text{for all} \quad \tau \in \text{supp}\ \tilde{\beta}^{(k)}. \tag{3.42}$$

Now, given an element $\mu \in \mathscr{U}$ and an orientable subset A of $\mathscr{N}(\mathscr{T})$ containing supp(μ), we can always extend μ to another element $\mu' \in \mathscr{U}$ with supp(μ')$=A$ by taking

$$\mu'_\tau = \begin{cases} \mu_\tau & \text{for} \quad \tau \in \text{supp}(\mu) \\ 1_\tau & \text{for} \quad \tau \in A\text{-supp}(\mu) \end{cases}. \tag{3.43}$$

We shall call such an extension trivial (for the obvious reason that the corresponding element of $\tilde{\mathscr{U}}$ is left unchanged by such an extension).

Using such a trivial extension, if necessary, we can choose representatives $\alpha^{(p)}$ and $\beta^{(k)}$ of $\tilde{\alpha}^{(p)}$ and $\tilde{\beta}^{(k)}$, respectively, such that supp($\alpha^{(p)}$)$=$supp($\beta^{(k)}$). Equation (3.42) now gets replaced by

$$\beta_\tau^{(k)} = \alpha_\tau^{(p)} \oplus \in_\tau^{(k,p)} \quad \text{for all} \quad \tau \in \text{supp}(\alpha^{(p)}). \tag{3.44}$$

When $\underline{\beta} = \underline{1}$ we have, with $\beta \in \mathscr{U}$ introduced as above, the analogue of Eq. (3.44) directly:

$$\beta_\tau (= 1_\tau) = \alpha_\tau^{(p)} \oplus \neg \alpha_\tau^{(p)} \quad \text{for all} \quad \tau \in \text{supp}(\alpha^{(p)}). \tag{3.45}$$

Now consider Eq. (3.44) for $p=j$ and q where q is any of the values $j',j'',\ldots$ of p in (3.37). Since $\alpha^{(j)} \perp \alpha^{(q)}$, we have

$$\alpha_{\tau_0}^{(q)} \leqslant \in_{\tau_0}^{(k,j)} \quad \text{for some} \quad \tau_0 \in (\text{supp}\ \alpha^{(j)}) \cap (\text{supp}\ \alpha^{(q)}). \tag{3.46}$$

Appealing to Eq. (3.9) once again, we have

$$\in_{\tau_0}^{(k,j)} = \alpha_{\tau_0}^{(q)} \oplus \cdots.$$

Equation (3.44) now gives

$$\beta_{\tau_0}^{(k)} = \alpha_{\tau_0}^{(j)} \oplus \alpha_{\tau_0}^{(q)} \oplus \cdots\ . \tag{3.47}$$

Let

$$\beta^{(k)} = \lambda' \circ \beta_{\tau_0}^{(k)} \circ \lambda'', \tag{3.48}$$

where λ' and λ'' are elements of $\mathscr{U}$ representing entries in the irreducible decomposition of $\beta^{(k)}$ ''before'' and ''after'' τ_0, respectively. From Eqs. (3.48) and (3.47), we have

$$\{\beta^{(k)}\} = \{\lambda' \circ \alpha_{\tau_0}^{(j)} \circ \lambda''\} \oplus \{\lambda' \circ \alpha_{\tau_0}^{(q)} \circ \lambda''\} \oplus \cdots\ . \tag{3.49}$$

Recalling Eq. (3.44) (with $p=j,q$) we have

$$\{\lambda' \circ \alpha_{\tau_0}^{(j)} \circ \lambda''\} = \{\alpha^{(j)}\} \oplus \cdots \tag{3.50a}$$

and

$$\{\lambda' \circ \alpha_{\tau_0}^{(q)} \circ \lambda''\} = \{\alpha^{(q)}\} \oplus \cdots\ . \tag{3.50b}$$

Equations (3.49), (3.50a), and (3.50b) together complete the proof of Eqs. (3.39) and (3.40) and hence that of the existence of the promised $\underline{\gamma}$ modulo possible support problems (arising from support requirements in the definition of elements of Ω).

All support problems are taken care of by the following two observations:

(i) Since $\underline{\alpha} \in \Omega$, the union of supports of any finite subcollection of $\tilde{\alpha}^{(j)}$'s is given as orientable.

(ii) The right-hand sides of all equations in the proof involving possibly infinite $\oplus$ operations are such that the union of supports of any finite number of ''summands'' equals the union of supports of a finite number of $\tilde{\alpha}^{(j)}$'s.

The uniqueness of $\underline{\gamma}$ follows immediately from proposition 3.6 (ii). Q.E.D.

Corollary (3.8): For every $\underline{\alpha} \in \Omega$, there is a unique $\underline{\gamma} \in \Omega$ (which is $\perp$ to $\underline{\alpha}$) such that $\underline{\alpha} \oplus \underline{\gamma} = \underline{1}$.

Proof: Take $\underline{\beta} = \underline{1}$ in *theorem (3.7).* Q.E.D.

We denote the history proposition $\underline{\gamma}$ given by *corollary (3.8)* as $\neg \underline{\alpha}$ and call it the negation of $\underline{\alpha}$. It is the unique history proposition which is realized if and only if $\underline{\alpha}$ is not realized.

Clearly, the mapping $\neg : \Omega \to \Omega$ taking $\underline{\alpha}$ to $\neg \underline{\alpha}$ is a bijection satisfying the conditions (i) $\neg(\neg \underline{\alpha}) = \underline{\alpha}$, (ii) $\underline{\alpha} \oplus \neg \underline{\alpha} = \underline{1}$, and (iii) $\neg \underline{0} = \underline{1}$; $\neg \underline{1} = \underline{0}$. These are the traditional defining properties of negation (or orthocomplementation).

Proposition (3.9): Given $\underline{\alpha}$, $\underline{\beta} \in \Omega$ which are support-compatible, we have $\underline{\alpha} \perp \underline{\beta}$ if and only if $\underline{\alpha} \leqslant \neg \underline{\beta}$.

Proof: (i) Given $\underline{\alpha} \perp \underline{\beta}$. Let $\underline{\gamma} = \underline{\alpha} \oplus \underline{\beta}$. We have

$$\underline{1} = \underline{\gamma} \oplus \neg \underline{\gamma} = \underline{\alpha} \oplus \underline{\beta} \oplus (\neg \underline{\gamma}) = \underline{\beta} \oplus \neg \underline{\beta}$$

giving

$$\underline{\alpha} \oplus (\neg \underline{\gamma}) = \neg \underline{\beta}$$

which implies, by Eq. (3.35), $\underline{\alpha} \leqslant (\neg \underline{\beta})$.

(ii) Given $\underline{\alpha} \leqslant \neg \underline{\beta}$. We have $\neg \underline{\beta} = \underline{\alpha} \oplus \underline{\delta}$, say. Now $(\neg \underline{\beta}) \perp \underline{\beta}$ implies $\underline{\alpha} \perp \underline{\beta}$ (recall the definition of $\oplus$ in Ω). Q.E.D.

It is clear from the developments in this section that Ω is an orthoalgebra as envisaged in the scheme of Isham and Linden.[10]

C. States and observables; temporal evolution

As the propositions in each $\mathscr{U}_\tau$ have the structure of a logic, we can define observables, states, and probability distributions of observables as in the traditional proposition calculus. Of course, since $\mathscr{U}_\tau$'s for different τ's are generally not isomorphic, a similar nonisomorphism of spaces of observables and states at different τ's will hold in the present formalism.

A state at ''time'' $\tau \in \mathscr{N}(\mathscr{T})$ is a kind of generalized probability on $\mathscr{U}_\tau$; more precisely, it is a map $p_\tau : \mathscr{U}_\tau \to R$ such that

(i) $0 \leqslant p_\tau(\alpha) \leqslant 1$ for each $\alpha \in \mathscr{U}_\tau$;
(ii) $p_\tau(0_\tau) = 0$, $p_\tau(1_\tau) = 1$;
(iii) given a sequence $\alpha_1, \alpha_2, \ldots$ in $\mathscr{U}_\tau$ which is pairwise disjoint (i.e., $\alpha_i \leqslant \neg \alpha_j$, for $i \neq j$), we have

$$p_\tau(\vee_i \alpha_i) = \sum_i p_\tau(\alpha_i). \tag{3.51}$$

We shall denote the collection of states at ''time'' τ by $\mathscr{S}(\tau)$.

An observable at ''time'' τ is a map $A_\tau : B(R) \to \mathscr{U}_\tau$ [where $B(R)$ is the σ-algebra of Borel sets in R, the smallest σ-algebra containing all the open intervals] such that

(i) $A_\tau(\phi) = 0_\tau$, $A_\tau(R) = 1_\tau$;
(ii) given disjoint sets E, F in $B(R)$, we have $A_\tau(E)$ and $A_\tau(F)$ disjoint;
(iii) if $E_1, E_2, \ldots$ is at most a countable collection of pairwise disjoint sets in $B(R)$, we have

$$A_\tau(\cup_k E_k) = \vee_k A_\tau(E_k). \tag{3.52}$$

We shall denote the collection of observables at ''time'' τ by $\mathcal{O}(\tau)$.

The probability distribution of the observable A_τ in the state p_τ is given by the measure $\mu^{(A_\tau,p_\tau)}$ on the measurable space $(R,B(R))$ given by

$$\mu^{(A_\tau,p_\tau)}(E)=p_\tau(A_\tau(E)) \quad \text{for all } E\in B(R). \tag{3.53}$$

It is worth remarking here that the ''time'' dependence of our states and observables corresponds neither to the Schrödinger picture nor Heisenberg picture (our states and observables both have τ dependence). This is because we are not operating in the framework of a fixed logic; we have different (generally nonisomorphic) logics at different τ's. When all the $\mathcal{U}_\tau$'s are isomorphic, we can recover the (analogue of) Heisenberg picture by referring all the states p_τ's in various $\mathcal{S}(\tau)$'s to a single $\mathcal{S}(\tau)$, say $\mathcal{S}(\tau_0)$; similarly, a Schrödinger type picture is realized by referring all the observables to $\mathcal{O}(\tau_0)$.

It appears natural to assume that the temporal evolution of the system is given by homomorphisms (structure preserving mappings) of logics; we do this in our next axiom.

A_4 (temporal evolution axiom)

The temporal evolution of the system is given by a family of mappings $V(\tau',\tau):\mathcal{U}_\tau\to\mathcal{U}_{\tau'}$ [defined for each pair $\tau,\ \tau'\in\mathcal{N}(\mathcal{T})$ such that $\tau\lhd\tau'$] such that

(i) $V(\tau',\tau)$ is onto;
(ii) $V(\tau',\tau)(0_\tau)=0_{\tau'}$, $V(\tau',\tau)(1_\tau)=1_{\tau'}$;
(iii) given $\alpha^{(1)},\ \alpha^{(2)},\ldots\in\mathcal{U}_\tau$ we have

$$V(\tau',\tau)\left(\bigvee_j \alpha^{(j)}\right)=\bigvee_j V(\tau',\tau)(\alpha^{(j)}),$$

$$V(\tau',\tau)\left(\bigwedge_j \alpha^{(j)}\right)=\bigwedge_j V(\tau',\tau)(\alpha^{(j)});$$

(iv) $V(\tau',\tau)(\neg\alpha)=\neg[V(\tau',\tau)(\alpha)]$ for all $\alpha\in\mathcal{U}_\tau$;
(v) if $\tau\lhd\tau'$, $\tau'\lhd\tau''$, and $\tau\lhd\tau''$, we have

$$V(\tau'',\tau')\cdot V(\tau',\tau)=V(\tau'',\tau),$$

where the dot between the V's indicates composition of mappings. (Note: These requirements have not been stated in minimal terms; there is some redundancy.) It is easily seen by employing Eq. (3.9) and (iii) and (iv) above that the evolution mappings $V(.,.)$ preserve partial order, i.e., given $\alpha\leqslant\beta$ in $\mathcal{U}_\tau$, we have $V(\tau',\tau)(\alpha)\leqslant V(\tau',\tau)(\beta)$ in $\mathcal{U}_\tau{}'$.

A comment is in order about condition (i) above. It reflects the view that everything that is in the system at a ''later time'' must have evolved from something in the system (supposedly closed) at an ''earlier time.'' An evolution of a closed system (through structure preserving mappings) which is not onto does not appear to make physical sense.

What about the property of $V(\tau',\tau)$ being injective (one-one)? In fact, structure preserving mappings of logics are generally taken to be injective.[14] Let us say that an evolution is nondegenerate if the evolution mapping is injective; otherwise it is degenerate. For a nondegenerate evolution, the mapping $V(\tau',\tau)$ will be bijective and therefore an isomorphism of the logics $\mathcal{U}_\tau$ and $\mathcal{U}_{\tau'}$. It follows that, if the generality of nonisomorphic $\mathcal{U}_\tau$'s is to be retained, the possibility of degenerate evolution must be admitted.

In situations where the $\mathcal{U}_\tau$'s are mutually isomorphic, we shall generally take the evolution maps $V(\tau',\tau)$ to be bijective.

The evolution described by $V(\tau',\tau)$ induces a mapping from $\mathcal{O}(\tau)$ to $\mathcal{O}(\tau')$ which maps $A_\tau\in\mathcal{O}(\tau)$ to $A_{\tau'}\in\mathcal{O}(\tau')$ given by

$$A_{\tau'}(E)=V(\tau',\tau)(A_\tau(E)) \quad \text{for all } E\in B(R). \tag{3.54}$$

If the mapping $V(\tau',\tau)$ is invertible, we also have a mapping on states taking $p_\tau\in\mathcal{S}(\tau)$ to $p_{\tau'}\in\mathcal{S}(\tau')$ given by

$$p_{\tau'}(\beta)=p_{\tau}(V(\tau',\tau)^{-1}(\beta)) \quad \text{for all} \quad \beta\in\mathscr{O}_{\tau'}. \tag{3.55}$$

The probability distribution $\mu^{(A_\tau,p_\tau)}$ of A_τ in the state p_τ is mapped to the probability distribution $\mu^{(A_{\tau'},p_{\tau'})}$ of $A_{\tau'}$ in the state $p_{\tau'}$ given by, for every $E\in B(R)$,

$$\mu^{(A_{\tau'},p_{\tau'})}(E)=p_{\tau'}(A_{\tau'},(E))=p_{\tau'}[V(\tau',\tau)(A_\tau(E))]=p_\tau(A_\tau(E))=\mu^{(A_\tau,p_\tau},(E). \tag{3.56}$$

The invariance of the probability measure μ reflected in Eq. (3.56) is essentially a consequence of the ''picture'' we are employing [see the remark after Eq. (3.53) above]. To see this we consider the corresponding situation in traditional quantum mechanics. Let $\hat{A}$ be a self-adjoint operator and E_λ its spectral family. In any state Ψ, we have

$$(\Psi,\hat{A}\Psi)=\int_R \lambda\, d(\Psi,E_\lambda\Psi). \tag{3.57}$$

The probability distribution $\mu^{(\hat{A},\Psi)}$ is given by

$$\mu^{(\hat{A},\Psi)}(E)=\int_E d(\Psi,E_\lambda\Psi) \quad \text{for all} \quad E\in B(R). \tag{3.58}$$

Now consider time dependence of states and observables (in our composite picture) given by the unitary evolution operator $U(t',t)$:

$$\Psi(t')=U(t',t)\Psi(t),$$

$$\hat{A}(t')=U(t',t)\hat{A}(t)U(t',t)^{-1}. \tag{3.59}$$

This gives

$$(\Psi(t'),\hat{A}(t')\Psi(t'))=(\Psi(t),\hat{A}(t)\Psi(t)) \tag{3.60}$$

which implies

$$\mu^{(\hat{A}_{t'},\Psi(t'))}=\mu^{(\hat{A}_t,\Psi(t))} \tag{3.61}$$

as claimed.

D. Decoherence functionals

Our fifth axiom relates to decoherence functionals. It has two parts.

A_5 (a) (Decoherence functionals)

Given a state $p_0\in\mathscr{S}(\tau_0)$ for some $\tau_0\in\mathscr{N}(\mathscr{T})$ and a law of evolution $V(\tau',\tau)$, we have a decoherence functional $d=d_{p_0,V}$ which is a mapping $d:\Omega\times\Omega\to C$ such that

(i) $d(\underline{\alpha},\underline{\beta})^*=d(\underline{\beta},\underline{\alpha})$ (hermiticity). (3.62a)

(ii) $d(\underline{\alpha},\underline{\alpha})\geqslant 0$ (positivity). (3.62b)

(iii) If $\underline{\alpha}$, $\underline{\beta}$, ... is at most a countable collection of pairwise disjoint of elements of Ω, we have

$$d(\underline{\alpha}\oplus\underline{\beta}\oplus\ldots,\underline{\gamma})=d(\underline{\alpha},\underline{\gamma})+d(\underline{\beta},\underline{\gamma})+\cdots \quad \text{(countable additivity)}. \tag{3.62c}$$

(iv) $d(\underline{1},\underline{1})=1$ (normalization). (3.62d)

The space of decoherence functionals will be denoted as $\mathscr{D}$.

A complete set $\mathscr{C}$ of history propositions is said to be (weakly) decoherent (or consistent) with respect to a decoherence functional d if

$$\text{Re } d(\underline{\alpha},\underline{\beta})=0, \quad \underline{\alpha},\underline{\beta}\in\mathscr{C}, \quad \underline{\alpha}\neq\underline{\beta}. \tag{3.63}$$

A_5 (b) (Probability interpretation)

The probability that a history $\underline{\alpha}$ in a complete set $\mathscr{C}$ which is decoherent with respect to a decoherence functional d is realized is given by

$$P(\underline{\alpha})=d(\underline{\alpha},\underline{\alpha}). \tag{3.64}$$

For $\underline{\alpha},\underline{\beta}\in\mathscr{C}$, we have the classical probability sum rule:

$$P(\underline{\alpha}\oplus\underline{\beta})=d(\underline{\alpha}\oplus\underline{\beta},\underline{\alpha}\oplus\underline{\beta})=d(\underline{\alpha},\underline{\alpha})+d(\underline{\beta},\underline{\beta})+2\,\text{Re}\,d(\underline{\alpha},\underline{\beta})=P(\underline{\alpha})+P(\underline{\beta}). \tag{3.65}$$

Finally

$$1=d(\underline{1},\underline{1})=d(\underline{\alpha}\oplus\underline{\beta}\oplus,\ldots,\underline{\alpha}\oplus\underline{\beta}\oplus\cdots)=\sum_{\underline{\alpha}\in\mathscr{C}}P(\underline{\alpha}). \tag{3.66}$$

We shall give an explicit construction of $d_{p_0,V}$ in a subclass of theories in Sec. III E below.

E. Hilbert space-based theories

An important subclass of the class of theories covered by the formalism presented above are those in which, corresponding to each $\tau\in\mathscr{N}(\mathscr{T})$, we have a separable Hilbert space $\mathscr{H}_\tau$ (there being generally no natural isomorphism between $\mathscr{H}_\tau$'s for different τ's) and $\mathscr{U}_\tau=\mathscr{P}(\mathscr{H}_\tau)$, the lattice of projection operators in $\mathscr{H}_\tau$. Here $\mathscr{T}$ is a general space of temporal supports satisfying the conditions of axioms A_1 and A_2. The object $\mathscr{U}$ in such a theory is a psg whose elements α have irreducible decompositions of the form

$$\alpha=[\cdots\alpha_{\tau_1}\circ\alpha_{\tau_2}\circ\alpha_{\tau_3}\circ\cdots], \tag{3.67}$$

where

$$\cdots\lhd\tau_1\lhd\tau_2\lhd\tau_3\lhd\cdots \tag{3.68}$$

and the bracket in Eq. (3.67) is to serve as a reminder that the decompositions can be at most semi-infinite.

In a straightforward extension of the HPO formalism given in the Appendix, elements of $\mathscr{U}$ (more appropriately, of $\tilde{\mathscr{U}}$) are homogeneous projection operators in the Hilbert space

$$\tilde{\mathscr{H}}=\bigotimes_{\tau\in N(\mathscr{T})}{}^{w}\,\mathscr{H}_\tau. \tag{3.69}$$

Corresponding to α of Eq. (3.67), we have a projection operator $\overline{\alpha}$ in $\tilde{\mathscr{H}}$ given by [compare Eq. (A4)]

$$\overline{\alpha}=[\cdots\oplus\alpha_{\tau_1}\oplus\alpha_{\tau_2}\oplus\alpha_{\tau_3}\oplus\cdots]. \tag{3.70}$$

Objects like $\overline{\alpha}$ of Eq. (3.70), in which the number of nontrivial α_{τ_i}'s is not restricted to be finite, should be understood as elements of the space

$$\mathscr{B}=\bigotimes_{\tau\in N(\mathscr{T})}\mathscr{B}(\mathscr{H}_\tau). \tag{3.71}$$

Here $\mathscr{B}(\mathscr{H}_\tau)$ denotes the algebra of bounded linear operators on $\mathscr{H}_\tau$. The construction[9] of $\mathscr{B}$ is similar to that of $\tilde{\mathscr{H}}$. One first defines a space $\mathscr{A}$ (analogous to the spaced $\mathscr{F}$ in the Appendix) whose general element A is a map from $\mathscr{N}(\mathscr{T})$ to the Cartesian product

$$X=\prod_{\tau\in N(\mathscr{T})}\mathscr{B}(\mathscr{H}_\tau) \tag{3.72}$$

such that $A(\tau)=I_\tau$ (the identity operator on $\mathscr{H}_\tau$) for all but a finite set of values of τ. Clearly $\mathscr{A}$ is a subset of X [identifying $A\in\mathscr{A}$ with the set of values $A(\tau)$]. Algebraic operations on $\mathscr{A}$ are defined in the obvious manner:

$$(aA+bB)(\tau)=aA(\tau)+bB(\tau);\quad AB(\tau)=A(\tau)B(\tau)\quad \text{for all } a,b,\in C,\qquad \text{and}\quad \tau\in N(\mathscr{T}).$$

Weak operator topologies on $\mathscr{B}(\mathscr{H}_\tau)$'s define the corresponding product topology π_W on X. The space $\mathscr{B}$ is defined as the closure of $\mathscr{A}$ in the topological space (X,π_W).

The process of association of homogeneous projection operators in $\mathscr{B}$ with elements of $\mathscr{U}$ takes care of the formality of going from the triple $(\mathscr{U},\mathscr{T},\sigma)$ to $(\tilde{\mathscr{U}},\tilde{\mathscr{T}},\tilde{\sigma})$. This is because the superfluous I_τ's get automatically ignored in passing from α to $\underline{\alpha}$ above and the presence of a 0_τ anywhere in α makes $\underline{\alpha}=0$.

The operations in $\tilde{\mathscr{U}}$ described in Sec. III A get translated into those on homogeneous projection operators in $\tilde{\mathscr{H}}$. Partial order ($\leqslant$) translates to the partial order among projectors. Disjointness gets translated to orthogonality of projectors. The operation $\oplus$ becomes orthogonal sum. Finally, the meet operation is easily seen to correspond to the meet operation on projectors (which is equivalent to that on the subspaces of the Hilbert space $\tilde{\mathscr{H}}$).

Elements of Ω are inhomogeneous projection operators in $\tilde{\mathscr{H}}$ expressible as countable sums of mutually orthogonal homogeneous projection operators. Statements in the previous paragraph apply, with due alteration of details, also to the operations in Ω described in Sec. III B. The negation operation $\neg$ translates into subtraction from the unit operator $\tilde{I}$.

For each $\tau\in\mathscr{N}(\mathscr{T})$, the state space $\mathscr{S}(\tau)$ is the family of density operators in $\mathscr{H}_\tau$ and the space $\mathscr{O}(\tau)$ of observables is the family of projectors of the form [see Eq. (3.58)]

$$p^{(\hat{A})}(E)=\int_E dE_\lambda, \tag{3.73}$$

where $\hat{A}$ is a self-adjoint operator in $\mathscr{H}_\tau$ and E is a Borel set in R. The maps $P^{(\cdot)}$: $B(R)\to\mathscr{P}(\mathscr{H}_\tau)$ are in one-to-one correspondence with self-adjoint operators in $\mathscr{H}_\tau$.

The history version of traditional quantum mechanics presented in Sec. I is clearly a special case of these theories with $\mathscr{T}=\mathscr{K}_1$ of Sec. II [which implies $\mathscr{N}(\mathscr{T})=R$, the traditional time] and, for each $\tau\in R$, $\mathscr{H}_\tau$ an isomorphic copy of the quantum mechanical Hilbert space $\mathscr{H}$.

The decoherence functional (1.5) can be easily extended to finite histories in general Hilbert space-based theories. The one constructed below [Eq. (3.77)] is essentially a generalization of Eq. (4.19) of Ref. 10 to the case of general temporal support space $\mathscr{T}$. Let

$$\alpha=\alpha_{\tau_1}\circ\cdots\circ\alpha_{\tau_n},\quad \beta=\beta_{\tau_1'}\circ\cdots\circ\beta_{\tau_m'}$$

be two histories with the same initial state $\rho(\tau_0)$. It is understood here that $\tau_0\lhd\tau_1$ and $\tau_0\lhd\tau_1'$. For every pair τ, $\tau'\in\mathscr{N}(\mathscr{T})$ with $\tau\lhd\tau'$, let $K(\tau',\tau)$: $\mathscr{H}_\tau\to\mathscr{H}_{\tau'}$ be the linear evolution maps satisfying the condition

$$K(\tau'',\tau')K(\tau',\tau)=K(\tau'',\tau) \tag{3.74}$$

for all triples τ, τ', τ'' such that $\tau\lhd\tau'\lhd\tau''$ and $\tau\lhd\tau''$. Let us assume that there exists $\tau_f\in\mathscr{N}(\mathscr{T})$ such that

$$\tau_n\lhd\tau_f\qquad\text{and}\qquad\tau_m'\lhd\tau_f. \tag{3.75}$$

[The existence of such a τ_f (which is trivial when $\mathscr{N}(\mathscr{T})=R$) is not guaranteed by our axioms and is a new assumption.] Let [compare Eq. (1.3)]

$$C_\alpha'=K(\tau_f,\tau_n)\alpha_{\tau_n}K(\tau_n,t_{n-1})\cdots\alpha_{\tau_2}K(\tau_2,\tau_1)\alpha_{\tau_1}K(\tau_1,\tau_0) \tag{3.76}$$

with a similar expression for C_β'. We now define

$$d(\alpha,\beta)=N\ \mathrm{Tr}[C'_\alpha \rho(\tau_0) C'^{+}_\beta] \tag{3.77a}$$

with

$$N^{-1}=\mathrm{Tr}[A\rho(\tau_0)B^{+}], \tag{3.77b}$$

where A and B are operators obtained from C'_α and C'_β, respectively, by putting each of the α_{τ_i} and $\alpha_{\tau'_i}$ equal to the unit operator. It is implicitly assumed here that the right-hand side of Eq. (3.77b) does not vanish. If the temporal relations among the temporal supports of α and β are such that compositions of the form (3.74) are permitted for all successive pairs, we have $A=K(\tau_f,\tau_0)$ and $B=K(\tau_f,\tau_0)^{+}$. Now, if the maps $K(.,.)$ satisfy the condition

$$K(\tau',\tau)^{\dagger}K(\tau',\tau)=I_\tau, \tag{3.78}$$

we have $N=1$.

To be consistent, we must connect the maps $K(\tau',\tau)$ to the evolution maps $V(\tau',\tau)$ postulated in the axiom A_4. In the present case the latter are maps $V(\tau',\tau):\mathscr{P}(\mathscr{H}_\tau)\to\mathscr{P}(\mathscr{H}_{\tau'})$ satisfying the conditions of axiom A_4 (i.e., they are onto and logic homomorphisms). To have this evolution implemented by maps $K(\tau',\tau):\mathscr{H}_\tau\to\mathscr{H}_{\tau'}$ employed above, it appears necessary to assume that $V(.,.)$'s are injective (one-one) as well. In this case they are logic isomorphisms; Wigner's theorem[14] then implies the existence of unitary or antiunitary maps $K(\tau',\tau):\mathscr{H}_\tau\to\mathscr{H}_{\tau'}$ such that, for any $P\in\mathscr{P}(\mathscr{H}_\tau)$,

$$V(\tau',\tau)(P)=K(\tau',\tau)PK(\tau',\tau)^{+}. \tag{3.79}$$

Equation (3.74) shows that $K(\tau'',\tau)$ is unitary when $K(\tau',\tau)$ and $K(\tau'',\tau')$ are both unitary or both antiunitary. The simplest possibility, therefore, is that all $K(\tau',\tau)$ are unitary.

Conversely, if linear maps $K(\tau',\tau)$ are given and are used to define $V(\tau',\tau)$ through Eq. (3.79), we must have the relation (3.78) if the condition $P^2=P$ is to be preserved. The condition that the map $V(\tau',\tau)$ maps the identity operator I_τ to $I_{\tau'}$ demands that

$$K(\tau',\tau)K(\tau',\tau)^{\dagger}=I_{\tau'}, \tag{3.80}$$

implying that $K(.,.)$ be unitary.

The subclass of theories considered in this section is general enough to include history version of Hilbert space-based quantum field theory on general (i.e., not necessarily globally hyperbolic) space times.

F. Classical mechanics

As promised earlier, we shall now present the history version of classical mechanics in the framework of theories described in Secs. III A–III D.

We consider classical mechanics of a system with phase space Γ. For simplicity we take $\mathscr{T}=\mathscr{K}_1$ of Sec. II which gives $\mathscr{N}(\mathscr{T})=R$, the traditional space for the flow of time. For each $t\in R$, the space $\mathscr{U}_t$ of ''single time propositions'' at time t is the collection $B(\Gamma)$ of all Borel subsets of Γ which is a Boolean logic. A general element of $\mathscr{U}$ is a collection

$$\alpha=\{\alpha(\tau_1),\ldots,\alpha(t_n);t_i\in R,t_1<\cdots<t_n;\alpha(t_i)\in\mathscr{U}_{t_i}\} \tag{3.81a}$$

which is represented, in the notation of Sec. III A, as

$$\alpha=\alpha(t_1)\circ\alpha(t_2)\circ\cdots\circ\alpha(t_n). \tag{3.81b}$$

The transition from $\mathscr{U}$ to $\tilde{\mathscr{U}}$ is made by the stipulation that the null history $\tilde{0}$ and the unit history $\tilde{1}$ are to be taken as single elements of $\tilde{\mathscr{U}}$ [corresponding, respectively, to situations where $\alpha(t)=\phi$ for at least one $t\in\mathrm{supp}(\alpha)$ and $\alpha(t)=\Gamma$ for all $t\in\mathrm{supp}(\alpha)$] and all other elements of $\tilde{\mathscr{U}}$ are $\alpha(t)$'s of the form (3.81) [now called $\tilde{\alpha}(t)$] such that $\tilde{\alpha}(t)\neq\phi$ or Γ for any $t\in\mathrm{supp}(\tilde{\alpha})$.

Given $\tilde{\alpha}$, $\tilde{\beta} \in \tilde{\mathscr{U}}$ with supp $\tilde{\alpha}=A$ and supp $\tilde{\beta}=B$, the various operations in $\tilde{\mathscr{U}}$ are to be interpreted as follows:

(i) $\tilde{\alpha} \leqslant \tilde{\beta}$ if $B \subset A$ and $\tilde{\alpha}(t) \subset \tilde{\beta}(t)$ for all $t \in B$.
(ii) $\tilde{\alpha} \perp \tilde{\beta}$ if $A \cap B \neq \phi$ and $\tilde{\alpha}(t) \cap \tilde{\beta}(t) = \phi$ or at least one $t \in A \cap B$.
(iii) Given $\tilde{\alpha}$ and $\tilde{\beta}$ weakly disjoint [i.e., $\tilde{\alpha}, \tilde{\beta}$ are disjoint, $\tilde{\alpha}(t_0) \cap \tilde{\beta}(t_0) = \phi$, where $t_0 \in A=B$ and $\tilde{\alpha}(t)=\tilde{\beta}(t)$ for $t \in A-\{t_0\}$] we have $\tilde{\alpha} \oplus \tilde{\beta} \in \tilde{\mathscr{U}}$ given by

$$(\tilde{\alpha} \oplus \tilde{\beta})(t) = \begin{cases} \tilde{\alpha}(t_0) \cup \tilde{\beta}(t_0) & \text{for } t=t_0 \\ \tilde{\alpha}(t) (=\tilde{\beta}(t)) & \text{for } t \in A-\{t_0\} \end{cases}. \tag{3.82}$$

(iv) $\tilde{\alpha} \wedge \tilde{\beta} = \tilde{0}$ if $S \equiv \text{supp } \tilde{\alpha} \cup \text{supp } \tilde{\beta}$ is not orientable. When S is orientable, we have [see Eq. (3.18)]

$$(\tilde{\alpha} \wedge \tilde{\beta})(t) = \begin{cases} \tilde{\alpha}(t) & \text{for } t \in A-B \\ \tilde{\beta}(t) & \text{for } t \in B-A, \\ \tilde{\alpha}(t) \subset \tilde{\beta}(t) & \text{for } t \in A \cap B. \end{cases} \tag{3.83}$$

Elements of Ω are, of course, at most countable collections of mutually disjoint elements of $\tilde{\mathscr{U}}$. The operations $\leqslant$, $\perp$, and $\oplus$ in Ω have a straightforward description which is left to the reader. We only describe $\neg \underline{\alpha}$ for $\underline{\alpha}=\{\tilde{\alpha}^{(1)}, \tilde{\alpha}^{(2)}, \ldots\}$.

First we define $\neg\{\tilde{\alpha}\}$ for any $\tilde{\alpha} \in \tilde{\mathscr{U}}$. Let $\text{supp}(\tilde{\alpha})=A=\{t_1, \ldots, t_n\}$ and let $h(\tilde{\alpha})$ be the collection of all elements of $\tilde{\mathscr{U}}$ of the form $\tilde{\alpha}'(t_1) \circ \cdots \circ \tilde{\alpha}'(t_n)$ where $\tilde{\alpha}'(t_i)=\tilde{\alpha}(t_1)$ or $\Gamma - \tilde{\alpha}(t_1)$ $[=\neg\tilde{\alpha}(t_1)$ in the notation of Sec. III A]. The collection $h(\tilde{\alpha})$ includes $\tilde{\alpha}$ itself and history filters disjoint with $\tilde{\alpha}$; it is an element of Ω. In fact

$$h(\tilde{\alpha}) = \underline{1}; \tag{3.84}$$

this is because $h(\tilde{\alpha})$ contains all the possible 2^n history propositions corresponding to the possible choices of the system point being in the subset $\tilde{\alpha}(t_i)$ or $\Gamma - \tilde{\alpha}(t_i)$ at time t_i for $i=1,\ldots,n$. It therefore represents a history proposition which is sure to be realized. We now have

$$\neg\{\tilde{\alpha}\} = h(\tilde{\alpha}) - \{\tilde{\alpha}\}. \tag{3.85}$$

Now let $\underline{\alpha}=\{\tilde{\alpha}^{(1)}, \tilde{\alpha}^{(2)}, \ldots\}$. Put

$$h(\underline{\alpha}) = \bigcup_i h(\tilde{\alpha}^{(i)}), \tag{3.86}$$

where the index i labels the constituents $\tilde{\alpha}^{(i)}$ of $\underline{\alpha}$. By the argument given above, we have again

$$h(\underline{\alpha}) = \underline{1} \tag{3.87}$$

and finally

$$\neg\underline{\alpha} = h(\underline{\alpha}) - \underline{\alpha}. \tag{3.88}$$

States at any time are probability measures on the measurable space $(\Gamma, B(\Gamma))$. Observables at any time t are measurable maps $A_t : B(R) \to B(\Gamma)$. For $E \in B(R)$, $A_t(E)$ represents the subset of the phase space corresponding to the observable (represented by the mapping) A_t having values in E. The probability that, at time t, the observable A_t has values in E, the state being p_t, is

$$P\{A_t \in E | p_t\} = p_t(A_t(E)). \tag{3.89}$$

Temporal evolution, according to the scheme of Sec. III C, is given, for $t<t'$, by [identifying $\mathscr{U}_t = \mathscr{U}_{t'} = B(\Gamma)$] a bijective measurable map $V(t',t)$: $B(\Gamma) \to B(\Gamma)$. This, of course, includes the traditional Hamiltonian evolution as a special case.

Given an initial state p_{t_0} and the family of temporal evolution maps $V(.,.)$, we construct the decoherence functional $d=d_{p_0,V}$ taking a clue from the D_{cl} of Ref. 6 [Eq. IV. 5.3] constructed for Hamiltonian evolution with a given Hamiltonian. We do it for two histories of the form $\alpha=(\alpha_{t_1},\ldots,\alpha_{t_n})$ and $\beta=(\beta_{t_1},\ldots,\beta_{t_n})$ such that $t_0<t_1<\cdots<t_n$. (The general case can be reduced to this by trivially extending the temporal supports of α and β to the union of their temporal supports.) We have [writing $V_{t't}$ for $V(t',t)$]

$$d(\alpha,\beta)=\int_\Gamma dp_{t_0}(\xi_0)K^{(\alpha,\beta)}(\xi_0), \tag{3.90a}$$

where [using the notation $\xi(t;\xi_0)=V_{tt_0}(\xi_0)$]

$$K^{(\alpha,\beta)}(\xi_0)=\begin{cases}1 & \text{if, for every } t_j(j=1,\ldots,n),\xi(t_j;\xi_0)\in\alpha_{t_j}\cap\beta_{t_j}\\ 0 & \text{otherwise}\end{cases}. \tag{3.90b}$$

Explicitly

$$K^{(\alpha,\beta)}(\xi_0)=\int_{\alpha_{t_1}}d\xi_1\int_{\beta_{t_1}}d\eta_1\cdots\int_{\alpha_{t_n}}d\xi_n\int_{\beta_{t_n}}d\eta_n\,\delta(\xi_1-\eta_1)\cdots\delta(\xi_n-\eta_n)\cdot$$

$$\delta[\xi_1-V_{t_1t_0}(\xi_0)]\cdots\delta[\xi_n-V_{t_nt_{n-1}}(\xi_{n-1})]. \tag{3.91}$$

Equation (3.90b) shows that $K^{(\alpha,\beta)}$ is the characteristic function of the subset $E_{\alpha\beta}$ of Γ consisting of those points ξ_0 for which $\xi(t_j;\xi_0)$ lies in $\alpha_{t_j}\cap\beta_{t_j}$ for each $j=1,\ldots,n$. We can, therefore, write

$$d(\alpha,\beta)=p_{t_0}(E_{\alpha\beta}). \tag{3.92}$$

In most practical situations, the probability measure p_{t_0} admits a density and we have $dp_{t_0}(\xi_0)=\rho_{t_0}(\xi_0)d\xi_0$. The δ-functions $\delta(\xi_i-\eta_i)$ in Eq. (3.91) ensure that $d(\alpha,\beta)=0$ for $\alpha\neq\beta$ (in any complete set of histories) showing that the decoherence condition (3.63) is trivially satisfied. Finally, the probability $P(\alpha)=d(\alpha,\alpha)$ that the history α is realized, given by Eq. (3.90), is an expected result.

APPENDIX: HPO (HISTORY PROJECTION OPERATOR) VERSION[9] OF HISTORIES IN STANDARD QUANTUM THEORY

Taking the view that histories of a system are (multitime) propositions about the system, it is desirable to have them represented, if possible, by projection operators in a suitable Hilbert space. To construct this space, consider the Cartesian product of the (naturally isomorphic) copies $\mathscr{H}_t$ $(t\in R)$ of the quantum mechanical Hilbert space $\mathscr{H}$ of the system:

$$\mathscr{V}=\Pi_{t\in R}\mathscr{H}_t. \tag{A1}$$

An element v of the $\mathscr{V}$ is a function $v:R\to\mathscr{H}$ taking $t\in R$ to $v_t\in\mathscr{H}_t\equiv\mathscr{H}$. Let w be a fixed vector in $\mathscr{V}$ whose ''component vectors'' w_t are unit vectors: $\|w_t\|_{\mathscr{H}_t}=1$. Let $\mathscr{F}$ be the subspace of $\mathscr{V}$ consisting of vectors v such that $v_t=w_t$ for all but a finite set of t values. The scalar product $(,)$ on $\mathscr{H}$ induces the following scalar product on $\mathscr{F}$:

$$(v',v)_{\mathscr{F}}=\Pi_{t\in R}(v'_t,v_t). \tag{A2}$$

The completion $\tilde{\mathscr{H}}$ of this inner product space is the desired Hilbert space; it is the infinite tensor product of the $\mathscr{H}_t$'s denoted as

$$\tilde{\mathscr{H}}=\underset{t\in R}{\otimes^w}\mathscr{H}_t. \tag{A3}$$

General linear operators on $\tilde{\mathscr{H}}$ are linear combinations of operators of the form $A=A_{t_1}\otimes\cdots\otimes A_{t_n}$, where A_{t_i} is a linear operator on $\mathscr{H}_{t_i}$ (it should be considered as a tensor product $\otimes_t A_t$ of operators such that $A_t=I_t$, the identity operator on $\mathscr{H}_t$ for all but a finite number of t's) or limits of such linear combinations. Given a set of projection operators $(\alpha_{t_1},\ldots,\alpha_{t_n})$ constituting a history α, the operator

$$\overline{\alpha}=\alpha_{t_1}\otimes\cdots\otimes\alpha_{t_n} \tag{A4}$$

is easily seen to be a projection operator in $\tilde{\mathscr{H}}$; such projection operators are referred to as homogeneous projection operators. Given a set $\alpha^{(1)},\ldots,\alpha^{(k)}$ of homogeneous projection operators in $\tilde{\mathscr{H}}$ which are mutually orthogonal (i.e., $\alpha^{(i)}\,\alpha^{(j)}=0$ for $i\neq j$), the sum $\alpha^{(1)}+\cdots+\alpha^{(k)}$ is also an (inhomogeneous) projection operator. In the HPO formalism, histories are represented by such projection operators in $\tilde{\mathscr{H}}$. One refers to histories as homogeneous or inhomogeneous depending on whether they are represented by homogeneous or inhomogeneous projection operators. If $\overline{\alpha}$ and β are mutually orthogonal homogeneous projection operators representing the histories (more precisely, history propositions) α and β, respectively, then the projection operator $\overline{\alpha}+\beta$ represents the history proposition which means that either α or β is realized.

Inclusion of inhomogeneous histories facilitates the introduction of the logical operation of negation of a history proposition. Given α, $\overline{\alpha}$ as above, the projection operator representing the negation of the history α is the inhomogeneous projection operator $\tilde{I}-\overline{\alpha}$ where $\tilde{I}$ is the identity operator on $\tilde{\mathscr{H}}$.

(Received 28 July 1997; accepted for publication 7 October 1997)

We analyze the structure of the $\kappa=0$ limit of a family of algebras $\mathscr{A}_\kappa$ describing noncommutative versions of space–time, with κ a parameter of noncommutativity. Assuming the Poincaré covariance of the $\kappa=0$ limit, we show that, besides the algebra of functions on Minkowski space, $\mathscr{A}_0$ must contain a nontrivial extra factor $\mathscr{A}_0^I$ which is Lorentz covariant and which does not commute with the functions whenever it is not commutative. We give a general description of the possibilities and analyze some representative examples. © *1998 American Institute of Physics.* [S0022-2488(98)03201-0]

I. INTRODUCTION

In this paper we wish to give a heuristic analysis of the structure of a noncommutative space–time, as might arise from the interplay of quantum theory with gravity, in the limit where the space–time is the usual commutative Minkowski space, that is in the limit when the Planck length tends to zero (when gravity is switched off). We shall show that in this limit one necessarily captures a nontrivial extra factor in the limit algebra besides the algebra $\mathscr{C}(M)$ of functions on Minkowski space M. In view of what is known of particle interactions, it is natural to expect that this extra factor has something to do with gauge theory. We have been aware of this conclusion for some time; it was indeed one of our main motivations in studying gauge theory over the noncommutative algebra of matrix-valued functions,[1] the model for the extra factor being then described by the matrix algebra. We shall see, however, that a matrix algebra is too small to be the extra factor and that furthermore a noncommutative extra factor cannot commute with the algebra $\mathscr{C}(M)$.

We recall briefly the arguments which suggest that the interplay between quantum theory and gravitation leads to a noncommutative space–time. There is first an old semi-classical argument which is recalled Ref. 2, showing that localization loses its meaning at distances of the order of the Planck length λ_p. The argument is that, because of quantum theory, in order to localize an event to within $\Delta x^\mu \sim a$, one needs to transfer an amount of energy of order $1/a$ and that then, in view of general relativity, if a is too small, say $a<\lambda_p$, the energy would create a ''black hole.'' In fact this semi-classical argument can be made more precise[2] and leads to limitations of the form $\Delta x^0 \Sigma \Delta x^k \gtrsim \lambda_p^2$ and $\Sigma_{k<\ell} \Delta x^k \Delta x^\ell \gtrsim \lambda_p^2$ in order to avoid the above phenomena. This suggests that the x^μ do not commute, that the space–time is noncommutative. It is worth noticing here that this is not the only conclusion. For instance, one can argue that since in this argument the x^μ have a length scale, then the metric must enter somewhere and that the above uncertainty relations can be consequences of the quantization of the metric instead of a ''quantization'' of space–time itself.

There is, however, a second argument of a different nature. In classical general relativity, one solves locally Einstein's equations and one extends maximally the solutions. Doing this one obtains possibly a space–time carrying a nontrivial topology. This extension is not just a math-

ematical artifact but is physically relevant. Consider, for instance, the analog of the classical self-energies of point charges. More generally, this has to be taken into account in order to use the old physical idea[3] that gravitation acts as an ultraviolet ''regularization'' because of the fact that it is attractive and has also its own energy-momentum density source. A problem arises when one quantizes the gravitational field. The topology of space–time must then be sensitive to the states of the field. This suggests again that the functions on space–time should be replaced by elements of a noncommutative *-algebra acting on the same states as the quantized gravitation field.

In short there are several arguments suggesting that the space–time becomes noncommutative on the scale of Planck length. Although this is certainly not the only possibility, it is worth studying the consequences which follow from such an assumption when the gravitational interaction is switched off. It is the aim of the next section to analyze the ''shadow'' of such a noncommutativity in the limit when one recovers the Poincaré-covariant physical theory in the usual Minkowski space. This analysis is sharpened in Sec. III where it is pointed out that the limit has a structure of crossed product and the Hochschild two-cocycle associated with the deformation is identified as a group cocycle of the dual of the group of space–time translations. Then, in Sec. IV, we shall discuss in this context various recent proposals and, in particular, the generalizations of gauge theory using noncommutative differential calculi.[1,4,5]

II. THE COMMUTATIVE SPACE–TIME LIMIT

Let $\mathscr{A}_\kappa$ be a one-parameter family of associative algebras. Here we think of κ as being the gravitational constant λ_p^2 and we think of $\mathscr{A}_\kappa$ as being a noncommutative version of the functions on space–time. Technically, we use the framework of formal deformation theory of associative algebras.[6,7] This means that we assume that, as vector spaces, all the $\mathscr{A}_\kappa$ coincide with a fixed vector space E and that, for $f,g\in E$, one can expand their product $(fg)_\kappa$ in $\mathscr{A}_\kappa$ as

$$(fg)_\kappa = fg + \kappa c(f,g) + o(\kappa^2), \tag{1}$$

where $fg=(fg)_0$ is the product in $\mathscr{A}_0$. We also assume that there is a distinguished element, $1\in E$, which is the unit for each algebra $\mathscr{A}_\kappa$. The bilinear map $(f,g)\mapsto c(f,g)$ is then a normalized Hochschild two-cocycle of $\mathscr{A}_0$ with values in $\mathscr{A}_0$.[6] In terms of commutators, (1) yields

$$[f,\ g]_\kappa = [f,\ g] - i\kappa\{f,g\} + o(\kappa^2), \tag{2}$$

where the bracket $(f,g)\mapsto\{f,g\}$ is defined by

$$\{f,g\} = i(c(f,g) - c(g,f)) \tag{3}$$

and where $[f,\ g]_\kappa$ and $[f,\ g]$ denote the commutator in $\mathscr{A}_\kappa$ and in $\mathscr{A}_0$, respectively. The first order in κ of the identity $[h,\ (fg)_\kappa]_\kappa = ([h,\ f]_\kappa g)_\kappa + (f[h,\ g]_\kappa)_\kappa$ yields the condition

$$i([h,\ c(f,g)] - c([h,\ f],g) - c(f,[h,\ g])) = f\{h,g\} - \{h,fg\} + \{h,f\}g. \tag{4}$$

This implies that, if h is an element of the center $Z(\mathscr{A}_0)$ of $\mathscr{A}_0$, then the endomorphism δ_h of $\mathscr{A}_0$ defined by $\delta_h(f)=\{h,f\}$ is a derivation of $\mathscr{A}_0$. The center $Z(\mathscr{A}_0)$ of $\mathscr{A}_0$ is stable under the derivations of $\mathscr{A}_0$ and therefore $Z(\mathscr{A}_0)$ is stable under the bracket (3). On the other hand, if f, g, and h are elements of $Z(\mathscr{A}_0)$, then the lowest nontrivial order in κ (i.e., the second order) of $[[f,\ g]_\kappa,\ h]_\kappa = [[f,\ h]_\kappa,\ g]_\kappa + [f,\ [g,h]_\kappa]_\kappa$ yields the condition

$$\{\{f,g\},h\} = \{\{f,h\},g\} + \{f,\{g,h\}\}. \tag{5}$$

So one can summarize the above discussion by the following proposition:

Proposition 1: The center $Z(\mathscr{A}_0)$ of $\mathscr{A}_0$ is a (commutative) Poisson algebra with Poisson bracket given by (3) and one defines a linear mapping $z\mapsto\delta_z$ of $Z(\mathscr{A}_0)$ into the Lie algebra Der$(\mathscr{A}_0)$ of all derivations of $\mathscr{A}_0$ by setting $\delta_z(f)=\{z,f\}$ for $z\in Z(\mathscr{A}_0)$ and $f\in\mathscr{A}_0$ which satisfies $\delta_{zz'}=z\delta_{z'}+z'\delta_z$ for $z,z'\in Z(\mathscr{A}_0)$.

This result is known; it is the first part of Proposition 1.2 of Ref. 8 (see also Ref. 9).

We wish to represent the noncommutative analog of real functions by Hermitian elements. This leads us to add the following reality condition to the above general structure. We assume that

the $\mathscr{A}_\kappa$ are complex $*$-algebras such that all the underlying complex involutive vector spaces coincide. Thus the vector space E must be a complex vector space equipped with an antilinear involution, $f\mapsto f^*$, and a distinguished Hermitian element $\mathbb{1}=\mathbb{1}^*$. The parameter κ is real (consistently) and one has $(fg)^*_\kappa=(g^*f^*)_\kappa$ and $(f\mathbb{1})_\kappa=(\mathbb{1}f)_\kappa=f$. It follows that the normalized cocycle c satisfies $c(f,g)^*=c(g^*,f^*)$, which implies that the bracket (3) is real, i.e., $\{f,g\}^*=\{f^*,g^*\}$. Therefore, *the set* $Z_{\mathbb{R}}(\mathscr{A}_0)$ *of all Hermitian elements of the center* $Z(\mathscr{A}_0)$ *of* $\mathscr{A}_0$ *is a real (commutative) Poisson algebra and the map* $z\mapsto\delta_z$ *induces a real linear mapping of* $Z_{\mathbb{R}}(\mathscr{A}_0)$ *into the real Lie algebra* $\mathrm{Der}_{\mathbb{R}}(\mathscr{A}_0)$ *of all Hermitian derivations of* $\mathscr{A}_0$.

We now return to our specific problem. The $\mathscr{A}_\kappa$ are noncommutative versions of the algebra of functions on space–time and we wish to recover Poincaré-invariant physics on Minkowski space M in the limit $\kappa=0$. We thus assume that the Poincaré group $\mathfrak{P}$ acts by $*$-automorphisms $(\Lambda,a)\to\alpha_{(\Lambda,a)}$ on $\mathscr{A}_0$, that $\mathscr{A}_0$ contains as a $*$-subalgebra the (commutative) algebra $\mathscr{C}(M)$ of (smooth) functions on Minkowski space, and that the action of $\mathfrak{P}$ on $\mathscr{A}_0$ induces its usual action on $\mathscr{C}(M)$ associated with the corresponding transformations of M. We now argue that $\mathscr{C}(M)$ cannot be the whole $\mathscr{A}_0$. In fact, assume that $\mathscr{C}(M)$ is equal to $\mathscr{A}_0$. Then, in view of Proposition 1, there is a Poisson bracket on M. This Poisson bracket is nontrivial since we have assumed that the $\mathscr{A}_\kappa$ are noncommutative. On the other hand, there does not exist a nontrivial Poincaré-invariant Poisson bracket on M. Indeed let $(f,g)\mapsto\{f,g\}$ be such a Poisson bracket. Then $\{f,g\}=\omega^{\mu\nu}(\partial_\mu f)(\partial_\nu g)$ where $\omega^{\mu\nu}=\{x^\mu,x^\nu\}$ must be an antisymmetric tensor field on M which is constant by translational invariance and Lorentz invariant. However rotational invariance already implies that the three-vector $E^i=\omega^{0i}$ and $B^i=\Sigma_{j,k=1}^3\epsilon_{ijk}\omega^{jk}$, $i\in\{1,2,3\}$, vanish which implies $\omega^{\mu\nu}=0$ and therefore $\{f,g\}=0\forall f$, $g\in\mathscr{C}(M)$. It seems unreasonable to us that the Poincaré invariance be broken at the first order in κ. In fact, at this order, we expect a Poincaré-invariant theory involving a spin-2 field linearly coupled to the other fields. Once this hypothesis is accepted, it follows that the inclusion $\mathscr{C}(M)\subset\mathscr{A}_0$ must be a strict one; the $\kappa=0$ limit $\mathscr{A}_0$ of the $\mathscr{A}_\kappa$ must contain an extra factor. It follows also that the normalized two-cocycle c of $\mathscr{A}_0$ defined by (1) is Poincaré invariant, so one has the condition

$$\alpha_{(\Lambda,a)}(c(f,g))=c(\alpha_{(\Lambda,a)}(f),\alpha_{(\Lambda,a)}(g)),\quad\forall(\Lambda,a)\in\mathfrak{B},\quad\forall f,g\in\mathscr{A}_0,\tag{6}$$

which implies the invariance of the bracket (3).

Let $x^\mu\in\mathscr{C}(M)$ be Minkowskian coordinates. Then the algebra $\mathscr{C}(M)$ is generated by the x^ν and the action of the Poincaré group on it is given by

$$\alpha_{(\Lambda,a)}x^\mu=\Lambda^{-1\mu}_\nu(x^\nu-a^\nu\mathbb{1}).\tag{7}$$

By choosing an origin, one can identify $\mathscr{C}(M)$ with the Hopf algebra of functions on the group of translations. Since $\mathscr{C}(M)$ is a subalgebra of $\mathscr{A}_0$, the latter is (in particular) a bimodule over $\mathscr{C}(M)$. Furthermore, by restricting attention to the action of translations, $\mathscr{A}_0$ is in fact a bicovariant bimodule over the algebra of functions on the group of translations.[10,11] By standard arguments,[10,11] $\mathscr{A}_0$ is isomorphic as left $\mathscr{C}(M)$-module to $\mathscr{C}(M)\otimes\mathscr{A}_0^I$ where $\mathscr{A}_0^I$ denotes the subalgebra of translationally invariant elements of $\mathscr{A}_0$: $\mathscr{A}_0^I=\{f\in\mathscr{A}_0|\,\alpha_{(1,a)}f=f,\forall a\}$. In fact $\mathscr{A}_0$ is isomorphic to $\mathscr{C}(M)\otimes\mathscr{A}_0^I$ as $(\mathscr{C}(M),\mathscr{A}_0^I)$-bimodule. Thus in order to recover the complete structure of algebra of $\mathscr{A}_0$ in the representation $\mathscr{C}(M)\otimes\mathscr{A}_0^I$, it is sufficient to describe the right multiplication by elements of $\mathscr{C}(M)$ of elements of $\mathscr{A}_0^I$. For each Minkowskian coordinate x^μ, it follows from (7) that $\mathscr{A}_0^I$ is stable under the derivation $f\mapsto\mathrm{ad}(x^\mu)(f)=[x^\mu,f]$ and therefore one has $fx^\mu=x^\mu f-\mathrm{ad}(x^\mu)(f)$, $\forall f\in\mathscr{A}_0^I$, which can be written in the representation $\mathscr{A}_0=\mathscr{C}(M)\otimes\mathscr{A}_0^I$:

$$fx^\mu=x^\mu\otimes f-\mathbb{1}\otimes\mathrm{ad}(x^\mu)(f),\quad\forall f\in\mathscr{A}_0^I.\tag{8}$$

From this one deduces the right multiplication by elements of $\mathscr{C}(M)$, i.e., the right $\mathscr{C}(M)$-module structure of $\mathscr{C}(M)\otimes\mathscr{A}_0^I$, which is in fact isomorphic to $\mathscr{A}_0^I\otimes\mathscr{C}(M)$ as right $\mathscr{C}(M)$-module. In the following, we shall denote by X^μ the four commuting derivations of $\mathscr{A}_0^I$ induced by the $\mathrm{ad}(x^\mu)$. The algebra $\mathscr{A}_0^I$ is invariant under the automorphisms $\alpha_{(\Lambda,0)}$. We shall denote by $\alpha^I:\Lambda\mapsto^I_\Lambda$, the corresponding homomorphism of the Lorentz group into the group Aut $(\mathscr{A}_0^I)$ of all $*$-automorphisms of $\mathscr{A}_0^I$.

One can thus summarize the above discussion by the following presentation of $\mathscr{A}_0$. One starts with a unital $*$-algebra $\mathscr{A}_0^I$ equipped with four commuting anti-Hermitian derivations X^μ and an action $\Lambda \mapsto \alpha_\Lambda^I$ of the Lorentz group by automorphisms of $\mathscr{A}_0^I$ such that

$$\alpha_\Lambda^I \circ X^\mu = \Lambda_\nu^{-1\mu} X^\nu \circ \alpha_\Lambda^I \tag{9}$$

and $\mathscr{A}_0$ is ''generated'' as unital $*$-algebra by $\mathscr{A}_0^I$ and four Hermitian elements x^μ with relations $x^\mu x^\nu = x^\nu x^\mu$ and $x^\mu f = f x^\mu + X^\mu(f)$, $f \in \mathscr{A}_0^I$. We put quotes on the word generated in the above sentence because we do not pay attention here to functional analysis aspects, for instance appropriate completions, etc. The Poincaré group acts on $\mathscr{A}_0$ by the action $\alpha_{(\Lambda,a)}$ on $\mathscr{C}(M)$ defined by (7) and by $\alpha_{(\Lambda,a)}(f) = \alpha_\Lambda^I(f)$ for $f \in \mathscr{A}_0^I$.

We have assumed that the bracket (3) is not identically zero on $\mathscr{C}(M)$. This implies that the $c^{\mu\nu} = c(x^\mu, x^\nu)$ do not all vanish. On the other hand, it follows from (7) that $c^{\mu\nu}$ are elements of $\mathscr{A}_0^I$ and (6) implies then that one has

$$\alpha_\Lambda^I(c^{\mu\nu}) = \Lambda_\alpha^{-1\mu} \Lambda_\beta^{-1\nu} c^{\alpha\beta}. \tag{10}$$

Thus the homomorphism $\alpha^I : \mathfrak{L} \to \mathrm{Aut}(\mathscr{A}_0^I)$ of the Lorentz group $\mathfrak{L}$ into the group of $*$-automorphisms of $\mathscr{A}_0^I$ *is never trivial*. This places severe restrictions on the structure of the extra factor $\mathscr{A}_0^I$. For instance, $\mathscr{A}_0^I$ cannot be a finite-dimensional matrix algebra because on such an algebra all automorphisms are inner and, on the other hand, it is known that the Lorentz group has no nontrivial finite-dimensional unitary representation. The same argument shows that, if $\mathscr{A}_0^I$ admits an injective (eventually unbounded) $*$-representation in a Hilbert space, then $\mathscr{A}_0^I$ must be infinite dimensional.

III. CROSSED-PRODUCT STRUCTURE OF $\mathscr{A}_0$

There is another useful presentation of $\mathscr{A}_0$ which is a sort of exponentiation of the previous one and which can be used for a functional-analytic development of the framework. Let $\mathfrak{T}^*$ be the space $\mathbb{R}^4$ considered as the dual of the group $\mathfrak{T}$ of translations of the Minkowski space M. Instead of taking the x^μ as generators of $\mathscr{C}(M)$ we now choose the exponentials $u(k) = \exp(ik_\mu x^\mu)$ for $k \in \mathfrak{T}^*$. One has

$$u(0) = \mathbb{1}, \quad u(k)u(\ell) = u(k+\ell), \quad u(k)^* = u(-k) = u(k)^{-1}, \tag{11}$$

and (7) now yields with $(\Lambda k)_\mu = k_\nu \Lambda_\mu^{-1\nu}$,

$$\alpha_{(\Lambda,a)} u(k) = u(\Lambda k) \exp(-i(\Lambda k)_\mu a^\mu). \tag{12}$$

If $f \in \mathscr{A}_0^I$, then $\tau_k(f) = u(k) f u(-k)$ is also in $\mathscr{A}_0^I$ and $k \mapsto \tau_k$ is a homomorphism of the additive group $\mathfrak{T}^*$ into the group of $*$-automorphisms of $\mathscr{A}_0^I$. This homomorphism is in fact the exponential version of the derivations X^μ, $(\tau_k = \exp(ik_\mu X^\mu))$, and (9) is replaced by

$$\alpha_\Lambda^I \circ \tau_k = \tau_{\Lambda k} \circ \alpha_\Lambda^I. \tag{13}$$

The $*$-algebra $\mathscr{A}_0$ is generated by the $*$-algebra $\mathscr{A}_0^I$ and the $u(k)$, $k \in \mathfrak{T}^*$ with the relations (11) and the relation

$$u(k) f = \tau_k(f) u(k), \quad \forall f \in \mathscr{A}_0^I \quad \text{and} \quad \forall k \in \mathfrak{T}^*. \tag{14}$$

The action of the Poincaré group on $\mathscr{A}_0$ is given by (12) and by

$$\alpha_{(\Lambda,a)}(f) = \alpha_\Lambda^I(f), \quad \forall f \in \mathscr{A}_0^I. \tag{15}$$

The consistency is ensured by the relation (13). We can summarize the above discussion by the following proposition:

Proposition 2: The $*$-subalgebra $\mathscr{A}_0^I$ of translationally invariant elements of $\mathscr{A}_0$ is equipped with an action τ of the dual group $\mathfrak{T}^*$ of the group $\mathfrak{T}$ of translations by $*$-automorphisms and $\mathscr{A}_0$

is isomorphic to the crossed product of $\mathscr{A}_0^I$ with $\mathfrak{T}^*$ for τ. Furthermore, $\mathscr{A}_0^I$ is equipped with an action α^I of the Lorentz group by $*$-automorphisms which is connected with τ by (13) and the action of the Poincaré group on $\mathscr{A}_0$ is given by (12) and (15).

In this proposition, the crossed product is taken in the category of unital $*$-algebras. However, one can accommodate various functional analytic generalizations by working in the appropriate categories of topological $*$-algebras. This partly depends what one has in mind for the algebra $\mathscr{C}(M)$ of functions on space–time [the linear decomposition of the elements of $\mathscr{C}(M)$ over the $u(k)$ being the Fourier transformation].

Let us now consider the description of the cocycle c in this framework. The restriction of c to $\mathscr{C}(M)\times\mathscr{C}(M)$ is an $\mathscr{A}_0$-valued normalized Hochschild two-cocycle on $\mathscr{C}(M)$ which is described by the $c(u(k),u(l))$, $k,l\in\mathfrak{T}^*$. The invariance and the reality conditions yield

$$\alpha_{(\Lambda,a)}c(u(k),u(\ell))=c(u(\Lambda k),u(\Lambda\ell))\exp(-i(\Lambda(k+\ell))_\mu a^\mu), \tag{16}$$

$$c(u(k),u(\ell))^*=c(u(-\ell),u(-k)). \tag{17}$$

Define $\gamma(k,\ell)\in\mathscr{A}_0$ for $k,\ell\in\mathfrak{T}^*$ by

$$c(u(k),u(\ell))=\gamma(k,\ell)u(k+\ell). \tag{18}$$

It follows from (16) (with $\Lambda=I$) that the $\gamma(k,\ell)$ are translationally invariant, that is $\gamma(k,\ell)\in\mathscr{A}_0^I$, $\forall k,\ell\in\mathfrak{T}^*$. The reality condition (17) becomes

$$\gamma(k,\ell)^*=\tau_{k+\ell}\gamma(-\ell,-k) \tag{19}$$

and (16) yields the action

$$\alpha_\Lambda^I\gamma(k,\ell)=\gamma(\Lambda k,\Lambda\ell). \tag{20}$$

On the other hand the cocycle relation on $\mathscr{C}(M)$

$$u(k)c(u(\ell),u(m))-c(u(k)u(\ell),u(m))+c(u(k),u(\ell)u(m))-c(u(k),u(\ell))u(m)=0.$$

is equivalent to the relation

$$\tau_k\gamma(\ell,m)-\gamma(k+\ell,m)+\gamma(k,\ell+m)-\gamma(k,\ell)=0, \tag{21}$$

and, since $\gamma(k,0)=\gamma(0,k)=0$ follows from $c(\mathbb{1},x)=c(x,\mathbb{1})=0$, one has the following result:

Lemma 1: The mapping $\gamma:\mathfrak{T}^*\times\mathfrak{T}^*\to\mathscr{A}_0^I$ defined by (18) is an $\mathscr{A}_0^I$-valued normalized two-cocycle of the group $\mathfrak{T}^*$ for τ which is real, in the sense of (19), and Lorentz invariant, in the sense of (20).

Thus starting from $(\mathscr{A}_0^I,\tau,\alpha^I)$, one reconstructs $\mathscr{A}_0$ with its Poincaré automorphism by using Proposition 2 and one reconstructs the restriction to $\mathscr{C}(M)\times\mathscr{C}(M)$ of the Hochschild cocycle c from the $\mathscr{A}_0^I$-valued group cocycle γ as in Lemma 1 by formula (18). The missing items are the values of c on $\mathscr{A}_0^I\times\mathscr{C}(M)$ and on $\mathscr{A}_0^I\times\mathscr{A}_0^I$. Indeed let f and g be arbitrary elements of $\mathscr{A}_0^I$ and k,ℓ be in $\mathfrak{T}^*$. Then the cocycle relation implies

$$\begin{aligned}c(fu(k),u(\ell)g)=&(f\gamma(k,\ell)\tau_{k+\ell}(g)+c(f,\tau_{k+\ell}(g)))u(k+\ell)\\&+c(f\tau_{k+\ell}(g),u(k+\ell))-fu(k)c(u(\ell),g)-c(f,u(k))u(\ell)g\\&+fc(u(k+\ell),g)-fc(\tau_{k+\ell}(g),u(k+\ell)).\end{aligned} \tag{22}$$

This relation expresses the cocycle c on $\mathscr{A}_0\times\mathscr{A}_0$ in terms of its restrictions to $\mathscr{C}(M)\times\mathscr{C}(M)$, to $\mathscr{A}_0^I\times\mathscr{A}_0^I$, to $\mathscr{A}_0^I\times\mathscr{C}(M)$, and to $\mathscr{C}(M)\times\mathscr{A}_0^I$. By taking into account the reality condition (17), the restriction of c to $\mathscr{C}(M)\times\mathscr{A}_0^I$ can be expressed in terms of its restriction to $\mathscr{A}_0^I\times\mathscr{C}(M)$. Thus c is known whenever its restrictions to $\mathscr{C}(M)\times\mathscr{C}(M)$, to $\mathscr{A}_0^I\times\mathscr{A}_0^I$, and to $\mathscr{A}_0^I\times\mathscr{C}(M)$ are known. It follows from (6) that the restriction c^I of c to $\mathscr{A}_0^I\times\mathscr{A}_0^I$ is $\mathscr{A}_0^I$-valued and, therefore, c^I is a normalized ($\mathscr{A}_0^I$-valued) two-cocycle of $\mathscr{A}_0^I$ which satisfies the invariance condition

$$\alpha^I_\Lambda c^I(f,g)=c^I(\alpha^I_\Lambda f,\alpha^I_\Lambda g), \tag{23}$$

and the reality condition

$$c^I(f,g)^*=c^I(g^*,f^*), \tag{24}$$

for any $f,\ g\in\mathscr{A}^I_0$ and $\Lambda\in\mathfrak{L}$.

We define $\lambda(f,k)$ for $f\in\mathscr{A}^I_0$ and $k\in\mathfrak{T}^*$ by

$$c(f,u(k))-c(u(k),\tau_{-k}(f))=\lambda(f,k)u(k). \tag{25}$$

It follows from (12) that $\lambda(f,k)$ belongs to $\mathscr{A}^I_0$ and, therefore, λ is a map of $\mathscr{A}^I_0\times\mathfrak{T}^*$ into $\mathscr{A}^I_0$, linear in the first factor, which satisfies the Lorentz-invariance condition

$$\alpha^I_\Lambda\lambda(f,k)=\lambda(\alpha^I_\Lambda f,\Lambda k), \tag{26}$$

the normalization conditions

$$\lambda(f,0)=0,\quad \lambda(\mathbb{1},k)=0, \tag{27}$$

and the reality condition

$$\lambda(f,k)^*=-\tau_k(\lambda(\tau_{-k}(f^*),-k)). \tag{28}$$

The cocycle relation for c implies that one has

$$f\gamma(k,\ell)-\gamma(k,\ell)f=\tau_k(\lambda(\tau_{-k}(f),\ell))-\lambda(f,k+\ell)+\lambda(f,k) \tag{29}$$

and

$$c^I(f,g)-\tau_k(c^I(\tau_{-k}(f),\tau_{-k}(g)))=f\lambda(g,k)-\lambda(fg,k)+\lambda(f,k)g \tag{30}$$

for any $k,l\in\mathfrak{T}^*$ and $f,g\in\mathscr{A}^I_0$. Conversely if c^I, γ, λ as above are such that c^I is a Hochschild two-cocycle on $\mathscr{A}^I_0$ and such that (21), (29), and (30) are satisfied, then c is a two-cocycle on $\mathscr{A}_0$, i.e., the cocycle relation for c is equivalent to the cocycle relation for c^I and the relations (21), (29), and (30).

We now describe another way to present these relations. We first extend the action τ of $\mathfrak{T}^*$ on $\mathscr{A}^I_0$ into an action on the $\mathscr{A}^I_0$-valued Hochschild cochains on $\mathscr{A}^I_0$ by setting $\tau_k(\omega)(f_1,\ldots,f_n)=\tau_k(\omega(\tau_{-k}(f_1),\ldots,\tau_{-k}(f_n)))$ for $k\in\mathfrak{T}^*$, $f_i\in\mathscr{A}^I_0$, where $\omega\in C^n(\mathscr{A}^I_0,\mathscr{A}^I_0)$ is an $\mathscr{A}^I_0$-valued Hochschild n-cochain on $\mathscr{A}^I_0$. Let $C^{r,s}$ denote the space of $C^r(\mathscr{A}^I_0,\mathscr{A}^I_0)$-valued s-cochains on the group $\mathfrak{T}^*$. One has two differentials on the direct sum $C=\oplus C^{r,s}$. The first one is the composition with the Hochschild differential of $C(\mathscr{A}^I_0,\mathscr{A}^I_0)$ which will be denoted by $\delta^{(1,0)}$. The second one is the group differential of $\mathfrak{T}^*$ for its action τ on $C^r(\mathscr{A}^I_0,\mathscr{A}^I_0)$ which will be denoted by $(-1)^r\delta^{(0,1)}$. One has $\delta^{(1,0)}(C^{r,s})\subset C^{r+1,s}$ $\delta^{(0,1)}(C^{r,s})\subset C^{r,s+1}$ and $\delta^{(1,0)}\delta^{(0,1)}+\delta^{(0,1)}\delta^{(1,0)}=0$. Therefore $\delta=\delta^{(1,0)}+\delta^{(0,1)}$ is again a differential of degree one for the total degree $r+s$. One can restrict all differentials to the space of normalized cochains (i.e., normalized group cochains with values in normalized Hochschild cochains). One has $c^I\in C^{2,0}$, $\lambda\in C^{1,1}$, and $\gamma\in C^{0,2}$. Furthermore, the cocycle condition for c^I and the relations (21), (29), and (30) reduce to $(\delta^{(1,0)}+\delta^{(0,1)})(c^I+\lambda+\gamma)=0$. Indeed the (3,0) part of this relation $\delta^{(1,0)}c^I=0$ is the cocycle relation for c^I, the (2,1) part $\delta^{(0,1)}c^I+\delta^{(1,0)}\lambda=0$ is relation (30), and (1,2) part $\delta^{(0,1)}\lambda+\delta^{(1,0)}\gamma=0$ is relation (29), and the (0,3) part $\delta^{(0,1)}\gamma=0$ is the group cocycle relation (21).

Proposition 3: The cocycle condition for c is equivalent to $(\delta^{(1,0)}+\delta^{(0,1)})(c^I+\lambda+\gamma)=0$, i.e., to the cocycle condition for $c^I+\lambda+\gamma$ in C. Moreover, the addition of the Hochschild coboundary of a translationally invariant one-cochain to c is equivalent to the addition to $c^I+\lambda+\gamma$ of a term $(\delta^{(1,0)}+\delta^{(0,1)})(\beta^{(1,0)}+\beta^{(0,1)})$ with $\beta^{(1,0)}\in C^{(1,0)}$ and $\beta^{(0,1)}\in C^{(0,1)}$.

Indeed, if one adds to c the coboundary of b with b such that $\alpha_{(1,a)}(b(f))=b(\alpha_{(1,a)}(f))$ for $a\in\mathfrak{T}$ and $f\in\mathscr{A}_0$, then $\beta^{(1,0)}$ is the restriction of b to $\mathscr{A}^I_0$ and $\beta^{(0,1)}$ is given by $\beta^{(0,1)}(k)=b(u(k))u(-k)$ for $k\in\mathfrak{T}^*$; the invariance of b implies that $\beta^{(1,0)}$ and $\beta^{(0,1)}$ are $\mathscr{A}^I_0$ valued.

The above result is a particular case of results of Ref. 12 on the Hochschild cohomology of crossed products. Here the simplification comes from the fact that we are only interested on cochains of $\mathscr{A}_0$ which are invariant by translations (and in fact by Poincaré transformations).

It is worth noticing here that the data c^I, λ, and γ do not determine c completely. However, by using the formula (22) one can show that c is determined by c^I, λ, and γ to within the coboundary of a translationally invariant one-cochain b of $\mathscr{A}_0$ which is such that the corresponding $\beta^{(1,0)}$ and $\beta^{(0,1)}$ as above vanish identically.

For $\kappa \neq 0$, the algebra $\mathscr{A}_\kappa$ is generated by the noncommutative version of the functions on space–time. This implies that $\mathscr{A}_0$ is generated by the algebra $\mathscr{C}(M)$ of functions on space–time and the iterated applications of the cocycle c on $\mathscr{C}(M)$. More precisely, we define an increasing filtration F^n of $\mathscr{A}_0$ by unital *-subalgebras $F^n(\mathscr{A}_0)$ by setting $F^0(\mathscr{A}_0)=\mathscr{C}(M)$ and $F^{n+1}(\mathscr{A}_0)$ $=\{$*the subalgebra of $\mathscr{A}_0$ generated by $F^n(\mathscr{A}_0)$ and by $c(F^r(\mathscr{A}_0), F^s(\mathscr{A}_0)\}$* for $r+s=n(\in\mathbb{N})$. Then, our assumption means that one has $\mathscr{A}_0=\cup_n F^n(\mathscr{A}_0)=F^\infty(\mathscr{A}_0)$. Correspondingly one has an increasing filtration of $\mathscr{A}_0^I$ by unital *-subalgebras $F^n(\mathscr{A}_0^I)$ $=F^n(\mathscr{A}_0)\cap\mathscr{A}_0^I$ which is such that $F^0(\mathscr{A}_0^I)=\mathbb{C}\!\!1$, $\mathscr{A}_0^I=\cup F^n(\mathscr{A}_0^I)=F^\infty(\mathscr{A}_0^I)$ and which is Lorentz invariant, i.e., $\alpha_\Lambda^I F^n(\mathscr{A}_0^I)\subset F^n(\mathscr{A}_0^I)$ for $\Lambda\in\mathscr{L}$.

IV. DISCUSSION

The simplest cases correspond to the situation where $\mathscr{C}(M)$ is in the center of $\mathscr{A}_0$, i.e., where τ is trivial. In this case, one can assume that, up to a coboundary, c is antisymmetric on $\mathscr{C}(M)$ and in fact on $Z(\mathscr{A}_0)$ [this corresponds to a weak regularity assumption on the commutative algebra $Z(\mathscr{A}_0)$]. It then follows from the discussion in the end of last section that one has $\mathscr{A}_0$ $=Z(\mathscr{A}_0)$, i.e., that $\mathscr{A}_0$ is a commutative Poisson algebra and that the $\mathscr{A}_\kappa$ are obtained by ''quantization'' of $\mathscr{A}_0$. In this case $\mathscr{A}_0$ is, as algebra, the tensor product $\mathscr{C}(M)\otimes\mathscr{A}_0^I$. Since the $\{x^\mu,x^\nu\}$ are elements of $\mathscr{A}_0^I$ and since the Lorentz group acts there by automorphisms, $\mathscr{A}_0^I$ must contain as subalgebra an algebra of functions on a union of Lorentz orbits of antisymmetric two-tensors. The $\{x^\mu,x^\nu\}$ are then coordinate functions on this manifold of antisymmetric tensors and the orbits occurring are labeled by the pairs (α,β) of real numbers such that α is in the spectrum of $g_{\mu\mu'}g_{\nu\nu'}\{x^\mu,x^\nu\}\{x^{\mu'},x^{\nu'}\}$ and β is in the spectrum of $\varepsilon_{\alpha\beta\gamma\delta}\{x^\alpha,x^\beta\}\{x^\gamma,x^\delta\}$. It is natural to require time reversal and parity be defined and therefore to assume that whenever one has the orbit (α,β), one also has the orbit $(\alpha,-\beta)$. When furthermore one has $\{x^\lambda,\{x^\mu,x^\nu\}\}$ $=0(\forall\lambda,\mu,\nu)$, then $\mathscr{A}_0^I$ is just such an algebra of functions on a union of orbits of antisymmetric tensors. This is precisely the case for the algebra $\mathscr{A}_0$ which is the $\kappa=0$ limit of the model of Doplicher, Fredenhagen, and Robert[2] where the orbits there are (0,1) and $(0,-1)$. It is not very difficult to construct examples with $\{x^\lambda,\{x^\mu,x^\nu\}\}\neq 0$.

As pointed out above, in order to have a noncommutative algebra $\mathscr{A}_0$, it is necessary (and obviously sufficient) that the algebra $\mathscr{C}(M)$ of functions on space–time not be included in the center of $\mathscr{A}_0$, which means that τ is nontrivial. Since by assumption the cocycle γ defined by (18) is nontrivial, the simplest cases with τ nontrivial are the cases where λ and c^I vanish. In such a case, it follows from (29) that the image of γ is in the center of $\mathscr{A}_0^I$ and that $F^{n+1}(\mathscr{A}_0)$ $=F^1(\mathscr{A}_0)$, $\forall n\in\mathbb{N}$. Therefore, in view of the discussion at the end of last section, $\mathscr{A}_0$ $=F^1(\mathscr{A}_0)$ and $\mathscr{A}_0^I$ is the commutative algebra generated by the $\gamma(k,\ell)$, (or, equivalently, by the $\{x^\mu,x^\nu\}$). Thus in such a case $\mathscr{A}_0$ is the crossed product of the commutative algebra $\mathscr{A}_0^I$ with $\mathfrak{T}^*$ for τ. An example of this situation is provided by the $\kappa=0$ limit of an example elaborated by Doplicher and Fredenhagen described in Section 2 of Ref. 13. It is worth noticing here that in the $\kappa=0$ limits of examples of Refs. 2 and 13 the orbits of antisymmetric two-tensors occurring are (0,1) and $(0,-1)$ (recall that in these examples $\mathscr{A}_0^I$ is commutative). This is connected with the fact that these authors construct $\mathscr{A}_\kappa$ in such a way that physically motivated space–time uncertainty relations are implemented.

Generically τ is nontrivial and λ and c^I do not vanish. A simple example of this kind can be easily found. For $\kappa\in\mathbb{R}$, let $\mathscr{A}_\kappa$ be the unital *-algebra generated by Hermitian elements x^μ, L^μ, and $I^{\mu\nu}$ $(\mu,\nu=0,1,2,3)$ satisfying the relations

$$[x^\mu,x^\nu]=i\kappa I^{\mu\nu},$$

$$[x^\lambda,I^{\mu\nu}]=i(g^{\lambda\nu}L^\mu-g^{\lambda\mu}L^\nu), \tag{31}$$

$$[x^\mu, L^\nu] = i\kappa I^{\mu\nu},$$

$$[I^{\lambda\rho}, I^{\mu\nu}] = i(g^{\lambda\nu} I^{\mu\rho} - g^{\rho\nu} I^{\mu\lambda} + g^{\rho\mu} I^{\nu\lambda} - g^{\lambda\mu} I^{\nu\rho}),$$

$$[L^\lambda, I^{\mu\nu}] = i(g^{\lambda\nu} L^\mu - g^{\lambda\mu} L^\nu), \tag{32}$$

$$[L^\mu, L^\nu] = i\kappa I^{\mu\nu},$$

where $g^{\mu\nu}$ denotes the Minkowskian metric with $g^{00} = -1$ and $g^{11} = g^{22} = g^{33} = 1$. It follows from these relations that for $\kappa \neq 0$, $\mathscr{A}_\kappa$ is generated by the x^μ. This implies that $\mathscr{A}_0$ satisfies the property $\mathscr{A}_0 = \cup_n F^n(\mathscr{A}_0)$ of the end of last section. In fact here one has again $F^{n+1}(\mathscr{A}_0) = F^1(\mathscr{A}_0)$, $\forall n \in \mathbb{N}$. Furthermore there is (for any κ) an action of the Poincaré group $\mathfrak{B}$ by *-automorphisms $(\Lambda, a) \mapsto \alpha_{(\Lambda,a)}$ on $\mathscr{A}_\kappa$ given by

$$\alpha_{(\Lambda,a)} x^\mu = \Lambda^{-1\mu}_{\ \ \nu}(x^\nu - a^\nu), \quad \alpha_{(\Lambda,a)} L^\mu = \Lambda^{-1\mu}_{\ \ \nu} L^\nu, \quad \alpha_{(\Lambda,a)} I^{\mu\nu} = \Lambda^{-1\mu}_{\ \ \alpha} \Lambda^{-1\nu}_{\ \ \beta} I^{\alpha\beta}.$$

The commutation relations (32) between the $I^{\mu\nu}$ and the L^λ are the relations of the Lie algebra of SO(4,1) if $\kappa > 0$, of SO(3,2) if $\kappa < 0$, and of the Poincaré group if $\kappa = 0$. It follows that the $I^{\mu\nu}$ and the L^λ generate the corresponding enveloping algebra. The $x^\mu - L^\mu$ are in the center $Z(\mathscr{A}_\kappa)$ of $\mathscr{A}_\kappa$. Therefore the algebra $\mathscr{A}_\kappa$ is the tensor product of the commutative algebra generated by the $x^\mu - L^\mu$ ($\mu = 0,1,2,3$) with the above enveloping algebra. In fact the center $Z(\mathscr{A}_\kappa)$ of $\mathscr{A}_\kappa$ is generated by the $x^\mu - L^\mu$ and the two casimirs $\mathfrak{c}_2$ and $\mathfrak{c}_4$ given by

$$\mathfrak{c}_2 = \kappa g_{\lambda\mu} g_{\rho\nu} I^{\lambda\rho} I^{\mu\nu} + 2 g_{\alpha\beta} L^\alpha L^\beta, \tag{33}$$

$$\mathfrak{c}_4 = g^{\rho\rho'} \varepsilon_{\rho\lambda\mu\nu} L^\lambda I^{\mu\nu} \varepsilon_{\rho'\lambda'\mu'\nu'} L^{\lambda'} I^{\mu'\nu'}, \tag{34}$$

where $\varepsilon_{\rho\lambda\mu\nu}$ is the completely antisymmetric tensor with $\varepsilon_{0123} = 1$. Therefore $\mathscr{A}_0$ is the tensor product of the commutative algebra generated by the $x^\mu - L^\mu$ with the enveloping algebra of the Poincaré Lie algebra generated by the $I^{\mu\nu}$ and the L^λ. Notice, however, that the $I^{\mu\nu}$ and the L^λ have nothing to do with the physical Poincaré group $\mathfrak{B}$ acting on $\mathscr{A}_0$ by the automorphisms $\alpha_{(\Lambda,a)}$; in particular the L^λ have the dimension of a length. The algebra $\mathscr{A}_0^I$ is simply the subalgebra generated by the $I^{\mu\nu}$ and the L^λ ($\simeq$ enveloping algebra of a Poincaré Lie algebra). The τ_k are given by $\tau_k(I^{\mu\nu}) = I^{\mu\nu} + k^\mu L^\nu - k^\nu L^\mu$ and $\tau_k(L^\lambda) = L^\lambda$. One can compute the cocycle c, e.g., one has $c(x^\mu, x^\nu) = -\frac{1}{2} I^{\mu\nu}$. Finally, allowing exponentials, the cocycle γ is given by

$$\gamma(k, \ell) = -\frac{i}{2}\left(k_\mu \ell_\nu I^{\mu\nu} - \left(\frac{2}{3} k_\rho \ell^\rho + \frac{1}{3} \ell_\rho \ell^\rho\right) k_\lambda L^\lambda + \left(\frac{1}{3} k_\rho \ell^\rho + \frac{2}{3} k_\rho k^\rho\right) \ell_\lambda L^\lambda\right),$$

and one has $\lambda(L^\mu, k) = -k_\nu (I^{\mu\nu} + \frac{1}{2}(k^\mu L^\nu - k^\nu L^\mu))$ and $c^I(L^\mu, L^\nu) = -\frac{1}{2} I^{\mu\nu}$ and so forth. Since $\mathfrak{c}_2$ and $\mathfrak{c}_4$ are in the center of $\mathscr{A}_\kappa$ and since they are translationally invariant it is natural to fix them and to add the corresponding relations in the definition of the $\mathscr{A}_\kappa$. Since the element $\mathfrak{c}_2$ has the dimension of a length squared, there are three natural ways to fix it: (i) $\mathfrak{c}_2 = \kappa$, (ii) $\mathfrak{c}_2 = -\kappa$, and (iii) $\mathfrak{c}_2 = 0$. Any of these choices leads to $g_{\mu\nu} L^\mu L^\nu = 0$ in $\mathscr{A}_0$ (in fact in $\mathscr{A}_0^I$). Remembering that $\mathscr{A}_0^I$ has the structure of the enveloping algebra of a Poincaré Lie algebra, the latter condition is the analog of a zero mass condition (although here it has a different meaning as we pointed out). Thus if one assumes furthermore that $\mathfrak{c}_4$ is fixed in such a way that the representations occurring are ''zero mass'' representations with strictly positive ''spin,'' one finds again a characteristic two-sheeted structure for $\mathscr{A}_0^I$ (by allowing the two helicities). The origin of the frequent occurrence of this two-sheeted structure in this context is obviously due to the fact that the full Lorentz group is not connected.

In all the above examples the $\mathscr{A}_\kappa$ are Poincaré covariant. This is not needed; only $\mathscr{A}_0$ must have this property. In fact one can easily produce an example where only $\mathscr{A}_0$ is Poincaré covariant by deforming the universal enveloping algebras occurring in the previous example for $\kappa \neq 0$ (in the sense used in the theory of quantum groups).

If one wishes to establish a connection between the extra factor $\mathscr{A}_0^I$ here and the one occurring in recent noncommutative versions of gauge theory,[1,4,5] one should remember that, according

to our analysis, $\mathcal{A}_0^I$ dimensional and that it can be noncommutative only if some of its elements do not commute with the functions on space–time. Concerning the first point, one could expect that, by some contractibility argument, a finite-dimensional approximation can be found. However the second point remains. This suggests that it is worth trying to enlarge the setting of the noncommutative models of gauge theory.

ACKNOWLEDGMENTS

It is a pleasure to thank Ivan Todorov for stimulating discussions, Victor Nistor for enlightening correspondence, and Sunggoo Cho for pointing out to us a mistake in the previous version of the paper.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 2 FEBRUARY 1998

The role of a form of vector potential — normalization of the antisymmetric gauge

Wojciech Florek[a] and Stanisław Wałcerz[b]
A. Mickiewicz University, Institute of Physics, Computational Physics Division, ul. Umultowska 85, 61–614 Poznań, Poland

(Received 23 July 1997; accepted for publication 14 October 1997)

Results obtained for the antisymmetric gauge $\mathbf{A}=[Hy,-Hx]/2$ by Brown and Zak are compared with those based on pure group-theoretical considerations and corresponding to the Landau gauge $\mathbf{A}=[0,Hx]$. Imposing the periodic boundary conditions one has to be very careful since the first gauge leads to a factor system which is not normalized. A period N introduced in Brown's and Zak's papers should be considered as a *magnetic* one, whereas the *crystal* period is in fact $2N$. The ''normalization'' procedure proposed here shows the equivalence of Brown's, Zak's, and other approaches. It also indicates the importance of the concept of *magnetic cells*. Moreover, it is shown that factor systems (of projective representations and central extensions) are gauge-dependent, whereas a commutator of two magnetic translations is gauge-independent. This result indicates that a *form* of the vector potential (a gauge) is also important in physical investigations. © *1998 American Institute of Physics.* [S0022-2488(98)01202-X]

I. INTRODUCTION

The discovery of the quantum Hall effect[1,2] led to remarkable interest in two-dimensional electron systems subjected to a magnetic field.[3] Since 1980 authors working in different fields — from applied to mathematical physics — have considered related problems and many new features have been observed and discussed.[4] One of the most interesting questions is the dynamic of two-dimensional electrons in a periodic potential and an external magnetic field.[5] The first results, in the tight binding approximation, were presented by Peierls,[6] shortly after Landau's[7] discovery of the quantization of electron states in a magnetic field. A new impact was due to Brown[8] and Zak[9,10] who independently introduced magnetic translation operators in two different, but equivalent, ways. Both approaches were based on group-theoretical considerations and led to the broadening of the Landau levels and quantization of a magnetic field.[8,11] Although more than thirty years have passed, their papers are still considered as fundamental ones.[5] Brown and Zak proved that the problem considered is in fact two-dimensional and their investigations confirmed the importance of projective representations and central extensions in quantum physics.[12] On the other hand, Zak's and Brown's results were not gauge-independent — only a completely antisymmetric vector potential was considered by both authors. An attempt to consider gauge-equivalent vector potentials leads to some ambiguities and misconceptions if it is not done carefully. A bit simpler and more clear results can be obtained from pure group-theoretical considerations. For example, Divakaran and Rajagopal did not consider gauges at all and they worked with central extensions and projective representations only.[13] However, pure mathematical description may not provide us with an intuitive image of the physical phenomena. Moreover, many experiments and theories indicate the importance of vector potential,[14] so it is necessary to include gauges and potentials in considerations.

The aim of this paper is to show sources of misconceptions, ambiguities, and unexpected gauge-dependence of the problem. In particular, factor systems of projective representations and central extensions introduced by Brown and Zak have been carefully checked and compared with those obtained from pure group-theoretical considerations.[13,15,16] It occurs that they can be con-

sidered as standard but they are not normalized.[12,17] This last fact is the main source of differences between Brown's and Zak's approaches. Moreover, it indicates points at which a form of the vector potential is important, i.e., the points at which the problem is not gauge-independent.

In this paper we propose a procedure of ''normalization'' of those factor systems, which enables us to identify irreps introduced by Brown and Zak. A comparison of these irreps with those obtained for central extensions of finite translation groups leads to a concept of the so-called *magnetic cells*[10] and shows that Brown and Zak considered in fact finite lattices with a period $2N$ not N.

For the sake of clarity, the following simplifications arising from the quoted papers are assumed. Position ($\mathbf{r}$, $\mathbf{R}$), momentum ($\mathbf{p}$), and vector potential ($\mathbf{A}$) are considered to be two-dimensional vectors. Note that $\mathbf{r}=(x,y)$ is any vector of $\mathbb{R}^2$, whereas $\mathbf{R}=(X,Y)\in\mathbb{Z}^2$ denotes a vector of a square lattice with $\mathbf{a}_1=\hat{\mathbf{x}}$ and $\mathbf{a}_2=\hat{\mathbf{y}}$, so the area of the elementary cell is equal to 1. The magnetic field is perpendicular to the x-y plane and $\mathbf{H}=H\hat{\mathbf{z}}$. The periodic boundary conditions are imposed on representations of $\mathbb{Z}^2$ and the periods are equal, i.e., $N_1=N_2=N$; the finite translation group and its representations can be considered equivalently.

The paper is organized as follows. In Sec. II the most fundamental formulas of Brown's and Zak's papers are recalled and equivalence of their approaches are indicated. Basic properties of projective representations are briefly presented, too. The role of factor systems is briefly discussed in Sec. III. The next section is devoted to determination of the equivalence of different approaches. From the physical point of view it is done by introducing the concept of magnetic cells. The results obtained are discussed in Sec. V.

II. DIFFERENT DESCRIPTIONS OF MAGNETIC TRANSLATION GROUPS

From the algebraic point of view there are two equivalent descriptions of the magnetic translation operators. Brown[8] investigated a *projective* representation of the translation group T then imposed the magnetically periodic boundary conditions on it. On the other hand, Zak[9] introduced a closed set of noncommuting operators which, in fact, form a covering group T' of T so its standard (vector) representations are *projective* representations of T.[17] The finiteness of these representations was again achieved by imposing the periodic boundary conditions. These two approaches are related by a formula which follows from the induction procedure if one constructs representations of the covering group. Since T' is a central extension of T by the group $\mathrm{U}(1)$ (or its subgroup referred to hereafter as a group of factors and denoted F)[15,16] then its (vector) representations can be written as

$$\Xi[\alpha,\mathbf{R}]=\Gamma(\alpha)D(\mathbf{R}), \tag{1}$$

where $\alpha\in F\subset\mathrm{U}(1)$, $\mathbf{R}\in T$, Γ is a vector representation of F and D is a *projective* representation of T. A factor system $m(\mathbf{R},\mathbf{R}')$ of this representations is determined by the relation[17]

$$D(\mathbf{R})D(\mathbf{R}')=m(\mathbf{R},\mathbf{R}')D(\mathbf{R}+\mathbf{R}'), \tag{2}$$

whereas the multiplication rule for T' reads

$$[\alpha,\mathbf{R}][\alpha',\mathbf{R}']=[\alpha\alpha'\mu(\mathbf{R},\mathbf{R}'),\mathbf{R}+\mathbf{R}'] \tag{3}$$

with $\mu(\mathbf{R},\mathbf{R}')$ being a factor system of a central extension. These factor systems are related to each other by the formula

$$m(\mathbf{R},\mathbf{R}')=\Gamma[\mu(\mathbf{R},\mathbf{R}')]. \tag{4}$$

This relation establishes the equivalence of both approaches. Moreover, both authors assumed the antisymmetric vector potential (gauge) $\mathbf{A}=(\mathbf{H}\times\mathbf{r})/2=[Hy,-Hx]/2$ and were not able to generalize their considerations to other gauges, in particular their approaches did not include the Landau gauge. On the other hand, their results and some conclusions are different in some points which will be discussed here[18] and compared with the results obtained for the Landau gauge.

All considerations and formulas given above are also valid for a finite group T_N and its (finite-dimensional) representations. In addition, we can apply to this case a version of the Burnside theorem which reads that nonequivalent irreducible projective representations of T_N with the same factor system $m(\mathbf{R},\mathbf{R}')$ satisfy the following condition[17]

$$\sum_j [{}^jD]^2 = |T_N| = N^2, \tag{5}$$

where j labels nonequivalent representations (there is no expression for a number of these representations) and $[{}^jD]$ denotes the dimension of ${}^jD$. Since F is an Abelian group then it has $|F|$ irreducible nonequivalent representations and each of them determines different (nonequivalent) factor system $m(\mathbf{R},\mathbf{R}')$ according to (4). It follows from (5) that irreducible representations of T'_N determined by (1) satisfy the Burnside theorem.

Brown[8] defined a magnetic translation operator as

$$\hat{T}(\mathbf{R}) = \exp[-i\mathbf{R}\cdot(\mathbf{p} - e\mathbf{A}/c)/\hbar], \tag{6}$$

where $\mathbf{p}$ is the kinetic momentum and $\mathbf{A}$ is the vector potential such that $\nabla\times\mathbf{A} = \mathbf{H}$. These operators form a projective representation of T with a factor system[8]

$$m(\mathbf{R},\mathbf{R}') = \exp[-\pi i(\mathbf{R}\times\mathbf{R}')\cdot\mathbf{H}/\varphi_0], \tag{7}$$

where $\varphi_0 = ch/e$. Brown showed that one can impose the periodic boundary conditions $\hat{T}(N\mathbf{a}_j)\psi = \psi$ if (notice simplifications assumed in this paper — in fact, H denotes hereafter the magnetic flux through one primitive cell)

$$H = \frac{l}{N}\varphi_0, \tag{8}$$

where l is mutually prime with N, i.e., $\gcd(l,N) = 1$. Hence a factor system of a finite projective representation ${}^lD$ for H satisfying (8) is given as

$$m_l([X,Y],[X',Y']) = \exp[-\pi i l(XY' - YX')/N]. \tag{9}$$

Brown showed that there is the unique (up to equivalence) irreducible projective representation with a dimension N and matrix elements[8]

$${}^l_1D_{jk}[X,Y] = \exp\left[\pi i \frac{lX}{N}(Y + 2j)\right]\delta_{j,k-Y}, \tag{10}$$

where $j,k = 0,1,\ldots,N-1$ and $\delta_{j,k}$ is calculated modulo N (Brown labeled rows and columns by $j,k = 1,2,\ldots,N$).

Zak[9] considered a covering group of the translation group consisting of operators

$$\tau(\mathbf{R}|\mathbf{R}_1,\ldots,\mathbf{R}_j) = \hat{T}(\mathbf{R})\exp[2\pi i\phi(\mathbf{R}_1,\ldots,\mathbf{R}_n)/\varphi_0], \tag{11}$$

where $\Sigma_i\mathbf{R}_i = \mathbf{R}$ and $\phi(\mathbf{R}_1,\mathbf{R}_2,\ldots,\mathbf{R}_j)$ is the flux of the magnetic field through a polygon enclosed by a loop consisting of the vectors $\mathbf{R}_1,\mathbf{R}_2,\ldots,\mathbf{R}_j,-\mathbf{R}$. The periodicity condition was the same as (8) for even N but for odd N Zak proved that the condition

$$H = 2\frac{l}{N}\varphi_0 \tag{12}$$

should be satisfied. This condition implies that for even N the number of different factors is $2N$, whereas it equals N for odd N.[9,10] The result obtained by Zak agreed with Azbel's considerations[19] who showed that wave functions had to be periodic functions of H with the period $2\varphi_0$. It is worthwhile noting that Azbel also worked with the antisymmetric gauge. Zak did not introduce a factor system in an explicit way (it was not necessary in his constructions of representations) but

it can be easily found by considering multiplication of coset representatives $\tau(\mathbf{R}|\mathbf{R})$,[17,20] which simply are equal to $\hat{T}(\mathbf{R})$ [see (11)]. Therefore the factor system is also given by (9), but now it is the factor system of the covering group being a central extension so it should be denoted as $\mu_l(\mathbf{R},\mathbf{R}')$. Zak[10] also showed that matrix elements of an irreducible N-dimensional representation should be [only the coset representatives $\tau(\mathbf{R},\mathbf{R})$ are taken into account here][21]

$$ {}^{l}_{2}D_{jk}[\tau([X,Y]|[X,Y])]=\exp\left[2\pi i\frac{lX}{bN}(Y+2k)\right]\delta_{j,k+Y}, \tag{13}$$

where $b=1,2$ for N odd and even, respectively. It is obvious that this representation corresponds to the irreducible representation $\Gamma(\alpha)=\alpha$ of the factor group F, so $m_l(\mathbf{R},\mathbf{R}')=\mu_l(\mathbf{R},\mathbf{R}')$. According to (8) and (12) changes of H are related to changes of l but they were interpreted in different ways. In Brown's considerations H determines a factor system of projective representations in a direct way — different values of H satisfying (8) lead to nonequivalent projective representations. On the contrary, Zak considered different (nonequivalent) central extensions of T with factor systems μ_l. However, Zak assumed that only the representations $\Gamma(\alpha)=\alpha$ were physical whereas the others were rejected as nonphysical in further considerations.[10,22] It means, according to Zak, that for a central extension with a factor system μ_l one has to find projective representations ${}^{l}D$ with a factor system $m_l=\Gamma(\mu_l)=\mu_l$. The same result can be obtained while considering only the factor system μ_1 and next all irreducible representations Γ_l of F such that $\Gamma_l(\mu_1)=m_l$. Thus all representations necessary in physical applications, considered by Zak as representations of different although isomorphic groups, can be obtained by use of ''nonphysical'' representations Γ_l with $l>1$. Nevertheless, it seems that the representations introduced by Brown (10) could be used in Zak's approach to construct (vector) representations of T' (finite or not) according to (1). A comparison of (10) and (13) shows that for odd N Brown and Zak used different representations. However, for even N $(b=2)$ we have

$$ {}^{l}_{1}D_{jk}[X,-Y]={}^{l}_{2}D_{jk}[\tau([X,Y]|[X,Y])], \tag{14}$$

where the sign ''$-$'' originates from a different choice of the sign of e assumed by Zak[18] (in Zak's approach eigenvectors of $D[1,0]$ are permuted by $D[0,1]$ in the opposite direction than that assumed in Brown's definition).

The third approach is based on pure group-theoretical considerations and consists in determination of all possible central extensions of a finite group $\mathbb{Z}_N^2$ (in general $\mathbb{Z}_{N_1}\otimes\mathbb{Z}_{N_2}$) by an infinite (U(1)) or finite ($C_N=\{\alpha\in\mathbb{C}|\alpha^N=1\}$) group of factors F.[13,15,16] It was shown, by means of the Mac Lane method, that all nonequivalent factor systems corresponding to finite magnetic translation groups can be written as[15,16]

$$\mu_k([X,Y],[X',Y'])=\exp(2\pi ikYX'/N) \tag{15}$$

with $k=0,1,\ldots,N-1$. Some important facts have to be mentioned:

This formula resembles the Landau gauge $\mathbf{A}=[0,Hx]$; recently it has been shown that this convergence is not accidental.[23]

The fraction k/N can be interpreted as H/φ_0,[15,16] so the resulting numbers constitute a periodic function of H with the period φ_0 in agreement with Brown's result but contrary to Zak's and Azbel's results.

In both Brown's and Zak's approaches a (group-theoretical) commutator of two magnetic translations, corresponding to vectors $[X,Y]$ and $[X',Y']$, is equal to

$$c([X,Y],[X',Y'])=\exp[-2\pi i(XY'-YX')H/\varphi_0] \tag{16}$$

and it is the same as obtained in the cited papers[15,16] if H does not satisfy (12) but (8).

There are no additional conditions imposed on k and on N [i.e., the results are valid for both odd and even N and for $\gcd(k,N)>1$]. Taking into account only parameters $k=l$ mutually prime with N it can be shown that N-dimensional irreducible projective representations of T_N (or ''physical'' vector representations of the extension of T_N by C_N) have the following matrix elements

$$ {}^{l}_{3}D_{jk}[X,Y]=\exp\left(2\pi i\frac{l}{N}Xj\right)\delta_{j,k-Y}. \tag{17}$$

Representations with $\gcd(k,N)>1$ were briefly discussed elsewhere,[22] but the difference between odd and even N was not considered there.

III. PROJECTIVE REPRESENTATIONS — STANDARD AND NORMALIZED FACTOR SYSTEMS

To compare different descriptions of the magnetic translation groups we have to discuss not only projective representations themselves but also their factor systems. To begin with we recall now some definitions related to factor systems and their properties.[17,20,24,25] As one can see factor systems appear in the definition of a projective representation (2) and in the multiplication rule for a central extension of groups (3). Factor systems m_l are determined directly (as in Brown's approach) or via factor systems μ_l for central extensions by means of the ''physical'' representations $\Gamma(\alpha)=\alpha$ and the formula (4).

A factor system $m:T\times T\to\mathbb{C}$ has to satisfy the following condition[20,25]

$$m(\mathbf{R},\mathbf{R}')m(\mathbf{R}+\mathbf{R}',\mathbf{R}'')=m(\mathbf{R}',\mathbf{R}'')m(\mathbf{R},\mathbf{R}+\mathbf{R}'') \tag{18}$$

for all $\mathbf{R},\mathbf{R}',\mathbf{R}''$. A *trivial* factor system $t(\mathbf{R},\mathbf{R}')$ is determined by any mapping $f:T\to\mathbb{C}$ according to

$$t(\mathbf{R},\mathbf{R}')=f(\mathbf{R})f(\mathbf{R}')/f(\mathbf{R}+\mathbf{R}'). \tag{19}$$

Since T is Abelian then each trivial factor system is symmetric, i.e., $t(\mathbf{R},\mathbf{R}')=t(\mathbf{R}',\mathbf{R})$. If

$$m'(\mathbf{R},\mathbf{R}')=t(\mathbf{R},\mathbf{R}')m(\mathbf{R},\mathbf{R}') \tag{20}$$

then factor systems m and m' are called *equivalent*. Notice, however, that the projective representations determined by equivalent factor systems are *nonequivalent*.[17] Since all factor systems for a given T form an Abelian group Φ and a set of trivial factor systems Θ is its normal subgroup then elements of the factor group $M=\Phi/\Theta$ (known as the *Schur multiplicator*) correspond to representatives of classes of an equivalent factor system. A factor system is called *standard* if it satisfies

$$m(\mathbf{R},\mathbf{0})=m(\mathbf{0},\mathbf{R})=1,\quad \forall\mathbf{R}. \tag{21}$$

A factor system of an N-dimensional projective representation is *normalized* if

$$m(\mathbf{R},\mathbf{R}')\in C_N,\quad \forall\mathbf{R},\mathbf{R}' \tag{22}$$

(i.e., each factor is the Nth root of 1).

It is well known that the Schur multiplicator of $\mathbb{Z}_N^2$ is C_N,[26] so the factor system (15) is normalized and standard since $m_k([0,0],[X,Y])=1$. Moreover, it is periodic with respect to Y and X' — the period is equal to N. In particular we have $m_k([N,0],[X,Y])=m_k([X,Y],[N,N])=1$, etc. On the other hand, the factor system (9) of N-dimensional representations (10) or (13) is not normalized because some of factors do not belong to C_N but to C_{2N} instead. It also means that this system is standard, because $m_l([0,0],[X,Y])=1$, but it appears that N does not serve as a period because, for example, $m_l([0,N],[1,0])=\exp(\pi il)=(-1)^l$. This fact stirs up a conflict between the conditions obtained by Brown and those obtained by Zak and, moreover, leads to difficulties in studying magnetic translations for the antisymmetric gauge. Of course, one may work with factor systems (and, hence, representations) which are neither standard nor normalized, but such considerations have to be carried very carefully and results obtained have to be carefully interpreted, too.[17] Brown and Zak did not check normalization of their factor systems and this led to ambiguity of their results [cf. (8) and (12)].

At first let us notice that Brown took into account one requirement only, namely[8]

$$\hat{T}(N\mathbf{a}_j)\hat{T}(\mathbf{R})=\hat{T}(\mathbf{R})\hat{T}(N\mathbf{a}_j), \tag{23}$$

i.e., that $\hat{T}(N\mathbf{a}_j)$ would commute with any other operator. On the other hand, Zak demanded in addition that[9]

$$m(N\mathbf{a}_j, N\mathbf{a}_k) = 1\,, \tag{24}$$

i.e., that ${}^lD(N\mathbf{a}_j)$ should behave as a constant factor. As follows from (9)

$$m_l([N,0],[0,N]) = (-1)^{lN},$$

so for odd N the magnetic field H has to be twice as high as in (8). Note that representations (17), corresponding to the Landau gauge, satisfy, for both odd and even N, the following stronger condition

$${}^l_3D(N\mathbf{a}_j)\,{}^l_3D(\mathbf{R}) = {}^l_3D(\mathbf{R}+N\mathbf{a}_j) = {}^l_3D(\mathbf{R}), \tag{25}$$

i.e., both $N\mathbf{a}_j$ and $\hat{T}(N\mathbf{a}_j)$ are equal to the unit element in the translation group T_N and in the group of magnetic translation operators, respectively. The condition (12) (for odd N) removes these problems but, however, leads to another question why odd and even N should be considered separately while both cases can be evidently treated as one with the use of the Landau gauge.

While considering restrictions imposed on H by the periodic boundary conditions with the Landau gauge, i.e., the standard factor system (15), one can see that the condition $H = k\varphi_0/N$ is sufficient. So, it seems that Brown's approach is well-supported. Moreover, it should be noted that Zak weakened his requirements and later on he considered only Brown's condition.[27] To enlighten the problem we have to check whether the factor systems (9) and (15) are equivalent or not. At first note that the group-theoretical commutator of operators of any projective representations (of an Abelian group T) is equal to

$$c(\mathbf{R},\mathbf{R}') = D(\mathbf{R})D(\mathbf{R}')[D(\mathbf{R}')D(\mathbf{R})]^{-1} = \frac{m(\mathbf{R},\mathbf{R}')}{m(\mathbf{R}',\mathbf{R})}, \tag{26}$$

then it is the same for all equivalent factor systems. Since the equivalence of factor systems means the equivalence of vector potentials (gauges),[2,23] then the above commutator does not depend on **A** but rather on **H**, and in this sense this commutator only (not a factor system) has the physical meaning — if $D(\mathbf{R})$ represents a lattice translation in the presence of a magnetic field then the commutator corresponds to a loop determined by vectors $\mathbf{R},\mathbf{R}',-\mathbf{R},-\mathbf{R}'$ and its value depends on the flux through a nonprimitive, in general, cell determined by these vectors. So, Brown's requirement (23) leading to the condition (8) was based on a reasonable assumption. However, the factor system considered was not normalized which led to a disagreement with Zak's results.

IV. EQUIVALENCE OF FACTOR SYSTEMS AND REPRESENTATIONS

Let us consider a mapping $f_w[X,Y] = \exp(2\pi i w XY)$, $w \in \mathbb{R}$, which determines the following trivial factor system

$$t_w([X,Y],[X',Y']) = \exp[-2\pi i w(XY' + YX')]. \tag{27}$$

The factors obtained belong to C_N, i.e., t is standard and normalized, if $w = j/N$. For example for $j = k$ the factor system (15) is transformed to

$$\overline{\mu_k}([X,Y],[X',Y']) = (\mu_k \circ t_{k/N})([X,Y],[X',Y']) = \exp(-2\pi \mathrm{i} k XY'/N), \tag{28}$$

which corresponds to another form of the Landau gauge $\overline{\mathbf{A}} = [-Hy,0]$. It is important that if t is not normalized then a new factor system $m' = tm$ is not normalized, too. This is, however, the case which leads to the factor system (9) determined by Brown and Zak — one has to put $w = k/2N$. This, and the previous discussion on the commutator, proves that the stronger condition introduced by Zak following from (24) is superfluous. It can be easily shown for odd N, since for l mutually

prime with odd N also $\gcd(2l,N)=1$ (the mapping $l\mapsto 2l$ is an automorphism of $\mathbb{Z}_N$ which changes the order of elements only). Therefore in the formulas obtained by Brown, (8)–(10), one can replace $l<N$ in the following way

$$l=\begin{cases} 0, \text{ for } l=0 \\ 2k=2l', \text{ for even } l\neq 0 \\ 2k-1=2(k+N')=2l', \text{ for odd } l, \end{cases} \tag{29}$$

where $N'=(N-1)/2$, $k=1,2,\ldots,N'$, and $l'=1,2,\ldots,2N'=N-1$. In this way a relation similar to (14) is obtained

$${}^{l}_{1}D_{jk}[X,-Y]={}^{l'}_{2}D_{jk}[\tau([X,Y]|[X,Y])], \tag{30}$$

where l and l' are interrelated by (29). In the same way one can transform the factor system (15) into (9). If $\gcd(l,N)=1$ then l is replaced by l', so

$$m_l([X,Y],[X',Y'])=\exp[2\pi i(2l')YX'/N] \tag{31}$$

and next w is taken to be l'/N. The factor system obtained

$$t_w m_l([X,Y],[X',Y'])=\exp[\pi i l(YX'-XY')/N] \tag{32}$$

is exactly the same as (9). In a sense, we have performed a ''normalization'' of the factor system used by Brown and Zak. In other words, the projective representations (10) do not satisfy the condition (24) for odd N since they are not given in *normalized* form. Such a form can be obtained by substitution $l\to 2l'$ which leads to the condition (12) determined by Zak.

Anyway, this way of normalization is not possible in the case of even N, since in general $\gcd(l,N)\neq\gcd(2l,N)$. However, we can use a hint given by Zak, who did not exploit it in full. At the end of his paper[9] Zak noticed that a finite magnetic translation group contains N^3 elements[21] for odd N whereas for even N the number of elements is two times bigger. It suggests that a group considered by him was, in fact, an extension of T_N by C_{2N} — the factors obtained were not normalized since they did not belong to the multiplicator of T_N.

In a previous paper[15] it was shown that central extensions of T_N by C_{2N} which correspond to magnetic translation groups have factor systems

$${}_2m_k([X,Y],[X',Y'])=\exp\left(\frac{\pi i}{N}2kYX'\right) \tag{33}$$

with $k=0,1,\ldots,N-1$. A mapping f_w assigns to each $[X,Y]$ an element of C_{2N} so it is well defined for $w=k/2N$, i.e.,

$$f_w[X,Y]=\exp\left(\frac{\pi i}{N}kXY\right).$$

Note that the product kXY is calculated modulo $2N$ and, therefore, f_w is a multivalued function: in $\mathbb{Z}_N$ numbers X and $X+N$ represent the same element, whereas

$$f_w[X+N,Y]=(-1)^{kY}\exp\left(\frac{\pi i}{N}kXY\right)$$

is not equal to $f_w[X,Y]$, in a general case. To calculate a trivial factor system t_w according to (19) one has to determine $f_w(\mathbf{R}+\mathbf{R}')$. Let us assume, at this moment only formally, that a sum of vectors in this formula will *not* be calculated modulo N. Then

$$t_w([X,Y],[X',Y'])=\exp\left[-\frac{\pi i}{N}k(XY'+X'Y)\right] \tag{34}$$

and

$$_2m_k t_w([X,Y],[X',Y'])=\exp\left[\frac{\pi i}{N}k(YX'-XY')\right],$$

which coincides with (9). It means that in order to obtain the above results we have to treat $[X,Y]$ as an element of T_{2N} rather than that of T_N. So, in fact, we have considered a larger, $2N\times 2N$, lattice although a parameter labeling nonequivalent central extensions has been taken to be equal $2k$. Even for $\gcd(k,N)=1$ we have $\gcd(2k,2N)=2$, so the condition accompanying (8) that l is mutually prime with the period, is not fulfilled in this case. This leads to the magnetic periodicity with a period N though the lattice (crystal) period is $2N$. This problem was briefly discussed by Brown[8] and Zak[10] and its solution is possible through a concept of *magnetic cells* — if $\gcd(l,N)=\lambda>1$ [in (8) and (12)] then the $N\times N$ lattice can be decomposed into $(N/\lambda)\times(N/\lambda)$ magnetically periodic sublattices, which form a $\lambda\times\lambda$ lattice of magnetic cells. In the case considered $\lambda=2$ and the $(2N)\times(2N)$ lattice is decomposed into four $N\times N$ sublattices consisting of points $[X,Y]$, $[X+N,Y]$, $[X,Y+N]$, and $[X+N,Y+N]$, respectively, where $X,Y\in\mathbb{Z}_N$. According to (17) and (33) an irreducible projective representation of T_{2N} should be N-dimensional in this case. It follows from the Burnside's theorem that there are *four* such representations and they can be chosen as

$$_3^lD_{jk}^{\kappa_x,\kappa_y}[X,Y]=(-1)^{\kappa_x\epsilon_x+\kappa_y\epsilon_y}\exp\left(2\pi i\frac{l}{N}Xj\right)\delta_{j,k-Y}, \tag{35}$$

where $\kappa_x,\kappa_y=0,1$ and ϵ_x (ϵ_y) is equal to 0 for $X<N$ ($Y<N$) and to 1 otherwise. Therefore the representations considered by Brown and Zak (14) are equivalent to $_3^lD^{0,0}$. However, the latter is clearly periodic with the period N and satisfies the condition (25). Since the trivial factor system (34) is not normalized in C_N then the representations (14) satisfy the condition (24) and do not satisfy (25).

V. DISCUSSION AND FINAL REMARKS

Summarizing the above discussion on odd and even periods N we can state that the antisymmetric gauge $\mathbf{A}=[Hy,-Hx]/2$, considered by Brown and Zak, corresponds in fact to the crystal period $2N$ and the magnetic period N. If one, like Brown and Zak, does not take this fact into account then results obtained can lead to erroneous conclusions. For example, in this way the additional condition (12) was derived. Investigations of the standard and normalized factor system (15), corresponding to the Landau gauge, have clearly indicated points at which the magnetic translation groups are ''gauge-dependent'' and how one can ''normalize'' factor systems and representations.

The magnetically periodic boundary conditions of projective representations, when the Landau gauge is assumed, can be invoked if

$$H=\frac{l}{N}\varphi_0, \tag{36}$$

where $l=0,1,\ldots,N-1$. [If $\gcd(l,N)=\lambda$ then the magnetic period is equal to N/λ, whereas the crystal period is still N.] The factor system (15) [and also the representation (17) and the physical properties] is a periodic function of H with a period φ_0. Hence the different magnetic response of the considered system can be observed only for N values of $H=l\varphi_0/N$.

If N is an odd integer then $\gcd(2l,N)=\gcd(l,N)$ so the magnetic periodicity is the same in both cases and l in (36) can be replaced by $2l'$, which is equivalent to Zak's condition (12). However, the successively counted values of HN/φ_0 have to be arranged in a different order: $0,\ N+1,\ 2,\ N+3,\ldots,2N-2,\ N-1$. If these values were arranged in the increasing order, i.e., $0,\ 2,\ldots,N-1,\ N+1,\ldots,2N-2$, it might suggest that the condition (12) has to be taken into

account and that the magnetic period is $2\varphi_0$. The only way to settle this problem is by investigation of a system described by a Hamiltonian with a nonperiodic part, e.g., the paramagnetic term.

The case of even N has quite a different nature. As was shown above, the factor systems and representations considered by Brown and Zak describe a lattice with the crystal period $2N$ and the magnetic period equal N. The condition (36) yields $H=l\varphi_0/(2N)$, with $l=0,1,\ldots,2N-1$, but to achieve the magnetic period N only even values of $l=2l'$ are considered, so $H=l'\varphi_0/N$. The representation (10) [see also (14)] is one of four nonequivalent irreducible representations which can be determined in this case. It can be easily seen that Brown's considerations for odd N can also be interpreted in this way [since the decomposition of a $(2N)\times(2N)$ lattice into four $N\times N$ lattices does not depend on the parity of N]. It means, in particular, that the antisymmetric gauge for $N=2$ can be introduced only if one considers the 4×4 lattice with $H=0$ (a trivial case) or $H=\varphi_0/2$.

In this work the descriptions of the magnetic translation group proposed by Brown and Zak were compared with the results obtained by means of the Mac Lane method.[15] The first authors assumed the antisymmetric gauge, whereas the Mac Lane method led to the Landau gauge. Due to a factor $\frac{1}{2}$ in the antisymmetric gauge some problems arise when one introduces the magnetically periodic boundary conditions. More careful considerations put forward by Zak gave the additional condition (12) for an odd period N. However, the condition (36) obtained for the Landau gauge resembles the Brown's condition (8) and does not depend on the parity of N. This condition was obtained from the group-theoretical considerations leading to the factor system (15). In the next step k/N was interpreted as H/φ_0. At first sight it can be interpreted as any value proportional to H, e.g., as $2H/\varphi_0$. However, the first choice is confirmed by the value of group-theoretical commutator, which does not depend on the gauge or, in the other words, is identical for all equivalent factor systems.

Let us also remind that in this work H in fact denotes the magnetic flux through one primitive cell. Therefore, according to (8) or (36), the total flux through the $N\times N$ lattice is equal to

$$\Phi=lN\varphi_0, \tag{37}$$

i.e., to an integer multiplicity of the fluxon. To introduce the antisymmetric gauge one has to consider a $(2N)\times(2N)$ lattice and even $l=2l'$. Hence the total flux equals $\Phi=4l'N\varphi_0$, so the flux through one $N\times N$ magnetic cell is equal to $l'N\varphi_0$, which is consistent with the previous value (37), and the flux trough one primitive cell is equal to $H_a=l'\varphi_0/N$. On the other hand, the flux through one primitive cell of the $(2N)\times(2N)$ lattice (assuming the Landau gauge) is $H_L=l\varphi_0/(2N)$, so in general it is a half of H_a. Therefore we can set up the certain procedure: For a given magnetic field H_a the antisymmetric gauge can be introduced if the magnetically periodic boundary conditions admit two times smaller H_L. For the sake of illustration let us consider the $(2N)\times(2N)$ lattice and $H=\varphi_0/N$. Then, from (16), one obtains a commutator corresponding to the primitive vectors $[1,0]$ and $[0,1]$ as

$$c([1,0],[0,1])=\exp(-2\pi i/N).$$

The formula (9) gives the following values of the corresponding factors [see (26)]

$${}_1m([1,0],[0,1])=\exp(-\pi i/N)$$

and

$${}_1m([0,1],[1,0])=\exp(\pi i/N),$$

whereas (15) leads to

$${}_2m([1,0],[0,1])=1$$

and

$${}_2m([0,1],[1,0])=\exp(2\pi i/N).$$

So, the flux through the primitive cell, corresponding to the commutator and independent of the gauge, was decomposed in two different ways into fluxes through ''primitive'' triangles. However, the first decomposition (related to the antisymmetric gauge) is not possible for the minimal flux $H=\varphi_0/(2N)$. If considering any other trivial factor system (27) determined by the parameter $w\in\mathbb{R}$ one can obtain many other decompositions of the commutator into factors. It can be viewed as the decomposition of the flux through the primitive cell into fluxes through the ''lower'' and ''upper'' triangle. In particular, the other Landau gauge, corresponding to the factor system (28), changes roles of these triangles since one obtains

$$\overline{m}([1,0],[0,1])=\exp(2\pi i/N)$$

and

$$\overline{m}([0,1],[1,0])=1\,.$$

Despite the fact that the physical properties are gauge-independent we have noticed that the form of the vector potential **A** has a certain importance in the mathematical description of a system. One has to be especially careful considering projective representations or extensions of groups, since some equivalent factor systems are neither standard nor normalized. However, it may occur that in certain applications or in other descriptions of the same problem it is more convenient to use such a form of **A**.

Renormalized contact potential in two dimensions

R. J. Henderson and S. G. Rajeev
Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627

(Received 14 April 1997; accepted for publication 22 September 1997)

We obtain for the attractive Dirac δ-function potential in two-dimensional quantum mechanics a renormalized formulation that avoids reference to a cutoff and running coupling constant. Dimensional transmutation is carried out before attempting to solve the system, and leads to an interesting eigenvalue problem in $N-2$ degrees of freedom (in the center of momentum frame) when there are N particles. The effective Hamiltonian for $N-2$ particles has a nonlocal attractive interaction, and the Schrodinger equation becomes an eigenvalue problem for the logarithm of this Hamiltonian. The three-body case is examined in detail, and in this case a variational estimate of the ground-state energy is given. © *1998 American Institute of Physics.* [S0022-2488(98)01702-2]

I. INTRODUCTION

Scale invariance, and the ultraviolet divergences for which it is responsible, is an essential feature of the quantum field theories, QCD and electroweak, that comprise the standard model of elementary particle interactions. The divergences that are obtained in the process of quantizing the classical field theories on which the quantum dynamics are based can be removed via the mathematical procedure of renormalization. In condensed matter physics renormalization techniques are used to obtain mathematical models of physical phenomena (e.g., phase transitions) which, despite the presence of a characteristic scale, provided by a lattice spacing, are scale independent in nature. In contrast, renormalization in the context of elementary particle interactions is necessary to make the fundamental theory physically sensible.

That an awkward renormalization procedure is necessary to permit the quantum field theory paradigm to successfully describe elementary particle interactions might be viewed as evidence that quantum field theory is not the proper framework for this problem. Some other exotic and finite theory might be more conceptually accurate and less mathematically cumbersome. On the other hand, one may take Wilson's point of view[1] on the role of renormalization in particle physics: a renormalizable quantum field theory may be viewed as an *effective model* which approximates for low enough energies (or long enough distances) a more fundamental and comprehensive theory. In addition, then, to seeking a more fundamental theory underlying renormalizable quantum field theories, we may aspire to a deeper understanding of the very successful effective theories we have.

Toward this end we take the point of view that renormalizable interactions might be given a *finite formulation*,[2] which avoids the need for renormalization altogether, without the necessity of discarding the framework of quantum field theory. The *renormalized interactions* that would be part of this formulation could not be scale invariant; the scaling symmetry would be broken explicitly at the outset, and not through the renormalization procedure. Other properties of the erstwhile ''fundamental'' interactions might be modified as well.

This approach to finding a finite, effective theory of particle interactions would be tantamount to a reordering of the conventional analysis. It would require renormalizing the theory completely *before* embarking on efforts to solve it, rather than renormalizing in parallel with the finding of solutions. No nonphysical cutoffs or running parameters would appear in the formulation or solutions of the renormalized theory. Rather, such a theory could be formulated as a well-posed mathematical problem: a set of differential equations with appropriate boundary conditions, for example. If this point of view is the correct one, then the reason we cannot write down such a formulation of QCD or electroweak theory is not because they are only low-energy effective theories (though they may be), but rather because we have not yet achieved a deep enough

 © 1998 American Institute of Physics

understanding of these theories to write them down in the simplest way.

Although we believe finding a finite formulation of renormalizable interactions to be a worthwhile goal, attacking this problem directly, in say QCD, appears too formidable at this time. We have in the past, though, found examples of simpler, asymptotically free renormalizable theories that lend themselves to this approach. In Ref. 3 we renormalized the large-N limit of the $1+1$-dimensional non-Abelian Thirring (or Gross–Neveu) model before finding some exact solutions. The scale-breaking renormalized interaction manifested itself as a restriction on the domain of the Hamiltonian operator. A similar role for the Hamiltonian domain was found in Ref. 4 in the study of a quantum mechanical system of two particles in two dimensions attracted by a Dirac δ-function potential. The same system was also examined in the path integral picture, where it was found that the renormalized interaction appeared as a subtle modification to the Wiener measure.

In this paper we continue with our investigation of quantum mechanical particles interacting through an attractive Dirac δ-function potential in two dimensions. We first work out the case of three particles in detail, and eventually extend our ideas to the N-body case.

II. REVIEW OF THE TWO-BODY PROBLEM

Before embarking in the next section on the three-body problem, let us recall the renormalized formulation, in the Hamiltonian picture, of the two-body problem. In the two-body case, after separating out the center of mass coordinate, the original Schrodinger equation in configuration space is

$$-2\Delta\Psi_\lambda(\overline{x})-g\,\delta^2(\overline{x})\Psi_\lambda(\overline{x})=\lambda\Psi_\lambda(\overline{x}), \tag{1}$$

where Δ is the two-dimensional Laplacian, and g is a positive, dimensionless coupling constant. We have taken the masses of the two particles to be $m_1=m_2=\frac{1}{2}$ and chosen units such that $\hbar=1$. In momentum space the Schrodinger equation reads

$$2p^2\Psi_\lambda(\overline{p})-\frac{g}{(2\pi)^2}\int d^2p\,\Psi_\lambda(\overline{p})=\lambda\Psi_\lambda(\overline{p}). \tag{2}$$

This eigenvalue problem, however, is nonphysical since, due to scale invariance, the presence of even a single negative energy solution implies a continuum of negative energy states extending down to minus infinity. On the other hand, if one attempts to restrict the domain of the Hamiltonian to the positive energy sector only, one finds that a complete set of eigenstates cannot be found: there will be no zero angular momentum eigenstate.[2] The Hamiltonian cannot be self-adjoint under such a choice of domain. (The situation is analogous to the presence of solutions to the Dirac equation of unbounded negative energy, and the impossibility of ignoring or ''throwing away'' these states.)

This system's illness can be cured via renormalization. First one regularizes the system by introducing a momentum cutoff (upper bound). Then the coupling constant, g, is required to depend on the cutoff in such a way that the ground-state energy of the regularized system remains finite as the cutoff is removed, i.e., taken to infinity, This procedure removes g from the problem, replacing it with a parameter having dimensions of energy, a trade sometimes called ''dimensional transmutation.'' This new parameter is arbitrary, characterizes the strength of the interaction, and can be taken to be the ground-state energy of the two-body system.

The customary way to obtain renormalized solutions to the problem (see Refs. 5–9), then, is to solve the regularized system first, and then take the limits of solutions (wave functions, scattering amplitudes, etc.) as the cutoff is taken to infinity. In Ref. 4 we showed that an equivalent, but simpler, formulation is given by the following two equations:

$$2p^2\Psi_\lambda(\overline{p})-\lim_{p\to\infty}2p^2\Psi_\lambda(\overline{p})=\lambda\Psi_\lambda(\overline{p}) \tag{3}$$

and

$$\int d^2p \left(\Psi_\lambda(\overline{p}) - \frac{\eta_{\Psi_\lambda}}{2p^2+\mu^2} \right) = 0, \tag{4}$$

where $\eta_\lambda \equiv \lim_{p\to\infty} 2p^2\Psi_\lambda(\overline{p})$.

These two equations give an example of what we mean by a *finite formulation* of a renormalizable theory. The theory at this stage has been renormalized, and can be treated as a well-posed mathematical problem. The first equation is recognized as a renormalized version of the Schrodinger equation. The interaction has become the term $-\eta_{\Psi_\lambda} = -\lim_{p\to\infty} 2p^2\Psi(\overline{p})$ on the left-hand side. This term is the *renormalized interaction.* Wave functions for which η_{Ψ_λ} is zero do not take part in the interaction. Interestingly, there is no adjustable parameter in the Hamiltonian operator appearing in this equation. In fact, the appropriate Hamiltonian in configuration space is the Laplacian with no interaction term at all: the deviation from the free theory is contained entirely in the specification of the Laplacian's domain.

The second equation specifies the domain of the Hamiltonian. In configuration space it is a local condition that implies that wave functions with zero angular momentum diverge logarithmically at the origin; in configuration space, then, the interaction appears as this boundary condition on wave functions. The parameter μ^2 has dimensions of energy, and can be picked arbitrarily. For any choice of $\mu^2 > 0$, the Hamiltonian will be self-adjoint (and in fact is a self-adjoint extension of the free Hamiltonian[10]). Choosing μ^2 corresponds to selecting the strength of the attractive interaction and it turns out that $-\mu^2$ is the ground-state energy, and that the free theory corresponds to letting $\mu^2 = 0$.

The above pair of equations can be solved completely to yield all the energy eigenstates in the two-body case.[2,4] Although we cannot analytically solve the N-body, or even the three-body, system, we can formulate the problem in a similar way, finding the analogs of Eqs. (3) and (4), which can then be solved approximately.

III. RENORMALIZING THE THREE-BODY PROBLEM

The original three-body Schrodinger equation in configuration space is, when $m_1 = m_2 = m_3 = 1/2$ and $\hbar = 1$,

$$(-\Delta_1 - \Delta_2 - \Delta_3)\Psi_\lambda - g(\delta^2(\overline{x_1} - \overline{x_2}) + \delta^2(\overline{x_2} - \overline{x_3}) + \delta^2(\overline{x_3} - \overline{x_1}))\Psi_\lambda = \lambda\Psi_\lambda, \tag{5}$$

where Δ_i is the two-dimensional Laplacian in coordinate $\overline{x_i}$, $\Psi_\lambda = \Psi_\lambda(\overline{x_1}, \overline{x_2}, \overline{x_3})$, and g is the positive, dimensionless coupling constant. In momentum space this becomes

$$(k_1^2 + k_2^2 + k_3^2)\Psi_\lambda - \frac{g}{(2\pi)^2}\left(\int d^2k_{12}\, \Psi_\lambda + \int d^2k_{23}\, \Psi_\lambda + \int d^2k_{31}\, \Psi_\lambda \right) = \lambda\Psi_\lambda, \tag{6}$$

where $\Psi_\lambda = \Psi_\lambda(\overline{k_1}, \overline{k_2}, \overline{k_3})$ and $\overline{k_{ij}} = \frac{1}{2}(\overline{k_i} - \overline{k_j})$.

As in the two-body problem, we work in momentum space, in the center of momentum frame where $K \equiv k_1 + k_2 + k_3 = 0$. Defining $\overline{p_1} \equiv \frac{2}{3}(\frac{1}{2}(k_2 + k_3) - k_1)$ (see Ref. 11 for a discussion of coordinate choices in the general three-body problem), the Schrodinger equation in this frame is

$$\left(2k_{23}^2 + \frac{3}{2}\, p_1^2 \right)\Psi_\lambda - \frac{g}{(2\pi)^2}\left(\int d^2k_{12}\, \Psi_\lambda + \int d^2k_{23}\Psi_\lambda + \int d^2k_{31}\, \Psi_\lambda \right) = \lambda\Psi_\lambda, \tag{7}$$

where we choose the two independent coordinates to be $(\overline{k_{23}}, \overline{p_1})$, such that $\Psi_\lambda = \Psi_\lambda(\overline{k_{23}}, \overline{p_1})$, in which case k_{12} and k_{31} stand for $-\frac{1}{2}k_{23} - \frac{3}{4}\overline{p_1}$ and $-\frac{1}{2}k_{23} + \frac{3}{4}\overline{p_1}$, respectively. We could just as well have chosen $(k_{31}, \overline{p_2})$ or $(k_{12}, \overline{p_3})$ and would have found the same Schrodinger equation, as $2k_{23}^2 + \frac{3}{2}p_1^2 = 2k_{31}^2 + \frac{3}{2}p_2^2 = 2k_{12}^2 + \frac{3}{2}p_3^2$ since the three particles are identical. From now on we will use this symmetry to write this combination simply as $2k^2 + \frac{3}{2}p^2$. The particle singled out by the choice of coordinates [e.g., particle ''1'' with the choice $(\overline{k_{23}}, \overline{p_1})$] is sometimes called the ''spectator'' particle. Then the other two may be referred to as the ''interacting pair,'' even though in reality all three particles interact with each other.

For the same reasons that (2) was found to be nonphysical, (6) also represents an ill-posed physical problem. In this case if one tries to restrict the Hamiltonian domain to positive energy states, one will find that states with zero angular momentum in the $\overline{k_{23}}$ variable are missing.[2] A renormalization of the system is again necessary. By carrying out the renormalization before, and independent of, solving the system, we can cast the problem in a form analogous to (3) and (4) above.

The first step in our renormalization program is to regularize the system by reconsidering the problem in an artificial momentum space wherein the momenta are bounded above by a cutoff. From Wilson's point of view, this cutoff represents some scale beyond which we are not entitled to apply our low-energy effective theory. Here it is convenient to impose this condition by requiring $2k^2+\frac{3}{2}p^2<\Lambda^2$. We must also allow the coupling constant, g, to depend on Λ. By doing this we will be able to specify that g change with Λ in such a way that the physics predicted by the effective theory we derive is independent of the cutoff. The resulting Schrodinger equation is

$$\left(2k^2+\frac{3}{2}\,p^2-\lambda\right)\Psi_\lambda^\Lambda=\frac{g(\Lambda/\nu)}{(2\pi)^2}\sum_i\ \int^\Lambda d^2k_i\ \Psi_\lambda^\Lambda, \tag{8}$$

where ν is an arbitrary parameter with dimensions of momentum, $\int^\Lambda$ indicates the restriction $2k^2+\frac{3}{2}p^2<\Lambda^2$, the sum has three terms, and from now on k_1, k_2, and k_3 will correspond to, and be used interchangeably with, k_{23}, k_{31}, and k_{12}, respectively.

The presence of Λ breaks scale invariance, such that there is no longer the instability problem preventing us from allowing negative energy states. Also, if we define $f_{\lambda,i}^\Lambda(\overline{p_i})\equiv[g(\Lambda/\nu)/(2\pi)^2]\int^\Lambda d^2k_i\ \Psi_\lambda^\Lambda$, then (8) can be written

$$\left(2k^2+\frac{3}{2}\,p^2-\lambda\right)\Psi_\lambda^\Lambda=\sum_i\ \ f_{\lambda,i}^\Lambda(\overline{p_i}). \tag{9}$$

If we decide to consider Ψ_λ^Λ to be a function of $\overline{k_{23}}$ and $\overline{p_1}$, then it is also useful to note

$$\overline{p_2}\equiv\tfrac{2}{3}(\tfrac{1}{2}(\overline{k_3}+\overline{k_1})-\overline{k_2})=-\overline{k_{23}}-\tfrac{1}{2}\overline{p_1} \tag{10}$$

and

$$\overline{p_3}\equiv\tfrac{2}{3}(\tfrac{1}{2}(\overline{k_1}+\overline{k_2})-\overline{k_3})=\overline{k_{23}}-\tfrac{1}{2}\overline{p_1}. \tag{11}$$

It is left to determine what $g(\Lambda/\nu)$ must be in order that this regularized system will have a well-defined limit as we let $\Lambda\to\infty$. By integrating (8) over any of the k_i it is not difficult to show[2] that $g(\Lambda/\nu)$ must satisfy, for large enough Λ/ν,

$$\frac{(2\pi)^2}{g(\Lambda/\nu)}=\int_{k<\Lambda}\frac{d^2k}{2k^2+\nu^2}, \tag{12}$$

where we keep in mind that ν^2 is arbitrary. Equation (12) implies that $g(\Lambda/\nu)\to 0$ as we let $\Lambda\to\infty$, indicating that the interaction we consider is *asymptotically free*. This expression for g is, with ν^2 replaced by μ^2, precisely what was found during the renormalization of the two-body system.[4] This is a result we should expect. In fact it would be reasonable to fix $g(\Lambda/\nu)$ using the two-body result rather than to rederive it in the three-body case. This correspondence allows us to identify $-\nu^2=-\mu^2$ as the binding energy of the two particle bound state, i.e., the ground-state energy of the two-body system. From now on we will use $-\mu^2$ to denote this quantity.

By taking the $k_{23}\to\infty$ limit of (8) we can make the identification

$$\lim_{k_{23}\to\infty}2k_{23}^2\Psi_\lambda^\Lambda=\frac{g(\Lambda/\mu)}{(2\pi)^2}\int^\Lambda d^2k_{23}\ \Psi_\lambda^\Lambda=f_{\lambda,1}^\Lambda(\overline{p_1}). \tag{13}$$

This equation has counterparts with $\overline{k_{23}}$ replaced by $\overline{k_{31}}$ or $\overline{k_{12}}$, such that (8) could also be written

$$\left(2k^2+\frac{3}{2}\,p^2-\lambda\right)\,\Psi_\lambda^\Lambda=\sum_i\,\lim_{k_i\to\infty}\,2k_i^2\Psi_\lambda^\Lambda. \tag{14}$$

This equation does not contain g, and will remain valid as we let $\Lambda\to\infty$. In this limit, (14) becomes the three-body renormalized Schrodinger equation, comparable to (3) in the two-body case. Again, no coupling parameter appears in the renormalized Hamiltonian. The parameter characterizing the interaction strength, which we continue to take to be the two-body binding energy, will appear in the domain (boundary condition) equation.

We can find the domain equation by combining (12) and (13). Together, as $\Lambda\to\infty$, these equations impose the following conditions on wave functions:

$$\int\,d^2k_i\left(\Psi_\lambda(\overline{k_i},\overline{p_i})-\frac{f_{\lambda,i}(\overline{p_i})}{2k_i^2+\mu^2}\right)=0, \tag{15}$$

where $f_\lambda(\overline{p_i})=\lim_{k_i\to\infty}2k_i^2\Psi_\lambda$. One way of understanding the choice of $g(\Lambda/\nu)=g(\Lambda/\mu)$ in (12) is that g must have the form which ensures that (13) will continue to hold true as we let $\Lambda\to\infty$.

Equation (15) is in fact three equations, one each for $i=1,2,3$. They are integrals over momentum space, but in configuration space they are local conditions dictating that the wave functions either go to zero or diverge logarithmically, at a rate determined by μ, whenever the coordinates of two particles are made to coincide. That the wave function can blow up under these circumstances is unusual, but not proscribed since the singularities are square integrable.

We thus find that the three-body analogs of the two-body equations (4) and (3) are (15) and the three-body renormalized Schrodinger equation:

$$\left(2k^2+\frac{3}{2}\,p^2-\lambda\right)\Psi_\lambda=\sum_i\,f_{\lambda,i}(\overline{p_i}). \tag{16}$$

The equations (15) and (16) comprise the renormalized, finite formulation of the three-body problem we seek. The form of these equations indicates that the unknown parts of the wave functions are essentially their limits as the relative momenta of particles are taken to infinity, i.e., the functions $f_{\lambda,i}$, $i=1,2,3$. We will require the particles to satisfy Bose statistics, in which case Ψ_λ must be symmetric under permutations of particle indices. Then the $f_{\lambda,i}$ must all be the same function, which we will call f_λ. f_λ is a function of one momentum variable rather than two, and so the eigenvalue problem has already been simplified. The analogous quantity, $\eta_{\Psi_\lambda}\equiv\lim_{p\to\infty}2p^2\,\Psi_\lambda(\overline{p})$, in the two-body case was simply a constant which could be fixed by normalization, so that the eigenvalue problem could be trivially solved. In the N-body case we will find an eigenvalue problem in $N-2$ degrees of freedom in the center of momentum frame.

Although the crux of our problem in solving the system is finding the functions f_λ for all eigenvalues λ, (15) and (16) contain not only f_λ but the wave function Ψ_λ as well. It would be convenient to eliminate Ψ_λ from the problem altogether, and obtain the equation satisfied by f_λ alone. This we can do by employing the Lippmann–Schwinger formulation[12] of the Schrodinger equation. The Lippmann–Schwinger approach is conventionally reserved for scattering states, but here we will find it a convenient starting point in both the scattering and bound state sectors of the theory.

The Lippmann–Schwinger equation for our three-body system can be written down by inspection using (16). It is

$$\Psi_\lambda=g(\overline{p_1},\overline{k_{23}})\,\delta\left(2k^2+\frac{3}{2}\,p^2-\lambda\right)+\frac{\Sigma_i f_\lambda^\pm(\overline{p_i})}{2k^2+\frac{3}{2}p^2-\lambda\mp i\epsilon}. \tag{17}$$

We choose for concreteness to write (17) in the basis $(\overline{k_{23}},\overline{p_1})$. $g(\overline{p_1},\overline{k_{23}})$ is arbitrary, excepting the fact that it must be symmetric under permutations of particle indices.

The energy $\epsilon>0$ in (17) is infinitesimally small. It must appear when $\lambda>0$ to make the division by the singular operator $2k^2+\frac{3}{2}p^2-\lambda$ well defined. The choice of sign, $\pm$ in the denominator corresponds to a choice of boundary conditions: the upper sign implying outgoing scattered

waves (which is ordinarily the physical case), and the lower sign meaning converging scattered waves. Eventually ϵ can be taken to zero, but will serve to regulate otherwise divergent integrals in intermediate steps. We add the label $\pm$ to $f_\lambda^\pm$ to signify this choice of boundary conditions.

The first term in (17) represents the kernel of the operator $2k^2+\frac{3}{2}p^2-\lambda$, which appears on the left-hand side of (16). It is a solution to the *free* Schrodinger equation. In the case $\lambda>0$ it represents the unscattered portion of the wave, and in configuration space gives the wave function its asymptotic behavior as particles become infinitely separated. When $\lambda<0$ this term disappears. Negative energy states are comprised of only the second term, and their form is specified by (17) up to the unknown function f_λ. All information contained in (16) is also in (17).

At this point we must part ways with the usual Lippmann–Schwinger analysis. No potential appears in (17), and we cannot use the self-consistency of this equation alone to solve for the wave function. In place of the usual term involving the potential stands the unknown function $f_\lambda^\pm$. The only further information we can glean about $f_\lambda^\pm$ from (17) comes from taking the limit of this equation as $k_{23}\to\infty$. Since $f_\lambda^\pm(\overline{p_1})=\lim_{k_{23}\to\infty} 2k_{23}^2\Psi_\lambda$, taking this limit and using (10) and (11) gives

$$\lim_{k_{23}\to\infty}\left(f_\lambda(\overline{k_{23}})+f_\lambda(-\overline{k_{23}})\right)=0. \tag{18}$$

However, the bosonic symmetry requires that $f_\lambda(-\overline{k_{23}})=f_\lambda(\overline{k_{23}})$, so that (18) becomes the simple asymptotic condition:

$$\lim_{k_{23}\to\infty} f_\lambda(\overline{k_{23}})=0. \tag{19}$$

To gain more information about f_λ, we need to use (15). This once more highlights the fact that, in this system, the interaction between particles is encoded in the boundary conditions on wave functions rather than in a conventional potential energy term. Inserting (17) into (15) and performing integrations where possible yields the following implicit equation for f_λ:

$$\left(\ln\left(\frac{1}{\mu^2}\left|\lambda-\frac{3}{2}p^2\right|\right)\mp i\pi\Theta\left(\lambda-\frac{3}{2}p^2\right)\right)f_\lambda^\pm(\overline{p})-\frac{2}{\pi}\int d^2k\,\frac{f_\lambda^\pm(\overline{k})}{[k^2+p^2+\overline{p\cdot k}-(\lambda/2)\mp(i\epsilon/2)]}$$
$$=\frac{4}{\pi^2}\int d^2k\; g(\overline{p,k})\,\delta\left(2k^2-\frac{3}{2}p^2-\lambda\right). \tag{20}$$

This ungainly looking equation contains all the information about wave functions and energy eigenvalues we need. Imposing the requirement that $f_\lambda^\pm$ has asymptotic behavior such that the integral in (20) converges will ensure (18) holds true. When $\lambda>0$, this equation is an inhomogeneous linear equation in $f_\lambda^\pm$. Operating on $f_\lambda^\pm$ on the left-hand side of (20) is a symmetric integral operator, which must be inverted to get $f_\lambda^\pm$ for any given g. When $\lambda<0$, the inhomogeneous term proportional to g vanishes identically, leaving an eigenvalue problem for $f_\lambda^\pm$ and λ. In the following section we partially solve the problem of finding $f_\lambda^\pm$ for positive and negative energies, and show that the negative energy sector yields an explicit form for a renormalized, nonlocal effective Hamiltonian.

IV. TOWARD SOLVING THE THREE-BODY PROBLEM

All solutions to the *free* Schrodinger equation have positive energy and can be categorized by the following choice of basis:

$$\Psi_\lambda^{\text{Free}}=g(\overline{p_1},\overline{k_{23}})\,\delta(2k^2+\tfrac{3}{2}p^2-\lambda), \tag{21}$$

where

$$g(\overline{p_1},\overline{k_{23}})=\sum_\Pi\;\delta^2\left(\overline{k_{23}}-\frac{1}{2}\left(\overline{\kappa_{\Pi(2)}}-\overline{\kappa_{\Pi(3)}}\right)\right)\delta^2\left(\overline{p_1}-\left(\overline{\kappa_{\Pi(2)}}+\overline{\kappa_{\Pi(3)}}\right)\right). \tag{22}$$

The constant vectors $\overline{\kappa_1}$, $\overline{\kappa_2}$, and $\overline{\kappa_3}$ are the momenta of the three particles and label the states. There are no restrictions on them other than they represent the particles in the center of momentum frame wherein $\overline{\kappa_1}+\overline{\kappa_1}+\overline{\kappa_3}=0$. The energy is $\lambda=\kappa_1^2+\kappa_2^2+\kappa_3^2$. The sum in (22) is over the six permutations of (1,2,3), and gives g the bosonic symmetry we require. For our purposes it is convenient to absorb the k_{23} dependence into p_1 using the delta function in (21) and to diagonalize the angular momentum in the angle, θ_{23}, of k_{23}. In this case g becomes

$$g_n(\overline{p_1},\theta_{23})=e^{in\theta_{23}}\sum_{\Pi} e^{-in\theta_{\Pi(2),\Pi(3)}}\delta\left(k_{23}^2-\frac{1}{4}(\overline{\kappa_{\Pi(2)}}-\overline{\kappa_{\Pi(3)}})^2\right)\delta^2(\overline{p_1}-(\overline{\kappa_{\Pi(2)}}+\overline{\kappa_{\Pi(3)}})), \tag{23}$$

where n is an integer, and $\theta_{i,j}$ denotes the angle of $\frac{1}{2}(\overline{\kappa_i}-\overline{\kappa_j})$.

Recall that in the two-body problem only those states carrying zero angular momentum participated in the interaction. The wave functions with nonzero angular momentum were just the free ones. We find a similar situation in the three-body case. The free wave functions

$$\Psi_{n,\lambda}=g_n(\overline{p_1},\theta_{23})\,\delta(2k^2+\tfrac{3}{2}p^2-\lambda) \tag{24}$$

for $n\neq 0$ are the positive energy solutions we seek in the sector of the Hilbert space where the angular momenta of any pair of particles is nonzero. Clearly (24) solves (16) with $f_\lambda=0$, for any n. For $n=0$, due to the integration over θ_{23}, these wave functions also satisfy (15) for $f_\lambda=0$. Note that the right-hand side of (20) becomes zero in this case. This is consistent with the linear operator on the left-hand side being nonsingular.

Free wave functions with quantum number n not equal to zero do not scatter. Nontrivial, i.e., interacting, wave functions can therefore be taken to have the form (17), with $g(\overline{p_1},\overline{k_{23}})\to g_0(\overline{p_1})$. g_0 is the symmetrized $[g_0(\overline{p_1})=g_0(\overline{p_2})=g_0(\overline{p_3})]$ function, for $n=0$, given in (23). It is independent of θ_{23}, so the integral on the right-hand side of (20) is trivial, and this equation becomes

$$\left(\ln\left(\frac{1}{\mu^2}\left|\lambda-\frac{3p^2}{2}\right|\right)\mp i\pi\Theta\left(\lambda-\frac{3}{2}p^2\right)\right)f_\lambda^{\mp}(\overline{p})-\frac{2}{\pi}\int d^2k\,\frac{f_\lambda^{\pm}(\overline{k})}{[k^2+p^2+\overline{p\cdot k}-(\lambda/2)\mp(i\epsilon/2)]}$$
$$=\frac{2}{\pi}\Theta\left(\lambda-\frac{3}{2}p^2\right)g_0(\overline{p}). \tag{25}$$

Positive energy scattering solutions $f_\lambda^{\pm}$ exist for all $\lambda>0$ and all g_0. Note that the operator acting on $f_\lambda^{\pm}$ in (25) is rotationally invariant. One can let $f_\lambda^{\pm}(\overline{p})\sim e^{il\theta_p}$, where the integer l is the total angular momentum of the three-particle system, and solve each angular momentum sector independently. It is also worth noting that a rotation in the angle θ_{23} is *not* a symmetry of the interacting Hamiltonian; although scattered wave functions have a free part independent of this angle, the scattered components of these states will in general depend on θ_{23}. Equation (25) is as far as we will take our analysis in the positive energy sector.

For the consideration of negative energy states, let us take $\lambda=-\eta^2$. In this case, (17) gives the form of the wave functions as

$$\Psi_\lambda=\frac{\Sigma_i f_\lambda(\overline{p_i})}{2k^2+\frac{3}{2}p^2+\eta^2}. \tag{26}$$

The infinitesimal parameter ϵ can be set to zero in this case. When $\lambda=-\eta^2$, (25) becomes an eigenvalue problem for f_λ and λ:

$$\ln\left(\frac{1}{\mu^2}\left(\eta^2+\frac{3}{2}p^2\right)\right)f_\lambda(\overline{p})-\frac{2}{\pi}\int d^2k\,\frac{f_\lambda(\overline{k})}{[k^2+p^2+\overline{p\cdot k}+(\eta^2/2)]}=0. \tag{27}$$

For a separable attractive potential [i.e., one having the form $\langle\overline{k}|V|\overline{k'}\rangle=-v(k)v(k')$] the Faddeev integral equation for the T-matrix,[13] written as an equation for the wave function, can be

reduced to an equation in just one variable. Bruch and Tjon[14] have shown that, in the limit in which such a potential is made to have zero range in real space, this equation is precisely the eigenvalue equation we have found in (27).

Our eigenvalue problem can be brought to a more conventional form by writing it in terms of dimensionless variables. We let $\overline{p}=\eta\overline{x}$, $\overline{k}=\eta\overline{y}$, and $f_\lambda(\overline{p})=u_\lambda(\overline{x})$. Then (27) becomes

$$\ln\left(1+\frac{3}{2}x^2\right)u_\lambda(\overline{x})-\frac{2}{\pi}\int d^2y\,\frac{u_\lambda(\overline{y})}{(y^2+x^2+\overline{x\cdot y}+\frac{1}{2})}=\ln\left(\frac{\mu^2}{\eta^2}\right)u_\lambda(\overline{x}). \tag{28}$$

Denoting the operator on the left-hand side of (28) by W, we can rewrite that equation as

$$Wu_\lambda=\ln\left(\frac{\mu^2}{\eta^2}\right)u_\lambda\,. \tag{29}$$

We find, therefore, a linear eigenvalue problem for the eigenfunction u_λ and the eigenvalue $\ln(\mu^2/\eta^2)$. Note that W is a symmetric, nonlocal operator. Its eigenfunctions, u_λ, give us the undetermined part [see (26)] of the wave function, Ψ_λ.

Since the energy is $-\eta^2$, we can identify the operator

$$H\equiv-\mu^2e^{-W} \tag{30}$$

as the Hamiltonian, with one degree of freedom (in addition to the center of mass) effectively integrated out, of the renormalized system in the negative energy sector. We thus find that the logarithm of the effective Hamiltonian of the spectator particle, in momentum space, is an integral operator. The form of the integral operator W reveals that the renormalized, effective ''spectator Hamiltonian'' includes an attractive potential which is nonlocal. It is important to realize, however, that the nonlocality of this Hamiltonian arises because we have effectively integrated out one degree of freedom, a simplification we could make because the actual interaction is of zero range. A positive attribute of the formulation in terms of this one-particle Hamiltonian is that the boundary conditions, and therefore the interactions, are built in, and do not come in through some supplementary condition on wave functions.

The operator W consists of two terms: an unbounded positive kinetic-energy-like operator [a multiplication by $\ln(\frac{3}{2}x^2+1)$ in momentum space] and an interaction term [the integral operator in (28)]. In light of numerical and variational evidence we conjecture, but have not proved, that the interaction part of W is bounded below. Certainly the Hamiltonian including both the ''kinetic'' and ''potential'' energy terms is bounded below. For a proof of this see Ref. 14.

If the effective potential energy term alone is in fact bounded below, it indicates that there are a finite number of normalizable bound states, as well as a continuum of negative energy scattering states wherein a bound state of two particles scatters from the third particle, and the kinetic energy of scattering is less in magnitude than the two-particle binding energy, $-\mu^2$. These states will have counterparts in the positive energy sector for which the kinetic energy dominates. Also in the positive energy sector will be scattering states of three unbound fundamental particles. In fact Bruch and Tjon[14] have carried out a numerical study of (28) and concluded that there are just two three-particle bound states, a result consistent with the above picture.

The expression for H in (30), in combination with the explicit form of W, is one of our key results. It gives us a rare glimpse at an explicit renormalized Hamiltonian, which in most theories can at best be asymptotically approached order by order in perturbation theory. In this system the entire interaction appears in the domain of the renormalized Hamiltonian. The fact that the interaction is of zero range allows us to obtain a compact form for the eigenvalue problem by effectively integrating out one degree of freedom. That the simplest way to write the resulting Hamiltonian is in terms of its logarithm is interesting, but should not surprise us in light of the prevalence of logarithmic dependences in asymptotically free theories. We will find in the N-body case, as well, that the Hamiltonian is best written in terms of its logarithm. Before doing this, however, we will analyze the three-body case a little further, finding in the next section an approximation to the ground state and ground state energy.

V. APPROXIMATING THE THREE-BODY GROUND STATE

Our system of three particles is invariant under rotations, so that we may use this symmetry to simultaneously diagonalize the Hamiltonian and the total angular momentum. Letting the integer l be the angular momentum quantum number, the form of negative energy wave functions becomes

$$\Psi_{\lambda,l}=\frac{\Sigma_i e^{il\theta_i} f_{\lambda,l}(p_i)}{2k^2+\frac{3}{2}p^2+\eta^2}, \tag{31}$$

where θ_i is the angle of $\overline{p_i}$.

Letting $u_{\lambda,l}(x)=f_{\lambda,l}(p)$, the eigenvalue equation, (28), can be decomposed into separate angular momentum sectors, giving us

$$\ln\left(\frac{3}{2}x+1\right)u_{\lambda,l}(x)-2\int_0^\infty \frac{dy}{(xy)^{l/2}}\frac{(\sqrt{(x+y+\frac{1}{2})^2-xy}-(x+y+\frac{1}{2}))^l}{\sqrt{(x+y+\frac{1}{2})^2-xy}}u_{\lambda,l}(y)=\ln\left(\frac{\mu^2}{\eta^2}\right)u_{\lambda,l}(x). \tag{32}$$

The ground state will correspond to the (or one of the) $l=0$ negative energy state(s). Letting $-\gamma^2$ be the ground state energy, the form of this state, which we will call Ψ_0, is

$$\Psi_0=\frac{\Sigma_i f_0(p_i)}{2k^2+\frac{3}{2}p^2+\gamma^2}, \tag{33}$$

with $f_0(p)=u_0(x)$ being the eigenstate corresponding to the lowest eigenvalue $\ln(\mu^2/\eta^2)$ solving the equation

$$\ln\left(\frac{3}{2}x+1\right)u(x)-2\int_0^\infty dy\,\frac{u(y)}{\sqrt{(x+y+\frac{1}{2})^2-xy}}=\ln\left(\frac{\mu^2}{\eta^2}\right)u(x). \tag{34}$$

By definition u_0 solves this equation for the value $\eta^2=\gamma^2$. Equivalently we can regard u_0 as the function which minimizes the quadratic functional:

$$Q[u]\equiv\int_0^\infty \ln\left(\frac{3}{2}x+1\right)u^2(x)-2\int_0^\infty dx\int_0^\infty dy\,\frac{u(x)u(y)}{\sqrt{(x+y+\frac{1}{2})^2-xy}} \tag{35}$$

subject to the constraint $\int_0^\infty dx\ u^2(x)=1$.

One way of obtaining an approximation to the ground state wave function is to numerically solve a discretized version of (34). That is, we can diagonalize the matrix version of the operator W, W_{ij}, obtained by replacing the continuous variables $0<x,\ y<\infty$ by discrete ones $0<i\Delta$, $j\Delta<N\Delta$ for integers i, j, and N and positive Δ. The task then is to diagonalize W_{ij}. Doing this amounts to making a discrete approximation to the regularized problem within which there is a high momentum cutoff. For large $N\Delta$ the unique positive eigenvector should give a useful picture of the ground state of the renormalized problem.

Using this method to obtain a numerical estimate of the ground state wave function shows that u_0 has a long, power-law-type tail. In fact, $u_0(x)$ is quite well approximated by a function of the form $\sqrt{b}/(b+x)$. This rational function is normalized such that the integral of its square on the positive real line is unity, and therefore can be taken as a variational ansatz for u_0. Inserting this form in the quadratic functional $Q[u]$ and minimizing with respect to the parameter b yields the upper bound on the ground state energy:

$$\lambda_0=-\gamma^2<-\mu^2e^{2.6}\approx-13.5\mu^2. \tag{36}$$

Recalling that $-\mu^2$ has the meaning of the two-body ground state energy, we see that the three-body energy is significantly less, which is physically reasonable. Also, this bound is consistent with the estimate $\lambda_0 \approx -16.1\mu^2$ found by Bruch and Tjon using a numerical diagonalization of the Hamiltonian. In addition they find one other bound state, with spectator particle angular momentum $l=1$, having energy $\approx -1.25\mu^2$.

VI. THE *N*-BODY PROBLEM

The original Schrodinger equation of the N-body problem in momentum space is

$$\sum_{i=1}^{N} k_i^2 \Psi_\lambda - \frac{g}{(2\pi)^2} \sum_{i<j} \int d^2 k_{ij}\, \Psi_\lambda = \lambda \Psi_\lambda , \tag{37}$$

where we again take $\hbar = 1$ and the particle masses to be $m_i = 1/2$. $\overline{k_{ij}} = \frac{1}{2}(\overline{k_i} - \overline{k_j})$ are, as in the three-body case, the relative momenta of pairs of particles. As before the system is ill defined due to scale invariance. We regularize the problem with a momentum cutoff Λ such that $\Sigma_i k_i^2 < \Lambda^2$, and define for each pair of particles the functions

$$f^{\Lambda}_{\lambda,ij} = \frac{g(\Lambda/\mu)}{(2\pi)^2} \int^{\Lambda} d^2 k_{ij}\, \Psi_\lambda . \tag{38}$$

$g(\Lambda/\mu)$ is as given in (12), and the superscript Λ on the integral indicates the restriction $\Sigma_i k_i^2 < \Lambda^2$. Recall that $-\mu^2$ is the two-body ground state energy.

As Λ is taken to ∞ in (38), $g(\Lambda/\mu)$ is driven to zero, and picks out only the logarithmically divergent part of the integral over the relative momenta of particles. The renormalized Schrodinger equation then becomes

$$\left(\sum_{i=1}^{N} k_i^2 - \lambda \right) \Psi_\lambda = \sum_{i<j} f_{\lambda,ij} . \tag{39}$$

The functions $f_{\lambda,ij}$ are the limits as $\Lambda \to \infty$ of the $f^{\Lambda}_{\lambda,ij}$, and in this limit (38) and (12) ensure that $f_{\lambda,ij} = \lim_{k_{ij}\to\infty} 2k_{ij}^2 \Psi_\lambda$. $f_{\lambda,ij}$ is independent, then, of k_{ij}, and if we continue to consider the particles to be bosons, then the necessary permutation symmetry will imply that only one of these functions need be specified. The others will follow by permutation of particle indices.

In a similar manner as in the two- and three-body problems, we can show that the renormalized Schrodinger equation, (39), must be supplemented by the domain equations:

$$\int d^2 k_{ij} \left(\Psi_\lambda - \frac{f_{\lambda,ij}}{2k_{ij}^2 + \mu^2} \right) = 0. \tag{40}$$

There is no difficulty in using the Lippmann–Schwinger form of (39) in combination with (40) to derive an equation like (20) for the N-body problem. The full equation is not very illuminating, however, so we do not reproduce it here. Rather we confine ourselves to the negative energy sector and again let $\lambda = -\eta^2$. The wave functions then have the form

$$\Psi_\lambda = \frac{\Sigma_{i<j} f_{\lambda,ij}}{\Sigma_{i=1}^{N} k_i^2 + \eta^2} . \tag{41}$$

Inserting this form into (40), taking, for example, the integration to be over the relative momentum k_{12}, and transforming to dimensionless variables $\overline{x_i} = k_i/\eta$, yields the eigenvalue equation:

$$\ln\left(1 + \frac{1}{2}(\overline{x_1} + \overline{x_2})^2 + \sum_{i=3}^{N} x_i^2 \right) u_{\lambda,ij} - \frac{2}{\pi} \int d^2 x_{12} \frac{\Sigma_{\substack{i<j \\ (i,j)\neq(1,2)}} u_{\lambda,ij}}{\Sigma_{i=1}^{N} x_i^2 + 1} = \ln\left(\frac{\mu^2}{\eta^2} \right) u_{\lambda,ij} , \tag{42}$$

where $u_{\lambda,ij}(\overline{x_1},\ldots,\overline{x_N})=f_{\lambda,ij}(\overline{k_1},\ldots,\overline{k_N})$. One must keep in mind that $u_{\lambda,ij}$ is independent of $\frac{1}{2}(\overline{x_i}-\overline{x_j})$, so that in the center of the momentum frame this function depends on $N-2$ two-dimensional vectors. The linear operator on the left-hand side of (42) is the N-body version of the operator W. We may, as in the three-body system, identify the renormalized spectator Hamiltonian in the negative energy sector as the exponential of this operator, i.e., $H=-\mu^2 e^{-W}$.

We conclude that the N-body problem can be given a renormalized formulation that is in principle no more complicated than for the three-body problem. Of course it is much more difficult to solve, or even to estimate its ground state and ground state energy. Our most intriguing result, however, that the simplest renormalized formulation is in terms of the logarithm of the Hamiltonian which is an integral operator in momentum space, continues to hold in the negative energy sector of the N-body problem for arbitrary N.

We have found, therefore, for all N, a renormalized, i.e., *finite*, formulation of the system of N particles interacting through an attractive Dirac δ-function potential.

An undesirable feature of our formulation is the schism between the treatment of positive and negative energy states. States for all positive values of energy exist, and are found by inverting a linear integral operator in momentum space. Negative energy states, in contrast, come as solutions to an eigenvalue problem. This is the price we pay for combining Eqs. (16) and (15) into a formulation of the problem in which the boundary condition on wave functions is built in, and not a supplementary condition.

In a sense, however, all the essential features of the system are included in the negative energy sector. In this sector are contained normalizable bound states, scattering among these composite particles, as well as scattering of the composite particles with the elementary excitations of the theory. It is possible, in fact, that as we allow $N\to\infty$, keeping the ground state energy finite, that it is only this sector which evolves into the resulting field theory. The field theory found this way should admit a finite formulation along the lines presented here, and is a natural direction for future research.

(Received 28 March 1997; accepted for publication 4 September 1997)

This is the continuation of notes written for the NATO-ASI conference in Il Ciocco (September 96) consisting of the analysis of the links between estimating the splitting between the two first eigenvalues for the Schrödinger operator H and the proof of infrared estimates for quantities attached to Gaussian-type measures. These notes were mainly reporting on the ''old'' contributions of Dyson, Fröhlich, Glimm, Jaffe, Lieb, Simon, and Spencer (in the 1970s) in connection with more recent contributions of Pastur, Khoruzhenko, Barbulyak, and Kondrat'ev which treat in general more sophisticated models. Here we concentrate on the simplest model related to field theory and extend the results of Barbulyak and Kondrat'ev by mixing ideas coming from Pastur and Khozurenko related to the use of Bogolyubov's inequality with classical inequalities due to Ginibre, Lebowitz, Sokal, and others, or, in the case when the temperature T is zero, by applying rather elementary estimates on Schrödinger operators, in order to find lower bounds for second-order moments attached to the measure $\phi \mapsto \mathrm{Tr}\phi \exp -\beta H/\mathrm{Tr} \exp -\beta H$ with $\beta = 1/T$. This question was ''left to the reader'' in lectures given by J. Fröhlich in 1976 [Acta Phys. Austriaca, Suppl. XV, 133–269 (1976)], but we think that it is worthwhile to do this ''homework'' carefully. © *1998 American Institute of Physics.* [S0022-2488(98)03002-3]

I. INTRODUCTION

Our aim is to understand in the large dimension limit $L \to +\infty$ the splitting between the two lowest eigenvalues of the following Schrödinger operator

$$H_\Lambda^{\mathrm{per}} := -h^2\Delta + \sum_{j \in \Lambda} v(x_j) + \frac{\mathscr{J}}{2} \sum_{j \sim k} |x_j - x_k|^2, \tag{I.1}$$

where

(i) Λ is a square periodic lattice $\Lambda := \Lambda(L) = (\mathbb{Z}/L\mathbb{Z})^d$ identified (up to translation) with $\{0,...,L-1\}^d$ in $\mathbb{Z}^d$,
(ii) $j \sim k$ means j nearest neighbor of k in Λ (seen as a periodic lattice),
(iii) v is a one-particle even potential on $\mathbb{R}^n$ defining as typical cases either a single well or a symmetric double well,
(iv) $\mathscr{J}$ is the intensity of the interaction.

As is well known, the first eigenvalue of the Schrödinger operator is simple, so the splitting is always strictly positive. Its behavior with respect to L as $L \to +\infty$ depends actually heavily on the nature of v and on the size of $\mathscr{J}$, which is always assumed positive.

The parameter $\mathscr{J}$ satisfies the condition

$$\mathscr{J} > 0. \tag{I.2}$$

The case $\mathscr{J} = 0$, which could be considered for comparison, corresponds to the case without interaction and the analysis in this case is immediately reduced to the semi-classical analysis of the so-called one-particle Hamiltonian on $L^2(\mathbb{R}^n)$,

 © 1998 American Institute of Physics

$$H_0 := -h^2\Delta_y + v(y). \tag{I.3}$$

This model can also be written as

$$H_\Lambda^{\mathrm{per}} = -h^2\Delta + \sum_{\ell \in \Lambda} \tilde{v}(x_\ell) - \mathscr{J}\sum_{i\sim j} x_i \cdot x_j\,, \tag{I.4}$$

with

$$\tilde{v}(y) = v(y) + \mathscr{J}dy^2 \quad \forall y \in \mathbb{R}^n. \tag{I.5}$$

This sometimes leads (see Ref. 1) to another notion of one-particle operator:

$$\tilde{H}_0 := -h^2\Delta_y + \tilde{v}(y). \tag{I.6}$$

In this article we will in particular discuss the relevance of these various one-particle Hamiltonians in the problem of the phase transition.

For a one-dimensional lattice ($d=1$), this model was analyzed in Ref. 2 by extension of the study of another model analyzed in collaboration with J. Sjöstrand.[3] It was proved that

$$\lambda_2(L;h) - \lambda_1(L;h) \leqslant C \exp -\left(\frac{\epsilon L}{h}\right), \tag{I.7}$$

for C, ϵ independent of L and for $h<h_0$, h_0 independent of L.

But we met an additional and unfortunate condition

$$L \leqslant Ch^{-N_0}, \tag{I.8}$$

without knowing if it was a technical or deep condition.

The main object of the NATO-ASI notes was to analyze another approach based on the so-called infrared estimates which were developed by many authors in the late 70's including Fröhlich, Simon, and Spencer,[4] Dyson, Lieb, and Simon,[5] and Glimm and Jaffe,[6] and more recently by Pastur and Khozurenko[7] and Barbulyak and Kondrat'ev.[1] In particular, we show how this infrared approach also gives information about the splitting for our initial questions. It gave actually a rather complete answer for all the lattices of dimension strictly greater than 1. In this case, the result does not seem to be related to tunneling properties. In the case when the lattice is of dimension 1, we obtained only a partial result under the condition

$$|\Lambda| \leqslant \exp \frac{\varepsilon}{h}, \tag{I.9}$$

for some suitable $\varepsilon>0$. All these results were obtained relatively easily as extensions of these contributions. Because, particularly in Ref. 1 semi-classical analysis is involved, we tried to be more precise than in the original paper, using our more precise knowledge of the tunneling.[8] On the other hand we progressively got the impression that some assumptions were actually irrelevant in the problem and our main goal is to present here rather optimal results, although limited by the bounds of this approach (see Ref. 9 for discussions).

Let us now recall the main results obtained through the infrared estimates. Following Ref. 1, we now consider the operator $\exp -\beta H_\Lambda^{\mathrm{per}}$ and the associated

$$\left\langle \left| \frac{1}{|\Lambda|} \sum_{k\in\Lambda} x_k \right|^2 \right\rangle_{\beta,\Lambda} := \frac{\mathrm{Tr}\,(|(1/|\Lambda|)\Sigma_{k\in\Lambda} x_k|^2 \exp(-\beta H_\Lambda^{\mathrm{per}}))}{\mathrm{Tr}\,(\exp(-\beta H_\Lambda^{\mathrm{per}}))}. \tag{I.10}$$

Physically the strictly positive parameter β corresponds to the inverse of the temperature.

We now introduce the so-called parameter of long-range order

$$P(\beta) = \lim_{|\Lambda|\to\infty} P_\Lambda(\beta), \tag{I.11}$$

with

$$P_\Lambda(\beta)=\left\langle \left| \frac{1}{|\Lambda|}\sum_{k\in\Lambda} x_k \right|^2 \right\rangle_{\beta,\Lambda}. \tag{I.12}$$

The presence of the long-range order, i.e., the strict positivity of $P(\beta)$, will serve as a test for phase transition (cf. Refs. 5 and 7).

When the limit of $\langle\cdot\rangle_{\beta,\Lambda}$ as $|\Lambda|\to+\infty$ exists, we shall denote it by $\langle\cdots\rangle_\beta$. Let

$$E(p)=\sum_{i=1}^{d}(1-\cos p^{(i)}), \tag{I.13}$$

where Λ^* is the dual lattice

$$\Lambda^*=\{p=(p^{(1)},\ldots,p^{(d)})|p^{(i)}=2\pi k^{(i)}/m,\ \ 0\leqslant k^{(i)}\leqslant m-1;\ \ 1\leqslant i\leqslant d\}. \tag{I.14}$$

The method of infrared estimates gives (cf., for example, Ref. 5, (52), p. 368, and also Theorem 3.2 and Theorem 5.1 in this article) the following lower bound.

Theorem I.1: *If $d\geqslant 3$ and under the following assumption on v,*

$$v(x)\geqslant ax^2+b,\quad \text{with}\ \ a>0, \tag{I.15}$$

we have

$$P(\beta)\geqslant\langle x_k^2\rangle_\beta-\frac{n}{2}\cdot\frac{1}{(2\pi)^d}\int_{]-\pi,\pi[^d}\left(\frac{h^2}{\mathscr{F}E(p)}\right)^{1/2}\coth\left[(h^2\beta^2\mathscr{F}E(p))^{1/2}\right]dp. \tag{I.16}$$

This lower bound is deduced by a limiting argument (thermodynamic limit) from the actually more useful inequality (for our questions relative to the splitting), which is relative to the finite lattice case, and which is given by the following theorem essentially due to Ref. 5.

Theorem I.2: *Under the assumption (I.15) on v, we have, for any $k\in\Lambda$, the following universal estimates:*

$$P_\Lambda(\beta)\geqslant\langle x_k^2\rangle_{\beta,\Lambda}-\frac{n}{2}\cdot\frac{1}{|\Lambda|}\sum_{p\in\Lambda^*\setminus\{0\}}\left(\frac{h^2}{\mathscr{F}E(p)}\right)^{1/2}\coth[(\beta^2h^2\mathscr{F}E(p))^{1/2}]. \tag{I.17}$$

Pastur and Khozurenko[7] and more recently Barbulyak and Kondrat'ev[1] try (in particular) to analyze how one can control the quantity $\langle x_k^2\rangle_{\beta,\Lambda}$ from below in order to deduce existence for long-range order. The second authors use semi-classical analysis for the one-particle Hamiltonian operator $\widetilde{H}_0$ and standard inequalities (GKS) reducing the problem to this case. The first authors use for a rather specific model the Bogolyubov inequality. Their result is no more semi-classical and explicit conditions for long-range order are given.

Extending preliminary results announced in Ref. 10, we push these results in various directions:

(i) very weak assumptions in the limit case $\beta=+\infty$, without using (GKS),
(ii) stronger but still rather weak assumptions for the case β large, but using standard moment inequalities.

We obtain, for example, the following theorem.

Theorem I.3: *Let us assume $d\geqslant 2$. If the potential v satisfies (I.15),*

$$v(x)=v(-x), \tag{I.18}$$

$$v(0)>\inf v, \tag{I.19}$$

then there exists h_0 such that we have, for $0<h<h_0$,

$$\lim_{|\Lambda|\to+\infty}(\lambda_2^{\Lambda}(h)-\lambda_1^{\Lambda}(h))=0, \tag{I.20}$$

where λ_1^{Λ} *and* λ_2^{Λ} *are the two lowest eigenvalues of* $H_{\Lambda}^{\mathrm{per}}$.

The direct application of the result by Barbulyak and Kondrat'ev would have given, in the limit $\beta\to+\infty$, the conditions $d\geqslant 3$, $n=1$, and the conditions on $\tilde{v}$ that

$$\tilde{v}(y)\geqslant ay^2+b, \quad \text{with } a>\mathscr{J}d, \tag{I.21}$$

and that

$$\text{for some } q_0>0, \text{ the function } \tilde{v} \text{ attains its strong global minimum at the points } \pm q_0. \tag{I.22}$$

On the other hand, the conditions given by the authors are much stronger [but lead to a stronger result (treatment of the case β large) which will be analyzed later].

In any case, what seems still open is the complete analysis of the tunneling with control of the dimension and we recall from Ref. 9 the important point that the Peierls approch will give additional information, particularly for $d=1$, which cannot be analyzed by this method. In reference to these enlightening lectures, what we are doing here is essentially what was left to the reader in these notes (Ref. 9, p. 237). We recently received a preprint of Albeverio, Kondratiev, and Rebenko[11] based on the Peierls argument.

This article is organized as follows.

(i) In Sec. II, we recall the relations between the splitting and some notions related to the absence of long-range order. We recall also the general strategy of the infrared estimates.
(ii) In Sec. III, we recall a family of estimates extending in various directions the FKG estimates: GKS, FKG, GHS, Lebowitz, and Gaussian domination estimates. These estimates will play an important role in the treatment of the case of β large but are not used in the treatment of $\beta=+\infty$.
(iii) Section IV is devoted to the analysis of lower bounds for the second-order moments in the case $\beta=+\infty$. This is a combination of standard semi-classical analysis with control with respect to the dimension (harmonic approximation) in combination with *a priori* estimates. Although this would be very interesting to analyze, no study of the tunneling is involved and only a rather weak localization of the first eigenfunction.
(iv) In Sec. V, we extend the results proposed by Barbulyak and Kondrat'ev by following the same strategy but instead of reducing, through Ginibre-type inequalities GKS, to a one-particle problem, we take advantage of a reduction to a p-particle problem.
(v) Section VI is mainly reporting on the partially alternative strategy followed by Pastur and Khozurenko and based on the use of the Bogolyubov inequality. This approach is not semi-classical and gives more explicit estimates for specific models.
(vi) In Sec. VIII we propose extensions of the model treated by Pastur and Khozurenko by implementation of the results recalled in Sec. III. This leads to less explicit results but permits, for example, the analysis of the dependence on $\mathscr{J}$ of the transition of phase.
(vii) The last section presents some open questions.

II. CONNECTION WITH THE SPLITTING

We recall here rather standard relations connecting the splitting between the two first eigenvalues of the Schrödinger operator with various quantities introduced in the preceding section. They are quite general and true for any Schrödinger operator

$$H_V:=-h^2\Delta+V,$$

where V is C^{∞} semi-bounded, tending to ∞ as $|x|\to+\infty$ and satisfying

$$V(-x)=V(x).$$

We have the following lemma.

Lemma II.1:

$$\int \left| \frac{1}{|\Lambda|} \sum_i x_i \right|^2 \phi_i^\Lambda(x^\Lambda)^2 dx^\Lambda \leqslant \frac{n}{|\Lambda|} (\lambda_2^\Lambda - \lambda_1^\Lambda)^{-1}. \tag{II.1}$$

This is indeed just the minimax principle saying that

$$(\lambda_2^\Lambda - \lambda_1^\Lambda) = \inf_{\substack{f \in C_0^\infty \\ \int f(x^\Lambda)\phi_1^\Lambda(x^\Lambda)^2\, dx^\Lambda = 0}} \frac{\langle |\nabla f|^2 \rangle}{\langle |f|^2 \rangle}, \tag{II.2}$$

where $\langle \cdot \rangle$ is computed for the measure $\phi_1^\Lambda(x^\Lambda)^2 dx^\Lambda$:

$$\langle \cdot \rangle = \langle \cdot \rangle_{\infty,\Lambda} \tag{II.3}$$

(remembering that it corresponds to the case $\beta = +\infty$). Here dx^Λ is the Lebesgue measure on $(\mathbb{R}^n)^{|\Lambda|}$.

This is then applied to the function

$$f^{(j)}(x^\Lambda) = \frac{1}{|\Lambda|} \sum_{i \in \Lambda} x_i^{(j)}, \tag{II.4}$$

for $j = 1,...,n$. The condition of symmetry on V (which is a consequence of the symmetry of v for our specific example) gives the orthogonality of $f^{(j)}\Phi_1^\Lambda$ to Φ_1^Λ.

In the case when $x_i \in \mathbb{R}^n$ with $n > 1$, we have to introduce the functions $f^{(j)}(x^\Lambda) = (1/|\Lambda|)\Sigma_{i \in \Lambda} x_i^{(j)}$ (for $j = 1,...,n$).

This means that if we can prove by other means the property that

$$\left[\int \left| \frac{1}{|\Lambda|} \sum_i x_i \right|^2 \phi_1^\Lambda(x^\Lambda)^2 dx^\Lambda \right] \geqslant \rho > 0, \tag{II.5}$$

with ρ independent of Λ, then we get that

$$\lim_{|\Lambda| \to +\infty} |\lambda_2^\Lambda - \lambda_1^\Lambda| = 0. \tag{II.6}$$

A lower bound for $P_\Lambda(+\infty)$ gives an upper bound for the splitting, but Theorem I.2 gives the starting point for finding this lower bound and this will then permit us to prove Theorem I.3. We shall mainly follow the proof of Barbulyak and Kondrat'ev but with a small change.

In Ref. 1, the authors indeed take first the limit $|\Lambda| \to +\infty$ and then the limit $\beta \to +\infty$. We shall proceed for the application to the splitting in the inverse order.

Proof of Theorem I.3, modulo a lower bound of $\langle x_k^2 \rangle_{\beta,\Lambda}$: We assume in this part that we have proved the existence of a constant $\delta(\beta,h) > 0$ such that for any Λ (with sometimes a restriction $L \geqslant L_0$)

$$\langle x_k^2 \rangle_{\beta,\Lambda} \geqslant \delta(\beta,h). \tag{II.7}$$

We shall sometimes get in the next sections a control of $\delta(\beta,h)$, with β and h, of the following type.

(i) In the case $\beta = +\infty$,
(As1) there exists $\delta_0 > 0$ and $h_0 > 0$ such that for $h \in]0,h_0]$
$$\delta(\infty,h) \geqslant \delta_0.$$

(i) In the case β large,
(As2) there exists $\delta_0 > 0$, $h_0 > 0$ such that for $h \in]0,h_0]$ there exists $\beta_0(h)$ such that, for all $\beta \geqslant \beta_0(h)$,

$$\delta(\beta,h)\geqslant\delta_0,$$

or

(As3) there exists $\delta_0>0$, $h_0>0$, and β_0 such that for $h\in]0,h_0]$ and $\beta\geqslant\beta_0$,

$$\delta(\beta,h)\geqslant\delta_0.$$

What is common to all these estimates is that they are independent of Λ with possibly the restriction L large enough. This last restriction is usually not important because we shall always take the limit $L\to+\infty$ at the end.

We start from (I.17)

$$P_\Lambda(\beta)\geqslant\langle x_k^2\rangle_{\beta,\Lambda}-\frac{nh}{2}\cdot\frac{1}{|\Lambda|}\sum_{p\in\Lambda^*\setminus\{0\}}\left(\frac{1}{\mathscr{J}E(p)}\right)^{1/2}\coth\left[(h^2\beta^2\mathscr{J}E(p))^{1/2}\right]. \tag{II.8}$$

This leads, under assumption (II.7) to

$$P(\beta)\geqslant\delta(\beta,h)-\frac{nh}{2\mathscr{J}^{1/2}}\cdot\frac{1}{(2\pi)^d}\int_{]-\pi,\pi[^d}E(p)^{-1/2}\coth\left[(h^2\beta^2\mathscr{J}E(p))^{1/2}\right]\,dp. \tag{II.9}$$

The discussion of the case β large is then related to the analysis of $\delta(\beta,h)$ for β large and its comparison with the quantity

$$\frac{nh}{2\mathscr{J}^{1/2}}\cdot\frac{1}{(2\pi)^d}\int_{]-\pi,\pi[^d}E(p)^{-1/2}\coth\left[(h^2\beta^2\mathscr{J}E(p))^{1/2}\right]\,dp.$$

The condition $d\geqslant3$ appears naturally in this case to keep the integral appearing on the rhs of (II.9) convergent.

Taking the limit $\beta\to+\infty$ in (II.8), we first obtain

$$\lim_{\beta\to+\infty}P_\Lambda(\beta)\geqslant\langle x_k^2\rangle_{+\infty,\Lambda}-\frac{nh}{2}\cdot\frac{1}{|\Lambda|}\sum_{p\in\Lambda^*\setminus\{0\}}\left(\frac{1}{\mathscr{J}E(p)}\right)^{1/2}. \tag{II.10}$$

Now, as $|\Lambda|\to+\infty$ and if $d\geqslant2$, the right-hand side is estimated from below, under the assumption (As1) by

$$P(+\infty)\geqslant\delta_0-\frac{nh}{2}\,\mathscr{J}^{-1/2}I_d, \tag{II.11}$$

where we recall that

$$I_d=\frac{1}{(2\pi)^d}\int_{]-\pi,\pi[^d}E(p)^{-1/2}\,dp. \tag{II.12}$$

We now observe that I_d is finite for $d\geqslant2$. Then $P(\infty)$ becomes strictly positive when $h\leqslant h_0$ and

$$\delta_0-\frac{nh}{2}\,\mathscr{J}^{-1/2}I_d>0. \tag{II.13}$$

In some cases h_0 will be explicitly computed (e.g., in the cases considered by Ref. 7) and we can in this case discuss the influence of $\mathscr{J}$ for fixed h, in particular (II.13) is satisfied for $\mathscr{J}$ large enough. In other cases (e.g., in the cases considered by Ref. 1), h_0 is not explicited by the (semi-classical) analysis and we can only say that (II.13) is satisfied for h small enough.

In particular we obtain the proof of Theorem I.3 modulo the verification of (As1).

The case $d=1$. Another interesting point is to analyze the case $d=1$. The sum

$$\frac{1}{|\Lambda|}\sum_{p\in\Lambda^*\setminus\{0\}}\left(\frac{1}{\mathscr{J}E(p)}\right)^{1/2}$$

is divergent as $|\Lambda| \to +\infty$, but this divergence is controlled in $\ln(|\Lambda|)$. This leads to the statement that the splitting remains in $\mathcal{O}(1/|\Lambda|)$ for $h \leqslant h_0$ and $|\Lambda| \leqslant \exp T/h$, where T is explicitly computable.

This condition is much weaker than the condition (I.8) given in Ref. 3. As $h \to 0$, the estimate still works, under assumption (As1), if

$$\ln |\Lambda| \leqslant C \frac{\delta_0}{h} [2\mathscr{J}]^{1/2}, \tag{II.14}$$

where C is a universal constant. We note also that the phenomenon is effectively related to $\mathscr{J} \neq 0$.

To summarize, we prove in this case that the following holds.

Theorem II.2: *Let $d=1$ and v satisfy (I.15), (I.18), and (I.19). Then there exists a constant C such that*

$$\lambda_2^\Lambda - \lambda_1^\Lambda \leqslant \frac{C}{|\Lambda|} \frac{1}{(1 - Ch \log|\Lambda|)_+}. \tag{II.15}$$

As mentioned in the Introduction and as was communicated to us by J. Fröhlich, this condition on $|\Lambda|$ is due to the method (when $n=1$). An approach using the Peierls trick could be more effective in this case[9] (see also Refs. 12 and 13).

III. GINIBRE- OR LEBOWITZ-TYPE INEQUALITIES

Ginibre-type inequalities are well presented in Refs. 14 and 15. They correspond to extensions of the so-called FKG inequalities[16] (see Ref. 17 for a more recent review) and permit the estimate of $\langle x_k^2 \rangle_{\beta,\Lambda}$ from below by the average $\langle x_k^2 \rangle_{\beta,\hat{H}}$ taken over the measure corresponding to the ''formal'' decoupled Hamiltonian

$$\hat{H} = -h^2 \sum_{k \in \mathbb{Z}^d} \frac{\partial^2}{\partial x_k^2} + \sum_{k \in \mathbb{Z}^d} \tilde{v}(x_k) \equiv \sum_{k \in \mathbb{Z}^d} \tilde{H}_k, \tag{III.1}$$

with separate variables.

Less formally, we introduce

$$\hat{H}^\Lambda = \sum_{k \in \Lambda} \tilde{H}_k \tag{III.2}$$

and we obtain[1] the following.

Proposition III.1: Under the assumptions (I.15), (I.18), and (I.21)–(I.22) on the potential $\tilde{v}$ and $\mathscr{J}$, the following inequality is true, for any $k \in \Lambda$:

$$\langle x_k^2 \rangle_{\beta,\Lambda} \geqslant \langle x_k^2 \rangle_{\beta,\Lambda,\tilde{H}^\Lambda}. \tag{III.3}$$

Let us describe briefly the version of the Ginibre inequalities which is needed here. This is related to the control of the sign of the correlations attached to the more general measure

$$Z^{-1} \exp \sum_{ij} J_{ij} x_i x_j \prod_{j=1}^{m} d\nu_j(x_j). \tag{III.4}$$

We look at the partial derivative of $\langle (x_k)^2 \rangle$ with respect to J_{ij}. Here $\langle \cdot \rangle$ is taken with respect to the measure (III.4).

This gives

$$\partial_{J_{ij}} \langle (x_k)^2 \rangle = \langle x_i x_j (x_k)^2 \rangle - \langle (x_k)^2 \rangle \cdot \langle x_i x_j \rangle.$$

The right-hand side appears as the pair correlation of the two functions $f = x_i x_j$ and $g = x_k^2$.

We shall deduce from the Ginibre's inequalities that this expression is positive:

$$\partial_{J_{ij}}\langle (x_k)^2\rangle \geqslant 0. \tag{III.5}$$

Let us briefly recall some elements of this theory (cf. Ref. 15, pp. 119–124, for a nice exposition). We recall the following.

Theorem III.2: *Let $\mathscr{F}_1$ be the set of functions on $\mathbb{R}$ which are non-negative and monotone on $[0,+\infty)$ and either even or odd. Let $\mathscr{F}_n$ be the functions on $\mathbb{R}^m$ of the form $f_1(x_1)\cdots f_n(x_n)$ with $f_i \in \mathscr{F}_1$. Let $d\mu$ be a probability measure of the form (III.4) where $J_{ij}\geqslant 0$ and each $d\nu_j$ has the form* $\exp(f_j(x))d\lambda_j(x)$ *with $f_j \in \mathscr{F}_1$ and $d\lambda_j$ even. Then*

$$\begin{aligned} &\text{(GKS1)} \quad \langle f\rangle \geqslant 0, \\ &\text{(GKS2)} \quad \langle fg\rangle \geqslant \langle f\rangle \cdot \langle g\rangle, \end{aligned} \tag{III.6}$$

for all $f,g \in \mathscr{F}_{m+1}$.

The reader can find a proof of the theorem in Ref. 15.

The measure in consideration is attached to the restriction to the diagonal of the distribution kernel of $\exp -\beta H_\Lambda^{\text{per}}$, where $\mathscr{J}$ becomes a parameter in $[0, \mathscr{J}_0]$ and has not exactly the structure which is introduced above. However, using the Trotter product formula which describes the kernel of $\exp -\beta H_\Lambda^{\text{per}}$ as the limit in a weak sense of $(\exp -[\beta V(x)/N]\exp(\beta\Delta/N))^N$, we observe that the measure is a limit of measures satisfying the assumptions of the theorem for $\mathscr{J}\geqslant 0$. We just have to control (cf. Ref. 15, pp. 120 and 122) the limit procedure in order to obtain the result.

Application: The Hamiltonian $\hat{H}^\Lambda$ describes a system of noninteracting particles. Consequently, we obtain immediately, for $k \in \Lambda$,

$$\langle x_k^2\rangle_{\beta,\Lambda;\tilde{H}} = \langle x_k^2\rangle_{\beta,\tilde{H}_k} = \langle x_0^2\rangle_{\beta,\tilde{H}_0}, \tag{III.7}$$

for all $k \in \mathbb{Z}^d$.

Here we recall that $\tilde{H}_k$ is the one-particle Hamiltonian at $k \in \mathbb{Z}^d$.

We consequently have obtained the following.

Proposition III.3: Under the previous assumptions on $\tilde{v}$ and $\mathscr{J}$ (in particular $n=1$), we have

$$\langle x_k^2\rangle_{\beta,\Lambda} \geqslant \langle x_0^2\rangle_{\beta,H_0}. \tag{III.8}$$

In particular we obtain the condition (As2) mentioned in the previous section by observing that it is sufficient for treating the case β large enough to analyze the case $\beta = +\infty$ for $\langle x_0^2\rangle_{\beta,H_0}$ and to use weak estimates for one-particle Hamiltonians. This will be generalized in one of the next sections.

Remark III.4: When $n>1$, we can no longer apply this technique directly. The case when we have a rotational symmetry can probably be treated by taking polar coordinates. The results in this case are mentioned in Ref. 6. Pastur and Khoruzenko proceeded differently in the case of the model $v(x)=(1-|x|^2)^2$. We shall discuss this point later.

We now present two other inequalities which may be important in order to compare moments relative to various Hamiltonians. We discover these inequalities in the nice paper by A. Sokal,[18] who refers to Refs. 19 and 20. The name of Lebowitz[21] is in reference to the particular case of spin systems.

Theorem III.5 (GS and Lebowitz inequalities): *Let $d\mu(x)$ be a probability measure on $\mathbb{R}^m$ of the type*

$$d\mu(x) = Z^{-1}\exp\left[\frac{1}{2}\sum_{i,j} J_{ij}x_ix_j + \sum_i h_ix_i\right]\prod_{i=1}^m d\nu_i(x_i) \tag{III.9}$$

with

$$J_{ij} = J_{ji} \geqslant 0, \quad h_i \geqslant 0, \tag{III.10}$$

where $d\nu_i$ is for each i a measure on $\mathbb{R}$ of the type

$$d\nu_i(y)=\exp\,-\widetilde{v}_i(y)\;dy, \tag{III.11}$$

where $\widetilde{v}_i$ *is an even differentiable function such that*

$$\widetilde{v}'\ \ is\ \ convex\ \ on\ \ ]0,+\infty[. \tag{III.12}$$

Then we have

$$(\mathrm{GS})\ \langle x_ix_jx_k\rangle\leqslant\langle x_ix_j\rangle\langle x_k\rangle++\langle x_ix_k\rangle\langle x_j\rangle+\langle x_jx_k\rangle\langle x_i\rangle-2\langle x_i\rangle\langle x_j\rangle\langle x_k\rangle, \tag{III.13}$$

and, when $h=(h_1,\ldots,h_m)=0$,

$$(\mathrm{Leb})\ \langle x_ix_jx_kx_\ell\rangle\leqslant\langle x_ix_j\rangle\langle x_kx_\ell\rangle+\langle x_ix_\ell\rangle\langle x_jx_k\rangle+\langle x_ix_k\rangle\langle x_jx_\ell\rangle. \tag{III.14}$$

We shall also use the following extension mentioned by Sokal who refers to Refs. 22–25.

Theorem III.6 (Gaussian domination inequalities): *Under the assumptions of validity of Theorem III.5, we have, with* $h=(h_1,\ldots,h_m)=0$, *for any multindex* $\alpha=(\alpha_1,\ldots,\alpha_p)$ *with* p *even and* $\alpha_j\in\{1,...,m\}$ *and with* $x^\alpha=\Pi_{j=1}^p x_{\alpha j}$,

$$\langle x^\alpha\rangle\leqslant\sum_{\text{pairings}}\prod\langle x_kx_\ell\rangle, \tag{III.15}$$

where the sum is over all the pairs giving a decomposition of α.

IV. SEMI-CLASSICAL ANALYSIS OF THE MANY-PARTICLE PROBLEM. THE CASE $\beta=+\infty$

We have seen in Sec. III that we can estimate from below, using the Ginibre inequalities, the quantity $\langle x_j^2\rangle_{\beta,\Lambda}$ (for $j\in\Lambda$) by the corresponding quantity $\langle y^2\rangle_{\beta,H_{\widetilde{v}}}$, attached to one particle potential $\widetilde{v}$. We can then first analyze the limit case $\beta=+\infty$ by semi-classical analysis and prove that for β large enough an analogous estimate from below remains true.

This was the approach developed by Barbulyak and Kondrat'ev[1] that we further developed in Ref. 10.

This result appears to be only semi-satisfactory because it does not seem so natural to impose that $\widetilde{v}$ creates a double well and one is more likely waiting for the weaker assumption that v creates a double well. Of course this is not important when $\mathscr{J}$ is sufficiently small, but it appears more important as $\mathscr{J}$ is large.

Our alternative idea is to treat the case $\beta=+\infty$ by analyzing directly the quantity $\langle x_j^2\rangle_{\infty,\Lambda}$, without reducing to a one-particle Hamiltonian. If successful, the advantage is that we do not need any assumption related to the application of statistical mechanics like the Ginibre inequalities.

This is of course not sufficient for having the result for large β independently of Λ but is sufficient for the analysis of the splitting. The proposition is the following.

Proposition IV.1: Let us assume that v *is* C^∞, *positive, satisfying*

$$\lim\inf_{|x|\to+\infty}v(x)>0, \tag{IV.1}$$

such that there exists $q_0>0$, *with*

$$v(x)>0,\ \forall x\ \ s.t.\ \ |x|<q_0, \tag{IV.2}$$

and the property that there exists $y_0\in\mathbb{R}^n$ *such that* $|y_0|=q_0$ *and*

$$v(y_0)=0. \tag{IV.3}$$

Then, for any $\epsilon>0$, *there exists* $h_0(\epsilon)>0$ *such that, for* $h\in]0,h_0(\epsilon)]$, $\forall j\in\Lambda$, *we have*

$$\langle x_j^2\rangle_{\infty,\Lambda}\geqslant(q_0-\epsilon)^2. \tag{IV.4}$$

This contains the double-well case. The even character of v is not assumed in this proposition, but note that this assumption is quite important in other parts of the problem in order, for example, to have $\langle x_j \rangle_{\infty,\Lambda} = 0$.

The argument is actually the conjunction of the existence of a minimum of v outside the origin and of the property that $v > 0$ in a neighborhood of 0.

Let us explain for simplification the proof in the case $n = 1$ and when v is even.

Let us denote by Φ_1 the first normalized eigenfunction of H_Λ^{per}. We have to estimate from below $\int x_j^2 \Phi_1^2 \, dx$. It is trivial that, for any ϵ such that $q_0 > \epsilon > 0$, we have

$$\int x_j^2 \Phi_1^2 \, dx \geqslant (q_0 - \epsilon)^2 \int_{x \in \mathbb{R}^{|\Lambda|}; |x_j| \geqslant q_0 - \epsilon} \Phi_1^2 \, dx. \tag{IV.5}$$

We rewrite this inequality in the form

$$\int x_j^2 \Phi_1^2 \, dx \geqslant (q_0 - \epsilon)^2 - (q_0 - \epsilon)^2 \int_{x \in \mathbb{R}^{|\Lambda|}; |x_j| \leqslant q_0 - \epsilon} \Phi_1^2 \, dx. \tag{IV.6}$$

We are then reduced to the control of $\int_{x \in \mathbb{R}^{|\Lambda|}; |x_j| \leqslant q_0 - \epsilon} \Phi_1^2 \, dx$. For this estimate, we come back to the equation satisfied by Φ_1 and obtain, also using the invariance by translation of H_Λ^{per},

$$\int v(x_j) \Phi_1^2 \, dx \leqslant \lambda_1^\Lambda / |\Lambda|. \tag{IV.7}$$

Let $m_\epsilon = \inf_{y \in [-q_0 + \epsilon, q_0 - \epsilon]} v(y)$. This quantity is strictly positive by assumption. We obtain in particular

$$\int_{|x_j| \leqslant q_0 - \epsilon} \Phi_1^2 \, dx \leqslant \frac{1}{m_\epsilon} \cdot \frac{\lambda_1^\Lambda}{|\Lambda|}. \tag{IV.8}$$

We have to control $\lambda_1^\Lambda / |\Lambda|$ independently of $|\Lambda|$. This point is the consequence of the rather standard proof of the existence of the thermodynamic limit (see, for example Ref. 2), but we need more, that is, the control with dependence on h. We can add to v the potential $(y^2 - q_0^2)^2$ in order to get a potential with two nondegenerate wells at $\pm q_0$. Using the minimax principle and the harmonic approximation, the following lemma is proved in Ref. 2 and we state it here in a very weak form.

Lemma IV.2: Let us assume that v has nondegenerate minima q_i with $v(q_i) = 0$. Then there exists a constant $C >$ and h_0 such that for $h \in]0, h_0]$ we have

$$\frac{\lambda_1^\Lambda}{|\Lambda|} \leqslant Ch. \tag{IV.9}$$

Proof of Theorem I.3: As explained in Sec. II, this is an immediate consequence of the infrared estimates once we have proven the existence of $\delta_0 > 0$ such that $\langle x_j^2 \rangle_{\beta,\Lambda} \geqslant \delta_0$. We can first assume that $\inf v = 0$. Under the assumption that $v(0) > 0$ and (I.15), it is clear that there exists y_0 such that $v(y_0) = 0$ and such that the conditions of Proposition IV.1 are satisfied.

Remark IV.3: The proof also gives a ''weak'' control of the convergence of the type; for any $\epsilon > 0$, there exists $h_0(\epsilon)$ such that, for $h \in]0, h_0(\epsilon)]$,

$$\lambda_2^\Lambda(h) - \lambda_1^\Lambda(h) \leqslant n \, \frac{1 + \epsilon}{q_0^2} \cdot \frac{1}{|\Lambda|}.$$

Remark IV.4: Let us emphasize that the assumptions are much weaker than the assumptions given by Barbulyak and Kondrat'ev, but their proof is still valid for β large. This is not the case for our proof. We shall see in the next section how we can analyze this case.

Let us also emphasize that we have not used any result of Sec. III.

Remark IV.5: Similar to the case treated in Sec. II, we can have, in the case $d=1$, some estimate like (II.15) under the weaker assumptions of Theorem I.3, (I.15), (I.18), and (I.19).

V. THE CASE β FINITE, LARGE ENOUGH

We want to treat the case when β is finite by improving the ideas of Barbulyak and Kondrat'ev. Our theorem will be the following

Theorem V.1: *Let us assume that v is a C^∞ potential on $\mathbb{R}$ with two nondegenerate minima at $\pm q_0$. Then, for all $\varepsilon>0$, there exists $h(\varepsilon)>0$ such that, for all $h\in]0,h(\varepsilon)]$, there exists $\beta_1(h)$ such that, for $|\Lambda|=L^d$, large enough, for any $k\in\Lambda$,*

$$\langle x_k^2\rangle_{\beta,\Lambda}\geqslant(1-\varepsilon)q_0^2. \tag{V.1}$$

This proof is modeled on the proof sketched by Barbulyak and Kondrat'ev.[1] These authors reduce, through the Ginibre inequalities, to the study of a one-particle problem attached to the potential $\tilde{v}$. The condition $n=1$ appears only in the application of these inequalities.

For simplicity, we explain the case when $d=1$. In the general case, this will correspond to the idea that Λ may be decomposed in smaller boxes.

Our unique idea is to replace the reduction to a one-particle problem by a reduction to a p-particle problem with p large enough but then fixed in the thermodynamic limit.

Let us divide L by p. The number p will be chosen large enough later. We start from

$$L=pL_0+\ell.$$

This leads to a natural decomposition of $\{1,...,L\}$ in L_0+1 intervals I_k $(k=1,...,L_0+1)$ with $I_k=\{(k-1)p,\ldots,kp-1\}$ for $k=1,...,L_0$. Following Ref. 1, we destroy the terms $\mathscr{J}x_jx_k$ when j and k do not belong to the same interval. We recall that these interaction terms appear only for j and k nearest neighbors in $\mathbb{Z}/L\mathbb{Z}$.

Using the Ginibre inequalities, we obtain

$$\langle x_k^2\rangle_{\beta,\Lambda}=\frac{1}{L}\sum_{k=1}^{L}\langle x_k^2\rangle_{\beta,\Lambda}\geqslant\left(1-\frac{\ell}{L}\right)\left(\frac{1}{p}\sum_{q=1}^{p}\langle x_q^2\rangle_{\beta,H^{(p)}}\right). \tag{V.2}$$

Here the last mean value is associated with the operator $\exp-\beta H^{(p)}$ and $H^{(p)}$ is the p-particle operator

$$H^{(p)}=\sum_{j=1}^{p}v(x_j)+\frac{\mathscr{J}}{2}\sum_{j=1}^{p-1}|x_j-x_{j+1}|^2+\frac{\mathscr{J}}{2}(x_1^2+x_p^2). \tag{V.3}$$

When $p=1$, we recover the one-particle Hamiltonian $H^{(1)}=\widetilde{H}_0$ introduced by Ref. 1. So, what we have written above is just the extension of what was written in the case $p=1$ by these authors.

In the case when $p=1$, the inequalities obtained from the semi-classical analysis of $H^{(1)}$ were rather weak, particularly when $\mathscr{J}$ was large, and lead to (I.21) and (I.22). Our aim is to eliminate this condition by playing with p large enough.

We now implement the ideas appearing in Sec. IV but for $H^{(p)}$. The new point is that we have destroyed the invariance by circular permutation of the model and we have to measure the effect of this modification.

The first problem is that we have now for the first eigenvalue $\lambda_1^{(p)}(h)$ of $H^{(p)}$ a weaker estimate than for the first eigenvalue of $H^\Lambda(h)$.

Lemma V.2: There exists C and h_0 such that, for any $h\in]0,h_0]$ and any p,

$$\lambda_1^{(p)}(h)\leqslant Cph+C. \tag{V.4}$$

This gives in particular that $\lambda_1^{(p)}(h)/p$ will be small for large p and small h. Following our previous analysis, we now observe that

$$\sum_{j=1}^{p} \int_{\mathbb{R}^p} v(x_j)(\varphi_1^{(p)}(x))^2 \, dx^{(p)} \leqslant \lambda_1^{(p)}(h). \tag{V.5}$$

The difference with the previous argument is that we can no longer study independently the different terms of the sum on the left-hand side of (IV.6). This does not appear to be a big problem.

As for (IV.6), we can write

$$\sum_j \int x_j^2(\varphi_1^{(p)}(x))^2 \, dx^{(p)} \geqslant p(q_0-\epsilon)^2 - q_0^2 \sum_j \int_{|x_j|\leqslant q_0-\epsilon} (\varphi_1^{(p)}(x))^2 \, dx^{(p)}. \tag{V.6}$$

We then obtain

$$\sum_j \int x_j^2(\varphi_1^{(p)}(x))^2 \, dx^{(p)} \geqslant p(q_0-\epsilon)^2 - \frac{q_0^2}{m_\epsilon} \cdot \sum_j \int_{|x_j|\leqslant q_0-\epsilon} v(x_j)(\varphi_1^{(p)}(x))^2 \, dx^{(p)}, \tag{V.7}$$

hence

$$\sum_j \int x_j^2 |\varphi_1^{(p)}(x)|^2 \, dx^{(p)} \geqslant p(q_0-\epsilon)^2 - \frac{q_0^2}{m_\epsilon} \cdot \sum_j \int v(x_j)|\varphi_1^{(p)}(x)|^2 \, dx^{(p)},$$

$$\geqslant p(q_0-\epsilon)^2 - \frac{q_0^2}{m_\epsilon} \cdot \lambda_1^{(p)}(h). \tag{V.8}$$

Finally, using Lemma V.2, we prove

$$\sum_j \int x_j^2 |\varphi_1^{(p)}(x)|^2 \, dx^{(p)} \geqslant p(q_0-\epsilon)^2 - \widetilde{C}(ph+1). \tag{V.9}$$

This is equivalent, dividing by p, to

$$\frac{1}{p}\left(\sum_j \int x_j^2 |\varphi_1^{(p)}(x)|^2 \, dx^{(p)} \right) \geqslant (q_0-\epsilon)^2 - \widetilde{C}h - \widetilde{C}\,\frac{1}{p}. \tag{V.10}$$

So we have proved the following lemma.

Lemma V.3: For any $\epsilon>0$, there exists h_ϵ and p_ϵ such that, for $h \in]0, h_\epsilon]$ and $p \geqslant p_\epsilon$,

$$\frac{1}{p}\left(\sum_{j=1}^{p} \int x_j^2 |\varphi_1^{(p)}|^2 \, dx^{(p)} \right) \geqslant (q_0-\epsilon)^2. \tag{V.11}$$

Using (V.2), this gives Theorem V.1. The argument for comparing the situation $\beta = +\infty$ and the situation β large is now possible, once p is fixed.

VI. ABOUT THE BOGOLYUBOV INEQUALITY

Let us first recall some of the results obtained by Pastur and Khozurenko. We shall then analyze the technique which is involved in order to prepare the improvements of the next section. These authors discussed the case when

$$v(x) = -\frac{a}{2}|x|^2 + \frac{b}{4}|x|^4 \tag{VI.1}$$

with $a>0$ and $b>0$.

They prove the following theorem.

Theorem VI.1: *If $d \geqslant 3$ and if*

$$\mathscr{J} > h^2(n+2)^2 b^2 I_d^2/4a^2, \tag{VI.2}$$

then there exists a temperature β_0^{-1} *such that, for* $\beta > \beta_0$, *the corresponding* $P(\beta)$ *is strictly positive.*

The control of $\langle x_k^2 \rangle_{\beta,\Lambda}$ is obtained by using the Bogolyubov inequality. We recall that this inequality (see Ref. 26, Lemma 5.5.1) states the following.

Lemma VI.2: Under suitable assumptions, as discussed in detail in Ref. 27, on the various domains of the possibly not bounded operator C *and of the self-adjoint operator* H, *we have the following inequality:*

$$\langle [[C^*, H], C] \rangle_{\beta,\Lambda} \geqslant 0. \tag{VI.3}$$

In our context, this inequality is applied with

$$C = \frac{1}{i} \sum_{j \in \Lambda} \partial_{x_j}. \tag{VI.4}$$

This leads to by considering the limit $\beta \to +\infty$ before to take the thermodynamic limit, the following result for the splitting between the two first eigenvalues as $|\Lambda|$ tends to ∞.

Theorem VI.3: *If* $d \geqslant 2$, *then, for* v *defined by (VI.1) and* $h_0 = 2a\mathscr{J}^{1/2}/(n+2)bI_d$, *we have, for* $h \in]0, h_0[$,

$$\lim_{|\Lambda| \to +\infty} |\lambda_2^\Lambda - \lambda_1^\Lambda| = 0. \tag{VI.5}$$

For this theorem, we need only the Bogolyubov inequality in the limiting case $\beta = +\infty$. In this case and when $H = -\Delta + V$ is a Schrödinger operator, the inequality (VI.3) becomes simply

$$\int ([[C^*, H], C]\Phi)(x)\Phi(x)\, dx \geqslant 0, \tag{VI.6}$$

where Φ is the first normalized positive eigenfunction of H. This is easily and directly obtained by the minimax principle. In particular, if C is given by (VI.4), we obtain the following.

Lemma VI.4:

$$\sum_{jk} \int (\partial^2 V/\partial x_j \partial x_k)(x)\Phi(x)^2\, dx \geqslant 0. \tag{VI.7}$$

When $V(x)$ has the form (we take for simplification $n = 1$)

$$V(x) = \sum_j v(x_j) + J \sum_{i \sim j} |x_i - x_j|^2,$$

we simply obtain

$$\sum_j \int v''(x_j)\Phi(x)^2\, dx \geqslant 0. \tag{VI.8}$$

By invariance of Φ in this case, we obtain the following.

Proposition VI.5: For any j,

$$\int v''(x_j)\Phi(x)^2\, dx \geqslant 0. \tag{VI.9}$$

More generally, for any β, *we have the property*

$$\langle v''(x_j) \rangle_{\beta,\Lambda} \geqslant 0. \tag{VI.10}$$

In the more specific case when $v(x)=(b/4)x^4-(a/2)x^2$, we obtain

$$\int x_j^2\Phi(x)^2\,dx\geqslant\frac{a}{3b}. \tag{VI.11}$$

The proof through the infrared estimates is then easy using the arguments presented in Sec. II.

VII. EXTENSIONS OF PASTUR AND KHOZURENKO: UNIVERSAL LOWER BOUNDS

A. Introduction

If we compare (VI.11) with the semi-classical lower bound obtained by Barbulyak and Kondrat'ev, we note that when $n=1$ and $a>2\mathscr{J}d$, the minimum of $\widetilde{v}$ is for $q=q_0$ with $q_0^2=(a-2\mathscr{J}d)/b$. This leads asymptotically (as $h\to 0$) to (VI.11) with $a/3b$ replaced by $(a-2\mathscr{J}d)/b-\varepsilon$ with $\varepsilon>0$. The improvement we gave in Sec. IV leads asymptotically (as $h\to 0$) to a lower bound by $a/b-\varepsilon$ with $\varepsilon>0$, which seems optimal in the semi-classical regime.

The main goal of this section is to extend the results proposed by Pastur and Khozurenko.

Theorem VII.1: *Let us assume that $n=1$ and that v satisfies (I.15), (I.18), and the condition*

$$v''(x)\leqslant-\gamma_0+\gamma_1x^2, \tag{VII.1}$$

for some real γ_0,γ_1 with $\gamma_0>0$. Then, for any $h>0$,

$$\frac{\gamma_0}{\gamma_1}\leqslant\langle x_j^2\rangle_{\beta,\Lambda}. \tag{VII.2}$$

In many cases, we can take $\gamma_0=-v''(0)$. The point 0 corresponds, for example, to the top between the two wells.

We note also that this approach does not make use of the Ginibre inequalities. This leaves possible extensions for the case $n>1$ in the case when Hess $v(0)$ has a strictly negative eigenvalue which seems generic for a double-well problem and also true in the radial case considered by Ref. 7.

We observe also that the left-hand side in (VII.2) is independent of h.

B. Proof of the theorem

The Bogolyubov inequality was giving

$$\langle v''(x_j)\rangle_{\beta,\Lambda}\geqslant 0. \tag{VII.3}$$

The theorem follows immediately from (VII.1).

Because the left-hand side of (VII.2) is independent of β and Λ, the arguments developed in Sec. II work in the same way: long-range order for h small enough or $\mathscr{J}$ large enough. Moreover, the control of ''h small enough'' is explicit.

We recall that in the semi-classical approach developed in the spirit of Barbulyak and Kondratev ''h small enough'' is implicit.

As already mentioned, the condition (VII.2) can be verified when

$$v''(0)<0, \tag{VII.4}$$

which is a condition of concavity at 0, and when the condition at ∞

$$v''(x)\leqslant Cx^2,\quad\forall x>C, \tag{VII.5}$$

is satisfied. The first one seems natural in the context. The second one is apparently more technical, at least in the semi-classical context, as we shall see in the next subsection for an example.

C. The case $n=1$, $v(x)=bx^{2k}-ax^2$

In this case we have

$$v''(x)=2k(2k-1)bx^{2k-2}-2a, \tag{VII.6}$$

with $a>0$. We then obtain the inequality, for any $j\in\Lambda$,

$$\frac{a}{k(2k-1)b}\leqslant\langle x_j^{(2k-2)}\rangle_{\beta,\Lambda}, \tag{VII.7}$$

as a consequence of the Bogolyubov inequality.

For $k=2$, this was enough for having a universal lower bound for $\langle x_j^2\rangle_{\beta,\Lambda}$, which was decisive for the use of the infrared estimate.

The problem is then to treat the case $k>2$. The Gaussian domination inequalities give a rather satisfactory answer. They give indeed the inequality

$$\langle x_j^{(2k-2)}\rangle_{\beta,\Lambda}\leqslant C(k)\langle x_j^2\rangle^{k-1}, \tag{VII.8}$$

where $C(k)$ is a universal constant counting the number of pairings. Newman[23] gives

$$C(k)=\frac{(2k-2)!}{2^{k-1}(k-1)!}. \tag{VII.9}$$

Consequently, a lower bound for $\langle x_j^2\rangle_{\beta,\Lambda}$ (which has to be uniform with respect to Λ, β, and j) will be a consequence of an upper bound for $\langle x_j^{2k}\rangle_{\beta,\Lambda}$. We note here that everything is actually independent of j.

The first idea could be to analyze first the case when $\beta=+\infty$. This leads to some results which are not basically better than the results obtained in Sec. IV. We just mention that these results are obtained by combination of (VI.9) and the inequality

$$\langle v(x_j)\rangle_{\infty,\Lambda}\leqslant\frac{\lambda_1^{\Lambda}}{|\Lambda|}. \tag{VII.10}$$

In the case β large, the arguments of the preceding example work if we have control of $\langle x_j^{2k}\rangle_{\beta,\Lambda}$ by a constant (using in this case a Hölder inequality) or if we can more directly have a control of $\langle x_j^{2k-2}\rangle_{\beta,\Lambda}$ by a power of $\langle x_j^2\rangle_{\beta,\Lambda}$. In the next section, we shall exploit this idea in combination with the Ginibre's inequalities.

D. Using Lebowitz inequality or Gaussian domination inequalities

As already said, the general principle of the Lebowitz inequalities is to control any correlation by the pair correlations under rather weak assumptions. Our strategy will be to modify the initial potential v in order to get a new potential v_1 satisfying the assumptions of Theorem III.6. This will lead to the following improvement of Theorem VII.1.

Theorem VII.2: *Let us assume that* $n=1$ and *that* v *satisfies (1.15), (1.18), and the condition*

$$v''(0)<0. \tag{VII.11}$$

Let us also assume the existence of ℓ *and* C *such that*

$$|v'''(x)|\leqslant Cx^{\ell}\quad\forall x>C. \tag{VII.12}$$

Then, there exists $\rho>0$ *such that, for any* $h>0$, $\beta>0$ *and* Λ, *we have*

$$\rho\leqslant\langle x_j^2\rangle_{\beta,\Lambda}. \tag{VII.13}$$

Outside this unfortunate condition $n=1$ due to the fact that we use the Ginibre inequality, this theorem is rather satisfactory. The computation of ρ is not very explicit but can be done on examples.

Proof of Theorem VII.2: The main new step is the following lemma.

Lemma VII.3: Under the assumption of Theorem VII.2, there exists $k\in\mathbb{N}$, $\alpha_0>0$, *and* $\alpha_1>0$ *such that*

$$v_1(x)=v(x)+\alpha_0 x^4+\alpha_1 x^{2k} \tag{VII.14}$$

satisfies

$$v_1'(x) \text{ is convex on } \mathbb{R}^+. \tag{VII.15}$$

We observe that v_1 satisfies (I.15), (I.18), and for suitable $\gamma_0>0$ and $\gamma_1>0$ the estimate

$$v_1''(x)\leqslant -\gamma_0+\gamma_1 x^{2k}. \tag{VII.16}$$

The key remark is that the Ginibre inequalities give the estimate

$$\langle x_j^2\rangle_{\beta,\Lambda,v}\geqslant\langle x_j^2\rangle_{\beta,\Lambda,v_1}. \tag{VII.17}$$

Here $\langle x_j^2\rangle_{\beta,\Lambda,v}$(resp. $\langle x_j^2\rangle_{\beta,\Lambda,v_1}$) means that we consider H_Λ^{per} with the one-particle potential v (resp. v_1).

We are now reduced to the problem of finding a lower bound for $\langle x_j^2\rangle_{\beta,\Lambda,v_1}$. With the properties of convexity of v_1' and the estimate (VII.17), this case is easily treated by combination of the Bogolyubov inequality and of the Gaussian domination inequality.

VIII. CONCLUSION

In this article, we have given explicit conditions on the potential v under which a good lower bound can be found for the second-order moment.

When $\beta=+\infty$, the results are not far from the optimal one and no restriction in the dimension n is involved. Nevertheless, restrictions on d appear when applying these inequalities in the infrared estimate strategy for proving transition of phase.

When we want to extend this study to the case β large, we meet immediately the condition $n=1$ [which could probably be extended to the case $n>1$ but with invariance by SO(n)] and this is due to the fact that we use these monotonicity arguments related to various extensions of FKG inequalities. The importance of the two restrictions on d and n is sometimes technical, sometimes perhaps deeper, and has surely to be investigated more carefully. The analysis of the splitting given here is rather rough due to our weak control of the localization of the first eigenfunction in the thermodynamic limit. This also has to be analyzed in the future in order to see the effects of the tunneling between the wells in the spirit of our previous works with J. Sjöstrand.[3,28]

ACKNOWLEDGMENTS

Preliminary results were announced at the conference in Ascona (June 1996) and the NATO conference in Castel Vecchio (September 1996). We thank J. Fröhlich for a motivating discussion in Ascona.

We thank also the European Union which partially supported this research through the TMR Programme of the European Commission–Network Postdoctoral training program in partial differential equations and application in quantum mechanics.

(Received 27 May 1997; accepted for publication 24 September 1997)

For the case of infinitely many photon (Boson) modes we investigate the unitary implementability of a class of symplectic one-parameter groups (more exactly, of the associated groups of Bogoliubov automorphisms on the CCR algebra) in the Fock representation and in representations of the CCR algebra, which are symplectically related and inequivalent to Fock. Furthermore, the existence of the associated (squeezing) quadratic Hamiltonians is discussed. Finally, applications in the theory of quantization in QED and in the Luttinger model are pointed out. © *1998 American Institute of Physics.* [S0022-2488(98)01701-0]

I. INTRODUCTION

In the theoretical descriptions of squeezing processes, quadratic Hamiltonians of the form $(1/2)\Sigma_{k=1}^{N}(\zeta_k a_k^* a_k^* + \overline{\zeta_k} a_k a_k)$ with finite mode number $N<\infty$ are commonly used in the interaction picture.[1] For finitely many modes, however, by the Stone-von Neumann uniqueness theorem (e.g., Ref. 2, Corollary 5.2.12, and Refs. 3, 4) the only relevant representation of the CCR is the Fock representation. Thus, for $N<\infty$ it suffices to treat the above Hamiltonian in Fock space, only.

For $N=\infty$, the above quadratic Hamiltonian has a meaning as an operator in the Fock representation, if and only if the squeezing parameters $\zeta_k \in \mathbb{C}$ (the classical pumping fields) are square summable, that is $\Sigma_{k=1}^{\infty}|\zeta_k|^2<\infty$, a result that is derived in Ref. 5. However, for infinitely many photon modes, $N=\infty$, there exist various inequivalent representations of the CCR, which from the physical point of view describe different macroscopic aspects (sectors) of the considered Boson system. Hence, it seems interesting to investigate quadratic Hamiltonians also in representations, which are inequivalent to the Fock representation.

For the infinite mode case we continue here and supplement our discussions from Refs. 5 and 6 by the investigation of quadratic Hamiltonians of the more general type,

$$H=\sum_{k=1}^{\infty}\left[\frac{1}{2}(\zeta_k a_k^* a_k^* + \overline{\zeta_k} a_k a_k) + c_k a_k^* a_k\right], \tag{1.1}$$

where $\zeta_k \in \mathbb{C}$ (with the complex conjugates $\overline{\zeta_k}$) and $c_k \in \mathbb{R}$. It is assumed that the complete set of orthonormalized eigenmodes u_k is indexed by $k \in \mathbb{N}$, such that for the annihilation operators holds $a_k \equiv a(u_k)$, etc. We further assume that the modes $\{u_k | k \in \mathbb{N}\}$ constitute a basis for the complex one-photon test function space E the completion of which is the Hilbert space $\mathscr{H}$. The unique C^*-Weyl algebra $\mathscr{W}(E)$, which is simply called the *CCR-algebra*, is considered as the field algebra of our photon system. For each $k \in \mathbb{N}$ we define the mode e_k by the phase shift $e_k := \exp\{(i/2)\arg(\zeta_k)\}u_k$. By the (complex) linearity of the (smeared) creation operators, $E \ni f \mapsto a^*(f)$, and the (complex-) antilinearity of the annihilation operators, $E \ni f \mapsto a(f)$, our Hamiltonian (1.1) then takes the form

$$H=\sum_{k=1}^{\infty}\left[\frac{s_k}{2}(a^*(e_k)^2 + a(e_k)^2) + c_k a^*(e_k)a(e_k)\right], \tag{1.2}$$

where we have set $s_k := |\zeta_k|, \forall k \in \mathbb{N}$.

In general, one treats squeezing processes, Bogoliubov transformations, renormalizations, and diagonalizations on the level of the second quantization, only. We deal here first with the one-Boson features, which we lift in a second step to the level of the second quantization. Proceeding

 © 1998 American Institute of Physics

this way, especially for our infinite mode case, demonstrates that many problems of the above types are already solvable on the one-particle level, which is easier to handle.

In fact, with the Hamiltonian (1.2), resp. (1.1), there are associated two self-adjoint (complex-) linear one-photon operators on the one-photon Hilbert space $\mathscr{H}$,

$$C:=\sum_{k=1}^{\infty} c_k|e_k\rangle\langle e_k|, \quad S:=\sum_{k=1}^{\infty} s_k|e_k\rangle\langle e_k|, \tag{1.3}$$

and the (complex-) antilinear involution J satisfying

$$J_f=\sum_{k=1}^{\infty}\langle f|e_k\rangle e_k, \quad \forall f\in\mathscr{H} \tag{1.4}$$

(the scalar product $\langle\cdot|\cdot\rangle$ on $\mathscr{H}$ is assumed to be linear in the right factor). Hence C, S, and J are mutually commuting operators on $\mathscr{H}$ having the phase-transformed orthonormalized photon modes e_k, $k\in\mathbb{N}$, as eigenvectors. In a sense described in Ref. 6, the Hamiltonian H is a formal second quantization of $C-JS$.

We first regard quite general one-parameter groups of the type $T_t=\exp\{it(C-JS)\}$, $t\in\mathbb{R}$, on the infinite-dimensional one-photon Hilbert space $\mathscr{H}$, resp. on E. Each real-linear operator T_t turns out to be a symplectic transformation on $\mathscr{H}$, that is

$$\mathrm{Im}\langle T_t f|T_t g\rangle=\mathrm{Im}\langle f|g\rangle, \quad \forall f,g\in\mathscr{H}.$$

On the second quantized level in the algebraic sense for every time $t\in\mathbb{R}$ there exists a unique *-automorphism α_{T_t} on the CCR-algebra $\mathscr{W}(E)$—a Bogoliubov transformation—such that

$$\alpha_{T_t}(W(f))=W(T_t f), \quad \forall f\in E.$$

Here $W(f)=\exp\{i2^{-1/2}(a^*(f)+a(f))\}\in\mathscr{W}(E), f\in E$, denote the Weyl operators, which generate the CCR-algebra $\mathscr{W}(E)$.

Let us assume a representation Π of the CCR-algebra $\mathscr{W}(E)$ on the representation Hilbert space $\mathscr{K}_\Pi$. Then, from purely algebraic calculations it follows, that α_{T_t} is *formally* implemented by $\exp\{itH\}$, that is, for every $t\in\mathbb{R}$ one has

$$\Pi(\alpha_{T_t}(A))=\exp\{itH\}\Pi(A)\exp\{-itH\}, \quad \forall A\in\mathscr{W}(E). \tag{1.5}$$

We use the notion *formally*, since the existence of the unitaries $\exp\{itH\}$ is not ensured and the operator series in (1.2) may not converge to a well-defined self-adjoint operator on $\mathscr{K}_\Pi$. However, in some cases there may exist a well-defined self-adjoint operator $\widetilde{H}$, which unitarily implements the group $T_t, t\in\mathbb{R}$, in Π in the sense of (1.5). In this case $\widetilde{H}$ is a renormalization of the (possibly not existing) Hamiltonian H from (1.2).

In the present work we investigate the existence of unitary implementations (1.5) for one-parameter symplectic groups of the above type $T_t=\exp\{it(C-JS)\}$ (more exactly, of the associated group of Bogoliubov automorphisms α_{T_t} on the CCR-algebra) in the Fock representation Π_F, and in representations that are symplectically related to Fock. The T_t are not necessarily bounded operators on E. For the symplectically related representations $\Pi_T:=\Pi_F\circ\alpha_T$ of the CCR-algebra, we restrict ourselves to Bogoliubov transformations α_T associated with symplectic one-photon transformations of the form $T=\exp\{JR\}$, where the self-adjoint (complex-) linear R commutes with S, C, and J, and thus has the spectral representation,

$$R=\sum_{k=1}^{\infty} r_k|e_k\rangle\langle e_k|, \tag{1.6}$$

with some $r_k\in\mathbb{R}$. The specialization to discrete operators C, S, and R is justified for many applications in physics (cf. also Sec. V). Even if C would have a continuous part of the spectrum, it could be made discrete by an arbitrarily small Hilbert–Schmidt perturbation. As we shall demonstrate, the Hilbert space representations Π_F and Π_T of $\mathscr{W}(E)$ are unitarily equivalent, if

and only if R is Hilbert–Schmidt. Our main interest, however, concerns the case where R is not Hilbert–Schmidt, since then Π_F and Π_T are *disjoint* representations, and thus they physically belong to *different macroscopic* sectors of the infinite Boson (photon) system (see Theorem 2.3 and Proposition 3.3 below).

For $s_k=0,\forall k\in\mathbb{N}$, that is $S=0$, we are in the situation of Warchall's work,[7] who completely analyzed the implementability of a unitary (and thus symplectic) one-parameter group $T_t=\exp\{itC\}$ with a positive self-adjoint C in representations symplectically related to Fock. Here, with our discrete C one gets more insight into the basic structure of Warchall's result revealing the role of an *essential infrared part* of the one-photon Hamiltonian C (cf. Theorem 2.7 below).

In the Secs. III B and IV C we generalize Warchall's result to true one-parameter squeezing groups (i.e., with nontrivial S) and give as a main result of our work necessary and sufficient criteria for their unitary implementability.

We investigate in Sec. IV the existence of Hamiltonians of the type (1.2), resp. of renormalizations of H for the above representations Π_F and Π_T. For the Fock representation it is demonstrated that for the class of quadratic Hamiltonians (1.2) one obtains more involved results than the Hilbert–Schmidt property for S given in Ref. 6, allowing even some unbounded squeezing parts S. Especially, in Theorem 4.10, it is elaborated a renormalization concept, which treats the infrared and the ultraviolet part of a generating Hamiltonian in a different manner. Also, the diagonalizability of the quadratic Hamiltonian H, resp. of the group T_t, by symplectic transformations $T=\exp\{JR\}$ of the above kind is analyzed. In Theorems 4.12 and 4.13 we take up and work out an old idea of Segal[8] (cf. also Ref. 9), that a positive diagonal form of an implementing (renormalized) Hamiltonian is not only of practical but also of fundamental conceptual importance, providing a particle interpretation of the quantized system. We formulate necessary and sufficient conditions for the diagonalizability, discuss the equivalence class of this distinguished representation, and demonstrate that positivity is a logical consequence of the diagonalization requirement.

In Sec. V we apply our results to two typical problems of Boson field theory. First, we clarify the connection between the Dirac- and the harmonic oscillator-quantization schemes in nonrelativistic QED and discuss the corresponding field Hamiltonians. Then we study the Bosonic version of the Luttinger Hamiltonian and point out how a considerable generalization of the treated class of interactions for the Luttinger model may be achieved, including strictly local potentials.

As indicated above, there occur on the one-particle level complex-linear, complex-antilinear, and real-linear operators. If not stated otherwise, we always mean with the expressions ''operator'' and ''linear operator'' complex-linear mappings. On the level of the second quantization (C^*-algebraic level, and operators on Fock space), however, we are concerned with complex-linear operators, only.

II. IMPLEMENTATIONS OF SYMPLECTIC TRANSFORMATIONS

Let us first introduce our notation and collect some preliminary results.

Throughout the present section let E be an arbitrary separable complex pre-Hilbert space with (right-linear) scalar product $\langle\cdot|\cdot\rangle$ and norm completion $\mathscr{H}$. In physical applications E is interpreted as the one-Boson test function space of a Boson system. For scalar Bosons E is a (dense) subspace of $\mathsf{L}^2(\Lambda)$, whereas $E\subseteq\mathsf{L}^2(\Lambda)\otimes\mathbb{C}^{2s+1}$ for Bosons with the spin s.[10,2] Here $\Lambda\subseteq\mathbb{R}^3$ denotes the quantization volume in position space. For photons the quantization procedure in the Coulomb gauge leads to a test function space E, as described in Sec. V A.

Since E and $\mathscr{H}$ are complex vector spaces, each real-linear operator $B:E\to\mathscr{H}$ decomposes uniquely into its (complex-) linear part B_l and its (complex-) antilinear part B_a, that is, $B=B_l+B_a$ with (the multiplication with the complex i commutes with B, if and only if B is complex-linear),

$$B_l:=\tfrac{1}{2}(B-iBi)\qquad\text{and}\qquad B_a:=\tfrac{1}{2}(B+iBi). \tag{2.1}$$

A. Symplectic transformations

The imaginary part of the scalar product is a nondegenerate symplectic form on E. A mapping $T:E\to E$ is called a *symplectic transformation* on E, if it is real linear, with range $T(E)=E$, and fulfills

$$\mathrm{Im}\langle Tf|T_g\rangle = \mathrm{Im}\langle f|g\rangle, \quad \forall f,g \in E. \tag{2.2}$$

The set of all symplectic transformations on E is denoted by $\mathscr{T}(E)$. The relation (2.2) implies the injectivity of T, and thus each symplectic transformation T acts bijectively on E. The inverse mapping $T^{-1}: E \to E$ is a symplectic transformation on E, too. Hence $\mathscr{T}(E)$ forms a group (with respect to the multiplication).

As a transformation in $\mathscr{H}$, a symplectic $\mathscr{T} \in \mathscr{T}(E)$ is a densely defined, real-linear, operator with domain E. The following results are shown in Ref. 6.

Lemma 2.1: Let $\mathscr{T} \in \mathscr{T}(E)$. Then on $\mathscr{H}$ there exist a self-adjoint (linear) operator R, a (linear) unitary U, and an antilinear involution J commuting with R (that is, $J = J^* = J^{-1}$ and $J\phi(R) = \phi(R)^* J$ for every bounded measurable function $\phi: \mathbb{R} \to \mathbb{C}$), so that

$$T_l \subseteq U \cosh(R), \quad T_a \subseteq UJ \sinh(R),$$
$$(T^{-1})_l \subseteq \cosh(R) U^*, \quad (T^{-1})_a \subseteq -J \sinh(R) U^*,$$

and all these operators leave E invariant [T_l is the linear part and T_a the antilinear part of T according to (2.1)]. This decomposition is unique, if $R \geqslant 0$.

Moreover, the following assertions hold:

(a) *Let $T \in \mathscr{T}(E)$. If one of the mappings R, T, T_l, resp., T_a is bounded, then all are bounded.*
(b) *If $T \in \mathscr{T}(E)$ is bounded, then T extends by continuity to an element of $\mathscr{T}(\mathscr{H})$.*
(c) *If T is symplectic on the whole of $\mathscr{H}$, that is $T \in \mathscr{T}(\mathscr{H})$, then T is bounded.*
Thus, $\{T \in \mathscr{T}(E) | T \text{ is bounded}\} \equiv \{T \in \mathscr{T}(\mathscr{H}) | T(E) = E\}$ is a subgroup of $\mathscr{T}(\mathscr{H})$.

A symplectic one-parameter group is a family $\{T_t | t \in \mathbb{R}\} \subset \mathscr{T}(E)$, which satisfies the group properties $T_0 = \mathbf{1}$ and $T_s T_t = T_{s+t}$, $\forall s,t \in \mathbb{R}$. In the literature the notion of strong continuity of (semi-) groups is treated on *complete* spaces.[2] Since symplectic transformations are real linear, the above lemma suggests we take the (complete) real Hilbert space $\mathscr{H}_r$, which coincides with $\mathscr{H}$, but is equipped with the real scalar product $\mathrm{Re}\,\langle \cdot | \cdot \rangle$, when considering strong continuity for symplectic one-parameter groups. That is, a *strongly continuous* symplectic group $\{T_t | t \in \mathbb{R}\}$ consists of symplectic transformations $T_t \in \mathscr{T}(\mathscr{H})$ [each $T_t \in \mathscr{T}(E)$ has to be bounded and thus extends continuously to the whole of $\mathscr{H}$] and fulfills the continuity $\lim_{t \to 0} \|T_t f - f\| = 0$ for every $f \in \mathscr{H}_r \equiv \mathscr{H}$.

In general, a strongly continuous symplectic group $T_t \in \mathscr{T}(\mathscr{H})$, $t \in \mathbb{R}$, has the growth property $\|T_t\| \leqslant c \exp\{\beta|t|\}$, $\forall t \in \mathbb{R}$, for some $\beta \geqslant 0$ and $c \geqslant 1$; cf., e.g., Ref. 2, Proposition 3.1.3. If there is no $\beta \geqslant 0$ such that c may be chosen equal to unity, then by Ref. 6 the antilinear part G_a of the real-linear generator G of $T_t = \exp\{tG\}$, has to be unbounded, provided that G_a exists as a densely defined (closable) operator.

In Ref. 6 the generator G of a strongly continuous symplectic group $T_t = \exp\{tG\} \in \mathscr{T}(\mathscr{H})$, $t \in \mathbb{R}$, with the growth property $\|T_t\| \leqslant \exp\{\beta|t|\}$, $\forall t \in \mathbb{R}$ for some $\beta \geqslant 0$ is determined to be of the form $G = iC + D$ with a self-adjoint linear (possibly unbounded) operator C on $\mathscr{H}$ and an antilinear self-adjoint bounded operator D on $\mathscr{H}$. Conversely, for a self-adjoint linear C the group $u_t := \exp\{itC\}$, $t \in \mathbb{R}$, regarded as a strongly continuous unitary group on the real Hilbert space $\mathscr{H}_r$, may be perturbed with an antilinear bounded D,[2]

$$\exp\{t(iC+D)\} = \sum_{n=0}^{\infty} \int_{t_n=0}^{t} dt_n \cdots \int_{t_1=0}^{t_2} dt_1 \; u_{t_1} D u_{t_2 - t_1} D \cdots u_{t_n - t_{n-1}} D u_{t - t_n}, \tag{2.3}$$

where the norm convergence is ensured by the boundedness of D. Then the series (2.3) gives a strongly continuous symplectic group in $\mathscr{T}(\mathscr{H})$ with the growth estimates $\|\exp\{t(iC+D)\}\| \leqslant \exp\{\|D\||t|\}$ for all $t \in \mathbb{R}$. Since the u_t are linear and the perturbation D is antilinear, we have that the linear part of the real-linear $\exp\{t(iC+D)\}$ is given by summing over the even powers in the expansion series (2.3), and the antilinear part by summing over the odd ones.

B. Unitary implementations

The C^*-algebra for the Boson system with test function space E is the Weyl algebra $\mathscr{W}(E)$ over E—the CCR-algebra—, which is generated by the unitary Weyl operators $W(f)$, $f\in E$, satisfying Ref. 2, Theorem 5.2.8.

$$W(f)W(g)=\exp\{-i/2\,\mathrm{Im}\langle f|g\rangle\}W(f+g),\quad W(f)^*=W(-f),\quad \forall f,\quad g\in E. \tag{2.4}$$

The self-adjoint field operators for the regular representation Π of $\mathscr{W}(E)$ are given by

$$\Phi_\Pi(f):=-i\,\frac{d}{dt}\,\Pi(W(tf))|_{t=0},\quad f\in E. \tag{2.5}$$

The functional $E\ni f\mapsto\Phi_\Pi(f)$ is real linear. The smeared annihilation and creation operators,

$$a_\Pi(f):=2^{-1/2}(\Phi_\Pi(f)+i\Phi_\Pi(if)),\quad a_\Pi^*(f):=2^{-1/2}(\Phi_\Pi(f)-i\Phi_\Pi(if)), \tag{2.6}$$

respectively, fulfill the CCR $[a_\Pi(f),a_\Pi^*(g)]=\langle f|g\rangle\mathbb{1}$, $\forall f,\,g\in E$. It is $a_\Pi(f)^*=a_\Pi^*(f)$, the map $E\ni f\mapsto_\Pi(f)$ is antilinear and $E\ni f\mapsto a_\Pi^*(f)$ is linear (e.g., Ref. 2, Subsection 5.2.3).

For each $T\in\mathscr{T}(E)$ there exists a (unique) *-automorphism α_T on $\mathscr{W}(E)$ with

$$\alpha_T(W(f))=W(Tf),\quad \forall f\in E, \tag{2.7}$$

which is called the *Bogoliubov transformation associated with* T. Thus, the mapping $\mathscr{T}(E)\ni T\mapsto\alpha_T$ is a representation of the group $\mathscr{T}(E)$ as *-automorphisms on $\mathscr{W}(E)$.

Definition 2.2 (implementation): Consider a representation Π *of the CCR-algebra* $\mathscr{W}(E)$ *on the representation Hilbert space* $\mathscr{K}_\Pi$.

(a) *The Bogoliubov transformation* α_T *on* $\mathscr{W}(E)$, *or briefly the associated symplectic* $T\in\mathscr{T}(E)$, *is denoted to be (unitarily) implementable in* Π, *if there exists a unitary operator* U *(depending on the symplectic* T*) acting on* $\mathscr{K}_\Pi$, *such that*

$$\Pi(\alpha_T(A))=U\Pi(A)U^*,\quad \forall A\in\mathscr{W}(E). \tag{2.8}$$

The set $\mathscr{T}_\Pi(E)$ *of those symplectic transformations* $T\in\mathscr{T}(E)$, *that are implementable in* Π, *constitutes a subgroup of* $\mathscr{T}(E)$. *But, in general,* $\mathscr{T}_\Pi(E)\neq\mathscr{T}(E)$.

(b) *The one-parameter group* $\{T_t|t\in\mathbb{R}\}$ *of symplectic transformations* $T_t\in\mathscr{T}_\Pi(E)$, $\forall t\in\mathbb{R}$ *is denoted to be continuously implementable in* Π, *if the associated implementing unitaries* U_t, $t\in\mathbb{R}$, *on* $\mathscr{K}_\Pi$ *may be chosen as a strongly continuous one-parameter group, that is,* $U_t=\exp\{itH_\Pi\}$ *with some implementing self-adjoint operator* H_Π *on* $\mathscr{K}_\Pi$, *such that*

$$\Pi(\alpha_{T_t}(A))=\exp\{itH_\Pi\}\Pi(A)\exp\{-itH_\Pi\},\quad \forall A\in\mathscr{W}(E),\quad \forall t\in\mathbb{R}. \tag{2.9}$$

The implementing U and H_Π from (2.8), resp. (2.9), are, in general, nonunique. However, if the representation Π is irreducible, then U is unique up to a phase, and H_Π is unique up to a constant.

Let us remark, that $T_t\in\mathscr{T}_\Pi(E)$ for all $t\in\mathbb{R}$ with the implementing unitaries U_t, $t\in\mathbb{R}$, from (2.8) does not imply the continuous implementability of the symplectic group $\{T_t|t\in\mathbb{R}\}$. In general, the unitaries U_t, $t\in\mathbb{R}$ are not even choosable to constitute a group.

C. Representations symplectically related to Fock

In the present work we exclusively are interested in the Fock representation Π_F, and in representations $\Pi_T:=\Pi_F\circ\alpha_T$ of $\mathscr{W}(E)$, where $T\in\mathscr{T}(E)$. Obviously, for $T=\mathbb{1}$ we have the Fock representation $\Pi_1=\Pi_F$. The representation Π_T is called *symplectically related* to the Fock representation.[7] We briefly write $\mathscr{T}_F(E)$ and $\mathscr{T}_T(E)$, for the groups consisting of those symplectic $\widetilde{T}\in\mathscr{T}(E)$, which are implementable in Π_F, resp., in Π_T.

By construction the representation Hilbert space for the symplectically related representation $\Pi_T=\Pi_F\circ\alpha_T$ of $\mathscr{W}(E)$, $T\in\mathscr{T}(E)$, is the same as for the Fock representation Π_F, namely the Bose–Fock space $F_+(\mathscr{H})$, and we stick to this realization in the following for convenience.

The field, annihilation, and creation operators associated with Π_F are denoted by an index F, that is, $\Phi_F(f)$, $a_F(f)$, resp., $a_F^*(f)$, $f\in E$, and those associated with Π_T by an index T, that is $\Phi_T(f)$, $a_T(f)$, resp. $a_T^*(f)$, $f\in E$, according to Eqs. (2.5) and (2.6). All these operators act on the Fock space $F_+(\mathscr{H})$, and it holds that

$$\Phi_T(f)=\Phi_F(Tf),\quad a_T(f)=a_F(T_lf)+a_F^*(T_af),\quad \forall f\in E. \tag{2.10}$$

It is well known that the Fock representation Π_F is the GNS representation (cf. e.g., Ref. 2, Definition 2.3.18) of the vacuum state ω_F on $\mathscr{W}(E)$, which is uniquely given by

$$\langle\omega_F;W(f)\rangle=\exp\{-\tfrac{1}{4}\|f\|^2\}=\langle\Omega_F|\Pi_F(W(f))\Omega_F\rangle,\quad \forall f\in E,$$

where $\Omega_F\in F_+(\mathscr{H})$ is the Fock vacuum vector. Thus $(\Pi_T,F_+(\mathscr{H}),\Omega_F)$ is (unitarily equivalent to) the GNS triple of the Bogoliubov transformed vacuum state:

$$\omega_T:=\omega_F\circ\alpha_T,$$

the so-called squeezed vacuum.[1,11,12,5] We see that the GNS triple for ω_T is realized with the Fock space $F_+(\mathscr{H})$ as a GNS Hilbert space. The Fock representation Π_F is irreducible,[2] and thus Π_T is so, too. Hence, the associated von Neumann algebra $\Pi_T(\mathscr{W}(E))''$ is equal to $\mathscr{B}(F_+(\mathscr{H}))$, the algebra of all bounded operators on Fock space.

If $T\in\mathscr{T}(E)$ is bounded, then it extends continuously to $T\in\mathscr{T}(\mathscr{H})$ by Lemma 2.1, and thus then one may extend Π_T to the enlarged Weyl algebra $\mathscr{W}(\mathscr{H})\supseteq\mathscr{W}(E)$, since $\mathscr{H}\ni f\mapsto\Pi_T(W(f))=\Pi_F(W(Tf))$ is continuous in the strong operator topology by Ref. 2, Proposition 5.2.4. For the general theory concerning continuous enlargements of testfunction spaces and representations, we refer to Ref. 13.

Let us introduce the folium $\mathscr{F}_T$ consisting of the Π_T-normal states on $\mathscr{W}(E)$ (cf., e.g., Ref. 2, Definition 2.4.25, Ref. 14, Section 1, 15, 16), that is, for each $\omega\in\mathscr{F}_T$ there is a density operator $\rho_{\omega,T}$ on Fock space such that

$$\langle\omega;A\rangle=\mathrm{tr}[\rho_{\omega,T}\Pi_T(A)],\quad \forall A\in\mathscr{W}(E),\quad \omega\in\mathscr{F}_T. \tag{2.11}$$

Since Π_T is irreducible, Eq. (2.11) defines a one-to-one correspondence between $\mathscr{F}_T$ and the density operators on Fock space. For $T=\mathbf{1}$ we obtain the folium $\mathscr{F}_1\equiv\mathscr{F}_F$ of the Fock-normal states on $\mathscr{W}(E)$.

In the case of $T\in\mathscr{T}_F(E)$ there is, by Definition 2.2(a), a unitary U_T on Fock space (unique up to a phase), such that

$$\Pi_T(A)=\Pi_F(\alpha_T(A))=U_T\Pi_F(A)U_T^*,\quad \forall A\in\mathscr{W}(E). \tag{2.12}$$

This relation expresses the unitary equivalence of Π_F and Π_T. Moreover, for $T\in\mathscr{T}_F(E)$ the Bogoliubov transformed field operators (2.10) are obtained with the unitary transformation U_T,

$$\Phi_T(f)=\Phi_F(Tf)=U_T\Phi_F(f)U_T^*,\quad \forall f\in E. \tag{2.13}$$

Theorem 2.3: *Let $T\in\mathscr{T}(E)$. Then the following holds:*
(a) The following conditions are equivalent:

(i) $T\in\mathscr{T}_F(E)$;
(ii) *the closure of the antilinear part T_a of T is Hilbert–Schmidt[17] on $\mathscr{H}$;*
(iii) *there is a normalized $\psi_T\in F_+(\mathscr{H})$ with $a_T(f)\psi_T=0\,\forall f\in E$ (where then $\psi_T=U_T\Omega_F$ up to a phase);*
(iv) $\omega_T\in\mathscr{F}_F$ *(or equivalently,* $\omega_F\in\mathscr{F}_T$);
(v) $\mathscr{F}_T=\mathscr{F}_F$;
(vi) Π_T *and* Π_F *are quasiequivalent (and thus unitarily equivalent by their irreducibility);*

(vii) *there is an *-automorphism* γ_T *on* $\mathcal{B}(F_+(\mathcal{H}))$ *such that* $\gamma_T(\Pi_F(A))=\Pi_T(A)$, $\forall A \in \mathcal{W}(E)$ *(which then is given by* U_T *according to Eq. (2.12)).*

(b) The following conditions are equivalent:

(i) $T \notin \mathcal{T}_F(E)$;
(ii) $\mathcal{T}_T \cap \mathcal{T}_F = \emptyset$;
(iii) Π_T *and* Π_F *are disjoint representations of* $\mathcal{W}(E)$ *(e.g., Ref. 2, Subsection 4.2.2);*
(iv) *the (algebraic) transition probability (cf. Ref. 18) between the vacuum* $\omega_F \in \mathcal{T}_F$ *and every other state* $\omega \in \mathcal{T}_T$ *is zero.*

Proof: (a)(i)⇔(a)(ii) is proven in Ref. 19 (cf. also Refs. 20, 21, Sec. IX, and 22), and is generalized in Ref. 6. (a)(i)⇔(a)(iii)⇔(a)(iv) is also shown in Ref. 6. (a)(iv)⇔(a)(v) follows from the fact that $\mathcal{T}_T$ (resp., $\mathcal{T}_F$) is the smallest folium in the state space of $\mathcal{W}(E)$ containing ω_T (resp. ω_F). The equivalences (a)(v)⇔(a)(vi)⇔(a)(vii) are standard results for quasiequivalence, e.g. Ref. 2, Subsection 2.4.4, applied to our specific situation. (b)(i)⇔(b)(ii)⇔(b)(ii) is the negation of (a), since Π_T and Π_F are the (irreducible) GNS representations of the pure states ω_T, resp. ω_F. (b)(iii)⇔(b)(iv) is proved in Ref. 18, Proposition 2.8. ■

We see that the antilinear part T_a being Hilbert–Schmidt induces a lot of further properties. For the use of the folium $\mathcal{T}_T$ for a generalized Schrödinger dynamics we refer to Ref. 15.

Let us remark, that for $T \in \mathcal{T}_F(E)$ we have T_a to be Hilbert–Schmidt by the above theorem, which yields T_a and thus T to be bounded. Consequently, T extends continuously to an element of $\mathcal{T}_F(\mathcal{H})$ by Lemma 2.1. That is, $\mathcal{T}_F(E)$ is the subgroup of $\mathcal{T}_F(\mathcal{H})$ consisting of those $T \in \mathcal{T}_F(\mathcal{H})$ with $T(E)=E$.

D. Implementations in the Fock representation

By Theorem 2.3 the symplectic $T \in \mathcal{T}(\mathcal{H})$ is implementable in the Fock representation Π_F, if and only if its antilinear part T_a is Hilbert–Schmidt on $\mathcal{H}$. Let us turn to the implementability of symplectic *one-parameter groups* of the type (2.3) and communicate a result proven in Ref. 6.

Theorem 2.4: *For linear* $C=C^*$ *and antilinear Hilbert–Schmidt* $D=D^*$ *on* $\mathcal{H}$*, it holds that* $\exp\{t(iC+D)\} \in \mathcal{T}_F(\mathcal{H}) \forall t \in \mathbb{R}$ *(cf. Section II A). Moreover, the symplectic one-parameter group* $\{\exp\{t(iC+D)\} | t \in \mathbb{R}\}$ *is continuously implementable in* Π_F.

E. Implementations in symplectically related representations

As discussed above, the representation Hilbert space of the symplectically related representation $\Pi_T=\Pi_F \circ \alpha_T$ of $\mathcal{W}(E)$ is the Fock space. Thus, the implementability in Π_T leads back to the implementability in Π_F, but for the transformed symplectic transformation:

Lemma 2.5: For $T \in \mathcal{T}(E)$ *consider the symplectically related representation* $\Pi_T=\Pi_F \circ \alpha_T$. *Then for each* $\tilde{T} \in \mathcal{T}(E)$ *it holds:* $\tilde{T} \in \mathcal{T}_T(E)$, *if and only if* $T\tilde{T}T^{-1} \in \mathcal{T}_F(E)$.

Furthermore, the associated implementing unitaries U, *for* $\tilde{T}$ *in* Π_T *and for* $T\tilde{T}T^{-1}$ *in* Π_F *(both acting on Fock space), agree up to a phase. That is, for all* $f \in E$ *we have, according to the equations (2.7) and (2.8):*

$$\Pi_T(W(\tilde{T}f))=\Pi_T(\alpha_{\tilde{T}}(W(f)))=U\Pi_T(W(f))U^*,$$

$$\Pi_F(W(T\tilde{T}T^{-1}f))=\Pi_F(\alpha_{T\tilde{T}T^{-1}}(W(f)))=U\Pi_F(W(f))U^*.$$

Proof: With Eq. (2.8) and $\Pi_F \circ \alpha_T=\Pi_T$, we have $U\Pi_T(W(f))U^*=(\Pi_T \circ \alpha_{\tilde{T}})(W(f))=\Pi_T(W(\tilde{T}f))$, $\forall f \in E$, if and only if $U\Pi_F(W(Tf))U^*=\Pi_F(W(T\tilde{T}f)) \forall f \in E$. Since T acts bijectively on E, we may put $f=T^{-1}g$, and thus the last equation is equivalent to $U\Pi_F(W(g))U^*=\Pi_F(W(T\tilde{T}T^{-1}g))=(\Pi_F \circ \alpha_{T\tilde{T}T^{-1}})(W(g))$, $\forall g \in E$. Hence the unitary implementability of $\tilde{T}$ in Π_T is equivalent to the unitary implementability of $T\tilde{T}T^{-1}$ in Π_F, and the associated implementing unitaries agree up to a phase since Π_F and Π_T are irreducible. ■

Obviously, this Lemma immediately extends to continuously implementable *one-parameter groups* of symplectic transformations: For $T \in \mathcal{T}(E)$ consider the symplectically related representation $\Pi_T=\Pi_F \circ \alpha_T$ of $\mathcal{W}(E)$. Then the symplectic group $T_t \in \mathcal{T}(E)$, $t \in \mathbb{R}$, is continuously imple-

mentable in Π_T, if and only if the transformed symplectic group $\hat{T}_t := TT_tT^{-1} \in \mathscr{T}(E)$, $t \in \mathbb{R}$, is continuously implementable in Π_F. For the implementing strongly continuous unitary group $U_t = \exp\{itH_{\mathrm{im}}\}$, $t \in \mathbb{R}$, with some self-adjoint H_{im} on Fock space (which is unique up to a constant), it follows according to Eq. (2.9) that

$$\begin{aligned} \Pi_T(W(T_t f)) &= \Pi_T(\alpha_{T_t}(W(f))) = \exp\{itH_{\mathrm{im}}\}\Pi_T(W(f))\exp\{-itH_{\mathrm{im}}\}, \\ \Pi_F(W(TT_tT^{-1}f)) &= \Pi_F(\alpha_{TT_tT^{-1}}(W(f))) = \exp\{itH_{\mathrm{im}}\}\Pi_F(W(f))\exp\{-itH_{\mathrm{im}}\}. \end{aligned} \tag{2.14}$$

For the norm-complete test function space $E = \mathscr{H}$, Warchall investigated in Ref. 7 the implementability in Π_T of a unitary (and thus symplectic) one-parameter group $T_t = \exp\{itC\}$, $t \in \mathbb{R}$, on $\mathscr{H}$ with a self-adjoint linear generator $C \geqslant 0$. The unitary group $\{\exp\{itC\} | t \in \mathbb{R}\}$ is continuously implementable in the Fock representation by Segal's second quantized $\Gamma(\exp\{itC\}) = \exp\{it d\Gamma(C)\}$, cf., e.g., Ref. 2, Subsection 5.2.1 or Ref. 3, Sec. X.7.

Definition 2.6 (infrared part): Since the neighborhood of the zero frequency determines the infrared behavior of a Hamiltonian, we call here the self-adjoint operator C on $\mathscr{H}$ to have an essential infrared part, if the dimension of $P_C([-a,a])\mathscr{H}$ is infinite for every $a > 0$, where $P_C(\cdot)$ is the spectral projection valued measure for C.

If $P_C([-\varepsilon,\varepsilon])\mathscr{H}$ is finite for some $\varepsilon > 0$, then C has an inessential infrared part (which, e.g., is valid for strictly positive C, i.e., $C \geqslant c\mathbb{1}$ for some $c > 0$).

Observe that C has an essential infrared part, if and only if zero is an element of the essential spectrum of the self-adjoint linear operator C, Ref. 3, Subsection VII.2. Using Definition 2.6 we are able to cast a main result of Ref. 7 into the following concise form.

Theorem 2.7 (Warchall): *Let $C \geqslant 0$ be a self-adjoint operator on $\mathscr{H}$. We denote by $\mathscr{C}_{\mathrm{im}}(C)$ the class of those $T \in \mathscr{T}(\mathscr{H})$, for which $\{\exp\{itC\} | t \in \mathbb{R}\}$ is continuously implementable in Π_T. (Each $T \in \mathscr{T}(\mathscr{H})$ is bounded by Lemma 2.1.) The following holds*:

(a) *If C has an inessential infrared part, then $\mathscr{C}_{\mathrm{im}}(C) = \mathscr{T}_F(\mathscr{H})$.*
(b) *Let C have an essential infrared part. Then the inclusion $\mathscr{T}_F(\mathscr{H}) \subset \mathscr{C}_{\mathrm{im}}(C)$ is proper. However, one has in general $\mathscr{C}_{\mathrm{im}}(C) \neq \mathscr{T}(\mathscr{H})$.*

Thus the group $\{\exp\{itC\} | t \in \mathbb{R}\}$ is continuously implementable in some symplectically related representations Π_T inequivalent (disjoint) to the Fock representation Π_F (cf. Theorem 2.3), if and only if C has an essential infrared part.

In the Secs. III B and IV C, we generalize Warchall's result in a certain sense.

By definition, $\mathscr{T}_F(E)$ is the group of those symplectic transformations T on E for which T is unitarily implementable in the Fock representation Π_F, which immediately implies the following result concerning the implementability in Π_F.

Lemma 2.8: Suppose $T \in \mathscr{T}_F(E)$ in the situation of the Lemma 2.5. Because of the group property of $\mathscr{T}_F(E)$ we have the following equivalence; $\tilde{T} \in \mathscr{T}(E)$ is implementable in Π_F, if and only if $T\tilde{T}T^{-1}$ is implementable in Π_F, or in other words, $\tilde{T}$ is implementable in Π_F, if and only if $\tilde{T}$ is implementable in Π_T. Assume in this case that U_T, $U_{\tilde{T}}$, and $U_{T\tilde{T}T^{-1}}$ are the unitaries implementing T, $\tilde{T}$, resp., $T\tilde{T}T^{-1}$ in Π_F, then $U \equiv U_{T\tilde{T}T^{-1}} = U_T U_{\tilde{T}} U_T^*$ (up to a phase; the implementing U is from Lemma 2.5), which also implements $\tilde{T}$ in Π_T.

Furthermore, the symplectic group $T_t \in \mathscr{T}(E)$, $t \in \mathbb{R}$, is continuously implementable in Π_F, if and only if the transformed symplectic group $\hat{T}_t := TT_tT^{-1} \in \mathscr{T}(E)$, $t \in \mathbb{R}$, is continuously implementable in Π_F. If H and $\hat{H}$ are the implementing self-adjoint operators for T_t, resp., $\hat{T}_t$ in Π_F, then $H_{\mathrm{im}} \equiv \hat{H} = U_T H U_T^*$ [up to an additive constant; the implementing H_{im} is from the equation (2.14)].

III. SYMPLECTICALLY TRANSFORMED GROUPS

Let $\mathscr{H}$ be an infinite-dimensional separable complex Hilbert space with fixed ONB $\{e_k | k \in \mathbb{N}\}$. Let C, S, and R be possibly unbounded, self-adjoint, linear operators on $\mathscr{H}$ having the e_k as eigenvectors:

$$Ce_k = c_k e_k, \quad Se_k = s_k e_k, \quad \mathrm{Re}_k = r_k e_k, \quad \text{with } c_k, s_k, r_k \in \mathbb{R}, \quad \forall k \in \mathbb{N}. \tag{3.1}$$

Finally, let J be the antilinear involution on $\mathscr{H}$ satisfying $Je_k = e_k$, $\forall k \in \mathbb{N}$. Obviously, C, S, R, and J mutually commute [cf. the Eqs. (1.3), (1.4), and (1.6), but in contrast to the Introduction here also $s_k < 0$ is allowed].

For convenience we choose from now on the one-particle test function space E as the space of all finite (complex-) linear combinations of our ONB $\{e_k | k \in \mathbb{N}\}$. The exponentials,

$$T_t := \exp\{it(C - JS)\} \in \mathscr{T}(E), \quad t \in \mathbb{R}, \tag{3.2}$$

constitute a well-defined one-parameter group of symplectic transformations on E, which follows from the application of Sec. II A [cf. Eq. (2.3) with $\mathrm{D} = -iJS$) to each invariant subspace $T_t(\mathbb{C}e_k) = \mathbb{C}e_k$, $k \in \mathbb{R}$. Another group of this kind is introduced by a *symplectic shift* as follows:

$$\hat{T}_t := TT_tT^{-1} \in \mathscr{T}(E), \quad t \in \mathbb{R}, \tag{3.3}$$

where

$$T := \exp\{JR\} = \cosh(R) + J\sinh(R) \in \mathscr{T}(E). \tag{3.4}$$

Because C, S, R, J, and thus $T_t, T, \hat{T}_t$ decompose according to $\mathscr{H} = \oplus_{k=1}^{\infty} \mathbb{C}e_k$, it holds that $\lim_{t\to 0} \|T_t f - f\| = 0$ and $\lim_{t\to 0} \|\hat{T}_t f - f\| = 0$ for every $f \in E$. Since E is not complete, these continuity relations do not imply the strong continuity of both groups on the complete $\mathscr{H}$, as described in Sec. II A. In general, T_t, resp. $\hat{T}_t$, and T may be unbounded symplectic transformations on E (by Lemma 2.1, since E is not complete).

We stick to the notation (3.1)–(3.4) throughout the present and the following sections.

A. The generator of the shifted group

The following result ensures that shifts with symplectic transformations of the form (3.4) leave the class (3.2) of symplectic groups invariant, that is, $\hat{T}_t$ is of the type (3.2), too.

Lemma 3.1: The generator of the symplectic group $\{\hat{T}_t | t \in \mathbb{R}\} \subset \mathscr{T}(E)$ is given by $i(\hat{C} - J\hat{S})$, that is, $\hat{T}_t = \exp\{it(\hat{C} - J\hat{S})\}$, $\forall t \in \mathbb{R}$, with the self-adjoint linear operators on $\mathscr{H}$,

$$\hat{C} := \cosh(2R)C + \sinh(2R)S, \quad \hat{S} := \cosh(2R)S + \sinh(2R)C, \tag{3.5}$$

and the e_k, $k \in \mathbb{N}$, are the eigenvectors for $\hat{C}$ and $\hat{S}$ with the associated eigenvalues,

$$\hat{c}_k := \cosh(2r_k)c_k + \sinh(2r_k)s_k, \quad s_k := \cosh(2r_k)s_k + \sinh(2r_k)c_k. \tag{3.6}$$

Conversely, C and S are obtained from $\hat{C}$ and $\hat{S}$ by

$$C = \cosh(2R)\hat{C} - \sinh(2R)\hat{S}, \quad S = \cosh(2R)\hat{S} - \sinh(2R)\hat{C}.$$

Proof: It follows from (3.3) that $\hat{T}_t = \exp\{t\hat{G}\}$, and thus its generator $\hat{G}$ leaves each $\mathbb{C}e_k$, $k \in \mathbb{N}$, invariant, E being a complex-linear space we may decompose $\hat{G}$ into its linear and antilinear part, $\hat{G}_l =: i\hat{C}$ and $\hat{G}_a =: -iJ\hat{S}$, respectively. Now $Ti(C - JS)T^{-1} = i(\hat{C} - J\hat{S})$, the decomposition (3.4), and $T^{-1} = \exp\{-JR\} = \cosh(R) - J\sinh(R)$, and the formulas

$$\cosh(x)^2 = \sinh(x)^2 + 1, \quad 2\sinh(x)^2 = \cosh(2x) = -1, \quad 2\cosh(x)\sinh(x) = \sinh(2x) \tag{3.7}$$

imply the remaining statements. ■

We now study the growth estimations of the groups T_t and $\hat{T}_t$ in the case where they constitute strongly continuous one-parameter groups on the whole of the real Hilbert space $\mathscr{H}_r$ ($\mathscr{H}$ equipped with the real scalar product $\mathrm{Re}\langle \cdot | \cdot \rangle$), that is, $\|T_t\| < \infty$ for all $t \in \mathbb{R}$ and thus each T_t extends continuously to the whole of $\mathscr{H}$ by Lemma 2.1, and $\lim_{t\to 0} \|T_t f - f\| = 0$ for all $f \in \mathscr{H}$, and analogous relations for $\hat{T}_t$ (see Sec. II A).

Theorem 3.2 (growth property): *If S is bounded, then the group $\{T_t|t\in\mathbb{R}\}$ is strongly continuous on $\mathscr{H}_r$ with $\|T_t\|\leqslant\exp\{\|S\||t|\}$ for all $t\in\mathbb{R}$.*

Let S and R both be bounded. Then $\|T\|=\exp\{\|R\|\}=\|T^{-1}\|$, and the symplectic one-parameter group $\{\hat{T}_t|t\in\mathbb{R}\}$ is strongly continuous on $\mathscr{H}_r$ with $\|\hat{T}_t\|\leqslant\exp\{2\|R\|\}\exp\{\|S\|t\}$ for all $t\in\mathbb{R}$ (also for unbounded $\hat{S}$). But $\hat{T}_t$ has the growth estimation $\|\hat{T}_t\|\leqslant\exp\{\beta|t|\}$, $\forall t\in\mathbb{R}$ with some $\beta\geqslant 0$, if and only if $\hat{S}$ is bounded (in which case β may be chosen as $\|\hat{S}\|$).

Proof: For bounded T (which is equivalent with R being bounded by Lemma 2.1) it follows from the construction (3.3) that the shifted group $\hat{T}_t$ is strongly continuous on $\mathscr{H}_r$, if and only if T_t is strongly continuous on $\mathscr{H}_r$. Now our assertions are consequences of the results stated in Sec. II A. ■

From (3.5) it is seen that for unbounded C but bounded S and bounded R, it may occur that $\hat{S}$ is unbounded, too [e.g., if $C\geqslant 0$ and $R\geqslant\gamma\mathbb{1}$ for some $\gamma>0$, then $\hat{S}\geqslant\sinh(2\gamma)C$]. The above Theorem then implies the growth estimation $\|\hat{T}_t\|\leqslant c\ \exp\{\beta|t|\}$, $\forall t\in\mathbb{R}$ with some $c>1$ and $\beta\geqslant 0$, and one cannot find a $\beta\geqslant 0$ such that c may be chosen as $c=1$. Thus, we have here some examples of strongly continuous groups (not only semigroups), where it is not possible to put $c=1$, supplementing the rare instances in the literature; cf. Ref. 23, p. 14.

B. Unitary implementations

Let us first consider the symplectic shift $T=\exp\{JR\}$ from Eq. (3.4). By Theorem 2.3 the condition $T\in\mathscr{T}_F(E)$ is equivalent to the unitary equivalence of the representations Π_F and Π_T (which then physically are not distinguishable). This contrasts the case $T\notin\mathscr{T}_F(E)$, where Π_F and Π_T are inequivalent (disjoint) representations of $\mathscr{W}(E)$, and thus describe the macroscopically different sectors $\mathscr{F}_F$ and $\mathscr{F}_T$ (disjoint folia) of the Boson system.

Proposition 3.3: For our $T=\exp\{JR\}\in\mathscr{T}(E)$ we have the following equivalences:

(i) *R is Hilbert–Schmidt on $\mathscr{H}$ (especially, R is bounded)*;
(ii) $\sinh(R)$ *is Hilbert–Schmidt on $\mathscr{H}$*;
(iii) $\tanh(R)$ *is Hilbert–Schmidt on $\mathscr{H}$*;
(iv) *$T=\exp\{JR\}\in\mathscr{T}_F(E)$ (especially, T is bounded).*

Proof: From Theorem 2.3 and Eq. (3.4), it follows that $T\in\mathscr{T}_F(E)$, if and only if $T_a=J\sinh(R)$ is Hilbert–Schmidt, or equivalently, if and only if $\sinh(R)$ is Hilbert–Schmidt (since J is an antiunitary). Let us first assume $\sinh(R)$ to be Hilbert–Schmidt. Then from $\sinh(x)=\Sigma_{n\,\mathrm{odd}}x^n/n!\geqslant x$ for $x\geqslant 0$, one gets

$$\|\sinh(R)\|_{\mathrm{HS}}^2=\sum_{k=1}^{\infty}\ \sinh(r_k)^2=\sum_{k=1}^{\infty}\ \sinh(|r_k|)^2\geqslant\sum_{k=1}^{\infty}\ |r_k|^2,$$

which implies R to be Hilbert–Schmidt, too. The converse relation, that R Hilbert–Schmidt implies $\sinh(R)$ to be Hilbert–Schmidt, follows from the power series for $\sinh(R)$, respectively, from Theorem 2.4. Now observe that the Hilbert–Schmidt operators on $\mathscr{H}$ constitute an ideal in the algebra of all bounded operators on $\mathscr{H}$. But R bounded implies $\cosh(R)$ and $\cosh(R)^{-1}$ to be bounded. Then the equivalence of (ii) and (iii) follows from $\cosh(R)\tanh(R)=\sinh(R)$, and from the fact that $\sinh(R)$, resp., $\tanh(R)$ Hilbert–Schmidt yields R bounded ($\Sigma_k\tanh(r_k)^2<\infty$ implies $\sup_k|\tanh(r_k)|<1$, which yields $\sup_k|r_k|<\infty$, and thus R is bounded). ■

If S is Hilbert–Schmidt, then Theorem 2.4 implies $T_t\in\mathscr{T}_F(E)$, $\forall t\in\mathbb{R}$. Beside this result, we have another case, which allows S not to be Hilbert–Schmidt.

Proposition 3.4: Let $SC^{-1}|_{\ker(C)^\perp}+S|_{\ker(C)}$ be Hilbert–Schmidt on $\mathscr{H}$ (here $\ker(C)^\perp$ is the (complex) orthogonal complement of the kernel $\ker(C)$ of C in $\mathscr{H}$), that is $\Sigma_{k,c_k\neq 0}(s_k^2/c_k^2)+\Sigma_{k,c_k=0}s_k^2<\infty$. Then we have $T_t\in\mathscr{T}_F(E)$, $\forall t\in\mathbb{R}$.

Proof: For $t\in\mathbb{R}$ consider the continuous functions $f_t:\mathbb{R}\to\mathbb{C}$ with $f_t(x)=(\exp\{-i2tx\}-1)/x$ for $x\neq 0$ and $f_t(0)=-i2t$. Since $J\exp\{i\tau C\}=\exp\{-i\tau C\}J$, $\forall\tau\in\mathbb{R}$ and $[S,C]=0$ we have for each $t\in\mathbb{R}$,

$$F_t := \int_0^t \exp\{i\tau C\}(-iJS)\exp\{-i\tau C\}\mathrm{d}\tau = \frac{1}{2} JSf_t(C).$$

Now the assumption exhibits $t \in \mathbb{R} \mapsto \|F_t\|_{\mathrm{HS}}$ to be continuous. Finally, use the expansion series for $(T_t)_a$ [summing over the odd numbers in the Dyson series (2.3)] to show that $(T_t)_a$ is Hilbert–Schmidt. ■

Now we turn to the continuous implementability of the symplectic *one-parameter groups* T_t and $\hat{T}_t$, $t \in \mathbb{R}$. By Lemma 2.5, $\{T_t | t \in \mathbb{R}\}$ is continuously implementable in the symplectically related representation $\Pi_T = \Pi_F \circ \alpha_T$, if and only if $\{\hat{T}_t | t \in \mathbb{R}\}$ is continuously implementable in the Fock representation Π_F.

First, let us consider the case $T \in \mathscr{T}_F(E)$, where Π_F and Π_T are unitarily equivalent.

Proposition 3.5: Let S and R be Hilbert–Schmidt. Then $\{T_t | t \in \mathbb{R}\}$ *and* $\{\hat{T}_t | t \in \mathbb{R}\}$ *are continuously implementable in the Fock representation* Π_F.

Proof: Consequence of Lemma 2.8, Proposition 3.3, and Theorem 2.4. ■

Example 3.6: Even in the situation of the above proposition, where S and R both are Hilbert–Schmidt (and thus bounded), the operator C may be chosen such that $\hat{S}$ *is unbounded: Let,* e.g., $r_k > 0 \forall k \in \mathbb{N}$, *and choose C with* $c_k \geqslant k/\sinh(2r_k)$, $\forall k \in \mathbb{R}$. *Then (3.5) yields* $\hat{S}$ *to be unbounded (since* $\hat{s}_k \geqslant k$, $\forall k \in \mathbb{N}$*), and it is nevertheless* $\hat{T}_t \in \mathscr{T}_F(E)$, $\forall t \in \mathbb{R}$.

Suppose S to be Hilbert–Schmidt. Then $\{T_t | t \in \mathbb{R}\}$ is continuously implementable in Π_F by Theorem 2.4. Let us now construct some $T \notin \mathscr{T}_F(E)$ so that $\{T_t | t \in \mathbb{R}\}$ also is continuously implementable in Π_T. We arrive at the mentioned generalization of Warchall's result[7] (cf. Theorem 2.7). Observe that in our context the spectral projections $P_C(\mathscr{B})$ of C ($\mathscr{B} \subseteq \mathbb{R}$ denotes an arbitrary Borel subset) and the operators S, R, and J mutually commute.

Theorem 3.7: *Let us write* $R \in \mathscr{R}(C)$, *whenever our operators R* and *C from (3.1) fulfill the condition that for some* $a > 0$ *the operators* $\tanh(R) C P_C([-a,a])$ *and* $R P_C(\mathbb{R} \backslash [-a,a])$ *both are Hilbert–Schmidt on* $\mathscr{H}$. The following holds.

(I) If R is bounded and S is Hilbert–Schmidt, then for $T = \exp\{JR\}$ *it is equivalent:*

(i) $T_t = \exp\{it(C - JS)\} \in \mathscr{T}_T(E)$ *for all* $t \in \tau$ *for an arbitrary open interval* $\tau \subseteq \mathbb{R}$ *containing the origin,*

(ii) $R \in \mathscr{R}(C)$,

(iii) *the symplectic group* $\{T_t | t \in \mathbb{R}\}$ *is continuously implementable in* Π_T *(which is equivalent to the continuous implementability of* $\{T_t | t \in \mathbb{R}\}$ *in* Π_F*).*

(II) For the condition $\mathscr{R}(C)$ *the following assertions are valid:*

(a) *If R is Hilbert–Schmidt (and thus bounded), then* $R \in \mathscr{R}(C)$.

(b) *Let C have an inessential infrared part. Then* $R \in \mathscr{R}(C)$, *if and only if R is Hilbert–Schmidt.*

(c) *There exist some bounded and some unbounded* $R \in \mathscr{R}(C)$, *which are not Hilbert–Schmidt, if and only if C has an essential infrared part.*

(d) $\mathscr{R}(C)$ *consists of all bounded and all unbounded operators R of the form (3.1), if and only if C is Hilbert–Schmidt on* $\mathscr{H}$.

Proof: HS_r denotes the real-linear Hilbert–Schmidt operators on $\mathscr{H}_r$, and HS the (complex-) linear Hilbert–Schmidt operators on $\mathscr{H}$. It is $\mathrm{HS} \subset \mathrm{HS}_r$. In the proof we use the ideal property of HS (resp. HS) in the algebra of bounded operators on $\mathscr{H}$ (resp., $\mathscr{H}_r$). (I)(iii)⇒(I)(i) is immediate. Let us prove (I)(ii)⇒(I)(iii): We decompose the Fock representation and the Fock space into a tensor product, $\Pi_F = \Pi_{F,1} \otimes \Pi_{F,2}$ on $F_+(\mathscr{H}) = F_+(\mathscr{H}_1) \otimes F_+(\mathscr{H}_2)$, where $\mathscr{H}_1 := P_C \times([-a,a])\mathscr{H}$ and $\mathscr{H}_2 := P_C(\mathbb{R} \backslash [-a,a])\mathscr{H}$. Restricting first to $\mathscr{H}_2$, we have that $S|_{\mathscr{H}_2} \in \mathrm{HS}$ and $R|_{\mathscr{H}_2} \in \mathrm{HS}$. Thus, it follows from Proposition 3.5 that the restricted group $\hat{T}_t|_{\mathscr{H}_2}$ is continuously implementable in $\Pi_{\mathrm{F},2}$. Now we restrict to $\mathscr{H}_1$. If $\hat{S}|_{\mathscr{H}_1} \in \mathrm{HS}$, then the restricted group $\hat{T}_t|_{\mathscr{H}_1}$ is continuously implementable in $\Pi_{F,1}$ by Theorem 2.4. Forming the direct sum $\hat{T}_t$

$=\hat{T}_t|_{\mathscr{H}_1}\oplus\hat{T}_t|_{\mathscr{H}_2}$ yields the result. But $\cosh(R)$ being bounded implies $2\cosh(R)^2\tanh(R)CP_C$ $2\cosh(R)^2\tanh(R)CP_C([-a,a])=\sinh(2R)CP_C([-a,a])\in\mathrm{HS}$, and thus Eq. (3.5) gives $\hat{S}|_{\mathscr{H}_1}$ $\in\mathrm{HS}$.

The proof of (I)(i)⇒(I)(ii) picks up and generalizes some features of Warchall's original proof. For later purposes let us generalize the situation to an arbitrary $X\in\mathscr{T}(E)$. Let $X_l\subseteq W\cosh(Z)$ and $X_a\subseteq WI\sinh(Z)$ be the decomposition of X stated in Lemma 2.1 with the unitary W, the antilinear involution I commuting with the self-adjoint operator Z. Then

$$\begin{aligned}\cosh(Z)^{-1}W^*(XT_tX^{-1})_aW\cosh(Z)^{-1}&=\cosh(Z)^{-1}W^*\{X_a(T_t)_l(X^{-1})_l+X_l(T_t)_a(X^{-1})_l\\&\quad+X_l(T_t)_l(X^{-1})_a+X_a(T_t)_a(X^{-1})_a\}W\cosh(Z)^{-1}\\&=[I\tanh(Z),T_t]-[I\tanh(Z),(T_t)_a]+(T_t)_a\\&\quad-I\tanh(Z)(T_t)_aL\tanh(Z).\end{aligned}$$

But by assumption it is $S\in\mathrm{HS}$, that is, $T_t\in\mathscr{T}_F(E)$ or equivalently $(T_t)_a\in\mathrm{HS}_r$ by Theorem 2.3. Hence, the Dyson expansion (2.3) with $D=-iJS\in\mathrm{HS}_r$ yields the decomposition $T_t=\exp\{itC\}$ $+B_t$ with some $B_t\in\mathrm{HS}_r$. Since $\cosh(Z)^{-1}$ and $\tanh(Z)$ are bounded (also for unbounded Z), we thus have

$$(XT_tX^{-1})_a\in\mathrm{HS}_r\Leftrightarrow[I\tanh(Z),T_t]\in\mathrm{HS}_r\Leftrightarrow[I\tanh(Z),\exp\{itC\}]\in\mathrm{HS}_r.$$

Now for $a\in\mathbb{R}$ let $P_a^+:=P_C([a,\infty[)$ and $P_a^-:=P_C(]-\infty,-a])$, and assume $XT_tX^{-1}\in\mathscr{T}_F(E)$. Since $[P_a^\pm,\exp\{itC\}]=0$, it is $[P_a^\pm I\tanh(Z)P_0^\pm,\exp\{itC\}]=P_a^\pm[I\tanh(Z),\exp\{itC\}]P_0^\pm\in\mathrm{HS}_r$. From arguments similar to the part I⇒III (of the proof) from Ref. 7, Theorem 2, we obtain

$$P_a^-I\tanh(Z)P_0^-\in\mathrm{HS},\quad P_a^+I\tanh(Z)P_0^+\in\mathrm{HS}\quad\forall a>0. \tag{3.8}$$

Here in our concrete situation, however, we have $X=T$ with $W=1$, $I=J$, and $Z=R$, where C, J, and R commute. Thus, (3.8) implies $\tanh(R)P_C(\mathbb{R}\backslash[-a,a])\in\mathrm{HS}$, which with Proposition 3.3 yields $RP_C(\mathbb{R}\backslash[-a,a])\in\mathrm{HS}$ for all $a>0$. Also with the same arguments as in Ref. 7, Theorem 2 one finally gets $\tanh(R)CP_C([-a,a])\in\mathrm{HS}$ for all $a>0$.

Part (II) is easily checked; also see the examples below. ■

The above theorem includes Warchall's result[7] applied to our context: For $S=0$, and $C\geqslant 0$ one has $T=\exp\{JR\}\in\mathscr{C}_{\mathrm{im}}(C)$ [where the class $\mathscr{C}_{\mathrm{im}}(C)\subseteq\mathscr{T}(\mathscr{H})$ is defined in Theorem 2.7], if and only if $R\in\mathscr{R}(C)$ and R is bounded (in Ref. 7 they are considered bounded symplectic transformations T on the whole of $\mathscr{H}$; cf. Lemma 2.1).

From Proposition 3.3 and Theorem 2.3 one immediately obtains the following consequence of Theorem 3.7.

Corollary 3.8: Let S be Hilbert–Schmidt. Then the group $\{T_t|t\in\mathbb{R}\}$ is continuously implementable in some symplectically related representations Π_T, $T=\exp\{JR\}$, inequivalent, resp. disjoint to the Fock representation Π_F, if and only if C has an essential infrared part; these Π_T are characterized in terms of the operator R as follows:

(a) *$R\in\mathscr{R}(C)$ is bounded but not Hilbert–Schmidt.*
(b) *For unbounded R, however, the condition $R\in\mathscr{R}(C)$ is necessary but not sufficient for the continuous implementability of $\{T_t|t\in\mathbb{R}\}$ in Π_T. For example, a sufficient condition is the Hilbert–Schmidt property of $\hat{S}P_C([-a,a])=(\cosh(2R)S+\sinh(2R)C)P_C([-a,a])$ for some $a>0$.*

Finally, let us give examples for the cases $R\in\mathscr{R}(C)$ and $R\notin\mathscr{R}(C)$.

Example 3.9: Choose a subset $N\subseteq\mathbb{N}$ with $\Sigma_{k\in N}c_k^2<\infty$, and define R by $r_k=0$ for $k\notin N$ and $r_k\in\mathbb{R}$ arbitrary for $k\in N$. Then one observes the following:

(a) It holds *$RP_C(\mathbb{R}\backslash[-a,a])=0$ for each $a>\sup_{k\in N}|c_k|$ and $\tanh(R)C$ is Hilbert–Schmidt, and thus $R\in\mathscr{R}(C)$.*
(b) *Only if the cardinality of N is infinite, it is possible to choose R not to be Hilbert–Schmidt*

[that is, $T=\exp\{JR\}\notin\mathscr{T}_F(E)$], which makes the representation Π_T disjoint to the Fock representation. But an infinite N is selectable, if and only if C has an essential infrared part.

(c) *For C with an essential infrared part select an infinite N, and let, e.g., $|r_k|\geqslant d$ for all $k\in N$ with some $d>0$. Then R is not Hilbert–Schmidt, but $R\in\mathscr{R}(C)$. Here R may be chosen bounded as well as unbounded.*

Example 3.10: Let S be Hilbert–Schmidt and suppose C to have an essential infrared part. Hence for (each) $q>1$ there exists an infinite subset $N\subseteq\mathbb{N}$ with $\Sigma_{k\in N}q^k c_k^2<\infty$ and $\Sigma_{k\in N}q^k s_k^2<\infty$. Define an unbounded R by $r_k=0$ for $k\notin N$ and $\cosh(2r_k)\leqslant q^k$ for $k\in N$. Then $\cosh(2R)S$ and $\sinh(2R)C$ both are Hilbert–Schmidt, and thus $\hat{\mathrm{S}}$ is so, too. Consequently, $\{T_t|t\in\mathbb{R}\}$ is continuously implementable in Π_T by Corollary 3.8 (b).

Example 3.11: Suppose C not to be Hilbert–Schmidt. Define a (bounded or unbounded) R with $|r_k|\geqslant d$ for all $k\in\mathbb{N}$ and some $d>0$. Then $R\notin\mathscr{R}(C)$ (which forces Π_T to be disjoint to Π_F), and thus $\{T_t|t\in\mathbb{R}\}$ is not (continuously) implementable in Π_T.

IV. QUADRATIC HAMILTONIANS IN REPRESENTATION SPACES

Let us first consider a representation Π of $\mathscr{W}(E)$ with the representation Hilbert space $\mathscr{K}_\Pi$. With the annihilation and creation operators of the representation Π from Eq. (2.6), $a_\Pi(f)$, resp. $a_\Pi^*(f)$, $f\in E$, one may introduce the formal Hamiltonian,

$$H_{C,S}^{\Pi}:=\sum_{k=1}^{\infty}\left[\frac{s_k}{2}\,(a_\Pi^*(e_k)^2+a_\Pi(e_k)^2)+c_k a_\Pi^*(e_k)a_\Pi(e_k)\right], \tag{4.1}$$

on the representation Hilbert space $\mathscr{K}_\Pi$. It is not clear whether the operator series in (4.1) converges at all, and thus, whether $H_{C,S}^{\Pi}$ is indeed a well-defined self-adjoint operator on $\mathscr{K}_\Pi$. However, from purely algebraic calculations it follows that $\exp\{itH_{C,S}^{\Pi}\}$ formally implements our symplectic group $\{T_t=\exp\{it(C-JS)\}|t\in\mathbb{R}\}\subset\mathscr{T}(E)$ in the representation Π. If the Hamiltonian $H_{C,S}^{\Pi}$ has no mathematical meaning as a self-adjoint operator on $\mathscr{K}_\Pi$, then nevertheless a well-defined self-adjoint operator H_Π may exist on $\mathscr{K}_\Pi$, which (continuously) implements $\{T_t|t\in\mathbb{R}\}$ in Π according to Definition 2.2 (b). Then H_Π is a *renormalized* Hamiltonian of the system, which differs from the formal (nonexisting) $H_{C,S}^{\Pi}$ by an additive diverging renormalization term.

Here we investigate Hamiltonians of the type (4.1) in the Fock representation $\Pi\equiv\Pi_F$ and in the symplectically related representation $\Pi\equiv\Pi_T=\Pi_F\circ\alpha_T$, where $T=\exp\{JR\}$ with R from (3.1). Thus we have here analoguously to (4.1) the two formal Hamiltonians,

$$H_{C,S}^{F}:=\sum_{k=1}^{\infty}\left[\frac{s_k}{2}\,(a_F^*(e_k)^2+a_F(e_k)^2)+c_k a_F^*(e_k)a_F(e_k)\right], \tag{4.2}$$

$$H_{C,S}^{T}:=\sum_{k=1}^{\infty}\left[\frac{s_k}{2}\,(a_T^*(e_k)^2+a_T(e_k)^2)+c_k a_T^*(e_k)a_T(e_k)\right], \tag{4.3}$$

on Fock space. Especially $H_{C,S}^{T}$ coincides with $H_{C,S}^{F}$ for $T=\mathbb{1}$, resp., $R=0$. We also discuss the formal Hamiltonian $H_{\hat{C},\hat{S}}^{F}$, which formally implements the shifted group $\{\hat{T}_t=\exp\{it(\hat{C}-J\hat{S})\}|t\in\mathbb{R}\}$ in the Fock representation Π_F. It is obtained from (4.2) by replacing C and S by $\hat{\mathrm{C}}$ and $\hat{\mathrm{S}}$, that is, by replacing the associated eigenvalues s_k and c_k by the eigenvalues $\hat{s}_k$ and $\hat{c}_k$ of $\hat{\mathrm{S}}$ and $\hat{\mathrm{C}}$ from (3.6), respectively.

The formal Hamiltonian $H_{C,S}^{T}$ should be approximated (in some sense) by the sequence

$$H_{CP_n,SP_n}^{T}=\sum_{k=1}^{n}\left[\frac{s_k}{2}\,(a_T^*(e_k)^2+a_T(e_k)^2)+c_k a_T^*(e_k)a_T(e_k)\right],\quad n\in\mathbb{N}, \tag{4.4}$$

where the orthogonal projections $P_n:=\Sigma_{k=1}^{n}|e_k\rangle\langle e_k|$, $n\in\mathbb{N}$, commute with all the operators C, $\hat{\mathrm{C}}$, S, $\hat{\mathrm{S}}$, R, and J. These *local* Hamiltonians H_{CP_n,SP_n}^{T}, $n\in\mathbb{N}$, are well-defined self-adjoint operators on Fock space, which follows from Eq. (4.6) and Theorem 4.3 below.

The Bogoliubov transformed annihilation operators are given on Fock space by

$$a_T(e_k)=\cosh(r_k)a_F(e_k)+\sinh(r_k)a_F^*(e_k),\quad k\in\mathbb{N}, \tag{4.5}$$

which follows from (2.10) and the fact that by (3.4) $T_l=\cosh(R)$ and $T_a=J\sinh(R)$ for our symplectic $T=\exp\{JR\}\in\mathscr{T}(E)$.

Observation 4.1: For every $k\in\mathbb{N}$ it holds on Fock space:

$$\left[\frac{s_k}{2}\,(a_T^*(e_k)^2+a_T(e_k)^2)+c_k a_T^*(e_k)a_T(e_k)\right]=\left[\frac{\hat{s}_k}{2}\,(a_F^*(e_k)^2+a_F(e_k)^2)+\hat{c}_k a_F^*(e_k)a_F(e_k)\right]$$
$$+\tfrac{1}{2}\,(\hat{c}_k-c_k)\mathbb{1}.$$

Proof: Insert (4.5) on the left side. Then the CCR $[a_F(e_k),a_F^*(e_l)]=\delta_{k,l}\mathbb{1}$, Eq. (3.6) and the formulas (3.7) yield the result. ■

The above lemma implies immediately the following connection for the local Hamiltonians:

$$H^T_{CP_n,SP_n}=H^F_{CP_n,\hat{S}P_n}+\kappa_n\mathbb{1},\quad \forall n\in\mathbb{N}, \tag{4.6}$$

where κ_n is given by

$$\kappa_n:=\frac{1}{2}\,\mathrm{tr}[(\hat{C}-C)P_n]=\frac{1}{2}\sum_{k=1}^{n}\,(\hat{c}_k-c_k), \tag{4.7}$$

with the relation [following from (3.5)]

$$\hat{C}-C=2\,\sinh(R)^2C+\sinh(2R)S. \tag{4.8}$$

Observation 4.2: *The convergence of the series $\kappa:=\lim_{n\to\infty}\kappa_n=\frac{1}{2}\Sigma_{k=1}^{\infty}(\hat{c}_k-c_k)$ does not mean that $\hat{C}-C$ is of trace class on $\mathscr{H}$. But $\hat{C}-C$ being of trace class is equivalent to the* absolute *convergence of the series, in which case $\kappa=\frac{1}{2}\,\mathrm{tr}[\hat{C}-C]$.*

A. Hamiltonians in the Fock representation

Let us first investigate the limit of the local Hamiltonians $H^F_{CP_{n,SPn}}$, $n\in\mathbb{N}$.

Theorem 4.3: *The following assertions are valid.*

(a) *Let S be Hilbert–Schmidt. Then the operator series in (4.2), respectively, the limit*

$$\lim_{n\to\infty}\,H^F_{CP_n,SP_n}=H^F_{C,S},$$

converge in the strong resolvent sense to the self-adjoint $H^F_{C,S}$, and they also converge pointwise [with respect to the norm of $F_+(\mathscr{H})$] on the dense set L_C of the finite particle number vectors over the domain of C of one-particle wave functions. L_C is a core for $H^F_{C,S}$. Especially the vacuum vector Ω_F is contained in the domain of $H^F_{C,S}$, and it holds that $\|H^F_{C,S}\Omega_F\|=1/\sqrt{2}\|S\|_{HS}$. Moreover, the unitary group $\exp\{itH^F_{C,S}\}$, $t\in\mathbb{R}$, *implements the symplectic group $\{T_t|t\in\mathbb{R}\}$ in the Fock representation Π_F.*

(b) *Suppose the operator series (4.2) to converge in the strong resolvent sense to a selfadjoint operator $H^F_{C,S}$ on Fock space. Then we have the following equivalences:*

(i) The vacuum vector Ω_F is contained in the domain of $H^F_{C,S}$;
(ii) S is Hilbert–Schmidt on $\mathscr{H}$.

Proof: (a) By Ref. 6, $\lim_{n\to\infty}H^F_{CP_nSP_n}\psi=H^F_{C,S}\psi$ converges in Fock space for the vectors ψ from the core L_C. Thus, by Ref. 24, Theorem 9.16 the operator series in (4.2), respectively, the limit $\lim_{n\to\infty}H^F_{CP_n,SP_n}=H^F_{C,S}$, converge in the strong resolvent sense.

(b) By Ref. 6, Theorem 3.7, $\exp\{itH^F_{CP_n,SP_n}\}$ implements $T_{t,n}:=\exp\{it(C-JS)P_n\}$ in Π_F. But $\lim_{n\to\infty}H^F_{CP_n,SP_n}=H^F_{C,S}$ in the resolvent sense is equivalent to $\lim_{n\to\infty}\exp\{itH^F_{CP_n,SP_n}\}=\exp\{itH^F_{C,S}\}$ in the strong operator topology. Consequently, $\exp\{itH^F_{C,S}\}$ implements T_t

$=\lim_{n\to\infty} T_{t,n}$ in Π_F, which yields $T_t \in \mathscr{T}_F(E)$. Now Ref. 6, Theorem 3.8 implies that the condition $\Omega_F \in \mathscr{D}(H^F_{C,S})$ is equivalent to the Hilbert–Schmidt property of S. ■

Observation 4.4: If S is Hilbert–Schmidt, then one has $H^F_{C,S}=H^F_{C,0}+H^F_{O,S}$, *where* $H^F_{C,O} \equiv d\Gamma(C)$ *is the second quantization of C, and* $\exp\{itH^F_{C,S}\}$ *is obtained by a Dyson expansion with the ''free'' evolution* $\exp\{itH^F_{C,0}\}$ *and the perturbation* $H^F_{0,S}$.[6] *However, if S is not a Hilbert–Schmidt operator, then the expression* $H^F_{0,S}$ *has no meaning as an operator on Fock space, which is shown in Ref. 5.*

Subsequently, in Corollary 4.6(b) we derive that for $C\neq 0$ *also some operators S are allowed, which are not Hilbert–Schmidt (and possibly unbounded), so that the self-adjoint limiting operator* $H^F_{C,S}$ *of the form (4.2) exists in the strong resolvent sense. But then the vacuum vector* Ω_F *is not contained in the domain of definition of* $H^F_{C,S}$, *and the additive decomposition* $H^F_{C,S}=H^F_{C,0}+H^F_{0,S}$ *is meaningless.*

From now on in the present section *let us suppose S and R to be Hilbert–Schmidt.* Then $T=\exp\{JR\}\in\mathscr{T}_F(E)$ by Proposition 3.3 and by Theorem 4.3 we have for all $t\in\mathbb{R}$ that $T, T_t, T_t \in \mathscr{T}_F(E)$ since $\mathscr{T}_F(E)$ is a group, and T_t is (continuously) implemented by $\exp\{itH^F_{C,S}\}$ in the Fock representation Π_F. By Theorem 2.3 the condition $T\in\mathscr{T}_F(E)$ is equivalent to the unitary equivalence of the representations Π_F and Π_T, where the associated implementing unitary U_T is defined in Eq. (2.12).

Proposition 4.5: Let R be Hilbert–Schmidt on $\mathscr{H}$. *Then the symplectic group* $\{\exp\{tJR\}|t\in\mathbb{R}\}\subset\mathscr{T}(E)$ *is continuously implemented by* $\exp\{itQ_R\}$ *in the Fock representation* Π_F *with the self-adjoint operator,*

$$Q_R := \sum_{k=1}^{\infty} \frac{r_k}{2}\,(a^*_F(e^{i\pi/r}e_k)^2 + a_F(e^{i\pi/4}e_k)^2) = i\sum_{k=1}^{\infty}\frac{r_k}{2}\,(a^*_F(e_k)^2 - a_F(e_k)^2),$$

on Fock space, where the operator series converges in the strong resolvent sense, and it also converges pointwise on the finite particle number vectors L. L *is a core for* Q_R.

Especially the implementing unitary U_T *for our symplectic* $T=\exp\{JR\}\in\mathscr{T}_F(E)$ *is given (up to a phase) by* $U_T=\exp\{iQ_R\}$.

Proof: One has $\exp\{tJR\}=\exp\{-it\hat{J}R\}$, where the antilinear involution $\hat{J}:=iJ$ on $\mathscr{H}$ satisfies $\widetilde{J}(e^{i\pi/4}e_k)=e^{i\pi/4}e_k, \forall k\in\mathbb{N}$. The involution $\widetilde{J}$ commutes with our $R=\Sigma_{k=1}^{\infty} r_k|e_k\rangle\langle e_k| = \Sigma_{k=1}^{\infty} r_k|e^{i\pi/4}e_k\rangle\langle e^{i\pi/4}e_k|$. Thus, the result follows from Ref. 6, or in a way similar to the proof of Theorem 4.3(a). ■

Here the Bogoliubov transforms from Eq. (4.5) are obtained with the unitary transformation U_T, that is, $a_T(e_k)=U_T a_F(e_k) U_T^* = \cosh(r_k)a_F(e_k)+\sinh(r_k)a^*_F(e_k)$, which follow from (2.13). Thus (4.6) takes the form

$$H^T_{CP_n,SP_n} = U_T H^F_{CP_n,SP_n} U_T^* = H^F_{CP_n,\hat{S}P_n} + \kappa_n \mathbb{1}, \quad \forall n\in\mathbb{N}, \tag{4.9}$$

with κ_n from (4.7). Performing the limit $n\to\infty$ in (4.9), we gain with standard results on the strong resolvent convergence (cf., e.g., Ref. 3, Sec. VIII.), with Lemma 2.8, and with Theorem 4.3 the following result.

Corollary 4.6: Let S and R both be Hilbert–Schmidt. Then it holds on Fock space.

(a) *The self-adjoint limiting operator,*

$$H^T_{C,S} = U_T H^F_{C,S} U_T^* = \lim_{n\to\infty} H^T_{CP_n,SP_n}$$

exists, where the limit and the series converge in the strong resolvent sense, and they also converge pointwise on $U_T(L_C)$ *with respect to the norm of* $F_+(\mathscr{H})$. $U_T(L_C)$ *is a core for* $H^T_{C,S}$, *and* $\exp\{itH^T_{C,S}\}$ *implements* $\hat{T}_t$ *in* Π_F *and* T_t *in* Π_T.

(b) *If* $\lim_{n\to\infty}\kappa_n=\kappa\in\mathbb{R}$ *exists, then the self-adjoint operator*

$$H^F_{\hat{C},\hat{S}} = \lim_{n\to\infty} H^F_{\hat{C}P_n,\hat{S}P_n}$$

exists, where the limit and the series converge in the strong resolvent sense, and they also

converge pointwise on $U_T(L_C)$ with respect to the norm of $F_+(\mathscr{H})$. Moreover, $U_T(L_C)$ is a core for $H^F_{\hat{C},\hat{S}}$, and we have $H^F_{\hat{C},\hat{S}}=H^T_{C,S}-\kappa\mathbf{1}$. Thus, both $\exp\{itH^F_{\hat{C},\hat{S}}\}$ *and* $\exp\{itH^T_{C,S}\}$ *implement $\hat{T}_t$ in Π_F and T_t in Π_T.*

(c) *If $\lim_{n\to\infty}\kappa_n$ does not exist, then $H^F_{\hat{C},\hat{S}}$ has no meaning as a self-adjoint operator on Fock space, and the limit and the operator series in (b) do not converge in the weak (and thus strong) resolvent sense.*

Thus, for S and R being Hilbert–Schmidt, the implementing self-adjoint operator $H^T_{C,S}$ for T_t in Π_T has the form (4.3). However, for the implementation of the shifted group $\hat{T}_t$ in the Fock representation Π_F, the associated formal Hamiltonian $H^F_{\hat{C},\hat{S}}$ of the desired form (4.2) may not exist. Hence, the self-adjoint $H^T_{C,S}$ is a *renormalization* of $H^F_{\hat{C},\hat{S}}$, where the difference is given by the additive (possibly diverging) renormalization term $\kappa=\lim_{n\to\infty}\kappa_n$ in the sense of

$$H^T_{C,S}=U_T H^F_{C,S}U_T^*=\lim_{n\to\infty}(H^F_{\hat{C}P_n,\hat{S}P_n}+\kappa_n\mathbf{1}).$$

Example 4.7: Let S and R both be Hilbert–Schmidt.

(a) We use (4.8) to construct situations in which $\kappa=\frac{1}{2}\,\mathrm{tr}[\hat{C}-C]$ exists.

• Assume $\hat{S}$ to be Hilbert-Schmidt [which, e.g., is a consequence of (3.5) for bounded C]. Then $\hat{C}-C$ is of trace class on $\mathscr{H}$.

• Define R and C by $\sinh(r_k):=k^{-3}$ *and $c_k:=k^4$ for all $k\in\mathbb{N}$. Then R is Hilbert–Schmidt and $\hat{C}-C$ is of trace class. If in addition $S\geqslant 0$, then $\hat{S}\geqslant\mathbb{1}$ is unbounded (since $\hat{s}_k\geqslant k$, $\forall k\in\mathbb{N}$). Nevertheless, the quadratic self-adjoint Hamiltonian $H^F_{\hat{C},\hat{S}}$ exists and differs from $H^T_{C,S}$ by the finite $\kappa\mathbb{1}$.*

(b) Let us give an example where κ does not exist: Let $r_k>0$ and $S\geqslant 0$, and define C by $c_k\geqslant\sinh(r_k)^{-2}$, then $\hat{C}-C\geqslant 2\mathbb{1}$ by (4.8), and thus $\kappa=\infty$.

Proof: We prove the first part of (a): The Hilbert–Schmidt operators constitute an ideal in the bounded operators on $\mathscr{H}$. Thus, from the boundedness of $\cosh(R)^{-1}$ and $\cosh(R)$ (since R is bounded), from (3.5) and the formula $2\cosh(x)\sinh(x)=\sinh(2x)$, we obtain

$$\sinh(R)C=\tfrac{1}{2}\,(\hat{S}-\cosh(2R)S)\cosh(R)^{-1},$$

to be Hilbert–Schmidt (also for unbounded C). Now observe that the product of two Hilbert–Schmidt operators gives a trace class operator, and the result follows from (4.8) and the fact that $\sinh(2R)$ and $\sinh(R)$ are Hilbert–Schmidt by Proposition 3.3. The other parts follow by direct computation. ■

B. Hamiltonians in symplectically related (non-Fock) representations

Here we allow R to not be Hilbert–Schmidt, which by Proposition 3.3 is equivalent to $T=\exp\{JR\}\notin\mathscr{T}_F(E)$. Then the symplectically related representation Π_T is disjoint to the Fock representation Π_F, and the above implementing unitary U_T does not exist.

Performing the limit $n\to\infty$ in (4.6), we obtain with Theorem 4.3 (a) applied to $\hat{C}$ and $\hat{S}$ and with the analogous arguments as in the previous section the following result.

Proposition: 4.8: Let $\hat{S}$ be Hilbert–Schmidt. Then the following holds.

(a) *The self-adjoint limiting operator,*

$$H^F_{\hat{C},\hat{S}}=\lim_{n\to\infty}H^F_{\hat{C}P_n,\hat{S}P_n},$$

exists in the strong resolvent sense. The unitary group $\exp\{itH^F_{\hat{C},\hat{S}}\}$ *continuously implements the symplectic one-parameter group $\{\hat{T}_t|t\in\mathbb{R}\}$ in Π_F and the group $\{T_t|t\in\mathbb{R}\}$ in the representation Π_T (which is disjoint to Π_F for R not Hilbert–Schmidt).*

(b) *If* $\lim_{n\to\infty}\kappa_n=\kappa\in\mathbb{R}$ *exists, then performing the limit* $n\to\infty$ *in (4.6) gives the Hamiltonian* $H^T_{C,S}=H^F_{\hat{C},\hat{S}}+\kappa\mathbb{1}$ *from (4.3) as a well-defined self-adjoint operator on Fock space, and its series converges in the strong resolvent sence. Furthermore, both* $\exp\{itH^T_{C,S}\}$ *and* $\exp\{itH^F_{\hat{C},\hat{S}}\}$ *continuously implement* $\hat{T}_t$ *in* Π_F *and* T_t *in* Π_T.

(c) *If* $\lim_{n\to\infty}\kappa_n$ *does not exist, then* $H^T_{C,S}$ *has no meaning as a self-adjoint operator on Fock space.*

The self-adjoint operator $H^F_{\hat{C},\hat{S}}$ *is a renormalization of the formal Hamiltonian* $H^T_{C,S}$ *differring therefrom by the (possibly diverging) renormalization term* κ *in the sense of*

$$H^F_{\hat{C},\hat{S}}=\lim_{n\to\infty}(H^T_{CP_n,SP_n}-\kappa_n\mathbb{1}). \tag{4.10}$$

Example 4.9 (continuation of Example 3.9): Let S *be of trace class (thus* S *is Hilbert–Schmidt, and* T_t *is implementable in* Π_F *by* $\exp\{itH^F_{C,S}\}$*), and choose a subset* $N\subseteq\mathbb{N}$ *with* $\Sigma_{k\in N}|c_k|<\infty$*, and define* R *by* $r_k=0$ *for* $k\notin N$ *and* $r_k\in\mathbb{R}$ *arbitrary for* $k\in N$*, but with* $\sup_k|r_k|<\infty$*, such that* R *is bounded. Then the following holds.*

(a) *The equations (4.8) and (3.5) imply* $\hat{C}-C$ *and* $\hat{S}$ *to be of trace class, which ensures* $\hat{S}$ *to be Hilbert–Schmidt and the existence of* $\kappa=\frac{1}{2}\,\mathrm{tr}[\hat{C}-C]$.

(b) *Only if the cardinality of* N *is infinite, it is possible to choose* R *not to be Hilbert–Schmidt, which makes the representation* Π_T *disjoint to the Fock representation. But an infinite* N *is selectable, if and only if* C *has an essential infrared part.*

Collecting the results of Observation 4.1, Corollary 4.6 (a), and Proposition 4.8 (a), we get a mixed implementing Hamiltonian in the case of Theorem 3.7 (I). From its proof [especially from part (I)(ii)⇒(I)(iii)] we obtain the following form of a more involved renormalization.

Theorem 4.10 (continuation of Theorem 3.7): *Let* S *be Hilbert–Schmidt, and suppose* $R\in\mathscr{R}(C)$ *such that* $\hat{S}P_C([-a,a])$ *is Hilbert–Schmidt for an* $a>0$ [*this automatically follows for each bounded* $R\in\mathscr{R}(C)$]. *Then it holds for each* $b>0$: $\hat{S}P_C([-b,b])$ *is Hilbert–Schmidt and the well-defined self-adjoint operator,*

$$H_b:=H^F_{\hat{C}P_C([-b,b]),\hat{S}P_C([-b,b])}+H^T_{CP_C(\mathbb{R}\setminus[-b,b]),SP_C(\mathbb{R}\setminus[-b,b])},$$

implements the symplectic one-parameter group $\{\hat{T}_t|t\in\mathbb{R}\}$ *in* Π_F *and the group* $\{T_t|t\in\mathbb{R}\}$ *in the non-Fock representation* Π_T. *Thus* H_b *is a renormalization of the (formal) expressions* $H^F_{\hat{C},\hat{S}}$*, resp.* $H^T_{C,S}$*, in the sense of*

$$\begin{aligned}H_b&=\lim_{n\to\infty}(H^F_{\hat{C}P_n,\hat{S}P_n}+\tfrac{1}{2}\,\mathrm{tr}[(\hat{C}-C)P_C(\mathbb{R}\setminus[-b,b])P_n]\mathbb{1})\\&=\lim_{n\to\infty}(H^T_{CP_n,SP_n}-\tfrac{1}{2}\,\mathrm{tr}[(\hat{C}-C)P_C([-b,b])P_n]\mathbb{1}).\end{aligned}$$

Furthermore, if $(\hat{C}-C)P_C(\mathbb{R}\setminus[-b,b])$ *is of trace class, then* $H^F_{\hat{C},\hat{S}}$ *exits as a well-defined self-adjoint operator on Fock space, and if* $(\hat{C}-C)P_C([-b,b])$ *is of trace class, then* $H^T_{C,S}$ *exists as a well-defined self-adjoint operator on Fock space [in which case the series from (4.2), resp. (4.3), converge in the strong resolvent sense].*

C. Diagonalization

In the literature diagonalizations mostly are performed in the Fock representation, cf., e.g., Ref. 25 and 20. Thus, in terms of our notion a Fock representation diagonalization of the *existing* quadratic operator $H^F_{C,S}$ with (possibly unbounded) $S\neq 0$ means to find a Hilbert–Schmidt operator R, such that $\hat{S}=0$ and $\lim_{n\to\infty}\kappa_n=\kappa\in\mathbb{R}$ exists. Then all terms in Eq. (4.9) exist in the limit $n\to\infty$, where U_T is the implementing unitary for $T=\exp\{JR\}\in\mathscr{T}_F(E)$ by the Propositions 3.3 and 4.5, and the self-adjoint operator,

$$H^F_{C,0}=H^T_{C,S}-\kappa\mathbb{1}=U_T H^F_{C,S}U_T^*-\kappa\mathbb{1}, \tag{4.11}$$

is referred to as the (Fock) *diagonalization* of $H^F_{C,S}$.

However, here we do not restrict ourselves to the Fock representation and also allow arbitrary unbounded operators S, R, and C of the type (3.1) and nonexisting renormalization terms κ. The following definition characterizes *diagonalization* only on the one-particle level and does not use the notion of a continuous implementation of the symplectic one-parameter group $\{T_t|t\in\mathbb{R}\}$.

Definition 4.11 (diagonalization): The symplectic group $T_t=\exp\{it(C-JS)\}\in\mathscr{T}(E)$, $t\in\mathbb{R}$, is called diagonalizable by $T=\exp\{JR\}\in\mathscr{T}(E)$, if $\hat{S}=0$. Then the shifted (unitary) group $TT_tT^{-1}=\hat{T}_t=\exp\{it\hat{C}\}$ is denoted the diagonalization of T_t [cf. Eq. (3.3) and Lemma 3.1].

Theorem 4.12: *We have the following equivalences:*

(i) $\{T_t=\exp\{it(C-JS)\}|t\in\mathbb{R}\}$ is diagonalizable;

(ii) $|s_k|<|c_k|$ for every $k\in\mathbb{N}$ with $s_k\neq 0$.

If the conditions (i) and (ii) are satisfied, then the eigenvalues r_k, $k\in\mathbb{N}$, for the diagonalizing $T=\exp\{JR\}\in\mathscr{T}(E)$ are given by $c_k\tanh(2r_k)=-s_k$; thus r_k is unique for $c_k\neq 0$ and arbitrary for $c_k=0$.

Furthermore, if (i) and (ii) are valid, then the following holds.

(a) *$\hat{C}=\sqrt{C^2-S^2}\geqslant 0$ [observe that $C^2\geqslant S^2$ by (ii)], which yields $H^F_{\hat{C},0}\geqslant 0$.*

(b) *R is bounded, if and only if $\sup\{|s_k|/|c_k||k,c_k\neq 0\}<1$ (provided the eigenvalues r_k are chosen for those $k\in\mathbb{N}$ with $c_k=0$ such that $\sup\{|r_k||k,c_k=0\}<\infty$).*

(c) *R is Hilbert–Schmidt (which is equivalent to $T=\exp\{JR\}\in\mathscr{T}_F(E)$, resp., to the existence of the above implementing unitary U_T,), if and only if $\Sigma_{k,c_k\neq 0}s_k^2/c_k^2<\infty$ (provided the eigenvalues r_k are chosen for those $k\in\mathbb{N}$ with $c_k=0$, such that $\Sigma_{k,c_k=0}r_k^2<\infty$).*

(d) *$\hat{C}-C$ is of trace class, if and only if $\Sigma_{k,c_k\neq 0}s_k^2/|c_k|<\infty$, in which case κ exists (cf. Observation 4.2) with $\kappa=\frac{1}{2}\,\mathrm{tr}[\hat{C}-C]=-1/2\Sigma_{k,c_k\neq 0}c_k(1-\sqrt{1-s_k^2/c_k^2})$.*

Proof: By (3.5), resp. (3.6), diagonalization condition $\hat{S}=0$ is equivalent to $s_k=-\tanh(2r_k)c_k$, $\forall k\in\mathbb{N}$. Since $|\tanh(x)|<1$, $\forall x\in\mathbb{R}$, it is only possible to realize $s_k=-\tanh(2r_k)c_k$ with an $r_k\in\mathbb{R}$ if (ii) is fulfilled.

If $c_k=0=s_k$, then (3.6) gives $\hat{c}_k=0$. But for $c_k\neq 0$ we obtain with the formulas $\tanh(2r_k)=-s_k/c_k$, $\cosh(x)^2-\sinh(x)^2=1$ and $1/\cosh(x)=\sqrt{1-\tanh(x)^2}$, $\forall x\in\mathbb{R}$,

$$\begin{aligned}\hat{c}_k=\cosh(2r_k)c_k+\sinh(2r_k)s_k&=c_k\left(\cosh(2r_k)+\sinh(2r_k)\,\frac{s_k}{c_k}\right)\\&=c_k\left(\cosh(2r_k)-\frac{\sinh(2r_k)^2}{\cosh(2r_k)}\right)=\frac{c_k}{\cosh(2r_k)}\\&=c_k\,\sqrt{1-\tanh(2r_k)^2}=\sqrt{c_k^2-s_k^2},\end{aligned}$$

which implies the operator relation $\hat{C}=\sqrt{C^2-S^2}\geqslant 0$. Thus $\hat{c}_k-c_k=-c_k(1-\sqrt{1-s_k^2/c_k^2})$. Now observe that $0\leqslant(1-\sqrt{1-s_k^2/c_k^2})\leqslant 1$ and that $1\leqslant(1+\sqrt{1-s_k^2/c_k^2})\leqslant 2$, which implies

$$\left(1-\sqrt{1-\frac{s_k^2}{c_k^2}}\right)\leqslant\left(1-\sqrt{1-\frac{s_k^2}{c_k^2}}\right)\left(1+\sqrt{1-\frac{s_k^2}{c_k^2}}\right)=\frac{s_k^2}{c_k^2}\leqslant 2\left(1-\sqrt{1-\frac{s_k^2}{c_k^2}}\right).$$

Thus, we obtain the estimation

$$\mathrm{tr}[|\hat{C}-C|]=\sum_{k=1}^{\infty}|\hat{c}_k-c_k|=\sum_{k,c_k\neq 0}|c_k|\left(1-\frac{s_k^2}{c_k^2}\right)\leqslant\sum_{k,c_k\neq 0}\frac{s_k^2}{|c_k|}\leqslant 2\,\mathrm{tr}[\hat{C}-C|],$$

which gives (d). Part (c) follows from Proposition 3.3. ∎

Since $\hat{S}=0$ is Hilbert–Schmidt we may apply Proposition 4.8, and we obtain from Eq. (4.10) the following generalization of the Fock diagonalization (4.11), which is appropriate for many

models (cf., e.g., Sec. V), and that gives another generalization of Warchall's result in Theorem 2.7. Observe that, in contrast to Theorem 2.7, here E is a proper dense subspace of $\mathscr{H}$, and thus by Lemma 2.1 there occur also unbounded symplectic transformations $V \in \mathscr{T}(E)$.

Theorem 4.13 (particle representation of squeezed Bosons): *Let be given the dynamical symplectic group* $\{T_t = \exp\{it(C-JS)\} | t \in \mathbb{R}\} \subset \mathscr{T}(E)$ *for squeezed Bosons with possibly unbounded* S *and* C.

(i) *The diagonalization condition* $|s_k| < |c_k|$ *for all* $k \in \mathbb{N}$ *with* $s_k \neq 0$ *is necessary and sufficient that there exists a Fock symplectically related representation* Π_T *of the CCR-algebra* $\mathscr{W}(E)$, *in which the one-particle dynamics* T_t *is continuously implemented in terms of a (renormalized) diagonal self-adjoint operator,*

$$H^F_{\hat{C},0} = \lim_{n\to\infty} (H^T_{CP_n, SP_n} - \kappa_n \mathbf{1}) = \sum_{k=1}^{\infty} \hat{c}_k a^*_F(e_k) a_F(e_k). \tag{4.12}$$

$T = \exp\{JR\} \in \mathscr{T}(E)$*—and thus* Π_T*—is unique up to the modes* k *with vanishing* c_k, *and* R *is not necessarily bounded. This holds also in the case where the implementing* U_T *does not exist [i.e.,* $T \notin \mathscr{T}_F(E)$*] or the limit* $\lim_{n\to\infty} \kappa_n = \kappa$ *diverges (which then implies that* $H^T_{C,S}$ *does not exist). The positivity of the second quantized* $H^F_{\hat{C},0} \equiv d\Gamma(\hat{C})$ *follows automatically [cf. part (a) of Theorem 4.12], and thus allows for a particle interpretation (cf. Ref. 8).*

(ii) *Suppose the diagonalization condition* $|s_k| < |c_k|$ *for every* $k \in \mathbb{N}$ *with* $s_k \neq 0$ *to be valid. Let us denote by* $\mathscr{C}_{\mathrm{im}}(C,S)$ *the class of those* $V \in \mathscr{T}(E)$ *[not necessarily of the form (3.4)], for which* $\{T_t | t \in \mathbb{R}\}$ *is continuously implementable in* Π_V. *Then it holds for the diagonalizing* $T = \exp\{JR\}$:

(a) *If* $\hat{C} = \sqrt{C^2 - S^2}$ *has an inessential infrared part, then* $\mathscr{C}_{\mathrm{im}}(C,S) = \mathscr{T}_T(E)$. *That is, each representation* Π_V, $V \in \mathscr{T}(E)$, *in which* $\{T_t | t \in \mathbb{R}\}$ *is continuously implementable, is unitarily equivalent to the diagonal representation* Π_T.

(b) *If* $\hat{C} = \sqrt{C^2 - S^2}$ *has an essential infrared part, then the inclusion* $\mathscr{T}_T(E) \subset \mathscr{C}_{\mathrm{im}}(C,S)$ *is proper. However, one has, in general,* $\mathscr{C}_{\mathrm{im}}(C,S) \neq \mathscr{T}(E)$. *Observe that an essential infrared part of* C *implies always an essential infrared part for* $\hat{C} = \sqrt{C^2 - S^2}$. *However, if* C *has an inessential infrared part, then both an essential, resp. an inessential, infrared part may occur for* $\hat{C}$.

Proof: Since $\mathscr{T}(E)$ is a group, there exists for each $V \in \mathscr{T}(E)$ a unique $X \in \mathscr{T}(E)$ such that $V = XT$, resp., $X = VT^{-1}$. Let us first reduce the implementability of T_t in Π_V to the implementability of $\hat{T}_t$ in Π_X. If $V \in \mathscr{C}_{\mathrm{im}}(C,S)$ with the implementing strongly continuous unitary group $\{U_t | t \in \mathbb{R}\}$, then $\Pi_X(W(TT_t f)) = \Pi_V(W(T_t f)) = U_t \Pi_V(W(f)) U_t^* = U_t \Pi_X(W(Tf)) U_t^*$ for all $f \in E$. Since T acts bijectively on E, we may put $f = T^{-1}g$, and obtain $U_t \Pi_X(W(g)) U_t^* = \Pi_X(W(TT_t T^{-1} g))$ for all $g \in E$. Hence, T_t is continuously implementable in Π_V, if and only if the diagonal $TT_t T^{-1} = \hat{T}_t = \exp\{it\hat{C}\}$ is continuously implementable in Π_X. Now we reduce the unitary equivalence of Π_V and Π_T to the unitary equivalence of Π_X and Π_V. Let $X \in \mathscr{T}_F(E)$, that is, $\Pi_X(A) = U_X \Pi_F(A) U_X^*$ for all $A \in \mathscr{W}(E)$ with some unitary U_X on Fock space; see (2.12). Then $\Pi_X(W(f)) = U_X \Pi_T(W(T^{-1} f)) U_X^*$. Replacing $h = T^{-1} f$ yields $\Pi_V(W(h)) = \Pi_X(W(Th)) = U_X \Pi_T(W(h)) U_X^*$ for all $h \in E$. Hence, $X \in \mathscr{T}_F(E)$, if and only if $V = XT \in \mathscr{T}_T(E)$. Summarizing, we have shown the following relations:

$$\mathscr{T}_T(E) = \mathscr{T}_F(E) T \subseteq \mathscr{C}_{\mathrm{im}}(C,S) = \mathscr{C}_{\mathrm{im}}(\hat{C},0) T.$$

By Lemma 2.1 there exist in the hypothetic case $E = \mathscr{H}$ only bounded symplectic transformations, and thus the result immediately would arise from Warchall's Theorem 2.7. But for our proper dense $E \subset \mathscr{H}$ here we know that $\{X \in \mathscr{T}(E) | X \text{ is bounded}\} \equiv \{X \in \mathscr{T}(\mathscr{H}) | X(E) = E\}$ is a proper subgroup of $\mathscr{T}(\mathscr{H})$. For proving (II)(b) the reader may apply the Examples 3.9 and 3.10 to $\hat{C}$ to construct various $X = \exp\{JR_0\} \in \mathscr{T}(E)$ of the type (3.4) with self-adjoint, bounded (or possibly unbounded) operators R_0 having the e_k as eigenvectors but not being Hilbert–Schmidt, such that $R_0 \in \mathscr{R}(\hat{C})$ [and such that $\sinh(2R_0)\hat{C} P_{\hat{C}}([-a,a]) \in \mathrm{HS}$ for an $a > 0$ in the case of unbounded R_0]. Then, by Corollary 3.8 $\hat{T}_t = \exp\{it\hat{C}\}$ is continuously implementable in Π_X, or equivalently T_t in Π_{XT}. For proving part (II)(a) we replace T_t by $\hat{T}_t$ in the proof of part (I)(i)$\Rightarrow$(I)(ii) in Theorem 3.7, then we obtain from Eq. (3.8) that $P_{\hat{C}}([a,\infty[) \tanh(Z) \in \mathrm{HS}$ for all $a > 0$ [since $P_0^+ = \mathbf{1}$ for $\hat{C}$

$\geqslant 0$ and $I=I^{-1}$ commutes with $\tanh(Z)$]. The existence of an inessential infrared part for $\hat{C}$ is equivalent to the existence of an $a>0$ for which $P_{\hat{C}}([0,a[)\mathscr{H}$ is finite dimensional. Thus $\tanh(Z)\in \mathrm{HS}$, which yields $Z\in \mathrm{HS}$, and thus $X=W\exp\{IZ\}\in\mathscr{T}_F(E)$, which may be shown similarly to Proposition 3.3. ■

In order to study the diagonalization procedure in detail let us consider the two series $\Sigma_{k,c_k\neq 0}(s_k^2/c_k^2)$ and $\Sigma_{k,c_k\neq 0}(s_k^2/|c_k|)$ of the parts (c), resp. (d), of Theorem 4.12. The reader may easily construct examples for C and S with $|s_k|<|c_k|$ for $s_k\neq 0$ (diagonalization condition), such that none, resp. only one, resp. both, power series converge. However, there is some redundancy in the case of an inessential infrared part for C.

Proposition 4.14: If C has an inessential infrared part, then the condition $\Sigma_{k,c_k\neq 0}(s_k^2/|c_k|)<\infty$ implies $\Sigma_{k,c_k\neq 0}(s_k^2/c_k^2)<\infty$. This means that $\hat{C}-C$ being of trace class (i.e., the existence of κ) implies $T=\exp\{JR\}\in\mathscr{T}_F(E)$ and thus the existence of the implementing unitary U_T, provided that $\Sigma_{k,c_k=0}r_k^2<\infty$.

Proof: The condition of an inessential infrared part yields $c:=\inf\{|c_k||c_k\neq 0\}>0$, and thus

$$\infty>\sum_{k,c_k\neq 0}\frac{s_k^2}{|c_k|}=\sum_{k,c_k\neq 0}|c_k|\,\frac{s_k^2}{c_k^2}\geqslant c\sum_{k,c_k\neq 0}\frac{s_k^2}{c^2},$$

which gives the result. ■

V. APPLICATIONS

A. Connection between the Dirac- and the harmonic oscillator-quantization in QED

Let us consider a specific Boson system, namely, the photon field. We assume $\mathscr{H}$ to be the Hilbert space $\mathbf{L}^2_{\mathrm{div}}(\Lambda,\mathbb{C}^3)$ of $\mathbb{C}^3$-valued, divergence-free (i.e., $\boldsymbol{\nabla}\cdot f=0$ in the distributional sense) functions on the quantization volume $\Lambda\subseteq\mathbb{R}^3$ in position space, where Λ is equipped with suitable boundary conditions for the component-wise acting Laplacian Δ. The antilinear involution J on $\mathscr{H}$ is chosen to be the component-wise complex conjugation, i.e., $Jf(x)=\overline{f(x)}$, $\forall x\in\Lambda$, $f\in\mathscr{H}$.

A dense complex testfunction space $E\subseteq\mathscr{H}$ is appropriate for QED in the Coulomb gauge, where the conjugate fields are the vector potential $\mathbf{A}$ and $\boldsymbol{\Pi}=-\epsilon_0^{-1}\mathbf{E}^T$ (ϵ_0 is the dielectric constant of the vacuum) with the transversal electric field $\mathbf{E}^T$ (cf., e.g., Ref. 26). As usual, we rescale the physical constants ϵ_0, the velocity of light, and $\hbar$ to unity. After smearing,[27] we form the fundamental field expressions

$$\Phi_D(f)=\mathbf{A}(\mathrm{Re}(f))+\boldsymbol{\Pi}(\mathrm{Im}(f)),\quad f\in E, \tag{5.1}$$

which, according to the analogy with $\Sigma_{j=1}^n(q_j\,\mathrm{Re}(c_j)+p_j\,\mathrm{Im}(c_j))$ for finitely many degrees of freedom, formally have to satisfy the canonical commutation relations CCR,

$$[\Phi_D(f),\Phi_D(g)]\subseteq i\,\mathrm{Im}\langle f|g\rangle\mathbb{1},\quad f,g\in E. \tag{5.2}$$

The mathematical realization of the CCR in Eq. (5.2), however, requires a complex Hilbert space on which the field expressions $\Phi_D(f)$, $f\in E$, are well-defined self-adjoint operators. Thus, one commonly turns over to the Weyl form of the CCR (2.4), which defines also here the C^*-algebra $\mathscr{W}(E)$ of observables for the photon field. Then the CCR (5.2) are recovered in every regular representation Π of $\mathscr{W}(E)$, where the field operators $\Phi_D(f)\equiv\Phi_\Pi(f)$, $f\in E$, are realized according to Eq. (2.5) as well-defined self-adjoint operators on the representation Hilbert space $\mathscr{K}_\Pi$. This procedure is a straightforward generalization of Dirac's quantization description [as indicated by the index D in $\Phi_D(f)$] and is in coincidence with Ref. 28, $D_{III}1(9)$, if one makes explicit the projection onto the transversal components in the scalar product (cf. also Refs. 29–31).

For simplicity, we assume Λ to be bounded and its boundary conditions such that $\langle f|-\Delta g\rangle=\langle\boldsymbol{\nabla}\times f|\boldsymbol{\nabla}\times g\rangle$ for $f,g\in E$. Since Δ and J commute, there exists an orthonormal base (ONB) $\{e_k|k\in\mathbb{N}\}$ of $\mathscr{H}$ consisting of common eigenvectors, $-\Delta e_k=\omega_k^2 e_k$, where the increasing eigenfrequencies $0<\omega_1<\omega_2<\cdots$ accumulate at infinity depending linearly on the absolute momentum values, and $Je_k=e_k$, i.e., $e_k(x)\in\mathbb{R}^3$, $\forall x\in\Lambda$. Then the classical Hamiltonian function,

$$H_{\text{class}}=\frac{1}{2}\int_{\Lambda}[\mathbf{\Pi}(x)^2+(\nabla\times\mathbf{A}(x))^2]d^3x,$$

leads—after replacing the classical functions $\mathbf{A}(x)$ and $\mathbf{\Pi}(x)$, $x\in\Lambda$, by the associated field operators from Eq. (5.1)[32]—to the (formal) quantized Hamiltonian of the free field with respect to the Dirac quantization,

$$\begin{aligned}H&=\frac{1}{2}\sum_{k=1}^{\infty}[\Phi_D(ie_k)^2+\omega_k^2\Phi_D(e_k)^2]\\&=\sum_{k=1}^{\infty}\left[\frac{\omega_k^2-1}{4}(a_D^*(e_k)^2+a_D(e_k)^2)+\frac{\omega_k^2+1}{2}a_D^*(e_k)a_D(e_k)+\frac{\omega_k^2+1}{4}\mathbb{1}\right]\end{aligned}\tag{5.3}$$

(for more details we refer to Ref. 29). The annihilation and creation operators, $a_D(f)$ and $a_D^*(f)$, $f\in E$ are defined as in (2.6). Let us emphasize, that up to now the representation Π of $\mathscr{W}(E)$ is not specified, in which the field operators $\Phi_D(f)$, resp. the Hamiltonian H, are considered to be realized.

The more popular quantization procedure uses field operators, which lead to the diagonalized oscillator form of the field Hamiltonian. This Hamiltonian is obtained by means of the Bogoliubov transformation $(\alpha_T)^{-1}=\alpha_{T^{-1}}$ of $\mathscr{W}(E)$ associated with the symplectic $T=\exp\{JR\}=\cosh(R)+J\sinh(R)\in\mathscr{T}(E)$, where the self-adjoint operator R acting on $\mathscr{H}$ is defined by

$$R:=\ln((-\Delta)^{-1/4}).$$

Observation 5.1: R has a purely discrete spectrum: $Re_k=r_ke_k$, where $r_k:=\ln(\omega_k^{-1/2})$ for all $k\in\mathbb{N}$, which implies $Te_k=\omega_k^{-1/2}e_k$ and $T(ie_k)=\omega_k^{1/2}(ie_k)$, $\forall k\in\mathbb{N}$. Moreover, it holds that $Tf=(-\Delta)^{-1/4}\,\mathrm{Re}(f)+i(-\Delta)^{1/4}\,\mathrm{Im}(f)$ for all $f\in E$ (for more details to this decomposition we refer to Ref. 12, Subsection 3.1).

Assuming $\Phi_D(f)$ to be realized in the representation Π with Hilbert space $\mathscr{K}_\Pi$, the transformed field operators $\Phi_{\text{osc}}(f)$ are then given by

$$\Phi_{\text{osc}}(Tf)=\Phi_D(f),\quad \forall f\in E,\tag{5.4}$$

resp. $\Phi_{\text{osc}}(f)=\Phi_D(T^{-1}f)$, $\forall f\in E$, where the $\Phi_{\text{osc}}(f)$, $f\in E$, are the field operators for the representation $\Pi\circ(\alpha_T)^{-1}$ of $\mathscr{W}(E)$ (also having $\mathscr{K}_\Pi$ as representation Hilbert space). With Observation 5.1 we obtain for every $k\in\mathbb{N}$ the relations $\Phi_D(e_k)=\omega_k^{-1/2}\Phi_{\text{osc}}(e_k)$ and $\Phi_D(ie_k)=\omega_k^{1/2}\Phi_{\text{osc}}(ie_k)$. Insertion into (5.3) gives

$$H=\frac{1}{2}\sum_{k=1}^{\infty}w_k[\Phi_{\text{osc}}(ie_k)^2+\Phi_{\text{osc}}(e_k)^2]=\sum_{k=1}^{\infty}w_k\left[a_{\text{osc}}^*(e_k)a_{\text{osc}}(e_k)+\frac{1}{2}\mathbb{1}\right]\tag{5.5}$$

[the annihilation and creation operators, $a_{\text{osc}}(f)$ and $a_{\text{osc}}^*(f)$, $f\in E$, are defined in the standard manner (2.6)]. Thus, the Bogoliubov transformation (5.4) formally diagonalizes indeed the Hamiltonian H.

In order to give (5.5) a rigorous meaning as a self-adjoint operator, H is usually interpreted in the (oscillator-) Fock representation Π_F of $\mathscr{W}(E)$. That is, one makes the identification $\Pi_F\equiv\Pi\circ(\alpha_T)^{-1}$ and the $\Phi_{\text{osc}}(f)\equiv\Phi_F(f)$, $f\in E$, are identified with the Fock field operators. If one drops the vacuum self-energy $\frac{1}{2}\sum_{k=1}^{\infty}\omega_k$ one finds, in fact, that H reduces to

$$H^F_{\sqrt{-\Delta},0}=\sum_{k=1}^{\infty}w_ka_F^*(e_k)a_F(e_k)\geqslant 0,\tag{5.6}$$

which is a well-defined self-adjoint operator on Fock space, and which is just the second quantization of the so-called one-photon Hamiltonian $\sqrt{-\Delta}$ (for the second quantization, see, e.g., Refs. 33, Ref. 2, Sec. 5.2.1, or Ref. 3, Sec. X.7).

Since we have interpreted Eq. (5.5) in the Fock representation Π_F, Eq. (5.3) has to be interpreted in the symplectically related representation $\Pi_T=\Pi_F\circ\alpha_T\equiv\Pi$, that is, $\Phi_D(f)\equiv\Phi_T(f)$, $f\in E$. Hence H from (5.3) agrees [up to the diverging constant $\frac{1}{4}\Sigma_{k=1}^{\infty}(\omega_k^2+1)$] with the formal Hamiltonian $H_{C,S}^T$ defined in (4.3), where the self-adjoint one-photon operators C and S on $\mathscr{H}$ have the modes e_k as eigenvectors,

$$Ce_k=c_ke_k,\quad Se_k=s_ke_k,\quad \text{where}\quad c_k:=\frac{w_k^2+1}{2},\quad s_k:=\frac{w_k^2-1}{2},\quad \forall k\in\mathrm{N}. \tag{5.7}$$

However, $H_{C,S}^T$ differs from the diagonal $H^F_{\sqrt{-\Delta},0}$ by the diverging renormalization term $\kappa=1/4\Sigma_{k=1}^{\infty}(2\omega_k-\omega_k^2-1)$ according to Eq. (4.12). Thus, the formal Hamiltonian $H_{C,S}^T$ does not exist as a self-adjoint operator.

Let us turn to the one-photon level. With the operators C,S,R, and the involution J we are in the situation of Sec. III. As mentioned at the beginning of Sec. IV, the expression $\exp\{itH_{C,S}^T\}$ formally implements the symplectic group $T_t:=\exp\{it(C-JS)\}\in\mathscr{T}(E)$, $t\in\mathbb{R}$, in the symplectically related representation Π_T. (The one-photon test function space E has to be chosen so that the T_t and $T=\exp\{JR\}$ leave E invariant, e.g., as the finite (complex-) linear combinations of the ONB elements.) However, since R is not Hilbert–Schmidt, the Bogoliubov transformation α_T, resp. its inverse, is *not* unitarily implementable in the Fock representation, and thus the symplectically related representation Π_T is *disjoint* to the Fock representation Π_F (see Theorem 2.3 and Proposition 3.3).

For the transformed symplectic group $\hat{T}_t=TT_tT^{-1}=\exp\{it(\hat{C}-J\hat{S})\}\in\mathscr{T}(E)$ from (3.3), we obtain by the equations (3.5) that $\hat{S}=0$ and that $C=\sqrt{-\Delta}$ is the one-photon Hamiltonian, i.e., $\hat{c}_k=\omega_k$, $\forall k\in\mathbb{N}$. This means that our $T=\exp\{JR\}$ diagonalizes T_t in the sense of Definition 4.11 [observe that (5.7) implies $|s_k|<|c_k|$, $\forall k\in\mathbb{N}$, and thus the Theorems 4.12 and 4.13 are applicable] with the diagonalization

$$\hat{T}_t=\exp\{it\hat{C}\}=\exp\{it\sqrt{-\Delta}\},\quad t\in\mathbb{R},$$

which is the one-photon dynamics on the one-photon test function space. From Proposition 4.8 we know that the diagonal self-adjoint operator $H^F_{\sqrt{-\Delta},0}$ from (5.6), resp. the unitary group $\exp\{itH^F_{\sqrt{-\Delta},0}\}$, (continuously) implements the symplectic group $\hat{T}_t$ in the Fock representation Π_F and T_t in the symplectically related representation Π_T.

Summing up our somewhat complicated analysis of the usual quantization procedure, we want to emphasize the following points: The fundamental quantization strategy of Dirac leads to a unique C^*-Weyl algebra $\mathscr{W}(E)$, and in combination with a kind of correspondence principle to a formal squeezing Hamiltonian (5.3). In order to find a well-defined dynamics, which comes as close to the formal procedure as possible, one should first extract from (5.3) the one-photon dynamics $T_t=\exp\{it(C-JS)\}$ and introduce the corresponding quasifree automorphism dynamics on $\mathscr{W}(E)$. Since the diagonalization condition is fulfilled, one has a particle representation for the quantized electrodynamic field system. By Theorem 4.13 (II) (a) this representation is unique up to unitary equivalence in a finite cavity, for which $\hat{C}=\sqrt{-\Delta}$ has an inessential infrared part. The infinite volume limit apparently has an essential infrared part, but transcends the present formalism.

B. The Luttinger Hamiltonian

The expression (1.1) is not the most general form of a quadratic Hamiltonian. However, the form (1.1) comprises also some quadratic Hamiltonians, which on-the first look seem to be more general than (1.1). Consider the Hamiltonian,

$$H=\sum_{m=1}^{\infty}\left[(\eta_m a^*(u_{1,m})a^*(u_{2,m})+\overline{\eta_m}a(u_{1,m})a(u_{2,m}))+p_m(a^*(u_{1,m})a(u_{1,m})+a^*(u_{2,m})a(u_{2,m}))\right], \tag{5.8}$$

where $\eta_m\in\mathbb{C}$ and $p_m\in\mathbb{R}$. The indices 1 and 2 distinguish two kinds of modes $u_{1,m}$ and $u_{2,m}$, $m\in\mathbb{N}$, which all are normalized and mutually orthogonal (in quantum optical squeezing processes

1 may stand for the signal modes and 2 for the idler modes). Here for each $m \in \mathbb{N}$ the modes $u_{1,m}$ and $u_{2,m}$ are assumed to have the same eigenfrequencies p_m. Such quadratic Hamiltonians are brought into the form (1.2) by superposing both kinds of modes: The combined orthonormalized modes e_k, $k \in \mathbb{N}$, are chosen as

$$e_{2m-1} := \frac{\alpha_m}{\sqrt{2}}(u_{1,m}+u_{2,m}), \quad e_{2m} := \frac{\alpha_m}{\sqrt{2}}(u_{1,m}-u_{2,m}), \quad \forall m \in \mathbb{N},$$

where $\alpha_m := \exp\{(i/2)\arg(\eta_m)\}$ (cf. the phase transformation from u_k to e_k in the Introduction; also Refs. 5 and 6). From the linearity of $f \mapsto a^*(f)$, one obtains the transformation $\eta_m a^*(u_{1,m})a^*(u_{2,m}) = (|\eta_m|/2)(a^*(e_{2m-1})^2 - a^*(e_{2m})^2)$, which finally leads to

$$H = \sum_{k=1}^{\infty} \left[\frac{s_k}{2}(a^*(e_k)^2 + a(e_k)^2) + c_k a^*(e_k)a(e_k) \right], \tag{5.9}$$

where $s_{2m-1} = |\eta_m|$, $s_{2m} = -|\eta_m|$, and $c_{2m-1} = c_{2m} = p_m$ for all $m \in \mathbb{N}$. Such a situation occurs in the popular Luttinger model.

The Luttinger model (cf., e.g., Ref. 34 for more physical references, and Refs. 35, 36 for more mathematical references) deals with the thermodynamics and statistical mechanics of a self-interacting, one-dimensional Fermion field enclosed in a one-dimensional periodic box of length $0 < L < \infty$. It is directly connected with the Thirring model in field theory and the Tomonaga model for massive, spinless Fermions. In the literature on solid-state physics and on field theory there also exist various generalizations of the Luttinger model (cf. Refs. 34–36, and references therein).

The attraction of the Luttinger model arises from its complete solubility. This is insofar important since certain infrared divergences make an approach based on conventional Fermion many-body perturbation theory useless. The solution in effect resums all these divergences. Hence the Luttinger model attracted much attention and has been used for checking the validity of approximations and testing new ideas.

The feature that allows the solution of the Luttinger model is its exact linear Fermion dispersion. Then by means of the so-called bosonization, the interacting (Fermionic) Hamiltonian K_L can be transformed into a quadratic expression H_L in Boson collective modes and the charge operators $Q_\pm$ for the Fermions moving in the plus and minus direction, that is, $K_L = H_L + (\pi/L)(Q_+^2 + Q_-^2)$, where H_L is of type (5.8) with $p_m = (2\pi/L)m$ and $\eta_m = -p_m w_m$ for all $m \in \mathbb{N}$, and the $w_m \in \mathbb{C}$ are the Fourier coefficients of the 4-Fermion potential.[36] More exactly, the bosonization leads to an orthonormalized set of modes u_m of unspecified nature, where first $m = \pm 1, \pm 2, \pm 3, \ldots$. Then the form (5.8) for H_L arises when identifying the above two kinds of Bosons by $u_{1,m} \equiv u_m$ and $u_{2,m} \equiv u_{-m}$, where now $m = 1,2,3,\ldots$. The Fourier coefficients w_m are assumed to be real and to satisfy the following three conditions:[36]

$$(L-1)\ |w_m| < 1, \quad \forall m \in \mathbb{N}; \quad (L-2)\ \sum_{m=1}^{\infty} |w_m|^2 < \infty; \quad (L-3)\ \sum_{m=1}^{\infty} m|w_m|^2 < \infty.$$

As mentioned above, H_L may be transformed into the form (5.9), where now $c_{2m-1} = c_{2m} = p_m = (2\pi/L)m$ and $s_{2m-1} = -s_{2m} = p_m|w_m|$ for all $m \in \mathbb{N}$. Applying the diagonalization Theorems 4.12 and 4.13 for the complex one-Boson test function space E, which is (finitely) spanned by $\{e_k | k \in \mathbb{N}\}$, resp. by $\{u_m | m = \pm 1, \pm 2, \ldots\}$, we find the following results.

- $(L-1)$ is equivalent to the diagonalizability of H_L [in our generalized sense, where in Eq. (4.12) the operator $H_{C,S}^T$ is identified with H_L).
- $(L-2)$ is equivalent to the implementability of the diagonalizing symplectic $T = \exp\{JR\}$ in the Fock representation Π_F of $\mathscr{W}(E)$ with the implementing unitary U_T (which in turn is equivalent to R being Hilbert–Schmidt).
- $(L-3)$ is equivalent to the existence of the renormalization constant $\kappa \in \mathbb{R}$.

That $(L-3)$ implies $(L-2)$ is immediate and reveals an application of Proposition 4.14. Thus, whenever $(L-1)$ to $(L-3)$ are valid, the diagonalization of H_L may be treated according to Eq. (4.11) in the Fock representation. Of course, for the Luttinger Hamiltonian this Fock diagonalization [that is, by assuming the conditions $(L-1)$ to $(L-3)$] has been done in the literature, but on the level of the Bosonic operators (the level of the second quantization), only.

It has been shown in the literature that the commuting charges $Q_\pm$ both have the discrete spectrum $\mathbb{Z}$. Since the $Q_\pm$ also commute with the Bosonic annihilation and creation operators, and thus with H_L, each joint spectral subspace of the $Q_\pm$ reduces the CCR system. This suggests the realization of the Luttinger dynamics as a tensor product: Let us realize the dynamics arising from the part $(\pi/L)(Q_+^2+Q_-^2)$ of K_L as a group of *-automorphisms $\beta_t, t\in\mathbb{R}$, on an associated commutative C^*-algebra $\mathscr{A}$. As mentioned at the beginning of Sec. IV, the formal Luttinger–Boson Hamiltonian H_L in its canonical form (5.9) leads to the symplectic group $T_t=\exp\{it(C-JS)\}\in\mathscr{T}(E)$. Consequently, the dynamics arising from H_L is given by the group of Bogoliubov *-automorphisms $\alpha_{T_t}, t\in\mathbb{R}$, on the CCR-algebra $\mathscr{W}(E)$. The combination of both gives the Luttinger dynamics in terms of the tensor product,

$$\{\alpha_{T_t}\otimes\beta_t | t\in\mathbb{R}\}, \quad \text{on} \quad \mathscr{W}(E)\otimes\mathscr{A}. \tag{5.10}$$

Thus we arrived at a purely C^*-algebraic formulation of the Luttinger dynamics, which is independent of any Hilbert space representation and is also independent of the existence of the formal Hamiltonian H_L as a self-adjoint operator on any representation Hilbert space. Obviously, the diagonalization of T_t (if it exists) takes place only on the first factor of the tensor product, and it is given according to Definition 4.11 and Theorem 4.12 on the one-Boson level, only. This illustrates the one-Boson aspects accompanying the dynamics and the diagonalization of the Luttinger Hamiltonian.

The insight we gain from our foregoing analysis is the possibility of a considerable generalization of the Luttinger model. Since the C^*-algebraic formulation of the Luttinger dynamics in (5.10) is well defined for arbitrary Fourier coefficients $w_m\in\mathbb{C}$, $m\in\mathbb{N}$, it is not necessary that the symplectic Luttinger-one-Boson dynamics $T_t=\exp\{it(C-JS)\}$ is diagonalizable at all. Thus, the Luttinger model is treatable with very arbitrary 4-Fermion potentials. A well-defined, in general, renormalized Hamiltonian is found in each representation, where the dynamics (5.10) is continuously implementable.

However, if in order to have a particle interpretation a diagonalization is desired (in our generalized sense), then the complex Fourier coefficients w_m only have to fulfill the necessary and sufficient condition $(L-1)$ for the diagonalizability of $\{T_t | t\in\mathbb{R}\}$. Then the diagonalized Hamiltonian may be well defined in a representation, which is disjoint to the original representation.

As is demonstrated in Ref. 37 the connection to the Fermion algebra is mathematically subtle. Assuming this Boson–Fermion correspondence being solved, our foregoing analysis allows us to consider the model on the C^*-algebraic level independently of any Hilbert space representation (and thus also in every implementing representation inequivalent to Fock) and to incorporate very arbitrary 4-Fermion potentials in the theory of the Luttinger model, e.g., our class of interactions would cover purely local 4-Fermion theories.

Quantum theory of the real and the complexified projective line

Frank Leitenberger[a)]
Institut für Theoretische Physik, Universität Wien, Boltzmanngasse 5, 1090 Wien, Austria

(Received 28 October 1996; accepted for publication 6 October 1997)

Quantum deformations of sets of points of the real and the complexified projective line are constructed. These deformations depend on the deformation parameter q and certain further parameters λ_{ij}. The deformations for which the subspace of polynomials of degree three has a basis of ordered monomials are selected. We show that the corresponding algebras of three points have ''polynomiality.'' Invariant elements which turn out to be cross ratios in the classical limit are defined. For the special case $|\lambda_{ij}|=1$ a quantum cross ratio with properties similar to the classical case is presented. As an application a quantum version of the real Euclidean distance is given. © *1998 American Institute of Physics.*

I. INTRODUCTION

Noncommutative geometry can be viewed as the quantum deformation of an increasing set of mathematical objects and theories. In this article we introduce a quantized version of the projective geometry in one dimension.

First we consider the algebra of coordinates of points t_i, $i \in I$, of the real line. All possible Poisson brackets between these variables (which are covariant with respect to the action of the standard Poisson structure of the Möbius group) are parametrized by a large set of parameters λ_{ij}, $i,j \in I$, which obey certain second-order polynomial conditions. These quasi-classical structures give a good insight into the quantized situation.

In Sec. III we replace the algebra of coordinates t_i by a $U_q(\mathrm{sl}(2,\mathbb{R}))$-module algebra of noncommutative coordinates v_i. We show that (up to reordering the points) third degree polynomials have a basis of ordered polynomials if a condition in analogy to the Jacobi identity is satisfied. There is one exceptional structure, which has no quasi-classical limit.

For algebras of three points we give a proof that the subspaces of homogeneous polynomials of higher degrees have also the classical dimension. The condition (which plays the role of the Jacobi identity) takes the form of the Einstein addition law for velocities, where the light velocity corresponds to the quantization parameter q. We consider also the complexified case.

In Sec. IV we consider invariant elements C_{ijkl} of four points, which turn out to be cross ratios in the classical limit. Invariant elements occurred first in Ref. 1 in a similar situation for the quantum sphere. Our class of invariant elements contain the elements of the type of Ref. 1 as a subclass. However, these elements do not satisfy a reality condition (*-invariance) and have no simple behavior with respect to permutations of the four points. We show that for parameters $|\lambda_{ij}|=1$ certain rational functions $f(C_{ijkl},q)$ have the classical properties of the cross ratio.

As an application we define a quantization of the Euclidean distance on the real line.

One can say that we quantize products of one-dimensional spaces equipped with general $\mathrm{SL}(2,\mathbb{R})$ covariant Poisson brackets. We discuss algebraic aspects with topological aspects left open.

This article is the first part of a program of the author to develop a quantum deformation of certain parts of the geometry and analysis of the real line (cross ratios, invariant theory of binary forms, elliptic and Abelian differentials, etc.).

We used the computer algebra program Mathematica 3.0 forming computations in III.C and III.E.

II. THE QUASI-CLASSICAL LIMIT

Consider the one-dimensional real projective line $\mathbb{P}$, the action of the Möbius group G on it, and an arbitrary set of variable points $P_i \in \mathbb{P}$, $i \in I$, on it. Let t be a coordinate on $\mathbb{P}$ and t_i the coordinates of the points P_i and let the Möbius group $G \cong \mathrm{SL}(2,\mathbb{R})/\{\pm I\}$ act on the points P_i according to

$$t_i \to \frac{at_i + b}{ct_i + d}.$$

Endow G with the structure of a Poisson group:

$$\{a,b\} = ab, \quad \{a,c\} = ac, \quad \{a,d\} = 2bc,$$

$$\{b,c\} = 0, \quad \{b,d\} = bd, \quad \{c,d\} = cd.$$

Let I be an arbitrary set. The general G-covariant (cf. Ref. 2) pre-Poisson bracket on the algebra of polynomials of the variables t_i, $i \in I$, is given by

$$\{t_j, t_i\} = t_j^2 - t_i^2 - \lambda_{ij}(t_i - t_j)^2 \tag{1}$$

with arbitrary coefficients $\lambda_{ij} = -\lambda_{ji}$.

Proof: The G-covariant pre-Poisson brackets are given as sums of a special G-covariant bracket and an arbitrary G-invariant bracket (cf. Ref. 2). The general G-invariant bracket is given by

$$\{t_j, t_i\} = \lambda_{ij}(t_i - t_j)^2.$$

Therefore it is sufficient to check the G-covariance for one of the above structures by explicit calculation. ■

A calculation yields that this pre-Poisson bracket becomes a Poisson bracket (i.e., it satisfies the Jacobi identity) if and only if

$$\lambda_{ij}\lambda_{jk} - \lambda_{ij}\lambda_{ik} - \lambda_{ik}\lambda_{jk} = -1 \tag{2}$$

for three different arbitrary $i,j,k \in I$. The relation is invariant with respect to a permutation of the indices.

Instead of giving the general solution of this equation we prefer to describe some basic examples.

Example 1: Let I be a linear ordered set. I may have arbitrary cardinality. Set $\lambda_{ij} = 1$ for $i < j$, $i,j \in I$. We obtain

$$\{t_j, t_i\} = 2t_i(t_j - t_i), \quad i < j.$$

Conversely, let $|\lambda_{ij}| = 1$ for arbitrary different $i,j \in I$. Then we can define a linear order relation on I. We set $i < j$, if $\lambda_{ij} = 1$ (the transitivity law of the order relation corresponds to the Jacobi identity).

Example 2: Let $I = \mathbb{Z}$ be the set of integers, $(\alpha_k)_{k \in \mathbb{Z}}$ be a sequence of positive integers, and let

$$\lambda_{ij} = \coth\left(\sum_{k=i}^{j-1} \alpha_k\right), \quad \alpha_k > 0, \quad i < j.$$

The Poisson property follows from the addition formula

$$\coth(\alpha + \beta) = \frac{1 + \coth(\alpha)\coth(\beta)}{\coth(\alpha) + \coth(\beta)}.$$

We have

$$\{t_j,t_i\}=t_j^2-t_i^2-\coth\left(\sum_{k=i}^{j-1}\alpha_k\right)(t_i-t_j)^2,\quad i<j.$$

Note that $|\lambda_{ij}|>1$ because of $|\coth(\alpha)|>1$ for $\alpha\neq 0$. We obtain again Example 1 in the limit $\alpha_k\to\infty$.

Example 3: In order to get examples with $|\lambda_{ij}|<1$ for certain $i,j\in I$, let $I=\mathbb{Z}$ and

$$\lambda_{ij}=\coth\left(\sum_{k=i}^{j-1}\left(\alpha_k+\frac{i\pi}{2}\right)\right),\quad \alpha_k>0.$$

Then we have $|\lambda_{ij}|<1$ for $i-j$ odd and $|\lambda_{ij}|>1$ for $i-j$ even.

Example 4: Now we give an example with $\lambda_{ij}=0$ for certain $i,j\in I$. We remark that if i is fixed, there is only one different index j with $\lambda_{ij}=0$ [because of Eq. (2)]. Let $I=\mathbb{Z}\times\mathbb{Z}_2$ and $z_i:=v_{(i,0)}$ and $z_{\overline{i}}^*:=v_{(i,1)}$ be the corresponding variables. One can check Eq. (2) for $\lambda_{i,\overline{i}}=0$ and $\lambda_{ij}=\lambda_{\overline{i}\,\overline{j}}=\lambda_{i\,\overline{j}}=\lambda_{\overline{i}j}=1$ for $i<j$. The Poisson bracket is given by

$$\{z_{\overline{i}}^*,z_i\}=(z_{\overline{i}}^{*2}-z_i^2),$$

$$\{z_j,z_i\}=2z_i(z_j-z_i),\quad i<j,$$

$$\{z_{\overline{j}}^*,z_{\overline{i}}^*\}=2z_{\overline{i}}^*(z_{\overline{j}}^*-z_{\overline{i}}^*),\quad i<j,$$

$$\{z_j,z_{\overline{i}}^*\}=2z_{\overline{i}}^*(z_j-z_{\overline{i}}^*),\quad i<j,$$

$$\{z_{\overline{j}}^*,z_i\}=2z_i(z_{\overline{j}}^*-z_i),\quad i<j.$$

Because z_i and z_i^* transform according to

$$z_i\to\frac{az_i+b}{cz_i+d},\quad z_i^*\to\frac{az_i^*+b}{cz_i^*+d},$$

we identify z_i and z_i^* with complex and conjugate complex coordinates of the complexified projective line.

Example 5: Now we explain how to put structures together to a new one. Let I' be an ordered set. Consider variables $t_i^{(j)}$, $i\in I^{(j)}$, $j\in I'$ (i.e., $I=\cup_{j\in I'}I^{(j)}$). Suppose that for fixed j the variables $t_i^{(j)}$, $i\in I^{(j)}$, carry an arbitrary Poisson structure. We combine these structures according to

$$\{t_{i'}^{(j')},t_i^{(j)}\}=2t_i^{(j)}(t_{i'}^{(j')}-t_i^{(j)}),\quad j<j'.$$

The verification uses the fact that Eq. (2) is satisfied, if two of the numbers λ_{ij}, λ_{ik}, and λ_{jk} are equal to 1.

Example 6: An example with complex λ_{ij} is given by $I=\{1,2,3,4\}$ and $\lambda_{12}=\lambda_{23}=\lambda_{34}=i$, $\lambda_{14}=-i$, and $\lambda_{13}=\lambda_{24}=0$.

III. QUANTIZATION OF POINT SETS OF THE REAL AND COMPLEX PROJECTIVE LINE

A. A class of $U_q(sl_2,\mathbb{R})$-module algebras

Let $U_q(sl_2,\mathbb{R})$, $|q|=1$, $q\neq\pm 1,\pm i$, be the unital *-algebra, given by generators E, F, K, K^{-1} and relations

$$KK^{-1}=K^{-1}K=I,\quad KE=qEK,\quad KF=q^{-1}FK,$$

$$[E,F]=\frac{K^2-K^{-2}}{q-q^{-1}},$$

and the involution

$$E^*=F, \quad F^*=E, \quad K^*=K^{-1}.$$

For an arbitrary set I consider the unital complex algebra A which is freely generated by the elements x_i, $i\in I$.

An action of $\mathrm{U}_q(\mathrm{sl}(2,\mathbb{R}))$ on A is given, if we set

$$E(1)=F(1)=0, \quad K(1)=1, \quad E(x_i)=1, \quad F(x_i)=-x_i^2, \quad K(x_i)=q^{-1}x_i, \tag{3}$$

and require for $x,y\in A$

$$K(xy)=K(x)K(y), \tag{4}$$

$$E(xy)=E(x)K(y)+K^{-1}(x)E(y), \tag{5}$$

$$F(xy)=F(x)K(y)+K^{-1}(x)F(y). \tag{6}$$

A proof can be given along the lines of Ref. 3, where a similar module of two variables occurs.

Further we consider ideals I of A, which are generated by all (nonvanishing) elements of the form

$$X_{ij}:=a_{ij}x_ix_j+b_{ij}x_i^2+c_{ij}x_j^2+d_{ij}x_jx_i, \tag{7}$$

where $a_{ij}=d_{ji}$ and $b_{ij}=c_{ji}$ (i.e., the elements are invariant with respect to a change of i and j). The action of $\mathrm{U}_q(\mathrm{sl}(2,\mathbb{R}))$ on A induces an action on the factor algebra A/I if and only if I is $\mathrm{U}_q(\mathrm{sl}(2,\mathbb{R}))$ invariant. We denote the image of the quotient map of x_i by v_i.

Proposition 1: The ideal I is $\mathrm{U}_q(\mathrm{sl}(2,\mathbb{R}))$ *invariant if and only if*

$$a_{ij}q^2+b_{ij}(1+q^2)+d_{ij}=0$$

and

$$a_{ij}+c_{ij}(1+q^2)+d_{ij}q^2=0. \tag{8}$$

The ideal I is generated by the elements

$$I_{ij}^{\lambda}=[x_j,x_i]-\frac{q^2-1}{q^2+1}\,(x_j^2-x_i^2-\lambda_{ij}(x_i-x_j)^2),$$

with

$$\lambda_{ij}=\frac{q^2+1}{q^2-1}\,\frac{a_{ij}+d_{ij}}{a_{ij}-d_{ij}}, \quad \lambda_{ij}=-\lambda_{ji}, \quad i,j\in I,$$

for $a_{ij}\neq d_{ij}$ and

$$I_{ij}^{\infty}=(x_i-x_j)^2,$$

for $a_{ij}=d_{ij}$.

Proof: First we consider the case $a_{ij}\neq d_{ij}$. Using (3)–(6), we have

$$\begin{aligned}E(X_{ij}):&=E(a_{ij}x_ix_j+b_{ij}x_i^2+c_{ij}x_j^2+d_{ij}x_jx_i)\\&=\left(a_{ij}q+b_{ij}\left(q+\frac{1}{q}\right)+d_{ij}\,\frac{1}{q}\right)x_i+\left(a_{ij}\,\frac{1}{q}+c_{ij}\left(q+\frac{1}{q}\right)+d_{ij}q\right)x_j.\end{aligned}$$

Because there are no linear relations between the generators, the last expression is contained in I, if and only if it is zero. Therefore the equations (8) are necessary.

Now we show that the equations (8) are also sufficient. We have to show that $K(X_{ij})$, $F(X_{ij}) \in I$. We have

$$K(X_{ij}) := q^{-2} X_{ij} \in I.$$

Further

$$F(X_{ij}) := -\frac{a_{ij}}{q} x_i^2 x_j - a_{ij} q x_i x_j^2 - \frac{b_{ij}}{q} x_i^3 - b_{ij} q x_i^3 - \frac{c_{ij}}{q} x_j^3 - c_{ij} q x_j^3 - \frac{d_{ij}}{q} x_j^2 x_i - d_{ij} q x_i x_j^2.$$

Now let

$$\alpha := \frac{1+q^2}{q} \frac{a_{ij}}{d_{ij} - a_{ij}}, \quad \beta := \frac{1+q^2}{q} \frac{d_{ij}}{a_{ij} - d_{ij}}.$$

Because of (8) we have

$$\alpha(a_{ij} + b_{ij}) = -\frac{a_{ij}}{q}, \quad \alpha(a_{ij} + c_{ij}) = -a_{ij} q, \quad \beta(c_{ij} + d_{ij}) = -\frac{d_{ij}}{q},$$

$$\beta(b_{ij} + d_{ij}) = -d_{ij} q, \quad (\alpha + \beta) = -\left(q + \frac{1}{q} \right), \quad (d_{ij}\alpha + a_{ij}\beta) = 0.$$

Therefore

$$\begin{aligned} F(X_{ij}) &= \alpha(a_{ij} + b_{ij}) x_i^2 x_j + \alpha(a_{ij} + c_{ij}) x_i x_j^2 + \beta(c_{ij} + d_{ij}) x_j^2 x_i + \beta(b_{ij} + d_{ij}) x_j x_i^2 + (\alpha + \beta) b_{ij} x_i^3 \\ &\quad + (\alpha + \beta) c_{ij} x_j^3 + (d_{ij}\alpha + a_{ij}\beta) x_i x_j x_i + (d_{ij}\alpha + a_{ij}\beta) x_j x_i x_j \\ &= \alpha(x_i X_{ij} + X_{ij} x_j) + \beta(x_j X_{ij} + X_{ij} x_i) \in I, \end{aligned}$$

i.e., the equations (8) are sufficient.

Further we confirm the second statement of the proposition. We show that the generators X_{ij} and I_{ij}^{λ} differ only by a constant nonzero factor:

$$\begin{aligned} I_{ij}^{\lambda} &= \left(-1 - \lambda_{ij} \frac{q^2-1}{q^2+1} \right) x_i x_j + (1 + \lambda_{ij}) \frac{q^2-1}{q^2+1} x_i^2 + (-1 + \lambda_{ij}) \frac{q^2-1}{q^2+1} x_j^2 + \left(1 - \lambda_{ij} \frac{q^2-1}{q^2+1} \right) x_j x_i \\ &= \frac{-2}{a_{ij} - d_{ij}} \left(a_{ij} x_i x_j + \frac{-a_{ij} q^2 - d_{ij}}{1+q^2} x_i^2 + \frac{-a_{ij} - d_{ij} q^2}{1+q^2} x_j^2 + d_{ij} x_j x_i \right) \\ &= \frac{-2}{a_{ij} - d_{ij}} (a_{ij} x_i x_j + b_{ij} x_i^2 + c_{ij} x_j^2 + d_{ij} x_j x_i). \end{aligned}$$

The second statement of the proposition follows.

Finally, let $a_{ij} = d_{ij} \neq 0$. We obtain $b_{ij} = c_{ij} = -a_{ij} = -d_{ij}$. The proposition follows.

We exclude the case I_{ij}^{∞} from the following considerations. Proposition 1 admits the following Definition.

Definition 1: Let I be an arbitrary set. A'_{λ}, $\lambda = (\lambda_{ij}; i, j \in I)$ is the left $U_q(sl_2, \mathbb{R})$-module algebra given by generators v_i, $i \in I$, and relations

$$[v_j, v_i] = \frac{q^2-1}{q^2+1} (v_j^2 - v_i^2 - \lambda_{ij} (v_i - v_j)^2). \tag{9}$$

Let λ_{ij} be fixed. In the quasi-classical limit $q \to 1$ the bracket (9) becomes the pre-Poisson bracket (1). By Proposition 1 the modules A'_{λ} are the most general $U_q(sl(2, \mathbb{R}))$-modules given by generators and quadratic relations.

In order to define cross ratios (see below) we need also elements of the form $(\Sigma \alpha_i v_i)^{-1}$.

Definition 2: We obtain the extension A_λ of A'_λ if we adjoin the inverses of the nonvanishing finite sums $(\Sigma \alpha_i v_i)^{-1}$ to A_λ and require that

$$\left(\sum \alpha_i v_i\right)^{-1}\left(\sum \alpha_i v_i\right)=\left(\sum \alpha_i v_i\right)\left(\sum \alpha_i v_i\right)^{-1}=1. \tag{10}$$

The $U_q(sl_2,\mathbb{R})$-module structure extends by the requirements (2)–(4) to all $x,y\in A_\lambda$.

B. Polynomials of degree three

There is a principle about a correspondence between the Jacobi identity for Poisson brackets and the Poincaré–Birkhoff–Witt (PBW) theorem for the quantized algebras. We will prove the statement of the PBW theorem only for polynomials of degree three. We obtain that condition (2) for the Jacobi identity characterizes also the classical behavior of third-order polynomials [with the exception of two special values for $\lambda_{i,j}$ and one structure where (2) is not satisfied]. The main part of the proof is Lemma 2.

Remark: Let b_{ij}, $c_{ij}\neq 0$ (i.e., $|\lambda_{ij}|\neq 1$). Then on the right side in relation (12) occurs a monomial which is lexicographically smaller and a monomial which is lexicographically greater than the monomial on the left side. Therefore we can not use the Bergman theory (cf. Ref. 4) for a proof of the PBW theorem.

Let $i<j$ and suppose $d_{ij}\neq 0$ [or the equivalent condition $\lambda_{i,j}\neq(q^2+1)/(q^2-1)$]. It follows

$$v_j v_i := \alpha_{ij} v_i v_j+\beta_{ij} v_i^2+\gamma_{ij} v_j^2 \tag{11}$$

with

$$\alpha_{ij}:\frac{-a_{ij}}{d_{ij}}=\frac{-(q^2+1)-\lambda_{ij}(q^2-1)}{\lambda_{ij}(q^2-1)-(q^2+1)},$$

$$\beta_{ij}:=\frac{-b_{ij}}{d_{ij}}=\frac{1-q^2\alpha_{ij}}{1+q^2}=\frac{(q^2-1)(1+\lambda_{ij})}{\lambda_{ij}(q^2-1)-(q^2+1)},$$

$$\gamma_{ij}:=\frac{-c_{ij}}{d_{ij}}=\frac{q^2-\alpha_{ij}}{1+q^2}=\frac{(q^2-1)(-1+\lambda_{ij})}{\lambda_{ij}(q^2-1)-(q^2+1)}$$

[cf. formulas (7)–(9)].

Lemma 1: (i) *Let* $i<j$, $\lambda_{i,j}\neq(q^2+1)/(q^2-1)$, and v_i and v_j *be two of the generators of* A'_λ. *Then*

$$(1-\beta_{ij}\gamma_{ij})v_j^2 v_i=(\beta_{ij}^2(1+\alpha_{ij}))v_i^3+(\alpha_{ij}\beta_{ij}(1+\alpha_{ij}))v_i^2 v_j+(\alpha_{ij}^2+\alpha_{ij}\beta_{ij}\gamma_{ij})v_i v_j^2 + (\gamma_{ij}(1+\alpha_{ij}))v_j^3.$$

We have $1-\beta_{ij}\gamma_{ij}\neq 0$ *for the coefficient on the left side if and only if* $\lambda_{i,j}\neq(q^4+1)/(q^4-1)$.

(ii) *Let* $1-\beta_{ij}\gamma_{ij}\neq 0$. *Then we can reduce every monomial of degree three into a sum of ordered monomials.*

Proof: (i) We have

$$\begin{aligned} v_j v_j v_i &= \alpha_{ij} v_j v_i v_j+\beta_{ij} v_j v_i^2+\gamma_{ij} v_j^3 \\ &= \alpha_{ij} v_j v_i v_j+(\beta_{ij}\alpha_{ij} v_i v_j v_i+\beta_{ij}\beta_{ij} v_i^3+\gamma_{ij}\beta_{ij} v_j^2 v_i)+\gamma_{ij} v_j^3 \\ &= (\alpha_{ij}\alpha_{ij} v_i v_j^2+\alpha_{ij}\beta_{ij} v_i^2 v_j+\alpha_{ij}\gamma_{ij} v_j^3)+(\beta_{ij}\alpha_{ij}\alpha_{ij} v_i^2 v_j \\ &\quad +\beta_{ij}\alpha_{ij}\beta_{ij} v_i^3+\beta_{ij}\alpha_{ij}\gamma_{ij} v_i v_j^2)+\beta_{ij}\beta_{ij} v_i^3+\gamma_{ij}\beta_{ij} v_j^2 v_i+\gamma_{ij} v_j^3. \end{aligned}$$

The identity follows. Further

$$(1-\beta_{ij}\gamma_{ij})=1-\frac{(q^2-1)(1+\lambda_{ij})}{(\lambda_{ij}(q^2-1)-(q^2+1))}\frac{(q^2-1)(-1+\lambda_{ij})}{(\lambda_{ij}(q^2-1)-(q^2+1))}=\frac{2(q^4+1)-2\lambda_{ij}(q^4-1)}{(\lambda_{ij}(q^2-1)-(q^2+1))^2}.$$

Therefore $1-\beta_{ij}\gamma_{ij}=0$ if and only if $\lambda_{i,j}=(q^4+1)/(q^4-1)$.

(ii) Using (11) we can replace every nonordered monomial by a sum of lexicographically smaller monomials or monomials of the type $v_jv_jv_i$. Because of Lemma 1(i) we can reduce $v_jv_jv_i$, $i<j$, to ordered monomials. Therefore we can reduce every polynomial of degree three with finite steps to a sum of ordered polynomials. ■

Lemma 2: (i) *Let $i<j<k$ be three indices, x_i,x_j,x_k, be three of the generators of A, $X_{ij}\in I$ [cf. (7)], $V\subset I$ be the subspace of all elements x_aX_{ab}, x_bX_{ab}, $X_{ab}x_a$, $X_{ab}x_b$, and*

$$X_{ijk}:=-a_{jk}a_{ik}X_{ij}x_k-a_{jk}x_jX_{ik}-X_{jk}x_i+x_kX_{ij}+a_{ij}X_{ik}x_j+a_{ik}a_{ij}x_iX_{jk}\in I.$$

Then we have

$$\begin{aligned}X_{ijk}=&\frac{(\lambda_{ij}\lambda_{jk}-\lambda_{ij}\lambda_{ik}-\lambda_{ik}\lambda_{jk}+1)(q^2-1)^2(q^2+1)}{k_{ij}k_{ik}k_{jk}}\\&\times(p_1x_i^3+p_2x_j^3+p_3x_k^3+p_4x_i^2x_j+p_5x_ix_j^2+p_6x_i^2x_k\\&+p_7x_ix_k^2+p_8x_j^2x_k+p_9x_jx_k^2)\mathrm{mod}(V)\end{aligned}\tag{12}$$

with

$$p_1:=\frac{4(\lambda_{ij}-\lambda_{ik})q^6(q^2-1)}{l_{ij}l_{ik}},\quad p_2:=\frac{-2(q^2-1)K}{l_{ij}l_{jk}},$$

$$p_3:=\frac{4(\lambda_{ik}-\lambda_{jk})(q^2-1)}{l_{ik}l_{jk}},$$

$$p_4:=\frac{-2m_{ij}q^2}{l_{ij}},\quad p_5:=\frac{2m_{ij}}{l_{ij}},\quad p_6:=\frac{2m_{ik}q^2}{l_{ik}},$$

$$p_7:=\frac{-2m_{ik}}{l_{ik}},\quad p_8:=\frac{-2m_{jk}q^2}{l_{jk}},\quad p_9:=\frac{2m_{jk}}{l_{jk}},$$

and

$$k_{ij}:=1+q^2+\lambda_{ij}(1-q^2),\quad l_{ij}:=1+q^4+\lambda_{ij}(1-q^4),$$

$$m_{ij}:=1+q^2+\lambda_{ij}(-1+q^2),$$

$$\begin{aligned}K:=&-(1+q^2+q^4+q^6)+\lambda_{12}(1-q^2+q^4+q^6)+\lambda_{23}(-1-q^2+q^4-q^6)\\&+\lambda_{12}\lambda_{23}(1-q^2-q^4+q^6).\end{aligned}$$

The right side of (12) vanishes if and only if $\lambda_{ij}\lambda_{jk}-\lambda_{ij}\lambda_{ik}-\lambda_{ik}\lambda_{jk}=-1$ or $\lambda_{ij}=(1+q^2)/(1-q^2)$, $\forall i<j$.

Proof: One can check that in X_{ijk} all terms $x_ax_bx_c$ with three different a,b,c cancel. The remaining monomials have only two different indices. Because we used in the reduction process of $v_av_bv_b$, $v_av_av_b$, and $v_av_bv_a$ in the proof of Lemma 1.1 only reduction rules which correspond to x_aX_{ab}, x_bX_{ab}, $X_{ab}x_a$, and $X_{ab}x_b$, we can replace the remaining monomials of type $x_ax_bx_b$, $x_ax_ax_b$, and $x_ax_bx_a$ by sums of ordered polynomials mod (V). This was done, using a computer calculation.

The right side of (12) vanishes if and only if (2) is satisfied or $p_1,\ldots,p_9=0$. From $p_1=p_3=p_4=0$ follows $\lambda_{ij}=\lambda_{ik}=\lambda_{jk}=(1+q^2)/(1-q^2)$. It follows $p_5,\ldots,p_9=0$ and $p_2=0$ because of

$$(1-q^2)^2K=-(1-q^2)^2(1+q^2+q^4+q^6)+(1-q^2)(1+q^2)(-2q^2+2q^4)$$
$$+(1+q^2)^2(1-q^2-q^4+q^6)=0,$$

i.e., $p_1,\ldots,p_9=0$ if and only if $\lambda_{ij}=(1+q^2)/(1-q^2)$. ■

Theorem 1: *Let A'_λ be the algebra of n points. We can represent every polynomial of degree less than three as a unique sum of ordered polynomials v_i, v_iv_j, and $v_iv_jv_k$, $i\leqslant j\leqslant k$, if and only if every three parameters $\lambda_{ij},\lambda_{ik},\lambda_{jk}, i<j<k$ satisfy the conditions (2):*

$$\lambda_{ij}\lambda_{jk}-\lambda_{ij}\lambda_{ik}-\lambda_{ik}\lambda_{jk}=-1$$

and the additional conditions $\lambda_{ij}\neq(q^2+1)/(q^2-1),(q^4+1)/(q^4-1)$, $i<j$, or if

$$\lambda_{ij}=\lambda_{ik}=\lambda_{jk}=\frac{1+q^2}{1-q^2}\,.$$

Proof: (i) Let $\lambda_{ij}=(q^2+1)/(q^2-1)$ (i.e., $d_{ij}=0$). Because of (7) we obtain the linear dependence of ordered monomials $a_{ij}v_iv_j+b_{ij}v_i^2+c_{ij}v_j^2=0$.

Let $\lambda_{ij}=(q^4+1)/(q^4-1)$. Because of Lemma 1 we obtain a linear dependence of ordered monomials.

Finally let i,j,k be three indices, such that (2) is not satisfied and let $\lambda_{ij}\neq(1+q^2)/(1-q^2)$ for $i<j$. If we apply the quotient map $A\to A/I$ to (12) we obtain a linear dependence between ordered monomials.

Therefore the conditions of Theorem 1 are necessary.

(ii) Now let the conditions of the Theorem be satisfied. Because the relations (9) are homogeneous, A'_λ is the direct sum of the subspaces of homogeneous polynomials.

Because of $\lambda_{ij}\neq(q^2+1)/(q^2-1)$ (i.e., $d_{ij}\neq0$) we can represent every polynomial of degree $\leqslant2$ as a sum of ordered monomials.

It remains to consider monomials of degree three. Because of $\lambda_{ij}\neq(q^4+1)/(q^4-1)$ and Lemma 1(ii) we can reduce every monomial of degree three in finite steps to a sum of ordered monomials.

We show that the ordered monomials are linear independent. The space of third degree polynomials in the free algebra A is n^3-dimensional. The Ideal I is generated by the $2n\binom{n}{2}$ elements x_iX_{jk} and $X_{jk}x_i$, $j<k$. Because (2) is satisfied for $i<j<k$ or $\lambda_{ij}=(1+q^2)/(1-q^2)$ for $i<j$, the left side of (12) in Lemma 2 vanishes mod (V). Therefore we have $\binom{n}{3}$ relations between the generators x_iX_{jk} and $X_{jk}x_i$ of I. These relations are independent, because elements x_iX_{jk} and $X_{jk}x_i$ with three fixed different indices occur only in one of the relations. Therefore $\dim I\leqslant2n\binom{n}{2}-\binom{n}{3}$. It follows that the dimension of the space of third degree polynomials in the factor algebra $A'_\lambda=A/I$ is greater than or equal $n^3-2n\binom{n}{2}+\binom{n}{3}=n^2+\binom{n}{3}$. We have shown above that this space is spanned by ordered polynomials, i.e., the dimension of this space space is less than or equal $n+2\binom{n}{2}+\binom{n}{3}=n^2+\binom{n}{3}$. Therefore the ordered monomials are linear independent. ■

Remark: If (2) is satisfied and $\lambda_{ij}=(q^2+1)/(q^2-1)$ or $(q^4+1)/(q^4-1)$ for certain $i<j$ one can change the order of the indices in order to satisfy the conditions of Theorem 1.

Remark: We expect an analogue of Theorem 1 for polynomials of higher degrees. One difficulty is to classify the additional conditions. For example, for fourth-order polynomials one can derive the additional condition $\beta_{ij}\gamma_{ij}(1+\alpha_{ij})\neq1$.

Remark: If we introduce the new parameters $c:=i(q^2+1)/(q^2-1)$ and $\phi_{ij}:=c/\lambda_{ij}$, $(\lambda_{ij}\neq0)$ we have

$$[v_j,v_i]=\frac{i}{c}\,(v_j^2-v_i^2)-\frac{i}{\phi_{ij}}\,(v_i-v_j)^2.$$

For condition (2) we get the form

$$\phi_{ik}=\frac{\phi_{ij}+\phi_{jk}}{1+\phi_{ij}\phi_{jk}/c^2}$$

of the Einstein addition theorem for velocities.

In subsections C and D we give some examples.

C. Points of the real projective line

Consider A_λ with real λ_{ij} and endow A_λ with the trivial involution $v_i^*=v_i$. The relations (9) are obviously $*$-invariant. Therefore the involution on A induces an involution on A'_λ and A_λ.

In view of Theorem 1 and the Remark after Theorem 1 we give the following definition.

Definition 3: The algebra $A_\lambda^{\mathbb{R}}$ of coordinates of noncommutative points v_i of the real line is the $U_q(\mathrm{sl}(2,\mathbb{R}))$ module A_λ, if A_λ carries the involution $*$ and A'_λ has the property (2) or is the exceptional structure of Theorem 1.

Example 7: Let I be an arbitrary linear-ordered set and let $\lambda_{ij}=1$ for $i<j$ (cf. Example 1). It follows

$$[v_j,v_i]=(q^2-1)v_i(v_j-v_i),\quad i<j.$$

We denote this structure by $A_1^{\mathbb{R}}$.

Example 8: Let I be the set $\mathbb{Z}$ of integers and $\lambda_{ij}=\coth(\Sigma_{k=i}^{j-1}\alpha_k)$, $\alpha_k>0$, $i<j$ (cf. Example 2). It follows

$$[v_j,v_i]=\frac{q^2-1}{q^2+1}\left(v_j^2-v_i^2-\coth\left(\sum_{k=i}^{j-1}\alpha_k\right)(v_i-v_j)^2\right),\quad i<j.$$

Example 9: Let I be the set of integers $\lambda_{ij}=(1+q^2)/(1-q^2)$, $i<j$ (cf. Theorem 1). It follows

$$v_jv_i=\frac{v_i^2+q^2v_j^2}{1+q^2}.$$

We denote this structure by $A_E^{\mathbb{R}}$. Because of $\lambda_{ij}\to\infty$ for $q\to1$ this structure has no quasi-classical limit.

D. Points of the complexified projective line

Let I' be an arbitrary set and $I=I'\times\mathbb{Z}_2$. We use the notations $w_i:=v_{(i,0)}$ and $w_{\overline{i}}^*:=v_{(i,1)}$, $i\in I'$. Let w_i and $w_{\overline{i}}^*$, $i\in I'$, be connected by the involution $*$ (i.e., $w_{\overline{i}}^{**}=w_i$). Then the relations (9) get the form

$$[w_j,w_i]=\frac{q^2-1}{q^2+1}\,(w_j^2-w_i^2-\lambda_{ij}(w_i-w_j)^2),$$

$$[w_j,w_{\overline{i}}^*]=\frac{q^2-1}{q^2+1}\,(w_j^2-w_{\overline{i}}^{*2}-\lambda_{\overline{ij}}(w_{\overline{i}}^*-w_j)^2),$$

$$[w_{\overline{j}}^*,w_{\overline{i}}^*]=\frac{q^2-1}{q^2+1}\,(w_{\overline{j}}^{*2}-w_{\overline{i}}^{*2}-\lambda_{\overline{ij}}(w_{\overline{i}}^*-w_{\overline{j}}^*)^2).$$

Lemma 3: The above relations are $*$-invariant (and therefore induce an involution on A'_λ), if and only if $\overline{\lambda_{ij}}=\lambda_{\overline{ij}}$ and $\overline{\lambda_{\overline{ij}}}=\lambda_{\overline{ij}}$.

We denote the algebra generated by elements w_i and w_i^* and the above relations with $\overline{\lambda_{ij}}=\lambda_{\overline{ij}}$ and $\overline{\lambda_{\overline{ij}}}=\lambda_{\overline{ij}}$ by A_λ^c.

In order to check (2) for A_λ^c it is sufficient to check $\lambda_{\alpha\beta}\lambda_{\beta\gamma}-\lambda_{\alpha\beta}\lambda_{\alpha\gamma}-\lambda_{\alpha\gamma}\lambda_{\beta\gamma}=-1$ for $(\alpha,\beta,\gamma)=(i,j,k),(i,j,k),(i,i,j)$, $\forall i<j<k$. [For real coefficients one has to check the case $(\alpha,\beta,\gamma)=(i,j,k)$ and $\lambda_{\overline{ij}}=\lambda_{ij},\lambda_{i\overline{j}}=\lambda_{\overline{i}j}=\lambda_{ij}^{-1}$ (i.e., $\lambda_{i\overline{i}}=0$).]

Definition 4: By the algebra $A_\lambda^{\mathbb{C}}$ of quantized complex points w_i of the complexified projective line we denote the $U_q(\mathrm{sl}_2,\mathbb{R})$ module A_λ^c, if A_λ^c satisfies (2) and A_λ^c carries the involution $*$.

We consider the elements w_i and $w_{\bar{i}}^*$, respectively, as quantized complex and quantized complex conjugated points, respectively.

Example 10: Let I' be a linear ordered set, $I=I'\times\mathbb{Z}_2$, and let λ_{ij} be defined as in Example 4. We obtain

$$[w_{\bar{i}}^*,w_i]=\frac{q^2-1}{q^2+1}\,(w_{\bar{i}}^{*2}-w_i^2),$$

$$[w_j,w_i]=(q^2-1)w_i(w_j-w_i),\quad i<j,$$

$$[w_{\bar{j}}^*,w_{\bar{i}}^*]=(q^2-1)w_{\bar{i}}^*(w_{\bar{j}}^*-w_{\bar{i}}^*),\quad i<j,$$

$$[w_j,w_{\bar{i}}^*]=(q^2-1)w_{\bar{i}}^*(w_j-w_{\bar{i}}^*),\quad i<j,$$

$$[w_{\bar{j}}^*,w_i]=(q^2-1)w_i(w_{\bar{j}}^*-w_i),\quad i<j.$$

We denote this structure by $A_1^{\mathbb{C}}$

Example 11: Let $I'=\mathbb{Z}$, $I=I'\times\mathbb{Z}_2$, and $\lambda_{ij}=\coth(\Sigma_{k=i}^{j-1}\alpha_k)$, $\alpha_k>0$, $i<j$. It follows

$$[w_{\bar{i}}^*,w_i]=\frac{q^2-1}{q^2+1}\,(w_{\bar{i}}^{2*}-w_i^2),$$

$$[w_j,w_i]=\frac{q^2-1}{q^2+1}\left(w_j^2-w_i^2-\coth\left(\sum_{k=i}^{j-1}\alpha_k\right)(w_i-w_j)^2\right),\quad i<j,$$

$$[w_j,w_{\bar{i}}^*]=\frac{q^2-1}{q^2+1}\left(w_j^2-w_{\bar{i}}^{*2}-\tanh\left(\sum_{k=i}^{j-1}\alpha_k\right)(w_{\bar{i}}^*-w_j)^2\right),\quad i<j,$$

$$[w_{\bar{j}}^*,w_i]=\frac{q^2-1}{q^2+1}\left(w_{\bar{j}}^{*2}-w_i^2-\tanh\left(\sum_{k=i}^{j-1}\alpha_k\right)(w_i-w_{\bar{j}}^*)^2\right),\quad i<j,$$

$$[w_{\bar{j}}^*,w_{\bar{i}}^*]=\frac{q^2-1}{q^2+1}\left(w_{\bar{j}}^{*2}-w_{\bar{i}}^{*2}-\coth\left(\sum_{k=i}^{j-1}\alpha_k\right)(w_{\bar{i}}^*-w_{\bar{j}}^*)^2\right),\quad i<j.$$

Example 10 arises again in the limit $\alpha_k\to\infty$.

Example 12: An example with complex coefficients is given by $I=\{1,2,\overline{1,2}\}$ and $\lambda_{12}=\lambda_{2\bar{2}}=\lambda_{\bar{2}\bar{1}}=\lambda_{\bar{1}\bar{1}}=i$ and $\lambda_{1\bar{2}}=\lambda_{\bar{1}\bar{2}}=O$ (cf. Example 6).

E. Algebras of three points

We will say that $A_\lambda{}'$ is polynomial, if the subspaces of homogeneous polynomials have the classical dimensions.

From Theorem 1 and the Remark after Theorem 1 follows that the subspaces of homogeneous polynomials of degree $\leqslant 3$ of the algebras $A_\lambda{}'$ which satisfy (2) and of the exceptional algebra $A_E^{\mathbb{R}}$ have the classical dimensions.

We expect that these algebras are polynomial. We give a proof for algebras of three points.

Lemma 4: Let $A_\lambda{}'$ be the algebra with three generators v_1,v_2,v_3 and let (2) be satisfied. $A_\lambda{}'$ is equivalent to the algebra with generators u_1,u_2,u_3 and relations

$$u_2u_1=\frac{1}{q^2}\,u_1u_2,$$

$$u_3u_1=\frac{1}{q^2}\,u_1u_3+\left(\frac{1}{q^2}-1\right)(\lambda_{1,2}-1)(\lambda_{2,3}+1)u_2^2, \tag{13}$$

$$u_3u_2=\frac{1}{q^2}\,u_2u_3.$$

The equivalence is given by a linear transformation between the generators u_i and v_i.

Proof: Consider the transformation

$$\begin{pmatrix} u_1\\ u_2\\ u_3\end{pmatrix}=\begin{pmatrix} \lambda_{1,2}-1 & -(\lambda_{1,2}+\lambda_{2,3}) & \lambda_{2,3}+1\\ -(\lambda_{1,2}+1) & \lambda_{1,2}+\lambda_{2,3} & -(\lambda_{2,3}-1)\\ (\lambda_{1,2}+1)^2(\lambda_{2,3}+1) & -(\lambda_{1,2}+\lambda_{2,3})(\lambda_{1,2}-1)(\lambda_{2,3}+1) & (\lambda_{2,3}-1)^2(\lambda_{1,2}-1)\end{pmatrix}\times\begin{pmatrix} v_1\\ v_2\\ v_3\end{pmatrix}. \tag{14}$$

We denote the matrix by (k_{ij}). For the determinant one obtains

$$\det((k_{ij}))=-8(\lambda_{1,2}+\lambda_{2,3})^2.$$

[If $\det((k_{ij}))=0$, there exists a permutation of the three indices such that $\det((k_{ij}))\neq 0$.]

Let

$$\begin{aligned} A_{12}&:=2u_1u_2-2q^2u_2u_1,\\ A_{13}&:=2u_1u_3-2q^2u_3u_1+(1-q^2)(\lambda_{1,2}-1)(\lambda_{2,3}+1)u_2^2,\\ A_{23}&:=2u_2u_3-2q^2u_3u_2.\end{aligned} \tag{15}$$

Because of (13) we have $A_{12}=A_{13}=A_{23}=0$. We form the vanishing expressions

$$\begin{aligned} B_{12}&:=(k_{33}A_{12}-k_{23}A_{13}+k_{13}A_{23})/\det(K),\\ B_{13}&:=(-k_{32}A_{12}+k_{22}A_{13}-k_{12}A_{23})/\det(K),\\ B_{23}&:=(k_{31}A_{12}-k_{21}A_{13}+k_{11}A_{23})/\det(K).\end{aligned} \tag{16}$$

If we insert (15) and (14) in B_{12} by a computer calculation, we obtain

$$B_{12}=(1-q^2)(\lambda_{12}+1)v_1^2+(1-q^2)(\lambda_{12}-1)v_2^2+(q^2(\lambda_{12}+1)+(-\lambda_{12}+1))v_1v_2+(q^2(\lambda_{12}-1)+(-\lambda_{12}-1))v_2v_1.$$

We transform this expression in

$$B_{12}=-(1+q^2)(v_2v_1-v_1v_2)+(1-q^2)(v_1^2-v_2^2+\lambda_{12}(v_1-v_2)^2).$$

Similarly we obtain

$$B_{13}=-(1+q^2)(v_3v_1-v_1v_3)+(1-q^2)\left(v_1^2-v_3^2+\frac{1+\lambda_{12}\lambda_{23}}{\lambda_{12}+\lambda_{23}}\,(v_1-v_3)^2\right),$$

$$B_{23}=-(1+q^2)(v_3v_2-v_2v_3)+(1-q^2)(v_2^2-v_3^2+\lambda_{13}(v_2-v_3)^2).$$

Because B_{12}, B_{13}, and B_{23} vanish, the formulas (9) follow. ■

Proposition 2: Let (2) be satisfied. Then $A_\lambda{}'$ is polynomial.

Proof: The transformation between the v_i and u_i does not change the dimensions of the subspaces of homogeneous polynomials. We have to show the polynomiality of the algebra (13).

By the Diamond lemma (cf. Ref. 4) this algebra has the PBW property (and is therefore ''polynomial'') if and only if the ''overlap''

$$(u_3u_2)u_1-u_3(u_2u_1)$$

gives zero when it is reduced by means of (13) to a linear combination of ordered monomials (cf. Ref. 4 for details). Let $a:=1/q^2$ and $\epsilon:=(1/q^2-1)(\lambda_{1,2}-1)(\lambda_{2,3}+1)$. We obtain

$$\begin{aligned}(u_3u_2)u_1-u_3(u_2u_1)&=au_2(u_3u_1)-a(u_3u_1)u_2\\&=a^2(u_2u_1)u_3+a\epsilon u_2^3-a^2u_1(u_3u_2)-a\epsilon u_2^3\\&=a^3u_1u_2u_3-a^3u_1u_2u_3=0.\end{aligned}$$ ■

Finally we consider the exceptional structure $A_E^{\mathbb{R}}$. It is given by

$$v_jv_i=\frac{v_i^2+q^2v_j^2}{1+q^2},\quad i<j \tag{17}$$

(cf. Example 9).

Proposition 3: The algebra $A_E^{\mathbb{R}}$ is polynomial.

Proof: Consider the transformation

$$\begin{pmatrix}v_1\\v_2\\v_3\end{pmatrix}=\begin{pmatrix}q^2&q^2&q^2\\1&q^2&q^2\\1&1&q^2\end{pmatrix}\begin{pmatrix}u_1\\u_2\\u_3\end{pmatrix}. \tag{18}$$

We denote the matrix by (k_{ij}). We obtain for the determinant

$$\det((k_{ij}))=q^2(q^2-1)^2\neq 0.$$

Let

$$\begin{aligned}A_{12}&:=-(1+q^2)v_2v_1+v_1^2+q^2v_2^2,\\A_{13}&:=-(1+q^2)v_3v_1+v_1^2+q^2v_3^2,\\A_{23}&:=-(1+q^2)v_3v_2+v_2^2+q^2v_3^2.\end{aligned} \tag{19}$$

Because of (17) we have $A_{12}=A_{13}=A_{23}=0$. We form the vanishing expressions B_{12}, B_{13}, and B_{23} [cf. (16)] and insert (19) and (14). A calculation yields

$$\begin{aligned}B_{12}&=-(1+q^2)u_2u_1=0,\\B_{13}&=u_1u_2+u_2u_1+u_1u_3-q^2u_3u_1=0,\\B_{23}&=-u_1u_2-u_2u_1+u_2u_3-q^2u_3u_2=0.\end{aligned}$$

Therefore the algebra has generators u_1, u_2, and u_3 and relations

$$\begin{aligned}u_2u_1&:=0,\\u_3u_1&:=\frac{1}{q^2}(u_1u_3+u_1u_2),\\u_3u_2&:=\frac{1}{q^2}(u_2u_3-uu_2).\end{aligned} \tag{20}$$

The monomials on the left side are lexicographically greater than the monomials on the right side. Therefore it is sufficient to show that the ''overlap''

$$(u_3u_2)u_1-u_3(u_2u_1)$$

gives zero when it is reduced by means of (20) to a linear combination of ordered monomials (cf. Proof of Proposition 2). We have

$$(u_3u_2)u_1-u_3(u_2u_1)=\frac{1}{q^2}\,(u_2(u_3u_1)-u_1(u_2u_1))=\frac{1}{q^4}\,((u_2u_1)u_3+(u_2u_1)u_2)=0. \qquad \blacksquare$$

Remark: There is a close relation between the PBW property and the Jacobi identity. Consider an algebra with generators x, y, and z and relations $[x, y]=a$, $[z, x]=b$, and $[y, z]=c$, where a, b, and c are certain polynomials of x, y, and z. We obtain for zyx the two reductions

$$(zy)x=xyz-cx+yb-az$$

and

$$z(yx)=xyz-za+by-xc.$$

Therefore the vanishing of the ''overlap'' of the Diamond lemma has the form of the Jacobi identity, in the sense that

$$(zy)x-z(yx)=(xc-cx)+(yb-by)+(za-az)=0.$$

One can further show that the Jacobi identity for the three generators v_1, v_2, and v_3 with the commutator (9) is equivalent to the PBW property (cf. section 4.4 of Ref. 4).

F. Projective coordinates

As the algebra of *noncommutative projective coordinates* B_μ *for* A_λ we denote the $U_q(sl(2,\mathbb{R}))$-module algebra generated by elements x_i, y_i, y_i^{-1}, $(\sum \alpha_i x_i y_i^{-1})^{-1}$, $i, j \in I$, and relations

$$y_i y_i^{-1}=y_i^{-1}y_i=1,$$

$$\left(\sum\ \alpha_i x_i y_i^{-1}\right)^{-1}\left(\sum\ \alpha_i x_i y_i^{-1}\right)=\left(\sum\ \alpha_i x_i y_i^{-1}\right)\left(\sum\ \alpha_i x_i y_i^{-1}\right)^{-1}=1,$$

and

$$x_i y_i=q y_i x_i\,, \tag{21}$$

$$x_j x_i=\mu_{ij}^{(1)} x_i x_j\,, \tag{22}$$

$$y_j y_i=\mu_{ij}^{(1)} y_i x_j\,, \tag{23}$$

$$x_j y_i=\mu_{ij}^{(2)} y_i x_j+\left(\mu_{ij}^{(1)}-\frac{1}{q}\,\mu_{ij}^{(2)}\right)x_i y_j\,, \tag{24}$$

$$y_j x_i=\mu_{ij}^{(2)} x_i y_j+(\mu_{ij}^{(1)}-q\mu_{ij}^{(2)})y_i x_j \tag{25}$$

with

$$\mu_{ji}^{(1)}=\frac{1}{\mu_{ij}^{(1)}} \quad \text{and} \quad \mu_{ji}^{(2)}=1\Big/\left[\mu_{ij}^{(2)}\left(\frac{\mu_{ij}^{(1)}}{\mu_{ij}^{(2)}}\left(q+\frac{1}{q}-\frac{\mu_{ij}^{(1)}}{\mu_{ij}^{(2)}}\right)\right)\right].$$

The $U_q(sl(2,\mathbb{R}))$-module structure on B_μ is given by

$$E(x_i)=q^{1/2}y_i, \quad E(y_i)=0,$$

$$F(x_i)=0, \quad F(y_i)=q^{-1/2}x_i,$$

$$K(x_i)=q^{-1/2}x_i, \quad K(y_i)=q^{1/2}y_i.$$

and Eqs. (4)–(6).

Lemma 5: The elements $v_i:=q^{1/2}x_iy_i^{-1}$, $i\in I$, *satisfy (9) with*

$$\lambda_{ij}=\frac{q^2-2q(\mu_{ij}^{(1)}/\mu_{ij}^{(2)})+1}{1-q^2} \quad \text{or} \quad \mu_{ij}:=\frac{\mu_{ij}^{(1)}}{\mu_{ij}^{(2)}}=\frac{1+q^2+\lambda_{ij}(q^2-1)}{2q},$$

and $\mathrm{U}_q(\mathrm{sl}(2,\mathbb{R}))$ *acts on* v_i *according to (3).*

This can be checked by an explicit calculation. Therefore we can map A_λ onto a submodule of B_μ. We call x_i and y_i *noncommutative coordinates* of v_i.

Remark: One can show that the algebra of projective coordinates is *polynomial* if and only if $\mu_{ij}^{(1)}=q^{\pm 1}\mu_{ij}^{(2)}$, i.e., $\lambda_{ij}=\pm 1$. Therefore for $\lambda_{ij}\neq\pm 1$ the polynomiality of the algebra A'_λ does not yield the polynomiality of the algebra of projective coordinates.

IV. QUANTUM CROSS RATIOS

A. Invariant elements

In this section we investigate a class of invariant elements in A_λ.

Definition 5: We say that $x\in A_\lambda$ (or B_μ) is *invariant* if

$$E(x)=0, \quad F(x)=0, \quad K(x)=x.$$

Following Ref. 1 we define

$$(ij):=q^{-1/2}x_iy_j-q^{1/2}y_ix_j \quad \text{and} \quad [ij]:=v_i-v_j.$$

One can check that (ij) is invariant and we have

$$(ij)=y_i[ij]y_j. \tag{26}$$

Now we use the invariants $(ij)\in B_\mu$ to combine invariants of A_λ. We define

$$C_{ijkl}:=(il)(kl)^{-1}(kj)(ij)^{-1}.$$

Proposition 3: (i) $C_{ijkl}\in B_\mu$, $(i,j,k,l\in I)$ *is invariant.*

(ii) *We can represent* C_{ijkl} *by elements* v_i (i.e., $C_{ijkl}\in A_\lambda$) *and we have the formula*

$$\begin{aligned}C_{ijkl}:=&(q+q^{-1}-\mu_{il})(v_i-v_l)((q+q^{-1}-\mu_{ik})v_k-(q+q^{-1}-\mu_{il})v_l\\&+(\mu_{ik}-\mu_{il})v_i)^{-1}((q+q^{-1}-\mu_{ik})v_k-(q+q^{-1}-\mu_{ij})v_j\\&+(\mu_{ik}-\mu_{ij})v_i)(q+q^{-1}-\mu_{ij})^{-1}(v_i-v_j)^{-1}.\end{aligned} \tag{27}$$

Proof: The element $(ij)^{-1}$ and products of invariant elements are invariant because of (4)–(6). The assertion follows.

(ii) From (21)–(25) follow the commutation rules

$$y_iv_i=q^{-1}v_iy_i, \quad y_iv_j=((q+q^{-1}-\mu_{ij})v_j+(\mu_{ij}-q)v_i)y_i. \tag{28}$$

Further, because of (26) we have

$$C_{ijkl}=y_i[il][kl]^{-1}[kj][ij]^{-1}y_i^{-1}. \tag{29}$$

The assertion follows, if we move y_i to the right applying (28). ■

Proposition 4: In analogy to the classical case we have

$$C_{ilkj}=\frac{1}{C_{ijkl}},\quad C_{ijlk}=1-C_{ijkl},\quad C_{ikjl}=\frac{C_{ijkl}}{C_{ijkl}-1},$$

$$C_{iklj}=\frac{1}{1-C_{ijkl}},\quad C_{iljk}=1-\frac{1}{C_{ijkl}}.$$

Proof: One checks the equations $C_{ilkj}C_{ijkl}=1$ and $C_{ijlk}+C_{ijkl}=1$ using (29) and the rule $[ik]=[ij]+[jk]$. The five identities can combined from them. ■

Remark: In the general case, the elements C_{ijkl} are not $*$-invariant and the identities $C_{ijkl}=C_{lkji}=C_{klij}=C_{jilk}$ are in general not valid (see below).

B. The cross ratio

We restrict the consideration to the structure $A_1^{\mathbb{R}}$ of Example 7, i.e., $\lambda_{ij}=1$. [If $|\lambda_{ij}|=1$, we can reorder the indices such that $\lambda_{ij}=1$ (cf. Example 1).]

We can choose the algebra of projective coordinates with $\mu_{ij}^{(1)}=q^2$ and $\mu_{ij}^{(2)}=q$ (cf. Lemma 5), i.e.,

$$x_iy_i=qy_ix_i,\quad x_jx_i=q^2x_ix_j,\quad y_jy_i=q^2y_iy_j,$$

$$x_jy_i=qy_ix_j+(q^2-1)x_iy_j,\quad y_jx_i=qx_iy_j. \tag{30}$$

Lemma 6: Let $i<j<k<l$ be four ordered indices. Then we have

$$(kl)(ij)=q^6(ij)(kl),\quad (jk)(il)=(il)(jk),$$

$$(jl)(ik)=q^4(ik)(jl)+(q^6-q^4)(ij)(kl),$$

$$(jk)(ij)=q^4(ij)(jk),\quad (ik)(ij)=q^2(ij)(ik),$$

$$(jk)(ik)=q^2(ik)(jk),\quad (ij)^*=(ij).$$

Proof: We prove the fourth rule. Let $i<j<k$. From (30) follows

$$\begin{aligned}x_k(x_iy_j-qy_ix_j)&=q^2x_ix_ky_j-q^2y_ix_kx_j-(q^3-q)x_iy_kx_j\\&=q^3x_iy_jx_k+(q^4-q^2)x_ix_jy_k-q^4y_ix_jx_k\\&\quad-(q^4-q^2)x_ix_jy_k=q^3(x_iy_j-qy_ix_j)x_k,\end{aligned}$$

i.e., $x_k(ij)=q^3(ij)x_k$. Similarly, one derives $y_k(ij)=q^3(ij)y_k$, $x_j(ij)=q(ij)x_j$, and $y_j(ij)=q(ij)y_j$. The identity $(jk)(ij)=q^4(ij)(jk)$ follows. The proof of the remaining rules is similar. ■

In a similar situation some of the invariant elements C_{ijkl} were first considered in Ref. 1. Let $i<j<k<l$ be four elements of I in increasing order. With $C:=C_{ijkl}$ we derive using Proposition 4 and Lemma 6

$$C_{ijkl}=C_{klij}=C,\quad C_{jilk}=C_{lkji}=C^*=q^2C,$$

$$C_{ilkj}=C_{kjil}=\frac{1}{C},\quad C_{jkli}=C_{lijk}=C^*_{ilkj}=\frac{1}{q^2C}=\frac{c_{ilkj}}{q^2},$$

$$C_{ijlk}=C_{klji}=1-C,\quad C_{jikl}=C_{lkij}=C^*_{ijlk}=1-q^2C=q^2C_{ijlk}+(1-q^2),$$

$$C_{ikjl}=C_{kilj}=\frac{C}{C-1},\quad C_{jlik}=C_{ljki}=C^*_{ikjl}=\frac{q^2C}{q^2C-1}=\frac{q^2C_{ikjl}}{1+(q^2-1)C_{ikjl}},$$

$$C_{iklj}=C_{kijl}=\frac{1}{1-C},\quad C_{jlki}=C_{ljik}=C^*_{iklj}=\frac{1}{1-q^2C}=\frac{C_{iklj}}{q^2+(1-q^2)C_{iklj}},$$

$$C_{iljk}=C_{kjli}=1-\frac{1}{C},\quad C_{jkil}=C_{likj}=C^{*}_{iljk}=1-\frac{1}{q^2C}=\frac{1}{q^2}\,C_{iljk}+\left(1-\frac{1}{q^2}\right).$$

The Remark after Proposition 4 indicates that C_{ijkl} is not a good candidate of a quantum cross ratio. Now we make the following observation:

Lemma 7: Let i, j, k, l be four indices in arbitrary order and let $C^{*}_{ijkl}=:f(C_{ijkl},q^2)$, where f is a certain rational function. Then $f(C_{ijkl},q)$ is a $*$-invariant element of $A^{\mathbb{R}}_{\lambda}$.

This can be checked with the above formulas. Now we give the following definition.

Definition 6: We say that the $*$-invariant element $f(C_{ijkl},q)$ is the *quantum cross ratio* of the quadruple (v_i,v_j,v_k,v_l). We use the notation C_{ijkl}.

The elements C_{ijkl} have the desired properties. They tend to the classical cross ratio for $q\to 1$ and for $i<j<k<l$ we obtain

$$\mathscr{C}_{ijkl}=qC=q[il][kl]^{-1}[kj][ij]^{-1},$$

$$\mathscr{C}_{ilkj}=\frac{1}{C_{ijkl}}=\frac{1}{qC}=\frac{1}{q}\,C_{ilkj},$$

$$\mathscr{C}_{ijlk}=1-C_{ijkl}=1-qC=qC_{ijlk}+(1-q),$$

$$\mathscr{C}_{ikjl}=\frac{\mathscr{C}_{ijkl}}{\mathscr{C}_{ijkl}-1}=\frac{qC}{qC-1}=\frac{qC_{ikjl}}{1+(q-1)C_{ikjl}},$$

$$\mathscr{C}_{iklj}=\frac{1}{1-\mathscr{C}_{ijkl}}=\frac{1}{1-qC}=\frac{C_{iklj}}{q+(1-q)C_{iklj}},$$

$$\mathscr{C}_{iljk}=1-\frac{1}{\mathscr{C}_{ijkl}}=1-\frac{1}{qC}=\frac{1}{q}\,C_{iljk}+\left(1-\frac{1}{q}\right),$$

and

$$\mathscr{C}_{ijkl}=\mathscr{C}_{lkji}=\mathscr{C}_{klij}=\mathscr{C}_{jilk}.$$

C. The Euclidean distance

In the classical case a Euclidean distance on $P\mathbb{R}$ can be defined, if we fix the three points t_0 (zero-point), t_1 (one-point), and t_∞ (the point at infinity). The distance $d(t_j,t_i)$ of two points t_j, t_i is given by

$$d(t_j,t_i):=C_{0,1,\infty,j}-C_{0,1,\infty,i}.$$

This observation leads us to a notion of a noncommutative Euclidean distance. Fix three different generators v_0, v_1, and v_∞ of $A^{\mathbb{R}}_1$. Then the *noncommutative distance* of the generators v_i and v_j is given by the $*$-invariant element

$$D_{v_0,v_1,v_\infty}(v_j,v_i):=\mathscr{C}_{0,1,\infty,j}-\mathscr{C}_{0,1,\infty,i}.$$

Particles in singular magnetic field

Władysław Marcinek[a)]
Institute of Theoretical Physics, University of Wrocław,
Pl. Maksa Borna 9, 50-204 Wrocław, Poland

(Received 29 August 1997; accepted for publication 10 September 1997)

An algebraic formalism for description of quantum states of charged particle with spin moving in two-dimensional space under the influence of a singular magnetic field is developed in terms of graded algebras. The fundamental assumption is that the particle is transformed into a composite system which consists of quasiparticles, quasiholes, and magnetic fluxes. Such a system is endowed with generalized statistics determined by a grading group and a commutation factor on it. Composite systems corresponding to the quantum Hall effect and the electronic magnetotransport anomaly are described. The Fock space representation is also given. © *1998 American Institute of Physics.* [S0022-2488(98)01902-1]

I. INTRODUCTION

In the last few years charged particles moving under the influence of a strong and singular magnetic field have been studied from a few different points of view by many authors. New and very specific effects in two-dimensional systems of particles have been discovered (see Refs. 1–6, for example). A fundamental quantity for the description of these new effects is the so-called *filling factor* υ which is defined as the ratio p/N of the number of particles p by the number of magnetic fluxes N. *A magnetic flux* is a magnetic field concentrated completely on a vertical line carrying an elementary flux $\Phi_0 := h/e$. For integer-valued υ there is the well-known *integer quanlum Hall effect* (IQHE). For fractional-valued υ with odd denominator there is the famous *fractional quantum Hall effect* (FQHE).[1] It is a very interesting and fascinating fact that for a fractional-valued filling factor with an even denominator the corresponding effect is completely different from the above-mentioned quantum Hall effect. This is the so-called *electronic magnetotransport anomaly* (the $\frac{1}{2}$-anomaly). In this case the magnetic field is completely compensated such that particles move as though in the absence of the magnetic field! In this way we obtain the following scheme:

$$\upsilon = \begin{cases} 1,2,\ldots & \text{IQHE}, \\ \frac{1}{2}, \frac{1}{4}, \ldots & \text{the } \frac{1}{2} \text{ anomaly}, \\ \frac{1}{3}, \frac{1}{5}, \ldots & \text{FQHE}. \end{cases} \tag{1}$$

At present there is no satisfactory theory for unified description of all these effects. The most popular theory for the quantum Hall effect is the Chern–Simons–Landau–Ginzburg (CSLG) theory (see for example, Ref. 7 and references therein). In this theory electrons are described as bosons carrying an odd number of flux quanta. Such a composite system is said to be *a composite boson*. The $\frac{1}{2}$-anomaly can be explained in a similar way. In this case electrons can be considered as a degenerate system of new fermions in the absence of the magnetic field. Such particles are called *composite fermions*.[4,5,8] They can be imagined as electrons carrying an even number of magnetic fluxes.

An interesting concept for a composite system which consists of a particle with charge e and a singular magnetic field concentrated completely on a vertical line has been introduced by Wilczek[9] (see also Ref. 10). The charge is moving around the singular line in the flat region in which there is no influence of the magnetic field. Every rotation yields a certain phase factor q. Observe that the space on which the particle moving is $\mathscr{M} \equiv \mathbb{R}^2 \backslash \{s\}$, where $s \in \mathbb{R}^2$ is the point of

[a)]Electronic mail: wmar@ift.uni.wroc.pl

intersection of the magnetic line with the plane $\mathbb{R}^2$. The factor q can be in general a complex number of the following form: $q:=\exp(i\varphi)$, where $0\leqslant\varphi<2\pi$ is the so-called statistics parameter. This means that the statistics of the particle are determined by the value of φ. For $\varphi=0$ we have boson, for $\varphi=\pm\pi$—fermion. For arbitrary $\varphi\in[0,2\pi)$ we obtain anyons. Note that the name ''anyons'' is sometimes reserved for the case when q is the mth root of unity (see, for example, the papers of Majid,[11,12] where anyons are given in terms of certain Z_m-graded structures). The description of the statistics corresponding to composite fermions or bosons is a problem. A few remarks on this problem have been given by Jacak *et al.* in Ref. 13. According to their suggestion, the value of the statistics parameter need not be restricted to the interval $[0,2\pi)$, but can be an arbitrary real number. If $\varphi=(2k+1)\pi$, $k=1,2,...$, for example, then one can expect to obtain nothing else but the usual fermion statistics. However, according to Jacak, *et al.*, in this case we obtain a new kind of statistics, just the statistics of composite fermions. The case of $\varphi=2k\pi$, $k=1,2,...$, corresponds to composite bosons. An algebraic formalism for a particle system with generalized statistics has been considered by the author in Refs. 14–17 (see also Refs. 18–21). It is interesting that in this algebraic approach all commutation relations for particles equipped with arbitrary statistics can be described as a representation of the so-called quantum Weyl algebra $\mathscr{W}$ (or Wick algebra).[22–25] A similar approach has also been considered by other author (see Refs. 24, and 26–30). In this attempt the creation and anihilation operators act on a certain quadratic algebra $\mathscr{A}$. The creation operators act as the multiplication in $\mathscr{A}$ and the anihilation ones act as a noncommutative contraction (noncommutative partial derivatives). The algebra $\mathscr{A}$ plays the role of noncommutative Fock space. The applications for particles in a singular magnetic field have been described in Refs. 20 and 21. As a result the fact that at $\upsilon=\frac{1}{2}$ the system is degenerate and at $\upsilon=1/N$ for N odd the Landau level is fractionally filled has been obtained in an obvious way.

In this paper an algebraic formalism for a system of charged particles with spin $\frac{1}{2}$ in singular magnetic field is developed. We restrict our attention to the system with the filling factor $\upsilon=1/N$ for simplicity. The generalization for arbitrary filling factor is possible but it needs more complicated notation. The fundamental assumption of the paper is that the particle is transformed into a composite system which consists of quasiparticles, quasiholes, and magnetic fluxes. The transformation is a result of interactions of charged particle with spin with magnetic field. If N is even, then the system is identified as composite fermions, and if N is odd, then we obtain composite bosons. It is obvious that the statistics of our composite systems cannot be described by the scalar statistics parameter $q=\exp(i\varphi)$. We use here the concept of the commutation factor[31] in order to describe the statistics. The paper is organized as follows. The fundamental concept of the paper based on Refs. 19–21 is given in Sec. II. In Sec. III the quantum Weyl algebra is described in detail. It is shown that it is in fact a Γ-graded generalized (color) Lie algebra.[31] The representation of the quantum Weyl algebra is considered in Sec. IV. The Fock space of quantum states for composite fermions and composite bosons is described in Sec. V. The notion of commutation factors is briefly summarized in the Appendix. Note that the algebraic approach to the flat particle system in the singular magnetic field is not complete theory, but it can be further developed. One can write down the Hamiltonian and study the corresponding field theory. One can use the formalism described by Liguori and Mintchev[32] for such study. We hope that the possibility for the unified description of the quantum Hall effect and the electronic magnetotransport anomaly based on the algebraic formalism presented in this paper are clear.

II. FUNDAMENTAL ASSUMPTIONS

Let us consider a system of charged particles with spin $\frac{1}{2}$ moving on a flat space $\mathbb{R}^2$ under the influence of a singular perpendicular magnetic field. The magnetic field is sufficiently strong for the polarization effects of the spin. The *singularily* of the magnetic field means here that the field is completely concentrated into fluxes. We assume that there are on average N magnetic fluxes per particle. This means that the filling factor is $\upsilon=1/N$. Our fundamental assumption is that the problem of many particles interacting with the singular magnetic field can be reduced to the study of a system consisting of just one particle and N magnetic fluxes. In this way we can restrict our attention to the study of such system. It is known that quantum states of charged particles in the magnetic field are described by Landau levels. Here is an additional degeneracy of such states connected with the singular nature of the field. The structure of such degeneration is determined

by the change of phase of the particle. Let us study the degeneration in more details. We assume that the particle is in the lowest Landau level. The ''effective'' space for the particle in a singular magnetic field is $\mathscr{M}\equiv\mathbb{R}^2\backslash\{s_1,\ldots,s_N\}$, where s_i is the point of intersection of the ith magnetic flux with the plane. Let us denote by $P_m\mathscr{M}$ the space of all homotopy classes of paths which starts at m_0 and end at arbitrary point $m\in\mathscr{M}$. It is known that the union $\cup_m P_m\mathscr{M}=P\mathscr{M}$ is a covering space $P=(P\mathscr{M},\pi,\mathscr{M})$. The projection $\pi:P\mathscr{M}\to\mathscr{M}$ is given by

$$\pi(\xi)=m \quad \text{iff} \quad \xi\in P_m\mathscr{M}. \tag{2}$$

The homotopy class $P_{m_0}\mathscr{M}$ of all paths which start at m_0 and end at the same point m_0 (i.e. a loop space) can be naturally endowed with a group structure. This group is known as the fundamental group of $\mathscr{M}$ at m_0 and is denoted by $\pi_1(\mathscr{M},m_0)$. Observe that two groups $\pi_1(\mathscr{M},m_0)$ and $\pi_1(\mathscr{M},m)$ at two arbitrary points m_0 and m, respectively, are isomorphic. Hence we can introduce the fundamental group $\pi_1(\mathscr{M})$ for the whole space $\mathscr{M}$ in an obvious way. Note that in our case the fundamental group $\pi_1(\mathscr{M})$ for the space $\mathscr{M}\equiv\mathbb{R}^2\backslash\{S_1,\ldots,S_N\}$ is a free group generated by $\tilde{\sigma}_i$, $(i=1,...,N)$ and is denoted by $G_N\equiv G_N(\tilde{\sigma}_1,\ldots,\tilde{\sigma}_N)$, where $\tilde{\sigma}_i$ is the homotopy class of all paths which encloses the point m_i and none of the remaining points m_j for $j\neq i$, (see Ref. 33 for example in more detail). Next we assume that for every class of loops the phase change of particle under consideration is fixed. We introduce an equivalence relation in the fundamental group G_N. Two homotopy classes of loops in G_N are equivalent if and only if the phase changes corresponding to this classes are equal. The equivalence class of $\tilde{\sigma}_i$ with respect to the above relation is denoted by σ_i. Let Γ be a quotient group of the fundamental group G_N by the above relation. It is obvious that the phase change corresponding to $\tilde{\sigma}_i\tilde{\sigma}_j$ and $\tilde{\sigma}_j\tilde{\sigma}_i$ is the same for all $i\neq j$. Hence we have the relation $\sigma_i\sigma_j=\sigma_j\sigma_i$ in the quotient group Γ. Observe that generators σ_i of Γ can be identified with rotations around the axis at the point s_i. This means that the group Γ can be identified with the group $Z\oplus\cdots\oplus Z$ which contains N copies of the group of integers. Every rotation around the axis at s_i yields the same phase factor q_i. Two rotations around two different axis s_i and s_j are independent and they yield the phase factor c_{ij}. It is natural to assume that $c_{ij}c_{ji}=1$ and $c_{ii}\equiv q_i$. It is obvious that there is a commutation factor $c:\Gamma\times\Gamma\to\mathbb{C}\backslash\{0\}$ on the group Γ (see the Appendix) such that $c(\sigma_i,\sigma_j)\equiv c_{ij}$. The commutation factor c generalizes the scalar statistics parameter $q=\exp(i\varphi)$, where φ is an arbitrary real number. It follows from the above considerations that the structure of degenerations of Landau levels can be described by the commutation factor c on Γ. Structures of different kinds of degenerations correspond to nonequivalent classes of commutation factors on the group Γ. This means that we can use the concept of color statistics and related Γ-graded structures in order to obtain the algebraic formalism for the particle in the singular magnetic field.[17] It is interesting that in certain particular cases (see the Appendix) the grading group can be reduced to the group $\Gamma=Z_n^N\equiv Z_n\oplus\cdots\oplus Z_n$ for $n>2$ or to $Z_2^N\equiv Z_2\oplus\cdots\oplus Z_2$.

It is interesting that the structure of degeneration of the Landau levels can be described as quantum states of new particles equipped with generalized statistics. We assume that the particle under consideration is transformed into a composite system which consists of quasiparticles, quasiholes, and magnetic fluxes. Such a composite system is said to be *a composite parlticle or generalized quon.* The transformation of the particle into the composite system is a result of interactions of charged particles with spin with magnetic field. Note that if the particle is coupled with a certain flux in such a way that the magnetic field of this flux is canceled, then we say that we have *a quasiparticle.* In this case the particle is said to be *bound* to the flux. In the opposite case, i.e., when the magnetic field is not canceled, we say we have quasiholes. A *quasihole* is a ''free'' flux which behaves like a particle endowed with fermion statistics. Hence the points of intersection of N magnetic fluxes with the plane must be a set of N different points $s_1,\ldots,s_N$. The number of quasiparticles and quasiholes is equal to the number of magnetic fluxes. This means that the filling factor for the transformed system is $\nu'=(m+n)/N\equiv 1$, where m is the number of quasiparticles, and n is the number of quasiholes. The ''effective'' magnetic field is

$$B_{\text{eff}}:=B-m\Phi_0, \tag{3}$$

where B is the external magnetic field. Observe that if $B=N\Phi_0$ and the number of quasiparticles is equal to N, then the magnetic field is completely canceled! A quasiparticle is in fact the charged

particle bound to a single magnetic flux. The particles bound to two different magnetic fluxes are understood as a system of two different quasiparticles. Obviously the particle can not be bound to two fluxes at the same point! Quasiparticles as components of certain composite particles also have their own statistics. These statistics are determined by the commutation factor c on the group Γ. For an electron in a singular magnetic field it is natural to assume that we have $c_{ii} \equiv \exp(i\varphi)$, where $\varphi = \pi(N+1)$, i.e., $c_{ii} \equiv -(-1)^N$ and $c_{ij} \equiv \exp(i\pi N) \equiv (-1)^N$ for $i \neq j$. The reason that in the formula for c_{ii} we have that φ is equal to the number of magnetic fluxes N plus 1 is the spin of electrons. The above expressions for the factor c mean that two different quasiparticles for N even commute and for N odd anticommute. This also means that the composite boson can contain only one quasiparticle. The number of quasiparticles can be equal to N for composite fermions only! In other words, our quasiparticles are examples of particles equipped with the so-called color statistics, i.e., the parastatistics in Green's representation.[17] This means that one can use the concept of color statistics and related structures with the Abelian grading group in order to obtain an algebraic formalism for particles in a singular magnetic field.

III. ON QUANTUM WEYL ALGEBRAS

Let us denote by Θ^i the quantum quasiparticle state coupled with the flux at s_i. The corresponding conjugate state is denoted by Θ_j^*. It is natural to assume that there is a finite-dimensional vector space E equipped with a basis Θ^i, $i = 1,...,N = \dim E$. The complex conjugate space E^* is endowed with a basis Θ_i^* such that we have that $\langle \Theta_i^* | \Theta^j \rangle = \delta_i^j$ for $i,j = 1,...,N$. Let us give the notion of quantum Weyl algebras $\mathscr{W} \equiv \mathscr{W}_{\Gamma,c}(N)$ corresponding to an arbitrary grading group Γ and a commutation factor c on it.

Definition: A (Γ,c)-quantum Weyl algebra is a quotient algebra

$$\mathscr{W} \equiv \mathscr{W}_{\Gamma,c}(N) := T(E \oplus E^*)/I_{\Gamma,c}, \tag{4}$$

where $I_{\Gamma,c}$ is an $*$-ideal in the tensor algebra T(E⊕E) generated by the following elements*:

$$\begin{gathered} \Theta_i^* \otimes \Theta^j - c_{ij}\Theta^j \otimes \Theta_i^* - \delta_i^j \mathbf{1}, \quad \text{for all } i,j, \\ \Theta^i \otimes \Theta^j - c_{ij}\Theta^j \otimes \Theta^i, \quad \Theta_j^* \oplus \Theta_i^* - c_{ij}\Theta_i^* \otimes \Theta_i^*, \quad \text{for } i \neq j, \\ (\Theta^i)^2, \quad (\Theta_j^*)^2 \quad \text{if } c_{ii} = -1 \end{gathered} \tag{5}$$

(no sum), for i,j=1,...,N, where c_{ij} are coefficient of certain commutation factors on the grading group Γ.

The above definition means that $\mathscr{W}_{\Gamma,c}(N)$ is a $*$-algebra generated by Θ^i and Θ_j^* $(i,j = 1,...,N)$ subject to relations

$$\begin{gathered} \Theta_i^* \Theta^i = 1 + q_i \Theta^i \Theta_i^* \quad \text{for } i = j, \quad \Theta_i^* \Theta^j = c_{ji}\Theta^j \Theta_i^* \quad \text{for } i \neq j, \\ \Theta^i \Theta^j = c_{ij}\Theta^j \Theta^i \quad \text{for all } i,j, \quad \Theta_j^* \Theta_i^* = c_{ij}\Theta_i^* \Theta_j^* \quad \text{for all } i,j, \\ (\Theta^i)^2 = 0, \quad (\Theta_j^*)^2 = 0, \quad \text{if } c_{ii} = -1, \end{gathered} \tag{6}$$

where $q_i := c_{ii} : i = 1,...,N$ are diagonal elements of c (note that the same symbols for elements in the tensor algebra $T(E \oplus E^*)$ and for generators of the algebra $\mathscr{W}_{\Gamma,c}(N)$ have been used for simplicity). The algebra $\mathscr{W}_{\Gamma,c}(N)$ should be also denoted by $\mathscr{W}_{\Gamma,c}\langle \Theta^1,\ldots,\Theta^N,\Theta_i^*,\ldots,\Theta_N^* \rangle$.

Theorem: *The quantum Weyl algebra $\mathscr{W} \equiv \mathscr{W}(\Gamma,c)$ is a Γ-graded c-Lie algebra.*

Proof: We introduce the Γ-gradation of the algebra $\mathscr{W}$ as follows: for generators of the algebra we define that grade $(\Theta^i) \equiv |\Theta^i| := \sigma_i$, and grade $(\Theta_i^*) \equiv |\Theta_i^*| := -\sigma_i$, where $\{\sigma_i\}_{i=1}^N$ is a set of generators of Γ. All monomials in Θ^i and Θ_j^* modulo generating relations are homogeneous elements of $\mathscr{W}$. We use the formula $|XY| = |X| + |Y|$ for the extension of gradation for arbitrary homogeneous elements of the algebra. The generalized bracket $[.,.]_c : \mathscr{W} \otimes \mathscr{W} \to \mathscr{W}$ is defined by the formula

$$[.,.]_c X \otimes Y \equiv [X, Y]_c := XY - c(|X|,|Y|)YX, \tag{7}$$

where X,Y are arbitrary homogeneous elements of the algebra $\mathscr{W}$. We can calculate the bracket as follows: for generators we obtain the relation

$$[\Theta_i^*,\ \Theta^j]_c := \Theta_i^*\Theta_j - c(|\Theta_i^*|,|\Theta^j|)\Theta^j\Theta_i^* = \delta_i^j, \tag{8}$$

where $c(|\Theta_i^*|,|\Theta^j|)=c(-\sigma_i,\sigma_j)=c_{ji}$ and the relations (6) have been used. In a similar way we obtain the formula

$$\begin{aligned}[\Theta^i,\Theta_j^*]_c &:= \Theta^i\Theta_j^* - c(|\Theta^i|,|\Theta_j^*|)\Theta_j^*\Theta^i \\ &= -c(|\Theta^i|,|\Theta_j^*|)(\Theta_i^*\Theta_j - c(|\Theta_i^*|,|\Theta^j|)\Theta^j\Theta_i^*) \\ &= -c_{ij}\delta_i^j. \end{aligned} \tag{9}$$

For the extension of our generalized bracket to the higher-order homogeneous elements of the algebra we can use the following formulas:

$$\begin{aligned}[\Theta_i^*,\ \Theta^jX]_c &= c_{ij}\Theta^j[\Theta_i^*,\ X] + \delta_i^jX, \\ [0_i^*X,\ \Theta^j]_c &= \Theta_i^*[X,\ \Theta^j] - c_{ji}c(|X|,\sigma_j)\,\delta_i^jX, \end{aligned} \tag{10}$$

for arbitrary homogeneous X in $\mathscr{W}$. One can prove these formulas by induction. One can see that the generalized bracket is c-anticommutative,

$$[X,\ Y]_c = -c(|X|,|Y|)[Y,\ X]_c, \tag{11}$$

for homogeneous X and Y in $\mathscr{W}$. Finally, it is not difficult to calculate the following generalized Jacobi identity.

$$[X,\ [Y,\ Z]_c]_c = [[X,\ Y]_c,\ Z]_c + c(|X|,|Y|)[Y,\ [X,\ Z]_c]_c. \tag{12}$$

It is interesting that for arbitrary generalized Lie algebra $L\equiv L_{\Gamma,c}$ there is a corresponding Lie algebra or superalgebra $\mathrm{s}(L)$.[31,34] This algebra is called the superization of L and we have the following crossed product:

$$L := \mathrm{s}(L)\#C_{\Gamma,b}(N), \tag{13}$$

where $C_{\Gamma,b}(N)$ is Γ-graded b-commutative $*$-bialgebra. This means that we have the relation $gh=b(|g|,|h|)hg$ for all homogeneous $g,h\in C_{\Gamma,b}(N)$ of grade $|g|$ and $|h|$, respectively. The factor b is given by the formula (A6). The bialgebra $C_{\Gamma,b}(N)$ as a unital, associative algebra is generated by e^i,e_j^* and the following relations:

$$\begin{aligned} &e^ie^j = b_{ij}e^je^i, \quad e_i^*e_j^* = b_{ij}e_j^*e_i^*, \quad \text{for } i\neq j, \\ &e_i^*e^j = e^je_i^* = \delta_i^j, \quad \text{for all } i,j \end{aligned} \tag{14}$$

(no sum). The gradation is given in the standard way. This means that $|e^i|=\sigma_i$ and $|e_i^*| = -\sigma_i,\sigma_i$ are generators of the group Γ. The $*$-operation and the comultiplication by the formulas

$$(e^i)^* := e_i^*, \quad (e_i^*)^* := e^i, \tag{15}$$

i.e., $(e^i)^*\equiv(e^i)^{-1}$ and

$$\Delta(e^i) := e^i\otimes 1 + 1\otimes e^i, \tag{16}$$

respectively. The extension to the whole bialgebra is obvious. For the tensor product we have here the relation

$$(g\otimes h)(k\otimes l) = b(|h|,|k|)gk\otimes hl \tag{17}$$

for homogeneous $g,h,k,l \in C_{\Gamma,b}(N)$. Observe that the bialgebra $C_{\Gamma,b}(N)$ is not a usual Hopf algebra, but a Γ-graded generalized Hopf algebra (see Ref. 35) and a $*$-bialgebra.[36] The relation (13) means that L is a subalgebra of the tensor product $\mathrm{s}(L)\otimes C_{\Gamma,b}(N)$ spanned by elements of the form $X=x\otimes g$ for homogeneous $X\in L$, $x\in \mathrm{s}(L)$, $g\in C_{\Gamma,b}(N)$ of the same grade, i.e., $|X|=|x|=|g|=\alpha\in\Gamma$. The algebra $\mathrm{s}(L)$ is also Γ graded, but this gradation can be reduced to the group Γ/Γ_0. The reduction is given by the quotient map $\pi:\Gamma\to(\Gamma/\Gamma_0)$. In this way we obtain that the gradation of the algebra $\mathrm{s}(L)$ can be given by the group Z_2 or is trivial. Let us describe the superization $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))$ of the quantum Weyl algebra $\mathscr{W}_{\Gamma,c}(N)\equiv\mathscr{W}_{\Gamma,c}\langle\Theta^1,\ldots,\Theta^N,\Theta_1^*,\ldots,\Theta_N^*\rangle$ in terms of generators. The algebra $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))$ is generated by x^i and x_j^* $(i,j=1,\ldots,N)$ and relations

$$\begin{aligned} x_i^*x_i &= 1+q_ix_ix_i^* \quad \text{for } i=j,\\ x_i^*x_j &= c'_{ji}x_jx_i^* \quad \text{for } i\neq j,\\ x^ix^j &= c'_{ij}x^jx^i \quad \text{for all } i,j, \end{aligned} \tag{18}$$

where c' is given by the formula (A7). This means that $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))$ is also a quantum Weyl algebra, $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))\equiv\mathscr{W}_{\pi(\Gamma),c'}$. The crossed product of algebras $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))$ and $C_{\Gamma,b}(N)$ is a subalgebra of the tensor product $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))\otimes C_{\Gamma,b}(N)$ generated by elements

$$\Theta^i:=x^i\otimes e^i \quad \Theta_i^*:=x_i^*\otimes e_i^* \quad (\text{no sum}). \tag{19}$$

Note that the above expressions for Θ^i and Θ_j^* are not unique. There is a freedom of choosing the generators of the bialgebra $C_{\Gamma,b}(N)$ described by the orthogonal group $\mathrm{O}(N)$.[37] Let us consider a few simple examples.

Example 1: Assume that $\Gamma=Z\otimes\cdots\otimes Z$ (N-summands) and the factor c is given by the relation (A9), where $\Omega_{ij}=1$ for $i\neq j$. Hence the commutation rules (6) can be given in the following form:

$$\begin{aligned} \Theta_i^*\Theta^i-q_i\Theta^i\Theta_i^* &= 1 \quad \text{for } i=j,\\ \Theta_i^*\Theta^j-\omega^{-1}\Theta^j\Theta_i^* &= 0 \quad \text{for } i<j,\\ \Theta^i\Theta^j-\omega\Theta^j\Theta^i &= 0 \quad \text{for } i<j. \end{aligned} \tag{20}$$

Example 2: Let us consider the corresponding case for $\Gamma=Z_2\otimes\cdots\otimes Z_2$, in more detail. If we substitute the commutation factor c of the form (A13) into the formulas (6), then we obtain the following relations:

$$\begin{aligned} \Theta_i^*\Theta^i+(-1)^N\Theta^i\Theta_i^* &= 1 \quad \text{for } i=j,\\ \Theta_i^*\Theta^j-(-1)^{\Omega_{ij}}\Theta^j\Theta_i^* &= 0 \quad \text{for } i<j,\\ \Theta^i\Theta^j-(-1)^{\Omega_{ij}}\Theta^j\Theta^i &= 0 \quad \text{for } i<j. \end{aligned} \tag{21}$$

It is interesting that in this case the bialgebra $C_{\Gamma,b}(N)$ as algebra is reduced to the standard Clifford algebra C_N. In fact we have $(e^i)^*\equiv e^i$ and we obtain the well-known relations $e_ie_j+e_je_i=2\delta_{ij}$ for $i,j=1,\ldots,N$.

Example 3: If N is even, we obtain the following relations for composite fermions:

$$\begin{aligned} \Theta_i^*\Theta^i-\Theta^i\Theta_i^* &= 1 \quad \text{for } i=j,\\ \Theta_i^*\Theta^j+\Theta^j\Theta_i^* &= 0 \quad \text{for } i<j,\\ \Theta^i\Theta^j+\Theta^j\Theta^i &= 0 \quad \text{for } i<j, \end{aligned} \tag{22}$$

The quantum Weyl algebra generated by these relations is denoted by $\mathscr{W}_{cf}(N)$. We can see that the algebra $s(\mathscr{W}_{cf}(N))$ is generated by the usual canonical commutation relations for the system of N bosons.

Example 4: If N is odd, then we obtain relations for composite bosons:

$$\begin{aligned} &\Theta_i^*\Theta^i+\Theta^i\Theta_i^*=1 \quad \text{for } i=j,\\ &\Theta_i^*\Theta^j-\Theta^j\Theta_i^*=0 \quad \text{for } i<j,\\ &\Theta^i\Theta^j-\Theta^j\Theta^i=0 \quad \text{for } i<j, \end{aligned} \tag{23}$$

The corresponding quantum Weyl algebra is denoted by $\mathscr{W}_{cb}(N)$. In this case the algebra $s(\mathscr{W}_{cb}(N))$ is generated by the usual canonical anticommutation relations for the system of N fermions.

Example 5: Let C_N be the Clifford algebra. If we substitute $\Theta^i \equiv \Theta^* \equiv \frac{1}{2}e_i$, and

$$c_{ij}=\begin{cases} +1 & \text{for } i=j,\\ -1 & \text{for } i\neq j, \end{cases}$$

then we obtain a particular example of the quantum Weyl algebra denoted by $C_\Gamma(N)$.

IV. REPRESENTATION OF THE QUANTUM WEYL ALGEBRA

In this section we are going to construct a representation of the quantum Weyl algebra $\mathscr{W} \equiv \mathscr{W}_{\Gamma,c}(N)$ on the c-symmetric algebra $\mathscr{A}$. An algebra defined as the quotient $\mathscr{A} \equiv \mathscr{A}_c(E) := TE/I_c$ where I_c is an ideal in TE generated by the following relations,

$$\begin{aligned} &\Theta^i\Theta^j-c_{ij}\Theta^j\Theta^i \quad \text{for } i\neq j,\\ &(\Theta^i)^2 \quad \text{if } c_{ii}=-1, \end{aligned} \tag{24}$$

is said to be c-symmetric algebra over E.[14] The algebra $\mathscr{A} \equiv \mathscr{A}_c(E)$ can also be denoted by $\mathscr{A}_c\langle\Theta^1,\ldots,\Theta^N\rangle$, sometimes. It is easy to see that $\mathscr{A}_c(E)$ is a Γ-graded c-commulative algebra.

Theorem: *Let $\mathscr{W}$ be a Clifford–Weyl algebra and $\mathscr{A}$ be a c-symmetric algebra. Then there is a representation a: $\mathscr{W} \to End(\mathscr{A})$ of the quantum Weyl algebra $\mathscr{W} \equiv \mathscr{W}_{\Gamma,c}(N)$ on the Γ-graded c-commutative algebra $\mathscr{A}$.*

Proof: We must prove that there is a well-defined homogeneous homomorphism $a: \mathscr{W} \to \mathrm{End}(\mathscr{A})$ which transforms the algebra $\mathscr{W}$ as generalized Lie algebra into the generalized Lie algebra $\mathrm{End}(\mathscr{A})$ of linear endomorphisms of $\mathscr{A}$. This means that we have the relation

$$a_{[X,\,Y]_c}f=[a_X,\,a_Y]_c f \tag{25}$$

for every homogeneous $X, Y \in \mathscr{W}$ and $f \in \mathscr{A}$. The bracket on the right-hand side of the above formula is defined by the relation

$$[a_X,\,a_Y]_c := a_X a_Y - c(|X|,|Y|)a_Y a_X. \tag{26}$$

For generators Θ^i and $\Theta_j^*(i,j=1,\ldots,N)$ we define

$$a_{\Theta^i} f := m(\Theta^i \otimes f) \equiv \Theta^i f, \quad a_{\Theta_i^*}: f \equiv ev_k(\Theta_i^* \otimes f), \tag{27}$$

for every $f \in \mathscr{A}^k$, where $ev_k: E^* \otimes \mathscr{A}^{\otimes k} \to \mathscr{A}^{\otimes k-1}$ are a set of linear mappings defined by the following formulas:

$$\begin{aligned} &ev_1(\Theta_i^* \otimes \Theta^j) := \langle \Theta_i^* | \Theta^j \rangle = \delta_i^j,\\ &ev_k(\Theta_i^* \otimes \Theta^j f) := ev_1(\Theta_i^* \otimes \Theta^j) f + c_{ij}\Theta^j ev_{k-1}(\Theta_i^* \otimes f), \end{aligned} \tag{28}$$

for $f \in \mathscr{A}^k$. These mappings are said to be *a right evaluation*. Observe that we have the relation

$$ev_{k-1}(\Theta_i^*\otimes ev_k(\Theta_j^*\otimes f))-c_{ij}ev_{k-1}(\Theta_j^*\otimes(ev_k(\Theta_i^*\otimes f))=0 \tag{29}$$

on $E^*\otimes E^*\otimes\mathscr{A}^k$. We have for example,

$$ev_2(\Theta_i^*\otimes\Theta^k\Theta^1)=\delta_i^k\Theta^l+c_{ik}\delta_{il}\Theta^k. \tag{30}$$

We can see that the evaluation $ev:=\{ev_k:k=1,...\}$ can be well defined in a consistent way on the whole algebra $\mathscr{A}$ (see Refs. 18, 22, and 23). We can also see that the definition (27) can be extended in a consistent way for an arbitrary homogeneous element of the algebra $\mathscr{W}$. Obseve that we have here the following lemma: □

Lemma: We have on the algebra $\mathscr{A}$ the following commutation relations for the representation a of algebra $\mathscr{W}_{\Gamma,c}(N)$ on $\mathscr{A}$:

$$[a_{\Theta_i^*},\ a_{\Theta^j}]_c=\delta_i^j\mathbf{1},\quad [a_{\Theta^i},\ a_{\Theta^j}]_c=0,\quad [a_{\Theta_i^*},\ a_{\Theta_j^*}]_c=0. \tag{31}$$

Proof: Using the relations (27) for the first relation (31) we obtain

$$\begin{aligned}([a_{\Theta_i^*},\ a_{\Theta^j}]_c)f&=(a_{\Theta_i^*},\ a_{\Theta^j}-c_{ij}a_{\Theta_j^*}\ a_{\Theta^i})f\\&=[ev_{l+1}(\Theta_i^*\otimes\Theta^j f)-c_{ij}\Theta^j ev_l(\Theta_i^*\otimes f)]\\&=ev_1(\Theta_i^*\otimes\Theta^j)f=\delta_{ij}f,\end{aligned} \tag{32}$$

where $f\in\mathscr{A}^l$ and the relation (28) has been used. The second relation (31) follows immediately from the c-commutativity of the algebra $\mathscr{A}$. The last relation follows from the equation (29).

Let $a:\mathscr{W}_{\Gamma,c}(N)\to\mathrm{End}(\mathscr{A})$ be a Fock representation of $\mathscr{W}_{\Gamma,c}(N)$ on $\mathscr{A}$. Then there is a corresponding Fock representation $\tilde{a}:\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))\to\mathrm{End}(\mathrm{s}(\mathscr{A}_c))$ of the algebra $\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))$ on $\mathrm{s}(\mathscr{A})$, where $\mathrm{s}(\mathscr{A})$ is a commutative (or super, commutative) algebra, the superization of $\mathscr{A}$. For the representation a we have the following decomposition:

$$\begin{aligned}a_{\Theta^i}&\equiv a_{x^i}\otimes e^i:=\tilde{a}_{\Theta^i}\otimes L_{e^i},\\a_{\Theta_i^*}&\equiv a_{x_i^*}\otimes_{e_i^*}:=\tilde{a}_{\Theta_i^*}\otimes L_{e_i^*}\end{aligned} \tag{33}$$

where $x^i,\ x_i^*\in\mathrm{s}(\mathscr{W}_{\Gamma,c}(N))$ are given by (19), $e^i,\ e_i^*\in C_{\Gamma,b}(N)$, and $L:C_{\Gamma,b}(N)\to\mathrm{End}(C_{\Gamma,b}(N))$ is the left regular representation of $C_{\Gamma,b}(N)$ on itself, i.e., $L_g h=gh$ for arbitrary $g,h\in C_{\Gamma,b}(N)$. Obviously the above decomposition is not unique.

V. FOCK SPACE FOR COMPOSITE FERMION AND BOSSON

Let us describe the Fock space for composite fermion and composite boson in detail. The ground state vector $|0\rangle$ is defined as usual, i.e. $a_{\Theta_i^*}|0\rangle=0$. We use here the notation

$$a_{\Theta^i}|0\rangle\equiv a_i^+|0\rangle\equiv\Theta^i \tag{34}$$

and

$$a_a^+|0\rangle\equiv(a_1^+)^{a^1}\cdots(a_N^+)^{a^N}|0\rangle\equiv(\Theta^1)^{a^1}\cdots(\Theta^N)^{a^N}. \tag{35}$$

We use the similar notation for the operators $\tilde{a}_{x^i}$ and L_{e^i}. From relations (33) we obtain

$$a_\alpha^+|0\rangle=\tilde{a}_\alpha^+\otimes L_\alpha|0\rangle=(\Theta^1)^{\alpha^1}\cdots(\Theta^N)^{\alpha^N}\otimes(e^1)^{\alpha^1}\cdots(e^N)^{\alpha^N}. \tag{36}$$

Let us consider an example of representation corresponding to an electron in a singular magnetic field. We assume that the electron is represented by one Grassmann variable Θ, i.e., $\Theta^2=0$. For this representation we introduce here the following state vectors.

$$a_i^+|0\rangle := \begin{pmatrix} 1 \\ \vdots \\ \Theta \\ \vdots \\ 1 \end{pmatrix}, \tag{37}$$

where Θ is on the ith row. In this way an arbitrary state vector can be given in the following form,

$$a_\alpha^+|0\rangle := \begin{pmatrix} \Theta^{\alpha^1} \\ \vdots \\ \Theta^{\alpha^N} \end{pmatrix}, \tag{38}$$

for $\alpha=(\alpha^1,\ldots,\alpha^N)$, $\alpha^i=0$ or 1 for $i=1,...,N$. Now let us study this representation in more detail. Observe that for even N we obtain

$$\Theta^i\Theta^j=\Theta^j\Theta^i, \quad (\Theta^i)^2=0. \tag{39}$$

We have

$$\Theta^i\Theta^j=\begin{pmatrix} 1 \\ \vdots \\ \Theta \\ \vdots \\ \Theta \\ \vdots \\ 1 \end{pmatrix}=\Theta^j\Theta^i \tag{40}$$

and

$$(\Theta^i)^2=\begin{pmatrix} 1 \\ \vdots \\ \Theta^2 \\ \vdots \\ 1 \end{pmatrix}=0. \tag{41}$$

Let us consider the case of $N=2$ in more detail. In this case we have the following states:

$$\Theta^1=\begin{pmatrix} \Theta \\ 1 \end{pmatrix}, \quad \Theta^2=\begin{pmatrix} 1 \\ \Theta \end{pmatrix}, \tag{42}$$

and

$$\Theta^1\Theta^2=\begin{pmatrix} \Theta \\ \Theta \end{pmatrix}. \tag{43}$$

The filling factor for all these states (42) and (43) is $v=\frac{1}{2}$. These two states (42) contain quasihotes. Observe that the state (43) describes an electron bond to two fluxes which is transformed into a system containing two quasiparticles and two fluxes. This system is nonlocal due to the anticommutativity of fluxes. Note that the state (43) is the unique state corresponding to the filling factor $v=\frac{1}{2}$ without quasiholes. Observe that this state is completely filled by quasiparticles. This means that for $B=2\Phi_0$ we obtain that $B_{\text{eff}}=0$. In this way the state (43) corresponds to the $\frac{1}{2}$-anomaly.

For odd N we obtain

$$\Theta^i\Theta^j=-\Theta^j\Theta^i \quad \text{for } i\neq j. \tag{44}$$

For $i=j$ we obtain the identity $\Theta^i\Theta^i=\Theta^i\Theta^i$. In this case the space of states can also be represented by the variable Θ such that we have

$$\Theta^i=\begin{pmatrix}1\\ \vdots\\ \Theta\\ \vdots\\ 1\end{pmatrix}, \tag{45}$$

where Θ is on the ith row. We have

$$\Theta^i\Theta^j=\begin{pmatrix}1\\ \vdots\\ \Theta\\ \vdots\\ \Theta\\ \vdots\\ 1\end{pmatrix}=-\Theta^j\Theta^i. \tag{46}$$

This means that

$$\Theta^i\Theta^j=0 \tag{47}$$

for all $i\neq j$. Observe that the quantum state x^ix^j $(i\neq j)$ corresponding to particle coupled to magnetic fluxes at two different points disappear,

$$\Theta^i\Theta^j=x^ix^j\otimes e^ie^j=0, \tag{48}$$

and the state describing the particle coupled to a few fluxes at the same point is also impossible. In fact we have

$$(\Theta^i)^2=(x_i)^2\otimes(e_i)^2=(x_i)^2\otimes 1=(x_i)^2. \tag{49}$$

This means that the state $(\Theta^i)^2$ is not equipped with a flux. Let us consider as an example the case of $N=3$, i.e., the filling factor is $v=\frac{1}{3}$. In this case we have the states

$$\Theta^1=\begin{pmatrix}\Theta\\ 1\\ 1\end{pmatrix},\quad \Theta^2=\begin{pmatrix}1\\ \Theta\\ 1\end{pmatrix},\quad \Theta^3=\begin{pmatrix}1\\ 1\\ \Theta\end{pmatrix}, \tag{50}$$

which contain two quasiholes. Observe that the following states,

$$\Theta^1\Theta^2,\quad \Theta^1\Theta^3,\quad \Theta^2\Theta^3, \tag{51}$$

which contain one quasihole, and the state

$$\Theta^1\Theta^2\Theta^3, \tag{52}$$

which does not contain quasiholes, are impossible. Hence in this case the single quasiparticle states with two quasiholes are possible! This also means that the lowest Landau level cannot be completely filled by quasiparticles but fractionally filled only! This is just the FQHE.

We can see that there is a well-defined scalar product on $\mathscr{A}$ (Ref. 25),

$$\langle\Theta^\sigma|\Theta^\tau\rangle_{q,b}=\Sigma_{\pi\in S_n}\chi_n(\pi)\langle\Theta^{i_1}|\Theta^{\pi(j_1)}\rangle\cdots\langle\Theta^{i_n}|\Theta^{\pi(j_n)}\rangle, \tag{53}$$

where $\Theta^\sigma,\ \Theta^\tau\in\mathscr{A}^n$, $\Theta^\sigma=\Theta^{i_1}\cdots\Theta^{i_n}$, $\Theta^\tau=\Theta^{j_1}\cdots\Theta^{j_n}$, and

$$\chi(\pi):=\Pi_{(i,j)\in J(\pi)}c_{ij}=\Pi_{(i,j)\in J(\pi)}q_i^{n_i}b_{ij}, \tag{54}$$

$J(\pi):=\{(i,j):1\leqslant i\leqslant j\leqslant n\}$, $\pi(i)>\pi(j)$, and n_i is the number of elements of the set $K(\pi):=\{(i,j)\in J(\pi):i=j\}$. It follows immediately from the considerations of Bozejko and Speicher[38] that the corresponding scalar product is positive definite.

APPENDIX:

Let us briefly recall the concept of commutation factors on an arbitrary Abelian group Γ.[31] A mapping $c:\Gamma\times\Gamma\to\mathbb{C}$ such that

$$c(\alpha+\beta,\gamma)=c(\alpha,\gamma)c(\alpha,\gamma),\quad c(\alpha,\beta+\gamma)=c(\alpha,\beta)c(\beta\gamma), \tag{A1}$$

is said to be a bicharacter on Γ. If in addition we have the relation

$$c(\alpha,\beta)c(\beta,\alpha)=1, \tag{A2}$$

then c is said to be a commutation factor on Γ. We use here the following notation $c(\sigma_i,\sigma_i)\equiv c_{ii}\equiv q_i$ and $c(\sigma_i,\sigma_j)=c_{ij}$ for $i\neq j$, where $q_i=+1$ or -1 is said to be a parity of c, $c_{ij}\in\mathbb{C}\setminus\{0\}$ are deformation parameters such that $c_{ij}c_{ji}=1$, $\alpha=\Sigma_i\alpha^i\sigma_i$, $\beta=\Sigma_j\alpha^j\sigma_j$, and σ_i are generators of Γ. Note that we have in general the following formula for the commutation factor c on the group Γ:

$$c(\alpha,\beta)=\Pi_{i,j}(c_{ij})^{\alpha^i\beta^j}=\Pi_i(c_{ij})^{\alpha^i\beta^i}\Pi_{i<j}(c_{ij})^{\alpha^i\beta^j-\alpha^j\beta^i}. \tag{A3}$$

It is obvious that the set $\Gamma_0:=\{\alpha\in\Gamma:c(\alpha,\alpha)=1\}$ is a subgroup of Γ of index at most 2. This means that the quotient Γ/Γ_0 is isomorphic to the group Z_2 or is trivial. The commutation factor c can be given in the following form,

$$c(\alpha,\beta)=c'(\alpha,\beta)b(\alpha,\beta), \tag{A4}$$

where b and c' are two new commutation factors on Γ. The factor b is defined by the relations

$$b(\sigma_i,\sigma_j)\equiv b_{ij}:=\begin{cases}+1 & \text{for } i=j,\\ -c_{ij} & \text{for } i\neq j \text{ if } q_i=q_j=-1,\\ c_{ij} & \text{in the remaining cases.}\end{cases} \tag{A5}$$

It follows immediately from the formula (A3) that

$$b(\alpha,\beta)=\Pi_{i<j}(b_{ij})^{\alpha^i\beta^j-\alpha^j\beta^i}. \tag{A6}$$

The factor c' is defined by the formula $c'_{ii}\equiv c_{ii}\equiv q_i$ and

$$c'(\sigma_i,\sigma_j)\equiv c'_{ij}=\begin{cases}-1 & \text{if } q_i=q_j=-1,\\ +1 & \text{otherwise,}\end{cases} \tag{A7}$$

for $i\neq j$. It is interesting that the factor c' can be reduced to the group $\pi(\Gamma)\equiv\Gamma/\Gamma_0$, where $\pi:\Gamma\to\Gamma/\Gamma_0$ is the quotient map. We can see that there is the relation

$$c'(\alpha,\beta)=(-1)^{\pi(\alpha)\pi(\beta)}. \tag{A8}$$

For $\Gamma=Z^N\equiv Z\oplus\cdots\oplus Z$ (N-summands) we have

$$q_i=(-1)^{S_i},\quad b_{ij}=\omega^{\Omega_{ij}}, \tag{A9}$$

where $S_i=0,1$, and Ω_{ij} are elements of a skew-symmetric integer-valued matrix, and $\omega\neq -1$ is some complex parameter.[39] If $\omega=\exp(2\pi i/n)$, $n\geqslant 3$, and $S_i\equiv 0$, then the grading group $G\equiv Z^N$ can be reduced to $\Gamma=Z_n^N\equiv Z_n\oplus\cdots\oplus Z_n$. If $\omega=-1$, then the grading group Γ can be reduced to the group

$$G\equiv Z_2^N:=Z_2\oplus\cdots\oplus Z_2 \quad (N \ \ summands). \tag{A10}$$

It follows from our considerations in Sec. II that for the charged particle in the singular magnetic field we have $S_i=N+1 \pmod 2$, and

$$\Omega_{ij}:=\begin{cases} 0 & \text{for } i=j, \\ 1 & \text{for } i\neq j. \end{cases} \tag{A11}$$

This means that

$$b_{ij}:=\begin{cases} +1 & \text{for } i=j, \\ -1 & \text{for } i\neq j, \end{cases} \tag{A12}$$

and the factor c is given by the formula

$$c_{ij}=-(-1)^N(-1)^{\Omega_{ij}}. \tag{A13}$$

In such case if the number N of fluxes is even (i.e., for composite fermions) we obtain

$$c_{ij}=-(-1)^{\Omega_{ij}}=\begin{cases} -1 & \text{for } i=j, \\ +1 & \text{for } i\neq j. \end{cases} \tag{A14}$$

If N is odd (composite bosons), then we obtain

$$c_{ij}=(-1)^{\Omega_{ij}}:=\left\{\begin{matrix} +1 & \text{for } i=j, \\ -1 & \text{for } i\neq j. \end{matrix}\right\}. \tag{A15}$$

(Received 13 May 1997; accepted for publication 17 September 1997)

A nonperturbative approach to the vacuum polarization for quantized fermions in external vector potentials is discussed. It is shown that by a suitable choice of counterterms the vacuum polarization phase is both gauge and renormalization independent, within a large class of nonperturbative renormalizations. © *1998 American Institute of Physics.* [S0022-2488(98)02602-4]

I. INTRODUCTION

For Dirac fermions in (non-second quantized) external Yang–Mills fields the one-particle scattering matrix S is a well-defined unitary operator, and, moreover, it has a canonical second quantization $\hat{S}$ operating in the fermionic Fock space;[1] for twice differentiable vector potentials one only needs to assume certain falloff properties at spatial and time infinity.

On the other hand, if one tries to expand the quantum scattering matrix in ordinary Dyson–Feynman perturbation series one meets the well-known vacuum polarization divergences, which must be taken care by suitable (infinite) subtractions. Actually, it is only the phase of the vacuum expectation value $\langle 0|\hat{S}|0\rangle$ that is diverging; the absolute value is uniquely defined and finite by canonical quantization. The crucial point is that when passing from S to $\hat{S}$ using the rules of canonical Hamiltonian quantization the phase remains ill defined. It is exactly this quantity that is diverging in perturbation theory.

One of the basic principles of relativistic quantum field theory is locality. The fields are supposed to either commute (bosons) or anticommute (fermions) at space-like separations. This is the case at least in four or higher space–time dimensions; in lower dimensions there are more alternatives. For this reason one prefers field theories in which the action is a local differential polynomial of the fields. On the other hand, the requirement that the action is a function of the fields and their derivatives up to a finite degree at the same space–time point is by no means a necessary condition for the locality in the above sense. In this paper we continue the work on a nonperturbative renormalization, which breaks the locality in the narrow sense (the renormalized action contains field derivatives up to infinite degree) but nevertheless is local in the framework of Wightman axioms.

This work was initiated in Ref. 2 and further generalized in Ref. 3. In the previous paper[3] the question of gauge and renormalization independence was left open. We fill the gap in the present paper in the case of infinitesimal gauge and renormalization variations.

II. THE RENORMALIZATION

We shall study massless Dirac fermions coupled to a gauge potential A in Minkowski space. The potential is a smooth 1-form $A_\mu(x)dx^\mu$ in space–time with values in the Lie algebra $\mathbf{g}$ of a compact gauge group G. The elements of $\mathbf{g}$ are represented by Hermitian (according to physics literature convention) matrices in the complex vector space $\mathbb{C}^N$. The free Dirac operator is then $i\gamma^\mu\partial_\mu$. The metric is $x^\mu x_\mu = x_0^2 - x_1^2 - \cdots - x_d^2$. The Dirac gamma matrices satisfy $\gamma_\mu\gamma_\nu + \gamma_\nu\gamma_\mu = 2g_{\mu\nu}$, γ_0 is Hermitian, and γ_k is anti-Hermitian for $k \neq 0$. We fix a Hermitian matrix Γ such that $\Gamma^2 = 1$ and $\Gamma\gamma_\mu = -\gamma_\mu\Gamma$. The chiral projectors are $P_\pm = \frac{1}{2}(\Gamma \pm 1)$.

The Dirac Hamiltonian in background gauge field A is

$$D_A = -\gamma^0\gamma^k(i\partial_k + A_k) - A_0.$$

 © 1998 American Institute of Physics

We shall assume that $A(x)$ and its derivatives vanish faster than $|x|^{-d/2}$ when $|x|\to\infty$.

The one-particle scattering operator S is defined as the limit of the time evolution operator in the interaction picture, $U_I(t,-t)\to S$, as $t\to\infty$. The time evolution in the Schrödinger picture is defined by

$$i\ \partial_t U(t,t_0)=h(t)U(t,t_0),\quad \text{with}\ \ U(t_0,t_0)=1, \tag{1}$$

and in the interaction picture by

$$i\ \partial_t U_I(t,t_0)=V_I(t)U_I(t,t_0),\quad \text{with}\ \ U_I(t_0,t_0)=1. \tag{2}$$

The interaction is $V_I(t)=e^{ith_0}V(t)e^{-ith_0}$, the total Hamiltonian being $h(t)=D_A=h_0+V(t)$ with $h_0=D_0=-i\gamma_0\gamma^k\partial_k$. The quantum divergences are related to the fact that when $V=-\gamma^0\gamma^k A_k(\mathbf{x},t)-A_0(\mathbf{x},t)$ is the interaction with a Yang–Mills potential, then the quantization of $\hat{U}_I(t,-\infty)$ for intermediate times $t<\infty$ is not well defined. Let $\epsilon=h_0/|h_0|$ be the sign of the free Hamiltonian. In general, a one-particle operator K has a canonical quantization in the Fock space of free fermions iff $[\epsilon,K]$ is Hilbert–Schmidt. For a review of this and other properties of representations of CAR algebra, see Ref. 4. Generally, the Hilbert–Schmidt property is not satisfied when $K=V(t)$.

Let us recall the basic facts about (free) Fock space quantization of the canonical anticommutation relations. To each vector $u\in H$ in the one-particle Hilbert space one associates a creation operator $a^*(u)$ and an annihilation operator $a(u)$, the latter depending antilinearly on the parameter and the former linearly, with the only nonzero anticommutation relations,

$$a^*(u)a(v)+a(v)a^*(u)=\langle v,u\rangle,$$

where $\langle v,u\rangle$ is the inner product in H. Let $H=H_+\oplus H_-$ be splitting to a pair of closed infinite-dimensional subspaces. In our discussion below H_+ will be the spectral subspace corresponding to non-negative energies with respect to the free Dirac hamiltonian D_0. There is a unique (up to equivalence) irreducible representation of the CAR algebra in a Hilbert space $\mathscr{F}$ such that

$$a^*(u)|0\rangle=0=a(v)|0\rangle,\quad \text{for}\ \ u\in H_-\quad\text{and}\quad v\in H_+,$$

where $|0>\in\mathscr{F}$ is a normalized vector, the vacuum.

Let a_i^*, a_j, with $i,j\in\mathbb{Z}$, be a complete set of creation and annihilation operators such that the index $i\geqslant 0$ corresponds to non-negative energies and $i<0$ to negative energies,

$$a_i^*a_j+a_ja_i^*=\delta_{ij}.$$

The normal ordering is defined by $a_i^*a_j:=a_i^*a_j$, except when $i=j<0$, and then $a_i^*a_j:=-a_ja_i^*$. If X,Y is a pair of one-particle operators then the canonical quantizations,

$$\hat{X}=\sum\ X_{ij}:a_i^*a_j:,$$

satisfy the algebra

$$[\hat{X},\hat{Y}]=\widehat{[X,Y]}+\omega(X,Y),$$

and the quantum operators are defined such that $[\hat{X},a_i^*]=\Sigma X_{ji}a_j^*$. The 2-cocycle ω is defined by[5]

$$\omega(X,Y)=\tfrac{1}{4}\ \mathrm{tr}\ \epsilon[\epsilon,X][\epsilon,Y]. \tag{3}$$

Here we meet again the Hilbert–Schmidt condition: The 2-cocycle is defined only for bounded operators X such that $[\epsilon,X]$ is Hilbert–Schmidt.

The starting point for our discussion here is the following renormalization that makes U_I quantizable.[2,3] For each (smooth) potential $A=A_0\ dt+A_k\ dx^k$ one defines a unitary operator T_A in the one-particle space with the following property. Define $U_{\mathrm{ren}}(t,t_0)=T_A(t)U_I(t,t_0)T_A(t_0)^{-1}$.

Then (1) $[\epsilon, U_{\rm ren}(t,t_0)]$ is Hilbert–Schmidt, and (2) $T_A(t)\to 1$ as $t\to\pm\infty$. The last property quarantees that the renormalization does not affect the scattering matrix S whereas the first condition guarantees that the renormalized time evolution is quantizable in the free Fock space.

The Hilbert–Schmidt condition on operators $[\epsilon, g]$ defines the restricted unitary group U_1 of unitary operators g.[6] The second quantization of elements in U_1 defines a central extension $\hat{U}_1$, as discussed in detail in Ref. 6. Now we have a smooth path of operators $g(t)=U_{\rm ren}(t)=U_{\rm ren}(t,-\infty)$ in U_1 with the initial condition $g(-\infty)=1$ and $g(+\infty)=S$. The central extension of U_1 defines a natural connection in the circle bundle $\hat{U}_1\to U_1$. The curvature of this connection has a simple formula: It is simply given as $\mathrm{curv}(X,Y)=\omega(X,Y)$, where X,Y are tangent vectors at $g\in U_1$, identified through left translation on the group as elements of the Lie algebra of U_1. The phase of $\hat{S}$ is defined *through parallel transport*, with respect to the connection above.

Our definition of phase of $\hat{S}$ is *causal*: A scattering process in an external field A followed by the scattering in A' defines the same phase as the scattering for $A''=A\cup A'$, when both A,A' have finite nonoverlapping support in time and A'' denotes a field $A''(t)=A(t)$ for $t<t_0$ and $A''(t)=A'(t)$ for $t>t_0$; here t_0 separates the supports of A,A'. The operator T_A is not uniquely defined. It is more convenient to define the transformation first in the Schrödinger picture (1). A simple formula that works is (here $\not{A}=\gamma^0\gamma^k A_k$ and $\not{E}=\partial_t\not{A}-\not{\partial}A_0+[A_0,\not{A}]$)

$$T_A=\exp\left(\frac{1}{4}\left[\frac{1}{D_0},\not{A}\right]-\frac{1}{8}\left[\frac{1}{D_0}\not{A}\frac{1}{D_0},\not{A}\right]-\frac{i}{4}\frac{1}{D_0}\not{E}\frac{1}{D_0}\right), \tag{4}$$

where it is understood that the singularity at the zero modes of D_0 is taken care of by an infrared regularization, for example, $1/D_0\to D_0/(D_0^2+\alpha^2)$ for some nonzero real number α. In the interaction picture one uses the operator $\exp(ith_0)T_A\exp(-ith_0)$. Note that this choice commutes with the chiral projection operators $P_\pm$.

For the proof of validity of the choice (4) it is convenient to use the symbol calculus for pseudodifferential operators. A PSDO B acting on vector-valued functions in $\mathbb{R}^d$ is represented by a smooth matrix-valued function $b(x,p)$ of coordinates x_i and momenta p_i. The operators that we need have an asymptotic expansion,

$$b(x,p)\sim b_k+b_{k-1}+b_{k-2}+\cdots,$$

where each b_j is a smooth function of x,p for $|p|>1$, homogeneous of degree j in the momenta. The asymptotic expansion for the product of two operators A,B is obtained from the formula

$$a*b=\sum\frac{(-i)^{|m|}}{m!}\frac{\partial^m a}{\partial x^m}\frac{\partial^m b}{\partial p^m},$$

where the multi-index notation $m=(m_1,m_2,\ldots,m_d)$ is used; $|m|=m_1+m_2+\cdots m_d$, $m!=m_1!m_2!\cdots m_d!$, etc. In particular, the degree of the highest term in the product is the sum of degrees of the factors. Each differentiation in momentum space lowers the degree of the operator by one.

If A is an operator with symbol a such that $a(x,p)\to 0$ faster than $|x|^{-d}$ as $|x|\to\infty$ and $\deg a<-d$ then A is a trace-class operator and

$$\mathrm{tr}\,A=\frac{1}{(2\pi)^d}\int \mathrm{tr}\,a(x,p)dx\,dp.$$

We shall now assume that the components A_μ of the vector potential satisfy the above boundary condition at $|x|\to\infty$.

The time evolution equation for $U_{\rm ren}(t,t_0)=T_A(t)U(t,t_0)T_A(t_0)^{-1}$ in the Schrödinger picture is

$$i\,\partial_t U_{\rm ren}(t,t_0)=(h_0+W(t))U_{\rm ren}(t,t_0),$$

with

$$W(t)=(i\ \partial_t T_A)T_A^{-1}+T_A(h_0+V(t))T_A^{-1}-h_0. \tag{5}$$

Expanding the exponential and arranging terms according to powers of the inverse of momentum (i.e., of D_0,) one gets $[\epsilon,W]=R_1+R_2+\cdots$, where the dots denote terms that behave explicitly as $|D_0|^k$ with $k\leqslant -2$ for high momenta, and

$$R_1=\frac{1}{2}\frac{D_0}{|D_0|}\mathcal{A}-\frac{1}{2}\mathcal{A}\frac{D_0}{|D_0|}+\frac{1}{4}|D_0|\mathcal{A}\frac{1}{D_0}-\frac{1}{4}D_0\mathcal{A}\frac{1}{|D_0|}+\frac{1}{4}\frac{1}{|D_0|}\mathcal{A}D_0-\frac{1}{4}\frac{1}{D_0}\mathcal{A}|D_0|,$$

and the second term, which is quadratic in $\mathcal{A}$, is

$$R_2=\frac{1}{4}\frac{1}{D_0}[|D_0|,\mathcal{A}^2]\frac{1}{D_0}+\frac{1}{4}\left[\frac{1}{|D_0|},\mathcal{A}^2\right]+\frac{1}{8}D_0\left[\mathcal{A}\frac{1}{D_0}\mathcal{A},\frac{1}{|D_0|}\right]+\frac{1}{8}\left[\mathcal{A}\frac{1}{D_0}\mathcal{A},\frac{1}{|D_0|}\right]D_0$$
$$+\frac{1}{8}\frac{1}{D_0}\left[\mathcal{A}\frac{1}{D_0}\mathcal{A},|D_0|\right]+\frac{1}{8}\left[\frac{1}{D_0}\mathcal{A}\frac{1}{D_0},|D_0|\right]\frac{1}{D_0}.$$

Since the commutator $[|D_0|^k,\mathcal{A}]$ is of order $|D_0|^{k-1}$ in momenta, all terms in R_2 are actually of order -2 or less. In order to estimate R_1 we write it in equivalent form,

$$R_1=\frac{1}{4}\frac{D_0}{|D_0|}\left[[\mathcal{A},|D_0|],\frac{1}{|D_0|}\right]-\frac{1}{4}\left[[\mathcal{A},|D_0|],\frac{1}{|D_0|}\right]\frac{D_0}{|D_0|},$$

and observe both terms are of order -2 for the same reason as in the case of R_2. We have disregarded all the low-order terms because in three space dimensions the condition that a PSDO is Hilbert–Schmidt (which was required for canonical quantization) is precisely the requirement that the operator vanishes for high momenta faster than $|p|=|D_0|$ raised to power $-3/2$. Thus, after our renormalization (=conjugation by the time-dependent unitary operator T_A) the gauge interaction can be lifted to a finite operator in the fermionic Fock space.

The total renormalized Hamiltonian is now a sum of the free (unbounded) self-adjoint Hamiltonian and the bounded self-adjoint interaction. By the Kato–Rellich theorem[7] the total Hamiltonian is self-adjoint, and according to Stone's theorem it defines the time evolution as a strongly continuous unitary one-parameter group in the Fock space.

This method can be extended to other interactions as well, under very general conditions.[3] It has been also used to derive the chiral anomaly in the Hamiltonian framework.[2,3]

The curvature formula (3) is *nonlocal*. The computation of the trace involves space derivatives up to arbitrary high power because of the Green's function $1/D_0$ in the renormalization prescription. However, the curvature is equivalent in cohomology to a local formula. We use the residue formula,[8]

$$\text{Res } B=\frac{1}{(2\pi)^d}\int_{|p|=1}\text{tr } b_{-d}(x,p)d^dx\ d^{d-1}p.$$

It behaves like trace, $\text{Res}[A,B]=0$. Let $\mathbf{g}$ be the Lie algebra of bounded pseudodifferential operators satisfying the conditions (1) that the degree of the commutator $[\epsilon,X]$ is strictly less than $-d/2$ (here the space dimension $d=3$), (2) the symbol of X and its derivatives decrease faster than $|x|^{-d/2}$ as $|x|\to\infty$. We have then the following.

Theorem 1: *Define the following 2-cocycle on* $\mathbf{g}$*:*

$$\omega_{\text{loc}}(X,Y)=\text{Res }\epsilon[\log|p|,X]Y, \tag{6}$$

where $|p|$*, the length of three momentum, is the symbol of* $|D_0|$*. Then the difference* $\omega-\omega_{\text{loc}}$ *is a coboundary.*

For a proof see Ref. 9 (and Ref. 2 for the special case of renormalized current operators). Actually, in Ref. 9 it was assumed that the manifold is compact. This was needed for the convergence of the integral over x in the trace formula for PSDOs. Our boundary condition does the same job.

Without the sign ϵ this formula would give the Radul cocycle, which is a 2-cocycle on the algebra of *all* PSDOs on a compact manifold.[10] In quantum field theory it is important to keep the sign because this is the cocycle arising from normal ordering. The equivalence of the two cocycles means simply that if $\widetilde{X}=\hat{X}+\lambda(X)$ for a suitable complex linear form on the algebra of one-particle operators then

$$[\widetilde{X},\widetilde{Y}]=\widetilde{[X,Y]}+\omega_{\mathrm{loc}}(X,Y). \tag{7}$$

The great advantage of the residue formula is that it only depends on the term in the appropriate PSDO that is precisely of asymptotic degree $-d$ (here -3) when expanded asymptotically in powers of $1/|p|$. In operator products each derivative in configuration space is associated with a derivative in momentum space. Since a differentiation in momentum space decreases the homogeneous degree of the operator, it follows that a calculation of the residue can involve derivatives with respect to x_i's only up to a finite order.

III. GAUGE INDEPENDENCE

The prescription for the vacuum polarization phase in Sec. II is not gauge independent. Furthermore, if we change the renormalization operator T_A the phase will be changed, too. Of course, in the case of chiral fermions the gauge dependence is to be expected because of the chiral anomaly; this was discussed in Ref. 3.

In the case of Dirac fermions we expect on topological grounds that one should be able to construct counterterms in the Hamiltonian such that the gauge variance of the counterterms exactly balances the gauge variation of the phase, so that the total phase would be gauge invariant. We shall confirm this explicitly below in the case of infinitesimal variations. At the same time we shall also get rid of the renormalization-dependent part of the phase.

Suppose that we have constructed another renormalization operator T'_A that commutes with the chiral projection operators and with γ_0, such that each term in the asymptotic expansion,

$$T'_A=1+t_{-1}(A)+t_{-2}(A)+\cdots,$$

in homogeneous terms t_k of degree k in momenta, is a local differential polynomial in the components of the vector potential A. The condition that the renormalization commutes with γ_0 means that the action of T'_A on the left chiral sector is equivalent to the action on the right-hand spinors.

The change of phase of the quantum scattering is given by a parallel transport around a loop of time evolution operators obtained by first traveling the path $g(t)$ from the point $g(-\infty)=1$ to $g(\infty)=S$ defined by the renormalized time evolution due to T_A and then following backward in time the time evolution defined by the renormalization T'_A. But the logarithm of the parallel transport phase is equal to the integral of the curvature over a surface bounded by the loop.

In the following we shall use the local curvature formula (6). This has the advantage that the parallel transport around a closed loop is given by a space integral of a local differential expression in the vector potential. This is in the spirit of local quantum field theory: A change in the renormalization corresponds to a local counterterm in the Lagrangian.

Since all our operators, the (renormalized) Hamiltonian, the renormalization operator, and gauge transformations, are composed of a pair of operators (K_L,K_R) acting on the two chiral sectors, we can split the curvature into chiral constituents as follows. The left and right spinors are indentified through the unitary transformation γ_0 so that we can think of K_L and K_R as acting in the same space. Thus we may define $K_\pm=K_L\pm K_R$. Since the sign ϵ is odd, $\epsilon_L=-\epsilon_R$, we can write

$$2\omega(X,Y)=\omega_L(X_-,Y_+)+\omega_L(X_+,Y_-).$$

Here $l=\log|p|$, $|p|$ is the symbol of $|h_0|$, and $\omega_L(X;Y)=\mathrm{Res}\ \epsilon_L[l,X_L]Y_L$. We want to show that this is equivalent to a 2-form ω_- such that $\omega_-(X,Y)=0$ if either $X_-=0$ or $Y_-=0$. We denote $\mathrm{Res}'\ X=\mathrm{Res}\ \epsilon_L X$.

Let GL_1 denote the group of all invertible bounded PSDOs g in H such that the degree of $[\epsilon,g]$ is strictly less than $-d/2$. The Lie algebra of GL_1 is then equal to $\mathbf{g}$. Let $GL_{1,c}$ be the subgroup of GL_1 consisting of the chirally diagonal operators $f=(f_L,f_R)$.

The time evolution operator in Schrödinger picture does not have a good asymptotic expansion in inverse powers of momenta and therefore it is not immediately clear that one can define the Wodzicki residue for a product involving $U(t)$ as a factor. For example, the free time evolution $\exp(it\not{\partial})$ contains arbitrary high powers of momenta and therefore it is not a classical PSDO. However, the time evolution $U_I(t)=U_I(t,-\infty)$ in the interaction picture has a well-behaved symbol. The leading terms (in powers of momenta) are obtained from the Dyson expansion in which the individual terms are composed of products of the Green's function of the Dirac operator and the interaction Hamiltonian. This gives directly a classical asymptotic expansion for the PSDO $U_I(t)$.

In the following we deal with the ''Maurer–Cartan'' form $\theta=[l,f]f^{-1}$. This is a classical PSDO when $f=U_I(t)$. In the case of the Schrödinger picture it is replaced by $\exp(ith_0)\theta\times\exp(-ith_0)$. The computation of residues for this type of operators involves oscillatory integrals. These can be handled by Guillemin's method for Fourier integral operators.[11] For this reason the curvature formula extends to the bigger group GL_F, which is the smallest group containing GL_1, and the free time evolution operators $\exp(ith_0)$.

Lemma: The restriction of the curvature ω_{loc} to the chirally diagonal subgroup $GL_{F,c}\subset GL_F$ is equivalent in de Rham cohomology to the 2-form

$$\omega'(X,Y)=\omega_-(X_-,Y_-)=-\mathrm{Res}'[l,X_-]Y_-+\mathrm{Res}'[l,f_L]f_L^{-1}[X_-,Y_-].$$

Proof: Define the 1-form,

$$\phi(f;X)=\mathrm{Res}'[l,f_L]f_L^{-1}X_-,$$

on the group $GL_{F,c}$. The exterior derivative of this is computed through

$$(d\phi)(X,Y)=\mathscr{L}_X\phi(f;Y)-\mathscr{L}_Y\phi(f;X)-\phi(f;[X,Y]),$$

using the definition of the left action, $\mathscr{L}_XF(f)=(\partial/\partial t)F(e^{-tX}f)|_{t=0}$. The result is

$$(d\phi)(X,Y)=-\mathrm{Res}'[l,X_-]Y_--\mathrm{Res}'[l,X_L]Y_L+\mathrm{Res}'[l,X_R]Y_R+\mathrm{Res}'[l,f_L]f_L^{-1}[X_-,Y_-].$$

Adding the right-hand side to $\omega(X,Y)$ gives $\omega_-(X,Y)$.

We denote by $q(R)$ the canonical second quantization of an operator R and $W=W(A,T)$ is the renormalized interaction (5).

Theorem 2: *The modified quantum Hamiltonian,*

$$q'(h_0+W)=q(h_0+W)+\phi(U(A;t);h_0+W),$$

has the property that the phase of the quantum scattering matrix is invariant under infinitesimal gauge transformations. Moreover, the phase is invariant with respect to all infinitesimal variations X of T_A such that (1) X is a PSDO in the Lie algebra of U_1, (2) X is chirally even, i.e., it commutes with γ_0 and Γ.

Proof: The second term on the right-hand side means that we compute the quantum phase using a modified connection, corresponding to adding to the old connection (with curvature ω_{loc}) the 1-form ϕ. In general, a variation of the parallel transport phase defined by a connection θ on any manifold is given by

$$\mathscr{L}_X\int\theta(\gamma'(t))dt=\int\Omega_{g(t)}(\gamma'(t),X)dt,$$

where Ω is the curvature form and $X(t)$ is a vector field along the curve $\gamma(t)$. Applying this to the case when $\gamma(t)=U(t)$ [the tangent vector $\gamma'(t)$ is replaced by the element $h_0+W=iU'(t)U(t)^{-1}$], and X is an infinitesimal gauge transformation, shows that at time t the infinitesimal gauge variation of the phase is

$$\mathscr{L}_X(\text{phase}) = \omega'(h_0 + W, X). \tag{8}$$

But now $X_- = 0$ and therefore this expression vanishes and thus also the total gauge variation of the quantum phase as an integral with respect to t of (8).

Remark: We started from the standard minimal coupling of fermions to external gauge fields. We performed a renormalization by the field-dependent unitary operator T_A. The new interaction Hamiltonian, although nonlocal, is still unitarily equivalent to the original local interaction. There is a very natural generalization of our discussion in the spirit of noncommutative geometry.[12] The original interaction $\gamma^\mu A_\mu$ could be replaced by any bounded pseudodifferential operator without affecting our results (or even by a larger class of operators; see Ref. 3). This would lead to a Hamiltonian counterpart of the noncommutative Yang–Mills action functional. It would be an intermediate step between the ordinary Yang–Mills theory and the abstract universal Yang–Mills theory proposed by Rajeev.[13]

Ladder operators for isospectral oscillators

S. Seshadri, V. Balakrishnan, and S. Lakshmibala
Department of Physics, Indian Institute of Technology, Madras 600 036, India

(Received 10 June 1997; accepted for publication 9 October 1997)

We present, for the isospectral family of oscillator Hamiltonians, a systematic procedure for constructing raising and lowering operators satisfying any prescribed ''distorted'' Heisenberg algebra (including the q-generalization). This is done by means of an operator transformation implemented by a shift operator. The latter is obtained by solving an appropriate partial isometry condition in the Hilbert space. Formal representations of the nonlocal operators concerned are given in terms of pseudo-differential operators. Using the new annihilation operators, new classes of coherent states are constructed for isospectral oscillator Hamiltonians. The corresponding Fock–Bargmann representations are also considered, with specific reference to the order of the entire function family in each case. © *1998 American Institute of Physics.* [S0022-2488(98)03301-5]

I. INTRODUCTION

Generalized coherent states of different kinds have been defined and investigated for some years now, particularly in quantum optics and quantum measurement theory.[1–6] Recently, two different kinds of coherent states (CS) have been constructed[7,8] in relation to a one-parameter (λ) family of Hamiltonians $\tilde{H}$ that are isospectral companions of the standard oscillator Hamiltonian $H=a^{\dagger}a$. (The latter corresponds to the limit $|\lambda|\to\infty$.) For each finite value of λ, the eigenstates of $\tilde{H}$ consist of a zero-energy state $|\theta_0\rangle$ and a set of states $\{|\theta_n\rangle\}$ with eigenvalues $n=1,2,...$, the *latter* being obtained from the oscillator states $|n\rangle$ ($n=0,1,...$) by a nonunitary transformation [see Eq. (2.5) below]. Fernandez *et al.*[7] have constructed coherent states that are eigenstates of an annihilation operator associated with $\{|\theta_n\rangle, n\geqslant 1\}$. However, these states are not coherent states in the group-theoretic or Perelomov sense,[9] since they are not obtained by the action of a unitary ''displacement'' operator on the base state $|\theta_1\rangle$. On the other hand, Kumar and Khare[8] have shown that $\tilde{H}$ itself is essentially unitarily equivalent to H. This fact enables them to obtain coherent states simply by a unitary transformation of the standard oscillator CS. These states are thus coherent states in the group-theoretic sense in addition to being annihilation operator eigenstates. As may be anticipated, they reduce to the standard oscillator CS in the limit $|\lambda|\to\infty$. Subsequently, Fernandez *et al.*[10] have generalized their earlier work[7] by introducing a real parameter w as follows: the commutator of the lowering and raising operators in the $\{|\theta_n\rangle, n\geqslant 0\}$ basis is a diagonal operator given by diag $(0,w,1,1,1,...)$. This has been termed a ''distorted'' Heisenberg algebra. In the special case $w=1$, the CS constructed are also CS in the group-theoretic sense.

A number of interesting problems arise, which we address in this paper: the generalization of the algebra to encompass an arbitrary diagonal operator as the basic commutator, including the corresponding q-generalization; the development of a systematic procedure to find raising and lowering operators in this case; and the construction of the corresponding CS (which are *not* unitarily equivalent to the standard oscillator CS). Our strategy is to find a suitable operator transformation that takes the original ladder operators to the required new ones. The transformation is implemented by means of a *shift operator* that is constructed so as to satisfy appropriate partial isometry conditions dictated by the algebra imposed. We also derive representations for the new raising and lowering operators in terms of pseudo-differential operators, to enable one to compare their structure explicitly with their original counterparts. Finally, we examine the Fock–Bargmann (or entire analytic function) representation of states based on the CS obtained in various cases, with particular reference to the order of the entire function families concerned.

II. NOTATION AND REVIEW

For ready reference, we recapitulate briefly the relevant parts of Refs. 7, 8, and 10. Given $H=a^\dagger a$ with $[a,a^\dagger]=1$, we have $H|n\rangle=n|n\rangle$ $(n=0,1,...)$. In the position representation, $a=2^{-1/2}(x+d)$ and $a^\dagger=2^{-1/2}(x-d)$, where $d=d/dx$. Operators b and $b^\dagger$ are then defined, given in the position representation by

$$b=2^{-1/2}(x+d+\phi(x)), \quad b^\dagger=2^{-1/2}(x-d+\phi(x)), \tag{2.1}$$

and the condition $bb^\dagger=aa^\dagger$ imposed. This implies that the function $\phi(x)$ satisfies the Riccati equation

$$\phi'+2x\phi+\phi^2=0, \tag{2.2}$$

where $\phi'=d\phi/dx$. Equation (2.2) has the one-parameter family of solutions

$$\phi_\lambda(x)=\frac{e^{-x^2}}{(\lambda+\int_0^x dy e^{-y^2})}, \tag{2.3}$$

where λ is a real number such that $|\lambda|>\sqrt{\pi}/2$ (to avoid a singular ϕ_λ). Now consider the Hamiltonian (actually, a family of Hamiltonians, parametrized by λ)

$$\tilde{H}=b^\dagger b. \tag{2.4}$$

In order to keep the notation simple, the λ dependence of b, $b^\dagger$, and $\tilde{H}$ has not been indicated explicitly. Although $bb^\dagger=aa^\dagger$ (that is, the supersymmetric partners of H and $\tilde{H}$ are identical to each other), $b^\dagger b\neq a^\dagger a$. It is straightforward to check that the states

$$|\theta_n\rangle=n^{-1/2}b^\dagger|n-1\rangle (n=1,2,...) \tag{2.5}$$

are eigenstates of the Hamiltonian $\tilde{H}$ with eigenvalues $n=1,2,...$. The *ground state* $|\theta_0\rangle$ of $\tilde{H}$ is obtained by requiring that

$$b|\theta_0\rangle=0. \tag{2.6}$$

The eigenstates $\{|\theta_n\rangle, n=0,1,...\}$ form a complete orthonormal set of states in the Hilbert space $\mathscr{H}$ spanned by the Fock basis $\{|n\rangle\}$. It will be useful to write $\mathscr{H}_0=\text{span}|0\rangle$, $\mathscr{H}_1=\text{span}\{|n\rangle, n\geq 1\}$, $\tilde{\mathscr{H}}_0=\text{span}|\theta_0\rangle$, and $\tilde{\mathscr{H}}_1=\text{span}\{|\theta_n\rangle, n\geq 1\}$, so that $\mathscr{H}=\mathscr{H}_0+\mathscr{H}_1=\tilde{\mathscr{H}}_0+\tilde{\mathscr{H}}_1$. (For easy identification, we shall use a tilde for spaces and operators pertaining to the isospectral case and drop the tilde for their counterparts relating to the standard oscillator.) It is evident that H and $\tilde{H}$ are isospectral, and that $\tilde{H}\to H$ in the limit $|\lambda|\to\infty$. However, since $b^\dagger b\neq a^\dagger a$, the commutator $[b, b^\dagger]\neq 1$. Thus $b^\dagger$ and b are *not* the appropriate raising and lowering operators for $\tilde{H}$. Fernandez *et al.*[7] consider the lowering operator (in their notation)

$$A=b^\dagger a b, \tag{2.7}$$

which annihilates not only $|\theta_0\rangle$ but also $|\theta_1\rangle$. One finds

$$A|\theta_0\rangle=0, \quad A|\theta_n\rangle=(n-1)n^{1/2}|\theta_{n-1}\rangle. \tag{2.8}$$

Similarly,

$$A^\dagger|\theta_0\rangle=0, \quad A^\dagger|\theta_n\rangle=n(n+1)^{1/2}|\theta_{n+1}\rangle. \tag{2.9}$$

These relations help us understand how the Hilbert space $\mathscr{H}$ breaks up in a natural fashion into the direct sum $\tilde{H}_0+\tilde{H}_1$. As A is an annihilation operator in $\tilde{H}_1$, its eigenstates, satisfying $A|z;\theta_1\rangle=z|z;\theta_1\rangle (z\in\mathscr{C})$, may be regarded as coherent states. They are given by[7]

$$|z;\theta_1\rangle = (\text{const}) \sum_{n=0}^{\infty} \frac{z^n}{n!\sqrt{(n+1)!}} |\theta_{n+1}\rangle. \tag{2.10}$$

However, since $[A, A^\dagger] \neq 1$ even in the subspace $\tilde{H}_1$, the state $|z;\theta_1\rangle$ cannot be obtained by a unitary transformation of the form $\exp(zA^\dagger - \overline{z}A)$ acting on the ground state $|\theta_1\rangle$. Therefore $|z;\theta_1\rangle$ is not a CS in the group-theoretic sense, nor can *generalized* coherent states be built up from it by the standard procedure—namely, by using $|z:\theta_1\rangle$ as the ground state of an appropriate Hamiltonian obtained by a unitary transformation of $\tilde{H}$.

In contrast to the foregoing, Kumar and Khare[8] have shown that b and $b^\dagger$ can be written in the form

$$b = aU^\dagger, \quad b^\dagger = Ua^\dagger, \tag{2.11}$$

where U is unitary ($UU^\dagger = U^\dagger U = 1$) in the full space $\mathscr{H}$, and formally determined the matrix elements of U in the basis $\{|n\rangle\}$. Therefore $bb^\dagger = aa^\dagger$, as required. Further, $\tilde{H} = b^\dagger b = UHU^\dagger$, so that $\tilde{H}$ and H are actually unitarily equivalent. Writing $\tilde{a} = UaU^\dagger$, one has $\tilde{H} = \tilde{a}^\dagger \tilde{a}$ where $[\tilde{a}, \tilde{a}^\dagger] = 1$. The eigenstates $|\theta_n\rangle$ of $\tilde{H}$ are just the unitary transforms of those of H, i.e.,

$$|\theta_n\rangle = U|n\rangle \quad \text{and} \quad U^\dagger|\theta_n\rangle = |n\rangle, \quad n = 0,1,\ldots. \tag{2.12}$$

The operator $\tilde{a}$ only annihilates the vacuum $|\theta_0\rangle$. The state

$$|\alpha;\theta_0\rangle = \exp\left(-\frac{|\alpha|^2}{2}\right) \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} |\theta_n\rangle \quad (\alpha \in \mathscr{C}) \tag{2.13}$$

is both an annihilation operator eigenstate and a CS in the Perelomov sense. It is readily verified that (i) $|\alpha;\theta_0\rangle = U|\alpha\rangle$ where $|\alpha\rangle$ is the standard oscillator CS; (ii) $|\alpha;\theta_0\rangle$ is obtainable by a unitary displacement operator acting on $|\theta_0\rangle$; and (iii) $|\alpha;\theta_0\rangle \to |\alpha\rangle$ in the limit $|\lambda| \to \infty$. Generalized CS may be constructed from $|\alpha;\theta_0\rangle$ in essentially the same manner as in the case of $|\alpha\rangle$. Viewed in this manner, the isospectral case is simply a unitary transformation of the standard oscillator problem, and nothing new is gained by considering it in preference to the latter.

In order to have ladder operators in $\tilde{\mathscr{H}}_1$ whose commutator is equal to unity, and also to generalize this algebra to some extent, Fernandez *et al.* have subsequently defined[10] a new lowering operator C_w (in their notation) according to

$$C_w = b^\dagger f(H) ab. \tag{2.14}$$

Here, the form of $f(H)$ is deduced from the requirement that the commutator $[C_w, C_w^\dagger]$ be equal to diag $(w,1,1,\ldots)$ in $\tilde{\mathscr{H}}_1$, where w is any positive number. (The operators C_w and $C_w^\dagger$ continue to annihilate the subspace $\tilde{\mathscr{H}}_0$). It is found that

$$f(H) = \frac{1}{1+H}\left(\frac{w+H}{2+H}\right)^{1/2}. \tag{2.15}$$

It is evident that diag $(w,1,1,\ldots)$ is not the most general diagonal form possible for the basic commutator, although it can be shown to be the only consistent one once the specific form given by Eq. (2.14) is assumed for the lowering operator. As we shall see, a procedure of wider applicability is to look for an operator transformation on $\tilde{a}$ of the type $\tilde{S}^\dagger \tilde{a} \tilde{S}$. In the next section, we develop a systematic procedure to find the transformation $\tilde{S}$, and from it the ladder operators *for any prescribed diagonal form of their commutator*, including the case of the q-generalization of the isospectral oscillator.

III. SHIFT OPERATORS AND OPERATOR TRANSFORMATIONS

We wish to implement transformations on the ladder operators $\tilde{a}$ and $\tilde{a}^\dagger$ so as to obtain a lowering operator

$$\tilde{a}_1 = \tilde{S}^\dagger \tilde{a} \tilde{S} \tag{3.1}$$

and a Hermitian conjugate raising operator

$$\tilde{a}_1^\dagger = \tilde{S}^\dagger \tilde{a}^\dagger \tilde{S} \tag{3.2}$$

with the following properties: (i) both operators must annihilate $|\theta_0\rangle$ (so that $\tilde{\mathscr{H}}_0$ is the kernel of the transformation) and (ii) their commutator is a prescribed diagonal operator in $\tilde{\mathscr{H}}_1$. For the sake of clarity, we solve the problem first in the standard Fock basis, and then use the operator U to transform to the isospectral case.

Accordingly, we first seek to eliminate the subspace $\mathscr{H}_0$ from $\mathscr{H}$, and to find conjugate lowering and raising operators in $\mathscr{H}_1$ given by

$$a_1 = S^\dagger a S, \quad a_1^\dagger = S^\dagger a^\dagger S, \tag{3.3}$$

whose commutator is equal to *unity* throughout the latter space. For this we need to find an operator S in $\mathscr{H}$ that satisfies the *partial isometry*

$$SS^\dagger = 1, \quad S^\dagger S = 1 - |0\rangle\langle 0|. \tag{3.4}$$

It is easy to see that this is solved by the *shift* operator

$$S = \sum_{n=0}^{\infty} |n\rangle\langle n+1|. \tag{3.5}$$

Equations (3.3) then yield

$$a_1 = \sum_{n=1}^{\infty} n^{1/2} |n\rangle\langle n+1|, \quad a_1^\dagger = \sum_{n=1}^{\infty} n^{1/2} |n+1\rangle\langle n|. \tag{3.6}$$

Therefore $[a_1,\ a_1^\dagger] = 1 - |0\rangle\langle 0| = \mathrm{diag}\,(0,1,1,\ldots)$, as required. It is easily verified that

$$a_1|0\rangle = a_1|1\rangle = 0, \quad a_1|n\rangle = (n-1)^{1/2}|n-1\rangle, \quad n \geqslant 1, \tag{3.7}$$

and

$$a_1^\dagger|0\rangle = 0, \quad a_1^\dagger|n\rangle = n^{1/2}|n+1\rangle, \quad n \geqslant 1. \tag{3.8}$$

Further, we note that the operator S has the closed form $(1+H)^{-1/2}a$ in $\mathscr{H}$. Hence we may also write

$$a_1 = a^\dagger (1+H)^{-1/2} a (1+H)^{-1/2} a, \quad a_1^\dagger = a^\dagger (1+H)^{-1/2} a^\dagger (1+H)^{-1/2} a. \tag{3.9}$$

Next, consider the *general* ''distorted'' Heisenberg algebra in which the commutator is specified (in the Fock basis) to be

$$[a_1,\ a_1^\dagger] = \mathrm{diag}(0, w_1, w_2, \ldots) = \sum_{n=1}^{\infty} w_n |n\rangle\langle n|, \tag{3.10}$$

where $\{w_n\}$ are real positive constants. Now S is found by generalizing the partial isometry condition, Eq. (3.4), to read

$$SS^\dagger = \sum_{n=0}^{\infty} c_n |n\rangle\langle n|, \quad S^\dagger S = \sum_{n=0}^{\infty} c_n |n+1\rangle\langle n+1|, \tag{3.11}$$

where the coefficients c_n are to be determined. The deviation of the c_n's from unity is a measure of the extent to which the shift operator deviates from the exact partial isometry specified in Eqs. (3.4). Solving for S and $S^\dagger$ in the form

$$S=\sum_{n=0}^{\infty} c_n^{1/2}|n\rangle\langle n+1|, \quad S^\dagger=\sum_{n=0}^{\infty} c_n^{1/2}|n+1\rangle\langle n| \tag{3.12}$$

and using Eqs. (3.3) and (3.10), we obtain the recursion relations

$$c_0c_1=w_1, \quad (n+1)c_nc_{n+1}-nc_nc_{n-1}=w_{n+1}, \quad n=1,2,3,\ldots . \tag{3.13}$$

We may choose $c_0=1$ without loss of generality, and solve the recursion relations to obtain

$$c_n=\frac{(n-1)!!}{n!!}\,\frac{(w_1+w_2+\cdots+w_n)!!}{(w_1+w_2+\cdots+w_{n-1})!!}. \tag{3.14}$$

Here the notation $(w_1+w_2+\ldots+w_n)!!$ stands for the product

$$(w_1+w_2+\cdots+w_n)\times(w_1+w_2+\cdots+w_{n-2})\cdots .$$

Substituting the values for c_n given above in Eq. (3.12) yields S and $S^\dagger$. The corresponding expressions for a_1 and $a_1^\dagger$ are then obtained from Eqs. (3.3), and their commutator is guaranteed to satisfy Eq. (3.10).

We are ready now to go over to the isospectral case. As the corresponding shift and ladder operators are merely the unitary transformations

$$\tilde{S}=USU^\dagger, \quad \tilde{a}_1=Ua_1U^\dagger, \quad \tilde{a}_1^\dagger=Ua_1^\dagger U^\dagger, \tag{3.15}$$

we find

$$\tilde{S}=\sum_{n=0}^{\infty} c_n^{1/2}|\theta_n\rangle\langle\theta_{n+1}|, \tag{3.16}$$

where $c_0=1$ as already stated, and c_n is given by Eq. (3.14). We thus obtain the solutions

$$\tilde{a}_1=\sum_{n=1}^{\infty} (w_1+w_2+\cdots+w_n)^{1/2}|\theta_n\rangle\langle\theta_{n+1}|, \tag{3.17}$$

$$\tilde{a}_1^\dagger=\sum_{n=1}^{\infty} (w_1+w_2+\cdots+w_n)^{1/2}|\theta_{n+1}\rangle\langle\theta_n| \tag{3.18}$$

for the ladder operators in $\tilde{\mathscr{H}}$. It is easily verified from these expressions that $[\tilde{a}_1, \tilde{a}_1^\dagger]$ is diag $(0,w_1,w_2,\cdots)$ in the *transformed* basis, i.e.,

$$[\tilde{a}_1,\tilde{a}_1^\dagger]=\sum_{n=1}^{\infty} w_n|\theta_n\rangle\langle\theta_n|, \tag{3.19}$$

as required [cf. Eq. (3.10)]. The action of $\tilde{a}_1$ and $\tilde{a}_1^\dagger$ on $|\theta_n\rangle$ is given by

$$\tilde{a}_1|\theta_0\rangle=\tilde{a}_1|\theta_1\rangle=0, \quad \tilde{a}_1|\theta_n\rangle=(w_1+w_2+\cdots+w_{n-1})^{1/2}|\theta_{n-1}\rangle, \quad n\geqslant 2, \tag{3.20}$$

and

$$\tilde{a}_1^\dagger|\theta_0\rangle=0, \quad \tilde{a}_1^\dagger|\theta_n\rangle=(w_1+w_2+\cdots+w_n)^{1/2}|\theta_{n+1}\rangle, \quad n\geqslant 1. \tag{3.21}$$

For ready reference, the various lowering operators involved and the transformations connecting them are indicated schematically in Fig. 1.

In order to see how our general expressions simplify in particular cases, it is convenient to use Eq. (2.5) and the usual representation of a in the Fock basis to express Eq. (3.17) in the form

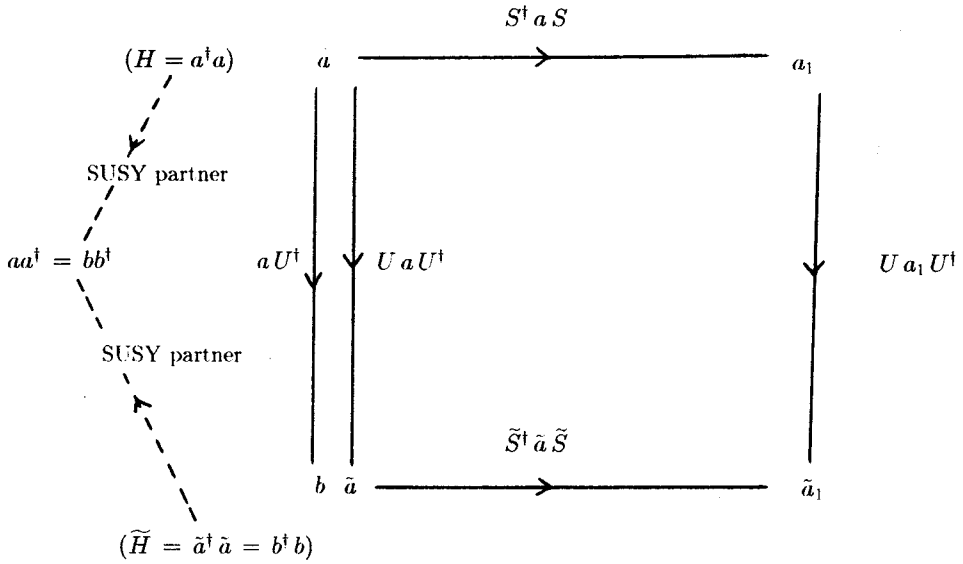

FIG. 1. The various transformed versions of the lowering operator a. S is the general shift operator given by Eq. (3.12) while U is the unitary transformation connecting the Fock basis $\{|n\rangle\}$ to the isospectral basis $\{|\theta_n\rangle\}$. $\tilde{S}$ stands for $USU^\dagger$.

$$\tilde{a}_1 = b^\dagger \sum_{n=0}^{\infty} \left(\frac{W_{n+1}}{(n+1)(n+2)} \right)^{1/2} |n\rangle\langle n+1|b, \tag{3.22}$$

or in the equivalent form

$$\tilde{a}_1 = b^\dagger (1+H)^{-1/2} \left\{ \sum_{n=0}^{\infty} W_{n+1}^{1/2} |n\rangle\langle n+1| \right\} (1+H)^{-1/2} b, \tag{3.23}$$

where we have written

$$W_n = w_1 + w_2 + \cdots + w_n \tag{3.24}$$

for brevity. It is clear from the above that, whenever $W_{n+1}^{1/2}$ can be written as some function of n, say $F(n)$, we obtain the closed-form expression

$$\tilde{a}_1 = b^\dagger (1+H)^{-1} f(H) a (1+H)^{-1/2} b. \tag{3.25}$$

If, further, $F(n)$ is a product of the form $(n+1)^{1/2} G(n) G(n+1)$, we obtain the *symmetric* form

$$\tilde{a}_1 = b^\dagger (1+H)^{-1/2} G(H) a G(H) (1+H)^{-1/2} b. \tag{3.26}$$

Corresponding expressions obtain, of course, for $a_1^\dagger$ as well. A remark is in order here on the square-root operator occurring in these expressions. As $(1+H)^{-1}$ is a bounded positive definite operator in $\mathscr{H}$, it has a unique positive square root in that space, by virtue of the square-root lemma.[11] Following the procedure of Ref. 12, this can be defined rigorously in terms of the resolvent operator $(\xi + 1 + H)^{-1}$ as

$$(1+H)^{-1/2} = \frac{1}{\pi} \int_0^\infty d\xi \, \xi^{-1/2} (1+\xi+H)^{-1}. \tag{3.27}$$

We are now ready to read off various special cases of the foregoing.

(i) First of all, if we set $w_n = w$ for *all* $n \geq 1$, the operator in curly brackets in Eq. (3.23) above is simply $w^{1/2} a$, and we get the symmetric expression

$$\tilde{a}_1 = w^{1/2} b^\dagger (1+H)^{-1/2} a (1+H)^{-1/2} b. \tag{3.28}$$

(ii) Next, we note that the ''distorted'' Heisenberg algebra introduced in Ref. 10 corresponds to setting $w_1=w$ and $w_n=1$ for $n\geqslant 2$, so that $W_{n+1}=(w+n)$. Therefore $\tilde{a}_1$ reduces, in this special case, to a closed-form expression— namely, the operator C_w defined in Eqs. (2.14) and (2.15).

(iii) Again, if we choose $w_n=n$ itself—i.e., we have the algebra

$$[\tilde{a}_1,\ \tilde{a}_1^\dagger]=UHU^\dagger=\tilde{H}=b^\dagger b, \tag{3.29}$$

we obtain

$$\tilde{a}_1=2^{-1/2}b^\dagger(1+H)^{-1/2}ab. \tag{3.30}$$

(iv) On the other hand, if we set $w_1=w$ and $w_n=0$ for $n\geqslant 2$, we obtain

$$\tilde{a}_1=w^{1/2}b^\dagger(1+H)^{-1}a(1+H)^{-1/2}b. \tag{3.31}$$

(v) Finally, the q-generalization[13] of the isospectral case is immediately found by setting $w_n=q^n$: this implies that

$$[\tilde{a}_1,\ \tilde{a}_1^\dagger]=q^{\tilde{H}}, \tag{3.32}$$

which is a transformed, equivalent, version of a q-commutation relation between a conjugate pair of ladder operators. We obtain in this case the result

$$\tilde{a}_1=q^{1/2}b^\dagger(1+H)^{-1}\left(\frac{1-q^{1+H}}{1-q}\right)^{1/2}a(1+H)^{-1/2}b. \tag{3.33}$$

It is readily seen that Eq. (3.33) reduces to Eq. (3.28) (with $w=1$) in the limit $q\to 1$.

IV. REPRESENTATION IN TERMS OF PSEUDO-DIFFERENTIAL OPERATORS

The expressions obtained in the preceding section involve various nonlocal operators, for which it is appropriate to exhibit suitable explicit representations. Kernels in the position basis for the integral operators represented by $\tilde{a}_1$ and $\tilde{a}_1^\dagger$ may of course be written down at once from Eqs. (3.17) and (3.18) in terms of the wave function $\tilde{\psi}_n(x)=\langle x|\,\theta_n\rangle$ and its complex conjugate. *Formal* representations for the operators concerned in a form that is an extension of the standard ones $a=2^{-1/2}(x+d)$, $a^\dagger=2^{-1/2}(x-d)$, may be given in terms of pseudo-differential operators,[14,15] i.e., operators of the form

$$\sum_{n=0}^{N}u_n(x)d^n+\sum_{n=0}^{\infty}u_{-n}(x)d^{-n},$$

where N is a finite positive integer (and $d\equiv d/dx$). Here d^{-1} is the antiderivative, defined recursively through

$$d^{-1}(f\cdot)=\sum_{n=0}^{\infty}(-1)^n f^{(n)}d^{-1-n}(\cdot), \tag{4.1}$$

where $f^{(n)}$ is the nth derivative of $f(x)$. This leads to the basic relationship

$$[d^{-r},\ f]=\sum_{n=1}^{\infty}(-1)^n\binom{n+r-1}{n-1}f^{(n)}d^{-n-r}. \tag{4.2}$$

With the help of the foregoing we can find expansions for the operators $(d^2+u(x))^{1/2}$ and $(d^2+u(x))^{-1/2}$ in powers of d^{-1}. In particular, we find

$$(1+H)^{-1/2}=-2^{1/2}i(d^2-x^2-1)^{-1/2}=-2^{1/2}i\{d^{-1}+\tfrac{1}{2}(1+x^2)d^{-3}-\tfrac{3}{2}xd^{-4}+\cdots\}. \tag{4.3}$$

Using these results, formal expansions for $\tilde{a}_1$ and $\tilde{a}_1^\dagger$ may be derived in those cases discussed in Sec. III in which closed-form expressions obtain for these operators. In particular, corresponding to the algebra[10] $[\tilde{a}_1, \tilde{a}_1^\dagger] = \mathrm{diag}\,(w,1,1,...)$ in $\tilde{\mathscr{H}}_1$, for which $\tilde{a}_1$ is the operator C_w given by Eqs. (2.14) and (2.15), we obtain the following expansions [quoted up to $\mathscr{O}(d^{-2})$ for brevity]:

$$2^{1/2}\tilde{a}_1 = x + d - (w - 2 - \phi_\lambda')d^{-1} + [x(2-w) + \phi_\lambda\phi_\lambda' + x\phi_\lambda' + 2\phi_\lambda]d^{-2} + \cdots \tag{4.4}$$

and

$$2^{1/2}\tilde{a}_1^\dagger = x - d + (w - 2 - \phi_\lambda')d^{-1} + [x(2-w) - x\phi_\lambda' - \phi_\lambda\phi_\lambda']d^{-2} + \cdots . \tag{4.5}$$

Further, we find

$$\tilde{a}_1\tilde{a}_1^\dagger = \tfrac{1}{2}(-d^2 + x^2 + 2w - 3) - \phi_\lambda', \tag{4.6}$$

while in the space $\mathrm{span}\{|\theta_n\rangle, n \geqslant 2\}$ we also have

$$\tilde{a}_1^\dagger\tilde{a}_1 = \tfrac{1}{2}(-d^2 + x^2 + 2w - 5) - \phi_\lambda'. \tag{4.7}$$

When $w = 1$, Eq. (4.7) is valid in all of $\tilde{\mathscr{H}}_1$.

Finally, we remark that in the limit $|\lambda| \to \infty$, $\phi_\lambda(x)$ and its derivatives vanish, $U \to 1$, $b \to a$, $\tilde{\mathscr{H}}_1 \to \mathscr{H}_1$, $\tilde{a}_1 \to a_1$, etc., in all the foregoing expressions.

V. COHERENT STATES

With the operators $\tilde{a}_1$, $\tilde{a}_1^\dagger$ in $\tilde{\mathscr{H}}_1$ and their commutation relation at hand [Eqs. (3.17)–(3.19)], we may construct coherent states (CS) in the usual manner, i.e., as eigenstates of $\tilde{a}_1$ built upon the base state $|\theta_1\rangle$. We find, for every $\zeta \in \mathscr{C}$,

$$\tilde{a}_1|\zeta;\theta_1\rangle = \zeta|\zeta;\theta_1\rangle, \tag{5.1}$$

where the normalized eigenstate is given by

$$|\zeta;\theta_1\rangle = h^{-1/2}(|\zeta|^2)\sum_{n=0}^{\infty} d_n^{1/2}\zeta^n|\theta_{n+1}\rangle \tag{5.2}$$

with

$$d_0 = 1, \quad d_n = (W_1 \cdots W_n)^{-1}. \tag{5.3}$$

The normalization factor in Eq. (5.2) is defined by

$$h(|\zeta|^2) = \sum_{n=0}^{\infty} d_n|\zeta|^{2n}. \tag{5.4}$$

A question of interest is the kind of Fock–Bargmann or entire function representation of states[9,16] in $\tilde{\mathscr{H}}_1$ associated with the CS constructed above—specifically, the *order*[17] of the class of entire functions involved. A state $|\Psi\rangle$ of finite norm is represented by the analytic function

$$\Psi(\zeta) = \sum_{n=0}^{\infty} d_n^{1/2}\langle\theta_{n+1}|\Psi\rangle\zeta^n. \tag{5.5}$$

As the state $|\zeta;\theta_1\rangle$ in Eq. (5.2) is normalized to unity, we have $|\Psi(\zeta)| \leqslant \|\Psi\||h|^{1/2}$. Hence the asymptotic behavior of $\Psi(\zeta)$ is decided by that of $h^{1/2}$ which, in turn, is controlled by the growth properties of the sequence $\{d_n\}$. In particular, the *order* of the class of entire functions to which $\Psi(\zeta)$ belongs is given by

$$\rho = \lim_{n\to\infty} \frac{2n \log n}{\log(W_1 \cdots W_n)}. \tag{5.6}$$

In the special cases (i)–(v) considered at the end of Sec. III, this leads to the following results: In case (i), $(W_1 \ldots W_n) = w^n n!$, while in case (ii)[10] it is $\Gamma(n+w)/\Gamma(n)$. In both cases it follows easily from Eq. (5.6) that $\rho = 2$, i.e., the order is exactly the same as it is for the Fock–Bargmann representation corresponding to the standard oscillator CS. In case (iii), $(W_1 \ldots W_n) = 2^{-n} n!(n+1)!$, leading to $\rho = 1$. All these cases are covered by the following generalization: if the coefficient w_n of the algebra $[\tilde{a}_1, \tilde{a}_1^\dagger] = \mathrm{diag}(w_1, w_2, \ldots)$ has the leading asymptotic behavior n^ν for large n, with $\nu > -1$, then $(W_1 \cdots W_n) \sim n^{n(1+\nu)}$, which leads to the result

$$\rho = \frac{2}{1+\nu} \tag{5.7}$$

for the order of the corresponding entire function representation of $\tilde{\mathscr{H}}_1$. Cases (i) and (ii) correspond to $\nu = 0$, while $\nu = 1$ in case (iii). In case (iv), $h = w(w - |\zeta|^2)^{-1}$, so that the representation is not in terms of entire functions at all.

For the q-generalization, case (v), $(W_1 \cdots W_n)$ is a ''q-factorial'' given by

$$q(q+q^2)\cdots(q+q^2+\cdots+q^n) = q^n (q-1)^{(1-n)} (q^2-1)\cdots(q^n-1). \tag{5.8}$$

When $q < 1$, it is readily established that the series defining h has a finite radius of convergence ($|\zeta| = q^{1/2}$), as in case (iv). When $q = 1$, of course, we recover case (i) or (ii) with $w = 1$, so that $\rho = 2$. On the other hand, when $q > 1$, $(W_1 \cdots W_n)$ has the leading asymptotic behavior $q^{n^2/2}$, which implies that $\rho = 0$.

The CS considered above have been constructed as annihilation operator eigenstates. In the special case $w_n = 1$ for all $n \geqslant 1$, they are also CS in the group-theoretic sense. Each coefficient c_n in Eq. (3.14) is now equal to unity, and the shift operator $\tilde{S}$ obeys the exact partial isometry condition

$$\tilde{S}\,\tilde{S}^\dagger = 1, \quad \tilde{S}^\dagger \tilde{S} = 1 - |\theta_0\rangle\langle\theta_0|. \tag{5.9}$$

We then have $[\tilde{a}_1, \tilde{a}_1^\dagger] = 1$ in $\tilde{\mathscr{H}}_1$, and the Hamiltonian $\tilde{H}_1 = \tilde{a}_1^\dagger \tilde{a}_1$ with eigenstates $|\theta_n\rangle$ and eigenvalues $(n-1)$, $n = 1,2,\ldots$, is the exact analog in $\tilde{\mathscr{H}}_1$ of the Hamiltonian $H = a^\dagger a$ in $\mathscr{H}$. The transformation from $(a, a^\dagger)$ to $(\tilde{a}_1, \tilde{a}_1^\dagger)$ is now a true operator map, in the sense that any function $\phi(a, a^\dagger)$ transforms as

$$\phi(a, a^\dagger) \to \phi(\tilde{a}_1, \tilde{a}_1^\dagger) = \tilde{S}^\dagger \phi(a, a^\dagger) \tilde{S}. \tag{5.10}$$

The coherent states

$$|\zeta; \theta_1\rangle = \exp\left(-\frac{|\zeta|^2}{2}\right) \sum_{n=0}^{\infty} \frac{\zeta^n}{\sqrt{n!}} |\theta_{n+1}\rangle, \quad \zeta \in \mathscr{C}, \tag{5.11}$$

are normalized eigenstates of the annihilation operator $\tilde{a}_1$. They are *also* CS in the Perelomov sense, for we have $|\zeta; \theta_1\rangle = D(\zeta, \bar{\zeta})|\theta_1\rangle$, where the displacement operator

$$D(\zeta, \bar{\zeta}) = \exp(\zeta \tilde{a}_1^\dagger - \bar{\zeta} \tilde{a}_1) \tag{5.12}$$

is unitary in $\tilde{\mathscr{H}}_1$. Moreover, as in the case of the standard oscillator CS, the state $|\zeta; \theta_1\rangle$ is the ground state of the displaced Hamiltonian $D\tilde{H}_1 D^\dagger$. The excited states $|\zeta; \theta_n\rangle$ $(n \geqslant 2)$ of this Hamiltonian, i.e., the generalized coherent states corresponding to $|\zeta; \theta_1\rangle$, are obtained *either* by operating on $|\zeta; \theta_1\rangle$ by the transformed raising operator $(D\tilde{a}_1^\dagger D^\dagger)^{n-1}$, *or* by displacing the corresponding base state $|\theta_n\rangle$:

$$|\zeta; \theta_n\rangle = (D\tilde{a}_1^\dagger D^\dagger)^{n-1} |\zeta; \theta_1\rangle = D|\theta_n\rangle, \quad n = 2,3,\ldots. \tag{5.13}$$

Thus, these coherent states and generalized CS have in $\tilde{\mathscr{H}}_1$ the same standing as their standard oscillator counterparts have in $\mathscr{H}$. They therefore constitute the closest analogs of the latter for the isospectral family of oscillators in $\tilde{\mathscr{H}}_1$, while remaining a distinctly new (unitarily inequivalent) class of coherent states. However, the generalized algebra of Eq. (3.19) leads, as we have seen, to an even wider variety of possible coherent states with interesting properties.

(Received 5 February 1997; accepted for publication 23 September 1997)

A cohomological characterization of a class of linearly broken Ward identities is provided. The examples of the topological vector supersymmetry and of the Landau ghost equation are discussed. The existence of these linearly broken Ward identities lies in the BRST exactness of suitable antifield dependent cocycles with negative ghost number. This algebraic set up turns out to be related to the cohomological reformulation of the Noether theorem given by G. Barnich, F. Brandt, and M. Henneaux, Commun. Math. Phys. **174**, 57, 93 (1995); M. Henneaux, J. Pure Appl. Algebra **100**, 3 (1995). © *1998 American Institute of Physics.*

I. INTRODUCTION

The topological field theories TFT (Ref. 1) are known to be characterized, besides their BRST symmetry, by the so-called *vector supersymmetry*;[2–5] an additional invariance with many properties.

The first property is that the generators of the vector susy carry a Lorentz index and, together with the BRST operator, give rise to an algebra of the Wess–Zumino-type which, closing on-shell on the space–time translations, allows for a supersymmetric interpretation of the TFT.[2–5]

The second feature is that, in the case of the TFT of the Schwartz-type, the vector susy is present only after the introduction of all the ghost fields needed in order to quantize the model. It is therefore an invariance of the fully quantized action but not of its classical part.[4] This property is unavoidably related to the choice of the gauge fixing term, meaning that the vector susy can exist only for certain values of the gauge parameters present in the gauge fixing condition. As an example, let us mention that in the case of the three-dimensional Chern–Simons model the vector susy turns out to select, among the class of the linear covariant gauge fixings, the Landau gauge.[2,3]

For the TFT of the cohomological type the use of the equivariant approach[6] allows us to obtain the vector susy through the introduction of the ghost fields corresponding to the so called shift symmetry.[1] In this case the vector susy can be related to the twisted version of extended supersymmetry. For instance, in the case of the Witten's four-dimensional Euclidean topological Yang–Mills[7] in flat space–time the vector susy can be obtained by twisting the standard $N=2$ super Yang–Mills.[8,9] After the twist, the fermionic spinor generators of $N=2$ become a self-dual two form, a vector and a scalar. The vector susy is identified here with the twisted vector generators.

The third aspect is that after the introduction of the antifields (or BRST external sources), the algebra between the vector susy Ward operator and the BRST operator closes off-shell on the space–time translations, without making use of the equations of motion. Moreover the vector susy loses now the property of being an exact invariance of the fully quantized action. Rather, it yields a broken Ward identity.[3–5] It is a remarkable feature, however, that the corresponding breaking term is a classical breaking, i.e., a breaking which is purely linear in the quantum fields. It is known that this kind of breaking does not get renormalized by the quantum corrections and does not spoil the usefulness of the corresponding Ward identity.[10] The latter turns out to be free from

 © 1998 American Institute of Physics

anomalies and has been shown to play a crucial role in order to establish the ultraviolet finiteness of the TFT.[3–5]

Let us also mention that the vector susy Ward operator can be introduced on a more abstract geometrical level,[11–15] independently from the fact of being a (linearly broken) symmetry of the action. In this case the vector Ward operator turns out to be useful in order to solve the BRST consistency condition for anomalies and invariant counterterms. In addition, it allows us to encode the relevant informations (BRST transformations, cohomology classes, etc.) into a unique equation which takes the form of a generalized zero curvature condition.[16–18]

These properties make the vector susy interesting and motivate further research about its origin. This is particularly needed for the non-Abelian TFT of the Schwartz-type which are not manifestly related to an extended supersymmetric algebra. (In the case of the free Abelian BF models in two and three dimensions the vector susy can be obtained by means of a suitable twist of extended supersymmetry for matter multiplets.[19]) In this case the vector susy has been introduced essentially by hand[2–4] and later on has been related to the existence of a conserved current obtained from the BRST exactness of the corresponding energy-momentum tensor.[20,10]

Moreover, a general set up accounting for all the features of the vector susy has not yet been completely worked out. This is the aim of the present work. We shall be able to provide an algebraic cohomological characterization of the existence of the vector susy and of the related linear classical breaking term. It will be also seen that it is precisely the requirement of linearity in the quantum fields which selects a particular set of gauge parameters, clarifying thus the relationship between the vector susy and the gauge fixing condition.

We shall prove, in particular, that the vector susy is deeply related to a BRST antifield dependent cocycle with ghost number -1. When this cocycle is trivial the vector susy Ward identity can be established and turns out to be necessarily accompanied by a breaking term linear in the fields. On the other hand, when this cocycle is nontrivial, the vector susy cannot be implemented and we are left with an example of an antifield dependent cohomology class.

The algebraic framework presented here is related to the cohomological reformulation of the Noether theorem given by Ref. 21. We shall observe indeed that the aforementioned vector cocycle can be related to a set of currents among which one can identify the BRST invariant energy-momentum tensor, meaning that this vector cocycle is related to the Poincaré transformations.[21] Recently, it has been considered in connection with the problem of collecting additional global invariances into a unique generalized Slavnov–Taylor identity.[22]

The paper is organized as follows. In Sec. II we introduce the general algebraic setup; we present the relevant properties of the vector antifield cocycle and we discuss its relation with the BRST invariant energy-momentum tensor. In Sec. III the pure Yang–Mills model is considered. We shall check that in this case the vector cocycle is nontrivial. Section IV is devoted to a detailed analysis of several examples of TFT. In these cases the BRST triviality of the vector cocycle will be at the origin of the existence of the vector susy Ward identities. Finally, in Sec. V we shall present a second example of a linearly broken Ward identity whose contact terms can be obtained through an exact antifield cocycle carrying a group index. The corresponding Ward identity, known as the *Landau ghost equation*,[23] turns out to be related to the rigid gauge invariance.

II. GENERAL NOTATIONS AND THE VECTOR COCYCLE

In order to present the general algebraic set up let us begin by fixing the notations. We shall work in a flat D-dimensional space–time equipped with a set of fields generically denoted by $\{\varphi^i\}$, i labeling the different kinds of fields needed in order to properly quantize the model; gauge fields, ghosts, ghosts for ghosts, etc. Following the standard quantization procedure we introduce for each field φ^i of ghost number $\mathcal{N}^{\cdot}_{\varphi^i}$ and dimension d_{φ^i}, the corresponding antifield φ^{i*} with ghost number $-(1+\mathcal{N}^{\cdot}_{\varphi^i})$ and dimension $(D-d_{\varphi^i})$. We shall also assume that the set of fields $\{\varphi^i\}$ do not explicitly contains the antighosts and their corresponding Lagrange multipliers which, being grouped in BRST doublets, do not contribute to the BRST cohomology.[24] Accordingly, some of the antifields φ^{i*} have to be understood as shifted antifields[10] which already take into account the antighosts.

In order to define the model we have now to introduce the classical gauge fixed *reduced* action[10] $\Sigma(\varphi,\varphi^*)$. (The name *reduced* action is used to denote the part of the complete gauge fixed

action which does not depend on the Lagrange multipliers and which depends on the antighosts only through the shifted antifields. As it will be discussed in the next sections, the dependence of the complete action on the Lagrange multipliers as well as on the gauge parameters present in the gauge fixing condition will be determined by requiring that the breaking term corresponding to the topological vector susy Ward identity is at most linear in the quantum fields.) This is done by requiring Σ to be power counting renormalizable and to be the solution of the classical homogeneous Slavnov–Taylor (or master equation) identity[25]

$$\int d^D x \, \frac{\delta \Sigma}{\delta \varphi^i} \, \frac{\delta \Sigma}{\delta \varphi^{i*}} = \frac{1}{2} \, \mathscr{B}_\Sigma \Sigma = 0, \tag{2.1}$$

where $\mathscr{B}_\Sigma$ denotes the nilpotent linearized Slavnov–Taylor operator,

$$\mathscr{B}_\Sigma = \int d^D x \left(\frac{\delta \Sigma}{\delta \varphi^i} \, \frac{\delta}{\delta \varphi^{i*}} + \frac{\delta \Sigma}{\delta \varphi^{i*}} \, \frac{\delta}{\delta \varphi^i} \right), \tag{2.2}$$

$$\mathscr{B}_\Sigma \mathscr{B}_\Sigma = 0, \tag{2.3}$$

As usual, the classical action $\Sigma(\varphi,\varphi^*)$ will be assumed to be invariant under the space–time translations, i.e.,

$$\mathscr{P}_\mu \Sigma = \int d^D x \left(\partial_\mu \varphi^i \, \frac{\delta \Sigma}{\delta \varphi^i} + \partial_\mu \varphi^{i*} \, \frac{\delta \Sigma}{\delta \varphi^{i*}} \right) = 0, \tag{2.4}$$

The classical Slavnov–Taylor identity (2.1) and the translation invariance (2.4) will be taken therefore as the basic starting points for the characterization of the classical action $\Sigma(\varphi,\varphi^*)$ and for the algebraic analysis which will be carried out in the next sections. We remark here that the requirement of the translation invariance, as expressed by Eq. (2.4), does not imply any further restrictions on Σ than those that are tacitly assumed in any local field theory.

Let us now introduce the following integrated local vector polynomial, linear in the antifields φ^{i*}, of ghost number -1 and dimension $(D+1)$,

$$\Omega_\nu^{-1} = \int d^D x [\, \omega_\nu^{-1}]_{D+1} \equiv \int d^D x (-1)^{(1+\mathscr{N}_{\varphi^i})} \varphi^i \partial_\nu \varphi^{i*}. \tag{2.5}$$

It is easily proven that the above expression is $\mathscr{B}_\Sigma$-invariant. In fact, one has

$$\mathscr{B}_\Sigma \Omega_\nu^{-1} = \int d^D x \left(\partial_\nu \varphi^i \, \frac{\delta \Sigma}{\delta \varphi^i} + \partial_\nu \varphi^{i*} \, \frac{\delta \Sigma}{\delta \varphi^{i*}} \right) = \mathscr{P}_\nu \Sigma = 0, \tag{2.6}$$

due to the translation invariance of the classical action $\Sigma(\varphi,\varphi^*)$. Having proven the invariance of Ω_ν^{-1} we have now to establish if it eventually identifies a cohomology class of the operator $\mathscr{B}_\Sigma$. We have the following two possibilities, namely,

(1) Ω_ν^{-1} is $\mathscr{B}_\Sigma$-exact, i.e.,

$$\Omega_\nu^{-1} = \mathscr{B}_\Sigma \Xi_\nu^{-2}, \tag{2.7}$$

Ξ_ν^{-2} being an integrated local polynomial of ghost number -2 and dimension $(D+1)$.
(2) Ω_ν^{-1} belongs to the integrated cohomology of $\mathscr{B}_\Sigma$,

$$\Omega_\nu^{-1} \neq \mathscr{B}_\Sigma \Xi_\nu^{-2}. \tag{2.8}$$

The detailed analysis of the two equations (2.7), (2.8) will be the main subject of the next sections. Let us limit here to underline that while the first possibility (2.7) turns out to be a feature

of the TFT, the second one (2.8) is typical of a Yang–Mills theory and, more generally, of any model possessing an invariant energy-momentum tensor $T_{\mu\nu}$ which cannot be written as a pure $\mathscr{B}_\Sigma$-variation, i.e.,

$$\mathscr{B}_\Sigma T_{\mu\nu}=0, \quad T_{\mu\nu}\neq\mathscr{B}_\Sigma\Lambda_{\mu\nu}. \tag{2.9}$$

In this latter case Ω_ν^{-1} provides an example of a nontrivial antifield dependent cocycle of the operator $\mathscr{B}_\Sigma$, giving thus an explicit realization of the general results of Ref. 21.

Concerning now the first equation (2.7), it is worthwhile to recall that one of the properties of the TFT is precisely that of having a nonphysical energy momentum tensor.[1,7] This means that the energy momentum tensor $T^{\rm top}_{\mu\nu}$ of a TFT can be written as a pure $\mathscr{B}_\Sigma$-variation,

$$T^{\rm top}_{\mu\nu}=\mathscr{B}_\Sigma\Lambda_{\mu\nu}, \tag{2.10}$$

for some local $\Lambda_{\mu\nu}$, yielding thus a more direct indication of the BRST exactness of the vector cocycle Ω_ν^{-1}.

For a better understanding of the relationship between Ω_ν^{-1} and the energy-momentum tensor, let us write down the descent equations[10,21,24] corresponding to the integrated invariance condition (2.6),

$$\begin{aligned}
&\mathscr{B}_\Sigma[\,\omega_\nu^{-1}]_{D+1}=\partial^{\mu_1}[\,\omega^0_{\mu_1\nu}]_D,\\
&\mathscr{B}_\Sigma[\,\omega^0_{\mu_1\nu}]_D=\partial^{\mu_2}[\,\omega^1_{[\mu_1\mu_2]\nu}]_{D-1},\\
&\mathscr{B}_\Sigma[\,\omega^1_{[\mu_1\mu_2]\nu}]_{D-1}=\partial^{\mu_3}[\,\omega^2_{[\mu_1\mu_2\mu_3]\nu}]_{D-2},\\
&\cdots,\\
&\cdots,\\
&\mathscr{B}_\Sigma[\,\omega^{D-2}_{[\mu_1\mu_2\ldots\mu_{D-1}]\nu}]_2=\partial^{\mu_D}[\,\omega^{D-1}_{[\mu_1\mu_2\ldots\mu_{D-1}\mu_D]\nu}]_1,\\
&\mathscr{B}_\Sigma[\,\omega^{D-1}_{[\mu_1\mu_2\ldots\mu_{D-1}\mu_D]\nu}]_1=0,
\end{aligned} \tag{2.11}$$

where the $[\,\omega^{j-1}_{[\mu_1\mu_2\ldots\mu_j]\nu}]_{D-j+1}$ with $(j=0,\ldots,D)$ are local currents of ghost number $(j-1)$, antisymmetric in the lower indices $(\mu_1,\mu_2,\ldots,\mu_j)$, and of dimension $(D-j+1)$. The usefulness of working with the system (2.11) is due to the fact that these equations relate the local cocycle $[\,\omega_\nu^{-1}]_{D+1}$ with currents of lower dimension which can provide a more easy and transparent interpretation of the physical meaning of Ω_ν^{-1}. We observe indeed that the cocycle $[\,\omega^0_{\mu_1\nu}]_D$ entering the second equation of the system (2.11) has the same quantum numbers of the energy momentum tensor, being of dimension D, of ghost number 0, and possessing two Lorentz indices. From the general results on the BRST cohomology[24] it follows that, independently from the fact that the cohomology of the operator $\mathscr{B}_\Sigma$ is empty in the sectors with dimension lower than D, the existence of a nontrivial local cohomology in the sector of dimension D and with two free Lorentz indices necessarily implies the nontriviality of the upper level of dimension $D+1$. It becomes apparent thus that the nontriviality of the BRST invariant energy-momentum tensor is deeply related to the existence of a nontrivial integrated cohomology in the sector of dimension $D+1$ and negative ghost-number.

In fact, as we shall see explicitly in the case of the Yang–Mills theory, the current $[\,\omega^0_{\mu_1\nu}]_D$ is the improved BRST invariant energy-momentum tensor. On the other hand, the use of the descent equations (2.11) gives us a simple way to establish the triviality of the vector cocycle Ω_ν^{-1} in the case of the TFT. This is actually due to the fact that the field content of the topological models gives rise to a BRST cohomology which is empty in the various sectors of the descent equations (2.11), implying that the corresponding energy momentum tensor is BRST trivial, according to Eq. (2.10). Moreover, as we shall see in detail later on, the right-hand side of Eq. (2.7) expressing the

BRST triviality of Ω_ν^{-1} will provide the contact terms of the vector susy Ward identity of the topological theories. In this latter case we shall also check that the left-hand side of Eq. (2.7) reduces to a classical linear breaking, showing then that the topological vector susy Ward identity is always linearly broken.

III. PURE YANG–MILLS THEORY

As a first application of the general algebraic set up discussed in the previous section, let us prove here that in the case of pure Yang–Mills the vector cocycle Ω_ν^{-1} cannot be written as an exact $\mathscr{B}_\Sigma$-term. Let us begin by considering the complete fully quantized gauge fixed Yang–Mills action which, choosing a Feynman gauge, reads

$$\mathscr{S}=\int d^4x\left(-\frac{1}{4g^2}F^a_{\mu\nu}F^{a\mu\nu}+b^a\partial A^a+\frac{\alpha}{2}b^ab^a+\partial^\mu\overline{c}^a(D_\mu c)^a\right)+\int d^4x\hat{A}^{a*}_\mu(D^\mu c)^a$$
$$-\tfrac{1}{2}f_{abc}C^{*a}c^bc^c, \tag{3.1}$$

where $(c,\overline{c},b)$ are the Faddeev–Popov ghost, the antighost and the Lagrange multiplier fields and

$$(D_\mu c)^a=\partial_\mu c^a+f^a_{bc}A^b_\mu c^c \tag{3.2}$$

is the covariant derivative with f_{abc} the totally antisymmetric structure constants of a compact semisimple Lie group G. The two antifields $(\hat{A}^*,C^*)$ are introduced in order to properly define the nonlinear BRST transformations of the gauge field A and of the ghost c. The dimensions and the ghost numbers of all the fields and antifields are assigned as in the following diagram:

	A	$\hat{A}^*$	c	C^*	$\bar{c}$	b
dim.	1	3	0	4	2	2
gh-numb.	0	-1	1	-2	-1	0

(3.3)

As it is well known,[10] the complete action $\mathscr{S}$ is characterized by the classical Slavnov–Taylor identity expressing the invariance of (3.1) under the BRST transformations

$$\int d^4x\left(\frac{\delta\mathscr{S}}{\delta A^a_\mu}\frac{\delta\mathscr{S}}{\delta\hat{A}^{*a\mu}}+\frac{\delta\mathscr{S}}{\delta c^a}\frac{\delta\mathscr{S}}{\delta C^{*a}}+b^a\frac{\delta\mathscr{S}}{\delta\overline{c}^a}\right)=0, \tag{3.4}$$

and by the linear gauge fixing condition[10]

$$\frac{\delta\mathscr{S}}{\delta b^a}=\partial A^a+\alpha b^a. \tag{3.5}$$

A further identity, the antighost equation[10]

$$\frac{\delta\mathscr{S}}{\delta\overline{c}^a}+\partial^\mu\frac{\delta\mathscr{S}}{\delta\hat{A}^{*a\mu}}=0, \tag{3.6}$$

follows from the gauge fixing condition (3.5) and from the Slavnov–Taylor identity (3.4), implying that the antighost $\overline{c}$ and the antifield $\hat{A}^*$ can enter only through the shifted antifield $A^{*a\mu}$ of ghost number -1 and dimension 3,

$$A^{*a\mu}=\hat{A}^{*a\mu}+\partial^\mu\overline{c}^a. \tag{3.7}$$

Introducing now the reduced Yang–Mills action $\Sigma(A,A^*,c,C^*)$ defined by the identities (3.5) and (3.6),

$$\mathscr{S}=\Sigma+\int d^4x\left(b^a\partial A^a+\frac{\alpha}{2}\,b^a b^a\right), \tag{3.8}$$

i.e.,

$$\Sigma=\int d^4x\left(-\frac{1}{4g^2}\,F^a_{\mu\nu}F^{a\mu\nu}+A^{*a\mu}(D_\mu c)^a-\frac{1}{2}\,f_{abc}C^{*a}c^b c^c\right), \tag{3.9}$$

it is easily verified that Σ obeys the homogeneous Slavnov–Taylor identity,

$$\int d^4x\left(\frac{\delta\Sigma}{\delta A^a_\mu}\frac{\delta\Sigma}{\delta A^{*a\mu}}+\frac{\delta\Sigma}{\delta c^a}\frac{\delta\Sigma}{\delta C^{*a}}\right)=\frac{1}{2}\,\mathscr{B}_\Sigma\Sigma=0, \tag{3.10}$$

with

$$\mathscr{B}_\Sigma=\int d^4x\left(\frac{\delta\Sigma}{\delta A^a_\mu}\frac{\delta}{\delta A^{*a\mu}}+\frac{\delta\Sigma}{\delta A^{*a\mu}}\frac{\delta}{\delta A^{a\mu}}+\frac{\delta\Sigma}{\delta c^a}\frac{\delta}{\delta C^{*a}}+\frac{\delta\Sigma}{\delta C^{*a}}\frac{\delta}{\delta c^a}\right), \tag{3.11}$$

and

$$\mathscr{B}_\Sigma\mathscr{B}_\Sigma=0. \tag{3.12}$$

For the vector cocycle Ω^{-1}_ν of Eq. (2.5) we have now

$$\Omega^{-1}_\nu=\int d^4x[\,\omega^{-1}_\nu]_5\equiv\int d^4x(c^a\partial_\nu C^{*a}-A^a_\mu\partial_\nu A^{*a\mu}). \tag{3.13}$$

Expression (3.13) turns out to be $\mathscr{B}_\Sigma$-invariant, according to Eq. (2.6),

$$\mathscr{B}_\Sigma\Omega^{-1}_\nu=\mathscr{P}_\nu\Sigma=0. \tag{3.14}$$

We are now ready to show that in the case of Yang–Mills theory the vector cocycle Ω^{-1}_ν of Eq. (3.13) is nontrivial. Let us proceed by assuming the converse. We suppose then that Ω^{-1}_ν can be written as an exact $\mathscr{B}_\Sigma$-term,

$$\Omega^{-1}_\nu=\mathscr{B}_\Sigma\Xi^{-2}_\nu, \tag{3.15}$$

for some integrated local polynomial Ξ^{-2}_ν of ghost number -2 and dimension 5. From Table I it follows that the most general form for Ξ^{-2}_ν is given by

$$\Xi^{-2}_\nu=\zeta\int d^4x C^{*a}A^a_\nu, \tag{3.16}$$

where ζ is an arbitrary parameter which has to be fixed by the exactness condition (3.15). Thus, from Eq. (3.15), we should have the algebraic equality

$$\int d^4x(c^a\partial_\nu C^{*a}-A^a_\mu\partial_\nu A^{*a\mu})=\zeta\int d^4x(C^{*a}\partial_\nu c^a+A^a_\nu(D_\mu A^{*\mu})^a). \tag{3.17}$$

However it is almost immediate to check that the above equation has no solution for ζ, showing then that Ω^{-1}_ν cannot be written as a pure $\mathscr{B}_\Sigma$-variation,

$$\Omega^{-1}_\nu\neq\mathscr{B}_\Sigma\Xi^{-2}_\nu. \tag{3.18}$$

Therefore in the case of Yang–Mills theory the vector cocycle Ω^{-1}_ν identifies a cohomology class of the operator $\mathscr{B}_\Sigma$ in the sector of the integrated local polynomials of ghost number -1 and dimension 5, providing thus an explicit example of an antifield dependent cohomology class of $\mathscr{B}_\Sigma$.

For a better understanding of the nontriviality of the vector cocycle Ω_ν^{-1} let us discuss now its relationship with the energy-momentum tensor. To this purpose we analyze the descent equations corresponding to the local polynomial $[\omega_\nu^{-1}]_5$,

$$\begin{aligned}
\mathscr{B}_\Sigma[\omega_\nu^{-1}]_5 &= \partial^{\mu_1}[\omega^0_{\mu_1\nu}]_4,\\
\mathscr{B}_\Sigma[\omega^0_{\mu_1\nu}]_4 &= \partial^{\mu_2}[\omega^1_{[\mu_1\mu_2]\nu}]_3,\\
\mathscr{B}_\Sigma[\omega^1_{[\mu_1\mu_2]\nu}]_3 &= \partial^{\mu_3}[\omega^2_{[\mu_1\mu_2\mu_3]\nu}]_2,\\
\mathscr{B}_\Sigma[\omega^2_{[\mu_1\mu_2\mu_3]\nu}]_2 &= \partial^{\mu_4}[\omega^3_{[\mu_1\mu_2\mu_3\mu_4]\nu}]_1,\\
\mathscr{B}_\Sigma[\omega^3_{[\mu_1\mu_2\mu_3\mu_4]\nu}]_1 &= 0.
\end{aligned} \tag{3.19}$$

After some straightforward algebraic manipulations, for the local currents $(\omega^{j-1}_{[\mu_1\ldots\mu_j]\nu},\ j=1,\ldots,4)$ one finds

$$[\omega^0_{\mu_1\nu}]_4 = \frac{1}{g^2}\left(F_{\mu_1\sigma}F^{a\sigma}_\nu - \frac{1}{4}\,g_{\mu_1\nu}F^a_{\rho\sigma}F^{a\rho\sigma}\right) + \mathscr{B}_\Sigma(A^{*a}_{\mu_1}A^a_\nu), \tag{3.20}$$

$$[\omega^1_{[\mu_1\mu_2]\nu}]_3 = \epsilon_{\mu_1\mu_2}{}^{\mu_3\mu_4}\partial_{\mu_3}[\tilde{\omega}^1_{\mu_4\nu}]_2, \tag{3.21}$$

$$[\omega^2_{[\mu_1\mu_2\mu_3]\nu}]_2 = \epsilon_{\mu_1\mu_2\mu_3\mu_4}.\mathscr{B}_\Sigma[\tilde{\omega}^1_{\mu_4\nu}]_2 + \epsilon^{\mu_4}_{\mu_1\mu_2\mu_3}\partial_{\mu_4}[\tilde{\omega}^2_\nu]_1, \tag{3.22}$$

$$[\omega^3_{[\mu_1\mu_2\mu_3\mu_4]\nu}]_1 = \epsilon_{\mu_1\mu_2\mu_3\mu_4}.\mathscr{B}_\Sigma[\tilde{\omega}^2_\nu]_1, \tag{3.23}$$

with $[\tilde{\omega}^1_{\mu_4\nu}]_2$ and $[\tilde{\omega}^2_\nu]_1$ local arbitrary polynomials in the fields and their derivatives. From the above expressions we observe that while the last three currents are trivial solutions of the descent equations (3.19), the first one, $[\omega^0_{\mu_1\nu}]_4$, yields the familiar expression of the BRST invariant improved energy-momentum tensor which, as it is well known, belongs to the cohomology of $\mathscr{B}_\Sigma$.[24] One sees thus that, as already remarked in Sec I, the existence of a nontrivial invariant energy-momentum tensor is at the origin of the nontriviality of the vector cocycle Ω_ν^{-1}. Let us conclude this section by remarking that the exact term $\mathscr{B}_\Sigma(A^{*a}_{\mu_1}A^a_\nu)$ which naturally appears in the right-hand side of Eq. (3.20) is needed in order to ensure the off-shell conservation of the improved Yang–Mills energy-momentum tensor $T^{\rm YM}_{\mu\nu} = F^a_{\mu\sigma}F^{a\sigma}_\nu - \frac{1}{4}g_{\mu\nu}F^a_{\rho\sigma}F^{a\rho\sigma}$. Of course, the same conclusions hold if the pure Yang–Mills action is supplemented with the introduction of matter fields.

IV. THE CASE OF THE TOPOLOGICAL FIELD THEORIES

Having established the nontriviality of Ω_ν^{-1} for the Yang–Mills case, we analyze now the vector cocycle (2.5) in the context of the TFT. In this case, it turns out that Ω_ν^{-1} is always BRST exact,

$$\Omega_\nu^{-1} = \mathscr{B}_\Sigma \Xi_\nu^{-2}, \tag{4.1}$$

for some integrated local field polynomial Ξ_ν^{-2} with ghost number -2. The reason for the exactness of Ω_ν^{-1} in the TFT relies on their field content which, as proven by several authors,[26–29,4,5,10] does not allow for cohomology classes with free Lorentz indices, as the ones needed in order to have nontrivial solutions of the descent Eqs. (2.11). In fact, in the case of the TFT of the cohomological type,[30–32] the topological shift symmetry implies the emptiness of the BRST cohomology[1,5,26–28] and therefore the triviality of the vector cocycle Ω_ν^{-1}. (Let us remark here that, as discussed by Refs. 26–29, the relevant cohomology for the topological theories of the Witten's type is the so-called equivariant cohomology. The latter is the restriction of the BRST, cohomology to gauge invariant local field polynomials which do not depend on the Faddeev–

Popov ghost field c. Contrary to the BRST cohomology, the equivariant cohomology is not empty and turns out to provide a consistent definition of the Witten's observables.) Concerning now the Schwartz-type models, it can be proven that their field content allows for nontrivial cohomology classes.[3,4,10] Moreover, as observed in Refs. 16 and 17, these models can be formulated in a pure geometrical way due to the fact that all the fields (gauge fields, ghosts, ghosts for ghosts, antifields, etc.) can be viewed as being the components of a generalized gauge connection obeying a zero curvature condition. This structure, called complete ladder structure, implies that all the BRST cohomology classes can be identified with invariant polynomials in the undifferentiated dimensionless scalar ghosts present in the models.[3,4,10] From this result it follows that the cohomology relevant for the solutions of Eqs. (2.11) vanishes, meaning thus that also in the case of the Schwartz-type TFT the vector cocycle Ω_ν^{-1} is trivial.

Although Eq. (4.1) could seem empty of any interesting information because of its BRST exactness, it turns out that its content is far from being irrelevant. In fact the right-hand side of Eq. (4.1), due to the form (2.2) of the operator $\mathscr{B}_\Sigma$, is easily seen to provide the contact terms of a Ward identity. This identity, due to the presence of Ω_ν^{-1} in the left-hand side of Eq. (4.1), cannot express an exact invariance of the theory. Instead, Eq. (4.1) will have the meaning of a broken Ward identity. Furthermore, it is not difficult to convince oneself that this breaking term is linear in the quantum fields. Therefore it does not get renormalized by the radiative corrections and does not spoil the usefulness of the corresponding Ward identity. As one can easily understand, the existence of this linear breaking term is a direct consequence of the fact that the general expression of Ω_ν^{-1} given in Eq. (2.5) is linear in the fields, apart from possible quadratic terms coming from the fact that some of the antifields φ^{i*} have been shifted in order to account for the antighosts. We shall check, however, that these quadratic terms turn out to be handled in a very simple way, being reinterpreted as pure contact terms by means of an appropriate choice of the gauge parameters present in the gauge fixing. This means that the corresponding Ward identity is consistent with the Quantum Action Principles[33] only for certain classes of gauge fixings. This feature will be shown later on in the cases of the vector susy for three-dimensional Chern–Simons and of the Landau ghost equation.

Equation (4.1) has thus the meaning of a purely algebraic cohomological characterization of a Ward identity. Indeed, once one is able to prove that the cocycle Ω_ν^{-1} is trivial, one knows automatically that Eq. (4.1) has to be necessarily satisfied for some local polynomial Ξ_ν^{-2}. The strategy to be followed is now straightforward. One writes down the most general expression for Ξ_ν^{-2} compatible with the dimension of the space–time and with the field content of the model under consideration. This expression will, in general, depend on a set of free constant coefficients which will be fixed by the validity of Eq. (4.1). Recalling then that the functional form of the operator $\mathscr{B}_\Sigma$ [see Eq. (2.2)] depends on the reduced action Σ, it becomes apparent that the coefficients of Ξ_ν^{-2} are determined by the form of the classical action Σ. This means that whenever Ω_ν^{-1} is trivial, Eq. (4.1) tells us that the classical action Σ obeys a further Ward identity whose contact terms are precisely given by Eq. (4.1). This provides a simple mechanism for an algebraic characterization of a linearly broken symmetry of the action. Of course, this additional Ward identity will have the same quantum numbers of the vector cocycle Ω_ν^{-1}. It will carry a Lorentz index and it will have a negative ghost number. This vector identity, always present in the TFT, is known as the topological vector supersymmetry.[2–5]

Let us spend now a few words on the possibility of generalizing this algebraic mechanism in order to find other kinds of unknown global symmetries. What seems to emerge from the previous analysis is that the antifield cocycles which are relevant for the existence of a *class of linearly broken* Ward identities are those which are linear in the fields $\{\varphi^i\}$ and in the antifields $\{\varphi^{i*}\}$, and that are BRST exact. It is this last property which, when cast in the form of Eq. (4.1), allows us to identify the contact terms of the corresponding Ward identity. It is worthwhile to remark that an equation of the kind of (4.1) implies that the related Ward identity is always broken, due to the existence of a nonvanishing term in left-hand side of (4.1). However, being this term linear in the quantum fields, the resulting breaking term is classical. In Sec. V, we will discuss another example of a linearly broken Ward identity related to the rigid gauge invariance, whose contact terms can be characterized in a cohomological way by means of an equation of the type of (4.1).

Let us first focus on the discussion of the vector susy Ward identity in the case of the TFT. We shall present in detail the examples of the three-dimensional Chern–Simons, of the four-

dimensional BF model and of the so-called two-dimensional b-c and b-c β-γ ghost systems.

A. The three-dimensional Chern–Simons model

Using the same notations of the Sec. III, for the complete three-dimensional Chern–Simons action[1] quantized in the Landau gauge we have

$$\mathscr{S}=\mathscr{S}_{cs}+\int d^3x\left(b^a\partial A^a+\partial^\mu\overline{c}^a(D_\mu c)^a+\hat{A}^*_\mu(D^\mu c)^a-\frac{1}{2}f_{abc}C^{*a}c^bc^c\right), \tag{4.2}$$

where $\mathscr{S}_{cs}$ is given by

$$\mathscr{S}_{cs}=-\frac{k}{4\pi}\int d^3x\,\epsilon^{\mu\nu\rho}\left(A^a_\mu\partial_\nu A^a_\rho+\frac{1}{3}f_{abc}A^a_\mu A^b_\nu A^c_\rho\right), \tag{4.3}$$

k identifying the inverse of the coupling constant. The fields and the antifields have now the following quantum numbers:

	A	$\hat{A}^*$	c	C^*	$\bar{c}$	b
dim.	1	2	0	3	1	1
gh-numb.	0	-1	1	-2	-1	0

(4.4)

For the classical Slavnov–Taylor identity one has

$$\int d^3x\left(\frac{\delta\mathscr{S}}{\delta A^a_\mu}\frac{\delta\mathscr{S}}{\delta\hat{A}^{*a\mu}}+\frac{\delta\mathscr{S}}{\delta c^a}\frac{\delta\mathscr{S}}{\delta C^{*a}}+b^a\frac{\delta\mathscr{S}}{\delta\overline{c}^a}\right)=0. \tag{4.5}$$

Making use of the Landau gauge condition

$$\frac{\delta\mathscr{S}}{\delta b^a}=\partial A^a, \tag{4.6}$$

and of the antighost equation

$$\frac{\delta\mathscr{S}}{\delta\overline{c}^a}+\partial^\mu\frac{\delta\mathscr{S}}{\delta\hat{A}^{*a\mu}}=0, \tag{4.7}$$

for the reduced Chern–Simons action $\Sigma(A,A^*,c,C^*)$,

$$\mathscr{S}=\Sigma+\int d^3x\,b^a\partial A^a, \tag{4.8}$$

we obtain

$$\Sigma=\mathscr{S}_{cs}+\int d^3x\left(A^{a*}_\mu(D^\mu c)^a-\frac{1}{2}f_{abc}C^{*a}c^bc^c\right), \tag{4.9}$$

where, as usual, A^{a*}_μ is the shifted antifield,

$$A^{*a\mu}=\hat{A}^{*a\mu}+\partial^\mu\overline{c}^a. \tag{4.10}$$

Finally, taking into account Eqs. (4.6), (4.7) and the expression (4.9), the Slavnov–Taylor identity (4.5) becomes

$$\int d^3x\left(\frac{\delta\Sigma}{\delta A^a_\mu}\frac{\delta\Sigma}{\delta A^{*a\mu}}+\frac{\delta\Sigma}{\delta c^a}\frac{\delta\Sigma}{\delta C^{*a}}\right)=\frac{1}{2}\,\mathscr{B}_\Sigma\Sigma=0, \tag{4.11}$$

with

$$\mathscr{B}_\Sigma=\int d^3x\left(\frac{\delta\Sigma}{\delta A^a_\mu}\frac{\delta}{\delta A^{*a\mu}}+\frac{\delta\Sigma}{\delta A^{*a\mu}}\frac{\delta}{\delta A^{a\mu}}+\frac{\delta\Sigma}{\delta c^a}\frac{\delta}{\delta C^{*a}}+\frac{\delta\Sigma}{\delta C^{*a}}\frac{\delta}{\delta c^a}\right), \tag{4.12}$$

and

$$\mathscr{B}_\Sigma\mathscr{B}_\Sigma=0. \tag{4.13}$$

Repeating the same procedure done in the case of the Yang–Mills theory, for the vector cocycle Ω^{-1}_ν we can write

$$\Omega^{-1}_\nu=\int d^3x[\,\omega^{-1}_\nu]_4\equiv\int d^3x(c^a\partial_\nu C^{*a}-A^a_\mu\partial_\nu A^{*a\mu}), \tag{4.14}$$

and

$$\mathscr{B}_\Sigma\Omega^{-1}_\nu=\mathscr{P}_\nu\Sigma=0. \tag{4.15}$$

In this case, as already mentioned, Ω^{-1}_ν turns out to be exact

$$\Omega^{-1}_\nu=\mathscr{B}_\Sigma\Xi^{-2}_\nu, \tag{4.16}$$

where Ξ^{-2}_ν is an integrated local polynomial of dimension 4 and ghost number -2. From Table II it follows that the most general expression for Ξ^{-2}_ν is given by

$$\Xi^{-2}_\nu=\int d^3x\left(\sigma C^{*a}A^a_\nu+\frac{\tau}{2}\,\epsilon_{\nu\sigma\tau}A^{*a\sigma}A^{*a\tau}\right), \tag{4.17}$$

where σ and τ are arbitrary parameters. Using now the expressions of the linearized Slavnov–Taylor operator (4.12) and of the reduced Chern–Simons action (4.9), for the right-hand side of Eq. (4.16) we have

$$\mathscr{B}_\Sigma\Xi^{-2}_\nu=\int d^3x\left(\sigma A^a_\nu\frac{\delta\Sigma}{\delta c^a}+\sigma C^{*a}\frac{\delta\Sigma}{\delta A^{*a\nu}}-\tau\epsilon_{\nu\sigma\tau}A^{*a\sigma}\frac{\delta\Sigma}{\delta A^a_\tau}\right). \tag{4.18}$$

Comparing then both sides of Eq. (4.16), for the coefficients σ and τ we get

$$\sigma=-1,\quad \tau=\frac{2\pi}{k}, \tag{4.19}$$

so that Eq. (4.16) can be rewritten as

$$\int d^3x\left(A^a_\nu\frac{\delta\Sigma}{\delta c^a}+C^{*a}\frac{\delta\Sigma}{\delta A^{*a\nu}}+\frac{2\pi}{k}\,\epsilon_{\nu\sigma\tau}A^{*a\sigma}\frac{\delta\Sigma}{\delta A^a_\tau}+c^a\partial_\nu C^{*a}-A^a_\mu\partial_\nu A^{*a\mu}\right)=0. \tag{4.20}$$

Finally, moving from the reduced action Σ to the complete action $\mathscr{S}$ of Eq. (4.2) and making use of the gauge condition (4.6), the identity (4.20) can be cast in the form of a linearly broken Ward identity, namely,

$$\mathscr{W}_\nu\mathscr{S}=\Delta^{\rm cl}_\nu, \tag{4.21}$$

with

$$\mathscr{W}_\nu = \int d^3x \left(A^a_\nu \frac{\delta}{\delta c^a} + C^{*a} \frac{\delta}{\delta \hat{A}^{*a\nu}} + \frac{2\pi}{k} \epsilon_{\nu\sigma\tau} (\hat{A}^{*a\sigma} + \partial^\sigma \overline{c^a}) \frac{\delta}{\delta A^a_\tau} + \partial_\nu \overline{c^a} \frac{\delta}{\delta b^a} \right), \quad (4.22)$$

and

$$\Delta^{\rm cl}_\nu = \int d^3x \left(C^{*a} \partial_\nu c^a - \hat{A}^{*a\mu} \partial_\nu A^a_\mu - \frac{2\pi}{k} \epsilon_{\nu\sigma\tau} \hat{A}^{*a\sigma} \partial^\tau b^a \right). \quad (4.23)$$

Equation (4.21) is easily recognized to be the well known topological vector susy Ward identity of the three-dimensional Chern–Simons theory.[2,3] Let us conclude this section by observing that in the case in which instead of a Landau gauge fixing condition we had adopted a Feynman gauge [see Eq. (3.5)], the right-hand side of Eq. (4.21) would have been modified by the additional term

$$\alpha \int d^3x b^a \partial_\nu \overline{c^a}, \quad (4.24)$$

which, being quadratic in the quantum fields, would have spoiled the usefulness of the identity (4.21). We see therefore that the requirement that the breaking term $\Delta^{\rm cl}_\nu$ is at most linear in the quantum fields leads to the vanishing of the gauge parameter, $\alpha=0$, selecting thus the Landau gauge.

B. The four-dimensional BF model

As the second example, we shall present the four-dimensional BF model[1] whose classical invariant action is given by

$$\mathscr{S}_{\rm BF} = -\frac{1}{4} \int d^4x \epsilon^{\mu\nu\rho\sigma} F^a_{\mu\nu} B^a_{\rho\sigma}. \quad (4.25)$$

The quantization of this model requires the BV procedure[25] due to the presence of ghosts for ghosts. We shall limit here only to report the final result, reminding the reader the numerous references[1] for the technical details. Using the same notations of Ref. 4, in order to gauge fix the invariant action (4.25) we introduce a set of Lagrange multipliers $(b^a, h^a_\mu, \omega^a, \lambda^a)$, a set of anti-ghosts $(\overline{c^a}, \overline{\xi^a_\mu}, \overline{\phi^a}, e^a)$, and a triple of ghosts (c^a, ξ^a_μ, ϕ^a). For the gauge fixing action S_{gf} we have

$$\begin{aligned} \mathscr{S}_{gf} = \int d^4x (& b^a \partial A^a - \partial^\mu \overline{c^a} (D_\mu c)^a + h^a_\nu \partial_\mu B^{a\mu\nu} + \omega^a \partial \xi^a + h^{a\mu} \partial_\mu e^a + \omega^a \lambda^a - \partial^\mu \overline{\phi^a} ((D_\mu \phi)^a \\ & + f_{abc} c^b \xi^c_\mu) + \tfrac{1}{2} f_{abc} \epsilon^{\mu\nu\rho\sigma} (\partial_\mu \overline{\xi^a_\nu}) (\partial_\rho \overline{\xi^b_\sigma}) \phi^c - \partial^\mu \overline{\xi^a}{}^\nu ((D_\mu \xi_\nu)^a - (D_\nu \xi_\mu)^a + f_{abc} B^b_{\mu\nu} c^c) \\ & - \lambda^a \partial \overline{\xi^a}). \end{aligned} \quad (4.26)$$

The quantum numbers of all the fields and ghosts are assigned as follows:

	A	B	c	ξ	ϕ	$\bar{c}$	$\bar{\xi}$	$\bar{\phi}$	e	b	h	ω	λ
dim.	1	2	0	1	0	2	1	2	2	2	1	2	2
gh-numb.	0	0	1	1	2	−1	−1	−2	0	0	0	−1	1

(4.27)

Introducing a set of antifields $(\hat{A}^{*a\mu}, \hat{B}^{*a\mu\nu}, C^{*a}, \phi^{*a}, \hat{\xi}^{*a\mu})$ associated, respectively, to the fields $(A^{a\mu}, B^{a\mu\nu}, c^a, \phi^a, \xi^{a\mu})$,

$$\mathscr{S}_{\rm ext}=\int d^4x\Big(\frac{1}{2}\,\hat{B}^{*a\mu\nu}((D_\nu\xi_\mu)^a-(D_\mu\xi_\nu)^a-f_{abc}B^b_{\mu\nu}c^c+f_{abc}\epsilon_{\mu\nu\rho\sigma}\partial^\rho\overline{\xi^{b\sigma}}\phi^c)+\hat{\xi}^{*a\mu}((D_\mu\phi)^a$$
$$+f_{abc}c^b\xi^c_\mu)+\frac{1}{8}\,f_{abc}\epsilon_{\mu\nu\rho\sigma}\hat{B}^{*a\mu\nu}\hat{B}^{*b\rho\sigma}\phi^c-\hat{A}^{*a\mu}(D_\mu c)^a+\frac{1}{2}\,f_{abc}C^{*a}c^bc^c$$
$$+f_{abc}\phi^{*a}c^b\phi^c\Big), \tag{4.28}$$

	$\hat{A}^*$	$\hat{B}^*$	C^*	ϕ^*	$\hat{\xi}^*$
dim.	3	2	4	4	3
gh-numb.	−1	−1	−2	−3	−2

(4.29)

we have that the complete action $\mathscr{S}$

$$\mathscr{S}=\mathscr{S}_{\rm BF}+\mathscr{S}_{gf}+\mathscr{S}_{\rm ext}, \tag{4.30}$$

obeys the following Slavnov–Taylor identity:

$$\int d^4x\Big(\frac{\delta\mathscr{S}}{\delta A^a_\mu}\frac{\delta\mathscr{S}}{\delta\hat{A}^{*a\mu}}+\frac{\delta\mathscr{S}}{\delta c^a}\frac{\delta\mathscr{S}}{\delta C^{*a}}+\frac{1}{2}\frac{\delta\mathscr{S}}{\delta B^a_{\mu\nu}}\frac{\delta\mathscr{S}}{\delta\hat{B}^{*a\mu\nu}}+\frac{\delta\mathscr{S}}{\delta\phi^a}\frac{\delta\mathscr{S}}{\delta\phi^{*a}}+\frac{\delta\mathscr{S}}{\delta\xi^a_\mu}\frac{\delta\mathscr{S}}{\delta\hat{\xi}^{*a\mu}}+h^a_\mu\frac{\delta\mathscr{S}}{\delta\overline{\xi^a_\mu}}$$
$$+b^a\frac{\delta\mathscr{S}}{\delta\overline{c^a}}+\omega^a\frac{\delta\mathscr{S}}{\delta\overline{\phi^a}}+\lambda^a\frac{\delta\mathscr{S}}{\delta e^a}\Big)=0. \tag{4.31}$$

In order to define the reduced action for the BF model let us write down the gauge-fixing conditions,

$$\frac{\delta\mathscr{S}}{\delta b^a}=\partial A^a,\quad\frac{\delta\mathscr{S}}{\delta h^{a\mu}}=\partial_\mu e^a+\partial^\nu B^a_{\nu\mu},$$
$$\frac{\delta\mathscr{S}}{\delta\omega^a}=\lambda^a+\partial\xi^a,\quad\frac{\delta\mathscr{S}}{\delta\lambda^a}=-\partial\overline{\xi^a}-\omega^a. \tag{4.32}$$

Commuting the above conditions with the Slavnov–Taylor identity (4.31) we get the antighost equations (see Tables III and IV),

$$\frac{\delta\mathscr{S}}{\delta\overline{c^a}}+\partial^\mu\frac{\delta\mathscr{S}}{\delta\hat{A}^{*a\mu}}=0,\quad\frac{\delta\mathscr{S}}{\delta\overline{\phi^a}}-\partial^\mu\frac{\delta\mathscr{S}}{\delta\hat{\xi}^{*a\mu}}=0,$$
$$\frac{\delta\mathscr{S}}{\delta e^a}=-\partial h^a,\quad\frac{\delta\mathscr{S}}{\delta\overline{\xi^{a\nu}}}+\partial^\mu\frac{\delta\mathscr{S}}{\delta\hat{B}^{*a\mu\nu}}=-\partial_\nu\lambda^a. \tag{4.33}$$

Introducing the following shifted antifields:

$$A^{*a\mu}=\hat{A}^{*a\mu}+\partial^\mu\overline{c^a},\quad\xi^{*a\mu}=\hat{\xi}^{*a\mu}-\partial^\mu\overline{\phi^a},$$
$$B^{*a\mu\nu}=\hat{B}^{*a\mu\nu}+(\partial^\mu\overline{\xi^{a\nu}}-\partial^\nu\overline{\xi^{a\mu}}), \tag{4.34}$$

for the reduced BF action Σ we get

$$\mathscr{S}=\Sigma+\int d^4x(b^a\partial A^a+h^a_\nu\partial_\mu B^{a\mu\nu}+\omega^a\partial\xi^a+h^{a\mu}\partial_\mu e^a+\omega^a\lambda^a+-\lambda^a\partial\overline{\xi^a}), \tag{4.35}$$

and

$$\Sigma = \int d^4x \Big(-\frac{1}{4}\,\epsilon^{\mu\nu\rho\sigma} F^a_{\mu\nu} B^a_{\rho\sigma} + \frac{1}{2}\, B^{*a\mu\nu}((D_\nu \xi_\mu)^a - (D_\mu \xi_\nu)^a - f_{abc} B^b_{\mu\nu} c^c + f_{abc}\epsilon_{\mu\nu\rho\sigma}\partial^\rho \overline{\xi^{b\sigma}} \phi^c)$$
$$+ \xi^{*a\mu}((D_\mu \phi)^a + f_{abc} c^b \xi^c_\mu) + \frac{1}{8}\, f_{abc}\epsilon_{\mu\nu\rho\sigma} B^{*a\mu\nu} B^{*b\rho\sigma} \phi^c - A^{*a\mu}(D_\mu c)^a + \frac{1}{2}\, f_{abc} C^{*a} c^b c^c$$
$$+ f_{abc} \phi^{*a} c^b \phi^c \Big). \tag{4.36}$$

As usual, the reduced action Σ obeys the homogeneous Slavnov–Taylor identity

$$\frac{1}{2}\,\mathscr{B}_\Sigma \Sigma = 0 = \int d^4x \Big(\frac{\delta\Sigma}{\delta A^a_\mu}\frac{\delta\Sigma}{\delta A^{*a\mu}} + \frac{\delta\Sigma}{\delta c^a}\frac{\delta\Sigma}{\delta C^{*a}} + \frac{1}{2}\,\frac{\delta\Sigma}{\delta B^a_{\mu\nu}}\frac{\delta\Sigma}{\delta B^{*a\mu\nu}} + \frac{\delta\Sigma}{\delta \phi^a}\frac{\delta\Sigma}{\delta \phi^{*a}} + \frac{\delta\Sigma}{\delta \xi^a_\mu}\frac{\delta\Sigma}{\delta \xi^{*a\mu}} \Big), \tag{4.37}$$

with

$$\mathscr{B}_\Sigma = \int d^4x \Big(\frac{\delta\Sigma}{\delta A^a_\mu}\frac{\delta}{\delta A^{*a\mu}} + \frac{\delta\Sigma}{\delta A^{*a\mu}}\frac{\delta}{\delta A^a_\mu} + \frac{\delta\Sigma}{\delta c^a}\frac{\delta}{\delta C^{*a}} + \frac{\delta\Sigma}{\delta C^{*a}}\frac{\delta}{\delta c^a} + \frac{1}{2}\,\frac{\delta\Sigma}{\delta B^a_{\mu\nu}}\frac{\delta}{\delta B^{*a\mu\nu}}$$
$$+ \frac{1}{2}\,\frac{\delta\Sigma}{\delta B^{*a\mu\nu}}\frac{\delta}{\delta B^a_{\mu\nu}} + \frac{\delta\Sigma}{\delta \phi^a}\frac{\delta}{\delta \phi^{*a}} + \frac{\delta\Sigma}{\delta \phi^{*a}}\frac{\delta}{\delta \phi^a} + \frac{\delta\Sigma}{\delta \xi^a_\mu}\frac{\delta}{\delta \xi^{*a\mu}} + \frac{\delta\Sigma}{\delta \xi^{*a\mu}}\frac{\delta}{\delta \xi^a_\mu} \Big), \tag{4.38}$$

and

$$\mathscr{B}_\Sigma \mathscr{B}_\Sigma = 0. \tag{4.39}$$

Let us turn now to the invariant vector cocycle (2.5), which in the present case takes the form

$$\Omega^{-1}_\nu \equiv \int d^4x \Big(c^a \partial_\nu C^{*a} - A^a_\mu \partial_\nu A^{*a\mu} + \xi^a_\mu \partial_\nu \xi^{*a\mu} - \phi^a \partial_\nu \phi^{*a} - \frac{1}{2}\, B^a_{\mu\tau} \partial_\nu B^{*a\mu\tau} \Big), \tag{4.40}$$

and

$$\mathscr{B}_\Sigma \Omega^{-1}_\nu = \mathscr{P}_\nu \Sigma = 0. \tag{4.41}$$

As in the case of the Chern–Simons model, the vanishing of the cohomology of the operator $\mathscr{B}_\Sigma$ (Refs. 4 and 10) in the sector of the integrated local polynomials with ghost number -1 and with a free Lorentz index implies that Ω^{-1}_ν is an exact cocycle,

$$\Omega^{-1}_\nu = \mathscr{B}_\Sigma \Xi^{-2}_\nu, \tag{4.42}$$

for some local integrated polynomial Ξ^{-2}_ν of dimension 5 and ghost number -2. In fact, repeating the same procedure done in the previous example, Ξ^{-2}_ν is easily found to be

$$\Xi^{-2}_\nu = \int d^4x \Big(C^{*a} A^a_\nu + \frac{1}{2}\, \epsilon_{\sigma\tau\mu\nu} A^{*a\sigma} B^{*a\tau\mu} - \phi^{*a} \xi^a_\nu - \xi^{*a\mu} B^a_{\mu\nu} \Big). \tag{4.43}$$

Finally, moving from the reduced action (4.36) to the complete one (4.30), we get the linearly broken vector Ward identity,

$$\mathscr{W}_\nu \mathscr{S} = \Delta^{\mathrm{cl}}_\nu, \tag{4.44}$$

with

$$\mathscr{W}^{*}_{\nu}=\int d^4x\Big(\frac{1}{2}\,\epsilon_{\sigma\tau\mu\nu}(\hat{B}^{*a\tau\mu}+\partial^{\tau}\overline{\xi}^{a\mu}-\partial^{\mu}\overline{\xi}^{a\tau})\,\frac{\delta}{\delta A^{a}_{\sigma}}+A^{a}_{\nu}\,\frac{\delta}{\delta c^{a}}-\partial_{\nu}\overline{c}^{a}\,\frac{\delta}{\delta b^{a}}-\frac{1}{2}\,\epsilon_{\sigma\tau\mu\nu}(\hat{A}^{*a\sigma}$$
$$+\partial^{\sigma}\overline{c}^{a})\,\frac{\delta}{\delta B^{a}_{\tau\mu}}-B^{a}_{\mu\nu}\,\frac{\delta}{\delta\xi^{a}_{\mu}}-\xi^{a}_{\nu}\,\frac{\delta}{\delta\phi^{a}}+\overline{\phi}^{a}\,\frac{\delta}{\delta\overline{\xi}^{a\mu}}-\partial_{\nu}\overline{\phi}^{a}\,\frac{\delta}{\delta\omega^{a}}+\partial_{\nu}e^{a}\,\frac{\delta}{\delta\lambda^{a}}$$
$$-(\omega^{a}\delta^{\tau}_{\nu}+\partial_{\nu}\overline{\xi}^{a\tau})\,\frac{\delta}{\delta h^{a\tau}}+C^{*a}\,\frac{\delta}{\delta\hat{A}^{*a\nu}}+\phi^{*a}\,\frac{\delta}{\delta\hat{\xi}^{*a\nu}}-\hat{\xi}^{*a\mu}\,\frac{\delta}{\delta\hat{B}^{*a\mu\nu}}\Big),\tag{4.45}$$

and the classical breaking $\Delta^{\mathrm{cl}}_{\nu}$ given by

$$\Delta^{\mathrm{cl}}_{\nu}=\int d^4x\Big(\hat{A}^{*a\mu}\partial_{\nu}A^{a}_{\mu}-C^{*a}\partial_{\nu}c^{a}-\hat{\xi}^{*a\mu}\partial_{\nu}\xi^{a}_{\mu}+\phi^{*a}\partial_{\nu}\phi^{a}+\frac{1}{2}\,\hat{B}^{*a\tau\mu}\partial_{\nu}B^{a}_{\tau\mu}$$
$$-\frac{1}{2}\,\epsilon_{\sigma\tau\mu\nu}\hat{B}^{*a\tau\mu}\partial^{\sigma}b^{a}+\frac{1}{2}\,\epsilon_{\sigma\tau\mu\nu}\hat{A}^{*a\sigma}\partial^{\tau}h^{a\mu}\Big).\tag{4.46}$$

Equation (4.44) is recognized to be the well known topological vector susy Ward identity of the four-dimensional BF systems.[4] Let us conclude by remarking that the above construction can be easily generalized to the BF systems in higher space–time dimensions, reproducing the results of Refs. 4 and 10. In particular, it is not difficult to check that the requirement that the breaking term (4.46) is at most linear in the quantum fields completely fixes the gauge parameters which would be left free by the Slavnov–Taylor identity.[4]

C. The *b*-*c* ghost system

We present here, as a two-dimensional example of a topological model, the so-called b-c ghost system whose action reads

$$\mathscr{S}_{bc}=\int dz d\overline{z}\; b\,\overline{\partial} c,\tag{4.47}$$

where the fields $b=b_{zz}$ and $c=c^{z}$ are anticommuting and carry, respectively, ghost number -1 and $+1$. The action (4.47) is recognized to be the ghost part of the quantized bosonic string[1,34] and is invariant under the following nonlinear BRST transformations:

$$sc=c\partial c,\quad sb=-(\partial b)c-2b\partial c.\tag{4.48}$$

In particular, the expression in the right-hand side of the BRST transformation of the field b is the component T_{zz} of the energy-momentum tensor corresponding to the action (4.47). This property allows for the topological interpretation of the b-c ghost system.

Transformations (4.48) being nonlinear, one needs to introduce two antifields $(b^{*}=b^{z*}_{\overline{z}},c^{*}=c^{*}_{zz\overline{z}})$ of ghost number 0 and -2,

$$\mathscr{S}_{\mathrm{ext}}=\int dz d\overline{z}(c^{*}c\partial c+b^{*}(c\partial b-2b\partial c)).\tag{4.49}$$

The complete action

$$\mathscr{S}=\mathscr{S}_{bc}+\mathscr{S}_{\mathrm{ext}},\tag{4.50}$$

obeys thus the Slavnov–Taylor identity

$$\int dz d\overline{z}\Big(\frac{\delta\mathscr{S}}{\delta b}\,\frac{\delta\mathscr{S}}{\delta b^{*}}+\frac{\delta\mathscr{S}}{\delta c}\,\frac{\delta\mathscr{S}}{\delta c^{*}}\Big)=\frac{1}{2}\,\mathscr{B}_{\mathscr{S}}\mathscr{S}=0,\tag{4.51}$$

$\mathscr{B}_{\mathscr{S}}$ denoting the linearized operator

$$\mathscr{B}_{\mathscr{S}}=\int dzd\overline{z}\left(\frac{\delta\mathscr{S}}{\delta b}\frac{\delta}{\delta b^*}+\frac{\delta\mathscr{S}}{\delta b^*}\frac{\delta}{\delta b}+\frac{\delta\mathscr{S}}{\delta c}\frac{\delta}{\delta c^*}+\frac{\delta\mathscr{S}}{\delta c^*}\frac{\delta\mathscr{S}}{\delta c}\right), \tag{4.52}$$

and

$$\mathscr{B}_{\mathscr{S}}\mathscr{B}_{\mathscr{S}}=0. \tag{4.53}$$

	c	b	c^*	b^*
dim	0	1	1	0
$gh-numb$	1	−1	−2	0

(4.53)

Concerning now the vector cocycle (2.5), here written in components, we have

$$\begin{aligned}\Omega_z^{-1}&=\int dzd\overline{z}(b\partial b^*+c\partial c^*),\\ \Omega_{\overline{z}}^{-1}&=\int dzd\overline{z}(b\partial\overline{b}^*+c\partial\overline{c}^*),\end{aligned} \tag{4.55}$$

and

$$\mathscr{B}_{\mathscr{S}}\Omega_z^{-1}=\mathscr{P}_z\mathscr{S}=0,\quad \mathscr{B}_{\mathscr{S}}\Omega_{\overline{z}}^{-1}=\mathscr{P}_{\overline{z}}\mathscr{S}=0. \tag{4.56}$$

As done before, we look for the solution of the BRST exact conditions

$$\Omega_z^{-1}=\mathscr{B}_{\mathscr{S}}\Xi_z^{-2},\quad \Omega_{\overline{z}}^{-1}=\mathscr{B}_{\mathscr{S}}\Xi_{\overline{z}}^{-2}, \tag{4.57}$$

for some local integrated polynomials $(\Xi_z^{-2},\Xi_{\overline{z}}^{-2})$ of ghost number -2 and dimension 1 (see Table 5). After some trivial algebraic manipulations one easily finds

$$\Xi_z^{-2}=-\int dzd\overline{z}\,c^*,\quad \Xi_{\overline{z}}^{-2}=-\int dzd\overline{z}\,c^*b^*. \tag{4.58}$$

Turning then Eqs. (4.57) into contact terms by means of the linearized operator $\mathscr{B}_{\mathscr{S}}$ of Eq. (4.52), we get the two linearly broken Ward identities

$$\int dzd\overline{z}\frac{\delta\mathscr{S}}{\delta c}=-\int dzd\overline{z}(b\partial b^*+c\partial c^*), \tag{4.59}$$

and

$$\int dzd\overline{z}\left(b^*\frac{\delta\mathscr{S}}{\delta c}+c^*\frac{\delta\mathscr{S}}{\delta b}\right)=-\int dzd\overline{z}(b\partial\overline{b}^*+c\partial\overline{c}^*), \tag{4.60}$$

which are nothing but the topological vector susy Ward identities of the b-c ghost system.[13,17,10]

D. The b-c β-γ ghost system

It is known that the b-c system can be generalized to include the so-called β-γ ghosts,

$$\mathscr{S}_{bc\beta\gamma}=\int dzd\overline{z}\,(b\partial\overline{c}+\beta\partial\overline{\gamma}), \tag{4.61}$$

where $\beta=\beta_{zzz}$ and $\gamma=\gamma^{zz}$ are anticommuting fields of ghost number -1 and 1, respectively. The action (4.61) is the simplest example of a b-c β-γ system and can be easily generalized to the case of ghosts of higher conformal weight.[35] The BRST transformations read now

$$sc = c\partial c, \quad s\gamma = c\partial\gamma - 2(\partial c)\gamma,$$

$$sb = -(\partial b)c - 2b\partial c - 2(\partial\beta)\gamma - 3\beta\partial\gamma, \tag{4.62}$$

$$s\beta = -(\partial\beta)c - 3\beta\partial c.$$

Introducing external fields $(c^*, b^*, \beta^*, \gamma^*)$,

$$\mathscr{S}_{\text{ext}} = \int dz d\overline{z}\,(c^* sc + b^* sb + \beta^* s\beta + \gamma^* s\gamma), \tag{4.63}$$

for the Slavnov–Taylor identity we get

$$\int dz d\overline{z}\left(\frac{\delta\mathscr{S}}{\delta b}\frac{\delta\mathscr{S}}{\delta b^*} + \frac{\delta\mathscr{S}}{\delta c}\frac{\delta\mathscr{S}}{\delta c^*} + \frac{\delta\mathscr{S}}{\delta\gamma}\frac{\delta\mathscr{S}}{\delta\gamma^*} + \frac{\delta\mathscr{S}}{\delta\beta}\frac{\delta\mathscr{S}}{\delta\beta^*}\right) = 0, \tag{4.64}$$

with

$$\mathscr{S} = \mathscr{S}_{bc\beta\gamma} + \mathscr{S}_{\text{ext}}. \tag{4.65}$$

Finally, following the same procedure of the previous example, the linearly broken Ward identities of Eqs. (4.59), (4.60) generalize now to

$$\int dz d\overline{z}\,\frac{\delta\mathscr{S}}{\delta c} = -\int dz d\overline{z}\,(b\partial b^* + c\partial c^* + \gamma\partial\gamma^* + \beta\partial\beta^*), \tag{4.66}$$

and

$$\int dz d\overline{z}\left(b^*\frac{\delta\mathscr{S}}{\delta c} + c^*\frac{\delta\mathscr{S}}{\delta b} + \beta^*\frac{\delta\mathscr{S}}{\delta\gamma} + \gamma^*\frac{\delta\mathscr{S}}{\delta\beta}\right) = \overline{\Delta}^{\text{cl}}, \tag{4.67}$$

with

$$\overline{\Delta}^{\text{cl}} = -\int dz d\overline{z}\,(b\partial\overline{b}^* + c\partial\overline{c}^* + \gamma\partial\overline{\gamma}^* + \beta\partial\overline{\beta}^*). \tag{4.68}$$

V. THE CASE OF THE RIGID GAUGE INVARIANCE: THE LANDAU GHOST EQUATION

In this last section we shall analyse another interesting example of a linearly broken Ward identity whose contact terms can be characterized in the same purely algebraic cohomological way of the topological vector susy. This Ward identity is not related to a specific gauge model, being present in all the cases in which the rigid gauge invariance is an exact symmetry of the action. In order to present its derivation in a detailed way we shall consider the four dimensional pure Yang–Mills theory of the Sec. III, the generalization to other models being straightforward.

The rigid gauge invariance is an exact symmetry of the Yang–Mills action (3.9), expressing the simple fact that all the fields and antifields belong to the adjoint representation of the gauge group,

$$\mathscr{R}_a^{\text{rig}}\Sigma = \int d^4x f_{abc}\left(A^b_\mu\frac{\delta\Sigma}{\delta A^c_\mu} + A^{*b}_\mu\frac{\delta\Sigma}{\delta A^{*c}_\mu} + c^b\frac{\delta\Sigma}{\delta c^c} + C^{*b}\frac{\delta\Sigma}{\delta C^{*c}}\right) = 0. \tag{5.1}$$

Let us consider now the following integrated local polynomial, linear in the (shifted) antifields (A^*_μ, C^*), of ghost number -1, dimension four, and possessing a group index in the adjoint representation

$$\Omega_a^{-1} = \int d^4x f_{abc}(A^{b\mu}A^{*c}_\mu - c^b C^{*c}) \tag{5.2}$$

As in the case of the vector cocycle of Eq. (2.5), the above expression turns out to be the BRST invariant. In fact we have

$$\mathscr{B}_\Sigma \Omega_a^{-1} = \mathscr{R}_a^{\rm rig}\Sigma = 0, \tag{5.3}$$

due to the rigid invariance (5.1). The operator $\mathscr{B}_\Sigma$ appearing in the above equation is the linearized Slavnov–Taylor operator defined in Eq. (3.11). However, unlike the vector cocycle Ω_ν^{-1}, the cocycle Ω_a^{-1} is always $\mathscr{B}_\Sigma$-exact, due to a very well known result of the BRST cohomology stating that there are no nontrivial cohomology classes with one group index.[24] Therefore we may write

$$\Omega_a^{-1} = \mathscr{B}_\Sigma \Xi_a^{-2}, \tag{5.4}$$

for some local integrated polynomial Ξ_a^{-2} of ghost number -2 and dimension four. From Table I it follows that the most general form for Ξ_a^{-2} can be written as

$$\Xi_a^{-2} = \zeta \int d^4x C_a^*, \tag{5.5}$$

ζ being an arbitrary parameter. Using the expression of the operator $\mathscr{B}_\Sigma$ of Eq. (3.11) and of the reduced Yang–Mills action Σ given in Eq. (3.9), the condition (5.4) becomes

$$\int d^4x f_{abc}(A^{b\mu}A_\mu^{*c} - c^b C^{*c}) = \zeta \int d^4x \, \frac{\delta \Sigma}{\delta c^a} = \zeta \int d^4x f_{abc}(A^{b\mu}A_\mu^{*c} - c^b C^{*c}), \tag{5.6}$$

which gives $\zeta = 1$. Moving now from the reduced action Σ to the complete Yang–Mills action $\mathscr{S}$ (3.9) and making use of the gauge condition (3.5) and of the definition (3.7), Eq. (5.6) takes the form

$$\int d^4x \left(\frac{\delta \mathscr{S}}{\delta c^a} - f_{abc}\overline{c}^b \frac{\delta \mathscr{S}}{\delta b^c} \right) = \int d^4x f_{abc}(A^{b\mu}\hat{A}_\mu^{*c} - c^b C^{*c}) + \alpha \int d^4x f_{abc} b^b \overline{c}^c. \tag{5.7}$$

We observe that the left-hand side of this equation, besides a pure linear breaking, contains a term which is quadratic in the quantum fields, i.e., $\alpha f_{abc} b^b \overline{c}^c$. This term, being subject to renormalization, would have been defined as an insertion, spoiling then the usefulness of Eq. (5.7). Therefore we see that the requirement that the breaking term is at most linear in the quantum fields implies again the vanishing of the gauge parameter, $\alpha = 0$. Setting then $\alpha = 0$ in the gauge condition (3.5), we obtain the linearly broken identity

$$\int d^4x \left(\frac{\delta \mathscr{S}}{\delta c^a} - f_{abc}\overline{c}^b \frac{\delta \mathscr{S}}{\delta b^c} \right) = \int d^4x f_{abc}(A^{b\mu}\hat{A}_\mu^{*c} - c^b C^{*c}), \tag{5.8}$$

which is recognized to be the so-called *ghost equation* Ward identity,[23] always present in the Landau gauge. Let us conclude by recalling that the ghost equation (5.8), although valid only in the Landau gauge, turns out to be a very useful tool in order to study the ultraviolet finiteness properties of a large class of gauge invariant local field polynomials.[36] These gauge invariant polynomials can be promoted at the quantum level to local insertions whose anomalous dimensions are independent from the gauge fixing parameter α. Therefore they can be studied without loss of generality in the Landau gauge. In particular, the ghost equation (5.8) allows us to prove the vanishing of the anomalous dimensions of the invariant ghost monomials $\mathrm{tr}(c^{2n+1})$, which are deeply related to the gauge anomalies and to the generalized Chern–Simons terms.[10] (We have used here the matrix notation $c = c^a T_a$, T_a being the generators of the gauge group, $[T_a, T_b] = i f_{ab}{}^c T_c$.) This result is of great importance in order to prove the Adler–Bardeen nonrenormalization theorem for the gauge and the $U(1)$ axial anomalies.[36,37,10] We mention, finally, that the ghost equation (5.8) has been proven to be renormalizable.[10,23] Recently, it has been extended to the case of $N = 1$ supersymmetric gauge theories in superspace.[38]

VI. CONCLUSION

A purely algebraic characterization of the topological vector susy and of the Landau ghost equation Ward identities has been provided. These Ward identities, always linearly broken, are obtained by exploiting the BRST exactness condition of suitable antifield cocycles with ghost number -1. Applications to other kinds of linearly broken Ward identities as well as to other TFT and to superspace supersymmetric models are under investigation.

Quantization of a particle in a background Yang–Mills field

Yihren Wu
Department of Mathematics, Hofstra University, Hempstead, New York 11550

(Received 27 June 1997; accepted for publication 29 October 1997)

Two classes of observables defined on the phase space of a particle are quantized, and the effects of the Yang–Mills field are discussed in the context of geometric quantization. © *1998 American Institute of Physics.* [S0022-2488(98)02202-6]

I. INTRODUCTION

Let Q be a Riemannian manifold considered as the configuration space of a particle, the purpose of this paper is to discuss the quantization of the observables on the phase space T^*Q of this particle when it is moving under the influence of a background Yang–Mills field, the Yang–Mills potential is a connection α on a principal bundle N over Q.

The free G action on N can be lifted to a Hamiltonian G action on T^*N with an equivariant moment map $J:T^*N\to\mathfrak{g}^*$. Let $\mu\epsilon\mathfrak{g}^*$, and denote by $\mathcal{O}_\mu$ the coadjoint orbit through μ. Then $J^{-1}(\mathcal{O}_\mu)/G$ has a canonical symplectic structure given by the Marsden–Weinstein reduction.[1] This reduced phase space is the appropriate phase space of a particle in a background Yang–Mills field α of charge μ.[2]

We will denote by $\mathcal{Q}(X)$ the quantization of the phase space X, suppressing in our notation the choices of polarizations and prequantization line bundles, etc., via the standard procedure of geometric quantization.[3,4] Suppose we choose the vertical polarization on T^*N so that the quantization $\mathcal{Q}(T^*N)$ of T^*N gives $L^2(N)$. Moreover, suppose the coadjoint orbit $\mathcal{O}_\mu$ is integral, so that the quantization of this coadjoint orbit gives an irreducible representation space $\mathcal{H}_\mu$ of G.[5,6] A theorem of Guillemin–Sternberg[7] (also see Ref. 8) then suggests that the quantization of $J^{-1}(\mathcal{O}_\mu)/G$ is given by $\mathrm{Hom}_G(\mathcal{H}_\mu, L^2(N))$, the space of G-equivariant linear maps from $\mathcal{H}_\mu$ to $L^2(N)$. And this result holds independent of whether there is a Yang–Mills field present in the background. Thus, when some technical assumptions are made so that the procedure of geometric quantization can be carried out smoothly, the Yang–Mills field plays no role in the quantization of the phase space $J^{-1}(\mathcal{O}_\mu)/G$.

We will discuss the effect of the Yang–Mills field in quantizing observables that are lifted from functions on T^*Q. We will show that the resulting quantum operators are expressed in terms of the covariant derivatives, which is defined by the connection α. In particular, we will show that the quantum operators for f of the form $\frac{1}{2}\|p\|^2+V(q)$ are expressed in terms of the covariant Laplace operator and the Ricci curvature. This is obtained by a standard Blattner–Kostant–Sternberg (BKS) pairing approach.[9] Our results are in agreement with those of Landsman,[10] who arrived at the conclusion via deformation quantization.

Outline of this paper is as follows; In Sec. II we give a detailed exposition of our problem in order to standardize the notations used throughout this paper. As a prelude to our result, we note that if the gauge group is Abelian, we will recover the Dirac quantization of a charge particle in the presense of an electromagnetic field. In Sec. III we introduce local coordinates to facilitate our calculation, and state some results concerning the Hamiltonian vector fields for our observables. We follow closely the treatment of[8] on the polarization chosen for the phase space in Sec. IV. Our results when f is polarization preserving are given in Sec. V, and the quantization of $\frac{1}{2}\|p\|^2+V(q)$ using BKS pairing appears in Sec. VI.

II. PRELIMINARY DISCUSSIONS

Let N be a principal G bundle over Q where G is compact, with Lie algebra $\mathfrak{g}$, and the group action is on the right. We define two functions $R_g:N\to N$ and $\hat{n}:G\to N$, where

 © 1998 American Institute of Physics

$$R_g(n)=\hat{n}(g)=ng, \tag{1}$$

and we denote by F_* the Jacobian of F. A connection is a linear map $\alpha(n):T_nN\to\mathfrak{g}$ for each $n\in N$, satisfying
(i) $\mathrm{Ad}_{g^{-1}}\alpha(n)=\alpha(ng)R_{g*}:T_nN\to\mathfrak{g}$,
(ii) $\alpha(n)\hat{n}_*=\mathrm{Id}:\mathfrak{g}\to\mathfrak{g}$.

The free G action on N can be lifted to a Hamiltonian G action on T^*N with moment map $J:T^*N\to\mathfrak{g}^*$ given by $J(\xi,n)=\hat{n}^*\cdot\xi$.

Let $N^{\#}$ be the pullback bundle over T^*Q: Explicitly,

$$N^{\#}=\{(p,n)|p\in T_q^*Q,\ \text{where}\ \ q=\pi(n)\}.$$

Define a diffeomorphism,

$$\begin{gathered}\chi:N^{\#}\times\mathfrak{g}^*\to T^*N,\\ (p,n,\mu)\to(\xi,n)\quad \text{where}\ \ \xi=\pi^*(p)+\langle\mu,\alpha\rangle\in T_n^*N.\end{gathered} \tag{2}$$

This map in turn induces an α-dependent projection $\pi_\alpha:T^*N\to T^*Q$, and their corresponding symplectic forms are related by

$$\Omega_{T^*N}=\pi_\alpha^*\Omega_{T^*Q}+\mathrm{d}\langle\mu,\alpha\rangle. \tag{3}$$

One shows that the moment map is simply the projection $N^{\#}\times\mathfrak{g}^*\to\mathfrak{g}^*$, i.e., $\chi^{-1}(J^{-1}(\mu))=N^{\#}\times\{\mu\}$. Thus, for each μ, the G action on $N^{\#}$ induces a G action on $J^{-1}(\mu)$. This action is noncanonical ($R_g^*\Omega_{T^*N}\neq\Omega_{T^*N}$) in general:

$$(\xi,n)\to(\xi_g,ng),\quad \text{where}\ \ \xi_g=R_{g^{-1}}^*\xi+R_{g^{-1}}^*[(\mathrm{Ad}_{g^{-1}}^*-\mathrm{Id})\mu]\alpha(n).$$

However, this action coincides with the canonical G action when restricted to the isotropy subgroup,

$$H=\{g\in G|\mathrm{Ad}_g^*\mu=\mu\},$$

of μ. (There $\mathrm{Ad}_{g^{-1}}^*\mu=\mu$ and $\xi_g=R_{g^{-1}}^*\xi$.) The relevant phase space becomes $J^{-1}(\mathcal{O}_\mu)/G=J^{-1}(\mu)/H=N^{\#}/H\times\{\mu\}$.

Given an observable on the phase space of the particle $f:T^*Q\to\mathbf{R}$, by the projection π_α, the pullback map, which we continue to denote by f,

$$f=\pi_\alpha^*f:T^*N\simeq N^{\#}\times\mathfrak{g}^*\to\mathbf{R}, \tag{4}$$

is invariant with respect to both the canonical G action and the noncanonical one. In particular, f is independent on the charge variables $\mu\in\mathfrak{g}^*$.

We assume that $\mathcal{O}_\mu$ is integral, so that $\mathcal{Q}(\mathcal{O}_\mu)=\mathcal{H}_\mu$ is an irreducible representation space of G induced by $\rho_\mu:H\to U(1)$. Choose an orthonormal basis $\{\phi_i\}$ for $\mathcal{H}_\mu$, where ϕ_i is a holomorphic function on the Kähler manifold G/H.[5] Then $\Psi\in\mathcal{Q}(J^{-1}(\mu)/H)=\mathrm{Hom}_G(\mathcal{H}_\mu,L^2(N))$ is determined by $\Psi(\phi_i)=\Psi_i\in L^2(N)$. Using orthonormality of ϕ_i and G equivariance of Ψ, we write

$$\Psi=\sum\ \Psi_i\phi_i:N\times G/H\to N\times_G G/H\to\mathbf{C},$$

which is uniquely determined by $\psi=\Psi(-,eH):N\to\mathbf{C}$ with the condition $\psi(nh)=\rho_\mu(h^{-1})\psi(n)$ for all $h\in H$. So we see that the Yang–Mills potential plays no role in quantizing the relevant phase space, it simply picks up the multiplicity of the charge sector $\mathcal{O}_\mu$ in $L^2(N)$ (cf. Refs. 7 and 8).

If we are to quantize an observable that is a pullback of f on the phase space of the particle T^*Q, the connection α plays an important role. As an illustration, suppose the charge $\mu\in\mathfrak{g}^*$ is G

invariant, then $H=G$. This will be the case if, for instance, G is Abelian. Under this condition, $J^{-1}(\mu)/H$ is diffeomorphic to T^*Q via the projection π_α, and the canonical symplectic form on the reduction space pushes forward onto T^*Q. So $J^{-1}(\mu)/H$ is symplectomorphic to T^*Q if T^*Q is equipped with the ''effective'' symplectic form $\Omega_{\text{eff}}=\Omega_{T^*Q}+\langle\mu,\Omega_{\mathbf{\nabla}}\rangle$, where $\Omega_{\mathbf{\nabla}}$ is a two-form on Q that pulls back to the curvature form $d\alpha$ on N.[11] It is with respect to this effective symplectic form that the quantization procedure must be carried out. Since the adjustment is a two-form on Q, quantization of T^*Q using the vertical polarization still gives $L^2(Q)$. However, Hamiltonian vector fields $\mathscr{H}_{f_i}$ associated with observables f_i and the Poisson bracket are defined in terms of the effective form

$$\Omega_{\text{eff}}(\mathscr{H}_{f_i},-)=-df_i,\quad \{f_1,f_2\}=\Omega_{\text{eff}}(\mathscr{H}_{f_1},\mathscr{H}_{f_2}).$$

The quantization of observables must preserve the Poisson bracket,

$$[\mathscr{Q}(f_1),\mathscr{Q}(f_2)]=i\hbar\mathscr{Q}(\{f_1,f_2\}).$$

When we carry out the geometric quantization with respect to Ω_{eff}, the result is the Dirac quantization with α as the vector potential associated with an electromagnetic field (cf. Ref. 3).

III. THE HAMILTONIAN VECTOR FIELDS

Let us first introduce local canonical coordinates (ξ_i,n_i) on T^*N so that $\Omega_{T^*N}=\mathrm{d}\xi_i\ \mathrm{d}n_i$, similarly (p_a,q_a) on T^*Q with $\Omega_{T^*Q}=\mathrm{d}p_a\ \mathrm{d}q_a$, and let $\alpha=A_{si}\ \mathrm{d}n_i$, where $i=1\cdots$ dim N, $a=1\cdots$ dim Q, $s=1\cdots$ dim G, and repeated indices are summed. For each $n\in N$, let us denote the horizontal lift $T_qQ\to T_nN$ by the matrix $M_{i\sigma}(n)$, $i=1\cdots$ dim N, $\sigma=1\cdots$ dim Q. We have

$$\frac{\partial q_a}{\partial n_i}M_{ib}=\delta_{ab}, \tag{5}$$

and the covariant derivative is the horizontal lift of $\partial/\partial q_a$:

$$\mathscr{D}_a=M_{ia}\frac{\partial}{\partial n_i}. \tag{6}$$

In these coordinates, the canonical one-form and the symplectic two-form of T^*N can be calculated using (3),

$$\begin{aligned}\chi^*\xi_i\ \mathrm{d}n_i&=\left(p_a\frac{\partial q_a}{\partial n_i}+\mu_sA_{si}\right)\mathrm{d}n_i,\\ \chi^*\Omega_{T^*N}&=\frac{\partial q_a}{\partial n_i}\mathrm{d}p_a\ \mathrm{d}n_i+\mu_s\frac{\partial A_{si}}{\partial n_j}\mathrm{d}n_j\ \mathrm{d}n_i+A_{si}\ \mathrm{d}\mu_s\ \mathrm{d}n_i.\end{aligned} \tag{7}$$

Let $f:N^{\#}\times\mathfrak{g}^*\to\mathbf{R}$ be a pullback function from T^*Q, and let $\mathscr{H}_f$ be its Hamitonian vector field,

$$\mathscr{H}_f=B_a\frac{\partial}{\partial p_a}+C_i\frac{\partial}{\partial n_i}+U_s\frac{\partial}{\partial\mu_s}.$$

Using $\chi^*\Omega_{T^*N}(\mathscr{H}_f,-)=-\mathrm{d}f$, we get

$$\begin{aligned}\frac{\partial f}{\partial q_a}\frac{\partial q_a}{\partial n_i}&=-B_a\frac{\partial q_a}{\partial n_i}+\mu_s\left(\frac{\partial A_{sj}}{\partial n_i}-\frac{\partial A_{si}}{\partial n_j}\right)C_j-A_{si}U_s,\\ \frac{\partial f}{\partial p_a}&=\frac{\partial q_a}{\partial n_i}C_i,\end{aligned} \tag{8}$$

$$\frac{\partial f}{\partial \mu_s} = A_{si} C_i .$$

Since f is invariant with respect to the canonical G action, $\mathscr{H}_f$ is tangent to the subspace $J^{-1}(\mu) \simeq N^{\#} \times \{\mu\}$, thus $U_s = 0$. As remarked after (4), f is independent of μ, thus $A_{si} C_i = 0$, which implies $\mathscr{H}_f$ is horizontal. Moreover, letting $B_a = -\partial f / \partial q_a + E_a$, we have

$$\mathscr{H}_f = \left[-\frac{\partial f}{\partial q_a} \frac{\partial}{\partial p_a} + C_i \frac{\partial}{\partial n_i} \right] + E_a \frac{\partial}{\partial p_a}.$$

The terms in the bracket is the horizontal lift of the Hamiltonian vector field of f with respect to the usual symplectic form Ω_{T^*Q} on T^*Q. E_a satisfies

$$E_a \frac{\partial q_a}{\partial n_i} = \mu_s \left(\frac{\partial A_{sj}}{\partial n_i} - \frac{\partial A_{si}}{\partial n_j} \right) C_j .$$

So we summarize the properties of $\mathscr{H}_f$ needed for our purpose.

Proposition 1: If $f: T^*N \to \mathbf{R}$ is a pullback of a function on T^*Q, then for all $\mu \in \mathfrak{g}$ the Hamiltonian vector field $\mathscr{H}_f$ is a vector field on the subspace $J^{-1}(\mu)$, and as the total space of a principal bundle over T^*Q with connection α, $\mathscr{H}_f$ is horizontal. If differs from the horizontal lift of the standard Hamiltonian vector field on T^*Q by a field in the vertical direction. With respect to the local coordinates chosen, we have explicitly

$$\mathscr{H}_f = \left[-\frac{\partial f}{\partial q_a} \frac{\partial}{\partial p_a} + M_{ia} \frac{\partial f}{\partial p_a} \frac{\partial}{\partial n_i} \right] + \mu_s M_{ia} M_{jb} \left(\frac{\partial A_{sj}}{\partial n_i} - \frac{\partial A_{si}}{\partial n_j} \right) \frac{\partial f}{\partial p_b} \frac{\partial}{\partial p_a}. \tag{9}$$

Furthermore, we have

$$\langle \chi^* \xi_i \, dn_i, \mathscr{H}_f \rangle = p_a \frac{\partial f}{\partial p_a}. \tag{10}$$

IV. POLARIZATION

We first state some well-known results concerning the quantization of integral coadjoint orbits $\mathscr{O}_\mu$. Let $\mathfrak{h}$ be the Lie algebra of H, we say that $\mathscr{O}_\mu$ is integral if the map

$$v \in \mathfrak{h} \to 2\pi i \langle v, \mu \rangle \tag{11}$$

is the derivative of a global character, i.e., there is a group homomorpism $\rho_\mu : H \to U(1)$ such that $\rho_{\mu *}$ is the map given in (11). A version of the Borel–Weil theorem, due to Kirillov[5] and Kostant[6] asserts that there is a one-to-one correspondence between the integral orbits of G and its unitary irreducible representations, and these representations can be constructed by the method of geometric quantization applied to the coadjoint orbit $\mathscr{O}_\mu$, which we will briefly explain.

Let $\mathscr{L}$ be the prequantization line bundle $G \times_{\rho_\mu} \mathbf{C}$ over $\mathscr{O}_\mu \simeq G/H$ with the connection induced by the map ρ_μ. It is known that $\mathscr{O}_\mu$ is a Kähler manifold with complex coordinates with respect to which the G action is holomorphic. There is a standard G–equivariant polarization quantizing with respect to the line bundle and this polarization gives $\mathscr{H}_\mu$ whose elements are holomorphic functions on $\mathscr{O}_\mu$. The polarization, known as the positive Kähler polarization, is given by left translation of a set of $v_k \in \mathfrak{g} \otimes \mathbf{C}$, the complexification of $\mathfrak{g}$, so that the polarization is generated by

$$V_k(\mathrm{Ad}_g \, \mu) = g_* v_k \in T_{\mathrm{Ad}_g \, \mu} \mathscr{O}_\mu . \tag{12}$$

As a polarization, v_k thought of as vectors in $T_\mu \mathscr{O}_\mu$ satisfies

$$\Omega_{\mathscr{O}_\mu}(v_h, v_k) = 0, \tag{13}$$

where $\Omega_{\mathcal{O}_\mu}$ is the canonical symplectic form on $\mathcal{O}_\mu$. The specifics of the choices of v_k will not be important in what follows. It is worth mentioning that V_k is contained in the vertical polarization on T^*N.

Consider the complex distribution on $N^\# \times \mathcal{O}_\mu$ generated by $\{\partial/\partial p_a, V_k\}$; it is G equivariant and thus projects onto $N^\# \times_G \mathcal{O}_\mu \simeq N^\#/H \times \{\mu\}$. One checks that the image is a polarization, which we denote by $\mathcal{P}$.[8]

It is easy to represent $\mathcal{P}$ in local coordinates on $N^\#$; $\partial/\partial p_a$ are vector fields on $N^\#$, and V_k corresponds to $\hat{n}_* v_k$ as complex vector fields on N, $\hat{n}_*$ as in (1). This is so since the assignment $(p,n,\mathrm{Ad}_g\mu) \mapsto (p,ng,\mu)$ defines the projection $N^\# \times \mathcal{O}_\mu \to N^\# \times_G \mathcal{O}_\mu \simeq N^\#/H \times \{\mu\}$. Thus, the vector field generated by G action on $\mathcal{O}_\mu$ translates to the vector field generated by G action on N.

The Hilbert space structure on $L^2(N)$ is given by integration with respect to the measure $\mathrm{d}n = \mathrm{d}\sigma \sqrt{\det(g)}\mathrm{d}q$, where $\mathrm{d}\sigma$ is a Haar measure on G that we transfer to a measure on the fiber in the projection $N \to Q$ and g is the metric on Q. Using the half-form bundle formalism the wave functions are of the form $\psi(n)\sqrt{\mathrm{d}n}$. It is clear that the of the Haar measure will play no role in our consideration as the polarization and all Hamiltonians in question are G invariant. To keep the half-form bundle formalism to a minimum, we may identify the wave functions as $\psi(n)\det g^{1/4}$. We will determine explicitly the differential operators corresponding to f, so that

$$\psi(n)\det g^{1/4} \mapsto [\mathcal{Q}(f)\psi(n)]\det g^{1/4}. \tag{14}$$

In quantizing f that is linear in the momentum variables, the $\det g^{1/4}$ term will give rise to the covariant divergence, and for $f = \frac{1}{2}\|p\|^2 + V(q)$, it results in the Ricci curvature. The appearance of the Ricci curvature is also reported in Ref. 4.

V. POLARIZATION PRESERVING CASE

If $f: T^*Q \to \mathbf{R}$ is linear in p, $f = K_a(q)p_a$, then one easily checks, using (9), that $\exp t\mathcal{H}_{f*}\mathcal{P} = \mathcal{P}$. In fact, we have the following.

Proposition 2:

$$\left[\mathcal{H}_f, \frac{\partial}{\partial p_a}\right] = \frac{\partial K_a}{\partial q_b}\frac{\partial}{\partial p_b}, \tag{15}$$

$$[\mathcal{H}_f, V_k] \in \mathrm{span}\left\{\frac{\partial}{\partial p_a}\right\}, \tag{16}$$

where the brackets refer to the Lie algebra bracket on vector fields.

Proof: Equation (15) is by direct computation. We have

$$\mathcal{H}_f = \left(E_b - p_c\frac{\partial K_c}{\partial q_b}\right)\frac{\partial}{\partial p_b} + K_b M_{ib}\frac{\partial}{\partial n_i}, \tag{17}$$

where E_b is independent of p_a, and (15) results.

To show (16), we first realize from Proposition 1 that $\mathcal{H}_f = W_1 + W_2$, where W_1 is the horizontal lift of a vector field on T^*Q, thus $[W_1, V_k] = 0$ as V_k is generated by the group action on N. W_2 is of the form $F_a(\partial/\partial p_a)$. Since V_k is independent of p, $[W_2, V_k] = V_k(F_a)(\partial/\partial p_a)$, where $V_k(F_a)$ refers to applying the vector field as a differential operator to the coefficient function F_a. □

The importance of (16) is that $[\mathcal{H}_f, V_k]$ is a combination of vectors fields in $\mathcal{P}$ that does not involve the V_h vector fields. According to (7.12) of Ref. 3, the quantization of f is then given by

$$\mathscr{Q}(f)\psi = -\frac{i\hbar}{\det g^{1/4}}\left[\mathscr{H}_f(\psi(n)\det g^{1/4}) + \frac{1}{2}\sum_{a=1}^{\dim Q}\frac{\partial K_a}{\partial q_a}(\psi(n)\det g^{1/4})\right]$$

$$= -i\hbar\left[\mathscr{H}_f(\psi) + \frac{1}{2}\left(\frac{1}{\sqrt{\det g}}\mathscr{H}_f\left(\sqrt{\det g}\right) + \sum_{a=1}^{\dim Q}\frac{\partial K_a}{\partial q_a}\right)\psi\right]. \tag{18}$$

The Hamiltonian vector field $\mathscr{H}_f$ projects to a vector field $V^{\#}$ on N, which is the horizontal lift to the projection of $\mathscr{H}_f$ onto Q, where $V = K_b(\partial/\partial q_b)$. Note that $\mathscr{H}_f(\sqrt{\det g}) = V(\sqrt{\det g})$. The divergence of the vector field V on Q is defined[12] through the relation

$$\mathrm{d}*V = \mathrm{div}\ V\sqrt{\det g}\,\mathrm{d}q.$$

The covariant divergence on N is defined as the divergence of the horizontal lift $V^{\#}$. We have

$$\mathrm{div}\ V = \frac{1}{\sqrt{\det g}}V\left(\sqrt{\det g}\right) + \sum_{a=1}^{\dim Q}\frac{\partial K_a}{\partial q_a}\ .$$

.

Using (17), (18), and the fact that ψ is independent of p, we have

Proposition 3: $\mathscr{Q}(f)\psi = -i\hbar(K_a\mathscr{D}_a + \frac{1}{2}\mathrm{div}\ V)\psi$, where $\mathscr{D}$ is the covariant derivative with respect to the connection α.

Since $\det g$ is a function of n through q, the divergence and the covariant divergence are the same.

VI. BKS PAIRING CASE

Let $\mathscr{P}$ and $\mathscr{P}'$ be transversal polarizations on T^*N, and denote their associated quantum spaces by $\mathscr{Q}$ and $\mathscr{Q}'$. The BKS pairing gives rise to a map $B:\mathscr{Q}' \to \mathscr{Q}$ such that

$$\langle B(\psi), \phi\rangle = \int_{T^*N}\psi\overline{\phi}(\det\omega)^{1/2}\,\mathrm{d}l,$$

where $\mathrm{d}l$ is the Liouville form $\mathrm{d}\xi_1\cdots\mathrm{d}\xi_n\,\mathrm{d}n_1\cdots\mathrm{d}n_n$. Since the volume form on N is $\mathrm{d}n = \sqrt{\det g}\mathrm{d}n_1\cdots\mathrm{d}n_n$, we have

$$B\psi(n) = \frac{1}{\sqrt{\det g}}\int_{T^*_nN}\psi(\det\omega)^{1/2}\,\mathrm{d}\xi_1\cdots\mathrm{d}\xi_n. \tag{19}$$

Let $f = \frac{1}{2}g^{ab}p_ap_b + V(q)$, where g^{ab} is the inverse of the metric g_{ab}. From (9), we have

$$\mathscr{H}_f = -\left(\frac{\partial V}{\partial q_a} + \frac{1}{2}\frac{\partial g^{bc}}{\partial q_a}p_bp_a\right)\frac{\partial}{\partial p_a} + M_{ia}g^{ab}p_b\frac{\partial}{\partial n_i} + \mu_sM_{ia}M_{jb}\left(\frac{\partial A_{sj}}{\partial n_i} - \frac{\partial A_{si}}{\partial n_j}\right)g^{bc}p_c\frac{\partial}{\partial p_a},$$

and note the linear dependence of the coefficients on the p variables. We denote by $\mathscr{P}_t = \exp t\mathscr{H}_{f*}\mathscr{P}$, here the two polarizations $\mathscr{P}$ and $\mathscr{P}_t$ do not intersect transversely. We claim the following.

Proposition 4: Vector fields generated by the group action are in $\mathscr{P}\cap\mathscr{P}_t$.

Proof: It suffices to show that

$$\Omega\left(\exp t\mathscr{H}_{f*}V_k, \frac{\partial}{\partial p_a}\right) = 0 \tag{20}$$

and

$$\Omega(\exp t\mathscr{H}_{f*}V_k, V_h) = 0, \tag{21}$$

with Ω as in (7). Let $\overline{p(}p,n,t)$ and $\overline{n(}p,n,t)$ denote the flow generated by $\exp t\mathscr{H}_f$ at $(p,n) \in N^{\#}$ with μ fixed, $(\overline{p,n,}\mu)=\exp t\mathscr{H}_f(p,n,\mu)$. Then $\exp t\mathscr{H}_{f*}V_k=V_k(\overline{p_a})(\partial/\partial p_a)+V_k(\overline{n_i}) \times(\partial/\partial n_i)$. So $\Omega(\exp t\mathscr{H}_{f*}V_k,\partial/\partial p_a)=(\partial q_a/\partial n_i)V_k(\overline{n_i})$. Recall that $V_k=\hat{n}_* v_k$ is vertical and $\partial q_a/\partial n_i$ is the Jacobian of the projection $\pi:N\to Q$. Then $\pi_*\hat{n}_*=0$ implies that (20) holds.

Equation (21) follows from general principle; since f is G-invariant (with respect to the noncanonical G action), V_h is equivariant with respect to the flow: $\exp t\mathscr{H}_{f*}V_h(p,n) =V_h(\exp t\mathscr{H}_f(p,n))$. Since the flow of a Hamiltonian vector field preserves the symplectic form, we have

$$\Omega(\exp t\mathscr{H}_{f*}V_k(p,n),V_h(\exp t\mathscr{H}_f(p,n)))=\Omega(V_k,V_h)=\Omega_{\mathscr{O}_\mu}(v_h,v_k)=0,$$

where v_h and v_k belong to a polarization on $\mathscr{O}_\mu$ to begin with (13). □

This being the case, quantization of f via BKS pairing involves integrating only over the p variables, i.e., the fiber coordinates of the projection $\Pi:N^{\#}\to N$. According to (7.20) of Ref. 3, together with the similarity transform (14) adjustment and the adjustment in the BKS pairing described in (19),

$$\mathscr{Q}(f)\psi(n)=\frac{1}{\det g^{1/2}}\frac{1}{\det g^{1/4}}\, i\hbar\frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{t=0}\Psi_t(n), \tag{22}$$

where

$$\Psi_t(n)=(i\hbar)^{-\dim Q/2}\int_{\Pi^{-1}(n)}[\det\omega_{ab}]^{1/2}\exp(i\hbar^{-1}L)\Psi(p,n,t)\mathrm{d}p, \tag{23}$$

$$\Psi(p,n,t)=\psi(\overline{n(}p,n,t))\times[\det g(\overline{n(}p,n,t))]^{1/4}, \tag{24}$$

$$\omega_{ab}=\Omega\left(\frac{\partial}{\partial p_a},\exp t\mathscr{H}_{f*}\frac{\partial}{\partial p_b}\right), \tag{25}$$

$$L=t\left(\frac{1}{2}\|p\|^2+V(q)\right)-2\int_0^t V(\overline{n(}p,n,s))\mathrm{d}s. \tag{26}$$

The manipulation follows closely that of Sniatycki.[3] Making the substitution $x_a=tp_a$, we have results analogous to (7.26) and (7.27) of Ref. 3.

Proposition 5:

$$\lim_{t\to 0+} t^{-\dim Q/2}\exp\left(\frac{i}{\hbar}\frac{\|x\|^2}{2t}\right)=(2\pi\hbar)^{\dim Q/2}e^{\pi i\,\mathrm{sgn}(g)/4}\sqrt{\det g}\,\delta(x), \tag{27}$$

$$\frac{\partial}{\partial t}t^{-\dim Q/2}\exp\left(\frac{i}{\hbar}\frac{\|x\|^2}{2t}\right)=\frac{i\hbar}{2}g_{ab}\frac{\partial^2}{\partial x_a\,\partial x_b}t^{-\dim Q/2}\exp\left(\frac{i}{\hbar}\frac{\|x\|^2}{2t}\right). \tag{28}$$

Proof: The first equation follows from the method of the stationary phase (cf. Ref. 13), which for n-dimensional space reads as

$$\int_{\mathbf{R}^n}\alpha(y)e^{ik\phi(y)}\,\mathrm{d}y=\left(\frac{2\pi}{k}\right)^{n/2}\sum_{y|\mathrm{d}\phi(y)=0}e^{\pi i\,\mathrm{sgn}\,H(y)/4}\frac{e^{ik\phi(y)}\alpha(y)}{\sqrt{|\det H(y)|}}+O(k^{-n/2-1}). \tag{29}$$

The $1/t$ factor in (27) plays the role of the large parameter k. H is the Hessian of ϕ, which in our case is $g^{\mu\nu}$; thus $\det H=\det g^{-1}$ and sgn is the signature of the metric. The only stationary point in (27) is $x=0$, thus the right-hand side of (27) has a (dim Q-dimensional) delta function at $x=0$.

The second equation is a straightforward computation. We need the fact that $g_{\alpha\mu}g^{\mu b}=\delta_{ab}$, and $\Sigma_a\Sigma_b g_{ab}g^{ab}=\Sigma_a\delta_{aa}=\dim Q$ in the course of the computation. □

One checks that ω_{ab} in (25) is

$$\frac{\partial q_a}{\partial n_i}\,\frac{\partial \overline{n_i}}{\partial p_b} = t g^{ab} + \text{higher-order terms in } t,$$

using (30) below. Then $[\det \omega_{ab}]^{1/2}\, \mathrm{d}p \sim t^{-\dim Q/2}\, \mathrm{d}x$, providing us with the needed factor to apply the results of Proposition 5. Thus, in determining $\mathrm{d}/\mathrm{d}t\big|_{t=0}\Psi_t(n)$, we need only to consider terms involving t, tp_a, and $t^2 p_a p_{\underline{b}}$ while ignoring terms of the form $t^2 p_a$ and all higher-order terms. Using (9), the expansion of $\overline{n}$, expressed in the t and x_a variables up to the relevant terms, are

$$\widetilde{n}_i(n,x) = n_i + M_{ia} g^{\mu a} x_\mu + \frac{1}{2}\left[M_{jb}\left(\frac{\partial M_{ia}}{\partial n_j}\, g^{\nu b} g^{\mu a} + M_{ia}\, \frac{\partial g^{\mu a}}{\partial q_b}\, g^{\nu b} \right) - \frac{1}{2}\, M_{ia}\, \frac{\partial g^{\mu\nu}}{\partial q_b}\, g^{ba} \right] x_\mu x_\nu, \tag{30}$$

which is independent of t. And $\Psi_t(n)$ in (23) is reduced to

$$\Psi_t(n) = (i\hbar)^{-\dim Q/2} \int_{\Pi^{-1}(n)} t^{-\dim Q/2}\, \exp\left(\frac{i}{\hbar}\, \frac{\|x\|^2}{2t} \right) \Phi(n,x,t)\, \mathrm{d}x,$$

where

$$\Phi(n,x,t) = \exp(-i\hbar^{-1} t V(q)) \times \psi(\overline{n}(n,x)) \det g(\overline{n}(n,x))^{1/4}. \tag{31}$$

By applying Proposition 5, integration by parts yields

$$\mathscr{Q}(f)\psi(n) = \frac{(-2\pi i)^{\dim Q/2} e^{\pi i\, \mathrm{sgn}/4}}{\det g^{1/4}} \left[-\frac{\hbar^2}{2}\, g_{ab}\, \frac{\partial^2 \Phi}{\partial x_a\, \partial x_b}\bigg|_{x,t=0} + i\hbar\, \frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{x=t=0} \Phi \right]. \tag{32}$$

The $\sqrt{\det H}$ term that appears in the method of stationary phase formula results in a $g^{1/2}$ factor (27) that cancels with the $\det g^{1/2}$ on the right-hand side of (22).

Since n is fixed, we can choose a normal coordinate system[12] around $q = \pi(n)$ so that $\partial g^{\mu\nu}/\partial q_a = 0$ for all μ, ν, and q_a when evaluated at n (i.e., at $x = t = 0$). A direct computation shows that

$$\frac{\mathrm{d}}{\mathrm{d}t}\bigg|_{x=t=0} \Phi(n,x,t) = -i\hbar^{-1} V(q)\psi(n) \det g^{1/4}, \tag{33}$$

$$g_{ab}\, \frac{\partial^2}{\partial x_a\, \partial x_b}\bigg|_{x=t=0} \Phi(n,x,t) = \det g^{1/4} \bigg[g^{\mu\nu} M_{j\nu}\, \frac{\partial M_{i\mu}}{\partial n_j}\, \frac{\partial \psi}{\partial n_i} + g^{\mu\nu} M_{i\mu} M_{j\nu}\, \frac{\partial^2 \psi}{\partial n_i\, \partial n_j} + \frac{1}{4}\, g^{\mu\nu} g^{ab}\, \frac{\partial^2 g_{\mu\nu}}{\partial q_a\, \partial q_b} \bigg]. \tag{34}$$

Here we have made repeated use of the identity (Ref. 12 p. 302)

$$\frac{1}{\det g}\, \frac{\partial \det g}{\partial q_b} = \frac{1}{\det g}\, \frac{\partial \det g}{\partial g_{\mu\nu}}\, \frac{\partial g_{\mu\nu}}{\partial q_b} = g^{\mu\nu}\, \frac{\partial g_{\mu\nu}}{\partial q_b}.$$

In normal coordinates, the covariant Laplace operator reduces to

$$\Delta_\alpha \psi = \frac{1}{\det g^{1/2}}\, \mathscr{D}_\mu (\det g^{1/2} g^{\mu\nu}\, \mathscr{D}_\nu \psi) = g^{\mu\nu} M_{i\mu} M_{j\nu}\, \frac{\partial^2 \psi}{\partial n_i\, \partial n_j} + g^{\mu\nu} M_{j\nu}\, \frac{\partial M_{i\mu}}{\partial n_j}, \tag{35}$$

and the Ricci curvature becomes

$$R = g^{ik}(\partial_k \Gamma^j_{ji} - \partial_j \Gamma^j_{ki} + \Gamma^j_{km}\Gamma^m_{ji} - \Gamma^j_{jm}\Gamma^m_{ki}) = (g^{ik} g^{\mu\nu} - g^{i\nu} g^{k\mu})\partial_i\, \partial_k g_{\mu\nu} = \tfrac{3}{2} g^{ik} g^{\mu\nu} \partial_i\, \partial_k g_{\mu\nu}. \tag{36}$$

Here Γ^k_{ij} are the Christoffel symbols, and the identity

$$\Gamma^m_{ij,k}+\Gamma^m_{jk,i}+\Gamma^m_{ki,j}=0$$

is used to show $g^{i\nu}g^{k\mu}\partial_i\,\partial_k g_{\mu\nu}=-\frac{1}{2}g^{ik}g^{\mu\nu}\partial_i\,\partial_k g_{\mu\nu}$. We must caution the readers that these expressions only hold in normal coordinates. However, by combining (32)–(36) we can express our final result in a coordinate invariant form.

Proposition 6. Quantization of $f=\frac{1}{2}\|p\|2+V(q)$ gives

$$\mathscr{Q}(f)\psi(n)=(-2\pi i)^{\dim Q/2}e^{\pi i\,\mathrm{sgn}(g)/4}\left(-\frac{\hbar^2}{2}\left[\Delta_\alpha+\frac{1}{6}R\right]+V(q)\right)\psi(n).$$

We conclude with a final remark. The Yang–Mills field is defined[14] as the curvature $\mathscr{D}\alpha$ of the Yang–Mills potential α, whereas the contribution of this connection in the local expression of the symplectic form is $d\alpha$. They are related by

$$\mathscr{D}\alpha(v,w)=\mathrm{d}\,\alpha(\mathrm{hor}\,v,\mathrm{hor}\,w),$$

where hor denotes the horizontal projection. Since the vector fields of concern are all horizontal, the effect of $\mathrm{d}\alpha$ is equivalent to the curvature.

ACKNOWLEDGMENT

We wish to thank N. P. Landsman for helpful comments on the preliminary version of this work.

(Received 7 April 1997; accepted for publication 12 September 1997)

The Hamiltonian framework on symplectic and cosymplectic manifolds is extended in order to consider classical field theories. To do this, the notion of *k*-cosymplectic manifold is introduced, and a suitable Hamiltonian formalism is developed so that the field equations for scalar and vector Hamiltonian functions are derived. © *1998 American Institute of Physics.* [S0022-2488(98)01102-5]

I. INTRODUCTION

There are many attempts in recent years to develop a Hamiltonian formalism for classical field theories. In the 1960s the so-called multisymplectic formalism was developed by the Tulczyjew school in Warsaw (see Refs. 1–4) and independently by García and Pérez-Rendón[5,6] and Goldschmidt and Sternberg.[7] This approach was revisited by Martin,[8,9] Gotay,[10,11] and more recently by Cantrijn *et al.*,[12–14] de León *et al.*,[15,16] Sardanashvily,[17,18] Kanatchikov,[19] and Echevarría *et al.*[20] (also see Refs. 21 and 22).

At the same time, other approaches were suggested, with different names but defining the same geometrical object. Thus, Gunther introduced the so-called polysymplectic structures,[23] Awane[24,25] the *k*-symplectic manifolds, also discussed by Puta[26] and Norris (see Ref. 27 and the references therein), and de León *et al.*[28,29] studied the so-called *p*-almost cotangent structures. Along this paper, we shall adopt the name of a (almost) *k*-symplectic structure. The original idea in all these papers was to abstract the geometrical ingredients of the *k*-cotangent bundle $(T^1_k)^*Q$ of a manifold Q, say the manifold of 1-jets with target $0 \in \mathbf{R}^k$ of all the mappings from Q into $\mathbf{R}^k$. Since $(T^1_k)^*Q$ may be canonically identified with the Whitney sum of k copies of T^*Q, we can transport the canonical symplectic structure on it to $(T^1_k)^*Q$. It should be noticed that the vertical distribution has to be incorporated in the game. This structure can be also derived by using the solder form of the linear frame bundle of Q (see Ref. 27). We also remark that in Ref. 29 it was presented an integrability theorem that provides Darboux coordinates as in the symplectic case.

Given a *k*-symplectic manifold, we obtain a Hamiltonian system by introducing a Hamiltonian function. Thus, the corresponding field equations can be derived[23] as the integral sections of a *k*-vector field. Moreover, if we consider vector-valued Hamiltonian functions, we obtain a Hamiltonian vector field, and in this case, the Hamiltonian has to be of polynomial form.[24,25]

The purpose of this paper is to extend the study to the case of field equations involving the independent parameters in an explicit way; in other words, the Hamiltonian function is of the form $H(t^i,x^\alpha,x^i_\alpha)$, where $1 \leqslant i \leqslant k$, $1 \leqslant \alpha \leqslant n$. To define a convenient geometrical structure, we extract the geometric ingredients of the so-called stable cotangent bundle of k^1-covelocities $\mathbf{R}^k$

 © 1998 American Institute of Physics

$\times(T^1_k)^*Q$ of a manifold Q. Thus, a family $(\eta_i,\omega_i,V;\ 1\leqslant i\leqslant k)$, where each η_i is a 1-form, each ω_i is a 2-form, and V is an nk-dimensional distribution on a $k(n+1)+n$-dimensional manifold M satisfying some compatibility relations, will be called an almost k-cosymplectic structure on M, and M an almost k-cosymplectic manifold. After identifying such a structure as a kind of G-structure on M, an integrability theorem is proved and Darboux coordinates are introduced on a k-cosymplectic manifold (Sec. II). This result shows that a k-cosymplectic manifold is locally isomorphic to a stable cotangent bundle of k^1-covelocities; in Sec. III we prove that, under some global conditions, there is also a global isomorphism. In Sec. IV, we introduce the dynamics; in fact, the geometry of a k-cosymplectic manifold allows us to write the field equations in a global way. An example is discussed. The case of vector-valued Hamiltonian functions is studied in Sec. V. Finally, we compare our geometrical approach with the so-called multisymplectic formalism (Sec. VI). In a forthcoming paper we shall examine the corresponding Euler–Lagrange formalism.

II. ALMOST *k*-COSYMPLECTIC STRUCTURES

Let $\pi:\mathbf{R}^k\times Q\to Q$ be a trivial fibered manifold and denote by $J^1\pi$ the manifold of 1-jets of local sections of π, $J^1\pi$ will be called the stable cotangent bundle of k^1-covelocities of the manifold Q. $J^1\pi\to Q$ is a vector bundle over Q with standard fiber $\mathbf{R}^k\times\mathbf{R}^{nk}$, where $\dim Q=n$. We have a canonical identification $J^1\pi\cong\mathbf{R}^k\times(T^1_k)^*Q$ in such a way that we can introduce local coordinates on $\mathbf{R}^k\times(T^1_k)^*Q$ as follows. If (x^α) are local coordinates on Q, then $(t^i,x^\alpha,x^i_\alpha)$, $1\leqslant i\leqslant k$, $1\leqslant\alpha\leqslant n$, is a local coordinate system on $\mathbf{R}^k\times(T^1_k)^*Q$. The reason for the above notation is the following. For $k=1$ we have $J^1\pi\cong\mathbf{R}\times T^*Q$, and (t,q^α,p_α) stands for the canonical coordinates on it.

Define a family $((\eta_0)_i,(\omega_0)_i,V_0)$ of 1-forms $(\eta_0)_i$, 2-forms $(\omega_0)_i$ and a distribution V_0 given by

$$(\eta_0)_i=dt^i,\quad (\omega_0)_i=dx^\alpha\wedge dx^i_\alpha,\quad V_0=\left\langle\frac{\partial}{\partial x^1_\alpha},\ldots,\frac{\partial}{\partial x^k_\alpha}\right\rangle.$$

A simple inspection in local coordinates shows that the following relations hold:

(i) $(\eta_0)_1\wedge\cdots\wedge(\eta_0)_k\neq 0$,
(ii) $\dim(\ker(\omega_0)_1\cap\cdots\cap\ker(\omega_0)_k)=k$,
(iii) $\ker(\eta_0)_1\cap\cdots\cap\ker(\eta_0)_k\cap\ker(\omega_0)_1\cap\cdots\cap\ker(\omega_0)_k=\{0\}$,
(iv) $(\eta_0)_{i|V0}=0$, $(\omega_0)_{i|V0\times V0}=0$ $(1\leqslant i\leqslant k)$.

Inspired in the above geometrical model, we introduce the following definition.

Definition II.1: Let M be a differentiable manifold of dimension $k(n+1)+n$. A family $(\eta_i,\omega_i,V;\ 1\leqslant i\leqslant k)$ where each η_i is a 1-form, each ω_i is a 2-form, and V is an nk-dimensional distribution on M, such that

(i) $\eta_1\wedge\cdots\wedge\eta_k\neq 0$,
(ii) $\dim(\ker\omega_1\cap\cdots\cap\ker\omega_k)=k$,
(iii) $\ker\eta_1\cap\cdots\cap\ker\eta_k\cap\ker\omega_1\cap\cdots\cap\ker\omega_k=\{0\}$,
(iv) $\eta_{i|V}=0$, $\omega_{i|V\times V}=0$ $(1\leqslant i\leqslant k)$,

will be called an *almost k-cosymplectic structure*, and the manifold M an *almost k-cosymplectic manifold.*

In particular, if $k=1$, then $\dim M=2n+1$, and (η,ω) is an almost cosymplectic structure on M,[30,31] and (η,ω,V) an almost stable cotangent structure on M.[32] From the conditions of Definition II.1 we deduce that there exist k vector fields $\xi_1,\ldots,\xi_k$ on M satisfying

$$\iota_{\xi_i}\eta_j=\delta_{ij},\quad \iota_{\xi_i}\omega_j=0, \tag{1}$$

with $1\leqslant i,\ j\leqslant k$, and that will be called the Reeb vector fields associated to the almost k-cosymplectic structure. Our intention is to get integrability conditions that provide Darboux coordinates for such a kind of geometrical structure. To go further in this direction, we first shall

describe an almost k-cosymplectic structure as a type of G-structure. Let us recall that a G-structure on an m-dimensional manifold M is a G-reduction of the linear frame bundle of M.[33] Here G a Lie subgroup of $Gl(m,\mathbf{R})$.

Define k distributions $V_1,\ldots,V_k$ on M by

$$V_i=\cap_{j\neq i}\ \ker\ \omega_j\cap\ker\ \eta_1\cap\cdots\cap\ker\ \eta_k.$$

Then

$$V_i\subset V,\quad \dim\ V_i=n,\quad V_i\cap(+_{j\neq i}V_j)=\{0\},$$

for all $1\leqslant i\leqslant k$, and therefore we have

$$V=V_1\oplus\cdots\oplus V_k.$$

Since (1) we can choose a linear frame at a point $x\in M$ of the form $\{\xi_1,\ldots,\xi_k,Y_{k+1},\ldots,Y_{k(n+1)+n}\}$, such that

$$\langle Y_{k+1},\ldots,Y_{k(n+1)+n}\rangle=\ker\ \eta_1\cap\cdots\cap\ker\ \eta_k,$$

$$\langle Y_{k+in+1},\ldots,Y_{k+in+n}\rangle=V_i,$$

for all $1\leqslant i\leqslant k$. Moreover, we have $\langle\xi_1,\ldots,\xi_k\rangle=\ker\ \omega_1\cap\cdots\cap\ker\ \omega_k$. With respect to this linear frame, each ω_i is written as

$$\omega_i=\begin{pmatrix}0&0&\cdots&0&\cdots&0\\0&P_i&\cdots&-Q_i^t&\cdots&0\\\vdots&\vdots&&\vdots&&\vdots\\0&Q_i&\cdots&0&\cdots&0\\\vdots&\vdots&&\vdots&&\vdots\\0&0&\cdots&0&\cdots&0\end{pmatrix},$$

with $P_i=-P_i^t$ and $\det Q_i\neq 0$. We construct a new frame $\{\xi_1,\ldots,\xi_k,X_{k+1},\ldots,X_{k(n+1)+n}\}$ at x given by the formula

$$\begin{pmatrix}\xi_1\\\vdots\\\xi_k\\X_{k+1}\\\vdots\\X_{k(n+1)+n}\end{pmatrix}=(\xi_1,\ldots,\xi_k,Y_{k+1},\ldots,Y_{k(n+1)+n})\begin{pmatrix}I_k&0&0&\cdots&0\\0&A&0&\cdots&0\\0&B_1&C_1&\cdots&0\\\vdots&\vdots&\vdots&&\vdots\\0&B_k&0&\cdots&C_k\end{pmatrix},$$

where

$$A=Q_k^{-1},\quad C_k=I_n,\quad B_k=\tfrac{1}{2}\,(Q_k^{-1})^tP_kQ_k^{-1},$$

$$C_i=(Q_i^{-1})^tQ_k^t,\quad B_i=\tfrac{1}{2}\,(Q_i^{-1})^tP_iQ_k^{-1},$$

for all $1\leqslant i\leqslant k$. With respect to this new frame (called adapted to the k-cosymplectic structure) the forms $\omega_1,\ldots,\omega_k$, are expressed by the matrices $(\omega_1)_0,\ldots,(\omega_k)_0$ given by

$$(\omega_1)_0=\begin{pmatrix} 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & -I_n & \cdots & 0 \\ 0 & I_n & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix},\ldots,(\omega_k)_0=\begin{pmatrix} 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & -I_n \\ 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & I_n & 0 & \cdots & 0 \end{pmatrix}.$$

Each pair of adapted frames is related by a change with associated matrix

$$\begin{pmatrix} I_k & 0 & 0 & \cdots & 0 \\ 0 & A & 0 & \cdots & 0 \\ 0 & B_1 & C & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & B_k & 0 & \cdots & C \end{pmatrix},$$

with $B_i^tA=A^tB_i$ and $C=(A^{-1})^t$ for all $1\leqslant i\leqslant k$. The group G of such matrices is a Lie subgroup of $Gl(k(n+1)+n,\mathbf{R})$. Now we obtain a G-structure on M by collecting all the adapted linear frames at all the points of M. Conversely, let us suppose a given G-structure $\mathbf{B}$ on M. Then we may define an almost k-cosymplectic structure $(\eta_i,\omega_i,V;1\leqslant i\leqslant k)$ on M, as follows. If $\{e_1,\ldots,e_{k(n+1)+n}\}$ is the canonical basis of $\mathbf{R}^{k(n+1)+n}$ and $\{e^1,\ldots,e^{k(n+1)+n}\}$ is the corresponding dual basis, we set $(\eta_i)_x(X)=e^i(u^{-1}(X))$, $(\omega_i)_x(X,Y)=(u^{-1}(X)(\omega_i)_0(u^{-1}(Y))^t$, and

$$V_x=u(\langle e_{k+n+1},\ldots,e_{k(n+1)+n}\rangle),$$

where $x\in M$, $X,Y\in T_xM$, and $u\in B$ is an adapted linear frame,

$$u:\mathbf{R}^{k(n+1)+n}\to T_xM.$$

Summing up, we have proved the following.

Proposition II.2: A manifold M of dimension $k(n+1)+n$ admits an almost k-cosymplectic structure if and only if the structure group of its tangent bundle is reducible to the group G of matrices of the form

$$\begin{pmatrix} I_k & 0 & 0 & \cdots & 0 \\ 0 & A & 0 & \cdots & 0 \\ 0 & B_1 & C & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & B_k & 0 & \cdots & C \end{pmatrix},$$

with $B_i^tA=A^tB_i$ and $C=(A^{-1})^t$ for all $1\leqslant i\leqslant k$.

Definition II.3: Let M be a $k(n+1)+n$-dimensional manifold with an almost k-cosymplectic structure (η_i,ω_i,V). We say that (η_i,ω_i,V) is integrable if the corresponding G-structure is integrable, and in such a case it is called *k-cosymplectic.*

A G structure on a manifold M is said to be integrable[33] if around each point of M there exist local coordinates (z^u) such that the local frame $\{\partial/\partial z^u\}$ is adapted to the G-structure, that is, it takes values in the reduced G-bundle.

Therefore, an almost k-cosymplectic structure (η_i,ω_i,V) on a manifold M is integrable if around each point of M there exist local coordinates $(s^i,x^\alpha,x^i_\alpha;1\leqslant i\leqslant k,1\leqslant\alpha\leqslant n)$ such that

$$\eta_i=ds^i,\quad \omega_i=dx^\alpha\wedge dx^i_\alpha,\quad V=\left\langle\frac{\partial}{\partial x^1_\alpha},\ldots,\frac{\partial}{\partial x^k_\alpha}\right\rangle_{\alpha=1,\ldots,n}. \tag{2}$$

Such coordinate functions will be called *Darboux* or *canonical coordinates*.

The following theorem characterizes the integrability of a k-cosymplectic structure.

Theorem II.4: *An almost k-cosymplectic structure* (η_i,ω_i,V) *on a manifold* M *is integrable if and only if the following conditions are satisfied:*

$$d\eta_i=0, \quad d\omega_i=0, \quad [V,V]\subset V \quad (1\leqslant i\leqslant k). \tag{3}$$

Proof: The integrability of a G structure obviously implies (3). Conversely, let us suppose that (3) holds. Define $K_x=\ker\ \eta_1(x)\cap\cdots\cap\ker\ \eta_k(x)$, for each $x\in M$. We have

$$T_xM=\langle\xi_1\rangle_x\oplus\cdots\oplus\langle\xi_k\rangle_x\oplus K_x,$$

and the distributions

$$\langle\xi_1\rangle,\langle\xi_2\rangle,\ldots,\langle\xi_k\rangle,K_x,$$

are all of them integrable. Moreover, the sum of each pair of these distributions is also integrable and $TM=\langle\xi_1\rangle\oplus\cdots\oplus\langle\xi_k\rangle\oplus K$. From Lemma 1.3 of Ref. 34 we deduce that for every point $x\in M$ there exists a local coordinate system $(\overline{t_i},\overline{x^\alpha},\overline{x^i_\alpha};1\leqslant i\leqslant k,1\leqslant\alpha\leqslant n)$ in a neighborhood U of x, such that

$$\langle\xi_i\rangle=\left\langle\frac{\partial}{\partial t_i}\right\rangle, \quad K=\left\langle\frac{\partial}{\partial\overline{x^\alpha}},\frac{\partial}{\partial\overline{x^i_\alpha}}\right\rangle_{\substack{1\leqslant\alpha\leqslant n\\ 1\leqslant i\leqslant k}}.$$

On $\overline{U}$, for each fixed $1\leqslant i\leqslant k$, we have

$$\xi_i=f_i\,\frac{\partial}{\partial\overline{t_i}},$$

and, since $\eta_j(\xi_i)=\delta_{ij}$, we deduce that

$$\eta_i=\frac{1}{f_i}\,d\overline{t_i}=g_i\,d\overline{t_i}.$$

Since the 1-forms $\eta_1,\ldots,\eta_k$ are closed, we get

$$0=d\eta_i=\frac{\partial g_i}{\partial\overline{t_j}}\,d\overline{t_j}\wedge d\overline{t_i}+\frac{\partial g_i}{\partial\overline{x^\alpha}}\,d\overline{x^\alpha}\wedge d\overline{t_i}+\frac{\partial g_i}{\partial\overline{x^\alpha_j}}\,d\overline{x^\alpha_j}\wedge d\overline{t_i},$$

which implies

$$\frac{\partial g_i}{\partial\overline{x^\alpha}}=0=\frac{\partial g_i}{\partial\overline{x^\alpha_j}},$$

for all $1\leqslant i,\ j\leqslant k,\ 1\leqslant\alpha\leqslant n$, and

$$\frac{\partial g_i}{\partial\overline{t_j}}=0,$$

for all $1\leqslant i,\ j\leqslant k,\ i\neq j$. Then $g_i=g_i(\overline{t_i})$ and we can define k functions $h^i=h^i(\overline{t_i})$ where each h^i is a primitive function of g_i. Define a new coordinate system $(\widetilde{t}_i,\widetilde{x}^\alpha,\widetilde{x}^i_\alpha)$ on a neighborhood $\widetilde{U}$ of x by

$$\widetilde{t}_i=h^i(\overline{t_i}), \quad \widetilde{x}^\alpha=\overline{x^\alpha}, \quad \widetilde{x}^i_\alpha=\overline{x^i_\alpha},$$

for $1\leqslant i\leqslant k$ and $1\leqslant\alpha\leqslant n$. With respect to these coordinates, we write

$$\eta_i = d\widetilde{t}_i, \quad \xi_i = \frac{\partial}{\partial \widetilde{t}_i}, \quad K = \left\langle \frac{\partial}{\partial \widetilde{x}^\alpha}, \frac{\partial}{\partial \widetilde{x}^i_\alpha} \right\rangle_{\substack{1\leqslant\alpha\leqslant n \\ 1\leqslant i\leqslant k}}.$$

Since K is an integrable distribution there exists an integral submanifold W of K through x such that $(W,\omega_1,\ldots,\omega_k,V)$ is a k-symplectic manifold (see Refs. 24, 25, 28, and 29). Then there exists a coordinate neighborhood (U',x^α,x^i_α) with $1\leqslant i\leqslant k$, $1\leqslant\alpha\leqslant n$, in W such that

$$\omega_{i_{|U'}} = dx^\alpha \wedge dx^i_\alpha, \quad V_{|U'} = \left\langle \frac{\partial}{\partial x^1_\alpha}, \ldots, \frac{\partial}{\partial x^k_\alpha} \right\rangle_{1\leqslant\alpha\leqslant n},$$

for all $1\leqslant i\leqslant k$. If the coordinate functions $\widetilde{t}_i$ of $\widetilde{U}$ are defined in $(-\epsilon_i,\epsilon_i)$, for each $1\leqslant i\leqslant k$, we take the following coordinate neighborhood of x in M:

$$(\mathbf{U} = (-\epsilon_1,\epsilon_1)\times\cdots\times(-\epsilon_k,\epsilon_k)\times U', s^i, x^\alpha, x^i_\alpha),$$

with $s^i = \widetilde{t}_i$, and then we have

$$\begin{aligned}\omega_i = {} & (A_i)^j_r\, ds^j\wedge ds^r + (B_i)^j_\alpha\, ds^j\wedge dx^\alpha + (C_i)^j_{\alpha,s} ds^j\wedge dx^r_\alpha \\ & + (D_i)^\alpha_{\beta,j}\, dx^\alpha\wedge dx^j_\beta + (E_i)^\alpha_\beta\, dx^\alpha\wedge dx^\beta + (F_i)^{\alpha,j}_{\beta,s}\, dx^j_\alpha\wedge dx^r_\beta.\end{aligned}$$

Since $\iota_{\xi_j}\omega_i = 0$, we deduce that

$$(A_i)^j_r = (B_i)^j_\alpha = (C_i)^j_{\alpha,s} = 0,$$

for all $1\leqslant i,j,\ s\leqslant k$, $1\leqslant\alpha\leqslant n$, and from $d\omega_i = 0$ we obtain

$$\frac{\partial (E_i)^\alpha_\beta}{\partial s^j} = \frac{\partial (F_i)^{\alpha,j}_{\beta,s}}{\partial s^l} = \frac{\partial (D_i)^\alpha_{\beta,j}}{\partial s^r} = 0.$$

Therefore

$$(E_i)^\alpha_\beta(s^j,x^\sigma,x^j_\sigma) = (E_i)^\alpha_\beta(0,x^\sigma,x^j_\sigma) = 0,$$

$$(F_i)^{\alpha,j}_{\beta,s}(s^l,x^\sigma,x^l_\sigma) = (F_i)^{\alpha,j}_{\beta,s}(0,x^\sigma,x^l_\sigma) = 0,$$

$$(D_i)^\alpha_{\beta,j}(s^r,x^\sigma,x^r_\sigma) = (D_i)^\alpha_{\beta,j}(0,x^\sigma,x^r_\sigma) = \delta_{\alpha\beta}\delta_{ij},$$

from which we get that

$$\omega_i = dx^\alpha\wedge dx^i_\alpha.$$

Moreover, for each $x\in U$, we have

$$V(x)\subset T_xU',$$

and then

$$V = \left\langle \frac{\partial}{\partial x^1_\alpha}, \ldots, \frac{\partial}{\partial x^k_\alpha} \right\rangle_{1\leqslant\alpha\leqslant n},$$

which completes the proof of the theorem. ■

Remark II.5: When $k=1$, the condition $[\xi,V]\subset V$ is a necessary condition for the integrability of the almost stable cotangent structure (η,ω,V), and it is an independent condition of the other ones (see Ref. 32). For $k>1$, we have the following.

Proposition II.6: If M is an almost k-cosymplectic manifold with $k>1$, and $\xi_1,\ldots,\xi_k$ are the Reeb vector fields associated to the almost k-cosymplectic structure, then

$$(d\eta_j=0, d\omega_j=0, \quad \forall 1\leqslant j\leqslant k)\Rightarrow [\xi_i, V]\subset V,$$

for all $1\leqslant i\leqslant k$.

III. *k*-COSYMPLECTIC MANIFOLDS THAT ARE STABLE *k*-COTANGENT BUNDLES

Let $(M, \eta_i, \omega_i, V; 1\leqslant i\leqslant k)$ be a k-cosymplectic manifold. For each $1\leqslant i\leqslant k$, we consider the distributions

$$V_i=\ker\ \eta_1\cap\cdots\cap\ker\ \eta_k\cap_{j\neq i}\ker\ w_j,$$

$$K_i=\ker\ \eta_1\cap\cdots\cap\ker\ \eta_k\cap\ker\ \omega_i=\oplus_{j\neq i}V_j,$$

which are all of them involutive and hence define foliations on M. If $\xi_1,\ldots,\xi_k$ are the Reeb vector fields, then we put

$$W=\langle\xi_1,\ldots,\xi_k\rangle\oplus V,$$

$$W_i=\langle\xi_1,\ldots,\hat{\xi}_i,\ldots,\xi_k\rangle\oplus K_i,$$

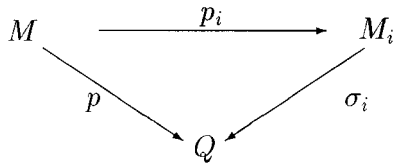
where $\hat{}$ over an element means that this element is omitted. Again, W and W_i are integrable distributions of dimension $k(n+1)$ and $(n+1)(k-1)$, respectively.

Definition III.1: The k-cosymplectic structure (η_i, ω_i, V) defines a fibration on M when the following conditions are satisfied.

(i) The leaf space $M_i=M/W_i$ defined by the involutive distribution W_i is a quotient manifold of M, and the canonical projection $p_i: M\to M_i$ is a fibration for each $1\leqslant i\leqslant k$.

(ii) The leaf space $Q=M/W$ defined by the involutive distribution W is a quotient manifold of M and the canonical projection $p: M\to Q$ is a fibration.

In such a case, we have the following commutative diagram:



where σ_i is the induced projection. Moreover, we can choose a suitable coordinate system $(s^i, x^\alpha, x^i_\alpha)$, such that

$$p_i(s^1,\ldots,s^k,x^\alpha,x^1_\alpha\ldots,x^k_\alpha)=(s^i,x^\alpha,x^i_\alpha),$$

$$p(s^1,\ldots,s^k,x^\alpha,x^1_\alpha,\ldots,x^k_\alpha)=(x^\alpha),$$

$$\sigma_i(s^i,x^\alpha,x^i_\alpha)=(x^\alpha).$$

On each M_i we define a cosymplectic structure $(\overline{\eta_i}, \overline{\omega_i})$ by putting

$$\overline{\eta_i}(X)=\eta_i(\overline{X}), \quad \overline{\omega_i}(X,Y)=\omega_i(\overline{X,Y}),$$

with $\overline{X,Y}\in TM$, such that $(p_i)_*(\overline{X})=X$ and $(p_i)_*(\overline{Y})=Y$. Moreover, each V_i defines a distribution V_i on M_i such that $(\overline{\eta_i}, \overline{\omega_i}, \overline{V_i})$ is a stable almost cotangent structure on M.[32]

Definition III.2: Let $y\in M$ be such that $p(y)=x$ and $p_i(y)=y_i$ for each $1\leqslant i\leqslant k$. If $\beta\in T^*_xQ$, the i-vertical lift of β to T_yM is the unique vector $\beta^{(i)}\in T_yM$, such that $\beta^{(i)}\in V_i(y)$ and

$$\iota_{T(p_i)\beta^{(i)}}\overline{\eta_i}=0, \quad \iota_{T(p_i)\beta^{(i)}}\overline{w_i}=(\sigma_i)^*\beta.$$

In a similar way to the case of k-symplectic and stable almost cotangent structures (see Ref. 29), we have the following results.

Proposition III.3: Given the 1-forms β, γ on Q, we have

$$[\beta^{(i)},\gamma^{(j)}]=0, \quad [\beta^{(i)},\xi_j]=0,$$

for all $1\leqslant i,\ j\leqslant k$.

Proposition III.4: If ∇ is a symmetric connectic adapted to the k-cosymplectic structure on M that define a fibration, then ∇ induces, by restriction, a flat connection on each leaf of the fibrations $p_i:M\to M_i$.

It should be noticed that such an adapted symmetric connection always exists from the general theory of G structures (see Ref. 33). Now we can prove the main theorem of this section.

Theorem III.5: *Let $(M,\eta_1,\ldots,\eta_k,\omega_1,\ldots,\omega_k,V)$ be a k-cosymplectic manifold that defines a fibration $p:M\to Q$. Let ∇ be a symmetric connection adapted to the structure. If the flat connection induced by ∇ is geodesically complete, each fiber of p is connected and simply connected and each leaf of $\langle\xi_i\rangle\oplus V_i$ is connected for all $1\leqslant i\leqslant k$, then M is an affine bundle modeled in the vector bundle $\mathbf{R}^k\times(T^1_k)^*Q$. Therefore, M admits a structure of vector bundle on Q isomorphic to $\mathbf{R}^k\times(T^1_k)^*Q$.*

Proof: We need only to define a mapping,

$$\rho:M\times_Q(\mathbf{R}^k\times(T^1_k)^*Q)\to M,$$

such that, for each $z\in Q$,

$$\rho_z:p^{-1}(z)\times(\tau^k)^{-1}(z)\to p^{-1}(z),$$

is a free and transitive action. For any $\beta\in T^*Q$ and any $t\in\mathbf{R}^k$, we can define k vector fields $\hat{\beta}^{t^k}_i=t^i\xi_i+\beta^{(i)}$. Each $(\hat{\beta}^{t^k}_i)$ is a geodesic vector field and then its flow $\exp t\hat{\beta}^{t^i}_i$ is global. For any $(t^1,\ldots,t^k)\in\mathbf{R}^k$, $(\beta_1,\ldots,\beta_k)\in(T^1_k)^*Q$, and $y\in p^{-1}(z)$, we then define

$$\rho_z(y,t^1,\ldots,t^k,\beta_1,\ldots,\beta_k)=(\exp\hat{\beta}^{t^k}_k)\cdots(\exp\hat{\beta}^{t^2}_2)(\exp\hat{\beta}^{t^1}_1)(y). \qquad \blacksquare$$

Therefore, M is an affine bundle modeled over $\mathbf{R}^k\times(T^1_k)^*Q$, and if $s:Q\to M$ is a global section of p we can define an isomorphism $F_s:M\to\mathbf{R}^k\times(T^1_k)^*Q$ by identifying s with the zero section in M.

Proposition III.6: For any global section s of p, the diffeomorphism $F_s:M\to\mathbf{R}^k\times(T^1_k)^*Q$ defined above, satisfies

$$\eta_i=F_s^*((\eta_0)_i+(\tau^k)^*\beta_i), \quad \omega_i=F_s^*((\omega_0)_i+(\tau^k)^*\phi_i),$$

where $(\eta_0)_i$, $(\omega_0)_i$ are the canonical forms on $\mathbf{R}^k\times(T^1_k)^*Q$.

Proof: The result follows from the formulas:

$$F_*(\alpha^{(i)})=\alpha^{(i)0}, \quad F_*(\xi_i)=(\xi_0)_i,$$

where $\alpha^{(i)}$ and $\alpha^{(i)_0}$ are the (i) lifts of α to M and $\mathbf{R}^k\times(T^1_k)^*Q$, respectively, and ξ_i, $(\xi_0)_i$ are the Reeb vector fields on M and $\mathbf{R}^k\times(T^1_k)^*Q$, respectively. $\blacksquare$

Definition III.7: A k-cosymplectic structure satisfying all the hypotheses of Theorem III.5 will be called *regular*.

Two regular k-cosymplectic structures $(M,p,Q,\eta_i\omega_i,V)$ and $(\overline{M},\overline{p},Q,\overline{\eta_i},\overline{\omega_i},\overline{V})$ over the same manifold Q are equivalent if there exists a bundle isomorphism $F:M\to M$ over the identity on Q, such that

$$F^*\overline{\eta_i}-\eta_i=p^*(df_i), \quad F^*\overline{\omega_i}-\omega_i=p^*(d\beta_i),$$

for all $1\leqslant i\leqslant k$, where f_i is a function on Q and β_i is a 1-form on Q. Then $F^*\overline{\eta_i}-\eta_i$ and $F^*\overline{\omega_i}-\omega_i$ are cohomologous to zero for all $1\leqslant i\leqslant k$.

Proposition III.8: There is a 1–1 correspondence between the set of equivalence classes of regular k-cosymplectic structures over Q and the elements of

$$(H^1(Q,\mathbf{R})\times\cdots\times H^1(Q,\mathbf{R}))\oplus(H^2(Q,\mathbf{R})\times\cdots\times H^2(Q,\mathbf{R})),$$

where $H^1(Q,R)$ and $H^2(Q,R)$ are, respectively, the first and the second de Rham cohomology groups of Q.

The above results are a natural extension of those obtained by Thompson and Schwardmann.[35,36]

An alternative procedure can be developed by using the following theorem due to Nagano.[37]

Theorem III.9: *Suppose that there exists a vector field C on a manifold M satisfying the following conditions.*

(i) *C generates a global one-parameter transformation group on M.*
(ii) *For each point $x\in M$ there exists a unique* $\lim_{t\to-\infty}(\exp tC)(x)$, where $\exp tC$ *denotes the flow of C.*
(iii) *The characteristic operator $(A_C)_x$ associated to C satisfies $((A_C)_x)^2=(A_C)_x$ for each singular point x of C.*
(iv) *The set of S of the singular points of C is a submanifold of M such that codimension S* $=\operatorname{rank}(A_C)_x$, *for all $x\in S$.*

Then there exists a unique vector bundle structure on M such that C is the canonical vector field.

Theorem III.10: *Let M be a $k(n+1)+n$-dimensional manifold endowed with a k-cosymplectic structure $(\eta_i,\omega_i,V;1\leqslant i\leqslant k)$ such that the 1-forms η_i and the 2-forms ω_i are globally exact, i.e., there exist k functions f_i and k 1-forms α_i such that*

$$\eta_i=df_i,\quad \omega_i=d\alpha_i,$$

for all $1\leqslant i\leqslant k$, and with $(\alpha_i)_{]V}=0$ and $\alpha_i(\xi_j)=0$. Let $\overline{C_1},\ldots,\overline{C_k}$ be the vector fields on M, defined by

$$\iota_{\overline{C_i}}\eta_j=0,\quad \iota_{\overline{C_i}}\omega_j=\delta_{ij}\alpha_j,$$

for all $1\leqslant i,j\leqslant k$, and define

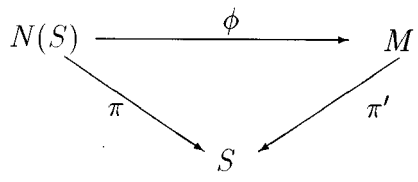
$$C_i=f_i\xi_i+\overline{C_i},$$

for $1\leqslant i\leqslant k$, where $\xi_1,\ldots,\xi_k$ are the Reeb vector fields. Then

$$\iota_{C_i}\eta_j=\delta_{ij}f_j,\quad \iota_{C_i}\omega_j=\delta_{ij}\alpha_j.$$

If the vector fields $C_1,\ldots,C_k$ satisfy (i)–(ii) *then there exists a unique vector bundle structure on M that is isomorphic to the stable bundle of k^1-covelocities $\mathbf{R}^k\times(T^1_k)^*S$ of the singular submanifold S of $C=C_1+\cdots+C_k$. Moreover, this isomorphism transports the canonical k-cosymplectic structure and the canonical vector field of $\mathbf{R}^k\times(T^1_k)^*S$ to (η_i,ω_i,V) and C, respectively.*

Proof: The vector field $C=C_1+\cdots+C_k$ satisfies the conditions (i)–(iv) in Theorem III.9, and then there exists a vector bundle isomorphism ϕ over the manifold S of the singular points of C:



where π is the canonical projection and π' is the projection induced from π via ϕ. Then, for each

$x \in S$, we can transport the k-cosymplectic structure on T_xM to a k-cosymplectic structure $(\eta_i(x), \omega_i(x), M_x)$ on the vector space $T_xM \oplus M_x$, with $M_x = \pi^{-1}(x)$, by using the linear isomorphism:

$$1 + \phi_x : T_xM = T_xS \oplus N_xS \to T_xS \oplus M_x .$$

In fact, if we put $f_i(x) = \phi_x(\xi_i(x))$ and $W_i(x) = \phi_x(V_i(x))$, we have

$$M_x = \langle f_1(x), \ldots, f_k(x) \rangle \oplus W_1(x) \oplus \cdots \oplus W_k(x),$$

and we define a linear isomorphism,

$$G_x : M_x \to \mathbf{R}^k \times (T_x^*S \oplus \cdots \oplus T_x^*S),$$

by

$$G_x(f_i, 0, \ldots, 0) = (e_i 0, \ldots, 0),$$

$$G_x(0, 0, \ldots, v_i, \ldots, 0) = (0, 0, \ldots, \iota_{v_i}\omega_i, \ldots, 0),$$

where $\{e_i, 1 \leqslant i \leqslant k\}$ is the canonical basis of $\mathbf{R}^k$ and $v_i \in W_i(x)$. We finally get a vector bundle isomorphism:

$$G : M = \cup_{x \in S} M_x \to \mathbf{R}^k \times (T_k^1)^*S = \cup_{x \in S} (\mathbf{R}^k \times (T_x^*S \oplus \cdots \oplus T_x^*S)).$$

■

IV. HAMILTONIAN SYSTEMS ON *k*-COSYMPLECTIC MANIFOLDS

In order to introduce dynamics on a k-cosymplectic manifold we need to consider a Hamiltonian function defined on it. The dynamics will be given by k-vector fields, thus we first recall this notion, which is a natural extension of the notion of vector fields. Let M be an arbitrary manifold and

$$\tau^k : T_k^1 M \to M,$$

its tangent bundle of k^1-velocities. Let us recall that $T_k^1 M$ is the manifold of 1-jets at $0 \in \mathbf{R}^k$ of mappings from R^k into M.

Definition IV.1: A section $s : M \to T_k^1 M$ of the projection τ^k will be called a *k-vector field* on M.

Since $T_k^1 M$ may be canonically identified with the Whitney sum of k copies of TM, say

$$T_k^1 M \equiv TM \oplus \cdots \oplus TM,$$

we deduce that a k-vector field s defines k vector fields $X_1, \ldots, X_k$ on M by projecting s onto every factor. From now on, we shall identify s with the k-tuple $(X_1 \ldots, X_k)$.

Definition IV.2: An application $\sigma : U \subset \mathbf{R}^k \to M$ defined on some open neighborhood of $0 \in \mathbf{R}^k$ will be called an *integral section* of a k-vector field $(X_1, \ldots, X_k)$ passing through a point $x \in M$ if and only if

$$\sigma(0) = x, \quad \sigma_*(t)\left(\frac{\partial}{\partial t^i}\right) = X_i(\sigma(t)) \quad \text{for all} \quad t \in U.$$

We say that a k-vector field $(X_1, \ldots, X_k)$ on M is *integrable* if there is an integral section passing through each point of M.

Let us remark that if σ is an integral section of a k-vector field $(X_1, \ldots, X_k)$, then each curve on M defined by $\sigma_i = \sigma \circ J_i$, where $J_i : \mathbf{R} \to \mathbf{R}^k$ is the natural inclusion $J_i(t) = (0, \ldots, t, \ldots, 0)$, is an integral curve of the vector field X_i on M, with $1 \leqslant i \leqslant k$.

Now, assume that M is a k-cosymplectic manifold with k-cosymplectic structure $(\eta_1, \ldots, \eta_k, \omega_1, \ldots, \omega_k, V)$. We define two vector bundle morphisms $\Omega^\flat$ and $\Omega^\sharp$ as follows:

$$\Omega^\flat : TM \to (T^1_k)^* M$$

$$X \to \Omega^\flat(X) = (\iota_X \omega_1 + \eta_1(X)\,\eta_1, \ldots, \iota_X \omega_k + \eta_k(X)\,\eta_k)$$

and

$$\Omega^\sharp : T^1_k M \to T^* M$$

$$(X_1, \ldots, X_k) \to \Omega^\sharp(X_1, \ldots, X_k),$$

such that

$$\Omega^\sharp(X_1, \ldots, X_k)(Y) = \operatorname{trace}((\Omega^\flat(X_j))_i(Y)) = \sum_{i=1}^{k} (\Omega^\flat(X_i))_i(Y) = \sum_{i=1}^{k} (\omega_i(X_i, Y) + \eta_i(X_i)\,\eta_i(Y)),$$

for all $Y \in TM$. The above morphisms induce two morphism of $C^\infty(M)$ modules between the corresponding spaces of sections.

Remark IV.3: If $k=1$ then $\Omega^\flat = \Omega^\sharp$ is defined from TM onto T^*M, and it is the morphism $\chi_{\eta,\omega}$ defined on the cosymplectic manifold (M, η, ω) by (see Refs. 30 and 31)

$$\chi_{\eta,\omega}(X) = \iota_X \omega + \eta(X)\,\eta.$$

If $(s^i, x^\alpha, x^i_\alpha;\ 1 \leqslant i \leqslant k,\ 1 \leqslant \alpha \leqslant n)$ are Darboux coordinates for the k-cosymplectic structure (η_i, ω_i, V), and if the k-vector field $(X_1, \ldots, X_k)$ is expressed with respect to this system by

$$X_i = (X_i)^j \frac{\partial}{\partial s^j} + (X_i)^\alpha \frac{\partial}{\partial x^\alpha} + (X_i)^j_\alpha \frac{\partial}{\partial x^i_\alpha},$$

then

$$\Omega^\sharp(X_1, \ldots, X_k) = \sum_i (X_i)^i\, ds^i - \sum_{i,\alpha} (X_i)^i_\alpha\, dx^\alpha + \sum_{i,\alpha} (X_i)^\alpha\, dx^i_\alpha. \tag{4}$$

Let $H : M \to \mathbf{R}$ be a function on M. If $(X_1, \ldots, X_k)$ is a k-vector field on M, the equations

$$\eta_i(X_j) = \delta_{ij}, \quad \forall i, j,$$

$$\Omega^\sharp(X_1, \ldots, X_k) = dH + \sum_{i=1}^{k} (1 - \xi_i(H))\,\eta_i, \tag{5}$$

would imply

$$(X_i)^j = \delta_{ij} \quad \frac{\partial H}{\partial x^\alpha} = -\sum_{i=1}^{k} (X_i)^i_\alpha, \quad \frac{\partial H}{\partial x^i_\alpha} = (X_i)^\alpha. \tag{6}$$

From these local conditions we can define, in a neighborhood of each point $x \in M$, a k-vector field that satisfies (6). For example, we can put

$$(X_i)^j = \delta_{ij}, \quad (X_1)^1_\alpha = \frac{\partial H}{\partial x^\alpha}, \quad (X_i)^j_\alpha = 0, \quad \text{for } i \neq 1 \neq j, \quad (X_i)^\alpha = \frac{\partial H}{\partial x^i_\alpha}.$$

Now one can construct a global k-vector field, which is a solution of (6), by using a partition of the unity.

Remark IV.4: Equations (6) have not, in general, a unique solution. In fact, if we denote by $\mathscr{M}_k(C^\infty(M))$ the space of matrices of order k whose entries are functions on M, and we define the map

$$\eta^\sharp : T^1_k M \to \mathscr{M}_k(C^\infty(M))$$

$$(X_1,\ldots,X_k) \to (\eta_i(X_j)),$$

the solutions of (6) are given by $(X_1,\ldots,X_k)+(\ker \Omega^\sharp \cap \ker\ \eta^\sharp)$, where $(X_1,\ldots,X_k)$ is a particular solution.

Definition IV.5: Any k-vector field $(X_1,\ldots,X_k)$ on M, such that

$$\eta_i(X_j)=\delta_{ij},$$

$$\Omega^\sharp(X_1,\ldots,X_k)=dH+\sum_{i=1}^{k}(1-\xi_i(H))\eta_i,$$

for all $1\leqslant i,j\leqslant k$, will be called an *evolution k-vector field* on M associated with the Hamiltonian function H.

Let $(X_1,\ldots,X_k)$ be an evolution k-vector field associated to H, and assume that it is integrable. Let

$$\sigma : \mathbf{R}^k \to M$$

$$(t^i) \to (\sigma^j(t^i), \alpha^\alpha(t^i), \sigma^j_\alpha(t^i)),$$

be an integral section of $(X_1,\ldots,X_k)$; then, we have

$$\frac{\partial \sigma^j}{\partial t^i}=\delta_{ij}, \quad \frac{\partial \sigma^\alpha}{\partial t^i}=(X_i)^\alpha, \quad \frac{\partial \sigma^j_\alpha}{\partial t^i}=(X_i)^j_\alpha,$$

for all $1\leqslant i,\ j\leqslant k$ and $1\leqslant\alpha\leqslant n$. Therefore, Eqs. (6) give

$$\frac{\partial H}{\partial x^\alpha}=-\sum_{i=1}^{k}\frac{\partial \sigma^i_\alpha}{\partial t^i},$$

$$\frac{\partial H}{\partial x^i_\alpha}=\frac{\partial \sigma^\alpha}{\partial t^i},$$

with $1\leqslant i\leqslant k$ and $1\leqslant\alpha\leqslant n$, which are the field equations for H.

Remark IV.6: Let $(X_1,\ldots,X_k)$ be an evolution k-vector field. Since $\eta_i(X_j)=\delta_{ij}$, it follows that the vector fields $X_1,\ldots,X_k$ on M are linearly independent.

Example IV.7: We shall use the above formalism to obtain an intrinsic version for the electrostatic equations. Consider $\mathbf{R}^3$ with a metric g with components g_{ij}. Let $\phi:\mathbf{R}^3\to\mathbf{R}$ be the electric potential and $p=(p_1,p_2,p_3)$: $\mathbf{R}^3\to\mathbf{R}^3$ the electric field. Denote by (t^1,t^2,t^3) the standard coordinates on $\mathbf{R}^3$, and set $\sqrt{g}=\sqrt{\det g_{ij}}$. By $r(t)$ we denote the scalar function that gives the density of electric charge on $\mathbf{R}^3$. Consider on $M=\mathbf{R}^3\times(T^1_3)^*\mathbf{R}$ the canonical 3-cosymplectic structure $(\eta_i,\omega_i,V;1\leqslant i\leqslant 3)$. We denote by $(t^1,t^2,t^3,x,x^1,x^2,x^3)$ the local coordinates on $\mathbf{R}^3\times(T^1_3)^*\mathbf{R}$ induced by the standard coordinate (x) on $\mathbf{R}$, and define a Hamiltonian function,

$$H:\mathbf{R}^3\times(T^1_3)^*\mathbf{R}\to\mathbf{R}$$

$$(t^1,t^2,t^3,x,x^1,x^2,x^3)\to\sqrt{g}\left(4\pi r(t^1,t^2,t^3)x+\frac{1}{2g}\,g_{ij}x^ix^j\right).$$

Consider the equations

$$\eta i_i(X_j)=\delta_{ij} \quad (1\leqslant i,j\leqslant 3),$$

$$\Omega^\sharp(X_1,X_2,X_3)=dH+\sum_{i=1}^{3}(1-\xi_i(H))\eta_i, \tag{7}$$

where ξ_1, ξ_2, ξ_3 are the Reeb vector fields and (X_1,X_2,X_3) is a 3-vector field on $\mathbf{R}^3\times(T_3^1)^*\mathbf{R}$. Let $\sigma:\mathbf{R}^3\to\mathbf{R}^3\times(T_3^1)^*\mathbf{R}$, $\sigma(t)=(t,\psi(t),\psi^1(t),\psi^2(t),\psi^3(t))$ be an integral section of an evolution 3-vector field that is a solution of (7). Then we obtain

$$4\pi r(t^1,t^2,t^3)\sqrt{g}=-\left(\frac{\partial\psi^1}{\partial t^1}+\frac{\partial\psi^2}{\partial t^2}+\frac{\partial\psi^3}{\partial t^3}\right),$$

$$\frac{1}{\sqrt{g}}\left(\sum_{i=1}^{3}g_{ij}\psi^j\right)=\frac{\partial\psi}{\partial t^i},$$

which are the electrostatic equations, and then the components $\psi(t)$ and $(\psi^1(t),\psi^2(t),\psi^3(t))$ of σ are, respectively, the electric potential ϕ and electric field $p=(p_1,p_2,p_3)$ on $\mathbf{R}^3$.

Actually, in most of the real electrostatic problems, one has to deal with finite regions and with the boundary conditions established in the limits of those regions. To do that the Green identities have to be used.

Thus, the suitable boundary conditions to the Poisson (Laplace) equations to present a unique well-behaved solution inside a finite region are modeled. Physically, we know that the specification of the potential on a closed surface defines a unique boundary problem (Dirichlet boundary conditions). The specification of the electric field at any point of the closed surface, i.e., the specification of the distribution charge on the surface (Neumann boundary conditions), also defines a unique problem. Those propositions can be shown by taking into account the first Green identity (see Ref. 38 and the references therein).

V. R^k-VALUED HAMILTONIANS

We can also consider Hamiltonian functions $\mathbf{R}^k$-valued on a k-cosymplectic manifold M.

In Darboux coordinates we have

$$H=(H^1(s^i,x^\alpha,x^i_\alpha),\ldots,H^k(s^i,x^\alpha,x^i_\alpha)),$$

or equivalently,

$$H=H^ie_i,$$

where $\{e_1,\ldots,e_k\}$ denotes the standard basis in $\mathbf{R}^k$.

Definition V.1: If M is a k-cosymplectic manifold, a vector field X on M such that

$$\eta_i(X)=1, \quad \text{for all } i=1,...,k,$$

$$\Omega^b(X)=dH+\left[\sum_{i=1}^{k}((1-\xi_i(H^i))\eta_i)e_i\right], \tag{8}$$

where $\xi_1,\ldots,\xi_k$ are the Reeb vector fields associated with the k-cosymplectic structure, will be called a *k-Hamiltonian system* associated to H.

In Darboux coordinates, we have

$$X=\frac{\partial}{\partial s^1}+\cdots+\frac{\partial}{\partial s^k}+X^\alpha\frac{\partial}{\partial x^\alpha}+X^i_\alpha\frac{\partial}{\partial x^i_\alpha},$$

where

$$\frac{\partial H^i}{\partial s^j}=0, \quad \text{if } i\neq j, \quad \frac{\partial H^i}{\partial x^\alpha}=-X^i_\alpha, \quad \frac{\partial H^i}{\partial x^j_\alpha}=\delta_{ij}X^\alpha.$$

If

$$\sigma:(-\epsilon,\epsilon)\subset\mathbf{R}\to M$$

$$t\to(\sigma^i(t),\sigma^\alpha(t),\sigma^i_\alpha(t))$$

is an integral curve of X, then we obtain the Hamilton equations associated to the $\mathbf{R}^k$-valued Hamiltonian H:

$$\frac{\partial H^i}{\partial x^\alpha}=-\frac{d\sigma^i_\alpha}{dt},$$

$$\frac{\partial H^i}{\partial x^j_\alpha}=\delta_{ij}\frac{d\sigma^\alpha}{dt}.$$

From these equations and using the same argument as in Refs. 24 and 25, we can prove the following result.

Proposition V.2: An admissible Hamiltonian function $H=(H^1,\ldots,H^k)$ is necessarily of the form

$$H^i=\sum_{\alpha=1}^{n}\varphi_\alpha(s^i,x_1,\ldots,x_n)x^i_\alpha+\psi^{\,i}(s^i,x_1,\ldots,x_n),$$

for $1\leqslant i\leqslant k$.

Given an admissible Hamiltonian function $H=(H^1,\ldots,H^k)$ on M, we can define the local vector field,

$$X=\frac{\partial}{\partial s^1}+\cdots+\frac{\partial}{\partial s^k}+\frac{\partial H^i}{\partial x^i_\alpha}\frac{\partial}{\partial x^\alpha}-\frac{\partial H^i}{\partial x^\alpha}\frac{\partial}{\partial x^i_\alpha},$$

which satisfies (8). By using a partition of the unity, it is possible to define a unique global vector field X on M satisfying (8).

An application. Let $L:\mathbf{R}\times TQ\to\mathbf{R}$ be a hyperregular Lagrangian function, that is, the Legendre transformation $\mathrm{Leg}:\mathbf{R}\times TQ\to\mathbf{R}\times T^*Q$ defined by L is a diffeomorphism. Denote by $H=E_L\circ\mathrm{Leg}^{-1}$ the Hamiltonian energy, where $E_L=C(L)-L$, C being the infinitesimal generator of the dilations on TQ. We construct a 2-cosymplectic structure on the manifold $M=\mathbf{R}^2\times(TQ\oplus T^*Q)$ as follows.

First of all, let ω_Q denote the canonical symplectic form on T^*Q and $\omega_L=\mathrm{Leg}^*\,\omega_Q$ the Poincaré–Cartan two-form on TQ.[39] If (q^α) are coordinates on Q we denote by (q^α,v^α) and (q^α,p_α) the induced coordinates on TQ and T^*Q, respectively. So, we have coordinates $(t^1,t^2,q^\alpha,v^\alpha,p_\alpha)$ on M. Denote by τ: $M\to\mathbf{R}\times TQ$ and $\pi:M\to\mathbf{R}\times T^*Q$ the canonical projections, locally given by

$$\tau(t^1,t^2,q^\alpha,v^\alpha,p_\alpha)=(t^1,q^\alpha,v^\alpha),$$

$$\pi(t^1,t^2,q^\alpha,v^\alpha,p_\alpha)=(t^2,q^\alpha,p_\alpha).$$

If we put

$$\eta_1=dt^1, \quad \eta_2=dt^2, \quad \omega_1=\tau^*\omega_L, \quad \omega_2=\pi^*\omega_Q,$$

we deduce that $(\eta_1,\eta_2,\omega_1,\omega_2,V)$ is a 2-cosymplectic structure on M where $V=\mathrm{Ker}\,T\rho$, $\rho:M\to Q$ being the canonical projection.

Consider now a Hamiltonian function,

$$H:M\to\mathbf{R}^2,$$

given by

$$H(t^1,t^2,X_q,\alpha_q)=(\tau^*E_L,\langle X_q,\alpha_q\rangle-\tau^*L).$$

In local coordinates we obtain

$$H(t^1,t^2,q^\alpha,v^\alpha,p_\alpha)=\left(v^\alpha\frac{\partial L}{\partial v^\alpha}-L,q^\alpha p_\alpha-L\right).$$

Let now X be a vector field on M, which is Hamiltonian for H. After a direct computation, we deduce

$$X=\frac{\partial}{\partial t^1}+\frac{\partial}{\partial t^2}+v^\alpha\frac{\partial}{\partial q^\alpha}+X^1_\alpha\frac{\partial}{\partial v^\alpha}-\frac{\partial H}{\partial q^\alpha}\frac{\partial}{\partial p_\alpha},$$

where

$$\frac{\partial^2 L}{\partial t^1\,\partial v^\beta}+v^\alpha\frac{\partial^2 L}{\partial q^\alpha\,\partial v^\beta}+X^1_\alpha\frac{\partial^2 L}{\partial v^\alpha\,\partial v^\beta}-\frac{\partial L}{\partial q^\beta}=0.$$

If $\sigma(t)=(\sigma_1(t),\sigma_2(t),\sigma^\alpha(t),\sigma^1_\alpha(t),\sigma^2_\alpha(t))$ is an integral curve of X, we have

$$\frac{d\sigma^\alpha}{dt}=v^\alpha,\quad \frac{d\sigma^1_\alpha}{dt}=X^1_\alpha,\quad \frac{d\sigma^2_\alpha}{dt}=-\frac{\partial H}{\partial q^\alpha}.$$

Therefore, the projections of σ onto Q satisfy simultaneously the Euler–Lagrange and Hamilton equations.

VI. MULTISYMPLECTIC FORMALISM ON JET BUNDLES

In this section we obtain the Hamiltonian formalism above as a particular case of the multisymplectic formalism on jet bundles.[12]

Let $\pi:E\to M$ be a fibered manifold. We denote by Λ^k_0E and Λ^k_1E the following vector bundles on E:

$$\Lambda^k_0E=\{\sigma\in\Lambda^kE/\iota_v\sigma=0,\quad \forall_v\in V\pi\},$$

$$\Lambda^k_1E=\{\sigma\in\Lambda^kE/\iota_{v_1}\iota_{v_2}\sigma=0,\quad \forall v_1,v_2\in V\pi\},$$

where $V\pi$ is the vertical bundle of π. Here, Λ^rE denotes the space of r-forms on the manifold E, that is,

$$\Lambda^rE=\cup_{z\in E}\Lambda^r(T^*_zE).$$

If we take fibered coordinates (s^i,x^α), then each element in Λ^k_0E can be expressed as $x(s^i,x^\alpha)d^ks$, and each element of Λ^k_1E as $x(s^i,x^\alpha)d^ks+x^i_\alpha(s^i,x^\alpha)dx^\alpha\wedge d^{k-1}s_i$, where $d^ks=ds^1\wedge\cdots\wedge ds^k$ and $d^{k-1}s^i=\iota(\partial/\partial s^i)\,d^ks$. Thus, we can introduce local coordinates (s^i,x^α,x) and $(s^i,x^\alpha,x,x^i_\alpha)$ on Λ^k_0E and Λ^k_1E, respectively.

We denote by $\mathscr{M}\pi=\Lambda^k_1E$. Since Λ^k_0E is a vector subundle of $\mathscr{M}\pi$, then $\mathscr{M}\pi/\Lambda^k_0E=J^1\pi^*$ is a quotient manifold of dimension $(k+1)n+k$ with local coordinates $(s^i,x^\alpha,x^i_\alpha)$.

Moreover, we have the following canonical projections:

$$\mu: \mathscr{M}\pi \to J^1\pi^*,$$

$$\pi^*_{1,0}: J^1\pi^* \to E,$$

$$\pi^*_1: J^1\pi^* \to M.$$

On $\mathscr{M}\pi$ there is a canonical k-form Θ, which is defined as follows:

$$\Theta_\omega(X_1,\ldots,X_k) = \omega(\nu_* X_1,\ldots,\nu_* X_k),$$

for all $X_i \in T_\omega \mathscr{M}\pi$ and $\omega \in \mathscr{M}\pi$, where $\nu: \mathscr{M}\pi \to E$ is the canonical projection.

Definition VI.1: The $(k+1)$-form on $\mathscr{M}\pi$, defined by

$$\Omega = d\Theta,$$

is called the *multisymplectic structure* on $\mathscr{M}\pi$.

Definition VI.2: A global section $h: J^1\pi^* \to \mathscr{M}\pi$ of μ is called a *Hamiltonian.* Given a Hamiltonian h on $J^1\pi^*$, we can define a $(k+1)$-form on $J^1\pi^*$ given by

$$\Omega_h = -h^*\Omega.$$

Definition VI.3: A section $\gamma: M \to J^1\pi^*$ of π^*_1 satisfies the Hamilton equations associated to a Hamiltonian h if and only if

$$\gamma^*(\iota_X \Omega_h) = 0,$$

for all vector field X on $J^1\pi^*$.

Put

$$h(s^i, x^\alpha, x^i_\alpha) = (s^i, x^\alpha, x = -H(s^i, x^\alpha, x^i_\alpha), x^i_\alpha),$$

with $H: J^1\pi^* \to \mathbf{R}$.

Then a section $\gamma(s^i) = (s^i, \gamma^\alpha(s^i), \gamma^j_\alpha(s^i))$ as in Definition VI.3 satisfies the following system of differential equations:

$$\frac{\partial H}{\partial x^\alpha} = -\sum_{i=1}^{k} \frac{\partial \gamma^i_\alpha}{\partial s^i},$$

$$\frac{\partial H}{\partial x^i_\alpha} = \frac{\partial \gamma^\alpha}{\partial s^i},$$

which are the field equations for H (see Sec. IV).

Next, we shall consider the particular case where $\pi: E \to M$ is the trivial bundle $(\mathbf{R}^k \times Q, \pi, \mathbf{R}^k)$.

In this case we get

$$\mathscr{M}\pi = \mathbf{R}^k \times \mathbf{R} \times (T^1_k)^* Q, \quad J^1\pi^* = \mathbf{R}^k \times (T^1_k)^* Q.$$

Consider the canonical k-cosymplectic structure $((\eta_0)_i, (\omega_0)_i, V_0)$ on $J^1\pi^* = \mathbf{R}^k \times (T^1_k)^* Q$ described in Sec. II. Notice that $(\omega_0)_i = -d(\lambda_0)_i$, where $(\lambda_0)_i = x^i_\alpha \, dx^\alpha$, and $(t^i, x^\alpha, x^i_\alpha)$ are Darboux coordinates (see Sec. II).

If $h: J^1\pi^* = \mathbf{R}^k \times (T^1_k)^* Q \to \mathscr{M} = \mathbf{R}^k \times \mathbf{R} \times (T^1_k)^* Q$ is a Hamiltonian on $J^1\pi^*$ such that

$$h(t^i, x^\alpha, x_\alpha) = (t^i, -H(t^i, x^\alpha x^i_\alpha), x^\alpha, x^\alpha_i),$$

then we obtain the following.

Lemma VI.4: We have

$$\Theta_h = -H(\eta_0)_1 \wedge \cdots \wedge (\eta_0)_k + \sum_{i=1}^{k} (\lambda_0)_i \wedge \iota_{\xi_i}((\eta_0)_1 \wedge \cdots \wedge (\eta_0)_k),$$

where $(\xi_0)_i = \partial/\partial t^i (1 \leqslant i \leqslant k)$, *are the Reeb vector fields on* $\mathbf{R}^k \times (T_k^1)^*Q$.

Thus, we deduce the following.

Proposition VI.5: A section ψ *of the canonical projection* $\pi^*: \mathbf{R}^k \times (T_k^1)^*Q \to \mathbf{R}^k$ *satisfies the Hamilton equations in Definition VI.3 if and only if* ψ *is an integral section of an evolution k-vector field on* $\mathbf{R}^k \times (T_k^1)^*Q$ *associated to* H.

A plane acoustic wave is incident upon an infinite, rough, impenetrable surface S. The aim is to find the scattered field by deriving a boundary integral equation over S, using Green's theorem and the free-space Green's function. This requires careful consideration of certain integrals over a large hemisphere of radius r; it is known that these integrals vanish as $r\to\infty$ if the scattered field satisfies the Sommerfeld radiation condition, but that is not the case here—reflected plane waves must be present. It is shown that the well-known Helmholtz integral equation is not valid in all circumstances. For example, it is not valid when the scattered field includes plane waves propagating away from S along the axis of the hemisphere. In particular, it is not valid for the simplest possible problem of a plane wave at normal incidence to an infinite flat plane. Some suggestions for modified integral equations are discussed. © *1998 American Institute of Physics.* [S0022-2488(98)01302-4]

I. INTRODUCTION

A bounded three-dimensional obstacle with a smooth surface S is surrounded by a compressible fluid. A plane time-harmonic sound wave is incident on the obstacle; the problem is to calculate the scattered field u. In order to have a well-posed boundary-value problem (with existence and uniqueness), one imposes the Sommerfeld radiation condition,

$$r\left(\frac{\partial u}{\partial r}-iku\right)\to 0 \quad \text{as } r\to\infty, \tag{1}$$

uniformly in all directions. Here r is a spherical polar coordinate, k is the wave number, and the time-dependence is $e^{-i\omega t}$. Physically, the radiation condition ensures that the scattered waves propagate outwards, away from the obstacle.

A well-known method for solving the above problem is to derive a boundary integral equation for the boundary values of u on S. In the derivation, Green's theorem is applied to u and a fundamental solution G, in the region bounded internally by S and externally by C_r, a large sphere of radius r. It turns out that the radiation condition implies that the integral

$$I(u;C_r)\equiv\int_{C_r}\left(u\frac{\partial G}{\partial r}-G\frac{\partial u}{\partial r}\right)ds\to 0 \quad \text{as } r\to\infty, \tag{2}$$

and so only boundary integrals over S remain. For more information, see Colton and Kress.[1]

Assume that S is a sound-hard surface (Neumann condition). Then, the method described above leads to the following boundary integral equation:

$$u(p)-\int_S u(q)\frac{\partial G}{\partial n_q}(p,q)ds_q=\int_S\frac{\partial u_{\text{inc}}}{\partial n_q}G(p,q)ds_q, \quad p\in S, \tag{3}$$

 © 1998 American Institute of Physics

here, u_{inc} is the given incident wave. One can also derive an equation for the boundary values of the total field $u_{\text{tot}}=u_{\text{inc}}+u$; this boundary integral equation is

$$u_{\text{tot}}(p)-\int_S u_{\text{tot}}(q)\frac{\partial G}{\partial n_q}(p,q)\,ds_q=2u_{\text{inc}}(p), \quad p\in S. \tag{4}$$

We shall refer to Eqs. (3) and (4) as *standard Helmholtz integral equations*. Similar equations can be derived for sound-soft surfaces ($u_{\text{tot}}=0$ on S).

Suppose now that the obstacle is *unbounded*. The prototypical problem is scattering (reflection) of a plane wave by an infinite flat plane, S. As is well known, the incident wave is reflected specularly as a single propagating plane wave. More generally, if S is an infinite rough surface, an incident plane wave will be scattered into a spectrum of plane waves. For such problems, the Sommerfeld radiation condition is definitely inappropriate as it is not satisfied by a plane wave. Nevertheless, it is customary to proceed, *assuming* that the scattered field can be represented in terms of plane waves, at least at some distance from S. Typically, this requires the discarding of an integral such as (2), but with the large sphere C_r replaced by a large *hemisphere* H_r. This paper began as an attempt to justify this step.

In a previous paper,[2] we derived boundary integral equations of Helmholtz type for *one-dimensional* rough surfaces. We found that the standard Helmholtz integral equations are valid, except that the right-hand side of Eq. (4) must be replaced by $u_{\text{inc}}(p)$ for grazing incidence.

It is perhaps surprising that an analysis of this kind has not been given before: most authors have been content to write down an integral equation such as Eq. (4), prior to extensive numerical computations. However, it turns out that the necessary analysis for scattering by a *two-dimensional* rough surface is not straightforward and, moreover, it yields some surprises. For example, the simplest problem, namely reflection of a plane wave at *normal* incidence upon a *flat* surface, leads to divergent integrals: the standard Helmholtz integral equation (3) is not valid for this problem.

The paper is organized as follows. Section II is devoted to formulating the problem, with some background on angular-spectrum representations and integral representations (using G). Green's theorem is applied inside a volume whose closed boundary is made up of three pieces: the large hemisphere H_r; a large circular piece, S_r, of the rough surface; and a cylindrical surface T_r, joining S_r and H_r. Estimation of integrals over H_r is carried out in Secs. III–V. Thus the method of stationary phase for multiple integrals and an expansion method are used in Secs. III and IV, respectively, but only for a single plane wave. Results for $I(u;H_r)$ are obtained in Sec. V. The contribution from integrating over T_r is considered in Sec. VI. Unlike in two dimensions (one-dimensional rough surface), this contribution may not be negligible; it is evaluated under additional, but reasonable, *a priori* assumptions on the form of the scattered field near S. This is a weakness of the present analysis. Finally, boundary integral equations of the Helmholtz type are derived in Sec. VII. Further work is needed to tighten up the analysis and to investigate the numerical consequences.

II. FORMULATION

Consider the scattering of a plane wave by a two-dimensional rough surface, S, described by

$$z=s(x,y), \quad -\infty<x<\infty, \quad -\infty<y<\infty$$

with $-h<s(x,y)\leqslant 0$ and some constant $h\geqslant 0$. The acoustic medium occupies $z>s$ and, for definiteness, we assume that S is a smooth, sound-hard surface. Thus we can write the total field as

$$u_{\text{tot}}=u_{\text{inc}}+u,$$

where u is the scattered field. The incident plane wave is

$$u_{\text{inc}}(r,\theta,\phi)=\exp\{i\mathbf{k}_i\cdot\mathbf{x}\}, \quad 0\leqslant\theta_i\leqslant\tfrac{1}{2}\pi, \tag{5}$$

where $\mathbf{k}_i = k(\sin\theta_i, 0, -\cos\theta_i)$, θ_i is the angle of incidence (it is the angle between the direction of propagation and the negative z-axis),

$$\mathbf{x} = r\hat{\mathbf{x}} = r(\sin\theta\,\cos\phi, \sin\theta\,\sin\phi, \cos\theta),$$

and (r, θ, ϕ) are spherical polar coordinates: $x = r\,\sin\theta\cos\phi$, $y = r\,\sin\theta\sin\phi$ and $z = r\cos\theta$. All the fields $u_{\rm tot}$, $u_{\rm inc}$, and u satisfy the Helmholtz equation,

$$(\nabla^2 + k^2)u = 0$$

for $z > s$. The boundary condition is

$$\frac{\partial u_{\rm tot}}{\partial n} = 0 \quad \text{on } S, \tag{6}$$

where $\partial/\partial n$ denotes normal differentiation *out* of the acoustic medium.

A. Reflection by a flat surface

It is instructive to consider the very simple problem of reflection by a flat surface, so that $s = 0$. The textbook solution for the scattered field is

$$u(r, \theta, \phi) = \exp\{i\mathbf{k}_{\rm s}\cdot\mathbf{x}\} \quad \text{for } 0 \leqslant \theta_i < \tfrac{1}{2}\pi, \tag{7}$$

where $\mathbf{k}_{\rm s} = k(\sin\theta_i, 0, \cos\theta_i)$. When $\theta_i = \frac{1}{2}\pi$ (''grazing incidence''), we have $u \equiv 0$: the incident wave satisfies the boundary condition on S.

So, for $0 \leqslant \theta_i < \frac{1}{2}\pi$,

$$u_{\rm tot} = 2\,e^{ikx\sin\theta_i}\cos(kz\cos\theta_i)$$

solves the problem. But consider

$$u'_{\rm tot} \equiv u_{\rm tot} + u_g \tag{8}$$

with

$$u_g = V(\beta)e^{ik(x\cos\beta + y\sin\beta)},$$

where β and $V(\beta)$ are arbitrary, with $-\pi < \beta \leqslant \pi$. $u'_{\rm tot}$ also ''solves'' the problem, in that it satisfies the Helmholtz equation and the boundary condition. Of course, we disallow this second solution, unless $V \equiv 0$: but why? The answer is because of the radiation condition (which we have yet to specify). For example, take $\beta = 0$ and $V(0) = 1$, so that $u_g = e^{ikx}$; this gives an ''outgoing'' grazing wave at $x = +\infty$ but it is an ''incoming'' grazing wave at $x = -\infty$, we must therefore exclude it. Indeed, we must exclude *all* contributions u_g, for any β and V.

A similar condition is imposed on the two-dimensional problem.[3] However, the three-dimensional problem has another feature, for we could consider replacing u_g in Eq. (8) by

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} V(\beta)e^{ik(x\cos\beta + y\sin\beta)}d\beta,$$

where V is a continuous function; but, as u_g has been excluded, we must also exclude all linear combinations of such plane grazing waves. In particular, by taking $V(\beta) = (-i)^n e^{in\beta}$, we see that we must exclude the cylindrical standing waves

$$J_n(kR)e^{in\phi}, \tag{9}$$

where J_ν is a Bessel function,[4] $R = r\sin\theta$, and (R, ϕ, z) are cylindrical polar coordinates of the point at $\mathbf{x}$. On the other hand, the exact scattered field, given by Eq. (7), when evaluated on any plane $z =$ constant, has an azimuthal Fourier component proportional to

$$J_n(k_i R)e^{in\phi}, \tag{10}$$

where $k_i = k\sin\theta_i < k$. Thus if one wants to formulate a radiation condition, mathematically, it must be such that fields (9) are excluded but fields (10) are permitted.

This discussion suggests that the specification of a *mathematical* radiation condition for the present class of problems (plane-wave scattering by an infinite two-dimensional rough surface) will not be straightforward. However, the *physical* purpose of a radiation condition is clear: it is to exclude all ''incoming'' waves apart from the incident wave. We shall return to radiation conditions in Sec. II B.

B. Angular-spectrum representations

For any rough surface S, the scattered field in the half-space $z>0$ may be written using an angular-spectrum representation,

$$\begin{aligned} u(x,y,z) &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} F(\mu,\nu)e^{ik(\mu x+\nu y+mz)}\frac{d\mu\ d\nu}{m(\kappa)} \\ &= \int_0^{\pi/2}\int_{-\pi}^{\pi} A(\alpha,\beta)v(r,\theta,\phi;\alpha,\beta)d\alpha\ d\beta + \text{evanescent terms}. \end{aligned} \tag{11}$$

Here F is the *spectral amplitude*, $A(\alpha,\beta)=F(\sin\alpha\cos\beta,\ \sin\alpha\sin\beta)$, $\kappa=\sqrt{\mu^2+\nu^2}$, and

$$m(\kappa)=\begin{cases}\sqrt{1-\kappa^2}, & 0\leqslant\kappa<1,\\ i\sqrt{\kappa^2-1}, & \kappa>1,\end{cases}$$

the function v is defined by

$$v(r,\theta,\phi;\alpha,\beta)=\exp\{i\mathbf{k}\cdot\mathbf{x}\},\quad 0\leqslant\alpha\leqslant\frac{1}{2}\pi,\quad |\beta|\leqslant\pi, \tag{12}$$

where

$$\mathbf{k}=k\hat{\mathbf{k}}=k(\sin\alpha\ \cos\beta,\sin\alpha\ \sin\beta,\cos\alpha).$$

The integrals are superpositions of plane waves; they are propagating, homogeneous plane waves when $0\leqslant\kappa<1$, and they are evanescent, inhomogeneous plane waves when $\kappa>1$. In Eq. (11), we see the propagating plane waves explicitly: they propagate in the direction of $\hat{\mathbf{k}}$, with an (unknown) complex amplitude, $A(\alpha,\beta)$; the ''evanescent terms'' decay exponentially with z. For more information on angular-spectrum representations, see Clemmow[5] and DeSanto and Martin.[6]

In general, the spectral amplitude must be considered as a generalized function. Thus it is convenient to extract a continuous component from F, writing the scattered field as

$$u=u_{\rm pr}+u_{\rm ev}+u_{\rm con}, \tag{13}$$

where

$$u_{\rm pr}(r,\theta,\phi)=\sum_{n=0}^{N} A_n v(r,\theta,\phi;\alpha_n,\beta_n),$$

$$u_{\rm ev}(r,\theta,\phi)=\sum_{m=1}^{M} B_m w(r,\theta,\phi;\mu_m,\nu_m), \tag{14}$$

$$u_{\rm con}(x,y,z)=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\mathscr{C}(\mu,\nu)\ e^{ik(\mu x+\nu y+mz)}\frac{d\mu\ d\nu}{m(\kappa)}, \tag{15}$$

$$w(r,\theta,\phi;\mu,\nu)=\exp\{ikr\sin\theta\,[\mu\cos\phi+\nu\sin\phi]-kr\cos\theta\,\sqrt{\kappa^2-1}\},\tag{16}$$

and $\kappa=\sqrt{\mu^2+\nu^2}>1$ in Eq. (16). The first term in Eq. (13) is a sum of propagating waves; the coefficients A_n and the angles, α_n and β_n, are unknown in general. The second term in Eq. (13) is a sum of evanescent waves; B_m, μ_m, and ν_m are unknown in general. The third term in Eq. (13) is a continuous spectrum of plane waves; the unknown function $\mathscr{C}$ is continuous. See Sec. V for further comments.

Let us now return to the radiation condition. Having chosen an origin O, arbitrarily, we consider a large hemisphere H_r, with radius r and center O. We then require that all propagating plane-wave components $v(r,\theta,\phi;\alpha_n,\beta_n)$ in u propagate *outwards* through H_r, away from O. This is almost built into the decomposition (13): we have to be careful with grazing waves [$\alpha_n=\frac{1}{2}\pi$; see the discussion following Eq. (8)]. A simple way to impose our radiation condition is to split the half-space $z>0$ and the hemisphere H_r into four parts. Thus with

$$H_r^m=\left\{(r,\theta,\phi):0\leqslant\theta\leqslant\frac{1}{2}\pi,\frac{1}{2}(m-3)\pi\leqslant\phi<\frac{1}{2}(m-2)\pi\right\},\quad m=1,2,3,4,$$

being the surfaces of four octants of a sphere, we require the following conditions for the regions specified:

$$\begin{aligned}
&m=1:\quad \text{in } x<0,\ y\leqslant 0,\quad \text{use } -\pi\leqslant\beta_n<-\tfrac{1}{2}\pi,\\
&m=2:\quad \text{in } x\geqslant 0,\ y<0,\quad \text{use } -\tfrac{1}{2}\pi\leqslant\beta_n<0,\\
&m=3:\quad \text{in } x>0,\ y\geqslant 0,\quad \text{use } 0\leqslant\beta_n<\tfrac{1}{2}\pi,\\
&m=4:\quad \text{in } x\leqslant 0,\ y>0,\quad \text{use } \tfrac{1}{2}\pi\leqslant\beta_n<\pi.
\end{aligned}\tag{17}$$

This partitioning makes it easy to ensure that only plane waves propagating out through H_r^m are included. This is the form of radiation condition used to derive boundary integral equations.

C. Boundary integral equations

One way to determine the scattered field is to derive a boundary integral equation over the rough surface S. An appropriate fundamental solution is the free-space Green's function

$$G(P,Q)=G(\mathbf{y},\mathbf{x})=\frac{-1}{2\pi}\,\frac{\exp\{ik|\mathbf{x}-\mathbf{y}|\}}{|\mathbf{x}-\mathbf{y}|},$$

where $\mathbf{x}$ and $\mathbf{y}$ are the position vectors of Q and P, respectively, with respect to the origin O. Apply Green's theorem to u and G in the region D_r with boundary $\partial D_r=H_r\cup S_r\cup T_r$, where H_r is a large hemisphere H_r of radius r and center O,

$$S_r=\{(x,y,z):z=s(x,y),\ 0\leqslant x^2+y^2<r^2\}$$

is a truncated rough surface, and

$$T_r=\{(x,y,z):x^2+y^2=r^2,\ s(x,y)\leqslant z\leqslant 0\}\tag{18}$$

is the surface of a truncated circular cylinder joining H_r and S_r. The result is

$$2u(P)=\int_{\partial D_r}\left\{u(q)\,\frac{\partial G}{\partial n_q}(P,q)-\frac{\partial u}{\partial n}\,G(P,q)\right\}dS_q,$$

where $P\in D_r$, $q\in\partial D_r$, and $\partial/\partial n_q$ denotes normal differentiation at q. Use of the boundary condition (6) yields

$$2u(P)=\int_{S_r}\left\{u(q)\frac{\partial G}{\partial n_q}(P,q)+\frac{\partial u_{\rm inc}}{\partial n}\,G(P,q)\right\}\,dS_q+I(u;H_r)+I(u;T_r), \tag{19}$$

where

$$I(u;\mathscr{S})=\int_{\mathscr{S}}\left\{u(q)\,\frac{\partial G}{\partial n_q}(P,q)-\frac{\partial u}{\partial n}\,G(P,q)\right\}\,dS_q$$

and normal differentiation is taken in a direction away from the origin [so that $\partial/\partial n=\partial/\partial r$ on H_r, consistent with Eq. (2)].

The next step is to estimate $I(u;H_r)$ and $I(u;T_r)$ for large r. Before estimating $I(u;H_r)$, using Eq. (13), we consider a single propagating plane-wave component in Eq. (13). Thus we shall evaluate $I(v;H_r)$ as $r\to\infty$, where v is defined by Eq. (12). In fact, as $v(r,\theta,\phi;\alpha,\beta)=v(r,\theta,\phi-\beta;\alpha,0)$, we can assume without loss of generality that $\beta=0$; we write

$$v(r,\theta,\phi;\alpha,0)=v(r,\theta,\phi;\alpha)=v(\mathbf{x};\alpha),\quad 0\leqslant\alpha\leqslant\frac{1}{2}\pi.$$

Indeed, we shall evaluate the limit using two different methods; these are the method of stationary phase (Sec. III) and an expansion method (Sec. IV). The reasons for this twofold evaluation are (i) the results are surprising, and (ii) the expansion method is natural but it is complicated and it leads to some subtle nonuniform behavior. We shall discuss the evaluation of $I(u;H_r)$ itself for large r in Sec. V. We then consider the contribution from $I(u;T_r)$ to Eq. (19) in Sec. VI. Finally, we will derive boundary integral equations from Eq. (19) in Sec. VII.

III. THE METHOD OF STATIONARY PHASE

We use the method of stationary phase[7] to estimate $I(v;H_r)$. It turns out that there are three cases, depending on the angle α.

We are interested in large values of $r=|\mathbf{x}|$, for fixed $\mathbf{y}$ and k. We have

$$G(P,q)\simeq(B/r)\,\exp\{ik(r-\mathbf{y}\cdot\hat{\mathbf{x}})\}, \tag{20}$$

where $B=-\frac{1}{2}/\pi$. Hence for large r,

$$v\,\frac{\partial G}{\partial r}-G\,\frac{\partial v}{\partial r}\simeq ik\frac{B}{r}\,(1-\hat{\mathbf{k}}\cdot\hat{\mathbf{x}})\,\exp\{ikr(1+\hat{\mathbf{k}}\cdot\hat{\mathbf{x}})\}\,\exp\{-ik\mathbf{y}\cdot\hat{\mathbf{x}}\}$$

and then

$$I(v;H_r)\simeq iB\,e^{ikr}\,L(kr),$$

where

$$L(\lambda)=\lambda\int_{\mathscr{D}}g(\theta,\phi)\,e^{i\lambda F(\theta,\phi)}\,d\theta\,d\phi, \tag{21}$$

$$g(\theta,\phi)=(1-\hat{\mathbf{k}}\cdot\hat{\mathbf{x}})\,\exp\{-ik\mathbf{y}\cdot\hat{\mathbf{x}}\}\,\sin\theta, \tag{22}$$

$$F(\theta,\phi)=\hat{\mathbf{k}}\cdot\hat{\mathbf{x}}\quad\text{and}\quad\mathscr{D}=\{(\theta,\phi):0\leqslant\theta\leqslant\theta_0<\pi,-\pi\leqslant\phi\leqslant\pi\}$$

is the rectangular domain of integration; this corresponds to integrating over a spherical cap subtending an angle of $2\theta_0$ at the origin, for the hemisphere H_r, we set $\theta_0=\frac{1}{2}\pi$.

We now examine three cases in turn. These are $\alpha=0$, $0<\alpha<\frac{1}{2}\pi$, and $\alpha=\frac{1}{2}\pi$.

TABLE I. Stationary-phase points for $L(\lambda)$.

	c_1	c_2	c_3	c_4	c_5	c_6	c_7
θ	0	0	π	π	α	$\pi-\alpha$	$\pi-\alpha$
ϕ	$\frac{1}{2}\pi$	$-\frac{1}{2}\pi$	$\frac{1}{2}\pi$	$-\frac{1}{2}\pi$	0	π	$-\pi$

A. The method of stationary phase: $\alpha=0$

Consider the special case $\alpha=0$, corresponding to a plane wave v propagating along the z-axis. Then we have $F(\theta,\phi)=\cos\theta$, which means that the only dependence on ϕ is through $\mathbf{y}\cdot\hat{\mathbf{x}}$:

$$L(\lambda)=\lambda\int_0^{\theta_0}(1-\cos\theta)\ b(\theta;\mathbf{y})\ e^{i\lambda\cos\theta}\sin\theta\ d\theta, \tag{23}$$

where

$$b(\theta;\mathbf{y})=\int_{-\pi}^{\pi}\exp\{-ik\mathbf{y}\cdot\hat{\mathbf{x}}\}\ d\phi.$$

Introducing spherical polar coordinates for $\mathbf{y}$,

$$\mathbf{y}=\rho\hat{\mathbf{y}}=\rho(\sin\Theta\ \cos\Phi,\sin\Theta\ \sin\Phi,\cos\Theta), \tag{24}$$

we can integrate over ϕ to obtain

$$b(\theta;\mathbf{y})=2\pi\ e^{-ik\rho\cos\theta\ \cos\Theta}\ J_0(k\rho\sin\theta\ \sin\Theta).$$

Now, the integral (23) can be estimated for large λ using the (one-dimensional) method of stationary phase. The only stationary-phase point is at $\theta=0$; as the integrand vanishes at $\theta=0$, we deduce that $L(\lambda)=O(1)$ as $\lambda\to\infty$. In fact, an integration by parts shows that

$$L(\lambda)\sim i(1-\cos\theta_0)\ b(\theta_0;\mathbf{y})\ e^{i\lambda\cos\theta_0}\quad\text{as }\lambda\to\infty,$$

in particular, for the hemisphere ($\theta_0=\frac{1}{2}\pi$), we obtain

$$I(v;H_r)=e^{ikr}\ J_0(k\rho\sin\Theta)+O((kr)^{-1/2})\quad\text{as } kr\to\infty,\quad\text{for } \alpha=0. \tag{25}$$

B. The method of stationary phase: $0<\alpha<\frac{1}{2}\pi$

Return to the integral $L(\lambda)$, defined by Eq. (21). We estimate $L(\lambda)$ for large λ, using the method of stationary phase for two-dimensional integrals.[8] Thus we look for stationary-phase points $\mathbf{c}=(\theta,\phi)\in\mathscr{D}$ at which grad $F=\mathbf{0}$; such points may be in the interior of $\mathscr{D}$ or on the boundary, $\partial\mathscr{D}$. Each $\mathbf{c}$ contributes a term to $L(\lambda)$ proportional to

$$g(\mathbf{c})\ e^{i\lambda F(\mathbf{c})},$$

the next term being $O(\lambda^{-1})$.[9] In general, $\partial\mathscr{D}$ contributes terms of $O(\lambda^{-1/2})$, whereas corners of $\partial\mathscr{D}$ contribute terms of $O(\lambda^{-1})$; all these contributions are smaller than those from stationary-phase points.

We have

$$F(\theta,\phi)=\sin\theta\ \cos\phi\ \sin\alpha+\cos\theta\ \cos\alpha.$$

Elementary calculations show that grad $F=\mathbf{0}$ at seven points $\mathbf{c}_j$ ($j=1,2,\ldots,7$) in the range $0\leqslant\theta\leqslant\pi$, $|\phi|\leqslant\pi$ (which is larger than $\mathscr{D}$); see Table I. Substituting into Eq. (22), we see that

$$g(\mathbf{c}_1)=g(\mathbf{c}_2)=g(\mathbf{c}_3)=g(\mathbf{c}_4)=g(\mathbf{c}_5)=0$$

and

$$g(\mathbf{c}_6)=g(\mathbf{c}_7)=2\sin\alpha\ \exp\{i\mathbf{k}\cdot\mathbf{y}\}.$$

So, if we integrate over a region $\mathscr{D}$ that does *not* include $\mathbf{c}_6$ and $\mathbf{c}_7$, then $L(\lambda)=o(1)$ as $\lambda\to\infty$. This will be the case if

$$\alpha<\theta_0<\pi-\alpha,$$

in particular, for the hemisphere, we obtain

$$I(v;H_r)=O((kr)^{-1/2}) \quad \text{as } kr\to\infty, \quad \text{for } 0<\alpha<\tfrac{1}{2}\pi.$$

C. The method of stationary phase: $\alpha=\frac{1}{2}\pi$

For the hemisphere, with $\alpha=\theta_0=\frac{1}{2}\pi$, we find that $\mathbf{c}_6$ and $\mathbf{c}_7$ are on $\partial\mathscr{D}$. Their contribution can be found;[10] the result is

$$I(v;H_r)=2\exp\{i\mathbf{k}\cdot\mathbf{y}\}+O((kr)^{-1/2}) \quad \text{as } kr\to\infty, \quad \text{for } \alpha=\tfrac{1}{2}\pi.$$

D. Summary

The axis of symmetry of the hemisphere H_r is the z-axis. We have considered plane waves v propagating out of the hemisphere, at an angle α to the z-axis. We have seen that $I(v;H_r)\to 0$ as $r\to\infty$, for $0<\alpha<\frac{1}{2}\pi$. For $\alpha=\frac{1}{2}\pi$ (''grazing waves,'' with respect to the plane $z=0$), $I(v;H_r)\to 2\exp\{i\mathbf{k}\cdot\mathbf{y}\}$, a finite quantity, as $r\to\infty$. For $\alpha=0$ (''normal waves,'' with respect to $z=0$), $I(v;H_r)\sim e^{ikr}\,J_0(k\rho\sin\Theta)$, which means that $I(v;H_r)$ does not have a limit (in this case) as $r\to\infty$. This unpleasant result can be verified directly when $\rho=0$; in this special case, we have

$$\begin{aligned}L(\lambda)&=2\pi\lambda\int_0^{\pi/2}(1-\cos\theta)\ e^{i\lambda\cos\theta}\sin\theta\ d\theta\\&=2\pi i\{1-i\lambda^{-1}(1-e^{i\lambda})\}\end{aligned}$$

exactly, after an integration by parts. In fact, in this special case, we can evaluate I exactly, without using the approximation (20); the result is

$$I(v;H_r)=e^{ikr}, \quad \rho=\alpha=0. \tag{26}$$

As in the two-dimensional case,[2] it is possible to derive a uniform approximation for α near $\frac{1}{2}\pi$.[11] The situation for small α is more complicated.[12] We shall not pursue these nonuniformities here.

IV. AN EXPANSION METHOD

We shall evaluate the integral over the hemisphere, $I(v;H_r)$, using suitable expansions of v and G in spherical polar coordinates. Thus

$$v(\mathbf{x};\alpha)=\exp\{i\mathbf{k}\cdot\mathbf{x}\}=\sum_{n=0}^{\infty}(2n+1)\ i^n\ j_n(kr)\ P_n(\cos\theta_1),$$

where $j_n(x)=(\frac{1}{2}\pi/x)^{1/2}\,J_{n+1/2}(x)$ is a spherical Bessel function,

$$\cos\theta_1=\hat{\mathbf{k}}\cdot\hat{\mathbf{x}}=\sin\theta\ \sin\alpha\ \cos\phi+\cos\theta\ \cos\alpha$$

and P_n is a Legendre polynomial. Similarly,

$$G(P,q)=G(\mathbf{y},\mathbf{x})=\frac{-ik}{2\pi}\sum_{n=0}^{\infty}(2n+1)\ j_n(k\rho)\ h_n(kr)\ P_n(\cos\theta_2)$$

for $r>\rho$, where

$$\cos\theta_2=\hat{\mathbf{y}}\cdot\hat{\mathbf{x}}=\sin\theta\ \sin\Theta\ \cos(\phi-\Phi)+\cos\theta\ \cos\Theta,$$

$h_n(x)\equiv h_n^{(1)}(x)=(\frac{1}{2}\pi/x)^{1/2}\ H_{n+1/2}^{(1)}(x)$ is a spherical Hankel function and $H_\nu^{(1)}$ is a Hankel function. Hence

$$I(v;H_r)=\sum_{l=0}^{\infty}\sum_{s=0}^{\infty}(2l+1)(2s+1)\ i^s\ j_l(k\rho)\ W_{ls}(kr)\ A_{ls},$$

where

$$W_{ls}(w)=-iw^2\{j_s(w)h_l'(w)-j_s'(w)h_l(w)\} \tag{27}$$

and

$$A_{ls}=\frac{1}{2\pi}\int_{-\pi}^{\pi}\int_0^{\pi/2}P_l(\cos\theta_2)\ P_s(\cos\theta_1)\ \sin\theta\ d\theta\ d\phi.$$

Note that W_{ll} is essentially a Wronskian, given by $W_{ll}=1$.

Let us evaluate A_{ls}. The addition theorem for Legendre polynomials gives

$$P_s(\cos\theta_1)=\sum_{m=0}^{s}\epsilon_m c_s^m P_s^m(\cos\theta)\ P_s^m(\cos\alpha)\ \cos m\phi,$$

$$P_l(\cos\theta_2)=\sum_{n=0}^{l}\epsilon_n c_l^n P_l^n(\cos\theta)\ P_l^n(\cos\Theta)\ \cos n(\phi-\Phi),$$

where P_n^m is an associated Legendre function, $\epsilon_0=1$, $\epsilon_m=2$ for $m\geqslant 1$, and

$$c_s^m=[(s-m)!]/[(s+m)!].$$

Hence, integrating over ϕ, we obtain

$$A_{ls}=\sum_{m=0}^{s}\epsilon_m c_l^m c_s^m P_l^m(\cos\Theta)\ P_s^m(\cos\alpha)\ B_{ls}^m\cos m\Phi, \tag{28}$$

where

$$B_{ls}^m=\int_0^{\pi/2}P_l^m(\cos\theta)\ P_s^m(\cos\theta)\ \sin\theta\ d\theta=\int_0^1 P_l^m(\mu)\ P_s^m(\mu)\ d\mu.$$

[Actually, the upper limit on the summation in Eq. (28) should be $\min\{l,s\}$, but this is of no consequence as $P_n^m\equiv 0$ for $m>n$.] B_{ls}^m has been evaluated by Hulme.[13] It turns out that

$$B_{2l+m,2s+m+1}^m=\frac{2^{2m}(-1)^{l+s+1}\Gamma(l+m+\frac{1}{2})\Gamma(s+m+\frac{3}{2})}{\pi(2l-2s-1)(l+s+m+1)\ l!\ s!}, \tag{29}$$

$$B_{2l+m+1,2s+m}^m=\frac{2^{2m}(-1)^{l+s+1}\Gamma(l+m+\frac{3}{2})\Gamma(s+m+\frac{1}{2})}{\pi(2s-2l-1)(l+s+m+1)\ l!\ s!}, \tag{30}$$

$B_{ll}^m=[(2l+1)\ c_l^m]^{-1}$ and $B_{ls}^m=0$ if $|l-s|$ is a positive even integer.

Now, returning to I, we see that it can be expressed in the form

$$I(v;H_r)=\sum_{l=0}^{\infty}\sum_{s=0}^{\infty}\sum_{m=0}^{s}\epsilon_m Q_{ls}^m\cos m\Phi,$$

where

$$Q_{ls}^m=(2l+1)(2s+1)\ i^s\ j_l(k\rho)\ W_{ls}(kr)\ c_l^m c_s^m\ B_{ls}^m\ P_l^m(\cos\Theta)\ P_s^m(\cos\alpha).$$

Interchanging the summations over s and m, we obtain

$$I(v;H_r)=\sum_{l=0}^{\infty}\sum_{m=0}^{\infty}\sum_{s=m}^{\infty}\epsilon_m Q_{ls}^m\cos m\Phi=\sum_{m=0}^{\infty}\epsilon_m\left\{\sum_{l=0}^{\infty}\sum_{s=m}^{\infty}Q_{ls}^m\right\}\cos m\Phi.$$

But $Q_{ls}^m\equiv 0$ for $m>l$, whence

$$I(v;H_r)=\sum_{m=0}^{\infty}\epsilon_m\Lambda_m\cos m\Phi,$$

where

$$\Lambda_m=\sum_{l=0}^{\infty}\sum_{s=0}^{\infty}Q_{l+m,s+m}^m.$$

This shows that I can be expressed as a Fourier series in the azimuthal coordinate of the observation point **y**, which is as expected.

A. A special case: $\rho=0$ ($\mathbf{y}=0$)

The expression for Λ_m is complicated. To gain some insight into its evaluation, we start with the special case of $\rho=0$. Then, only Q_{0s}^0 is not identically zero, whence

$$\begin{aligned}I(v;H_r)&=\sum_{s=0}^{\infty}Q_{0s}^0\\&=1+i\sum_{n=0}^{\infty}(4n+3)(-1)^n\ W_{0,2n+1}(kr)\ B_{0,2n+1}^0\ P_{2n+1}(\cos\alpha),\end{aligned}$$

where we have used $B_{00}^0=W_{00}=1$ and $B_{0,2n}^0=0$; also

$$B_{0,2n+1}^0=\int_0^1 P_{2n+1}(\mu)\ d\mu=\frac{(-1)^n\ \Gamma(n+\frac{1}{2})}{2\sqrt{\pi}\ (n+1)!}.$$

Given the definition (27), we define

$$S(\lambda;\alpha)=\sum_{n=0}^{\infty}(4n+3)(-1)^n\ B_{0,2n+1}^0\ j_{2n+1}(\lambda)\ P_{2n+1}(\cos\alpha)\tag{31}$$

so that

$$I(v;H_r)=1+\lambda\ e^{i\lambda}\{S+iS'+i\lambda^{-1}S\},\tag{32}$$

where we have simplified using $h_0(\lambda)=e^{i\lambda}/(i\lambda)$.

Proceeding formally, we substitute the known asymptotic approximation

$$j_m(\lambda)\sim\lambda^{-1}\sin\left(\lambda-\frac{1}{2}m\pi\right)\quad\text{as }\lambda\to\infty, \tag{33}$$

into Eq. (31), giving $S(\lambda;\alpha)\simeq -C(\alpha)\ \lambda^{-1}\cos\lambda$, where

$$C(\alpha)=\sum_{n=0}^{\infty}(4n+3)\ B^0_{0,2n+1}\ P_{2n+1}(\cos\alpha).$$

Hence, from Eq. (32),

$$I(v;H_r)\simeq 1-C(\alpha)\quad\text{as } kr\to\infty.$$

But $C(\alpha)$ is a known Fourier–Legendre expansion:

$$C(\alpha)=\begin{cases}1, & 0<\alpha<\frac{1}{2}\pi,\\ -1, & \frac{1}{2}\pi<\alpha<\pi,\\ 0, & \alpha=0,\ \frac{1}{2}\pi,\pi,\end{cases}$$

and is defined by periodicity for other values of α. Hence we deduce that

$$I(v;H_r)=o(1)\quad\text{as } kr\to\infty,\quad\text{for } \rho=0\ \text{ and }\ 0<\alpha<\tfrac{1}{2}\pi,$$

which is correct, but

$$I(v;H_r)=1+o(1)\quad\text{as } kr\to\infty,\quad\text{for } \rho=0\text{ and }\alpha=0,\tfrac{1}{2}\pi,$$

which is incorrect. This last result follows from $C(0)=0$, giving $S(\lambda;0)=o(\lambda^{-1})$ as $\lambda\to\infty$. In fact, we have

$$S(\lambda;0)=\sum_{n=0}^{\infty}\frac{(4n+3)\Gamma(n+\frac{1}{2})}{2\sqrt{\pi}\ (n+1)!}\ j_{2n+1}(\lambda)=\frac{1-\cos\lambda}{\lambda}, \tag{34}$$

exactly. This can be shown either by using a formula due to Gegenbauer,[14] namely

$$\left(\frac{1}{2}\lambda\right)^{\gamma}=\sum_{n=0}^{\infty}\frac{(2n+\gamma)\ \Gamma(n+\gamma)}{n!}\ J_{2n+\gamma}(\lambda)$$

with $\gamma=-\frac{1}{2}$, or by an application of the Mellin transform with respect to λ (the resulting series can be summed using the known formula for $F(a,b;c;1)$ where F is the Gauss hypergeometric function; the sum can be inverted using the Mellin convolution theorem).

The formal calculation above shows that we cannot expect to obtain the correct result if we simply replace the spherical Bessel functions by their large-argument asymptotic approximations, at least in the special cases of grazing ($\alpha=\frac{1}{2}\pi$) and normal ($\alpha=0$) plane waves. We examine the latter case next.

B. Another special case: $\alpha=0$

When $\alpha=0$, only those terms with $m=0$ contribute, giving

$$I(v;H_r)=\sum_{l=0}^{\infty}\sum_{s=0}^{\infty}Q^0_{ls}=\sum_{l=0}^{\infty}(2l+1)\ i^l\ b_l(kr)\ j_l(k\rho)\ P_l(\cos\Theta),$$

where

$$b_l(\lambda)=\sum_{s=0}^{\infty}(2s+1)\,i^{s-l}\,W_{ls}(\lambda)\,B^0_{ls}$$
$$=1+\lambda^2\{h_l'(\lambda)\,S_l(\lambda)-h_l(\lambda)\,S_l'(\lambda)\},\tag{35}$$

$$S_l(\lambda)=\sum_{\substack{s=0\\ s\neq l}}^{\infty}(2s+1)(-i)^{l-s+1}\,B^0_{ls}\,j_s(\lambda),$$

and we have used Eq. (27). It remains to evaluate $S_l(\lambda)$, and thence $b_l(\lambda)$ for large λ. Before doing this, let us consider the expected final answer, namely Eq. (25). From another formula due to Gegenbauer,[15] we have

$$\int_0^{\pi}J_0(w\sin\theta)\,P_n(\cos\theta)\,\sin\theta\,d\theta=\begin{cases}2\,(-1)^{n/2}\,P_n(0)\,j_n(w), & n \text{ even},\\ 0, & n \text{ odd},\end{cases}$$

whence

$$J_0(w\sin\theta)=\sum_{n=0}^{\infty}(4n+1)(-1)^n\,P_{2n}(0)\,j_{2n}(w)\,P_{2n}(\cos\theta).$$

Thus we are expecting to find that

$$b_{2l}(\lambda)=e^{i\lambda}\,P_{2l}(0)=e^{i\lambda}\,\frac{(-1)^l\,\Gamma(l+\frac{1}{2})}{\sqrt{\pi}\,l!}\quad\text{and}\quad b_{2l+1}=0.\tag{36}$$

Now, consider S_{2l+1}. From Eq. (30) with $m=0$, we have

$$S_{2l+1}(\lambda)=\frac{\Gamma(l+\frac{3}{2})}{2\pi\,l!}\sum_{n=0}^{\infty}\frac{(4n+1)\,\Gamma(n+\frac{1}{2})}{(n+l+1)(n-l-\frac{1}{2})n!}j_{2n}(\lambda).\tag{37}$$

Using

$$[\Gamma(n+a)]/[\Gamma(n+b)]\sim n^{a-b}\quad\text{as } n\to\infty,\tag{38}$$

we see that, for large n, the terms in the series (37) behave like $n^{-3/2}\,j_{2n}(\lambda)$. Given that $|J_\nu(\lambda)|\leqslant 1$ for all real λ and for all positive ν,[16] we deduce that the series (37) is absolutely and uniformly convergent. Thus we can replace $j_{2n}(\lambda)$ by its large-argument asymptotic approximation (33) to obtain

$$S_{2l+1}(\lambda)\sim\mathscr{A}_l\lambda^{-1}\sin\lambda\quad\text{as }\lambda\to\infty,$$

where

$$\mathscr{A}_l=\frac{\Gamma(l+\frac{3}{2})}{\pi\,l!}\sum_{n=0}^{\infty}\frac{(2n+\frac{1}{2})\,\Gamma(n+\frac{1}{2})}{(n+l+1)(n-l-\frac{1}{2})}\,\frac{(-1)^n}{n!}$$

is a real constant. Substituting into Eq. (35), using $h_n(\lambda)\sim\lambda^{-1}(-i)^{n+1}\,e^{i\lambda}$ as $\lambda\to\infty$, we find that

$$b_{2l+1}(\lambda)=1+(-1)^l\mathscr{A}_l+o(1)\quad\text{as }\lambda\to\infty.\tag{39}$$

Finally, we evaluate $\mathscr{A}_l$ using a contour-integral method. Splitting into partial fractions, the series can be written as

$$\sum_{n=0}^{\infty} \frac{\Gamma(n+\frac{1}{2})}{n+l+1} \frac{(-1)^n}{n!} + \sum_{n=0}^{\infty} \frac{\Gamma(n+\frac{1}{2})}{n-l-\frac{1}{2}} \frac{(-1)^n}{n!}. \tag{40}$$

Then, consider integrating the function $\Gamma(\frac{1}{2}-z)\ \Gamma(z)/(l-z+1)$ around a large circular contour in the complex z-plane. $\Gamma(z)$ has simple poles at $z=-n$, $n=0,1,2,\ldots$, with residue $(-1)^n/n!$. Thus the residues at the poles of $\Gamma(z)$ and $\Gamma(\frac{1}{2}-z)$ give rise to the first and second sums, respectively, in Eq. (40). The residue from the pole at $z=l+1$ is

$$-\Gamma(-\tfrac{1}{2}-l)\ \Gamma(l+1) = (l+\tfrac{1}{2})^{-1} l!\ \Gamma(\tfrac{1}{2}-l).$$

Combining Eq. (38) with the formula

$$\Gamma(\tfrac{1}{2}+z)\ \Gamma(\tfrac{1}{2}-z) = \pi \sec \pi z \tag{41}$$

shows that the contribution from integrating around the large circular contour vanishes as the circle expands to infinity. Hence the calculus of residues gives

$$\frac{\pi l!}{\Gamma(l+\frac{3}{2})} \mathscr{A}_l + \frac{l!\ \Gamma(\frac{1}{2}-l)}{l+\frac{1}{2}} = 0$$

whence $\mathscr{A}_l = (-1)^{l+1}$, using Eq. (41). Hence Eq. (39) gives $b_{2l+1}(\lambda) \to 0$ as $\lambda \to \infty$, as predicted by Eq. (36).

Next, consider S_{2l}. From Eq. (29) with $m=0$, we have

$$S_{2l}(\lambda) = \frac{\Gamma(l+\frac{1}{2})}{2\pi\ l!} \sum_{n=0}^{\infty} \frac{(4n+3)\ \Gamma(n+\frac{3}{2})}{(n+l+1)(n-l+\frac{1}{2})\ n!}\, j_{2n+1}(\lambda). \tag{42}$$

The terms in this series decay like $n^{-1/2}\, j_{2n+1}(\lambda)$ as $n \to \infty$, which is not fast enough to guarantee uniform convergence. However, we have

$$S_0(\lambda) = S(\lambda;0) = \lambda^{-1}(1-\cos\lambda)$$

from Eq. (34), so that

$$S_{2l}(\lambda) = \frac{\Gamma(l+\frac{1}{2})}{\sqrt{\pi}\ l!}\, S_0(\lambda) + T_{2l}(\lambda),$$

where

$$T_{2l}(\lambda) = \frac{\Gamma(l+\frac{1}{2})}{2\pi\ l!} \sum_{n=0}^{\infty} \frac{(4n+3)\ \Gamma(n+\frac{3}{2})}{n!} \left\{ \frac{1}{(n+l+1)(n-l+\frac{1}{2})} - \frac{1}{(n+1)(n+\frac{1}{2})} \right\} j_{2n+1}(\lambda),$$

this series is absolutely and uniformly convergent, whence $T_{2l}(\lambda) \sim \mathscr{B}_l \lambda^{-1} \cos\lambda$ as $\lambda \to \infty$, where

$$\mathscr{B}_l = \frac{\Gamma(l+\frac{1}{2})}{\pi\ l!} \sum_{n=0}^{\infty} \Gamma(n+\tfrac{3}{2}) \left\{ \frac{1}{n+1} + \frac{1}{n+\frac{1}{2}} - \frac{1}{n+l+1} - \frac{1}{n-l+\frac{1}{2}} \right\} \frac{(-1)^n}{n!}$$

is a real constant. Substituting back into Eq. (35), we find that

$$b_{2l}(\lambda) = \frac{(-1)^l\ \Gamma(l+\frac{1}{2})}{\sqrt{\pi}\ l!}\, e^{i\lambda} + 1 - \frac{(-1)^l\ \Gamma(l+\frac{1}{2})}{\sqrt{\pi}\ l!} + (-1)^l \mathscr{B}_l + o(1) \tag{43}$$

as $\lambda \to \infty$. The first term on the right-hand side is in accord with the prediction (36). The next three terms sum to zero, as expected. This can be shown by evaluating $\mathscr{B}_l$ using a contour-integral method (as for $\mathscr{A}_l$): use

$$\Gamma\left(\frac{3}{2}-z\right)\ \Gamma(z)\{(1-z)^{-1}-(l-z+1)^{-1}\}.$$

This completes the proof for $\alpha=0$ using an expansion method. It demonstrates that the expansion method is much more complicated to use (and more subtle, due to nonuniform convergence of one of the component series) than an approach based on the method of stationary phase.

V. ASYMPTOTIC BEHAVIOR OF $I(u;H_r)$

When a plane wave is reflected by a rough surface S, we can use the angular-spectrum representation (13) for the reflected field in $z>0$. Thus we have

$$I(u;H_r)=I(u_{\rm pr};H_r)+I(u_{\rm ev};H_r)+I(u_{\rm con};H_r).$$

For $I(u_{\rm ev};H_r)$, with $u_{\rm ev}$ defined by Eq. (14), we have

$$I(w;H_r)\simeq iB\lambda\ e^{i\lambda}\int_{\mathscr{D}} g(\theta,\phi)\ e^{i\lambda F(\theta,\phi)}\ d\theta\ d\phi,$$

where w is defined by Eq. (16), $\lambda=kr$, $B=-\frac{1}{2}/\pi$,

$$F(\theta,\phi)=[\mu\cos\phi+\nu\sin\phi]\sin\theta+i\cos\theta\ \sqrt{\kappa^2-1},$$

$$g(\theta,\phi)=[1-F(\theta,\phi)]\ \exp\{-ik\mathbf{y}\cdot\hat{\mathbf{x}}\}\ \sin\theta,$$

and $\mathscr{D}$ is defined below Eq. (22) with $\theta_0=\frac{1}{2}\pi$. As $\kappa>1$, grad $F\neq\mathbf{0}$ in $\mathscr{D}$, whence the vector

$$\mathbf{f}(\theta,\phi)=g(\text{grad } F)/|\text{grad } F|^2$$

is well defined. Then, use of the identity

$$ge^{i\lambda F}=(i\lambda)^{-1}\{\text{div }(e^{i\lambda F}\mathbf{f})-e^{i\lambda F}\text{div }\mathbf{f}\},$$

together with the divergence theorem in $\mathscr{D}$, shows that $I(w;H_r)=o(1)$ as $kr\to\infty$.[17] Hence from Eq. (14),

$$I(u_{\rm ev};H_r)\to 0 \quad \text{as } r\to\infty.$$

As $\mathscr{C}$ in Eq. (15) is continuous, we know that $u_{\rm con}$ satisfies the Sommerfeld radiation condition.[18] It follows that

$$I(u_{\rm con};H_r)\to 0 \quad \text{as } r\to\infty.$$

Finally, consider $I(u_{\rm pr};H_r)$. If $0\leqslant\alpha_n<\frac{1}{2}\pi$, the results of the previous sections are immediately applicable. For a typical grazing-wave component v, propagating at some angle β, our radiation condition implies that we consider $I(v;H_r^m)$, with m chosen according to Eq. (17). The stationary-phase analysis of Sec. III shows that $I(v;H_r^m)\to 0$ as $r\to\infty$. For the other three values of m, v will either be incoming through the corresponding H_r^m, and so its contribution must be discarded; or the contribution is negligible, using the method of stationary phase again.

Thus, in summary, let us extract the normal waves ($\alpha=0$) from $u_{\rm pr}$, and write

$$u_{\rm pr}(r,\theta,\phi)=A_0\ e^{ikr\cos\theta}+\text{other propagating waves with } 0<\alpha<\tfrac{1}{2}\pi, \tag{44}$$

where the coefficient A_0 is unknown. Then

$$I(u;H_r)\sim A_0\ e^{ikr}\ \mathscr{U}_0(P) \quad \text{as } r\to\infty, \tag{45}$$

where

$$\mathscr{U}_0(P)\equiv\mathscr{U}_0(\rho,\Theta,\Phi)=J_0(k\rho\sin\Theta). \tag{46}$$

VI. ASYMPTOTIC BEHAVIOR OF $I(u;T_r)$

The truncated cylindrical surface T_r is defined by Eq. (18). A point $q\in T_r$, with position vector $\mathbf{x}$, has cylindrical polar coordinates (r,ϕ,z). Then, for large r,

$$|\mathbf{x}-\mathbf{y}|\simeq r-\rho\sin\Theta\ \cos(\phi-\Phi),$$

where the fixed point P has position vector $\mathbf{y}$ and spherical polar coordinates (ρ,Θ,Φ) defined by Eq. (24). Hence as $\partial/\partial n=\partial/\partial r$ on T_r,

$$u\frac{\partial G}{\partial n}-G\frac{\partial u}{\partial n}\simeq\frac{B}{r}\ e^{ikr}\left(iku-\frac{\partial u}{\partial r}\right)\exp\{-ik\rho\sin\Theta\ \cos(\phi-\Phi)\},$$

where $B=-\frac{1}{2}/\pi$. Let

$$\mathscr{E}(r,\phi)=\int_s^0\left(\frac{\partial u}{\partial r}-iku\right)\ dz,$$

where the lower limit is $s(r\cos\phi,r\sin\phi)$. Then

$$I(u;T_r)\sim\frac{1}{2\pi}\ e^{ikr}\int_{-\pi}^{\pi}\mathscr{E}(r,\phi)\ \exp\{-ik\rho\sin\Theta\ \cos(\phi-\Phi)\}\ d\phi \quad \text{as } r\to\infty.$$

When is it true that $I(u;T_r)\to 0$ as $r\to\infty$? One sufficient condition is that

$$s\to 0 \ \text{ as } \ r\to\infty, \quad \text{for all } \phi,$$

this means that the rough surface approaches the flat plane $z=0$ at large distances, in all directions.

Another sufficient condition is that

$$\frac{\partial u}{\partial r}-iku=o(1) \ \text{ as } r\to\infty, \quad \text{for all } \phi \ \text{ and } \ s\leqslant z\leqslant 0,$$

so that u satisfies a form of radiation condition in directions parallel to $z=0$. In particular, this will be the case if u comprises outgoing cylindrical or spherical waves.

Next, consider a typical plane wave v, defined by Eq. (12); thus let

$$v=e^{ikr\sin\alpha\cos\phi}\ e^{ikz\cos\alpha} \ \text{ with } \ 0<\alpha\leqslant\tfrac{1}{2}\pi.$$

Then, a Fourier expansion in ϕ leads to Fourier components involving $J_n(kr\sin\alpha)$ and $J_n'(kr\sin\alpha)$. As $J_n(w)=O(w^{-1/2})$ as $w\to\infty$, we deduce that $I(v;T_r)\to 0$ as $r\to\infty$. This result includes grazing waves, but not normal waves for which $\alpha=0$. When $\alpha=0$, $v=e^{ikz}$ whence $\partial v/\partial r=0$ and the integration over z in $\mathscr{E}$ is trivial. The result is

$$\begin{aligned}I(v;T_r)&\sim\frac{1}{2\pi}\ e^{ikr}\int_{-\pi}^{\pi}(e^{iks}-1)\ \exp\{-ik\rho\sin\Theta\ \cos(\phi-\Phi)\}\ d\phi\\&=\frac{1}{2\pi}\ e^{ikr}\int_{-\pi}^{\pi}e^{iks}\ \exp\{-ik\rho\sin\Theta\ \cos(\phi-\Phi)\}\ d\phi-e^{ikr}\ J_0(k\rho\sin\Theta) \ \text{ as } r\to\infty.\end{aligned}$$

Thus, in summary, suppose that for $s\leqslant z\leqslant 0$ and large r,

$$u = A_0\, e^{ikz} + \tilde{u},$$

where the coefficient A_0 is the same as in Eq. (44) and $\tilde{u}$ is such that $I(\tilde{u};T_r)\to 0$ as $r\to\infty$. Then

$$I(u;T_r)\sim A_0\, e^{ikr}\{\mathscr{U}_s(r;P)-\mathscr{U}_0(P)\} \quad \text{as } r\to\infty, \tag{47}$$

where $\mathscr{U}_0$ is defined by Eq. (46) and

$$\mathscr{U}_s(r;P)\equiv\mathscr{U}_s(r;\rho,\Theta,\Phi)=\frac{1}{2\pi}\int_{-\pi}^{\pi} e^{iks}\,\exp\{-ik\rho\sin\Theta\,\cos(\phi-\Phi)\}\,d\phi; \tag{48}$$

the dependence on r comes from the exponent $s=s(r\cos\phi, r\sin\phi)$.

VII. BOUNDARY INTEGRAL EQUATIONS

In Sec. II, we used Green's theorem to obtain the integral representation

$$2u(P)=\int_{S_r}\left\{u(q)\,\frac{\partial G}{\partial n_q}(P,q)+\frac{\partial u_{\rm inc}}{\partial n}\,G(P,q)\right\}\,dS_q+I(u;H_r)+I(u;T_r), \tag{49}$$

when $P\in D_r$, the region bounded by the hemisphere H_r, the truncated rough surface S_r, and the truncated circular cylinder T_r. Note that the left-hand side of this equation does not depend on r, so that the right-hand side of the equation must have a limit as $r\to\infty$. Before taking this limit, it is instructive to consider a very simple example.

A. An example

Consider a plane wave *normally* incident upon a *flat* surface at $z=-h$. Thus

$$u_{\rm inc}=e^{-ikz} \quad \text{and } u=A_0\, e^{ikz} \quad \text{with } A_0=e^{2ikh}.$$

This is the exact solution. Let us see how this solution is reconstructed by the representation (49). For simplicity, we take P at the origin; this will permit all the integrals to be evaluated exactly (without any asymptotic approximations). Thus, from Eq. (26), we have

$$I(u;H_r)=A_0\, e^{ikr}. \tag{50}$$

On S_r, we have $u=A_0\, e^{-ikh}$, $\partial u/\partial n=-iku$,

$$G=BR_\sigma^{-1}e^{ikR_\sigma},\quad \partial G/\partial n=hR_\sigma^{-2}(ik-R_\sigma^{-1})G$$

and $R_\sigma=\sqrt{\sigma^2+h^2}$, whence the integral over S_r is

$$\begin{aligned} I(u;S_r)&=2\pi A_0 B\, e^{-ikh}\int_0^r e^{ikR_\sigma}\{ik+hR_\sigma^{-1}(ik-R_\sigma^{-1})\}\frac{\sigma d\sigma}{R_\sigma}\\ &=-A_0\, e^{-ikh}\int_h^R e^{ikt}\{ik+ht^{-1}(ik-t^{-1})\}dt\\ &=-A_0\, e^{-ikh}\,[e^{ikt}+ht^{-1}\,e^{ikt}]_{t=h}^{R}\\ &=2A_0-A_0\left(1+\frac{h}{R}\right)e^{ik(R-h)}, \end{aligned} \tag{51}$$

where $R=\sqrt{r^2+h^2}$.

On T_r, we have $u=A_0\, e^{ikz}$ and $\partial u/\partial n=\partial u/\partial r=0$, whence

$$I(u;T_r)=2\pi A_0 Br\int_{-h}^{0} e^{ikz}\frac{\partial}{\partial r}\left(\frac{e^{ikR_z}}{R_z}\right)dz$$

$$=-A_0\,[(1-zR_z^{-1})\,e^{ik(R_z+z)}]_{z=-h}^{0}$$

$$=-A_0\,e^{ikr}+A_0\left(1+\frac{h}{R}\right)e^{ik(R-h)}, \tag{52}$$

where $R_z=\sqrt{r^2+z^2}$.

Adding Eqs. (50)–(52), we see that their sum is exactly $2A_0$, which is $2u(P)$ evaluated at the origin. Note that, as $r\to\infty$,

$$I(u;S_r)\sim 2A_0-A_0\,e^{ik(r-h)},$$

$$I(u;T_r)\sim -A_0\,e^{ikr}+A_0\,e^{ik(r-h)},$$

and $I(u;H_r)$ does not simplify further. Thus the boundary integral over the truncated rough surface does not have a limit as $r\to\infty$. Moreover, the integral over the truncated cylinder T_r does not have a limit as $r\to\infty$, and it is not negligible. This is a genuine three-dimensional effect, which is not seen in the two-dimensional case.[2]

B. Taking the limit: A new finite-part integral

Letting $r\to\infty$ in Eq. (49), we obtain

$$2u(P)=\oint_S\left\{u(q)\,\frac{\partial G}{\partial n_q}(P,q)+\frac{\partial u_{\rm inc}}{\partial n}\,G(P,q)\right\}dS_q,\quad P\in D_\infty, \tag{53}$$

where D_∞ is the unbounded region $z>s$,

$$\oint_S\cdots dS=\lim_{r\to\infty}\left\{\int_{S_r}\cdots dS+A_0\,e^{ikr}\,\mathscr{U}_s\right\} \tag{54}$$

and $\mathscr{U}_s$ is defined by Eq. (48). Note that the terms involving $\mathscr{U}_0$ in Eqs. (45) and (47) cancel.

The definition (54) is a nonstandard form of finite-part integral. It reduces to the standard definition of a principal-value integral at infinity if the coefficient A_0 vanishes; in other words, the standard definition is only appropriate if the scattered field does *not* include a discrete plane wave propagating up the z-axis. For a general rough surface, we do not know *a priori* whether $A_0=0$ or not.

We can express A_0 in terms of the values of $u(r,\theta,\phi)$ on $z=0$ ($\theta=\frac{1}{2}\pi$). Thus write

$$u\left(r,\frac{1}{2}\pi,\phi\right)=\sum_{n=-\infty}^{\infty}u_n(r)\,e^{in\phi}.$$

Hence, as a plane wave propagating along the z-axis is constant on planes of constant z, we have

$$A_0=\lim_{r\to\infty}u_0(r)=\frac{1}{2\pi}\lim_{r\to\infty}\int_{-\pi}^{\pi}u\left(r,\frac{1}{2}\pi,\phi\right)\,d\phi.$$

However, this formula is not useful, as we do not know u on $z=0$. What we would like is a similar formula, involving the boundary values of u on S.

Let us combine the identity

$$A_0=\frac{2}{r^2}\int_0^r u_0(\sigma)\;\sigma\,d\sigma+\frac{2}{r^2}\int_0^r[A_0-u_0(\sigma)]\sigma\,d\sigma$$

with an assumption that $u_0(r)=A_0+O(r^{-\delta})$ as $r\to\infty$, where $\delta>0$. Then, the second integral is $o(1)$ as $r\to\infty$, whence

$$A_0=\lim_{r\to\infty}\frac{2}{r^2}\int_0^r u_0(\sigma)\ \sigma\ d\sigma$$

$$=\frac{1}{\pi}\lim_{r\to\infty}\frac{1}{r^2}\int_{\mathscr{D}_r} u\left(\sigma,\frac{1}{2}\pi,\phi\right)\ \sigma\ d\sigma\ d\phi, \tag{55}$$

where $\mathscr{D}_r$ is the circular disk on $z=0$ with $x^2+y^2<r^2$. This is another formula for A_0 in terms of u on $z=0$. However, this formula involves u everywhere on $\mathscr{D}_r$, so we can relate it to an integral over S_r, using Green's theorem.

Consider the truncated circular cylinder V_r with axis along the z-axis and radius r, between $z=0$ and $z=s$. Thus one end of V_r is S_r and the other is the circular disk $\mathscr{D}_r$. Apply Green's theorem in V_r to u and $\sin kz$, giving

$$k\int_{\mathscr{D}_r} u\ dS+\int_{S_r}\left\{u\ \frac{\partial}{\partial n}(\sin kz)-\frac{\partial u}{\partial n}\sin kz\right\}\ dS-\int_{T_r}\frac{\partial u}{\partial n}\sin kz\ dS=0,$$

where T_r, defined by Eq. (18), is the curved part of V_r on which $x^2+y^2=r^2$. The third integral is $O(r)$ as $r\to\infty$, as it is bounded by $2\pi rM\max(s)$, where M is a bound on $|\partial u/\partial r|$. Hence, comparing with Eq. (55), and making use of Eq. (6), we see that

$$A_0=\lim_{r\to\infty}\mathscr{A}(r)\quad\text{where}\quad\mathscr{A}(r)=\frac{-1}{\pi kr^2}\int_{S_r}\left\{u\ \frac{\partial}{\partial n}(\sin kz)+\frac{\partial u_{\rm inc}}{\partial n}\sin kz\right\}\ dS, \tag{56}$$

which is a formula for A_0 in terms of the boundary values of u.

For the example in Sec. VII A, one can check that Eq. (56) does produce the correct value for A_0.

C. A boundary integral equation for the scattered field

Letting $P\to p\in S$ in Eq. (53) gives

$$u(p)=\oint_S\left\{u(q)\ \frac{\partial G}{\partial n_q}(p,q)+\frac{\partial u_{\rm inc}}{\partial n}\ G(p,q)\right\}\ dS_q,\quad p\in S. \tag{57}$$

This would be a boundary integral equation for u on S if we knew A_0. A_0 is defined by the formula (56), which requires $u(q)$ for $q\in S$; but we can only find $u(q)$ by solving Eq. (57).

Two possible ways to proceed are as follows. First, one could *assume* that $A_0=0$. In that case, the integral in Eq. (57) becomes an ordinary principal-value integral at infinity. However, the integral will diverge if it turns out that $A_0\neq 0$; see the example in Sec. VII A.

Second, from Eq. (56), we could replace the constant A_0 by $\mathscr{A}(r)$, where r is the radius of the truncated rough surface. This gives

$$u(p)=\int_{S_r}\left\{u(q)\ \frac{\partial\widetilde{G}}{\partial n_q}(r;p,q)+\frac{\partial u_{\rm inc}}{\partial n}\ \widetilde{G}(r;p,q)\right\}dS_q,\quad p\in S_r, \tag{58}$$

where

$$\widetilde{G}(r;P,Q)=G(P,Q)-(\pi kr^2)^{-1}\ e^{ikr}\ \mathscr{U}_s(r;P)\ \sin kz, \tag{59}$$

$Q=(x,y,z)$ and $\mathscr{U}_s$ is defined by Eq. (48). Thus we have a plausible boundary integral equation for u on S_r. Note that, in any numerical treatment, the rough surface would have to be truncated to S_r, so our ''plausible'' integral equation seems to be optimal in some sense. It remains to carry out numerical experiments.

VIII. CONCLUSION

In this paper we have considered the three-dimensional problem of the reflection of a plane wave by an infinite two-dimensional rough surface, defined by $z=s(x,y)$ with $-h\leqslant s\leqslant 0$. We have shown that the derivation of a boundary integral equation for this problem, akin to the Helmholtz integral equation for scattering by a bounded obstacle, is by no means straightforward. In particular, if the scattered field includes a plane wave propagating along the z-axis away from the rough surface (''normal waves''), then the usual Helmholtz integral equation is not valid: the boundary integral diverges. We have offered a modified integral equation which reduces to the standard Helmholtz integral equation when normal waves are absent.

The situation just described is unsatisfactory, even though the mathematical difficulty may be overcome. Indeed, this difficulty is due entirely to the unphysical problem posed at the outset: *plane-wave* reflection by an *infinite* rough surface. Clearly, we can realize neither a plane wave nor an infinite rough surface. Moreover, the mathematical difficulty disappears if we consider either point-source insonification or a finite patch of roughness on an otherwise flat surface.[2]

Several papers have been written in which a Helmholtz integral equation was used to provide ''exact'' or ''benchmark'' numerical solutions for plane-wave reflection by an infinite one-dimensional rough surface, the purpose being to validate various approximate theories.[19] We have shown here that the same integral equation cannot be used for two-dimensional surfaces, in general, unless one changes the problem, as suggested in the previous paragraph.

and Department of Physics, Sharif University of Technology, PO Box 11365-9161, Tehran, Iran

(Received 2 January 1997; accepted for publication 12 September 1997)

We show that the integrability of the dynamical system recently proposed by Calogero and characterized by the Hamiltonian $H=\Sigma_{j,k}^{N} p_j p_k\{\lambda+\mu\ \cos[\nu(q_j-q_k)]\}$ is due to a simple algebraic structure. It is shown that this system is canonically equivalent to the classical Heisenberg magnet with long-range interactions. Our method shows clearly how these types of systems can be generalized and provides the mechanism of integrability of a large class of similar systems. © *1998 American Institute of Physics.* [S0022-2488(98)03101-6]

I. INTRODUCTION

It has recently been shown[1] that the dynamical system characterized by the Hamiltonian

$$H=\sum_{j,k=1}^{N} p_j p_k\{\lambda+\mu\ \cos[\nu(q_j-q_k)]\} \tag{1}$$

and the standard Poisson brackets

$$\{q_i,q_j\}=\{p_i,p_j\}=0,\quad \{q_i,p_j\}=\delta_{ij}, \tag{2}$$

is completely integrable. Before going on we perform a canonical transformation $q\to q/\nu$, $p\to\nu p$, and set the parameter ν equal to unity. In Ref. 1 Calogero showed that this system has the following properties:

(1) The quantities

$$c_{jk}=p_j p_k\{1-\cos(q_j-q_k)\} \tag{3}$$

are constants of the motion.

(2) There are N independent constants of the motion in involution with each other and H is a function of these integrals. These are the total momentum $P=\Sigma_{i=1}^{N} p_i$ and

$$h_m=\sum_{j,k=1}^{m} c_{j,k},\quad m=2,3,...,N,$$

$$\{h_m,h_{m'}\}=\{h_m,P\}=0. \tag{4}$$

(3) The quantities C and S defined by

$$C=\sum_{j=1}^{N} p_j\cos q_j,\quad S=\sum_{j=1}^{N} p_j\sin q_j \tag{5}$$

are constants of the motion if $\lambda+\mu=0$ or if $P=0$, otherwise they evolve simply in time.

(4) The following extra relations hold:

$$\{C,P\}=-S,\quad \{S,P\}=C,\quad \{C,S\}=-P, \tag{6}$$

 © 1998 American Institute of Physics

$$\{C,H\}=-2(\lambda+\mu)PS, \quad \{S,H\}=2(\lambda+\mu)PC. \tag{7}$$

The last two relations verify the statement made in part (3) above.

(5) The initial value problem for this Hamiltonian system was solved in explicit form.

The starting point of Calogero and his main line of reasoning is to demand that a Hamiltonian of the general form

$$H=\sum_{j,k=1}^{N} p_j p_k f(q_j-q_k) \tag{8}$$

has constants of the motion of the following form:

$$c_{jk}=p_j p_k g(q_j-q_k), \tag{9}$$

where f and g are functions to be specified. By this requirement he arrives at a functional equation for f and g, one solution of which leads to the Hamiltonian (1) and the conserved quantities (3). However, the mutual Poisson brackets of these integrals of motion are complicated:[1]

$$\begin{aligned}\{c_{jk},c_{j'k'}\}=&\delta_{jj'}p_j p_k p_k'\{\sin(q_j-q_k)+\sin(q_k-q_k')+\sin(q_{k'}-q_j)\}\\&+(j\leftrightarrow k)+(j'\leftrightarrow k')+(j\leftrightarrow k,j'\leftrightarrow k').\end{aligned} \tag{10}$$

The clever guess of Calogero is that the quantities given in (4) are the required integrals of motion which are in involution, hence the integrability of the system. He also demonstrated that the equations of motion can be derived from a Lax pair.

After all these calculations one is tempted to ask the following natural questions: Is there any algebraic structure behind the integrability of this system? Is the integrability of this system related somehow to the existence of the classical Yang–Baxter matrix or to some bi-Hamiltonian structure? Can one construct more general systems?

It is the aim of this paper to answer the above questions. We will find that the integrability of these systems is due to a very simple algebraic and geometrical structure which is related to the long-range interactions and the factorizability of the Hamiltonian. This structure is completely different from the ones which are encountered in the study of systems with local interactions.

II. THE ALGEBRAIC STRUCTURE

Let us define the variables

$$x_j=p_j\cos q_j, \quad y_j=p_j\sin q_j, \quad z_j=ip_j. \tag{11}$$

In the following we also use the notation $x^1=x$, $x^2=y$, and $x^3=z$. The Hamiltonian can now be written as

$$H=\sum_{j,k=1}^{N} -\lambda z_j z_k+\mu(x_j x_k+y_j y_k), \tag{12}$$

where the new variables satisfy the following su(2) Poisson bracket relations:

$$\{x_i^a,x_j^b\}=i\epsilon^{abc}x_j^c\delta_{ij}. \tag{13}$$

Remark: We use the complex number i only for notational convenience in later manipulations. In fact, the Poisson bracket between the real dynamical variables x_i, y_i, and $z'_j = p_j$ is related to the su(1,1) algebra with the Casimir $C = x^2 + y^2 - z'^2$.
Now define the variables

$$X^a_m = x^a_1 + x^a_2 + x^a_3 + \cdots + x^a_m . \tag{14}$$

It is obvious that for each m these sets of variables satisfy the same relations among themselves as in (13) and form a copy of su(2) algebra, and, furthermore, since the smaller copies of the algebra are embedded in the larger copies, we have

$$\{X^a_i , X^b_j\} = i\epsilon^{abc} X^c_{(i,j)} , \tag{15}$$

where (i,j) is meant to denote the minimum of i and j, i.e.,

$$\{X^a_2 , X^b_2\} = i\epsilon^{abc} X^c_2 , \quad \{X^a_2 , X^b_3\} = i\epsilon^{abc} X^c_2 .$$

Defining for each copy, say the mth one, the Casimir function

$$C_m = \sum_{a=1}^{3} X^a_m X^a_m , \tag{16}$$

we obtain

$$\{C_i , X^b_j\} = 2i\epsilon^{abc} X^a_i X^c_{(i,j)} , \tag{17}$$

$$\{C_i , C_j\} = 4i\epsilon^{abc} X^a_i X^b_j X^c_{(i,j)} . \tag{18}$$

We now note that in the last formula the indices i and j are not dummy variables; however, the index (i,j) is either equal to i or to j. In any case, the tensor which is contracted with ϵ^{abc} is symmetric with respect to the interchange of two of the indices (a,c) or (b,c), hence the right-hand side identically vanishes:

$$\{C_i , C_j\} = 0.$$

It is interesting to note that although the Casimir of one copy does not commute with the generators of another copy as seen from (17), the Casimirs of different copies commute among themselves. The Hamiltonian can now be written as

$$H = -\lambda Z^2_N + \mu(X^2_N + Y^2_N) = -(\lambda + \mu) Z^2_N + \mu C_N . \tag{19}$$

Using (17), (14), and (15) the following relations can also be verified directly:

$$\{C_i , X^b_N\} = 0, \quad b = 1,2,3, \quad \{H, Z_N\} = 0, \tag{20}$$

$$\{X_N , H\} = 2i(\lambda + \mu) Z_N Y_N , \quad \{Y_N , H\} = -2i(\lambda + \mu) Z_N X_N . \tag{21}$$

We see very clearly the essence of integrability of the system and have been able to avoid the intermediate constants of the motion c_{jk} with their complicated Poisson brackets and directly reach the integrals of motion which are in involution.

Proposition: The Casimir functions C_i, $i = 2,3,...,N$, and $P \equiv -iZ_N$ are N involutive integrals of motion. Note that C_1 (even if it were not zero) is a constant which characterizes the phase space of the system and is not to be counted as an integral of the motion. The Casimir functions C_m modulo a minus sign are exactly equal to the integrals h_m defined in Ref. 1.

In fact we have

$$C_m=\sum_{a=1}^{3} X_m^a X_m^a=\sum_{a=1}^{3}\sum_{j,k=1}^{m} x_j^a x_k^a \tag{22}$$

$$=\sum_{j,k=1}^{m}(x_j x_k+y_j y_k+z_j z_k)=-\sum_{j,k=1}^{m} p_j p_k\{1-\cos(q_j-q_k)\}. \tag{23}$$

From (11) and (13) we readily find the algebraic meaning of all the quantities introduced in Ref. 1 and summarized in the Introduction:

$$Z_N=iP, \quad C_m=-h_m, \quad X_N=C, \quad Y_N=S. \tag{24}$$

All the algebraic and Poisson bracket relations between these quantities found in Ref. 1, follow from the above identification.

Remark: The Casimir functions are all functionally independent, since for any pair of integers m and n, with $m<n$, C_n depends on dynamical variables not present in C_m.

III. THE INITIAL VALUE PROBLEM

Integrability of a system does not always imply that the system can be solved in closed form. However, the system (1) has the additional virtue that its initial value problem is also solved in closed form.[1] The aim of this section is to show algebraically why this is possible.

In terms of the new variables one can easily write the equations of motions. From (17) we have

$$\{C_N, X_j^b\}=2i\epsilon^{abc}X_N^a X_j^c, \tag{25}$$

or

$$\{C_N, X_j\}=2i(Z_N Y_j-Y_N Z_j), \tag{26}$$

$$\{C_N, Y_j\}=2i(X_N Z_j-Z_N X_j), \tag{27}$$

$$\{C_N, X_j\}=2i(Y_N X_j-X_N Y_j), \tag{28}$$

from which we can obtain the equations of motion,

$$\begin{pmatrix} \frac{d}{dt}X_j \\ \frac{d}{dt}Y_j \\ \frac{d}{dt}Z_j \end{pmatrix}=2i\begin{pmatrix} 0 & \lambda Z_N & \mu Y_N \\ -\lambda Z_N & 0 & -\mu X_N \\ -\mu Y_N & \mu X_N & 0 \end{pmatrix}\begin{pmatrix} X_j \\ Y_j \\ Z_j \end{pmatrix}, \tag{29}$$

which is of the form

$$\frac{d}{dt}\Psi_j=A\Psi_j. \tag{30}$$

The time dependence of the matrix A is itself determined from

$$\frac{d}{dt}X_N=\{X_N,H\}=2i(\lambda+\mu)Z_NY_N, \tag{31}$$

$$\frac{d}{dt}Y_N=\{Y_N,H\}=-2i(\lambda+\mu)Z_NX_N, \tag{32}$$

$$\frac{d}{dt}Z_N=\{Z_N,H\}=0, \tag{33}$$

or simply

$$\frac{d}{dt}\mathbf{S}_N=i\omega J_3\mathbf{S}_N, \tag{34}$$

where we have set $\mathbf{S}_N=(X_N,Y_N,Z_N)$ and J_1, J_2, and J_3 are generators of the rotation group: $(J_i)_{kl}=-i\epsilon_{ikl}$. In any case Z_N is constant and the dynamics of X_N and Y_N is given by

$$X_N(t)=X_N(0)\cos\,h\omega t+iY_N(0)\sin\,h\omega t,\quad Y_N(t)=Y_N(0)\cos\,h\omega t-iX_N(0)\sin\,h\omega t,$$

where $\omega=2(\lambda+\mu)Z_N$.

Note that from the above equations $X_N(t)^2+Y_N(t)^2=X_N(0)^2+Y_N(0)^2$. Once the time dependence of A is determined, the time dependence of Ψ_j will be determined from (30):

$$\Psi_j(t)=T\,\exp\int_0^t A(t')dt'\;\Psi_j(0). \tag{35}$$

However, one can go beyond this formal solution. We note that A can be written as follows:

$$A=-\omega J_3+2\mu(\mathbf{S}_N\cdot\mathbf{J}). \tag{36}$$

Knowing the dynamics of $\mathbf{S}_N$ from (34), we have

$$\mathbf{S}_N(t)\cdot\mathbf{J}=U(t)^{-1}\mathbf{S}_N(0)\cdot\mathbf{J}U(t), \tag{37}$$

where

$$U(t)=e^{\omega tJ_3}. \tag{38}$$

Therefore the dynamics of A is just a simple rotation around the z axis:

$$A(t)=e^{-\omega tJ_3}A(0)e^{\omega tJ_3}\equiv U^{-1}(t)A(0)U(t). \tag{39}$$

Multiplying both sides of this equation by $U(t)$ and defining $\Phi_i(t)=U(t)\Psi_i(t)$ we find

$$\frac{d}{dt}\Phi_i(t)=(\omega J_3+A(0))\Phi_i(t)=(2\mu\mathbf{S}_N(0)\cdot\mathbf{J})\Phi_i(t). \tag{40}$$

This is a simple evolution equation governed by a constant matrix the solution of which is simply

$$\Phi_i(t)=e^{2\mu\mathbf{S}_N(0)\cdot\mathbf{J}t}\Phi_i(0) \tag{41}$$

or

$$\Psi_i(t)=e^{-\omega tJ_3}e^{2\mu\mathbf{S}_N(0)\cdot\mathbf{J}t}\Psi_i(0). \tag{42}$$

Note that from Eq. (14) the vectors

$$\psi_j = \begin{pmatrix} x_j \\ y_j \\ z_j \end{pmatrix} = \Psi_j - \Psi_{j-1}$$

have the same equation of motion as above. We have thus arrived at a closed form solution of the initial value problem for Ψ_i and thus for ψ_i. Our analysis shows clearly why the initial value problem in Ref. 1 can be solved in closed form. Compared with the solution of Ref. 1, our solution has the merit that the initial data $\psi_j(0)$ appear explicitly in the solution, and no intermediate parameters (e.g., the parameters t_j in eqs. 2.19 and 2.20 of Ref. 1) are involved. Obtaining the evolution of the original variables q_i and p_i is now a matter of a change of coordinates, which I leave for the interested reader. I personally think, when viewed as a system of interacting classical spins (see example 2 in Sec. V), this solution is more interesting physically.

IV. GENERALIZATIONS

We can now generalize our construction and include the models of Calogero as a special case. Let g be a simple Lie algebra of ank r with generators e^a, $a=1,2,...,\dim g$, and relations

$$[e^a,\ e^b] = C^{ab}{}_c e^c. \tag{43}$$

Also, let g^* be its dual with basis e_a. It is well known[2] that the Lie structure on g induces a Poisson structure on $C^\infty(g^*)$,

$$\{x^a, x^b\} = C^{ab}{}_c x^c, \tag{44}$$

where the x^a, $a=1,2,...,\dim g = \dim g^*$ are the local coordinates in g^*.

In general the Poisson bracket is degenerate. To make it nondegenerate one restricts it to the submanifolds of $C^\infty(g^*)$ naturally defined by setting the values of the Casimir functions equal to constants. These submanifolds (symplectic leaves) are always even dimensional and the Poisson bracket becomes nondegenerate on them. By Darboux theorem one can then define local canonical coordinates and momenta on these submanifolds [the analogue of Eq. (11) above].

One can now define the variables X^a_m exactly as in (14). All the formalism of Sec. II can be followed exactly except that there are r Casimir functions involved labeled by

$$C^\alpha_m, \quad \alpha = 1,2,...,r, \quad m = 2,3,...,N,$$

with

$$\{C^\alpha_m, C^\beta_n\} = 0. \tag{45}$$

Furthermore one has

$$\{C^\alpha_m, h^\beta_N\} = 0, \tag{46}$$

where h^β_N correspond to the Cartan subalgebra elements of the Nth copy of g. Obviously any Hamiltonian of the general form

$$H = H(C^1_2, \ldots, C^r_N, h^1_N, \ldots, h^r_N) \tag{47}$$

defines an integrable system which is a generalization of the one introduced in Ref. 1.

The simplest of such Hamiltonians reads

$$H=(\lambda+\mu)\cdot h_N+\mu C_N. \tag{48}$$

Here

$$\lambda\cdot h_N\equiv\sum_\alpha \lambda_\alpha h_N^\alpha$$

and

$$C_N=\sum_{a,b} g_{ab}X_N^a X_N^b$$

with g_{ab} being the Cartan metric of the Lie algebra. The dynamical equations of motion for this system can be solved exactly along the same lines outlines in Sec. III.

Example 1: Consider again the algebra su(1,1) with relations

$$\{x,y\}=-z',\quad \{y,z'\}=x,\quad \{z',x\}=y. \tag{49}$$

The symplectic leaves are defined by

$$x^2+y^2-z'^2=c,$$

where c is a constant. These submanifolds are of two completely different geometries. For $c=0$ they are double cones with a singularity at the apex. This is the leaf chosen by Calogero with the canonical coordinates (11). The other leaves where $c\neq 0$ are hyperboloids with the following canonical coordinates:

$$z'=p,\quad x=\sqrt{p^2+c}\,\cos q,\quad y=\sqrt{p^2+c}\,\sin q. \tag{50}$$

Hence a generalization of the model of Ref. 1 is defined by

$$H=\sum_{j,k=1}^{N}\lambda p_j p_k+\mu\{\sqrt{p_j^2+c}\sqrt{p_k^2+c}\,\cos[(q_j-q_k)]\} \tag{51}$$

with the integrals of motion given by

$$h_m=\sum_{j,k=1}^{m} p_j p_k-\{\sqrt{p_j^2+c}\sqrt{p_k^2+c}\,\cos[(q_j-q_k)]\}$$

and

$$P=\sum_{i=1}^{N} p_i.$$

Example 2: Classical Heisenberg magnet with long-range interactions. We replace the su(1,1) algebra with su(2). The Casimirs are now equal to $C=x^2+y^2+z^2$ and the symplectic leaves are two-dimensional spheres. This is the classical Heisenberg Magnet describing a system of classical spins interacting with each other.

All the results we have obtained are readily adopted to this case simply by the following replacement: $\mathbf{x}_i^a\to i\mathbf{S}_i^a$, $a=1,2,3$.

The Hamiltonian (12) now turns into

$$H=\sum_{j,k=1}^{N}\lambda\mathbf{S}_j^z\mathbf{S}_k^z-\mu(\mathbf{S}_j^x\mathbf{S}_k^x+\mathbf{S}_j^y\mathbf{S}_k^y). \tag{52}$$

For $\lambda+\mu=0$ we have the isotropic magnet with su(2) symmetry.

The physical interpretation of the solution [Eqs. (34) and (42)] is now clear. In the isotropic case where $\omega=0$ the total magnetization $\mathbf{S}_N$ is constant and all the other spins simply rotate around the total spin with equal frequency $2\mu|\mathbf{S}_N|$. In the unisotropic case $\omega\neq 0$ the total spin rotates around the z axis with frequency ω and all the other spins rotate around the instantenous position of the total spin with the same frequency as in the isotropic case.

Example 3: Classical Heisenberg magnet with more general interactions. One can also define the Hamiltonian to be

$$H=\lambda_1 C_1+\lambda_2 C_2+\cdots,\ \lambda_N C_N+BZ_N, \tag{53}$$

which can be rewritten as

$$H=\sum_{i,j}\ \eta_{ij}\mathbf{S}_i\cdot\mathbf{S}_j+B\sum_i\ \mathbf{S}_i^z, \tag{54}$$

where

$$\eta_{ii}=\sum_{r=i}^{N}\lambda_r, \quad \eta_{ij}=2\sum_{r=\max(i,j)}^{N}\lambda_r.$$

Here the coupling parameters between different spins are not equal and with a suitable choice of the parameters λ_i's may represent a system of more physical interest than the Hamiltonian (53). The last term in the Hamiltonian represents the interaction of the spins with the magnetic field.

Remark: In Refs. 3 and 4, systems of very similar form to (1), where the momenta p_j come under the square root, have been shown to be exactly solvable. The integrable structure of these models is completely different[5] and should not be confused with that of the present model.

Quantum critical fluctuations in a ferroelectric model: Quasi-average approach

Patrice Joussot[a] and Valentin A. Zagrebnov[b]
Centre de Physique Théorique, CNRS-Luminy, Case 907, 13288 Marseille cedex 09, France

(Received 30 October 1996; accepted for publication 10 October 1997)

We show that critical fluctuations in a quantum ferroelectric model depend not only on the range of harmonic interactions but also on infinitesimal perturbations breaking symmetry of the model. This means that algebra of fluctuation operators is degenerated for (unique) critical equilibrium state. © *1998 American Institute of Physics.* [S0022-2488(98)00502-7]

I. INTRODUCTION

The idea to construct *pure equilibrium states* (phases) by infinitesimal perturbations of Hamiltonians comes back to the Bogoliubov ''quasi-averages.'' [1] It was generalized later to include *mixed states*.[2] For a lattice system defined by a Hamiltonian H_Λ (Λ is a finite subset of d-dimensional hypercubic lattice $\mathbb{Z}^d$ of the volume $V=|\Lambda|$), it can be formulated as follows:

(i) Let $\{\tau_l(-)\}_{l\in\mathbb{Z}^d}$ be space-translation automorphisms and $\{B_l=\tau_l(B)\}_{l\in\mathbb{Z}^d}$, where B is a local self-adjoint operator in the site $l=0$. Define a perturbed Hamiltonian

$$H_\Lambda(h)\equiv H_\Lambda-\sum_{l\in\Lambda} hB_l, \quad h\in\mathbb{R}^1. \tag{1.1}$$

If for $h\neq 0$ the perturbation breaks a symmetry G of H_Λ, then the limiting state for $\Lambda\to\mathbb{Z}^d$ (the Bogoliubov's quasi-average),

$$\langle-\rangle^*=\lim_{h\to 0}\lim_{\Lambda}\langle-\rangle_{\Lambda,h}, \tag{1.2}$$

picks out pure states for which the symmetry G can be broken at low temperatures (see, e.g., Ref. 3, Ch. 6).

(ii) If the external field has the form

$$h=\hat{h}/V^\alpha, \tag{1.3}$$

then an obvious generalization of (1.2) either coincides with pure states (for $\alpha<\alpha_c$) or gives a family of mixed states enumerated by $\hat{h}$ and $\alpha\geqslant\alpha_c$ (Ref. 2).

As is proven in Refs. 4 and 5 for the case of a quantum model of ferroelectrics (structural phase transitions), the algebra of quantum fluctuations depends on the parameter α *in pures states (1.2) with broken symmetry*.

The aim of the present paper is to scrutinize this algebra on the critical line (i.e., for a *unique* equilibrium state) by explicit calculation of its dependence on perturbations (1.3). As far as the corresponding critical equilibrium state exhibits long-range correlations, one might to assume that *critical fluctuations* have to be sensitive with respect to these kind of perturbations. On the other hand, they also have to be sensitive to the decay of direct interaction between particles: in the model[4–6] it corresponds to the decay of harmonic-force matrix elements $\{\phi_{l,l'}\}_{l,l'\in\mathbb{Z}^d}$ given by

$$\phi_{l,l'} \sim |l-l'|^{-(d+\sigma)} \quad \text{for } |l-l'| \to \infty. \tag{1.4}$$

If $\sigma \geqslant 2$, one classifies (1.4) as a *short-range* interaction while the case $0<\sigma<2$ corresponds to *long-range* interactions because the corresponding lattice Fourier transforms of $\phi_{l,l'}$ have the following asymptotics for $q \to 0$:

$$\widetilde{\phi}(q) \sim \begin{cases} s^{\sigma} q^{\sigma} + o(q^{\sigma}), & 0<\sigma<2, \\ s^2 q^2 + o(q^2), & \sigma \geqslant 2, \end{cases} \tag{1.5}$$

with a constant $s>0$.

Let A be a local operator. Then the corresponding fluctuation operator for a limiting translation-invariant state $\langle - \rangle$ is defined as the limit of the finite-volume fluctuation operator:

$$F^{\delta_A}(A) = \lim_{\Lambda} F_{\Lambda}{}^{\delta_A}(A) = \lim_{\Lambda} \frac{1}{V^{1/2+\delta_A}} \sum_{l \in \Lambda} (\tau_l(A) - \langle A_l \rangle_{\Lambda,h}),$$

where the exponent δ_A is defined via the noncommutative central limit theorem and corresponds to the condition that the variance $\lim_{\lambda} \langle (F_{\Lambda}{}^{\delta_A}(A))^2 \rangle$ is nontrivial.[4–6] In fact, dependence of the fluctuation operator exponent δ_A on σ is studied on the critical line for $h \equiv 0$ in Ref. 6. Therefore, our aim is to find dependence of exponent δ_A on the parameter α in the presence of the long-range interaction (1.4). Note that $\delta_A = \delta_A(\alpha, \sigma)$ is directly related to the critical exponent η describing decay of the two-point correlation function on the critical line: $\eta = 2 - 2d\,\delta_A$.

The paper is organized as follows. In the next section (using notations from Refs. 4–6) we briefly recall our anisotropic quantum ferroelectric model. Detailed analysis of fluctuations on the critical line as well as the main result, calculations of exponents $\delta_Q(\alpha, \sigma)$ and $\delta_P(\alpha, \sigma)$ for displacement and momentum fluctuations, are collected in Sec. III. Concluding remarks are left to Sec. IV.

II. MODEL AND PHASE TRANSITION

Let $\mathbb{Z}^d$ be a d-dimensional hypercubic lattice. With each lattice site $l \in \mathbb{Z}^d$ occupied by a particle of mass m, we associate position and momentum operators $Q_l \in \mathbb{R}^1$ and $P_l = (\hbar/i) \times (\partial/\partial Q_l)$ corresponding to anisotropic one-dimensional particle displacements from this site. Let Λ be a finite rectangular subset of $\mathbb{Z}^d$ with periodic boundary conditions and Λ^* be the lattice dual to Λ. The local Hamiltonian of the model[4–6] is given by

$$H_{\Lambda}(h) = \sum_{l \in \Lambda} \frac{P_l^2}{2m} + \frac{1}{4} \sum_{l,l' \in \Lambda} \phi_{l,l'} (Q_l - Q_{l'})^2 + \frac{a}{2} \sum_{l \in \Lambda} Q_l^2 + VW\left(\frac{1}{V} \sum_{l \in \Lambda} Q_l^2 \right) - h \sum_{l \in \Lambda} Q_l. \tag{2.1}$$

The second term in (2.1) represents a harmonic potential between particles, whereas the last term corresponds to external field breaking the $\{Q_l \to -Q_l\}_{l \in \mathbb{Z}^d}$ symmetry. The fourth term in (2.1) represents a one-site lattice anharmonic potential in the *spherical approximation*[4] known as the concept of *self-consistent phonons*.[7] The model (2.1) can be solved by the approximation Hamiltonian method.[4] The corresponding approximating Hamiltonian has the form

$$H_{\Lambda}(c,h) = \sum_{l \in \Lambda} \frac{P_l^2}{2m} + \frac{1}{4} \sum_{l,l' \in \Lambda} \phi_{l,l'} (Q_l - Q_{l'})^2 + \frac{a}{2} \sum_{l \in \Lambda} Q_l^2$$

$$+ W'(c) \sum_{l \in \Lambda} Q_l^2 - h \sum_{l \in \Lambda} Q_l + V(W(c) - cW'(c)).$$

Then the free-energy density of the system (2.1) is equal to

$$f(T,h) = \lim_{\Lambda} f_{\Lambda}[H_{\Lambda}(h)] = \lim_{\Lambda} \sup_{c} f_{\Lambda}[H_{\Lambda}(c,h)],$$

where

$$\sup_c f_\Lambda[H_\Lambda(c,h)] = f_\Lambda[H_\Lambda(c_{\Lambda,h}(T,\lambda))]$$

$$= \frac{1}{\beta V}\sum_{q\in\Lambda^*} \ln\left[2\sinh\frac{\beta\lambda\Omega_q(c_{\Lambda,h}(T,\lambda))}{2}\right] - \frac{1}{2}\frac{h^2}{\Delta(c_{\Lambda,h}(T,\lambda))}$$

$$+ [W(c_{\Lambda,h}(T,\lambda)) - c_{\Lambda,h}(T,\lambda)W'(c_{\Lambda,h}(T,\lambda))]. \tag{2.2}$$

Here $c_{\Lambda,h}(T,\lambda)>0$ is a solution of the spherical self-consistency equation

$$c = \frac{h^2}{\Delta^2(c)} + \frac{1}{V}\sum_{q\in\Lambda^*}\frac{\lambda}{2\Omega_q(c)}\coth\frac{\beta\lambda}{2}\,\Omega_q(c), \tag{2.3}$$

with

$$\Omega_q^2(c) = \Delta(c) + \omega_q^2, \tag{2.4}$$

$$\Delta(c) = a + 2W'(c), \tag{2.5}$$

$$\omega_q^2 = \tilde{\phi}(0) - \tilde{\phi}(q), \tag{2.6}$$

$$\tilde{\phi}(q) = \sum_{l\in\Lambda}\phi_{l,0}\exp(-iql), \tag{2.7}$$

$$\lambda = \frac{\hbar}{\sqrt{m}}, \tag{2.8}$$

$$\beta = (kT)^{-1}, \tag{2.9}$$

where $\{\Omega_q(c)\}_{q\in\Lambda^*}$ are frequencies of the approximating harmonic Hamiltonian $H_\Lambda(c,h)$, $\Delta(c)$ is a gap in the spectrum of (self-consistent) phonons, and λ is the quantum parameter of the model.

Let $a>0$ and $W:\mathbb{R}^1_+\to\mathbb{R}^1_+$ be a monotonous decreasing function with $W''(c)\geqslant w>0$ and $\Delta(c=0)<0$. Then by (2.5) and (2.6) one gets that stability domain $D=[c^*,\infty)$ of the approximating Hamiltonian $H_\Lambda(c,h)$ corresponds to

$$c^* = \inf\{c: c\geqslant 0, \Delta(c)\geqslant 0\} > 0, \tag{2.10}$$

and $\Delta(c^*)=0$.

To study the phase diagram of the model (2.1) we have to pass in (2.3) to the thermodynamic limit $\Lambda\to\mathbb{Z}^d$. Then limiting solutions satisfy

$$c_h(T,\lambda) = \rho_h(T,\lambda) + I_d(c_h(T,\lambda),T,\lambda), \tag{2.11}$$

where

$$\rho_h(T,\lambda) = \lim_\Lambda\left\{\frac{1}{V}\frac{\lambda}{2\sqrt{\Delta(c_{\Lambda,h}(T,\lambda))}}\coth\frac{\beta\lambda}{2}\sqrt{\Delta(c_{\Lambda,h}(T,\lambda))} + \frac{h^2}{\Delta^2(c_{\Lambda,h}(T,\lambda))}\right\} \tag{2.12}$$

and

$$I_d(c,T,\lambda) = \frac{\lambda}{(2\pi)^d}\int_{q\in B_d} d^dq\,\frac{1}{2\Omega_q}\coth\frac{\beta\lambda}{2}\,\Omega_q(c).$$

Here, $B_d=\{q\in\mathbb{R}^d; |q|\leqslant\pi\}$ is the first Brillouin zone.

From (2.11) one gets that for $h=0$ and $T=0$, there is λ_c such that $c^*\leqslant I_d(c^*,0,\lambda)$ for $\lambda\geqslant\lambda_c$. Then the line of critical temperatures $T_c=T_c(\lambda)$ which separates the phase diagram (see Fig. 1) is defined by the condition

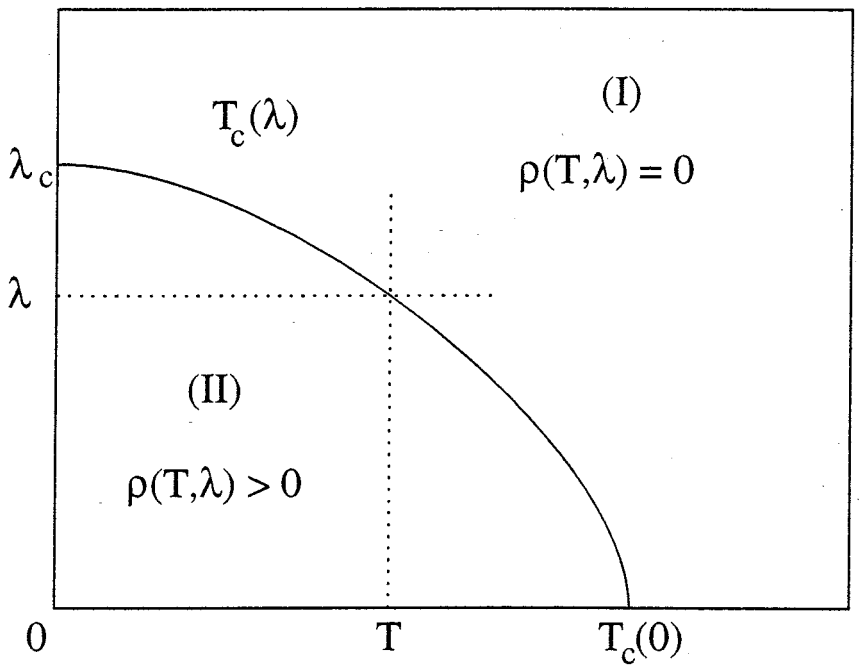

FIG. 1. Phase diagram of the model (2.1).

$$c^* = I_d(c^*, T_c(\lambda), \lambda), \quad \lambda \leqslant \lambda_c . \tag{2.13}$$

For a fixed $\lambda < \lambda_c$ we observe a well-known temperature-driven phase transition at $T_c(\lambda) > 0$ with an order parameter related to $\rho \equiv \rho_{h=0}$, while for a fixed $T < T_c(0)$ one gets a phase transition driven by the quantum parameter (2.8).

Let $\eta_{\Lambda,h}(\cdot) \equiv \langle \cdot \rangle_{H_{\Lambda,h}}$ be finite-volume equilibrium state corresponding to (2.1). Note that the $\{Q_l \to -Q_l\}_{l \in \mathbb{Z}^d}$ symmetry of the Hamiltonian (2.1) for $h = 0$ implies

$$\lim_{\Lambda} \langle Q_l \rangle_{H_{\Lambda,h=0}} = 0.$$

Now let $h \neq 0$. Then for the limiting state one obtains

$$\eta_h(Q_l) = \lim_{\Lambda} \eta_{\Lambda,h}(Q_l) = \frac{h}{\Delta(c_h)}. \tag{2.14}$$

Above the critical line $T_c(\lambda) < T$ (disordered phase) Eqs. (2.3) and (2.11) give that $\lim_{h \to 0} c_h(T,\lambda) = c(T,\lambda) > c^*$. Therefore, $\Delta(c_h) > 0$. Hence, by (2.12) $\rho_{h=0}(T,\lambda) = 0$ and by (2.14) one obtains

$$\lim_{h \to 0} \eta_h(Q_l) = 0.$$

In ordered phase, i.e., for $T < T_c(\lambda)$, by (2.3) and (2.11) we get $\lim_{h \to 0} c_h(T,\lambda) = c^*$. Then

$$\rho(T,\lambda) = \lim_{h \to 0} \rho_h(T,\lambda) = c^* - I_d(c^*, T, \lambda) = \lim_{h \to 0} \frac{h^2}{\Delta^2(c_h)} > 0, \tag{2.15}$$

and Eqs. (2.14) and (2.15) yield

$$\eta_{\pm}(Q_l) = \lim_{h \to \pm 0} \eta_h(Q_l) = \pm \sqrt{\rho(T,\lambda)} \neq 0. \tag{2.16}$$

Therefore, using the Bogoliubov quasi-averages, we obtain two extremal translation invariant equilibrium states η_+ and η_-.

Consider now fluctuation operators corresponding to particle position and momentum displacements defined by

$$F^{\delta_Q}(Q)=\lim_{\Lambda}\frac{1}{V^{1/2+\delta_Q}}\sum_{i\in\Lambda}(Q_i-\eta_{\Lambda,h}(Q_i)), \tag{2.17}$$

and

$$F^{\delta_P}(P)=\lim_{\Lambda}\frac{1}{V^{1/2+\delta_P}}\sum_{i\in\Lambda}(P_i-\eta_{\Lambda,h}(P_i)), \tag{2.18}$$

where exponents δ_Q and δ_P are chosen so that variances of $F^{\delta_Q(Q)}$ and $F^{\delta_P(P)}$ in the state η_h are nontrivial.

Calculation of variances of (2.17) and (2.18) gives

$$\lim_{\Lambda}\eta_{\Lambda,h}\left(\left\{\frac{1}{V^{1/2+\delta_Q}}\sum_{i\in\Lambda}(Q_i-\eta_{\Lambda,h}(Q_i))\right\}^2\right)$$

$$=\lim_{\Lambda}\frac{1}{V^{2\delta_Q}}\frac{\lambda}{2\sqrt{\Delta(c_{\Lambda,h}(T,\lambda))}}\coth\frac{\beta\lambda}{2}\sqrt{\Delta(c_{\Lambda,h}(T,\lambda))} \tag{2.19}$$

and

$$\lim_{\Lambda}\eta_{\Lambda,h}\left(\left\{\frac{1}{V^{1/2+\delta_P}}\sum_{i\in\Lambda}(P_i-\eta_{\Lambda,h}(P_i))\right\}^2\right)$$

$$=\lim_{\Lambda}\frac{1}{V^{2\delta_P}}\frac{\lambda m\sqrt{\Delta(c_{\Lambda,h}(T,\lambda))}}{2}\coth\frac{\beta\lambda}{2}\sqrt{\delta(c_{\Lambda,h}(T,\lambda))}. \tag{2.20}$$

By Eqs. (2.3) and (2.11), above the critical line for any h one has $\lim_\Lambda \Delta(c_{\Lambda,h}(T,\lambda))>0$. Consequently, (2.19) and (2.20) imply that $\delta_Q=\delta_P=0$, i.e., both momentum and displacement fluctuation operators are normal. Below the critical line, quasi-averages controled by the external field $h=\hat{h}/V^\alpha$ show (for $T>0$ and finite range interactions $\sigma\geqslant 2$) that the momentum fluctuation operator is normal while the position fluctuation operator is abnormal with the exponent δ_Q which depends on α.[4] Of course, the domain $\rho(T,\lambda)\neq 0$ is a particular one because there we have more than one pure equilibrium state. That is why a challenge problem is to study whether exponents δ_Q and δ_P depend on the parameter $\alpha>0$ for the *long-range* interaction $0<\sigma<2$ exactly on the critical line where the equilibrium state is *unique*.

III. FLUCTUATIONS ON THE CRITICAL LINE

Since by (2.13) and (2.15) one has $\rho(T_c(\lambda),\lambda)=0$, on the critical line Eq. (2.12) gets the following form:

$$\lim_{\Lambda}\left\{\frac{1}{V}\frac{\lambda}{2\sqrt{\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))}}\coth\frac{\lambda\beta_c(\lambda)}{2}\sqrt{\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))}+\frac{\hat{h}^2}{V^{2\alpha}\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))^2}\right\}=0, \tag{3.1}$$

where by $h=\hat{h}/V^\alpha$ and (2.11)–(2.13) we have $\lim_\Lambda c_{\Lambda,h}(T_c(\lambda),\lambda)=c^*$. Hence

$$\lim_{\Lambda}\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))=0. \tag{3.2}$$

Now we have to distinguish two cases:

(a) $T_c(\lambda)>0$, then (3.1) reduces to

$$\lim_{\Lambda}\left\{\frac{1}{V\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))\beta_c(\lambda)}+\frac{\hat{h}^2}{V^{2\alpha}\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))^2}\right\}=0; \tag{3.3}$$

(b) $T_c(\lambda_c)=0$, then (3.1) takes the form

$$\lim_{\Lambda}\left\{\frac{\lambda_c}{2V\sqrt{\Delta(c_{\Lambda,h}(0,\lambda_c))}}+\frac{\hat{h}^2}{V^{2\alpha}\Delta(c_{\Lambda,h}(0,\lambda_c))^2}\right\}=0. \tag{3.4}$$

These cases both imply that, for $V\to\infty$, the gap Δ (3.2) has the asymptotic behavior $\Delta\simeq V^{-\gamma}$: with $0<\gamma<\min(1,\alpha)$ [see (3.3)] or $0<\gamma<\min(2,\alpha)$ [see (3.4)].

It is Eq. (2.3) that is the key allowing one to obtain these asymptotics in explicit form. To make it evident, we rewrite (2.3) as

$$\begin{aligned}&(c_{\Lambda,h}-c^*)+[c^*-I_d(c_{\Lambda,h},T_c,\lambda)]+\left[I_d(c_{\Lambda,h},T_c,\lambda)\right.\\&\left.-\sum_{q\in\Lambda^*,q\neq 0}\frac{\lambda}{2\Omega_q(c_{\Lambda,h})}\coth\frac{\beta_c\lambda\Omega_q(c_{\Lambda,h})}{2}\right]\\&=\left(\frac{\hat{h}}{V^{\alpha}\Delta}\right)^2+\frac{1}{V}\frac{\lambda}{2\sqrt{\Delta}}\coth\left(\frac{\beta_c\lambda\sqrt{\Delta}}{2}\right).\end{aligned} \tag{3.5}$$

Lemma 3.1: If (T,λ) belongs to the critical line $(T_c(\lambda),\lambda)$ and $T_c(\lambda)>0$, then the asymptotic volume behavior of the gap $\Delta(c_{\Delta,h}(T_c(\lambda),\lambda))$ for $h=\hat{h}/V^{\alpha}$ is defined by

$$\gamma=\begin{cases}\text{if } d>2\sigma:\\ \frac{2}{3}\alpha \quad \text{for } \alpha<\frac{3}{4}=\alpha_c,\\ \frac{1}{2} \quad \text{for } \alpha\geqslant\frac{3}{4},\\ \text{if } d=2\sigma:\\ \frac{2}{3}\alpha+0 \quad \text{for } \alpha<\frac{3}{4}=\alpha_c,\\ \frac{1}{2}+0 \quad \text{for } \alpha\geqslant\frac{3}{4},\\ \text{if } \sigma<d<2\sigma:\\ \alpha\,\frac{\sigma}{d+\sigma} \quad \text{for } \alpha<\frac{1}{2}+\frac{\sigma}{2d}=\alpha_c,\\ \frac{\sigma}{d} \quad \text{for } \alpha\geqslant\frac{1}{2}+\frac{\sigma}{2d}.\end{cases}$$

Proof: Since $T_c(\lambda)>0$, the right-hand side of (3.5) has asymptotics (3.3) or

$$O\left\{\left(\frac{\hat{h}}{V^{\alpha}\Delta}\right)^2+\frac{1}{V\Delta}\right\}. \tag{3.6}$$

We define α_c by the condition $O[(1/V^{\alpha_c}\Delta)^2]=O(1/V\Delta)$. Then for the asymptotics of (3.6) one obtains

$$O\left(\left(\frac{\hat{h}}{V^{\alpha_c}\Delta}\right)^2+\frac{1}{V\Delta}\right)=O\left(\frac{1}{V\Delta}\right), \tag{3.7}$$

i.e., for $\alpha\geqslant\alpha_c$, the gap Δ has the same asymptotic behavior as for $h=0$[6].

Now we have to consider three regimes for the harmonic-force matrix element decay (1.4):

(a) Let $\sigma<d<2\sigma$. Then for $h=0$ Eq. (3.5) gives[6] the exponent $\gamma=\sigma/d$, i.e., $\Delta\simeq V^{-\sigma/d}$, and (3.7) yields $\alpha_c=\sigma/2d+1/2$.
(b) Let $d=2\sigma$. In this limiting case one has $\gamma=1/2+0$, so we obtain $\alpha_c=3/4$.
(c) Let $d>2\sigma$. Then (3.5) provides[6] $\gamma=1/2$. Hence $\alpha_c=3/4$.

We consider first the case $\alpha\geqslant\alpha_c$. Asymptotics in (3.5) are the same as for $\hat{h}=0$, i.e., we reproduce the results of Ref. 6: $\gamma=\sigma/d$, if $\sigma<d<2\sigma$; $\gamma=1/2+0$, if $d=2\sigma$; and $\gamma=1/2$, if $d>2\sigma$. Then we consider $\alpha<\alpha_c$ for the three cases (a), (b), and (c) correspondingly. Now the asymptotics of the first term in (3.6) will dominate.

(a) Let $\sigma<d<2\sigma$. Then (3.5) has the following asymptotic form[6]:

$$O[(\Delta+\Delta^{d/\sigma-1}+V^{\sigma/d-1})V^{2\alpha}\Delta^2]=O(1).$$

By the condition $\sigma<d<2\sigma$, one obtains

$$\gamma=2\alpha\,\frac{\sigma}{d+\sigma}. \tag{3.8}$$

(b) Let $d=2\sigma$. Then asymptotic form of (3.5) is

$$O[(\Delta+\Delta\ln(\Delta)+V^{1/2})V^{2\alpha}\Delta^2]=O(1).$$

Therefore, we obtain

$$\gamma=\frac{2\alpha}{3}+0. \tag{3.9}$$

(c) Let $d>2\sigma$. Then the asymptotic form of (3.5) is

$$O[(\Delta=V^{\sigma/d-1})V^{2\alpha}\Delta^2]=O(1).$$

By $d>2\sigma$, one gets that

$$\gamma=\frac{2\alpha}{3}. \tag{3.10}$$

The lemma is proven.

Proposition 3.2: If (T,λ) belongs to the critical line $(T_c(\lambda),\lambda)$ and $T_c(\lambda)>0$, then the algebra of fluctuation operators is Abelian. The momentum fluctuation operator $F^{\delta_P}(P)$ is normal ($\delta_P=0$) while the position fluctuation operator $F^{\delta_Q}(Q)$ is abnormal with critical exponent given by

$$\delta_Q=\begin{cases}
\text{if } d>2\sigma:\\
\frac{1}{3}\alpha \quad \text{for } \alpha<\frac{3}{4}=\alpha_c,\\
\frac{1}{4} \quad \text{for } \alpha\geqslant\frac{3}{4},\\
\text{if } d=2\sigma:\\
\frac{1}{3}\alpha+0 \quad \text{for } \alpha<\frac{3}{4}=\alpha_c,\\
\frac{1}{4}+0 \quad \text{for } \alpha\geqslant\frac{3}{4},\\
\text{if } \sigma<d<2\sigma:\\
\alpha\,\frac{\sigma}{d+\sigma} \quad \text{for } \alpha<\frac{1}{2}+\frac{\sigma}{2d}=\alpha_c,\\
\frac{\sigma}{2d} \quad \text{for } \alpha\geqslant\frac{1}{2}+\frac{\sigma}{2d}.
\end{cases}$$

Proof: To check that the algebra of fluctuation operators generated by F^{δ_Q} and F^{δ_F} is Abelian it is enough to calculate limit of the commutator:

$$\lim_{\Lambda}[F_{\Lambda}^{\delta_P},F_{\Lambda}^{\delta_Q}]=\lim_{\Lambda}\frac{1}{|\Lambda|^{1+\delta_P+\delta_Q}}\sum_{l,l'\in\Lambda}[P_l,Q_{l'}]. \tag{3.11}$$

The second part of the Proposition results from Eqs. (2.19) and (2.20). On the critical line and for $h=\hat{h}/V^{\alpha}$ they get the form

$$\lim_{\Lambda}\eta_{\Lambda,h}\left(\left\{\frac{1}{V^{1/2+\delta_Q}}\sum_{i\in\Lambda}(Q_i-\eta_{\Lambda,h}(Q_i))\right\}^2\right)=\lim_{\Lambda}\frac{1}{V^{2\delta_Q}}\frac{kT_c(\lambda)}{\Delta(c_{\Lambda,h}(T_c(\lambda),\lambda))}. \tag{3.12}$$

and

$$\lim_{\Lambda}\eta_{\Lambda,h}\left(\left\{\frac{1}{V^{1/2+\delta_P}}\sum_{i\in\Lambda}(P_i-\eta_{\Lambda,h}(P_i))\right\}^2\right)=\lim_{\Lambda}\frac{1}{V^{2\delta_P}}mkT_c(\lambda). \tag{3.13}$$

So, the variance (3.12) is nontrivial if and only if $\delta_Q=\gamma/2>0$, while (3.13) is nontrivial if and only if $\delta_P=0$. Hence, the limit of commutator (3.11) is equal to zero. One gets explicit values of δ_Q by Lemma (3.1).

Remark that if we put $\sigma=2$, then Proposition 3.2 reproduces results for short-range interactions $\sigma\geqslant 2$ (see Ref. 5).

Lemma 3.3: If (T,λ) coincides with the point $(0,\lambda_c,)$ then the asymptotic volume behavior of the gap $\Delta(c_{\Lambda,h}(0,\lambda_c),\lambda_c)$ is given by

$$\gamma=\begin{cases}\text{if } d>\frac{3\sigma}{2}:\\ \frac{2}{3}\alpha \quad \text{for } \alpha<1=\alpha_c,\\ \frac{2}{3} \quad \text{for } \alpha\geqslant 1,\\ \\ \text{if } d=\frac{3\sigma}{2}:\\ \frac{2}{3}\alpha+0 \quad \text{for } \alpha<1=\alpha_c,\\ \frac{1}{2}+0 \quad \text{for } \alpha\geqslant 1,\\ \\ \text{if } \frac{\sigma}{2}<d<\frac{3\sigma}{2}:\\ \alpha\ \frac{\sigma}{2d+3\sigma} \quad \text{for } \alpha<\frac{1}{2}+\frac{3\sigma}{4d}=\alpha_c,\\ \frac{\sigma}{d} \quad \text{for } \alpha\geqslant\frac{1}{2}+\frac{3\sigma}{4d}.\end{cases}$$

Proof: At this particular point on the critical line the right-hand side of (3.5) gets the following asymptotic form:

$$O\left[\left(\frac{\hat{h}}{V^{\alpha}\Delta}\right)^2+\frac{1}{V\Delta^{1/2}}\right]. \tag{3.14}$$

Similar to Lemma 3.1 we define α_c in such a way that $O[(1/V^{\alpha_c}\Delta)^2]=O(1/V\Delta^{1/2})$ and we distinguish three cases of the interaction decay: (a) $\sigma/2<d<3\sigma/2$, (b) $d=3\sigma/2$, and (c) $d>3\sigma/2$.

If $\alpha\geqslant\alpha_c$, then the gap Δ has the same asymptotic behavior as for $\hat{h}=0$[6]:

(a) For $\sigma/2<d<3\sigma/2$, it gives $O(\Delta)=O(V^{-\sigma/d})$. So by (3.14) we get $\alpha_c=3\sigma/4d+\frac{1}{2}$.
(b) If $d=3\sigma/2$, then $O(\Delta)=O(V^{-(2/3+0)})$, so we obtain $\alpha_c=1$.

(c) Let $d>3\sigma/2$. Then one gets $O(\Delta)=O(V^{-2/3})$, so $\alpha_c=1$.

Therefore, if $\alpha\geqslant\alpha_c$, then the last term in (3.14) dominates. Hence, γ has same values as for $\alpha=\alpha_c$.

Now we pass to $\alpha<\alpha_c$. Then for (a) $\sigma/2<d<3\sigma/2$, the asymptotic form of (3.5) is[6]

$$O([(\Delta+\Delta^{d/\sigma-1/2}+V^{\sigma/2d-1})])=O\left(\frac{1}{V^{2\alpha}\Delta^2}\right),$$

which yields $\gamma=4\alpha\sigma/(2d+3\sigma)$. For (b) $d=3\sigma/2$, one gets similarly to (3.9) that $\gamma=2\alpha/3+0$. Finally, for (c) $d>3\sigma/2$ the asymptotic form of (3.5) becomes

$$O((\Delta+V^{\sigma/2d-1}))=O\left(\frac{1}{V^{2\alpha}\Delta^2}\right)$$

and we find $\gamma=2\alpha/3$.

Proposition 3.4: If (T,λ) coincides with the point $(0,\lambda_c)$, then algebra of fluctuation operators is non-Abelian: the position fluctuation operator $F^{\delta_Q}(Q)$ is abnormal ($\delta_Q>0$), while the momentum fluctuation operator $F^{\delta_P}(P)$ is supernormal with $\delta_P=-\delta_Q$ and

$$\delta_Q=\begin{cases}\text{if } d>\frac{3\sigma}{2}:\\ \frac{1}{6}\,\alpha \text{ for } \alpha<1=\alpha_c,\\ \frac{1}{6} \text{ for } \alpha\geqslant 1,\\ \\ \text{if } d=\frac{3\sigma}{2}:\\ \frac{1}{6}\,\alpha+0 \text{ for } \alpha<1=\alpha_c,\\ \frac{1}{6}+0 \text{ for } \alpha\geqslant 1,\\ \\ \text{if } \frac{\sigma}{2}<d<\frac{3\sigma}{2}:\\ \alpha\,\frac{\sigma}{2d+3\sigma} \text{ for } \alpha<\frac{1}{2}+\frac{3\sigma}{4d}=\alpha_c,\\ \frac{\sigma}{4d} \text{ for } \alpha\geqslant\frac{1}{2}+\frac{3\sigma}{4d}.\end{cases}$$

Proof: If $T=0$ and $\lambda=\lambda_c$, variances (2.19) and (2.20) get the form

$$\lim_{\Lambda}\ \eta_{\Lambda,h}\left(\left\{\frac{1}{V^{1/2+\delta_Q}}\sum_{i\in\Lambda}(Q_i-\eta_{\Lambda,h}(Q_i))\right\}^2\right)=\lim_{\Lambda}\frac{1}{V^{2\delta_Q}}\frac{\lambda_c}{\sqrt{\Delta(c_{\Lambda,h}(0,\lambda_c))}}$$

and

$$\lim_{\Lambda}\ \eta_{\Lambda,h}\left(\left\{\frac{1}{V^{1/2+\delta_P}}\sum_{i\in\Lambda}(P_i-\eta_{\Lambda,h}(P_i))\right\}^2\right)=\lim_{\Lambda}\frac{1}{V^{2\delta_P}}\frac{\lambda_c m}{2}\sqrt{\Delta(c_{\Lambda,h}(0,\lambda_c))},$$

which implies $\delta_Q=-\delta_P$. For the rest one just has to apply Lemma 3.3 with $\delta_Q=\gamma/4$. Since $\delta_Q+\delta_P=0$, the non-Abelian nature of the algebra of fluctuation operators follows from the nontrivial commutator (3.11).

IV. CONCLUSION

Using a particular example of exactly soluble ferroelectric model we show that critical fluctuations depend on parameters σ and α. The first of them measures the power decay of the

harmonic-force matrix elements with the distance between sites of the lattice, while the second one controls the rate of the ''switching off'' of the infinitesimal external field breaking the Hamiltonian symmetry related to a phase transition.

The sensitivity with respect to σ is perfectly understandable: the long-range interaction is obviously involved in the formation of the long-range correlations in the critical equilibrium state. On the other hand, dependence of the exponents δ_P and δ_Q on α is less evident and is unexpected on the critical line where the limiting Gibbs state is unique. This means that the quasi-average perturbation $\sim \hat{h}/V^{\alpha}$, $\alpha>0$, is able to change fluctuations in the case of unique equilibrium state if the latter is critical. Note that there is no trace of perturbation $\sim \hat{h}/V^{\alpha}$, $\alpha>0$, above the critical line, i.e., for a unique noncritical state, while it appears again below the critical line even in pure states.[4]

The dependence of δ_P and δ_Q on α on the critical line means that such macro-observables as order parameters or fluctuations may have nontrivial structure in the unique critical equilibrium state. It seems that for the first time this kind of phenomenon has been observed in Ref. 8 in the example of a nontrivial structure of magnetization and its fluctuations in the ground state of the one-dimensional Ising model.

ACKNOWLEDGMENTS

One of us (VAZ) benefited greatly from discussions with André Verbeure, Charles-Edouard Pfister, and Senya Shlosman on problems discussed in this paper. We thank André Verbeure for directing our attention to Ref. 8. We are indebted to the referee for numerous constructive critical remarks.

Colored noise and a characteristic level crossing problem

In this paper we discuss the activation of a dynamical system of one spatial variable forced by an external Gaussian stationary colored noise. The model is an analog of the Smoluchowski equation when external fluctuations are present. We assume that the underlying deterministic dynamics are derived from a potential forming a well. We enlarge the state space by including the noise variable, and then use half-range expansion techniques, singular perturbations, and matched asymptotics to solve the boundary value problem for the steady-state probability density function, in the asymptotic limit of small correlation time and over the entire regime of noise strength. We find a uniformly valid expression for the activation rate to the top of the potential barrier (a characteristic point for the unforced dynamical system). We show the important effects of the boundary behavior of the process on its activation rate. If the intensity of the noise is small compared to the autocorrelation of the noise, then the effective activation energy is modified by the noise autocorrelation. We consider an example of the activation process in a double well potential, and compare our uniformly valid results with results reported in the literature. © *1998 American Institute of Physics.* [S0022-2488(98)00501-5]

I. INTRODUCTION

Over the years activation phenomena in noisy dynamical systems have been studied extensively. There are two commonly distinguished classes of problems. The first is when the noisy fluctuations and the underlying deterministic dynamics are related by the fluctuation–dissipation principle (i.e., detailed balance holds).[1] The second is the class of open systems, in which deterministic dynamics are acted on by external fluctuations.

In this paper we discuss the activation of a one-dimensional spatial variable, $x(t)$, by an external Markovian Gaussian colored noise, $y(t)$, with nonzero correlation time. The underlying deterministic dynamics are assumed to occur in a potential well and the activation of $x(t)$ to the top of the potential barrier is the subject of this paper.

The deterministic dynamics for one spatial variable and in one degree of freedom can be viewed as the high damping limit of Newtonian dynamics—the analog of the Smoluchowski approximation to the Langevin equation.[1] The model has been derived independently a number of times with the spatial variable having specific physical interpretations. For example, one spatial variable has been used to describe dynamics along the reaction coordinate in a liquid medium;[1] models of rotational diffusion lead to one-dimensional dynamics for the angular coordinate in the presence of external fluctuations;[2] reconfiguration of proteins between two states under external temperature changes can be described by one-dimensional dynamics;[3] the time evolution of the phase of a laser obeys a first-order differential equation;[4] to name but a few.

We model the external fluctuations by Gaussian colored noise: the Ornstein–Uhlenbeck process.[5] This noise carries a finite energy and thus is a more realistic description of physical fluctuations than Gaussian white noise. In the limit of small correlation time the colored noise approaches the white noise. The white noise case is much easier to handle analytically than the colored noise case, and for that reason white noise has been used extensively to describe the fluctuation phenomena. However, colored noise may provide a more accurate description of the noisy phenomena; for example, in the context of laser-induced transitions,[4,6,7] as a model for

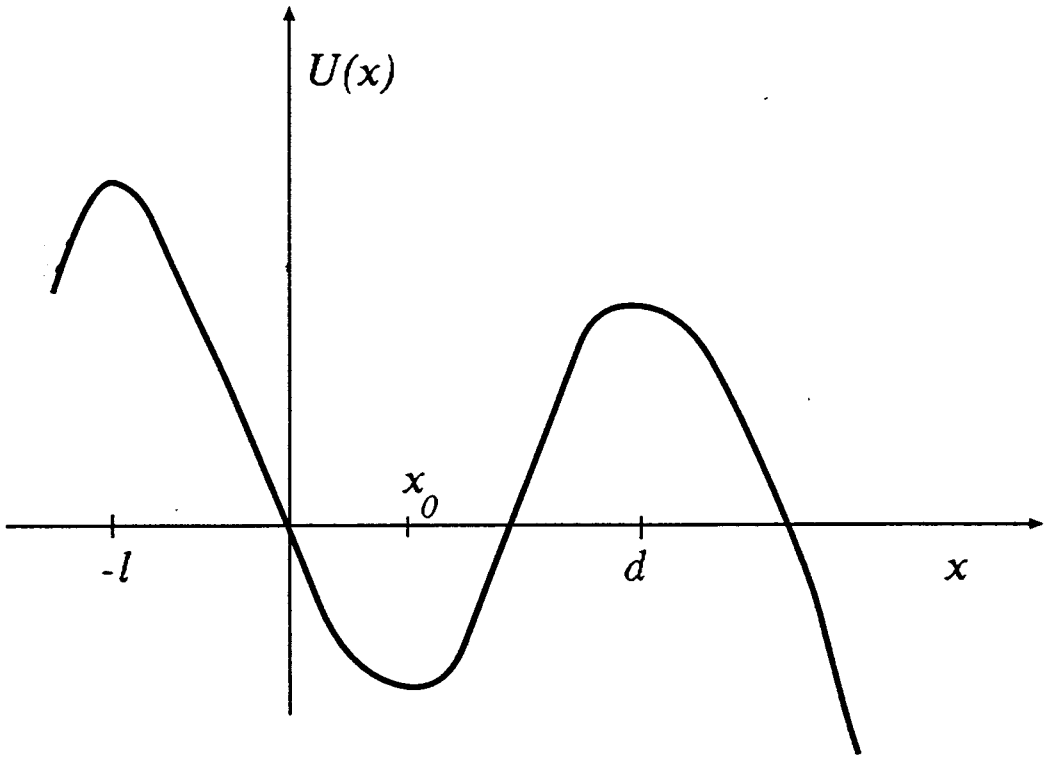

FIG. 1. A typical potential $U(x)$.

deviations from the thermal equilibrium by including nonzero correlation times,[8] with regard to modeling of biological membranes,[9] and many others.

The state variable $x(t)$ acted on by colored noise $y(t)$ is neither a diffusion nor a Markov process, due to the nonzero correlation time of $y(t)$. The phenomena of the activation of a non-Markovian process $x(t)$ and its numerical characterization require careful description. The concept of the reaction rate is well understood in the framework of diffusion processes, which are constructed from dynamical systems acted on by weak Gaussian white noise. If the underlying deterministic dynamics exhibit in the phase space (say) two domains of attraction of stable equilibria separated by the deterministic separatrix, then we say that activation occurs if a trajectory that originates at a stable equilibrium reaches an arbitrarily small neighborhood of the other stable equilibrium; that is, if a well-to-well transition occurs. In the weak noise limit, the transition rate between the stable equilibria is half the rate of a transition from a stable equilibrium to the deterministic separatrix. The activation rate to the separatrix can be calculated as the inverse of the mean first passage time for the trajectories to reach the separatrix from the stable state. Equivalently, the activation rate is inversely proportional to the first principal eigenvalue of the Fokker–Planck operator with absorbing boundary conditions on the separatrix.[10] In particular, in the case of one-dimensional dynamics in a potential well, as shown in Fig. 1, acted on by a weak Gaussian white noise, the domain of attraction of the stable equilibrium at x_0 is the interval $(-l,d)$, and the points $-l$ and d form the zero-dimensional separatrix.

The formalism described above is not directly applicable to the case of non-Markovian processes. Here we define the activation for the process $x(t)$ in the case when the underlying deterministic dynamics exhibit a well, as shown in Fig. 1. We say that the state variable x is activated if its coordinate changes from x_0 to d or $-l$, so that a trajectory reaches the top of the barrier. This definition corresponds, for example, to a deviation of the polarization angle;[2] reconfiguration of proteins;[3] phase fluctuations of laser light;[4] the orbiting model for ion–molecule reactions;[11] and others. Moreover, it is a straightforward generalization of activation by Gaussian white noise, as discussed above. We refer to the deviation of trajectories from their initial (stable) position to the barrier top as the characteristic level crossing problem.

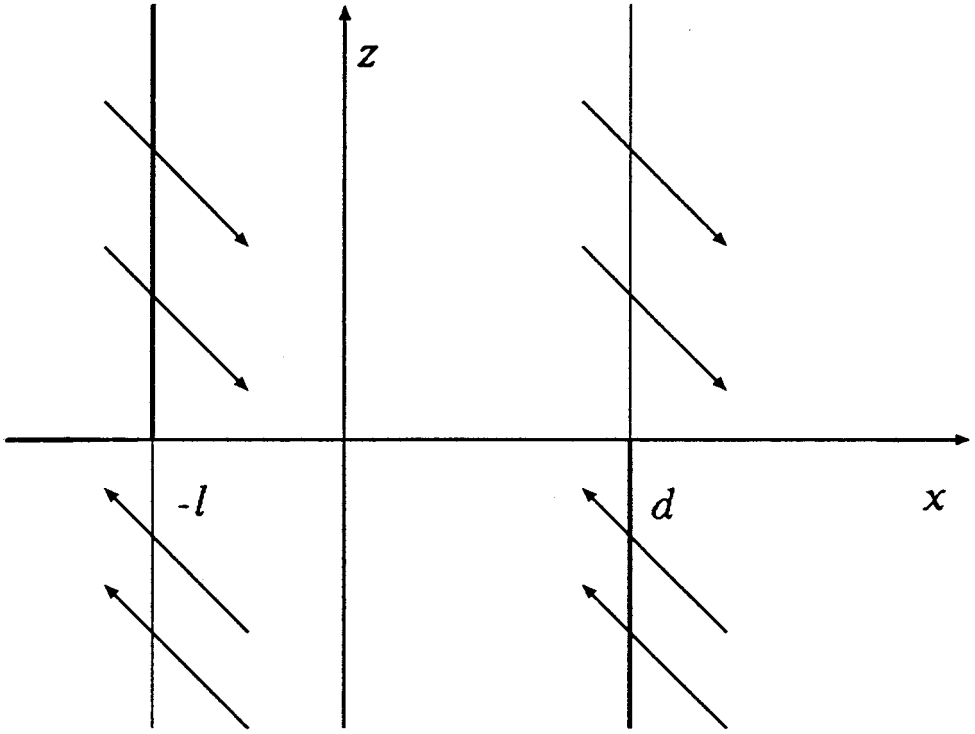

FIG. 2. The strip $D\equiv(-l,d)\times\mathscr{R}$. Arrows indicate the direction of the deterministic flow. The absorbing boundary conditions for the forward Fokker–Planck operator can only be prescribed on the parts of the boundaries where the flow is inwardly directed.

Next, we define the measure of the activation from the stable equilibrium for a non-Markovian process $x(t)$. In the case considered here, the difficulty of dealing with non-Markovian processes can be avoided by enlarging the state space by the noise variable $y(t)$ so that the two-dimensional process $(x(t),y(t))$ becomes Markov. Since the noise takes any value in $\mathscr{R}$, then the state space for the process $(x(t),y(t))$ is a strip $D=(-l,d)\times\mathscr{R}$, as shown in Fig. 2. We use the formalism of Markovian processes to calculate the mean first passage time of this two-dimensional diffusion to either level at $x=-l$, or d, and we take it to be the measure of the activation. A different (and nonequivalent) way to define the activation rate for the non-Markovian process $x(t)$ can be based on the observation that the process $(x(t),y(t))$ is a two-dimensional diffusion process acted on by Gaussian white noise, and the mean first passage time to the deterministic separatrix for the two-dimensional dynamics is a measure of the activation rate, as has been calculated elsewhere.[12] If we assume that trajectories originate with a random value of the noise (e.g., taken according to the stationary distribution), then it is possible for the transition to have occurred before the state variable equals the coordinate of the barrier top—see Fig. 3. Such an approach does not correspond to the class of problems in which the activation is determined solely by the deviation of the variable $x(t)$ from the equilibrium (cf. the above examples). In the enlarged phase plane, this latter class of problems corresponds to the situation when trajectories of the process $(x(t),y(t))$ reach a line $x=$const, with any value of the noise.

To summarize, in this paper we define the activation of the process $x(t)$ to be the activation of the Markov process $(x(t),y(t))$ to a prescribed level $x=$const. Our measure of the activation is the mean first passage time (mfpt) of the trajectories of the Markov process $(x(t),y(t))$ to $x=$const. This definition is relevant to situations in which the measure of transition depends only on the value of x and not on the value of the noise. We are able to solve the boundary value problem for the mean first passage time (mfpt) thanks to the newly developed analytical technique of half-range expansions.[13–15]

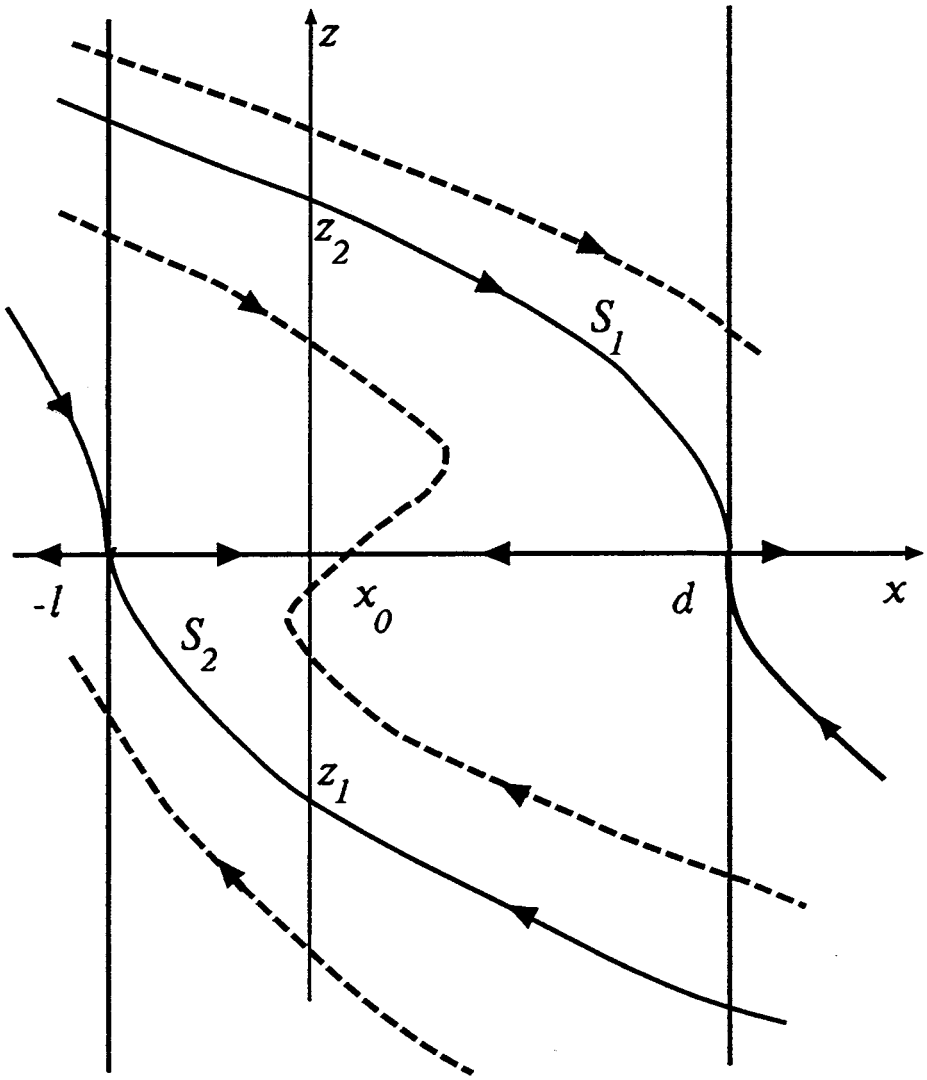

FIG. 3. The curve $S_1 \cup S_2$ (marked with a solid line) is the deterministic separatrix: the boundary of the domain of attraction in the two-dimensional phase space of the stable equilibrium at $(x_0,0)$. If the initial state of the noise, z_0, falls outside of the interval (z_1,z_2), then the initial state (x_0,z_0), of the two-dimensional system is outside of the domain of attraction of the stable equilibrium. According to the definition of the activation as the transition to the deterministic separatrix, this would mean that the system has been already activated, before the state variable x reached the level at either $-l$ or d. According to the definition of activation used in this work x must reach $-l$ or d, with any value of z.

II. MATHEMATICAL PRELIMINARIES AND RESULTS

We study activation of a system in which the deterministic dynamics has one degree of freedom,

$$\dot{x}(t) = -U'(x) + y(t), \tag{2.1}$$

and is acted on by a stationary Ornstein–Uhlenbeck process $y(t)$. The process $y(t)$ is a solution to the stochastic differential equation,[5]

$$\dot{y}(t) = -\frac{1}{\epsilon^2}\, y(t) + \frac{\sqrt{2\sigma}}{\epsilon^2}\, \dot{w}(t), \tag{2.2}$$

with the initial probability density $y(0) \sim \mathcal{N}(0,\sigma/\epsilon^2)$. Here $\dot{w}(t)$ denotes Gaussian white noise. It follows that the average $\langle y(t) \rangle = 0$, hence the autocorrelation of the process $y(t)$ is given by

$$\langle (y(t_1)-\langle y(t_1)\rangle)(\mathbf{y}(t_2)-\langle y(t_2)\rangle)\rangle = \langle y(t_1)y(t_2)\rangle = \frac{\sigma}{\epsilon^2}\, e^{-|t_1-t_2|/\epsilon^2}. \tag{2.3}$$

The parameters σ and ϵ are selected so ϵ^{-2} measures the width of the power spectrum of the noise and σ measures the noise intensity. In the limit as $\epsilon \to 0$, the colored noise $y(t)$ approaches, in distribution, Gaussian white noise of intensity σ; that is, $y(t) \to \sqrt{2\sigma}\dot{w}(t)$. We consider the process $x(t)$ on the interval $[-l,d]$ assuming that the deterministic potential has local extrema at $x=-l,d$, that is, $U'(-l)=U'(d)=0$, so the boundaries are characteristic.

The case of dynamics (2.1) in a bistable potential has played a special role in the literature.[16–18] Even in this ''simple'' case, the analysis of such a random system poses several analytical difficulties. For one, the stochastic process of the state variable $x(t)$ is non-Markovian. On the other hand, the stochastic process in the enlarged state space obtained by including the noise variable is Markovian. However, the (quasi-)stationary probability density function (pdf) of this Markovian process cannot be found explicitly for arbitrary deterministic dynamics. Therefore it is natural to pose questions about how a small but nonzero correlation time of the stochastic forcing term affects the activation of the system. The statistics for the case of zero correlation time forcing term, that is, the Gaussian standard white noise, are known. The problem of finding the asymptotic correction to the activation due to color of the forcing noise has led to a prolific discussion in the literature.[16–18] The discussion evolved about the fact that several methods that were proposed to solve the problem led to different results. One reason for some confusion has been the fact that the enlarged Markovian process depends not on one but on two perturbation parameters: the autocorrelation (color) ϵ^2 and the strength (intensity) σ of the noise. We will show below that the asymptotic limits of weak and nearly white noise are not interchangeable.

In this paper we present uniformly valid results on the activation of the process (2.1). We conduct a systematic asymptotic analysis, which allows us to keep track of the interplay of the parameters ϵ and σ. Specifically, we discuss activation by colored noise over the entire range of its intensity; that is, we do not take the strength σ to be necessarily small compared to the color ϵ, as is customarily assumed in the literature. We find that three distinct regimes need to be considered. The first regime occurs when the correlation time ϵ^2 is asymptotically smaller than the noise strength σ; the noise strength σ itself may be $O(1)$ or smaller in this regime, but $\epsilon^2 \ll \sigma$. We find that in this regime the color of the noise effects the activation rate algebraically. A distinguished regime occurs when $\sigma = O(\epsilon^2)$. In this regime the leading-order effects change from algebraic in color of the noise to the exponential in the noise intensity. Finally, we consider the third regime $\sigma \ll \epsilon^2 \ll 1$. In all three regimes a systematic treatment of the boundary behavior is essential to obtain the correct activation rate from the calculations of the mfpt.

Mathematically, the problem of calculating the mfpt can be formulated in terms of a boundary value problem for either the forward Fokker–Planck operator, $\mathscr{L}_{x,y}$,

$$\frac{\partial p}{\partial t} = \mathscr{L}_{x,y}p \equiv -\frac{\partial}{\partial x}\left[(-U'(x)+y)p\right] + \frac{\partial}{\partial y}\left(\frac{1}{\epsilon^2}\, yp\right) + \frac{\sigma}{\epsilon^4}\frac{\partial^2 p}{\partial y^2}, \tag{2.4}$$

or its adjoint, the backward Kolmogorov operator $\mathscr{L}^{*}_{x,y}$. The boundary conditions for the operator $\mathscr{L}_{x,y}$ can only be prescribed on parts of the boundary where the deterministic flow is inwardly directed.[19] In the present case this implies that the boundary conditions can be prescribed on half-lines: $\{x=-l, y>0\}$ and $\{x=d, y<0\}$ (cf. Fig. 2). The analytical solution to such a boundary value problem became possible only recently with the development of the closed form half-range expansion technique[13,14] and its generalization.[15]

In the limit as $\epsilon \to 0$ the process $y(t)$ approaches in distribution the standard Gaussian white noise of intensity σ. Hence the generator of the process $(x(t),y(t))$, $\mathscr{L}_{x,y}$, approaches the generator, $\mathscr{L}_x$, of a one-dimensional diffusion process of the dynamics $x(t)$ driven by the Gaussian white noise of intensity σ. Several authors[16–18,20] attempted to derive a diffusion approximation to the non-Markovian process $x(t)$, in the asymptotic limit of $\epsilon \ll 1$, by constructing a generator whose coefficients depend on the parameter ϵ, and that reduces to $\mathscr{L}_x$ when $\epsilon = 0$. This approach has been criticized since the meaning of the approximation of the non-Markov process by a Markov process is not well defined.[12] Moreover, these procedures have been applied to the free space operator $\mathscr{L}_{x,y}$ without reference to boundary conditions. We show that the statistics of the

non-Markovian process $(x(t),y(t))$, for example the mfpt, are the same as those of a diffusion process whose generator can be derived from the generator of $\mathscr{L}_{x,y}$, but very specific boundary conditions must be supplied for this diffusion process. That is, it is not enough to construct the free space generator $\mathscr{L}_x$, but rather the asymptotic analysis must be conducted on the boundary value problem for the generator $\mathscr{L}_{x,y}$, which in turn leads to a boundary value problem for the generator $\mathscr{L}_x$.

In this paper we solve the boundary value problem for the forward operator $\mathscr{L}_{x,y}$ with absorbing boundary conditions on half-lines $\{x=-l,y>0\}$ and $\{x=d,y<0\}$. We conduct a perturbation analysis, using boundary layer and half-range expansion techniques. Then we employ the solution to calculate various statistics of the process $(x(t),y(t))$ such as the mfpt and the distribution of exit points. Our results are uniformly valid for $\epsilon\ll 1$ and $\sigma=O(1)$ or smaller. We show that the mfpt of the process $(x(t),y(t))$ to a prescribed level $x=\text{const}$ depends on the mfpt of a one-dimensional diffusion process, $X(t)$, with absorbing boundary conditions imposed at different spatial locations than the boundary conditions for the process $(x(t),y(t))$ were prescribed. The parameters of this one-dimensional diffusion process depend on the color of the noise ϵ and the strength of the noise σ. The locations of the effective boundaries are extrapolated beyond the original interval in proportion to the color and the square root of the intensity of the noise. If $\epsilon\ll 1$ and σ is arbitrary, then the mfpt depends algebraically on the color of the noise. The effects of the color are seen in the effective diffusion coefficient, $D(x)$, the effective potential, $\Psi(x)$, the extrapolated boundaries, and the boundary layer solutions at the absorbing boundaries. If $\sigma\ll 1$, the mfpt is exponentially large in σ. The effects of the boundary layer analysis are of order $O(\epsilon^2)$; thus, they are transcendentally small compared to the other effects. The asymptotic limits of $\epsilon\ll 1$ and $\sigma\ll 1$ are not interchangeable. The expression for the mfpt depends on the relative size of the parameters. If $\epsilon\ll\sqrt{\sigma}$ then, to leading order, corrections to the mfpt are independent of the color of the noise; that is, the white noise approximation holds. In the distinguished limit regime of $\epsilon=O(\sqrt{\sigma})$, the effects due to the color and the intensity of the noise give terms of the same order. If $\sigma\ll\epsilon^2$ then the color of the noise gives the leading-order corrections both in the preexponential factor and in the exponent. This novel result shows that if the noise intensity is sufficiently small compared to the noise autocorrelation, then the activation energy (in addition to the preexponential factor) is changed due to the color of the noise. We call this a non-Markovian effect. This phenomena is similar to the energy gap observed in some ion–molecule reactions.[21]

To summarize, we construct the effective diffusion process $X(t)$, which is the solution to the Itô stochastic differential equation,

$$\dot{X}(t)=-\frac{\Psi'(X)}{D(X)}+\sqrt{\frac{2\sigma}{D(X)}}\,\dot{w}, \tag{2.5}$$

where the effective potential $\Psi(x)$ and the effective diffusion coefficient $D(x)$ are given by

$$\Psi(x)=U(x)+\frac{\epsilon^2}{2}\,(U'(x))^2-\frac{\epsilon^4}{2}\int_{x_0}^{x}U'^2(s)U'''(s)ds+O(\epsilon^6), \tag{2.6}$$

$$D(x)=1+\epsilon^2U''(x)+\epsilon^4\left[\tfrac{1}{2}\sigma U^{iv}(x)+\tfrac{1}{4}U''^2(x)-U'(x)U'''(x)\right]+O(\epsilon^6), \tag{2.7}$$

respectively. The process $X(t)$ satisfies absorbing boundary conditions at the points

$$x_R^*=d+\epsilon\sqrt{\sigma}\,|\zeta(1/2)|+O(\epsilon^3), \tag{2.8}$$

$$x_L^*=-l-\epsilon\sqrt{\sigma}\,|\zeta(1/2)|+O(\epsilon^3), \tag{2.9}$$

where ζ denotes the Riemann zeta function. Statistics of the process $x(t)$ can be approximated by statistics of the process $X(t)$ with an $O(\epsilon^3)$ error. In the entire range of the parameters the exit probabilities are the same for the two processes—compare Eqs. (5.18) and (5.19). If $\sigma=O(1)$, then the mfpt of the process $x(t)$ equals the mfpt for the process $X(t)$ plus an $O(\epsilon^2)$ correction due to the boundary layer solutions—compare Eq. (5.17). If $\sigma\ll 1$, then the mfpt of the two processes are equal within a transcendentally small error. Therefore the process $X(t)$ can be

interpreted as the Markovian approximation to the non-Markovian process $x(t)$ in the asymptotic limit of $\sigma \ll 1$. It is necessary to retain an $O(\epsilon^4)$ term in the expansion of Ψ in Eq. (2.6) in order to construct an expression for the mfpt uniformly valid for $\sigma \ll 1$ and $\epsilon \ll 1$. In particular, this order of the expansion is required to handle the distinguished limit regime of the parameters—see Eq. (6.5) and the discussion of Sec. VI.

The double well potential has played a special role in studying activation by colored noise. It has been established that for such a potential the leading-order correction to the mfpt due to the color of the noise appears in the preexponential factor at the $O(\epsilon^2)$ order, and it is proportional to 3/2. Our systematic perturbation analysis shows that if terms of $O(\epsilon^2)$ are to be kept in the preexponential factor, then additional terms must also be included in the formula for the mfpt. In Eq. (7.2) we illustrate the uniform formula (6.5) for the case of the double well potential. A term of $O(\epsilon)$ due to the extrapolated boundaries must be kept in the preexponential factor. More importantly, other terms due to the strength and the color of the noise must be retained to keep the asymptotic accuracy in the formula for the mfpt. In particular, Eq. (6.7) shows that if $\sigma \ll \epsilon^2$, then an exponential term proportional to ϵ^4/σ must be retained. These results are new—compare Refs. 16, 17, 18, and 22.

Our results give new insight to activation phenomena by driven external fluctuations. These results are only possible due to recent developments of rigorous mathematical techniques for solving explicitly the boundary layer problems when data is given only on half the boundaries to the domain.[13–15]

III. FORMULATION OF THE PROBLEM

We study the activation of the process $x(t)$ [Eq. (2.1)] due to the noise $y(t)$ [Eq. (2.2)], to boundaries of the interval $[-l,d]$, given that the process originates at $x_0 \in (-l,d)$, $O(1)$ away from the boundaries $x=-l(d)$. We assume that the deterministic potential $U(x)$ has a local minimum at x_0, and local maxima at $-l$ and d, such that $U'(-l)=0$, $U'(d)=0$ [the case of noncharacteristic boundaries $U'(-l)\neq 0$, $U'(d)\neq 0$ will be considered elsewhere].[23] Without any loss of generality we assume that $U'(x)\neq 0$ for $x \in (-l,x_0)\cup(x_0,d)$—see Fig. 1.

We rewrite

$$y(t)=\frac{\sqrt{\sigma}}{\epsilon}\, z(t), \tag{3.1}$$

and we observe that the pair $(x(t),z(t))$ is a Markov process that satisfies the system of stochastic differential equations,

$$\begin{aligned} \dot{x}(t) &= -U'(x)+\frac{\sqrt{\sigma}}{\epsilon}\, z, \\ \dot{z}(t) &= -\frac{1}{\epsilon^2}\, z+\sqrt{\frac{2}{\epsilon^2}}\, \dot{w}(t). \end{aligned} \tag{3.2}$$

The transition probability density function (tpdf), of the process (x,z), $p(x,z,t|x_0,z_0)$, satisfies the forward Fokker–Planck equation,[24]

$$\frac{\partial p}{\partial t}=\mathscr{L}_{x,z}p \equiv -\frac{\partial}{\partial x}\left[\left(-U'(x)+\frac{\sqrt{\sigma}}{\epsilon}\, z\right)p\right]+\frac{\partial}{\partial z}\left(\frac{1}{\epsilon^2}\, zp\right)+\frac{1}{\epsilon^2}\,\frac{\partial^2 p}{\partial z^2}. \tag{3.3}$$

We consider the process (x,z) on the strip $D \equiv (-l,d)\times\mathscr{R}$. We assume that all trajectories of the process (x,z) originate at (x_0,z_0), where the coordinate z_0 is selected according to the stationary noise density $r(z)=(1/\sqrt{2\pi})\exp\{-z^2/2\}$:

$$\lim_{t\to 0} p(x,z,t|x_0,z_0)=\delta(x-x_0)r(z_0)\,\delta(z-z_0). \tag{3.4}$$

The fact that no other trajectories enter the domain D implies absorbing boundary conditions on the left and on the right, respectively,

$$p(-l,z,t|x_0,z_0)=0, \quad \text{for} \quad z>0,$$

$$p(d,z,t|x_0,z_0)=0, \quad \text{for} \quad z<0; \tag{3.5}$$

see Fig. 2. We solve the problem (3.3–3.5) and we calculate the mean first passage time (mfpt) of the process (x,z) to the boundaries $x=-l$ and $x=d$. First we introduce the function $\hat{P}(x,z|x_0)$,

$$\hat{P}(x,z|x_0)=\int_{-\infty}^{+\infty}\int_{0}^{+\infty} p(x,z,t|x_0,z_0)dt\ dz_0. \tag{3.6}$$

The function $\hat{P}$ can be interpreted as the time spent by a trajectory at (x,z) given it originated at x_0, prior to absorption.[25] We seek the solution to Eq. (3.3) in the form

$$\overline{P}(x,z|x_0)=\frac{1}{\sqrt{2\pi}}\,e^{-z^2/2}Q(x,z|x_0). \tag{3.7}$$

The function Q satisfies the boundary value problem

$$L_{x,z}Q\equiv Q_{zz}-zQ_z+\epsilon^2[U'(x)Q]_x-\epsilon\sqrt{\sigma}zQ_x=-\epsilon^2\delta(x-x_0), \tag{3.8}$$

$$Q(-l,z|x_0)=0, \quad \text{for } z>0, \tag{3.9}$$

$$Q(d,z|x_0)=0, \quad \text{for } z<0. \tag{3.10}$$

In Sec. IV we solve the problem (3.8)–(3.10) in the asymptotic limit of $\epsilon\ll 1$. We do not assume that the strength of the noise σ is small compared to other parameters of the problem. The problem (3.8)–(3.10) with boundary conditions prescribed only on the parts of the boundaries where the deterministic flow is inward is a typical case to analyze with the half-range expansion technique.[13,15]

After we calculate the solution Q we use it in Sec. IV to compute the following: (1) the mfpt of a trajectory to the level $x=-l,d$, $E\tau(x_0)$, given that the trajectory started at x_0,

$$E\tau=\int\int_{D}\frac{1}{\sqrt{2\pi}}\,e^{-z^2/2}Q(x,z|x_0)dx\ dz; \tag{3.11}$$

(2) the probability density that the trajectory exits D with the value of the noise z,

$$p(x(\tau)=d,z(\tau)\in(z,z+dz)|x(0)=x_0)=\frac{\sqrt{\sigma}}{\epsilon}\,\frac{z}{\sqrt{2\pi}}\,e^{-z^2/2}Q(d,z|x_0)dz, \tag{3.12}$$

$$p(x(\tau)=-l,z(\tau)\in(z,z+dz)|x(0)=x_0)=-\frac{\sqrt{\sigma}}{\epsilon}\,\frac{z}{\sqrt{2\pi}}\,e^{-z^2/2}Q(-l,z|x_0)dz; \tag{3.13}$$

(3) the probability that the trajectory exits D on the left, p^{LEFT}, and the probability that the trajectory exits D on the right p^{RIGHT},

$$p^{\mathrm{LEFT}}=-\frac{\sqrt{\sigma}}{\epsilon}\int_{-\infty}^{0}\frac{z}{\sqrt{2\pi}}\,e^{-z^2/2}Q(-l,z|x_0)dz, \tag{3.14}$$

$$p^{\mathrm{RIGHT}}=\frac{\sqrt{\sigma}}{\epsilon}\int_{0}^{+\infty}\frac{z}{\sqrt{2\pi}}\,e^{-z^2/2}Q(d,z|x_0)dz. \tag{3.15}$$

The factor $\sqrt{\sigma}/\epsilon$ in Eqs. (3.12)–(3.15) results from the scaling (3.1).

In Sec. V we calculate the mfpt of the trajectories of the process (x,y) to the absorbing boundaries in the asymptotic limit of $\epsilon \ll 1$ and $\sigma \ll 1$.

IV. ANALYSIS

A. Outer solution

Away from the source and the boundaries, at a distance greater than $O(\epsilon)$, the function Q satisfies the outer problem,

$$L_{x,z} Q^{\mathrm{OUT}}(x,z) = 0. \tag{4.1}$$

As shown in Appendix A, in the limit of $\epsilon \ll \sqrt{\sigma}$, the solution to Eq. (4.1) can be expanded in an asymptotic series in powers of ϵ. In the limit of $\sigma \ll 1$, the (quasi-)stationary solution to Eq. (4.1) has a WKB structure; that is, it is exponential in $1/\sigma$. The transition between the two asymptotic behaviors of Q^{OUT} occurs for $\epsilon = O(\sqrt{\sigma})$, which is where the validity of the expansion in powers of ϵ breaks down. In Appendix A we also calculate the solution to Eq. (4.1) in the distinguished limit $\epsilon = O(\sqrt{\sigma})$—see Eqs. (A25) and (A28). We use it to construct the solution to Eq. (4.1), which is uniformly valid for $\epsilon \ll 1$, $\sigma = O(1)$ or smaller. We write

$$Q^{\mathrm{OUT}}(x,z) = \begin{cases} C_1 Q_1^{\mathrm{OUT}}(x,z) + D_1 Q_2^{\mathrm{OUT}}(x,z), & -l < x < x_0 \\ C_2 Q_1^{\mathrm{OUT}}(x,z) + D_2 Q_2^{\mathrm{OUT}}(x,z), & x_0 < x < d \end{cases}, \tag{4.2}$$

where

$$Q_1^{\mathrm{OUT}}(x,z) = \exp\left\{ -\frac{\Psi(x)}{\sigma} \right\} K(x,z), \tag{4.3}$$

$$Q_2^{\mathrm{OUT}}(x,z) = Q_1^{\mathrm{OUT}}(x,z) \int_{x_0}^{x} e^{\Psi(s)/\sigma}\, ds + M(x,z), \tag{4.4}$$

and where functions $\Psi(x)$, $K(x,z)$, and $M(x,z)$ have asymptotic expansions

$$\Psi(x) = U(x) + \frac{\epsilon^2}{2} (U'(x))^2 - \frac{\epsilon^4}{2} \int_{x_0}^{x} U'^2(s) U'''(s) ds + O(\epsilon^6), \tag{4.5}$$

$$K(x,z) = \left[1 + \frac{3}{2} \epsilon^2 U''(x) + O(\epsilon^3) \right] \exp\left\{ -\frac{1}{2} (1 + \epsilon^2 U''(x)) \left(z - \frac{\epsilon}{\sqrt{\sigma}} U'(x) \right)^2 + \frac{1}{2} z^2 + O(\epsilon^3/\sqrt{\sigma}) \right\}, \tag{4.6}$$

$$M(x,z) = \frac{\sigma}{U'(x)} \left[1 - \exp\left\{ \frac{\epsilon}{\sqrt{\sigma}} z U'(x) - \frac{\epsilon^2}{2\sigma} U'^2(x) \right\} \right] + O(\sigma^2). \tag{4.7}$$

We observe that Q^{OUT} is a well-defined function, even at points where $U'(x)$ vanishes. Here C_1, C_2, D_1, and D_2 are arbitrary constants, which are determined in the course of further analysis. We note that if $\epsilon \ll \sqrt{\sigma}$ and we expand the functions Ψ, K, and M in powers of ϵ, then we recover the expansion (A8). For $\sigma \ll 1$, after rearranging terms, Q_1^{OUT} agrees with the WKB expansion (A17), while for $\epsilon = O(\sqrt{\sigma})$ it equals the distinguished limit expansion given by Eqs. (A25) and (A28).

B. Analysis near the source

We introduce a local variable $\tilde{x} \equiv (x - x_0)/\epsilon\sqrt{\sigma}$. Since the point x_0 is a minimum of the potential, we expand $U(x)$ about x_0 as

$$U(x)=U(x_0)+\tfrac{1}{2}U''(x_0)(x-x_0)^2+\cdots . \tag{4.8}$$

We denote by Q^S the solution to Eq. (3.8) written in terms of $\tilde{x}$. We have

$$Q^S_{zz}-zQ^S_z-zQ^S_{\tilde{x}}+O(\epsilon^3)=0, \quad \text{for } \tilde{x}\neq 0, \tag{4.9}$$

$$Q^S(\tilde{x}=0^+,z)-Q^S(\tilde{x}=0^-,z)=\frac{\epsilon}{\sqrt{\sigma}}\frac{1}{z}. \tag{4.10}$$

Moreover Q^S must match Q^{OUT} as $\tilde{x}\to-\infty,+\infty$, respectively.

According to the calculations in Appendix B, we expand the right-hand side of Eq. (4.10) in terms of eigenfunctions $\{V_0,\tilde{V}_0,V_n^{\pm}\}$ as shown in Eqs. (B8) and (B10). Then the solution to Eq. (49) that satisfies the jump condition (4.10) is given by

$$\begin{aligned} Q^{S+}(\tilde{x},z)&=a_0+\tilde{a}_0(\tilde{x}-z)+\frac{\epsilon}{\sqrt{\sigma}}\sum_{n=1}^{\infty} I_n^- e^{-\sqrt{n}\tilde{x}}V_n^-(z), \quad \text{if } \tilde{x}>0,\\ Q^{S-}(\tilde{x},z)&=b_0+\tilde{b}_0(\tilde{x}-z)-\frac{\epsilon}{\sqrt{\sigma}}\sum_{n=1}^{\infty} I_n^+ e^{\sqrt{n}\tilde{x}}V_n^+(z), \quad \text{if } \tilde{x}<0, \end{aligned} \tag{4.11}$$

where $a_0=b_0$, $\tilde{b}_0-\tilde{a}_0=\epsilon/\sqrt{\sigma}$. The matching conditions between Q^{S+} and Q^{OUT} give $a_0=C_2\exp\{-U(x_0)/\sigma\}$, $\tilde{a}_0=\epsilon\sqrt{\sigma}D_2$, and the matching conditions between Q^{S-} and Q^{OUT} give $b_0=C_1\exp\{-U(x_0)/\sigma\}$, $\tilde{b}_0=\epsilon\sqrt{\sigma}D_1$, so

$$C_1=C_2, \quad D_2-D_1=1/\sigma. \tag{4.12}$$

C. Boundary layer analysis

In this section we construct the boundary layer solutions at $x=-l$ and at $x=d$, under the assumption $U'(-l)=U'(d)=0$. First we introduce a local variable $\xi\equiv(x+l)/\epsilon\sqrt{\sigma}$, and rewrite Eq. (3.8) for the local solution Q^L in terms of ξ and z as

$$\begin{aligned} &Q^L_{zz}-zQ^L_z-zQ^L_{\xi}+O(\epsilon^2)=0,\\ &Q^L(\xi=0,z)=0, \quad \text{for } z>0. \end{aligned} \tag{4.13}$$

Moreover, we require that Q^L matches the outer solution Q^{OUT} as $\xi\to\infty$, that is

$$Q^L\sim\left[D_1\int_{-l}^{x_0}e^{\Psi(y)/\sigma}\,dy+C_1\right]e^{-\Psi(-l)/\sigma}+D_1\epsilon\sqrt{\sigma}(\xi-z), \quad \text{as } \eta\to\infty. \tag{4.14}$$

According to the results of Refs. 13 and 14 quoted in Appendix B, the solution to Eq. (4.13) is given by

$$Q^L(\xi,z)=A^L\left[\alpha+\xi-z+\sum_{n=1}^{\infty}\beta_n V_n^-(z)e^{-\sqrt{n}\xi}\right]. \tag{4.15}$$

We recall that $\alpha\equiv|\zeta(1/2)|$ and the coefficients β_n and the eigenfunctions V_n are defined in Eq. (B13) and Eq. (B4), respectively. The constant A^L is to be determined from the matching condition (4.14).

Similarly, analysis about $x=d$ in the local variable $\eta\equiv(d-x)/\epsilon\sqrt{\sigma}$ leads to the boundary value problem for Q^R, given by

$$Q^R_{zz} - zQ^R_z + zQ^R_\eta = 0,$$

$$Q^R(\eta = 0, z) = 0, \qquad \text{for} \quad z < 0, \tag{4.16}$$

$$Q^R \sim \left[D_2 \int_{x_0}^{d} e^{\Psi(y)/\sigma}\, dy + C_2 \right] e^{-\Psi(d)/\sigma} + D_2 \epsilon \sqrt{\sigma}(\eta - z), \quad \text{as} \ \eta \to \infty.$$

We write the solution to Eq. (4.16) as

$$Q^R(\eta, z) = A^R \left[\alpha + \eta + z + \sum_{n=1}^{\infty} (-1)^n \beta_n V_n^+(z) e^{-\sqrt{n}\eta} \right], \tag{4.17}$$

where A^R is an arbitrary constant to be determined from matching conditions. Matching between Q^R and Q^{OUT} gives

$$\begin{aligned} A^R \alpha e^{\Psi(d)/\sigma} &= D_2 \int_{x_0}^{d} e^{\Psi(y)/\sigma}\, dy + C_2, \\ A^R &= -D_2 \epsilon \sqrt{\sigma}, \end{aligned} \tag{4.18}$$

while the matching between Q^L and Q^{OUT} gives

$$\begin{aligned} A^L \alpha e^{\Psi(-l)/\sigma} &= -D_1 \int_{-l}^{x_0} e^{\Psi(y)/\sigma}\, dy + C_1, \\ A^L &= D_1 \epsilon \sqrt{\sigma}. \end{aligned} \tag{4.19}$$

Combining Eqs. (4.12), (4.18), and (4.19) we determine all constants

$$\begin{aligned} D_2 &= -\frac{1}{\sigma} \frac{K(-l)}{K(-l) + K(d)}, \\ D_1 &= \frac{1}{\sigma} \frac{K(d)}{K(-l) + K(d)}, \\ C_1 = C_2 &= \frac{1}{\sigma} \frac{K(d)K(-l)}{K(-l) + K(d)}, \end{aligned} \tag{4.20}$$

where

$$K(-l) \equiv \int_{-l - \epsilon\sqrt{\sigma}\alpha}^{x_0} e^{\Psi(x)/\sigma}\, dx + O(\epsilon^3), \tag{4.21}$$

$$K(d) \equiv \int_{x_0}^{d + \epsilon\sqrt{\sigma}\alpha} e^{\Psi(x)/\sigma}\, dx + O(\epsilon^3). \tag{4.22}$$

V. SOLUTIONS

A. Uniform solution

We write the uniform solution to the problem (3.8) in the form

$$Q^{\mathrm{UNI}}(x,z) = Q^{\mathrm{OUT}}(x,z) + Q^{\mathrm{IN}(-l)}(x,z) + Q^{\mathrm{IN}(d)}(x,z) + Q^{\mathrm{IN}(S)}(x,z), \tag{5.1}$$

where $Q^{\mathrm{IN}(-l)}$, $Q^{\mathrm{IN}(d)}$ and $Q^{\mathrm{IN}(S)}$ denote the contributions due to the boundary layer on the left, on the right, and at the location of the source, respectively. They are given by

$$Q^{\mathrm{IN}(-l)}(x,z)=\frac{\epsilon}{\sqrt{\sigma}}\frac{K(d)}{K(-l)+K(d)}\sum_{n=1}^{\infty}\beta_n e^{-\sqrt{n}(x+l)/\epsilon\sqrt{\sigma}}V_n^-(z), \tag{5.2}$$

$$Q^{\mathrm{IN}(d)}(x,z)=\frac{\epsilon}{\sqrt{\sigma}}\frac{K(-l)}{K(-l)+K(d)}\sum_{n=1}^{\infty}\beta_n e^{-\sqrt{n}(d-x)/\epsilon\sqrt{\sigma}}V_n^-(-z), \tag{5.3}$$

$$Q^{\mathrm{IN}(S)}(x,z)=\begin{cases}\dfrac{\epsilon}{\sqrt{\sigma}}\displaystyle\sum_{n=1}^{\infty}I_n^-V_n^-(z)e^{-\sqrt{n}(x-x_0)/\epsilon\sqrt{\sigma}}, & \text{if } x>x_0,\\ -\dfrac{\epsilon}{\sqrt{\sigma}}\displaystyle\sum_{n=1}^{\infty}I_n^+V_n^+(z)e^{\sqrt{n}(x-x_0)/\epsilon\sqrt{\sigma}}, & \text{if } x<x_0,\end{cases} \tag{5.4}$$

with the coefficients β_n given by Eq. (B13) and the eigenfunctions $V_n^{\pm}$ given by Eq. (B4).

B. Effective diffusion

Next, we discuss the marginal steady-state pdf corresponding to the outer solution, that is, $P_{\mathrm{mar}}^{\mathrm{OUT}}\equiv\langle Q^{\mathrm{OUT}}(x,z),1\rangle$. Here $\langle\cdot,\cdot\rangle$ denotes the inner product defined in Appendix B in Eq. (B3) as $\langle f,g\rangle=1/\sqrt{2\pi}\int_{-\infty}^{+\infty}f(z)g(z)\exp(-z^2/2)dz$. We obtain

$$P_{\mathrm{mar}}^{\mathrm{OUT}}(x)=[1+\epsilon^2U''(x)]e^{-\Psi(x)/\sigma}\begin{cases}D_1\displaystyle\int_{-l-\epsilon\sqrt{\sigma}\alpha}^{x}e^{\Psi(y)/\sigma}\,dy, & x<x_0,\\ -D_2\displaystyle\int_{d+\epsilon\sqrt{\sigma}\alpha}^{x}e^{\Psi(y)/\sigma}\,dy, & x>x_0.\end{cases} \tag{5.5}$$

We observe that $P_{\mathrm{mar}}^{\mathrm{OUT}}$ does not vanish at $x=-l,d$, but rather it vanishes at the points extrapolated beyond the interval $(-l,d)$ whose coordinates are given by

$$x_R^*=d+\epsilon\sqrt{\sigma}\alpha+O(\epsilon^3), \tag{5.6}$$

$$x_L^*=-l-\epsilon\sqrt{\sigma}\alpha+O(\epsilon^3). \tag{5.7}$$

$P_{\mathrm{mar}}^{\mathrm{OUT}}$ can be interpreted as the steady-state pdf of a diffusion process X, which is the solution to the Itô stochastic differential equation,

$$\dot{X}(t)=-\frac{\Psi'(X)}{D(X)}+\sqrt{\frac{2\sigma}{D(X)}}\,\dot{w}, \tag{5.8}$$

where $\Psi(X)$ is given by Eq. (4.5) and $D(X)\equiv1+\epsilon^2U''(x)$. The process $X(t)$ has absorbing boundaries at x_R^* and x_L^*, with a trajectory originating at $x=x_0$ with probability one. In other words, the steady-state pdf, $P(X,t)$ of the process $X(t)$ satisfies the problem

$$\frac{\partial P(X,t)}{\partial t}=\mathscr{L}_XP(X,t)\equiv\frac{\partial}{\partial X}\left(\frac{\Psi'(X)}{D(X)}\,P(X,t)\right)+\sigma\,\frac{\partial^2}{\partial X^2}\left(\frac{1}{D(X)}\,P(X,t)\right), \tag{5.9}$$

$$\lim_{t\to0}P(X,t|x_0)=\delta(X-x_0), \tag{5.10}$$

$$P(X,t|x_L^*)=0,\quad P(X,t|x_R^*)=0. \tag{5.11}$$

The process $X(t)$ can be interpreted as a Markovian approximation of a non-Markovian process $x(t)$. We refer to $X(t)$ as the effective diffusion. The meaning and the validity of this approximation is discussed here and in the subsequent sections. We solved the boundary value problem for the generator, $\mathscr{L}_{x,z}$, of the diffusion process $(x(t),z(t))$ with absorbing boundary conditions—Eqs. (3.3)–(3.5). The projection of this two-dimensional problem on a one-dimensional space is

given by the generator $\mathscr{L}_X$ of a diffusion process (5.8) with absorbing boundary conditions at the extrapolated points (5.6) and (5.7). The error of this approximation is of $O(\epsilon^3)$. The effective potential Ψ and the effective diffusion coefficient $D(X)$ depend on the potential $U(x)$ and on the small parameter ϵ. The dependence of the effective diffusion on ϵ has been observed before.[16–18,12] In contrast to previous work[16,12,22] we keep the expansion of Ψ up to $O(\epsilon^4)$ in order to derive properties of the processes $(x(t),z(t))$ and $X(t)$, which are uniformly valid in ϵ and σ. This asymptotic order of the expansion of Ψ plays an essential role in understanding how the intensity and the color of the noise affect the activation of the process $x(t)$. In particular, it is important in the case when the two parameters are small, and as they change their relative magnitudes through the distinguished limit regime. The absorbing boundary conditions for the process X are prescribed at the points extrapolated beyond the original spatial location of the boundaries for the process $x(t)$. The size of the extrapolation depends on both ϵ and σ, but it is independent of the potential $U(x)$. This is due to the fact that the boundaries are characteristic, and to leading order the process $(x(t),z(t))$ in the boundary layer regime behaves like the integral of the Ornstein–Uhlenbeck process. Hence the extrapolated boundaries are the same as found in Refs. 13 and 14.

C. The mfpt

Next we use $Q^{\mathrm{UNI}}(x,z)$ to calculate the mfpt to the boundary of the strip D. According to the formula (3.11) we have

$$\begin{aligned} E\tau &= \int_{-l}^{d} \langle Q^{\mathrm{UNI}}(x,z),1\rangle dx = \int_{-l}^{d} \langle Q^{\mathrm{OUT}}(x,z),1\rangle dx + \int_{-l}^{d} \langle Q^{\mathrm{IN}(s)}(x,z),1\rangle dx \\ &\quad + \int_{-l}^{d} [\langle Q^{\mathrm{IN}(-l)}(x,z),1\rangle + \langle Q^{\mathrm{IN}(d)}(x,z),1\rangle] dx \\ &\equiv E\tau^{\mathrm{OUT}} + E\tau^{S} + E\tau^{\mathrm{BL}}. \end{aligned} \tag{5.12}$$

Here $E\tau^{\mathrm{OUT}}$, $E\tau^{S}$, and $E\tau^{\mathrm{BL}}$ denote the contribution to the mfpt due to the outer solution, the solution in the neighborhood of the source, and the absorbing boundary layer solution, respectively. We write

$$E\tau^{\mathrm{OUT}} = \int_{-l}^{d} P_{\mathrm{mar}}^{\mathrm{OUT}}(x)dx = \int_{x_L^*}^{x_R^*} R_{\mathrm{mar}}^{\mathrm{OUT}}(x)dx - \epsilon^2 \frac{\alpha^2}{2} + O(\epsilon^3) \equiv E\tau_{ExB}^{\mathrm{OUT}} - \epsilon^2 \frac{\alpha^2}{2} + O(\epsilon^3), \tag{5.13}$$

where $E\tau_{ExB}^{\mathrm{OUT}}$ denotes the mfpt of the diffusion process (5.8) to the extrapolated boundaries (5.6) and (5.7). The contribution to the mfpt in Eq. (5.12) due to the boundary layers is given by

$$E\tau^{\mathrm{BL}} = \int_{-l}^{d} \langle Q^{\mathrm{IN}(-l)},1\rangle dx + \int_{-l}^{d} \langle Q^{\mathrm{IN}(d)},1\rangle dx = \mu\epsilon^2, \tag{5.14}$$

where the coefficient μ is calculated numerically as the sum of the series

$$\mu \equiv \sum_{n=1}^{\infty} \beta_n \frac{1}{\sqrt{n}} \langle V_n^-(z),1\rangle = -0.206\,184\ldots . \tag{5.15}$$

The contribution to the mfpt due to the boundary layer at the location of the source is given by

$$E\tau^{S} = \int_{-l}^{d} \langle Q^{\mathrm{IN}(S)},1\rangle dx = \epsilon^2 \left[\sum_{n=1}^{-\infty} \frac{1}{\sqrt{n}} I_n^- \langle V_n^-(z),1\rangle - \frac{1}{\sqrt{n}} I_n^+ \langle V_n^+(z),1\rangle \right] = \epsilon^2. \tag{5.16}$$

The last identity follows from Eqs. (B16) and (B20). Combining Eqs. (5.13), (5.14), and (5.16), we write

$$E\tau = E\tau_{ExB}^{\mathrm{OUT}} + \epsilon^2\left(-\frac{\alpha^2}{2}+\mu+1\right)+O(\epsilon^3). \tag{5.17}$$

Equation (5.17) shows the dependence of the statistics of the marginal process $x(t)$ on the color and the intensity of the noise. First, one of the contributions to the mfpt of the process $X(t)$ comes from the statistics of the process $X(t)$ defined in Eq. (5.8). The diffusion coefficient, $D(X)$, and the effective potential, Ψ, depend on the color of the noise. Second, the absorbing boundary conditions for the process $X(t)$ are extrapolated beyond the location of absorbing boundaries of the process $x(t)$ by a distance proportional to the color of the noise. Third, the correction $\epsilon^2 \times(-\alpha^2/2+\mu+1)$ is due to the boundary layers at the absorbing boundaries and at the location of the source. The effects both of the color of the noise and the potential on the mfpt can be seen in $E\tau_{ExB}^{\mathrm{OUT}}$. We study asymptotic properties of $E\tau_{ExB}^{\mathrm{OUT}}$ as ϵ and σ vary in Sec. VI.

We also use Q^{UNI} to calculate the probabilities of exiting on the left and right. According to Eqs. (3.14) and (3.15), we have

$$p^{\mathrm{LEFT}} = \frac{\sqrt{\sigma}}{\epsilon}A^L = \frac{K(d)}{K(-l)+K(d)} = \frac{\int_{x_0}^{x_R^*} e^{\Psi(x)/\sigma}\,dx}{\int_{x_L^*}^{x_R^*} e^{\Psi(x)/\sigma}\,dx}+O(\epsilon^3), \tag{5.18}$$

$$p^{\mathrm{RIGHT}} = \frac{\sqrt{\sigma}}{\epsilon}A^R = \frac{K(-l)}{K(-l)+K(d)} = \frac{\int_{x_L^*}^{x_0} e^{\Psi(x)/\sigma}\,dx}{\int_{x_L^*}^{x_R^*} e^{\Psi(x)/\sigma}\,dx}+O(\epsilon^3). \tag{5.19}$$

The probabilities p^{LEFT} and p^{RIGHT} are equal to the exit probabilities on the left and right for the process $X(t)$.

VI. ASYMPTOTIC LIMIT OF WEAK NEARLY WHITE COLORED NOISE

The dependence of the mfpt on the two parameters is complicated, as can be seen from the simple considerations below. As an example, we assume that $\epsilon \ll 1$, and write

$$E\tau_{ExB}^{\mathrm{OUT}} = E\tau^0 + \epsilon E\tau^1 + \epsilon^2 E\tau^2 + O(\epsilon^3). \tag{6.1}$$

Here $E\tau^0$ denotes the mfpt of the diffusion process,

$$\dot{x} = -U'(x) + \sqrt{2\sigma}\dot{w}, \tag{6.2}$$

to absorption at $x=-l,d$. That is, the leading term corresponds to the approximation of the colored process by the white noise. The term $E\tau^1$ can be interpreted as the effect of the extrapolated boundaries, and so on. Formulas for $E\tau^i$, $i=0,1,...$, are rather complicated and one could try to simplify them by considering them in the standard asymptotic limit of small noise strength, $\sigma \ll 1$. Assuming that $U(-l)>U(d)$, we would obtain

$$E\tau^0 = \frac{\pi}{\sqrt{-U''(d)U''(x_0)}}\, e^{[U(d)-U(x_0)]/\sigma}[1+O(\sqrt{\sigma})]. \tag{6.3}$$

The last step of this analysis poses several problems. We derived the uniform solution to Eq. (3.8)–(3.10) and hence we calculated the formula for the mfpt, Eq. (5.12), valid in the asymptotic limit of $\epsilon \ll 1$. In particular, our results are valid for $\epsilon \ll \sqrt{\sigma}$. Therefore the term of $O(\sqrt{\sigma})$ in Eq. (6.3) is asymptotically greater than the first-order correction, $\epsilon E\tau^1$, which contains effects of the color of the noise. Therefore, disregarding the term of $O(\sqrt{\sigma})$ while keeping terms of $O(\epsilon)$ and $O(\epsilon^2)$ is incorrect. In order to obtain a correct asymptotic formula for the mfpt in the limit of $\sigma \ll 1$, one should retain as many terms in the expansion (6.3) as necessary for the order of magnitude of the disregarded terms to be asymptotically smaller than ϵ.

In order to fully understand the dependence of the mfpt on the two parameters we construct the formula for the mfpt that is uniformly valid in the asymptotic limit of $\epsilon \ll 1$ and $\sigma \ll 1$. If $\sigma \ll 1$ then the mfpt is exponentially large in this parameter, and according to Eq. (5.17) with a transcendentally small error we have

$$E\tau = E\tau_{ExB}^{\mathrm{OUT}} = \int_{x_L^*}^{x_R^*} P_{mar}^{\mathrm{OUT}}(x)dx = D_1 \int_{x_L^*}^{x_0} D(x) e^{-\Psi(x)/\sigma} \int_{x_L^*}^{x} e^{\Psi(y)/\sigma}\, dy\, dx - D_2 \int_{x_0}^{x_R^*} D(x) e^{-\Psi(x)/\sigma} \int_{x}^{x_R^*} e^{\Psi(y)/\sigma}\, dy\, dx. \tag{6.4}$$

We evaluate the Laplace-type integrals in Eq. (6.4) for $\sigma \ll 1$. First we note that the asymptotic expansion of the function Ψ in Eq. (4.5) was derived including terms up to $O(\epsilon^4)$. We assume that $\epsilon^6 \ll \sigma \ll 1$. (In order to obtain the answer for smaller values of σ, additional terms in the asymptotic expansion of Ψ should be kept.) Without any loss of generality we assume that $U(-l) > U(d)$, and we obtain

$$\begin{aligned} E\tau^{\mathrm{OUT}} &= \frac{\pi}{2\sqrt{-U''(x_0)U''(d)}} \exp\left\{ \frac{U(d)-U(x_0)}{\sigma} - \frac{\epsilon^4}{2\sigma} \int_{x_0}^{d} U'^2(y) U'''(y) dy \right\} \\ &\times \left\{ 1 + \sqrt{\frac{2}{\pi}} \sqrt{-U''(d)} \left(\epsilon\alpha - \sqrt{\sigma}\, \frac{1}{3} \frac{U'''(d)}{3U''^2(d)} \right) + \sigma \left[\frac{1}{8} \frac{U^{iv}(d)}{U''^2(d)} - \frac{5}{24} \frac{U'''^2(d)}{U''^3(d)} \right] - \epsilon^2 \frac{U''(d)}{2} \right\} \\ &\times \left\{ 1 - \sqrt{\frac{2}{\pi}} \sqrt{\sigma}\, \frac{1}{3} \frac{U'''(x_0)}{U''^{3/2}(x_0)} \right) + \sigma \left[-\frac{1}{8} \frac{U^{iv}(x_0)}{U''^2(x_0)} + \frac{5}{24} \frac{U'''^2(x_0)}{U''^3(x_0)} \right] + \epsilon^2 \frac{U''(x_0)}{2} \right\} \\ &\times \{1 + O(\epsilon^4, \epsilon^2\sqrt{\sigma}, \sigma^{3/2})\}. \end{aligned} \tag{6.5}$$

Equation (6.5) is uniformly valid for $\epsilon \ll 1$, $\epsilon^6 \ll \sigma \ll 1$. It shows that, depending on the asymptotic values of ϵ and σ, the main contributions to the formula (6.5) result from different effects. The terms proportional to powers of σ in the preexponential factor in Eq. (6.5) stem from the evaluation of the Laplace-type integrals. The term proportional to ϵ is the effect of the extrapolated boundaries, while the term proportional to ϵ^2 comes from the effective diffusion coefficient. The term in the exponent proportional to ϵ^4/σ is due to the effective potential. If $\epsilon \ll \sigma \ll 1$ then the leading-order terms in the preexponential term of Eq. (6.5) are due to the Laplace-type integrals; the effects of the color of the noise show up only as lower-order contributions. In this case the white noise approximation is valid with an error $O(\sqrt{\sigma})$. If $\epsilon = O(\sigma)$ then the order of magnitude of the term due to the extrapolated boundaries is the same as the order of magnitude of the second-order correction in the Laplace-type integral. So that if σ decreases to be $O(\epsilon)$, the effects of the color of the noise begin to show in Eq. (6.5). As σ decreases to the distinguished limit case, $\epsilon = O(\sqrt{\sigma})$, the effects of the color of the noise (through the effective diffusion coefficient and the effective potential, and the extrapolated boundaries) and the noise intensity (through the Laplace-type integrals) are of the same order and all of them must be retained in Eq. (6.5). If $\epsilon^6 \ll \sigma \ll \epsilon^4$ then the color of the noise gives the main order contribution. In the case of $\sigma \ll \epsilon^2$ the contribution in Eq. (6.5) due to the effective potential (the term proportional to ϵ^4/σ) shows that the color of the noise changes the activation energy. We refer to this phenomena as the non-Markovian effects on the activation rate.

If the strength of the noise is asymptotically larger than the color of the noise, then the noise strength gives the main contribution to the mfpt. In the distinguished limit regime, both parameters give main order contributions to the mfpt. If the noise strength is asymptotically smaller than the color of the noise, then the expression for the mfpt is changed due to the color of the noise, both in the preexponential factor and in the exponent. Thus, due to the color of the noise the effective activation energy is changed by a term of $O(\epsilon^4)$.

VII. EXAMPLE: THE DOUBLE WELL POTENTIAL

We illustrate the discussion of the preceding section with an example of the double well potential $U(x)=x^4/4-x^2/2$. We take $x_0=-1$ and $d=0$. The mfpt from x_0 to d due to the white noise is, to leading order, given by—compare Eq. (6.3),

$$E\tau_{\mathrm{WN}}=\frac{\pi}{2\sqrt{2}}\,e^{1/4\sigma}. \tag{7.1}$$

Then the formula (6.5) reduces to

If $\epsilon\ll\sigma\ll 1$ then

$$E\tau=E\tau_{\mathrm{WN}}\left\{1+\sqrt{\sigma}\sqrt{\frac{1}{\pi}}+\frac{3}{2}\,\sigma+O(\epsilon,\sigma^{3/2})\right\}.$$

If $\sigma=O(\epsilon)$ then

$$E\tau=E\tau_{\mathrm{WN}}\left\{1+\epsilon\alpha\sqrt{\frac{2}{\pi}}+\sqrt{\sigma}\sqrt{\frac{1}{\pi}}+\frac{3}{2}\,\sigma+O(\epsilon\sqrt{\sigma},\epsilon^2,\sigma^{3/2})\right\}.$$

If $\epsilon^2\ll\sigma\ll\epsilon$ then

$$E\tau=E\tau_{\mathrm{WN}}\left\{1+\epsilon\alpha\sqrt{\frac{2}{\pi}}+\sqrt{\sigma}\sqrt{\frac{1}{\pi}}+\frac{3}{2}\,\sigma+\epsilon\sqrt{\sigma}\,\frac{\sqrt{2}}{\pi}+O(\epsilon\sqrt{\sigma},\epsilon^2,\sigma^{3/2})\right\}.$$

If $\sigma=\epsilon^2$ then

$$E\tau=E\tau_{\mathrm{WN}}\left\{1+\epsilon\sqrt{\frac{2}{\pi}}\left(\alpha+\frac{\sqrt{2}}{2}\right)+\epsilon^2\left(\frac{3}{2}+\frac{\sqrt{2}}{\pi}\right)+O(\epsilon^3)\right\}.$$

If $\epsilon^4\leqslant\sigma\leqslant\epsilon^2$ then

$$E\tau=E\tau_{\mathrm{WN}}\left\{1+\epsilon\sqrt{\frac{2}{\pi}}\,\alpha+\sqrt{\sigma}\,\frac{1}{\sqrt{\pi}}+\frac{3}{2}\,\epsilon^2+O(\epsilon^3,\sigma^{3/2},\epsilon\sqrt{\sigma})\right\}.e^{\epsilon^4/(8\sigma)}.$$

If $\epsilon^6\leqslant\sigma\leqslant\epsilon^4$ then

$$E\tau=E\tau_{\mathrm{WN}}\left\{1+\epsilon\sqrt{\frac{2}{\pi}}\,\alpha+\frac{3}{2}\,\epsilon^2+O(\sigma^{1/2})\right\}\cdot e^{\epsilon^4/(8\sigma)}. \tag{7.2}$$

The ''famous'' factor $3\epsilon^2/2$ does not show in the preexponential factor until $\sigma=O(\epsilon^2)$ or smaller. If $\epsilon^6\ll\sigma\ll\epsilon^4$ then no term proportional to a power of σ shows up to leading order in the preexponential factor. The term proportional to ϵ is the result of the extrapolated boundaries or equivalently the boundary layer analysis at the absorbing boundary location of the original problem. The factor $3\epsilon^2/2$ is due to the effective diffusion coefficient. However, if it is to be included in the formula for the mfpt, the exponential term with the exponent proportional to ϵ^4/σ must also be included in this expression. It is necessary in order for the mfpt expression to be asymptotically correct. Therefore, if the term of $3\epsilon^2/2$ order is to be included, other terms must be kept as well. Equation (6.7) gives the asymptotically exact expression for the mfpt to of the trajectories to the top of the potential barrier in the double well potential. The last two cases in Eq. (6.7) illustrate the effective change in the activation energy due to the color of the noise for sufficiently small noise intensity. In this case the effective activation energy increases from 1/4 to $1/4+\epsilon^4/8$.

VIII. SUMMARY

In this paper we analyze the activation of one-dimensional dynamics $x(t)$ by stationary Gaussian colored noise. We define the activation as the variation of the spatial variable $x(t)$ from its

initial state to a prescribed level $x=\text{const}$. In the examples considered here we took the level to be the coordinate of the barrier top, so that the boundary is characteristic. A different way of defining the activation is related to the transitions up to the deterministic separatrix in the two-dimensional state space $(x(t),y(t))$. These two types of activation problems are distinct, and they apply to different physical situations. Mathematically, the two problems lead to boundary value problems for the same Fokker–Planck operator, but with boundary conditions applied on different curves. In the latter case the conditions are prescribed on a separatrix. In contrast, for the level crossing problem, we must impose boundary conditions at (half-)lines $x=\text{const}$ Consequently, the activation rates differ between the two cases. In the past, some authors have defined the activation problem of the non-Markovian process $x(t)$ as the level crossing problem, but then tried to calculate the well-to-well transition. This has led to some confusion in the field—see Refs. 16–18 and the discussions therein. In the Introduction we clarify the distinction between these two problems. Another confusing topic in the literature has been the use of Markovian approximations to the evolution of the process $x(t)$. We show that the evolution of the process $x(t)$ cannot be treated separately from its boundary behavior.

Our analysis extends and corrects the analysis of Ref. 22. We analyze the level crossing problem for colored noise whose autocorrelation is taken to be small compared to $O(1)$ quantities like principal frequencies, the distance of the initial point to the level, etc. However, the correlation time can be large compared to the noise strength, when the latter is taken to be asymptotically small. This interplay of these small parameters and a systematic perturbation analysis lead to new insights into non-Markovian activation phenomena.

We are able to construct the outer solution to the problem (3.8)–(3.10), which is uniformly valid in the entire considered range of the parameters. Next, we match the outer solution to the half-range boundary layer solution. Consequently we obtain in Eq. (5.1) the uniform solution to the problem (3.8)–(3.10). These calculations allow the construction of the outer effective diffusion operator in Eqs. (5.9), which depends on the color of the noise at $O(\epsilon^2)$. An analog to this result is the Smoluchowski approximation to the Längevin equation since we construct a one-dimensional approximation $X(t)$ to the two-dimensional process $(x(t),y(t))$. The outer equation is equipped with the absorbing conditions at the extrapolated boundaries (5.6) and (5.7). The location of the new boundaries follows from the boundary layer analysis in Sec. IV. The validity of the approximation (5.9) to the original problem depends on the relative size of the color and intensity of the noise. If the intensity of the noise σ is of $O(1)$, while $\epsilon\ll 1$, then the outer problem alone (5.9)–(5.11) does not give the correct approximation to the original problem (3.3)–(3.5). From Eq. (5.17) we see that the boundary layer functions give a correction of $O(\epsilon^2)$ to the mfpt. This correction is of the same asymptotic order as the corrections to the outer diffusion operator due to the color of the noise and so cannot be ignored. This effect of the boundaries has not been derived before. If σ is asymptotically small compared to $O(1)$ quantities of the original problem, then Eqs. (5.9)–(5.11) provide a valid approximation to the original problem.

In Sec. VI we use Eq. (5.9)–(5.11) to calculate the mfpt in the asymptotic limit of $\sigma\ll 1$. We observe that the effects of the color of the noise on the activation rate change from algebraic to exponential as the intensity of the noise decreases through the distinguished limit of $\sigma=O(\epsilon)$. If $\sigma\ll\epsilon\ll 1$, then the color of the noise changes the activation energy, and thus modifies the Arrhenius factor. We call these new results non-Markovian effects on the activation rate.

We note that the half-range expansion technique of Refs. 13 and 14 outlined here, and its extensions in Ref. 15, are applicable to a larger class of diffusion-type transport problems. The example of the colored noise activation problem shows that the correct analytical treatment of the boundary conditions affects coefficients and parameters of such transport problems in a nontrivial way.

APPENDIX A: OUTER SOLUTION

In this appendix we calculate the solution to the outer problem (4.1),

$$Q_{zz}(x,z)-zQ_z(x,z)+\epsilon^2[U'(x)Q(x,z)]_x-\epsilon\sqrt{\sigma}zQ_x(x,z)=0, \tag{A1}$$

in the asymptotic limit $\epsilon\ll 1$ with σ being of $O(1)$ or smaller. First for $\epsilon\ll\sqrt{\sigma}$ we seek Q in the form of the asymptotic series,

$$Q(x,z)=\sum_{n=0}^{\infty}\frac{(-\epsilon\sqrt{\sigma})^n}{n!}Q^n(x)\mathrm{He}_n(z), \tag{A2}$$

where $\mathrm{He}_n(z)$ denotes the Hermite polynomials.[26] Substituting the series (A2) into Eq. (A1) we obtain the recursive system of equations for Q^n,

$$\sigma Q^1_x+[U'(x)Q^0]_x=0,$$

$$Q^n=Q^{n-1}_x+\frac{\epsilon^2}{n}[\sigma Q^{n+1}+U'(x)Q^n]_x, \quad n=1,2,3,\ldots. \tag{A3}$$

Next we solve the system (A3) by seeking Q^n in the form of the asymptotic series,

$$Q^n(x)=Q^n_0(x)+\epsilon^2Q^n_1(x)+\epsilon^4Q^n_2(x)+\cdots, \quad n=0,1,2,\ldots. \tag{A4}$$

We determine $Q^0(x)$ with an $O(\epsilon^6)$ error by solving the system of equations,

$$\hat{L}Q^0_0\equiv\sigma[Q^0_0(x)]_{xx}[U'(x)Q^1_0]_x=0,$$

$$\hat{L}Q^0_1=-\sigma[\sigma Q^2_0+U'(x)Q^1_0]_{xx}, \tag{A5}$$

$$\hat{L}Q^0_2=-\sigma[\sigma Q^2_1+U'(x)Q^1_1]_{xx},$$

where

$$Q^1_0(x)=[Q^0_0(x)]_x \quad Q^2_0(x)=[Q^0_0(x)]_{xx},$$

$$Q^1_1(x)=[Q^0_1(x)-U''(x)Q^0_0(x)]_x, \tag{A6}$$

$$Q^2_1(x)=[Q^0_1(x)]_{xx}-[\tfrac{3}{2}U'''(x)Q^0_0(x)+2U''(x)(Q^0_0(x))_x]_x.$$

In particular,

$$Q^0_0(x)=\left[D_1\int_{x_0}^{x}e^{U(t)/\sigma}\,dt+C_1\right]e^{-U(x)/\sigma}. \tag{A7}$$

Combining terms up to $O(\epsilon^2)$ we observe that Q^{OUT} can be written in the form

$$Q^{\mathrm{OUT}}(x,z)=C_1Q^{\mathrm{OUT}}_1(x,z)+D_1Q^{\mathrm{OUT}}_2(x,z), \tag{A8}$$

where

$$Q^{\mathrm{OUT}}_1(x,z)=\left[1+\frac{3}{2}\epsilon^2U''(x)+O(\epsilon^3)\right]\exp\left\{\frac{-\psi(x)}{\sigma}+\frac{z^2}{2}-\frac{\epsilon^2U''(x)z^2}{2}-\frac{1}{2}\left(\frac{\epsilon U'(x)}{\sqrt{\sigma}}-z\right)^2\right\}, \tag{A9}$$

$$Q^{\mathrm{OUT}}_2(x,z)=Q^{\mathrm{OUT}}_1(x,z)\int_{x_0}^{x}e^{\psi(s)/\sigma}\,ds-\epsilon\sqrt{\sigma}z-\frac{1}{2}\epsilon^2z^2U'(x)+\frac{1}{2}\epsilon^2U'(x)+O(\epsilon^3), \tag{A10}$$

with

$$\psi(x)\equiv U(x)+\tfrac{1}{2}\epsilon^2U'^2(x). \tag{A11}$$

Next we calculate the (quasi-)stationary pdf of the marginal process $x(t)$. We have

$$P^{\mathrm{mar}}(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}Q(x,z)e^{z^2/2}dz=Q^0(x)=Q_0^0(x)+\epsilon^2Q_1^0(x)+\epsilon^4Q_2^0(x)+O(\epsilon^6). \quad \text{(A12)}$$

Taking $Q^0(x)=\exp(-U(x)/\sigma)$ in Eq. (A12), we obtain

$$\begin{aligned}P^{\mathrm{mar}}(x)&=e^{-U(x)/\sigma}\left[1+\epsilon^2\left(U''(x)-\frac{1}{2\sigma}U'^2(x)\right)+\epsilon^4\left[\frac{\sigma}{2}U^{iv}(x)+\frac{1}{4}U''^2(x)-3U'''(x)U'(x)\right.\right.\\&\left.\left.+\frac{1}{2\sigma}\int_{x_0}^{x}U'^2(y)U'''(y)dy+\frac{1}{8\sigma^2}U'^4(x)\right]+O(\epsilon^6)\right]\\&=\{1+\epsilon^2U''(x)+O(\epsilon^4)]\}\\&\times\exp\left\{-\frac{1}{\sigma}\left[U(x)+\frac{\epsilon^2}{2}U'^2(x)-\frac{\epsilon^4}{2}\int_{x_0}^{x}U'^2(y)U'''(y)dy+O(\epsilon^6)\right]\right\}. \quad \text{(A13)}\end{aligned}$$

Next we outline the calculations of the (quasi-)stationary pdf in the asymptotic limit $\sqrt{\sigma}\ll\epsilon\ll1$. First we rescale the process $y(t)$ in Eq. (2.1) as—compare Ref. 12,

$$y(t)=\frac{1}{\epsilon}v(t), \quad \text{(A14)}$$

and we write the system for the Markov process (x,v) in the form equivalent to Eq. (3.2) as

$$\begin{aligned}\dot{x}(t)&=-U'(x)+\frac{1}{\epsilon}v,\\\dot{v}(t)&=-\frac{1}{\epsilon^2}v+\sqrt{\frac{2\sigma}{\epsilon^2}}\dot{w}(t).\end{aligned} \quad \text{(A15)}$$

The (quasi-)stationary pdf $p(x,v)$ satisfies the forward Fokker–Planck operator for Eq. (A15)

$$\mathscr{L}_{x,v}p\equiv-\frac{\partial}{\partial x}\left[\left(-U'(x)+\frac{1}{\epsilon}v\right)p\right]+\frac{\partial}{\partial v}\left(\frac{1}{\epsilon^2}vp\right)+\frac{\sigma}{\epsilon^2}\frac{\partial^2p}{\partial v^2}=0. \quad \text{(A16)}$$

We seek the solution to Eq. (A16) in the WKB form,

$$p(x,v)=\mathscr{K}(x,v)e^{-v^2/2\sigma}e^{-\Phi(x,v)/\sigma}. \quad \text{(A17)}$$

Upon substituting Eq. (A17) into Eq. (A16) we find the eikonal equation for Φ,

$$\Phi_v^2+v\Phi_v-[\epsilon^2U'(x)-\epsilon v]\Phi_x=0, \quad \text{(A18)}$$

and the transport equation for $\mathscr{K}$,

$$-\Phi_{vv}.\mathscr{K}-2\Phi_v.\mathscr{K}_v-v.\mathscr{K}_v+\epsilon^2U''(x).\mathscr{K}+[\epsilon^2U'(x)-\epsilon v].\mathscr{K}_x=0. \quad \text{(A19)}$$

We are unable to solve the system (A18)–(A19) exactly, but we determine its solution in the asymptotic series in powers of ϵ (cf. Ref. 12). We seek Φ in the form of the asymptotic series,

$$\Phi(x,v)=\phi^0(x,v)+\epsilon\phi^1(x,v)+\epsilon^2\phi^2(x,v)+\cdots. \quad \text{(A20)}$$

Upon substituting the series (A20) into Eq. (A18), and equating to zero coefficients of separate powers of ϵ we obtain a recursive system of equations for ϕ^i. We solve this system requiring Φ to be nonsingular in v. We obtain

$$\phi^0(x,v)=U(x),$$

$$\phi^1(x,v)=-vU'(x),$$

$$\phi^2(x,v)=\frac{v^2}{2}U''(x)+U'^2(x), \tag{A21}$$

$$\phi^3(x,v)=-\frac{v^3}{6}U'''(x)-vU'(x)U''(x),$$

$$\phi^4(x,v)=\frac{v^4}{24}U^{iv}(x)+\frac{v^2}{4}U'(x)U'''(x)+\int_{x_0}^{x}U'(y)U''^2(y)dy,$$

and so on. Then we seek the solution to the transport equation (A19) for $\mathscr{K}\equiv\mathscr{K}(x,v)$,

$$-\phi_{vv}\mathscr{K}-2\Phi_v\mathscr{K}_v-v\mathscr{K}_v+\epsilon^2U''(x)\mathscr{K}+[\epsilon^2U'(x)-\epsilon v]\mathscr{K}_x=0, \tag{A22}$$

in the asymptotic series of powers of ϵ. Using the expansion (A21), we obtain

$$\mathscr{K}(x,v)=1+\tfrac{3}{2}\epsilon^2U''(x)+O(\epsilon^3). \tag{A23}$$

Next we calculate the (quasi-)stationary pdf of the marginal process $x(t)$ in the asymptotic limit $\sqrt{\sigma}\ll\epsilon\ll1$. Using the fact that $\int U'U''^2\,dx=U'^2U''/2-\int U'^2U'''\,dy/2$, we have

$$\begin{aligned}P^{\mathrm{mar}}(x)&=\frac{1}{\sqrt{2\pi\sigma}}\int_{-\infty}^{\infty}\mathscr{K}(x,v)e^{-v^2/2\sigma}e^{-\Phi(x,v)/\sigma}\,dv\\&=[1+\epsilon^2U''(x)]\\&\quad\times\exp\left\{-\frac{1}{\sigma}\left[U(x)+\frac{\epsilon^2}{2}U'^2(x)-\frac{\epsilon^4}{2}\int_{x_0}^{x}U'^2(y)U'''(y)dy\right]\right\}(1+O(\epsilon^3)).\end{aligned} \tag{A24}$$

We retain the $O(\epsilon^4)$ term in the exponent while disregarding $O(\epsilon^3)$ terms in the preexponential factor in order to construct the uniform approximation to the pdf and the mfpt, as discussed in Sec. III.

Next, we construct the solution to Eq. (4.1) in the distinguished limit $\epsilon=O(\sqrt{\sigma})$. To this end we seek Q^{OUT} in the form

$$Q^{\mathrm{OUT}}=\exp\left\{-\frac{1}{\sigma}U(x)-\frac{\epsilon^2}{\sigma}U'^2(x)+\frac{\epsilon}{\sqrt{\sigma}}zU'(x)\right\}K(x,z). \tag{A25}$$

Substituting the expansion (A25) into Eq. (4.1), then changing variables $(x,z)\to(x,v\equiv2\epsilon U'(x)/\sqrt{\sigma}-z)$ and writing $\sqrt{\sigma}=l\epsilon$ we obtain the equation for K,

$$K_{vv}-vK_v+\epsilon^2\left\{\frac{2}{l}U'[lv-U']K_v+l\left[v-\frac{U'}{l}\right]K_x+\left[U''+\frac{1}{l}U'U''v-v^2U''\right]K\right\}=0. \tag{A26}$$

We seek the solution Eq. (A26) in the form of the asymptotic series,

$$K=K_0+\epsilon^2K_1+\epsilon^4K_2+\cdots, \tag{A27}$$

to obtain

$$K(x,z)=1+\epsilon^2\left[\frac{3}{2}\,U''-\frac{z^2}{2}\,U''+\frac{z}{l}\,U'U''-\frac{1}{2}\,\frac{U'^2U''}{l^2}-\frac{1}{2l^2}\int_{x_0}^{x}U'^2(y)U'''(y)dy\right]+O(\epsilon^4). \tag{A28}$$

APPENDIX B: BOUNDARY LAYER SOLUTION

The local analysis about the location of the source and about the location of the absorbing characteristic boundaries leads to a problem for the differential operator given by

$$Q_{zz}-zQ_z-zQ_x=0. \tag{B1}$$

Separation of variables in Eq. (B1) leads to the eigenvalue problem for the operator L given by

$$LV\equiv V''-zV'=\lambda zV. \tag{B2}$$

We observe that L is self-adjoint in the inner product,

$$\langle V,W\rangle=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}e^{-z^2/2}V(z)W(z)dz. \tag{B3}$$

Following the analysis, of Refs. 13 and 14 we find that $\lambda=0$ is a double eigenvalue of L with the eigenfunction $V_0=1$, and the generalized eigenfunction $\tilde{V}_0=z$. All other eigenvalues and their corresponding eigenfunctions of L are given by

$$\lambda_n^{\pm}=\pm\sqrt{n}\leftrightarrow V_n^{\pm}(z)=e^{z^2/4}e^{-(z\pm2\sqrt{n})^2/4}\,\mathrm{He}_n(z\pm2\sqrt{n}), \tag{B4}$$

where $\mathrm{He}_n(x)$ denotes the Hermite polynomial.[26] The eigenfunctions $\{V_0,\tilde{V}_0,V_n^{\pm}\}$ are orthogonal in the inner product (B3) with the weight function $w(z)=z$, that is,

$$\langle zV_n^{\pm},V_m^{\pm}\rangle=\langle zV_0,\tilde{V}_0\rangle=\langle zV_n^{\pm},V_0\rangle=0,\quad \text{for } n\neq m, \tag{B5}$$

$$\langle zV_n^{\pm},\tilde{V}_0\rangle=0,\quad \langle zV_n^{\pm},V_m^{\mp}\rangle=0, \tag{B6}$$

and the normalization constants are

$$\langle zV_n^{\pm},V_n^{\pm}\rangle=\mp2\sqrt{n}n!. \tag{B7}$$

The set $\{V_0,\tilde{V}_0,V_n^{\pm},\ n=1,2,3,...\}$ is a complete set of eigenfunctions of the operator L.[27,28] The expansion of a function $f(z)$ in terms of this basis can be written as

$$f(z)=I_0V_0(z)+\tilde{I}_0\tilde{V}_0(z)+\sum_{n=1}^{\infty}I_n^{+}V_n^{+}(z)+\sum_{n=1}^{\infty}I_n^{-}V_n^{-}(z), \tag{B8}$$

where

$$I_n^{\pm}=\frac{\langle zf(z),V_n^{\pm}(z)\rangle}{\langle zV_n^{\pm}(z),V_n^{\pm}(z)\rangle},\quad I_0=\frac{\langle z^2f(z),1\rangle}{\langle z^2,1\rangle},\quad \tilde{I}_0=\frac{\langle zf(z),1\rangle}{\langle z^2,1\rangle}. \tag{B9}$$

In particular if $f(z)=1/z$ then the coefficients (B9) become

$$I_0=0,\quad \tilde{I}_0=1,\quad I_n^{+}=-\frac{e^{-n/2}n^{n/2}}{2\sqrt{n}n!},\quad I_n^{-}=-(-1)^nI_n^{+}. \tag{B10}$$

According to the analysis of Refs. 13, 14, the solution to Eq. (B1), which satisfies the absorbing boundary conditions,

$$Q(x=0,z)=0,\quad \text{for}\quad z>0, \tag{B11}$$

and does not grow faster than linearly as $x\to\infty$ is given by

$$Q(x,z)=A\left[\alpha+x-z+\sum_{n=1}^{\infty}\beta_n V_n^-(z)e^{-\sqrt{n}x}\right]. \tag{B12}$$

Here $\alpha\equiv|\zeta(1/2)|$, where ζ denotes the Riemann zeta function, and

$$\beta_n=-(-1)^n\frac{N(\sqrt{n})}{2n!\sqrt{n}} \tag{B13}$$

and

$$N(s)=\prod_{k=1}^{\infty}\left(1+\frac{s}{\sqrt{k}}\right)^{-2s(\sqrt{k}-\sqrt{k-1})}\left(\frac{k+1}{k}\right)^{s^2/2}. \tag{B14}$$

We evaluate the following sum numerically [compare Eq. (5.14)]

$$\sum_{n=1}^{\infty}\frac{1}{\sqrt{n}}\beta_n\langle V_n^-(z),1\rangle=-\sum\nolimits_{n=1}^{\infty}\frac{N(\sqrt{n})n^{n/2}e^{-n/2}}{2nn!}\equiv\mu=-0.206\,184\ldots. \tag{B15}$$

We also need to evaluate the following sum [see Eq. (5.16)]:

$$\mathscr{S}_1\equiv\sum_{n=1}^{\infty}\frac{1}{\sqrt{n}}[I_n^-\langle V_n^-(z),1\rangle-I_n^+\langle V_n^+(z),1\rangle]=\sum_{n=1}^{\infty}\frac{\langle 1,V_n^-\rangle^2}{\sqrt{n}\langle zV_n^-,V_n^-\rangle}-\sum_{n=1}^{\infty}\frac{\langle 1,V_n^+\rangle^2}{\sqrt{n}\langle zV_n^+,V_n^+\rangle}. \tag{B16}$$

First, we observe that as a result of Eq. (B6) we have

$$\langle 1,V_n^-\rangle=\langle 1-z\tilde{V}_0,V_n^-\rangle=\frac{1}{2}\langle Lz^2,V_n^-\rangle=-\frac{\sqrt{n}}{2}\langle z^2,zV_n^-\rangle. \tag{B17}$$

Similarly,

$$\langle V_n^+,1\rangle=\frac{\sqrt{n}}{2}\langle z^2,zV_n^+\rangle. \tag{B18}$$

We observe that if f and g are any square integrable functions in the inner product (B3) then

$$\langle zf,g\rangle=\langle z^2,f\rangle\langle z,g\rangle+\langle z,f\rangle\langle z^2,g\rangle+\sum_{n=1}^{\infty}\frac{\langle zf,V_n^+\rangle\langle zg,V_n^+}{\langle zV_n^+,V_n^+\rangle}+\sum_{n=1}^{\infty}\frac{\langle zf,V_n^-\rangle\langle zg,V_n^-}{\langle zV_n^-,V_n^-\rangle}. \tag{B19}$$

Hence, combining Eqs. (B8), (B17), (B18), and (B19) we have

$$\mathscr{S}_1=-\frac{1}{2}\left[\sum_{n=1}^{\infty}\frac{\langle z^2,zV_n^-\rangle}{\langle zV_n^-,V_n^-\rangle}\langle 1,V_n^-\rangle+\sum_{n=1}^{\infty}\frac{\langle z^2,zV_n^+\rangle}{\langle zV_n^+,V_n^+\rangle}\langle 1,V_n^+\rangle\right]=\left\langle\frac{1}{2}(3-z^2),1\right\rangle=1. \tag{B20}$$

(Received 26 February 1997; accepted for publication 8 September 1997)

A variational method for Hamiltonian systems is analyzed. Two different variational characterization for the frequency of nonlinear oscillations is also supplied for non-Hamiltonian systems. © *1998 American Institute of Physics.* [S0022-2488(98)02702-9]

I. INTRODUCTION

The dynamical study of nonlinear oscillatory systems is often reduced to numerical calculus or to some approximated analytical techniques. Most of them are based in perturbation methods[1] as for instance the Poincaré–Lindsted method, the averaging (Krylov–Bogoliuvov–Mitropolsky) method, the Shohat expansion, or the multiscale method, to mention a few. They provide approximate solutions as well as the relationship between the frequency of the nonlinear oscillations and a small parameter (physically identified for the system, as the amplitude of the oscillations). Other approximate techniques consist in the qualitative analysis on the phase space by linearizing the differential equation around the fixed points. Periodic or exponential behavior of the system may be predicted after studying the stability of the fixed points.

Many different physical systems reduce to one-dimensional nonlinear ODE of second order, which may be studied by using the approximate techniques mentioned above.[2,3] An important property of them is that the frequency depends explicitly on the amplitude of the oscillations. As we have mentioned, the perturbative techniques yield to an approximate solution in power series of the amplitude only.

Recently, Benguria and Depassier (BD for short)[4] have made use of a variational principle in order to solve the bifurcation problem for second-order nonlinear Hamiltonian systems. They also apply the principle to obtain simple approximate closed formulas for the frequency of large-amplitude oscillations.

In this work we extend this method to other situations. Basically, the method consists in transforming the differential equation $\ddot{u}+u=N(u)$, which may be written in the phase space variables (p,u), with $p=-u'$ (where the prime means differentiation with respect to the variable $\tau=2\omega t/\pi$) in an integral equation multiplying the differential equation by an auxiliary function $g(u)$, and integrating. The variational method provide a lower bound for an integral functional. From the Euler–Lagrange equations for the functional, one may calculate the auxiliary function $g(u)$ at a first approximation by taking $p(u)$ from the linear case $(N=0)$.

First of all, we generalize this transformation for Hamiltonian systems. We multiply the differential equation by $p^n g$ and apply the variational method. From this generalization we obtain the first interesting result: the variational characterization depends strongly on the exponent n. In this sense, we obtain a better fit for $n=-1$ than for $n=0$ (the BD's case).

However, as the systems are Hamiltonian, it is possible to find a relationship between p and u in the nonlinear situation. Using it, instead of its linear approach, one can find a new relationship for g being the variational result for the frequency, always equal to the exact solution. This is shown in three specific and physically interesting cases.

Second, as non-Hamiltonian systems are very often found in practice and arise in many physical systems, we introduce in this work a special analysis for them. Following the same ideas employed for Hamiltonian systems, one obtains an explicit dependence of the variational characterization on $p(u)$. For non-Hamiltonian systems it is not possible to obtain a relationship between p and u, at least exactly. In consequence, we adopt two ways to proceed. From one hand, we apply twice the variational method and find two coupled Euler–Lagrange equations, one of them corresponding to the same functional that appears in Hamiltonian systems and the other one to the

 © 1998 American Institute of Physics

new one that contains $p(u)$. The consequent variational characterization does not depend now on $p(u)$. This method also apply for large amplitude. On the other hand, we find for a class of non-Hamiltonian systems in which the above method does not hold, a perturbative solution to $p(u)$ for small nonlinearities. As a special example we treat the Van der Pol oscillator.

II. VARIATIONAL PRINCIPLES FOR HAMILTONIAN SYSTEMS

In this section we generalize the BD's method and we show, by using the Duffing oscillator as an example, the generality of the principle. Starting from a nonlinear Hamiltonian dynamical system of the form

$$\ddot{u}+u=N(u), \quad \text{with } u(0)=a, \quad \dot{u}(0)=0, \tag{1}$$

this becomes

$$u''+\lambda u=N(u,\lambda), \tag{2}$$

where the prime symbol stands for the differentiation respect to the angular variable $\tau=2\omega t/\pi$, ω being the angular frequency of the nonlinear system (1) and $\lambda=(\pi/2\omega)^2$. We restrict our study to $u\in(0,a)$, where a is the initial amplitude of movement, so $u(\tau=1)=0$. Defining the variable $p=-u'>0$ we reduce the order of (2), and it is written as

$$p\,\frac{dp}{du}+\lambda u=N(u,\lambda). \tag{3}$$

Multiplying (3) by $p^n g(u)$, where $g(u)$ is an auxiliary function to be determined such that $g(0)=0$, and integrating, we obtain

$$\lambda\int_0^a up^n g(u)du=\int_0^a\left(p^n N(u,\lambda)g(u)+\frac{1}{n+2}\,p^{n+2}g'(u)\right)du. \tag{4}$$

Notice that for $n=0$ we recover the Benguria and Depassier case. We consider now, for a fixed g and $n>-2$, the functional

$$J_g[v]=\frac{(-1)^n}{n+2}\int_0^a (v')^{n+2}g'(v)dv=\frac{(-1)^{n+1}}{n+2}\int_0^1 (v')^{n+3}g'(v)d\tau, \tag{5}$$

defined for v such that it satisfies $v(0)=a$, $v(1)=0$, and $v'<0$ in $\tau\in(0,1)$. Defining $\phi(v,v')=(-1)^{n+1}(v')^{n+3}g'(v)/(n+2)$, the Euler–Lagrange equations for J_g may be integrated once to obtain $\phi-v'\,\partial\phi/\partial v'=\text{const}$, provided that ϕ does not depend explicitly on τ. From the Euler–Lagrange equation we obtain

$$(-1)^{n+1}(\tilde{v}')^{n+3}g'(\tilde{v})=K>0, \tag{6}$$

where $\tilde{v}$ is the value of v such that for a fixed g, $J_g\geqslant 0$ has a unique minimum. The auxiliary function g may be obtained by integrating (6). So, once g is determined, we get

$$J_g[v]\geqslant J_g[\tilde{v}]=\frac{K(a)}{n+2}, \tag{7}$$

where $K(a)$ is determined through the boundary condition on $\tilde{v}$. So, we have from (4), (5), and (7),

$$\lambda\geqslant\frac{\int_0^a N(u,\lambda)g(u)du+\dfrac{K}{n+2}}{\int_0^a up^n g(u)du}. \tag{8}$$

This constitutes the result of our first variational principle applied to nonlinear Hamiltonian oscillators. Notice the strong dependence of the variational principle on the exponent n, which we will show later in a specific example. For values of n lower than -2 this variational principle does not apply and for the other values the upper bound for the frequency depends explicitly on n.

If we take $n=0$ in (8), we recover the Benguria and Depassier situation,[4] where (8) reduces to

$$\lambda \geqslant \frac{\int_0^a N(u,\lambda)g(u)du + \frac{K}{2}}{\int_0^a ug(u)du}, \tag{9}$$

and (6) is $(u')^3 g'(u) = -K$. Taking $n=-1$, (8) becomes

$$\lambda \geqslant \frac{\int_0^a \frac{N(u,\lambda)g(u)}{p(u)}\,du + K}{\int_0^a \frac{ug(u)}{p(u)}\,du}, \tag{10}$$

and the Euler–Lagrange equation reduces to $(u')^2 g'(u) = K$.

Following Ref. 5, we can also derive, from another variational principle, a new restriction on the characteristic parameters of the system. Taking $n=0$ in (4), we may define the function

$$\psi(p) = \lambda f(u)g + \tfrac{1}{2}\, p^2 g'(u),$$

where $N(\lambda,u) = \lambda f(u)$. This function has, for each value of u, a minimum at $p_{\min}=0$, provided that $g'(u)>0$. So $\psi(p_{\min}) = \lambda f(u)g \leqslant \psi(p)$, and finally

$$\int_0^a ug(u)du \geqslant \int_0^a f(u)g(u)du. \tag{11}$$

This constitutes the second variational principle for Hamiltonian systems. Let us now apply both principles on the Duffing oscillator and the nonlinear pendulum.

A. The Duffing oscillator

It is known that the exact solution for the Duffing oscillator,[2]

$$\ddot{u} + u + \delta u^3 = 0, \quad \text{with } u(t=0)=a, \quad \dot{u}(t=0)=0, \tag{12}$$

is given by

$$u(t,\delta) = a\ \ \mathrm{cn}(t\sqrt{1+\delta a^2}; k), \tag{13}$$

where cn is the Jacobi elliptic function and $k^2 \equiv \delta a^2/2(1+\delta a^2)$. The exact expression for the frequency is then

$$\omega_{\mathrm{ex}} = \frac{\pi}{2}\sqrt{1+\delta a^2}\,\frac{1}{F\left(\frac{\pi}{2},k\right)}, \tag{14}$$

where $F(k)$ is called the complete elliptic integral of the first order. Taking $n=0$ in (8) we recover the BD situation,[4] which yields

$$\omega_{n=0} \leqslant \sqrt{1+\frac{3}{4}\,\delta a^2}. \tag{15}$$

Let us show in this example and in the following one the dependence of the frequency on the value of n taken in (8). First, we analyze the linear case, for the Duffing oscillator, and compare the results obtained for $n=0$ and for $n=-1$. In this case, (10) leads to

$$\lambda \geqslant \frac{K}{\int_0^a \frac{ug(u)}{p(u)}\,du}, \tag{16}$$

K and $g(u)$ must be calculated from

$$(u')^2 g'(u) = K. \tag{17}$$

In the linear case ($N=0$), corresponding to the linear oscillator, one has $(u')^2=\lambda(a^2-u^2)$. Replacing this in (17), we obtain

$$g(u) = \ln\left(\frac{a+u}{a-u}\right), \tag{18}$$

as the expression for the auxiliary function. Solving (17) with $u(0)=a$, $u(1)=0$, one obtains $K=a\pi^2/2$. On the other hand, defining $x \equiv u/a$, one has, from (18),

$$\int_0^a \frac{ug(u)}{p(u)}\,du = \frac{a}{\sqrt{\lambda}} \int_0^1 \ln\left(\frac{1+x}{1-x}\right) \frac{x\,dx}{\sqrt{1-x^2}} = \frac{a\pi}{\sqrt{\lambda}}.$$

Finally, from (16) we find $\lambda \geqslant (\pi/2)^2$, which is the same result obtained by BD.[4] For the nonlinear case ($N \neq 0$), we find a different result, as we show in turn. The main difference between the cases $n=-1$ and $n=0$ is that, to solve the latter, one does not need the relationship between p and u, while for $n=-1$ this is necessary. For the Duffing oscillator, we find, by making use of the Hamiltonian as a constant of motion, that

$$p = \sqrt{\lambda a^2\left(1+\frac{\delta a^2}{2}\right)}\sqrt{(1-x^2)(sx^2+1)}, \tag{19}$$

where $s \equiv \delta a^2/(2+\delta a^2)$. From (10) and defining the following integrals:

$$I_1(s) = \int_0^1 \ln\left(\frac{1+x}{1-x}\right) \frac{x\,dx}{\sqrt{(1-x^2)(sx^2+1)}},$$

$$I_1(s) = \int_0^1 \ln\left(\frac{1+x}{1-x}\right) \frac{x^3\,dx}{\sqrt{(1-x^2)(sx^2+1)}},$$

we obtain

$$\lambda \geqslant \left(\frac{\pi^2}{2}\right)\left(1+\frac{\delta a^2}{2}\right) \frac{1}{(I_1+\delta a^2\, I_2)^2}. \tag{20}$$

The integrals I_1 and I_2 may be calculated, after some integrations by parts, in terms of the complete elliptic integral of the second kind, and we find finally for the frequency that

$$\omega_{n=-1} \leqslant \frac{2}{\pi}\sqrt{1+\delta a^2} E\left(\frac{\pi}{2}, \sqrt{\frac{s}{s+1}}\right). \tag{21}$$

In Fig. 1 we represent the exact value ω_{ex} given by (14), the BD solution $\omega_{n=0}$ given by (15) in solid lines, and the new approach $\omega_{n=-1}$ given by (21) in dashed lines. As one can see, the

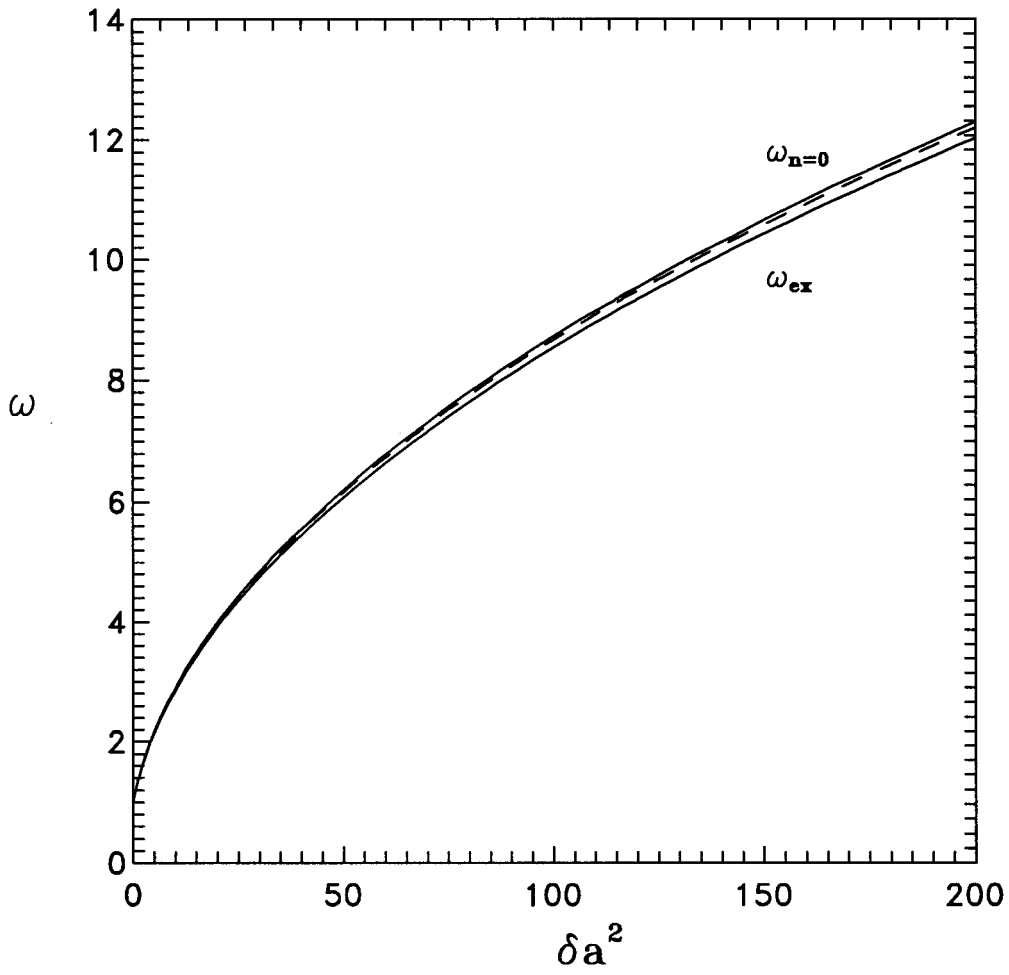

FIG. 1. The frequency of the Duffing oscillator obtained by the BD method ($\omega_{n=0}$, solid lines), the new variational method ($\omega_{n=-1}$, dashed lines) versus the numerical exact solution (ω_{ex}, solid line).

latter is a slightly better result than the BD solution. So, we have shown the dependence of the frequency on the value of n. Applying now the second variational method (11) to the Duffing equation, and taking the BD method we find the following restriction:

$$\frac{-4}{3a^2} \leqslant \delta.$$

For $\delta > 0$ the second variational method does not add any additional information, but for $\delta < 0$ this may be understood[3] as a bound for δ, that is, $\delta \leqslant 4/3a^2$. For $\delta < 0$ we have that

$$\omega_{n=0} \leqslant \sqrt{1 - \frac{3}{4}\,\delta a^2}.$$

The frequency has real value if $\delta \leqslant 4/3a^2$, which coincides with the result obtained by using the second variational method.

B. The nonlinear pendulum

We study with some detail another very known nonlinear dynamical system namely the nonlinear pendulum. First of all we show that the $n = -1$ case may lead us to the exact solution. Later, we apply the BD approach to this solution. As it is widely known, the equation for the nonlinear pendulum is given by

$$\ddot{u}+\frac{g}{l}\sin(u)=0, \quad \text{with } u(t=0)=a, \quad \dot{u}(t=0)=0. \tag{22}$$

Defining again $\tau=2\omega t/\pi$ and

$$\lambda\equiv\left(\frac{\pi}{2}\right)^2\frac{g}{l}, \tag{23}$$

and taking into account the conditions $u(t=0)=a$ and $u(t=\pi/2\omega)=0$, (22) is written as

$$u''+\lambda\ \sin(u)=0, \quad \text{with } u(\tau=0)=a, \quad u'(\tau=1)=0.$$

The exact solution[2] is given by

$$\omega_{\text{ex}}=\frac{\pi}{2}\ \sqrt{\frac{g}{l}}\ \frac{1}{F\left(\frac{\pi}{2},\sin\left(\frac{\alpha}{2}\right)\right)}. \tag{24}$$

Let us now to apply the $n=-1$ approach. The variational method leads to

$$\lambda\geqslant\frac{K}{\int_0^a\frac{g(u)}{p(u)}\sin(u)du}, \tag{25}$$

with

$$(u')^2g'=K. \tag{26}$$

As (22) may be integrated once, we get

$$p(u)=\sqrt{2\lambda[\cos(u)-\cos(a)]}. \tag{27}$$

So, omitting overall multiplicative constants we identify

$$g'(u)=\frac{1}{\cos(u)-\cos(a)},$$

and integrating, we find for the auxiliary function

$$g(u)=\frac{1}{\sin(a)}\ln\left[\frac{\sin(a)\tan\left(\frac{u}{2}\right)+1-\cos(a)}{\sin(a)\tan\left(\frac{u}{2}\right)-1+\cos(a)}\right]. \tag{28}$$

The value of K is found to be

$$K=2F^2\left(\frac{\pi}{2},\sin\left(\frac{a}{2}\right)\right), \tag{29}$$

from (26). Calculating the integral in (25), we obtain

$$\int_0^a\frac{g(u)}{p(u)}\sin(u)du=\frac{2}{\sqrt{\lambda}}F\left(\frac{\pi}{2},\sin\left(\frac{a}{2}\right)\right),$$

after some integrations by parts. Finally, from (23), (25), and (29), one gets

$$\omega_{n=-1} \leqslant \frac{\pi}{2} \sqrt{\frac{g}{l}} \frac{1}{F\left(\frac{\pi}{2}, \sin\left(\frac{a}{2}\right)\right)},$$

which coincides within the exact result. If we had made some approximations, as, for instance, take for $g(u)$ or $p(u)$ the same value as for the linear oscillator, the final result had not been equal to the exact one. We show this now for $n=0$. Equation (8) writes in the BD case,

$$\lambda \geqslant \left(\frac{\pi}{2}\right)^2 + \frac{4}{\pi a^3} \int_0^a \frac{uN(u,\lambda)du}{\sqrt{1-u^2/a^2}}, \tag{30}$$

where we take $N(u,\lambda)=\lambda(u-\sin(u))$. Calculating the integral in (30) and from the definition of λ, one obtains

$$\omega_{n=0} \leqslant \sqrt{\frac{g}{l}} \sqrt{\frac{2}{a} J_1(a)}, \tag{31}$$

where $J_1(a)$ is the Bessel function of the first kind. Because $J_1(a)$ alternates the sign, we must restrict the solution given by (31) to those values of a such that $J_1(a)$ is positive. For small values of a this condition requires $a \lesssim 3$. Precisely this condition may be recovered from the second variational principle. Taking $f(u)=u-\sin(u)$ and (28) we find from (11) $J_1(a) \geqslant 0$. In Fig. 2 we plot the exact solution and the variational solution for the BD's method.

C. Systems of the form $\ddot{u}+\alpha u^n=0$

We consider now kinds of dynamical systems, which, in their linear approximation ($N=0$) do not reduce to linear oscillators. These systems may also be treated as the previous ones. First we apply the variational methods and we compare the solution with the exact one. We make, for mathematical simplicity the analysis by using the particular case[6] $n=3$. It is known that this system describes periodic oscillations.[2] The system may be integrated once by using the same initial conditions as in previous examples. Hence, we get, after using the independent variable τ,

$$p(u) = \sqrt{\frac{\alpha\lambda}{2}} \sqrt{a^4-u^4}, \tag{32}$$

and this one may be integrated once again to get

$$\omega_{\mathrm{ex}} = \frac{\pi}{2} a\sqrt{\alpha} \frac{1}{F\left(\frac{\pi}{2}, \frac{1}{\sqrt{2}}\right)}. \tag{33}$$

Applying the first variational method (10) (with $n=-1$) one obtains

$$\alpha\lambda \geqslant \frac{K}{\int_0^a \frac{u^3 g(u)}{p(u)} du} \tag{34}$$

where $(u')^2 g' = K$. So, the auxiliary function $g(u)$ is given by

$$g(u) = \frac{1}{2} \ln\left(\frac{a+u}{a-u}\right) + \arctan\left(\frac{u}{a}\right), \tag{35}$$

and K by

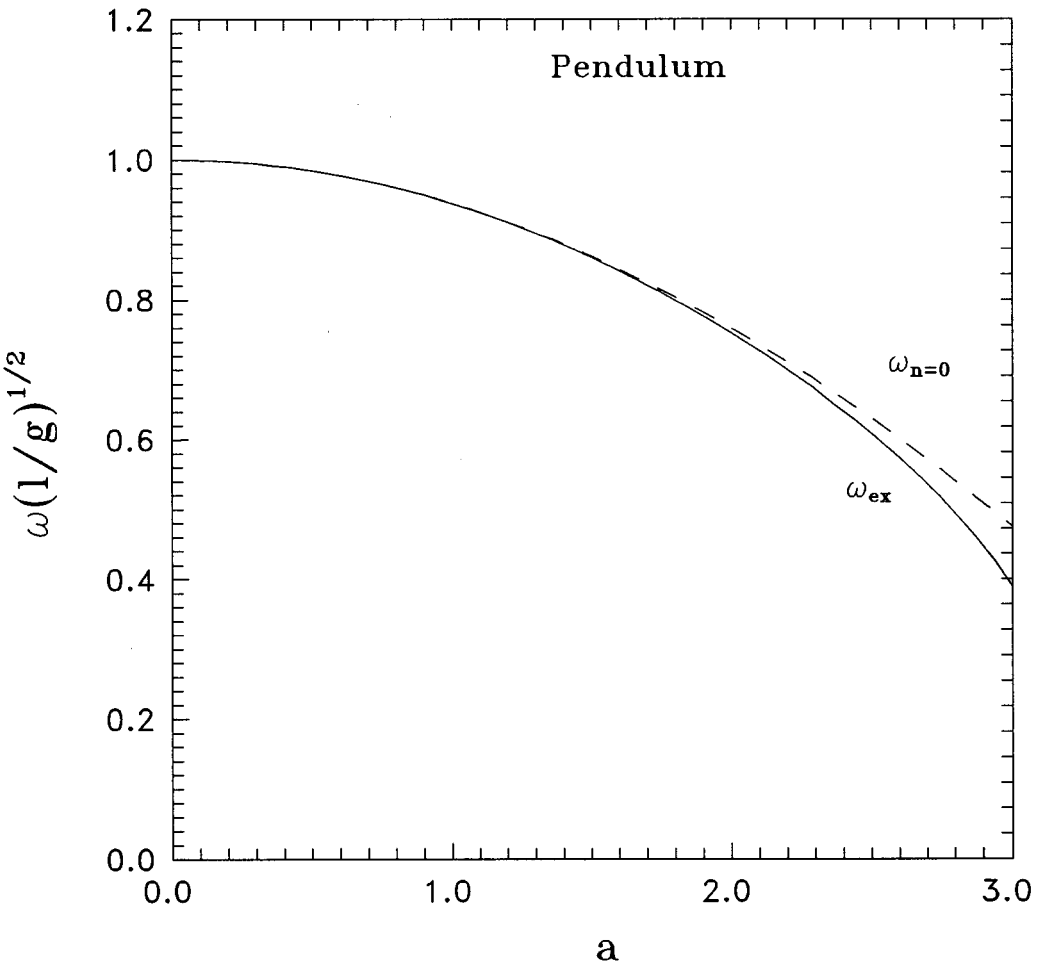

FIG. 2. The frequency of the nonlinear pendulum obtained by the BD method ($\omega_{n=0}$, dashed lines), versus the numerical exact solution (ω_{ex}, solid line).

$$K(a)=aF^2\left(\frac{\pi}{2},\frac{1}{\sqrt{2}}\right).$$

The integral involved in (34) is given by

$$\int_0^a \frac{u^3 g(u)}{p(u)}\,du=a^2\sqrt{\frac{2}{\alpha\lambda}}\int_0^1 \frac{x^3\,dx}{\sqrt{1-x^4}}\left[\frac{1}{2}\ln\left(\frac{1+x}{1-x}\right)+\arctan(x)\right]=\frac{a^2}{\sqrt{\alpha\lambda}}F\left(\frac{\pi}{2},\frac{1}{\sqrt{2}}\right).$$

Using the previous calculations, we may write (34) in terms of the frequency by

$$\omega_{n=-1}\leqslant\frac{\pi}{2}\,a\sqrt{\alpha}\,\frac{1}{F\left(\frac{\pi}{2},\frac{1}{\sqrt{2}}\right)},$$

where the equality gives the exact result (33). On the other hand, we may also apply the BD's method to this case. Taking in (2) $N=\lambda(u-u^3)$ and $n=0$ is (8) we find $K=(\pi/2)^3a^3$ and the auxiliary function is given by

$$g(u)=\frac{u}{\sqrt{1-u^2/a^2}}. \tag{36}$$

We finally find for the frequency

$$\omega_{n=0}\leqslant\frac{a}{2}\sqrt{3\alpha}. \tag{37}$$

Calculating numerically $\omega_{n=-1}(=\omega_{ex})$ we find $\omega_{\mathrm{ex}}=0.847a\sqrt{\alpha}$ and $\omega_{n=0}\leqslant 0.866a\sqrt{\alpha}$. We may observe the good agreement between the exact and the BD's solutions.

III. DYNAMICAL SYSTEMS DEPENDING ON THE FIRST DERIVATIVE

We extend here the variational principles found in the first section to nonlinear dynamical systems that contains explicitly the term $\dot{u}$ and powers of it. Some of them are Hamiltonian systems, that is, they have a first integral, and others are dissipative, such as the Van der Pol's equation. We focus our attention to systems of the form

$$\ddot{u}+\epsilon f(u)\dot{u}^n+u=0. \tag{38}$$

This equation may be written as

$$p\,\frac{dp}{du}+\lambda u+\epsilon\lambda^{(2-n)/2}f(u)p^n=0. \tag{39}$$

By using the change of variables $\tau=2\omega t/\pi$ and the definition of λ, we may arrive to

$$\lambda\geqslant\frac{\epsilon(-1)^{n+1}\lambda^{(2-n)/2}\int_0^a f(u)g(u)p^n du+\frac{K}{2}}{\int_0^a ug(u)du}, \tag{40}$$

with $(u')^3g'(u)=-K$. Notice that in the variational method given by (40) we must know the explicit expression of $p(u)$ and this is only possible if the system admits a first integration. In general, one must use a new approach to (40). In this sense, we derive two new ways to proceed; one of them consists in applying the variational method on the functional of the numerator of (40) but this method only holds if $\int(u)>0$ for any $u\in(0,a)$, the other one consists in making a perturbative expansion on the phase space in order to find an approximate solution for $p(u)$. Let us illustrate the first way.

From (40) we define the functional

$$J_g^*[v]=(-1)^{n+1}\int_0^a f(v)g(v)p^n\,dv=\int_0^1 f(v)g(v)(v')^{n+1}\,d\tau, \tag{41}$$

where v is such that satisfies $v(0)=a$, $v(1)=0$, and $v'<0$ in $\tau\in(0,1)$. Defining $\phi(v,v')=f(v)g(v)(v')^{n+1}$, we get from the Euler–Lagrange equations,

$$nf(\tilde{v})g(\tilde{v})(\tilde{v}')^{n+1}=K^* \tag{42}$$

where $\tilde{v}$ is the value of v such that for a fixed g, $J_g\geqslant 0$ has a unique minimum. Notice that $f(\tilde{v})\geqslant 0$ is required for any $\tilde{v}\in(0,a)$, and this is not possible for the Van der Pol's equation. So, once g is determined from $(\tilde{v}')^3g'(\tilde{v})=-K$, we get

$$J_g[v]\geqslant J_g[\tilde{v}]=\frac{K^*(a)}{n}, \tag{43}$$

and $K^*(a)$ may be calculated from (42). Thus, from (40), we get the variational restriction

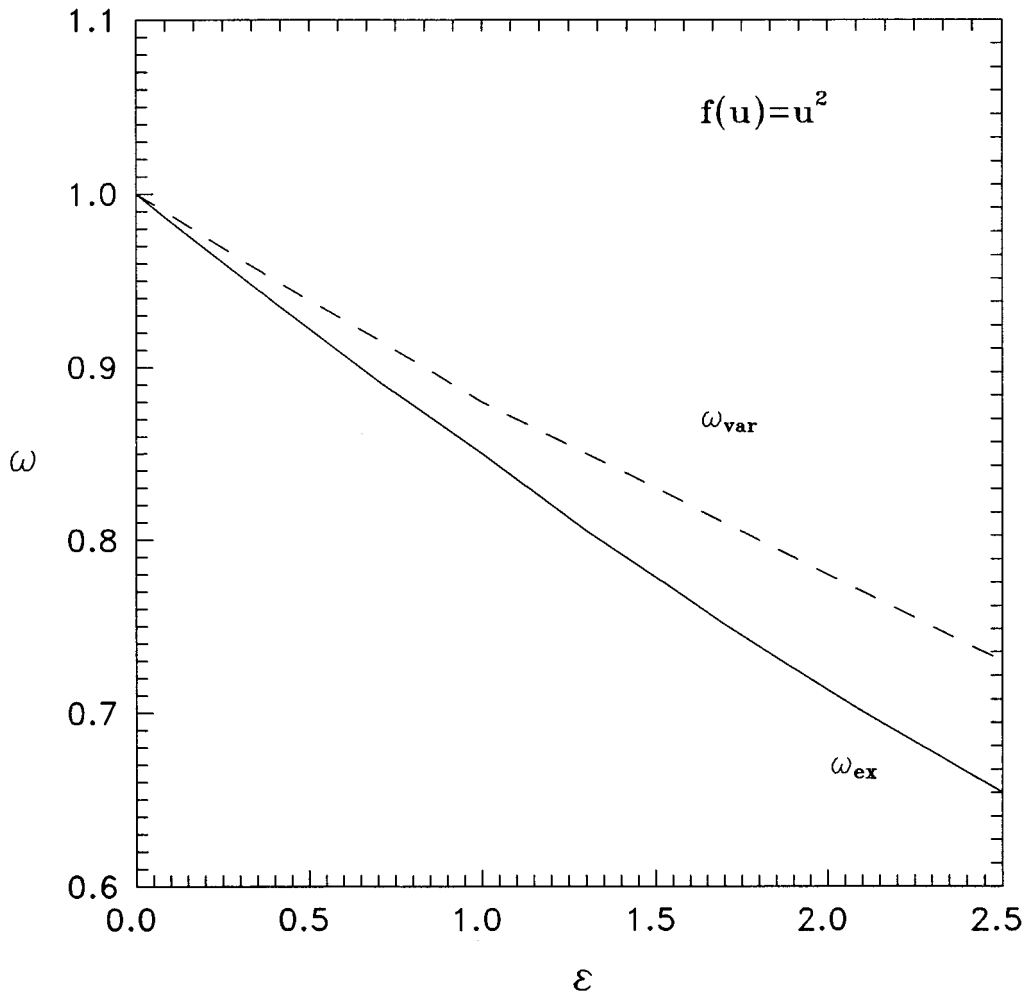

FIG. 3. The frequency of a non-Hamiltonian oscillator given in (46) obtained by the variational method (ω_{var}, dashed lines), versus the numerical exact solution (ω_{ex}, solid line).

$$\lambda \geqslant \frac{\epsilon \lambda^{(2-n)/2} \dfrac{K^*}{n} + \dfrac{K}{2}}{\int_0^a u g(u) du}. \tag{44}$$

Taking the auxiliary function g given in the linear case $\epsilon = 0$ [Eq. (36)], Eq. (44) becomes

$$\lambda \geqslant \left(\frac{\pi}{2}\right)^2 + \frac{4\epsilon}{\pi a^3} \lambda^{(2-n)/2} \frac{K^*}{n}. \tag{45}$$

Let us to apply this variational method to the specific case

$$\ddot{u} + \epsilon u^2 \dot{u} + u = 0, \quad \text{with} \quad u(t=0) = a, \quad \dot{u}(t=0) = 0. \tag{46}$$

In this case, $f(u) = u^2$ and $n = 1$. From (42) we obtain $K^* = \pi^2 a^5/32$, and from (45),

$$\omega_{var} \leqslant \frac{-b + \sqrt{b^2+4}}{2}, \quad \text{with} \quad b = \frac{a^2 \epsilon}{4}. \tag{47}$$

In Fig. 3 we plot the exact numerical solution for the frequency versus its variational solution (47). We develop now the second variational method for the specific situation in which $f < 0$ for

some $u \in (a,0)$. Starting from (40) the problem is to find an expression for $p(u)$. As a first approximation, we may take the expression for p given by the linear case. In this approach we obtain

$$\lambda \geqslant \left(\frac{\pi}{2}\right)^2 + \frac{4\epsilon(-1)^{n+1}}{\pi a^2}\lambda \int_0^a u(a^2-u^2)^{(n-1)/2} f(u)du. \tag{48}$$

A better approach may be obtained by the perturbative solution in the phase space. Solving perturbatively (39) for small ϵ, we get

$$p(u) = p_0(u,\lambda) + \epsilon p_1(u,\lambda) + O(\epsilon^2),$$

where

$$p_0(u,\lambda) = \sqrt{\lambda(a^2-u^2)},$$

$$p_1(u,\lambda) = -\frac{\lambda^{(5-n)/2}}{\sqrt{a^2-u^2}} \int_a^u (a^2-z^2)^2 f(z)dz.$$

So, the variational method yields

$$\lambda \geqslant \left(\frac{\pi}{2}\right)^2 - \frac{4\epsilon}{\pi a^2} \int_0^a \frac{u f(u)(p_0+\epsilon p_1)^n}{\sqrt{a^2-u^2}}\, du. \tag{49}$$

Both approaches are applied as an illustration to the Van der Pol oscillator.

Taking $n=1$ and $f(u)=u^2-1$ in (38), we recover the well-known differential for the Van der Pol oscillator,

$$\ddot{u} + \epsilon(u^2-1)\dot{u} + u = 0, \tag{50}$$

with the initial conditions $u(t=0)=a$, $\dot{u}(t=0)=0$. It is known that (50) presents a limit cycle for $a=2$. Thus, we study the periodic behavior, and the frequency, in particular, of (50) near of the limit cycle given by $a=2$. In the first approximation (assuming g and p are given by the linear case, $\epsilon=0$), given by (48) we find for the frequency

$$\omega_1 \leqslant \sqrt{1-\frac{2\epsilon}{\pi}}. \tag{51}$$

Using the second approximation, that is, p given up to first order in ϵ, we obtain

$$p_1(u) = -\sqrt{\lambda}\,\frac{u}{4}(4-u^2),$$

and finally

$$\omega_2 \leqslant \sqrt{1-\frac{2\epsilon}{\pi}+\frac{\epsilon^2}{4}}. \tag{52}$$

We may solve numerically the Van der Pol's equation for different ϵ and obtain ω_{ex}. We plot in Fig. 4 the exact numerical solution and the ω_2 solution for the frequency.

IV. CONCLUSIONS

A variational principle applied to Hamiltonian systems has been developed by Benguria and Depassier.[4] In this paper we extend their method along the following new lines:

(i) The initial transformation, for Hamiltonian systems, which transforms the differential equation in an integral equation, is generalized by introducing an exponent n. The final variational

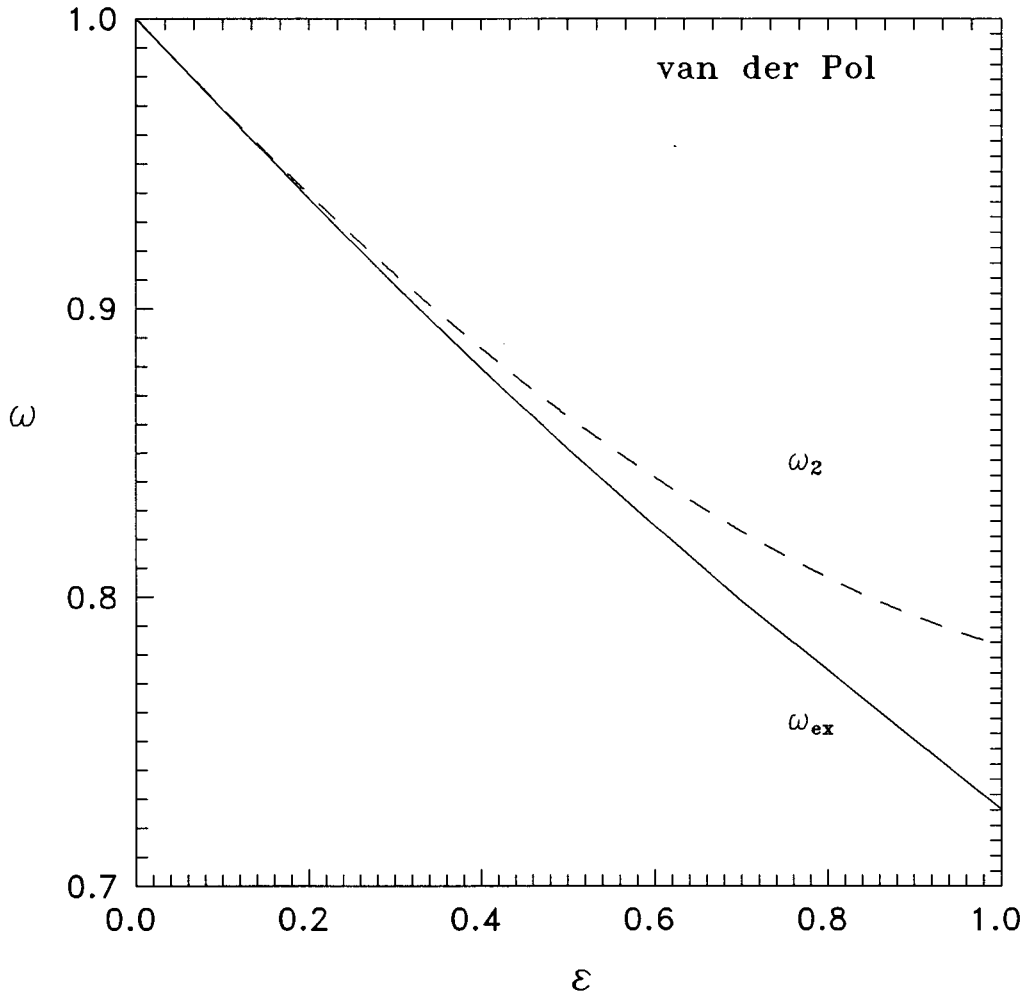

FIG. 4. The frequency of the Van der Pol oscillator obtained by the variational method (ω_2, dashed lines), versus the numerical exact solution (ω_{ex}, solid line).

restriction that relates the frequency with the amplitude, depends strongly on n. The variational method proposed by BD only holds for $n>-2$. A second variational method is also applied to Hamiltonian systems and it supplies new constraints between the characteristic parameters involved in the system. We have specified the results to some selected systems as the Duffing oscillator, the nonlinear pendulum, and systems of the form $\ddot{u}+\alpha u^n=0$. Better fits those obtained by the method of BD, to the exact solution for the frequency have been discovered.

(ii) The variational principle is also applied to systems with an explicit dependence on the first time derivative. Some of them are Hamiltonian, and they may be exactly characterized. Others are non-Hamiltonian and we may proceed in two different ways. First, we have proposed a new variational method that is applied to two different functionals in order to avoid the explicit dependence on $p(u)$. This method does not hold for systems with $f<0$ for some $u\in(0,a)$. So, we develop an approximate variational method for them. The results are not as good as those obtained for Hamiltonian systems, but they may be understood as upper bounds on the frequency. This approximation consists in finding a perturbative solution for p and the results fit very well for weak nonlinearities.

ACKNOWLEDGMENTS

I dedicate this paper to Professor José Casas-Vázquez on his 60th birthday. I also would like to thank Professor David Jou for helpful and stimulating discussions. JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 2 FEBRUARY 1998

Distortion of a phase space under the Darboux transformation

Boris F. Samsonov[a)]
Tomsk State University, 36 Lenin Avenue, 634050 Tomsk, Russia

(Received 21 April 1997; accepted for publication 23 September 1997)

The Darboux transformation operator technique is applied to construct exactly solvable anharmonic singular oscillator potentials and to study their coherent states. Classical system corresponding to a transformed quantum system is constructed with the help of the coherent states technique. It is shown that at classical level the Darboux transformation may be treated as a transformation of Kähler potential, which leads to a distortion of the initial phase space. © *1998 American Institute of Physics.* [S0022-2488(98)01601-6]

I. INTRODUCTION

In quantum mechanics there exists a beautiful recipe to construct a family of exactly solvable Hamiltonians starting from an initial Hamiltonian h_0 for which the solutions of the Schrödinger equation $h_0\psi_E=E\psi_E$ are known. Since this method is very simple in applications and possesses an intrinsic charm, it attracts a thorough attention of several generations of research. A central point of this theory is a notion of a transformation operator introduced and investigated by Delsart and Lions.[1] According to their approach, every operator L intertwining the initial Hamiltonian h_0 and transformed Hamiltonian h_1,

$$Lh_0=h_1L, \tag{1}$$

is a *transformation operator* (originally called a transmutation operator[1]). It is obvious that L transforms solutions ψ_E ($\psi_E\notin\ker L$) of the initial Schrödinger equation onto solutions $\varphi_E=L\psi_E$ of a *transformed Schrödinger equation* $h_1\varphi_E=E\varphi_E$, corresponding to the same eigenvalue E. In the case of a first-order differential operator L and a one-dimensional Hamiltonian h_0, the relation (1) leads to[2] the transformation proposed by Moutard[3] and studied by Darboux[4] (also see Ref. 5). If L is a differential operator of order N, it is called[2] *N-order Darboux transformation operator*. In this paper we will restrict ourselves by first-order transformations.

The Darboux transformation operator technique is a very useful tool in obtaining and investigating new exactly solvable quantum problems. It enters many fields of physics and mathematics. In soliton theory, the Darboux transformation permits one to construct and investigate properties of multisoliton solutions to nonlinear evolution equations (see Ref. 6 and references therein). In quantum mechanics this technique takes the form of a factorization method. Using this method, Schrödinger[7] was able to solve the hydrogen atom problem in a pure algebraic manner. Subsequently, Infeld and Hall[8] generalized the Schrödinger method and obtained a wide class of solvable potentials. In the inverse quantum scattering problem,[9] this transformation is used to construct potentials with given properties and to obtain appropriate solutions to the Schrödinger equation. New developments in this field have recently been presented in Ref. 10. In the context of supersymmetric quantum mechanics (for reviews see Ref. 11), the Hamiltonian h_0 and its superpartner h_1 form a matrix-valued Hamiltonian (so-called super-Hamiltonian) $\mathscr{H}$. Darboux transformation operator L and its Hermitian conjugate L^+ participate in the construction of supercharge operators, which, together with $\mathscr{H}$, form a superalgebra. Initially the supersymmetric quantum mechanics served as a toy model to illustrate the problem of supersymmetry breaking in quantum field theories. Recently, new features in supersymmetry breakdown in quantum mechanics caused by

a)Electronic mail: samsonov@phys.tsu.tomsk.su

 © 1998 American Institute of Physics

higher-order Darboux transformations have been discovered.[12] Besides quantum field theories, the same ideas find applications in many others fields of theoretical physics such as nuclear, atomic, solid state, and statistical physics.[11]

In spite of the long period of application of the Darboux transformation operator method to quantum mechanical problems, the question of correspondence between the transformed quantum system and a classical system has not been properly discussed in the literature. In a recent paper[13] a classical mechanics counterpart of the transformed system has been described. It consists in addition of a total time derivative of a purely imaginary function to the Lagrangian of a classical system. This transformation does not affect the equations of motion. Canonical quantization of the new classical system gives the transformed quantum system.

The concept of coherent states plays an important role in several fields of physics and mathematics (see, for example, Refs. 14 and 15). In this paper we exploit the property of coherent states to establish the correspondence between the quantum mechanics and the classical mechanics. For any quantum system we can construct using the coherent states technique,[14,16] a classical system possessing the following remarkable property. The geometric quantization[17] of the resulting system gives a holomorphic representation of the initial quantum system. By these means we may establish a correspondence between quantum and classical systems. Recently it has been noted[18] that an application of the Darboux transformation operator to the coherent states of the initial quantum system gives a set of states that may be treated as coherent states of the transformed system. This observation opens the door to establishing a correspondence between transformed quantum and classical systems and obtaining a classical counterpart of the Darboux transformation.

In this paper we realize the above program for a system with the Hamiltonian,

$$h_0=-d^2/dx^2+x^2/4+b/x^2, \quad b>0, \quad x\in[0,\infty). \tag{2}$$

We will not discuss the significance of the spectral problem for the Hamiltonian (2) (more precisely, for its closure in the Hilbert space H of square integrable on interval $[0,\infty)$ functions with the zero boundary condition at the origin). We only notice the fact that this Hamiltonian appears in different physical problems such as the central potential problem, the Calogero problem,[19] fractional statistics, and anyons,[20] two-dimensional QCD,[21] and others.

We obtain exactly solvable partners for the Hamiltonian (2). Next, we construct the coherent states for the transformed *a lá* Darboux Hamiltonians. These states, as well as the coherent states for the input system (initial coherent states), are labeled by the points of a unite disk on the complex z plane. We consider two different Kähler structures on the unit disk. The first one is the well-known Poincaré model of the Lobachevsky plane and the second is the Darboux transformation of the first. The expression for the transformed Kähler potential is obtained. We also notice that in contrast to the initial manifold the transformed one has a varying curvature. The integration measure realizing the identity decomposition for the transformed coherent states is calculated. The holomorphic representation for the discrete basis set as well as for the coherent states, lowering and raising operators and Darboux transformation operators is constructed. It is established that at the classical level the Darboux transformation may be considered as such a transformation of the Kähler potential and Hamilton function that preserves the equations of motion.

II. COHERENT STATES OF SINGULAR OSCILLATOR

In this section we briefly review the well-known[14] properties of the coherent states for the Hamiltonian (2) that we will need further.

The dynamical symmetry algebra for the quantum system with the Hamiltonian (2) is su(1,1). In coordinate representation, the generators of this algebra are expressed in terms of the harmonic oscillator annihilation a and creation a^+ operators,

$$k_0=\tfrac{1}{2}h_0, \quad k_+=\tfrac{1}{2}[(a^+)^2-b/x^2], \quad k_-=\tfrac{1}{2}[a^2-b/x^2], \quad a=d/dx+x/2, \quad a^+=-d/dx+x/2,$$

and satisfy the standard commutation relations,

$$[k_0,\ k_\pm]=\pm k_\pm, \quad [k_-,\ k_+]=2k_0.$$

Since we consider an irreducible representation the corresponding su(1,1) Casimir operator takes the constant value $\mathscr{C}=1/2[k_+k_-+k_-k_+]-k_0^2=3/16-b/4=k(1-k)$. The value of $k=1/2+(1/4)\sqrt{1+4b}$ defines the ground state (vacuum) energy $E_0=2k$. The vacuum state $|0\rangle$ is defined by the equations $k_-|0\rangle=0$ and $k_0|0\rangle=k|0\rangle$. Other discrete basis eigenfunctions $|n\rangle$ of the Hamiltonian h_0 are defined by means of the raising operator k_+,

$$k_+|n\rangle=-\sqrt{(n+1)(n+2k)}|n+1\rangle,$$

$$|n\rangle=(-1)^n\sqrt{\frac{\Gamma(2k)}{n!\Gamma(2k+n)}}\,(k_+)^n|0\rangle,\quad k_0|n\rangle=(k+n)|n\rangle,$$

and in the coordinate representation they have the form

$$\psi_n(x)=\langle x|n\rangle=[n!2^{1-2k}\Gamma^{-1}(n+2k)]^{1/2}x^{2k-1/2}\exp(-x^2/4)L_n^{2k-1}(x^2/2), \tag{3}$$

where $L_n^{\alpha}(z)$ are the Laguerre polynomials.

The coherent states $|z\rangle$ can be obtained by applying the unitary displacement operator D_z to the vacuum state,

$$|z\rangle=D_z|0\rangle=e^{zk_+}\exp[\ln(1-z\overline{z})k_0]e^{-\overline{z}k_-}|0\rangle=N_{0z}\sum_{n=0}^{\infty}a_nz^n|n\rangle,$$

$$N_{0z}=(1-z\overline{z})^k,\quad a_n=(-1)^n\sqrt{\frac{\Gamma(2k+n)}{n!\Gamma(2k)}},\quad |z|<1.$$

In the coordinate representation they look like

$$\psi_z(x)=2^{1/2-k}\Gamma^{-1/2}(2k)(1-z)^{-2k}(1-z\overline{z})^kx^{2k-1/2}\exp[-(1/4)(1-z)^{-1}(1+z)x^2],\quad |z|<1. \tag{4}$$

The linear manifold spanned by the vectors $\{|z\rangle\}$ forms an everywhere dense set in the Hilbert space H with the following identity decomposition:

$$\int_{|z|<1}|z\rangle\langle z|d\mu(z)=1,\quad d\mu(z)=\frac{2k-1}{\pi}\,(1-z\overline{z})^{-2}\,dz\,d\overline{z}. \tag{5}$$

The system $\{|z\rangle\}$ is overcomplete. The completeness of different subsystems of this system was studied in detail in Ref. 22.

The Fourier coefficients c_n of a vector $|\psi\rangle\in H$ with respect to the basis $\{|n\rangle\}$ define a holomorphic representation $\psi(z)$ of the vector $|\psi\rangle$ in the space of functions that are holomorphic in the unit disk,

$$\langle\overline{z}|\psi\rangle=N_{0z}\psi(z),\quad \psi(z)=\sum_{n=0}^{\infty}a_nc_nz^n.$$

The functions $\psi_n(z)=a_nz^n$ realize the holomorphic representation of the basis vectors $|n\rangle$. For the holomorphic representation of the coherent state vectors we have

$$\zeta^{(0)}(z)=N_{0z}^{-1}\langle\overline{z}|\zeta\rangle=(1-\zeta\overline{\zeta})^k(1-\zeta z)^{-2k}.$$

Let $\mathscr{L}$ be the lineal of entire analytic functions $\psi(z)$ defined in the unit disk, such that

$$\int_{|z|<1}|\psi(z)|^2(1-|z|^2)^{2k}\,d\mu(z)<\infty.$$

If now we define an inner product in the lineal $\mathscr{L}$,

$$\langle \psi_1(z)|\psi_2(z)\rangle \equiv \int_{|z|<1} e^{-f^{(0)}} \overline{\psi_1}(z)\psi_2(z)d\mu(z) = \langle \psi_1|\psi_2\rangle, \tag{6}$$

where $\langle \psi_1|\psi_2\rangle$ is the inner product in the Hilbert space H then the completion of $\mathscr{L}$ with respect to this inner product gives the Hilbert space $\mathscr{H}$. The function $f^{(0)}=\ln|\langle 0|z\rangle|^{-2}=\ln(1-z\overline{z})^{-2k}$ is the Kähler potential in the unit disk. The corresponding metric has the form

$$ds^2 = g\ dz\ d\overline{z}, \quad g=\frac{\partial^2 f^{(0)}}{\partial z\ \partial \overline{z}}=\frac{2k}{(1-z\overline{z})^2}.$$

As usually the imaginary part of this metric defines a symplectic 2-form $\omega=-ig\ dz\wedge d\overline{z}$ and consequently a Poisson bracket $\{H_1,H_2\}$ of the functions H_1 and H_2 defined on the unit disk. The unit disk represents now a phase space of a constant Gauss curvature $\mathscr{K}^{(0)}=-2/k$. Making use of the covariant Berezin symbols,[23] we establish a one-to-one correspondence between the classical observables and the holomorphic representation of the quantum mechanical operators. For example, the following classical observables:

$$K_0=\langle \overline{z}|k_0|\overline{z}\rangle = k\,\frac{1+z\overline{z}}{1-z\overline{z}},$$

$$K_-=\langle \overline{z}|k_-|\overline{z}\rangle=\frac{2k\overline{z}}{1-z\overline{z}}, \quad K_+=\langle \overline{z}|k_+|\overline{z}\rangle=\frac{2kz}{1-z\overline{z}},$$

correspond to the generators of su(1,1) algebra of quantum operators. They form the basis of the algebra isomorphic to su(1,1) with respect to the introduced Poisson bracket.

If we choose K_0 as a classical Hamilton function, then the evolution of the system is described by the Hamiltonian equations,

$$\dot{z}=\{z,K_0\}=-iz, \quad \dot{\overline{z}}=\{\overline{z},K_0\}=i\overline{z},$$

where the overdot stands for the time derivative.

Geometric quantization[17] of the obtained classical system leads to the holomorphic representation of the quantum system described above. (In our case this is a quantization on the Lobachevsky plane,[14] which really is a Berezin[24] quantization on a Kähler manifold.) The value $h=(2k)^{-1}$ plays the role of the Plank constant.[14]

To conclude this section we present the explicit expressions for the Bergman kernel, which takes off the integration in the $\mathscr{L}$ space,

$$\delta^{(0)}(z,\overline{z'})=\sum_{n=0}^{\infty}\psi_n(z)\overline{\psi_n}(z')=(1-z\overline{z'})^{-2k},$$

and for the su(1,1) generators

$$k_0(z)=z\,\frac{d}{dz}+k, \quad k_+(z)=z^2\,\frac{d}{dz}+2kz, \quad k_-(z)=\frac{d}{dz},$$

in holomorphic representation.

III. DARBOUX TRANSFORMATION OF COHERENT STATES

In a simplest case[5,2] the Darboux transformation operator is the first-order differential operator of the form

$$L=-L_0(x)+d/dx=-u'(x)/u(x)+d/dx, \tag{7}$$

where the prime denotes the derivative with respect to x. When acting on the solutions $\psi_n(x)$ of the initial Schrödinger equation,

$$h_0\psi_n(x)=E_n\psi_n(x), \quad E_n=2n+2k,$$

it transforms them into the solutions of another Schrödinger equation,

$$\varphi_n(x)=N_nL\psi_n(x), \quad h_1\varphi_n(x)=E_n\varphi_n(x), \tag{8}$$

with the same eigenvalues E_n. The factor N_n is introduced to ensure that the states φ_n are normalized to unity. New exactly solvable Hamiltonian $h_1=h_0+A(x)$ is defined by the potential difference $A=A(x)=-2(\ln u)''$. The function $u=u(x)$, called a *transformation function*,[2] is a solution to the initial Schrödinger equation,

$$h_0u(x)=\alpha u(x), \tag{9}$$

with $\alpha\leqslant E_0$.

For the sake of simplicity we will restrict ourselves to the case when $\alpha<E_0$, $u(x)\neq 0$, $\forall x\in(0,\infty)$ and $1/u(x)$ is not a square integrable function in the interval $[0,\infty)$. In this case $u\notin H$ and the set $\{|\varphi_n\rangle\}$ constitutes a complete basis in the Hilbert space H, provided the initial system $\{|\psi_n\rangle\}$ is complete.[2] In terms of the supersymmetric quantum mechanics this case corresponds to a broken supersymmetry.

Let us now choose the following solution of the initial equation (9):

$$u=u_p(x)=x^{2k-1/2}L_p^{2k-1}(y)\exp(x^2/4), \quad y=-x^2/2,$$

$$\alpha=-2(k+p), \quad p=0,1,2,...,$$

as the transformation function. It is worth stressing that $L_p^{2k-1}(y)\neq 0$, $\forall x\neq 0$ when $y=-x^2/2$ (<0) and, hence, the function $u_p(x)$ is nodeless for $x>0$. The function $L_0(x)=L_{0p}(x)$ has in this case the form

$$L_{0p}(x)=\frac{1-4k}{2x}-\frac{x}{2}-\frac{xL_{p-1}^{2k}(y)}{L_p^{2k-1}(y)},$$

and for the potential difference we obtain

$$A=A_p(x)=-1+\frac{4k-1}{x^2}-2\frac{x^2L_{p-2}^{2k+1}(y)+L_{p-1}^{2k}(y)}{L_p^{2k-1}(y)}+2x^2\left[\frac{L_{p-1}^{2k}(y)}{L_p^{2k-1}(y)}\right]^2, \quad y=-x^2/2.$$

It is worth noticing that because of the condition $L_p^{2k-1}(y)\neq 0$ for $x\neq 0$, the potential difference $A_p(x)$ has a single pole at $x=0$. The asymptotic behavior of this function near the point $x=0$ is as follows: $A_p(x)\to -1-p/k+(4k-1)/x^2$. In the limit as $x\to\infty$ this function tends to -1. For $b\neq 0$ the behavior of the transformed potentials $V_p(x)=V_0(x)+A_p(x)$ is nearly the same as the behavior of the initial potential $V_0(x)=x^2/4+b/x^2$. There is only a small difference in the region of the minimum. When $b=0$ the initial potential is regular at $x=0$, whereas all $V_p(x)$ are singular: $V_p(x)\to -1-4p/3+2/x^2$. As an illustration, we give the explicit expression for two first potential differences:

$$A_0(x)=-1+\frac{4k-1}{x^2}, \quad A_1(x)=A_0(x)+\frac{4}{4k+x^2}-\frac{32k}{(4k+x^2)^2}.$$

Thus, the transformed Hamiltonians $h_1=h_1^{(p)}=-d^2/dx^2+V_p(x)$ are bounded from below and are essentially self-adjoint operators defined on the dense set in the Hilbert space H. All these Hamiltonians have only a discrete spectrum. The position of the energy levels is the same as before transformation: $E_n=2n+2k$, $n=0,1,2,...$.

The operator $L^+=-L_0(x)-d/dx$ realizes the transformation in the inverse direction,

$$|\psi_n\rangle=N_nL^+|\varphi_n\rangle,$$

and together with L participates in the following factorization:

$$L^+L=h_0-\alpha, \quad LL^+=h_1-\alpha. \tag{10}$$

We note that in our case operators L and L^+ are well defined $\forall\psi\in H$ and are conjugated to each other with respect to the inner product in the space H. This observation, together with the factorization properties (10), is very useful in calculating integrals involving transformed functions. In particular, for the normalization constant N_n we readily find $N_n^{-2}=\langle\varphi_n|h_1-\alpha|\varphi_n\rangle=E_n-\alpha=2p+4k+2n$.

Now, by following the method of Ref. 18 we find the transformed coherent states,

$$\varphi_z(x)=N_{1z}L\psi_z(x)=N\sum_{n=0}^{\infty} b_n z^n\varphi_n,$$

$$N=N_{0z}N_{1z}/N_0, \quad b_n=a_nN_0/N_n.$$

From the factorization properties (10) one readily derives the value of the normalization constant

$$N_{1z}^{-2}=\frac{4k+2p-2pz\overline{z}}{1-z\overline{z}}.$$

Using the identity operator,

$$\sum_{n=0}^{\infty}|\varphi_n\rangle\langle\varphi_n|=1, \tag{11}$$

one can calculate the integration measure $\nu(z)$, which realizes the following identity decomposition:

$$\int_{|z|<1}|\varphi_z\rangle\langle\varphi_z|d\nu(z)=1. \tag{12}$$

For this purpose we pass from the complex variables z and $\overline{z}$ to the polar ones $z=\sqrt{x}\exp i\phi$ and look for the measure in the form $d\nu=1/2h(x)dx\,d\phi$. The integration over the angle variable ϕ in (12) is trivial. Then, making use of the formula (11), we obtain the equation for the function $h(x)$:

$$\pi\int_0^1 dx\ h(x)\ \frac{x^n(1-x)^{2k+1}}{2k+p-px}=\frac{n!\Gamma(2k)}{\Gamma(n+2k)(n+2k+p)}.$$

So, we arrive at a moments problem well known in mathematics.[25] In our case the solution to this problem can readily be obtained with the help of the integral representation of the beta function,

$$B(a,b)=\frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}=\int_0^1 x^{a-1}(1-x)^{b-1}\,dx,$$

and the following identity:

$$\frac{\Gamma(n+1)\Gamma(2k)}{(n+2k+p)\Gamma(n+2k)}=\sum_{j=0}^{p}C_p^j\,\frac{2k-1}{2k+p-j-1}\,B(n+j-1,2k+p-j),$$

where C_p^j are the binomial coefficients. It is not difficult to prove this identity by induction. The final expression for the function $h(x)$ is

$$h(x)=\frac{2k-1}{\pi}\,(2k+p-px)\sum_{j=0}^{p}C_p^j\,\frac{x^j(1-x)^{p-j-2}}{2k+p-j-1}.$$

Once we know the measure $\nu(z)$ we can construct the holomorphic representation $\varphi(z)$ in the unit disk of a vector $|\varphi\rangle \in H$, which is defined by its Fourier coefficients c_n with respect to the base $\{|\varphi_n\rangle\}$,

$$\langle \varphi_{\overline{z}}|\varphi\rangle = N\varphi(z), \quad \varphi(z) = \sum_{n=0}^{\infty} b_n c_n z^n.$$

It follows from these relations the holomorphic representation for the transformed discrete basis vectors $\varphi_n(z) = b_n z^n$ and for the transformed coherent states,

$$\zeta^{(1)}(z) = N^{-1}\langle \varphi_{\overline{z}}|\varphi_\zeta\rangle = \frac{2k+p+p\zeta z}{\sqrt{2k+p}} \frac{(1-\zeta\overline{\zeta})^{k+1/2}}{(1-\zeta\overline{z})^{2k+1}} (2k+p-p\zeta\overline{\zeta})^{-1/2}.$$

With the help of the transformation operators L and L^+, we construct the lowering and raising operators $p_\pm = Lk_\pm L^+$ for the transformed discrete basis functions (8),

$$p_+|\varphi_n\rangle = -(N_n N_{n+1})^{-1}[(n+1)(n+2k)]^{1/2}|\varphi_{n+1}\rangle,$$

$$p_-|\varphi_n\rangle = -(N_n N_{n-1})^{-1}[n(n+2k-1)]^{1/2}|\varphi_{n-1}\rangle.$$

Together with the operator $p_0 = 1/2h_1$ they form a nonlinear algebra,

$$[p_0, p_\pm] = \pm p_\pm, \quad [p_-, p_+] = 2[2k(1-k) - p_0\alpha + 4p_0^2](2p_0 - \alpha).$$

It is interesting that the operators $p_\pm$ are of the fourth degree in the derivative in the coordinate representation while in the holomorphic one they are of the second degree,

$$p_0(z) = z\frac{d}{dz} + k, \quad p_-(z) = 2z\frac{d^2}{dz^2} + 2(2k+p)\frac{d}{dz},$$

$$p_+(z) = 2z^3\frac{d^2}{dz^2} + 2z(2k+p+2)\left(z\frac{d}{dz} + 2k\right).$$

Since the operators L and L^+ realize the correspondence between the basis sets $\{|\psi_n\rangle\}$ and $\{|\varphi_n\rangle\}$ we can find their holomorphic representation,

$$L(z) = \sqrt{\frac{2}{2k+p}}\left(z\frac{d}{dz} + 2k + p\right), \quad L^+(z) = \sqrt{2(2k+p)}.$$

By assuming that the inner product of two vectors $|\varphi_1\rangle$ and $|\varphi_2\rangle$ is independent on the representation used and taking into account the identity decomposition (12), we can equip the lineal $\mathscr{L}$ with a new inner product,

$$\langle \varphi_1|\varphi_2\rangle = \langle \varphi_1(z)|\varphi_2(z)\rangle = \int_{|z|<1} \overline{\varphi_1}(z)\varphi_2(z)e^{-f^{(1)}}\, d\nu(z). \tag{13}$$

It is natural to declare the function

$$f^{(1)} = f^{(1)}(z,\overline{z}) = \ln|\langle \varphi_0|\varphi_z\rangle|^{-2} = f^{(0)} + \ln\frac{\langle \psi_z|h_0 - \alpha|\psi_z\rangle}{E_0 - \alpha},$$

a new Kähler potential. It then follows the expression for a new Hermit metric:

$$g^{(1)} = f^{(1)}_{z\overline{z}} = \frac{2k+1}{(1-z\overline{z})^2} - \frac{p(2k+p)}{(2k+p-pz\overline{z})^2}.$$

The unit disk represents now a phase space with the varying Gauss curvature $\mathscr{K}^{(1)}=-(2/g)\times(\partial^2/\partial z\partial\overline{z})\ln g^{(1)}$. The explicit expression for $\mathscr{K}^{(1)}$ is rather complicated so it is omitted here. We will note only that $\mathscr{K}^{(1)}\to 0$ when $k\to\infty$.

The function

$$\delta^{(1)}(z,\overline{z'})=\sum_{n=0}^{\infty}\varphi_n(z)\overline{\varphi_n}(z')=(1-z\overline{z'})^{-2k-1}\,\frac{2k+p-pz\overline{z}}{2k+p}$$

plays the role of the transformed Bergman kernel that takes off the integration with respect to the new inner product (13).

By making use of the covariant Berezin symbols, we can establish correspondence between the quantum mechanical operators and the classical observables that are the functions of a point in the unit disk. The function

$$H_1=\langle\varphi_z^-|h_1|\varphi_z^-\rangle=2k+\frac{4kz\overline{z}(2k+p+1-pz\overline{z})}{(1-z\overline{z})(2k+p-pz\overline{z})}$$

corresponds to the transformed Hamiltonian operator, and therefore it is the transformed Hamilton function. Similarly, the functions P_+ and P_-,

$$P_+=\overline{P_-}=\langle\varphi_z^-|p_+|\varphi_{\overline{z}}^-\rangle=\frac{4k\overline{z}}{2k+p-pz\overline{z}}\left[\frac{(2k+1)(2k+2)}{(1-z\overline{z})^2}+(p-1)\,\frac{2k+1}{1-z\overline{z}}+p(p-1)\right],$$

correspond to the lowering and raising operators.

The change of the Kähler potential induces the change of the symplectic form that remains closed because of its dimension. As a consequence, we have another Poisson bracket in the unit disk. The functions $P_0=1/2H_1$ and $P_\pm$ form now neither a closed Lie algebra nor a polynomial one with respect to the new Poisson bracket, but it is not difficult to check the following relations:

$$\{P_0,P_\pm\}=\pm iP_\pm,\quad \{P_0,z\}=iz,\quad \{P_0,\overline{z}\}=-i\overline{z}.$$

Two latter relations mean that the equation of trajectories for the transformed classical system in the transformed phase space remains unchanged under the Darboux transformation.

IV. CONCLUSION

Using the coherent states technique we have constructed a classical counterpart of the transformed *a lá* Darboux quantum singular oscillator. It has been shown that the Darboux transformation for this system translates into the transformation of the Kähler potential. New Kähler potential has a supplementary summand of the form $\ln(H_0-\alpha)$, where H_0 is the initial Hamilton function corresponding to the quantum Hamiltonian operator for the singular oscillator. This leads to the distortion of the initial phase space. However, the distortion is consistent with the change of the Hamilton function in such a manner that the curves of a constant energy (classical trajectories) in the transformed phase space remain unchanged. A similar observation has recently been discussed in a Lagrangian formalism and for the canonical method of quantization.[13]

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 39, NUMBER 2 FEBRUARY 1998

The reduced self-dual Yang–Mills equation, binary and infinitesimal Darboux transformations

N. V. Ustinov[a)]
Department of Theoretical Physics, Kaliningrad State University, Al. Nevsky street 14, 236041, Kaliningrad, Russia

(Received 12 May 1997; accepted for publication 4 September 1997)

The self-dual Yang–Mills equation in the (2+1)-dimensional space–time is considered. Binary Darboux transformation of a new kind is applied to obtain the infinite hierarchy of solutions expressed through ones of corresponding Lax pairs on an initial solution of the equation studied. Sufficient conditions are given for the solutions built to take values in the class of unimodular positive-definite matrices. A new infinitesimal Darboux transformation is introduced and a particular solution of the linearization of the self-dual Yang–Mills equation is given. Two hierarchies of infinitesimal symmetries depending on a solution of the nonlinear equation are extracted. © *1998 American Institute of Physics.* [S0022-2488(97)00612-9]

I. INTRODUCTION

The self-dual Yang–Mills equation (SDYM) has been thoroughly investigated by various authors. In particular, it has been found that many famous nonlinear integrable equations can be deduced from SDYM.[1–3] An extension of this relationship to the higher-dimensional space–time seems to become an attractive problem in the theory of integrable equations.[4,5] Nevertheless, it is worth paying more attention to some classical results concerning SDYM.

In the case of gauge group SU(n), SDYM is equivalent to an equation for the unimodular positive-definite matrix-valued function. It is well known that in the space–time with signature (2,2) this equation is reduced to the evolution equation

$$(J_t J^{-1})_t = (J_z J^{-1})_{\bar{z}}, \tag{1}$$

assuming matrix-valued function J being independent of one of the coordinates.[6] This equation, which is the relativistic-invariant three-dimensional reduction of the full SDYM, will be considered hereafter.

The Cauchy problem of Eq. (1) for rapidly decreasing initial values was solved by means of the inverse scattering transformation method (IST) based on the Riemann conjugation problem.[6] The reductions on scattering data, which guarantee the unimodularity and hermiticity of matrix J, were given. Soliton solutions corresponding to a purely discrete part of the scattering data[7] were considered. The explicit formula of the one-soliton solution was presented and the solutions finite in all directions were obtained. However, there are some difficulties in using the IST formalism. The problem of recovering a positive-definite solution of Eq. (1) from the scattering data has not yet been discussed. A recurrent formula of the multisoliton solution contains no contributions of single soliton components in a uniform way. Moreover, a modification of IST presented in the work[8] led to the wrong expression of a two-soliton solution.

In this paper we apply the Darboux transformation (DT) technique[9] to overcome the problems noted above. In Sec. II we recall the representations of the equation considered as the compatibility condition of linear systems of differential equations (Lax pairs) and introduce an automorphism[10] determined by the reduction constraint on matrix J. A theorem establishing binary DT (BDT) is presented. It should be stressed that the BDT introduced here differs from the known one.[9] This transformation is a particular case of the sequence of elementary DTs[11] and gives the usual BDT as a result of an appropriate number of iterations. (It was noted in Ref. 12 that

a)Electronic mail: ustinov@theor.phys.ksu.kern.ru

 © 1998 American Institute of Physics

the usual BDT makes sense after substituting the vector solutions for matrix ones. However, a factorization of such a BDT was not considered.) Sufficient conditions covariant with respect to the BDT are given to construct the solutions of Eq. (1) belonging to the class of unimodular positive-definite matrices. The infinite hierarchies of solutions of Eq. (1) and corresponding ones of Lax pairs are obtained in Sec III. The scattering data of the solutions built are shown to differ by the discrete part only. To put it another way, the solution of Eq. (1) with the given spectral data is generated by BDT iterations starting from one having the same continuous part. A basic property underlying the DT technique allows one to express the formula of successive iterations of BDT through the Lax pair solutions corresponding to an initial solution of the reduced SDYM equation. The contributions of one-soliton solutions are included in this formula uniformly. The DT technique is developed in Sec. IV to obtain a particular solution for the linearization of Eq. (1). An infinitesimal DT is introduced and two hierarchies of infinitesimal symmetries, which contain explicitly matrix J, are extracted.

II. BINARY DARBOUX TRANSFORMATION

Equation (1) arises from the compatibility condition of a system of linear equations (Lax pair),[6]

$$\begin{aligned} \Psi_t &= -\lambda \Psi_{\bar{z}} + U\Psi, \\ \Psi_z &= -\lambda \Psi_t + V\Psi. \end{aligned} \tag{2}$$

Here λ is the spectral parameter ($\lambda \in C$), $z = x_1 + ix_2$, $\Psi \equiv \Psi(t, z, \bar{z}, \lambda)$ is the nondegenerate $n*n$ matrix, currents U and V are defined by the solution of Eq. (1),

$$\begin{aligned} U &= J_t J^{-1}, \\ V &= J_z J^{-1}. \end{aligned} \tag{3}$$

Let us introduce for the sake of convenience the dual Lax pair with spectral parameter æ,

$$\begin{aligned} \Xi_t &= -æ\Xi_{\bar{z}} - \Xi U, \\ \Xi_z &= -æ\Xi_t - \Xi V, \end{aligned} \tag{4}$$

on the matrix-valued function $\Xi \equiv \Xi(t, z, \bar{z}, æ)$. Spaces of the matrix solutions of direct and dual pairs (2), (4) are connected:

$$\Xi(t, z, \bar{z}, \lambda) = \Phi(\bar{z}\lambda t + \lambda^2 z)\Psi(t, z, \bar{z}, \lambda)^{-1},$$

where $\Phi(\bar{z}\lambda t + \lambda^2 z)$ is a solution of Eq. (2) on the zero background.

Matrix-column and matrix-row solutions of Lax pairs will be called *vector solutions* in the following. A vector solution of the direct pair with spectral parameter λ and one of the dual pair with spectral parameter æ will be, respectively, designated ψ and ξ, omitting a dependence on the arguments for brevity.

It should be noted that Eq. (1) may be represented as a set of first-order equations,

$$\begin{aligned} U_t &= V_{\bar{z}}, \\ U_z - V_t &= [V, U]. \end{aligned} \tag{5}$$

The second equation in (5) is nothing but the compatibility condition of system (3) according to a statement,

$$J\Phi(\bar{z}) = \Psi(t, z, \bar{z}, \lambda)|_{\lambda = 0}. \tag{6}$$

This relation will be used in obtaining Darboux transformation formulas.

As it was mentioned in the previous section, the additional restrictions are imposed on solutions of Eq. (1) in the gauge group SU(n) case, namely,

$$\det J = 1, \tag{7a}$$

$$J^+ = J, \tag{7b}$$

$$\varphi^+ J \varphi > 0 \quad (\varphi = (\varphi_1, \ldots \varphi_n)^T, \quad \varphi^+ \varphi \neq 0). \tag{7c}$$

If J is a $2*2$ matrix satisfying these constraints then Eq. (1) has a local real Lagrangian and a corresponding Hamiltonian to be positively defined.[13]

Condition (7b) defines an automorphism[10] in the spaces of Lax pair solutions,

$$\Psi(\lambda) \to J[\Psi(\overline{\lambda^{-1}})^+]^{-1} \in \{\Psi(\lambda)\},$$

$$\Xi(æ) \to [\Xi(\overline{æ^{-1}})^+]^{-1} J^{-1} \in \{\Xi(æ)\},$$

and gives a connection between the spaces of vector solutions: matrix-row $\psi^+ J^{-1}$ is a solution of the dual pair with spectral parameter $\overline{\lambda^{-1}}$. One can consequently put

$$\xi = \psi^+ J^{-1}, \tag{8}$$

implying $æ = \overline{\lambda^{-1}}$. Lax pair solutions satisfying condition (8) will be called *connected through automorphism*. It is obvious that an existence of the automorphism leads to the restrictions on the scattering data. In particular, the locations of zeros and poles of the Riemann conjugate problem are related. A solution of a Lax pair having the zero at point μ on the spectral parameter plane has also the pole at point $\overline{\mu^{-1}}$, and vice versa.

The usual DT[9] and also the elementary DTs (EDTs)[11,14] may be used to obtain the new solutions of Eq. (1) together with the corresponding solutions of Lax pairs. The method of keeping the reduction constraints under DT iterations[11,14,15] allows us to restrict our consideration on binary DT (BDT)[11] (its relation with EDTs will be noted below).

Theorem: *Let φ and χ be the vector solutions of direct and dual Lax pairs* (2,4) *with spectral parameters μ and ν, respectively ($\mu \neq \nu$). Then the matrix functions $\Psi[1]$ and $\Xi[1]$, defined as*

$$\Psi[1] = \left(E - \frac{\mu - \nu}{\lambda - \nu} P \right) \Psi, \tag{9a}$$

$$\Xi[1] = \Xi \left(E - \frac{\mu - \nu}{\mu - æ} P \right), \tag{9b}$$

where

$$P = \frac{\varphi \chi}{(\chi, \varphi)}, \qquad (\chi, \varphi) = \chi \varphi \equiv \sum_{i=1}^{n} \chi_i \varphi_i, \tag{10}$$

are solutions of Lax pairs with new currents,

$$U[1] = U - (\mu - \nu) P_{\overline{z}}, \qquad V[1] = V - (\mu - \nu) P_t. \tag{11}$$

The corresponding solution of Eq. (1) is given by the formula

$$J[1]=\alpha\left(E+\frac{\mu-\nu}{\nu}P\right)J \tag{12}$$

(α is a constant).

Proof: Substituting quantities (9a), (9b), and (11) into the systems

$$\begin{aligned}\Psi[1]_t&=-\lambda\Psi[1]_{\bar{z}}+U[1]\Psi[1],\\ \Psi[1]_z&=-\lambda\Psi[1]_t+V[1]\Psi[1],\end{aligned} \tag{13a}$$

and

$$\begin{aligned}\Xi[1]_t&=-æ\Xi[1]_{\bar{z}}-\Xi[1]U[1],\\ \Xi[1]_z&=-æ\Xi[1]_t-\Xi[1]V[1],\end{aligned} \tag{13b}$$

one obtains a set of differential equations on matrix P,

$$\begin{aligned}P_t&=-\tfrac{1}{2}(\mu+\nu)P_{\bar{z}}+[P,\tfrac{1}{2}(\mu-\nu)P_{\bar{z}}-U],\\ P_z&=-\tfrac{1}{2}(\mu+\nu)P_t+[P,\tfrac{1}{2}(\mu-\nu)P_t-V].\end{aligned} \tag{14}$$

The left-hand side of Eq. (10) solves it. Therefore, systems (13) are compatible and new currents (11) satisfy system (5). Expression (12) for new solution $J[1]$ follows from its relation with the transformed solution of the direct Lax pair (13a):

$$J[1]\Phi(\overline{z})=\Psi[1]|_{\lambda=0.} \tag{15}$$

■

The formulas (9)–(12) constitute binary DT. In the sequel we shall state that BDT is performed *with* vector solutions φ and χ. The definitions of transformed vector solutions $\psi[1]$ and $\xi[1]$ follow from Eqs. (9), replacing the matrix solutions by corresponding vector ones. Transformation $\{\psi,\xi\}\rightarrow\{\psi[1],\xi[1]\}$ has the next property: $\psi[1]=0$ if $\lambda=\mu$ and $\psi=\varphi$, $\xi[1]=0$ if $æ=\nu$ and $\xi=\chi$. An existence of the kernel is a common feature of any DT and underlies this technique. The statement may be proven, allowing for that BDT is a particular case of successive carrying out of two EDTs (namely, one of the EDTs of the direct Lax pair and a proper one of the dual pair[11]). Such a representation of BDT also yields a relation,

$$\det\Psi[1]=\frac{\lambda-\mu}{\lambda-\nu}\det\Psi, \tag{16}$$

displaying a presence of additional zero and pole in the discrete part of the scattering data[7] of the transformed solution $J[1]$. The vector solutions φ and χ complete a description of the new scattering data and define an evolution of them. The successive iterations of BDT give rise to a solution of Eq. (1) with the arbitrary discrete part of the scattering data.

Consider the constraints on BDT allowing us to build a solution of SDYM satisfying conditions (7). It is seen from Eqs. (15) and (16) that a unimodular solution is obtained, putting in Eq. (12)

$$\alpha=(\nu/\mu)^{1/n}.$$

A Hermiticity of Eq. (1) solutions imposes the restrictions on scattering data. Therefore, one has to choose the vector solutions φ and χ connected through the automorphism for the transformed solution to inherit this reduction. It is remarkable that relation (8) occurs then to be covariant (within an unimportant scalar factor) with respect to such a BDT:

$$\xi[1]=|\mu|^{-2/n}\psi[1]^{+}J[1]^{-1},\quad\text{if}\quad\xi=\psi^{+}J^{-1}.$$

Combining these constraints on a BDT (9)–(12), the expression for the new unimodular Hermitian solution of Eq. (1) becomes

$$J[1]=|\mu|^{-2/n}\left(J+(|\mu|^2-1)\,\frac{\varphi\varphi^+}{(\varphi^+,J^{-1}\varphi)}\right). \tag{17}$$

The last formula may be written down in the form

$$J[1]=AJ^{-1}A,$$

where

$$A=|\mu|^{-1/n}\left(J+(-1\pm|\mu|)\,\frac{\varphi\varphi^+}{(\varphi^+,J^{-1}\varphi)}\right).$$

It shows obviously that, assuming an initial solution to satisfy condition (7c), we generate the new positive-definite solution of Eq. (1) by keeping the reduction (7b). Therefore, the problem of recovering a positive-definite solution of SDYM is reduced to the case of the scattering data having the continuous part only.

III. ITERATIONS OF BINARY DARBOUX TRANSFORMATION

Let $\varphi^{(i)}$ and $\chi^{(i)}$ $(i=1,\ \ldots\ ,N)$ be the vector solutions of direct and dual Lax pairs (2), (4) with spectral parameters $\mu^{(i)}$ and $\nu^{(i)}$. For the sake of simplicity we suggest that the values of the spectral parameters are mutually different. The matrix-column and matrix-row functions,

$$\varphi^{(i)}[1]=\left(E-\frac{\mu^{(1)}-\nu^{(1)}}{\mu^{(i)}-\nu^{(1)}}\,P[1]\right)\varphi^{(i)},$$

$$\chi^{(i)}[1]=\chi^{(i)}\left(E-\frac{\mu^{(1)}-\nu^{(1)}}{\mu^{(1)}-\nu^{(i)}}\,P[1]\right),$$

$$\left(P[1]=\frac{\varphi^{(1)}\chi^{(1)}}{(\chi^{(1)},\varphi^{(1)})}\right),$$

are the vector solutions of the transformed direct and dual pairs with spectral parameters $\mu^{(i)}$ and $\nu^{(i)}$ with the new currents. The corresponding solution of Eq. (1) is obtained by performing the BDT (9)–(12) with solutions $\varphi^{(1)}$ and $\chi^{(1)}$. Carrying out successively the iterations of BDT with transformed vector solutions $\varphi^{(i)}[i-1]$ and $\chi^{(i)}[i-1]$ $(i=2,\ \ldots\ ,N)$, defined as follows:

$$\varphi^{(i)}[i-1]=\left(E-\frac{\mu^{(i-1)}-\nu^{(i-1)}}{\mu^{(i)}-\nu^{(i-1)}}\,P[i-1]\right)\cdots\left(E-\frac{\mu^{(1)}-\nu^{(1)}}{\mu^{(i)}-\nu^{(1)}}\,P[1]\right)\varphi^{(i)},$$

$$\chi^{(i)}[i-1]=\chi^{(i)}\left(E-\frac{\mu^{(1)}-\nu^{(1)}}{\mu^{(1)}-\nu^{(i)}}\,P[1]\right)\cdots\left(E-\frac{\mu^{(i-1)}-\nu^{(i-1)}}{\mu^{(i-1)}-\nu^{(i)}}\,P[i-1]\right),$$

where

$$P[i]=\frac{\varphi^{(i)}[i-1]\chi^{(i)}[i-1]}{(\chi^{(i)}[i-1],\varphi^{(i)}[i-1])},$$

produces the recurrent formulas for the transformed matrix solutions,

$$\Psi[N]=\left(E-\frac{\mu^{(N)}-\nu^{(N)}}{\lambda-\nu^{(N)}}\,P[N]\right)\cdots\left(E-\frac{\mu^{(1)}-\nu^{(1)}}{\lambda-\nu^{(1)}}\,P[1]\right)\Psi,$$

$$\Xi[N]=\Xi\left(E-\frac{\mu^{(1)}-\nu^{(1)}}{\mu^{(1)}-æ}\,P[1]\right)\cdots\left(E-\frac{\mu^{(N)}-\nu^{(N)}}{\mu^{(N)}-æ}\,P[N]\right).$$

Using the definitions of the transformed vector solutions and, as a consequence, the identities similar to the next one,

$$\frac{(\chi^{(i)}[1],\varphi^{(i)}[1])}{\mu^{(i)}-\nu^{(i)}}\,\frac{(\chi^{(1)},\varphi^{(1)})}{\mu^{(1)}-\nu^{(1)}}=\begin{vmatrix}\dfrac{(\chi^{(i)},\varphi^{(i)})}{\mu^{(i)}-\nu^{(i)}} & \dfrac{(\chi^{(1)},\varphi^{(i)})}{\mu^{(i)}-\nu^{(1)}}\\ \dfrac{(\chi^{(i)},\varphi^{(1)})}{\mu^{(1)}-\nu^{(i)}} & \dfrac{(\chi^{(1)},\varphi^{(1)})}{\mu^{(1)}-\nu^{(1)}}\end{vmatrix}, \tag{18}$$

allows us to express the projectors $P[i]$ in terms of the initial Lax pair solutions. Taking then into account that $\psi[N]=0$ if $\lambda=\mu^{(i)}$, $\psi=\varphi^{(i)}$, and $\xi[N]=0$ if $æ=\nu^{(i)}$, $\xi=\chi^{(i)}$, one leads the Nth iteration formulas to the form

$$\Psi[N]=\left(E-\sum_{i,k=1}^{N}(\Delta[N]^{-1})_{ik}\,\frac{\varphi^{(i)}\chi^{(k)}}{\lambda-\nu^{(k)}}\right)\Psi, \tag{19a}$$

$$\Xi[N]=\Xi\left(E-\sum_{i,k=1}^{N}(\Delta[N]^{-1})_{ik}\,\frac{\varphi^{(i)}\chi^{(k)}}{\mu^{(i)}-æ}\right), \tag{19b}$$

$$\Delta[N]_{ik}=\frac{(\chi^{(i)},\varphi^{(k)})}{\mu^{(k)}-\nu^{(i)}},$$

$$(i,k=1,\ \ldots\ ,N).$$

The relation of $\Psi[N]$ with new solution $J[N]$ of Eq. (1) yields

$$J[N]=\alpha[N]\left(E+\sum_{i,k=1}^{N}(\Delta[N]^{-1})_{ik}\,\frac{\varphi^{(i)}\chi^{(k)}}{\nu^{(k)}}\right)J. \tag{20}$$

So, we rewrite the recurrent formula in a more convenient manner, displaying obviously an equal contribution of each soliton component. Roughly speaking, these solutions of SDYM describe N-soliton solutions developing on an initial background.

Now we shall set out to construct the new solutions satisfying reductions (7). It was proven in the previous section that the condition keeping reduction (7b) is sufficient to inherit reduction (7c) by the transformed solution of SDYM and the connection through the automorphism (8) is covariant with respect to such a BDT. These properties impose the next conditions under BDT iterations for expression (20) to ensure the unimodular positive-definite solution of Eq. (1),

$$\nu^{(i)}=(\overline{\mu^{(i)}})^{-1}, \tag{21a}$$

$$\chi^{(i)}=\varphi^{(i)+}J^{-1}, \tag{21b}$$

$$\alpha[N]=\prod_{i=1}^{N}|\mu^{(i)}|^{-2/n}. \tag{21c}$$

This way the DT technique solves the problem of recovering the positive-definite solutions of Eq. (1) for the discrete part of scattering data. A problem remaining is to build the solutions taking values in the class of unimodular positive-definite matrices for the case of purely continuous scattering data. It should be noted that matrix J in Eq. (20) is an arbitrary positive-definite solution of SDYM. It may be, for example, the self-similar solution satisfying an equation for principal chiral field on the plane.[6]

The BDT iterations formulas (19)–(20) with restrictions (21) imposed allow us to produce a great variety of positive-definite solutions of Eq. (1). It was supposed here that the spectral

parameters of vector solutions forming the BDT are different. Then the solution built possesses, in the general case, the additional pairs of zeros and poles in the discrete part of scattering data and corresponds to the many-soliton solution ''added'' on an initial background. The case of some spectral parameters values to be equal is treated as a limit by assuming the analytical dependence of the vector solutions on spectral parameters. This way, the solutions of Eq. (1), which are not imbedded into the usual IST scheme, arise.

Consider, for example, the second iteration of BDT keeping reductions (7). Let $\mu^{(1)}=\mu$, $\mu^{(2)}=\overline{\mu^{-1}}+\epsilon$, and $(\varphi^{(1)+}J^{-1},\varphi^{(2)})=O(\epsilon)$. Taking the limit $\epsilon\to 0$, the coefficients of matrix $J[2]$ become

$$J[2]_{ik}=\begin{vmatrix} J_{ik} & -(\varphi^{(1)+}J^{-1},J^{(k)}) & -(\varphi^{(2)+}J^{-1},J^{(k)}) \\ \varphi_i^{(1)} & \dfrac{(\varphi^{(1)+}J^{-1},\varphi^{(1)})}{|\mu|^{(2)}-1} & \mu^{-1}(A^{+}J^{-1},\varphi^{(1)}) \\ \varphi_i^{(2)} & \bar{\mu}^{-1}(\varphi^{(1)+}J^{-1},A) & \dfrac{|\mu|^2}{1-|\mu|^2}(\varphi^{(2)+}J^{-1},\varphi^{(2)}) \end{vmatrix} \Bigg/ \begin{vmatrix} \dfrac{(\varphi^{(1)+}J^{-1},\varphi^{(1)})}{|\mu|^2-1} & \mu^{-1}(A^{+}J^{-1},\varphi^{(1)}) \\ \bar{\mu}^{-1}(\varphi^{(1)+}J^{-1},A) & \dfrac{|\mu|^2}{1-|\mu|^2}(\varphi^{(2)+}J^{-1},\varphi^{(2)}) \end{vmatrix}, \tag{22}$$

where

$$A=\left.\frac{\partial\varphi^{(2)}}{\partial\mu^{(2)}}\right|_{\mu^{(2)}=\overline{\mu^{-1}}},\quad J=(J^{(1)},\ \ldots\ ,J^{(n)}).$$

As it is seen from Eqs. (16) and (21a), the solution constructed has no additional zeros and poles in the scattering data. A zoo of solutions finite in all directions is generated by expressions (22) starting from the zero background.

IV. INFINITESIMAL DARBOUX TRANSFORMATION

In this section we obtain the explicit expressions for infinitesimal symmetries of Eq. (1). A functional is said to be the infinitesimal symmetry if it satisfies the linearized equation for given nonlinear equation. The infinitesimal transformation $J\to J+\epsilon\ \delta J$ (ϵ is an infinitesimal parameter) gives the linearization of Eq. (1), namely,

$$(J(J^{-1}\ \delta J)_t J^{-1})_t=(J(J^{-1}\ \delta J)_z J^{-1})_{\bar{z}}. \tag{23}$$

The particular solution of Eq. (23) is derived from the BDT (9)–(12). Let $\nu=\mu+\epsilon$, $(\chi,\varphi)=1+O(\epsilon)$ and proceed to the limit $\epsilon\to 0$. From Eq. (12) one has

$$\delta J=-\frac{\varphi\chi}{\mu}J. \tag{24a}$$

The corresponding infinitesimal transformations of the solutions and the currents of Lax pairs (2), (4) $\{\Psi,\Xi,U,V\}\to\{\Psi+\epsilon\ \delta\Psi,\Xi+\epsilon\ \delta\Xi,U+\epsilon\ \delta U,V+\epsilon\ \delta V\}$ are produced by the BDT formulas also,

$$\delta\Psi=\frac{\varphi\chi}{\lambda-\mu}\Psi,$$

$$\delta\Xi=\Xi\,\frac{\varphi\chi}{\mu-æ},$$
$$\delta U\equiv(\delta J)_t J^{-1}-U\;\delta J\;J^{-1}=(\varphi\chi)_{\overline{z}},\tag{24b}$$
$$\delta V\equiv(\delta J)_z J^{-1}-V\;\delta J\;J^{-1}=(\varphi\chi)_t.$$

We name these formulas the infinitesimal Darboux Transformation (IDT). Having yielded a solution of the linear equation, the expression for symmetry (24a) is generalized,

$$\delta J=\int\Psi(\lambda)\Xi(\lambda)\,\frac{d\lambda}{\lambda}\,J.\tag{25a}$$

This representation of infinitesimal symmetry may be used in the study of the stability of SDYM solutions. Infinitesimal transformations $\delta\Psi(\mu)$ and $\delta\Xi(\mu)$ of Lax pair solutions with spectral parameter μ, which are associated with symmetry (25a), are given by the expressions

$$\delta\Psi(\mu)=\int\frac{\Psi(\lambda)\Xi(\lambda)}{\lambda-\mu}\,d\lambda\;\Psi(\mu),$$
$$\delta\Xi(\mu)=\Xi(\mu)\int\frac{\Psi(\lambda)\Xi(\lambda)}{\mu-\lambda}\,d\lambda.\tag{25b}$$

For a Hermitian solution of Eq. (1), one obtains Hermitian symmetry by adding into Eq. (25a) the integral with solutions connected through the automorphism,

$$\delta J=\int(\lambda^{-1}\Psi(\lambda)\Xi(\lambda)J+\overline{\lambda^{-1}}J\Xi(\lambda)^{+}\Psi(\lambda)^{+})da,$$

where the solutions of Lax pairs depend on the real parameter a through their dependence on spectral parameter $\lambda\equiv\lambda(a)$.

Hierarchies of infinitesimal symmetries expressed in terms of the Eq. (1) solution result from expanding the solutions of Lax pairs in a power series on the spectral parameter. Consider the expansions in the neighborhoods of two points on spectral parameter plane $\lambda=0$ and $\lambda=\infty$. Let $A^{(i)}$, $B^{(i)}$, $C^{(i)}$, $D^{(i)}$ $(i=0,1,...)$ be the matrices of functions of the space–time coordinates. Substitution in Eqs. (2) and (4) of formal Taylor series,

$$\Psi(\lambda)=\sum_{i=0}^{\infty}\lambda^{i}A^{(i)},$$
$$\Xi(æ)=\sum_{i=0}^{\infty}æ^{i}B^{(i)},$$

for the first case and

$$\Psi(\lambda)=\sum_{i=0}^{\infty}\lambda^{-i}C^{(i)},$$
$$\Xi(æ)=\sum_{i=0}^{\infty}æ^{-i}D^{(i)},$$

for the second one gives

$$A^{(0)}=-J\Phi^{(0)}(\overline{z}),$$

$$A^{(i)}=-J\left(\int (J^{-1}A_{\overline{z}}^{(i-1)}\,dt+J^{-1}A_t^{(i-1)}\,dz)+\Phi^{(i)}(\overline{z})\right),$$

$$B^{(0)}=-F^{(0)}(\overline{z})J^{-1},$$

$$B^{(i)}=-\left(\int (B_{\overline{z}}^{(i-1)}J\,dt+B_t^{(i-1)}J\,dz)+F^{(i)}(\overline{z})\right)J^{-1},$$

$$C^{(0)}=G^{(0)}(z),$$

$$C^{(i)}=-\int (J(J^{-1}C^{(i-1)})_z\,dt+J(J^{-1}C^{(i-1)})_t\,d\overline{z})+G^{(i)}(z),$$

$$D^{(0)}=H^{(0)}(z),$$

$$D^{(i)}=-\int ((D^{(i-1)}J)_zJ^{-1}\,dt+(D^{(i-1)}J)_tJ^{-1}\,d\overline{z})+H^{(i)}(z).$$

Inserting these expansions in Eq. (25a) generates two infinite hierarchies of symmetries $\delta J^{(i)}$ ($i=0,\ 1,\ ...$). The first members are

$$\delta J^{(0)}=JT(\overline{z}),$$

$$\delta J^{(1)}=J\left[T(\overline{z}),\int (J^{-1}J_{\overline{z}}dt+J^{-1}J_t\,dz)\right]-JT'(\overline{z})t$$

and

$$\delta J^{(0)}=S(z)J,$$

$$\delta J^{(1)}=\left[S(z),\int (J_zJ^{-1}\,dt+J_tJ^{-1}\,d\overline{z})\right]J+S'(z)Jt,$$

where $T(\overline{z})=\Phi^{(0)}(\overline{z})F^{(0)}(\overline{z})$, $S(z)=G^{(0)}(z)H^{(0)}(z)$.

A solution of the linearized equation and a hierarchy of infinitesimal symmetries may be obtained by means of the BDT for other integrable nonlinear equations. The approach suggested in this section resembles the infinitesimal version of the ''dressing'' method.[16] An expansion on spectral parameter powers of the bilinear product of Lax pairs solutions was also used in the work of Ref. 17 to derive a hierarchy of symmetries of the KP equation.

V. CONCLUSION

The technique developed may be applied to the equation for the principal chiral field on the plane, which coincides with the self-similar reduction of Eq. (1),[6] as well as to SDYM in $4k$-dimensional space–time.[4] Moreover, expressions (20) and (25) give new solutions of generalized self-dual Yang–Mills flows[5] and of the linearization of them by supposing that the vector functions $\varphi^{(i)}$, $\chi^{(i)}$ and matrix ones $\Psi(\lambda)$, $\Xi(\lambda)$ are the solutions of corresponding direct and dual Lax pairs. Different reduction constraints on a solution of SDYM are treated in the similar manner, employing the associated automorphism.[11] An analysis of the solutions for these equations, their stability, and the scattering properties of the Eq. (1) solutions, which are not described by the usual IST formalism, are the subjects of the future study.

Nonlinear constraints and soliton solutions of 1+2-dimensional three-wave equation

Zixiang Zhou
Institute of Mathematics, Fudan University, Shanghai 200433, China

(Received 27 January 1997; accepted for publication 7 July 1997)

Using the nonlinear constraint method, the explicit expressions of localized solitons of the 1+2-dimensional three-wave equation are obtained. After the lth Darboux transformation, each component of the solution has, at most, l^2 peaks when the parameters for each single Darboax transformation are large enough. This gives a corresponding asymptotic property for the DSI equation, although all the peaks of each component move in the same velocity here. © *1998 American Institute of Physics.* [S0022-2488(98)03701-3]

I. INTRODUCTION

The 1+2-dimensional three-wave equation describes the nonlinear interaction of three waves and is widely investigated.[1] The inverse scattering transformation has been developed systematically[2–6] and there are many other considerations for this equation.[7,8]

Since the work of Ref. 9 on the 1+1-dimensional problem, the method of nonlinear constraint has been discussed in various papers. In 1+2 dimensions, this method is first applied to the KP equation by Refs. 10 and 11. Generally, the nonlinear constraint in 1+2 dimensions is a method to reduce the original problem to a new 1+2-dimensional problem that can be dealt with by a 1+1-dimensional method. For that new problem, the Darboux transformation has been well developed.[12,13] Using the nonlinear constraint and Darboux transformation methods, Ref. 14 proved that for any equation in the hyperbolic $su(n)$ AKNS system, which includes the three-wave equation, there are localized solitons (i.e., the solitons that decay at infinity in all directions).

If a certain condition [condition (16) of Remark 1] is satisfied so that different solitons have different velocities, the asymptotic solution as $t\to\pm\infty$ has, at most, l^2 peaks if the solution is given by the lth Darboux transformation from the zero solution. This is true for the DSI equation. However, for the three-wave equation, that condition never holds, and all the solitons in each component move in the same velocity. Therefore, the asymptotic solution is still very complicated (not split up into several single solitons). In this paper, we show that when certain parameters are large enough, these peaks can also be separated. This is true, not only for the asymptotic solution (under a weaker condition), but also for the solution at finite time t (under a stronger condition).

In Sec. II of this paper we describe the Lax pair of the three-wave equation, whose nonlinear constraint and the Darboux transformation. The main conclusion has been obtained in Ref. 14. In Sec. III the behavior of a single-soliton solution is discussed in detail. In Sec. IV, the asymptotic behavior of the multisoliton solutions is obtained when the parameters of each single Darboux transformation (not time t) are large enough. This gives a corresponding property for the asymptotic solutions of the DSI equation, although all the solitons move in the same velocity here. Some figures describing the behaviors and interactions of the ''two-soliton'' solutions are shown.

II. NONLINEAR CONSTRAINT AND DARBOUX TRANSFORMATION

The 1+2-dimensional three-wave equation is

$$\begin{aligned} f_{1,t}&=\alpha_1 f_{1,y}+\beta_1 f_{1,x}+(\alpha_3-\alpha_2)f_2\overline{f_3},\\ f_{2,t}&=\alpha_2 f_{2,y}+\beta_2 f_{2,x}+(\alpha_1-\alpha_3)f_1 f_3,\\ f_{3,t}&=\alpha_3 f_{3,y}+\beta_3 f_{3,x}+(\alpha_2-\alpha_1)\overline{f_1}f_2, \end{aligned} \tag{1}$$

 © 1998 American Institute of Physics

where α_i, β_i are real constants.

It is known that this equation has a Lax pair

$$\begin{aligned}\Psi_y &= J\Psi_x + U(x,y,t)\Psi,\\ \Psi_t &= K\Psi_x + V(x,y,t)\Psi,\end{aligned} \tag{2}$$

where

$$J=\begin{pmatrix} J_1 & 0 & 0\\ 0 & J_2 & 0\\ 0 & 0 & J_3\end{pmatrix},\quad K=\begin{pmatrix} K_1 & 0 & 0\\ 0 & K_2 & 0\\ 0 & 0 & K_3\end{pmatrix},\quad U=(u_{ij})=\begin{pmatrix} 0 & f_1 & f_2\\ -\overline{f_1} & 0 & f_3\\ -\overline{f_2} & -\overline{f_3} & 0\end{pmatrix},$$

J_i, K_i are real constants with $J_i \neq J_j$ for $i \neq j$, and V is a 3×3 matrix whose diagonal entries are zero. Moreover, we suppose that

$$\det\begin{pmatrix} 1 & J_1 & K_1\\ 1 & J_2 & K_2\\ 1 & J_3 & K_3\end{pmatrix} \neq 0. \tag{3}$$

The integrability conditions of (2) are

$$[J,V]=[K,U],\quad U_t - V_y + JV_x - KU_x + [U,V]=0. \tag{4}$$

Eliminating V, we get an equation of U, which is just (1) with $\alpha_1=(K_1-K_2)/(J_1-J_2)$, $\alpha_2=(K_1-K_3)/(J_1-J_3)$, $\alpha_3=(K_2-K_3)/(J_2-J_3)$, $\beta_i=K_i-J_i\alpha_i$ $(i=1,2,3)$.

There is another linear system related with (2), which is

$$\Phi_x=\begin{pmatrix} i\lambda I & iP\\ iP^* & 0\end{pmatrix}\Phi,\quad \Phi_y=\begin{pmatrix} i\lambda J+U & iJP\\ iP^*J & 0\end{pmatrix}\Phi,\quad \Phi_t=\begin{pmatrix} i\lambda K+V & iKP\\ iP^*K & 0\end{pmatrix}\Phi, \tag{5}$$

where $P(x,y,t)$ is a 3×3 matrix. The integrability conditions of (5) give

$$P_y = JP_x + UP,\quad P_t = KP_x + VP, \tag{6}$$

$$U_x=[J,PP^*], \tag{7}$$

$$U_t - V_y + [U,V] - JPP^*K + KPP^*J = 0. \tag{8}$$

Clearly the system (6) is the same as (2), except that Ψ is replaced by P. If (7) is considered, (8) is just the three-wave equation (4). Moreover, (7) gives a nonlinear constraint between U and P [P is a solution of the Lax pair (2)]. Therefore, we relate the $1+2$-dimensional problem (2) with the problem (5) by the nonlinear constraint (7). For (5), the standard method in $1+1$ dimensions can be applied.

In Ref. 15, this method was applied for 3×1 matrix P. In that case, nonlocalized solutions of the $1+2$-dimensional three-wave equation are obtained. However, localized solutions can only be obtained by choosing P as a $3\times s$ $(s\geqslant 3)$ matrix with rank 3.

If we can solve (6)–(8), the explicit solutions (f_i) of (1) are obtained, although they are not all solutions of (1).

Reference 14 showed that the equations (1) have localized soliton solutions that tend to zero exponentially at infinity. These solutions can be obtained by a Darboux transformation for (5), provided that the parameters in the Darboux transformation are chosen properly. More precisely, the Darboux transformation can be constructed as follows from the zero seed solution.

Take l complex numbers $\lambda_1,\ldots,\lambda_l$ such that $\lambda_j \neq \lambda_k$ $(j\neq k)$ and $\lambda_j \neq \overline{\lambda_k}$ for all $1\leqslant j,k\leqslant l$. Let

$$H_j=\begin{pmatrix} e^{\sqrt{-1}\lambda_j(x+Jy+Kt)}\\ C^{(j)}\end{pmatrix}, \tag{9}$$

where $C^{(j)}$'s are 3×3 nondegenerate constant matrices. Let $\Sigma=(\Sigma_{jk})_{1\leqslant j,k\leqslant l}$ be a block matrix given by

$$\Sigma_{jk}=\frac{H_j^* H_k}{\lambda_k-\overline{\lambda}_j}. \tag{10}$$

Then

$$G(\lambda)=\prod_{j=1}^{l}(\lambda-\overline{\lambda}_j)\left(1-\sum_{j,k=1}^{l}\frac{H_j}{\lambda-\lambda_k}(\Sigma^{-1})_{jk}H_k^*\right) \tag{11}$$

is a Darboux matrix of degree l for (5) with $U=P=0$. That is, for any solution Φ of (5) with $U=P=0$, $\widetilde{\Phi}=G\Phi$ satisfies (5) for certain U and P. It is known that the action of the Darboux matrix of degree l is equivalent to the successive actions of l Darboux matrices of degree one.

From the standard calculation of a Darboux transformation, we have

$$\begin{aligned} u_{\alpha\beta}&=2\sqrt{-1}\sum_{j,k=1}^{l}(h_j(\Sigma^{-1})_{jk}h_k^*)_{\alpha\beta}\\ &=2\sqrt{-1}\sum_{j,k=1}^{l}(\Sigma^{-1})_{\alpha\beta}e^{\sqrt{-1}(\lambda_j-\overline{\lambda}_k)x+\sqrt{-1}(\lambda_j J_\alpha-\overline{\lambda}_k J_\beta)y+\sqrt{-1}(\lambda_j K_\alpha-\overline{\lambda}_k K_\beta)t}. \end{aligned} \tag{12}$$

Reference 14 proved that when $C^{(j)}$'s are nondegenerate, the solution (12) is localized, and it decays at infinity exponentially. Moreover, the peaks in $u_{\alpha\beta}$ move in the velocity (v_x,v_y) given by

$$v_x=-\frac{J_\alpha K_\beta-J_\beta K_\alpha}{J_\alpha-J_\beta},\quad v_y=-\frac{K_\alpha-K_\beta}{J_\alpha-J_\beta}. \tag{13}$$

For a three-wave equation, these velocities are independent of λ. Therefore, all the solitons move in the same velocity for given J_α, K_α.

Remark 1: For a more general linear system [it comes from the hyperbolic $su(N)$ AKNS system),

$$\begin{gathered} \Phi_x=\begin{pmatrix} i\lambda I & iP\\ iP^* & 0\end{pmatrix}\Phi,\quad \Phi_y=\begin{pmatrix} i\lambda J+U & iJP\\ iP^*J & 0\end{pmatrix}\Phi,\\ \Phi_t=\begin{pmatrix} W(x,y,t,\lambda) & X(x,y,t,\lambda)\\ -X^*(x,y,t,\lambda) & Z(x,y,t,\lambda)\end{pmatrix}\Phi, \end{gathered} \tag{14}$$

the multisoliton solutions are taken from $U=P=0$, $X=0$, $Z=0$,

$$W(x,y,t,\lambda)=\begin{pmatrix} i\beta_1(\lambda) & & \\ & \ddots & \\ & & i\beta_N(\lambda)\end{pmatrix}. \tag{15}$$

In that case, Proposition 4 of Ref. 14 shows that if

$$\det\begin{pmatrix} 1 & J_i & \beta_{iI}(\lambda_\alpha)/\lambda_{\alpha I}\\ 1 & J_j & \beta_{jI}(\lambda_\beta)/\lambda_{\beta I}\\ 1 & J_k & \beta_{kI}(\lambda_\gamma)/\lambda_{\gamma I}\end{pmatrix}\neq 0 \tag{16}$$

for any mutually different pairs (i,α), (j,β), and (k,γ), then as $t\to\infty$, each entry $U_{ij}^{[l]}$ of the solution $U^{[l]}$ given by the lth Darboux transformations splits up into at most l^2 peaks. Here z_I is the imaginary part of a complex number z. Actually, (16) implies that different solitons have different velocities.

For a three-wave equation, $\beta_i(\lambda)=K_i$, which is independent of λ. (16) is always violated by taking pairs (i,α), (i,β), (i,γ) for different α,β,γ. Hence Proposition 4 of Ref. 14 is no longer valid. From (13), the formula for the velocities for the solitons, the solitons will not split as $t\to\infty$.

Remark 2: Since $u_{\beta\alpha}^*=-u_{\alpha\beta}$, we will always consider $u_{\alpha\beta}$ $(\alpha<\beta)$ from now on.

III. SINGLE-SOLITON SOLUTIONS

Take $l=1$,

$$H=\begin{pmatrix} e^{\sqrt{-1}\lambda_0(x+Jy+Kt)} & \\ & C \end{pmatrix}, \tag{17}$$

where $C=(C_{jk})$ is a 3×3 nondegenerate constant matrix, then

$$\Sigma=\frac{1}{2b\sqrt{-1}}\,(e^{-2b(\zeta+J_\mu\eta)-2b\pi_\mu t}\delta_{\mu\nu}+g_{\mu\nu})_{3\times3}, \tag{18}$$

with

$$\begin{gathered} x=v_x t+\xi,\quad y=v_y t+\eta,\\ \pi_\mu=v_x+J_\mu v_y+K_\mu,\quad a=\mathrm{Re}(\lambda_0),\quad b=\mathrm{Im}(\lambda_0),\quad g_{\mu\nu}=C_{\sigma\mu}^* C_{\sigma\nu}. \end{gathered} \tag{19}$$

Since the solitons moves in a fixed velocity for each component $u_{\alpha\beta}$, we consider the solution in a moving frame with velocity (v_x,v_y). The asymptotic behavior of the soliton is clearly seen in this frame.

When (v_x,v_y) takes the value in (13), $\pi_\alpha=\pi_\beta=0$. Without loss of generality, suppose $\pi_2=\pi_3=0$, then $\pi_1\neq0$ by considering (3).

Let $(h_{\mu\nu})=(g_{\mu\nu})^{-1}$, $g=(g_{\mu\nu})$, $h=(h_{\mu\nu})$, then by direct calculation from (12), we get the new solution of (1) as follows:

$$\begin{aligned} u_{12}&=-\frac{4b}{\Delta}\,(h_{12}\sqrt{\det g}\,e^{b\xi+\theta_3}-g_{12}\sqrt{\det h}\,e^{-b\xi-\theta_3})e^{\sqrt{-1}a(J_1-J_2)\eta+\sqrt{-1}a\pi_1 t},\\ u_{13}&=-\frac{4b}{\Delta}\,(h_{13}\sqrt{\det g}\,e^{b\xi+\theta_2}-g_{13}\sqrt{\det h}\,e^{-b\xi-\theta_2})e^{\sqrt{-1}a(J_1-J_3)\eta+\sqrt{-1}a\pi_1 t},\\ u_{23}&=-\frac{4b}{\Delta}\,(h_{23}e^{s(t)}-g_{23}e^{-s(t)})e^{\sqrt{-1}a(J_2-J_3)\eta}, \end{aligned} \tag{20}$$

where

$$\begin{aligned} \Delta&=e^{s(t)}(e^{\rho}+g_{11}\det h e^{-\rho}+h_{22}e^{\theta_3-\theta_2}+h_{33}e^{\theta_2-\theta_3})\\ &\quad+e^{-s(t)}(e^{-\rho}+h_{11}\det g e^{\rho}+g_{22}e^{\theta_2-\theta_3}+g_{33}e^{\theta_3-\theta_2}),\\ s(t)&=b(\xi+J_1\eta+\pi_1 t)+\tfrac{1}{2}\ln(\det g),\\ \rho&=b(2\xi+J_2\eta+J_3\eta),\quad \theta_j=bJ_j\eta\quad(j=1,2,3). \end{aligned} \tag{21}$$

Whenever $b\neq0$, u_{23} tends to a single localized peak as $t\to\pm\infty$, and both u_{12}, u_{13} tend to zero exponentially. More precisely, when $b\pi_1 t\to+\infty$ (ξ, η bounded),

$$u_{12}\sim 0, \quad u_{13}\sim 0,$$
$$u_{23}\sim \frac{-4bh_{23}e^{\sqrt{-1}a(J_2-J_3)\eta}}{e^{\rho}+g_{11}\det he^{-\rho}+h_{22}e^{\theta_3-\theta_2}+h_{33}e^{\theta_2-\theta_3}}, \tag{22}$$

and when $b\pi_1 t\to-\infty$ (ξ, η bounded),

$$u_{12}\sim 0, \quad u_{13}\sim 0,$$
$$u_{23}\sim \frac{4bg_{23}e^{\sqrt{-1}a(J_2-J_3)\eta}}{e^{-\rho}+h_{11}\det ge^{\rho}+g_{22}e^{\theta_2-\theta_3}+g_{33}e^{\theta_3-\theta_2}}. \tag{23}$$

The asymptotic solutions of u_{23} for $t\to-\infty$ and $t\to+\infty$ differ in the amplitudes as well as the phases. That is because there is an interaction of u_{12}, u_{13} and u_{23} around $t=0$. The total energy $\int(|u_{12}|^2+|u_{13}|^2+|u_{23}|^2)dx\,dy$ still conserves.

At an extreme case, let $h_{23}=0$ and $g_{23}\neq 0$ [this is always possible since the only constraints on $(g_{\mu\nu})$ are Hermitian and positivity], then a u_{23} wave disappears as $t\to+\infty$ although it exists as $t\to-\infty$.

On the other hand, if $(g_{\mu\nu})$ is unitary, then $h_{\mu\nu}=\overline{g_{\nu\mu}}$ and the asymptotic behavior of $|u_{23}|$ as $t\to-\infty$ and $t\to+\infty$ are the same.

The asymptotic behavior of u_{12} is similar when $\pi_1=\pi_2=0$, so is that of u_{13} when $\pi_1=\pi_3=0$.

IV. MULTISOLITON SOLUTIONS

Since the velocities of solitons do not depend on the choice of λ, Proposition 4 of Ref. 14 that is explained in Remark 1 fails. However, we can still see several peaks after twice Darboux transformations, although all these peaks move in the same velocity.

For $l>1$, we have obtained the solution $u^{[l]}_{\alpha\beta}$ given by (12). Now that the limit $t\to\pm\infty$ cannot separate these peaks, we consider the asymptotic behavior of the solutions when $C\to\infty$ in some way. This describes the separation of the peaks when the phase of each single soliton is large enough.

It is well known that H_j and $H_j\cdot\mathrm{diag}(\gamma_1^{(j)},\gamma_2^{(j)},\gamma_3^{(j)})$ ($\gamma_1^{(j)},\gamma_2^{(j)},\gamma_3^{(j)}$ are constants) give the same solution $u^{[l]}_{\alpha\beta}$ [see also (10) and (11)]. Therefore, we can rewrite H_j in (9) as

$$H_j=\begin{pmatrix} e^{\sqrt{-1}\lambda_j(x+Jy+Kt)-QL^{(j)}} & \\ & D^{(j)}\end{pmatrix}e^{QL^{(j)}}, \tag{24}$$

where $L^{(j)}=\mathrm{diag}(L_1^{(j)},L_2^{(j)},L_3^{(j)})$ are arbitrary real constant diagonal matrices, Q is a real number, and $D^{(j)}=C^{(j)}e^{-QL^{(j)}}$.

The discussion in Secs. IV and VI of Ref. 14 can be used directly here. Let $x=\xi_0+Qw_\xi$, $y=\eta_0+Q\omega_\eta$ where w_ξ, w_η are real constants (''velocity'' with respect to Q). Let

$$\begin{aligned}\sqrt{-1}\phi_{i\alpha}&\equiv\sqrt{-1}\lambda_i(x+J_\alpha y+K_\alpha t)-QL_\alpha^{(i)}\\&=\sqrt{-1}\lambda_i(\xi_0+J_\alpha\eta_0+K_\alpha t)+(\sqrt{-1}\lambda_i(w_\xi+J_\alpha w_\eta)-L_\alpha^{(i)})Q.\end{aligned}$$

Suppose

$$\det\begin{pmatrix}1 & J_\alpha & L_\alpha^{(i)}/\lambda_{iI}\\ 1 & J_\beta & L_\beta^{(j)}/\lambda_{jI}\\ 1 & J_\gamma & L_\gamma^{(k)}/\lambda_{kI}\end{pmatrix}\neq 0 \tag{25}$$

for mutually different pairs (α,i), (β,j), (γ,k). Here λ_{iI} is the imaginary part of λ_α.

Now fix $D^{(j)}$, $L^{(j)}$, and let $Q\to+\infty$ or $-\infty$. Note that

$$\mathrm{Re}(\sqrt{-1}\lambda_i(w_\xi+J_\alpha w_\eta)-L_\alpha^{(i)})=-\lambda_{iI}(w_\xi+J_\alpha w_\eta)-L_\alpha^{(i)}.$$

Therefore, Im $\phi_{i\alpha}$ keeps finite if and only if $\lambda_{iI}(w_\xi+J_\alpha w_\eta)+L_\alpha^{(i)}=0$.

The discussion in Secs. IV and VI of Ref. 14 implies the following.

Proposition 1: Suppose the matrix H_j in (9), (10), (11) can be written as

$$H_j=\begin{pmatrix} e^{QA^{(j)}+B^{(j)}} \\ D^{(j)} \end{pmatrix}$$

where Q is a parameter, $A^{(j)}=diag(A_1^{(j)},\ldots,A_N^{(j)}),B^{(j)}=diag(B_1^{(j)},\ldots,B_N^{(j)})$ are $N\times N$ diagonal matrices independent of $Q,D^{(j)}$ are $N\times N$ matrices independent of Q. Let $u_{\alpha\beta}^{[l]}$ be the solution given by l Darboux transformations. Then the following occurs.

(1) If there is at most one pair (α,i) such that $A_\alpha^{(i)}=0$, then $u_{\mu\nu}^{[l]}\to 0$ for all $\mu<\nu$ when $Q\to+\infty$ or $-\infty$.

(2) If there are exactly two pairs $(\alpha,i)\neq(\beta,j)$ $(\alpha<\beta)$ such that $A_\alpha^{(i)}=A_\beta^{(j)}=0$, then, when $Q\to+\infty$ or $-\infty$, $u_{\mu\nu}^{[l]}\to 0$ for all $\mu<\nu$ except $\mu=\alpha$, $\nu=\beta$.

For the H_j's in (24), Proposition 1 implies the following.

(1) If (w_ξ,w_η) is chosen so that there is at most one pair (α,i), such that $\lambda_{iI}(w_\xi+J_\alpha w_\eta)+L_\alpha^{(i)}=0$, then $u_{\mu\nu}^{[l]}\to 0$ for all $\mu<\nu$ when $Q\to+\infty$ or $-\infty$.

(2) If (w_ξ,w_η) is chosen so that there are exactly two pairs $(\alpha,i)\neq(\beta,j)(\alpha<\beta)$ such that

$$\begin{aligned}\lambda_{iI}(w_\xi+J_\alpha w_\eta)+L_\alpha^{(i)}=0,\\ \lambda_{jI}(w_\xi+J_\beta w_\eta)+L_\beta^{(j)}=0,\end{aligned}\tag{26}$$

i.e.,

$$w_\xi=-\frac{L_\alpha^{(i)}/\lambda_{iI}-L_\beta^{(j)}/\lambda_{jI}}{J_\alpha-J_\beta},\quad w_\eta=-\frac{J_\alpha L_\beta^{(j)}/\lambda_{jI}-J_\beta L_\alpha^{(i)}/\lambda_{iI}}{J_\alpha-J_\beta},\tag{27}$$

then, when $Q\to+\infty$ or $-\infty$, $u_{\mu\nu}^{[l]}\to 0$ for all $\mu<\nu$ except $\mu=\alpha$, $\nu=\beta$.

(3) If (25) holds for mutually different pairs (α,i), (β,j), (γ,k), then for any (w_ξ,w_η), there are at most two pairs (α,i), (β,j) such that (26) holds.

Therefore, for any α, β, unless (w_ξ,w_η) takes the value in (27), $u_{\alpha\beta}^{[l]}\to 0$. Since i,j in (27) can be $1,\ldots,l$, respectively, $u_{\alpha\beta}^{[l]}$ has at most l^2 peaks. Thus, we have the following.

Theorem 1: *Let λ_j $(j=1,\ldots,l)$ be complex numbers such that $\lambda_j\neq\lambda_k(j\neq k),\lambda_j\neq\overline{\lambda_k}$ for all $1\leqslant j,k\leqslant l$. Let $L^{(j)}$'s be 3×3 constant diagonal matrices such that (25) holds, $D^{(j)}$'s be 3×3 nondegenerate constant matrices. Let $C^{(j)}=D^{(j)}e^{QL^{(j)}}$ and construct H_j as in (9). Then as $Q\to+\infty$ or $-\infty$, each component $u_{\alpha\beta}^{[l]}$ of the solution derived by the Darboux transformation of degree l has at most l^2 peaks for fixed time t.*

Remark 3: Generally, when (26) holds, $u_{\alpha\beta}^{[l]}$ tends to a nonzero function unless its coefficient tends to zero. Hence, usually there are exact l^2 peaks for each $u_{\alpha\beta}^{[l]}$ when Q is large enough. Of course, if a certain coefficient vanishes (e.g., $h_{23}=0$ or $g_{23}=0$ for u_{23} in a single-soliton case), the corresponding peak disappears.

When we only consider the asymptotic behavior of $u_{\alpha\beta}^{[l]}$, a condition weaker than (25) is enough to separate the peaks as $Q\to\infty$. This is because as $t\to\infty$, the interaction between $u_{\alpha\beta}^{[l]}$ and any other $u_{\mu\nu}^{[l]}$ vanishes.

As in Sec. III consider u_{23} and choose the velocity such that $\pi_2=\pi_3=0$, then $\pi_1\neq 0$. Take the coordinates ξ, η given by (19). Since $b_j\equiv\lambda_{jI}\neq 0$, $b_j\pi_1 t\to\infty$ as $t\to\infty$. Therefore, the limit Darboux matrix can be constructed by

$$H_j(-\infty)=\begin{pmatrix} 0 & 0 & 0 \\ 0 & e^{\sqrt{-1}\lambda_j(\xi+J_2\eta)-QL_2^{(j)}} & 0 \\ 0 & 0 & e^{\sqrt{-1}\lambda_j(\xi+J_3\eta)-QL_3^{(j)}} \\ D_{11} & D_{12} & D_{13} \\ D_{21} & D_{22} & D_{23} \\ D_{31} & D_{32} & D_{33} \end{pmatrix}$$

if $b\pi_1 t\to-\infty$, or

$$H_j(+\infty)=\begin{pmatrix} 1 & 0 & 0 \\ 0 & e^{\sqrt{-1}\lambda_j(\xi+J_2\eta)-QL_2^{(j)}} & 0 \\ 0 & 0 & e^{\sqrt{-1}\lambda_j(\xi+J_3\eta)-QL_3^{(j)}} \\ 0 & D_{12} & D_{13} \\ 0 & D_{22} & D_{23} \\ 0 & D_{32} & D_{33} \end{pmatrix}$$

if $b\pi_1 t\to+\infty$. Now let $\xi=\xi_0+Qw_\xi$, $\eta=\eta_0+Qw_\eta$. Clearly, if $(H_j(-\infty))_{(1,1)}$ is replaced by $e^{-|Q|}$ and $(H_j(+\infty))_{(1,1)}$ is replaced by $e^{|Q|}$, the limit Darboux transformation is the same when $Q\to\infty$. Then, the coefficients of Q in the power of $(H_j(\pm\infty))_{(1,1)}$ are always nonzero. Therefore, according to Proposition 1, we only need to guarantee that (25) holds for $(\alpha,i)\neq(\beta,j)$ with $\alpha,\beta\in\{2,3\}$ so that $u_{\alpha\beta}^{[I]}(-\infty)$, the asymptotic solution for $t\to-\infty$, does not tend to zero, and $u_{\mu\nu}^{[I]}(-\infty)\to0$ for any $(\mu,\nu)\neq(\alpha,\beta)$. This implies that we only need that (25) holds for all mutually different pairs (α,i), (β,j), (γ,k) with $\alpha,\beta,\gamma\in\{2,3\}$.

Since α, β, γ can only take two values and J_α's are mutually different, (25) is equivalent to

$$L_\alpha^{(i)}/\lambda_{iI}\neq L_\alpha^{(j)}/\lambda_{jI}\quad(\alpha=2,3,\quad i\neq j).$$

The same argument can be applied to $u_{23}^{[I]}(+\infty)$, the asymptotic solution for $t\to+\infty$.

Clearly, there are corresponding conclusions for $u_{12}^{[I]}$, $u_{13}^{[I]}$. Therefore, we have the following.

Theorem 2: *Given two integers α, β with $1\leqslant\alpha<\beta\leqslant3$. Let λ_j $(j=1,...,l)$ be as in Theorem 1, $D^{(j)}$'s be 3×3 nondegenerate constant matrices. Let $L^{(j)}$'s be 3×3 constant diagonal matrices such that $L_\alpha^{(i)}/\lambda_{iI}\neq L_\alpha^{(j)}/\lambda_{jI}$, $L_\beta^{(i)}/\lambda_{iI}\neq L_\beta^{(j)}/\lambda_{jI}$ for $i\neq j$. Let $C^{(j)}=D^{(j)}e^{QL^{(j)}}$ and construct H_j as in (9). Then as $Q\to+\infty$ or $-\infty$, the asymptotic solutions $u_{\alpha\beta}^{[I]}(-\infty)$ and $u_{\alpha\beta}^{[I]}(+\infty)$ have at most l^2 peaks respectively.*

Remark 4: Both Theorem 1 and Theorem 2 are valid for the N-wave equation, except that 3 is replaced by N. Here we discuss three-wave equation for its simplicity and importance.

Remark 5: Return to the case of single-soliton solutions. In (20), (21), the phase of the soliton is characterized by

$$\phi_1=\ln(e^{s^{(j)}(t)}+e^{-s^{(j)}(t)}h_{11}^{(j)}\det g^{(j)})-\ln(e^{-s^{(j)}(t)}+e^{s^{(j)}(t)}g_{11}^{(j)}\det h^{(j)}),$$

$$\phi_2=\ln(e^{s^{(j)}(t)}h_{22}^{(j)}+e^{-s^{(j)}(t)}g_{33}^{(j)})-\ln(e^{-s^{(j)}(t)}g_{22}^{(j)}+e^{s^{(j)}(t)}h_{33}^{(j)}).$$

If we let $L_{\alpha\alpha}^{(j)}=g_{\alpha\alpha}^{(j)}/Q$, then, when $L^{(j)}$ is fixed, $Q\to+\infty$ implies $\phi_1\to+\infty$ and ϕ_2 is bounded.

Here we show some figures that describe the behavior of the solitons given by a Darboux transformation of degree 2. Figures 1, 3, 5, and 7 correspond to time $t=-16$, 0, 12, and 16, respectively. As discussed above, these solitons have at most four peaks. Here the vertical axis is $|u|^{1/2}\equiv(|u_{12}|^2+|u_{13}|^2+|u_{23}|)^{1/4}$. Therefore, all three components are shown in one figure. The corresponding parameters are

(Received 12 May 1997; accepted for publication 6 August 1997)

We define under which circumstances two multiwarped product spacetimes can be considered equivalent and then we classify the spaces of constant curvature in the Euclidean and Lorentzian signature. For dimension $D=2$, we get essentially twelve representations, for $D=3$ exactly eighteen. More generally, for every even D, $5D+2$ cases exist, whereas for every odd D, $5D+3$ cases exist. For every D, exactly one half of them has the Euclidean signature. Our definition is well suited for the discussion of multidimensional cosmological models, and our results give a simple algorithm to decide whether a given metric represents the inflationary de Sitter spacetime (in unusual coordinates) or not. © *1998 American Institute of Physics.* [S0022-2488(98)02301-9]

I. INTRODUCTION

Recently, a lot of papers have dealt with multidimensional cosmological models, cf., e.g. Refs. 1–3 and references cited there. In these works, the ansatz for the metric is a generalized warped product of several spaces, with the warping functions depending on the time t only, i.e.,

$$ds^2=dt^2-\sum_{k=1}^{n} a_k^2(t)d\sigma_k^2, \tag{1.1}$$

where each $d\sigma_k^2$ represents a Riemannian space of dimension $d_k\geqslant 1$. In the usual interpretation, one requires $d_1=3$ and $d\sigma_1^2$ to be the physical 3-space, whereas all other spaces $d\sigma_k^2$, $k\geqslant 2$ are internal spaces. However, our approach is not restricted to this interpretation.

One of the often discussed questions in this context is the appearance of an inflationary phase of cosmic evolution. Its geometry is usually represented by a spacetime of constant negative curvature, called de Sitter spacetime. It is well-known how to represent the de Sitter spacetime of arbitrary dimension in the form (1.1), but up to now there does not exist a classification of the metrics of the general form (1.1) to decide which of them corresponds to spaces of constant curvature.

To elucidate what this means, let us consider the metrics (1.2) and (1.3),

$$ds^2=dt^2-\sinh^2t dx^2-\cosh^2t(dy^2+\sin^2y dz^2) \tag{1.2}$$

[see, e.g., Ref. 4, Eq. (3.18)]. The metric (1.2) is of the type (1.1) and is obviously a cosmological model of Kantowski–Sachs type. The metric (1.2) is known to represent a vacuum solution of Einstein's equations with a positive cosmological term. In agreement with the cosmological no-hair theorem it is asymptotically de Sitter. In the coordinates used, the metric (1.2) seems to define an anisotropic model, however (cf. Ref. 4) it is nothing but a piece of the isotropic de Sitter spacetime in unusual coordinates, and moreover, the coordinate transformation necessary to bring it to the classical form is quite involved.

A related metric is (cf. Ref. 5, Eq. (4.6)),

$$ds^2=dt^2+\sin^2t dx^2+\cos^2t dy^2, \tag{1.3}$$

 © 1998 American Institute of Physics

which is the metric of the standard 3-sphere in unusual coordinates.

It is the purpose of the present paper to give a complete classification of all the metrics of type (1.1) which represent spaces of constant curvature.

The paper is organized as follows: Section II introduces the generalized warped products and defines the normal form of the metric (1.1). Section III gives the results for the dimension $D\leqslant 3$ and Section IV covers the remaining cases $D\geqslant 4$. In Sec. V, we consider a slightly different form of the metric, where the a_k can additionally depend on one of the spatial coordinates, but the $d\sigma_k^2$ have dimension 1. Section VI discusses the results.

II. GENERALIZED WARPED PRODUCTS

Usually, a warped product is the conformally transformed Cartesian product between two Riemannian spaces, where the conformal factor, called the warping function, depends on the coordinates of one of the factors only. If there are more than two factor spaces, then there exist several possible generalizations of that notion. We will restrict ourselves to the following types of generalized warped products: all $a_k>0$ and

$$ds^2=dt^2\pm\sum_{k=1}^{n} a_k^2(t)d\sigma_k^2 \tag{2.1}$$

and each $d\sigma_k^2$ is a Riemannian space of dimension $d_k\geqslant 1$. Thus we consider the Euclidean (upper sign) and the Lorentzian (lower sign) signatures of the metric. In this way we are able to cover both Eqs. (1.2) and (1.3). Obviously, the metric (2.1) represents a usual warped product for $n=1$. The dimension of ds^2 is $D=1+\Sigma d_k$. We want to find out under which circumstances the metric (2.1) represents a space of constant curvature locally (so we do not discuss whether zeroes of the functions $a_k(t)$ give rise to coordinate singularities and whether our metrics are geodesically complete).

To get a uniquely defined classification, we start by explaining under which circumstances two metrics of type (2.1) will be considered to be the same:

(A) Any constant $c_k>0$ can be shifted between $a_k^2(t)$ and $d\sigma_k^2$.
(B) ds^2 can be multiplied by a positive constant, or in other words: t and every $a_k(t)$ can be multiplied by the same positive factor.
(C) Linear transformations of t will be allowed.
(D) Permutations of the indices k are allowed.
(E) Coordinate transformations involving only the coordinates of one of the spaces $d\sigma_k^2$ are allowed.
(F) If two warping functions coincide, $a_j(t)=a_k(t)$, $(j\neq k)$, then $a_j^2(t)d\sigma_j^2+a_k^2(t)d\sigma_k^2$ can be replaced by $a_j^2(t)(d\sigma_j^2+d\sigma_k^2)$.

Comment: (B) means that we do not distinguish between homothetically equivalent spaces, or, in other words, a change of the length unit will not be considered essential. (F) means that the number n of terms in the sum of Eq. (2.1) is not fixed. However, we can define the normal form of the representation (2.1) as follows: whenever possible (if necessary by the help of introducing suitable constants c_k according to (A), the replacement (F) shall be done (of course, this procedure terminates uniquely). Equivalently we may say: the normal form of the representation is that one where the number n is minimal. Furthermore it holds that the metric (2.1) is in normal form if the quotients $a_j(t)/a_k(t)$ are constant for $k=j$ only.

For technical reasons, we will sometimes discuss spaces in non-normal form. However, if the number n of factors is explicitly mentioned, we always refer this to the normal form and, without loss of generality, we may restrict to metrics (2.1) in normal form.

III. CLASSIFICATION FOR DIMENSION $D\leqslant 3$

$D=1$ implies $n=0$ and $ds^2=dt^2$ represents flat space. So we have just one representation for $D=1$.

A. Dimension $D=2$

Let $D=2$, then $d\sigma_1^2=dx^2$ is flat. (Spaces of constant curvature in $D=2$ have been discussed, for example, in Ref. 6.)

We write $a(t)$ instead of $a_1(t)$ and get

$$ds^2=dt^2\pm a^2(t)dx^2, \tag{3.1}$$

which is already in normal form. This space is of constant curvature iff the curvature scalar $R=-2\ddot{a}/a$ is constant, where a dot denotes d/dt. Both signatures can be considered simultaneously, because they are related by the imaginary coordinate transformation $x\to ix$. (Here we give the derivation for the known case $D=2$ in detail in order to show how our formulation works, we do not repeat the analogous arguments in the other cases.) According to (B), we may restrict to the three cases $R=0$, $R=2$ and $R=-2$. For $R=0$, $a(t)$ must be linear in t, and according to (A) and (C), the following representations are singled out:

$$ds^2=dt^2\pm dx^2 \tag{3.2}$$

and

$$ds^2=dt^2\pm t^2dx^2. \tag{3.3}$$

Clearly, these are the Cartesian and polar coordinates respectively for the flat space. For $R=2$, $\ddot{a}+a=0$ has to be solved. According to (A) and (C), only one representation, the standard metric of the 2-sphere, appears:

$$ds^2=dt^2\pm\sin^2 t dx^2. \tag{3.4}$$

For $R=-2$, however, three different representations appear for each of the two signatures: (By condition (C) the solution e^{-2t} can be excluded.)

$$ds^2=dt^2\pm e^{2t}dx^2 \tag{3.5}$$

further

$$ds^2=dt^2\pm\sinh^2 t dx^2 \tag{3.6}$$

and

$$ds^2=dt^2\pm\cosh^2 t dx^2. \tag{3.7}$$

An explicit coordinate transformation between the metrics (3.5) and (3.6) is deduced in the appendix of Ref. 4. Metric (3.4) and (3.6) are related by multiplying s, t and x by i.

Thus we have exactly twelve different representations of a space of constant curvature for $D=2$. Six of them have $R<0$ and only two have $R>0$.

B. Dimension $D=3$: First part

Let $D=3$. The space is of constant curvature iff the three eigenvalues of the Ricci tensor coincide. Let us start recalling the known cases. The Cartesian product of flat spaces is flat. So we can get from Eqs. (3.2), (3.3) for the $R=0$ cases:

$$n=1,\quad ds^2=dt^2\pm(dx^2+dy^2) \tag{3.8}$$

and

$$n=2,\quad ds^2=dt^2\pm(t^2dx^2+dy^2) \tag{3.9}$$

For $R>0$ we know the examples

$$n=1,\quad ds^2=dt^2+\sin^2 t(dx^2+\sin^2 x dy^2) \tag{3.10}$$

and

$$n=2, \quad ds^2=dt^2\pm(\sin^2 t dx^2+\cos^2 t dy^2). \tag{3.11}$$

Here, (3.10) is the standard three-sphere and (3.11) is the metric (1.3).[5] Replacing x by ix, we get from the metric (3.10) the Lorentzian signature with $R>0$:

$$n=1, \quad ds^2=dt^2-\sin^2 t(dx^2+\sinh^2 x dy^2). \tag{3.12}$$

For $R<0$ we get analogously, as in Section III A:

$$n=1, \quad ds^2=dt^2\pm e^{2t}(dx^2+dy^2) \tag{3.13}$$

and

$$n=2, \quad ds^2=dt^2\pm(\sinh^2 t dx^2+\cosh^2 t dy^2) \tag{3.14}$$

(cf. Ref. 5, Eq. (3.9)). So, we have again twelve different cases. However, before checking their completeness in Section III D, we have to discuss the case $n=1$ in the next section.

C. The case $n=1$ in arbitrary dimension

Let $D\geqslant 3$ be arbitrary and be $n=1$ in Eq. (2.1). So the index 1 may be omitted and $d=D-1$. We write $d\sigma^2=h_{\alpha\beta}dx^\alpha dx^\beta$, where $h_{\alpha\beta}$ depends on the spatial coordinates only, $\alpha,\beta=1,\ldots,d$. For $ds^2=dt^2\pm a^2(t)d\sigma^2$ we get $R_{00}=-d\ddot{a}/a$. Indices $j,k,\ldots$ take the D values $0,1,\ldots,d$. If ds^2 is a space of constant curvature, then it must be an Einstein space, i.e. Ricci tensor and metric tensor differ by a constant factor only. So we may assume, without loss of generality due to condition (B), that

$$R_{jk}=\lambda d g_{jk} \quad \text{with } \lambda\in\{-1,1,0\} \tag{3.15}$$

Now, $g_{00}=1$ and we set $\lambda=-\ddot{a}/a$. So we are in a case similar to that of Sec. III A. Consequently, only the same six functions $a(t)$ may appear: $a=1$ and $a=t$ for $R=0$, $a=\sin t$ for $R>0$, and $a=e^t$, $a=\sinh t$, $a=\cosh t$ for $R<0$.

Let us now apply the $\alpha\beta$-component of Eq. (3.15), and let $P_{\alpha\beta}$ denote the Ricci tensor of $d\sigma^2$. We get:

$$P_{\alpha\beta}=R_{\alpha\beta}\pm h_{\alpha\beta}[a\ddot{a}+(d-1)\dot{a}^2]. \tag{3.16}$$

From (3.15) and (3.16) we get

$$P_{\alpha\beta}=\Lambda h_{\alpha\beta}, \quad \Lambda=\pm(d-1)(\dot{a}^2+\lambda a^2). \tag{3.17}$$

It is easy to see that Λ is a constant. Concluding, for $n=1$, $d\sigma^2$ must be an Einstein space of constant curvature scalar.

D. Dimension $D=3$: Second part

Now we are ready to complete the discussion for $D=3$. For $n=1$, we have $d=2$, and by Sec. III C, $d\sigma^2$ has constant curvature scalar. This means that $d\sigma^2$ is of constant curvature here, and (3.17) reads $\dot{a}^2+\lambda a^2=\pm\Lambda$. $\lambda=0$, $a=1$ gives the metric (3.8). $\lambda=0$, $a=t$, gives $\Lambda=\pm 1$, namely

$$n=1, \quad ds^2=dt^2+t^2(dx^2+\sin^2 x dy^2) \tag{3.18}$$

which is flat space in spherical coordinates, and

$$n=1, \quad ds^2=dt^2-t^2(dx^2+\sinh^2 x dy^2), \tag{3.19}$$

$\lambda=1$, $a=\sin\ t$ gives $\Lambda=\pm 1$, i.e., the metric (3.10) and (3.12). $\lambda=-1$, $a=e^t$ yields $\Lambda=0$, i.e., the metric (3.13). $\lambda=-1$, $a=\sinh t$ yields $\Lambda=\pm 1$, i.e.,

$$n=1, \quad ds^2=dt^2+\sinh^2\ t(dx^2+\sin^2\ xdy^2) \tag{3.20}$$

and

$$n=1, \quad ds^2=dt^2-\sinh^2\ t(dx^2+\sinh^2\ xdy^2). \tag{3.21}$$

Finally, $\lambda=-1$, $a=\cosh t$ yields $\Lambda=\mp 1$, i.e.,

$$n=1, \quad ds^2=dt^2+\cosh^2\ t(dx^2+\sinh^2\ xdy^2) \tag{3.22}$$

and

$$n=1, \quad ds^2=dt^2-\cosh^2\ t(dx^2+\sin^2\ xdy^2). \tag{3.23}$$

This completes the discussion for $n=1$, and the six metrics (3.18)–(3.23) together with the twelve metrics of Section III B form already eighteen different representations of a space of constant curvature in $D=3$. It remains to check completeness for the case $n=2$. So we have to use the ansatz

$$ds^2=dt^2\pm(a^2(t)\ dx^2+b^2(t)\ dy^2) \tag{3.24}$$

and have to ensure that the three eigenvalues of the Ricci tensor of (3.24) coincide. This is equivalent to

$$\frac{\ddot{a}}{a}=\frac{\ddot{b}}{b}=\frac{\dot{a}}{a}\frac{\dot{b}}{b}. \tag{3.25}$$

A detailed investigation of Eq. (3.25) shows that all solutions are already covered by the eighteen cases mentioned before.

Let us summarize the results for $D=3$: six representations with $n=2$ and twelve representations with $n=1$ form a complete classification. Six of these are flat, four have positive curvature and the remaining eight have $R<0$.

IV. CLASSIFICATION FOR DIMENSION $D\geqslant 4$

From now on, we put $D\geqslant 4$. It holds: ds^2 is of constant curvature iff it is an Einstein space with vanishing Weyl tensor. In Sec. IV A we review the known cases, and in Sec. IV B we give a general account of conformal flatness.

A. Dimension $D\geqslant 4$: First part

Let $\delta_{\alpha\beta}$ be the Kronecker tensor. The generalization of Eqs. (3.8), (3.9) with $R=0$ reads

$$n=1, \quad ds^2=dt^2\pm\delta_{\alpha\beta}dx^\alpha dx^\beta \tag{4.1}$$

and

$$n=2, \quad ds^2=dt^2\pm(t^2dx^2+\delta_{\alpha\beta}dx^\alpha dx^\beta). \tag{4.2}$$

Generalizing (3.18), (3.19) with $R=0$ yields

$$n=1, \quad ds^2=dt^2+t^2d\Omega_k^2 \tag{4.3}$$

and

$$n=1, \quad ds^2=dt^2-t^2d\overline{\Omega_k^2} \tag{4.4}$$

where $k=D-1$ and $d\Omega_k^2$ is the metric of the standard sphere of dimension k, while $d\overline{\Omega_k^2}$ denotes the corresponding space of constant negative curvature.

For $R>0$ we get from (3.10) and (3.12)

$$n=1, \quad ds^2=dt^2+\sin^2 t d\Omega_k^2 \tag{4.5}$$

and

$$n=1, \quad ds^2=dt^2-\sin^2 t d\overline{\Omega_k^2}, \tag{4.6}$$

Equation (4.6) is the anti-de Sitter spacetime written as an open Friedman model for $D=4$.

For $R<0$, we get from (3.13)

$$n=1, \quad ds^2=dt^2\pm e^{2t}\delta_{\alpha\beta}dx^\alpha dx^\beta \tag{4.7}$$

and from (3.20)–(3.23)

$$n=1, \quad ds^2=dt^2+\sinh^2 t d\Omega_k^2 \tag{4.8}$$

and

$$n=1, \quad ds^2=dt^2-\sinh^2 t d\overline{\Omega_k^2}. \tag{4.9}$$

Further,

$$n=1, \quad ds^2=dt^2+\cosh^2 t d\overline{\Omega_k^2} \tag{4.10}$$

and

$$n=1, \quad ds^2=dt^2-\cosh^2 t d\Omega_k^2. \tag{4.11}$$

The metric (4.11) represents the de Sitter spacetime as a closed Friedman model for $D=4$. So, for every $D\geqslant 4$, we have found twelve representations with $n=1$, namely Eqs. (4.1) and (4.3)–(4.11).

A further generalization of (4.3)–(4.4) is possible with $R=0$ and $2\leqslant k\leqslant D-2$,

$$n=2, \quad ds^2=dt^2+t^2 d\Omega_k^2+\delta_{\alpha\beta}dx^\alpha dx^\beta \tag{4.12}$$

and

$$n=2, \quad ds^2=dt^2-t^2 d\overline{\Omega_k^2}-\delta_{\alpha\beta}dx^\alpha dx^\beta \tag{4.13}$$

Together with (4.2) this yields $2(D-2)$ representations with $R=0$, $n=2$.

For $D=4$, the following representations are known, cf. Eq. (1.2) above and Ref. 4 for details.

$R>0$,

$$n=2, \quad ds^2=dt^2+\sin^2 t dx^2+\cos^2 t d\Omega_2^2 \tag{4.14}$$

and

$$n=2, \quad ds^2=dt^2-\sin^2 t dx^2-\cos^2 t d\overline{\Omega_2^2}. \tag{4.15}$$

$R<0$,

$$n=2, \quad ds^2=dt^2+\sinh^2 t dx^2+\cosh^2 t d\overline{\Omega_2^2} \tag{4.16}$$

and

$$n=2, \quad ds^2=dt^2-\sinh^2 t dx^2-\cosh^2 t d\Omega_2^2. \tag{4.17}$$

Further,

$$n=2, \quad ds^2=dt^2+\cosh^2 t dx^2+\sinh^2 t d\Omega_2^2 \tag{4.18}$$

and

$$n=2, \quad ds^2=dt^2-\cosh^2 t dx^2-\sinh^2 t d\overline{\Omega}_2^2. \tag{4.19}$$

So, for $D=4$, we have already 10 representations with $n=2$. By the way, the metric (4.17) is the same as (1.2).

B. Conformal flatness

Spaces of constant curvature are conformally flat, and for $D\geqslant 4$, conformal flatness is equivalent to the vanishing of the conformally invariant Weyl tensor C^i_{jkl}, defined as

$$C_{ijkl}=R_{ijkl}-\frac{1}{D-2}(R_{ik}g_{jl}+R_{jl}g_{ik}-R_{jk}g_{il}-R_{il}g_{jk})+\frac{R}{(D-1)(D-2)}(g_{ik}g_{jl}-g_{jk}g_{il}). \tag{4.20}$$

Now, let $n=1$, i.e., $ds^2=dt^2\pm a^2(t)d\sigma^2$. According to Sec. III C, $d\sigma^2$ must be an Einstein space. But ds^2 is conformally flat, hence $d\hat{s}^2=ds^2/a^2(t)$ is conformally flat too. After a time-rescaling, we set

$$d\hat{s}^2=d\hat{t}^2\pm d\sigma^2.$$

Inserting this metric into Eq. (4.20), applying $\hat{C}_{ijkl}=0$ and the fact that $d\sigma^2$ is an Einstein space, gives as a result that $d\sigma^2$ must be a space of constant curvature. This proves that our classification for the case $n=1$ given in Sec. IV A is already complete.

Let $n\geqslant 2$ in the following. We want to show that every $d\sigma_k^2$ is a space of constant curvature. For $d_k=1$, this is trivial. For any $d_k\geqslant 2$ we denote d_k by d and $D-d$ by m. Because of $n\geqslant 2$ we have $m\geqslant 2$. Let $d\sigma_k^2=h_{\alpha\beta}(x^\alpha)dx^\alpha dx^\beta$ with $\alpha,\beta=1,\ldots,d$, and we write

$$ds^2=\pm a_k^2(t)d\sigma_k^2+d\Omega^2,$$

where $d\Omega^2$ is simply a description of the rest. Let $d\hat{s}^2=\pm ds^2/a_k^2(t)$, then we may write

$$d\hat{s}^2=h_{\alpha\beta}(x^\alpha)dx^\alpha dx^\beta+h_{AB}(x^A)dx^A dx^B,$$

where $A,B=0,d+1,\ldots,D-1$ (h_{AB} has unspecified signature). $d\sigma_k^2$ has curvature scalar $R_{(1)}$ and $d\hat{\Omega}^2=h_{AB}dx^A dx^B$ curvature scalar $R_{(2)}$. Therefore, the metric $d\hat{s}^2$ has curvature scalar $\hat{R}=R_{(1)}+R_{(2)}$. Then we apply (4.20) and the fact that $C_{\alpha A\beta B}$ vanishes. This gives

$$R_{\alpha\beta}h_{AB}+R_{AB}h_{\alpha\beta}=\frac{\hat{R}}{D-1}h_{\alpha\beta}h_{AB}. \tag{4.21}$$

We calculate the trace of this equation by multiplying with $h^{\alpha\beta}h^{AB}$. Observing that $d\geqslant 2$ and $m\geqslant 2$ this leads to

$$\frac{R_{(1)}}{d(d-1)}+\frac{R_{(2)}}{m(m-1)}=0. \tag{4.22}$$

$R_{(1)}$ depends on x^α only, $R_{(2)}$ on x^A only, consequently both of them are constant. By the way, for $m=d=D/2$ we get additionally $\hat{R}=0$. Knowing the constancy of $R_{(1)}$, we multiply Eq. (4.21) by h^{AB} and get the result that $d\sigma_k^2$ is an Einstein space with constant curvature scalar. In the last step we apply $C_{\alpha\beta\gamma\delta}=0$ with Eq. (4.20) to show that $d\sigma_k^2$ is a space of constant curvature.

C. Dimension $D \geqslant 4$: Second part

According to the previous results, it remains to discuss the cases with

$$n \geqslant 2, \quad ds^2 = dt^2 \pm \sum_{k=1}^{n} a_k^2(t) d\sigma_k^2, \tag{4.23}$$

where each of the spaces $d\sigma_k^2$ represents a space of constant curvature, and the quotients $a_k(t)/a_j(t)$ are constant for $k=j$ only. Let us start with the simplest case: every $d_k=1$, i.e., $n=D-1$, and we have to check the positive signature case only

$$n \geqslant 3, \quad ds^2 = dt^2 + \sum_{k=1}^{n} a_k^2(t)(dx^k)^2. \tag{4.24}$$

We define $\alpha_k = \dot{a}_k/a_k$, $H = \Sigma \alpha_k$, $H_2 = \Sigma \alpha_k^2$, and $\beta_k = \alpha_k - H/n$. Consequently, $\Sigma \beta_k = 0$. The equation $R_{AB} = \lambda g_{AB}$, λ = const, $A,B = 0,\ldots,n$ yields

$$\lambda + \dot{H} + H_2 = 0, \tag{4.25}$$

and

$$\lambda + \dot{\alpha}_k + \alpha_k H = 0. \tag{4.26}$$

Summing up the n equations (4.26), we get

$$n\lambda + \dot{H} + H^2 = 0. \tag{4.27}$$

It holds: $a_k(t)/a_j(t)$ is constant iff $\beta_k = \beta_j$.

Let $B = \Sigma \beta_k^2$, then it holds: the metric (4.23) has $n \geqslant 2$ in the normal form iff $B \neq 0$.

Proof: $B=0$ iff $\beta_k = 0$ for every k. But equality of all the β_k implies $\beta_k = 0$ because of $\Sigma \beta_k = 0$. q.e.d.

Inserting $H_2 = B + H^2/n$ into Eq. (4.25) we get

$$n\lambda + n\dot{H} + nB + H^2 = 0. \tag{4.28}$$

Equation (4.26) can be written as

$$n\lambda + n\dot{\beta}_k + \dot{H} + n\beta_k H + H^2 = 0. \tag{4.29}$$

(Of course, summing up the n equations (4.29) we recover (4.27).) The difference between (4.27) and (4.28) leads to

$$\dot{H} = -\frac{n\ B}{n-1}. \tag{4.30}$$

Because of $B>0$ we have $\dot{H}<0$.

The difference between (4.29) and (4.27) reads

$$\dot{\beta}_k + \beta_k H = 0. \tag{4.31}$$

This implies $\dot{B} = -2HB$ and with (4.30)

$$\left(\frac{\dot{B}}{B}\right) = \frac{2n}{n-1} B. \tag{4.32}$$

For $\lambda = 0$, we get from (4.27) $H = 1/t$, $(t>0)$, i.e., with (4.30),

$$B=\frac{n-1}{nt^2}. \tag{4.33}$$

With $H=1/t$, we can solve Eq. (4.31), obtaining $\beta_k=p_k/t$, $p_k=$const. Together with Eq. (4.33), we finally get

$$\sum p_k=0, \quad \sum p_k^2=\frac{n-1}{n}.$$

Consequently, $\alpha_k=\beta_k+1/(nt)=q_k/t$, with

$$\sum q_k=\sum q_k^2=1. \tag{4.34}$$

One can integrate these equations to $a_k(t)=t^{q_k}$ and Eqs. (4.34) give the defining condition for the d-dimensional Kasner solution.

Now we have to check under which conditions the Kasner solution

$$ds^2=dt^2+\sum_{k=1}^{n} t^{2q_k}(dx^k)^2 \tag{4.35}$$

is flat. (By the way, $n>1$ and (4.34) already imply $B>0$.) However, this requires the calculation of the Weyl tensor.

D. Calculating the Weyl tensor

Now we take the metric (4.24), assume that it is already an Einstein space, and calculate the Weyl tensor with the notations used in Sec. IV C. In this section the sum conventions will not be used. It turns out that the non-trivial components of the Weyl tensor read

$$0=C^{0k}_{0k}=-\dot{\alpha}_k-\alpha_k^2+c_1 \tag{4.36}$$

and

$$0=C^{jk}_{jk}=-\alpha_j\alpha_k+c_2, \quad j\neq k, \tag{4.37}$$

where c_1 and c_2 are constants which vanish iff ds^2 has vanishing curvature scalar. Now we are prepared to continue our discussion.

E. Dimension $D\geqslant 4$: Third part

Let $R=0$, i.e., $c_2=0$ in Eq. (4.37). This means that at most one of the functions α_j may be different from zero. If all of them are zero, we get Eq. (4.1), if one of them is non-zero, then we get (4.2), so no new representations are found here.

Let $R\neq 0$, i.e., $c_2\neq 0$ in Eq. (4.37). Let j,k,l be three different indices (which is possible because $n\geqslant 3$). Then (4.37) implies $c_2=\alpha_l\alpha_j=\alpha_l\alpha_k\neq 0$, hence $\alpha_l\neq 0$, and consequently $\alpha_j=\alpha_k$. Because of the arbitrariness in the choice of j and k, we conclude that all the functions α_k coincide. So we have the case $n=1$ in the normal form which has already been discussed above. This concludes the discussion for the case that all the spaces $d\sigma_k^2$ are flat. By condition (D) (see Sec. II), we may now assume that $d\sigma_1^2$ has non-vanishing curvature and consequently $d_1\geqslant 2$. So we have to check under which circumstances (again, the index 1 will be omitted)

$$ds^2=\pm a^2(t)d\sigma^2+dt^2\pm\sum_{k=2}^{n} a_k^2(t)d\sigma_k^2 \tag{4.38}$$

represents a space of constant curvature. If $a(t)$ is constant, this is impossible. Hence, $\alpha=\dot{a}/a\neq 0$. So, we have again the same situation as in Sec. IV B and we may apply Eq. (4.22) as follows: let

$$d\overline{s^2}=\frac{1}{a^2(t)}\left[dt^2\pm\sum_{k=2}^{n}a_k^2(t)d\sigma_k^2\right], \tag{4.39}$$

then $d\overline{s^2}$ must be a space of non-vanishing constant curvature.

Let $D=4$. Then necessarily $n=2$, and $d\sigma_k^2$ is one-dimensional, hence a flat space and $d\sigma^2$ has to be a plane of constant curvature. The results are easily calculated and are given by Eqs. (4.12)–(4.19), where we have to insert $k=2$ and $D=4$ in Eqs. (4.12) and (4.13).

Higher dimensions can be discussed by induction over D: Eq. (4.39) has the same structure (up to a redefinition of t), and therefore we can deduce all possible metrics, from which we can calculate the corresponding metrics (4.38) of dimension at least higher by two.

However, this is quite involved, so we prefer a different approach. A more careful inspection of Eq. (4.38) leads to the observation that Eq. (4.37) remains valid. Therefore, the discussion at the beginning of Sec. IV E still holds. Thus we can restrict to the case $n=2$ in the following. So we have to check: $R=0$,

$$ds^2=dt^2\pm(a^2(t)d\sigma^2+\delta_{\alpha\beta}dx^\alpha dx^\beta) \tag{4.40}$$

with $\dot{a}=0$ and $d\sigma^2$ not flat.

$R\neq 0$,

$$ds^2=dt^2\pm(a^2(t)d\sigma^2+b^2(t)d\sigma_2^2) \tag{4.41}$$

with $\dot{a}\neq 0$, $\dot{b}\neq 0$, and $d\sigma^2$ not flat.

For the case $R=0$, we get $a(t)=t$ and the metrics (4.12), (4.13). For the case $R\neq 0$, we get the generalization of (4.14)–(4.19) to higher dimensions, which read

$$n=2,\quad ds^2=dt^2+\sin^2 t d\Omega_j^2+\cos^2 t d\Omega_k^2 \tag{4.42}$$

and

$$n=2,\quad ds^2=dt^2-\sin^2 t d\overline{\Omega_j^2}-\cos^2 t d\overline{\Omega_k^2} \tag{4.43}$$

for $R>0$ and

$$n=2,\quad ds^2=dt^2+\sinh^2 t d\Omega_j^2+\cosh^2 t d\overline{\Omega_k^2} \tag{4.44}$$

and

$$n=2,\quad ds^2=dt^2-\cosh^2 t d\Omega_j^2-\sinh^2 t d\overline{\Omega_k^2} \tag{4.45}$$

for $R<0$, with $j+k=D-1$. In Eq. (4.42), only $2\leqslant j\leqslant k$ give new cases, these are $(D-4)/2$ for even D and $(D-3)/2$ for odd D. The same result appears for Eq (4.43). In Eq. (4.44), all $j,\ k\geqslant 2$ give new cases, $D-4$ in sum, as does Eq. (4.45).

V. A MORE GENERAL ANSATZ

In this section, we consider a slightly different ansatz for the metric of a space of constant curvature, which is suitable for a direct determination of its general form from the solution of a simple system of differential equations. It is well-known, in fact, that a maximally symmetric space is uniquely characterized by the property that

$$R_{ijkl}=\lambda(g_{ik}g_{jl}-g_{il}g_{jk}) \tag{5.1}$$

with a constant λ. Adopting an appropriate ansatz for the metric, (5.1) gives a set of differential equations which determine the conditions under which the space is of constant curvature.

We take a metric of the form

$$ds^2=dt^2\pm\left[a^2(t)d\rho^2+\sum_{i=1}^{D-2}b_i^2(\rho,t)(dx^i)^2\right], \tag{5.2}$$

where the metric functions depend on t and one ''spatial'' coordinate ρ. A more general form of the ansatz would require that $a=a(t,\rho)$, but our choice is necessary in order to obtain a tractable set of differential equations from (5.1). Anyway, our choice is not restrictive since the metric (5.2) can be seen as a multi-warped product of a two-dimensional space, spanned by the coordinates t and ρ, with a $(D-2)$-dimensional space, and is well known that the metric of a two-dimensional space of constant curvature can always be put in the form $dt^2\pm a^2(t)d\rho^2$ by a suitable choice of coordinates.

For simplicity, in this section we consider the case of Lorentzian signature. The Euclidean case is easily obtained following the same procedure. Inserting the ansatz (5.2) into (5.1), one obtains the following equations

$$\ddot{a}=\lambda a, \tag{5.3}$$

$$\ddot{b}_i=\lambda b_i, \tag{5.4}$$

$$\dot{a}\dot{b}_i-\frac{b_i''}{a}=\lambda a b_i, \tag{5.5}$$

$$\dot{b}_i\dot{b}_j-\frac{b_i'b_j'}{a^2}=\lambda b_i b_j, \tag{5.6}$$

$$a\dot{b}_i'-\dot{a}b_i'=0, \tag{5.7}$$

where a dot denotes a derivative with respect to t and a prime a derivative with respect to ρ. Equation (5.7) implies that

$$\frac{d}{dt}\left(\frac{b_i'}{a}\right)=0. \tag{5.8}$$

Hence, either $b_i'=0$ or $b_i=a(t)g_i(\rho)$. We can now pass to discuss the solutions of (5.3)–(5.7). In the following, we tacitly assume that the transformations of Section II can be applied to change the form of the solutions to their normal form.

A. $\lambda>0$

If $\lambda>0$, without loss of generality we can take $\lambda=1$ by condition (B). Equation (5.3) then implies $a=Ae^t+Be^{-t}$ with A and B integration constants. Moreover, if $b_i'=0$, Eq. (5.4) implies that $b_i=C_ie^t+D_ie^{-t}$, with C_i and D_i integration constants. Equations (5.5) and (5.6) then read

$$AD_i=-BC_i, \quad C_iD_j=-C_jD_i. \tag{5.9}$$

Only two distinct classes of solutions are available: if either $A=C_i=0$ or $B=D_i=0$, one has for any dimension D a solution of the general form (4.7). Further non-trivial solutions are available only in $D=3$, when $D_1=-BC_1/A$, or in $D=2$ and, modulo the transformations of Sec. II they reduce to the form (3.14) in $D=3$ or (3.6), (3.7) in $D=2$.

If $b_i'\neq0$, instead, one has

$$b_i=A(t)g_i(\rho)=(Ae^t+Be^{-t})g_i(\rho),$$

which substituted in (5.5), (5.6) gives

$$g_i''=-4ABg_i, \quad g_i'g_j'=4ABg_ig_j. \tag{5.10}$$

One must distinguish the case $AB>0$ from $AB<0$. If $AB>0$, $a(t)$ can be reduced to $\cosh t$, while, after a rescaling of ρ, $g_i=F_i\sin\rho+G_i\cos\rho$ and (5.10) implies $F_iF_j+G_iG_j=0$. A solu-

tion to the last equation is available only for $D\leqslant 4$, and can be put in the form (here and in the following, lower dimensional solutions can be obtained by suppressing some of the coordinates $x,y,\ldots$)

$$ds^2=dt^2-\cosh^2 t(d\rho^2+\sin^2 \rho dx^2+\cos^2 \rho dy^2), \tag{5.11}$$

which is of the type (4.11).

If $AB<0$, instead, $a(t)$ can be reduced to $\sinh t$, while $g_i=F_ie^{\rho}+G_ie^{-\rho}$ and (5.10) implies $F_iG_j+G_iF_j=0$. A solution to this equation valid in any dimensions, is given by $F_i=0$ or $G_i=0$ and can be written

$$ds^2=dt^2-\sinh^2 t\left(d\rho^2+e^{2\rho}\sum dx_k^2\right). \tag{5.12}$$

Another solution is available when $D\leqslant 4$, if $F_2G_1=-F_1G_2$, which can be reduced to the form

$$ds^2=dt^2-\sinh^2 t(d\rho^2+\sinh^2 \rho dx^2+\cosh^2 \rho dy^2). \tag{5.13}$$

Both solutions (5.11) and (5.12) are special cases of (4.9). A last possibility remains to be investigated, namely the case in which some of the b_i are independent of ρ and some are not. It is easy to see that in this case, Eq. (5.6) is a consequence of (5.5) and hence one gets two new five-dimensional solutions, and one in arbitrary dimensions, by combining (5.11)–(5.13) with (3.14)

$$ds^2=dt^2-\sinh^2 t\left(d\rho^2+e^{2\rho}\sum dx_k^2\right)-\cosh^2 tdy^2, \tag{5.14}$$

$$ds^2=dt^2-\sinh^2 t(d\rho^2+\sinh^2\rho dx^2+\cosh^2 \rho dy^2)-\cosh^2 tdz^2, \tag{5.15}$$

$$ds^2=dt^2-\cosh^2 t(d\rho^2+\sin^2 \rho dx^2+\cos^2 \rho dy^2)-\sinh^2 tdz^2. \tag{5.16}$$

The solutions (5.14)–(5.16) are all special cases of (4.45).

B. $\lambda<0$

If $\lambda<0$, (5.3) yields $a=A\sin t+B\cos t$, with A and B integration constants. If $b_i'=0$, Eq. (5.4) is solved by $b_i=C_i\sin t+D_i\cos t$ and Eqs. (5.5) and (5.6) imply

$$AC_i=-BD_i, \quad C_iC_j=-D_iD_j. \tag{5.17}$$

These relations admit solutions only for $D=3$, for example $B=C_1=0$ or $A=D_1=0$. All these solutions are equivalent, via the transformations of Section II, to (3.11).

If $b_i'\neq 0$, instead, one has

$$b_i=A(t)g_i(\rho)=(A\sin t+B\cos t)g_i(\rho)$$

which substituted in (5.5), (5.6) give respectively,

$$g_i''=-(A^2+B^2)g_i, \quad g_i'g_j'=-(A^2+B^2)g_ig_j. \tag{5.18}$$

These equations have solution $g_i=F_ie^{\rho}+G_ie^{-\rho}$, with $F_iG_j+G_iF_j=0$. Solutions to this equation exist up to four dimensions and take the form

$$ds^2=dt^2-\sin^2 t(d\rho^2+\sinh^2 \rho dx^2+\cosh^2 \rho dy^2) \tag{5.19}$$

and hence are of the type (4.6).

Finally, in the case in which some of the b_i are independent of ρ and some are not, it is easy to see that Eq. (5.10) is always satisfied and hence one gets one new five-dimensional solution, which again is a special case of (4.43)

$$ds^2=dt^2-\sin^2 t(d\rho^2+\sinh^2 \rho dx^2+\cosh^2 \rho dy^2)+\cos^2 tdz^2. \tag{5.20}$$

C. $\lambda = 0$

If $\lambda = 0$, a and b must be linear in t. Proceeding as before, one obtains the following possibilities: if $a = t$, b_i is constant for any i or can have the form $b_1 = t \sinh \rho$, $b_2 = t \cosh \rho$. One then recovers the solutions (4.2), or

$$ds^2 = dt^2 - t^2(d\rho^2 + \sinh \rho^2 dx^2 + \cosh^2 \rho dy^2), \tag{5.21}$$

which is equivalent to (3.19). If a is constant, one can have $b_1 = \rho$, $b_i = \text{const}$, $i \neq 1$ and hence (4.13).

To conclude this section, we observe that no new solutions are introduced by the ansatz (5.2). However, we did not formally define which is the generalization of condition (F), and so in this section, the classification is not such a strict one as in Sec. IV. This fact may lead to the conjecture that even assuming a more general dependence of the metric on the ''spatial'' coordinates, no new forms can be obtained for the solutions, in addition to those listed in the previous sections.

VI. DISCUSSION

Now we have finished the classification of the spaces of constant curvature, and it is useful to sum up potential applications of this. First, consider any type of cosmic no-hair theorem stating that under certain circumstances every solution of the Einstein field equation is asymptotically a space of constant curvature. To find out regions where this theorem applies it is necessary to know which spacetimes of a given class, e.g., the multidimensional warped products we considered here, is exactly a (generalized) de Sitter spacetime. We found unexpected forms on the one hand, and on the other hand, it came out that the Cartesian product between a four-dimensional de Sitter spacetime and one or more static internal spaces is never a space of constant curvature.

Example: metric (4.19) is a metric for a cosmological model of Bianchi type III. Usually, Bianchi type III consists of anisotropic models only, and so (4.19) may be used to test the range of validity of the no-hair theorem within the class of Bianchi type III models, which seems not to have been done up to now.

This list may help identifying ''new solutions'' of Einstein's field equations with or without cosmological term in an arbitrary number of dimensions. The most remarkable result of our paper seems to be that no metric with more than two factors is possible. If n is the number of factors, we have found for every $D \geqslant 2$ twelve representations with $n = 1$ and $5D - 10$ representations with $n = 2$ if D is even and $5D - 9$ representations with $n = 2$ if D is odd.

A fixed point of a gravitational lensing map represents those positions from which a pointlike light source has a lensed image that, despite gravitational lensing, corresponds to the original position of the source. In this paper we study fixed points of lensing maps due to a generic gravitational lens with applications to nonsingular isolated lenses, and to point-mass lenses with continuous matter and shear. Counting formulas and bounds on the number of fixed points are determined. The results include an odd-number fixed-point theorem for nonsingular isolated deflectors. Information on the positions of fixed points are found for the case of point masses on a lens plane with and without shear. The methods of the paper are based on Morse theory, complex variables, and resultants. © *1998 American Institute of Physics.* [S0022-2488(98)02002-7]

I. INTRODUCTION

Consider a light source at y in R^2 undergoing gravitational lensing by a matter distribution with Newtonian potential ψ. Associated with ψ is a planar lensing map defined by $\boldsymbol{\eta}(x)=x-\text{grad}\,\psi(x)$. The lensed images of a light source at y are solutions x of the lens equation: $\boldsymbol{\eta}(x)=y$. Due to light deflection, a lensed image of a light source does not represent the actual position or magnification of the source. We are interested in studying those positions from which a light source has a lensed image that, in spite of a deflector, coincides with the original position of the light source. They are ''fixed points'' due to the lens. Formally, a *fixed point* of $\boldsymbol{\eta}$ is a point x_0 such that $\boldsymbol{\eta}(x_0)=x_0$. Note that by construction, fixed points of $\boldsymbol{\eta}$ are critical points of ψ. To the best of our knowledge, these points have not been studied before in gravitational lensing. In addition, given the fundamental role of this notion in mathematics, fixed-point lensed images warrant investigation, at least on mathematical grounds. Fixed points are vital to the field of discrete dynamical systems, and the planar mappings arising in gravitational lensing may be analyzed using geometric techniques from this field.

We will show that fixed points not only exist, but obtain counting formulas and lower bounds, as well as some results on their positions. Our methods employ the Morse-theoretic and Resultant techniques in the recent papers of Petters[1,2] and Petters and Witt.[3] Some of these results were announced at the Eighth Marcel Grossman Meeting on General Relativity.

The outline of our paper is as follows. In Sec. II we present counting formulas and lower bounds on the number of fixed points due to a ''generic'' gravitational lens. The remainder of the paper then deals with applications to nonsingular isolated lenses (Sec. III), point masses (Sec. IV), and point masses with continuous matter and shear (Sec. V). Section V also includes upper bounds on the number of fixed points.

II. FIXED POINTS DUE TO A GENERAL LENS

Some basic terminologies. Let $L=R^2-A$, where A is a finite collection of points in R^2, and denote the Laplacian on R^2 by Δ. A *gravitational lens potential with infinite singularities A* is a smooth map $\psi: L\to R$ such that $\Delta\psi(x)\geqslant 0$ for all $x\in L$, and $\psi(x)\to-\infty$ as $x\to a$ for each $a\in A$. We call ψ *isolated* if $\psi(x)\to+\infty$ as $|x|\to\infty$. Also, ψ is *nonsingular* when $A=\varnothing$; otherwise,

 © 1998 American Institute of Physics

ψ is *singular*. The *(single-plane) lensing map* induced by ψ is the map $\boldsymbol{\eta}: L \to S$ defined by $\boldsymbol{\eta}(x) = x - \boldsymbol{\alpha}(x)$, where $S = R^2$ and $\alpha = \text{grad}\, \psi$. We call L and S, resp., the *lens* and *light source plane* of $\boldsymbol{\eta}$, while $\boldsymbol{\alpha}$ is the *bending-angle vector field* of ψ.

A lensed image of a light source at $y \in S$ is a solution x of the lens equation $y = \boldsymbol{\eta}(x)$. If x_0 is a fixed point of $\boldsymbol{\eta}$, then x_0 is a lensed image of a light source at $y = x_0$. We can also assign a critical point type to lensed images. In fact, the lensed images of a light source at y are critical points of the *time-delay function* $T_y: L \to R$ induced at y by ψ:

$$T_y(x) = \frac{|x-y|^2}{2} - \psi(x).$$

We have grad $T_y(x) = 0$ if and only if $\boldsymbol{\eta}(x) = y$. The *magnification* of a lensed image x_0 of y is defined to be $1/|\det[\text{Jac}\ \boldsymbol{\eta}](x_0)| = 1/|\det[\text{Hess}\ T_y](x_0)|$. If the magnification of x_0 is 1 and a tiny disc is centered about y, then the resulting extended lensed image about x_0 has approximately the same area as the disc.

Morse Boundary Conditions B. It is practically unfeasible to study the fixed points of lensing maps due to arbitrary gravitational lens potentials ψ. However, if ψ satisfies certain ''generic'' properties, then we can obtain a lower bound and counting formula for the number of fixed points of the induced lensing map $\boldsymbol{\eta}$. First, we shall assume that ψ is nondegenerate. In fact, for almost all a in R^2 with $|a|$ sufficiently small, the linear perturbation,

$$\psi^a(x) = \psi(x) - a \cdot x,$$

of ψ is nondegenerate gravitational lens potential on L.[4] As $|a| \to 0$, the potential ψ^a becomes an arbitrarily small linear perturbation of ψ on any bounded open subset of L. Second, let D be a *regular domain* in L, i.e., a compact subset of L whose boundary ∂D is a disjoint union of smooth simple closed curves. Since the critical points of a nondegenerate ψ are isolated, we can choose D such that ∂D contains no critical point of ψ. *Denote by* D_- *the union of all open subsets of* ∂D *where the bending-angle vector field of* ψ *points into the interior of* D. If ψ is nondegenerate, then for almost all points $a \in R^2$, the critical points in D of a linear perturbation ψ^a tend uniformly and bijectively with preservation of critical point type to those of ψ in D as $|a| \to 0$. Moreover, for $|a|$ sufficiently small, the restricted map $\psi^a|_{\partial D}$ is nondegenerate. Proofs of these results appear in Ref. 5. We shall then define ψ to obey *Morse boundary conditions B* relative to a regular domain D in L if all critical points of ψ lying in D are nondegenerate, no critical point of ψ lies on ∂D, and the restriction $\psi|_{\partial D}$ is nondegenerate. This property is ''generic'' in the sense that it is satisfied by an arbitrarily small linear perturbation of ψ in any bounded open subset containing D.

Notation:

(1) $F(\boldsymbol{\eta}; D)$ = set of fixed points of $\boldsymbol{\eta}$ in D. $|F(\boldsymbol{\eta}; D)|$ = total number of fixed points of $\boldsymbol{\eta}$ in D.
(2) $M_{\min}(\psi; D)$ = total number of minima critical points of ψ in D. $M_{\text{sad}}(\psi; D)$ = total number of saddle critical points of ψ in D. Note that ψ has no maximum critical point [since $\Delta\psi(x) \geqslant 0$ for all $x \in L$].
(3) $M'_{\min}(\psi|_{D_-})$ = total number of minima critical points of $\psi|_{D_-}$. $M'_{\max}(\psi|_{D_-})$ = total number of maxima critical points of $\psi|_{D_-}$.

Since a regular domain represents a portion of the sky where observations are made, it suffices to consider regular domains that are *closed g-hole discs* (i.e., a manifold that is diffeomorphic to a closed disc from which g disjoint open discs are excised). Think of the holes as places where a singularity of the gravitational lens is located.

Theorem 1: *Let* $\boldsymbol{\eta}: L \to S$ *be a lensing map induced by a gravitational lens potential* ψ *with infinite singularities A. Suppose that* ψ *obeys Morse boundary conditions B relative to a closed g-hole disc D, where each hole of D has exactly one element of A. (Note that the number of singularities of* ψ *may exceed g.) Then the fixed points of* $\boldsymbol{\eta}$ *in D satisfy*

$$\begin{aligned} |F(\boldsymbol{\eta}; D)| &= 2M_{\min}(\psi; D) + g - 1 + [M'_{\min}(\psi|_{D_-}) - M'_{\max}(\psi|_{D_-})] \\ &= 2M_{\text{sad}}(\psi; D) - g + 1 - [M'_{\min}(\psi|_{D_-}) - M'_{\max}(\psi|_{D_-})]. \end{aligned}$$

Proof: This theorem immediately follows from application of Morse inequalities B. (An introduction to these powerful inequalities, with detailed proofs, appears in a work by Morse and Cairns.[6]) First, since ψ is nondegenerate with no critical point on ∂D, compactness of D implies that ψ has finitely many critical points in D. Consequently, $|F(\boldsymbol{\eta};D)| = M_{\min}(\psi;D) + M_{\text{sad}}(\psi;D)$, which is finite. Second, because ψ also satisfies Morse boundary conditions B relative to D, Morse inequalities B yield

$$M_{\min}(\psi;D) \geqslant B_0(D) - M'_{\min}(\psi|_{D_-}),$$

$$M_{\text{sad}}(\psi;D) - M_{\min}(\psi;D) \geqslant [B_1(D) - M'_{\max}(\psi|_{D_-})] - [B_0(D) - M'_{\min}(\psi|_{D_-})],$$

$$M_{\max}(\psi;D) - M_{\text{sad}}(\psi;D) + M_{\min}(\psi;D) = B_2(D) - [B_1(D) - M'_{\max}(\psi|_{D_-})] + [B_0(D) - M'_{\min}(\psi|_{D_-})],$$

where $B_i(D)$ is the ith Betti number of D. The Betti numbers of a closed g-hole disc are $B_0(D)=1$, $B_1(D)=g$, and $B_2(D)=0$ (e.g., Ref. 7). Since $M_{\max}(\psi;D)=0$ and $|F(\boldsymbol{\eta};D)| = M_{\min}(\psi;D)+M_{\text{sad}}(\psi;D)$, the theorem follows. q.e.d.

In the sequel, we will usually abbreviate $F(\boldsymbol{\eta};D)$ by $F(\boldsymbol{\eta})$, $M_{\min}(\psi;D)$ by $M_{\min}(\psi)$, etc. We will also define $\psi_- = -\psi$ and $\boldsymbol{\alpha}_- = -\boldsymbol{\alpha}$.

III. APPLICATIONS: NONSINGULAR ISOLATED LENSES

Theorem 2: *Let ψ be a nonsingular isolated nondegenerate gravitational lens potential. Suppose that ψ obeys Morse boundary conditions B. Then fixed points of the lensing map $\boldsymbol{\eta}$ induced by ψ exist, and satisfy the following*:

(1) $1 \leqslant |F(\boldsymbol{\eta})| < \infty$.
(2) *Odd-number fixed-point theorem:* $|F(\boldsymbol{\eta})| = 2M_{\min}(\psi) - 1 = 2M_{\text{sad}}(\psi) + 1$.

Proof: The fixed points of $\boldsymbol{\eta}$ coincide with the critical points of ψ_-. Since ψ is isolated, all critical points of ψ_- lie in the interior of some closed disc D. By choosing the radius of D sufficiently large, we can also assume that $\boldsymbol{\alpha}_-$ is inward pointing on ∂D (so $\boldsymbol{\alpha}$ is outward pointing on ∂D). Consequently, $|F(\boldsymbol{\eta})| < \infty$ and D_- is empty. The theorem is now a consequence of Theorem 1. q.e.d.

Without explicitly knowing the gravitational lens potential modeling a particular smooth nonsingular isolated mass distribution, Theorem 2 enables us to conclude that the lens produces an *odd* number of fixed points and, hence, at least one.

Example (elliptic potential): An elliptical potential with ellipticity ϵ and finite core x_c is of the form

$$\psi_{\text{ep}}(x) = C\sqrt{x_{\text{cr}}^2 + (1-\epsilon)u^2 + (1+\epsilon)v^2},$$

where $x=(u,v)$, $C>0$, $x_{\text{cr}}>0$, and $0 \leqslant \epsilon < 1$. The bending-angle vector field is

$$\boldsymbol{\alpha}_{\text{ep}}(x) = C^2((1-\epsilon)u, (1+\epsilon)v)/\psi_{\text{ep}}(x).$$

There is only one fixed point, namely, the origin.

Although Theorem 2 is stated for isolated potentials, the proof of the theorem shows that we can also determine an odd-number fixed-point theorem for any nonsingular potential for which $M'_{\min}(\psi|_{D_-}) - M'_{\max}(\psi|_{D_-})$ is an even number.

Example (perturbed Plummer potential): A perturbed Plummer potential with shear γ at infinity is of the form

$$\psi_{\text{ppl}}(x) = \frac{\kappa_0}{2} \ln(1+|x|^2) - \frac{\gamma}{2}(u^2 - v^2),$$

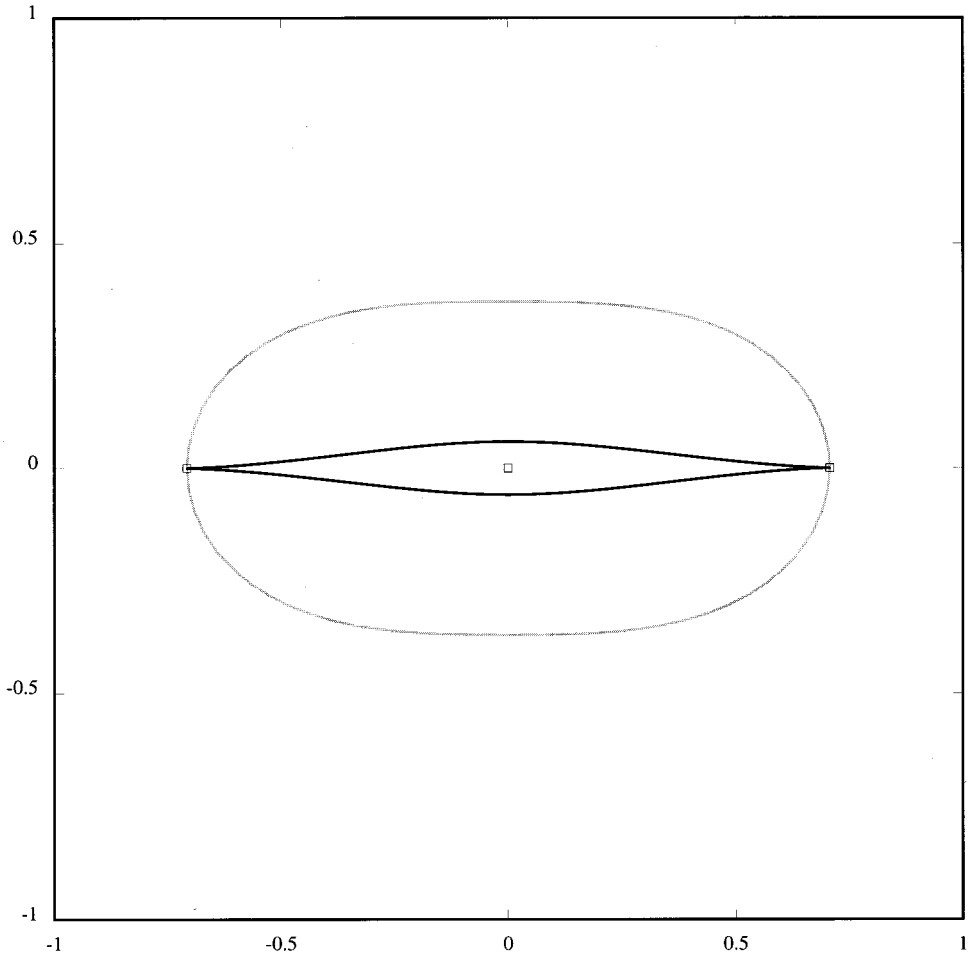

FIG. 1. A superposition of the critical curves (grey) and caustics (black) for the perturbed Plummer model, $\kappa_0=0.75$, $\gamma=0.5$. There are three fixed points (marked by boxes), one at the origin and one at each cusp $(\pm 1/\sqrt{2}, 0)$.

where κ_0 and γ are positive. This potential is not isolated. Employing polar coordinates (R,θ), the potential is approximated for large values of R by $\tilde{\psi}(R,\theta)=-\gamma R^2\cos 2\theta$. On a large disc of radius R, D_- is approximated by the intervals $-\pi/4<\theta<-\pi/4$ and $3\pi/4<\theta<5\pi/4$. Hence $\tilde{\psi}|_{D_-}$ has two critical points, both minima. Hence $M'_{\min}(\psi|_{D_-})-M'_{\max}(\psi|_{D_-})=2-0=2$, and so there will be an odd number of fixed points.

In fact, for this potential we can explicitly compute the fixed points. Since the associated bending-angle vector field is

$$\boldsymbol{\alpha}_{\text{ppl}}(x)=\left(\left(\frac{\kappa_0}{1+|x|^2}-\gamma\right)u,\left(\frac{\kappa_0}{1+|x|^2}+\gamma\right)v\right),$$

there is always a real fixed point at $x=(0,0)$. If $\kappa_0>\gamma$, two more fixed points occur at $x=(\pm\sqrt{\kappa_0/\gamma-1},0)$. Note that for $\kappa_0<\gamma$, the origin is a saddle; for $\kappa_0>\gamma$, the origin is a minimum, and the other two fixed points are saddle points. Figure 1 depicts the locations of these fixed points. Notice the lensing of a disc light source centered at the fixed point in Fig. 2.

In the (typical) case that no explicit formula for the location of the fixed points exists, iterative methods may be used to numerically approximate the fixed points (e.g., Ref. 8) These methods typically use some sort of Newton iteration and require the use of an initial guess (or ''seed'') to start the iteration; these methods are not guaranteed to find all of the fixed points that exist, even if the algorithm is run using thousands of initial seeds. It is imperative, therefore, to have estimates

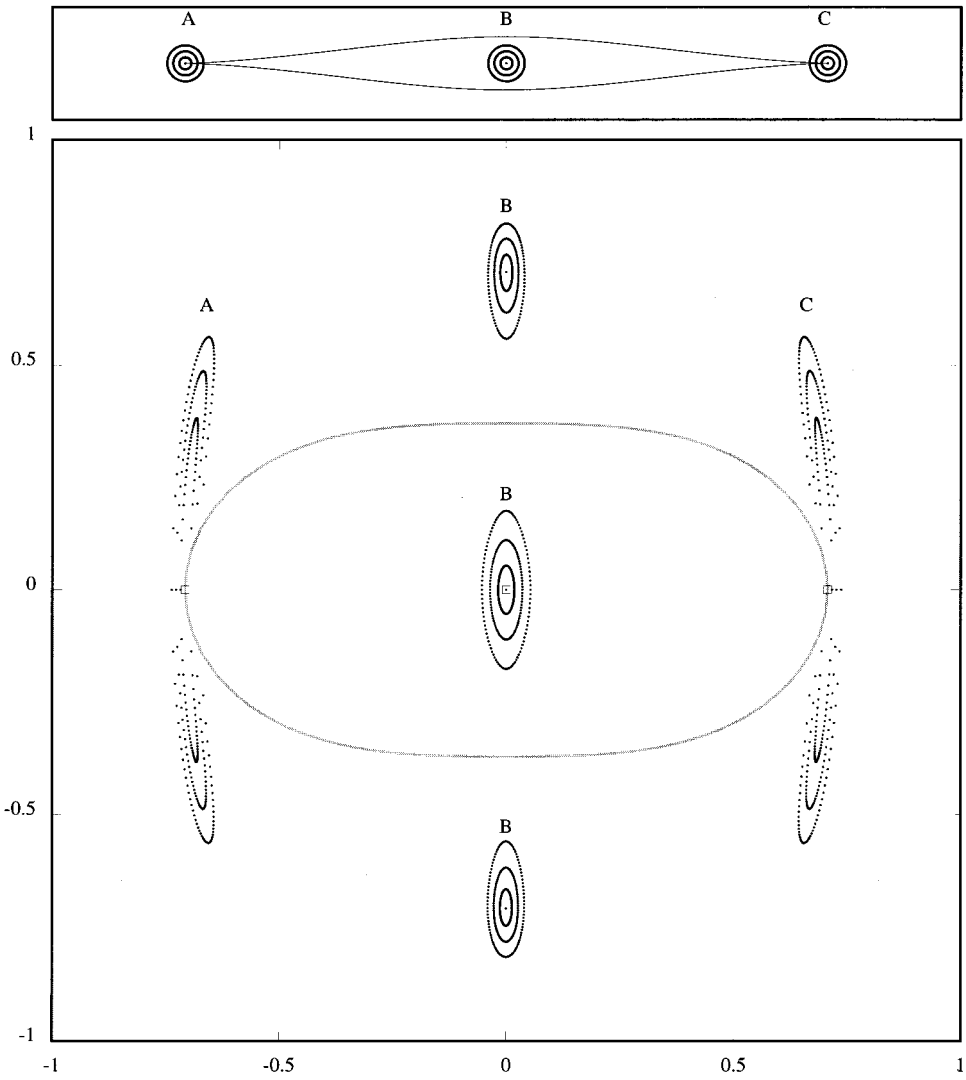

FIG. 2. (Upper) An extended light source is placed at each fixed point, A, B, and C, in the perturbed Plummer model. (Lower) Images of the extended sources. The fixed point at the origin has three images; the fixed point at each cusp is arclike.

and bounds on the number and location of fixed points, so that we may be more confident in the results of our numerics. All of the theorems in this paper provide estimates of this sort, and therefore provide important practical information to computational mathematicians and physicists.

The reader may wonder about the likelihood of a fixed point located on a critical curve. These situations appear in Figs. 1 and 2, but, in general, these are not generic occurrences. If ξ is a fixed point, then grad $\psi(\xi)=0$, but this condition is independent of the condition that ξ is on a critical curve: $\det[d\boldsymbol{\eta}](\xi)=\det[I-\mathrm{Hess}\,(\psi)](\xi)=0$. These two conditions mean that the condition that a fixed point is on a critical curve is a codimension-1 phenomenon. For example, evaluating $\det[I-\mathrm{Hess}\,(\psi)]$ for the perturbed Plummer model at the fixed point gives a determinant of $(1+2\gamma(1-\gamma/\kappa_0))(1-2\gamma)$ and this quantity only vanishes along the curve $\kappa_0=2\gamma^2/(1+2\gamma)$ in the two-dimensional parameter space.

It is even more unlikely that a fixed point on a critical curve is mapped onto a cusp point by $\boldsymbol{\eta}$. The point ξ is a cusp point if the critical curve is nonsingular at ξ, and the tangent vector to the critical curve is contained in the kernel of $d\boldsymbol{\eta}$. In symbols, if T is a tangent vector to the critical curve at ξ, then $d\boldsymbol{\eta}(\xi)\cdot T=0$. (To be certain that ξ is mapped to a ''mathematical cusp,'' and not a higher-order singularity, we should also check that the family of tangent vectors near ξ pass

transversally through the kernel of $d\boldsymbol{\eta}$, but we will not go into these details here.) For example, since the Plummer potential is invariant under the Z_2-symmetry $(u,v)\to(u,-v)$, we know that critical curves passing through the line $v=0$ must have vertical tangent vectors. The Jacobian of the lensing map (evaluated at the fixed point) sends the vector $[0,1]$ to the vector $[0,\ 1-2\gamma]$, and so we see that $d\boldsymbol{\eta}(\xi)$ sends a tangent vector to the zero vector only when $\gamma=\frac{1}{2}$. Of course, for extended light sources, there is an open set of parameter values for which the geometry of Fig. 2 would be observable, so the physical realization of this figure will not be as rare as is indicated by a mathematical analysis of the point-source case.

IV. APPLICATIONS: POINT MASSES WITH CONTINUOUS MATTER AND SHEAR

A. Preliminaries

The negative of the gravitational lens potential due to g point masses m_l at positions $\boldsymbol{\xi}_l$ on a plane lens with constant-density continuous matter κ_c (in units of the critical density) and non-normalized shear $\gamma\geqslant 0$ (at infinity) is given by

$$\psi_-(x)=\frac{(\gamma-\kappa_c)}{2}\,u^2-\frac{(\gamma+\kappa_c)}{2}\,v^2-\sum_{l=1}^{g} m_l \ln|x-\boldsymbol{\xi}_l|, \tag{1}$$

where $x=(u,v)$. The fixed points due to ψ are solutions x of the equation $\boldsymbol{\alpha}_-(x)=0$, where

$$\boldsymbol{\alpha}_-(x)=((-\kappa_c+\gamma)u,(-\kappa_c-\gamma)v)-\sum_{l=1}^{g} m_l\,\frac{x-\boldsymbol{\xi}_l}{|x-\boldsymbol{\xi}_l|^2}. \tag{2}$$

The lensing map $\boldsymbol{\eta}:L\to S$ induced by ψ is given by $\boldsymbol{\eta}(x)=x+\boldsymbol{\alpha}_-(x)$, where $L=R^2-\{\boldsymbol{\xi}_1,\ldots,\boldsymbol{\xi}_g\}$ and $S=R^2$. Explicitly,

$$\boldsymbol{\eta}(x)=\begin{pmatrix}1-\kappa_c+\gamma & 0\\ 0 & 1-\kappa_c-\gamma\end{pmatrix}x-\sum_{l=1}^{g} m_l\,\frac{x-\boldsymbol{\xi}_l}{|x-\boldsymbol{\xi}_l|^2}. \tag{3}$$

Now, since $\psi_-(x)\to+\infty$ as $x\to\boldsymbol{\xi}_l$, where $l=1,\ldots,g$, there is an open disc about $\boldsymbol{\xi}_l$ that contains no critical point of ψ_-. In addition, if $\kappa_c=\gamma$, then $\psi_-(x)\to-\infty$ as $|x|\to\infty$. Moreover, if $\kappa_c\neq\gamma$, then $|\boldsymbol{\alpha}_-(x)|\to+\infty$ as $|x|\to\infty$. Consequently, all critical points lie in a bounded region. Let D be a closed g-hole disc, where each hole of D has exactly one singularity of ψ. By choosing the circumradius of the inner-boundary curves and inradius of the outer-boundary curve of D sufficiently small and large, resp., we can assume that all critical points of ψ_- lie in the interior of D. Hence, *if ψ_- is nondegenerate, then it has finitely many critical points, that is, $|F(\boldsymbol{\eta})|=M_{\min}(\psi)+M_{\mathrm{sad}}(\psi)<\infty$, where $\boldsymbol{\eta}$ is the lensing map induced by ψ.* Note that $M_{\max}=0$ since $\Delta\psi=2\kappa_c\geqslant 0$.

Though Theorem 1 yields counting formulas and lowers bounds on $|F(\boldsymbol{\eta})|$, it provides no upper bound. However, by introducing complex variables,[9,10] we shall determine upper bounds on $|F(\boldsymbol{\eta})|$ for point masses on a lens plane with shear and continuous matter.

Express x and $\boldsymbol{\xi}_l$ in complex form: $x=z=u+iv$ and $\boldsymbol{\xi}_l=\xi_l^1+i\xi_l^2$. By Eq. (2), we must investigate the zeros of

$$\boldsymbol{\alpha}_-(z,\overline{z})=-\kappa_c z+\gamma\overline{z}+\sum_{l=1}^{g}\frac{m_l}{\boldsymbol{\xi}_l-\overline{z}}, \tag{4}$$

which is equivalent to finding the simultaneous roots of

$$p(z,\overline{z})=-\kappa_c z\prod_{l=1}^{g}(\overline{\boldsymbol{\xi}_l}-\overline{z})+\gamma\overline{z}\prod_{l=1}^{g}(\overline{\boldsymbol{\xi}_l}-\overline{z})+\sum_{l=1}^{g} m_l\prod_{\substack{r=1\\ r\neq l}}^{g}(\overline{\boldsymbol{\xi}_r}-\overline{z}) \tag{5}$$

and

$$\overline{p(z,\overline{z})}=\gamma z\prod_{l=1}^{g}(\xi_l-z)-\kappa_c\overline{z}\prod_{l=1}^{g}(\xi_l-z)+\sum_{l=1}^{g}m_l\prod_{\substack{r=1\\r\neq l}}^{g}(\xi_r-z). \tag{6}$$

Thus, if x is a fixed point of η*, then* $(z,\overline{z})$ *is a root of both (5) and (6). We can then translate the study of fixed points into that of the common zeros of* $p(z,\overline{z})$ *and* $\overline{p(z,\overline{z})}$*. Applications of the theory of resultants will then yield upper bounds on* $|F(\eta)|$*.*

B. Fixed points due to point masses with $\kappa_c=0$ and $\gamma\geqslant 0$

Throughout this subsection, assume that $\gamma\geqslant\kappa_c=0$.

Notation:

(1) $M_{\text{tot}}=m_1+\cdots+m_g$.
(2) $\hat{M}_l=M_{\text{tot}}-m_l$.

Theorem 3: *Let* ψ *be a nondegenerate gravitational lens potential due to g point masses on a lens plane with shear* $\gamma\geqslant 0$ *and no continuous matter* $(\kappa_c=0)$*. Then the fixed points of the lensing map* η *induced by* ψ *satisfy the following*:

(1) *The set* $F(\eta)$ *consists of all roots of the equation* $\overline{p(z)}=0$*, where*

$$\overline{p(z)}=\gamma z\prod_{l=1}^{g}(\xi_l-z)+\sum_{l=1}^{g}m_l\prod_{\substack{r=1\\r\neq l}}^{g}(\xi_r-z) \tag{7}$$

and has only simple zeros. Consequently,

$$|F(\eta)|=M_{\text{sad}}(\psi)=\begin{cases}g+1, & \text{if } \gamma>0,\\ g-1, & \text{if } \gamma=0.\end{cases} \tag{8}$$

(2) *The fixed points* $y_1,\ldots,y_{n(\gamma)}$ *of* η *obey*

$$y_1+\cdots+y_{n(\gamma)}=\begin{cases}\dfrac{\xi_1+\cdots+\xi_g}{\gamma}, & \text{if } \gamma>0,\\ \dfrac{\hat{M}_1\xi_1+\cdots+\hat{M}_g\xi_g}{M_{\text{tot}}}, & \text{if } \gamma=0,\end{cases} \tag{9}$$

where $n(\gamma)=g+1$ *if* $\gamma>0$*, and* $n(\gamma)=g-1$ *if* $\gamma=0$*. Moreover, no fixed point of* η *has magnification 1.*

Proof: (1) We have $|F(\eta)|=M_{\text{sad}}(\psi)+M_{\min}(\psi)$. But $\Delta\psi=2\kappa_c=0$. Hence, $M_{\min}(\psi)=0$. Since $\kappa_c=0$, Eqs. (5) and (6) are equivalent to the single-variable equation $\overline{p(z)}=0$, where $\overline{p}$ is given by Eq. (7). In addition,

$$\frac{d\overline{\alpha}_-}{dz}(z)=\frac{p'(z)\Pi_{l=1}^{g}(\xi_l-z)-p(z)[\Pi_{l=1}^{g}(\xi_l-z)]'}{\Pi_{l=1}^{g}(\xi_l-z)^2}$$

and $\det[\text{Hess}\,\psi](y)=|(d\overline{\alpha}_-/dz)(y)|^2\neq 0$, where $\overline{\alpha}_-$ is the conjugate of $\overline{\alpha}_-$ and $'$ denotes differentiation relative to z. Hence, all zeros of $p(z)$ are simple. The remainder of part (1) now follows from the degree of $\overline{p(z)}$.

(2) We want to expand the products in Eq. (6). Recall that the kth elementary symmetric function in $t_1,\ldots,t_n$ is

$$s_k=\sum_{1\leqslant j_1<\cdots<j_k\leqslant n}\xi_{j_1}^{l}\cdots\xi_{j_k}^{l},$$

where $1\leqslant k\leqslant n$ (e.g., $s_1=t_1+\cdots+t_n$ and $s_n=t_1\cdots t_n$). Let

$$\xi_j^l=\begin{cases}\xi_j, & j<l\\ \xi_{j+1}, & j\geqslant l,\end{cases}$$

where $1\leqslant j\leqslant g-1$ and $1\leqslant l\leqslant g$. Denote the kth elementary symmetric function in $\xi_1^l,\ldots,\xi_{g-1}^l$ by ξ_k^l (e.g., $\xi_j^1=\xi_{j+1}$ and $\xi_j^g=\xi_j$). Note that $s_1^l=\xi_1^l+\cdots+\xi_{g-1}^l=\xi_1+\cdots+\hat{\xi}_l+\cdots+\xi_g^l$, where $\hat{\xi}_l$ is omitted, and $s_{g-1}^l=\xi_1^l\cdots\xi_{g-1}^l$. Also, $s_1^1=\xi_2+\cdots+\xi_{g-1}$ and $s_{g-1}^g=\xi_1\cdots\xi_{g-1}$.

We expand Eq. (7) as follows:

$$\begin{aligned}\overline{p(z)}&=\gamma z\prod_{l=1}^{g}(\xi_l-z)+(-1)^{g-1}\sum_{l=1}^{g}m_l\prod_{j=1}^{g-1}(z-\xi_j^l)=(-1)^g z(z^g-s_1z^{g-1}+\cdots+(-1)^{g-1}s_g)\\&\quad+(-1)^{g-1}\left\{M_{\mathrm{tot}}z^{g-1}-\sum_{l=1}^{g}m_l(\xi_1+\cdots+\hat{\xi}_l+\cdots+\xi_g)z^{g-2}+\text{lower-order terms}\right\}\\&=(-1)^g(z^{g+1}-s_1z^g+\cdots+(-1)^{g-1}s_gz)\\&\quad+(-1)^{g-1}\left\{M_{\mathrm{tot}}z^{g-1}-\left(\sum_{l=1}^{g}\hat{M}_l\xi_l\right)z^{g-2}+\text{lower-order terms}\right\}.\end{aligned}$$

Since the sum of the zeros of a complex polynomial $a_nz^n+a_{n-1}z^{n-1}+\cdots+a_0$ is $-a_{n-1}/a_n$, the first claim in part (2) of the Theorem follows. For the second claim, observe that the determinant of the Jacobian of $\boldsymbol{\eta}$ is given by

$$\det J(z,\overline{z})=\frac{\partial w}{\partial z}\frac{\overline{\partial w}}{\partial z}-\frac{\partial w}{\partial\overline{z}}\frac{\overline{\partial w}}{\partial\overline{z}}=1-\left|\frac{d\overline{\boldsymbol{\alpha}}_-}{dz}(z)\right|^2.$$

Hence, a fixed-point lensed image z_0 has magnification 1 if and only if $|(d\overline{\boldsymbol{\alpha}}_-/dz)(z_0)|=0$. Nondegeneracy of ψ rules out this possiblity. q.e.d.

Theorem 3 shows that a one point-mass lens has no fixed points, while a point-mass with shear generically produces two fixed points, as shown in Figs. 3 and 4. In the nongeneric case (i.e., the gravitational lens potential is degenerate), the latter has one fixed point of multiplicity two; it is a minimum lensed image with magnification 1. A nondegenerate binary lens has a fixed point at position

$$y=\frac{m_1\xi_2+m_2\xi_1}{m_1+m_2}.$$

If the positions ξ_1 and ξ_2 of the masses m_1 and m_2 are switched, then y is the *center of mass* of the resulting system. For a ternary lens system, the fixed points can also be located theoretically. In fact, note that zeros of Eq. (7) are solutions of

$$\sum_{l=1}^{g}\frac{m_l}{z-\xi_l}=0.$$

The zeros of this equation for $g=3$ was studied by Siebeck as early as 1864. He established (see Ref. 11) that the zeros are the foci of the ellipse which meets the line segment between ξ_j and ξ_k at the point ζ_{jk}, where $|\zeta_{jk}-\xi_j|=(m_j/m_k)|\zeta_{jk}-\xi_k|$ (see Fig. 3). Siebeck also covered the case for general g, where the fixed points become the foci of a certain algebraic curve. Part (2) of Theorem 3 further shows that the sum of the positions of the fixed points (counting with multiplicity) of a g-point mass lens, where $g\geqslant 2$, is the center of mass of the lens system if m_l is replaced by $\hat{M}_l$.

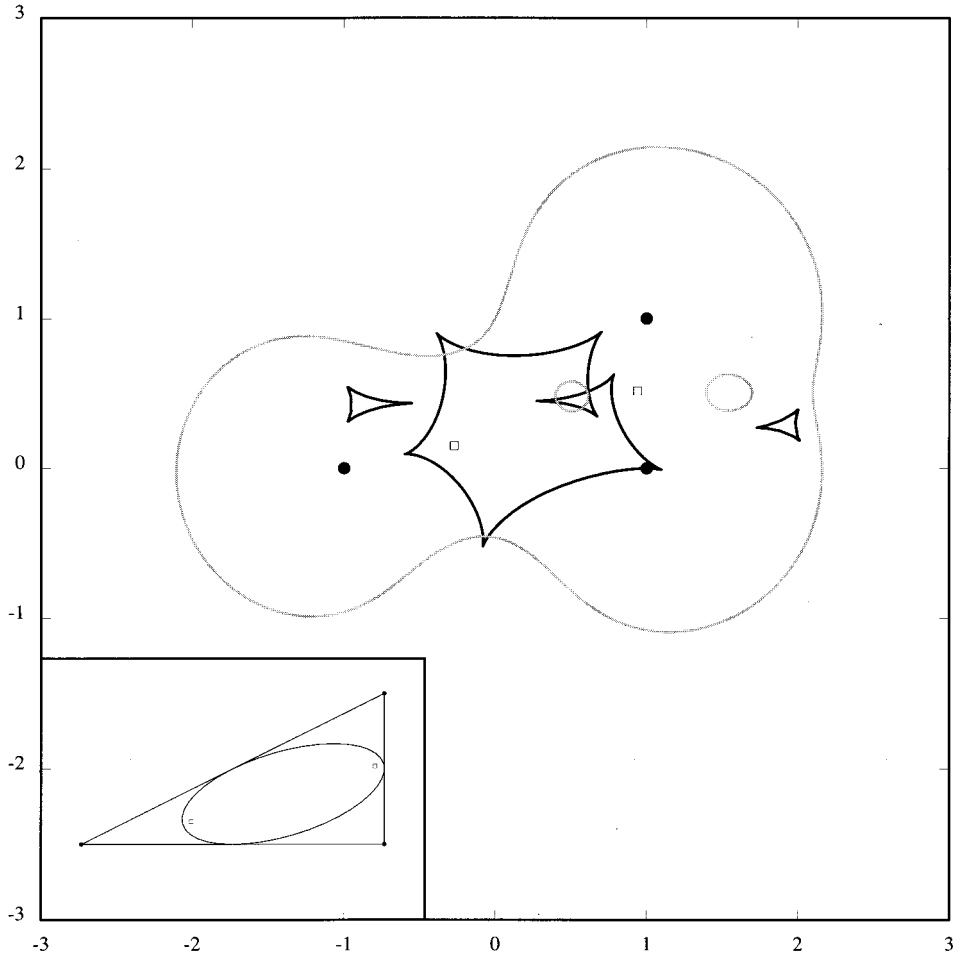

FIG. 3. A superposition of the critical curves (grey) and caustics (black) for three equal masses, $m_i=1$, and $\kappa_c=\gamma=0$. The positions of the masses are indicated by dots (●): $d_1=(-1,0)$, $d_2=(1,0)$, and $d_3=(1,1)$. The position of the fixed points are marked by boxes (□): (0.93912, 0.51675) and (−0.27245, 0.14992). The insert illustrates that the fixed points are foci of an ellipse inscribed in the triangle defined by the three masses and meeting the triangle at the pairwise centers of the sides.

C. Fixed points due to point masses with $0\leqslant\gamma\leqslant\kappa_c$ and $0<\kappa_c<\gamma$

1. Counting formulas: $0\leqslant\gamma\leqslant\kappa_c$ and $0<\kappa_c<\gamma$

For $0\leqslant\gamma<\kappa_c$, we define the ellipse parametrized by

$$\theta\rightarrow\left(\sqrt{\frac{2}{\kappa_c-\gamma}}\,R\,\cos(\theta),\sqrt{\frac{2}{\kappa_c+\gamma}}\,R\,\sin(\theta)\right),$$

whereas we choose

$$\theta\rightarrow\left(\sqrt{\frac{2}{\gamma-\kappa_c}}\,R\,\cos(\theta),\sqrt{\frac{2}{\kappa_c+\gamma}}\,R\,\sin(\theta)\right)$$

when $0\leqslant\kappa_c<\gamma$. Let $D(R)$ be the interior of the ellipse punctured by disjoint open discs $D_{\xi_1},\cdots,D_{\xi_g}$ centered at the point masses. By choosing the radii of the discs D_{ξ_l} sufficiently small, we can assume that at points of the boundary ∂D_{ξ_g}, grad ψ_- points into the exterior of $D(R)$. Moreover, for R sufficiently large we can also assume that all critical points of ψ_- lie in $D(R)$. *Henceforth, we shall assume the previous properties hold for D(R) and all critical points of* ψ_- *lie*

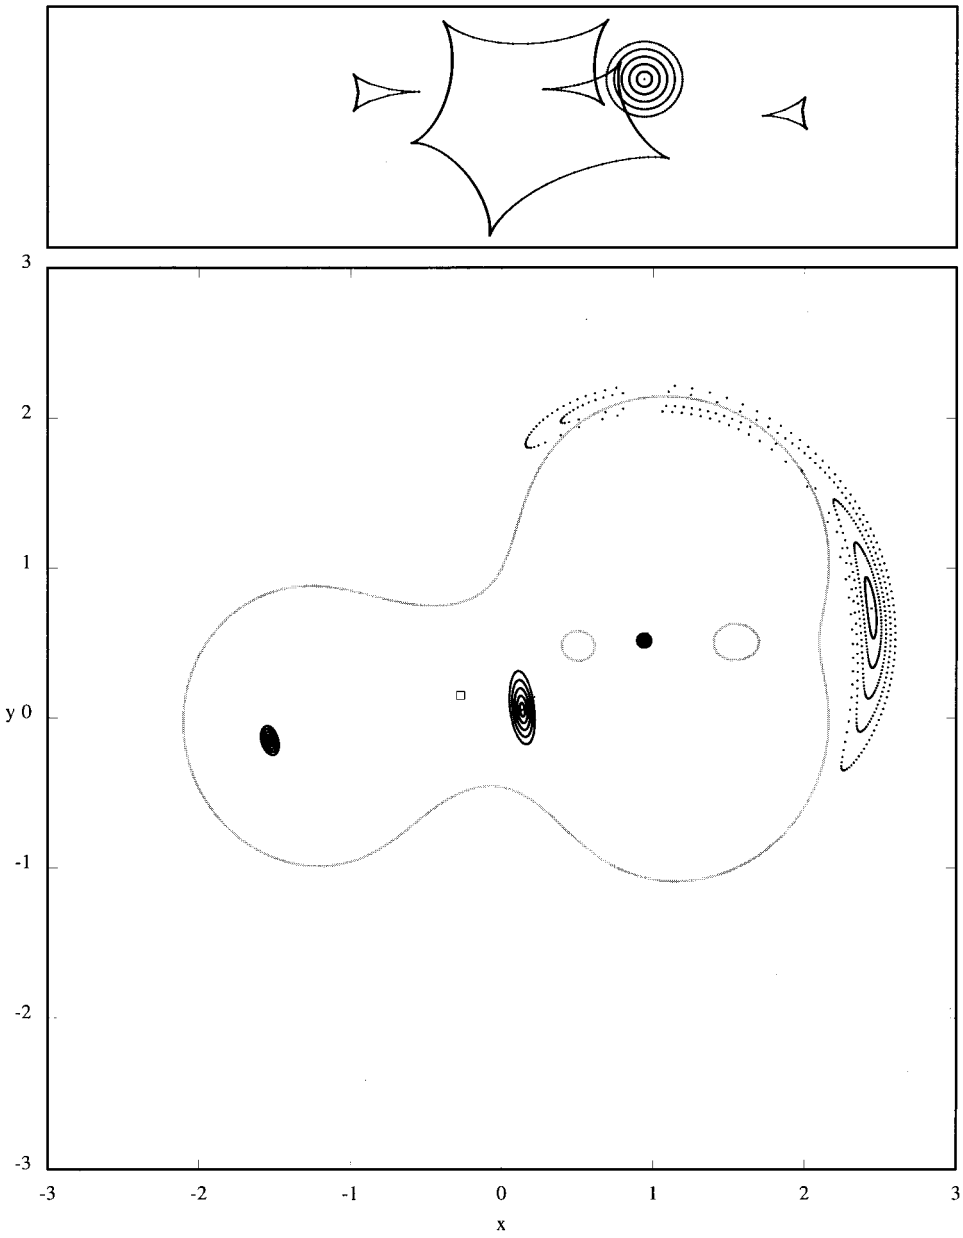

FIG. 4. (Upper) An extended light source, located at one of the fixed points, that crosses a caustic. (Lower) Four images of the source. The arclike image is due to the fact that the source crosses a caustic.

in the interior of D(R). Finally, let $D_-(R)$ be the union of all submanifolds of $\partial D(R)$ at whose points grad ψ_- points into the *exterior* of $D(R)$. In other words, $D_-(R)=D_-$.

Theorem 4: *Suppose that ψ obeys Morse boundary conditions B relative to D(R).*

(1) *If* $0\leqslant\gamma\leqslant\kappa_c$, *then* $|F(\boldsymbol{\eta})|=2M_{\min}(\psi)+g-1=2M_{\text{sad}}(\psi)-g+1$.
(2) *If* $0<\kappa_c<\gamma$, *then* $|F(\boldsymbol{\eta})|=2M_{\min}(\psi)+g+1=2M_{\text{sad}}(\psi)-g-1$.

The theorem shows that $|F(\boldsymbol{\eta})|$ and g have opposite parity (i.e., even or oddness).

Proof: We have $M_{\min}(\psi)=M_{\max}(\psi_-)$, $M_{\text{sad}}(\psi)=M_{\text{sad}}(\psi_-)$, $M'_{\min}(\psi|_{D_-(R)})=M'_{\max}(\psi_-|_{D_-(R)})$, and $M'_{\max}(\psi|_{D_-(R)})=M'_{\min}(\psi_-|_{D_-(R)})$. Theorem 1 implies that

$$|F(\boldsymbol{\eta})| = 2M_{\min}(\psi) + g - 1 + [M'_{\max}(\psi_-|_{D_-(R)}) - M'_{\min}(\psi_-|_{D_-(R)})]$$
$$= 2M_{\text{sad}}(\psi) - g + 1 - [M'_{\max}(\psi_-|_{D_-(R)}) - M'_{\min}(\psi_-|_{D_-(R)})]. \quad (10)$$

(1) For R sufficiently large, the hypothesis that $\gamma \leqslant \kappa_c$ implies that $\boldsymbol{\alpha}_-$ points into the interior of $D(R)$ at all points of the outer boundary of $\partial D(R)$. Recall that if $\gamma = \kappa_c$, then $\psi_-(x) \to -\infty$ as $|x| \to \infty$. In addition, $\boldsymbol{\alpha}_-$ points into the exterior of $D(R)$ at all points of the g inner-boundary curves of $\partial D(R)$. Consequently, $D_-(R)$ is a union of g disjoint circles S^1. Since $\psi_-|_{D_-(R)}$ is nondegenerate, the Morse inequalities for boundaryless manifolds (see Ref. 12) also apply and yield

$$M'_{\max}(\psi_-|_{D_-(R)}) - M'_{\min}(\psi_-|_{D_-(R)}) = B_1(D_-(R)) - B_0(D_-(R))$$
$$= g(B_1(S^1) - B_0(S^1)) = g(1-1) = 0.$$

Application of Eq. (10) yields the desired result.

(2) By restricting ψ_- to ∂D and employing our parametrization of the ellipse, we obtain

$$\psi_-|_{\partial D(R)}(\theta) = R^2 \cos(2\theta) - \sum_{l=1}^{g} m_l \ln\left(R\sqrt{\widetilde{G}_l(\theta)}\right),$$

where

$$\widetilde{G}_l(\theta) = \frac{2}{\gamma - \kappa_c}\cos^2\theta + \frac{2}{\kappa_c + \gamma}\sin^2\theta - \frac{2\xi_l^1}{R}\sqrt{\frac{2}{\gamma - \kappa_c}}\cos\theta - \frac{2\xi_l^2}{R}\sqrt{\frac{2}{\kappa_c + \gamma}}\sin\theta + \left(\frac{|\boldsymbol{\xi}_l|}{R}\right)^2.$$

For large values of R, the function $\psi_-|_{\partial D(R)}(\theta)$ is approximately $R^2\cos(2\theta)$. Hence, $D_-(R)$ is approximated by portions of ∂D for $-\pi/4 < \theta < \pi/4$ and $3\pi/4 < \theta < 5\pi/4$. Thus the map $\psi_-|_{D_-(R)}$ has two critical points, both maxima: $M'_{\max}(\psi_-|_{D_-(R)}) = 2$ and $M'_{\min}(\psi_-|_{D_-(R)}) = 0$. The result now follows from Eq. (10). q.e.d.

2. Bounds: $0 \leqslant \gamma \leqslant \kappa_c$ and $0 < \kappa_c < \gamma$

Theorem 5: *Suppose that ψ obeys Morse boundary conditions B.*

(1) *If $0 \leqslant \gamma \leqslant \kappa_c$, then*

$$g - 1 \leqslant |F(\boldsymbol{\eta})| \leqslant \begin{cases} (g+1)^2, & \text{if } \gamma > 0, \\ g^2 - 1, & \text{if } \gamma = 0. \end{cases}$$

(2) *If $0 < \kappa_c < \gamma$, then*

$$g + 1 \leqslant |F(\boldsymbol{\eta})| \leqslant (g+1)^2.$$

Proof: For the lower bounds in the theorem, note that Theorem 4(1) implies that if $0 \leqslant \gamma \leqslant \kappa_c$, then $|F(\boldsymbol{\eta})| = 2M_{\min}(\psi) + g - 1 \geqslant g - 1$. In addition, by Theorem 4(2), we have $|F(\boldsymbol{\eta})| = 2M_{\min}(\psi) + g + 1 \geqslant g + 1$ for $0 < \kappa_c < \gamma$.

In order to prove the upper bounds in the theorem, we must introduce some facts from the theory of resultants. The x_1-Sylvester resultant of two polynomials

$$P(x_1, x_2) = a_0(x_2) + a_1(x_2)x_1 + \cdots + a_m(x_2)x_1^m$$

and

$$Q(x_1, x_2) = b_0(x_2) + b_1(x_2)x_1 + \cdots + b_n(x_2)x_1^n,$$

is defined by

$$\text{Res}\ (x_2) = \det\ (S_{m+n}),$$

where

$$S_{m+n}=\begin{bmatrix} a_m & a_{m-1} & a_{m-2} & \cdot & \cdot & \cdot & a_0 & 0 & 0 & \cdots & 0 \\ 0 & a_m & a_{m-1} & \cdot & \cdot & \cdot & a_1 & a_0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & a_m & a_{m-1} & a_{m-2} & \cdot & \cdot & \cdot & a_1 & a_0 \\ b_n & b_{n-1} & \cdot & \cdot & \cdot & b_0 & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & b_n & b_{n-1} & \cdot & \cdot & \cdot & b_0 & \cdot & \cdot & \cdot & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdot & \cdot & \cdot & 0 & b_n & b_{n-1} & \cdot & \cdot & \cdot & b_0. \end{bmatrix} \tag{11}$$

Explicitly, the lth row of S_{m+n}, where $1\leqslant l\leqslant n$, consists of $l-1$ zeros, followed by a_m, $a_{m-1},\ldots,a_0$, and the remainder of the row filled with zeros; for $n+1\leqslant l\leqslant m+n$, the lth row has $l-n-1$ zeros followed by b_n, $b_{n-1},\ldots,b_0$, and the remaining entries are zeros.

The Resultant Theorem (see Refs. 13 and 14) states that β satisfies Res $(\beta)=0$ if and only if either $a_m(\beta)=b_n(\beta)=0$ or $P(\alpha,\beta)=Q(\alpha,\beta)=0$ for some α. Another fact we shall need is that the resultant is a polynomial of degree n in the coefficients a_l and of degree m in b_l. That is, if we write Res $(x_2)=$Res $(a_0,\ldots,a_m,b_0,\ldots,b_n)$, then

$$\text{Res }(a_0,\ldots,a_m,b_0,\ldots,b_n)=\sum S_{i_0\ldots i_m j_0\ldots j_n}a_0^{i_0}\ldots a_m^{i_m}b_0^{i_0}\cdots b_n^{j_n}$$

and $i_0+\cdots+i_m=n$ and $j_0+\cdots+j_n=m$. Therefore,

$$\deg[\text{Res }(x_2)]\leqslant(n)(\max\{\deg[a_l]_{l=0}^m\})+(m)(\max\{\deg[b_l]_{l=0}^n\}). \tag{12}$$

The previous results will now be applied to Eqs. (5) and (6) to obtain the upper bounds in the theorem. We begin with $\gamma=0$. We then consider the common roots of

$$p(z,\overline{z})=a_1(\overline{z})z+a_0(\overline{z})$$

and

$$\overline{p(z,\overline{z})}=b_g(\overline{z})z^g+\cdots+b_0(\overline{z}).$$

Denote the z-resulant of p and $\overline{p}$ by Res $(\overline{z})$. If a is a fixed point, then $(a,\overline{a})$ is a common zero of p and $\overline{p}$. By the Resultant Theorem, a is a solution of Res $(\overline{z})=0$. Since $\gamma=0$,

$$\max\{\deg[a_0],\deg[a_1]\}=g$$

and

$$\max\{\deg[b_l]_{l=0}^g\}=1,$$

Eq. (12) implies

$$|F(\boldsymbol{\eta})|\leqslant\deg[\text{Res }(\overline{z})]\leqslant(g)(g)+(1)(1)=g^2+1.$$

Expanding the coefficients $a_1(\overline{z})$ and $b_g(\overline{z})$ we find that

$$a_1(\overline{z})=-\kappa_c\prod_{l=1}^{g}(\overline{\boldsymbol{\xi}_l}-\overline{z})=(-1)^{g+1}\kappa_c(\overline{z^g}-\overline{s_1z^{g-1}}+\cdots+(-1)^{g-2}\overline{s_{g-1}}\overline{z}+(-1)^{g-1}\overline{s_g})$$

and

$$b_g(\overline{z})=(-1)^{g+1}\kappa_c\overline{z}.$$

Without loss of generality, assume that $\xi_1 = 0$. Then $\overline{z} = 0$ is a common zero of $a_1(\overline{z})$ and $b_g(\overline{z})$. By the Resultant Theorem, $\overline{z} = 0$ is a zero of Res $(\overline{z})$. Since the origin is the position of the first point mass, $\overline{z} = 0$ is not a fixed point; hence, $|F(\boldsymbol{\eta})| \leq g^2$. By Theorem 4(1), $|F(\boldsymbol{\eta})|$ is even if and only if g is odd. Thus, we can reduce the upper bound by one: $|F(\boldsymbol{\eta})| \leq g^2 - 1$.

The proof for the upper bound when $\gamma > 0$ and $\kappa_c > 0$ (either $\gamma \leq \kappa_c$ or $\gamma > \kappa_c$ may apply) follows the proof above, except that Eq. (5) now has coefficients (in $\overline{z}$) of maximal degree $g+1$ and Eq. (6) is now a degree $g+1$ polynomial in z. Hence, by Eq. (12),

$$|F(\boldsymbol{\eta})| \leq (g+1)(g+1) + (1)(1) = g^2 + 2g + 2.$$

Again we can reduce this bound by one by noting that $\overline{z} = 0$ is a common root of $a_1(\overline{z})$ and $b_g(\overline{z})$, but the parity argument no longer applies. Thus we may only claim that $|F(\boldsymbol{\eta})| \leq (g+1)^2$. q.e.d.

As a last example, we again consider the ternary point-mass system with continuous matter and shear. Theorem 4 predicts that there will be an even number of fixed points when $g = 3$. Theorem 5 predicts that $2 \leq |F(\boldsymbol{\eta})| \leq 8$ if $0 = \gamma < \kappa_c$. If we perturb the lensing system shown in Fig. 3 to, say, $\gamma = 0$ and $\kappa_c = 0.1$, then we find that the constellation is essentially the same, but that the two fixed points slightly perturb to the locations (0.92698, 0.52446) and (−0.28041, 0.14101). By contrast, when $0 < \kappa_c < \gamma$, Theorem 5 predicts that $4 \leq |F(\boldsymbol{\eta})| \leq 16$. If we perturb the lensing system shown in Fig. 3 to $\kappa_c = 0.1$ and $\gamma = 0.3$, then we find that two new fixed points appear ''from infinity,'' resulting in four fixed points: (0.96570, 0.54376), (−0.246848, 0.13689), (−3.81466, −100.95612), and (4.0949, 56.2398).

Stationary generalized Kerr–Schild spacetimes

Carlos F. Sopuerta[a)]

(Received 11 June 1997; accepted for publication 4 November 1997)

In this paper we have applied the generalized Kerr–Schild transformation finding a new family of stationary perfect-fluid solutions of the Einstein field equations. The procedure used combines some well-known techniques of null and timelike vector fields, from which some properties of the solutions are studied in a coordinate-free way. These spacetimes are algebraically special being their Petrov types II and D. This family includes all the classical vacuum Kerr–Schild spacetimes, excepting the plane-fronted gravitational waves, and some other interesting solutions as, for instance, the Kerr metric in the background of the Einstein Universe. However, the family is much more general and depends on an arbitrary function of one variable.

I. INTRODUCTION

Since the discovery of the Kerr metric[1] until now, the Kerr–Schild Ansatz[2–4] has been a powerful tool to find new explicit solutions of the Einstein equations. Roughly speaking, this technique consists in generating new solutions from the Minkowski spacetime and its null geodesic vector fields, and it can be applied to several types of energy–momentum content: vacuum, electromagnetic field, pure radiation, etc. With regard to the results obtained, we should note that some of the solutions found have been of crucial importance in general relativity and they have received too much attention, especially in relation to the description of black holes or radiating bodies. Well-known examples are the Kerr–Newman family of spacetimes, the Vaidya metric, etc. A complete review of the classical Kerr–Schild transformation can be found in Reference 5 (chapter 28).

Some generalizations of this generation technique have appeared, so that they overcome some of the limitations that the classical Kerr–Schild transformation had. In particular, the energy–momentum tensor of the classical Kerr-Schild spacetimes generated have the null vector field used in the transformation as a null eigenvector and hence, they cannot be perfect-fluid solutions. A generalization which allows us to find perfect-fluid spacetimes is the generalized Kerr–Schild (GKS hereafter) transformation, which has been studied widely in Refs. 6–15. The GKS transformation is a generation technique in which the metrics of the initial and the final spacetimes are related by the following expression:

$$\tilde{g}_{ab} = g_{ab} + 2\,\mathscr{H}\ell_a\ell_b\,, \tag{1}$$

where the starting metric g_{ab}, which we shall call the *seed metric*, is any metric, $\vec{\ell}$ is a null vector field for the metric g_{ab}, and $\mathscr{H}$ is a scalar field. In the case in which $\vec{\ell}$ is geodesic, an illuminating result was proved in Refs. 6 and 7 (see also Refs. 8–10). It states that the energy–momentum tensor of the GKS spacetimes has $\vec{\ell}$ as an eigenvector if and only if $\vec{\ell}$ is an eigenvector for the energy–momentum tensor of the seed spacetimes. Therefore, if we are interested in finding perfect–fluid spacetimes, we should start with a seed spacetime whose energy–momentum tensor does not have null eigenvectors. In this line, a particularization of the GKS transformation for the search of perfect–fluid solutions was developed in Refs. 6, 7, where the seed spacetime was taking to be conformally-flat. From the application of this technique to several cases, new perfect-fluid

solutions of Einstein equations have been obtained. In some of these applications the solutions represent inhomogeneous cosmological models while in others they are static and stationary spacetimes (see Refs. 6–9, 12, and 16).

The subject of this paper is to apply the GKS transformation, in combination with techniques of null and timelike vector fields, in order to find new perfect-fluid solutions of Einstein's equations. The result found is a wide new family of stationary perfect-fluid spacetimes.

In the development of this work we follow the spirit of the classical Kerr–Schild transformation, where the seed spacetime was very simple (the Minkowski spacetime) and the richness of the transformation lay on the choice of the null vector fields $\vec{\ell}$ used. In this sense, we apply the GKS transformation to the FLRW models with a constant scale factor and taking their most general shear-free geodesic null (SFGN hereafter) vector field as the vector field $\vec{\ell}$. These objects, which are the basic ingredients to carry out the GKS transformation, are studied in section II. In that situation, we study the perfect-fluid Einstein field equations for the GKS metrics, from which we obtain the form of the GKS energy–momentum tensor (energy density, pressure, and fluid velocity) and some partial differential equations for the function $\mathscr{H}$ (section III). Then, through the study of the kinematical quantities of the GKS fluid velocity we impose some rectrictions in order to find stationary perfect-fluid solutions. Moreover, these restrictions together with the choice of the null basis will allow us to integrate the equations for $\mathscr{H}$ without the explicit use of a coordinate system. In addition, we deduce the Petrov type of the GKS spacetimes as well as expressions for the non-zero kinematical quantities of the fluid velocity (section IV).

In section V, we find the explicit form of the solutions. As far as we know, this family was previously unknown. It is noted that it contains all the classical vacuum Kerr–Schild spacetimes, excepting the plane–fronted gravitational waves, and hence the Kerr metric[1] is included too. It is also pointed out that the generalization of the Kerr metric in the Einstein background, due to Vaidya,[16] is also included. However, the family of stationary spacetimes found is much more general and depends on an arbitrary function of one variable. On the other hand, the efficiency of the procedure is shown in section VI, where the Killing equations are completely solved without using coordinates. It is remarkable that, in general, these spacetimes have only one symmetry. Moreover, we discuss the conditions in which other symmetries can appear and their consequences on the GKS spacetimes.

The main equations in this paper are written in the Newman–Penrose formalism.[17] The conventions that we use here are the same as those in Ref. 5 with the only exception that the name for the main vector field of the null basis here is $\vec{\ell}$ whereas in Ref. 5 it is $\vec{k}$. Moreover, throughout this paper we have used units in which $8\pi G=c=1$. Latin indexes run from 0 to 3. The abbreviation ''c.c.'' will stand for complex conjugate.

II. BASIC INGREDIENTS FOR THE GKS TRANSFORMATION

In the classical Kerr–Schild transformation the seed spacetime was the simplest one, the Minkowski spacetime being the important object the null vector field of the transformation, which was the most general SFGN vector field for Minkowski spacetime. Following this line, we take as seeds the subclass of the FLRW spacetimes with a constant scale factor and their most general SFGN vector field as the vector field $\vec{\ell}$ for the transformation.

In what follows, we give the characterization and the explicit form of the seed spacetimes g_{ab} as well as of the SFGN vector fields $\vec{\ell}$.

A. The seed metrics

As we have said, the seed spacetimes are the FLRW spacetimes with a constant scale factor, or equivalently, without expansion. Taking into account the form of the FLRW spacetimes given in appendix A, the line element for the seed spacetimes can be written in the following explicitly conformally-flat form:

$$ds^2=\frac{a^2}{(1+\varepsilon U^2)(1+\varepsilon V^2)}\left\{-4\,dU dV+4\left(\frac{V-U}{1+\xi\bar{\xi}}\right)^2 d\xi d\bar{\xi}\right\}, \tag{2}$$

where a is the constant scale factor and a bar denotes complex conjugation. In the case $\varepsilon=0$ this line element corresponds to the Minkowski spacetime in double null coordinates; in the case $\varepsilon=1$ to the Einstein static Universe and, in the case $\varepsilon=-1$, it corresponds to a spacetime usually not considered because the energy density is negative, however we consider it as a seed spacetime because it may lead to GKS solutions with good physical properties.

These conformally-flat spacetimes have a perfect-fluid matter content and therefore, its energy–momentum tensor is given by

$$T_{ab}=(\varrho+p)u_a u_b+p g_{ab}, \quad g_{ab}u^a u^b=-1,$$

where the energy density ϱ and the pressure p are constant,

$$\varrho=\frac{3\,\varepsilon}{a^2}=-3\,p,$$

and in addition, the fluid velocity is

$$\vec{u}=u^a\frac{\partial}{\partial x^a}=\frac{\partial}{\partial t}=\frac{1}{2\,a}\left\{(1+\varepsilon U^2)\frac{\partial}{\partial U}+(1+\varepsilon V^2)\frac{\partial}{\partial V}\right\},$$

$$\mathbf{u}=u_a dx^a=-dt=-a\left\{\frac{dU}{1+\varepsilon U^2}+\frac{dV}{1+\varepsilon V^2}\right\}.$$

It can be checked that $\vec{u}$ is a constant vector field, that is $\nabla_a u_b=0$. On the other hand, the case $\varepsilon=0$ is Minkowski ($\varrho=p=0$), and although we can define $\vec{u}$, it is not a preferred vector field.

B. The shear-free geodesic null vector field $\vec{\ell}$

In analogy with the pioneering works[4] on the classical Kerr–Schild transformation, we restrict ourselves to the class of shear–free geodesic null vector fields. Although the Goldberg–Sachs theorem[18] tells us that such a kind of vector fields may not exist in general spacetimes, it is common knowledge that in the Minkowski spacetime there is a big family of such vector fields and all of them are known explicitly: this result constitutes the so-called *Kerr's theorem* (see Refs. 5, 19). Moreover, it is well known that a SFGN vector field for Minkowski is also a SFGN vector field for any conformally-flat spacetime, which means that we have the same large class of such vector fields for the seed spacetimes (2). Here, we are going to construct all of them and after this, we will construct an appropriate null basis associated with them.

To begin with, the most general null one-form field for the seed spacetimes (2) can be written in the following form:

$$\vec{\ell}=F\left\{dU+Y\overline{Y}dV+\frac{V-U}{1+\xi\overline{\xi}}(\overline{Y}d\xi+Yd\overline{\xi})\right\}, \tag{3}$$

where F and Y are real and complex arbitrary scalar fields, respectively. Then, in order that $\vec{\ell}$ be geodesic and shear-free, the complex function Y must be a solution of the following system of non-linear partial differential equations:

$$(1+\xi\overline{\xi})YY_{,\xi}=(V-U)Y_{,V}+Y(1+\overline{\xi}Y), \tag{4}$$

$$(1+\xi\overline{\xi})Y_{,\overline{\xi}}=(V-U)YY_{,U}-Y(Y-\xi), \tag{5}$$

where commas stand for partial derivatives with respect to the subscript that follows.

Now, in order to simplify further calculations, we take a null basis $\{\ell,\mathrm{k},\mathrm{m},\overline{\mathrm{m}}\}$ for the seed spacetimes (2) associated with $\vec{\ell}$. We choose this null basis in such a way that $\vec{\ell}$ be affinely parametrized and such that the unit timelike vector field $\vec{u}$ can be written in the following way:

$$\vec{u}=\frac{1}{\sqrt{2}}(\vec{\ell}+\vec{\mathrm{k}}),\quad \mathbf{u}=\frac{1}{\sqrt{2}}(\ell+\mathbf{k}).$$

Part of the remaining freedom is used for setting the imaginary part of the spin coefficient ϵ equals to zero. After some calculations, the explicit expressions for such a null basis $\{\ell,\mathrm{k},\mathrm{m},\overline{\mathrm{m}}\}$ are (3) and

$$\mathbf{k}=F\left\{\frac{1+\varepsilon V^2}{1+\varepsilon U^2}Y\overline{Y}dU+\frac{1+\varepsilon U^2}{1+\varepsilon V^2}dV-\frac{V-U}{1+\xi\overline{\xi}}(\overline{Y}d\xi+Yd\overline{\xi})\right\},$$

$$\mathbf{m}=-F\left\{\sqrt{Y\overline{Y}}\left(-\sqrt{\frac{1+\varepsilon V^2}{1+\varepsilon U^2}}dU+\sqrt{\frac{1+\varepsilon U^2}{1+\varepsilon V^2}}dV\right)\right.$$
$$\left.+\frac{V-U}{1+\xi\overline{\xi}}\sqrt{\frac{\overline{Y}}{Y}}\left(\sqrt{\frac{1+\varepsilon U^2}{1+\varepsilon V^2}}d\xi-Y^2\sqrt{\frac{1+\varepsilon V^2}{1+\varepsilon U^2}}d\overline{\xi}\right)\right\},$$

where the case $Y=0$ can be obtained by taking $Y/\overline{Y}=1$, and F is the following function:

$$F=\frac{-\sqrt{2}a}{(1+\varepsilon U^2)+(1+\varepsilon V^2)Y\overline{Y}}.$$

After long but straightforward calculations we find that the spin coefficients associated with this null basis satisfy the relations

$$\begin{aligned}&\kappa=\sigma=\epsilon=\pi=\lambda=0,\\ &\tau-\overline{\nu}=\rho-\overline{\mu}=\alpha+\overline{\beta}=\gamma+\overline{\gamma}=0.\end{aligned}\tag{6}$$

Furthermore, the Newman–Penrose symbols for the Riemann tensor are the following:

Ricci tensor,

$$\Phi_{01}=\Phi_{02}=\Phi_{12}=0,\quad \Phi_{00}=2\,\Phi_{11}=\Phi_{22}=\frac{1}{4}(\varrho+p)=\frac{\varepsilon}{2a^2},\quad \Lambda=\frac{1}{24}(\varrho-3p)=\frac{\varepsilon}{4a^2};$$

Weyl tensor,

$$\Psi_0=\Psi_1=\Psi_2=\Psi_3=\Psi_4=0.$$

III. THE CONSTRUCTION OF THE GKS SPACETIMES

In this section we study the GKS transformation (1) for the seed spacetimes (2) with (3) as the SFGN vector field $\vec{\ell}$. To that end, we use the fact that given a null basis $\{\ell,\mathrm{k},\mathrm{m},\overline{\mathrm{m}}\}$ associated with the seed metric, we can construct a null basis $\{\widetilde{\ell},\widetilde{\mathrm{k}},\widetilde{\mathrm{m}},\overline{\widetilde{\mathrm{m}}}\}$ associated with the GKS metric by taking (see Refs. 12 and 6)

$$\begin{aligned}&\widetilde{\ell}^a=\ell^a,\quad \widetilde{\ell}_a=\ell_a,\\ &\widetilde{\mathrm{k}}^a=\mathrm{k}^a+\mathscr{H}\ell^a,\quad \widetilde{\mathrm{k}}_a=\mathrm{k}_a-\mathscr{H}\ell_a,\\ &\widetilde{\mathrm{m}}^a=\mathrm{m}^a,\quad \widetilde{\mathrm{m}}_a=\mathrm{m}_a,\end{aligned}\tag{7}$$

where, from now on, objects with an overtilde are associated with the GKS spacetimes in contrast with objects without an overtilde which are associated with the seed spacetimes.

These relationships between null bases allow us to compute all objects associated with the GKS spacetimes as functions of the same objects associated with the seed spacetimes, and the function $\mathscr{H}$ and their derivatives. In this sense, we can compute all the Newman–Penrose symbols for the GKS spacetimes. Taking into account the expressions of the previous section, the result for the components of the Ricci tensor is the following:

$$\widetilde{\Phi}_{00}=\frac{\varepsilon}{2\,a^2},\quad \widetilde{\Phi}_{01}=\widetilde{\Phi}_{02}=0, \tag{8}$$

$$\widetilde{\Phi}_{11}=\frac{\varepsilon}{4\,a^2}+\frac{1}{2}\left[(\rho-\overline{\rho})^2+\frac{\varepsilon}{2\,a^2}\right]\mathscr{H}+\frac{1}{4}(\rho+\overline{\rho})\mathscr{V}-\frac{1}{4}D\mathscr{V}, \tag{9}$$

$$\widetilde{\Phi}_{12}=[\delta\overline{\rho}+(\rho-\overline{\rho})\tau]\mathscr{H}+\overline{\rho}\mathscr{H}+\frac{1}{2}(\tau\mathscr{V}-\delta\mathscr{V}), \tag{10}$$

$$\widetilde{\Phi}_{22}=\frac{\varepsilon}{2\,a^2}+\frac{1}{2}[2\,\triangle(\rho+\overline{\rho})-(\rho-\overline{\rho})^2]\mathscr{H}+\frac{1}{2}(\rho+\overline{\rho})\triangle\mathscr{H}+\frac{1}{2}(\rho+\overline{\rho})\mathscr{V}$$
$$+(\overline{\tau}+\alpha)\mathscr{U}+(\tau+\overline{\alpha})\overline{\mathscr{U}}-\frac{1}{2}(\delta\overline{\mathscr{U}}+\overline{\delta}\mathscr{U})+\frac{\varepsilon}{2\,a^2}\mathscr{H}^2, \tag{11}$$

$$\widetilde{\Lambda}=\frac{\varepsilon}{4\,a^2}+\frac{1}{6}\left[(\rho+\overline{\rho})^2+2\,\rho\overline{\rho}-\frac{3\,\varepsilon}{2\,a^2}\right]\mathscr{H}-\frac{1}{4}(\rho+\overline{\rho})\mathscr{V}+\frac{1}{12}D\mathscr{V}, \tag{12}$$

where $\mathscr{V}$ and $\mathscr{U}$ are defined by

$$\mathscr{V}\equiv D\mathscr{H}+(\rho+\overline{\rho})\mathscr{H},\quad \mathscr{U}\equiv\delta\mathscr{H}.$$

In the same way, we can obtain the components of the Weyl tensor. Their expressions are

$$\widetilde{\Psi}_0=0,\quad \widetilde{\Psi}_1=0, \tag{13}$$

$$3\,\widetilde{\Psi}_2=-(\rho-\overline{\rho})^2\mathscr{H}-\frac{3}{2}(\rho-\overline{\rho})\mathscr{V}-\frac{1}{2}D\mathscr{V}, \tag{14}$$

$$\widetilde{\Psi}_3=-(\rho-\overline{\rho})\overline{\mathscr{U}}+\frac{1}{2}(\overline{\tau}\mathscr{V}-\overline{\delta}\mathscr{V}),\quad \widetilde{\Psi}_4=2\,(\overline{\tau}-\alpha)\overline{\mathscr{U}}-\overline{\delta\mathscr{U}}. \tag{15}$$

As we can see directly from these equations, all the GKS spacetimes that we can obtain are algebraically special because the null vector field $\vec{\ell}=\vec{\ell}$ is a multiple null eigenvector of the Weyl tensor.

Now, we must study the Einstein field equations for the GKS metrics with a perfect–fluid source. They read as follows:

$$\widetilde{G}_{ab}+C\widetilde{g}_{ab}=\widetilde{T}_{ab}, \tag{16}$$

where $\widetilde{G}_{ab}$ is the Einstein tensor for the GKS metrics, C is the cosmological constant, and $\widetilde{T}_{ab}$ is the energy–momentum tensor, which has the form

$$\widetilde{T}_{ab}=(\widetilde{\varrho}+\widetilde{p})\widetilde{u}_a\widetilde{u}_b+\widetilde{p}\,\widetilde{g}_{ab},\quad \widetilde{g}_{ab}\widetilde{u}^a\widetilde{u}^b=-1, \tag{17}$$

where $\tilde{\varrho}$, $\tilde{p}$ and $\tilde{\vec{u}}$ are the energy density, the pressure, and the fluid velocity of the GKS perfect fluid, respectively. In this situation, we project the Einstein equations (16) onto the null basis $\{\tilde{\ell},\tilde{\mathrm{k}},\tilde{\mathrm{m}},\tilde{\overline{\mathrm{m}}}\}$ and then, using (17) we obtain other expressions for the Ricci tensor components,

$$\tilde{\Phi}_{00}=\frac{1}{2}(\tilde{\varrho}+\tilde{p})(\tilde{\ell}^a\tilde{u}_a)^2, \tag{18}$$

$$\tilde{\Phi}_{01}=\frac{1}{2}(\tilde{\varrho}+\tilde{p})(\tilde{\ell}^a\tilde{u}_a)(\tilde{\mathrm{m}}^b\tilde{u}_b), \quad \tilde{\Phi}_{02}=\frac{1}{2}(\tilde{\varrho}+\tilde{p})(\tilde{\mathrm{m}}^a\tilde{u}_a)^2, \tag{19}$$

$$\tilde{\Phi}_{11}=\frac{1}{4}(\tilde{\varrho}+\tilde{p})[(\tilde{\ell}^a\tilde{u}_a)(\tilde{\mathrm{k}}^b\tilde{u}_b)+(\tilde{\mathrm{m}}^a\tilde{u}_a)(\tilde{\overline{\mathrm{m}}}^b\tilde{u}_b)], \tag{20}$$

$$\tilde{\Phi}_{12}=\frac{1}{2}(\tilde{\varrho}+\tilde{p})(\tilde{\mathrm{k}}^a\tilde{u}_a)(\tilde{\mathrm{m}}^a\tilde{u}_a), \quad \tilde{\Phi}_{22}=\frac{1}{2}(\tilde{\varrho}+\tilde{p})(\tilde{\mathrm{k}}^a\tilde{u}_a)^2, \tag{21}$$

$$\tilde{\Lambda}=\frac{1}{24}(\tilde{\varrho}-3\,\tilde{p})+\frac{1}{6}C. \tag{22}$$

The next step in this process is to compare the expressions for the Ricci tensor (8)–(12) with the Einstein equations for the GKS metrics (18)–(22). We do this for the seed metrics with $\varepsilon\neq 0$, so that $\tilde{\varrho}+\tilde{p}\neq 0$, and later we will extend the results for the $\varepsilon=0$ case. The outcome of this comparison is the following.

• The components, in the null bases $\{\ell,\mathrm{k},\mathrm{m},\overline{\mathrm{m}}\}$ and $\{\tilde{\ell},\tilde{\mathrm{k}},\tilde{\mathrm{m}},\tilde{\overline{\mathrm{m}}}\}$, for the fluid velocity $\tilde{\vec{u}}$ of the GKS perfect fluid:

$$(\tilde{\ell}^a\tilde{u}_a)^2=(\ell^a\tilde{u}_a)^2=\frac{\varepsilon}{2a^2}\left[\frac{\varepsilon}{a^2}+2\left((\rho-\overline{\rho})^2+\frac{\varepsilon}{2a^2}\right)\mathscr{H}+(\rho+\overline{\rho})\mathscr{V}-D\mathscr{V}\right]^{-1}, \tag{23}$$

$$\tilde{\mathrm{k}}^a\tilde{u}_a=\mathrm{k}^a\tilde{u}_a+\mathscr{H}\ell^a\tilde{u}_a=[2\,(\tilde{\ell}^a\tilde{u}_a)]^{-1}, \tag{24}$$

$$\tilde{\mathrm{m}}^a\tilde{u}_a=\mathrm{m}^a\tilde{u}_a=0. \tag{25}$$

• The energy density and the pressure of the GKS perfect fluid:

$$\tilde{\varrho}=\frac{3\,\varepsilon}{a^2}-C+2\,(2\,\rho^2-\rho\,\overline{\rho}+2\,\overline{\rho^2})\mathscr{H}-D\mathscr{V}, \tag{26}$$

$$\tilde{p}=-\frac{\varepsilon}{a^2}+C+2\left(-3\,\rho\,\overline{\rho}+\frac{\varepsilon}{a^2}\right)\mathscr{H}+2\,(\rho+\overline{\rho})\mathscr{V}-D\mathscr{V}. \tag{27}$$

• Two second order partial differential equations for $\mathscr{H}$:

$$\delta\mathscr{V}=\tau\mathscr{V}+2\,\overline{\rho}\,\mathscr{U}+2\,[\delta\overline{\rho}+(\rho-\overline{\rho})\,\tau]\mathscr{H}, \tag{28}$$

$$\begin{aligned}(\rho+\overline{\rho})\triangle\mathscr{H}=&\left[(\rho-\overline{\rho})^2+\frac{\varepsilon}{a^2}-2\,\Delta(\rho+\overline{\rho})\right]\mathscr{H}-(\rho+\overline{\rho})\mathscr{V}+\delta\overline{\mathscr{U}}\\&+\overline{\delta}\mathscr{U}-2\,(\overline{\tau}+\alpha)\mathscr{U}-2\,(\tau+\overline{\alpha})\overline{\mathscr{U}}+\left(\frac{\varepsilon}{a^2}\right)^{-1}\mathscr{W},\end{aligned} \tag{29}$$

where $\mathscr{W}$ is given by

$$\mathscr{W}=[D\mathscr{V}-(\rho+\overline{\rho})\mathscr{V}-2(\rho-\overline{\rho})^2.\mathscr{H}]\left[D\mathscr{V}-(\rho+\overline{\rho})\mathscr{V}-2(\rho-\overline{\rho})^2.\mathscr{H}-\frac{2\,\varepsilon}{a^2}(1+\mathscr{H})\right]. \tag{30}$$

As we can see, equation (29) is a nonlinear partial differential equation for $\mathscr{H}$ due to the term with $\mathscr{W}$.

IV. CHARACTERIZATION OF THE GKS SPACETIMES THROUGH THE KINEMATICAL QUANTITIES

Until now, the only assumption we have made on the GKS spacetimes is that their energy–momentum tensor must be of the perfect-fluid type. Then, once we have a function $\mathscr{H}$ solution of the system (28)–(29), we have the explicit form of the GKS metric as well as of the matter content variables. However, there is not a systematic way of solving (28)–(29), especially because (29) is a nonlinear equation. For this reason, we are going to introduce some additional assumptions on the GKS spacetimes which can help us to integrate these equations. Of course, it would be advisable to impose conditions which have a physical meaning. In this sense, an interesting way to control these conditions is through the study of the kinematical quantities for the fluid velocity $\vec{\tilde{u}}$ of the GKS perfect fluid.

From equations (23)–(25) it follows that $\vec{\tilde{u}}$ lies in the two-planes generated by $\vec{\ell}$ and $\vec{\tilde{k}}$. Then, by making the following change of basis:

$$\vec{\ell}\to\vec{L}=\mathscr{A}\vec{\ell},\quad \vec{\tilde{k}}\to\vec{K}=\mathscr{A}^{-1}\,\vec{\tilde{k}},\quad \vec{\tilde{m}}\to\vec{\tilde{m}}, \tag{31}$$

where

$$\mathscr{A}^2\equiv[2\,(\ell^a\tilde{u}_a)^2]^{-1}, \tag{32}$$

we get the following form for $\vec{\tilde{u}}$:

$$\vec{\tilde{u}}=\frac{1}{\sqrt{2}}(\vec{L}+\vec{K}).$$

Therefore, we can now use the formulas given in Appendix B to obtain the kinematical quantities of $\vec{\tilde{u}}$. To that end, we compute the spin coefficients associated with the null basis $\{L,K,\tilde{m},\overline{\tilde{m}}\}$, which we denote with a hat. The most useful results are

$$\hat{\rho}+\hat{\tilde{\rho}}=(\rho+\overline{\rho}).\mathscr{A},\quad \hat{\mu}+\hat{\tilde{\mu}}=(\rho+\overline{\rho})(1-\mathscr{H}).\mathscr{A}^{-1},\quad \hat{\epsilon}+\hat{\tilde{\epsilon}}=D.\mathscr{A},$$

$$\hat{\gamma}+\hat{\tilde{\gamma}}=-\mathscr{A}^{-1}D.\mathscr{H}+(\triangle.\mathscr{A}+\mathscr{H}D.\mathscr{A}).\mathscr{A}^{-2},\quad \hat{\alpha}+\hat{\tilde{\beta}}=\mathscr{A}^{-1}\overline{\delta}.\mathscr{A},$$

$$\hat{\pi}+\hat{\tilde{\tau}}-\hat{\nu}-\hat{\tilde{\kappa}}=\overline{\tau}+[\,\overline{\delta}.\mathscr{H}-\overline{\tau}(1+\mathscr{H})].\mathscr{A}^{-2},\quad \hat{\sigma}=\hat{\lambda}=0,$$

$$\hat{\rho}-\hat{\overline{\tilde{\rho}}}=(\rho-\overline{\rho}).\mathscr{A},\quad \hat{\mu}-\hat{\tilde{\mu}}=-(\rho-\overline{\rho})(1+\mathscr{H}).\mathscr{A}^{-1}.$$

In this situation, we are going to impose conditions which can lead to stationary spacetimes. To that end, we impose the vanishing of the shear and expansion of the fluid velocity $\vec{\tilde{u}}$, that is,

$$\tilde{\theta}=\tilde{\sigma}_{ab}=0. \tag{33}$$

These conditions are necessary in order to have $\vec{\tilde{u}}$ proportional to a time-like Killing vector field. Then, from the vanishing of the expansion and the $m_{(a}\overline{m}_{b)}$-component of the shear tensor (see appendix B) we have

$$(\rho+\overline{\rho})(\mathscr{A}^2-1+\mathscr{H})=0,$$

so that, two different cases may appear: $\rho+\overline{\rho}=0$ or $\mathscr{A}^2=1-\mathscr{H}$. If $\rho+\overline{\rho}=0$ the SFGN vector field $\vec{\ell}$ is expansion–free. In addition, from the Newman–Penrose equations[17] we obtain that $\rho^2+\varepsilon/(2\,a^2)=0$, which means that only the case $\varepsilon=1$ is possible. However, further analysis of the equations for this case shows that there are not solutions in this case. Therefore, from now on we will consider that $\rho+\overline{\rho}\neq 0$, and then we must follow through the second possibility,

$$\mathscr{A}^2=1-\mathscr{H}. \tag{34}$$

From this equation and using the expressions (23), (32) we get another differential equation for $\mathscr{H}$,

$$D\mathscr{V}=(\rho+\overline{\rho})\mathscr{V}+2\left[(\rho-\overline{\rho})^2+\frac{\varepsilon}{a^2}\right]\mathscr{H}. \tag{35}$$

If we use this equation, we can see from (30) that $\mathscr{W}=-4\,(\varepsilon^2/a^2).\mathscr{H}$, and therefore (29) is a linear differential equation for $\mathscr{H}$. Moreover, from the remaining components of equations (33) we have the following two additional conditions on $\mathscr{H}$ and Y:

$$(D+\triangle).\mathscr{H}=0, \tag{36}$$

$$\tau=0, \tag{37}$$

respectively. The first is a further differential equation for $\mathscr{H}$, while the second one is a constraint on the possible complex functions Y that we can use to construct the SFGN vector fields $\vec{\ell}$. Then, replacing (34) into expressions (23)–(25) for the fluid velocity $\tilde{\vec{u}}$ we obtain

$$\tilde{\vec{u}}=\frac{1}{\sqrt{2\,(1-\mathscr{H})}}[(1-\mathscr{H})\tilde{\vec{\ell}}+\tilde{\vec{\mathrm{k}}}]=\frac{1}{\sqrt{2\,(1-\mathscr{H})}}(\vec{\ell}+\vec{\mathrm{k}})=\frac{1}{\sqrt{1-\mathscr{H}}}\vec{u}, \tag{38}$$

that is to say, $\tilde{\vec{u}}$ is proportional to $\vec{u}$. On the other hand, it can be shown that the vector field $\vec{\mathrm{u}}$, which is a Killing vector field for the seed spacetimes (2), is also a Killing vector field for the GKS spacetimes provided that (36) and (37) hold. Thus, $\tilde{\vec{u}}$ is parallel to a Killing vector field. We can see this fact from the following expression:

$$\tilde{\boldsymbol{\nabla}}_a\tilde{u}'_b+\tilde{\boldsymbol{\nabla}}_b\tilde{u}'_a=\sqrt{2}\{(D+\triangle).\mathscr{H}\ell_a\ell_b+2[\tau\ \mathrm{k}_{(a}\mathrm{m}_{b)}+\text{ c.c.}].\mathscr{H}=0, \tag{39}$$

where $\tilde{u}'_a=\tilde{g}_{ab}u^b$. Here, we have used (6) and the second equality follows from (36),(37). Notice that this is not a trivial result because, even though conditions (33) are necessary for $\tilde{u}$ to be proportional to a Killing, they are not sufficient (we also need the acceleration $\tilde{\mathbf{a}}$ to be an exact 1-form). Therefore, we have proved that (33) implies $\mathbf{d}\tilde{\mathbf{a}}=\mathbf{0}$ under our conditions.

On the other hand, in the last section we restricted ourselves to the cases $\varepsilon=\pm 1$. Now, we can include the case $\varepsilon=0$ by defining the vector field $\tilde{\vec{u}}$ through the expression (38), and by taking the same partial differential equations (28)–(29) and (35)–(36) for $\mathscr{H}$.

The next point is to find which are the integrability conditions for the system of *linear* partial differential equations for $\mathscr{H}$. In this process we find two different cases.

• *Case A:* $\overline{\delta\rho}=0\Rightarrow\rho-\overline{\rho}=0$. It can be shown that all the GKS metrics that we can find in this case are included in a particular case of Ref. 8, where the authors use the GKS transformation with the interior Schwarzschild metric as the seed metric. The resultant GKS spacetimes in that paper are stationary spherically symmetric and they contain a subfamily of regular solutions with equation of state $\tilde{\varrho}+3\,\tilde{p}=\text{const}$. Among these spacetimes we have the Whittaker metric[20] as a special case, which, at the same time, is the static limit of the Wahlquist metric.[21]

• *Case B:* $\overline{\delta\rho}\neq 0$. In this case the procedure to find the integrability conditions of the system of partial differential equations (28)–(29) and (35)–(36) for $\mathscr{H}$, leads us to the following equations for the first derivatives of $\mathscr{H}$:

$$D.\mathscr{H}=\frac{\rho^2+\overline{\rho^2}+(\varepsilon/a^2)}{\rho+\overline{\rho}}\mathscr{H}=-\Delta.\mathscr{H},\quad \delta.\mathscr{H}=\frac{\delta\overline{\rho}}{\rho+\overline{\rho}}\mathscr{H}. \tag{40}$$

These equations can be easily solved without the explicit use of coordinates and the solution is

$$\mathscr{H}=m(\rho+\overline{\rho}), \tag{41}$$

where m is an arbitrary constant.

The energy–momentum tensor of these GKS spacetimes can be obtained by substituting $\mathscr{H}$ in the explicit form of the fluid velocity, the energy density, and the pressure, given in (38) and (26)–(27), respectively. In particular, the energy density and the pressure are

$$\widetilde{\varrho}=\frac{3\,\varepsilon}{a^2}[1-m(\rho+\overline{\rho})]-C,\quad \widetilde{p}=\frac{\varepsilon}{a^2}[-1+m(\rho+\overline{\rho})]+C, \tag{42}$$

so that we have the following equation of state:

$$\widetilde{\varrho}+3\,\widetilde{p}=2C.$$

The most interesting case from the physical point of view is the one given by $C\geqslant 0$ and $\varepsilon=1$, for which there are spacetime regions where all the energy conditions are fulfilled (see Ref. 22). In this case, from the form (38) of $\tilde{\tilde{u}}$, it follows that the region of the spacetime in which we can define this unit timelike vector field is

$$1-\mathscr{H}>0.$$

Moreover, the case $\varepsilon=C=0$ corresponds to vacuum solutions. In the next section we will analyze to which solutions correspond each case.

On the other hand, from the expressions (13)–(15) for the Weyl tensor we already know that the GKS spacetimes are algebraically special. In this case, the Petrov type is II in general, except when the following relation holds:

$$3\,\widetilde{\Psi}_2\widetilde{\Psi}_4=2\,\widetilde{\Psi}_3^2\Rightarrow\left(\rho^2+\frac{\varepsilon}{2\,a^2}\right)(\overline{\delta\,\delta\rho}+2\,\alpha\,\overline{\delta\rho})=3\,\rho(\overline{\delta\rho})^2. \tag{43}$$

In that case the Petrov type is D and the fluid velocity does not lie in the preferred two-space spanned by the two multiple null eigenvectors of the Weyl tensor.

Finally, the non-vanishing kinematical quantities for $\tilde{\tilde{u}}$ are

$$\tilde{\tilde{a}}=-\frac{D.\mathscr{H}}{\sqrt{2\,(1-\mathscr{H})}}\tilde{\tilde{v}}-\left(\frac{\overline{\delta}.\mathscr{H}}{1-\mathscr{H}}\tilde{\tilde{m}}+\text{ c.c.}\right),$$

$$\widetilde{\omega}_{ab}=-\left(\frac{\overline{\delta}.\mathscr{H}}{1-\mathscr{H}}\widetilde{v}_{[a}\widetilde{m}_{b]}+\text{ c.c.}\right)-\frac{\sqrt{2}(\rho-\overline{\rho}).\mathscr{H}}{\sqrt{1-\mathscr{H}}}\widetilde{m}_{[a}\widetilde{\overline{m}}_{b]}, \tag{44}$$

where $\widetilde{v}^a$ is a unit spacelike vector field, orthogonal to $\widetilde{u}^a$, and is defined as follows:

$$\widetilde{v}^a\equiv\frac{(1-\mathscr{H})\widetilde{\gamma}^a-\widetilde{k}^a}{\sqrt{2\,(1-\mathscr{H})}}\Rightarrow\widetilde{v}^a\widetilde{v}_a=1,\quad \widetilde{v}^a\widetilde{u}_a=0.$$

It is interesting to note that from expression (44) and from equations (40)–(41) we can deduce that the rotation $\widetilde{\omega}_{ab}$ of $\widetilde{u}^a$ vanishes if and only if so does the rotation $\rho-\overline{\rho}$ of ℓ^a.

V. EXPLICIT FORM OF THE SOLUTIONS

After the integration of the equations for $\mathscr{H}$, we are going to find an explicit expression for the line element of the GKS spacetimes. For this we must find explicitly all the SFGN vector fields $\vec{\ell}$ satisfying the condition (37), that is, we must find the explicit solutions of the partial differential equations (4)–(5) together with (37). To do that, it is more convenient to consider a new function Ω instead of Y, which is defined by

$$Y(U,V,\xi,\overline{\xi})\equiv\sqrt{\frac{1+\varepsilon U^2}{1+\varepsilon V^2}}\Omega(t,\chi,\xi,\overline{\xi}),$$

and also, it is better to change from the coordinates $\{U,V\}$ to the $\{t,\chi\}$ ones (see appendix A). Once we have performed these changes, the equations (4)–(5) and (37) read as follows:

$$(1+\xi\overline{\xi})\Omega\Omega_{,\xi}-\overline{\xi}\Omega^2=\Sigma\Omega_{,\chi}+\Sigma'\Omega, \tag{45}$$

$$(1+\xi\overline{\xi})\Omega_{,\overline{\xi}}+\xi\Omega=-\Sigma\Omega\Omega_{,\chi}+\Sigma'\Omega^2, \tag{46}$$

$$\Omega_{,t}=0, \tag{47}$$

where $\Sigma(\varepsilon,\chi)$ is given in appendix A. The most general solution of these equations can be given implicitly by

$$G\left(\frac{e^{-\sqrt{-\varepsilon}\chi}\Omega-\xi}{1+\overline{\xi}\,e^{-\sqrt{-\varepsilon}\chi}\Omega},\frac{(1-\xi\overline{\xi})\Sigma'\Omega-\xi+\overline{\xi}\Omega^2}{(1+\xi\overline{\xi})\Sigma\Omega}\right)=0, \tag{48}$$

where $G(z_1,z_2)$ is any analytic complex function of two complex variables $\{z_1,z_2\}$. It is interesting to note that, in the same way, we could have found the general solution of only equations (45) and (46), then we would have obtained all the possible SFGN vector fields for the seed metrics (2), which constitutes the analogous result of the Kerr theorem. However, for the sake of brevity we do not give here the explicit form of the general solution. From the definition of the spin coefficient ρ, and using (45)–(47) we have

$$\rho=\begin{cases}\dfrac{1}{\sqrt{2}a}\dfrac{\Omega_{,\chi}}{\Omega}, & \text{for } \Omega\neq 0,\\[2ex] \dfrac{1}{\sqrt{2}a}\dfrac{\Sigma'}{\Sigma}, & \text{for } \Omega=0,\end{cases}$$

and then, the solution (41) for $\mathscr{H}$ is

$$\mathscr{H}=\begin{cases}\dfrac{m}{\sqrt{2}a}[\ln(\Omega\overline{\Omega})]_{,\chi}, & \text{for } \Omega\neq 0,\\[2ex] \dfrac{\sqrt{2}m}{a}\dfrac{\Sigma'}{\Sigma}, & \text{for } \Omega=0.\end{cases}$$

Now, making the substitution of the expressions (41) for the function $\mathscr{H}$ and (38) for the SFGN 1-form $\vec{\ell}$ into the definition of the GKS transformation (2), we find the following explicit form for the line element of the GKS metrics:

$$ds^2=-dt^2+a^2\left(d\chi^2+\frac{4\Sigma^2 d\xi d\overline{\xi}}{(1+\xi\overline{\xi})^2}\right)$$
$$+\frac{a^2\mathscr{H}}{(1+\Omega\overline{\Omega})^2}\left[(1+\Omega\overline{\Omega})\frac{dt}{a}-(1-\Omega\overline{\Omega})d\chi+\frac{2\Sigma}{1+\xi\overline{\xi}}(\overline{\Omega}d\xi+\Omega d\overline{\xi})\right]^2. \qquad (49)$$

It is interesting to point out that this family of stationary solutions of Einstein's equations has an arbitrary function, namely Ω. Moreover, as far as we know, these metrics were previously unknown.

With regard to the complex function Ω, if the function $G(z_1,z_2)$ does not depend on z_2 we have

$$\Omega=\mathrm{e}^{\sqrt{-\varepsilon}\chi}f(\xi,\overline{\xi}),$$

where f is a complex function that we can find by solving the system of differential equations (45)–(46). This form of Ω implies that

$$\mathscr{H}=\begin{cases}0, & \text{if } \varepsilon=0,1,\\ \dfrac{\sqrt{2}m}{a}, & \text{if } \varepsilon=-1,\end{cases}$$

and this means that in order to avoid $\mathscr{H}=0$ for the cases $\varepsilon=0,1$ (which would mean that the GKS transformation is trivial), we must impose that

$$\frac{\partial G}{\partial z_2}\neq 0,$$

and therefore, by the implicit function theorem, we can write (48) as follows:

$$\Upsilon\left(\frac{\mathrm{e}^{-\sqrt{-\varepsilon}\chi}\Omega-\xi}{1+\overline{\xi}\,\mathrm{e}^{-\sqrt{-\varepsilon}\chi}\Omega}\right)+\frac{(1-\xi\overline{\xi})\Sigma'\Omega-\xi+\overline{\xi}\Omega^2}{(1+\xi\overline{\xi})\Sigma\Omega}=0,$$

where $\Upsilon(z)$ is any analytic complex function of one complex variable z. Moreover, as we can see directly from the last equation, or from equations (45)–(47) and the expression for the line-element (49), the transformation

$$\Omega\to\Omega'=-\frac{1}{\overline{\Omega}},\quad \chi\to\chi'=-\chi,$$

is a *gauge* transformation since it induces the change $\vec{\ell}\to\vec{\ell}\,'=-\vec{\ell}$, and therefore both solutions of equations (45)–(47), Ω and Ω', determine the same GKS metric. Apart from this gauge, we have not been able to find any other. On the other hand, we can think, as Debney[23] did, that part of the complex functions Ω are gauges of the seed metric, or in other words, that the GKS metrics we obtain are the seed metrics. Looking at the expressions (13)–(15) for the Weyl tensor, this can only happen when $\rho+\overline{\rho}=0\Rightarrow\overline{\delta\rho}=0$, which corresponds to Case A. Therefore, the GKS metrics (49) are always different from the seed metrics.

As we said before, the family of solutions (49) is too wide in the sense that it depends on the arbitrary function Ω. Analyzing the form of the metric (see also Ref. 10) the solutions contained in each case are the following.

• Case $\varepsilon=0$: If we do not consider the cosmological constant ($C=0$), the metrics (49) are all the classical vacuum Kerr–Schild metrics[4] with the exception of the plane-fronted gravitational waves.[24,23,25] This exception is due to the fact that this class of solutions corresponds to the case $\rho=0$ (see Ref. 5). The Schwarzschild spacetime is obtained when $Y=\Omega=0$, and the Kerr spacetime when we choose Υ in the following way:

$$\Upsilon = -\frac{1}{\sqrt{2}\,\mathrm{i}c}, \tag{50}$$

where c is an arbitrary real constant. In this case, if we carry out the suitable changes (see Ref. 10), we can identify the mass and the angular momentum as measured from infinity with $m/(4\sqrt{2}a)$ and $(mc)/(4\sqrt{2}a)$, respectively.

• Case $\varepsilon=1$: All the spacetimes within this case were unknown with the exception of the case given by (50), corresponding to a metric due to Vaidya[16] (it is also a particular case of the Wahlquist metric[21,26]) which has been interpreted as the Kerr metric in the cosmological background of the Einstein Universe. In this sense, the metrics of this class can be interpreted as the vacuum Kerr–Schild configurations in the background of the Einstein Universe.

• Case $\varepsilon=-1$: These spacetimes were also unknown and they correspond to the Kerr–Schild configurations in the background of the seed spacetimes (2) with $\varepsilon=-1$. From the physical point of view these spacetimes have less interest since they do not satisfy the usual energy conditions.[22]

VI. SOLUTION OF THE KILLING EQUATIONS AND STUDY OF THE SYMMETRIES

The subject of this section is the study of the symmetries of the GKS spacetimes (49). A remarkable point in this study is the fact that it is possible to integrate the Killing equations without the explicit use of coordinates, as it happened with the equations for $\mathscr{H}$. To carry out this integration, we consider the Killing equations for these metrics,

$$\tilde{\nabla}_a\zeta_b+\tilde{\nabla}_b\zeta_a=0, \tag{51}$$

where $\vec{\zeta}$ is a hypothetical Killing vector field for the metrics (49), and we project them onto the null basis $\{\ell,\mathrm{k},\mathrm{m},\overline{\mathrm{m}}\}$ associated with the seed spacetimes, which allows us to use its spin coefficients and their properties (6).

After making the integration (see Ref. 10 for details), we find that in the general case, that is to say, without additional assumptions on the complex function Ω, there is only one independent Killing vector field. Obviously, this Killing vector field is the timelike one that we already know,

$$\vec{\zeta}=\frac{1}{\sqrt{2}}[(1-\mathscr{H})\tilde{\vec{\ell}}+\tilde{\vec{\mathbf{k}}}]=\frac{1}{\sqrt{2}}(\vec{\ell}+\vec{\mathbf{k}})=\vec{u}\propto\tilde{\vec{u}}. \tag{52}$$

Thus, the solution (49) is stationary in general with *no* further symmetries. The norm of this Killing vector field is $\mathscr{H}-1$, which for the cases $\varepsilon\pm1$ is always negative [otherwise we cannot define $\tilde{\vec{u}}$ (38)], but in the case $\varepsilon=0$ there are not restrictions and then, the sign of the norm divides the spacetime into three regions: (A) $1-\mathscr{H}>0$, where the Killing is timelike. (B) $1-\mathscr{H}<0$, where the Killing is spacelike. (C) $1-\mathscr{H}=0$, where the Killing is null. In fact, that is the stationary limit hypersurface (this can be checked easily for the Schwarzschild and Kerr spacetimes). This division according to the norm of the Killing vector field (52) is an interesting fact because these three regions are usually seen as different spacetimes (see Ref. 5).

Apart from the general case, there are specific cases with additional symmetries. These cases appear when the quantity $\Gamma+\overline{\Gamma}$ vanishes, where Γ is a complex function defined by

$$\Gamma\equiv\frac{1}{(\overline{\delta\rho})^2}\left\{\left(\rho^2+\frac{\varepsilon}{2\,a^2}\right)(\overline{\delta\,\delta\rho}+2\,\alpha\,\overline{\delta\rho})-3\,\rho(\overline{\delta\rho})^2\right\}. \tag{53}$$

Now, two different cases appear depending on whether the complex function Γ vanishes or not.

Case (i): $\Gamma\neq0$. After integrating the Killing equations (51) we find that there are two independent Killing vector fields, which we can take as ζ^a, given in (52), and ζ_1^a, given by

$$\vec{\zeta}_1=\frac{1}{\sqrt{|\Gamma|}}\left\{(1+\mathscr{H})\vec{\ell}-\vec{\mathrm{k}}-\frac{2(\overline{\rho^2}+\varepsilon/(2a^2))}{\delta\overline{\rho}}\vec{\tilde{\mathrm{m}}}-\frac{2(\rho^2+\varepsilon/(2a^2))}{\overline{\delta\rho}}\vec{\mathrm{m}}\right\}. \tag{54}$$

It is clear that we can write the most general Killing vector field as follows:

$$C_1\vec{\zeta}+C_2\vec{\zeta}_1, \tag{55}$$

where C_1 and C_2 are two arbitrary constants. It can be shown that this general Killing vector field commutes with the timelike one $\vec{\zeta}$ given in (52). Furthermore, we can study the possible existence of an axial Killing vector field. To that end we must check the regularity condition,

$$\frac{\tilde{\nabla}^a\zeta^2\tilde{\nabla}_a\zeta^2}{4\,\zeta^2}\overset{\text{axis}}{\to}1, \quad \zeta^2\equiv\zeta^a\zeta_a. \tag{56}$$

For the general Killing vector field (55) this condition is not satisfied for any value of C_1 and C_2 and therefore, there is no axial symmetry in this case.

Case (ii): $\Gamma=0$. In this case, equation (43) implies that the GKS spacetimes (49) are Petrov type D. When we integrate the Killing equations (51), we find that there are also two independent Killing vector fields, which can be taken as (52) and

$$\vec{\zeta}_2=\frac{1}{(\rho^2+\varepsilon/(2a^2))^{3/2}(\overline{\rho^2}+\varepsilon/(2a^2))^{3/2}}$$
$$\times\left\{\overline{\delta\rho}\,\delta\overline{\rho}[(1+\mathscr{H})\vec{\ell}-\vec{\mathrm{k}}]-2\left(\overline{\rho^2}+\frac{\varepsilon}{2\,a^2}\right)\overline{\delta\rho}\vec{\tilde{\mathrm{m}}}-2\left(\rho^2+\frac{\varepsilon}{2\,a^2}\right)\delta\rho\,\vec{\overline{\mathrm{m}}}\right\}. \tag{57}$$

In the same way as in case (i), we can check that the general expression for a Killing vector field $C_1\vec{\zeta}+C_2\vec{\zeta}_2$, where C_1 and C_2 are two arbitrary constants, commutes with the timelike Killing vector field $\vec{\zeta}$. In addition, and with regard to the possibility of axial symmetry, it can be shown that we can only have a spacelike Killing vector field vanishing in a certain region of the spacetime when $C_1=0$, and then, this region is defined by $|\overline{\delta\rho}|=0$. Moreover, it can be checked that if the following relation holds:

$$(\rho-\overline{\rho})^{-2}\left(\rho^2+\frac{\varepsilon}{2\,a^2}\right)\left(\overline{\rho^2}+\frac{\varepsilon}{2\,a^2}\right)\Bigg|_{|\overline{\delta\rho}|\to0}\to\text{const}, \tag{58}$$

and we choose the constant C_2 as follows:

$$C_2=\sqrt{\frac{(\rho^2+\varepsilon/(2\,a^2))(\overline{\rho^2}+\varepsilon/(2\,a^2))}{-8(\rho-\overline{\rho})^2}}\Bigg|_{|\overline{\delta\rho}|\to0},$$

the axis regularity condition (56) is satisfied for the Killing vector field $C_2\vec{\zeta}_2$, and therefore, it is an axial Killing vector field. In that case, the GKS spacetimes would be stationary axially symmetric spacetimes in *rigid rotation* because $\vec{\tilde{u}}$ is proportional to the timelike Killing vector field (52). For the Kerr and the Kerr–Vaidya metrics, which are given by (50) and $\varepsilon=0,1$, respectively, it can be checked that the condition (58) is fulfilled. In general, following Ref. 27, we can conclude that all the spacetimes in this case with axial symmetry are subcases of the Wahlquist family.[21]

ACKNOWLEDGMENTS

I would like to express my gratitude to Dr. J. M. M. Senovilla for helpful discussions, many valuable suggestions and for his collaboration in the preparation of this manuscript. Some calculations have been performed with the help of the computer program REDUCE.

APPENDIX A: CONFORMALLY FLAT FORM OF THE FLRW SPACETIMES

In this appendix we are going to give a coordinate change to pass from the following well-known form for the line element of the FLRW spacetimes,

$$ds^2=-dt^2+a^2(t)\{d\chi^2+\Sigma^2(\varepsilon,\chi)(d\theta^2+\sin^2\theta d\varphi^2)\}, \tag{A1}$$

where $\varepsilon^3=\varepsilon$ and $\Sigma(\varepsilon,\chi)$ satisfy the differential equation

$$\Sigma'^2+\varepsilon\Sigma^2=1\Leftrightarrow\Sigma(\varepsilon,\chi)=\begin{cases}\sin\chi, & \text{if } \varepsilon=1,\\ \chi, & \text{if } \varepsilon=0,\\ \sinh\chi & \text{if } \varepsilon=-1,\end{cases}$$

to the following explicitly conformally-flat form:

$$ds^2=\Phi^2(T,R)\{-dT^2+dR^2+R^2(d\theta^2+\sin^2\theta d\varphi^2)\}.$$

This transformation can be achieved by using the following coordinate change:

$$T=\frac{2\,\Sigma(\varepsilon,\psi)}{\Sigma'(\varepsilon,\psi)+\Sigma'(\varepsilon,\chi)},\quad R=\frac{2\,\Sigma(\varepsilon,\chi)}{\Sigma'(\varepsilon,\psi)+\Sigma'(\varepsilon,\chi)},$$

where ψ is the so-called *parametric time*, defined by

$$\dot{\psi}=\frac{d\psi}{dt}\equiv\frac{1}{a}.$$

After making this coordinate change, the conformal factor Φ becomes

$$\Phi^2=\frac{a^2}{[1+\varepsilon((T-R)/2)^2][1+\varepsilon((T+R)/2)^2]}.$$

In these coordinates the fact that the scale factor a depends only on t reads as follows:

$$a=a\left(\frac{T}{1-(\varepsilon/4)(T^2-R^2)}\right).$$

Another interesting form for the line element (A1) is obtained by passing to the following null spherical coordinates:

$$U=\frac{T-R}{2},\quad V=\frac{T+R}{2},\quad \xi=e^{i\varphi}\tan\left(\frac{\theta}{2}\right);$$

then we obtain

$$ds^2=\Phi^2(U,V)\left\{-4dUdV+4\left(\frac{V-U}{1+\xi\bar{\xi}}\right)^2 d\xi d\bar{\xi}\right\},\quad \Phi^2(U,V)=\frac{a^2}{(1+\varepsilon U^2)(1+\varepsilon V^2)},$$

where

$$a=a\left(\frac{V+U}{1-\varepsilon UV}\right).$$

APPENDIX B: KINEMATICAL QUANTITIES AND THE NEWMAN–PENROSE FORMALISM

In this appendix we give some useful formulae due to Wainwright,[28] for the kinematical quantities of a unit timelike vector field. Let $\vec{u}$ be any unit timelike vector field and let $\{\ell, \mathrm{k}, \mathrm{m}, \overline{\mathrm{m}}\}$ be a null basis such that we can write down $\vec{u}$ in the following way:

$$\vec{u} = \frac{1}{\sqrt{2}}(\vec{\ell} + \vec{\mathrm{k}}).$$

Then, we can write the kinematical quantities associated with $\vec{u}$ using only the null basis $\{\ell, \mathrm{k}, \mathrm{m}, \overline{\mathrm{m}}\}$ and the spin coefficients associated with them as follows:

Expansion,

$$\theta = \frac{1}{\sqrt{2}}(\epsilon + \overline{\epsilon} - \gamma - \overline{\gamma} + \mu + \overline{\mu} - \rho - \overline{\rho});$$

acceleration,

$$\vec{\mathrm{a}} = \frac{1}{\sqrt{2}}(\epsilon + \overline{\epsilon} + \gamma + \overline{\gamma})\vec{v} + \frac{1}{2}\{(\pi - \overline{\tau} + \nu - \overline{\kappa})\vec{\mathrm{m}} + \text{ c.c.}\};$$

shear,

$$\sigma_{ab} = \frac{1}{3\sqrt{2}}\{2(\epsilon + \overline{\epsilon}) + \rho + \overline{\rho} - 2(\gamma + \overline{\gamma}) - \mu - \overline{\mu}\}(v_a v_b - \mathrm{m}_{(a}\overline{\mathrm{m}}_{b)})$$

$$+ \frac{1}{2}\{(2(\alpha + \overline{\beta}) + \pi + \overline{\tau} - \nu - \overline{\kappa})v_{(a}\mathrm{m}_{b)} + \text{ c.c.}\} + \frac{1}{\sqrt{2}}\{(\lambda - \overline{\sigma})\mathrm{m}_a \mathrm{m}_b + \text{ c.c.}\};$$

rotation,

$$\omega_{ab} = \frac{1}{2}\{(2(\alpha + \overline{\beta}) + \nu + \overline{\kappa} - \pi - \overline{\tau})v_{[a}\mathrm{m}_{b]} + \text{ c.c.}\} + \frac{1}{\sqrt{2}}(\rho - \overline{\rho} + \mu - \overline{\mu})\mathrm{m}_{[a}\overline{\mathrm{m}}_{b]},$$

where

$$\vec{v} \equiv \frac{1}{\sqrt{2}}(\vec{\ell} - \vec{\mathrm{k}}) \Rightarrow v^a v_a = 1, \quad v^a u_a = 0.$$

Let M be a compact Riemannian manifold with smooth boundary. We study the vacuum expectation value of an operator Q by studying $\mathrm{Tr}_{L^2}Qe^{-tD}$, where D is an operator of Laplace type on M, and where Q is a second order operator with scalar leading symbol; we impose Dirichlet or modified Neumann boundary conditions. © *1998 American Institute of Physics.* [S0022-2488(98)03102-8]

I. INTRODUCTION

Let M be a compact smooth Riemannian manifold of dimension m with smooth boundary ∂M. We say that a second order operator D on the space of smooth sections $C^\infty(V)$ of a smooth vector bundle over M has *scalar leading symbol* if the leading symbol is $h^{ij}I_V\xi_i\xi_j$ for some symmetric 2-tensor h. We say that D is of *Laplace type* if h^{ij} is the metric tensor on the cotangent bundle. Let D be an operator of Laplace type. If the boundary of M is non-empty, we impose Dirichlet or Neumann boundary conditions $\mathscr{B}$ to define the operator $D_{\mathscr{B}}$, see Sec. IV for further details. Let Q be an auxiliary second order partial differential operator on V with scalar leading symbol; if the order of Q is at most 1, then this hypothesis is satisfied trivially. As $t\downarrow 0$, there is an asymptotic expansion

$$\mathrm{Tr}_{L^2}(Qe^{-tD_{\mathscr{B}}})\sim\sum_{n=-2}^{\infty}a_n(Q,D,\mathscr{B})t^{(n-m)/2}$$

[see Ref. 1 (Lemma 1.9.1)] where a different numbering convention was used. The invariants $a_n(Q,D,\mathscr{B})$ are locally computable. We have $a_{-2}(Q,D,\mathscr{B})=0$ and $a_{-1}(Q,D,\mathscr{B})=0$ if Q has order at most 1. If the boundary of M is empty, the boundary condition $\mathscr{B}$ plays no role and we drop it from the notation; in this case, if n is odd, then $a_n(Q,D)=0$.

Our paper is motivated by several physical examples. First, consider a Euclidean quantum field theory with a propagator D^{-1} depending on external fields. Typically, D is a second order differential operator of Laplace type. In the one-loop approximation, the vacuum expectation value $\langle Q\rangle$ of a second order differential operator is given by $\langle Q\rangle=\mathrm{Tr}_{L^2}(QD^{-1})$. By formal manipulations, this can be represented in the form

$$\langle Q\rangle\sim\int_0^\infty dt\ \mathrm{Tr}_{L^2}(Qe^{-tD})\sim\int_0^\infty dt\sum_{n=-2}^{\infty}a_n(Q,D,\mathscr{B})t^{(n-m)/2}.$$

These integrals are divergent at the lower limit and need to be regularized. This can be done by replacing 0 by $1/\Lambda$ in the limits of integration; Λ is called the ultraviolet cutoff parameter. The coefficients $a_n(Q,D,\mathscr{B})$ define the asymptotics of $\langle Q\rangle$ as $\Lambda\to\infty$. The first m terms are divergent

and are essential for renormalization. The coefficients $a_n(Q,D,\mathscr{B})$ also define large mass asymptotics of $\langle Q\rangle$ in the theory of a massive quantum field; for details see, for example, Ref. 2.

A second example is provided by quantum anomalies. In the Fujikawa approach,[3] the anomaly $\mathscr{A}$ is defined as $\mathscr{A}=\lim_{\Lambda\to\infty}\operatorname{Tr}(Qe^{-D/\Lambda^2})$, where Q is the generator of an anomalous symmetry transformation, and D is a regulator. Usually divergent terms may be absorbed in renormalization and one has that $\mathscr{A}\sim a_{m-2}(Q,D,\mathscr{B})$. Other examples where these asymptotics arise naturally are the study of the anomaly for an arbitrary local symmetry transformation, and in the study of the vacuum expectation value of the stress-energy tensor.

In this paper, we will study the asymptotics $a_n(Q,D,\mathscr{B})$ in a general mathematical framework. In Sec. II, we review the geometry of operators of Laplace type and derive some variational formulas. The operator D determines the metric g, a connection ∇ on V, and an endomorphism E of V. Conversely, given these data, we can define an operator of Laplace type $D(g,\nabla,E)$; see Lemma II.1 for details. Let q_2 be a symmetric 2-tensor and let q_1 be a 1-form valued endomorphism of V. We shall use q_2 to define a variation of the metric $g(\varepsilon):=g+\varepsilon q_2$ and we shall use q_1 to define a variation of the connection $\nabla(\varepsilon):=\nabla+\varepsilon q_1$. Let $Q_2:=\partial_\varepsilon D(g(\varepsilon),\nabla,E)\big|_{\varepsilon=0}$ and let $Q_1:=\partial_\varepsilon D(g,\nabla(\varepsilon),E)\big|_{\varepsilon=0}$. Let Q be a second order operator with scalar leading symbol. We may decompose $Q=Q_2+Q_1+Q_0$ for $Q_0\in\operatorname{End}(V)$ and for Q_2 and Q_1 defined by suitably chosen q_2 and q_1. Since $a_n(Q,D)=\Sigma_i a_n(Q_i,D)$, it suffices to compute the $a_n(Q_i,D)$. In Lemma II.2, we will study the operators Q_2 and Q_1 and show that $\partial_\varrho a_{n+2}(1,D(\varrho),\mathscr{B})=-a_n(\partial_\varrho D(\varrho),D(\varrho),\mathscr{B})$ for any 1-parameter family of operators of Laplace type and fixed boundary condition $\mathscr{B}$. In Secs. III and IV we use this variational formula and apply results of Refs. 4 and 5 to study the invariants $a_n(Q,D,\mathscr{B})$; in Sec. III we consider manifolds without boundary and in Sec. IV we consider manifolds with boundary.

An operator A is said to be of Dirac type if A^2 is of Laplace type. Branson and Gilkey[4] studied the asymptotics of $\operatorname{Tr}_{L^2}(Ae^{-tA^2})$ for an operator A of Dirac type on a closed manifold. In Sec. V, we use the results of Sec. III to rederive these results and to compute some additional terms in the asymptotic expansion. The numbering convention we shall use in this paper differs from that used in Ref. 4; the invariants $a_n(A,A^2)$ of this paper were denoted by $a_{n-1}(A,A^2)$ in Ref. 4.

II. GEOMETRY OF OPERATORS OF LAPLACE TYPE

We adopt the following notational conventions. Greek indices μ, ν, etc. will range from 1 through $m=\dim(M)$ and index local coordinate frames ∂_ν and dx^ν for the tangent and cotangent bundles TM and T^*M. Roman indices i, j will also range from 1 through m and index local orthonormal frames e_i and e^i for TM and T^*M. We shall suppress the bundle indices for tensors arising from V. We adopt the Einstein convention and sum over repeated indices. Let D be an operator of Laplace type. This means that we can decompose D locally in the form

$$D=-(g^{\nu\mu}I_V\partial_\nu\partial_\mu+a^\sigma\partial_\sigma+b), \tag{2.1}$$

where a and b are local sections of $TM\otimes\operatorname{End}(V)$ and $\operatorname{End}(V)$, respectively. It is important to have a more invariant expression than that which is given in equation (2.1). Let Γ be the Christoffel symbols of the Levi-Civita connection of the metric g on M, let ∇ be an auxiliary connection on V, and let $E\in C^\infty(\operatorname{End}(V))$. Define

$$\begin{aligned}D(g,\nabla,E)&:=-(\operatorname{Tr}_g\nabla^2+E)\\&=-g^{\mu\sigma}\{I_V\partial_\mu\partial_\sigma+2\omega_\mu\partial_\sigma-\Gamma_{\mu\sigma}{}^\nu I_V\partial_\nu+\partial_\mu\omega_\sigma+\omega_\mu\omega_\sigma-\Gamma_{\mu\sigma}{}^\nu\omega_\nu\}-E.\end{aligned} \tag{2.2}$$

We compare equations (2.1) and (2.2) to prove the following Lemma.

Lemma II.1: If D is an operator of Laplace type, then there exists a unique connection ∇ on V and a unique endomorphism E of V so that $D=D(g,\nabla,E)$.

(1) If ω is the connection 1-form of ∇, then $\omega_\delta=g_{\nu\delta}(a^\nu+g^{\mu\sigma}\Gamma_{\mu\sigma}{}^\nu I_V)/2$.
(2) We have $E=b-g^{\nu\mu}(\partial_\mu\omega_\nu+\omega_\nu\omega_\mu-\omega_\sigma\Gamma_{\nu\mu}{}^\sigma)$.

Let $D=D(g,\nabla,E)$. We use the Levi-Civita connection of the metric g and the connection ∇ on V to covariantly differentiate tensors of all types. We shall let ';' denote multiple covariant differentiation. Thus, for example, $Df=-(f_{;kk}+Ef)$.

Lemma II.2: Let $D=D(g,\nabla,E)$ be an operator of Laplace type. Let $q_2=q_{2,ij}$ be a symmetric 2-tensor and let $q_1=q_{1,i}$ be an endomorphism valued 1-tensor. Then

(1) $Q_1f:=\partial_\varepsilon D(g,\nabla+\varepsilon q_1,E)f|_{\varepsilon=0}=-2q_{1,i}f_{;i}-q_{1,i;i}f$.
(2) $Q_2f:=\partial_\varepsilon D(g+\varepsilon q_2,\nabla,E)f|_{\varepsilon=0}=q_{2,ij}f_{;ij}+(2q_{2,ij;j}-q_{2,jj;i})f_{;i}/2$.
(3) *Let $D(\varrho)$ be a smooth 1-parameter family of operators of Laplace type and fix $\mathscr{B}$. Then* $a_n(\partial_\varrho D(\varrho),D(\varrho),\mathscr{B})=-\partial_\varrho a_{n+2}(1,D(\varrho),\mathscr{B})$.

Proof: Fix a point $x_0\in M$; we may assume that x_0 is in the interior of M. Choose coordinates centered at x_0 and a local frame for V so that $g_{\nu\mu}(x_0)=\delta_{\nu\mu}$, $\Gamma(x_0)=0$, and so that $\omega(x_0)=0$. We use equation (2.2) to compute

$$\partial_\varepsilon D(g,\nabla+\varepsilon q_1,E)(x_0)|_{\varepsilon=0}=-g^{\nu\sigma}(2q_{1,\nu}\partial_\sigma+\partial_\nu q_{1,\sigma})(x_0)$$

$$=(-2q_{1,i}\nabla_i-q_{1,i;i})(x_0),$$

$$\partial_\varepsilon\{g+\varepsilon q_2\}^{\nu\sigma}(x_0)|_{\varepsilon=0}=-q_{2,\nu\sigma}(x_0),$$

$$2\partial_\varepsilon\Gamma(g+\varepsilon q_2)_{\nu\sigma}{}^\mu(x_0)|_{\varepsilon=0}=(q_{2,\mu\nu;\sigma}+q_{2,\mu\sigma;\nu}-q_{2,\nu\sigma;\mu})(x_0),$$

$$\partial_\varepsilon D(g+\varepsilon q_2,\nabla,E)(x_0)|_{\varepsilon=0}=(q_{2,\nu\sigma}(\partial_\nu\partial_\sigma+\partial_\nu\omega_\sigma)+\partial_\varepsilon\Gamma(g+\varepsilon q_2)_{\mu\mu}{}^\nu\partial_\nu)(x_0)|_{\varepsilon=0}.$$

The first two assertions now follow. We use Ref. 1 (Lemma 1.9.3) to see that the asymptotic series of the variation is the variation of the asymptotic series. We equate coefficients in the following two asymptotic expansions to complete the proof:

$$\sum_n \partial_\varrho a_n(1,D(\varrho),\mathscr{B})t^{(n-m)/2}\sim\partial_\varrho\mathrm{Tr}_{L^2}(e^{-tD(\varrho)\mathscr{B}})$$

$$=\mathrm{Tr}_{L^2}(-t\partial_\varrho D(\varrho)e^{-tD(\varrho)\mathscr{B}})$$

$$\sim-\sum_k a_k(\partial_\varrho D(\varrho),D(\varrho),\mathscr{B})t^{(k+2-m)/2}.\qquad\square$$

To use Lemma II.2, we shall need some variational formulas. Let $R_{\mu\nu\sigma}{}^\delta$ be the curvature of the Levi-Civita connection with the sign convention that the Ricci tensor is given by $\rho_{\nu\sigma}:=R_{\mu\nu\sigma}{}^\mu$ and the scalar curvature is given by $\tau:=g^{\nu\sigma}\rho_{\nu\sigma}$. Let $\Delta_0=\delta d$ be the scalar Laplacian, let $d\mathrm{vol}$ be the Riemannian measure, and let $F_{\mu\nu}$ be the curvature tensor of ∇.

Lemma II.3: Let $\nabla(\varepsilon):=\nabla+\varepsilon q_1$ and let $g(\varrho):=g+\varrho q_2$. Let $\mathscr{T}_{ij}:=(\partial_\varepsilon|_{\varepsilon=0}F)_{ij}$, let $\mathscr{R}_{\mu\nu\sigma}{}^\delta:=(\partial_\varrho|_{\varrho=0}R)_{\mu\nu\sigma}{}^\delta$, and let $\mathscr{D}:=\partial_\varrho|_{\varrho=0}\Delta_0$. Then

(1) $\mathscr{T}_{ij}=q_{1,j;i}-q_{1,i;j}$ *and* $\partial_\varepsilon|_{\varepsilon=0}(\nabla F)_{ij;k}=\mathscr{T}_{ij;k}+[q_{1,k},\mathscr{T}_{ij}]$.
(2) $\mathscr{D}f=q_{2,ij}f_{;ij}+(2q_{2,ij;j}-q_{2,jj;i})f_{;i}/2$.
(3) $\partial_\varrho d\mathrm{vol}|_{\varrho=0}=q_{2,ii}d\mathrm{vol}/2$.
(4) $(\partial_\varrho\Gamma)_{\mu\nu}{}^\sigma|_{\varepsilon=0}=g^{\sigma\gamma}(q_{2,\mu\gamma;\nu}+q_{2,\nu\gamma;\mu}-q_{2,\mu\nu;\gamma})/2$.
(5) $\mathscr{R}_{\mu\nu\sigma}{}^\delta=g^{\delta\gamma}(q_{2,\mu\sigma;\gamma\nu}+q_{2,\nu\gamma;\sigma\mu}-q_{2,\mu\gamma;\sigma\nu}-q_{2,\nu\sigma;\gamma\mu}+q_{2,\sigma\beta}R_{\mu\nu\gamma}{}^\beta+q_{2,\gamma\beta}R_{\mu\nu\sigma}{}^\beta)/2$.
(6) $\partial_\varrho|_{\varrho=0}\tau=-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik}$.
(7) $\partial_\varrho|_{\varrho=0}|\rho|^2=2\mathscr{R}_{kijk}\rho_{ij}-2q_{2,ij}\rho_{ik}\rho_{jk}$.
(8) $\partial_\varrho|_{\varrho=0}|R|^2=2\mathscr{R}_{ijkl}R_{ijkl}-2q_{2,jn}R_{ijkl}R_{inkl}$.

Proof: The assertion (1) is immediate from the definition. Assertion (2) follows from Lemma II.2. Assertions (3) and (4) are straightforward calculations. Assertion (5) follows from assertion (4) and from the identity

$$q_{2,\sigma\gamma;\nu\mu}-q_{2,\sigma\gamma;\mu\nu}=q_{2,\gamma\rho}R_{\mu\nu\sigma}{}^\rho+q_{2,\sigma\rho}R_{\mu\nu\gamma}{}^\rho.$$

Raising and lowering indices does not commute with varying the metric so we emphasize that the tensor $\mathscr{R}$ is the variation of a tensor of type (3,1). The remaining assertions now follow. □

III. MANIFOLDS WITHOUT BOUNDARY

Lemma II.2 reduces the computation of $a_n(Q,D)$ to the special cases $a_n(Q_i,D)$ where $i=0,1,2$. Recall that $a_n(Q,D)=0$ for n odd; $a_{-2}(Q,D)=0$ if $\mathrm{ord}(Q)\leqslant 1$. If $\mathscr{P}$ is a scalar invariant, let $\mathscr{I}[M]:=\int_M \mathscr{P}(x)d\mathrm{vol}(x)$. Let tr_V be the fiber trace. We refer to Ref. 6 for the proof of the following result:

Theorem III.1: *Let M be a compact Riemannian manifold without boundary, let D be an operator of Laplace type, and let $Q_0\in \mathrm{End}(V)$. Then*

(1) $a_0(Q_0,D)=(4\pi)^{-m/2}\mathrm{tr}_V\{Q_0\}[M]$.
(2) $a_2(Q_0,D)=(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V\{Q_0(6E+\tau)\}[M]$.
(3) $a_4(Q_0,D)=(4\pi)^{-m/2}360^{-1}\mathrm{tr}_V\{Q_0(60E_{;kk}+60\tau E+180E^2+12\tau_{;kk}+5\tau^2-2|\rho|^2+2|R|^2+30F_{ij}F_{ij})\}[M]$.
(4) $a_6(Q_0,D)=(4\pi)^{-m/2}\mathrm{tr}_V\{Q_0/7!(18\tau_{;iijj}+17\tau_{;k}\tau_{;k}-2\rho_{ij;k}\rho_{ij;k}-4\rho_{jk;n}\rho_{jn;k}+9R_{ijk\ell;n}R_{ijk\ell;n}+28\tau\tau_{;nn}-8\rho_{jk}\rho_{jk;nn}+24\rho_{jk}\rho_{jn;kn}+12R_{ijk\ell}R_{ijk\ell;nn}+35/9\tau^3-14/3\tau\rho^2+14/3\tau R^2-208/9\rho_{jk}\rho_{jn}\rho_{kn}-64/3\rho_{ij}\rho_{k\ell}R_{ikj\ell}-16/3\rho_{jk}R_{jn\ell i}R_{kn\ell i}-44/9R_{ijkn}R_{ij\ell p}R_{kn\ell p}-80/9R_{ijkn}R_{i\ell kp}R_{j\ell np})+360^{-1}Q_0(8F_{ij;k}F_{ij;k}+2F_{ij;j}F_{ik;k}+6F_{ij;kk}F_{ij}+6F_{ij}F_{ij;kk}-12F_{ij}F_{jk}F_{ki}-6R_{ijkn}F_{ij}F_{kn}-4\rho_{jk}F_{jn}F_{kn}+5\tau F_{kn}F_{kn}+6E_{;iijj}+30EE_{;ii}+30E_{;ii}E+30E_{;i}E_{;i}+60E^3+12EF_{ij}F_{ij}+6F_{ij}EF_{ij}+12F_{ij}F_{ij}E+10\tau E_{;kk}+4\rho_{jk}E_{;jk}+12\tau_{;k}E_{;k}-6E_{;j}F_{ij;i}+6F_{ij;i}E_{;j}+30EE\tau+12E\tau_{;kk}+5E\tau^2-2E\rho_{jk}\rho_{jk}+2ER^2)\}[M]$.

Next, we study the invariants $a_n(Q_1,D)$.

Theorem III.2: *Let M be a compact Riemannian manifold without boundary, let D be an operator of Laplace type, and let $Q_1=\partial_\varepsilon D(g,\nabla+\varepsilon q_1,E)|_{\varepsilon=0}$. Then*

(1) $a_0(Q_1,D)=0$.
(2) $a_2(Q_1,D)=-(4\pi)^{-m/2}360^{-1}\mathrm{tr}_V\{60F_{ij}\mathscr{F}_{ij}\}[M]$.
(3) $a_4(Q_1,D)=-(4\pi)^{-m/2}360^{-1}\mathrm{tr}_V\{-8F_{ij;k}\mathscr{F}_{ij;k}-8F_{ij;k}q_{1,k}F_{ij}+8F_{ij;k}F_{ij}q_{1,k}+4F_{ij;j}\mathscr{F}_{ik;k}+4F_{ij;j}q_{1,k}F_{ik}-4F_{ij;j}F_{ik}q_{1,k}-36F_{ij}F_{jk}\mathscr{F}_{ki}-12R_{ijkn}F_{ij}\mathscr{F}_{kn}-8\rho_{jk}F_{jn}\mathscr{F}_{kn}+10\tau F_{kn}\mathscr{F}_{kn}-60E_{;k}q_{1,k}E+60E_{;k}Eq_{1,k}+30EF_{ij}\mathscr{F}_{ij}+30E\mathscr{F}_{ij}F_{ij}\}[M]$.

Proof: We use Lemma II.2 and Theorem III.1. Note that $\Delta_0(f)=-f_{;kk}$ is independent of the connection ∇ for $f\in C^\infty(M)$. We compute the following.

(1) $\partial_\varepsilon \mathrm{tr}_V(60E_{;kk})|_{\varepsilon=0}=60\partial_\varepsilon \mathrm{tr}_V(E)_{;kk}|_{\varepsilon=0}=-60\partial_\varepsilon\Delta_0\mathrm{tr}_V(E)=0$.
(2) $\partial_\varepsilon \mathrm{tr}_V(30F^2)|_{\varepsilon=0}=\mathrm{tr}_V(60F_{ij}\mathscr{F}_{ij})$.
(3) $\partial_\varepsilon \mathrm{tr}_V(8F_{ij;k}F_{ij;k}+6F_{ij;kk}F_{ij}+6F_{ij}F_{ij;kk})|_{\varepsilon=0}$
$=\partial_\varepsilon\{\mathrm{tr}_V(-4F_{ij;k}F_{ij;k})+\mathrm{tr}_V(6F_{ij}F_{ij})_{;kk}\}|_{\varepsilon=0}$
$=\mathrm{tr}_V(-8F_{ij;k}\mathscr{F}_{ij;k}-8F_{ij;k}q_{1,k}F_{ij}+8F_{ij;k}F_{ij}q_{1,k})$.
(4) $\partial_\varepsilon \mathrm{tr}_V(30EE_{;ii}+30E_{;ii}E+30E_{;i}E_{;i})|_{\varepsilon=0}=\partial_\varepsilon\{\mathrm{tr}_V(-30E_{;i}E_{;i})+\mathrm{tr}_V(30EE)_{;ii}\}|_{\varepsilon=0}$
$=\mathrm{tr}_V(-60E_{;k}q_{1,k}E+60E_{;k}Eq_{1,k})$. □

We conclude this section by studying $a_n(Q_2,D)$. The following result is a consequence of Lemma II.2, Lemma II.3, and Theorem III.1. We omit the formula for $a_4(Q_2,D)$ in the interest of brevity.

Theorem III.3: *Let M be a compact Riemannian manifold without boundary, let D be an operator of Laplace type on $C^\infty(V)$, and let $Q_2=\partial_\varepsilon D(g+\varepsilon q_2,\nabla,E)|_{\varepsilon=0}$.*

(1) $a_{-2}(Q_2,D)=-\frac{1}{2}a_0(q_{2,ii},D)$.
(2) $a_0(Q_2,D)=-\frac{1}{2}a_2(q_{2,ii},D)-(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V\{(-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik})I_V\}[M]$.
(3) $a_2(Q_2,D)=-\frac{1}{2}a_4(q_{2,ii},D)-(4\pi)^{-m/2}360^{-1}\{-\mathscr{D}\mathrm{tr}_V(60E+12\tau I_V)+\mathrm{tr}_V\{10(-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik})\tau I_V-2(2\mathscr{R}_{kijk}\rho_{ij}-2q_{2,ij}\rho_{ik}\rho_{jk})I_V+2(2\mathscr{R}_{ijkl}R_{ijkl}-2q_{2,jn}R_{ijkl}R_{inkl})I_V+60(-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik})E-60q_{2,ik}F_{ij}F_{ik}\}[M]$.

IV. MANIFOLDS WITH BOUNDARY

We now suppose M has smooth non-empty boundary ∂M. Near ∂M, let e_i be a local orthonormal frame for TM where we normalize the choice so that e_m is the inward unit normal. We let indices $a,b,\dots$ range from 1 through $m-1$ and index the resulting orthonormal frame for the tangent bundle $T(\partial M)$ of the boundary. Let $f\in C^\infty(V)$. Let S be an endomorphism of V defined on ∂M. The Neumann boundary operator is defined by the operator $B_S^+ f:=(\nabla_m+S)f|_{\partial M}$ and the Dirichlet boundary operator is defined by the operator $B_S^- f=f|_{\partial M}$; we set $S=0$ with Dirichlet boundary conditions to have a uniform notation. Let $L_{ab}=(\nabla_{e_a}e_b,e_m)$ be the second fundamental form. Let ':' denote multiple covariant differentiation tangentially with respect to the Levi-Civita connection of the metric on the boundary and the connection ∇ on V. The difference between ';' and ':' is given by the second fundamental form. For example, $E_{;a}$ and $E_{:a}$ agree since there are no tangential indices in E to be differentiated while $E_{;ab}=E_{:ab}-L_{ab}E_{;m}$. There are some new features here which are not present in the case of manifolds without boundary in the following formulas. The invariants $a_n(Q,D,\mathscr{B})$ are non-zero for odd n and the normal derivatives of Q_0 enter. We still have $a_{-2}(Q,D,\mathscr{B})=0$ if $\mathrm{ord}(Q)\leqslant 1$.

Theorem IV.1: *Let M be a compact Riemannian manifold with smooth boundary, let D be an operator of Laplace type and let* $Q_0\in\mathrm{End}(V)$. *Then*

(1) $a_0(Q_0,D,\mathscr{B}_S^\pm)=(4\pi)^{-m/2}\mathrm{tr}_V\{Q_0\}[M]$.
(2) $a_1(Q_0,D,\mathscr{B}_S^\pm)=\pm(4\pi)^{-(m-1)/2}4^{-1}\mathrm{tr}_V\{Q_0\}[\partial M]$.
(3) $a_2(Q_0,D,\mathscr{B}_S^\pm)=(4\pi)^{-m/2}6^{-1}\{\mathrm{tr}_V\{Q_0(6E+\tau)\}[M]$
$+\mathrm{tr}_V\{Q_0(2L_{aa}+12S)+(3^+,-3^-)Q_{0;m}\}[\partial M]\}$.
(4) $a_3(Q_0,D,\mathscr{B}_S^\pm)=(4\pi)^{-(m-1)/2}384^{-1}\mathrm{tr}_V\{Q_0((96^+,-96^-)E+(16^+,-16^-)\tau$
$+(8^+,-8^-)R_{amam}+(13^+,-7^-)L_{aa}L_{bb}+(2^+,10^-)L_{ab}L_{ab}$
$+96SL_{aa}+192S^2)+Q_{0;m}((6^+,30^-)L_{aa}+96S)$
$+(24^+,-24^-)Q_{0;mm}\}[\partial M]$.
(5) $a_4(Q_0,D,\mathscr{B}_S^\pm)=(4\pi)^{-m/2}360^{-1}\{\mathrm{tr}_V\{Q_0(60E_{;kk}+60\tau E+180E^2+30F_{ij}F_{ij}+12\tau_{;kk}$
$+5\tau^2-2\rho^2+2R^2)\}[M]+\mathrm{tr}_V\{Q_0(240^+,-120^-)E_{;m}+(42^+,-18^-)\tau_{;m}$
$+24L_{aa:bb}+120EL_{aa}+20\tau L_{aa}+4R_{amam}L_{bb}-12R_{ambm}L_{ab}+4R_{abcb}L_{ac}$
$+360(SE+ES)+21^{-1}\{(280^+,40^-)L_{aa}L_{bb}L_{cc}+(168^+,$
$-264^-)L_{ab}L_{ab}L_{cc}+(224^+,320^-)L_{ab}L_{bc}L_{ac}\}+120S\tau+144SL_{aa}L_{bb}$
$+48SL_{ab}L_{ab}+480S^2L_{aa}+480S^3+120S_{:aa}+Q_{0;m}((180^+,-180^-)E$
$+(30^+,-30^-)\tau+(84^+,-180^-)/7\cdot L_{aa}L_{bb}+(84^+,60^-)/7\cdot L_{ab}L_{ab}$
$+72SL_{aa}+240S^2+Q_{0;mm}(24L_{aa}+120S)+(30^+,-30^-)Q_{0;iim}\}[\partial M]\}$.

Theorem IV.2: *Let M be a compact Riemannian manifold with smooth boundary, let D be an operator of Laplace type, and let* $Q_1=\partial_\varepsilon D(g,\nabla+\varepsilon q_1,E)|_{\varepsilon=0}$. *Then*

(1) $a_{-1}(Q_1,D,\mathscr{B}_S^\pm)=0$.
(2) $a_0(Q_1,D,\mathscr{B}_S^\pm)=-(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V((-12^+,0^-)q_{1,m})[\partial M]$.
(3) $a_1(Q_1,D,\mathscr{B}_S^\pm)=-(384)^{-1}(4\pi)^{-(m-1)/2}\mathrm{tr}_V((-96^+,0^-)q_{1,m}L_{aa}-384Sq_{1,m})[\partial M]$.
(4) $a_2(Q_1,D,\mathscr{B}_S^\pm)=-(4\pi)^{-m/2}360^{-1}\{\mathrm{tr}_V(60F_{ij}\cdot\mathscr{F}_{ij})[M]+\mathrm{tr}_V\{(-720^+,0^-)q_{1,m}E$
$+(-120^+,0^-)q_{1,m}\tau+(-144^+,0^-)q_{1,m}L_{aa}L_{bb}+(-48^+,0^-)q_{1,m}L_{ab}L_{ab}$
$-960Sq_{1,m}L_{aa}-1440S^2q_{1,m}\}[\partial M]\}$.
(5) $a_3(Q_1,D,\mathscr{B}^-)=5760^{-1}(4\pi)^{(m-1)/2}\mathrm{tr}_V\{240F_{ab}\cdot\mathscr{F}_{ab}-720F_{am}\cdot\mathscr{F}_{am}\}[\partial M]$.
(6) *If the boundary of M is totally geodesic, then*
$a_3(Q_1,D,\mathscr{B}_S^\pm)=-5760^{-1}(4\pi)^{(m-1)/2}\mathrm{tr}_V(-1440E_{;m}q_{1,m}+1440(q_{1,m}E-Eq_{1,m})S$
$+240F_{ab}\cdot\mathscr{F}_{ab}-960\tau Sq_{1,m}-240\rho_{mm}Sq_{1,m}+180F_{am}\cdot\mathscr{F}_{am}-270\tau_{;m}q_{1,m}$
$+720S_{:a}q_{1,m:a}+720S_{:a}(q_{1,a}S-Sq_{1,a})-2880E(Sq_{1,m}+q_{1,m}S)$
$-5760q_{1,m}S^3)[\partial M]$.

Proof: If $Q_0=q_0I_V$ for $q_0\in C^\infty(M)$ is a scalar operator, then Theorem IV.1 follows from Ref. 4. If Q_0 is not a scalar operator, we must worry about the lack of commutativity; the only point at which this enters is in the coefficient of $\mathrm{tr}_V(Q_0SE)$ and $\mathrm{tr}_V(Q_0ES)$. We express

$$a_4(Q_0,D,\mathscr{B}_S)=(4\pi)^{-m/2}360^{-1}\mathrm{tr}_V(C_1Q_0SE+C_2Q_0ES)[\partial M]+\text{ other terms;}$$

the sum $C_1+C_2=720$ is determined by the scalar case. If D, Q_0, and S are real, then $\mathrm{Tr}_{L^2}(Q_0e^{-tD})$ is real; this shows that C_1 and C_2 are real. If Q_0, D, and S are self-adjoint, $\mathrm{Tr}_{L^2}(Q_0e^{-tD})$ is real so $\mathrm{tr}_V(Q_0(C_1SE+C_2ES))[\partial M]$ is real; this now shows $C_1=C_2$ and completes the proof of Theorem IV.1.

To keep boundary conditions constant, let $S(\varepsilon):=S-\varepsilon q_{1,m}$ so $\partial_\varepsilon S|_{\varepsilon=0}=-q_{1,m}$. Assertions (1)–(5) of Theorem IV.2 now follow directly from Lemma II.2, from Lemma II.3, and from Theorem IV.1. In Ref. 5, we showed that

$$\begin{aligned}a_5(1,D,\mathscr{B}_S^{\pm})=&\pm 5760^{-1}(4\pi)^{(m-1)/2}\mathrm{tr}_V\{(360E_{;mm}+1440E_{;m}S\\&+720E^2+240E_{:aa}+240\tau E+120F_{ab}F_{ab}+48\tau_{;ii}+20\tau^2-8\rho^2\\&+8R^2-120\rho_{mm}E-20\rho_{mm}\tau+480\tau S^2+(90^+,-360^-)F_{am}F_{am}\\&+12\tau_{;mm}+24\rho_{mm:aa}+15\rho_{mm;mm}+270\tau_{;m}S+120\rho_{mm}S^2\\&+960S_{:aa}S+600S_{:a}S_{:a}+16R_{ammb}\rho_{ab}-17\rho_{mm}\rho_{mm}\\&-10R_{ammb}R_{ammb}+2880ES^2+1440S^4)+\mathscr{E}\}[\partial M].\end{aligned}$$

The variation of the terms other than $\mathscr{E}$ gives rise to the expressions listed in Theorem IV.2 (5) and (6). The remainder term $\mathscr{E}$ is given below. It vanishes if the boundary is totally geodesic and involves 40 undetermined coefficients:

$$\begin{aligned}\mathscr{E}=&d_1^{\pm}L_{aa}E_{;m}+d_2^{\pm}L_{aa}\tau_{;m}+d_3^{\pm}L_{ab}R_{ammb;m}+d_4^{+}L_{aa}S_{:bb}+d_5^{+}L_{ab}S_{:ab}\\&+d_6^{+}L_{aa:b}S_{:b}+d_7^{+}L_{ab:a}S_{:b}+d_8^{+}L_{aa:bb}S+d_9^{+}L_{ab:ab}S+d_{10}^{\pm}L_{aa:b}L_{cc:b}\\&+d_{11}^{\pm}L_{ab:a}L_{cc:b}+d_{12}^{\pm}L_{ab:a}L_{bc:c}+d_{13}^{\pm}L_{ab:c}L_{ab:c}+d_{14}^{\pm}L_{ab:c}L_{ac:b}\\&+d_{15}^{\pm}L_{aa:bb}L_{cc}+d_{16}^{\pm}L_{ab:ab}L_{cc}+d_{17}^{\pm}L_{ab:ac}L_{bc}+d_{18}^{\pm}L_{aa:bc}L_{bc}+d_{19}^{\pm}L_{bc:aa}L_{bc}\\&+1440^{+}L_{aa}SE+d_{20}^{+}L_{aa}S\rho_{mm}+240^{+}L_{aa}S\tau+d_{21}^{+}L_{ab}S\rho_{ab}\\&+d_{22}^{+}L_{ab}SR_{mabm}+(195^{+},105^{-})L_{aa}L_{bb}E+(30^{+},150^{-})L_{ab}L_{ab}E\\&+(195^{+}/6,105^{-}/6)L_{aa}L_{bb}\tau+(5^{+},25^{-})L_{ab}L_{ab}\tau+d_{23}^{\pm}L_{aa}L_{bb}\rho_{mm}\\&+d_{24}^{\pm}L_{ab}L_{ab}\rho_{mm}+d_{25}^{\pm}L_{aa}L_{bc}\rho_{bc}+d_{26}^{\pm}L_{aa}L_{bc}R_{mbcm}+d_{27}^{\pm}L_{ab}L_{ac}\rho_{bc}\\&+d_{28}^{\pm}L_{ab}L_{ac}R_{mbcm}+d_{29}^{\pm}L_{ab}L_{cd}R_{acbd}+d_{30}^{+}L_{aa}S^3+d_{31}^{+}L_{aa}L_{bb}S^2\\&+d_{32}^{+}L_{ab}L_{ab}S^2+d_{33}^{+}L_{aa}L_{bb}L_{cc}S+d_{34}^{+}L_{aa}L_{bc}L_{bc}S+d_{35}^{+}L_{ab}L_{bc}L_{ac}S\\&+d_{36}^{\pm}L_{aa}L_{bb}L_{cc}L_{dd}+d_{37}^{\pm}L_{aa}L_{bb}L_{cd}L_{cd}+d_{38}^{\pm}L_{ab}L_{ab}L_{cd}L_{cd}\\&+d_{39}^{\pm}L_{aa}L_{bc}L_{cd}L_{db}+d_{40}^{\pm}L_{ab}L_{bc}L_{cd}L_{da}.\end{aligned}$$

The variation of $\mathscr{E}$ is zero for Dirichlet boundary conditions or if the boundary is totally geodesic. □

To study $a_n(Q_2,D,\mathscr{B}_S^{\pm})$ we need some additional formulas.

Lemma IV.3:

(1) *Let* $g(\varrho):=g+\varrho q_2$, $\mathscr{N}:=\partial_\varrho|_{\varrho=0}e_m(\varrho)$, and $\mathscr{L}_{\alpha\beta}:=\partial_\varrho|_{\varrho=0}L_{\alpha\beta}$. *Then*
   (a) $\mathscr{N}=-q_{2,am}e_a-q_{2,mm}e_m/2$.
   (b) $\mathscr{L}_{ab}=(q_{2,am;b}+q_{2,bm;a}-q_{2,ab;m}-q_{2,mm}L_{ab})/2$.
(2) $q_{2,am;a}=q_{2,am:a}-L_{aa}q_{2,mm}+L_{ab}q_{2,ab}$.
(3) $\mathscr{R}_{kiik}=q_{2,ki;ki}-q_{2,ii;kk}$.

Proof: Let $1\leqslant\alpha,\beta\leqslant m-1$. Let $y=(y^\alpha)$ be local coordinates on the boundary ∂M centered at y_0. We suppose $g_{\alpha\beta}(y_0)=\delta_{\alpha\beta}+O(|y|^2)$. Introduce coordinates $x=(y,x^m)$ so the curves $t\mapsto(y,t)$ are unit speed geodesics perpendicular to the boundary. Then $g_{mm}=1$ and $g_{\alpha m}=0$; ∂_m is the

inward geodesic normal vector field for g. Let $N(\varrho)$ be the inward geodesic normal vector field for the metric $g(\varrho)$. Expand $N(\varrho)(y_0)=\partial_m+\varrho(c^m\partial_m+c^\beta\partial_\beta)+O(\varrho^2)$. We prove the first assertion by solving the equations

$$0=g(\varrho)(N(\varrho),\partial_\alpha)(y_0)=\varrho(c^\alpha+q_{2,\alpha m})(y_0)+O(\varrho^2),$$

$$1=g(\varrho)(N(\varrho),N(\varrho))(y_0)=1+\varrho(2c^m+q_{2,mm})(y_0)+O(\varrho^2)$$

to see $c^\alpha(y_0)=-q_{2,m\alpha}(y_0)$ and $c^m(y_0)=-q_{2,mm}/2$. We use Lemma II.3 to compute the variation of the Christoffel symbols and complete the proof by computing:

$$L_{\alpha\beta}=\Gamma(\rho)_{\alpha\beta}{}^i g(N(\varrho),\partial_i),$$

$$\mathscr{L}_{\alpha\beta}(y_0)=(\dot\Gamma_{\alpha\beta}{}^m-q_{2,mm}L_{\alpha\beta}/2)(y_0).$$

The second assertion is immediate, the third follows from Lemma II.3. □

Dirichlet boundary conditions are unchanged by a variation of the metric g. The following result follows from Lemma II.2, Theorem IV.1, and Lemma IV.3. We omit the formula for a_2 in the interest of brevity.

Theorem IV.4: *Let M be a compact Riemannian manifold with smooth boundary, let D be an operator of Laplace type, and let $Q_2:=\partial_\varepsilon|_{\varepsilon=0}D(g+\varepsilon q_2,\nabla,E)$. Then*

(1) $a_{-2}(Q_2,D,\mathscr{B}^-)=-(4\pi)^{-m/2}\mathrm{tr}_V\{q_{2,ii}/2\}[M]$.
(2) $a_{-1}(Q_2,D,\mathscr{B}^-)=(4\pi)^{-(m-1)/2}4^{-1}\mathrm{tr}_V\{q_{2,aa}/2\}[\partial M]$.
(3) $a_0(Q_2,D,\mathscr{B}^-)=-(4\pi)^{-m/2}6^{-1}\{\mathrm{tr}_V\{q_{2,ii}(6E+\tau)/2-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik}\}[M]$
$+\mathrm{tr}_V\{q_{2,aa}L_{aa}+2\mathscr{L}_{aa}-2q_{2,ab}L_{ab}\}[\partial M]\}$.
(4) $a_1(Q_2,D,\mathscr{B}^-)=(4\pi)^{-(m-1)/2}384^{-1}\mathrm{tr}_V\{q_{2,aa}(96E+16\tau+8R_{amam}+7L_{aa}L_{bb}-10L_{ab}L_{ab})/2$
$+16(-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik})+8(\mathscr{R}_{amam}-q_{2,ab}R_{ambm}+2R_{ama\mathscr{N}})$
$+7(2\mathscr{L}_{aa}L_{bb}-2q_{2,ab}L_{ab}L_{cc})-10(2\mathscr{L}_{ab}L_{ab}-2q_{2,ac}L_{ab}L_{cb})\}[\partial M]$.
(5) *Suppose for simplicity that the metric g is flat, i.e., that $R_{ijkl}=0$. Then*
$a_2(Q_2,D,\mathscr{B}^-)=-(4\pi)^{-m/2}360^{-1}\{-\mathscr{D}\mathrm{tr}_V(60E)+\mathrm{tr}_V(60\mathscr{R}_{ijji}E+30q_{2,ii}E_{;kk}+90q_{2,ii}E^2$
$+15q_{2,ii}\Omega^2)\}[M]-(4\pi)^{-m/2}360^{-1}\mathrm{tr}_V\{60E_{;m}q_{2,mm}+120E_{;a}q_{2,am}$
$-18\mathscr{R}_{ikki;m}+L_{aa}(20\mathscr{R}_{ikki}+4\mathscr{R}_{bmbm})+12\mathscr{R}_{ambm}L_{ab}+4\mathscr{R}_{abcb}L_{ac}$
$+q_{2,dd}(-60E_{;m}+60EL_{aa}+12L_{aa:bb}+20/21L_{aa}L_{bb}L_{cc}+44/7L_{ab}L_{ab}L_{cc}$
$+160/21L_{ab}L_{bc}L_{ac})+(120E+40/7L_{aa}L_{bb}+88/7L_{ab}L_{ab})(\mathscr{L}_{cc}-q_{2,cd}L_{cd})$
$+88/7(2\mathscr{L}_{ab}L_{ab}L_{cc}-2q_{2,bd}L_{ab}L_{ad}L_{cc})+320/7(\mathscr{L}_{ab}L_{bc}L_{ca}$
$-q_{2,ad}L_{ab}L_{bc}L_{cd})+12L_{bb:c}q_{2,aa:c}\}[\partial M]$.

We now study Neumann boundary conditions. The situation is quite different as Neumann boundary conditions are **not** invariant under general perturbations of the metric; if $q_{am}\neq 0$ on ∂M, $\mathscr{B}_S^+(\varrho)$ will involve tangential derivatives regardless of how S is varied. Thus Lemma II.2 is not directly applicable. Nevertheless, we can still compute the first three terms in the asymptotic expansion.

Theorem IV.5: *Let M be a compact Riemannian manifold with smooth boundary, let D be an operator of Laplace type, and let $Q_2:=\partial_\varepsilon D(g+\varepsilon q_2,\nabla,E)|_{\varepsilon=0}$. Then*

(1) $a_{-2}(Q_2,D,\mathscr{B}_S^+)=-(4\pi)^{-m/2}\mathrm{tr}_V\{q_{2,ii}/2\}[M]$.
(2) $a_{-1}(Q_2,D,\mathscr{B}_S^+)=-(4\pi)^{-(m-1)/2}4^{-1}\mathrm{tr}_V\{q_{2,aa}/2\}[\partial M]$.
(3) $a_0(Q_2,D,\mathscr{B}_S^+)=-(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V\{q_{2,ii}(6E+\tau)/2-q_{2,ij}\rho_{ij}\}[M]$
$-(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V\{q_{2,aa}L_{bb}-q_{2,ab}L_{ab}-6q_{2,mm}S+6q_{2,aa}\}[\partial M]$.

Proof: Define $\mathrm{ord}(q_{2,ij})=0$, $\mathrm{ord}(E)=2$, $\mathrm{ord}(R_{ijkl})=2$, $\mathrm{ord}(F)=2$, $\mathrm{ord}(L)=1$, and $\mathrm{ord}(S)=1$. Increase the order by 1 for each explicit covariant derivative which is present. Dimensional analysis then shows the interior integrands in the formula for $a_n(Q_2,D,\mathscr{B})$ are homogeneous of order $n+2$ while the boundary integrands are homogeneous of degree $n+1$. We use H. Weyl's theorem to write a spanning set for the set of invariants and express

$$a_{-2}(Q_2,D,\mathscr{B}_S^+)=-(4\pi)^{-m/2}\mathrm{tr}_V(b_1q_{2,ii}/2)[M],\tag{4.1}$$

$$a_{-1}(Q_2,D,\mathscr{B}_S^+)=-(4\pi)^{-(m-1)/2}4^{-1}\mathrm{tr}_V(c_1q_{2,aa}/2+c_2q_{2,mm})[\partial M], \tag{4.2}$$

$$\begin{aligned}a_0(Q_2,D,\mathscr{B}_S^+)=&-(4\pi)^{-m/2}6^{-1}\{\mathrm{tr}_V(q_{2,ii}(6b_2E+b_3\tau)/2-b_4q_{2,ij}\rho_{ij})[M]+\mathrm{tr}_V(c_3q_{2,aa}L_{bb}\\&+c_4q_{2,ab}L_{ab}+c_5q_{2,mm}L_{aa}+c_6q_{2,mm}S+c_7q_{2,aa}S+c_8q_{2,mm;m}\\&+c_9q_{2,aa;m})[\partial M]\}.\end{aligned} \tag{4.3}$$

Product formulas then show the constants are independent of the dimension m; these invariants form a basis for the integral invariants and are uniquely determined for m large. A word of explanation for the formula in equation (4.3) is in order. We can integrate by parts to replace the interior integrals $q_{2,ij;ij}$ and $q_{2,ii;jj}$ by boundary integrals of $q_{2,mm;m}$, $q_{2,am;a}$, and $q_{2,aa;m}$. Since $q_{2,am;a}[\partial M]=0$, we use Lemma IV.3 to omit the variable $q_{2,am;a}$. If we take ∂M empty, the boundary condition plays no role and $\mathscr{R}_{kiik}[M]=0$ (see equation (4.5) below). We use Theorem III.3 to see $b_1=b_2=b_3=b_4=1$; this completes the proof of assertion (1) and the first part of assertion (3).

The $q_{2,am;*}$ variables do not appear in equations (4.1), (4.2), and (4.3). Thus we may take a variation with $q_{2,am}=0$ on ∂M. This is an essential simplification since it means $N(\varrho)=g^{mm}(\varrho)^{1/2}\partial_m$. Thus the boundary conditions do not involve any tangential derivatives. We set $S(\varrho)=g^{mm}(\varrho)^{1/2}S$. Then the boundary condition is preserved; $\nabla_{N(\varrho)}+S(\varrho)=g^{mm}(\varrho)^{1/2}(\nabla_m+S)$. We have $\partial_\varrho S(\varrho)|_{\varrho=0}=-q_{2,mm}S/2$. By Lemma II.2, $a_{-1}(Q_2,D,B_S^+)=-(4\pi)^{-(m-1)/2}4^{-1}\mathrm{tr}_V(q_{2,aa}/2)[\partial M]$. This shows $c_1=1$ and $c_2=0$ and completes the proof of assertion (2).

We use Lemma II.2 and Theorem IV.1 to see

$$\begin{aligned}a_0(Q_2,D,B_S^+)=&-(4\pi)^{-(m-1)/2}6^{-1}\{\mathrm{tr}_V(q_{2,ii}(6E+\tau)/2-q_{2,ij}\rho_{ij}+\mathscr{R}_{kiik})[M]\\&+\mathrm{tr}_V(q_{2,aa}(L_{bb}+6S)-2q_{2,ab}L_{ab}+2\mathscr{L}_{aa}-6q_{2,mm}S)[\partial M]\}.\end{aligned} \tag{4.4}$$

We have that

$$\begin{aligned}\mathscr{R}_{kiik}[M]&=(q_{2,ki;ki}-q_{2,ii;kk})[M]\\&=(-q_{2,am;a}+q_{2,aa;m})[\partial M]\\&=(L_{aa}q_{2,mm}-L_{ab}q_{2,ab}+q_{2,aa;m})[\partial M],\\2\mathscr{L}_{aa}[\partial M]&=(2q_{2,am;a}-q_{2,aa;m}-q_{2,mm}L_{aa})[\partial M]\\&=(-3L_{aa}q_{2,mm}+2L_{ab}q_{2,ab}-q_{2,aa;m})[\partial M].\end{aligned} \tag{4.5}$$

We use equation (4.5) to compare equations (4.3) and (4.4). This shows

$$c_3=1,\quad c_4=-1,\quad c_5=-2,\quad c_6=-6,\quad c_7=6,\quad c_8=0,\quad c_9=0. \qquad \square$$

V. OPERATORS OF DIRAC TYPE

In this section, we study the invariants $a_n(HA,A^2)$, where M is a closed manifold, A is an operator of Dirac type, and H is a smooth endomorphism; we refer to Ref. 7 for a discussion of the case of manifolds with boundary. We begin with a technical result:

Lemma V.1: Let $A=\gamma^\nu\partial_\nu-\psi$ be an operator of Dirac type and let $D=A^2$ be the associated operator of Laplace type. Let $D=D(g,\nabla,E)$ and let $H\in C^\infty\mathrm{End}(V)$.

(1) $\omega_\mu=g_{\nu\mu}(-\gamma^\sigma\partial_\sigma\gamma^\nu+\psi\gamma^\nu+\gamma^\nu\psi+g^{\sigma\rho}\Gamma_{\sigma\rho}{}^\nu)/2$.
(2) *Let $\phi:=\psi+\gamma^\nu\omega_\nu$. Then $A=\gamma^\nu\nabla_\nu-\phi$, and ϕ is invariantly defined.*
(3) $\gamma_{i;j}+\gamma_{j;i}=0$.
(4) $E=-\psi^2+\gamma^\mu\partial_\mu\psi-g^{\nu\mu}(\partial_\mu\omega_\nu+\omega_\nu\omega_\mu-\omega_\sigma\Gamma_{\nu\mu}{}^\sigma)=-\gamma_i\gamma_jF_{ij}/2+\gamma_i\phi_{;i}-\phi^2$.
(5) *Let $q_{1,i}:=-H\gamma_i/2$, and $Q_0:=-H\phi-H_{;i}\gamma_i/2$, then $HA=Q_1+Q_0$.*

Proof: We compute

$$\begin{aligned} D=A^2&=(\gamma^\nu\partial_\nu-\psi)(\gamma^\mu\partial_\mu-\psi)\\ &=\gamma^\nu\gamma^\mu\partial_\nu\partial_\mu+(\gamma^\nu\partial_\nu\gamma^\mu-\gamma^\mu\psi-\psi\gamma^\mu)\partial_\mu+\psi^2-\gamma^\mu\partial_\mu\psi,\end{aligned}$$

$$a^\mu=-\gamma^\nu\partial_\nu\gamma^\mu+\gamma^\mu\psi+\psi\gamma^\mu, \text{ and } b=-\psi^2+\gamma^\mu\partial_\mu\psi.$$

Assertion (1) and the first assertion of (4) follows from Lemma II.1. We prove assertion (2) by computing: $\gamma^i\nabla_i-\phi=\gamma^i\partial_i+\gamma^i\omega_i-\phi=\gamma^i\partial_i-\psi$. We choose a system of coordinates and a local frame so that $\Gamma(x_0)=0$ and so that $\omega(x_0)=0$. Then at x_0, we have

$$\begin{aligned} D&=(\gamma^\nu\nabla_\nu-\phi)(\gamma^\mu\nabla_\mu-\phi)\\ &=(\gamma^\nu\gamma^\mu+\gamma^\mu\gamma^\nu)/2\nabla_\nu\nabla_\mu+(\gamma^\mu\gamma^\nu{}_{;\mu}-\phi\gamma^\nu-\gamma^\nu\phi)\nabla_\nu\\ &\quad-\gamma^\nu\phi_{;\nu}+\gamma^\nu\gamma^\mu\Omega_{\nu\mu}/2+\phi^2\\ &=-g^{\nu\mu}\nabla_\nu\nabla_\mu-E.\end{aligned}$$

We equate coefficients to derive the second part of assertion (4). Choose a coordinate system centered at x_0 so $g_{\mu\nu}=\delta_{\nu\mu}+O(|x|^2)$. We use Ref. 8 (Lemma 1.2) to see that we can choose a local frame for V so $\partial_\mu\gamma^\nu(x_0)=0$. Then we have that $\omega_\mu(x_0)=(\psi\gamma_\mu+\gamma_\mu\psi)(x_0)/2$. We prove assertion (3) by computing at x_0

$$\begin{aligned} 2(\gamma_{\nu;\mu}+\gamma_{\mu;\nu})&=[\psi\gamma_\mu+\gamma_\mu\psi,\gamma_\nu]+[\psi\gamma_\nu+\gamma_\nu\psi,\gamma_\mu]\\ &=\psi\gamma_\mu\gamma_\nu+\gamma_\mu\psi\gamma_\nu-\gamma_\nu\psi\gamma_\mu-\gamma_\nu\gamma_\mu\psi+\psi\gamma_\nu\gamma_\mu+\gamma_\nu\psi\gamma_\mu\\ &\quad-\gamma_\mu\psi\gamma_\nu-\gamma_\mu\gamma_\nu\psi\\ &=\psi\gamma_\mu\gamma_\nu+\psi\gamma_\nu\gamma_\mu-\gamma_\mu\gamma_\nu\psi-\gamma_\mu\gamma_\nu\psi\\ &=\psi\delta_{\mu\nu}-\delta_{\mu\nu}\psi=0.\end{aligned}$$

If we set $q_{1,i}=-H\gamma_i/2$, then $Q_1=H\gamma_i\nabla_i+H_{;i}\gamma_i/2$ by Lemma II.2 since $\gamma_{i;i}=0$. We must therefore take $Q_0=-H\phi-H_{;i}\gamma_i/2$. □

The following theorem now follows from Theorem III.1, Theorem III.2, and from Lemma III.3.

Theorem V.2: *Let $A=\gamma_\nu\partial_\nu-\psi$ be an operator of Dirac type on $C^\infty(V)$ over a closed manifold M. Adopt the notation of Lemma V.1.*

(1) $a_0(HA,A^2)=(4\pi)^{-m/2}\mathrm{tr}_V\{Q_0\}[M]$.
(2) $a_2(HA,A^2)=(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V\{Q_0(\tau+6E)-F_{ij}\mathscr{F}_{ij}\}[M]$.
(3) $a_4(HA,A^2)=(4\pi)^{-m/2}360^{-1}\mathrm{tr}_V\{Q_0(60E_{;kk}+60\tau E+180E^2+12\tau_{;kk}+5\tau^2-2|\rho|^2+2|R|^2$
$+30F_{ij}F_{ij})+8F_{ij;k}\mathscr{F}_{ij;k}+8F_{ij;k}q_{1,k}F_{ij}-8F_{ij;k}F_{ij}q_{1,k}-4F_{ij;j}\mathscr{F}_{ik;k}$
$-4F_{ij;j}q_{1,k}F_{ik}+4F_{ij;j}F_{ik}q_{1,k}+36F_{ij}F_{jk}\mathscr{F}_{ki}+12R_{ijkn}F_{ij}\mathscr{F}_{kn}+8\rho_{jk}F_{jn}\mathscr{F}_{kn}$
$-10\tau F_{kn}\mathscr{F}_{kn}+60E_{;k}q_{1,k}E-60E_{;k}Eq_{1,k}-30EF_{ij}\mathscr{F}_{ij}-30E\mathscr{F}_{ij}F_{ij}\}[M]$.

The first two authors Ref. 8 (Theorem 2.7) computed a_0 and a_2 for f scalar and showed that

$$a_0(fA,A^2)=-(4\pi)^{-m/2}\mathrm{tr}_V(f\phi)[M], \tag{5.1}$$

and

$$a_2(fA,A^2)=-(4\pi)^{-m/2}6^{-1}\mathrm{tr}_V\{f(\phi\tau+6\phi E-F_{ij;j}\gamma_i)\}[M]. \tag{5.2}$$

For scalar f, $\mathrm{Tr}_{L^2}(f_{;i}\gamma_ie^{-tA^2})=\mathrm{Tr}_{L^2}(Afe^{-tA^2}-fAe^{-tA^2})=0$ so $a_n(f_{;i}\gamma_i,A^2)=0$ for all n and we may replace Q_0 by $-f\phi$ in performing our computations. It then follows that Theorem V.2(1) agrees with equation (5.1). We see Theorem V.2 (2) agrees with equation (5.2) by using Lemma II.3 and integrating by parts:

$$-\mathrm{tr}_V(F_{ij}\mathscr{F}_{ij})[M]=\mathrm{tr}_V((f\gamma_j)_{;i}-(f\gamma_i)_{;j})F_{ij}[M]/2$$
$$=-\mathrm{tr}_V(f\gamma_jF_{ij;i}[M])=\mathrm{tr}_V(f\gamma_iF_{ij;j})[M].$$

(Received 29 October 1996; accepted for publication 8 October 1997)

Results concerning the occurrence of (kinematical) singularities obtained by Majda *et al.* [Commun. Math. Phys. **94**, 61–66 (1984)] for the incompressible Euler equations and of Chemin [Commun. Math. Phys. **133**, 323–329 (1990)] for the compressible Euler equations are generalized for the compressible Euler–Poisson system. This generalization is applied to two situations of physical interest, namely, either the evolution of a compact body with a freely falling boundary or a cosmological solution with finite, spatially periodic, deviations of a Newtonian, Friedman-like cosmological model. Both situations are briefly reviewed. For the compact body the solutions belong to a special class, introduced by Makino [*Patterns and Waves* (North-Holland, Amsterdam, 1986), pp. 459–479]. In Sec. III, uniqueness is shown for these and therewith one of the severe disadvantages of these solution is eliminated. In both situations the qualitative behavior is similar to the gravitation free case in the sense that only some of the kinematical quantities of the fluid and the gradient of the matter variable diverge; in other words, no specific ''gravitation singularity'' appears. The differences between the two situations considered here is that, for technical reasons, a nonlinear function $w=M(\varrho)$ has to be introduced as a new matter variable for the compact body. Because ϱ has compact support the blow-up of grad w in the L^{∞}-norm implies two possibilities, one being that the singularity is in the interior of the body. In that case the blow-up of grad w implies the blow-up of grad ϱ. If, on the other hand, the singularity is near the boundary of the body, then no precise information is available. © *1998 American Institute of Physics.* [S0022-2488(98)03401-X]

I. INTRODUCTION

One of the most important problems in the relativistic theory of gravitation is the so-called cosmic censorship hypothesis which, in the version considered here, conjectures that all *physical relevant singularities* are not visible ''for a distant observer.'' Here the term ''for a distant observer'' will not be made more precise as it is of no relevance for the task of the following discussion. One serious drawback of the conjecture, as stated above, is the lack of a precise definition of a physical relevant singularity. It is common, though, to distinguish mainly two types of singularities, namely, *matter singularities* and *gravitational singularities*. Gravitational singularities should be those which are caused *only* due to the *presence* of the gravitational field, while matter singularities would also occur in the gravitational free case. One considers the case of a fluid as a typical example for *matter singularities* like shock waves or rotational singularities. There is, however, no mathematical result known which would allow a justification of this sort of distinction. Since the relativistic case is too difficult to attack directly with mathematical methods known at the moment, it may be useful and instructive to start with the analogous problem in the Newtonian case. The idea would then be to try to generalize results about singularities for the gravitational free case to the situation where self-gravitation is considered. The results of most relevance would be an article by Chemin,[1] in which he generalized results obtained by Beale *et al.*[2] earlier on.

 © 1998 American Institute of Physics

Here the following pragmatic point of view is adopted. If ''typical'' gravitational terms, such as, for example, the tidal tensor, appeared in the continuation criteria for the Euler–Poisson system, this then would be taken as evidence of a gravitational singularity. This, however, is not the case. As in the gravitational free case, only the kinematical quantities of the fluid control the breakdown of smooth solutions.

The Euler–Poisson system that will be considered in the following consists of the following equations:

$$\partial_t \varrho + v^a \partial_a \varrho + \varrho \partial_a v^a = 0, \tag{I.1a}$$

$$\varrho(\partial_t v^a + v^b \partial_b v^a) + \partial^a p = -\varrho \partial^a \phi, \tag{I.1b}$$

$$\Delta \phi = \varrho. \tag{I.1c}$$

Here $\varrho(\mathbf{x},t)$, $p(\mathbf{x},t)$, $\phi(\mathbf{x},t)$, and $\mathbf{v}(\mathbf{x},t)$ depend on the Cartesian coordinates ($\mathbf{x}\in\mathbb{R}^3$ and $\mathbf{x}\in\mathbb{T}^3$, respectively) and the absolute Newtonian time t. The mass density is denoted by $\varrho(\mathbf{x},t)$ and is connected with the pressure p via some equation of state, the only restriction on *the equation of state* being that for $\varrho>0$, p depends smoothly and monotonously on ϱ in such a way that $p=f(\varrho)$ is invertible. An example for this restriction is the so-called *barotropic* equation of state $p=K\varrho^\gamma$, K, $\gamma\in\mathbb{R}^+ 1<\gamma<\frac{5}{3}$, which describes the adiabatic changes of an ideal gas. The case of boundaries with $\varrho=0$ is somewhat subtle and requires further investigation—at the moment no more general statements about the equation of state are made.

A. Helmholtz decomposition and main idea

The gradient of the velocity can be decomposed into the antisymmetric rotation tensor Ω_{ab} and the symmetric deformation tensor θ_{ab}, which in turn can be split into the traceless shear tensor σ_{ab} and in the expansion θ, the trace of θ_{ab}:

$$\partial_a v_b = \tfrac{1}{2}(\partial_a v_b - \partial_b v_a) + \tfrac{1}{2}(\partial_a v_b + \partial_b v_a) = \theta_{ab} - \Omega_{ab} \tag{I.2a}$$

$$= \sigma_{ab} - \Omega_{ab} + \tfrac{1}{3}\delta_{ab}\theta. \tag{I.2b}$$

This is the so-called Helmholtz decomposition and combinations of these kinematical quantities will appear in the continuation criterion presented in Sec. V. Use will be made of the rotation vector Ω^a given by $\Omega^a=\epsilon^{abc}\Omega_{bc}$ which satisfies the propagation equation (V.2) expressing the conservation of rotation. This equation will be used to prove a continuation criterion in which the L^∞-norm of the deformation tensor and the gradient of the matter variable control the occurrence of singularities.

As indicated above, one of the main tasks of this article is to investigate whether gravitational singularities can be formed for self-gravitation fluids. The question is investigated in the following two situations:

(1) The time evolution of a compact body denoted as case I from now on, or
(2) the time evolution of finite spatially periodic deviations from a Newtonian Friedmann-like cosmological model, called case II from now on.

Local in time existence for the first situation has been shown by the author[3] and for the second it has been shown in Ref. 4.

This article proceeds as follows: In the next section some notation is fixed; appropriate function spaces and the definition of symmetric–hyperbolic systems are presented. The fact that the Euler equations, written as a symmetric–hyperbolic system, are not regular at $\varrho=0$ is discussed as well as the implications for describing a compact body. Furthermore, the possible

breakdowns of solutions of symmetric hyperbolic systems are discussed. In Sec. II we deal with the evolution of a compact body. As it turns out, the usual way of deriving boundary conditions via conservation laws is not sufficient to prove that, for the case of vanishing boundary density, the boundary is generated by the fluid lines. This fact never seems to be pointed out in the literature. However, the Makino solutions, treated here, have this ''boundary feature.''

Next uniqueness is proven for the Makino solutions and so an existing gap of these solutions is eliminated. Section IV contains the main results together with some fairly easy to prove corollaries. In Sec. V the proof of the main result is presented. In the last section the differences of the cosmological situation in the main result, weak points of the main result, and possible improvements and generalizations are discussed. In the Appendix finally some details of the proofs are given. Especially the nonlocal elliptic estimate for the gradient of the velocity, one of the key elements of the proof, had to be proved for the $\mathbb{T}^3$.

II. PRELIMINARIES

The symbol $H^s(M)$ denotes the Sobolev space of order s on M. The norm is

$$\|f\|_{H^s(M)}=\left\{\sum_{|\alpha|\leqslant s}\int_M(|\partial_\alpha f|)^2\,dV\right\}^{1/2},$$

where s in a non-negative integer, $s\geqslant 1$, α is a multi-index, M is either $\mathbb{R}^3$ or the torus $\mathbb{T}^3$ with the flat Euclidian metric δ_{ij}, and dV is the volume form associated with the metric δ_{ij}.

The norm of a tensor T in a given coordinate basis as $T=T^{ij\cdots}\partial_i\partial_j\partial\ldots$, is taken with respect to the metric δ_{ij}. For example, $\|U\|_{L^2}=\int_M\delta_{ij}U^iU^j\,dV$. We denote the space of continuously differentiable functions of order k by C^k. It is a Banach space with norm given by

$$\|u\|_{C^k}=\sum_{|\alpha|\leqslant k}\sup|D^\alpha u|. \tag{II.1}$$

Here L^∞ is a Banach space of almost everywhere defined measurable functions bounded almost everywhere (that means everywhere except on a set of measure zero). L^∞ has the norm

$$\|f\|_{L^\infty}=\operatorname{ess\,sup}|f(x)|.$$

$C^k([0,T];H^s)$ (abbreviated by $C^{k,s}_{T,M}$) denotes the space of all H^s-valued functions on $[0,T]$ that have continuous derivatives of order $\leqslant k$.

H^s is a *Banach algebra*, that is, the pointwise multiplication is continuous if $s>\frac{3}{2}$. Furthermore, use will be made of the Sobolev inequalities, that is, let k be a non-negative integer. Then for $f\in H^{s+k}$, the following holds:

$$\|f\|_{C^k}\leqslant\text{const}\,\|f\|_{H^s}\quad\text{if}\ \ s\geqslant 2+k.$$

A. Symmetric hyperbolic systems

Let $U^\alpha:V\subset M\times I\to G\subset\mathbb{R}^l$ be a vector-valued function, G denote an open set of the target space $\mathbb{R}^l$, and I be an open subset of $\mathbb{R}^+$. (In the following indices are used whenever it is convenient.) As will be pointed out later in case II, G consists of all those ϱ with $\varrho>0$. $U\in C(V,G)$ fulfills the system of quasilinear partial differential equations of the form

$$L[U]=A^0_{\alpha\beta}(U)\,\frac{\partial U^\beta}{\partial t}+\sum_{k=1}^{n}A^k_{\alpha\beta}(U)\,\frac{\partial U^\beta}{\partial x^k}+B_{\alpha\beta}(U), \tag{II.2}$$

where the matrix $A^\alpha:V\times G\to\mathscr{M}_{l\times l}$ (the symbol $\mathscr{M}_{l\times l}$ denoting the set of real matrices) is symmetric. The system (II.2) is *symmetric-hyperbolic* iff for an arbitrary $U^\alpha\in G$ there exists a

covector ξ_α such that $A^\alpha \xi_\alpha$ is positive definite. The covector ξ_α is spacelike with respect to the equation. Here ξ_α is chosen to be t_α and therefore A^0 has to be positive definite. Local existence on the strip $M\times[0,T]$ can be shown if A^α and B fulfill the conditions A^0, $A^k \in C^\infty(V \times G; \mathscr{M}_{l\times l})$, $B\in C^\infty(V\times G;\mathbb{R}^l)$, and especially

$$C\delta_{\alpha\beta}U^\alpha U^\beta \leqslant A^0_{\alpha\beta}U^\alpha U^\beta \leqslant C^{-1}\delta_{\alpha\beta}U^\alpha U^\beta, \quad C\in\mathbb{R}^+. \tag{II.3}$$

For details, see, for example, Ref. 5. From now on condition (II.3) will be called the ''A^0 *condition*.''

The Euler equations as a symmetric-hyperbolic system and their singular behavior at $\varrho=0$: To discuss this problem it is sufficient to use the Euler equations (with $\phi=0$) alone; the presence of gravitation does not influence the problem. The difficulty can be seen if system (I.1a) and (I.1b) is written as a symmetric–hyperbolic system in the ''*obvious way*,'' namely by multiplying (I.1a) and (I.1b) by suitable factors of $\varrho^{-n}(\partial p/\partial\varrho)^m$, for example, (I.1a) with $\varrho^{-2}\partial p/\partial\varrho$. However, this procedure leads to $A^0_{\alpha\beta}$, $A^k_{\alpha\beta}$, which contain terms of the form ϱ^{-2}.

$$\begin{pmatrix} \frac{1}{\varrho^2}p' & 0 \\ 0 & \delta_{ab} \end{pmatrix}\partial_l\begin{pmatrix}\varrho\\ v^b\end{pmatrix} + \begin{pmatrix} \frac{1}{\varrho^2}p'v^c & \frac{1}{\varrho}p'\delta^c_b \\ \frac{1}{\varrho}p'\delta^c_a & \delta_{ab}v^c \end{pmatrix}\partial_c\begin{pmatrix}\varrho\\ v^b\end{pmatrix}=0. \tag{II.4}$$

Therefore for $\varrho=0$ the ''A^0 *condition*'' is not fulfilled, the equations are singular at $\varrho=0$, and a local existence theorem cannot be proven on the strip $M\times[0,T]$. There seems to be no possibility to write the Euler system for the variables $(\varrho,\mathbf{v})$ in such a way that they are regular at $\varrho=0$ and the ''A^0 *condition*'' is satisfied, an exemption being that $\lim_{\varrho\to 0} p'/\varrho^2$ exists and is positive, for example, $p=K\varrho^3$. Another possibility is to introduce a new scalar matter variable $w=M(\varrho)$, as will be explained shortly.

III. TIME EVOLUTION OF A COMPACT BODY

In the following section a self-gravitating, compact, isolated body will be described and therefore the gravitational potential has to satisfy the following boundary condition:

$$\lim_{|x|\to\infty}\phi(x,t)=0. \tag{III.1}$$

The boundary conditions for a fluid ball are a special case of the Rankine–Huginot conditions in shock wave theory. However, there is a certain subtle worth discussing further. Let us start with the boundary conditions for the fluid body to be specializing the Rankine–Huginot in order to obtain

$$(\varrho)_+ N_t + (\varrho v^a)_+ N_a = 0, \tag{III.2}$$

$$\{(\varrho)_+ N_t + (\varrho v^a)_+ N_a\} v^b_+ = -p_+ N^b. \tag{III.3}$$

A couple of conclusions can be drawn from these equations:

(1) The first equation implies

$$p_+ = 0, \tag{III.4}$$

which is the usual boundary condition of a compact fluid ball.

(2) Now, two cases have be distinguished depending on the behavior of the density at the boundary.

(2a) The first possibility is that $\varrho_+ \neq 0$ (hard boundary). Then it follows from Eq. (III.2) that

$$N_t + v_+^a N_a = 0 \tag{III.5}$$

holds. This equation states that the normal component of the velocity U^α coincides with the velocity of the boundary or, in other words, the flow lines of the fluid generate the boundary of the body.

(2b) The second possibility is that the density at the boundary vanishes $\varrho_+ = 0$ (soft boundary), but then there are no conditions on the normal component of U^α. In other words, using the conservation laws it is not possible to conclude that the boundary is generated by the flow lines of the fluid supposing $\varrho_+ = 0$. This fact never seems to be stated in the literature.

As will be shown in the next section, the Makino solution has vanishing boundary density, but nevertheless it is possible to show that the boundary is generated by the flow lines of the fluid by means of other tools.

A. Introduction of the Makino variable

I will deal in the following with the situation of a body with vanishing boundary density and solve the problem mentioned above by introducing a new scalar matter variable w, which is related to the density ϱ via the equation

$$w = M(\varrho') = \int_0^{\varrho'} \frac{\sigma}{\varrho}\, d\varrho = \int_0^{\varrho'} \frac{1}{\varrho} \left(\frac{\partial p}{\partial \varrho}\right)^{1/2} d\varrho. \tag{III.6}$$

For the barotropic equation of state w is a kind of ''*weighted sound velocity*.'' With this variable our system takes the form

$$\begin{pmatrix} 1 & 0 \\ 0 & \delta_{ab} \end{pmatrix} \partial_t \begin{pmatrix} w \\ v^b \end{pmatrix} + \begin{pmatrix} v^c & \sigma \delta_b^c \\ \sigma \delta_a^c & \delta_{ab} v^c \end{pmatrix} \partial_c \begin{pmatrix} w \\ v^b \end{pmatrix} = \begin{pmatrix} -\partial_a \phi \\ 0 \end{pmatrix}, \tag{III.7a}$$

$$\Delta \phi = \varrho. \tag{III.7b}$$

Now the ''*regularized*'' evolution equations for $\mathbf{v}$ and the ''*unphysical*'' quantity w satisfy the ''A^0 *condition*'' even for $\varrho = 0$.

This new variable demands a couple of restrictions on the equation of state which are listed below. First these conditions will be stated in general, i.e., without specifying a concrete equation of state, and then applied to the barotropic equation of state.

(1) The first condition is related to the existence of the Makino variable

$$\int_0^{\varrho'} \frac{1}{\varrho} \left(\frac{\partial p}{\partial \varrho}\right)^{1/2} d\varrho < \infty. \tag{III.8}$$

For the barotropic equation of state $p = K\varrho^\gamma$ with K, $\gamma \in \mathbb{R}^+$, $p' = K\gamma\varrho^{\gamma-1}$, and $\sqrt{p'} = \sqrt{\gamma K}\varrho(\gamma-1)/2$, which implies $1 < \gamma$.

(2) The second condition deals with the differentiability conditions of σ and ϱ as functions of w, i.e., $\sigma = S(w)$ and $\varrho = M^{-1}(w)$. Two subproblems have to be considered.

(2a) One restriction on the equation of state is that $\sigma \in C^\infty(\mathbb{R})$ for $\varrho = 0$ which is needed to satisfy the regularity conditions for the local existence Theorem 1. For the barotropic equation of state $\sigma = [(\gamma-1)/2]w$ holds, which satisfies the needed requirements.

(2b) It is necessary for the proof of the existence theorem as well as for the proof of the continuation criterion to estimate ϱ by w even at $\varrho=0$ since the resulting system consists of the variables (w,v^i) for the evolution equations and ϱ for the Poisson equation. Therefore the general requirement for the equation of state is that, for $\varrho=0$,

$$\text{if } w(x,t)\in H^k \quad \text{it should follow that } \varrho(x,t)\in H^k. \tag{III.9}$$

Consider $p=K\varrho^\gamma$. Then the above restriction that $\varrho\in H^3$ even for $\varrho=0$ leads to a restriction of γ, namely, $1<\gamma\leqslant\frac{5}{3}$.

Taking all that into account one can prove the following local in time existence theorem for the Euler–Poisson system with the Makino variable (for details see Ref. 4).

Theorem 1 (Local existence of Makino solutions): *Let the equation of state be such that*

(1) *the Makino variable* $w=M(\rho)$ *exists*;
(2) *for* w *as a function of* (x,t), $w(x,0)\in H^s(\mathbb{R}^3)$ *with* $s\geqslant 3$ *holds*;
(3) *the sound velocity* σ *as a function of the Makino variable is* C^∞, *i.e.*, $\sigma=S(w)\rangle C^\infty(\mathbb{R})$ *holds*;
(4) $\varrho(0)$ *has compact support; and*
(5) $v_a(0,x)\rangle H_s(\mathbb{R}^3)$ *with* $s\geqslant 3$.

Then there exists a time $T>0$ *which depends on the* H^s *-norm of the initial data and there exists a unique solution* $U^\alpha=(\varrho,v^a)^t$ *of system (III.7a), and (III.7b) with*

$$U\in C^{0,s}_{T,\mathbb{R}^3}\cap C^{1,s-1}_{T,\mathbb{R}^3}. \tag{III.10}$$

The density ϱ *has compact support.*

Remarks: Here, contrary to Makino, the equation of state has not been specified. If one wants to do so, the restriction mentioned above has to be taken into account. Although the introduction of w allows us to prove a local (in time) existence theorem, this approach has some particularities which are listed below.

(1) Makino solutions have additional regularity conditions as one would expect to hold for usual regular (ϱ,v) solutions. This additional properties originated from the requirement that $w=\varrho^{(\gamma-1)/2}\rangle H^3$ even at $\varrho=0$ (which implies $w\in C^1$). These conditions are not obvious at all for the γ values considered (recall that $0<(\gamma-1)/2<\frac{5}{3}$). To emphasize these properties Makino denoted his solutions ''*sweet*,'' ''*tame*,'' or ''*gentle*'' solutions. Here these solutions will be denoted as *Makino* solutions. The central point is that one cannot draw, in general, conclusions from the behavior of the Makino solutions about the behavior of the regular (ϱ,v) ones. Insofar as the occurrence of singularities is concerned, the fact that $\|\nabla w\|_{L^\infty}$ blows up does not necessarily imply that $\|\nabla\varrho\|_{L^\infty}$ blows up.
(2) It has been shown by Makino that his solutions do not include the class of regular spherically symmetric static solutions of the Euler–Poisson system which are described for the equation of state $p=K\varrho^\gamma$ by

$$\frac{d^2u}{dz^2}+\frac{2}{z}\frac{du}{dz}+u^{1/(\gamma-1)}=0, \tag{III.11}$$

where $z=Ar$, $A=[(\gamma-1)/\gamma K]\varrho_c^{(2-\gamma)/\gamma}$, and $u=(\varrho/\varrho C)^{\gamma-1}$, ϱ_c being the central density; for details see Ref. 6 Chap. IV, p. 87 ff.
(3) Theorem 1 does not contain any statement about unique determination of a solution by the (physically meaningful) initial data. Of course, uniqueness does hold for the basic symmetric-hyperbolic system used to provide the solution, but the data for that include initial data for v^k outside of the compact support of ϱ. In other words $\varrho=0$ does not imply $v^k=0$. This property requires some further discussion. According to the local existence Theorem 1, w, ϱ, and v are C^1, ϱ has compact support and, according to Proposition 1, v is nonzero at the boundary.

According to its regularity properties v is nonzero also outside the compact support of the body. This situation of ''*velocity without matter*'' is a phenomenon which reminds one of the grin without a cat of the Cheshire Cat of *Alice in Wonderland*. Nevertheless, uniqueness holds for the physical relevant quantities. Using the fact that at the boundary $\sigma=0$ $\varrho=0$ holds, it will be shown below that the space–time region covered by the Makino solution has ''*a lens shaped form*'' which allows the use of energy estimates in order to show the desired uniqueness.

(4) In addition the Makino solutions do not only belong to the class of spherically symmetric static solutions, but they also have the property that their boundary is freely falling as stated in the following proposition:

Proposition 1 (free fall of the boundary): The Makino solutions with compact support describe a compact body with freely falling boundary and the following holds:

$$\left.\frac{\partial^a p}{\varrho}\right|_{\mathscr{R}}=\frac{p'}{\varrho}\,\partial^a\varrho|_{\mathscr{R}}=0. \tag{III.12}$$

Proof of Proposition 1: First consider the flow lines $x^k(x(t),t)$ of the vector field $v^k(x(t),t)$ with $dx^k/dt=v^k$ and

$$\frac{d^2x^k}{dt^2}=\partial_t v^k+v^i\partial_i v^k. \tag{III.13}$$

The Euler equation with the Makino variable has the following form:

$$\frac{d^2x^k}{dt^2}=\partial_t v^k+v^i\partial_i v^k=-Cw\partial^k w-\partial^k\phi. \tag{III.14}$$

Now $\lim_{\varrho\to 0} w\partial^k w=0$ holds, because $\lim_{\varrho\to 0} w=0$ and $|\partial^k w|<C$ is valid. The last inequality follows from the local existence Theorem 1. Hence Eq. (III.14) takes the form $d_t^2x^k=-\partial^k\phi$, which describes the free fall of the boundary.

Remark: In principle the class of solutions with freely falling boundary could be much larger than the class of Makino solutions.

B. Uniqueness for the Makino solutions

Now I want to prove, in spite of the remark (3) of the last section, uniqueness for the Makino system, i.e., that the solution is determined by the initial data on the support of ϱ alone. For this purpose, use will be made of the following properties of the Makino solution:

(1) As long as the solution exists, the flow lines are regular; that means they do not cross. Because the boundary is freely falling and consists of the flow lines, the boundary is regular.
(2) At the boundary, at $p=0$, $\sigma=0$ holds. Therefore the sound cone degenerates to a line there.

From (1) and (2) follows that the boundary is an outer characteristic hypersurface. This means the following. First of all, the boundary is a characteristic hypersurface because the covectors ξ_a belonging to the boundary which vanish on any vector of the boundary v^a lay in the conormal cone. Furthermore, these covectors are outer characteristic covectors in the sense that the expression $A^\alpha\xi_\alpha$ is positive semi-definite. The reason is that the covectors of the boundary are the limit of spacelike covectors, simply because the limit of positive matrices is positive semi-definite. Therefore the space–time region, called L from now on, covered by the collapsing body has a lenslike shape which will play a role in the energy estimates. The intersection between a spacelike

hypersurface Σ_t and L is denoted by $L_t=\Sigma_t\cap L$. The boundary ∂L is given by $\partial L=\partial L_{t_0}+\partial L_{t_1}+\partial L_{C/R}$, $\partial L_{C/R}$ consisting either of outer characteristics or spacelike hypersurfaces.

Proposition 2 (uniqueness of the Makino solutions): Under the conditions of Theorem 1 there exists a unique solution $U\in C^1([0,T];H^{s-1}(\mathbb{R}^3))\cap C^0([0,T];H^s(\mathbb{R}^3))$ *of system (III.7a) and (III.7b). Given two Makino solutions* f_1 *and* f_2 *with* $f_1(0)=f_2(0)$ *on the compact support of the initially density* L_0*, then the following holds*:

(1) *As long as the solution* f_1 *exists, there exists also* f_2*, and the compact support of* ρ *corresponding to* f_1L_1 *is equal to* L_2*, i.e., and* $L_{1t}=L_{2t}$ *holds.*
(2) *Furthermore,* $f_1(t)=f_2(t)$ *and* $\phi_1(t)=\phi_2(t)$ *hold on* L_t.

Remark: The functions ϕ_1 and ϕ_2 are identical not only on the support of the matter but also on the whole $\mathbb{R}^3$. The reason is that if the matter quantities are identical on the support, then, with the help of Eq. (III.23), it follows that the gradient of ϕ is identical for both solutions on the support. That is why ϕ_1 and ϕ_2 differ at most by a constant. Now because ϕ_1 and ϕ_2 solve the Poisson equation with the boundary condition (III.1) both functions vanish at infinity and hence the constant, in fact, is zero.

Proof of Proposition 2: Now shortly the method will be presented with which uniqueness will be proven. Let us recall the procedure for a linear symmetric–hyperbolic equation of the form (for reasons of convince the indices have been omitted)

$$u_t+A^k(x,t)\partial_k u+B(x,t)u=0, \tag{III.15}$$

where A^k and B have continuous derivatives. One gets uniqueness with the help of energy estimates for Eq. (III.15) by integration on a lens shape space–time region L (for details, see Ref. 7, p. 441 ff). One gets an estimate of the form

$$\|u\|_{D^2(L_{t_1})}\leqslant C\|u\|_{L^2(L_{t_0})}. \tag{III.16}$$

This inequality is already sufficient to prove uniqueness of Eq. (III.15) just by taking the difference $z={}^1u-;{}^2u$. In the case of the quasilinear symmetric–hyperbolic Euler equation (for the moment without gravitation) one has, instead of (III.15),

$$u_t+A^k(u)\partial_k u+B(u)=0. \tag{III.17}$$

In order to prove uniqueness one has, similar to the linear case, to consider ${}^1u$ and ${}^2u$ two solutions with the same initial data. Let their difference be called $z={}^1u-{}^2u$, insert it into (III.17), and form the difference of the two corresponding equations, which leads to

$$\partial_t z+A^k({}^2u)\partial_k z+[A^k({}^1u)-A^k({}^2u)]\partial_k^1 u+B^k({}^1u)-B^k({}^2u)=0. \tag{III.18}$$

Now we can apply the mean value theorem,

$$A^k({}^1u)-A^k({}^2u)=H^k({}^1u,{}^2u)z,\quad B({}^1u)-B({}^2u)=K({}^1u,{}^2u)z, \tag{III.19}$$

because A and B are C^1 functions of their variables. Now ${}^1u$, ${}^2u$, and ∂_k^u are considered as known expressions in x, t and these expressions are substituted in H, K, and $A({}^2u)$; thereby (III.18) becomes a linear differential equation for z of the form

$$z_t+az_x+bz=0 \tag{III.20}$$

and the result for the linear system can be applied. In our case, where (III.17) is replaced by

$$u_t+A(u,x,t)u_x=Q, \tag{III.21}$$

u consists of $(w(\varrho),v)$, and $G=\operatorname{grad}\phi$ is coupled with ϱ by $\Delta\phi=\varrho$, the situation is a little different. Applying the idea of considering the difference of solutions with the same initial data for Eq. (III.21) leads to

$$\partial_t z+A^k({}^2u)\partial_k z+[A^k({}^1u)-A^k({}^2u)]\partial_k^1 u=\delta Q. \tag{III.22}$$

So instead of (III.18) we obtain (III.22) where $\delta Q={}^1Q-{}^2Q$. The aim is now to estimate δQ by z or, to be more precise,

$$\|{}^1Q-{}^2Q\|_{L_2(L_t)}\leqslant C\|{}^1\varrho-{}^2\varrho\|_{L_2(L_t)}. \tag{III.23}$$

If such an estimate holds, the proof would be finished. The reason is that one would get an inequality of a special form for which one can derive via the Gronwall inequality an inequality of the form (III.16).

To do so, mainly two steps have to be done:

(1) estimate δQ by $\delta\varrho$ and then
(2) estimate $\delta\varrho$ by $\delta w(\varrho)$.

First of all weighted Sobolev spaces will be introduced, which are a generalization of the usual Sobolev spaces as introduced in Sec. II. They carry the norm. (In the following the quantity which usually is denoted by δ will be denoted by σ in order to avoid confusion with differences of quantities like δQ.)

$$\|f\|_{H_{s,\sigma}(\mathbb{R}^3)}=\left\{\sum_{|\alpha|\leqslant s}\int_{\mathbb{R}^3}((1+\|x\|^2)^{(\sigma+|\alpha|)/2}|\partial_\alpha f|)^2\,dV\right\}^{1/2}. \tag{III.24}$$

Details concerning the properties of these spaces can be found in Ref. 8. By using these spaces one obtains the following inequality:

$$\|\delta Q\|_{L_2(L_t)}\leqslant C\|\delta Q\|_{L_{2,\sigma}(L_t)}. \tag{III.25}$$

after choosing an appropriate constant C. Furthermore, for the Laplace operator it holds that for $s\geqslant 2$ and $-\frac{3}{2}<\sigma<-\frac{1}{2}$, the map

$$\Delta: H_{s,\sigma}\rightarrow: H_{s-2,\sigma+2} \tag{III.26}$$

is an isomorphism, i.e., from

$$\Delta\phi=\varrho \tag{III.27}$$

it follows

$$\|\phi\|_{H_{s,\sigma}(\mathbb{R}^3)}\leqslant C\|\varrho\|_{H_{s-2,\sigma+2}(\mathbb{R}^3)}, \tag{III.28a}$$

and

$$\|\nabla\phi\|_{H_{s,\sigma}(\mathbb{R}^3)}\leqslant C\|\varrho\|_{H_{s-1,\sigma+1}(\mathbb{R}^3)}. \tag{III.28b}$$

Obviously

$$\|\delta Q\|_{L_{2,\sigma}(L_t)}\leqslant\|\delta Q\|_{L_{2,\sigma}(\mathbb{R}^3)}\leqslant C\|\delta Q\|_{H_{1,\sigma}(\mathbb{R}^3)} \tag{III.29a}$$

holds. With the help of (III.28b) one obtains

$$\|\delta Q\|_{H_{1,\sigma}(\mathbb{R}^3)}=\|\nabla\phi\|_{H_{1,\sigma}(\mathbb{R}^3)}\leqslant\|\varrho\|_{H_{0,\sigma+1}(\mathbb{R}^3)}. \tag{III.29b}$$

Now because ϱ has compact support the estimate

$$\|\varrho\|_{H_{0,\sigma+1}(\mathbb{R}^3)}=\|\varrho\|_{H_{0,\sigma+1}(L_t)}\leqslant C\|\varrho\|_{H_0(L_t)} \tag{III.29c}$$

holds by choosing a suitable constant. Furthermore, on L the estimate

$$\|\delta Q\|_{L_2(L_t)}\leqslant C\|\delta Q\|_{L_{2,\sigma}(L_t)} \tag{III.29d}$$

is valid. It remains to prove the inequality

$$\|\delta\varrho\|_{L_2(L_t)}\leqslant C\|\delta w(\varrho)\|_{L_2(L_t)}. \tag{III.29e}$$

This follows from the remarks that were made shortly after the introduction of the Makino variable. Hence the mean value theorem can be applied to obtain

$$\|\delta\varrho\|_{L_2(L_t)}\leqslant\|f'\|_{L_\infty}\|\delta w(\varrho)\|_{L_2(L_t)}. \tag{III.29f}$$

Herewith Lemma 2 is proven. ■

IV. THE COSMOLOGICAL CASE

In the following, the cosmological case will be treated, but in a far less detailed manner than the Makino case. The conceptual problems, the method of describing finite deviations of a given Friedman solution, and some results concerning local existence and stability can be found in Ref. 3 so that here only the local existence theorem is quoted. The starting point is the Euler–Poisson system written for small but finite deviations from the given Friedmann solution given by

$$\begin{pmatrix} \dfrac{g'}{(\hat\varrho+\varrho)^2} & 0 \\ 0 & \delta_{ab} \end{pmatrix}\partial_t\begin{pmatrix}\varrho\\ v^a\end{pmatrix}+\begin{pmatrix} \dfrac{g'}{(\hat\varrho+\varrho)^2}\,v^k & \dfrac{1}{a}\dfrac{g'}{\hat\varrho+\varrho}\,\delta_a^k \\ \dfrac{1}{a}\dfrac{g'}{\hat\varrho+\varrho}\,\delta_b^k & \dfrac{1}{a}\,v^k\delta_{ab} \end{pmatrix}\partial_k\begin{pmatrix}\varrho\\ v^a\end{pmatrix}$$
$$+\begin{pmatrix} \dfrac{3Hg'}{(\hat\varrho+\varrho)^2} & 0 \\ 0 & H\delta_{ab} \end{pmatrix}\begin{pmatrix}\varrho\\ v^a\end{pmatrix}=\begin{pmatrix}0\\ -\partial_a\phi\end{pmatrix}, \tag{IV.1a}$$

$$\frac{1}{a^2}\,\Delta\phi=\varrho, \tag{IV.1b}$$

where $\hat\varrho$ denotes the density and $H(t)=\dot a/a$ is the Hubble constant of the background Friedman solution which satisfies the relations

$$(\varrho a^3)=\text{const},\quad \left(\frac{\dot a}{a}\right)^2=\frac{2}{3}\,\varrho-\frac{k}{a^2}. \tag{IV.2}$$

The difference for the pressure of the background and the ''*real*'' density is denoted by $f(\hat\varrho+\varrho)-f(\hat\varrho)=:g(\varrho,t)$ and g' denotes $dg/d\varrho$.

In order to apply the standard local existence theorem of quasilinear symmetric–hyperbolic systems the ''A^0 *condition*'' has to be satisfied. In the cosmological case, however, the background consists of an overall positive density $\hat\varrho$ so that the ''A^0 *condition*'' does not cause a

problem nor does it force the introduction of a Makino variable contrary to the compact body case. The open set G is not the complete target space as it is in the Makino case, but only an open subset, i.e., $G\subset\mathbb{R}^l$. Here G consists of all ϱ for which $\hat{\varrho}+\varrho>0$ holds. Especially for every compact subset $K\subset G$, $\hat{\varrho}+\varrho$ is bounded uniformly from below and above by a positive constant. This fact plays a role later on in the formulation of the continuation criterion. For this system the following local existence theorem can be proven (see Ref. 3).

Theorem 2 (local existence theorem for cosmological solutions): *Let* $\varrho(0)\in H^s(\mathbb{T}^3)$, $v^a(0)\in H^s(\mathbb{T}^3)$, $s\geqslant 3$, *and* $p=g(\varrho,t)$ *be an equation of state with* $g'>0$. *Let* $\varrho(0)$ *have vanishing integral over the torus, i.e.,* $\int_{\mathbb{T}^3}\varrho(0)\,dV=0$, *and let* $\varrho(0)$ *be chosen such that* $\hat{\varrho}(0)+\varrho(0)>0$ *holds. Then there exists a time* $T>0$ *which depends on the* H^s*-norm of the initial data and* $a(t)$, *and there exists for given initial data a unique solution* $U^\alpha=(\varrho,v^a)^t$ *of the system (IV.1a) and (IV.1b) with*

$$U\in C^{0,s}_{T,\mathbb{T}^3}\cap C^{1,s-1}_{T,\mathbb{T}^3}. \tag{IV.3}$$

The density ϱ *has vanishing integral over the torus, i.e.,* $\int_{\mathbb{T}^3}\varrho\,dV=0$.

V. CONTINUATION CRITERIA FOR THE EULER–POISSON SYSTEM

The following theorem is the main result of the present paper.

Theorem 3 (strong continuation criterion for Makino and cosmological solutions): *Let* U^α *be a maximal solution of the Euler–Poisson system (V.1a) and (V.1b) with the property* $U\in C^1([0,T^*]);H^{s-1}(M))\cap C^0([0,T^*]);H^s(M))$ *of*

$$A^0_{\alpha\beta}(U)\partial_t U^\beta+\sum_{k=1}^{3}A^k_{\alpha\beta}(U)\partial_k U^\beta+B_{\alpha\beta}U^\beta=G_\alpha, \tag{V.1a}$$

$$\Delta\phi=\varrho, \tag{V.1b}$$

where the quantities have the following form:

$$\textit{in case I}\quad U^\alpha=(w(\varrho),v^a)^T,\quad A^0=\delta_{\alpha\beta},\quad B_{\alpha\beta}=0,\quad G_\alpha=(0,\partial_a\phi)^T;$$

$$\textit{in case II}\quad U^\alpha=(\varrho,v^a)^T,\quad A^0\neq\delta_{\alpha\beta},\quad B_{\alpha\beta}\neq 0,\quad G_\alpha=(0,\partial_a\phi)^T,$$

and $A^0_{\alpha\beta}$ *is given in case II by (IV.1a). Then either*

$$(i)\quad T^*=\infty,$$

$$(ii)\ \textit{or case I}\quad T^*<\infty\ \textit{and}\ \int_0^{T^*}(\|\theta\|_{L^\infty}+\|\Omega_{ab}\|_{L^\infty}+\|\nabla w\|_{L^\infty})dt=\infty,$$

$$\textit{or case II}\quad T^*<\infty\ \textit{and}\ \int_0^{T^*}(\|\theta\|_{L^\infty}+\|\Omega_{ab}\|_{L^\infty}+\|\nabla\varrho\|_{L^\infty})dt=\infty.$$

Remarks: Theorem 3 states the not all components of $\varrho_a v_b$ are needed to continue the solution.

This theorem has the following two corollaries:

Corollary 1: Under the assumptions of Theorem 3 and the assumption that the fluid is pressure free and curl free, there are the following possibilities:

(*i*) *either* $T^*=\infty$,

(*ii*) *or, in case II,* $T^*<\infty$ *and* $\int_0^{T^*}(\|\theta\|_{L^\infty})dt=\infty$.

Proof of Corollary 1: If one considers the system (I.1a)–(I.1c), one sees that the equations decouple for $p=0$ *partly because the density does not appear in the Euler equation (I.1b) but* div v *does appear in the continuity equation (I.1a). If* $\int_0^T\|\theta\|_{L^\infty}$ *is bounded on the maximal interval of existence, then, by Lemma 2,* ϱ *is bounded from above and below. To show that* v *is bounded as well, one considers the Euler equation (I.1b) as an independent quasilinear symmetric–hyperbolic equation for* v. *One repeats the steps used for the proof of Theorem 3 and obtains Corollary 1 because* rot $v=0$. ■

Another corollary is the following:

Corollary 2: Under the assumptions of Theorem 3 there are the following possibilities:

(*i*) *either* $T^*=\infty$,

(*ii*) *or case I,* $T^*<\infty$ *and* $\int_0^{T^*}(\|\theta_{ab}\|_{L^\infty(\mathbb{R}^3)}+\|\nabla w(\varrho)\|_{L^\infty(\mathbb{R}^3)})\,dt=\infty$,

(*iii*) *or case II,* $T^*<\infty$ *and* $\int_0^{T^*}(\|\theta_{ab}\|_{L^\infty(\mathbb{T}^3)}+\|\nabla\varrho\|_{L^\infty(\mathbb{T}^{-3})})\,dt=\infty$

Proof of Corollary 2: In order to show the propagation equation for Ω_{ab},

$$\partial_t\Omega_{ab}+v^c\partial_c\Omega_{ab}+\theta_a{}^d\Omega_{db}+\Omega_a{}^d\theta_{db}=0, \tag{V.2}$$

is used. One integrates along the stream lines of $\mathbf{v}$ *and takes the* L^∞*-norm in order to obtain*

$$\|\Omega_{ab}(t)\|_{L^\infty}\leqslant\|\Omega_{ab}(0)\|_{L^\infty}+C\int_0^t\|\delta^{di}\Omega_{ai}\theta_b^i\|_{L^\infty}\,dt. \tag{V.3}$$

By using the Gronwall inequality one obtains

$$\|\Omega_{ab}(t)\|_{L^\infty}\leqslant\|\Omega_{ab}(0)\|_{L^\infty}e^{C\int_0^t\|\theta_{ab}\|_{L^\infty}\,dt}. \tag{V.4}$$

Suppose $\int_0^{T^*}\|\theta_{ab}\|_{L^\infty}\,dt$ *is bounded on the maximal interval of existence. Then* $\int_0^{T^*}\|\theta\|_{L^\infty}\,dt$ *is bounded as well, because* θ *is the trace of* θ_{ab}. *With the help of Eq. (V.4)* Ω_{ab} *is bounded and Theorem 3 can be applied and therefore Corollary 1 is proven.* ■

VI. PROOF OF THE MAIN THEOREM

The proof of Theorem 3 is very much in the line of Kato[2] and Chemin.[1] However, due to the more complicated character of the system, some modifications are necessary; first, the matrix $A^0\neq 0$, so time derivatives of the form $\|\partial_t U\|_{L^\infty}$ have to be controlled. Second, because the Poisson equation is coupled to the fluid equations system, additionally the term $\|U\|_{L^\infty}$ has to be controlled. Finally, one of the key elements of the proof of Kato[2] and Chemin[1] has been a nonlocal elliptic estimate of the gradient of the velocity in terms of its divergence and rotation. It turns out that the part for the $\mathbb{R}^3$ elaborated by Chemin can be completely adopted, while in the spatially periodic case, also sketched by Kato *et al.*, it had to be completely rewritten. This estimate is demonstrated in the Appendix. To sum up the demonstration, the proof consists in the following steps:

Step 1: A general *weak continuation criterion* (3) for the Euler–Poisson is derived. Such a criterion consists of the following two main possibilities.

Step 1.1: Nondivergence singularities: Either the the solutions ''leave their domain of definition'' (for the Euler equations that means that the density turns to zero) or the density/velocity itself diverges.

Step 1.2: Divergence singularities: Derivatives of the solution itself blow up.

Step 2: In order to prove Theorem 3, starting with Theorem 3 the following steps are done:

Step 2.1: Elimination of the possibility of a *non-divergence singularity*.

Step 2.2: The variety of *divergence singularities* is reduced by

Step 2.2.a: The time derivative $\|\partial_t U\|_{L^\infty}$ is eliminated.

Step 2.2.b: Finally some of the spatial derivatives of the velocity are eliminated by a nonlocal elliptical estimate.

Step 1: Weak continuation criterion for Makino and cosmological solutions: General continuation criterion for the compressible Euler equations has been first, formulated by Majda.[5] The following theorem is direct generalization of his result. The content, however, is a little different due to the fact that $A^0 \neq 0$ and due to the presence of the Poisson equation.

Theorem 4 (weak continuation criterion for Makino and cosmological solutions): *Under the conditions of Theorem 3, then either*

(i) $T^* = \infty$,

(ii) *or, in case I,* $T^* < \infty$ *and* $\int_0^{T^*} \|\nabla U^\alpha\|_{L^\infty}\, dt = \infty$,

(iii) *or, in case II,* $T^* < \infty$ *and* $\int_0^{T^*} (\|\partial_t U^\alpha\|_{L^\infty(M)} + \|\nabla U^\alpha\|_{L^\infty(M)})\, dt = \infty$,

(iv) *or* $T^* < \infty$ *and, for* $t \to T^*$,

U *leaves* K *for every compact subset* $K \subset G$.

Remarks: For case I $G = \mathbb{R}^l$, while for case II G consists of all ϱ for which $\hat{\varrho} + \varrho > 0$ holds. One example for possibility (iii) in Theorem 3 is that

(1) for cases I and II $\|U\|_{L^\infty}$ tends to infinity, and
(2) for case II the ''A^0 *condition*'' is violated, for example if ϱ tends to zero.

The proof of this theorem is based on one hand, on the local existence theorem in the cases which are considered here—these are 1 and 2—and, on the other hand, on, an *a priori* estimate on the interval $[0, T)$:

$$\text{case I:} \quad \|U\|_{H^s}^2 \leqslant \|U(0)\|_{H^s}^2 e^{C(\|U\|_{L^\infty}) \int_0^t \|\partial_t U\|_{L^\infty} + \|\nabla U\|_{L^\infty}\, dt}, \quad t \in [0,T), \tag{VI.1a}$$

$$\text{case II:} \quad \|U\|_{H^s}^2 \leqslant \|U(0)\|_{H^s}^2 e^{C(\|U\|_{L^\infty}) \int_0^t \|\nabla U\|_{L^\infty} dt}. \tag{VI.1b}$$

The derivation of these estimates will be outlined in the Appendix.

First a lemma useful for further considerations is presented.

Lemma 1 (L^∞ *estimate for the Poisson equation): Let*

$$\Delta\phi=\varrho \tag{VI.2}$$

and let

(1) case I: ϱ *have compact support,* $\lim_{|x|\to\infty}\phi=0$ *hold and*

(2) case II: ϱ *have vanishing integral over the torus, i.e.,* $\int_{\mathbb{T}^3}\varrho\ dV=0$.

Then the following inequality,

$$\|\text{grad }\phi\|_{L^\infty(M)}\leqslant C\|\varrho\|_{L^\infty(M)}, \tag{VI.3}$$

holds where for case I the constant C depends on the support of the function ρ.

The proof of this lemma will be outlined in the Appendix.

Step 2.1: Eliminating the nondivergence singularities: In the following $\|\varrho\|_{L^\infty(M)}$ and $\|v^a\|_{L^\infty(M)}$ will be estimated by $\int_0^{T^*}\|\theta\|_{L^\infty(M)}\ dt$, and by $\int_0^{T^*}\|\nabla\varrho\|_{L^\infty(M)}\ dt$, or $\int_0^{T^*}\|\nabla w\|_{L^\infty(M)}\ dt$, respectively, and the following lemma will be proven.

Lemma 2 (bounds for ϱ *and* v^a *): Let*

$$\textit{(1)}\quad \int_0^{T^*}\|\theta\|_{L^\infty(M)}\ dt<\infty. \tag{VI.4}$$

$$\textit{(2) In case I,}\quad \int_0^{T^*}\|\nabla w\|_{L^\infty(M)}\ dt<\infty\quad \textit{and, in case II,}\quad \int_0^{T^*}\|\nabla\varrho\|_{L^\infty(\mathbb{T}^3)}dt<\infty. \tag{VI.5}$$

Then the following holds:

$$\textit{(1a) for case I}\quad w<C; \tag{VI.6}$$

$$\textit{(1b) for case II}\quad C<\varrho<C^{-1}\ \textit{on}\ \mathbb{T}^3;\ \textit{and} \tag{VI.7}$$

$$\textit{(2) for both cases}\quad \int_0^{T^*}\|v\|_{L^\infty(M)}\ dt<\infty. \tag{VI.8}$$

Proof of Lemma 2: We first start with case II. To prove statement (1) one first makes use of the continuity equation (using the notation ϱ instead of $\hat{\varrho}+{}^p\varrho$)

$$\partial_t\varrho+v^a\partial_a\varrho+\varrho\,\theta=0, \tag{VI.9}$$

then integrates along the streamlines v^a *and divides by* ϱ *and one obtains*

$$D_t(\ln\varrho)=-\theta. \tag{VI.10}$$

Integrating with respect to time on the interval $[0,T^*)$ *and taking the* L^∞*-norm over* $\mathbb{T}^3$ *one obtains the inequality*

$$\|\ln\varrho\|_{L^\infty(\mathbb{T}^3)}\leqslant\|\ln\varrho(0)\|_{L^\infty(\mathbb{T}^3)}+C\int_0^{T^*}\|\theta\|_{L^\infty}\ dt<\infty. \tag{VI.11}$$

According to assumption (1) $\|\theta\|_{L^\infty}\ dt<\infty$ *holds. It then follows from Eq. (VI.11) that, supposing* $\|\ln\varrho(0)\|_{L^\infty(\mathbb{T}^3)}$ is bounded, *then* $\|\ln\varrho(0)\|_{L^\infty(\mathbb{T}^3)}$ *is bounded on the maximal interval of existence and therefore* ϱ *is bounded above and below by a positive constant. For case I one just uses the fact that it is a monotone function of* ϱ. *Then it follows that if* ϱ *is bounded, then* w *is bounded.*

In order to prove statement (2), one proceeds in a similar way, but uses the Euler equation which has, in case II, the form

$$\partial_t v^a + v^b \partial_b v^a + \frac{f'}{\varrho}\,\partial^a \varrho = -\partial^a \phi, \tag{VI.12}$$

and again one integrates along the streamlines v^a *where one obtains*

$$D_t v^a + \frac{f'}{\varrho}\,\partial^a \varrho = -\partial^a \phi. \tag{VI.13}$$

By integrating with respect to t *and taking the* L^∞*-norm using Lemma 1 one obtains*

$$\|v^a\|_{L^\infty} \leqslant \int_0^{T^*} \left\| \frac{1}{\varrho} \right\|_{L^\infty} \|f'\|_{L^\infty} \|\nabla \varrho\|_{L^\infty} + \|\varrho\|_{L^\infty}\, dt. \tag{VI.14}$$

According to (i), ϱ *is bounded above and below by a positive constant on the maximal interval of existence. Because, as stated in the Introduction, the equation of state* $p(\varrho)$ *will be* C^∞ *for positive* ϱ*,* f' *is bounded for bounded values of* ϱ*. According to the underlying assumptions, furthermore,* $\int_0^{T^*} \|\nabla \varrho\|_{L^\infty}\, dt$ *is bounded and therefore Lemma 2 is proven. For case I again one just uses the fact that* $w = M(\varrho)$ *is a monotone function of* ϱ*; it then follows that if* ϱ *is bounded, then* w *is bounded.*

Step 2.2a. Elimination of $\|\partial_t U\|_{L^\infty}$ *in Theorem 3:* The following result will be proven for case II:

Lemma 3 (Estimate by $\|\partial_t U\|_{L^\infty}$ *by* $\|\nabla U\|_{L^\infty}$*): Under the assumptions of Theorem 3 it holds that*

$$\int_0^T \|\partial_t U\|_{L^\infty}\, dt \leqslant C \int_0^T \|\nabla U\|_{L^\infty}\, dt. \tag{VI.15}$$

In other words, suppose $\int_0^T \|\nabla U\|_{L^\infty}\, dt$ *is bounded on the interval* $[0,T)$*. Then* $\int_0^T \|\partial_t U\|_{L^\infty}\, dt$ *is bounded.*

The key ingredient for the proof of the above lemma is the Lipschitz property of the matrices $\widetilde{A}^k_{\alpha\beta} = (A^0_{\alpha\nu})^{-1} A^k_{\nu\beta}$ of system (IV.1a), i.e., $|\widetilde{A}^k({}^1U) - \widetilde{A}^k({}^2U)| \leqslant C|{}^1U - {}^2U|$. This property can be checked easily for both cases. It follows from the Lipschitz property via the triangle inequality

$$|\widetilde{A}^k(U)| \leqslant C_1|U| + C_2. \tag{VI.16}$$

Proof of Lemma 3: First of all the evolution equation (IV.1a) will be multiplied by $(A^0)^{-1}$. Taking the L^∞-norm one obtains

$$\|\partial_t U\|_{L^\infty} = \|\widetilde{A}^k(U)\partial_k U + \widetilde{B}U + \widetilde{Q}\|_{L^\infty}. \tag{VI.17}$$

In order to estimate the single terms one uses the Lipschitz property of the matrix $\widetilde{A}^k(U)$ on each compact subset $K \subset G$. Furthermore, it will be used that the term $\widetilde{B}$ (which is zero in case II) only depends on t, as one can see easily in Eq. (IV.1b). Therefore one obtains an inequality of the form

$$\|\widetilde{B}U\|_{L^\infty} \leqslant C\|U\|_{L^\infty}. \tag{VI.18}$$

Furthermore, an estimate of the form

$$\|\widetilde{Q}\|_{L^\infty} \leqslant C\|U\|_{L^\infty} \tag{VI.19}$$

will be used which follows from Eq. (VI.3) in Lemma (1):

$$\|\partial_t U\|_{L^\infty} \leqslant \|\widetilde{A}^k(U)\partial_k U\|_{L^\infty} + \|\widetilde{B}U\|_{L^\infty} + \|\widetilde{Q}\|_{L^\infty} \tag{VI.20a}$$

$$\leqslant (C_1\|U\|_{L^\infty} + C_2)\|\nabla U\|_{L^\infty} + C\|U\|_{L^\infty} \tag{VI.20b}$$

$$= C_2\|\nabla U\|_{L^\infty} + C\|U\|_{L^\infty}(C_3\|\nabla U\|_{L^\infty} + 1) \tag{VI.20c}$$

or

$$\int_0^T \|\partial_t U\|_{L^\infty}\, dt \leqslant \int_0^T C_2\|\nabla U\|_{L^\infty} + C\|U\|_{L^\infty}(C_3\|\nabla U\|_{L^\infty} + 1)dt. \tag{VI.21}$$

According to Lemma 2, $\|U\|_{L^\infty}$ is bounded on the interval $[0,T)$ if $\int_0^T \|\theta\|_{L^\infty}\, dt$ and $\int_0^T \|\nabla \varrho\|_{L^\infty}\, dt$ are bounded. Hence, Lemma 3 is proved.

The *a priori* estimate now has the following form:

$$\|U\|_{H^s}^2 \leqslant C\|U(0)\|_{H^s}^2 e^{C\int_0^t \|\nabla U\|_{L^\infty}\, dt}, \quad t \in [0,T), \tag{VI.22}$$

where the constant C does not depend on $\|U\|_{L^\infty}$ any longer.

Step 2.2.b. Elimination of some spatial derivative of the velocity: The final step can be summarized as follows.

Lemma 4: Under the assumptions of Theorem 3 the following holds:

$$\|U\|_{H^s}^2 \leqslant \|U(0)\|_{H^s}^2 e^{C\int_0^t \|\nabla \varrho\|_{L^\infty} + \|A\|_{L^\infty}\, dt}, \quad t \in [0,T), \tag{VI.23}$$

where $\|A\|_{L^\infty} = \|\theta\|_{L^\infty} + \|\Omega_{ab}\|_{L^\infty}$.

Proof of Lemma 4: The central tool of the proof is the following nonlocal decomposition of the gradient of the velocity.

Lemma 5 (nonlocal decomposition of the gradient of) $\nabla \otimes \mathbf{v}$*: Let* $\mathbf{v} \in H^3(M)$*, where* $s \geqslant 3$*. Let* $\operatorname{div} \mathbf{v} = \theta$ *and* $\operatorname{rot} \mathbf{v} = \boldsymbol{\Omega}$*. Then the following inequalities hold*:

(1) For $\mathbb{T}^3$,

$$\|\boldsymbol{\nabla} \mathbf{v}\|_{L^\infty(\mathbb{T}^3)} \leqslant C\{1 + (1 + \ln^+ \|\mathbf{v}\|_{H^s(\mathbb{T}^3)})(\|\theta\|_{L^\infty(\mathbb{T}^3)} + \|\boldsymbol{\Omega}\|_{L^\infty(\mathbb{T}^3)})\}. \tag{VI.24}$$

(2) For $\mathbb{R}^3$,

$$\|\boldsymbol{\nabla} \mathbf{v}\|_{L^\infty(\mathbb{R}^3)} \leqslant C\{1 + (1 + \ln^+ \|\mathbf{v}\|_{H^s(\mathbb{R}^3)})(\|\theta\|_{L^\infty(\mathbb{R}^3)} + \|\boldsymbol{\Omega}\|_{L^\infty(\mathbb{R}^3)}) + \|\mathbf{v}\|_{L^\infty(\mathbb{R}^3)}\}, \tag{VI.25}$$

where

$$\ln^+ a = \begin{cases} \ln a, & \text{if } a \geqslant 1, \\ 0, & \textit{otherwise}. \end{cases}$$

Remark: The proof of (2) can be found in Ref. 1; the proof of (1) will be done in the Appendix.

The estimates (VI.24) and (VI.25) differ about the term $\|v\|_{L^\infty}$. As it has been shown in Lemma 2, $\|v\|_{L^\infty}$ is bounded by $\int_0^{T^*} \|\theta\|_{L^\infty}\, dt$ and $\int_0^{T^*} \|\nabla w\|_{L^\infty}\, dt$ in the maximal interval of existence. Therefore the difference in the proof of the main theorem concerning the use of Lemma 4 in both cases is marginal.

Use will be made of the following obvious inequalities,

$$\ln^+ v + 1 = \ln^+ v + \ln e \leqslant C \ln^+(v + e) \tag{VI.26}$$

and

$$0 \leqslant \int_0^t 1+(1+\ln^+ \|v\|_s)\|A\|_{L^\infty}+e \; d\tau, \tag{VI.27}$$

which lead to

$$\|\nabla v\|_{L^\infty} \leqslant C\{1+(1+\ln^+ \|v\|_s)\|A\|_{L^\infty}\} \leqslant C\{1+(\ln^+ \|v\|_s+e)\|A\|_{L^\infty}\}. \tag{VI.28}$$

Now the improved *a priori* estimate (VI.22) and Eq. (VI.28) will be used so that one gets the following estimates:

$$\|v\|_{H^s}^2 \leqslant \|v(0)\|_{H^s}^2 e^{\int_0^t \|\nabla v\|_{L^\infty}+\|\nabla \varrho\|_{L^\infty} d\tau} \leqslant \|v(0)\|_{H^s}^2 \underbrace{e^{\int_0^t \|\nabla \varrho\|_{L^\infty} d\tau}}_{=C} e^{\int_0^t C\{1+\|A\|_{L^\infty}(\ln^+(\|v\|_s+e))\}d\tau}, \tag{VI.29a}$$

$$\|v\|_{H^s}^2+e \leqslant (C\|v(0)\|_{H^s}^2+e) e^{\int_0^t C\{1+\|A\|_{L^\infty}(\ln^+(\|v\|_s+e))\}d\tau}. \tag{VI.29b}$$

In Eq. (VI.29a) the expression $e^{\int_0^t \|\nabla \varrho\|_{L^\infty} d\tau}$ has been replaced by a constant, because this expression appears on the continuation criterion. Defining $y(\tau)=\|v\|_{\mathrm{H^s}}^2+e$, Eq. (VI.29b) becomes

$$y(t) \leqslant y(0) e^{\int_0^t C\{1+\|A\|_{L^\infty}(\ln^+ y(\tau))\}d\tau}. \tag{VI.30a}$$

Let $z(\tau)=\ln y(\tau)$. Then

$$e^{z(t)} \leqslant e^{z(0)} e^{\int_0^t C\{1+\|A\|_{L^\infty} z(\tau)\}d\tau}, \tag{VI.30b}$$

and

$$z(t) \leqslant z(0)+\int_0^t C\{1+\|A\|_{L^\infty} z(\tau)\}d\tau, \tag{VI.30c}$$

hold, respectively. By using Gronwall's inequality on the interval $[0,t)$, one obtains

$$z(t) \leqslant z(0) e^{\int_0^t C\{1+\|A\|_{L^\infty}\}d\tau}. \tag{VI.30d}$$

Therefore $z(t)$ is bounded by a constant which depends on $\|v\|_{\mathrm{H^s}}^2$, t, and $\int_0^t \|\nabla \varrho\|_{L^\infty}+\|\Omega\|_{L^\infty}+\|\theta\|_{L^\infty}$. From the boundness of $\int_0^T \|\nabla \varrho\|_{L^\infty}+\|\Omega\|_{L^\infty}+\|\theta\|_{L^\infty} dt$ follows the boundness of $\int_0^t \|\nabla \varrho\|_{L^\infty}+\|\Omega\|_{L^\infty}+\|\theta\|_{L^\infty} dt$ and Lemma 4 is proven. ■

VII. DISCUSSIONS

To put the results obtained in context, the following remarks should be taken in account:

(1) *What conclusions can be drawn from the divergence of* $\int_0^{T^*} \|\nabla_x w\|_{L^\infty}$*?* First of all $\|\nabla_x w\|_{L^\infty}$ is given by $\|\nabla_x w\|_{L^\infty}=\|\varrho^{(\gamma-3)/2}\nabla_x \varrho\|_{L^\infty}$. Now two cases have to be distinguished:

(1a) The singularity occurs in the interior of the body; then $\int_0^{T^*} \|\nabla_x w\|_{L^\infty}=\infty$ implies that $\int_0^{T^*} \|\nabla_x \varrho\|_{L^\infty}=\infty$ holds.

(1b) The singularity appears near to the boundary; then $\int_0^{T^*} \|\nabla_x w\|_{L^\infty}=\infty$ implies one of the following possibilities:

(1b I) Either $\int_0^{T^*}\|\nabla_x w\|_{L^\infty}=\infty$ holds or

(1b II) ϱ has no suitable falloff condition such that $\int_0^{T^*}\|\nabla_x w\|_{L^\infty}=\infty$ diverges but not $\int_0^{T^*}\|\nabla_x \varrho\|_{L^\infty}=\infty$. Because one cannot decide which of the possibilities is realized, there is no information available about the the behavior of $\int_0^{T^*}\|\nabla_x \varrho\|_{L^\infty}=\infty$.

(2) *In the cosmological situation* the background solution contains a density that is positive everywhere. Therefore the introduction of the quantity w is not necessary.

(3) *Intuitive picture*: In a fluid free of vorticity the singularities which occur first are shock waves, i.e., $\|\theta\|_{L^\infty}\to\infty$ $\|\nabla\varrho\|_{L^\infty}\to\infty$. In that case Ref. 9 has obtained a lower bound of the form $Ce^{1/\epsilon}$ for the lifespan, where ϵ measures the size of the initial data. In a general flow it is expected that much sooner than that, in a time of order $1/\epsilon$, singularities due to concentration of vorticity will occur.

(4) *Localization of singularities*: To clarify this point let us consider the case of the compact body. The occurrence of singularities is determined by the initial data and by

$$\int_0^{T^*}(\|\theta\|_{L^\infty(\mathbb{R}^3)}+\|\Omega\|_{L^\infty(\mathbb{R}^3)}+\|\nabla\varrho\|_{D^\infty(\mathbb{R}^3)})dt,$$

as one can see from the energy estimate of the form

$$\|u\|_{H^s(L_t)}\leqslant\|u(0)\|_{H^s(L_t)}e^{\int_0^{T^*}(\|\theta\|_{L^\infty(\mathbb{R}^3)}+\|\Omega\|_{L^\infty(\mathbb{R}^3)}+\|\Omega\|_{L^\infty(\mathbb{R}^3)}+\|\nabla\varrho\|_{L^\infty(\mathbb{R}^3)})dt}.$$

This inequality is an equivalent form to express possibility (ii) of Theorem 3. Let the compact support of ϱ be denoted by L_t. Now the initial data for v are changed outside L_t. Then the solutions inside L_t are not influenced by this change. In that sense the occurrence of singularities is influenced by the initial data on L_t. On the other hand $\partial_b v^a$ was estimated by a *nonlocal* elliptic estimated of the form

$$\|\nabla v\|_{L^\infty(\mathbb{R}^3)}\leqslant C\{1+|v|_{L^\infty(\mathbb{R}^3)}+(1+\ln^+\|v\|_{H^s(\mathbb{R}^3)})(\|\Omega\|_{L^\infty(\mathbb{R}^3)}+\|\theta\|_{L^\infty(\mathbb{R}^3)}\}$$

on the whole $\mathbb{R}^3$. This estimate leads to the energy estimate mentioned above. This inequality implies that one has to control the L^∞-norm of θ, Ω, and $\nabla\varrho$ on the whole $\mathbb{R}^3$. This is not the desired estimate to localize the singularities. The estimated needed for this purpose must have the form

$$\|u\|_{H^s(L_t)}\leqslant\|u(0)\|_{H^s(L_t)}e^{\int_0^{T^*}(\|\theta\|_{L^\infty(L_t)}+\|\Omega\|_{L^\infty(L_t)}+\|\nabla\varrho\|_{L^\infty(L_t)})dt}.$$

In this estimate one has only to control the L^∞-norm of θ, Ω, and $\nabla\varrho$ on the support of the matter L_t. It was not possible to derive such an estimate up to now.

(5) *Comparison with known results:* As pointed out already, one weak point of the results obtained here is that they do not state positively that, in fact, singularities do occur. There are, however, two special subcases, both for a spherical symmetric fluid. For this situation Makino and Perthame[10] could show that the lifespan of every smooth spherically symmetric positive Makino solution is finite. In fact they proved the following.

Theorem 5 (finite lifespan of classical spherical symmetric Makino solutions): *Let $\varrho(t)$, $v^a(t)$ be a spherically symmetric Makino solution of the Euler–Poisson system on $0\leqslant t<T^*$. If the support of $\varrho(0)$, $v^a(0)$ is compact and if $\varrho(0)\neq 0$, then T^* is finite.*

Given even this result the continuation criteria are of limited value as far as the question of the structure of singularities is concerned. Let us discuss this somewhat subtle point in the following. For that, let us consider the two relevant criteria, that is, Theorem 3 and Corollary 2. The only difference between them is the different kinematical quantities controlling the possible breakdown. The following discussion hence will be focused only on these different objects. On one hand, if these criteria are used to continue a solution, in the case of spherical symmetry, the former is

superior to the latter because by Theorem 3 it is simply sufficient to control the expansion and not additionally the shear. On the other hand, as far as the appearance of singularities is concerned, each of these criteria is nearly as good or bad as the other. The point is that if we use the Makino–Perthame theorem together with criterion 3 or 2 it cannot be decided whether the expansion alone or the shear as well will blow up. However, at least we know that the shear definitively cannot diverge while the expansion stays bounded. So only singularities of the type *unbounded-expansion–unbounded-shear* or *unbounded-expansion–bounded-shear* but not *bounded-expansion–unbounded-shear* are possible.

More detailed information about the structure of the singularity, such as whether shock waves occur, clearly is not possible.

There is, however, a very special case, namely that of a spherically symmetric shear-free solution of the Euler–Poisson equation with the special equation of state $p=\varrho^{4/3}$. The time-independent version of this solution is a special subcase of the Lane–Emden solution. The time-dependent solution, on the contrary, has not been investigated over the years. Makino[11] recently proved the following result:

Theorem 6 (blow-up solutions of the Euler–Poisson for $p=\varrho^{4/3}$): *If $\gamma=\frac{4}{3}$, then there exists a family of classical solutions of the Euler–Poisson system which tends, in the distribution sense, to the delta distribution after finite time.*

In some sense this type of collapse is very dustlike. Because no shock waves are formed, the shear stays bounded by definition and only the density (and therefore, via the continuity equation, the expansion too) blows up. The reason for this behavior lies partly in the *soft* equation of state.

APPENDIX: ESSENTIAL ELLIPTICAL AND HYPERBOLIC ESTIMATES

In the following Lemma 5 for the three-dimensional torus $\mathbb{T}^3$ is proven and furthermore the proof of the *a priori* estimates VI.1a and VI.1b is sketched.

1. Proof of Lemma (5)

Use has been made of elliptic estimates on the flat three-dimensional torus $\mathbb{T}^3=\mathbb{S}^1\times\mathbb{S}^1\times\mathbb{S}^1$. To prove these estimates it is convenient to use methods that have been used for the $\mathbb{R}^3$ as far as possible. An essential tool is the Green's function for the Poisson equation. The existence of a Green's function and some of its properties have been shown in Ref. 12 for periodic functions on $\mathbb{R}^3$. In order to make use of these results it is necessary to clarify the connection between periodic functions on $\mathbb{R}^3$ and functions on the torus $\mathbb{T}^3$ which will be done in the following. Let us define a flat three-dimensional torus $\mathbb{T}^3$ as the quotient of $\mathbb{R}^3$ by the translations $x^i\mapsto x^i+1$ Here x^i denote the Cartesian coordinates. The metric and the volume form is the flat Riemannian metric and the volume form dV of $\mathbb{R}^3$. Let Q be the subset $(-\frac{1}{2},\frac{1}{2})^3$ of the $\mathbb{R}^3$. The set which is translated by z is denoted by $Q+z$ and is given by

$$z+Q=\{x\in\mathbb{R}^3: x-z\in Q\}. \tag{A1}$$

Let p be a map $p:W\to\mathbb{T}^3$ on the torus and let $U_z=p(z+Q)$. Since the torus is the quotient of $\mathbb{R}^3$ for all points $x\in\mathbb{R}^3$, every point $\overline{x}=p(x)\in\mathbb{T}^3$ is the equivalence class of x. Every set U_z is a open and dense subset of $\mathbb{T}^3$ and the inverse of the restriction of p on $z+Q$ defines a chart with the domain of definition U_z. These charts cover the torus. If now a function f is defined on the torus, then $\tilde{f}=f\circ p$ is a periodic function on $\mathbb{R}^3$. On the contrary, if a periodic function $\tilde{f}$ is given on $\mathbb{R}^3$, there exists a unique function f on $\mathbb{T}^3$ such that $\tilde{f}=f\circ p$ holds. Furthermore, the following relation exists between integrals for f and integrals for $\tilde{f}$:

$$\int_{\mathbb{T}^3} f(\overline{x})dV=\int_{U_z} f(\overline{x})dV=\int_{z+Q}\tilde{f}(x)dx. \tag{A2}$$

Here the point z is arbitrary.

In the following a theorem from Ref. 12 about the Green's function for periodic functions on $\mathbb{R}^3$ will be used.

Lemma 6 (Green's function for periodic functions on the $\mathbb{R}^3$): Let $\mathscr{P}(Q):=\{f:\mathbb{R}^3\to\mathbb{R};\ f(x+\alpha=f(x),x\in\mathbb{R}^3,\ \alpha\in\mathbb{Z}^3\}$ be the set of all periodic functions on $\mathbb{R}^3$ and $C^n_\pi(Q):=C^n(\mathbb{R}^3)\cap\mathscr{P}(Q)$ be the set of all differentiable and periodic functions on $\mathbb{R}^3$. There exists a function $\hat{G}\in C^\infty(\mathbb{R}^3\backslash\mathbb{Z}^3)\cap\mathscr{P}(Q)$ with the following properties:

(1) There exists a function $\hat{G}_0\in C^\infty(\mathbb{R}^3\backslash\mathbb{Z}^3)\cup\{(0,0,0)\}$, so that $\hat{G}:\mathbb{R}^3\to\mathbb{R}$ has the form

$$\hat{G}=\hat{G}_0+\hat{G}_1=\hat{G}_0-\frac{1}{4\pi|x|},\quad x\in\mathbb{R}^3\backslash Z^3. \tag{A3}$$

(2) For all $\varrho\in C^1_\pi(Q)$ with $\int_Q\varrho\ dV=0$, the function

$$\phi(x)=\int_Q\hat{G}(x-y)\varrho(y)dy=\int_{Q+z}\hat{G}(x-y)\varrho(y)dy \tag{A4}$$

with $\phi\in C^2_\pi(Q)$, and $\int_Q\phi dV=0$ is the unique solution of the equation

$$\Delta\phi=\varrho. \tag{A5}$$

To use these statements for functions on the torus one has to keep in mind that the expression

$$G(x-y):\mathbb{R}^3\to\mathbb{R} \tag{A6}$$

has no coordinate-independent meaning on the torus. Because of that the function $\widetilde{G}(x,y):\mathbb{R}^3\times\mathbb{R}^3\to\mathbb{R}$ will be defined by

$$\widetilde{G}(x,y)=\hat{G}(x-y). \tag{A7}$$

Now $\hat{G}(x-y)$ is periodic in x and y and therefore $\widetilde{G}(x,y)$ is periodic in x and y as well. As mentioned already in the discussion of Eq. (A2), there exists a unique local integrable function $G:\mathbb{T}^3\times\mathbb{T}^3\to\mathbb{R}$ with $\widetilde{G}(x,y)=G(p(x),p(y))$. Let ϱ be a (sufficiently differentiable) function on $\mathbb{T}^3$ with zero integral and let $\widetilde{\varrho}=\varrho\circ p$. Now $\widetilde{\phi}(x)$ is defined by

$$\widetilde{\phi}(x)=\int_{z+Q}\hat{G}(x-y)\widetilde{\varrho}(y)dy, \tag{A8}$$

and, according to Lemma (6), $\widetilde{\phi}$ fulfills the equation $\Delta\widetilde{\phi}=\widetilde{\varrho}$. Because $\hat{G}(x-y)$ is periodic in x, $\widetilde{\phi}$ is periodic as well. Therefore there exists a function ϕ on $\mathbb{T}^3$ with $\widetilde{\phi}=\phi\circ p$. This function satisfies $\Delta\phi=\varrho$. From Eqs. (A1) and (A2) it follows that

$$\phi(x)=\int_{\mathbb{T}^3}G(\overline{x,y})\varrho(\overline{y})dV \tag{A9}$$

holds.

Therefore

$$G(\overline{x,y}):\mathbb{T}^3\times\mathbb{T}^3\to\mathbb{R} \tag{A10}$$

has the desired properties of a Green's function on the torus.

The statement (ii) of the Lemma 6, i.e., $\hat{G}=\hat{G}_0+1/4\pi|x|$, has to be translated in the following way. Because $\hat{G}_0(x-y)$ is only defined if the coordinates x^i are not integers or if x, the origin of

$\hat{G}_0$, is not periodic and therefore cannot be defined on the torus. To get a similar decomposition on the torus one proceeds as follows. Let ψ be a smooth function on $\mathbb{R}^3$ whose compact support is in the subset $(-\frac{1}{2},\frac{1}{2})^3$ and who is identical to one in an open neighborhood $|x|<r_0$ of the origin. This neighborhood will be denoted by W. The function ψ can, without loss of generality, be chosen in such a way that the support of ψ lies in a region of the form $|x|<r_1$ where $r_0<r_1<\frac{1}{2}$ holds. Let

$$\overline{G_0}(x,y)=\psi(x-y)\hat{G}_0(x-y) \tag{A11}$$

for x,y in $(-1/2),1/2)^3$ and let $\widetilde{G}_0$ be periodic in x and y. The function $\widetilde{G}_0(x,y)$ is smooth and can be projected to a smooth function $G_0(\overline{x,y}):\mathbb{T}^3\times\mathbb{T}^3\to\mathbb{R}$. Let $d(\overline{x,y})$ be the distance between the points $\overline{x}$ and $\overline{y}$ on the torus. The construction is done in such a way that $G(\overline{x,y})=G_0(\overline{x,y})+1/d(\overline{x,y})$ holds in an open neighborhood Y of the diagonal which is given by

$$Y=\{(\overline{x,y})\in\mathbb{T}^3\times\mathbb{T}^3: d(\overline{x,y})<r_0\}. \tag{A12}$$

In other words, if one defines $G_1=G-G_0$, then $G_1(\overline{x,y})=1/d(\overline{x,y})$ holds in Y.

2. Nonlocal decomposition of ∇v

Starting from the relation $\Delta\mathbf{v}=\nabla\nabla\cdot\mathbf{v}-\nabla\times\nabla\times\mathbf{v}$—keeping in mind the relation $\int v\,dV=0$—and solving this relation with the help of the Green's function one obtains

$$\nabla\mathbf{v}(\overline{x})=\nabla\int_{\mathbb{T}^3}\theta\nabla G(\overline{x,y})d\overline{y}+\nabla\int_{\mathbb{T}^3}\Omega\times\nabla G(\overline{x,y})d\overline{y}. \tag{A13}$$

In the following $A(y)$ is used as an abbreviation for θ and Ω^a, and $K(\overline{x-y})$ as an abbreviation for $\nabla G(\overline{x-y})$ whenever it is convenient.

To estimate the first term the integral will be transformed back to $\mathbb{R}^3$ and basically the methods of Ref. 2 will be used. In order to calculate an L^∞-norm one has to calculate the absolute value of a function in an arbitrary point $\overline{x}\in\mathbb{T}^3$. Therefore, one chooses a z such that $p(z)=\overline{x}$. Then $\overline{x}$ is centralized in the chart on U_z:

$$\int_{\mathbb{T}^3}\nabla G_1(\overline{x,y})A(\overline{y})dV=\int_{z+V}\psi(z-y)A(p(z-y))\nabla\left(\frac{1}{|z-y|}\right)dy. \tag{A14}$$

Next a cutoff function is introduced which has the form

$$\xi_r=\begin{cases}1, & |z|<r,\\ 0, & |z|>2r,\end{cases} \tag{A15}$$

and the properties

$$\xi_r(z)\in C_0^\infty,\quad \|\xi_r(z)\|_{L^\infty}\leqslant\frac{C}{r}. \tag{A16}$$

It will be presumed that $2r\leqslant r_0$ holds so that $\psi(z)=1$ on the support on ξ_r. The integral (A14) will be written with the help of $\xi_r(z-y)+[1-\xi_r(z-y)]$:

$$\nabla_z v(z)=\nabla_z\int_{z+V}\psi(z-y)A(p(z-y))\nabla\left(\frac{1}{|z-y|}\right)dy=\nabla v^{(1)}+\nabla v^{(2)}+\nabla v^{(2)} \tag{A17}$$

where

$$\nabla v^{(1)}=\nabla_z\int_{z+V}\xi_r(z-y)A(p(z-y))\nabla\left(\frac{1}{|z-y|}\right)dy,$$

$$\nabla v^{(2)}=\nabla_z\int_{|z-y|<r_0}\left(1-\xi_r(z-y)\right)A(p(z-y))\nabla\left(\frac{1}{|z-y|}\right)dy,$$

$$\nabla v^{(3)}=\nabla_z\int_{|z-y|>r_0}\psi(z-y)(1-\xi_r(z-y))A(p(z-y))\nabla\left(\frac{1}{|z-y|}\right)dy.$$

The third integral can be estimated by a constant times $\|A\|_{L^\infty}$ because A is multiplied by an continuous function under the integral and it is integrated in a region with finite volume.

a. Estimation of $\nabla v^{(1)}$

Using the antisymmetry of $K_1(z-y)$ and $\xi(z-y)$ and integrating by parts leads to

$$\nabla_z v^{(1)}\int_{|z-y|<2r}[\xi_r(z-y)K_1(z-y)]\nabla_y A(y)dy. \tag{A18}$$

Using the Young inequalities for convolutions on Eq. (A18) leads to

$$\begin{aligned}\|\nabla v\|_{L^\infty}&\leqslant\|K_1(z-y)\|_{L^{4/3}}\|\nabla_y A(y)\|_{L^4}\leqslant\|(z-y)^{-2}\|_{L^{4/3}}\|\nabla_y A(y)\|_{L^4}\leqslant Cr^{1/4}\|\nabla_y A(y)\|_{L^4}\\&\leqslant Cr^{1/4}\|\nabla_y A(y)\|_{H^1}\leqslant Cr^{1/4}\|v\|_{H^3}.\end{aligned}\tag{A19}$$

In the second to last step the Sobolev inequality has been used. In the first step it was used that

$$K_1(z-y)\in L_{2p}(y:|z-y|<2r),\quad p<\tfrac{3}{2}, \tag{A20}$$

holds as one can easily check.

b. Estimation of $\nabla v^{(2)}$

This term again is estimated by the Young inequality where one obtains

$$\|\nabla v\|_{L^\infty}\leqslant\|A\|_{L^\infty}\|\nabla_z\{K_1(z-y)[1-\xi_r(z-y)]\}\|_{L^1}. \tag{A21}$$

Now the L^1-norm in that inequality can be transformed to

$$\begin{aligned}\|\nabla_z\{K_1(z-y)[1-\xi_r(z-y)]\}\|_{L^1}=&\int_{|z-y|>r}\{\nabla_z K_1(z-y)\}[1-\xi_r(z-y)]dy\\&+\int_{|z-y|>r}K_1(z-y)\nabla_z[1-\xi_r(z-y)]dy.\end{aligned}\tag{A22}$$

For the integration polar coordinates have been used and the integration was done between $0<r<2r<r_0$. Also the inequalities $|K_1(z-y)|\leqslant|z-y|^{-3}$ and $\|\xi_\tau(z)\|_{L^\infty}\leqslant C/r$ have been used. Furthermore, for $|z-y|>2r$, $[1-\xi_r(z-y)]=1$ holds and hence $\nabla[1-\xi_\tau(z-y)]=0$. One obtains

$$\begin{aligned}\|\nabla_z\{K_1(z-y)[1-\xi_r(z-y)]\}\|_{L^1} &= \int_{r<|z-y|<r_0}\{\nabla_z K_1(z-y)\}[1-\xi_r(z-y)]dy \\ &\quad + \int_{r<|z-y|<2r} K_1(z-y)\nabla_z[1-\xi_r(z-y)]dy \\ &= \left\{4\pi\int_r^{r_0} s^{-3}[1-\xi_r(z-y)]s^2ds + 4\pi\int_r^{2r} s^{-2}\nabla[1-\xi_r]s^2ds\right\} \\ &= \left\{4\pi\int_r^{1/2} s^{-1}ds + 4\pi\,\frac{1}{r}\int_r^{2r} ds\right\} = \{C(\ln(r_0)-\ln r+1)\}.\end{aligned} \tag{A23}$$

Combining Eqs. (A23) and (A19) one obtains

$$\|\nabla v\|_{L^\infty} \leqslant C\{r^{1/4}\|v\|_{H^3} + (\ln(r_0)+1-\ln r)\|A\|_{L^\infty}\}. \tag{A24}$$

Now two cases are treated separately. If $\|v\|_{H^3} \leqslant (r_0/2)^{-1/4}$, then $r = r_0/2$. Otherwise $r = \|v\|_{H^3}^{-4}$ and therefore $\log r = -4\log\|v\|_{H^3}$. In the first case one gets an estimate of the form

$$\|\nabla v\|_{L^\infty} \leqslant C(1+\|A\|_{L^\infty}), \tag{A25}$$

and in the second case

$$\|\nabla v\|_{L^\infty} \leqslant C(1+(1+\log\|v\|_{H^3})\|A\|_{L^\infty}). \tag{A26}$$

Now $C(1+(1+\log_+\|v\|_{H^3})\|A\|_{L^\infty})$ is greater than the expressions on the right-hand side of both inequalities. Therefore the estimate of Lemma 5 holds. Here $\log_+ = \max\{R_1, R_2\}$ holds where R_1 and R_2 are the right-hand sides of Eqs. (A26) and (A25). ■

Proof of the a priori estimate: For both situations the proof consists of the following two steps:

(1) energy estimates for the symmetric hyperbolic part, and
(2) elliptic estimates for the Poisson equation.

The first step is somehow standard and can be found, for example, in Ref. 5. Therefore it will not repeated here. One obtains, after differentiating the equation with respect to $x^{|\alpha|}$ (where $|\alpha|$ is a multiindex), and with respect to t,

$$\tfrac{1}{2}\partial_t\|U\|_{E,s} \leqslant \tfrac{1}{2}C(\|U\|_{L^\infty})\|(\partial_t U + \nabla U)\|_{L^\infty}\|U\|_{H^s}^2 + C\|U\|_{H^s}^2 + C\|Q\|_{H^s}\|U\|_{H^s}. \tag{A27}$$

Here the usal energy norm $\|U\|_E^2 = \langle A^0U, U\rangle_{L_2}$ and $\|D^{|\alpha|}U\|_E^2 = \langle A^0(D^{|\alpha|}U), (D^{|\alpha|}U)\rangle_{L_2}$ and, respectively, $\|U\|_{E,s}^2 = \Sigma_{\alpha\leqslant s}\|D^\alpha U\|_E^2$. The notation in the last expressions means that one takes the L^2-norm (and the energy norm) for every $D^\alpha f$ for all fixed $|\alpha|$. Both norms have the properties

$$C\langle D^\alpha U, D^\alpha U\rangle_{L_2} \leqslant \langle A^0 D^\alpha U, D^\alpha U\rangle_{L_2} \leqslant C^{-1}\langle D^\alpha U, D^\alpha U\rangle_{L_2}, \tag{A28}$$

$$C\|U\|_{H^s}^2 \leqslant \|u\|_{E,s}^2 \leqslant C^{-1}\|U\|_{H^s}^2. \tag{A29}$$

In case II the equations consist of a lower-order term $B(t)$ that can be estimated by a constant, therefore the term $C\|U\|_{H^s}^2$ appears. In case I there is no lower-order term and therefore inequality (A27) does not contain the term $C\|U\|_{H^s}^2$. It remains for us to derive an estimate for $\|Q\|_{H^s}$ of the form

$$\|Q\|_{H^s} \leqslant C\|U\|_{H^s}, \tag{A30}$$

where Q satisfies the equation

$$Q = \text{grad } \phi \quad \text{and} \quad \Delta\phi = \varrho. \tag{A31}$$

That estimate (A30) holds follows from the following lemma:

Lemma 7 (H^s *estimate for the Poisson equation): Let*

$$\Delta\phi = \varrho \tag{A32}$$

and

(1) *case I: let* ϱ *have compact support, let* ϕ *satisfy the boundary condition* $\lim_{|x|\to\infty} \phi = 0$, *and*
(2) *case II: let* ϱ *have vanishing integral, i.e.,* $\int_{\mathbb{T}^3} \varrho \, dV = 0$.

Then there exists a unique solution ϕ *with the property*

(1) *case I:* $\lim_{|x|\to\infty} \phi = 0$ *and*
(2) *case II:* $\int_{\mathbb{T}^3} \phi \, dV = 0$.

Furthermore,

$$\|\phi\|_{H^s(M)} \leqslant C\|\varrho\|_{H^{s-1}(M)}. \tag{A33}$$

holds, *where for case I the constant C depends on the compact support of* ϱ.

The proof in case I can be found in Ref. 4. The proof of case II is in Ref. 3

So, finally, one has

$$\tfrac{1}{2}\partial_t \|U\|^2_{E,N} \leqslant C(\|\partial_t U\|_{L^\infty} + \|\nabla U\|_{L^\infty} + 1)\|U\|^2_{H^s}. \tag{A34}$$

One uses the relation (A29) and Gronwall's inequality to obtain

$$\|U\|^2_{H^s} \leqslant \|U(0)\|^2_{H^s} e^{C(\|U\|_{L^\infty}) \int_0^T |\partial_t U|_{L^\infty} + |\nabla U|_{L^\infty} \, dt}. \tag{A35}$$

This is the desired estimate and therefore (VI.1b) is proven for case II.

Now let us mention the differences from case I. The main difference is that we have an evolution equation for the nonlinear function $w(\varrho)$ but the source $Q(=\text{grad } \phi)$ is coupled to ϱ. Therefore the same energy estimates are done for $U = (w(\varrho), v^a)$ as well as the elliptic estimate,

$$\|Q\|_{H^s} \leqslant C\|\varrho\|_{H^{s-1}} \leqslant C\|\varrho\|_{H^s}, \tag{A36}$$

and then ϱ has to be estimated by $w(\varrho)$ with the help of the Moser inequalities. ■

The global additive and multiplicative properties of Laplace-type operators acting on irreducible rank 1 symmetric spaces are considered. The explicit form of the zeta function on product spaces and of the multiplicative anomaly is derived. © *1998 American Institute of Physics.* [S0022-2488(98)00702-6]

I. INTRODUCTION

Among the most important geometric structures on manifolds[1–3] almost-product structures play an essential role. Structures of this kind appear in a natural way from a variational principle based on a general class of Lagrangians depending on the Ricci square invariant constructed out of a metric and a symmetric connection.[4,5] Geometric properties of (pseudo-) Riemannian almost-product structures have been studied in Refs. 1 and 6–9.

In this class of structures an almost-product structure on an Einstein manifold is associated with an Einstein metric $\mathbf{g}$ [i.e., $\mathrm{Ric}(\mathbf{g})=\gamma\mathbf{g}$ holds, where $\mathrm{Ric}(\mathbf{g})$ is the Ricci tensor and γ is a constant]. It is well known that gravitational Lagrangians which are nonlinear in the scalar curvature of a metric give rise to equations with higher derivatives or to the appearance of additional matter fields. An important example of a nonlinear Lagrangian leading to equations with higher derivatives is given by Calabi's variational principle.[10] The nonlinear gravitational Lagrangians which still generate Einstein equations are particularly important since they provide a general approach to governing topology in low-dimension models and can be adapted in string theory.

In higher derivative field theories (for example, in higher derivative quantum gravity) as a consequence one has to deal with the product of two (or more) elliptic differential operators.[11,12] In some cases an elliptic (pseudo-) differential operator has a well-defined zeta-regularized determinant. It is natural to investigate multiplicative properties of the determinants of differential operators, in particular the so-called multiplicative anomaly;[13–15] for the definition of the anomaly see Sec. III. The multiplicative anomaly can be expressed by means of the noncommutative residue associated with a classical pseudo-differential operator, the Wodzicki residue.[16]

Recently the important role of this residue has been recognized in physics. The Wodzicki residue, which is the unique extension of the Dixmier trace to the wider class of pseudo-differential operators (PDOs),[17,18] has been considered within the noncommutative geometrical approach to the standard model of the electroweak interactions.[19–24] This residue is also used to write down the Yang–Mills action functional. Other recent papers along these lines can be found in Refs. 25–27. The residue formulas have been used also for dealing with the singularity structure of zeta functions[28] and the commutator anomalies of current algebras.[29]

The purpose of the present paper is to investigate the global additive and multiplicative properties of invertible elliptic operators of Laplace type acting on Einstein manifolds, especially on a noncompact symmetric space, and related zeta functions. The contents of the paper are the following. In Sec. II we summarize some properties of the spectral zeta function $\zeta(s|\oplus_p \mathscr{L}_p)$ related to the Laplace-type operators $\mathscr{L}_p, p=1,2$, each of them acting on an irreducible rank 1 symmetric space of noncompact type. The explicit form of the zeta function is given for a wide

class of symmetric space products, in particular for the simplest case $H^2\otimes H^2$. In Secs. III and IV the spectral zeta function $\zeta(s|\otimes_p \mathscr{L}_p)$ and the corresponding multiplicative anomaly (for the spaces mentioned above) are studied. The explicit calculation is given for essentially all rank 1 symmetric spaces. We end with some conclusions in Sec. V.

II. SPECTRAL ZETA FUNCTIONS AND PRODUCT OF EINSTEIN MANIFOLDS

In this section we consider the problem of the global existence of zeta functions on pseudo-Riemannian product manifolds, a product of two Einstein manifolds[1,30]

$$(M,\mathbf{g},\mathscr{P})=(M_1,\mathbf{g}_1,\mathscr{P}_1)\otimes(M_2,\mathbf{g}_2,\mathscr{P}_2), \tag{2.1}$$

where $\mathbf{g}=\mathbf{g}_1\otimes\mathbf{g}_2$ and the metric $\mathbf{g}$ separates the variables, i.e.,

$$ds^2=\mathbf{g}_{\alpha\beta}(x)dx^\alpha\otimes dx^\beta+\mathbf{g}_{\mu\nu}(y)dy^\mu\otimes dy^\nu. \tag{2.2}$$

The tangent bundle splits as $TM=TM_1\oplus TM_2$ and $\mathscr{P}=\mathscr{P}_1+\mathscr{P}_2$, where $\mathscr{P}_p(p=1,2)$ are the corresponding projections on TM_p,

$$\mathrm{Ric}(\mathbf{g})=\gamma\mathbf{g}, \tag{2.3}$$

$$\mathscr{P}^2=\mathrm{Id},\quad \mathbf{g}(\mathscr{P}\mathscr{X},\mathscr{P}\mathscr{Y})=\mathbf{g}(\mathscr{X},\mathscr{Y}),\quad \mathscr{X},\mathscr{Y}\in\chi(M), \tag{2.4}$$

and where $\chi(M)$ is the Lie algebra of vector fields $\mathscr{X}$ and $\mathscr{Y}$ on M. The trivial examples of an almost-product structure are given by the choices $\mathscr{P}=\pm\mathrm{Id}$ ($\pm$identity).

Consider an almost-product (pseudo-) Riemannian structure $(M,\mathbf{g},\mathscr{P})$ which is integrable iff $\Delta_{\mathbf{g}}\mathscr{P}=0$ for the Levi–Civita connection $\Delta_{\mathbf{g}}$ of $\mathbf{g}$. The integrable complementary subbundles, i.e., both foliations, are totally geodesic.[1,30] Suppose M is a pseudo-Kähler manifold; the metric $\mathbf{g}$ splits as $\mathbf{g}=\mathbf{g}_1\otimes\mathbf{g}_2$. Such a manifold is an Einstein manifold iff in any adapted coördinates (x^α,y^α) both metrics $\mathbf{g}_1$ and $\mathbf{g}_2$ are Einstein metrics for the same constant γ,[1,30,31] i.e.,

$$R_{\alpha_p\beta_p}=\gamma g_{\alpha_p\beta_p},\quad p=1,2. \tag{2.5}$$

Our consideration will be restricted to only locally decomposable manifolds. A wide class of (pseudo-) Riemannian manifolds includes nonlocally decomposable manifolds as well, which are given by warped product space–times.[32–34] Note that many exact solutions of Einstein equations (associated with Schwarzschild, Robertson–Walker, Reissner–Nordström, de Sitter space–times) and p-brane solutions[35,5] are, in fact, warped product space–times.[31,34]

A. The spectral zeta function of a space form

We shall be working with irreducible rank 1 symmetric spaces $M_p\equiv X_p=G_p/K_p$ of noncompact type. Thus G_p will be connected noncompact simple split rank 1 Lie groups with finite center and $K_p\subset G_p$ will be maximal compact subgroups. Let $\Gamma_p\subset G_p$ be discrete, co-compact, torsion-free subgroups.

Let $L_p: C^\infty(V(M_p))\mapsto C^\infty(V(M_p))$ be partial differential operators acting on smooth sections of vector bundles $V(M_p)$. Let χ_p be a finite-dimensional unitary representation of Γ_p, let $\{\lambda_l(p)\}_{l=0}^\infty$ be the set of eigenvalues of the second-order operator of Laplace type $L_p=-\Delta_{\Gamma_p}$ acting on smooth sections of the vector bundle $V(M_p)$ over $\Gamma_p\backslash X_p$ induced by χ_p, and let $n_l(\chi_p)$ denote the multiplicity of $\lambda_l(p)$.

We shall need further a suitable regularization of the determinant of an elliptic differential operator, since the naive definition of the product of eigenvalues gives rise to a badly divergent quantity. We shall make the choice of zeta-function regularization [see (3.2)]. The zeta functions associated with the operators $\mathscr{L}_p\equiv L_p+b_p$ have the form

$$\zeta(s|\mathscr{L}_p)=\sum_l n_l(\chi_p)\{\lambda_l(p)+b_p\}^{-s}; \tag{2.6}$$

here the b_p are arbitrary constants [endomorphisms of the vector bundle $V(M_p)$], called in the physical literature the potential terms. $\zeta(s|\mathscr{L}_p)$ is a well-defined analytic function for $\mathrm{Re}\, s > \dim(M_p)/2$, and can be analytically continued to a meromorphic function on the complex plane $\mathbf{C}$, regular at $s=0$. One can define the heat kernel of the elliptic operator $\mathscr{L}_p$ by

$$\omega_{\Gamma_p}(t) \equiv \mathrm{Tr}(e^{-T\mathscr{L}_p}) = \frac{-1}{2\pi i}\,\mathrm{Tr}\int_{\mathscr{C}_0} e^{-zt}(z-\mathscr{L}_p)^{-1}\,dz, \tag{2.7}$$

where $\mathscr{C}_0$ is an arc in the complex plane $\mathbf{C}$. By standard results in operator theory there exist $\epsilon, \delta > 0$ such that for $0 < t < \delta$ the heat kernel expansion holds

$$\omega_{\Gamma_p}(t) = \sum_{l=0}^{\infty} n_l(\chi_p) e^{-(\lambda_l(p)+b_p)t} = \sum_{o \leqslant l \leqslant l_0} a_l(\mathscr{L}_p) t^{-l} + O(t^{\epsilon}). \tag{2.8}$$

$\zeta(s|\mathscr{L}_p)$ and $\omega_{\Gamma_p}(t)$ are related by

$$\Gamma(s)\zeta(s|\mathscr{L}_p) = \int_0^{\infty} \omega_{\Gamma_p}(t) t^{s-1}\,dt. \tag{2.9}$$

Eventually we would like also to take $b_p = 0$, but for now we consider only nonzero modes: $b_p + \lambda_l(p) > 0$, $\forall l: \lambda_0(p) = 0$, $b_p > 0$.

B. The explicit form of the zeta function

The following representations of X_p up to local isomorphism can be chosen:

$$X_p = \begin{bmatrix} \mathrm{SO}_1(n,1)/\mathrm{SO}(n) & (I) \\ \mathrm{SU}(n,1)/\mathrm{U}(n) & (II) \\ \mathrm{SP}(n,1)/(\mathrm{SP}(n)\otimes \mathrm{SP}(1)) & (III) \\ F_{4(-20)}/\mathrm{Spin}(9) & (IV) \end{bmatrix}, \tag{2.10}$$

where $n \geqslant 2$, and $F_{4(-20)}$ is the unique real form of F_4 (with Dynkin diagram $\circ - \circ = \circ - \circ$) for which the character $(\dim X - \dim K)$ assumes the value (-20).[36] We assume that if G_1 or $G_2 = \mathrm{SO}(m,1)$ or $\mathrm{SU}(q,1)$, then m is even and q is odd.

We study the zeta function

$$\zeta\left(s\left|\bigoplus_p \mathscr{L}_p\right.\right) = \zeta_{\Gamma_1\backslash X_1 \otimes \Gamma_2 \backslash X_2}(s; b_1, b_2) = \frac{1}{\Gamma(s)} \int_0^{\infty} \prod_p \omega_{\Gamma_p}(t) t^{s-1} dt, \mathrm{Re}\, s > \frac{d_1+d_2}{2}, \tag{2.11}$$

where $d_p = \dim X_p$; see Eq. (2.9). The suitable Harish–Chandra–Plancherel measure is given as follows:

$$|C_p(r)|^{-2} = C_{G_p} \pi r P_p(r) \tanh(a(G_p) r) = C_{G_p} \pi \sum_{l=0}^{d_p/2-1} a_{2l}(p) r^{2l+1} \tanh(a(G_p) r), \tag{2.12}$$

where

$$a(G_p) = \begin{bmatrix} \pi & \text{for } G_p = \mathrm{SO}_1(2n,1) \\ \dfrac{\pi}{2} & \text{for } G_p = \mathrm{SU}(q,1), \quad q \text{ odd} \\ & \text{or } G_p = \mathrm{SP}(m,1), \quad F_4(-20) \end{bmatrix}, \tag{2.13}$$

while C_{G_p} is some constant depending on G, and where the $P_p(r)$ are even polynomials [with suitable coefficients $a_{2l}(p)$] of degree $d-2$ for $G \neq \mathrm{SO}(2n+1,1)$, and of degree $d-1=2n$ for $G = \mathrm{SO}_1(2n+1,1)$.[37,38]

Before starting the main theorem of this section (Theorem 1 below) we shall need further notation, and a few more definitions, some of which arise in connection with Selberg's trace formula-a formula of crucial importance for our purposes which we review. For the data (G,K,Γ) as above, the trace formula[39,40] reads

$$\omega_\Gamma(t;b,\chi)=V\int_{\mathbf{R}} dr\ e^{-(r^2+b+\rho_0^2)t}|C(r)|^{-2}+\theta_\Gamma(t;b,\chi), \tag{2.14}$$

where

$$V\overset{\text{def}}{=}\frac{1}{4\pi}\chi(1)\ \text{vol}\ (\Gamma\backslash G), \tag{2.15}$$

χ is a finite-dimensional unitary representation (or a character) of Γ, and where the number ρ_0 is associated with the positive restricted (real) roots of G (with multiplicity) with respect to a nilpotent factor N of G in an Iwasawa decomposition $G=KAN$. One has $\rho_0=(n-1)/2,n$, $2n+1$, and 11 in the cases $(I)-(IV)$, respectively, in Eq. (2.10). Finally the function $\theta_\Gamma(t;b,\chi)$ is defined as follows:

$$\theta_\Gamma(t;b,\chi)\overset{\text{def}}{=}\frac{1}{\sqrt{4\pi t}}\sum_{\gamma\in C_\Gamma-\{1\}}\chi(\gamma)t_\gamma j(\gamma)^{-1}C(\gamma)e^{-(bt+\rho_0^2t+t_\gamma^2/(4t))}, \tag{2.16}$$

for a function $C(\gamma)$, $\gamma\in\Gamma$, defined on $\Gamma-\{1\}$ by

$$C(\gamma)\overset{\text{def}}{=}e^{-\rho_0 t_\gamma}|\det{}_{n_0}(\text{Ad}(m_\gamma e^{t_\gamma H_0})^{-1}-1)|^{-1}. \tag{2.17}$$

The notation used in Eqs. (2.16) and (2.17) is the following. Let a_0, n_0 denote the Lie algebras of A,N. Since the rank of G is 1, dim $a_0=1$ by definition, say $a_0=\mathbf{R}H_0$ for a suitable basis vector H_0. One can normalize the choice of H_0 by $\beta(H_0)=1$, where $\beta:a_0\mapsto\mathbf{R}$ is the positive root which defines n_0; for more detail see Ref. 38. Since Γ is torsion free, each $\gamma\in\Gamma-\{1\}$ can be represented uniquely as some power of a primitive element δ: $\gamma=\delta^{j(\gamma)}$ where $j(\gamma)\geqslant 1$ is an integer and δ cannot be written as γ_1^j for $\gamma_1\in\Gamma$, $j>1$ an integer. Taking $\gamma\in\Gamma$, $\gamma\neq 1$, one can find $t_\gamma>0$ and $m_\gamma\in K$ satisfying $m_\gamma a=am_\gamma$ for every $a\in A$ such that γ is G conjugate to $m_\gamma\exp(t_\gamma H_0)$, namely for some $g\in G$, $g\gamma g^{-1}=m_\gamma\exp(t_\gamma H_0)$. For Ad denoting the adjoint representation of G on its complexified Lie algebra, one can compute t_γ as follows:[39]

$$e^{t_\gamma}=\max\{|c|\,|\,c=\text{an eigenvalue of Ad}(\gamma)\}, \tag{2.18}$$

in case $G=\text{SO}_1(m,1)$, with $|c|$ replaced by $|c|^{1/2}$ in the other cases of Eq. (2.10).

We will write V_k for $G=G_k$ in (2.15), $k=1,2$, G_1,G_2 being one of the groups in (2.10). Similarly we write $\rho_0(k)$, $a_{2j}(k)$, C_{G_k}, etc., in place of ρ_0,a_{2j},C_G for $G=G_k$. Let

$$\begin{gathered}B\overset{\text{def}}{=}\rho_0^2(1)+\rho_0^2(2)+b_1+b_2,\quad B_p\overset{\text{def}}{=}\rho_0^2(p)+b_p,\quad p=1,2,\\ y_p(s;z)\overset{\text{def}}{=}\frac{s}{2}+(-1)^{p-1}z,\quad \text{for}\quad s,z\in\mathbf{C}.\end{gathered} \tag{2.19}$$

Also for $a,\delta>0$, $n\in\mathcal{N}$, and $s\in\mathbf{C}$, define entire functions $\mathcal{K}_n(s;\delta,a)$ of s by

$$\mathcal{K}_n(s;\delta,a)\overset{\text{def}}{=}\int_{\mathbf{R}}\frac{dr\ r^{2n}\ \text{sech}^2(ar)}{(\delta+r^2)^s}. \tag{2.20}$$

Finally we denote by $\psi_\Gamma(s;\chi)$ the logarithmic derivative of Selberg's zeta function $Z_\Gamma(s;\chi)$, suitably normalized, attached to (G,K,Γ,χ).[37,41–48] For convenience we have assumed (recall) that if G_1 or G_2 is $\mathrm{SO}_1(m,1)$ or $\mathrm{SU}(q,1)$, then m is even and q is odd. We can now state the following.

Theorem 1: *The function $\zeta(s|\oplus_p \mathscr{L}_p)$ admits an explicit meromorphic continuation to* **C** *with at most a simple pole at $s=1,2,\ldots,(d_1+d_2)/2$. In particular on the domain* Re $s<1$,

$$\begin{aligned}\zeta(s|\oplus_p \mathscr{L}_p)=&\frac{\pi^2}{2}\prod_k^2 V_k a(G_k) C_{G_k}\sum_{j=0}^{d_1/2-1}\sum_{l=0}^{j}\sum_{\mu=0}^{d_2/2-1}\sum_{\nu=0}^{\mu}\frac{a_{2j}(1)a_{2\mu}(2)j!\mu!}{(j-l)!(\mu-\nu)!}\\
&\times\frac{\int_0^\infty r^{2(j-l)}\ \mathrm{sech}^2(a(G_1)r)\mathscr{K}_{\mu-\nu}(s-l-\nu-2;r^2+B,a(G_1))dr}{(s-1)(s-2)\ldots(s-(l+1))(s-(l+2))\cdots(s-(l+1+\nu+1))}\\
&+C_{G_1}V_1\ \sin(\pi s)\sum_{j=0}^{d_1/2-1}a_{2j}(1)\int_{\mathbf{R}}dr\ r^{2j+1}\ \tanh(a(G_1)r)\\
&\times\left[\int_0^\infty dt\ \Psi_{\Gamma_2}(\rho_0(2)+t+\sqrt{r^2+B};\chi_2)(2t\sqrt{r^2+B}+t^2)^{-s}\right]\\
&+C_{G_2}V_2\ \sin(\pi s)\sum_{j=0}^{d_2/2-1}a_{2j}(2)\int_{\mathbf{R}}dr\ r^{2j+1}\ \tanh(a(G_2)r)\\
&\times\left[\int_0^\infty dt\ \psi_{\Gamma_1}(\rho_0(1)+t+\sqrt{r^2+B};\chi_1)(2t\sqrt{r^2+B}+t^2)^{-s}\right]\\
&+\frac{1}{2\pi^3 i\Gamma(s)}\int_{\mathrm{Re}\ z=\epsilon}dz\left[\sin\ \pi\left(z+\frac{s}{2}\right)\right]\\
&\times\left[\sin\ \pi\left(\frac{s}{2}-z\right)\right]\Gamma\left(z+\frac{s}{2}\right)\Gamma\left(\frac{s}{2}-z\right)\\
&\times\prod_k^2\left[\int_0^\infty dt\ \Psi_{\Gamma_k}(\rho_0(k)+t+B_k^{1/2};\chi_1)(2tB_k^{1/2}+t^2)^{-y_k(s,z)}\right],\end{aligned}\tag{2.21}$$

for any $-\frac{1}{2}\leqslant\epsilon\leqslant\frac{1}{2}$. All of the integrals are entire functions of s.

Here $\zeta(s|\oplus_p \mathscr{L}_p)$ is defined by Eq. (2.11), which involves the parameters b_1,b_2. In Theorem 1 we require that $b_1,b_2>0$. One can, however, consider zero modes. More precisely assume $b_1,b_2\geqslant 0$, but at least either $b_1>0$ or $b_2>0$. Then Theorem 1 holds on the domain Re $s<0$ when the condition $-\frac{1}{2}\leqslant\epsilon\leqslant\frac{1}{2}$ is replaced by the condition Re $s/2<\epsilon<-$Re $s/2$.

The proof of Theorem 1 involves quite a number of steps. One of the steps, among many, is an analysis of the Mellin transform

$$\hat{\theta}_\Gamma(s;b,\chi)\overset{\mathrm{def}}{=}\int_0^\infty dt\ \theta_\Gamma(t;b,\chi)t^{s-1}\tag{2.22}$$

of the theta function $\theta_\Gamma(t;b,\chi)$ in Eq. (2.16). Let

$$K_\nu(s)=\frac{1}{2}\int_0^\infty dt\ e^{-(s/2)(t+1/t)}t^{\nu-1}\tag{2.23}$$

be the modified Bessel function. Then by results of Refs. 37 and 38,

$$\hat{\theta}_\Gamma(s;b,\chi)=\frac{\sin(\pi s)}{2\pi}\Gamma(s)\int_0^\infty dt\ \psi_\Gamma(\rho_0+t+a(b);\chi)(2a(b)t+t^2)^{-s},\tag{2.24}$$

on $\mathrm{Re}\, s<1$, for $a(b)\overset{\text{def}}{=}\sqrt{b+\rho_0^2}$, $b>0$. Equation (2.24) holds for $b=0$ (the zero modes case) on the domain $\mathrm{Re}\, s<0$. Given the notation in Eq. (2.19) the following holds:

Proposition 1: One has the equality of entire functions of s

$$\int_0^\infty dt\ \prod_p\ \theta_{\Gamma_p}(t;b_p,\chi_p)t^{s-1}=\frac{1}{2\pi i}\ \int_{\mathrm{Re}\, z=c} dz\ \prod_p\ \hat{\theta}_{\Gamma_p}(y_p(s,z);b_p,\chi_p)$$

$$=\frac{1}{2i\pi^3}\ \int_{\mathrm{Re}\, z=c} dz\ \prod_l^2\ \Gamma(y_l(s;z))[\sin\ \pi(y_l(s,z))]$$

$$\times\prod_p\ \int_0^\infty dt\ \psi_{\Gamma_p}(\rho_0(p)+t+B_p^{1/2};\chi_p)(2B_p^{1/2}t+t^2)^{-y_p(s;z)}, \quad (2.25)$$

for $c\in\mathbf{R}$ *with* $\mathrm{Re}\, s/2<c<-\mathrm{Re}\, s/2$, *and* $b_p\geqslant 0$ *with at least* $b_1>0$ *or* $b_2>0$.

The proposition is a consequence of the first integral transformation of Eq. (2.25) as an integral in the complex plane with the help of the Mellin–Parseval identity

$$\int_0^\infty dt\ h(t)g(t)=\frac{1}{2\pi i}\ \int_{\mathrm{Re}\, z=c} dz\ \hat{h}(z)\hat{g}(1-z), \quad c\in\mathbf{R}.$$

To this end one can choose $h(t)=\theta_{\Gamma_1}(t;b_1,\chi_1)t^{s/2}$ and $g(t)=\theta_{\Gamma_1}(t;b_2,\chi_2)t^{s/2-1}$. One makes use of Eq. (2.24).

The meromorphic continuation of $\zeta(s|\oplus_p\mathscr{L}_p)$ to the full complex plane, whereby Theorem 1 follows in particular, can be expressed as follows. For $a,b>0$, $l=0,1,2,3,...$, set

$$f_l(t;a,G)\overset{\text{def}}{=}\int_0^\infty dr\ r^{2l+1}e^{-(r^2+a)t}\ \tanh(a(G)r),$$

$$H_\Gamma^{(1)}(s;a,b,\chi,G)\overset{\text{def}}{=}\int_0^\infty dt\ f_l(t;a,G)\,\theta_\Gamma(t;b,\chi)t^{s-1}, \quad (2.26)$$

for $t>0$ and $s\in\mathbf{C}$. $H_\Gamma^{(l)}(s;a,b,\chi,G)$ is an entire function of s. Then for $b_1,b_2\geqslant 0$ with either $b_1>0$ or $b_2>0$ we have the following.

Theorem 2: *Suppose* $G_p\neq \mathrm{SO}_1(m,1)$, $\mathrm{SU}(q,1)$ *with m odd and q even. Then for* $\mathrm{Re}\, s>d_1/2+d_2/2$,

$$\zeta(s|\underset{p}{\oplus}\mathscr{L}_p)\overset{\text{def}}{=}\frac{1}{\Gamma(s)}\ \int_0^\infty dt\ \prod_p\ \omega_{\Gamma_p}(t,b_p,\chi_p)t^{s-1}$$

$$=\frac{\pi^2}{2}\ \prod_k^2\ V_k a(G_k)C_{G_k}\ \sum_{j=0}^{d_1/2-1}\ \sum_{l=0}^{j}\ \sum_{\mu=0}^{d_2/2-1}\ \sum_{\nu=0}^{\mu}\ \frac{a_{2j}(1)a_{2\mu}(2)j!\mu!}{(j-l)!(\mu-\nu)!}$$

$$\times\frac{\int_0^\infty dr r^{2(j-l)}\ \mathrm{sech}^2(a(G_1)r).\mathscr{K}_{\mu-\nu}(s-l-\nu-2;r^2+B,a(G_1))dr}{(s-1)(s-2)\cdots(s-(l+1))(s-(l+2))\cdots(s-(l+1+\nu+1))}$$

$$+\frac{2\pi}{\Gamma(s)}\left\{V_1C_{G_1}\ \sum_{j=0}^{d_1/2-1}\ a_{2j}(1)H_{\Gamma_2}^{(j)}(s;b_1+B_1,b_2,\chi_2,G_1)\right.$$

$$\left.+V_2C_{G_2}\ \sum_{j=0}^{d_2/2-1}\ a_{2j}(2)H_{\Gamma_1}^{(j)}(s;b_2+B_2,b_1,\chi_1,G_2)\right\}$$

$$+\frac{1}{\Gamma(s)}\int_0^\infty dt\ \prod_k^2\ \theta_{\Gamma_k}(t,b_k,\chi_k)t^{s-1}. \tag{2.27}$$

The simplest case of Theorem 1 is, for example, $G_1=G_2=G=\mathrm{SO}_1(2,1)\simeq\mathrm{SL}(2,R)$; besides $X_1=X_2=H^2$ is a two-dimensional real hyperbolic space. Then we have $\rho_0^2=\rho_0^2(1)+\rho_0^2(2)=\frac{1}{4}+\frac{1}{4}=\frac{1}{2}$, $a_{20}=1$, $C_G=1$, $a(G)=\pi$, $\Gamma_1=\Gamma_2=\Gamma$, and finally $|C(r)|^{-2}=\pi r\tanh(\pi r)$. Using Eq. (2.21) of Theorem 1 for $\mathrm{Re}\,s<1$ we have

$$\begin{aligned}\zeta(s|\underset{p}{\oplus}\mathscr{L}_p)=&\frac{\pi^3V_1^2}{2(s-1)(s-2)}\int_0^\infty dr\ \mathrm{sech}^2(\pi r)\mathscr{K}_0(s-2;r^2+B,\pi)\\&+2V_1\ \sin(\pi s)\int_R dr\ r\ \tanh(\pi r)\int_0^\infty dt\ \psi_\Gamma\left(\frac{1}{2}+t+\sqrt{r^2+B};\chi\right)(2t\sqrt{r^2+B}+t^2)^{-s}\\&+\frac{1}{2\pi^3i\Gamma(s)}\int_{\mathrm{Re}\,z=\epsilon}dz\left[\sin\ \pi\left(z+\frac{s}{2}\right)\right]\left[\sin\ \pi\left(\frac{s}{2}-z\right)\right]\Gamma\left(z+\frac{s}{2}\right)\\&\times\Gamma\left(\frac{s}{2}-z\right)\int_0^\infty dt\ \psi_\Gamma\left(\frac{1}{2}+t+B_1^{1/2};\chi\right)(2tB_1^{1/2}+t^2)^{-y_1(s;z)}\int_0^\infty dt\\&\times\psi_\Gamma\left(\frac{1}{2}+t+B_2^{1/2};\chi\right)(2tB_2^{1/2}+t^2)^{-y_2(s;z)},\end{aligned} \tag{2.28}$$

where $B=\frac{1}{2}+b_1+b_2$ and $B_p=\frac{1}{4}+b_p$ $(p=1,2)$.

C. The zeta function of the product of Laplace-type operators

The spectral zeta function associated with the product $\otimes\mathscr{L}_p$ has the form

$$\zeta(s|\underset{p}{\otimes}\mathscr{L}_p)=\sum_{j\geqslant 0}n_j\prod_p^2\ (\lambda_j+b_p)^{-s}. \tag{2.29}$$

We shall always assume that $b_1\neq b_2$, say $b_1>b_2$. If $b_1=b_2$, then $\zeta(s|\otimes\mathscr{L}_p)=\zeta(2s|\mathscr{L})$ is a well-known function. For $b_1,b_2\in\mathbf{R}$, set $b_+\underset{\mathrm{def}}{=}(b_1+b_2)/2$, $b_-\underset{\mathrm{def}}{=}(b_1-b_2)/2$; thus $b_1=b_++b_-$ and $b_2=b_+-b_-$. Also let

$$I_\nu(s)=\left(\frac{s}{2}\right)^\nu\sum_{m=0}^\infty\ \frac{(s/2)^{2m}}{m!\Gamma(m+\nu+1)}. \tag{2.30}$$

Theorem 3: *The spectral zeta function can be written as follows:*

$$\zeta(s|\underset{p}{\otimes}\mathscr{L}_p)=(2b_-)^{1/2-s}\frac{\sqrt{\pi}}{\Gamma(s)}\int_0^\infty dt\ \omega_\Gamma(t,b_+)I_{s-1/2}(b_-t), \tag{2.31}$$

where the integral converges absolutely for $\mathrm{Re}\,s>d/4$ $[d=\dim(G/K)]$.

This formula is a main starting point to study the zeta function. It expresses $\zeta(s|\otimes\mathscr{L}_p)$ in terms of the Bessel function $I_{s-1/2}(b_-t)$ and $\omega_\Gamma(t,b_+)$, where the trace formula applies to $\omega_\Gamma(t,b_+)$. Thus we can study the zeta function by the trace formula. One can use the trace formula for $\omega_\Gamma(t,b_+)$; see Eq. (2.14). As a result

$$\zeta(s|\underset{p}{\otimes}\mathscr{L}_p)=(2b_-)^{1/2-s}\frac{\sqrt{\pi}}{\Gamma(s)}\int_0^\infty dt\ t^{s-1/2}I_{s-1/2}(b_-t)$$

$$\times\left[\frac{\chi(1)\mathrm{vol}(\Gamma\backslash G)}{4\pi}\int_{\mathbf{R}}dr\ e^{-(r^2+b_++\rho_0^2)t}|C(r)|^{-2}+\theta_\Gamma(t)\right]. \tag{2.32}$$

Then for $\mathrm{Re}\,s>0$ Fubini's theorem gives

$$\int_0^\infty dt\ \frac{\chi(1)\mathrm{vol}(\Gamma\backslash G)}{4\pi}\int_{\mathbf{R}}dr\ e^{-(r^2+b_++\rho_0^2)t}|C(r)|^{-2}I_{s-1/2}(b_-t)t^{s-1/2}$$

$$=(2b_-)^{1/2-s}\ \frac{\chi(1)\mathrm{vol}(\Gamma\backslash G)\Gamma(s)}{4\pi^{3/2}}\int_{\mathbf{R}}dr|C(r)|^{-2}\prod_p\ (r^2+B_p)^{-s}. \tag{2.33}$$

In order to analyze the last integral in Eq. (2.33) (for the possibility of a meromorphic continuation) it is useful to rewrite the function $|C(r)|^{-2}$ [see Eq. (2.12)], using the identity $\tanh(ar)\equiv 1-2(1+e^{2ar})^{-1}$. Then one can calculate a suitable integral in terms of the hypergeometric function $F(\alpha,\beta;\gamma;z)$, namely,

$$\int_0^\infty dr\ r^{2j+1}\prod_p\ (r^2+B_p)^{-s}=\frac{\sqrt{\pi}\Gamma(2s-j-1)j!}{2^{2s}\Gamma(s)\Gamma(s+\frac{1}{2})}\ B_1^{-s}B_2^{j+1-s}\left(\frac{2B_1}{B_1+B_2}\right)^{j+1}$$

$$\times F\left(\frac{j+1}{2},\frac{j+2}{2};s+\frac{1}{2};\left(\frac{B_1-B_2}{B_1+B_2}\right)^2\right), \tag{2.34}$$

which is a holomorphic function on $\mathrm{Re}\,s>(j+1)/2$ and admits a meromorphic continuation to $\mathbf{C}$ with only simple poles at points $s=(j+1-n)/2$, $n\in\mathcal{N}$. Let us introduce the function

$$E_j(s)\overset{\mathrm{def}}{=}2\int_0^\infty\frac{dr\ r^{2j+1}}{(1+e^{2a(G)r})}\prod_p\ (r^2+B_p)^{-s},$$

which is an entire function of s. Then a consequence of Eqs. (2.31)–(2.34) is the following.

Theorem 4: *For* $\mathrm{Re}\,s>d/4$ *the explicit meromorphic continuation holds:*

$$\zeta(s|\underset{p}{\otimes}\mathscr{L}_p)=\mathscr{F}(s)-2A\sum_{j=0}^{d/2-1}\ a_{2j}E_j(s)+\mathscr{I}(s), \tag{2.35}$$

where

$$A\overset{\mathrm{def}}{=}\frac{1}{4}\ \chi(1)\mathrm{vol}(\Gamma\backslash G)C_G,$$

$$\mathscr{F}(s)\overset{\mathrm{def}}{=}A(B_1B_2)^{-s}\sum_{j=0}^{d/2-1}\ \frac{a_{2j}j!\left(\frac{2B_1B_2}{B_1+B_2}\right)^{j+1}F\left(\frac{j+1}{2},\frac{j+2}{2};s+\frac{1}{2};\left(\frac{B_1-B_2}{B_1+B_2}\right)^2\right)}{(2s-1)(2s-2)\cdots(2s-(j+1))}, \tag{2.36}$$

$$\mathscr{I}(s)\overset{\mathrm{def}}{=}(2b_-)^{1/2-s}\ \frac{\sqrt{\pi}}{\Gamma(s)}\int_0^\infty dt\ \theta_\Gamma(t,b_+)I_{s-1/2}(b_-t)t^{s-1/2}.$$

The goal now is to compute the derivative of the zeta function at $s=0$. Thus we have

$$\zeta'(0|\underset{p}{\otimes}\mathscr{L}_p)=A\sum_{j=0}^{d/2-1}\ a_{2j}\sum_l^4\ \mathscr{E}_l, \tag{2.37}$$

where

$$\mathscr{E}_1 = j!(B_1^{j+1}+B_2^{j+1})\sum_{k=0}^{j}\frac{(-1)^{k+1}}{k!(j-k)!(j+1-k)!},$$

$$\mathscr{E}_2 = B_2^{j+1}\left(\frac{B_1-B_2}{2B_1}\right)\frac{(-1)^j}{(j+1)!}\sum_{k=1}^{\infty}\frac{(j+k+1)!}{(k+1)!}\,\sigma_k\left(\frac{B_1-B_2}{B_1}\right)^k,$$

$$\mathscr{E}_3 = \log(B_1B_2)\,\frac{(-1)^j}{2(j+1)}\,(B_1^{j+1}+B_2^{j+1}) - 4\int_0^{\infty}\frac{dr\ r^{2j+1}\log\left(\frac{r^2+B_1}{r^2+B_2}\right)}{1+e^{2a(G)r}},$$

$$\mathscr{E}_4 \equiv \mathscr{T}'(s=0) = T_\Gamma(0,b_1,\chi_1)+T_\Gamma(0,b_2,\chi_2), \tag{2.38}$$

and

$$T_\Gamma(0,b_p,\chi_p) \overset{\text{def}}{=} \int_0^{\infty} dt\ \theta_\Gamma(t,b_p)t^{-1}, \quad \sigma_k \overset{\text{def}}{=} \sum_{k=1}^{n}\frac{1}{k}. \tag{2.39}$$

Similarly using results from Ref. 49 one can show

$$\zeta'(0|\mathscr{L}_p) = A\sum_{j=0}^{d/2} a_{2j}\left\{ j!B_p^{j+1}\left[\sum_{k=0}^{j}\frac{(-1)^{k+1}}{k!(j-k)!(j+1-k)^2}+\frac{(-1)^j}{(j+1)!}\log B_p\right]\right.$$
$$\left. +4\int_0^{\infty}\frac{dr\ r^{2j+1}\log(r^2+B_p)}{1+e^{2a(G)r}}\right\} + T_\Gamma(0,b_p,\chi_p). \tag{2.40}$$

Then we can put these results together to compute the anomaly

$$\mathscr{A}(\mathscr{L}_1,\mathscr{L}_2) \overset{\text{def}}{=} \zeta'(0|\otimes\mathscr{L}_p)-\zeta'(0|\mathscr{L}_1)-\zeta'(0|\mathscr{L}_2). \tag{2.41}$$

Proposition 2: A preliminary form of the multiplicative anomaly is

$$\mathscr{A}(\mathscr{L}_1,\mathscr{L}_2) = A\sum_{j=0}^{d/2-1} a_{2j}B_2^{j+1}\left(\frac{B_1-B_2}{2B_1}\right)\frac{(-1)^j}{(j+1)!}\sum_{k=1}^{\infty}\sigma_k\left(\frac{B_1-B_2}{B_1}\right)^k\frac{(j+k+1)!}{(k+1)!}$$
$$+A\sum_p \log(B_p)\sum_{j=0}^{d/2-1} a_{2j}\,\frac{(-1)^{j+p}}{2(j+1)}\,(B_1^{j+1}-B_2^{j+1}). \tag{2.42}$$

To obtain the final explicit form of the anomaly we must compute the infinite series appearing in the statement of Proposition 2. For $0<x<1$, $j=0,1,2,...$, let

$$S_j(x) = \sum_{k=1}^{\infty}\frac{(j+k+1)!}{(k+1)!}\,\sigma_k x^k. \tag{2.43}$$

Thus in Proposition 2 we choose $x=(B_1-B_2)/B_1$. After a tedious calculation one obtains the following result.

Theorem 5: *The function $S_j(x)$ admits the representation*

$$(1-x)^{j+1}S_j(x) = P_j(x)+Q_j(x)\log(1-x), \tag{2.44}$$

where $P_j(x)$ and $Q_j(x)$ are polynomials of degree j given by

$$\frac{P_j(x)}{(j+1)!} = \frac{jx}{2}\,(1-x)^{j-1}+\frac{j(j-1)}{4}\,x^2(1-x)^{j-2}+\sum_{p=3}^{j}\frac{j!}{(p+1)!(j-p)!}$$

$$\times\left[\frac{1}{p}+\frac{1}{p-1}+\sum_{q=1}^{p-2}\frac{1}{p-q-1}\right]x^p(1-x)^{j-p},$$
$$\frac{xQ_j(x)}{(j+1)!}=-\frac{1}{j+1}\,[1-(1-x)^{j+1}]. \tag{2.45}$$

III. THE MULTIPLICATIVE ANOMALY AND ASSOCIATED ONE-LOOP CONTRIBUTIONS

In this section the product of the second-order operators of Laplace type $\otimes\mathscr{L}_p$, $p=1,2$, will be considered. We are interested in multiplicative properties of determinants, the multiplicative anomaly,[50,13,14] related with one-loop approximation in quantum field theory. This approximation can be given in terms of the multiplicative anomaly $F(\mathscr{L}_1,\mathscr{L}_2)$, which has the form

$$F(\mathscr{L}_1,\mathscr{L}_2)=\det{}_\zeta\Big[\oplus_p\mathscr{L}_p\Big]\big[\det{}_\zeta(\mathscr{L}_1)\det{}_\zeta(\mathscr{L}_2)\big]^{-1}, \tag{3.1}$$

where we assume a ζ-regularization of determinants, i.e.,

$$\det{}_\zeta(\mathscr{L}_p)\overset{\text{def}}{=}\exp\left(-\frac{\partial}{\partial s}\,\zeta(s=0|\mathscr{L}_p)\right). \tag{3.2}$$

Generally speaking, if a multiplicative anomaly related to elliptic operators is nonvanishing, then the relation $\log\det(\otimes\mathscr{L}_p)=\mathrm{Tr}\,\log(\otimes\mathscr{L}_p)$ does not hold.

The operator product $\otimes\mathscr{L}_p$ can arise in higher-derivative field theories. Note also that the partition function Z, associated with the product of two elliptic differential operators, for the simplest $O(2)$ invariant model of self-interacting charged fields in $\mathbf{R}^4$ (Ref. 51) has been analyzed recently in Ref. 15:

$$\log Z\propto-\log\det(\otimes\mathscr{L}_p). \tag{3.3}$$

We come now to a key result of this paper. Recall Eqs. (2.37) and (2.40), definition (2.41), Proposition 2, Theorem 5, and the notation $B_p=b_p+\rho_0^2(p)$, $p=1,2$, of Eq. (2.19). We assume $b_1>b_2>0$, and if $G=\mathrm{SO}_1(m,1)$ or $\mathrm{SU}(q,1)$ in Eq. (2.9), then m is even and q is odd.

Theorem 6: *The explicit formula for the multiplicative anomaly in Eq. (2.41) is*

$$\mathscr{A}(\mathscr{L}_1,\mathscr{L}_2)=A\sum_{j=0}^{d/2-1}\frac{a_{2j}(-1)^j}{2}\left\{\frac{j}{2}\,(B_1-B_2)^2B_2^{j-1}+\frac{j(j-1)}{4}\,(B_1-B_2)^3B_2^{j-2}\right.$$
$$\left.+\sum_{p=3}^{j}\frac{j!}{(p+1)p!(j-p)!}\left[\frac{1}{p}+\frac{1}{p-1}+\sum_{q=1}^{p-2}\frac{1}{p-q-1}\right](B_1-B_2)^{p+1}B_2^{j-p}\right\}, \tag{3.4}$$

where the coefficients a_{2j} are given by Eq. (2.11).

In the case $G=\mathrm{SO}_1(m,1)$ with m odd, $\mathscr{A}(\mathscr{L}_1,\mathscr{L}_2)=0$. In the special case $G=\mathrm{SO}_1(2,1)$ ($d=\dim X=2$) Theorem 6 gives $\mathscr{A}(\mathscr{L}_1,\mathscr{L}_2)=0$. In general for odd-dimensional manifolds [$X=\mathrm{SO}_1(m,1)/\mathrm{SO}(m)$ with m odd being a special case] one has $\mathscr{A}(\mathscr{L}_1,\mathscr{L}_2)=0$; see, for example, Ref. 15.

IV. THE RESIDUE FORMULA AND THE MULTIPLICATIVE ANOMALY

The value of $F(\mathscr{L}_1,\mathscr{L}_2)$ can be expressed by means of the noncommutative Wodzicki residue.[16] Let $\mathscr{O}_p$, $p=1,2$, be invertible elliptic PDOs of real nonzero orders α and β such that $\alpha+\beta\neq0$. Even if the zeta functions for operators $\mathscr{O}_1,\mathscr{O}_2$ and $\mathscr{O}_1\otimes\mathscr{O}_2$ are well defined and if their principal symbols obey the Agmon–Nirenberg condition (with appropriate spectra cuts) one has in general that $F(\mathscr{O}_1,\mathscr{O}_2)\neq1$. For such invertible elliptic operators the Wodzicki's formula for the anomaly of commuting operators holds:[15,16]

$$\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2)=\mathcal{A}(\mathcal{O}_2,\mathcal{O}_1)=\log\left(F(\mathcal{O}_1,\mathcal{O}_2)\right)=(2\alpha\beta(\alpha+\beta))^{-1}\,\mathrm{res}\left[(\log(\mathcal{O}_1^{\beta}\otimes\mathcal{O}_2^{-\alpha}))^2\right]. \tag{4.1}$$

More general formulas have been derived in Refs. 13 and 14. Furthermore, the anomaly can be iterated consistently. Indeed, using Eqs. (3.2) and (4.1) we have

$$\begin{aligned}
&\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2)=\zeta'(0|\mathcal{O}_1\mathcal{O}_2)-\zeta'(0|\mathcal{O}_1)-\zeta'(0|\mathcal{O}_2),\\
&\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\mathcal{O}_3)=\zeta'\left(0\left|\bigotimes_j^3\mathcal{O}_j\right.\right)-\sum_j^3\zeta'(0|\mathcal{O}_j)-\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2),\\
&\cdots\\
&\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\ldots,\mathcal{O}_n)=\zeta'\left(0\left|\bigotimes_j^n\mathcal{O}_j\right.\right)-\sum_j^n\zeta'(0|\mathcal{O}_j)-\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2)-\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\mathcal{O}_3)\cdots\\
&\qquad-\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\ldots,\mathcal{O}_{n-1}).
\end{aligned} \tag{4.2}$$

In particular, for $n=2$ and $\mathcal{O}_p\equiv\mathcal{L}_p$ the explicit form of anomaly is given by Eq. (2.41) and Theorem 6. We note that for the four-dimensional space with $G=\mathrm{SO}_1(4,1)$, one derives from Theorem 6 the result

$$\mathcal{A}(\mathcal{L}_1,\mathcal{L}_2)=-A_G(b_1-b_2)^2,\quad d=4, \tag{4.3}$$

which also follows from Wodzicki's formula (4.1), where $A_G=\frac{1}{4}Aa_2$.

V. CONCLUSIONS

In this paper the global additive and multiplicative properties of Laplace-type operators and related zeta functions have been studied. We have considered product structures on Einstein manifolds, especially on an irreducible rank 1 symmetric space.

In fact the explicit form of the zeta function on product spaces (Theorem 1) is derived. As an example the zeta function associated with the Kronecker sum of Laplacians acting on two-dimensional real hyperbolic spaces is calculated.

We have obtained also the explicit formula for the multiplicative anomaly in the main theorem, Theorem 6. It has been shown that the anomaly is equal to zero for $d=2$ and for the odd-dimensional cases; this result is in agreement with the calculation given in Ref. 15. We have preferred to limit ourselves here to discussing in detail various particular cases and emphasizing the general picture. It seems to us that the explicit results for the anomaly (3.4) and (4.3) are not only interesting as mathematical results but are of physical interest, in view of future applications to concrete problems in field theory and gravity, both at classical and quantum level. Note also that spectral properties of products of differential operators related to higher spin fields might differ in principal from the properties considered in this paper; we hope to return to this problem elsewhere.

ACKNOWLEDGMENTS

We thank Professor E. Elizalde, Professor L. Vanzo, and Professor S. Zerbini for useful discussions. A. A. Bytsenko wishes to thank CNPq and the Department of Physics of Londrina University for financial support and kind hospitality. The research of A. A. Bytsenko was supported in part by Russian Foundation for Fundamental Research Grant No. 95-02-03568-a and by Russian Universities Grant No. 95-0-6.4-1.

Clebsch–Gordan coefficients in the asymptotic limit

Hubert de Guise[a] and David J. Rowe
Department of Physics, University of Toronto, Toronto, Ontario M5S 1A7, Canada

(Received 24 March 1997; accepted for publication 12 September 1997)

We investigate the graded structure of the tensor product space $V^{\lambda_2}\otimes V^{\lambda_1}$, which arises in the coupling of two irreducible representations λ_1 and λ_2 of a semisimple Lie algebra $\mathcal{G}$, in the limit in which one of the highest weights becomes asymptotically large. The construction of asymptotic coupling coefficients is considered.

I. INTRODUCTION

It is known that every unitary irreducible representation (unirrep) of a compact semisimple Lie group is characterized by a highest weight $\lambda=(\lambda^1,\lambda^2,\lambda^3,\ldots)$. Often, the unirreps of physical interest of noncompact semisimple Lie groups are likewise characterized by extremal (highest or lowest) weights.

In this paper, we consider the tensor product $V^{\lambda_2}\otimes V^{\lambda_1}$ of modules for two unirreps of highest weights λ_1 and λ_2 of a semisimple Lie algebra $\mathcal{G}$ in the limit in which λ_1 becomes asymptotically large. (A weight λ is said to be asymptotically large if one or more of its components is asymptotically large.) We show that $V^{\lambda_2}\otimes V^{\lambda_1}$ is expressible as a sum of graded subspaces which carry representations of a subalgebra $\mathcal{H}\subset\mathcal{G}$, where $\mathcal{H}$ is uniquely determined by specification of which components of λ_1 are asymptotically large. We also show that the graded subspaces of $V^{\lambda_2}\otimes V^{\lambda_1}$ are simple products of graded subspaces of V^{λ_1} and V^{λ_2}. This factorization implies simple expressions for the Clebsch–Gordan coupling coefficients of $\mathcal{G}$ in the asymptotic limit.

Our motivation for studying asymptotic limits arises because the limiting process is generally associated with group contractions. Thus if a noncompact group of interest is the asymptotic limit of a compact group, one can determine, for instance, Clebsch–Gordan coefficients for the noncompact group by taking the asymptotic limit of Clebsch–Gordan coefficients for the corresponding compact group.

An interesting example of this procedure can be found in the work of W. T. Sharp.[1] Sharp was able to obtain formulas for various products of Bessel functions by considering them as contractions of Legendre functions (see Ref. 2, Sec. 5.71). The coupling coefficients for Bessel functions then emerged naturally as asymptotic limits of ordinary SO(3) coupling coefficients.

Our analysis is appropriate for the less ambitious task of computing some coupling coefficients involving one representation of a group and one representation of its contraction. The need for such coupling coefficients arises in physics when quantum numbers become large. For example, it is well known, in nuclear physics, that the representations of su(3) approach those of the noncompact rigid rotor algebra for large values of the su(3) highest weight.[3] The asymptotic properties of tensor product spaces are also needed for other purposes. For example, they were recently considered by Rowe and Repka[4] in the construction of the coherent shift tensors of Flath and Towber.[5]

The nontrivial unitary representations of a noncompact group are usually infinite dimensional, even when their extremal weights are finite. To avoid confusion, we use the adjective ''asymptotic'' rather than ''infinite'' to describe properties which approach infinity as one or many components of an extremal weight become large. Thus, in the asymptotic limit, the number of basis states in a unirrep of a compact group becomes asymptotically large. Similarly, some chains of weights, which would be finite for finite highest weights, become asymptotic chains in the limit.

The paper is organized as follows. Sections II and III A, respectively, deal with the basics of grade space decompositions and provide definitions and examples of asymptotic representations. We give, in Sec. III B, results for highest weight states of semisimple compact Lie algebras, starting with su(2) and followed by the general case of any semisimple compact rank N Lie algebras (with N finite) in III C. In Sec. III D, the theory of the previous section is applied to the Lie algebra su(3). The main result on asymptotic Clebsch–Gordan coefficients is presented in Sec. III E.

Although close in spirit to the corresponding compact cases, the results for the noncompact cases only apply to some of the representations appearing in the decomposition of the tensor product of two unirreps of the positive (or negative) discrete series. The results for noncompact cases are specialized to sp(m,R) and presented in Sec. IV, starting with sp(1,R) and followed by sp(m,R).

Section V deals with the coupling of a finite dimensional, nonunitary representation to an asymptotic unirrep.

II. GRADE-SPACE DECOMPOSITIONS

In calculating Clebsch–Gordan coefficients for a semisimple Lie algebra $\mathscr{G}$, in a basis which reduces a subalgebra $\mathscr{H}\subset\mathscr{G}$, one encounters a need to decompose tensor products of $\mathscr{G}$-invariant spaces into irreducible $\mathscr{G}$- and $\mathscr{H}$-invariant subspaces. Thus, if V^λ is a module for a unirrep of $\mathscr{G}$ with highest weight λ, we need to express $W=V^{\lambda_2}\otimes V^{\lambda_1}$ as a sum

$$W=\sum_{\rho\lambda} W^{\rho\lambda}=\sum_{\rho\lambda\,\gamma\omega} W^{\rho\lambda}_{\gamma\omega}, \tag{1}$$

where ρ indexes the multiplicity of $\mathscr{G}$-invariant subspaces $\{W^{\rho\lambda}\}$ of highest weight λ in W and γ indexes the multiplicity of $\mathscr{H}$-invariant subspaces of highest weight ω in $W^{\rho\lambda}$.

Such a decomposition is simplest when $\mathscr{H}$ is a reductive subalgebra of $\mathscr{G}$ containing the Cartan subalgebra $\mathscr{T}$ and a subset of simple root vectors for $\mathscr{G}$. The Lie algebra $\mathscr{G}$ can then be expressed as a sum of graded subspaces

$$\mathscr{G}=\sum_k \mathscr{G}_k, \tag{2}$$

in which $\mathscr{H}=\mathscr{G}_0$ is the zero-grade subspace and $\mathscr{G}_1$ is the $\mathscr{H}$-invariant subspace of $\mathscr{G}$ containing all simple root vectors not in $\mathscr{H}$. It then follows that

$$[\mathscr{G}_k,\mathscr{G}_l]\subseteq\mathscr{G}_{k+l}. \tag{3}$$

This grading induces a corresponding grading $V=\Sigma_l V_l$ of any module for a representation of $\mathscr{G}$ with the property

$$\mathscr{G}_k: V_l\to V_{k+l}. \tag{4}$$

It will be convenient to introduce the notation $[\omega]$ to denote the grade of a weight ω. Of particular importance is the highest grade subspace $V^\lambda_{[\lambda]}$, since it is the subspace of V^λ containing the highest weight state. This is because the highest grade subspace $V^\lambda_{[\lambda]}$ of an irreducible $\mathscr{G}$-module is an irreducible $\mathscr{H}$-module having the same highest weight.

We denote by $W^k\subset W$ the sum of $\mathscr{G}$-invariant subspaces of $W=V^{\lambda_2}\otimes V^{\lambda_1}$ whose highest weight states are of grade k. Let $W^k=\Sigma_l W^k_l$ be the grade-space decomposition of W^k so that

$$W=\sum_k W^k=\sum_{kl} W^k_l. \tag{5}$$

W^k can in turn be expressed as

$$W^k=\sum_{\rho\lambda} W^{\rho\lambda}, \qquad [\lambda]=k, \tag{6}$$

where $W^{\rho\lambda}$ is as in Eq. (1) but the sum is restricted to highest weights which satisfy $[\lambda]=k$, and

$$W_l^k=\sum_{\rho\lambda} W_l^{\rho\lambda}=\sum_{\rho\lambda}\sum_{\gamma\omega} W_{\gamma\omega}^{\rho\lambda}, \qquad [\lambda]=k\ ,[\omega]=l\ , \tag{7}$$

where $W_{\gamma\omega}^{\rho\lambda}$ is also as in Eq. (1) but the sum is now restricted by the condition $[\omega]=l$.

The grade-space decomposition of W is the first step towards obtaining the full decomposition of Eq. (1). Moreover, if one already knows the Clebsch–Gordan coefficients for the subalgebra $\mathscr{H}$, it is the most important step in the evaluation of asymptotic Clebsch–Gordan coefficients for, as we show in the following, the subspaces W_l^k acquire the very simple expressions

$$W_l^k \to V^{\lambda_2}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]-k+l}\ , \tag{8}$$

in suitable asymptotic limits. A consequence of Eq. (8) is that asymptotic Clebsch–Gordan coefficients for $\mathscr{G}$ can be reduced to Clebsch–Gordan coefficients for $\mathscr{H}$.

III. COMPACT, SEMISIMPLE LIE ALGEBRAS

For a compact, semisimple Lie algebra, the highest weights are dominant integral (i.e., nonnegative and integer valued). [For su(2) it will be convenient to follow the physics convention of labeling irreps by the angular momentum j which can take integer or half-odd integer values. Thus the su(2) angular momentum is half the standard, integer-valued, weight.]

A. Asymptotic representations

We follow the convention of saying that a unirrep is asymptotic if its highest weight is asymptotically large, and simply write $\lambda\to\infty$ if one or more components of λ are asymptotically large. We will denote by $\Delta_+=\{\alpha_1,\alpha_2,\ldots,\alpha_N,\alpha_{N+1},\ldots,\alpha_q\}$ an ordered set of positive roots of $\mathscr{G}$ such that the first N are simple, i.e., $\{\alpha_1,\ldots,\alpha_N\}$ is a basis for Δ_+, and denote by $\{e_1,e_2,\ldots,e_N,e_{N+1},\ldots,e_q\}$ the corresponding root vectors.

If α_k is a root and ω is a weight, then we shall refer to the set of weights of the type $\omega+n\alpha_k$ (n is an integer) that occur within the weight space of a given irrep as an α_k-string. An α_k-string can be labeled by its highest weight. Then, if an α_k-string has highest weight $2j$, its weights are those of an su(2) irrep of angular momentum j. An α_k-string will be said to be asymptotic if and only if $j\to\infty$ as $\lambda\to\infty$.

Let Δ_+ be expressed as the sum of two subsets $\Delta_+=\mathscr{L}_+ +\mathscr{F}_+$, defined as follows. A positive root $\alpha_k\in\Delta_+$ is an element of $\mathscr{L}_+$ if the α_k-string of weights through the highest weight state $|\lambda\rangle$ of V^λ is an asymptotic string, whereas it is an element of $\mathscr{F}_+$ if the α_k-string is not asymptotic. Corresponding sets, $\Delta_-,\mathscr{L}_-$, and $\mathscr{F}_-$, contain the negatives of the roots in $\Delta_+,\mathscr{L}_+$, and $\mathscr{F}_+$, respectively.

If all the components of λ are finite, then $\mathscr{L}_+=\varnothing$ and $\mathscr{F}_+=\Delta_+$. Figure 1(b) is an example of a representation of a rank 2 compact algebra where λ^2, the second component of the highest weight λ, is asymptotically large. In Fig. 1(a), $\alpha_1\in\mathscr{F}_+$, while α_2 and all the other positive roots belong to $\mathscr{L}_+$. In a situation where all the components of the weight are asymptotically large, $\mathscr{F}_+=\varnothing$ and $\mathscr{L}_+=\Delta_+$.

The separation of Δ_+ into subsets $\Delta_+=\mathscr{L}_+ +\mathscr{F}_+$ leads to a grading of $\mathscr{G}$ of the type given in Eq. (2), in which $\mathscr{H}=\mathscr{G}_0$ contains a Cartan subalgebra $\mathscr{T}$ for $\mathscr{G}$ as well as all root vectors whose roots are in $\mathscr{F}_+$ and $\mathscr{F}_-$. The complementary nilpotent subalgebras

$$\mathscr{N}_+=\sum_{k\geqslant 1}\mathscr{G}_k \quad \text{and} \quad \mathscr{N}_-=\sum_{k\geqslant 1}\mathscr{G}_{-k} \tag{9}$$

are spanned by root vectors whose roots are in $\mathscr{L}_+$ and $\mathscr{L}_-$, respectively.

For example, for an asymptotic representation of $\mathscr{G}=$ su(2), $\mathscr{N}_\pm=\mathscr{G}_\pm$ are the one-dimensional algebras spanned by $J_\pm$, respectively, and $\mathscr{H}$ is the Cartan subalgebra of su(2) spanned by J_0. In the example of Fig. 1(a), $\mathscr{H}$ is spanned by $\mathscr{T}$, e_1, and f_1 while $\mathscr{N}_\pm$ contain the remaining positive and negative root vectors, respectively.

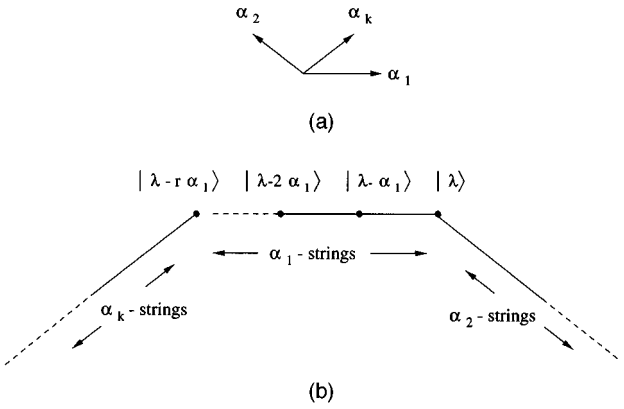

FIG. 1. Example of the weight diagram of a unirrep λ, with $\lambda^2 \to \infty$. (a) Some roots of a rank 2 algebra; (b) An asymptotically large irrep of this algebra.

Throughout this paper, we will assume that the Lie algebra $\mathscr{G}=\Sigma_k \mathscr{G}_k$ is graded such that $\mathscr{G}_1$ is spanned by simple root vectors $\{e_i\}$ for which the corresponding α_i-chains are asymptotically long in the limit where $\lambda_1 \to \infty$. Thus $\mathscr{G}_+$ will always contain positive roots of $\mathscr{G}$ that are asymptotic for the irrep λ_1.

B. Highest grade subspaces of su(2)

The generators of su(2) satisfy the well-known commutation relations

$$[J_0, J_\pm] = \pm J_\pm, \quad [J_+, J_-] = 2J_0, \tag{10}$$

with matrix elements given by

$$J_0|jm\rangle = m|jm\rangle, \quad m = j, j-1, \ldots, -j,$$
$$J_\pm|jm\rangle = \sqrt{(j \mp m)(j \pm m + 1)}\ |j, m+1\rangle. \tag{11}$$

Lemma 1: The highest weight state $|jj\rangle$ of an su(2) unirrep j appearing in the decomposition of the tensor product $j_2 \otimes j_1$ is given, when j_2 is finite and $j_1 \to \infty$, by

$$\lim_{j, j_1 \to \infty} |jj\rangle = |j_2\ \Delta\rangle\ |j_1 j_1\rangle, \qquad \Delta = j - j_1. \tag{12}$$

Proof: Consider the state

$$|jj\rangle = \sum_{m_1 m_2} (j_1\ m_1; j_2\ m_2 | j\ j) |j_2\ m_2\rangle |j_1\ m_1\rangle. \tag{13}$$

Since $m_1 + m_2 = j$, we must have $m_1 = j_1, m_2 = j_2$ when $j = j_1 + j_2$. There is then only one term in the sum and the appropriate coupling coefficient is 1. Thus Eq. (12) holds trivially when $\Delta = j_2$.

When $\Delta = j - j_1 \neq j_2$, we have, in general, more than one term in the sum (13). The equation

$$0 = [\langle j_2 m_2| \langle j_1 m_1|] L_+ |jj\rangle = (j_1\ m_1 - 1; j_2\ m_2 | j\ j) \sqrt{j_1(j_1+1) - m_1(m_1-1)}$$
$$+ (j_1\ m_1; j_2\ m_2 - 1 | j\ j) \sqrt{j_2(j_2+1) - m_2(m_2-1)} \tag{14}$$

implies that the Clebsch–Gordan coefficients satisfy the equation

$$\frac{(j_1\ m_1 - 1; j_2\ m_2 | j\ j)}{(j_1\ m_1; j_2\ m_2 - 1 | j\ j)} = -\sqrt{\frac{j_2(j_2+1) - m_2(m_2-1)}{j_1(j_1+1) - m_1(m_1-1)}}, \tag{15}$$

and hence that

$$\frac{(j_1\ j_1-n;j_2\ m_2|j\ j)}{(j_1\ j_1-n+1;j_2\ m_2-1|j\ j)}=-\sqrt{\frac{j_2(j_2+1)-m_2(m_2-1)}{2nj_1-n(n-1)}}\,, \tag{16}$$

$$\lim_{j_1\to\infty}\frac{(j_1\ j_1-n;j_2\ m_2|j\ j)}{(j_1\ j_1-n+1;j_2\ m_2-1|j\ j)}=-\sqrt{\frac{j_2(j_2+1)-m_2(m_2-1)}{2nj_1}}\,, \tag{17}$$

where n is in the range $0\leqslant n\leqslant 2j_2$. It follows that, for $\Delta<j_2$,

$$\lim_{j_1\to\infty}\frac{(j_1\ j_1-n;j_2\ m_2|j\ j)}{(j_1\ j_1;j_2\ \Delta|j\ j)}<\frac{(-1)^n}{\sqrt{n!}}(2j_1)^{-n/2}[j_2(j_2+1)-\Delta(\Delta+1)]^{n/2}\,. \tag{18}$$

The coupling coefficients are normalized such that

$$\sum_{m_1m_2}|\,(j_1\ m_1;j_2\ m_2|j\ j)|^2=1\,. \tag{19}$$

This sum contains finitely many terms because m_2 ranges over finitely many values. Thus, using Eq. (18), the only nonvanishing contribution to the above sum, in the limit $j_1\to\infty$, is from the term $(j_1\ j_1;j_2\ \Delta|j\ j)$. Furthermore, we must have $|(j_1\ j_1;j_2\ \Delta|j\ j)|=1$. Hence the highest weight state approaches the simple form of Eq. (12), i.e.,

$$|j\ j\rangle\overset{j_1,j\to\infty}{\to}|j_2\ \Delta\rangle|j_1\ j_1\rangle\,, \tag{20}$$

and the proof is complete.

The converse result, that every product state of the type $|j_2\Delta\rangle|j_1j_1\rangle$ becomes a highest weight state $|jj\rangle$ with $j=j_1+\Delta$ as $j_1\to\infty$, is easily shown starting from the general expression

$$|j_2\Delta\rangle|j_1j_1\rangle=\sum_j\,|j,j_1+\Delta\rangle\,(j_1\ j_1;j_2\ \Delta|j\ j_1+\Delta)\,. \tag{21}$$

All of these asymptotic properties can be verified directly from the exact expression[6]

$$(j_1\ m_1;j_2\ m_2|J\ J)=(-1)^{j_1-m_1}\times\sqrt{\frac{(2J+1)!(j_1+j_2-J)!(j_1+m_1)!(j_2+m_2)!}{(j_1+j_2+J+1)!(j_1-j_2+J)!(-j_1+j_2+J)!(j_1-m_1)!(j_2-m_2)!}}\,. \tag{22}$$

The above lemma can be seen as a special case of Eq. (8) by observing first that, for su(2), $\mathscr{H}$ is the u(1) $\subset$ su(2) subalgebra spanned by J_0, so that the graded subspaces of W contain states of a given m value. Since the su(2) coupling is multiplicity free, the subspaces W^k of Eq. (5) contain a single su(2) unirrep and the subspace W^j_j contains only the highest weight state of the unirrep j. Thus, in the notation of Sec. II, Eq. (12) is equivalent to the statement

$$\lim_{j,j_1\to\infty}W^j_j=V^{j_2}_{j-j_1}\otimes V^{j_1}_{j_1}\,. \tag{23}$$

C. Highest grade subspaces of rank *N* Lie algebras

Lemma 2: Let V^λ denote the carrier space for a unirrep of $\mathscr{G}$ of highest weight λ and let W be the tensor product $W=V^{\lambda_2}\otimes V^{\lambda_1}$. Let W^k be the $\mathscr{G}$-invariant subspace of W containing the highest weight states of grade k. Then, the highest grade subspace $W^k_k\subset W^k\subset W$ is given asymptotically by

$$W_k^k \to V^{\lambda_2}_{k-[\lambda_1]} \otimes V^{\lambda_1}_{[\lambda_1]}, \quad \text{as} \quad \lambda_1 \to \infty . \tag{24}$$

Proof: Since W_k^k is the highest grade subspace of the $\mathscr{G}$-invariant subspace $W^k \subset W$, it follows that, if $|\Psi\rangle \in W_k^k$, then $e_i|\Psi\rangle = 0$, $\forall e_i \in \mathscr{N}_+$. Let $\mathscr{A}_i$ denote an su(2) subalgebra of $\mathscr{G}$ with a positive root $\alpha_i \in \mathscr{L}_+$, where we recall that $\mathscr{L}_+$ contains the positive roots of $\mathscr{G}$ which are asymptotic for the irrep λ_1.

Since $e_i|\Psi\rangle = 0$ for any $|\Psi\rangle \in W_k^k$, it follows that W_k^k is spanned by a set of states which are all highest weight states for unirreps of $\mathscr{A}_i$. Moreover, since $\alpha_i \in \mathscr{L}_+$, it follows that such a highest weight state $|\Psi\rangle$ is an asymptotic su(2) highest weight state for the su(2) subalgebra generated by e_i and f_i. Therefore, by *Lemma 1*, $|\Psi\rangle = |\varphi\rangle|\psi\rangle$ is a product of a state $|\varphi\rangle \in V^{\lambda_2}$ and a state $|\psi\rangle \in \sigma_i$, where

$$\sigma_i = \{|\psi\rangle \in V^{\lambda_1}; \quad e_i|\psi\rangle = 0\} . \tag{25}$$

Since this result holds for all $\mathscr{A}_i \subset \mathscr{G}$ with $\alpha_i \in \mathscr{L}_+$, and since

$$V^{\lambda_1}_{[\lambda_1]} = \{|\psi\rangle \in V^{\lambda_1} \ ; e_i|\psi\rangle = 0, \quad \forall \alpha_i \in \mathscr{L}_+\} \tag{26}$$

it follows, in the asymptotic limit, that every state in W_k^k lies in $V^{\lambda_2}_{k-[\lambda_1]} \otimes V^{\lambda_1}_{[\lambda_1]}$. The converse likewise follows from the converse of *Lemma 1*. This completes the proof.

The decomposition of a highest grade subspace W_k^k is a special case of Eq. (7) since, in W_k^k, a highest weight state for a unirrep of $\mathscr{G}$ is also a highest weight state for a unirrep of $\mathscr{H}$. Therefore, we have, in the notation of Eq. (7),

$$W_k^k = \sum_{\rho\lambda} W_\lambda^{\rho\lambda}, \qquad [\lambda] = k . \tag{27}$$

By the same argument, $V^{\lambda_1}_{[\lambda_1]}$ is irreducible under $\mathscr{H}$, since V^{λ_1} is irreducible under $\mathscr{G}$. This implies that $V^{\lambda_1}_{[\lambda_1]} = V^{\lambda_1}_{\lambda_1}$. On the other hand, $V^{\lambda_2}_{k-[\lambda_1]}$ is a sum of $\mathscr{H}$-irreducible subspaces

$$V^{\lambda_2}_{k-[\lambda_1]} = \sum_{\gamma\omega_2} V^{\lambda_2}_{\gamma\omega_2}, \qquad [\omega_2] = k - [\lambda_1]. \tag{28}$$

Now, let $[V^{\lambda_2}_{\gamma\omega_2} \otimes V^{\lambda_1}_{\lambda_1}]_{\alpha\omega}$ denote the $\mathscr{H}$-coupled tensor product of irreducible $\mathscr{H}$-modules, where ω is a highest weight for an $\mathscr{H}$-unirrep and α indexes its multiplicity in the tensor product space $V^{\lambda_2}_{\gamma\omega_2} \otimes V^{\lambda_1}_{\lambda_1}$. It follows from the lemma that

$$W_k^k = \sum_{\rho\lambda} W_\lambda^{\rho\lambda} \to \sum_{\lambda} \sum_{\gamma\omega_2\alpha} [V^{\lambda_2}_{\gamma\omega_2} \otimes V^{\lambda_1}_{\lambda_1}]_{\alpha\lambda}, \qquad [\lambda] = k \tag{29}$$

and

$$W_\lambda^{\rho\lambda} \to \sum_{\gamma\omega_2\alpha} C^\lambda_{\rho,\gamma\omega_2\alpha} [V^{\lambda_2}_{\gamma\omega_2} \otimes V^{\lambda_1}_{\lambda_1}]_{\alpha\lambda}, \tag{30}$$

where C^λ is a $\rho \times \rho$ matrix which combines equivalent unirreps of $\mathscr{H}$.

Now, if τ indexes a basis $\{|\Psi_\tau^{\rho\lambda}\rangle\}$ for $W_\lambda^{\rho\lambda}$, we can write

$$|\Psi_\tau^{\rho\lambda}\rangle = \sum_{\substack{\gamma\omega_2\alpha \\ ij}} C^\lambda_{\rho,\gamma\omega_2\alpha} \ (\lambda_1 \ i; \omega_2 \ j | \alpha\lambda \ \tau) |\varphi^{\lambda_2}_{\gamma\omega_2 j}\rangle |\psi_i^{\lambda_1}\rangle , \tag{31}$$

where i indexes a basis $\{|\psi_i^{\lambda_1}\rangle\}$ for $V^{\lambda_1}_{\lambda_1}$, j indexes a basis $\{|\varphi^{\lambda_2}_{\gamma\omega_2 j}\rangle\}$ for $V^{\lambda_2}_{\gamma\omega_2}$, and $(\lambda_1 \ i; \omega_2 \ j | \alpha\lambda \ \tau)$ is a Clebsch–Gordan coupling coefficient for $\mathscr{H}$.

The matrix C^{λ} depends only on the way in which the multiplicities ρ and α of the $\mathscr{H}$-unirrep λ are separated. Since this separation is arbitrary, there exists a choice of ρ and α that will make C^{λ} diagonal. This implies a remarkable property of asymptotic coupling coefficients for basis states of $\mathscr{G}$ in W_k^k: they can always be chosen to be equal to coupling coefficients for the subalgebra $\mathscr{H}\subset\mathscr{G}$.

D. An example: su(3)

The coupling of two su(3) unirreps provides the simplest application of Eq. (31). For su(3), we have a Cartan subalgebra $\mathscr{T}$ with basis $\{h_1,h_2\}$ and positive roots $\Delta_+=\{\alpha_1,\alpha_2,\alpha_3\}$, where α_1 and α_2 are simple roots, and $\{e_1,e_2,e_3\}$ are the corresponding raising operators. Let $|\psi^{\lambda}_{\beta\sigma}\rangle$ denote a state of weight $\sigma=(\sigma^1,\sigma^2)$ of an su(3) unirrep of highest weight λ, where β indexes multiple occurrences of the weight σ; the label β will be suppressed when not needed. The highest weight state of the unirrep $\lambda=(\lambda^1,\lambda^2)$ will be denoted by $|\lambda\rangle=|\psi^{\lambda}_{\lambda}\rangle$.

We will consider the tensor product of two su(3) unirreps $\lambda_2\otimes\lambda_1$ in the limit in which, say, the second component λ_1^2 of λ_1 is asymptotically large. Then, $\mathscr{T}_+=\{\alpha_1\}$, $\mathscr{L}_+=\{\alpha_2,\alpha_3\}$, and $\mathscr{H}$ is the subalgebra of $\mathscr{G}$ spanned by $\{e_1,f_1,h_1,h_2\}$, where e_1 and f_1 are root vectors corresponding to the roots α_1 and α_{-1}, respectively.

We choose h_1 and h_2 such that

$$[h_1,e_1]=2e_1,\quad [h_1,f_1]=-2f_1,\quad [e_1,f_1]=h_1, \tag{32}$$

and

$$h_1|\psi^{\lambda}_{\beta\sigma}\rangle=\sigma^1|\psi^{\lambda}_{\beta\sigma}\rangle\ ,\quad h_2|\psi^{\lambda}_{\beta\sigma}\rangle=\sigma^2|\psi^{\lambda}_{\beta\sigma}\rangle\ . \tag{33}$$

$\mathscr{H}$ is then the direct sum $\mathscr{H}=\mathrm{su}(2)+\mathrm{u}(1)$, where su(2) is the algebra spanned by e_1,f_1, and h_1, and u(1) is spanned by h_2. Since states of a given grade have identical values of σ^2, we can identify the grade with σ^2.

The subspace $V^{\lambda_1}_{[\lambda_1]}$ contains states with the property

$$V^{\lambda_1}_{[\lambda_1]}=\{|\psi\rangle\in V^{\lambda_1};e_i|\psi\rangle=0,\ \ i=2,3\}\ . \tag{34}$$

States in $V^{\lambda_1}_{[\lambda_1]}$ are generated from the highest weight state $|\lambda_1\rangle$ by repeatedly acting on $|\lambda_1\rangle$ with the lowering operator f_1. Thus they carry a unirrep of angular momentum $j_1=\lambda_1^1/2$ of su(2) $\subset\mathscr{H}$ and a unirrep λ_1^2 of u(1) $\subset\mathscr{H}$. The state $|\lambda_1-r\alpha_1\rangle$ [see Fig. 1(b)], which is obtained by lowering r times from $|\lambda_1\rangle$, can be written, in an $\mathscr{H}=$ su(2)+u(1) basis,

$$|\lambda_1-r\alpha_1\rangle=|\psi^{\lambda_1}_{j_1m_1\lambda_1^2}\rangle\ , \tag{35}$$

where $m_1=j_1-r$.

The subspace $V_l^{\lambda_2}\subset V^{\lambda_2}$ has decomposition into $\mathscr{H}$-irreducible subspaces given, in the notation of Eq. (28), by

$$V_l^{\lambda_2}=\sum_{j_2}\ V^{\lambda_2}_{j_2\sigma^2}\ ,\quad \sigma^2=l\ , \tag{36}$$

where the multiplicity label γ of Eq. (28) is suppressed because the unirrep $j_2\sigma^2$ occurs at most once in $V_l^{\lambda_2}$. An su(2)+u(1) basis for $V^{\lambda_2}_{j_2\sigma^2}$ is then given by $\{|\varphi^{\lambda_2}_{j_2m_2\sigma^2}\rangle\ ;m_2=-j_2,\ldots,j_2.\}$.

From *Lemma 2*, we know that a basis for W_k^k is given by products of the type $|\varphi^{\lambda_2}_{j_2m_2\sigma^2}\rangle|\psi^{\lambda_1}_{j_1m_1\lambda_1^2}\rangle$, with $k=\lambda_1^2+\sigma^2$. These states can be combined to form a good su(2)+u(1)-coupled basis $\{|\Psi_{JMk}\rangle\}$ for W_k^k with

$$|\Psi_{JMk}\rangle=[|\varphi^{\lambda_2}_{j_2\sigma^2}\rangle\otimes|\psi^{\lambda_1}_{j_1\lambda_1^2}\rangle]^{Jk}_M=\sum_{m_1m_2}\ (j_1\ m_1;j_2\ m_2|J\ M)|\varphi^{\lambda_2}_{j_2m_2\sigma^2}\rangle|\psi^{\lambda_1}_{j_1m_1\lambda_1^2}\rangle\ , \tag{37}$$

where $(j_1\ m_1;j_2\ m_2|J\ M)$ is an ordinary su(2) coupling coefficient. The u(1) coupling is fulfilled by the requirement that $\lambda_1^2+\sigma^2=k$.

Since W_k^k is a highest grade subspace, an su(2)+u(1) highest weight state $|\Psi_{JJk}\rangle$ is also a highest weight state for an su(3) unirrep of highest weight $\lambda=(\lambda^1=2J,\lambda^2=k)$. We then have the identification $|\Psi_{JJk}\rangle=|\lambda\rangle$.

Although the su(2)+u(1) coupling is multiplicity-free, there may be more than one $|\Psi_{JJk}\rangle$ (and hence more than one occurrence of $|\lambda\rangle$) because, in general, $V_l^{\lambda_2}$ contains more than one value of j_2 such that the coupling $j_2\otimes j_1\rightarrow J$ exists. Since there is one copy of $|\Psi_{JJk}\rangle$ for every j_2 satisfying the above condition, an obvious way to distinguish these multiple copies of $|\Psi_{JJk}\rangle$ is to label them with j_2. Highest weight states for the su(2)+u(1) unirrep Jk will henceforth be denoted $|\Psi_{j_2JJk}\rangle$.

If ρ labels multiple occurrences of the su(3) highest weight state $|\lambda\rangle$, the set $\{|\rho\lambda\rangle\}$ may still differ from $\{|\Psi_{j_2JJk}\rangle\}$ by an arbitrary unitary transformation; this is the matrix C^λ of Eq. (31). Thus, the identification $\rho\leftrightarrow j_2$, which provides a convenient resolution of the multiplicities in the $\lambda_2\otimes\lambda_1\rightarrow\lambda$ coupling, makes this matrix diagonal. Furthermore, for this choice, we have

$$|j_2\lambda\rangle=\sum_{m_1m_2}(j_1\ m_1;j_2\ m_2|J\ J)|\varphi^{\lambda_2}_{j_2m_2\sigma^2}\rangle|\psi^{\lambda_1}_{j_1m_1\lambda_1^2}\rangle\ , \tag{38}$$

where $2J=\lambda^1$ and $\lambda_1^2+\sigma^2=\lambda^2$. Other states with $M\neq J$ are obtained by lowering with f_1, and we have, in general,

$$|j_2\lambda\,\tau\rangle=\sum_{m_1m_2}(j_1\ m_1;j_2\ m_2|J\ M)|\varphi^{\lambda_2}_{j_2m_2\sigma^2}\rangle|\psi^{\lambda_1}_{j_1m_1\lambda_1^2}\rangle\ , \tag{39}$$

where $2M=\tau$.

Thus, in the limit where one component of λ_1 becomes asymptotically large, we find that su(3) coupling reduces to su(2)+u(1) coupling, with

$$(\lambda_1j_1m_1\sigma_1^2,\lambda_2j_2m_2\sigma_2^2|\rho\lambda\,\tau)\rightarrow\delta_{\rho,j_2}\delta_{\sigma_1^2,\lambda_1^2}(j_1m_1,j_2m_2|JM)\ . \tag{40}$$

This conclusion is confirmed when we take the limit of the expressions obtained, for instance, by Hecht[7] for some su(3) coupling coefficients (cf. also Rowe and Repka[8]).

Suppose now that both components $(\lambda_1^1,\lambda_1^2)$ of λ_1 are asymptotically large. Since $2j_1=\lambda_1^1$ and $2J=\lambda^1$, the coupling coefficient appropriate to this case is obtained from Eq. (40) by taking the limit of the su(2) coefficient:

$$\lim_{\lambda_1,\lambda\rightarrow\infty}(\lambda_1j_1m_1\sigma_1^2,\lambda_2j_2m_2\sigma_2^2|\rho\lambda\,\tau)\rightarrow\delta_{\rho,j_2}\delta_{\sigma_1^2,\lambda_1^2}\ \times\ \lim_{j_1,J\rightarrow\infty}(j_1m_1,j_2m_2|JM)\ . \tag{41}$$

In the next section, we show how Clebsch–Gordan coefficients of the type $(j_1m_1,j_2m_2|JM)$ can be evaluated in the $j_1\rightarrow\infty$ limit.

E. Asymptotic Clebsch–Gordan coefficients

Let $\mathcal{G}$ be a compact semisimple Lie algebra of rank N, and let V^{λ_1}, V^{λ_2} be defined as before.

Lemma 3: Let $|\varphi\rangle\in V^{\lambda_2}$, $|\psi\rangle\in V^{\lambda_1}_{[\lambda_1]-p}$, and assume that p is finite. Then, in the limit in which $\lambda_1\rightarrow\infty$, the state $|\Psi\rangle=|\varphi\rangle|\psi\rangle\in V^{\lambda_2}\otimes V^{\lambda_1}$ is such that

$$f_k|\Psi\rangle\rightarrow|\varphi\rangle[f_k|\psi\rangle]\ ,\quad\forall f_k\in\mathcal{N}_-\ . \tag{42}$$

Proof: Recall that $\mathcal{N}_-$ contains root vectors whose corresponding roots are asymptotic for $\lambda_1\rightarrow\infty$. Then, we have

$$f_k|\Psi\rangle=[f_k|\varphi\rangle]|\psi\rangle+|\varphi\rangle[f_k|\psi\rangle]\ . \tag{43}$$

We may assume, without loss of generality, that $|\varphi\rangle$ and $|\psi\rangle$ are normalized states so that $\||\varphi\rangle\|^2=\||\psi\rangle\|^2=1$. Then

$$\|f_k|\Psi\rangle\|^2=\|f_k|\varphi\rangle\|^2+\|f_k|\psi\rangle\|^2 \ . \tag{44}$$

Now

$$\|f_k|\psi\rangle\|^2=\langle\psi|e_kf_k|\psi\rangle=\langle\psi|[e_k,f_k]|\psi\rangle+\|e_k|\psi\rangle\|^2=\langle\psi|h_k|\psi\rangle+\|e_k|\psi\rangle\|^2 \ , \tag{45}$$

which, since $\langle\psi|h_k|\psi\rangle\to\infty$ as $\lambda_1\to\infty$, implies that

$$\|f_k|\psi\rangle\|^2\to\infty \quad \text{as} \quad \lambda_1\to\infty \ . \tag{46}$$

On the other hand, $\|f_k|\varphi\rangle\|^2$ remains finite and the lemma is shown.

Two important properties for the norms of asymptotic states follow from this lemma. First, set $|\Psi_{ij}\rangle=|\varphi_i\rangle|\psi_j\rangle$, where i labels a basis $\{|\varphi_i\rangle\}$ for V^{λ_2}, and j labels a basis $\{|\psi_j\rangle\}$ for $V^{\lambda_1}_{[\lambda_1]-p}$, and consider the linear combination

$$|\Theta\rangle=\sum_{ij} c_{ij}|\Psi_{ij}\rangle \ , \tag{47}$$

where c_{ij} are complex coefficients satisfying $\Sigma_{ij}c_{ij}c^*_{ij}=1$, but otherwise arbitrary. Then, by *Lemma 3*, it follows that $\|f_k|\psi_j\rangle\|$ is independent of j. [*Proof:* act on $|\Theta\rangle$ to construct the normalized state $f_k|\Theta\rangle/\|f_k|\Theta\rangle\|$ in terms of $|\varphi_i\rangle$ and $|\psi_j\rangle$. Since $|\varphi_i\rangle$ is normalized, and since $\Sigma_{ij}c_{ij}c^*_{ij}=1$, we deduce that $\|f_k|\psi_j\rangle\|=\|f_k|\Theta\rangle\|\forall j$.]

Next, it follows immediately from Eq. (45) that $\|f_k|\Theta\rangle\|=\|f_k|\psi_j\rangle\|$ is also independent of any component of λ or λ_1 that is asymptotically large. [*Proof:* Eq. (45) is unchanged if we use the unirrep $\tilde{\lambda}_1$ whose highest weight is related to the highest weight of λ_1 by $\tilde{\lambda}_1=\lambda_1+\Delta$, where $\Delta=(\delta_1,\ldots,\delta_n)$ contains only finite integers.]

Theorem 1: Let p be a finite integer. Then,

$$W^k_{k-p}\to V^{\lambda_2}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]-p}, \quad \text{as} \quad \lambda_1\to\infty \ . \tag{48}$$

Proof: Let $|\varphi\rangle\in V^{\lambda_2}_{k-[\lambda_1]}$ and $|\psi\rangle\in V^{\lambda_1}_{[\lambda_1]-p}$. Assume the theorem holds for some p, and act on $|\Psi\rangle=|\varphi\rangle|\psi\rangle\in W^k_{k-p}$ with any $f_r\in\mathcal{G}_{-q}, q>0$. Since W^k is $\mathcal{G}$-invariant, we have, by Eq. (4), $f_r|\Psi\rangle\in W^k_{k-p-q}$, and, by *Lemma 3* and Eq. (4),

$$f_r|\Psi\rangle\to|\varphi\rangle[f_r|\psi\rangle]\in V^{\lambda_2}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]-p-q} \ . \tag{49}$$

Hence, if the theorem holds for p, it holds for $p+q$. The seed of the recursion is Lemma 2, which is Theorem 1 for $p=q=0$. Going over all f_r in all $\mathcal{G}_{-q}$ completes the proof.

Consider, for example, the su(2) coupling $j_2\otimes j_1$ in the limit in which $j_1\to\infty$ but j_2 remains finite. Application of the theorem implies that, for a finite value of p, the state

$$|j,j-p\rangle=\sum_{m_1,m_2}(j_1\ m_1;j_2\ m_2|j\ j-p)|j_2,m_2\rangle|j_1m_1\rangle \tag{50}$$

becomes, in the $j_1\to\infty$ limit,

$$|j,j-p\rangle\to|j_2,j-j_1\rangle|j_1,j_1-p\rangle \ . \tag{51}$$

It follows that, for finite p, the asymptotic SU(2) coupling coefficients are given by

$$(j_1\ m_1;j_2\ m_2|j\ j-p)\to\delta_{m_1,j_1-p}\quad\delta_{m_2,j-j_1} \ . \tag{52}$$

For an arbitrary compact semisimple Lie algebra, the highest grade states in the tensor product space $V^{\lambda_2}\otimes V^{\lambda_1}$ become, by Theorem 1, of the form

$$|\Psi^{\rho\lambda}_{\lambda\tau}\rangle \to \sum_{\omega_2\sigma} C^{\lambda}_{\rho,\gamma_2\omega_2\sigma}\ [|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle \otimes |\psi^{\lambda_1}_{\lambda_1}\rangle]_{\sigma\lambda\tau}, \tag{53}$$

in the asymptotic limit $\lambda_1 \to \infty$, where C^{λ} is a unitary transformation. If a particular resolution of the multiplicity is chosen, equivalent to setting $\rho \equiv (\gamma_2\omega_2\sigma)$, such that C^{λ} is an identity matrix, then we have

$$|\Psi^{\rho\lambda}_{\lambda\tau}\rangle \to [|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle \otimes |\psi^{\lambda_1}_{\lambda_1}\rangle]_{\sigma\lambda\tau}, \quad \rho \equiv (\gamma_2\omega_2\sigma) \tag{54}$$

and the $\mathscr{H}$-reduced asymptotic CG coefficients

$$(\lambda_1\gamma_1\omega_1, \lambda_2\gamma_2\omega_2 \| \rho\lambda\lambda)_{\sigma} \to \delta_{\omega_1,\lambda_1}\delta_{\rho,\gamma_2\omega_2\sigma}, \tag{55}$$

in accordance with Eq. (31).

To obtain the asymptotic limits of coefficients $(\lambda_1\gamma_1\omega_1, \lambda_2\gamma_2\omega_2 \| \rho\lambda\,\gamma\omega)_{\sigma}$ for finite values of $[\lambda]-[\omega]$, let the state $|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle$ be expressed in the form

$$|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle = [P_n(f) \otimes |\Psi^{\rho\lambda}_{\lambda}\rangle]_{\alpha\omega\tau}, \tag{56}$$

where $P_n(f)$ is an $\mathscr{H}$-tensor of highest weight n whose components are polynomials in the elements of $\mathscr{N}_-$ and we identify the multiplicity index γ with the pair of indices $(n\alpha)$. Then, in the asymptotic limit,

$$|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle \to [P_n(f) \otimes [|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle \otimes |\psi^{\lambda_1}_{\lambda_1}\rangle]_{\sigma\lambda}]_{\alpha\omega\tau}. \tag{57}$$

Let $\phi(\lambda_1, \omega_2; \sigma\lambda)$ be the phase factor for which

$$[|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle \otimes |\psi^{\lambda_1}_{\lambda_1}\rangle]_{\sigma\lambda} = \phi(\lambda_1, \lambda_2; \sigma\lambda)[|\psi^{\lambda_1}_{\lambda_1}\rangle \otimes |\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle]_{\sigma\lambda}. \tag{58}$$

Using Theorem 1 and setting $\rho \equiv (\gamma_2\omega_2\sigma)$, we have

$$\begin{aligned} |\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle &\to \phi(\lambda_1, \omega_2; \sigma\lambda) \sum_{\beta\kappa\omega_1} U(\omega_2\lambda_1\omega n; \lambda\sigma\alpha, \omega_1\beta\kappa)[[P_n(f) \otimes |\psi^{\lambda_1}_{\lambda_1}\rangle]_{\beta\omega_1} \otimes |\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle]_{\kappa\omega\tau}, \\ &\to \phi(\lambda_1, \omega_2; \sigma\lambda) \sum_{\beta\kappa\omega_1} \phi(\omega_2, \omega_1; \kappa\omega) U(\omega_2\lambda_1\omega n; \lambda\sigma\alpha, \omega_1\beta\kappa)[|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle \otimes |\psi^{\lambda_1}_{n\beta\omega_1}\rangle]_{\kappa\omega\tau}, \end{aligned} \tag{59}$$

where $U(\omega_2\lambda_1\omega n; \lambda\sigma\alpha, \omega_1\beta\kappa)$ is a Racah recoupling coefficient for $\mathscr{H}$, and κ labels multiple copies of ω in the coupling $\omega_1 \otimes \omega_2$. In deriving Eq. (59), we have used properties of the norms of asymptotic states discussed as corollaries of Lemma 3. Furthermore, we use $(n\beta)$ to label multiple occurrences of γ_1. Thus we find

$$\begin{aligned} (\lambda_1\gamma_1\omega_1, \lambda_2\gamma_2\omega_2 \| \rho\lambda\,\gamma\omega)_{\sigma} \to \sum_{\kappa}\ & \phi(\lambda_1, \omega_2; \sigma\lambda)\phi(\omega_2, \omega_1; \alpha\omega)\ \ U(\omega_2\lambda_1\omega n; \lambda\sigma\alpha, \omega_1\beta\kappa) \\ & \times\ M^{\omega}_{\gamma\kappa}\ \times\ \delta_{\rho,\gamma_2\omega_2\sigma}\ \ \delta_{\gamma,n\alpha}\ \ \delta_{\gamma_1,n\beta}, \quad \text{as}\ \ \lambda_1 \to \infty\ , \end{aligned} \tag{60}$$

where the matrix M^{ω} combines the equivalent $\mathscr{H}$-representations ω. Since this matrix depends only on the arbitrary way in which the multiplicities γ and κ of the $\mathscr{H}$-unirrep ω are separated, we set $\kappa = \gamma$ and choose the phases so that M^{ω} is the unit matrix. It then follows that the $\mathscr{H}$-reduced asymptotic coupling coefficients for basis states of $\mathscr{G}$ in $W^{k}_{[\lambda]-[\omega]}$, for finite values of $[\lambda] - [\omega]$, are given simply by a recoupling coefficient for the subalgebra $\mathscr{H}$ times some phases, i.e.,

$$(\lambda_1\gamma_1\omega_1,\lambda_2\gamma_2\omega_2\|\rho\lambda\,\gamma\omega)_\sigma \to \phi(\lambda_1,\omega_2;\sigma\lambda)\,\phi(\omega_2,\omega_1;\alpha\omega) \times U(\omega_2\lambda_1\omega n;\lambda\sigma\alpha,\omega_1\beta\gamma)\,\delta_{\rho,\gamma_2\omega_2\sigma}\ \ \delta_{\gamma,n\alpha}\ \ \delta_{\gamma_1,n\beta}, \quad \text{as } \lambda_1\to\infty. \tag{61}$$

Combining Eq. (59) with Eq. (61), we finally obtain the simple expression

$$|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle \to \phi(\lambda_1,\omega_2;\sigma\lambda)\sum_{\beta\omega_1}\phi(\omega_2,\omega_1;\kappa\omega)U(\omega_2\lambda_1\omega n;\lambda\sigma\alpha,\omega_1\beta\omega) \times[|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle\otimes|\psi^{\lambda_1}_{n\beta\omega_1}\rangle]_{\gamma\omega\tau}\delta_{\rho,\gamma_2\omega_2\sigma}\ \ \delta_{\gamma,n\alpha}, \quad \text{as } \lambda_1\to\infty\ . \tag{62}$$

IV. THE REAL SYMPLECTIC sp(m,R) ALGEBRAS

In this section, we discuss the generalization of the above results to noncompact semisimple Lie algebras. For simplicity we restrict considerations to sp(m,R), although the results are much more widely applicable. We also restrict considerations to products of harmonic series of representations.[9,10] These representations, which include the positive discrete series, have lowest weights but no highest weights. Thus we consider subspaces of $W=V^{\lambda_2}\otimes V^{\lambda_1}$ that are lowest (rather than highest) in grade. $W^k\subset W$ is now the sp(m,R)-invariant subspace containing the lowest weight states of grade k, and W^k_{k+p} is the subspace of W^k of grade $k+p$.

A. Factorization for sp(1,R)

The elements of sp(1,R) satisfy

$$[J_-,J_+]=2J_0, \quad [J_0,J_\pm]=\pm J_\pm, \tag{63}$$

with matrix elements given by

$$\begin{aligned} J_0|jm\rangle &= m|jm\rangle\ , \quad m=j,j+1,j+2,\ldots\ , \\ J_+|jm\rangle &= \sqrt{(m+j)(m-j+1)}\,|j,m+1\rangle\ , \\ J_-|jm\rangle &= \sqrt{(m-j)(m+j-1)}\,|j,m-1\rangle\ , \end{aligned} \tag{64}$$

where $j=\frac{1}{4},\frac{3}{4},\frac{5}{4},\ldots$. Now, consider the coupling of two harmonic series unirreps $j_2\otimes j_1$ with $j_1\to\infty$ and j_2 finite. It can be verified, e.g., by comparing the number of states of weight m $=m_1+m_2$ with the number of states of weight $m-1$, that

$$j_2\otimes j_1=(j_1+j_2)\oplus(j_1+j_2+1)\oplus(j_1+j_2+2)\oplus\cdots\ . \tag{65}$$

Next, consider the lowest weight state $|jj\rangle$ of a subrepresentation in Eq. (65), with $j=j_1+j_2$ $+s$, where j_2 and $s\geqslant 0$ are finite, in the limit $j_1\to\infty$. Write

$$|jj\rangle=\sum_{m_1m_2}\ (j_1\ m_1;j_2\ m_2|j\ j)\ \ |j_2m_2\rangle|j_1m_1\rangle\ , \tag{66}$$

where $(j_1\ m_1;j_2\ m_2|j\ j)$ is now an sp(1,R) coupling coefficient. If we use $J_-|jj\rangle=0$, we get

$$\begin{aligned} 0=&\ (j_1\ m_1+1;j_2\ m_2-1|j\ j)\ \ \sqrt{(m_1+1-j_1)(m_1+j_1)} \\ &+(j_1\ m_1;j_2\ m_2|j\ j)\ \ \sqrt{(m_2-j_2)(m_2+j_2-1)}\ . \end{aligned}$$

This equation can then be rewritten as

$$\frac{(j_1\ m_1+1;j_2\ m_2-1|j\ j)}{(j_1\ m_1;j_2\ m_2|j\ j)}=-\sqrt{\frac{(m_2-j_2)(m_2+j_2-1)}{(m_1+1-j_1)(m_1+j_1)}}\ . \tag{67}$$

Since $m_1+j_1\geqslant 2j_1$ and $j_1\to\infty$ while j_2 and m_2 remain finite, it follows that

$$\frac{(j_1\ m_1+1;j_2\ m_2-1|j\ j)}{(j_1\ m_1;j_2\ m_2|j\ j)}\to 0 \quad \text{as } j_1\to\infty\ . \tag{68}$$

If we now suppose that $|j,j+\delta\rangle\to|j_2,j-j_1\rangle|j_1,j_1+\delta\rangle$ as $j_1\to\infty$, when δ is some finite integer, then, by acting on $|j,j+\delta\rangle$ with J_+, we find, on the one hand,

$$J_+|j,j+\delta\rangle=\sqrt{(2j+\delta)(\delta+1)}|j,j+\delta+1\rangle\ , \tag{69}$$

while, on the other hand,

$$\begin{aligned}J_+[|j_2,j-j_1\rangle|j_1,j_1+\delta\rangle]&=\sqrt{(2j_1+\delta)(\delta+1)}|j_2,j-j_1\rangle|j_1,j_1+\delta+1\rangle\\&\quad+\sqrt{(2j_2+s)(s+1)}|j_2,j-j_1+1\rangle|j_1,j_1+\delta\rangle\ .\end{aligned} \tag{70}$$

Comparison of these equations gives

$$\begin{aligned}|j,j+\delta+1\rangle&=\sqrt{\frac{(2j_1+\delta)}{(2j+\delta)}}|j_2,j-j_1\rangle|j_1,j_1+\delta+1\rangle\\&\quad+\sqrt{\frac{(2j_2+s)(s+1)}{(2j+\delta)(\delta+1)}}|j_2,j-j_1+1\rangle|j_1,j_1+\delta\rangle\ ,\end{aligned} \tag{71}$$

and implies that

$$|j,j+\delta+1\rangle\to|j_2,j-j_1\rangle|j_1,j_1+\delta+1\rangle\ ,\quad \text{as}\ \ j_1\to\infty\ . \tag{72}$$

Hence we have shown by recursion that the following holds:

Lemma 4: Let $j=j_1+j_2+s$ with $s\geqslant 0$. Then, if j_2 and s are finite,

$$|j,j+\delta\rangle\to|j_2,j-j_1\rangle|j_1,j_1+\delta\rangle\ ,\quad \text{as}\ \ j_1\to\infty\ . \tag{73}$$

B. Asymptotic unirreps of sp(m,R)

Every harmonic series representation of sp(m,R) is contained within the space of some A-particle harmonic oscillator in m dimensions.[9,10] For these representations, the sp(m,R) algebra is realized as the set of bilinear products of creation and destruction operators:

$$\begin{aligned}A_{ij}&=\sum_{a=1}^{\mathrm{A}} b_{ai}^\dagger b_{aj}^\dagger,\\C_{ij}&=\sum_{a=1}^{\mathrm{A}}\frac{1}{2}\,(b_{ai}^\dagger b_{aj}+b_{aj}b_{ai}^\dagger)\ ,\\B_{ij}&=\sum_{a=1}^{\mathrm{A}} b_{ai}b_{aj},i,\quad j=1,\ldots,m\ .\end{aligned} \tag{74}$$

Sp(m,R) and u(m) have a common Cartan algebra, spanned by $\{C_{ii},i=1,\ldots,m\}$. Thus a u(m) unirrep is labeled by a highest weight $\lambda=(\lambda^1,\ldots,\lambda^m)$ where λ^i is an eigenvalue of C_{ii} and $\lambda^i\geqslant\lambda^{i+1}$. However, the sp($m$,R) unirreps we consider have no highest weight. The carrier spaces of these sp(m,R) unirreps comprise infinitely many u(m) invariant subspaces each labeled by a u(m) highest weight. The lowest of these u(m) highest weights uniquely characterizes the sp(m,R) unirrep and will be referred to as the lowest weight of the sp(m,R) irrep.

We will consider states of sp(m,R) unirreps in the limit where $\lambda^m\to\infty$. This implies that all the other components of λ are also asymptotically large.

There are two types of sp(m,R) raising operators: the compact su(m) raising operators $\{C_{ij};1\leqslant j<i\leqslant m\}$ and the noncompact raising operators $\{A_{ij};1\leqslant i,j\leqslant m\}$. The action of an A_{ij} operator connects weights belonging to an sp(1,R) chain. States of an sp(1,R) chain carry a unirrep

of an sp(1,R) subalgebra of sp(m,R). If such a unirrep is labeled by j, we define the corresponding sp(1,R) chain of weights to be an asymptotic chain if and only if $j\to\infty$ as $\lambda\to\infty$. Moreover, we note that, when $\lambda^m\to\infty$, all the $\{A_{ij}\}$ operators generate asymptotic chains. Thus, when $\lambda^m\to\infty$, all the noncompact roots are in $\mathscr{S}_+$.

Chains of weights associated with the compact su(m) roots are conveniently analyzed by reexpressing a u(m) weight λ as an su(m)+u(1) weight with components $(\lambda^1-\lambda^2,\lambda^2-\lambda^3,\ldots,\lambda^{m-1}-\lambda^m)\lambda^m$. The chains of weights associated with the compact su(m) roots then become asymptotic when the differences $\lambda^i-\lambda^{i+1}$ of consecutive components of a u(m) weight become large.

We assume, for the moment, that $\lambda^i-\lambda^{i+1}$ remains finite for all i, so that $\mathscr{T}_+$ contains all the positive su(m) roots; i.e., $\mathscr{T}_+$ contains the compact positive roots and $\mathscr{S}_+$ contains the noncompact positive roots. We then have $\mathscr{K}=$ u(m), and sp(m,R) (or, more precisely, its complex extension) has the graded decomposition

$$\mathrm{sp}(m,\mathrm{R})=\mathscr{G}_0+\mathscr{G}_+ +\mathscr{G}_-\,, \tag{75}$$

where $\mathscr{G}_0$ is the u(m) subalgebra spanned by the $\{C_{ij}\}$, $\mathscr{G}_+$ is spanned by the raising operators $\{A_{ij}\}$, and $\mathscr{G}_-$ is spanned by the lowering operators $\{B_{ij}\}$. The grade is conveniently identified with the eigenvalue of the operator

$$\hat{N}=\sum_{i=1}^{m} C_{ii}\,. \tag{76}$$

The lowest grade subspace $V^\lambda_{[\lambda]}$ of an sp(m,R)-irreducible vector space V^λ is defined as the subset of states that are annihilated by the elements of $\mathscr{G}_-$:

$$V^\lambda_{[\lambda]}=\{|\psi\rangle\in V^\lambda;\ \ B_{ij}|\psi\rangle=0,\ \forall B_{ij}\in\mathscr{G}_-\}\ . \tag{77}$$

If one or more of the su(m) labels $\lambda^i-\lambda^{i+1}$ becomes asymptotically large, then $\mathscr{T}_+$ and $\mathscr{S}_+$ must be shrunk and expanded accordingly. However, as the process of taking $\lambda^m\to\infty$ ''commutes'' with the process of taking any su(m) label to ∞, we will assume henceforth that all the $\lambda^i-\lambda^{i+1}$ are finite, knowing that the extra simplifications that arise should one or more su(m) labels become asymptotically large can be made once the analysis of the large-λ^m limit has been completed.

C. Lowest grade subspaces of sp(m,R)

Lemma 5: Let V^λ denote the carrier space for a unirrep of sp(m,R) of lowest weight λ. Let $W^k\subset W$ be the sp(m,R) invariant subspace of $W=V^{\lambda_2}\otimes V^{\lambda_1}$ containing the lowest weight states of grade k, where $k=[\lambda_1]+[\lambda_2]+s$, with s a finite integer. Then, the lowest grade subspace $W^k_k\subset W^k$ is given asymptotically by

$$W^k_k\to V^{\lambda_2}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]}\,,\qquad \text{as } \lambda_1^m\to\infty\ . \tag{78}$$

Proof: The proof parallels that given for Lemma 2 and is omitted.

It is possible to use this lemma to derive asymptotic sp(m,R) coupling coefficients. Since $\mathscr{K}=$ u(m) in the $\lambda_1^m\to\infty$ limit, it follows, in the notation of Eq. (31), that a basis $\{|\Psi^{\rho\lambda}_\tau\rangle\}$ for $W^{\rho\lambda}_\lambda\subset W^k_k$ is given by the states

$$|\Psi^{\rho\lambda}_\tau\rangle=\sum_{\substack{\gamma\omega_2\alpha\\ ij}} C^\lambda_{\rho,\gamma\omega_2\alpha}\ (\lambda_1\ i;\omega_2\ j|\alpha\omega\ \tau)|\varphi^{\lambda_2}_{\gamma\omega_2 j}\rangle|\psi^{\lambda_1}_i\rangle, \tag{79}$$

where α labels the multiplicity of the u(m) coupling $\omega_2\otimes\lambda_1\to\lambda$, i indexes a basis $\{|\psi^{\lambda_1}_i\rangle\}$ for the u(m) unirrep λ_1 in $V^{\lambda_1}_{[\lambda_1]}$, j indexes a basis $\{|\varphi^{\lambda_2}_{\gamma\omega_2 j}\rangle\}$ for the γth copy of the u(m) unirrep ω_2 in $V^{\lambda_2}_{k-[\lambda_1]}$, and $(\lambda_1\ i;\omega_2\ j|\alpha\omega\ \tau)$ is a u(m) Clebsch–Gordan coupling coefficient.

The derivation of Eq. (79) is identical to the derivation of Eq. (31) and therefore omitted.

D. Asymptotic states of sp(m,R)

Lemma 6: Let $|\psi\rangle \in V^{\lambda_1}$ and $|\varphi\rangle \in V^{\lambda_2}_{[\lambda_2]+q}$ be normalized states, where q is a finite positive integer. Then, in the $\lambda_1^m \to \infty$ limit, the state $|\Psi\rangle = |\varphi\rangle|\psi\rangle \in V^{\lambda_2} \otimes V^{\lambda_1}$ satisfies

$$A_{ij}|\Psi\rangle \to |\varphi\rangle[A_{ij}|\psi\rangle] \ , \quad \forall ij \ . \tag{80}$$

Proof: We have

$$A_{ij}|\Psi\rangle = [A_{ij}|\varphi\rangle] \ |\psi\rangle + |\varphi\rangle[A_{ij}|\psi\rangle] \tag{81}$$

and, since $|\varphi\rangle$ and $|\psi\rangle$ are normalized states,

$$\|A_{ij}|\Psi\rangle\| = \|A_{ij}|\varphi\rangle\| + \|A_{ij}|\psi\rangle\| \ . \tag{82}$$

To evaluate $\|A_{ij}|\psi\rangle\|$, observe that

$$\begin{aligned} \|A_{ij}|\psi\rangle\|^2 &= \langle\psi|[B_{ij},A_{ij}]|\psi\rangle + \|B_{ij}|\psi\rangle\|^2 \\ &= \langle\psi|C_{ii}+C_{jj}+2\delta_{ij}C_{ii}|\psi\rangle + \|B_{ij}|\psi\rangle\|^2 \ . \end{aligned} \tag{83}$$

Since

$$\langle\psi|C_{ii}|\psi\rangle \geqslant \langle\psi|C_{mm}|\psi\rangle \geqslant \lambda_1^m , \tag{84}$$

it follows that $\|A_{ij}|\psi\rangle\|^2 \to \infty$ as $\lambda_1^m \to \infty$. On the other hand, for $|\varphi\rangle \in V^{\lambda_2}_{[\lambda_2]+q}$, with q finite, the norm $\|A_{ij}|\varphi\rangle\|$ remains finite. Hence we have $\|A_{ij}|\Psi\rangle\| \to \|A_{ij}|\psi\rangle\|$ and the proof is complete.

Theorem 2: In the $\lambda_1^m \to \infty$ limit,

$$W^k_{k+p} \to V^{\lambda_2}_{k-[\lambda_1]} \otimes V^{\lambda_1}_{[\lambda_1]+p} \tag{85}$$

for finite values of p.

Proof: The proof is by induction, starting with Lemma 5. It parallels that for Theorem 1, but uses Lemma 6 rather than Lemma 3 to iterate between the graded subspaces.

Asymptotic coupling coefficients for the large-λ_1^m limit of sp(m,R) can be derived in the manner of Sec. III E, provided that the polynomial $P_n(f)$ appearing in Eqs. (56), (57), and (59) is replaced by the corresponding polynomial $P_n(A)$ in terms of raising operators. Thus in the $\lambda_1^m \to \infty$ limit and for finite values of $[\omega]-[\lambda]$, where ω and λ label unirreps of u(m), the state $|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle$ is given by Eq. (62), where all coupling and recoupling coefficients are u(m) coefficients.

V. sp(m,R) TENSOR OPERATORS

In this section, we extend the results on sp(m,R) to the coupling of a nonunitary finite-dimensional representation of sp(m,R) to a unitary infinite-dimensional representation. Interest in such couplings arises because tensor operators often belong to finite-dimensional irreps.

A. sp(1,R) tensor operators

The components $\{T^{\tilde{j}}_{\tilde{m}}; \tilde{m} = -\tilde{j}, \ldots, +\tilde{j}\}$ of a finite-dimensional (nonunitary) sp(1,R) tensor operator $T^{\tilde{j}}$ are related[10] by the equations

$$\begin{aligned} [J_\pm, T^{\tilde{j}}_{\tilde{m}}] &= \mp\sqrt{(\tilde{j}\mp\tilde{m})(\tilde{j}\pm\tilde{m}+1)}\,T^{\tilde{j}}_{\tilde{m}\pm 1}, \\ [J_0, T^{\tilde{j}}_{\tilde{m}}] &= \tilde{m}T^{\tilde{j}}_{\tilde{m}}. \end{aligned} \tag{86}$$

The decomposition of the coupling $\tilde{j} \otimes j$, where j is the lowest weight for a unirrep, can be inferred by simply counting the number of states with a given weight $M = \tilde{m} + m$. This shows that $\tilde{j} \otimes j$ is the finite sum of unitary irreducible representations

$$\tilde{j}\otimes j=|j-\tilde{j}|\oplus|j-\tilde{j}+1|\oplus\cdots\oplus|j+\tilde{j}| \ . \tag{87}$$

We are interested in the lowest weight states of these couplings, which we express in the form

$$[T^{\tilde{j}}\otimes|j\rangle]^J_J=\sum_{m,\tilde{m}} (j\ m;\tilde{j}\ \tilde{m}|J\ J)T^{\tilde{j}}_{\tilde{m}}\ |jm\rangle \ . \tag{88}$$

Applying the lowering operator J_- to Eq. (88), we get

$$\begin{aligned}0=&\sum_{m,\tilde{m}} (j\ m-1;\tilde{j}\ \tilde{m}+1|J\ J)[J_-,T^{\tilde{j}}_{\tilde{m}+1}]|jm-1\rangle\\ &+\sum_{m,\tilde{m}} (j\ m;\tilde{j}\ \tilde{m}|J\ J)T^{\tilde{j}}_{\tilde{m}}\ [J_-|jm\rangle] \ ,\end{aligned} \tag{89}$$

from which it follows, using Eqs. (64) and (86), that

$$\begin{aligned}0=&\sqrt{(\tilde{j}+\tilde{m}+1)(\tilde{j}-\tilde{m})}\ (j\ m-1;\tilde{j}\ \tilde{m}+1|J\ J)\\ &+\sqrt{(m-j)(m+j-1)}\ (j\ m;\tilde{j}\ \tilde{m}|J\ J) \ .\end{aligned} \tag{90}$$

Combined with the fact that there are finitely many coupling coefficients when $\tilde{j}$ is finite, Eq. (90) can be used to establish that

$$(j\ m;\tilde{j}\ \tilde{m}|J\ J)\to k\left(\frac{1}{\sqrt{2j}}\right)^{m-j}(j\ j;\tilde{j}\ J-j|J\ J) \ , \quad \text{as } j\to\infty \ , \tag{91}$$

where k is some finite constant. It then follows that

$$[T^{\tilde{j}}\otimes|j\rangle]^J_J\to T^{\tilde{j}}_{J-j}|jj\rangle \ , \quad \text{as } j\to\infty \ . \tag{92}$$

Furthermore, since

$$\begin{aligned}J_+[T^{\tilde{j}}\otimes|j\rangle]^J_J=&\sqrt{2J}[T^{\tilde{j}}\otimes|j\rangle]^J_{J+1}\to[J_+,T^{\tilde{j}}_{J-j}]|jj\rangle+T^{\tilde{j}}_{J-j}[J_+|jj\rangle]\\ =&-\sqrt{(\tilde{j}-J+j)(\tilde{j}+J-j+1)}T^{\tilde{j}}_{J-j+1}|jj\rangle+\sqrt{2j}T^{\tilde{j}}_{J-j}|j,j+1\rangle \ ,\end{aligned} \tag{93}$$

we have

$$[T^{\tilde{j}}\otimes|j\rangle]^J_{J+1}\to T^{\tilde{j}}_{J-j}|j,j+1\rangle \ , \quad \text{as} \quad j\to\infty \ . \tag{94}$$

By acting now on $[T^{\tilde{j}}\otimes|j\rangle]^J_{J+1}$ with J_+, we find, in the same manner, that

$$[T^{\tilde{j}}\otimes|j\rangle]^J_{J+2}\to T^{\tilde{j}}_{J-j}|j_1,j_1+2\rangle \ , \quad \text{as } j\to\infty \ . \tag{95}$$

These are the first two steps of an inductive proof of the following lemma.

Lemma 7: For finite values of $\tilde{j}$,

$$[T^{\tilde{j}}\otimes|j\rangle]^J_{J+\delta}\to T^{\tilde{j}}_{J-j}|j,j+\delta\rangle \ , \quad \text{as} \quad j\to\infty \ . \tag{96}$$

B. sp(3,R) tensor operators

The coupling of an sp(3,R) tensor operator $T^{\tilde{\lambda}}$, that transforms according to a nonunitary, finite dimensional representation $\tilde{\lambda}$, to a unitary asymptotic irrep λ of sp(3,R) can be reduced as follows.

Let us denote by $\langle\lambda\rangle$ the character of the Sp(3,R) irrep with lowest weight λ and by $\{\lambda\}=\{\lambda^1,\lambda^2,\lambda^3\}$ the character of the U(3) irrep with highest weight $\lambda=(\lambda^1,\lambda^2,\lambda^3)$. Then, for $\lambda^3\geqslant 3$, the Sp(3,R) $\rightarrow$ U(3) branching rule is given in terms of characters,[10] by

$$\mathrm{Sp}(3,\mathrm{R})\rightarrow \mathrm{U}(3)\ \ ;\ \ \langle\lambda\rangle\mapsto\{\lambda\}\cdot\{D\}\ , \tag{97}$$

where D denotes the sum of U(3) irreps with character

$$\{D\}=\{0\}+\{2\}+\{4\}+\{2,2\}+\{6\}+\{4,2\}+\{2,2,2\}+\cdots\ . \tag{98}$$

Let

$$\langle\lambda\rangle\mapsto\sum_p\ m_p\{\omega_p\}=\sum_p\ m_p\{\omega_p^1,\omega_p^2,\omega_p^3\}\ , \tag{99}$$

denote the decomposition of the character of $\tilde{\lambda}$ into its U(3) characters $\{\omega_p\}=\{\omega_p^1,\omega_p^2,\omega_p^3\}$, where m_p is the multiplicity of ω_p in $\tilde{\lambda}$. Since $\tilde{\lambda}$ is finite dimensional, the sum in Eq. (99) will contain finitely many U(3) unirreps. Then, if $\langle\tilde{\lambda}\rangle\cdot\langle\lambda_1\rangle$ denotes the character for the tensor product $\tilde{\lambda}\otimes\lambda_1$ of a finite Sp(3,R) irrep $(\tilde{\lambda})$ and an infinite unitary irrep (λ_1), we have

$$\mathrm{Sp}(3,\mathrm{R})\rightarrow \mathrm{U}(3)\ \ ;\ \ \langle\tilde{\lambda}\rangle\cdot\langle\lambda_1\rangle\mapsto\sum_p\ m_p\{\omega_p\}\cdot\{\lambda_1\}\cdot\{D\}\ . \tag{100}$$

By comparing this expression with Eq. (97), we deduce that an Sp(3,R) unirrep with lowest weight λ will occur $\Sigma_p m_p\times\rho_\lambda$ times, where ρ_λ is the multiplicity of the U(3) highest weight λ in the reduction of the U(3) product $\omega_p\otimes\lambda_1$; i.e., if

$$\langle\lambda\rangle\mapsto\sum_p\ m_p\{\omega_p\}\quad\text{and}\quad\{\omega_p\}\cdot\{\lambda_1\}=\sum_\lambda\ \rho_\lambda\{\lambda\}\ , \tag{101}$$

then

$$\langle\tilde{\lambda}\rangle\cdot\langle\lambda_1\rangle=\sum_{p\lambda}\ m_p\rho_\lambda\langle\lambda\rangle\ . \tag{102}$$

Lemma 8: Let $T^{\tilde{\lambda}}$ be an sp(3,R) tensor operator, and let V^{λ_1} be defined as usual. Let $W^k\subset W$ be the sp(3,R) invariant subspace of $W=T^{\tilde{\lambda}}\otimes V^{\lambda_1}$ containing the lowest weight of grade k. Then, the lowest grade subspace $W_k^k\subset W^k$ is given, in the limit where $\lambda_1^3\rightarrow\infty$, by

$$W_k^k\rightarrow T^{\tilde{\lambda}}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]}\ , \tag{103}$$

where $T^{\tilde{\lambda}}_{k-[\lambda_1]}$ is the subspace of $T^{\tilde{\lambda}}$ spanned by the components of $T^{\tilde{\lambda}}$ with grade $k-[\lambda_1]$.

Proof: Let $\{A_{ij},B_{ij},[A_{ij},B_{ij}]\}$ denote a basis for $\mathscr{A}_{ij}$, the sp(1,R) subalgebra of sp(3,R) generated by A_{ij} and B_{ij}. Since W_k^k is a lowest grade subspace of the sp(3,R) invariant subspace $W^k\subset W$, it follows that $B_{ij}|\Psi\rangle=0$ for any $|\Psi\rangle\in W_k^k$. Thus W_k^k is spanned by a set of states which are all lowest weight states for unirreps of $\mathscr{A}_{ij}$. If $|\Psi\rangle$ is such a lowest weight state, it is, by Lemma 7, a product $|\Psi\rangle=T^{\tilde{\lambda}}_q\ \ |\psi\rangle$ of a state $|\psi\rangle\in\sigma_{ij}$ and a component of $T^{\tilde{\lambda}}$, where

$$\sigma_{ij}=\{|\psi\rangle\in V^{\lambda_1};\ \ B_{ij}|\psi\rangle=0\}\ . \tag{104}$$

Since this result holds for all $\mathscr{A}_{ij}$, and since

$$V^{\lambda_1}_{[\lambda_1]}=\{|\psi\rangle\ ;B_{ij}|\psi\rangle=0\ ;\forall\ ij\}\ , \tag{105}$$

it follows that, in the asymptotic limit, every state in W_k^k lies in $T^{\tilde{\lambda}}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]}$, and the proof is complete.

Now, if α labels the components $\{T^{\tilde{\lambda}}_{\gamma_p\omega_p\alpha}\}$ of the U(3) tensor $T^{\tilde{\lambda}}_{\gamma_p\omega_p}$ whose components are a subset of components of the sp(3,R) tensor $T^{\tilde{\lambda}}$, we have

$$T^{\tilde{\lambda}}_{\gamma_p\omega_p\alpha}|\psi^{\lambda_1}_{\beta}\rangle \in W^k, \quad k=[\omega_p]+[\lambda_1]\ , \tag{106}$$

where β labels basis states $\{|\psi^{\lambda_1}_{\beta}\rangle\}$ in $V^{\lambda_1}_{[\lambda_1]}$. Furthermore, since

$$[A_{ij},T^{\tilde{\lambda}}_{\gamma_p\omega_p\alpha}]=\sum_{\gamma'\omega'\beta'} c_{\gamma_p\omega_p\alpha,\gamma'\omega'\beta'}T^{\tilde{\lambda}}_{\gamma'\omega'\beta'}\ , \tag{107}$$

and, for finite values of $\tilde{\lambda}$, the coefficients $c_{\gamma_p\omega_p\alpha,\gamma'\omega'\beta'}$ are finite for all values of the indices, we immediately find that

$$A_{ij}T^{\tilde{\lambda}}_{\gamma_p\omega_p\alpha}|\psi^{\lambda_1}_{\beta}\rangle \to T^{\tilde{\lambda}}_{\gamma_p\omega_p\alpha}A_{ij}|\psi^{\lambda_1}_{\beta}\rangle\ , \quad \forall|\psi^{\lambda_1}_{\beta}\rangle\in V^{\lambda_1}\ , \tag{108}$$

since, as seen before, $\|A_{ij}|\psi\rangle\|\to\infty$ in the $\lambda_1^3\to\infty$ limit. From this, we now have

Theorem 3: In the $\lambda_1^3\to\infty$ limit of λ_1,

$$W^k_{k+q}\to T^{\tilde{\lambda}}_{k-[\lambda_1]}\otimes V^{\lambda_1}_{[\lambda_1]+q}\ . \tag{109}$$

Proof: The proof is once again inductive starting this time with Lemma 8 and using Eq. (108) to step between the graded subspaces. The details are omitted.

Using the theorem, we find, in the notation of Eq. (62), that

$$\begin{aligned}|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle \to \phi(\lambda_1,\omega_p;\sigma\lambda)\sum_{\beta\omega_1}\ \phi(\omega_p,\omega_1;\gamma\omega)\ \ U(\omega_2\lambda_1\omega n;\lambda\sigma\alpha,\omega_1\beta\gamma)\\ \times[T^{\tilde{\lambda}}_{\gamma_p\omega_p}\otimes|\psi^{\lambda_1}_{n\beta\omega_1}\rangle]_{\gamma\omega\tau}\ \ \delta_{\rho,\gamma_p\omega_p\sigma}\ \ \delta_{\gamma,n\alpha},\ \text{ as }\ \lambda_1^3\to\infty\ ,\end{aligned} \tag{110}$$

where the coupling is a u(3) coupling, and U is a Racah recoupling coefficient for u(3).

VI. DISCUSSION AND CONCLUSION

In this paper we have investigated the properties of asymptotic representations by looking at matrix elements of some ladder operators of semisimple Lie algebras. Ladder operators are naturally associated with gradings of representations. Thus we have made use of the fact that a contraction, corresponding to an asymptotic limit $\lambda\to\infty$, preserves a suitably defined graded structure of a Lie algebra and its ladder representations.

The formalism singles out a subalgebra $\mathscr{H}\subset\mathscr{G}$ which, by construction, contains all the ladder operators of $\mathscr{G}$ with finite matrix elements. We have shown that, in the asymptotic limit as $\lambda_1\to\infty$, the basis states $\{|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle\}$, for which $[\lambda]-[\omega]$ is finite, for the tensor product space $W=V^{\lambda_2}\otimes V^{\lambda_1}$, depend only on the coupling and recoupling coefficients of $\mathscr{H}$. Thus a major result of this paper is given by Eq. (62)

$$\begin{aligned}|\Psi^{\rho\lambda}_{\gamma\omega\tau}\rangle \to \phi(\lambda_1,\omega_2;\sigma\lambda)\sum_{\beta\omega_1}\ \phi(\omega_2,\omega_1;\kappa\omega)U(\omega_2\lambda_1\omega n;\lambda\sigma\alpha,\omega_1\beta\omega)\\ \times[|\varphi^{\lambda_2}_{\gamma_2\omega_2}\rangle\otimes|\psi^{\lambda_1}_{n\beta\omega_1}\rangle]_{\gamma\omega\tau}\ \ \delta_{\rho,\gamma_2\omega_2\sigma}\ \delta_{\gamma,n\alpha},\ \text{as}\ \lambda_1\to\infty\ ,\end{aligned}$$

where $\phi(\lambda_1,\omega_2;\sigma\lambda)$ and $\phi(\omega_2,\omega_1;\gamma\omega)$ are phase factors and $U(\omega_2\lambda_1\omega n;\lambda\sigma\alpha,\omega_1\beta\gamma)$ is a Racah coefficient for $\mathscr{H}$. In deriving this explicit expression, we have made use of a result, given in Sec. III C, that the arbitrariness of separating multiple copies of equivalent irreducible subrepresentations in the tensor product $\lambda_2\otimes\lambda_1$ has a natural resolution in the $\lambda_1\to\infty$ limit.

In the $\lambda_1 \to \infty$ limit, a unirrep of a semisimple Lie algebra $\mathscr{G}$ approaches a (possibly reducible) representation of a contraction $\mathscr{G}^c$ of $\mathscr{G}$. Consider, for example, a representation of the su(2) Lie algebra

$$[J_+, J_-] = 2J_0, \quad [J_0, J_\pm] = \pm J_\pm \tag{111}$$

with angular momentum j and basis states $\{|jm\rangle\}$. Let $\mathscr{J}_\pm$ and $\mathscr{I}$ denote the renormalized operators

$$\mathscr{J}_\pm = \frac{J_\pm}{\sqrt{2j}}, \quad \mathscr{I} = \frac{J_0}{j}. \tag{112}$$

In terms of these operators, the su(2) commutation relations become

$$[\mathscr{J}_+, \mathscr{J}_-] = \mathscr{I}, \quad [\mathscr{I}, \mathscr{J}_\pm] = \pm \frac{\mathscr{J}_\pm}{j}. \tag{113}$$

Thus, in the asymptotic limit as $j \to \infty$, we obtain the İnönü–Wigner[12] contraction of su(2) to a Heisenberg–Weyl algebra with

$$[\mathscr{J}_+, \mathscr{J}_-] = \mathscr{I}, \quad [\mathscr{I}, \mathscr{J}_\pm] = 0. \tag{114}$$

The latter algebra is more usually expressed in terms of harmonic oscillator raising and lowering operators

$$[c, c^\dagger] = I, \quad [\mathscr{I}, c] = [I, c^\dagger] = 0. \tag{115}$$

Note also that we still have the commutation relation

$$[J_0, \mathscr{J}_\pm] = \pm \mathscr{J}_\pm \tag{116}$$

which can be compared with the harmonic oscillator equations

$$[H, c^\dagger] = c^\dagger, \quad [H, c] = -c, \tag{117}$$

with $H = c^\dagger c$.

The way in which the states $\{|jm\rangle\}$ of the su(2) representation approach those of a harmonic oscillator is given by the identification

$$|jm\rangle \equiv |n\rangle, \quad \text{with} \quad n = j - m. \tag{118}$$

As $j \to \infty$, we have, for small values of n,

$$\mathscr{J}_+ |n\rangle = \sqrt{\frac{1}{2j} n(2j+1)}\, |n-1\rangle \to \sqrt{n}\, |n-1\rangle,$$

$$\mathscr{J}_- |n\rangle = \sqrt{\frac{1}{2j}(2j-n)(n+1)}\, |n+1\rangle \to \sqrt{n+1}\, |n+1\rangle, \qquad \mathscr{J}_0 |n\rangle = n|n\rangle. \tag{119}$$

Thus we obtain the correspondence

$$\mathscr{J}_+ \to c, \quad \mathscr{J}_- \to c^\dagger, \quad \mathscr{I} \to I, \quad \mathscr{J}_0 \to c^\dagger c \tag{120}$$

valid whenever $n \ll j$. In terms of special functions, the contraction of spherical harmonics to Hermite polynomials can be found in Ref. 13.

Note that such a contraction of a semisimple Lie algebra is not semisimple. Since representations of the non-semisimple algebra can be obtained as asymptotic limits of those of the semisimple algebra $\mathscr{G}$, we can *define* the coupling of an irrep of $\mathscr{G}^c$ to an irrep of $\mathscr{G}$ as the asymptotic limit of the coupling of irreps of $\mathscr{G}$. Asymptotic coupling coefficients of $\mathscr{G}$ are precisely the

coupling coefficients for the coupling $\mathscr{G}^c \times \mathscr{G} \to \mathscr{G}^c$. Furthermore, the renormalization of the Lie algebra implies a renormalization of the representation labels of $\mathscr{G}$, so that the labels specifying representations of $\mathscr{G}^c$ can take finite values. Thus we have the remarkable fact that the asymptotic coupling coefficients become exact for $\mathscr{G}^c \times \mathscr{G} \to \mathscr{G}^c$, even for finite values of the representation labels of $\mathscr{G}^c$.

The Clebsch–Gordan coefficients for the coupling of two irreps, $\lambda_1 \otimes \lambda_2$, of $\mathscr{G}^c$ are given precisely by the double limit $\lambda_1, \lambda_2 \to \infty$ of Clebsch–Gordan coefficients for $\mathscr{G}$. Unfortunately, it appears difficult to compute such coefficients within the current formalism.

In a previous work,[13] we obtained asymptotic Clebsch–Gordan coefficients for the su(3) $\supset$ so(3) subalgebra chain by a projection method. This projection method is different from the technique presented in Sec. III E. Nevertheless, it shares a ''factorization'' property with the current work. To be precise, it is implicit in Ref. 14 that

$$\frac{\|Q_0|\varphi\rangle\|}{\|Q_0|\psi\rangle\|} \to 0 \quad \text{as } \lambda_1^1 \to \infty \ , \tag{121}$$

where $|\psi\rangle \in V^{\lambda_1}$ and $|\varphi\rangle \in V^{\lambda_2}$ as usual, and where Q_0 is the $\nu = 0$ component of an so(3) $\subset$ su(3) tensor operator. This leads immediately to the factorization

$$Q_0|\Psi\rangle \to |\varphi\rangle[Q_0|\psi\rangle] \quad \text{as } \lambda_1^1 \to \infty \ , \tag{122}$$

which can be compared with Eq. (42) for components of $\mathscr{H} \subset \mathscr{G}$ tensors. However, unlike the $\mathscr{H} \subset \mathscr{G}$ tensors, not all components of the su(3) quadrupole moment Q_ν satisfy Eq. (121) in general. Thus it would be interesting to know if asymptotic coupling always implies such a factorization of some matrix elements and if, conversely, such a factorization implies asymptotic coupling.

Asymptotic Clebsch–Gordan coefficients have so far been used to analyze coupled systems having two different scales. For instance, in some core-plus-particle models of the nucleus, the so-called ''collective'' part of multipole operators can dwarf the single particle contribution, so that Eqs. (42) or (122) are true to a first approximation. The eigenfunctions of such two-scale systems are often found, to leading order, by using the Born–Oppenheimer (BO) approximation.[15] This suggests a useful parallel between the physically insightful BO approach and the mathematical technique of asymptotic coupling.[16] It remains to see if this parallel extends to higher orders, i.e., if corrections to the BO wave functions have a corresponding group-theoretical interpretation in terms of corrections to the asymptotic limit.

Finally, an obvious question which remains unanswered in the present work is the evaluation and properties of asymptotic coupling coefficients for finite values of the grade $[\omega]$. In Ref. 14, we computed su(2) $\supset$ u(1) Clebsch–Gordan coefficients for finite value of the projection m in the limit where $j \to \infty$. This was done by embedding the u(1) subalgebra so that the set of states obtained from the highest weight state by the action of all elements of the corresponding U(1) subgroup spanned the whole su(2) representation. In contrast, the theory and examples presented in the present paper are closely related to the work found in Ref. 8, where the subalgebra $\mathscr{H}$ does not connect states in a unitary representation of $\mathscr{G}$ having different grades. This suggests that different embeddings of $\mathscr{H}$, when equivalent, will yield results applicable to different ranges of values of $[\omega]$.

Invariant polynomials and Molien functions

Michael Forger

(Received 12 February 1997; accepted for publication 9 June 1997)

The Molien function associated with a finite-dimensional representation of a compact Lie group is a useful tool in representation theory because it acts as a generating function for counting the number of invariant polynomials on the representation space. The main purpose of this paper is to introduce a more general (and apparently new) generating function which, in the same sense, counts not only the number of invariant real polynomials in a real representation or the number of invariant complex polynomials in a complex representation, as a function of their degree, but encodes the number of invariant real polynomials in a complex representation, as a function of their bidegree (the first and second component of this bidegree being the number of variables in which the polynomial is holomorphic and antiholomorphic, respectively). This is obviously an additional and non-trivial piece of information for representations which are truly complex (i.e., not self-conjugate) or are pseudo-real, but it provides additional insight even for real representations. In addition, we collect a number of general formulas for these functions and for their coefficients and calculate them in various irreducible representations of various classical groups, using the software package MAPLE.

I. INTRODUCTION

Determining the ring of invariant polynomials in arbitrary representations is perhaps one of the most important open problems in group theory. Trying to solve this problem in full generality—for example, in the framework of arbitrary finite-dimensional representations of compact Lie groups (including finite groups)—is presently considered to be a hopeless enterprise. What is, however, a tractable problem is to determine at least the number of (linearly independent) invariant polynomials, or more precisely, the dimension of the space of invariant homogeneous polynomials of any given degree, and this is often an extremely useful piece of information when it comes to calculating invariant polynomials for a concrete representation of a concrete group.

The present investigation originated from the recent work of J. E. M. Hornos and Y. M. M. Hornos[1] on the origin of the genetic code that has found great repercussion in the international scientific literature.[2,3] According to their proposal, the degeneracy of the universal genetic code for protein synthesis is not (as many molecular biologists used to and some continue to believe) purely accidental, but can be understood as resulting from an evolutionary process which involves symmetry breaking: evolution from a highly symmetric initial state to a final state in which this symmetry is strongly broken. This evolution must have occurred, in several consecutive steps, far back in earth's early history, and so is not accessible to direct observation. For the time being, the scheme proposed by Hornos and Hornos is purely group theoretical, its main virtue being that—within the limits of the originally proposed scheme—the initial symmetry and all intermediate steps in the sequence can be uniquely reconstructed from presently available data. (More recently, the scope of the scheme has been extended and, as a result, a second possibility has emerged.)[4]

The great challenge for the future is to identify a dynamical system modelling the underlying evolutionary process, so that the sequence of symmetry breakings found can be associated with a sequence of (generic) bifurcations. In fact, it is well known that in dynamical systems with symmetry and with external parameters, bifurcations that occur under appropriate variations of the parameters almost unavoidably lead to symmetry breaking.[5] In this general framework, of course, the variety of possibilities is enormous, so that for the time being, we have decided to perform our search in the more restricted class of Hamiltonian dynamical systems. But the most natural can-

 © 1998 American Institute of Physics

didates for a Hamiltonian function capable of reproducing the desired symmetry breaking pattern are just the polynomial functions on the representation space which are invariant under the full symmetry group and which, if possible, should be of degree $\leqslant 4$. (This would correspond to some kind of anharmonic oscillator type model.) In the case at hand, the full symmetry group is the rank 3 symplectic group Sp(6) and the representation is the 64-dimensional irreducible representation of highest weight (1,1,0)—a complex representation which is self-conjugate but is pseudo-real, rather than real, and which has come to be called the codon representation of Sp(6).

Before attempting to explicitly construct all invariant polynomials up to a given degree, in any given representation of any group, it is obviously of great help to know precisely how many such polynomials there are. To see how useful this information can be and how it may help to avoid unpleasant surprises, consider as an example the problem of finding the invariant polynomials of degree 4 in, say, the spin 3 representation of the ordinary rotation group. (This example has been chosen because of certain similarities with the codon representation.) Given the fact that vectors in this representation space can be realized as totally symmetric tensors t of rank 3 over three-dimensional Euclidean space which are traceless in any pair of indices, it is easy to construct invariant polynomials of degree 4 by considering all possibilities of contracting indices in a product of four such tensors, using the invariant scalar product. Symmetry implies that the only relevant information is how many indices of any given tensor are contracted with how many indices of any other given tensor (not which with which), while tracelessness forbids contraction of two indices that appear within the same tensor. Therefore, there are three different possibilities to contract the 12 indices (each one ranging from 1 to 3) in the product

$$t_{i_1 j_1 k_1} t_{i_2 j_2 k_2} t_{i_3 j_3 k_3} t_{i_4 j_4 k_4}$$

which come to mind.

(1) Every tensor has only one partner for the contraction. Contract, for example, i_1 with i_2, j_1 with j_2, k_1 with k_2 and i_3 with i_4, j_3 with j_4, k_3 with k_4:

$$P_{4,1}(t) = P_2(t)^2, \quad P_2(t) = \sum_{i,j,k=1}^{3} t_{ijk}^2.$$

(2) Every tensor has two partners for the contraction. Contract, for example, i_1 with i_2, j_1 with j_2, k_1 with i_3, k_2 with i_4, j_3 with j_4, k_3 with k_4:

$$P_{4,2}(t) = \sum_{i,j,k,l,m,n=1}^{3} t_{ijk} t_{ijl} t_{kmn} t_{lmn}\,.$$

(3) Every tensor has three partners for the contraction. Contract, for example, i_1 with i_2, j_1 with i_3, k_1 with i_4, j_2 with j_3, k_2 with j_4, k_3 with k_4:

$$P_{4,3}(t) = \sum_{i,j,k,l,m,n=1}^{3} t_{ijk} t_{ilm} t_{jln} t_{kmn}\,.$$

The first possibility corresponds to the square of the quadratic polynomial stemming from the invariant scalar product in this representation, while the other two are genuinely quartic and apparently independent. Therefore, it comes as a surprise that the number of invariant polynomials of degree 4 in this representation, as computed by the techniques to be discussed (and further developed) in the present paper, turns out to be 2, and not 3. This means that the three polynomials obtained above must be linearly dependent! And indeed, writing out these polynomials as explicit functions of the seven variables $t_{112}, t_{122}, t_{113}, t_{133}, t_{223}, t_{233}, t_{123}$, we find, using MAPLE, the following linear relation:

$$P_{4,1} = 2(P_{4,2} + P_{4,3}).$$

This simple example shows that independent information on the correct number of invariant polynomials is crucial if one wants to avoid naive overcounting. It is equally crucial if one wants to avoid undercounting, which may occur as a result of overlooking non-obvious, ''hidden''

invariants. (One fairly well-known example that comes to mind is the Pfaffian—an invariant in the adjoint representation of the special orthogonal groups in even dimensions which is hard to detect by tensorial methods.)

The basic strategy for determining the number of invariant polynomials of any given degree is to encode all of them into a generating function, which is commonly called the Molien function and which can often be calculated in closed form, at least in sufficiently simple situations. But even when this is not possible in practice, the existing formulas for the generating function can be exploited to compute at least the first few coefficients.

Unfortunately, the standard Molien function M_π associated with a given finite-dimensional representation π of a given compact Lie group G is inadequate for handling the problem at hand in its full generality, due to a discrepancy between ground fields. On the one hand, the representation spaces encountered in group theory are always assumed to be complex (this guarantees that one can simultaneously diagonalize maximal commuting sets of linear transformations); the usual convention for handling real representations is then to view them as complex representations possessing an invariant antilinear involution. On the other hand, we are typically interested in finding all invariant real polynomials and not just the complex ones. The standard Molien function, however, does not allow one to identify the extent to which a real polynomial on the space of a complex representation is holomorphic or antiholomorphic in its variables. What is worse, it does not detect invariant polynomials of mixed type. The obvious prototype of such a polynomial is the invariant scalar product—a quadratic polynomial on the representation space, holomorphic in one variable and antiholomorphic in the other—which exists in any finite-dimensional representation of any compact Lie group and, in addition, is the only polynomial of its kind (up to a constant multiple) in case the representation is irreducible. The fact that the standard Molien function captures only purely holomorphic (or purely antiholomorphic) invariants, but fails to detect mixed invariants, including the invariant scalar product, can already be illustrated by looking at the simplest of all representations: the fundamental spin 1/2 representation of the ordinary rotation group (or rather its universal covering group SU(2)).

The natural way out of this dilemma, proposed and elaborated in the present paper, is to invent a new generating function F_π which generalizes the usual Molien function and is specifically designed to capture all real polynomials in complex representations, discriminating between holomorphic ones, purely antiholomorphic ones and mixed ones, according to their bidegree.

As far as the specific case of the codon representation of Sp(6) is concerned, the techniques developed in the present work allow one to conclude that: (a) there are no invariant quadratic polynomials of bidegree (2,0) (purely holomorphic) or of bidegree (0,2) (purely antiholomorphic), while there is one invariant quadratic polynomial of bidegree (1,1) (the scalar product), (b) there are no invariant cubic polynomials of any kind and (c) the numbers of invariant quartic polynomials are as follows: 3 of bidegree (4,0) (purely holomorphic), 3 of bidegree (0,3) (purely antiholomorphic), 6 of bidegree (3,1), 6 of bidegree (1,3) and finally 15 of bidegree (2,2). Since a Hamiltonian function must be real, we may therefore conclude that the general candidate for a Hamiltonian capable of describing the evolution of the genetic code through an anharmonic oscillator type model must be a linear combination of the invariant scalar product, its square and another 14 genuinely quartic invariant polynomials of bidegree (2,2). What remains to be determined are the explicit form of these polynomials and the conditions to be imposed on their coefficients in order to guarantee positivity of the energy. (The remaining final freedom of modifying the Hamiltonian by an additive constant may then be used to normalize its minimum value to 0.)

The paper is organized as follows. In Sec. II, we briefly review the definition of the Molien function, whereas in Sec. III we define our new generating function for counting invariant real polynomials in complex representations. Both sections contain comments on the relations between the analytic form of the generating functions and the structure of the (graded or bigraded) algebra of invariant polynomials, in terms of generators and relations. In Sec. IV, we derive integral formulas for both generating functions, with emphasis on their explicit form for unitary representations of compact connected Lie groups, in terms of roots and weights. In Sec. V, we present purely combinatorial formulas for the coefficients, involving the multiplicities of the weights and a set of integer coefficients called ''decomposition indices'' associated with the vectors in the root lattice. In Sec. VI, we discuss as an example the results we have obtained for the simplest among

all compact connected simple Lie groups: SU(2). Finally, in Sec. VII, we present calculations for various irreducible representations of the rank 2 symplectic group Sp(4) and the rank 3 symplectic group Sp(6), including the fundamental representations and the other irreducible representations which appear in the symmetry breaking scheme of Hornos and Hornos.[1]

II. THE MOLIEN FUNCTION: DEFINITION AND ELEMENTARY PROPERTIES

Given an arbitrary finite-dimensional representation π of a compact Lie group G on some n-dimensional vector space V, and denoting by $c_k(\pi)$ the number of (linearly independent) G-invariant polynomials of degree k on V, one defines the corresponding Molien function M_π by the power series

$$M_\pi(z)=\sum_{k=0}^{\infty} c_k(\pi)z^k. \tag{1}$$

Note that identifying homogeneous polynomials of degree k on V with totally symmetric tensors of degree k over V^*, we easily obtain the estimate

$$0\leqslant c_k(\pi)\leqslant\binom{n+k-1}{k}=\binom{n+k-1}{n-1},$$

so $c_k(\pi)$ grows at most polynomially as $k\to\infty$ (the highest power being k^{n-1}); therefore, the above power series is absolutely convergent on the open unit disk in the complex z plane and hence M_π is a complex analytic function there—a function from which we may obviously recover all the numbers $c_k(\pi)$ as Taylor coefficients:

$$c_k(\pi)=\frac{1}{k!}\frac{d^k}{dz^k}M_\pi(z)\bigg|_{z=0}. \tag{2}$$

Note also that this definition can be used both in the real and in the complex setting, and more generally, for representations π of G by $\mathbb{F}$-linear transformations on finite-dimensional vector spaces V over $\mathbb{F}$, where $\mathbb{F}$ is an arbitrary field of characteristic 0.

Some initial information on the structure of the Molien function can be gained by describing the graded ring of G-invariant polynomials on V in terms of generators and relations. In fact, the Hilbert–Weyl theorem guarantees that this graded ring is finitely generated, i.e., that there exists a finite set $\{P_1,\ldots,P_N\}$ of homogeneous G-invariant polynomials on V such that every (homogeneous) G-invariant polynomial P on V can be written in the form

$$P(v)=p(P_1(v),\ldots,P_N(v)). \tag{3}$$

where p is some (homogeneous) polynomial on $\mathbb{F}^N$, provided we define homogeneity of polynomials on $\mathbb{F}^N$ as referring to a modified notion of degree, namely,

$$\deg\ p_{m_1,\ldots,m_N}=m_1\ \deg\ P_1+\ldots+m_N\ \deg\ P_N, \tag{4}$$

for the monomial $p_{m_1},\ldots,m_N$ given by

$$p_{m_1,\ldots,m_N}(u_1,\ldots,u_N)=u_1^{m_1}\ldots u_N^{m_N}. \tag{5}$$

(See, for example, Ref. 5, p. 46 for a statement and pp. 54–58 for a proof. However, I prefer to avoid the term ''Hilbert basis'' used in Ref. 5, which I consider to be potentially misleading and therefore unfortunate.) Note that the polynomial p is in general not uniquely fixed by the polynomial P because there may be relations, i.e., polynomials R on $\mathbb{F}^N$ satisfying

$$R(P_1(v),\ldots,P_N(v))\equiv 0. \tag{6}$$

Note also that the relations R form a graded ring which is nothing but the kernel of the degree-preserving homomorphism, defined by (3), from the graded ring of polynomials p on $\mathbb{F}^N$ onto the graded ring of G-invariant polynomials P on V. Being a graded ideal in a polynomial ring, this kernel is finitely generated, i.e., there exists a finite set $\{R_1,\ldots,R_M\}$ of homogeneous polynomials on $\mathbb{F}^N$ such that every (homogeneous) polynomial R on $\mathbb{F}^N$ satisfying (6) can be written in the form

$$R(u_1,\ldots,u_N)=r(R_1(u_1,\ldots,u_N),\ldots,R_M(u_1,\ldots,u_n)), \tag{7}$$

where r is some (homogeneous) polynomial on $\mathbb{F}^M$, provided we define homogeneity of polynomials on $\mathbb{F}^M$ as referring to a modified notion of degree, namely,

$$\deg\ r_{n_1,\ldots,n_M}=n_1\ \deg\ R_1+\ldots+n_M\ \deg\ R_M, \tag{8}$$

for the monomial $r_{n_1,\ldots,n_M}$ given by

$$r_{n_1,\ldots,n_M}(v_1,\ldots,v_M)=v_1^{n_1}\ldots v_M^{n_M}. \tag{9}$$

(See, for example, Ref. 5, Corollary 6.2, p. 54.) In general, neither the set $\{P_1,\ldots,P_N\}$ of generators nor the set $\{R_1,\ldots,R_M\}$ of relations is unique, but we can at least fix the number N of generators and the number M of relations by requiring both N and M to be minimal.

The simplest case is, of course, when $M=0$, i.e., there are no relations. Counting the number $c_k(\pi)$ of G-invariant polynomials of degree k on V gives

$$c_k(\pi)=\mathrm{card}\left\{(m_1,\ldots,m_N)\in\mathbb{N}_0^N \Big/ \sum_{j=1}^N m_j\ \deg\ P_j=k\right\}.$$

But this is just the coefficient of z^k in the power series expansion of the function

$$M_\pi(z)=\frac{1}{\prod_{j=1}^N(1-z^{\deg\ P_j})}. \tag{10}$$

Conversely, it is clear that if the Molien function for the representation π of G on V has this form, then there can be no relations, because otherwise the number of G-invariant polynomial functions on V of degree k would have to be strictly less than the coefficient of z^k in the power series expansion of Eq. (10), at least for some k. Thus the Molien function detects the presence or absence of relations among the generators of the ring of invariant polynomials.

For later use, it is also of some interest to write down the corresponding result for the next-simplest case $M=1$, i.e., when there is a single relation $R=r(P_1,\ldots,P_N)$. Due to the fact that polynomials of the form $p(P_1,\ldots,P_N)\ r(P_1,\ldots,P_N)$ will vanish identically, counting the number $c_k(\pi)$ of G-invariant polynomials of degree k on V now gives

$$\begin{aligned}c_k(\pi)=&\,\mathrm{card}\left\{(m_1,\ldots,m_N)\in\mathbb{N}_0^N \Big/ \sum_{j=1}^N m_j\ \deg\ P_j=k\right\}\\ &-\mathrm{card}\left\{(m_0;m_1,\ldots,m_N)\in\mathbb{N}_0^{N+1} \Big/ \sum_{j=1}^N m_0 m_j\ \deg\ R\ \deg\ P_j=k\right\}.\end{aligned}$$

But this is just the coefficient of z^k in the power series expansion of the function

$$M_\pi(z)=\frac{1-z^{\deg\ R}}{\prod_{j=1}^{N}(1-z^{\deg\ P_j})}. \tag{11}$$

Again, it is clear that if the Molien function for the representation π of G on V has this form, then there can be no other relations, because otherwise the number of G-invariant polynomial functions on V of degree k would have to be strictly less than the coefficient of z^k in the power series expansion of Eq. (11), at least for some k.

III. A NEW GENERATING FUNCTION

As remarked previously, the above definition of the Molien function applies equally well in the real and in the complex setting. Often, however, it is of interest to also determine the number of (linearly independent) G-invariant real polynomials in a complex representation, the typical example for a quadratic polynomial of this kind being the square of the norm in a unitary representation. Therefore, it is useful to introduce a generating function for counting the number of such invariants as well. The main new feature that must be taken into account is the fact that real polynomials over a complex vector space carry, over and above their usual degree, a bidegree that counts the number of variables in which they are holomorphic and antiholomorphic, respectively. This will lead to a generating function which depends on two variables, rather than one.

Indeed, given an arbitrary representation π of a compact Lie group G on some n-dimensional complex vector space V, let us first of all define $\bar{V}$ to be the n-dimensional complex vector space which is ''V with the opposite complex structure'' and $V_r=\bar{V}_r$ to be the $2n$-dimensional real vector space obtained from V or $\bar{V}$ by ''forgetting the complex structure''. In other words, V, $\bar{V}$ and V_r are identical as sets and as real vector spaces, while the complex structures on V and on $\bar{V}$ are in this picture encoded into real linear transformations $J:V_r\to V_r$ and $J:V_r\to\bar{V}_r$, which are nothing but multiplication by i in V and in $\bar{V}$, respectively, so $J^2=-1$ and $J^2=-1$; then ''opposite'' means that $J=-J$. (The idea behind this construction is that it enables us to identify, for any complex vector space W, complex antilinear maps from V to W with complex linear maps from $\bar{V}$ to W.) Next, recall that homogeneous real polynomials of degree k on V can be identified with totally symmetric $\mathbb{R}$-multilinear mappings from $V_r\times\ldots\times V_r$ (k copies) to $\mathbb{R}$—or to $\mathbb{C}$ if we allow such polynomials to be complex-valued, as will be assumed throughout the following. We shall say that such a polynomial is homogeneous of bidegree (p,q), with $p+q=k$, if under this identification it corresponds to a totally symmetric $\mathbb{C}$-multilinear mapping from $V\times\ldots\times V\times\bar{V}\times\ldots\times\bar{V}$ to $\mathbb{C}$, with p copies of V and q copies of $\bar{V}$. For such a polynomial P, we call the number p its holomorphic degree, denoted by $\deg_h P$, and the number q its antiholomorphic degree, denoted by $\deg_a P$. It is easy to show that any homogeneous real polynomial of degree k may be uniquely decomposed into a sum of homogeneous polynomials of bidegree (p,q), as follows:

$$P_k=\sum_{\substack{p,q=0\\ p+q=k}}^{k} P_{p,q}.$$

Namely, given P_k, we may set

$$\widetilde{P}_{p,q}(v_1,\ldots,v_k)=\frac{1}{2^k}\sum_{l_1,\ldots l_k=0}^{1}(-i)^{l_1+\ldots+l_p}\,i^{l_{p+1}+\ldots+l_{p+q}}\,P_k(i^{l_1}v_1,\ldots,i^{l_k}v_k),$$

which defines a real multilinear function, complex linear and symmetric in the first p variables and complex antilinear and symmetric in the last q variables; then the above decomposition holds with $P_{p,q}$ obtained from $\widetilde{P}_{p,q}$ by symmetrization in all k arguments,

$$P_{p,q}(v_1,\ldots,v_k)=\frac{1}{k!}\sum_{\sigma\in S_k}\widetilde{P}_{p,q}(v_{\sigma(1)},\ldots,v_{\sigma(k)}).$$

This decomposition can be stated in more concrete terms by introducing an arbitrary basis $\{v_1,\ldots,v_n\}$ of V (over $\mathbb{C}$), together with the induced basis $\{v_1,iv_1,\ldots,v_n,iv_n\}$ of V_r (over $\mathbb{R}$), and expanding vectors in the representation space into components:

$$v=\sum_{j=1}^{n}\zeta_j v_j=\sum_{j=1}^{n}(\xi_j+i\eta_j)v_j.$$

Then any polynomial P on V_r can be written either as a linear combination of monomials which are products of powers of the real coordinates ξ_j and η_j or as a linear combination of monomials which are products of powers of the complex coordinates ζ_j and their complex conjugates $\overline{\zeta_j}$. Using the latter representation and employing multi-index notation, we have

$$P(v)=\sum_{\alpha,\beta}a_{\alpha,\beta}\zeta^{\alpha}\overline{\zeta^{\beta}},$$

so

$$P(v)=\sum_{k}P_k(v)=\sum_{p,q}P_{p,q}(v),$$

with

$$P_k(v)=\sum_{|\alpha|+|\beta|=k}a_{\alpha,\beta}\zeta^{\alpha}\overline{\zeta^{\beta}},\quad P_{p,q}(v)=\sum_{\substack{|\alpha|=p\\|\beta|=q}}a_{\alpha,\beta}\zeta^{\alpha}\overline{\zeta^{\beta}}.$$

(All sums are supposed to be finite.)

The crucial point is now that since G acts on V by complex linear transformations $\pi(g)$, these decompositions preserve G-invariance, that is, if P is G-invariant, so are not only the P_k but also the $P_{p,q}$. Therefore, denoting by $c_{p,q}(\pi)$ the number of (linearly independent) G-invariant polynomials of bidegree (p,q), we define the following generating function F_π of two variables, which for later convenience we shall assume to be mutually complex conjugate:

$$F_\pi(z,\overline{z})=\sum_{p,q=0}^{\infty}c_{p,q}(\pi)z^p\overline{z^q}. \tag{12}$$

As before, this power series is absolutely convergent on the open unit disk in the complex z plane and hence F_π is a real analytic function there—a function from which we may obviously recover all the numbers $c_{p,q}(\pi)$ as Taylor coefficients:

$$c_{p,q}(\pi)=\frac{1}{p!}\frac{1}{q!}\frac{\partial^p}{\partial z^p}\frac{\partial^q}{\partial\overline{z^q}}F_\pi(z,\overline{z})\big|_{z=0,\overline{z}=0}. \tag{13}$$

As a first elementary property of this new generating function, note that it behaves naturally under complex conjugation. Namely, introducing an arbitrary conjugation σ on V, that is, an involutive antilinear transformation $\sigma:V\to V$ to define the complex conjugate representation $\overline{\pi}$ of π according to

$$\overline{\pi}(g)=\sigma\pi(g)\sigma\quad\text{for } g\in G, \tag{14}$$

we note that $c_{p,q}(\overline{\pi})=c_{q,p}(\pi)$ and hence

$$F_{\overline{\pi}}(z,\overline{z})=F_\pi(\overline{z},z). \tag{15}$$

Obviously, this relation does not depend on the choice of the conjugation σ because the representations $\overline{\pi_1}$ and $\overline{\pi_2}$ defined by means of two different conjugations σ_1 and σ_2 are equivalent (with $\sigma_2\sigma_1^{-1}$ as the intertwining operator). Note also that F_π contains the Molien functions M_π and $M_{\overline{\pi}}$ as special cases:

$$M_\pi(z)=F_\pi(z,0), \quad M_{\overline{\pi}}(z)=F_\pi(0,z). \tag{16}$$

As in the case of the ordinary Molien function M_π, the generating function F_π allows one to read off important information about the generators of the bigraded ring of G-invariant real polynomials on V and about the relations that exist between them. Indeed, observe first of all that the set $\{P_1,\ldots,P_N\}$ of generators and the set $\{R_1,\ldots,R_M\}$ of relations may without loss of generality (and at most at the expense of increasing the ''minimum'' number N of generators and the '' minimum'' number M of relations required) be assumed to consist of polynomials which are homogeneous in bidegree. Then it is not difficult to see that in the simplest case $M=0$ (no relations),

$$c_{p,q}(\pi)=\mathrm{card}\left\{(m_1,\ldots,m_N)\in\mathbb{N}_0^N \;\middle/\; \sum_{j=1}^N m_j\ \deg_h P_j=p,\ \sum_{j=1}^N m_j\ \deg_a P_j=q\right\}.$$

and hence

$$F_\pi(z,\overline{z})=\frac{1}{\prod_{j=1}^N(1-z^{\deg_h P_j}\overline{z}^{\deg_a P_j})}, \tag{17}$$

while in the next-simplest case $M=1$ (a single relation),

$$\begin{aligned} c_{p,q}(\pi)=&\mathrm{card}\left\{(m_1,\ldots,m_N)\in\mathbb{N}_0^N \;\middle/\; \sum_{j=1}^N m_j\ \deg_h P_j=p,\ \sum_{j=1}^N m_j\ \deg_a P_j=q\right\}\\ &-\mathrm{card}\left\{(m_0;m_1,\ldots,m_N)\in\mathbb{N}_0^{N+1} \;\middle/\; \begin{array}{l}\displaystyle\sum_{j=1}^N m_0 m_j\ \deg_h R\ \deg_h P_j=p\\ \displaystyle\sum_{j=1}^N m_0 m_j\ \deg_a R\ \deg_a P_j=q\end{array}\right\}. \end{aligned}$$

and hence

$$F_\pi(z,\overline{z})=\frac{1-z^{\deg_h R}\,\overline{z}^{\deg_a R}}{\prod_{j=1}^N(1-z^{\deg_h P_j}\,\overline{z}^{\deg_a P_j})}. \tag{18}$$

IV. INTEGRAL FORMULAS

To begin with, we quote a well-known integral formula which allows one to compute the Molien function M_π in terms of an integral over the group. Namely, let μ_G be the biinvariant Haar measure on G, normalized so that the total volume of G with respect to μ_G is 1. Then

$$M_\pi(z)=\int_G d\mu_G(g)\ \frac{1}{\det(1-z\,\pi(g))}. \tag{19}$$

This formula is easily generalized to an integral formula for the generating function F_π; it reads

$$F_\pi(z,\overline{z})=\int_G d\mu_G(g)\ \frac{1}{\det(1-z\,\pi(g))}\ \frac{1}{\det(1-\overline{z}\,\overline{\pi(g)})}. \tag{20}$$

The proof is similar to that for the usual Molien function (see, e.g., Ref. 6 p. 204) and is based on calculating the character χ_P of the representation π_P of G on the algebra of polynomial functions on V induced by the given representation π of G on V according to

$$(\pi_P(g)P)(v)=P(\pi(g)^{-1}v),$$

as follows: Since G is a compact Lie group, the given representation π of G on V may without loss of generality be assumed to be unitary (starting from some arbitrary scalar product on V, a G-invariant scalar product on V is obtained by integration over the group), so for fixed $g\in G$, $\pi(g)^{-1}$ can be diagonalized, i.e., there exists a basis $v_1,\ldots,v_n$ of V consisting of eigenvectors of $\pi(g)^{-1}$ with eigenvaleus $\lambda_1,\ldots,\lambda_n$. As a result, the monomials $\zeta^\alpha\overline{\zeta^\beta}$ (see above) form a basis of the space of polynomials on V of bidegree (p,q) consisting of eigenvectors of $\pi_P(g)$ with eigenvalues $\lambda^\alpha\overline{\lambda^\beta}$, so that the character $\chi_{p,q}$ of the representation $\pi_{p,q}$ on the space of homogeneous polynomials on V of bidegree (p,q) induced by the given representation π of G on V is given by

$$\chi_{p,q}(g)=\text{trace }\pi_{p,q}(g)=\sum_{\substack{|\alpha|=p\\|\beta|=q}}\lambda^\alpha\overline{\lambda^\beta}.$$

Multiplying by $z^p\overline{z^q}$ and summing over p and q gives, in the sense of formal power series,

$$\sum_{p,q=0}^{\infty}\chi_{p,q}(g)z^p\overline{z^q}=\sum_{p,q=0}^{\infty}\sum_{\substack{|\alpha|=p\\|\beta|=q}}(z\lambda)^\alpha(\overline{z\lambda})^\beta$$
$$=\prod_{j=1}^{n}(1-z\lambda_j)^{-1}\prod_{j=1}^{n}(1-\overline{z\lambda}_j)^{-1}=\det(1-z\pi(g))^{-1}\det(1-\overline{z\pi(g)})^{-1}.$$

The result now follows due to a standard fact from the representation theory of compact groups, namely, that the dimension of the fixed subspace of a given representation—or to put it differently, the multiplicity with which the trivial representation occurs in a given representation—is equal to the integral of the character of that representation over the group.

An important aspect of Eqs. (19) and (20) which greatly facilitates the evaluation of the integrals is the fact that the determinants appearing under the integral signs are central functions on the group (i.e., are invariant under conjugation), so that the integral over the whole group can be reduced to an integral over the space of conjugacy classes.

Before performing this reduction, we note that the integral representations (19) and (20) are valid in two special cases which are at opposite extremes. One of these occurs when G is discrete, that is, a finite group, so that the integrals reduce to finite sums,

$$M_\pi(z)=\frac{1}{|G|}\sum_{g\in G}\frac{1}{\det(1-z\pi(g))},\tag{21}$$

$$F_\pi(z,\overline{z})=\frac{1}{|G|}\sum_{g\in G}\frac{1}{\det(1-z\pi(g))}\frac{1}{\det(1-\overline{z\pi(g)})},\tag{22}$$

which can be reduced to sums over conjugacy classes; their explicit evaluation, by means of various techniques, has been studied in the literature (see, e.g., Refs. 6, pp. 204–207, 7, and 8). The other and apparently much less studied case occurs when G is a compact connected Lie group, so that the integrals over the whole group G can be reduced to integrals over a maximal torus T: it is this situation that we shall now investigate in some detail.

Thus let G be a compact connected Lie group, let T be a maximal torus in G and let μ_T be the bi-invariant Haar measure on T, normalized so that the total volume of T with respect to μ_T is 1.

Moreover, let $\mathfrak{g}$ be the Lie algebra of G and $\mathfrak{t}\subset\mathfrak{g}$ be the Lie algebra of $T\subset G$. Introducing a G-invariant inner product $(.,.)$ on $\mathfrak{g}$, we may decompose $\mathfrak{g}$ into the orthogonal direct sum

$$\mathfrak{g}=\mathfrak{t}\oplus\mathfrak{t}^{\perp}$$

of $\mathfrak{t}$ and its orthogonal complement $\mathfrak{t}^{\perp}$; this decomposition is $\mathrm{Ad}(T)$-invariant and does not depend on the choice of the inner product $(.,.)$. Finally, let W_G be the Weyl group of G ($W_G=N_G(T)/T$ where $N_G(T)$ is the normalizer of T in G, defined by $N_G(T)=\{g\in G/gtg^{-1}\in T$ for all $t\in T\}$) and $|W_G|$ be its order. Then

$$\mathrm{Ad}(t)=1+\mathrm{Ad}^{\perp}(t)\quad\text{for } t\in T$$

and (see, e.g., Ref. 9, pp. 101–103)

$$M_{\pi}(z)=\frac{1}{|W_G|}\int_T d\mu_T(t)\,\frac{\det(1-\mathrm{Ad}^{\perp}(t))}{\det(1-z\,\pi(t))}, \tag{23}$$

$$F_{\pi}(z,\overline{z})=\frac{1}{|W_G|}\int_T d\mu_T(t)\,\frac{\det(1-\mathrm{Ad}^{\perp}(t))}{\det(1-z\,\pi(t))\det(1-\overline{z\,\pi(t)})}. \tag{24}$$

These integrals can be further evaluated in terms of the root system Δ of $\mathfrak{g}$ and the weight system Φ for the representation π. The procedure is standard when $\mathfrak{g}$ is semisimple, but to a certain degree it works just as well in the more general case when $\mathfrak{g}$ has a non-trivial center. The starting point is the fact that T being Abelian, the restriction from G to T of any unitary representation of G, such as the complexified adjoint representation Ad on the complexification $\mathfrak{g}^c$ of $\mathfrak{g}$ or the representation π on V, splits into the direct sum of irreducible one-dimensional representations. Grouping together all subspaces characterized by the same eigenvalues under all elements of T leads to the well-known root space decomposition

$$\mathfrak{g}^c=\mathfrak{t}^c\oplus\bigoplus_{\alpha\in\Delta}\mathfrak{g}_{\alpha}$$

of $\mathfrak{g}^c$ and to the weight space decomposition

$$V=\bigoplus_{\lambda\in\Phi}V_{\lambda}$$

of V; the dimension of the subspace V_{λ} is commonly known as the multiplicity $m(\lambda)$ of λ. The action of T on each of these subspaces is given by a character of T, i.e., a Lie group homomorphism from T to the unit circle, written as $t\to t^{\alpha}$ and $t\to t^{\lambda}$, respectively, according to

$$\mathrm{Ad}(t)(X)=t^{\alpha}X\quad\text{for } t\in T \text{ and } X\in\mathfrak{g}_{\alpha}, \tag{25}$$

and

$$\pi(t)(v)=t^{\lambda}v\quad\text{for } t\in T \text{ and } v\in V_{\lambda}, \tag{26}$$

respectively. At the Lie algebra level, Eqs. (25) and (26) imply the usual relations

$$\mathrm{ad}(H)(X)=\alpha(H)X\quad\text{for } H\in\mathfrak{t} \text{ and } X\in\mathfrak{g}_{\alpha}, \tag{27}$$

and

$$\dot{\pi}(H)(v)=\lambda(H)v\quad\text{for } H\in\mathfrak{t} \text{ and } v\in V_{\lambda}, \tag{28}$$

respectively. By complex conjugation of Eqs. (26) and (28), we obtain

$$\overline{\pi}(t)(v)=t^{-\lambda}v \quad \text{for } t\in T \text{ and } v\in\sigma V_\lambda, \tag{29}$$

$$\dot{\overline{\pi}}(H)(v)=-\lambda(H)v \quad \text{for } H\in\mathfrak{t} \text{ and } v\in\sigma V_\lambda. \tag{30}$$

We follow here the standard mathematical convention of considering roots α and weights λ as real linear forms on $\mathfrak{t}$, or as complex linear forms on the complexification $\mathfrak{t}^c$ of $\mathfrak{t}$, which—in accordance with the fact that $\mathfrak{g}$ is the compact real form of $\mathfrak{g}^c$—take purely imaginary values on $\mathfrak{t}$ (eigenvalues of antihermitean matrices are purely imaginary). Moreover, roots α and weights λ are transferred to generators H_α and H_λ using the isomorphism induced by the G-invariant nondegenerate complex bilinear form $(.,.)$ on $\mathfrak{g}^c$ obtained from the G-invariant inner product $(.,.)$ on $\mathfrak{g}$ by complex bilinear extension:

$$(H_\alpha,H)=\alpha(H), \quad (H_\lambda H)=\lambda(H) \quad \text{for all } H\in\mathfrak{t}^c.$$

This isomorphism is, by definition, an isometry:

$$(\alpha,\beta)=(H_\alpha,H_\beta), \quad (\lambda,\mu)=(H_\lambda,H_\mu).$$

The reality properties may then be summarized in the statement that roots α and weights λ belong to the real vector space $i\mathfrak{t}^*$, while the vectors H_α and H_λ belong to the real vector space $i\mathfrak{t}$. With this notation, we can rewrite the integrals in Eqs. (23) and (24) as follows:

$$M_\pi(z)=\frac{1}{|W_G|}\int_T d\mu_T(t)\,\frac{\Pi_{\alpha\in\Delta}(1-t^\alpha)}{\Pi_{\lambda\in\Phi}(1-zt^\lambda)^{m(\lambda)}}, \tag{31}$$

$$F_\pi(z,\overline{z})=\frac{1}{|W_G|}\int_T d\mu_T(t)\,\frac{\Pi_{\alpha\in\Delta}(1-t^\alpha)}{\Pi_{\lambda\in\Phi}(1-zt^\lambda)^{m(\lambda)}(1-\overline{zt^{-\lambda}})^{m(\lambda)}}. \tag{32}$$

A further condition to be employed is that roots α and weights λ must be integral linear forms in the sense of taking values in $2\pi i\mathbb{Z}$ on the so-called unit lattice

$$L_1=\{H\in\mathfrak{t}/\exp(H)=1\} \tag{33}$$

of G: such integral linear forms are precisely the ones that arise as differentials of characters of T (Ref. 9, pp. 94–95). This lattice is the essential ingredient for understanding how to convert the integrals (31) and (32) into integrals over the product of r unit circles ($r=\text{rank } G=\dim T$), which can then be evaluated by an r-fold successive application of the residue theorem. Indeed, let us assume that $\{2\pi H_1,\ldots,2\pi H_r\}$ is a basis of L_1 and define

$$\begin{aligned} h(\alpha)&=(h_1(\alpha),\ldots,h_r(\alpha))=(-i\alpha(H_1),\ldots,-i\alpha(H_r)) \quad \text{for } \alpha\in\Delta,\\ h(\lambda)&=(h_1(\lambda),\ldots,h_r(\lambda))=(-i\lambda(H_1),\ldots,-i\lambda(H_r)) \quad \text{for } \lambda\in\Phi. \end{aligned} \tag{34}$$

Then the map

$$\begin{aligned} &S^1\times\ldots\times S^1\to T,\\ &w=(w_1,\ldots,w_r)=(e^{i\theta_1},\ldots,e^{i\theta_r})\mapsto t=\exp\left(\sum_{j=1}^r\theta_jH_j\right) \end{aligned} \tag{35}$$

is an isomorphism of compact Abelian Lie groups such that, in multi-index notation (generalized to include negative integer powers),

$$t^{\alpha}=w^{h(\alpha)}=w_1^{h_1(\alpha)}\ldots w_r^{h_r(\alpha)} \quad \text{for } \alpha\in\Delta,$$
$$t^{\pm\lambda}=w^{\pm h(\lambda)}=w_1^{\pm h_1(\lambda)}\ldots w_r^{\pm h_r(\lambda)} \quad \text{for } \lambda\in\Phi. \tag{36}$$

Thus we obtain

Theorem 1: *Assume π is a finite-dimensional unitary representation of a compact connected Lie group G. Then in terms of the multi-index notation for roots and weights with respect to a basis of the unit lattice of G, as introduced in Eqs. (33–36), the generating functions M_π and F_π are given by*

$$M_\pi(z)=\frac{1}{|W_G|}\prod_{j=1}^{r}\oint\frac{dw_j}{2\pi i w_j}\frac{\Pi_{\alpha\in\Delta}(1-w^{h(\alpha)})}{\Pi_{\lambda\in\Phi}(1-zw^{h(\lambda)})^{m(\lambda)}}, \tag{37}$$

$$F_\pi(z,\overline{z})=\frac{1}{|W_G|}\prod_{j=1}^{r}\oint\frac{dw_j}{2\pi i w_j}\frac{\Pi_{\alpha\in\Delta}(1-w^{h(\alpha)})}{\Pi_{\lambda\in\Phi}(1-zw^{h(\lambda)})^{m(\lambda)}(1-\overline{zw}^{-h(\lambda)})^{m(\lambda)}}. \tag{38}$$

The expressions $w^{h(\alpha)}$ and $w^{\pm h(\lambda)}$ will often be abbreviated to w^{α} and $w^{\pm\lambda}$, respectively.

When G is semisimple, which is by far the most important case for applications, the exponents $h(\alpha)$ and $h(\lambda)$ are easily calculated from the root system Δ of $\mathfrak{g}$ and the weight system Φ for the representation π. To this end, it is convenient to introduce the following two lattices in $\mathfrak{t}$:

(a) the coroot lattice L_{cr}, which is dual to the standard weight lattice (Ref. 10, p. 67), in the sense that

$$L_{cr}=\{\check{\alpha}\in\mathfrak{t}/\lambda(\check{\alpha})\in 2\pi i\mathbb{Z} \quad \text{for all weights } \lambda\}, \tag{39}$$

and identical with the Δ-lattice which forms the translation part of the affine Weyl group (Ref. 11, p. 314) and generated by the vectors $4\pi i H_\alpha/(H_\alpha,H_\alpha)$ with $\alpha\in\Delta$ (Ref. 11, pp. 317–318),

(b) the coweight lattice L_{cw}, which is dual to the standard root lattice (Ref. 10, p. 67), in the sense that

$$L_{cw}=\{\check{\lambda}\in\mathfrak{t}/\alpha(\check{\lambda})\in 2\pi i\mathbb{Z} \quad \text{for all roots } \alpha\}, \tag{40}$$

and identical with the central lattice, defined as

$$L_c=\{H\in\mathfrak{t}/\exp(H)\in Z\}, \tag{41}$$

where Z is the center of G (Ref. 9, p. 95, Ref. 11, p. 311).

Obviously, the coroot lattice is contained in the coweight lattice, and the unit lattice lies in between:

$$L_{cr}\subset L_1\subset L_{cw}. \tag{42}$$

Note also that the unit lattice is sensitive to coverings, while the coroot lattice and the coweight lattice are not: they depend on the Lie group G only through its Lie algebra $\mathfrak{g}$. In fact, we have two extreme cases, between which the general case is intermediate:

(i) When G is simply connected, the unit lattice is minimal and coincides with the coroot lattice.
(ii) When G has trivial center, the unit lattice is maximal and coincides with the coweight lattice.

Therefore, when G is simply connected (which we may always assume to be the case, without loss of generality), one possible choice of the basis $\{2\pi H_1,\ldots,2\pi H_r\}$ is to set

$$H_j=\frac{2iH_{\alpha_j}}{(H_{\alpha_j},H_{\alpha_j})}, \tag{43}$$

where $\{\alpha_1,\ldots,\alpha_r\}$ is a basis of simple roots. In this case, the exponents $h(\alpha)$ and $h(\lambda)$ are precisely the coefficients in the expansion

$$\alpha=\sum_{j=1}^{r} h_j(\alpha)\lambda_j, \quad \lambda=\sum_{j=1}^{r} h_j(\lambda)\lambda_j \tag{44}$$

of a root $\alpha\in\Delta$ and of a weight $\lambda\in\Phi$ in terms of the basis $\{\lambda_1,\ldots,\lambda_r\}$ of fundamental weights, which is dual to the basis of simple roots in the usual sense:

$$\frac{2(\lambda_j,\alpha_k)}{(\alpha_k,\alpha_k)}=\delta_{jk}. \tag{45}$$

Observe that the relevant parts of this construction do not depend on the choice of the scalar product (.,.): a different choice would simply amount to a change of an overall normalization factor on each simple ideal which drops out of the definition of the generators appearing on the rhs of Eq. (43) or the definition (45) of the fundamental weights. When we want to be specific about normalization, we shall not use the Killing form, but rather the so-called standard form, which is normalized so that the long roots have length $\sqrt{2}$.

The additional assumption that G should be semisimple is less restrictive than it may seem. Indeed, when G is not semisimple, that is, has a non-discrete center Z, consider the orthogonal direct decomposition $\mathfrak{g}=\mathfrak{z}\oplus\mathfrak{g}_s$ of $\mathfrak{g}$ into its center $\mathfrak{z}$ and its maximal semisimple ideal $\mathfrak{g}_s=[\mathfrak{g},\mathfrak{g}]$, together with the corresponding orthogonal direct decomposition $\mathfrak{t}=\mathfrak{z}\oplus\mathfrak{t}_s$ of the maximal Abelian subalgebra $\mathfrak{t}$ of $\mathfrak{g}$ into the center $\mathfrak{z}$ of $\mathfrak{g}$ and a maximal Abelian subalgebra $\mathfrak{t}_s$ of $\mathfrak{g}_s$. Then the roots α ($\alpha\in\Delta$) only generate the subspace $i\mathfrak{t}_s^*$ of $i\mathfrak{t}^*$ and the vectors H_α ($\alpha\in\Delta$) only generate the subspace $i\mathfrak{t}_s$ of $i\mathfrak{t}$, as real vector spaces. We can still define the unit lattice L_1 (cf. Eq. (33)) and introduce a basis $\{2\pi H_1,\ldots,2\pi H_r\}$ as before, as well as the exponents $h(\alpha)$ and $h(\lambda)$ (cf. Eq. (34)), but the unit lattice is now very flexible: any lattice in $\mathfrak{g}$ which contains the coroot lattice of $\mathfrak{g}_s$ and whose orthogonal projection to $\mathfrak{g}_s$ is contained in the coweight lattice of $\mathfrak{g}_s$ is admissible (Ref. 9, p. 97). Therefore, there is now no general way to proceed beyond Eqs. (37) and (38); their explicit evaluation must for each representation π be carried out separately.

A final important observation concerns the form of the generating functions M_π and F_π when π is the adjoint representation Ad. In this case, we may appeal to Chevalley's theorem, which provides a complete description of the ring of invariant polynomials on a semisimple Lie algebra $\mathfrak{g}$: it is freely generated by $r=\mathrm{rank}(\mathfrak{g})$ elementary polynomials $P_1,\ldots,P_r$, whose degrees $p_1,\ldots,p_r$ are commonly known as the exponents of $\mathfrak{g}$. Therefore, the usual Molien function for the adjoint representation reads

$$M_{\mathrm{Ad}}(z)=\prod_{j=1}^{r}\frac{1}{1-z^{p_j}}. \tag{46}$$

Explicitly, for the classical groups, the polynomials $P_1,\ldots,P_r$ can (with one exception) be written as trace polynomials in the defining representation:

(i) $A_r: \mathfrak{g}=\mathfrak{sl}(r+1)$ or $\mathfrak{su}(r+1)$ (compact real form):

$$P_j(X)=\mathrm{tr}(X^{j+1}) \quad \text{for } X\in\mathfrak{g},\ j=1,...,r.$$

(ii) $B_r: \mathfrak{g}=\mathfrak{so}(2r+1,\mathbb{C})$ or $\mathfrak{so}(2r+1)$ (compact real form):

$$P_j(X)=\mathrm{tr}(X^{2j}) \quad \text{for } X\in\mathfrak{g},\ j=1,...,r.$$

(iii) $C_r: \mathfrak{g}=\mathfrak{sp}(2r,\mathbb{C})$ or $\mathfrak{sp}(2r)$ (compact real form):

$$P_j(X)=\mathrm{tr}(X^{2j}) \quad \text{for } X\in\mathfrak{g},\ j=1,...,r.$$

(iv) $D_r: \mathfrak{g}=\mathfrak{so}(2r,\mathbb{C})$ or $\mathfrak{so}(2r)$ (compact real form):

$$P_j(X)=\mathrm{tr}(X^{2j}) \quad \text{for } X\in\mathfrak{g},\ j=1,...,r-1,$$

$$P_r(X)=Pf(X) \quad \text{for } X\in\mathfrak{g},$$

where $Pf(X)$ denotes the Pfaffian of X. See, for example, Ref. 12, pp. 253–263.

It should be pointed out that Chevalley's theorem refers to invariant complex polynomials on complex semisimple Lie algebras, or equivalently, to invariant real polynomials on real semisimple Lie algebras (including compact real forms), but not to invariant real polynomials on complex semisimple Lie algebras. There is thus no reason to believe that this polynomial ring has an equally simple structure. In fact, it does not. To show this, we have calculated the generating function F_{Ad} for the simple Lie algebra $B_2=C_2$: the result (cf. Eq. (125) in Sec. VII below) exhibits a complicated structure, with lots of generators and relations.

V. COMBINATORIAL FORMULAS

In the following, we shall derive combinatorial formulas which allow one to determine the coefficients c_k and $c_{p,q}$ of the generating functions M_π and F_π solely in term of the root system Δ and the weight system Φ of the representation π.

Our starting point will be the integral representations (37) of M_π and (38) of F_π. First of all we need the following

Proposition: Let $f_1,\ldots,f_n$ be polynomials of degree 1 in the variable x (with coefficients that are rational functions of other variables $w_1,\ldots,w_r$). Then for non-negative integers $m_1,\ldots,m_n$ and k,

$$\frac{1}{k!}\frac{\partial^k}{\partial x^k}\left(\prod_{i=1}^n f_i^{-m_i}\right)=(-1)^k\sum_{|l|=k}\prod_{i=1}^n\binom{m_i-1+l_i}{l_i}\left(f_i^{-m_i-l_i}\right)\left(\frac{\partial f_i}{\partial x}\right)^{l_i}, \tag{47}$$

where we use multi-index notation, i.e., $l=(l_1,\ldots,l_n)$, where the l_i are non-negative integers, and $|l|=l_1+\ldots+l_n$.

Proof: For $k=1$, the above formula reduces to the statement that

$$\frac{\partial}{\partial x}\left(\prod_{i=1}^n f_i^{-m_i}\right)=-\sum_{j=1}^n\prod_{i=1}^n\left(f_i^{-m_i}\right)\left(\frac{m_j}{f_j}\frac{\partial f_j}{\partial x}\right),$$

which is obvious. The general case is proved by induction on k, using the hypothesis that

$$\frac{\partial^2 f_i}{\partial x}=0,$$

as follows:

$$\frac{1}{(k+1)!}\frac{\partial^{k+1}}{\partial x^{k+1}}\left(\prod_{i=1}^{n} f_i^{-m_i}\right)=\frac{(-1)^{k+1}}{k+1}\sum_{|p|=k}\sum_{j=1}^{n}\left[\prod_{\substack{i=1\\ i\neq j}}^{n}\binom{m_i-1+p_i}{p_i}(f_i^{-m_i-p_i})\left(\frac{\partial f_i}{\partial x}\right)^{p_i}\right]$$
$$\times\binom{m_j-1+p_j}{p_j}(m_j+p_j)(f_j^{-m_j-p_j-1})\left(\frac{\partial f_j}{\partial x}\right)^{p_j+1}$$
$$=(-1)^{k+1}\sum_{|p|=k}\sum_{j=1}^{n}\left[\prod_{\substack{i=1\\ i\neq j}}^{n}\binom{m_i-1+l_i}{l_i}(f_i^{-m_i-l_i})\left(\frac{\partial f_i}{\partial x}\right)^{l_i}\right]$$
$$\times\binom{m_j-1+l_j}{l_j}\frac{l_j}{k+1}(f_j^{-m_j-l_j})\left(\frac{\partial f_j}{\partial x}\right)^{l_j},$$

where l is defined in terms of p and j by putting $l_i=p_i$ for $i\neq j$ and $l_j=p_j+1$. Converting the double sum over p and j to a single sum over l yields the desired result.

As a result, we can explicitly differentiate the integrands of Eqs. (37) and (38):

$$\frac{1}{k!}\frac{\partial^k}{\partial z^k}\frac{1}{\prod_{\lambda\in\Phi}(1-zw^{\lambda})^{m(\lambda)}}\bigg|_{z=0}=\sum_{|l|=k}N(l,m)w^{\Lambda(l)},$$

$$\frac{1}{p!}\frac{1}{q!}\frac{\partial^p}{\partial z^p}\frac{\partial^q}{\partial\overline{z}^q}\frac{1}{\prod_{\lambda\in\Phi}(1-zw^{\lambda})^{m(\lambda)}(1-\overline{z}\overline{w}^{-\lambda})^{m(\lambda)}}\bigg|_{z=0,\overline{z}=0}=\sum_{|r|=p,|s|=q}N(r,m)N(s,m)w^{\Lambda(r-s)},$$

where

$$N(l,m)=\prod_{\lambda\in\Phi}\binom{m(\lambda)+l(\lambda)-1}{l(\lambda)},$$

and

$$\Lambda(l)=\sum_{\lambda\in\Phi}l(\lambda)\lambda.$$

In order to carry out the residue integrals in Eqs. (37) and (38), we must also expand the numerator in powers of w. The net result is most conveniently formulated in terms of the following concepts:

Definition 1: The extended root system $\tilde{\Delta}$ associated with a given root system Δ is the set of all linear combinations

$$\tilde{\alpha}=\sum_{\alpha\in\Delta}a(\alpha)\alpha \tag{48}$$

of roots with coefficients $a(\alpha)$ which are either 0 or 1. (Thus $\tilde{\Delta}$ is a (finite) subset of the root lattice generated by Δ.) To any such extended root $\tilde{\alpha}$, we associate its decomposition index $i(\tilde{\alpha})$, defined as the difference

$$i(\tilde{\alpha})=n_+(\tilde{\alpha})-n_-(\tilde{\alpha}), \tag{49}$$

between the number $n_+(\tilde{\alpha})$ of such decompositions of $\tilde{\alpha}$ into a sum of roots with an even number of nonzero coefficients and the number $n_-(\tilde{\alpha})$ of such decompositions of $\tilde{\alpha}$ into a sum of roots with an odd number of nonzero coefficients. In other words,

$$i(\tilde{\alpha}) = \sum_a (-1)^{|a|}, \tag{50}$$

where the sum is over all sequences $(a(\alpha))_{\alpha \in \Delta}$ of coefficients $a(\alpha) \in \{0,1\}$ satisfying Eq. (48), and

$$|a| \equiv \sum_{\alpha \in \Delta} a(\alpha). \tag{51}$$

We extend the definition of the decomposition index to the whole root lattice by setting

$$i(\tilde{\alpha}) = 0 \quad \text{if} \quad \tilde{\alpha} \notin \tilde{\Delta}. \tag{52}$$

In these terms, we have

$$\prod_{\alpha \in \Delta} (1 - w^{\alpha}) = \sum_{\tilde{\alpha} \in \tilde{\Delta}} i(\tilde{\alpha}) w^{\tilde{\alpha}}. \tag{53}$$

Note that just like the usual root system, the extended root system is invariant under the action of the corresponding Weyl group W, and so is the decomposition index (it is constant along Weyl group orbits). Two particular values that can be computed immediately are

$$i(2\rho) = (-1)^{|\Delta|/2}, \quad i(0) = |W|, \tag{54}$$

where 2ρ is the vector obtained as the sum of all positive roots. (The first formula follows by observing that in this case there is only one possible sequence, namely (1,...,1), which has the parity stated above, while the second formula follows by combining the previous formula at $w = 0$ with the fact that $M_{\pi}(0) = 1$.) For the simplest rank 1 algebra A_1, for example, we have $\Delta = \{\alpha, -\alpha\}$ and $\tilde{\Delta} = \{\alpha, 0, -\alpha\}$ with $i(\alpha) = i(-\alpha) = -1$ and $i(0) = 2$. The result for the simple rank 2 algebras A_2, $B_2 = C_2$ and G_2 is shown in Figures 1–3.

Definition 2: For any positive integer k, the k-extended weight system $\tilde{\Phi}(k)$ associated with a given weight system Φ is the set of all linear combinations

$$\tilde{\lambda} = \sum_{\lambda \in \Phi} l(\lambda) \lambda \tag{55}$$

of weights with coefficients $l(\lambda)$ which are non-negative integers, such that

$$|l| \equiv \sum_{\lambda \in \Phi} l(\lambda) = k. \tag{56}$$

(Thus $\tilde{\Phi}(k)$ is a (finite) subset of the weight lattice.) To any such k-extended weight $\tilde{\lambda}$, we associate its k-extended multiplicity $m_k(\tilde{\lambda})$, defined as the sum of the combinatorial coefficients

$$N(l,m) = \prod_{\lambda \in \Phi} \binom{m(\lambda) - 1 + l(\lambda)}{l(\lambda)} = \prod_{\lambda \in \Phi} \binom{m(\lambda) - 1 + l(\lambda)}{m(\lambda) - 1} \tag{57}$$

over all such representations of $\tilde{\lambda}$. In other words,

$$m_k(\tilde{\lambda}) = \sum_l N(l,m), \tag{58}$$

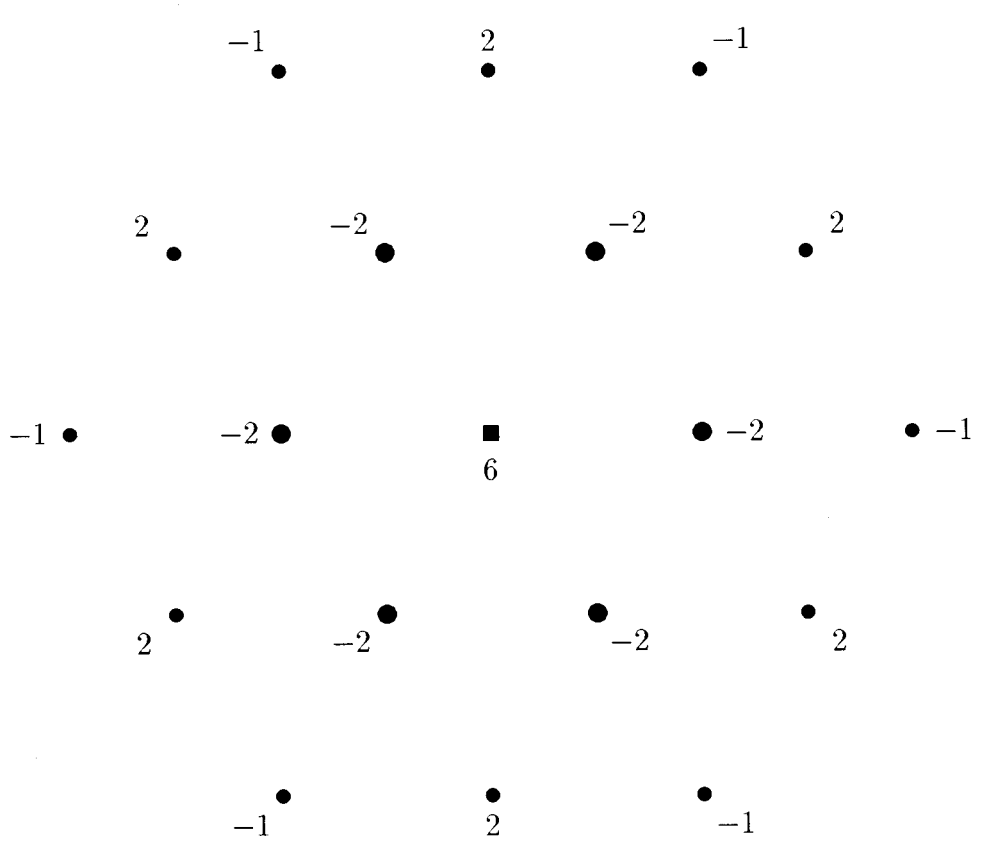

FIG. 1. Root system and extended root system, with decompostion indices: A_2.

where the sum is over all sequences $(l(\lambda))_{\lambda\in\Phi}$ of coefficients $l(\lambda)\in\mathbb{N}$ satisfying Eqs. (55) and (56).

Note that just like the usual weight system and the usual multiplicity, the k-extended weight system and the k-extended multiplicity are invariant under the action of the corresponding Weyl group W, and that $\tilde{\Phi}(1)=\Phi$, $m_1(\lambda)=m(\lambda)$.

Now we are ready to formulate the main result of this section:

Theorem 2: *Assume π is a finite-dimensional unitary representation of a compact connected Lie group G. Then in terms of the multi-index notation for roots and weights with respect to a basis of the unit lattice of G, as introduced in Eqs. (33–36), and with the notation introduced above, the number $c_k(\pi)$ of (linearly independent) G-invariant complex polynomials of degree k and the number $c_{p,q}(\pi)$ of (linearly independent) G-invariant real polynomials of bidegree (p,q) on the carrier space of π are given by the combinatorial formulas*

$$c_k(\pi)=\frac{1}{|W_G|}\sum_{\tilde{\lambda}\in\tilde{\Phi}(k)} i(\tilde{\lambda})m_k(\tilde{\lambda}), \tag{59}$$

and

$$c_{p,q}(\pi)=\frac{1}{|W_G|}\sum_{\tilde{\lambda}\in\tilde{\Phi}(p),\tilde{\mu}\in\tilde{\Phi}(q)} i(\tilde{\lambda}-\tilde{\mu})m_p(\tilde{\lambda})m_q(\tilde{\mu}), \tag{60}$$

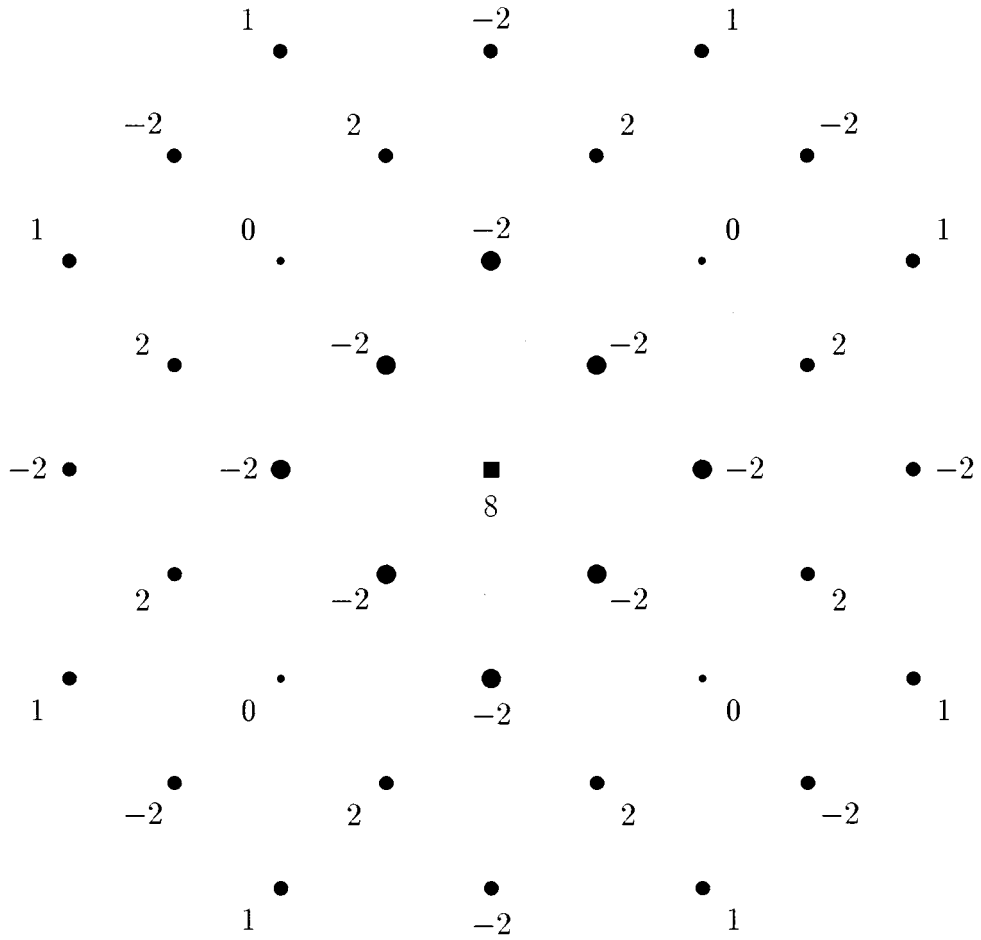

FIG. 2. Root system and extended root system, with decomposition indices: C_2.

respectively. (Note that the terms on the rhs of these equations yield non-vanishing contributions only when $\tilde{\lambda}$ *and* $\tilde{\lambda}-\tilde{\mu}$*, respectively, belongs to the extended root system* $\tilde{\Delta}$*.)*

We believe that on the basis of this theorem, it should be possible to develop a computer program for calculating the numbers c_k and $c_{p,q}$, up to reasonably high orders, for arbitrary groups and representations. The amount of computing time can be reduced by a factor of the order of $|W_G|$ by an appropriate implementation of the Weyl group symmetry.

VI. EXAMPLE: SU(2)

As a first example, let us apply Eqs. (37) and (38) to the case where $G=\mathrm{SU}(2)$, with maximal torus $T=\mathrm{U}(1)$ and $\pi=\pi_s$ the irreducible spin s representation. Then $\mathfrak{g}=\mathfrak{su}(2)$ is the Lie algebra of complex traceless antihermitean matrices and $\mathfrak{t}=\mathfrak{u}(1)$ the maximal Abelian subalgebra of imaginary traceless diagonal matrices, with invariant scalar product $(.,.)$ given by

$$(X,Y)=\mathrm{tr}(XY) \quad \text{for } X,Y\in\mathfrak{su}(2). \tag{61}$$

Using the Pauli matrices

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}, \quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \tag{62}$$

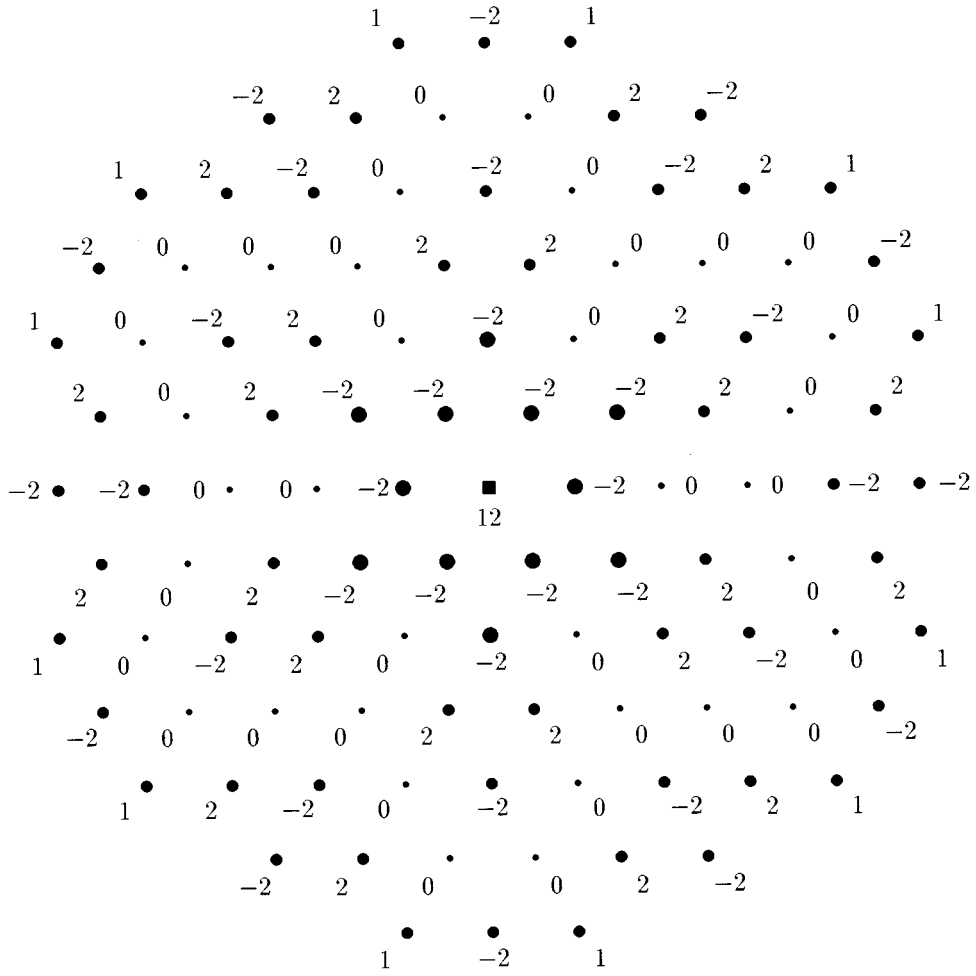

FIG. 3. Root system and extended root system, with decomposition indices: G_2.

which satisfy

$$\sigma_j \sigma_k = \delta_{jk} + i \epsilon_{jkl} \sigma_l , \tag{63}$$

we see that the nonzero roots are $\pm \alpha$, where

$$\alpha(H) = H_{11} - H_{22} = \mathrm{tr}(H \sigma_3) \quad \text{for } H \in \mathfrak{u}(1), \tag{64}$$

with root vectors

$$E_{\pm \alpha} = \sigma_1 \pm i \sigma_2 , \tag{65}$$

implying

$$H_\alpha = \sigma_3 , \tag{66}$$

which does have length $\sqrt{2}$, in accordance with our previous convention. The fundamental weight is given by

$$\lambda(H)=\tfrac{1}{2}(H_{11}-H_{22})=\tfrac{1}{2}\mathrm{tr}(H\sigma_3) \quad \text{for } H\in\mathfrak{u}(1), \tag{67}$$

so

$$H_\lambda=\tfrac{1}{2}\,\sigma_3. \tag{68}$$

Note that the root lattice is generated by α and the weight lattice is generated by λ, whereas the coroot lattice (which coincides with the unit lattice for SU(2) since SU(2) is simply connected) is generated by $2\pi H_\alpha$ and the coweight lattice (which coincides with the unit lattice for $\mathrm{SO}(3)=\mathrm{SU}(2)/\mathbb{Z}_2$ since $\mathbb{Z}_2$ is the center of SU(2)) is generated by $2\pi H_\lambda$. The highest weight of the irreducible spin s representation is precisely $2s\lambda$, and its complete weight system consists of the multiples $2m\lambda$ with m taking all integer (half-integer) values between $-s$ and s (inclusive) when s is integer (half-integer). Therefore, Eqs. (37) and (38) yield for this case

$$M_s(z)=\frac{1}{4\pi i}\oint\frac{dw}{w}\frac{(1-w^2)(1-w^{-2})}{\prod_{m=-s}^{s}(1-zw^{2m})}, \tag{69}$$

$$F_s(z,\overline{z})=\frac{1}{4\pi i}\oint\frac{dw}{w}\frac{(1-w^2)(1-w^{-2})}{\prod_{m=-s}^{s}(1-zw^{2m})(1-\overline{z}\,\overline{w}^{-2m})}. \tag{70}$$

(We have abbreviated M_{π_s} to M_s and F_{π_s} to F_s.) See Ref. 6, p. 94, noting that the formula given there is correct only for integer spin, in which case it can be deduced from Eq. (69) by the variable transformation $w=\exp(i\theta/2)$, together with the observation that the resulting integral from 0 to 4π may actually be reduced to an integral from 0 to π because the argument is a periodic function of θ with period 2π and, in addition, invariant under the reflection $\theta\to-\theta$.

For integer spin s, these equations are equivalent to

$$M_s(z)=-\frac{1}{2(1-z)}\frac{1}{2\pi i}\oint dw\,\frac{w^{s(s+1)-3}(1-w^2)^2}{\prod_{k=1}^{s}(1-zw^{2k})(w^{2k}-z)}, \tag{71}$$

$$F_s(z,\overline{z})=-\frac{1}{2(1-z)(1-\overline{z})}\frac{1}{2\pi i}\oint dw\,\frac{w^{2s(s+1)-3}(1-w^2)^2}{\prod_{k=1}^{s}(1-zw^{2k})(1-\overline{z}\,\overline{w}^{2k})(w^{2k}-z)(w^{2k}-\overline{z})}, \tag{72}$$

while for half-integer spin s, they are equivalent to

$$M_s(z)=-\frac{1}{2}\frac{1}{2\pi i}\oint dw\,\frac{w^{(s+1/2)^2-3}(1-w^2)^2}{\prod_{k=1}^{s+1/2}(1-zw^{2k-1})(w^{2k-1}-z)}, \tag{73}$$

$$F_s(z,\overline{z})=-\frac{1}{2}\frac{1}{2\pi i}\oint dw\,\frac{w^{2(s+1/2)^2-3}(1-w^2)^2}{\prod_{k=1}^{s+1/2}(1-zw^{2k-1})(1-\overline{z}\,\overline{w}^{2k-1})(w^{2k-1}-z)(w^{2k-1}-\overline{z})}. \tag{74}$$

For integer spin, however, it is more convenient to work with the complex variable $u=w^2$; then Eqs. (69), (70) and (71), (72) become

$$M_s(z)=\frac{1}{4\pi i}\oint\frac{du}{u}\frac{(1-u)(1-u^{-1})}{\prod_{m=-s}^{s}(1-zu^{m})}, \tag{75}$$

$$F_s(z,\overline{z})=\frac{1}{4\pi i}\oint\frac{du}{u}\frac{(1-u)(1-u^{-1})}{\prod_{m=-s}^{s}(1-zu^{m})(1-\overline{z}\,\overline{u}^{-m})}, \tag{76}$$

and

$$M_s(z) = -\frac{1}{2(1-z)}\frac{1}{2\pi i}\oint du\,\frac{u^{s(s+1)/2-2}(1-u)^2}{\Pi_{k=1}^{s}(1-zu^k)(u^k-z)}, \tag{77}$$

$$F_s(z,\overline{z}) = -\frac{1}{2(1-z)(1-\overline{z})}\frac{1}{2\pi i}\oint du\,\frac{u^{s(s+1)-2}(1-u)^2}{\Pi_{k=1}^{s}(1-zu^k)(1-\overline{zu}^k)(u^k-z)(u^k-\overline{z})}, \tag{78}$$

respectively. (Note that in the last four equations, a factor of 2 has disappeared because we must take into account that $u=w^2$ winds twice around the unit circle when w winds around once.)

We now proceed to calculate the generating functions M_s and F_s for a few irreducible representations of low spin, by applying the residue theorem (and remembering that $|z|<1$).

A. Spin 0

For the trivial representation, the integrands in Eqs. (77), (78) both have a double pole at $u=0$, and

$$M_0(z) = -\frac{1}{2(1-z)}\frac{1}{2\pi i}\oint du\,\frac{1-2u+u^2}{u^2},$$

$$F_0(z,\overline{z}) = -\frac{1}{2(1-z)(1-\overline{z})}\frac{1}{2\pi i}\oint du\,\frac{1-2u+u^2}{u^2},$$

that is,

$$M_0(z) = \frac{1}{1-z}, \tag{79}$$

$$F_0(z,\overline{z}) = \frac{1}{(1-z)(1-\overline{z})}. \tag{80}$$

This corresponds to the fact that for the one-dimensional trivial representation, every polynomial is invariant, and the ring of all (complex and real, respectively) polynomials in one variable is generated by the linear monomial(s) ζ and, ζ, $\overline{\zeta}$, respectively.

B. Spin 1/2

For spin 1/2, the integrand in Eq. (73) has a double pole at $w=0$, the coefficient of w in the Taylor expansion of the remaining factor around this pole being

$$\begin{aligned}
&\frac{d}{dw}\frac{(1-w^2)^2}{(1-zw)(w-z)}\bigg|_{w=0} \\
&\quad = \frac{(1-zw)(w-z)2(1-w^2)(-2w)-(1-w^2)^2(-z(w-z)+(1-zw))}{(1-zw)^2(w-z)^2}\bigg|_{w=0} \\
&\quad = -\frac{1+z^2}{z^2},
\end{aligned}$$

and a simple pole at $w=z$, whereas the integrand in Eq. (74) has simple poles at $w=0$, $w=z$ and $w=\overline{z}$, so

$$M_{1/2}(z) = -\frac{1}{2}\frac{1}{2\pi i}\oint dw\,\frac{(1-w^2)^2}{w^2(1-zw)(w-z)}$$
$$= -\frac{1}{2}\left\{-\frac{1+z^2}{z^2}+\frac{(1-z^2)^2}{z^2(1-z^2)}\right\} = \frac{1}{2}\left\{\frac{1+z^2}{z^2}-\frac{1-z^2}{z^2}\right\},$$

whereas

$$F_{1/2}(z,\overline{z}) = -\frac{1}{2}\frac{1}{2\pi i}\oint dw\,\frac{(1-w^2)^2}{w(1-zw)(1-\overline{z}w)(w-z)(w-\overline{z})}$$
$$= -\frac{1}{2}\left\{\frac{1}{z\overline{z}}+\frac{(1-z^2)^2}{z(1-z^2)(1-z\overline{z})(z-\overline{z})}+\frac{(1-\overline{z}^2)^2}{\overline{z}(1-z\overline{z})(1-\overline{z}^2)(\overline{z}-z)}\right\}$$
$$= -\frac{1}{2z\overline{z}(1-z\overline{z})(z-\overline{z})}\{(1-z\overline{z})(z-\overline{z})+\overline{z}(1-z^2)-z(1-\overline{z}^2)\},$$

that is

$$M_{1/2}(z) = 1, \tag{81}$$

$$F_{1/2}(z,\overline{z}) = \frac{1}{1-z\overline{z}}. \tag{82}$$

This confirms the idea that for the two-dimensional spinor representation, there are no invariant complex polynomials except 1—in accordance with the fact that the jth symmetric tensor power of this fundamental representation is just the irreducible representation of spin $j/2$ and therefore cannot contain the trivial representation as a subrepresentation, except when $j=0$—whereas the ring of invariant real polynomials is freely generated by the quadratic form $\zeta\cdot\zeta$, which is nothing but the invariant scalar product used in the definition of the group SU(2).

C. Spin 1

For the vector representation, the integrand in Eq. (77) has simple poles at $u=0$ and at $u=z$, whereas the integrand in Eq. (78) has simple poles at $u=z$ and $u=\overline{z}$, so

$$M_1(z) = -\frac{1}{2(1-z)}\frac{1}{2\pi i}\oint du\,\frac{(1-u)^2}{u(1-zu)(u-z)} = \frac{1}{2(1-z)}\left\{\frac{1}{z}-\frac{(1-z)^2}{z(1-z^2)}\right\},$$

whereas

$$F_1(z,\overline{z}) = -\frac{1}{2(1-z)(1-\overline{z})}\frac{1}{2\pi i}\oint du\,\frac{(1-u)^2}{(1-zu)(1-\overline{z}u)(u-z)(u-\overline{z})}$$
$$= -\frac{1}{2(1-z)(1-\overline{z})}\left\{\frac{(1-z)^2}{(1-z^2)(1-z\overline{z})(z-\overline{z})}+\frac{(1-\overline{z})^2}{(1-z\overline{z})(1-\overline{z}^2)(\overline{z}-z)}\right\}$$
$$= -\frac{1}{2(1-z)(1-\overline{z})(1-z\overline{z})(z-\overline{z})}\left\{\frac{1-z}{1+z}-\frac{1-\overline{z}}{1+\overline{z}}\right\},$$

that is,

$$M_1(z) = \frac{1}{1-z^2}, \tag{83}$$

$$F_1(z,\overline{z}) = \frac{1}{(1-z^2)(1-z\overline{z})(1-\overline{z^2})}. \tag{84}$$

This confirms the idea that for the three-dimensional vector representation, the ring of invariant (complex and real, respectively) polynomials is freely generated by the quadratic forms $\boldsymbol{\zeta}^2$ and $\boldsymbol{\zeta}^2$, $\boldsymbol{\zeta}\cdot\overline{\boldsymbol{\zeta}}$, $\overline{\boldsymbol{\zeta}^2}$, respectively. Alternatively, representing three-dimensional vectors as anti-symmetric (3×3)-matrices A, these generators may be written as $\mathrm{tr}(A^2)$ and $\mathrm{tr}(A^2)$, $\mathrm{tr}(AA)$, $\mathrm{tr}(\overline{A^2})$, respectively.

For higher spin, these calculations become increasingly cumbersome because, according to Eqs. (77), (78) and (73), (74), the integrands have poles at $|z|^{1/p}$ times the pth roots of unity, for all integers p from 1 to s if s is integer and for all odd integers p from 1 to $2s$ if s is half-integer. They can, however, be simplified by combining a decomposition of the integrand into partial fractions with the fact that the residue integral with a single factor in the denominator can be easily evaluated, even when the numerator is a complicated polynomial in the integration variable, without having to sum over roots of unity. In fact, we may use the following elementary

Proposition: Let P be a polynomial in w with coefficients that are rational functions of z (and possibly of other variables $z_1,\ldots,z_r$):

$$P(z_1,\ldots,z_r,z,w) = \sum_{n=1}^{N} a_n(z_1,\ldots,z_r,z)w^{n-1}. \tag{85}$$

For any integer $k\geqslant 1$, let M be the largest integer such that $kM\leqslant N$, and define

$$Q_k(z_1,\ldots,z_r,z) = \sum_{m=1}^{M} a_{km}(z_1,\ldots,z_r,z)z^{m-1}. \tag{86}$$

Then

$$\oint \frac{dw}{2\pi i}\,\frac{P(z_1,\ldots,z_r,z,w)}{w^k-z} = Q_k(z_1,\ldots,z_r,z). \tag{87}$$

Proof: Let a be any kth root of z and ϵ be any primitive kth root of unity, e.g., $\epsilon=\exp(2\pi i/k)$. Then

$$\sum_{l=0}^{k-1} x^l = \frac{x^k-1}{x-1} = \prod_{j=1}^{k-1}(x-\epsilon^j),$$

so taking the limit $x\to 1$, we obtain

$$\prod_{j=1}^{k-1}(1-\epsilon^j) = k,$$

while putting $x=\epsilon$ gives

$$\sum_{l=0}^{k-1}\epsilon^l = 0.$$

More generally, we have

$$\sum_{l=0}^{k-1}\epsilon^{ln} = 0$$

if k and n are relatively prime, because in this case, ln mod k will assume every value between 0 and $k-1$ exactly once when l ranges from 0 to $k-1$. Still more generally, we have

$$\sum_{l=0}^{k-1} \epsilon^{ln} = \begin{cases} 0 & \text{if } n \text{ is not a multiple of } k \\ k & \text{if } n \text{ is a multiple of } k \end{cases},$$

because denoting by m the greatest common divisor of k and n, $p=k/m$ and $r=n/m$ are relatively prime while ϵ^m will be a primitive pth root of unity, so decomposing the summation variable l according to $l=pj+i$ and using the previous equation,

$$\sum_{l=0}^{k-1} \epsilon^{ln} = \sum_{l=0}^{k-1} (\epsilon^m)^{lr} = \sum_{j=0}^{m-1} \sum_{i=0}^{p-1} (\epsilon^m)^{ir} = m \sum_{i=0}^{p-1} (\epsilon^m)^{ir} = \begin{cases} 0 & \text{if } m \neq k \\ k & \text{if } m = k \end{cases}.$$

Now we are ready to prove the proposition (for simplicity, we suppress the variables $z_1,\ldots,z_r$):

$$\oint \frac{dw}{2\pi i} \frac{P(z,w)}{w^k - z} = \oint \frac{dw}{2\pi i} \frac{P(z,w)}{\prod_{m=0}^{k-1}(w-\epsilon^m a)} = \sum_{l=0}^{k-1} \left. \frac{P(z,w)}{\prod_{\substack{m=0 \\ m\neq l}}^{k-1}(w-\epsilon^m a)} \right|_{w=\epsilon^l a}$$

$$= \sum_{l=0}^{k-1} \frac{P(z,\epsilon^l a)}{\prod_{\substack{m=0 \\ m\neq l}}^{k-1}(\epsilon^l a - \epsilon^m a)} = \sum_{l=0}^{k-1} \frac{P(z,\epsilon^l a)}{(\epsilon^l a)^{k-1} \prod_{j=1}^{k-1}(1-\epsilon^j)} = \frac{1}{kz} \sum_{l=0}^{k-1} \epsilon^l a P(z,\epsilon^l a)$$

$$= \frac{1}{kz} \sum_{n=1}^{N} \sum_{l=0}^{k-1} a_n(z) \epsilon^{ln} a^n = \frac{1}{z} \sum_{\substack{n=1 \\ n \text{ multiple of } k}}^{N} a_n(z) z^{n/k} = Q_k(z).$$

This proposition is combined with partial fraction decompositions of the form

$$\prod_{k=1}^{s} \frac{1}{(w^k - z)(1 - z w^k)} = \sum_{k=1}^{s} \left(\frac{a_k(z,w)}{w^k - z} + \frac{b_k(z,w)}{1 - z w^k} \right),$$

$$\prod_{k=1}^{s} \frac{1}{(w^k - z)(w^k - \overline{z})(1 - z w^k)(1 - \overline{z}\,\overline{w}^k)}$$

$$= \sum_{k=1}^{s} \left(\frac{a_k(\overline{z},z,w)}{w^k - z} + \frac{a_k(z,\overline{z},w)}{w^k - \overline{z}} + \frac{b_k(\overline{z},z,w)}{1 - z w^k} + \frac{b_k(z,\overline{z},w)}{1 - \overline{z}\,\overline{w}^k} \right),$$

for integer spin s, where the a_k and b_k are polynomials in w of degree strictly less than k whose coefficients are rational functions of z and of z, $\overline{z}$, respectively, and of the form

$$\prod_{k=1}^{s+1/2} \frac{1}{(w^{2k-1} - z)(1 - z w^{2k-1})} = \sum_{k=1}^{s+1/2} \left(\frac{a_k(z,w)}{w^{2k-1} - z} + \frac{b_k(z,w)}{1 - z w^{2k-1}} \right),$$

$$\prod_{k=1}^{s+1/2} \frac{1}{(w^{2k-1} - z)(w^{2k-1} - \overline{z})(1 - z w^{2k-1})(1 - \overline{z}\,\overline{w}^{2k-1})}$$

$$= \sum_{k=1}^{s+1/2} \left(\frac{a_k(\overline{z},z,w)}{w^{2k-1} - z} + \frac{a_k(z,\overline{z},w)}{w^{2k-1} - \overline{z}} + \frac{b_k(\overline{z},z,w)}{1 - z w^{2k-1}} + \frac{b_k(z,\overline{z},w)}{1 - \overline{z}\,\overline{w}^{2k-1}} \right),$$

for half-integer spin s, where the a_k and b_k are polynomials in w of degree strictly less than $2k-1$ whose coefficients are rational functions of z and of z, $\overline{z}$, respectively; these functions and

coefficients can be calculated recursively, by induction on the number of factors (that is, induction on s) and repeated application of the Euclid algorithm. Using these two techniques, we have developed, within MAPLE, a program which allows to calculate the function F up to spin 2 and the function M up to spin 4 within reasonable limits of a few minutes of computing time on a standard 386 PC, with the following results:

Spin 3/2:

$$M_{3/2}(z)=\frac{1}{1-z^4}, \tag{88}$$

$$F_{3/2}(z,\overline{z})=\frac{(1-z^4\overline{z^4})(1-z^6\overline{z^6})}{(1-z\overline{z})(1-z^4)(1-z^3\overline{z})(1-z\overline{z^3})(1-\overline{z^4})(1-z^3\overline{z^3})}. \tag{89}$$

Spin 2:

$$M_2(z)=\frac{1}{(1-z^2)(1-z^3)}, \tag{90}$$

$$F_2(z,\overline{z})=\frac{1-z^6\overline{z^6}}{(1-z^2)(1-z\overline{z})(1-\overline{z^2})(1-z^3)(1-z^2\overline{z})(1-z\overline{z^2})(1-\overline{z^3})(1-z^2\overline{z^2})}. \tag{91}$$

Spin 5/2:

$$M_{5/2}(z)=\frac{1-z^{36}}{(1-z^4)(1-z^8)(1-z^{12})(1-z^{18})}. \tag{92}$$

Spin 3:

$$M_3(z)=\frac{1-z^{30}}{(1-z^2)(1-z^4)(1-z^6)(1-z^{10})(1-z^{15})}. \tag{93}$$

Spin 7/2:

$$\begin{aligned}\mathrm{numer}(M_{7/2}(z))=&1+2z^8+4z^{12}+4z^{14}+5z^{16}+9z^{18}+6z^{20}+9z^{22}+8z^{24}+9z^{26}+6z^{28}+9z^{30}\\&+5z^{32}+4z^{34}+4z^{36}+2z^{40}+z^{48},\end{aligned} \tag{94}$$

$$\mathrm{denom}(M_{7/2}(z))=(1-z^4)(1-z^8)(1-z^{12})^2(1-z^{20}).$$

Spin 4:

$$M_4(z)=\frac{1+z^8+z^9+z^{10}+z^{18}}{(1-z^2)(1-z^3)(1-z^4)(1-z^5)(1-z^6)(1-z^7)}. \tag{95}$$

These formulas lead to several interesting observations.

To begin with, let us comment on the result for the five-dimensional spin 2 representation, which can be interpreted most conveniently by realizing five-dimensional vectors as traceless symmetric (3×3)-matrices A. Equation (90) confirms the idea that the ring of invariant complex polynomials in this representation is freely generated by the quadratic form $\mathrm{tr}(A^2)$ and the cubic form $\mathrm{tr}(A^3)$, whereas Eq. (91) states that the ring of invariant real polynomials in this representation is generated by three quadratic forms of bidegree (2,0), (1,1) and (0,2), respectively, together with four cubic forms of bidegree (3,0), (2,1), (1,2) and (0,3), respectively, plus an extra quartic form of bidegree (2,2), and that these generators should satisfy a relation of bidegree (6,6).

Obviously, the quadratic forms are given by $\mathrm{tr}(A^2)$, $\mathrm{tr}(A\overline{A})$ and $\mathrm{tr}(\overline{A^2})$, respectively, and the cubic forms by $\mathrm{tr}(A^3)$, $\mathrm{tr}(A^2\overline{A})$, $\mathrm{tr}(A\overline{A^2})$ and $\mathrm{tr}(\overline{A^3})$, respectively, but the extra generator of bidegree (2,2) comes as a surprise, especially in view of the fact that the usual Molien function provides no hint toward its existence. To see why there should be such an extra generator, note first that the natural invariant quartic forms $\mathrm{tr}(A^4)$ of bidegree (4,0), $\mathrm{tr}(A^3\overline{A})$ of bidegree (3,1), $\mathrm{tr}(A\overline{A^3})$ of bidegree (1,3) and $\mathrm{tr}(\overline{A^4})$ of bidegree (0,4) are not independent, but can be expressed in terms of the natural invariant quadratic forms $\mathrm{tr}(A^2)$, $\mathrm{tr}(A\overline{A})$ and $\mathrm{tr}(\overline{A^2})$:

$$\mathrm{tr}(A^4) = \tfrac{1}{2}\,(\mathrm{tr}(A^2))^2,$$

$$\mathrm{tr}(A^3\overline{A}) = \tfrac{1}{2}\,\mathrm{tr}(A^2)\mathrm{tr}(A\overline{A}),$$

$$\mathrm{tr}(A\overline{A^3}) = \tfrac{1}{2}\,\mathrm{tr}(A\overline{A})\mathrm{tr}(\overline{A^2}),$$

$$\mathrm{tr}(\overline{A^4}) = \tfrac{1}{2}\,(\mathrm{tr}(\overline{A^2}))^2.$$

On the other hand, there are four natural invariant quartic forms of bidegree (2,2), namely

$$\mathrm{tr}(A^2\overline{A^2}),\ \ \mathrm{tr}((A\overline{A})^2),\ \ \mathrm{tr}(A^2)\mathrm{tr}(\overline{A^2}),\ \ \mathrm{tr}(A\overline{A})^2,$$

between which there exists precisely one linear relation:

$$4\,\mathrm{tr}(A^2\overline{A^2}) + 2\,\mathrm{tr}((A\overline{A})^2) = \mathrm{tr}(A^2)\mathrm{tr}(\overline{A^2}) - 2\ \ \mathrm{tr}(A\overline{A})^2.$$

The extra generator of bidegree (2,2) can therefore be chosen to be any linear combination of $\mathrm{tr}(A^2\overline{A^2})$ and $\mathrm{tr}((A\overline{A})^2)$ which is not proportional to the lhs of this equation. As far as the relation of bidegree (6,6) is concerned, we have not been patient enough to determine its explicit form: this seems a formidable task in view of the fact that a power series expansion of Eq. (91) shows, using MAPLE, that the coefficient of $z^6\overline{z^6}$ in $F_2(z,\overline{z})$ is 36, so one has to find exactly one linear relation between 37 polynomials of bidegree (6,6) in 10 variables (5 holomorphic and 5 antiholomorphic)!

A similar situation, though somewhat more complicated, occurs for the four-dimensional spin 3/2 representation. Here, we encounter one invariant quadratic form of bidegree (1,1) (the invariant scalar product, as usual) and four invariant quartic forms of bidegree (4,0), (3,1), (1,3) and (0,4), respectively, plus an extra invariant form of bidegree (3,3) (besides the cube of the invariant scalar product), as generators. There are two relations: one relation of bidegree (4,4), expressing a linear dependence between the four invariant polynomials $P(4,0)\cdot P(0,4)$, $P(3,1)\cdot P(1,3)$, $P(1,1)^4$ and $P(1,1)\cdot P(3,3)$, and one relation of bidegree (6,6), expressing a linear dependence between the seven invariant polynomials $P(4,0)\cdot P(0,4)\cdot P(1,1)^2$, $P(3,1)\cdot P(1,3)\cdot P(1,1)^2$, $P(1,1)^6$, $P(1,1)^3\cdot P(3,3)$, $P(4,0)\cdot P(1,3)^2$, $P(0,4)\cdot P(3,1)^2$ and $P(3,3)^2$, over and above the relation obtained by multiplying the previous one by $P(1,1)^2$. These two relations are, however, not independent, because the presence of an additional generator of bidegree (10,10) suggests that their product reduces to a trivial identity.

As far as the Molien functions for representations of spin >2 are concerned, the results indicate that for spin 5/2 and spin 3, the generators of the ring of invariant complex polynomials are subject to a single relation, while for spin 7/2 and spin 4, the structure of the relations themselves becomes complicated and no longer fits into the relatively simple scheme given by Eq. (11): there are lots of additional generators satisfying complicated relations, relations between the relations, etc. It is not even clear what is in general the most adequate way to present these functions, since numerator and denominator may have common factors. For example, the numerator and the denominator of the Molien function for spin 7/2 as given in Eq. (94) have a common factor $(1+z^6)(1+z^{10})$ which has been introduced to eliminate factors $1-z^6$ and $1-z^{10}$ from the denominator, so as to comply with the fact that there are no invariant polynomials of degree 6 and

of degree 10 in this representation (as can be seen upon Taylor expansion). At any rate, the polynomials in the numerator of Eq. (94) and of Eq. (95) have roots of modulus $\neq 1$ and hence cannot possibly be reduced to an expression of the form $1-z^k$ or to a product of such expressions. (More precisely, a numerical calculation, using MAPLE, shows that the quotient of the numerator of Eq. (94) by $(1+z^6)(1+z^{10})$, considered as a polynomial of degree 16 in z^2, has 8 roots of modulus 1, 2 roots of modulus 1.46292, 2 roots of modulus 1.36453, 2 roots of modulus 0.73285 and 2 roots of modulus 0.68356, while the numerator of Eq. (95) has 14 roots of modulus 1, 2 roots of modulus 1.10697 and 2 roots of modulus 0.90377.)

In summary, everything indicates that with increasing spin, the situation becomes extremely complex. We shall therefore not pursue this matter any further and instead pass to other groups and representations.

VII. THE CODON REPRESENTATION AND ITS REDUCTIONS

Apart from the circle group, U(1), and the ordinary rotation group (or rather its universal covering group), SU(2), the compact simple Lie groups appearing in the symmetry breaking scheme of Hornos and Hornos[1] for describing the degeneracy of the genetic code involve the symplectic groups Sp(4) and Sp(6). With these applications in mind, we begin by collecting a few pertinent facts about the symplectic groups $\mathrm{Sp}(2r)$ and some of their irreducible representations, especially for the cases $r=2$ and $r=3$. (Note that we shall be dealing exclusively with the compact real form $\mathrm{Sp}(2r)$ of the complex symplectic group $\mathrm{Sp}(2r,\mathbb{C})$, which can be defined as a group of $(r\times r)$-matrices with quaternionic entries, not with the normal real form $\mathrm{Sp}(2r,\mathbb{R})$ that appears, e.g., in Hamiltonian mechanics.

The symplectic group $\mathrm{Sp}(2r)$ is a compact, connected, simply connected Lie group with center $\mathbb{Z}_2$, and its Lie algebra $\mathfrak{sp}(2r)$ is the compact real form of the complex simple Lie algebra $\mathfrak{sp}(2r,\mathbb{C})$; in the Cartan classification this is C_r, of rank r and dimension $r(2r+1)$. To construct its root system and the weight systems of various other irreducible representations besides the adjoint, we identify the spaces $\mathfrak{t}$ and $i\mathfrak{t}^*$ used before (cf. Sec. 4) with $\mathbb{R}^r$ by introducing bases $\{H_1,\ldots,H_r\}$ of $\mathfrak{t}$ and $\{e_1,\ldots,e_r\}$ of $i\mathfrak{t}^*$, dual to each other in the sense that

$$e_j(H_k)=i\,\delta_{jk}, \tag{96}$$

and orthonormal except for an overall normalization factor of $\sqrt{2}$; more precisely, we assume that

$$(e_j,e_k)=\tfrac{1}{2}\,\delta_{jk}, \quad (H_j,H_k)=2\,\delta_{jk}. \tag{97}$$

Then the root system Δ of $\mathfrak{sp}(2r)$, when written as the disjoint union

$$\Delta=\Delta_l\cup\Delta_s \tag{98}$$

of the set Δ_l of long roots (of length $\sqrt{2}$) and the set Δ_s of short roots (of length 1), is given by

$$\Delta_l=\{\pm 2e_j/1\leqslant j\leqslant r\}, \tag{99}$$

$$\Delta_s=\{\pm e_j\pm e_k/1\leqslant j<k\leqslant r\}. \tag{100}$$

(All signs are to be read independently.) We choose an ordering in this root system such that the set of positive roots becomes

$$\Delta^+=\Delta_l^+\cup\Delta_s^+, \tag{101}$$

where

$$\Delta_l^+=\{2e_j/1\leqslant j\leqslant r\}, \tag{102}$$

$$\Delta_s^+ = \{e_j \pm e_k / 1 \leqslant j < k \leqslant r\}, \tag{103}$$

leading to the following basis $\{\alpha_1, \ldots, \alpha_r\}$ of simple roots:

$$\alpha_1 = e_1 - e_2, \quad \ldots, \quad \alpha_{r-1} = e_{r-1} - e_r, \quad \alpha_r = 2e_r. \tag{104}$$

The highest root is

$$\delta = 2e_1. \tag{105}$$

Moreover, the vector ρ defined as half the sum of the positive roots, or equivalently, as the sum of the fundamental weights, which plays an important role in representation theory, is given by

$$\rho = re_1 + (r-1)e_2 + \ldots + 2e_{r-1} + e_r. \tag{106}$$

Passing to irreducible representations, we first compute the fundamental weights, defined by the condition (45), which in the present case leads to

$$\lambda_1 = e_1, \quad \lambda_2 = e_1 + e_2, \quad \ldots, \quad \lambda_{r-1} = e_1 + \ldots + e_{r-1}, \quad \lambda_r = e_1 + \ldots + e_r. \tag{107}$$

This implies that $\{e_1, \ldots, e_r\}$ is a basis of the weight lattice and $\{2\pi H_1, \ldots, 2\pi H_r\}$ is a basis of the coroot lattice (which coincides with the unit lattice for $\mathrm{Sp}(2r)$ since $\mathrm{Sp}(2r)$ is simply connected); these are much more convenient than the basis $\{\lambda_1, \ldots, \lambda_r\}$ of fundamental weights and the basis $\{2\pi\check{\alpha}_1, \ldots, 2\pi\check{\alpha}_r\}$ formed by the simple coroots, respectively, because they are orthonormal (except for the aforementioned overall normalization factor of $\sqrt{2}$).

With these generalities out of the way, we can proceed to write down the weight systems and, as a consequence, the generating functions M_π and F_π for the irreducible representations of Sp(4) and Sp(6) that appear in Ref. 1. For completeness, we also list their dimension and height, recalling that all irreducible representations of $\mathrm{Sp}(2r)$ are self-conjugate and that the height $\mathrm{ht}(\Lambda)$ of a self-conjugate representation of highest weight Λ allows one to decide whether the representation is real or pseudo-real: it is real iff $\mathrm{ht}(\Lambda)$ is even and pseudo-real iff $\mathrm{ht}(\Lambda)$ is odd (see Ref. 13, pp. 31–33). Finally, we list the coefficients $c_{p,q}$ in the Taylor expansion of F_π, up to fourth order, which have been calculated by differentiating under the integral sign and then computing the residues, using MAPLE. The results obtained for $c_{0,0}$, $c_{1,0}$, $c_{0,1}$ and $c_{1,1}$ are not listed because they come out to be what they must be for any irreducible representation:

$$c_{0,0} = 1, \quad c_{1,0} = 0 = c_{0,1}, \quad c_{1,1} = 1. \tag{108}$$

The result for $c_{0,0}$ reflects the correct normalization: there is (up to a constant multiple) always precisely one invariant polynomial of bidegree (0,0), namely the constant 1. The results for $c_{1,0}$ and for $c_{0,1}$ reflect the fact that an irreducible representation does not admit any invariant vectors, while the result for $c_{1,1}$ corresponds to the theorem that in an irreducible representation, the invariant scalar product is unique (up to a constant multiple), due to Schur's lemma.

A. Sp(4)

For an irreducible representation π_Λ of highest weight $\Lambda = a_1\lambda_1 + a_2\lambda_2$, we have

$$\dim(\pi_\Lambda) = (1+a_1)(1+a_2)\left(1 + \frac{a_1+a_2}{2}\right)\left(1 + \frac{a_2+2a_3}{3}\right), \tag{109}$$

$$\mathrm{ht}(\pi_\Lambda) = 3a_1 + 4a_2. \tag{110}$$

The Weyl group of Sp(4) is $\mathbb{Z}_2 \times \mathbb{Z}_2 \times S_2$, generated by the reflections $e_1 \leftrightarrow -e_1$, $e_2 \leftrightarrow -e_2$ and the permutation of e_1 with e_2; it has order 8. Therefore,

$$M_\Lambda(z)=\frac{1}{8}\oint\frac{dw_1}{2\pi i}\oint\frac{dw_2}{2\pi i}\frac{w_1^{-5}w_2^{-5}f_N(w_1,w_2)^2}{f_{\Lambda,D}(z,w_1,w_2)},\tag{111}$$

$$F_\Lambda(z,\overline{z})=\frac{1}{8}\oint\frac{dw_1}{2\pi i}\oint\frac{dw_2}{2\pi i}\frac{w_1^{-5}w_2^{-5}f_N(w_1,w_2)^2}{f_{\Lambda,D}(z,w_1,w_2)f_{\Lambda,D}(\overline{z},w_1,w_2)},\tag{112}$$

with

$$f_N(w_1,w_2)=(1-w_1^2)(1-w_2^2)(1-w_1w_2)(w_1-w_2).\tag{113}$$

(The definition of $f_{\Lambda,D}$ follows below.)

1. First fundamental representation (1,0)

The highest weight is $\Lambda=\lambda_1=e_1$, the dimension is 4, the height is 3 (so the representation is pseudo-real), the complete weight system (cf. Figure 4) is

$$\Phi_{(1,0)}=\{\pm e_1,\pm e_2\}\tag{114}$$

(all weights have multiplicity 1; the signs are to be read independently), so

$$f_{(1,0),D}(x,w_1,w_2)=(1-xw_1)(1-xw_1^{-1})(1-xw_2)(1-xw_2^{-1}).\tag{115}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=0=c_{0,2},$$

$$c_{3,0}=0=c_{0,3},\quad c_{2,1}=0=c_{1,2},\tag{116}$$

$$c_{4,0}=0=c_{0,4},\quad c_{3,1}=0=c_{1,3},\quad c_{2,2}=1.$$

Without much difficulty, the generating function F can be computed in closed form; the result is

$$F_{(1,0)}(z,\overline{z})=\frac{1}{1-z\overline{z}}\tag{117}$$

2. Second fundamental representation (0,1)

The highest weight is $\Lambda=\lambda_2=e_1+e_2$, the dimension is 5, the height is 4 (so the representation is real), the complete weight system (cf. Figure 4) is

$$\Phi_{(0,1)}=\{0,\pm e_1\pm e_2\}\tag{118}$$

(all weights have multiplicity 1; the signs are to be read independently), so

$$f_{(0,1),D}(x,w_1,w_2)=(1-x)(1-xw_1w_2)(1-xw_1^{-1}w_2)(1-xw_1w_2^{-1})(1-xw_1^{-1}w_2^{-1}).\tag{119}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=1=c_{0,2},$$

$$c_{3,0}=0=c_{0,3},\quad c_{2,1}=0=c_{1,2},\tag{120}$$

$$c_{4,0}=1=c_{0,4}, \quad c_{3,1}=1=c_{1,3}, \quad c_{2,2}=2.$$

Again, the generating function F can be computed in closed form; the result is

$$F_{(0,1)}(z,\overline{z})=\frac{1}{(1-z^2)(1-z\overline{z})(1-\overline{z^2})}. \tag{121}$$

3. Adjoint representation (2,0)

The highest weight is $\Lambda=2\lambda_1=2e_1$, the dimension is 10, the height is 6 (so the representation is real), the complete weight system (cf. Figure 4) is the union of $\{0\}$ with the root system Δ,

$$\Phi_{(2,0)}=\{0\}\cup\{\pm 2e_1,\pm 2e_2,\pm e_1\pm e_2\} \tag{122}$$

(0 has multiplicity 2 and the roots have multiplicity 1; the signs are to be read independently), so

$$\begin{aligned} f_{(2,0),D}(x,w_1,w_2)=&(1-x)^2(1-xw_1^2)(1-xw_1^{-2})(1-xw_2^2)(1-xw_2^{-2})\\ &\times(1-xw_1w_2)(1-xw_1^{-1}w_2)(1-xw_1w_2^{-1})(1-xw_1^{-1}w_2^{-1}). \end{aligned} \tag{123}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=1=c_{0,2},$$

$$c_{3,0}=0=c_{0,3}, \quad c_{2,1}=0=c_{1,2}, \tag{124}$$

$$c_{4,0}=2=c_{0,4}, \quad c_{3,1}=2=c_{1,3}, \quad c_{2,2}=4.$$

With considerable effort, the generating function F can be computed in closed form; the result is

$$\begin{aligned} \mathrm{numer}(F_{(2,0)}(z,\overline{z}))=&1+z^2\overline{z^2}+z^3\overline{z^3}+z^4\overline{z^3}+z^3\overline{z^4}+z^4\overline{z^4}+z^6\overline{z^3}+z^5\overline{z^4}\\ &+z^4\overline{z^5}+z^3\overline{z^6}+z^5\overline{z^5}+z^6\overline{z^5}+z^5\overline{z^6}+z^6\overline{z^6}+z^7\overline{z^7}+z^9\overline{z^9}, \end{aligned} \tag{125}$$

$$\begin{aligned} \mathrm{denom}(F_{(2,0)}(z,\overline{z}))=&(1-z^2)(1-z\overline{z})(1-\overline{z^2})(1-z^4)(1-z^3\overline{z})(1-z^2\overline{z^2})\\ &\times(1-z\overline{z^3})(1-\overline{z^4})(1-z^4\overline{z^2})(1-z^2\overline{z^4}). \end{aligned}$$

4. Reduced codon representation (1,1)

The highest weight is $\Lambda=\lambda_1+\lambda_2=2e_1+e_2$, the dimension is 16, the height is 7 (so the representation is pseudo-real), the complete weight system (cf. Figure 4) is the union

$$\Phi(1,1)=\Phi^{(1)}_{(1,1)}\cup\Phi^{(2)}_{(1,1)}, \tag{126}$$

where

$$\Phi^{(1)}_{(1,1)}=\{\pm 2e_1\pm e_2,\pm 2e_2\pm e_1\} \tag{127}$$

(these weights have multiplicity 1; the signs are to be read independently) and

$$\Phi^{(2)}_{(1,1)}=\{\pm e_1,\pm e_2\} \tag{128}$$

(these weights have multiplicity 2; the signs are to be read independently), so

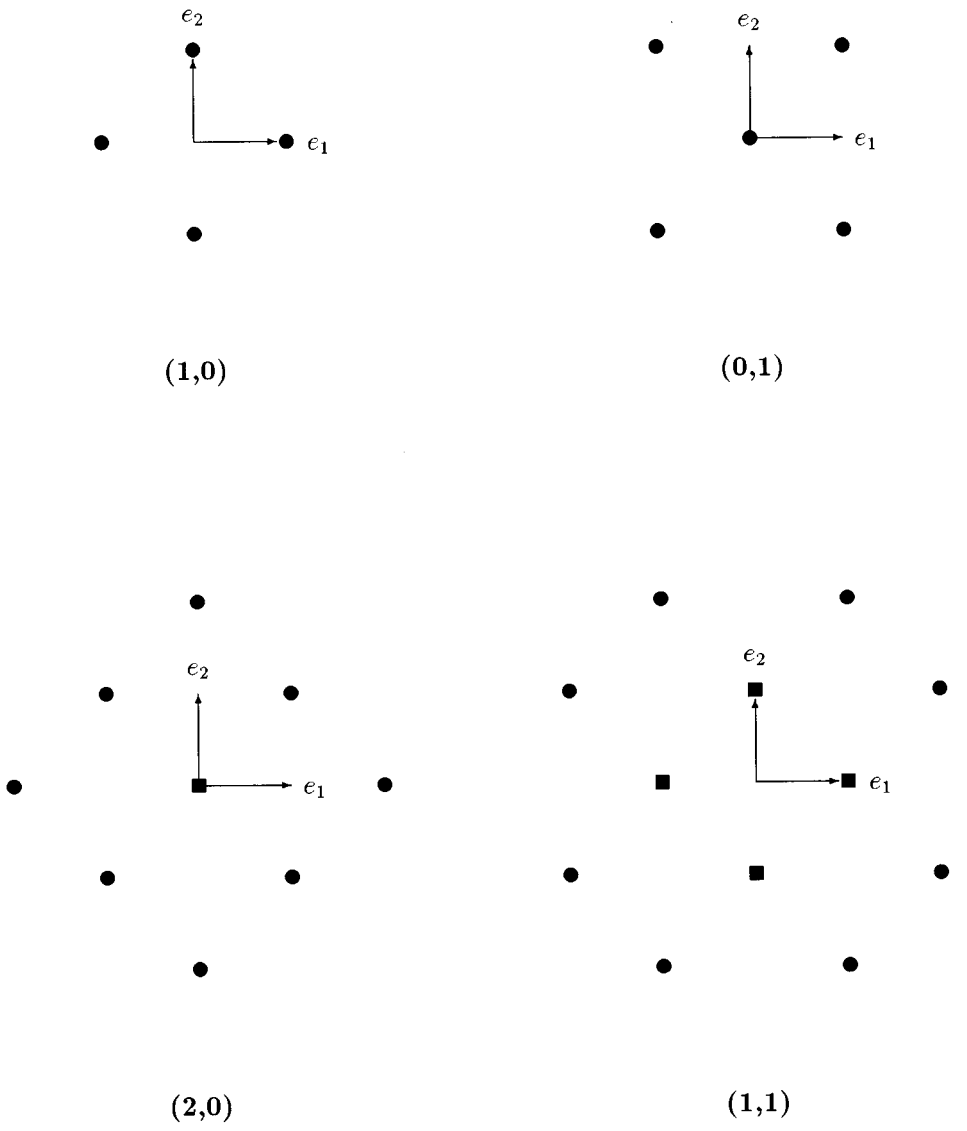

FIG. 4. Weight diagrams for some irreducible representations of Sp(4).

$$f_{(1,1),D}(x,w_1,w_2)=(1-xw_1)^2(1-xw_1^{-1})^2(1-xw_2)^2(1-xw_2^{-1})^2$$
$$\times(1-xw_1^2w_2)(1-xw_1^{-2}w_2)(1-xw_1^2w_2^{-1})(1-xw_1^{-2}w_2^{-1})$$
$$\times(1-xw_1w_2^2)(1-xw_1^{-1}w_2^2)(1-xw_1w_2^{-2})(1-xw_1^{-1}w_2^{-2}). \quad (129)$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=0=c_{0,2},$$

$$c_{3,0}=0=c_{0,3}, \quad c_{2,1}=0=c_{1,2}, \quad (130)$$

$$c_{4,0}=1=c_{0,4}, \quad c_{3,1}=2=c_{1,3}, \quad c_{2,2}=6.$$

B. Sp(6)

For an irreducible representation π_Λ of highest weight $\Lambda = a_1\lambda_1 + a_2\lambda_2 + a_3\lambda_3$, we have

$$\dim(\pi_\Lambda) = (1+a_1)(1+a_2)(1+a_3)\left(1+\frac{a_1+a_2}{2}\right)\left(1+\frac{a_2+a_3}{2}\right)\left(1+\frac{a_2+2a_3}{3}\right)$$
$$\times\left(1+\frac{a_1+a_2+a_3}{3}\right)\left(1+\frac{a_1+a_2+2a_3}{4}\right)\left(1+\frac{a_1+2a_2+2a_3}{5}\right), \tag{131}$$

$$\mathrm{ht}(\pi_\Lambda) = 5a_1 + 8a_2 + 9a_3. \tag{132}$$

The Weyl group of Sp(6) is $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times S_3$, generated by the reflections $e_i \leftrightarrow -e_i$ and the permutations of the e_i $(i=1,2,3)$; it has order 48. Therefore,

$$M_\Lambda(z) = \frac{1}{48}\oint\frac{dw_1}{2\pi i}\oint\frac{dw_2}{2\pi i}\oint\frac{dw_3}{2\pi i}\frac{w_1^{-7}w_2^{-7}w_3^{-7}f_N(w_1,w_2,w_3)^2}{f_{\Lambda,D}(z,w_1,w_2,w_3)}, \tag{133}$$

$$F_\Lambda(z,\overline{z}) = \frac{1}{48}\oint\frac{dw_1}{2\pi i}\oint\frac{dw_2}{2\pi i}\oint\frac{dw_3}{2\pi i}\frac{w_1^{-7}w_2^{-7}w_3^{-7}f_N(w_1,w_2,w_3)^2}{f_{\Lambda,D}(z,w_1,w_2,w_3)f_{\Lambda,D}(\overline{z},w_1,w_2,w_3)}, \tag{134}$$

with

$$f_N(w_1,w_2,w_3) = -(1-w_1^2)(1-w_2^2)(1-w_3^2)(1-w_1w_2)(1-w_1w_3)$$
$$\times(1-w_2w_3)(w_1-w_2)(w_1-w_3)(w_2-w_3). \tag{135}$$

(The definition of $f_{\Lambda,D}$ follows below.)

1. First fundamental representation (1,0,0)

The highest weight is $\Lambda = \lambda_1 = e_1$, the dimension is 6, the height is 5 (so the representation is pseudo-real), the complete weight system is

$$\Phi_{(1,0,0)} = \{\pm e_1, \pm e_2, \pm e_3\} \tag{136}$$

(all weights have multiplicity 1; the signs are to be read independently), so

$$f_{(1,0,0),D}(x,w_1,w_2,w_3) = (1-xw_1)(1-xw_1^{-1})(1-xw_2)(1-xw_2^{-1})(1-xw_3)(1-xw_3^{-1}). \tag{137}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0} = 0 = c_{0,2},$$

$$c_{3,0} = 0 = c_{0,3}, \quad c_{2,1} = 0 = c_{1,2},$$

$$c_{4,0} = 0 = c_{0,4}, \quad c_{3,1} = 0 = c_{1,3}, \quad c_{2,2} = 1. \tag{138}$$

2. Second fundamental representation (0,1,0)

The highest weight is $\Lambda = \lambda_2 = e_1 + e_2$, the dimension is 14, the height is 8 (so the representation is real), the complete weight system is

$$\Phi_{(0,1,0)} = \{0\} \cup \{\pm e_1 \pm e_2, \pm e_1 \pm e_3, \pm e_2 \pm e_3\} \tag{139}$$

(0 has multiplicity 2 and all other weights have multiplicity 1; the signs are to be read independently), so

$$\begin{aligned} f_{(0,1,0),D}(x,w_1,w_2,w_3) &= (1-x)^2(1-xw_1w_2)(1-xw_1^{-1}w_2)(1-xw_1w_2^{-1})(1-xw_1^{-1}w_2^{-1}) \\ &\times(1-xw_1w_3)(1-xw_1^{-1}w_3)(1-xw_1w_3^{-1})(1-xw_1^{-1}w_3^{-1}) \\ &\times(1-xw_2w_3)(1-xw_2^{-1}w_3)(1-xw_2w_3^{-1})(1-xw_2^{-1}w_3^{-1}). \end{aligned} \tag{140}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=1=c_{0,2},$$

$$c_{3,0}=1=c_{0,3}, \quad c_{2,1}=1=c_{1,2}, \tag{141}$$

$$c_{4,0}=1=c_{0,4}, \quad c_{3,1}=1=c_{1,3}, \quad c_{2,2}=3.$$

3. Third fundamental representation (0,0,1)

The highest weight is $\Lambda=\lambda_3=e_1+e_2+e_3$, the dimension is 14, the height is 9 (so the representation is pseudo-real), the complete weight system is

$$\Phi_{(0,0,1)}=\{\pm e_1,\pm e_2,\pm e_3,\pm e_1\pm e_2\pm e_3\} \tag{142}$$

(all weights have multiplicity 1; the signs are to be read independently), so

$$\begin{aligned} f_{(0,0,1),D}(x,w_1,w_2,w_3) &= (1-xw_1)(1-xw_1^{-1})(1-xw_2)(1-xw_2^{-1})(1-xw_3)(1-xw_3^{-1}) \\ &\times(1-xw_1w_2w_3)(1-xw_1^{-1}w_2w_3)(1-xw_1w_2^{-1}w_3) \\ &\times(1-xw_1^{-1}w_2^{-1}w_3)(1-xw_1w_2w_3^{-1})(1-xw_1^{-1}w_2^{-1}w_3^{-1}). \end{aligned} \tag{143}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=0=c_{0,2},$$

$$c_{3,0}=0=c_{0,3}, \quad c_{2,1}=0=c_{1,2}, \tag{144}$$

$$c_{4,0}=1=c_{0,4}, \quad c_{3,1}=1=c_{1,3}, \quad c_{2,2}=1.$$

4. Codon representation (1,1,0)

The highest weight is $\Lambda=\lambda_1+\lambda_2=2e_1+e_2$, the dimension is 64, the height is 13 (so the representation is pseudo-real), the complete weight system is the union

$$\Phi_{(1,1,0)}=\Phi^{(1)}_{(1,1,0)}\cup\Phi^{(2)}_{(1,1,0)}\cup\Phi^{(4)}_{(1,1,0)}, \tag{145}$$

where

$$\Phi^{(1)}_{(1,1,0)}=\{\pm 2e_1\pm e_2,\pm 2e_2\pm e_1,\pm 2e_1\pm e_3,\pm 2e_3\pm e_1,\pm 2e_2\pm e_3,\pm 2e_3\pm e_2\} \tag{146}$$

(these weights have multiplicity 1; the signs are to be read independently),

$$\Phi^{(2)}_{(1,1,0)}=\{\pm e_1\pm e_2\pm e_3\} \tag{147}$$

(these weights have multiplicity 2; the signs are to be read independently), and

$$\Phi^{(4)}_{(1,1,0)}=\{\pm e_1,\pm e_2,\pm e_3\} \tag{148}$$

(these weights have multiplicity 4; the signs are to be read independently), so

$$\begin{aligned} f_{(1,1,0),D}(x,w_1,w_2,w_3)=&(1-xw_1)^4(1-xw_1^{-1})^4(1-xw_2)^4(1-xw_2^{-1})^4(1-xw_3)^4(1-xw_3^{-1})^4\\ &\times(1-xw_1w_2w_3)^2(1-xw_1^{-1}w_2w_3)^2(1-xw_1w_2^{-1}w_3)^2\\ &\times(1-xw_1^{-1}w_2^{-1}w_3)^2(1-xw_1w_2w_3^{-1})^2(1-xw_1^{-1}w_2^{-1}w_3^{-1})^2\\ &\times(1-xw_1^2w_2)(1-xw_1^{-2}w_2)(1-xw_1^2w_2^{-1})(1-xw_1^{-2}w_2^{-1})\\ &\times(1-xw_1w_2^2)(1-xw_1^{-1}w_2^2)(1-xw_1w_2^{-2})(1-xw_1^{-1}w_2^{-2})\\ &\times(1-xw_1^2w_3)(1-xw_1^{-2}w_3)(1-xw_1^2w_3^{-1})(1-xw_1^{-2}w_3^{-1})\\ &\times(1-xw_1w_3^2)(1-xw_1^{-1}w_3^2)(1-xw_1w_3^{-2})(1-xw_1^{-1}w_3^{-2})\\ &\times(1-xw_2^2w_3)(1-xw_2^{-2}w_3)(1-xw_2^2w_3^{-1})(1-xw_2^{-2}w_3^{-1})\\ &\times(1-xw_2w_3^2)(1-xw_2^{-1}w_3^2)(1-xw_2w_3^{-2})(1-xw_2^{-1}w_3^{-2}). \end{aligned} \tag{149}$$

The non-trivial coefficients $c_{p,q}$ up to fourth order are

$$c_{2,0}=0=c_{0,2},$$

$$c_{3,0}=0=c_{0,3},\quad c_{2,1}=0=c_{1,2},$$

$$c_{4,0}=3=c_{0,4},\quad c_{3,1}=6=c_{1,3},\quad c_{2,2}=15. \tag{150}$$

ACKNOWLEDGMENTS

The author would like to thank J. E. M. Hornos and Y. M. M. Hornos for introducing him to their work on the origin of the genetic code, which provided the motivation for the present investigation, and for generously sharing their insights into this fascinating subject. Thanks are also due to Renato Zornoff Táboas and Viktor Bojarczuk for discussions, and last but not least to all the people who developed the software package MAPLE, without which many of the calculations reported here would never have been performed. Finally, the financial support by CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico) and by FAPESP (Fundação de Amparo à Pesquisa do Estado de São Paulo), Brazil, is gratefully acknowledged.

Generalization of the algebra of the matrix pseudodifferential operators

Jarosław Gawrylczyk[a)]
Institute for Theoretical Physics, University of Wroclaw, Pl.Maxa Borna 9, 50-205 Wroclaw, Poland

(Received 6 March 1997; accepted for publication 6 August 1997)

We introduce the new nonhomogeneous graded matrix algebra $\mathrm{Mat}_n(\mathfrak{R})$ over the ring $\mathfrak{R}$ of the pseudodifferential operators of the arbitrary orders. This algebra forms the generalization of the algebra of the standard matrix pseudodifferential operators. We show that the $\mathrm{Mat}_n(\mathfrak{R})$ algebra admits the nontrivial central extension. The case $n=2$ is considered in some detail. As the example we consider the $\mathrm{Mat}_2(\mathrm{W}_{1+\infty})$, $\mathrm{Mat}_2(\mathrm{Virasoro})$ and $\mathrm{Mat}_2(\mathrm{sl}(2,\mathbb{C}))$ algebras. © *1998 American Institute of Physics.* [S0022-2488(97)03111-3]

I. INTRODUCTION

It is well known that the algebras of the differential and pseudodifferential (psd) operators play the crucial role in the wide classes of the physical models, e.g., theory of the integrable systems,[1,2] conformal field theory,[3] matrix models,[4] two dimensional gravity,[5] and string theory.[6] Among other things, it was recognized that there exists the close relationship between the algebras of the psd operators and so-called W algebras[7–9] which are the higher-spin extensions of the Virasoro algebra. It was shown[10,11] that the Lie algebras of the differential operators admit the nontrivial central extensions which are isomorphic with the central extensions of the W algebras. The systematic way to obtain the suitable 2-cocycles (so-called ''logarithmic cocycles'') on these algebras was first considered in Ref. 12 and was further studied by several authors.[13–15]

One of the classes of the psd operators is the class of the matrix psd operators of the integer orders which has been investigated in the context of the examination of the multicomponent KP[16,17] and KdV[18] hierarchies as well as of the theory of the representations of the $\mathrm{W}_{1+\infty}$ algebra.[19–23] The generalizations of the matrix psd operators to the case of the complex orders were considered in Ref. 14.

The aim of this paper is the presentation of the another generalization of the algebra of the matrix psd operators to the case of the nonhomogeneous gradation. In our approach we consider the algebras which are generated by the matrices whose matrix elements are determined by the psd operators of the arbitrary orders. The essential point is that the orders of the each psd operator (which form the matrix elements of the single generator) can in general be different. In the case of the standard, homogeneous gradation the orders of such operators are the same. We show that the nonhomogeneous graded algebra of the $n\times n$-matrix differential operators admit the central extension and that this algebra is isomorphic with the central extended $n\times n$-matrix $\mathrm{W}_{1+\infty}$ algebra (which is different from the ones considered in Refs. 19–24). Next, we reduce the obtained in the explicit form 2×2-matrix $\mathrm{W}_{1+\infty}$ algebra to the $\mathrm{W}_{1+\infty}$ Virasoro subalgebra and the latter to the finite dimensional 2-index $\mathrm{sl}(2,\mathbb{R})$ algebra.

The paper is organized as follows. In Sec. II, we review some of the standard facts on the algebra of the pseudodifferential operators of the integer and the complex orders. In Sec. III, we introduce the nonhomogeneous graded algebra of the 2×2-matrix psd operators. Section IV is devoted to the study of the central extension of this algebra and their generalization to the $n\times n$ case. In Sec. V, we define the nonhomogeneous graded 2×2-matrix $\mathrm{W}_{1+\infty}$ algebra and their two subalgebras. Finally, we present some concluding remarks in Sec. VI.

II. THE ALGEBRA OF THE PSEUDODIFFERENTIAL OPERATORS ON A CIRCLE

Let $\mathfrak{R}(\mathbb{C},\mathbf{k})$ denote the ring of the pseudodifferential operators of order $\mathbb{C}$ with the coefficients belonging to the algebra $C^\infty(\mathbb{S}^1,\mathbf{k})$ of smooth $\mathbf{k}$-valued functions on $\mathbb{S}^1$ ($\mathbf{k}=\mathbb{R}$ or $\mathbb{C}$):

$$\mathfrak{R}(\mathbb{C},\mathbf{k})=\left\{A(x,\partial)=\sum_{i=0}^{\infty} a_i(x)\partial_x^{\alpha-i}\,\middle|\, a_i(x)\in C^\infty(\mathbb{S}^1,\mathbf{k}),\alpha\in\mathbb{C}\right\}. \tag{2.1}$$

The multiplication law in $\mathfrak{R}(\mathbb{C},\mathbf{k})$ is determined by the Leibniz rule

$$A(x,\partial)\circ B(x,\partial)=\sum_{i,j=0}^{\infty}\sum_{k=0}^{\infty}\binom{\alpha-i}{k}a_i(x)b_j^{(k)}(x)\partial_x^{\alpha+\beta-i-j-k}, \tag{2.2}$$

where

$$\binom{\alpha}{k}\equiv\frac{\alpha(\alpha-1)\cdots(\alpha-k+1)}{k!}\quad\text{and}\quad b_j^{(k)}(x)\equiv\partial_x^k b_j(x).$$

The law (2.2) determines the Lie algebra structure on $\mathfrak{R}(\mathbb{C},\mathbf{k})$

$$[A,B]=A\circ B-B\circ A=\sum_{i,j=0}^{\infty}\sum_{k=0}^{\infty}\left[\binom{\alpha-i}{k}a_i(x)b_j^{(k)}(x)-\binom{\beta-j}{k}b_j(x)a_i^{(k)}(x)\right]\partial_x^{\alpha+\beta-i-j-k}. \tag{2.3}$$

Restricting the orders $\mathrm{ord}A(x,\partial)$ of the pseudodifferential operators on those satisfying the condition $\mathrm{ord}A(x,\partial)\in\mathbb{Z}$, we obtain the algebra $\mathfrak{R}(\mathbb{Z},\mathbf{k})=\mathfrak{R}(\mathbb{Z}_+,\mathbf{k})\oplus\mathfrak{R}(\mathbb{Z}_-,\mathbf{k})$ consisting the standard algebra of the differential and integral (Voltera's) operators.

It is well known that the algebra $\mathfrak{R}(\mathbb{Z}_+,\mathbf{k})$ allows the central extension given by the following 2-cocycle:[19]

$$c(a_i(x)\partial_x^i,b_i(x)\partial_x^j)=\frac{i!j!}{(i+j+1)!}\int_{S^1}a_i^{(j)}(x)b_j^{(i+1)}(x)dx,\quad (i,j=0,1,2,...), \tag{2.4}$$

where $a_i\partial_x^i$ and $b_j\partial_x^j$ are the purely differential operators. The relation (2.4) can be obtained by using, for example, the Khesin–Kravchenko construction.[12]

It is well known that the $\mathfrak{R}(\mathbb{Z}_+,\mathbf{k})$ algebra is isomorphic with the $W_{1+\infty}$ algebra.[19] Restricting the differential operators on the operators of the first order one can obtain the Virasoro algebra.

The algebra $\mathfrak{R}(\mathbb{C},\mathbf{k})$ can be generalized to the matrix case.[13,14] Let $\mathcal{G}$ be a matrix Lie algebra. Then the algebra $\mathfrak{R}(\mathbb{C},\mathcal{G})$ consists the matrix pseudodifferential operators of the form

$$\mathfrak{R}(\mathbb{C},\mathcal{G})=\left\{A(x,\partial)=\sum_{i=0}^{\infty} a_i(x)\partial_x^{\alpha-i}\,\middle|\, a_i(x)\in C^\infty(\mathbb{S}^1,\mathcal{G}),\alpha\in\mathbb{C}\right\}. \tag{2.5}$$

The multiplication law in $\mathfrak{R}(\mathbb{C},\mathcal{G})$ is the same as (2.2) but, in this case, the matrix product of the coefficients must be taking into account. If the condition $\mathrm{ord}A(x,\partial)\in\mathbb{Z}$ is fulfilled, we obtain the algebra $\mathfrak{R}(\mathbb{Z},\mathcal{G})=\mathfrak{R}(\mathbb{Z}_+,\mathcal{G})\oplus\mathfrak{R}(\mathbb{Z}_-,\mathcal{G})$ of the matrix differential and integral operators.

It has been shown[13] that the algebra $\mathfrak{R}(\mathbb{Z}_+,\mathcal{G})$ admits the nontrivial central extension given by the 2-cocycle

$$c(a_i(x)\partial_x^i,b_i(x)\partial_x^j)=\mathrm{tr}\left[\frac{i!j!}{(i+j+1)!}\int_{S^1}a_i^{(j)}(x)b_j^{(i+1)}(x)dx\right], \tag{2.6}$$

where the symbol tr denotes the standard trace of a matrix.

The particular cases of the $\mathfrak{R}(\mathbb{Z}_+,\mathcal{G})$ algebras are, for example, the colored W_∞^p algebra[20] and non-abelian current version of $W_{1+\infty}$.[24]

III. THE NONHOMOGENEOUS GRADED $\mathfrak{R}(\mathbb{C},\mathscr{G})$ ALGEBRA

Let us consider the algebra $\mathfrak{R}(\mathbb{C},\mathscr{G})$ (2.5). Let us assume that, for simplicity, $\mathscr{G}$ is some space of the 2×2 matrices. In this case, the generators of the $\mathfrak{R}(\mathbb{C},\mathscr{G})$ algebra are the matrix pseudodifferential operators of the form

$$A(x,\partial_x)=\sum_{i=0}^{\infty}\begin{pmatrix} a_i^{11}(x) & a_i^{12}(x)\\ a_i^{21}(x) & a_i^{22}(x)\end{pmatrix}\begin{pmatrix}\partial^{\alpha-1} & 0\\ 0 & \partial^{\alpha-1}\end{pmatrix}=\sum_{i=0}^{\infty}\begin{pmatrix} a_i^{11}(x)\partial_x^{\partial-1} & a_i^{12}(x)\partial_x^{\alpha-1}\\ a_i^{21}(x)\partial_x^{\alpha-i} & a_i^{22}(x)\partial_x^{\alpha-i}\end{pmatrix}. \quad (3.1)$$

It easy to see that the orders of the matrix elements of the operator (3.1) are the same. The operators which have this property, we shall call the homogeneous graded operators. Now, we would like to extend the definition of the admissible matrix pseudodifferential operators by assumption that the matrix elements of such operators can be chosen to be the psd operators of the arbitrary orders. In this way, we obtain what will be referred to as the nonhomogeneous graded algebra of the matrix pseudodifferential operators $\mathrm{Mat}_2(\mathfrak{R})$. Indeed, let us consider the operators of the form

$$\mathbb{A}(x,\partial_x)=\begin{pmatrix}\sum_{i=0}^{\infty} a_i^{11}(x)\partial_x^{\alpha_{11}-i} & \sum_{i=0}^{\infty} a_i^{12}(x)\partial_x^{\alpha_{12}-i}\\ \sum_{i=0}^{\infty} a_i^{21}(x)\partial_x^{\alpha_{21}-i} & \sum_{i=0}^{\infty} a_i^{22}(x)\partial_x^{\alpha_{22}-i}\end{pmatrix}\equiv\begin{pmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{pmatrix}, \quad (3.2)$$

where, in general, $\alpha_{11}\neq\alpha_{12}\neq\alpha_{21}\neq\alpha_{22}$, and the coefficients a's belong to the space

$$\text{case 1: } a_i^{mn}(x)\in C^{\infty}(\mathbb{S}^1,\mathbf{k}), \text{ or} \quad (3.3)$$

$$\text{case 2: } a_i^{mn}(x)\in C^{\infty}(\mathbb{S}^1,\mathscr{G}), \ (m,n=1,2). \quad (3.4)$$

Definition: The operators of the form (3.2) generates the matrix algebra:
case 1: $\mathrm{Mat}_2(\mathfrak{R}(\mathbb{C},\mathbf{k}))$, if the coefficients satisfy the condition (3.3), or
case 2: $\mathrm{Mat}_2(\mathfrak{R}(\mathbb{C},\mathscr{G}))$, if the coefficients satisfy the condition (3.4).

Using the multiplication law (2.2) one can check that the algebra $G_{\cdot,*}\equiv\mathrm{Mat}_2(\mathfrak{R}(\cdot,*))$, ($*\equiv\mathbf{k}$ or $\mathscr{G}$ and $\cdot\equiv\mathbb{C}$ or $\mathbb{Z}$) has the form

$$[\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)]=\mathbb{C}(x,\partial_x), \quad (3.5)$$

where $\mathbb{C}(x,\partial_x)\equiv\begin{pmatrix}c_{11} & c_{12}\\ c_{21} & c_{22}\end{pmatrix}$, and

$$\begin{aligned} c_{11}&\equiv K(\alpha_{11},\beta_{11})-L(\beta_{11},\alpha_{11})+K(\alpha_{12},\beta_{21})-L(\beta_{12},\alpha_{21}),\\ c_{12}&\equiv K(\alpha_{11},\beta_{12})-L(\beta_{12},\alpha_{22})+K(\alpha_{12},\beta_{22})-L(\beta_{11},\alpha_{12}),\\ c_{21}&\equiv K(\alpha_{21},\beta_{11})-L(\beta_{22},\alpha_{21})+K(\alpha_{22},\beta_{21})-L(\beta_{21},\alpha_{11}),\\ c_{22}&\equiv K(\alpha_{22},\beta_{22})-L(\beta_{22},\alpha_{22})+K(\alpha_{21},\beta_{12})-L(\beta_{21},\alpha_{12}),\end{aligned} \quad (3.6)$$

where

$$K(\alpha,\beta)=\sum_{i,j=0}^{\infty}\sum_{k=0}^{\alpha-j}\binom{\alpha-j}{k}a_i(x)b_j^{(k)}(x)\partial_x^{\alpha+\beta-i-j-k},$$

$$L(\beta,\alpha)=\sum_{i,j=0}^{\infty}\sum_{k=0}^{\beta-j}\binom{\beta-j}{k}b_j(x)a_i^{(k)}(x)\partial_x^{\alpha+\beta-i-j-k}.$$

Let us consider the special cases of the algebra $G_{\cdot,*}$.

(i) If $A_{12}=A_{21}=A_{22}=0$ and $A_{11}\neq 0$ as well as $\alpha_{11}\in\mathbb{C}$ and $\beta\in\mathbb{C}$ then $G_{\mathbb{C},\mathcal{G}}\equiv\mathfrak{R}(\mathbb{C},\mathcal{G})$ and $G_{\mathbb{C},\mathbf{k}}\equiv\mathfrak{R}(\mathbb{C},\mathbf{k})$.

(ii) If $A_{11}\neq 0$, $A_{12}\neq 0$, $A_{21}\neq 0$ and $A_{22}\neq 0$ as well as $\alpha_{11}=\alpha_{12}=\alpha_{21}=\alpha_{22}\in\mathbb{C}$ and $\beta_{11}=\beta_{12}=\beta_{21}=\beta_{22}\in\mathbb{C}$ then $G_{\mathbb{C},\mathbf{k}}\equiv\mathfrak{R}(\mathbb{C},\mathcal{G})$. (The homogeneous graded algebra.)

(iii) If $A_{11}=A_{21}=A_{22}=0$ and $A_{11}\neq 0$ as well as $\alpha_{11}\in\mathbb{Z}$ and $\beta_{11}\in\mathbb{Z}$ then $G_{\mathbb{Z},\mathcal{G}}\equiv\mathfrak{R}(\mathbb{Z},\mathcal{G})$ and $G_{\mathbb{Z},\mathbf{k}}\equiv\mathfrak{R}(\mathbb{Z},\mathbf{k})$.

(iv) If $A_{11}\neq 0$, $A_{12}\neq 0$, $A_{21}\neq 0$ and $A_{22}\neq 0$ as well as $\alpha_{11}=\alpha_{12}=\alpha_{21}=\alpha_{22}\in\mathbb{Z}$ and $\beta_{11}=\beta_{12}=\beta_{21}=\beta_{22}\in\mathbb{Z}$ then $G_{\mathbb{Z},\mathbf{k}}\equiv\mathfrak{R}(\mathbb{Z},\mathcal{G})$. (The homogeneous graded algebra.)

For the other values of the orders of the operators which form the matrix elements of (3.2), we obtain the new non-homogeneous graded matrix algebras.

IV. THE CENTRAL EXTENSION OF THE $\mathrm{Mat}_n(\mathfrak{R}(\mathbb{Z},\mathbf{k}))$ ALGEBRA

Using the Kravchenko–Khesin construction[12,13] we show that the $n\times n$ matrix algebra $G_{\mathbb{Z},\mathbf{k}}\equiv\mathrm{Mat}_n(\mathfrak{R}(\mathbb{Z},\mathbf{k}))$ over the ring of the pseudodifferential operators of the integer orders admits the nontrivial central extension.

First, let us consider the 2×2 matrix $G_{\mathbb{Z},\mathbf{k}}$ algebra generated by the operators of the integer form

$$\mathbb{A}(x,\partial_x)=\begin{pmatrix}\sum_{i=-\infty}^{n_{11}} a_i^{11}(x)\partial_x^i & \sum_{i=-\infty}^{n_{12}} a_i^{12}(x)\partial_x^i\\ \sum_{i=-\infty}^{n_{21}} a_i^{21}(x)\partial_x^i & \sum_{i=-\infty}^{n_{22}} a_i^{22}(x)\partial_x^i\end{pmatrix}\equiv\begin{pmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{pmatrix},\tag{4.1}$$

where $a_i^{mn}(x)\in\mathbb{C}^\infty(\mathbb{S}^1,\mathbf{k})$ $(m,n=1,2)$.

The algebra of the symbols of the operators (4.1) is defined by the elements

$$\mathbb{A}(x,\xi)=\begin{pmatrix}\sum_{i=-\infty}^{n_{11}} a_i^{11}(x)\xi^i & \sum_{i=-\infty}^{n_{12}} a_i^{12}(x)\xi^i\\ \sum_{i=-\infty}^{n_{21}} a_i^{21}(x)\xi^i & \sum_{i=-\infty}^{n_{22}} a_i^{22}(x)\xi^i\end{pmatrix},\tag{4.2}$$

and the multiplication law

$$\left(\sum_{i=-\infty}^{n} a_i(x)\xi^i\right)\circ\left(\sum_{j=-\infty}^{m} b_j(x)\xi^j\right)=\sum_{i=-\infty}^{n}\sum_{j=-\infty}^{m}\sum_{k\geqslant 0}\frac{1}{k!}[\partial_\xi^k(a_i(x)\xi^i)][\partial_x^k(b_j(x)\xi^j)].\tag{4.3}$$

Let us introduce the operator

$$\mathbb{R}\mathrm{es}:\begin{pmatrix}\mathfrak{R}(\mathbb{Z},\mathbf{k}) & \mathfrak{R}(\mathbb{Z},\mathbf{k})\\ \mathfrak{R}(\mathbb{Z},\mathbf{k}) & \mathfrak{R}(\mathbb{Z},\mathbf{k})\end{pmatrix}\to\begin{pmatrix}C^\infty(\mathbb{S},\mathbf{k}) & C^\infty(\mathbb{S},\mathbf{k})\\ C^\infty(\mathbb{S},\mathbf{k}) & C^\infty(\mathbb{S},\mathbf{k})\end{pmatrix},\tag{4.4}$$

defined by the relation

$$\mathbb{R}\mathrm{es}\ \mathbb{A}(x,\partial_x)=\begin{pmatrix}\mathrm{res}\ A_{11} & \mathrm{res}\ A_{12}\\ \mathrm{res}\ A_{21} & \mathrm{res}\ A_{22}\end{pmatrix}=\begin{pmatrix}a_{-1}^{11}(x) & a_{-1}^{12}(x)\\ a_{-1}^{21}(x) & a_{-1}^{22}(x)\end{pmatrix}.\tag{4.5}$$

Lemma 1: Let $\mathbb{A}(x,\partial_x)$ and $\mathbb{B}(x,\partial_x)\in G_{\mathbb{Z},\mathbf{k}}$ and $A_{11}=A_{22}$, $A_{12}=A_{21}$, $B_{11}=B_{22}$, and $B_{12}=B_{21}$ then the following relation:

$$\int_{\mathbb{S}^1}\mathbb{R}\mathrm{es}[\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)]=0\tag{4.6}$$

holds.

Proof: From (4.1) and (4.5) it follows that:

$$\int_{S^1}\mathbb{R}\mathrm{es}[\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)]$$

$$=\begin{pmatrix} \int \mathrm{res}[A_{11},B_{11}]+\int \mathrm{res}[A_{12},B_{12}] & \int \mathrm{res}[A_{11},B_{12}]+\int \mathrm{res}[A_{12},B_{11}] \\ \int \mathrm{res}[A_{12},B_{11}]+\int \mathrm{res}[A_{11},B_{12}] & \int \mathrm{res}[A_{12},B_{12}]+\int \mathrm{res}[A_{11},B_{11}] \end{pmatrix}=0,$$

since $\int_{s^1}\mathrm{res}[A_{ij},B_{kl}]=0$ $(i,j,k,l,=1,2)$. □

Let us consider the formal expression

$$\mathbb{L}\mathrm{og}\ \partial_x:=\begin{pmatrix} \log\partial_x & 0 \\ 0 & \log\partial_x \end{pmatrix}. \tag{4.7}$$

One can show that the formal commutator $[\mathbb{L}\mathrm{og}\ \partial_x,\mathbb{A}(x,\partial_x)]=\mathbb{L}\mathrm{og}\ \partial_x\circ\mathbb{A}(x,\partial_x)-\mathbb{A}(x,\partial_x)\circ\mathbb{L}\mathrm{og}\ \partial_x$ belongs to $G_{Z,\mathbf{k}}$. Indeed, using the algebra of the symbols, it is easy to see that:

$$[\mathbb{L}\mathrm{og}\ \partial_x,\mathbb{A}(x,\partial_x)]=\begin{pmatrix} [\log\partial_x,A_{11}] & [\log\partial_x,A_{12}] \\ [\log\partial_x,A_{21}] & [\log\partial_x,A_{22}] \end{pmatrix}$$

$$=\begin{pmatrix} \sum_{k\geqslant 1}\frac{(-1)^{k-1}}{k}(\partial_x^k A_{11})\partial_x^{-k} & \sum_{k\geqslant 1}\frac{(-1)^{k-1}}{k}(\partial_x^k A_{12})\partial_x^{-k} \\ \sum_{k\geqslant 1}\frac{(-1)^{k-1}}{k}(\partial_x^k A_{21})\partial_x^{-k} & \sum_{k\geqslant 1}\frac{(-1)^{k-1}}{k}(\partial_x^k A_{22})\partial_x^{-k} \end{pmatrix}. \tag{4.8}$$

Lemma 2: The following relation

$$[\mathbb{L}\mathrm{og}\ \partial_x,\mathbb{A}(x,\partial_x)\circ\mathbb{B}(x,\partial_x)]$$

$$=[\mathbb{L}\mathrm{og}\ \partial_x,\mathbb{A}(x,\partial_x)]\circ\mathbb{B}(x,\partial_x)+\mathbb{A}(x,\partial_x)\circ[\mathbb{L}\mathrm{og}\ \partial_x,\mathbb{B}(x,\partial_x)] \tag{4.9}$$

holds.

Proof: It follows immediately from the formulas (4.1)–(4.3). □

Now, we can formulate the main result of this section.

Theorem: The central extended algebra

$$\hat{G}_{Z,\mathbf{k}}=G_{Z,\mathbf{k}}\oplus\begin{pmatrix} \mathbb{C} & \mathbb{C} \\ \mathbb{C} & \mathbb{C} \end{pmatrix}$$

has the form

$$[\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)]_c=[\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)]+c(\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)), \tag{4.10}$$

where $\mathbb{A}(x,\partial_x)$ and $\mathbb{B}(x,\partial_x)\in G_{Z,\mathbf{k}}$ and $c(\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x))$ is defined by the relation

$$c(\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x))=\begin{pmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{pmatrix}; \tag{4.11}$$

where

$$\begin{aligned} c_{11}=c_{22}&\equiv[\mathscr{P}(A_{11},B_{11})+\mathscr{P}(A_{12},B_{12})]\Delta_1, \\ c_{12}=c_{21}&\equiv[\mathscr{P}(A_{11},B_{12})+\mathscr{P}(A_{12},B_{11})]\Delta_2, \end{aligned} \tag{4.12}$$

where

$$\mathscr{P}(A_{ij},B_{mn})\equiv\int_{S^1}\mathrm{res}([A_{ij},\log\,\partial_x]\circ B_{mn})=\int_{S^1}\mathrm{res}\left(\sum_{k\geqslant 1}\frac{(-1)^k}{k}(\partial_x^k A_{ij})\partial_x^{-k}B_{mn}\right),\quad(4.13)$$

$(i,j,m,n\in\{1,2\})$, and

$$\Delta_1\equiv\delta_{A_{11},A_{22}}\delta_{A_{12},A_{21}}\delta_{B_{11},B_{22}}\delta_{B_{12},B_{21}},$$

$$\Delta_2\equiv\delta_{A_{11},A_{12}}\delta_{A_{11},A_{21}}\delta_{A_{11},A_{22}}\delta_{B_{11},B_{12}}\delta_{B_{11},B_{21}}\delta_{B_{11},B_{22}},\quad(4.14)$$

$$\delta_{A_{ij},A_{mn}}=\begin{cases}1 & \text{if ord } A_{ij}=\text{ord } A_{mn}\\ 0 & \text{in the other}\end{cases}$$

and B_{mn} $(m,n=1,2)$ are the matrix elements of the operator $\mathbb{B}(x,\partial_x)$.

Proof: By direct calculations [using the Jacobi identity and the relations (4.6), (4.8), and (4.9)] one can check that the function (4.11) satisfy the 2-cocycle condition

$$\sum_{\text{cyclic}}c(\mathbb{A},[\mathbb{B},\mathbb{C}])=\int_{S^1}\mathbb{R}\mathrm{es}([\mathbb{A},\mathbb{L}\mathrm{og}\,\partial_x]\circ[\mathbb{B},\mathbb{C}]+[\mathbb{B},\mathbb{L}\mathrm{og}\,\partial_x]\circ[\mathbb{C},\mathbb{A}]+[\mathbb{C},\mathbb{L}\mathrm{og}\,\partial_x]\circ[\mathbb{A},\mathbb{B}])=0.$$

□

The restriction of the 2-cocycle (4.11) on the purely differential operators $\mathbb{A}_+(x,\partial_x)$ and $\mathbb{B}_+(x,\partial_x)$ (which satisfy the conditions ord $\mathbb{A}_+\in\mathbb{Z}_+$ and ord $\mathbb{B}_+\in\mathbb{Z}_+$) determines the central extension $\hat{G}_{Z_+,\mathbf{k}}$ of the $G_{Z_+,\mathbf{k}}$ algebra

$$[\mathbb{A}_+(x,\partial_x),\mathbb{B}_+(x,\partial_x)]_c=[\mathbb{A}_+(x,\partial_x),\mathbb{B}_+(x,\partial_x)]+c(\mathbb{A}_+(x,\partial_x),\mathbb{B}_+(x,\partial_x)).\quad(4.15)$$

Using the relations (4.1) and (4.10)–(4.14) one can compute the explicit form of the 2-cocycle $c(\mathbb{A}_+,\mathbb{B}_+)$

$$c(\mathbb{A}_+(x,\partial_x),\mathbb{B}_+(x,\partial_x))=\begin{pmatrix}\tilde{c}_{11} & \tilde{c}_{12}\\ \tilde{c}_{21} & \tilde{c}_{22}\end{pmatrix},\quad(4.16)$$

where

$$\tilde{c}_{11}=\tilde{c}_{22}\equiv[\tilde{\mathscr{P}}(n_{11},m_{11})+\tilde{\mathscr{P}}(n_{12},m_{12})]\tilde{\Delta}_1,$$
$$\tilde{c}_{12}=\tilde{c}_{21}\equiv[\tilde{\mathscr{P}}(n_{11},m_{12})+\tilde{\mathscr{P}}(n_{12},m_{11})]\tilde{\Delta}_2,\quad(4.17)$$

where

$$\tilde{\mathscr{P}}(n,m)\equiv\sum_{i=0}^{n}\sum_{j=0}^{m}\frac{i!j!}{(i+j+1)!}\int_{S^1}[\partial_x^j a_i(x)][\partial_x^{i+1}b_j(x)],\quad(4.18)$$

and

$$\tilde{\Delta}_1\equiv\delta_{n_{11},n_{22}}\delta_{n_{12},n_{21}}\delta_{m_{11},m_{22}}\delta_{m_{12},m_{21}},$$
$$\tilde{\Delta}_2\equiv\delta_{n_{11},n_{12}}\delta_{n_{11},n_{21}}\delta_{n_{11},n_{22}}\delta_{m_{11},m_{12}}\delta_{m_{11},m_{21}}\delta_{m_{11},m_{22}};\quad(4.19)$$

n_{ij} and m_{kl} $(i,j,k,l\in\{1,2\})$ are the orders of the elements of the operators $\mathbb{A}_+(x,\partial_x)$ and $\mathbb{B}_+(x,\partial_x)$.

The relations (4.16)–(4.19) describe the generalization of the Kac–Peterson 2-cocycles.[10] In particular, putting $n_{12}=n_{21}=n_{22}=m_{12}=m_{21}=m_{22}=0$ into these relations, we obtain the standard 2-cocycle on $\mathfrak{R}(\mathbb{Z}_+,\mathbf{k})$ (2.4). In the case $n_{11}=n_{12}=n_{21}=n_{22}\neq 0$ and $m_{11}=m_{12}=m_{21}=m_{22}\neq 0$, we obtain the 2-cocycle on $\mathfrak{R}(\mathbb{Z}_+,\mathscr{G})$ (2.6).

The above results one can generalize to the case of the $n\times n$ matrices. It follows from the Jacobi identity that the $n\times n$ matrix generalization of the $\hat{G}_{Z,\mathbf{k}}$ algebra (4.10) has the form:

$$[\mathbb{A}(x,\partial_x),\mathbb{B}(x,\partial_x)]_c=\begin{pmatrix} a_1 & a_2 & \cdots & a_2 \\ a_2 & a_1 & & \vdots \\ \vdots & & \ddots & \vdots \\ a_2 & \cdots & \cdots & a_1 \end{pmatrix}+\begin{pmatrix} c_1 & c_2 & \cdots & c_2 \\ c_2 & c_1 & & \vdots \\ \vdots & & \ddots & \vdots \\ c_2 & \cdots & \cdots & c_1 \end{pmatrix}, \tag{4.20}$$

where

$$\mathbb{A}(x,\partial_x)\equiv\begin{pmatrix} A_1 & A_2 & \cdots & A_2 \\ A_2 & A_1 & & \vdots \\ \vdots & & \ddots & \vdots \\ A_2 & \cdots & \cdots & A_1 \end{pmatrix}, \tag{4.21}$$

$$A_j=\sum_{i=0}^{\infty} a_i^j(x)\partial_x^{\alpha_j-i}, \quad (j=1,2),$$

and

$$\begin{aligned} a_1&=[A_1,B_1]+(n-1)[A_2,B_2], \\ a_2&=[A_1,B_2]+[A_2,B_1]+(n-2)[A_2,B_2], \end{aligned} \tag{4.22}$$

and

$$\begin{aligned} c_1&\equiv\mathscr{P}(A_1,B_1)+(n-1)\mathscr{P}(A_2,B_2), \\ c_2&\equiv\mathscr{P}(A_1,B_2)+\mathscr{P}(A_2,B_1)+(n-2)\mathscr{P}(A_2,B_2). \end{aligned} \tag{4.23}$$

The symbol $\mathscr{P}(A_i,B_j)$ is defined by the relation (4.13) and n denotes the dimension of the matrices $\mathbb{A}$ and $\mathbb{B}$. We note that the commutator of the $n\times n$ matrices other than (4.21) cannot be extended by some 2-cocycles because their elements are not the commutators of the operators A_j and does not satisfy the assumptions of the lemmas 1 and 2. Therefore the $n\times n$ matrix central extended $\hat{G}_{Z,\mathbf{k}}$ algebra is generated by only two classes of the pseudodifferential operators of the different orders. If orders of these operators are the same then the relation (4.20) describe the standard algebra of the $n\times n$ matrix pseudodifferential operators.

V. THE EXAMPLE OF THE $\mathrm{Mat}_2(\mathfrak{R})$-TYPE ALGEBRAS

Example 1: The $\mathrm{Mat}_2(W_{1+\infty})$ algebra.

Let us consider the following differential operators on $\mathbb{S}^1$, which form the basis of the standard $W_{1+\infty}$ algebra[13]

$$V_m^s=-B(s)\sum_{k=1}^{s}\alpha_k^s\binom{m+s-1}{k-1}z^{m+s-k}D^{s-k}, \tag{5.1}$$

where $z=e^{ix}$ $(x\in S^1)$, $D\equiv\partial_z$ and

$$B(s)=\frac{2^{s-3}(s-1)!}{(2s-3)!!} \quad \text{and} \quad \alpha_k^s=\frac{(2s-k-1)!}{[(s-k)!]}. \tag{5.2}$$

From the relations (4.15)–(4.19) and (5.1) it follows that the nonhomogeneous graded matrix $W_{1+\infty}$ algebra has the form

$$\left[\begin{pmatrix} V^{s_1}_{m_1} & V^{s_2}_{m_2} \\ V^{s_3}_{m_3} & V^{s_4}_{m_4} \end{pmatrix}, \begin{pmatrix} V^{r_1}_{n_1} & V^{r_2}_{n_2} \\ V^{r_3}_{n_3} & V^{r_4}_{n_4} \end{pmatrix}\right] = \begin{pmatrix} A_1 & A_2 \\ A_3 & A_4 \end{pmatrix} + \begin{pmatrix} C_1 & C_2 \\ C_3 & C_4 \end{pmatrix}, \tag{5.3}$$

where

$$\begin{aligned} A_1 &= V^{s_1}_{m_1} * V^{r_1}_{n_1} - V^{r_1}_{n_1} * V^{s_1}_{m_1} + V^{s_2}_{m_2} * V^{r_3}_{n_3} - V^{r_2}_{n_2} * V^{s_3}_{m_3}, \\ A_2 &= V^{s_1}_{m_1} * V^{r_2}_{n_2} - V^{r_2}_{n_2} * V^{s_4}_{m_4} + V^{s_2}_{m_2} * V^{r_4}_{n_4} - V^{r_1}_{n_1} * V^{s_2}_{m_2}, \\ A_3 &= V^{s_3}_{m_3} * V^{r_1}_{n_1} - V^{r_4}_{n_4} * V^{s_3}_{m_3} + V^{s_4}_{m_4} * V^{r_3}_{n_3} - V^{r_3}_{n_3} * V^{s_1}_{m_1}, \\ A_4 &= V^{s_4}_{m_4} * V^{r_4}_{n_4} - V^{r_4}_{n_4} * V^{s_4}_{m_4} + V^{s_3}_{m_3} * V^{r_2}_{n_2} - V^{r_3}_{n_3} * V^{s_2}_{m_2}, \end{aligned} \tag{5.4}$$

and the symbol $*$ denotes the lone star product defined by the relation[25]

$$V^s_m * V^r_n = \frac{1}{2} \sum_{i \geqslant 0} g^{sr}_i(m,n) V^{s+r-i}_{m+n}, \tag{5.5}$$

where

$$g^{sr}_i(m,n) = \frac{\varphi^{sr}_i}{2(i+1)!} N^{sr}_i(m,n), \tag{5.6}$$

$$\varphi^{sr}_i = \sum_{k=0} \frac{(\frac{1}{2})_k (\frac{1}{2})_k (-(i+1)/2)_k (-\frac{1}{2})_k}{k!(-s+\frac{3}{2})_k (-r+\frac{3}{2})_k (s+r-i-\frac{3}{2})_k}, \tag{5.7}$$

and

$$N^{sr}_i(m,n) = \sum_{k=0}^{i+1} (-1)^k \binom{i+1}{k} (2s-i-2)_k [2r-k-2]_{i+1-k} [s-1+m]_{i+1-k} [r-1+n]_k, \tag{5.8}$$

where

$$(a)_k = a(a+1)\cdots(a+k-1); \quad [a]_k = a(a-1)\cdots(a-k+1). \tag{5.9}$$

By using the lone star product (5.5) the commutation relations of $W_{1+\infty}$ algebra can be defined as $[V^s_m, V^r_n] = V^s_m * V^r_n - V^r_n * V^s_m$. In the relation (5.3) the matrix $\left(\begin{smallmatrix} C_1 & C_2 \\ C_3 & C_4 \end{smallmatrix}\right)$ denotes the central terms in which the elements C's have the form

$$\begin{aligned} C_1 &= [\beta(s_1,m_1)\delta_{s_1,r_1}\delta_{m_1+n_1,0} + \beta(s_2,m_2)\delta_{s_2,r_3}\delta_{m_2+n_3,0}]\Delta_1, \\ C_2 &= [\beta(s_1,m_1)\delta_{s_1,r_2}\delta_{m_1+n_2,0} + \beta(s_2,m_2)\delta_{s_2,r_4}\delta_{m_2+n_4,0}]\Delta_2, \\ C_3 &= [\beta(s_3,m_3)\delta_{s_3,r_1}\delta_{m_3+n_1,0} + \beta(s_4,m_4)\delta_{s_4,r_3}\delta_{m_4+n_3,0}]\Delta_2, \\ C_4 &= [\beta(s_3,m_3)\delta_{s_3,r_2}\delta_{m_3+n_2,0} + \beta(s_4,m_4)\delta_{s_4,r_4}\delta_{m_4+n_4,0}]\Delta_1, \end{aligned} \tag{5.10}$$

where

$$\beta(s,m) = -\frac{B(s)^2}{2s-1} \frac{(m+s-1)!}{(m-s)!}, \tag{5.11}$$

and

$$\Delta_1=\delta_{s_1,s_4}\delta_{s_2,s_3}\delta_{r_1,r_4}\delta_{r_2,r_3}\delta_{m_1,m_4}\delta_{m_2,m_3}\delta_{n_1,n_4}\delta_{n_2,n_3},$$
$$\Delta_2=\delta_{s_1,s_2}\delta_{s_1,s_3}\delta_{s_1,s_4}\delta_{r_1,r_2}\delta_{r_1,r_3}\delta_{r_1,r_4}\delta_{m_1,m_2}\delta_{m_1,m_3}\delta_{m_1,m_4}\delta_{n_1,n_2}\delta_{n_1,n_2}\delta_{n_1,n_4}. \tag{5.12}$$

It is known that the generator V_m^s of the $W_{1+\infty}$ algebra corresponds to the mth Fourier mode of a conformal spin s field ($s\geqslant 1$). From the above fact and from the relations (5.3)–(5.12) it follows that the central extended $\mathrm{Mat}_2(W_{1+\infty})$ algebra (5.3) describe the algebra of the Fourier modes of the systems of conformal fields of the following conformal dimensions (spins) Δ:

$$\begin{pmatrix}\Delta_{s_1} & \Delta_{s_2}\\ \Delta_{s_2} & \Delta_{s_1}\end{pmatrix} \quad \text{and} \quad \begin{pmatrix}\Delta_{r_1} & \Delta_{r_2}\\ \Delta_{r_2} & \Delta_{r_1}\end{pmatrix},$$

where $\Delta_{s_i}=s_i$ and $\Delta_{r_i}=r_i$ (s_i and $r_i=1,2,3,\ldots$; $i=1,2$). We note that the constraints $s_1=s_4$, $s_2=s_3$, $r_1=r_4$ and $r_2=r_3$ arise from the 2-cocycle conditions (5.10).

Example 2: The Mat_2(Virasoro) algebra.

It is known that the Virasoro algebra[7] is the subalgebra of the standard $W_{1+\infty}$ algebra. It follows from the relation (5.3) that the closed subalgebra of $\mathrm{Mat}_2(W_{1+\infty})$ corresponding with the matrix Virasoro algebra Mat_2(Virasoro) has the form

$$\left[\begin{pmatrix}V_{m_1} & V_{m_2}\\ V_{m_2} & V_{m_1}\end{pmatrix},\begin{pmatrix}V_{n_1} & V_{n_2}\\ V_{n_2} & V_{n_1}\end{pmatrix}\right]=\begin{pmatrix}A_1 & A_2\\ A_2 & A_1\end{pmatrix}+\begin{pmatrix}C_1 & C_2\\ C_2 & C_1\end{pmatrix}, \tag{5.13}$$

where

$$A_1=(n_1-m_1)V_{m_1+n_1}+(n_2-m_2)V_{m_2+n_2},$$
$$A_2=(n_2-m_1)V_{m_1+n_2}+(n_1-m_2)V_{m_2+n_1}, \tag{5.14}$$

and

$$C_1=\alpha_1\beta(m_1)\,\delta_{m_1+n_1,0}+\alpha_2\beta(m_2)\,\delta_{m_2+n_2,0},$$
$$C_2=[\,\alpha_1\beta(m_1)\,\delta_{m_1+n_2,0}+\alpha_2\beta(m_2)\,\delta_{m_2+n_1,0}]\,\delta_{m_1,m_2}\delta_{n_1,n_2}, \tag{5.15}$$

where $\beta(m)=m^3-m$ as well as α_1 and α_2 are the arbitrary constants.

It is easy to see, that the algebra (5.13) admits the representation described in the terms of the following differential operator:

$$\begin{pmatrix}V_{m_1} & V_{m_2}\\ V_{m_2} & V_{m_1}\end{pmatrix}\equiv\begin{pmatrix}z^{m_1+1}D & z^{m_2+1}D\\ z^{m_2+1}D & z^{m_1+1}D\end{pmatrix}. \tag{5.16}$$

Since the orders of the differential operators in (5.16) are the same, we conclude from this fact that the Mat_2(Virasoro) algebra (5.13) has the homogeneous gradation.

Example 3: The $\mathrm{Mat}_2(\mathrm{s1}(2,\mathbb{R}))$ algebra.

It is well known that the standard Virasoro algebra (generated by $V_m=z^{m+1}D$) contains the finite dimensional subalgebra isomorphic with the $\mathrm{s1}(2,\mathbb{R})$ algebra, which is generated by the set $\{V_{-1},V_0,V_1\}$. Analogously, the algebra Mat_2(Virasoro) (5.13) also contains the finite subalgebra which we shall call the $\mathrm{Mat}_2(\mathrm{sl}(2,\mathbb{R}))$ algebra. Indeed, using the relations (5.13) and (5.14) one can check that the generators

$$V_{i,j}=\begin{pmatrix}V_i & V_j\\ V_j & V_i\end{pmatrix}, \quad (i,j=-1,0,1), \tag{5.17}$$

close the 2-index algebra of the form

$$[V_{0,0},V_{0,0}]=[V_{0,1},V_{0,1}]=[V_{0,1},V_{1,0}]=[V_{0,-1},V_{0,-1}]=[V_{0,-1},V_{-1,0}]=[V_{1,0},V_{1,0}]$$

$$[V_{1,1},V_{1,1}]=[V_{1,-1},V_{1,-1}]=[V_{1,-1},V_{-1,1}]=[V_{-1,0},V_{-1,0}]=[V_{-1,1},V_{-1,1}]=[V_{-1,-1},V_{-1,-1}]$$
$$=0,$$

$$[V_{0,0},V_{0,1}]=[V_{0,0},V_{1,0}]=[V_{0,1},V_{1,1}]=[V_{1,0},V_{1,1}]=V_{1,1},$$

$$[V_{0,0},V_{0,-1}]=[V_{0,0},V_{-1,0}]=[V_{0,-1},V_{-1,-1}]=[V_{-1,0},V_{-1,-1}]=-V_{-1,-1},$$

$$[V_{1,1},V_{1,-1}]=[V_{1,1},V_{-1,1}]=[V_{1,-1},V_{-1,-1}]=[V_{-1,1},V_{-1,-1}]=-2V_{0,0},$$

$$[V_{0,0},V_{1,-1}]=[V_{0,0},V_{-1,1}]=V_{1,1}-V_{-1,-1},$$

$$\begin{aligned}
&[V_{0,0},V_{1,1}]=2V_{1,1}, \quad [V_{0,0},V_{-1,-1}]=-2V_{-1,-1},\\
&[V_{0,1},V_{0,-1}]=-V_{0,-1}-V_{0,1}, \quad [V_{0,1},V_{-1,0}]=-V_{-1,0}-V_{1,0},\\
&[V_{0,1},V_{-1,0}]=-V_{-1,0}-V_{1,0}, \quad [V_{0,1},V_{-1,0}]=-V_{-1,0}-V_{1,0},\\
&[V_{1,0},V_{-1,1}]=V_{1,-1}-2V_{0,-1}, \quad [V_{0,1},V_{-1,1}]=V_{-1,1}-2V_{-1,0},\\
&[V_{1,0},V_{-1,-1}]=-V_{-1,-1}-2V_{0,0}, \quad [V_{0,1},V_{-1,-1}]=-V_{-1,-1}-2V_{0,0},\\
&[V_{1,1},V_{-1,0}]=-V_{1,1}-2V_{0,0}, \quad [V_{0,-1},V_{1,0}]=V_{1,0}+V_{-1,0},\\
&[V_{1,-1},V_{-1,0}]=V_{-1,1}-2V_{0,1}, \quad [V_{0,-1},V_{1,1}]=V_{1,1}+2V_{0,0}\\
&[V_{-1,0},V_{-1,-1}]=-V_{1,-1}+2V_{1,-1}, \quad [V_{0,-1},V_{1,-1}]=-V_{1,-1}+2V_{1,0},\\
&[V_{1,0},V_{-1,0}]=-2V_{0,-1}, \quad [V_{0,-1},V_{-1,1}]=-V_{-1,1}+2V_{0,1},\\
&[V_{1,1},V_{-1,-1}]=-4V_{0,0}.
\end{aligned} \tag{5.18}$$

We also point out that the algebra (5.18) has the homogeneous gradation.

VI. FINAL REMARKS

In this paper we have presented the generalization of the central extended algebra $\hat{G}_{\mathbb{Z},\mathbf{k}}$ of the $n\times n$-matrix psd operators on the circle to the case of the nonhomogeneous gradation ($\mathrm{Mat}_n(\hat{G})$). We have shown that the $\mathrm{Mat}_n(\hat{G})$ algebra is isomorphic with the central extended algebra $\mathrm{Mat}_n(W_{1+\infty})$ whose matrix elements are determined by the compositions of two arbitrary generators of the $W_{1+\infty}$. Therefore, the $\mathrm{Mat}_n(W_{1+\infty})$ algebra can be interpreted as the algebra of the Fourier modes of the systems of two conformal fields with the arbitrary (integer) dimensions. However, in the case of the homogeneous gradation the conformal dimensions of the each pair of the fields are the same.

As the example, we have also shown that the $\mathrm{Mat}_2(W_{1+\infty})$ algebra contains the two, homogeneous graded subalgebras, namely, the Mat_2(Virasoro) and the finite dimensional $\mathrm{Mat}_2(\mathrm{sl}(2,\mathbb{R}))$ algebras. It is known[25] that the $W_{1+\infty}$ algebra can be viewed as extension of the $\mathrm{sl}(2,\mathbb{R})$ tensor algebras $\tau(\mu)$, where the parameter μ is the value of the quadratic Casimir Q of $\mathrm{sl}(2,\mathbb{R})$. Thus one may ask whether the nonhomogeneous graded $\mathrm{Mat}_n(W_{1+\infty})$ algebra can also be obtained as the universal enveloping algebra of the homogeneous graded Mat_n(Virasoro) or $\mathrm{Mat}_n(\mathrm{sl}(2,\mathbb{R}))$ algebra?

It seems to be interesting to find the representations of the central extended $\mathrm{Mat}_n(\hat{G})$ algebra ($n\geqslant 2$) in the terms of the bosonic and fermionic fields. Further, one can study their connections with the representations of the homogeneous graded matrix $W_{1+\infty}$ algebras.[19–24]

Another problem worth studying is determining the completely integrable hierarchies of the nonlinear equations (KdV and KP-type) associated with the nonhomogeneous graded algebras of the matrix psd operators.

ACKNOWLEDGMENT

The author wishes to thank the referee for many helpful suggestions on an earlier version of this paper and W. Ziubiński for fruitful discussions.

Enlarged test-function spaces for the global free folia dynamics on the CCR-algebra

Reinhard Honegger
Institut für Theoretische Physik, Universität Tübingen, D-72076 Tübingen, Germany

(Received 19 May 1997; accepted for publication 9 July 1997)

The global free dynamics for the boson field is investigated for the test-function space $\mathscr{D}(\mathbb{R}^3)$ of infinitely differentiable functions with compact support in the position space $\mathbb{R}^3$. $\mathscr{D}(\mathbb{R}^3)$ is not invariant with respect to the one-boson dynamics, and thus the free dynamics cannot be formulated in terms of Bogoliubov automorphisms on the CCR-algebra over $\mathscr{D}(\mathbb{R}^3)$. In the Schrödinger picture the free dynamics here is constructed in terms of a group of affine bijections on suitable folia of the CCR-algebra so that the expectations are continuous in time. These folia contain a continuum of disjoint subfolia, namely the squeezed vacuum sectors. Those squeezed vacuum sectors are determined which give rise to covariant dynamical subdescriptions, that is, for which the time evolution of the states satisfies the stronger time-continuity with respect to the norm, and thus in the Heisenberg picture lead to W^*-dynamical systems. © *1998 American Institute of Physics.* [S0022-2488(98)02101-X]

I. INTRODUCTION

Infinite boson resp. photon systems occur in various algebraic investigations in statistical physics, QED, quantum optics, solid state physics, and quantum chemistry (cf., e.g., Refs. 1–10, and references therein). In these works, however, the reader may find a wide range of different choices for the one-boson test-function space E for the same infinite boson resp. photon field.[11] But the bosonic resp. photonic C^*-Weyl algebra $\mathrm{CCR}(E)$ of the *c*anonical *c*ommutation *r*elations depends sensitively from the selection of the test-function space. The inclusion $E \subseteq \mathscr{E}$ implies $\mathrm{CCR}(E) \subseteq \mathrm{CCR}(\mathscr{E})$, where $\mathrm{CCR}(E) = \mathrm{CCR}(\mathscr{E})$, if and only if $E = \mathscr{E}$.[2]

For example, in the whole Euclidean space $\mathbb{R}^3$ (position space) for the massive (spinless) boson field, resp. for the photon field with one direction of polarization, the one-particle test-function space E is a dense complex subspace of the Hilbert space of complex-valued square integrable functions $L^2(\mathbb{R}^3)$. In statistical physics for thermodynamical reasons E should consist of functions with compact support. So E usually is chosen as the complex vector space $\mathscr{D}(\mathbb{R}^3)$ of infinitely differentiable functions with compact support in $\mathbb{R}^3$, but it is also taken the subspace of those functions $f \in L^2(\mathbb{R}^3)$ which have compact support.[1–3] Unfortunately here E is not invariant with respect to the one-particle dynamics $\exp\{it(-\Delta)^{q/2}\}$, where $-\Delta \geqslant 0$ is the usual self-adjoint Laplacian on $L^2(\mathbb{R}^3)$, and $q = 1$ stands for the radiation field, whereas one has $q = 2$ for the boson field.

In other works the test-function space E is chosen to be invariant with respect to the one-particle dynamics.[4,5]

The time evolution of a quantum mechanical system can be described either in the Heisenberg or in the Schrödinger picture. For infinite C^*-algebraic systems, however, these pictures no longer are equivalent (cf. Refs. 12, 2, and references therein). The Schrödinger picture is the more general one, but the Heisenberg picture is easier to handle. Usually the Heisenberg time evolution is described by a time-continuous one-parameter group of automorphisms.

For the infinite boson resp. photon system there exists a group of Bogoliubov automorphisms on $\mathrm{CCR}(E)$ describing the free time evolution in the Heisenberg picture, if and only if the test-function space E is invariant with respect to the one-particle dynamics. However, in case of existence this automorphism group lacks any continuity in time.

The present investigation is devoted to a formulation of the global free dynamics for the massive boson field with the test-function space $E = \mathscr{D}(\mathbb{R}^3)$, which is not invariant with respect to

 © 1998 American Institute of Physics

the one-boson dynamics $\exp\{it(-\Delta)\}$. The dynamics is constructed in the Schrödinger picture not on the whole state space of CCR(E), but on suitable subsets thereof, more exactly on folia, which are large enough to contain the physically relevant states [e.g., thermodynamic equilibrium (limiting Gibbs) states for the Bose–Einstein condensation, classical states, coherent states, and also squeezed states]. Hereby we follow Roos' general global dynamical concept,[12] which in detail is outlined in Sec. II.

In the previous work [13] we studied the unique extension of certain classes of states (and representations) from CCR(E) to the enlarged CCR-algebra CCR($\mathscr{E}$) in the case where the original E is a proper subspace of the enlarged test-function space $\mathscr{E}$. Such extensions require a topology τ (stronger than or equal to the norm) so that E is τ-dense in $\mathscr{E}$. Here $\mathscr{E}:=\mathscr{S}(\mathbb{R}^3)$ is chosen as the Schwartz space, whereon the one-boson dynamics $\exp\{it(-\Delta)\}$ is τ-continuous for suitable topologies τ. Then the techniques from Ref. 13 apply to the construction of the free dynamics in terms of a group of affine bijections ν_t, $t\in\mathbb{R}$, on the folium $\mathscr{F}_\tau$ of the τ-continuous states on CCR(E) (Schrödinger picture).

The global free dynamics ν_t turns out to be time-continuous with respect to the expectations

$$\lim_{t\to 0}\langle \nu_t(\omega);A\rangle=\langle \omega;A\rangle \quad \forall A\in \mathrm{CCR}(E) \quad \forall \omega\in\mathscr{F}_\tau. \tag{1}$$

In the Heisenberg picture the free dynamics is given by a group of W^*-automorphisms α_t, $t\in\mathbb{R}$, on the weak closure of the represented CCR-algebra CCR(E), corresponding to the representation Π_τ of the folium $\mathscr{F}_\tau$. The group α_t does not leave the represented CCR-algebra invariant and does not define a W^*-dynamical system because of the absence of the W^*-continuity in time. A W^*-dynamical system, however, is only obtained when restricting the Schrödinger dynamics ν_t to an invariant subfolium $\mathscr{F}$ of $\mathscr{F}_\tau$ such that the time evolution $\mathbb{R}\ni t\mapsto\nu_t(\omega)$ is norm-continuous for every $\omega\in\mathscr{F}$—the covariance of the dynamical subdescription on $\mathscr{F}$—and then turning over to the Heisenberg subpicture.

Finally, we show that the folium $\mathscr{F}_\tau$ contains a continuum of disjoint subfolia, namely the squeezed vacuum sectors for bounded squeezing transformations. We completely determine those squeezed vacuum sectors which give rise to a covariant dynamical subdescription. The free dynamics acts noncovariant on the other ones, that is, for those states the evolution $\mathbb{R}\ni t\mapsto\nu_t(\omega)$ is not norm-continuous, but nevertheless satisfies the time-continuity of the evolving expectations of Eq. (1).

The presented results show that the global free folia dynamics in a certain sense is independent from the specific chosen test-function space E. They also outline how the global free dynamics may be formulated for other bosonic systems, especially for the photon field.

II. FOLIA, REPRESENTATIONS, AND GLOBAL DYNAMICS

Let $\mathscr{A}$ be the C^*-algebra describing a physical system. $\mathscr{S}(\mathscr{A})$ denotes the state space of $\mathscr{A}$, and for the state $\omega\in\mathscr{S}(\mathscr{A})$ the expectation at the observable $A\in\mathscr{A}$ is written as $\langle\omega;A\rangle$.

A. Folia and representations

A folium $\mathscr{F}$ of $\mathscr{A}$ is a norm-closed, convex subset of the state space $\mathscr{S}(\mathscr{A})$, which is invariant under ''perturbations,'' that is, $\omega\in\mathscr{F}$ implies $\omega_B\in\mathscr{F}$ for all $B\in\mathscr{A}$ with $\langle\omega;B^*B\rangle\neq 0$, where ω_B is the state on $\mathscr{A}$ given by $\langle\omega_B;.\rangle=\langle\omega;B^*.B\rangle\langle\omega;B^*B\rangle^{-1}$. $V\subseteq\mathscr{S}(\mathscr{A})$ is called a generating set of states for the folium $\mathscr{F}$, if $\mathscr{F}$ is the smallest folium of $\mathscr{A}$ containing all the states $\omega\in V$. Obviously, if $V\subseteq\mathscr{F}_1$ for the folium $\mathscr{F}_1$, then $\mathscr{F}\subseteq\mathscr{F}_1$.

There is a one-to-one correspondence between the folia of $\mathscr{A}$ and the (quasiequivalence classes of) representations of $\mathscr{A}$, which preserves the partial orderings, respectively; that is, if $\Pi_\mathscr{F}$ is the representation of $\mathscr{A}$ uniquely corresponding to the folium $\mathscr{F}$, then

$$\mathscr{F}_1\subseteq\mathscr{F}_2\subseteq\mathscr{S}(\mathscr{A})\Leftrightarrow\Pi_{\mathscr{F}_1}\leqslant\Pi_{\mathscr{F}_2}\leqslant\Pi_u,$$

where Π_u is the universal representation of $\mathscr{A}$. The folium $\mathscr{F}$ consists just of the $\Pi_\mathscr{F}$-normal states, that is, $\mathscr{M}_\mathscr{F}:=\overline{\Pi_\mathscr{F}(\mathscr{A})}^w=LH(\mathscr{F})^*$, where $\mathscr{N}^w$ is the weak closure of $\mathscr{N}$. The representation $\Pi_\mathscr{F}$ is quasiequivalent to the direct sum of the GNS representations Π_ω of all the states ω

in $\mathscr{F}$, resp. in a generating set V, $\Pi_{\mathscr{F}}=\oplus_{\omega\in\mathscr{F}}\Pi_\omega=\oplus_{\omega\in V}\Pi_\omega$. Especially, the GNS folium $\mathscr{F}_\omega$, that is the smallest folium containing $\omega\in\mathscr{S}(\mathscr{A})$, corresponds to the GNS representation Π_ω, i.e., Π_ω is quasiequivalent to $\Pi_{\mathscr{F}_\omega}$.

A folium constitutes a face in the state space of $\mathscr{A}$. Every folium $\mathscr{F}$ expresses a certain range of classical, macroscopic aspects of the physical system described by $\mathscr{A}$. These one also may refind in the center of the W^*-algebra $\mathscr{M}_{\mathscr{F}}$. Thus, dealing with a subfolium instead of $\mathscr{F}$ itself, means a restriction of the considered collective, macroscopic structure of the physical system. Disjoint folia belong to macroscopically totally different aspects and thus define two different superselection sectors, then

$$\|\omega_1-\omega_2\|=2\ \forall\,\omega_1\in\mathscr{F}_1\forall\,\omega_2\in\mathscr{F}_2,\quad\text{where}\quad\mathscr{F}_1\cap\mathscr{F}_2=\emptyset. \tag{2}$$

For more details to the present subsection we refer to Ref. 14, Sec. 1 and Ref. 15. A physical interpretation of the basic concepts of properties resp. filters, classical properties (that are split-faces resp. folia), disjointness (i.e., nonoverlapping classical properties) in the convex state space approach may be found in Ref. 16 for the Josephson junction and the SQUID.

B. Global Schrödinger dynamics on folia

1. Roos' dynamical concept

In the Schrödinger picture Roos[12] introduced the dynamical description of our physical system not on the whole state space, but on a folium $\mathscr{F}$ of $\mathscr{A}$.

Definition 1 (dynamical description): *Let the time evolution of the states in the folium $\mathscr{F}$ of $\mathscr{A}$ be given in terms of a one-parameter group of affine bijections $\nu_t:\mathscr{F}\to\mathscr{F}$, $t\in\mathbb{R}$, which obeys the time-continuity of the expectations*

$$\lim_{t\to 0}\langle\nu_t(\omega);A\rangle=\langle\omega;A\rangle\quad\forall A\in\mathscr{A} \tag{3}$$

for every state $\omega\in\mathscr{F}$ (group property: ν_0 is the identity, and $\nu_s\circ\nu_t=\nu_{s+t}\forall s,t\in\mathbb{R}$). Then the triple $(\mathscr{A},\mathscr{F},\nu_t)$ is denoted a dynamical description of our physical system.

In our notation we do not distinguish between $\omega\in\mathscr{F}$ as a state on $\mathscr{A}$ and its unique normal extension to $\mathscr{M}_{\mathscr{F}}$. By the duality

$$\langle\nu_t(\omega);A\rangle=\langle\omega;\alpha_t(A)\rangle\quad\forall\,\omega\in\mathscr{F}\ \forall A\in\mathscr{M}_{\mathscr{F}} \tag{4}$$

[observe that the linear hull LH($\mathscr{F}$) is the predual of $\mathscr{M}_{\mathscr{F}}$ by Sec. II A], there exists for each $t\in\mathbb{R}$ a unique Jordan automorphism α_t on $\mathscr{M}_{\mathscr{F}}$ (Ref. 2, Theorem 3.2.8). In applications, however, the group α_t actually consists of automorphisms (which is assumed in the sequel) describing the dynamics in the Heisenberg picture on the W^*-algebra $\mathscr{M}_{\mathscr{F}}$.[18] In general, however, α_t may not leave the represented C^*-algebra $\Pi_{\mathscr{F}}(\mathscr{A})$ invariant.

Roos' dynamical concept is a generalization of Kadison's original definition of a dynamical system,[17] and it is also more general than the concepts of C^*-, resp. W^*-dynamical systems given, e.g., in Ref. 2, Definition 2.7.1. $(\mathscr{M}_{\mathscr{F}},\alpha_t)$ defines a W^*-dynamical system, if and only if (3) is valid for each $A\in\mathscr{M}_{\mathscr{F}}$ (and not only for $A\in\mathscr{A}$), which is equivalent to the norm-continuity $\lim_{t\to 0}\|\nu_t(\omega)-\omega\|=0$ for all $\omega\in\mathscr{F}$. The C^*-dynamical system $(\mathscr{A},\alpha_t)$ is obtained, if and only if the folium $\mathscr{F}$ in Definition 1 is the whole state space $\mathscr{S}(\mathscr{A})$. (See Refs. 12 and 14 for more details.)

2. Covariant dynamical (sub-) descriptions and W^*-dynamical systems

The subfolium $\mathscr{F}_0\subseteq\mathscr{F}$ implies the existence of a unique orthogonal projection $c_{\mathscr{F}_0}$ in the center of $\mathscr{M}_{\mathscr{F}}$, so that $\Pi_{\mathscr{F}_0}(A)=c_{\mathscr{F}_0}\Pi_{\mathscr{F}}(A)\forall A\in\mathscr{A}$, and thus $\mathscr{M}_{\mathscr{F}_0}=c_{\mathscr{F}_0}\mathscr{M}_{\mathscr{F}}$ for the associated W^*-algebras. It holds: $\mathscr{F}_0$ is ν_t-invariant [that is $\nu_t(\mathscr{F}_0)\subseteq\mathscr{F}_0\forall t\in\mathbb{R}$], if and only if $c_{\mathscr{F}_0}$ resp. $\mathscr{M}_{\mathscr{F}_0}$ are α_t-invariant [that is $\alpha_t(c_{\mathscr{F}_0})=c_{\mathscr{F}_0}\forall t\in\mathbb{R}$]. In this case, ν_t restricted to $\mathscr{F}_0$, resp. α_t restricted to $\mathscr{M}_{\mathscr{F}_0}$, determines a dynamical subdescription of our physical system. Furthermore, for the dynamical subdescription $(\mathscr{A},\mathscr{F}_0,\nu_t)$ we have the following equivalences:

(i) The restricted Heisenberg dynamics α_t defines a W^*-dynamical system on $\mathscr{M}_{\mathscr{F}_0}$;

(ii) The more stringent time-continuity $\lim_{t\to 0}\|\nu_t(\omega)-\omega\|=0 \forall \omega\in\mathscr{F}_0$ is fulfilled;

(iii) There exists a normal representation of the W^*-algebra $\mathscr{M}_{\mathscr{F}_0}$ on some Hilbert space $\mathscr{H}_{\mathscr{F}_0}$ such that the restricted Heisenberg dynamics α_t is implementable by a strongly continuous unitary group e^{itH} acting on $\mathscr{H}_{\mathscr{F}_0}$, i.e., $\alpha_t(A)=e^{itH}Ae^{-itH}\forall A\in\mathscr{M}_{\mathscr{F}_0}$.

(The proof uses duality arguments and standard representations of W^*-algebras.[19]) Let us remark, that in general the selfadjoint Hamiltonian H in (iii) is not affiliated with $\mathscr{M}_{\mathscr{F}_0}$.

Definition 2 (covariant dynamical description): If the equivalent conditions (i)–(iii) are fulfilled, then the dynamical (sub-) description $(\mathscr{A},\mathscr{F}_0,\nu_t)$ *is called* covariant.

Suppose $\omega\in\mathscr{F}$ is a ν_t-invariant state [i.e., $\nu_t(\omega)=\omega\forall t\in\mathbb{R}$], then the GNS folium $\mathscr{F}_\omega\subseteq\mathscr{F}$ is ν_t-invariant, and thus constitutes a dynamical subdescription. Because of the uniqueness of the GNS representation $(\Pi_\omega,\mathscr{H}_\omega,\Omega_\omega)$ up to unitary equivalence, there exists a group of unitary operators U_t on $\mathscr{H}_\omega$ with $\alpha_t(A)=U_tAU_t^*\forall A\in\mathscr{M}_{\mathscr{F}_\omega}$ and $U_t\Omega_\omega=\Omega_\omega$ for each $t\in\mathbb{R}$. Equation (3) implies the strong continuity of $t\mapsto U_t$, which yields the dynamical subdescription $(\mathscr{A},\mathscr{F}_\omega,\nu_t)$ to be covariant.

III. GLOBAL QUASIFREE DYNAMICS ON THE CCR-ALGEBRA

A. Enlarged test-function space for the CCR

The one-boson test-function space is chosen as the symplectic space (E,σ), that is, E is a real vector space and $\sigma: E\times E\to\mathbb{R}$ is a (real-) bilinear mapping on E satisfying $\sigma(f,g)=-\sigma(g,f)\forall f,g\in E$. The symplectic form σ is denoted nondegenerate, if $\sigma(f,g)=0\forall g\in E$ implies $f=0$. But here σ also may be degenerate.

The associated bosonic C^*-algebra is the Weyl resp. CCR-algebra $\mathscr{W}(E,\sigma)$ over (E,σ), which is generated (with the minimal regular norm) by the unitary Weyl operators $W(f)$, $f\in E$, satisfying the Weyl relations

$$W(f)W(g)=\exp\left\{-\frac{i}{2}\,\sigma(f,g)\right\}W(f+g),\quad W(f)^*=W(-f),\quad \forall f,g\in E. \tag{5}$$

$\mathscr{W}(E,\sigma)$ is simple, if and only if σ is nondegenerate.[20,2] The state space of $\mathscr{W}(E,\sigma)$ is denoted by $\mathscr{S}(E,\sigma)$. For more details, proofs and references to the present Subsection we refer to Refs. 13,14.

1. The folium of τ-continuous states

Let τ be a vector space topology on E, such that σ is *separately* τ-continuous [i.e., $E\ni g\mapsto\sigma(f,g)=-\sigma(g,f)$ is τ-continuous for every $f\in E$]. Then the set of all τ-continuous states,

$$\mathscr{F}_\tau(E,\sigma):=\{\omega\in\mathscr{S}(E,\sigma)\,|\,E\ni f\mapsto\langle\omega;W(f)\rangle \text{ is } \tau\text{-continuous}\}, \tag{6}$$

defines a folium of the CCR-algebra $\mathscr{W}(E,\sigma)$.[13,14]

Moreover, the representation Π_τ of $\mathscr{W}(E,\sigma)$, which uniquely associates to the folium $\mathscr{F}_\tau(E,\sigma)$ by Sec. II A, is τ-continuous (and thus each subrepresentation $\Pi\leqslant\Pi_\tau$), i.e., $E\ni f\mapsto\Pi_\tau(W(f))$ is continuous with respect to τ on E and the strong operator topology on the W^*-algebra $\mathscr{M}_\tau:=\Pi_\tau(\mathscr{W}(E,\sigma))^w$.

2. Enlarged one-boson test-function spaces

An *enlarged* one-boson test-function space is a symplectic space $(\mathscr{E},\sigma)$, so that E is a subspace of $\mathscr{E}$ and the restriction of σ to E gives our genuine one-boson test-function space (E,σ). Then $\{W(f)|f\in E\}$ generates a C^*-subalgebra of $\mathscr{W}(\mathscr{E},\sigma)$, which agrees with the Weyl algebra $\mathscr{W}(E,\sigma)$, that is, we have the implication

$$(E,\sigma)\subseteq(\mathscr{E},\sigma)\Rightarrow\mathscr{W}(E,\sigma)\subseteq\mathscr{W}(\mathscr{E},\sigma).$$

It holds $\mathcal{W}(E,\sigma)=\mathcal{W}(\mathcal{E},\sigma)$, if and only if $E=\mathcal{E}$.[20,2] Thus, if E is a proper subspace of $\mathcal{E}$, then $\mathcal{W}(E,\sigma)$ is a proper C^*-subalgebra of $\mathcal{W}(\mathcal{E},\sigma)$.

3. Unique extension of τ-continuous states

Let us here suppose the enlarged test-function space $(\mathcal{E},\sigma)$ to be equipped with a vector space topology τ such that

(a) E is a *proper but τ-dense* subspace of $\mathcal{E}$, and
(b) σ is *jointly* τ-continuous [i.e., $\sigma:\mathcal{E}\times\mathcal{E}\to\mathbb{R}$ is continuous with respect to the product τ-topology on $\mathcal{E}\times\mathcal{E}$, which is equivalent to $\sigma(f_\alpha,g_\alpha)\to\sigma(f,g)$ for two arbitrary converging nets $f_\alpha\to f\in\mathcal{E}$ and $g_\alpha\to g\in\mathcal{E}$].

The original test-function space E is supposed to be equipped with the relative τ-topology. From Ref. 13 the following result is known.

Theorem 3 (τ-continuous extension of states): *Let all be as above. Then each state $\omega\in\mathcal{F}_\tau(E,\sigma)$ extends uniquely to a state $\tilde{\omega}\in\mathcal{F}_\tau(\mathcal{E},\sigma)$, that is, ω is the restriction of $\tilde{\omega}$ from $\mathcal{W}(\mathcal{E},\sigma)$ to the C^*-subalgebra $\mathcal{W}(E,\sigma)$, $\omega=\tilde{\omega}|_{\mathcal{W}(E,\sigma)}$.*

In this sense the folia $\mathcal{F}_\tau(E,\sigma)$ resp. $\mathcal{F}_\tau(\mathcal{E},\sigma)$ of the two CCR-algebras $\mathcal{W}(E,\sigma)\subset\mathcal{W}(\mathcal{E},\sigma)$ coincide,

$$\mathcal{F}_\tau\equiv\mathcal{F}_\tau(E,\sigma)\cong\mathcal{F}_\tau(\mathcal{E},\sigma). \tag{7}$$

As a consequence, the representation Π_τ (and thus each subrepresentation $\Pi\leqslant\Pi_\tau$) extends τ-continuously from $\mathcal{W}(E,\sigma)$ to $\mathcal{W}(\mathcal{E},\sigma)$, where

$$\mathcal{M}_\tau=\overline{\Pi_\tau(\mathcal{W}(E,\sigma))}^{w}=\overline{\Pi_\tau(\mathcal{W}(\mathcal{E},\sigma))}^{w}. \tag{8}$$

Example 4 (jointly continuous symplectic form): In physical applications (cf. e.g. Refs. 1–10, and Sec. IV below) the test-function space E in general is a complex pre-Hilbert space, and $\sigma(.,.)=\mathrm{Im}\langle .|.\rangle$ is defined to be the imaginary part of the complex scalar product $\langle\cdot|\cdot\rangle$, but on E, only. Let $\mathcal{E}\supset E$ be an enlarged real vector space equipped with a vector space topology τ, which is stronger than (or equal to) the norm $\|\cdot\|$ on E and for which E is τ-dense in $\mathcal{E}$. Then σ is jointly continuous with respect to the relative τ-topology on E (since σ is jointly $\|\cdot\|$-continuous), and has a unique jointly τ-continuous extension to a symplectic form on $\mathcal{E}$. Whereas σ on E is nondegenerate, its extension to $\mathcal{E}$ may lose this property (for examples, see Proposition 9 below).

B. The formulation of the global quasifree dynamics

1. Bogoliubov transformations for noninvariant test-function space

In statistical physics, and in quantum optics, resp. in nonrelativistic QED, one often is confrontated with the following situation:[13]

(a) The boson (resp. photon) system is determined in terms of a test-function space (E,σ).
(b) There exists an enlarged test-function space $(\mathcal{E},\sigma)\supset(E,\sigma)$, such that E is a proper subspace of $\mathcal{E}$.
(c) On the enlarged test-function space $(\mathcal{E},\sigma)$ there is given a symplectic transformation T, that is, T is a (real-) linear bijection $T:\mathcal{E}\to\mathcal{E}$ fulfilling the symplectic property

$$\sigma(Tf,Tg)=\sigma(f,g)\quad\forall f,g\in\mathcal{E}. \tag{9}$$

The Bogoliubov automorphism β_T on the extended Weyl algebra $\mathcal{W}(\mathcal{E},\sigma)$, which is associated with the symplectic T, is given in the Heisenberg picture by $\beta_T(W(f))=W(Tf)\forall f\in\mathcal{E}$ (cf. the Ref. 20 and 2). β_T lifts in the Schrödinger picture to the affine bijection ν_T on the state space $\mathcal{S}(\mathcal{E},\sigma)$ satisfying

$$\langle\nu_T(\omega);W(f)\rangle=\langle\omega;W(Tf)\rangle=\langle\omega;\beta_T(W(f))\rangle,\quad\forall\omega\in\mathcal{S}(\mathcal{E},\sigma)\forall f\in\mathcal{E}. \tag{10}$$

The inverse T^{-1} is a symplectic transformation on $(\mathcal{E},\sigma)$, too. Thus $(\nu_T)^{-1}=\nu_{T^{-1}}$.

However, the physically relevant one-particle test-function space is (E,σ) and not $(\mathscr{E},\sigma)$, which implies $\mathscr{W}(E,\sigma)$ to be the correct C^*-algebra describing our boson system and not $\mathscr{W}(\mathscr{E},\sigma)$. Hence it is necessary to transfer the Bogoliubov transformation ν_T (resp. β_T) from the enlarged $(\mathscr{E},\sigma)$ to the original test-function space (E,σ). Two cases have to be distinguished.

(1) Let us first assume the rare case $T(E)=E$. Then the automorphism β_T leaves the C^*-subalgebra $\mathscr{W}(E,\sigma)\subset\mathscr{W}(\mathscr{E},\sigma)$ invariant. Thus restricting β_T and the states $\nu_T(\omega)\in\mathscr{S}(\mathscr{E},\sigma)$ and $\omega\in\mathscr{S}(\mathscr{E},\sigma)$ in (10) to $\mathscr{W}(E,\sigma)$ gives the Bogoliubov transformation ν_T and β_T as a dual pair on $\mathscr{S}(E,\sigma)$ resp. $\mathscr{W}(E,\sigma)$.
(2) Unfortunately, in general the relevant one-particle test-function space E is not T-invariant [i.e., $T(f)\notin E$ for some $f\in E$], which implies that β_T does not leave the genuine CCR-algebra $\mathscr{W}(E,\sigma)$ invariant, that is, $\beta_T(A)\notin\mathscr{W}(E,\sigma)$ for some $A\in\mathscr{W}(E,\sigma)$. Thus by (10) it is not possible to transfer the Bogoliubov bijection ν_T resp. β_T uniquely from $(\mathscr{E},\sigma)$ to the original (E,σ). However, if E, $\mathscr{E}$, and T are connected with a suitable topology τ, then such a transfer can be carried through. The following result is valid for both cases.

Theorem 5: *On the enlarged test-function space $(\mathscr{E},\sigma)\supseteq(E,\sigma)$ let be given the symplectic transformation T. Suppose a vector space topology τ on the enlarged $\mathscr{E}$ such that*

(a) *E is τ-dense in $\mathscr{E}$ and σ is jointly τ-continuous.*
(b) *T and T^{-1} are τ-continuous, i.e., T is a τ-homeomorphism.*

Then it follows $\nu_T(\mathscr{F}_\tau)=\mathscr{F}_\tau$ for the folium $\mathscr{F}_\tau$ of τ-continuous states on the extended CCR-algebra $\mathscr{W}(\mathscr{E},\sigma)$.

But by Sec. III A 3, especially Eq. (7), $\mathscr{F}_\tau$ also is a folium on the genuine physically relevant CCR-algebra $\mathscr{W}(E,\sigma)$. Hence, in the restriction of ν_T to $\mathscr{F}_\tau$ we have found the Bogoliubov transformation associated with the symplectic T for our boson system with test-function space (E,σ) (Schrödinger picture).

Proof: Applying (10) to T and T^{-1} we obtain the relations $\langle\nu_T(\omega);\,W(f)\rangle=\langle\omega;W(Tf)\rangle$ and $\langle\nu_{T^{-1}}(\omega);W(f)\rangle=\langle\omega;W(T^{-1}f)\rangle$ for all $f\in\mathscr{E}$. Since by assumption T and T^{-1} are τ-continuous, these relations and the definition of $\mathscr{F}_\tau$ imply $\nu_T(\omega)\in\mathscr{F}_\tau$ and $\nu_{T^{-1}}(\omega)\in\mathscr{F}_\tau$ for every $\omega\in\mathscr{F}_\tau$. Thus $\nu_T(\mathscr{F}_\tau)\subseteq\mathscr{F}_\tau$ and $\nu_{T^{-1}}(\mathscr{F}_\tau)\subseteq\mathscr{F}_\tau$. Now $(\nu_T)^{-1}=\nu_{T^{-1}}$ gives the result. ■

In both cases the Heisenberg picture may be formulated on the W^*-algebra $\mathscr{M}_\tau$ from Eq. (8), but only in the case (a) it exists on the genuine C^*-algebra $\mathscr{W}(E,\sigma)$. By the duality $\langle\nu_T(\omega);B\rangle=\langle\omega;\alpha_T(B)\rangle,\omega\in\mathscr{F}_\tau,B\in\mathscr{M}_\tau$ [cf. Eq. (4)], we obtain the automorphism α_T on $\mathscr{M}_\tau$, which satisfies $\alpha_T(\Pi_\tau(A))=\Pi_\tau(\beta_T(A))\forall A\in\mathscr{W}(\mathscr{E},\sigma)$. Thus α_T extends the Bogoliubov transformation β_T normally in the representation Π_τ from $\mathscr{W}(\mathscr{E},\sigma)$ to $\mathscr{M}_\tau$.

Lemma 6 (joint continuity and symplectic τ-homeomorphism): Let $\mathscr{E}$ with τ constitute a Fréchet space (τ is a metrizable locally convex topology, and $\mathscr{E}$ is τ-complete). Furthermore, suppose σ to be a separately τ-continuous symplectic form on $\mathscr{E}$. Then it follows:

(a) *σ is jointly τ-continuous.*
(b) *In addition let σ be nondegenerate. Then each symplectic transformation T on $(\mathscr{E},\sigma)$ (and thus its inverse T^{-1}) is τ-continuous.*

Proof: Part (a) is a consequence of the principle of uniform boundedness (see Ref. 21, Sec. V.2). For proving part (b) we show that the graph $G(T)=\{(f,Tf)\,|\,f\in\mathscr{E}\}$ of T is a closed linear subspace of the Cartesian product Fréchet space $\mathscr{E}\times\mathscr{E}$ (product topology). Then the result follows from the closed graph theorem. Let $(f,g)\in G(T)$, that is, there is a sequence $f_n\in\mathscr{E}$, $n\in\mathbb{N}$, with $f_n\to f$ such that $Tf_n\to g$ converges, too. From $\sigma(Th_1,h_2)=\sigma(h_1,T^{-1}h_2)\forall h_j\in\mathscr{E}$, which follows from (9), and the τ-continuity of our symplectic form σ it follows

$$\sigma(g,h)=\lim_{n\to\infty}\sigma(Tf_n,h)=\lim_{n\to\infty}\sigma(f_n,T^{-1}h)=\sigma(f,T^{-1}h)=\sigma(Tf,h),\quad\forall h\in\mathscr{E}.$$

The nondegeneracy of σ gives $g=Tf$, that is $(f,g)=(f,Tf)\in G(T)$. Thus $G(T)$ is closed. ■

2. The global quasifree dynamics for noninvariant test-function space

The above concept of Bogoliubov transformations for noninvariant test-function space E especially applies to one-particle dynamics defined on enlarged test-function spaces. We consider the following situation:

(a) The boson (resp. photon) system is determined in terms of a test-function space (E,σ).
(b) On an enlarged test-function space $(\mathscr{E},\sigma)\supseteq(E,\sigma)$ there is given the one-boson dynamics, that is a group of symplectic transformations $v_t, t\in\mathbb{R}$, on $(\mathscr{E},\sigma)$ (v_0 is the identity on $\mathscr{E}$, and $v_s\circ v_t=v_{s+t}$ for all times $s,t\in\mathbb{R}$).

Let us remark here, that physicists are interested in a Schrödinger dynamics for physically relevant states, only, and not necessarily for the whole state space. A dynamics in addition should obey some continuity in time, at least for the expectations as in Eq. (3). For nontrivial one-particle dynamics such a time-continuity is not given by the (above) group of Bogoliubov transformations $\nu_t:=v_{v_t}$ on $\mathscr{S}(\mathscr{E},\sigma)$ (Schrödinger picture), resp. $\beta_t:=\beta_{v_t}$ on $\mathscr{W}(\mathscr{E},\sigma)$ (Heisenberg picture), since $\|W(f)-W(g)\|=2\forall f\neq g$. As in Theorem 5 let us connect E, $\mathscr{E}$, and ν_t with a suitable topology τ.

Theorem 7 (global quasifree dynamics): *Let all be as above, and suppose a vector space topology τ on the enlarged $\mathscr{E}$ such that*

(a) *E is τ-dense in $\mathscr{E}$ and σ is jointly τ-continuous.*
(b) *$\mathscr{E}\ni f\mapsto v_t f\in\mathscr{E}$ is τ-continuous for each $t\in\mathbb{R}$. [Since $\nu_{-t}=(\nu_t)^{-1}\forall t\in\mathbb{R}$ by the group property, it follows that each ν_t is a τ-homeomorphism.]*
(c) *$\mathbb{R}\ni t\mapsto v_t f\in\mathscr{E}$ is τ-continuous for each $f\in\mathscr{E}$.*

Then it holds $\nu_t(\mathscr{T}_\tau)=\mathscr{T}_\tau\forall t\in\mathbb{R}$, and the evolving expectations $\mathbb{R}\ni t\mapsto\langle\nu_t(\omega);A\rangle$ are continuous for all $\omega\in\mathscr{T}_\tau$ and all $A\in\mathscr{W}(\mathscr{E},\sigma)\supset\mathscr{W}(E,\sigma)$.

Since $\mathscr{T}_\tau$ is also a folium on the genuine CCR-algebra $\mathscr{W}(E,\sigma)$, we arrive at the dynamical description $(\mathscr{W}(E,\sigma),\mathscr{T}_\tau,\nu_t)$, which defines the time-continous quasifree Schrödinger dynamics for our boson system with test-function space (E,σ) and one-boson dynamics ν_t on the enlarged $(\mathscr{E},\sigma)$.

Proof: $\nu_t(\mathscr{T}_\tau)=\mathscr{T}_\tau$ follows from Theorem 5. (10) implies $\langle\nu_t(\omega);W(f)\rangle=\langle\omega;W(v_t f)\rangle$. The τ-continuity of $t\mapsto v_t f$ for $f\in\mathscr{E}$ yields the continuity of the expectations $t\mapsto\langle\nu_t(\omega);W(f)\rangle=\langle\omega;W(v_t f)\rangle$ for all $\omega\in\mathscr{T}_\tau$ and $f\in\mathscr{E}$. With an $\epsilon/3$-argument one obtains the continuity of an arbitrary evolving expectation $t\mapsto\langle\nu_t(\omega);A\rangle$ with $\omega\in\mathscr{T}_\tau$ and $A\in\mathscr{W}(\mathscr{E},\sigma)\supset\mathscr{W}(E,\sigma)$. ■

The quasifree dynamics ν_t is an example of Roos' dynamical concept outlined in Sec. II B 1, especially Definition 1, and it generalizes the idea in Ref. 12, Appendix B. However, in general $(\mathscr{W}(E,\sigma),\mathscr{T}_\tau,v_t)$ is not covariant, which is shown in Sec. IV H 4 below.

The present formulation of a quasifree dynamics already has been used in our recent works[14,22] on the global dynamics for a class of interactions between the boson gas and an infinite mean field quantum lattice system. Applications are found in the Dicke model[6] and in the Josephson oscillator model,[7] where the radiation field couples weakly to infinitely many two-level atoms resp. to two superconductors. There the one-boson resp. one-photon dynamics on complete enlarged test-function spaces plays an important role for the interacting dynamics and for the emitted radiation, which is quantum optically coherent and which reflects the classical, collective ordering of the atoms resp. superconductors.

IV. THE GLOBAL FREE DYNAMICS FOR THE BOSON FIELD

Let us make some notational remarks. Throughout the present section the one-boson test-function space is a complex vector space. On the one-particle level, with the expressions linear and antilinear we always mean complex-linear resp. complex-antilinear mappings, and in the notations operator and unitary we include complex-linearity. (Complex) scalar products always are chosen to be (complex-) linear in the right factor. Real-linear one-particle objects (operators resp. scalar products) always are denoted so.

A. The one-boson test-function space

Let us from now on consider massive spinless bosons in the euclidean space $\mathbb{R}^p$, where $p \in \mathbb{N}$. In statistical physics for thermodynamical reasons one usually takes the complex vector space $\mathscr{D}(\mathbb{R}^p)$ of infinitely differentiable functions with compact support in $\mathbb{R}^p$ (position space) for the test-function space E. The symplectic form σ on E is chosen as the imaginary part of the usual scalar product $\langle f|g\rangle = \int_{\mathbb{R}^p} f g\, d^p x$. This ensures the quasilocal structure, which decomposes the bosonic Weyl algebra $\mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|.\rangle)$ into the local C^*-algebras $\mathscr{W}(\mathscr{D}(\Lambda), \mathrm{Im}\langle .|.\rangle)$ for certain open bounded regions $\Lambda \subset \mathbb{R}^p$. Thus, defining the local Gibbs states on the local algebras one may perform the thermodynamic limit $\Lambda \to \mathbb{R}^p$, e.g., for obtaining Bose–Einstein condensation.[1,2]

B. The one-boson dynamics on the enlarged symplectic space

The one-boson dynamics $v_t = \exp\{-it\Delta\}$ is obtained as the thermodynamic limit of the local one-boson time translations. Here the one-boson Hamiltonian $-\Delta \geqslant 0$ is the usual selfadjoint Laplacian on the complex Hilbert space $L^2(\mathbb{R}^p)$ of square integrable functions with respect to the Lebesgue measure $d^p x$, Ref. 21, Sec. IX 7.

It is well known that for $0 \neq f \in \mathscr{D}(\mathbb{R}^p)$ the evolved $v_t(f)$ no longer has compact support, i.e., $v_t(f) \notin \mathscr{D}(\mathbb{R}^p)$ for $t \neq 0$ [this may be shown by use of Fourier transformation, and analyticity arguments, and the Paley–Wiener theorem (Ref. 21, Theorem IX.11)]. Since the unitaries v_t are symplectic on $(L^2(\mathbb{R}^p), \mathrm{Im}\langle .|.\rangle)$, we are in the situation of Sec. III B 2. We need an enlarged test-function space $(\mathscr{E}, \mathrm{Im}\langle .|.\rangle)$ with a complex, v_t-invariant space $\mathscr{D}(\mathbb{R}^p) \subset \mathscr{E} \subseteq L^2(\mathbb{R}^p)$, which is connected with $\mathscr{D}(\mathbb{R}^p)$ by a suitable topology τ on $\mathscr{E}$. A suitable choice is the Schwartz space $\mathscr{S}(\mathbb{R}^p)$, the complex-valued functions of rapid decrease on $\mathbb{R}^p$, which is v_t-invariant. Thus, for our enlarged test-function space $(\mathscr{E}, \sigma)$ let us take here $(\mathscr{S}(\mathbb{R}^p) \mathrm{Im}\langle .|.\rangle)$. Summarizing we have the following situation:

(a) Our boson system is determined by the test-function space $(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|.\rangle)$.
(b) On the enlarged test-function space $(\mathscr{S}\,\mathbb{R}^p), \mathrm{Im}\langle .|.\rangle)$ there is given the one-boson dynamics in terms of the group of symplectic transformations $v_t = \exp\{-it\Delta\}$, $t \in \mathbb{R}$.

C. Topologies on the enlarged symplectic space

The natural Fréchet topology on $\mathscr{S}(\mathbb{R}^p)$ is denoted by τ_{Fr}. The original test-function space $\mathscr{D}(\mathbb{R}^p)$ is τ_{Fr}-dense in $\mathscr{S}(\mathbb{R}^p)$.

As usual the τ_{Fr}-dual is denoted by $\mathscr{S}'(\mathbb{R}^p)$, the space of the tempered distributions (Ref. 21, Sec. V.3). Let $\mathscr{S}'_m(\mathbb{R}^p)$ be the set of those positive measures μ on $\mathbb{R}^p$, for which $\mathscr{S}(\mathbb{R}^p) \ni f \to \int_{\mathbb{R}^p} f\, d\mu$ is τ_{Fr}-continuous, a tempered distribution, in which sense $\mathscr{S}'_m(\mathbb{R}^p)$ is a subspace of $\mathscr{S}'(\mathbb{R}^p)$. Using the Fourier transformation $f \mapsto \hat{f}$ we construct for each $\mu \in \mathscr{S}'_m(\mathbb{R}^p)$ the new scalar product

$$\langle f|g\rangle_\mu := \langle f|g\rangle + \int_{\mathbb{R}^p} \overline{\hat{f}(k)}\,\hat{g}(k)\, d\mu(k), \quad f,g \in \mathscr{S}(\mathbb{R}^p).$$

Obviously, $\mu = 0$ gives $\langle .|.\rangle_0 = \langle .|.\rangle$, the usual scalar product.

Proposition 8: For each $\mu \in \mathscr{S}'_m(\mathbb{R}^p)$ we have the following orderings:

$$\|.\| \leqslant \|.\|_\mu < \tau_{\mathrm{Fr}}, \quad \mathscr{T}_{\|.\|} \subseteq \mathscr{T}_{\|.\|_\mu} \subset \mathscr{T}_{\mathrm{Fr}}$$

for the topologies $\|.\|$, and $\|.\|_\mu$, and τ_{Fr}, resp. for the associated folia of continuous states. The last inclusion is proper. It is $\mathscr{T}_{\|.\|} \neq \mathscr{T}_{\|.\|_\mu}$, if and only if the norm-topology $\|.\|_\mu$ is strictly stronger than the usual norm $\|.\|$.

Proof: First recall that the multiplication $(f,g) \to fg$ of functions on $\mathscr{S}(\mathbb{R}^p)$ is jointly τ_{Fr}-continuous, and that the Lebesgue measure $d^p k$ is an element of $\mathscr{S}'_m(\mathbb{R}^p)$. Thus $\|.\|_\mu$ is strictly weaker than τ_{Fr}. The implication for the folia of continuous states immediately follows from the ordering of the topologies and the definition (6). Let us prove that $\mathscr{T}_{\|.\|_\mu} \neq \mathscr{T}_{\mathrm{Fr}}$. For each complex-linear form $L: \mathscr{S}(\mathbb{R}^p) \to \mathbb{C}$ consider the fully coherent state ω_L defined in terms of the characteristic

function $\langle \omega_L ; W(f)\rangle = \exp\{-\frac{1}{4}\| f \|^2 + i\sqrt{2}\,\mathrm{Re}(L(f))\}$.[8] Since there exists a linear form L, which is τ_{Fr}-continuous, but not $\|.\|_\mu$-continuous, it follows that $\omega_L \in \mathscr{F}_{\mathrm{Fr}}$ but $\omega_L \notin \mathscr{F}_{\|.\|_\mu}$. ■

D. The global free boson dynamics in the Schrödinger picture

Since in momentum space (Fourier transformation) the operator $v_t = \exp\{it(-\Delta)\}$ is the multiplication with the function $\mathbb{R}^p \ni k \to \exp\{it\|k\|^2\}$, it is easily seen that the one-boson dynamics v_t on $\mathscr{S}(\mathbb{R}^p)$ is continuous with respect to every topology $\|.\|_\mu$, $\mu \in \mathscr{S}'_m(\mathbb{R}^p)$, and the Fréchet topology τ_{Fr}, that is, $f \to v_t f$ is continuous for each $t \in \mathbb{R}$ and $t \to v_t f$ is continuous for each $f \in \mathscr{S}(\mathbb{R}^p)$. The joint continuity of the symplectic form $\mathrm{Im}\langle .|. \rangle$ with respect to $\|.\|_\mu$ resp. τ_{Fr} follows from the joint continuity of the scalar product $\langle .|. \rangle$ with respect to the usual norm $\|.\|$ and from the relation $\|.\| \leqslant \|.\|_\mu < \tau_{\mathrm{Fr}}$ (cf. also Example 4).

Thus all assumptions of Theorem 7 are fulfilled. According to Sec. III B 2 and by use of the topology τ_{Fr} we now construct the global free boson dynamics in the Schrödinger picture in terms of the dynamical description $(\mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle), \mathscr{F}_{\mathrm{Fr}}, \nu_t)$ for the original one-boson test-function space $(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$. By construction it holds

$$\langle \nu_t(\omega); W(f)\rangle = \langle \omega; W(\exp\{-it\Delta\} f)\rangle \quad \forall \omega \in \mathscr{F}_{\mathrm{Fr}} \quad \forall f \in \mathscr{S}(\mathbb{R}^p). \tag{11}$$

Since the one-boson dynamics v_t also is $\|.\|_\mu$-continuous, it is immediate to check that the subfolium $\mathscr{F}_{\|.\|_\mu}$ is ν_t-invariant for each $\mu \in \mathscr{S}'_m(\mathbb{R}^p)$, and thus defines the dynamical subdescription $(\mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle), \mathscr{F}_{\|.\|_\mu}, \nu_t)$. This dynamical subdescription obviously agrees with the dynamical description constructed according to Theorem 7 directly on $\mathscr{F}_{\|.\|_\mu}$ by use of the topology $\|.\|_\mu$.

E. Further enlarged test-function spaces

The Schwartz space $\mathscr{S}(\mathbb{R}^p)$ is complete with respect to τ_{Fr}, but not with respect to $\|.\|_\mu$, $\mu \in \mathscr{S}'_m(\mathbb{R}^p)$. The one-boson dynamics ν_t continuously extends from $\mathscr{S}(\mathbb{R}^p)$ to a strongly continuous unitary group on the $\|.\|_\mu$-completion $\mathscr{K}(\mu)$. Thus the original test-function space $\mathscr{D}(\mathbb{R}^p)$ may be enlarged to the complex Hilbert space $\mathscr{K}(\mu)$, where the symplectic form $\sigma \equiv \mathrm{Im}\langle .|. \rangle$ also extends from $\mathscr{D}(\mathbb{R}^p)$, resp. $\mathscr{S}(\mathbb{R}^p)$ to $\mathscr{K}(\mu)$ by joint $\|.\|_\mu$-continuity, its extension is denoted by σ_μ. Thus, according to Eq. (7) it holds

$$\mathscr{F}_{\|.\|_\mu} \equiv \mathscr{F}_{\|.\|_\mu}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle) \cong \mathscr{F}_{\|.\|_\mu}(\mathscr{S}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle) \cong \mathscr{F}_{\|.\|_\mu}(\mathscr{K}(\mu), \sigma_\mu). \tag{12}$$

Obviously, since $\|.\| = \|.\|_0$ it is $\mathscr{K}(0) = L^2(\mathbb{R}^p)$ and $\sigma_0 = \mathrm{Im}\langle .|. \rangle$ for $\mu = 0$. Using the topology $\|.\|_\mu$ we here also may take $(\mathscr{K}(\mu), \sigma_\mu)$ as the enlarged test-function space. However, the free dynamics constructed on $\mathscr{F}_{\|.\|_\mu}$ this way agrees with the one constructed by use of $(\mathscr{S}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$ as enlarged test-function space.

F. Independence from the test-function spaces

If E is an arbitrary τ_{Fr}-dense complex subspace of $\mathscr{S}(\mathbb{R}^p)$, then by the above construction one also may take $(E, \mathrm{Im}\langle .|. \rangle)$ for the test-function space,

$$\mathscr{F}_{\mathrm{Fr}} \equiv \mathscr{F}_{\mathrm{Fr}}(E, \mathrm{Im}\langle .|. \rangle) \cong \mathscr{F}_{\mathrm{Fr}}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle) \cong \mathscr{F}_{\mathrm{Fr}}(\mathscr{S}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle).$$

Similarly, if $(E, \sigma_\mu) \subseteq (\mathscr{K}(\mu), \sigma_\mu)$ is a $\|.\|_\mu$-dense symplectic subspace, then in addition to (12) it holds $\mathscr{F}_{\|.\|_\mu} \cong \mathscr{F}_{\|.\|_\mu}(E, \sigma_\mu)$. In both cases the free dynamics ν_t is well-defined.

This demonstrates some kind of independence of the chosen test-function space. But subsequently, as above, we take $(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$ for our test-function space.

G. Physically relevant Fréchet-continuous states

Here let us illustrate, that the folium $\mathscr{F}_{\mathrm{Fr}}$ contains a whole range of physically relevant states.

1. The (Fock) vacuum sector

Let $\mathscr{F}_{\rm vac}$ be the GNS folium of the (Fock) vacuum state $\omega_{\rm vac}$ (the smallest folium containing $\omega_{\rm vac}$). By Sec. II A the so-called vacuum sector $\mathscr{F}_{\rm vac}$ corresponds to the Fock representation $\Pi_{\rm Fock}$ of the CCR-algebra (the GNS representation of $\omega_{\rm vac}$). Thus $\mathscr{F}_{\rm vac}$ consists of all states, which are Fock-normal, i.e., which are given by density operators on Fock space.

The vacuum state $\omega_{\rm vac}$ has the characteristic function[2]

$$\langle \omega_{\rm vac}; W(f)\rangle = \exp\{-\tfrac{1}{4}\|f\|^2\}, \quad f\in\mathscr{D}(\mathbb{R}^p).$$

Hence $\omega_{\rm vac}\in\mathscr{F}_{\|.\|}$, and thus $\mathscr{F}_{\rm vac}\subseteq\mathscr{F}_{\|.\|}$.

The characteristic function of the vacuum implies $\nu_t(\omega_{\rm vac})=\omega_{\rm vac}\forall t\in\mathbb{R}$ by (11). Thus from Sec. II B 2 it follows that the vacuum sector $\mathscr{F}_{\rm vac}$ defines the covariant dynamical subdescription $(\mathscr{W}(\mathscr{D}(\mathbb{R}^p),{\rm Im}\langle .|.\rangle),\mathscr{F}_{\rm vac},\nu_t)$, see Definition 2. It is well known that $\exp\{itd\Gamma(-\Delta)\}$ unitarily implements the free Heisenberg dynamics α_t restricted to the Fock vacuum sector, where $d\Gamma(-\Delta)$ means the self-adjoint second quantization of the one-boson Hamiltonian $-\Delta$ [cf. condition (iii) of Sec. II B 2, and Ref. 2, Sec. 5.2].

2. The limiting Gibbs states for the Bose–Einstein condensation

The local Gibbs states by construction are elements of $\mathscr{F}_{\rm vac}$ [they are given on Fock space by density operators which are constructed in terms of the second quantization of the Laplacians $-\Delta_\Lambda$ for the local regions $\Lambda\subset\mathbb{R}^p$ (Ref. 2, Sec. 5.2.5)]. Folia are norm-closed subsets of the state space $\mathscr{S}(\mathscr{D}(\mathbb{R}^p),{\rm Im}\langle .|.\rangle)$. But the thermodynamic limiting procedures are done in the weak*-topology, which is strictly weaker than the norm. Thus one may not expect that the limiting Gibbs states are Fock normal, too. Indeed, by the subsequent result the limiting Gibbs states are not contained in $\mathscr{F}_{\|.\|}$, and hence the thermodynamic limits lead beyond the folia $\mathscr{F}_{\rm vac}$, resp. $\mathscr{F}_{\|.\|}$. We set $\mathbb{R}_+:=[0,\infty[$.

Proposition 9: The following assertions hold:

(a) *Let $F:\mathbb{R}_+\to\mathbb{R}$ be a measurable function such that there exist constants $c>0$ and $n\in\mathbb{N}$ with $|F(\lambda)|^2\leqslant c\lambda^{(1-p)/2}$ for $0<\lambda<1$ and $|F(\lambda)|^2\leqslant c\lambda^n$ for $\lambda\geqslant 1$. Then $\mu_F\in\mathscr{S}'_m(\mathbb{R}^p)$ for the measure $d\mu_F(k):=|F(\|k\|^2)|^2d^pk$. Moreover, $\|.\|_{\mu_F}$ is the graph norm of the self-adjoint operator $F(-\Delta)$ on $L^2(\mathbb{R}^p)$. $\mathscr{S}(\mathbb{R}^p)$ is a core for $F(-\Delta)$ and the $\|.\|_{\mu_F}$-completion $\mathscr{K}(\mu_F)\subseteq L^2(\mathbb{R}^p)$ is the domain of $F(-\Delta)$. The extended symplectic form $\sigma_{\mu_F}(f,g)={\rm Im}\langle f|g\rangle$, $f,g\in\mathscr{K}(\mu_F)$, is nondegenerate.*

(b) *Let F be as in (a). Denote by δ_{k_0} the point measure $\delta_{k_0}(\hat f)=\hat f(k_0)\forall f\in\mathscr{S}(\mathbb{R}^p)$ at some $k_0\in\mathbb{R}^p$ in momentum space (Fourier transformation $f\mapsto\hat f$). Then $\mu_F+\delta_{k_0}\in\mathscr{S}'_m(\mathbb{R}^p)$, and $\mathscr{K}(\mu_F+\delta_{k_0})=\mathscr{K}(\mu_F)\oplus\mathbb{C}$ with the embedding $\mathscr{S}(\mathbb{R}^p)\ni f\to f\oplus\hat f(k_0)$. Moreover, the extended symplectic form $\sigma_{\mu_F+\delta_{k_0}}(f\oplus\alpha,g\oplus\beta)={\rm Im}\langle f|g\rangle$, $f\oplus\alpha,g\oplus\beta\in\mathscr{K}(\mu_F)\oplus\mathbb{C}$, is degenerate.*

(c) *Each limiting Gibbs state $\omega_{\beta,\gamma}\in\mathscr{S}(\mathscr{D}(\mathbb{R}^p),{\rm Im}\langle .|.\rangle)$ for the Bose–Einstein condensation (Refs. 1 and 2, Sec. 5.2.5, also Refs. 23, 24) has the characteristic function*

$$\langle \omega_{\beta,\gamma}; W(f)\rangle = \exp\{-\tfrac{1}{4}\|f\|^2-\tfrac{1}{2}\|T_\beta^{1/2}f\|^2-\gamma|\hat f(0)|^2\}, \quad f\in\mathscr{D}(\mathbb{R}^p),$$

where $T_\beta:=e^{\beta\Delta}(\mathbb{1}-e^{\beta\Delta})^{-1}$ at the inverse temperature $\beta>0$. No condensation implies $\gamma=0$. With condensation it is $\gamma>0$, which depends on the particle density.

Let $G(\lambda):=\lambda^{-1/2}$ for $0<\lambda<\infty$ and dimension $p\geqslant 2$. Then for each $\beta>0$ and $\gamma\geqslant 0$ it follows that $\omega_{\beta,\gamma}\in\mathscr{F}_{\|.\|_\mu}$, where $\mu:=\mu_G+\delta_0$. But it holds $\omega_{\beta,\gamma}\notin\mathscr{F}_{\|.\|}$.

Proof: (a) For each $f\in\mathscr{S}(\mathbb{R}^p)$ it is

$$\left|\int_{\mathbb{R}^p} f(k)d\mu_F(k)\right| \leqslant c\int_{\|k\|<1}\frac{|f(k)|}{\|k\|^{p-1}}\,d^pk \;+\; c\int_{\|k\|\geqslant 1}(|f(k)|\|k\|^{2n+p+1})\,\frac{1}{\|k\|^{p+1}}\,d^pk$$
$$\leqslant c'\|f\|_\infty + c'\|\,|.|^{2n+p+1}f\|_\infty,$$

for some constant $c'>0$, since $\int_{\|k\|<1}\|k\|^{-p+1}d^pk<\infty$ and $\int_{\|k\|\geq 1}\|k\|^{-p-1}d^pk<\infty$. But $\|f\|_\infty$ and $\|\|.\|^{2n+p+1}f\|_\infty$ are τ_{Fr}-continuous seminorms on $\mathscr{S}(\mathbb{R}^p)$, which ensures $\mu_F\in\mathscr{S}'_m(\mathbb{R}^p)$. In momentum space (Fourier transformation) the operator $F(-\Delta)$ is the multiplication with $k\to F(\|k\|^2)$. It is well known that $\mathscr{S}(\mathbb{R}^p)$ is a core for locally bounded multiplication operators on $L^2(\mathbb{R}^p)$ (Ref. 25, p. 92).

(b) Let us show that the embedding of $\mathscr{S}(\mathbb{R}^p)$, $f\mapsto f\oplus\hat{f}(k_0)=:E(f)$, is dense in the Hilbert space $\mathscr{K}(\mu_F)\oplus\mathbb{C}$. Let $h\in\mathscr{S}(\mathbb{R}^p)$ so that $\hat{h}$ has support in $\{k\in\mathbb{R}^p|\|k\|\leq 1\}$ and $\hat{h}(0)=1$. Define the sequence $h_n\in\mathscr{S}(\mathbb{R}^p)$ by $\widehat{h_n}(k):=\hat{h}(n(k-k_0))$, $n\in\mathbb{N}$. Let first $k_0=0$. Then with $q:=nk$ we get

$$\|h_n\|^2_{\mu_F}\leq\int_{\mathbb{R}^p}|\hat{h}(nk)|^2\left(1+\frac{c}{\|k\|^{p-1}}\right)d^pk\overset{q=nk}{=}\frac{\|h\|^2}{n^p}+\frac{c}{n}\int_{\mathbb{R}^p}\frac{|\hat{h}(q)|^2}{\|q\|^{p-1}}d^pq.$$

If $k_0\neq 0$, then there is an $n_0\in\mathbb{N}$ with $0\notin\{k|\|k-k_0\|\leq 1/n_0\}$, and there is a $\tilde{c}>0$ with $|F(\|k\|^2)|^2\leq\tilde{c}$ for $\|k-k_0\|\leq 1/n_0$. For all $n\geq n_0$ we obtain

$$\|h_n\|^2_{\mu_F}\leq\int_{\mathbb{R}^p}|\hat{h}(n(k-k_0))|^2(1+\tilde{c})d^pk=\frac{(1+\tilde{c})\|h\|^2}{n^p}.$$

Thus in both cases $\|h_n\|_{\mu_F}\to 0$, but $\widehat{h_n}(k_0)=1\,\forall n\in\mathbb{N}$. [That is, the linear form $f\mapsto\hat{f}(k_0)$ is unbounded with respect to $\|.\|_{\mu_F}$.] It follows $h_n\oplus\widehat{h_n}(k_0)\to 0\oplus 1$, which implies $0\oplus\mathbb{C}$ to be a subspace of the closure of the embedded E($\mathscr{S}(\mathbb{R}^p)$), and thus $\mathscr{S}(\mathbb{R}^p)\oplus 0$ is so, too. Now observe that by part (a) it holds that $\mathscr{S}(\mathbb{R}^p)$ is $\|.\|_{\mu_F}$-dense in $\mathscr{K}(\mu_F)$.

(c) We show that for each $\beta>0$ the graph norm of $T_\beta^{1/2}$ is equivalent to the norm $\|.\|_{\mu_G}$, the graph norm of $G(-\Delta)=(-\Delta)^{-1/2}$. The unboundedness of the operators $T_\beta^{1/2}$ and $(-\Delta)^{-1/2}$ on $L^2(\mathbb{R}^p)$ arises at the spectral value zero. Thus it sufficess to prove the equivalence around zero. It is $\beta\lambda\leq e^{\beta\lambda}-1\leq b\lambda$, and thus $(\beta\lambda)^{-1}\geq e^{-\beta\lambda}(1-e^{-\beta\lambda})^{-1}=(e^{\beta\lambda}-1)^{-1}\geq(b\lambda)^{-1}$ for $0<\lambda\leq\epsilon$ for some $b>\beta$ and $\epsilon>0$. Then the equivalence of the graph norms follows from the spectral calculus, especially the domains of $T_\beta^{1/2}$ and $(-\Delta)^{-1/2}$ agree to be $\mathscr{K}(\mu_G)$. Finally, use part (b). ■

The limiting Gibbs states $\omega_{\beta,\gamma}$, $\beta>0,\gamma\geq 0$, are ν_t-invariant, which, e.g., is seen from applying (11) to their characteristic functions. Thus by Sec. II B 2 their GNS folia define covariant dynamical subdescriptions of $(\mathscr{W}(\mathscr{D}(\mathbb{R}^p),\mathrm{Im}\langle.|.\rangle),\mathscr{T}_{\mathrm{Fr}},\nu_t)$.

3. Quasifree states

The above local and limiting Gibbs states are examples of quasifree states, also called Gaussian states. Each *quasifree* state ω on $\mathscr{W}(\mathscr{D}(\mathbb{R}^p),\mathrm{Im}\langle.|.\rangle)$ has the characteristic function

$$\langle\omega;\mathscr{W}(f)\rangle=\exp\{i\sqrt{2}\ \mathrm{Re}(L(f))-\tfrac{1}{4}s(f,f)\},\quad f\in\mathscr{D}(\mathbb{R}^p),$$

where $L:\mathscr{D}(\mathbb{R}^p)\to\mathbb{R}$ is a complex-linear form and $s:\mathscr{D}(\mathbb{R}^p)\times\mathscr{D}(\mathbb{R}^p)\to\mathbb{R}$ is a positive symmetric real-bilinear form satisfying $|\mathrm{Im}\langle f|g\rangle|^2\leq s(f,f)s(g,g)\,\forall f,g\in\mathscr{D}(\mathbb{R}^p)$. Conversely, for each such L and s, there exists a unique quasifree state ω of the above form.[2,24,10]

If L is τ_{Fr}-continuous and s is jointly τ_{Fr}-continuous, then $\omega\in\mathscr{T}_{\mathrm{Fr}}$. Observe, if s is a symmetric real-bilinear form on the enlarged, τ_{Fr}-complete $\mathscr{S}(\mathbb{R}^p)$, then the joint τ_{Fr}-continuity of s arises from the separate τ_{Fr}-continuity, i.e., $\mathscr{S}(\mathbb{R}^p)\ni g\mapsto s(f,g)=s(g,f)$ is τ_{Fr}-continuous for every $f\in\mathscr{S}(\mathbb{R}^p)$ [this is a consequence of the principle of uniform boundedness (see. Ref. 21, Sec. V.2)].

4. Classical states

The above local and limiting Gibbs states also are examples for classical states. In quantum optics a classical state of the photon field is defined by the positivity of its P-representation (for more informations and references we refer to Refs. 10 and 26). The generalization to our infinite

dimensional test-function space leads to the following definition: A state ω on the CCR-algebra $\mathscr{W}(\mathscr{D}(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle)$ is called *classical*, if its characteristic function decomposes multiplicatively according to

$$\langle \omega; W(f)\rangle = \langle \omega_{\mathrm{vac}}; W(f)\rangle P_\omega(f), \quad f\in\mathscr{D}(\mathbb{R}^p), \tag{13}$$

with a positive-definite function $P_\omega:\mathscr{D}(\mathbb{R}^p)\to\mathbb{C}$ on the test-function space $\mathscr{D}(\mathbb{R}^p)$ regarded as an additive group. Conversely, if $P:\mathscr{D}(\mathbb{R}^p)\to\mathbb{C}$ is a positive-definite function with the normalization $P(0)=1$, then there exists a unique classical state ω with $P=P_\omega$.

If P_ω is τ_{Fr}-continuous, then $\omega\in\mathscr{F}_{\mathrm{Fr}}$. In this case we may decompose the positive-definite P_ω with help of the Bochner–Minlos theorem,

$$P_\omega(f)=\int_{\mathscr{S}'(\mathbb{R}^p)} \exp\{i\sqrt{2}\ \mathrm{Re}(L(f))\}\ \ d\rho_\omega(L), \quad f\in\mathscr{S}(\mathbb{R}^p), \tag{14}$$

[ω extends to $\mathscr{S}(\mathbb{R}^p)$, thus P_ω does so, too] with respect to a unique probability measure ρ_ω on the tempered distributions $\mathscr{S}'(\mathbb{R}^p)$.[27] Equations (13) and (14) imply the decomposition of the classical state $\omega\in\mathscr{F}_{\mathrm{Fr}}$,

$$\omega=\int_{\mathscr{S}'(\mathbb{R}^p)} \omega_L\ \ d\rho_\omega(L), \tag{15}$$

into the pure, fully coherent states $\omega_L\in\mathscr{F}_{\mathrm{Fr}}$, $L\in\mathscr{S}'(\mathbb{R}^p)$, with respect to the weak*-topology. For arbitrary linear form $L:\mathscr{D}(\mathbb{R}^p)\to\mathbb{C}$ the pure, fully coherent ω_L is given with the characteristic function (see Ref. 8 and Sec. IV G 5 below),

$$\langle \omega_L; W(f)\rangle = \langle \omega_{\mathrm{vac}}; W(f)\rangle \exp\{i\sqrt{2}\ \mathrm{Re}(L(f))\}, \quad f\in\mathscr{D}(\mathbb{R}^p).$$

These states have been used already in the proof of Proposition 8.

The measure ρ_ω is the P-representation of our classical state $\omega\in\mathscr{F}_{\mathrm{Fr}}$. And for $\|.\|$-continuous linear forms L, the states ω_L are just the Glauber vector states, which are well known from quantum optics.

5. Coherent states

A smearing procedure of Glauber's original factorization condition[28] leads to the algebraic formulation of quantum optical coherence, where Glauber's factorizing coherence function is replaced by a (complex-) linear form $G:\mathscr{D}(\mathbb{R}^p)\to\mathbb{C}$. For more details on coherent states we refer to Ref. 8. An analytic state ω on $\mathscr{W}(\mathscr{D}(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle)$ is called *G-coherent in nth order*, $n\in\mathbb{N}\cup\{\infty\}$, if the normally ordered expectations factorize up to degree n,

$$\langle \omega; a^*(f_1)\cdots a^*(f_j)a(g_1)\cdots a(g_j)\rangle = G(f_1)\cdots G(f_j)\overline{G(g_1)}\cdots\overline{G(g_j)}$$

for all f_k, $g_t\in\mathscr{D}(\mathbb{R}^p)$ and each $1\leqslant j\leqslant n$ [here, $a(f)$ and $a^*(f)$ are the annihilation resp. creation operators for the test-function f].

For $\|.\|$-continuous linear form G, the G-coherent states in every order are Fock normal, i.e., they are elements of the vacuum sector $\mathscr{F}_{\mathrm{vac}}$. If G is unbounded with respect to the norm $\|.\|$, then each G-coherent state ω automatically is classical and decomposes with a suitable probability measure ρ_ω^G on $\mathbb{C}$ into the pure coherent states ω_{zG},

$$\omega=\int_{\mathbb{C}} \omega_{zG}\ \ d\rho_\omega^G(z). \tag{16}$$

Obviously, if $G\in\mathscr{S}'(\mathbb{R}^p)$, then this decomposition agrees with (15) with the measure $\rho_\omega^G\cong\rho_\omega$ supported by $\mathbb{C}\cong\mathbb{C}G\subset\mathscr{S}'(\mathbb{R}^p)$.

Summarizing, if the linear form G is a tempered distribution, $G\in\mathscr{S}'(\mathbb{R}^p)$, then the G-coherent states in all orders are elements of the folium $\mathscr{F}_{\mathrm{Fr}}$.

6. Squeezed states

Squeezing operations in quantum optics usually are described in terms of Bogoliubov transformations.[29,9,10,26,30] We adopt this notion also for our massive bosons.

Let T be a symplectic transformation on $(\mathcal{S}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$. Then T and T^{-1} are τ_{Fr}-continuous by Lemma 6(b). In Proposition 13(c) below we give an example for such a τ_{Fr}-continuous symplectic transformation. By Theorem 5 the associated (squeezing) Bogoliubov transformation ν_T is an affine bijection on the folium $\mathcal{F}_{\mathrm{Fr}}$ that is $\nu_T(\mathcal{F}_{\mathrm{Fr}}) = \mathcal{F}_{\mathrm{Fr}}$.

Thus applying the squeezing operation ν_T to the states from the previous subsections, we obtain squeezed quasifree, classical, resp. coherent states, which are τ_{Fr}-continuous, too.

H. Squeezed vacua and their time evolutions

In contrast to Sec. IV G 6 we here exclusively consider symplectic transformations T on the enlarged test-function spaces $(L^2(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$ as candidates for (squeezing) Bogoliubov transformations ν_T.

Let us denote by $\mathcal{B}$ the group of all symplectic transformations T on $(L^2(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$. Remark, in general $T \in \mathcal{B}$ is only real-linear; T commutes with the multiplication with the complex "i" (that is the complex-linearity of T), if and only if T is a (complex-linear) unitary on $L^2(\mathbb{R}^p)$. By Lemma 6(b) each $T \in \mathcal{B}$ is $\|.\|$-bounded, and thus $T^{-1} \in \mathcal{B}$ is so, too. Consequently, according to Theorem 5 the Bogoliubov transformations $\nu_T, T \in \mathcal{B}$, act on the folium $\mathcal{F}_{\|.\|}$ of $\|.\|$-continuous states on the CCR-algebra $\mathcal{W}(\mathcal{S}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$.

1. The polar decomposition of symplectic transformations

With the following procedure one may construct all $T \in \mathcal{B}$. Let $S \geqslant 0$ be a bounded self-adjoint operator on $L^2(\mathbb{R}^p)$ commuting with the antilinear involution J, and let U be an arbitrary unitary. Then the real-linear operator

$$T = U \exp\{JS\} = U(\cosh(S) + J \sinh(S)) \tag{17}$$

on $L^2(\mathbb{R}^p)$ is an element of $\mathcal{B}$, i.e., T is a symplectic transformation with respect to Im $\langle .|. \rangle$. Conversely, each $T \in \mathcal{B}$ is of the form (17) with unique bounded self-adjoint $S \geqslant 0$ commuting with the antilinear involution J, and unitary U. (17) is the polar decomposition of $T \in \mathcal{B}$.[9]

2. The squeezed vacuum sectors

It is $\omega_{\mathrm{vac}} \in \mathcal{F}_{\mathrm{vac}} \subseteq \mathcal{F}_{\|.\|}$. We denote the transformed state $\nu_T(\omega_{\mathrm{vac}})$ a *squeezed vacuum*, and the transformed folium $\nu_T(\mathcal{F}_{\mathrm{vac}})$ a *squeezed vacuum sector*, where $T \in \mathcal{B}$. Obviously, the squeezed vacuum sector $\nu_T(\mathcal{F}_{\mathrm{vac}})$ is the GNS folium of the squeezed vacuum state $\nu_T(\omega_{\mathrm{vac}})$, the smallest folium containing $\nu_T(\omega_{\mathrm{vac}})$, which is also a subfolium of $\mathcal{F}_{\|.\|}$.

Let us denote by $\mathcal{B}_{\mathrm{vac}}$ the subgroup of $\mathcal{B}$ consisting of those $T \in \mathcal{B}$ for which $\nu_T(\mathcal{F}_{\mathrm{vac}}) = \mathcal{F}_{\mathrm{vac}}$. By the Appendix it holds $T \in \mathcal{B}_{\mathrm{vac}}$, if and only if the self-adjoint $S \geqslant 0$ occurring in the polar decomposition $T = U \exp\{JS\}$ of (17) is a Hilbert–Schmidt operator on $L^2(\mathbb{R}^p)$. Especially, for the one-boson dynamics it is $v_t \in \mathcal{B}_{\mathrm{vac}}$ for all times $t \in \mathbb{R}$.

Proposition 10: Let $T_1, T_2 \in \mathcal{B}$. *Then the following assertions hold:*

(a) $T_1 T_2^{-1} \in \mathcal{B}_{\mathrm{vac}} \Leftrightarrow \nu_{T_1}(\omega_{\mathrm{vac}}) \in \nu_{T_2}(\mathcal{F}_{\mathrm{vac}}) \Leftrightarrow \nu_{T_1}(\mathcal{F}_{\mathrm{vac}}) = \nu_{T_2}(\mathcal{F}_{\mathrm{vac}})$.

(b) $T_1 T_2^{-1} \notin \mathcal{B}_{\mathrm{vac}} \Leftrightarrow \nu_{T_1}(\mathcal{F}_{\mathrm{vac}}) \cap \nu_{T_2}(\mathcal{F}_{\mathrm{vac}}) = \emptyset$.

Especially, it holds $\nu_T(\mathcal{F}_{\mathrm{vac}}) \cap (\mathcal{F}_{\mathrm{vac}}) = \emptyset \Leftrightarrow T \in \mathcal{B} \setminus \mathcal{B}_{\mathrm{vac}}$.

Proof: (a) $\nu_{T_1}(\mathcal{F}_{\mathrm{vac}}) = \nu_{T_2}(\mathcal{F}_{\mathrm{vac}})$ is equivalent to $\nu_V(\mathcal{F}_{\mathrm{vac}}) = \mathcal{F}_{\mathrm{vac}}$ for $V = T_1 T_2^{-1}$ (observe $\nu_V = (\nu_{T_2}{}^{-1} \circ \nu_{T_1})$. Now use the Appendix. (b) Suppose $\omega \in \nu_V(\mathcal{F}_{\mathrm{vac}}) \cap \mathcal{F}_{\mathrm{vac}} \neq \emptyset$. Then $\mathcal{F}_\omega \in \nu_V(\mathcal{F}_{\mathrm{vac}}) \cap \mathcal{F}_{\mathrm{vac}}$ for the GNS folium $\mathcal{F}_\omega$ of ω. But the irreducibility of the GNS representations of $\nu_V(\omega_{\mathrm{vac}})$ and ω_{vac} (the Fock representation is irreducible) implies $\nu_V(\mathcal{F}_{\mathrm{vac}}) = \mathcal{F}_\omega = \mathcal{F}_{\mathrm{vac}}$. ■

3. Squeezed vacuum sectors as covariant dynamical (sub-) descriptions

Let us denote by $\mathscr{B}_{\mathrm{cov}}$ the set of those symplectic transformations $T\in\mathscr{B}$, for which the squeezed vacuum sector $\nu_T(\mathscr{F}_{\mathrm{vac}})$ is invariant with respect to our free boson dynamics ν_t, i.e., $\nu_t(\nu_T(\mathscr{F}_{\mathrm{vac}}))=\nu_T(\mathscr{F}_{\mathrm{vac}})\forall\, t\in\mathbb{R}$. Especially, by Sec. IV G 1 the vacuum sector $\mathscr{F}_{\mathrm{vac}}$ is ν_t-invariant, but it is $\nu_T(\mathscr{F}_{\mathrm{vac}})=\mathscr{F}_{\mathrm{vac}}$ for all $T\in\mathscr{B}_{\mathrm{vac}}$. Consequently, $\mathscr{B}_{\mathrm{vac}}\subseteq\mathscr{B}_{\mathrm{cov}}$.

All $T\in\mathscr{B}_{\mathrm{cov}}$ are determined by Theorem 11.

Theorem 11: *For $T\in\mathscr{B}$ we have the following equivalences*:

(i) $T\in\mathscr{B}_{\mathrm{cov}}$, *that is,* $\nu_t(\nu_T(\mathscr{F}_{\mathrm{vac}}))=\nu_T(\mathscr{F}_{\mathrm{vac}})$ *for all* $t\in\mathbb{R}$;

(ii) $Tv_tT^{-1}\in\mathscr{B}_{\mathrm{vac}}$ *for all* $t\in\mathbb{R}$;

(iii) $\nu_t(\nu_T(\omega_{\mathrm{vac}}))\in\nu_T(\mathscr{F}_{\mathrm{vac}})$ *for all* $t\in\mathbb{R}$;

(iv) *for some* $a>0$ *both* $P_a(T^+T-\mathbb{I})$ *and* $[T^+T,i(\mathbb{I}-P_a)\Delta]$ *are real-linear Hilbert–Schmidt operators on the Hilbert space* $L^2(\mathbb{R}^p)$ *regarded as a real Hilbert space with the real scalar product* $\mathrm{Re}\,\langle .|.\rangle$ *(here the real adjoint* T^+ *is with respect to* $\mathrm{Re}\langle .|.\rangle$, *and* P_a *is the complex-linear spectral projection of* $-\Delta$ *for the spectral values larger than a; with the decomposition (17) it is* $T^+T=\exp\{2JS\}=\cosh(2S)+J\sinh(2S)$).

Furthermore, the dynamical subdescription $(\mathscr{W}(\mathscr{D}(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle),\nu_T(\mathscr{F}_{\mathrm{vac}}),\nu_t)$ *is covariant (cf. Definition 2) for every* $T\in\mathscr{B}_{\mathrm{cov}}$.

Proof: Let us extend v_t to $L^2(\mathbb{R}^p)$, so that the Bogoliubov automorphisms β_T and $\beta_t=\beta_{v_t}$ act on $\mathscr{W}(L^2(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle)$. Then $\Pi_T:=\Pi_{\mathrm{Fock}}\circ\beta_T$ is the representation of $\mathscr{W}(L^2(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle)$ which corresponds to the folium $\nu_T(\mathscr{F}_{\mathrm{vac}})$ by Sec. II A, and which commonly is called symplectically related to the Fock representation. Observe, $\nu_V=(\nu_T)^{-1}\circ\nu_t\circ\nu_T$ with the symplectic $V:=Tv_tT^{-1}\in\mathscr{B}$ is the dual Bogoliubov bijection to the automorphism $\beta_V=\beta_T\beta_t(\beta_T)^{-1}$ on $\mathscr{W}(L^2(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle)$. Thus, applying Theorem 14 of the Appendix yields (ii) to be equivalent to the unitary implementability of β_V in the Fock representation Π_{Fock}, which agrees with the unitary implementability of β_t in Π_T. Now the theorem is a reformulation of Warchall's results.[31] Warchall analyzed the implementability of Bogoliubov transformations associated to a unitary group $\exp\{itC\}$ with self-adjoint generator $C\geqslant 0$ on the complex separable Hilbert space $\mathscr{V}$ [thus symplectic on $(\mathscr{V},\mathrm{Im}\,\langle .|.\rangle)$] in representations of $\mathscr{W}(\mathscr{V},\mathrm{Im}\langle .|.\rangle)$ symplectically related to Fock. An important feature of Warchall's results is the fact that the ν_t-invariance of a squeezed vacuum sector $\nu_T(\mathscr{F}_{\mathrm{vac}})$ for every $t\in\mathbb{R}$, that is $T\in\mathscr{B}_{\mathrm{cov}}$, automatically gives its covariance. ■

In Ref. 31 there are some examples for $T\in\mathscr{B}_{\mathrm{cov}}$ but $T\notin\mathscr{B}_{\mathrm{vac}}$, and in Proposition 13(b) below there are constructed examples for $T\in\mathscr{B}\setminus\mathscr{B}_{\mathrm{cov}}$. Hence we have the proper inclusions

$$\mathscr{B}_{\mathrm{vac}}\subset\mathscr{B}_{\mathrm{cov}}\subset\mathscr{B}.$$

4. Noncovariant free dynamics on squeezed vacuum sectors

As a consequence of Theorem 11 we obtain Corollary 12.

Corollary 12: The following assertions are valid:

(a) *For* $T\in B_{\mathrm{cov}}$ *it is* $\lim_{t\to 0}\|\nu_t(\omega)-\omega\|=0$ *for all* $\omega\in\nu_T(\mathscr{F}_{\mathrm{vac}})$.

(b) *Let* $T\in B$ *but* $T\notin B_{\mathrm{cov}}$. *Then there exists a sequence* $t_n\neq 0$, $n\in\mathbb{N}$, *with* $\lim_{n\to\infty}t_n=0$, *but it holds* $\|\nu_{t_n}(\omega)-\omega\|=2$ *for all* $n\in\mathbb{N}$ *and all* $\omega\in\nu_T(\mathscr{F}_{\mathrm{vac}})$.

Proof: (a) expresses the covariance, see Sec. II B 2. (b) If there would exist a neigborhood $\mathscr{N}$ of $t=0$ with $\nu_t(\nu_T(\omega_{\mathrm{vac}}))\in\nu_T(\mathscr{F}_{\mathrm{vac}})\forall\, t\in\mathscr{N}$, then the group property of ν_t implies that this is valid for all $t\in\mathbb{R}$. Thus by Theorem 11 in each neighborhood of $t=0$ there exist some $t\neq 0$ with $\nu_t(\nu_T(\omega_{\mathrm{vac}}))\notin\nu_T(\mathscr{F}_{\mathrm{vac}})$, and thus $\nu_t(\nu_T(\mathscr{F}_{\mathrm{vac}}))\cap\nu_T(\mathscr{F}_{\mathrm{vac}})=\emptyset$. With (2) the result follows. ■

Let us construct an example to part (b) of the above Corollary. For the bounded continuous function $\zeta:\mathbb{R}_+\to\mathbb{R}_+$ define the bounded self-adjoint $S:=\zeta(-\Delta)\geqslant 0$ with the one-boson Hamiltonian $-\Delta$, and let the antilinear involution J be the ordinary complex conjugation on $L^2(\mathbb{R}^p)$, $Jf=\bar{f}$. Then by Sec. IV H 1 the real-linear operator $T_\zeta:=\exp\{JS\}=\cosh(\zeta(-\Delta))+J\sinh(\zeta(-\Delta))$ is symplectic on $(L^2(\mathbb{R}^p),\mathrm{Im}\langle .|.\rangle)$, that is $T_\zeta\in\mathscr{B}$. Here, J, S, and v_t, resp $-\Delta$

mutually commute (observe, $v_t J = J v_{-t}$), a situation which is similarly to our investigation[30] concerning unitary implementations of Bogoliubov automorphism groups in representations symplectically related to Fock.

Proposition 13: Let $\zeta, \eta: \mathbb{R}_+ \to \mathbb{R}_+$ *be bounded and continuous. Then it holds*:

(a) *It is* $\nu_{T_\zeta}(\mathscr{F}_{\rm vac}) \cap \nu_{T_\eta}(\mathscr{F}_{\rm vac}) = \emptyset$, *if and only if* $\zeta \neq \eta$. *Especially, if* $\zeta \neq 0$, *then* $\nu_{T_\zeta}(\mathscr{F}_{\rm vac}) \cap \mathscr{F}_{\rm vac} = 0$, *that is,* $T_\zeta \in \mathscr{B} \setminus \mathscr{B}_{\rm vac}$.

(b) *Let* $\zeta \neq 0$. *Then* $\nu_s(\nu_{T_\zeta}(\mathscr{F}_{\rm vac})) \cap \nu_t(\nu_{T_\zeta}(\mathscr{F}_{\rm vac})) = \emptyset$ *for all times* $s \neq t$, *especially it holds* $T_\zeta \in \mathscr{B} \setminus \mathscr{B}_{\rm cov}$. *Thus* $\|\nu_s(\omega_1) - \nu_t(\omega_2)\| = 2 \quad \forall\, \omega_1, \omega_2 \in \nu_{T_\zeta}(\mathscr{F}_{\rm vac})$ *for each* $s \neq t$ *by Eq. (2).*

(c) *If* ζ *is infinitely differentiable with polynomially bounded derivatives, then* T_ζ *leaves the Schwartz space* $\mathscr{S}(\mathbb{R}^p)$ *invariant,* $T_\zeta(\mathscr{S}(\mathbb{R}^p)) = \mathscr{S}(\mathbb{R}^p)$, *and the restrictions* $T_\zeta|_{\mathscr{S}(\mathbb{R}^p)}$ *and* $T_\zeta^{-1}|_{\mathscr{S}(\mathbb{R}^p)}$ *are* $\tau_{\rm Fr}$*-continuous symplectic transformations on* $(\mathscr{S}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$. *Thus the Bogoliubov bijection* ν_{T_ζ} *may be defined to act on the folium* $\mathscr{F}_{\rm Fr}$ *of* $\tau_{\rm Fr}$*-continuous states on the original CCR-algebra* $\mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$.

Proof: (a) $\Leftrightarrow \nu_{T_\zeta T_\eta^{-1}}(\mathscr{F}_{\rm vac}) \cap \mathscr{F}_{\rm vac} = \emptyset \Leftrightarrow$ the antilinear part $(T_\zeta T_\eta^{-1})_a$ is not Hilbert–Schmidt on $L^2(\mathbb{R}^p)$, by the Appendix. But $(T_\zeta T_\eta^{-1})_a = J \sinh(\zeta(-\Delta) - \eta(-\Delta))$.

(b) $\Leftrightarrow \nu_{T_\zeta v_{t-s} T_\zeta^{-1}}(\mathscr{F}_{\rm vac}) \cap \mathscr{F}_{\rm vac} = \varnothing \Leftrightarrow$ the antilinear part $(T_\zeta v_{t-s} T_\zeta^{-1})_a$ is not Hilbert–Schmidt on $L^2(\mathbb{R}^p)$, by the Appendix. But $(T_\zeta v_{t-s} T_\zeta^{-1})_a = iJ \sinh(2\zeta(-\Delta)) \sin((t-s)\Delta)$.

(c) By (Ref. 21, Sec. V.3) the operator of multiplication with $\mathbb{R}^p \ni k \mapsto \exp\{\pm\zeta(\|k\|^2)\}$ acts $\tau_{\rm Fr}$-continuous on the Schwartz space. Thus with Fourier transformation it follows that $\cosh(\zeta(-\Delta))$ and $\sinh(\zeta(-\Delta))$ are $\tau_{\rm Fr}$-continuous on $\mathscr{S}(\mathbb{R}^p)$. But then $T_\zeta = \exp\{JS\} = \cosh(S) + J \sinh(S)$ and $T_\zeta^{-1} = \exp\{-JS\} = \cosh(S) - J \sinh(S)$ are $\tau_{\rm Fr}$-continuous on $\mathscr{S}(\mathbb{R}^p)$, too. This especially implies $T_\zeta(\mathscr{S}(\mathbb{R}^p)) \subseteq \mathscr{S}(\mathbb{R}^p)$ and $T_\zeta^{-1}(\mathscr{S}(\mathbb{R}^p)) \subseteq \mathscr{S}(\mathbb{R}^p)$, which yields the result.

■

5. Summary

We have seen that the folium $\mathscr{F}_{\|.\|} \subset \mathscr{F}_{\rm Fr}$ of $\|.\|$-continuous states on $\mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle)$ contains a continuum of disjoint subfolia, namely the squeezed vacuum sectors $\nu_T(\mathscr{F}_{\rm vac}), T \in \mathscr{B}$, see Proposition 10 and Proposition 13(a).

By the construction in Sec. IV D the global free dynamics ν_t on $\mathscr{F}_{\|.\|}$ is time-continuous with respect to the expectations (3),

$$\lim_{t \to 0} \langle \nu_t(\omega); A \rangle = \langle \omega; A \rangle \quad \forall A \in \mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle) \quad \forall\, \omega \in \mathscr{F}_{\|.\|}. \tag{18}$$

The set of those symplectic transformations $T \in \mathscr{B}$, for which the squeezed vacuum sector $\nu_T(\mathscr{F}_{\rm vac})$ is invariant with respect to the free dynamics ν_t, has been denoted by $\mathscr{B}_{\rm cov}$. Let $\mathscr{F}_{\rm sq,cov}$ be the folium generated by $\{\nu_T(\mathscr{F}_{\rm vac}) | T \in \mathscr{B}_{\rm cov}\}$. Then, restricting in (18) the states ω to the ν_t-invariant subfolium $\mathscr{F}_{\rm sq,cov} \subset \mathscr{F}_{\|.\|}$, we obtain from Corollary 12(a) the stronger time-continuity with respect to the norm,

$$\lim_{t \to 0} \|\nu_t(\omega) - \omega\| = 0 \quad \forall\, \omega \in \mathscr{F}_{\rm sq,cov},$$

which ensures the dynamical subdescription $(\mathscr{W}(\mathscr{D}(\mathbb{R}^p), \mathrm{Im}\langle .|. \rangle), \mathscr{F}_{\rm sq,cov}, \nu_t)$ to be covariant according to Definition 2.

For every state ω from the squeezed vacuum sectors $\nu_T(\mathscr{F}_{\rm vac})$ with $T \in \mathscr{B} \setminus \mathscr{B}_{\rm cov}$, however, the norm-continuity of $\mathbb{R} \ni t \mapsto \nu_t(\omega)$ fails by Corollary 12(b).

APPENDIX: UNITARY IMPLEMENTATIONS ON FOCK SPACE

Let us present a result, which is used in Sec. IV H. It is due to Shale,[32] and generalized in Ref. 9, Theorem 3.1. Let $\mathscr{V}$ be a complex Hilbert space with scalar product $\langle .|. \rangle$, and V a symplectic

transformation on $(\mathscr{V},\mathrm{Im}\langle .|.\rangle)$. The associated Bogoliubov automorphism on the CCR-algebra $\mathscr{W}(\mathscr{V},\mathrm{Im}\langle .|.\rangle)$ is denoted by β_V, that is, $\beta_V(W(f))=W(Vf)\forall f\in\mathscr{V}$, its dual transformation is ν_V according to (10).

Theorem 14: *The following assertions are equivalent*:

(i) $\nu_V(\omega_{\mathrm{vac}})\in\mathscr{F}_{\mathrm{vac}}$,
(ii) $\nu_V(\mathscr{F}_{\mathrm{vac}})=\mathscr{F}_{\mathrm{vac}}$,
(iii) *β_V is unitarily implementable in the Fock representation Π_{Fock}, that is, there exists a unitary U on Fock space with $\Pi_{\mathrm{Fock}}(\beta_V(A))=U\Pi_{\mathrm{Fock}}(A)U^*\forall A\in\mathscr{W}(\mathscr{V},\mathrm{Im}\langle .|.\rangle)$*;
(iv) *the antilinear part $V_a=\frac{1}{2}(V+iVi)$ of the symplectic V is Hilbert–Schmidt on $\mathscr{V}$, or equivalently, $V^+V-\mathbb{1}$ is Hilbert–Schmidt on $\mathscr{V}$ regarded as real Hilbert space with the real scalar product* $\mathrm{Re}\,\langle .|.\rangle$ *(here the real adjoint V^+ is taken with respect to* $\mathrm{Re}\,\langle .|.\rangle$*)*;
(v) *the self-adjoint operator $S\geqslant 0$ is Hilbert–Schmidt, where S is from the polar decomposition $V=U\exp\{JS\}$ of (17).*

The irreducibility of the Fock representation[2] *implies U in (iii) to be unique up to a phase.*

ACKNOWLEDGMENT

[11] Usually in physics (cf., e.g., Refs. 1–10 and Sec. IV) the one-boson test-function space E (resp. $\mathscr{E}$) is a (in general noncomplete) complex pre-Hilbert space with complex scalar product $\langle .|.\rangle$. The symplectic form σ on E, which is necessary for the Weyl form of the CCR in Eq. (5), is chosen as the imaginary part of the scalar product, $\sigma(f,g)=\mathrm{Im}\langle f|g\rangle\forall f,g\in E$. With the notation used in Sec. III A the CCR-algebra is given by $\mathrm{CCR}(E)=\mathscr{W}(E,\sigma)$.

(Received 1 July 1996; accepted for publication 6 August 1997)

An original regular approach to constructing special type symmetries for boundary value problems, namely renormgroup symmetries, is presented. Different methods of calculating these symmetries based on modern group analysis are described. An application of the approach to boundary value problems is demonstrated with the help of a simple mathematical model. © *1998 American Institute of Physics.* [S0022-2488(98)03901-2]

I. INTRODUCTION

The paper is devoted to the problem of constructing a special class of symmetries for boundary value problems (BVPs) in mathematical physics, namely *renormalization group symmetries* (hereafter referred to as RG-symmetries).

Symmetries of this type appeared about forty years ago in the context of the renormalization group (RG) concept. This concept originally arose[1–4] in the ''depth'' of quantum field theory (QFT) and was connected with a complicated procedure of renormalization, that is ''removing of ultra-violet infinities.'' In QFT, the renormalization group was based upon finite Dyson transformations and appeared as a continuous group in a usual mathematical sense. It was successfully used for improving an approximate perturbation solution to restore a correct structure of a solution singularity.

In the seventies, it was found that the RG concept was fruitful in some other fields of microscopic physics: phase transitions in large statistical systems, polymers, turbulence, and so on. However, in some cases, following Wilson's approach[5] to spin lattice, the original *exact symmetry* underlying the renormalization group notion in QFT was changed to an approximate one with the corresponding transformations forming a semi-group (not a group as in the QFT case). Here, in this paper, by RG-symmetry we mean the original exact property of a solution—as it was formulated in Refs. 3, 4 (see also Ref. 6) by Bogoliubov and one of the present authors. Thus, by RG-symmetry we mean a symmetry that characterizes a solution of a BVP and corresponds to *transformations* involving both ''dynamical'' (i.e., equation) *variables* and *parameters* entering into a solution via equations and boundary conditions.

For a simple illustration we consider some BVP that produces a family of solutions. The simplest variant of RG transformation is given by a simultaneous one-parameter point transformation,

$$T_a:\{x\to x'=x/a,\ \ g\to g'=G(a,g)\},\quad G(1,g)=g, \tag{1}$$

of a dimensionless ''coordinate'' x and a one-argument ''characteristic'' (e.g., initial value) g of each solution, the quantity of a direct physical interest. The transformation function $G(x,g)$, which depends upon two arguments,[7] should satisfy the functional equation,

$$G(x,g)=G(x/a,G(a,g)), \tag{2}$$

that guarantees the group property $T_a\cdot T_b=T_{ab}$ fulfillment.

 © 1998 American Institute of Physics

The functional equation (2) and transformation (1) arise, for example, in the massless QFT with one coupling. In that case $x=Q^2/\mu^2$ is the ratio of a 4-momentum Q squared to a ''reference momentum'' μ squared, g is the coupling constant, and G is the so-called *effective coupling*.

Later on the (1)–(2)-type symmetry underlying the renormgroup invariance was also found in a number of problems of macroscopic physics like, e.g., mechanics, transfer theory, hydrodynamics, and a close relation of RG-symmetry to the notion of self-similarity was established.[9,10]

The infinitesimal form of transformation (1) can be written down as a differential equation,

$$R\ G=0\,,\quad \text{with}\quad R=x\partial_x-\beta(g)\partial_g\,,\quad \beta(g)=\left.\frac{\partial G(a;g)}{\partial a}\right|_{a=1}\,, \tag{3}$$

where R is the infinitesimal operator of RG-symmetry (or, simply, *RG-operator*) with the coordinate $\beta(g)$ defined by the derivative of the function G.

Therefore, instead of relations (1) and (2), the RG transformation can also be introduced by means of an RG-operator. And vice versa, being given an RG-operator one can reconstruct the functional equation for the solution G with the help of the characteristic equation for (3). Moreover, for a given β-function or, in other words, for the given RG-symmetry, one can get an explicit expression for the invariant of the group transformation $G(x,g)$ by solving the corresponding Lie equations,[11]

$$-\frac{dx'}{x'}=\frac{dg'}{\beta(g')}=\frac{da}{a}, \tag{4}$$

with the initial conditions $x'|_{a=1}=x,\ \ g'|_{a=1}=g$.

Along with (3) a different form of the *invariance condition* for the function $G(x,g)$ is often employed,

$$\frac{d}{da}\,G(x/a,G(a,g))|_{a=1}=0\,. \tag{5}$$

Equation (3), reflecting the invariance of G under the RG transformation can be treated as a vanishing condition for the coordinate æ of the RG-operator (3) in the canonical form,[12]

$$\overline{R=}\ \text{æ}\,\partial_G\,,\qquad \text{æ}\equiv xG_x-\beta(g)G_g=0\,, \tag{6}$$

identically valid on a particular BVP solution $G=G(x,g)$.

At the same time, the relation

$$RS(x,g)\equiv(x\partial_x-\beta(g)\partial_g)S(x,g)=\gamma(g)S(x,g) \tag{7}$$

corresponds to the function $S(x,g)$ that is a *covariant*[13] of the RG transformation. In the QFT case, this relates, e.g., to a propagator amplitude (see Refs. 4 and 6). Here, $\gamma(g)$ is known as the *anomalous dimension* of $S(x,g)$.

Generally, the differential equation akin to (3),

$$xf_x-\beta(g)f_g=0, \tag{8}$$

states an invariance of a function f under the RG transformation (1). Its solution $f(x,g)=F(G(x,g))$ precisely corresponds to the same property emphasized by (2).

In a particular case, when the function G is linear in the last argument, $G\sim kg$, equation (2) defines a solution that has a power x dependence, i.e., $G(x,g)=gx^k$ with k being an arbitrary number. Then, equation (2) takes a form of power scaling (or *power self-similarity*) transformation,

$$x'=x/a,\qquad g'=ga^k,$$

that is well-known in mathematical physics and widely used in the problems of hydrodynamics of liquids and gases.

Therefore, transformation (2) can be considered[10] as a functional generalization $gx^k \to G(x,g)$ of a usual (i.e., power) self-similarity transformation. One can refer to it as to *functional self-similarity transformation*: this term was first introduced in Ref. 9 as a synonym of the RG transformation as defined above.

It is widely known that in QFT, as well as in other mentioned fields of theoretical physics, the RG method allows one to improve the perturbation theory results and to simplify the analysis of a singular behavior of a solution which becomes scale-invariant in the vicinity of a singularity. The latter reminds a situation, which is typical of asymptotic analysis of solutions of differential equations (DEs): long-time asymptotics demonstrate self-similar regimes.[14] Hence, it looks natural to use the RG methods to study strong nonlinear regimes and to investigate asymptotic behavior of physical systems described by DEs. We have no possibility to discuss this in detail here and would limit ourselves to mentioning some successful attempts of using the RG ideas in mathematical physics.

To our knowledge, the very first results in this field were obtained about a decade ago by two of the co-authors[15] of this paper by applying RG ideas to a problem of generating of higher harmonics in plasma. This problem, after some simplification, was reduced to a couple of partial DEs with the boundary parameter—solution ''characteristic''—explicitly included. It was proved that these DEs admit an exact symmetry group similar to that, defined by Eq. (3). The group obtained was then utilized to construct the desired nonlinear solution of the BVP. This approach has further been developed (see Ref. 16 and references therein) and we shall describe it in some detail in the next Section.

The methods of QFT RG were exploited by Goldenfeld, Martin, and Oono with co-authors (Urbana group) (see, e.g., Refs. 17 and 18) to find asymptotics of the solutions of parabolic-type nonlinear differential equations, that describe a variety of physical phenomena, such as ground-water flow under gravity, shock waves dynamics, radiative heat transfer, and so on. As an auxiliary tool, they used the concept of *intermediate asymptotics* first introduced by Barenblatt and Zeldovich[19]—see also the review monographs, Refs. 14 and 20. In this way, the Urbana team was able to determine values of exponents in the ratios of invariants forming arguments of self-similar solutions.

Later on, with the goal to a global asymptotic analysis they developed and illustrated, by numerous examples, the ''perturbative renormalization group theory'' (see Ref. 21 and references therein) that exploited the form of the invariance condition akin to that (5) used in QFT. The geometrical formulation of the perturbative RG theory for global analysis was presented by Kunihiro[22] on the basis of a classical theory of envelopes.

On the other hand, Bricmont and Kupiainen[23–25] attracted RG ideas for nonlinear DEs analyzing in a bit different manner. They used an iterative set of rescalings borrowed from the Wilson version of renormalization group, that is semi-group. On the basis of that RG-mapping procedure they succeeded in proving the global existence and detailed long time asymptotics for classes of nonlinear parabolic equations.

Generally, the procedure of revealing RG transformations, or some group features, similar to RG regularities, in any partial case (QFT, spin lattice, polymers, turbulence, and so on) up to now is not a regular one. In practice, it needs some imagination and atypical manipulation (see the discussion in Refs. 8, 26, 17) ''invented'' for every particular case. For example, the above described RG methods applied to an asymptotic analysis of differential equations were based on the *a priori* assumption of the existence of some scaling transformations or on the invariance condition of an approximate solution. By this reason, the possibility to find a regular approach to constructing RG-symmetries is of principal interest. In this paper we give an account of our efforts for creating a possible scheme of this kind in application to physical systems that are described by DEs. The leading idea in this case is based on the fact that symmetries of such systems can be found in a regular manner by using the well-developed methods of modern group analysis.

The paper is organized as follows: in Section II we describe the general scheme of constructing RG-symmetry for a BVP. It appears that the implementation of this scheme strongly depends on the mathematical model used and on the form of boundary conditions. As a result, different approaches to finding RG-symmetries are possible, and these are illustrated by examples in the

following five sections. In Section III, RG-symmetries are calculated using the classical Lie symmetries. In Section IV RG-symmetries are obtained on the basis of Lie–Bäcklund symmetries. In the next two sections RG-symmetries are found when boundary conditions are presented either in the form of a differential constraint (Section V), or in the form of an embedding equation (Section VI). In Section VII one more approach to RG-symmetries constructing is presented which is based on an approximate group symmetry. In conclusion, we make a summary of the approach and discuss some further applications.

II. APPROACH TO CONSTRUCTING RG-SYMMETRIES

First of all, we emphasize that the desired regular approach to constructing RG-symmetries turns out to be possible for those mathematical models of physical systems that are based on differential or, in some particular cases, integro-differential equations. The key idea uses the fact[27,28] that such models can be analyzed by algorithms of modern group analysis.

The proposed scheme comprises a sequence of the four steps.

(I) A specific manifold (differential, integro-differential, etc.) should be primarily constructed. This manifold that will be referred to as *renormgroup manifold* (RG-manifold) generally differs (see below) from the manifold given by the original system of DEs.

(II) The second step consists in calculating the most general symmetry group $\mathscr{G}$ admitted by the RG-manifold.

(III) The restriction of the group $\mathscr{G}$ on the desired BVP solution (exact or approximate) constitutes the next step. The group of transformations thus obtained (renormgroup) is characterized by a set of infinitesimal operators (RG-operators), each containing the solution of a BVP in its invariant manifold.

(IV) The last, fourth step implies utilization of RG-operators to find analytical expressions for solutions of the BVP.

Being formulated in a concise form these steps deserve further comments.

Comment to I. In the scheme described above the first step, constructing the RG-manifold is of fundamental importance. The form of its realization depends both on a mathematical model and on a form of a boundary condition.

Here we show the following different approaches to RG-manifold constructing.

(a) In the first more simple case, the RG-manifold, as is usual in classical group analysis, is presented by a system of basic DEs with only one substantial difference: parameters, entering into a solution via the equation and boundary conditions are included in the list of independent variables.

(b) Another approach to constructing the RG-manifold implies an extension of a space of variables involved in group transformations, for example, by including differential variables of higher order and nonlocal variables. It means that in this case Lie–Bäcklund transformation groups and nonlocal transformation groups should be invoked.[12,29]

(c) In the third approach, the procedure of construction of the RG-manifold is based on the invariant embedding method.[30] Here the RG-manifold is given by a system of equations that consists of original DEs and/or embedding equations which correspond to the BVP under consideration.

(d) The fourth approach, to some extent, is similar to the previous one. In this event boundary conditions are reformulated in terms of a differential constraint which is then combined with original equations to form the desired RG-manifold.

(e) The last approach utilizes approximate transformation groups. Here, the RG-manifold is given by a system of DEs with small parameters and can be analyzed by perturbation methods.[31]

Comment to II. Searching the symmetry of the RG-manifold is the main problem of the second step. The term ''symmetry'' as used in the classical group analysis means the property of a system of DEs to admit a Lie group of point transformations in the basic space of all independent and dependent (differential) variables entering these DEs. The Lie calculational algorithm of finding such symmetries is reduced to constructing tangent vector fields with coordinates that are functions of these basic group variables and can be defined from the solution of an overdetermined system of DEs, called *determining equations*. In modern group analysis different modification of a classical Lie scheme are in use (see, e.g., Refs. 29, 32, and references therein). If the problem of finding symmetries for a given system of DEs (RG-manifold) is solved, then the result is presented

in the form of Lie algebra of infinitesimal operators (also known as group generators), which correspond to the admitted vector field. In what follows these operators will be denoted by X.

Comment to III. The goal of a group restriction is the construction of a transformation group with a tangent vector field (point, Lie–Bäcklund, etc.) infinitesimal operators of which (hereinafter referred as R) contain the desired BVP solution in an invariant manifold. This means that the coordinate of the canonical operator of RG-symmetry vanishes on the BVP solution and on its differential consequences.

Mathematically, the procedure of a group restriction appears as a ''combining'' of different coordinates of group generators X admitted by the RG-manifold. The vanishing condition for this combination on a solution of the BVP leads to algebraic equalities that couple different coordinates and give rise to desired RG-symmetries. In a particular case, when RG is constructed from a Lie group admitted by the original system of DEs, it turns out to be a subgroup of this group and a solution of the BVP appears as an invariant solution with respect to the point RG obtained (compare with Ref. 11). In the general case, not only Lie point group, but Lie–Bäcklund groups, approximate groups, nonlocal transformation groups, etc. (see, e.g., Ref. 29), are also employed as basic groups which are then to be restricted on the solution of a BVP.

Comment to IV. A technique for constructing group invariant solutions corresponding to a symmetry group when its infinitesimal operators are known has been detailed in various monographs (see, e.g., Refs. 11, 32, 29). Therefore, the final step is performed in a usual way and needs no specific comments.

Before proceeding any further, we make a short review of results, that were obtained on the basis of the formulated scheme. The first application of the RG-approach to a particular problem of laser plasma was announced in Ref. 15. This problem, namely the problem of a nonlinear interaction of a powerful laser radiation with inhomogeneous plasma, has been detailed in subsequent publications.[16,33,34] A mathematical model was given by a system of nonlinear DEs for components of electron velocity, electron density, and the electric and magnetic fields. The presence of small parameters (such as weak inhomogeneity of the ion density, low electron thermal pressure, and small angles of incidence of a laser beam on plasma surface) in the initial system of equations provided a way for constructing the RG-manifold using the (e) approach, based on approximate group methods. The desired RG-symmetry appears as Lie point symmetry that takes account transformations of a boundary parameter [common to the (a) approach], which is related to the amplitude of the magnetic field at a critical density point. RG-symmetry obtained made it possible to get the exact solution of original equations, that was then used to evaluate the efficiency of harmonics generation in cold and hot plasma (see Ref. 16).

The advantageous use of the RG-approach in solving the above particular problem gave the promise that it may work in other cases. This was illustrated in Ref. 35 by a series of examples for different BVPs. Various methods of constructing RG-symmetries were described, based on the use of point symmetries, approximate symmetries, embedding equations, and transformations of Fourier components. As is shown in Ref. 35, different formulations of BVPs give rise to various methods of finding RG-symmetries. Thus, further development of the scheme was concentrated on analyzing these methods.

The first one was concerned with the initial value problem for the modified Burgers equation with parameters of nonlinearity and dissipation included explicitly. This example[36] yielded a detailed illustration of the method of constructing RG-symmetries when a basic RG-manifold is given by an original DE with parameters included in the list of independent variables [the (a) approach]. It was argued that the exact solution can be reconstructed from the perturbative solution with the help of any of the admitted RG-symmetry operators which form an eight-dimensional algebra. Two illustrative examples were given, dealing with perturbation theory in time and in nonlinearity parameter.

To demonstrate the method of constructing Lie–Bäcklund RG-symmetries that uses the (Ib) approach, the initial value problem for a linear parabolic equation was considered in Ref. 27. It was shown that appending Lie–Bäcklund RG-symmetries to point RG-symmetries extends the algebra of RG-symmetries up to an arbitrary order.

The same mathematical model was also employed within the (c) approach when the boundary condition is described by a differential constraint.[37] It was found that RG-symmetries obtained can not be reduced to point RG-symmetries which arise from the (a) case. However, some of them can

be reformulated in terms of RG-symmetries previously found in the (a) approach while the others can be constructed from the Lie–Bäcklund symmetries of basic equations in view of the given differential constraint.

An idea of the (d) approach to constructing the RG-manifold based on the invariant embedding method was realized in Ref. 35 for ordinary DEs. Here, embedding equations can be treated as a specific form of a differential constraint, that takes boundary data into account. The method of finding RG-symmetry using the (d) approach proves to be of particular interest for the first order ordinary DEs when using the (a) approach faces standard problems in calculating point symmetries admitted by the RG-manifold. Provided the embedding equation has the form of a first order DE of an evolutionary type there appear no difficulties in the group analysis of a joint system of the basic and the embedding equations.

Worthy of mention is an example that demonstrates the utilization of RG-symmetries to constructing solutions of the BVP for a system of two first order partial DEs that describes the propagation of a laser beam in a nonlinear focusing medium.[38–43] It was revealed that RG-symmetries are related to formal symmetries that are constructed in the form of an infinite series in the medium nonlinearity parameter. For a specific form of boundary data infinite series are truncated with RG-symmetries presented by finite sums. Generally, for arbitrary boundary data this is not the case and in that event a finite sum describes approximate RG-symmetry for a small nonlinearity parameter. Based on the (a), (b), and (e) approaches both point and Lie–Bäcklund (exact and approximate) RG-symmetries were obtained and then used to find an analytical solution of the problem.

To clarify the idea of constructing RG-symmetries several examples are given below which demonstrate different approaches to the problem. To gain better understanding of these approaches, a simple mathematical model is used.[44] This model corresponds to BVP for a system of two first-order partial DEs that were studied by Chaplygin[45] in gas dynamics,

$$v_t+vv_x-a\varphi(n)n_x=0\,,\quad n_t+vn_x+nv_x=0\,;$$
$$v(0,x)=V(x)\,,\quad n(0,x)=N(x)\,, \tag{9}$$

where $\varphi(n)$ is an arbitrary function of n and a is a nonlinearity parameter. Despite its simplicity, this mathematical model has a wide field of application and was used to describe various physical phenomena (in the so-called quasi-gaseous media[46]). In such a case the physical meaning of variables t, x, v, and n may differ from that in gas dynamics. For example, in nonlinear geometrical optics, t and x are coordinates, respectively, along and transverse to the direction of laser beam propagation, v is the derivative of eikonal with respect to x, and n is a laser beam intensity. In this case, functions V and N characterize the curvature of the wave front and the beam intensity distribution upon the coordinate x and the entrance of a medium $t=0$.

Along with (9) another form of basic equations will be used,

$$a\tau_v-(n/\varphi(n))\chi_n=0\,,\quad \chi_v+\tau_n=0\,. \tag{10}$$

These linear equations for new variables $\tau=nt$ and $\chi=x-vt$ results from (9) under hodograph transformations.

III. RG AS LIE POINT SUBGROUP

In this section we present an illustration of the method of constructing RG-symmetries when a basic RG-manifold is given by the original DEs with parameters included in the list of independent variables. Boundary conditions are taken into account while restricting the group admitted by RG-manifolds up to the desired RG on the exact or approximate solution of a BVP which thus appears as an invariant solution with respect to any of RG operators obtained.

3.1. First we shall consider a particular case of equations (9) when the nonlinearity parameter a is equal to zero: in the application to optical equations discussed above this means that nonlinear effects are neglected. Then by introducing a new variable $v=\varepsilon u$, the system of equations (9) is rewritten in the following form:

$$u_t+\varepsilon u u_x=0\,,\quad n_t+\varepsilon u n_x+\varepsilon n u_x=0\,; \tag{11}$$

$$u(0,x)=U(x)\,,\quad n(0,x)=N(x)\,. \tag{12}$$

The continuous point Lie group admitted by the differential manifold (11) (RG-manifold) is given by the infinitesimal operator (a general element of Lie algebra) with six independent terms:

$$X=\xi^1\partial_t+\xi^2\partial_x+\xi^3\partial_\varepsilon+\eta^1\partial_u+\eta^2\partial_n\equiv\sum_{i=1}^{6}X_i\,, \tag{13}$$

$$X_1=(1/\varepsilon)\ \Delta J^1\ \partial_t+(J^1+u\ \Delta J^1)\partial_x-nJ^1_\chi\partial_n\,,\quad \Delta J^k\equiv(\varepsilon t J^k_\chi-J^k_u)\,,$$

$$X_2=(1/n)\ J^2(\partial_t+\varepsilon u\partial_x)\,,\quad X_3=nJ^3\partial_n\,,\quad X_4=J^4(-t\partial_t+n\partial_n+\varepsilon\partial_\varepsilon)\,,$$

$$X_5=\Delta J^5 D+J^5(\varepsilon t\partial_x+\partial_u)\,,\quad X_6=-(1/n)\ J^6 D\,,\quad D\equiv(t\partial_t+\varepsilon u t\partial_x-n\partial_n)\,.$$

Coordinates ξ and η of this infinite-dimensional group operator depend upon five functions $J^i(\chi,u,\varepsilon)$, $i=1,2,3,5,6$ which appear as arbitrary functions of their arguments $\chi=x-vt$, u and ε. The sixth one, J^4, that enters the operator which describes the group transformation of parameter ε, is an arbitrary function of this parameter only. The restriction of the group admitted by RG-manifold (11) on the solution of the BVP $u=\overline{u}(t,x,\varepsilon)$, $n=\overline{n}(t,x,\varepsilon)$ leads to zero equalities for two coordinates of the operator (13) in the canonical form—the conditions of functional self-similarity:

$$\eta^1+\xi^1\varepsilon\,\overline{u\,u_x}-\xi^2\overline{u_x}-\xi^3\overline{u_\varepsilon}=0\,,\quad \eta^2+\xi^1\varepsilon(\overline{n\,u})_x-\xi^2\overline{n_x}-\xi^3\overline{n_\varepsilon}=0\,. \tag{14}$$

These equalities should be valid for any values of t, and certainly for $t=0$, when dependencies $\overline{u}$ and $\overline{n}$ upon x are given by boundary conditions (12). This yields two linear relations between J^i and J^1_χ:

$$J^5=U_x J^1\,,\quad J^6=N_x J^1+NJ^1_\chi-N(U_x)_u J^1-\varepsilon U_x J^2-NJ^3-NJ^4\,. \tag{15}$$

Here, and in what follows functions U and N and their derivatives with respect to x should be expressed either in terms of u or in terms of χ. Substituting (15) in (13) gives the desired RG-symmetries with the RG-operator,

$$R=\sum_{i=1}^{4}R_i\,, \tag{16}$$

$$R_1=X_1+\left[\left(\varepsilon t(U_x)_\chi-\left(1-\frac{N}{n}\right)(U_x)_u-\frac{N_x}{n}\right)J^1\right.$$

$$\left.+\left(\varepsilon tU_x-\frac{N}{n}\right)J^1_\chi-U_xJ^1_u\right]D+U_xJ^1(\varepsilon t\partial_x+\partial_u)\,,$$

$$R_2=X_2+\frac{\varepsilon U_x}{n}J^2D,\quad R_k=X_k+\frac{N}{n}J^kD\,,\quad k=3,4\,.$$

We see that RG-symmetries for (11), (12) are presented as a combination of symmetries of infinite-dimensional algebra with the infinitesimal operator (13). Any of the four operators R_k (and their linear combinations with coefficients that are arbitrary functions of ε) contains the BVP solution $u=\overline{u}(t,x,\varepsilon)$ and $n=\overline{n}(t,x,\varepsilon)$ in the invariant manifold and enables us to obtain group transformation of both group variables and different functionals of the solution (for a method of calculating transformation of a functional see Ref. 47).

Generally, the renormalization group using is capable of improving a perturbation theory solution. As an example, consider the perturbative solution of (11), (12) for small value of $\varepsilon t \ll 1$,

$$u = U(x) - (\varepsilon t) U U_x + O(\varepsilon^2 t^2) \ , \quad n = N(x) - (\varepsilon t)(U N_x + N U_x) + O(\varepsilon^2 t^2) \ . \tag{17}$$

This approximate solution in the limit $(\varepsilon t) \to 0$ is invariant with respect to RG transformation defined by the operator R_2 with arbitrary $\varepsilon J^2 \neq 0$. Assuming $J^2 = 1/\varepsilon$, we obtain the explicit expression for the RG-operator,

$$R = \frac{1}{n}[(1 + \varepsilon t U_x)(\partial_t + \varepsilon u \partial_x) - \varepsilon U_x n \partial_n] \ , \tag{18}$$

and invariance conditions written in the form of two first order DEs:

$$u_t + \varepsilon u u_x = 0 \ , \ (1 + \varepsilon t U_x)(n_t + \varepsilon u n_x) + \varepsilon n U_x = 0 \ . \tag{19}$$

Solving Lie equations which correspond to the RG-operator (18) [and coincide with characteristics equations for (19)] enables us to reconstruct the desired exact solution of (11), (12) from the perturbative solution (17),

$$u = U(x - \varepsilon u t) \ , \quad n = \frac{1}{1 + \varepsilon t U_x} N(x - \varepsilon t u) \ , \tag{20}$$

where U_x should be expressed in terms of u. For example, in the particular case of $N(x) = N_0 \exp(-x^2)$, $U(x) = -x$ and $\varepsilon = 1/T$ the latter formulas describe the focusing of a Gaussian laser beam in geometrical optics,

$$n = \frac{T}{T - t} N_0 \exp\left(-x^2 \left(\frac{T}{t - T} \right)^2 \right) \ , \quad u = x \frac{T}{t - T} \ , \quad t \leqslant T. \tag{21}$$

3.2. Now let us turn to a more general case of $a \neq 0$. The Lie point symmetry group, admitted by the RG-manifold (10), is characterized by a canonical infinitesimal operator[12] with six independent terms X_i, $i = 1, \ldots, 5$ and X_∞,

$$X = X_\infty + \sum_{i=1}^{5} c_i X_i \equiv \left(\overline{f} + \sum_{i=1}^{5} c_i f_i \right) \partial_\tau + \left(\overline{g} + \sum_{i=1}^{5} c_i g_i \right) \partial_\chi , \tag{22}$$

where coordinates f_i and g_i are linear combinations of τ and χ and their first derivatives $\tau_1 = (\partial \tau / \partial n)$ and $\chi_1 = (\partial \chi / \partial n)$ with coefficients depending only on v and n.[40,41] For a particular case $\varphi = 1$ they are

$$\begin{aligned}
&f_1 = \tau, \quad g_1 = \chi; \quad f_2 = -(1/a) n \chi_1, \quad g_2 = \tau_1; \\
&f_3 = -\tau/2 + n \tau_1 + (1/2a) n v \chi_1, \quad g_3 = -(v/2) \tau_1 + n \chi_1; \\
&f_4 = -(1/2) n \chi + v n \tau_1 + [(1/4a) v^2 - n] n \chi_1, \\
&g_4 = (a/2) \tau + (1/2) v \chi + v n \chi_1 + [a n - (1/4) v^2] \tau_1; \\
&f_5 = (n \tau_1 - \tau) - a \tau_a, \quad g_5 = n \chi_1 - a \chi_a .
\end{aligned} \tag{23}$$

''Evident'' symmetries f_1, g_1 and f_2, g_2 describe dilations of τ and χ and translations along the v-axis, respectively, for an arbitrary nonlinearity $\varphi(n)$. Two more symmetries f_3, g_3 and f_4, g_4 appear due to a special form of the function $\varphi = 1$ under consideration. The symmetry f_5, g_5 involves the parameter a transformation along with transformations of dynamic variables.

The operator X_∞ with coordinates $\overline{f}=\xi^1(v,n), \overline{g}=\xi^2(v,n)$ that are arbitrary solutions of partial DEs,

$$\xi^1_v-(n/a)\xi^2_n=0, \quad \xi^2_v+\xi^1_n=0\,, \tag{24}$$

results from the linearity of basic Equations (10); it is an ideal of an infinite-dimensional Lie algebra L_∞ formed by operators $X_1,\ldots,X_5$ and X_∞.

The restriction of the group (23) on the BVP solution means that coordinates f and g of the canonical operator (22) turns to zero on this solution, that is,

$$\overline{f}=-\sum_{i=1}^{5} c_i f_i\,, \quad \overline{g}=-\sum_{i=1}^{5} c_i g_i\,. \tag{25}$$

These relations express functions $\overline{f}$ and $\overline{g}$ in terms of $f_i,\ g_i,\ i=1,\ldots,5$ taken on a solution $\tau=\overline{\tau}(v,n),\ \chi=\overline{\chi}(v,n)$ of a BVP (exact or approximate). Substitution of (25) in (22) gives five RG-operators,

$$R=\sum_{i=1}^{5} c_i(a)R_i\,, \tag{26}$$

each being determined by corresponding coordinates $f_i,\ g_i$ and by a pair of functions $A^i,\ B^i$,

$$\begin{aligned}
&R_1=(\tau-A^1)\partial_\tau+(\chi-B^1)\partial_\chi, \quad R_2=-A^2\partial_\tau-B^2\partial_\chi+\partial_v\,,\\
&R_3=(-(\tau/2)-A^3)\partial_\tau-B^3\partial_\chi-(v/2)\partial_v-n\partial_n\,,\\
&R_4=(-(n/2)\chi-A^4)\partial_\tau+((a/2)\tau+(v/2)\chi-B^4)\partial_\chi\\
&\qquad +(-(1/4)v^2+an)\partial_v+vn\partial_n\,,\\
&R_5=(-\tau-A^5)\partial_\tau-B^5\partial_\chi-n\partial_n+a\partial_a.
\end{aligned} \tag{27}$$

Here, ten functions A^i,B^i are defined by expressions (23) for f^i and g^i where one should replace $\tau,\ \chi$ by $\overline{\tau}(n,v),\ \overline{\chi}(n,v)$. Explicit formulas for RG-operators depend upon the specific solution of the BVP. For example, for the particular solution of the BVP (9) with $V=0$ and $N(x)=\cosh^{-2}(x)$, described by[48]

$$\begin{aligned}
&\tau=\frac{(v/2)^{1/2}}{a^{3/4}}(\sqrt{\kappa^2+1}-\kappa)^{1/2}\,, \quad \kappa=\frac{\sqrt{a}}{v}\left(1-n-\frac{v^2}{4a}\right),\\
&\chi=-\frac{1}{2}\ln\frac{(v/2\sqrt{a})^{1/2}+(\sqrt{\kappa^2+1}-\kappa)^{1/2}}{-(v/2\sqrt{a})^{1/2}+(\sqrt{\kappa^2+1}-\kappa)^{1/2}}\,,
\end{aligned} \tag{28}$$

functions $A^5,\ B^5$ in (27) are expressed as follows:[40]

$$A^5=-\frac{(v/2)^{1/2}}{4a^{3/4}\sqrt{1+\kappa^2}}(\sqrt{\kappa^2+1}-\kappa)^{1/2}\left(\kappa+\sqrt{1+\kappa^2}-2\frac{\sqrt{a}}{v}\right)\,,$$

$$B^5=\frac{(v/2)^{1/2}}{4a^{1/4}\sqrt{1+\kappa^2}}\,\frac{(\sqrt{\kappa^2+1}-\kappa)^{1/2}}{(\sqrt{\kappa^2+1}-\kappa-(v/2\sqrt{a}))}\left(\sqrt{1+\kappa^2}-3\kappa+2\frac{\sqrt{a}}{v}-\frac{v}{\sqrt{a}}\right)\,.$$

It should be noticed that the solution of the presented above BVP is unique, but a number of RG-operators that give rise to this solution is different from one [in the first example case we have four RG-operators with arbitrary functions of $(n,\ \chi)$, and in the second example five RG-operators with arbitrary functions of a]. In the next section we will show that the number of RG-operators may be enlarged to an arbitrary value, provided not only point but Lie–Bäcklund groups are taken into account.

IV. RG AS LIE–BÄCKLUND SUBGROUP

The method of constructing RG-symmetries from Lie point symmetries admitted by the original DE is naturally generalized to include Lie–Bäcklund (L–B) symmetries. The extension of the space of differential variables increases the amount of BVPs that allow restriction of a group on their solution. A complete set of RG-symmetries is obtained by appending L–B RG-symmetries to point RG-symmetries. In this section we present an example of constructing L–B RG-symmetries of the second order for the BVP (9). As in the previous section we use a transformed form of the basic equations (10).

L–B symmetries admitted by the RG-manifold (10) are characterized by the same canonical infinitesimal operator (22) where additional terms proportional to higher-order derivatives of τ and χ should be added in coordinates f and g. Similar to first-order symmetries, these terms are linear combinations of τ and χ and their derivatives $\tau_i=(\partial^i\tau/\partial n^i)$ and $\chi_i=(\partial^i\chi/\partial n^i)$ with coefficients that depend only on v and n.[39–41] For the second order Lie–Bäcklund symmetries in a particular case $\varphi(n)=1$, we have five additional operators X_i with $i=7,\ldots,11$ (the term with $i=6$ corresponds to X_∞ and is omitted in the sum, i.e., $c_6=0$),

$$X=X_\infty+\sum_{i=1}^{11} c_iX_i\equiv\left(\overline{f}+\sum_{i=1}^{11} c_if_i\right)\partial_\tau+\left(\overline{g}+\sum_{i=1}^{11} c_ig_i\right)\partial_\chi. \tag{29}$$

It should be noted that expressions for all coordinates in (29) can be obtained by the action of the following three recursive operators[41] L_i, $i=1,2,3$,

$$L_1=\begin{pmatrix} 0 & -(n/a)D_n \\ D_n & 0 \end{pmatrix},\quad L_2=\begin{pmatrix} 2nD_n-1 & (n/a)vD_n \\ -vD_n & 2nD_n \end{pmatrix},$$
$$L_3=\begin{pmatrix} 2nvD_n & n(v^2/2a-2n)D_n-n \\ (-v^2/2+2an)D_n+a & 2nvD_n+v \end{pmatrix}, \tag{30}$$

on the ''trivial'' operator with $f=\tau$ and $g=\chi$ (here, D_n is the operator of total differentiation with respect to n). Below, we present only three of these five second-order L–B operators,

$$f_7=n\tau_2,\ g_7=\chi_1+n\chi_2;$$
$$f_8=(1/2a)n[-\chi_1+v\tau_2-2n\chi_2],\ g_8=(1/2a)v\chi_1+n\tau_2+\frac{1}{2a}nv\chi_2; \tag{31}$$
$$f_9=(1/4)\tau-n\tau_1-(5/4a)vn\chi_1+(-n+(1/4a)v^2)n\tau_2-(1/a)vn^2\chi_2,$$
$$g_9=(3/4)v\tau_1-(2n-(1/4a)v^2)\chi_1+vn\tau_2+(-n+(1/4a)v^2)n\chi_2.$$

The procedure of restriction of the L–B group obtained on the solution of the BVP leads to expressions for $\overline{f}$ and $\overline{g}$ akin to (25),

$$\overline{f} = -\sum_{i=1}^{11} c_i f_i, \quad \overline{g} = -\sum_{i=1}^{11} c_i g_i. \tag{32}$$

Substitution of (32) in (29) yields additional terms in the expression (26) for the RG-operator R that depends on higher-order derivatives of τ and χ,

$$R = \sum_{i=1}^{11} c_i(a) R_i \equiv \sum_{i=1}^{11} c_i(a)((f_i - A^i)\partial_\tau + (g_i - B^i)\partial_\chi) \ . \tag{33}$$

Here functions A^i and B^i are given by the corresponding formulas for coordinates f_i and g_i to be evaluated on the solution $\overline{\tau}(n,v)$ and $\overline{\chi}(n,v)$. It appears that coordinates of L–B RG-operators are obtained from point RG-operators with the help of the above-mentioned recursive operators, hence, one can obtain L–B RG-operators of an arbitrary high order. Despite an unusual form, we still call them RG-operators since they possess the main property of RG-operators, namely, they contain a solution of the BVP in their invariant manifold.

The procedure of using L–B RG-operators is not as simple as for point RG-operators. Yet we can describe two possible ways.

Firstly, coordinates of canonical L–B RG-operators can be used to construct a set of relations, differential constraints, that are compatible with the original DEs and satisfy specific boundary conditions. The use of such constraints is described in Section VI. In the general case, for an arbitrary L–B group of a given order, coordinates of the corresponding canonical operator can be treated as a set of differential expressions, zero equalities for which impose appropriate restrictions on the basic DEs, consistent either with physical or with symmetry conditions. These equalities can also be treated as embedding equations (see Ref. 27).

Secondly, L–B RG-operators can be used to construct invariant solutions that automatically fit boundary conditions. It should be noticed that in some particular cases, L–B RG-symmetries can be constructed from a L–B group with a finite number of operators. For example, RG-symmetry for (9) with boundary conditions $V=0$ and $N=\cosh^{-2}(x)$ appear as a linear combination of three L–B symmetries,

$$R = (f_3 + 2(f_7 + f_9))\partial_\tau + (g_3 + 2(g_7 + g_9))\partial_\chi. \tag{34}$$

The desired solution of the BVP can be found as the invariant solution with respect to the RG-operator (34) and is presented by formulas (28).

The recipe of constructing the L–B renormgroup formulated in this section goes far beyond a simple illustrative example for the BVP (9). In a similar way, L–B RG-operators are constructed for different BVPs of mathematical physics that admit L–B symmetries; other examples are presented in Ref. 27 for the linear parabolic and modified Burgers equation. It is essential that when parameters entering into the equation and boundary conditions are involved in group transformations, coordinates of canonical L–B RG-operators contain not only first but higher-order derivatives with respect to these parameters. This means that in addition to recursive operators containing operators of total differentiation with respect to n [for BVP (9)], new recursive operators comprise operators of differentiation with respect to parameters, as well [$\propto D_\epsilon$ and D_a in the case of BVPs (11) and (10)].

V. RG DEVISING BASED ON EMBEDDING EQUATIONS

In this section we present a specific method of constructing RG-symmetries,[35,27] which is based on embedding equations.[30] It is of prime interest for physical systems described by ordinary differential equations (ODEs). In the context of the discussed model of quasi-Chaplygin media such equations arise, e.g., when constructing invariant solutions with respect to symmetries obtained. We demonstrate the idea of this method for the very simple BVP,

$$u_t = f(t,u,a) \ ; \quad t=\tau \ , \quad u=x \ . \tag{35}$$

Extension of the original differential manifold by adding, to the original equation, the embedding equation that appears as a linear first-order partial DE,

$$u_\tau + f(\tau,x,a)u_x = 0\,, \tag{36}$$

gives the desired RG-manifold, where u is now treated as the function of four variables $\{t,\ \tau,\ x,\ a\}$. Performing the group analysis for this RG-manifold involves boundary data and parameter a in group transformations, while the subsequent restriction of the group obtained on any solution of the BVP yields the desired RG-symmetries. We give two examples of such calculations for $f=au^2$ and $f=u^2+au^3$.

5.1. In the event of $f=au^2$ the RG-manifold (35)–(36) is given by two equations:

$$u_t = au^2\,, \quad u_\tau + ax^2u_x = 0, \tag{37}$$

that admit an infinite-dimensional Lie point algebra with five independent elements,

$$X=\sum_{i=1}^{5}\alpha_i X_i\,,$$

$$X_1=\partial_t+au^2\partial_u\,, \quad X_2=\partial_\tau+ax^2\partial_x\,, \tag{38}$$

$$X_3=u^2\partial_u\,, \quad X_4=x^2\partial_x\,, \quad X_5=x^2\tau\partial_x+u^2t\partial_u+\partial_a\,.$$

Here, functions α_1 and α_2 depend upon five variables $\{t,\ \tau,\ x,\ a,\ u\}$, whereas α_i, $i=3,4,5$ are arbitrary functions of three combinations $at+(1/u)$, $a\tau+(1/x)$, a.

The procedure of restriction of the group obtained leads to the invariance condition

$$U^2(\alpha_3+a\alpha_1+\alpha_5 t)-\alpha_1U_t-\alpha_2U_\tau-x^2(\alpha_4+a\alpha_2+\alpha_5\tau)U_x-\alpha_5U_a=0, \tag{39}$$

to be fulfilled on an exact or approximate solution $u=U(t,x,\tau,a)$ of the BVP (35)–(36); for example, one can take the perturbative solution as an expansion in powers of a,

$$u=U(t,x,\tau,a)\equiv x+ax^2(t-\tau)+O(a^2), \quad a\ll 1\,. \tag{40}$$

Substituting (40) into (39) shows that the invariance condition (39) is fulfilled for $\alpha_3=\alpha_4\equiv\alpha$ and arbitrary α_1,α_2, and α_5. Assuming $\alpha_1=\alpha_2=\alpha=0$ and $\alpha_5=1$ in (38) yields one of the RG-operators,

$$R=x^2\tau\partial_x+\partial_a+u^2t\partial_u\,, \tag{41}$$

which enables us to transform the perturbative solution of (35) for small $a\ll 1$ to the following exact solution:

$$u=\frac{x}{1-ax(t-\tau)}\,.$$

This result is found by solving the Lie equations, that correspond to the RG-operator (41).

5.2. For another value of the function $f=u^2+au^3$, the RG-operator that is similar to (41) is given as follows:

$$R=(x^2(1+ax)\tau+x)\partial_x+(u^2(1+au)t+u)\partial_u-a\partial_a\,. \tag{42}$$

The invariance condition for the solution of the BVP with respect to the RG-operator (42) has the form of the first order partial DE,

$$-(x^2(1+ax)\tau+x)u_x+au_a+u^2(1+au)t+u=0\,. \tag{43}$$

Solving the characteristic equations for (43) (Lie equations) yields the following exact solution of the BVP (35) with $f=u^2+au^3$:

$$t-\tau=\frac{1}{x}-\frac{1}{u}+a\ln\left|\frac{x}{u}\frac{(1+au)}{(1+ax)}\right| .$$

What all renormgroups obtained for the BVPs for the first-order ODE in the above examples have in common is that their operators depend upon arbitrary functions α_i, which means that RG can be expressed in terms of different RG-operators with various particular expressions for their coordinates. This situation is the same as that obtained for the BVP in the case of partial DE: different RG-operators yield the same unique specific solution of the given BVP contained in the invariant manifold of RG-operators. The previous procedure of RG constructing for the BVP for the ODE was based on the use of point groups. However, L–B groups can also be employed for constructing RG-symmetries for the first-order ODE, especially, in view of embedding equations (see the references in Ref. 27).

The structure of embedding equations depends not only on the form of the original equation, but also on the boundary conditions. This means that for given basic equations we may obtain different embedding equations. For example, if the function f in the r.h.s. of (35) depends upon x,

$$u_t=f(t,x,a,u)\ ; \quad t=\tau\ , \ u=x, \tag{44}$$

we arrive at the embedding equation

$$u_\tau+f(\tau,x,a,x)u_x=f(\tau,x,a,x) + \int_\tau^t d\ t' f_x(t',x,a,u(t'))\exp\left[-\int_t^{t'} d\ t'' f_u(t'',x,a,u(t''))\right] . \tag{45}$$

Hence, the RG-manifold in this case is defined by a system of integro-differential equations (44) and (45) and one should employ the modern group analysis techniques which give a possibility of analyzing such equations, as well.[49,50]

VI. RG AND DIFFERENTIAL CONSTRAINT

In the previous section RG-manifold was obtained by combining an original DE and an embedding equation. More generally instead of an embedding equation, an additional differential constraint can be used that satisfy two conditions: firstly, it must be compatible with the original DE and, secondly, it should explicitly take boundary conditions into account. This constraint naturally emerges when a coordinate of a canonical operator of the L–B RG admitted by BVP is assumed to be equal to zero. Adding this constraint to original equations we obtain the RG-manifold.

6.1. To illustrate, consider first a BVP (9) with $a=0$ which we rewrite using hodograph transformations in a simple form [compare with (10)]

$$\chi_n=0\ , \quad \chi_v+\tau_n=0\ . \tag{46}$$

L–B symmetries of this system of DEs are given by a canonical operator,

$$X=f\partial_\tau+g\partial_\chi, \tag{47}$$

with coordinates f and g depending upon v and derivatives $\tau_s+n\chi_{s+1}$, χ_s of an arbitrary order $s\geqslant 0$,

$$f=F(v,\chi_s,\tilde{\tau}_s)-n\left[\partial_v+\sum_{k=0}^{\infty}(\tilde{\tau}_{k+1}\partial_{\tilde{\tau}_s}+\chi_{k+1}\partial_{\chi_k})\right]G, \quad g=G(v,\chi_s,\tilde{\tau}_s)\ , \tag{48}$$

$$\tilde{\tau}_s=\tau_s+n\chi_{s+1}, \quad \tau_s=(\partial^s\tau/\partial v^s)\ , \quad \chi_s=(\partial^s\chi/\partial v^s)\ .$$

Consider a particular case of a BVP (9) with boundary conditions defined by $V(x)=-\varepsilon x$ and arbitrary $N(x)$. In terms of the variables τ and χ, these conditions are described, for example, by a pair of differential constraints,

$$\chi_{vv}=0\,,\quad \tau_{vv}-N_{vv}\chi_v-N_v\chi_{vv}=0\,. \tag{49}$$

Here the dependence of N upon x is given in terms of v with the use of the above boundary condition.

It is easily checked by direct substituting into (48) that left-hand sides of these equalities are the corresponding coordinates g and f of the second-order L–B symmetry operator (47). Adding differential constraints (49) to the original equation (46), we obtain the desired RG-manifold,

$$\chi_n=0\,,\quad \chi_v+\tau_n=0\,,\quad \chi_{vv}=0\,,\quad \tau_{vv}-N_{vv}\chi_v=0\,. \tag{50}$$

The latter admits a 17-parameter group of point transformations given by the following operators:

$$X=\sum_{i=1}^{m} c_iX_i\,,\quad m=17\,, \tag{51}$$

$$X_1=v^2\partial_v+v(2(n-N)+vN_v)\partial_n+(\chi(N-n)+\tau v)\partial_\tau+v\chi\partial_\chi,$$

$$X_2=v\chi\partial_v+(\chi(n-N)+v(\chi N_v-\tau))\partial_n+2\tau\chi\partial_\tau+\chi^2\partial_\chi,$$

$$X_3=-v\partial_v+(N-n-vN_v)\partial_n,\quad X_4=v\chi\partial_n-\chi^2\partial_\tau,$$

$$X_5=v\partial_n,\quad X_6=(N-n)\partial_n+\chi\partial_\chi,\quad X_7=(n-N)\partial_n+\tau\partial_\tau,$$

$$X_8=\partial_\tau,\quad X_9=v\partial_\tau,\quad X_{10}=(N-n)\partial_\tau+v\partial_\chi,$$

$$X_{11}=\partial_\chi,\quad X_{12}=\chi\partial_\tau,\quad X_{13}=-v^2\partial_n+v\chi\partial_\tau.$$

$$X_{14}=-\partial_v-N_v\partial_n,\quad X_{15}=\partial_n,\quad X_{16}=\chi\partial_n,\quad X_{17}=-\chi\partial_v+(\tau-\chi N_v)\partial_n.$$

The usual procedure of restriction of the group obtained on a solution of the BVP (46) relates different coefficients in the sum (51) and gives the desired RG-operators,

$$R=\sum_{i=1}^{13} c_iR_i\,, \tag{52}$$

$$R_1=X_1,\quad R_2=X_2,\quad R_3=X_3+\varepsilon X_{17},\quad R_4=X_4,$$

$$R_5=X_5+\epsilon X_{16},\quad R_6=X_6+\varepsilon X_{17},\quad R_7=X_7+\varepsilon X_{16},$$

$$R_8=X_8+\varepsilon X_{15},\quad R_9=X_9-\varepsilon^2X_{16},\quad R_{10}=X_{10}-\varepsilon^2X_{17},$$

$$R_{11}=X_{11}+\varepsilon X_{14},\quad R_{12}=X_{12}+\varepsilon X_{16},\quad R_{13}=X_{13}.$$

The exact solution of the BVP $\chi=-v/\varepsilon$, $\tau=(1/\varepsilon)(n-N)$ is found either by solving Lie equations corresponding to any of these RG-operators, or as the intersection of all invariant manifolds.

6.2. Now let us turn to a general case of a BVP (9) with $a\neq 0$. We shall consider the problem of constructing RG-symmetries using the RG-manifold given by basic equations in the form (10)

and the most simple differential constraint yielded by the linear combination of the second-order L–B symmetry (31) f_7, g_7 and trivial infinite-dimensional symmetry $f_\infty=0$, $g_\infty=-1$,

$$a\tau_v-n\chi_n=0\,,\quad \chi_v+\tau_n=0\,,\quad n\tau_{nn}=0\,,\quad \chi_n+n\chi_{nn}-1=0\,. \tag{53}$$

This differential constraint describes, in particular, a linear dependence of N upon x and $V(x)=0$. The Lie point group admitted by the RG-manifold (53) is characterized by seven infinitesimal operators [use the formula (51) for $m=7$],

$$X_1=-2v\partial_v-4n\partial_n-6n(v/a)\partial_\tau+(2\chi-6n+3v^2/a)\partial_\chi,$$

$$X_2=v\partial_v+2n\partial_n+(\tau+2nv/a)\partial_\tau+(2n-v^2/a)\partial_\chi,\quad X_3=\partial_v\,,$$

$$X_4=n\partial_\tau-v\partial_\chi,\quad X_5=(v/a)\partial_\tau+\ln n\partial_\chi,\quad X_6=\partial_\tau,\quad X_7=\partial_\chi\,.$$

The restriction of this group on the solution of the BVP with the above-mentioned boundary conditions leads to the three-parameter RG,

$$R_1=X_1,\quad R_2=X_2,\quad R_3=aX_3+X_4.$$

As in the previous case, the exact solution of the BVP $\tau=nw$, $\chi=n-aw^2/2$ appears as an intersection of all invariant manifolds that correspond to these RG-operators.

The characteristic feature of the described approach is the formulation of boundary data in the form of a differential constraint and the subsequent search of the group admitted by this constraint and basic equations. It is evident that there exists an infinite number of other differential constraints that adequately describe the same boundary data and the use of which leads to different RG algebras. As an example, we can point to differential constraints that arise from the zero equality of appropriate coordinates of the infinite L–B algebra.

The example of RG-symmetry constructing on the basis of L–B symmetry reveals the practical importance of the latter and, on the other hand, demonstrates point symmetries that are not admitted by the original equation. The procedure of construction of RG-symmetries with the help of a differential constraint was also carried out in Ref. 37 for the linear parabolic equation.

VII. RG AS A SUBGROUP OF AN APPROXIMATE SYMMETRY GROUP

An attractive method of RG constructing is that based on approximate symmetries.[31] This method can be applied to systems described in terms of models based on DEs with small parameters. These small parameters allows us to consider a simple subsystem of the original DEs that usually admits an extended symmetry group inherited by the original DEs. Restricting this approximate group on the solution of the BVP yields the desired RG-symmetries. The merits of the described method is illustrated below for the BVP (9) with a small nonlinearity parameter $a\ll 1$. In terms of the variable $w=v/a$ the following basic system of linear DEs is obtained instead of (10):

$$\tau_w-(n/\varphi(n))\chi_n=0\,,\quad \chi_w+a\tau_n=0\,. \tag{54}$$

For $a=0$, it admits an infinite L–B symmetry group,

$$X=f\partial_\tau+g\partial_\chi, \tag{55}$$

characterized by an arbitrary dependence of the zeroth-order coordinates $f=f^0$ and $g=g^0$ upon n, τ, χ, and the derivatives $\widetilde{\tau}_s$, χ_s of an arbitrary order,

$$f^0=F^0+\int dw\{(n/\varphi)Yg^0\},\quad g^0=G^0\,. \tag{56}$$

Here and below in (57),

$$Y=\partial_n+\sum_{s=0}^{\infty}\left(\tau_{s+1}\partial_{\tau_s}+\chi_{s+1}\partial_{\chi_s}\right),$$

$$\tau_s=\frac{\partial^s\tau}{\partial n^s},\quad \chi_s=\frac{\partial^s\chi}{\partial n^s},\quad \tilde{\tau}_s=\tau_s-w\sum_{p=0}^{s}\binom{s}{p}\frac{\partial^p(n/\varphi)}{\partial n^p}\chi_{s-p+1},$$

$F^i(n,\chi_s,\tilde{\tau}_s)$ and $G^i(n,\chi_s,\tilde{\tau}_s)$ are arbitrary functions of their arguments, and expressions in curly brackets before integrating over w should be given in terms of $\tilde{\tau}_s$, χ_s, n, w.

For $0<a\ll 1$, this symmetry is inherited as an approximate one by equations (54) which thus represent an approximate RG-manifold. For example, for $\varphi(n)=1$ the following result is obtained:

$$f^i=F^i+\int dw\left\{Zf^{i-1}+nYg^i\right\},\quad g^i=G^i+\int dw\{Zg^{i-1}-Yf^{i-1}\},$$
$$Z=\sum_{s=0}^{\infty}\tau_{s+1}\partial_{\chi_s},\quad \tilde{\tau}_s=\tau_s-w(n\chi_{s+1}+s\chi_s),\quad i\geqslant 1. \tag{57}$$

One can see that the symmetry of equations (54) for $a=0$ is inherited by the symmetry of these equations for $a\neq 0$ up to an arbitrary order of this parameter. It should be noticed that both zeroth-order and higher-order approximate symmetries may appear as Lie point symmetries or L–B symmetries, and this parameter may be involved in group transformations as well.

The restriction of the approximate group obtained on a particular solution of the BVP defines the specific form of the zeroth-order symmetries. It means that while constructing RG-symmetries for the BVP (54) in view of the boundary data from (9), coordinates f^0, g^0 and ''integration constants'' F^i, G^i, $i\geqslant 1$ are not arbitrary functions, but should be chosen so that relations $f=0$, $g=0$ satisfy desired boundary conditions $\tau_s=0$, $\chi=H(n)$ at $w=0$. Provided that the functions F^i and G^i, $i\geqslant 1$ are also equal to zero in this case, boundary conditions are correlated with the form of functions f^0 and g^0. In general, invariance conditions $f=0$ and $g=0$ appear as differential constraints (or algebraic relations) to be fitted by boundary data.

Of special interest are such zeroth-order functions f^0 and g^0 for which infinite series (57) are truncated for some finite value of $i=i_{max}$, and we arrive at finite sums. In this case, instead of an approximate group with respect to a small parameter a we obtain the exact symmetry group (compare with Ref. 31, Sec. 11). A simple example of this is given by the RG-operator (34). It is easily checked that in terms of n and w, the combinations of coordinates $f_3+2(f_7+f_9)$ and $g_3+2(g_7+g_9)$ are expressed as a binomial in a, i.e., expressions for f and g are represented as zeroth-order and first-order terms $f=f^0+af^1$ and $g=g^0+ag^1$, where f^0, g^0 and f^1, g^1 according to (56) and (57) are defined by the formulas

$$f^0=2n(1-n)\tau_2-n\tau_1-2nw(\chi_1+n\chi_2),$$
$$g^0=2n(1-n)\chi_2+(2-3n)\chi_1, \tag{58}$$
$$f^1=\tfrac{1}{2}nw^2\tau_2,\quad g^1=2nw\tau_2+w\tau_1+\tfrac{1}{2}(nw^2\chi_2+w^2\chi_1).$$

From here, in view of (57), it follows that higher-order corrections vanish, and we obtain an exact second-order L–B symmetry of DEs (54) at $\varphi=1$ for arbitrary $a\neq 0$; this symmetry gives rise to the exact solution[38,39] satisfying the boundary condition $N=\cosh^{-2}(x)$ defined by the zeroth-order term g^0.

The arbitrariness in functions f^0, g^0 enables us to construct RG-symmetries for any boundary conditions. As an illustration, we present RG-symmetries for the BVP with

$$H(n)=(\ln(1/n))^{1/2}\,, \tag{59}$$

describing space evolution (self-focusing) of the Gaussian beam with the originally plane phase front at $\tau=0$. To satisfy the initial distribution (59), one can choose the following functions $f^0=1+2n\chi\chi_1$ and $g^0=0$. For this value of f^0 the inherited point group of the BVP is constructed with the help of formulas (57) and is given by the operator

$$R=-2\chi\partial_w+2a\tau\partial_n+\left(1+\frac{a\tau^2}{n}\right)\partial_\tau. \tag{60}$$

The invariance condition for the solution of the BVP with respect to RG with this operator is presented in the form of two partial DEs,

$$\chi\chi_w-a\tau\chi_n=0\,,\quad 2\chi\tau_w-2a\tau\tau_n+1+(a\tau^2/n)=0\,,$$

the solution of which yields the desired approximate analytical solution of the problem

$$x^2=(ant^2-\ln n)[1-2Q(\sqrt{ant^2})]^2\,,\quad v=-2\frac{x}{t}\,\frac{Q(\sqrt{ant^2})}{[1-2Q(\sqrt{ant^2})]}\,. \tag{61}$$

Here the function $Q(z)$ is expressed as follows:

$$Q(z)=ze^{-z^2/2}\int_0^z dt\ e^{t^2/2}\,.$$

The first-order approximate symmetry obtained can be used to calculate a higher-order approximation of the RG-operator (60) and, thus, to improve the analytical solution (61). One can also obtain new-type RG-operators just by substituting the approximate solution (61) into formulas (27).

VIII. CONCLUSION

In this paper we present a new approach to constructing RG-symmetries based on the mathematical apparatus of classical and modern group analysis. It differs from the traditionally used methods of constructing RGs in theoretical physics and is formulated as a sequence of the following steps

(I) *Constructing the RG-manifold*, that takes into account both basic equations and the corresponding boundary conditions.

(II) *Calculating the symmetry group*, admitted by the RG-manifold.

(III) *Restricting the group* obtained *on the solution of the BVP*.

(IV) Utilizing the RG-operators to *find analytical expressions for solutions*.

As it was shown there exists a set of different algorithms for finding RG-symmetries. The choice of a particular one for a given physical problem depends on a mathematical model used for the problem description.

It should be noted that different methods of constructing RG-symmetries described above do not exhaust the suggested approach (see, e.g., Refs. 42, 43). The procedure of constructing RG-symmetries may combine different algorithms; for example, of interest is a simultaneous use of the method based on approximate symmetries and the invariant embedding method, and so on.

Our approach reveals a close relation of the *functional self-similarity* property (i.e., ''classical'' RG–symmetry as an exact property of a solution) to an invariance condition of a BVP solution with respect to the RG-operator. Mathematically, the latter is formulated as the vanishing condition for the coordinate of a canonical RG-operator on a solution of BVP.

One can readily see that RG-operators may appear in the form that is different from the QFT case,[6] e.g., operators of Lie–Bäcklund RG-symmetries. However, in some cases ''our'' RG-operators can look like the ones in the QFT renormalization group. For example, a linear combination of operators α_1X_1 and $\alpha_3(X_3+X_4)$ for the BVP (35) with $\alpha_1=1$, $\alpha_3=-a$ gives

$$R = \partial_t - ax^2\partial_x, \tag{62}$$

which is formally equivalent [with an appropriate change of variables $t = \ln x$, $x = g$ and $\beta(g) = ag^2$] to the differential operator for the one-coupling massless QFT model in the one-loop approximation.

Up to now this approach is feasible for systems that can be described by DEs and is based on the formalism of modern group analysis.

It seems also possible to extend our approach on physical systems that are not described just by differential equations. A chance of such an extension is based on recent advances in group analysis of systems of integro-differential equations[49,50] that allow transformations of both dynamical variables and functionals of a solution to be formulated.[47] More intriguing is the issue of a possibility of constructing a regular approach for more complicated systems, in particular to that ones having an infinite number of degrees of freedom. The former can be represented in a compact form by functional integrals (or *path integrals*).

One finds the moduli spaces of isocurved homogeneous metrics on S^3. Then, one determines the germs of three-dimensional analytic metrics with a spherical homogeneous model. © *1998 American Institute of Physics.* [S0022-2488(98)00202-3]

I. INTRODUCTION

Assume $(\mathbf{M}_0,\mathbf{g}_0)$ is a homogeneous pseudo-Riemannian manifold of curvature tensor field ${}_0\mathbf{R}$. Following Ref. 1, we will say that $(\mathbf{M}_0,\mathbf{g}_0)$ is a *homogeneous model* of $(\mathbf{M},\mathbf{g})$ if for each point $\mathbf{p}$ in $\mathbf{M}$, there is a point $\mathbf{p}_0$ in $\mathbf{M}_0$ and an isometry $\mathbf{F}:\mathbf{T}_p\mathbf{M}\to\mathbf{T}_{p_0}\mathbf{M}_0$ such that $\mathbf{F}^*{}_0\mathbf{R}_{p_0}=\mathbf{R}_p$, where $\mathbf{R}$ is the curvature tensor field of $\mathbf{M}$.

In this paper one is concerned with those germs of analytic manifolds whose homogeneous model $\mathbf{M}_0$ is $\mathbb{S}^3$.

In Sec. II, based on the $\mathfrak{h}$-triples algorithm in Ref. 2 and of the list of invariant Lorentz structures on three-dimensional unimodular Lie groups in Ref. 3, one takes care of the homogeneous spherical model, that is the moduli space of homogeneous Lorentz structures on $\mathbb{S}^3$; this is a three-dimensional stratified set, slightly more complicated than its Riemannian analog:[4] Let α be the action of $\mathbb{Z}_2$ on the first quadrant of $\mathbb{R}^2$, generated by the symmetry about the diagonal. Let Q be the quotient space $\mathbb{R}_+{}^2/\alpha$ and $L=Q\times(0,\infty)$. A point λ in L has a unique representative, $(\lambda_1,\lambda_2,\lambda_3)\in\mathbb{R}^3$, $\lambda_1\geqslant\lambda_2>0$, $\lambda_3>0$.

Let $\sigma=\sigma^1e_1+\sigma^2e_2+\sigma^3e_3$ be the dual form of the unit quaternions, which is given in real coordinates of a point $\mathbf{x}$ in $\mathbb{S}^3\subseteq\mathbb{R}^4$ is by

$$\begin{aligned}\sigma^1&=-x^2dx^1+x^1dx^2-x^4dx^3+x^4dx^3,\\ \sigma^2&=-x^3dx^1+x^4dx^2-x^1dx^3+x^2dx^4,\\ \sigma^3&=-x^4dx^1+x^3dx^2-x^2dx^3+x^1dx^4.\end{aligned}\tag{1.1}$$

Theorem 1.1: *There is a one to one map* $\mathbf{G}$ *from* L *onto isometry classes of homogeneous Lorentz structures on* $\mathbf{S}^3$, *given by* $\mathbf{G}(\lambda)=$ *isometry class of* $\mathbf{g}_\lambda$,

$$\mathbf{g}_\lambda=4((\lambda_2\lambda_3)^{-1}\sigma_1^2+(\lambda_3\lambda_1)^{-1}\sigma_2^2-(\lambda_1\lambda_2)^{-1}\sigma_3^2).\tag{1.2}$$

The dimension of the total isometry group I_λ *of* $(\mathbf{S}^3,\mathbf{g}_\lambda)$, is 4, *when* $\lambda_1=\lambda_2$, *respectively*, 3 *when* $\lambda_1\neq\lambda_2$.

We shall also prove:

Theorem 1.2: (a) *The local geometry of a homogeneous Lorentz structure* $\mathbf{g}$ *on* $\mathbf{S}^3$ *is uniquely determined by the value at one point of the curvature tensor, whenever zero is a regular value of the Ricci operator.*

(b) *Assume zero is one of the principal Ricci curvatures of a homogeneous Lorentz structure on* $\mathbb{S}^3$. *Then zero is a double root of the Ricci polynomial, and the third principal Ricci curvature is a positive constant* k^2. *For each positive* k, *there is a one-parameter family of nonisometric homogeneous Lorentz structures on* $\mathbb{S}^3$, *with same curvature tensor of Ricci spectrum* $(\mathbf{0},k^2,\mathbf{0})$.

Assume (**M**,**g**) has a spherical model. In this case **g** is a *curvature homogeneous* (**ch**) metric on **M**, that is, its curvature tensor field is punctually self-equivalent. In dimension 3, a curvature tensor is uniquely determined by its Ricci tensor. The Ricci operator is self-adjoint and in the Lorentz case there are four types of Ricci tensors,[5–7] among which those that are diagonalizable w.r.t. an orthobasis are said to be of *type I*. Three-dimensional chR metrics with a generic Ricci tensor, have been studied in Refs. 8–12. The nongeneric three-dimensional Lorentz case was investigated in Refs. 13–15.

Using the technique of homotopy operators,[12] one may determine the structure of chL generic metrics in general, but homogeneous Lorentz structure on $\mathbb{S}^3$ have a type I Ricci tensor, as shown in Sec. II. As such in Sec. III, we prove the following.

Theorem 1.3: *Assume* **R** *is a generic Ricci tensor of type I. Then the space of germs of analytic ch metrics whose Ricci spectrum is* **R**, *depends on three functions of three variables and three functions of two variables*. This result also holds in the generic Riemannian analytic case; for other less general, still more definitive results, see Ref. 16, where the ''local moduli space'' of such metrics depends on functions in one variable only. Notice that the topologies of **M** and its model may differ drastically. It suffices to recall examples of complete noncompact manifolds with a compact homogeneous model.[15,17] All these examples have a nongeneric Ricci tensor. Bryant conjectured that there are no nonhomogeneous chR metric on $\mathbb{S}^3$, of a nongeneric Ricci tensor.[9] ■

II. HOMOGENEOUS METRICS ON $\mathbb{S}^3$

A partial classification of isometry groups of compact Lorentz manifolds has been given in Ref. 18 based on some previous results of D'Ambra.[19] Yet, even for three-dimensional compact manifolds **M**, despite new techniques, such as those of flows introduced in Ref. 20, the homogeneous Lorentz metrics on $\mathbb{S}^3$, with a multiply transitive group of isometries were omitted.

In this section we classify homogeneous Lorentz structures on $\mathbb{S}^3$. The metric classification of homogeneous Riemannian structures on $\mathbb{S}^3$, is given in Ref. 4. Our approach differs also from the classical characterization of Killing vector fields.[21]

Assume **g** is a homogeneous Lorentz metric on $\mathbb{S}^3$. From Ref. 18, one may infer that the isometry group **K** of $(\mathbb{S}^3,\mathbf{g})$ is compact. As such, the isotropy group **H** is a compact subgroup of $SO(2,1)$, thus being trivial or isomorphic to $SO(2)$. By considering the Levi decomposition, one sees that up to finite covers, **K** is isomorphic to $\mathbb{S}^3$ or to $\mathbb{S}^3\times\mathbb{S}^1$, since tori do not fiber over $\mathbb{S}^3$.

In order to determine the moduli space of **K**-invariant Lorentz metrics on $\mathbb{S}^3=\mathbf{K}/\mathbf{H}$, we will use the technique of $\mathfrak{h}$-triples introduced in Ref. 2. There $\mathfrak{h}$ stands for the Lie algebra of **H**.

Assume the restriction of the Killing form of $\mathfrak{o}(2,1)$ to $\mathfrak{h}$ is nondegenerated; then $\mathfrak{h}^\perp$ is the orhtocomplement of $\mathfrak{h}$ in $\mathfrak{o}(2,1)$ is w.r.t. the Killing form.

Let $\boldsymbol{\nabla},\boldsymbol{\nabla}^0$ be Levi-Civita and Ambrose–Singer (canonical) connection on $(\mathbb{S}^3,\mathbf{g})$, and let **G** be their difference tensor $\boldsymbol{\nabla}-\boldsymbol{\nabla}^0$. If **p** is a point of $\mathbb{S}^3$, **G** yields a map $\mathbf{G}_p:\mathbf{T}_p\mathbb{S}^3\to\mathrm{End}\,\mathbf{T}_p\mathbb{S}^3$, and if one selects an orthoframe $\mathbf{u}=(\mathbf{u}_1,\mathbf{u}_2,\mathbf{u}_3)$ in $\mathbf{T}_p\mathbb{S}^3$, one may identify $\mathbf{G}_p$ with the so-called *Cartan–Singer map* $\Gamma:\mathbb{R}^3\to\mathfrak{h}^\perp$.[2]

With respect to the splitting $\mathfrak{o}(2,1)=\mathfrak{h}\oplus\mathfrak{h}^\perp$, the curvature at **p** has the components

$$\overline{\Omega}:\mathbb{R}^3\times\mathbb{R}^3\to\mathfrak{h}$$

and

$$\Omega_\perp=[\Gamma(X),\Gamma(Y)]_{\mathfrak{h}^\perp}+\Gamma(T(X,Y)), \tag{2.1}$$

where $[\ ,\ ]_{\mathfrak{h}^\perp}$ is the $\mathfrak{h}^\perp$ part of the commutator and

$$T(X,Y)=\Gamma(Y)X-\Gamma(X)Y.$$

The curvature operator at **p** is

$$\hat{\Omega}=\overline{\Omega}\oplus\Omega_\perp. \tag{2.2}$$

The Ricci form associated with $(\mathfrak{k},\mathbf{E})$ is the bilinear symmetric form $\rho:\mathbb{R}^3\times\mathbb{R}^3\to\mathbb{R}$, given by

$$\rho(\mathbf{e}_i,\mathbf{e}_j)=\mathrm{Tr}(\mathbf{x}\to\hat{\Omega}(\mathbf{x},\mathbf{e}_i)\mathbf{e}_j), \tag{2.3}$$

and the *Ricci polynomial* Ric is defined by

$$\mathrm{Ric}(t)=\det(\boldsymbol{\rho}(\mathbf{e}_i,\mathbf{e}_j)-t\ {}_1\delta_{ij}), \tag{2.4}$$

where ${}_1\delta_{1j}=\delta_{1j}$ for $i=1,2$ and ${}_1\delta_{3j}=-\delta_{3j}$; Ric(**t**) is a local metric invariant of **g**.

Another such invariant is $\|\Gamma\|^2$, the *square pseudonorm* of the Cartan–Singer map (see Ref. 4, for the Riemannian case),

$$\|\Gamma\|^2={}_1\delta^{ij}k(\Gamma(\mathbf{e}_i),\Gamma(\mathbf{e}_j)), \tag{2.5}$$

where Einstein's summation convention applies.

We recall that $\mathbf{f}^i_j=\mathbf{E}^i_j-{}_1\delta_{1j}\mathbf{E}^j_i$, where $\mathbf{E}^i_j(\mathbf{e_k})=\delta^i_{\mathbf{k}}\mathbf{e}_j$, $1\leqslant j<i\leqslant 3$, is a basis of $\mathfrak{o}_1(3)$.

(a) *Assume* $\mathbf{H}=\mathbb{S}^1$, and select an orthoframe **u** at **p**, such that $\mathbb{S}^1$ fixes $\mathbf{u}_3$, that is, $\mathfrak{h}=\mathfrak{o}(2)$.

Straightforward computations based on this $\mathfrak{h}$-triple technique, show that

$$\begin{gathered}\Gamma(e_1)=b\mathbf{f}^3_2,\quad \Gamma(e_2)=-b\mathbf{f}^3_1,\quad \Gamma(e_3)=0,\\ \overline{\Omega}(e_1,e_2)=\Omega_{12}\mathbf{f}^2_1,\quad \overline{\Omega}(e_1,e_3)=\overline{\Omega}(e_2,e_3)=\mathbf{0},\quad \Omega_{12}>3b^2,\quad b\neq 0,\end{gathered} \tag{2.6}$$

and one finds the following Ricci polynomial:

$$\mathrm{Ric}(t)=(t+2b^2)(t+b^2-\Omega_{12})^2. \tag{2.7}$$

Note that the restriction of the action of $\mathbf{K}=\mathbb{S}^1\times\mathbb{S}^3$ on $\mathbb{S}^3$ to $\mathbb{S}^1\times 1$ is not trivial. At Lie algebra level, $\mathfrak{k}$, the Lie algebra of **K** is isomorphic to $(\mathfrak{o}(2)\oplus\mathbb{R}^3,[\ ,\ ])$, where the bracket $[\ ,\ ]$ is defined by

$$\begin{gathered}[\mathbf{e}_1,\mathbf{e}_2]=2b\mathbf{e}_3+(b^2-\Omega_{12})\mathbf{f}^2_1,\quad [\mathbf{e}_1,\mathbf{e}_3]=b\mathbf{e}_2,\\ [\mathbf{e}_2,\mathbf{e}_3]=-b\mathbf{e}_1,\quad [\mathbf{f}^2_1,\mathbf{e}_1]=-\mathbf{e}_2,\\ [\mathbf{f}^2_1,\mathbf{e}_2]=\mathbf{e}_1,\quad [\mathbf{f}^2_1,\mathbf{e}_3]=0.\end{gathered} \tag{2.8}$$

The last three equations in (2.8) stand for the linear isotropic representation of $\mathbb{S}^1\times\mathbf{1}$ on $\mathbf{T}_1\mathbb{S}^3$.

On the other hand, $\mathrm{Span}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3+(2b)^{-1}(b^2-\Omega_{12})\mathbf{f}^2_1)$ is a transitive Killing subalgebra of $\mathfrak{k}$ isomorphic to $\mathfrak{o}(3)$, showing that the homogeneous metric of $\mathbb{S}^3$ is actually a left-invariant metric on $\mathbb{S}^3$ regarded as a Lie group.

(b) *Assume* now $\mathfrak{h}=0$, that is, we look for left-invariant Lorentz metrics **g** on $\mathbb{S}^3$. Set $\mathbf{p}=\mathbf{1}_{\mathbb{S}^3}$. Using a unimodular-type argument (Ref. 3 or 5), it follows that there a **g** orthoframe $\mathbf{u}=(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)$ of the Lie algebra of $\mathbb{S}^3$, w.r.t. which the structure equations take the form

$$[\mathbf{e}_1,\mathbf{e}_2]=\lambda_3\mathbf{e}_3,\quad [\mathbf{e}_2,\mathbf{e}_3]=\lambda_1\mathbf{e}_1,\quad [\mathbf{e}_3,\mathbf{e}_1]=\lambda_2\mathbf{e}_2, \tag{2.9}$$

with positive $\lambda-s$. W.l.o.g. one may assume that $\lambda_1\geqslant\lambda_2>0$, $\lambda_3>0$. Indeed, if $\lambda_1<\lambda_2$, we set $\mathbf{e}'_1=\mathbf{e}_2$, $\mathbf{e}'_2=\mathbf{e}_1$, $\mathbf{e}'_3=-\mathbf{e}_3$, and then get an orthobasis $(\mathbf{e}'_1,\mathbf{e}'_2,\mathbf{e}'_3)$ that satisfies similar equations with structure constants λ' such that $\lambda'_1>\lambda'_2$.

u extends to a global moving frame on $\mathbb{S}^3$, and by the moving frame method, one may determine the components of the Ricci curvature w.r.t. this frame field. We set

$$\lambda_3=\mu_1-\mu_2,\quad \lambda_1=\mu_2-\mu_3,\quad \lambda_2=-\mu_1-\mu_3. \tag{2.10}$$

The Cartan–Singer map is

$$\Gamma(\mathbf{e}_1)=\mu_1\mathbf{f}^3_2,\quad \Gamma(\mathbf{e}_2)=\mu_2\mathbf{f}^3_1,\quad \Gamma(\mathbf{e}_3)=\mu_3\mathbf{f}^2_1. \tag{2.11}$$

Then, up to a permutation of the indices, the possible nonzero components of the Riemannian curvature tensor are

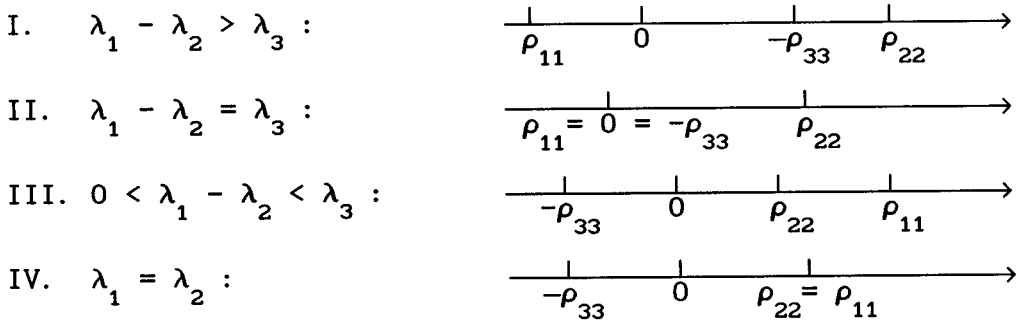
$$R^1_{212}=-\mu_1\mu_2-\mu_3\lambda_3,\quad R^1_{313}=-\mu_1\mu_3+\mu_2\lambda_2,\quad R^2_{323}=\mu_2\mu_3-\mu_1\lambda_1. \tag{2.12}$$

Our basis diagonalizes the Ricci curvature:

$$\rho_{11}=2\mu_2\mu_3,\quad \rho_{22}=-2\mu_1\mu_3,\quad \rho_{33}=-2\mu_1\mu_2. \tag{2.13}$$

We are ready for the following proof.

Proof of Theorem 1.1: We have noticed that the set of roots of the Ricci polynomial is an invariant of the isometry class of a given homogeneous Lorentz manifold. If M is the geometric realization of a **0**-triple, defined by $\lambda\in L$, this set is $\Sigma=\{\rho_{11},\rho_{22},-\rho_{33}\}$. The relative position of the elements in Σ on the real line is shown below:



We proved the following.

Proposition 2.1: The Ricci tensor of a homogeneous Lorentz metric on $\mathbb{S}^3$ is of type I. In the generic situation, the Ricci operator has two negative eigenvalues, whose eigenvectors are one spatial and the other temporal, and the third eigenvalue is positive.

We would like to identify those Lorentz–Lie group structures on $\mathbb{S}^3$, with a nontrivial isotropy group of isometries. The Killing algebra $\mathfrak{k}(\mathbb{S}^3,\mathbf{g})$ is four dimensional. From (2.7), it follows that in this case there are some constants b, Ω_{12}, with $\Omega_{12}-3b^2>0$, and the Ricci polynomial has one positive double root $\Omega_{12}-b^2$, and one nonpositive simple root $-2b^2\leqslant 0$. We compare with the above chart; this may happen only when we are in case IV, and $\rho_{11}=\rho_{22}=\Omega_{12}-b_2$, $\rho_{33}=2b^2$. Then $\lambda_1=\lambda_2=(\Omega_{12}-3b^2)/2b$, $\lambda_3=2b$, which shows that our Killing algebra is indeed isomorphic to the subalgebra $\mathrm{Span}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3+(2b)^{-1}(b^2-\Omega_{12})\mathbf{f}_1^2)$ of $\mathfrak{k}$ in (2.8).

We consider now the other cases I, II, III. If $\lambda,\lambda'\in\Lambda$, define two 0-triples, whose geometric realizations are locally isometric geometric models, an inspection of their equal Ricci spectra Σ,Σ', shows that either (a) λ,λ' are in the same case; or (b) λ is in case I and λ' is of case III.

Let us examine (b) first. Then the chart shows that

$$\rho_{11}=-\rho'_{33},\quad \rho_{22}=\rho'_{11},\quad \rho_{33}=-\rho'_{22}.$$

This is

$$\mu_2\mu_3=\mu'_1\mu'_2,\quad \mu_1\mu_3=\mu'_2\mu'_3,\quad \mu_1\mu_2=-\mu'_1\mu'_3.$$

We manipulate these equalities and find $\mu_1^2=\mu_3'^2$, $\mu_2^2=\mu_1'^2$, $\mu_3^2=\mu_2'^2$, or $\mu_1=\mu'_3$, $\mu_2=\mu'_1$, $\mu_3=-\mu'_2$, and from here $-\lambda_3=\lambda'_1+\lambda'_3$, which yields a contradiction, since both sides are positive.

It is obvious that if both λ,λ' are in same case, I, or III, then $\Sigma=\Sigma'$ implies $\mu=\mu'$. That is, $\lambda=\lambda'$.

We are left with the case when λ,λ' are both in case II. Then by (2.11), the corresponding Cartan–Singer maps are defined by

$$\Gamma(\mathbf{e}_1)=\mu_1\mathbf{f}_2^3,\quad \Gamma(\mathbf{e}_2)=0,\quad \Gamma(\mathbf{e}_3)=\mu_3\mathbf{f}_1^2,$$

$$\Gamma'(\mathbf{e}_1)=\mu'_1\mathbf{f}_2^3,\quad \Gamma'(\mathbf{e}_2)=0,\quad \Gamma'(\mathbf{e}_3)=\mu'_3\mathbf{f}_1^2,$$

and are $\mathbf{0}_1(3)$ conjugated. The square pseudonorms of Γ and Γ' being equal, it turns out that $\mu_1{}^2+\mu_3{}^2=\mu_1'{}^2+\mu_3'{}^2$. But in case II, $\mu_1=\lambda_3$, $\mu_3=-\lambda_1$, the nonzero Ricci curvature is $2\lambda_1\lambda_3$, and $\lambda_2=\lambda_1-\lambda_3$ is positive. As such, we have

$$\lambda_1{}^2+\lambda_3{}^2=\lambda_1'{}^2+\lambda_3'{}^2,\lambda_1\lambda_3=\lambda_1'\lambda_3', \quad \lambda_1>\lambda_3, \quad \lambda_1'>\lambda_3'. \tag{2.14}$$

The identities (2.14) clearly imply that $\lambda=\lambda'$.
The structure equations expressed in the dual coframe are

$$d\theta^1+\lambda_1\theta^2\wedge\theta^3=0, \quad d\theta^2+\lambda_2\theta^3\wedge\theta^1=0, \quad d\theta^3+\lambda_3\theta^1\wedge\theta^2=0, \tag{2.15}$$

we may find constants α_i, $i=1,2,3$ such that after the transformation $\theta^i=\alpha_i\sigma^i$, we obtain in the σ's some equations of the form (2.15) where all the coefficients of $\sigma^i\wedge\sigma^j$ are 2. Up to a diffeomorphism these are the dual forms of the moving frame that trivializes $\mathbf{T}S^3$ given in (1.1). ■

Proof of Theorem 1.2. Part a: Since $\mathbf{0}$ is not a Ricci principal curvature, we are in one of the cases I, III, or IV outlined in the previous proof. Due to (2.11), it follows that if I or III holds true, then $\hbar=\mathrm{Span}\,(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)$ is the Lie algebra of $\mathbf{I}(\mathbf{M})$. In each of these cases, we have seen in the previous proof that the curvature tensor uniquely determines the parameters λ, and therefore the geometries are determined by the curvature at one point. In case IV, the two distinct Ricci principal curvatures, ρ_{11} and ρ_{33}, uniquely determine the parameters Ω_{12} and b, as shown in the analysis of this case does in the proof of Theorem 1. These two parameters ''separate'' two such nonisometric Lorentz manifolds.

Part b. It is obvious from the chart in the proof of Theorem 1.1 that simple Ricci principal curvatures cannot occur. If the Ricci curvature operator has a zero eigenvalue, then we are in case II of the aforementioned chart, and the third eigenvalue is positive, say k^2. Assume the Lorentz–Lie groups have the Ricci spectrum $(\mathbf{0},k^2,\mathbf{0})$. The group is unimodular and all the nonzero components curvatures [see (3.4)] are determined by $k^2=\rho_{22}=\lambda_3(\lambda_2+\lambda_3)$. Therefore no other restriction on λ_2,λ_3 is imposed if this Lorentz Lie group has a homogeneous model in curvature with the Ricci spectrum $(\mathbf{0},k^2,\mathbf{0})$. From Theorem 1.1, it follows that for each t in $(\mathbf{0},k)$, there is a unique unimodular Lorentz Lie group, which is itself a total isometry group, corresponding with λ in L with

$$(\lambda_1,\lambda_2,\lambda_3)=\left(\frac{k^2}{t},\ \frac{k^2}{t}-t,t\right).$$

These are the only nonisometric three-dimensional homogeneous Lorentz structures on S^3, with the same homogeneous model in curvature. ■

Note. Interestingly enough, there are noncompact Lorentz–Lie groups with a spherical homogeneous model of the Ricci spectrum $(\mathbf{0},k^2,\mathbf{0})$. Such an example is provided by the Lorentz–Lie structures. $\mathbf{g}_t$ on $S1(2,\mathbb{R})$, whose Lie algebra of a $\mathbf{g}_t$ orthobasis $(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)$ are the structure equations (2.9), where $\lambda_1=t<0$, $\lambda_2=t-k^2/2t$, $\lambda_3=k^2/2t$. ■

The first nonhomogeneous Lorentz examples with a homogeneous model in curvature also have double Ricci principal curvatures.[14]

III. CURVATURE HOMOGENEOUS MANIFOLDS WITH A GENERIC RICCI TENSOR OF TYPE I

Although we consider only the Lorentz case, the results (see also Ref. 9 for an EDS approach) or techniques (compare with Ref. 12) involved in the Riemannian case should be the same.

As far as the curvature is concerned, we have the following hierarchy:

constant curvature	R isotropic
locally symmetric	R LC-parallel ⇒ (LC = AS)
locally homogeneous	R,T AS-parallel, T = LC - AS
curvature homogeneous	R punctually self equivalent
Ricci curvature homogeneous	Ric punctually self equivalent
constant scalar curvature	

Unlike the top three structures listed in this chart that admit an algebraic approach (Refs. 21 and 22), constant scalar curvature manifolds do not, even in the analytic situation. Their study amounts to solving an EDS.

Four-dimensional chL's are reasonable-models for intergalactic travelers.[23]

In three dimensions, there is no distinction between chm's and the Ricci curvature homogeneous manifolds.

Three-dimensional chm's with a nongeneric Ricci curvature tensor, were studied in Refs. 8 and 24 in the Riemannian case, and in Refs. 13 and 15 in the Lorentz case. The Riemannian three-dimensional generic case was investigated in Refs. 9, 10, and 12.

In this section, we will determine the three-dimensional germs of generic chL metrics of Ricci tensor of type I, that is, those of distinct principal Ricci curvatures $\rho_1,\rho_2,-\rho_3$.

The local structure equations of an analytic three-dimensional chLm (**M**,**g**), in the moving frame approach:

$$d\theta+\omega\wedge\theta=0,\quad d\omega+\omega\wedge\omega=\Omega, \tag{3.1}$$

under the additional hypothesis that the frame field **X** consists of eigenvectors of a generic Ricci operator of type I, yield the following integrability conditions of (3.1):

$$\begin{aligned}&(\rho_2+\rho_3)\,\theta^1\wedge\theta^3\wedge\omega_3^2-(\rho_1+\rho_3)\,\theta^2\wedge\theta^3\wedge\omega_3^1=0,\\&(\rho_2+\rho_3)\,\theta^1\wedge\theta^2\wedge\omega_3^2-(\rho_1-\rho_2)\,\theta^2\wedge\theta^3\wedge\omega_2^1=0,\\&(\rho_1-\rho_2)\,\theta^1\wedge\theta^3\wedge\omega_2^1+(\rho_1+\rho_3)\,\theta^1\wedge\theta^2\wedge\omega_3^1=0.\end{aligned} \tag{3.2}$$

Let α be a vector-valued differential form. We denote by α_p the homogeneous polynomial component of α of degree p around a fixed point **x**. With this notation, $\theta=\Sigma_{p\geqslant 0}\theta_p$, $\omega=\Sigma_{p\geqslant 0}\omega_p$ and $\Omega=\Sigma_{p\geqslant 0}\Omega_p$ are the Taylor series around a fixed point **x** of **M** (the equations are restricted to a neighborhood **U** of **x**). The EDS (3.1)+(3.2) breaks into the following pieces:

$$d\theta_{p+1}=-\sum_{r+s=p}\omega_r\wedge\theta_s,\quad d\omega_{p+1}=-\sum_{r+s=p}\omega_r\wedge\omega_s+\Omega_p, \tag{3.3}$$

and

$$\begin{aligned}&(\rho_2+\rho_3)\sum_{r+s+t=p+1}\theta^1{}_r\wedge\theta^3{}_s\wedge\omega^2_{3,t}-(\rho_1+\rho_3)\sum_{r+s+t=p+1}\theta^2{}_r\wedge\theta^3{}_s\wedge\omega^1_{3,t}=0,\\&(\rho_2+\rho_3)\sum_{r+s+t=p+1}\theta^1{}_r\wedge\theta^2{}_s\wedge\omega^2_{3,t}-(\rho_1-\rho_2)\sum_{r+s+t=p+1}\theta^2{}_r\wedge\theta^3{}_s\wedge\omega^1_{2,t}=0,\\&(\rho_1-\rho_2)\sum_{r+s+t=p+1}\theta^1{}_r\wedge\theta^3{}_s\wedge\omega^1_{2,t}+(\rho_1+\rho_3)\sum_{r+s+t=p+1}\theta^1{}_r\wedge\theta^2{}_s\wedge\omega^1_{3,t}=0,\end{aligned} \tag{3.4}$$

W.l.o.g., we may assume that $\mathbf{x}=\mathbf{0}$ and $\theta|_{\mathbf{x}=0}=d_0id=id$, $\omega_0|_{\mathbf{x}=0}={}_0\Gamma^i_{jk}\,dx^k\,f^j_i$. Let **U** be an open set (an open neighborhood of the origin in $\mathbb{R}^3$), where the Taylor series are assumed to be convergent. Also, let **V** be a real vector space. $\Omega(\mathbf{U};\mathbf{V})$, the set of all **V**-valued analytic forms is first quadrant **V**-valued double complex: $\Omega(\mathbf{U};\mathbf{V})=\Sigma_{r,s}\Omega^{r,s}$, where $\Omega^{r,s}$ is the set of all differential forms of degree s with coefficients of homogeneous polynomials of degree r. In particular, $\Omega(\mathbf{U}):=\Omega(\mathbf{U};\mathbb{R})$ is the tensor product of a symmetric algebra with an exterior algebra.

The differential $d=\Sigma d^{r,s}$, $d^{r,s}:\Omega^{r,s}\to\Omega^{r-1,s+1}$ has total degree 0.
We will consider a variant of homotopy operators as defined in classical textbooks, such as Ref. 25: more precisely, assume the radial homotopy defined in a neighborhood of the origin in $\mathbb{R}\times\mathbf{U}$, is $\mathbf{H}:\mathbb{R}\times\mathbf{U}\to\mathbf{U}$, $\mathbf{h}(\mathbf{s},\mathbf{p})=\mathbf{sp}$, and for any differential form α on $\mathbf{U}$, let $\mathbf{H}^*\alpha=\mathbf{ds}\wedge\beta+\gamma$, where β and γ do not contain the differential $\mathbf{ds}$. Then $\mathbf{h}\alpha=\int_0^1\beta$.

The homotopy operators are the components of $\mathbf{h}$, $\mathbf{h}^{r-1,s+1}:\Omega^{r-1,s+1}\to\Omega^{r,s}$, and they act on an ordinary form $(i_1+\cdots+i_n=r-1, j_1<\cdots<j_{s+1})$ by

$$h^{r-1,s+1}((x^1)^{i_1}\cdots(x^n)^{i_n}\,dx^{j_1}\wedge\cdots\wedge dx^{j_{s+1}})$$

$$=\frac{1}{(r+s)}\,(x^1)^{i_1}\cdots(x^n)^{i_n}\left(\sum_{\alpha=1}^{s+1}(-1)^{\alpha-1}x^{j_\alpha}dx^{j_1}\wedge\cdots\wedge dx^{j_\alpha}\wedge\cdots\wedge dx^{j_{s+1}}\right). \tag{3.5}$$

Since

$$\mathbf{dh}+\mathbf{hd}=\mathbf{id}, \tag{3.6}$$

it follows that locally $\alpha\in\Omega^{r-1,s+1}$ $d\alpha=\beta$, iff

$$\alpha=h\beta+dh\ \ \alpha=h\beta+d\phi,\quad \phi\in\Omega^{r,s}. \tag{3.7}$$

The key point is that one may solve (3.3)–(3.4) inductively: from (3.6), the formal solution is

$$\theta_{p+1}=-\sum_{r+s=p}h(\omega_r\wedge\theta_s)+d\phi_{p+2}, \tag{3.8}$$

$$\omega_{p+1}=h\left(\Omega_p-\sum_{r+s=p}\omega_r\wedge\omega_s\right)+d\psi_{p+2}, \tag{3.9}$$

where $\phi_{p+2}\in\Omega(\mathbf{U};\mathbb{R}^3)$, $\psi_{p+2}\in\Omega(\mathbf{U};\mathfrak{o}_1(3))$ are homogeneous polynomial forms, such that (3.4) holds true.

In order to prove that $\theta=\Sigma_{p\geqslant 0}\ \theta_p$, $\omega=\Sigma_{p\geqslant 0}\ \omega_p$ given by (3.8), (3.9), and (3.4) is a solution of (3.3), (3.4), one has to find inductively ϕ_{p+1}, ψ_{p+1} satisfying these equations, such that the corresponding series $\Sigma_{p\geqslant 0}\ \theta_p$, $\Sigma_{p\geqslant 0}\ \omega_p$ are convergent. To be more precise, at each point $\mathbf{p}$ in $\mathbf{U}$, one has the pointwise defined scalar products $\langle\alpha,\beta\rangle_{\mathbf{p}}$ on differential forms, at the point $\mathbf{p}$, given a structure of a Riemannian vector bundle of $\Omega^s(\mathbf{U};\mathbf{V})$ of forms of degree $\mathbf{s}$. For each radius $\mathbf{r}$, define

$${}_{\mathbf{r}}\langle\alpha,\beta\rangle=\int_{B_{\mathbf{r}}(0)}\langle\alpha,\beta\rangle_{\mathbf{p}}\,\mathbf{dp}.$$

Assume $j_1<\cdots<j_{s+1}$. Then, due to (3.5), it follows that for any homogeneous polynomial f_{r-1} of degree $r-1$,

$${}_{\mathbf{r}}\|\mathbf{h}^{r-1,s+1}(f_{r-1}(x)dx^{j_1}\wedge\cdots\wedge dx^{j_{s+1}})\|^2<\frac{s+1}{(r+s)^2}\,\mathbf{r}^2{}_{\mathbf{r}}\|f_{r-1}(x)dx^{j_1}\wedge\cdots\wedge dx^{j_{s+1}}\|^2,$$

which for any form α in $\Omega^{r-1,s+1}$ imply

$${}_{\mathbf{r}}\|\mathbf{h}^{r-1,s+1}\alpha\|^2<\frac{s+1}{(r+s)^2}\,\mathbf{r}^2{}_{\mathbf{r}}\|\alpha\|^2. \tag{3.10}$$

For $r=p$, $s=2$ this inequality can be bettered,

$${}_{\mathbf{r}}\|\mathbf{h}^{1,2}\alpha\|<\frac{1}{p+2}\,\mathbf{r}_{\mathbf{r}}\|\alpha\|. \tag{3.11}$$

From (3.8), it follows that

$$_{\mathbf{r}}\|\theta_{p+1}\|<\frac{2p+2}{p+2}\,\mathbf{r}\,\max(_{\mathbf{r}}\|\omega_r\|,\quad _{\mathbf{r}}\|\theta_s\|)^2+{}_{\mathbf{r}}\|d\phi_{p+2}\|.$$

Since

$$\Omega_p=k_3\left(\sum_{r+s=p}\theta^1{}_r\wedge\theta^2{}_s\right)f_1^2-k_2\left(\sum_{r+s=p}\theta^1{}_r\wedge\theta^3 s\right)f_1^3+k_1\left(\sum_{r+s=p}\theta^2{}_r\wedge\theta^3{}_s\right)f_2^3.$$

from (3.9) and a number of inequalities, one gets

$$_{\mathbf{r}}\|\omega_{p+1}\|<\frac{2p+2}{p+2}\,\mathbf{r}\,\max(_{\mathbf{r}}\|\omega_r\|,{}_{\mathbf{r}}\|\theta_s\|)^2(|k_1|+|k_2|+|k_3|+1)+{}_{\mathbf{r}}\|d\psi_{p+2}\|.$$

Let $a_p=\max(_{\mathbf{r}}\|\omega_r\|,{}_{\mathbf{r}}\|\theta_s\|,r,s\leqslant p)$. The above inequalities can be rewritten as

$$\begin{gathered}
_{\mathbf{r}}\|\theta_{p+1}\|<\frac{2p+2}{p+2}\,\mathbf{r}a_p{}^2+{}_{\mathbf{r}}\|d\phi_{p+2}\|,\\
_{\mathbf{r}}\|\omega_{p+1}\|<\frac{2p+2}{p+2}\,\mathbf{r}a_p{}^2(|k_1|+|k_2|+|k_3|+1)+{}_{\mathbf{r}}\|d\psi_{p+2}\|.\\
\text{If}\quad b_p=\max(_{\mathbf{r}}\|d\phi_{p+1}\|,\quad _{\mathbf{r}}\|d\psi_{p+1}\|),
\end{gathered}\tag{3.12}$$

then

$$a_{p+1}<\frac{2p+2}{p+2}\,\mathbf{r}a_p{}^2(|k_1|+|k_2|+|k_3|+1)+b_{p+1}.\tag{3.13}$$

Let $\mathbf{K}$ be such that $[(2p+2)/(p+2)](|k_1|+|k_2+|k_3|+1)<\mathbf{K}$.

Theorem 3.1: *If* $\mathbf{c}=\mathbf{Kr}$ *is a sufficiently small and the series* $\phi=\Sigma\phi_p$, $\psi=\Sigma\psi_p$ *are uniformly convergent on* $\mathbf{B}(0,\mathbf{r})$, *then so are the series* $\theta=\Sigma_{p\geqslant 0}\theta_p$ and $\omega=\Sigma_{p\geqslant 0}\omega_p$, *whose general terms are solutions of (3.8) and (3.9).*

Proof: $a_{p+1}<\mathbf{K}\mathbf{r}a_p{}^2+b_{p+1}$.

Assumption: Let α_p, be defined by $\alpha_{p+1}=c\alpha_p{}^2+b_{p+1}$, $\alpha_1=a_1$. Since all the sequences are positive, one may prove by induction that $a_{p+1}<\alpha_{p+1}$.

Claim: The series $\Sigma\alpha_p$ is convergent.

Let $\beta_p=\max(b_s,s\geqslant p)$. Then β_p is decreasing and $\beta_p\geqslant b_p$. The series $\Sigma\beta_p$ is as well convergent, and if one defines the sequence α'_p, by $\alpha'_{p+1}=c\alpha'_p{}^2+\beta_{p+1}$, $\alpha'_1=a_1$, it is obvious that $\alpha_p\leqslant\alpha'_p$. Therefore w.l.o.g. we may assume that b_p is decreasing. Also, since b_p approaches 0, one may select $\mathbf{c}<1$, such that $\alpha_{p+1}<\max(\alpha_p,1)$ for some p, and therefore α_p is decreasing, and w.l.o.g. one may assume that $\alpha_p<1$. Then $\alpha_{p+1}<\mathbf{c}\alpha_p+b_{p+1}$, and therefore $(1-\mathbf{c})\Sigma_p^n\alpha_s<\Sigma_p^n b_s-\alpha_{n+1}$, which proves the claim. ■

The inductive step is the following.

Lemma 3.1: Assume $\theta_{p+1},\omega_{p+1}$ *defined in (3.8) and (3.9) is a solution of (3.3) and (3.4), for* $p=\overline{0,q}$ *and let* θ_{q+2} *given by (3.8) for* $p=q$, *with* ϕ_{q+2} *arbitrary. Then there is a solution* ω_{q+2} *given in* (3.9) *for* $p=q+1$, *which satisfies to the integrability conditions (3.4) for* $p=q+1$, *if the subspace of homogeneous polynomial solutions* $\psi^0_{q+2}=\psi^{0\ j}_{q+2,\mathbf{i}}\mathbf{f}^i_j\in\Omega^{q+2,0}$ *of the system of linear PDE's,*

$$\begin{gathered}
(\rho_1+\rho_3)\frac{\partial}{\partial x^1}\Psi^0_{q+2,3}{}^1-(\rho_2+\rho_3)\frac{\partial}{\partial x^2}\Psi^0_{q+2,3}{}^2=0,\\
(\rho_2+\rho_3)\frac{\partial}{\partial x^3}\Psi^0_{q+2,3}{}^2-(\rho_1-\rho_2)\frac{\partial}{\partial x^1}\Psi^0_{q+2,2}{}^1=0,
\end{gathered}\tag{3.14}$$

$$(\rho_1-\rho_2)\frac{\partial}{\partial x^2}\Psi^0_{q+2,2}{}^1+(\rho_1+\rho_3)\frac{\partial}{\partial x^3}\Psi^0_{q+2,3}{}^1=0,$$

is $3(q+3)$ *dimensional.*

Proof: If we make the assumption following (3.4), and identify the coefficients of $dx^1\wedge dx^2\wedge dx^3$ in the integrability conditions for $p=q$, we obtain the following linear partial differential system of equations in the components of the new added 2-form $d\Psi_{q+2}\in\Omega(\mathbf{U};\mathfrak{o}_1(3))$ with homogeneous polynomial coefficients:

$$(\rho_1+\rho_3)\frac{\partial}{\partial x^1}\Psi_{q+2,3}{}^1-(\rho_2+\rho_3)\frac{\partial}{\partial x^2}\Psi_{q+2,3}{}^2+F_{q,2}{}^1=0,$$

$$(\rho_2+\rho_3)\frac{\partial}{\partial x^3}\Psi_{q+2,3}{}^2-(\rho_1-\rho_2)\frac{\partial}{\partial x^1}\Psi_{q+2,2}{}^1+F_{q,3}{}^1=0,$$

$$(\rho_1-\rho_2)\frac{\partial}{\partial x^2}\Psi_{q+2,2}{}^1+(\rho_1+\rho_3)\frac{\partial}{\partial x^3}\Psi_{q+2,3}{}^1+F_{q,3}{}^2=0, \tag{3.15}$$

where F_q is a homogeneous $\mathfrak{o}_1(3)$-valued function, depending on $d\phi_s$, $s\leqslant q+2$, and $d\psi_s$, $s\leqslant q+1$. (3.14) is equivalent to the equation $F(d\Psi_{q+2})=F_q$, where F is the linear p.d.o. from **S** to **T** whose action on $d\Psi_{q+2}$ is given by the left-hand side of (3.15), with F_q identically 0. The result follows, given that both the source and target of F are finite dimensional, and then the Fredholm alternative applies. **T** is isomorphic to the product of three copies of the space of homogeneous polynomials of degree $q+1$ in three variables, and **S** to the product if three copies of the space of homogeneous polynomials of degree $q+2$ in three variables, and obviously $\dim S-\dim \mathbf{T}=3(q+3)$. ■

Proof of Theorem 1.3. Indeed, assume ψ^0_{q+2} is in $\ker F$. Since the Ricci operator is generic, $(\rho_1+\rho_3)(\rho_2+\rho_3)(\rho_1-\rho_2)\neq 0$. Let us set $X=-(\rho_2+\rho_3)\Psi^0_{q+2,3}{}^2$, $Y=(\rho_1+\rho_3)\Psi^0_{q+2,3}{}^1$, $Z=(\rho_1-\rho_2)\Psi^0_{q+2,2}{}^1$. Then $\partial Y/\partial x^1+\partial X/\partial x^2=0$, $\partial X/\partial x^3+\partial Z/\partial x^1=0$, $\partial Z/\partial x^2+\partial Y/\partial x^3=0$. If one takes on more partial derivative, one finds that $\partial X/\partial x^2=A(x^1,x^2)$, $\partial Y/\partial x^3=B(x^2,x^3)$, $\partial Z/\partial x^1=C(x^1,x^3)$, where A,B,C are arbitrary homogeneous functions in two variables of degree $q+2$, proving that $\dim\ker F=3(q+3)$. Theorem 1.3, follows from Theorem 3.1 and Lemma 3.1. ■

(Received 4 June 1997; accepted for publication 10 September 1997)

We extend the notion of dually conjugate Hopf (super)algebras to the colored Hopf (super)algebras $\mathscr{H}^c$ that we recently introduced. We show that if the standard Hopf (super)algebras $\mathscr{H}_q$ that are the building blocks of $\mathscr{H}^c$ have Hopf duals $\mathscr{H}_q^*$, then the latter may be used to construct coloured Hopf duals $\mathscr{H}^{c*}$, endowed with colored algebra and antipode maps, but with a standard coalgebraic structure. Next, we review the case where the $\mathscr{H}_q$'s are quantum universal enveloping algebras of Lie (super)algebras $U_q(g)$, so that the corresponding $\mathscr{H}_q^*$'s are quantum (super) groups G_q. We extend the Fronsdal and Galindo universal $\mathscr{T}$-matrix formalism to the colored pairs $(\mathrm{U}^c(g),G^c)$ by defining colored universal $\mathscr{T}$-matrices. We then show that together with the colored universal $\mathscr{R}$-matrices previously introduced, the latter provide an algebraic formulation of the colored RTT-relations, proposed by Basu-Mallick. This establishes a link between the colored extensions of Drinfeld–Jimbo and Faddeev–Reshetikhin–Takhtajan pictures of quantum groups and quantum algebras. Finally, we illustrate the construction of colored pairs by giving some explicit results for the two-parameter deformations of (U(gl(2)),Gl(2)), and (U(gl(1/1)),Gl(1/1)). © *1998 American Institute of Physics.*

I. INTRODUCTION

In a recent paper[1] (henceforth referred to as I and whose equations will be subsequently quoted by their number preceded by I), we did introduce some new algebraic structures $\mathscr{H}^c=(\mathscr{H},\mathscr{C},\mathscr{G})$, termed colored Hopf algebras (see also Ref. 2). They are constructed by starting from a standard Hopf algebra set $\mathscr{H}=\{\mathscr{H}_q|q\in\mathscr{Q}\}$, corresponding to some parameter set $\mathscr{Q}$, and by generalizing the definitions of coalgebra maps, and antipodes, by combining the standard ones with the transformations of an algebra isomorphism group $\mathscr{G}$, called color group. Such transformations are labeled by some color parameters, taking values in a color set $\mathscr{C}$. Whenever the starting Hopf algebras $\mathscr{H}_q$ are quasitriangular, the resulting colored one $\mathscr{H}^c$ is characterized by the existence of a colored universal $\mathscr{R}$-matrix, denoted by $\mathscr{R}^c$, and satisfying the colored Yang–Baxter equation (YBE), i.e., the YBE with nonadditive spectral parameters.[3,4]

In I, we applied these new concepts to the Drinfeld–Jimbo formulation of quantum algebras,[5] and constructed various examples of colored quantum universal enveloping algebras (QUEA's) of both semisimple and nonsemisimple Lie algebras.

In a more recent paper[6] (henceforth referred to as II), we showed that our definitions can be easily extended to deal with graded algebraic structures,[7] thereby leading to colored Hopf superalgebras in general, and to colored QUEA's of Lie superalgebras in particular. In such cases, quasitriangularity implies that $\mathscr{R}^c$ is a solution of the colored graded YBE.

In the literature, there exist other extensions of Hopf algebras related to the colored YBE, and using either the Drinfeld–Jimbo,[5] or the Faddeev–Reshetikhin–Takhtajan[8] approach to quantum groups and quantum algebras. In the former class, one should mention two previous introductions of some algebraic structures called colored Hopf algebras, the first one by Ohtsuki[9] in the context of knot theory, and the second one by Bonatsos *et al.*[10] in the study of some nonlinear deformation of su(2). In the latter class, some extensions of the Faddeev–Reshetikhin–Takhtajan RLL- and

RTT-relations, where R is replaced by a colored R-matrix, have been considered by Kundu and Basu-Mallick,[11,12] thereby leading to colored $U(R)$ and $A(R)$ Hopf algebras, respectively.

As shown in I, some direct connections exist between our colored Hopf algebras, and those previously introduced by Ohtsuki,[9] and by Bonatsos *et al.*,[10] as the former may be considered as generalizations of the latter. On the contrary, possible relationships with colored $U(R)$ and $A(R)$ Hopf algebras have not been investigated so far.

It is one of the aims of the present paper to fill in this gap for the colored $A(R)$ algebras, introduced by Basu-Mallick.[12] For such a purpose, we shall have to extend the notion of dually conjugate Hopf algebras[13] to the colored context.

In the case of standard Hopf algebras, the interest of such a duality concept was recently highlighted by Fronsdal and Galindo,[14] who constructed dual bases for the two-parameter deformations of Gl(2) and U(gl(2)), and used them to build a universal $\mathscr{T}$-matrix, providing an algebraic formulation of the RTT-relations, and yielding the quantum group generalization of the familiar exponential map from a Lie algebra to a Lie group. A similar construction was carried out for some other quantum group and algebra pairs,[15–18] and used to get representations of one member of the pair from those of the other.[19,20] Moreover, the Fronsdal and Galindo approach was also recently generalized to quantum supergroups and superalgebras.[21]

We plan to show here that this universal $\mathscr{T}$-matrix formalism can be extended to colored QUEA's and their duals, and that the resulting colored universal $\mathscr{T}$-matrix, to be denoted by $\mathscr{T}^c$, provides the key notion for establishing a link between such duals and Basu-Mallick's colored $A(R)$ algebras.

This paper is organized as follows. In Sec. II, duals $\mathscr{H}^{c*}$ of colored Hopf (super)algebras $\mathscr{H}^c$ are defined. In Sec. III, the case of colored QUEA's of Lie (super)algebras is considered, and colored universal $\mathscr{T}$-matrices are introduced. In Secs. IV and V, the theory developed in the previous section is applied to construct pairs $(\mathscr{H}^c,\mathscr{H}^{c*})$ for the two-parameter deformations of (U(gl(2)),Gl(2)), and (U(gl(1/1)),Gl(1/1)), respectively. Section VI contains some concluding remarks.

II. DUALS OF COLORED HOPF (SUPER)ALGEBRAS

Let $\mathscr{H}^c=(\mathscr{H},\mathscr{C},\mathscr{G})=(\mathscr{H}_q,+,m_q,\iota_q,\Delta_{q,\nu}^{\lambda,\mu},\epsilon_{q,\nu},S_{q,\nu}^{\mu};k,\mathscr{Q},\mathscr{C},\mathscr{G})$ be a colored Hopf algebra over some field k ($=\mathbb{C}$ or $\mathbb{R}$).[1,2] Here $\mathscr{Q}$, $\mathscr{C}$, and $\mathscr{G}=\{\sigma^\nu:\mathscr{H}_q\to\mathscr{H}_{q^\nu}|q,q^\nu\in\mathscr{Q},\nu\in\mathscr{C}\}$ denote the parameter set, the color set, and the color group, respectively. Hence, by definition, the σ^ν's satisfy Eqs. (I2.1)–(I2.4). The maps $m_q:\mathscr{H}_q\otimes\mathscr{H}_q\to\mathscr{H}_q$, and $\iota_q:k\to\mathscr{H}_q$ are standard multiplication and unit maps, whereas $\Delta_{q,\nu}^{\lambda,\mu}\equiv(\sigma^\lambda\otimes\sigma^\mu)\circ\Delta_q\circ\sigma_\nu:\mathscr{H}_{q^\nu}\to\mathscr{H}_{q^\lambda}\otimes\mathscr{H}_{q^\mu}$, $\epsilon_{q,\nu}\equiv\epsilon_q\circ\sigma_\nu:\mathscr{H}_{q^\nu}\to k$, and $S_{q,\nu}^{\mu}\equiv\sigma^\mu\circ S_q\circ\sigma_\nu:\mathscr{H}_{q^\nu}\to\mathscr{H}_{q^\mu}$, defined in terms of standard comultiplication Δ_q, counit ϵ_q, and antipode S_q, with $\sigma_\nu\equiv(\sigma^\nu)^{-1}$, are called colored comultiplication, counit, and antipode maps, respectively, and satisfy some generalized axioms, stated in Proposition II.2 of I.

Let us now assume that the standard Hopf algebras $\mathscr{H}_q$, belonging to $\mathscr{H}$, have Hopf duals $(\mathscr{H}_q^*,+,\widetilde{m}_q,\widetilde{\iota}_q,\widetilde{\Delta}_q,\widetilde{\epsilon}_q,\widetilde{S}_q;k)$ (or in short $\mathscr{H}_q^*$), and let us set $\mathscr{H}^*=\{\mathscr{H}_q^*|q\in\mathscr{Q}\}$. This means[13] that for any $q\in\mathscr{Q}$, there exists a doubly nondegenerate bilinear form $\langle,\rangle_q$, such that the bialgebra and antipode maps of the dual pair $(\mathscr{H}_q,\mathscr{H}_q^*)$ are related by

$$\langle\widetilde{m}_q(x\otimes y),X\rangle_q=\langle x\otimes y,\Delta_q(X)\rangle_q,\quad \langle\widetilde{\iota}_q(1),X\rangle_q=\langle\widetilde{1}_q,X\rangle_q=\epsilon_q(X), \tag{2.1}$$

$$\langle\widetilde{\Delta}_q(x),X\otimes Y\rangle_q=\langle x,m_q(X\otimes Y)\rangle_q,\quad \widetilde{\epsilon}_q(x)=\langle x,\iota_q(1)\rangle_q=\langle x,1_q\rangle_q, \tag{2.2}$$

$$\langle\widetilde{S}_q(x),X\rangle_q=\langle x,S_q(X)\rangle_q, \tag{2.3}$$

for any $x,y\in\mathscr{H}_q^*$, and any $X,Y\in\mathscr{H}_q$.

Let us next introduce

Definition II.1: Let $\rho^\nu:\mathscr{H}_q^*\to\mathscr{H}_{q^\nu}^*$ *be defined by*

$$\langle \rho^{\nu}(x), \sigma^{\nu}(X) \rangle_{q^{\nu}} = \langle x, X \rangle_{q}, \tag{2.4}$$

for any $x \in \mathscr{H}_q^*$, $X \in \mathscr{H}_q$, $q \in \mathscr{Q}$, *and* $\nu \in \mathscr{C}$.

From the properties of the σ^{ν}'s and the nondegeneracy of $\langle , \rangle_q$, it is then straightforward to show

Proposition II.2: The maps ρ^{ν}, *defined in Eq. (2.4), are coalgebra isomorphisms, and the set* $\{\rho^{\nu} | \nu \in \mathscr{C}\}$ *is a group isomorphic to* $\mathscr{G}$ *(and denoted by the same symbol) with respect to the composition of maps. In other words, the* ρ^{ν}'s *are one-to-one, and satisfy the properties*

$$\widetilde{\Delta}_{q^{\nu}} \circ \rho^{\nu} = (\rho^{\nu} \otimes \rho^{\nu}) \circ \widetilde{\Delta}_q, \quad \widetilde{\epsilon}_{q^{\nu}} \circ \rho^{\nu} = \widetilde{\epsilon}_q, \tag{2.5}$$

and

$$\forall \nu, \nu' \in \mathscr{C}: \rho^{\nu' \circ \nu} = \rho^{\nu'} \circ \rho^{\nu}: \mathscr{H}_q^* \to \mathscr{H}_{q^{\nu' \circ \nu}}^*,$$

$$\rho^{\nu^0} = \mathrm{id}: \mathscr{H}_q^* \to \mathscr{H}_{q^{\nu^0}}^* = \mathscr{H}_q^*, \tag{2.6}$$

$$\forall \nu \in \mathscr{C}: \rho^{\nu^i} = \rho_{\nu} \equiv (\rho^{\nu})^{-1}: \mathscr{H}_{q^{\nu}}^* \to \mathscr{H}_q^*,$$

where $\nu' \circ \nu$, ν^0, *and* ν^i *have the same meaning as in Eqs. (I2.2)–(I2.4).*

Proceeding as for $\mathscr{H}$ in I, we may now combine the definitions of $\mathscr{H}^*$, $\mathscr{C}$, and $\mathscr{G}$ into

Definition II.3: The maps $\widetilde{m}^{\nu}_{q,\lambda,\mu}: \mathscr{H}_{q^{\lambda}}^* \otimes \mathscr{H}_{q^{\mu}}^* \to \mathscr{H}_{q^{\nu}}^*$, $\widetilde{\iota}_q^{\nu}: k \to \mathscr{H}_{q^{\nu}}^*$, *and* $\widetilde{S}^{\nu}_{q,\mu}: \mathscr{H}_{q^{\mu}}^* \to \mathscr{H}_{q^{\nu}}^*$, *defined by*

$$\widetilde{m}^{\nu}_{q,\lambda,\mu} \equiv \rho^{\nu} \circ \widetilde{m}_q \circ (\rho_{\lambda} \otimes \rho_{\mu}), \quad \widetilde{\iota}_q^{\nu} \equiv \rho^{\nu} \circ \widetilde{\iota}_q, \quad \widetilde{S}^{\nu}_{q,\mu} \equiv \rho^{\nu} \circ \widetilde{S}_q \circ \rho_{\mu}, \tag{2.7}$$

for any $q \in \mathscr{Q}$, *and any* λ, μ, $\nu \in \mathscr{C}$, *are called colored multiplication, unit, and antipode, respectively.*

By using the dual pairing (2.1)–(2.3), Definitions II.1 and II.3, as well as Definition II.1 and Proposition II.2 of I, it is easy to establish

Proposition II.4: The colored multiplication, unit, and antipode maps, defined in Eq. (2.7), are dual to the colored comultiplication, counit, and antipode of $\mathscr{H}^c$, *i.e.,*

$$\forall x \in \mathscr{H}_{q^{\lambda}}^*, \forall y \in \mathscr{H}_{q^{\mu}}^*, \forall X \in \mathscr{H}_{q^{\nu}}: \langle \widetilde{m}^{\nu}_{q,\lambda,\mu}(x \otimes y), X \rangle_{q^{\nu}} = \langle x \otimes y, \Delta^{\lambda,\mu}_{q,\nu}(X) \rangle_{q^{\lambda},q^{\mu}},$$

$$\forall X \in \mathscr{H}_{q^{\nu}}: \langle \widetilde{\iota}_q^{\nu}(1), X \rangle_{q^{\nu}} = \epsilon_{q,\nu}(X), \tag{2.8}$$

$$\forall x \in \mathscr{H}_{q^{\mu}}^*, \forall X \in \mathscr{H}_{q^{\nu}}: \langle \widetilde{S}^{\nu}_{q,\mu}(x), X \rangle_{q^{\nu}} = \langle x, S^{\mu}_{q,\nu}(X) \rangle_{q^{\mu}}.$$

In addition, they transform under $\mathscr{G}$ *as*

$$\widetilde{m}^{\nu}_{q,\alpha,\beta} \circ (\rho^{\alpha}_{\lambda} \otimes \rho^{\beta}_{\mu}) = \widetilde{m}^{\nu}_{q,\lambda,\mu} = \rho^{\nu}_{\gamma} \circ \widetilde{m}^{\gamma}_{q,\lambda,\mu},$$

$$\rho^{\nu}_{\alpha} \circ \widetilde{\iota}_q^{\alpha} = \widetilde{\iota}_q^{\nu}, \tag{2.9}$$

$$\widetilde{S}^{\nu}_{q,\alpha} \circ \rho^{\alpha}_{\mu} = \widetilde{S}^{\nu}_{q,\mu} = \rho^{\nu}_{\beta} \circ \widetilde{S}^{\beta}_{q,\mu},$$

and satisfy generalized associativity, unit, and antipode axioms

$$\widetilde{m}^{\nu}_{q,\lambda,\mu} \circ (\widetilde{m}^{\lambda}_{q,\alpha,\beta} \otimes \rho^{\mu}_{\gamma}) = \widetilde{m}^{\nu}_{q,\lambda',\mu'} \circ (\rho^{\lambda'}_{\alpha} \otimes \widetilde{m}^{\mu'}_{q,\beta,\gamma}),$$

$$\widetilde{m}^{\nu}_{q,\lambda,\mu} \circ (\widetilde{\iota}_q^{\lambda} \otimes \rho^{\mu}_{\alpha}) = \widetilde{m}^{\nu}_{q,\lambda',\mu'} \circ (\rho^{\lambda'}_{\alpha} \otimes \widetilde{\iota}_q^{\mu'}) = \rho^{\nu}_{\alpha}, \tag{2.10}$$

$$\widetilde{m}^{\nu}_{q,\lambda,\mu} \circ (\widetilde{S}^{\lambda}_{q,\alpha} \otimes \rho^{\mu}_{\alpha}) \circ \widetilde{\Delta}_{q^{\alpha}} = \widetilde{m}^{\nu}_{q,\lambda',\mu'} \circ (\rho^{\lambda'}_{\alpha} \otimes \widetilde{S}^{\mu'}_{q,\alpha}) \circ \widetilde{\Delta}_{q^{\alpha}} = \widetilde{\iota}_q^{\nu} \circ \widetilde{\epsilon}_{q^{\alpha}},$$

as well as generalized bialgebra axioms

$$\begin{gathered}\widetilde{\Delta}_{q^\nu}\circ\widetilde{m}^{\ \nu}_{q,\lambda,\mu}=(\widetilde{m}^{\ \nu}_{q,\lambda,\mu}\otimes\widetilde{m}^{\ \nu}_{q,\lambda,\mu})\circ(\mathrm{id}\otimes\tau\otimes\mathrm{id})\circ(\widetilde{\Delta}_{q^\lambda}\otimes\widetilde{\Delta}_{q^\mu}),\\ \widetilde{\Delta}_{q^\nu}\circ\widetilde{\iota}^{\nu}_{q}=\widetilde{\iota}^{\nu}_{q}\otimes\widetilde{\iota}^{\nu}_{q},\\ \widetilde{\epsilon}_{q^\nu}\circ\widetilde{m}^{\ \nu}_{q,\lambda,\mu}=\widetilde{\epsilon}_{q^\lambda}\otimes\widetilde{\epsilon}_{q^\mu},\\ \widetilde{\epsilon}_{q^\nu}\circ\widetilde{\iota}^{\nu}_{q}=\mathrm{id},\end{gathered}\tag{2.11}$$

where $\rho^{\lambda}_{\mu}\equiv\rho^{\lambda}\circ\rho_{\mu}$, τ *is the twist map, and no summation is implied over repeated indices.*

Remarks: (1) As usual for Hopf algebras, the twist map is defined by $\tau(x\otimes y)=y\otimes x$ for any x, y belonging to appropriate spaces. (2) As shown in Eqs. (2.10) and (I2.7), the colored antipodes $\widetilde{S}^{\ \nu}_{q,\mu}$, and $S^{\ \mu}_{q,\nu}$ satisfy distinct generalized axioms. A similar remark is valid for the generalized bialgebra structures given in Eqs. (2.11) and (I2.8), respectively.

From Proposition II.4, one obtains

Corollary II.5: For any $q\in\mathcal{Q}$, *any* $\nu\in\mathcal{C}$, *and* $q_\nu\equiv q^{\nu^i}$, $(\mathcal{H}^{\ *}_{q},+,\widetilde{m}^{\ \nu}_{q_\nu,\nu,\nu},\widetilde{\iota}^{\nu}_{q_\nu},\widetilde{\Delta}_{q},\widetilde{\epsilon}_{q},\widetilde{S}^{\ \nu}_{q_\nu,\nu};k)$ *is a Hopf algebra over k with multiplication* $\widetilde{m}^{\ \nu}_{q_\nu,\nu,\nu}$, *unit* $\widetilde{\iota}^{\nu}_{q_\nu}$, *and antipode* $\widetilde{S}^{\ \nu}_{q_\nu,\nu}$, *defined by particularizing Eq. (2.7). Moreover, it is the Hopf dual of the Hopf algebra* $(\mathcal{H}_q,+,m_q,\iota_q,\Delta^{\nu,\nu}_{q_\nu,\nu},\epsilon_{q_\nu,\nu},S^{\ \nu}_{q_\nu,\nu};k)$, *considered in Corollary II.3 of I.*

Remark: In particular, for $\nu=\nu^0$, we get back the original Hopf structures of $\mathcal{H}^{\ *}_{q}$ and $\mathcal{H}_q$.

This result can be generalized as follows:

Definition II.6: If the standard Hopf algebras $\mathcal{H}_q$ *that are the building blocks of a colored Hopf algebra* $\mathcal{H}^c$ *have Hopf duals* $\mathcal{H}^{\ *}_{q}$, *then the set* $\mathcal{H}^*=\{\mathcal{H}^{\ *}_{q}\,|\,q\in\mathcal{Q}\}$, *endowed with colored multiplication, unit, and antipode maps* $\widetilde{m}^{\ \nu}_{q,\lambda,\mu}$, $\widetilde{\iota}^{\nu}_{q}$, $\widetilde{S}^{\ \nu}_{q,\mu}$, *as defined in (2.7), is called colored Hopf dual of* $\mathcal{H}^c$, *and denoted by any one of the symbols* $(\mathcal{H}^{\ *}_{q},+,\widetilde{m}^{\ \nu}_{q,\lambda,\mu},\widetilde{\iota}^{\nu}_{q},\widetilde{\Delta}_{q},\widetilde{\epsilon}_{q},\widetilde{S}^{\ \nu}_{q,\mu};k,\mathcal{Q},\mathcal{C},\mathcal{G})$, $(\mathcal{H}^*,\mathcal{C},\mathcal{G})$, *or* $\mathcal{H}^{c*}$.

The colored antipode $\widetilde{S}^{\ \nu}_{q,\mu}$ satisfies some additional properties, which are again distinct from the corresponding ones of $S^{\ \mu}_{q,\nu}$, given in Proposition II.5 of I.

Proposition II.7: The colored antipode $\widetilde{S}^{\ \nu}_{q,\mu}$ *of a colored Hopf dual* $\mathcal{H}^{c*}$ *fulfills the relations*

$$\begin{gathered}\widetilde{S}^{\ \nu}_{q,\gamma}\circ\widetilde{m}^{\ \gamma}_{q,\alpha,\beta}=\widetilde{m}^{\ \nu}_{q,\mu,\lambda}\circ\tau\circ(\widetilde{S}^{\lambda}_{q,\alpha}\otimes\widetilde{S}^{\mu}_{q,\beta}),\quad \widetilde{S}^{\ \nu}_{q,\mu}\circ\widetilde{\iota}^{\mu}_{q}=\widetilde{\iota}^{\nu}_{q},\\ (\widetilde{S}^{\ \nu}_{q,\mu}\otimes\widetilde{S}^{\ \nu}_{q,\mu})\circ\widetilde{\Delta}_{q^\mu}=\tau\circ\widetilde{\Delta}_{q^\nu}\circ\widetilde{S}^{\ \nu}_{q,\mu},\quad \widetilde{\epsilon}_{q^\nu}\circ\widetilde{S}^{\ \nu}_{q,\mu}=\widetilde{\epsilon}_{q^\mu}.\end{gathered}\tag{2.12}$$

The case where the $\mathcal{H}_q$'s are Hopf superalgebras $(\mathcal{H}_q,+,\gamma_q,m_q,\iota_q,\Delta_q,\epsilon_q,S_q;k)$ (Ref. 7) can be dealt with only some minor changes. Here $\gamma_q:\mathcal{H}_q\to\mathcal{H}_q$ denotes their grading automorphism, i.e.,

$$\gamma_q(X)=(-1)^{\deg X}X,\tag{2.13}$$

for any homogeneous $X\in\mathcal{H}_q$, where $\deg X=0$ or 1 according to whether X is even or odd. As all vector spaces are now graded, the tensor product and the twist map are such that

$$(X\otimes Y)(Z\otimes T)=(-1)^{(\deg Y)(\deg Z)}XZ\otimes YT,\quad \tau(X\otimes Y)=(-1)^{(\deg X)(\deg Y)}Y\otimes X,\tag{2.14}$$

for any homogeneous X, Y, Z, $T\in\mathcal{H}_q$.

Then, according to Definition 3.1 of II, a colored Hopf superalgebra $(\mathcal{H}_q,+,\gamma_q,m_q,\iota_q,\Delta^{\lambda,\mu}_{q,\nu},\epsilon_{q,\nu},S^{\ \mu}_{q,\nu};k,\mathcal{Q},\mathcal{C},\mathcal{G})$ is a colored Hopf algebra, whose building blocks are Hopf superalgebras, and whose color group elements σ^ν are superalgebra isomorphisms. In other words, the σ^ν's satisfy Eqs. (I2.1)–(I2.4), and in addition are grade-preserving maps, i.e.,

$$\sigma^\nu\circ\gamma_q=\gamma_{q^\nu}\circ\sigma^\nu,\tag{2.15}$$

for any $q\in\mathcal{Q}$, and $\nu\in\mathcal{C}$. Such colored Hopf superalgebras, which will still be denoted by $\mathcal{H}^c$, fulfill similar properties as ordinary colored Hopf algebras, provided Eq. (2.14) is taken into

account. In particular, if the $\mathscr{H}_q$'s are quasitriangular, then the colored universal $\mathscr{R}$-matrix $\mathscr{R}^c = \{\mathscr{R}_q^{\lambda,\mu} | q \in \mathscr{Q}, \lambda, \mu \in \mathscr{C}\}$ of $(\mathscr{H}^c, \mathscr{R}^c)$ satisfies the colored graded YBE,

$$R_{q,12}^{\lambda,\mu} R_{q,13}^{\lambda,\nu} R_{q,23}^{\mu,\nu} = R_{q,23}^{\mu,\nu} R_{q,13}^{\lambda,\nu} R_{q,12}^{\lambda,\mu}, \tag{2.16}$$

which has the same form as the nongraded one, but wherein the first relation in Eq. (2.14) is used to evaluate the products.

Turning now to dual structures, let us assume that the Hopf superalgebras $\mathscr{H}_q$ have Hopf duals $(\mathscr{H}_q^*, +, \tilde{\gamma}_q, \tilde{m}_q, \tilde{\iota}_q, \tilde{\Delta}_q, \tilde{\epsilon}_q, \tilde{S}_q; k)$ with corresponding grading maps denoted by $\tilde{\gamma}_q$, i.e.,

$$\tilde{\gamma}_q(x) = (-1)^{\deg x} x, \tag{2.17}$$

for any homogeneous $x \in \mathscr{H}_q^*$, and $\deg x = 0$ or 1 for x even or odd, respectively. The doubly nondegenerate bilinear forms $\langle , \rangle_q$ not only satisfy Eqs. (2.1)–(2.3), but are also consistent or, in other words, fulfill the relation

$$\langle \tilde{\gamma}_q(x), X \rangle_q = \langle x, \gamma_q(X) \rangle_q, \tag{2.18}$$

for any homogeneous $x \in \mathscr{H}_q^*$, and $X \in \mathscr{H}_q$.

It is then straightforward to show

Proposition II.8: In the case of Hopf superalgebras, the maps $\rho^\nu : \mathscr{H}_q^* \to \mathscr{H}_{q^\nu}^*$, *defined in Eq. (2.4), preserve the grading of the* $\mathscr{H}_q^*$'s, *i.e.*,

$$\rho^\nu \circ \tilde{\gamma}_q = \tilde{\gamma}_{q^\nu} \circ \rho^\nu, \tag{2.19}$$

for any $q \in \mathscr{Q}$, $\nu \in \mathscr{C}$, *in addition to satisfying Proposition II.2. Moreover the colored multiplication, unit, and antipode maps* $\tilde{m}_{q,\lambda,\mu}^{\nu}$, $\tilde{\iota}_q^{\nu}$, $\tilde{S}_{q,\mu}^{\nu}$, *defined in Eq. (2.7), satisfy Propositions II.4 and II.7, provided the counterpart of Eq. (2.14) for the duals* $\mathscr{H}_q^*$ *is taken into account.*

Finally, Definition II.6 can be extended to colored Hopf duals of colored Hopf superalgebras with $\mathscr{H}^{c*} = (\mathscr{H}_q^*, +, \tilde{\gamma}_q, \tilde{m}_{q,\lambda,\mu}^{\nu}, \tilde{\iota}_q^{\nu}, \tilde{\Delta}_q, \tilde{\epsilon}_q, \tilde{S}_{q,\mu}^{\nu}; k, \mathscr{Q}, \mathscr{C}, \mathscr{G})$.

III. DUALS OF COLORED QUEA'S OF LIE (SUPER)ALGEBRAS

Whenever the Hopf (super)algebras $\mathscr{H}_q$ are QUEA's of Lie (super)algebras $U_q(g)$, their Hopf duals $\mathscr{H}_q^*$ (if they exist) are Hopf (super)algebras of quantized functions on the corresponding Lie (super)groups, $\mathrm{Fun}_q(G) = G_q$.

Let $\{X_A\}$ and $\{x^A\}$ be dual bases of $\mathscr{H}_q$ and $\mathscr{H}_q^*$, respectively. Hence

$$\langle x^A, X_B \rangle_q = \delta_B^A. \tag{3.1}$$

The universal $\mathscr{T}$-matrix of G_q (Refs. 14,16) is defined as the element of $G_q \otimes U_q(g)$ given by

$$\mathscr{T}_q = \sum_A x^A \otimes X_A. \tag{3.2}$$

In terms of the bases $\{X_A\}$ and $\{x^A\}$, the duality relations (2.2), and (2.8), between $\mathscr{H}^c = U^c(g)$ and $\mathscr{H}^{c*} = G^c$ can be written as

$$m_q(X_A \otimes X_B) = \sum_C f_{AB}^C(q) X_C, \quad 1_q = \iota_q(1) = \sum_A g^A(q) X_A,$$

$$\Delta_{q,\nu}^{\lambda,\mu}(X_A) = \sum_{BC} h_A^{BC}(q^\lambda, q^\mu, q^\nu) X_B \otimes X_C, \quad \epsilon_{q,\nu}(X_A) = \tilde{g}_A(q^\nu), \tag{3.3}$$

$$S_{q,\nu}^{\mu}(X_A) = \sum_B s_A^B(q^\mu, q^\nu) X_B,$$

and

$$\widetilde{m}^{\nu}_{q,\lambda,\mu}(x^B\otimes x^C)=\sum_A h_A^{BC}(q^\lambda,q^\mu,q^\nu)x^A,\quad \widetilde{\iota}^{\nu}_q(1)=\sum_A \widetilde{g}_A(q^\nu)x^A,$$

$$\widetilde{\Delta}_q(x^C)=\sum_{AB} f^C_{AB}(q)x^A\otimes x^B,\quad \widetilde{\epsilon}_q(x^A)=g^A(q), \tag{3.4}$$

$$\widetilde{S}^{\nu}_{q,\mu}(x^B)=\sum_A s^B_A(q^\mu,q^\nu)x^A,$$

where the structure constants for the multiplication (resp. colored comultiplication) in $\mathrm{U}^c(g)$ become the structure constants for the comultiplication (resp. colored multiplication) in G^c, and similarly for the unit and counit, or the antipodes. Note that here we denote by the same symbol basis elements X_A (resp. x^A) belonging to different members $\mathscr{H}_{q^\nu}=\mathrm{U}_{q^\nu}(g)$ (resp. $\mathscr{H}^*_{q^\nu}=G_{q^\nu}$) of the Hopf algebra set $\mathscr{H}$ (resp. $\mathscr{H}^*$) in order not to overload the notation by adding an extra index referring to the corresponding algebra. This should cause no confusion since from the context, it is always clear to which Hopf algebra X_A (resp. x^A) belongs.

Let us now introduce

Definition III.1: The set $\mathscr{T}^c=\{\mathscr{T}^\lambda_q | q\in\mathscr{Q},\lambda\in\mathscr{C}\}$, *where* $\mathscr{T}^\lambda_q\equiv\mathscr{T}_{q^\lambda}$ *is defined in Eq. (3.2), is called the universal* $\mathscr{T}$*-matrix of* G^c.

Definition III.2: For any $q\in\mathscr{Q}$, *and any* $\lambda,\mu,\nu,\alpha,\beta\in\mathscr{C}$, *let* $\mathscr{U}^{\lambda,\mu}_q\in G_{q^\lambda}\otimes U_{q^\mu}(g)$, $\mathscr{A}^{\alpha,\mu}_q\dot{\otimes}\mathscr{B}^{\beta,\mu}_q\in G_{q^\alpha}\otimes G_{q^\beta}\otimes U_{q^\mu}(g)$, *and* $\mathscr{A}^{\lambda,\alpha}_q\overset{\nu}{\ddot{\otimes}}\mathscr{B}^{\mu,\beta}_q\in G_{q^\nu}\otimes U_{q^\alpha}(g)\otimes U_{q^\beta}(g)$ *be defined by*

$$\mathscr{U}^{\lambda,\mu}_q\equiv(\mathrm{id}\otimes S^\mu_{q,\lambda})(\mathscr{T}^\lambda_q),$$

$$\mathscr{A}^{\alpha,\mu}_q\dot{\otimes}\mathscr{B}^{\beta,\mu}_q\equiv\sum_{ABCD} a^C_A b^D_B x^A\otimes x^B\otimes m_{q^\mu}(X_C\otimes X_D), \tag{3.5}$$

$$\mathscr{A}^{\lambda,\alpha}_q\overset{\nu}{\ddot{\otimes}}\mathscr{B}^{\mu,\beta}_q\equiv\sum_{ABCD} a^C_A b^D_B \widetilde{m}^{\nu}_{q,\lambda,\mu}(x^A\otimes x^B)\otimes X_C\otimes X_D,$$

where

$$\mathscr{A}^{\lambda,\mu}_q\equiv\sum_{AC} a^C_A x^A\otimes X_C,\quad \mathscr{B}^{\lambda,\mu}_q\equiv\sum_{BD} b^D_B x^B\otimes X_D, \tag{3.6}$$

with a^C_A, $b^D_B\in k$, *denote any two elements of* $G_{q^\lambda}\otimes U_{q^\mu}(g)$.

From Definitions III.1, III.2, Eqs. (3.3), (3.4), and the generalized antipode axiom for $\widetilde{S}^{\nu}_{q,\mu}$, given in Eq. (2.10), it is straightforward to show

Proposition III.3: The elements of the colored universal $\mathscr{T}$*-matrix of* G^c *satisfy the relations*

$$\mathscr{T}^\lambda_q\dot{\otimes}\mathscr{T}^\lambda_q=(\widetilde{\Delta}_{q^\lambda}\otimes\mathrm{id})(\mathscr{T}^\lambda_q),$$

$$\mathscr{T}^\lambda_q\overset{\nu}{\ddot{\otimes}}\mathscr{T}^\mu_q=(\mathrm{id}\otimes\Delta^{\lambda,\mu}_{q,\nu})(\mathscr{T}^\nu_q),$$

$$\mathscr{U}^{\lambda,\mu}_q=(\widetilde{S}^\lambda_{q,\mu}\otimes\mathrm{id})(\mathscr{T}^\mu_q), \tag{3.7}$$

$$(\widetilde{m}^{\nu}_{q,\lambda,\mu}\otimes\mathrm{id})(\mathscr{T}^\lambda_q\dot{\otimes}\mathscr{U}^{\mu,\lambda}_q)=(\widetilde{m}^{\nu}_{q,\mu',\lambda}\otimes\mathrm{id})(\mathscr{U}^{\mu',\lambda}_q\dot{\otimes}\mathscr{T}^\lambda_q)=\widetilde{\iota}^\nu_q(1)\otimes 1_{q^\lambda},$$

$$(\mathrm{id}\otimes m_{q^\lambda})(\mathscr{T}^\lambda_q\overset{\nu}{\ddot{\otimes}}\mathscr{U}^{\mu,\lambda}_q)=(\mathrm{id}\otimes m_{q^\lambda})(\mathscr{U}^{\mu',\lambda}_q\overset{\nu}{\ddot{\otimes}}\mathscr{T}^\lambda_q)=\widetilde{\iota}^\nu_q(1)\otimes 1_{q^\lambda}.$$

Remark: The first relation in Eq. (3.7) is a well-known property of the universal $\mathscr{T}$-matrix of G_{q^λ},[16] but the remaining relations are new. Whenever the color parameters reduce to that characterizing the unit element of $\mathscr{G}$, they go over into corresponding relations for the universal $\mathscr{T}$-matrix, with $\mathscr{U}_q^{\lambda,\mu}$ becoming the element of $G_q \otimes \mathrm{U}_q(g)$ denoted as $\mathscr{T}_q^{-1}$ in Ref. 16.

With the purpose of generalizing the algebraic formulation of the RTT-relations,[16] let us introduce the colored counterparts of $\mathscr{T}_{q1} \equiv \Sigma_A x^A \otimes (X_A \otimes 1_q)$, and $\mathscr{T}_{q2} \equiv \Sigma_A x^A \otimes (1_q \otimes X_A)$.

Definition III.4: Let $\mathscr{T}_{q,1\mu}^{\lambda} \in G_{q^\lambda} \otimes U_{q^\lambda}(g) \otimes U_{q^\mu}(g)$, *and* $\mathscr{T}_{q,2\lambda}^{\mu} \in G_{q^\mu} \otimes U_{q^\lambda}(g) \otimes U_{q^\mu}(g)$ *be defined by*

$$\mathscr{T}_{q,1\mu}^{\lambda} \equiv \sum_A x^A \otimes (X_A \otimes 1_{q^\mu}), \quad \mathscr{T}_{q,2\lambda}^{\mu} \equiv \sum_B x^B \otimes (1_{q^\lambda} \otimes X_B), \tag{3.8}$$

where $\mathscr{T}_q^{\lambda} = \Sigma_A x^A \otimes X_A$, *and* $\mathscr{T}_q^{\mu} = \Sigma_B x^B \otimes X_B$ *are the universal* $\mathscr{T}$*-matrices of* G_{q^λ} *and* G_{q^μ}, *respectively.*

The searched for result is expressed in

Proposition III.5: If the colored Hopf (super)algebra $\mathrm{U}^c(g)$ *has a colored universal* $\mathscr{R}$*-matrix, then the colored universal* $\mathscr{T}$*-matrix of the colored Hopf dual* G^c *satisfies the relation*

$$(\tilde{1}_{q^\nu} \otimes \mathscr{R}_q^{\lambda,\mu})(\mathscr{T}_{q,1\mu}^{\lambda} \overset{\nu}{\cdot} \mathscr{T}_{q,2\lambda}^{\mu}) = (\mathscr{T}_{q,2\lambda}^{\mu} \overset{\nu}{\cdot} \mathscr{T}_{q,1\mu}^{\lambda})(\tilde{1}_{q^\nu} \otimes \mathscr{R}_q^{\lambda,\mu}), \tag{3.9}$$

where $\overset{\nu}{\cdot}$ *denotes a generalized multiplication such that*

$$\mathscr{T}_{q,1\mu}^{\lambda} \overset{\nu}{\cdot} \mathscr{T}_{q,2\lambda}^{\mu} \equiv \sum_{AB} \tilde{m}_{q,\lambda,\mu}^{\nu}(x^A \otimes x^B) \otimes (X_A \otimes X_B), \tag{3.10}$$

$$\mathscr{T}_{q,2\lambda}^{\mu} \overset{\nu}{\cdot} \mathscr{T}_{q,1\mu}^{\lambda} \equiv \sum_{AB} \tilde{m}_{q,\mu,\lambda}^{\nu}(x^B \otimes x^A) \otimes (X_A \otimes X_B). \tag{3.11}$$

Proof: Comparing Eq. (3.10) with the last relation in Eq. (3.5), and taking Proposition III.3 into account, we successively get

$$\mathscr{T}_{q,1\mu}^{\lambda} \overset{\nu}{\cdot} \mathscr{T}_{q,2\lambda}^{\mu} = \mathscr{T}_q^{\lambda} \overset{\nu}{\ddot{\otimes}} \mathscr{T}_q^{\mu} = (\mathrm{id} \otimes \Delta_{q,\nu}^{\lambda,\mu})(\mathscr{T}_q^{\nu}). \tag{3.12}$$

Moreover, from Eqs. (3.10)–(3.12), we also obtain

$$\mathscr{T}_{q,2\lambda}^{\mu} \overset{\nu}{\cdot} \mathscr{T}_{q,1\mu}^{\lambda} = (\mathrm{id} \otimes \tau)(\mathscr{T}_{q,1\lambda}^{\mu} \overset{\nu}{\cdot} \mathscr{T}_{q,2\mu}^{\lambda}) = (\mathrm{id} \otimes \tau \circ \Delta_{q,\nu}^{\mu,\lambda})(\mathscr{T}_q^{\nu}). \tag{3.13}$$

Equation (3.9) then directly follows from Eq. (I2.15), expressing that $\mathrm{U}^c(g)$ is almost cocommutative. ∎

To explicitly show that Proposition III.5 provides an algebraic formulation of the colored RTT-relations, introduced by Basu-Mallick,[12] one has to consider matrix representations of Eq. (3.9). For such a purpose, let us denote by $D_q^{(i)}$ matrix representations of $U_q(g)$ in some n_i-dimensional k-modules $V_q^{(i)}$, where index i distinguishes between inequivalent representations. We may now represent the elements of the colored universal $\mathscr{R}$- and $\mathscr{T}$-matrices by

$$R_q^{\lambda(i),\mu(j)} \equiv (D_{q^\lambda}^{(i)} \otimes D_{q^\mu}^{(j)})(\mathscr{R}_q^{\lambda,\mu}), \quad T_q^{\lambda(i)} \equiv \sum_A x^A D_{q^\lambda}^{(i)}(X_A), \tag{3.14}$$

which are $n_i n_j \times n_i n_j$ and $n_i \times n_i$ matrices, valued in k and G_{q^λ}, respectively. Such definitions can be extended to provide representations of the operators in Eqs. (3.8), (3.10), and (3.11), as $n_i n_j \times n_i n_j$ matrices valued in G_{q^λ}, G_{q^μ}, G_{q^ν}, and G_{q^ν}, respectively,

$$T_{q,1\mu(j)}^{\lambda(i)} \equiv \sum_A x^A (D_{q^\lambda}^{(i)}(X_A) \otimes I^{(j)}),$$

$$T^{\mu(j)}_{q,2\lambda(i)} \equiv \sum_B x^B (I^{(i)} \otimes D^{(j)}_{q^\mu}(X_B)),$$

$$T^{\lambda(i)}_{q,1\mu(j)} \overset{\nu}{\cdot} T^{\mu(j)}_{q,2\lambda(i)} \equiv \sum_{AB} \widetilde{m}^{\nu}_{q,\lambda,\mu} (x^A \otimes x^B)(D^{(i)}_{q^\lambda}(X_A) \otimes D^{(j)}_{q^\mu}(X_B)), \tag{3.15}$$

$$T^{\mu(j)}_{q,2\lambda(i)} \overset{\nu}{\cdot} T^{\lambda(i)}_{q,1\mu(j)} \equiv \sum_{AB} \widetilde{m}^{\nu}_{q,\mu,\lambda} (x^B \otimes x^A)(D^{(i)}_{q^\lambda}(X_A) \otimes D^{(j)}_{q^\mu}(X_B)).$$

Here $I^{(i)}$, and $I^{(j)}$ denote $n_i \times n_i$, and $n_j \times n_j$ unit matrices.

In the case of QUEA's of Lie superalgebras, since the $D^{(i)}_q$'s are graded matrices, their tensor product has to be evaluated in conformity with Eq. (2.14). According to the usual convention,[7] matrix multiplication of graded matrices is assumed to be the same as that of nongraded ones, whereas the tensor product of two graded matrices is defined by

$$(A \otimes B)_{ij,kl} \equiv (-1)^{\pi_k(\pi_j + \pi_l)} A_{i,k} B_{j,l}. \tag{3.16}$$

Here π_k denotes the $\mathbb{Z}_2$-grade of the kth row or column of matrix A or B. In particular, if A is homogeneous, its degree is given by $\deg A = \pi_k + \pi_l$ for any row index k, and any column index l. Special cases of Eq. (3.16) are

$$(A \otimes I)_{ij,kl} = A_{i,k} \delta_{j,l}, \quad (I \otimes A)_{ij,kl} = (-1)^{\pi_i(\pi_j + \pi_l)} \delta_{i,k} A_{j,l}. \tag{3.17}$$

From Proposition III.5, it is now straightforward to obtain

Corollary III.6: In the representation $D^{(i)}_{q^\lambda} \otimes D^{(j)}_{q^\mu}$ of $U_{q^\lambda}(g) \otimes U_{q^\mu}(g)$, Eq. (3.9) becomes

$$R^{\lambda(i),\mu(j)}_q (T^{\lambda(i)}_{q,1\mu(j)} \overset{\nu}{\cdot} T^{\mu(j)}_{q,2\lambda(i)}) = (T^{\mu(j)}_{q,2\lambda(i)} \overset{\nu}{\cdot} T^{\lambda(i)}_{q,1\mu(j)}) R^{\lambda(i),\mu(j)}_q, \tag{3.18}$$

where the various matrices are defined in Eqs. (3.14), and (3.15).

Remark: If we consider, in particular, the defining representations of $U_{q^\lambda}(g)$ and $U_{q^\mu}(g)$, Eq. (3.18) can be rewritten in a simplified notation as

$$R^{\lambda,\mu}_q (T^{\lambda}_{q1} \overset{\nu}{\cdot} T^{\mu}_{q2}) = (T^{\mu}_{q2} \overset{\nu}{\cdot} T^{\lambda}_{q1}) R^{\lambda,\mu}_q. \tag{3.19}$$

This relation is formally identical with the colored RTT-relations,

$$R^{\lambda,\mu}_q T^{\lambda}_{q1} T^{\mu}_{q2} = T^{\mu}_{q2} T^{\lambda}_{q1} R^{\lambda,\mu}_q, \tag{3.20}$$

introduced by Basu-Mallick.[12] The dependence upon ν in Eq. (3.19), which is absent in Eq. (3.20), only means that we may evaluate the latter in various dual Hopf algebras G_{q^ν}, with ν running over $\mathscr{C}$.

In the next two sections, we shall proceed to illustrate the new concepts and results presented here on two simple, but nevertheless significant examples.

IV. THE COLORED TWO-PARAMETER QUEA $U^c(gl(2))$ AND ITS DUAL $Gl^c(2)$

In I, we constructed a colored QUEA by starting from the two-parameter deformation of U(gl(2)) (Refs. 22,23) in the Burdík and Hellinger formulation.[24] On the other hand, Fronsdal and Galindo[14] analyzed the duality relationship between the pair of Hopf algebras $U_{p,q}(gl(2))$ and $Gl_{p,q}(2)$, and constructed the universal $\mathscr{T}$-matrix of the latter. It is therefore interesting to study how this duality picture can be extended to the colored context. For such a purpose, it will prove convenient to use the approach to $U_{p,q}(gl(2))$ considered in Refs. 14,20, instead of that of Ref. 24. The resulting colored QUEA will therefore differ from that constructed in I. One should remember in this respect that there exist many ways of transforming a given Hopf algebra into a colored one, depending upon the set of generators and the color group that are used.

A. The dual Hopf algebras $U_{p,q}(gl(2))$ and $Gl_{p,q}(2)$

In the standard formulation,[20,22] the quantum algebra $U_{p,q}(gl(2))$ is defined as the algebra generated by the elements $\{J_0, J_\pm, Z\}$, subject to the relations

$$[J_0, J_\pm] = \pm J_\pm, \quad [J_+, J_-] = [2J_0]_Q, \quad [Z, J_0] = [Z, J_\pm] = 0, \tag{4.1}$$

where as usual

$$[X]_t \equiv \frac{t^X - t^{-X}}{t - t^{-1}}, \tag{4.2}$$

and the following combinations of p, q are considered:

$$Q \equiv \sqrt{pq}, \quad P \equiv \sqrt{p/q}. \tag{4.3}$$

Whereas the algebraic relations (4.1) only depend upon the first of these combined parameters, the coalgebraic structure depends upon both of them.

To describe the duality relationship between $U_{p,q}(gl(2))$ and $Gl_{p,q}(2)$, one has to consider another set of $U_{p,q}(gl(2))$ generators $\{\hat{J}_0, \hat{J}_\pm, \hat{Z}\}$, defined in terms of the first one by [20]

$$\hat{J}_0 = J_0, \quad \hat{J}_\pm = J_\pm Q^{\mp J_0 - 1/2} P^{Z - 1/2}, \quad \hat{Z} = Z, \tag{4.4}$$

and satisfying the commutation relations

$$[\hat{J}_0, \hat{J}_\pm] = \pm \hat{J}_\pm, \quad [\hat{J}_+, \hat{J}_-] = P^{2\hat{Z}-1}[2\hat{J}_0]_Q, \quad [\hat{Z}, \hat{J}_0] = [\hat{Z}, \hat{J}_\pm] = 0. \tag{4.5}$$

The remaining Hopf algebra maps are

$$\begin{gathered}
\Delta_{p,q}(\hat{J}_0) = \hat{J}_0 \otimes 1 + 1 \otimes \hat{J}_0, \quad \Delta_{p,q}(\hat{Z}) = \hat{Z} \otimes 1 + 1 \otimes \hat{Z}, \\
\Delta_{p,q}(\hat{J}_+) = \hat{J}_+ \otimes Q^{-2\hat{J}_0} P^{2\hat{Z}} + 1 \otimes \hat{J}_+, \quad \Delta_{p,q}(\hat{J}_-) = \hat{J}_- \otimes 1 + Q^{2\hat{J}_0} P^{2\hat{Z}} \otimes \hat{J}_-, \\
\epsilon_{p,q}(X) = 0, \quad X \in \{\hat{J}_0, \hat{J}_\pm, \hat{Z}\}, \\
S_{p,q}(\hat{J}_0) = -\hat{J}_0, \quad S_{p,q}(\hat{Z}) = -\hat{Z}, \\
S_{p,q}(\hat{J}_+) = -\hat{J}_+ Q^{2\hat{J}_0} P^{-2\hat{Z}}, \quad S_{p,q}(\hat{J}_-) = -Q^{-2\hat{J}_0} P^{-2\hat{Z}} \hat{J}_-,
\end{gathered} \tag{4.6}$$

and the universal $\mathscr{R}$-matrix can be written as[20,25]

$$\mathscr{R}_{p,q} = Q^{-2\hat{J}_0 \otimes \hat{J}_0} P^{2(\hat{Z} \otimes \hat{J}_0 - \hat{J}_0 \otimes \hat{Z})} \sum_{n=0}^{\infty} \frac{(1 - Q^2)^n P^n}{[n]_Q!} Q^{-n(n+1)/2} \hat{J}_+^{\,n} \otimes \hat{J}_-^{\,n}, \tag{4.7}$$

where $[n]_Q! \equiv [n]_Q [n-1]_Q \cdots [1]_Q$ for $n \in \mathbb{N}^+$, and $[0]_Q! \equiv 1$.

In the 2×2 defining representation $D_{p,q}$ of $U_{p,q}(gl(2))$, given by

$$\begin{gathered}
D_{p,q}(\hat{J}_0) = \frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad D_{p,q}(\hat{Z}) = \frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \\
D_{p,q}(\hat{J}_+) = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad D_{p,q}(\hat{J}_-) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},
\end{gathered} \tag{4.8}$$

the universal $\mathscr{R}$-matrix (4.7) is represented by the 4×4 matrix

$$R_{p,q}\equiv(D_{p,q}\otimes D_{p,q})(\mathscr{R}_{p,q})=Q^{1/2}\begin{pmatrix} Q^{-1} & 0 & 0 & 0\\ 0 & P^{-1} & Q^{-1}-Q & 0\\ 0 & 0 & P & 0\\ 0 & 0 & 0 & Q^{-1}\end{pmatrix}. \tag{4.9}$$

For the corresponding quantum group $\mathrm{Gl}_{p,q}(2)$, the defining T-matrix is specified by[14,20]

$$T_{p,q}=\begin{pmatrix} a & b\\ c & d\end{pmatrix}, \tag{4.10}$$

with the commutation relations

$$\begin{gathered} ab=qba,\quad ac=pca,\quad bd=pdb,\quad cd=qdc,\\ bc=(p/q)cb,\quad ad-da=(q-p^{-1})bc,\end{gathered} \tag{4.11}$$

following from the RTT-relations corresponding to the R-matrix (4.9). The coalgebra maps are given by

$$\widetilde{\Delta}_{p,q}(T_{p,q})=T_{p,q}\dot{\otimes}T_{p,q}=\begin{pmatrix} a\otimes a+b\otimes c & a\otimes b+b\otimes d\\ c\otimes a+d\otimes c & c\otimes b+d\otimes d\end{pmatrix},\quad \widetilde{\epsilon}_{p,q}(T_{p,q})=I. \tag{4.12}$$

The quantum determinant, defined by

$$\mathscr{D}\equiv ad-qbc=ad-pcb=da-p^{-1}bc=da-q^{-1}cb, \tag{4.13}$$

is a group-like element, i.e.,

$$\widetilde{\Delta}_{p,q}(\mathscr{D})=\mathscr{D}\otimes\mathscr{D},\quad \widetilde{\epsilon}_{p,q}(\mathscr{D})=1, \tag{4.14}$$

but is not central (except for $p=q$), since

$$\mathscr{D}a=a\mathscr{D},\quad \mathscr{D}b=P^{-2}b\mathscr{D},\quad \mathscr{D}c=P^{2}c\mathscr{D},\quad \mathscr{D}d=d\mathscr{D}. \tag{4.15}$$

With the assumption that $\mathscr{D}$ is invertible, $\mathrm{Gl}_{p,q}(2)$ is endowed with an antipode map

$$\widetilde{S}_{p,q}(T_{p,q})=(T_{p,q})^{-1}=\mathscr{D}^{-1}\begin{pmatrix} d & -p^{-1}b\\ -pc & a\end{pmatrix}=\begin{pmatrix} d & -q^{-1}b\\ -qc & a\end{pmatrix}\mathscr{D}^{-1}, \tag{4.16}$$

such that $\widetilde{S}_{p,q}(\mathscr{D})=\mathscr{D}^{-1}$. This completes the Hopf algebraic structure of $\mathrm{Gl}_{p,q}(2)$.

Following Fronsdal and Galindo,[14] one may consider a Gauss decomposition of the T-matrix (4.10),

$$T_{p,q}=\begin{pmatrix} 1 & 0\\ \gamma & 1\end{pmatrix}\begin{pmatrix} a & 0\\ 0 & \hat{d}\end{pmatrix}\begin{pmatrix} 1 & \beta\\ 0 & 1\end{pmatrix}, \tag{4.17}$$

where a and $\hat{d}$ are assumed invertible, thence $\beta=a^{-1}b$, $\gamma=ca^{-1}$, $\hat{d}=d-ca^{-1}b$. By assuming that the algebra can be augmented with the logarithms of a and $\hat{d}$, and by using the maps

$$a=e^{\alpha},\quad \hat{d}=e^{-\delta}, \tag{4.18}$$

and the reparametrization

$$P=e^{\theta},\quad Q=e^{\varphi}, \tag{4.19}$$

the quantum determinant (4.13) is transformed into $\mathscr{D}=\exp(\alpha-\delta)$, and the new variables $\{\alpha,\beta,\gamma,\delta\}$ are seen to satisfy the commutation relations of a solvable Lie algebra

$$[\alpha,\beta]=(\varphi-\theta)\beta, \quad [\alpha,\gamma]=(\varphi+\theta)\gamma, \quad [\alpha,\delta]=0,$$
$$[\delta,\beta]=(\varphi+\theta)\beta, \quad [\delta,\gamma]=(\varphi-\theta)\gamma, \quad [\beta,\gamma]=0, \tag{4.20}$$

with a noncocommutatitve coproduct structure. As a consequence, $\mathrm{Gl}_{p,q}(2)$ can be embedded into the enveloping algebra $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ of such a Lie algebra. As shown by Fronsdal and Galindo,[14] $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ is dual to the QUEA $\mathrm{U}_{p,q}(\mathrm{gl}(2))$. Following common practice, we shall mean the larger enveloping algebra $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ whenever speaking of the duality between $\mathrm{U}_{p,q}(\mathrm{gl}(2))$ and $\mathrm{Gl}_{p,q}(2)$.

Dual bases of $\mathrm{U}_{p,q}(\mathrm{gl}(2))$ and $\mathrm{Gl}_{p,q}(2)$ are given by[14]

$$X_A=\frac{Q^{a_1(a_1-1)/2}\hat{J}_-^{a_1}}{[a_1]_Q!}\frac{H^{a_2}}{a_2!}\frac{\widetilde{H}^{a_3}}{a_3!}\frac{Q^{-a_4(a_4-1)/2}\hat{J}_+^{a_4}}{[a_4]_Q!}, \tag{4.21}$$

and

$$x^A=\gamma^{a_1}\alpha^{a_2}\delta^{a_3}\beta^{a_4}, \tag{4.22}$$

respectively, where

$$H\equiv\hat{J}_0+\hat{Z}, \quad \widetilde{H}\equiv\hat{J}_0-\hat{Z}, \tag{4.23}$$

$A=(a_1,a_2,a_3,a_4)$, and a_1, a_2, a_3, $a_4\in\mathbb{N}$. From Eqs. (3.2), (4.21), and (4.22), the universal $\mathscr{T}$-matrix of $\mathrm{Gl}_{p,q}(2)$ can be written as

$$\mathscr{T}_{p,q}=\mathscr{E}xp_{Q^{-2}}(\gamma\otimes\hat{J}_-)\exp(\alpha\otimes H+\delta\otimes\widetilde{H})\mathscr{E}xp_{Q^2}(\beta\otimes\hat{J}_+), \tag{4.24}$$

in terms of the basic exponential function

$$\mathscr{E}xp_{t^2}(z)=\sum_{n=0}^{\infty}\frac{t^{-n(n-1)/2}}{[n]_t!}z^t. \tag{4.25}$$

In the next subsection, it will prove convenient to consider another set of dual bases

$$\overline{X_A}=\sum_B c_A^B X_B=\frac{Q^{a_1(a_1-1)/2}\hat{J}_-^{a_1}}{[a_1]_Q!}\frac{\hat{J}_0^{a_2}}{a_2!}\frac{\hat{Z}^{a_3}}{a_3!}\frac{Q^{-a_4(a_4-1)/2}\hat{J}_+^{a_4}}{[a_4]_Q!}, \tag{4.26}$$

$$\overline{x^A}=\sum_B (c^{-1})_B^A x^B=\gamma^{a_1}h^{a_2}\widetilde{h}^{a_3}\beta^{a_4}. \tag{4.27}$$

Here, A has the same meaning as in Eqs. (4.21), (4.22),

$$h\equiv\alpha+\delta, \quad \widetilde{h}\equiv\alpha-\delta, \tag{4.28}$$

and

$$c_A^B=2^{-a_2-a_3}(c^{-1})_A^B=\delta_{a_1}^{b_1}\delta_{a_2+a_3}^{b_2+b_3}\delta_{a_4}^{b_4}2^{-a_2-a_3}\sum_{t=\max(0,b_2-a_2)}^{\min(b_2,a_3)}(-1)^{a_3-t}\binom{b_2}{t}\binom{b_3}{a_3-t}, \tag{4.29}$$

where $\binom{s}{t}$ denotes a standard binomial coefficient. In terms of such dual bases, the universal $\mathscr{T}$-matrix (4.24) can be written as

$$\mathscr{T}_{p,q}=\mathscr{E}xp_{Q^{-2}}(\gamma\otimes\hat{J}_-)\exp(h\otimes\hat{J}_0+\widetilde{h}\otimes\hat{Z})\mathscr{E}xp_{Q^2}(\beta\otimes\hat{J}_+). \tag{4.30}$$

B. The colored Hopf algebra $U^c(gl(2))$ and its dual $Gl^c(2)$

The defining relations (4.5) of the $U_{p,q}(gl(2))$ algebra are left invariant under the transformations

$$\sigma^\nu(\hat{J}_0)=\hat{J}_0, \quad \sigma^\nu(\hat{J}_\pm)=P^{(\nu-1)/2}\hat{J}_\pm, \quad \sigma^\nu(\hat{Z})=\nu\hat{Z}, \tag{4.31}$$

where $\nu\in\mathscr{C}=\mathbb{C}\backslash\{0\}$, provided P is replaced by its νth power, while Q is left unchanged, or equivalently[26]

$$(p,q)\rightarrow(p^{(\nu)},q^{(\nu)})=(p^{(1+\nu)/2}q^{(1-\nu)/2},p^{(1-\nu)/2}q^{(1+\nu)/2}). \tag{4.32}$$

Hence, the σ^ν's are isomorphic mappings between two $U_{p,q}(gl(2))$ algebras with different parameters, as given in Eq. (4.32), and they define a color group $\mathscr{G}=Gl(1,\mathbb{C})$, since $\nu'\circ\nu=\nu'\nu$, $\nu^0=1$, and $\nu^i=\nu^{-1}$.

By choosing the parameter set $Q=(\mathbb{C}\backslash\{0\})\times(\mathbb{C}\backslash\{0\})$, we therefore obtain a colored quasitriangular Hopf algebra $U^c(gl(2))$, whose colored comultiplication, counit, antipode, and $\mathscr{R}$-matrix are given by

$$\Delta^{\lambda,\mu}_{p,q,\nu}(\hat{J}_0)=\hat{J}_0\otimes 1+1\otimes\hat{J}_0, \quad \Delta^{\lambda,\mu}_{p,q,\nu}(\hat{Z})=\frac{\lambda}{\nu}\hat{Z}\otimes 1+\frac{\mu}{\nu}1\otimes\hat{Z},$$

$$\Delta^{\lambda,\mu}_{p,q,\nu}(\hat{J}_+)=P^{(\lambda-\nu)/2}\hat{J}_+\otimes Q^{-2\hat{J}_0}P^{2\mu\hat{Z}}+P^{(\mu-\nu)/2}1\otimes\hat{J}_+,$$

$$\Delta^{\lambda,\mu}_{p,q,\nu}(\hat{J}_-)=P^{(\lambda-\nu)/2}\hat{J}_-\otimes 1+P^{(\mu-\nu)/2}Q^{2\hat{J}_0}P^{2\lambda\hat{Z}}\otimes\hat{J}_-,$$

$$\epsilon_{p,q,\nu}(X)=0, \quad X\in\{\hat{J}_0,\hat{J}_\pm,\hat{Z}\},$$

$$S^{\mu}_{p,q,\nu}(\hat{J}_0)=-\hat{J}_0, \quad S^{\mu}_{p,q,\nu}(\hat{J}_+)=-P^{(\mu-\nu)/2}\hat{J}_+Q^{2\hat{J}_0}P^{-2\mu\hat{Z}}, \tag{4.33}$$

$$S^{\mu}_{p,q,\nu}(\hat{J}_-)=-P^{(\mu-\nu)/2}Q^{-2\hat{J}_0}P^{-2\mu\hat{Z}}\hat{J}_-, \quad S^{\mu}_{p,q,\nu}(\hat{Z})=-\frac{\mu}{\nu}\hat{Z},$$

$$\mathscr{R}^{\lambda,\mu}_{p,q}=Q^{-2\hat{J}_0\otimes\hat{J}_0}P^{2(\lambda\hat{Z}\otimes\hat{J}_0-\mu\hat{J}_0\otimes\hat{Z})}\sum_{n=0}^{\infty}\frac{(1-Q^2)^n}{[n]_Q!}Q^{-n(n+1)/2}P^{(\lambda+\mu)n/2}\hat{J}_+^n\otimes\hat{J}_-^n,$$

respectively.

In the defining representation (4.8), the colored universal $\mathscr{R}$-matrix is represented by the 4×4 matrix,

$$R^{\lambda,\mu}_{p,q}=Q^{1/2}\begin{pmatrix} Q^{-1}P^{(\lambda-\mu)/2} & 0 & 0 & 0 \\ 0 & P^{-(\lambda+\mu)/2} & Q^{-1}-Q & 0 \\ 0 & 0 & P^{(\lambda+\mu)/2} & 0 \\ 0 & 0 & 0 & Q^{-1}P^{-(\lambda-\mu)/2} \end{pmatrix}, \tag{4.34}$$

which is a matrix solution of the colored YBE (I1.5), and gives back matrix (4.9) whenever λ, $\mu\rightarrow1$.

Under transformation (4.31), the basis elements $\overline{X_A}$ of $U_{p,q}(gl(2))$, defined in Eq. (4.26), become

$$\sigma^\nu(\overline{X_A})=P^{(\nu-1)(a_1+a_4)/2}\nu^{a_3}\overline{X_A}. \tag{4.35}$$

Hence, from Eqs. (2.4) and (3.1), it follows that

$$\rho^\nu(\overline{x^A})=P^{(1-\nu)(a_1+a_4)/2}\nu^{-a_3}\overline{x^A} \tag{4.36}$$

defines an isomorphic mapping between the $\mathrm{Gl}_{p,q}(2)$ coalgebras whose parameters are given in Eq. (4.32). By taking Eqs. (4.27) and (4.28) into account, and by summing both sides of Eq. (4.36) over a_2 and a_3, we also obtain the relation

$$\rho^{\nu}(\gamma^{a_1}e^{r(\alpha+\delta)}e^{s(\alpha-\delta)}\beta^{a_4})=P^{(1-\nu)(a_1+a_4)/2}\gamma^{a_1}e^{r(\alpha+\delta)}e^{s(\alpha-\delta)/\nu}\beta^{a_4}, \tag{4.37}$$

valid for any a_1, $a_4\in\mathbb{N}$, and any r, $s\in\mathbb{C}$.

The action of ρ^{ν}, and of its inverse ρ_{ν}, on α, β, γ, δ,

$$\begin{aligned}
&\rho^{\nu}(\alpha)=\frac{\nu+1}{2\nu}\,\alpha+\frac{\nu-1}{2\nu}\,\delta, \quad \rho^{\nu}(\beta)=P^{(1-\nu)/2}\beta,\\
&\rho^{\nu}(\gamma)=P^{(1-\nu)/2}\gamma, \quad \rho^{\nu}(\delta)=\frac{\nu-1}{2\nu}\,\alpha+\frac{\nu+1}{2\nu}\,\delta,
\end{aligned} \tag{4.38}$$

$$\begin{aligned}
&\rho_{\nu}(\alpha)=\frac{1+\nu}{2}\,\alpha+\frac{1-\nu}{2}\,\delta, \quad \rho_{\nu}(\beta)=P^{(\nu-1)/2}\beta,\\
&\rho_{\nu}(\gamma)=P^{(\nu-1)/2}\gamma, \quad \rho_{\nu}(\delta)=\frac{1-\nu}{2}\,\alpha+\frac{1+\nu}{2}\,\delta,
\end{aligned} \tag{4.39}$$

and on a, b, c, d, $\mathscr{D}$,

$$\begin{aligned}
&\rho^{\nu}(a)=\mathscr{D}^{(1-\nu)/(2\nu)}a, \quad \rho^{\nu}(b)=(P^{\nu}\mathscr{D})^{(1-\nu)/(2\nu)}b,\\
&\rho^{\nu}(c)=(P^{-\nu}\mathscr{D})^{(1-\nu)/(2\nu)}c, \quad \rho^{\nu}(d)=\mathscr{D}^{(1-\nu)/(2\nu)}d, \quad \rho^{\nu}(\mathscr{D})=\mathscr{D}^{1/\nu},
\end{aligned} \tag{4.40}$$

$$\begin{aligned}
&\rho_{\nu}(a)=\mathscr{D}^{(\nu-1)/2}a, \quad \rho_{\nu}(b)=(P\mathscr{D})^{(\nu-1)/2}b,\\
&\rho_{\nu}(c)=(P^{-1}\mathscr{D})^{(\nu-1)/2}c, \quad \rho_{\nu}(d)=\mathscr{D}^{(\nu-1)/2}d, \quad \rho_{\nu}(\mathscr{D})=\mathscr{D}^{\nu},
\end{aligned} \tag{4.41}$$

can be obtained as special cases of Eqs. (4.36), and (4.37), respectively.[27]

By using Eqs. (2.7), (4.11), (4.15), (4.16), (4.17), (4.18), (4.37), and (4.41), it is straightforward to determine the colored maps of $\mathrm{Gl}^{c}(2)$. The results are listed in Appendix A.

We shall now proceed to show that the relations obtained for $\widetilde{m}^{\nu}_{p,q,\lambda,\mu}$ can be rewritten in an alternative way. For such a purpose, in analogy with Eq. (3.15), let us define

$$x(\lambda)\overset{\nu}{\cdot}y(\mu)\equiv\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes y), \tag{4.42}$$

where to avoid ambiguity, we specify the algebra to which each element belongs by the corresponding color parameter, e.g., $x(\lambda)\in\mathrm{Gl}_{p^{(\lambda)},q^{(\lambda)}}(2)$.

The 16 relations expressing $\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes y)$, x, $y\in\{a,b,c,d\}$, as elements of $\mathrm{Gl}_{p^{(\nu)},q^{(\nu)}}(2)$, and given in Eqs. (A1), (A5), can be combined into two different sets. The first one contains the relations

$$\begin{aligned}
&a(\lambda)\overset{\nu}{\cdot}b(\mu)=q^{(\lambda)}b(\mu)\overset{\nu}{\cdot}a(\lambda), \quad a(\lambda)\overset{\nu}{\cdot}c(\mu)=p^{(\lambda)}c(\mu)\overset{\nu}{\cdot}a(\lambda),\\
&b(\lambda)\overset{\nu}{\cdot}d(\mu)=p^{(\mu)}d(\mu)\overset{\nu}{\cdot}a(\lambda), \quad c(\lambda)\overset{\nu}{\cdot}d(\mu)=q^{(\mu)}d(\mu)\overset{\nu}{\cdot}c(\lambda),\\
&b(\lambda)\overset{\nu}{\cdot}c(\mu)=\left(\frac{p^{(\lambda)}p^{(\mu)}}{q^{(\lambda)}q^{(\mu)}}\right)^{1/2}c(\mu)\overset{\nu}{\cdot}b(\lambda),
\end{aligned} \tag{4.43}$$

$$a(\lambda)\overset{\nu}{\cdot}d(\mu)-d(\mu)\overset{\nu}{\cdot}a(\lambda)=\{(q^{(\lambda)}q^{(\mu)})^{1/2}-(p^{(\lambda)}p^{(\mu)})^{-1/2}\}b(\lambda)\overset{\nu}{\cdot}c(\mu),$$

giving back the $\mathrm{Gl}_{p,q}(2)$ defining relations (4.11) in the λ, μ, $\nu\to1$ limit, while the second set is given by the equations

$$
\begin{gathered}
a(\lambda)\overset{\nu}{\cdot}a(\mu)=a(\mu)\overset{\nu}{\cdot}a(\lambda), \quad a(\lambda)\overset{\nu}{\cdot}b(\mu)=P^{(\mu-\lambda)/2}a(\mu)\overset{\nu}{\cdot}b(\lambda), \\
a(\lambda)\overset{\nu}{\cdot}c(\mu)=P^{(\lambda-\mu)/2}a(\mu)\overset{\nu}{\cdot}c(\lambda), \quad a(\lambda)\overset{\nu}{\cdot}d(\mu)=a(\mu)\overset{\nu}{\cdot}d(\lambda), \\
b(\lambda)\overset{\nu}{\cdot}b(\mu)=P^{\mu-\lambda}b(\mu)\overset{\nu}{\cdot}b(\lambda), \quad b(\lambda)\overset{\nu}{\cdot}c(\mu)=b(\mu)\overset{\nu}{\cdot}c(\lambda), \\
b(\lambda)\overset{\nu}{\cdot}d(\mu)=P^{(\mu-\lambda)/2}b(\mu)\overset{\nu}{\cdot}d(\lambda), \quad c(\lambda)\overset{\nu}{\cdot}c(\mu)=P^{\lambda-\mu}c(\mu)\overset{\nu}{\cdot}c(\lambda), \\
c(\lambda)\overset{\nu}{\cdot}d(\mu)=P^{(\lambda-\mu)/2}c(\mu)\overset{\nu}{\cdot}d(\lambda), \quad d(\lambda)\overset{\nu}{\cdot}d(\mu)=d(\mu)\overset{\nu}{\cdot}d(\lambda),
\end{gathered}
\tag{4.44}
$$

which have no standard counterpart.

Similarly, the relations for the colored multiplication involving the quantum determinant, given in Eqs. (A2), (A3), (A4), (A6), and (A7), can be rewritten as

$$
\begin{gathered}
\mathscr{D}(\lambda)\overset{\nu}{\cdot}a(\mu)=a(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda), \quad \mathscr{D}(\lambda)\overset{\nu}{\cdot}b(\mu)=P^{-2\lambda}b(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda), \\
\mathscr{D}(\lambda)\overset{\nu}{\cdot}c(\mu)=P^{2\lambda}c(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda), \quad \mathscr{D}(\lambda)\overset{\nu}{\cdot}d(\mu)=d(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda),
\end{gathered}
\tag{4.45}
$$

and

$$
\begin{gathered}
\mathscr{D}(\lambda)\overset{\nu}{\cdot}a(\mu)=(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(\mathscr{D}(\mu)\overset{\nu}{\cdot}a(\lambda)), \\
\mathscr{D}(\lambda)\overset{\nu}{\cdot}b(\mu)=P^{(\mu-\lambda)/2}(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(\mathscr{D}(\mu)\overset{\nu}{\cdot}b(\lambda)), \\
\mathscr{D}(\lambda)\overset{\nu}{\cdot}c(\mu)=P^{(\lambda-\mu)/2}(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(\mathscr{D}(\mu)\overset{\nu}{\cdot}c(\lambda)), \\
\mathscr{D}(\lambda)\overset{\nu}{\cdot}d(\mu)=(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(\mathscr{D}(\mu)\overset{\nu}{\cdot}d(\lambda)), \\
\mathscr{D}(\lambda)\overset{\nu}{\cdot}\mathscr{D}(\mu)=\mathscr{D}(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda),
\end{gathered}
\tag{4.46}
$$

where the first set leads to Eq. (4.15) in the λ, μ, $\nu\rightarrow 1$ limit, while the second has again no standard counterpart.

The simplicity of Eqs. (4.43), and (4.44) should be stressed. It is also remarkable that these equations are entirely independent of the final Hopf algebra color parameter ν. Such a property reflects the fact that the two sets of equations (4.43), (4.44) are equivalent to the single matrix equation (3.19), where $R^{\lambda,\mu}_{p,q}$ is given by Eq. (4.34), and

$$
T^{\lambda}_{p,q}=T_{p^{(\lambda)},q^{(\lambda)}}=\begin{pmatrix} a(\lambda) & b(\lambda) \\ c(\lambda) & d(\lambda) \end{pmatrix}.
$$

It can indeed be checked by expressing Eq. (3.19) in elementwise form that the resulting independent relations can be grouped together in two sets, given by Eqs. (4.43), and (4.44). Since, moreover, the coalgebraic structure of $\mathrm{Gl}^c(2)$ coincides with that of each individual standard quantum group $\mathrm{Gl}_{p,q}(2)$, for (p,q) running over $\mathcal{Q}$, we did show in a very explicit way that our colored $\mathrm{Gl}^c(2)$ is equivalent to the colored extension of $\mathrm{Gl}_{p,q}(2)$, defined through colored RTT-relations, according to Basu-Mallick's prescription.[12]

By the way, it is worth noting that since parameter Q is left unchanged by the color group transformations, the elements $\mathscr{T}^{\lambda}_{p,q}$ of the colored universal $\mathscr{T}$-matrix, considered in Definition III.1, have no explicit λ-dependence, so that they are all given by Eq. (4.30) with $\hat{J}_0$, $\hat{J}_{\pm}$, $\hat{Z}$ $\in \mathrm{U}_{p^{(\lambda)},q^{(\lambda)}}(\mathrm{gl}(2))$, and h, $\tilde{h}$, β, $\gamma \in \mathrm{Gl}_{p^{(\lambda)},q^{(\lambda)}}(2)$.

As a final point of this section, let us mention that the colored maps $\tilde{m}^{\nu}_{p,q,\lambda,\mu}$, $\tilde{\iota}^{\nu}_{p,q}$, and $\tilde{S}^{\nu}_{p,q,\mu}$ may be extended from $\mathrm{Gl}^c(2)$ to the whole dual of $\mathrm{U}^c(\mathrm{gl}(2))$ by considering the enveloping algebras $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ for (p,q) running over Q. For the colored multiplication, for instance, one finds that the 16 relations giving $\tilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes y)$, $x,\ y\in\{\alpha,\beta,\gamma,\delta\}$, can be combined into six generalized commutation relations

$$
\begin{aligned}
&[\alpha(\lambda),\beta(\mu)]^{\nu}=P^{(\mu-\nu)/2}(\varphi-\lambda\theta)\beta(\nu), \quad [\alpha(\lambda),\gamma(\mu)]^{\nu}=P^{(\mu-\nu)/2}(\varphi+\lambda\theta)\gamma(\nu),\\
&[\delta(\lambda),\beta(\mu)]^{\nu}=P^{(\mu-\nu)/2}(\varphi+\lambda\theta)\beta(\nu), \quad [\delta(\lambda),\gamma(\mu)]^{\nu}=P^{(\mu-\nu)/2}(\varphi-\lambda\theta)\gamma(\nu),\\
&[\alpha(\lambda),\delta(\mu)]^{\nu}=0, \quad [\beta(\lambda),\gamma(\mu)]^{\nu}=0,
\end{aligned}
\tag{4.47}
$$

where

$$
[x(\lambda),y(\mu)]^{\nu}\equiv x(\lambda)\overset{\nu}{\cdot}y(\mu)-y(\mu)\overset{\nu}{\cdot}x(\lambda), \tag{4.48}
$$

and ten additional relations

$$
\begin{aligned}
&[\alpha(\lambda),\alpha(\mu)]^{\nu}=[\beta(\lambda),\beta(\mu)]^{\nu}=[\gamma(\lambda),\gamma(\mu)]^{\nu}=[\delta(\lambda),\delta(\mu)]^{\nu}=0,\\
&\alpha(\lambda)\overset{\nu}{\cdot}\beta(\mu)=P^{(\mu-\lambda)/2}(2\mu)^{-1}((\lambda+\mu)\alpha(\mu)\overset{\nu}{\cdot}\beta(\lambda)-(\lambda-\mu)\delta(\mu)\overset{\nu}{\cdot}\beta(\lambda)),\\
&\gamma(\lambda)\overset{\nu}{\cdot}\alpha(\mu)=P^{(\lambda-\mu)/2}(2\lambda)^{-1}((\lambda+\mu)\gamma(\mu)\overset{\nu}{\cdot}\alpha(\lambda)+(\lambda-\mu)\gamma(\mu)\overset{\nu}{\cdot}\delta(\lambda)),\\
&\alpha(\lambda)\overset{\nu}{\cdot}\delta(\mu)=\alpha(\mu)\overset{\nu}{\cdot}\delta(\lambda)+(\lambda-\mu)(\lambda+\mu)^{-1}(\alpha(\mu)\overset{\nu}{\cdot}\alpha(\lambda)-\delta(\mu)\overset{\nu}{\cdot}\delta(\lambda)),\\
&\gamma(\lambda)\overset{\nu}{\cdot}\beta(\mu)=\gamma(\mu)\overset{\nu}{\cdot}\beta(\lambda),\\
&\delta(\lambda)\overset{\nu}{\cdot}\beta(\mu)=P^{(\mu-\lambda)/2}(2\mu)^{-1}(-(\lambda-\mu)\alpha(\mu)\overset{\nu}{\cdot}\beta(\lambda)+(\lambda+\mu)\delta(\mu)\overset{\nu}{\cdot}\beta(\lambda)),\\
&\gamma(\lambda)\overset{\nu}{\cdot}\delta(\mu)=P^{(\lambda-\mu)/2}(2\lambda)^{-1}((\lambda-\mu)\gamma(\mu)\overset{\nu}{\cdot}\alpha(\lambda)+(\lambda+\mu)\gamma(\mu)\overset{\nu}{\cdot}\delta(\lambda)).
\end{aligned}
\tag{4.49}
$$

Whenever $\lambda,\ \mu,\ \nu\to 1$, the former set reproduces the defining relations (4.20) of $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$, whereas the latter has no standard counterpart. Let us stress that contrary to what happens in Eqs. (4.43) and (4.44), there appears an explicit ν-dependence in Eqs. (4.47), and (4.49).

V. THE COLORED TWO-PARAMETER QUEA $\mathrm{U}^c(\mathrm{gl}(1/1))$ AND ITS DUAL $\mathrm{Gl}^c(1/1)$

One of the simplest examples of dual pairs made of a QUEA of a Lie superalgebra and of a quantum supergroup consists in the two-parameter deformations of U(gl(1/1)) and Gl(1/1),[28–32] which find some interesting applications to the multivariable Alexander–Conway polynomial and the free fermion model,[33] and, in another context, to the XY quantum chain in a magnetic field.[34]

In II, a colored QUEA was constructed by starting from the two-parameter deformation of U(gl(1/1)) in the Bednar *et al.* formulation.[30,31] Moreover, Chakrabarti and Jagannathan[21] recently extended the Fronsdal and Galindo universal T-matrix formalism[14] to the pair of Hopf superalgebras $\mathrm{U}_{p,q}(\mathrm{gl}(1/1))$ and $\mathrm{Gl}_{p,q}(1/1)$. So all the ingredients needed to build an example of colored Hopf dual in the graded case are available. To solve such a problem, we shall use the approach to $\mathrm{U}_{p,q}(\mathrm{gl}(1/1))$ employed in Ref. 21, instead of that of Refs. 30,31; hence, the results for $\mathrm{U}^c(\mathrm{gl}(1/1))$ derived here will slightly differ from those obtained in II.

A. The dual Hopf superalgebras $\mathrm{U}_{p,q}(\mathrm{gl}(1/1))$ and $\mathrm{Gl}_{p,q}(1/1)$

The quantum superalgebra $\mathrm{U}_{p,q}(\mathrm{gl}(1/1))$ is defined[21] as the algebra generated by two even elements $\{J_0,Z\}$, and two odd ones $\{J_+,J_-\}$, subject to the relations

$$
[J_0,J_\pm]=\pm J_\pm, \quad \{J_+,J_-\}=[2Z]_Q, \quad J_\pm^2=0, \quad [Z,J_0]=[Z,J_\pm]=0, \tag{5.1}
$$

where $[X]_t$, and Q, P are still defined by Eqs. (4.2) and (4.3), respectively. As in the $U_{p,q}(gl(2))$ case, the coalgebraic structure depends upon both P and Q.

The duality relationship between $U_{p,q}(gl(1/1))$ and $Gl_{p,q}(1/1)$ is most easily described in terms of another set of $U_{p,q}(gl(1/1))$ generators $\{\hat{J}_0,\hat{J}_\pm,\hat{Z}\}$, with $\hat{J}_0$, $\hat{Z}$ even, and $\hat{J}_\pm$ odd. The new generators are defined in terms of the old ones by

$$\hat{J}_0=J_0, \quad \hat{J}_\pm=J_\pm Q^{\pm Z}P^{Z-1/2}, \quad \hat{Z}=Z, \tag{5.2}$$

and satisfy the superalgebra (anti)commutation relations

$$\begin{gathered}[\hat{J}_0,\hat{J}_\pm]=\pm\hat{J}_\pm, \quad \{\hat{J}_+,\hat{J}_-\}=\frac{p^{2\hat{Z}}-q^{-2\hat{Z}}}{p-q^{-1}}, \quad \hat{J}_\pm^2=0,\\ [\hat{Z},\hat{J}_0]=[\hat{Z},\hat{J}_\pm]=0.\end{gathered} \tag{5.3}$$

The remaining Hopf superalgebra maps are given by

$$\begin{gathered}\Delta_{p,q}(\hat{J}_0)=\hat{J}_0\otimes 1+1\otimes\hat{J}_0, \quad \Delta_{p,q}(\hat{Z})=\hat{Z}\otimes 1+1\otimes\hat{Z},\\ \Delta_{p,q}(\hat{J}_+)=\hat{J}_+\otimes p^{2\hat{Z}}+1\otimes\hat{J}_+, \quad \Delta_{p,q}(\hat{J}_-)=\hat{J}_-\otimes 1+q^{-2\hat{Z}}\otimes\hat{J}_-,\\ \epsilon_{p,q}(X)=0, \quad X\in\{\hat{J}_0,\hat{J}_\pm,\hat{Z}\},\\ S_{p,q}(\hat{J}_0)=-\hat{J}_0, \quad S_{p,q}(\hat{Z})=-\hat{Z},\\ S_{p,q}(\hat{J}_+)=-p^{-2\hat{Z}}\hat{J}_+, \quad S_{p,q}(\hat{J}_-)=-q^{2\hat{Z}}\hat{J}_-,\end{gathered} \tag{5.4}$$

and the universal $\mathscr{R}$-matrix can be written as[31,32]

$$\mathscr{R}_{p,q}=p^{2\hat{Z}\otimes\hat{J}_0}q^{2\hat{J}_0\otimes\hat{Z}}\{1\otimes 1-(p-q^{-1})\hat{J}_+\otimes\hat{J}_-\}. \tag{5.5}$$

In the 2×2 defining representation $D_{p,q}$ of $U_{p,q}(gl(1/1))$, given by Eq. (4.8), the universal $\mathscr{R}$-matrix (5.5) is represented by the 4×4 matrix,

$$R_{p,q}\equiv(D_{p,q}\otimes D_{p,q})(\mathscr{R}_{p,q})=\begin{pmatrix} Q & 0 & 0 & 0\\ 0 & P^{-1} & Q-Q^{-1} & 0\\ 0 & 0 & P & 0\\ 0 & 0 & 0 & Q^{-1}\end{pmatrix}. \tag{5.6}$$

In deriving Eq. (5.6), use is made of Eq. (3.16) with the $\mathbb{Z}_2$-grade of the first (resp. second) row or column of $D_{p,q}(X)$ defined as zero (resp. one).

The defining T-matrix of the corresponding quantum supergroup $Gl_{p,q}(1/1)$ is still given by Eq. (4.10), where a, d, and b, c are now even and odd, respectively, and satisfy the relations

$$\begin{gathered}ab=p^{-1}ba, \quad ac=q^{-1}ca, \quad bd=pdb, \quad cd=qdc,\\ bc=-(p/q)cb, \quad ad-da=(q-p^{-1})bc, \quad b^2=c^2=0.\end{gathered} \tag{5.7}$$

The latter follow from the RTT-relations corresponding to the R-matrix (5.6), with convention (3.17) taken into account. The coalgebra maps are given by Eq. (4.12), while the antipode one is

$$\widetilde{S}_{p,q}(T_{p,q})=(T_{p,q})^{-1}=\begin{pmatrix} a^{-1}+a^{-1}bd^{-1}ca^{-1} & -a^{-1}bd^{-1}\\ -d^{-1}ca^{-1} & d^{-1}+d^{-1}ca^{-1}bd^{-1}\end{pmatrix}, \tag{5.8}$$

where a and d are assumed invertible. The quantum superdeterminant, defined by

$$\mathscr{D}\equiv ad^{-1}-bd^{-1}cd^{-1}, \tag{5.9}$$

is both central and group-like, with $\widetilde{S}_{p,q}(\mathscr{D})=\mathscr{D}^{-1}=da^{-1}+ba^{-1}ca^{-1}$.

Gauss decomposition (4.17) still holds, but now a and $\hat{d}$ are invertible even elements, while β and γ are odd. The antipode map and the quantum superdeterminant may be rewritten as

$$\widetilde{S}_{p,q}(T_{p,q})=\begin{pmatrix} a^{-1}-p^{-1}qca^{-2}\hat{d}^{-1}b & -p^{-1}a^{-1}\hat{d}^{-1}b \\ -qca^{-1}\hat{d}^{-1} & \hat{d}^{-1} \end{pmatrix}, \tag{5.10}$$

and

$$\mathscr{D}=a\hat{d}^{-1}, \tag{5.11}$$

respectively.

By assuming that the superalgebra can be augmented with the logarithms of a and $\hat{d}$, and by using the maps

$$a=e^{\alpha}, \quad \hat{d}=e^{\delta}, \tag{5.12}$$

and the reparametrization

$$p=e^{-\omega}, \quad q=e^{-\eta}, \tag{5.13}$$

the quantum superdeterminant is transformed into $\mathscr{D}=\exp(\alpha-\delta)$, and the new variables $\{\alpha,\beta,\gamma,\delta\}$ satisfy the (anti)commutation relations of a solvable Lie superalgebra

$$\begin{gathered} [\alpha,\beta]=\omega\beta, \quad [\alpha,\gamma]=\eta\gamma, \quad [\delta,\beta]=\omega\beta, \quad [\delta,\gamma]=\eta\gamma, \\ [\alpha,\delta]=0, \quad \{\beta,\gamma\}=0, \quad \beta^2=0, \quad \gamma^2=0, \end{gathered} \tag{5.14}$$

with a noncocommutative coproduct structure.[21] This shows that $\mathrm{Gl}_{p,q}(1/1)$ can be embedded into the enveloping algebra $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ of such a Lie superalgebra. According to Chakrabarti and Jagannathan,[21] $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ is dual to the QUEA $\mathrm{U}_{p,q}(\mathrm{gl}(1/1))$.[35]

Dual bases of $\mathrm{U}_{p,q}(\mathrm{gl}(1/1))$ and $\mathrm{Gl}_{p,q}(1/1)$ are given by[21]

$$X_A=\hat{J}_{-}^{a_1}\frac{H^{a_2}}{a_2!}\frac{\widetilde{H}^{a_3}}{a_3!}\hat{J}_{+}^{a_4}, \quad x^A=\gamma^{a_1}\alpha^{a_2}\delta^{a_3}\beta^{a_4}, \tag{5.15}$$

respectively, where $H\equiv\hat{Z}+\hat{J}_0$, $\widetilde{H}\equiv\hat{Z}-\hat{J}_0$, $A=(a_1,a_2,a_3,a_4)$, a_1, $a_4\in\{0,1\}$, and a_2, $a_3\in\mathbb{N}$. From Eqs. (3.2), and (5.15), the universal $\mathscr{T}$-matrix of $\mathrm{Gl}_{p,q}(1/1)$ can be written as

$$\mathscr{T}_{p,q}=\exp(\gamma\otimes\hat{J}_{-})\exp(\alpha\otimes H+\delta\otimes\widetilde{H})\exp(\beta\otimes\hat{J}_{+}), \tag{5.16}$$

in terms of standard exponentials.

In the next subsection, it will prove convenient to consider another set of dual bases

$$\overline{X_A}=\sum_B c_A^B X_B=\hat{J}_{-}^{a_1}\frac{\hat{J}_0^{a_2}}{a_2!}\frac{\hat{Z}^{a_3}}{a_3!}\hat{J}_{+}^{a_4}, \tag{5.17}$$

$$\overline{x^A}=\sum_B (c^{-1})_B^A x^B=\gamma^{a_1}h^{a_2}\widetilde{h}^{a_3}\beta^{a_4}, \tag{5.18}$$

where A has the same meaning as in Eq. (5.15),

$$h\equiv\alpha-\delta, \quad \widetilde{h}\equiv\alpha+\delta, \tag{5.19}$$

and

$$c_A^B=2^{-a_2-a_3}(-1)^{a_2-b_2}(c^{-1})_A^B$$

$$= \delta^{b_1}_{a_1}\delta^{b_2+b_3}_{a_2+a_3}\delta^{b_4}_{a_4} 2^{-a_2-a_3} \sum_{t=\max(0,b_2-a_2)}^{\min(b_2,a_3)} (-1)^{a_2-b_2+t} \begin{pmatrix} b_2 \\ t \end{pmatrix} \quad \begin{pmatrix} b_3 \\ a_3-t \end{pmatrix}. \tag{5.20}$$

In terms of them, the universal $\mathscr{T}$-matrix (5.16) can be rewritten as

$$\mathscr{T}_{p,q} = \exp(\gamma \otimes \hat{J}_-) \exp(h \otimes \hat{J}_0 + \tilde{h} \otimes \hat{Z}) \exp(\beta \otimes \hat{J}_+). \tag{5.21}$$

B. The colored Hopf superalgebra $U^c(gl(1/1))$ and its dual $Gl^c(1/1)$

The defining relations (5.3) of the $U_{p,q}(gl(1/1))$ superalgebra are left invariant under the grade-preserving transformations,

$$\sigma^\nu(\hat{J}_0) = \hat{J}_0, \quad \sigma^\nu(\hat{J}_\pm) = \left(\frac{p^\nu - q^{-\nu}}{p - q^{-1}} \right)^{1/2} \hat{J}_\pm, \quad \sigma^\nu(\hat{Z}) = \nu \hat{Z}, \tag{5.22}$$

where $\nu \in \mathscr{C} = \mathbb{C} \setminus \{0\}$, provided p and q are replaced by their νth powers, p^ν and q^ν (and the same for P and Q). The σ^ν's are therefore isomorphic mappings between the $U_{p,q}(gl(1/1))$ and $U_{p^\nu,q^\nu}(gl(1/1))$ superalgebras, and define a color group $\mathscr{G} = Gl(1,\mathbb{C})$.

By choosing the parameter set $\mathscr{Q} = (\mathbb{C} \setminus \{0\}) \times (\mathbb{C} \setminus \{0\})$, we obtain a colored quasitriangular Hopf superalgebra $U^c(gl(1/1))$, whose colored comultiplication, counit, antipode, and $\mathscr{R}$-matrix are given by

$$\begin{gathered}
\Delta^{\lambda,\mu}_{p,q,\nu}(\hat{J}_0) = \hat{J}_0 \otimes 1 + 1 \otimes \hat{J}_0, \quad \Delta^{\lambda,\mu}_{p,q,\nu}(\hat{Z}) = \frac{\lambda}{\nu} \hat{Z} \otimes 1 + \frac{\mu}{\nu} 1 \otimes \hat{Z}, \\
\Delta^{\lambda,\mu}_{p,q,\nu}(\hat{J}_+) = A^\lambda_\nu \hat{J}_+ \otimes p^{2\mu\hat{Z}} + A^\mu_\nu 1 \otimes \hat{J}_+, \quad \Delta^{\lambda,\mu}_{p,q,\nu}(\hat{J}_-) = A^\lambda_\nu \hat{J}_- \otimes 1 + A^\mu_\nu q^{-2\lambda\hat{Z}} \otimes \hat{J}_-, \\
\epsilon_{p,q,\nu}(X) = 0, \quad X \in \{\hat{J}_0, \hat{J}_\pm, \hat{Z}\}, \\
S^\mu_{p,q,\nu}(\hat{J}_0) = -\hat{J}_0, \quad S^\mu_{p,q,\nu}(\hat{J}_+) = -A^\mu_\nu p^{-2\mu\hat{Z}} \hat{J}_+, \\
S^\mu_{p,q,\nu}(\hat{J}_-) = -A^\mu_\nu q^{2\mu\hat{Z}} \hat{J}_-, \quad S^\mu_{p,q,\nu}(\hat{Z}) = -\frac{\mu}{\nu} \hat{Z}, \\
\mathscr{R}^{\lambda,\mu}_{p,q} = p^{2\lambda\hat{Z}\otimes\hat{J}_0} q^{2\mu\hat{J}_0\otimes\hat{Z}} \{1 \otimes 1 - \sqrt{(p^\lambda - q^{-\lambda})(p^\mu - q^{-\mu})} \hat{J}_+ \otimes \hat{J}_-\},
\end{gathered} \tag{5.23}$$

where $A^\lambda_\nu \equiv ((p^\lambda - q^{-\lambda})/(p^\nu - q^{-\nu}))^{1/2}$.

In the defining representation (4.8), the colored universal $\mathscr{R}$-matrix is represented by the 4×4 matrix,

$$R^{\lambda,\mu}_{p,q} = \begin{pmatrix} Q^{(\lambda+\mu)/2} P^{(\lambda-\mu)/2} & 0 & 0 & 0 \\ 0 & Q^{-(\lambda-\mu)/2} P^{-(\lambda+\mu)/2} & Q^{-(\lambda-\mu)/2} B^{\lambda,\mu} & 0 \\ 0 & 0 & Q^{(\lambda-\mu)/2} P^{(\lambda+\mu)/2} & 0 \\ 0 & 0 & 0 & Q^{-(\lambda+\mu)/2} P^{-(\lambda-\mu)/2} \end{pmatrix}, \tag{5.24}$$

with $B^{\lambda,\mu} \equiv \sqrt{(Q^\lambda - Q^{-\lambda})(Q^\mu - Q^{-\mu})}$. Such a matrix is a solution of the colored graded YBE, and gives back matrix (5.6) whenever $\lambda, \mu \to 1$.

Under transformation (5.22), the basis elements $\overline{X_A}$ of $U_{p,q}(gl(1/1))$, defined in Eq. (5.17), become

$$\sigma^\nu(\overline{X_A}) = (A^\nu_1)^{(a_1+a_4)/2} \nu^{a_3} \overline{X_A}. \tag{5.25}$$

Hence, from Eqs. (2.4) and (3.1), it follows that

$$\rho^{\nu}(\overline{x^A}) = (A^{\ 1}_{\nu})^{(a_1+a_4)/2}\nu^{-a_3}\overline{x^A}, \tag{5.26}$$

and

$$\rho^{\nu}(\gamma^{a_1}e^{r(\alpha-\delta)}e^{s(\alpha+\delta)}\beta^{a_4}) = (A^{\ 1}_{\nu})^{(a_1+a_4)/2}\gamma^{a_1}e^{r(\alpha-\delta)}e^{s(\alpha+\delta)/\nu}\beta^{a_4}, \tag{5.27}$$

where $r,\ s \in \mathbb{C}$.

As special cases of Eqs. (5.26) and (5.27), we obtain[27]

$$\begin{gathered}\rho^{\nu}(\alpha) = \frac{1+\nu}{2\nu}\,\alpha + \frac{1-\nu}{2\nu}\,\delta, \quad \rho^{\nu}(\beta) = A^{\ 1}_{\nu}\beta, \\ \rho^{\nu}(\gamma) = A^{\ 1}_{\nu}\gamma, \quad \rho^{\nu}(\delta) = \frac{1-\nu}{2\nu}\,\alpha + \frac{1+\nu}{2\nu}\,\delta,\end{gathered} \tag{5.28}$$

$$\begin{gathered}\rho_{\nu}(\alpha) = \frac{\nu+1}{2}\,\alpha + \frac{\nu-1}{2}\,\delta, \quad \rho_{\nu}(\beta) = A^{\ \nu}_{1}\beta, \\ \rho_{\nu}(\gamma) = A^{\ \nu}_{1}\gamma, \quad \rho_{\nu}(\delta) = \frac{\nu-1}{2}\,\alpha + \frac{\nu+1}{2}\,\delta,\end{gathered} \tag{5.29}$$

and

$$\begin{gathered}\rho^{\nu}(a) = \mathscr{D}^{(\nu-1)/(2\nu)}a^{1/\nu}, \quad \rho^{\nu}(b) = A^{\ 1}_{\nu}\mathscr{D}^{(\nu-1)/(2\nu)}a^{(1-\nu)/\nu}b, \\ \rho^{\nu}(c) = q^{1-\nu}A^{\ 1}_{\nu}\mathscr{D}^{(\nu-1)/(2\nu)}a^{(1-\nu)/\nu}c, \\ \rho^{\nu}(d) = \mathscr{D}^{(\nu-1)/(2\nu)}a^{(1-\nu)/\nu}\{d - p(A^{\ \nu-1}_{\nu})^2 ca^{-1}b\}, \quad \rho^{\nu}(\mathscr{D}) = \mathscr{D},\end{gathered} \tag{5.30}$$

$$\begin{gathered}\rho_{\nu}(a) = \mathscr{D}^{(1-\nu)/2}a^{\nu}, \quad \rho_{\nu}(b) = A^{\ \nu}_{1}\mathscr{D}^{(1-\nu)/2}a^{\nu-1}b, \\ \rho_{\nu}(c) = q^{\nu-1}A^{\ \nu}_{1}\mathscr{D}^{(1-\nu)/2}a^{\nu-1}c, \\ \rho_{\nu}(d) = \mathscr{D}^{(1-\nu)/2}a^{\nu-1}\{d - p^{\nu}(A^{\ 1-\nu}_{1})^2 ca^{-1}b\}, \quad \rho_{\nu}(\mathscr{D}) = \mathscr{D}.\end{gathered} \tag{5.31}$$

By proceeding as in Sec. IV, it is straightforward to determine the colored maps of $\mathrm{Gl}^c(1/1)$, listed in Appendix B, and to combine the results for the colored multiplication $\widetilde{m}^{\ \nu}_{p,q,\lambda,\mu}(x\otimes y)$, $x,\ y \in \{a,b,c,d\}$, given in Eqs. (B1)–(B4), and (B10), into two sets of eight relations each,

$$\begin{gathered}a(\lambda)\overset{\nu}{\cdot}b(\mu) = p^{-\lambda}b(\mu)\overset{\nu}{\cdot}a(\lambda), \quad a(\lambda)\overset{\nu}{\cdot}c(\mu) = q^{-\lambda}c(\mu)\overset{\nu}{\cdot}a(\lambda), \\ b(\lambda)\overset{\nu}{\cdot}d(\mu) = p^{\mu}d(\mu)\overset{\nu}{\cdot}a(\lambda), \quad c(\lambda)\overset{\nu}{\cdot}d(\mu) = q^{\mu}d(\mu)\overset{\nu}{\cdot}c(\lambda), \\ b(\lambda)\overset{\nu}{\cdot}c(\mu) = -p^{\mu}q^{-\lambda}c(\mu)\overset{\nu}{\cdot}b(\lambda), \quad b(\lambda)\overset{\nu}{\cdot}b(\mu) = c(\lambda)\overset{\nu}{\cdot}c(\mu) = 0, \\ a(\lambda)\overset{\nu}{\cdot}d(\mu) - d(\mu)\overset{\nu}{\cdot}a(\lambda) = p^{-\mu}q^{\lambda}\sqrt{(p^{\lambda}-q^{-\lambda})(p^{\mu}-q^{-\mu})}\,b(\lambda)\overset{\nu}{\cdot}c(\mu),\end{gathered} \tag{5.32}$$

and

$$\begin{gathered}a(\lambda)\overset{\nu}{\cdot}a(\mu) = a(\mu)\overset{\nu}{\cdot}a(\lambda), \quad a(\lambda)\overset{\nu}{\cdot}b(\mu) = A^{\ \mu}_{\lambda}a(\mu)\overset{\nu}{\cdot}b(\lambda), \\ a(\lambda)\overset{\nu}{\cdot}c(\mu) = q^{\mu-\lambda}A^{\ \mu}_{\lambda}a(\mu)\overset{\nu}{\cdot}c(\lambda), \\ a(\lambda)\overset{\nu}{\cdot}d(\mu) - a(\mu)\overset{\nu}{\cdot}d(\lambda) = q^{\lambda-\mu}A^{\ \lambda-\mu}_{\lambda}A^{\ \lambda-\mu}_{\mu}b(\lambda)\overset{\nu}{\cdot}c(\mu),\end{gathered} \tag{5.33}$$

$$b(\lambda)\overset{\nu}{\cdot}c(\mu)=(pq)^{\mu-\lambda}b(\mu)\overset{\nu}{\cdot}c(\lambda),\quad b(\lambda)\overset{\nu}{\cdot}d(\mu)=p^{\mu-\lambda}A^{\lambda}_{\mu}b(\mu)\overset{\nu}{\cdot}d(\lambda),$$

$$c(\lambda)\overset{\nu}{\cdot}d(\mu)=A^{\lambda}_{\mu}c(\mu)\overset{\nu}{\cdot}d(\lambda),\quad d(\lambda)\overset{\nu}{\cdot}d(\mu)=d(\mu)\overset{\nu}{\cdot}d(\lambda).$$

Similarly, the relations for the colored multiplication involving the quantum superdeterminant, given in Eqs. (B5)–(B9), and (B11), can be rewritten as

$$\mathscr{D}(\lambda)\overset{\nu}{\cdot}x(\mu)=x(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda),\quad x\in\{a,b,c,d\},\tag{5.34}$$

and

$$\mathscr{D}(\lambda)\overset{\nu}{\cdot}a(\mu)=(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(a(\nu))^{(\mu-\lambda)/\nu}(\mathscr{D}(\mu)\overset{\nu}{\cdot}a(\lambda)),$$

$$\mathscr{D}(\lambda)\overset{\nu}{\cdot}b(\mu)=A^{\mu}_{\lambda}(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(a(\nu))^{(\mu-\lambda)/\nu}(\mathscr{D}(\mu)\overset{\nu}{\cdot}b(\lambda)),$$

$$\mathscr{D}(\lambda)\overset{\nu}{\cdot}c(\mu)=q^{\mu-\lambda}A^{\mu}_{\lambda}(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(a(\nu))^{(\mu-\lambda)/\nu}(\mathscr{D}(\mu)\overset{\nu}{\cdot}c(\lambda)),\tag{5.35}$$

$$\begin{aligned}\mathscr{D}(\lambda)\overset{\nu}{\cdot}d(\mu)=&q^{\mu-\lambda}(A^{\mu-\nu}_{\lambda-\nu})^2(\mathscr{D}(\nu))^{(\lambda-\mu)/(2\nu)}(a(\nu))^{(\mu-\lambda)/\nu}(\mathscr{D}(\mu)\overset{\nu}{\cdot}d(\lambda))\\&+p^{\mu-\nu}(A^{\lambda-\mu}_{\lambda-\nu})^2(\mathscr{D}(\nu))^{(3\nu-\mu)/(2\nu)}(a(\nu))^{(\mu-\lambda)/\nu}d(\nu),\end{aligned}$$

$$\mathscr{D}(\lambda)\overset{\nu}{\cdot}\mathscr{D}(\mu)=\mathscr{D}(\mu)\overset{\nu}{\cdot}\mathscr{D}(\lambda).$$

In the λ, μ, $\nu\to 1$ limit, Eqs. (5.32) and (5.34) give back the $\mathrm{Gl}_{p,q}(1/1)$ defining relations (5.7) and the central property of $\mathscr{D}$, while Eqs. (5.33), and (5.35) have no standard counterpart.

The two ν-independent sets of equations, contained in (5.32) and (5.33), can be explicitly shown to be equivalent to the single matrix equation (3.19), where $R^{\lambda,\mu}_{p,q}$ is given by Eq. (5.24). Moreover, as in Sec. IV, the elements $\mathscr{T}^{\lambda}_{p,q}$ of the colored universal $\mathscr{T}$-matrix have no explicit λ-dependence.

The counterparts of Eqs. (4.47) and (4.49), for the colored multiplication extended to the whole dual $\mathrm{U}_{p,q}(\{\alpha,\beta,\gamma,\delta\})$ of $\mathrm{U}^c\mathrm{gl}(1/1))$, are

$$[\alpha(\lambda),\beta(\mu)]^{\nu}=\lambda\omega A^{\mu}_{\nu}\beta(\nu),\quad [\alpha(\lambda),\gamma(\mu)]^{\nu}=\lambda\eta A^{\mu}_{\nu}\gamma(\nu),$$

$$[\delta(\lambda),\beta(\mu)]^{\nu}=\lambda\omega A^{\mu}_{\nu}\beta(\nu),\quad [\delta(\lambda),\gamma(\mu)]^{\nu}=\lambda\eta A^{\mu}_{\nu}\gamma(\nu),\tag{5.36}$$

$$[\alpha(\lambda),\delta(\mu)]^{\nu}=0,\quad \{\beta(\lambda),\gamma(\mu)\}^{\nu}=\beta(\lambda)\overset{\nu}{\cdot}\beta(\mu)=\gamma(\lambda)\overset{\nu}{\cdot}\gamma(\mu)=0,$$

and

$$[\alpha(\lambda),\alpha(\mu)]^{\nu}=[\delta(\lambda),\delta(\mu)]^{\nu}=0,$$

$$\alpha(\lambda)\overset{\nu}{\cdot}\beta(\mu)=A^{\mu}_{\lambda}(2\mu)^{-1}((\lambda+\mu)\alpha(\mu)\overset{\nu}{\cdot}\beta(\lambda)+(\lambda-\mu)\delta(\mu)\overset{\nu}{\cdot}\beta(\lambda)),$$

$$\gamma(\lambda)\overset{\nu}{\cdot}\alpha(\mu)=A^{\lambda}_{\mu}(2\lambda)^{-1}((\lambda+\mu)\gamma(\mu)\overset{\nu}{\cdot}\alpha(\lambda)-(\lambda-\mu)\gamma(\mu)\overset{\nu}{\cdot}\delta(\lambda)),$$

$$\alpha(\lambda)\overset{\nu}{\cdot}\delta(\mu)=\alpha(\mu)\overset{\nu}{\cdot}\delta(\lambda)+(\lambda-\mu)(\lambda+\mu)^{-1}(-\alpha(\mu)\overset{\nu}{\cdot}\alpha(\lambda)+\delta(\mu)\overset{\nu}{\cdot}\delta(\lambda)),$$

$$\gamma(\lambda)\overset{\nu}{\cdot}\beta(\mu)=\gamma(\mu)\overset{\nu}{\cdot}\beta(\lambda),\tag{5.37}$$

$$\delta(\lambda)\overset{\nu}{\cdot}\beta(\mu)=A^{\mu}_{\lambda}(2\mu)^{-1}((\lambda-\mu)\alpha(\mu)\overset{\nu}{\cdot}\beta(\lambda)+(\lambda+\mu)\delta(\mu)\overset{\nu}{\cdot}\beta(\lambda)),$$

$$\gamma(\lambda)\overset{\nu}{\cdot}\delta(\mu)=A^{\lambda}_{\mu}(2\lambda)^{-1}(-(\lambda-\mu)\gamma(\mu)\overset{\nu}{\cdot}\alpha(\lambda)+(\lambda+\mu)\gamma(\mu)\overset{\nu}{\cdot}\delta(\lambda)),$$

where

$$\{x(\lambda),y(\mu)\}^{\nu}\equiv x(\lambda)\overset{\nu}{\cdot}y(\mu)+y(\mu)\overset{\nu}{\cdot}x(\lambda). \tag{5.38}$$

Equation (5.36) gives back Eq. (5.14) whenever λ, μ, $\nu\rightarrow 1$.

All the results obtained for the dual pair ($U^c(gl(1/1))$, $Gl^c(1/1)$) are therefore entirely similar to those derived for ($U^c(gl(2))$, $Gl^c(2)$) in Sec. IV.

VI. CONCLUSION

In the present paper, we extended the notion of dually conjugate Hopf (super)algebras to the colored Hopf (super)algebras $\mathscr{H}^c$, introduced in I and II. We showed that if the standard Hopf (super)algebras $\mathscr{H}_q$ that are the building blocks of $\mathscr{H}^c$ have Hopf duals $\mathscr{H}_q^*$, then the latter may be used to construct colored Hopf duals $\mathscr{H}^{c*}$, endowed with colored algebra and antipode maps, but with a standard coalgebraic structure.

Next, we reviewed the case where the $\mathscr{H}_q$'s are QUEA's of Lie (super)algebras $U_q(g)$, so that the $\mathscr{H}_q^*$'s are quantum (super)groups G_q. We extended the Fronsdal and Galindo universal $\mathscr{T}$-matrix formalism[14] to the colored pairs $(U^c(g),G^c)$ by introducing colored universal $\mathscr{T}$-matrices. We then proved that the colored RTT-relations, defining colored $A(R)$ Hopf (super) algebras in Basu-Mallick's approach,[12] may be considered as the realization in the $U_q(g)$ defining representation of a representation-free relation satisfied by the colored universal $\mathscr{R}$- and $\mathscr{T}$-matrices.

Such results were finally illustrated by constructing two physically-relevant examples of colored pairs, corresponding to the two-parameter deformations of (U(gl(2)), Gl(2)), and (U(gl(1/1)), Gl(1/1)), respectively.

In conclusion, we did prove that the formalism developed in I, II, and the present paper, provides an algebraic formulation of the colored RTT-relations, and establishes a link between the colored extensions of Drinfeld–Jimbo[5] and Faddeev–Reshetikhin–Takhtajan[8] pictures of quantum groups and quantum algebras. Since transfer matrices of quantum integrable models may be obtained from $\mathscr{T}$ by specialization to given representations, we do think that the colored extension of $\mathscr{T}$, and the related new algebraic structures introduced here, may have some interesting applications to such models.

There remain some open questions, which might be interesting topics for future study. We would like to mention here two of them. The first one consists in investigating the complementary approach to that considered in the present paper, namely trying to transform a set of quantum (super)groups G_q into a colored Hopf (super)algebra $\mathscr{H}^c$ by defining an appropriate color group, then transferring the colored structure to the duals $U_q(g)$ to build a colored Hopf dual $\mathscr{H}^{c*}$. The second problem is to understand the relation, if any, between the latter and the colored $U(R)$ Hopf (super)algebras introduced by Kundu and Basu-Mallick, and defined in terms of colored RLL-relations.[11]

APPENDIX A: COLORED MAPS OF $Gl^c(2)$

In this Appendix, we list the results obtained for the colored multiplication, unit, and antipode of $Gl^c(2)$. For their derivation, we used Eqs. (2.7), (4.11), (4.15), (4.16), (4.17), (4.18), (4.37), (4.41), and the fact that $\overline{x^{0000}}$ is the unit of $Gl_{p,q}(2)$.

The colored multiplication is given by

$$\tilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes y)=P^{t\,\nu}_{\lambda,\mu}{}^{(x,y)/2}\mathscr{D}^{(\lambda+\mu-2\nu)/(2\nu)}xy, \tag{A1}$$

$$\tilde{m}^{\nu}_{p,q,\lambda,\mu}(\mathscr{D}\otimes x)=P^{t\,\nu}_{\lambda,\mu}{}^{(\mathscr{D},x)/2}\mathscr{D}^{(2\lambda+\mu-\nu)/(2\nu)}x, \tag{A2}$$

$$\tilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes\mathscr{D})=P^{t\,\nu}_{\lambda,\mu}{}^{(x,\mathscr{D})/2}\mathscr{D}^{(\lambda+2\mu-\nu)/(2\nu)}x, \tag{A3}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(\mathscr{D}\otimes\mathscr{D})=\mathscr{D}^{(\lambda+\mu)/\nu}, \tag{A4}$$

where

$$t^{\nu}_{\lambda,\mu}(x,y)=0,\mu-\nu,-\mu+\nu,0,\lambda+2\mu-3\nu,\lambda+3\mu-4\nu,\lambda+\mu-2\nu,\lambda+2\mu-3\nu,-\lambda-2\mu+3\nu,$$
$$-\lambda-\mu+2\nu,-\lambda-3\mu+4\nu,-\lambda-2\mu+3\nu,0,\mu-\nu,-\mu+\nu,0, \tag{A5}$$

$$t^{\nu}_{\lambda,\mu}(\mathscr{D},x)=0,\mu-\nu,-\mu+\nu,0, \tag{A6}$$

$$t^{\nu}_{\lambda,\mu}(x,\mathscr{D})=0,\lambda+4\mu-\nu,-\lambda-4\mu+\nu,0, \tag{A7}$$

whenever x,y run over $\{a,b,c,d\}$, and are listed in lexicographical order.

For the colored unit and antipode, the results read

$$\widetilde{\iota}^{\nu}_{p,q}(1_k)=\widetilde{\iota}_{p^{(\nu)},q^{(\nu)}}(1_k), \tag{A8}$$

and

$$\widetilde{S}^{\nu}_{p,q,\mu}(a)=\mathscr{D}^{-(\mu+\nu)/(2\nu)}d,\quad \widetilde{S}^{\nu}_{p,q,\mu}(b)=-Q^{-1}(P^{\nu}\mathscr{D})^{-(\mu+\nu)/(2\nu)}b, \tag{A9}$$

$$\widetilde{S}^{\nu}_{p,q,\mu}(c)=-Q(P^{-\nu}\mathscr{D})^{-(\mu+\nu)/(2\nu)}c,\quad \widetilde{S}^{\nu}_{p,q,\mu}(d)=\mathscr{D}^{-(\mu+\nu)/(2\nu)}a, \tag{A10}$$

$$\widetilde{S}^{\nu}_{p,q,\mu}(\mathscr{D})=\mathscr{D}^{-\mu/\nu}, \tag{A11}$$

respectively.

APPENDIX B: COLORED MAPS OF $\mathrm{Gl}^c(1/1)$

In this Appendix, we list the results obtained for the coloured multiplication, unit, and antipode of $\mathrm{Gl}^c(1/1)$. For their derivation, we used Eqs. (2.7), (4.17), (5.7), (5.10), (5.12), (5.27), (5.31), and the fact that $\overline{x^{0000}}$ is the unit of $\mathrm{Gl}_{p,q}(1/1)$.

The colored multiplication is given by

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes y)=C^{\nu}_{\lambda,\mu}(x,y)\mathscr{D}^{(2\nu-\lambda-\mu)/(2\nu)}a^{(\lambda+\mu-2\nu)/\nu}xy, \tag{B1}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(a\otimes d)=\mathscr{D}^{(2\nu-\lambda-\mu)/(2\nu)}a^{(\lambda+\mu-2\nu)/\nu}\{ad-p^{\mu}q^{-\nu}(A^{\nu-\mu}_{\nu})^2cb\}, \tag{B2}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(d\otimes a)=\mathscr{D}^{(2\nu-\lambda-\mu)/(2\nu)}a^{(\lambda+\mu-2\nu)/\nu}\{da+p^{\mu}(q^{-\nu}(A^{\nu-\mu}_{\nu})^2-p^{\lambda}(A^{2\nu-\lambda-\mu}_{\nu})^2)cb\}, \tag{B3}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(d\otimes d)=\mathscr{D}^{(2\nu-\lambda-\mu)/(2\nu)}a^{(\lambda+\mu-2\nu)/\nu}\{d^2-p^{\lambda+\mu}(A^{2\nu-\lambda-\mu}_{\nu})^2ca^{-1}db\}, \tag{B4}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(\mathscr{D}\otimes x)=C^{\nu}_{\lambda,\mu}(\mathscr{D},x)\mathscr{D}^{(3\nu-\mu)/(2\nu)}a^{(\mu-\nu)/\nu}x, \tag{B5}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(\mathscr{D}\otimes d)=\mathscr{D}^{(3\nu-\mu)/(2\nu)}a^{(\mu-\nu)/\nu}\{d-p^{\mu}(A^{\nu-\mu}_{\nu})^2ca^{-1}b\}, \tag{B6}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(x\otimes\mathscr{D})=C^{\nu}_{\lambda,\mu}(x,\mathscr{D})\mathscr{D}^{(3\nu-\lambda)/(2\nu)}a^{(\lambda-\nu)/\nu}x, \tag{B7}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(d\otimes\mathscr{D})=\mathscr{D}^{(3\nu-\lambda)/(2\nu)}a^{(\lambda-\nu)/\nu}\{d-p^{\lambda}(A^{\nu-\lambda}_{\nu})^2ca^{-1}b\}, \tag{B8}$$

$$\widetilde{m}^{\nu}_{p,q,\lambda,\mu}(\mathscr{D}\otimes\mathscr{D})=\mathscr{D}^2. \tag{B9}$$

In Eq. (B1), x,y run over $\{a,b,c,d\}$ with the exceptions of $(x,y)=(a,d)$, (d,a), (d,d), and

$$C^{\nu}_{\lambda,\mu}(x,y)=1,A^{\mu}_{\nu},q^{\mu-\nu}A^{\mu}_{\nu},p^{\mu-\nu}A^{\lambda}_{\nu},1,(pq)^{\mu-\nu}A^{\lambda}_{\nu}A^{\mu}_{\nu},p^{\mu-\nu}A^{\lambda}_{\nu},q^{\lambda+\mu-2\nu}A^{\lambda}_{\nu},$$
$$q^{\lambda+\mu-2\nu}A^{\lambda}_{\nu}A^{\mu}_{\nu},1,q^{\lambda+\mu-2\nu}A^{\lambda}_{\nu},A^{\mu}_{\nu},q^{\mu-\nu}A^{\mu}_{\nu}, \tag{B10}$$

for (x,y) listed in lexicographical order. Similarly, in Eqs. (B5) and (B7), x runs over $\{a,b,c\}$, and

$$C^{\nu}_{\lambda,\mu}(\mathscr{D},x)=1,A^{\mu}_{\nu},q^{\mu-\nu}A^{\mu}_{\nu}, \quad C^{\nu}_{\lambda,\mu}(x,\mathscr{D})=1,A^{\lambda}_{\nu},q^{\lambda-\nu}A^{\lambda}_{\nu}. \tag{B11}$$

For the colored unit and antipode, the results read

$$\tilde{\iota}^{\nu}_{p,q}(1_k)=\tilde{\iota}_{p^{\nu},q^{\nu}}(1_k), \tag{B12}$$

and

$$\tilde{S}^{\nu}_{p,q,\mu}(a)=\mathscr{D}^{(\mu-\nu)/(2\nu)}\{a^{-\mu/\nu}-p^{-\mu}q^{\mu}(A^{\mu}_{\nu})^2ca^{-(\mu+\nu)/\nu}\hat{d}^{-1}b\}, \tag{B13}$$

$$\tilde{S}^{\nu}_{p,q,\mu}(b)=-p^{-\mu}A^{\mu}_{\nu}a^{-(\mu+\nu)/(2\nu)}\hat{d}^{-(\mu+\nu)/(2\nu)}b, \tag{B14}$$

$$\tilde{S}^{\nu}_{p,q,\mu}(c)=-q^{\mu}A^{\mu}_{\nu}ca^{-(\mu+\nu)/(2\nu)}\hat{d}^{-(\mu+\nu)/(2\nu)}, \tag{B15}$$

$$\tilde{S}^{\nu}_{p,q,\mu}(d)=\mathscr{D}^{-(\mu-\nu)/(2\nu)}\hat{d}^{-\mu/\nu}, \tag{B16}$$

$$\tilde{S}^{\nu}_{p,q,\mu}(\mathscr{D})=\mathscr{D}^{-1}, \tag{B17}$$

respectively.

Yang–Mills field equations for the Coriolis tensor in the *n*-body problem

Matthias Reinsch
Department of Physics, University of California, Berkeley, California 94720

(Received 3 September 1996; accepted for publication 3 November 1997)

The configuration space of a system of n particles has the structure of a principal fiber bundle under the action of the rotation group. In this paper, identities are derived for the curvature of the natural connection on this bundle. These identities are translated into statements about the Coriolis tensor, the local expression for this curvature on the base space of the bundle. The Coriolis tensor is shown to obey field equations of the Yang–Mills type. © *1998 American Institute of Physics.* [S0022-2488(98)02502-X]

I. INTRODUCTION

The subject of gauge fields in the separation of rotations and internal motions in the n-body problem has attracted much attention in recent years.[1,2] Early works in this area include those of Guichardet[3] and Iwai,[4] and numerous authors have contributed since then. The study is especially relevant to molecular physics, but could also be applied to atomic or nuclear physics, or even celestial mechanics. The reason for this large range of applications is that the system under consideration is quite general. It is that of n distinguishable nonrelativistic particles interacting via some potential that is invariant under overall translations and rotations of the system. Both the classical and quantum mechanical versions of the problem can be treated using the same gauge fields. This subject has been reviewed in Ref. 1, in which it is shown that the problem involves certain static fields that arise in a natural way. There are fields defined on the configuration space of the particles and fields defined on the internal space (shape space,[1,5] the space of all possible shapes of the n-particle system, explained below). The moment of inertia tensor with respect to the laboratory frame is an example of a field on configuration space. Other fields include the mechanical connection[6] and its curvature, to be discussed in the next section. This paper contains the derivation of several identities for this curvature. One of these identities has the form of Yang–Mills field equations.

The motivation for this study originated from an analysis of the n-body problem[1] in a way that involves fields on shape space. A field called the Coriolis tensor $\mathbf{B}_{\mu\nu}$ arises naturally in the dynamics. This is a static field defined on shape space. It is the curvature form in a non-Abelian gauge theory, in analogy with Yang–Mills theories. For the three-body problem, the Coriolis tensor has the form of a monopole on shape space.[4] It satisfies the identity $\mathbf{B}_{\mu\nu}{}^{;\nu}=0$ (this notation is explained later in this paper) in addition to the Bianchi identities that are known to hold for all values of n. We calculated $\mathbf{B}_{\mu\nu}{}^{;\nu}$ for the four-body problem and for several larger values of the number of particles and found that it vanished in these cases as well. Eventually we were able to prove the $\mathbf{B}_{\mu\nu}{}^{;\nu}=0$ identity for arbitrary values of the number of particles n, but the original proof was rather complex and required lengthy calculations. In this paper we present a simpler proof of the identity and also include proofs of new identities for the curvature of the mechanical connection.

The proof of the identities consists of two main parts. The first part deals with certain differential forms defined on the configuration space of the particles. These forms are the connection 1-form[7,8] and the curvature 2-form, defined in the next section. Such Lie-algebra-valued forms are common today in mathematics and theoretical physics, and it is interesting to see them appear in an area with as much history as the n-body problem. The second part of the proof involves a transition from quantities defined on configuration space to quantities defined on shape space. The identities derived in the first part of the paper are translated to identities for the Coriolis tensor.

In an Appendix, the relationship between covariant differentiation of tensors on shape space

 © 1998 American Institute of Physics

and corresponding quantities on configuration space is explained. This result is then used to state the Yang–Mills type identity for the Coriolis tensor in a way which involves simpler types of differentiation.

II. THE *n*-BODY PROBLEM

The recent realizations about gauge fields in the n-body problem are closely tied to a certain mathematical structure called a principal fiber bundle with a connection. We assume some familiarity with these concepts[7–9] on the part of the reader, but we do recall the basic definitions here. We begin by explaining how they relate to the problem at hand.

As stated above, the system under consideration is that of n nonrelativistic distinguishable particles interacting via a potential that is invariant under overall translations and rigid rotations of the system. The particles are in a three-dimensional Cartesian physical space with the usual Euclidean metric. The configuration space of the n-particle system is thus $\mathbb{R}^{3n}$. References 1 and 5 explain how the kinetic energy of the center-of-mass motion can be separated out by performing a linear change of coordinates on configuration space. The new coordinates are the center of mass of the n-particle system (a three-component vector) and $n-1$ mass-weighted Jacobi vectors, each of which is a three-component vector. The details of this transformation are not relevant to the present paper; we may take as our starting point the problem of $n-1$ unit-mass particles with only a rotational symmetry about a laboratory origin. References 1 and 5 explain how this problem is related to the original n-body problem. Briefly, the Jacobi vectors are linear combinations of the interparticle displacement vectors and are defined in such a way that the kinetic energy of the system is equal to the kinetic energy of the center of mass plus one-half the sum of the squares of the time derivatives of the $n-1$ Jacobi vectors. We call the configuration space of these $n-1$ unit-mass particles translation-reduced configuration space, or sometimes just ''configuration space'' for brevity. We use the symbol $\mathscr{C}$ for this space, and it is isomorphic to $\mathbb{R}^{3n-3}$. The Jacobi vectors are denoted by $\boldsymbol{\rho}_{s\alpha}, \alpha=1,\ldots,n-1$, with the subscript ''$s$'' indicating that the components of these vectors are referred to the space or laboratory frame, an inertial frame. Boldface is used to indicate three-component vectors. We use lower-case letters from the beginning of the Greek alphabet $\alpha,\beta,\ldots=1,\ldots,n-1$ to index the $n-1$ Jacobi vectors. The indices $i,j,k,\ldots=1,2,3$ are used to index components of vectors and matrices with respect to axes in three-dimensional physical space. In this notation, translation-reduced configuration space is parametrized by $3n-3$ coordinates, $\{\rho_{s\alpha i};\alpha=1,\ldots,n-1;i=1,2,3\}$, each of which runs from $-\infty$ to ∞.

The group of rotations in three-dimensional physical space [which is isomorphic to the matrix group $SO(3)$] acts on configuration space by left multiplication. An element R of $SO(3)$ defines an automorphism on configuration space by mapping a point $\{\rho_{s\alpha i};\alpha=1,\ldots,n-1;i=1,2,3\}$ to the point $\{R_{ij}\rho_{s\alpha j};\alpha=1,\ldots,n-1;i=1,2,3\}$ (here a sum on j is implied). For $n\geqslant 3$ the resulting structure is that of a principal fiber bundle, as discussed in Ref. 1. Shape space is the space of equivalence classes of configurations under the action of the rotation group, i.e., two configurations are defined to be equivalent if they differ by a proper rotation. Because $SO(3)$ is a three-dimensional Lie group, the dimensionality of shape space is $3n-6$. A technicality is that collinear configurations must be discarded from configuration space in order to obtain a principal fiber bundle. Aside from this technicality, the base space of the bundle is shape space. A pedagogical introduction to the fields defined on shape space that are relevant to the n-body problem is given in Ref. 1. In this paper, we will briefly recall the definitions of these fields as we encounter them in the proofs.

We will begin this discussion with fields defined on configuration space. An example is the moment of inertia tensor with respect to the laboratory axes. This is called the space moment of inertia tensor, M_s. The tensorial nature of this object is explained below. The definition of the usual space moment of inertia tensor can be expressed in terms of the mass-weighted Jacobi vectors,

$$(\mathsf{M}_s)_{ij}=\delta_{ij}\boldsymbol{\rho}_{s\alpha}\cdot\boldsymbol{\rho}_{s\alpha}-\rho_{s\alpha i}\rho_{s\alpha j}. \tag{2.1}$$

We use a summation convention in which repeated indices are summed over, so, for example, in the preceding equation there is a sum on α. As explained above, the subscript ''s'' is not an index.

The components $(\mathsf{M}_s)_{ij}$ of M_s would transform in the usual way under a rotation of the laboratory axes, and M_s would be considered a second rank tensor under rotations. However, we will not consider such redefinitions of the laboratory axes; they are assumed to be a fixed choice of axes in three-dimensional physical space. Thus, M_s is a 3×3 array of zero-forms (a matrix-valued function) on configuration space. It is a matrix-valued rank zero tensor on configuration space. We use the term ''moment of inertia tensor,'' because this is the standard term used in the literature. The moment of inertia tensor with respect to body-fixed axes, to be discussed later in this paper, is a different object and has more complicated transformation properties.

Another quantity defined on configuration space is the connection. The connection relevant to the n-body problem is called the mechanical connection in Ref. 6. A connection is a definition of a ''horizontal'' subspace of the tangent space of configuration space at each point in configuration space. The horizontal subspace at a point in configuration space is defined to be the set of vectors which correspond to instantaneous motion of the system with zero total angular momentum. In other words, the horizontal subspace is the set of vectors which give zero when acted on by the three dual vectors obtained by evaluating the three 1-forms,

$$\boldsymbol{\rho}_{s\alpha}\times d\boldsymbol{\rho}_{s\alpha}, \tag{2.2}$$

at the point in configuration space. The cross in this expression denotes the usual cross product of three-component vectors, and the result is a three-component vector (an ordered triple) of one-forms on configuration space. Written out explicitly, the three 1-forms are

$$\epsilon_{ijk}\rho_{s\alpha j}d\rho_{s\alpha k}, i=1,2,3, \tag{2.3}$$

the ϵ_{ijk} tensor being the usual totally antisymmetric tensor with $\epsilon_{123}=1$. For each value of the index i, there is a sum on α, j and k, and the result is a 1-form on configuration space. Since we have three conditions, the dimensionality of each horizontal subspace is three less than that of configuration space; i.e., it is $3n-6$.

A. An expression for the connection

In the previous section, the connection was introduced as a definition of horizontal subspaces. In order to calculate its curvature, it will be useful to describe the connection using a ''connection 1-form,'' as described in references such as Refs. 7 and 8. We use the symbol ϕ to denote the connection 1-form (and later Φ for the curvature 2-form), as in Ref. 8. The differential form ϕ is a Lie-algebra-valued 1-form on configuration space with the property that when acting on a tangent vector it returns the Lie-algebra element that corresponds to the vertical part of the tangent vector. The definition of the vertical part of a tangent vector and the correspondence between Lie-algebra elements and vertical vectors is as follows. The Lie algebra of the group $SO(3)$ is isomorphic to the set of antisymmetric 3×3 matrices. Given an antisymmetric 3×3 matrix X, the function $\exp(t\mathsf{X})$ is a parametrized curve in the group $SO(3)$ with parameter t. If one takes a point in configuration space and lets $\exp(t\mathsf{X})$ act on it using the left action defined earlier, one obtains a curve in configuration space. At the parameter value $t=0$, this curve identifies a vector in the tangent space of configuration space at the specified point. This vector is defined to be the vertical vector corresponding to X. An arbitrary vector in the tangent space of configuration space can be written as the sum of a horizontal and vertical part in a unique way, so the map that takes a vector to the Lie algebra element corresponding to the vector's vertical part is well-defined. In Sec. III we will show that there is a simple relationship between the connection 1-form and the vector potential $\mathbf{A}_\mu$ used in Ref. 1.

Next, we work toward an explicit expression for the connection 1-form. We start by introducing some convenient notation. As a basis for Lie algebra of $SO(3)$ we use the three elements corresponding to the antisymmetric 3×3 matrices $\mathsf{J}_\ell, \ell=1,2,3$. The J_ℓ matrices are the usual generators of rotations, whose entries are

$$(\mathsf{J}_\ell)_{ij}=-\epsilon_{\ell ij}. \tag{2.4}$$

The choice of a basis for the Lie algebra of $SO(3)$ results in a one-to-one correspondence between ordered triples of real numbers and the elements of the Lie algebra. Since the connection 1-form

is a Lie-algebra-valued form, this correspondence can be used to define an $\mathbb{R}^3$-valued 1-form, which we denote by boldface $\boldsymbol{\phi}$. The explicit expression for $\boldsymbol{\phi}$ works out to be

$$\boldsymbol{\phi} = \mathsf{M}_s^{-1} \cdot (\boldsymbol{\rho}_{s\alpha} \times d\boldsymbol{\rho}_{s\alpha}), \tag{2.5}$$

as in Ref. 6. In order to verify this expression for $\boldsymbol{\phi}$, one must show that it returns the correct values when acting on a basis of the tangent space of configuration space at a point in configuration space. That the expression correctly returns a zero for horizontal vectors follows from the definition of the horizontal subspace in Eq. (2.2). As for the vertical vectors, we calculate the result of $\mathsf{M}_s^{-1} \cdot (\boldsymbol{\rho}_{s\alpha} \times d\boldsymbol{\rho}_{s\alpha})$ acting on the vertical vector corresponding to J_{ℓ}. When $d\boldsymbol{\rho}_{s\alpha}$ acts on this vector the result is $\mathsf{J}_{\ell}\boldsymbol{\rho}_{s\alpha}$, as can be seen from the discussion of vertical vectors in the previous paragraph and from the definition of the left action of $SO(3)$ on configuration space, defined earlier. Thus, the result of letting $\mathsf{M}_s^{-1} \cdot (\boldsymbol{\rho}_{s\alpha} \times d\boldsymbol{\rho}_{s\alpha})$ act on this vector is $\mathsf{M}_s^{-1} \cdot [\boldsymbol{\rho}_{s\alpha} \times (\mathsf{J}_{\ell}\boldsymbol{\rho}_{s\alpha})]$. Using the ''BAC-CAB'' rule, Eq. (A3), this simplifies to a unit vector with a one at position ℓ, and completes the verification of Eq. (2.5). In this proof of Eq. (2.5), we have used the compact three-vector notation. Alternatively, one can work with $\mathbb{R}$-valued differential forms. The i-th component of the right-hand side of Eq. (2.5) is $(\mathsf{M}_s^{-1})_{ij}\epsilon_{jkm}\rho_{s\alpha k}d\rho_{s\alpha m}$, an $\mathbb{R}$-valued 1-form. The result of this 1-form acting on the vertical vector is $(\mathsf{M}_s^{-1})_{ij}\epsilon_{jkm}\rho_{s\alpha k}(\mathsf{J}_{\ell}\boldsymbol{\rho}_{s\alpha})_m$ which works out to be $\delta_{i\ell}$, using Eq. (2.1) and Eq. (A3). Physically speaking, the right-hand side of Eq. (2.5) may be thought of as a mapping which maps a specification of particle positions and velocities to an angular-velocity three-vector. This angular velocity has the property that the total angular momentum of the system is obtained by multiplying it by M_s.

B. Curvature of the connection

Having defined the connection, we can move on to its curvature. The curvature is defined below and expresses the fact that if a closed path in the base space is lifted horizontally[1,7–10] into configuration space, the resulting path in general will not be closed. A standard way to describe this curvature is with a curvature 2-form. This is a Lie-algebra-valued 2-form on configuration space. Again we will use the correspondence between elements of the Lie algebra and elements of $\mathbb{R}^3$ (induced by our choice of basis) to define an $\mathbb{R}^3$-valued curvature 2-form, which we will denote by boldface $\boldsymbol{\Phi}$. The curvature 2-form is defined to be the exterior derivative of the connection 1-form, composed with projection onto the horizontal subspace. This definition results in a standard formula for the curvature 2-form $\boldsymbol{\Phi}$ in terms of the connection 1-form $\boldsymbol{\phi}$,

$$\Phi^i = d\phi^i - \frac{1}{2}\epsilon_{ijk}\phi^j \wedge \phi^k. \tag{2.6}$$

Here Φ^i denotes the i-th component of the vector $\boldsymbol{\Phi}$, and ϕ^i denotes the i-th component of the vector $\boldsymbol{\phi}$.

Next, we consider writing $\boldsymbol{\phi}$ and $\boldsymbol{\Phi}$ with respect to a coordinate basis of differential forms on configuration space. We start with arbitrary coordinates x^a on configuration space. The index a runs from 1 to $3n-3$, and we write

$$\boldsymbol{\phi} = \boldsymbol{\phi}_a dx^a,$$

$$\boldsymbol{\Phi} = \frac{1}{2}\boldsymbol{\Phi}_{ab} dx^a \wedge dx^b. \tag{2.7}$$

For fixed values of the indices a and b, the quantities $\boldsymbol{\phi}_a$ and $\boldsymbol{\Phi}_{ab}$ are three-component vector-valued functions on configuration space. Now we use

$$d\boldsymbol{\phi} = \boldsymbol{\phi}_{a,b} dx^b \wedge dx^a$$

$$= \frac{1}{2}(\boldsymbol{\phi}_{b,a} - \boldsymbol{\phi}_{a,b}) dx^a \wedge dx^b, \tag{2.8}$$

where the comma denotes differentiation, to obtain

$$\mathbf{\Phi}_{ab} = \boldsymbol{\phi}_{b,a} - \boldsymbol{\phi}_{a,b} - \boldsymbol{\phi}_a \times \boldsymbol{\phi}_b \,. \tag{2.9}$$

This expression will be used to obtain a coordinate expression for the curvature 2-form.

C. A coordinate expression for the curvature of the connection

The coordinates $\{\rho_{s\alpha i}\}$ on configuration space are useful for doing calculations. Thus, we now take the x^a coordinates in Eq. (2.7) to be the $\rho_{s\alpha i}$ coordinates. The index a becomes a pair, (αi), written without a comma in order to avoid confusion with a notation for differentiation. From Eq. (2.5) we see that $\phi^i_{(\alpha \not{)}} = (\mathsf{M}_s^{-1})_{ij} \epsilon_{jk \not{)}} \rho_{s\alpha k}$, so that

$$\boldsymbol{\phi}_{(\alpha \not{)}} = -\mathsf{M}_s^{-1} \mathsf{J}_{\not{)}} \boldsymbol{\rho}_{s\alpha} \,. \tag{2.10}$$

With this expression at hand, Eq. (2.9) can be used to calculate the coefficients $\mathbf{\Phi}_{(\alpha j)(\beta k)}$ of the curvature 2-form with respect to the coordinate basis. This is done in Appendix A. The result may be written in the form

$$\Phi^i_{(\alpha j)(\beta k)} = 2(\mathsf{M}_s^{-1})_{im} \epsilon_{mjk} \delta_{\alpha\beta} + \boldsymbol{\rho}_{s\alpha} \cdot \mathsf{C}^i_{jk} \cdot \boldsymbol{\rho}_{s\beta} \,, \tag{2.11}$$

where $\delta_{\alpha\beta}$ is the Kronecker delta symbol, and the quantity C^i_{jk} is a 3×3 matrix for each set of values of the indices i, j and k, given by

$$\begin{aligned} \mathsf{C}^i_{jk} = {} & [2\mathbf{e}_j \otimes \mathbf{e}_i \mathsf{M}_s^{-1} - \mathsf{M}_s^{-1} \mathbf{e}_i \otimes \mathbf{e}_j - (\mathsf{M}_s^{-1})_{ij} \mathsf{I}] \mathsf{M}_s^{-1} \mathsf{J}_k \\ & + \mathsf{J}_j \mathsf{M}_s^{-1} [2\mathsf{M}_s^{-1} \mathbf{e}_i \otimes \mathbf{e}_k - \mathbf{e}_k \otimes \mathbf{e}_i \mathsf{M}_s^{-1} - (\mathsf{M}_s^{-1})_{ik} \mathsf{I}] - \mathsf{J}_j \mathsf{M}_s^{-1} \mathsf{J}_i \mathsf{M}_s^{-1} \mathsf{J}_k \,. \end{aligned} \tag{2.12}$$

Here the symbol $\mathbf{e}_i$ is a three-component vector that has a one at position i and zeroes for the other two entries; in other words, it is a unit vector in the direction of the i-th laboratory or ''space'' axis (these axes were fixed at the beginning of the problem, as described at the beginning of Sec. II). The symbol $\otimes$ denotes a tensor product, so that $\mathbf{e}_i \otimes \mathbf{e}_j$ is a 3×3 matrix whose entries are all zeroes except the entry at position (i,j), which is a one. The symbol I is the 3×3 identity matrix.

D. Identities for the curvature

The expression for the coefficients $\Phi^i_{(\alpha j)(\beta k)}$ given in Eqs. (2.11) and (2.12) can be used to derive some simple identities for the curvature 2-form. We start by setting j equal to i in Eq. (2.12) and summing on i. This results in

$$\begin{aligned} \mathsf{C}^i_{ik} = {} & [\mathsf{M}_s^{-1} - \mathrm{Tr}(\mathsf{M}_s^{-1}) \mathsf{I}] \mathsf{M}_s^{-1} \mathsf{J}_k \\ & + \mathsf{J}_i \mathsf{M}_s^{-1} [-\mathbf{e}_k \otimes \mathbf{e}_i \mathsf{M}_s^{-1} - (\mathsf{M}_s^{-1})_{ik} \mathsf{I}] - \mathsf{J}_i \mathsf{M}_s^{-1} \mathsf{J}_i \mathsf{M}_s^{-1} \mathsf{J}_k \,, \end{aligned} \tag{2.13}$$

where the symbol Tr denotes the trace of a matrix. Now we use the ''BAC-CAB'' rule in the form $\mathsf{J}_i \mathsf{M}_s^{-1} \mathsf{J}_i = \mathsf{M}_s^{-1} - \mathrm{Tr}(\mathsf{M}_s^{-1}) \mathsf{I}$ to obtain

$$\mathsf{C}^i_{ik} = 0. \tag{2.14}$$

This equation will be used in proving identities about the curvature 2-form which will then be used to prove the Yang–Mills type fields equations.

The three identities for the curvature 2-form that will be of use to us are

$$\Phi^j_{(\alpha j)(\beta k)} = 0, \tag{2.15}$$

$$\Phi^i_{(\alpha j)(\beta k)} \boldsymbol{\rho}_{s\alpha j} = 0, \tag{2.16}$$

$$\Phi^i_{(\alpha j)(\beta k)} \boldsymbol{\rho}_{s\alpha i} = 0. \tag{2.17}$$

As always, the repeated indices in these equations are summed over. Equation (2.15) follows from the $\mathsf{C}^i_{ik}=0$ identity and the coordinate expression for the curvature 2-form, Eq. (2.11). The definition of the space moment of inertia tensor M_s, given in Eq. (2.1), is used in the proof of Eq. (2.16). A proof of Eq. (2.17) is given in Appendix B.

The identities in Eqs. (2.15), (2.16) and (2.17) make reference to the coefficients $\Phi^i_{(\alpha j)(\beta k)}$ of the curvature 2-form with respect to a coordinate basis. These identities may also be written in ways that do not make reference to these expansion coefficients. Equation (2.15) is equivalent to

$$\frac{\partial}{\partial \boldsymbol{\rho}_{s\alpha j}} \lrcorner \Phi^j = 0, \tag{2.18}$$

where the symbol $\lrcorner$ is used for the inner product of a vector and a differential form, and a common notation for vectors has been used: $\partial/\partial\rho_{s\alpha j}$ is the vector obtained by holding all of the coordinates except $\rho_{s\alpha j}$ fixed and using the coordinate $\rho_{s\alpha j}$ as the parameter for a parametrized curve.

The identity in Eq. (2.16) may also be written in a form similar in appearance to Eq. (2.18). We start by considering the quantity $\mathrm{Tr}\mathsf{M}_s$, a scalar field on configuration space. The exterior derivative of this quantity is

$$d\mathrm{Tr}\mathsf{M}_s = d(2\boldsymbol{\rho}_{s\alpha}\cdot\boldsymbol{\rho}_{s\alpha}) = 4\boldsymbol{\rho}_{s\alpha}\cdot d\boldsymbol{\rho}_{s\alpha}. \tag{2.19}$$

The Euclidean metric on configuration space[1] makes possible a correspondence between 1-forms and vectors. The symbol $\sharp$ is used to indicate the vector corresponding to a 1-form. The vector corresponding to $d\mathrm{Tr}\mathsf{M}_s$ is the gradient of $\mathrm{Tr}\mathsf{M}_s$ and is given by

$$(d\mathrm{Tr}\mathsf{M}_s)^\sharp = 4\boldsymbol{\rho}_{s\alpha}\cdot\frac{\partial}{\partial\boldsymbol{\rho}_{s\alpha}}. \tag{2.20}$$

Now the identity in Eq. (2.16) may be written in the form

$$(d\mathrm{Tr}\mathsf{M}_s)^\sharp \lrcorner \boldsymbol{\Phi} = 0. \tag{2.21}$$

The identity in Eq. (2.17) can be written as a sum of inner products of vectors with 2-forms,

$$\rho_{s\alpha i}\frac{\partial}{\partial\boldsymbol{\rho}_{s\alpha j}} \lrcorner \Phi^i = 0. \tag{2.22}$$

In other words, for any fixed value of the index j, the sum on i of the inner product of the vector $\rho_{s\alpha i}(\partial/\partial\rho_{s\alpha j})$ with the 2-form Φ^i vanishes.

III. TRANSITION TO QUANTITIES ON SHAPE SPACE

The identities for the curvature 2-form on configuration space derived in the previous section can be translated into statements about fields defined on shape space, the base space of the rotation-group fiber bundle described at the beginning of Sec. II. The Coriolis tensor,[1] to be described below, is the field on shape space that corresponds to the curvature 2-form. In Ref. 1 the Coriolis tensor is derived from a vector potential. We start by showing how this vector potential is related to the connection 1-form and how the Coriolis tensor is related to the curvature 2-form. These relationships are standard in the study of connections on fiber bundles. The concept of a local section of the fiber bundle[1,7,8] is central to the understanding of these relationships. A local section is a differentiable mapping from an open subset U of shape space to configuration space $\mathscr{C}$, with the property that a point in shape space is mapped to a point in configuration space that is in the equivalence class identified by the point in shape space. We use the symbol σ for such a mapping, and use the notation $\{\boldsymbol{\rho}_\alpha(q)\}$ (not to be confused with the $\rho_{s\alpha i}$ coordinates on configuration space) for the image of a shape q under this mapping,

$$\sigma: U \to \mathscr{C}, \tag{3.1}$$

$$q \mapsto \{\boldsymbol{\rho}_\alpha(q)\}.$$

As in Ref. 1, we use the notation $q^\mu, \mu = 1, \ldots, 3n-6$ for arbitrary coordinates on shape space.

The local section may be thought of as an assignment of a body frame[1] to each shape in the domain of definition of σ. This makes it possible to define a body-frame moment of inertia tensor M,

$$\mathsf{M} = \mathsf{M}_s \circ \sigma. \tag{3.2}$$

The $\circ$ denotes functional composition. M is a 3×3 matrix-valued function on shape space that depends on the choice of local section. We note that since M_s is an array of 0-forms, Eq. (3.2) may also be written as $\mathsf{M} = \sigma^* \mathsf{M}_s$, where σ^* denotes the pullback operation, which is discussed in the next section.

The components of the body-frame moment of inertia tensor M are found from the definition of M_s, Eq. (2.1), to be

$$M_{ij} = \delta_{ij} \boldsymbol{\rho}_\alpha \cdot \boldsymbol{\rho}_\alpha - \rho_{\alpha i} \rho_{\alpha j}. \tag{3.3}$$

A. Local expressions for the connection and its curvature

Other fields on configuration space can be pulled back[7–9] by a local section to give fields on shape space. First we will consider the pullback of the connection 1-form $\boldsymbol{\phi}$ by the local section σ. This is denoted $\sigma^* \boldsymbol{\phi}$ and is a Lie algebra valued 1-form on shape space. This form evaluated on a vector in the tangent space of shape space at a point in shape space is found in the following way. If the vector is called $v = v^\mu \partial/\partial q^\mu$, one first pushes v forward by the local section σ to a vector on configuration space,

$$v^\mu \frac{\partial \boldsymbol{\rho}_\alpha}{\partial q^\mu} \cdot \frac{\partial}{\partial \boldsymbol{\rho}_{s\alpha}}. \tag{3.4}$$

Then one lets the connection 1-form $\boldsymbol{\phi}$ act on this vector,

$$(\sigma^* \boldsymbol{\phi}) v = \boldsymbol{\phi}\left(v^\mu \frac{\partial \boldsymbol{\rho}_\alpha}{\partial q^\mu} \cdot \frac{\partial}{\partial \boldsymbol{\rho}_{s\alpha}} \right). \tag{3.5}$$

The right-hand side of this equation can be evaluated using the expression for the connection 1-form given in Eq. (2.5). The result is

$$(\sigma^* \boldsymbol{\phi}) v = \mathsf{M}^{-1} \cdot \left(\boldsymbol{\rho}_\alpha \times \frac{\partial \boldsymbol{\rho}_\alpha}{\partial q^\mu} \right) v^\mu. \tag{3.6}$$

We recognize the right-hand side of Eq. (3.6) as the vector potential,[1]

$$\mathbf{A} = \mathbf{A}_\mu dq^\mu = \mathsf{M}^{-1} \cdot \left(\boldsymbol{\rho}_\alpha \times \frac{\partial \boldsymbol{\rho}_\alpha}{\partial q^\mu} \right) dq^\mu, \tag{3.7}$$

acting on the vector v. Thus, we have shown that the relationship between the connection 1-form $\boldsymbol{\phi}$ and the vector potential $\mathbf{A}$ is

$$\mathbf{A} = \sigma^* \boldsymbol{\phi}. \tag{3.8}$$

Next, we move on to the relationship between the Coriolis tensor and the curvature 2-form. We start by letting the pullback of $\boldsymbol{\Phi}$ by the local section act on the vectors $\partial/\partial q^\mu$ and $\partial/\partial q^\nu$. Using a procedure similar to that used above for the connection 1-form, one obtains

$$(\sigma^*\mathbf{\Phi})\left(\frac{\partial}{\partial q^\mu},\frac{\partial}{\partial q^\nu}\right)=\mathbf{A}_{\nu,\mu}-\mathbf{A}_{\mu,\nu}-\mathbf{A}_\mu\times\mathbf{A}_\nu,$$

$$=\mathbf{B}_{\mu\nu}. \tag{3.9}$$

Equation (2.9) has been used in this calculation. The final equality in Eq. (3.9) expresses the definition of the Coriolis tensor given in Ref. 1. Equation (3.9) shows that

$$\mathbf{B}=\sigma^*\mathbf{\Phi}, \tag{3.10}$$

where the Lie-algebra-valued 2-form $\mathbf{B}$ on shape space is defined to be

$$\mathbf{B}=\frac{1}{2}\mathbf{B}_{\mu\nu}dq^\mu\wedge dq^\nu. \tag{3.11}$$

B. Identities for quantities on shape space

The relationships between fields on shape space and fields on configuration space derived in the previous section can be used to translate the identities for the curvature derived in Sec. II into identities for the fields on shape space. There is one more equation that is necessary in order to carry out this process. This is a certain statement about the vector fields $\partial/\partial\rho_{s\alpha i}$ on configuration space and the vector fields $\partial/\partial q^\mu$ on shape space. The statement also involves the projection π from configuration space to shape space. This projection is part of the definition of configuration space as a rotation group fiber bundle. It maps a point in configuration space to the equivalence class to which it belongs. A vector on configuration space such as $\partial/\partial\rho_{s\alpha i}$ can be projected onto shape space. The notation for this projected vector (the ''push-forward'' by the projection) is

$$\pi_*\frac{\partial}{\partial\rho_{s\alpha i}}.$$

The point at which the vector $\partial/\partial\rho_{s\alpha i}$ is based is suppressed in this notation. We will consider the case in which this point is ''on the gauge surface,'' that is, the point is the image under the local section σ of a point q in shape space. The projected vector may be expressed in terms of the basis $\{\partial/\partial q^\mu,\mu=1,\ldots,3n-6\}$ of the tangent space of shape space at the point q. This can be done by calculating the Jacobian of the coordinate transformation on configuration space from the $\rho_{s\alpha i}$ coordinates to the coordinates that are the $3n-6$ shape coordinates q^μ and three coordinates on the rotation group. Such a local coordinate transformation is possible once a local section of the bundle has been chosen. The Jacobian of this coordinate transformation is presented in Ref. 1, and the result for the projected vector is

$$\pi_*\frac{\partial}{\partial\rho_{s\alpha i}}=g^{\mu\nu}\rho_{\alpha i;\nu}\frac{\partial}{\partial q^\mu}. \tag{3.12}$$

In this equation, $g^{\mu\nu}$ denotes the inverse of the metric tensor on shape space, and $\boldsymbol{\rho}_{\alpha;\nu}=\boldsymbol{\rho}_{\alpha,\nu}-\mathbf{A}_\nu\times\boldsymbol{\rho}_\alpha$ is the covariant derivative of $\boldsymbol{\rho}_\alpha$ with respect to the coordinate q^ν, as explained in Ref. 1. The metric $g_{\mu\nu}dq^\mu\otimes dq^\nu$ is the metric induced on shape space by the (rotationally invariant) Euclidean metric on configuration space. Covariant differentiation is also discussed in Appendix C.

Next, we consider projecting other vectors from configuration space to shape space. The vector $(d\mathrm{TrM}_s)^\sharp$ that appears in Eq. (2.20) is a linear combination of the vectors in the $\{\partial/\partial\rho_{s\alpha i}\}$ basis,

$$(d\mathrm{TrM}_s)^\sharp=4\rho_{s\alpha i}\frac{\partial}{\partial\rho_{s\alpha i}}. \tag{3.13}$$

Thus, it projects according to

$$\pi_*[(d\mathrm{Tr}\mathsf{M}_s)^\sharp]=4\rho_{\alpha i}\pi_*\frac{\partial}{\partial\rho_{s\alpha i}}=g^{\mu\nu}(2\rho_{\alpha i}\rho_{\alpha i})_{;\nu}\frac{\partial}{\partial q^\mu}=(\mathrm{Tr}\mathsf{M})^{;\mu}\frac{\partial}{\partial q^\mu}, \tag{3.14}$$

where the index in the final expression has been raised with $g^{\mu\nu}$, as is standard in tensor analysis, and we note that the covariant derivative of a scalar such as $\rho_{\alpha i}\rho_{\alpha i}$ is equal to the ordinary derivative of the scalar.

We are now in a position to calculate $\mathbf{B}_{\mu\nu}(\mathrm{Tr}\mathsf{M})^{;\nu}$, a quantity that will be needed later in the proof. The question is what happens when the 2-form $\mathbf{B}$ acts on the vector $(\mathrm{Tr}\mathsf{M})^{;\nu}\partial/\partial q^\nu$ and any other vector. According to Eq. (3.10), this equals $\mathbf{\Phi}$ acting on the vectors pushed forward by the local section σ. Thus, we are interested in the inner product of $\mathbf{\Phi}$ with the push-forward of $(\mathrm{Tr}\mathsf{M})^{;\nu}\partial/\partial q^\nu$ by σ. However, since the original definition of $\mathbf{\Phi}$ involved projection onto the horizontal subspace (the form $\mathbf{\Phi}$ is ''horizontal'' in the terminology of Ref. 8), we can consider the inner product of $\mathbf{\Phi}$ with any vector that projects to the vector $(\mathrm{Tr}\mathsf{M})^{;\nu}\partial/\partial q^\nu$ on shape space. Equation (3.14) shows that $(d\mathrm{Tr}\mathsf{M}_s)^\sharp$ is such a vector. The vanishing of the inner product of $\mathbf{\Phi}$ with this vector, shown in Eq. (2.21), thus results in

$$\mathbf{B}_{\mu\nu}(\mathrm{Tr}\mathsf{M})^{;\nu}=0. \tag{3.15}$$

In a similar manner, we now calculate $\mathbf{B}_{\mu\nu}\cdot\boldsymbol{\rho}_\alpha{}^{;\nu}$. The center dot denotes a contraction on the three-vector indices; written out this is $B^i_{\mu\nu}\rho_{\alpha i}{}^{;\nu}$. Thus, we are considering a sum on i of the inner product of the 2-form B^i on shape space with the vector $\rho_{\alpha i}{}^{;\nu}\partial/\partial q^\nu$. As in the previous calculation, Eq. (3.12) leads us to the inner product of the 2-form Φ^i on configuration space with the vector $\partial/\partial\rho_{s\alpha i}$. Equation (2.18) shows that when this is summed on i, the result is zero. Therefore, we have shown

$$\mathbf{B}_{\mu\nu}\cdot\boldsymbol{\rho}_\alpha{}^{;\nu}=0. \tag{3.16}$$

This result can be obtained by other means, but the calculations are lengthy and do not use geometrical ideas.

The third of the identities for the curvature 2-form on configuration space, Eq. (2.17), enables us to show

$$B^i_{\mu\nu}\rho_{\alpha i}\rho_{\alpha j}{}^{;\nu}=0, \tag{3.17}$$

which may be seen as follows. For any value of the free index j, the left-hand side of this equation, contracted with dq^μ, is a 1-form. This 1-form is a sum on i of the inner product of the 2-form B^i on shape space with the vector $\rho_{\alpha i}\rho_{\alpha j}{}^{;\nu}\partial/\partial q^\nu$. As above, for each value of the index i, Eq. (3.12) leads us to the inner product of the 2-form Φ^i on configuration space with the vector $\rho_{s\alpha i}\partial/\partial\rho_{s\alpha j}$. Equation (2.22) shows that when this is summed on i, the result is zero, providing the proof of Eq. (3.17).

Equations (3.15), (3.16) and (3.17) make it possible to prove the Yang–Mills type identity $\mathbf{B}_{\mu\nu}{}^{;\nu}=0$ for the Coriolis tensor on shape space. One begins by calculating $\mathsf{M}^{;\nu}\cdot\mathbf{B}_{\mu\nu}$. The covariant derivative of the moment of inertia tensor on shape space $\mathsf{M}_{;\mu}$ is given by

$$M_{ij;\mu}=\frac{1}{2}\delta_{ij}(\mathrm{Tr}\mathsf{M})_{;\mu}-\rho_{\alpha i;\mu}\rho_{\alpha j}-\rho_{\alpha i}\rho_{\alpha j;\mu}, \tag{3.18}$$

[see Eq. (3.3)]. Thus

$$\begin{aligned}M_{ij}{}^{;\nu}B^j_{\mu\nu}&=\frac{1}{2}B^i_{\mu\nu}(\mathrm{Tr}\mathsf{M})^{;\nu}-B^j_{\mu\nu}\rho_{\alpha i}{}^{;\nu}\rho_{\alpha j}-B^j_{\mu\nu}\rho_{\alpha i}\rho_{\alpha j}{}^{;\nu},\\&=0,\end{aligned} \tag{3.19}$$

where Eqs. (3.15), (3.16) and (3.17) have been used.

Having proved the identity $\mathsf{M}^{;\nu}\cdot\mathbf{B}_{\mu\nu}=0$, we now use the fact that configuration space is Riemann flat, in order to arrive at the identity $\mathbf{B}_{\mu\nu}{}^{;\nu}=0$. This involves a translation of the Rie-

mann flatness of configuration space into a number of identities for the fields on shape space. Such calculations are done in Ref. 10 in a general setting, and in Ref. 1 for the case of the rotational symmetry in the n-body problem. Among the resulting identities is the relation

$$2(\mathsf{M}\cdot\mathbf{B}_{\mu\tau})_{;\nu}-\mathsf{M}_{;\mu}\cdot\mathbf{B}_{\tau\nu}-\mathsf{M}_{;\tau}\cdot\mathbf{B}_{\nu\mu}=0. \tag{3.20}$$

Contracting this with $g^{\tau\nu}$ results in

$$(\mathsf{M}\cdot\mathbf{B}_{\mu\nu})^{;\nu}=0, \tag{3.21}$$

which may be expanded into two terms using the Leibnitz rule. The relation $\mathsf{M}^{;\nu}\cdot\mathbf{B}_{\mu\nu}=0$ implies that in fact both of these terms vanish. This completes the proof of the Yang–Mills type identity for the Coriolis tensor on shape space,

$$\mathbf{B}_{\mu\nu}{}^{;\nu}=0. \tag{3.22}$$

In summary, we have derived several simple identities, Eqs. (2.15), (2.16) and (2.17), for the curvature 2-form on configuration space, and shown that together with the Riemann flatness of configuration space these identities imply that the Coriolis tensor $\mathbf{B}_{\mu\nu}$ obeys field equations of the Yang–Mills type.

APPENDIX A: A COORDINATE EXPRESSION FOR THE CURVATURE 2-FORM

The subject of this appendix is the proof of the coordinate expression for the curvature 2-form given in Eq. (2.11). Using the coordinates $\{\rho_{s\alpha i}\}$ on configuration space, Eq. (2.9) reads as

$$\mathbf{\Phi}_{(\alpha j)(\beta k)}=\boldsymbol{\phi}_{(\beta k),(\alpha j)}-\boldsymbol{\phi}_{(\alpha j),(\beta k)}-\boldsymbol{\phi}_{(\alpha j)}\times\boldsymbol{\phi}_{(\beta k)}. \tag{A1}$$

When the coordinate expression for $\boldsymbol{\phi}$ given in Eq. (2.10) is substituted into this equation, it is necessary to differentiate the moment of inertia tensor M_s. In doing this, it is helpful to write the definition of M_s in the form

$$\mathsf{M}_s=-\rho_{s\alpha i}\rho_{s\alpha j}\mathsf{J}_i\mathsf{J}_j. \tag{A2}$$

The equivalence of this expression and the definition of the moment of inertia tensor given in Eq. (2.1) can be seen from the definition of the J matrices [Eq. (2.4)] and the ''BAC-CAB'' rule, Eq. (A3). The expression that results for $\Phi^i_{(\alpha j)(\beta k)}$ may be separated into two parts. The first part is the first term on the right-hand side of Eq. (2.11). The second part is a linear combination of the nine quantities $\rho_{s\alpha i}\rho_{s\beta j}; i,j=1,2,3$. The coefficients in this linear combination are functions of the location in configuration space and can be expressed in terms of the moment of inertia tensor. One way to write the final expression is as a matrix sandwiched between the vectors $\boldsymbol{\rho}_{s\alpha}$ and $\boldsymbol{\rho}_{s\beta}$. The ''BAC-CAB'' rule,

$$\epsilon_{ijk}\epsilon_{i\ell m}=\delta_{j\ell}\delta_{km}-\delta_{jm}\delta_{k\ell}, \tag{A3}$$

is useful in doing this. The final result for the coordinate expression for Φ^i is given in Eq. (2.11).

APPENDIX B: PROOF OF AN IDENTITY FOR THE CURVATURE

This appendix contains a summary of the calculation involved in proving the identity Eq. (2.17) for the curvature 2-form. One starts with the coordinate expression for the curvature 2-form given in Eq. (2.11). This is then contracted with $\rho_{s\alpha i}$ as shown in Eq. (2.17). The definition of the

space moment of inertia tensor, Eq. (2.1), is used to eliminate the explicit occurrences of sums over Jacobi vectors. One is left with an expression that may be written as a matrix contracted with the vectors $\mathbf{e}_j$ and $\boldsymbol{\rho}_{s\beta}$. This matrix,

$$[\mathrm{Tr}\mathsf{M}_s(\mathsf{M}_s^{-1}-\mathsf{I}\mathrm{Tr}\mathsf{M}_s^{-1})+2\mathsf{I}-M_{s\not m}\mathsf{J}_{\not m}\mathsf{M}_s^{-1}\mathsf{J}_m]\mathsf{M}_s^{-1}\mathsf{J}_k+(\mathsf{M}_s^{-1})_{\not k}\mathsf{J}_{\not}+\mathsf{J}_k\mathsf{M}_s^{-1},$$

can be shown to vanish using only the fact that M_s is a 3×3 symmetric matrix. In doing this, one uses the Cayley–Hamilton Theorem, which may be written as

$$\mathsf{M}_s^3-(\mathrm{Tr}\mathsf{M}_s)\mathsf{M}_s^2=\det(\mathsf{M}_s)\{\mathsf{I}-[\mathrm{Tr}(\mathsf{M}_s^{-1})]\mathsf{M}_s\}, \tag{B1}$$

for a 3×3 matrix. One also uses the fact that $\mathsf{M}_s\mathsf{J}_k+\mathsf{J}_k\mathsf{M}_s$ is antisymmetric and can therefore be expressed in terms of the J matrices,

$$\mathsf{M}_s\mathsf{J}_k+\mathsf{J}_k\mathsf{M}_s=\mathsf{J}_{\not}(\delta_{\not k}\mathrm{Tr}\mathsf{M}_s-\mathsf{M}_{s\not k}). \tag{B2}$$

APPENDIX C: COVARIANT DIFFERENTIATION

The subject of this appendix is the relationship between covariant differentiation of fields defined on shape space[1] and covariant differentiation of corresponding quantities on configuration space. Covariant differentiation on configuration space has a simple definition, involving only the metric connection,[7,8] and it is easily carried out in the $\{\rho_{s\alpha i}\}$ coordinates because this space is Riemann flat.

We are especially interested in the curvature 2-form; the projection onto shape space of the covariantly differentiated $\boldsymbol{\Phi}$ is equal to the covariant derivative of the Coriolis tensor on shape space. This relationship is used to translate the Yang–Mills identity for the Coriolis tensor, Eq. (3.22), into a statement about the curvature 2-form on configuration space.

1. Covariant differentiation of the curvature 2-form on configuration space

We begin with the covariant derivative of the curvature 2-form on configuration space. The first step is to express this Lie-algebra-valued 2-form with respect to the basis of the Lie algebra of $SO(3)$ defined in Eq. (2.4), as discussed in Sec. II. This results in three real-valued 2-forms $\Phi^i, i=1,2,3$. The covariant derivative of such a 2-form is defined using the metric connection on configuration space. In the language of tensor analysis, this means that for a choice of coordinates on configuration space, one calculates Christoffel symbols and uses these to obtain the covariant derivative of Φ^i_{ab} as a second-rank tensor. This covariant derivative involves a term that contains ordinary directional differentiation and two terms that involve Christoffel symbols. If $\{\rho_{s\alpha i}\}$ coordinates are used, the Christoffel symbols vanish because the metric tensor is constant in these coordinates. Thus, we may describe covariant differentiation of the curvature 2-form on configuration space as follows. Given a vector U in the tangent space of configuration space at a point, one obtains $\nabla_U\boldsymbol{\Phi}$, the covariant derivative of $\boldsymbol{\Phi}$ in the direction U, by first expressing $\boldsymbol{\Phi}$ with respect to the basis $d\rho_{s\alpha i}\wedge d\rho_{s\beta j}$ as in Eq. (2.7),

$$\boldsymbol{\Phi}=\frac{1}{2}\boldsymbol{\Phi}_{(\alpha i)(\beta j)}d\rho_{s\alpha i}\wedge d\rho_{s\beta j}, \tag{C1}$$

and then applying directional differentiation to these coefficients,

$$\nabla_U\boldsymbol{\Phi}=\frac{1}{2}U[\boldsymbol{\Phi}_{(\alpha i)(\beta j)}]d\rho_{s\alpha i}\wedge d\rho_{s\beta j}, \tag{C2}$$

where the square brackets denote directional differentiation.

2. Relation between covariant differentiation on configuration space and on shape space

Next we turn to the subject of the relationship between covariant differentiation on shape space and the simple covariant differentiation on configuration space. The result is

$$\mathbf{B}_{;\mu}=\sigma^{*}[(\nabla_{e_\mu}\mathbf{\Phi})\circ\Pi_h], \tag{C3}$$

where e_μ is the horizontal vector defined in Ref. 1 (the horizontal lift of the vector $\partial/\partial q^\mu$), $\mathbf{B}_{;\mu}$ is defined by

$$\mathbf{B}_{;\mu}=\frac{1}{2}\mathbf{B}_{\lambda\nu;\mu}dq^\lambda\wedge dq^\nu, \tag{C4}$$

and Π_h denotes projection onto the horizontal subspaces (the orthogonal complements of the vertical subspaces). The methods in Ref. 1 can be used to verify Eq. (C3). This equation expresses the fact that the projection onto shape space of the covariant derivative of $\mathbf{\Phi}$ on configuration space is the covariant derivative of the Coriolis tensor on shape space.

We recall the definition of the covariant derivative of the Coriolis tensor on shape space from Ref. 1,

$$\mathbf{B}_{\mu\nu;\sigma}=\mathbf{B}_{\mu\nu,\sigma}-\mathbf{A}_\sigma\times\mathbf{B}_{\mu\nu}-\Gamma^\tau_{\sigma\mu}\mathbf{B}_{\tau\nu}-\Gamma^\tau_{\sigma\nu}\mathbf{B}_{\mu\tau}. \tag{C5}$$

In this equation, the quantities $\Gamma^\tau_{\sigma\mu}$ are the Christoffel symbols calculated from the metric tensor $g_{\mu\nu}$ on shape space. Each of the terms in this equation can be obtained by carrying out the operations on the right-hand side of Eq. (C3).

3. The Yang–Mills identity

It is possible to express the Yang–Mills field equations for the Coriolis tensor, Eq. (3.22), as a statement about quantities defined on configuration space, i.e., without the use of local sections of the bundle. One way to do this is to start with an arbitrary orthonormal basis $\{u_{(i)}, i=1,\ldots,3n-6\}$ of the tangent space of shape space, at some point q. This means that $u^\mu_{(i)}g_{\mu\nu}u^\nu_{(j)}=\delta_{ij}$, which implies $u^\mu_{(i)}u^\nu_{(i)}=g^{\mu\nu}$. Thus, the $\mathbf{B}_{\mu\nu}{}^{;\nu}=0$ identity may be written as

$$\mathbf{B}_{\mu\nu;\lambda}u^\nu_{(i)}u^\lambda_{(i)}=0. \tag{C6}$$

This equation translates into a statement about the curvature 2-form with the help of Eq. (C3),

$$u_{(j)}\lrcorner\sigma^{*}[(\nabla_{u^\mu_{(j)}e_\mu}\Phi)\circ\Pi_h]=0. \tag{C7}$$

The horizontal lifts of the vectors $\{u_{(i)}, i=1,\ldots,3n-6\}$ form an orthonormal basis of the horizontal subspace of the tangent space. This follows from the definition of the induced metric on shape space. The Yang–Mills identity may now be stated as follows. Given any orthonormal basis $\{U_{(i)}, i=1,\ldots,3n-6\}$ of the horizontal subspace of the tangent space of configuration space, we have

$$(U_{(j)}\lrcorner\nabla_{U_{(j)}}\Phi)\circ\Pi_h=0. \tag{C8}$$

We note that this may also be written as $U_{(j)}\lrcorner[(\nabla_{U_{(j)}}\Phi)\circ\Pi_h]=0$. An equivalent way to state the contents of Eq. (C8) is to say that the form $U_{(j)}\lrcorner\nabla_{U_{(j)}}\Phi$ is vertical.[8] Also, we recall again that the covariant differentiation in Eq. (C8) is simple, involving only directional differentiation if the $\{\rho_{sai}\}$ coordinates are used.

The inverse loop transform

T. Thiemann[a)]
Albert Einstein Institut, Max Planck Institut für Gravitationsphysik, Schlaatzweg 1, 14473 Potsdam, Germany

(Received 3 March 1997; accepted for publication 7 October 1997)

The loop transform in quantum gauge field theory can be recognized as the Fourier transform (or characteristic functional) of a measure on the space of generalized connections modulo gauge transformations. Since this space is a compact Hausdorff space, conversely, we know from the Riesz–Markov theorem that every positive linear functional on the space of continuous functions thereon qualifies as the loop transform of a regular Borel measure on the moduli space. In the present article we show how one can compute the finite joint distributions of a given characteristic functional, that is, we derive the inverse loop transform. © *1998 American Institute of Physics.* [S0022-2488(98)00302-8]

I. INTRODUCTION

Quite some time ago[1] it became clear that for the canonical formulation of quantum gauge field theories it seems to be of advantage to work in a so-called ''loop representation.'' By this is meant the following: Let A be a smooth connection of a compact gauge group G on some manifold Σ and let α be a loop in Σ. From these data one can construct the holonomy (or parallel transport) $h_\alpha(A)$ of A along α. One knows[2] that the gauge invariant information of a smooth connection is encoded in the holonomies of A as one considers all possible loops. Thus, a gauge invariant function f of A may be written as a function of holonomies. The idea behind the loop representation is then to define a measure μ on a space of connections modulo gauge transformations ''$\mathcal{A}/\mathcal{G}$'' (we set inverted commas because, as one can imagine, the support of the measure will not be contained in the space of smooth connections modulo gauge transformations $\mathcal{A}/\mathcal{G}$) and to define the loop transform of f as a kind of Fourier transform via $\tilde{f}(\alpha) := \int d\mu(A)\overline{\mathrm{tr}[h_\alpha(A)]}f(A)$.

This idea has been rediscovered by Rovelli and Smolin[3] in the context of canonical quantum gravity based on the observation by Ashtekar[4] that general relativity can be formulated as a theory of SL(2, $\mathbb{C}$) connections. The virtue of these complex-valued variables is that they allow for a polynomial formulation of the theory that for a highly nonpolynomial theory as general relativity is a major breakthrough.

The status of the loop transform had been rather formal then for several reasons: First of all, for gauge theories for compact gauge groups, the measure μ was never specified, partly because it was unknown over which space of connections to integrate. Second, for quantum gravity the situation was even worse since the gauge group was noncompact, and this made several of the techniques developed for gauge theories inaccessible. Finally, in Ref. 5 a quantum configuration space $\overline{\mathcal{A}/\mathcal{G}}$ of generalized (distributional) connections was defined and in Refs. 6 and 7 measures on this space were constructed. This put the loop transform on a mathematically rigorous foundation, at least for compact gauge groups. Expectedly, the space of smooth connections modulo gauge transformations $\mathcal{A}/\mathcal{G}$ was seen to be contained in a measure zero measurable set with respect to the measures μ constructed.[8]

On the mathematical side, several additional quite powerful techniques associated with $\overline{\mathcal{A}/\mathcal{G}}$ have been constructed, such as differential geometry[9] on $\overline{\mathcal{A}/\mathcal{G}}$ based on its description as a projective limit,[8,10] the complete set of diffeomorphism invariant states[11] for any diffeomorphism invariant quantum gauge field theory for a compact gauge group and a coherent state transform from a theory for compact gauge groups to a theory with noncompact gauge groups.[12]

 © 1998 American Institute of Physics

On the physical side, in applications to quantum gravity a Wick rotation transform was developed[13,14] that uses the techniques of Ref. 12, but, in addition, solves the problem of the nonpolynomial reality conditions on the complex-valued Ashtekar variables. Suffice it to say that due to a recently developed technique (see Ref. 15 and references therein), following Ref. 16, a Wick rotation transform is not necessary anymore so that the framework developed in Refs. 5–8 can be immediately applied to equip quantum gravity with a Hilbert space structure. For an account of these various transforms, including the one discussed in the present paper, the reader is referred to Ref. 17. In applications to gauge field theory a new constructive quantum field theory framework in the sense of Ref. 18 was developed,[19,20] and, in particular, applied to two-dimensional Yang–Mills theory.[21]

In this paper we make yet another contribution to this subject, namely we construct the analog of the inverse Fourier transform on $\mathbb{R}^n$,[22] which we call the ''inverse loop transform.'' This will allow us to reconstruct a measure as defined by its finite joint distributions from its characteristic functional. In particular, given a (singular) knot invariant satisfying certain additional conditions, we can find out to what measure it corresponds.

The plan of the paper is as follows.

In Sec. II we recall the basic notions from calculus on $\overline{\mathcal{A}/\mathcal{G}}$ as far as necessary for the present context. The interested reader is referred to the article in Ref. 11 for further details.

In Sec. III we first formulate and prove the analog of the inverse Fourier transform theorem for compact gauge groups and then give a new definition of the loop transform based on the notion of ''loop networks.'' [23,24] This notion will prove useful in proving the inverse loop transform.

In Sec. IV we display the inverse loop transform of physically interesting characteristic functionals.

In an Appendix we indicate how all the results of this paper can be rewritten in terms of edges rather than loops, which is sometimes more convenient in applications beyond integration on $\overline{\mathcal{A}/\mathcal{G}}$. In particular, we introduce the notion of an ''edge network'' that generalizes the notion of a ''spin network'' [23,24] to an arbitrary compact gauge group and also allows us to give (a) a closed and compact expression for a spin-network state without referring to a graphical notation,[23] and (b) an explicit algebraic expression for the in[24] only abstractly defined ''intertwiners'' for an arbitary compact gauge group.

II. PRELIMINARIES

We give here only the absolutely necessary information in order to fix the notation. For further details see Ref. 11 and references therein.

The space $\overline{\mathcal{A}/\mathcal{G}}$ of generalized connections modulo gauge transformations is the Gel'fand spectrum of the Abelian C^* algebra generated by the Wilson-loop functionals for smooth connections, that is, traces of the holonomy for piecewise analytic loops in the base manifold Σ. As such, it is a compact Hausdorff space and therefore measures on that space are in one to one correspondence with positive linear functionals on $C(\overline{\mathcal{A}/\mathcal{G}})$.

A certain natural measure μ_0 will play a very crucial role in this article so that we go now into more detail.

In what follows, $\gamma \subset \Sigma$ will always denote a finite, unoriented, piecewise analytic graph, meaning that it is the union of a finite number of analytic edges and vertices. Its fundamental group $\pi_1(\gamma)$ is then finitely generated by some loops $\beta_1(\gamma),\ldots,\beta_{n(\gamma)}(\gamma)$ that we fix once and for all together with some orientation and that are based at some arbitrary but fixed base point $p \in \Sigma$, $n(\gamma) := \dim(\pi_1(\gamma))$ being the number of independent generators of the fundamental group of γ. A function f on $\overline{\mathcal{A}/\mathcal{G}}$ is said to be cylindrical with respect to a graph $\gamma, f \in \mathrm{Cyl}_\gamma(\overline{\mathcal{A}/\mathcal{G}})$, if it is a function only of the finite set of arguments $p_\gamma(A) := (h_{\beta_1}(A),\ldots,h_{\beta_n}(A))$, where $h_\alpha(A)$ is the holonomy of A along the loop α. A measure μ is now specified by its finite joint distributions μ_γ, which are defined by

$$\int_{\overline{\mathcal{A}/\mathcal{G}}} d\mu(A) f(A) = \int_{G^n} d\mu_\gamma(g_1,\ldots,g_n) f_\gamma(g_1,\ldots,g_n), \tag{II.1}$$

where $f=f_\gamma\circ p_\gamma$ and $f_\gamma: G^m\to\mathbb{C}$ is a gauge invariant function. In order that this definition makes sense, we have to make sure that if we write $f=f_\gamma\circ p_\gamma=f_{\gamma'}\circ p_{\gamma'}$ in two different ways as a cylindrical function where $\gamma\subset\gamma'$ is a subgraph of γ', then we should have that the so-called consistency conditions

$$\int_{G^n} d\mu_\gamma\, f_\gamma=\sum_{G^{n'}} d\mu_{\gamma'}\, f_{\gamma'}, \tag{II.2}$$

are satisfied.

The natural measure μ_0 is the induced Haar measure, meaning that $d\mu_{0,\gamma}(g_1,\ldots,g_n)=d\mu_H(g_1)\ldots d\mu_H(g_n)$. One can check that the consistency conditions are satisfied[6] and that the so-defined cylindrical measure has a σ-additive extension μ_0 on the projective limit measurable space of the family of measurable spaces $\overline{\mathcal{A}/\mathcal{G}}_\gamma$.[8] The space $\overline{\mathcal{A}/\mathcal{G}}_\gamma$ is defined to be the set of all homomorphisms from the group of based loops restricted to γ into the gauge group modulo conjugation while $\overline{\mathcal{A}/\mathcal{G}}$ is the set of all homomorphisms from the whole loop group into G modulo conjugation. Note that the semigroup of loops with respect to compositions of loops can be given a group structure by identifying paths that are traversed in the opposite direction with the inverse of the original path.

III. THE INVERSE LOOP TRANSFORM

A. The inverse Fourier transform for compact groups

Let us recall some basic facts from harmonic analysis on compact gauge groups.[25]

Definition III.1: Let $\{\pi\}$ denote the set of all finite-dimensional, nonequivalent (we fix one representant from each equivalence class once and for all), unitary, irreducible representations of the compact gauge group G, let d_π be the dimension of π, and let μ_H be the normalized Haar measure on G.

For any $f\in L_1(G,d\mu_H)$ define the Fourier transform of f by

$$\hat{f}^{ij}_\pi:=\int_G d\mu_{\rm H}(g)\sqrt{d_\pi}\,\overline{\pi_{ij}}(g)f(g),\quad i,j=1,\ldots,d_\pi, \tag{III.1}$$

where $\pi_{ij}(g)$ denotes the matrix elements of $\pi(g)$.

Note that this definition makes sense because the matrix elements of $\pi(g)$ are bounded by 1.

Definition III.2: The Fourier transform of a function is said to be ℓ_1 or ℓ_2, respectively, iff,

$$\|\hat{f}\|_1:=\sum_\pi\sum_{i,j=1}^{d_\pi}\sqrt{d_\pi}|f^{ij}_\pi|<\infty\quad\text{or}\quad\|\hat{f}\|_2:=\sum_\pi\sum_{i,j=1}^{d_\pi}|f^{ij}_\pi|^2<\infty. \tag{III.2}$$

The Fourier series associated with a function f on G such that $\hat{f}\in\ell_1$ is given by

$$\widetilde{f}(g):=\sum_\pi\sum_{i,j=1}^{d_\pi}\hat{f}^{ij}_\pi\pi_{ij}(g)\sqrt{d_\pi}. \tag{III.3}$$

The analog of the Plancherel theorem for $\mathbb{R}^n$ is the Peter and Weyl theorem.

Theorem III.1 (Peter and Weyl): (1) *The functions $g\to\sqrt{d_\pi}\pi_{ij}(g)$, $i,j=1,\ldots,d_\pi$ form a complete and orthonormal system on $L_2(G,d\mu_H)$.*

(2) *For any $f\in L_2(G,d\mu_H)$ it holds that $f=\widetilde{f}$ in the sense of L_2 functions and the Fourier transform is a unitary map $\wedge: L_2(G,d\mu_H)\to\ell_2$.*

The author was unable though to find the analog of the inverse Fourier transform theorem for groups in the literature that we therefore prove here. This theorem answers the question of whether a function that is only L_1 can be represented, in the L_1 sense, by its Fourier transform. Although the proof that follows applies directly to a compact group only for which a different, less complicated proof is available, the method of proof below hints at how to extend the result to locally compact groups and is therefore of interest.

Theorem III.2: *Let $f\in L_1(g,d\mu_H)$ such that also $\hat{f}\in\ell_1$. Then $f(g)=\widetilde{f}(g)$ on L_1.*

Proof: Let be given any $\hat{k} \in \ell_1$. Then the Fourier series

$$\tilde{f}_k := \sum_{\pi,i,j} \left[\sum_k f_\pi^{ij} \overline{k_\pi^{jk}} \right] \pi_{ij}(g) \sqrt{d_\pi} \tag{III.4}$$

still converges absolutely, as can be seen from the following considerations: Upon using the Schwarz inequality we obtain the estimate

$$\left| \sum_k f_\pi^{ik} \overline{k_\pi^{jk}} \right| \leq \sum_k |f_\pi^{ik}||k_\pi^{jk}| \leq \sqrt{\sum_k |f_\pi^{ik}|^2} \sqrt{\sum_l |k_\pi^{jk}|^2} \leq \left[\sum_k |f_\pi^{ik}| \right] \left[\sum_l |k_\pi^{jl}| \right],$$

so that

$$\|\tilde{f}_k\|_1 \leq \sum_\pi \left[\sum_{i,k} |f_\pi^{ik}| \sqrt{d_\pi} \right] \left[\sum_{j,l} |k_\pi^{jl}| \sqrt{d_\pi} \right] \leq \left[\sum_{\pi,i,k} |f_\pi^{ik}| \sqrt{d_\pi} \right] \left[\sum_{\sigma,j,l} |k_\sigma^{jl}| \sqrt{d_\sigma} \right] = \|\hat{f}\|_1 \|\hat{k}\|_1 . \tag{III.5}$$

Hence (III.4) is well defined, and we may write

$$\begin{aligned} \tilde{f}_k(g) &= \sum_{\pi,j,k} \sqrt{d_\pi} \overline{k_\pi^{jk}} \left[\int d\mu_{\mathrm{H}}(h) \pi(h^{-1}g)_{kj} f(h) \right] \\ &= \sum_{\pi,j,k} \overline{k_\pi^{jk}} \sqrt{d_\pi} \left[\int d\mu_{\mathrm{H}}(h) \pi(h^{-1})_{kj} (L_g f)(h) \right] \\ &= \int d\mu_{\mathrm{H}}(h) (L_g f)(h) \overline{\sum_{\pi,j,k} \sqrt{d_\pi} k_\pi^{jk} \pi_{jk}(h)} \\ &= \int d\mu_{\mathrm{H}}(h) (L_g f)(h) \bar{\tilde{k}}(h). \end{aligned} \tag{III.6}$$

In the second line we have made use of the translation invariance of the Haar measure and the unitarity of the representation, $(L_g f)(h) = f(gh)$ is the definition of the left regular representation of G, in the third line we could switch integration and summation because $\hat{k} \in \ell_1$ and $\overline{\pi_{jk}} L_g f \in L_1(G, d\mu_{\mathrm{H}})$, and finally in the last step we have used the definition of the Fourier series (III.3).

We now choose $k_\pi^{ij} := \sqrt{d_\pi} \pi_{ij}(1) e^{-t\lambda_\pi}$, where λ_π are the eigenvalues of the Casimir operator Δ in the representation π. Then $\tilde{k}(g) = \rho_t(g)$ becomes the heat kernel on G,[26] that is, the fundamental solution of the equation

$$\left[\frac{\partial}{\partial t} - \Delta \right] \rho_t(g) = 0, \quad \rho_0(g) = \delta_{\mu_{\mathrm{H}}}(g, 1). \tag{III.7}$$

The motivation for this choice is of course that for $t \to 0$ the lhs of (III.6) tends to $\tilde{f}(g)$ while the rhs should tend to $f(g)$. Indeed, since ρ_t tends to the δ distribution on G wrt the Haar measure, this would be straightforward to see if $f \in C^\infty(G)$. To show that this is true even for $f \in L_1(G, d\mu_{\mathrm{H}})$, we argue as follows: denote $(f \star \rho_t)(g) := \int d\mu_{\mathrm{H}}(h) (L_g f)(h) \rho_t(h)$; then we have

$$\begin{aligned} \|f \star \rho_t - f\|_1 &= \int d\mu_{\mathrm{H}}(g) \left| \int d\mu_{\mathrm{H}}(h) [R_h f - f](g) \rho_t(h) \right| \\ &\leq \int d\mu_{\mathrm{H}}(g) \int d\mu_{\mathrm{H}}(h) |R_h f - f|(g) \rho_t(h), \end{aligned} \tag{III.8}$$

where we have used the normalization and positivity of the heat kernel and $(R_h f)(g) = f(gh)$.

The idea is now to split the integration domain of the inner integral into a compact neighborhood U of the identity of μ_{H} volume δ and its complement $G - U$ in G:

$$\|f\star\rho_t - f\|_1 \leq \int_G d\mu_{\rm H}(g) \int_U d\mu_{\rm H}(h) |R_h f - f|(g)\rho_t(h)$$
$$+ \int_G d\mu_{\rm H}(g) \int_{G-U} d\mu_{\rm H}(h) |R_h f - f|(g)\rho_t(h)$$
$$=: {\rm I} + {\rm II}. \tag{III.9}$$

Since the heat kernel gets concentrated at the identity for $t\to 0$, we can estimate the second integral while we will estimate the first integral by a compactness argument.

The details are as follows. We first assume that $f\in C(G)$. This assumption will be dropped later again. Then f is uniformly continuous on the compact set $gU=\{R_h g; h\in U\}$ and therefore there is a non-negative function $\omega(\delta)$, $\lim_{\delta\to 0}\omega(\delta)=0$, such that $|R_h f - f|(g)\leq\omega(\delta)$, $\forall h\in U$. Accordingly,

$${\rm I}\leq\omega(\delta)\int_U d\mu_{\rm H}(h)\rho_t(h)\leq\omega(\delta), \tag{III.10}$$

due to the normalization of the heat kernel.

The continuous function $(g,h)\to(R_h f - f)(g)\rho_t(h)$ is measurable on $G\times G$ wrt the Borel measure $\mu_{\rm H}\times\mu_{\rm H}$ (recall Ref. 26 that ρ_t is even real analytic). Since $|\int_G d\mu_{\rm H}(h)\rho_t(h)\int d\mu_{\rm H}(g) \times(R_h f - f)(g)|\leq 2\|f\|_1<\infty$, the theorem of Fubini allows us to switch the integrations in the second integral, and we arrive at

$${\rm II} = \int_{G-U} d\mu_{\rm H}(h)\rho_t(h)\int_G d\mu_{\rm H}(g)|R_h f - f|(g)$$
$$= \int_{G-U} d\mu_{\rm H}(h)\rho_t(h)\|R_h f - f\|_1$$
$$\leq 2\|f\|_1\int_{G-U} d\mu_{\rm H}(h)\rho_t(h). \tag{III.11}$$

Now for any $\epsilon>0$ we find a $\delta(\epsilon)$ such that $\omega(\delta(\epsilon))<\epsilon/2$ and for this so chosen $\delta(\epsilon)$ we find a $t(\epsilon,f)$ so that $2\|f\|_1\int_{G\text{-}U} d\mu_{\rm H}\rho_t<\epsilon/2$, since the support of ρ_t gets more and more concentrated at the identity for $t\to 0$. Therefore we conclude that for any $f\in C(G)$, $\epsilon>0$ there exists a $t(\epsilon)>0$ such that $\|\rho_t\star f - f\|_1<\epsilon$.

Now let us focus on a general $f\in L_1(G,d\mu_{\rm H})$ and consider an arbitrary $k\in C(G)$. Then we expand

$$\|\rho_t\star f - f\|_1 \leq \|\rho_t\star(f-k)-(f-k)\|_1 + \|\rho_t\star k - k\|_1. \tag{III.12}$$

Now G is a compact Hausdorff space and $\mu_{\rm H}$ is a Borel measure on G so that $C(G)$ is dense in $L_1(G,d\mu_{\rm H})$.[27] We can therefore find a k such that $\|f-k\|_1<\epsilon/4$ and therefore $\|\rho_t\star(f-k)-(f-k)\|\leq 2\|f-k\|_1\|\rho_t\|_1\leq\epsilon/2$ for any $t>0$ while we have shown above that for any given $k\in C(G)$ we can always choose t sufficiently small such that $\|\rho_t\star k - k\|_1<\epsilon/2$.

This furnishes the proof. □

The theorem can obviously be extended to functions of more than one variable. This will enable us to define the finite-dimensional joint distributions of a measure.

B. Computation of the finite joint distributions of a measure

Recall[28] that every representation of a compact group is equivalent to a unitary one, so that we may restrict ourselves to unitary representations in the sequel. Also, every such representation is completely reducible. In what follows we will assume that we have fixed, in each equivalence class of irreducible representations that arise in the decomposition into irreducibles of a tensor product of irreducible representations (the ones that were fixed in Definition 3.1), a standard base

of independent representations that project onto orthogonal representation spaces. For the case of SU(2) this is the familiar Clebsh–Gordan decomposition and for SU(n) this can be established, for instance, by choosing the representations associated with the standard tableaux of the corresponding Young diagrams.[28] For the general case of a compact group we assume to have made a similar choice.

First we introduce a new notion.

Definition III.3: (i) A loop network is a triple $(\gamma, \boldsymbol{\pi}, \pi)$ *consisting of a graph* γ, *a vector* $\boldsymbol{\pi}=(\pi_1,\ldots,\pi_{n(\gamma)})$ *of irreducible representations of* G *and an irreducible representation* π *of* G *that takes values in the set of irreducible representations of* G *contained in the decomposition into irreducibles of the tensor product* $\otimes_{k=1}^{n}\pi_k$.

(ii) A loop network state is a map from $\overline{\mathcal{A}/\mathcal{G}}$ *into* $\mathbb{C}$ *defined by*

$$T_{\gamma,\boldsymbol{\pi},\pi}(A):=\mathrm{tr}[\otimes_{k=1}^{n(\gamma)}\pi_k(h_{\beta_k(\gamma)}(A))\cdot c(\boldsymbol{\pi},\pi)], \tag{III.13}$$

where the matrix c *is defined by*

$$c(\boldsymbol{\pi},\pi):=\sqrt{\frac{\Pi_{k=1}^{n(\gamma)}d_{\pi_k}}{d_\pi}}\,\pi(1). \tag{III.14}$$

Loop-network states satisfy the following important properties.

Lemma III.1: (i) Given a graph γ, *the set of all loop network states provides an orthonormal basis of* $L_2(\overline{\mathcal{A}/\mathcal{G}}_\gamma, d\mu_{0,\gamma})=L_2(\overline{\mathcal{A}/\mathcal{G}}, d\mu_0)\cap Cyl_\gamma(\overline{\mathcal{A}/\mathcal{G}})$.

(ii) Given a graph γ', *consider all its subgraphs* $\gamma<\gamma'$. *Remove all the loop-network states on* γ' *that are pull-backs of loop-network states on* γ. *The collection of all loop-network states so obtained provides an orthonormal basis of* $L_2(\overline{\mathcal{A}/\mathcal{G}}, d\mu_0)$.

Proof: (i) The orthogonality relations for loop-network states on a given graph γ follow easily from basic group integration theory. By the Peter and Weyl theorem we have

$$\langle T_{\gamma,\boldsymbol{\pi},\pi}, T_{\gamma,\boldsymbol{\pi}',\pi'}\rangle=\overline{c(\boldsymbol{\pi},\pi)}^{(i_1,j_1),\ldots,(i_n,j_n)}c(\boldsymbol{\pi}',\pi')^{(k_1,l_1),\ldots,(k_n,l_n)}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\,\frac{1}{\Pi_{k=1}^{n}d_{\pi_k}}\,\delta_{i_1,k_1}\delta_{j_1,l_1}$$

$$\cdot\,\delta_{i_n,k_n}\delta_{j_n,l_n}=\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\,\frac{1}{\sqrt{d_\pi d_{\pi'}}}\,\mathrm{tr}[\pi^\dagger(1)\pi'(1)]=\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\delta_{\pi,\pi'}, \tag{III.15}$$

where we have used that the nonequivalent irreducible—as well as our choice of equivalent—representations of a compact gauge groups are orthogonal, that is, $\pi(1)$ is a projector. The completeness of these states on $L_2(\overline{\mathcal{A}/\mathcal{G}}_\gamma, d\mu_{0,\gamma})$ follows also from the Peter and Weyl theorem together with a gauge-invariance argument. We know that the states

$$T_{\gamma,\boldsymbol{\pi}}^{(i_1,j_1)..(i_n,j_n)}:=[\otimes_{k=1}^{n}\pi_k(h_{\beta_k(\gamma)}(A))]^{(i_1,j_1),\ldots(i_n,j_n)}, \tag{III.16}$$

contain an overcomplete set of states for $L_2(\overline{\mathcal{A}/\mathcal{G}}_\gamma, d\mu_{0,\gamma})$, and thus we only need to select all the independent gauge-invariant combinations of those, that is, we need to find all the matrices c, called contractors, which turn (III.16) into gauge invariant states when being contracted with them. Notice that all the generators β are based loops. Therefore under a gauge transformation,

$$\mathrm{tr}(T_{\gamma,\boldsymbol{\pi}}\cdot c)\to\mathrm{tr}[T_{\gamma,\boldsymbol{\pi}}\cdot(\otimes_{k=1}^{n}\pi_k)(g^{-1})\cdot c\cdot(\otimes_{k=1}^{n}\pi_k)(g)], \tag{III.17}$$

and gauge invariance requires choosing c such that

$$(\otimes_{k=1}^{n}\pi_k)(g^{-1})\cdot c\cdot(\otimes_{k=1}^{n}\pi_k)(g)=c \quad \text{for all } g\in G. \tag{III.18}$$

Now notice that the matrix c in (III.17) is already projected on the reducible representation space defined by the tensor product representation $\otimes_{k=1}^{n}\pi_k$ because the matrix $(\otimes_{k=1}^{n}\pi_k)(1)$ is a projector on that space and leaves the matrix $T_{\gamma\boldsymbol{\pi}}$ in (III.16) invariant under multiplication from both sides. It follows that we can expand

$$c=\sum_{\pi\in\otimes_{k=1}^{n}\pi_k} c_\pi, \tag{III.19}$$

where the sum is over the irreducibles contained in the decomposition of $\otimes_{k=1}^{n}\pi_k$ into irreducibles and the matrix c_π is projected onto the representation space labeled by π, namely, $\pi(1)c_\pi = c_\pi\pi(1)=c_\pi$. Let us also decompose

$$(\otimes_{k=1}^{n}\pi_k(g))=\sum_{\pi\in\otimes_{k=1}^{n}\pi_k}\pi(g). \tag{III.20}$$

We now plug (III.19) and (III.20) into (III.18) and obtain

$$\sum_{\pi\in\otimes_{k=1}^{n}\pi_k}\pi(g)c_\pi\pi(g)^{-1}=\sum_{\pi\in\otimes_{k=1}^{n}\pi_k}c_\pi, \tag{III.21}$$

which we multiply by $\pi(1)$ to obtain

$$\pi(g)c_\pi\pi(g)^{-1}=c_\pi, \tag{III.22}$$

that is, c_π commutes with the representation and therefore must be proportional to $\pi(1)$ by the lemma of Schur.

(ii) It follows immediately from (i) that the union of all the loop-network states for all the graphs γ is an overcomplete (uncountable) set of states on $L_2(\overline{\mathcal{A}/\mathcal{G}},d\mu_0)$ (the graphs label cylindrical functions that are dense in $L_2(\overline{\mathcal{A}/\mathcal{G}},d\mu_0)$; compare also Ref. 24). The redundant states are eliminated by the recipe stated in the lemma. In particular, then all the representations involved in $\boldsymbol{\pi}$ are required to be nontrivial (except for the empty graph) since any loop network with trivial representations can be realized already on a smaller graph.

It remains to show that then two loop-network states that are defined on different graphs are orthogonal. But this is trivial because for two graphs $\gamma\neq\gamma'$ there is at least one generator β in which they differ and the representation π associated with that generator is nontrivial. Therefore the inner product between these loop-network states will contain the integral $\int d\mu_{\mathrm{H}}(g)\pi(g)=0$. Therefore we get altogether,

$$\langle T_{\gamma,\boldsymbol{\pi},\pi},T_{\gamma',\boldsymbol{\pi}',\pi'}\rangle=\delta_{\gamma,\gamma'}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\delta_{\pi,\pi'}. \tag{III.23}$$

Remark: More concretely, the redundant states can be removed by imposing the following constraints on the vector $\boldsymbol{\pi}$: given an edge e of γ (that is, a maximally analytic piece of γ) determine the generators, say $\beta_1,\ldots,\beta_k$, that contain e. If β_i is cloured with the representation π_i then require that the tensor product $\pi_1\otimes\ldots\otimes\pi_k$ does not contain any trivial representation, otherwise the loop-network state would contain a piece defined on a smaller graph.

This restriction leads to the definition of edge-network states (compare the Appendix).

The next thing to do is to define the Fourier transform of a measure on $\overline{\mathcal{A}/\mathcal{G}}$.

Definition III.4: The loop transform (Fourier transform, characteristic functional) of a measure μ on $\overline{\mathcal{A}/\mathcal{G}}$ is defined by

$$\chi_\mu(\gamma,\boldsymbol{\pi},\pi):=\langle\overline{T}_{\gamma,\boldsymbol{\pi},\pi}\rangle:=\int_{\overline{\mathcal{A}/\mathcal{G}}}d\mu(A)\overline{T}_{\mu,\boldsymbol{\pi},\pi}(A). \tag{III.24}$$

This definition differs from the one given in Refs. 5 and 19, however, both definitions are equivalent in the sense that they allow for a reconstruction of μ according to the Riesz–Markov theorem.[27] Namely, the former definition is based on the vacuum expectation value of products of Wilson loop functionals, and according to Refs. 5 and 2, these functions are an overcomplete set of functions on $\overline{\mathcal{A}/\mathcal{G}}$ (that is, they are subject to Mandelstam identities) so that we can reexpress them in terms of loop networks and vice versa.

Now let be given a functional χ on loop networks. Provided it is positive (note that there are no Mandelstam relations between loop-network states anymore and that the product of loop-

network states is a linear combination of loop-network states), we know by the Riesz–Markov theorem that there is a measure μ whose Fourier transform is given by χ. This measure will be known if we know its finite joint distributions that automatically form a self-consistent system of measures whose projective limit (known to exist) gives us back μ. We now compute these joint distributions.

Lemma III.2: If the Fourier transform of a (complex) regular Borel measure μ on a compact gauge group G is in ℓ_1, then it is absolutely continuous with respect to the Haar measure on G.

Proof: Given the Fourier coefficients χ_π^{ij} of the measure μ the Fourier series $\hat{\chi}$ associated with these coefficients is an $L_1(G,d\mu_{\rm H})$ function due to the anticipated ℓ_1 property of the Fourier coefficients. Moreover, the measure $d\hat{\mu}(g):=\hat{\chi}(g)d\mu_{\rm H}(g)$ has the same Fourier transform as μ. Since the functions defined by finite linear combinations of the functions $\sqrt{d_\pi}\pi_{ij}$ form a dense set in $C(G)$, G being a compact Hausdorff group, it follows that both measures define the same bounded linear functional. Now we infer from the uniqueness part of the Riesz–Markov theorem that indeed $\mu=\hat{\mu}$ from which absolute continuity follows. If μ is even a positive measure then $\hat{\chi}$ is positive.

The theorem can obviously extended to any finite number of variables. □

Theorem III.3: *Let χ be a positive linear functional on $C(\overline{\mathcal{A}/\mathcal{G}})$. Then χ is the loop transform of a positive regular Borel measure μ on $\overline{\mathcal{A}/\mathcal{G}}$. If for a given graph γ with n generators the sequence $\{\chi(\gamma,\boldsymbol{\pi},\pi)\sqrt{d_\pi\Pi_{k=1}^n d_{\pi_k}}\}$ is in ℓ_1, then the finite joint distributions of μ_γ are [in the sense of $L_1(\overline{\mathcal{A}/\mathcal{G}}_\gamma,\mu_{0,\gamma})$] given by*

$$\frac{d\mu_\gamma(A)}{d\mu_{0,\gamma}(A)}=\sum_{\boldsymbol{\pi}}\sum_{\pi\in\otimes_{k=1}^n\pi_k}\chi(\gamma,\boldsymbol{\pi},\pi)T_{\gamma,\boldsymbol{\pi},\pi}(A). \tag{III.25}$$

Proof: The proof is a straightforward application of the inverse Fourier transform, Theorem 3.2. The convergence condition on the characteristic functional mentioned in the theorem together with Lemma 3.2 allows us to conclude that on cylindrical subspaces the measure μ_γ is absolutely continuous with respect to the induced Haar measure $\mu_{0,\gamma}$. Therefore there exists a positive $L_1(G^n,d^n\mu_H)$ function $\rho_\gamma(g_1,\ldots,g_n)$ such that it is the Radon–Nikodym derivative of $d\mu_\gamma$ with respect to $d\mu_{0,\gamma}$.[27] Since μ is a gauge-invariant measure, the Fourier coefficients of ρ_γ satisfy

$$(\otimes_{k=1}^n\pi_k(g^{-1}))_{(i_1,k_1)\cdots(i_n,k_n)}\rho_{\gamma,\boldsymbol{\pi}}^{(k_1,l_1)\cdots(k_n,l_n}(\otimes_{k=1}^n\pi_k(g))_{(l_1,j_1)\cdots(l_n,j_n)}=\rho_{\gamma,\boldsymbol{\pi}}^{(i_1,j_1)\cdots(i_n,j_n)}, \tag{III.26}$$

so they lie in the invariant subspace spanned by the matrices $\pi(1)$, where $\pi\in\otimes_{k=1}^n\pi_k$. Thus

$$\begin{aligned}\rho_{\gamma,\boldsymbol{\pi}}^{(i_1,j_1)..(i_n,j_n)}&=\sum_{\pi\in\otimes_{k=1}^n\pi_k}\frac{1}{d_\pi}\,\mathrm{tr}[\rho_{\gamma,\boldsymbol{\pi}}\pi(1)]\pi(1)_{(i_1,j_1),\cdots,(i_n,j_n)}(1)\\&=\sum_{\pi\in\otimes_{k=1}^n\pi_k}\frac{1}{\sqrt{d_\pi}}\,\chi(\gamma,\boldsymbol{\pi},\pi)\pi_{(i_1,j_1),\cdots,(i_n,j_n)}(1).\end{aligned} \tag{III.27}$$

Now

$$\begin{aligned}&\sum_{i_1,j_1=1}^{d_{\pi_1}}\sqrt{d_{\pi_1}}\cdots\sum_{i_n,j_n=1}^{d_{\pi_n}}\sqrt{d_{\pi_n}}|\rho_{\gamma,\boldsymbol{\pi}}^{(i_1,j_1)\cdots(i_n,j_n)}|\\&\quad\leqslant\sum_{\pi\in\otimes_{k=1}^n\pi_k}|\chi(\gamma,\boldsymbol{\pi},\pi)|\sum_{i_1,j_1=1}^{d_{\pi_n}}\cdots\sum_{i_n,j_n=1}^{d_{\pi_n}}|c(\boldsymbol{\pi},\pi)_{(i_1,j_1),\cdots,(i_n,j_n)}(1)|\\&\quad=\sum_{\pi\in\otimes_{k=1}^n\pi_k}|\chi(\gamma,\boldsymbol{\pi},\pi)|\sqrt{d_\pi\prod_{k=1}^n d_{\pi_k}}.\end{aligned} \tag{III.28}$$

Therefore the convergence condition on χ mentioned in the theorem implies that $\hat{\rho}_\gamma \in \ell_1$ and the theorem on the inverse Fourier transform tells us that in the sense of L_1,

$$\rho_\gamma(g_1,\ldots,g_n)=\sum_{\vec{\pi}} \sum_{i_1,j_1=1}^{d_{\pi_1}} \sqrt{d_{\pi_1}}\cdots \sum_{i_n,j_n=1}^{d_{\pi_n}} \sqrt{d_{\pi_n}}\rho_{\gamma,\vec{\pi}}^{(i_1,j_1)\cdots(i_n,j_n)}(\otimes_{k=1}^n \pi_k)_{(i_1,j_1)\cdots(i_n,j_n)}(g_1,\ldots,g_n)$$

$$=\sum_{\vec{\pi}} \sum_{\pi\in\otimes_{k=1}^n \pi_k} \chi(\gamma,\vec{\pi},\pi)T_{\gamma,\vec{\pi},\pi}, \tag{III.29}$$

where we used (III.27) and the definition of a loop network. This furnishes the proof. □

IV. EXAMPLES OF INVERSE LOOP TRANSFORMS

In order to determine whether a given function χ from (singular) knots into the complex numbers arises as the loop transform of a measure one has to check two things.

(1) All the identities that are satisfied by products of traces of holonomies of loops have to be satisfied (Mandelstam identities; see Ref. 2). Alternatively, it has to be true that χ can be written purely in terms of loop-network states.

(2) It is a positive linear functional on any cylindrical subspace of $C(\overline{\mathcal{A}/\mathcal{G}})$.

(a) An example of a (singular) knot function that satisfies these criteria is of course the Fourier transform of any σ-additive measure on $\overline{\mathcal{A}/\mathcal{G}}$. Let us look at the Fourier transform of the measure μ_0 that is even diffeomorphism invariant so that χ is a singular knot invariant:

$$\chi_{\mu_0}(\gamma,\vec{\pi},\pi)=\delta_{\vec{\pi},\vec{0}}\delta_{\pi,0}, \tag{IV.1}$$

where 0 denotes the trivial representation. In other words, χ is nonvanishing only on the trivial loop network 1. Therefore we find for the finite joint distribution precisely $\rho_\gamma(g_1,\ldots,g_n)=1$ according to (III.25).

(b) A second example of a singular knot invariant is given as follows.

Let K be a regular knot invariant and let $\mathrm{orb}(\alpha_0)$ be the orbit of the regular knot α_0 under the diffeomorphism group under question. Then the formal expression

$$d\mu(A):=\sum_{\alpha\in \mathrm{orb}(\alpha_0)} \overline{T_\alpha}(A)\,d\mu_0(A) \tag{IV.2}$$

is a diffeomorphism invariant measure on $\overline{\mathcal{A}/\mathcal{G}}$, where $T_\alpha=\mathrm{tr}h_\alpha$, namely its Fourier transform,

$$\chi_\mu(\gamma,\vec{\pi},\pi)=\chi_{\mathrm{orb}(\alpha_0)}(\gamma)\,\delta_{\vec{\pi},\mathrm{def}}\delta_{\pi,\mathrm{def}} \tag{IV.3}$$

(χ_S means the characteristic function of a set S) is a bounded linear functional on $C(\overline{\mathcal{A}/\mathcal{G}})$ and thus by the extension of the Riesz–Markov theorem[27] we know that it corresponds to a unique complex regular Borel measure on $\overline{\mathcal{A}/\mathcal{G}}$ that is rigorously defined. So we get a new singular knot invariant from a regular one!

(c) Now we provide an example of a Fourier transform for a nondiffeomorphism invariant measure.

In two Euclidean space–time dimensions one can choose the generators of a graph to be simple, meaning that they do not have self-intersections, and nonoverlapping, meaning that the intersection of the surfaces that any two of them enclose have zero Euclidean area.[21] Then the characteristic functional (in the continuum) for pure Yang–Mills theory on the Euclidean plane is given by

$$\chi_{\mu_{\mathrm{YM}}^{(2)}}(\gamma,\vec{\pi},\pi)=\exp\left(-\frac{g_0^2}{2}\sum_{k=1}^n \lambda_{\pi_k}\mathrm{Ar}(\beta_k)\right)\sqrt{d_\pi\prod_{k=1}^n d_{\pi_k}}, \tag{IV.4}$$

where g_0 is the bare coupling constant, $-\lambda_\sigma$ is the eigenvalue of the Casimir operator on the matrix element functions $\sigma_{ij}(g)$ for an irreducible representation σ, and $\mathrm{Ar}(\alpha)$ is the area of the surface enclosed by a simple loop α.

Let us compute, for instance, the one-dimensional joint distributions. We find from (III.25) (if $\boldsymbol{\pi}$ is one dimensional then of course also $\pi=\boldsymbol{\pi}$ is the only possible choice),

$$\rho_{\gamma=\beta}(g)=\sum_{\pi} d_\pi \exp\left(-\frac{g_0^2}{2}\mathrm{Ar}(\beta)\lambda_\pi\right)\chi_\pi(g), \tag{IV.5}$$

therefore $\rho_{\gamma=\beta}(g)=\rho_{g_0^2\mathrm{Ar}(\beta)}(g)$, where, as before, ρ_t is the heat kernel on G.

(d) In the literature it has been argued[29] that the exponential of the Chern–Simons action S is a (formal) solution to all constraints of canonical quantum gravity in four space–time dimensions with nonzero cosmological constant λ in the connection representation. Rigorously speaking, this could only be true for Euclidean gravity: for Lorentzian gravity it could at most be a rigorous solution in the complex Ashtekar representation, however, no Hilbert space has so far been defined for this theory. We will therefore understand in the sequel that this claim was made for the Euclidean signature only for which the gauge group is SU(2).

However, even for the Euclidean theory there is an immediate problem: the Chern–Simons action is not invariant under all, possibly nonsmooth (as required on $\overline{\mathcal{A}/\mathcal{G}}$) gauge transformations, and so it cannot even be written as a measurable function on $\overline{\mathcal{A}/\mathcal{G}}$. Thus, it is not an element of the Hilbert space and, even worse, not even an element of $L_1(\overline{\mathcal{A}/\mathcal{G}},d\mu_0)$ and so one cannot compute its Fourier transform with respect to $d\mu_0$. On the other hand, what one has tried to do in the literature is the following (see Ref. 30 and references therein): If one pretends that there is an infinite-dimensional Lebesgue measure ν on (some extension of) $\mathcal{A}/\mathcal{G}$ then one can just compute the integral of $e^{iS/\lambda}$ with respect to the ''measure'' $d\nu\,\mathrm{tr}(h_\alpha(A))$ and get an answer very much in the same way as perturbative calculations in quantum field theory are performed. The result is a formal series expansion of the form $e^{w(\alpha)}\sum_{n=0}^{\infty}\lambda^{-n}a_n(\alpha)$. Here, w is depends on the writhe of the loop and captures the framing dependence of the integral computed (the Chern–Simons propagator in three dimensions is too singular on intersecting loops and one introduces a regulator in the form of a framing of the loop), but the coefficients $a_n(\alpha)$ are truly diffeomorphism invariant, they are singular knot invariants, and the lowest orders were verified to be solutions to a Hamiltonian constraint in the loop representation in various contexts (see, e.g., Ref. 30 and references therein). For nonintersecting and singly retraced loops they are related to the Jones polynomial. It is therefore meaningful to ask whether the $a_n(\alpha)$ qualify as the loop transform of a measure on $\overline{\mathcal{A}/\mathcal{G}}$. The problem is that one would have to check an infinite number of Mandelstam identities that has not been done to the present and, moreover, one needs to extend the definition of a regular knot invariant to arbitrarily singular knots before a decision can be made.

(e) In Ref. 31, which was published later than Ref. 17 or the present paper on the net, the authors show that if one defines an inner product in the loop representation by requiring that spin-network states (compare the Appendix) $\tilde{T}_{\gamma,\boldsymbol{\pi},\pi}$ form an orthonormal basis then one gets the same inner product as in the connection representation. This result is, from our perspective of course, a triviality: in the loop representation a state $\tilde{f}$ is characterized completely by evaluating it on a spin-network γ, $\boldsymbol{\pi}$, π. A spin-network state in the loop representation $\tilde{T}_{\gamma,\boldsymbol{\pi},\pi}$ is then defined by $\tilde{T}_{\gamma,\boldsymbol{\pi},\pi}(\gamma',\boldsymbol{\pi}',\pi')=\delta_{\gamma,\gamma'}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\delta_{\pi,\pi'}$. However, this is precisely the inner product between the loop-network states $T_{\gamma,\boldsymbol{\pi},\pi}, T_{\gamma',\boldsymbol{\pi}',\pi'}$ in the connection representation, which, in turn, is the loop transform of the state $T_{\gamma,\boldsymbol{\pi},\pi}$. That therefore the $\tilde{T}_{\gamma,\boldsymbol{\pi},\pi}$ form an orthonormal basis in the loop representation is the statement that the loop transform (Fourier transform) is a unitary map between L_2 and l_2, which, since μ_0 is effectively a product of Haar measures on cylindrical subspaces, is merely the statement of the Peter and Weyl theorem, and so is nothing new.

APPENDIX: EDGE NETWORKS

In this appendix we show how the developments of this paper can be written in terms of edges that are more convenient to deal with if
(a) one wants to write down a complete orthonormal basis[23,24] of $L_2(\overline{\mathcal{A}/\mathcal{G}},d\mu_0)$ without having to make use of the recipe mentioned in (ii) of Lemma 3.1, and
(b) if one is interested in applications to quantum gravity, in particular, if one is to obtain the spectrum of certain area and volume operators.[32]

Again we consider an unoriented graph γ and fix an orientation for each of its edges once and for all. Note that we do not have to make a choice of edges in this case because they are defined to be the maximally analytic pieces of the given graph. Denote by E_γ and V_γ the set of edges and vertices of γ, respectively, $n_E(\gamma)$ and $n_V(\gamma)$ are the number of these edges and vertices, respectively, and, in general, we will denote edges by the symbol e and vertices by the symbol v.

Definition A1: (i) An edge network is a triple $(\gamma,\boldsymbol{\pi},\boldsymbol{\sigma})$ *consisting of a graph* γ *an edge vector of irreducible nontrivial representations* $\boldsymbol{\pi}=(\pi_1,\ldots,\pi_{n_E(\gamma)})$ *and a vertex vector of irreducible trivial representations* $\boldsymbol{\sigma}=(\sigma_1,\ldots,\sigma_{n_V(\gamma)})$. *The irreducible representation* σ_v *takes values in the set of trivial irreducible representations that are contained in the decomposition into irreducibles of* $\otimes_{e^-=v}\overline{\pi_e}\otimes_{e^+=v}\pi_e$, $e^\pm$ *being the starting or ending point of* e *(these representations are automatically orthogonal to each other). We assume that* $\boldsymbol{\pi}$ *is such that the space of possible* $\boldsymbol{\sigma}$ *is nonempty.*

(ii) An edge network state is a function from $\overline{\mathcal{A}/\mathcal{G}}$ *into the complex numbers defined by*

$$T_{\gamma,\boldsymbol{\pi},\boldsymbol{\sigma}}(A):=\mathrm{tr}[\otimes_{e\in E_\gamma}\pi_e(h_e(A))\cdot c(\gamma,\boldsymbol{\pi},\boldsymbol{\sigma})], \tag{A1}$$

where the matrix c *is defined as follows.*

There exist permutation matrices $P_\gamma^\pm$ such that

$$(P_\gamma^\pm)^{-1}\cdot\otimes_{e\in E_\gamma}\pi_e(h_e)\cdot P_\gamma^\pm=\otimes_{v\in V_\gamma}\otimes_{e^\pm=v}\pi_e(h_e); \tag{A2}$$

then

$$c(\gamma,\boldsymbol{\pi},\boldsymbol{\sigma}):=\sqrt{\prod_{e\in E_\gamma}d_{\pi_e}}P_\gamma^-\cdot\otimes_{v\in V_\gamma}c_v(\boldsymbol{\sigma})\cdot(P_\gamma^+)^{-1}, \tag{A3}$$

where the vertex contractor is given by

$$c_v(\boldsymbol{\sigma})_{ij}:=\frac{\sigma_v(1)(i_0j_0),(ij)}{\sqrt{\sigma_v(1)_{(i_0j_0),(i_0j_0)}}}, \tag{A4}$$

and where (i_0j_0) *is an arbitrary but fixed choice of index pairs such that the denominator of (A4) is nonvanishing (since* σ_v *is a trivial representation, any choice of* i_0,j_0 *leads to the same vector* c_v *up to a multiple constant). Here the index structure comes from* $[\otimes_{e^-=v}\overline{\pi_e}]\otimes[\otimes_{e^+=v}\pi_e]_{(ij),(i_0j_0)}$.

The composition of loops can result in a loop that is defined already on a smaller graph. This is the source of the redundancy mentioned in Lemma 3.1. Something similar cannot happen with edges whence there is no redundancy in the definition of edge networks.

In the special case of $G=\mathrm{SU}(2)$ the notion of edge networks coincides with the notion of spin networks.[23,24] In this case the vertex contractors can easily be seen to be the usual Clebsh–Gordan coefficients $c_v=\langle 0,\{(j_v,l_v)\}\rangle$ for the addition of all the angular momenta corresponding to the irreducible representations with which the edges starting and ending at v are colored. Note that our analytical expression (A1) for an edge-network state does not need any graphical visualization and no preferred role is played by trivalent graphs.[23]

Theorem A1: *The set of all edge networks provides for a complete orthonormal basis of* $L_2(\overline{\mathcal{A}/\mathcal{G}},d\mu_0)$.

Proof: (1) Orthonormality: Note that $P_\gamma^T=P_\gamma^\dagger=P_\gamma^{-1}$ for any permutation matrix P_γ, which merely reshuffles the order of the factors in the tensor product $\otimes_{e\in E_\gamma}\pi_e$. Therefore

$$\begin{aligned}\langle T_{\gamma,\boldsymbol{\pi},\boldsymbol{\sigma}}, T_{\gamma',\boldsymbol{\pi}',\boldsymbol{\sigma}'}\rangle &= \delta_{\gamma,\gamma'}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\ \mathrm{tr}[c(\gamma,\boldsymbol{\pi},\boldsymbol{\sigma})^\dagger c(\gamma,\boldsymbol{\pi},\boldsymbol{\sigma})]\\ &= \delta_{\gamma,\gamma'}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\ \mathrm{tr}[((P^-_\gamma\cdot\otimes_{v\in V_\gamma}c_v(\boldsymbol{\sigma})\cdot(P^+_\gamma)^{-1})^\dagger\times P^-_\gamma\cdot\otimes_{v\in V_\gamma}c_v(\boldsymbol{\sigma}')\cdot(P^+_\gamma)^{-1})]\\ &= \delta_{\gamma,\gamma'}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\ \mathrm{tr}[\otimes_{v\in V_\gamma}(c_v(\boldsymbol{\sigma}))^\dagger c_v(\boldsymbol{\sigma}')]\\ &= \delta_{\gamma,\gamma'}\delta_{\boldsymbol{\pi},\boldsymbol{\pi}'}\delta_{\boldsymbol{\sigma},\boldsymbol{\sigma}'},\end{aligned} \tag{A5}$$

we have orthonormality. We have used that two different graphs differ in at least one edge which carries a nontrivial irreducible representation and therefore the integral (A5) with respect to the Haar measure vanishes as well as the reality and symmetry of the projectors $\pi(1)$ for any irreducible representation π.

(2) Completeness: As in (III.16) we start from the observation that the states

$$(T_{\gamma,\boldsymbol{\pi}})_{(i_1j_1)\cdots(i_{n(E_\gamma)}j_{n(E_\gamma)})} = (\otimes_{e\in E_\gamma}\pi_e(h_e))_{(i_1j_1)\cdots(i_{n(E_\gamma)}j_{n(E_\gamma)})} \tag{A6}$$

contain a complete set of states for $L_2(\overline{\mathscr{A}/\mathscr{G}}_\gamma, d\mu_{0,\gamma})$ so that we only need to contract (A6) in all the possible gauge-invariant ways. Making use of (A2), we see that under a gauge transformation g_v at every vertex v, we have

$$\mathrm{tr}[T_{\gamma,\boldsymbol{\pi}}\cdot c]\to\mathrm{tr}[T_{\gamma,\boldsymbol{\pi}}\cdot P^-_\gamma\cdot[\otimes_v\otimes_{e^-=v}\pi_e(g_v^{-1})][(P^-_\gamma)^{-1}\cdot c\cdot P^+_\gamma]\cdot[\otimes_v\otimes_{e^+=v}\pi_e(g_v)]\cdot(P^+_\gamma)^{-1}] \tag{A7}$$

so that gauge invariance requires that

$$[\otimes_v\otimes_{e^-=v}\pi_e(g_v^{-1})]\cdot[(P^{-1}_\gamma)^{-1}\cdot c\cdot P^+_\gamma][\otimes_v\otimes_{e^+=v}\pi_e(g_v)] = [(P^{-1}_\gamma)^{-1}\cdot c\cdot P^+_\gamma]. \tag{A8}$$

Without loss of generality we write $c = P^-_\gamma\cdot\Sigma_{i=1}^n\otimes_v s_v^{(i)}\cdot(P^+_\gamma)^{-1}$ for some n and arrive at

$$\sum_i\otimes_v s_v^{(i)} = \sum_i\otimes_v[\otimes_{e^-=v}\pi_e(g_v^{-1})]\cdot s_v^{(i)}\cdot[\otimes_{e^+=v}\pi_e(g_v)], \tag{A9}$$

which we can write more conveniently as the eigenvalue equation,

$$\sum_i\otimes_v s_v^{(i)} = \left[\sum_i\otimes_v s_v^{(i)}\right]\cdot[\otimes_v\nu_v(g_v)], \tag{A10}$$

where we have abbreviated

$$\nu_v(g_v) = [\otimes_{e^-=v}\overline{\pi_e}\otimes_{e^+=v}\pi_e](g_v). \tag{A11}$$

Since $\nu_v(1)$ is a projector, it follows that the eigenvector on the lhs of (A10) lies in the (reducible) subspace corresponding to $\otimes_v\nu_v$, that is, each $s_v^{(i)}$ lies in the (reducible) subspace corresponding to ν_v.

We now ask for the possible solutions x of the equation $x[\otimes_v\nu_v(g_v)] = x$, $\forall(g_v)_{v\in V_\gamma}\in G^{n(V_\gamma)}$. Setting $g_{v'}=1$ for all $v'\in V_\gamma$ except for one, v, say, shows that x has to project onto one of the trivial representations σ_v contained in ν_v. Therefore x has the general form $\Sigma_{\boldsymbol{\sigma}\in\boldsymbol{\nu}=\text{trivial}}\,k_{\boldsymbol{\sigma}}\otimes_v c_v(\boldsymbol{\sigma})$ for some complex numbers $k_{\boldsymbol{\sigma}}$, which is precisely of the form (A4). Since the space of vectors spanned by the matrix elements of the trivial representation is one-dimensional the choice made in (A4) means no loss of generality. This proves completeness. □

It is straightforward to see how the inverse loop transform theorem can be translated into an ''inverse edge transform'' theorem.

[S0022-2488(98)01502-3]

Due to the author's inaccuracy, there are misprints in Eqs. (8), (19), and (25), where $|C|^2$ should be replaced by $\rho|C|^2$. The same should be done in the expression for ν after Eq. (4). The second term in the expression for w after Eq. (7) should read $2\rho\gamma|C|^2$. Equation (26) takes the form $\sigma=0$ which should also be inserted into Eqs. (27) and (28).

We extend ideas developed for the loop representation of quantum gravity to diffeomorphism-invariant gauge theories coupled to fermions. Let $P \to \Sigma$ be a principal G-bundle over space and let F be a vector bundle associated to P whose fiber is a sum of continuous unitary irreducible representations of the compact connected gauge group G, each representation appearing together with its dual. We consider theories whose classical configuration space is $\mathcal{A}\times\mathcal{F}$, where $\mathcal{A}$ is the space of connections on P and $\mathcal{F}$ is the space of sections of F, regarded as a collection of Grassmann-valued fermionic fields. We construct the ''quantum configuration space'' $\overline{\mathcal{A}}\times\overline{\mathcal{F}}$ as a completion of $\mathcal{A}\times\mathcal{F}$. Using this, we construct a Hilbert space $L^2(\overline{\mathcal{A}}\times\overline{\mathcal{F}})$ for the quantum theory on which all automorphisms of P act as unitary operators, and determine an explicit ''spin network basis'' of the subspace $L^2((\overline{\mathcal{A}}\times\overline{\mathcal{F}})/\overline{\mathcal{G}})$ consisting of gauge-invariant states. We represent observables constructed from holonomies of the connection along paths together with fermionic fields and their conjugate momenta as operators on $L^2((\overline{\mathcal{A}}\times\overline{\mathcal{F}})/\overline{\mathcal{G}})$. We also construct a Hilbert space $\mathcal{H}_{\mathrm{diff}}$ of diffeomorphism-invariant states using the group averaging procedure of Ashtekar, Lewandowski, Marolf, Mourão and Thiemann. © *1998 American Institute of Physics.* [S0022-2488(98)01403-0]

I. INTRODUCTION

In this paper we address the problem of the quantization of a wide class of diffeomorphism-invariant theories. We consider theories whose degrees of freedom are described in the Hamiltonian framework by a connection on some principal G-bundle on space together with a set of fermionic fields on space taking values in representations of the compact connected gauge group G. Theories of this class can be thought of as giving a diffeomorphism-invariant description of fermionic matter interacting by means of gauge fields. One of the main motivations for considering such theories is that general relativity can be reformulated as a diffeomorphism-invariant theory having as canonically conjugate variables a connection on space and a densitized triad field.[1] This means that the gravitational force coupled to Yang-Mills gauge fields and fermionic matter fits into our framework.

Our approach builds upon existing work on the loop representation of quantum gravity and other diffeomorphism-invariant theories of connections.[2] The loop quantization of theories of connections is based on an assumption that Wilson loop functionals of connection become well-defined quantum operators. Similarly, our approach is based on an assumption that certain fermionic analogs of Wilson observables become well-defined operators. An important feature of our scheme is that we do not introduce closed Wilson loops as fundamental observables, as typical in the loop representation of a pure gauge theory. Instead, we use open Wilson paths with fermions or their conjugate momenta at the endpoints, which we call ''fermionic path observables.'' Closed loops arise as secondary quantities.

The basic strategy of the paper can be summarized as follows. We introduce a set of path observables on the classical phase space of our theory that forms a closed algebra with respect to Poisson brackets. The main idea then is to construct a ''kinematical'' Hilbert space for the theory and represent our algebra by operators on this Hilbert space. This is not the space of physical states, because the constraints—gauge-invariance, spatial diffeomorphism-invariance, and the Hamiltonian constraint—have not yet been implemented. The quantization procedure we adopt satisfies some natural requirements; for example, gauge-invariant classical quantities become operators that preserve the gauge-invariant subspace of the kinematical Hilbert space, ''real'' quantities become self-adjoint operators, and so on. It turns out, however, that representation of our algebra is, in general, reducible even on the subspace of gauge-invariant states.

An important issue in quantizing diffeomorphism-invariant gauge theories coupled to fermions is that of respecting the classical reality conditions on the quantum level. In field theories on Minkowski spacetime the operator † of Hermitian conjugation of fermionic fields sends configuration fermionic fields into their canonically conjugate momenta. However, in diffeomorphism-invariant theories the † operation is more complicated. Consider, for example, a theory in which the only gauge field is the gravitational field, described by the connection field A_a canonically conjugate to the densitized triad field.[1] The configuration and momentum fermionic fields (that we shall denote here by ξ and $\tilde{\pi}$, respectively) have different density weights, and the action of † operator involves the square root of the determinant of the metric:

$$\tilde{\pi}^{\dagger} = -i\sigma\xi. \tag{1}$$

Here σ is the square root of the determinant of the metric, defined in terms of the densitized triad field.

In the quantum theory, one wants to impose this ''reality condition'' in an appropriate form. However, the following difficulties may arise. In general relativity the triad field is a dynamical variable. In the quantum theory, therefore, the quantity σ constructed from the triad field becomes an operator. One might require that the adjoint of the operator $\hat{\tilde{\pi}}$ corresponding to the fermionic momentum be given by

$$(\hat{\tilde{\pi}})^{\dagger} = -i\hat{\sigma}\hat{\xi}.$$

Let us now consider the commutator

$$\left[\int d^n x \hat{\tilde{\pi}}(x) f(x), \int d^n x \ \mathrm{Tr}(\hat{A}_a(x) g^a(x))\right]$$

of operators $\hat{\tilde{\pi}}$ and $\hat{A}_a$ smeared with test functions. This commutator should vanish, since the corresponding Poisson bracket is zero in the classical theory. However, if one assumes that the connection A_a is real, and applies the † operation to this commutator, one obtains

$$\left[\int d^n x(-i\hat{\sigma})\hat{\xi}(x), \int d^n x \ \mathrm{Tr}(\hat{A}_a(x) g^a(x))\right]$$

which appears to be nonzero, since the operator $\hat{\sigma}$ does not commute with $\hat{A}_a$. This inconsistency, however, may not arise if one does not assumes the connection to be real. In fact, it is known[3] that in the case when fermionic fields are coupled to the self-dual gravity the connection must be complex, and its real and imaginary parts depend on the fermionic fields. Unfortunately, the functional analysis required to quantize theories of complex connections is not fully developed.

The strategy we adopt in this paper for dealing with the issue of reality conditions is as follows. We assume that the theories of interest can be cast into a form in which the connection becomes real by an appropriate canonical transformation, as it happens, for instance, in the case of pure gravity.[4] After this is achieved, no non-trivial reality conditions on the connection should be imposed in the quantum theory. We then impose the fermionic reality conditions by requiring that classical real quantities are represented by self-adjoint operators at the quantum level. One has a satisfactory quantum theory if a sufficient number of physically interesting real observables are

represented by self-adjoint operators. The quantization scheme adopted in this paper respects the classical reality conditions in the sense that a certain set of real observables is represented by self-adjoint operators. Note, however, that in this paper only a rather small set of real observables is treated. For instance, the quantization of the Hamiltonian constraint, which is itself a real functional on the phase space of the theory (in its ''real'' formulation used in Ref. 5), is not considered in this paper.

Note that our way of dealing with the reality conditions (1) does not allow us to prove that the inner product we construct is selected by these reality conditions. Indeed, we treat only a rather small set of real observables, while to prove that the inner product is selected by the classical reality conditions one has to show that a sufficiently large set of real observables become self-adjoint operators.

The organization of this paper is as follows. In Sec. II we start by reviewing the main results of the loop representation approach to quantizing diffeomorphism-invariant theories of connections. In Sec. III we specify the class of theories which are of interest to us here and give some examples of theories belonging to this class. In Sec. IV we describe the path observables which are the basic building blocks of our quantum theory. In Sec. V we describe the classical configuration space and a certain completion of it which we call the ''quantum configuration space.'' We then construct the kinematical Hilbert space as a space of functions on the quantum configuration space. In Sec. VI we construct the Hilbert space of gauge-invariant states, and describe a basis of this space given by ''open spin networks'' with ends labelled by fermionic fields. In Sec. VII we define operators representing the path observables. The issue of diffeomorphism-invariant states is discussed in Sec. VIII. We conclude with a discussion of the results obtained, focusing on the issue of superselection sectors.

Despite its great importance, we do not discuss dynamics in this paper, as the correct treatment of the Hamiltonian constraint is still a matter of controversy in the loop representation of pure gravity, despite recent progress on this front.[5] After this work was completed, papers by Thiemann[6] appeared in which both kinematical and dynamical aspects of diffeomorphism-invariant theories with fermions are treated. Thiemann proposes a different strategy to deal with the fermionic reality conditions (1) on the quantum level. His work also contains a proposal for the quantum Hamiltonian constraint for theories with fermions.

II. QUANTIZATION OF DIFFEOMORPHISM-INVARIANT THEORIES OF CONNECTIONS

This section reviews the main steps of quantization of diffeomorphism-invariant theories of connections. See references 2,7,8 for more details.

In the Hamiltonian formalism, the kinematical phase space of such a theory consists of pairs $(A,\tilde{E})$ satisfying suitable regularity conditions. Here A is a connection on a principal G-bundle P over a manifold Σ which represents ''space,'' and the field $\tilde{E}$ is the canonically conjugate momentum (the tilde means that it is a densitized vector field). For technical reasons we assume that Σ is real-analytic and G is a compact connected Lie group. Actually the assumption that Σ is analytic is unnecessary;[9] much of what we do in this paper generalizes to the smooth case, but analyticity makes things a bit simpler.

The classical configuration space of our theory is the space of smooth connections on P, which we denote as $\mathscr{A}$. In the case of canonical quantization of a theory with a finite number of degrees of freedom, one normally represents quantum states by square-integrable functions on the classical configuration space. The Hilbert space of states is then constructed as the space of such functions with the inner product being defined by the usual integral over the configuration space, $\langle\psi|\phi\rangle=\int\bar{\psi}\phi d\mu$, where $d\mu$ is some measure on the configuration space. However, in the case of theories with an infinite number of degrees of freedom, which is of interest to us here, there often does not exist an appropriate measure on the classical configuration space. For example, there is no ''Lebesgue measure'' on an infinite-dimensional vector space. However, one can often complete the classical configuration space in some topology and construct a suitable measure on the resulting ''quantum configuration space.'' In field theories, this larger space usually includes distributional fields in addition to smooth fields. Also, it is common in field theories for the classical configuration space to have zero measure with respect to the measure on the quantum configuration space.

The quantum configuration space depends on a choice of functions on the classical configuration space that play the role of distinguished observables. In our case we work with (smooth) ''cylinder functions'' on $\mathscr{A}$, that is, functions depending smoothly on the holonomy of the connection A along finitely many analytic paths. In other words, Ψ is a cylinder function if it is of the form

$$\Psi(A)=\psi\left(\mathscr{P}\exp\int_{e_1}A,\ldots,\mathscr{P}\exp\int_{e_n}A\right)$$

for some analytic paths $e_1,\ldots,e_n$ in Σ and some smooth function ψ on G^n. The most well-known functions of this form are the Wilson loops, introduced as observables for quantum gravity by Rovelli and Smolin[10] in their original paper on the loop representation. Unlike the Wilson loops, the above cylinder functions are not necessarily gauge-invariant. This allows them to serve as a complete set of functions on $\mathscr{A}$.

One can complete the algebra of cylinder functions with respect to the sup norm to obtain a commutative C*-algebra Fun($\mathscr{A}$) for which the $*$-operation is just pointwise complex conjugation. The Gelfand-Naimark theorem then tells us that this C*-algebra is isomorphic to the algebra of all continuous functions on its spectrum. We take the spectrum of Fun($\mathscr{A}$) to be the quantum configuration space of our theory. We denote this space by $\overline{\mathscr{A}}$, because it contains the classical configuration space $\mathscr{A}$ as a dense subset.

Elements of the quantum configuration space are called ''generalized connections,'' and can be described as follows. First, define a ''transporter'' from the point p to the point q to be a map from P_p to P_q that commutes with the right action of G on the bundle P. If we trivialize the bundle over p and q, we can think of such a transporter simply as an element of G. A ''generalized connection'' A is a map assigning to each oriented analytic path e in Σ a parallel transporter $A_e:P_p\to P_q$, where p is the initial point of the path e and q is the final point. We require that A satisfy certain obvious consistency conditions: A should assign the same transporter to two paths that differ only by an orientation-preserving reparametrization, it should assign to the inverse of any path the inverse transporter, and it should assign to the composite of two paths the composite transporter.

An ordinary smooth connection A gives a generalized connection where the parallel transporter A_e along any path e is simply the holonomy of A along this path, so $\mathscr{A}\subseteq\overline{\mathscr{A}}$. Also, any cylinder function extends to a continuous function on $\overline{\mathscr{A}}$ by setting

$$\Psi(A)=\psi(A_{e_1},\ldots,A_{e_n})$$

for any generalized connection A. This lets us think of cylinder functions as functions on the quantum configuration space.

There is a natural measure μ_0 on $\overline{\mathscr{A}}$, which comes from Haar measure on the group G. One can show that any reasonable measure on $\overline{\mathscr{A}}$ is determined by the values of the integrals of all cylinder functions. Thus, to define the measure μ_0 we specify the values of the integrals $\int\Psi\,d\mu_0$ for all cylinder functions Ψ given as above. Such an integral is defined as the integral over the corresponding copies of the group G:

$$\int\Psi\,d\mu_0=\int\psi(g_1,\ldots,g_n)\,dg_1\cdots dg_n,$$

where dg denotes the normalized Haar measure on G. The measure μ_0 has three important properties. First, it is gauge-invariant. More precisely, note that any gauge transformation g acts on $A\in\overline{\mathscr{A}}$ to give a generalized connection A' with $A'_e=g(q)^{-1}\circ A_e\circ g(p)$, where p,q are the final and the initial point of the path e, respectively. This gives an action of the group $\mathscr{G}$ of gauge transformations of P on the space $\overline{\mathscr{A}}$, and this action preserves the measure μ_0. Second, μ_0 is diffeomorphism-invariant. More precisely, μ_0 is invariant under all automorphisms of the bundle P, not necessarily acting as the identity on the base space Σ. Third, μ_0 is strictly positive, meaning that $\int\Psi\,d\mu_0>0$ for any non-negative integrable function on $\overline{\mathscr{A}}$ except the function 0.

We define the kinematical Hilbert space $L^2(\overline{\mathscr{A}})$ to be the space of functions on $\overline{\mathscr{A}}$ that are square-integrable with respect to the measure $d\tilde{\mu}_0$. This space is not the physical state space, since it contains states that are not invariant under the ''gauge'' symmetries of our theory, that is, gauge transformations and diffeomorphisms of spacetime. One way to try to find physical states is to look for solutions of quantum constraints in $L^2(\overline{\mathscr{A}})$. In general, the solutions may not live in $L^2(\overline{\mathscr{A}})$, but in some completion thereof, but for the Gauss law constraint this problem does not occur: there is a large subspace of $L^2(\overline{\mathscr{A}})$, the ''gauge-invariant Hilbert space,'' consisting of gauge-invariant square-integrable functions on $\overline{\mathscr{A}}$. Alternatively, since the measure μ_0 is gauge-invariant, it gives rise to a well-defined measure on the space $\overline{\mathscr{A}}/\mathscr{G}$ of generalized connections modulo gauge transformations. Then we may equivalently define the gauge-invariant Hilbert space to be the space $L^2(\overline{\mathscr{A}}/\mathscr{G})$ of square-integrable functions on $\overline{\mathscr{A}}/\mathscr{G}$.

We can construct an explicit basis of $L^2(\overline{\mathscr{A}}/\mathscr{G})$ using ''spin networks.''[8,11] A spin network is a triple (γ,ρ,ι) consisting of:

(1) a graph γ analytically embedded in Σ,
(2) a labelling ρ of each edge e of γ with an irreducible representation ρ_e of G,
(3) a labelling ι of each vertex v of γ with an intertwining operator ι_v.
Here the edges of the graph γ are assumed to be unparametrized but oriented, and ι_v is an interwining operator from the tensor product of the representations corresponding to the incoming edges at the vertex v to the tensor product of the representations labelling the outgoing edges. (For more details see references 7,8. Here we allow graphs with isolated vertices, i.e., vertices that are not vertices of any edge. This is unimportant now but will be important when we come to fermions.) Without loss of generality, spin networks Γ are always assumed to satisfy a fourth non-degeneracy condition:
(4) All representations ρ_e are non-trivial and γ is a ''minimal'' graph, in the sense that it cannot be obtained from another graph γ' by subdividing edges of γ'.

The ''spin network state'' Ψ_Γ is a gauge-invariant cylinder function on $\overline{\mathscr{A}}$ constructed from the spin network Γ as follows:

$$\Psi_\Gamma(A)=[\otimes_e \rho_e(A_e)]\cdot[\otimes_v \iota_v],$$

where ''$\cdot$'' stands for contracting, at each vertex v of γ, the upper indices of the matrices corresponding to the incoming edges, the lower indices of the matrices assigned to the outgoing edges, and the corresponding indices of the intertwining operator ι_v. Being gauge invariant, such states lie in $L^2(\overline{\mathscr{A}}/\mathscr{G})$. We obtain an orthonormal basis of $L^2(\overline{\mathscr{A}}/\mathscr{G})$ if we use spin network states corresponding to all possible choices of γ and ρ and a choice of an orthonormal basis of intertwining operators ι_v for each vertex v and each choice of representations labeling incident edges.

The states in $L^2(\overline{\mathscr{A}}/\mathscr{G})$ are still not invariant under the action of diffeomorphisms of Σ. There is a natural unitary representation of Diff(Σ) on $L^2(\overline{\mathscr{A}}/\mathscr{G})$. For instance, the action of the operator $U(\phi)$ corresponding to a diffeomorphism ϕ of Σ on any spin network state is given by

$$U(\phi)\Psi_{(\gamma,\rho,\iota)}=\Psi_{(\phi\gamma,\phi\rho,\phi\iota)}.$$

Here $\phi\gamma$ is the image of the graph γ under the diffeomorphism ϕ, and $\phi\rho,\phi\iota$ are the corresponding representations and intertwining operators associated with the new graph $\phi\gamma$.

To find diffeomorphism-invariant states one has to impose the quantum diffeomorphism constraint. There are very few diffeomorphism-invariant states in $L^2(\overline{\mathscr{A}}/\mathscr{G})$, so here we have to follow the strategy of looking for solutions in some larger space. One often needs to do this when solving quantized constraint equations, and the larger space is usually chosen to be a space of linear functionals on some dense subspace of the initial Hilbert space. That is, we should choose some dense subspace $\mathscr{C}$ of the gauge-invariant Hilbert space $L^2(\overline{\mathscr{A}}/\mathscr{G})$, equip it with some topology in which it is complete, and look for solutions in the topological dual $\mathscr{C}^*$. Note that $\mathscr{C}\subset L^2(\overline{\mathscr{A}}/\mathscr{G})\subset\mathscr{C}^*$.

Since there is a simple geometrical action of diffeomorphisms on cylinder functions, it is natural to choose the subspace of gauge-invariant cylinder functions as $\mathscr{C}$. This has a natural topology in which it is complete, the inductive limit topology. To solve the diffeomorphism constraint, we then seek diffeomorphism-invariant vectors in $\mathscr{C}^*$.

We obtain these by averaging gauge-invariant cylinder functions over the action of the diffeomorphism group, following the procedure of Ashtekar, Lewan-dowski, Marolf, Mourão and Thiemann.[2] It is easiest to average a special sort of gauge-invariant cylinder function, namely, a spin network state Ψ_Γ, where $\Gamma=(\gamma,\rho,\iota)$ is some spin network. For technical reasons we assume γ is ''type I,'' i.e., that for every edge of γ there is an analytic function on Σ that vanishes only on the maximal analytic curve extending that edge. Let $S(\gamma)$ be any set of diffeomorphisms of Σ with the following property: For any graph γ' which equals $\phi\gamma$ for some $\phi\in\mathrm{Diff}(\Sigma)$, there is a unique diffeomorphism $\phi\in S(\gamma)$ with $\gamma'=\phi\gamma$. Also let $GS(\gamma)$ be the group of ''graph symmetries'' of γ, that is, the group $\mathrm{Iso}(\gamma)/\mathrm{TA}(\gamma)$, where $\mathrm{Iso}(\gamma)$ is the group of diffeomorphisms mapping γ to itself, and $\mathrm{TA}(\gamma)$ is the subgroup fixing each edge of γ. We may define an element $\overline{\Psi}_\Gamma\in\mathscr{C}^*$ by

$$\overline{\Psi}_\Gamma(\Phi)=\sum_{\phi_1\in S(\gamma)}\ \sum_{[\phi_2]\in GS(\gamma)}\langle\Psi_{(\phi_1\circ\phi_2)\Gamma}|\Phi\rangle,$$

where $\Phi\in\mathscr{C}$, and where we choose one representative ϕ_2 for each equivalence class $[\phi_2]\in GS(\gamma)$. It is easy to check that $\overline{\Psi}_\Gamma$ is diffeomorphism-invariant. More generally, suppose the cylinder function Ψ is a (possibly infinite) linear combination of such spin network states $\Sigma_\Gamma a_\Gamma\Psi_\Gamma$. Then we define $\overline{\Psi}\in\mathscr{C}^*$ by

$$\overline{\Psi}(\Phi)=\sum_\Gamma\ a_\Gamma\overline{\Psi}_\Gamma(\Phi).$$

It is easy to see that the sum converges and defines a diffeomorphism-invariant element $\overline{\Psi}\in\mathscr{C}^*$.

We may define the inner product of diffeomorphism-invariant vectors of this form by

$$\langle\overline{\Psi}|\overline{\Phi}\rangle=\overline{\Psi}(\Phi).$$

Completing the space of such vectors in this inner product we thus obtain a Hilbert space, the ''diffeomorphism-invariant Hilbert space'' $\mathscr{H}_{\mathrm{diff}}$. The diffeo-morphism-invariant spin network states $\overline{\Psi}_\Gamma$ form an orthogonal (but not orthonormal) basis of $\mathscr{H}_{\mathrm{diff}}$ as we let Γ range over a set of spin networks containing one from each diffeomorphism equivalence class (but restricting ourselves to those whose graph is type I). For any spin network Γ, the diffeomorphism-invariant state $\overline{\Psi}_\Gamma$ takes a zero value on spin networks that do not belong to the same equivalence class, and a nonzero value on spin networks from the same equivalence class.

In short, the main steps of the quantization procedure include: (i) construction of the kinematical Hilbert space of states $L^2(\overline{\mathscr{A}})$, which requires the specification of a quantum configuration space together with an appropriate measure on this space; (ii) construction of the gauge-invariant Hilbert space $L^2(\overline{\mathscr{A}}/\mathscr{G})$ (and, conveniently, an explicit basis for this space), and (iii) construction of the diffeomorphism-invariant Hilbert space $\mathscr{H}_{\mathrm{diff}}$. In what follows we generalize all these steps to the case of theories involving fermions. Finally, there is the problem of imposing the Hamiltonian constraint and the problem of finding solutions to this constraint. In this paper we do not enter into this all-important problem.

In the next section we describe the class of theories which are considered in this paper and give several examples of physically interesting theories belonging to this class. Their quantization will be discussed in the following sections.

III. THE CLASS OF THEORIES

In this paper we consider a special class of theories with fermionic degrees of freedom. Each theory belonging to this class is specified, first, by (i) a principal G-bundle $P\to\Sigma$, where the

gauge group G is a compact connected Lie group and Σ is a real-analytic manifold. We also need to specify (ii) a finite list I of irreducible continuous unitary representations of G. Each representation in I corresponds to an elementary fermion appearing in the theory. Using any representation $\rho \in I$ we may associate to P a vector bundle $P \times_G \rho$ over Σ. It will be convenient to lump these together by forming a single vector bundle

$$F = P \times_G (\oplus_{\rho \in I} \rho),$$

sections of which simultaneously describe all the fermionic fields in the theory.

From this data we can construct the classical configuration space and phase space of the theory. We have already described the classical configuration space for the gauge fields; this is the space $\overline{\mathscr{A}}$ of smooth connections on P. The corresponding classical phase space is the space of pairs $(A, \widetilde{E})$, where A is a smooth connection on P and $\widetilde{E}$ is a smooth Ad P-valued vector field of density weight 1. We denote this classical phase space as $T^*\mathscr{A}$, since we can think of $\widetilde{E}$ as a cotangent vector to $\mathscr{A}$ satisfying certain smoothness conditions. Both $\mathscr{A}$ and $T^*\mathscr{A}$ become infinite-dimensional smooth manifolds in a natural way.

Similarly, the classical configuration space for the fermionic fields is the space $\mathscr{F}$ of smooth sections of F, and the classical phase space for the fermionic fields is space of pairs consisting of a smooth section of F together with a densitized smooth section of F^* with density weight 1. We denote this classical phase space as $T^*\mathscr{F}$. Both $\mathscr{F}$ and $T^*\mathscr{F}$ become infinite-dimensional topological vector spaces in a natural way.

The classical configuration space for the whole theory is thus the product $\mathscr{A} \times \mathscr{F}$, while the classical phase space is $T^*\mathscr{A} \times T^*\mathscr{F}$. In down-to-earth terms, a point in the classical phase space is simply a list of pairs $(A, \widetilde{E}), (\xi, \widetilde{\pi}), \ldots, (\eta, \widetilde{\omega})$. Here A is the connection on P and $\widetilde{E}$ is its canonically conjugate momentum. Similarly, the fields $\xi, \ldots, \eta$ are fermionic configuration fields corresponding to the representations in I, while the fields $\widetilde{\pi}, \ldots, \omega$ are their canonically conjugate momenta.

In what follows we shall treat the fermionic fields as Grassmann-valued, in order to guarantee that the Pauli principle holds for our fermions. This amounts to treating $\mathscr{F}$ as a supermanifold with all odd coordinates.[12] Thus we define the algebra $C^\infty(\mathscr{F})$ of ''smooth functions'' on $\mathscr{F}$ to be the exterior algebra $\Lambda \mathscr{F}^*$ generated by the continuous linear functionals on $\mathscr{F}$. Note that these are not functions on $\mathscr{F}$ in the standard sense, but only in the sense of supermanifold theory. Similarly, we define the algebra $C^\infty(T^*\mathscr{F})$ of ''smooth functions'' on the fermionic classical phase space $T^*\mathscr{F}$ to be the exterior algebra generated by the continuous linear functions on $T^*\mathscr{F}$. We also define ''smooth functions'' on the configuration space and phase space of the whole theory as follows:

$$C^\infty(\mathscr{A} \times \mathscr{F}) = C^\infty(\mathscr{A}) \otimes C^\infty(\mathscr{F}),$$

$$C^\infty(T^*\mathscr{A} \times T^*\mathscr{F}) = C^\infty(T^*\mathscr{A}) \otimes C^\infty(T^*\mathscr{F}).$$

The latter algebra is the algebra of classical observables of the theory.

Theories may have the same phase space and differ only in the form of the Hamiltonian, so a theory is finally determined by (iii) the Hamiltonian. Since we shall not actually treat dynamics in this paper, we shall not be very precise about the class of allowed Hamiltonians, but we are interested in those for which the action can be written as follows:

$$S = \int dt \int d^3x (\mathrm{Tr}\ \widetilde{E}^a \mathscr{L}_t A_a + \widetilde{\pi} \mathscr{L}_t \xi + \widetilde{\omega} \mathscr{L}_t \eta + \cdots + \underset{\sim}{N} \tilde{\tilde{H}} + N^a \widetilde{H}_a + \mathrm{Tr}\ \mathbf{N} \widetilde{G}. \tag{2}$$

Here $\mathscr{L}_t$ stands for the time derivative and the quantities $\underset{\sim}{N}$, N^a, and $\mathbf{N}$ are Lagrange multipliers. The quantities $\tilde{\tilde{H}}$, $\widetilde{H}_a$, and $\widetilde{G}$ are functionals on the phase space corresponding to the Hamiltonian, diffeomorphism and Gauss law constraints. Here tildes over the momentum fields keep track of density weights: a single tilde over a symbol stands for a density of weight 1, a double tilde over a symbol stands for a density of weight 2, and a single tilde under a symbol denotes a density of weight -1.

Once the canonical variables are chosen (or in other words, once the phase space is chosen), a theory is determined solely by the Hamiltonian. The other two constraint functionals are determined by the requirement that they generate diffeomorphisms and gauge transformations on the phase space of the theory.

Let us give several examples.

a) An example of such a theory is Husain-Kuchař model with fermions.[13] In its simplest version it describes a massless SU(2) fermionic field interacting with the gravitational field, with the 4-metric being degenerate in a very special way.[14] In the canonical formulation the Lagrangian of this model is of the form (2), *without* the Hamiltonian constraint term. Thus, the only constraints in the theory are Gauss and diffeomorphism constraints. All fields in the model are real, so there are no reality conditions to deal with. Thus the quantization scheme developed in the present paper gives a complete quantization of this model.

b) Another example was considered in Ref. 15. It describes a massless fermionic field interacting with a gravitational field in four-dimensional (Riemannian) spacetime, with the gravitational field being described using a chiral spin connection. The gauge group is SU(2), and the gravitational degees of freedom are described by the SU(2) connection A_a and its canonically conjugate momentum field $\tilde{E}^a$. The only fermionic field of the theory, ξ, takes values in the spin-1/2 representation. The Hamiltonian constraint of the theory consists of two parts:

$$\tilde{\tilde{H}} = \tfrac{1}{2}\,\mathrm{Tr}(\tilde{E}^a \tilde{E}^b F_{ab}) + \tilde{E}^{aB}_A \mathscr{D}_a \xi_B \tilde{\pi}^A,$$

where the first part is the Hamiltonian of the gauge field and the second part is responsible for the dynamics of the fermionic field. Here F_{ab} is the curvature of the connection field A_a, and $\mathscr{D}_a = \partial_a + A_a$ is the covariant derivative operator. This theory is the simplest theory of matter coupled to Einstein gravity.

c) One more example is the theory describing massive fermions interacting both gravitationally and electromagnetically, which was considered in Ref. 16. The gauge group here is SU(2) $\times$U(1). The gravitational and electromagnetic degrees of freedom are described together by a SU(2)$\times$U(1) connection field A_a and canonically conjugate momentum field $\tilde{E}^a$. The fermionic degrees of freedom are described by two Grassmann-valued fields ξ, η taking values in the representations of spin 1/2 and charge ± 1. The Hamiltonian of the theory consists of the following three parts. The part generating the dynamics of the gravitational field is

$$\tilde{\tilde{H}}_{\mathrm{grav}} = \tfrac{1}{2}\,\underset{\sim}{\eta}_{abc}\,\mathrm{Tr}(\tilde{E}^a \tilde{E}^b \tilde{B}^c),$$

where the magnetic field $\tilde{B}^a$ is the dual of the curvature $F_{ab} = \underset{\sim}{\eta}_{abc}\tilde{B}^c$, $\underset{\sim}{\eta}_{abc}$ being the totally antisymmetric tensor of weight -1. The part generating the dynamics of the electromagnetic field is

$$\begin{aligned}\tilde{\tilde{H}}_{\mathrm{em}} = \tfrac{1}{32}\sigma^{-2}\,\underset{\sim}{\eta}_{abe}\underset{\sim}{\eta}_{cdf}\,\mathrm{Tr}(\tilde{E}^a\tilde{E}^c)[&\mathrm{Tr}(\tilde{E}^b\tilde{E}^d)\mathrm{Tr}(\tilde{B}^e)\mathrm{Tr}(\tilde{B}^f) - \mathrm{Tr}(\tilde{E}^b\tilde{E}^d)\mathrm{Tr}(\tilde{E}^e)\mathrm{Tr}(\tilde{E}^f)\\ &- \mathrm{Tr}(\tilde{E}^b)\mathrm{Tr}(\tilde{E}^d)\mathrm{Tr}(\tilde{B}^e)\mathrm{Tr}(\tilde{B}^f)],\end{aligned}$$

where σ is the square root of the determinant of the metric, as defined using the $\tilde{E}$ field. Finally, the part of the Hamiltonian responsible for the fermionic fields is

$$\tilde{\tilde{H}}_{\mathrm{ferm}} = [\tilde{E}^{aB}_A - \tfrac{1}{2}\,\mathrm{Tr}(\tilde{E}^a)\,\delta^B_A](\mathscr{D}_a \xi_B \tilde{\pi}^A + \mathscr{D}_a \eta^A \tilde{\omega}_B) + im[\tilde{\pi}^A \tilde{\omega}_A - (\sigma)^2 \eta^A \xi_A],$$

where m is the fermion mass.

In all the theories above particles appear in the theory with their antiparticles. Mathematically this is manifested by the fact that each irreducible representation that appears in the theory appears with its dual. However, this comes about in very different ways for the different theories above. The SU(2) theory in examples a) and b) contains only one fermionic field, but this field transforms under a representation that is isomorphic to its dual. It describes a particle that is its

own antiparticle. In example c) we have two different fermionic fields transforming under dual representations of the group $\mathrm{SU}(2)\times\mathrm{U}(1)$. This theory describes a particle that is distinct from its antiparticle.

One can see that representations must appear with their duals in order to construct a gauge-invariant mass term in the Hamiltonian, or any other gauge-invariant expression bilinear in the configuration fermionic fields. It is sensible therefore to limit our attention to theories for which each irreducible representation of G appears in the list I together with its dual. Actually, to streamline the exposition, we shall consider only the case where particles are distinct from their antiparticles. That is, we assume: (iia) the list I of representations of G is of the form $(\rho_1,\rho_1^*,\ldots,\rho_n,\rho_n^*)$. It is not difficult to extend our analysis to the case of particles that are their own antiparticles, and we mention a few of the changes that need to be made as we come to them.

Having described the class of theories which are the subject of this paper we are now ready to proceed with the quantization program. For this we need to construct fermionic path observables, which are the basic building blocks of the quantum theory.

IV. FERMIONIC PATH OBSERVABLES

We now introduce ''path observables,'' which play in our theories a role similar to that of the standard Wilson loop observables in theories of connections. We start by describing some path observables that are functions on the classical configuration space $\mathscr{A}\times\mathscr{F}$. These observables are built from the holonomy of the connection along a path in space together with fermion fields at the endpoints of this path.

Note first that given two fermionic fields ξ,η transforming under dual representations ρ and ρ^* of the gauge group, one can construct a gauge-invariant quantity from these fields using the G-invariant bilinear pairing between ρ^* and ρ. This quantity depends on the values ξ_p,η_p of these fields at a point $p\in\Sigma$ and is given simply by (ξ_p,η_p). More generally, given points p and p' and a path e from p to p', one can parallel transport ξ_p to p' along the path e using the connection A and then pair it with $\eta_{p'}$, obtaining the gauge-invariant quantity

$$(\xi_p|e|\eta_{p'})=\left(\rho\left(\mathscr{P}\exp\int_e A\right)\xi_p,\eta_{p'}\right)$$

which we call a ''configurational path observable.'' It is also helpful to have a graphical notation for a configurational path observable, in which we represent the oriented path e by a line with an arrow on it, and draw the fermionic fields ξ and γ as dots at the endpoints:

$$(\xi_p|e|\eta_{p'}) \qquad \xi \bullet\!\!\xrightarrow{\;e\;}\!\!\bullet\ \eta \tag{3}$$

We may think of the dot labelled by ξ as a particle and the the dot labelled by η as its antiparticle. Configurational path observables can be introduced for any representation in the list I together with its dual, or in other words, for any particle in the theory together with its antiparticle.

Note that the configurational path observables are even since they involve a product of two fermion fields. As a result they commute. We may also think of them as functions on the classical phase space, since they involve no momenta they all Poisson-commute. Let us now introduce the basic path observables involving fermionic momentum fields and describe the Poisson algebra these observables generate.

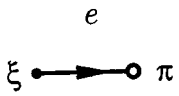
Recall that the momentum field $\tilde{\pi}$ canonically conjugate to ξ transforms under the dual representation. This means that one can apply the above construction to the $\xi,\tilde{\pi}$ fields. Namely, given two points p,p' and a path e connecting them, one can construct the quantity

$$(\xi_p|e|\tilde{\pi}_{p'})=\left(\rho\left[\mathscr{P}\exp\int_e A\right]\xi_p,\tilde{\pi}_{p'}\right),$$

which is gauge invariant and depends only on the values of fields $\xi, \widetilde{\pi}$ at the endpoints p, p' of the path e and on the holonomy of the connection field along e.

The quantity $(\xi|\gamma|\widetilde{\pi})$ is almost the one which we need. However, the Poisson bracket of this quantity with a configurational path observable $(\xi|\gamma|\eta)$ is a distribution. Following Ref. 16, let us introduce some ''averaged'' momentum observables in such a way that the Poisson bracket of a configurational path observable with a momentum observable is again a configurational path observable. In other words, let us introduce momentum observables in such a way that the resulting Poisson algebra contains no distributions. To do this we choose an arbitrary rule which specifies a path $e_{pp'}$ from p to p' given points p, p' in some region $\mathscr{R} \subset \Sigma$, an open set whose closure is compact. Having this rule at our disposal, we can integrate $(\xi|e_{pp'}|\widetilde{\pi})$ over $\mathscr{R}$ as a function of p'. We obtain the quantity

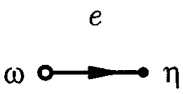
$$\int_{\mathcal{R}} d^n p' \, (\xi_p | e_{pp'} | \tilde{\pi}_{p'}) \qquad (4)$$



Here in our graphical notation we use a dot as before to stand for the fermionic configuration field, but use a little circle to represent the averaged fermionic momentum field. The result is a gauge-invariant quantity, which depends on values of the momentum field $\widetilde{\pi}$ and the connection field A over a region of the spatial manifold, on the value of ξ at the point p, and on a rule $(p, p') \mapsto e_{pp'}$.

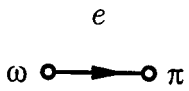
Similarly, one can introduce a quantity

$$\int_{\mathcal{R}} d^n p' \, (\tilde{\omega}_{p'} | e_{p'p} | \eta_p) \qquad (5)$$



depending on the momentum field $\widetilde{\omega}$ canonically conjugate to η (or, physically, the momentum field of the antiparticle). One can also construct quantities involving two momentum fields

$$\int_{\mathcal{R}} d^n p \int_{\mathcal{R}'} d^n p' (\tilde{\omega}_p | e_{pp'} | \tilde{\pi}_{p'}), \qquad (6)$$



Again we represent averaged momentum fields by little circles.

Note that were we to consider a theory in which ξ coincided with its antiparticle η, there would be only one path observable linear in the momentum field, instead of two different quantities (4) and (5). Some of the Poisson brackets below would be different in this case, but the necessary modifications are not difficult.

The quantities we have described so far are not invariant under the Hermitian conjugation operation ''†.'' This operation is defined when the gauge fields of our theory include gravity, and the crucial property it satisfies is given by equation (1). Let us now introduce a set of ''real'' observables, by which we mean functions on the classical phase space that are preserved by this † operation. Since Hermitian conjugation sends fermionic momentum fields into configuration fields, real observables should involve both fields. Let us introduce the following observables which are linear in the fermionic momenta

$$\int_{\mathcal{R}} d^n p \, (\xi_p, \tilde{\pi}_p), \qquad (7)$$

$$\int_{\mathcal{R}} d^n p \, (\tilde{\omega}_p, \eta_p), \qquad (8)$$

where $(\cdot,\cdot)$ is the bilinear pairing between the dual representations ρ and ρ^*. As we shall see, when quantized these observables play the role of number operators measuring the number of particles of the appropriate sort in the region $\mathscr{R}$. The graphical representation that we use for these observables is as shown above.

The quantities we have introduced form a set of functions on the phase space of the theory. Let us now describe the Poisson algebra which these quantities generate (we also give a graphical description). First, the Poisson brackets of the observables linear in the momentum (4–5) with the configurational path observables (3) are again configurational path observables. The following identities can be verified:[16]

$$\left\{ \int_{\mathscr{R}} d^n p'(\xi_p|e_{pp'}|\tilde{\pi}_{p'}),(\xi_q|f|\eta_{q'}) \right\} = (\xi_p|e_{pq}\circ f|\eta_{q'}),$$

$$\left\{ \begin{array}{ccc} & e & \\ \xi \bullet & \longrightarrow & \circ\ \pi \end{array} , \begin{array}{ccc} & f & \\ \xi \bullet & \longrightarrow & \bullet\ \eta \end{array} \right\} = \begin{array}{ccc} & e\circ f & \\ \xi \bullet & \longrightarrow & \bullet\ \eta \end{array} \tag{9}$$

$$\left\{ \int_{\mathcal{R}} d^n p'(\tilde{\omega}_{p'}|e_{p'p}|\eta_p)\ ,\ (\xi_q|f|\eta_{q'}) \right\} = (\xi_q|f\circ e_{q'p}|\eta_p).$$

$$\left\{ \begin{array}{ccc} & e & \\ \omega \circ & \longrightarrow & \bullet\ \eta \end{array} , \begin{array}{ccc} & f & \\ \xi \bullet & \longrightarrow & \bullet\ \eta \end{array} \right\} = \begin{array}{ccc} & f\circ e & \\ \xi \bullet & \longrightarrow & \bullet\ \eta \end{array} \tag{10}$$

Here we use ''$\circ$'' to denote composition of paths. Also, it is assumed in (9) that $q \in \mathscr{R}$. If the point q lies outside of the region $\mathscr{R}$ the Poisson bracket is zero. Similarly, in (10) we assume $q' \in \mathscr{R}$; otherwise the Poisson bracket is zero. Note that if the result is not zero, in both cases it is given by a configurational path observable with the path being the composite of the paths e,f compatible with their orientation.

The Poisson bracket of a momentum observable (4) with another observable of this sort gives

$$\left\{ \int_{\mathscr{R}} d^n p'(\xi_p|e_{pp'}|\tilde{\pi}_{p'}), \int_{\mathscr{R}'} d^n q'(\xi_q|f_{qq'}|\tilde{\pi}_{q'}) \right\}$$

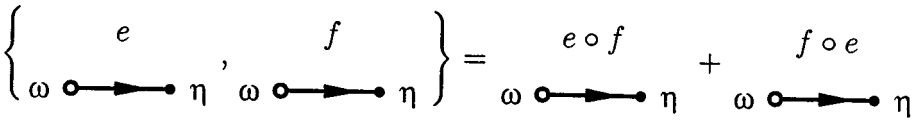
$$= \int_{\mathscr{R}'} d^n q'(\xi_p|e_{pp'}\circ f_{p'q'}|\tilde{\pi}_{q'}) + \int_{\mathscr{R}} d^n p'(\xi_q|f_{qq'}\circ e_{q'p'}|\tilde{\pi}_{p'}). \tag{11}$$

$$\left\{ \begin{array}{ccc} & e & \\ \xi \bullet & \longrightarrow & \circ\ \pi \end{array} , \begin{array}{ccc} & f & \\ \xi \bullet & \longrightarrow & \circ\ \pi \end{array} \right\} = \begin{array}{ccc} & e\circ f & \\ \xi \bullet & \longrightarrow & \circ\ \pi \end{array} + \begin{array}{ccc} & f\circ e & \\ \xi \bullet & \longrightarrow & \circ\ \pi \end{array}$$

Similarly, for (5) we get

$$\left\{ \int_{\mathscr{R}} d^n p'(\tilde{\omega}_{p'}|e_{p'p}|\eta_p), \int_{\mathscr{R}'} d^n q'(\tilde{\omega}_{q'}|f_{q'q}|\eta_q) \right\}$$

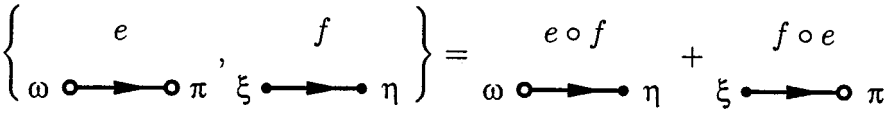
$$= \int_{\mathscr{R}} d^n p'(\tilde{\omega}_{p'}|e_{p'p}\circ f_{pq}|\eta_q) + \int_{\mathscr{R}'} d^n q'(\tilde{\omega}_{q'}|f_{q'q}\circ e_{qp}|\eta_p). \tag{12}$$



where we assume that the point where the configuration field in each of the observables is evaluated lies inside the region over which the momentum field in the other is smeared; otherwise one or both terms of the Poisson bracket vanishes.

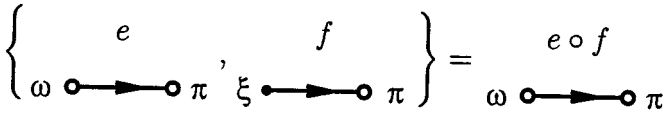
The Poisson bracket of (6) and a configuration observable also consists of two terms:

$$\left\{ \int_{\mathscr{R}} d^n p \int_{\mathscr{R}'} d^n p' (\tilde{\omega}_p | e_{pp'} | \tilde{\pi}_{p'}), (\xi_q | f | \eta_{q'}) \right\}$$
$$= \int_{\mathscr{R}} d^n p (\tilde{\omega}_p | e_{pq} \circ f | \eta_{q'}) + \int_{\mathscr{R}'} d^n p' (\xi_q | f \circ e_{q'p'} | \tilde{\pi}_{p'}). \tag{13}$$

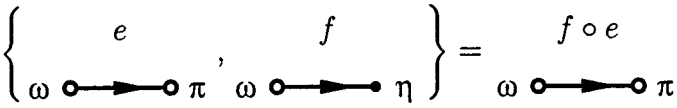


where again we assume $q \in \mathscr{R}'$ and $q' \in \mathscr{R}$. For the Poisson brackets between (6) and observables linear in momentum we have

$$\left\{ \int_{\mathscr{R}} d^n p \int_{\mathscr{R}'} d^n p' (\tilde{\omega}_p | e_{pp'} | \tilde{\pi}_{p'}), \int_{\mathscr{R}''} d^n q' (\xi_q | f_{qq'} | \tilde{\pi}_{q'}) \right\}$$
$$= \int_{\mathscr{R}} d^n p \int_{\mathscr{R}''} d^n q' (\tilde{\omega}_p | e_{pq} \circ f_{qq'} | \tilde{\pi}_{q'}), \tag{14}$$



$$\left\{ \int_{\mathscr{R}} d^n p \int_{\mathscr{R}'} d^n p' (\tilde{\omega}_p | e_{pp'} | \tilde{\pi}_{p'}), \int_{\mathscr{R}''} d^n q' (\tilde{\omega}_{q'} | f_{q'q} | \eta_q) \right\}$$
$$= \int_{\mathscr{R}''} d^n q' \int_{\mathscr{R}'} d^n p' (\tilde{\omega}_{q'} | f_{q'q} \circ e_{qp'} | \tilde{\pi}_{p'}). \tag{15}$$



where in (14) we assume $q' \in \mathscr{R}'$, and in (15) we assume $q \in \mathscr{R}$; otherwise the brackets vanish.

One can also write down Poisson brackets between (3–6) and the real quantities (7–8). For example, the Poisson brackets between configurational path observables and these real quantities

are given by

$$\left\{ \int_{\mathcal{R}} d^n p(\xi_p, \tilde{\pi}_p) \ , \ (\xi_q|e|\eta_{q'}) \right\} = (\xi_q|e|\eta_{q'}),$$

$$\left\{ \xi \circledcirc \pi \ , \ \xi \xrightarrow{e} \eta \right\} = \xi \xrightarrow{e} \eta \tag{16}$$

$$\left\{ \int_{\mathcal{R}} d^n p(\tilde{\omega}_p, \eta_p) \ , \ (\xi_q|e|\eta_{q'}) \right\} = (\xi_q|e|\eta_{q'}).$$

$$\left\{ \omega \circledcirc \eta \ , \ \xi \xrightarrow{e} \eta \right\} = \xi \xrightarrow{e} \eta \tag{17}$$

Here in (16) we assume q is contained in $\mathcal{R}$, and in (17) we assume q' is contained in $\mathcal{R}$; otherwise the Poisson brackets vanish.

A nice feature of the graphical notation is that it gives a simple mnemonic for the Poisson bracket formulas (9–17) above. Note that in every case, the terms appearing in the Poisson bracket of two of our observables correspond to the ways of attaching them together by filling little empty circles (i.e., momentum fields) of one observable with dots (i.e., configurational fields) of the other, in a manner compatible with the orientations of the paths. (In theories for which particles coincided with their antiparticles, we would not include orientation arrows on the paths in our graphical notation, and not require compatibility of orientations when attaching paths together. This would give precisely the extra terms in the Poisson bracket relations that actually appear in such theories.)

We see that the observables we have introduced are closed with respect to Poisson brackets: A Poisson bracket of any two our observables is a linear combination of these observables. Note, however, that the path observables involving fermionic momenta depend on a rule assigning to any two points $p,p' \in \Sigma$ a path $e_{pp'}$. The rules that appear on the right hand side of (9)-(15) are of the form $e_{pq} \circ f_{qq'}$, i.e., they are formed by composition from the rules we started with, so if we fix a rule we do not obtain a Poisson algebra. Instead, we work with the ''big'' algebra generated by all observables of the form (3–8), allowing all possible choices of a rule $e_{pp'}$ and all possible regions $\mathcal{R}$ (open sets whose closure is compact). We denote this algebra as $\mathcal{B}$.

We may summarize by saying that we have introduced a Poisson algebra $\mathcal{B}$ of smooth functions on the classical phase space $T^*\mathcal{A} \times T^*\mathcal{F}$. This algebra is not closed under the Hermitian conjugation operator †. However, it has a distinguished subalgebra of observables preserved by the † operation, namely the real-linear combinations of products of the observables (7–8).

Our aim now is to quantize the observables (3–8), finding operators on some Hilbert space whose commutators mimic the classical Poisson bracket relations. We proceed in several steps. We first construct a kinematical Hilbert space. Then we describe a subspace of gauge invariant states in this space, which can be thought of as a Hilbert space of solution of Gauss law constraint, and represent the observables in $\mathcal{B}$ as operators on this space.

V. QUANTUM CONFIGURATION SPACE AND KINEMATICAL HILBERT SPACE

Recall that for diffeomorphism-invariant theories of connections, the quantum configuration space was most efficiently obtained by completing the algebra of cylinder functions to obtain a commutative C*-algebra, and taking the spectrum of this C*-algebra. We would like to follow a similar strategy for our theories with fermions. However, in our case the Gelfand-Naimark theorem is not applicable because of the presence of Grassmann-valued fields. Another strategy is needed.

Recall that in the case of theories of connections, we could also describe the quantum configuration space as a certain completion of the classical configuration space. We can implement this idea in our case and construct the fermionic quantum configuration space $\overline{\mathcal{F}}$ as a completion

of the classical configuration space $\mathscr{F}$. Namely, we define $\overline{\mathscr{F}}$ to be the space of all (not necessarily smooth) sections of the vector bundle F over Σ. The space $\mathscr{F}$ is dense in $\overline{\mathscr{F}}$ in the topology of pointwise convergence.

Alternatively, one can describe $\overline{\mathscr{F}}$ as the projective limit of configuration spaces of certain fermionic systems with finitely many degrees of freedom. Namely, given any finite subset of points $V \subset \Sigma$ we may consider the configuration space of a system of fermions living at the points of V; this is the product

$$\mathscr{F}_V = \prod_{p \in V} F_p$$

of copies of fibers of F, one for each point in V. Given finite subsets $V \subseteq V'$ of points in Σ there is a natural projection from $\mathscr{F}_{V'}$ to $\mathscr{F}_V$, and the projective limit of all these spaces $\mathscr{F}_V$ is $\overline{\mathscr{F}}$.

We also wish to have a kinematical Hilbert space for the fermion fields. Although we shall denote this Hilbert space by $L^2(\overline{\mathscr{F}})$, it is not a space of square-integrable functions on $\overline{\mathscr{F}}$ in the standard sense. We use the notation $L^2(\overline{\mathscr{F}})$ just to emphasize the similarity in notations between the fermionic and the gauge fields degrees of freedom.

The space $L^2(\overline{\mathscr{F}})$ can be constructed in a variety of equivalent ways. Perhaps the easiest is to use the fact that the fibers F_p are finite-dimensional Hilbert spaces and let $L^2(\overline{\mathscr{F}})$ be the fermionic Fock space over the Hilbert space direct sum $\oplus_{p \in \Sigma} F_p$. This is the natural Hilbert space completion of the exterior algebra

$$\Lambda(\oplus_{p \in \Sigma} F_p).$$

Alternatively, we can think of $L^2(\overline{\mathscr{F}})$ as the infinite ''grounded'' tensor product

$$\otimes_{p \in \Sigma} \Lambda F_p$$

of the fermionic Fock spaces ΛF_p, one for each point p in space. (For an introduction to the mathematics of fermionic Fock spaces and infinite grounded tensor products, see Ref. 17.)

In the case of connection fields we can define the kinematical Hilbert space as a completion of an algebra of cylinder functions. An analogous fact holds for fermion fields if we define a ''cylinder function'' on $\mathscr{F}$ to be a smooth function on $\mathscr{F}$ depending only on the value of the fermion fields at finitely many points of Σ. The space of cylinder functions is thus

$$\Lambda(\oplus_{p \in \Sigma} F_p^*) \subseteq \Lambda \mathscr{F}^*,$$

the exterior algebra over the algebraic direct sum $\oplus_{p \in \Sigma} F_p^*$. Since each F_p is a Hilbert space, this space is naturally isomorphic to

$$\Lambda(\oplus_{p \in \Sigma} F_p),$$

and by the above remarks we see that it can be completed to obtain $L^2(\overline{\mathscr{F}})$.

Finally, we may also describe $L^2(\overline{\mathscr{F}})$ in the following physically appealing way. For each finite set V of points of Σ we may start with the theory of fermions living at these points. The configuration space for this theory is the finite-dimensional space $\mathscr{F}_V$ described above. Quantizing this system we obtain the fermionic Fock space over $\mathscr{F}_V$, which is just the exterior algebra $\Lambda \mathscr{F}_V$ equipped with its standard inner product. Given finite subsets $V \subset V'$ of points in Σ there is a natural projection from $\Lambda \mathscr{F}_{V'}$ to $\Lambda \mathscr{F}_V$, and the projective limit of these Hilbert spaces is the kinematical Hilbert space $L^2(\overline{\mathscr{F}})$.

Putting together the quantum configuration spaces for the gauge field and fermionic degrees of freedom, we obtain the quantum configuration space $\overline{\mathscr{A}} \times \overline{\mathscr{F}}$ for the whole theory. Similarly, the kinematical Hilbert space for the full theory is $L^2(\overline{\mathscr{A}}) \otimes L^2(\overline{\mathscr{F}})$, which we denote by $L^2(\overline{\mathscr{A}} \times \overline{\mathscr{F}})$. Note that cylinder functions on $\mathscr{A}$ are dense in $L^2(\overline{\mathscr{A}})$, and cylinder functions on $\mathscr{F}$ are

dense in $L^2(\overline{\mathscr{F}})$. Thus if we define the algebra of ''cylinder functions'' on $\mathscr{A}\times\mathscr{F}$ to be the tensor product of the algebras of cylinder functions on $\mathscr{A}$ and cylinder functions on $\mathscr{F}$, it follows immediately that cylinder functions on $\mathscr{A}\times\mathscr{F}$ are dense in $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$.

In simple terms, a cylinder function on $\mathscr{A}\times\mathscr{F}$ is a wavefunction depending on the connection only via its holonomies along finitely many paths in Σ and on the fermionic fields only via their values at finitely many points of Σ. As we shall see in the next section, cylinder functions may be thought of as states of gauge theories coupled to fermions living on graphs in Σ with finitely many edges and vertices. Cylinder functions play an important role in the quantum theory, for it is natural to define quantum operators first on the dense subspace of cylinder functions, and then to extend them to the entire Hilbert space $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$.

The Hilbert space $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$ serves only as an auxiliary Hilbert space of the theory, since its states are typically not invariant under gauge transformations, diffeomorphisms of space, or time evolution. To find physical states we must impose constraints corresponding to invariance under these symmetries. In the next section we describe a basis of solutions to the Gauss law constrant, that is, gauge-invariant elements of $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$.

VI. GAUGE-INVARIANT STATES

There is a natural unitary representation of the group $\mathscr{G}$ of smooth gauge transformations on the Hilbert space of quantum states $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$. In this section we describe the subspace of $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$ consisting of the states which are invariant under these gauge transformations. We denote this space by $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$. We also describe an orthonormal basis for $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$ that is a generalization of the spin network basis of $L^2(\overline{\mathscr{A}}/\mathscr{G})$.

Given any graph γ analytically embedded in Σ, let E be its set of edges and let V be its set of vertices. Any edge $e\in E$ begins at some vertex $s(e)$ called its ''source'' and ends at some vertex $t(e)$ called its ''target''. We define the space of connections on γ to be

$$\mathscr{A}_\gamma=\prod_{e\in E}\mathscr{A}_e,$$

where $\mathscr{A}_e$ is the space of transporters from $s(e)$ to $t(e)$. If we trivialize P at all the vertices of γ we can think of $\mathscr{A}_\gamma$ as a product of copies of the gauge group G, one for each edge. Similarly, we define the classical configuration space for fermion fields on γ to be

$$\mathscr{F}_\gamma=\prod_{p\in V}F_p.$$

We define $L^2(\mathscr{A}_\gamma)$ using normalized Haar measure on G, define $L^2(\mathscr{F}_\gamma)$ to be the fermionic Fock space over $\mathscr{F}_\gamma$, and set

$$L^2(\mathscr{A}_\gamma\times\mathscr{F}_\gamma)=L^2(\mathscr{A}_\gamma)\otimes L^2(\mathscr{F}_\gamma).$$

We may think of this as a subspace of $L^2(\overline{\mathscr{A}}\times\overline{\mathscr{F}})$.

For any graph γ there is a unitary representation of $\mathscr{G}$ on $L^2(\mathscr{A}_\gamma\times\mathscr{F}_\gamma)$, and we denote the subspace consisting of gauge-invariant elements by $L^2((\mathscr{A}_\gamma\times\mathscr{F}_\gamma)/\mathscr{G})$. As in the case of pure gauge fields,[7,8] the union of these spaces as γ ranges over all graphs is dense in $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\overline{\mathscr{G}})$. Thus to describe $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$, it suffices to describe these spaces for arbitrary graphs γ.

Trivializing P at all the vertices of γ we have

$$L^2(\mathscr{A}_\gamma\times\mathscr{F}_\gamma)=\otimes_{e\in E}L^2(G)\otimes\otimes_{v\in V}\Lambda F_v. \tag{18}$$

Let us decompose the Grassmann algebra ΛF_v at each vertex as an orthogonal direct sum of irreducible representations of G: $\Lambda F_v=\oplus_{\rho\in S}\rho$, where we have denoted by S the list of irreduc-

ible representations appearing in ΛF_v. Similarly, the Peter-Weyl theorem says that $L^2(G) \cong \oplus_{\rho \in \mathrm{Rep}(G)} \rho \otimes \rho^*$, where the set $\mathrm{Rep}(G)$ contains one irreducible continuous unitary representation of G from each equivalence class, so that (18) implies

$$L^2(\mathscr{A}_\gamma \times \mathscr{F}_\gamma) = \otimes_{e \in E}(\oplus_{\rho \in \mathrm{Rep}(G)} \rho \otimes \rho^*) \otimes \otimes_{v \in V}(\oplus_{\rho \in S} \rho). \tag{19}$$

The right hand side of (19) can be rewritten as follows:

$$L^2(\mathscr{A}_\gamma \times \mathscr{F}_\gamma) = \oplus_{\rho_e \in \mathrm{Rep}(G), \rho_v \in S} \otimes_{v \in V}((\otimes_{t(e)=v} \rho_e^* \otimes \otimes_{s(e)=v} \rho_e) \otimes \rho_v). \tag{20}$$

The sum here runs over all labellings of edges e by irreducible representations ρ_e of the group G, and by all labellings of vertices by irreducible representations from the list S. It follows that

$$L^2((\mathscr{A}_\gamma \times \mathscr{F}_\gamma)/\mathscr{G}) = \oplus_{\rho_e \in \mathrm{Rep}(G), \rho_v \in S} \otimes_v \mathrm{Inv}((\otimes_{t(e)=v} \rho_e^* \otimes \otimes_{s(e)=v} \rho_e) \otimes \rho_v), \tag{21}$$

where Inv denotes the G-invariant subspace of the given representation. Note that $\mathrm{Inv}(\otimes_{t(e)=v} \rho_e^* \otimes \otimes_{s(e)=v} \rho_e \otimes \rho_v)$ has a natural inner product, and is isomorphic to the space of intertwining operators from $\otimes_{t(e)=v} \rho_e$ to $(\otimes_{s(e)=v} \rho_e) \otimes \rho_v$. We denote this space of intertwining operators by

$$\mathrm{Hom}(\otimes_{t(e)=v} \rho_e, (\otimes_{s(e)=v} \rho_e) \otimes \rho_v).$$

As in the case of pure gauge fields, the above discussion also gives an orthonormal basis of spin network states for $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$. Unlike spin networks for theories describing only gauge fields, the spin networks for theories with fermions can contain edges with ''open ends.'' Such open ends represent fermionic degrees of freedom. We describe the spin network basis for $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$ in the following theorem summarizing the results of this section:

Theorem 1: *The space $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$ has an orthonormal basis of ''fermionic spin network states,'' each such state being specified by a choice of*:

1. *a graph γ analytically embedded in Σ,*
2. *a labelling of each edge e of γ by an irreducible representation $\rho_e \in \mathrm{Rep}(G)$,*
3. *a labelling of each vertex v of γ by an irreducible representation $\rho_v \in S$,*
4. *a labelling of each vertex v of γ by an intertwining operator*

$$\iota_v \in \mathrm{Hom}(\otimes_{t(e)=v} \rho_e, (\otimes_{s(e)=v} \rho_e) \otimes \rho_v)$$

chosen from an orthonormal basis of such intertwining operators.

We call the data $\Gamma = (\gamma, \rho, \iota)$ a ''fermionic spin network,'' and denote the fermionic spin network state corresponding to Γ as above by Ψ_Γ.

It is interesting to note the similarity between these fermionic spin networks and the extended spin networks introduced by Ashtekar and Lewandowski[18] as a basis of $L^2(\overline{\mathscr{A}})$. Note, however, that unlike extended spin networks of theories of connections, fermionic spin networks describe fermionic degrees of freedom and are gauge invariant.

VII. QUANTIZATION OF FERMIONIC PATH OBSERVABLES

We have now constructed the kinematical Hilbert space $L^2(\overline{\mathscr{A}} \times \overline{\mathscr{F}})$ as a completion of the space of cylinder functions on $\overline{\mathscr{A}} \times \overline{\mathscr{F}}$, and found a spin network basis for the gauge-invariant subspace $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$. Our construction so far has nothing directly to do with the fermionic path observables introduced in Sec. IV. Thus, we have to make sure that there is a way to quantize these observables and obtain operators on $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$. In fact, we shall obtain operators on $L^2(\overline{\mathscr{A}} \times \overline{\mathscr{F}})$ that commute with gauge transformations, and thus map $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$ to itself.

There is an obvious way to promote the configurational path observables into operators. We represent the quantities $(\xi | e | \eta)$ by multiplication operators $(\xi | \hat{e} | \eta)$ on the space of cylinder functions on $\mathscr{A} \times \mathscr{F}$ as follows:

$$(\xi|\hat{e}|\eta)\Psi = (\xi|e|\eta)\Psi, \tag{22}$$

where $(\xi|e|\eta)$ on the right hand side is considered as a cylinder function on $\mathcal{A}\times\mathcal{F}$. Note that if Ψ is a cylindrical function so is $(\xi|e|\eta)\Psi$. One has, therefore, a well-defined action of $(\xi|\hat{e}|\eta)$ on the space of cylinder functions.

The observables (4–8) involving fermionic momenta can also be first promoted to operators on the space of cylinder functions. The natural way to do this is to replace the fermionic momentum field $\tilde{\pi}$ in such observables by the corresponding Berezin derivative $\delta/\delta\xi$. Berezin derivatives[19] are usually used in the context of field theories in Minkowski spacetime. However, we can also make sense of this notion in the context of diffeomorphism-invariant theories.

We introduce Berezin derivatives as operators on the space of cylinder functions as follows. Recall that the algebra of cylinder functions on $\mathcal{F}$ is the exterior algebra

$$\Lambda(\oplus_{p\in\Sigma}F_p^*).$$

For any point p choose an orthonormal basis $\xi^\alpha(p)$ of the subspace of F_p^* corresponding to the representation $\rho\in I$ under which the field ξ transforms. Note that $\xi^\alpha(p)$ is a cylinder function on $\mathcal{F}$, and the algebra of cylinder functions on $\mathcal{F}$ is generated by functions of this form. Thus, formally speaking, we may define the Berezin derivative operator to be the superderivation (i.e., graded derivation) of the algebra of cylinder functions such that

$$\frac{\delta}{\delta\xi^\alpha(p)}\xi^\beta(p') = \delta_\alpha^\beta\tilde{\delta}^n(p,p'), \tag{23}$$

where δ_α^β is the Kroneker delta. However, the right hand side is distributional, so strictly speaking we should smear this equation with a ''test function.'' In other words, for any section f of $P\times_G\rho$, we define

$$\int_\Sigma d^n p f^\beta(p)\frac{\delta}{\delta\xi^\beta(p)}$$

to be the unique superderivation on the algebra of cylinder functions such that

$$\left(\int_\Sigma d^n p f^\beta(p)\frac{\delta}{\delta\xi^\beta(p)}\right)\xi^\alpha(p') = f^\alpha(p').$$

To describe the action of this operator on an arbitrary cylinder function, let us introduce the interior product operator $i[\xi]_\alpha(p)$, namely, the adjoint of exterior multiplication by $\xi^\alpha(p)$. We then have

$$\left(\int_\Sigma d^n p f^\beta(p)\frac{\delta}{\delta\xi^\beta(p)}\right)\Psi = \sum_{p\in\Sigma} f^\alpha(p) i[\xi]_\alpha(p)\Psi,$$

where the right hand side, for any cylinder function Ψ, contains only a finite number of non-zero terms.

Using this definition of Berezin derivative one can proceed with the quantization of observables (4–6). However, there is an operator ordering ambiguity that needs to be resolved in this procedure. Since the observables (4–6) involve both fermion fields and their canonically conjugate momenta, which do not anticommute, we must specify which acts first. Note that one of our classical quantities, namely, $\int_{\mathcal{R}} d^n p(\xi_p, \tilde{\pi}_p)$, has a natural interpretation as the number of particles of type ξ within the region $\mathcal{R}$. To obtain this number operator when we quantize, we need to choose the operator ordering in which the Berezin derivative corresponding to the momentum field $\tilde{\pi}_p$ acts before the multiplication operator corresponding to the configuration field ξ_p. Let us therefore demand that derivatives act before multiplication operators for all our observables, which amounts to a ''normal ordering'' prescription.

Following this choice of operator ordering we can now quantize all our fermionic observables, obtaining operators on the space of cylinder functions. More precisely, we define the quantum analogs of the observables (4–6) as follows:

$$\int_{\mathscr{R}} d^n p'(\xi_p|\hat{e}_{pp'}|\tilde{\pi}_{p'}) = \sum_{p' \in \mathscr{R}} \xi^\alpha(p) \left(\mathscr{P} \int_e A \right)_\alpha^\beta i[\xi]_\beta(p'), \tag{24}$$

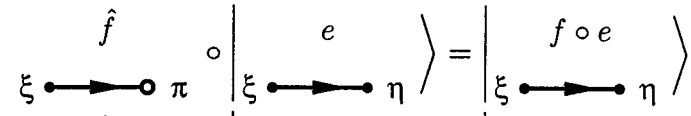
$$\int_{\mathscr{R}} d^n p'(\tilde{\omega}_{p'}|\hat{e}_{p'p}|\eta_p) = \sum_{p' \in \mathscr{R}} \eta_\alpha(p) \left(\mathscr{P} \int_e A \right)_\beta^\alpha i[\eta]^\beta(p'), \tag{25}$$

$$\int_{\mathscr{R}} d^n p \int_{\mathscr{R}'} d^n p'(\tilde{\omega}_p|\hat{e}_{pp'}|\tilde{\pi}_{p'}) = \sum_{p \in \mathscr{R}} \sum_{p' \in \mathscr{R}'} i[\eta]^\alpha(p) \left(\mathscr{P} \int_e A \right)_\alpha^\beta i[\xi]_\beta(p'), \tag{26}$$

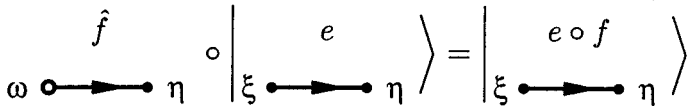
$$\int_{\mathscr{R}} d^n p(\xi_p, \tilde{\pi}_p) = \sum_{p \in \mathscr{R}} \xi^\alpha(p) i[\xi]_\alpha(p), \tag{27}$$

$$\int_{\mathscr{R}} d^n p(\tilde{\omega}_p, \eta_p) = \sum_{p \in \mathscr{R}} \eta_\alpha(p) i[\eta]^\alpha(p). \tag{28}$$

The operators (22–28) map cylinder functions to cylinder functions, and extend uniquely to bounded linear operators on $L^2(\bar{\mathscr{A}} \times \bar{\mathscr{F}})$. Since they commute with gauge transformations they may also be thought of as operators on $L^2((\bar{\mathscr{A}} \times \bar{\mathscr{F}})/\mathscr{G}$. Finite linear combinations of fermionic spin network states are dense in $L^2((\bar{\mathscr{A}} \times \bar{\mathscr{F}})/\mathscr{G})$, so the actions of these operators on $L^2((\bar{\mathscr{A}} \times \bar{\mathscr{F}})/\mathscr{G})$ are determined by their actions on fermionic spin network states. On such states the action is simply described in our graphical notation, which is very nice for explicit computations. Let us give several simple examples; generalization to arbitrary spin network states is straightforward. We consider the action of our operators on a fermionic spin network state containing a single path, that is, a cylinder function of the form $(\xi|e|\eta)$. First, the fermionic path observables linear in momentum, (25–26), act to compose the path e with a path f. That is,

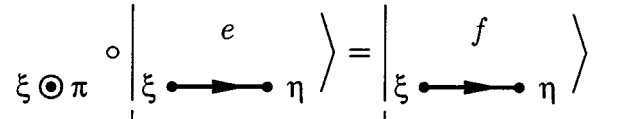


(29)

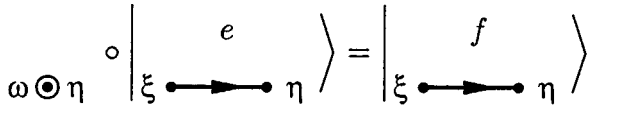


(30)

if the relevant endpoint of e lies within the region $\mathscr{R}$; otherwise we get zero. The operators (27–28) on the same state are given as follows:



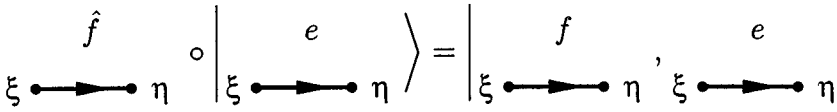
(31)



(32)

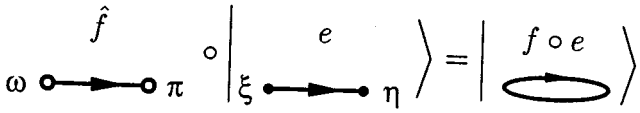
if the relevant endpoint of e lies within the region $\mathscr{R}$; otherwise we get zero. In general, these operators count the number of the fermions (resp. antifermions) in the region $\mathscr{R}$. One can easily see that all fermionic spin network states are eigenstates of these operators.

The operator corresponding to a configurational path observable acts to create a path:



(33)

The result is a spin network state containing two paths. The operator involving two momentum fields acts to close off a path:



(34)

if the endpoints of e lie within the corresponding regions of integration in the operator $\int_{\mathscr{R}} d^n p \int_{\mathscr{R}'} d^n p' (\tilde{\omega}_p | \hat{e}_{pp'} | \tilde{\pi}_{p'})$; otherwise we get zero. Note that the result here is the simple loop state so familiar from the loop representation of pure gravity.

In short, we can quantize our fermionic path observables, implementing them as operators on $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$. As usual in quantization, we do not obtain a true representation of the Poisson algebra $\mathscr{B}$, in which Poisson brackets of arbitrary observables in $\mathscr{B}$ are mapped to commutators of the corresponding operators. However, if we restore the factors of $\hbar$ which we have suppressed above, and work with $\hbar\, \delta/\delta\xi^\alpha(p)$ where above we use $\delta/\delta\xi^\alpha(p)$, we find that the commutators of operators (22–28) match the Poisson brackets of the observables (3–8) up to terms of order $\hbar^2$.

VIII. DIFFEOMORPHISM-INVARIANT STATES

The Hilbert space $L^2((\overline{\mathscr{A}} \times \overline{\mathscr{F}})/\mathscr{G})$ of gauge-invariant states is still too large to be the space of physical states of the theory. The group of diffeomorphisms $\mathrm{Diff}(\Sigma)$ acts non-trivially on the elements of $L^2((\overline{\mathscr{A}} \times \mathscr{F})/\mathscr{G})$. To find diffeomorphism-invariant states one should adopt the strategy described in Sec. II, namely the ''group averaging'' technique of Ashtekar, Lewandowski, Marolf, Mourão and Thiemann.[2] Since the details of the construction are very similar to those in the case of theories with pure connection degrees of freedom, we only sketch the main steps here.

We look for diffeomorphism-invariant elements of the space $\mathscr{C}^*$, the topological dual of the space $\mathscr{C}$ of gauge-invariant cylindrical functionals. We construct such solutions by averaging fermionic spin network states, just as described in Sec. II. Any state $\Psi \in \mathscr{C}$ that is a linear combination of such states defines in this way a diffeomorphism-invariant element $\overline{\Psi}$ of $\mathscr{C}^*$. There is an inner product on the space of such diffeomorphism-invariant states given by

$$\langle \overline{\Psi} | \overline{\Phi} \rangle = \overline{\Psi}(\Phi).$$

Completing this space in this inner product, we obtain the Hilbert space $\mathscr{H}_{\mathrm{diff}}$ of diffeomorphism-invariant states. This space has an orthogonal basis given by states of the form Ψ_Γ, where Γ as we let Γ range over a set of fermionic spin networks containing one from each diffeomorphism equivalence class (again restricting ourselves to graphs of type I).

IX. CONCLUSIONS

Having set up a kinematical framework for diffeomorphism-invariant gauge theories coupled to fermions, and dealt with the Gauss law and diffeomorphism constraints, there are still some interesting questions concerning superselection sectors to deal with before moving on to the much deeper problem of the Hamiltonian constraint. In general, one can obtain superselection sectors (invariant subspaces) for the action of an algebra on a Hilbert space by studying the orbits of

various states under the action of this algebra. Let $\hat{\mathscr{B}}$ denote the algebra of operators generated by the quantized fermionic path observables (22–28) of Sec. (VII). It is especially interesting to consider the orbit of the ''empty state'' under this algebra. By the ''empty state'' we mean the vector in $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$ given by

$$1\otimes 1 \in L^2(\overline{\mathscr{A}})\otimes\Lambda(\oplus_{p\in\Sigma}F_p).$$

This is the fermionic spin network state corresponding to a graph with no vertices and no edges. In general the empty state is not a cyclic vector for $\hat{\mathscr{B}}$; i.e., the orbit $\hat{\mathscr{B}}(1\otimes 1)$ is not dense in $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$. Thus $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$ has non-trivial superselection sectors.

There are various reasons why the empty state may not be a cyclic vector. First, there may be a non-trivial subgroup $H\subseteq G$ that acts trivially on all the representations in our list I corresponding to the fermions in our theory. If this occurs, the empty state will never be a cyclic vector for $\hat{\mathscr{B}}$. To see this, note that H is a closed normal subgroup of G so $G'=G/H$ is a compact connected Lie group. We may naturally construct from P a principal G'-bundle P' and think of F as associated to P'. Letting $\mathscr{G}'$ denote the group of gauge transformations of P', and letting $\mathscr{A}'$ denote the space of smooth connections on P', one may check that $L^2(\overline{\mathscr{A}}'\times\overline{\mathscr{F}}')/\mathscr{G}')$ is in a natural way a proper closed subspace of $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$. One may also check that the orbit of the empty state lies in $L^2(\overline{\mathscr{A}}'\times\overline{\mathscr{F}}')/\mathscr{G}')$, so the empty state is not a cyclic vector.

It is easy to get around this problem, though, because in this situation there is no harm in replacing the gauge group G of our theory by G' and taking $L^2(\overline{\mathscr{A}}'\times\overline{\mathscr{F}}')/\mathscr{G}')$ as our space of gauge-invariant states. For example, consider the gravitational and electromagnetic fields coupled to a charged fermionic field as in example c) of Sec. III. The particle in this theory transform according to the spin 1/2, charge 1 representation of $G=\mathrm{SU}(2)\times\mathrm{U}(1)$, while its antiparticle transforms according to the spin 1/2, charge -1 representation. The group H thus consists of the elements $\pm(1,1)$, so there is no harm in replacing G by the group $G/H=\mathrm{U}(2)$.

Suppose therefore that this problem does not occur: only the identity element of G acts trivially on all the representations in the list I. The empty state may still fail to be a cyclic vector. In fact, this always occurs if $G=\mathrm{SU}(n)$ for odd values of $n>2$ when the list I consists only of the fundamental representation and its dual. The reason is that the nth exterior power of the fundamental representation is the trival representation, so one may construct a gauge-invariant quantity of order n in the fermion field. Applying this to the empty state gives a fermionic spin network state living on the graph with one vertex and no edges. This element $L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$ cannot be in the orbit of the empty state because the operators (22–28) always change the total fermion number by an even integer.

However, the question of whether the empty state is a cyclic vector remains open for the interesting cases of $G=\mathrm{SU}(2)$ and $G=\mathrm{SU}(2)\times\mathrm{U}(1)$. Another interesting open question is as follows. At least for $G=\mathrm{U}(n)$ and $G=\mathrm{SU}(n)$ one knows that products of Wilson loop operators labelled by the fundamental representation span $L^2(\overline{\mathscr{A}}/\mathscr{G})$. As noted in Sec. VII, such Wilson loops can be expressed as products of fermionic path observables. Therefore in theories with these gauge groups and fermions tranforming under the fundamental representation one knows that the closure of the orbit of the empty state at least contains $L^2(\overline{\mathscr{A}}/\mathscr{G})\subseteq L^2((\overline{\mathscr{A}}\times\overline{\mathscr{F}})/\mathscr{G})$. For what other groups and choices of representations does this result hold?

ACKNOWLEDGMENTS

We would like to thank H. Morales-Técotl and Y. Shtanov for many stimulating discussions when the basic ideas behind this work were being developed. K. K. also thanks A. Ashtekar for a useful discussion. We are grateful to the Erwin Schrödinger Institute for Mathematical Physics in Vienna for their hospitality while much of this paper was written, and especially to Peter Aichelburg and Abhay Ashtekar for running the Workshop on Mathematical Problems of Quantum Gravity held there. J. B. also thanks the Center for Gravitational Physics and Geometry for their

hospitality while this paper was being completed. K. K. was supported, in part, by the International Soros Science Education Program (ISSEP) through grant No. PSU062052, and this research was also supported in part by NSF Grant No. PHY95-14240.

Ginzburg–Landau theory has provided an effective method for understanding the onset of superconductivity in the presence of an external magnetic field. In this paper we examine the instability of the normal state to superconductivity with decreasing magnetic field for a closed smooth cylindrical region of arbitrary cross-section subject to a vertical magnetic field. We examine the problem asymptotically in the boundary layer limit (i.e., when the Ginzburg–Landau parameter, k, is large). We demonstrate that instability first occurs in a region exponentially localized near the point of maximum curvature on the boundary. The transition occurs at a value of the magnetic field associated with the half-plane at leading order, with a small positive correction due to the curvature (which agrees with the transition problem for the disc), and a smaller correction due to the second derivative of the curvature at the maximum. © *1998 American Institute of Physics.*

I. INTRODUCTION

The application of a sufficiently large magnetic field is known to destroy the superconducting property of a superconductor. If one keeps a sample below some critical temperature, however, then experiments reveal the emergence of a superconducting state once the external field is lowered below some critical value. In addition to a loss of normal resistivity, the material in the superconducting state gains the ability to expel the applied magnetic field. Here we investigate this bifurcation using the Ginzburg–Landau theory of superconductivity as a model.[1]

This problem has been treated analytically in various settings in which the sample is cylindrical (i.e., of constant cross section), and the applied magnetic field points in the axial direction. This assumption allows for a two-dimensional approach to the analysis. Saint-James and de Gennes[2] consider the case of a half-plane and infinite slab, and using the Ginzburg–Landau theory they linearize the equations about the so-called ''normal state'' in which the applied field totally permeates the medium. Through an explicit solution, they find the critical value of the applied field where the normal state loses stability—frequently referred to as H_{c_3} in the literature—to be approximately $1.7k$. Here k is the Ginzburg–Landau parameter, a dimensionless material constant defined as the ratio of two important length scales in the system. In their analysis and in ours as well, k is taken to be greater than $1/\sqrt{2}$, so that the material is a so-called type-II superconductor. Saint-James and de Gennes also find that the superconducting state concentrates along a thin neighborhood of the boundary of the sample and then tails off exponentially in the interior, a property referred to as ''surface superconductivity.'' More recently, Chapman[3,4] carried out a more detailed formal mathematical treatment of the half-plane problem as part of a general analysis of onset for decreasing fields, starting from a perturbation theory developed by Millman and Keller.[5] (See also Refs. 6–8 for related rigorous work and more recently,[9] for rigorous estimates on the upper critical field, above which only normal states solve the Ginzburg–Landau equations.)

Following these studies, Bauman, Phillips, and Tang[10] studied this bifurcation when the cross section of the sample is a disc. By separating variables and using a highly nontrivial O.D.E.

analysis, they rigorously show that the value of H_{c_3} is raised above the half-plane value of $1.7k$ by a quantity proportional to the curvature of the disc. As in the case of a half-plane, they find the superconducting state concentrates near the boundary of the disc with an exponentially small tail.

It was this last result which caught our attention and lead us to ask the question: what is the nature of the bifurcating superconducting state when the cross section of the sample has an arbitrary shape? Here we investigate this problem using formal asymptotic expansions in the regime where k is large. We discover that the transition occurs at a value of the external field associated with the half-plane at leading order, with a small positive correction proportional to the maximum of curvature (which agrees with the transition problem for the disc), and a smaller correction due to the second derivative of the curvature at the maximum. Furthermore, the amplitude of the order parameter measuring the presence of superconductivity is exponentially localized about the point on the boundary where curvature is a maximum. We note that recently Chapman[11] studied a complementary bifurcation problem in which a small applied magnetic field is gradually raised until it reaches a critical field (H_{c_1}) at which the purely superconducting state loses stability to a vortex state. In that setting it turns out that the bifurcating vortex state emerges near the point of maximum curvature of the boundary as well.

In the section which follows we introduce the Ginzburg–Landau model and then present the asymptotic analysis leading to the conclusions stated above.

II. ASYMPTOTIC ANALYSIS

We consider a sample occupying an infinite cylinder with two-dimensional cross section consisting of an arbitrary simply connected smooth bounded region $\Omega \subset \mathbf{R}^2$. The sample is adjacent to a vacuum and is subjected to an applied magnetic field $\mathbf{H}$ pointing in the axial direction, so that $\mathbf{H}=H\hat{\mathbf{z}}$ for some positive scalar H. We use the Ginzburg–Landau theory to model the superconductor, thus the system is described by two quantities, an order parameter $\Psi:\Omega\to\mathbf{C}$ and the magnetic potential $\mathbf{A}:\Omega\to\mathbf{R}^2$. The pair $(\Psi,\mathbf{A})$ is an equilibrium state for the energy

$$G(\Psi,\mathbf{A})=\int_\Omega\left(\frac{1}{2}\left|\left(\frac{i}{k}\nabla+\mathbf{A}\right)\Psi\right|^2+\frac{1}{4}(1-|\Psi|^2)^2+\frac{1}{2}\left|\text{curl }\mathbf{A}-H\hat{\mathbf{z}}\right|^2\right)dx, \tag{2.1}$$

where curl $\mathbf{A}=(\partial_x A_2-\partial_y A_1)\hat{\mathbf{z}}$, k is the Ginzburg–Landau parameter and we have used the penetration depth as a length scale. This energy is well-defined for Ψ belonging to the Sobolev space $H^1(\Omega;C)$ and $\mathbf{A}$ belonging to the Sobolev space $H^1(\Omega;\mathbf{R}^2)$. Setting the first variation of G to zero, one finds that the pair $(\Psi,\mathbf{A})$ satisfies the Ginzburg–Landau equations

$$\left(\frac{i}{k}\nabla+\mathbf{A}\right)^2\Psi-\Psi+|\Psi|^2\Psi=0 \quad \text{in } \Omega, \tag{2.2}$$

$$(\text{curl})^2\mathbf{A}+\frac{i}{2k}(\Psi^*\nabla\Psi-\Psi\nabla\Psi^*)+|\Psi^2|\mathbf{A}=0 \quad \text{in } \Omega, \tag{2.3}$$

along with the boundary conditions

$$\hat{\mathbf{n}}\cdot\left(\frac{i}{k}\nabla+\mathbf{A}\right)\Psi=0 \quad \text{on } \partial\Omega, \tag{2.4}$$

$$\text{curl}\mathbf{A}=H\hat{\mathbf{z}} \quad \text{or } \partial\Omega. \tag{2.5}$$

Here $\hat{\mathbf{n}}$ is the inward unit normal to $\partial\Omega$ and $(\cdot)^*$ denotes complex conjugation. We refer to Ref. 12 for more background on the model. We also note that in light of our assumption of smoothness on $\partial\Omega$, standard elliptic regularity theory shows that solutions to (2.2)–(2.5) are classical (C^2) solutions.

The problem is invariant under the gauge transformation $(\Psi,\mathbf{A})\to(\Psi',\mathbf{A}')$ where

$$\Psi'\equiv\Psi e^{ik\phi}, \quad \mathbf{A}'\equiv\mathbf{A}+\nabla\phi \tag{2.6}$$

for an arbitrary real-valued $H^2(\Omega)$ function ϕ. Throughout this analysis it will be convenient to impose the additional conditions

$$\text{div } \mathbf{A}=0 \text{ in } \Omega, \quad \mathbf{A}\cdot\hat{\mathbf{n}}=0 \text{ on } \partial\Omega. \tag{2.7}$$

This amounts to choosing a gauge, thus eliminating the degeneracy associated with the gauge invariance of our problem.

Within the Ginzburg–Landau model the normal state corresponds to the conditions

$$\Psi\equiv 0, \quad \mathbf{A}=\overline{\mathbf{A}},$$

where $\overline{\mathbf{A}}$ satisfies

$$(\text{curl})^2\,\overline{\mathbf{A}}=0 \text{ in } \Omega,$$

$$\text{curl } \overline{\mathbf{A}}=H\hat{\mathbf{z}} \text{ on } \partial\Omega,$$

$$\text{div } \overline{\mathbf{A}}=0 \text{ in } \Omega,$$

$$\overline{\mathbf{A}}\cdot\hat{\mathbf{n}}=0 \text{ on } \partial\Omega.$$

For a vector with only two components the condition $(\text{curl})^2\overline{\mathbf{A}}=0$ implies that curl $\overline{\mathbf{A}}$ is constant so the conditions above reduce to simply

$$\text{curl } \overline{\mathbf{A}}=H\hat{\mathbf{z}} \text{ in } \Omega,$$

$$\text{div } \overline{\mathbf{A}}=0 \text{ in } \Omega,$$

$$\overline{\mathbf{A}}\cdot\hat{\mathbf{n}}=0 \text{ on } \partial\Omega.$$

It is convenient to introduce the vector field $\overline{\mathbf{a}}$ through the relation $\overline{\mathbf{A}}=H\overline{\mathbf{a}}$, so that

$$\text{curl } \overline{\mathbf{a}}=\hat{\mathbf{z}} \text{ in } \Omega,$$

$$\text{div } \overline{\mathbf{a}}=0 \text{ in } \Omega,$$

$$\overline{\mathbf{a}}\cdot\hat{\mathbf{n}}=0 \text{ on } \partial\Omega. \tag{2.8}$$

We note that obtaining the existence of a classical solution to (2.8) in a smooth bounded domain is simple. For example, one can obtain $\overline{\mathbf{a}}$ in the form $\overline{\mathbf{a}}=\frac{1}{2}(-y,x)+\nabla u$, where u is a harmonic function satisfying the Neumann condition $\nabla u\cdot\hat{\mathbf{n}}=-\frac{1}{2}(-y,x)\cdot\hat{\mathbf{n}}$ on $\partial\Omega$. The uniqueness of $\overline{\mathbf{a}}$ follows from the assumption of simple connectivity on Ω. That is, letting say $\mathbf{b}$ denote the difference between any two solutions to (2.8), one finds that $\mathbf{b}$ must be the gradient of a harmonic scalar function whose normal derivative vanishes on $\partial\Omega$. Thus the scalar function is constant and $\mathbf{b}\equiv 0$.

Since we seek a description of the initial bifurcation of the solution from the normal state $(0,H\overline{\mathbf{a}})$ as the applied magnetic field is decreased, we begin our formal analysis by introducing a small parameter ϵ (which measures the magnitude of $|\Psi|$) and assuming asymptotic expansions for the quantities Ψ, $\mathbf{A}$, and H of the form

$$\Psi=0+\epsilon\Psi^{(1)}+\cdots,$$

$$\mathbf{A}=h\overline{\mathbf{a}}+\epsilon^2\mathbf{A}^{(2)}+\cdots,$$

$$H=h+\epsilon^2H^{(1)}+\cdots$$

(cf. Refs. 3 and 5). The relative scalings of Ψ, $\mathbf{A}$, and H are motivated by the need to balance the term $|\Psi|^2\Psi$ with the terms involving $\mathbf{A}-H\overline{\mathbf{a}}$ in (2.2). Inserting these expansions into (2.2)–(2.5) yields a linear problem for $\Psi^{(1)}$ at leading order,

$$\left(\frac{i}{k}\nabla+h\overline{\mathbf{a}}\right)^2\Psi^{(1)}-\Psi^{(1)}=0 \quad \text{in} \quad \Omega, \tag{2.9}$$

$$\hat{\mathbf{n}}\cdot\left(\frac{i}{k}\nabla+h\overline{\mathbf{a}}\right)\Psi^{(1)}=0 \quad \text{on} \quad \partial\Omega. \tag{2.10}$$

As h is decreased, one expects the instability of the normal state to occur when (2.9)–(2.10) has a nontrivial solution. Here, h plays the role of an eigenvalue and we define H_{c_3} to be the largest positive eigenvalue for the linearized problem (2.9)–(2.10). When k is sufficiently large, nonlinear analysis suggests that this bifurcation is a supercritical pitchfork (cf. Refs. 3 and 4).

At this point, we wish to analyze (2.9)–(2.10) via formal matched asymptotic expansions in the regime where the Ginzburg–Landau parameter k is large. Experiments (both physical and numerical) indicate that the superconducting state nucleates on the boundary of Ω and the factor of $(1/k)$ in (2.9) suggests that the order parameter $\Psi^{(1)}$ will vary there with a characteristic length scale $1/k$. Thus, we will seek a boundary layer solution which matches to the normal state in the interior of the domain. (Indeed, we will find that the modulus of this boundary layer solution decays exponentially to zero as we depart from $\partial\Omega$.)

To this end, we introduce coordinates (s,η) valid in a neighborhood of $\partial\Omega$. Here s is arclength along $\partial\Omega$ and η is the distance from a point within Ω to the boundary. We can arbitrarily select a point on $\partial\Omega$ corresponding to $s=0$; without loss of generality we will choose this point to coincide with the maximum of curvature on the boundary. We will use $\kappa=\kappa(s)$ to denote the curvature of $\partial\Omega$ (not to be confused with the Ginzburg–Landau parameter k!).

This local coordinate system will be well-defined in the rectangle

$$S\equiv\{(s,\eta):-L/2<s<L/2,\ 0<\eta<C\},$$

where L denotes the arclength of the boundary, and C is any positive constant smaller than $[1/\kappa(0)]$. We adopt the convention that for Ω a disc κ is positive. We denote by $\hat{\mathbf{t}}=\hat{\mathbf{t}}(s)$ a unit tangent vector to $\partial\Omega$ and we recall that $\hat{\mathbf{n}}=\hat{\mathbf{n}}(s)$ denotes the inner unit normal vector. Thus, in particular, any vector field $\mathbf{F}$ defined in a neighborhood of $\partial\Omega$ can be expressed as $\mathbf{F}(s,\eta)=F_1(s,\eta)\hat{\mathbf{t}}(s)+F_2(s,\eta)\hat{\mathbf{n}}(s)$. We now proceed to rewrite problem (2.9)–(2.10) in $s-\eta$ coordinates so that we may pursue a boundary layer construction in the region S.

For this purpose, we record here that for any scalar-valued function $f=f(s,\eta)$ one has the identities,

$$\nabla f=\partial_\eta f\hat{\mathbf{n}}+\frac{1}{1-\kappa\eta}\,\partial_s f\hat{\mathbf{t}}, \tag{2.11}$$

$$\nabla^2 f=\partial_{\eta\eta}f-\frac{\kappa}{1-\kappa\eta}\,\partial_\eta f+\frac{1}{1-\kappa\eta}\,\partial_s\left(\frac{1}{1-\kappa\eta}\right)\partial_s f, \tag{2.12}$$

and for any vector field $\mathbf{F}=F_1(s,\eta)\hat{\mathbf{t}}+F_2(s,\eta)\hat{\mathbf{n}}$ we have

$$\text{div}\ \mathbf{F}=\frac{1}{1-\kappa\eta}\,\partial_s F_1+\frac{1}{1-\kappa\eta}\,\partial_\eta[(1-\kappa\eta)F_2], \tag{2.13}$$

$$\text{curl}\ \mathbf{F}=\text{div}(F_2\hat{\mathbf{t}}-F_1\hat{\mathbf{n}})\hat{\mathbf{z}}. \tag{2.14}$$

These identities can be computed using standard planar differential geometry (see e.g., Ref. 13) and are explicitly derived for example in Ref. 14.

For a general domain Ω, although $\overline{\mathbf{a}}\cdot\hat{\mathbf{n}}=0$ on $\partial\Omega$, $\overline{\mathbf{a}}$ is not purely tangential. That is, writing $\overline{\mathbf{a}}=\overline{\mathbf{a}}(s,\eta)$ we have $\overline{\mathbf{a}}(s,\eta)\cdot\hat{\mathbf{n}}(s)=0$ only for $\eta=0$ but not for $0<\eta<C$. However in the coordinate rectangle S, we can decompose $\overline{\mathbf{a}}$ into components $\mathbf{p}$ and $\mathbf{q}$,

$$\overline{\mathbf{a}}=\mathbf{p}+\mathbf{q}$$

as follows. We first define $\mathbf{q}$ as the solution to the problem

$$\text{curl } \mathbf{q}=\hat{\mathbf{z}} \text{ in } S, \quad \mathbf{q}\cdot\hat{\mathbf{n}}=0 \text{ in } S, \quad \text{and } \mathbf{q}(s,0)=0. \tag{2.15}$$

Note in particular that $\mathbf{q}$ will be purely tangential is the sense mentioned above.

Seeking a solution to (2.15) in the form $\mathbf{q}=q(s,\eta)\hat{\mathbf{t}}$, we can solve for the scalar q through the use of (2.13) and (2.14). We find that q must satisfy the first order differential equation

$$\frac{-1}{1-\kappa\eta}\,\partial_\eta((1-\kappa\eta)q)=1, \quad q(s,0)=0,$$

so that

$$\mathbf{q}(s,\eta)=q(s,\eta)\hat{\mathbf{t}}(s)=-\eta\left(\frac{1-\kappa(s)\,\eta/2}{1-\kappa(s)\,\eta}\right)\hat{\mathbf{t}}(s). \tag{2.16}$$

We then define $\mathbf{p}$ by the relation $\overline{\mathbf{a}}=\mathbf{p}+\mathbf{q}$. Note in particular that $\mathbf{p}$ will then be conservative,

$$\text{curl } \mathbf{p}=0 \text{ in } S. \tag{2.17}$$

Motivated by the gauge invariance, and utilizing (2.17), we now introduce a phase Φ on the rectangle S through the relation $\nabla\Phi=h\mathbf{p}$. Hence, for any $(s,\eta)\in S$, we let

$$\Phi(s,\eta)=h\int_\gamma \mathbf{p}\cdot d\mathbf{r}, \tag{2.18}$$

where γ is any path in S joining (0,0) to (s,η). We then introduce the function ψ by writing the solution $\Psi^{(1)}$ to (2.9)–(2.10) near $\partial\Omega$ in the form

$$\Psi^{(1)}=\psi e^{ik\Phi}e^{ik\beta s}, \tag{2.19}$$

where β is a constant to be determined. Through the gauge transformation it becomes apparent that the complex exponential of Φ eliminates $\mathbf{p}$, the conservative component of $\overline{\mathbf{a}}$. The factor $e^{ik\beta s}$ represents a contribution to the phase evident in the earlier investigations of Saint-James and de Gennes[2] and Chapman[3] that arises when the problem is posed on the half-plane. Our motivation for this change of variables is to make the leading-order balance conform with the known results for the half-plane problem. In particular this is not a polar decomposition; although ψ will have real solutions at leading order, the higher-order corrections may be complex in nature.

Using (2.6), we find that in a neighborhood of $\partial\Omega$, the problem (2.9)–(2.10) for $\Psi^{(1)}$ as a function of x transforms to the following problem for ψ as a function of s and η,

$$\left(\frac{i}{k}\,\boldsymbol{\nabla}+h\mathbf{q}-\beta\boldsymbol{\nabla}s\right)^2\psi-\psi=0 \text{ in } S, \tag{2.20}$$

$$\hat{\mathbf{n}}\cdot\left(\frac{i}{k}\,\nabla+h\mathbf{q}-\beta\nabla s\right)\psi=0 \text{ on } \eta=0. \tag{2.21}$$

Then using (2.11) to compute ∇s and exploiting the fact that $h\mathbf{q}-\beta\nabla s$ has no $\hat{\mathbf{n}}$ component, we see that (2.20)–(2.21) can be written as

$$\left(\frac{i}{k}\,\nabla+\left(hq-\frac{\beta}{1-\kappa\eta}\right)\hat{\mathbf{t}}\right)^2\psi-\psi=0 \text{ in } S,$$

$$\nabla\psi\cdot\hat{\mathbf{n}}=0 \text{ on } \eta=0.$$

A further expansion of this equation yields

$$\left(\frac{1}{k^2}\,\Delta+\frac{i}{k}\,\frac{2V}{1-\kappa\eta}\,\partial_s+\frac{i}{k}\,\frac{V_s}{1-\kappa\eta}+1-V^2\right)\psi=0 \quad \text{in} \quad S, \tag{2.22}$$

$$\psi_\eta=0 \quad \text{on} \quad \eta=0, \tag{2.23}$$

where

$$V(\eta,s)=\frac{h\,\eta(1-\kappa\eta/2)+\beta}{1-\kappa\eta}. \tag{2.24}$$

So far we have simply rewritten the linearized problem (2.9)–(2.10) in terms of the function ψ (introduced via the changes of variables (2.19)) and in terms of the independent variables s and η to obtain a convenient formulation of the problem valid near $\partial\Omega$. At this point, we wish to begin a process of formal matched asymptotic expansion (based on the assumption $k\gg 1$) by introducing stretched coordinates to solve a boundary layer problem which will then be matched to the normal state in the interior.

As we are seeking a boundary layer solution and we have a factor of $(1/k^2)$ multiplying the Laplacian in (2.22) it is natural to seek a solution which depends not on the normal variable η but on the stretched variable

$$\xi=k\,\eta. \tag{2.25}$$

What is not so obvious, but nonetheless necessary, is that we must stretch the tangential variable as well, by introducing

$$\tau=k^{1/4}(s-s_0). \tag{2.26}$$

Here s_0 is a value of arc length along the boundary which remains to be determined. The transverse length scale $(1/k^{1/4})$ represents a balance between the quadratic nature of the curvature at the maximum and the transverse modulation of the amplitude, a fact best explained *a posteriori*. Putting it another way, any expansion which fails to incorporate this stretched tangential dependence—that is, which fails to sufficiently promote the appearance of tangential derivatives of the solution as we expand—will lead to inconsistencies later in the asymptotic analysis.

Once one resolves to seek a solution depending on ξ and τ, however, one is obligated to pursue a solution which is not only localized near $\partial\Omega$, but localized near the (so far arbitrary) point corresponding to $s=s_0$ as well. Accordingly, this solution must be matched to the normal state both in the interior of Ω (ξ large) *and along the boundary away from* $s=s_0$ ($|\tau|$ large).

Thus, we assume an expansion for ψ of the form

$$\psi=\psi_0(\xi,\tau)+\frac{1}{k^{1/4}}\,\psi_1(\xi,\tau)+\frac{1}{k^{1/2}}\,\psi_2(\xi,\tau)+\frac{1}{k^{3/4}}\,\psi_3(\xi,\tau)+\cdots \tag{2.27}$$

and an expansion for $h=h(k)$ of the form

$$h=h_0k+h_1k^{3/4}+h_2k^{1/2}+h_3k^{1/4}+h_4+\cdots\ . \tag{2.28}$$

To carry out the analysis, we need an expansion for the expression V in powers of k. To this end, we first express the curvature κ as a function of τ, say $K(\tau)$, and Taylor expand about $s=s_0$ using (2.26) to obtain

$$K(\tau)=\kappa(s_0)+\frac{1}{k^{1/4}}\,\kappa_s(s_0)\,\tau+\frac{1}{k^{1/2}}\,\kappa_{ss}(s_0)\,\frac{\tau^2}{2}+\mathcal{O}\left(\frac{1}{k^{3/4}}\right)=\overline{\kappa}+\frac{1}{k^{1/4}}\,\overline{\kappa_s}\,\tau+\frac{1}{k^{1/2}}\,\overline{\kappa_{ss}}\,\frac{\tau^2}{2}+\mathcal{O}\left(\frac{1}{k^{3/4}}\right), \tag{2.29}$$

where $\overline{\kappa}$, $\overline{\kappa_s}$, and $\overline{\kappa_{ss}}$ denote $\kappa(s_0)$, $\kappa_s(s_0)$, and $\kappa_{ss}(s_0)$, respectively.

To expand V, we substitute (2.25) and (2.29) in (2.24) to find

$$V=(h_0\xi+\beta)+\frac{1}{k^{1/4}}(h_1\xi)+\frac{1}{k^{1/2}}(h_2\xi)+\frac{1}{k^{3/4}}(h_3\xi)$$
$$+\frac{1}{k}\left\{\left(h_4\xi+\left(\frac{h_0}{2}\xi^2+\beta\xi\right)\overline{\kappa}\right\}+\frac{1}{k^{5/4}}\left\{\left(h_5\xi+\frac{h_1}{2}\xi^2\overline{\kappa}+\left(\frac{h_0}{2}\xi^2+\beta\xi\right)\overline{\kappa_s}\tau\right\}\right.$$
$$+\frac{1}{k^{3/2}}\left\{\left(h_6\xi+\frac{h_2}{2}\xi^2\overline{\kappa}+\frac{h_1}{2}\xi^2\overline{\kappa_s}\tau+\left(\frac{h_0}{2}\xi^2+\beta\xi\right)\overline{\kappa_{ss}}\frac{\tau^2}{2}\right\}+\mathcal{O}\left(\frac{1}{k^{7/4}}\right).\right. \tag{2.30}$$

Using (2.12) and (2.27), we expand the Laplacian

$$\frac{1}{k^2}\Delta=\partial^2_{\xi\xi}-\frac{1}{k}\overline{\kappa}\partial_\xi-\frac{1}{k^{5/4}}\overline{\kappa_s}\tau\partial_\xi+\frac{1}{k^{3/2}}\left\{\partial_{\tau\tau}-\overline{\kappa_{ss}}\frac{\tau^2}{2}\partial_\xi\right\}+\mathcal{O}\left(\frac{1}{k^{7/4}}\right). \tag{2.31}$$

The imaginary terms in (2.22) can be expanded using (2.13), (2.25) and (2.26)

$$\frac{i}{k}\frac{2V}{1-\kappa\eta}\partial_s+\frac{i}{k}\frac{V_s}{1-\kappa\eta}=\frac{i}{k^{3/4}}2V\partial_\tau+\frac{i}{k^{3/4}}V_\tau+\mathcal{O}\left(\frac{1}{k^{7/4}}\right). \tag{2.32}$$

We can now proceed to expand and solve for successive orders in the expansion for ψ.

A. Leading order balance: The half-plane problem

The basis for our expansion is that the leading-order balance in the problem is exactly equivalent to the instability problem for the half-plane. This problem was first considered by Saint-James and de Gennes,[2] and yields an exponentially localized superconducting region near the boundary. In the general domain we will construct a solution whose leading order structure is equivalent to the solution of the half-plane problem with an amplitude that varies along the boundary.

We can now expand the problem at leading order ($\mathcal{O}(1)$); Eqs. (2.22) and (2.23) yield

$$\psi_{0_{\xi\xi}}+(1-(h_0\xi+\beta)^2)\psi_0=0 \quad \text{for} \quad 0<\xi<\infty,$$
$$\psi_{0_\xi}(0)=0, \quad \psi_{0_\xi}(\infty)=0, \tag{2.33}$$

where the second boundary condition allows us to match the boundary layer solution to the normal state in the interior of Ω. This is exactly the half-plane problem considered formally in Refs. 2 and 3, and treated rigorously in Refs. 6 and 7.
